The Significance Of Ectopic Germinal Center In Minor Salivary Gland Of Patients With Sjögren's Syndrome. Kyung-Eun Lee[1], Dong-Jin Park[1], Jeong-Won Lee[1], Ji-Hyoun Kang[1], Lihui Wen[1], Tae-Jong Kim[2], Yong-Wook Park[1] and Shin-Seok Lee[1] [1]Chonnam National University Medical School, Gwangju, South Korea, [2]Chonnam National University Medical School and Hospital, Gwangju, South Korea.

Background/Purpose: To investigate whether the presence of germinal center (GC) in minor salivary glands of patients with Sjögren's syndrome (SS) is associated with different clinical and laboratory features.

Methods: Minor salivary gland tissue biopsies from 93 SS patients were used to identify GC-like structures and germinal center was confirmed by CD21-positive follicular dendritic cell networks. Sociodemographic, glandular, and extraglandular manifestations, and laboratory findings including autoantibodies, complement, and immunoglobulin levels, were analyzed. EULAR SS disease activity index (ESSDAI) and SS disease damage index (SSDDI) were also measured.

Results: GC-like structures were observed in 28 of 93 SS patients (30.1%). Mean focus score was significantly higher in GC-positive patients than in GC-negative patients. GC-positive patients had higher CRP levels and had higher prevalence of rheumatoid factor, anti-CCP antibody, and anti-SSA/Ro antibody compared to GC-negative patients. However, glandular and extra-glandular manifestations were not different between the two groups.

Conclusion: Our findings showed that SS patients who had GC-like structures in minor salivary glands had different laboratory profiles compared to those patients who didn't have. Long-term follow-up of these patients will be necessary to see whether these laboratory abnormalities translate into changes in clinical features.

Diagnostic Value Of Labial Minor Salivary Gland Biopsy For Primary Sjögren's Syndrome. Raquel Altoe[1], Valeria Valim[1], Maria Carmem S. Santos[2], Erica V. Serrano[1] and Samira T. Miyamoto[3]. [1]Universidade Federal do Espírito Santo, Vitória, Brazil, [2]Universidade de Vila Velha, Vitória, Brazil, [3]Universidade Federal do Espírito Santo, Vitoria, Brazil.

Background/Purpose: The presence of lymphocytic infiltrate with ≥ 1 focus score/4mm^2 in minor salivary gland is a useful tool for the diagnosis of Sjögren's syndrome (SS) and was included in the American–European Consensus Criteria (AECC) (2002) and the criteria proposed by the American College of Rheumatology (ACR) in 2012. The purpose of this study is to evaluate the sensitivity and specificity of the histological analysis of minor salivary gland and the clinical profile of patients undergoing labial salivary biopsy for investigation of glandular SS.

Methods: Retrospective chart review was performed of all patients underwent labial salivary biopsy in Rheumatology Outpatient Clinic of Hospital Universitário Cassiano Antônio de Moraes/Universidade Federal do Espírito Santo (UFES) from March 2008 to March 2011. Biopsy indication, dryness symptons (AECC), unstimulated salivary flow (USF), Schirmer test (ST), presence of autoantibodies, number of foci score were obtained. The sensitivity and specificity of biopsy were calculated considering the expert opinion as the gold standard.

Results: Two-hundred forty-three patients underwent to labial salivary biopsies, 95.9% (233) were female, mean of age was 48.49 ±12.4, 95.88% (233) had dryness symptoms and 4.11% (10) systemic manifestation without dryness (parotid hypertrophy (3), pancytopenia (1), lymphopenia (1), arthritis and positive ANA (4), anemia + arthralgia and positive ANA (1)). The frequency of ≥ 1 focus score/4mm^2 was 35.8% (87), USF ≤ 1.5ml/15min was positive in 56.8% (138) and ST in 45.7% (111). For analysis of sensitivity and specificity, patients were excluded due to insufficient clinical data (N = 40), presence of another autoimmune rheumatic disease (N = 19), hepatitis C (N = 1), diagnosis by the rheumatologist expert opinion that was not described (N = 31).Of the 183 patients analyzed, 32.78% (60 patients) were classified as primary SS by AECC. In these, the frequency of positive biopsy SS, oral and ocular subjective criteria were 88.7% (53), 91.7% (55) and 93.3% (56) respectively. Only 1 patient with SS (with objective criteria, biopsy and anti-Ro positives) showed no dry mouth and eye, 81.7% (49) showed USF ≤ 1.5, 66.7% (40) ST ≤5mm/5min and 33.33% (20) positive anti-SSA and/or anti-SSB antibodies, 66.7% (40) positive ANA, 25% (15) positive rheumatoid factor. Among the systemic manifestations presented there were 1.65% (1) increase of the parotid glands, 1.65% (1) lymphoma, 20% (12) peripheral arthritis, 8.3% (5) cutaneous involvement, 6.7% (4) respiratory involvement, 6.7% (4) renal involvement, 13.3% (8) peripheral neuropathy. For 65% (39) biopsy was necessary to confirm the diagnosis of SS. Of patients with fibromyalgia and dry syndrome (87), 58.3% (35) were diagnosed with SS. The sensitivity and specificity of the biopsy found were 86.57% and 98.23% respectively.

Conclusion: The frequency of Sjögren's syndrome in suspected patients referred to be biopsy submission was 32.78%. The sensitivity and specificity of the salivary biopsy presented high values consistent with other data from the literature. The frequency of SS confirmed by biopsy in patients with fibromyalgia syndrome is high and SS should be investigated in patients with dryness.

EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) Is Increased In Sjögren's Syndrome Patient With Fibromyalgia. Valeria Valim[1], Samira T. Miyamoto[2], Mauricio Paganotti[3], Erica V. Serrano[1] and Raquel Altoe[1]. [1]Universidade Federal do Espírito Santo, Vitória, Brazil, [2]Universidade Federal do Espírito Santo, Vitoria, Brazil, [3]Universidade de Vila Velha, Vitória, Brazil.

Background/Purpose: The *EULAR Sjögren's Syndrome Patient Reported Index* (ESSPRI) is a patient-reported index designed to assess the severity of patients' symptoms such as dryness, pain and fatigue in primary Sjögren Syndrome (pSS). Considering these symptoms are also very common in fibromyalgia (FM), the association between pSS and FM could contribute to higher scores of ESSPRI. The purpose of this study was to determine if score of ESSPRI differed between pSS patients with and without FM.

Methods: Sixty two women with pSS fulfilling the American–European Consensus Criteria (AECC) were recruited from the Rheumatology Outpatient Clinic of Hospital Universitário Cassiano Antônio de Moraes/Universidade Federal do Espírito Santo (UFES). All were submitted to American College of Rheumatology 1990 Criteria (ACR) for Fibromyalgia and submitted to ESSPRI and *EULAR Sjogren's syndrome Disease Activity Index* (ESSDAI). Student's t-test and Mann-Whitney were used to compare scores of ESSPRI between pSS patients with and without FM ($p<0.05$) and Pearson's Correlation was used to correlate score of ESSPRI and ESSDAI ($p<0.05$).

Results: The mean of age was 49.4 ± 11.6, beginning of symptoms was 7.2 ± 5.4 years and diagnostic time was 3.0 ± 3.3 years. Sixty eight percent were non-Caucasian and 32% Caucasian. ESSPRI mean was 6.87 ± 1.97 and ESSDAI mean was 4.95 ± 6.73, indicating low activity. There was no correlation between ESSDAI score and ESSPRI score ($r=0.051$; $p<0.696$). The frequency of fibromyalgia in pSS patients was 43.5%. Stratified analysis showed that pSS patients with FM have higher score of ESSPRI than those without FM (7.35 ± 1.69 vs. 6.17 ± 2.34, $p=0.028$) (Table 1).

Table 1. Descriptive statistics and score of ESSPRI between primary Sjögren Syndrome patients with and without Fibromyalgia

ESSPRI	Fibromyalgia	Median	Mean	Standard deviation	p-value
Dryness**	Yes	7.00	7.00	2.62	0.251
	No	6.00	6.15	2.92	
Fatigue**	Yes	8.00	7.00	3.32	0.067
	No	6.00	5.03	4,07	
Pain**	Yes	8.00	8.04	2.05	0.441
	No	8.00	7.33	2.89	
Total score*	Yes	7.67	7.35	1.69	0.028***
	No	6.00	6.17	2.34	

* Student's t-test; ** Mann-Whitney test; ***p<0,05

Conclusion: Fibromyalgia is a common comorbidity in pSS patients and it could raise the ESSPRI score and also could explain part of no correlation between ESSPRI and ESSDAI.

Does Multiplex Flow Immunoassay Underdetect SSA and SSB Antibodies? An Evaluation Of The Sjogren's International Collaborative Clinical Alliance (SICCA) Cohort. Alan N. Baer[1], Laura Gutierrez[1], Mara McAdams DeMarco[2], Mi Y. Lam[3], Livia Casciola-Rosen[1], Stephen Shiboski[4], Caroline Shiboski[3] and Lindsey A. Criswell[5]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [3]University of California San Francisco, San Francisco, CA, [4]University of California, San Francisco, San Francisco, CA, [5]University of California, San Francisco, Rosalind Russell Medical Research Center for Arthritis, San Francisco, CA.

Background/Purpose: Multiplex flow immunoassays (MFIA) are used by clinical laboratories to test for antibodies to extractable nuclear antigens. The use of blended Ro52 and Ro60 antigens in an MFIA can mask their reactivities, otherwise detectable with single antigen assays (Autoimmun Rev. 2009;8:632). We tested the hypothesis that single antigen solid-phase assays are more sensitive than MFIA for the detection of SSA and SSB antibodies.

Methods: We studied 162 consecutively enrolled SICCA registrants selected independently of their serologic results, including 120 with Sjogren's syndrome (SS) defined by the ACR criteria, and 42 without SS (controls). SSA and SSB antibody testing was performed by a Bio-Rad Bioplex 2200 MFIA (Quest Laboratories) and positive results were expressed in "antibody index" (AI) units and provided as continuous variable measures up to a prespecified upper limit. Levels >6 AI were stratified as strong positive, >3 to ≤6 AI moderate positive, >1 to ≤3 AI weak positive, and ≤1 AI negative. We independently tested the same samples using individual assays for Ro52 and SSB (Quantalite ELISA) and Ro60 (immunoprecipitation using in vitro transcription/translated protein: IVTT-IP). Ro52 and SSB results were stratified as negative (<20 U), weak positive (20–39 U), moderate positive (40–80 U), and strong positive (>80 U). The concordance rate was determined from individuals positive for both plus those negative for both divided by the total.

Results: SSA antibodies were detected in 92 (56.8%) subjects by MFIA and in 87 (53.7%) by ELISA/IVTT-IP. SSB antibodies were detected in 66 (40.7%) by MFIA and in 63 (38.9%) by ELISA. The concordance rate for SSA antibody testing was 93.2% and for SSB 90.7%. MFIA detected SSA antibodies in 8 subjects who tested negative for Ro52 and Ro60; 5/8 had weak SSA reactivity. Conversely, 3 subjects had Ro52 (weak reactivity) without Ro60 antibodies, but tested negative for SSA by MFIA. SSB antibodies were detected by MFIA in 9 subjects (weakly in 4) who tested negative by ELISA. Conversely, SSB antibodies were detected in 6 subjects by ELISA (weak reactivity in 3) who tested negative by MFIA. The 26 discordant (positive/negative) results were distributed evenly among the SS and control groups and the positive reactivity was weak in 15, moderate in 7 and strong in 4.

Conclusion: MFIA and single antigen solid phase immunoassays had a concordance rate of over 90% in this sample of the SICCA cohort, and there was no evidence that MFIA underperformed relative to the single antigen assays.

516

Prevalence Of Seronegative Sjogren's Syndrome: A Comparative Study From The Sjogren's International Collaborative Clinical Alliance (SICCA) Cohort. Alan N. Baer[1], Laura Gutierrez[1], Mara McAdams DeMarco[2], Mi Y. Lam[3], Livia Casciola-Rosen[1], Stephen Shiboski[4], Caroline Shiboski[3] and Lindsey A. Criswell[5]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [3]University of California San Francisco, San Francisco, CA, [4]University of California, San Francisco, San Francisco, CA, [5]University of California, San Francisco, Rosalind Russell Medical Research Center for Arthritis, San Francisco, CA.

Background/Purpose: Individuals with primary Sjogren's syndrome (SS) may lack systemic autoantibodies. When defined by the absence of anti-SSA and –SSB antibodies, the reported range is 26–67%(J Autoimmun 2012;39:15). We sought to: 1) determine the prevalence of seronegativity, defined more broadly by the absence of antibodies to SSA fine specificities (Ro52 and Ro60, assayed individually) and to other relevant antigens, including cyclic citrullinated peptide (CCP), centromere (CENT), and rheumatoid factor (RF) and 2) compare these antibody profiles with non-SS controls.

Methods: We studied 149 consecutively enrolled SICCA registrants who had SS, defined by focal lymphocytic sialadenitis with a focus score ≥1 (FLS) and ocular surface staining score (OSS) ≥3, irrespective of serologic test results. Control subjects were 50 consecutive registrants lacking FLS, OSS ≥3, or whole unstimulated sialometry ≤0.1 ml/min. Subjects with known rheumatoid arthritis (RA) or systemic lupus (SLE) were eligible for SICCA, while those with systemic sclerosis (SSc) were excluded. Antibodies were assayed by ELISA (Ro52, SSB, and CCP), immunoprecipitation using in vitro transcription/translated protein (Ro60), or immunofluorescent staining (CENT).

Results: 137 subjects had 1° and 12 had 2° SS (4 SLE, 8 RA). In 1°SS, anti-SSA and/or SSB were detected in 102 (74%, [66,82 CI]), including 32 with only anti-SSA and 2 with only anti-SSB; anti-CCP in 7 (5%); and anti-CENT in 8 (6%). The 50 control subjects included 1 with anti-SSA and -SSB, 4 with anti-SSB without -SSA, 6 with anti-CCP, and 1 with anti-CENT. One or more of these specificities were present in 109 (80%) of 1°SS and in 10 (20%) of control subjects. Of the 8 1°SS subjects with anti-CENT, 3 (38%) were judged to have limited SSc, and 4 (50%) had anti-SSA and/or -SSB. Inclusion of [ANA≥1:320 + RF] increased the autoantibody prevalence among 1°SS to 122 (82%), but not among the control subjects.

Conclusion: The prevalence of anti-SSA and –SSB seronegativity in this 1° SS sample was substantially less than in other cohorts. Anti-CCP and -CENT were present in an additional 6% of these seronegative patients, indicating the importance of other autoantibodies in the definition of 1° SS autoimmune subsets, particularly those with SSc overlap. The combination of ANA≥1:320 and RF, an alternative ACR classification criterion, only identified 2 (1.3%) additional 1°SS patients and thus has limited SS diagnostic utility. The 8–14% prevalence of anti-SSB, anti-CCP, RF, and ANA≥1:320 in the control population limited the diagnostic specificity of these autoantibodies.

Antibody Responses To Oral Bacteria In Patients With Primary Sjögren's Syndrome and Comparison With Rheumatoid Arthritis and Periodontitis. Bozo Lugonja[1], Michael Milward[1], Diana Pearson[2], Thomas Dietrich[1], Iain Chapple[1], John Hamburger[1], Francesca Barone[1], Saaeha Rauz[1], Lorraine Yeo[1], Ana Povedo-Gallego[2], Geraint Williams[1], Paola de Pablo[1], Andrea Richards[2], Christopher D. Buckley[1], Dagmar Scheel-Toellner[1] and Simon J. Bowman[3]. [1]University of Birmingham, Birmingham, United Kingdom, [2]Birmingham Dental Hospital, Birmingham, United Kingdom, [3]Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom.

Background/Purpose: We set out to examine peripheral blood antibody ELISA responses to common oral bacteria in primary Sjögren's syndrome (pSS) to identify potential bacterial triggers linked to HLA-DR3 and anti-Ro/La antibodies. We also assessed the prevalence of periodontitis in relation to these antibody responses and in comparison to other patient groups.

Methods: Following Research Ethics Committee approval, 65 patients (64,female) with pSS according to American-European Criteria (mean age = 61 years; 59/65 with anti-Ro/La antibodies; 2 smokers, 22 ex-smokers), 47 female patients with rheumatoid arthritis (RA) (mean age = 59; 46 anti-CCP positive; 8 smokers, 16 ex-smokers), 35 patients with osteoarthritis (OA) (mean age = 58 years; 2 smokers, 17 ex-smokers) and 41 people (28 female, mean age = 53) previously recruited to a therapeutic study in non-smokers with periodontitis (1), participated in this study. Sonicated whole bacteria lysates from 10 common oral bacteria were used as substrates for an in-house ELISA of anti-bacterial responses. Oral periodontal status was assessed using standard approaches according to the American Academy of Periodontology/ Centres for Disease Control criteria.

Results: Periodontitis was identified in 20/42 patients with pSS who took part in this component of the study, 22/35 patients with RA and 17/30 patients with OA (not significant). RA patients were more likely than pSS to be current smokers (p=0.01). ELISA responses to *P. gingivalis*, *P. denticola*, *P. intermedia* and *S. sanguis* were significantly higher in patients with RA and periodontitis than in OA controls. *P. denticola* and *S. mutans* had greater responses in pSS patients than in OA controls. *C. showae*, *E. faecalis* and *A. actinomycetemcomitans* were particularly associated with the periodontitis group and *F. nucleatum* and *C. gingivalis*had no apparent associations with any groups.

Conclusion: Previous studies of the frequency of periodontitis in pSS have yielded conflicting results. This study did not identify an increased overall frequency of periodontitis in pSS although additional data analyses are planned. Periodontitis has been linked to active RA and *Porphyromonas gingivalis* has been proposed to play a central role in relation to anti-CCP antibody responses (2). *Prevotella intermedia* has also been identified by microbiome analysis (3) to be of potential interest in RA. Our data in RA patients supports these findings. Furthermore we have identified bacterial responses of potential interest in pSS such as to *P. denticola* and *S. mutans*. Oral microbiome analysis in pSS is now indicated to identify further bacteria of interest to direct research in this area.

Vitamin D In Sjogren's Syndrome. Suneet Grewal[1], Judith A. James[2], R. Hal Scofield[2], Kathy L. Sivils[2], Michael H. Weisman[1] and Swamy Venuturupalli[1]. [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: Unlike other autoimmune diseases in which an association with vitamin D deficiency has been established, the role of vitamin D in Sjogren's syndrome has been much less studied and data are conflicting. Vitamin D deficiency may contribute to B cell hyperactivity and autoantibody production in SLE. Given some autoantibody, genetic, and clinical similarities between Sjogren's syndrome and SLE, we hypothesized that vitamin D levels would be lower in patients with primary Sjogren's syndrome (SS) compared to patients with sicca symptoms who do not meet SS criteria and healthy controls. We studied a well characterized cohort of primary SS patients for prevalence of vitamin D deficiency as well as for the relationship between vitamin D levels and autoantibody positivity.

Methods: Samples from 70 patients who met the 2002 American-European Consensus Group classification criteria for primary SS, 78 patients with sicca symptoms who did not meet SS criteria, and 148 healthy controls matched for age, gender and race were studied. Participants were enrolled and evaluated as part of the multidisciplinary Oklahoma Sjogren's Syndrome Cohort. Clinical and laboratory data, including 25(OH)D levels, presence of sicca symptoms, anti-nuclear antibody (ANA) status, anti-SSA/Ro status, and anti-SSB/La status were utilized in the study.

Results: Mean age for primary SS patients and patients with sicca symptoms who did not meet SS criteria was 51.8 years and mean age for controls was 51.9 years. Eighty-nine percent of the population studied was Caucasian. The prevalence of Vitamin D deficiency (as defined by recommendations put forth by the Institute of Medicine) in patients with primary SS and patients with sicca symptoms who did not meet SS criteria was 16.9% whereas prevalence of Vitamin D deficiency in matched healthy controls was 52.7%. Patients with primary SS had higher 25(OH)D levels when compared to matched healthy controls (28.1 ng/mL vs. 19.1 ng/mL; p <0.0001). Patient with sicca symptoms who did not meet SS criteria also had higher vitamin D levels when compared to matched healthy controls (30.1 ng/mL vs. 22.5 ng/mL; p <0.0001). No difference in 25(OH)D levels between patients with primary SS and patients with sicca symptoms who did not meet SS criteria (p=0.78) was detected. No difference in the 25(OH)D levels of anti-SSA/Ro positive vs. anti-SSA/Ro negative patients (p=0.22) nor in the 25(OH)D levels of anti-SSB/La positive vs. anti-SSB/La negative patients (p=0.42) were detected. We also detected no difference in the 25(OH)D levels of ANA positive vs. ANA negative patients (p=0.96).

Conclusion: In our well characterized cohort, patients with either primary SS or sicca symptoms who did not meet SS criteria had significantly higher vitamin D levels than matched healthy controls. These findings are similar to those of the few studies conducted in the past, which did not show a lower vitamin D level in patients with primary SS as compared to controls, and suggest that vitamin D deficiency does not contribute to the pathogenesis of Sjogren's syndrome. Furthermore, these results also suggest that vitamin D deficiency does not contribute to autoantibody production as it may in SLE.

Identification Of IgG4-Related Disease and Analysis Of IgG4 Serum Levels In Different Subgroups Of Patients With Sjögren's Syndrome. Antónia Szántó[1], Gábor Nagy[1], Csaba Molnár[2] and Margit Zeher[1]. [1]University of Debrecen, Medical and Health Science Center, Institute for Medicine, Debrecen, Hungary, [2]University of Debrecen, Medical and Health Science Center, Institute for Pathology, Debrecen, Hungary.

Background/Purpose: In the clinical diagnostic criteria of IgG4-related disease (IgG4-RD), Sjögren's syndrome (SS) appears as one of the exclusion criteria. However, in Europe, where Mikulicz's disease and SS were merged into one syndrome, some of the IgG4-RD patients might be hidden as a subset of SS.

There are special symptoms during the disease course of SS that raise the possibility of IgG4-RD whereas other symptoms identify certain SS patients as having high risk for developing malignant lymphoma (lymphoma high risk - LHR).

The aim of this study was to identify patients with IgG4-RD among patients followed up because of SS and to compare the aforementioned two subsets, with special attention on their IgG4 levels.

Methods: Data of 65 SS patients were analysed. Patients are followed up in the University o Debrecen, Hungary. Patients were divided into 4 subgroups:

- IgG4-RDsusp (n=15): patients at whom IgG4-RD can be raised (male gender, negative anti-Ro/SS-A and anti-La/SS-B, autoimmune pancreatitis, autoimmune hepatitis or sclerotizing cholangitis, persisting salivary gland swelling (SGS), lymphadenopathy)

- LHR (n=16): patients with high risk of malignant lymphoma: persisting leukopenia, low complement levels, polyneuropathy, vasculitis, gammopathy, cryoglobulinemia, persisting SGS or lymphadenopathy

- IgG4-RDsusp+LHR (n=20): patients eligible for both IgG4-RD and LHR group

- Control (n=14): patients with SS who are not eligible for any of the aforementioned groups.

Clinical course, total IgG and IgG4 levels, IgG4/IgG ratios and EULAR SSDAIs were compared.

Statistical analyses were performed with SPSS 19.0 software. $P<0.05$ was considered statistically significant.

Results: Four patients fulfilled the diagnostic criteria for IgG4-RD.

Total IgG level of the LHR group was significantly higher than that of IgG4-RDsusp patients (18.7 g/l vs. 11.6 g/l, p=0.0033). IgG4 concentrations were significantly higher at the IgG4-RDsusp patients than in the LHR group (0.46 g/l vs. 0.12 g/l, p=0.032).

IgG4/IgG ratio was significantly higher both in the IgG4-susp and in the IgG4-susp+LHR group compared to the other two groups.

The two common features of the IgG4-RDsusp and the LHR group, namely SGS and lymphadenopathy, were analysed separately, too.

Among patients with SGS (n=35), IgG4/IgG ratio was significantly higher (p=0.036). Neither total IgG, nor IgG4 levels differed significantly. Lymphadenopathic patients (n=10) had significantly higher IgG4 levels than those without lymphadenopathy (p=0.042).

ESSDAI median was higher in patients with elevated IgG4 concentrations (2 vs. 6, p=0.026). Average ESSDAI score was elevated in the LHR group (4.0 vs. 1.3, p=<0.001).

Conclusion: Our results support the hypothesis that some patients may be "hidden" under the diagnosis of SS unless their serum IgG4 level is measured. Measurement of IgG4 serum level is recommended before the introduction of any immunosuppressive treatment.

Based on our findings, although patients with LHR and patients with possible IgG4-RD share some clinical symptoms (SGS and lymphadenopathy), they differ significantly regarding their IgG and IgG4 levels such as IgG4/IgG ratio.

Chronic Obstructive Pulmonary Disease Is Very Common in Primary Sjögren's Syndrome. Anna M. Nilsson[1], Elke Theander[2], Roger Hesselstrand[3], Eeva Piitulainen[4], Sandra Diaz[5], Olle Ekberg[5], Per Wollmer[6] and Thomas Mandl[7]. [1]Skane University Hospital Malmo, Lund University, Malmo, Sweden, [2]Lund University, Malmö, Sweden, [3]Skane University Hospital Lund, Lund University, Lund, Sweden, [4]Lund University & Skåne University Hospital, Malmö, Sweden, [5]Skåne University Hospital Malmo, Lund University, Malmö, Sweden, [6]Skane University Hospital Malmo, Lund University, Malmö, Sweden, [7]Skåne University Hospital Malmo, Lund University, Sweden, Malmö, Sweden.

Background/Purpose: To study the prevalence of chronic obstructive pulmonary disease (COPD) in patients with primary Sjögren's syndrome (pSS) and its association with respiratory symptoms, pulmonary radiographic findings and clinical features of pSS.

Methods: Fifty-one consecutive pSS patients, diagnosed according to the American-European Classification Criteria (AECC), were recruited from the open clinic at the Dept of Rheumatology, Malmö, Sweden and included in the study. The patients were studied by pulmonary function tests (PFT), CT scan of the lungs, the St George's Respiratory Questionnaire (SGRQ), The EULAR Sjögren's syndrome disease activity (ESSDAI) and patient reported indices (ESSPRI) and by laboratory and serological tests. The results were compared with 270 male and 186 female population-based PFT controls standardizing the variables with regard to gender, age, height, weight and tobacco consumption.

Results: pSS patients displayed a significantly decreased vital capacity (VC), forced expiratory volume in 1 second (FEV_1), FEV_1/VC, and diffusion capacity for carbon monoxide whilst the residual volume was significantly increased (Table 1). COPD, according to the GOLD criteria, was diagnosed in 41% of pSS patients (30% in never-smoking and 54% in ever-smoking pSS patients) (Table 2). The SGRQ and ESSDAI total scores were inversely correlated with the VC, TLC and D_{LCO}. However, radiographic abnormalities, IgG, C3, C4, anti-SS-A and anti-SS-B antibodies, ANA, RF and disease duration were poorly associated with PFT variables.

Table 1. Comparison of Pulmonary Function Test (PFT) results in patients with primary Sjögren's syndrome (pSS). PFT results are presented as % of predicted and in absolute numbers (mean ± SD) and COPD diagnosis in %. In comparisons between measured and predicted PFT values, the paired samples t-test was used.

	pSS patients	Predicted values	p-value
VC (L)	3.33 ± 0.82	3.60 ± 0.86	0.001
VC (% of predicted)	93.3 ± 14.2		
TLC (L)	5.61 ± 1.01	5.64 ± 0.72	0.938
TLC (% of predicted)	99.5 ± 12.8		
RV (L)	2.27 ± 0.49	2.03 ± 0.37	< 0.001
RV (% of predicted)	114.1 ± 22.5		
FEV_1 (L/s)	2.31 ± 0.64	2.70 ± 0.66	< 0.001
FEV_1 (% of predicted)	85.9±14.7		
FEV_1/VC	69.4 ± 8.2	74.8 ± 3.0	< 0.001
FEV_1/VC (% of predicted)	92.8 ± 9.8		
D_{LCO} (mmol/min kPa)	6.49 ± 1.86	7.03 ± 1.61	0.003
D_{LCO} (% of predicted)	92.4±17.6		
COPD (%)	41	–	–

VC = vital capacity, TLC = total lung capacity, RV = residual volume, FEV_1 = forced expiratory volume in one second, FEV_1/VC = ratio of FEV_1 to VC, D_{LCO} = diffusing capacity for carbon monoxide, COPD=Chronic Obstructive Pulmonary Disease.

Table 2. Prevalence of chronic obstructive pulmonary disease (COPD) in ever-smoking and never-smoking patients with primary Sjögren's syndrome (pSS).

	COPD	Not COPD
Ever-smokers	13 (54% in ever-smokers)	11
Never-smokers	8 (30% in never-smokers)	19

Conclusion: pSS patients showed signs of both obstructive and restrictive pulmonary disease and 41% fulfilled GOLD criteria for COPD. Respiratory symptoms and disease activity was associated with PFT, whilst radiographic abnormalities, laboratory and serological features of the disease were generally poorly associated with PFT in pSS patients.

Tornú, Buenos Aires, Argentina, [10]Hospital Británico, Buenos Aires, Argentina, [11]Buenos Aires British Hospital, Buenos Aires, Argentina, [12]OMI, Buenos Aires, Argentina, [13]Sanatorio Allende de Córdoba, Córdoba, Argentina, [14]Rivadavia Hospital, Buenos Aires, Argentina, [15]Sanatorio Allende de Córdoba, Cordoba, Argentina, [16]Hospital Córdoba, Córdoba, Argentina, [17]Sanatorio Allende, cordoba, Argentina, [18]Centro de enfermedades Reumaticas, Santiago Del Estero, Argentina.

Background/Purpose: Sjögren's syndrome (SS) is an autoimmune inflammatory disease that affects exocrine glands and may have extraglandular involvement. The respiratory compromise (RC) occurs in 19%–65% of the patients with SS and the most common type is nonspecific interstitial pneumonia (NSIP) (30–60%).

Objectives: To determine the frequency, time of occurrence and type of RC in patients with primary SS. To establish the relationship between RC and antibody profile, complement levels, leukopenia, and other extraglandular manifestations.

Methods: Observational, transversal and analytical study. We included patients who met ACR-EULAR criteria for primary Sjögren's syndrome, over 18 years old from the GESSAR (argentine SS study group) database from Jan/2011 to Jul/2011 inclusive. We evaluated demographic data, time of evolution, the presence of extraglandular manifestations and laboratory parameters. Categorical variables were compared with X2 test or Fisher test and continuous variables with the Mann-Whitney test, The p was considered significant when ≤ 0.05. We performed multivariate logistic regression analysis.

Results: Total N: 285. 95.9% female, age 55.8 ± 14.8 y. Time of evolution of SS until the RC developed: 4 years (IQR 2–6 a). 75 patients (26.3%) had RC, of which the most frequent were xerotrachea (58,6%), recurrent infections (24%), NSIP (13,3%) and pulmonary fibrosis (12.5) (Box 1). RC was more common in patients with Raynaud syndrome (22.2% vs 12.3%, p = 0.04), fibromyalgia (26.8% vs 14.3%, p: 0.01) and tinnitus (5.9% vs 1.2%, p: 0.050). There were no significant differences in laboratory parameters. In the multivariate logistic regression analysis there was an independent association of with Raynaud's (OR = 2.32, 95% CI 1.08 to 4.96, P = 0.03) and fibromyalgia (OR = 2.50, 95% CI 1.21 to 5.13, p = 0, 01) with RC.

Table 1. Distribution of the Types of Respiratory Compromise

Xerotrachea **n (%)**	44 (58,6)
Recurrent infections **n (%)**	18 (24)
Nonspecific interstitial pneumonia (NSIP) **n (%)**	10 (13,3)
Pulmonary fibrosis (UIP) **n (%)**	9 (12,5)
Lymphocytic interstitial pneumonia **n (%)**	3 (4)
Pulmonary **hipertensión n (%)**	2 (2,6)
Pulmonary thromboembolism **n (%)**	2 (2,6)
Bronchiectasis **n (%)**	2 (2,6)
Bronchiolitis obliterans **n (%)**	2 (2,6)
Pleural effusion **n (%)**	1 (1,3)
Nonspecific interstitial pneumonia **n (%)**	1 (1,3)
Solitary nodule **n (%)**	1 (1,3)

Conclusion: A quarter of patients with SS had RC of which the most frequent were xerotraquea, recurrent infections, NSIP and pulmonary fibrosis. There was no association with laboratory parameters. RC was independently associated with the presence of lung disease raynaud and fibromyalgia.

The authors declare no conflicts of interest.

Abatacept Reduces Disease Activity In Early Primary Sjögren's Syndrome:One Year Results From a Phase II Open-Label Study. PM Meiners, A Vissink, Fkl Spijkervet, EA Haacke, WH Abdulahad, E Brouwer, MG Huitema, N Sillevis Smitt-Kamminga, FGM Kroese, S Arends and H Bootsma. University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: Traditional DMARDs have limited effects in primary Sjögren's (pSS) patients. B cell depletion therapy with rituximab showed efficacy, but had some side-effects. T and B cells are known to play a critical role in the pathophysiology of pSS. Abatacept, a selective co-stimulation modulator of T lymphocytes, could be an alternative treatment option for pSS. In this study the efficacy and safety of abatacept in early pSS patients was assessed.

Methods: All patients (12 female, 3 male) included in the open-label Active Sjögren Abatacept Pilot (ASAP) study met the revised American-European Consensus Group criteria. Disease duration was <5 years. Traditional DMARDs, hydroxychloroquine or corticosteroids were discontinued ≤ 1 month before baseline. Patients were biological DMARD naïve, and were treated with 8 abatacept infusions (≈10 mg/kg of body weight) administered intravenously on days 1, 15, and 29 and then every 4 weeks thereafter (total treatment period 24 weeks). Follow-up was conducted at 4, 12, 24 (on treatment), 36 and 48 weeks (off treatment). Disease activity was assessed with EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) and Patient Reported Index (ESSPRI). Several other functional, laboratory and subjective variables were analysed. Parotid gland biopsies were taken at baseline and week 24. Generalized estimating equations were used to analyse parameters over time.

Results: Median age and disease duration were 43 years and 11 months, respectively. Median ESSDAI decreased significantly from 11 (range 2–21) before abatacept to 2 (range 0–9) 24 weeks after abatacept (p<0.000) (Figure 1). ESSDAI increased significantly post-treatment (p<0.000). Median ESSPRI decreased significantly from 7.7 (range 3.7–8.7) to 5.8 (range 2.3–9.7) during treatment (p=0.015), followed by a trend towards increased ESSPRI post-treatment. Similar patterns were found for rheumatoid factor and IgG levels. Salivary and lacrimal gland function remained stable during treatment. Absolute numbers of T and B cells changed slightly (<12%). Fatigue and health-related quality of life improved significantly during treatment. No serious side effects or infections were seen. Histological findings are currently analysed and will be presented at the ACR meeting.

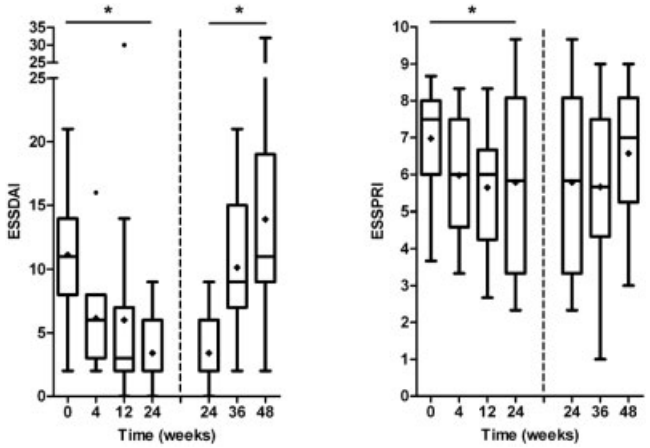

Figure 1. Change in disease activity over time, on treatment (0–24 weeks) and off treatment (24–48 weeks). Box-and-whisker plots (Tukey); boxes=medians with interquartile ranges; +=means; whiskers=1.5 times the interquartile distances; ●=outliers. *=p<0.05 over time.

Conclusion: This open label pilot study indicates that abatacept is well tolerated, safe and results in reduced disease activity, laboratory and subjective parameters in pSS patients. Most patients experienced a clinically relevant improvement in their well-being. These very promising results warrant confirmation in a randomized, double-blind, placebo-controlled clinical trial.

Association Between The Presence Of Amyloidosis In Patients With Ankylosing Spondylitis and Polymorphisms In Type 1/Type 2 Serum Amyloid A Protein Genes, Mediterranean Fever Genes. Gozde Yildirim Cetin[1], Eda Ganiyusufoglu[2], Dilek Solmaz[3], Yonca Cagatay[4], Sibel Yilmaz Oner[5], Burak Erer[6], Hasan Sabit Sagliker[7], Ali Berkant Avci[8], Servet Akar[3], Omer Nuri Pamuk[9], Metin Kilinc[2], Timucin Kasifoglu[10], Haner Direskeneli[5] and Mehmet Sayarlioglu[11]. [1]Sutcu Imam University, School of Medicine, Department of Internal Medicine, Division of Rheumatology, Kahramanmaras, Turkey, [2]Sutcu Imam University, School of Medicine, Department of Biochemistry Research Laboratory, Kahramanmaras, Turkey, [3]Dokuz Eylul University School of Medicine, Izmir, Turkey, [4]Bilim University, Faculty of Medicine, Rheumatology Department, Istanbul, Turkey, [5]Marmara University, School of Medicine, Istanbul, Turkey, [6]Istanbul University, Istanbul Faculty of Medicine,, Istanbul, Turkey, [7]Sutcu Imam University, School of Medicine, Department of Internal Medicine, Kahramanmaras, Turkey, [8]Antalya University, School of Medicine, Department of Internal Medicine, Division of Rheumatology, Antalya, Turkey, [9]Trakya University Medical Faculty, Edirne, Turkey, [10]Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey, [11]Ondokuz Mayis University School of Medicine, Samsun, Turkey.

Background/Purpose: Ankylosing spondylitis (AS) is a chronic autoinflammatory disease. The most severe complication of this disease is development of

renal amyloidosis. The etiology of AS remains largely unknown but both genetic and environmental factors are in play. This article explores the existence of a possible association between polymorphisms of the the type 1 and type 2 serum amyloid A protein (*SAA1/2)* genes and development of amyloidosis in AS patients, and also explores the Mediterranean fever (*MEFV*) genotype of AS patients.

Methods: The numbers of AS patients with amyloidosis are limited and a multicenter study was thus performed. *MEFV* mutations in exons 2 and 10 were screened and *SAA1/2* polymorphisms and HLA-B27 status evaluated in 23 AS patients with amyloidosis (M/F:18/5) and 49 AS patients without amyloidosis (M/F: 43/6).

Results: The single-nucleotide rs12218 polymorphism of *SAA1* was significantly more prevelant in AS patients with amyloidosis ($p=0.006$) than in AS patients without the complication. The prevelance of the *SAA2* rs2445174 and rs2468844 polymorphisms did not differ signicificantly between the two groups ($p=0.17$ and $p=0.65$, respectively)

HLA-B27 positivity was evident in 63 of 72 patients with AS (87.5%).

MEFV mutations were found in 47 of 72 (study and control) AS patients (65.2%) and in 53 of their 144 alleles (36.8%). Genotyping of *MEFV*exon 10 failed for one AS patient with amyloidosis and one without. Twelve M694V mutations were found (5 in the amyloidosis group and 7 in controls). Thirty-two R202Q mutations were found (9 in the amyloidosis group and 23 in controls). Ten E148Q mutations were found, the number was significantly higher in the amyloidosis group (7) than in controls (3) ($p=0.007$)

Conclusion: A relationship between the presence of amyloidosis and *SAA1* genotype has been shown in recent studies of (principally) FMF patients. To date, no study has explored *SAA1/2* polymorphisms in AS patients. We found that, as in FMF patients, the *SAA1* rs12218 polymorphism was significantly more prevelant in amyloidosis patients.

The allelic frequency of M694V among AS patients was 8.3% in our present study. Two uncontrolled studies conducted in central Turkey estimated the allelic frequency of M694V among AS patients at 6.3% and 12.3%. The corresponding figure in the general population of the same region was about 1.1%. These studies and our work suggest a role for M694V in AS pathogenesis in the Turkish population.In our study, the E148Q mutation was significantly higher in AS patients with amyloidosis than in those with AS alone. FMF patients who are compound E148Q-V726A heterozygotes appear to be more likely than other FMF patients to have severe renal amyloidosis. In a recent study in which few patients were evaluated, E148Q mutation was found in 3 of 9 patients with secondary amyloidosis due to different inflammatory diseases.

In our work, the R202Q mutation was the most prevelent *MEFV* mutation.The significance of this observation is uncertain. Earlier, it was found that the R202Q mutation occurred at a significantly higher level in FMF patients than in healthy controls. The R202Q mutation may thus contribute to the etiology of FMF. Our work shows that this may also be true of AS. Further large-scale screening is required.

Expansion Of DC-STAMP$^+$ IL-17$^+$ Cells In Bone Marrow From Psoriasis and Psoriatic Arthritis Patients. Yahui Grace Chiu[1], Edward M. Schwarz[1], Jamie Biear[1], Debbie Campbell[2], Jennifer Hossler[1], Jennifer H. Anolik[3], R. John Looney[1] and Christopher T. Ritchlin[1]. [1]University of Rochester, Rochester, NY, [2]Univerity of Rochester, Rochester, NY, [3]University of Rochester Medical Center, Rochester, NY.

Background/Purpose: Focal erosions in inflammatory arthritis are mediated by bone marrow (BM) derived osteoclasts (OC) that enter the joint as OC precursors (OCP) from peripheral blood. We have previously shown that DC-STAMP (Dendritic Cell-Specific Transmembrane protein), a 7-pass transmembrane protein essential for cell-to-cell fusion during OC differentiation, is a valid biomarker of circulating OCPs. In bone marrow (BM), naive lymphocytes encounter self-antigens to establish immune tolerance and interact with OC and osteoblast progenitors. Herein, we dissected T cell, B cell and monocyte populations, compared the percentage of these cell populations between patients and healthy individuals, examined the potential of these cells in lineage differentiation, and searched for cell subsets uniquely present in BM.

Methods: BM and PBMC collected from 2 psoriatic arthritis (PsA), 2 psoriasis (Ps) patients and 4 healthy controls (HC) were processed and purified by Ficoll gradient, stained by antibodies, and analyzed by flow cytometry. To assess differentiation potential, cells were cultured in dendritic cell (DC)-promoting, Th17-promoting, and OC-promoting media. Phagocytic activity was assessed by FITC-dextran beads.

Results: The OCP frequency of BM and PBMC was 3,423±306 and 1,340±120 per 10e6 monocytes, respectively. Monocytes in BM differentiated into functional DC with phagocytic activity as evidenced by the intake of FITC-dextran beads. T cells in BM differentiated into Th17-like T cells (IL17A+ IL23R+DC-STAMP+CCR6+) after in vitro culture in Th-17-promoting media. Patients with both Ps and PsA had a higher percentage of DC-STAMP$^+$ IL17A$^+$ cells in the BM (patients:11.4%, HC:2.6%) and a higher percentage of IgD+CD27+CXCR3+ memory B cells in both BM and PBMC than HC (HC/patients=3/60 for BM and 24/69 for PBMC). Intriguingly, a novel DC-STAMP-expressing monocyte subset (DC-STAMP$^+$CD14$^+$CD11b$^+$CD16-CD34$^-$CD45 (intermediate)), composing of approximately 18% of rosette monocytes, was only present in BM but absent in PBMC.

Conclusion: In this study, we (1) identified a novel subset of DC-STAMP$^+$ monocytes which is uniquely present in BM but absent in PBMC; (2) showed that BM has 3-fold more OCPs than peripheral blood; (3) found that monocytes and T cells in BM can differentiate into OC/DC and Th17 cells with full effector functions; (4) identified variations in T, B, monocyte populations between PBMC and BM; (5) found that patients with Ps and PsA had a higher % of 1A2+IL17A+CD3+ T cells and IgD+CD27+CXCR3+ B cells in BM than controls.

Evidence For Enhanced Induction Of Unfolded Protein Response Target Genes In Peripheral Blood Mononuclear Cells From Spondyloarthritis Patients. Grace Kwon, Eva Yang, Keith A. Sikora, Hemalatha Srinivasalu, Gerlinde Layh-Schmitt and Robert A. Colbert. NIAMS NIH, Bethesda, MD.

Background/Purpose: Spondyloarthritis (SpA) is an immune-mediated inflammatory disease strongly associated with HLA-B27 (B27). In a transgenic rat model where B27 causes SpA-like disease, CD8 T cells that recognize B27 peptides are not required. B27 has a tendency to misfold, and when upregulated in rat cells can cause endoplasmic reticulum (ER) stress resulting in an unfolded protein response (UPR). The UPR can promote cytokine production and activate autophagy, and may be important in SpA pathogenesis. Since B27 transgenic rats carry multiple transgene copies, an important question is whether B27 upregulation in human cells is sufficient to cause ER stress. We sought to determine whether B27 upregulation in peripheral blood mononuclear cells (PBMC) activates the UPR.

Methods: PBMC from 25 healthy controls (HCs) and 32 adult or pediatric SpA patients (27 B27 positive) meeting age-appropriate classification criteria for SpA were cultured for 20 hours without or with IFNγ, TNFα, or both (IT). Total RNA was isolated and expression of HLA-B and UPR-target genes (BiP, XBP1) was quantitated by real-time PCR. Relative gene expression was determined by normalizing to 3 housekeeping genes, and fold change calculated by comparing treated and untreated samples with statistical assessment by Mann-Whitney U test. Correlations were assessed by Spearman's. XBP1 mRNA splicing was determined on agarose gels.

Results: HLA-B expression increased 1.9-fold with IFNγ in SpA PBMC and 1.6-fold in HCs ($p<0.05$ SpA vs. HCs). When treated with TNFα or IT, HLA-B expression in SpA patients increased 1.3-fold and 2.1-fold, respectively, compared to 1.1-fold and 1.9-fold in healthy controls (NS SpA vs. HCs). BiP expression in TNFα-treated PBMC increased 1.3-fold in SpA patients vs. 1.1-fold in HCs ($p=0.05$) while no significant difference between SpA patients and HCs was seen with IFNγ (1.3-fold and 1.2 fold) or IT (1.3-fold and 1.3-fold). We also asked whether individual fold changes in BiP correlated with HLA-B upregulation. With IFNγ and/or TNFα treatment, fold change in BiP and XBP1 positively correlated with fold change in HLA-B in SpA patients ($p<0.005$), while in HCs significant correlation was only observed in TNFa-treated PBMC ($p<0.05$, $p<0.005$, respectively). More importantly, the slopes of the correlation plots between HLA-B and BiP or XBP1 were 1.3–2.3 times greater for SpA patients than HCs. In addition, XBP1 splicing was significantly increased by cytokine treatments in patient samples but not in HCs ($p<0.05$). Subanalyses of B27-positive and negative SpA patients is inconclusive due to the low number of B27-negative patients.

Conclusion: Our results reveal greater upregulation of the UPR-target gene BiP as well as increased XBP1 mRNA splicing in response to cytokines in SpA patients compared to HCs. These preliminary results support the idea that low-level HLA-B27 upregulation may be sufficient to generate ER stress in certain cell types. Further exploration of cell types affected by this response, and additional conditions that may enhance B27 heavy chain accumulation, is necessary to better understand the potential role of ER stress in SpA pathogenesis.

Endochondral Bone Formation and Advanced Enthesitis Are Key Features Of Proteoglycan Induced Spondylitis Mouse Model Of Ankylosing Spondylitis. Gethin P Thomas[1], Hsu-Wen Tseng[1], Allison Pettit[2], Tibor T. Glant[3], Allan McRae[1] and Matthew A. Brown[4]. [1]University of Queensland Diamantina Institute, Woolloongabba, Australia, [2]University of Queensland Centre for Clinical Research, Herston, Australia, [3]Rush University Medical Center, Chicago, IL, [4]University of Queensland Diamantina Institute, Brisbane, Australia.

Background/Purpose: Transition from an initial inflammatory phase to the disabling osteoproliferative phase in ankylosing spondylitis (AS) is very poorly understood. Elucidation of the mechanisms underlying this disease progression would identify new therapeutic targets and strategies.

The proteoglycan induced spondylitis (PGISp) mouse mirrors human AS disease progression with an initial inflammatory insult resulting in excessive osteoproliferation and frequently joint fusion. We therefore sought to model human AS progression by extensively characterizing the morphological, cellular and molecular changes over a time course of disease in the PGISp mouse.

Methods: Spine and spleen cells from PGISp and control mice were analysed over a 6 month timecourse. The histological features were described using a novel scoring regime including many features seen in human AS, such as inflammation, disc destruction, bone erosion, excess tissue formation (mesenchymal tissue expansion or fibrocartilage formation) around IVDs as well as ectopic tissue formation in the longitudinal ligament. Immunohistochemistry for collagens type I, II and X was used to delineate the nature of the excessive tissue formation seen in this model. Key factors involved both at the joint and systemic levels were analyzed using FACS and qPCR.

Results: Initial inflammation at the periphery of the discs was seen from week 6 which corresponded with an upregulation in expression of inflammatory markers such as TNFa, MMP3 and MMP13. Inflammation progressed over the next 4 weeks with massive inflammatory cell infiltration, disc destruction and erosion of bone and growth plate cartilage. A switch to an "anabolic" phase was then evident with upregulation of collagen II and X, and a corresponding decrease in inflammatory/catabolic genes. An extensive fibrocartilaginous matrix is laid down (excessive tissue formation) by large numbers of chondrocytes. One key feature of severely affected vertebrae is the appearance of ectopic chondrocytes laying down a cartilaginous matrix between the vertebral joints possibly corresponding to entheseal junctions. Such a feature potentially supports a role for endochondral ossification in the disease progression in this model.

Conclusion: The PGISp mouse model displays many features of AS. Of key interest is the initial inflammation giving way to extensive tissue formation. The presence of ectopic chondrocytes indicative of endochondral ossification at the entheses is a key insight into the disease process that can be translated to the human condition.

Presence Of Gastrointestinal Symptoms and Autoantibodies In Patients With Spondyloarthritis In A Colombian Population. Consuelo Romero-Sanchez[1], Wilson Bautista-Molano[2], Diana M Munoz C[2], Viviana Parra I[2], Alejandro Escobar[2], Carlos Martínez[3], Ferney Garcia[3], Daniel Herrera[4], Sebastían Segura[2], Juliette De Ávila[1], Ana MAría Mesa[2], Haroldo Juliao[5], John Londono[2] and Rafael Valle-Oñate[2]. [1]UIBO Institute (Oral Basic Research Unit), School of Dentistry, Universidad El Bosque, Bogotá, Colombia, [2]Spondyloarthropathy Group, Rheumatology Department, Hospital Militar Central/ Universidad de La Sabana, Bogotá, Colombia, [3]Coloproctology Deparment, Hospital Militar Central, Bogotá, Colombia, [4]Instituto de Genética Humana, Facultad de Medicina, Pontificia Universidad Javeriana, Bogotá, Colombia, [5]Gastroenterology Deparment, Hospital Militar Central, Bogotá, Colombia.

Background/Purpose: The frequency of gastrointestinal (GI) involvement in spondyloarthritis (SpA) ranges from 21% to 30% and 5% to 10% are associated with inflammatory bowel disease (IBD). The percentage of patients with SpA having subclinical intestinal inflammation documented by endoscopy and histology is significative. Due to the persistent joint inflammation in these patients, as well as the established association between SpA and GI inflammation, not only endoscopic evaluation, but also measure of auto-antibodies related to IBD is recommended. To investigate whether there is an association between clinical variables and IBD autoantibodies in SpA patients receiving treatment.

Methods: A transversal observation study was designed to compare three groups of patients. Eighty one patients with SpA according to ESSG classification criteria, 14 patients with IBD (ulcerative colitis (UC) (n=8), Chron′s disease (CD) (n=1) and undifferentiated colitis (n=5) and 80 healthy subjects (HS). Anti-*Saccharomyces cerevisiae* IgG/IgA (ASCA), anti polymorphonuclear neutrophil P (ANCA-P), anti transglutaminase (tTG) IgG/IgA, anti deaminated gliadin peptide (DGP) IgG/IgA autoantibodies, ANAS and IgA were measured in all patients. A specific questionary was applied asking for GI symptoms in the SpA group. The association between clinical variables and auto-antibodies were evaluated using the chi square test.

Results: 81 SpA patients were included with mean age of 43 ± 13.4 years, BASFI mean 4,78 ± 1,8, and BASDAI mean 4,58 ± 1,8. 64% were men, 49,4% receiving anti-TNF, and 34.6% were HLA B27(+). In the HS, 47% were men, mean age 37,7± 13,6, IgG/IgA (tTG) was negative in 98.8%, ASCA IgG/IgA was positive in 8.8%, and 6.3% were positive for p-ANCAS.

The patients with SpA in the IgG/IgA ASCA were positive with 30.9%, pANCAS were positive by 11.1%, and the IgG/IgA (tTG) were positive by 2.5%. There was a significant difference in the frequency of autoantibodies IgG/IgA ASCA's (p=0.008) and p-ANCAS (p= 0.001) between SpA and HS. When the questionary for GI symptoms was applied in the SpA patients, abdominal pain and discomfort were reported in 53% of patients, abdominal inflammation (51%) and diarrhea (33%). ANAS test was positive in 54.3%. A significative association was found between the presence of abdominal pain and BASDAI>4 (p=0,017), as well as between abdominal inflammation and BASDAI > 4 (p=0,008). SpA patients have higher titers of total IgA in patients with BASDAI >4 (p=0,012).

Conclusion: Our results shows that SpA patients have a higher presence of IgG/IgA ASCAS and p-ANCAS compared to healthy controls and IBD patients. The report of GI symptoms was associated with high disease activity; however there was not association with the presence of auto-antibodies. Therefore, it may suggest that the active search of auto-antibodies as well as the presence of gastrointestinal symptoms should be performed in Colombian SpA patients. In Colombia there is not information about this association.

Upregulated Th17 and Innate Pathways Are More Characteristic Of The Skin Than The Synovium In Psoriatic Arthritis. Jennifer Belasco[1], Hiroshi Mitsui[1], Mayte Suarez-Farinas[1], James S. Louie[2], N. Wei[3], Nicholas Gulati[1] and James G. Krueger[1]. [1]The Rockefeller University, New York, NY, [2]UCLA School of Medicine, Los Angeles, CA, [3]Arthritis Treatment Center, Frederick, MD.

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory joint disease associated with psoriasis. There is little understanding of the relative levels of cytokines and chemokines between the skin and synovium in PsA. The purpose of this study was to better define inflammatory pathways in paired lesional skin and affected synovial tissue in patients with psoriatic arthritis. We conducted a comprehensive cytokine profile in psoriatic skin and joint disease.

Methods: RT-PCR was performed using coupled directed pre-amplification technique.

Results: Of all the cytokines evaluated, only Th17- associated cytokines (IL17A, IL17F) and IL1a were significantly increased in psoriatic skin when compared to affected synovium. IL6 was significantly increased in synovium. Th1- (IFNg) and Th2- (IL4, IL13) associated cytokines were not significantly different. Th9-(IL9), Th22- (IL22), and Treg- (FOXP3) associated cytokines, as well as IL1b, IL2, IL2RA, TNFa and IL8, were also not significantly different. There was no correlation of gene expression levels between pairs of skin and synovium from the same subject.

Conclusion: This is the first comprehensive molecular comparison of paired lesional psoriatic skin and affected synovium in psoriatic arthritis. This is also the first study to investigate IL9 in psoriatic arthritis tissue. These results demonstrate that there are many shared cytokines and chemokines between matched pairs of lesional psoriatic skin and synovium from inflamed joints in patients with PsA. However, IL1a, IL6, IL17A and IL17F were significantly different. No correlation between gene products was noted between paired samples of synovium and skin, suggesting that there are distinct immunological phenotypes for synovium and skin within the same person. Therefore, the pathomechanisms of these two symptomatic organs may be at least partially independent from one another. This could have implications for the direction of future therapies.

Ankylosing Spondylitis and Dysfunctional Dkk. Rajbir Gulati[1], Maripat Corr[2], Michael H. Weisman[3] and David Hallegua[4]. [1]Cedars Sinai Medical Center, Los Angeles, CA, [2]Univ of California-San Diego, La Jolla, CA, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]Cedars-Sinai/UCLA, Beverly Hills, CA.

Background/Purpose: Ankylosing Spondylitis (AS) is characterized by inflammation of the spine and entheses followed by formation of syndesmophytes.

Wnt pathway is a regulator of bone and cartilage remodeling; modulated by several biomarkers like Dickkopf (DKK-types 1, 2, 3 & 4), sclerostin, etc.

DKK1 is an inhibitor of Wnt. TNF-alpha inhibits bone formation by inducing Dkk-1.

AS patients display either low levels of functional DKK1 (DKK1 that binds to LRP5/6- Low-density lipoprotein receptor related protein) or high levels of total DKK1 indicating that it is dysfunctional.

Maksymowych et al, showed that new syndesmophytes developed more frequently in vertebral corners with inflammation on baseline MRI; and more so where inflammation had resolved after 2 years of anti-TNF therapy.

We examined the relationship between inflammation, bone formation and bone biomarkers in AS patients not on anti-TNF therapy. The anthrax toxin binding protein (CMG2) is a decoy receptor for DKK; which has been found to be associated with AS; we examined its association with DKK.

Methods: We recruited 35 patients with spondyloarthritis, (34 fulfilling New York criteria & 1 fulfilling ASAS criteria for axial spondyloarthritis) from a preexisting cohort, Prospective Study on Ankylosing spondylitis Severity (PSOAS) and from the office of the principal investigator.

During the study visit, metrology measurements were done and BASMI calculated. Bath AS Disease Activity and Functional Indices (BASDAI, BASFI) were also obtained. Blood samples were examined for the following: ESR, CRP, Vitamin D, PTH, DKK, LRPDKK, OPG (Osteoprotegrin), sclerostin, antiDKK, SFRP 3, CMG2DKK, and CMG2LRP. X-rays of the pelvis and the entire spine that were available for 35 and 28 patients respectively were scored for the sacroilitis grade (SI grade) and the modified Stokes Ankylosing Spondylitis Spine Score (mSASSS). Statistical analysis was performed using Spearman correlation coefficient and Student t-test.

Results:

1. Significant correlation between DKK, LRPDKK& CMGDKK as well as between mSASSS, SI grade and BASMI. (Table 1).

2. LRPDKK increases with inflammation in AS. Bone formation as indicated by mSASSS trended higher in patients with higher levels of inflammation.

3. Patients with low CRP when separated based on high or low mSASSS, showed that high mSASSS correlated negatively with DKK and LRPDKK.

Variable	N	Mean	Std. Dev	Median	Minimum	Maximum	Correlation	P-value
Markers of inflammation and function								
CRP	32	1.99	4.64	0.57	0.03	22.9	ESR 0.83 BASDAI 0.43	< .0001 0.0119
ESR	33	23.42	23.42	14.00	1.00	98.00		
BASDAI	34	4.10	4.49	3.08	0.00	24.9	BASFI 0.55	0.0008
BASFI	34	23.70	25.52	14.95	0.00	99.00		
Bone biomarkers associated with bone formation								
DKK	35	4.03	2.93	3.47	0.39	15.52	LRPDKK 0.87 CMG2DKK 0.51	< .0001 0.0035
LRPDKK	30	2.92	1.52	2.91	0.22	6.39	CMG2DKK 0.55	0.0015
CMG2DKK	30	0.70	0.57	0.39	0.39	2.15		
Radiologic and Mobility measurements								
mSASSS	28	18.54	22.47	6.5	0.00	72.00	SIJ 0.75 BASMI 0.80	< 0.0001 <0.0001
SIJ Grade	34	3.29	1.00	4.00	0.00	4.00	BASMI 0.52	0.009
BASMI	25	3.75	1.64	4.00	0.6	6.8		
Low versus High CRP groups								
LRPDKK(low CRP)	15	–	–	1.98	0.23	4.9	–	0.0009
LRPDKK(high CRP)	12	–	–	4.04	1.38	6.39	–	
mSASSS(low CRP)	16	–	–	5.5	0	62	–	0.082
mSASSS(high CRP)	11	–	–	24	0	72	–	
DKK and LRPDKK levels influencing mSASSS in low CRP group								
DKK(low CRP,low mSASSS)	12	–	–	3.36	2	7.41	–	0.013
DKK(Low CRP, high mSASSS)	4	–	–	0.78	0.39	3.09	–	
LRPDKK(low CRP, low mSASSS)	10	–	–	2.32	1.56	4.91	–	0.008
LRPDkk(low CRP,high mSASSS)	4	–	–	1.01	0.23	1.85	–	

Conclusion: Our pilot study suggests that inflammation and low levels of functional DKK are associated with increased bone formation in anti-TNF naïve AS patients. Functional DKK levels increases with active inflammation. However, with low levels of inflammation, functional DKK correlated negatively with AS x-ray changes. A positive correlation exists between the binding of LRPDKK to a decoy receptor CMG2 and LRPDKK levels in these patients.

Pattern Recognition Receptor Stimulated Cytokine Expression By Spondyloarthritis Patient Macrophages. Yi-Ping Liu, Ashley Bomkamp, Jens Eickhoff, Jack Schneck, Mike Khan and Judith Smith. University of Wisconsin-Madison, Madison, WI.

Background/Purpose: Spondyloarthritis (SpA) encompasses a group of chronic inflammatory conditions involving axial arthritis that includes ankylosing spondylitis (AS). GWAS studies in AS have implicated multiple genes regulating the development and activity of Th17 cells. IL23, a cytokine required for driving the pathogenicity of Th17 cells, is sufficient to cause spondylitis-like pathology in mice. Thus, excessive production of IL-23 in response to environmental stimuli might predispose towards the development of SpA. The aim of this study was to determine if macrophages from SpA patients produce excess inflammatory cytokines (including IL-23) in response to different pattern-recognition receptor (PRR) agonists.

Methods: Monocytes isolated by CD14 magnetic beads from 12 AS, 12 non-AS SpA, and 12 control subjects were differentiated into macrophages with M-CSF. Macrophages were stimulated with LPS (TLR4), CL097 (TLR7/8), PGN (TLR2), and Curdlan (Dectin-1) and IL6, IL8, IL10, IL23, and TNF-α quantitated by Luminex Multiplex assay or ELISA. Comparisons between groups were conducted using analysis of variance with adjustment for multiple comparisons. Subgroup analyses were conducted for sex, current TNF-blocker, presence of axial disease, and HLA-B27.

Results: Subjects: AS and SpA patients differed in HLA-B27 positivity (92% vs. 42% respectively, $p=0.027$), current biologic therapy (25% vs. 67%, $p=0.041$) and axial disease (100% vs. 50%, $p=0.014$). Cytokine results: No differences were observed for IL-10. AS macrophages produced more IL-8 than controls in response to PGN ($p=0.017$). LPS stimulated comparably elevated IL-6 by both AS and SpA macrophages ($p\geq0.029$). AS and SpA cells produced comparably increased TNF-α in response to LPS and PGN ($p\geq0.042$), but only SpA macrophages produced increased TNF-α in response to CL097 ($p=0.029$). IL-23 production differed in AS and SpA macrophages: Only non-AS SpA cells produced increased IL-23 in response to all agonists as compared to control ($p\geq0.042$). Subgroup analysis: Axial disease and sex were not significant. HLA-B27 presence was only significant in unstimulated SpA IL-23 ($p=0.006$). Current biologic therapy only affected AS TNF-α and IL-6 responses to PGN and LPS, respectively ($p=0.016$). Response patterns: No one patient produced the maximum amount of every cytokine analyzed. Also, different patients were maximal producers for individual agonists. Groups of 2–5 subjects displayed nearly identical patterns of response to the different agonists. For example, paired subjects showed a correlation in IL-23 production $R\geq0.92$ ($p\leq0.028$).

Conclusion: Both AS and SpA patients produced excess IL-6 and TNF-α in response to PRR agonists, but only non-AS patients produced excess IL-23 in this study. Potential issues were sample size, positive selection of monocytes, less biologic use and more female subjects compared to previous studies. Although numbers are small, the different results (e.g. effects of biologic use) in AS and non-AS SpA puts into question the extent of shared pathogenesis. Finally, the emergence of distinct patterns of PRR response may reflect shared variations at individual immunomodulatory gene loci.

Influenza Infection Of MHC-I Transgenic Mice Reveals That Erap Is Necessary and Sufficient For Generation Of The B27-Specific Immunodominant Epitope. Ali Akram[1] and Robert Inman[2]. [1]University of Toronto and University Health Network (UHN), Toronto, ON, [2]University of Toronto and Toronto Western Hospital, Toronto, ON.

Background/Purpose: Although HLA-B27 and ERAP are known to confer susceptibility to spondyloarthritis (SpA), the role of these elements in modulating host response to infection is undefined. Despite co-dominant expression of class I MHC alleles, immune response to viral infections is characterized by immunodominance (ImDc). The exact mechanisms underlying ImDc are not clear. Defining factors contributing to ImDc has proved difficult due to multiple MHC-I allele co-expression in humans and normal mice.

Methods: To overcome this limitation, we generated human MHC-I transgenic (Tg) mice deficient for endogenous mouse MHC-I molecules and expressing only one human MHC-I allele (e.g. HLA-B7, HLA-B27, HLA-A2). To assess whether co-expression of additional MHC-I alleles in the presence or absence of ERAP influences the pattern of anti-flu CTL epitope recognition and ImDc, novel Tg mice in the context of ERAP deficiency were established.

Results: In flu-infected, double Tg A2/B7 or A2/B27 mice, IFN-γ ELISpot assays with the flu epitopes A2/M1.58–66 and B7/NP418–426 or B27/NP383–391 showed specific recognition of both peptides by both alleles respectively. In contrast, flu-infected B7/B27 Tg mice demonstrated a significantly reduced B27-restricted CTL response to NP383 while there was no change in the response of B7-restricted CTL response to NP418. Profiling the T cell response revealed that co-expression of B7 and B27 is associated with i) a partial deletion of $V\beta8.1^+$ B27-restricted/NP383 $CD8^+$ T cells and ii) a failure of $V\beta12^+$ $CD8^+$ T cell expansion following flu infection in B7/B27 Tg mice. Studies in flu infection of ERAP-deficient Tg B27 and Tg B7/B27 mice revealed complete abrogation of the B27-restricted response to NP383–391, indicating the importance of ERAP in generation of this peptide.

Conclusion: The HLA-B27 immundominant response to infection is critically dependent on ERAP. This provides a possible mechanistic basis for the findings in genetic studies of the interdependence of B27 and ERAP in conferring susceptibility to SpA.

Role Of Baseline C-Reactive Protein In Response To Infliximab Plus Naproxen Vs Naproxen Alone In Patients With Axial Spondyloarthritis. J Sieper[1], M Rudwaleit[1], J Lenaerts[2], J Wollenhaupt[3], L Myasoutova[4], S Park[5], Y Song[6], R Yao[7], M Govoni[8], D Chitkara[7] and N Vastesaeger[9] [1]University Clinic Benjamin Franklin, Berlin, Germany, [2]Practice Rheumatology, Hasselt, Belgium, [3]Schön-Klinik, Hamburg, Germany, [4]Kazan State Medical University, Kazan, Russia, [5]Catholic University of Korea, Seoul, South Korea, [6]Seoul National University, Seoul, South Korea, [7]Merck Sharp & Dohme, Kenilworth, NJ, [8]Merck Sharp & Dohme, Rome, Italy, [9]Merck Sharp & Dohme, Brussels, Belgium.

Background/Purpose: Baseline inflammation has been shown to influence response to tumor necrosis factor alpha antagonist treatment in patients with axial spondyloarthritis (SpA). This study evaluated the role of C-reactive protein (CRP) in the response to treatment with infliximab (IFX)+nonsteroidal anti-inflammatory drugs (NSAIDs) vs NSAIDs alone in patients with axial SpA who had early, active disease.

Methods: Part 1 of the INFAST trial was a double-blind, randomized controlled trial of IFX in biologic-naïve patients 18–48 years of age with early, active axial SpA (Assessment of SpondyloArthritis international Society [ASAS] criteria, disease duration ≤3 years, chronic back pain, and active inflammation of the sacroiliac [SI] joints on magnetic resonance imaging [MRI]). Patients naïve to NSAIDs or treated with a submaximal dose of NSAIDs were randomized (2:1) to receive 28 weeks of treatment with either intravenous (IV) IFX 5 mg/kg (weeks 0, 2, 6, 12, 18, and 24)+naproxen (NPX) 1000 mg/d or IV placebo (PBO)+NPX 1000 mg/d. ASAS partial remission was evaluated in patients with high CRP (>upper limit of normal [ULN], per local laboratory limits) or low CRP (≤ULN). Response was also evaluated in patients who met the New York modified criteria for ankylosing spondylitis (AS) by SI X-ray (bilateral ≥grade 2 or unilateral ≥grade 3, based on local rheumatologist judgement) and were not naïve to NSAIDs (AS group) versus patients with nonradiographic axial SpA (nr-axSpA group). Data were analyzed descriptively.

Results: 156 patients were included in efficacy analyses. Overall, ASAS partial remission rate was greater for the IFX+NPX group (n=105) than the PBO+NPX group (n=51) (61.9% vs 35.3%, $P=0.0021$). For patients treated with IFX+NPX, partial remission rate was greater in the 49 patients with high CRP than in the 44 with low CRP (71.4% vs 59.1%). However, for patients treated with NPX alone, partial remission rates were similar whether CRP was high or low (40.7% [n=27] vs 38.5% [n=13]). In analysis of the AS and nr-axSpA groups, partial remission was greater in the AS group than the nr-axSpA group after treatment with IFX+NPX (72.2% [n=54] vs 56.4% [n=39]); after treatment with NPX alone, partial remission was greater in the nr-axSpA than the AS group (46.7% [n=25] vs 36.0% [n=15]). This pattern might be explained by the higher baseline mean CRP values in the AS group (n=83) than the nr-axSpA group (n=63) (CRP 2.59 vs 0.92 mg/dL). Within the AS group, the difference between the 2 treatments was clear in patients with high baseline CRP (IFX+NPX, 75.8% [n=33] vs NPX, 30% [n=20]); but not with low baseline CRP (IFX+NPX, 66.7% [n=21] vs NPX, 60% [n=5]). This pattern was not observed in the nr-axSpA group, perhaps because of low baseline CRP or because of the small number of subjects available for analysis.

Conclusion: In this population of axial SpA patients with early disease and established MRI inflammation at baseline, elevated baseline CRP was associated with a better response to IFX therapy.

Peripheral Blood Gene Expression Profiling Of Psoriatic Arthritis Patient. Bidisha Dasgupta, Yauheniya Cherkas, Sarah Lamberth and Carrie Brodmerkel. Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: Although PsA is heterogeneous and shows signs of rheumatoid arthritis (RA) and psoriasis (PsO), genetic studies indicate that PsA is a distinct disease with a strong heritable component. PsA is categorized into 5 overlapping clinical patterns: polyarthritis (POLY), arthritis of distal interphalangeal joints (DIP), spondylitis (SPON), and asymmetric peripheral arthritis (ASYM). This study examines if whole blood (WB) gene expression profiles can be utilized to: identify a baseline disease profile (DP) for pts with PsA, differentiate among the clinical subtypes, and compare/contrast the disease mechanisms of PsA, RA and PsO.

Methods: mRNA from 270 WB samples collected at wk0 in a Ph3 study of ustekinumab(PSUMMIT I) from pts with active PsA were isolated and profiled using the Affymetrix HT HG-U133+ PM Array (Santa Clara, CA). 36 healthy control WB samples were obtained from Bioreclamation (Hicksville, NY). Baseline gene expression profiling data comparing disease to healthy control (mRNA isolated from WB and run on Affymetrix HT HG-U133+ PM Array) from 487 RA patients in a Ph3 study of golimumab (GO-FURTHER) and 186 PsO patients in a Ph4 study of ustekinumab (TRANSIT) were used to compare the PsA disease profile to RA and PsO. All data were analyzed by iReport® and Ingenuity Pathway Analysis® (Ingenuity Systems).

Results: We identified a disease profile for PsA (PsA vs Healthy); the majority of the differentially expressed genes are upregulated and fall into diverse categories, such as cellular proliferation, inflammation and immune response. There were no differentially expressed genes that separated PsA subtypes. PsA showed a distinct gene expression profile from RA and PsO with moderate overlap at the gene level. The genes common to all 3 diseases are largely upregulated and the biology represented by these shared genes comprise immune/inflammatory processes and connective tissue disorders. Although PsA shows greater similarity to RA than PsO at the functional pathway level, the PsA disease profile is significantly different in that a majority of the genes are upregulated in PsA. Pathways related to cell proliferation, inflammation, B and T cell signaling are increased in PsA (these pathways are largely downregulated or not significant in RA and PsO). The differentially expressed genes unique to PsA were enriched for the Protein Kinase A and Ephrin signaling pathways. There is emerging evidence that the Ephrin signaling pathway is implicated in bone remodeling and homeostasis and these data may suggest evidence for differential pathways related to structural damage in PsA than RA.

Conclusion: PsA has a distinct gene expression profile, although the PsA clinical subtypes could not be differentiated at a molecular level. Disease profile is best represented by activated pathways related to immune function and immune response; data showed a novel association of PsA with the Ephrin signaling pathway. Majority of the differentially expressed genes are unique to PsA and provide molecular support for PsA as a distinct disease entity. WB gene expression profile of PsA pts may help in the diagnosis of PsA, provide insight into disease pathogenesis, and identification of novel disease markers and therapeutic targets.

Death Receptor 3 Increases Region-Specific, Osteoblast-Dependent Aberrant New Bone Formation In The Axial Skeleton Of Mice In a Spontaneous Model Of Ankylosing Enthesopathy. Fraser L. Collins[1], Jessica O Williams[1], Anja C. Bloom[1], Michael D. Stone[2], Ernest Choy[1], Edward C. Wang[1] and Anwen S. Williams[1]. [1]Cardiff University, Institute of Infection and Immunity, Cardiff, United Kingdom, [2]University Hospital Llandough, Cardiff & Vale University Health Board, Cardiff, United Kingdom.

Background/Purpose: Clinical management of localised bone formation and joint ankylosis constitute major challenges in patients with seronegative inflammatory spondyloarthropathies (SpAs). Whether TNF receptor superfamily members, such as Death Receptor 3 (DR3) and their ligands modulate bone pathology in SpAs is not characterised. For the first time we evaluated DR3's role in controlling osteoblast(OB)-dependent new bone formation using the spontaneous ankylosing enthesopathy model in aging DBA/1 mice.

Methods: Osteoprogenitor cells (OPCs) cultured from the bone marrow of male DR3-deficient ($DR3^{ko}$) and age-matched wild-type (WT) DBA/1 mice were differentiated into OB using β-glycerophosphate, ascorbic acid and dexamethasone. DR3 and RANKL expression were tested by flow cytometry (fold change over isotype reported). Functional analyses; OB differentiation (by alkaline phosphatase (ALP) staining) and mineralisation (by alizarin red staining) were performed. Cellular (TNF-like protein 1A (TL1A) mRNA) and soluble cytokines (osteopontin (OPN), osteoprotegerin (OPG) and soluble RANKL) were measured by RT-PCR and ELISA respectively. Finally, a fluorescent optical probe (BoneTag™) was used to visualise and measure *in vivo* mineralization in 10-month old WT and $DR3^{ko}$mice. Mean$\pm$SEM values reported; statistical significance tested by One or 2-way ANOVA as appropriate.

Results: DR3 was expressed on both OPC (1.8 ± 0.2) and OB (1.4 ± 0.8) from WT mice. In $DR3^{ko}$ levels (1.2 ± 0.1, $P<0.05$) were comparable in both OPC and OB but significantly lower than WT. For the first time, we showed that TL1A (DR3's ligand) was constitutively expressed by OPC and OB from WT and $DR3^{ko}$. Thus autocrine signalling via the DR3/TL1A pathway functionally translated into a significant elevation in ALP ($P<0.05$), expression of the Ca2+ binding osteoid protein OPN ($P=<0.0001$) and mineral apposition ($P<0.0001$) over the 26 day OB differentiation timecourse (WT versus $DR3^{ko}$ cultures). OB derived cytokines (RANKL and OPG) control bone formation by regulating osteoclastogenesis. Pro-osteoclastogenic RANKL expression on OPCs and OB was comparable in WT versus $DR3^{ko}$ whilst soluble RANKL was not detectable in any of the culture supernatants. However, OPG, a soluble inhibitor of osteoclast formation, was significantly elevated across the timecourse in WT versus $DR3^{ko}$ ($P<0.05$). When compared against $DR3^{ko}$, *in vivo* incorporation of a fluorescent calcium-chelating probe was striking and significantly higher ($P<0.01$) in the thoracic vertebrae of WT mice 24 hours after injection. In contrast, the efficiency of probe uptake in WT knee joints and tails was low and comparable with $DR3^{ko}$levels in the spine.

Conclusion: These data identify new OB-dependent homeostatic roles for DR3 in bone and potentially explain the atypical pattern of new bone formation in the axial skeleton of mice that spontaneously develop ankylosing enthesopathy. Further studies in human disease are justified to explore the clinical implications of our findings.

Membrane-Bound TNF Drives Axial and Peripheral Inflammation and Pathologic New Bone Formation. Leonie M. van Duivenvoorde[1], Melissa N. van Tok[1] and Dominique L. Baeten[2]. [1]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands.

Background/Purpose: The morbidity of spondyloarthritis (SpA) is determined not only by inflammation but also by structural damage, in particular osteoproliferation leading to joint ankylosis. The failure of TNF blockers to halt osteoproliferation raised the concept that inflammation and osteoproliferation are uncoupled processes in SpA. The observation that inflammation and osteoproliferation are linked in experimental and human SpA and that NSAID treatment can retard new bone formation, suggest an alternative hypothesis: inflammatory mediators distinct from soluble TNF (sTNF) are responsible for pathologic new bone formation in SpA. Here, we tested this hypothesis by studying inflammation and new bone formation in mice selectively overexpressing membrane-bound TNF (mTNF).

Methods: mTNF mice have normal levels of sTNF and increased levels of mTNF[1]. mTNF mice and non-transgenic littermates were clinically studied over time for arthritis and spondylitis development. At 3, 6 and 8 months peripheral and axial joints were collected and analyzed for inflammation and bone- and cartilage destruction by staining with HE and Saffranin-O. Additionally, X-ray images were obtained from 8 months old mice.

Results: All mTNF mice (100%; n>50) spontaneously developed arthritis, visualized by deformation of joints and loss of grip strength, and spondylitis as evidenced by crinkled tails and hunchback formation, starting at 4 weeks of age and progressing over time. Compared to hTNF and $TNF^{\Delta ARE}$ mice the severity of this arthritic disease was mild; moreover mTNF mice did not lose weight due to disease and can survive for more than 8 months.

Analysis of 3 months old mice revealed that arthritis was characterized by inflammation of synovial and entheseal tissue, which also invaded cartilage and bone in some animals. The inflammation was dominated by polymorphonuclear cells (PMNs). Interestingly, multinucleated giant cells, or osteoclasts, were not increased in affected compared to healthy joints. Hypertrophic chondrocytes, as marker for osteoproliferation, were observed outside the bone in the connective tissue next to the inflammatory infiltration. In spondylitis, inflammation was found in connective tissue located at the junction of the annulus fibrosus with the vertebral bone. More severe inflammatory infiltrate could also erode the vertebrae. Also, axial inflammation/destruction was predominantly characterized by PMNs and lack of increased numbers of osteoclasts. Hypertrophic chondrocytes were observed at the edge of the vertebral body, in conjunction with the ongoing inflammation. X-ray images from 8 months old mice also revealed bridging of the tail vertebra. These typical SpA-like features were not observed in any of the non-transgenic littermates analyzed.

Conclusion: Mice selectively overexpressing mTNF develop a SpA-phenotype with axial and peripheral joint involvement. Radiographic and histologic analysis confirmed new bone formation in this model. Based on these results, we conclude that mTNF, as inflammatory mediator, can drive osteoproliferation in experimental SpA.

Investigating a Novel Locus For Psoriatic Arthritis. Ashley Budu-Aggrey[1], John Bowes[2], Pauline Ho[1], James Bluett[2], Harry Hébert[3], Helena Marzo-Ortega[4], Ann W. Morgan[4], Matthew A. Brown[5], Ross McManus[6], Neil McHugh[7], Oliver M. FitzGerald[8], Ian N. Bruce[1] and Anne Barton[2]. [1]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academy of Health Sciences, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, Centre for Musculoskeletal Research, Institute of Inflammation and repair, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [3]The Dermatology Centre, Salford Royal NHS Foundation Trust, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom, [4]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [5]The University of Queensland Diamantina Insititute, Brisbane, Australia, [6]Department of Clinical Medicine, Institute of Molecular Medicine, Trinity College Dublin, Ireland, Dublin, Ireland, [7]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [8]St.Vincent's University Hospital, Dublin, Ireland.

Background/Purpose: Psoriatic arthritis (PsA) is a complex genetic disorder with a prevalence of up to 1% in the general population. The association of PsA with psoriasis has been demonstrated in the overlap of clinical features as well as the susceptibility loci identified from genetic studies. However, there are very few specific PsA risk loci that have been found. The strong heritability of this disease in comparison to psoriasis suggests that there are more specific PsA susceptibility loci that remain to be discovered.

Methods: Dense genotyping of known autoimmune susceptibility loci was carried out with a custom Illumina array (Immunochip) in a total of 1,960 Caucasian PsA patients and 8923 Caucasian healthy controls. Expression quantitative trait loci (eQTL) analysis of the 5q31 region was performed using publically available data. The regulatory role of the region was characterised and potential functional variants were identified with data sourced from the encyclopaedia of DNA elements (ENCODE) project.

Results: A significant association was detected to the SNP rs715285 on chromosome 5q31 ($P = 3.06\times10^{-10}$, OR = 1.25). This peak of association encompasses the genes *P4HA2, PDLIM4* and *SLC22A4*, and is independent from an association signal previously identified in the region with variants of the *IL13* gene. Bioinformatic analysis of the region identified potential eQTLs that influence the expression of *P4HA2, SLC22A4* and *SLC22A5*. Differential expression of *P4HA2* was found in lymphoblastoid cell lines, while *SLC22A4* and *SLC22A5* were differentially expressed in monocytes indicating the potential for cell specific effects. Functional variants that could affect the regulatory role of the region were identified, including rs10065787, rs721121, rs708455 and rs27437. These SNPs lie within gene enhancers, regions of open chromatin and transcription factor binding sites, including that of BATF. This transcription factor regulates the function of interleukin 17 – a pro-inflammatory cytokine involved in the pathogenesis of PsA.

Conclusion: We have identified a novel association on chromosome 5q31 in a region previously suggested to be specific for PsA. A number of interesting candidate genes in the region have been implicated which encode proteins involved in collagen synthesis and bone development - processes which are affected in PsA. Bioinformatics analysis supports evidence for functional SNPs in the region which now need to be validated in the laboratory. These findings can aid in further understanding of the underlying pathogenic pathways that are specific to PsA. This in turn could potentially enable the identification of a novel therapeutic target to provide more effective treatment therapies to patients.

Ankylosing Spondylitis Associated Endoplasmic Reticulum Aminopeptidase 1 Variants Alter The Unfolded Protein Response. Nigil Haroon and Zhenbo Zhang. Toronto Western Research Institute, Toronto, ON.

Background/Purpose: Endoplasmic reticulum aminopeptidase 1 (ERAP1) has recently been identified to be strongly associated with HLA-B27 positive AS. We have shown that ERAP1 variants cause changes in free heavy chain (FHC) expression on peripheral blood mononuclear cells from HLA-B27 positive patients as well as on B27-expressing C1R cells by *in vitro* assays. Unfolding of HLA-B27 and the formation of FHC can cause the release of inflammatory cytokines by triggering the unfolded protein response (UPR). We tested if ERAP1 variants can affect the UPR.

Methods: Endogenous ERAP1 was silenced in C1R-HLA-B27 cells with ERAP1-shRNA ($C1R^{ERAP1sh}$). C1R cells with stable ERAP1-shRNA expression were identified by GFP expression and were selected with puromycin. Scrambled sequence shRNA was used as control. Western blot (WB) for ERAP1 suppression was done using ERAP1 antibody.

We then transfected either the common variant ERAP1 ($ERAP1^{WT}$) or one of the two AS-associated ERAP1 variants, K528R or Q730E into the $C1R^{ERAP1sh}$ cells. Lentivirus expression vector alone was used as control and exogenous ERAP1 expression was tracked with HA-tag. Stable cells expressing $ERAP1^{WT}$ or ERAP1-variants were selected by hygromycin. UPR was measured using PCR for spliced variants of XBP-1 and by qRT-PCR and western blot for BiP, CHOP and ATF-6.

Results: Almost all C1R cells that were selected by antibiotics were GFP positive indicating stable ERAP1-shRNA expresion. Using WB we noted more than 90% suppression of ERAP1 and more than 75% suppression by qRT-PCR in $C1R^{ERAP1sh}$, compared to the cells with scrambled-sequence shRNA. Anti-HA WB showed uniform strong expression of $ERAP1^{WT}$ and variant forms of ERAP1 in the respective cell lines.

Spliced XBP1, a marker of UPR, was upregulated in the $C1R^{ERAP1sh}$ cells. Re-introduction of ERAP1 (C1R-$ERAP1^{WT}$ cells) reduces the UPR response while C1R-$ERAP1^{K528R}$ and C1R-$ERAP1^{Q730E}$ cells expressing the ERAP1 variants had higher UPR activation compared to C1R-$ERAP1^{WT}$ cells. Other UPR markers including BiP, CHOP and ATF6 expression followed the same pattern with AS-associated variants leading to higher UPR.

Conclusion: ERAP1 suppression leads to increased UPR. AS-associated ERAP1-variants, which are known to have reduced function, leads to more UPR compared to the common variant of ERAP1.

Effects Of ERAP1 Knockdown On HLA Class I and HLA-B27 Expression In Human Monocytic U937 Cells. Tri M. Tran[1], Sohee Hong[1] and Robert A. Colbert[2]. [1]NIAMS/NIH, Bethesda, MD, [2]NIAMS NIH, Bethesda, MD.

Background/Purpose: Polymorphisms in endoplasmic reticulum (ER) aminopeptidase 1 (ERAP1) are associated with susceptibility to ankylosing spondylitis in HLA-B27 (B27) positive individuals, implying a functional interaction between the gene products. A principle function of ERAP1 is to trim peptides that bind to HLA class I molecules such as B27. Since the quantity and quality of peptides is critical for the efficient folding and assembly of class I molecules, we developed a system to examine how reduced ERAP1 activity affects properties of HLA-B27 in cells expressing other HLA class I molecules. Our immediate objective was to determine how ERAP1 knockdown affects HLA class I and specifically B27 expression in U937 cells (U937.B27).

Methods: Lentiviral shRNA was used to knock down (KD) ERAP1 expression in U937.B27 cells (65% reduction), which were compared to U937.B27 cells expressing scrambled shRNA as a control. Total class I heavy chain expression was examined by immunoblotting whole cell lysates. Total folded and unfolded forms of HLA class I were assessed by immunoprecipation with conformation-specific monoclonal antibodies (mAb) W6/32 (anti-HLA-A,B,C) and HC10 (anti-HLA-B,C), respectively, followed by quantitative immunoblotting. Cell surface expression of folded and unfolded forms of class I were assessed by flow cytometry, and HLA-ABC.m3 was used to measure expression of folded B27.

Results: ERAP1 KD resulted in a ~20% increase in total HLA class I heavy chain in whole cell lysates by immunoblotting. Similarly, total folded and unfolded forms of immunoprecipitable HLA class I heavy chain were slightly increased, with folded forms predominating. In contrast, total folded and unfolded HLA class I heavy chain on the cell surface detected by flow was unchanged by ERAP1 KD. For HLA-B27, folded forms on the cell surface were increased by ~40%. Interestingly, treatment with IFNg resulted in more total folded heavy chain in ERAP1 KD cells, whereas the increase in total unfolded heavy chain was limited. Although IFNg induces ERAP1, the ERAP1 KD cells maintained a 50% reduction in ERAP1 expression compared to scrambled shRNA controls. Surprisingly, ERAP1 KD limited the increase in cell surface folded B27 by approximately ~15%. ERAP1 KD also resulted in greater accumulation of disulfide-linked heavy chain oligomers both without and with IFNg treatment.

Conclusion: These data demonstrate that folded and unfolded forms of HLA class I are clearly affected by reduced ERAP1 expression. Loss of ERAP1 function through KD results in a small increase in the accumulation of total cellular HLA class I heavy chain, with more folded compared to unfolded forms, but this difference is not readily apparent on the cell surface, suggesting that it may be intracellular. Differences are further increased with IFNg. Interestingly, while diminished ERAP1 function results in more folded B27 on the cell surface at steady state, upregulation of folded forms can be limited by ERAP1 KD. Our studies highlight the importance of ERAP1 in modulating folded and misfolded forms of B27, and provide a system to probe additional biological effects of these two gene products.

Exploration Of a Novel Therapeutic Target In a Murine Model Of Systemic Lupus Erythematosus: Targeting Sphingosine-1-Phosphate (S1P) Receptors. Christopher Tracy[1], Jess Edison[1], S. Frattalone[1] and C. Moratz[2]. [1]Walter Reed National Military Medical Center, Bethesda, MD, [2]Uniformed Services University of Health Sciences, Bethesda, MD.

Background/Purpose: Systemic lupus erythematous (SLE) is an autoimmune disease characterized by symptomatic flares that often result in terminal organ failure. The pathogenesis is characterized by complex immune dysfunction, including aberrant T-cell responses. FTY720, an FDA approved therapy for multiple sclerosis (MS), is a compound with the ability to modulate T-cell proliferation through S1P receptors. The aim of this study is to attenuate tissue injury and define a subset of S1P receptors and expression patterns that may be altered in the autoimmune prone ischemic reperfusion injury (IRI) mouse model.

Methods: Immune competent (C57BL/6) and autoimmune prone (B6.MRL/*lpr*) mice were exposed to FTY720 or Pertussis toxin followed by superior mesenteric artery ischemic reperfusion injury. Histological analysis of tissue samples was performed to assess tissue injury and the extent of inflammatory cell infiltration into the injured tissues. Multiplex array based cytokine analysis and immunohistochemistry analysis of isolated tissue lysates established and confirmed the extent of induction of inflammatory cytokine production. Immunofluorescence staining of tissue samples defined specific S1P receptor expression patterns.

Results: Targeting S1P receptors with FTY720 attenuates tissue injury in the autoimmune prone mice (B6.MRL/lpr) compared to the immune competent controls (C57BL/6). Multi-ligand targeting the S1P receptors decreased T-cell infiltration, IL-6 and IL1B levels in the autoimmune prone mice compared to the immune competent controls. Immunofluorescence staining of specific S1P receptors showed increased S1P1, S1P2 and S1P3 expression patterns in the autoimmune prone mice compared to the immune competent controls after ischemic reperfusion injury.

Conclusion: These findings support the hypothesis that S1P receptor interaction is a key regulator of T-cell mediated tissue injury and represents a novel therapeutic target in SLE. The role of specific S1P receptors in the pathophysiology of tissue injury is highlighted by the increased expression patterns of targeted S1P receptors after ischemic reperfusion injury in autoimmune prone mice. Defining S1P receptor expression in human lupus and how this expression influences the cell responsiveness during states of inflammation warrants further investigation.

An Essential Role For Caspase-1 In The Induction Of Murine Lupus and Its Associated Vascular Damage. J. Michelle Kahlenberg[1], Srilakshmi Yalavarthi[2], Wenpu Zhao[2], Jeffrey Hodgin[1], Tamra J. Reed[1], Noriko M. Tsuji[3] and Mariana J. Kaplan[2]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Rheumatology, Ann Arbor, MI, [3]3Biomedical Research Institute, National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a systemic autoimmune syndrome associated with organ damage and an elevated risk of cardiovascular disease (CVD) resulting from activation of both innate and adaptive immune pathways. Recently, increased activation of the inflammasome machinery in SLE has been described. This study explores if caspase-1, the central enzyme of the inflammasome, plays a role in the development of SLE and its associated vascular dysfunction, using the pristane model of lupus.

Methods: Eight-week old wild-type or caspase-1−/− mice were exposed to PBS or pristane via intraperitoneal injection. Six months post injection, mice were euthanized and the development of a lupus phenotype and vascular dysfunction was assessed.

Results: Both wild-type and caspase-1 KO mice develop a vigorous inflammatory response to pristane; however, cell death following pristane exposure is decreased in caspase-1−/− mice. While wild-type mice exposed to pristane develop autoantibodies and a strong type I IFN response, mice lacking caspase-1 are significantly protected from these features, including pristane-induced vascular dysfunction. Further, the development of immune-complex glomerulonephritis, prominent after pristane exposure in wild-type mice, is significantly abrogated in caspase-1−/− mice.

Conclusion: These results indicate that caspase-1 is an essential component in the development of lupus and its associated vascular dysfunction following exposure to pristane. Importantly, caspase-1 may modulate autoantigen generation through regulation of cell death. Thus, caspase-1 may play an important role in the cross-talk between environmental exposures and autoimmunity development, providing a novel pathway for therapeutic targeting.

Evidence For Involvement Of C5a Receptor in Human and Murine Lupus Nephritis. Constanze Hess[1], Ditte Tornehave[2], Peter Helding Kvist[2], Yvonne Sundström[3], Louise Berg[3], Iva Gunnarsson[4], Søren Jacobsen[5], Claus Haase[1] and Lars Hornum[1]. [1]Department of Immunopharmacology, Novo Nordisk A/S, Måløv, Denmark, [2]Department of Histology, Novo Nordisk A/S, Måløv, Denmark, [3]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [4]Karolinska Institutet, Stockholm, Sweden, [5]Department of Rheumatology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark.

Background/Purpose: The complement system plays an important role in the pathogenesis of systemic lupus erythematosus (SLE). Apart from the activation of the early components of the classical complement cascade, C5a levels are elevated in SLE patient plasma and C5a receptor (C5aR)-positive cells are detected in kidneys from lupus nephritis (LN) patients. We compared the expression of C5a and C5aR in samples of LN patients to healthy control samples. Moreover, we investigated the efficacy of blocking C5aR by prophylactic treatment with an anti-C5aR monoclonal antibody (mAb) in the inducible nephrotoxic nephritis (NTN) mouse model, which can be viewed as a mechanistic disease model of kidney damage downstream of immune complex (IC) deposition in the glomeruli leading to glomerulonephritis (GN).

Methods: C5a was measured in urine samples of 20 LN patients and in 10 healthy controls by ELISA at 3 visits. The expression of C5aR, CD3 and CD68 was investigated by immunohistochemistry in kidney biopsies from 9 LN patients and from 3 non-inflamed controls. GN was induced by transferring nephrotoxic serum containing sheep anti-rat GBM IgG antibodies into C57BL/6 mice pre-immunized with sheep IgG in CFA. Prophylactic administration of 5 or 25 mg/kg anti-C5aR mAb, 25 mg/kg isotype control or PBS was performed 3x weekly (n=12 per group). Sheep IgG specific antibody titers were determined by ELISA and GN development was monitored by proteinuria measurements (Uristix). Pathological changes of the kidney were analysed by periodic acid-Schiff stain. Mouse C5a was measured in renal tissue and in urine samples by ELISA.

Results: In 17 out of 20 LN patients, C5a was detectable in the urine, but not in any of the healthy controls. In kidney biopsies, C5aR was expressed by infiltrating cells located in T cell (CD3+) and macrophage (CD68+) rich lymphoid aggregates in the tubulointerstitium in 7 out of 9 LN patients. No C5aR expression was observed in normal renal tissue. In the murine NTN model, both doses of anti-C5aR mAb inhibited development of proteinuria and reduced the frequency of glomeruli showing basal membrane (BM) thickening. The prevalence of affected glomeruli correlated with the development of proteinuria. C5a was detected in renal tissue and urine samples upon NTN induction. No changes in C5a or in anti-sheep IgG Ab titers were

detected following C5aR blockade, suggesting that anti-C5aR mAb treatment targets effector functions downstream of IC deposition.

Conclusion: Preventive treatment with anti-C5aR mAb diminishes the development of proteinuria and attenuates glomerular BM thickening. This demonstrates that blockade of C5aR abrogates the development of GN in the NTN mouse model. These data combined with the detection of C5a in LN patient urine and C5aR-positive infiltrating cells in renal samples from LN patients suggest that blocking C5aR with antagonistic mAbs might be a promising future therapy of patients with LN.

Inhibiting TWEAK (TNF-like weak inducer of apoptosis) Signaling Improves Blood Brain Barrier Integrity and Protects From Neuronal Damage In Murine Neuropsychiatric Lupus. Jing Wen[1], Jessica Doerner[1], Ariel Stock[1], Jennifer Michaelson[2], Linda Burkly[2], Maria Gulinello[1] and Chaim Putterman[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]Biogen Idec, Cambridge, MA.

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease characterized by involvement of multiple organs, including the central nervous system. While neuropsychiatric involvement in systemic lupus erythematosus (NPSLE) is relatively common and appears early, the underlying mechanisms are not fully understood. TWEAK is a cytokine member of the TNF superfamily; the TWEAK receptor, Fn14, is expressed in brain endothelial cells, astrocytes, microglia and neurons. TWEAK/Fn14 interactions can lead to cytokine production, neuron degeneration, and an increase in blood brain barrier (BBB) permeability. The disruption of the BBB is believed to be a key pathological feature in NPSLE, allowing the passage of neurotoxic autoantibodies into the brain. We recently found that lupus prone MRL/lpr Fn14 knockout (KO) mice display a markedly attenuated neuropsychiatric phenotype, as revealed by a significant reduction in depressive-like behavior and improved cognitive function. Similarly, NPSLE patients demonstrate high levels of TWEAK in the cerebrospinal fluid. We undertook the current studies to further investigate the mechanisms by which TWEAK signaling is involved in the pathogenesis of NPSLE.

Methods: Comprehensive neurobehavioral assessment including forced swim, anhedonia, open field, object recognition, object placement, and social preference were employed to quantify neuropsychiatric manifestations in MRL/lpr Fn14WT and MRL/lpr Fn14KO mice at 20 weeks of age. Mice were sacrificed after behavior profiling, and the brains prepared for qRT-PCR, Western blot and immunohistochemistry (IHC). To assess blood brain barrier (BBB) integrity, Western blot was performed to evaluate extravascular fibronectin and IgG deposition (which both increase with BBB permeability). Additionally, cellular infiltrates were quantified on hematoyxlin and eosin staining. Fluoro Jade B and TUNEL staining were used to analyze neuronal damage and apoptosis in the brain. Furthermore, gliosis, neuron loss and neurogenesis were assessed by immunostaining with GFAP, NeuN and Ki-67, respectively.

Results: We found that Fn14KO mice had improved BBB integrity, as shown by decreased fibronectin and IgG deposition in the brain. However, no clear differences in the magnitude of cellular infiltrates were observed in the choroid plexus. Additionally, neuronal damage, another important pathological change that can be seen in experimental NPSLE, was also ameliorated by Fn14 deficiency. Fn14KO mice displayed reduced apoptosis in the cortex, as well as less neuron loss and less gliosis in the hippocampus. Interestingly, there were no differences in neurogenesis and in microglia activation between Fn14KO and Fn14WT mice. Studies to compare cytokine expression in brain and cerebrospinal fluid of Fn14KO and Fn14WT mice are in progress.

Conclusion: Our studies indicate that TWEAK/Fn14 interactions can play a central role in the pathogenesis of NPSLE by improving BBB integrity and reducing neuronal damage, suggesting this pathway as a novel target for therapeutic intervention in this challenging disease manifestation.

Ultraviolet-B Induced Plasmacytoid Dendritic Cell Migration and Type 1 Interferon Signaling In The Skin. Clayton Sontheimer, Thomas H. Teal, Nalini Agrawal, Denny Liggitt and Keith B. Elkon. University of Washington, Seattle, WA.

Background/Purpose: Plasmacytoid dendritic cells (pDCs) are highly specialized cells of the innate immune system that secrete very high levels of interferon alpha (IFN-a) following nucleic acid ligand mediated activation of the Toll-like receptors (TLRs) 7 and 9. Although the presence of large numbers of pDC in the skin of patients with cutaneous lupus and exacerbation of cutaneous lupus by UVB exposure suggests a causal relationship, a direct link is difficult to prove. In mice, pDC have been observed in the skin following virus infections as well as following injury by tape stripping but studies of UVB are very limited. Here, we asked whether, and under what conditions, UVB-induced inflammation could recruit pDC and type 1 IFN to the skin.

Methods: Shaved C57BL/6 (B6) mice were irradiated with UVB with either a single dose of 500 mJ/cm^2 (acute profile) or with 100 mJ/cm^2/day for 5 consecutive days (subacute profile). Serial punch biopsies (6 mm) were obtained at 3, 24, and 72 hrs following UVB exposure. Skin samples were examined for mRNA expression by quantitative PCR of pro-inflammatory cytokines (IL-1β, IL-6, TNF-α) and Type 1 stimulated genes (MX1, ISG15, ISG20). mRNA fold change was calculated against non-irradiated control mice. Skin samples were also evaluated by histology with H&E staining and for the presence of pDCs by staining for the pDC-specific marker Siglec H by immunohistochemistry. The skin was also scored visually in a blinded manner based on degree of erythema and ulceration.

Results: While producing similar levels of IL-1β, TNF-α and IL-6, subacute UVB exposure of B6 mice preferentially induced expression of Type 1 IFN genes when compared to both acute UVB and non-irradiated controls. IFN-response genes were elevated at each time point with the greatest increase occurring at 72 hours post-UVB. Subacute UVB exposure also induced transient pDCs infiltration into the dermis and hypodermis that corresponded with Type 1 IFN response genes. To examine the role of UVB-induced Type 1 IFN, subacute UVB-mediated effects in B6 mice were compared to age matched IFNAR KO mice (also on a B6 background). IFNAR KO mice had increased levels of the pro-inflammatory cytokines, IL-1β and IL-6 at 3 and 24 hrs following UVB compared to B6 mice. Interestingly, TNF-α levels were similar between B6 and IFNAR KO mice. Skin scoring for erythema and ulceration showed increased levels of skin damage at 3 and 24 hrs.

Conclusion: Repeated moderate dose of UVB preferentially induced pDC recruitment and Type 1 interferon signature in the skin. Based on the findings that skin damage and inflammatory cytokines were higher in IFNAR KO compared to control mice following subacute UVB exposure, we conclude that Type 1 IFN plays a protective role in attenuating the acute inflammatory response following repeated UVB exposure. It is likely that repetitive UVB exposure as well as other genetic factors leading to hyperresponsiveness to nucleic acid debris, predispose to lupus.

Preferential Infiltration Of Double-Negative (DN) T Cells Into The Glomeruli Of NZM 2328 Lupus Mice. Ning Yu, Shunhua Guo, William Stohl and Chaim O. Jacob. University of Southern California Keck School of Medicine, Los Angeles, CA.

Background/Purpose: Lupus nephritis affects at least 50% of patients with SLE and is a major cause of morbidity. The pathologic picture of lupus nephritis is complex and the precise mechanisms that underlie the development of lupus nephritis remain unclear. The present study was undertaken to delineate the differential localization of lymphocytes infiltrating the glomeruli versus the tubulo-interstitium in NZM 2328 mice, a murine model that closely mimics human lupus nephritis.

Methods: Kidneys were evaluated by in situ histology and immunohistochemistry. Cells infiltrating the glomeruli were separated from those infiltrating the tubulo-interstitium through enzymatic, magnetic, and mechanical procedures and were characterized by flow cytometry.

Results: B cells and macrophages each represent ~5% of the cells infiltrating both the glomeruli and tubulo-interstitium, whereas CD3$^+$ T cells represent 40–60% and 70–80% of the infiltrating cells, respectively. In the

tubulo-interstitium, 50–60% of $CD3^+$ T cells are $CD4^+$, 15–25% are $CD8^+$, and 20–30% are DN. In contrast, the T cells infiltrating the glomeruli are only 1–5% $CD4^+$ cells and <1% $CD8^+$ cells, whereas 95–98% are DN. Furthermore, most of the T cells infiltrating the glomeruli display an activated memory phenotype ($CD62L^{neg}$, $CD44^{high}$, $CD69^+$). About 20–25% of these activated T cells are also CD1d tetramer positive, indicative of an iNKT cell phenotype. A significant difference in the abundance of $NK1.1^+$ cells was also observed. Among cells infiltrating the glomeruli, 20–35% are $NK1.1^+$, whereas only 3–10% of the cells infiltrating the tubulo-interstitium are $NK1.1^+$. These data are highly relevant in comparison with the composition of T cells in the spleen of NZM 2328 mice. The activated memory T cell subset serves as a major biological surrogate marker of clinical disease progression. As determined by gene-array analysis, these activated memory T cells display neither a Th1 nor Th2 profile but rather express a Th17 profile and produce IL-17. Most importantly, these activated memory cells progressively increase in numbers during disease development, not only in the spleen, but in the kidney as well. However, during migration of these cells from the periphery to the kidney and especially into the glomeruli, they lose their $CD4^+$ expression and become mostly DN.

Conclusion: The present study is, to our knowledge, the first direct and detailed analysis of the immune infiltrates in the glomeruli and the tubulo-interstitium in lupus kidneys. The identification of DN T cells bearing an activated memory phenotype as the major cell population in the glomeruli of clinically nephritic mice is likely highly relevant to the pathogenesis of human lupus nephritis. Given that DN T cells are found in kidney biopsies of patients with lupus nephritis and these cells are capable of producing IL-17, our results further support this subset of cells as contributory to development of kidney damage.

The Survival Of $Gr1^+CD11b^+$ cells Is Differentially Regulated In Male and Female Lupus-Prone Mice. Elena Gonzalez, Trine Jorgensen and Abhishek Trigunaite. Lerner Research Institute, Cleveland Clinic Foundation, Cleveland, OH.

Background/Purpose: Systemic Lupus Erythematosis (SLE) is a multi-system autoimmune disease that develops far more frequently in females than in males (9:1 ratio). The (NZBxNZW)F1 lupus-prone mouse model shares a female predominance of disease. Our recently published studies have shown decreased numbers of $Gr1^+CD11b^+$ cells in the spleens of female (NZBxNZW)F1 lupus-prone mice compared to males and that the level of these cells is modulated by testosterone. These cells have been found by our lab and others to suppress both T and B cell function *in vitro*. Depletion of this cell subset in male (NZBxNZW)F1 mice resulted in increased anti-nuclear antibody production. We suggest that the difference in cell numbers has a role to play in the gender differences in lupus-like disease development. We aimed to investigate the mechanism driving the difference in numbers of $Gr1^+CD11b^+$ cells in male and female mice. We hypothesized that the comparatively decreased levels of $Gr1^+CD11b^+$ cells in the female (NZBxNZW)F1 mice is due to either their decreased proliferative capacity or to their decreased survival.

Methods: Levels of proliferation and cell death of $Gr1^+CD11b^+$ cells from male and female (NZBxNZW)F1 mice were determined *ex vivo*using anti-Ki67 and Annexin V antibodies, respectively. The effect of hormonal manipulation on proliferation and cell death was assessed through pre-pubertal castration of male mice followed by DHT or placebo supplementation for 5 weeks. Total spleen and bone marrow cells from male and female mice were cultured in various conditions to determine the effect of cytokines and components of the male and female microenvironments on proliferation and cell death.

Results: Proliferation levels were not different in $Gr1^+CD11b^+$ cells from male and female mice, and these levels were unaffected by castration and DHT supplementation. Apoptosis levels were significantly higher in $Gr1^+CD11b^+$ splenocytes from female mice compared to male mice. There was no defect in clearance of apoptotic material in female (NZBxNZW)F1 mice compared to males. The level of cell death was elevated by castration of male mice, but not statistically significantly. Components of the male and female microenvironments were examined for their ability to alter levels of cell death *in vitro*, and we found that male bone marrow supernatants can significantly increase the survival of $Gr1^+CD11b^+$ cells when compared to female supernatants. We found higher levels of IL-1β in the male bone marrow supernatants and the level of IL-1β was modulated by castration and hormonal reconstitution. Culture of bone marrow cells from male and female (NZBxNZW)F1 mice with IL-1β significantly increased the survival of $Gr1^+CD11b^+$cells.

Conclusion: Increased apoptosis of female $Gr1^+CD11b^+$ cells may represent one of several mechanisms by which these cells are decreased in female mice compared to males, allowing autoimmunity to develop. The death of $Gr1^+CD11b^+$ cells was significantly decreased by exposure to male bone marrow supernatants *in vitro*, suggesting that the male microenvironment may support the survival of these cells. Additionally, our data implies that differences in IL-1β may be the factor in the male system that supports the survival of $Gr1^+CD11b^+$ cells.

Anti Ribosomal P Antibodies Accelerate Lupus Glomerulonephritis and Induce Lupus Nephritis In Naive Mice. Dana Ben-Ami Shor[1], Miri Blank[2], Sandra Reuter[3], Torsten Matthias[4], Alexander Volkov[5], Iris Barshack[6] and Yehuda Shoenfeld[7]. [1]Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center affiliated to Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Tel-Aviv, Israel, [2]Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, affiliated to Sackler Faculty of Medicine, Tel Aviv University, Tel-Aviv, Tel-Aviv, Israel, [3]AIRA e.V., AESKU.KIPP Institute, Wendelsheim, Germany, [4]AESKU.Diagnostics GmbH & Co. KG, Wendelsheim, Germany, [5]Institute of Pathology, Sheba Medical Center, affiliated to Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Tel-Aviv, Israel, [6]Institute of Pathology, Sheba Medical Center, affiliated to Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Tel-Aviv, Israel, [7]Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Affiliated to Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Tel-Aviv, Israel.

Background/Purpose: Circulating anti-phosphoribosomal protein antibodies (anti-Ribos.P) were found to be associated with lupus nephritis. We have assessed the direct role of anti-Ribos.P in the development of glomerulonephritis in-vitro and in animal models.

Methods: NZBxW/F1 lupus prone mice were immunized with recombinant Ribos.P0 (rRibos.P). The following lupus parameters were analyzed: autoantibodies screen directed to Ribos.P, dsDNA and Sm by ELISA. Proteinuria was determined by protein-sticks, kidney pathology by H&E staining and immunoglobulin deposits by immunofluorescence. Anti-Ribos.P deposited in the glomerular mesangium were eluted from the kidney. Anti-Ribos.P monoclonal Ab was prepared from the rRibos.P immunized NZBxW/F1 mice by hybridoma technology. MAPKs expression was analyzed by MAPKs protein-array and confirmed by real-time PCR. To elucidate whether anti-Ribos.P induce glomerulonephritis, naïve C3H mice were immunized with recombinant Ribos.P0 (rRibos.P) and the glomerulonephritis was followed up as described above.

Results: Our data demonstrate that rRibos.P0 immunized NZBxW/F1 mice developed accelerated glomerulonephritis characterized by anti-Ribos.P deposition in the glomerular mesangium. Primary mesangial cells exposed to mouse anti-Ribos.P mAb originated from the immunized lupus mice and to human anti-Ribos.P Abs, induced p38a MAPK expression. Moreover, naïve C3H/Hen mice immunized with rRibos.P0 developed experimental lupus nephritis manifested by circulating autoantibodies directed to Ribos.P, dsDNA, Sm and glomerulonephritis with anti-Ribos.P depositions. In conclusion, Our data show for the first time that anti-Ribos.P are nephritogenic autoantibodies, as illustrated by *in-vitro* and *in-vivo* experiments: a) They accelerate the development of glomerulonephritis in lupus prone mice; b) They induce nephritis in naïve mice. c) Anti-Ribos.P Abs trigger MAPKs expression in primary mesangial cells.

Conclusion: These data contribute a direct mechanistic link between anti-Ribos.P and nephritis in lupus mice.

Characterizing The Role Of The Granulocyte Colony Stimulating Factor Pathway In a Mouse Model Of Systemic Lupus Erythematosus. Laurence Morel and Ramya Sivakumar. University of Florida, Gainesville, FL.

Background/Purpose: Originally considered primarily a B cell disorder, lupus pathogenicity has recently been linked to enhanced functions of neutrophils. The genetic analysis of the lupus prone NZM2410 mouse has

identified a suppressor locus, *Sle2c2,* which confers resistance to spontaneous lupus in combination with NZM2410 susceptibility loci or in the chronic graft-vs.-host disease (cGVHD) induced model of SLE. We have shown that *Sle2c2* resistance is mediated by bone-marrow derived non-lymphoid cells. We hypothesize that a non-synonymous polymorphism in the granulocyte colony stimulating factor (G-CSF) receptor 3 (*Csf3r)* gene existing within *Sle2c2* is responsible for providing protection. G-CSF is required for neutrophil granulopoiesis, mobilization and activation. We hypothesize that the defective G-CSF receptor is associated with lupus resistance by controlling the homeostasis of pro-inflammatory neutrophils.

Methods: We have investigated the role of G-CSF pathway in both cGVHD induced lupus in B6.*Sle2c2* mice and spontaneous lupus in B6.*Sle1*.*Sle2*.*Sle3* triple congenic (TC) strain (also carrying the Sle2c2 locus) as compared to B6 mice. The ability of G-CSFR to bind mouse biotinylated G-CSF was compared between B6.Sle2c2 and B6 splenocytes and analyzed by flow cytometry. Treatments with varying doses of rh-GCSF (Neulesta) were tested in reversing or enhancing the course of disease in cGVHD induced SLE (B6.Sle2c2), and spontaneous lupus (TC). The effects of Neulesta on immune cell activation markers were assessed by flow cytometry and by ELISA's for antibodies against dsDNA and chromatin. Gene expression analyses by real time PCR for neutrophil and G-CSF specific genes were also employed as an alternative mechanism for studying the downstream effects of GCSF-GCSFR pathway.

Results: Neulesta treatments reversed cGVHD resistance in B6.Sle2c2 mice and increased anti-dsDNA IgG production in TC mice. Dose-dependent effects were however observed with high doses of Neulasta having a protective effect in B6.TC mice. In vitro and in vivo experiments have shown a reduced binding of G-CSF on myeloid cells and a decreased mobilization of neutrophils in response to Neulesta treatment in B6.*Sle2c2* mice compared to B6. Gene expression analyses have revealed a differential expression of G-CSFR-target genes between B6.Sle2c2 and B6 bone marrow cells and splenocytes in response to Neulesta. This included a lower expression of BAFF in B6.*Sle2c2* splenocytes than in B6, suggesting that BAFF production by neutrophils may represent a mechanism by which G-CSF regulates systemic autoimmunity.

Conclusion: Our results support the hypothesis that a G-CSF receptor with a defective binding for its ligand confers resistance to lupus. Future experiments aimed at elucidating the role of neutrophils as downstream effectors of the GCSF-GCSFR pathway will help in dissecting their pathogenic contribution to lupus. We predict that understanding the contribution of GCSFR axis towards SLE pathogenesis in mouse models of lupus will help us in identifying and designing potential and novel therapeutic targets for the disease.

Augmented Megakaryopoiesis Supports Accumulation Of Plasma Cells In Lupus-Prone Mice. Oliver Winter[1], Niels-Peter Becker[1], Stephanie Musiol[1], Katrin Moser[2], Falk Hiepe[3] and Rudolf A. Manz[4]. [1]Charité - University Medicine Berlin, Berlin, Germany, [2]German Arthritis Research Center (DRFZ Berlin), Berlin, Germany, [3]Charité University Hospital Berlin, Berlin, Germany, [4]University of Lübeck, Lübeck, Germany.

Background/Purpose: Autoantibodies - secreted by short- and long-lived plasma cells in bone marrow and spleen - trigger the immune response, and immune complex deposits in the kidneys can lead to the development of a severe nephritis. As such, autoreactive plasma cells contribute to the pathogenesis of the autoimmune disease Systemic Lupus Erythematosus (SLE). In NZB/W mice - a mouse model for SLE - both parental strains New Zealand Black (NZB) and New Zealand White (NZW) add different *sle-loci* to the formation of SLE. The NZB strain passes the *sle2c locus* that contains the gene for the Thrombopoietin (TPO)-receptor (*c-mpl*). According to the relevance of megakaryocytes for the plasma cell niche and the correlation between plasma cell and megakaryocyte numbers, we wanted to elucidate whether megakaryopoiesis, c-Mpl or c-Mpl signaling is altered in autoimmune mice.

Methods: We assessed the amount, and cellular environment of megakaryocytes and plasma cells in spleen and bone marrow of wildtype, NZB, NZW and NZB/W mice via flow-cytometry and confocal microscopy. We also investigated the intensity of megakaryopoiesis upon TPO stimulation, the occurrence of genetic variations for *c-mpl* and the activation of signaling pathways downstream of c-Mpl by *in vitro* studies, and by gene and protein analysis.

Results: We found the 10-fold amount of long-lived plasma cells and megakaryocytes in the spleens of NZB mice compared to wildtype, in NZW mice equal numbers, and in NZB/W mice numbers between those for NZB and NZW or wildtype. Furthermore, in the spleen a fraction of plasma cells clustered around megakaryocytes and *in vitro* megakaryocytes support plasma cell survival. Upon TPO stimulation of splenocyte and bone marrow cultures, NZB megakaryocytes proliferated significantly stronger resulting in the double amount of megakaryocytes compared to NZW cultures. Via sequence analysis we detected a missense mutation in the *c-mpl* gene of NZB mice leading to an amino acid replacement within the essential TPO-binding site. However, *in vitro* experiments with wildtype and mutant *c-mpl* BaF3-clones revealed that this mutation is actually hampering the proliferation upon TPO stimulation and hyperactivation of downstream signals is overcompensating.

Conclusion: In summary, our data indicate that augmented megakaryopoiesis enables the accumulation of a greater number of autoreactive plasma cells in lupus prone NZB/W mice. Thus, we propose that enhanced megakaryopoiesis and greater megakaryocyte numbers are contributing to the development and/or pathogenesis of SLE.

Neutrophil Gelatinase Associated Lipocalin (NGAL/Lipocalin-2) Regulates the Onset Of Serum Autoantibodies In Pristane Induced Lupus. Rahul Pawar[1], Beatrice Goilav[2], Yumin Xia[1], Haoyang Zuang[3], Leal Herlitz[4], Westley H. Reeves[3] and Chaim Putterman[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]Children's Hospital at Montefiore, Bronx, NY, [3]University of Florida, Gainesville, FL, [4]Columbia University Medical Center, New York, NY.

Background/Purpose: NGAL (lipocalin-2), a member of the lipocalin superfamily, is expressed by a variety of cells including neutrophils, hepatocytes, alveolar epithelial cells and renal resident cells. NGAL is a sensitive marker for tissue injury, and is upregulated following ischemia, inflammatory conditions, metabolic diseases and neoplastic disorders. Furthermore, several studies have demonstrated the use of NGAL as a biomarker in lupus nephritis. Previously, NGAL was reported to be involved in innate immune responses during bacterial infection, and was found to worsen renal disease in nephrotoxic serum nephritis. However, the role of NGAL in adaptive immunity is still largely unknown.

Methods: To investigate a possible role for NGAL in adaptive immune responses in an experimental lupus model, we injected pristane (tetramethylpentadecane) (0.5 ml/mouse intraperitoneally) into wild type B6 (n=10) and NGAL-deficient (LCN2−/−) (n=10) mice. Wild type (WT) B6 and LCN−/− mice receiving PBS injections served as controls. Serum autoantibodies were analyzed by ELISA, Hep-2 immunostaining, and immunoprecipitation. Autoantibody producing cells were quantitated by ELISPOT. Expression of mRNA in spleen was performed by real-time qPCR.

Results: Analyzing the levels of serum autoantibodies 4 months post pristane injection, we found that pristane challenged LCN2−/− mice had significant increases in IgG_{2b} anti-single and anti-double stranded DNA as well as IgG anti-histone antibodies as compared to pristane injected B6 mice. Furthermore, elevated levels of serum anti-ribonucleoprotein antibodies were observed in pristane injected LCN2−/− mice by immunoprecipitation. Confirming these results, analysis of serum anti-nuclear antibodies (ANA) on Hep-2 cells revealed significantly increased homogenous and speckled staining in pristane challenged LCN2−/− mice as compared to WT B6 mice, while ELISPOT revealed increased numbers of autoantibody producing cells to DNA, histone and RNP in the spleen. Moreover, we found significant upregulation of interferon regulatory factor-5 (IRF5), IP-10, CXCL13, CXCR5, CXCR3, and activation induced cytidine deaminase (AID) in spleens of LCN2−/− mice compared to B6 mice post pristane challenge. Pristane promoted NGAL secretion by splenocytes *in vitro*, while pristane challenge *in vivo* induced significant upregulation of NGAL expression in the spleen and serum of B6 mice.

Conclusion: NGAL/LCN2 deficiency accelerates the onset of antinuclear antibodies in pristane induced lupus, via increased levels of inflammatory mediators and autoantibody producing cells.

Different Cell Death Programs Contribute To Severity Of Lupus Glomerulonephritis In Males and Females. Neelakshi Jog[1] and Roberto Caricchio[2]. [1]Temple University, Philadelphia, PA, [2]Temple Univ Med Office Bldg, Philadelphia, PA.

Background/Purpose: Lupus glomerulonephritis (GN) is a leading cause of long-term disability in SLE. Although lupus is more common in females, GN occurs earlier and in a more accelerated manner in males. We propose that the severity of renal damage is defined by differences in cell death program during GN. Necrosis, a pro-inflammatory form of cell death can be regulated by two mediators: 1) Poly (ADP-Ribose) Polymerase-1 (PARP-1) and 2) Receptor Interacting Protein kinase 1/3 (RIP1/3). We demonstrated previously that the protection conferred by the absence or inhibition of PARP-1 from immune-mediated nephritis shows a sex-bias, with only male mice being protected. Several studies have shown that the response of males and females to stress differs. We therefore hypothesized that these differences might be due to cell death programs in the two sexes.

Methods: We used an established model of immune complex mediated nephritis to investigate cell death in vivo and an in vitro system where bone marrow cells were allowed to differentiate in vitro into macrophages in presence or absence of estrogens. The cells were stimulated by hydrogen peroxide or toll-like receptor ligand (TLR), lipopolysaccharide (LPS). Cell death was measured by flow cytometry and morphology; cytokine were measured by quantitative PCR.

Results: We demonstrate that during nephritis, females show increased apoptotic cell death in the kidney compared to males. We also show that estrogen treatment in males induced similar levels of apoptosis as in females and importantly inhibited necrosis. Although PARP-1 was activated in both males and females, PARP-1 inhibition decreased necrosis only in males. Interestingly inhibition of RIP1 with Necrostatin-1 did not show sex bias. To understand whether male and female cells show a differential cytokine expression pattern that may further contribute to the differences in cell death, we determined cytokine gene expression by bone marrow derived macrophages from male and female cells in response to TLR ligation in presence or absence of estrogens. We found that the expression of pro-inflammatory cytokines TNF alpha and MCP-1 were higher in male cells in absence of estrogens compared to females, suggesting that these cytokines may contribute to increased necrosis observed in males. We also observed that estrogens increased IL10 production in male cells upon TLR ligation. Interestingly IL10 has been previously shown to inhibit necrosis. Finally we found that estrogens reduced the levels of pro-inflammatory cytokines TNF alpha and MCP1.

Conclusion: Taken together our data suggest that males and females differ in their susceptibility to pro-inflammatory cell death, i.e. propensity toward necrosis in males and apoptosis in females. The contributing factors to this dichotomy are the effective activation of necrotic cell death, hormones and pro-inflammatory cytokines. Our results might help understanding the increased severity of lupus nephritis in males and develop novel therapeutic strategies based on sex.

Inhibitor Of Differentiation 3, A Transcription Factor Regulates Susceptibility To Kidney Disease. Dominika Nackiewicz, Ani Manichaikul, Barbara Szczerba, Paromita Dey, Stephen Rich, Coleen McNamara, Umesh Deshmukh and Harini Bagavant. University of Virginia, Charlottesville, VA.

Background/Purpose: Responses of renal cells to pathogenic stimuli play an important role in dictating susceptibility to kidney disease. Inhibitor of differentiation 3, ID3, is a member of the basic helix loop helix transcription factor family and is expressed in multiple cell types including glomerular mesangial cells. We have previously reported that a genetic deficiency of ID3, leads to mesangio-proliferative glomerulonephritis in spontaneously hyperlipidemic Apolipoprotein E knockout ($Apoe^{-/-}$) mice. In the present study, we investigated the mechanisms of ID3 related glomerular disease in hyperlipidemia and studied its relevance in humans. Influence of ID3 on immune mediated glomerulonephritis was also studied.

Methods: To study whether ID3 deficiency was sufficient for hyperlipidemic glomerulonephritis, C57BL/6 mice that were either ID3 sufficient wild type (WT) or ID3 deficient ($Id3^{-/-}$) mice were fed a high fat western diet and evaluated for different parameters of kidney disease. To investigate the potential mechanism of action, primary mesangial cell lines were generated from both mouse strains and stimulated with oxidized phospholipids. Cytokines and chemokines produced were measured by multiplex assays, ELISA, and QPCR. To study the relevance of ID3 in human disease, the association between *ID3* single nucleotide polymorphisms (SNPs) and kidney disease was studied in participants in the Multi-Ethnic Study of Atherosclerosis (MESA) and the influence of dyslipidemia on this association was investigated. As an additional model of kidney disease, WT and $Id3^{-/-}$ mice were injected with sheep anti-mouse glomerular basement membrane serum to induce immune mediated glomerular injury, and development of proteinuria was studied.

Results: $Id3^{-/-}$ mice on a western diet developed accelerated proteinuria and mesangio-proliferative glomerulonephritis. In vitro, $Id3^{-/-}$ glomerular mesangial cell lines produced higher levels of the monocyte chemoattractant, CXCL1 in response to oxidized phospholipids compared to WT controls. This was consistent with the rapid increase in glomerular CXCL1 expression followed by glomerular macrophage infiltration in $Id3^{-/-}$ mice fed a western diet. In humans, an analysis of MESA participants across three ethnic groups showed that of six tagging *ID3* SNPs, the T allele of a non-synonymous, functional SNP rs11574 showed a significant association with decreased urinary albumin creatinine ratios in Caucasians ($P=0.012$). This association was even stronger in participants carrying small low density lipoprotein particles ($p=0.0024$). This suggests the hypothesis that in the presence of lipid abnormalities, a change in ID3 influences kidney disease. The significance of functional ID3 in other forms of glomerular injury of kidney disease was further demonstrated in immune mediated nephrotoxic nephritis where $Id3^{-/-}$ mice developed severe and sustained proteinuria compared to WT mice.

Conclusion: A functional ID3 may regulate susceptibility to kidney disease and prevent glomerular injury by regulating local chemokine production and inflammatory cell recruitment.

Estrogen Receptor Alpha Deficiency Protects Against Development Of Cognitive Impairment In Murine Lupus. Melissa A. Cunningham[1], Jena Wirth[1], Heather A. Boger[2], Ann-Charlotte Granholm-Bentley[1] and Gary S. Gilkeson[3]. [1]MUSC, Charleston, SC, [2]Medical University of SC, Charleston, SC, [3]Medical University of South Carolina, Charleston, SC.

Background/Purpose: Up to 80% of SLE patients have cognitive defects or affective disorders. The mechanism of CNS injury responsible for cognitive impairment is unknown. Anti-dsDNA antibodies cross-reacting with NMDA receptors in the brain mediate excitotoxic cell death, causing behavioral changes in lupus–prone mice. A breach in the blood-brain barrier (BBB) is required for these effects. Data suggest that BBB breakdown, pathogenic autoantibodies, and subsequent neuronal damage in key areas are involved in the development of neuropsychiatric SLE. Since estrogen receptor alpha (ERα) deficiency significantly reduced renal disease and increased survival in murine lupus, we hypothesized that ERα deficiency would be similarly protective in the brain. In a pilot cohort, we previously showed that ERα deficiency reduces errors made in a water maze by lupus prone mice. We hypothesized that ERα plays a role in modulating BBB integrity and/or neuroinflammation leading to CNS dysfunction in lupus prone MRL/lpr mice.

Methods: MRL/lpr lupus mice (n=46) were ovariectomized at 4wks, received 90d-release estradiol pellets at 6wks, and underwent behavioral testing beginning at 8wks with radial arm water maze (RAWM) and novel object recognition (NOR). Mice were sacrificed at 12wks. Hippocampus, pre-frontal cortex and parietal cortex were dissected. Western blotting and IHC were used to evaluate tight junction proteins, BBB and inflammatory endpoints.

Results: MRL/lpr ER$\alpha-/-$ mice (n=21) performed significantly better in RAWM testing than WT MRL/lpr mice (n=25). There was a significant reduction in reference memory errors ($p<0.02$) and start arm errors ($p=0.02$) in ER$\alpha-/-$ mice at 8–10wks. There was a trend toward reduction in working memory errors ($p<.07$). There were significant differences in NOR testing: latency discrimination ratio ($p=.05$), time with objects ($p=.009$) and contact ratio ($p<.04$), with ERα deficiency normalizing behavior. There were no significant differences in serum estradiol or dsDNA. Eighteen of 43 brains were processed and analyzed to date, with no significant differences seen in tight junction proteins (Zo-1 or occludin), GFAP (astrogliosis marker), or Iba1 (microgliosis marker) in hippocampus. There is a trend toward decreased Zo-1 and Iba-1 in cortex of ER$\alpha-/-$ mice. There were no significant differences in Glut-1 or Evan's blue staining in sections analyzed to date.

There are CA1 lesions (utilizing MAP2 and NeuN staining) seen in a subset of animals, but these do not correlate with genotype or behavior in the animals analyzed to date.

Conclusion: ERα deficiency provides significant protection against cognitive deficits in MRL/lpr mice as early as 8 wks of age. Preliminary data suggest reduced microgliosis (marker of inflammation/insult) in cortex of ERα−/− mice. BBB proteins such as Zo-1 may also be involved.

Identification Of Stage Specific Genes Associated With Lupus Nephritis and Response To Remission induction In NZB/W Mice. Ramalingam Bethunaickan[1], Celine C. Berthier[2], Hong-dong Li[2], Weijia Zhang[3], Yuanfang Guan[2], Matthias Kretzler[2] and Anne Davidson[1]. [1]Feinstein Institute for Medical Research, Manhasset, NY, [2]University of Michigan, Ann Arbor, MI, [3]Mount Sinai School of Medicine, New York, NY.

Background/Purpose: Our goal was to use transcriptome analysis to elucidate the molecular mechanisms involved in the immunopathogenesis of renal inflammation during the onset, remission and impending relapse of nephritis in the NZB/W murine lupus model.

Methods: Targeted microarray analysis was performed on perfused kidneys obtained from NZB/W F1 mice at intervals during their disease course or after remission induction by cyclophosphamide combined with six doses of CTLA4Ig and anti-CD154 or by a combination CTLA4Ig and TACI-Ig. Validation of the differentially expressed genes was performed using real time PCR analysis. Comparisons between groups using SAM, and unbiased analysis of the entire dataset using Kohonen Networks were performed.

Results: Few changes in the renal molecular profile were detected prior to the onset of proteinuria but a significant shift in gene expression occurred at proteinuria onset. This profile reflected dendritic cell/macrophage and lymphoid cell infiltration and complement activation. As disease progressed, subsequent changes in gene expression predominantly reflected mitochondrial dysfunction and metabolic stress. Remission induction resulted in reversal of much of the inflammatory gene expression pattern however there was incomplete reversal of genes associated with early renal fibrosis, endothelial injury and hypoxia. Progression towards relapse was associated with increasing mitochondrial dysfunction and metabolic stress that preceded the onset of proteinuria. Using an unbiased approach we identified a major pattern of gene expression that was associated with proteinuria onset, nephritis progression and relapse. The top biological process identified for these genes was mitochondrial dysfunction. Finally, using Kohonen Networks we identified two major patterns of gene expression associated with progressive disease. The first, that associated with proteinuria onset and reversed with remission, involved multiple inflammatory pathways whereas the second, that associated with nephritis progression and relapse, involved multiple metabolic pathways. Using qRT-PCR we examined informative genes in a second murine lupus model NZM2410, in which remission of nephritis was induced with BAFF inhibition. While progression towards relapse was associated with recruitment of pro-inflammatory genes, the expression pattern that distinguished kidneys of mice harvested >30 weeks after remission induction from kidneys of mice with proteinuria and renal damage indicated that renal hypoxia, endothelial cell activation, tissue remodeling and tubular damage were the major mediators of renal loss.

Conclusion: Our findings show that immune cell infiltration and activation is associated with proteinuria onset and reverses with immunosuppressive therapy but that disease progression and impending relapse is associated with increasing renal hypoxia and metabolic stress. These findings suggest that that as nephritis progresses or during nephritis flares, therapeutic targeting only of inflammation becomes less likely to prevent eventual renal decline. Optimal therapy of SLE nephritis should target both immune and non-immune disease mechanisms.

Therapeutic Inhibition Of Anti-Apoptotic BCL-2 Family Proteins In a Murine Model Of Lupus Nephritis. Li Chun Wang[1], Stuart Perper[1], Danise Perron[1], Edit Tarcsa[2], Philip Bardwell[1], Neelufar Mozaffarian[3], Andrew Souers[3], Steven Elmore[3], Tariq Ghayur[1] and Lisa Olson[1]. [1]AbbVie Bioresearch Center, Inc, Worcester, MA, [2]AbbVie Bioresearch Center, Worcester, MA, [3]AbbVie, North Chicago, IL.

Background/Purpose: Apoptosis is both a conserved and highly regulated process that is essential for normal development and tissue homeostasis. This process, also known as programmed cell death, is tightly regulated by the BCL-2 family proteins. Dysregulation of these proteins has been linked to survival of autoreactive lymphocytes and to Systemic Lupus Erythematosus (SLE). Inhibition of BCL-2 proteins may therefore ameliorate autoimmunity.

This study evaluated the effects of inhibition of BCL-2 survival proteins in a murine model of lupus nephritis, as well as the effect on human leukocytes ex vivo.

Methods: We have established previously that adenovirus vector-mediated delivery of murine IFN-α in lupus-prone (NZB × NZW)F1 mice induces a rapid and severe disease with many characteristics of SLE, including death due to severe glomerulonephritis. These mice were treated daily with vehicle or 3, 10, 30 mg/kg of navitoclax, a BH3 mimetic that binds with high affinity to BCL-2, BCL-XL, and BCL-W. Mycophenolate (100 mg/kg) was used as a clinical benchmark and positive treatment control. Proteinuria and survival data were presented as Kaplan-Meyer survival curves using Prism. For ex vivo human lymphocyte studies, B and T cells from healthy donors were cultured and treated with navitoclax overnight, prior to flow cytometric analysis. Some cultures were incubated with anti-CD40L/IgM or anti-CD3/CD28 to stimulate B or T cells, respectively. IC50 calculations were performed using GraphPad. Results were considered significant at the level of $p < 0.05$.

Results: BCL-2 family inhibition by navitoclax in the IFNƒÑ-induced (NZB × NZW) F1 lupus model significantly reduced both the incidence of severe proteinuria (> 300mg/dL) and mortality as compared to vehicle controls ($p < 0.05$). In addition, chronic administration of navitoclax at 30 mg/kg demonstrated 95% survival rate and 50% of animals without proteinuria as compared to 80% and 20%, respectively, in mycophenolate-treated animals. Consistent with its mechanism of action, navitoclax caused a dose-dependent reduction in murine lymphocyte counts, which correlated with long-term efficacy. In ex vivo human cell cultures, navitoclax treatment led to a rapid reduction in the numbers of both stimulated and unstimulated human lymphocytes, with B cells showing a higher sensitivity to navitoclax compared to T cells.

Conclusion: Treatment of lupus nephritis-prone mice with the BCL-2 family inhibitor navitoclax resulted in preservation of renal function and overall survival. Furthermore, BCL-2 inhibition in ex vivo human lymphocyte cultures led to a rapid and selective reduction of B and T cells via apoptosis. Taken together, these data support a role for BCL-2 inhibition in the treatment of autoimmune diseases such as SLE.

Depletion Of The Gut Microbiota Prevents β_2-Glycoprotein I Antibody Production and Mortality In a Model Of Antiphospholipid Syndrome. Silvio M. Vieira, Andrew Yu, Odelya E. Pagovich, Eleni Tiniakou, John Sterpka and Martin A. Kriegel. Yale University School of Medicine, New Haven, CT.

Background/Purpose: Infectious triggers have been implicated in transient antiphospholipid antibody production in both mice and humans. The cause of persistent anti-β_2-glycoprotein I (β_2GPI) antibody production in the lupus-related antiphospholipid syndrome (APS) is unknown. We hypothesize that pathogenic antiphospholipid antibodies in the spontaneous (NZWx-BXSB)F_1 model of APS/SLE are induced and sustained by the gut microbiota that chronically colonizes its host. We therefore generated commensal-ablated animals in order to test if depletion of the microbiota with broad-spectrum antibiotics leads to attenuation of the APS phenotype characterized by multiple non-atherogenic, immune-mediated myocardial infarctions culminating in sudden deaths.

Methods: Broad-spectrum antibiotic- and control water-treated (NZWx-BXSB)F_1 hybrid males were followed until death from autoimmunity. DNA was isolated from fecal pellets (MoBio) and tested for eubacterial load by 16S ribosomal DNA real-time PCR (Bio-Rad). Urine and sera were collected longitudinally and analysed for proteinuria from lupus-related glomerulonephritis and anti-β_2-GPI titers by ELISA (Alpha Diagnostic), respectively. Hematoxylin and eosin-stained slides were prepared from myocardial tissues. Kaplan-Meier survival curves were generated comparing antibiotic- and control water-treated mice.

Results: 16S ribosomal DNA load was profoundly suppressed after treatment with a cocktail of vancomycin, metronidazole, neomycin and ampicillin that was initiated at 6 wks of age. Antibiotic-treated mice had significantly lower titers of anti-β_2GPI antibodies at 4 months of age ($p=0.014$) and were protected from APS-related deaths ($p=0.005$). Ceca were markedly enlarged on necropsy as typical also for germ-free animals. Surprisingly, SLE-related proteinuria, known to be driven by an endogenous retroviral protein, was also suppressed in antibiotic-treated mice compared to controls ($n=7–8$ mice; $p=0.026$).

Conclusion: Depletion of the gut microbiota with a regimen that approximates a germ-free state in the gastrointestinal tract leads to lower anti-β_2GPI titers and protection from APS-induced myocardial infarctions. These results suggest that gut commensals are fundamentally involved in the pathogenesis of APS. Intriguingly, endogenous retroviral-driven proteinuria secondary to lupus nephritis in the $(NZWxBXSB)F_1$ hybrid was also suppressed by this regimen, pointing towards a possible interaction between the gut microbiota and retroviruses in systemic autoimmunity. These findings support an unexpected role of commensals in both APS and SLE. Future work is aimed at identifying the causal triggers within the gut microbiome and dissecting the immunologic mechanisms behind the protective effects in this model.

Inhibition of Calcium/Calmodulin-Dependent Protein Kinase 4 Ameliorates Th17 Related Autoimmune Disorder. Tomohiro Koga, Christian Hedrich, Masayuki Mizui, Nobuya Yoshida, Linda Lieberman, José C. Crispin and George C. Tsokos. Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.

Background/Purpose: IL-17-producing T helper (Th17) cells have been causally linked to tissue inflammation in several autoimmune diseases including lupus and multiple sclerosis. Blockade of Th17 action or differentiation could therefore represent a useful therapeutic strategy in these settings.

Methods: We immunized C57B/6 mice or *Camk4* deficient C57B/6 (B6 *Camk4*$^{-/-}$) mice with MOG 35–55 emulsified in complete Freund's adjuvant (CFA) containing Mycobacterium tuberculosis and evaluated the disease activity. MRL/lpr mice were treated with KN-93, an antagonist of calcium/calmodulin-dependent protein kinase IV (CaMK4), and examined IL-17 producing T cell in the spleen and lymph node *in vivo* and *in vitro*. We also tested the number of infiltrated T cell and IL-17 related genes in lungs and kidneys. Furthermore, We compared the methylation status in *Il2* or *Il17A* promoter and the binding capacity of cAMP response element modulator (CREM)-α to these promoters in *Camk4* sufficient or deficetnt conditions. To determine the relevance of our findings to human SLE, we analyzed the effect of CaMK4 inhibition on Th17 cells function in T cells from patients.

Results: Here, we show that KN-93 inhibits Th17 cell differentiation both *in vivo* and *in vitro*. The relevance of this is reflected by the fact that B6 *Camk4*$^{-/-}$ mice suffer less experimental autoimmune encephalomyelitis (EAE) and MRL/*lpr* *Camk4*$^{-/-}$ have decreased autoimmunity and organ damage. Treatment of MRL/*lpr* mice with KN-93 decreases Th17 cell differentiation, prevents double negative T cells from infiltrating lungs and kidneys, and protects against organ damage. In *in vitro* experiments, KN-93 diminishes IL-17 production and reciprocally improves IL-2 production by CD4 T cells cultured under Th17-polarizing conditions. These effects are mediated through the activity of CREM-α that controls epigenetic remodeling of the *Il2* and *Il17a* loci. Analogously, silencing of *CaMK4* in T cells from patients with SLE and healthy controls decreases the expression of *IL17A* upon stimulation in the presence of TGF-β and IL-6.

Conclusion: Collectively, our results suggest that CaMK4 inhibition might be a promising therapeutic agent for autoimmune diseases mediated by Th17 cells.

Fli-1 Regulates Immune Cell Infiltration Through Affecting Local Chemokine Expression and IL-6 Expression In The Kidney Of Lupus Prone Mice. Shuzo Sato[1], Sarah Williams[2], Eva Karam[1] and Xian Zhang[3]. [1]Medical University of South Carolina, Charleston, SC, [2]Ralph H. Johnson VA Medical Center, Charleston, SC, [3]Medical University of South Carolina and Ralph H. Johnson VA Medical Center, Charleston, SC.

Background/Purpose: Fli-1 expression level, a member of the Ets family of transcription factors, is a mitigating factor in the development of nephritis in murine models of systemic lupus erythematosus. We have reported that reduced expression of Fli-1 in MRL/lpr mice, a murine model of lupus, resulted in significantly prolonged survival and reduced glomerulonephritis. Inflammatory cell infiltration into the kidney plays a critical role in lupus nephritis progression. In kidney, Fli-1 is mainly expressed in endothelial cells in the interstitial capillaries and glomerulus. The role of Fli-1 regarding immune cell infiltration into the kidney is still unclear. We hypothesized that reduced Fli-1 expression affects local chemokine expression, cytokine production and influences immune cell infiltration into the kidney. To investigate this hypothesis, we performed following experiments.

Methods: We generated MRL/lpr transgenic mice expressing green fluorescent protein (GFP), and isolated spleen cells from these mice (6 to 8 months old). One million cells were injected into 9 Fli-1 heterozygous (+/−) and 13 wild-type (WT) MRL/lpr mice (4 to 8-month-old). Mice were sacrificed 18 hours after injection, after that kidneys were removed and frozen sections were made. Inflammatory cells with GFP were counted by immunofluorescence studies. The expression of chemokines (CCL2, CCL3, CCL4, and CCL5) and IL-6 in the recipient kidney was analyzed by real-time PCR. To investigate whether the Fli-1 disruption actually reduces cytokine production *in vitro*, we transfected Fli-1 specific siRNA to the MS1 cells (murine endothelial cell line) and analyzed the supernatant IL-6 concentration after LPS stimulation. In addition, whether Fli-1 directly regulates IL-6 expression by binding IL-6 promoter region, we performed chromatin immunoprecipitation (ChIP) assay using anti-Fli-1 antibody in MS1 cells. Isolated ChIP DNA was amplified by real-time PCR using IL-6 promoter primers.

Results: The infiltrated GFP positive inflammatory cells were significantly decreased in kidneys of Fli-1+/− MRL/lpr mice. The number of infiltrated T cells, B cells and macrophages were also significantly decreased. The relative mRNA expression of chemokines (CCL2, 3 and 4) and IL-6 in the kidney (WT vs Fli-1+/−) showed significantly lower in Fli-1+/− MRL/lpr mice. CCL5 expression was also showed lower trends ($P=0.079$). Fli-1 disruption of MS1 cells using siRNA showed reduced production of IL-6 after LPS stimulation. Furthermore, ChIP assay using IL-6 promoter primers indicated that Fli-1 directly binds to IL-6 promoter regions in murine endothelial cells.

Conclusion: Fli-1 regulates lupus nephritis development by modulating expression of inflammatory chemokines, IL-6 and immune cell infiltration into the kidney.

Effects Of In Vivo Treatment With Hydroxychloroquine On Endothelial Function In a Murine Model Of Systemic Lupus Erythematosus. Marta Mosca[1], Chiara Tani[1], Sabrina Vagnani[1], Linda Carli[2], Rosaria Talarico[3], Chiara Baldini[3], Stefano Bombardieri[1] and Agostino Virdis[4]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]GenOMeC PhD, University of Siena, Siena, Italy, [3]Rheumatology Unit, Pisa, Italy, [4]Hypertension Unit, University of Pisa, Pisa, Italy.

Background/Purpose: Antimalarial drugs are a cornerstone of treatment of systemic lupus erythematosus (SLE). It has been suggested that antimalarial drugs may have a protective effect on thrombosis, may be beneficial on lipid profile, may reduce atherosclerosis accrual.

In the present study we aimed at assessing the endothelial function on mesenteric resistance arteries in a mouse model of SLE (NZB/W F1) treated with hydroxychloroquine (HCQ).

Methods: Sixty 12 weeks old female NZB/W F1 mice (mSLE) were divided in 3 groups: group A no therapy, Group B treated with HCQ 3 mg/Kg body weight/day (corresponding to 200 mg/day in humans), group C C56BL/6J (mC) mice as controls. Animals were monitored for 24-hours proteinuria, anti-dsDNA antibodies titers as disease progression parameters and were sacrificed at 18, 24, 30 and 42 weeks of age.

Endothelium-dependent relaxation of small arteries (pressurized myograph), was assessed by infusion of acetylcholine (Ach), while NO availability was assessed by repeating Ach under the nitric oxide synthase (NOS) inhibitor L-NAME.

Results: In Group A, a decline in relaxation to Ach emerged at 18 weeks of age, with a further worsening at 30 and 42. The inhibitory effect of L-NMMA on Ach was reduced at 18 and progressively blunted up to 30 and 42 weeks; interestingly, endothelial dysfunction (ED) appeared simultaneously to a significant increase in 24-hours proteinuria. In group B, HCQ treatment was associated with a significant delay in the appearance of

anti-dsDNA and proteinuria and concomitantly, HCQ prevented the decline of Ach-induced relaxation up to 30 weeks. Starting from this age, the protective effect of HCQ, although still present, was less evident. In group C, relaxation to Ach significantly started to decline at 30 weeks of age with a concomitant reduction of the inhibitory effect of L-NMMA on Ach. The response to sodium nitroprusside (SNP) started to decline at 30 weeks of age in Group A, while was preserved in group C (table 1).

Table 1. ED relaxation

Age (weeks)	18			24			30			42		
	Group A	Group B	Group C	Group A	Group B	Group C	Group A	Group B	Group C	Group A	Group B	Group C
Maximal vasodilation to Ach (%)	90 ± 2	98 ± 2	98 ± 2	81 ± 2	95 ± 1	98 ± 1	69 ± 2	87 ± 1	93 ± 1	63 ± 2	71 ± 1	83 ± 1
Inhibitory effect of L -NMMA on Ach (%)	42 ± 1	*Not done*	52 ± 3	30 ± 2	*Not done*	54 ± 3	10 ± 1	*Not done*	44 ± 1	7 ± 4	*Not done*	35 ± 2
Maximal vasodilation to SNP (%)	99 ± 2	*Not done*	97 ± 3	97 ± 2	*Not done*	98 ± 2	85 ± 3	*Not done*	94 ± 2	76 ± 1	*Not done*	83 ± 2

Conclusion: Treatment with HCQ seems to prevent the occurrence of ED in treated animals, suggesting an early vascular protective effect of this drug. Additional studies are underway to understand whether this observation has to be correlated with disease activity control or reflects an additional independent effect of HCQ.

Purified IgG From Patients With Systemic Lupus Erythematosus Enhances Apoptosis In Neonatal Rat Cardiomyocytes Exposed To Simulated Myocardial Ischaemic/Reperfusion Injury. Lauren Bourke[1], James McCormick[1], Vera Ripoll[1], Charis Pericleous[1], Anna Radziszewska[2], Anastasis Stephanou[1] and Yiannis Ioannou[2]. [1]University College London, London, United Kingdom, [2]Arthritis Research UK Centre for Adolescent Rheumatology at University College London, Great Ormond Street Hospital and UCLH, University College London, London, United Kingdom.

Background/Purpose: A significant amount of myocardial damage during a myocardial infarction (MI) occurs during the reperfusion stage which is known as ischaemic reperfusion (I/R) injury and can account for up to 50% of cell death. Systemic Lupus Erythematosus (SLE) is a condition associated with a high burden of cardiovascular morbidity and mortality, when compared to the matched healthy population. Patients with SLE have circulating autoantibodies which have been linked to an increased risk of suffering an MI. Studies performed by other groups have shown accelerated I/R injury in other systems such as mesenteric I/R injury in a lupus mouse model, however to date there has been no research focusing on the heart. The purpose of this study is to assess I/R injury in the presence of polyclonal IgG from patients with SLE in an *in vitro* model of simulated myocardial I/R injury in neonatal rat cardiomyocytes.

Methods: Polyclonal IgG was isolated by protein G purification from serum of patients with SLE (n=23) and healthy controls (n=11) which were age and gender matched. Endotoxin was removed using Detoxi-Gel columns to a level below 0.225 endotoxin U/mL. It was observed that cells treated with LPS at this level did not have altered caspase-3 cleavage. Fetal calf serum used in the buffers was also heat inactivated to remove complement mediated mechanisms. We utilised an established *in vitro* model of anoxia/reoxygenation to I/R injury. Cardiomyocytes were isolated from 1–2 day old rat pups and when beating synchronously were treated with 500 μg/ml polyclonal IgG from each group and the following day exposed to simulated I/R injury for 4hr in a hypoxic chamber (argon, 5% CO_2) followed by 4hr of reoxygenation. Apoptosis was measured by assessment of caspase-3 cleavage using immunoblot.

Results: In cells exposed to simulated I/R injury caspase-3 cleavage was not significantly increased in the presence of IgG from healthy volunteers (mean increase in caspase-3 cleavage of cells treated with healthy control IgG above untreated cell baseline − 12.28% ± SD 26.01, n=11). However, in the presence of IgG from patients with SLE, caspase-3 cleavage was increased by 54.79% (±SD 28.9, n=23) above untreated cell baseline and therefore significantly increased in comparison to healthy controls (p=0.0016). The effect observed with IgG from SLE patients was not altered when serum used in the buffers was heat inactivated suggesting a non-complement mediated mechanism.

Conclusion: In this *in vitro* simulated I/R injury model IgG purified from patients with SLE enhanced I/R injury as assessed by caspase-3 cleavage. This novel pathogenic role of these antibodies will now be tested *in vivo* to validate this finding and explore potential mechanisms of action.

Acyl-CoA Synthetase 1 Expression Is Increased In Murine Models Of Lupus As Well As In Human Systemic Lupus Erythematosus. Eyal Kedar[1], Shelley Barnhart[1], Keith B. Elkon[2] and Karin Bornfeldt[1] [1]University of Washington, Seattle, WA, [2]Division of Rheumatology, Department of Medicine, University of Washington, Seattle, WA.

Background/Purpose: The enzyme acyl-CoA synthetase 1 (ACSL1) converts free fatty acids into their biologically active acyl-CoA derivatives. It is induced by lipopolysaccharide and cytokines (including IFN-gamma and TNF-alpha) and is detected in macrophages in type 1 diabetes mellitus. Increased expression is associated with the inflammatory activation of these cells. ACSL1 promotes membrane phospholipid turnover in activated macrophages, which might contribute to its inflammatory effects. This study was conducted to investigate whether ACSL1 is upregulated in myeloid cells in both human and mouse lupus.

Methods: *Acsl1* mRNA levels were measured in human peripheral blood mononuclear cells of patients with lupus and controls, and in splenocytes of TLR7 transgenic mice. Bone marrow-derived macrophages and thioglycollate-elicited peritoneal macrophages from C57/B6 mice were also stimulated with universal type 1 interferon (5, 50 and 500 U/mL), and *Acsl1* mRNA and protein levels were measured. Finally, C57/B6 mice were injected i.p. with 0.5 mL of pristane, and blood monocytes and bone marrow monocytes were isolated by negative magnetic bead selection two weeks later. Messenger RNA levels of *Acsl1* as well as three lupus interferon signature genes (*Isg15, Irf7* and *Cxcl10*) were determined by real-time PCR.

Results: *ACSL1* mRNA expression was increased in peripheral blood mononuclear cells of patients with lupus (p=0.004) as compared to matched controls. Expression was also increased in splenocytes obtained from the TLR7 transgenic mouse model of lupus (p<0.05). Since *Acsl1* expression was increased in both mouse and human lupus, we asked whether *Acsl1* could be an interferon-stimulated gene (ISG). We observed that *Acsl1* mRNA was induced 3–4 fold by type 1 IFN in thioglycollate-elicited macrophages (p<0.05) and was induced 6–7 fold in bone marrow-derived macrophages (p=0.005), concomitant with an increase in the well-known ISG *Cxcl10*. Acsl1 protein was also increased following interferon stimulation. We observed that *Acsl1* was induced by pristane in bone marrow monocytes (p=0.03), and was positively associated with the rise of the three lupus interferon signature genes in blood monocytes (p<0.05).

Conclusion: This is the first demonstration of increased expression of *Acsl1* in human lupus as well as in mouse models of this disease. These findings demonstrate that ACSL1 is an ISG. The functional significance of these observations are that type 1 IFN's may drive expression of *Acsl1* in lupus, which in turn, given ACSL1's ability to promote membrane phospholipid turnover, may modulate the inflammatory potential of monocytes or macrophages in this disease. The direct variation of *Acsl1* with the three lupus interferon signature genes we studied further suggests a potential signaling role of ACSL1 and/or its downstream metabolites in either the TLR7 or IFN receptor (IFNAR) signaling pathways in lupus.

The Knock-Out Of TWEAK Receptor/Fn14 Ameliorates Lupus Nephritis In MRL/Lpr Mice. Yumin Xia[1], Leal Herlitz[2], Simona Gindea[1], Jing Wen[1], Rahul Pawar[1], Alexander Misharin[3], Harris R. Perlman[3], Ping Wu[4], Jennifer Michaelson[4], Linda Burkly[4] and Chaim Putterman[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]Columbia University Medical Center, New York, NY, [3]Northwestern University, Chicago, IL, [4]Biogen Idec, Cambridge, MA.

Background/Purpose: Renal mesangial cells, podocytes, and tubular cells express Fn14, the sole confirmed receptor for the tumor necrosis factor (TNF)-family member cytokine TWEAK (TNF-like weak inducer of apoptosis). The activation of the TWEAK/Fn14 pathway induces kidney resident

cells to produce multiple proinflammatory mediators as well as promotes their proliferation or death. In the chronic graft-versus-host and nephrotoxic serum models of antibody-mediated renal disease, we had previously found that genetic deficiency of Fn14, or treatment with an anti-TWEAK monoclonal antibody, decreases kidney inflammation and proteinuria without affecting systemic autoantibody titers. These studies suggest that inhibition of TWEAK/Fn14 interactions might be efficacious in the treatment of immune-mediated renal diseases. The purpose of this study was to evaluate the effect of Fn14 deficiency in spontaneous murine lupus nephritis (LN).

Methods: Fn14-knock out (KO) 129 mice were backcrossed for eight generations onto MRL-lpr/lpr (wild type, WT) mice to generate MRL/lpr, Fn14 KO mice. Age and sex-matched MRL/lpr Fn14 WT littermates and MRL/MpJ mice were used as control strains. The severity of renal damage was evaluated by measuring proteinuria and renal function, and immunohistochemical staining of kidney tissues. Immunofluorescent microscopy and transmission electron microscopy (TEM) were performed on frozen kidney sections. The systemic effect of Fn14 KO was assessed by determining the levels of autoantibodies in sera, assessing lymphadenopathy, and analyzing splenocytes numbers and subsets.

Results: We found that at 26 to 38 weeks of age, female MRL/lpr Fn14-WT mice had significantly higher levels of proteinuria, BUN, and serum creatinine as compared to female Fn14-KO mice. Moreover, MRL/lpr Fn14 KO mice had significantly improved renal histopathology, with less glomerular immune deposition, endocapillary hypercellularity, mesangial proliferation, and perivascular inflammation. TEM revealed less electron-dense deposits and fusion of podocyte foot processes along the glomerular basement membrane of Fn14 KO mice. Furthermore, scoring of renal injury markers revealed diminished expression of Ki-67 and TIM-1 in the Fn14-KO mice, while immunofluorescence staining revealed reduced glomerular nephrin expression in the Fn14-WT mice. While the lymphadenopathy score was significantly improved in Fn14-KO mice, there were no differences between the strains in both autoantibody titers (anti-dsDNA, chromatin, ribosomal P, or cardiolipin IgG) at any time point between 26–38 weeks, or in splenocyte subsets at 38 weeks of age, suggesting that TWEAK likely acts by modulating events locally in the kidney.

Conclusion: Our results demonstrate that the inhibition of TWEAK signaling by genetically deleting the Fn14 receptor significantly improved renal damage in spontaneous LN in MRL-lpr mice, suggesting that the TWEAK/Fn14 axis may be a novel therapeutic target for LN.

563

Hold The Rituximab: Neuropsychiatric Disease In Murine Lupus Is Not B-Cell Dependent. Jing Wen[1], Ariel Stock[1], Haowei Wang[2], Mark Shlomchik[2], Maria Gulinello[1] and Chaim Putterman[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]Yale University School of Medicine, New Haven, CT.

Background/Purpose: Neuropsychiatric disease is one of the earliest clinical manifestations in systemic lupus erythematosus (SLE). However, the mechanisms leading to neuropsychiatric SLE (NPSLE) are not fully understood, and the optimal treatment yet to be defined. In lupus, a compromised blood brain barrier may allow for the passage of circulating autoantibodies into the brain, where they can then induce neuropsychiatric abnormalities. Previous studies have reported that autoantibody titers correlate with the severity of depressive-like behavior, and that injection of anti-ribsomal P and anti-NMDA receptor antibodies into the brain induces neuronal damage and memory deficits. Since antibodies play an important role in lupus pathogenesis, B-cell depletion has been proposed as a targeted treatment approach. To determine if indeed B-cells and/or autoantibodies are instrumental in the pathogenesis of murine NPSLE, we evaluated neuropsychiatric disease in B-cell depleted (JhD/MRL/lpr) and wild type MRL/lpr lupus mice, the latter which are known to develop several cardinal features of human NPSLE.

Methods: Blood and cerebrospinal fluid (CSF) were collected from female JhD/MRL/lpr and MRL/lpr mice at 20 weeks of age. To confirm B cell depletion in JhD/MRL/lpr mice, PBMC were stained with CD19 and analyzed by FACS. Total IgG and IgG anti-DNA antibody concentrations in the serum and CSF were measured by ELISA. Comprehensive neurobehavioral testing including forced swim, anhedonia, open field, object recognition, object placement, and social preference were employed to evaluate the neuropsychiatric manifestations in JhD/MRL/lpr as compared to MRL/lpr mice.

Results: We confirmed that peripheral B-cells were substantially depleted in JhD/MRL/lpr mice, and that autoantibody levels were negligible in the serum and CSF. Nevertheless, we found that in the forced swim test, JhD/MRL/lpr mice showed dramatic depressive-like behavior (as indicated by increased floating time), which was no different than MRL/lpr mice (JhD/MRL/lpr: 56.2%+1.2%, n=7; MRL/lpr: 61.8%+6.9%, n=5; MRL/+: 19.9%+4.7%, n=5). Additionally, JhD/MRL/lpr mice displayed cognitive dysfunction in the object placement (OP) test, as demonstrated by the OP preference score (JhD/MRL/lpr: 40.8%+8%, n=5; MRL/lpr: 50.9%+12.5%, n=5; MRL/+: 66.0%+3.8%, n=5). Furthermore, there were no differences in object recognition and social preference between these two mice strains. However, in the open field test, an increased number of rears were observed in JhD/MRL/lpr mice.

Conclusion: B-cell depleted MRL/lpr mice surprisingly had no attenuation of key features of neuropsychiatric disease, including depressive-like behavior and cognitive dysfunction, despite negligible serum and CSF IgG concentrations. However, an increased number of rears were observed in JhD/MRL/lpr mice, indicating higher motor activity. Thus, constitutive depletion of B-cells was not sufficient to ameliorate lupus-associated neuropsychiatric disease, at least in the MRL/lpr strain. Whether conditional B-cell ablation later on in life will have the same effect remains to be determined.

Role of TLR3 and dsRNA Hyper-Responsiveness in the Generation of the Lupus-Like Phenotype of New Zealand Black Congenic Mice. Gillian Minty[1], Nan-Hua Chang[2], Kieran Manion[1], Yuriy Baglaenko[1], Evelyn Pau[1] and Joan E. Wither[3]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Toronto Western Hospital, Toronto, ON, [3]Toronto Western Research Institute, Toronto Western Hospital, University of Toronto, Toronto, ON.

Background/Purpose: New Zealand Black (NZB) mice develop a spontaneous lupus-like autoimmune disease, similar to human systemic lupus erythematosus. Genetic mapping studies have linked loci on NZB chromosome 13 to the generation of the autoimmune phenotype. Consistent with this, congenic mice with a homozygous NZB chromosome 13 interval introgressed onto the C57BL/6 (B6) background (B6.NZBc13 (c13)) develop an autoimmune phenotype that includes: anti-chromatin, anti-ssDNA, anti-dsDNA, and anti-SmRNP autoantibody production, increased B cell activation, marginal zone B cell expansion, increased T cell activation, and dendritic cell expansion. In previous experiments these mice were found to have an apoptosis clearance defect and hyper-responsiveness to the dsRNA TLR3 ligand poly (I:C) that mapped to different areas of the interval. To examine the role of the TLR3 and poly (I:C) hyper-responsiveness in the generation of the c13 autoimmune phenotype, a TLR3 knockout was backcrossed onto the c13 genetic background.

Methods: B6.TLR3$^{-/-}$ and c13.TLR3$^{-/-}$mice were aged to six months and their cellular phenotypes assessed by flow cytometry. B cell responses to TLR agonists were assessed by culturing cells for 2 days and then measuring B cell activation and TLR3 expression by flow cytometry. ELISA assays were used to quantify serum autoantibody production.

Results: Loss of TLR3 on both B6 and c13 genetic backgrounds rendered their splenocytes unresponsive to stimulation with poly (I:C), proving these mice to be true functional knockouts. De-novo B cell activation was attenuated in 6 month old c13.TLR3$^{-/-}$ mice. The expanded marginal zone B cell compartment of c13 mice was also lost in knockout mice. T cell activation was unaffected in c13.TCR3$^{-/-}$ mice, while there was a trend to decreased expansion of the dendritic cell population. Despite impaired B cell activation, autoantibody production was not completely abrogated in c13.TLR3$^{-/-}$ mice: IgG and IgM anti-chromatin antibodies were still produced, while anti-dsDNA and -ssDNA antibody production was attenuated.

Conclusion: Relieving the dsRNA hyper-responsive sensing defect by knocking out TLR3 led to a loss of many of the altered B cell phenotypes in c13 mice but had modest effects on autoantibody production, dendritic cell expansion, and T cell activation. These findings further support the presence

of at least two susceptibility loci within the c13 interval; one responsible for the dsRNA hyper-responsiveness and many of the characteristic B cell abnormalities, and the other which drives the other altered cellular phenotypes as well as chromatin autoantibody production.

Differential Efficacy Of Human Mesenchymal Stem Cells On Disease In Murine Lupus Based On Source Of Origin. Erin Collins[1], Fei Gu[2], Osama S. Naga[1], Phil Ruiz[3] and Gary S. Gilkeson[1]. [1]Medical University of South Carolina, Charleston, SC, [2]Division of Rheumatology and Immunology, Medical University of South Carolina, Charleston, SC, [3]University of Miami, Miami, FL.

Background/Purpose: Systemic lupus erythematosus (SLE) is a devastating autoimmune disease that targets multiple organ systems. Current treatment options for SLE often cause non-specific immune suppression, which can lead to undesirable side effects. Therefore a new treatment approach with limited harmful side effects, is of particular interest. A population of non-hematopoetic stem cells, mesenchymal stem cells (MSC), are of increasing interest as a therapeutic option for autoimmune diseases such as SLE. MSCs can be derived from various sources such as bone marrow or umbilical cords, and have proven successful at suppressing various immune cells. In this study we examine the efficacy of human MSCs with varying origin on disease in murine based lupus.

Methods: To define the efficacy of human MSCs on murine lupus we harvested MSCs from umbilical cords, healthy donor bone marrow, and lupus patient bone marrow (n=3–4 of each). At disease onset, 15–17 weeks of age, MRL/*lpr* mice were intravenously injected with 1×10^6 MSCs from one of the three MSC origins or PBS. Urine and blood were collected at 2,4,6 and 8 weeks post transfer to examine urine albumin excretion and anti-dsDNA antibody levels. Mice were euthanized at 8 weeks post transfer. Kidneys were collected for pathology and immunohistochemistry. Spleen and bone marrow were harvested to detect presence of plasma cells, B cells, T cells, and Tregs via flow cytometry.

Results: All mice receiving MSCs from the various sources showed improved survival, increased body weight, and decreased proteinuria compared to untreated controls. At 8 weeks post MSC transplant, glomerular IgG, but not C3, deposition was significantly decreased in mice receiving umbilical cord and healthy bone marrow MSCs. However, MSC from lupus patients caused an increase in glomerular C3 and IgG. Additionally, while the glomerular pathology score was significantly reduced in the umbilical cord and healthy bone marrow mouse groups, there was no change in pathology of the lupus MSC group when compared to PBS control mice. Although no differences were seen in the percentage of CD4+ or CD8+ T cells between treatment groups, the lupus MSC group experienced a 2-fold increase in the percentage of Foxp3+ cells in the spleen. These mice also experienced this percentage increase in TCRβ+, B220+, and CD138+ cells in the bone marrow.

Conclusion: Our results indicate that human MSC from various origins all made an impact on the disease severity of lupus prone mice. However, the inability of the lupus patient MSCs to prevent kidney damage suggests that umbilical cord or healthy donor bone marrow MSCs are more effective as disease modulators in vivo. These data indicate that MSCs derived from lupus patients are not a strong candidate for therapeutic intervention in lupus.

A Human Monoclonal Antibody Against Domain I Of β2-Glycoprotein I prevents Clotting and Fetal Loss Induced By Polyclonal Anti-Phospholipid Antibodies In Animal Models. Chiara Agostinis[1], Paolo Durigutto[2], Daniele Sblattero[2], Maria Orietta Borghi[3], Claudia Grossi[4], Roberta Bulla[2], Paolo Macor[2], Pier Luigi Meroni[5] and Francesco Tedesco[2]. [1]Institute for Maternal and Child Health, IRCCS Burlo Garofolo, Trieste, Italy, [2]Department of Life Sciences, University of Trieste, Trieste, Italy, [3]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy, [4]Laboratory of Immuno-rheumatology, IRCCS Istituto Auxologico Italiano, Milan, Italy, [5]Division of Rheumatology, Istituto G. Pini, Milan, Italy.

Background/Purpose: Anticoagulant, antiplatelet or immunosuppressive therapy are currently used to treat the clinical manifestations of the anti-phospholipid syndrome (APS). Side effects or recurrences in spite of the therapy suggest to develop new therapeutic tools.

Methods: We have developed a human minibody containing a single chain fragment variable fused to IgG1 CH2-CH3 domain that recognizes domain I of β2GPI from humans and other animal species.

Results: The minibody is pathogenic inducing clot formation and fetal loss in naive mice. Its biologic effect is complement-mediated as suggested by its ability to promote in-vitro and in-vivo complement deposition and its failure to induce thrombosis in C6 deficient rats and fetal loss in C5 depleted mice. We have further developed a CH2-domain-deleted minibody with the same antigen specificity but that does not activate complement. The minibody variant does not cause vessel occlusion and pregnancy loss and fails to promote complement deposition in mice. The CH2-deleted minibody is able to displace patients' antibodies bound to β2GPI and its passive infusion prevents fetal loss and clot formation induced by the anti-β2GPI antibodies from APS patients.

Conclusion: Our finding pave the way for the use of non pathogenic monoclonal antibody able to compete with the pathogenic polyclonal anti-β2GPI antibodies supporting its potential therapeutic use in patients with APS.

Contribution Of Marginal Zone B Cells To Autoimmunity In The B6.Sle1.Sle2.Sle3 Lupus Prone Mouse. Ying Yi Zheng and Laurence Morel. University of Florida, Gainesville, FL.

Background/Purpose: We used the B6.Sle1.Sle2.Sle3 triple congenic (TC) mouse, which expresses three lupus susceptibility loci derived from NZM2410 onto the C57BL/6 (B6) background, to investigate how marginal zone B (MZB) cells, a B cell subset enriched with autoreactive clones, contribute to autoimmune pathogenesis. Early B cells entering the spleen are transitional B cells which can differentiate into MZB cells in the presence of Notch2 signaling. Notch2 signaling is initiated when Notch2 receptor (Notch2R) on B cells engage delta like 1 (DL1) ligand on myeloid or stromal cells, and this leads to the transcription of Notch2 target genes, such as Deltex 1 (Dtx1). Previous results indicated that contrary to non-autoimmune B6 mice, a large number of MZB cells in TC mice enter the follicle (FO). This breach of follicular exclusion by TC MZB cells corresponds to a breach of tolerance associated with lupus pathology. We predict that TC MZB cells contribute to autoimmunity by either becoming anti-DNA IgM secreting plasma cells, and/or entering the FO and contributing to germinal centers, either directly as GC B cells or indirectly by shuttling autoantigen, or by activating autoreactive $CD4^+$ T cells which then proceed to activate autoreactive FOB cells that contribute to the anti-DNA antibody (Ab) production.

Methods: Age matched B6 and TC mice from pre- to post-disease onset are used for FACS analysis of MZB and FOB cells, and ELISA detection of autoreactive IgM. Notch2R and DL1 expression were assessed by FACS on B cell subsets and myeloid cells, respectively, in young B6 and TC spleens. Dtx1 expression was measured by quantitative RT-PCR in FACS-sorted MZB and FOB cells. In order to determine whether MZB cell depletion from TC mice will correlate with decrease in autoreactive IgM, old B6 and TC mice were subjected to anti-DL1 monoclonal Ab mediated MZB cell depletion. One week following treatment, the anti-DL1 treated and untreated mice were sacrificed for flow analysis of B cell subsets, immunofluorescence staining of spleen sections, and ELISA detection of autoreactive IgM.

Results: TC mice displayed a preferential expansion of MZB cells and an increased production of autoreactive IgM with progression of disease. TC MZB cells expressed a significantly higher level of Notch2R protein and Dtx1 mRNA than B6 MZB cells. A same trend was observed for TC FOB cells, which express a much lower level of Notch2R than MZB cells. Although DL1 was expressed at a lower level on TC than B6 myeloid cells; there were significantly more $DL1^+$ neutrophils and macrophages in TC than B6 spleens. As previously reported, anti-DL1 treatment depleted B6 MZB cells. The same treatment, however, only partially depleted TC MZB cells, and did not reduce the level of serum anti-DNA IgM.

Conclusion: The preferential expansion of MZB cells with disease progression in TC mice corresponds to an enhanced Notch2 signaling provided by increased expression of Notch2R on MZB cells and a large number of $DL1^+$ myeloid cells. Unlike B6 mice, TC mice are resistant to anti-DL1 mediated MZB cell depletion, which is consistent with a stronger Notch2 signaling. Additional studies are ongoing to determine the role of the Notch2 pathway in the B cells of lupus mice.

Pneumococcal Polysaccharide Vaccination Regulates T and B Lymphocyte Cytokine Responses and Decreases Kidney Stat1 Levels In MRL/Lpr Mice *In Vivo.* Victor Gazivoda, Shikha Mehta, Luhan Wang, Julia Ash, Kirk E. Sperber and Ioannis Tassiulas. New York Medical College, Valhalla, NY.

Background/Purpose: Zwitterionic polysaccharides can activate CD4+ T cells after processing and presentation by antigen-presenting cells. The 23-valent capsular polysaccharide pneumococcal vaccine, PneumoVax, protects against invasive pneumococcal pneumonia and is indicated for patients with chronic autoimmune diseases and/or on chronic immunosuppressive treatment. The effect of polysaccharide vaccines on the function of cellular immunity and the inflammatory response are not well defined. We studied the immunological effects of pneumococcal polysaccharide vaccination in the MRL/lpr mouse model of lupus, by analyzing the cytokine profile of activated T and B lymphocytes. We also analyzed the effect of polysaccharide vaccination on the expression of Stat1 in the kidney and brain, target organs of inflammation in this mouse model of lupus.

Methods: Eight week old MRL/lpr mice were purchased from Jackson Laboratories. The first group of mice (n=5) vaccinated with PneumoVax (0.5ml of a 23-valent unconjugated pneumococcal polysaccharide vaccine), the second group (n=5) received Mycophenolate mofetil (MMF) (100mg/kgr of body weight) in standard mouse chow, and the third group (n=5) was left untreated. Eight weeks after treatment the mice were sacrificed. T and B lymphocytes were isolated from the spleens. T cells were stimulated with soluble CD3/CD28 beads, PHA and plate bound polysaccharides. B lymphocytes were stimulated with plate bound IgM, plate bound polysaccharide, LPS and a R848. The culture supernatants of the stimulated lymphocytes were analyzed by specific ELISAs for cytokine production of IL-4, IFN-g, IL-17, IL-10, TNF-a and IL-6. Protein extracts were isolated from perfused kidneys. Stat1 and Stat3 protein levels from the extracts were analyzed with Western blotting.

Results: T lymphocytes from PneumoVax vaccinated mice showed differential regulation of cytokine production after CD3/CD28 stimulation, with complete block in IFN-g and IL-17 production compared with the non-vaccinated mice. CD3/CD28-induced IL-4 and TNF production by T cells did not differ in the two groups; however, IL-10 production was significantly increased in the vaccinated group. Interestingly, the decrease in T cell IFN-g and IL-17 production was comparable to the MMF treated group. B lymphocytes from PneumoVax vaccinated mice produced significantly decreased IL-6, IL-10 and TNF in response to plate bound IgM, LPS and R848 stimulation compared to the control group. Analysis of Stat1 protein levels in the kidneys, showed that PneumoVax vaccinated mice had significantly decreased expression compared with the control group, whereas Stat3 levels were not affected.

Conclusion: Pneumococcal polysaccharide vaccination preferentially modulates T and B lymphocyte cytokine responses, after antigen and pattern recognition receptor stimulation in the MRL/lpr mouse model of lupus. Moreover, the expression of Stat1 in the kidneys, a major target organ of inflammation in this model, was significantly decreased in the polysaccharide vaccinated animals. These results suggest that zwitterionic polysaccharides may have a role in re-establishing the immune and inflammatory homeostasis in chronic autoimmune/inflammatory conditions.

Hydroxycholorquine Is Cardioprotective In Neonatal Rat Cardiomyocytes Exposed To Simulated Myocardial Ischaemic/Reperfusion Injury.-An Effect Mediated Through ERK Phosphorylation. Lauren Bourke[1], James McCormick[1], Anastasis Stephanou[1] and Yiannis Ioannou[2]. [1]University College London, London, United Kingdom, [2]Arthritis Research UK Centre for Adolescent Rheumatology at University College London, Great Ormond Street Hospital and UCLH, University College London, London, United Kingdom.

Background/Purpose: A significant amount of myocardial damage during a myocardial infarction (MI) occurs during the reperfusion stage which is known as ischaemic reperfusion (I/R) injury and can account for up to 50% of cell death. Systemic Lupus Erythematosus (SLE) is a condition associated with a high burden of cardiovascular morbidity and mortality, when compared to the matched healthy population. A large proportion of these patients are treated with the anti-malarial drug Hydroxycholoroquine (HCQ) and whilst retrospective studies have suggested that SLE patients prescribed HCQ have a reduced risk of suffering an MI, inevitably there are patients who still do. Therefore the purpose of this study is to determine whether HCQ has an effect on the injury occurring during the reperfusion stage.

Methods: We utilised an established *in vitro* model of anoxia/reoxygenation to simulate ischaemic reperfusion (I/R) injury. Cardiomyocytes were isolated from 1–2 day old rat pups and when beating synchronously were treated with 1–2 μg/ml HCQ and the following day exposed to simulated I/R injury for 4hr in a hypoxic chamber (argon, 5% CO_2) followed by a time-course of reoxygenation. Total cell death was measured using a colorimetric cell proliferation assay (CellTiter96 Aqueous Cell Proliferation Assay) and apoptosis assessed using a TUNEL kit and assessment of caspase-3 cleavage by immunoblot. The activation of ERK, p-38, JNK and Akt were also assessed by immunoblot.

Results: Treatment of neonatal rat cardiomyocytes with HCQ prior to simulated I/R injury was protective and reduced cell death, specifically apoptosis. This was observed using TUNEL which showed that cells exposed to hypoxia alone saw a 20.7% ($\pm$SD 7.4) increase in TUNEL positivity when compared with cells in optimal conditions. This was further increased to 30.1 % ($\pm$SD 7.0)(p value $<$ 0.001) after reoxygenation and in the presence of HCQ was abrogated back down to16.93 % ($\pm$SD 3.0)(p value $<$0.0001). This was confirmed by an increase in cleaved caspase-3 (0.24 relative to GAPDH ($\pm$SD 0.10) (p value $<$ 0.0001)) in cells exposed to simulated I/R injury when compared to cells in optimal conditions (0.03 relative to GAPDH ($\pm$SD 0.03)). In the presence of HCQ this increase in caspase-3 cleavage was reduced by 54% (0.11 relative to GAPDH ($\pm$ SD 0.06) (p value $<$ 0.01)). The colorimetric cell proliferation assay confirmed that HCQ caused a reduction in total cell death in cells exposed to simulated I/R injury of 57.89%. Correlating with decreased cell death, enhanced ERK phosphorylation in HCQ treated cells was observed in a dose-dependent manner and no significant differences in p38, JNK and Akt were observed. Cells treated with HCQ and exposed to simulated I/R injury were incubated with the ERK inhibitor U1026 and protective effects of HCQ as assessed via caspase-3 cleavage was completely reversed.

Conclusion: HCQ is cardioprotective in this *in vitro* I/R injury model and results suggest this protection is dependent upon up-regulation of ERK phosphorylation. Experiments are now being performed to confirm this observation using an *in vivo* I/R injury animal model.

In Vivo Therapeutic Success Of Microrna-155 (miR-155) Antagomir In a Mouse Model Of Lupus Pulmonary Hemorrhage. Shiyu Zhou[1], Dong Liang[2], Xinfang Huang[3], Chunyuan Xiao[3], Yuanjia Tang[1], Qian Jia[3], John B. Harley[2] and Nan Shen[1]. [1]Shanghai Institutes for Biological Sciences Chinese Academy of Sciences & Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Shanghai Institute of Rheumatology, Renji Hospital, Shanghai Jiao-Tong University School of Medicine, Shanghai, China.

Background/Purpose: MiR-155 is a typical pleiotropic miRNA that participates in various aspects of immunity. Previous in vitro studies indicated that it is both a pro-inflammatory and an anti-inflammatory regulator.

Furthermore, studies in multiple mouse models (LPS shock, EAE, and CIA) revealed a pathogenic role of this miRNA in the development of tissue damage. Also, miR-155 is abnormally overexpressed among different lupus mouse models. However, aspects of the role of miR-155 in lupus acute tissue damage remain unclear. In this study, we systemically examined the role of miR-155 in the development of pulmonary hemorrhage (PH) in Pristane-induced lupus, by assessing the effect of the administration of chemically modified complementary oligonucleotides of miR-155, called the miR-155 antagomir.

Methods: Pristane-induced PH mouse model was established as previously reported. Briefly, miR-155 knockout (KO) and wild type (WT) control mice received a single i.p injection of 0.5 ml pristane. After 14 days, lung tissues were collected for pathologic assessment. The dynamic expression of miR-155 was evaluated 1, 3, 7, 14 days post Pristane injection. In intervention experiments, the mice were divided into two groups, receiving respectively three consecutive i.v injections of miR-155 antagomir (miRNA inhibitor) (n=5) or random sequence antagomir negative control (n=5) 3 days before Pristane injection. Two weeks later, the prevalence of PH was evaluated by H&E staining. Total lung RNAs were assayed by qPCR or subjected to gene profiling. Gene profiling data was analyzed by IPA software. Serum cytokines were messured by Bio-plex Pro™ Assays.

Results: We showed that miR-155 was elevated in lung tissues in the process of PH induced by Pristane. MiR-155 KO mice appeared to develop attenuated PH, with reduced levels of pro-inflammatory cytokines (TNF-a, IL-6, IL-1β) in sera and target tissues. IPA analysis of gene profiling data indicated that IL-6 signaling pathway was dramatically activated in WT mice but not in miR-155 KO mice 7 day post pristane injection. By integrating the gene expression profiling data from miR-155 KO mice with microRNA target predication, our data suggest that PPARα, an anti-inflammatory transcription factor, is a novel functional target of miR-155. Furthermore, we showed that in vivo silencing of miR-155 by a synthetic miRNA inhibitor—miR-155 antagomir significantly ameliorated PH induced by Pristane (miR-155 antagomir: 20% PH; random sequence antagomir negative control: 80% PH). Consistently, the pro-inflammatory cytokines (TNF-a, IL-6, IL-1β) were reduced upon miR-155 silencing.

Conclusion: Overall, our study shows that knockdown of miR-155 by miR-155 antagomir inhibits Pristane induced PH through reducing the production of pro-inflammatory cytokines. This finding suggests a promising therapeutic potential of miR-155 antagonist in the treatment of acute lung inflammation in lupus and reinforces the conclusion that antagomir may prove to be a very effective general therapeutic strategy for human disease.

Protective Effect Of Inducible Adeno-Associated Virus Mediated IL-2 Gene Therapy On Tissue Damages In Lupus-Prone Mice. Masayuki Mizui[1], Tomohiro Koga[1], Linda Lieberman[1], Jessica Beltran[1], Mark C. Johnson[2], José C. Crispin[1], Roland Tisch[2] and George C. Tsokos[1]. [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background/Purpose: IL-2 plays critical roles not only in immune responses but also in peripheral tolerance. Impairment of IL-2 production has been linked to the development and progression of autoimmune diseases such as type 1 diabetes and systemic lupus erythematosus (SLE).

Methods: We investigated the effect of IL-2 on lupus disease development using tetracyclin-inducible recombinant adeno-associated virus (rAAV) encoding IL-2 in MRLFas$^{lpr/lpr}$ (MRL/lpr) mice.

Results: IL-2 treatment significantly decreased the levels of CD3+CD4-CD8- double-negative (DN) T cells and increased the numbers of CD4+CD25+Foxp3+ Treg cells in the spleen and lymph nodes. Autoantibody production was not changed by rAAV treatment. Notably, IL-2 supplementation ameliorated inflammatory damage in several tissues including skin, lungs and kidneys. This effect was associated to decreased infiltration of mononuclear cells into kidneys and lungs and reduced expression of inflammatory cytokines and chemokines. DNT cells preferentially produced IL-17 in aged MRL/lpr mice, therefore, reduction of DNT cells by IL-2 could be associated with the attenuation of tissue inflammation. To further examine the specificity of the IL-2 effect on T cell subsets, we used an IL-2/anti-IL-2 monoclonal antibody (mAb) complex-mediated targeting delivery system. Delivery of IL-2 to non-Treg cells rather than Treg cells effectively reduced DNT cells. However, IL-2 to both non-Treg and Treg cells attenuated inflammatory cell infiltration into kidneys.

Conclusion: These results suggest that IL-2 therapy can regulate T cell populations in the periphery and normalize the aberrant T cell activation programs leading to inhibition of organ damage in lupus-prone mice.

Center for Autoimmune Diseases Research (CREA), Bogotá, Colombia, [8]Wolfson Medical Center; Sackler Faculty of Medicine, Tel-Aviv University, Holon, Israel, [9]Department of. Neurology and Sagol Neuroscience Center, Sheba Medical Center, Tel-Hashomer, Ramat Gan, Israel, [10]Sheba Medical Center, Ramat Gan, Israel.

Background/Purpose: Hepatitis-B vaccine (HBVv) was proven to be successful and cost effective in preventing HBV infection and associated liver disease. However, in recent years concerns were raised regarding its safety, particularly among patients with autoimmune diseases (i.e. SLE)[#]. Additionally, the Aluminum adjuvant included in HBVv has been related to immune mediated adverse events. Thus, in the current study we set to evaluate the effects of immunization with HBVv or Alum in an animal model of SLE.

Methods: Three groups of 20 NZB/W F_1 mice (Jackson Laboratory, Bar Harbor, ME), were immunized with HBVv (Engerix), Aluminum hydroxide (Alum) or phosphate buffered saline (PBS) at 8 and 12 weeks of age. Mice were followed for weight, autoantibodies titers, blood cell accounts, urine protein, kidney histology and neurocognitive functions (i.e. novel object recognition, staircase, Y-maze and the forced swimming tests).

Results: Mice immunized with HBVv had significantly higher titers of anti-dsDNA antibodies ($p<0.01$), accelerated proteinuria ($p<0.05$) and advanced kidney damage on biopsy compared to those immunized with PBS or Alum. Mice immunized with HBVv or Alum had decreased cells counts and hemoglobin levels ($p<0.001$) compare with mice immunized with PBS. Similarly, long and short term memory were significantly decreased following immunization with HBVv or Alum ($p<0.01$). Mice immunized with alum displayed anxiety-like behavior.

Conclusion: Herein we have found that immunization with the HBVv accelerates kidney disease in an animal model of SLE-like disease. Both Alum and HBVv, which contains alum as an adjuvant, affected blood counts and neurocognitive functions. Further studies are required to elucidate the mechanisms by which different ingredient of HBVv affect SLE-like disease in animal models.

Absence Of Estrogen Receptor Alpha Reduces The Number and Function Of Bone Marrow Derived Plasmacytoid Dendritic Cells In Lupus Prone Mice. Jennifer Scott[1], Osama S. Naga[1], Melissa A. Cunningham[2], Jena Wirth[2], Jackie G. Eudaly[1] and Gary S. Gilkeson[1]. [1]Medical University of South Carolina, Charleston, SC, [2]MUSC, Charleston, SC.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that affects women at a 9:1 ratio compared to men. Previous work in our laboratory showed that estrogen receptor alpha (ERα) deficient lupus prone mice have increased survival and less renal disease compared to wild type lupus prone mice. ERα deficient mice are protected from disease despite unaltered autoantibody levels and kidney IgG and C3 deposition. We hypothesize that ERα deficiency improves SLE by reducing the innate immune system's ability to respond to immune activation. To study the innate immune response this research focuses on the role of ERa in plasmacytoid dendritic cells (pDC) and their Toll-like receptor (TLR) mediated production of type I interferon (IFN).

Methods: Bone marrow was harvested from WT and ERα deficient B6 and NZM2410 lupus prone mice. The bone marrow was cultured with IL-4 and GM-CSF or Flt3 ligand under estrogen free conditions to enrich for conventional DCs or pDCs respectively. After 8 days of culture, cells were stimulated with TLR 7 and 9 agonists or PBS control for 24 hours. The cells were stained for flow cytometry or RNA was extracted. pDCs were defined as $CD11c^+$, $PDCA1^+$, or $SiglecH^+$ and an intracellular IFNα stain was used to identify IFNα producing cells. qRT-PCR was used to measure the expression of the interferon signature genes ISG-15, CXCL-10, IRF7, MX-1, and IFNβ. Ex vivo experiments were preformed on bone marrow and spleens. Bone marrow and spleen single cell suspensions were stained for flow cytometry. pDCs were identified as $B220^+$, $SiglecH^+$, $PDCA1^+$, and $CD11c^{int}$.

Results: ERα deficiency significantly reduces TLR 7 and 9 ligand mediated expression of type I IFN signature genes in bone marrow derived DCs from lupus prone mice. Since pDCs produce large amounts of type I IFN, we investigated the impact of ERα on pDC development and IFNα production. When total bone marrow from healthy mice was cultured with Flt3L under estrogen free conditions, ERα deficiency significantly reduced the number of IFNα producing cells in response to TLR 7 and 9 ligands. ERα deficiency also significantly reduced the percent of pDCs obtained from estrogen free Flt3L cultures of bone marrow. Wild-type bone marrow yielded 25% (±1.3%) pDCs and ERα deficient bone marrow yielded 8% (±.63%) pDCs. Using the same culture conditions, a similar trend was seen in NZM 2410 and SLE1,3 mouse models. To determine if ERα deficiency alters pDC numbers in vivo, bone marrow and spleen pDC numbers are being investigated ex vivo. Preliminary data suggests ERα deficiency reduces the percent of pDCs in bone marrow while the percent and number of spleen pDCs remain unchanged.

Conclusion: ERα deficiency reduces the TLR mediated type I IFN response in bone marrow derived dendritic cells from lupus prone mice under estrogen free conditions. The absence of ERα also reduces the percentage of IFNα producing cells and pDCs yielded in estrogen free bone marrow cultures. These findings suggest that the in vivo disease modulating effect of ERα is mediated via impacts on the development and response of pDCs.

Oral Candidiasis in Systemic Lupus Erythematosus. Monthida Fangtham, Hong Fang and Michelle Petri. Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: *Candida* is the most common opportunistic fungal infection identified in SLE. In a previous autopsy study, 14 percent of deaths in SLE patients were associated with *Candida* infection. We assessed the frequency of oral candidiasis and the association between demographic variables, disease-related variables, corticosteroid treatment, other treatments and the occurrence of oral candidiasis in the Hopkins Lupus Cohort.

Methods: In a prospective cohort study of 2,209 SLE patients, there were 92% female, 56% Caucasian, and 37% African-American patients. There were 318 (14.4%) patients with oral candidiasis. Among these 318 patients, 124 (39.0%) patients had more than 1 episode of oral candidiasis. The demographic, clinical and treatment associates of oral candidiasis were determined by univariate and multivariate analyses.

Results:

Variable	Odds Ratio (95% CI)	p-value*
African-American ethnicity (vs Caucasian)	2.6 (1.8, 3.7)	< .0001
Smoking	1.1 (0.7, 1.5)	0.79
Depression	1.1 (0.8, 1.5)	0.69
Prednisone dose (mg/day)	1.02 (1.01, 1.03)	0.0004
Hydroxychloroquine use	0.8 (0.6, 1.1)	0.11
Immunosuppressive use	1.4 (1.0, 2.0)	0.046
White blood count (per 1,000)	1.04 (0.99, 1.10)	0.10
Low C3	1.0 (0.6, 1.6)	0.99
Serum creatinine (mg/dl)	1.1 (0.9, 1.3)	0.26
Urine protein/creatinine ratio	1.1 (1.0, 1.2)	0.0048
Bacterial infection	1.6 (1.1, 2.3)	0.024

* Generalized estimating equations were used to account for multiple observations on the same patient

In the multivariable model, African-American ethnicity, prednisone, prednisone dose (in mg), immunosuppressive use, a history of bacterial infection and the urine protein to creatinine ratio remained significant. The use of hydroxychloroquine lowered the risk of oral thrush, but was not statistically significant.

Conclusion: This study identified multiple risk factors for oral candidiasis in SLE. African-American ethnicity, one of the strongest predictors, has never been recognized in previous studies. Prednisone use, prednisone dose (in mg), immunosuppressive use, and a history of bacterial infection were expected risk factors. Secondary Sjogren's syndrome, which we had hypothesized would be a risk factor, was not. Proteinuria had an independent association beyond the effect of prednisone and immunosuppressive use. Treatment with hydroxychloroquine reduced the risk, but was not statistically significant in the multivariate models.

Association Of Psoriasis and Psoriatic Arthritis With Systemic Lupus Erythematosus. Ashwini Shadakshari, Jianghong Yu and Andras Perl. SUNY Upstate Medical University, Syracuse, NY.

Background/Purpose: There is a paucity of literature on the prevalence of psoriasis (Ps) and psoriatic arthritis (PsA) in patients with systemic lupus erythematosus (SLE). To determine whether there are overlaps among these autoimmune diseases, we investigated the prevalence of Ps and PsA in patients with SLE.

Methods: We examined the prevalence of Ps and PsA in 445 patients with SLE based on history, physical examination, laboratory and radiological studies performed between 01/01/1990 and 07/31/12. A diagnosis of psoriasis was made by a dermatologist or rheumatologist while the diagnosis of PsA was made on the basis of CASPER criteria (Arth Rheum 2006; 54: 2665). The diagnosis of SLE was based on ACR criteria (Arth Rheum. 1997; 40: 1725). Prevalence of SLE diagnostic criteria were compared between SLE patients with and without Ps (SLE/Ps+ and Ps-) and with and without PsA (SLE/PsA+ and PsA-). Statistical analyses were performed with chi-square test using Graphpad Prism software with $p<0.05$ considered significant.

Results: Among 445 patients with SLE, 23 (5.1%) had Ps, out of which 20, (4.5%) patients had PsA. In the general population, the prevalence of Ps and PsA are estimated to be 2% (Rev Bras Reumatol. 2012; 52: 630) and 0.25% (Rev Bras Reumatol. 2012;52:98), respectively. Therefore, the prevalence of PsA, but not Ps, was increased in SLE patients ($p < 0.0001$). The prevalence of malar rash, discoid rash, photosensitivity, and arthritis were increased while antiphospholipid antibodies were less common in SLE patient with concurrent Ps and PsA (Table 1). There was no significant association of Ps or PsA with seizures, psychosis, oral ulcers, serositis, proteinuria, anemia, leucopenia, thrombocytopenia, hemolytic anemia, anti-Sm, or anti-DNA.

Table 1. Prevalence of SLE diagnostic criteria in patients with (SLE/Ps+) and without psoriasis (SLE/Ps+) as well as in patients with (SLE/PsA+) and without psoriatic arthritis (SLE/PsA+) in a cohort of 445 SLE subjects. The data were analyzed with chi-square test.

		Malar Rash	Discoid Rash	Photosensitivity	Arthritis	APLA
SLE/Ps+	Present	11	4	13	21	1
	Absent	12	19	10	2	22
SLE/Ps-	Present	118	21	142	211	108
	Absent	304	401	280	211	314
p value		0.0409	0.0118	0.025	0.0001	0.021
SLE/PsA+	Present	10	4	12	20	1
	Absent	10	16	8	0	19
SLE/PsA−	Present	119	21	143	213	108
	Absent	306	404	282	212	317
p value		0.0341	0.0043	0.0156	< 0.0001	0.038

Conclusion: PsA has increased prevalence in patients with SLE. Subjects with overlapping Ps and PsA may represent a distinct clinical entity within SLE.

Monitoring Of Opportunistic Virus Infections In Systemic Lupus Erythematosus. Lorenzo Cavagna[1], Sandra Calarota[2], Eva Scorletti[1], Roberto Caporali[3], Francesca Rovida[4], Carlomaurizio Montecucco[5] and Fausto Baldanti[4]. [1]University and IRCCS Foundation Policlinico S. Matteo, Pavia, Italy, [2]IRCCS Foundation Policlinico S. Matteo, Pavia, Italy, [3]Division of Rheumatology, IRCCS Policlinico San Matteo Foundation and University of Pavia, Pavia, Italy, [4]IRCCS Foundation Policlinico S. Matteo,, Pavia, Italy, [5]University and IRCCS Policlinico S. Matteo Foundation, Pavia, Italy.

Background/Purpose: due to disease characteristics and treatment approaches, systemic lupus erythematosus (SLE) patients are at high risk of opportunistic virus infections, as for example Epstein Barr virus (EBV) and human cytomegalovirus (hCMV). These viruses may complicate disease course, mimic SLE manifestations and have also been involved in SLE pathogenesis. An integrated clinical, virological and immunological monitoring may allow early diagnosis, characterization and right treatment of SLE patients. Aim of our study is to analyze the prevalence of both EBV and hCMV opportunistic infections in SLE and their relationship with disease characteristics/activity.

Methods: from 2/15/2013, after ethical committee approval and informed consent collection, adults SLE patients (1997 ACR classification criteria) referring consecutively to our Lupus Unit have been enrolled in this study. Quantification of EBV DNA and CMV DNA in blood was performed by real-time PCR. Detailed information regarding demographic characteristics and clinical data (disease duration, SLEDAI 2k score, occurrence of kidney involvement, etc) were obtained from the patients' medical records. Patients were stratified according to the degree of pharmacological immunosuppression (Group 1= hydroxychloroquine and/or prednisone≤5 mg/day; group 2= methotrexate/azathioprine/cyclosporine and/or prednisone>5 and <12.5 mg/day; group 3= mycophenolate mofetil/rituximab and/or prednisone≥12.5 mg/day).

Results: a total of 64 SLE patients (59 females/5 males) have been analyzed (table 1). Group 1 consisted of 20 patients, group 2 of 19 patients and group 3 of 25 patients. Although no patients were suspected for viral infection, 27 (42.2%) patients had detectable DNA either of EBV (n=24) or hCMV (n=1) or both (n=2). Viral load was generally low. Patients' age, disease duration, SLEDAI 2k score and kidney involvement did not significantly influenced viral DNA load. In group 2, detection of viral DNA was significantly higher than group 3 (p=0.0136), while no differences were observed between group 1 and 2 (p=0.3406) and group 1 and 3 (p=0.2047). Group 2 patients with detectable virus DNA (n=12) were mainly on methotrexate (n=8) and cyclosporine (n=3).

Conclusion: in our patients a high prevalence of EBV DNA and, to a lesser extent, hCMV DNA in blood has been observed. Detection of viral DNA is not related to disease and patients characteristics. However, patients treated with methotrexate and cyclosporine (group 2), were more prone to have viral DNA load with respect to patients treated with mycophenolate mofetil, rituximab or high dose corticosteroids. Our results suggest suggested the need of a careful monitoring of SLE patients for the increased risk of EBV and hCMV infections. Analyses to better understand how virus-specific immune responses relate to opportunistic viral infections in SLE patients are ongoing.

Table 1. main characteristics of patients up to now enrolled,

	Virus DNA +ve (blood)	Virus DNA –ve (blood)	p
Patients number	27	37	\
EBV DNA +	24	\	\
hCMV DNA +	1	\	\
EBV and hCMV DNA +	2	\	\
EBV DNA (copies/ml; median-IQR)	196 (115–478)	\	\
CMV DNA (copies/ml; median-IQR)	200 (150–600)	\	\
Age (years; mediana-IQR)	56 (41.5–59.5)	44 (33–52)	0.0666*
Disease duration (months; median-IQR)	118 (75–152)	84 (6–154)	0.5278*
SLEDAI-2K score (median –IQR)	2 (2–4)	2 (2–4)	0.9967*
Kidney involvement (history)	6	15	0.1893μ
Group 1 (low level immunosuppression)	9	11	0.3406 (vs group 2)μ
Group 2 (medium level immunosuppression)	12	7	0.0136 (vs group 3)μ

Is An Excess Risk Of Attention Deficit Hyperactivity Disorder In Children Born To Women With SLE Mediated By In Utero Drug Exposures? Preliminary Data From The O S L E R Cohort. Evelyne Vinet[1], Susan Scott[2], Christian A. Pineau[1], Lawrence Joseph[3], Ann E. Clarke[1], Eric Fombonne[4], Robert W. Platt[3] and Sasha Bernatsky[5]. [1]McGill University Health Center, Montreal, QC, [2]McGill University Health Centre, Montreal, QC, [3]McGill University, Montreal, QC, [4]Oregon Health and Sciences University, Portland, OR, [5]Research Institute of the McGill University Health Ctre, Montreal, QC.

Background/Purpose: Women with SLE display autoantibodies (e.g. anti-N-methyl-D-aspartate receptor antibodies) and cytokines (e.g. interleukin-6), which, in animal models, alter fetal brain development and induce behavioural anomalies in offspring. To date, no one has specifically assessed the risk of attention deficit hyperactivity disorder (ADHD) in children of SLE mothers. Using the "Offspring of Systemic Lupus Erythematosus mothers Registry (OSLER)", we aimed to determine if children born to SLE mothers have an increased risk of ADHD compared to children born to mothers without SLE.

Methods: OSLER is a large population-based cohort, which includes all women who had ≥1 hospitalization for delivery after SLE diagnosis, identified through Quebec's universal healthcare databases (1989–2009). OSLER also includes a randomly selected control group of women, matched at least 4:1 for age and year of delivery, who did not have a diagnosis of SLE prior to or at the time of delivery. We identified children born live to SLE mothers and their matched controls, and ascertained ADHD based on ≥1 hospitalization or physician visit with a relevant diagnostic code, through to end of database follow-up.

We performed multivariate analyses to adjust for maternal demographics, sex and birth order of child, and obstetrical complications. In a subsample analysis of children with maternal public drug coverage throughout pregnancy, we further adjusted for relevant maternal medications.

Results: 509 women with SLE had 719 children, while 5824 matched controls had 8493 children. Mean maternal age and follow-up were respectively 30.3 [standard deviation (SD) 5.0] and 9.1 (SD 5.8) years. Children born to women with SLE had more records of ADHD diagnoses [9.9% (95% CI 7.9, 12.3) vs 6.1% (95% CI 5.6, 6.6)]. Mean age at ADHD diagnosis was older in offspring of SLE mothers (12.5 years, 95% CI 11.7, 13.3) as opposed to controls (7.8 years, 95% CI 7.5, 8.1).

In multivariate analysis (Table 1), children born to women with SLE had substantially increased risk of ADHD (HR 1.73, 95% CI 1.25, 2.40) versus controls. Interestingly, in the subsample analysis further adjusting for in utero drug exposures (n=1925), there was no longer a clear association of SLE with

an increased risk of ADHD (HR 0.97, 95% CI 0.41, 2.28). However, in utero exposure to antidepressants appeared to be associated with a substantially increased risk of ADHD (HR 3.70, 95% CI 1.38, 9.94).

Conclusion: Compared to children from the general population, children born to women with SLE appear to have an increased risk of ADHD. Our evidence suggests that the excess risk of ADHD in SLE offspring might be mediated by in utero drug exposures.

Ultrasonographic Findings and Inter-Observer Reliability In Danish Patients With Systemic Lupus Erythematosus - a Comparison With Clinical Examination Of Wrist and Hand Joints. Lene Dreyer[1], Søren Jacobsen[2], Lars Juul[3] and Lene Terslev[4]. [1]Copenhagen University Hospital at Gentofte, Copenhagen, Denmark, [2]Department of Rheumatology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [3]Copenhagen University Hospital at Gentofte, Copenhagen, Denmark, [4]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark.

Background/Purpose: Patients with systemic lupus erythematosus (SLE) frequently encounter problems of musculoskeletal origin including arthralgia, tenosynovitis and arthritis in varying degrees of severity. Some patients develop hand deformities probably because of undetected inflammation in joints and tendons. Data on the sensitivity of clinical joint examination and inter-observer reliability of the Ultrasound (US) findings in SLE patients are limited. We aimed to determine 1) US findings in patients with SLE with and without clinical symptoms of arthritis in the hand and to compare findings with clinical evaluation 2) to determine the inter-observer reliability of the US findings.

Methods: Thirty-three female SLE patients with or without hand arthralgia (HA) at time of examination were included. They were examined twice by US by 3 trained examiners. B-mode and Doppler examination was performed of the wrist and MCP joints for synovitis and erosions and the extensor and flexor tendons at the wrist level for signs of tenosynovitis using a GE Logiq 9 US machine with Doppler settings for slow flow. All patients underwent clinical joint evaluation and were compared to 11 healthy controls (CTRLs).

Results: Among the 33 SLE patients 16(48%) had wrist synovitis +/−Doppler activity on US which was only observed in 1 CTRL (9%) ($p=0.03$). Corresponding figures for any mcp joint were 12(36%) and 0(0%) ($p=0.02$). In 21% of the SLE patients tenosynovitis was found and in 6% bone erosions in hands. Wrist synovitis +/−Doppler activity was observed significantly more in SLE patients (81%) with arthralgia in hands at time of US examination compared to patients with no symptoms (18%) ($p=0.0005$), for MCP joints this was 63% and 12% ($p=0.0071$), respectively. US findings were observed in 44% of 25 wrists of SLE patients with no tenderness at clinical examination and in 46% of 26 wrists with no swelling. Corresponding figures for 2mcp joints were 27% and 21%. The inter-observer reliability was good to excellent for MCP joints, wrists and tendons.

Conclusion: A majority of SLE patients with arthralgia in hands have US signs of synovitis, erosions and tenosynovitis indicating subclinical disease. Clinical joint examination underestimates synovitis in SLE patients compared to US examination. Good to excellent agreement for inter-observer reliability was found in US evaluation of hand joints in SLE patients. These results indicate that US examination of hand is a clinically reliable and sensitive diagnostic modality in SLE.

Switching Treatment Between Mycophenolate Mofetil and Azathioprine In Lupus Patients The Reasons and The Effect. Hesham Al Maimouni, Dafna Gladman, Dominique Ibanez and Murray B. Urowitz. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Disease activity in systemic lupus erythematosus is an important predictor of subsequent organ damage and mortality from lupus. However, the optimal agent for chronic immunosuppression of SLE is unknown. Our aim was to determine the reasons for changing treatment from MMF to AZA or vice versa in lupus patients and to evaluate the effect of the change.

Methods: Medical records of 92 lupus patients in whom treatment were changed from MMF to AZA or vice versa were reviewed. Global disease activity in the 6 months prior to the change in therapy and 6 months after the change was calculated using the Adjusted Mean SLEDAI (AMS) a validated measure of disease activity over time. The AMS was then calculated for both its clinical and laboratory parameters individually. The reasons for changing therapy were identified. AMS was compared in the 6 months prior to and after the switch using GEE adjusting for repeated measures.

Results: We identified 92 lupus patients in whom treatment was switched once in 80, twice in 8 and three times in 4 with total of 108 times between MMF and AZA. There were 89 switches from AZA to MMF: 76 (85.4%) for drug failure; 11 (12.4%) for side effects; 2 (2.2%) for renal transplant. There were 19 switches from MMF to AZA: 7 (36.8%) for pregnancy; 8 (42.1%) for side effects; 3 (15.8%) for drug failure and 1 (5.3%) for financial issues. There was a statistically significant improvement in AMS in the 6 months after drug switching compared to the 6 months prior to the switch when the reason was a drug failure, (11.2 ± 6.1) vs. (9.1 ± 5.7 $p<0.0001$).The improvement in the laboratory component was most significant ($p=0.0006$) and clinical component showed only a trend ($p=0.08$). There was no statistically significant deterioration in AMS or its clinical and laboratory components in 6 months after drug switching when the reason for the switch was a side effect, pregnancy, financial or other, AMS (6.7 ± 4.6)vs. (5.9 ± 4.6 $p<0.33$). Side effects occurred in 15 of 19 of the total group who switched (78.9%) and persisted in 4(21.1%) after drug switching. Modeling to adjust for repeated measures confirmed the results.

Conclusion: Switching from azathioprine to MMF is most often due to azathioprine failure and in that case a statistically significant improvement in disease activity occurs. When AZA is used to replace MMF, often due to pregnancy, there is no statistically significant deterioration in AMS. Switching between MMF and AZA for side effects usually resulted in elimination of the side effect.

Lupus Nephritis Flares Precipitated By Switching From Mycophenolate Mofetil to Azathioprine in Pre-Pregnancy Planning. Natasha Jordan and David D'Cruz. Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a complex autoimmune disease that affects women of childbearing age. Lupus nephritis is a major cause of morbidity and mortality in SLE and is characterized by unpredictable exacerbations and remissions. Following induction therapy of lupus nephritis, patients are generally maintained in remission by either mycophenolate mofetil or azathioprine. Pre-pregnancy planning is an important aspect of the clinical management of lupus nephritis. Due to potential teratogenicity, the use of mycophenolate mofetil is contraindicated during pregnancy. The aim of this research was to determine the rate of flare of lupus nephritis precipitated by switching from mycophenolate mofetil to azathioprine in pre-pregnancy planning and factors associated with or predictive of flare.

Methods: We retrospectively reviewed the clinical data and obstetric outcomes of eight female lupus nephritis patients in the maintenance phase of therapy who were switched from mycophenolate mofetil to azathioprine in pre-pregnancy planning.

Results: 62% ($n=5$) of patients did not experience a flare of nephritis when their medication was switched and of these 80% ($n=4$) had uneventful pregnancies. 38% ($n=3$) patients developed significant lupus nephritis flares when switched from mycophenolate mofetil to azathioprine. Two of these patients achieved pregnancy; one was delivered at 35 weeks by Caesarean section and the other by induction at 37 weeks, both due to pre-eclampsia. Both experienced post partum flare of nephritis, one requiring cyclophosphamide and the other was controlled with an increased corticosteroid dose and reintroduction of an angiotensin-converting-enzyme inhibitor.

Urinary protein creatinine ratio was significantly higher at time of medication switching in those who experienced renal flare ($p=0.027$). Serum creatinine, haemoglobin and serum albumin levels did not significantly differ between the two groups. Age at diagnosis, duration of disease, age at medication switch and duration since renal biopsy were not significantly different between the two groups. C3 levels, anti-dsDNA antibody % binding titres and ESR were significantly higher at time of medication switching in those who experienced renal flare ($p=0.03$, 0.024 and 0.049 respectively). C4 levels did not significantly differ between the two groups.

Conclusion: When switching apparently stable patients from mycophenolate mofetil to azathioprine it is important that adequate time and consideration is given to ensure the patient is stable on their new medication regimen before proceeding to pregnancy. Current recommendations advise that stable remission of renal disease is achieved for at least 6 months before conception. This study has found that urinary protein creatinine ratio, anti-dsDNA antibody titres and C3 levels are important predictors of flare in this subset of patients.

Predictive Value Of The Autoantibody Triad Of Anti-Ro, Anti-Sm and Anti-RNP For The Future Development Of Lupus Nephritis. Natasha Jordan and David D'Cruz. Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom.

Background/Purpose: Autoantibody production against nuclear components is a characteristic feature of SLE. Autoantibody clustering may provide a valuable tool to differentiate between clinical subsets and to predict lupus disease severity. There is increasing evidence to support the role played by RNA components of Ro and Sm/RNP small ribonucleoproteins as endogenous adjuvants in the pathogenesis of autoimmunity.

The objectives of this study were to determine the frequency of positivity of the RNA-containing antibody triad of anti-Ro/anti- Sm/anti-RNP in lupus nephritis versus SLE non-nephritis patients. In addition, we examined whether patients with this antibody combination had earlier onset disease, worse renal outcomes or more rapid progression to end-stage renal disease.

Methods: A retrospective case-control study was undertaken of 180 patients with biopsy-proven lupus nephritis and a control group of 179 ethnically matched SLE patients without nephritis. Data collected included age at disease onset, degree of renal impairment and progression of renal impairment over time based on the KDOQI guidelines (kidney disease outcomes quality initiative) and autoantibody profiles of individual patients.

Results: SLE patients with nephritis were significantly more likely to have the autoantibody triad of anti-Ro/anti-Sm/anti-RNP than SLE non-nephritis controls (12% versus 6%, $p=0.03$). There was a trend towards a higher rate of progression to end-stage renal disease in nephritis patients who were antibody triad positive (19% versus 8%, $p=0.052$). Mean renal survival was significantly shorter in nephritis patients who were antibody triad positive (14 years versus 21 years, $p=0.05$). Presence of the antibody triad was not associated with earlier onset disease (24.63 years $\pm$ 2.55 versus 26.23 years $\pm$ 1.08, $p=0.60$). 75% of SLE patients with this antibody profile were of African ancestry, 19% were Caucasian and 6% were of South Asian descent.

Conclusion: This study has shown that the RNA-containing autoantibody combination of anti-Ro/Sm/RNP was significantly more common in lupus nephritis than SLE non-nephritis patients. Progression to advanced renal disease was more common in antibody triad positive patients. Renal survival was significantly shorter in nephritis patients with this autoantibody profile. Based on these findings, we recommend particular vigilance for the detection of nephritis in newly diagnosed SLE patients with this antibody triad. SLE patients with known nephritis and this antibody profile may represent a more aggressive disease subset and thus warrant more intensive clinical monitoring.

A Real-World Survey Of Clinical Practice Among Rheumatologists and Nephrologists In The United States Reveals Differences In Care Of Non-Nephritis Systemic Lupus Erythematosus and Lupus Nephritis As Compared With American College Of Rheumatology Treatment Guidelines. Neelufar Mozaffarian[1], Steve Lobosco[2] and Adam Roughley[2]. [1]AbbVie, North Chicago, IL, [2]Adelphi Real World Ltd., Macclesfield, United Kingdom.

Background/Purpose: Current pharmacotherapy for systemic lupus erythematosus (SLE) and lupus nephritis (LN) includes combinations of nonsteroidal anti–inflammatory drugs (NSAIDs), antimalarials (AMs), glucocorticoids (GCs), and cytotoxic immune modulators (IMs). The objective of this analysis was to evaluate the use of therapies for SLE and LN in the United States and to compare these with current treatment recommendations for non–nephritis SLE (NNSLE) and LN issued by the American College of Rheumatology (ACR).

Methods: Data were extracted from the Adelphi Real World Lupus Disease–Specific Programme®, a cross–sectional survey of 50 rheumatologists and 25 nephrologists conducted (December 2009–May 2010) in the United States. Each physician completed a comprehensive form regarding his or her 5 most recent consulting lupus patients. Treatment history, current therapy, and other data were summarized and compared with the ACR treatment guidelines.

Results: Physicians reported data for 375 patients: 168 with NNSLE (164 treated by rheumatologists), and 207 with LN (121 treated by nephrologists). The 1999 ACR guidelines recommend the use of NSAIDs for milder NNSLE, AMs for skin and joint manifestations, corticosteroids for moderate to severe disease, and cytotoxic IMs for severe NNSLE. Survey results revealed that the proportion of all NNSLE patients (n=168) receiving NSAIDs, AMs, GCs, or IMs was 29%, 69%, 54%, and 39%, respectively. The predominant induction treatments prescribed by rheumatologists for NNSLE patients (n=164) were AMs alone (27%) or the following $\pm$ AMs: GCs (27%), IMs (15%), or IMs plus GCs (16%). In 2012, the ACR published their first set of guidelines for treating LN, recommending AM treatment for all patients, and IM plus GC induction therapy for LN classes III, IV, and V (categorized based on renal biopsy). Survey results did not include patients' renal pathology classifications; however, the data revealed that the proportion of all LN patients (n=204) receiving AMs, GCs, NSAIDs, and IMs was 42%, 76%, 17%, and 67%, respectively. However, only 20% of LN patients (n=121) treated by nephrologists began therapy with IMs plus GCs during the survey; more LN patients began IMs without GCs (28%), or GCs without IMs (27%). The proportion of LN patients receiving IMs plus GCs increased with second and third therapies to 42% and 33%, respectively. The ACR guidelines suggest that rituximab may be used in some LN patients after 6 months of treatment with IM plus GCs if nephritis worsens or does not improve. Within the overall LN patient group (n=204), 1.5% received biologic therapy at some point.

Conclusion: Real–world surveys of NNSLE and LN treatment by rheumatologists and nephrologists revealed some differences between current ACR treatment guidelines and real–world clinical practice in the United States. Differences from guidelines were minor for NNSLE and more pronounced for LN, possibly due to publication of LN guidelines (2012) after the survey period (2009–2010). However, the guidelines summarized current expert recommendations rather than proposing radical changes in therapy, and therefore the potential gaps in both NNSLE and LN treatment warrant further investigation.

Disclosure: N. Mozaffarian, AbbVie, 9, AbbVie, 1; **S. Lobosco**, Adelphi Real World Ltd., 3; **A. Roughley**, Adelphi Real World Ltd., 3.

Prognostic Significance Of Visit-To-Visit Variability, Maximum Systolic Blood Pressure, and Episodic Hypertension In Sytemic Lupus Erythematosus. George Stojan[1], Hong Fang[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD.

Background/Purpose: SLE is considered a coronary heart disease equivalent and aggressive management of all traditional risk factors is recommended. Hypertension is a major problem in SLE. Seventy-five percent of patients in our cohort are hypertensive. The presence of hypertension in SLE increases the risk of cardiovascular events 2.66-fold, as well as the risk of stroke and poor renal outcomes. Guidelines for diagnosis and treatment of hypertension focus only on mean systolic blood pressure (SBP). Our objective was to evaluate the prognostic significance of visit-to-visit variability in blood pressure, maximum blood pressure reached, and episodic hypertension on cardiovascular events in SLE.

Methods: The analysis was based on 1340 different patients with an average duration of follow-up of 74 months. For each month of follow-up for a patient in the cohort, the previous 8 blood pressure measurements were included in the analysis. The following variables were calculated: mean prior SBP and diastolic blood pressure (DBP), standard deviation of prior SBP and DBP, coefficient of variation of prior SBP and DBP, maximum prior SBP and DBP, and minimum prior SBP and DBP. Based on the maximum and minimum blood pressure values, the following categories were created: stable normotension (maximum always <= 140mmHg), episodic moderate hypertension (minimum <= 140mmHg, maximum 140–179mmHg) episodic severe hypertension (minimum <=140, maximum 180+) and stable hypertension (minimum > 140). This information was then linked with whether the patient had a cardiovascular event (CVE) in that month. Person-months were aggregated, and the risks of a CVE by monthly characteristics were calcu-

lated. Person-months after a previous CVE were excluded. CV events were defined as either stroke, myocardial infarction, incident angina, a coronary procedure (CABG or PCI), or claudication.

Results: There were 105 CV events with a rate of 12.6 per thousand person-years. Visit-to-visit SBP variability of ≥14mmHg (RR=1.9 (1.0, 3.3), p<0.05) and DBP variability of ≥9mmHg (RR=2.5 (1.3, 4.9), p<0.01) was predictive of future CVE. A single, maximum value of SBP≥150mmHg or DBP ≥ 92mmHg were strong predictors of CVE (RR=3.7 (1.7, 8.0), p<0.01). Episodic moderate (RR=2.0 (1.3, 3.2), p<0.01) and episodic severe hypertension (RR=3.1 (1.5, 6.5), p<0.01) were both highly associated with future CVE. Mean systolic blood pressure of >130mmHg was a strong, independent predictor of CVE (rate ratio 3.3 (0.6, 6.8), p<0.01). When data were controlled for mean systolic blood pressure, no other variable was statistically associated with CVE.

Conclusion: Mean systolic blood pressure is the dominant predictor of cardiovascular events in our cohort. However, visit-to-visit variability in SBP ≥14mmHg and DBP ≥9mmHg, episodic hypertension, and single, isolated maximum values of SBP≥150mmHg and DBP ≥ 92mmHg were all highly associated with cardiovascular events, drawing attention to the false reassurance of a few normal blood-pressure readings and the need for aggressive blood pressure management in SLE patients.

The Effect Of Ramipril On Endothelial Function and Endothelial Progenitor Cells In Patients With Systemic Lupus Erythematosus. Emilia I. Sato[1], Luiz Samuel G. Machado[2] and Ana Cecilia Machado[2]. [1]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo, São Paulo, Brazil.

Background/Purpose: Cardiovascular diseases (CVD) are one of major causes of morbidity and mortality in SLE patients. Traditional cardiovascular risk factors and disease intrinsic factors contribute to this pathogenesis. Endothelial progenitors cells (EPCs) are involved in the re-endothelialization of damaged vessels and contribute to endothelial dysfunction. SLE patients have endothelial dysfunction and have fewer EPCs than healthy controls. Angiotensin converting enzyme (ACE) inhibitors such as ramipril in patients with coronary heart disease improve endothelial function and reduced CV morbidity and mortality. The Objective of the study was to evaluate the effect of ramipril on endothelial function as well on the number and function of EPCs in SLE patients

Methods: Prospective, randomized, controlled trial. Female patients with SLE (ACR criteria) over 18 years of age, with stable medications were invited to participate. Risk factors for CVD were exclusion criteria. SLE patients who signed consent form were randomized into two groups: intervention group (IG) and control group (CG). The IG used ramipril 10mg/day for 12 weeks. All patients were assessed at baseline and after 12 weeks, with a physical exam and also collected blood sample. Disease activity was assessed by SLEDAI score and EPCs were evaluated by culture using Endocult (Stemcell Technologies, USA), according appropriate protocol and by flow cytometry using anti-KDR-APC (R&D Systems, USA), anti-CD34-FITC (Southern Biotech Assoc Inc, USA), anti-CD133-PE (Miltenyi Biotec, USA) and 7AAD (Southern Biotech Assoc. Inc, USA). The assessment of endothelial function was done through an ultrasonography of the brachial artery and flow mediated dilation (FMD), according the established protocol. Student t test was used for normally distributed variables, Fisher exact test for categorical variables and ANOVA for repeated measures. Intent to treat analysis was done. $P < 0.05$ was considered significant.

Results: 37 SLE patients were evaluated, 18 in IG and 19 in CG.

At baseline, there was no difference between IG and CG regarding the average of age, disease duration, arterial pressure, LDL cholesterol, BMI, FMD, use of immunosuppressive drug and SLEDAI score. We found a significant increase on FMD in IG (6.17±4.18% vs 11.14±5.4%, p<0.001), without difference in CG (5.37±3.91% vs 5, 02±3.62%, p=0.630), comparing first (baseline) and final (12 weeks) assessment. We also found a increase in the number of colony forming units (CFU) of EPCs in IG (21.3±10.4 vs 31.6±8.5, p<0.001), without difference in CG (24.8±13.5 vs 25.8±11.6, p=0.714). There was no difference concerning EPCs number evaluated by cytometry in IG (0.013 %±0.025 vs 0.02%±0.03 p=0.734) either in CG (0.0175±0.024 vs 0.012%±0.016%, p=0.734).

Conclusion: Ramipril improved endothelial function in patients with SLE and also increased the number of EPCs evaluated in cell culture, suggesting that the improvement of endothelial function can be due to the increase in EPCs function. ACE inhibitors should be used as a preferential drug to treat hypertension in SLE patients and may be could reduce CVD in these patients

Breast Cancer In Systemic Lupus (SLE): Do Demographic and Clinical Factors, Including DNA serology, Influence Risk? Sasha Bernatsky[1], Rosalind Ramsey-Goldman[2], Michelle Petri[3], Murray B. Urowitz[4], Dafna D. Gladman[5], Christine Peschken[6], William Foulkes[1], Yvan St. Pierre[7], Patrice Chrétien Raymer[7], Basile Tessier Cloutier[1], Guillermo Ruiz-Irastorza[8], Ann E. Clarke[1] and Systemic Lupus International Collaborating Clinics (SLICC)[9]. [1]McGill University, Montreal, QC, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]University of Toronto, Toronto Western Hospital, Toronto, ON, [5]Toronto Western Hospital and University of Toronto, Toronto, ON, [6]University of Manitoba, Winnipeg, MB, [7]McGill University Health Centre, Montreal, QC, [8]Hospital de Cruces, UPV/EHU, Barakaldo, Spain, Bizkaia, Spain, [9]Toronto Western Hospital, Toronto, ON.

Background/Purpose: There is an increase in cancer in SLE over-all, but decrease in other cancers, such as breast cancer. Of particular interest are autoantibodies targeting DNA, which may penetrate cells and interfere with DNA repair; these may be lethal to cancer cells and hence protect against breast cancer. Our primary objective was to assess breast cancer risk in females with SLE, comparing patients who test positive for anti-double stranded (ds) DNA antibodies, versus those who do not. We also assessed other demographic and clinical factors.

Methods: We used data from a very large multi-site international SLE cohort. The data presented in this preliminary analysis are from four centres: Toronto, Montreal, Winnipeg, and Baltimore. We used Cox proportional hazards regression to calculate the hazard ratio (HR) for breast cancer risk in female SLE patients, relative to their exposure in terms of anti-dsDNA positivity over time, in models that controlled for time-dependent medication exposures, demographics (age, race/ethnicity), and calendar year. Anti-dsDNA positivity was assessed on the basis of annual SLE Disease Activity Index, SLEDAI scores, assessed at baseline and annually. A weighted average of the number of times patients were anti-dsDNA positive was generated, and we included in our regression model, a time-dependent variable capturing this weighted average. We also included time-dependent measures of cumulative disease activity (adjusted mean SLEDAI scores, modified by removal of the item for anti-dsDNA). Time zero for the observation interval was SLE diagnosis, so that our analyses adjusted for SLE duration. We included cancers occurring after entry into the lupus cohort and up to the time of cohort exit (defined by death or date of last visit).

Results: These analyses include 34 SLE breast cancers cases and 3,391 female SLE patients without any cancer. Compared to controls without cancer, breast cancer cases tended to be white (78% versus 61% in controls), with a trend towards being older at cohort entry (mean 42.8 years, median 43.6; versus mean 38.4, median 36.8 in controls). The same proportion (20.6%) of cases and cancer-free controls were anti-dsDNA positive at cohort entry, and DNA positivity through the observation interval was also similar. Breast cancer cases were similar to cancer-free controls in terms of baseline disease activity and the profile of cumulative drug exposures over time. In both univariate and multivariate models, the principal factors associated with breast cancer risk were older age at cohort entry and calendar year. Of note, anti-malarial use was not demonstrated as a protective factor in these analyses, modelled either as a categorical or continuous (years exposed) variable.

Conclusion: In these preliminary data, we saw no difference in breast cancer risk in females with SLE, comparing patients who are positive for anti-ds DNA serology, versus those who are not. However, our analyses are based on only 34 cases (and 3,391 controls); as well, we have so far only assessed serology and not specifically cell-penetrating autoantibodies (which may be more important). Our analyses also did not establish anti-malarial agents as protective for breast cancer, but here further analyses are also needed.

Blood Pressure Variability and Age-Related Blood Pressure Patterns In Systemic Lupus Erythematosus. George Stojan[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD.

Background/Purpose: Increased visit-to-visit blood pressure (BP) variability has been associated with an increased risk of all-cause mortality, stroke, left ventricular diastolic dysfunction, and cognitive impairment among diverse populations. Despite the high prevalence of cardiovascular disease among patients with systemic lupus erythematosus (SLE), BP variability and the relationship between age, BP and BP variability has not been described in this population.

Methods: The means and variances of systolic and diastolic pressures in the general population using data from the National Health Statistics Reports (19,921 adults aged 18 and over with BP estimates calculated using the mean of up to three measurements) were compared with those in a cohort of SLE patients (1340 different patients, seen quarterly, with an average duration of follow-up of 74 months). The following variables were calculated: mean systolic blood pressure (SBP), mean diastolic blood pressure (DBP), and within-person standard deviation of SBP and DBP.

Results: The systolic BP in SLE follows the trend of increase with age seen in the general population, but was statistically significantly higher in young adults 18–39 years of age ($p<0.001$) regardless of sex and race. Surprisingly, with age this trend decreased and in females older than 60 years of age it reversed, with SLE patients having a statistically significantly lower SBP compared to the general population ($p<0.001$). Diastolic BP was statistically significantly ($p<0.001$) elevated among female SLE patients across all age groups with the exception of Caucasian women 40–59 years of age. Among males, we observed higher DBP in our SLE males compared to the general population in all age/ethnic groups, however, the differences were not all statistically significant, due to the low number of males in the cohort. BP variability in SLE is elevated across all age groups. Within person standard deviation (SD) of SBP increased with age and ranged between 12.2 mmHg among 20 year olds and 16.7 mmHg among 80 year olds, while DBP variability remained stable through all age groups and ranged between 8.7 mmHg and 8.9 mmHg. These values are substantially higher than the within-person BP variability reported by NHANES which is 7.7 mmHg for SBP and 5.8 mmHg for DBP, but is comparable to previously published data in stroke cohorts (UK-TIA, Dutch TIA, ESPS-1 trials).

Conclusion: The relationship of BP to age in SLE differs from that in the general population with significantly higher mean SBP among young adults and lower mean SBP among elderly females. BP variability in SLE is elevated across all age groups compared to the general population and is comparable to the variability seen in stroke cohorts. Consistent available data obtained in a wide spectrum of non-SLE populations (from a general population to high-risk patients) show an association between increased visit-to-visit BP variability and worse cardiovascular outcomes and target organ damage. Further studies are needed to determine the causes of visit-to-visit BP variability in SLE, its association with cardiovascular outcomes, and whether treatments that reduce BP variability may improve cardiovascular outcomes.

Low-Dose Aspirin Has An Anti-Platelet Effect In Systemic Lupus Erythematosus. Michelle Petri[1], Laurence S. Magder[2] and Thomas Kickler[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD.

Background/Purpose: Thrombosis is increased in SLE patients, with and without antiphospholipid antibodies. Aspirin and hydroxychloroquine are thought to have anti-platelet effects. We determined whether these drugs had an anti-platelet effect using formal platelet function studies in SLE patients.

Methods: SLE patients about to start aspirin (81 mg #51) or hydroxychloroquine (400 mg #56) had platelet function tests before and at least 1 month after starting the medication. The changes were assessed statistically using paired t-tests for quantitative variables and McNemar's test for binary variables.

Results: Aspirin led to a very significant reduction in urine thromboxane, and a borderline reduction in ADP. SLE patients also appeared to be very sensitive to aspirin in terms of reduction in epinephrine. Hydroxychloroquine also led to a reduction in urine thromboxane.

Variable	Mean change after treatment	StdError	P-value
Aspirin Treatment			
Arachidonic Acid Aggregation	−59.5200000	7.8713243	< 0.0001
ADP Agonist	−7.6938776	3.8310631	0.0503
Collagen ATP release (nm)	−0.0225208	0.1725624	0.8967
Collagen Agonist	−7.1020408	3.1146249	0.0271
Epinephrine Aggregation 10 μM	−32.5714286	6.4571089	< 0.0001
Aggregation ADP 10 μM	1.9285714	5.3738364	0.7225
Thromboxane	−1377.05	438.3165675	0.0049
Hydroxychloroquine Treatment			
Arachidonic Acid Aggregation	3.9454545	5.3208451	0.4616
ADP Agonist	−2.3454545	3.6381090	0.5219
Collagen ATP release (nm)	0.0629091	0.1104904	0.5715
Collagen Agonist	−1.4909091	3.3678888	0.6598
Epinephrine Aggregation 10 μM	−1.7297297	3.9517831	0.6642
Aggregation ADP 10 μM	−0.3947368	4.9373802	0.9367
Thromboxane	−612.3913043	191.7715594	0.0042

We next dichotomized urine thromboxane to < 1500 and > 1500.

Table 2. Pre-post results based on various treatments.

Treatment	Number (%) with low Thromboxane at both time points	Number (%) with low at baseline and high at follow-up	Number (%) with high at baseline and low at follow-up	Number (%) with high Thromboxane at both time points	P-value for difference in rates of High thromboxane pre vs. post[1]
Aspirin (all)	4 (11%)	2 (5%)	22 (59%)	9 (24%)	< 0.0001
Aspirin (no history of lupus anticoagulant)	4 (14%)	1 (4%)	17 (61%)	6 (21%)	0.0002
Aspirin (history of lupus anticoagulant)	0 (0%)	1 (11%)	5 (56%)	3 (33%)	0.21
Hydroxychloroquine	11 (22%)	1 (2%)	7 (14%)	31 (62%)	0.070

Conclusion: Aspirin led to a marked and significant change in urine thromboxane and epinephrine. Hydroxychloroquine also appeared to lead to a reduction in urine thromboxane. Because a major source of thromboxane is inflamed monocytes, this could represent an anti-inflammatory mechanism of hydroxychloroquine. Although not statistically significant (likely due to loss of power with only 9 patients with a history of the lupus anticoagulant), aspirin (81 mg) led to a reduction in urine thromboxane in the majority. About 25% of SLE patients appear to be aspirin resistent. Aspirin, in SLE patients at risk for, or who have had, arterial thrombosis, is a viable option.

Efficacy Of Rituximab In Patients With Refractory Lupus Nephritis, a Post-Hoc Analysis From Phase II Trial In Japan. Yoshiya Tanaka[1], Kazuhiko Yamamoto[2], Tsutomu Takeuchi[3], Nobuyuki Miyasaka[4], Takayuki Sumida[5], Tsuneyo Mimori[6], Takao Koike[7] and Kazuhiro Endo[8]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [3]Keio University School of Medicine, Tokyo, Japan, [4]Tokyo Medical and Dental University, Tokyo, Japan, [5]University of Tsukuba, Tsukuba, Japan, [6]Graduate School of Medicine, Kyoto University, Kyoto, Japan, [7]NTT Sapporo Medical Center, Sapporo, Japan, [8]Zenyaku Kogyo Co., Ltd., Tokyo, Japan.

Background/Purpose: B-cell depletion therapy by rituximab has been reported to be useful for treatment of lupus nephritis (LN) in many observational uncontrolled studies, however, placebo-controlled phase III study, LUNAR has failed to find clinical benefit of rituximab over placebo[1)]. The interpretation of the study is controversial because of intense background MMF. Then, rituximab is still gaining attention as a treatment option for LN and recent ACR guideline recommends rituximab as an alternative treatment option for refractory LN with class III/IV[2)]. In order to examine efficacy and safety of rituximab in LN who responded inadequately to conventional therapy, a post-hoc analysis was done for subset of LN patients who entered into Japanese phase II clinical study in refractory SLE.

Methods: Patients (pts) with proteinuria, Upr/Ucr >1.0 and active urine sediment were eligible to the study. The treatment protocol was the same as EXPLORER and LUNAR and rituximab was administrated at a dose of 1,000mg/body on days 1, 15, 169 and 183. After the first dose of rituximab, background steroid was tapered by 20% every two weeks. Pts were followed for 53 weeks and renal response was examined by the criteria used in LUNAR[1)] and ACR[3)].

Results: A total of 34 pts were enrolled into the study and 17 pts had renal involvement with Upr/Ucr >1.0 (median:2.2, range:1.0–10.0). 10 out of 17 pts were biopsy-verified class III/IV, and 9 pts had a treatment history with steroid pulse and/or IVCY. Median predonisolone dose before rituximab therapy was 50 mg/day (range:15–100 mg/day). In all 17 pts, peripheral blood of B-cells depleted after the first rituximab and kept low throughout the study. 2 pts discontinued the study prematurely because of renal flare and were classified as non-responder. Overall response rate by ACR criteria were 58.8%; complete renal response (CR) 35.3%, partial renal response (PR) 23.5%, 95%CI:32.9–81.6%. Response rate with LUNAR were 52.9% (CR 29.4%, PR 23.5%, 95%CI:27.8–77.0%). As far as the response was evaluated in 10 pts with histologically confirmed class III/IV, overall response rate by ACR or LUNAR were 70.0% (CR 40.0%, PR 30.0%, 95%CI:34.8–93.3%) and 60.0% (CR 40.0%, PR 20.0%, 95%CI:26.2–87.8%), respectively. Successful steroid tapering achieved in all 15 pts who completed the study and median predonisolone dose at Week 53 was 5 mg/day (4–12 mg/day). As for the safety, rituximab was well tolerated and 6 infusion-associated reactions were observed in 3 pts, which were all grade 1–2 in severity. Three grade 3/4 adverse events were observed in 2 pts for which causal relationship with rituximab was not completely excluded: herpes simplex (G3), neuralgia (G3) and leukocytopenia (G4).

Conclusion: 1. Rituximab is effective for treatment of LN who were poorly controlled by conventional therapy and recent ACR guideline for LN is also applicable to Japanese patient. 2. Further studies will be needed to clarify and maximize the benefit of rituximab for treatment of LN. 3. International cooperative study such as RING (Rituximab for Lupus Nephritis in Remission as a Goal) is expected to provide new insight in rituximab in LN.

A Survey Of Physician and Patient Satisfaction With Control Of Systemic Lupus Erythematosus and Lupus Nephritis. Neelufar Mozaffarian[1], Steve Lobosco[2] and Adam Roughley[2]. [1]AbbVie, North Chicago, IL, [2]Adelphi Real World Ltd., Macclesfield, United Kingdom.

Background/Purpose: Patient satisfaction with disease control is an important component of overall health and well-being. Current treatment options for systemic lupus erythematosus (SLE) ±lupus nephritis (LN) include antimalarials, glucocorticoids, and immune modulators, but unmet treatment needs remain. The objectives of this analysis were to evaluate (1) patient and physician satisfaction with treatment–mediated disease control and (2) degree of physician–patient agreement with respect to treatment satisfaction.

Methods: Data were extracted from the Adelphi Real World Lupus Disease–Specific Programme®, a cross–sectional US survey of 50 rheumatologists, 25 nephrologists, and their consulting patients, conducted December 2009–May 2010. Each physician completed a comprehensive form regarding his or her 5 most recent lupus patients (N=375); data collected included disease severity, treatment history, and current therapy(ies). Physician– and patient–reported satisfaction with the level of disease control was assessed using a 3–point scale.

Results: Physician–reported data were obtained regarding 168 patients with non–nephritis SLE (NNSLE), 164 of whom were treated by rheumatologists, and 206 LN–patients, 120 of whom were treated by nephrologists; patient–reported data were obtained from 212 of these patients (NNSLE, 99; LN, 113). Physicians were satisfied with disease control in 79% (132/168) of NNSLE–patients; 76% (75/99) of NNSLE–patients were satisfied. However, agreement (71%) on the level of satisfaction with disease control among NNSLE–patients and their rheumatologists was "slight" (kappa=.1445). Notably, agreement on the level of satisfaction with disease control declined significantly with NNSLE severity (p=.0062); the greatest agreement was observed for mild NNSLE (59/75; 79%), with less agreement for moderate NNSLE (9/21; 43%) or severe NNSLE (2/3; 67%). As the number of drugs taken by NNSLE–patients increased, agreement on the level of satisfaction decreased (nonsignificant trend, p=.2035): 1 drug, 22/27 (81%); 2 drugs, 22/30 (73%); ≥3 drugs, 26/42 (62%).

Physicians were satisfied with disease control in 74% (152/206) of LN–patients; 65% (74/113) of LN–patients were satisfied. Agreement (71%) on the level of satisfaction among LN–patients (112) and their nephrologists was "fair" (kappa=.3695). Agreement tended to be higher (nonsignificant trend [p=.0740]) in patients with mild (42/56; 75%) or moderate LN (31/41; 76%), compared with severe LN (7/15; 47%). As the number of drugs taken by LN–patients increased, agreement on the level of satisfaction decreased (nonsignificant trend, p=.0764): 1 drug, 17/20 (85%); 2 drugs, 30/39 (77%); ≥3 drugs, 31/51 (61%).

Conclusion: For NNSLE, 21% of rheumatologists and 24% of patients were not satisfied with the level of disease control. For LN, 26% of nephrologists and 35% of patients were not satisfied with the level of disease control. Patients with more severe disease and those taking a higher number of anti–lupus drugs were less likely to agree with their physicians' level of satisfaction. These disease–control disparities highlight the need for more effective treatment options for both NNSLE and LN.

Candidate Urinary Biomarkers May Predict The Future Development Of Renal Functional Loss With Lupus Nephritis In Children and Adults. Khalid Abulaban[1], Brad H. Rovin[2], Shannen Nelson[3], Huijuan Song[2], Paul Kimmel[4], John Kusek[4], Harold Feldman[5], Vasan Ramachandran[6], Michael Bennett[1], Jun Ying[7] and Hermine Brunner[8]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Ohio State University Medical Center, Columbus, OH, [3]Cincinnati Children's Hospital, Cincinnati, OH, [4]NIDDK, National Institutes of Health, Bethesda, MD, [5]The University of Pennsylvania, Philadelphia, PA, [6]Boston University School of Medicine, Boston, MA, [7]University of Cincinnati, Cincinnati, OH, [8]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background/Purpose: Lupus nephritis(LN) is frequently associated with a poor long-term prognosis. Current non-invasive blood and urine tests do not reliably predict the course of LN. The objective of this study was to evaluate the performance of candidate urine biomarkers in predicting future kidney function in adults and children with LN. The biomarker candidates studies were liver-type fatty acid binding protein (L-FABP), albumin (Alb), and monocyte chemoattractant protein 1 (MCP-1).

Methods: L-FABP, Alb and MCP-1 were measured by ELISA in urine from 70 adults and 29 children collected at the time of enrollment into prospective observational LN cohorts. Urine analytes were normalized to urine creatinine and logarithmically transformed. The association of each analyte to renal function loss (RFL), defined as a sustained increase of ≥ 25% in serum creatinine (SCr; adults) or a decrease in eGFR of ≥ 20% (children), was determined using a fixed effect model after adjusting for the age group (adult vs. child). Logistical models were used to predict the presence of RFL using each biomarker or a combination of all three biomarkers. Biomarker performance in predicting RFL was assessed as the area under reciever operating characteristic curve (AUC) corresponding to the logistical model.

Results: 8 children and 22 adults had RFL during the mean follow-up period of 6.1 months and 60 months, respectively. Overall patients with RFL showed significantly higher levels of L-FABP, ALB and MCP-1 than those without RFL (Table). The AUC using the combination of urine L-FABP, Alb and MCP-1 was 0.73, higher than those using any single biomarker as the predictor (all about 0.64).

Patient type	*Biomarker/ Cr$*	*Renal function loss$*	*Preserved renal function$*	*p-value*
All patients with LN	*N*	*30*	*69*	–
	LFABP	**1.96 ± 1.45**	**1.23 ± 1.62**	**0.038**
	Albumin	**5.82 ± 2.31**	**4.54 ± 2.23**	**0.012**
	MCP-1	**6.05 ± 1.14**	**4.77 ± 2.58**	**0.014**
Adults with LN	*N*	*22*	*48*	–
	LFABP	1.69 ± 1.26	1.28 ± 1.69	0.326
	Albumin	5.90 ± 2.14	5.01 ± 2.01	0.100
	MCP-1	**5.98 ± 1.16**	**4.80 ± 2.70**	**0.061**
Children with LN	*N*	*8*	*21*	–
	LFABP	**2.67 ± 1.75**	**1.09 ± 1.48**	**0.022**
	Albumin	**5.59 ± 2.86**	**3.41 ± 2.36**	**0.047**
	MCP-1	6.25 ± 1.16	4.70 ± 2.34	0.108

$ Values are mean + standard deviation

Conclusion: Urine L-FABP, Alb and MCP-1 are associated with RFL. The combination of these biomarkers was a better predictor of RFL than any individual biomarker.

Elevated Level Of cfDNA Mainly Derive From Netosis Of Common Neutrophils As Well As Low-Density Granulocytes In Systemic Lupus Erythematosus and Is Associated With Lupus Nephritis Severity. Sigong Zhang, Guochun Wang and Xin Lu. China-Japan Friendship Hospital, Beijing, China, Beijing, China.

Background/Purpose: Insufficient clearance of neutrophil extracellular traps (NETs) has been involved in lupus nephritis and can cause the increase of residual NETs in vivo, which is considered to be one main source of circulating cell-free DNA (cfDNA). However, whether elevated level of cfDNA could be attributed to excessive formation and insufficient clearance of NETs is still unknown in SLE. This study focused on it and explored whether cfDNA could be a biomarker for organ involvement related to abnormal formation and degradation of NETs in SLE.

Methods: Fifty four patients with SLE and 43 age- and sex-matched healthy controls were included in the study. cfDNA concentration was measured with Picogreen Kit, percentage of low-density granulocytes (LDGs) in peripheral blood mononuclear cells (PBMCs) was tested by flow cytometer and DNase I activity was measured by radial enzyme-diffusion method. Linear correlation analysis were performed between these three, SLE disease activity index (SLEDAI) and other serological parameters. Multiple linear regression was performed to identify the influencing factor of cfDNA.

Results: cfDNA in SLE group was 239.76±57.15 ng/ml, significantly higher than that in healthy control group (187.96±40.55 ng/ml, P<0.0001). DNase I activity in SLE group was 0.26±0.17 U/ml, significantly lower than that in healthy control group (0.43±0.26 U/ml, P<0.0001). Percentage of LDGs in PBMCs of SLE group was 8.29%±12.86%, significantly higher than that in healthy controls group (1.15%±0.71%, P=0.0036). In SLE group, cfDNA positively correlated with percentage of LDGs in PBMCs (r=0.651, P=0.002), neutrophils (r=0.584, P<0.0001), ESR (r=0.364, P=0.007), CRP (r=0.291, P=0.032) and urine protein (r=0.350, P=0.013) and reversely correlated with albumin (r=−0.500, P<0.0001) and Ccr (r=−0.354, P=0.044). Multiple linear regression indicated that plasma albumin and neutrophils can explain 38.2% of elevated cfDNA in SLE patients.

Conclusion: The elevated level of cfDNA may mainly derive from NETosis of common neutrophils as well as LDGs and is associated with lupus nephritis severity.

Analysis Of Relationship Between Clinical Manifestations and Autoantibody Profile In ISN/RPS Class V Lupus Nephritis. Masanori Hanaoka[1], Takahisa Gono[1], Yasushi Kawaguchi[1], Hisashi Yamanaka[2], Yasuhiro Katsumata[1], Kae Takagi[1], Hirotaka Kaneko[1], Hisae Ichida[1], Yuko Ota[1], Hidenaga Kawasumi[1], Sayumi Baba[1], Yuko Okamoto[1] and Sayuri Kataoka[1]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Clinical manifestations, pathohistology and treatment strategy are different between International Society of Nephrology/Renal Pathology Society (ISN/RPS) class III/IV and class V Lupus Nephritis (LN). However, it has remained unknown what factors contribute to differences of pathophysiology between ISN/RPS class III/IV LN and class V LN. Moreover, in some patients with class V LN, responses to treatment such as corticosteroid or immunosuppressive agents are refractory. Predictors for treatment response have remained unknown in class V LN. The aim of this study is to clarify the differences of autoantibody profile between ISN/RPS class III/IV LN and class V LN. We also investigate associations between clinical manifestations and each autoantibody in class V LN.

Methods: 55 LN patients were consecutively enrolled and underwent renal biopsy in this study. These patients were divided into two subsets, 31 patients with ISN/RPS class III/IV LN subset and 22 patients with class V LN subset. Combined class III/IV+ V LN cases were excluded in this study. Clinical manifestations, autoantibodies positivity (anti-dsDNA, anti-SS-A, anti-U1-snRNP, Anti-Sm and anti-ribosomal P) were compared between two subsets. In addition, we analyzed the relationship between clinical manifestation and each autoantibody in class V LN subset.

Results: Disease duration was significantly longer in class III/IV LN than class V LN (P = 0.01). Anti-dsDNA titer was significantly higher in class III/IV LN than class V LN (P < 0.01). The frequency of anti-Sm and anti-ribosomal P positivity was higher in class V LN than class III/IV LN (43% vs 20% and 50% vs 25%, respectively), although there were no significant differences. The frequency of both anti-dsDNA positive and anti-U1snRNP negative was significantly higher in class III/IV LN than class V LN (54.1% vs 19.1%, P = 0.03). In contrary, the frequency of both anti-dsDNA negative and anti-U1snRNP positive was significantly higher in class V LN than class III/IV LN (33% vs 0%, P < 0.01).

Among class V LN subset, complement levels were lower and renal remission rate was higher in anti-dsDNA-positive class V LN subset than anti-dsDNA-negative class V LN subset. SLEDAI score was significantly higher (P = 0.02) and 24hr proteinuria was higher in anti-Sm-positive class V LN subset than anti-Sm-negative class V LN subset. Rash and arthritis was higher in anti-ribosomal P-positive class V LN subset than anti-ribosomal P-negative class V LN subset.

Conclusion: Anti-U1snRNP is associated with complication of class V LN. Lower complement level and anti-dsDNA positivity are the predictive markers for renal remission in class V LN.

Urinary Prostaglandin D Synthetase As a Biomarker Of Lupus Nephritis Activity: One Year Longitudinal Study. Ranjan Gupta, Akhilesh Yadav, Ramnath Misra and Amita Aggarwal. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background/Purpose: Proteomic analysis of urine samples, from patients with active lupus nephritis (LN)[1–2] and from animal model of LN[3] has led to identification of Prostaglandin D synthetase (PGDS) as a potential biomarker in LN. The levels were increased in patients with active LN as compared to inactive LN[1].There is no longitudinal study available in patients with active LN to see its relationship with renal activity.

Methods: Patients fulfilling ACR criteria for diagnosis of SLE were included and categorized into active LN (ALN), active non renal disease (ANR) and inactive disease (ID). Urine was collected in the morning and stored after centrifugation. Patients with pregnancy or infection were excluded. Urine samples from 19 healthy young females were included as control. 25 patients with active lupus nephritis were followed up 3 monthly and urine samples were analyzed at 6, 9 and 12 months. Patients who had worsening renal disease at 3 months had sample analyzed at 3 months also. Urinary PGDS (uPGDS) was measured by ELISA using commercial kit. All values were normalized to urinary creatinine excretion.

Results: A total of 28 patients with ALN, 15 patients with ANR, 6 patients with ID and 19 healthy controls were included in cross-sectional study. Among the 49 patients, there were 46 females. Mean age was 27.8 (SD 9.5) years. The median SLEDAI in ALN was 20(6–32), in ANR was 9(4–18) and in ID was 3(0–4). In patients with ALN, the median renal SLEDAI was 10(4–16). The class of LN was II in 4, III in 11, IV in 6, V in 3 and in 4 patients biopsy could not be done.

In cross-sectional study, the median uPGDS excretion was higher in patients with ALN (61.85 ng) as compared to healthy controls (14.17ng; p<0.001), ANR (21.31ng; p=ns) and ID (5.62 ng; p<0.005). uPGDS had good correlation with renal SLEDAI (r=0.403; p=0.006) and total SLEDAI (r=0.406; p=0.007).

In longitudinal study of 28 patients with ALN, 25 patients had completed 6 months, 20 patients 9 months and 13 patients 12 months follow-up. uPDGS had excellent correlation with SLEDAI, rSLEDAI and urinary protein creatinine ratio over time. The median values are shown in the line diagram below at 0, 6, 9 and 12 months.

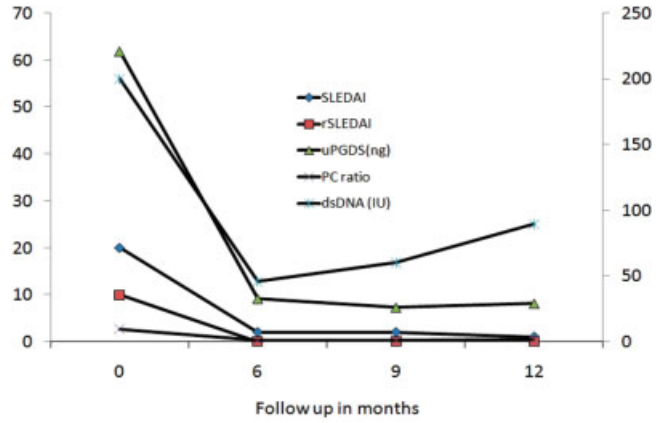

Figure.

One patient with class IV nephritis had no response at 3 months with rise in serum creatinine. Her urine sample at 3 months showed a marked rise in uPGDS (41.89 to 390.85ng). She was treated with Rituximab but developed ESRD at 6 months.

The only patient who showed a significant rise in uPGDS at 9 months (baseline: 13.9: 6 months: 10.9: 9 months 47.96 ng) relapsed at 11 months.

Conclusion: uPGDS is a good marker of lupus activity. uPGDS is partly serum derived[3] as its levels are higher in patients with ANR disease than ID. Its levels are higher in nephritis and can be used to monitor renal activity. It may be a potential marker to predict relapse.

Renal Biopsy Findings In Lupus Patient With Insignificant Proteinuria: Relation To Disease Activity and Clinical Manifestations. Abdel Azeim M. Al-Hefny[1], Samah El-bakry[2], Sameh A. Mobasher[3], Ola H. Nada[4] and Nouran Abaza[5]. [1]Professor of Internal Medicine and Rheumatology, Faculty of Medicine, Ain Shams University, Cairo, Egypt, Cairo, Egypt, [2]Assistant professor of Internal Medicine and Rheumatology, Faculty of Medicine, Ain Shams University, Cairo, Egypt, [3]Lecturer of Internal Medicine and Rheumatology, Faculty of Medicine, Ain Shams University, Cairo, Egypt, [4]Lecturer of Pathology, Faculty of Medicine, Ain Shams University, Cairo, Egypt, [5]Lecturer of Physical medicine, Rheumatology and Rehabilitation, Faculty of Medicine, Ain Shams University, Cairo, Egypt.

Background/Purpose: Lupus nephritis (LN) remains one of the most serious manifestations of systemic lupus erythematosus (SLE) and is associated with significant morbidity and mortality. Early and accurate detection of kidney involvement in SLE improves outcomes. Although renal biopsy is required for proper diagnosis of the histopathological subtype of LN and direction of proper treatment, the decision to recommend renal biopsy can be complex. We aimed to investigate whether SLE patients with insignificant proteinuria have significant renal involvement and need to be biopsied. We also studied the relation between severity of nephritis and the overall disease activity and other lupus manifestations.

Methods: Forty SLE patients with proteinuria <500 mg/24 hrs were recruited from Ain Shams University Hospitals. Disease activity was assessed according to SLE disease activity index (SLEDAI). Renal biopsy was done to all patients and assessed by light, immunofluorescent and electron microscopy for identification of different pathological classes according to WHO classification. Patients were classified into two groups: Group A: with mild renal affection [class I or II according to WHO-histopathological classification of renal biopsy] and Group B: with moderate to severe renal affection [class III, or more according to WHO classification].

Results: All patients (100%) had lupus nephritis by histo-pathological examination according to the WHO classification. About 32.5% of SLE patients with insignificant proteinuria had mild lupus nephritis and 67.5% had moderate to severe nephritis. In Group A: 2 patients (5 %) had class I LN and 11 patients (27.5 %) had class II LN, while in Group B: 13 patients (32.5%) had class III LN, 10 patients (25 %) with class IV LN and 4 patients (10%) with class V LN. Comparing clinical characteristics of both groups; patients with severe LN (Group B) had higher SLEDAI scores (P= 0.049), higher ESR levels, higher Anti-dsDNA titer (P= 0.020) and lower C3 and C4 levels (P= 0.028 and <0.001 respectively). As well, they were more anemic, leucopenic, lymphopenic and thrombocytopenic than patients with mild LN (group A) (P= 0.020, P= 0.005, P= <0.001and P= 0.050 respectively).

Urinary abnormalities; especially proteinuria and hematuria were significantly higher in patients with severe LN than those with milder LN (P= 0.009 and 0.047 respectively). Furthermore, patients with severe LN had significant polyarthralgia and history of recurrent thrombosis than those with mild LN (P =0.011 and 0.035 respectively).

Conclusion: We found significant renal involvement (Class III, IV, or V LN) in SLE patients with insignificant proteinuria. Our data suggest that for better outcome; renal biopsy should be justified in SLE patients with low proteinuria and without clinical signs of renal affection, especially if they have any of the following: polyarthlralgia, recurrent thrombosis, high Anti-dsDNA titer, consumed C3 &/or C4, rising ESR, high SLEDAI scores, anemia, leukopenia, lymphopenia, thrombocytopenia, and finally active urinary sediment; especially hematuria.

Extended Follow-Up Of a Investigator-Initiated trial Comparing Two Sequential Induction and Maintenance Treatment Regimens For Proliferative Lupus Nephritis Based Either On Cyclophosphamide Or Cyclosporine A. Jakub Zavada[1], Satu Pesickova[2], Romana Rysava[2], Pavel Horak[3], Zbynek Hrncir[4], Jozef Rovensky[5], Jozef Lukac[5], Jirina Vitova[6], Jana Böhmova[7], Marta Olejarova[1], Dana Tegzova[8] and Vladimir Tesar[2]. [1]Institute of Rheumatology, Prague, Prague, Czech Republic, [2]General University Hospital and First Faculty of Medicine, Charles University, Prague, Czech Republic, [3]3rd Department of Internal Medicine University Hospital Olomouc, Olomouc, Czech Republic, [4]Faculty of Medicine and University Hospital, Hradec Kralove, Czech Republic, [5]National Institute of Rheumatology, Piestany, Slovakia, [6]Hospital, Ceske Budejovice, Czech Republic, [7]Faculty Hospital St. Anna, Brno, Czech Republic, [8]Institute of Rheumatology, Prague, Czech Republic.

Background/Purpose: In the investigator-initiated CYLOFA-LUNE trial we tested the hypothesis that immunosuppressive regimen based on Cyclosporine A (CYA) may have similar efficacy but greater safety than that based on cyclophosphamide (CPH).

CYCLOFA-LUNE TRIAL a multicenter, randomized, open-label, controlled trial conducted from January 2002 through December 2006 in 7 centers in Czech Republic and one center in Slovakia

Eligibility criteria:

• The diagnosis of systemic lupus erythematosus (by meeting 4 criteria of the American College of Rheumatology)

• Renal biopsy documenting proliferative glomerulonephritis class III or IV according to WHO/ISN-RPS

• Clinical activity as defined by presence of at least two of the following: abnormal proteinuria (> 500mg/24-hours), active urinary sediment, and/or C3 hypocomplementemia

Treatment:

The duration of the controlled study protocol was 18 months Cyclophosphamide (CPH) arm: 8 boluses of intravenous cyclophosphamide (10mg/kg) given within 9 months in subsequently prolonged intervals (2×3weeks, 4×4 weeks, 2×6 weeks) followed by 4–5 oral cyclophosphamide boluses (10mg/d in 6–8 week intervals). Cyclosporine arm: oral cyclosporine A (CyA) 4–5mg/kg/day (given in two divided doses) for 9 months followed by gradually decreasing dose of cyclosporine (3.75-1.25 mg/kg/day) within the next 9 months Glucocorticoids: prescribed according to a unified protocol

The main purpose of the current analysis was to ascertain the long-term renal outcome of patients randomised in the CYCLOFA-LUNE trial.

Methods: Data for kidney function, and adverse events (death, cardiovascular event, tumor, premature menopause) were collected by a cross-

sectional suvey for 38 of 40 patients initially randomised in the CYCLOFALUNE trial.

Results: The median follow-up time was 7.7 years (range 5.0–10.3). Rates of renal impairment and end-stage renal disease, adverse events (death, cardiovascular event, tumor, premature menopause) did not differ between the CPH and CyA group, nor did mean serum creatinine, 24 h proteinuria and SLICC damage score at last follow-up. Most patients in both groups were still treated with glucocorticoids, other immunosuppressant agents, and blood pressure lowering drugs.

	All (n=38)	CPH (n=19)	CyA (n=19)
Age (years), mean (SD)	39 (10)	37 (5)	38 (8)
Female, n	27 (71)	13 (68)	14 (74)
Follow-up (years), median (range)	7.7 (5.0–10.3)	7.4 (5.0–9.7)	5.3–10.3
50% increase in creatinine concentration	5 (13)	3 (16)	2 (11)
Non-sustained doubling of the creatinine concentration	2 (5)	1 (5)	1 (5)
Sustained doubling of serum creatinine	2 (5)	1 (5)	1 (5)
End-stage renal disease	2 (5)	1 (5)	1 (5)
Current serum creatinine (μmol/l)	67 (19)	71 (23)	63 (15)
Current 24 h proteinuria (g)	0.4 (0.6)	0.5 (0.5)	0.4 (0.7)
Additional IS drugs ever received	1 (1)	1 (2)	1 (1)
Deaths	0 (0)	0 (0)	0 (0)
Malignancy	2 (5)	0 (0)	2 (11)
Cumulative cardiovascular events	1 (3)	1 (5)	0 (0)
Premature menopause*	1 (4)	1 (8)	0 (0)
Pregnant*	9 (33)	6 (46)	3 (21)
Current SLICC DI (median, IQR)	0.0 (1.0)	0.0 (1.0)	0.5 (1.0)

2 patients included in the ESRD group are counted within the other groups with less severe renal impairment), Figures are numbers (%) of patients, or median (IQR) * since the end of the CYCLOFA-LUNE protocol treatment.

Conclusion: Both regimens based either on CPH or CyA achieved good and similar clinical results in the very long term

Low Complement (C3), Male Gender and Methotrexate Use Are Associated With Noncalcified Plaque In Systemic Lupus Erythematosus.

Adnan Kiani[1], Armin Zadeh[2], Jens Vogel-Claussen[1], Joao Lima[2], Laurence S. Magder[3] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]University of Maryland, Baltimore, MD.

Background/Purpose: New technology (CTA) can measure noncalcified coronary plaque (NCP), which is highly unstable and prone to rupture. We quantified NCP in SLE and determined the association with SLE manifestations.

Methods: 64 (n=106) or 320 (n=156) slice coronary multidetector computed tomography (MDCT) was performed in 262 SLE patients (90% female, 64% Caucasian, 30% African-American, mean age 50 years). The MDCT scans were evaluated quantitatively by a radiologist, using dedicated software. NCP score was a sum of plaque severity multiplied by the plaque composition divided by the number of vessels examined.

Results: Table 1 shows the mean NCP score, by demographics, traditional cardiovascular risk factors, history of lupus serologies and current medications. In the univariate analysis age, male gender, weight and hypertension were the major variables associated with NCP. A history of low complement (C3,C4) and anti-dsDNA (but not current) was associated with NCP. Prednisone and hydroxychloroquine therapy had no effect, but methotrexate use was associated with NCP. Table 2 shows the multivariate regression model, in which age, male gender, history of low C3 and methotrexate use remained independent predictors.

Table 1. Mean NCP Score, by Demographics, Traditional CVRF, History of Lupus Serologies and Current Medications

	Group	Mean NCP Score	p-value	p-value when age is controlled
Age	< 45 (n=110)	0.13 (0.20)	< 0.0001	–

[1] P<.0001 for trend with weight as a continuous predictor
[2] P=.0014 for trend with weight as a continuous predictor, controlling for age
[3] P=.0072 for trend with BMI as a continuous predictor
[4] P=.036 for trend with BMI as a continuous predictor, controlling for age.

Table 2. Multivariable Regression Model for Mean NCP

Variable	Effect on mean NCP score (95% Confidence Interval)	P-value
Age (per 10 years)	0.094 (0.068, 0.120)	< 0.0001
Low BMI (vs. normal)	−0.059 (−0.134, 0.015)	0.12
High BMI (vs. normal)	0.001 (−0.078, 0.081)	0.98
Hypertension	0.062 (−0.005, 0.130)	0.070
History of Low C3	0.091 (0.023, 0.159)	0.0090
History of anti-dsDNA	0.017 (−0.053, 0.086)	0.64
Male sex	0.112 (0.011, 0.214)	0.030
Methotrexate	0.248 (0.100, 0.395)	0.0011

Conclusion: NCP is a measure of immediate risk of a cardiovascular event and contributes to overall atherosclerotic burden. Male gender, history of low C3 and hypertension associate with semi-quantified noncalcified plaque in SLE. The association with methotrexate is unexpected, as in rheumatoid arthritis methotrexate reduces cardiovascular risk. Methotrexate can increase homocysteine, a known risk factor for atherosclerosis, in SLE. However, methotrexate is also preferentially used to treat lupus arthritis. Because causality cannot be proven, we cannot recommend stopping the use of methotrexate in SLE at this time.

Gender Influence On Lupus Nephritis Outcomes In An Urban, Multi-ethnic Population. Cindy Johnston, Catarina Vila-Inda and Irene Blanco. Albert Einstein College of Medicine, Bronx, NY.

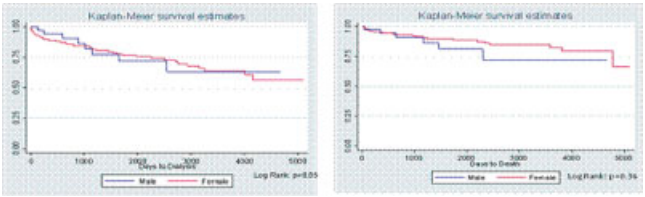
Background/Purpose: Systemic lupus erythematosus (SLE) is a disease predominately of young women that disproportionately affects minorities. Lupus Nephritis (LN) causes major morbidity and mortality in this population. It is suggested that men with SLE have worse disease outcomes with high rates of LN. This study was undertaken to identify major clinical differences and outcomes by gender in LN in an urban ethnic population.

Methods: All LN biopsies at Montefiore Medical Center, Bronx, NY were analyzed from Jan 1997- Jan 2012. All patients met ≥ 4/11 ACR SLE criteria. We collected demographics, clinical and serologic data and treatment regimens over a 1yr period post biopsy. The primary endpoints were gender differences in time to end stage renal disease (ESRD) as defined by the initiation of dialysis and inclusion in the US Renal Data System and all-cause mortality as reported to the Social Security Administration.

Results: 207 patients were included: 37 male (M) 170 female (F). Men trended to be diagnosed with SLE earlier (24.6y±14.4 v 28.2y±14.2, p=0.2) and have a shorter disease duration at the time of biopsy (median 1y v 2y, p=0.11). There were no differences with regards to ethnicity: African American 55.6% M v 55.1% F and Hispanic 36.1% M and 37.7% F (p=0.93). Both genders had similar rates of hypertension (p=0.91), diabetes (p=0.80), and cardiovascular disease (p=0.40). At biopsy, men had higher levels of dsDNA antibodies (median 263.9 v 126.3, p=0.007) but there were no difference in median C3 (p=0.74) and C4 levels (p=0.71), mean systolic BP (p=0.71), median serum creatinine (1.1 M v 1.0 F, p=0.23) or median protein to creatinine ratio (2.1 M v 2.2 F, p=0.53). The distribution of LN classes between the genders were similar: class III/IV - 59.5% M v 58.2% F; class V - 27.0% M v 25.3% F; mixed class - 8.1 %M v 12.4% F(p=0.88).

There was no difference in ACEi/ARB (p=0.54), hydroxychloroquine (p=0.72) or steroid use (p=0.14) between the genders. While men tended to get cyclophosphamide induction at higher rates than women (60.0% M v 48.8%F) both genders were mostly maintained on mycophenolate (64.0% M v 65.5% F).

Regardless of subtle, though not statistically significant, differences in treatment there was no difference between rates of ESRD (log rank, p=0.85) or all-cause mortality (log rank p=0.36) between the genders.



Conclusion: Our study suggests that there are few clinical differences between men and women lupus nephritis in this population. Race/ethnicity/socioeconomic status may play a greater role than gender when looking at disease severity and outcomes.

Association Between Serum Leptin and Adiponectin Levels With The Severity Of Proteinuria In Lupus Nephritis. Valeria Diaz-Rizo[1], Nicte Selene Fajardo-Robledo[2], Alan Joel Ruiz-Padilla[2], Dalia Sanchez-Mosco[3], Tania Marlene Rodriguez-Hernandez[4], Xochitl Trujillo[5], Miguel Huerta[5], Monica Vazquez del Mercado[6], Laura Gonzalez-Lopez[4] and Jorge Ivan Gamez-Nava[7]. [1]Doctorado en Ciencias Médicas, Centro Universitario de Investigación Biomédica, Universidad de Colima; UMAE, Hospital de Especialidades, Centro Médico Nacional de Occidente, IMSS, Guadalajara, Jalisco, Mexico, [2]Doctorado en Farmacología, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Jalisco, Mexico, [3]Centro Universitario de Investigación Biomédica, Universidad de Colima; Hospital General Regional 110 IMSS, Guadalajara, Jalisco, Mexico, [4]Hospital General Regional 110, Instituto Mexicano del Seguro Social (IMSS), Guadalajara, Jalisco, Mexico, [5]Centro Universitario de Investigación Biomédica, Universidad de Colima, Colima, Mexico, [6]Universidad de Guadalajara, Guadalajara, Mexico, [7]UMAE, Centro Médico Nacional de Occidente, IMSS; Doctorado en Farmacología, Universidad de Guadalajara, Jalisco, Mexico.

Background/Purpose: To identify the association between serum leptin and adiponectin levels and proteinuria secondary to lupus nephritis in women with systemic lupus erythematosus (SLE).

Methods: One-hundred and four women with SLE were included in the study. All of them were assessed in order to identify the presence of lupus nephritis; proteinuria levels in 24 hours were identified, patients were classified in two groups: SLE with proteinuria ≥0.5 g in 24 h secondary to lupus nephritis (SLE + proteinuria n=30) and SLE without nephritis (n=74). Patients with proteinuria secondary to causes different to nephritis were excluded. Other assessments included modified-SLEDAI (m-SLEDAI) for disease activity, SLICC/ACR and Body Mass Index (BMI). Serum levels of leptin, and adiponectin were measured by ELISA. Leptin was adjusted by BMI. Statistical analysis included a comparison of means between groups using Student t-test for independent samples, Pearson correlation test to identify strength of association between serum leptin and adiponectin levels with proteinuria and other quantitative variables. A multiple regression analysis was used to adjust for confounders.

Results: In the comparison between groups there were no statistically significant differences in age, weight or BMI between SLE + proteinuria versus SLE without nephritis. The group with SLE + proteinuria had higher serum adiponectin levels compared with SLE without nephritis (20.11±10.58 μg/mL vs. 15.36±7.83 μg/mL respectively; p=0.032). Serum leptin levels were not statistically different between the group with SLE + proteinuria compared with SLE without nephritis (28.68±25.79 ng/mL vs. 23.43±29.15 ng/mL respectively; p=0.39). Serum leptin levels had a positive correlation with weigh (r=0.306, p=0.002), BMI (r=0.327, p=0.001), serum creatinine in mg/dL (r=0.283, p=0.004), chloroquine (r=0.262, p=0.009) and prednisone doses (mg/day) (r=0.207, p=0.035) but did not correlated with proteinuria (r=−0.014, p=0.893) neither with m-SLEDAI (r=0.092, p=0.357) and SLICC/ACR (r=0.083, p=0.408). Serum adiponectin levels correlated with serum creatinine (r=0.255, p=0.010) and proteinuria (r=0.305, p=0.002), m-SLEDAI (r=0.299, p=0.002), chloroquine (r=0.203, p=0.046) and prednisone doses (r=0.343, p=<0.001), but there was no correlation between adiponectin and SLICC/ACR (r=0.085, p=0.394). A negative correlation was observed between adiponectin and weigh (r=−0.204, p=0.038), BMI (r=−0.203, p=0.039) and fast glucose serum levels (r=−0.347, p=<0.001). In the multivariate analysis, after adjusting by age, disease duration, BMI and leptin, serum adiponectin levels remained associated with severity of proteinuria (p=0.005).

Conclusion: Serum adiponectin levels were higher in women with SLE + proteinuria compared to SLE without nephritis. Longitudinal studies should be performed in order to identify if patients with proteinuria and high serum adiponectin levels have differences in the development of response to therapies directed against of nephritis.

Factors Associated With Long-Term Renal Function Deterioration In Lupus Nephritis Treated Initially With Combined Prednisolone and Mycophenolate Mofetil (MMF) Or Tacrolimus (Tac). Chi Chiu Mok[1], Chi Hung To[1], King Yee Ying[2], Cheuk-Wan Yim[3] and Woon Leung Ng[3]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Princess Margaret Hospital, Hong Kong, Hong Kong, [3]United Christian Hospital, Hong Kong, Hong Kong.

Background/Purpose: To study the risk factors for renal function decline in patients with lupus nephritis treated initially with combined steroid and MMF or Tac.

Methods: Data were extracted from a randomized controlled trial of the efficacy of MMF vs Tac for induction treatment of lupus nephritis. All patients recruited were treated with high-dose prednisolone (0.6mg/kg/day for 6–8 weeks and tapered) with either MMF (2–3g/day) or Tac (0.1-0.06mg/kg/day) for 6 months. Patients with good clinical response were shifted to azathioprine (AZA) (2mg/kg/day) and continued on low dose prednisolone (<10mg/day) for maintenance. Rescue therapies were given to patients who did not have response to treatment at the discretion of the attending physicians. Factors associated with renal function decline at 5 years were studied by Cox regression analyses.

Results: 150 patients (92% women) with biopsy confirmed active lupus nephritis were studied (ISN/RPS class III 17%; IVG 31%; IVS 12%; III/IV+V 21%; pure V 20%). The mean age was 35.5±12.8 years and SLE duration was 50.2±62 months at the time of renal biopsy. 102 (68%) patients had first time glomerulonephritis while the others had relapsed disease. The mean histological activity and chronicity score was 8.2±3.4 and 2.6±1.6, respectively. 59(39%) patients were hypertensive, 62(41%) had active urinary casts and 112(75%) had microscopic hematuria at presentation. The mean creatinine clearance (CrCl) was 79.0±30.8 ml/min and 67% patients had CrCl less than 90ml/min. At 6 months, 61% patients achieved good clinical response, 25% had partial response but 15% patients had no response (NR) (urine P/Cr improvement <50% or >3.0 or deterioration in CrCl (>20%) ± persistently active urinary sediments and lupus serology). Rescue regimens for NR patients included: oral or intravenous pulse cyclophosphamide (68%), Tac or MMF (14%) and MMF + Tac combination (18%). 128(85%) patients received AZA (83.1±23mg/day) for maintenance therapy. After a mean follow-up of 56±28 months, 27(18%) patients had loss of CrCl by >=30% and 17 (11%) patients developed stage 4/5 chronic kidney disease (CKD) (CrCl <30ml/min). The cumulative risk of loss of CrCl by ³30% or stage 4/5 CKD was 3% at 12 months, 7.7% at 24 months, 8.4% at 36 months, 13.6% at 48 months and 17.3% at 60 months. Cox regression revealed histological activity score (HR 0.78[0.65–0.94]; p=0.007), chronicity score (1.46[1.06–2.01]; p=0.02), non-response at 6 months (HR 3.87[1.34–11.2]; p=0.01), class V histology (HR 0.35[0.16–0.74]; p=0.006) and number of renal flares (HR 1.59[1.01–2.49; p=0.04] were independent risk factors for CrCl loss by 30% of stage 4/5 CKD, after adjustment for age, sex, SLE duration, first-time renal disease, proteinuria and CrCl at presentation and the treatment arm during induction phase (MMF or Tac).

Conclusion: Combined prednisolone with MMF or Tac is equally effective for the initial treatment of active lupus nephritis. No response at 6 months, proliferative types of lupus nephritis, lower activity but higher chronicity score on renal biopsy and the number of renal flares are predictive of renal function decline at 5 years.

601

Hypovitaminosis D and The Metabolic Syndrome In Patients With Systemic Lupus Erythematosus (SLE). Chi Chiu Mok[1], Ling Yin Ho[1] and Daniel Birmingham[2]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Ohio State University Medical Center, Columbus, OH.

Background/Purpose: Low vitamin D level has been linked to cardiovascular diseases and mortality in the general population. Hypovitaminosis D is associated with certain traditional vascular risk factors in patients with SLE. This study aims to evaluate the relationship between the metabolic syndrome (MetS) and serum 25-hydroxyvitamin D level in patients with SLE.

Methods: Consecutive patients who fulfilled >=4 ACR criteria for SLE in a two-month period were recruited from our out-patient lupus clinics. Blood was taken in the morning for the assay of 25-hydroxyvitamin D3 (enzyme immunoassay; Immunodiagnostic Systems Inc, Fountain Hills, AZ, USA) and high sensitivity C-reactive protein (hsCRP) (solid phase chemilluminescence immunometric assay; Siemens Healthcare Diagnostics, Deerfield, Il., USA). Clinical assessments (waist circumference, fasting glucose and lipid level, blood pressure) were made for each patient who was stratified for the MetS according to the 2009 International joint consensus criteria, using the Asian criteria for abdominal obesity (ref 1). The relationship between 25-hydroxyvitamin D level and the MetS was studied by linear regression, with adjustment for other confounding covariates.

Results: 257 SLE patients (94% women) were studied. All were ethnic Chinese. The mean age was 39.6±13.1 years and SLE duration was 8.3±6.9 years. Vitamin D insufficiency (25-hydroxyvitamin D3 <30ng/mL), deficiency (25-hydroxyvitamin D3 <15ng/mL, and severe deficiency (level<10ng/mL) was present in 95%, 25% and 3.5% of patients, respectively. The prevalence of the MetS was 8.3%, 11% and 22.2% in patients with vitamin D insufficiency, deficiency and severe deficiency, respectively. None of the patients with 25-hydroxyvitamin D3 levels >30ng/mL fulfilled the criteria for the MetS. Linear regression analysis revealed that levels of 25(OH)vitamin D3 were independently associated with age (Beta 0.19; p=0.002), the presence of the MetS (Beta −0.14; p=0.049) and hsCRP level (Beta −0.14; p=0.04) after adjustment for gender, SLE duration, duration of sunshine in the month of venepuncture, SLE damage scores (SDI), smoking ³3 years, renal insufficiency (estimated CrCl < 50ml/min), photosensitivity and ever use of glucocorticoids.

Conclusion: Vitamin D deficiency is prevalent in patients with SLE. Hypovitaminosis D is independently associated with the MetS and hsCRP, suggesting that it is a novel risk factor for vascular thrombosis in patients with SLE.

Repeat Biopsy In Lupus Nephritis: A Single-Center Experience. Josefina Marin[1], Marina Scolnik[1], Eliana Lancioni[1], Gustavo Greloni[2], Cristian Quiroz[1], Johana Zacariaz[1], Carla Saucedo[1], Luis J. Catoggio[3] and Enrique R. Soriano[3]. [1]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Nephrology Service, Buenos Aires, Argentina, [3]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Argentina.

Background/Purpose: Renal involvement in systemic lupus erythematosus (SLE) is an important cause of morbidity and even mortality. Lupus nephritis has diverse morphologic manifestations with varying clinical presentations and consequences.Treatment and prognosis accordingly range from excellent even with only observation with minimal mesangial deposits, to kidney failure despite aggressive immunosuppression in patients with severe proliferative disease. Renal biopsy plays a crucial role in the diagnosis of the specific form of lupus nephritis, and rebiopsy is often necessary during follow up in order to assess renal activity and guide treatment. The objective of our study was to describe characteristics of second biopsies in SLE patients and try to identify variables useful for prediction of histological form of lupus nephritis in second biopsies.

Methods: SLE patients (ACR criteria) who had a diagnosis of lupus nephritis and two or more renal biopsies after year 2001 were included. Electronic medical records were reviewed and clinical, laboratory and treatment data were obtained from each patient. Renal biopsy was classified according to the International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification of lupus nephritis.

Results: We identified 45 lupus patients (40 females) with at least two renal biopsies. These patients had a total of 116 biopsies. Class IV (51,8%) and V (17,2%) were the most frequent findings. Treatments received are shown in table 1. Laboratory findings at the moment of biopsy are shown in table 2 and showed no significant differences between different histology patterns. In multivariable analysis no variable was significantly associated with any histology class at time of the second biopsy. 27 patients (64%) changed histology class between successive biopsies. Those who did not change were mostly class IV (68.8%). 55 rebiopsies (82%) generated a treatment modification and 12 (18%) did not (insufficient data from 6).

Table 1. Treatment received after renal biopsies.

Induction treatment	Maintenance treatment
IV Cyclophosphamide >= 6 pulses (33%)	Mycophenolate (45,7%)
Mycophenolate (22,4%)	Azathioprine (17%)
IV cyclophosphamide < 6 pulses (13%)	Cyclophosphamide (9.5%)
Rituximab (8%)	Others (8,6%)
Others (21%)	

Table 2. Laboratory features at time of second biopsy.

	Class II	Class III	Class IV	Class V	Combination b/ III or IV + V
Mean proteinuria (g/24 hs)	0.92	1.24	2.29	3.57	5.92
Mean creatinine (mg/dl)	0.98	1.14	1.27	1.16	1
Patients with hematuria, (>4 RBC), %	88.9%	60%	69%	50%	50%
Mean Albumin (g/dl)	3.05	3.39	2.8	2.93	2.4
Low C3, %	57.1%	33%	76.7%	50%	67%
DNA +, %	66.7%	44.5%	81.8%	26.7%	50%

Conclusion: In this lupus nephritis cohort, 64 % of patients with a repeated biopsy showed change in the histological class. We were unable to identify variables capable of predicting histological class in second biopsies. In 82% of patients second biopsy was associated with treatment change.

603

Factors Associated With a Double Increase In Serum Creatinine In Biopsy Proven Lupus Nephritis From a Single Center In Spain. Raúl Menor Almagro[1], M. H. Cardiel[2], Javier Rubio Garrido[1], J. Luis de la Iglesia[1], José Javier Perez Venegas[1], María Mar Ruiz Tudela[1], José Javier Salaberri[1] and Manuel Paez-Camino[1]. [1]Hospital de Jerez, Jerez de la Frontera, Spain, [2]Centro de Investigacion Clinica de Morelia, Morelia, Mexico.

Background/Purpose: Lupus nephritis is a common and feared complication in systemic lupus erythematosus (SLE). Clinicians have relied on different variables to help to predict those subjects who will eventually develop a kidney function deterioration. Our objective was to identify those variables associated with a double increase in serum creatinine in biopsy proven lupus nephritis (LN).

Methods: All patients fulfilled ACR criteria for SLE. We identified 49 cases with biopsy proven lupus nephritis. Clinical charts were reviewed by a single trained rheumatologist following predefined criteria for different variables recorded when the biopsy was performed including clinical, laboratory, immunologic and histological information. All biopsies were evaluated by a single qualified and experienced pathologist who scored activity and chronicity indices. Forty nine patients were identified. Ten of them doubled their creatinine in their follow-up. These subjects were compared with the other thirty nine patients using chi square or Mann Whitney U test. In all cases significance was set at 0.05 alfa level. Odds ratio and 95% confidence intervals were also calculated.

Results: Mean age of onset of SLE was 30.1 +/−12 years, and mean age onset of LN was 32.5 +/−12 months. Main reasons for a first renal biopsy were persistent urine abnormalities (27 patients), proteinuria (17), nephritic syndrome (4) and acute renal failure (1). Histologic diagnosis (WHO criteria) were type IV (22/44%), II (14/28%), III (10/20%), V (2/10), VI (1/2%). Our study did not found significant relationship between double increase in serum creatinine and type of biopsies, but activity and chronicity index showed a clear trend almost reaching statistical significance. Other variables are presented in table 1.

Table 1.

Variable	Doubled creatinine (n:10)	Not doubled creatinine (n:39)	OR 95% CI	p value
Age (Mean/SD)	24/9	31/11		0.06
HBP*	10	24	7 (0.8–59)	0.02
Serositis	7	11	5.9 (1.2–27)	0.02
Edema	10	24	7 (0.8–59)	0.02
Lymphopenia	10	23	7.7 (0.9–66)	0.01
APLA (+)**	6	8	5.8 (1.3–25)	0.02
Activity Index	9.8/5.9	6/4.9		0.06
Chronicity Index	2.7/2.4	1.4/1.7		0.06

* HBP: High blood pressure
** Positive anticardiolipin antibodies

Conclusion: A subgroup of clinical, laboratory and histologic variables were identified as predictors to double creatinine in biopsy proven lupus nephritis. However increasing anti-double-stranded DNA antibody and hypocomplementemia no showed statistical significance as in previous studies. These can be useful to increase clinical surveillance in these patients.

Mycophenolate Mofetil Is Not Associated With Reduced Cardiovascular Or Lupus Damage Accumulation In a Cross-Sectional Lupus Cohort Study. Maureen A. McMahon[1], Maria Dall'era[2], Eliza Chakravarty[3], Joseph E. Craft[4], Gary S. Gilkeson[5], Kenneth C. Kalunian[6], R. John Looney[7], Gerald McGwin Jr.[8] and Meggan Mackay[9]. [1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]University of California, San Francisco, San Francisco, CA, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]Yale University School of Medicine, Internal Medicine, Section of Rheumatology, New Haven, CT, [5]Medical University of South Carolina, Charleston, SC, [6]UCSD School of Medicine, La Jolla, CA, [7]University of Rochester, Rochester, NY, [8]University of Alabama at Birmingham, Birmingham, AL, [9]Feinstein Institute for Medical Research, Manhasset, NY.

Background/Purpose: Mycophenolate mofetil (MMF) is frequently used for the treatment of lupus. The immune-modulating effects of MMF extend beyond effects on lymphocyte proliferation, and include inhibition of adhesion molecule expression, suppression of NO production, and reduction in cardiovascular morbidity and progression of atherosclerosis in cardiac and renal transplant patients. We examined the association between cardiovascular and non-cardiovascular damage among patients taking MMF, mycophenolic acid (MPA), AZA or methotrexate (MTX) in lupus centers participating in a North American patient registry of the Lupus Clinical Trials Consortium, Inc. (LCTC). We hypothesized that the use of MMF or MPA is protective against both overall and cardiovascular damage in patients with lupus, compared to azathioprine (AZA).

Methods: The LCTC registry consists of consecutively enrolled adults with SLE from 16 North American centers, each contributing approximately 100 patients. Patients who were taking MMF or MPA, AZA, or MTX at the time of enrollment into the registry were included in the current analysis. Patients taking MMF/MPA and AZA were compared as were patients taking MTX vs. AZA with respect to: a.) the prevalence of any damage on American College of Rheumatology/SLICC Damage Index at baseline (ACR/SDI), defined as SDI ≥1, and b.) the prevalence of cardiovascular damage at baseline, defined as myocardial infarction, angina/coronary artery bypass graft, claudication, and/or stroke on ACR/SDI. Patients were excluded from the analysis if they were taking more than one DMARD.

Results: Among 1507 patients enrolled, 430 patients were taking MMF or MPA, 183 were taking AZA, and 79 were taking MTX at baseline. Among treated patients, mean age was 48.1 ±13.5 in MTX group, 38.9 ±12.4 in the MMF group, and 39.4 ± 13.2 in the AZA group. A baseline history of renal disease was present in 10.1% of MTX subjects, 66.7% of MMF/MPA subjects, and 43.7% of AZA patients.

Any cardiovascular damage on the baseline SDI was seen in 9.2% of subjects. Any baseline damage on SDI (exclusive of cardiovascular damage) was present in 54.6% of subjects. The prevalence ratio (PR) for baseline cardiovascular damage present on the ACR/SDI in the MMF vs. AZA group was 0.83 (95% confidence interval [CI] 0.45 – 1.5, p=ns), while the PR for MTX vs. AZA was 1.17 (95% CI 0.5 – 2.7, p=ns). The PR for the presence of ANY non-cardiovascular damage on ACR/SDI at baseline for MMF/MPA vs. AZA was 0.96 (95% CI 0.75 – 1.2, p=ns), while the PR for MTX vs. AZA was 0.94 (95% CI 0.65 – 1.4, p=ns).

Conclusion: In this cross-sectional analysis, there was no difference in the baseline prevalence of either cardiovascular or total damage on SDI based on the use of MMF/MPA or MTX in comparison to AZA. Limitations of this study include the cross-sectional nature of the data, lack of information regarding the length of time of exposure to the medications of interest prior to study entry, and confounding by medication indication (e.g., nephritis).

Childhood Lupus Nephritis: Long Term Outcome Of 91biopsy Proven Cases From India. Puja Srivastava, Bonnie Abujam, Ramnath Misra, Able Lawrence, Vikas Agarwal and Amita Aggarwal. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background/Purpose: Childhood SLE has a higher prevalence of lupus nephritis (LN) as well as proliferative LN than adults. There is ethnic variation in response to treatment as well as outcome of LN. There is limited data on long-term outcome of Childhood LN from Indian subcontinent.

Methods: Retrospective analysis of case records of patients of SLE over last 24 years was done. The inclusion criteria were: fulfillment of ACR 1987 criteria for diagnosis, age of onset less than 18 years, biopsy proven lupus nephritis. Data on clinical features, treatment, outcome, complications and mortality was collected.

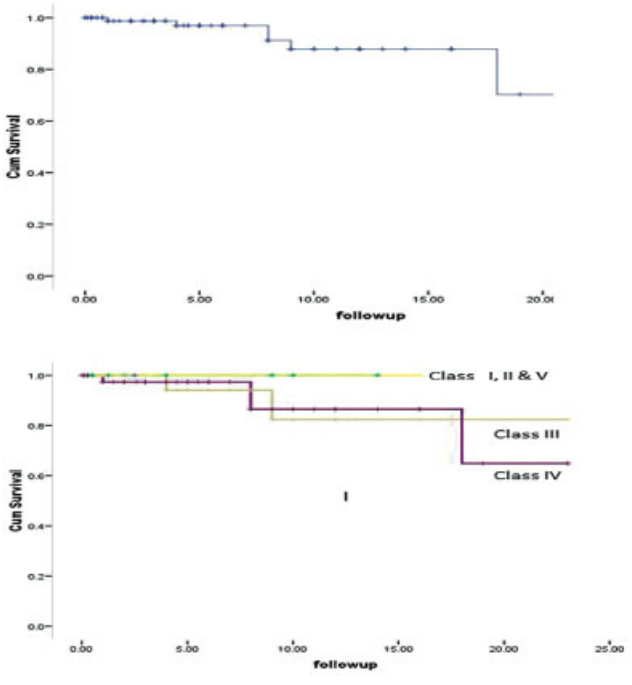
Results: Among 1015 patients with SLE there were 206 patients with childhood onset SLE. Among these 206 patients 145 had some evidence of renal disease of which 93 underwent biopsy (2 were inadequate) thus data on 91 patients was analyzed.

Among these 91 children (82 girls), the mean age at onset was 13.7± 3.5 years and the median duration of disease at presentation was 1 year. LN was present at onset in 76 patients.

Proteinuria was present in 92% (18% nephrotic range), hematuria in 75%, leucocyturia in 75% and 11% had cellular casts. 19 patients had raised serum creatinine at presentation. The distribution of histological classes was (class I: 1, class II:13, Class III: 24, Class IV: 41, Class V: 12 patients). Eight patients had associated membranous nephropathy along with proliferative GN. Out of these 63 received Cyclophosphamide and 5 received MMF as induction therapy.

The median follow up was 8 (0.1–23) years. Only 12 had less than 1 year follow up and 22 patients had more than 10 year follow up. At the last follow up 58 were in complete renal remission, 19 had partial remission, 5 had active renal disease, 3 had ESRD and 6 had died (one each due to staph sepsis, pancreatitis, disseminated TB, stroke, ESRD, unknown). 31 patients had infection of which 14 required hospitalization. 44 patients had major disease flare and 15 had minor flare.

The 5 year actuarial survival was 95% and the 10 year survival was 88%. Histological class had no effect on survival even though all deaths occurred in patients with proliferative LN. There was no effect of gender or age of onset.



Conclusion: Proliferative GN is the most common renal pathology. Almost two third patients are in complete remission at a median follow up of 7 years. 10% of children either died or had ESRD. The outcome is comparable to the Western data however the infection rate is higher.

606

Characteristics Of Lupus Nephritis: Data From a Large Multicenter Registry Of Patients With Systemic Lupus Erythematosus. Diane L. Kamen[1], Graciela S. Alarcon[2], Jill P. Buyon[3], Mary Anne Dooley[4], Richard A. Furie[5], David S. Pisetsky[6] and Tammy O. Utset[7]. [1]Medical University of South Carolina, Charleston, SC, [2]University of Alabama at Birmingham, Birmingham, AL, [3]NYU School of Medicine, New York, NY, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, [5]The Feinstein Institute for Medical Research and North Shore-Long Island Jewish Health System, Lake Success, NY, [6]Duke University Medical Center, Durham, NC, [7]University of Chicago Department of Medicine, Chicago, IL.

Background/Purpose: Renal disease is strongly associated with morbidity and mortality among SLE patients. We utilized the Lupus Clinical Trials Consortium, Inc. longitudinal registry of SLE patients from 16 academic lupus centers to estimate prevalence and incidence of renal disease and associated differences in demographics, comorbidities, biopsy rates, and therapeutic exposures.

Methods: Patients were consecutively enrolled and followed at outpatient visits by participating rheumatologists. Lupus nephritis (LN) was defined by ACR Classification Criteria. Damage (end-stage renal disease (ESRD), proteinuria (≥3.5 gm/d), low GFR) was determined by SLICC Damage Index (SDI). Descriptive statistics, chi square, Fisher's exact, and ANOVA was used as appropriate to compare disease characteristics. Multivariate regression modeling was used to adjust for disease duration and race. $P < 0.05$ was considered statistically significant.

Results: Of 1507 patients, 639 (42.4%) had LN at registry enrollment. Mean age was 41.3 yrs, disease duration 9.4 yrs, 5.5 ACR Criteria, 2.6 SLEDAI score, and 1.1 SLICC-DI score. LN patients were younger at SLE diagnosis (26.2 vs 32.1 yrs, $p<0.01$) and 11.9% LN vs 6.0% non-LN patients were male ($p<0.01$). LN prevalence in non-Hispanic Blacks (49%) and Asians (53%) was higher than non-Hispanic Whites (32%, $p<0.01$).

LN and non-LN patients had similar prevalence of cardiovascular disease (7.4 vs. 8.0%, $p=0.67$), though LN patients had higher prevalence of hypertension (57.0% vs. 29.5%, $p<0.01$), hyperlipidemia (23.2% vs. 11.4%, $p<0.01$), and pre-eclampsia (10.0 vs. 5.7%, $p<0.01$). Asians with LN had a lower renal biopsy rate of 66.2% compared to non-Hispanic Blacks (79.3%, $p=0.02$). LN patients with a confirmatory renal biopsy were more likely to have received cyclophosphamide (CTX, 51.4% vs 34.4%, $p=0.0002$), mycophenolate (MMF, 75.0% vs 56.9%, $p<0.0001$), or both CTX and MMF in the past (38.4 vs 21.3%, $p<0.0001$) compared to non-biopsied LN patients.

Of 868 non-LN patients at enrollment, 10 (1.2%) developed LN over an average of 1.8 yrs follow-up. Of the 1348 with no renal damage at enrollment, 28 (2.1%) developed renal damage over an average of 1.8 yrs follow-up. Patients without renal damage at enrollment taking hydroxychloroquine (72.0% overall) had subsequently lower renal damage incidence (1.3% vs 4.0%, $p=0.0023$). Patients on MMF (26.3% overall) had higher incidence of renal damage (3.7% vs 1.5%, $p=0.014$) but no difference seen with CTX or azathioprine.

At enrollment, 55 patients had ESRD with an additional 14 incident cases over 2.5 yrs follow-up. Eight patients (12%) with low GFR vs 0.04% without low GFR by SDI at enrollment progressed to ESRD over an average of 1.8 yrs follow-up. Seven patients (15%) with proteinuria vs 0.5% without proteinuria by SDI at enrollment progressed to ESRD over an average of 1.8 yrs follow-up.

Conclusion: This study describes prevalent and incident characteristics of LN and renal damage among a large cohort of patients with SLE. Consistent with other cohorts, LN rates vary by race and hydroxychloroquine use appears to help protect from renal damage. Prior renal damage associated with progression to ESRD emphasizes the importance of early identification of high-risk SLE patients.

Venous Thromboembolic Disease Is Associated With Increased Length Of Stay and In-Hospital Mortality In Hospitalized SLE Patients: A Multi-State, Population-Based Study. Matthew Cascino[1], Laura Trupin[2], Sara Murray[1], Mary Margaretten[1], Edward H. Yelin[1] and Jinoos Yazdany[1]. [1]University of California, San Francisco, San Francisco, CA, [2]UC San Francisco, San Francisco, CA.

Background/Purpose: Individuals with systemic lupus erythematosus (SLE) are at increased risk for venous thromboembolism (VTE). However, there is limited population-based data on outcomes associated with VTE in patients with SLE. The aims of our study were to determine 1) the prevalence of VTE among hospitalizations for SLE, and 2) the independent effect of VTE on hospital outcomes in SLE, including length of stay and in-hospital mortality.

Methods: Using data from the Health Care Cost and Utilization Project State Inpatient Databases, we performed a retrospective study of hospitalizations among adult patients with a diagnosis of SLE in five geographically dispersed states in 2009. Individuals with VTE were identified using validated administrative definitions of deep vein thrombosis (DVT) and pulmonary embolism (PE). We used multivariable regression analyses to examine the effect of VTE on length of stay and in-hospital mortality, the primary outcomes in our analysis. We adjusted for sociodemographic characteristics (age, sex, race/ethnicity), median household income based on zip code, modified Charlson comorbidity index, and a SLE-specific risk adjustment index for in-hospital mortality developed by Ward. In additional analyses, we examined the effect of DVT and PE separately.

Results: A total of 41,806 hospitalizations for patients with SLE were identified. 1,543 of these hospitalizations (3.7%) were associated with VTE; 1,063 patients had DVT (2.5%), 352 patients had PE (0.84%), and 128 (0.31%) had both. VTE patients were younger (48.1 years vs. 51.0 years, $p<0.001$), more likely to be black race (31.9% vs. 24.2%, $p>0.001$), more likely to have Medicaid as the primary payer (24.0% vs. 20.1%, $p<0.001$), had higher SLE-specific risk adjustment index (2.64 vs. 2.44, $p=0.005$), and were more likely to have nephritis (25.4% vs. 19.2%, $p<0.001$), hemolytic anemia (1.75% vs. 0.78%, $p<0.001$), thrombocytopenia (5.06% vs. 3.69%, $p<0.001$), and pleuritis (5.38% vs. 3.43%, $p<0.001$). In unadjusted analysis, VTE was associated with longer length of stay (9.8 vs. 5.8 days, $p<0.001$) and increased in-hospital mortality (4.0% vs. 2.0%, $p<0.001$). Results of adjusted analyses are depicted in the Table and demonstrate that VTE, DVT, and PE are independently associated with increased length of stay and in-hospital mortality.

Table. Adjusted regression analyses of VTE, DVT, and PE with length of stay and in-hospital mortality.

		Length of stay		Mortality	
	N (%)	B coeff. (95% C.I.)	p-value	OR (95% C.I.)	p-value
VTE	1,543 (3.69%)	3.84 (3.43–4.25)	< 0.001	2.00 (1.50–2.65)	< 0.001
PE	480 (1.15%)	2.95 (2.23–3.67)	< 0.001	2.42 (1.52–3.85)	< 0.001
DVT	1,063 (2.54%)	4.24 (3.75–4.73)	< 0.001	1.81 (1.28–2.58)	0.001

Adjusted for age, gender, race/ethnicity, median household income by zip code, primary payer, Charlson comorbidity index, and a SLE-specific risk adjustment index developed by Ward.
Separate analyses were performed to identify the individual effects of PE and DVT. Patients with both PE and DVT were classified as having PE for this analysis.

Conclusion: The development of VTE was associated with a significant increase in length of stay and in-hospital mortality among a representative population of hospitalized SLE patients.

Effect Of Renal Damage On Extra-Renal Organ Damage and Mortality In Patients With Systemic Lupus Erythematosus (SLE): A Longitudinal Cohort Study Of 756 Patients. Chi Chiu Mok, Ling Yin Ho, Kar Li Chan and Chi Hung To. Tuen Mun Hospital, Hong Kong, Hong Kong.

Background/Purpose: To study the effect of renal damage on extra-renal organ damage and mortality in patients with SLE.

Methods: Patients who fulfilled >=4 ACR criteria for SLE between 1995 and 2011 were longitudinally followed. Organ damage in 12 systems was assessed by the ACR SLICC damage scores (SDI). The cumulative rate of survival was studied by Kaplan-Meier's plot. For those who died during the disease course, data were censored at the time of death. For those who were lost follow-up, data were censored at the time of last clinic visits. Comparison of extra-renal organ damage and survival rate was made between patients with and without renal damage during the course of SLE.

Results: 756 SLE patients were studied (696 women, 92%). All were ethnic Chinese. The mean age of onset of SLE was 32.7±13.6 years and the mean follow-up time of the entire cohort of patients was 9.4±7.4 years. 76 (10%) patients died during the course of illness and 34 (4.5%) patients were lost to follow-up. 26 (3.4%) patients developed end stage renal failure (ESRF). The main contributing causes of death in those 76 patients were: infection (49%), cardiovascular events (12%), cerebrovascular events (13%), cancer (11%), suicide (3%) and others (13%). Overall, renal damage occurred in 84 (11%) patients (64% with impaired glomerular filtration rate; 6% persistently heavy proteinuria; 30% ESRF). Compared with patients without renal damage (renal SDI=0), those with renal damage had significantly higher incidence of damage in the eyes, central nervous system, pulmonary system, cardiovascular system, musculoskeletal system, gonads and the endocrine system ($P<0.001$ in all). The corresponding mean SDI scores in these systems were also significantly higher in patients with renal damage than those without. The cumulative survival rates of our patients were 94% at 5 years, 90% at 10 years and 86% at 15 years. Patients with renal damage had significantly higher mortality than those without (log rank test; $p<0.001$). The age and sex adjusted hazard ratio for mortality in patients with renal damage relative to those without renal damage was 3.55 (95% CI 2.22–5.66; <0.001).

Conclusion: In patients with SLE, renal damage significantly and adversely affects survival. The presence of renal damage significantly increases the incidence of extra-renal organ damage, particularly in the cardiovascular, pulmonary, neuropsychiatric, ophthalmological, musculoskeletal, gonadal and endocrine systems.

Increased Arterial Stiffness In Systemic Lupus Erythematosus (SLE) Patients At Low Risk For Cardiovascular Disease: A Cross-Sectional Controlled Study. Karim Sacre[1], Brigitte Escoubet[2], Maria Chauchard[3], Antoine Dossier[3], Marie-Paule Chauveheid[3] and Thomas Papo[1]. [1]University Paris-7, INSERM U699, APHP, Bichat Hospital, Paris, France, [2]University Paris-7, INSERM U872, APHP, Bichat Hospital, Paris, France, [3]University Paris-7, APHP, Bichat Hospital, Paris, France.

Background/Purpose: Accelerated atherosclerosis accounts for significant premature mortality rates among systemic lupus erythematosus (SLE) patients. Arterial stiffness reflects changes in mechanical properties of vascular wall that occurs early with onset of vascular disease. We aimed to characterize 1- the role for traditional and non-traditional CVD risk factors on carotid-femoral pulse wave velocity (PWV) as a measure of arterial stiffness, in this population and conversely, 2- if and how arterial stiffness impact on SLE-associated feature such as renal function.

Methods: Carotid-femoral pulse wave velocity (PWV) was prospectively in 42 SLE patients and 36 age- and sex-matched controls. Association between PWV and traditional and non-traditional risk factors for CVD, SLE disease history, steroid treatment, and renal function were analyzed.

Results: The mean age of SLE subjects was 40 ± 10 years and 34 (81%) were female. Five patients (11.9%) had antiphospholipid syndrome. All SLE patients were receiving hydroxychloroquine. All received long-term glucocorticoids and 28 (66.7%) were still under prednisone at a mean daily dose of 9 ± 3.2 mg (range: 5–17) at study time.

SLE patients were asymptomatic regarding cardiovascular diseases. Classical cardiovascular risks distribution did not differ between controls and SLE patients (Table 1).

PWV was higher in SLE patients than controls (7.1 ±1.6 m/s vs 6.4 ± 1 m/s; $p=0.03$). Among traditional and non-traditional CVD risk factors, PWV was associated with older age ($r^2=0.21$, $p=0.002$), higher systolic blood pressure (SBP) ($r^2=0.44$, $p<0.0001$) and higher cumulative glucocorticoid therapy ($r^2=0.14$, $p=0.01$). The impact of SBP on PWV was higher in SLE patients than controls ($p=0.0004$). Eventually, impaired renal function assessed by the reduction of glomerular rate filtration correlated with PWV in SLE ($r=-0.52$, $p=0.0004$). No statistical relationship was found between PWV and Framingham score, BMI, SELENA SLEDAI score, duration of SLE disease, and blood levels of LDL-cholesterol, glycated hemoglobin, homocystein and, 25(OH)-D3 vitamin.

Table 1. Characteristics of Subjects

	SLE patients (n=41)	Controls (n=35)	p
Female Sex, n (%)	34 (82.9)	28 (80)	0.77
Age, years	39.1 (± 10)	37 (±8)	0.21
Familial History of CAD, n (%)	1 (2.4)		
Smoking, n (%)	14 (34.1)	12 (34.3)	1
Hypertension, n (%)	12 (29.2)	8 (22.9)	0.61
Diabetes, n (%)	1 (2.4)	1 (2.8)	1
BMI, kg/m^2	25.5 (±5.4)	26.7 (±6.6)	0.69
Waist circumference, cm	93.4 (±15)	94.9 (±15.5)	0.63
LDL-Cholesterol, g/l	0.92 (±0.3)	1.2 (±0.3)	0.001
HbA1c, %	5.4 (±0.5)	5.4 (±0.4)	0.39
10-year risk of heart attack, %	1.8 (±3.6)	1.6 (±2.8)	0.53
Homocysteine/creatinine ratio	0.18 (±0.07)		
25 (OH)-D3 vitamin, ng/ml	23.4 (±11.5)		
GFR, ml/mn/1.73 m^2	84.9 (±34.6)	102 (±21)	0.002
Proteinuria/Creatininuria, mg/mmol	85.4 (±215)		
Duration of SLE disease, y	13 (±7.3)		
SELENA SLEDAI score	2.1 (±2.8)		
Lupus nephritis, n (%)	27 (65.8)		
APS, n (%)	5 (12.2)		
Cumulative years of steroid	10.5 (±7)		
Cumulative dose of steroid, g	42.3 (±29.2)		
Antiplatelet treatment, n (%)	7 (17.1)		
Anticoagulant treatment, n (%)	6 (14.6)		
Hormonal contraception, n (%)	12/34 (35.3)		
Statin, n (%)	10 (24.4)		
Hydroxychloroquine, n (%)	41 (100)		
Other therapy, n (%)	28 (68.3)		

Conclusion: Despite a low risk for CVD according to traditional factors, PWV was higher in SLE patients as compared to controls. Age, SBP and glucocorticoid therapy contribute to increased arterial stiffness. Conversely, arterial stiffness may contribute to alter renal function in SLE patients.

Disease Specific Quality Of Life Domains Are Impaired In Patients With Lupus Nephritis? Meenakshi Jolly[1], Zineb Aouhab[2], Sergio Toloza[3], Ana M. Bertoli[4], Ivana Blazevik[5], Luis M. Vila[6], Ioana Moldovan[7], Karina Marianne D. Torralba[8], Arif Kaya[9], Berna Goker[10], Mehmet E. Tezcan[11], Seminur Haznedaroglu[9], Josiane Bourré-Tessier[12], Ann E. Clarke[13], D.J. Wallace[14], Michael H. Weisman[14] and Graciela S. Alarcon[15]. [1]Rush University Medical Center, Chicago, IL, [2]John H Stroger Hospital, Chicago, IL, [3]Hospital San Juan Bautista, Catamarca, Argentina, [4]Instituto Reumatológico Strusberg, Cordoba, Cordoba, Argentina, [5]University of Buenos Aires, Buenos Aries, Argentina, [6]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [7]Loma Linda Univ Medical Center, Loma Linda, CA, [8]USC Keck Schl of Medicine, Los Angeles, CA, [9]Gazi University Medical School, Ankara, Turkey, [10]Gazi University, Ankara, Turkey, [11]Dr. Lutfi Kirdar Kartal EA Hastanesi, Istanbul, Turkey, [12]McGill University, Montréal, QC, [13]McGill University Health Center, Montreal, QC, [14]Cedars-Sinai Medical Center, Los Angeles, CA, [15]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Often systemic Lupus Erythematosus (SLE) patients with Lupus Nephritis (LN) require frequent visits with their health care providers, follow up, and exposure to immunosuppressive medications with potential for significant side effects (e.g. fertility). Thus far, studies have not examined the adverse effects of LN using a disease specific patient reported outcome tool, which can address these concerns. Herein, we compare quality of life (QOL) in patients with and without history of LN using a disease specific quality of life (QOL) questionnaire-LupusPRO.

Methods: 791 SLE patients from North and South America, the Philippines and Turkey completed LupusPRO, which has 12 domains involving health-related quality of life (HRQOL) and non-health related quality of life (N-HRQOL) construct in 33 questions (Domain scores range 0–100; Hi=Better QOL). Health outcomes including Physician Global Assessment (PGA), Systemic Lupus Erythematous Disease Activity Index (SELENA-SLEDAI) and the SLICC Damage Index were physician-assessed cross-sectionally. Rheumatologists indicated on the ACR criteria if patients had a history of LN (irrespective of current activity). These patient and physician outcomes were compared using Chi square and non parametric statistical tests; p value of ≤ 0.05 was considered significant.

Results: 304/791 SLE patients had LN. Renal biopsy results were available on 184/304 LN patients: 7 LN-WHO Class I; 25-LN Class II; 120 LN Class III or IV or combinations; 29 LN-Class V; 3 LN-Class VI. Demographic, physician assessed and patient reported outcomes are shown in Table 1.

Table 1: Comparison of health outcomes by Lupus Nephritis Status

	Lupus Nephritis (+) n = 304	Lupus Nephritis (−) n = 487	P value
Age (Mean ± SD) years	39 ± 12.7	42.81 ± 13.7	≤0.001

Emotional Health	61.3 ± 27.3	65.3 ± 27.7	0.03
Body Image	772. ± 25.3	78.1 ± 26.4	0.29
Lupus PRO Non-HRQOL (Mean ± SD)			
Desires and Goals	69.1 ± 27.64	73.1 ± 26.2	0.04
Cope	72.5 ± 25.6	69.7 ± 27.0	0.09
Social Support	70.5 ± 34.0	67.3 ± 34.0	0.18
Satisfaction with Care	76.7 ± 29.8	73.1 ± 33.7	0.47

PGA: Physician Global Assessment. SLEDAI: Systgemic Lupus Erythematous Disease Activity Index Score. SLICC/SDI Score: Systemic Lupus International Collaborating.

LN patients were younger, had greater disease activity and damage, were more often and on greater dose of prednisone, more often on mycophenolate-mofetil, and reported poorer health outcomes than SLE patients without LN, in both the HRQOL (Lupus medications, procreation, and emotional health) and the NHRQOL (Desires-Goals) constructs.

Conclusion: LN patients have worse physician and patient reported health outcomes than those without LN. They voiced concerns on several areas (concerns about lupus medications side effects, procreation, emotional health and effects on their personal goals and aspirations), which can be easily assessed with LupusPro.

Efficacy and Safety Of Transjugular Renal Biopsy In Systemic Lupus Erythematosus and Antiphospholipid Syndrome: A Retrospective Monocentric Study Of 91 Procedures. Alexis Mathian[1], Maud Cazenave[2], Laurent Arnaud[3], Nathalie Costedoat-Chalumeau[4], Du Boutin-LE Thi Huong[3], Ahlem Chaib[3], Fleur Cohen-Aubart[5], Julien Haroche[3], Miguel Hié[3], Makoto Miyara[3], Philippe Rouvier[6], Jean-Charles Piette[7], Philippe Cluzel[8] and Zahir Amoura[7]. [1]Hôpital Pitié-Salpêtrière, AP-HP, UPMC Univ Paris 06 & French National Reference Center For Systemic Lupus and Antiphospholipid Syndrome, Internal Medicine, Paris, France, [2]Service de médecine interne 2, Centre de référence National pour le Lupus et le Syndrome des antiphospholipides, CHU Pitié-Salpêtrière, APHP, Paris, France, Paris, France, [3]Hôpital Pitié-Salpêtrière, AP-HP, UPMC Univ Paris 06 & French National Reference Center For Systemic Lupus and Antiphospholipid Syndrome, Paris, France, [4]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France, [5]Pitié-Salpêtrière Hospital, APHP, Paris, France, [6]Service d'anatomie pathologie, CHU Pitié-Salpêtrière, APHP, Paris, France, Paris, France, [7]CHU Pitié-Salpêtrière, Paris, France, [8]Pitié-Salpétrière, Paris, France.

Background/Purpose: Percutaneous renal biopsy requires a long duration discontinuation of antithrombotic treatment which can increase the risk of thrombosis in patient with Systemic Lupus Erythematosus (SLE) or antiphospholipid syndrome (APS). *Transjugular kidney biopsy* has been used successfully to obtain renal tissue in patients with high risk of bleeding. The aim of this study was to describe the efficacy and safety of transjugular renal biopsy in SLE and APS.

Methods: We conducted a monocentric single-center and retrospective study of transjugular renal biopsies performed between January 2004 and September 2013 for patients with SLE or APS. Number of glomeruli per tissue core, histopathologic diagnosis, and rate and severity of complications were analyzed.

Results: Ninety-one consecutive procedures were analyzed: 56 patients with SLE without APS, 30 patients with SLE and APLS and 5 patients with APLS without SLE. The main indication to perform the kidney biopsy using the transjugular instead of the percutaneous way was a risk of excessive bleeding (antithrombotic treatment in 65 patients and thrombopenia in 3 patients). Renal tissue was obtained in 89 (97.8%) of 91 procedures. The median [range] numbers of intact glomeruli per tissue core were 14 [4–61] with optical microscopy and 7 [0–28] with immunofluorescent microscopy. Twenty-three (25.3%) biopsies for optical microscopy contained less than 10 glomeruli but only 3 (3.3%) less than 5 glomeruli. Tissue cores were adequate for histopathologic diagnosis in 89 procedures (97.8%). Symptomatic perirenal hematoma occurred in 7 patients with a good outcome without treatment. One patient had a major complication.

Conclusion: Use of transjugular renal biopsy provides a good diagnostic yield and safety for the diagnosis of kidney disease in SLE or APLS. It can be recommended in patients with percutaneous renal biopsy contraindication or failure.

Increased Expression Of Membrane Endothelial Protein C Receptor Associates With Poor Response In Lupus Nephritis Independent Of Chronicity Index. Barbara Mendez[1], Ming Wu[1], Dominick Santoriello[1], Laura Barisoni[2], Peter M. Izmirly[1], Jill P. Buyon[1] and Robert M. Clancy[1]. [1]New York University School of Medicine, New York, NY, [2]University of Miami Hospital, Miami, FL.

Background/Purpose: While a consensus is that a high chronicity index (CI) is associated with a greater risk for progression to renal failure in lupus nephritis (LN), it does not explain why patients with a low index can still have a poor response to conventional therapy. The need to identify novel biomarkers of poor response has never been more pressing as new biologics enter clinical trials. A focus on the endothelium surfaced when membrane endothelial protein C receptor (mEPCR), an integral membrane protein with both anti-inflammatory and anti-thrombotic properties expressed on endothelial cells was found to predict poor outcome. In accord with this provocative finding suggesting that changes in the renal microvasculature may be important determinants of prognosis and response to therapy, mEPCR was further evaluated.

Methods: A retrospective study of 34 patients with LN was performed. Clinical data were collected at biopsy and 1 year following biopsy. Response to therapy was defined as a 50% improvement of creatinine if abnormal and/or proteinuria without worsening of either measure. Histological analyses included ISN/RPS classification, Activity Index (AI), CI and Tubulo-interstitial Damage (TID) scores. mEPCR expression was evaluated by immunohistochemistry by two pathologists independently and blinded to the clinical outcome of the patients.

Results: The average age at the time of biopsy was 37. The cohort was comprised largely of females (74%) and minorities (82.4%). Mean baseline creatinine was 1.62 mg/dl, 24% had a GFR <60 and 38% had nephrotic range proteinuria. Proliferative nephritis was diagnosed in 77% and 53% were responders to standard of care therapy at 1 year. Positive mEPCR staining of >25% of the peritubular capillaries (PTCs) was observed in 12 renal biopsies. One year after biopsy, 75% (9/12) of patients with staining for mEPCR in >25% of the PTCs did not respond to therapy (1 progressing to end-stage renal disease) compared with 7/22 (32%) with mEPCR staining in ≤25% of the PTCs $P=0.029$. There was no association between response and baseline age, gender, creatinine, abnormal GFR, nephrotic range proteinuria, microthrombi on biopsy, ISN/RPS classification, AI, CI, or treatment regimen. The only other variables measured that associated with an absence of response included minorities (P=0.019) and TID (p=.018). However, mEPCR was clearly observed in areas of non-atrophic cortex. Thus, the extent of mEPCR was not solely accounted for by TID. After excluding patients with high TID scores, mEPCR remained strongly associated with a poor response to therapy, $P=0.028$. A subset of patients with LN who presented with a normal creatinine at biopsy were analyzed separately. At 1 year, 100% (16/16) of these patients with mEPCR staining ≤25% of the PTC maintained a normal creatinine and GFR compared with 2/4 (50%) with positive staining >25% of the PTC, $P=0.03$.

Conclusion: These data suggest that mEPCR staining be added to the evaluation to aid in the overall prognosis of LN. While the biology is perplexing given the function of mEPCR as generally protective, a high stain may suggest negative feedback reflecting a state of tissue unresponsiveness to be considered in clinical trial design.

The Influence Of Cumulative Dose Of Corticosteroids On The Presence Of Carotid Atherosclerosis In Patients With Longstanding Systemic Lupus Erythematosus. Maria Rubino[1], Ellie Aghdassi[2], Sun Makosso-Kallyth[3], Stacey Morrison[4], Lihi Eder[5] and Paul R. Fortin[6]. [1]Université Laval, Quebéc, QC, [2]University Health Network Research Institute and Department of Public Health, University of Toronto, Toronto, ON, [3]Centre de Recherche CHU de Québec, Québec, QC, [4]The Toronto Western Hospital, Toronto, ON, [5]University of Toronto, Toronto Western Hospital, Toronto, ON, [6]Division of Rheumatology, Université Laval, Québec, QC.

Background/Purpose: The purpose of this study is to determine the relationship between cumulative corticosteroid dose (CCD) with presence of carotid plaques (CP), total plaque area (TPA) and carotid intima media thickness (CIMT) in a population of women with longstanding systemic lupus erythematosus (SLE).

Methods: A retrospective cohort study, in which women with SLE followed by the University of Toronto Lupus Clinic and whom had undergone a carotid Doppler were included. Outcome variables looked at were CP, TPA and CIMT. Measured variables included were disease related factors, CCD and traditional atherosclerotic risk factors. Statistical analyses were performed using the SAS software, version 9.3. Depending on the nature of the variable, the appropriate statistical models were used to perform univariate, bivariate (Student's T-test or Chi-Square or Wilcoxon) and multivariate (logistic or linear regression) analyses. The Baron and Kenny's procedure was used to assess the mediating effect of CCD and the restricted cubic spline model was used to investigate the possible U-shaped relationship of CCD.

Results: One hundred and twelve participants were included in this study. All participants were female, their disease duration was 19 (SD=12) years and their baseline characteristics are presented in Table 1. CP was found in 37 % of the participants and the mean CIMT was of 0.611 mm (± SD 0.1). In the univariate regression models CCD significantly predicted presence of CP (P = 0.0106), as well as TPA (P = 0.0062) and CIMT (P = 0.0169). In the multivariate models (Table 2) CCD was not a significant determinant of

carotid atherosclerosis. Age, was the most influential variable in all our multivariable regression models. Other predictors were hypertension in the CP model, hypertension and diabetes in the TPA model. CCD was found to mediate the relationship between diabetes and CP as well as between diabetes and TPA. Non-linear relationships were not found between CCD and each of the outcome variables.

Table 1. Baseline Characteristics

Characteristic	Total Population (N = 112) Median (IQR)	Presence of Carotid Plaque (N = 42) Median (IQR)	Absence of Carotid Plaque (N = 70) Median (IQR)

Causes Of Mortality In Lupus Patients Followed Prospectively At a Large Single-Centre Lupus Clinic. Barry J. Sheane, Dominique Ibanez, Dafna D. Gladman and Murray B. Urowitz. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Survival rates of patients with systemic lupus erythematosus (SLE) have improved significantly over the last four decades. Mortality rates remain high, however, and are almost 4 times that of the general population. A bi-modal pattern of mortality in SLE has been described whereby death within the first year after diagnosis was associated with active lupus and infection, while death in later years was associated with atherosclerosis and corticosteroid use.

The aim of this study was to re-examine the causes of mortality in lupus patients followed prospectively at a large lupus clinic between 1970 and 2013.

Methods: Causes of death were recorded and acquired from autopsy reports (n=48), discharge summaries (n=64), hospital notes (n=23), and death certificates (n=20). Causes were divided into 5 categories: active lupus, atherosclerosis-related, infection, malignancy and 'other', and designated as either a 'primary' or 'secondary' cause. Atherosclerosis-related (AS) deaths were those attributable to acute myocardial infarction, congestive cardiac failure (as a direct result of coronary artery disease), or stroke, all in the absence of active SLE. 'Other' causes referred to those that were not attributable to active SLE, atherosclerosis, infection or malignancy.

Results: Out of 264 patients known to have died, causes of death were established in 206 cases. Mean disease duration at time of death was 14.6 ± 11.8 years, with 47 (23%) dying within 5 years and 62 (30%) dying 20 or more years after diagnosis. Mean age at death was 52.6 ± 17.5 years, with 56 (27%) dying before the age of 40. Infection was responsible for the majority of deaths (n=71 (34.5%)), followed by active SLE (n=38 (18.4%)), AS (n=38 (18.4%)), malignancy (n=24 (11.7%)) and 'other' (n=60 (29.1%)). Renal failure in inactive SLE (n=6) and bowel perforation (n=5) were among 'other' causes.

There was a significant decline in the number of deaths attributable to infection and active SLE with increasing disease duration: 49% (n=23) and 34%(n=16) of deaths in those with SLE for less than 5 years were due to infection and active lupus, respectively, compared with 26% (n=16) and 15% (n=9) of deaths in those with SLE for 20 or more years (p=0.01). Atherosclerosis was increasingly responsible for death with increasing disease duration: 13% (n=5) with less than 5 years disease duration, compared with 23% (n=14) after 20 years of SLE (p=0.11). Malignancy also increased in prevalence as a cause of death with greater disease duration (p=0.13).

Conclusion: Within the first 5 years of disease onset, infection and active SLE account for over 80% of deaths in lupus. Despite a significant reduction as a cause of death over time, infection remains the single biggest killer in those with disease over 20 years. The importance of atherosclerosis as a cause of death increases over time and replaces active SLE as the next most important cause of death in lupus patients with increasing disease duration.

Relationship Between 25-Hydroxyvitamin D [25(OH)D] and Risk For Cardiovascular Events In Systemic Lupus Erythematosus Over 11 Years In An Inception Cohort. Apinya Lertratanakul[1], Peggy Wu[2], Alan Dyer[1], Dafna D. Gladman[3], Murray B. Urowitz[3], Paul R. Fortin[4], Dominique Ibanez[3], Rosalind Ramsey-Goldman[2] and for the Systemic Lupus International Collaborating Clinics (SLICC)[5]. [1]Northwestern University, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]University of Toronto, Toronto Western Hospital, Toronto, ON, [4]Centre de Recherche du Chu de Québec et Université Laval, Quebec City, QC, [5]University of Toronto, Toronto Western Hospital (Coordinating Center), Toronto, ON.

Background/Purpose: 25(OH)D deficiency has been associated with increased cardiovascular disease (CVD) in the general population. We investigated the relationship between 25(OH)D and CVD events in a large international inception cohort of women and men with Systemic Lupus Erythematosus (SLE).

Methods: Baseline data were collected from 890 patients enrolled in the Systemic Lupus International Collaborating Clinics (SLICC) inception cohort. Those with previous CVD events (N=2) or who were pregnant (N=13) were excluded. CVD events and dates were recorded between 2000–2011. The intraassay and interassay coefficients of variation for the 25(OH)D testing were 10.8% and 9.4%, respectively. Linear regression models of 25(OHD) in quartiles with risk factors were examined. These models were then adjusted for age, sex, race, season, and country, all with and without body mass index. Cox proportional hazards models were used to investigate the relationship between 25(OH)D levels and CVD events (stroke, congestive heart failure, myocardial infarction, transient ischemic attack, angina, peripheral vascular disease).

Results: Of the 875 included patients, 786 (89.2%) were female and 89 were male with a mean ± SD age of 38.9 ± 13.1 and 42.9 ± 16.4 years, respectively, and mean ± SD 25(OH)D level of 23.8 ± 13.4 ng/ml. The quartile ranges were: 1st quartile (Q1) 3.6 – <13.4 ng/ml, 2nd quartile (Q2) 13.4 – <21.6 ng/ml, 3rd quartile (Q3) 21.6 – <30.8 ng/ml, 4th quartile (Q4) 30.8 – <91.3 ng/ml. Corticosteroids were used in 67% at baseline with a mean dose of 23.3 ± 15.9 mg daily. Renal disease by ACR criteria was present in 26%, 32% were taking calcium and 25% vitamin D supplementation. Hypertension (HTN) and hyperlipidemia (HL) were present in 34% and 15.7%, respectively. Diabetes was present in 6.5%.

Compared with Q1, those in the higher quartiles of 25(OH)D were less likely to have HTN or HL (Table 1). Those in the highest quartile of 25(OH)D were more likely to have lower C-reactive protein levels when compared with Q1. Each successively higher quartile was more likely to have lower Systemic

Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) compared with Q1.

Adjusted model 1: controls for age, season, white race, gender country (Korean, UK, US, other) except for diabetes - controls for age, white race, gender, season only.
Adjusted model 2: controls for same as model 1 plusbody mass index.
Q = 25(OH)D quartile
Q1 is the referent quartile.

25(OH)D levels were not associated with occurrence of CVD events (Table 2). The hazard ratios for CV occurrence in Q3 and Q4 were lower when compared with Q1.

Table 2. 25(OH)D Quartiles and cardiovascular disease events at follow-up

Events	**N**	**HR**	**95% CI**
A	32		
Q2	13	1.15	0.46, 2.84
Q3	5	0.68	0.21, 2.13
Q4	5	0.63	0.20, 1.97

Q1 is the referent quartile.

Conclusion: While higher levels of 25(OH)D are associated with lower likelihood of HTN and HL and less disease activity at baseline as measured by the SLEDAI-2K, 25(OH)D levels are not independently associated with likelihood of CVD events in patients with SLE. There may be a trend towards a lower likelihood of CVD events in those in the highest 25(OH)D quartiles.

Trends Of Mortality Associated To Systemic Lupus Erythematosus At The Nation Level: A Multiple Cause-Of-Death Analysis In France. Laurent Chiche Sr.[1], Guillemette Thomas[2], Albetine Aouba[3], Julien Mancini[2], Gabrielle Sarlon[4], Noémie Jourde[2], Eric Jougla[3] and Jean-Robert Harle[2]. [1]Internal Medicine, CHU Marseille, Marseille, France, [2]APHM, Marseille, France, [3]inserm CépiDc, paris, France, [4]APHM, marseille, France.

Background/Purpose: The overall mortality rate of Systemic Lupus Erythematosus (SLE) has improved significantly over the past 50 years but is still high as compared with the general population. A better knowledge of the causes of death and the related comorbidities is pivotal to improve strategies to prevent death in SLE patients. The aim of the MORTALUP study was to analyze the mortality profile related to SLE in France using a multiple cause-of-death analysis.

Methods: For the 2000–2009 period, data collected in the French Epidemiological Center for the Medical Causes of Death (CepiDc, Inserm) database and corresponding to death certificates (DC) of adults on which SLE was listed as an underlying or non-underlying cause of death were analyzed. All the DC were collected in a dedicated database after declaration to the Informatics and Liberty National Commission (CNIL). Gender, age, sex-ratio, standardized mortality rates as well as the respective weight and frequency of the various causes of death were assessed. The age-and sex-adjusted observed/expected death ratio (O/E ratio) was calculated for the main causes of death based on the proportional mortality in the general population between 2000 and 2009 by the same cause provided by the French National Institute for Statistics and Economic Studies (INSEE).

Results: Overall, 1593 adult SLE patients died during the study period. Sex-ratio was 3.5 (1238 female and 355 male) and mean age at death was 63.5 ± 17.3 years without significant difference between gender. The mean standardized mortality rate was 3.2 per 10^6 people. For SLE as an underlying cause (n=637, 40%), mean age at death was 61.3 ± 19.3 years and the main non-underlying causes of death were cardiovascular diseases (79.3%), infectious diseases (32.7%) and renal failure (24.8%). Among cardiovascular diseases, heart failure (20.2%) and cerebrovascular diseases (14.7%) were the most frequent.

For SLE as a non-underlying cause of death (n=956, 60%), mean age at death was 65 ± 17.5 years and was significantly higher than in the group where SLE is the underlying cause of death (61.3 ± 19.3 years, $p<0.001$) years and the most common underlying causes of death were cardiovascular diseases (35.7%), neoplasms (13.9%) and infectious diseases (10.3%). The overall death O/E ratio was > 1 for infectious, cardiovascular diseases and renal failure in both gender, but was <1 for neoplams.

No differences between the Mediterranean area and the rest of France were observed concerning the causes of death. In overseas departments, the standardized mortality rate was higher (10.8 per 10^6 people) and the mean age of death was earlier (50 years, $p< 0.001$), but there was no difference regarding the proportion of SLE as underlying/non-underlying cause of death, sex-ratio or causes of death.

Conclusion: To our knowledge, this is the first mortality study using a multiple cause-of-death analysis in SLE in a developed country. At the nation level, cardiovascular diseases are the most important cause of death associated to SLE in France with a significant excess of mortality compared to general population. Cardiovascular interventions should be prioritized in developed country in order to improve SLE survival.

The Potentiality Of Multi-Target Therapy With Cyclophosphamide and Tacrolimus For Lupus Nephritis. Ryota Sakai, Akiko Shibata, Kentaro Chino, Tsuneo Kondo, Ayumi Okuyama, Eiko Nishi, Hirofumi Takei, Hayato Nagasawa and Koichi Amano. Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.

Background/Purpose: Multi-target therapy for lupus nephritis (LN) had first reported by Bao et al. 2008 regarding the treatment of mixed diffuse proliferative and membranous LN using a combination of corticosteroids, mycophenolate mofetil and tacrolimus (Tac). Following this, several studies had suggested the efficacy of combination therapies utilizing two or more immunosuppressive agents with different mechanisms of action. The objective of this retrospective study is to assess the effectiveness of multi-target therapy with cyclophosphamide (CY) and Tac for class III and IV LN as a remission induction therapy in our single center experience and to discuss the potentiality of this multi-target therapy with renal pathological findings.

Methods: We evaluated 43 patients with active LN who performed renal biopsies at Saitama Medical Center between January 2007 and August 2012. The complete renal remission was defined as spot urine protein: creatinine ratio <0.5g/gCr or under plus and minus values in urinalysis and normal GFR or improvement of GFR according to the EULAR/ERA-EDTA recommendation. Renal pathological findings were assessed according to the 2003 ISN/RPS classification for LN. Crescents, fibrinoid necrosis, interstitial cell infiltration and chronicity were evaluated as well.

Results: The number of patients in each class was as follows; II: 9, III: 4, IV: 28, V: 2. In 32 cases with class III/IV, crescents: 15 (46.9%), fibrinoid necrosis: 8 (25.0%), interstitial cell infiltration: 15 (46.9%) and chronicity: 18 (56.3%). Four cases (12.5%) had membranous nephropathy (Class IV + V). CY was initiated in 24 cases with class III/IV. Eleven out of 24 (45.8%) cases received multi-target therapy with Tac (CY + Tac group) as a remission induction therapy. In the other 13 (54.2%) cases various immunosuppressants (Tac, azathioprine, cyclosporine, mizoribine pulse) were prescribed as a maintenance therapy after CY (CY-IS group). The complete remission rate at 12 months was 45.5% in CY + Tac group and 69.2% in CY-IS group (p=0.41). However patients' background of each group was quite different. Although chronicity was observed more commonly in CY + Tac group (p=0.047), the remission rate in patients with chronicity was 44.4% in CY + Tac group and 20.0% in CY-IS group (p=0.58).

Conclusion: Multi-target therapy such as CY + Tac may be effective for refractory LN with chronicity in renal pathological findings.

Active Renal Disease Is Associated With The Presence Of The Metabolic Syndrome (MetS) In Peruvian Patients With Systemic Lupus Erythematosus (SLE). Manuel F. Ugarte-Gil[1], Rocio V. Gamboa-Cardenas[1], Mariela Medina-Chinchon[1], Francisco Zevallos-Miranda[1], Karim E. Diaz-Deza[1], J. Mariano Cucho-Venegas[1], Zoila Rodriguez-Bellido[2], Jose L. Alfaro-Lozano[1], Risto A. Perich-Campos[2], Erika Noriega[1], Hugo Torrealva[1] and Cesar A. Pastor-Asurza[2]. [1]Hospital Almenara, Lima, Peru, [2]Universidad Nacional Mayor de San Marcos, Lima, Peru.

Background/Purpose: The MetS prevalence is increased in SLE patients, in particular in those of Hispanic origin and it is associated with a higher risk for cardiovascular disease and early mortality. Renal lupus seems to increase the risk for MetS. The aim of the study was to determine whether active renal disease is associated with the presence of the MetS in SLE patients after considering other possible risk factors.

Methods: This cross-sectional study was conducted in consecutive SLE patients seen in our Rheumatology Department from January 2012 to June 2013. An interview, medical records review, physical examination and laboratory tests were performed. SLE was defined using the ACR criteria; MetS was defined according to the 2009 consensus statement of the International Diabetes Foundation. Disease activity was ascertained using the SLEDAI and disease damage with the SLICC/ACR damage index (SDI). Active renal disease was defined as haematuria greater than five red blood cells/high power field, excluding other causes; pyuria greater than five white blood cells/ high power field, excluding infections; cast including granular o red blood cells; and/or new/recent increase of more than 500 mg/24h protein. Use of prednisone was recorded as current dose and total time of exposure. Antimalarials use was recorded as current, past or never. Traditional cardiovascular risk factors like uric acid and C-reactive protein levels and tobacco use were evaluated. The association of MetS and active renal disease and variables from the different domains was examined by Chi-square or Students' t tests, as appropriate. This was followed by multivariable analysis with a stepwise backward selection procedure. All analyses were performed using SPSS 16.0.

Results: Two-hundred and six patients were evaluated; their average (SD) age was 42.0 (12.6) years, 192 (93.2%) were female; almost all patients were mestizo (mixed Caucasian and Amerindian ancestral backgrounds). Three (1.5%) and 38 patients (18.4%) were current or past smokers, respectively. Disease duration was 7.2 (6.3) years. The SLEDAI was 5.8 (4.8) and the SDI 0.9 (1.3). The current dose of prednisone was 8.2 (5.7) mg/d and the total time of exposure to prednisone was 7.2 (6.1) years; 159 (77.2%) and 31 (15.0%) were current and former users of antimalarials, wheareas 16 (7.8%) were never users. Active renal disease was present in 27 (13.1%) patients. C-reactive protein and uric acid levels were 5.2 (10.0) mg/l and 4.6 (1.5) mg/dl, respectively. Eighty five or 41.3% patients presented the MetS. In the univariable analysis, active renal disease but not disease activity was associated with the MetS as were older age, higher SDI and higher uric acid levels; active renal disease (OR 3.41, 95% CI 1.09 to 10.61) remained associated in the multivariable analysis and so were; older age (OR 1.05, 95% CI 1.02 to 1.08) and higher uric acid levels (OR 1.34, 95% CI 1.00 to 1.80).

Conclusion: The prevalence of the MetS was high in our population, and it was associated with active renal disease. A better control of renal disease activity is desirable to reduce the increased cardiovascular risk these SLE patients have.

Survival and Prognostic Factors In Patients With Connective Tissue Disease Associated Pulmonary Arterial Hypertension: Results From Korean Nationwide Registry. Kwi Young Kang[1], Chan Hong Jeon[2], Sung Jae Choi[3], Seung-Ki Kwok[4], Seong-Kyu Kim[5], Hyoun-Ah Kim[6], Eon Jeong Nam[7], Yong-Beom Park[8], Kichul Shin[9], Jaejoon Lee[10], Chang-Hoon Lee[11], Chan-Bum Choi[12], Shin-Seok Lee[13] and Dae-Hyun Yoo[14]. [1]Catholic University of Korea, Incheon St. Mary's Hospital, Seoul, South Korea, [2]Soonchunhyang University College of Medicine, Bucheon, South Korea, [3]Korea University Medical Center, Seoul, South Korea, [4]The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, South Korea, [5]Catholic University of Daegu School of Medicine, Daegu, South Korea, [6]Ajou University School of Medicine, Suwon, South Korea, [7]Kyungpook National University School of Medicine, Daegu, South Korea, [8]Yonsei University College of Medicine, Seoul, South Korea, [9]College of Medicine, Seoul National University, Seoul, South Korea, [10]Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, South Korea, [11]Department of Internal Medicine, School of Medicine, Wonkwang University, Iksan, Chonbuk, South Korea, [12]Hanyang University Hospital for Rheumatic Diseases, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [13]Chonnam National University Medical School, Gwangju, South Korea, [14]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea.

Background/Purpose: Pulmonary arterial hypertension (PAH) is a major cause of mortality in connective tissue disease (CTD). We sought to quantify survival and determine factors predictive of mortality in a registry of Korean patients with CTD-associated PAH (CTD-PAH), Registry of Pulmonary Hypertension Associated with Rheumatic Disease (REOPARD).

Methods: Patients with CTD-PAH were enrolled between April 2008 and December 2012. Hemodynamic parameters and clinical data such as demographics, WHO functional class, underlying disease, organ involvement, laboratory tests and current treatment were investigated. Follow-up data of enrolled patients were recorded at the 5 year. Survival rate was calculated by the Kaplan–Meier method and the log-rank test. Factors associated with survival were examined by Cox proportional hazards regression analysis.

Results: One hundred seventy four incident cases were diagnosed by a right heart catheterization or a doppler echocardiograpy. Among 174 patients (61 (35%) with SLE, 50 (29%) with systemic sclerosis, 10 (6%) with MCTD, 22 (13%) with RA), during 3.8 ± 2.7 (mean ± SD) years of follow-up from PAH diagnosis, there were 25 (14%) deaths. One- and 3-year survival rates were 90.7 and 87.3%. Survival was worse for patients with RA-PAH (3-yr survival, 56%; p=0.022). In multiple regression analysis, Low DLCO (p=0.008), pleural effusion (p=0.04), and DM (p=0.009) were poor prognostic factors and anti-UI RNP antibody was a protective factor of mortality (p=0.022). In patients with WHO-FC III/IV, the survival rates were significantly better in patients were received with vasodilators than in patients were not (p=0.038).

Conclusion: In this study among Korean CTD-PAH patients, three –year survival was 87%. Low DLCO, pleural effusion, and DM were independent poor prognostic factors. Anti-UI RNP antibody was a protective factor of mortality. The prompt PAH specific vasodilator therapy may improve survival in patients with severe CTD-PAH.

Human Papillomavirus and Precancerous Lesions In Patients With Systemic Lupus Erythematosus. Eleonora Lucero[1], Laura Juarez[1], Veronica Bellomio[1], Francisco Colombres[1], Maximiliano Machado Escobar[1], Raúl Nicolás Martínez[1], Teresita Alvarellos[2], Agustina Lacaze[2], Ariel Sanchez[2], Pablo Agustín Apas Perez de Nucci[1], Guillermo Cohen Imach[1], Sonia Marcela Ortiz Mayor[1], Iris Aybar Odstrcil[1], Ana Cerón[1], Ricardo V. Juárez[3], Mirta Santana[1] and Alberto Berman[1]. [1]Padilla Hospital, Tucumán, Argentina, [2]Córdoba Private Hospital, Córdoba, Argentina, [3]Hospital Señor del Milagro, Salta, Argentina.

Background/Purpose: To evaluate the presence of Precancerous Lesions (PL) in uterine cervix in patients with Systemic Lupus Erythematosus (SLE) and its relationship with Human Papillomavirus (HPV). To determine the association between immunosuppressive therapy and the development of PL, and to compare with patients whith Rheumatoid Artrhritis (RA).

Methods: A cross sectional study was conducted. Since May 2011 to July 2012 women sexually active with RA (ACR-EULAR 2010) and SLE (ACR 1992), over 18 years old, were included in the study. They attended consecutively the Rheumatology Unit and they were matched by age with a control group without any rheumatic disease. Gynecological examination included: Papanicolaou test (PAP), Colposcopy (CP) and Polymerase Chain Reaction for HPV (PCR) for 13 genotypes (AMPLICOR Human Papillomavirus test, ROCHE). Pathology and laboratory Units were blind to both determinations.Clinical (DAS 28, HAQ, SLEDAI, SLICC) and therapeutic variables (drug, doses, cumulative doses, period of treatment) were studied.

Results: 172 women were included: 86 patients (48 SLE and 38 RA), mean age 41.4 + 12.1 years and 86 control, mean 38.3 + 11 years. Seventy one (82.5%) patients had normal PAP, while 55 (64%) of the controls had inflammatory PAP; Atypical Squamous Cellls of Undetermined Significance (ASCUS) was found in 5 patients (2 SLE, 3 RA) vs 8 controls, Low Grade Squamous Intraepitelial Lesion (LSIL) in 6 patients (5 LES, 1 AR) vs 10 controls and 6 High Grade Squamous Intraepitelial Lesion (HSIL) only in the control subjects (<0.0001). PCR for HPV was positive in 38.4% (33) patients and in 55% (47) of the control group ($p=0.046$). Discriminating by disease, the controls persisted with increasing frequency of HPV (12 RA vs 21 SLE vs 47 controls), $p<0.0001$. Estimating the prevalence of HPV adjusted to age, we found that RA group was significantly less prevalent, were in SLE and controls was similar. The logistic regression model showed that RA younger patients, had less chance of PCR+. In patients with SLE, LSIL was significantly associated with HPV, whereas in the controls was associated with ASCUS and HSIL ($p <0.0001$). In RA patients, no association was found between PAP and PCR. The use and accumulated doses of glucocorticoids and immunosuppressive therapy were not associated with HPV ($p=NS$).

Conclusion: We found no increased frequency of HPV or PL in patients with SLE compared to the control population. Immunosuppressive therapy was not associated with the presence of HPV.

Baseline Characteristics That Predict a Short-Term Response To Immunosuppressive Treatment In Patients With Pulmonary Arterial Hypertension Associated With Connective Tissue Disease. Hidekata Yasuoka[1], Yuichiro Shirai[1], Yuichi Tamura[1], Toru Satoh[2], Tsutomu Takeuchi[1] and Masataka Kuwana[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Kyorin University School of Medicine, Tokyo, Japan.

Background/Purpose: Pulmonary arterial hypertension (PAH) is one of devastating organ involvements in patients with connective tissue diseases (CTDs). Recent introduction of molecular-targeting PAH drugs, such as prostanoids, endothelin receptor antagonists, and phosphodiesterase-5 inhibitors, has prolonged time to clinical worsening and survival in patients with PAH-CTD. On the other hand, several reports suggest potential efficacy of immunosuppressive treatment for PAH-CTD, but positioning of immunosuppressive treatment in the PAH treatment algorithm still remains uncertain. In this study, we determined baseline characteristics that predict short-term efficacy of immunosuppressive treatment in patients with PAH-CTD, using our single-center cohort, including those in the pre- and post-PAH drug era.

Methods: This is a retrospective study involving 28 consecutive patients with PAH-CTD, consisting of 13 historical cases (diagnosis made between 1970 and 1990) and 15 recent cases (diagnosis made after 2000). These patients were selected from our PAH-CTD database, based on (i) diagnosis of PAH associated with systemic lupus erythematosus (SLE), mixed connective tissue disease (MCTD), or primary Sjögren syndrome (pSS), (ii) those who received corticosteroids ($\geq$0.5 mg/kg/day prednisolone equivalent) with or without PAH drugs as an initial therapy, and (iii) observation period $>$ 3 months. The short-term treatment response was regarded as improvement of WHO functional class (FC) at 3 months. Baseline clinical characteristics, including age at diagnosis of PAH and underlying CTD, WHO-FC, hemodynamic parameters, and immunologic and autoantibody profiles, and initial treatment regimen were obtained from prospectively collected database.

Results: PAH-CTD patients treated initially with immunosuppressive treatment consisted of 11 with SLE, 14 with MCTD, and 3 with pSS. Of these, 15 (54%), including 6 historical and 9 recent cases, were short-term responders. Simultaneous diagnosis of PAH and underlying CTD was more frequent in responders than in non-responders (80% versus 15%, $P = 0.002$), but there was no difference in distribution underlying CTD, WHO-FC, hemodynamic parameters, or immunologic and autoantibody profiles between responders and non-responders. In terms of the initial treatment regimen, use of cyclophosphamide (CY) was associated with a therapeutic response, while corticosteroids without any immunosuppressant was associated with no response ($P = 0.003$ and 0.0002, respectively). Interestingly, use of any PAH drugs was not associated with the short-term response.

Conclusion: Patients with SLE, MCTD, and pSS who were diagnosed as having underlying CTD and PAH simultaneously are likely to achieve a short-term response to immunosuppressive treatment. These patients should be treated with an intensive immunosuppressive regimen containing cyclophosphamide.

Serum Anti-Apolipoprotein 1 Antibodies Are Present In a Quarter Of Patients With Systemic Lupus Erythematosus At The Time Of Diagnosis and Are Associated With Earlier Mortality. Sara Croca, Maria Davari, D.A. Isenberg and Anisur Rahman. University College London, London, United Kingdom.

Background/Purpose: A large number of different autoantibodies have been reported in patients with systemic lupus erythematosus but not all have been related to clinical outcomes. Apolipoprotein A1 (ApoA1) is the main structural component of HDL, and its atheroprotective role has been firmly established. The presence of anti-ApoA1 antibodies has been reported in SLE and other non-autoimmune conditions associated with cardiovascular disease (CVD). Anti-apoA1 antibodies are higher in patients with current or persistent SLE disease activity, but it is not known whether measuring anti-apoA1 at the time of diagnosis of SLE would have clinical utility. This abstract describes the results of a cross sectional study of anti-apoA1 levels in a cohort of samples taken at the time of SLE diagnosis and correlates them with disease course, particularly CVD-related events and mortality.

Methods: Stored frozen serum samples obtained shortly after SLE diagnosis from a cohort of 499 patients with SLE and serum from 100 healthy controls (HC) were tested. Anti-apoA1 levels were measured using a direct ELISA and recorded as absorbance units (AU). Data on the initial immunological profile, mortality and CVD-related events were obtained from clinical records. SLE-associated cumulative damage was determined using the SLICC SLE damage index score.

Results: Mean anti-apoA1 levels were significantly higher in SLE than HC samples (50.5AU vs. 10.8AU, $P<0.05$). Defining a cut-off for anti-apoA1 positivity as 55AU (mean + 3SD of HC), 23.4% of SLE samples and 2% of HC samples were positive. No associations between anti-apoA1 level and gender, ethnicity or age at diagnosis were found. Patients who were positive for anti-dsDNA had higher mean anti-apoA1 levels than those who were negative (60.6AU vs 34.1 AU, $P<0.05$). Similarly, anti-cardiolipin-positive patients had higher mean anti-apoA1 levels than anti-cardiolipin-negative ones (80.1AU vs 41.6 AU $P<0.05$).

No further associations were found with other auto-antibodies or complement levels. We found no associations between anti-apoA1 levels and either CVD-related morbidity or damage score at 1,5,10,15,20 or 25 years. Mortality was 17.1% in anti-apoA1 positive patients and 12.4% in anti-apoA1 negative patients (P=0.11). When patients were divided into quartiles of anti-apoA1 activity, the top quartile had more deaths (39 vs 27 P=0.07), and significantly more early deaths - 21 vs 11 before the age of 50 (P=0.049) and 31 vs 17 before the age of 60 (p=0.023) than the lowest.

Conclusion: Anti-apoA1 levels are higher in patients with SLE compared with HC. Although no associations were found between anti-apoA1 levels and CVD-related events or overall mortality, a statistically significant association between high anti-apoA1 levels and early mortality emerged. These results suggest that the presence of anti-apoA1 antibodies early in the course of SLE may have prognostic implications. The mechanism through which anti-apoA1 may impact the course of SLE is not yet fully understood, therefore further studies to clarify this are required.

Lupus Patients Have a High Prevalence Of Abnormalities On Resting Electrocardiogram That Are Associated With Increased Risk For Cardiovascular Events. Zahi Touma[1], Paula Harvey[2], Dafna Gladman[1], Arthy Sabapathy[1] and Murray B. Urowitz[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]Women's College Hospital, Toronto, ON.

Background/Purpose: Patients with lupus are at increased risk for cardiovascular disease (CVD). Abnormalities detected on resting electrocardiography (ECG) that may be associated with an increased risk for subsequent cardiovascular (CV) events include ST-segment abnormalities, T-wave abnormalities, left ventricular hypertrophy (LVH), left-axis deviation, and bundle branch block.

We aimed to describe all abnormalities on resting ECG in a cohort of lupus patients and determine the prevalence of specific abnormalities associated with increased risk for CV events.

Methods: Resting ECG was performed on all consecutive patients attending The Lupus Clinic between October 2012-May 2013. Participants underwent a standard digitally recorded 12-lead ECG at supine rest. Coded ECGs were reviewed and interpreted by a cardiologist using the Minnesota code classification system.

ECGs were grouped as normal and abnormal. Abnormalities included: pathological Q waves, ST-segment and/or T-wave abnormalities, LVH, left or right bundle branch block, left-axis deviation, arrhythmia and atrial enlargement.

We further determined the prevalence of at least one or more of the ECG findings that may be associated with subsequent CV events: ST-segment and/or T-wave abnormalities, LVH, left-axis deviation, or bundle branch block. We also determined the number of patients who had at least one or more of these variables.

Results: 274 patients were studied. 88.7% of the patients were female with mean age of 47.7 +/− 14.0 and lupus duration of 17.0 +/− 11.5 years.

Of 274 resting ECGs 40.5% were abnormal (Figure 1). 21 patients had axis deviation of which 13 had left, 5 had right l and 3 fulfilled criteria for left anterior fascicular block. 7 patients had atrial enlargement (3 right and 4 left). 32 patients with arrhythmia were identified (3 1st degree atrioventricular block, 10 sinus bradycardia, 4 sinus tachycardia, 3 ectopic atrial rhythm, 3 long QTc, 2 isolated premature atrial and 1 isolated premature ventricular contractions, 2 ventricular bigeminy, and 2 short PR interval).

ST-segment abnormalities and/or T-wave abnormalities in 54 (19.7%) LVH in 27 (9.9%), left-axis deviation in 16 (5.8%) and bundle branch block in 13 (4.7%). LBBB were present in 1 patient (0.4%) and in RBBB12 (4.4%). 17 (6.2%) patients had pathological Q waves (which may indicate previous infarct).

115 (41.9%) patients had at least one of the 4 ECG findings that may be associated with subsequent CV events. 23 (8.4%) patients had 2 more ECG abnormalities and 6 (2.2%) were observed to have at least 3 ECG abnormalities.

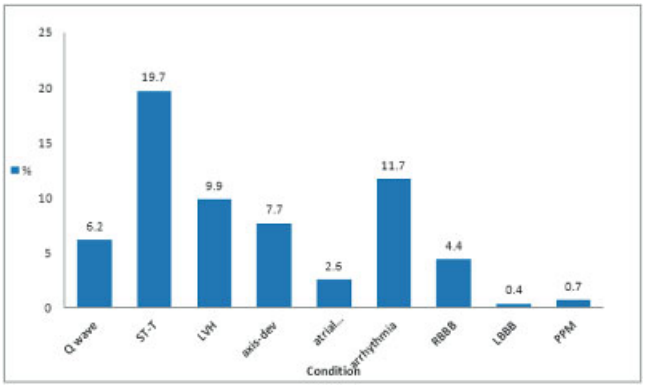

Figure 1. Percentage of abnormalities in resting ECG in lupus patients

Conclusion: 40.5% of the ECG had abnormal findings. All of the abnormal ECGs demonstrated at least one ECG finding associated with an increased risk for subsequent CV events. Further studies will determine whether ECG can serve as risk stratification factor for CVD in SLE patients.

Extremely High Coronary Artery Calcium Scores Among Patients With Systemic Lupus Erythematosus. Susan Due Kay[1], Anne Voss[2], Axel Cosmus Pyndt Diederichsen[3] and Mikael Kjær Poulsen[4]. [1]University of Southern Denmark, Odense - 5000, Denmark, [2]Odense University Hospital, Odense C, Denmark, [3]Odense University Hospital, Odens-5000, Denmark, [4]Odense University Hospital, Odense - 5000, Denmark.

Background/Purpose: Investigations of major lupus-cohorts have demonstrated cardiovascular disease to have major impact on morbidity and mortality (Am J Epidemiol 1997;145:408–15). The aim of this study was to determine the prevalence of coronary artery calcium and pattern of coronary artery calcium scores (CAC) among Danish patients with systemic lupus erythematosus (SLE).

Methods: In a population-based predominantly Caucasian cohort we recruited 84 SLE patients. To assess CAC a Toshiba 64-slice CT-scanner (Aquilion, Toshiba Medical Systems) with the following technical settings was used: gantry rotation time 450 msec, 3 mm collimation, 120 kV tube voltage and prospective gating at 75% of the R-R interval. Scan data were acquired during an inspiratory breathhold. CAC was expressed as Agatston score, that was calculated by summing-up the scores from each foci in the coronary arteries.

Results: Among the patients 91% were females, 98 % Caucasian, 2% Arabian, and mean age was 50,8 ± 14,2 yrs. In 43% coronary calcium was detected (CAC range 1 to 9725). Sixteen percent had a high CAC (>400), and 9% had an extremely high CAC (>1000). As shown in Table 1 patients with extremely high CAC had elevated BMI and were current smokers or previous smokers. Nephropathy and high SLICC scores were found in this group.

Table 1.

	Coronary calciumscore >1000	Coronary calcium score 0–1000
No.	8	76
Age, yrs, mean, SD	64,8 ± 13,3	53,25 ± 10,6
Female, no. (%)	5 (62)	73 (96)
Male, no. (%)	3 (37)	4 (5)
BMI, kg/m2, mean, SD	29,5 ± 5,3	25,44 ± 5,1
Ever smoker, no. (%)	7 (87)	47 (61)
Hypertension, no. (%)	7 (87)	41 (53)
Hypercholesterolemia	5 (62)	41 (53)
Hyperglycemia, no. (%)	2 (25)	8 (10)
Nephropathy, no. (%)	3 (37)	3 (3)
Disease duration, yrs, mean, SD	4 ± 1,4	12,8 ± 7,4
SLICC, mean, SD	5,6 ± 3,8	1,7 ± 1,6

Conclusion: In a population-based cohort 9% had extremely high CAC. Traditional as well as SLE related CVD risk factor predominated among these patients.

Disclosure: S. D. Kay, None; **A. Voss**, None; **A. C. P. Diederichsen**, None; **M. K. Poulsen**, None.

Smoking and Secondhand Smoke Exposure Among Patients With Systemic Lupus Erythematosus and Controls: Associations With Disease and Disease Damage. Samantha J. Minkin, Stephanie N. Slan, Gary S. Gilkeson and Diane L. Kamen. Medical University of South Carolina, Charleston, SC.

Background/Purpose: Previous reports suggest smoking may be a risk factor for developing systemic lupus erythematosus (SLE), however the significance of this relationship varies among studies. This study explores the impact of smoking and exposure to secondhand tobacco smoke on SLE compared to controls and on disease characteristics among patients.

Methods: Data from a longitudinal cohort of SLE patients, related controls and unrelated controls was utilized. All controls were African American (AA), therefore all comparisons between patients and controls excluded non-AA patients. Medical history, smoking and secondhand smoke exposure history, SLE Disease Activity Index (SLEDAI) and SLICC-Damage Index (SDI) scores were collected at an in-person enrollment visit and confirmed by chart review. Active disease was defined as a SLEDAI ≥ 6 and disease damage was defined as SDI >0. Statistical analysis used chi square testing for proportions and multivariate logistic regression to compare groups while adjusting for covariates.

Results: There were 545 SLE patients and 386 controls with data available for analysis (**Table**). At enrollment, the mean age was 37.6 +/− 14.7 years for patients and 42.0 +/− 15.4 years for controls. Mean disease duration at enrollment was 7.0 +/− 7.5 years for patients. Patients were 91.6% female, related controls (n=222) were 76.6% female and unrelated controls (n=164) were 86.0% female. Differences between current and never smokers (p=0.51) and ever and never smokers (p=0.70) were not significantly different between patients and controls. Compared to unrelated controls, AA patients were significantly more likely to be exposed in the home to secondhand smoke before the age of 18, adjusting for age, education level, and gender (OR 1.81, 95% CI 1.13–2.89).

	Never Smokers n (%)	Ever Smokers n (%)	Current Smokers n (%)	Secondhand Smoke < 18 yo n (%)	Secondhand Smoke Ever n (%)
All Patients N = 545	407 (74.7%)	138 (25.3%)	72 (15.1%)	132 of 372 (35.5%)	158 of 376 (42.0%)
African American Patients n=416	328 (78.9%)	88 (21.2%)	49 (11.8%)	111 of 313 (35.5%)	127 of 315 (40.3%)
Caucasian Patients n = 109	63 (57.8%)	46 (42.2%)	21 (19.3%)	19 of 47 (40.4%)	26 of 47 (55.3%)
Other Patients n = 20	16 (80%)	4 (20.0%)	2 (10%)	2 of 12 (16.7%)	5 of 14 (35.7%)
All Controls (African American) **N = 386**	284 (73.6%)	102 (26.4%)	57 (14.8%)	92 of 354 (25.6%)	120 of 357 (33.6%)
Related Controls n = 222	155 (69.8%)	67 (30.2%)	36 (16.2%)	51 of 205 (24.9%)	67 of 207 (32.4%)
Unrelated Controls n = 164	129 (78.7%)	35 (21.3%)	21 (12.8%)	41 of 149 (27.5%)	53 of 150 (35.3%)

SDI scores were available for 423 of the patients. Damage by SDI was significantly associated with ever smoking (OR 3.08, 95% CI 1.4–6.6), current smoking (OR 3.17, 95% CI 1.1–9.1), and secondhand smoke exposure in childhood (OR 1.91, 95% CI 1.0–3.6), adjusting for disease duration, ethnicity, baseline age, SLEDAI, hydroxychloroquine use, education level and gender. No significant relationship was found between smoking status and either active disease at enrollment or presence of dsDNA autoantibodies. A history of discoid rash was significantly associated with ever smoking (OR 2.74, 95% CI 1.5–5.1) and current smoking (OR 4.85, 95% CI 2.2–10.5), but not with secondhand smoke exposure, adjusting for disease duration, ethnicity, baseline age, hydroxychloroquine use, education level and gender.

Conclusion: Our study suggests that secondhand smoke during childhood may be an important risk factor for SLE. Secondhand smoke during childhood, in addition to current smoking and past smoking, contributes significantly to disease damage among patients with established SLE.

Ultrasound Assessment Of Both Carotid and Femoral Arteries In Patients With Systemic Lupus Erythematosus Increases Sensitivity For Detecting Asymptomatic Atherosclerosis. Sara Croca, D.A. Isenberg and Anisur Rahman. University College London, London, United Kingdom.

Background/Purpose: SLE is an independent risk factor for cardiovascular disease (CVD). Traditional risk assessment tools underestimate the actual CVD risk of these patients limiting the possibility of establishing primary prevention strategies. Vascular ultrasound (US) is an accurate, non-invasive, non-irradiating method to assess asymptomatic patients thus providing valuable insight into their real CVD risk. To our knowledge, to date only carotid US studies have been performed to assess atherosclerotic burden in patients with SLE. We propose that 4-point vascular assessment including both the carotid and femoral territories increases the sensitivity of the method and would be beneficial in assessing CVD risk in patients with SLE.

Methods: We performed US of carotid and femoral territories in 100 patients who fulfilled ACR classification criteria for SLE and had no prior diagnosis or symptoms of CVD. Intima-media thickness (IMT) of the common carotid artery (CCA) and carotid bulb were measured. Plaque and thickened IMT (>0.1cm) were defined according to the Mannheim Carotid IMT Consensus. Data on auto-antibody profile, lipids, treatment and smoking status were obtained through clinical records and patient interviews. The 10-year risk for myocardial infarction (MI) using the Framingham risk score was calculated

Results: Of the 100 asymptomatic patients, 95% were women and the overall mean age was 45.2 years (SD 12.4; range 20–66). 56 patients were Caucasian, 25 were of Afro-Caribbean-origin, 11 were Asian and 8 patients had other ethnic backgrounds (Chinese or mixed race).Only 2 had thickened IMT in the CCA but 37 had plaque. This included 14 with only carotid plaque, 7 with only femoral plaque and 16 with both. 15 had plaque in at least 3 sites. Patients with plaque were significantly older than patients without plaque at diagnosis (mean age 33 vs 27 yrs, P=0.006) and at time of scan (54 vs 40 yrs, P<0.0001) and had longer disease duration (21 vs 14 yrs, P=0.002). There were no differences in auto-antibody profile, lipids, smoking status and treatment between patients with or without plaque. The mean Framingham 10 year risk for MI for all 100 patients was <1% and there were no differences between patients with or without plaque. Interestingly, patients who had plaque on the femorals had significantly thicker carotid IMT compared to those who didn't even in the absence of carotid plaque (p=0.015).

Conclusion: Our results confirm a high prevalence of asymptomatic atherosclerotic plaque in patients with SLE even where Framingham risk scores are low and show that femoral as well as carotid ultrasound may well be valuable. In particular, almost a fifth of patients with plaque had femoral lesions only.

Estrogen Modulates The Expression Of Endosome-Associated Toll-Like Receptor 8 Through Estrogen Receptor-α Which May Contribute To Sex-Bias In Systemic Lupus Erythematosus. Nicholas A. Young[1], Lai-Chu Wu[1], Craig Burd[1], Alexandra Friedman[1], Benjamin Kaffenberger[1], Murugesan Rajaram[1], Larry S. Schlesinger[1], Hayley James[2], Margaret Shupnik[2] and Wael N. Jarjour[1]. [1]The Ohio State University Wexner Medical Center, Columbus, OH, [2]University of Virginia School of Medicine, Charlottesville, VA.

Background/Purpose: Epidemiological data suggests that females of child-bearing age are more resistant to infectious disease. The sex hormone estrogen (E2) is present at elevated levels in this population and has been shown to influence immune cell function by regulating the expression of multiple genes through binding of estrogen receptors (ER) α and β. Systemic lupus erythematosus (SLE) is a multi-organ auto-inflammatory disease

predominantly affecting child-bearing age females. We hypothesize that estrogenic effects could establish a heightened immune-activation state, which would have a survival advantage in the defense against infection, but may have deleterious effects when it comes to autoimmune development.

Methods: Human peripheral blood mononuclear cells (PBMCs) were stimulated with β-estradiol (E2) and/or BOOSTRIX® immunogen to measure cellular proliferation and cytokine expression. RNA was isolated from whole blood of healthy individuals and SLE patients. PBMCs, human hematopoietic cell lines, and primary monocyte derived macrophages (MDMs) were treated with a physiological dose of testosterone, E2, and/or toll-like receptor (TLR) agonists to look at gene expression by Western blotting and real time-RT-PCR. Furthermore, E2 was injected subcutaneously into wild-type mice and lymphoid tissue was collected for real time-RT-PCR analysis to measure TLR8 expression. Additionally, siRNA was used to target ERα or IFNα. EMSAs were performed with putative ERα-binding sites defined by ChIP-seq analysis and nuclear extracts or recombinant ERα protein.

Results: Cellular proliferation and cytokine production were most significantly enhanced with E2 treatment in female PBMCs challenged with immunogen. TLR8 was identified to be over-expressed in whole blood of SLE patients and its *ex vivo* expression was induced in PBMCs by estrogen, but not by testosterone. E2-induced TLR8 expression was also observed in mouse lymphoid tissue *in vivo*. Furthermore, both estrogen and TLR agonist stimulated the expression of endosomal TLRs, but not TLR4, which is cell membrane-associated. Female sex-biased expression of TLR8 was demonstrated in human PBMCs when stimulated with both agonist and estrogen simultaneously. Moreover, siRNA targeting ERα blocked E2-mediated TLR8 expression, while siRNA against IFNα had no effect. EMSA analysis suggested that E2 enhanced ERα binding to an ER response element 25 kb downstream from the 3' end of the TLR8 gene.

Conclusion: We find that the expression of TLR8 is positively regulated by estrogen and that TLR8 is over-expressed in SLE patients. We propose that estrogen-induced up-regulation of TLR8 expression is mediated directly through ERα, but not IFNα. In conjunction with the TLR8 autocrine feedback loop, estrogen lowers the inflammation threshold, which could promote an inflammatory state contributing to higher SLE incidence among women.

Altered ER Stress-Induced Autophagic Reactions Are Associated With Increased Apoptosis of T Lymphocytes in Systemic Lupus Erythematosus. Won Seok Lee[1], Myung-Soon Sung[1], Eun-Gyeong Lee[1], Chang-Hoon Lee[2], Myeung Su Lee[3], Yun-Hong Cheon[4], Sang-il Lee[4], Yun Kyoung Hong[5] and Wan-Hee Yoo[1]. [1]Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea, [2]Department of Internal Medicine, School of medicine, Wonkwang university, Iksan, Chonbuk, South Korea, [3]Department of Internal Medicine, School of Medicine, Wonkwang University, Iksan, Chonbuk, South Korea, [4]Gyeongsang National University School of Medicine, Jinju, South Korea, [5]Department of internal medicine, Presbyterian medical center, Jeonju, South Korea.

Background/Purpose: The autophagic responses to ER stress are involved in the regulation of the maintenance of lymphocyte homeostasis and has been implicated in the pathogenesis of autoimmunity. However, there were no studies about the roles of autophagic responses and its relations with apoptosis of T lymphocytes in systemic lupus erythematosus (SLE). Thus, we investigated to study about the pathogenetic roles of ER stress-mediated pathways, autophagic and apoptotic reactions in the T lymphocyte survival and death in SLE.

Methods: We investigated the spontaneous and induced autophagic and apoptotic behavior of T lymphocytes from patients with SLE compared with that of T lymphocytes from healthy donors by measuring the autophagy marker microtubule-associated protein 1 light chain 3 (LC3) II and autophagosome by scanning electron microscope. The molecular mechanism of the altered autophagic and apoptotic responses and their relations were investigated in T lymphocyte transfected with siRNA for beclin 1, CHOP and T lymphocyte with overexpression of GRP78 by transfection. The apoptosis, autophagy and ER stress signaling molecules were examined by immunoblotting.

Results: There were increased apoptosis and decreased autophagic responses to Thapsigargin (TG) in T lymphocytes from healthy controls compared with these cells from patients with SLE. The activation of ER stress signaling molecules, including PERK, p-eIF2a, IRE1 and ATF6 to TG were decreased in lupus T cells. The expression of anti-apoptotic molecules, Bcl-2, Bcl-XL were decrease and proapoptotic molecules, Bax, caspase-6 were increased in lupus T cells. Our results also revealed that CHOP expression was increased and GRP78 was decreased in lupus T cells. GRP78 overexpression and CHOP siRNA knockdown in T cells from healthy donors were associated with altered apoptotic cell death.

Conclusion: The autophagic and apoptotic responses to TG-induced, ER stress are altered and contribute to the abnormal T cell homeostasis with increased apoptotic T cell death. We hypothesize that aberrant autophagic and apoptotic reactions of T lymphocytes to ER stress are involved in the pathogenesis of SLE and might be an important target of treatment.

Galectin-3-Binding Protein Is Highly Increased On Circulating Microparticles In SLE Patients and Co-Localizes With IgG In Glomerular Deposits In Human Lupus Nephritis. Christoffer T. Nielsen[1], Ole Østergaard[2], Ole Petter Rekvig[3], Gunnar K. Sturfelt[4], Søren Jacobsen[5] and Niels H. H. Heegaard[6]. [1]University Hospital Rigshospitalet, Copenhagen, Denmark, [2]Statens Serum Institute, Copenhagen S, Denmark, [3]University Hospital, Tromsø, Norway, [4]Lund University, Lund, Sweden, [5]Department of Rheumatology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [6]Statens Serum Institut, Copenhagen, Denmark.

Background/Purpose: The origin of autoantigens in glomerular immune complex (IC) deposits in lupus nephritis patients is unknown. They may derive from the circulation (microparticle (MP)-ICs or soluble ICs) or from apoptotic glomerular cells. Galectin-3-binding protein (G3BP) may be a specific marker of SLE cell-derived MPs. Here, we characterize G3BP-positive MPs in plasma from SLE patients compared to healthy controls (HCs), explore clinical correlates, and use G3BP to identify MP-components in IC deposits in kidney biopsies from patients with lupus nephritis.

Methods: Plasma MPs were analyzed in 56 SLE patients and 36 healthy controls. MPs were enumerated by flow cytometry for G3BP exposure and annexin V (AnxV) binding. MP-quantitation of G3BP, IgG, and C1q were obtained by tandem mass spectrometry (LC-MS/MS). Co-localization of anti-G3BP antibodies with *in vivo*-bound IgG was examined in kidney biopsies from SLE patients with class IV (diffuse proliferative, n=2) and class IV (membranous, n=1) and in one control using co-localization immune electron microscopy.

Results: LC-MS/MS quantities of MP-G3BP, -IgG and -C1q were significantly increased in SLE patients ($p<0.05$ in all cases). Three different G3BP-positive MP-populations could be identified by flow cytometry. Two of these were significantly increased in SLE patients compared to HCs ($p=0.008$ and $p=0.001$, respectively). No significant clinical associations were observed. G3BP co-localized with *in vivo*-bound IgG in all three lupus nephritis biopsies while absent from control tissue. The G3BP was confined to the IC deposits and detected diffusely throughout the sections.

Conclusion: G3BP overexpression is a key feature of SLE-MPs irrespective of clinical manifestations or disease activity. The distinct overlap of glomerular G3BP and IC deposits strongly suggests MPs to be an important source of autoantigens in lupus nephritis.

Type I IFN Regulation Of IL-10 Is Detrimental To Endothelial Cell Differentiation and May Enhance Cardiovascular Risk In Systemic Lupus Erythematosus. J. Michelle Kahlenberg[1], Alyssa Cates[1], Victoria Holden[1], Carolyne K. Smith[1] and Mariana J. Kaplan[2]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Rheumatology, Ann Arbor, MI.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a heterogeneous disease resulting in organ damage and an elevated risk of cardiovascular disease (CVD). Previous reports have suggested that type-I interferon (IFN)-mediated repression of IL-1β and activation of IL-18 are important pathways leading to endothelial dysfunction and CVD in lupus patients.

While typically viewed as anti-inflammatory, Interleukin-10 (IL-10) levels are elevated in SLE patients, where they may play pathogenic roles related to immune activation of B cell responses. Furthermore, IL-10 induces transcriptional repression of IL-1β synthesis. This study explores whether IL-10 has a detrimental effect on endothelial progenitor cell (EPC) differentiation and function and whether it may play a role in type I IFN-mediated repression of IL-1β in SLE with secondary detrimental effects on neoangiogenesis.

Methods: Human and murine control and lupus EPCs were induced to differentiate into mature endothelial cells (ECs) in the presence or absence of graded concentrations of recombinant IL-10 or a neutralizing Ab to this cytokine. IL-10 deficient mice were used to assess the role of this cytokine in type I IFN-mediated inhibition of neoangiogenesis using an in vivo Matrigel plug assay.

Results: In murine EPC/CAC cultures, the inhibitory effects of IFN-α on EPC/CAC differentiation were abrogated using an anti-IL-10 neutralizing antibody or cultures from IL-10 $-/-$ mice. Further, the inhibitory effects of IFN-α on neoangiogensis in vivo were abrogated in IL-10 $-/-$ mice. In human EPC cultures, anti-IL-10 neutralizing antibodies did not significantly impact the differentiation of control cells, but improved the differentiation of SLE EPCs into mature ECs. Conversely, addition of recombinant IL-10 was detrimental to EPC growth and differentiation and this was enhanced by type I IFNs in both control and SLE cultures. Upregulation of IL-10 was detected following type I IFN treatment of early EPC cultures, while both recombinant IL-10 and IFN-α resulted in enhanced repression of IL-1β in these cells.

Conclusion: These results indicate that IL-10 is detrimental to vasculogenesis and is an important intermediary in the IFN-α-mediated repression of proangiogenic IL-1β previously observed in these cells. As type I IFNs induce IL-10 synthesis, these results indicate that elevated levels of IL-10 in SLE patients may be associated with cardiovascular risk.

Background/Purpose: Autoantibodies targeting ribosomal phosphoproteins (anti-Ribos.P) are detected in the sera of 10–45% patients with neuropsychiatric-systemice-lupus-erythemathosus-(NPSLE) and correlate with disease-activity. Intracerebroventricular administration of anti-Ribos.P induce depression like behavior in naïve mice. We assessed the capability of anti-Ribos.P to penetrate neuronal cells and affect the cellular function.

Methods: The penetration of human affinity purified anti-Ribos.P Abs into cultured neuronal cells, was shown by confocal microscopy. Endothelial Cells (HUVEC) were used as control Identification of the molecule targeted by anti-Ribos.P Abs was performed by screening a high content human cDNA-library The cross-reactivity between ribosomal-P0 and the identified neuron-growth-associated-protein-GAP43 was done by ELISA. Inhibition of neuronal cell proliferation was carried out by Bromodeoxyuridine-(BrdU).

Results: We show herein the penetration of human anti-Ribos.P Abs into human neuronal cells and rat hippocampal cells cultures, *in-vitro*. These Abs bind mouse brain sections of hippocampus, dentate and amygdala. Moreover, anti-Ribos.P Abs target neuronal cells through GAP43 binding. The anti-Ribos.P binding to mouse hippocampus, dentate and amygdala was prevented by GAP43 protein. Interestingly, GAP43 inhibited in a dose-dependent manner the anti-Ribos.P binding to ribosomal-P0 recombinant protein, indicating a cross-reactivity between the ribosomal-P0 protein and GAP43. Furthermore, anti-Ribos.P Abs reduced neuronal cells proliferation activity, *in-vitro* $p<0.001$) whereas GAP43 prevented this inhibitory activity by 7.6 times.

Conclusion: Anti-Ribos.P Abs penetrate neuronal cells *in-vitro* by targeting GAP43. Ribos.P0 cross-react with GAP43. Anti-Ribos.P Abs inhibit neuronal-cell proliferation. Our data contribute to deciphering the mechanism for anti-Ribos.P Abs pathogenic activity in NPSLE.

Reduced PD-1 Signaling Promotes Suppressive Function Of $CD4^+$ Regulatory T Cells In Patients With Systemic Lupus Erythematosus. Maida Wong, Jennifer M. Grossman, Antonio La Cava and Bevra H. Hahn. UCLA David Geffen School of Medicine, Los Angeles, CA.

Background/Purpose: Programmed death-1 (PD-1) has been regarded as a negative regulatory signal in T cells. Our laboratory has shown that PD-1 is important in T cell regulation of autoimmunity, as treatment with neutralizing anti-PD1 in the $NZB/NZWF_1$ mouse model of lupus increased regulatory T cell (T_{reg}) function and dramatically delayed SLE onset in young mice.

We hypothesized that SLE patients have increased PD-1 expression compared to healthy individuals, which may contribute to the compromised $CD4^+T_{reg}$ function in these patients.

Methods: Forty-five female SLE patients and twenty healthy female controls have been enrolled to date. Medical chart review was done to assess SLE disease activity index (Selena SLEDAI) score. PD-1 expression on $CD4^+T_{reg}$ (defined as $CD4^+CD25^{hi}Foxp3^+$) from the PBMC collected on the same day of the chart note was analyzed by flow cytometry, as were samples from healthy donors. Statistical analysis was performed to assess the relationship between PD-1 expression and SLEDAI. $CD4^+T_{reg}$ from patients were treated with neutralizing anti-PD-1 *in vitro* to test for their ability to induce B cell apoptosis, and $CD4^+CD25^-$ helper T cell (T_h) proliferation.

Results: SLE patients had fewer $CD4^+CD25^{hi}Foxp3^+$ T_{reg} in their PBMC compared to healthy controls ($p<0.03$), but these cells had significantly increased PD-1 expression ($p<0.02$). $CD4^+T_{reg}$ from patients with SLEDAI ≥ 4 tended to express more PD-1 than those from patients with SLEDAI <4 ($p<0.07$). Increased PD-1 expression was associated with vasculitis, thrombocytopenia and leukopenia ($p<0.05$). With *in vitro* PD-1 blockade, $CD4^+T_{reg}$ from the SLE patients were more resistant to apoptosis, and had increased ability to induce B cell apoptosis and to suppress T_h proliferation when compared to $CD4^+T_{reg}$ treated with IgG isotype.

Conclusion: SLE patients have aberrant, increased PD-1 expression on their circulating $CD4^+T_{reg}$ that may reduce the regulatory function of $CD4^+CD25^{hi}Foxp3^+$ T cells, which are important in the suppression of autoimmunity. One mechanism by which PD-1 sustains these T_{reg} is by reducing their susceptibility to apoptosis.

IL-21/IL-21R Interaction On Lymphocyte Subsets From Lupus Patients. Vinh Nguyen[1], Horea Rus[2], Cosmin Tegla[2] and Violeta Rus[2]. [1]University of Maryland School of Medicine, Baltimore, MD, [2]University of Maryland School of Medicine and Veteran Affairs Medical Center, Baltimore, MD.

Background/Purpose: We have previously shown that IL-21 promotes autoimmunity in a mouse model of lupus through both CD4 and B cell intrinsic mechanisms. Recent studies have shown increased expression of IL-21 in CD4 cells from lupus patients and a strong association between genetic polymorphisms in IL-21 and IL-21R and systemic lupus erythema-

tosus. While these data suggest that IL-21 blockade may be an attractive therapeutic option in SLE, factors responsible for IL-21 upregulation and the effects of IL-21/IL-21R interaction on T and B cell subsets in lupus patients have not been fully characterized. To this end we assessed the expression of IL-21 in response to cytokines, the expression of IL-21R on CD4 cells and B cells from lupus patients compared to controls and the effect of IL-21/IL-21R interaction on these cells.

Methods: IL-21, IL-17, IFNg levels and IL-21R expression were determined in CD4, CD8 T cells and B cells by immunostaining. The proliferative response of purified CD4 cells and B cells to IL-21 was determined by [^{3}H] -Thymidine incorporation. IL-21R binding ability using biotinylated IL-21, IL-21 induced STAT-3 phosphorylation, plasma cell differentiation, IgG and IL-10 production by lupus and control B cells were determined by immunostaining and ELISA, respectively.

Results: IL-21 expression was significantly increased in PMA/ionomycin stimulated CD4 and CD8 T cells from lupus patients compared to controls. Functionally, supernatants of TCR stimulated CD4 cells from lupus patients induced higher levels of STAT-3 phosphorylation (which was inhibited by IL-21R:Fc) in normal B cells compared to supernatants from controls. The expression of IL-21 in TCR stimulated lupus CD4 T cells was upregulated by agonistic ICOS ligation and IL-12 but not by IFNa, IL-6, IL-10, IL-27 or TNFa. Consistent with IL-12 mediated upregulation, a higher proportion of IL-21 positive CD4 cells coexpressed IFNg (20±4%) compared to IL-17 (7±3%). IL-21 expression correlated with IL-17 expression in unstimulated and TCR stimulated CD4 T cells from lupus patients and IL-21 increased the proportion of IL-17+ CD4 T cells. IL-21R was detected at low levels on unstimulated naïve and memory CD4 T cells from both lupus patients and controls and was upregulated to a similar degree by T cell stimulation. However, CD4 T cells from patients and controls displayed decreased susceptibility to IL-21 proliferative effects. B cells from lupus patients expressed significantly higher IL-21R expression at baseline compared to controls. Among B cells CD27+CD38+plasmablasts and CD27+CD38- memory B cells from lupus patients but not CD27-CD38- naïve cells had higher binding ability for IL-21 compared to normal controls. IL-21 induced significantly higher STAT-3 phosphorylation and proliferation but not IgG and IL-10 production in lupus B cells.

Conclusion: IL-12 and ICOS ligation upregulate the expression of IL-21 in CD4 T cells from lupus patients. IL-21R expression and responsiveness to IL-21 is higher in B cells than CD4 cells from lupus patients, especially in plasmablasts and memory B cells. Therefore IL-21 blockade may attenuate IL-21 dependent aspects of B cell hyperactivity to a larger extent than CD4 T cell abnormalities such as expansion of Th17 cells.

Multiple Altered Soluble Inflammatory Mediators Correlate With Disease Activity and Mark Impending Disease Flare In European-American Lupus Patients. Melissa E. Munroe[1], Jourdan R. Anderson[1], Krista M. Bean[1], Joan T. Merrill[1], Joel M. Guthridge[1], Virginia C. Roberts[1], Linda F. Thompson[2] and Judith A. James[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background/Purpose: SLE is a waxing and waning disease characterized by immune dysregulation, major organ involvement, and disease flares. Identifying mechanistic mediators of altered disease activity would help prevent damage and improve disease management. This study seeks to identify markers that correlate with disease activity and distinguish SLE patients with impending flare.

Methods: As part of the SLE Influenza Vaccination Cohort, 28 European-American SLE patients who exhibited SELENA-SLEDAI defined flare at 6 (n=13) or 12 (n=15) weeks post-vaccination had pre-vaccination (BL) and post-vaccination disease flare (FU) plasma samples assessed for 52 soluble analytes using a multiplex bead-based assay or sandwich ELISA (BLyS and APRIL). Each SLE patient was matched by race, gender, age (± 5 years), and time of sample procurement to a unique SLE patient who did not exhibit disease flare (NF). Samples from a subset of 13 SLE patients with flare were compared to samples from the same SLE patients from another year where disease flare did not occur (self nonflare, SNF). Soluble mediator concentrations were compared between flare and NF/SNF groups and correlated with SELENA-SLEDAI disease activity scores. As a gauge of impending disease flare, a soluble mediator score was adapted from the Studies of the Aetiology of Rheumatoid Arthritis (SERA) study: BL soluble mediator values from flare and NF/SNF samples were log transformed, standardized, and weighted by their respective disease activity Spearman coefficients, with the resulting values summed for a total score.

Results: Pre-vaccination concentrations of 22 out of 52 analytes significantly correlated ($p<0.04$) with post-vaccination SELENA-SLEDAI disease activity scores, including multiple innate (IL-1α, IL-β, IFNβ) and adaptive (Th1, Th2, and Th17) cytokines, chemokines (IP-10, MCP-3), adhesion molecule (ICAM-1) and TNF superfamily members (TNF-α, Fas, FasL, TNFRI, and TNFRII). Utilizing all 52 assessed analytes weighted by their correlation with disease activity, patients with impending disease flare had a median soluble mediator score of 4.14 (± 4.40) and were 13.8 times more likely to have a positive score ($p < 0.0001$, Fisher's exact test) compared to NF SLE patients (−1.70 ± 4.64). In the subset of flare vs SNF samples, SLE patients with impending flare had a median score of 4.36 (± 7.41) and were 11.1 times more likely to have a positive score ($p=0.0469$) compared to SNF samples (−3.09 ± 8.47). Additionally, significantly higher levels ($p< 0.04$) of regulatory mediators TGF-β and IL-1RA were observed in NF/SNF samples compared to periods of impending flare.

Conclusion: Multiple innate, adaptive, and shed TNF members are altered and correlate with disease activity. A soluble analyte score created to reflect overall inflammation in SLE patients is not affected by influenza vaccine responses and serves as a promising approach for future prospective studies.

Neutrophil-Mediated Interferon Activation In Systemic Lupus Erythematosus Bone Marrow. Anna Bird[1], Nida Meednu[1], Javier Rangel-Moreno[1], Srilakshmi Yalavarthi[2], Jennifer Barnard[1], Teresa Owen[1], Jason S. Knight[2], Alfred Rabinovich[1], Arumugam Palanichamy[1], Jane Liesveld[1], Jason W Bauer[3], Emily Baechler[3], Mariana J. Kaplan[2] and Jennifer H. Anolik[1]. [1]University of Rochester Medical Center, Rochester, NY, [2]University of Michigan Rheumatology, Ann Arbor, MI, [3]University of Minnesota, Minneapolis, MN.

Background/Purpose: Although SLE is known to be associated with a type I interferon signature in the peripheral blood, the precise site and mechanism of IFN pathway activation in SLE remain unclear. Given that IFN can impair B cell development in murine bone marrow (BM), we asked whether IFN activation is present in SLE BM and its potential consequences for disease pathogenesis.

Methods: The IFN signature was assessed in BM of SLE patients (n=28) and normal controls (NC, n=20) by examining the relative expression of 3 IFN inducible genes IFIT1, IRF7, and G1P2 by qPCR. Neutrophils were isolated using Percoll density gradient and phenotype confirmed by flow cytometry. Type I IFN, BAFF, and APRIL expression in total aspirates and purified neutrophils was measured by qPCR normalized to GAPDH. Neutrophil expression of BAFF and APRIL was confirmed by immunofluorescence. NZM2328 lupus prone female mice (pre-disease 12 wk) were compared to Balb/c (n=7 per group) for Type I IFN activation and production and secretion of cytokines that may alter B cell development. B cells were defined by flow cytometry using standard markers.

Results: The majority of SLE patients (57%) had an IFN signature in the BM that was more pronounced than the paired peripheral blood (PB) and associated with both higher autoantibodies and disease activity (BM vs. PB for IFN high group compared to NC: 45.7-fold vs. 18.5-fold, p=0.0009 for G1P2; 108.5-fold vs. 54-fold, p=0.005 for IFIT1). There was also a significantly higher expression of BAFF and APRIL in the IFN high SLE BM aspirates (BAFF: 2.45+/−0.66 fold compared to NC; APRIL: 6.04+/−2.5, p=0.01). BM neutrophils in SLE showed a significantly higher expression of APRIL and IFNα when compared to NC BM (p=0.04) and also a correlation between IFNα expression and APRIL (p=0.0004) and BAFF expression (p=0.0001), suggesting that IFNa may be driving APRIL and BAFF. SLE IFN high patients had profound alterations in the BM B cell compartment with significant reductions in precursor B cells (p=0.02) but increases in transitional B cells (27%, 4.6%, and 7.5% T1/T2 in IFN high SLE, IFN low SLE and NC, respectively; p=0.013). Lupus prone mice had similar alterations in B cell development. Notably, BM neutrophils from lupus mice displayed significant up-regulation of Mx-1 (10-fold, p=0.01), as well as increases in IFNα, IFNb, and BAFF (p=0.03, 0.03, 0.04). In bone sections, we also

detected numerous Gr-1+MPO+ neutrophils in NZM mice expressing APRIL and BAFF in close contact with B220+ B cells.

Conclusion: Overall, our results highlight the importance of the BM as a target organ in SLE and provide a previously unappreciated connection between IFN activation, neutrophils, and B cell selection.

Proteomic Approach and Validation Of Urinary Biomarkers In Lupus Nephritis. Joo Youn Lee[1], Sung Hae Chang[2], Hye Jin Oh[3], Yong Yook Lee[1], Min Jueng Kang[1], Eun Young Lee[4], Eun Bong Lee[4], Eugene C. Yi[1] and Young Wook Song[1]. [1]Department of Molecular Medicine and Biopharmaceutical Sciences, Seoul National University, Seoul, South Korea, [2]Seoul National University Bundang Hospital, Seongnam-si, South Korea, [3]Seoul National University, Seoul, South Korea, [4]Division of Rheumatology, Department of Internal Medicine, Seoul National University, Seoul, South Korea.

Background/Purpose: Renal involvement occurs in about half of systemic lupus erythematosus (SLE) patients. A number of biochemical markers are currently used to clinically assess lupus nephritis (LN) activity. Nevertheless, the correlation between these markers and LN is not satisfactory. We screened urinary biomarkers of LN using LTQ-Velos hybrid mass spectrometer and validated the biomarkers in a cohort of SLE patients.

Methods: Urine samples from SLE patients with nephritis (n=5) and without nephritis (n=5) were obtained from Seoul National University Hospital. We employed a nanospray interfaced LTQ-Velos hybrid mass spectrometer. Data were processed using Sorcerer™–SEQUEST. The searched data entered into Scaffold software (Proteome Software) for compilation, and the datasets were imported into the R to generate Power Law Global Error Model (PLGEM, www.bioconductor.org) values for each protein identified (FDR $< 1\%$). The spectral count was used for Gene Ontology, and pathway analysis using Ingenuity Pathway Analysis.

In 124 SLE patients (20 LN, 104 non-LN), 21 healthy controls, and 31 disease controls (IgA nephropathy and membraneous glomerulonephritis), urinary levels of retinol binding protein 4 (RBP4), vitamin D binding protein (VDBP), complement factor H (CFH), transthyretin (TTR), and prostaglandin D synthase, lipocalin type (PGDS) were measured by ELISA. Urinary levels of biomarkers were normalized against urine creatinine. Patient global assessment (PtGA), physician global assessment (PhGA) and SLE disease activity index 2K (SLEDAI 2K) were measured at the time of urine sampling.

Results: 487 unique proteins and 3550 unique peptides were identified in urine of SLE patients by MS spectroscopy. We selected five biomarker candidates with high confident level. SLE patients with LN showed significantly higher urinary levels of RBP4, VDBP, CFH, TTR, and PGDS compared with those without LN ($p = 0.0003$, $p < 0.0001$, $p = 0.0001$, $p = 0.0015$ and $p = 0.0001$, respectively) or healthy controls. Urinary level of PGDS was significantly higher in LN than disease controls (mean±SE, 7190.7 ± 2621.0 vs 1001.2 ± 126.3 ng/mgCr, $p = 0.0181$). Other biomarkers tended to be higher in LN compare to disease controls (RBP4, 22820.0 ± 17650.0 vs 2534.2 ± 983.8, $P = 0.2591$; VDBP, 413.5 ± 216.8 vs 186.6 ± 49.33, $p = 0.7589$; CFH, 100.4 ± 51.8 vs 55.5 ± 16.0, $p = 0.9923$; TTR, 267.0 ± 142.5 vs 126.3 ± 50.7, $p = 0.4813$).

Urinary levels of VDBP, CFH, TTR, and PGDS were significantly correlated with Ph GA in LN ($p = 0.0322$, $p = 0.0233$, $p = 0.0318$ and $p = 0.0009$, respectively). Urinary levels of TTR and PGDS were significantly correlated with SLEDAI 2K in LN ($p = 0.0042$ and $p = 0.0016$, respectively).

Conclusion: Urinary PGDS may serve as a biomarker for LN. It was significantly correlated with physician global assessment and SLEDAI 2K in LN.

Estrogen-Induced STAT1 and STAT4 Expression Is Estrogen Receptor α Dependent and IFNα Independent: A Novel Mechanism For Sex-Bias In Systemic Lupus Erythematosus Pathogenesis? Nicholas A. Young[1], Giancarlo R. Valiente[2], Lai-Chu Wu[1], Michael Bruss[1], Craig Burd[1] and Wael N. Jarjour[1]. [1]The Ohio State University Wexner Medical Center, Columbus, OH, [2]The Ohio State University College of Medicine, Columbus, OH.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a devastating multi-organ autoimmune disease displaying an overwhelming female predilection. Estrogen (E2) influences gene expression by binding to estrogen receptors (ERα and ERβ) and a role for E2 has been proposed in SLE pathogenesis. Further, E2 has been shown to regulate Signal Transducer and Activator of Transcription (STAT) 1 and STAT4 function. Toll-Like Receptor 8 (TLR8) has also been implicated in SLE and is a potent inflammatory mediator. The results of this study demonstrate the E2-mediated induction of STAT1 and STAT4 for the first time in primary human peripheral blood mononuclear cells (PBMCs) and mechanistically characterize the pathway that is operative in this induction.

Methods: PBMCs isolated from SLE patients and healthy controls were treated with a physiological dose of E2. Putative estrogen response elements (EREs) in the human genome were identified from ChIP-seq data of MCF-7 cells stimulated with E2 for one hour. Radio-labeled probes corresponding to STAT1 DNA binding regions were used in EMSA analysis to examine DNA-protein complex formation in a human monocytic cell line (THP-1). In the presence of E2, siRNA was used to block ERα or STAT1 expression in THP-1 cells lacking detectable IFNα expression.

Results: Expression of STAT1 and STAT4 was elevated in PBMCs of SLE patients relative to age and sex-matched healthy controls. Moreover, E2 stimulation of freshly isolated human PBMCs significantly induced STAT1 and STAT4 expression. Given that we have previously observed that TLR8 expression is higher in SLE and induced with E2 treatment, a *bona fide* STAT1 binding region located 24 kb from the 3' end of the TRL8 gene was used in EMSA analysis to show that enhanced DNA-protein complex formation was induced by E2 stimulation. Interestingly, STAT1 is located next to STAT4 and ChIP-seq data of cells stimulated with E2 revealed an intragenic ERE binding peak within the STAT1 locus, which suggests that E2 may be promoting the expression of both genes through this response element. Using siRNA to explore E2 induction of STAT1 mechanistically, we demonstrate that this response is mediated through ERα. Furthermore, siRNA blocking STAT1 significantly reduced TLR8 induction with E2 stimulation.

Conclusion: E2 can stimulate the expression of STAT1 and STAT4 in PBMCs and potentially contribute to the pathogenesis observed in SLE due to their potent signal transducing effects over the immune system. STAT1 promotes TLR8 expression after E2 stimulation and an ERE near both STAT1 and STAT4 has been identified through ChIP analysis. The identification of molecular targets to inhibit the TLR8 inflammatory pathway presents a significant therapeutic opportunity. Collectively, our results indicate that STAT1 and STAT4 may contribute to the E2-mediated sex-bias observed in autoimmunity through ERα signaling and may potentially be ideal targets in future therapy to treat SLE.

Examination Of The Cytokine Profile Of The Cerebrospinal Fluid In Neuropsychiatric Systemic Lupus Erythematosus. Kunihiro Ichinose[1], Takeshi Ushigusa[2], Yoshikazu Nakashima[1], Takahisa Suzuki[1], Yoshiro Horai[2], Shin-ya Kawashiri[2], Naoki Iwamoto[2], Mami Tamai[1], Kazuhiko Arima[2], Hideki Nakamura[2], Tomoki Origuchi[2] and Atsushi Kawakami[2]. [1]Unit of Translational Medicine, Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

Background/Purpose: Neuropsychiatric systemic lupus erythematosus (NPSLE) is a serious complication in systemic lupus erythematosus (SLE). NPSLE syndromes involve both the central and peripheral nervous systems. Despite advances in the understanding of the immunopathogenic and clinical aspects of SLE, NPSLE remains a diagnostic and therapeutic challenge.

Methods: We examined the cytokine profile in the cerebrospinal fluid (CSF) of NPSLE patients admitted to our hospital in a 7-year period from 2006 through 2012 and searched for markers that may be useful for the

diagnosis of NPSLE. We used the CSF of patients with multiple sclerosis (MS) or neuromyelitis optica (NMO) as a disease control group. We examined 27 types of cytokine, chemokines, and growth factors in the NPSLE group (n=27), MS group (n=10) and NMO group (n=10) using Bio-Plex Pro assays.

Results: All of the NPSLE patients were women. The mean ± SD disease duration of NPSLE was 10.6±9.56 years. The NPSLE patients' Safety of Estrogens in Lupus Erythematosus National Assessment–Systemic Lupus Erythematosus Disease Activity Index (SELENA-SLEDAI) score was 13.3±5.86, and their anti-ds-DNA antibody level was 23.3±58.6 U/mL. The percentages of anti-phospholipid antibody syndrome, anti-ribosomal P antibody positivity, and abnormality of brain MRI were 4/27 (14.8%), 5/27 (18.5%) and 9/27 (33.3%), respectively. Aside from the cytokines that are known to be related to NPSLE such as interleukin (IL)-6, the concentrations of basic FGF, and IL-1ra, -5, -7, -9, -15 and -17 were significantly higher in the NPSLE group compared to the other two groups. A multivariate analysis revealed that the protein levels of IL-5 ($p<0.036$), IL-9 ($p<0.0005$), IL-15 (<p0.0065) and IL-17 ($p<0.0336$) were significantly correlated with IL-6.

Conclusion: In NPSLE patients who do not show IL-6 elevation, it might be advisable to examine other cytokines. The determination of various types of CSF cytokine profiles may contribute to the diagnosis of NPSLE and may help elucidate the mechanisms underlying this disease.

Systemic Lupus Erythematosus Patients With Atherosclerosis Are Characterised By a Distinct *Invariant* Natural Killer T Cell Phenotype and Altered CD1d-Mediated Lipid Antigen Presentation. Edward Smith, Sara Croca, Andrew Pitcher, D.A. Isenberg, Anisur Rahman and Elizabeth C. Jury. University College London, London, United Kingdom.

Background/Purpose: It is widely reported that systemic lupus erythematosus (SLE) patients have an increased risk of atherosclerosis compared to the general population, irrespective of traditional risk factors. We investigated whether this was attributable to differences in the phenotype and function of *invariant* Natural Killer T cells (*i*NKT), which promote atherosclerosis by recognising and responding to lipid antigens presented by CD1d, yet have been shown to be deficient in SLE patients.

Methods: Peripheral blood was obtained from 20 healthy donors and 50 SLE patients assessed for carotid and femoral atherosclerotic plaque by ultrasound scan. Phenotyping of *i*NKT cells and $CD1d^+$antigen presenting cells was performed by flow cytomerty, confocal microscopy and ImageStream cytometry.

Results: The frequency of *i*NKT cells in SLE patients with plaque (n=20) was maintained at healthy levels compared to a significant deficiency in non-plaque SLE patients (n=30). Following adjustment for disease activity, *i*NKT cells from plaque-positive patients had a distinct phenotype compared to healthy and plaque-negative patients, characterised by an increased expression of activation markers CD25 and CD69, chemokine receptor CCR6 and elevated IL-4 and IL-10 production. Furthermore patients with more lipid rich plaque showed enhanced IL-4, IL-8 and IL-10 production compared to those with stable calcified plaque.

The distinct *i*NKT cell phenotype of plaque-positive patients could be driven by differences in their activation by $CD1d^+$ lipid-antigen presenting cells. CD1d expression was significantly reduced on B cells and pro-inflammatory $CD14^{low}$ monocytes in all SLE patients compared to healthy donors. However, a significant increased association of CD1d to membrane lipid rafts was detected only in B cells and $CD14^{low}$ monocytes from SLE patients with plaque. The defective *i*NKT cell phenotype and pattern of CD1d distribution identified in plaque-positive patients was recapitulated in cells from healthy donors by culture with serum isolated from plaque-positive SLE patients but not plaque-negative patients. Finally, we detected that altered activation of healthy *i*NKT cells could be driven *in vitro* by lipids isolated from $CD1d^+$antigen presenting cells from SLE patients but not from healthy donors.

Conclusion: These findings support a differential role for *i*NKT cells in the immunopathogenesis of SLE in patients with and without atherosclerosis that could be maintained by dylipidaemia. *i*NKT cell phenotype could represent a novel biomarker to predict atherosclerosis in SLE and could lead to improved treatment options for patients.

Vitamin D Increases The Number and Function Of Myeloid Angiogenic Cells In Systemic Lupus Erythematosus. John A. Reynolds[1], David W. Ray[2], Terence O'Neill[1], M. Yvonne Alexander[3] and Ian N. Bruce[1]. [1]Arthritis Research UK Epidemiology Unit and NIHR Manchester Musculoskeletal Biomedical Research Unit, The University of Manchester, Manchester, United Kingdom, [2]Institute of Human Development, The University of Manchester, Manchester, United Kingdom, [3]Healthcare Science Research Institute, Manchester Metropolitan University, Manchester, United Kingdom.

Background/Purpose: Patients with Systemic Lupus Erythematosus (SLE) have an increased prevalence of cardiovascular disease (CVD). Vitamin D deficiency is common in SLE and an independent risk factor for CVD in the general population. We have previously shown that low vitamin D is associated with arterial stiffness in SLE patients.

Myeloid angiogenic cells (MACs) have an important role in endothelial repair in animal models. Preliminary studies have demonstrated impaired function of these cells in lupus. Myeloid cells are able to respond to vitamin D *in vitro* and express functional vitamin D receptors. We propose that vitamin D may have beneficial effects on MAC function and thus endothelial repair.

Methods: Peripheral blood mononuclear cells (PBMCs) from vitamin D deficient (<20ng/ml) SLE patients, or vitamin D-replete (>20ng/ml) healthy controls, were cultured for 7 days on fibronectin in endothelial growth media +/− $1,25(OH)_2D_3$ (0.1–100nM). For survival studies, the number of cells able to uptake LDL was enumerated in random fields. Surface CD marker expression (CD14, CD68, CD86, CCR7, CD206) in MACs was determined using real-time quantitative PCR. Angiogenic factor secretion was measured using a Bio-Plex®Human Angiogenesis Suspension Array. Angiogenic function of MACs was determined using human aortic endothelial cells in a Matrigel model. Data were analysed using linear regression, paired t tests and one-way ANOVA where appropriate.

Results: MACs expressed high levels of CD206, and low CCR7 compared to PBMCs consistent with an M2 macrophage phenotype. Phagocytosis was demonstrated by MAC uptake of FITC-labelled beads. MAC secreted IL-8 (mean [sd] 13.9 [20.1] ug/ml), VEGF (37.2 [26.1] pg/ml), HGF (1414 [568] pg/ml), leptin (209 [144] pg/ml), and PDGF (564 [365] pg/ml) but not GCSF or angiopoetin.

Vitamin D (0.1–100nM) increased the number of lupus MAC on day 8 in those with a low number (<150/field) at baseline ($p=0.037$) in a dose-dependent manner. This effect was replicated in healthy MACs treated with 0.1ng/ml interferon-α2b ($p=<0.001$). Expression of all macrophage markers was reduced by vitamin D (10nM) but the M2 marker CD206 was preferentially reduced compared to M1 markers CCR7 ($p=0.008$) and CD86 ($p=0.043$).

Conditioned media from vitamin D (10nM) treated SLE MACs further increased endothelial tubule network density in the angiogenesis model (mean [sd] relative density 1.43 [0.12] vs 1.66 [0.15], $p=0.012$) compared to untreated SLE MACS. Vitamin D alone, however, did not increase tubule density (0.96 [0.10], $p=0.582$). In the Bio-Plex array, secretion of any of the angiogenic factors by MACs was not directly affected by vitamin D.

Conclusion: MACs are population of M2 macrophages with angiogenic capacity *in vitro*. Vitamin D increases the number of lupus MACs and changes the surface maker profile. The angiogenic capacity of MACs was increased by vitamin D *ex vivo*, but this was not due to changes in expression of common angiogenic factors. Further work will identify the mechanism by which vitamin D may augment endothelial repair in patients with SLE.

Serum Concentrations Of Type I Interferon-Regulated Chemokines Are Associated With Disease Activity In Systemic Lupus Erythematosus. Eric F. Morand, Kathryn Connelly and Alberta Y. Hoi. Monash University, Melbourne, Australia.

Background/Purpose: Expression array studies suggest the activity of Type I interferon (IFN), as reflected in IFN-induced genes, is associated

with phenotypic subsets in SLE. Three chemokines (CK) CCL2, CCL19, and CXCL10 induced by IFN are measurable in serum, and these have been correlated with IFN-induced gene expression and with SLE disease activity. Previous studies of clinical associations of IFN-induced CK were in patients with mild disease, were of short duration (<1y), and did not include Asian patients or analyse for the effects of glucocorticoids. We explored disease associations of IFN-CK in an SLE cohort followed for longer time periods and which included patients with more severe disease and Asians.

Methods: SLE patients (ACR criteria) attending a single centre between 2007–2012 had prospective recording of disease activity (SLEDAI-2k) at each visit and annual recording of organ damage (SLICC SDI). CCL2, CCL19, and CXCL10 were measured in matching serum samples by ELISA, and an integrated score (IFN-CK) (Bauer et al 2009) calculated.

Results: 1002 serum samples from 151 patients were analysed over a median (range) followup of 5 (1–27) visits over 2.75 (0–4.6) years. Patients were 84% female, 40% Asian ethnicity, median age 42y and disease duration 8.6y, median (range) SLEDAI 4 (0–22)) and time-adjusted mean SLEDAI (AMS) 4 (0–15). The individual chemokines CCL2, CCL19, and CXCL10 were highly correlated (P<0.0001). IFN-CK score exhibited a significant positive correlation with ESR and anti-dsDNA, and a significant negative correlation with C3 and C4. IFN-CK was significantly higher in active disease (SLEDAI>4) (P<0.0001), and accordingly SLEDAI was significantly higher in patients with high IFN-CK (P<0.001). Changes in IFN-CK and SLEDAI over time were also correlated (P=0.013), as were AMS and time-adjusted mean IFN-CK (P=0.008). Moreover, IFN-CK at baseline was correlated with subsequent disease activity as measured by AMS (P=0.04), and episodes of persistent active disease were 2-fold more likely during the period of observation in patients with high time-adjusted mean IFN-CK (RR = 2.05 (95% CI 1.06 – 3.99), P=0.0192). Patients who experienced an increase in SDI over the study period had significantly higher time-adjusted mean IFN-CK than those with no change in SDI. High IFN-CK was not associated with the presence of renal or CNS disease, but was associated with anti-ENA and dsDNA positivity (both P=0.02). Clinical associations of IFN-CK were more robust in the subset of patients of Asian ethnicity, but were less robust in patients on glucocorticoid therapy.

Conclusion: In a longitudinal cohort of SLE patients with severe disease, serum IFN-CK was strongly associated with indices of current and subsequent disease activity and damage. The associations between IFN-CK and disease activity were stronger in Asian SLE patients but were negatively influenced by glucocorticoids. Serum IFN-CK measurements appear to be a robust marker of disease activity in SLE.

Potential Immunopathological Roles Of The Novel Anti-Inflammatory Cytokine Interleukin-35 In Patients With Systemic Lupus Erythematous. Zhe Cai[1], Chun-Kwok Wong[2] and Lai Shan Tam[1]. [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]The Chinese University of Hong Kong, Hong Kong, China.

Background/Purpose: IL-35, a dimeric protein with two subunits, IL-12A (p35) and Epstein-Barr virus induced 3, is a novel IL-12 cytokine family regulatory T-cells (Treg)-specific immunosuppressive/anti-inflammatory cytokine. IL-35 is expressed by resting and activated regulatory T cells (Tregs/Tr35) by converting conventional T cells (Tconv) into IL-35-dependent induced Tregs (iTr35), but not effector T (Teff) cells. Similar to that of transforming growth factor-b and IL-10, IL-35 is the major component of the suppressive repertoire, but temporally different from them in the inhibition of inflammation. We hypothesize that IL-35 may play an important immunoregulatory roles in autoimmune diseases such as systemic lupus erythematous (SLE).

Methods: Plasma concentrations of IL-35 and soluble gp130 were measured using ELISA. Cell surface expression of IL-35 receptor components IL-12Rb2 and gp130 on the $CD4^+$ helper (Th) cells and $CD19^+$ B cells, and the number of $CD4^+CD25^{high}CD127^{low}$Treg cells were quantitated by flow cytometry.

Results: Plasma IL-35 levels were significantly higher in active SLE patients than healthy controls (HC). Percentages of Treg in active and inactive SLE patients were significantly higher than HC. The percentage of Treg in active SLE patient was significantly higher than in inactive SLE patients (all $p < 0.05$). Moreover, the percentage of Treg cells was positively correlated with the SLE disease activity index (SLEDAI), but it did not correlate with the expression of IL-12Rb2 and gp130 on Th and B cells. However, the expression of IL-12Rb2 on the Th cells and B cells of inactive and active SLE patients, respectively, was significantly higher than HC.

Conclusion: The above results may imply the potential immunological roles of anti-inflammatory cytokine IL-35 receptors. Since IL-35 receptor components IL-12Rb2 played the key role in the signaling transduction of the immunosuppressive mechanisms of the IL-35 in SLE immunopathogenesis, results of this cross-sectional clinical study may also furnish a biochemical basis for the development of potential therapeutic target of IL-35 for the treatment of autoimmune inflammation.

Expansion Of $CD4^+CXCR3^+$ T Cells In Patients With Systemic Lupus Erythematosus (SLE) Correlates With Subclinical Atherosclerosis. Karim Sacre[1], Brigitte Escoubet[2], Nicolas Charles[3], Antoine Dossier[4], Marie-Paule Chauveheid[4] and Thomas Papo[1]. [1]University Paris-7, INSERM U699, APHP, Bichat Hospital, Paris, France, [2]University Paris-7, INSERM U872, APHP, Bichat Hospital, Paris, France, [3]INSERM U699, Paris, France, [4]University Paris-7, APHP, Bichat Hospital, Paris, France.

Background/Purpose: The mechanisms for accelerated atherosclerosis in SLE remain unclear. As atherosclerosis is itself immune-mediated, features of SLE-associated immunity might explain accelerated cardiovascular disease beside traditional cardiovascular risk factors.We studied the relationship between T cells expressing CXCR3, a chemokine receptors involved in transendothelial migration, and subclinical vascular disease as assessed by common carotid intima-media thickness, internal carotid wall thickness, pulse wave velocity and pulse pressure measurements in SLE patients.

Methods: The expression of CXCR3 on PBMCs was measured by flow cytometry in 33 SLE subjects asymptomatic for cardiovascular diseases (CVD) and 18 controls. Patients with SLE were assessed for vascular disease with common carotid artery intima-media thickness (IMT), internal carotid artery wall thickness (ICWT), pulse wave velocity (PWV), and pulse pressure (PP) as well as for SLE disease history, corticoid exposure and classical risk factors for cardiovascular disease.

Results: All SLE subjects had received long-term glucocorticoid and 24 (73%) were still under prednisone at a mean daily dose of 8.7 ± 2.6 mg/day. All were receiving hydroxychloroquine. Twenty-four had been treated with immunosuppressive or immunomodulatory drugs during follow-up. Four patients also had APS. Classical cardiovascular risks distribution did not differ between controls and SLE patients (Table 1).

Table 1. Characteristics of Subjects

	SLE patients (n=33)	Controls (n=18)	p
Female Sex, n (%)	26 (78.8)	9 (50)	0.06
Age, years	40 (± 10)	41.3 (±11.6)	0.97
Smoking, n (%)	11 (33.3)	7 (38.9)	0.76
High blood pressure, n (%)	11 (33.3)	6 (33.3)	0.76
Diabetes, n (%)	1 (3)	0 (0)	1
BMI, kg/m2	26.1 (±5.1)	26 (±2.7)	0.77
Cholesterol level, g/l	1.77 (±0.43)	1.93 (±0.39)	0.43
10-year risk of heart attack, %	1.9 (±3.9)	3.6 (±3.9)	0.13
Duration of SLE disease, years	13.3 (±7.8)		
SELENA SLEDAI score	2.3 (±3.3)		
Lupus nephritis, n (%)	22 (66.7)		
APS, n (%)	4 (12.1)		
Cumulative years of steroid treatment	11.8 (±7)		
Cumulative dose of steroid treatment (g)	46.9 (±29.5)		
Oral contraceptive, n (%)	11/26 (42.3)		
Statin, n (%)	10 (30.3)		
Hydroxychloroquine, n (%)	33 (100)		
Other therapy, n (%)	24 (72.7)		
HbA1c, %	5.5 (±0.5)		
Homocysteinemia/ creatininemia, ratio	0.19 (±0.07)		
25(OH)D3 vitamin (ng/ml)	24.4 (±12.3)		
Creatininemia (μmol/l)	86.2 (±51)		
Proteinuria/Creatininuria (mg/mmol)	63.7 (±130)		
Lymphocytes (G/l)	1.5 (±0.7)		

SLE-subjects displayed a higher frequency of circulating $CD4^+$ T cells (35.1±17.7 vs 23.6±8.4%; $p<0.05$), $CD8^+$ T cells (72.4±19.5 vs 44.9±14.9%; $p<0.005$), NKT cells (56.9±19.1 vs 31.3±18.8%; $p<0.001$) and B cells (24.5±16.1 vs 12.4±5.9%; $p<0.05$) that expressed the chemokine receptor CXCR3, as compared to controls.

The mean IMT was 0.54 (±0.12) mm in SLE subjects. The mean internal carotid artery wall thickness (ICWT), pulse wave velocity (PWV), and pulse pressure (PP) was 1.34 (±0.74) mm, 7.1 (±1.65) m/s and 54.7 (± 13.3) mmHg, respectively.

In SLE subjects, infraclinical vascular disease -assessed with IMT ($r^2=0.15$, $p=0.02$), ICWT ($r^2=0.12$, $p=0.04$), PWV ($r^2=0.12$, $p=0.04$), and PP ($r^2=0.23$, $p=0.004$)- correlated with expression of $CD4^+CXCR3^+$ on T cells. $CD4^+CXCR3^+$ T cells were shown to be antigen-primed $CD45RA^-CD27^{+/-}$ and to produce high levels of TNF-α upon polyclonal TCR activation..

No significant association was found between peripheral expansion of $CD4^+CXCR3^+$ T cells and traditional (Framingham score, LDL-cholesterol), non-traditional (HbA1c, homocystein, 25(OH)-D3 vitamin; creatinine blood levels) cardiovascular risk factors or SLE-related risk factors (duration of disease, glucocorticoid therapy, SLEDAI score, renal function).

Conclusion: Our study suggests that $CD4^+CXCR3^+$ T cells are instrumental in SLE-associated atherosclerosis.

Transcript Profiling Of Blood and Kidney Biopsies From Chinese Patients With Lupus Nephritis Reveals Concordant Activation Of Type I IFN Signaling In The Blood and Kidney, Reduced B Cell Presence In The Blood, and Increased Macrophages In The Kidney. Zheng Liu[1], Chris, A. Morehouse[1], Xinfang Huang[2], Philip Brohawn[1], Nan Shen[2], Yihong Yao[1] and Brandon W. Higgs[1]. [1]MedImmune, LLC, Gaithersburg, MD, [2]Shanghai Ren Ji Hospital, Shanghai, China.

Background/Purpose: Up-regulated expression of type I interferon-regulated genes has consistently been observed within the peripheral blood in a large proportion of patients with active systemic lupus erythematosus (SLE). The activation of this pathway in inflamed tissues (e.g, the kidneys of patients with lupus nephritis [LN]) has been less studied. We investigated pathways most altered in the blood and kidney of LN to better understand the molecular and cellular mediators, and elucidate the concordance of type I IFN activation between the disease site and periphery.

Methods: Blood specimens were procured from 32 healthy and 94 LN Chinese subjects and kidney biopsies from 6 healthy and 80 LN Chinese subjects (75 matched). Among these patients, the distribution of the International Society of Nephrology and the Renal Pathology Services (ISN/RPS) classifications included: 1 Class-I, 2 Class-II, 16 proliferative LN (Class-III or -IV), 13 membranous LN (Class-V) and 21 mixed LN (Class-IV and -V or Class-V and -III), with SLEDAI scores ranging from 4–25. The Affymetrix U133+ array was used to transcript profile specimens. In the blood, 389 genes were significantly over-expressed in LN subjects (fold change (FC)≥2; $p< 0.01$) and 704 genes were under-expressed (FC′-2; $p< 0.01$). In the kidney, 166 genes were over-expressed in LN subjects (FC≥2; $p< 0.05$) and 66 genes were under-expressed (FC≤ -2; $p< 0.05$). Gene signatures were identified from ex vivo stimulation experiments with whole blood and pathway enrichment analysis was conducted.

Results: Within the blood specimens, type I IFN signaling was the most activated pathway, while complement system activation ranked first in kidney specimens. To further investigate the molecular landscape between blood and kidney in LN subjects, we surveyed a panel of different well characterized gene signatures. In both blood and kidney, a type I IFN signature was elevated in LN patients (73% and 43% patients with FC≥2, $p< 0.0001$ and $p=0.001$, respectively); the 75 matched specimens were well correlated ($r=0.82$; $p<0.0001$). A plasma cell gene signature showed no difference between LN patients and healthy controls in either blood or kidney tissues. However, in blood, a B cell gene signature was significantly lower in LN patients compared to healthy controls (59% patients with FC≤−2, $p< 0.0001$); the difference in kidney tissues was not observed. A macrophage gene signature was elevated in kidney tissue of LN patients compared to controls (54% patients with FC≥2, $p= 0.0005$).

Conclusion: Transcript profiling was used to better understand the molecular differences between the blood and disease site of patients with LN. The significantly decreased B cell gene signature in the blood, and not kidney of LN patients may reflect the migration of B cells from the periphery to local tissues, as well as the phenotype of lymphopenia in SLE patients. An elevated macrophage gene signature in the kidney may indicate the increased macrophage infiltration in diseased tissue from the blood. Type I IFN signaling was concordantly activated in both the blood and kidney tissue of LN subjects, suggesting a potential patient subgroup to target for anti-type I IFN therapies.

Expression Of Interferon-Inducible Gene (Lymphocyte Antigen 6 Complex Locus E) In Systemic Lupus Erythematosus Patients and Its Association With Disease Activity. Eman Omran[1], Tayseer M Khidre[2], Eman Alkady[3], Eman Mosaad[4] and Mona Hussein Abd Elsamea[3]. [1]Assiut University- Faulty of Medicne, Assiut, Egypt, [2]Assiut University, Faculty of Medicine, Assiut, Egypt, [3]Assiut University-Faculty of Medicine, Assiut, Egypt, [4]AssiutUniversity- Faculty of Medicine, Assiut, Egypt.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by immune dysregulation resulting in the production of antinuclear and other autoantibodies, generation of circulating immune complexes, and activation of the complement system. The disease course of SLE is heterogeneous, affecting different individuals with a wide range of manifestations.

Recent genetic studies identified a group of type I Interferon-inducible genes (IFIGs) that are significantly upregulated in peripheral blood cells from SLE patients. IFIGs show expression of 5 types [Myxovirus resistance 1 (Mx1), Oligoadenylate synthetase (OAS)1, and Lymphocyte antigen 6 complex, locus E (Ly6e), Oligoadenylate synthetase–like (OASL), and Interferon-inducible protein (clone IFI-15K) (ISG15)] in peripheral blood sample from SLE patients.

The aim of the study was to assess the expression of type I IFIGs (LY6E) in patients with SLE. In addition, we evaluated the association of its levels with disease activity and/or severity, and laboratory markers.

Methods: Peripheral blood sample were obtained from 40 SLE patients and 25 healthy donors and total RNA was extracted and reverse transcribed into complementary DNA. Level of expression of type I IFIGs (LY6E) was measured by real time polymerase chain reaction (PCR-RT), after which comparisons were performed between SLE patients and control individuals. Disease status was assessed according to the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) Damage Index.

Results: Type I IFIGs (LY6E) was highly expressed in SLE patients compared with normal controls ($P<0.000$).

Type I IFIGs (LY6E) was positively associated with the SLEDAI score ($p<0.02$). Elevated type I IFIGs (LY6E) was also associated with the presence of cumulative organ damage SLICC/ACR-Damage Index ($P<0.01$). Type I IFIGs (LY6E) was positively correlated with anti–double-stranded DNA (anti-dsDNA) antibodies ($P<0.01$) and negatively correlated with C3 ($P<0.03$). LY6E expression levels was positively associated with proteinuria ($P <0.009$).

Conclusion: Type I IFIGs (LY6E) was highly expressed in SLE patients, and higher expression of LY6E gene in SLE patients is closely correlated with disease activity, degree of organ damage, proteinuria, anti-dsDNA antibody and hypocomplementemia. Besides, its elevated level may predict SLE flares.

The data suggest that type I IFIGs (LY6E) may contribute to SLE pathogenesis and the finding of this study will shed new light on dysregulation of the immune system and the involvement of inflammation in the initiation and perpetuation of autoimmunity.

Enhanced Expression of CCR Receptors in Healthy AA and SSc ILD Monocytes. Rebecca Lee, Charles Reese, Beth Perry, Jonathan Heywood, Michael Bonner, Richard P. Visconti, Richard M. Silver, Stanley Hoffman and Elena Tourkina. Medical University of SC, Charleston, SC.

Background/Purpose: Scleroderma-associated Interstitial Lung Disease (SSc ILD) is more prevalent and more severe in African Americans (AA) than in Caucasian (C) patients, but little is known of the factors underlying this health disparity. We reported recently that healthy AA monocytes share abnormalities with SSc ILD monocytes including low caveolin-1 levels and hypermigration towards chemokine SDF-1 due to upregulation of its receptor CXCR4. In the current study we have investigated other chemokine receptors that are involved in SSc ILD, namely CCR1, CCR2, and CCR3. The aim of this study was to determine whether these receptors are also overexpressed in SSc ILD and healthy AA monocytes and the functional consequences of their overexpression.

Methods: The study was approved by the university's IRB for Human Subject Research. Monocytes were isolated from the blood of SSc ILD patients and healthy donors by negative selection. SSc ILD patients fulfilled the ACR criteria for the classification of systemic sclerosis. Monocyte migration was assayed in Multiwell Chemotaxis Chambers using cells treated with the caveolin-1 scaffolding domain (CSD) peptide or control peptide. CCR1, CCR2, CCR3, ERK, pERK, Src, pSrc, Lyn, pLyn, and caveolin-1 levels were determined by Western blotting and immunostaining.

Results: In the current study, we observed that the expression of CCR1, CCR2, and CCR3 is enhanced in SSc ILD monocytes and healthy AA monocytes compared to healthy C monocytes. In accord with these findings, compared to healthy C monocytes, the migration of healthy AA monocytes toward the CCR2 ligand MCP-1 was enhanced two-fold ($p < 0.05$) and toward the common CCR1,2,3 ligand MCP-3 was also enhanced two-fold ($p < 0.05$). SSc ILD monocyte migration (compared to C monocyte migration) toward MCP-1 was enhanced 10-fold ($p < 0.001$) and toward MCP-3 was enhanced 5-fold ($p < 0.001$). In all cases, treatment with CSD inhibited migration > 50 %, demonstrating that the enhanced migration of SSc ILD and healthy AA monocytes is due to their relative lack of caveolin-1. To study signaling downstream from CCR1, CCR2, and CCR3; healthy C, healthy AA, and SSc ILD patient monocytes were treated with MCP-1. Baseline activation of ERK and Src was two-fold increased in AA compared to C while Lyn activation was similar in C and AA. All three kinases were greatly enhanced in SSc ILD. MCP-1 activated ERK in both C and AA monocytes, but had no effect on Src and Lyn. MCP-1 did not increase the already high level of ERK activation in SSc ILD monocytes, but did further increase the already high levels of Src and Lyn activation. In contrast, MCP-3 appears to inhibit ERK, Src, and Lyn in all three groups; suggesting that MCP-1 and MCP-3 signaling during cell migration occur through distinct mechanism. The relevance of these observations to human disease was demonstrated in immunostaining experiments showing that CCR1, CCR2, CCR3, MCP-1, and MCP-3 are all overexpressed in SSc ILD lung tissue compared to control healthy lung tissue.

Conclusion: Low caveolin-1 levels may play a role in the predisposition of the AA population to SSc ILD via the regulation of the expression of chemokine receptors CCR1, CCR2, and CCR3 in monocytes and through the activation of ERK, Src, and Lyn.

A Possible Contribution of Inducible Costimulator to the Development of Skin Sclerosis and Interstitial Lung Disease in Systemic Sclerosis. Koichi Yanaba[1], Yoshihide Asano[2] and Shinichi Sato[2]. [1]The University of Tokyo, Tokyo, Japan, [2]University of Tokyo Graduate School of Medicine, Tokyo, Japan.

Background/Purpose: Systemic sclerosis (SSc) is a heterogeneous disorder characterized by excessive fibrosis and microvascular damage of the skin and various internal organs. Cutaneous mononuclear cell infiltrates in early SSc skin lesions are mostly activated T cells which are also increased in lung interstitium and bronchoalveolar fluid from patients with SSc and active interstitial lung disease. Furthermore, cytokines or growth factors regulate SSc induction by stimulating the synthesis of extracellular matrix components, which may injure endothelial cells and modulate leukocyte function. These infiltrating activated T cells are likely to release cytokines, chemokines, or growth factors, which play a crucial part in the initiation and development of fibrosis in SSc.

Inducible costimulator (ICOS), a member of the CD28 family of costimulatory molecules, is expressed in activated T cells, but not in naïve T cells. ICOS specifically binds to ICOS ligand (ICOSL), which is constitutively expressed on antigen-presenting cells such as B cells and macrophages. ICOS-mediated costimulation is crucial for T cell proliferation, production of various cytokines, and T cell-dependent B cell responses. ICOS–ICOSL interaction is likely to contribute to the development of autoimmune diseases such as systemic lupus erythematosus and rheumatoid arthritis. Therefore, we suggest that ICOS plays a role in the pathogenesis of SSc and, in this study, examined serum soluble ICOS (sICOS) levels in SSc patients, and evaluated the results with respect to clinical features.

Methods: Serum sICOS levels were examined by enzyme-linked immunosorbent assay in 38 patients with SSc, and 24 healthy individuals. In addition, the expression of ICOS and ICOSL in skin was examined immunohistochemically.

Results: Patients with diffuse cutaneous SSc had higher levels of sICOS than those with limited cutaneous SSc or healthy individuals. Serum sICOS levels correlated positively with the severity of skin sclerosis. Patients with SSc and elevated sICOS levels more often had interstitial lung disease and decreased vital capacity than those with normal sICOS levels. The serum sICOS levels were significantly greater in patients with early phase SSc than those with late-phase SSc. ICOS and ICOSL immunostaining was observed on infiltrating dermal mononuclear cells in lesional skin tissue.

Conclusion: The current study suggests that ICOS may contribute to the development of SSc. Given that no therapy has proven effective in suppressing or improving skin sclerosis and interstitial lung disease in SSc to date, our findings suggest that ICOS inhibition could be a potential treatment for patients with SSc who have severe skin sclerosis and interstitial lung disease. In addition, measurement of serum sICOS levels in patients with early SSc may offer an important means for further evaluation of SSc disease severity.

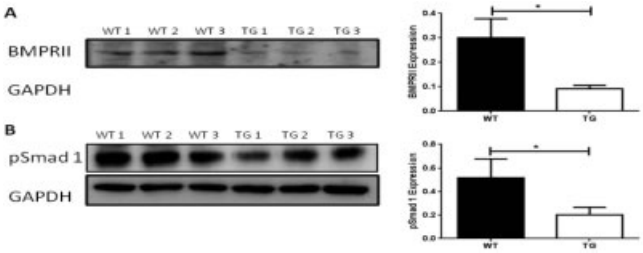
Altered BMP Signalling In a TGFβ Dependent Murine Model Of Scleroderma May Contribute To Development Of Pulmonary Arterial Hypertension. Adrian J Gilbane[1], Emma C. Derrett-Smith[1], Sarah Trinder[1], Andrew Pearce[2], Christopher P. Denton[1] and Alan M. Holmes[1]. [1]UCL Medical School, London, United Kingdom, [2]Novartis, London, United Kingdom.

Background/Purpose: Pulmonary arterial hypertension associated is an important complication of scleroderma (PAH-SSc) and has a poor prognosis compared to idiopathic (iPAH) or heritable (hPAH) forms of the disease. BMPRII mutations with concomitant effects on BMP signalling are an established cause of hPAH and some iPAH but these are not present in PAH-SSc. Furthermore, alterations in signalling through other TGFβ superfamily pathways have reciprocal effects on the BMP pathway.

Methods: We investigated BMP signalling in the lung in a mouse model of SSc in which TGFβ signalling is upregulated. Experiments were performed on whole lung isolates and explant cultured fibroblasts ($n=6$) from the TβRIIΔk-fib mouse and compared with wild type (WT) controls. Structural and biochemical analysis of components of the TGFβ superfamily and downstream signalling pathway was investigated by Western blot, immunohistochemistry and confirmed using qPCR measurement. Migration assays investigated the effects of PDGF-BB on lung fibroblasts from TβRIIΔk-fib and WT controls ($n=3$). Confirmatory biochemical and functional studies on scleroderma fibroblasts were also performed.

Results: The TβRIIΔk-fib model has increased levels of pSmad 2/3, indicative of enhanced TGFβ signalling. Consistent with an imbalance in the TGFβ/BMP axis we observed a significant reduction in BMPRII protein expression in the TβRIIΔk-fib model, both in whole lung isolates (1.43, 0.38) ($p<0.05$), and explant cultured fibroblasts (0.2985, 0.09) ($p<0.05$) (figure1). Explant cultured fibroblasts exhibited a blunted induction of phospho-Smad1 in response to BMP ligands ($p<0.05$) (figure1). TβRIIΔk-fib lung fibroblasts also exhibited enhanced migratory response compared to wild type controls ($p<0.05$). These findings were confirmed in scleroderma fibroblast studies, highlighting a reduction in BMPRII levels and an increased migratory response compared to healthy controls ($p<0.05$).



Conclusion: Association of altered BMPRII expression with PAH is well established in hPAH. Here we demonstrate the TβRIIΔk-fib model of SSc that develops a constitutive pulmonary vasculopathy, exhibits reduced expression of BMPRII as a reciprocal response to increased TGFβ signalling, with associated downstream signalling alterations independent of mutations in the BMPRII. Collectively our data suggests loss of BMPRII expression by non-genetic means may contribute to the development of PH in the TβRIIΔk-fib model of SSc.

Parental Influence On Systemic Sclerosis. Tracy M. Frech[1], Richard Pimentel[2], Allen D. Sawitzke[3], Gopi Penmetsa[4] and Jathine Wong[2]. [1]Salt Lake City VAMC, Salt Lake, UT, [2]University of Utah, Salt Lake, UT, [3]University of Utah Medical Ctr, Salt Lake City, UT, [4]University Of Utah Hospital, Salt lake City, UT.

Background/Purpose: A genealogic resource, the Utah Population Database (UPDB) has successfully identified systemic sclerosis (SSc) pedigrees and hereditable risk for this disease (1). We hypothesized that these pedigrees could be used to assess parental influence on a SSc proband by (a) examination of mitochondrial inheritance; (b) birth order (a possible surrogate marker for microchimerism); and (c) paternal age at conception (a possible surrogate marker for telomere erosion).

Methods: SSc was defined by ICD-9 710.1 and ICD-10 34.0, 34.1, and 34.9, and identified from statewide discharge data, the University of Utah Health Science Center Enterprise Data Warehouse, and death certificates and were linked to the UPDB for analysis. Mitochondrial inheritance was evaluated by familial standardized incidence ratio (FSIR). Chi squared test and logistic regression was used to evaluate birth order and maternal/paternal age at conception of the SSc proband.

Results: A software kinship analysis tool (KAT) was used to analyze 1949 unique SSc patients and 5 controls per case (9115), which were matched by birth year. Comparing the result of using mitochondrial pedigrees (MP) with autosomal pedigrees (AP), both pedigrees yield similar result in Cox proportional hazard regression model to predict relative risk as a function of fsir, lfsir log of (1+fsir), llfsir, log of (1+ log(1+ lfsir)), and *eb* empirical Bayes adjustment to llfsir (2). Both MP and AP have a RR of 1.00 for fsir. MP has a RR of 1.43 for *eb*, and AP has a similar RR of 1.37 for *eb*. MP has a very low population-attributable risk, PAR value, 0.03, where AP has a higher value of 0.11 to 0.13. It suggested approximately 3% of the population who has SSc could be from mitochondrial inheritance, whereas 13% of the population who has SSc are familial. Thus, there is no indication of SSc is caused by mitochondrial inheritance.

We compared the affected and the unaffected individuals in each birth order group, and the distribution showed from birth order group 1 to 9, they were almost evenly distributed, affected was approximately 16 to 17%, and the unaffected was approximately 83 to 84% of each of these birth order groups. Chi Square test result shows an insignificant p value of 0.738. Since some of the table cell expected values are below 5, we re-examined the dataset using a logistic regression generalized linear model which confirmed there were no differences in the birth order of the groups in the study.

A multivariate logistic regression model with 3 covariates, birth order, father's age at conception, and mother's age at conception indicate all 3 covariates do not increase the odds for having the disease.

Covariate	RR	Lower Level CI	Upper Level CI	P-value
Birth Order	1.03	0.98	1.08	0.246
Father's age of conceived	0.998	0.951	1.05	0.939
Mother's age of conceived	0.997	0.945	1.05	0.913

Conclusion: The UPDB is a resource that allows for meaningful inheritance analysis. These data suggest that while increased inheritance of SSc is seen, patterns suggesting mitochondrial inheritance, birth order (microchimerism), and parental age at conception of a SSc proband are not likely responsible for pathogenesis.

Growth Differentation Factor-15, a Marker Of lung disease In Systemic Sclerosis, Is Involved In Fibrosis Development But Does Not Impair Fibrosis Development. Stijn Lambrecht[1], Vanessa Smith[2], Katelijne De wilde[3], Julie Coudenys[3], Filip De Keyser[2] and Dirk Elewaut[4]. [1]Laboratory for Molecular Immunology and Inflammation, Ghent University, Ghent, Belgium, [2]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium, [3]Ghent University, Ghent, Belgium, [4]Department of Rheumatology Ghent University Hospital, Ghent, Belgium.

Background/Purpose: It is generally known that members of the TGF-β superfamily are involved in the regulation of connective tissue biology in systemic sclerosis (SSc). Growth differentiation factor 15 is a distant member of this TGF-β family. We aimed to evaluate the role of GDF15 in SSc-pathogenesis.

Methods: A longitudinal prospective cohort of SSc patients was screened for GDF15 serum levels by ELISA and associations with disease activity and tissue damage were analyzed. Moreover, in vitro stimulation experiments were performed in lung fibroblasts. The role of GDF15 in fibrosis development *in vivo* was evaluated by performing the bleomycin lung fibrosis model in GDF15 deficient mice.

Results: Baseline serum samples from a prospective cohort of 119 patients were screened for GDF15 levels. An increase in GDF15 levels was observed in patients classified as limited SSc, limited cutaneous SSc and diffuse SSc. Moreover, baseline GDF15 serum levels highly correlated with disease activity, extent of organ involvement, particularly clinical symptoms of lung fibrosis including impact on lung function in prospective follow up. This was also mimicked in the bleomycin mouse model of SSc. Here, bleomycin exposed animals displayed elevated expression levels of GDF15 in lung tissue. Isolated lung fibroblast of GDF15 deficient mice showed reduced induction of IL6 and CCL2 upon bleomycin stimulation compared to wild-type littermates. Surprisingly, no differences in fibrosis development were observed between wild-type and GDF15 deficient animals.

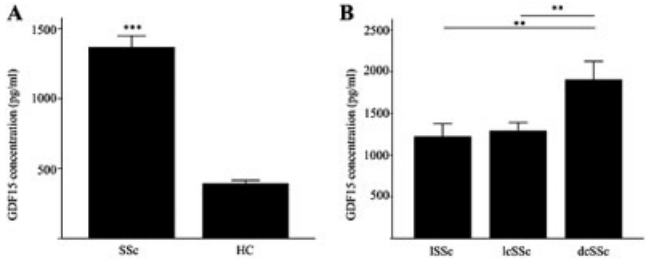

Figure 1. GDF15 serum levels are elevated in SSc patients. **Panel A:** An elevated level of GDF15 was detected in SSc patients (1367 pg/ml; n=119) compared to healthy controls (390,9 pg/ml; n=29), p<0,001. **Panel B:** An increase is observed in GDF15 serum levels of patients suffering from dcSSc (p=0,008, ANOVA).

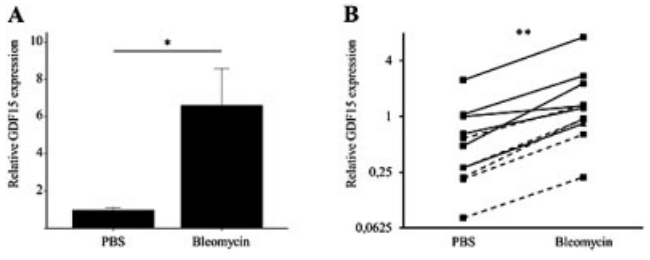

Figure 2. In vitro and in vivo experimental induction of fibrosis results in elevated GDF15 gene expression. **Panel A:** Bleomycin treated animals show elevated expression of GDF15 in lung tissue **Panel B:** Stimulation of lung fibroblasts from WT (solid line) and HZ (dashed line) with bleomycin resulted in an increased GDF15 expression compared to non-stimulated controls.

Conclusion: An intriguing profile of GDF15 serum levels was found in SSc patients. GDF15 expression is induced during fibrosis development and markedly correlates with lung function impairment in this disease. The protein may participate in fibrosis initiation, but is not indispensable in the course of fibrosis development *in vivo*.

Pirfenidone and BIBF1120 Suppress Collagen Synthesis In Skin Fibroblast From Patients With Systemic Sclerosis. Yuko Ota, Yasushi Kawaguchi, Kae Takagi, Hisae Ichida, Yasuhiro Katsumata, Takahisa Gono, Yuko Okamoto, Tomoaki Higuchi, Hidenaga Kawasumi and Hisashi Yamanaka. Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Pirfenidone (5-methyle-1-phenyl-2-[1H]-pyridone) and BIBF1120 (Nintedanib) are currently evaluated in clinical trials as a potential idiopathic pulmonary fibrosis (IPF). Pirfenidone was approved as the first antifibrotic therapy for IPF based on demonstrated sustained clinical efficacy. BIBF1120 is a triple tyrosine kinase inhibitor and potent antagonist of growth factors such as platelet-drived growth factor (PDGF), vascular endothelial growth factor (VEGF), and basic fibroblast growth factor (bFGF). The aim of the present study was to investigate the antifibrotic effects of pirfenidone and BIBF1120 on skin fibroblasts from patients with systemic sclerosis (SSc). We also examined signal transductions of these drugs.

Methods: Skin fibroblasts from six patients with diffuse cutaneous SSc were cultured with increasing concentrations of pirfenidone or BIBF1120 for various times. The resulting supernatants were collected and stored at −80°C. Procollagen type I C-peptide level was then measured using commercial ELISA kits. As we also evaluated the effects of pirfenidone or BIBF1120 for TGF-β1 induced skin fibrosis, skin fibroblasts stimulated with TGF-β1 were treated with pirfenidone or BIBF1120 and procollagen type I C-peptide level was measured using commercial ELISA kits. In addition, mRNA levels of collagen1α (I), collagen1a (II), TGF-β1, CTGF, IL-6 were estimated using real-time PCR.

Results: In the supernatants of fibroblasts cultured with 500 μg/ml of pirfenidone for 48 and 72 hours, the levels of procollagen type I C-peptide were significantly suppressed ($p = 0.034$ and $p = 0.009$, respectively) as compared with those in supernatants obtained from cultures lacking pirfenidone. Procollagen type I C peptide production was suppressed by 1 μM of BIBF1120 in cultured SSc fibroblasts ($p = 0.011$) compared to no stimulation. Both pirfenidone and BIBF1120 significantly down-regulated the collagen sysnthesis in TGF-b1-induced skin fibroblasts ($p < 0.05$, Figure 1). RT-PCR analysis revealed that *COL1A1, COL1A2, CTGF and TGFB1* mRNAs were suppressed by pirfenidone or BIBF1120 in cultured skin fibroblasts from patients with SSc. Inerestingly, pirfenidone inhibited IL-6 mRNA, but BIBF1120 promoted it adversely.

Conclusion: Our results showed that both pirfenidone and BIBF1120 attenuate collagen production via TGF-β1 and CTGF pathway in skin fibroblasts from patients with SSc. Pirfenidone and BIBF1120 may represent a novel therapy for skin fibrosis in patients with SSc.

Norepinephrine-Induced IL-6 Regulates Fibrosis In Systemic Sclerosis. Sei-ichiro Motegi, Akihito Uehara, Kazuya Yamada, Akihiko Uchiyama, Sachiko Ogino, Yoko Yokoyama, Yuko Takeuchi and Osamu Ishikawa. Gunma University Graduate School of Medicine, Gunma, Japan.

Background/Purpose: Raynaud phenomenon is freaquently observed in patients of systemic sclerosis (SSc) and characterized by episodic vasospasm and ischemia of extremities in response to cold or emotional stress. It has been recogized that cold- or stress-induced norepinephrine (NE) stimulates adrenoreceptor (AR) on pericytes or vascular smooth muscle cells, resulting in vasoconstriction. However, the roles of NE in fibrosis of SSc are not well understood. The aim of this study was to elucidate the role of NE in fibrosis in SSc.

Methods: Protein and mRNA levels of IL-6 and AR expression in normal and SSc fibroblasts treated with or without NE or ARα/β antagonists were measured by ELISA and real-time PCR. The effect of ARβ blocker and ERK inhibitor on NE-induced IL-6 production was analyzed by real-time PCR. The amount of phosphorylation of ERK and total ERK in normal and SSc fibroblasts were measured by Western blot analysis. Proliferation of fibroblasts was determined using the MTS assay.

Results: The serum levels of IL-6 was elevated in patients with early SSc, and correlated with the extent of skin fibrosis. Protein and mRNA levels of IL-6 expression in normal and SSc fibroblasts was increased by NE stimulation in a dose-dependent manner. In addition, NE-induced IL-6 production in SSc fibroblasts was significantly higher than that in normal fibroblasts. The production of IL-6 in fibroblasts was induced by ARβ antagonist, isoproterenol, but not by ARα antagonist, oxymetazoline. ARβ blocker, proplanolol, inhibited NE-induced IL-6 production in normal and SSc fibroblasts, suggesting that NE may induce IL-6 production via ARβ on fibroblasts. There was no change in ARβ expression in normal and SSc fibroblasts treated with or without NE. In addition, proplanolol enhanced NE-induced phosphorylation of ERK, and ERK inhibitor, PD98059, enhanced NE-induced IL-6 production in in normal and SSc fibroblasts, suggesting that NE-induced phosphorylation of ERK via ARα may inhibit NE-induced IL-6 production. Next, we assessed the effect of the treatment with NE and endothelin-1 (ET-1), which is supposed to contribute to the pathogenesis of fibrosis in SSc. Combined treatment with NE and ET-1 resulted in an additive increase in production of IL-6 in SSc fibroblasts. Finally, we identified that NE enhanced proliferation of SSc fibroblasts compared with that of normal fibroblasts.

Conclusion: We conclude that NE enhances IL-6 production and proliferation in SSc fibroblasts via ARβ more than those in normal fibroblasts. Our results indicate that avoidance of cold exposure or emotional stress may attribute to the suppression of fibrosis as well as Raynaud phenomenon in SSc.

Effects Of Macitentan and Its Active Metabolite In Modulating Extracellular Matrix Synthesis In Cultured Human Systemic Sclerosis and Normal Skin Fibroblasts. Maurizio Cutolo[1], Paola Montagna[2], Renata Brizzolara[2], Elisa Alessandri[3], Pietro Paolo Tavilla[4], Aurora Parodi[4], Alberto Sulli[3] and Stefano Soldano[2]. [1]University of Genova, Genova, Italy, [2]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy, [3]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, [4]Department of Endocrinologial and Medical Science, Unit of Dermatology, University of Genova, Genova, Italy.

Background/Purpose: Endothelin-1 (ET-1) has been shown to activate myofibroblasts and to enhance the synthesis of extracellular matrix proteins (ECM), such as collagen type I (COL-1) and fibronectin (FN), leading to tissue fibrosis in systemic sclerosis (SSc) progression (1, 2). Macitentan is a new molecule able to antagonize ET receptors. in plasma, besides macitentan, a circulating pharmacologically active metabolite (ACT-132577) has been identifyed (3, 4). We investigated the effects of macitentan and ACT-132577 on myofibroblast activation, by evaluating α-smooth musce actin (α-SMA) expression, and COL-1 and FN synthesis together with their gene expression, induced by ET-1 in cultured SSc and normal skin fibroblasts (Fbs). A comparison between the *in vitro* effects of macitentan, or ACT-132577 or bosentan was carried out.

Methods: Cultured human skin Fbs were obtained from biopsies of clinically involved skin of 6 SSc patients (4 females and 2 males, mean age 64.8±6.9 years) and 4 age-matched healthy subjects (3 females, 1 male) during diagnostic procedures (Dermatological Clinic, University of Genoa) and after signing informed consent. Following serum starvation (18 hrs), cultured human skin Fbs at 3rd culture passage were treated for 48 hrs with ET-1 (100nM), macitentan (concentration range from 1nM to 10μM), or ACT-132577 (concentration range from 10nM to 100μM), or bosentan (10μM) (Actelion Pharmaceuticals) in RPMI 1640 medium at 5% of fetal bovine serum. Cells were also pre-treated (1 hr) with macitentan, or ACT-132577 or bosentan, respectively, before treatment with ET-1 for 48 hrs. Untreated SSc and normal skin Fbs were used as controls. α-SMA expression was investigated by immunofluorescence (IF). COL-1 and FN synthesis and gene expressions were investigated by immunocytochemistry (ICC) and quantitative real time-polymerase chain reaction (qRT-PCR). Statistical analysis was performed by Mann-Whitney non-parametric t test.

Results: Macitentan and ACT-132577, at the concentration of 10μM, contrasted the increase in α-SMA expression induced by ET-1 in cultured human SSc skin Fbs, displaying same effects already showed by bosentan. Macitentan and ACT-132577 significantly antagonized the increase in COL-1 and FN synthesis induced by ET-1 ($p<0.01$; $p<0.01$ for macitentan; $p<0.05$; $p<0.05$ for ACT-132577 vs. only ET-1-treated cells). Bosentan significantly antagonized the ET-1 mediated increase in COL-1 and FN synthesis in SSc skin Fbs vs. only ET-1-treated cells ($p<0.01$; $p<0.05$). Data were confirmed by qRT-PCR. Same results were obtained in normal skin Fbs. Not significant differences were observed between macitentan, ACT-132577 and bosentan effects.

Conclusion: Macitentan and its active metabolite might down regulate the myofibroblast activation and the increased ECM protein synthesis induced by ET-1 in cultured human SSc skin Fbs at the same concentrations of bosentan.

DNA Methylation and Systemic Sclerosis. Gloria Salazar[1], Khurshida Begum[2], Xinjian Guo[3], Minghua Wu[1], Shervin Assassi[1], Maureen D. Mayes[1], John D. Reveille[1] and Xiaodong Zhou[1]. [1]University of Texas Health Science Center at Houston, Houston, TX, [2]Baylor College of Medicine, Houston, TX, [3]The University of Texas Medical School at Houston, Houston, TX.

Background/Purpose: Epigenetic modifications are stable and heritable alterations in gene expression and cellular function that do not involve changes to the original DNA sequence. They are now known to be essential regulators of multiple key biological processes. Epigenetic mechanisms are also vital for the development and function of the immune system.

DNA methylation is one of them and is mostly achieved by methylation of CpG dinucleotides of the mammalian genome. When methylated they cause a stable, heritable repression of transcription of the affected gene. DNA methylation was shown to play a role in the pathophysiology of systemic lupus erythematosus (SLE). A few studies have also shown important DNA methylation changes in systemic sclerosis (SSc).

The objective of this study was to establish the DNA methylation pattern differences between systemic sclerosis (SSc) and control fibroblasts as well as differences based on antibody profile.

Methods: DNA methylation profiling of fibroblasts from 16 SSc patients compared to 10 healthy controls was performed. Seven patients were anti-topoisomerase I (topo-1) positive and 9 were anti-centromere antibody (ACA) positive.

Roche NimbleGen 385K RefSeq promoter array was used. Candidate genes that were significantly hypomethylated in SSc fibroblasts compared to controls and are part of fibrotic or inflammatory pathways were selected for confirmation studies. Bisulfite conversion and sequencing methods for methylation detection was performed. We designed two sets of PCR primers (one for DNA without bisulfite conversion, and one for post-conversion). Bisulfite conversion of sample DNA was performed using EZ DNA methylation kit (Zymo Research, Irvine, CA). The samples were PCR-sequenced and examined for methylation using QUAMA software.

Results: Methylation changes of CpG islands of multiple genes showed significant difference between SSc and control fibroblasts by initial global profiling.

Ten candidate genes that were significantly hypomethylated in SSc fibroblasts compared to controls were chosen for confirmation studies (table 1).

Table 1. Hypomethylated genes selected for confirmatory studies

Chromosome	Pick start	Pick end	Gene Symbol	Gene name
16	65157526	65158226	CDH11	Cadherin 11
10	71562420	71563120	COL13A1	Collagen, type XIII, alpha 1 (COL13A1)
2	228045310	228045718	COL4A3	Collagen, type 4, alpha 3 (COL4A3)
5	74668878	74669278	COL4A3BP	Collagen type IV alpha-3-binding protein
3	185514988	185516194	IGF2BP2	Insulin-like growth factor 2 mRNA-binding protein 2
1	154430446	154430946	IL6R	Interleukin-6 Receptor
15	67009542	67010342	SMAD6	SMAD family member 6
20	39680072	39680672	TOP1	(DNA) topoisomerase 1
8	144420006	144420706	TOP1MT	(DNA) topoisomerase 1 mitochondrial
1	92373559	92351559	TGFBR3	Transforming growth factor-beta receptor 3

Bisulfite sequencing analyses showed hypomethylation of DNA topoisomerase I (TOP1) and mitochondrial DNA topoisomerase I (TOP1-MT) genes in ACA positive SSc patients compared to controls with a statistically significant difference in percentage methylation of these genes ($p=0.02$ for TOP1-MT and $p=0.005$ for TOP1). No difference was found for any of the studied genes between topo-1 positive patients and controls.

Conclusion: DNA methylation is an important epigenetic mechanism implicated in the pathophysiology of SSc. There are several candidate hypomethylated genes involved in collagen production and inflammatory pathways. Bisulfite sequencing showed significant hypomethylation of TOP1 and TOP1-MT in ACA positive SSc patient fibroblasts.

Gene Expression Variation and The Role Of Interferon In Patients With Morphea From The Morphea In Adults and Children Cohort. Daniel Grabell[1], Andrew Kim[2], Virginia Pascual[3], Shervin Assassi[4] and Heidi Jacobe[1]. [1]UT Southwestern Medical Center at Dallas, Dallas, TX, [2]Lenox Hill Hospital, New York, NY, [3]Baylor University, Dallas, TX, [4]University of Texas Health Science Center at Houston, Houston, TX.

Background/Purpose: Localized scleroderma (morphea) is characterized by inflammation and sclerosis of the dermis and underlying tissue and may be associated with significant morbidity. Overproduction of type I and III collagen by fibroblasts is thought to be a factor in the pathogenesis of morphea but, little is known about the mechanism by which these fibroblasts are activated. Endothelial cell injury, immunologic and inflammatory activation, and dysregulation of collagen production have all been proposed. The purpose of this study is to describe the transcriptosome of lesional morphea skin relative to non-lesional controls.

Methods: Skin samples from adult patients in the Morphea in Adults and Children Cohort (MAC) with active, untreated lesions were collected from the inflammatory border, sclerotic center, and site matched non-lesional skin. Gene expression analysis of the three tissue types was conducted using Illumina Human HT4 arrays. The gene expression profile of each tissue type was then compared to that of corresponding normal tissue in a self-controlled fashion. We considered differentially expressed genes (DEGs) with a cut-off of fold change >2.0 and a $p<0.05$. The data was evaluated without correction and with the Benjamini–Hochberg procedure. Ingenuity Pathway Analysis (IPA) was utilized to identify canonical pathways among differentially expressed genes. The DEGs were compared to known type I interferon genes as collected by Monash University's Interferome database.

Results: Principal components analysis demonstrated a clear difference between gene expression patterns of the inflammatory border and sclerotic center when compared to normal skin and each other. The total number of DEGs when comparing the inflammatory border (IB) and the sclerotic center (SC) grouped together compared to unaffected skin (UA) was 724. The number of genes shared between Morphea skin and UA skin was 397. The number of genes unique to the IB compared with the UA was 647 and to the sclerotic center were 562. Comparison with the Interferome database showed that 35 IB genes and 23 SC genes overlapped with the interferon pathway. Specifically we saw that CXCL10, a major component of the interferon pathway, showed a14.3 fold change when compared to normal skin. Through IPA analysis we showed that the top five pathways include iCOS-iCOSL Signaling in T Helper Cells, CD28 Signaling in T Helper Cells, CTLA4 Signaling in Cytotoxic T Lymphocytes, OX-40 Signaling Pathway, and Dendritic Cell Maturation.

Conclusion: These results demonstrate that gene expression differs between matched pairs of lesional morphea skin and non-lesional skin from the same patient. Interestingly the inflammatory border and sclerotic center showed different levels of gene expression with greater activation of CXCL10 in the IB versus the SC, implicating different molecular mechanisms at play in the initiation of lesions. Our results support the

theory that therapeutics targeting the CXCL10 pathway may lead to future treatments for Morphea.

Lipoic Acid Plays a Crucial Role In Scleroderma Dermal Fibroblasts. Pei-Suen Tsou[1], Beatrix Balogh[2], Adam J. Pinney[2], George Zakhem[2], Ann Kendzicky[2], Elena Schiopu[2], Dinesh Khanna[2], David A. Fox[2] and Alisa E. Koch[2]. [1]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI, [2]University of Michigan Medical School, Ann Arbor, MI.

Background/Purpose: Systemic sclerosis (SSc) is a connective tissue disease characterized by vasculopathy and fibrosis of the skin and organs. Increase in oxidative stress and platelet-derived growth factor receptor (PDGFR) activation promote collagen I (Col I) production, leading to fibrosis in SSc. Lipoic acid (LA) and its *active* metabolite dihydrolipoic acid (DHLA) are naturally occurring thiols that act as cofactors and antioxidants. The goal of this study was to examine whether LA, and lipoic acid synthetase (LIAS), the enzyme producing LA, were deficient in SSc patients. The effect of DHLA on the phenotype of SSc dermal fibroblasts was also determined. N-acetylcysteine (NAC), a commonly used thiol antioxidant, was included as a comparison.

Methods: Dermal fibroblasts were isolated from punch biopsies from healthy subjects and patients with diffuse cutaneous SSc. Oxidative stress was measured by dihydroethidium staining and hydrogen peroxide fluorescent assay. Immunofluorescence was performed to probe for LA, Col I and α-smooth muscle actin (αSMA). Matrix mettaloproteinase-1 (MMP-1) and 3, LIAS were measured by ELISA. Expression of phosphatases, PDGFR phosphorylation, and αSMA was measured by Western blotting.

Results: The expression of LA and LIAS in SSc dermal fibroblasts was lower than normal, however LIAS was significantly higher in SSc plasma (normal 79.5$\pm$6.0 vs. SSc 119.5$\pm$14.2 pg/ml, $p<0.05$). DHLA lowered cellular hydrogen peroxide (basal 2487$\pm$252 vs. plus DHLA 1908$\pm$61 fluorescent unit, $p<0.05$), and decreased PDGFR phosphorylation, Col I, and αSMA expression in SSc dermal fibroblasts. It also restored the activities of phosphatases that inactivated the PDGFR. SSc fibroblasts produced lower levels of MMP-1 and 3 then did normal fibroblasts (MMP-1: normal 15161$\pm$3525 vs. SSc 2094$\pm$405 pg/ml; MMP-3: normal 714$\pm$189 vs. SSc 216$\pm$69 pg/ml, both $p<0.05$), with levels increasing after DHLA incubation (MMP-1: 4789$\pm$1406 and MMP-3: 407$\pm$143 pg/ml, $p<0.05$ vs. without DHLA). DHLA showed better efficacy than NAC in most cases.

Conclusion: DHLA decreased PDGFR activation and increased MMPs that degrade Col I. It also lowered αSMA expression in SSc dermal fibroblasts. Since LA and LIAS were deficient in SSc dermal fibroblasts, this might be one of the reasons DHLA was beneficial. DHLA not only acted as an antioxidant but also an antifibrotic since it had the ability to reverse the profibrotic phenotype of SSc dermal fibroblasts.

Elevated 8-Isoprostane In Scleroderma: Implications Of Its Role In Inhibiting Vascular Endothelial Growth Factor-Induced Angiogenesis. Pei-Suen Tsou[1], George Zakhem[2], Beatrix Balogh[2], M. Asif Amin[2], Phillip Campbell[2], Gautam Edhayan[2], Ray Ohara[2], Elena Schiopu[2], Dinesh Khanna[3], Alisa E. Koch[2] and David A. Fox[1]. [1]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI, [2]University of Michigan Medical School, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI.

Background/Purpose: Scleroderma (SSc) is a complex disease characterized by inflammation, vasculopathy, and excessive disposition of extracellular matrix. Various studies have demonstrated a paradoxical increase in angiogenic mediators, such as vascular endothelial growth factor (VEGF), in both the skin and serum of patients with SSc. Despite this, angiogenesis does not occur normally. The signaling of the thromboxane A2 receptor (TXAR), which can be activated by 8-isoprostane (8-IP), has been shown to inhibit angiogenesis as well as VEGF-induced endothelial cell (EC) differentiation and migration. However, its role in SSc has not been examined. In this study we examined whether 8-IP was elevated in patient plasma and conditioned medium (CM) from ECs, and examined its' effect on VEGF-induced angiogenesis in SSc.

Methods: Dermal ECs were isolated from punch biopsies from healthy subjects or patients with diffuse cutaneous SSc. Angiogenesis was assessed by chemotaxis and *in vitro* Matrigel tube formation assays.

Results: SSc patients had significantly higher 8-IP plasma levels (60.9$\pm$8.4 pg/ml) compared to healthy subjects (24.9$\pm$5.0 pg/ml, $p<0.05$). When divided into disease subtypes, patients with diffuse SSc or interstitial lung disease showed elevated 8-IP, while those with limited SSc or pulmonary hypertension did not. Increased oxidative stress was detected in SSc ECs as increased 8-IP in SSc EC CM was observed (15.1$\pm$2.8 vs. 27.8$\pm$3.6 pg/ml, $p<0.05$). To test whether the increased 8-IP levels in CM affected angiogenesis, we performed Matrigel tube formation assay using NL ECs. SSc EC CM decreased VEGF-induced tube formation in NL ECs while addition of vitamin E restored it. In addition, 8-IP inhibited VEGF-induced healthy EC migration, and the inhibition of TXAR or ROCK pathways restored VEGF-induced angiogenesis inhibited by 8-IP. We then measured ROCK activity in NL and SSc ECs before and after VEGF or 8-IP stimulation. Basal ROCK activity was significantly higher in SSc ECs compared to healthy ECs. 8-IP-induced ROCK activation was significantly higher in SSc ECs while VEGF induced significantly higher ROCK activation in healthy ECs.

Conclusion: We show that 8-IP inhibits VEGF-induced migration in healthy ECs through the TXAR/ROCK pathway. SSc ECs produce high levels of 8-IP and exhibit elevated ROCK activity compared to healthy ECs, suggesting that this pathway plays a crucial role in impaired angiogenesis in SSc. This is supported by using vitamin E, which decreases 8-IP, in the Matrigel in vitro assay, in which it restores the inhibitory effect of SSc EC CM on VEGF-induced angiogenesis in healthy ECs. This study provides a potential link between oxidative stress and impaired angiogenesis in SSc, and shows that 8-IP is not just a by-product as a result of oxidative stress, rather it plays a significant role in impaired angiogenesis that characterizes SSc.

Circulating Cell-free microRNAs in Systemic Sclerosis. Samantha Steen[1], Anting L. Carlsen[1], Line V. Iversen[1], Christoffer T. Nielsen[2], Christian Lood[3], Anders A. Bengtsson[3] and Niels H. H. Heegaard[1]. [1]Statens Serum Institut, Copenhagen, Denmark, [2]University Hospital Rigshospitalet, Copenhagen, Denmark, [3]Lund University, Lund, Sweden.

Background/Purpose: microRNAs (miRNAs) are a class of small non-coding RNAs that regulate gene expression through target mRNAs and are involved in important physiological and pathological processes. Alterations in miRNA expression have been reported in autoimmune diseases including systemic lupus erythematosus (SLE) and rheumatoid arthritis, and in fibrotic disorders such as idiopathic pulmonary fibrosis. Systemic sclerosis (SSc) is characterized by fibrosis, vasculopathy and immunological disturbances, and the differential diagnosis and assessment of SSc disease activity can be challenging. The aim of this study was to identify putative circulating miRNAs in SSc patients as biomarkers for diagnosis, disease complications, and activity.

Methods: Total RNA was purified from platelet-poor plasma from 121 SSc patients, 29 SLE patients and 40 healthy controls, and the expression of 45 different specific miRNAs was determined using a quantitative real-time PCR dynamic array. Expression data and diagnosis and clinical parameters were analyzed for correlations.

Results: Twenty-seven miRNAs were significantly differentially expressed in SSc patients compared with healthy controls ($p < 0.05$). Nineteen miRNAs were down-regulated in SSc (miR-16, -17, -20a, -21, -24, -27a-3p, -29c-3p, -92a, -106a, -142-3p, -145-5p, -146b, -184, -192-5p, -221, -223, -342-3p, -375 and -423-5p), whereas 8 miRNAs were up-regulated in SSc (-29a, -29b-3p, -150, -181b, -203, -409-3p, -590-5p and -638). Ten miRNAs were found to be statistically differentially expressed in SSc patients compared with both healthy controls and SLE patients ($p < 0.05$). Receiver operating characteristic (ROC) analysis underlined the potential use of 4 miRNAs as biomarkers in SSc diagnostics, and revealed a promising 2

miRNA model to discriminate SSc patients from healthy controls when combining miR-106a with miR-181b (AUC = 0.91).

Conclusion: The expression of cell-free circulating miRNAs is altered in SSc compared with healthy controls and SLE patients. A promising 2 miRNA index differentiates SSc patients from healthy controls.

Bleomycin Delivery By Mini-Osmotic Pump: A Novel Multi-Organ Murine Model For Fibrosis. Rebecca Lee, Elena Tourkina, Richard P. Visconti and Stanley Hoffman. Medical University of SC, Charleston, SC.

Background/Purpose: Systemic sclerosis (SSc, Scleroderma) is a rare but severe systemic connective tissue disorder involving the skin and multiple internal organs, in particular lung, kidney, gastrointestinal tract, and heart. The hallmark pathophysiologic features of this disease include vascular injury, autoimmunity, inflammation, and extensive tissue fibrosis. Bleomycin is routinely used to create a model for SSc lung disease by direct administration into this target tissue. Systemic bleomycin treatment by multiple subcutaneous injections has occasionally been used to induce fibrosis in skin and lungs. However, this method is laborious and expensive, involving frequent injections of high concentrations of bleomycin over long time periods. Furthermore, fibrosis induced by this method has only been reported in locally injected skin and lung. In our study, for the first time, we report a bleomycin induced multi-organ fibrosis murine model for SSc by one-time subcutaneous implantation of a mini-osmotic pump containing bleomycin.

Methods: Mini-osmotic pumps are implanted into 10 week-old CD1 male mice. The pump delivers 100 U/kg bleomycin over 7 days. Mice are sacrificed on day 28. A variety of methods are used to analyze the progression of fibrosis.

Results: This model produces substantial and progressive multi-organ fibrosis, including dermal, pulmonary, renal, cardiovascular, and hepatic, as evaluated histologically and immunohistologically (Fig. 1 and 2). This model also mimics the vasculopathies observed in SSc patients, including loss of capillaries, proliferation of vascular smooth muscle cells, and dilation and hypertrophy of the right ventricle. Because caveolin-1 has been identified as a master regulator of fibrotic tissue remodeling, we evaluated whether systemic treatment of mice with the caveolin-1 scaffolding domain (CSD) peptide might have a beneficial effect on skin fibrosis. Indeed, bleomycin-induced skin thickening was almost completely blocked by CSD treatment ($p < 0.01$).

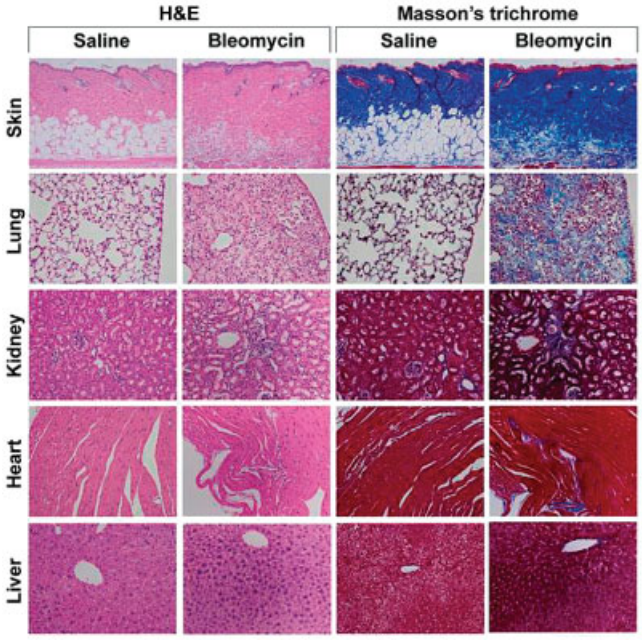

Fig. 1. Tissue morphology changes following bleomycin treatment. Sections are stained with H&E and Masson's trichrome.

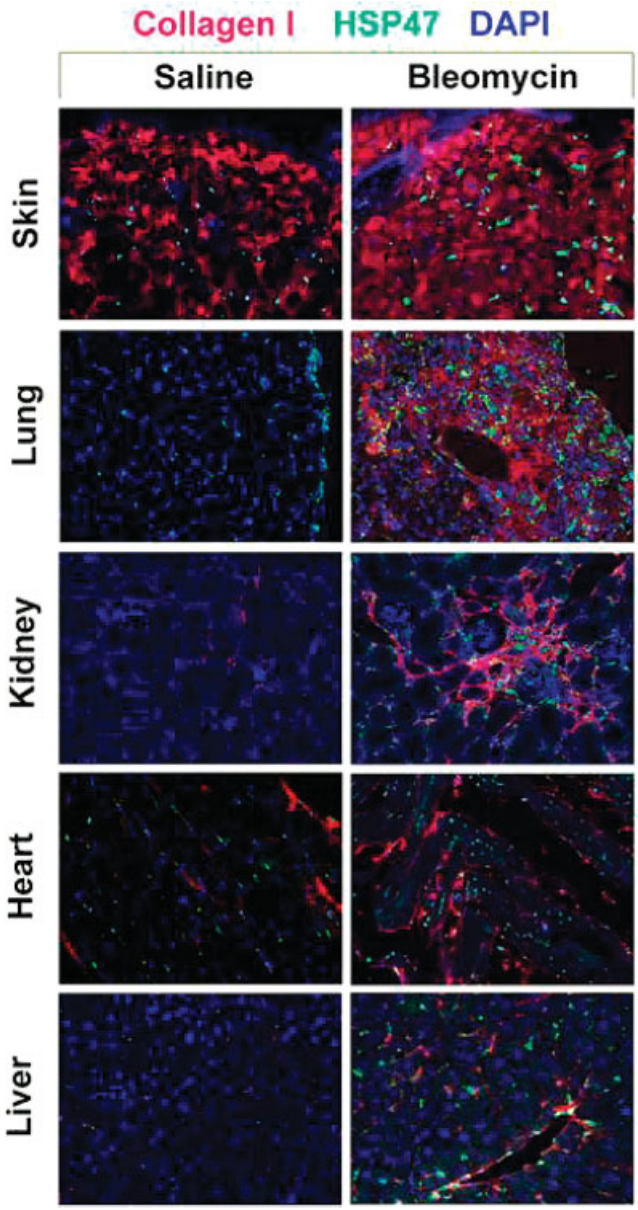

Fig. 2. Extracellular matrix protein expression in murine tissue sections following bleomycin treatment. Sections were stained with antibodies against collagen I and the collagen chaperone HSP47.

Conclusion: Bleomycin delivery by mini-osmotic pump effectively recapitulates the hallmark features of SSc in several organs, thereby providing a convenient model system to evaluate potential treatments for SSc (such as CSD) in each affected organ.

Topoisomerase-1 Specific T Cells Exhibit a Proinflammatory Th17 Phenotype and Are Associated With Interstitial Lung Disease In Scleroderma. Andrea Fava[1], Raffaello Cimbro[1], Antony Rosen[1], Qing-Rong Liu[2], Fredrick M. Wigley[3] and Francesco Boin[3]. [1]Johns Hopkins University, Baltimore, MD, [2]NIH/NIDA, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: Anti-topoisomerase-1 (Topo-1 or Scl70) autoantibodies are present in 30–45% of scleroderma (SSc) patients and identify a more aggressive disease phenotype with worse clinical outcome and reduced survival. While autoreactive T cells may be involved in SSc patho-

genesis driving tissue inflammation and damage, no study has to date reliably quantified and functionally characterized topo-1-specific T cells in SSc patients.

Methods: Peripheral blood mononuclear cells from 27 (15 Scl70-positive and 12 Scl70-negative) consecutive patients and 4 healthy donors (HD) were stimulated with topoisomerase-1 purified from baculovirus-infected insect cells in the presence of anti-CD40 blocking antibodies and autologous serum. Topo-1-responsive T cells were defined based on the expression of activation markers CD154 and CD69, and their frequency calculated as percentage of CD4+ cells. The polarized functional phenotype (Th1, Th2, Th17, Th1/17) of autoreactive T cells was further determined by the surface expression of specific chemokine receptors (CXCR3, CCR6, CCR4) and their cytokine secretion profile (IFNγ, IL-4, IL-17) quantified by ELISA and qPCR after cell sorting. Comprehensive clinical data were obtained at the time of blood draws.

Results: Topo-1-reactive CD4+ T cells were found in all topo-1-positive subjects compared to one topo-1-negative patient and no HD [p=<0.001 and p=0.005 respectively] with a frequency ranging between 0.11% and 0.42% of CD4+ T cells. Anti-HLA-DR antibodies effectively inhibited topo-1 presentation and the activation of topo-1-responsive CD4+ T cells. Topo-1-specific T cells exhibited a predominant Th17 phenotype compared to the parent CD4+ T cell population [37±16% vs 8±5%, p=0.001]. Among topo-1-positive patients, higher levels of topo-1-reactive CD4+ T cells were associated with presence of interstitial lung disease [p=0.03], lower forced vital capacity (FVC) [rho=−0.657, p=0.011], and lower carbon monoxide diffusing capacity (DLco) [rho=−0.592, p=0.026].

Conclusion: This study establishes a robust and sensitive assay to measure topo-1-reactive T cells, and suggests that Th17 differentiation may be of importance in SSc pathogenesis.

Oxidative Stress-Dependent Activation Of Collagen Synthesis Is Induced In Human Pulmonary Vascular Smooth Muscle Cells By Scleroderma Sera and Predicts Pulmonary Vascular Disease. Francesco Boin[1], Anna Maria Posadino[2], Annalisa Cossu[2], Roberta Giordo[2], Ami A. Shah[1], Gaia Spinetti[3], Gian Luca Erre[2], Costanza Emanueli[4], Giuseppe Passiu[2], Fredrick M. Wigley[1] and Gianfranco Pintus[2]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Sassari, Sassari, Italy, [3]Istitituto di Ricovero e Cura a Carattere Scientifico (IRCCS), Multi Medica, Milan, Italy, [4]University of Bristol, Bristol, United Kingdom.

Background/Purpose: Vascular disease is a dominant component of Systemic Sclerosis (SSc) pathogenesis. Hypoxia and oxidative stress have been linked to endothelial injury, intimal hyperplasia and progressive vessel occlusion in SSc and the aberrant function of vascular smooth muscle cells (VSMC) has been associated with the initiation and the amplification of this process. We hypothesize that in SSc patients with pulmonary vascular disease circulating factors may drive vascular damage by exerting pro-oxidant effects involving VSMC.

Methods: The generation of reactive oxygen species (ROS) and the activation of collagen synthesis was investigated in primary Human Pulmonary Vascular Smooth Muscle Cells (HPVSMC) after exposure to sera obtained from 19 SSc patients with pulmonary vascular disease (PVD) defined by echocardiographic criteria (right ventricular systolic pressure ≥ 45 mmHg), 17 patients with no PVD and 15 healthy donors (HD). Intracellular ROS levels were assessed using the general oxidative stress indicator dichlorodihy drofluorescein diacetate (H_2-DCFDA). Collagen type I (COL1A1) promoter activity was investigated using a GFP-based lentiviral vector, while collagen protein expression was assessed by ELISA in culture supernatants. In selected experiments, pretreatment of cells with diphenyleneiodonium (DPI), a general flavoprotein inhibitor, was performed.

Results: HPVSMC treated with SSc sera from PVD patients significantly increased intracellular ROS levels (248.8 ± 27.5 Relative Fluorescence Units - RFU) compared to no-PVD subjects (155.1 ± 10.5 RFU; p=0.008) and HD (124.9 ± 2.8 RFU; p=0.002). DPI effectively prevented the raise of intracellular ROS, implicating the involvement of Flavin Oxidases (FO) in this process. The pro-oxidant stimulus provided by SSc sera was associated with a parallel increase of both COL1A1 promoter activity (PVD-SSc sera 278.1 ± 24.2 RFU vs 194.4 ± 7.9 RFU; p=0.01 in no-PVD and 164.9 ± 5.1; p=0.002 in HD) and collagen protein expression in HPVSMC. Also this effect was abrogated by DPI pretreatment.

Conclusion: This study provides evidences that sera from SSc patients with pulmonary vascular disease drive pro-fibrotic responses mediated by Flavin Oxidases-derived ROS production in HPVSMC and suggests that antioxidant therapies should be further explored in the treatment of SSc vascular disease.

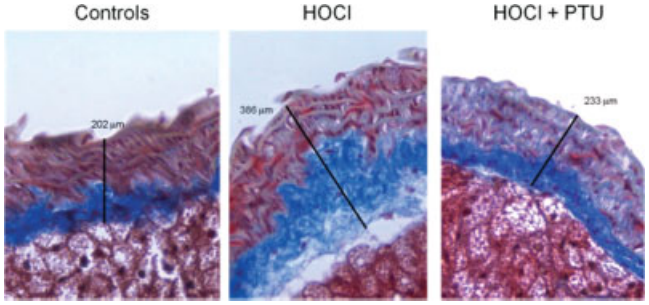
Propylthiouracil Attenuates Aortic Vasculopathy In An Animal Model Of Systemic Sclerosis. Gianluca Bagnato[1], Alessandra Bitto[1], Gabriele Pizzino[1], Neal Roberts[2], Domenica Altavilla[1], Francesco Squadrito[1], Gianfilippo Bagnato[1] and Antonino Saitta[1]. [1]University of Messina, Messina, Italy, [2]University of Louisville, Louisville, KY.

Background/Purpose: Systemic sclerosis (SSc) is a generalized connective tissue disorder of unknown etiology characterized by thickening and fibrosis of the skin and distinctive visceral involvement associated with vascular damage. Traditionally, the vasculopathy of SSc has been considered mainly to affect small arteries and capillaries but there is recent evidence showing that SSc is also associated with large vessel disease. Increased aortic augmentation index and pulse wave velocity in comparison to age and sex matched healthy controls indicate large-vessel involvement in patients with SSc. A second, and as yet poorly accounted for, endocrine feature of scleroderma is its overlap with thyroid abnormalities. Recent experimental data suggest that propylthiouracil (PTU) abrogates the development of cutaneous and pulmonary fibrosis in SSc murine model and reduces the development of plexiform lesions in an animal model of primary pulmonary hypertension. The aim of the study is therefore to evaluate the effect of propylthiouracil administration on intima-media (IM) thickness and ratio in a murine model of systemic sclerosis.

Methods: Chronic oxidant stress SSc was induced in BALB/c mice by daily subcutaneous injections of HOCl for 6 weeks, characterized in detail as the Cochin chronic oxidant stress model of SSc. Mice (n=25) were randomized in three arms: treatment with either propylthiouracil plus HOCl (n=10), HOCl (n=10), or vehicle alone (n=5). Propylthiouracil treatment (12 mg/kg) was initiated 30 minutes after HOCl subcutaneous injection and continued daily for the 6 weeks. Thoracic aorta was evaluated by histological methods. IM thickness and ratio were measured for statistical analysis.

Results: HOCl injections induced an increase in aortic IM thickness when compared to controls by 101% (p<0.0001). In mice treated with HOCl and PTU there was a 86% reduction of IM thickness (p<0.0001). PTU treated animals had a significantly thinner intima layer (−13%, p<0.0001) and media layer (−198%, p<0.0001) compared to HOCl group. IM ratio was also decreased in HOCl treated mice compared to controls (0.72 vs 1.76, p<0.0001) and significantly increased by PTU administration (1.62 vs 0.72, p<0.0001).



Conclusion: Our data suggest that PTU, probably through its antioxidant direct effect or indirectly through thyroid function inhibition, substantially moderates the increase of aortic thickness found in HOCl treated animals reducing collagen deposition in media layer and aortic fibrotic changes.

Formate, Acetate and Acetone: News Biomarkers in Systemic Sclerosis identified by Metabolomics. Emmanuel Chatelus[1], Francois Marie Moussallieh[1], Christelle Sordet[1], Arnaud Theulin[1], Alain Meyer[1], Karim El Bayed[2], Jean Francois Kleinmann[1], Jean Sibilia[1], Jacques-Eric Gottenberg[1] and Izzie Jacques Namer[1]. [1]Strasbourg University Hospital, Strasbourg, France, [2]UMR 7177 CNRS/Strasbourg University, Strasbourg, France.

Background/Purpose: High throughput study of metabolic pathways might help identify new biomarkers and therapeutic targets in autoimmune diseases. Systemic sclerosis (SSc) currently lacks prognostic biomarkers and efficacious and specific treatments. We therefore assessed serum levels of 40 metabolites in patients with SSc and healthy controls using high-resolution magic-angle spinning (HRMAS) proton magnetic resonance spectroscopy.

Methods: The blood samples of 97 successive patients with SSc (median age 59 years (22–85); disease duration 13 years (1–37); limited cutaneous SSc 57%; diffuse cutaneous SSc 43%) and 39 healthy controls were analysed in this study. After cryopreservation at −80°C, the samples were studied with HRMAS proton magnetic resonance spectroscopy (1H-MRS). Spectra were recorded on a Bruker Avance III 500 spectrometer operating at a proton frequency of 500 MHz. The speed revolution of the tube was 3000 Hz. The 1D MR spectra were acquired during 15 min (between 0.5 and 4,7 ppm). Supervised clustering was performed using principal component analysis (PCA).

Results: Supervised clustering of the 97 samples allowed to discriminate all patients with SSc from healthy controls ($R^2Y=0.76$ and $Q^2=0.72$) (Figure 1). Interestingly, 3 metabolites were significantly more expressed in SSc blood samples than in healthy controls: formate, acetate and acetone (median 19.6 *vs* 7.9 μmol/l, $p<0.0001$; 17.7 *vs* 5.4 μmol/l; $p<0.0001$; 10.4 *vs* 8.1 μmol/l, $p=0.043$ respectively). Supervised clustering also allowed to discriminate SSc patients with interstitial lung disease (ILD) from patients without ILD ($R^2Y=0.73$ and $Q^2=0.50$).

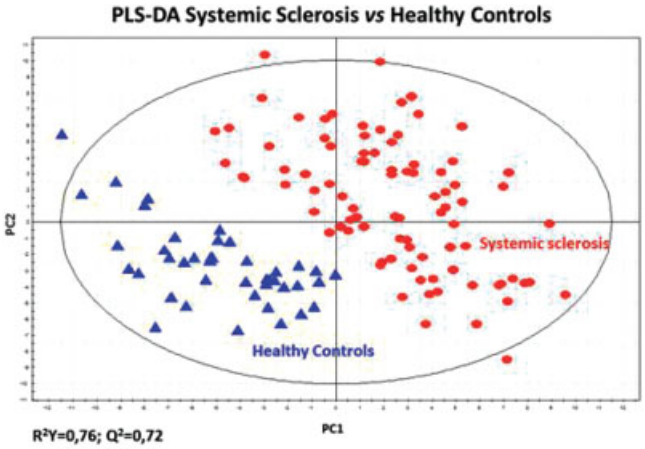

Figure 1 : PLS-DA scores plot based on NMR spectra of blood samples obtained from systemic sclerosis (red plot) and healthy controls (blue triangle)

Conclusion: This first high-throughput analysis of metabolic pathways disclosed a specific metabolomic signature of SSc allowing to discriminate all patients from controls and SSc patients with ILD. This new and very potent means of metabolic analysis may help to increase our knowledge on the pathogenesis of SSc, identify biomarkers, and new therapeutic targets.

DNA hypermethylation of Forkhead box protein 3 (FOXP3) locus leads to quantitative defects of regulatory T cells in systemic sclerosis. Yaoyao Wang[1], Ye Shu[2], Qing Wang[1], Ming Zhao[1], Gongping Liang[1], Qianjin Lu[1] and Rong Xiao[1]. [1]Second Xiangya Hospital, Central South University, Changsha, China, [2]Hunan Children's Hospital, Changsha, China.

Background/Purpose: Systemic sclerosis (SSc) is a systemic autoimmune disease of which the etiology and pathogenesis remains complex and poorly understood. Attention has recently been directed towards regulatory T cells (Tregs) because they are important in maintenance of immunologic self-tolerance as well as negatively regulating immune responses against non-specific stimuli. The normal development and suppressive phenotype of Tregs depends on stable expression of FOXP3. The methylation status of the CpG residues in the proximal promoter region has an essential role in FOXP3 expression. Transcriptional silencing of FOXP3 through hypermethylation in regulatory elements regions has been identified as a hallmark of committed Treg cells and several human diseases. The aim of this study was to investigate on how DNA methylation status of CpG islands in the proximal promoter region within the FOXP3 locus affect FOXP3 expression and defects in Tregs from patients with SSc.

Methods: 18 SSc patients and 16 healthy control subjects(HC) were recruited from the outpatient clinics, inpatient services and medical staff at the Second Xiangya Hospital of Central South University in China. Patients and controls were age- and sex-matched in all experiments.Peripheral blood mononuclear cells were isolated by Ficoll-Hypaque density-gradient centrifugation, and CD4+T cells were isolated by positive selection using immunomagnetic beads, according to protocols provided by the manufacturer. The percentage of CD4+CD25+FOXP3+ Treg cells in peripheral blood mononuclear cells was measured by flow cytometry from SSc patients and HC. FOXP3 expression in CD4+ T cells from patients with SSc and HC was measured by RT-PCR and western blot. Bisulfite sequencing was performed to determine the methylation status of the FOXP3 proximal promoter in CD4+ T cells from SSc patients, HC and in CD4+ T cells with DNA methylation inhibitors.

Results: The percentage of CD4+CD25+FOXP3+ Treg cell was decreased in SSc patients. FOXP3 expression was significantly reduced in patients with SSc. The methylation levels of the DNA regulatory sequences were elevated in patients with SSc compared with healthy controls, and there was a significant inverse correlation between the average methylation level and FOXP3 mRNA expression in patients with SSc. Further more, there was a significant inverse correlation between the the average methylation level and the percentage of Tregs in a cohort of SSc patients. Treatment with a DNA methylation inhibitor led to FOXP3 hypomethylation in the FOXP3 promoter resulting in FOXP3 overexpression and expansion of Tregs. The percentage of Tregs was positively correlated with disease activity.

Conclusion: Hypermethylation of the FOXP3 promoter contributes to the decreased FOXP3 expression and quantitative defects of Tregs in SSc patients correlating with disease activity. These data provide evidence that a quantitative defect of Treg cells could be considered a common biological hallmark of SSc. We propose that this reduction per se could sustain autoimmunity.

Involvement Of TCR Vdelta1$^+$ NKT Cells In Systemic Sclerosis: Association With Interstitial Pneumonia. Seiji Segawa[1], Daisuke Goto[2], Masanobu Horikoshi[2], Yuya Kondo[3], Naoto Umeda[2], Shinya Hagiwara[2], Masahiro Yokosawa[4], Tomoya Hirota[3], Haruka Miki[1], Hiroto Tsuboi[3], Hiroshi Ogishima[2], Takeshi Suzuki[4], Isao Matsumoto[3] and Takayuki Sumida[3]. [1]University of Tsukuba, Ibaraki, Japan, [2]University of Tsukuba, Tsukuba City, Japan, [3]University of Tsukuba, Tsukuba, Japan, [4]University of Tsukuba, Tsukuba, Ibaraki, Japan.

Background/Purpose: Interstitial pneumonia (IP) is one of the critical complications in patients with several autoimmune diseases. However, the exact mechanism of IP remains elusive. Recently, the pathological role of $\gamma\delta$ T cells was reported in several IP mice models. Previous our data showed that IP in Interleukin (IL)-2 plus IL-18 induced mice was similar to human IP. In this mice model, $\gamma\delta$NKT cells exacerbated IL-2 plus IL-18 induced lung inflammation via the production of IFN-γ. Thus, to examine whether TCR V$\delta1^+$ NKT cells play a crucial role, we carried out the number and function of TCR V$\delta1^+$ NKT cells in systemic sclerosis patients with IP.

Methods: 1) PBMCs were isolated from healthy controls (HC, n=22) and patients with rheumatoid arthritis (RA, n=17), systemic sclerosis (SSc, n=35), and polymyositis/dermatomyositis (PM/DM, n=14). We examined the proportion of TCR V$\delta1^+$ NKT cells in PBMCs by flow cytometry (FCM). 2) In SSc patients with IP, the correlation between proportion of TCR V$\delta1^+$ NKT cells in PBMCs and serum KL-6 levels was analyzed. 3) CD161$^-$ V$\delta1^+$ $\gamma\delta$T and CD161$^+$ V$\delta1^+$ $\gamma\delta$T cells (TCR V$\delta1^+$ NKT cells) in PBMCs were sorted out from HC (n=3). We performed GeneChip analysis using those two cell populations. 4) Cytokine (IFN-γ, TNF-α, IL-4, IL-17) and chemokine (CCL2, CCL3, CCL4, CCL5) secretion assay using TCR V$\delta1^+$ NKT cells from HC and SSc patients was performed. 5) The effect of

culture supernatant of TCR Vδ1$^+$ NKT cells on fibroblast proliferation was evaluated.

Results: 1) The proportion of TCR Vδ1$^+$ NKT cells in PBMCs from SSc patients (mean±SEM, 0.55±0.13%) was significantly higher than that of HC (0.23±0.09%, $p<0.05$), whereas RA (0.38±0.12%) and PM/DM patients (0.23±0.11%) were not. In SSc patients, the proportion of TCR Vδ1$^+$ NKT cells in PBMCs from IP-negative subjects (1.03±0.32%) was significantly higher than that of IP-positive subjects (0.28±0.07%, $p<0.05$). In RA and PM/DM patients, there was no difference between IP-negative and IP-positive subjects. 2) In IP-positive SSc patients, the proportion of TCR Vδ1$^+$ NKT cells correlated negatively with serum KL-6 values ($r=-0.464$, $p<0.05$). 3) 192 genes were highly expressed in TCR Vδ1$^+$ NKT cells compared to CD161$^-$ Vδ1$^+$ γδT cells. One of 192 genes was CCL3 chemokine associating with SSc and IP. 4) Upregulation of CCL3 and downregulation of IFN-γ production were noted in TCR Vδ1$^+$ NKT cells of IP-positive SSc patients upon TCR stimulation compared with HC ($p<0.05$). 5) Fibroblast proliferation was promoted with medium supplemented with culture supernatant derived from IP-positive SSc patients ($p<0.05$), whereas that from HC was not.

Conclusion: TCR Vδ1$^+$ NKT cells might play a regulatory role in the pathogenesis of IP in SSc patients.

IL6 and CCL2 Co-Regulate Fibroblast Dependent Trans-Endothelial Migration Of Mononuclear Cells and Fibrotic Response In Scleroderma. Rebecca Alade[1], Korsa Khan[2], Xu Shiwen[3], Christopher P. Denton[1] and Voon Ong[4]. [1]UCL Medical School, London, United Kingdom, [2]UCL Medical School, London, United Kingdom, [3]Royal Free Hospital, London, United Kingdom, [4]UCL Medical School, London, England.

Background/Purpose: IL6 is a key mediator recently implicated in activation of extracellular matrix (ECM) proteins in scleroderma (SSc) fibroblasts. CCL2 is a proinflammatory chemokine that is overexpressed in diffuse cutaneous systemic sclerosis (dcSSc). We explored interaction between these two major mediators and their role in the recruitment of inflammatory cells and fibroblast ECM production.

Methods: Dermal fibroblasts were cultured from skin biopsies from healthy controls (n=4) and early stage dcSSc (n=4). Peripheral blood mononuclear cells (PBMCs) were isolated from blood samples of the latter group. Induction of CCL2 in dermal fibroblasts by IL6 trans-signalling (via sIL-6R) and the ability of SSc fibroblast derived CCL2 to regulate migration of PBMCs across an endothelial layer in vitro was studied using Transwell migration assays in a co-culture system. The effect of PBMCs-fibroblast cross-talk on induction of ECM proteins: α-smooth muscle actin (αSMA) and Collagen type-I (Col-I) was assessed using neutralising antibodies against CCL2 and/or IL6 ligand-receptor axis and targeted ectodomain shedding inhibition using TNF-α processing inhibitor-1(TAPI-1).

Results: IL6 trans-signalling significantly increased CCL2 expression (mean ± SEM % basal expression) (33± 2.7% $p<0.03$ and 45±5.6% $p<0.04$) in control and SSc fibroblasts respectively. CCL2 expression was reduced in the presence of anti-IL6R in control fibroblasts (63±6.4%, $p<0.04$), but the reduction is not significant in the presence of SSc fibroblast IL6 trans-signalling increased migration of PBMCs (n=4) by 2.1 fold ($p<0.05$) and 4.5 fold ($p<0.03$) in the presence of control fibroblasts and SSc fibroblasts respectively. The migration of PBMCs was significantly reduced by the addition of neutralising antibodies against CCL2 and IL6R (44± 5.1%, $p<0.05$ and 62 ± 5.4%, $p=0.04$) respectively and both antibodies combined (44± 7.3.2%, $p<0.05$) in the presence of SSc fibroblasts.In response to IL-6 trans-signalling, there was increased expression of ECM proteins: αSMA (53 ± 5.9%, $p<0.04$) and Col-I (70± 2.6%, $p<0.03$) at 24-hour in the presence control fibroblasts and αSMA (37± 5.9%, $p<0.03$) and Col-I (47± 3.6%, $p<0.04$) in the presence of SSc fibroblasts. Activation of ECM was significantly abrogated by anti-IL6R by αSMA (46± 4.9%, $p<0.05$) and (58 ± 5.9%, $p<0.04$) in the presence of control and SSc fibroblasts respectively. TAPI-1 reduced PBMC migration in a concentration dependent manner with maximal effect at 50μM by (55± 4.1 % $p<0.04$) and TAPI-1 reduced synthesis of αSMA (37± 4.8 %, $p<0.05$) and Col-I (41± 3.6%, $p<0.03$) respectively. Together these data support a key role for IL-6 trans-signalling in regulating cell migration in SSc and confirm the potential importance of IL-6 and CCL2 in matrix overproduction

Conclusion: Our data suggests that fibroblast-derived CCL2 expression is in part dependent on IL-6 trans-signalling. The IL-6/CCL2 interplay regulates recruitment of PBMCs and IL-6 trans-signalling with intramembrane shedding of IL-6R mediates the fibrotic response. Thus,CCL2/IL6 interplay may be important in SSc pathogenesis and could be targeted therapeutically.

Enhanced Expression Of The Cold-Sensing Receptor-TRPM8 In Scleroderma Endothelial Cells and Skin and Endothelial Dysfunction Following TRPM8 Activation. Yongqing Wang, David R. Giovannucci and Bashar Kahaleh. University of Toledo, Toledo, OH.

Background/Purpose: Cold exposure induces vasospasm and incites reperfusion injury in SSc. The mechanisms responsible for enhanced cold sensitivity in SSc are poorly understood. Transient receptor potential melastatine8 (TRPM8) is a well characterized cold sensing cation channel. To date, TRPM8 expression has not been described in human microvascular endothelial cells (MVEC). In this study we thought to search for TRPM8 expression in SSc MVEC and skin. We also investigated the effects of TRPM8 activation on MVEC gene expression.

Methods: MVEC were isolated from involved SSc skin and from matched healthy control subjects. The expression of TRPM8 was determined by RT-PCR, immunohistochemistry and western blotting. TRPM8 activation in MVEC was triggered by the TRPM8 agonist menthol or by exposure of cells to cold temperature (18C°). The intracellular calcium concentration was determined by Ca^{2+} microfluorometry using the prototypical TRPM8 agonist menthol. The effects of TRPM8 activation on the mRNA expression levels of *ET1*, *NOS3* and *PTGIS* and the expression levels of TRPM8 in SSc-MVEC and SSc skin biopsies were quantitated by real time PCR.

Results: TRPM8 gene and protein expression in HMVEC are demonstrated by RT-PCR, Western blotting and immunohistochemistry. In Ca^{2+} microfluorometry studies, we showed increased MVEC intracellular calcium ($[Ca2^+]_i$) in response to the TRPM8 agonist menthol. The activation of the TRPM8 in HMVEC stimulated by cold significantly increased expression of *ET1* (2.39 folds ± 0.21) and decreased *NOS3* (62% ± 5.1 reduction) and *PTGIS* (61% ± 4.8) expression levels. These effects were attenuated by the addition of the TRPM8 antagonist capsazepine. Similar results were obtained with menthol treated HMVEC. The TRPM8 mRNA expression levels were significantly increased in SSc-MVEC (2.59 fold ± 0.22 vs. control MVEC) and SSc-skin biopsies (25.52 fold ± 2.28 vs. control skin biopsies).

Conclusion: The study demonstrates that human MVEC express functional TRPM8 and that there is increased expression of TRPM8 in SSc skin and in SSc-MVEC. TRPM8 may be involved in cold-induced vascular dysfunction through increase *ET1*, and decrease *NOS3* and *PTGIS* mRNA expression. The increased expression levels of TRPM8 in SSc-MVECs and SSc skin may be involved in enhanced cold sensitivity in SSc. The bulk of TRPM8 skin expression in SSc seems to be extravascular and possibly neuronal.

These results suggest that the blockade of TRPM8 activation could be an effective therapeutic strategy in SSc vasculopathy.

Up-Regulated Expression Of CXCL5 In Circulating Platelets From Patients With Systemic Sclerosis: A Role In Fibrosis. Hidekata Yasuoka, Ken Stern, Yuka Okazaki, Tetsuya Nishimoto, Tsutomu Takeuchi and Masataka Kuwana. Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Systemic sclerosis (SSc) is a systemic fibroproliferative disease characterized by concomitant occurrence of microvascular injury and autoantibody production. It has long been suggested that many processes are shared by physiological wound healing and pathological fibrosis. During wound healing process, platelets are the first cells that home to the site of injury, and contribute to the initiation phase through release of a variety of growth factors, chemokines, cytokines, and inflammatory mediators. Circulating platelets in patients with SSc are known to have activated phenotype, but there are few data regarding their functional properties. In this study, we identified potentially fibrogenic factors specifically up-regulated in platelets from SSc patients.

Methods: We used peripheral blood samples from 49 patients with SSc and 23 age- and sex-matched healthy controls. Proportions of activated platelets and platelet-derived microparticles were examined by expression of an activation marker CD62P using flow cytometry. Genes up-regulated in SSc platelets were screened with the RT^2 profiler™ PCR array that covered 168 genes, and were subsequently verified by semi-quantitative and TaqMan® quantitative PCR. The protein expression levels of candidate genes were examined by Proteome Profiler or immunoblots combined with densitometry using platelet lysates. We further evaluated roles of platelets or the platelet-derived molecule up-regulated in SSc platelets in production of fibronectin in cultures of human dermal fibroblasts. Finally, effects of CXCL5 on fibronectin production were confirmed in cultures of fibroblasts and SSc platelets in the presence or absence of a chemical antagonist or a neutralizing antibody.

Results: Proportions of activated platelets and microparticles were increased in SSc patients than in healthy controls ($P < 0.05$ for both comparisons). By stepwise screening strategies based on comparisons of gene/protein expression profiles between SSc and control platelets, CXCL5 was identified as a platelet-derived factor up-regulated in SSc patients. Fibronectin production was greater in fibroblast cultures with SSc platelets, compared with those with control platelets ($P < 0.05$). Enhanced fibronectin production in cultures with SSc platelets, but not in cultures with control platelets, was partially abolished by a CXCL5 receptor antagonist or a neutralizing antibody to CXCL5. In addition, recombinant CXCL5 promoted in vitro production of fibronectin from fibroblasts.

Conclusion: These results suggest that circulating platelets in SSc patients are phenotypically and functionally altered, and are involved in the fibrotic process through up-regulation of CXCL5.

Autoantibody Diversity In Scleroderma Patients With Antinucleolar Antibodies and Negative For Three Major Disease-Specific Markers. Sarada Nandiwada[1], Troy Jaskowski[2], Maureen D. Mayes[3], Minoru Satoh[4] and Anne E. Tebo[1]. [1]University of Utah, Salt Lake City, UT, [2]ARUP Laboratories, Salt Lake City, UT, [3]University of Texas Health Science Center at Houston, Houston, TX, [4]University of Florida, Gainesville, FL.

Background/Purpose: Antinuclear antibodies (ANA) in a nucleolar pattern (antinucleolar antibodies, ANoA) by indirect immunofluorescence technique correlate with several autoantibody specificities and clinical manifestations in scleroderma (systemic sclerosis, SSc). However, the full repertoire of this autoantibody diversity is not completely defined. In this study, we investigated the breadth of antibody specificities by radioimmunoprecipitation (IP) assay in a subset of SSc patients with ANoA but negative for three main disease markers [topoisomerase-I (topo-1/Scl-70), centromere (ACA) and RNA polymerase III (RNAP III)].

Methods: In a cohort of 1000 patients with SSc, we identified 160 individuals with a positive ANoA and negative for ACA by immunofluorescence and topo-1 and RNAP III by ELISA. All 160-serum samples were further evaluated by IP using ^{35}S-methionine labeled K562 cell extract to identify specificities of ANoA in the sera.

Results: Of the 160 patient specimens investigated, 152 (95%) had antibodies previously reported in SSc. No known antibodies were identified in 8 patients (5%). The repertoire of identifiable autoantibodies included scleroderma specific (U3-RNP, Th/To, PM/Scl, topo I, RNAP III) and non-specific (NOR90, U1-RNP, Su, and Ro60) autoantibodies. The distribution of the specific antibodies based on clinical manifestations and ethnicity is summarized in Table 1. The anti-U3RNP antibody was the most prevalent (49%; 78/160) and occurred predominantly in individuals of African American descent (68%; 53/78) with diffuse SSc (72%; 38/53). Although less prevalent in Caucasians and Hispanics, anti-U3-RNP also correlated with diffuse SSc in these groups. Of note, anti-Th/To autoantibodies were found mainly in limited SSc in Caucasians (85%; 22/26) and Hispanics (70%; 7/10). Anti-PM/Scl antibodies were primarily observed in Caucasians (70%; 16/23) and mostly in patients with limited (62%; 10/16) versus diffuse (38%; 6/16) disease.

Table 1. Scleroderma-specific Autoantibody profile based on race and clinical manifestations in antinucleolar antibody-positive patients

	African Americans (n=62)		Hispanic (n=33)			Caucasians (n=65)		
Marker(s)	Limited (n=19)	Diffuse (n=43)	Limited (n=12)	Diffuse (n=19)	SINE (n=2)	Limited (n=37)	Diffuse S (n=27)	SINE (n=1)
U3-RNP (n=78)	15 (28%)	38 (72%)	2 (17%)	10 (83%)	0 (0%)	0 (0%)	13 (100%)	0 (0%)
Th/To (n=39)	1 (33%)	2 (67%)	7 (70%)	2 (20%)	1 (10%)	22 (85%)	3 (12%)	1 (3%)
PM/Scl (n=23)	0 (0%)	2 (100%)	1 (20%)	3 (60%)	1 (20%)	10 (62%)	6 (38%)	0 (0%)
RNAP I/III (n=4)	0 (0%)	0 (0%)	0 (0%)	2 (100%)	0 (0%)	0 (0%)	2 (100%)	0 (0%)
Topo-1 (n=4)	0 (0%)	1 (100%)	1 (50%)	1 (50%)	0 (0%)	1 (100%)	0 (0%)	0 (0%)
Unknown (n=8)	1 (100%)	0 (0%)	1 (100%)	0 (0%)	0 (0%)	3 (50%)	3 (50%)	0 (0%)

Conclusion: Among AnoA positive SSc patients, anti-U3RNP is the most common specificity (85%, 53/62) in African American and Hispanic (36%, 12/33) whereas anti-Th/To is the most prevalent in Caucasians (40%, 26/65). This study further highlights the relevance of autoantibody diversity and ethnicity in the stratification of SSc patients for management.

Anti-Th/To Antibodies In Various Systemic Rheumatic Diseases Screened By Anti-Rpp25 ELISA. Ann D. Chauffe[1], Eric S. Sobel[1], Michael R. Bubb[1], Westley H. Reeves[1], Michael Mahler[2], Cristina Gascon[3], Jason Y.F. Chan[1], S. John Calise[1], Edward K.L. Chan[1] and Minoru Satoh[1]. [1]University of Florida, Gainesville, FL, [2]INOVA Diagnostics, San Diego, CA, [3]INOVA Diagnostics, Inc., San Diego, CA.

Background/Purpose: Anti-Th/To antibodies (anti-Th) are one of the specificities that show nucleolar staining in indirect immunofluorescence antinuclear antibody test. Anti-Th is associated with systemic sclerosis (SSc), mainly the limited cutaneous variant. However, cases of anti-Th also have been reported in other diseases. Although known for over 20 years, anti-Th is rarely used in routine testing algorithms because immunoprecipitation (IP) is not widely available. One of the components of the Th-complex, namely Rpp25, has been reported as a major autoantigen, recognized by ~80% of anti-Th positive sera in ELISA. The goal of the study was to better characterize the clinical features associated with anti-Th in various autoimmune disease cohorts as identified by anti-Rpp25 ELISA followed by confirmation IP.

Methods: Patients enrolled were seen at Autoimmune Disease Center from 2000 to 2012. All SSc patients' sera had previously undergone RNA-IP. Patients with other rheumatic diseases including 462 systemic lupus erythematosus (SLE), 131 autoimmune inflammatory myopathy (AIM), 63 primary Sjogren's syndrome (SS) and 138 Rheumatoid Arthritis (RA) were screened by anti-Rpp25 ELISA. Borderline and positive cases underwent confirmatory IP. Additionally, antinucleolar staining ANA positives were tested by RNA-IP. The clinical characteristics of the anti-Th (+) patients were then more closely evaluated by reviewing database and chart records.

Results: Overall, anti-Th was confirmed in 17 cases (7 SSc and 10 non-SSc) via Rpp25 ELISA and IP. Prevalence of anti-Th was 6% (7/125) in SSc, 0.6% (3/462) in SLE, 0.7% (1/131) in AIM, 0% (0/138) in RA, 3% (2/63) in SS and 4 others without a rheumatologic diagnosis. Of the 17 anti-Th patients, 15 were Caucasian and 2 were African American and had SLE. The anti-Th SSc patients were mainly the limited cutaneous variant (4/7) and none of them had interstitial lung disease (ILD) or pulmonary arterial hypertension (PAH). Of the non-SSc patients with other rheumatologic diagnoses 3 had SLE, 2 had SS and 1 had AIM but some also had features associated with SSc: 2/6 ILD, 3/6 Raynaud's (RP), 1/6 telangiectasia (TG), 1/6 pitting scars (PS). Four other non-SSc patients without a rheumatologic diagnosis had features typical of SSc: 3/4 RP, 1/4 PS, 3/4 TG, 1/4 ILD, 1/4 PAH which may represent sine-SSc variant.

	Systemic Sclerosis N=7	Other Rheum Diagnosis SLE (3) Sjogren's (2) myositis (1) N= 6	No Rheum Diagnosis N = 4
Female	100% (7/7)	100% (6/6)	75% (3/4)
Caucasian	100% (7/7)	67% (4/6)	100% (4/4)
Age in Years (mean)	48	50	40
ILD	0% (0/7)	33% (2/6)	25% (1/4)

Raynaud's	86% (6/7)	50% (3/6)	75% (3/4)
Telangiectasia	86% (6/7)	17% (1/6)	75% (3/4)
Pitting Scars	0% (0/7)	17% (1/6)	25% (1/4)

Conclusion: Based on anti-Rpp25 ELISA and IP screening, anti-Th is fairly specific for SSc. However, anti-Th was also found in other connective tissue diseases with features associated with SSc and some cases had feature of SSc without sclerodermatous skin changes, thus may be classified sine-SSc.

Systemic Sclerosis Disease Subset Is a Better Predictor Of Long Term Outcome Than Autoantibody Profile. Svetlana I. Nihtyanova[1], Voon H. Ong[2] and Christopher P. Denton[1]. [1]Royal Free and University College Medical School, London, United Kingdom, [2]The Royal Free and University College Medical School, London, United Kingdom.

Background/Purpose: Disease subset has been shown to strongly correlate with survival and risk of organ complications in patients with systemic sclerosis (SSc). Nevertheless evidence in the literature suggests that SSc-specific autoantibodies may be a better predictor of SSc-associated morbidity and mortality.

Methods: We explore subset and autoantibodies as predictors of outcome in a large, well-characterised cohort of consecutive unselected SSc patients.

Results: We analysed 649 contemporary SSc patients, 59% with limited cutaneous (lc)SSc and 41% with diffuse cutaneous (dc)SSc. Of those, 25% carried anti-centromere antibody (ACA), 23% anti-topoisomerase-I antibody (ATA), 10.5% anti-RNA polymerase antibody (ARA), 4.6% anti-U3RNP, 6% anti-U1-RNP, 4% anti-Pm-Scl, 18% were ANA positive, but without a defined ENA reactivity, 3.4% were ANA negative and 6% had other rarer antibodies, including Th/To, Ku, Jo1, Ro, La, SL, PL7, PL12, SL and XR.

As previously described, the strongest association with subset was observed in ACA+ patients, of whom 98% had lcSSc, while ARA+ subjects had predominantly dcSSc (91%). Although more frequent in dcSSc patients, 44% of ATA and 40% of anti-U3RNP subjects had lcSSc.

Cox regression analysis confirmed that ATA has the strongest positive association with pulmonary fibrosis (PF) – HR 3.8 (95%CI 2.9–5.1, $p<0.001$) and ACA has the strongest protective effect – HR 0.1 (95%CI 0.05–0.2, $p<0.001$). In this cohort there was also a significant negative association between PF and ARA (HR 0.5, 95%CI 0.3–0.9, $p=0.018$) and anti-U3RNP (HR 0.2, 95%CI 0.05–0.8, $p=0.023$). Although dcSSc is associated with significantly increased risk of PF, the effect of the antibodies was independent of subset.

Anti-U3RNP was associated with an increase (HR 2.9, 95%CI 1.4–5.8, $p=0.003$) while ATA with a reduction (HR 0.4, 95%CI 0.2–0.8, $p=0.01$) of the overall hazard for PH. Incidence of PH did not differ in the two subsets and correction for subset did not alter the predictive value of the antibodies.

We also confirmed the strong association between scleroderma renal crisis (SRC) and ARA (HR 7.5, 95%CI 4.2–13.2, $p<0.001$) and the protective role of ACA in SRC patients (HR 0.06, 95%CI 0.01–0.4, $p=0.005$), which were observed both within the subsets and for the cohort as a whole. There was also a negative association between SRC and ATA (HR 0.4, 95%CI 0.15–0.9, $p=0.037$) in the whole group, but in the subset analysis the effect held only for dcSSc patients. We found no associations between cardiac SSc and any of the antibodies.

The only antibody specificity that demonstrated significant association with survival in the whole cohort was ACA (HR 0.7, 95%CI 0.5–0.9, $p=0.022$), although in the analysis within subsets the association was no longer significant, suggesting that the better survival among ACA+ patients is due to the predominantly limited skin involvement in this group.

Conclusion: While ANA reactivities are strong predictors of organ complications, generally independent of disease subset, they correlate poorly with survival. Disease subset is a much better predictor of mortality and this may reflect severity rather than presence of individual organ-based complications.

Impact Of Male Sex On Survival In Systemic Sclerosis. Haseena Hussein[1], Peter Lee[2], Cathy Chau[3] and Sindhu R. Johnson[4]. [1]Toronto Scleroderma Research Program, Mount Sinai Hospital, Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Mt. Sinai Hospital, Toronto, ON, [3]Toronto Scleroderma Research Program, Toronto Western Hospital, Mount Sinai Hospital, University of Toronto, Toronto, ON, [4]Division of Rheumatology, Toronto Western Hospital, University Health Network Pulmonary Hypertension Programme, Toronto General Hospital, Mount Sinai Hospital and University of Toronto, Toronto, ON.

Background/Purpose: Systemic sclerosis (SSc) has a female predominance with a female-to-male ratio of 3:1. Sex differences have been seen in many autoimmune diseases; however, little is understood about the effect of sex on SSc disease manifestations and survival. The objectives of this study were to evaluate differences in survival and disease manifestatons between males and females with SSc.

Methods: We conducted a retrospective cohort study of patients from the Toronto Scleroderma Program who fulfilled the American College of Rheumatology (ACR) classification criteria for SSc and were >16 years of age. We evaluated differences in age of onset, disease manifestations, serology, and survival between males and females.

Results: 907 patients (745 females, 162 males) were included. Males more frequently had diffuse SSc than women (45% versus 31%, $p = 0.007$). Men were more likely to have renal crisis (10% versus 7%), abnormal nail fold capillaries (30% versus 25%), digital ulcers (35% versus 32%), esophageal dysmotility (89% versus 85%), telangiectasia (81% versus 77%), and interstitial lung disease (42% versus 32%). Females more frequently had anticentromere antibodies (19% versus 9%), pulmonary arterial hypertension (38% versus 33%), and Raynaud's phenomenon (96% versus 94%). There were 186 deaths (37 males, 149 females). Males had increased mortality compared to females (Hazard Ratio (HR) 1.56, $p=0.02$). The median survival time was 17.3 years for males and 24.7 years for females. After adjusting for differences in SSc subtype, serology and presence of interstitial lung disease, men still had increased mortality compared to females (HR 1.64, $p = 0.009$).

Conclusion: Males with SSc have an increased burden of disease and decreased survival compared to females with SSc.

Early Systemic Sclerosis: Marker Autoantibody Positive Patients Have A Faster Pace Of The Disease. Gabriele Valentini[1], Antonella Marcoccia[2], Michele Iudici[1], Serena Vettori[1] and Giovanna Cuomo[1]. [1]Rheumatology Unit, Second University of Naples, Naples, Italy, [2]Angiology Unit, Sandro Pertini Hospital, Rome, Italy.

Background/Purpose: To investigate whether patients affected with any of the 3 subsets of early systemic sclerosis (SSc) i.e. Raynaud's Phenomenon (RP) with SSc marker autoantibody (ACA or anti-Scl70 or anti-RNA polymerase III or anti-fibrillarin or anti-Th/To) and typical capillaroscopic findings (megacapillaries and/or avascular areas) (subset I); or autoantibody positive only (subset II); or capillaroscopy positive only (subset III) (1) and unsatisfying the 2012 ACR/EULAR classification criteria for SSc (2) at admission differ in the lag time to satisfy the new SSc classification criteria.

Methods: Early SSc patients consecutively admitted to a Rheumatology and an Angiology center and unsatisfying the 2012 ACR/EULAR classification criteria for SSc at admission, were subdivided into the 3 above referred subsets and followed-up for 7–101 months (median 45).

They were re-evaluated six-monthly by history, clinical examination, B-mode echoDopplercardiography and Lung functional study including DLCO evaluation and yearly by lung HRCT to assess whether and when each of them satisfied new ACR/EULAR classification criteria i.e. developed a disease score ≥9 (2).

Results: During the follow-up, 11 out of 21 subset I patients (52.3%) (baseline score 8); 10 out of 15 subset II patients (66.6%) (baseline score 6) and 0 out of 24 subset III patients (baseline score 5–7) satisfied the criteria; the difference being significant between each of the 2 autoantibody positive (subsets I and II) and the capillaroscopic positive-autoantibody negative subset (subset I versus III: X^2 by log rank test=17.45, p=0.0001; subset II versus III: X^2 =11.04, p=0.0009), no difference being detected between the 2 autoantibody positive subsets (X^2 =0.55, p=0.454). The 11 subset I patients satisfied the criteria because of the development of teleangectasias in 5 cases; puffy fingers in 3 cases; lung fibrosis in 2 cases; digital ulcers in 1 case. The 10 subset II patients did it because of the development of at least 2 of the following manifestations: scleroderma capillaroscopic pattern in 5 cases, teleangectasias in 5 cases, puffy fingers in 5 cases, digital ulcers in 3 cases, pulmonary hypertension in 1 case and lung fibrosis in 1 case. Despite the unfulfillment of the criteria, among the 24 subset III patients, 21 of whom already presented puffy fingers at baseline, 2 developed telangectasias, 1 digital ulcers, 4 a DLCO<80%.

Conclusion: We have recently pointed out that autoantibody positive early SSc patients differ from subset III patients in the pattern of activation markers (increased serum concentration of procollagen I carbossipropeptide versus increased serum concentration of E-selectin) and preclinical internal organ involvement (higher prevalence of decreased DLCO) (3). Here we point out that autoantibody positive patients present a faster pace of the disease.

Quantifying Change In Pulmonary Function As a Prognostic Marker In Systemic Sclerosis-Related Interstitial Lung Disease. Owen Moore[1], Susanna Proudman[2], Nicole Goh[3], Tamera Corte[4], Hannah Rouse[1], Oliver Hennessy[1], Vivek Thakkar[5], Joanne Sahhar[6], Janet E. Roddy[7], Peter Youssef[4], Eli Gabbay[7], Peter Nash[8], Jane Zochling[9], Wendy Stevens[5] and Mandana Nikpour[10]. [1]St. Vincent's Hospital, Melbourne, Australia, [2]Royal Adelaide Hospital, Adelaide, Australia, [3]Alfred Hospital, Melbourne, Australia, [4]Royal Prince Alfred Hospital, Sydney, Australia, [5]St Vincent's Hospital, Melbourne, Australia, [6]Monash Medical Centre, Clayton, Australia, [7]Royal Perth Hospital, Perth, Australia, [8]Nambour Hospital, Sunshine Coast, Australia, [9]Menzies Research Institute Tasmania, Hobart, Australia, [10]University of Melbourne, Fitzroy, Australia.

Background/Purpose: Interstitial lung disease (ILD) is a leading cause of mortality in systemic sclerosis (SSc) but it is not severe or progressive in all patients. Serial pulmonary function tests (PFTs) can predict outcomes but there are no established data regarding what is a clinically meaningful decline in these variables in SSc-ILD. We sought to quantify change in pulmonary function as a predictor of outcome in SSc-ILD.

Methods: Patients with SSc with ILD defined by high resolution CT lung scan were identified through a nationwide cohort study. All PFTs performed during follow-up, including forced expiratory volume in one second (FEV1) (L), forced vital capacity (FVC) (L), FEV1/FVC ratio (%), diffusing capacity of the lung for carbon monoxide (DLCO) (ml/min/mmHg) and DLCO by alveolar volume ratio (DLCO/VA) (ml/min/mmHg/L) were retrieved. Demographic and disease-related data were prospectively collected. The rate of change over four years in the absolute value for each variable was calculated for each patient using a regression line of best fit. Percentage change in absolute values over the first year of follow-up from diagnosis of SSc-ILD (±90 days) was determined. The composite outcome variable was deterioration, defined as need for home oxygen or lung transplantation, or death. Univariable Cox regression models were used to determine the relationship between each of rate of decline and percentage decline in each PFT variable and outcome. Receiver operating characteristics (ROC) curves were used to determine the best cut-off points to predict adverse outcomes.

Results: Among 264 patients in whom PFT data were available from time of ILD diagnosis, there were 49 events (38 deaths, 10 prescribed supplemental oxygen, one lung transplant) over a mean (±SD) follow-up of 3.0 (±1.7) years. The rates of decline over time in each of FVC, DLCO & DLCO/VA were significantly predictive of deterioration or death (hazard ratios [HR] of 0.06, 0.637 and 0.06 respectively, p values all <0.0001). Cut-off values of zero (i.e. no overall change in PFTs over four years) gave the optimal sensitivity-specificity trade-off with negative predictive values (NPVs) of 88–96%. The percentage changes in FVC, DLCO and DLCO/VA over one year from diagnosis (±90 days) were significantly associated with outcome (HRs 1.06 [p<0.04], 1.07 [p<0.0001] and 1.05 [p<0.04] respectively). The best trade-off between sensitivity and specificity was a decline in FVC of 10% and in DLCO and DLCO/VA of 15% with NPVs of 92–93%. A decline in DLCO/VA of 15% predicted a poor outcome with a likelihood ratio of 7.62.

Conclusion: The course that SSc-ILD takes is evident within the first 1–4 years following its diagnosis. Patients who have no decline in PFTs over the first 4 years do well. As seen in idiopathic pulmonary fibrosis, a decline within the first year in FVC of 10% or more and DLCO or DLCO/VA of 15% or more bodes badly and identifies patients who should be monitored more closely and considered for therapy.

Validation Of a Novel Radiographic Scoring System For Calcinosis Affecting The Hands Of Patients With Systemic Sclerosis. Lorinda Chung[1], Antonia Maria Valenzuela Vergara[2], David Fiorentino[3], Kate Stevens[2], Shufeng Li[2], Jonathan Harris[4], Charles E. Hutchinson[5], Shervin Assassi[6], Lorenzo Beretta[7], Santhanam Lakshminarayanan[8], Tatiana Rodriguez Reyna[9], Christopher P. Denton[10], Rebecca G. Taillefer[11], Solene Tatibouet[12], Ariane Herrick[13] and Murray Baron[14]. [1]Stanford Univ Medical Center, Palo Alto, CA, [2]Stanford University School of Medicine, Stanford, CA, [3]Stanford University School of Medicine, Redwood City, CA, [4]Salford Royal Hospital, Manchester, United Kingdom, [5]University of Warwick, Coventry, United Kingdom, [6]University of Texas Health Science Center at Houston, Houston, TX, [7]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [8]University of Connecticut School of Medicine, Farmington, CT, [9]Instituto Nacional de Ciencias Médicas y Nutrición, Mexico City, Mexico, [10]Royal Free and University College Medical School, London, United Kingdom, [11]University of Montreal, Montreal, QC, [12]McGill University, Montreal, QC, [13]University of Manchester, Salford, United Kingdom, [14]Jewish General Hospital, Montreal, QC.

Background/Purpose: Calcinosis affects approximately 25% of patients with systemic sclerosis (SSc) and is associated with substantial morbidity. There are currently no validated outcome measures to assess calcinosis severity. We sought to develop and validate a novel radiographic scoring system for calcinosis affecting the hands of patients with SSc for potential use in future clinical trials.

Methods: We assessed the reliability of two types (termed "simple" and "complex") of radiographic scoring systems using hand radiographs from patients with SSc obtained from the University of Manchester. The simple scoring system defined calcinosis severity as mild (single site of low density), moderate (medium density at one or more sites OR a single site of high density), or severe (more than one site of high or mixed density). The complex scoring system was calculated as the sum of scores for 22 weighted areas affecting each hand: % area coverage (0–100) × density (1–3) × weight for each area (Figure 1). Following a 1-hour teleconference training session, 12 investigators (8 rheumatologists, 1 dermatologist, 3 radiologists) scored 12 hand radiographs in random order using both simple and complex scoring systems. After a minimum of 24 hours, each investigator re-scored at least one radiograph. Inter-rater and intra-rater reliability were assessed using a Fleiss kappa or weighted kappa coefficient for the simple system, and intraclass correlation coefficient (ICC) for the complex system.

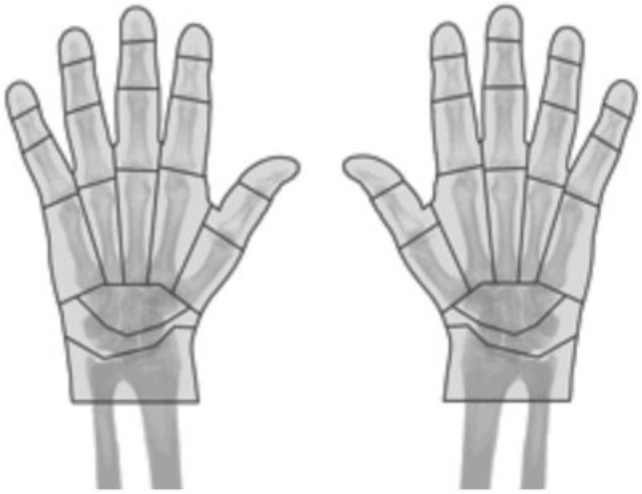

Figure 1. Anatomic Regions of Hand Radiographs for Complex Scoring System

Results: Of 144 assessments, 10 were categorized as mild, 67 as moderate, and 67 as severe using the simple scoring system. The mean time to complete the complex scoring system was significantly longer than the simple scoring system (4.0 vs. 0.4 min, $p<.0001$), and increased with increasing severity of calcinosis (2.0±1.2 min for mild, 3.2±2.3 min for moderate, 5.1±3.7 min for severe). Overall inter-rater reliability for the simple scoring system was poor (kappa=0.39, 95% CI 0.1–0.52), but improved if dichotomized as mild/moderate vs. severe (kappa=0.51, 95% CI 0.26–0.7). Inter-rater reliability was excellent for the complex scoring system (ICC=0.89, 95% CI 0.86–0.92). Intra-rater reliability was moderate for the simple scoring system (kappa=0.67, 95% CI 0.37–0.96), but almost perfect for the complex scoring system (ICC=0.93, 95%CI 0.89–0.97).

Conclusion: We developed a novel radiographic scoring system that accounts for the area coverage, density, and anatomic location of calcinosis affecting the hands in patients with SSc. This scoring system is feasible with excellent reliability and should undergo further validation testing for use in clinical trials.

Diastolic Dysfunction Amongst Autoantibody Subgroups Of Patients With Diffuse Scleroderma. Cory Perugino, John Stephens, Colin O'Rourke and Soumya Chatterjee. Cleveland Clinic, Cleveland, OH.

Background/Purpose: Scleroderma or systemic sclerosis (SSc) is an autoimmune disease characterized by microangiopathy, tissue hypoxia, and fibrosis. At least seven different autoantibodies have been identified with distinct phenotypic associations. A recent study involving patients with limited and diffuse SSc found the prevalence of diastolic dysfunction to be 23%.[1] Serious cardiac involvement defined as symptomatic heart failure, arrhythmia, or pericardial effusion, has been associated with Scl-70 antibodies when compared to RNA polymerase III (Pol-III) positive patients.[2] The aim of this study was to compare prevalence of subclinical diastolic dysfunction in diffuse SSc patients with Pol-III antibodies or Scl-70 antibodies.

Methods: Forty two patients from a major tertiary referral center with known SSc and Pol-III antibodies provided a cohort of 18 patients after the exclusion of those with limited disease. Similarly, 540 patients diagnosed with SSc were screened for Scl-70 antibodies providing a cohort of 24 patients after the exclusion of those with limited disease phenotype. Demographic and echocardiographic indices for diastology were collected. Welch's two-sample t-test and Pearson's chi-squared test were used for continuous and categorical variables, respectively. Logistic regression was used to compare binary measurements and linear regression models for continuous measurements after adjusting for disease duration. A significance level of 5% was used for all analyses.

Results: By unadjusted analysis, 26% of the Pol-III patients had diastolic dysfunction, compared to 74% of the Scl-70 group. This difference reached statistical significance with a p-value of 0.035. After adjusting for disease duration, the estimated odds ratio of having diastolic dysfunction was 4.2 times higher for Scl-70 patients than for Pol-III patients. Although the latter finding did not reach statistical significance, it can be thought of as a trend with a p-value of 0.052. There was no evidence that the septal E/E′ ratio, lateral E/E′ ratio, E/A ratio, or left ventricular mass index differ between the two groups.

Conclusion: Diastolic dysfunction is prevalent amongst SSc patients with diffuse disease. Scl-70 and Pol-III antibodies are associated with diastolic dysfunction in patient with diffuse SSc. After adjusting for disease duration, Scl-70 patients had a proportionally higher prevalence of diastolic dysfunction than Pol-III patients with a trend towards significance. These autoantibodies may be markers of risk for developing myocardial dysfunction.

Effects Of Extracoporeal Shock Wave Therapy To The Digital Ulcers Of Scleroderma:a Pilot Study. Shinichiro Saito[1], Yukiko Kamogawa[1], Kyohei Nakamura[1], Ryu Watanabe[1], Tsuyoshi Shirai[1], Yoko Fujita[1], Hiroshi Fujii[1], Yuko Shirota[1], Tomonori Ishii[1], Hideo Harigae[1], Katsuko Kikuchi[1] and Yasushi Kawaguchi[2]. [1]Tohoku University, Sendai, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Vasculopathy, immunological abnormalities and excessive tissue fibrosis are key elements in the pathogenesis of Scleroderma (SSc). In winter, patients often display Raynaud syndrome, which sometimes causes digital skin ulcers. As these ulcers do not depend on autoimmune or abnormal coagulation, conventional immunosuppressive therapies and anticoagulants are often ineffective. Extracorporeal shock waves (ESW) have been induced primarily in urology for lithotripsy, as its low energy application has yielded evidence for the successful treatment of myocardial ischemia and skin ulcers caused by diabetes. The rationale of this effectiveness is that, new angiogenesis induced by VEGF produced at arteries in the applied area. We tried to introduce ESWT to skin with Raynaud and digital ulcers of SSc.

Methods: We enrolled 9 SSc patients with newly observed digital ulcers: 8 females and 1 male. All 9 patients had been treated with currently available anti-coagulant therapies, especially 6 patients had received intravenous administration of prostaglandin E_1. One ESW therapies (ESWT) sitting consisted of 100 impulses at 0.08～0.25 mJ/mm^2 per area, 20 areas in both hands and 15 in both feet, totaling 7000 impulses. Sitting were done once a week for 9 weeks. We examined the patients, counting the number of skin ulcers, and checking the Rodnan Skin Score (RSS) as well as patient disability index (HAQ, EQ-5D), pain VAS and objective pain index using PainVision™, before and after ESWT. Additionally, the surface skin temperature of all fingers was measured by thermography.

Results: Numbers of skin ulcers were reduced from 5.4 per person to 1.1 by the last treatment of ESWT. Totally, 18 large ulcers (>5mm) were observed from 9 patients before ESWT, 10 disappeared and average size was diminished from 10.8mm into 3.7mm after ESWT. Average HAQ score of 9 patients was improved from 0.57 to 0.43 and other index as EQ5D and PainVision™ scores also showed improvement. Fingers with the lowest temperatures displayed a rise in temperature. This treatment was minimally invasive and could be repeated without any side effects.

Conclusion: ESWT may be a safe and efficacious treatment that can be used as a type of therapy for indolent digital ulcers caused by SSc.

HRCT Predictors Of Decline In FVC% predicted—Implications For Cohort Enrichment For Scleroderma Lung Disease (SLD) Trials. Dinesh Khanna[1], Chi-hong Tseng[2], Robert D. Suh[3], Fereidoun Abtin[4], Athol U. Wells[5], Donald Tashkin[6] and Jonathan Goldin[7]. [1]University of Michigan, Ann Arbor, MI, [2]University of California Los Angeles, David Geffen School of Medicine, Los Angeles, CA, [3]Ronald Reagan UCLA Medical Center, Los Angeles, CA, [4]University of California Los Angeles Medical Center, Santa Monica, CA, [5]Department of Radiology, London, United Kingdom, [6]David Geffen School of Medicine at UCLA, Los Angeles, CA, [7]David Geffen School of Medicine at UCLA, Santa Monica, CA.

Background/Purpose: Moderate-to-severe HRCT-defined lung involvement (total lung involvement or fibrosis) is a predictor of decline in FVC% predicted and mortality in SLD. Various staging systems have been proposed to evaluate lung involvement in SLD: 1. Visual read of maximum fibrosis score (MaxFib) calculated from the zone with the worst extent of abnormality (maximum score), 2. Goh and Wells scoring system of limited vs. extensive disease (visual read of HRCT for total lung involvement of >20% vs. < 20% and incorporation of FVC% predicted of >70% or < 70%, if indeterminate HRCT read), and 3. computer-aided diagnosis (CAD) of quantitative scoring for percentage with fibrosis (QLF) and total lung involvement (QILD) Our objective was to evaluate the performance of different staging systems in the placebo cohort of SLS-I over 1-year period.

Methods: QLF and QILD were assessed using the CAD and maximum fibrosis score (MaxFib) was calculated from the zone with the worst extent of abnormality (maximum score) based on average of 2 thoracic radiologists. 3 thoracic radiologists read the baseline HRCTs from the SLS-I for total lung involvement (as proposed by Goh and Wells) and read by 5% increments and for indeterminate results (15–25% lung involvement), FVC% was used to classify patients into limited vs. extensive disease. Paired t-test was used to assess for statistical significance for change in FVC% predicted (relative change) over 1-year.

Results: 79 patients were randomized to placebo group; 55 completed the 1-year study. Of these, 48 had FVC% data at baseline and 12 months and good quality HRCT and were included in the analysis. 60% of patients had MaxFib of >25%, 66% were classified as extensive disease, 11% and 79% had >20% QLF and QILD, respectively. Greater cut off for each staging system was associated with greater decline in FVC% predicted at 1-year (Table).

	N	Decline in FVC% predicted, Mean (SD)	P value
HRCT Fibrosis score			
0–25%	**19**	**1.1 (14.2)**	**.009**
26–100%	**29**	**−9.6 (12.5)**	
Limited disease	**16**	**2.0(15)**	**.009**
Extensive disease	**32**	**−9.0 (12)**	
Whole QILD			
< 20%	**10**	**−0.03 (8.08)**	**.07**
> 20%	**37**	**−6.8 (15.3)**	
Whole QLF			
< 20%	**42**	**−4.2 (13.8)**	**.09**
> 20%	**5**	**−15.4 (15.4)**	

Conclusion: HRCT-defined lung involvement is a predictor of decline in FVC% predicted over 1 year using different staging systems. The choice of system incorporated in a trial depends on the feasibility and available expertise.

Clinical Characteristics Of Scleroderma Patients With Calcinosis In a Single-Center Cohort. Danielle Velez[1] and Vivien M. Hsu[2]. [1]RWJMS, South Plainfield, NJ, [2]RWJ Med Schl Scleroderma Prog, New Brunswick, NJ.

Background/Purpose: Calcinosis is soft tissue deposition of calcium hydroxyapatite crystals in scleroderma spectrum disorder (SSc) patients. In our cohort, ≤5% of SSc patients have confirmed calcinosis. Common in pressure areas, deposits vary in size and shape, are solid or semi-solid, and range from asymptomatic to widespread and painfully disabling. Risk factors, pathophysiology, and clinical outcomes in SSc-calcinosis patients (SSc-Ca) are unknown, and there is no cure. Therefore, identifying those at risk may lead to understanding of calcinosis development and better management. Herein, we compare clinical characteristics of 17 SSc-Ca patients to 10 control SSc patients without calcinosis.

Methods: Outpatient SSc subjects were invited to enroll as they were seen consecutively in the UMDNJ Scleroderma Program. Clinical information was obtained and calcinosis confirmed by the examining physician or imaging. Fisher's Exact Test was used to measure significance.

Results: Table 1 summarizes clinical characteristics per group. SSc-Ca patients were generally older Caucasian females with limited SSc of longer disease duration, with more bowel (OR 5.71, p = 0.107) and fewer pulmonary complications (OR 0.14, p = 0.046). Calcinosis often presented years after SSc onset (mean 16 y, range 1–41 y). About 1/3 of each group also had polyarthritis or myositis.

Table 1. Clinical characteristics of SSc subjects with and without calcinosis

	Calcinosis (n = 17)	*Control* (n = 10)	*P value*
Gender			
Male	15	5	
Female	2	5	
Race			
Caucasian	16	8	
Non-Caucasian	1	2	
Ave age ± SD (y)	60.3 ± 17.05	48.0 ± 13.75	
SSc mean duration (y)			
From Raynaud	20.9 ± 12.67	10.0 ± 9.76	0.0272
From non-Raynaud	26.3 ± 15.36	9.7 ± 9.99	0.0057
SSc type			
Limited	10	4	
Diffuse	7	6	
Organ involvement (%):			
Small bowel	58	20	0.046
Pulmonary fibrosis	35	80	
Pulmonary hypertension	11	20	
Osteoporosis %	59	10	0.018
% myositis, polyarthritis overlap	35	40	

In this cohort, the most common calcinosis sites were fingertips (100%), IP joints (52%), and elbows (35%). Most subjects (80%) did not consider themselves disabled unless deposits were painful or affected function. Extensive extremity and trunk calcinosis completely disabled 2 patients. Over 50% took analgesics or sought surgical removal as the most common therapy. SSc-Ca patients were more likely to have osteoporosis (OR 12.86, p = 0.018); we observed 2 subjects whose bone density deteriorated rapidly as their disabling calcinosis became widespread.

Laboratory studies showed normal electrolyte and PTH levels in both groups. All subjects were taking vitamin D supplements. The most common antibody was anti-centromere in 44% of SSc-Ca patients and Scl70 in 67% of control patients.

Conclusion: Older Caucasian female subjects with limited SSc more commonly developed calcinosis years after SSc onset, usually involving the hands/fingers. SSc-Ca subjects tended to have osteoporosis, as well as more SSc-related small bowel, but fewer pulmonary complications. It is unclear why some SSc patients develop calcinosis. More studies are needed to evaluate risk factors and clinical outcomes in SSc-Ca patients.

Lung Function and Survival In Systemic Sclerosis Associated Interstitial Lung Disease. Samar M. Shadly[1], Sindhu R. Johnson[2], Cathy Chau[3] and Theodore K. Marras[4]. [1]University Health Network Interstitial Lung Diseases Program, University Health Network and Mount Sinai Hospital, Toronto, ON, [2]Division of Rheumatology, Toronto Western Hospital, University Health Network Pulmonary Hypertension Programme, Toronto General Hospital, Mount Sinai Hospital and University of Toronto, Toronto, ON, [3]Toronto Scleroderma Research Program, Toronto Western Hospital, Mount Sinai Hospital, University of Toronto, Toronto, ON, [4]University Health Network Interstitial Lung Diseases Program, University Health Network and Mount Sinai Hospital, University of Toronto, Toronto, ON.

Background/Purpose: We sought to assess for an association between baseline forced vital capacity (FVC) and diffusion capacity (DLCO) with mortality, and to identify threshold values of forced vital capacity (FVC) and diffusion capacity (DLCO) that predict mortality in systemic sclerosis-associated interstitial lung disease (SSc-ILD).

Methods: The Toronto ILD Program and the Toronto Scleroderma Program cohorts were used to identify SSc-ILD patients. Data were retrospectively collected using a standardized electronic database. The primary outcome was time to all-cause mortality or lung transplant. Kaplan Meier analysis was used to evaluate the association of threshold values of baseline FVC and DLCO and survival. Cox proportional hazards models were used to evaluate the adjusted association of FVC and DLCO with mortality or transplantation.

Results: 1200 patients with SSc were screened to identify 188 SSc-ILD patients, 140 (75%) were female, and 69% had never smoked. 55 (29.3%) patients had pulmonary hypertension. The mean±standard deviation (sd) baseline FVC was 78.1%±20.4% predicted, and DLCO was 59.5%±17.9% predicted. The mean (sd) baseline 6-minute walk test distance was 412 (119) meters. 45 (23.9%) patients received immunosuppressive treatment at baseline. 38 (20%) patients died, and five (2.7%) patients underwent lung transplant. Baseline FVC <80% predicted (p=0.003) or DLCO<80% predicted (p=0.01) were associated with mortality. Unadjusted survival analysis found baseline FVC (Hazard Ratio (HR) 0.97 (0.95, 0.98), p <0.001) and DLCO (HR 0.97 (0.96, 0.99), p=0.002) were associated with survival. In the adjusted analysis, FVC (HR 0.93, p=0.007) and smoking history (HR 5.08, p=0.049) were both independently associated with survival, however DLCO (HR 0.98, p=0.33), age (HR 1.00, p=0.77), pulmonary hypertension (HR 1.97, p=0.46), SSc-specific antibodies (HR 0.50, p=0.39), and immunosuppressive use (HR 0.64, p=0.64) were not.

Conclusion: Our study confirms and extends previous findings that even a mild decrease in baseline FVC (< 80%) is predictive of mortality. However, we did not observe a robust association between DLCO and mortality.

Blood Flow In The Hands Of a Predefined Homogeneous Systemic Sclerosis Population: The Presence Of Digital Ulcers and The Improvement With Bosentan. Jessica Meijs[1], Annemie J.M. Schuerwegh[1], Alexandre E. Voskuyl[2], Joanne P.J. Bloemsaat-Minekus[3] and Madelon C. Vonk[4]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands, [3]Actelion, Woerden, Netherlands, [4]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: Digital ulcers (DU) are complications of systemic sclerosis (SSc) and arise as a result of ischaemia due to vasculopathy of the digital arteries (1). Rosato et al (2) found that SSc patients, who had pulmonary arterial hypertension (PAH) and were treated with bosentan, had improved blood flow in the hands over time. However, as patients with active DU were excluded from their study they were unable to relate blood flow to the presence of DU. This is the first study to examine the relationship between blood flow in the hands of SSc patients and the presence of digital ulcers (DU). Additionally, the effect of bosentan on blood flow in the hand was assessed in a subset of patients who had reduced blood flow relative to healthy subjects.

Methods: Adult patients with SSc and a recent history of DU and healthy subjects were included. Patients were classified into 4 subgroups: no current DU or pitting scars; pitting scars only; new DU; or persistent DU. The hand was categorised into three regions of interest (ROI) and blood flow was measured by laser Doppler perfusion imaging at baseline, 4 and 12 weeks. Patients who had a reduction in blood flow of more than 50% relative to healthy control subjects in ROI 1 on baseline, in at least one of the hands, were treated with bosentan for 12 weeks.

Results: Fifty-two SSc patients and 51 healthy subjects and were included in the analysis. There was no significant difference in blood flow in the hand across the patient subgroups at baseline. Sixteen SSc patients had a reduction of blood flow of ≥50% versus healthy subjects and received bosentan. Bosentan significantly (p<0.05) increased the blood flow in the whole hand after 12 weeks compared with baseline (shown in figure 1).

NO FIGURE SUPPLIED FOR ABS0686Figure 1.** Change in blood flow from baseline to week 4 and 12 with bosentan treatment

Conclusion: No relationship was found between blood flow in the hands of SSc patients and presence of DU. After 12 weeks of bosentan treatment the blood flow had increased in the SSc patients but had not normalised to that of healthy subjects.

687

Role Of Class II Human Leukocyte Antigens In The Progression From Early To Definite Systemic Sclerosis. Barbara Vigone, Alessandro Santaniello, Maurizio Marchini, Gaia Montanelli, Monica Caronni, Adriana Severino, Stefania Celeste and Lorenzo Beretta. Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.

Background/Purpose: Criteria for the diagnosis of Early Systemic Sclerosis (EaSSc) have been formalized by LeRoy and Medsger in 2001 and later validated by Koenig et al (2008), who showed that the vast majority of EaSSc patients develops a definite SSc within few years from EaSSc. The genetic factors that may affect the progression from early to definite SSc are poorly studied.

Methods: One-hundred-fifty-eight consecutive subjects with Raynuad's phenomenon (RP) fulfilling the EaSSc criteria and no other manifestation indicative of SSc (Fransen et al, 2012) at referral were considered. All the patients underwent high-resolution HLA Class II typing by means of PCR with sequence-specific primers ad were retrospectively evaluated in an observational fashion for the appraisal of definite SSc according to the ACR/EULAR proposed criteria for SSc (Pope et al, 2012): patients with a score >9 are classified as definite SSc, where the single items scores are: skin thickening of the fingers of both hands extending proximal to the MCP joints (9); highest between puffy fingers (2) and skin thickening of the fingers (4); highest between digital tip ulcers (2) and pitting scars (3); telangiectasia (2); abnormal nailfold capillaries (2); lung involvement (interstitial lung disease/ PAH- 2), RP (3); SSc-specific antibodies (3). The time-to-event was analyzed by means of Kaplan-Meier and Cox regression analysis; multiple testing correction was performed by 1000-fold permutations test.

Results: One-hundred-nine subjects (69%) developed a definite SSc by the end of the 10-years follow-up period, with a median estimated time-to-progression equal to 45 months from referral. Twenty-eight (17.7%) patients tested positive for anti-Topoisomerase I antibodies, 96 (60.8%) for anti-centromere antibodies (ACA) and 17 (10.8%) for other SSc-specific antibodies. ACA-positivity was associated with a reduced the risk of progression (median=55 vs 23 months, HR=0.67, CI=0.458–0.979, p=0.038). The presence of the HLA DQ5-DR1 haplotype (HLA-DRB1*0101 - HLA-DQA1*0101(4) - HLA-DQB1*0501) strongly reduced the time and the risk of progression (median=108 vs 45 months; HR=0.388, CI=0.211–0.712, p=0.002, permutation p=0.009); the effect of the HLA DQ5-DR1 haplotype was independent from ACA positivity or from the duration of RP in a stepwise multivariate model. Similar results were observed when the single alleles within the HLA-DQ5-DR1 haplotypes were analyzed.

Conclusion: The occurrence of the HLA DQ5-DR1 haplotype reduces the risk of progression from early to definite SSc independently from the autoanticorpal subsets and other factors that may affect the time-to-progression.

Minimal Clinically Important Investigations In Systemic Sclerosis. Jessica Meijs, Anne A. Schouffoer, Nina Ajmone Marsan, Maarten K. Ninaber and Tom W.J. Huizinga. Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: The optimal management of Systemic Sclerosis (SSc) is a challenge due to the complexity of early diagnosis and identification of patients who are at risk of progressive disease. Furthermore, there is no consensus about minimal clinically relevant treatment effect outcome measurements [1]. Besides that, randomized clinical trials about medications that are disease modifying for SSc in terms of disease activity are scarce [2]. The aim of our study was to examine the minimally clinically important investigations for starting immunosuppression in patients with SSc.

Methods: For this study the baseline visits of SSc patients referred to an academically day patient clinic for a two-day health care program between 2009 and 2012 were recorded. This annual program compromised visits to health care professionals and laboratory investigation, HRCT-thorax, lung function, Cardiopulmonary Exercise Test (CPET), echocardiography, ECG, SSc Health Assessment Questionnaire (SHAQ) and Short Form-36 (SF-36). After 2 weeks a multidisciplinary consultation resulted in a change of treatment if appropriate. The change of treatment was divided in start with immunosuppression versus no start with immunosuppression for the analysis. Logistic regression analysis was used to determine the relationship between start and no start with immunosuppression as dependent variable and clinical parameters as independent variables.

Results: Two hundred twenty-seven patients participated in the day care program for at least one visit. Their mean age was 54 years, 82% of the patients were female and 75 patients had a diffuse cutaneous SSc (DcSSc). Fourteen patients had a previous autologous haemopoietic stem cell transplantation and were excluded for the logistic regression analysis. Forty-six patients started with immunosuppression after visiting the day patient clinic.

The univariate regression analysis showed that DcSSc, younger age, shorter disease duration, shorter duration of Raynaud Phenomenon and organ/skin involvement, contractures, dyspnea, crackles, not suffering from calcinosis, higher MRSS, anti-Scl70 positivity, anticentromere negativity, higher ESR, higher CRP, lower Vital Capacitiy, alveolitis on HRCT, pericardial fluid, and the CPET parameters lower wattage and lower VO2 max of predicted were significantly associated with the start of immunosuppression. Multivariate regression analysis showed that male gender, shorter disease duration, higher MRSS, anticentromere negativity, alveolitis and lower VO2 max of predicted were significantly associated with the start of immunosuppression.

Conclusion: Autoantibodies, MRSS, HRCT-thorax and CPET are minimally clinical important investigations that are advocated in clinical evaluation.

Subclinical Biventricular Systolic Function Is Impaired In Patients With Systemic Sclerosis: A Speckle Tracking-Based Echocardiographic Study. Sukru Taylan Sahin[1], Selen Yurdakul[2], Neslihan Yilmaz[3], Yonca Cagatay[3], Saide Aytekin[1] and Sule Yavuz[3]. [1]Istanbul Florence Nightingale Hospital, Cardiology, Istanbul, Turkey, [2]Bilim University, Faculty of Medicine, Cardiology Department, Istanbul, Turkey, [3]Bilim University, Faculty of Medicine, Rheumatology Department, Istanbul, Turkey.

Subclinical biventricular systolic function is impaired in patients with systemic sclerosis: A speckle tracking-based echocardiographic study

Background/Purpose: Myocardial involvement is associated with poor prognosis in patients with systemic sclerosis (SSc). In the present study we aimed to evaluate subclinical left ventricular (LV) and right ventricular (RV) systolic dysfunction in SSc patients without any cardiovascular disease, by using a strain imaging method, "speckle tracking echocardiography" (STE).

Methods: Thirty-six SSc patients were screened, 7 patients were excluded because of ischemic heart disease. We studied 29 patients with SSc (diffuse/ limited: 15/14) and 20 age and sex-matched healthy controls(HC), without any cardiac disease and with preserved LV-EF. Conventional echocardiography and STE-based strain imaging were performed to assess biventricular deformation analyse. Association with anti-Scl 70 was sought in patients with SSc.

Results: In SSc patients (Female/Male: 25/4) the mean age was 47.7 years. Anti Scl-70 was positive in 13 (44.8%) patients. Left ventricular conventional echocardiographic measurements (LV end diastolic diameter, LV end systolic diameter and LV EF) were similar between SSc and HC. Regarding RV conventional parameters, right atrium was significantly enlarged, tricuspidal annular plane systolic excursion (TAPSE) was decreased and systolic pulmonary artery pressure was increased in SSc compared to HC ($p<0.001$). Both LV and RV longitudinal peak systolic strain/ strain rate were significantly impaired in SSc, demonstrating subclinical LV and RV systolic dysfunction ($p\leq0.001$) (table).

Table. Conventional echocardiography and Speckle tracking echocardiography (STE) results of SSc patients and healthy controls.

	SSc	HC	p value
Right atrium (cm)	3.71 ± 0.30	3.43 ± 0.20	0.004
TAPSE (cm)	2.01 ± 0.41	2.82 ± 0.54	0.0001
Systolic PAB (mmHg)	34.13 ± 8.96	22.07 ± 3.87	0.0001
LV longitudinal peak systolic strain (%)	13.3 ± 1.51	18.87 ± 3.78	0.0001
LV strain rate (1/s)	0.31 ± 0.11	1.77 ± 0.54	0.0001
RV longitudinal peak systolic strain (%)	11.83 ± 1.93	14.19 ± 2.29	0.001
RV strain rate (1/s)	0.30 ± 0.18	2.66 ± 0.4	0.0001

Values were presented as mean ±SD. TAPSE;tricuspidal annular plane systolic excursion, PAB; pulmonary artery pressure, LV; left ventricle, RV; right ventricle

We obtained significant positive correlation between TAPSE and RV longitudinal peak systolic strain/strain rate ($r=0.744$ and $r=0.706$, respectively, $p=0.0001$). Systolic PAB was negatively correlated with both LV and RV longitudinal peak systolic strain/strain rate (LV: $r=-0.552$ and $r=-0.637$, respectively, $p<0.001$ and RV: $r=-0.547$ and $r=-0.638$, respectively, $p=0.001$). Anti Scl -70 positive patients had impaired LV longitudinal peak systolic strain and strain rate values, compared to the others, however the difference did not reach statistical significance (13.01 ± 1.26 % to 13.04 ± 1.90 %, $p=0.96$ for strain; 0.30 ± 0.06 1/s to 0.31 ± 0.15 1/s, $p=0.79$ for strain rate).

Conclusion: SSc is associated with myocardial systolic dysfunction. Deformation analysis by STE-based strain imaging is a novel promising modality allowing for detailed measurement of early deterioration in biventricular systolic function in patients with SSc.

Assessment Of The New American and European Classification Criteria For Systemic Sclerosis In The Norwegian Systemic Connective Tissue Disease and Vasculitis Registry. Anna-Maria Hoffmann-Vold[1], Torhild Garen[2], Oyvind Midtvedt[1] and Øyvind Molberg[1]. [1]Oslo University Hospital, Oslo, Norway, [2]Oslo University Hospital Rikshospitalet, Oslo, Norway.

Background/Purpose: To assess the newly established ACR/EULAR classification criteria for systemic sclerosis [1] (SSc) in a large Norwegian SSc registry cohort.

Methods: The Norwegian systemic connective tissue disease and vasculitis registry (NOSVAR) at the Department of Rheumatology, Oslo University Hospital (OUH) was interrogated for all systemic sclerosis (SSc) patients. All the SSc patients included in NOSVAR fulfil either the American Rheumatism Association 1980 classification criteria for SSc (ACR criteria) and/or LeRoy and Medsger's modified criteria for the classification of early SSc. Patients are scored according to the algorithm in the new ACR/EULAR criteria and classified as SSc if scoring 9 points or more. Descriptive statistics are applied to analyse the number of patients meeting the newly established classification criteria for SSc.

Results: NOSVAR includes 381 patients with SSc. 270 SSc patients (71%) fulfil the ACR criteria. The remaining 111 SSc patients meet the modified Medsger and LeRoy criteria for SSc. The mean age at onset is 48 years (SD 0.8), the median disease duration is 10 years (range 1–48 years) and the female to male ratio is estimated to 4:1. The cohort consists of 7 limited (l) SSc patients, 277 limited cutanoeus (lc) SSc patients and 98 diffuse cutaneous (dc) SSc patients. Altogether, 73/381 patients (19%) have bilateral skin thickening extending proximal to the metacarpophalangeal (MCP) joints and are classified as SSc by this criterion alone. Of the remaining 302 patients, 296 gain >9 points by fulfilling other parameters defined in the new ACR/EULAR criteria. Only 6 patients (2%) in the NOSVAR cohort do not meet the new criteria. These 6 patients fulfil only the LeRoy and Medsger's modified SSc criteria and have Raynauds phenomenon, pathological capillaroscopi and a positive antinuclear antibody, but no skin changes.

Conclusion: This study demonstrates the applicability of the new SSc classification criteria in a large, clinical registry cohort. Only 2% of SSc patients in the cohort do not meet the new ACR/EULAR criteria.

Descriptive Review Of Morphea Subjects From a Single Cohort Center. Lesley Portugal[1], Muneera Naeem[2], Lakshmi N. Moorthy[3] and Vivien M. Hsu[4]. [1]Robert Wood Johnson Medical School, New Brunswick, NJ, [2]Mountainside Hospital, Montclair, NJ, [3]Robert Wood Johnson Medical School-UMDNJ, New Brunswick, NJ, [4]RWJ Med Schl Scleroderma Prog, New Brunswick, NJ.

Background/Purpose: Morphea, or localized scleroderma, is an idiopathic, rare fibrotic skin disorder that may result in tissue atrophy, pigment changes, and contractures. Disability may range from purely cosmetic, causing great anxiety, to lifelong functional disability.

Methods: We conducted a retrospective chart review of pediatric and adults diagnosed with morphea at UMDNJ, and data on types of morphea, possible triggering events, disease course, complications and therapies. Descriptive analysis was done on all variables.

Results: Table 1 lists the clinical manifestations: there were 26 subjects (2 males), mostly Caucasians females of mean age 45±24 (10–85 years). Five had known associated autoimmune disease. Only 2 patients had a family history of morphea. Thirty-eight percent had a family history of autoimmune disease including SLE, RA, Crohn's and thyroid disease. Types of morphea, and known triggering events are listed in table 1.

Table 1. Clinical manifestations of 26 morphea subjects

Variables	*Frequency* (n = 26)	*% frequency*
Triggering event		
Unknown	23	88
Lovenox injection	1	
Chicken pox	1	
Previous Schamberg's	1	
Morphea type	7	27
Plaque	8	31
Generalized SQ	3	12
Linear	4	12
Coup de Sabre mixed	3	12
Eosinophilic fasciitis	1	< 1

Sizes ranged from small (<3±1.5 cm) to large (16±16 cm) with (85%) associated itching, tightness, dryness, burning, pain, or contracture requiring intervention. More than 90% had more than one lesion involving the trunk or extremity. Generalized SQ and eosinophilic fasciitis were only found in adults. Elevated CPK and inflammatory markers were more common with extensive disease. Extra-cutaneous manifestations presented in 18 subjects, including arthralgias, fatigue, and Raynaud. Two adults had monoclonal gammopathy associated with GSM. Tissue atrophy occurred in 14 subjects and 81% had long-term cosmetic issues (pigmentary changes), pain or depression due to their lesions. One was functionally disabled.

Twenty-four patients received the following therapy: Topical steroid (n=1), intra-lesional steroid (n=1), UV phototherapy (n=1). Immunosuppression was generally used for extensive disease: Methotrexate (n=17) alone or with systemic corticosteroids, etanercept, penicillamine, hydroxychloroquine, cyclosporine and cyclophosphamide. One patient with GSM required skin grafting. Morphea improved but did not resolve in 19 subjects; only one had resolution after 6 years. One patient had a relapse, two progressed and one child had limb length discrepancy. Of 18 patients with extra-cutaneous manifestations, 5 improved concurrently with their skin lesions.

Conclusion: Many morphea subjects sought therapy for their discomfort or complications. Long-term consequences, including joint pains and cosmetic issues, did not always resolve despite improvement of the morphea. More studies are needed to understand the various types of morphea and its clinical consequences to improve long-term outcomes.

Characterization Of Lower Limb Cutaneous Ulcers In Systemic Sclerosis: The Analysis of 424 Lesions. Jelena Blagojevic[1], Guya Piemonte[2], Laura Benelli[2], Francesca Braschi[2], Ginevra Fiori[2], Felice Galluccio[2], Francesca Bartoli[2], Lorenza Busco[2], Alberto Pignone[2], Giulia Carnesecchi[2], Gemma Lepri[2], Serena Guiducci[2] and Marco Matucci Cerinic[2]. [1]University of Siena, Siena, Italy, [2]University of Florence, Florence, Italy.

Background/Purpose: Cutaneous ulcers reppresent one of the most frequent complications in course of systemic sclerosis (SSc). They are often disabling and difficult to treat. The upper limb ulcers have been evaluated and characterized extensively, but there are only few studies on lower limb ulcers. SSc is characterized by a microangiopathy that represents the hallmark of disease, but concomitant alterations of arterial, venous and lymphatic circulation may contribute to the pathogenesis of the lower limb cutaneous lesions. The aim of the study is to assess the pathogenesis, characteristics and time to healing of the lower limb cutaneous lesions in course of SSc.

Methods: Fifthy-seven consecutive SSc patients with lower limb cutaneous lesions were followed up for four years. All patients performed an accurate health examination and evaluation of cutaneous lesions, routine blood and urine tests with autoantibodies, lipid and glycemic profile and creatinine clearance, videocapillaroscopy and arterial and venous lower limb Color Doppler Ultrasonography. Arteriography was performed in patients with occlusive peripheral arterial disease.

Results: Four hundred and twenty-four (424) lower limb cutaneous lesions were observed. Lesions were divided into: hyperkeratosis, ulcers (loss of tissue) and gangrene. We observed: 275 (64,9%) hyperkeratosis, 144 (33,9%) ulcers and 5 (1,2%) gangrene. The ulcers were subsetted in: primary ulcers (107 (74,3%)), ulcers secondary to hyperkeratosis (17 (11,8%)) and ulcers secondary to calcinosis (20(13,9%)). The mean time to healing was 152 ± 202 days, and recurrence was observed in 31,6% of lesions. The prevalence of amputations was 1,2%. As regards pathogenesis, 16 (28,1%) patients had a significative peripheral arterial disease, 22 (38,6%) had venous insufficiency and 7 (12,4%) presented lymphedema, besides the microangiopathy. Three patients presented simultaneously a peripheral arterial disease and venous pathology. One patient presented lymphedema and venous insufficiency and two patiens had lymphedema and peripheral arterial disease. Four patients with critical arterial stenosis performed the lower limb angiography which confirmed the presence of stenosis with distal distribution.

Conclusion: Our data indicate that lower limb lesions have often a multifactorial pathogenesis in SSc. This is the first study that characterized extensively a large number of lower limb cutaneous lesions in SSc. The comprehension of characteristics and pathogenesis of these lesions is essential for their correct management.

693

Pulmonary Involvement In Mixed Connective Tissue Disease: Slow Progression After 10 Years Of Follow-Up. Leticia Kawano-Dourado[1], Olivia M Dias[1], Fernando U Kay[1], Thais E H Gripp[1], Paula S Gomes[2], Ricardo Fuller[3], Bruno G Baldi[1], Ronaldo A Kairalla[1], Carlos R R Carvalho[1] and M.Teresa C. Caleiro[1]. [1]University of Sao Paulo, Sao Paulo, Brazil, [2]Hospital do Servidor do Estado de Sao Paulo, São Paulo, Brazil, [3]University of Sao Paulo, São Paulo, Brazil.

Background/Purpose: Evaluate the progression of interstitial lung disease (ILD) in a 10-year period of a group of 53 MCTD patients previously evaluated 10 years ago.

Methods: Pulmonary function tests (PFTs) and chest HRCT images were performed: current results were compared with the patientxs own results obtained ten years ago (baseline value). HRCT images were analyzed qualitatively and quantitatively. Two thoracic radiologists scored images independently using a global quantitative score (ILD-HRCT), that gives an estimate of lung involvement (0% – 100%), as previously described. Decreases in forced vital capacity (FVC) of 10%/200ml and/or in carbon monoxide diffusing capacity (DLCO) of 15% were considered significant. Structured interview, and retrospective collection of clinical data was also performed. Ethics committee approval: 0099/11.

Results: From the 53 patients, 7 patients lost follow-up, 3 died, and 4 changed diagnosis. Therefore 39 patients were re-evaluated (table 1): 92% underwent PFTs and 86% chest HRCT.

Table 1. Actual characteristics of the MCTD patients

Characteristic	patients
Number of patients	39
Female (%)	39 (100)
Age mean years (range)	53 (32–76)
Mean duration of MCTD symptoms in years (range)	21 (11–40)
Active smokers n (%)	1 (2,7%)
Ex-smokers n (%)	11 (30,5%)
Pulmonary Arterial Hypertension n (%)	2 (5,5%)
Shortness of breath n (%)	22 (56%)
Chronic cough n (%)	16 (41%)
Raynaud n (%)	32 (82%)
Autoantibodies n (%):	
ANA titer > 1/160	39 (100%)
Anti-dsDNA	0 (0%)
ENA titer > 1/1000	39 (100%)
Anti-SM	0 (0%)
Anti-Ro/SSA	11 (28%)
Anti-La/SSB	1 (2.5%)
Rheumatoid Factor	10 (25.6%)

Treatment was given according to the attending physician. All patients received omeprazol. 5% received only chloroquine, 18% received variable doses of corticosteroids and chloroquine, and 77% received corticosteroids, chloroquine and another medication: azathioprine, methotrexate, cyclophosphamide, or leflunomide.

22% of patients had normal HRCT (0% ILD-HRCT score) baseline and follow-up. In the remaining, ground glass opacities and reticulate were the most common image findings. Signs of fibrosis increased in the follow-up images (honeycomb and bronchiolectasis), nevertheless, overall lung involvement was mild and only slightly progressed (note baseline and follow-up ILD-HRCT score, table 2).

Table 2. Evolution of Chest HRCT findings in MCTD patients in 10 years

Image Finding	Baseline (% patients)	Follow-up (% patients)	p
ground-glass opacities (%)	74	77	ns
Reticulate (%)	65	77	ns
pleural irregularities (%)	35	61	0.042
traction bronchiolectasis (%)	32	58	0.041
Honeycomb cysts (%)	13	45	0.005
esophageal dilatation (%)	68	90	0.029
ILD-HRCT score mean ± SD (%)	9.3 ± 10.3	13.7 ± 15.9	0.016

From the subgroup of patients who had normal baseline PFTs, half of them worsened FVC and/or DLCO in follow-up (mean decrease: FVC −10.4% and DLCO −27%). Despite functional loss, 33% remained with normal follow-up chest HRCT images (0% ILD-HRCT score) and 22% with stable ILD-HRCT scores.

From the subgroup of patients with a restrictive pattern in baseline (mild reduction in FVC and FEV_1 with normal DLCO): Half of them presented a reduction in FVC and/or DLCO (mean decrease FVC: −17.5% and DLCO: −33%).

Conclusion: In this cohort, ILD associated with MCTD was mild in extent and slowly progressed in 10 years in half of the patients. These results suggest that a systematic lung assessment should be performed in all subjects with MCTD in a regular basis.

Peripheral Bone Marrow-Derived Endothelial Progenitor Cells and N-Terminal Probrain Natriuretic Peptide in Scleroderma Mexican Patients With and Without Diastolic Dysfunction: A Preliminary Report. Jesús Sepúlveda[1], Olga Vera-Lastra[2], Maria Pilar Cruz-Dominguez[3], Laura Montiel-Cervantes[1], Joaquín Gómez-León[1], Luis Robles-Espinoza[1], Ramón Lozano-Morales[1], Sergio Mendoza-Alvarez[1], Rubiraida Molina-Aguilar[1], Gabriela Medina[4], Jorge Vela-Ojeda[1] and Luis J. Jara[5]. [1]Instituto Mexicano del Seguro Social, Mexico City, Mexico, [2]MD, Mexico City, Mexico, [3]Hospital de Especialidades Centro Medico Nacional La Raza., Mexico, DF, Mexico, [4]Seris/Zachila s/n La Raza, Mexico City, Mexico, [5]Hospital de Especialidades Centro Medico La Raza, México City, Mexico.

Background/Purpose: Diastolic dysfunction (DD) in systemic sclerosis (SSc) is a marker of increased risk of death. The N-terminal pro-brain natriuretic peptide (NT-proBNP) is a neurohormone released by ventricular and atrial myocytes and cardiac fibroblasts in response to pressure overload. NT-proBNP is highly associated with pulmonary arterial hypertension in SSc and is a potent vasculogenic agent that enhances bone marrow-derived endothelial progenitor cells (EPC) mobilization to cardiac regeneration. Our purpose was to explore the relationship between NT-proBNP levels and peripheral EPC in SSc patients with and without DD.

Methods: Cross-sectional study in 56 SSc adult patients and 28 matched healthy controls. Exclusion criteria: systolic dysfunction, structural cardiopathy, neoplasms, overlap syndrome, diabetes and hypertension. DD (mild, moderate and severe) was determined according to 2009 EAE/ASE guidelines for the evaluation of diastolic function. EPC were characterized in peripheral blood by flow cytometry according to the expression surface markers CD309, CD34 and CD133 and 7AAD as a viability biomarker. CPE were divided in three phenotypes: 1.CD309+CD34+CD133-,2.CD309+CD133+CD34-, and 3. CD309+CD34+CD133+. Serum levels of NT-proBNP were measured by electroquimioluminiscence. SSc patients were divided according to the severity of DD. Statistical analysis data were expressed in median and range and comparison was made with Wilcoxon, Kruskal Wallis and Pearson correlation tests. P value<0.05 was considered significant.

Results: Results are summarized in Table 1. DD prevalence was 62%. NTproBNP was higher in mild, moderate and severe DD. NT-proBNP showed weak linear relation with CD309+CD34+ EPC cells (R=−0.36, p=0.04).

Table 1.

			SSc with DD n=35		
	Healthy controls n= 28	SSc without DD n=21	Mild (n=20)	Moderate or severe (n=15)	P Value
NTproBNP (pg/ml)	21 (15–50)	45.01 (17.3–162.6)	112.5 (35.6–617.5)	251.1 (84.95–965.6)	0.0083
EPC subtypes (cells/μl)					
CD309+CD34+CD133+	1.53 (0.05–5.45)	1.04 (0.07–2.52)	0.47 (0.07–2.91)		0.0007
CD309+CD34+CD133−	0.72 (0.10–3.12)	0.99 (0.16–4.35)	0.90 (0.05–5.51)		0.45
CD309+CD133+CD34−	1.42 (0.32–6.72)	1.19 (0.181–4.68)	1.06 (0.04–3.81)		0.23

Conclusion: NT-proBNP level is increased in patients with SSc and significantly correlates with severity of DD. On the other hand, the EPC subtype CD309+CD34+CD133+, was significantly diminished in patients with DD compared to patients without DD and healthy controls. These results support the role of NT-proBNP and EPC in the development of cardiac disease in SSc patients. A prospective study is necessary in order to define the prognostic significance of NT-proBNP and EPC alterations in SSc mexican patients.

Combined Pulmonary Fibrosis and Emphysema (CPFE) In Systemic Sclerosis. Nicolas Champtiaux[1], Vincent Cottin[2], Eric Hachulla[3], Dominique Valeyre[4], Hilario Nunes[4], David Launay[5], Alice Berezne[6], Bruno Crestani[7], Loic Guillevin[8], Jean-Francois Cordier[2] and Luc Mouthon[9]. [1]Service de Médecine Interne, hôpital Cochin, Assistance Publique-Hôpitaux de Paris (AP-HP), Paris, France, [2]Division of Pneumology, Hôpital Louis-Pradel, Hospices Civils de Lyon, Lyon 1, Lyon, France, [3]Internal Medicine, Lille CEDEX, France, [4]Avicenne Hospital (AP-HP), Bobigny, France, [5]Claude Huriez University Hospital, Lille, France, [6]Paris Descartes University, Internal Medicine department, Cochin Hospital, Paris, France, [7]Hôpital Bichat, Paris, France, [8]Cochin University Hospital, Paris, France, [9]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France.

Background/Purpose: Combined pulmonary fibrosis and emphysema (CPFE) is a recently defined syndrome, in which centrilobular and/or paraseptal emphysema in upper lung zones coexist with pulmonary fibrosis in the lower lobes. These patients have a characteristic lung function profile, with unexpected subnormal dynamic and static lung volumes, contrasting with a significant reduction of carbon monoxide transfer capacity (DLco) and exercise hypoxemia. CPFE has recently been described in association with connective tissue disease. The aim of this study was to describe the recently individualized syndrome of CPFE in a population of patients with systemic sclerosis (SSc).

Methods: In this multicenter case-control study, we retrospectively investigated data from patients with SSc who also had CPFE. The demographic characteristics of the patients, the results of pulmonary function testing, high-resolution computed tomography, and treatment, and the outcomes of the patients were analysed retrospectively. For each patient with CPFE and SSc, two patients with SSc and pulmonary fibrosis without emphysema were included as controls.

Results: Thirty one SSc patients with CPFE were identified and paired with 62 controls. In one center (Cochin), the prevalence of CPFE was 3.5% in SSc patients, and 8.2 % in SSc with interstitial lung disease. CPFE patients with SSc were more likely to be male (77% vs 18%, $p< 10^{-5}$), smokers (84 vs 37%, $p< 10^{-5}$), and to have a limited SSc (62 vs 26%, $p< 0.01$) than control SSc patients. Pulmonary function testing revealed a marked decrease in DLco at diagnosis (39% vs 50% of predicted, $p<0.001$) and at the end of follow-up (30% vs 44%, $p<0.0001$) in CPFE patients compared to controls, despite similar lung volumes (total lung capacity 78 vs 81%, forced vital capacity 78 vs 78%). Autoantibody profiles did not differ significantly between SSc patients with or without CFPE.

During follow up, CPFE patients with SSc developed more frequently pulmonary hypertension (48 vs 12%, $p<0.0001$), had more frequent unscheduled hospitalisation (48% vs 22%, $p<0.01$) and had decreased survival ($p<0.05$ by Log rank test) as compared to those with SSc and pulmonary fibrosis without emphysema.

Conclusion: The CPFE syndrome presents with distinct pulmonary manifestations within the spectrum of lung diseases occurring in patients with SSc, with a higher risk of pulmonary hypertension and a shorter survival as compared to those with pulmonary fibrosis without emphysema.

Chronic Periaortitis With Thoracic Aorta Involvement: A New Subtype Of Large Vessel Vasculitis. Alessandra Palmisano[1], Maria Letizia Urban[2], Domenico Corradi[3], Federico Alberici[1], Carlo Salvarani[4], Carlo Buzio[1] and Augusto Vaglio[1]. [1]University of Parma, Parma, Italy, [2]Nephrology University of Parma, Parma, Italy, [3]Pathology University of Parma, Parma, Italy, [4]Arcispedale S Maria Nuova-IRCCS, Reggio Emilia, Italy.

Background/Purpose: Chronic periaortitis (CP) is characterised by a fibroinflammatory tissue arising from the adventitia of the abdominal aorta and the iliac arteries and spreading into the surrounding retroperitoneum. CP is thought to have an autoimmune origin and to arise as a primary aortitis. Involvement of the thoracic aorta and its main branches has been anecdotally described. We analysed frequency and pattern of involvement of the large thoracic arteries in CP patients.

Methods: We studied 77 consecutive CP patients who had appropriate imaging studies to evaluate thoracic vessel involvement (chest contrast-enhanced CT/MRI, angio-CT/MRI, whole-body CT-PET). All patients underwent routine clinical assessment and laboratory tests.

Results: Twenty-eight patients (36.4%) showed thoracic vessel involvement: 21 had thoracic periaortitis, which surrounded an aneurysmal thoracic aorta in 6 cases and also involved the origin of the epiaortic vessels in 9 cases; 7 patients had thoracic aortic aneurysm without periaortitis. Analysis of demographic and clinical features in the groups with and without thoracic involvement showed, in the former, a higher female prevalence (M/F ratio 14/14 vs 39/10, $P=0.010$), a more advanced age at diagnosis [median(interquartile range) 64.5 (58.3–69.-5) vs 56.0 (50–59) years, $P=0.001$], a higher frequency of constitutional symptoms (86% vs. 59%, $P=0.021$), and a shorter relapse-free survival (log-rank $P=0.025$).

Conclusion: Involvement of large thoracic arteries occurs in about one-third of CP patients. This subset of patients with systemic large vessel involvement shows distinct clinical features, such as a higher female prevalence, a higher age at diagnosis, and a higher frequency of systemic symptoms; in addition, patients with thoracic involvement tend to have a frequently relapsing course. These findings raise the question as to whether this CP subset represents a distinct form of large-vessel vasculitis.

697

Longitudinal Assessment Of Pulmonary Function In 304 Norwegian Patients With Systemic Sclerosis. Anna-Maria Hoffmann-Vold[1], Torhild Garen[2], Oyvind Midtvedt[1], May-Brit Lund[3], Jan Tore Gran[1] and Øyvind Molberg[1]. [1]Oslo University Hospital, Oslo, Norway, [2]Oslo University Hospital Rikshospitalet, Oslo, Norway, [3]Oslo University Hospital, Rikshopitalet, Oslo, Norway.

Background/Purpose: The purpose of this study was to asses sequential pulmonary function measurements (forced vital capacity [FVC] % predicted) in a large systemic sclerosis (SSc) cohort over a mean observation period of 5.2 (+/− 2.8) years.

Methods: The study cohort included all the 304 SSc patients with sequential pulmonary measurements enrolled in the Norwegian systemic connective tissue disease and vasculitis registry (NOSVAR) at the Department of Rheumatology, Oslo University Hospital (OUH). Lung function measurements were registered at baseline and then prospectively at annual follow-up visits. Altogether, 1125 lung function tests were analysed. Patients were segregated according to their baseline unadjusted FVC % predicted (<70% and >70%). Descriptive statistics were applied to obtain baseline characteristics and the FVC% decline over the observation period. Vital status at 1 January 2013 was provided for all participants by the national population register. Kaplan-Meyer and Cox proportional hazard models were used to analyse survival.

Results: In total, 52 patients (17%) had a baseline FVC <70% (Table 1). Patients with a baseline FVC <70% were more often anti-topoisomerase antibody (ATA) positive than patients with baseline FVC >70% (p-value <0.05). They were also more frequently classified as diffuse cutaneous (dc) SSc (p-value <0.001) and with male gender (p-value <0.001). There were 52 deaths during the observation period and the death rate (22/52, 41%) in patients with a baseline FVC < 70% was significantly higher than in patients with baseline FVC >70% (47/205, 19%). The 10-year survival rate was estimated to 69% and 84% for FVC<70% and FVC>70%, respectively (p-value 0.006, data not shown).

Table 1. Clinical characteristics of 304 SSc patients stratified by baseline FVC%

	Baseline FVC		
	<70%	**>70%**	**p-value**
Number of patients (%)	52 (17)	254 (83)	
Age, years (SD)	52.4 (12.9)	54.3 (14.2)	
Disease duration (SD)	7.0 (7.7)	5.6 (7.0)	
Male sex, no (%)	23 (44)	43 (17)	0.000
Ever smoker, no (%)	15 (29)	67 (27)	0.318
Deceased, no (%)	22 (42)	47 (19)	0.000
SSc type			0.000
Diffuse cutaneous SSc, no (%)	26 (50)	51 (20)	
Limited cutaneous SSc, no (%)	26 (50)	201 (80)	
ATA positive	15 (29)	29 (12)	0.000
ACA positive	9 (17)	115 (46)	0.000
Declining FVC, no (%)	15 (29)	99 (39)	0.264

SSc: systemic sclerosis; ATA: anti-topoisomerase antibody, ACA: ant-centromere antibody

The longitudinal analyses showed that 114/304 patients (38%) had declining FVC values over the study period. The mean +/− SD decline in the FVC was −2.2 +/− 9% per year. No significant predictors were detected for progressive lung disease, but the 10-year survival rate was lower in patients with declining FVC compared to patients who did not display significant decline from their baseline FVC value, 74% versus 93% (p-value 0.03, data not shown).

Conclusion: The data from our large SSc cohort suggest that male gender, ATA and dcSSc are associated with early development of restrictive pulmonary disease, as evaluated by the baseline FVC. Moreover, survival is decreased for SSc patients with baseline FVC <70%. Interestingly, survival was also decreased in patients with progressive fall in FVC and this association was independent of the patients' baseline FVC value.

Adverse Events With The Use Of Radiotherapy In Patients With Connective Tissue Diseases and Cancer: A Systematic Review and Meta-Analysis. Maria A. Lopez-Olivo[1], Juan A Martínez-López[2], Jean H. Tayar[3], Mahesh Bavineni[4] and Maria E. Suarez-Almazor[5]. [1]University of Texas. M.D Anderson Cancer Center, Houston, TX, [2]Jiménez Díaz Foundation University Hospital, Madrid, Spain, [3]University of Texs, MD Anderson Cancer Center, Houston, TX, [4]Louisiana State University Lafayette, Lafayette, LA, [5]University of Texas MD Anderson Cancer Center, Houston, TX.

Background/Purpose: In the era of modern medicine, radiotherapy remains a cornerstone for the multi-modality cancer treatment.

Methods: We conducted a comprehensive search for any study describing patients with a connective tissue disorder (CTD) who received radiotherapy and reported adverse events (AEs) in electronic databases (MEDLINE, EMBASE, Web of Science, and The Cochrane Library) from inception through March 2013. Our search strategy was restricted to human subjects and studies published in English, French, or Spanish. Study selection, data collection and quality assessment were independently performed by two pairs of investigators. Our primary outcome was the incidence of AEs from radiotherapy in patients with CTDs. Secondary outcomes included: i) predictive factors of AEs ii) effects of radiotherapy on underlying CTD either flares or increased organ damage; and iii) incidence of de novo CTD in patients receiving radiotherapy and iv) Incidence of recurrent malignancies in patients with CTD receiving radiotherapy. Meta-analyses were performed when there were two or more studies with similar outcomes. AEs were recollected and classified in acute (<90 days) and late (>90 days).

Results: 46 publications were included (5 retrospective cohorts, 6 case series (7 publications), and 34 case reports). Study quality raged from fair to moderate. 832 patients received radiation at palliative or curative doses; 558 patients with a CTD and 274 controls. The age of the included patients ranged from 16–72. Pooled incidence of significant AEs was 8% (95%CI: 4%, 14%) for acute and 13% (95%CI 9%, 17%) for late. Patients with a CTD had 2.4 greater odds of developing a significant late AEs compared with patients without a CTD (95%CI 1.1, 3.9). No differences were found in the rate of significant acute AEs. AEs rates were affected by radiation site (abdominal, pelvic and CNS), concurrent CTD therapy (use of DMARDs, NSAIDs, or steroids versus no treatment), and type of CTD. Compared to patients without CTD, increased risk of severe AEs were observed in patients with rheumatoid arthritis (late AEs: Peto OR 3.8; 95%CI 1.4, 10.3) and scleroderma (acute AE: Peto OR 16.5; 95% CI 1.5, 186.2 and late AEs: Peto OR 6.8; 95%CI 4.0, 46.1). Regarding, the effects of radiation on underlying disease 19 out of 25 patients with scleroderma had exacerbation of symptoms, 2 patients improved with steroids and penicillamine. The pooled incidence of de novo CTD was 18% (95%CI 9%, 28%) and malignancy recurrence was observed in 3% of the patients.

Conclusion: We observed statistically significant increased rates of severe late AEs in patients with CTD undergoing radiotherapy. Although, radiotherapy is an essential component of cancer therapy, oncologists should be aware that patients with rheumatic diseases requiring radiotherapy as a part of the treatment regimen might be at a greater risk of developing severe adverse events.

699

Severity Of Muscle Weakness Predicts Disability In Scleroderma. Julie J. Paik[1], Fredrick M. Wigley[1], Amanda Mejia[2] and Laura K. Hummers[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins Bloomberg School of Publich Health, Baltimore, MD.

Background/Purpose: The Health assessment questionnaire disability index (HAQ-DI) is a self-administered questionnaire that is a patient reported outcome which provides a measure of disability responsive to change in clinical trials in scleroderma. The purpose of this study was to determine if the degree of muscle weakness in scleroderma associates with HAQ-DI scores.

Methods: We queried a large, well characterized cohort of patients with scleroderma to determine whether the presence of muscle weakness associates with abnormal HAQ-DI scores. A total of 2481 patients with scleroderma were enrolled in the database from 1990 until 2010. 1723 patients were included in the analyses since these patients had a complete muscle severity assessment. We defined muscle weakness using the Medsger Muscle Severity Score. A value of 0 indicates no weakness, and a value ranging from 1–4 characterizes the patient at various degrees of weakness. The maximum score recorded from all clinic visits was used. The outcome, HAQ-DI, at their most recent visit was used in this analysis.

Multivariate linear regression was used to calculate effect estimates. Muscle severity scores were modeled as a categorical variable, with an effect estimate for each category 1 to 4, with zero as the reference category. Linear regression on the original data, log-transformed data and inverse-transformed data was performed, but in all cases the residuals showed strong non-normality. A generalized linear model using the gamma distribution with identity link was seen to improve model fit.

Results: 407/1733 patients were weak based on their maximum muscle severity score. The mean age was 52.4 ± 13.7 years old among the weak patients. Age and gender were not different in those who were weak vs. not weak. There were also more weak scleroderma patients who were limited subtype rather than diffuse subtype (p<0.0001).

After controlling for age, sex, disease duration, signs of synovitis, disease subtype, level of gastrointestinal severity score (0–4), and lung function (most recent forced vital capacity (<70%)), the severity of weakness was significantly positively associated with higher scores of the HAQ-DI. For every unit of change in the Muscle Severity score at the Score level of >0 and <4, there was a positive association with the disability score (see Table).

	HAQ-DI (score of 0–3)		
Muscle Severity Score (Reference of 0)	Increase in HAQ-DI score	95% Confidence Interval	p-value
1	0.467	(0.33–.610)	< 0.0001
2	0.692	(0.30–1.09)	< 0.001
3	0.950	(0.78–1.82)	0.033
4	1.050	(0.078–2.01)	0.034

Summary: This study demonstrates that a history of muscle weakness is positively associated with self-reported disability as measured by the HAQ-DI.

Conclusion: Muscle weakness is an independent cause of disability among patients with scleroderma.

Disclosure: J. J. Paik, None; **F. M. Wigley**, None; **A. Mejia**, None; **L. K. Hummers**, None.

Osteoporosis and Fracture Risk In Outpatients With Systemic Sclerosis. Veronica Codullo[1], Flora Inverardi[2], Silvia Breda[3], Laura Bogliolo[4], Francesca De Nard[5], Giovanni Cagnotto[5], Roberto Caporali[6] and Carlomaurizio Montecucco[7]. [1]IRCCS Policlinico San Matteo Foundation, Pavia, Italy, [2]Division of Rheumatology, IRCCS Policlinico San Matteo Foundation and University of Pavia, Pavia, Italy, [3]University of Pavia, IRCCS Foundation Policlinico San Matteo, 27100, Italy, [4]IRCCS Foundation Policlinico San Matteo, Pavia, Italy, [5]University of Pavia/ IRCCS Policlinico San Matteo Foundation, Pavia, Italy, [6]Rheumatology, IRCCS Policlinico San Matteo Foundation and University of Pavia, Pavia, Italy, [7]University and IRCCS Policlinico S. Matteo Foundation, Pavia, Italy.

Background/Purpose: Osteoporosis (OP) is a frequent complication of a number of chronic inflammatory diseases. Only Rheumatoid Arthritis (RA) is included in the FRAX algorythm to calculate fracture risk but also Systemic Sclerosis (SSc) displays many disease-specific OP risk factors (chronic

inflammation, malnutrition, steroid use, etc.) Aim:To determine OP frequency and fracture risk by FRAX in outpatients with SSc

Methods: After consent, in outpatients with SSc (le Roy criteria) of a University Hospital, bone mineral density (BMD) was calculated by Dual Energy X-Ray Absorptiometry (DEXA) at the femoral neck and lumbar spine and FRAX was obtained by the calculation tool (http://www.shef.ac.uk/FRAX). A routine SSc evaluation (according to EUSTAR) was performed as well. Age- and BMI-matched early AR (ACR/EULAR 2010 criteria) patients were enrolled as controls

Results: Seventy-one SSc patients (3:68 M:F, age 66±9yrs, 57:14 limited:diffuse cutaneous, median disease duration 8.5, 2.4–14.7yrs, median disease activity 1, 0.25–2) and 44 AR (11:33 M:F, age 62±12yrs, median DAS28 4.42, 3.94–5) were enrolled. OP was detected in 42/71 (59%) SSc patients. Disease duration was significantly higher in SSc-OP patients (10.5, 4.3–16.6 vs 5.5, 1.6–9.8, $p<0.01$) and it was also significantly associated to OP (OR 1.4, 1.1–1.7, $p<0.01$), even when corrected at a multivariable analysis for other disease-specific features (skin and gastrointestinal involvement, autoantibody subset, median mRSS, disease activity) and OP risk factors (steroid use, smoke, BMI, chronic renal insufficiency). OP in RA patients was significantly lower than in SSc (9/44, 20%, $p<0.001$). Mean femoral BMD was 0.58 (0.53–0.7) in SSc vs 0.72 (0.64–0.82) in RA ($p<0.001$), lumbar mean BMD 0.82 (0.75–0.9) in SSc vs 0.92 (0.81–1) in RA. FRAX for major fracture was not significantly different between groups (low in 47% and 50%, medium in 28% and 40%, high in 25% and 10% of SSc and RA respectively). A diagnosis of SSc was significantly associated to OP (OR=13.2, 4–42.4), even when corrected for steroid use.

Conclusion: We have detected a very high OP frequency in our SSc patients, significantly higher than a control early AR cohort and significantly associated to disease duration. Routine DEXA evaluation and risk factors for OP should always be considered and treated when possible in every SSc patient, especially after 5 years of disease duration

Extension Of Cardiac Damage Through The Delayed Enhancement Of Cardiac Magnetic Resonance: Predictive Value Of a Combined Approach Based On Clinical and Laboratory Findings, EKG-Holter and Cardiac Magnetic Resonance. Silvia Laura Bosello[1], Giacomo De Luca[1], Agostino Meduri[2], Giorgia Berardi[1], Manuela Rucco[1], Giovanni Canestrari[1], Federico Parisi[1] and Gianfranco Ferraccioli[1]. [1]Division of Rheumatology, Institute of Rheumatology and Affine Sciences, Catholic University of the Sacred Heart, Rome, Italy, [2]INSTITUTE OF RADIOLOGY - Catholic University of the Sacred Heart, ROME, Italy.

Background/Purpose: Cardiac involvement is a relevant prognostic determinant in Systemic Sclerosis (SSc), but the diagnosis is often delayed due to the lack of a specific diagnostic algorithm.

Recent studies, screening the hearts of subclinical consecutive SSc patients by delayed enhancement (DE) - cardiac magnetic risonance (CMR), found that 21–66% had midwall DE-CMR. We studied the hearts of symptomatic SSc patients through CMR and we evaluated the role of a combined approach, based on evaluation of clinical symptoms, laboratory findings, EKG-holter and CMR, to characterize cardiac involvement in SSc-patients.

Methods: Thirty-six SSc-patients with symptoms of cardiac involvement (dyspnea, palpitation) and/or signs of cardiac failure and elevation of cardiac enzymes (MB-CK and/or troponin T) underwent EKG-holter and cardiac magnetic resonance (CMR). Median follow-up was 24±0.2 months.

Results: Major EKG-holter modifications were present in 30.6% of patients. CMR study demonstrated T2 hyperintensity in 3 patients while none of the patients presented early gadolinium enhancement and 18 (50.0%) patients presented late gadolinium enhancement (LGE). We identified 3 different patterns of distribution of LGE: subepicardial, midwall and subedocardial. Eleven patients presented a single pattern of distribution, while 7 patients (38.8%) presented more than one: 61.1% of patients presented a midwall distribution of LGE, 33.3% of patients presented a subepicardial LGE with a linear distribution pattern and 22.2% presented a subendocardial LGE distribution. 38% of patients showed hypokinetic area and only one patient an akinetic area. The mean EF of left ventricle was 61.7±10.8%, and of right ventricle was 58.1±10.3%. Hypokinetic and akinetic area corresponded with the LGE area. The extension of LGE on CMR was evaluated according to a standardized left-ventricular segmentation. When CMR demonstrated a DE, the mean number of involved cardiac segments was 3.3±2.7. Segment number *9* was involved in 44.4% of the patients, followed by segments number *3* and *5* (38.9%) and by segment *2* (27.8%). Patients with major abnormalities on EKG-holter presented a higher number of involved myocardial segments on CMR (3.7±2.3) with respect to the patients without EKG-abnormalities (0.9±1.4), ($p=0.012$). After a mean follow-up of 24±0.2 months, 4 patients (16%) died for arrhythmias or heart failure.

All patients, who died at follow-up, had severe dyspnea, elevated cardiac enzymes, myosytis, major EKG-holter abnormalities, reduction of EF and LGE on CMR at baseline; 75% of patients who died had a subendocardial distribution pattern of LGE on CMR.

Conclusion: Our study suggests that a combined approach, based on clinical presentation, laboratory findings, EKG-holter examination and study of distribution of LGE on CMR, is useful to characterize the extension of myocardial damage and to identify patients with a poor outcome related to heart involvement in SSc.

Prediction Of Worsening Of Skin Fibrosis In Patients With Diffuse Systemic Sclerosis Using The EULAR Scleroderma Trials and Research (EUSTAR) Registry. Britta Maurer[1], Nicole Graf[2], Beat A. Michel[1], Carola Metzig[3], Vivian Lanius[3], Dinesh Khanna[4] and Oliver Distler[1]. [1]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]graf biostatistics, Winterthur, Switzerland, [3]Bayer Pharma AG, Berlin, Germany, [4]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: To identify predictive parameters for the progression of skin fibrosis in patients with diffuse cutaneous SSc (dcSSc) to enable 1) risk-stratification in clinical practice and 2) improved cohort enrichment in clinical trials with skin fibrosis as the primary endpoint.

Methods: An observational prospective study using the EUSTAR database was performed. Worsening of skin fibrosis was defined as increase in modified Rodnan skin score (mRSS) >5 points and ≥25% from the 1st to the 2nd visit. Inclusion criteria: dcSSc, ACR criteria fulfilled, mRSS≥7 at 1st visit, valid data for mRSS at 2ndvisit, period in between visits 12±2 months. In the univariate analysis, patients with progressive skin fibrosis were compared to non-progressive patients. Predictive markers with $p<0.2$ were included in the multivariate logistic regression analysis. For validation of the regression models, a second cohort with new patients was extracted from the EUSTAR database 11 months after the first data extraction.

Results: Out of 637 patients fulfilling the inclusion criteria of the original cohort, 9.7% had progressive skin disease. Univariate analysis suggested the following prediction parameters: presence of joint synovitis ($p=0.009$), disease duration ($p=0.023$), mRSS at baseline ($p=0.015$), and the interaction between disease duration (≤15>/15 months, cut-off defined by ROC analysis) and sex ($p=0.020$) as well as the interaction between disease duration and CK elevation ($p=0.047$).

In the multivariate analysis, different prediction models with varying numbers and combinations of the predictors identified in the univariate analysis were compared. The model with the highest prediction success rate (n=8/18, 44.4%) showed an area under the ROC curve of 0.73 (95% CI=0.66–0.79, $p<0.0001$) with an overall accuracy of 89.9% (98.1% for no progression, 14.3% for progression) (Table1).

Table 1. Prediction model for skin progression in dcSSc

Predictors	p-value	OR	95%-CI
Joint synovitis	0.016	2.123	1.147–3.927
Female sex	0.143	0.541	0.238–1.230
Short disease duration* (≤15 months)	0.689	0.752	0.186–3.036
Female sex*short disease duration (≤15 months)	0.033	5.380	1.142–25.342
Low mRSS at baseline (≤22/51)	0.001	6.027	2.113–17.189

Other models with broader inclusion criteria revealed lower prediction success rates, but would simplify the recruiting process (e.g. prediction success rate 23.8% (n=20/84) for a model including low mRSS at baseline (≤22/51) and short disease duration (≤15 months)).

In the validation cohort, out of 188 patients, 6.5% had progressive skin

disease. In the multivariate analysis, essentially the findings from the original cohort were confirmed, including the model in Table 1.

Conclusion: These data from a large cohort analysis including a 2nd verification cohort clearly have an important impact on the future clinical study design in SSc. The identified and validated criteria allow the enrichment for dcSSc patients with progressive active skin fibrosis by up to 4.5-fold.

Correlation Between Patient Self-Report Of Symptoms Of Raynaud's Phenomenon and Objective Assessment Of Digital Microvascular Perfusion Using Infrared Thermography. Marina Scolnik[1], Bhavisha Vasta[2], Darren Hart[2], Jacqueline A. Shipley[2], Sue Brown[2], Eleanor Korendowych[2], Neil J McHugh[3] and John D. Pauling[3]. [1]Rheumatology Section, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [3]Department of Pharmacy and Pharmacology, University of Bath, Bath, United Kingdom.

Background/Purpose: Patient self-report of digital colour changes form the basis of a clinical diagnosis of Raynaud's phenomenon (RP) and help classify patients with early systemic sclerosis (SSc). There is a high reported prevalence of RP symptoms in fibromyalgia syndrome (FMS) but little evidence of a true vasculopathy. We report the findings of a retrospective study designed to evaluate the relationship between patient self-report of digital colour changes and objective assessment of digital microvascular function using infra-red thermography (IRT) in patients with primary RP, SSc and FMS.

Methods: Retrospective review of all patients referred for thermographic evaluation between 2010 and 2012 was undertaken. Our thermographic protocol includes the completion of a patient-reported questionnaire documenting symptoms of RP. Thermographic assessment of the resting longitudinal thermal gradient of all fingers was undertaken by calculating the mean distal dorsal difference (DDD) at 23°C. A negative DDD is suggestive of digital microvascular dysfunction and a DDD of −1 °C or less has previously been reported as clinically relevant. A subsequent case note review was undertaken to select out patients with a clinician diagnosis of primary RP (ANA negative), SSc (sclerodactyly in conjunction with a SSc-specific autoantibody and/or abnormal nail fold capillaroscopy) and FMS (1990 criteria).

Results: 138 patients were evaluated (83 PRP, 12 SSc, 43 FMS). No pattern of digital colour change discriminated between the three groups (Table). In all groups RP symptoms were most frequently monophasic, with white being the most common colour change. In the SSc group, triphasic colour changes were uncommonly reported but thumb involvement was more common than in the other groups (non-significant). Thermographic assessment revealed most pronounced peripheral microvascular dysfunction in SSc followed by primary RP and then FMS respectively. Using the DDD to differentiate between SSc and FMS, area under ROC curve analysis was 0.7 (95% CI, 0.558– 0.842, p 0.036), with an optimal DDD cutoff of −0.76 (66% sensitivity and 65% specificity). Regression analysis did not identify any relationship between thermographic analysis and specific colour changes, pattern of color change or body area affected by RP. After adjusting for vasodilator use and co-morbidities, only current smoking showed an increased risk for a lower DDD (OR 2.9, CI 95% 1.17–7.23, p 0.02).

* p=0.09 vs. FMS	Primary RP (n=83)	SSc (n=12)	FMS (n=43)
Age, mean (SD)	47.8 (14.8)	53.1 (13.6)	43.8 (10.8)
Females, n (%)	64 (77.1)	10 (83.3)	39 (90.7)
White, n (%)	58 (69.9)	9 (75)	29 (67.4)
Blue, n (%)	36 (43.4)	7 (58.3)	14 (32.6)
Red, n (%)	35 (42.2)	5 (41.7)	21 (48.8)
Purple, n (%)	39 (47)	3 (25)	16 (37.2)
Monophasic, n (%)	23 (27.7)	5 (41.7)	14 (32.6)
Biphasic, n (%)	21 (25.3)	4 (33.3)	11 (25.6)
Triphasic, n (%)	17 (20.5)	1 (8.3)	8 (18.6)
Numbness, n (%)	71 (85.5)	12 (100)	41 (95.3)
Symptoms in absence of cold, n (%)	45 (54.2)	8 (66.7)	25 (58.1)
Thumbs involvement, n (%)	30 (36.1)	7 (58.3)	17 (39.5)
Toes involvement, n (%)	65 (78.3)	8 (66.7)	35 (81.4)
Average DDD °C, median (IQR)	−1.05 (4.83)	−2.2 (4.5)	+0.62 (4.92)
Proportion of patients with a mean DDD <−1.0 °C, n (%)	42 (50.6)	8 (66.7)*	15 (34.9)

Conclusion: Patient self-report of RP symptoms are similar across primary RP, SSc and FMS and do not aid disease classification. Objective assessment using IRT revealed strong trends for differences in baseline digital microvascular function across the 3 groups although relatively low patient numbers for SSc hampered data analysis. Despite a similar burden of patient-reported symptoms of RP, normal thermographic appearances were identified in the majority of patients with FMS.

Evaluating The Effects Of Combination Aspirin and Dipyridamole (asasantin retard) On Platelet Function, Oxidative Stress and Peripheral Vascular Function In Primary Raynaud's Phenomenon and Systemic Sclerosis. John D. Pauling[1], Jacqueline A. Shipley[1], Darren Hart[1], Ginger L. Milne[2] and Neil J McHugh[3]. [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]Vanderbilt University, Nashville, TN, [3]Department of Pharmacy and Pharmacology, University of Bath, Bath, United Kingdom.

Background/Purpose: There is evidence of enhanced platelet activation in Raynaud's phenomenon (RP), particularly in systemic sclerosis (SSc). Upon activation, platelets release vasoconstrictive mediators (e.g. thromboxane and serotonin) which may contribute to microvascular compromise. Platelet activation can be inhibited using aspirin (ASA) and dipyridamole (DIP). Pleiotropic effects of DIP include vasodilation and direct antioxidant effects. We investigated the effects of combination ASA and DIP on digital vascular function, platelet function and oxidative stress in primary RP and SSc.

Methods: This was an investigator-led single-centre exploratory open-label phase IIB study. Patients with primary RP and SSc received combination ASA (25mg) and DIP (200mg), given as a single capsule twice daily for 2 weeks. The primary endpoints were the individual components of the Raynaud's Condition Score (RCS) diary. Secondary endpoints included objective assessment of digital vascular response to local cold challenge assessed using infrared thermography (IRT) and laser speckle contrast imaging (LSCI). Platelet function was assessed using light transmission aggregometry (LTA) to adenosine diphosphate (ADP) and arachidonic acid (AA). Plasma levels of p-selectin, soluble CD40 ligand and TGF-beta were measured using ELISA. Urinary levels of 11-dehydro-TxB_2 (metabolite of thromboxane), 2,3-dinor-6-keto-PGF_{1a} (metabolite of prostacyclin) and F_2-isoprostanes (biomarker of oxidative stress) were measured using gas chromatography mass spectrometry.

Results: Nineteen patients were recruited to the study (n=11 SSc). Four patients withdrew due to adverse drug reactions (ADR, headache n=3 and possible allergic reaction n=1). Fifteen patients completed the study (n= 9 SSc). There was significant improvement in the RCS score (median 2.29 [2.27] vs.1.11 [1.52], p=0.006) and the daily frequency of RP attacks (median 2.04 [2.67] vs. 1.32 [2.66], p=0.039). There was no improvement in mean daily duration of RP attacks. There was no improvemnt in objective assessment of digital microvascular responses to cold challenge using IRT or LSCI. There were significant reductions in aggregation to both ADP and AA ($p<0.005$ for all comparisons vs. baseline). The significant reduction in urinary 11-dehydro-TxB_2 levels (398 [198] vs. 157 [170] pg/mg, p=0.001) was lower than expected. There was also a significant reduction in urinary 2,3-dinor-6-keto-PGF_{1a} (147 [93] vs. 135 [130] pg/mg, p=0.017) but no significant change in urinary F_2-isoprostane levels or plasma levels of p-selectin, soluble CD40 ligand and TGF-beta. The commonest ADR was headache, reported in 16/19 (84.2%).

Conclusion: The apparent improvement of RP severity following combination ASA/DIP therapy in patients with primary RP and SSc is likely to be related to placebo effect although the high prevalence of headaches suggests a vasodilatory effect. We did not identify any beneficial effect of treatment on objective assessment of basal digital microvascular perfusion or recovery following local cold challenge. The results of this exploratory study do not support the initiation of larger controlled studies of combination ASA/DIP for peripheral vascular disease in RP or SSc.

Treatment With Rituximab Reduces Activation Of Scleroderma Dermal Fibroblasts. Paolo Fraticelli[1], Salvatore De Vita[2], Nicoletta Franzolini[3], Silvia Svegliati[4], Cecilia Tonnini[4], Barbara Gabrielli[4], Cathryn Anne Scott[5], Giovanni Pomponio[6], Gianluca Moroncini[4] and Armando Gabrielli[4]. [1]Istituto di Clinica Medica, Università Politecnica delle Marche, Ancona, Italy, [2]Rheumatology Clinic, DSMB, University of Udine, Udine, Italy, [3]Presidio Ospedaliero di San Daniele del Friuli, ASS 4 "Medio Friuli, Udine, Italy, [4]Università Politecnica delle Marche, Ancona, Italy, [5]Università degli studi di Udine ·, Udine, Italy, [6]Ospedali Riuniti, Ancona, Italy.

Background/Purpose: There is evidence that B lymphocytes play a role in the pathogenesis of systemic sclerosis (scleroderma). Stimulatory autoantibodies targeting PDGF receptor and activating normal human fibroblasts *in vitro* have been demonstrated in sera from scleroderma patients(1–3). Rituximab is a monoclonal antibody which selectively targets and depletes CD20+ B lymphocytes. We investigated the biological effects of rituximab in six patients with scleroderma and severe skin involvement.

Methods: Six patients with severe skin fibrosis documented by rapidly increasing skin score not responsive to immunosuppressive treatment were treated with 375 mg/m2 per week of intravenous rituximab for a total of four doses. Primary outcomes were the reduction of the levels of anti-PDGF receptor autoantibodies in patients sera and down-regulation of skin fibroblast activation *in vitro*. Stimulatory autoantibodies to the PDGF receptor were detected with a biological assay using IgG immunopurified from patients serum samples at baseline and 3 and 6 months after treatment. Secondary outcomes included the modified Rodnan's skin score, heath assessment of quality of life (HAQ) and visual analogic scale (VAS) for global wellness. CD19+ lymphocyte count was performed monthly to assess B cell depletion.

Results: Significant reduction of the serum levels of anti-PDGF receptor autoantibodies was observed in all patients 3 months after treatment. However, a slight increase was again detected six months after rituximab infusion. Fibroblasts grown from skin biopsies taken 6 months after treatment showed a significant reduction of type I collagen gene expression and down-regulation of the intracellular signalling triggered by anti PDGFR autoantibodies. A decrease of skin score and improvement of disability indexes paralleled biological results. No infusion reaction or adverse effects were recorded.

Conclusion: A single course of rituximab reduced scleroderma fibroblast activation in vitro and the serum levels of anti PDGFR stimulatory autoantibodies. The data provide further evidence of B-cell involvement in the pathophysiology of scleroderma. Targeting B cells may be a promising treatment for scleroderma patients and large, controlled clinical trials are warranted.

Effect Of Aminaftone On Raynaud's Phenomenon Secondary To Systemic Sclerosis: A Double-Blind Prospective, Randomized, Placebo-Controlled Pilot Study. Alessandro Santaniello, Barbara Vigone, Monica Caronni and Lorenzo Beretta. Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.

Background/Purpose: Raynaud's phenomenon (RP) is a pivotal manifestation of systemic sclerosis (SSc) which reflects an underlying vasculopathy. Endothelial activation with increased circulating levels of Endothelin-1 (ET1) are frequently observed in SSc patients due to a deranged vascular homeostasis. Aminaftone (AMNA) –a derivate of the 4-aminobenzoic acid- was found to be capable of reducing the production of ET-1 in endothelial cell cultures. The present work was conducted to assess the role of AMNA in the treatment of RP and vasculopathy secondary to SSc.

Methods: Single-centre, randomized, prospective, double-blinded comparison of AMNA vs placebo. Patients received either 75 mg AMNA 3 times per day for 12 weeks in wintertime, or matching doses of placebo. We compared the number and the severity of RP attacks at baseline and after 12 weeks; furthermore we investigated the effect of AMNA on serum concentrations of ET1.

Results: Twenty-five patients were randomized to receive AMNA or placebo; 23 patients (12 AMNA; 11 placebo) did complete the study; no drug-related averse events were observed. The two distinct groups were statistically overlapping for baseline clinical and demographical characteristics. An encouraging and strong trend on the reduction of the number of RP attacks in the AMNA vs placebo group was observed (median: −67.9% [−40.7%, −83.3%] vs −44.2% [−15.5%,−54.3%]; p=0.06; Mann-Whitney test); no differences in RP severity scores or Rp duration scores were observed. ET-1 serological concentrations were markedly reduced in the treatment arm compared to the placebo arm (median [IQR]: −43.5% [−25.5%, −46.2%] vs 4.9% [−0.6%, 15.9%]; p=0.02; Mann-Whitney test).

Conclusion: Although the primary clinical endpoint was not met, most likely due to the low sample size, AMNA was found to have meaningful effects on ET-1 serum levels. In light of the results of a previous report showing the non-inferiority of AMNA compared to bosentan in the log-term control of peripheral SS-related vascular clinical manifestations, when bosentan was not indicated, we believe that further wider and more focused studies (e.g. on the prevention of DU) may be warranted to investigate the long-term effect of AMNA in SSc.

707

Different Location and Extent Of Impaired Perfusion Of The Choroid Plexus In Primary and Secondary Raynaud's Phenomenon. Francesca Ingegnoli[1], Roberta Gualtierotti[2], Luisa Pierro[3], Elisabetta Miserocchi[4], Giulio Modorati[5], Claudia Del turco[3], Marco Gagliardi[3], Giuseppe Parrinello[3], Tommaso Schioppo[2] and Pier Luigi Meroni[6]. [1]Rheumatology, Istituto G. Pini, University of Milan, Milano, Italy, [2]Division of Rheumatology, Istituto G. Pini, University of Milan, Milano, Italy, [3]Vita-Salute University, San Raffaele Scientific Institute, Milano, Italy, [4]Scientific Institute San Raffaele, University Vita-Salute, Milan, Italy, [5]Ocular immunology and uveitis service, Milano, Italy, [6]Division of Rheumatology, Gaetano Pini Institute, Milano, Italy.

Background/Purpose: Raynaud's phenomenon (RP) is a disorder characterized by systemic vascular dysregulation which has been related with vasospasms and retinal blood flow abnormalities. Nevertheless among the potential complications of RP, eye involvement is often overlooked. The aim of this study was to evaluate the presence of vascular eye involvement measuring the choroidal and macular thickness in a cross-sectional cohort of RP at the first rheumatologic evaluation.

Methods: Thirty adult consecutive RP, without visual symptoms, underwent: clinical evaluation and nailfold capillaroscopy. Sera were tested for anti-nuclear antibodies, anti-dsDNA, anti-extractable nuclear antigens. Patients underwent a complete ocular examination including: best corrected visual acuity; slit lamp biomicroscopy; intraocular pressure measurements and fundus examination; choroidal thickness by Zeiss Cirrus Spectral Domain Optical Coherence Tomography with enhanced depth imaging scan system at the fovea and up to 2 mm at intervals of 1 mm from the fovea in the superior, inferior, nasal and temporal choroid; central foveal thickness (CFT) was also measured. 27 healthy, sex and age-matched, subjects were analysed as control group. Statistical analysis was performed by one-way ANOVA and multiple comparisons.

Results: Eight primary RP (pRP) (median age 53 yrs), 12 early systemic sclerosis (SSc) (median age 57 yrs), 10 RP secondary to suspected connective tissue disease (CTD) (i.e. capillaroscopy abnormalities or antibody positivity and without any symptoms/signs suggesting a CTD) (median age 54 yrs). Slit

lamp biomicrocopy was within normal limits in all patients and fundus examination revealed normal arterial and venous vessels with no capillary abnormalities. The mean best corrected visual acuity was 20/40 and the mean intraocular pressure measurement was 14 mmHg. In pRP, mean choroidal thickness was significantly thinner than healthy controls in the outer nasal (224.8μm vs 289μm; $p<0.05$) and outer temporal (263.3μm vs 299μm; $p<0.05$) regions. In patients with RP secondary to suspected CTD the inner and outer nasal were significantly thinner (244.1μm vs 297.4μm; $p<0.05$ and 199.7μm vs 289μm; $p<0.0001$ respectively). In SSc all the areas examined were significantly thinner than healthy controls except for the inner temporal region which however was decreased: central (250.5μm vs 313.2μm; $p<0.01$), inner inferior (239.9μm vs 293.1μm; $p<0.05$), inner nasal (221μm vs 297.4μm; $p<0.001$), inner superior (243.9μm vs 293.2μm; $p<0.05$), outer temporal (219.3μm vs 299μm; $p<0.001$), outer inferior (229.9μm vs 289.8 μm; $p<0.001$), outer nasal (187μm vs 289μm; $p<0.001$), outer superior (240.4μm vs 293.3μm; $p<0.05$). CFT was also thinner in all the patients than healthy controls although not significant.

Conclusion: A thinner choroidal and macular thickness was observed in all the patients, with progressive decrease from pRP to SSc. These data suggest an early involvement of ocular microcirculation with significant reduction of choroidal perfusion. This process likely starts from the external regions (outer nasal and temporal) in pRP, and becomes more severe and extensive in RP secondary to a suspected CTD and even more severe and in SSc.

Intravenous Immunoglobulin May Be An Effective Therapy In Scleroderma Patients With Refractory Active Diffuse Cutaneous Disease. Corrie Poelman, Laura K. Hummers, Fredrick M. Wigley, Cynthia Anderson, Francesco Boin and Ami A. Shah. Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: A subset of patients with active diffuse cutaneous scleroderma has refractory disease despite traditional immunosuppressive therapy. In this retrospective observational study, we investigated whether intravenous immunoglobulin (IVIG) improved skin thickening in patients with refractory disease compared to data from historical controls.

Methods: Scleroderma patients receiving IVIG to treat diffuse cutaneous disease that was active despite other therapy were identified from the Johns Hopkins Scleroderma Center database and medical record review. The mean modified Rodnan skin score (mRSS) at baseline was compared to the mRSS at 6, 12, 18 and 24 months post-IVIG initiation by paired t-test. Clinical "responders" at 6 and 12 months were defined by a mRSS decline of at least 5 points based on previously published data examining the minimal clinically important difference. Potential predictors of response were examined by Student's t-test, Fisher's exact test, and logistic regression analysis where appropriate. Changes in mRSS at 6 and 12 months were also compared to data from historical controls of 3 large, negative, multicenter, randomized clinical trials of other medications (D-penicillamine (D-pen), Recombinant Human Relaxin (Relaxin), and Oral Bovine Type I Collagen (Collagen) trials) using the Student's t-test.

Results: Out of 66 patients who received IVIG between 2004–2012, 30 were treated for active diffuse cutaneous disease and were included for analysis. The study population had a mean age of 42.7 $\pm$ 14.4 years at scleroderma onset, were predominantly female (80%) and white (86.7%), and had a mean scleroderma disease duration of 3.9 $\pm$ 5.9 years at initiation of IVIG. Patients received an average of 8.3 $\pm$ 4.6 monthly IVIG cycles. Concomitant medication use included methotrexate (10%), mycophenolate (70%), cyclophosphamide (20%), and corticosteroids (33.3%). The mean baseline mRSS was 29.6 $\pm$ 7.2, and this significantly decreased to 24.6 $\pm$ 9.4 ($N=28$; $p=0.0017$) at 6 months, 22.0 $\pm$ 10.1 ($N=26$; $p<0.0001$) at 12 months, 21.0 $\pm$ 11.5 ($N=23$; $p=0.0002$) at 18 months and 15.3 $\pm$ 6.4 ($N=15$; $p<0.0001$) at 24 months. 15/28 patients and 16/26 patients were "responders" to IVIG therapy at 6 and 12 months, respectively. None of the examined parameters (age, disease duration at IVIG initiation, duration of IVIG therapy, autoantibody status, and concomitant immunosuppressive therapy) were associated with responder status at 6 or 12 months.

The mean baseline mRSS in the IVIG group (29.6 $\pm$ 7.2) was similar to that of the Relaxin trial (27.3 $\pm$ 6.9, $p=0.09$), but was significantly higher than that observed in the D-pen (21.0 $\pm$ 8.0, $p<0.0001$) and Collagen (26.1 $\pm$ 7.8, $p=0.023$) trials. At 6 months, the mean change in mRSS was not significantly different in the IVIG group (-5.3 ± 8.0) compared to the Relaxin trial (-4.8 ± 6.99, $p=0.75$); however, at 12 months the mean change in mRSS was significantly better in the IVIG group (-7.9 ± 8.1) than in the D-pen (-2.5 ± 8.6, $p=0.0044$) and Collagen (-3.4 ± 7.1, $p=0.0047$) groups.

Conclusion: This study suggests that IVIG may be an effective therapy for active diffuse cutaneous disease in patients who have been refractory to other immunosuppressive therapies.

Nilotinib (Tasigna™) In The Treatment Of Early Diffuse Systemic Sclerosis: A Single Group, Open Label Pilot Clinical Trial – One Year Results. Jessica K. Gordon[1], Cynthia Magro[2], Uzunma Udeh[1], Daniele Lerner[1], Horatio F. Wildman[2], Wei-Ti Huang[1], Mary K. Crow[1] and Robert F. Spiera[1]. [1]Hospital for Special Surgery, New York, NY, [2]Weill-Cornell Medical Center, New York, NY.

Background/Purpose: Tyrosine kinase inhibitors (TKI) are under investigation for the treatment of diffuse cutaneous Systemic Sclerosis (dcSSc.) Nilotinib is a second-generation TKI which selectively antagonizes c-abl and PDGFR and has a different side-effect profile from imatinib and other TKIs. One year follow-up data from a single group, open label, pilot trial are presented here.

Methods: Ten adult patients (pts) with early progressive dcSSc of <3 yrs since the initial SSc symptom excluding Raynaud's were recruited. Pts were treated with nilotinib 400 mg PO twice daily. Pts were excluded if they had a QTc>450 ms. Concurrent immunosuppressive treatment was not allowed. The primary endpoint was safety as assessed by the number of adverse effects (AEs) and serious (S)AEs, and the primary efficacy endpoint was change in the Modified Rodnan Skin Score (MRSS) after 6 mo of treatment. Secondary endpoints include forced vital capacity (FVC), diffusion capacity (DLCO) and other measures. After 6 mo pts were offered continued treatment for 24 mo. Forearm skin biopsies were performed at baseline and after 6 and 12 mo.

Results: Nineteen pts were screened; 5 were excluded due to QTc>450 ms, and 10 were enrolled. At baseline the median age was 46 (IQR 33, 52), 80% were female, 50% were Caucasian, and disease duration was 0.7 yrs (0.5, 1.7). 30% were Scl70+ and 50% were RNAPol3+. 30% had ILD. 40% had tendon friction rubs. 70% had a worsening MRSS in the month prior to baseline, with a mean MRSS increase between screen and baseline of 2.9 ($p=0.02$) in the group.

Seven pts completed 12 mo of treatment and elected to continue on nilotinib. Three pts discontinued nilotinib within the first 3 mo of treatment - 2 due to Grade 1–2 QTc prolongation and 1 due to progression of preexisting coronary artery disease. During the 12 mo period of observation 71 AEs including 2 SAEs were observed; 75% were considered to be at least possibly related to nilotinib. 92% of AEs were grade 1 or 2.

The MRSS was significantly improved by a mean of 4.1 points or 15% at 6 months and by 6.7 or 25% at 12 months in the 7 completers. The physician global assessment improved significantly as well. No significant difference was observed in the FVC, DLCO, or Scleroderma health assessment questionnaire.

	Baseline	6 months	12 months	p-value 6 mo	p-value 12 mo
MRSS	26.9 $\pm$ 5.4	22.7 $\pm$ 8.0	20.1 $\pm$ 7.3	0.02	0.01
FVC (%pred)	77.4 $\pm$ 12.9	75.4 $\pm$ 12.5	71.7 $\pm$ 11.7	0.17	0.054
DLCO (%pred)	72 $\pm$ 9.9	69.9 $\pm$ 18.1	69.3 $\pm$ 12.39	0.56	0.26
Physician Global Assessment	62.5 $\pm$ 10.8	40.2 $\pm$ 12.7	32.3 $\pm$ 15.3	<0.01	<0.01

Skin biopsies were assessed in a blinded fashion by a dermatopathologist. No significant difference in morphology or skin thickness was observed.

Conclusion: Nilotinib was tolerated by the majority of patients in this study. Tolerability was limited primarily by mildly prolonged QTc, which is a known side effect of nilotinib and an exclusion criterion for continuation in this study. QTc elevation can be seen in dcSSc independent of nilotinib therapy and limited patient eligibility. Although this single-group pilot study is not conclusive, significant improvement of MRSS was seen in an early and actively progressing group of patients. Further study of TKI is warranted in a randomized controlled manner.

Interleukin-6 Driven STAT3 Phosphorylation In Circulating Lymphocytes Is Specific For CD4$^+$ T Cells In Early Rheumatoid Arthritis. Amy E. Anderson[1], Christine Routledge[2], Philip Mawson[2], John D. Isaacs[1] and Arthur G. Pratt[1]. [1]Newcastle University, Newcastle upon Tyne, United Kingdom, [2]The Freeman Hospital, Newcastle upon Tyne, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, inflammatory autoimmune disease, caused by a breakdown in self tolerance. Robust biomarkers are needed which, as well having diagnostic utility, enable its stratification into therapeutically relevant sub-sets. We recently identified a transcriptional signature in circulating CD4$^+$T-cells which predicted RA progression amongst patients attending an early arthritis clinic. As well as appearing most prominently in a diagnostically challenging sub-group of individuals who were seronegative for anti-citrullinated peptide autoantibodies (ACPAs), the signature contained an over-representation of signal transduction and activator of transcription-3 (STAT3) regulated genes, whose expression in turn correlated with serum interleukin (IL)-6. We therefore sought an improved understanding of STAT3 signalling amongst immune cell subsets of an independent early arthritis patient cohort.

Methods: 94 newly presenting patients, naïve to immunomodulatory treatment (including steroids), were recruited from an early arthritis clinic, and followed until diagnoses were confirmed. Basal and IL-6-induced expression levels of p_{Y705}STAT3 (pSTAT3) were determined in T-cell and B-cell subsets using Phosflow, a flow cytometry based method for measuring intracellular phospho-proteins. Contemporaneous serum IL-6, IL-6R and soluble gp130 levels were measured by immuno-assay.

Results: Basal pSTAT3 levels were high in circulating CD4$^+$ T-cells, but low in both CD8$^+$ T-cells and B-cells. Basal pSTAT3 expression correlated with serum IL-6 levels most strongly in CD4$^+$ T-cells and, to a lesser extent, CD8$^+$ T-cells, but not B-cells. The expected pSTAT3 induction following IL-6 stimulation, observed in all subsets, was most pronounced in CD4$^+$ T-cells, and this reflected significantly higher basal IL-6R surface expression in this cell population. Finally, when patients were categorised by diagnostic outcome, ACPA-negative RA patients had significantly higher basal pStat3 in CD4$^+$ T-cells than ACPA-positive RA, inflammatory non-RA and non-inflammatory arthritis patients – a pattern that was not seen in CD8$^+$T-cells or B-cells, and which corroborates our previous observations in respect of STAT3 target gene expression.

Conclusion: Our findings support a particular role for IL-6-driven CD4$^+$ T cell activation, primarily via STAT3, during the induction of RA. Since CD4$^+$ T-cells preferentially express surface IL-6R, a critical role in this setting for *classical* IL-6 signalling (as opposed to *trans* signalling, which is not dependent on IL-6R surface expression) is suggested. Expression of pSTAT3 in CD4$^+$ T-cells may serve as a biomarker for predicting the evolution of RA in ACPA-negative patients and may also be a useful tool for predicting efficacy of therapies which target IL-6 signalling.

1,25(OH)$_2$D$_3$ Inhibits Th17 Cytokine Production and RORγt Expression Through GATA3/IL4-Dependent and -Independent Mechanisms. Wendy Dankers[1], Jan Piet van Hamburg[2], Anne-Marie Mus[1], Patrick S. Asmawidjaja[1], Johannes van Leeuwen[1], Rudi W. Hendriks[1], Louis Boon[3], Edgar Colin[4] and Erik Lubberts[2]. [1]Erasmus MC, University Medical Center, Rotterdam, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands, [3]Bioceros, Utrecht, Netherlands, [4]ZGT, Almelo, Netherlands.

Background/Purpose: Vitamin D has suppressive effects on autoimmune diseases, such as rheumatoid arthritis (RA). One important mechanism of disease suppression by vitamin D is inhibition of Th17 cytokines and the Th17 transcription factor RORγt. On the other hand, vitamin D induces IL-4 and GATA3. Since GATA3 overexpression inhibits experimental Th17-mediated autoimmunity, we studied the contribution of GATA3 in vitamin D-mediated suppression of Th17 polarization.

Methods: We first sorted CD4$^+$ T cells from the spleen of naïve DBA-1 mice and DBA-1 mice immunized with collagen type II (CII) and cultured them under T helper cell polarizing conditions with or without 1,25(OH)$_2$D$_3$, the active form of vitamin D. Furthermore, splenic CD4$^+$ T cells are sorted from wild-type and CD2-GATA3 transgenic mice and cultured under these conditions. Finally, we performed gene-expression profiling on CCR6$^+$cells from treatment-naïve early RA patients.

Results: In cultures of CD4$^+$ T cells from naïve and CII-immunized mice, 1,25(OH)$_2$D$_3$ inhibits Th17 polarization while inducing IL-4 and GATA3 expression. IL-4 inhibition partly reversed the vitamin D-mediated inhibition of Th17 polarization. To study the role of GATA3, we compared CD4$^+$ T cells from wild-type and CD2-GATA3 transgenic mice after culture under Th17 polarizing conditions. In these cultures 1,25(OH)$_2$D$_3$ reduces Th17 differentiation, but the effect of GATA3 overexpression is stronger. Interestingly, combining GATA3 overexpression and 1,25(OH)$_2$D$_3$ treatment reduced IL-17A and RORγt expression even further. Subsequent analysis of gene expression in wild-type CD4$^+$ T cells cultured under Th17 polarizing conditions showed that NFAT-C2, which is involved in IL-17A production, was downregulated by 1,25(OH)$_2$D$_3$. In addition, gene expression analysis in CCR6$^+$ T cells from patients with RA showed that 1,25(OH)$_2$D$_3$also inhibits Th17 cytokine and RORγt expression in humans, while inducing IL-4 and GATA3 expression.

Conclusion: These data show that vitamin D-mediated regulation of Th17 polarization occurs through GATA3-dependent mechanisms, including direct effects on RORγt expression and IL-4-mediated inhibition of Th17 polarization. Moreover, GATA3-independent mechanisms are involved that may include modulation of NFAT-C2. These mechanisms may play a role in the suppressive effect of vitamin D on RA disease activity.

Increased IL-23 Receptor Expression Is Observed On KIR3DL2+ CD4+ T Cells In Ankylosing Spondylitis and Correlates With IL-23R Polymorphisms. A. Ridley, C. Cohen, T. Karaderi, S. Kollnberger, I. Wong-Baeza, J. Shaw, P. Wordsworth and P. Bowness. University of Oxford, Oxford, United Kingdom.

Background/Purpose: T helper 17 (Th17) cells are a subset of pro-inflammatory CD4+ T cells implicated in a number of inflammatory arthritides including the Spondyloarthritides (SpAs). Ankylosing Spondylitis (AS), the commonest spondyloarthropathy, has genetic associations both with HLA-B27 and with IL-23 receptor (IL-23R) single nucleotide polymorphisms (SNPs), however the link remains unexplained. We have previously shown that KIR3DL2+ CD4+ T cells are expanded in the peripheral blood of individuals with AS. The aim of the study was to further characterize KIR3DL2+ CD4+ T cells and to correlate IL-23R expression on KIR3DL2+ CD4+ T cells to IL-23R genotype.

Methods: The frequency and expression level of Th17 markers IL-23R, IL-1R and CCR6 on peripheral blood KIR3DL2+ CD4+ T cells was investigated by flow cytometry (n=15) and confirmed by qRT-PCR (n=3). IL-23R expression on paired peripheral blood and synovial fluid samples from SpA patients was investigated by flow cytometry (n=3). Cytokine production by anti-CD2/3/28-stimulated FACS-sorted KIR3DL2+ and KIR3DL2- CD4+ T cells was investigated using multiplex bead analysis. Immunochip GWAS and ENCODE data were integrated to predict functional SNPs in the IL-23R secondary region of association.

Results: KIR3DL2+ CD4+ T cells were increased in the peripheral blood of HLA-B27+ AS patients, as compared to HLA-B27- healthy controls ($p<0.001$, n= 15), confirming previous findings. KIR3DL2+ CD4+ T cells were enriched for expression of the Th17 phenotypic markers IL23R ($p<0.0001$, n=15), CCR6 ($p<0.0001$, n=15) and IL-1R ($p<0.0001$, n=15), compared to KIR3DL2- CD4+ T cells. IL-23R expression levels were also increased on KIR3DL2+ CD4+ T cells compared to KIR3DL2- CD4+ T cells from AS patients ($p<0.0001$, n=15). SNPs in three (non-coding) putative regulatory regions (PRRs) of

IL-23R were identified (PRR1–3). The presence of the AS risk-associated allele at PRR1 correlated with increased expression of IL-23R on KIR3DL2+ CD4+ T cells ($p=0.031$, $n=13$). KIR3DL2+ CD4+ T cells accounted for the majority of peripheral blood CD4+ T cell IL-23R expression in AS patients, and this was significantly greater compared to HLA-B27- healthy controls ($p<0.01$, $n=15$). KIR3DL2+ CD4+ T cells from AS patients produced significantly more IL-17 than KIR3DL2- CD4+ T cells ($p=0.037$, $n=7$). IL-17 production significantly increased in the presence rIL-23 and rIL-1 ($p=0.029$, $n=7$). Lastly IL-23R expression was increased on KIR3DL2+ CD4+ T cells from SpA synovial fluid samples compared to match peripheral blood samples when available ($p=0.017$, $n=3$).

Conclusion: KIR3DL2-expressing cells constitute the majority of peripheral blood CD4+ T IL-23R-expressing cells in AS and produce increased levels of IL-17. Correlation of IL-23R expression on KIR3DL2+ CD4+ T cells with putative regulatory SNPs suggest genetic and epigenetic control of IL-23R expression may contribute to the pathogenesis of AS.

Interferon Regulatory Factor 2 Haploinsufficiency Deteriorates Imiquimod-Induced Psoriasis-Like Skin Inflammation. Takayuki Kimura, Makoto Sugaya, Makiko Kawaguchi, Sohshi Morimura, Hiraku Suga and Shinichi Sato. The University of Tokyo, Tokyo, Japan.

Background/Purpose: Psoriasis is a T-cell-mediated immunological skin disease with a complex pathogenesis where both genetic and environmental factors are involved. Interferon regulatory factor (IRF)-2 is one of the potential susceptibility genes for psoriasis. IRFs are a family of transcription factors that regulate expression of pro- and anti-inflammatory genes. IRF-2 protein binds the same regulatory sequence as IRF-1, which suppresses transcription of interferon-inducible genes. Topical application of imiquimod, a TLR7/8 ligand, induces psoriasis-like inflamed skin lesions via the IL-17/23 axis. We hypothesized that combination of IRF2 gene status and environmental stimulus (imiquimod) would cause severer skin lesions, serving as a good model of human psoriasis.

Methods: IRF-$2^{+/-}$ and wild-type (WT) mice received a daily topical dose of 62.5 mg imiquimod cream (5%) on a shaved back and ears for 6 consecutive days. Erythema, scaling, and skin thickness were independently scored every day. Total RNA was isolated from skin specimens on day 2 and 5 and reverse-transcribed into cDNA. Macrophage were harvested from peritoneal cavity of naive IRF-$2^{+/-}$ and WT mice and stimulated with 1 or 5 μg/ml of imiquimod for 6 or 24 hours in vitro. Total RNA was isolated and reverse-transcribed into cDNA. Messenger RNA expression of different cytokines was analyzed using a real-time PCR quantification method.

Results: Imiquimod-induced skin inflammation assessed by erythema, scaling, and skin thickness was severer in IRF-$2^{+/-}$ mice than WT mice. In inflamed skin, mRNA expression of TNF-α, IL-12/23p40, IL-23p19, and inducible nitric oxide synthase (iNOS) was increased on day 2, and that of TNF-α, IL-12p35, IL-17A, and iNOS was increased on day 5 in IRF-$2^{+/-}$ mice compared to WT mice. In peritoneal macrophage of IRF-$2^{+/-}$ and WT mice stimulated with imiquimod, mRNA levels of TNF-α, IL-12/23p40, IL-23p19, IL-12p35, IL-36α, and IL-36γ were significantly elevated compared to non-stimulated macrophages. Interestingly, macrophages harvested from IRF-$2^{+/-}$ mice expressed higher levels of TNF-α, IL-12/23p40, IL-23p19 compared to those from WT mice 24 hours after stimulation, while they expressed similar levels of IL-12p35, IL-36α, and IL-36γ. Moreover, elevated mRNA expression of iNOS was observed only in stimulated macrophages derived from IRF-$2^{+/-}$ mice.

Conclusion: These results suggest that IRF-2 haploinsufficiency and a TLR7/8 stimulator regulate cytokine expression in a different manner, developing Th17-associated skin inflammation, which may serve as a good model of human psoriasis.

Combination Blocking Of Interleukin-6 and Interleukin-21 In Experimental Arthritis Inhibits Their Redundant Role In T Helper 17-Driven Joint Pathology. Debbie M. Roeleveld[1], Marije I. Koenders[2], Renoud J. Marijnissen[1], Cheryl L. Nickerson-Nutter[3], Fons A. van de Loo[1] and Wim B. van den Berg[4]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Rheumatology Research and Advanced Therapeutics, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, [3]Pfizer, Cambridge, MA, [4]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: Both IL-6 and IL-21 have been described to drive *in vitro* Th17 differentiation in the presence of TGF-β. We explored whether also *in vivo* IL-6 and IL-21 play an exchangeable and redundant role in Th17 differentiation during experimental arthritis, and to what extent combined blocking of these cytokines inhibits Th17 differentiation and suppresses arthritis development.

Methods: To investigate possible synergistic effects of the IL-6 and IL-21 pathways, arthritis development and Th17 cells were first studied in IL-$6^{-/-}$xIL-$21R^{-/-}$ mice and their wild-type (WT) and single-knockout controls during antigen-induced arthritis (AIA). In addition, the effects of combined IL-6R and IL-21 neutralization were studied in DBA-1J mice treated at various stages of collagen-induced arthritis (CIA).

Results: Mice deficient for either IL-6 or IL-21R showed suppressed AIA compared to WT controls. This disease reduction was accompanied by a significant reduction in CD4+IL17+ T cells in the draining lymph nodes as determined by FACS. Interestingly, mice lacking both the IL-6 and IL-21 signaling pathways showed even stronger disease suppression, and a striking reduction in Th17 levels was observed in these mice.

Based upon these findings, we aimed to confirm the synergistic effects of IL-6/IL-21 with a cytokine-neutralization approach using anti-IL-6R antibodies and sIL-21R-Fc treatment during CIA. Antibodies were given as single treatment or in combination, starting from immunization (day 0) or simultaneous with the booster (day 21).

Combined blocking of IL-6R and IL-21 early during arthritis development (day 0) was a very potent approach to prevent arthritis development, reaching a disease incidence of only 40% at day 35 (isotype control 100%, sIL-21R-Fc 100%, anti-IL-6R 60%). Analyzing the mice that did develop arthritis, we observed that the anti-IL-6R/sIL-21R-Fc combination was also clearly more potent in suppressing the arthritis severity in comparison with the single treatments. Interestingly, blocking the IL-6/IL-21 pathways at a later stage during arthritis development (day 21) was clearly less effective and did not show additional effects to anti-IL-6R treatment alone.

Conclusion: Combined blocking of the IL-6 and IL-21 pathways suppresses Th17 differentiation *in vivo* as demonstrated by our IL-6/IL-21R-deficient mice. However, our neutralization study during CIA shows that to influence arthritis development this IL-6/IL-21 blocking approach only has a limited therapeutic window. These findings suggests that to target Th17-driven joint pathology, blocking Th17 effector cytokines like IL-17 and IL-22 might be more effective than attempting to reduce Th17 cell numbers during active disease.

Protein Phosphatase 5 (PP5) Regulates Methylation Sensitive Gene Expression In CD4+ T Cells. Dipak R. Patel, Gabriela Gorelik and Bruce C. Richardson. University of Michigan, Ann Arbor, MI.

Background/Purpose: CD4+CD28- T cells are enriched in chronic inflammatory diseases like rheumatoid arthritis (RA) and lupus. They are cytotoxic and resistant to apoptosis. Compared to CD28+ cells, CD28- CD4 T cells over-express killer immunoglobulin-like receptors (KIRs) and other pro-inflammatory molecules. These genes are regulated by DNA methylation, so they are over-expressed by CD4 T cells that are demethylated in vitro. This is a result of decreased signaling through the ERK and JNK pathways and, consequently, decreased activity of the DNA methyltransferase enzymes (DNMTs) responsible for DNA methylation. Protein phosphatase 5 (PP5) is a stress induced regulator of gene expression in multiple signaling pathways,

including those involved in aging. It is expressed in CD4+CD28-, but not CD4+CD28+ T cells, and it inhibits both ERK and JNK signaling. We hypothesized that PP5 is over-expressed in CD4+ T cells in patients with RA and lupus, and that over-expressing PP5 in CD4 T cells from healthy donors will induce expression of methylation sensitive genes unique to CD4+CD28- T cells.

Methods: CD4+ T cells were isolated from healthy controls and patients, and PP5 mRNA was measured by RT-PCR. To study the effects of PP5 on gene expression, PBMCs from healthy donors were stimulated with phytohemagglutinin and cultured for 3 days with IL-2. CD4+ T cells were then isolated by negative selection, transfected (Amaxa Nucleofector) with constructs encoding GFP and PP5 or GFP alone, and cultured 24–72 hours. Expression of DNMT1 and methylation sensitive genes was assessed by RT-PCR in sorted CD4+GFP+ T cells. DNMT1 expression was measured 24 hours after transfection, and the other genes were analyzed 72 hours after transfection. Cell surface protein expression was measured by flow cytometry 72 hours after transfection.

Results: Compared to CD4+ T cells from healthy donors, PP5 mRNA is over-expressed in patients with lupus (1.97 fold change $\pm$0.18 SEM, $p=0.03$) and RA (1.6$\pm$0.2, $p<0.05$). When transfected into CD4+ T cells from healthy donors, PP5 increased mRNA levels of KIR (2DL4 gene, 2.4$\pm$0.7 fold, $n=3$, $p=0.04$), perforin (1.38$\pm$0.07 fold, $p=0.03$, $n=3$), CD11a (1.2$\pm$0.1 fold, $p=0.047$, $n=5$), and CD70 (10.5$\pm$4.1 fold, $p=0.03$, $n=7$). PP5 also increased the percentage of cells expressing surface KIRs (33$\pm$7% with control vs. 62$\pm$7% with PP5, $n=7$, $p<0.01$), CD70 (37% with control vs. 63% with PP5), and CD40L (30% with control vs. 54% with PP5). Finally, PP5 caused a corresponding 20$\pm$8% decrease ($n=3$, $p=0.05$) in DNMT1 mRNA expression.

Conclusion: CD4+CD28- T cells, which are enriched in lupus and RA, over-express pro-inflammatory methylation sensitive genes. These data demonstrate, for the first time, that PP5 contributes to the regulation of these genes (KIR, perforin, CD70, CD40L, and CD11a) in CD4+ T cells. PP5 is hypothesized to accomplish this by demethylating regulatory elements in the promoters for these genes, and this is currently being tested. PP5 has not been studied in T cells before, and it potentially links aging and DNA methylation with the pathogenesis of multiple rheumatologic disorders.

The Active Metabolite Of Spleen Tyrosine Kinase Inhibitor Fostamatinib Abrogates The T Cell Priming Capacity Of Dendritic Cells.

Andrew Platt[1], Ross McQueenie[1], Robert Benson[2], John Butcher[1], Martin Braddock[3], James M. Brewer[1], Iain B. McInnes[1] and Paul Garside[1]. [1]University of Glasgow, Glasgow, United Kingdom, [2]Institute of Infection, Immunity and Inflammation, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom, [3]AstraZeneca R&D Alderley Park, Macclesfield, United Kingdom.

Background/Purpose: Spleen tyrosine kinase (SYK) is a core signaling protein that drives inflammatory responses and is fundamental to the propagation of signals via numerous immune-receptors including the B cell receptor (BCR) and Fc receptors (FcRs). The small molecule SYK inhibitor, fostamatinib, has shown evidence of ameliorating inflammation in rheumatoid arthritis (RA) patients. We sought to understand how the active metabolite of fostamatinib, R406, affects the inflammatory response at the cellular level. It has been shown that R406 reduces the response of dendritic cells (DCs) to immune complexes (ICs) and we have previously demonstrated that the area and duration of interaction between T cells and DCs are key determinants in the outcome of an immune response.

Methods: Fluorescence microscopy was combined with CD4+ T cells from T cell receptor transgenic OT-II mice to track antigen-specific interactions between DCs and T cells in vitro.

Results: We have found that R406 reduces the DC-T cell contact area and the number of interactions lasting more than 5 minutes during the initial phase of cellular cross-talk between IC-activated DCs and antigen-specific CD4+ T cells. This led to diminished proliferation with 19.2$\pm$0.5% of OT-II CD4+ T cells undergoing proliferation (and only a maximum of two rounds) after R406 treatment compared with 79.6$\pm$2.0% in vehicle controls. This reduced proliferative capacity of CD4+ T cells was accompanied by reduced expression of the co-stimulatory molecules, ICOS and PD-1, and total blockade of the production of inflammatory cytokines such as IFNg and IL-17.

Conclusion: Our findings indicate a potential mechanism via which this compound may be effective in inhibiting FcR-driven T cell responses and ameliorating chronic articular inflammation.

Patients With Rheumatoid Arthritis Have Impaired Candida Albicans Specific Th17 Responses But Preserved Oral Candida Albicans Protective Immunity.

Shrinivas Bishu[1], E. Wern Su[1], Erich Wikerson[1], Donald M. Jones[1], Kelly A. Reckley[2], Sarah L. Gaffen[1] and Marc C. Levesque[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA.

Background/Purpose: Rheumatoid arthritis (RA) patients are susceptible to infections, even after controlling for the effects of medications. Recent data suggest an important role for the IL-17 producing CD4+ Th17 cell subset in the pathogenesis of RA. Development of Th17 cells is dependent on TNFa, IL-6 and T cell co-stimulation, targets for current biologic therapies for RA. In humans, Th17 cells and IL-17 are necessary for immunity to the commensal fungus *Candida albicans*, and response to biologics in RA is associated with reductions in Th17 cells. There is little published data on *Candida albicans* specific responses in RA. Therefore, our aim was to assess *Candida albicans* specific Th17 responses in RA and to determine the effect of biologic therapies on *Candida albicans* specific Th17 responses.

Methods: Subjects for this study were recruited from the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Registry (RACER). We used flow cytometry to compare the fraction of peripheral blood Th17 and Th1 cells between healthy controls ($n=23$) and RA subjects ($n=48$). To assess *C. albicans* specific peripheral blood Th17 responses and capacity for Th17 differentiation, we used ELISA to determine IL-17A production from peripheral blood mononuclear cells (PBMCs) cultured for 5 days from healthy controls ($n=10$) and RA subjects ($n=37$). PBMC were co-cultured with either heat-killed *C. albicans* (HKC) or Th17 polarizing cytokines. Th17 effector responses were determined by measuring oral *C. albicans* colonization and candidacidal killing using saliva collected from healthy control and RA subjects. Healthy control and RA subject data were compared using Mann-Whitney U tests.

Results: Patients with RA had significantly elevated production of IL-17A during PBMC culture without HKC or cytokines as compared to healthy control PBMC ($p=0.02$). However, IL-17A production by RA PBMC during co-culture with HKC was significantly diminished compared to healthy control PBMC ($p=0.006$) despite equal production of IL-17A during PBMC co-culture with Th17 differentiating cytokines ($p=0.91$). The *C. albicans* specific peripheral blood Th17 defect was associated with a higher propensity towards oral colonization with *C. albicans* of RA subjects compared to healthy controls ($p=0.04$), although RA subjects had preserved salivary candidacidal killing capacity compared to controls ($p=0.82$). Furthermore, the *C. albicans* specific defects were not associated with differences between RA and control subjects in either circulating Th17 cell numbers ($p=0.07$) or the distribution of Th17 cells in the CD161+ ($p=0.82$) and CD45RO+ (memory) ($p=0.37$) compartments. There were no differences in *C. albicans* specific responses in subgroups of RA subjects on oral DMARDs vs. biologics.

Conclusion: We found that despite increased basal IL-17A production by RA PBMC and a preserved ability to respond to Th17 inducing cytokines, RA patients have demonstrable impairments in *C. albicans* specific T cell responses and increased oral colonization with *C. albicans*. Fortunately, biologic therapy (as compared to oral DMARD therapy) did not appear to impact *C. albicans* specific responses.

Mesenchymal Stem Cells and Skin Fibroblasts Both Suppress Early Steps In T Cell Activation In a Nitric-Oxide Dependent Manner.

Runsheng Wang[1], Francoise Meylan[2], Jizhong Zou[3], Mahendra Rao[3] and Richard M. Siegel[4]. [1]NIH/NIAMS, Rheumatology fellowship and training branch, Bethesda, MD, [2]NIH/NIAMS, autoimmunity branch, Bethesda, MD, [3]NIH/NIAMS, center for regenerative medicine, Bethesda, MD, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD.

Background/Purpose: Mesenchymal stem cells (MSCs) are multipotent cells with capacity to differentiate into osteoblasts, chondrocytes, and adipocytes. A phase II study in Europe has shown intravenous infusion of *ex vivo* expanded MSCs might be an effective treatment for steroid-resistant, acute graft-versus-host disease. This result raised the question of whether a similar therapy would be beneficial for autoimmune diseases. Although some studies have shown that MSCs can suppress T cell proliferation, the mechanism (s) by which MSCs suppress T cell function are not well understood. Also, whether the immunosuppressive functions of MSCs are unique to MSCs or a more general function of stromal cells has been questioned. The purpose of this study is to compare the suppressive effect of MSCs from different sources and skin fibroblasts (FB) on T cell activation, proliferation and differentiation, and to examine whether the underlying mechanisms by which suppression occurs are similar.

Methods: Purified mouse TCRβ+ CD44- CD62L^{high} näive T cells were activated with anti-CD3/anti-CD28 antibodies, either alone or in transwell contact-independent co-cultured with human adipose derived stem cells (ADSC), human bone marrow stromal cells (BMSC), human fibroblasts (FB), human umbilical vein endothelial cells (HUVEC). T cell activation and proliferation was analyzed using carboxyfluorescein diacetate succinimidyl ester (*CFSE*) and FlowJo software. T cell surface markers, intracellular cytokine expression, MSCs and FB surface markers were analyzed by flow cytometry.

Results: ADSC and BMSC, but not FB, demonstrate trilineage differentiation potentials. After three days of co-culture of naïve T cells with ADSC, BMSC, FB or HUVEC, proliferation analysis showed that the percentage of divided cells (division index) was lower in ADSC, BMSC, FB groups compared to T-cell-only group and HUVEC group. However, after T cells had divided at least once, no difference in the further cell division (proliferation index) was observed. This indicates that ADSC, BMSC and FB suppress either activation or commitment to enter the cell cycle, rather than proliferation of activated T cells. Stromal cells needed to be present during the first 24 hours of T cell activation, and could not suppress T cell proliferation when added after that. By using sorted Foxp3$^-$T cells, the suppressive effect of stromal cells on T cell proliferation was shown to be independent of Treg. Analysis of naïve CD8 T cells showed similar results. L-NAME, an inhibitor of inducible nitric oxide synthetase (iNOS) reversed the suppressive effects of BMSC, ADSC and FB at a concentration of 50μM.

Conclusion: Mesenchymal stem cells (ADSC and BMSC) and fibroblasts can suppress T cell activation independent of Treg at a stage prior to the first cell division. This suppression can be reversed by inhibition of iNOS. These results indicate that immunomodulatory function is not unique to MSCs, and may be unrelated to their "stemness". Stromal cells with different tissue origins such as skin-derived fibroblasts probably share similar properties.

Disclosure: R. Wang, None; **F. Meylan**, None; **J. Zou**, None; **M. Rao**, None; **R. M. Siegel**, None.

719

Mammalian Target Of Rapamycin (mTOR) Skews T Cell Lineage Development In Systemic Lupus Erythematosus (SLE). Hiroshi Kato and Andras Perl. SUNY Upstate Medical University, Syracuse, NY.

Background/Purpose: mTOR activity is increased in SLE T cells and its blockade has therapeutic efficacy in SLE. Murine studies showed essential roles of mTORC1 in Th1/Th17 and mTORC2 in Th2 differentiation, whereas mTORC1 and 2 need to be blocked for Treg differentiation. Whether mTOR regulates T cell cytokine expression and Treg development in SLE remains elusive.

Methods: CD3$^+$ T cells were isolated from SLE patients and matched healthy controls (HC). A part of the CD3$^+$ T cells were stained with pS6RP, FoxP3, IFN-γ, IL-4, and IL-17 alone or together following CD4, CD8, and CD25 staining. The rest of the cells were cultured in RPMI culture media with 10% FCS, 1% Penicillin/Streptomycin, and 1% L-glutamine for 3 days in the absence or presence of plate bound anti-CD3 and soluble anti-CD28 with or without 100 nM rapamycin. After 3 day culture, cells were stained as previously described. pS6RP and cytokine expression by CD4$^+$, CD8$^+$, and DN T cells and frequency of CD4$^+$CD25$^+$FoxP3$^+$ Treg were assessed by flow cytometric analysis. Using day 3 T cell lysates, immunoblotting was performed using anti-Akt, anti-pAkt (Ser 473), anti-S6K1, and anti-pS6K1. The signal intensity was normalized to Actin.

Results: On day 0, frequency of pS6RP^{hi} cells was higher in DN T cells than CD4$^+$ or CD8$^+$ T cells (DN T cells: 29.40$\pm$6.37%, CD4$^+$ T cells: 1.04$\pm$0.16%; p=0.00028, CD8$^+$ T cells: 5.02$\pm$0.73%; p=0.00097 in SLE) and was higher in SLE than HC T cells, which was most prominent in DN T cells (29.40$\pm$6.37%, 17.59$\pm$4.47%, p<0.001). Rapamycin inhibited mTORC1 in T cells stimulated *in vitro* for 3 days based on the frequency of pS6RP^{hi} cells (41.85$\pm$7.67%, 1.53$\pm$0.27% in SLE; p<0.0001) and pS6K1 expression in T cell lysates (p=0.002) while it augmented mTORC2 based on pAkt expression (p=0.02). On day 0, SLE T cells had higher frequency of IL-4$^+$ cells, most prominently in CD8$^+$ T cells (7.72$\pm$2.40%, 4.00$\pm$0.45%, p=0.027). After 3 day *in vitro* stimulation, DN T cells had higher frequency of IL-4$^+$ cells than CD4$^+$ or CD8$^+$ T cells (DN T cells: 9.89$\pm$1.85%, CD4$^+$ T cells: 3.08$\pm$0.63%; p=0.0018, CD8$^+$ T cells: 4.94$\pm$0.81%; p=0.014 in SLE). Rapamycin suppressed T cell IL-4 expression, most robustly in DN T cells (9.89$\pm$1.85%, 4.92$\pm$0.80%, p=0.001). Frequency of IFN-γ^+ cells was reduced in SLE (p<0.0001). Rapamycin did not suppress T cell IFN-γ expression. After 3 day *in vitro* stimulation, SLE T cells had higher frequency of IL-17$^+$ cells, which was most prominent in CD4$^+$ T cells (5.31$\pm$1.57%, 2.71$\pm$0.63%, p=0.0196) and was suppressed by rapamycin (5.31$\pm$1.57%, 2.96$\pm$1.12%, p=0.0097). Frequency of Treg was reduced in SLE. Rapamycin blocked mTOR in Treg (pS6RP^{hi} cells: 45.13$\pm$10.97%, 3.39$\pm$0.38% in SLE; p<0.001) and promoted its expansion (11.49$\pm$1.92%, 19.60$\pm$2.80% in SLE; p<0.0001). Neutralization of IL-17 expanded Tregs (p<0.05).

Conclusion: The data indicate the pathogenic relevance of IL-4 and IL-17 in SLE, which are mainly produced by DN T and CD4$^+$ T cells respectively in an mTORC1-dependent manner. In contrast, IFN-γ is conceivably protective against SLE. Rapamycin expands Tregs by blocking mTOR in the Treg and suppressing IL-17. Our study reveals three distinct mechanisms of action by rapamycin in SLE: 1) suppression of DN T cell IL-4 production, 2) suppression of CD4$^+$ T cell IL-17 production, and 3) Treg expansion.

Abatacept Efficacy Is Overruled By IL-7 In TSLP-Primed Myeloid Dendritic cell driven T Cell Activation From Rheumatoid Arthritis Patients. F.M. Moret, T.R.D.J. Radstake, J.W.J. Bijlsma, F.P.J.G. Lafeber and J.A.G. van Roon. University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Abatacept is an effective treatment for a subset of rheumatoid arthritis (RA) patients, interfering in the interaction between antigen-presenting cells and T cells preventing T cell activation. Thymic stromal lymphopoietin (TSLP) and the related cytokine IL-7 are both increased in synovial fluid (SF) of RA patients and are shown to contribute to immunopathological mechanisms in RA. Recently, we have shown that TSLP potently activates CD4 T cells via myeloid dendritic cells (mDCs) depending on antigen presentation and co-stimulation. IL-7 directly acts on T cells and strongly induces T cell-dependent activation of antigen-presenting cells. The aim of this study was to investigate the potential of abatacept in inhibiting TSLP-mDC driven naïve and memory T cell activation in the presence of IL-7 in healthy controls (HC) and RA patients.

Methods: Naïve (Tn), central memory (Tcm) and effector memory (Tem) T cell subsets in PB of HC and in PB and SF of RA patients were assessed based on CD27 and CD45RO expression by flow cytometry. CD4 T cell subsets of HC isolated by flow cytometry and T cells from PB and SF of RA patients isolated by MACS were co-cultured with autologous TSLP-stimulated-mDCs with or without abatacept and/or IL-7 and subsequently T cell proliferation was measured.

Results: CD4 T cell subsets from PB of HC and RA patients were comparable and mainly consisted of Tn and Tcm cells (Tn 42 vs. 46%; Tcm 42 vs. 31%; Tem 8 vs. 10%, respectively), whereas SF of RA patients mainly consisted of Tcm and Tem cells (Tn 6%; Tcm 51%; Tem 34%). Activation of these T cell subsets by TSLP-mDCs from PB was completely blocked by abatacept (Tn: 6948 to 114; Tcm: 2347 to 207; Tem: 5718 to 199 cpm, all p<0.05, respectively). IL-7 strongly increased T cell activation and overruled the inhibitory capacity of abatacept (abatacept+IL-7 vs. abatacept, Tn 4836 vs. 114; Tcm 10128 vs. 207; Tem 11605 vs. 199 cpm, all p<0.05, respectively). This IL-7-induced reversal was associated with strong induction of IFNγ and TNFα secretion. Similarly, CD4 T cell proliferation induced by TSLP-stimulated mDCs from SF of RA patients was completely blocked by abatacept and largely reversed in the presence of IL-7.

Conclusion: Our data indicate that the presence of T cell activating cytokines, like IL-7, in joints of RA patients reduce the inhibitory capacity of abatacept on (TSLP-)mDC driven T cell activation. This could possibly explain the unresponsiveness to abatacept in a subset of patients.

T Cell Activation Induces Increased mRNA Expression Of The Splicing Factor SF2/ASF But Simultaneous Protein Downregulation Via Proteasome Mediated Degradation. Vaishali R. Moulton, Andrew R. Gillooly and George C. Tsokos. Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.

Background/Purpose: T cells from patients with systemic lupus erythematosus (SLE) are poor producers of the vital cytokine interleukin (IL)-2. We recently showed that SLE T cells exhibit reduced expression of the splicing factor 2/ Alternative splicing factor (SF2/ASF), more so in patients with worse disease as evidenced by higher SLE disease activity index (SLEDAI) scores compared to those with mild disease. SF2/ASF, a member of the serine arginine (SR) family of splicing proteins is not only a key regulator of alternative splicing via its RNA binding capacity, but also plays roles in transcription and translation by virtue of its protein-protein interaction properties. Increasing the expression of SF2/ASF in T cells from SLE patients restored their IL-2 production, indicating that SF2/ASF is an important regulator of T cell function, and its reduced expression is a potential molecular defect in SLE T cells. How the expression of SF2/ASF is controlled in T cells is not known. The goal of this study was to determine the mechanism/s controlling SF2/ASF expression in human T cells in resting state and during T cell activation.

Methods: T cells were isolated from peripheral blood of healthy volunteers. T cells were activated for various time points (3, 6, 24 hours) with either anti-CD3, anti-CD28 antibodies, or phorbol myristic acid (PMA) plus Ionomycin. mRNA expression was assessed by reverse transcription and real time quantitative PCR. Protein expression was studied by immunoblotting. Actinomycin D was used to block transcription and assess mRNA stability. To assess post translational mechanisms, the lysosome inhibitor Bafilomycin A1 and proteasome inhibitor MG132 were added during activation to block protein degradation.

Results: T cells in resting state expressed SF2/ASF mRNA and protein abundantly. T cell activation increased mRNA expression of SF2/ASF by 3- to 4- fold whereas protein expression did not change much, or even decreased. Stimulating T cells with PMA and Ionomycin similarly resulted in increased mRNA and reduced SF2/ASF protein expression. This discrepancy between mRNA and protein expression suggests that post-transcriptional and/or post-translational mechanisms regulate SF2/ASF expression during T cell activation. The discrepancy was not due to reduced transcript stability, as the rate of SF2/ASF mRNA decay in resting versus activated T cells showed no significant difference. Activating T cells in the presence of inhibitors of the lysosome or proteasome revealed that the proteasome but not lysosome is involved in the degradation of SF2/ASF.

Conclusion: Our results indicate that SF2/ASF mRNA and protein expression are differentially regulated during T cell activation, and that proteasome mediated degradation may represent an important physiologic mechanism to tightly control expression of this essential splicing factor. Our previous work showed that increased ubiquitination and proteasome degradation are important in the downregulation of the CD3 zeta signaling protein in SLE T cells. Therefore proteasome mediated SF2/ASF degradation may represent a molecular mechanism that contributes to its reduced expression in SLE T cells.

BAFF Promotes T Follicular Helper Cell Development and Germinal Center Generation In Mice. Song Guo Zheng, Maogeng Chen, Qiang Li and William Stohl. University of Southern California Keck School of Medicine, Los Angeles, CA.

Background/Purpose: BAFF (B cell activating factor belonging to the TNF family) promotes B cells maturation in germinal center. The generation of germinal center depends on T follicular helper cells (Tfh). Overexpression of BAFF and Tfh is found in many autoimmune diseases. However, whether BAFF has effects on Tfh development is still unclear. In this study, we explored the relationship between BAFF and Tfh in mice.

Methods: Mice were immunized with KLH for 10 days for the induction of Tfh in vivo. Mouse naive CD4+ cells cultured with IL-6 and IL-21 were used for Tfh differentiation *in vitro*. BAFF$^{-/-}$, BAFF transgenic (Tg), April$^{-/-}$, BR3$^{-/-}$, TACI$^{-/-}$ and BCMA$^{-/-}$ mice were used for the mechanism studies. To determine if B cells are required, μMT mice, BCL-2 Tg/μMT and BAFF$^{-/-}$/BCL-2 Tg mice were also used. Tfh cells and mature B cell were detected by FACS. Germinal centers were determined by immunofluorescence staining of PNA and IgD. The levels of IgG after KLH immunization were measured by ELISA. The mRNA expression of IL-6and IL-21 was determined by real-time qPCR.

Results: We showed that BAFF but not April promotes the development of Tfh cells in vivo and in vitro. Furthermore, the development of Tfh cells is dependent upon BR3, but independent on BCMA and TACI. BAFF facilitates the generation of germinal center, and promotes B cells maturation and secretion of IgG. B cells are required for BAFF-promoted Tfh cell formation. We demonstrated that BAFF increases IL-21 mRNA expression in CD4+ T cells, and IL-6 mRNA expression in B cells and dendritic cells.

Conclusion: In summary, these findings provide evidence that BAFF promotes Tfh development, germinal center generation and pathogenesis of autoimmune diseases.

Abatacept Is Highly Effective At Inhibiting T Cell Priming and Induces a Unique Transcriptional Profile In CD4$^+$ T Cells. Agapitos Patakas[1], Rui-Ru Ji[2], William Weir[1], Sean Connolly[2], Steven G. Nadler[2], James M. Brewer[1], Iain B. McInnes[1] and Paul Garside[1]. [1]University of Glasgow, Glasgow, United Kingdom, [2]Bristol Myers Squibb Co. Research and Development, Princeton, NJ.

Background/Purpose: Absence of co-stimulation in the presence of TCR-stimulation has been proposed to induce tolerance via deletion or anergy. Abatacept is a CTLA-4-Ig molecule that binds with high affinity to CD80/86 on antigen presenting cells (APC). It modulates CD28-mediated T cell co-stimulation and is currently approved for the treatment of rheumatoid arthritis, however it remains unclear whether its use leads to the development of immunological tolerance. The aim of this study was to investigate *in vivo* the capacity of abatacept to regulate development of antigen-specific immunological tolerance.

Methods: In order to generate antigen specific tolerised CD4$^+$ T cells, DO11.10 RAG2$^{-/-}$ mice, which have a CD4 cells specific for ovalbumin (OVA), were fed with OVA in their drinking water (50mg/ml) for 10 days. Priming was induced by s.c. injection of OVA in CFA in the presence of abatacept or control IgG (10mg/kg). The functionality of the generated CD4 populations was confirmed by their ability to respond to antigen rechallenge after adoptive transfer into BALB/c mice. The phenotype of purified CD4 and CD11c cells was assessed by flow cytometry, ELISA and complemented by detailed full genome transcriptional profiling.

Results: While T cells tolerised by ovalbumin feeding were unable to produce IL-2 after *ex-vivo* restimulation, T cells primed in the presence of abatacept produced copious amounts of this cytokine and resembled naïve T cells exposed to antigen for the first time in this respect. Tolerised T cell populations exhibited a significantly higher proportion of T_{REG} and CTLA-4$^+$ cells compared with naïve, primed or 'primed in the presence of abatacept' T cells. The latter were characterised by the absence of T_{REG}, more resembling naïve rather than tolerised T cells. However, abatacept treatment significantly reduced the expression of T cell markers (ICOS, CD71 and CD44) compared with primed and orally tolerised groups. When these T cells were adoptively transferred to BALB/c mice and rechallenged with OVA, only the orally tolerised CD4 cells failed to expand to antigen, suggesting that abatacept treatment does not induce anergy. Furthermore, T cells isolated from abatacept treated mice had a unique transcriptional profile, distinct from naïve, tolerant and primed T cells. Crucially we observed that this state is accompanied by an inhibition of the activation of dendritic cells at the transcriptional level, indicating a level of licensing of these cells by T cells. These results demonstrate that Abatacept treatment significantly modulates T-DC communication resulting in defective cell priming *in vivo* and a unique transcriptional profile which is distinct from anergic tolerance.

Conclusion: This study provides insight into the mode of action of Abatacept and its bidirectional impact upon both T cells and DC. We demonstrate that while abatacept does not induce T cell anergy, it generates a distinct T cell phenotype that most resembles naïve T cells and potentially modulates the function of APCs. This could have significant implications when considering its application in rheumatoid arthritis and other autoimmune conditions.

724

Dose-Dependent Suppression Of Cytokine Production From T Cells By a Novel Phosphoinositide 3-Kinase Delta Inhibitor. Emily E. Way[1], Kong Chen[1], Kamal D. Puri[2] and Jay K. Kolls[1]. [1]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [2]Gilead Sciences, Inc., Seattle, WA.

Background/Purpose: The use of specific cytokine inhibitors to treat inflammatory autoimmune conditions is common but typically utilizes monoclonal antibodies, fusion proteins, and other molecules whose large size necessitates parenteral administration. There remains a significant need for development of effective small molecule cytokine inhibitors for inflammatory conditions. Phosphoinositide 3-kinase (PI3K) is a direct upstream activator of AKT, and plays a critical role in multiple cell signaling pathways, cell cycle progression, and cell growth, and is thus a potential target for drug development. We examined the effect of a novel PI3Kδ inhibitor, GS-599220, on CD3/CD28 stimulated T-cell cytokine production.

Methods: Mouse Th17 cells were differentiated from naïve T cells in vitro, and GS-599220 was added on day 3 of differentiation prior to re-stimulation with anti-CD3/CD28 beads. On day 4, secretion of T helper signature cytokines by these cells were determined by both Luminex and ELISA, while real time PCR was used to quantify gene expression of these cytokines. The compound toxicity was determined by flow cytometry with 7AAD staining. Th17 cells were also transduced with a retrovirus encoding GFP-labeled myristoylated AKT, which renders the AKT constitutively active, and then treated with GS-599220.

Results: When added to culture after allowing naïve T-cells to polarize into different effector lineages, we observed dose-dependent suppression of multiple cytokines by Luminex and ELISA, including IL-17, IFNγ, and IL-4 from Th17, Th1, and Th2 cells, respectively. Real time PCR confirmed the suppression of cytokine gene expression suggesting the inhibition is mediated at the transcriptional level. Toxicity of this compound to Th17 cells was found to be minimal, indicating that the mechanism of cytokine inhibition is not by cell death. Experiments carried out under conditions free of antigen presenting cells suggest that this compound functions independently of antigen presenting cells and acts directly on the T cells. To investigate the downstream effects of this PI3Kδ inhibitor, constitutively active AKT was introduced into Th17 cells by retroviral transduction. Th17 cells containing constitutively active AKT appear to be resistant to PI3Kδ inhibition, as IL-17 production is not reduced even in the presence of high concentrations of GS-599220, suggesting that this inhibitor is acting through AKT signaling pathways.

Conclusion: These experiments show effectiveness of this small molecule inhibitor of PI3Kδ activity to modulate inflammation in vitro and exhibit promise as a treatment for in vivo models of inflammation.

Localization At The Immunological Synapse Of Adaptor Protein Grb2 and PLC Gamma-1 In Non-Stimulated Peripheral Blood T Lymphocytes From Patients With Systemic Lupus Erythematosus Suggests An In Vivo dysregulated Activation State. Nursamaa Abdoel[1], Mireyma Sanchez[1], Hector Rojas[2], Martin Rodriguez[1] and Ana M. Blasini[1]. [1]Hospital Universitario de Caracas, Caracas, Venezuela, [2]Instituto de Inmunologia, Escuela de Medicina, Universidad Central de Venezuela, Caracas, Venezuela.

Background/Purpose: We previously showed an increased metabolic rate of transmembrane adaptor protein LAT in TCR/CD3 stimulated lupus T cells, associated with delocalization of this adaptor molecule from lipid rafts and from the immunological synapse after TCR/CD3-CD28 stimulation of lupus T cells. Additionally, unstimulated T cells from systemic lupus erythematosus (SLE) patients seem to be in a preactivated state showing augmented phosphorylation of signaling proteins, among other evidences, compared to non-SLE patients and healthy controls. In this study we evaluated the presence of key signaling molecules in lipid rafts of lupus T cells.

Methods: SLE patients were diagnosed according to the American College of Rheumatology criteria. Healthy donors were from the blood bank of *Hospital Universitario de Caracas*. All individuals signed an informed consent previously approved by the Bioethics Committee. Highly enriched T cells, obtained from peripheral blood samples and subjected to RosetteSep™ isolation, were adhered to pLL coated slides and activated for 5 and 15 min at 37°C, with 4.5 μm superparamagnetic polystyrene beads coated with antibodies against CD3ϵ and CD28. The cells were fixed, permeabilized and stained with antibodies recognizing Grb2 and PLCγ1, and CT-B as a lipid raft marker. The cell-bead complexes were evaluated by confocal microscopy and densitometries were obtained using ImageJ, 1.44, National Institutes of Health, USA.

Results: We observed increased localization of adaptor protein Grb2 at the immunological synapse in unstimulated T cells from lupus patients compared to healthy controls (23.46 ± 3.57 vs. 20.67 ± 2.28, MFI ± SME, n=10). PLCγ1 showed the same pattern of increased localization at the immunological synapse in these cells (23.14 ± 4.10 vs. 17.22 ± 2.14, MFI ± SME, n=10). The colocalization of either Grb2 or PLCγ1 with GM1, as well as colocalization of Grb2 and PLCγ1 themselves was similar between SLE patients and healthy controls, suggesting normal coupling of signaling molecules in lipid rafts in lymphocytes from lupus patients.

Conclusion: Since partition of PLCγ1 and Grb2 in lipid rafts occurs after ligation of the TCR, we conclude that our findings suggest an in vivo dysregulated activation state in SLE T cells, which may contribute to known downstream signaling abnormalities such as MAPK activation.

Tofacitinib Does Not Inhibit Dendritic Cell Maturation and T Cell Proliferation In Vitro. Emmanuelle Le Bras[1], Dagmar Halbritter[2] and Martin Fleck[3]. [1]University Medical Center of Regensburg, Regensburg 93053, Germany, [2]University Medical Center of Regensburg, 93042 Regensburg, Germany, [3]Asklepios Clinic Bad Abbach, Bad Abbach, Germany.

Background/Purpose: Tofacitinib is the first approved Janus Kinase (JAK) Inhibitor for the treatment of rheumatoid arthritis (RA). The JAK/STAT pathway-inhibition leads to dysfunction of several processes of the acquired and innate immunity as well as haematopoesis. Beyond this, JAK3, which is exclusively expressed on haematopoetic cells, is known to be involved in the maturation and activation of dendritic cells (DCs), but its specific role remains controversial. Since DCs play a key role in the pathogenesis of RA, we investigated the in vivo effect of Tofacitinib on DC maturation and allogeneic T cell activation.

Methods: Monocytes were collected from healthy donors and cultured for 5 days in the presence of GM-CSF and IL-4 to generate immature dendritic cells (iDCs). To induce maturation, iDCs were cultured for 2 days in the presence of LPS (10 ng/ml) or a cocktail consisting of IL-1β (10 ng/ml), TNF-α (10 ng/ml), IL-6 (1000 U/ml) and Prostaglandin E2 (1mg/ml) or LPS with or without different concentrations of tofacitinib (10–300 nM). After seven days of culture, mature DCs (mDCs) were harvested and phenotypically characterized using FACS analysis. To evaluate mDC function, mixed leukocyte reactions (MLR) were established by incubation of 5×10^4 allogeneic T cells with different amounts of mDCs at stimulator:responder (S:R) ratios from 1:625 to 1:1 in the presence of different concentrations of tofacitinib, or abatacept. On day 5 of co-culture, 1 μCi of 3H-methylthymidine/well was added and T cell proliferation was determined after 24h using a liquid scintillation counter.

Results: There was no relevant inhibition of DC maturation in the presence of tofacitinib as FACS analysis revealed similar expression patterns for HLA-DR and CD83 in all cultures (HLA-DR+: 55.4%, 45.5%, 62.5%; CD83+: 82%, 74%, 80,3% for tofacitinib concentrations from 10nM, 30nM and 100nM, respectively). Furthermore, expression of co-stimulatory molecules CD80 and CD86 (>92% CD80+ and CD86+ for all tofacitinib concentrations) was not affected by tofacitinib. In addition, proliferation of allogeneic T cells in co-cultures with mDCs was not significantly impaired as similar proliferation rates could be observed at all S:R ratios despite the presence of tofacitinib (mean increase of 27% cpm for all S:R ratios vs untreated mDC after LPS stimulation, mean decrease of 6% cpm for all S:R ratios after stimulation with cytokine cocktail vs. untreated mDC). In contrast, there was a concentration dependent inhibition up to 75% of T cell proliferation in co-cultures treated with abatacept.

Conclusion: The present results demonstrate that DC maturation as well as proliferation of allogeneic T cells in MLR's is not significantly affected by tofacitinib. Therefore, modulation of the JAK pathway in other cell populations might be responsible for the anti-inflammatory effects observed upon tofacitinib treatment in vivo.

Adiponectin Promotes The Differentiation Of naïve T Cell To Th17 Cell and Aggravates Collagen-Induced Arthritis. Miaojia Zhang[1], Xiaoxuan Sun[2], Wenfeng Tan[3], Xiaoke Feng[4] and Ke Gan[3]. [1]the First Affiliated Hospital of Nanjing Medical University, Nanjing, CHINA., Nanjing, China, [2]the First Affiliated Hospital of Nanjing Medical University, Nanjing, CHINA, Nanjing, China, [3]the First Affiliated Hospital of Nanjing Medical University, Nanjing, China, [4]the First Affiliated Hospital of Nanjing Medical University, China, Nanjing, China.

Background/Purpose: To investigate a role of Adiponectin (AD) on the differentiation of naïve T cell to Th17 cell and bone erosion in collagen-induced arthritis (CIA) mice.

Methods: Purified naïve T cells were cultured in anti-CD3 mAb and anti-CD28 mAb precoated with TGF-β, IL-6, IL-23 in the presence and absence of AD (0.1, 1 or 10 μg/ml). After 72 hours of culture, the frequencies of Th17 cells were measured by flow cytometry; the expression of ROR-γt and IL-17 were determined by real-time PCR and ELISA. Intraarticularly injected of AD 10 μl (1 μg/1 μl) into the knee joint of CIA mice was to analysis the role of AD on CIA development and Th17 expression in vivo.

Results: The frequencies of Th17 cells were significantly increased with the concentration of AD 10 μg/ml, but AD treatment with 0.1 and 1 μg/ml showed no obvious effect on the differentiation of naïve T cell to Th17 cell. The expression of IL-17 and ROR-γt mRNA were significantly increased oupon AD 0.1 μg/ml and 10 μg/ml AD stimulation. Consistently with mRNA expression, IL-17 levels were significantly elevated in culture supernatants after 10 μg/ml AD treatment. Intraarticular injection of AD into the knee joint of CIA mice aggravated arthritic development and bone erosion, triggered higher expression of IL-17 mRNA and its transcription factor including ROR-γt, IL-21, IL-22 and IL-23 in CIA model.

Conclusion: These findings identify a role of AD on enhancing the differenation of naïve T cell to Th17 cell, contributed to CIA bone erosion in CIA mice.

Unraveling The Identity Of *FoxP3*$^+$ Regulatory T-Cells In Gpa-Patients. WH Abdulahad, Coen A. Stegeman, MG Huitema, Pieter C. Limburg, Abraham Rutgers, Peter Heeringa and Cees G.M. Kallenberg. University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: Human *FoxP3*$^+$ Th-cells are heterogeneous in function and include not only suppressive cells (T_{Regs}) but also non-suppressive cells that abundantly secrete proinflammatory cytokines. We have previously shown that *FoxP3*$^+$ Th-cells were increased in GPA-patients during remission as compared to healthy controls (HCs). In this group of patients, however, we observed a defective suppressor function of T_{Regs}, and an increase in the percentage of Th-17 cells. These observations make it tempting to investigate whether increased *FoxP3*$^+$ Th-cells in GPA-patients are attributed to an increase in the cytokine-secreting non-suppressive *FoxP3*$^+$Th-cells.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from 46 GPA-patients in remission and from 22 age- and sex-matched HCs. Expression of CD4, CD45RO, and *FoxP3* were determined by flow cytometric analysis. The expression levels of *FoxP3* and CD45RO were used for distinction between activated suppressor T_{Regs} (*FoxP3*^{High}CD45RO$^+$; $_{AS}T_{Reg}$), resting suppressor T_{Regs} (*FoxP3*^{Low}CD45RO$^-$; $_{RS}T_{Reg}$), and cytokine-secreting non-suppressor T_{Regs} (*FoxP3*^{Low}CD45RO$^+$; $_{NON}T_{Reg}$) cells. Intracellular expression of IFNg, IL-17, and IL-21 were determined in the various FoxP3$^+$ Th-cell subsets after *in vitro* activation of PBMCs by PMA and Ca-Ionophore.

Results: A significant increase in the frequency of $_{NON}T_{Reg}$ cells was observed in GPA-patients as compared with HCs, whereas no differences were detected in $_{RS}T_{Reg}$- and $_{AS}T_{Reg}$ cells between GPA-patients and HCs. The distribution of $_{RS}T_{Reg}$- and $_{NON}T_{Reg}$ cells did not differ between ANCA-negative and ANCA-positive patients, whereas lower percentages of $_{AS}T_{Reg}$ cells were observed in ANCA-positive patients as compared to ANCA-negative patients and HCs. Importantly, a significant increase in the percentage of IL-17$^+$ and IL-21$^+$ cells was seen within the $_{NON}T_{Reg}$cells from ANCA-positive patients (n= 9) when compared to ANCA-negative (n= 10) and HCs (n= 12), whereas no differences were found between ANCA-negative and HCs.

Conclusion: Increased *FoxP3* expression in Th-cells from GPA-patients is related to an increase in a subset of non-suppressive Th-cells. Increased production of IL-17 and IL-21 cytokines, in $_{NON}T_{Reg}$ cells from ANCA-positive patients points towards *FoxP3*$^+$ effector cells and decrease in suppressive T_{Reg} cells in relation to ANCA production.

Role Of Innate Immunity In The Pathogenesis Of ANCA-Associated Vasculitis. Angelica Gattamelata[1], Giovanna Peruzzi[2], Rossana Scrivo[1], Roberta Priori[1], Stefania Morrone[3], Angela Santoni[2] and Guido Valesini[1]. [1]Department of Internal Medicine and Medical Specialties, Sapienza University, Rome, Italy, [2]Department of Molecular Medicine, Sapienza University, Rome, Italy, [3]Department of Experimental Medicine, Sapienza University, Rome, Italy.

Background/Purpose: Natural killer cells (NK) represent one of the main effectors of the innate immune response through the defense against viral infections and the production of immunoregulatory cytokines. Recent evidence shows an increase in the expression of TLR2 and TLR9 on NK cells of patients with ANCA-associated vasculitis (AAV) compared with healthy controls (HC). This is of great interest considering that infections are implicated in the pathogenesis of these diseases.

The aim of our study was to characterize NK cells in patients with AAV, assessing their number, phenotype and functional status.

Methods: We enrolled 19 patients with AAV [M/F: 7/12; mean age 60.2 years (range 41–75)] according to the Chapel Hill criteria (11: granulomatosis with polyangiitis, 7: eosinophilic granulomatosis with polyangiitis, 1: microscopic polyangiitis) and 12 HC matched for age and sex with the patients. After obtaining informed consent, clinical data were collected and blood drawing was performed. Peripheral blood mononuclear cells (PBMCs) were isolated from heparinized blood by Lymphoprep gradient centrifugation. NK cells (CD3-CD56+) were evaluated by multi-parameter flow cytometry, distinguishing between cytotoxic CD56^{dim} and immunoregulatory CD56^{bright} NK cells, also divided into two recently identified subpopulations: memory NK cells (CD3-CD56+CD57+) and NK-22 cells (CD3-CD56+NKp44+ CCR6+). In addition, the expression of TLR2 and TLR9 was evaluated on these cells. Finally, NK cells were isolated by magnetic separation to assess the state of activation through the expression of intracellular IFNg following *in vitro* incubation with TLR2 (Pam3CSK4) and TLR9 (CpG ODN) ligands.

Results: We found no differences in the percentage of NK cells between patients (11.3%) and HC (12%). The percentage of CD56^{dim} and CD56^{bright} (80.5% vs 92% and 7.5% vs 8%, respectively), and the percentage of memory NK cells and NK-22 cells (0.550% vs 0.507% and 66% vs 67%, respectively) was comparable between AAV patients and HC. In NK cells, the expression of TLR2 was significantly higher in HC (14.8%) compared to patients (8.12%; p=0.0328) and TLR9 expression showed a tendency to be higher in patients (26%) compared to HC (15%), but the difference was not statistical significant. In the memory NK cells subset the expression of TLR2 was significantly decreased in patients (10.2%) compared to controls (19.2%; p=0.0434), while there was no difference in the expression of TLR9. Interestingly, the stimulation with TLR9 ligand induced a significant production of IFNg in patients (11%) compared to HC (2.8%; p=0.0071). No correlation with clinical and laboratory parameters was found.

Conclusion: The increased production of IFNg after stimulation with the ligand of TLR9 demonstrates a state of NK activation in AAV patients. Hence, TLR9 may be involved in the pathogenesis of these diseases, strengthening the possibility that infections may promote their onset and/or exacerbations. Further experiments are needed to confirm these data and to clarify the meaning of the reduced expression of TLR2 on CD57+ NK cells of patients compared to HC.

Cell-Mediated Immune Responses To Influenza and Herpesvirus Antigen Stimulation Are Conserved But Adversely Impacted By Immunosuppressive Therapy and Active Infection In Patients With Granulomatosis With Polyangiitis. John McKinnon[1], Robbie Mailliard[2], Dawn McClemens-McBride[2], Donald Jones[2], Charles Rinaldo Jr.[2] and Kathleen Maksimowicz-McKinnon[1]. [1]Henry Ford Hospital, Detroit, MI, [2]University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Reactivation of chronic herpesvirus infections is not uncommon in immunosuppressed patients, including those with granulomatosis with polyangiitis (GPA). The effects of GPA disease and therapy on cell-mediated immunity against herpesviruses are not well established. Although immunosuppressive therapy is clearly associated with viral reactivation disease, data from other cohorts demonstrate that altered immunocompetence from other infections may also be an important contributing factor. We examined the effects of recent and acute infections on cell-mediated immune response against influenza and herpesvirus antigens in a well-characterized cohort of patients with GPA.

Methods: Twenty GPA patients (mean age: 56 years; 55% female; 100% Caucasian) and 5 age-, race-, and gender-matched healthy controls were prospectively enrolled. Disease features, medications, current and recent infection data, and disease activity scores were obtained. Extended ELISPOTs for interferon-gamma (IFNg) production to CEF and VZV antigens were assessed.

Results: GPA patients had a median disease duration of 86.8 (54) months, median BVAS of 1.0 and VDI of 2.0. Prednisone was used in 15 (75%) of the patients (median dose: 12.5 mg) and steroid-sparing immunosuppressive agents in 14 (70) %; two patients were not receiving IS therapy. An active infection was identified in 30% of the patients at study entry, and 50% had a recent serious infection within the past year. GPA patients had a significant decline in IFNg median responses to CEF & VZV antigens with increasing prednisone dose (0mg=450 & 192.1; <11mg= 161.8, 7.3; 11–60mg= 202.5, 24.2; 1000mg= 22.5, 25.5) (p=0.21, 0.041 respectively) and with the number of immunosuppressive agents used (none= 457, 192.5; one= 161.3, 129.3; two or more= 202.5, 18.5) (none vs. one=0.53, 0.8; none vs. two: p=0.095, 0.095). The presence of an active infection at study entry was associated with a decrease in VZV IFNg response (p=0.024). However, prior herpesvirus infection (1 HSV pneumonia, 4 VZV disease) within the past year was associated with higher CEF response (p=0.036) and a trend towards higher VZV responses (p=0.099).

Conclusion: Immunosuppressive therapy and non-viral infections both decrease cell-mediated immune response against herpes viruses, potentially leading to reactivation disease in patients with GPA, as seen in other immunosuppressed populations. Prior herpesvirus infection is associated with increases in both CEF and VZV responses, suggesting a possible "crossover" protective effect against both CMV and VZV reactivation, which could be important when considering the need and timing of prophylactic interventions. .

C3 Activation Is Associated With The Disease Activity Of Microscopic Polyangiitis. Dan Liu[1], Jin-song Zhou[2], Qing-ping Chen[2], Chao-yang Duan[3], Li Wang[2], Yuan Jia[1] and Ke Li[3]. [1]Peking University People's Hospital, Beijing, China, [2]The Fifth Hospital of Xi'an, Xi'an, China, [3]The Second Affiliated Hospital, Xi'an Jiaotong University, Xi'an, China.

Background/Purpose: Microscopic polyangiitis (MPA) is the most common anti-neutrophil cytoplasmic antibodies(ANCA) associated small-vessel vasculitis with specificity of the ANCA to myeloperoxidase(MPO) of neutrophils. MPA mainly affects kidneys and lungs. The kidneys are the most commonly affected organ; and kidney vasculitis can result in renal failure. The interplay of ANCA, neutrophil and complement activation has been implicated in the pathogenesis of MPA. In this study, we tried to establish the relationship of complement activation and the disease activity of MPA and to identify potential biomarkers for this disease.

Methods: Blood samples were collected from 45 MPO-ANCA positive patients who had clinical diagnosis of MPA in People's Hospital, Peking University, after informed consent. The samples, according to serum C3 levels, were divided into two groups: normal C3 group: ≥0.8 g/L (n=18) and low C3 group: C3<0.8 g/L (n=27). Inflammatory markers (i.e. *ESR,* CRP), renal functional markers (i.e. BUN, creatinine, 24-hour urinary protein level), and lung diseases were evaluated in the two groups. Birmingham Vasculitis Activity Score-version 3 (BVAS[V3]) was calculated. Data was analyzed using corresponding *t* test, chi-square test, linear correlation analysis and binary logistic regression, respectively.

Results: We found that: 1) Compared with normal C3 group, low C3 group had significantly lowered C4 (0.17±0.08 g/L vs 0.25±0.08 g/L) but significantly increased CRP (101±57 mg/L vs 33±33 mg/L), 24-hour urinary protein (1.4±1.3g/d vs 0.6±0.5g/d), BUN (17.08±9.02 mmol/L vs 8.62±5.28 mmol/L) and BVAS(V3) (21.4±3.6 vs 15.4±3.8). 2) BVAS(V3) has a significant linear correlation with serum complement C3 level (R^2=0.43, P<0.01). 3) Morbidity of severe lung injury (i.e. interstitial lung disease, pneumorrhagia) in low C3 group was higher than that in normal C3 group (92.6% vs 33.3%, X^2=17.69, P<0.01). 4) C3, CRP and ESR levels were closely related to the occurrence of severe lung injury, and the logistic regression equation was: $P(y)=1/(1+e^{-2.1+7.54\times C3-0.054\times CRP-0.027\times ESR})$, in which the overall correct percentage was 93.3%.

Conclusion: Serum complement C3 levels were associated with the disease activity and clinical manifestations of MPA. Therefore, serum C3 level may represent as a biomarker for disease activity and an indicator for organ injury of MPA.

Expansion Of IgA-Plasma Cells As a Sign For Ear-Nose-Throat-Involvment In Granulomatosis With Polyangiitis? Bimba F. Hoyer[1], Adriano Taddeo[2], Qingyu Cheng[1], Laleh Khodadadi[1], Gerd Burmester[1] and Falk Hiepe[1]. [1]Charité University Medicine, Department of Medicine/ Rheumatology and Clinical Immunology and German Rheumatism Research Centre Berlin (DRFZ), Germany, Berlin, Germany, [2]Deutsches Rheuma-forschungszentrum, Berlin, Germany.

Background/Purpose: B cells are playing a major role in granulomatosis with polyangiitis (GPA, formarly known as Wegener's disease). This is reflected by the presence of autoantibodies directed against neutrophil granular encymes (ANCA) in a great majority of patients as well as in the success of B cell depleting therapies in GPA. Renal manifestations are directly mediated by autoantibodies. Whether mucosal plasma cells play a role in ENT-involvment is yet unknown. IgA-ANCA can be found in about 30% of GPA patients (Kelley et al). For a better understanding of the possible role of B cells in GPA we analyzed B cells subsets in the peripheral blood of patients and found major changes correlating with disease activity (BVAS).

Methods: 18 patients with GPA (11 with active disease, 7 in remission) were analyzed by flow cytometry and compared to 17 healthy donors. Stainings for CD19, 20, 27, IgD, IgA and MHCII were performed and analyzed by FlowJo-software. The study was approved by the Charité ethics committee and all patients signed informed consent. Statistical analysis was performed using GraphPadPrism.

Results: Marked differences (p=0,0018) were found regarding the number and frequency of plasmablasts and plasma cells in patients with active disease (6,4 ± 5,06/μl) as compared to patients in remission (2,5 ± 1,6/μl) or healthy donors (2,3 ± 1,2/μl). In patients with GPA a significant higher number of the plasma cells produced IgA as compared to healthy controls (p=0,0028).

The number of plasma cells as well as their frequency correlate with disease activity (r= 0,9135, p<0,0001). Interestingly, no expansion of the double negative memory B cells that has been described in SLE could be seen. For naive B cells significant differences could be detected as well.

Conclusion: The number of plasma cells in active GPA is increased. This implies a central role of plasma cells in the pathogenesis of GPA. A high frequency of these plasma cells is producing IgA, which could play a role in ENT-involvement. Further studies including the analysis of ENT biopsies are needed to further understand their role in disease pathogenesis.

Plasma Levels Of Fibrin/Fibrinogen Degradation Products Might Be a Useful Indicator Of Disease Activity, Classification and Nephritis Complications In Antineutrophil Cytoplasmic Antibody-Associated Vasculitis. Kuninobu Wakabayashi, Nao Oguro, Yoko Miura, Sho Ishii, Shinya Seki, Masayu Umemura, Takahiro Tokunaga, Hiroyuki Tsukamoto, Sakiko Isojima, Hidekazu Furuya, Ryo Yanai, Kumiko Otsuka, Ryo Takahashi, Takeo Isozaki, Nobuyuki Yajima, Yusuke Miwa and Tsuyoshi Kasama. Showa University School of Med, Shinagawa-ku Tokyo, Japan.

Background/Purpose: It is important to determine the biomarkers for assessing disease activity of patients with antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Plasma levels of fibrin/fibrinogen degradation products (FDP) are fibrinolytic markers and elevates after any thrombotic event. We hypothesized that plasma levels of FDP reflect to hypercoagulable state and thrombosis in AAV. The purpose of the present study is to investigate whether plasma levels of FDP could be an indicator of disease states and complications of organ involvements in patients of AAV.

Methods: Patients with microscopic polyangiitis (MPA), granulomatosis with polyangiitis (GPA) and eosinophilic granulomatosis with polyangiitis (EGPA) who were admitted to Showa University Hospital for induction therapy and had their plasma FDP levels checked in the active state from October 2005 to May 2013 were retrospectively included. Plasma FDP levels were compared between the active and inactive states of AAV. Among patients in the active state, vasculitis disease clinical activity was assessed using Birmingham Vasculitis Activity Scores (BVAS), and the relationship between plasma FDP levels and BVAS, scores of each system were discussed. Plasma FDP levels were evaluated for differences in each disease and were compared between patients with and without complications of nephritis, interstitial pneumonia and peripheral neuropathy. Laboratory markers of AAV and nephritis activity were examined to determine their correlations with plasma FDP levels.

Results: Thirty-seven MPA, 12 GPA, and 6 EGPA patients were included. Plasma FDP levels were high in the active state and decreased significantly after therapy ($p<0.001$). Among patients in the active state, plasma FDP levels significantly correlated with BVAS ($r_s=0.35$, $p<0.05$). Especially, positive correlations were observed among plasma FDP levels and the system of general ($r_s=0.57$, $p<0.001$) and renal involvement ($r_s=0.33$, $p<0.05$) in the systems of BVAS. Plasma FDP levels were significantly higher in patients with MPA than in patients with GPA ($p<0.05$) and with EGPA ($p<0.05$). Although plasma FDP levels were significantly higher in patients with nephritis than in patients without nephritis ($p<0.01$), there were no differences between patients with and without complications of interstitial pneumonia and peripheral neuropathy. Plasma FDP levels significantly correlated with serum C-reactive protein levels ($r_s=0.52$, $p<0.001$), peripheral blood neutrophil count ($r_s=0.53$, $p<0.001$), plasma D-dimer levels ($r_s=0.87$, $p<0.001$), serum creatinine levels ($r_s=0.34$, $p<0.05$), estimated glomerular filtration rates ($r_s=-0.43$, $p<0.01$), and urinary N-acetyl-beta-D-glucosaminidase index ($r_s=0.37$, $p<0.05$). Plasma FDP levels were significantly higher in the patients with proteinuria ($p<0.01$) and hematuria ($p<0.05$).

Conclusion: Plasma FDP levels might be a useful indicator of disease activity and complications of nephritis in patients with AAV. Better understanding of the association of thrombosis with inflammation in AAV might lead to development new approaches to therapy.

The Significance Of Anti-Myeloperoxidase and Anti-Proteinase 3 Antibodies In The Absence Of Anti-Neutrophil Cytoplasmic Antibody Immunofluorescence Positivity. Deepak A. Rao, Joseph F. Merola, William R. O'Brien, Kevin Wei, Samuel U. Takvorian, Paul F. Dellaripa and Peter H. Schur. Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Identification of serum anti-neutrophil cytoplasmic antibodies (ANCA) for the detection of ANCA-associated vasculitis (AAV) is often performed by screening with indirect immunofluorescence (IF), followed by testing of IF-positive samples for anti-proteinase-3 (PR3) and anti-myeloperoxidase (MPO) antibodies. Many institutions, including ours, analyze all samples by IF and anti-PR3/anti-MPO assays simultaneously. This strategy can identify patients with detectable anti-PR3 or anti-MPO antibodies despite a negative IF (IF-/Ab+); however, the significance of this discordant result is not clear. We attempted to determine whether IF-/Ab+ results identified any cases of clinically meaningful systemic vasculitis.

Methods: We conducted a retrospective chart review of all patients tested for serum ANCAs at a large academic center between January 2011 and May 2013 who had a negative IF but detectable anti-PR3 or anti-MPO antibodies (IF-/Ab+). IF was performed on serum diluted 1:20, with cytoplasmic or perinuclear patterns considered positive. Atypical patterns were excluded. Anti-PR3 and anti-MPO assays were performed by immunoassay. AAV diagnosis was based on the European Medicines Agency vasculitis algorithm.

Results: Of 2345 samples tested for ANCAs, 49 samples (2.1%), derived from 38 patients, contained a detectable anti-PR3 or anti-MPO antibody despite a negative IF. By comparison, 1950 samples (83%) had both negative IF and antibody assays, and 123 samples (5.2%), derived from 68 patients, had both a positive IF and a detectable anti-PR3 (44), anti-MPO antibody (77), or both antibodies (2). Of 76 samples with detectable anti-PR3 antibodies, 29 (38%) had a negative IF, while 20 of 115 (17%) anti-MPO-positive samples had a negative IF.

We identified only one case in which a patient with an IF-/Ab+ result was subsequently diagnosed with AAV. A repeat test 1 month later returned IF+/Ab+. Eleven of the IF-/Ab+ cases (29%) represented previously diagnosed and treated AAV, all with positive IF and antibody tests prior to treatment. The majority of patients with IF-/Ab+ results (20/38 (52%)) had non-vasculitic immunologic disorders, including SLE (5) inflammatory bowel disease (3), autoimmune hepatitis (1), Hashimoto's thyroiditis (1), relapsing polychondritis (1), pyoderma gangrenosum (1), hepatitis C (1), and graft versus host disease (1). In the comparator group, 42 of 68 (62%) patients with IF+/Ab+ results were diagnosed with AAV (anti-PR3 17, anti-MPO 25).

Conclusion: A positive anti-PR3 or anti-MPO assay in the absence of positive ANCA IF may rarely lead to a new diagnosis of systemic vasculitis; however, this immune profile can be observed in patients with previously known seropositive (IF+/Ab+) AAV. If one believes that serial ANCA testing is of value in monitoring clinical activity and response to therapy, our data suggest that both IF and specific antibody tests should be monitored, though the utility of this practice is controversial. Further investigation into the clinical implications of persistent antibody-positivity with negative immunofluorescence is warranted.

Clinical Research Of Microscopic Polyangiitis Combined With Autoimmune Hemolytic Anemia. Dan Liu[1], Qing-ping Chen[2], Hai-hong Yao[1], Ru Li[1], Yin Su[1], Jie Zhang[2], Yu Chen[2], Ke Li[3] and Yuan Jia[1]. [1]Peking University People's Hospital, Beijing, China, [2]The Fifth Hospital of Xi'an, Xi'an, China, [3]The Second Affiliated Hospital, Xi'an Jiaotong University, Xi'an, China.

Background/Purpose: Autoimmune hemolytic anemia (AIHA) and Microscopic polyangiitis (MPA) are both rare autoimmune conditions. AIHA is caused by autoantibody-induced hemolysis (the premature destruction of circulating red blood cells) while MPA is characterized by necrotizing glomerulonephritis and pulmonary capillaritis. Both diseases are mediated by activation of lymphocytes and complement. Here we describe the clinical and laboratory characteristics of MPA patients combined with AIHA, investigate their treatment and prognosis, so as to help to improve the prognosis of such patients.

Methods: MPA was diagnosed in 51 patients referred to Department of Rheumatology, People's Hospital, Peking University. All patients of MPA were divided into 2 groups, non-AIHA group (n=35), and MPA combined with AIHA group (n=16). Clinical and laboratory data were retrospectively analyzed. Disease activity was evaluated by Birmingham Vacuities Activity Score-version 3 (BVAS [V3]). Therapeutic response and prognosis were systemically reviewed during a two-year follow-up period.

Results: Sixteen of the 51 patients were combined with AIHA(31.4%) and 13 of them manifested as the first symptome. Incidence of fever, hypertension, and severe lung injury (i.e. interstitial lung disease, pneumorrhagia) of MPA combined with AIHA group were higher than that in non-AIAH group, fever (81.3% vs. 15%, $X^2=7.50$, $P<0.01$), hypertension

(50% vs. 17.1%, X^2=5.95, P<0.01) and severe lung injury (100% vs. 68.9%, X^2=4.69, P<0.01), respectively. Compared with non-AIHA group, MPA combined with AIHA group had significantly lower levels of RBC (2.3 ± 0.3×10^9/L vs. 3.0 ± 0.7 × 10^9/L), Hb (72.8 ± 15.3 vs. 102.3 ± 20.7g/L), and C3 (0.6 ± 0.2 g/L vs. 1 ± 0.2g/L), while higher level of ESR (103.4 ± 27.9mm/H vs. 76.5 ± 31.1mm/H), IgG (18.5 ± 6.1mg/ml vs. 13.9 ± 6.0mg/ml) and BVAS [V3] (22.3 ± 2.7 vs. 18.3 ± 5.1). In MPA combined with AIHA group, Methylprednisolone of 500mg/day and 40mg/day were used in nine and seven cases, respectively, in which 13 cases had combined with cyclophosphamide, and 1 case combined with mycophenolate mofetil. After 3 months' treatment, Hb level of MPA combined with AIHA group significantly increased (from 72.8 ± 15.3 to 100.1 ± 16.9g/L) while BAVS (V3) has remarkably decreased (from 22.3 ± 2.7 to 3.6 ± 3.2). Five of 16 cases of MPA-AIHA patients died of severe anemia, renal failure and pulmonary fungal infection, another five were rehospitalized for anemia or renal dysfunction; the remaining six underwent gradual improvements of disease.

Conclusion: AIHA can be the first manifestation of MPA. MPA-AIHA patients with hypocomplementemia and multiple organ damage had high mortality. Start treatment with sufficient glucocorticoid combined with immunosuppressant is beneficial to induce remission.

Antineutrophil Cytoplasmic Antibody-Associated Vasculitis Associated With Systemic Sclerosis In Japan: A Review Of The Literature. Natsumi Nagao, Yuri Sadanaga, Satoko Tashiro, Rie Suematsu, Syuichi Koarada, Akihide Ohta and Yoshifumi Tada. Saga University, Saga, Japan.

Background/Purpose: Cases of Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) during the course of systemic sclerosis (SSc) have recently been reported. Japanese cases of AAV associated with SSc were collected from the literature, and the characteristics of patients in Japan were analyzed.

Methods: A literature review was performed using MEDLINE and the database of the Japan Medical Abstracts Society. The following keywords were used: antineutrophil cytoplasmic antibody; vasculitis; and systemic sclerosis/scleroderma. Case reports, including proceedings and abstracts from Japan that were written in either English or Japanese, were identified. A total of 61 cases were reviewed, including 58 cases from 42 reports (6 in English and 36 in Japanese) and 3 cases from our hospital. The clinical features of SSc-associated AAV were compared with those reported by the AAV survey of the Ministry of Health, Labor and Welfare study group done between 2006 and 2008 in Japan.

Results: In SSc-associated AAV, the average age at onset was 57.0 years, which was 12.4 years earlier than for all AAV patients, and women developed the disease much more frequently than men. In SSc-associated AAV, the male:female ratio was 1:9, whereas the ratio was 1:1 in all AAV. In SSc, the proportions of the diffuse and the limited types were equal; anti-Scl-70 antibody was positive in 35 cases, and anti-centromere antibody was positive in 6 cases. The mean duration between diagnosis of SSc and AAV was 10.3 years (range, 1–41 years). In AAV, alveolar hemorrhage developed in 24%, and rapid progressive glomerulonephritis developed in 81%; both were more frequent than in all AAV as reported by the survey (11% and 63%, respectively). On the other hand, neurological manifestations were less frequent in SSc-associated AAV (24% versus 45%). No cases were positive for anti-PR3 antibody. Twelve cases died, and the most frequent cause of death was infection (7 cases).

Conclusion: SSc-associated AAV in Japan has several characteristics, including younger onset, female predominance, frequent pulmonary and renal manifestations, and long duration from SSc to AAV. It should be noted that this association is not extremely rare, and increased awareness may lead to earlier diagnosis and better prognoses.

Background/Purpose: The association of pulmonary fibrosis (PF) with anti neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV), especially microscopic polyangiitis (MPA), is rare but related to poor prognosis. The possible link between PF, occult alveolar hemorrhage, ANCA positivity and specificity, and vasculitis remains unclear. The aim of the current study was to describe the characteristic features and long-term outcome in a large cohort of patients with PF associated to AAV.

Methods: We performed a retrospective study of the characteristics and outcome of 49 patients with PF associated to AAV, diagnosed between 1996 and 2013, and according to the American College of Rheumatology criteria and/or Chapel Hill definitions.

Results: Data were obtained from 30 (61%) men and 19 (39%) women. The median age at diagnosis of AAV was 66.5 [IQR: 57−74] years. Thirty nine (80%) patients had MPA and 10 (20%) had granulomatosis with polyangiitis. Besides constitutional symptoms, main extra-pulmonary manifestations included kidney involvement (57%), peripheral neuropathy (52%), and myalgia (37%). All patients had pulmonary symptoms, including crackles (77%), dyspnea (76%), chronic cough (27%) and/or hemoptysis (10%). The diagnosis of PF preceded the development of vasculitis in 21 (43%) patients, was concomitant in 21 (43%) and occurred subsequently in 7 (14%). At AAV diagnosis, restrictive syndrome was present in 67% of patients. Alveolar hemorrhage was present in 43% of patients. Thoracic computed tomography showed usual interstitial pattern in 39 (80%) patients, nonspecific interstitial pneumonia in 5 (10%) patients, and combined pulmonary fibrosis and emphysema in 5 (10%) patients. ANCA had mostly anti-myeloperoxydase specificity (84%). Hypereosinophilia was frequently observed at diagnosis of AAV (n=15,31%). All patients were treated with steroids as induction therapy, combined with cyclophosphamide (CYC) (n=37, 76%) or rituximab (RTX) (n=1, 2%). The 1-year survival in patients treated with steroids alone or combined with CYC or RTX as induction therapy was of 60% and 92%, respectively (p=0.016). After a median follow-up of 48 [14−88] months, vasculitis relapses occurred in 18 (37%) patients. Eighteen (37%) patients died, related to respiratory failure in 11 (61%) of them.

Conclusion: PF is a rare manifestation of AAV with a very poor prognosis. Induction therapy with CYC might improve the outcome.

Cardiac Involvement In Granulomatosis With Polyangiitis. Lucy McGeoch[1], Simon Carette[2], David Cuthberston[3], Gary S. Hoffman[4], Nader A. Khalidi[5], Curry L Koening[6], Carol A. Langford[7], Paul A. Monach[8], Larry W. Moreland[9], Philip Seo[10], Ulrich Specks[11], Steven R. Ytterberg[11], Carol McAlear[12], Peter A Merkel[13], Christian Pagnoux[14] and The Vcrc[13]. [1]Mount Sinai Hospital, University Health Network, University of Toronto, Toronto, ON, [2]UHN/MSH, Toronto, ON, [3]University of South Florida, Tampa, FL, [4]Cleveland Clinic Foundation, Cleveland, OH, [5]McMaster University, Hamilton, ON, [6]George E. Wahlen Department of Veterans Affairs Medical Center Salt Lake City and University of Utah, University of Utah School of Medicine, Salt Lake City, UT, [7]Cleveland Clinic, Cleveland, OH, [8]Boston University, Boston, MA, [9]University of Pittsburgh, Pittsburgh, PA, [10]Johns Hopkins Vasculitis Center, Baltimore, MD, [11]Mayo Clinic, Rochester, MN, [12]University of Pennsylvania, Philadelphia, PA, [13]University of Pennsylvania and VA Medical Center, Philadelphia, PA, [14]Division of Rheumatology, Mount Sinai Hospital, Toronto, ON.

Background/Purpose: Prior cohort studies in Europe have found cardiac involvement to be rare in granulomatosis with polyangiitis (GPA) but associated with significant increases in mortality and risk of relapse. The aim of this study was to determine the frequency and associated clinical outcomes of cardiac disease in a large multicenter North American GPA cohort.

Methods: The data source was the Vasculitis Clinical Research Consortium (VCRC) Longitudinal Study of GPA which includes 517 patients satisfying the modified ACR criteria for GPA recruited into the cohort between 2006 and 2013. Information on cardiac disease was reported by expert investigators using a standardized protocol. The demographic and clinical characteristics of patients with GPA-related cardiac involvement at diagnosis or during follow-up were compared to those patients without cardiac disease.

Results: Seventeen (3.3%) patients with cardiac involvement were identified. Cardiac manifestations were observed both at diagnosis (n=9) or during subsequent disease course and/or relapse (n=8). Observed cardiac manifestations included pericarditis (n=8), cardiomyopathy (n=5, including 1 with pericarditis), coronary artery disease (n=4), and valvular disease (n=2, including 1 with CAD). There were no overt differences between patients with GPA with cardiac involvement and those without cardiac disease: 7/17 (41%) patients with cardiac disease were female (vs. 52% in those without cardiac disease; p= 0.36); mean age at diagnosis of patients with cardiac disease was 45.2 ± 19.9 yrs. (vs. 44.8 ± 16.5 yrs. for those without cardiac disease; p= 0.92); and 16/17 (94% [PR3 65%]) with cardiac disease were tested ANCA positive (vs. 81% [PR3 68%] in those without cardiac disease; p=0.33). Frequency of non-cardiac disease manifestations were comparable between the two groups and no significant differences were observed in the immunosuppressant agents. Lag time between symptom onset and diagnosis in the cardiac GPA group was comparable to the non-cardiac GPA group (18 ± 27 mo. vs. 14 ± 36 mo. respectively; p= 0.56).

Mean follow-up from diagnosis was 104 ± 68 mo. for cardiac GPA and 105 ± 71 mo. for non-cardiac GPA (p = 0.92). Rate of relapse was comparable between the 2 groups (53% of cardiac GPA patients experienced ≥1 GPA relapse vs. 66% of the non-cardiac GPA group; p= 0.25). At present, none of the patients with cardiac disease in the cohort have died.

Conclusion: This case series confirms that cardiac involvement in GPA is rare, heterogeneous, and can manifest at disease onset as well as during subsequent relapses. In contrast with previous reports, cardiac involvement was not associated in this population with a higher rate of relapse.

Clinically Apparent Arterial Thrombosis In Persons With Systemic Vasculitis. Alexander Tsoukas[1], Christian A. Pineau[2], Sasha Bernatsky[2], Lawrence Joseph[1] and Patrick Belisle[3]. [1]McGill University, Montreal, QC, [2]McGill University Health Center, Montreal, QC, [3]Research Institute of the McGill University Health Centre, Montreal, QC.

Background/Purpose: Systemic vasculitides are a group of heterogeneous, autoimmune disorders characterized by inflammation of blood vessels. As with other autoimmune disorders, inflammation and long-term medical therapies may lead to accelerated atherosclerosis, with subsequent arterial thrombosis being a significant adverse outcome. Our first goal is to compare the rate of arterial thrombotic events in patients with systemic vasculitis, namely polyarteritis nodosa (PAN) and granulomatosis with polyangiitis (GPA), with that of the general population. Our second goal is to determine if there is an increased rate of comorbidities related to atherosclerosis within the vasculitis group compared to the general population group.

Methods: Data was collected from the Quebec provincial health administrative database from the years 2002–2006. Incident cases of all systemic vasculitis (ICD 446.x), PAN (ICD 446.0)and GPA (ICD 446.4)were included in the cohort, and age (18–45, >45-<65, and ≥65 years old) and sex-matched controls were taken from the general population. Outcomes included acute myocardial infarction (AMI; ICD 410.x) and cerebrovascular accident (CVA; ICD 433.x, 434.x) which were assessed longitudinally via hospitalization records within the same administrative data. Outcomes in vasculitis cases were compared to those in the general population. Furthermore, the incidence of comorbidities, specifically type II diabetes, hypertension, and dyslipidemia were ascertained in vasculitis patients with adequate followup and compared with the general population.

Results: Within the systemic vasculitis group (n=1672) the incidence rate for AMI was most elevated for 18–45 y.o. females (n=96) at 495.6/100k-py [95% CI 222.7–1103.2] vs. 19.5/100k-py [95% CI 18.6–20.5] in the gen. pop. (relative rate=25.4), and 18–45 y.o. males (n=46) at 1048.8/100k-py [95% CI 471.2–2334.5] vs. 89.5/100k-py [95% CI 87.4–91.6] (RR=11.7). In the PAN/GPA subgroups, similarly elevated rates existed, most significant for young males with PAN at 1683.1/100k-py. The incidence rate for CVA was most elevated in 18–45 y.o. females at 247.2/100k-py vs. 8.8/100k-py (RR=28.1).

Amongst the 45–65 y.o. patients with PAN, there was a RR for AMI of 4.9 in males. In those with GPA, there was no statistical difference in AMI, and a 2–3 RR for CVA. In the ≥65 y.o. group, there was no elevation in RR in any subgroup for either outcome.

In 18–45 y.o. females with systemic vasculitis, there was a incidence of DMII of 10.1% (vs. 0.83% in the gen. pop), dyslipidemia 5.1% (vs. 0.49%), and hypertension 24.1% (vs. 1.37%). In 18–45 y.o. males the incidence of DMII was 7.9% (vs.0.74%), dyslipidemia 13.2% (vs. 1.05%), and hypertension 31.6% (vs.1.46%). In both the 45–65 and ≥65 y.o. groups there was an approximately 2–3 times incidence for the three comorbidities compared to the gen. pop.

Conclusion: Patients with systemic vasculitis have higher incidence rates of arterial thrombotic events, with the most significant difference seen in subjects under the age of 45 y.o. The high incidence of comorbidities is likely an important factor, possibly related to corticosteroid use. However, the difference in rates observed between PAN and GCA may point to possible disease specific factors.

Granulomatosis With Polyangiitis Central Nervous System Involvement: Presentation and Management. Gonzalo De Luna[1], Benjamin Terrier[1], Pierre Kaminsky[2], Francois Maurier[3], Roser Solans[4], Raphaèle Seror[5], Xavier Puéchal[6], Luc Mouthon[7] and Loic Guillevin[1]. [1]Cochin University Hospital, Paris, France, [2]Université de Lorraine, Nancy, F-54000, France; CHU de Nancy, Orphan disease unit, Nancy, F-54000, France;, Nancy, France, [3]Division of internal Medicine, CHR Metz, Metz, Metz, France, [4]Hospital Vall d'Hebron, Barcelona, Spain, [5]Bicetre university hospital, LE Kremlin-Bicetre, France, [6]Hôpital Cochin, AP-HP, Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [7]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France.

Background/Purpose: Granulomatosis with polyangiitis (GPA), a small-sized–vessel vasculitis, commonly involves ear, nose & throat (ENT), lungs and kidneys, and, more rarely, the central nervous system (CNS). Three different pathological CNS-involvement patterns are known: 1) a manifestation of generalized GPA, with vasculitis of small-sized brain or spinal cord vessels; 2) contiguous granulomatous CNS invasion from extracranial sites; 3) intracerebral (meninges (pachymeningitis) or brain) granulomatous lesions. We evaluated GPA CNS clinical features, imaging findings, treatments and outcomes.

Methods: GPA patients with CNS (pachymeningitis, meningitis, stroke, spinal cord and/or hypophyseal) involvement who met ACR criteria and/or Chapel Hill definitions, after excluding other causes, were studied retrospectively. Patient characteristics, treatments and outcomes were analyzed. Neurological sequelae were evaluated with a simplified modified Rankin scale (mRS) by telephone interview at the last follow-up.

Results: We included 31 patients (22 men), whose mean age at GPA diagnosis and onset of CNS involvement were 46±17 and 50±15 years, respectively. The latter was present in 14 (45%) patients at GPA diagnosis, and appeared in the other 17 (55%) after a median follow-up of 69 months. Headache was the main symptom (64%), along with motor (32%) and sensory impairments (41%). CNS lesions were: 19 pachymeningitis (16 cranial and 3 spinal cord), 14 ischemic or 3 hemorrhagic strokes, 5 cerebral vasculitides and/or 2 hypophyseal lesions. Extra-CNS manifestations affected ENT (81%), lungs (58%), peripheral nerves (48%) and kidneys (35%). ANCA detected in 27/31 (87%) patients had PR3 (n=22) or MPO (n=5) specificity.

Induction comprised corticosteroids (CS; 100%) combined with IV (61%) or oral (35%) cyclophosphamide (CYC), or rituximab (RTX; 3%). Maintenance therapy consisted of CS (100%) combined with azathioprine (58%), methotrexate (19%) or RTX (6%).

After 73±56 months of follow-up since GPA CNS onset, CNS manifestations had responded clinically in 26/31 (84%) patients, whereas 5 (16%) patients had refractory CNS GPA. Seven out of the 26 (27%) responders relapsed after a median of 13 months. Relapsed and/or refractory CNS GPA was seen in 9/14 (64%) of patients with initial vascular CNS manifestations but only in 5/19 (26%) of those with granulomatous lesions. Overall, relapsing and/or refractory CNS involvement was more frequently associated with vascular CNS manifestations (P=0.04).

Relapsing and/or refractory CNS (n=12) were treated with CS (100%) and RTX (58%), IV CYC (33%) or oral CYC (8%). All but one achieved remission after new induction regimen. One patient died. Neurological sequelae persisted in 10/31 (32%) patients. Diabetes insipidus related to hypophyseal GPA persisted after induction and maintenance regimens in the 2 patients.

Conclusion: Our series highlights the heterogeneity of GPA CNS involvement. Despite initial severe disease, most patients improved under conventional therapy. Baseline vascular CNS manifestations were more frequently associated with relapsing and/or refractory disease than granulomatous lesions. RTX deserve to be evaluated to treat GPA patients with CNS involvement.

Safety Of Remission Induction With Rituximab Versus Cyclosphosphamide In Patients 65 and Older With Severe ANCA-Associated Vasculitis. Eli Miloslavsky[1], Ulrich Specks[2], Peter A Merkel[3], Philip Seo[4], Robert F. Spiera[5], Carol A. Langford[6], Gary S. Hoffman[7], Cees G.M. Kallenberg[8], E. William St. Clair[9], Nadia Tchao[10], Linna Ding[11], David Ikle[12], Brett Jepson[12], Paul Brunetta[13] and John H. Stone[14]. [1]Massachusetts General Hopsital, Boston, MA, [2]Mayo Clinic, Rochester, MN, [3]University of Pennsylvania and VA Medical Center, Philadelphia, PA, [4]Johns Hopkins Vasculitis Center, Baltimore, MD, [5]Hospital for Special Surgery, New York, NY, [6]Cleveland Clinic, Cleveland, OH, [7]Cleveland Clinic Foundation, Cleveland, OH, [8]University Medical Center Groningen, Groningen, Netherlands, [9]Duke University Medical Center, Durham, NC, [10]Immune Tolerance Network, Bethesda, MD, [11]NIAID, Bethesda, MD, [12]Rho, Chapel Hill, NC, [13]Genentech, So San Francisco, CA, [14]Massachusetts General Hospital, Boston, MA.

Background/Purpose: Retrospective studies have demonstrated that patients of advanced age with systemic vasculitis experience a higher mortality and adverse events than their younger counterparts. However, no study has prospectively examined the safety of remission induction treatment of Granulomatosis with Polyangiitis (GPA) or Microscopic Polyangiitis (MPA) in patients of advanced age. We analyzed the results of the Rituximab in ANCA-associated vasculitis (AAV) (RAVE) trial in order to evaluate adverse events (AEs) and mortality in patients ≥ 65 years old.

Methods: Randomized controlled trial comparing rituximab (RTX, n=99) to cyclophosphamide (CYC) followed by azathioprine (AZA, n=98) for remission induction in patients with GPA or MPA. Glucocorticoids were tapered over 5 months. Subjects were followed for 18 months.

Results: 55 patients were ≥ 65 years old (36 RTX, 19 CYC/AZA) and 142 patients were < 65 years old (63 RTX, 79 CYC/AZA). Baseline characteristics of both groups are reported in the table. Treatment regimens achieved similar efficacy in both age groups.

While total adverse events were similar between both age groups, patients ≥ 65 had more severe AEs (Grade ≥ 3) than those < 65 (Table). Severe cytopenias occurred more frequently in older patients. All four deaths during the study period occurred in patients ≥ 65 (2 RTX, 2 CYC/AZA).

Table. Baseline characteristics and adverse events

	Under 65 (95% CI)	65 and Older (95% CI)
Mean baseline BVAS/WG	7.84	8.51
Mean baseline creatinine	1.33	1.74
PR3-ANCA	74.6%	45.5%
MPO-ANCA	25.4%	54.5%
Achieved complete remission at 6 mos	61.3%	50.9%
Remained in complete remission at 18 mos	37.3%	32.7%
Mean total prednisone dose (g)	7.07	5.73
Total adverse events/patient year	10.51 (10.07–10.97)	11.50 (10.73–12.3)
Severe adverse events (Grade ≥3)/ patient year	0.52 (0.42–0.63)	1.06 (0.83–1.32)
Severe infections/patient year	0.10 (0.06–0.16)	0.21 (0.12–0.34)
Severe cytopenias/patient year	0.03 (0.01–0.06)	0.23 (0.14–0.37)
Deaths	0	4

Comparing the two treatment arms among patients 65 and older, frequencies of total AEs or severe AEs were similar between the RTX and CYC/AZA groups (11.52/patient year RTX vs 11.44/patient year CYC/AZA; 1.15/patient year (95% CI 0.87–1.50) RTX vs 0.85/patient year (0.52–1.31) CYC/AZA, respectively). Similarly, the frequency of severe cytopenias and severe infections were comparable between the two groups (0.24 (95% CI 0.13–0.42)/patient year RTX vs 0.21 (95% CI 0.07–0.49)/patient year CYC/AZA; 0.22 (95% CI 0.11–0.40)/patient year RTX vs 0.17 (95% CI 0.05–0.43)/patient year CYC/AZA), respectively.

Conclusion: Patients ≥ 65 undergoing remission induction treatment for GPA or MPA may experience more severe adverse events than their younger counterparts, including more frequent severe cytopenias. Both RTX and CYC/AZA-based regimens have a similar adverse event profile in patients ≥ 65 years old.

743

Efficacy Of Rituximab For Otolaryngologic (ENT) Manifestations Of Granulomatosis With Polyangiitis (GPA, Wegener's granulomatosis). Lindsay Lally[1], Robert Lebovics[2], Wei-Ti Huang[1] and Robert F. Spiera[1]. [1]Hospital for Special Surgery, New York, NY, [2]St. Luke's-Roosevelt Hospital Center, New York, NY.

Background/Purpose: ENT involvement is the most prevalent manifestation of GPA. Rituximab (RTX) is a proven effective remission induction therapy for severe GPA with vasculitic manifestations. The efficacy of RTX for the granulomatous manifestations of GPA is debated. No previous studies have looked at the efficacy of RTX specifically for ENT manifestations of GPA. The aim of this study was to compare the efficacy of RTX to other therapies for the ENT manifestations of GPA, in a well-characterized cohort.

Methods: Subjects with GPA seen at a tertiary care ENT practice between 2003 and 2013 were identified via ICD-9 code. Charts were reviewed for demographics, organ involvement, ENT disease activity, medications, and procedures at each visit. At each visit subjects had complete ENT exam including endoscopic visualization of the upper airway and audiometry, for those with otologic involvement. Endoscopic exam and assessment of ENT disease activity were all performed by one otolaryngologist with specific expertise in GPA. Primary outcome was ENT disease activity at each visit in subjects on RTX versus those on all other therapy. RTX use was defined a priori as most recent infusion within 6 months or continued B cell depletion at the time of the visit. Secondary outcomes were comparison of ENT disease activity in subjects on RTX to those on MTX, AZA, CYC or TMP-SMX.

Results: 99 subjects with GPA were identified and 975 office visits from the subjects were analyzed. The mean age was 49.8 years, mean disease duration 8.1 years, 68.7% were female, 63.5% had limited disease and 76.8% had positive PR3. 48 subjects never received RTX and 51 received RTX at least once. Comparing patients who ever received RTX to those who did not, those treated with RTX were significantly more likely to have severe disease (48% vs 26%, p=0.027) and were also more likely to have ENT damage at baseline (94% vs73%, p=0.004). There were no other differences between the groups.

Outcomes: There was no active ENT disease at 92.4% of visits for subjects on RTX compared to 53.7% of visits for subjects not receiving RTX (OR 11.0; 95%CI 5.5–22.0, p<0.0001). Adjusting for ENT damage, extent and duration of disease, age, and sex, RTX was still favored (OR 12.0; 95%CI 5.9–24.3, p<0.0001). Subjects on RTX compared to MTX, AZA, CYC, or TMP-SMX were significantly more likely to be in ENT remission, p<.0001 for each comparison (Table 1).

Table 1.

Medication	Visits on Medication, n (%)	Visits with ENT Remission, n (%)	Adjusted OR, 95% CI	P value**
RTX	144 (14.8)	133 (92.4)		
Not RTX*	831 (85.2)	449 (53.7)	12.0 (5.9–24.3)	< .0001
MTX	197 (20.2)	116 (58.9)	11.5 (6.4–24.8)	< .0001
CYC	55 (5.6)	12 (21.8)	52.8 (19.1–145.9)	< .0001
AZA	98 (10.1)	53 (54.1)	8.1 (3.3–19.7)	< .0001
TMP–SMX	113 (11.6)	64 (56.2)	13.4 (5.9–30.6)	< .0001
Other	94 (9.6)	45 (47.9)	17.0 (6.9–41.6)	< .0001

*includes MTX, CYC, AZA, TMP–SMX, other and no therapy (not accounting for corticosteroids)
**mixed linear effect model

Conclusion: RTX is an effective treatment for ENT manifestations of GPA. Subjects treated with RTX were >11 times less likely to have active ENT disease compared to those not on RTX. Those treated with RTX were far less likely to have active ENT disease than those treated with other immunosuppressives. This represents the largest cohort of patients in whom meticulously assessed ENT outcomes with RTX versus other therapies is described and suggests RTX is superior to conventional immunosuppressives for ENT manifestations of GPA.

Background/Purpose: MAINRITSAN trial (NCT 00748644) results demonstrated that 500 mg of rituximab (RTX) every 6 months was superior to azathioprine (AZA) to maintain ANCA-associated–vasculitis (AAV) remission. Infection frequencies were comparable in the 2 arms, and other SAE were infrequent and resolved in most patients. This study aimed to determine whether globulin levels could be associated with infectious side effects.

Methods: Once remission was obtained with a conventional regimen, patients with newly diagnosed or relapsing AAV were randomly assigned to receive a 500-mg RTX infusion on D1, D15, 5.5 months later, then every 6 months for a total of 5 infusions over 18 months, or AZA (initial dose 2 mg/kg/d) for 22 months. The primary endpoint was the major relapse rate (EULAR/ACR criteria) at 28 months. Other outcome measures were the severe adverse event (SAE) rate (WHO definition) associated with each maintenance regimen. Infectious SAE occurring in both groups were one of the study's secondary endpoints, as were gammaglobulin, IgG and IgM levels (1/3 missing data for valid reasons).

Results: Among the 115 patients (50 men/65 women; mean age, 55±13 years; 92 newly diagnosed and 23 relapsers) study participants (57 RTX arm, 58 AZA arm): 87 had granulomatosis with polyangiitis, 23 microscopic polyangiitis and 5 kidney-limited diseases. The main clinical involvements at diagnosis or last relapse were: 89 (77.4%) ENT, 71 (61.7%) lung and 81 (70.4%) kidney. Major relapses occurred in 20 (17.3%) patients: 3 (3.5%) in the RTX arm and 17 (29.3%) in the AZA arm, with 3 AZA-arm deaths (1 sepsis, 1 pancreatic cancer, 1 mesenteric ischemia). Seven infectious SAE (12.2%) were recorded in the RTX arm and 8 (13.7%) in the AZA arm (Table). Respective RTX- and AZA-arm mean levels (g) of gammaglobulin were: 8.04 (±6.05) and 7.21 (±2.18) at M0, and 7.41 (±2.16) and 8.1 (±2.89) at M28; IgG were 6.06 (±2.66) and 5.44 (±1.58) **at M0**, and 6.87 (±2.50) in the RTX arm and 6.71 (±1.05) **at M28**; IgM were 0.64 (± 0.5) and 0.58 (± 0.51) at M0, and 0.44 (±0.62) and 0.6 (±0.32) at M28.

Infection	RTX 57 patients	AZA 58 patients
Bronchitis	2	0
Tuberculosis	1	0
Bacterial pneumonia	0	1
Pneumocystis jiroveci pneumonia	1	0
Bacterial endocarditis	0	1
Mycobacterial infection	0	1
Prostatitis	0	1
Herpes zoster	1	1
Angiocholitis	0	1
Septicemia	0	1 (died)
Esophageal candidiasis	1	0
Campylobacter jejuni diarrhea	1	1

Conclusion: These trial results demonstrated that 500 mg of RTX every 6 months was not only superior to AZA to maintain AAV remission but as safe as AZA. At the chosen dose, RTX did not significantly decrease gammaglobulin, IgG and IgM levels. The rare infections, observed in both groups, were reflected causes and mechanisms other than Ig levels.

Rate Of Infection and Development Of Malignancy In Patients With ANCA-Associated Vasculitis Treated With Rituximab: A Meta-Analysis From Randomized Trials. Carolina Mejia-Otero[1], Carlos J. Lozada[2] and Luis Arias-Urdaneta[3]. [1]Mount Sinai Medical Center, Miami, FL, [2]University of Miami Miller School of Medicine, Miami, FL, [3]Mount Sinai Medical Center, Miami Beach, FL.

Background/Purpose: Over the past 40 years failures to achieve remission in a proportion of patients and the potential development of significant adverse effects have been major drawbacks of cyclophosphamide (CYC)-based regimens. Rituximab, an anti-CD20 monoclonal antibody, has compared favorably to CYC-based regimens for remission-induction of ANCA-associated vasulitis (AAV) in controlled clinical trials. It has also been able to maintain clinical remission in some patients for several months of follow up without the need for medication-based maintenance regimens. We intend to describe the rates of major adverse events (malignancy, infections) with

rituximab and control interventions in existing randomized controlled trials for the treatment of AAV.

Methods: All randomized controlled trials of rituximab in patients with AAV were sought in PubMed, EMBASE, and Cochrane databases during December 2012. Pooled treatment effects were estimated using risk ratio (RR) with the Mantel–Haenszel risk ratio in a random-effects model. Heterogeneity was assessed using chi-square tests and I2 statistic; we defined I2 < 25% as low heterogeneity according to the Cochrane Handbook of Systematic Reviews. For statistical analysis, we used Review Manager 5.1

Results: Upon analysis of the pooled data of included trials [1, 2, 3], rituximab was shown to be more efficacious in achieving remission than the control interventions. Even though no statistically significant difference was found in the rates of adverse events, the rate of malignancy tended to be more prevalent in the rituximab group when compared to the control group (P= 0.85, *figure 1*). In contrast, infection rates were more prevalent in the control group when compared to rituximab (P= 0.84, *figure 2*). Patient exposure to several immunosuppressive drugs in these trials, makes appraising the direct responsibility of one agent, rituximab or CYC, in the occurrence of the adverse events reported by investigators a significant challenge. In addition, AAV itself may predispose patients to malignancy or infection. Long-term follow up of the patients from these trials may provide further information about the safety profile of rituximab.

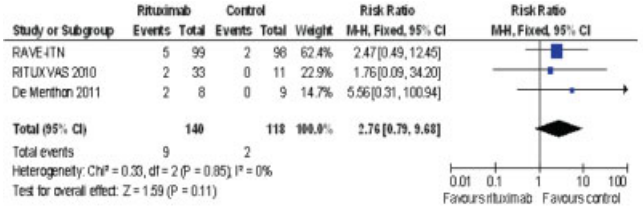

Figure 1. Malignancy rates

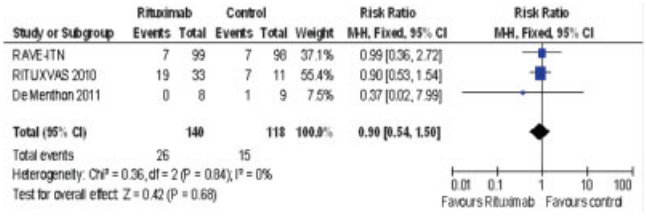

Figure 2. Infection rates

Conclusion: Rituximab has been shown an effective alternative for achieving remission in AAV when compared to the control interventions in this meta-analysis. This therapy may allow long term disease control with fewer side effects in patients with AAV but more randomized control trials are needed.

Glucocorticoid Treatment and Damage In The Antineutrophil- Cytoplasm Antibody Associated Vasculitides. Joanna Robson[1], Helen Doll[2], Ravi Suppiah[3], Oliver Flossmann[4], Lorraine Harper[5], Peter Hoglund[6], David Jayne[7], Alfred Mahr[8], Kerstin Westman[9] and Raashid A. Luqmani[10]. [1]Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, Botnar Research Centre, University of Oxford, Oxford, United Kingdom, [2]University of East Anglia, Norwich, United Kingdom, [3]Auckland District Health Board, Auckland, New Zealand, [4]Royal Berkshire Hospital, Reading, United Kingdom, [5]University of Birmingham, Birmingham, United Kingdom, [6]Skane University Hospital, Lund, Sweden, [7]Addenbrookes Hospital University of Cambridge, Cambridge, United Kingdom, [8]Department of Internal Medicine, Hospital Saint-Louis, Paris, France, [9]Skåne University Hospital Malmö, Lund University, Malmö, Sweden, [10]University of Oxford, Oxford, United Kingdom.

Background/Purpose: Granulomatosis with polyangiitis [Wegener's] (GPA) and microscopic polyangiitis (MPA) are antineutrophil-cytoplasm antibody associated vasculitides (AAVs). Damage is quantified by the Vasculitis Damage Index (VDI). Long term (up to 7 years) damage has been described for patients from four European Vasculitis Study Group (EUVAS) trials. The objective of this study is to determine the factors associated with long-term damage in the ANCA-associated vasculitides.

Methods: Data from N=535 patients from four EUVAS trials were studied. A long-term follow up (LTFU) questionnaire at 7 years post diagnosis was completed including VDI and glucocorticoid data. The associations between baseline (age, creatinine and BVAS scores) and follow-up data (number of relapses and duration of glucocorticoids) and damage over LTFU (total VDI scores and individual treatment related damage items) were explored. Multiple regressions were used to look for independent associations between baseline measures, cumulative factors and VDI scores at LTFU.

Results: 296 patients had steroid use and VDI data available at LTFU, with the mean length of use 40.4 (SD 16.7) months. On multiple linear regression, high levels of damage were associated with age at baseline (p=.048), serum creatinine (p=.042), number of relapses (p=.021), and cumulative glucocorticoid use (p=.026). Patients with a longer duration of glucocorticoid treatment [OR=1.21 per 10 months (95%CI 1.3 to 1.42), p=0.019] were more likely to have a total VDI score of ≥5 at LTFU.

Conclusion: Long term damage in the ANCA-associated vasculitides may be predicted by severity of initial disease, age, number of relapses and duration of steroids used; improvement in immunosuppressant therapies is therefore indicated.

Table 1. Independent associations between baseline factoss, relapse and steroid use and (A) overall damage, (B) treatment-related damage

Factor	B (SE)	p-value	OR (95% CI)	p-value
(A) Overall damage	**Total number of items**		**5+ items**

Efficacy Of Glucocorticoids To Treat Limited Flares In ANCA-Associated Vasculitis. Eli Miloslavsky[1], Ulrich Specks[2], Peter A. Merkel[3], Philip Seo[4], Robert F. Spiera[5], Carol A. Langford[6], Gary S. Hoffman[7], Cees G.M. Kallenberg[8], E. William St. Clair[9], Nadia Tchao[10], Linna Ding[11], David Ikle[12], Brett Jepson[12], Paul Brunetta[13] and John H. Stone[14]. [1]Massachusetts General Hopsital, Boston, MA, [2]Mayo Clinic, Rochester, MN, [3]University of Pennsylvania, Philadelphia, PA, [4]Johns Hopkins Vasculitis Center, Baltimore, MD, [5]Hospital for Special Surgery, New York, NY, [6]Cleveland Clinic, Cleveland, OH, [7]Cleveland Clinic Foundation, Cleveland, OH, [8]University Medical Center Groningen, Groningen, Netherlands, [9]Duke University Medical Center, Durham, NC, [10]Immune Tolerance Network, Bethesda, MD, [11]NIAID, Bethesda, MD, [12]Rho, Chapel Hill, NC, [13]Genentech, So San Francisco, CA, [14]Massachusetts General Hospital, Boston, MA.

Background/Purpose: The great majority of patients with granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) achieve disease remission initially, but relapses occur in up to 50% of patients within three years. Most disease flares are limited rather than severe. The most common approach to treating limited flares is to increase the glucocorticoid dose with or without a change in other immunomodulatory therapy. However, the effectiveness of this approach has never been studied.

Methods: This analysis explored the outcomes of patients with a first limited flare in the RAVE trial. Limited flares (BVAS/WG ≤ 3 and no major BVAS/WG items) were treated, per protocol, by increasing prednisone to a dose selected by the investigator. The new prednisone dose was maintained for 1 month before resumption of a protocol-specified taper with an endpoint of 0mg. Patients were followed for 18 months from study entry. The primary

outcome was the percentage of patients who achieved and maintained remission without additional changes in therapy.

Results: 47 patients (24%) experienced limited flares and were treated with an increase in prednisone. 25 limited flares occurred in the rituximab (RTX) group and 22 in the cyclophosphamide/azathioprine (CYC/AZA) group. 38 patients (81%) who flared were PR3-ANCA-positive and 29 (62%) had relapsing disease at baseline. 41 patients (87%) achieved remission before experiencing their first limited flare, which occurred on average 7.6 months (range 1.8–17.2) after entry. 28 patients (60%) who experienced a limited flare were off prednisone at the time of the flare, and the mean daily dose at flare among patients who remained on prednisone was 7.1 mg (range 2.5–20.0). Within the CYC/AZA group, 9% of the patients with limited flares were still receiving CYC and 86% were on azathioprine.

Following the limited flare, patients were followed for an average of 7.0 months (range 0.7–16.3). The average daily prednisone dose used to treat limited flares was 19.5mg (range 2.5–80). 36 patients (77%), (18 RTX and 18 CYC/AZA) achieved remission again, an average of 2.5 months after the increase in prednisone dose. However, 26 patients (55%) were unable to achieve and maintain remission throughout the follow-up period: 15 failed to sustain remission and 11 did not reach remission. 22 patients (47%) had recurrent flares: 13 limited (8 RTX, 5 CYC/AZA) and 9 severe (5 RTX, 4 CYC/AZA). Of these, 9 had discontinued prednisone and 13 patients were receiving 7.7mg (range 2.5–20) of prednisone on average. One patient had persistently elevated BVAS/WG (i.e., did not achieve remission again), and three withdrew from the trial. Only 11 patients (23%) who experienced limited flares were able to achieve remission, discontinue prednisone, and maintain remission through month 18.

Conclusion: Treatment of limited flares in AAV with a temporary increase of glucocorticoids is effective in restoring disease control in most patients, but recurrent flares within a relatively short time period are the rule in this scenario. Alternative approaches to the treatment of limited flares, including continuing glucocorticoids indefinitely or increasing or changing concomitant immunosuppressive therapies, must be considered.

748

Efficacy Of Methotrexate For Remission Induction and Maintenance In Granulomatosis With Polyangiitis In Routine Clinical Practice. Megan L. Krause, Misbah Baqir, Rodrigo Cartin-Ceba, Tobias Peikert, Karina Keogh and Ulrich Specks. Mayo Clinic, Rochester, MN.

Background/Purpose: Methotrexate has been shown to be effective for both induction (non-severe disease) and maintenance of remission in patients with Granulomatosis with Polyangiitis (GPA) in the context of controlled clinical trials. Limited data are available regarding the long term efficacy of methotrexate in the routine care of patients with GPA. We conducted this study to determine the outcomes of routine methotrexate use in a cohort of patients with GPA.

Methods: Single center retrospective study of patients of GPA treated with methotrexate for either induction or maintenance of remission between January 1997-December 2012. Measured outcomes included time to remission, time to relapse and adverse effects of methotrexate. Remission was defined as Birmingham Vasculitis Activity Score for Wegener's Granulomatosis (BVAS/WG) of 0 with prednisone dose < 10 mg/d. Disease relapse was defined as an increase in the BVAS/WG of 1 point or more after having achieved remission. Kaplan Meier estimation with Log-rank test was used for evaluation of the efficacy outcomes.

Results: Seventy-four patients with GPA were treated with methotrexate. Thirty-nine patients (53%) were c-ANCA/PR3 positive, 22 (30%) were p-ANCA/MPO positive and 13 (17%) were ANCA negative. The mean age (standard deviation, SD) at diagnosis was 48.6 (15.3) and 26 (35%) were men. GPA was biopsy proven in 57 patients (77%). At the time of diagnosis, the mean BVAS/WG was 7.0 (SD, 3.9). Of the total cohort, 18 patients (24%) used methotrexate for remission maintenance. The remaining 56 used methotrexate for induction of remission; eleven of these patients (15%) did not achieve remission with methotrexate. From the remaining 45 patients, 35 patients that used methotrexate for remission induction in newly diagnosed non-severe disease achieved remission at a median of 100 days (IQR, 84–153); 10 patients that used methotrexate for remission induction after a relapse were able to achieve remission after a median of 75 days (IQR, 50–114) ($p=0.04$). Nineteen patients relapsed, 15 (31%) in the induction group and 4 (28%) in the maintenance group ($p=0.99$). The time from achieving remission to relapse was 589 days (IQR 260–1153) in the induction group versus 781 days (IQR, 93–863) in the maintenance group, $p=0.7$. The cohort was followed at our institution for a median of 3.5 years (IQR, 1.6–10.3). At the time of conclusion of follow-up, 37 (50%) remained on methotrexate. Methotrexate had to be discontinued in 5 (6.8%) patients due to side effects. Liver toxicity followed by nausea/vomiting were the most commonly experienced adverse events. One patient developed *Pneumocystis jirovecii* pneumonia while on methotrexate.

Conclusion: In this clinical cohort of GPA patients treated with methotrexate, the time to achieve remission was significantly shorter for patients treated for induction after a relapse as compared to patients treated for initial induction. Time to relapse was not different for patients treated with methotrexate for maintenance therapy as compared to patients treated for induction of remission. Methotrexate is well tolerated long-term, and only a minority of patients had to discontinue methotrexate due to adverse events.

High Clinical Remission Rate With Relatively High Incidence Of Serious Infection In Newly-Onset ANCA-Associated Vasculitides In Japan - A Report From The Nationwide Prospective Cohort Study. Masayoshi Harigai[1], Ken-ei Sada[2], Takao Fujii[3], Masahiro Yamamura[4], Yoshihiro Arimura[5] and Hirofumi Makino[2]. [1]Tokyo Medical and Dental University, Tokyo, Japan, [2]Okayama University, Okayama, Japan, [3]Graduate School of Medicine, Kyoto University, Kyoto, Japan, [4]Okayama Saiseikai Hospital, Okayama, Japan, [5]Kyorin University School of Medicine, Tokyo, Japan.

Background/Purpose: Clinical characteristics and antineutrophil cytoplasmic antibody (ANCA)-serology of ANCA-associated vasculitis (AAV) patients are substantially different between Western and Asian countries. We investigated effectiveness and safety of remission induction therapy currently performed for patients with AAV in Japan using data from a nationwide prospective inception cohort study (UMIN000001648).

Methods: A total of 156 Japanese patients with newly diagnosed AAV (safety population) were registered by 22 university hospitals and referring hospitals from 2009 until 2010, and 155 had follow-up data (effectiveness population). Patients were classified according to the European Medicines Agency (EMEA) algorithm. Patients were evaluated at Months 3, 6, 12, 18, and 24 and at relapse. Remission, survival and renal survival rates were compared among groups by disease classification, disease severity (localized, early systemic, generalized, severe), and concomitant use of cyclophosphamide (CY).

Results: Of 156 patients, 14 patients were classified as having eosinophilic granulomatosis with polyangiitis (EGPA), 33 patients were granulomatosis with polyangiitis (GPA), 78 patients were microscopic polyangiitis (MPA), 31 patients were unclassified (U). Baseline characteristics of 156 patients were as follows: mean age, 68 years old; female, 61%; P-ANCA positive, 83%; C-ANCA positive, 12%; mean serum creatinine, 1.75 mg/dl; mean Birmingham vasculitis activity score (BVAS), 17. As remission induction therapy, all patients started corticosteroid with mean prednisolone-equivalent dosage of 42 mg/day, and 62 (40%) and 54 (35%) were given methylprednisolone pulse therapy and cyclophosphamide, respectively. Of the effectiveness population, 141 (91%) achieved remission by Month 18. The time to remission differ significantly by disease classification ($P=0.0004$, U<EGPA<MPA<GPA), but not by severity or treatment. Although survival rate did not differ by disease classification, the disease severity affected the survival rate significantly ($P=0.0001$, severe<early systemic <generalized<limited). Patients with concomitant use of CY had significantly better survival rate ($P=0.040$). Thirteen (8%) patients reached renal death. There were significant differences of time to renal death among the disease severity ($P=0.0121$, MPA<U<GPA=EGPA) and among disease classification ($P<0.0001$, severe<generalized<early systemic<limited). In the safety population, serious infections (SIs) were the most frequent serious adverse events. During the first six months, 63 SIs developed in 42 patients (88/100 patient-year). The median length of time to the onset of SIs was 57 days. Multivariate analyses revealed that male (HR 2.1, $p=0.024$), severe type (HR 2.2, $p=0.025$), and initial corticosteroid dosages >0.8mg/kg/day (PSL-equivalent) (HR 2.7, $p=0.002$) were identified as predictors for SIs.

Conclusion: More than 90% of newly onset AAV patients achieved BVAS remission in clinical practice in Japan with relatively high incidence of serious infection. Investigation to establish treatment strategy with better benefit-risk balance is warranted.

Maintenance Treatment In Childhood Granulomatosis With Polyangiitis. Marinka Twilt[1], Rayfel Schneider[1], Diane Hebert[1], Elizabeth Harvey[1], Ronald M. Laxer[1], Sharon Dell[1], Christoph Licht[1] and Susanne M. Benseler[2]. [1]The Hospital for Sick Children, Toronto, ON, [2]Hospital for Sick Children, Toronto, ON.

Background/Purpose: Granulomatosis with Polyangiitis (GPA) is a rare but life threatening disease. Most children present with pulmonary bleeds and/or renal failure. Most treatment regimens are derived from the adult literature, no studies have been performed in pediatric patients.

Methods: All consecutive children diagnosed with GPA since January 2000 in the Hospital for Sick Children were included. Demographic data, data at diagnosis and follow-up data were collected. Descriptive statistics were used for these preliminary results.

Results: 32 children were diagnosed with GPA since January 2000. Twenty-one girls and 11 boys, with a median age of 13.7 years at diagnosis. ANCA was positive in 30 children (26 c-ANCA with 25 anti-PR-3, 4 p-ANCA with 4 anti MPO) and 2 were ANCA negative (1 anti-PR3 positive). Eight children had limited disease and 24 systemic disease. All systemic patients were treated with pulses cyclophospamide iv (mean 7 pulses) and methylprednisone (mean 5 pulses) iv, and 6 children received plasmapheresis. Maintenance treatment in this group consisted of MTX in 7, AZA in 14, MMF in 3 children. In the limited disease group, treatment consited of oral prednisone in all, MTX in 7 children and AZA in 1. Relapses were seen in 14 children. One child did not receive any treatment at time of relapse. Two children with limited disease relapsed, both while still on MTX. 11 children with systemic disease were still on treatment, MTX in 4, AZA in 5, MMF in 2.

Conclusion: Relapses are seen often in childhood GPA when still receiving maintenance treatment. Relapses are higher in children with systemic GPA (50%) compared to limited GPA (25%).

Fatigue, Pain, and Functional Disability Among Patients With Vasculitis. Antoine G. Sreih[1], Narender Annapureddy[2] and Osama Elsallabi[3]. [1]The University of Pennsylvania, Philadelphia, PA, [2]Rush University Medical Center, Chicago, IL, [3]Creighton University, Omaha, NE.

Background/Purpose: Vasculitis is a heterogeneous group of diseases often resulting in severe morbidity affecting patients' quality of life. These morbidities are generally attributed to disease activity, end-organ damage, and the use of immunosuppressive therapy. Current tools for assessing vasculitis do not include patient-reported outcomes such as fatigue, pain, and functional disability. We measured various clinical outcomes using the Multi-Dimensional Health Assessment Questionnaire (MDHAQ) to determine if the outcomes correlate with disease activity, disease damage, glucocorticoid dose, and laboratory parameters.

Methods: Patients with large vessel vasculitis (LLV) and ANCA-associated vasculitides (AAV) treated at the Rush Vasculitis Clinic from 2010 to 2013 were administered the MDHAQ at every visit. The MDHAQ measures functional disability (score: 0–10), pain and fatigue (visual analogue scales: 0–10), and depression, anxiety, and sleep disturbance (each measure scored 0–3). For all MDHAQ scales higher scores mean worse symptom. The Birmingham Vasculitis Activity Score (BVAS) and the Vasculitis Damage Index (VDI) were used to calculate disease activity and damage, respectively. All evaluations reported here represent the baseline values at first visit.

Results: 51 patients participated in the study: 29 with AAV and 22 with LVV, 40 females, 31 Caucasians, 13 Hispanics, and 7 African-Americans. Mean age was 53.2 years. The mean BVAS was 5.1 ± 1.6 and mean VDI was 2.1 ± 0.3. 91% of patients were on prednisone, mean dose=23.2 ± 2.9 mg/day. Fatigue was the most frequently reported symptom (82%, mean=3.8 ± 0.4) followed by pain (77%, mean=3.2 ± 0.4), sleep disturbance (66%, mean=0.8 ± 0.1), anxiety (42%, mean= 0.52 ± 0.1) and depression (37%, mean= 0.4 ± 0.1). Functional disability was reported by 80% of patients (mean=1.7 ± 0.23). Fatigue, pain, and functional disability did not correlate with BVAS, VDI, dose of glucocorticoids, erythrocyte sedimentation rate (ESR) or hemoglobin level (Table 1).

Table 1. Correlations between fatigue, pain and functional disability with the BVAS, VDI, glucocorticoid dose, ESR and Hemoglobin.

	BVAS		VDI		GC dose		ESR		Hb	
	r	P	r	p	r	p	r	p	r	p
Fatigue	0.08	0.63	0.11	0.46	−0.03	0.82	−0.14	0.44	0.08	0.63
Pain	0.99	0.55	−0.4	0.06	0.04	0.82	0.4	0.06	0.04	0.85
Functional disability	0.04	0.75	−0.05	0.77	0.07	0.61	−0.19	0.25	−0.12	0.5

GC (Glucocorticoid), ESR (Erythrocyte Sedimentation Rate), Hb (Hemoglobin)

Conclusion: Fatigue, pain, and functional disability are frequent self-reported symptoms in patients with AAV and LVV. These symptoms do not correlate with disease activity, damage, glucocorticoid dose, ESR, or hemoglobin level. While disease control is of prime importance, it is also important to address these symptoms that may not reflect disease activity or disease damage but can substantially impact patients' quality of life.

Cardiovascular Outcomes Are Worse In Microscopic Polyangiitis Compared To Granulomatosis With Polyangiitis: Data From An Inception Cohort Of Patients With Anti-Neutrophil Cytoplasm Antibody Associated Systemic Vasculitis. Anna Mistry[1], Joanna Robson[2], Susan L Hogan[3], Caroline Poulton[3], Yichun Hu[3], Ronald Falk[4] and Raashid A. Luqmani[5]. [1]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, UK, Oxford, United Kingdom, [2]Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, Botnar Research Centre, University of Oxford, Oxford, United Kingdom, [3]UNC Kidney Centre, University of North Carolina, Chapel Hill, North Carolina, Chapel Hill, NC, [4]UNC Kidney Center, Chapel Hill, NC, [5]Nuffield Orthopaedic Centre, Oxford, United Kingdom.

Background/Purpose: A greater than three-fold increase in cardiovascular mortality as been reported within the first five years of diagnosis of anti-neutrophil cytoplasmic antibody (ANCA) associated systemic vasculitis (AASV) compared to the general population. A 5 year predictive cardiovascular risk model was developed using data derived from a trial cohort, to stratify patients into a high, moderate or low risk of a cardiovascular (CV) event.

We describe the CV events occurring in an inception cohort of patients with a new diagnosis of AASV within the first 5 years of diagnosis and test the validity of the existing predictive risk model in parallel.

Methods: A retrospective case note review was performed on 387 patients recruited to a vasculitis registry with a diagnosis of granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA).

CV events following the diagnosis of GPA or MPA in this cohort were analysed over time and results compared to the predicted rate per 1000 general population matched for age and gender. CV events were then stratified according to proteinase-3 (PR3) or myeloperoxidase (MPO) ANCA positivity. All results were then compared to the data from the published trials cohort.

Patients without pre-existing CV events were used to validate the existing predictive cardiovascular risk model.

Results: 39/387 (10.1%) patients experienced at least one CV event during follow up (0.02 – 27.8 years, median 3.6 years).

The CV event free-survival time was significantly reduced in the MPA patients vs GPA patients (p=0.0077) over 120 months (figure 1). However, no statistical difference was found between MPO or PR3 ANCA positive groups (p= 0.2767).

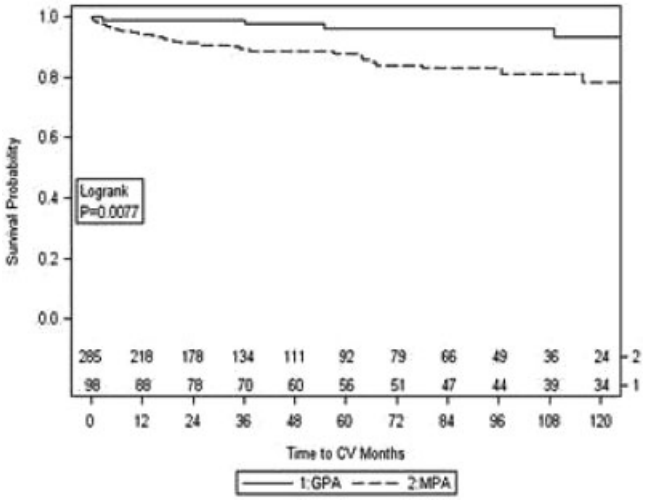

Figure 1. Survival probability against time to cardiovascular events (months): GPA vs MPA

A trend towards more CV events was observed within the AASV group compared to the predicted rates per 1000 general population although this did not reach statistical significance.

Regarding the predictive risk model, the inception cohort data was similar to the trial cohort data in predicting CV events based on age, hypertension and the absence of PR3 status when comparing the percentage of patients per risk group (p=0.5309) and CV events by risk group (p=0.9278).

Conclusion: We demonstrated an overall trend towards more CV events in vasculitis patients compared to the general population, although this does not reach statistical significance.

MPA is associated with significantly more CV events than GPA with events occurring earlier in the disease course. However, there is no difference in CV events between MPO or PR3 positive patients suggesting that clinical phenotype may be more relevant in identifying patients at risk of CV events than serological status.

We have provided further validation for the published 5 year cardiovascular model in this inception cohort, proving its transferability to clinical practice to allow stratification of individual CV risk.

Validation Of The New Histopathological Classification Of ANCA Glomerulonephritis and Its Association With Renal Outcomes In a Paediatric Population. Marinka Twilt[1], Damien Noone[1], Wesley Hayes[1], Paul Thorner[1], Susanne M. Benseler[2], Ronald M. Laxer[1], Rulan Parekh[1] and Diane Hebert[1]. [1]The Hospital for Sick Children, Toronto, ON, [2]Hospital for Sick Children, Toronto, ON.

Background/Purpose: Anti-Neutrophil Cytoplasmic Antibody (ANCA) associated glomerulonephritides (ANCA GN) include granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and Churg-Strauss. A novel histopathologic classification for GPA and MPA has been proposed and validated in adult populations and found to be predictive of long-term renal outcome. We aimed to validate this classification system in a paediatric population and identify clinical predictors of renal outcome.

Methods: We performed a retrospective review of all patients with ANCA GN, diagnosed and followed up until transfer to an adult centre at the Hospital for Sick Children between 1987 and 2012. Renal biopsies were reviewed by a pathologist blinded to patient outcome and classified using the new histopathological classification system of focal, crescentic, mixed, sclerotic and globally sclerotic groups. We determined time to CKD by estimated glomerular filtration rate (eGFR) with repeated creatinine measures using the Schwartz equation, or end stage kidney disease as defined as dialysis dependant. Survival and linear regression analyses were conducted.

Results: The study population consisted of 42 children (69% male) with ANCA GN (21 GPA, 21 MPA) with a median age of 11.96 (+3.52) years and eGFR 36.6 mls/min/1.73m^2 (IQR 15–87.4). Of the 40 patients with a renal biopsy at time of initial diagnosis, 12 (30%) had focal lesions, 20 (50%) crescentic, 3 (7.5%) mixed, 5 (12.5%) sclerotic and no globally sclerotic lesions. 13 (31 %) patients required dialysis at baseline. Survival analysis of time to the composite renal endpoint of at least 3 months of eGFR $<$ 60 ml/min/1.73 m^2 or ESKD differed among all 3 biopsy groups [p (logrank) = 0.0001; figure]. Probability (95% CI) of having an eGFR $<$ 60 mls/min/1.73m^2 at 2 years was 58.5% (35.1–76.0%) in the crescentic/mixed group. The sclerotic group all progressed to ESKD. Linear regression analysis demonstrated an association with slope of eGFR with baseline eGFR (p= 0.01), baseline proteinuria (p=0.037) and need for dialysis (p$<$0.001) after adjustment.

Conclusion: We demonstrate the clinical utility of the new new histopathologic classification system and its ability to clearly discriminate outcomes among paediatric ANCA GN patients. Additional factors predicting outcome include baseline eGFR and dialysis. The new classification can be adopted for both clinical use and research studies.

Outcome Of Kidney Transplantation In Paediatric Patients With ANCA Associated Glomerulonephritis: A Single-Center Experience. Marinka Twilt[1], Damien Noone[1], Wesley Hayes[1], Paul Thorner[1], Susanne M. Benseler[2], Ronald M. Laxer[1], Rulan Parekh[1] and Diane Hebert[1]. [1]The Hospital for Sick Children, Toronto, ON, [2]Hospital for Sick Children, Toronto, ON.

Background/Purpose: Kidney transplant outcomes for paediatric patients with end stage kidney disease (ESKD) secondary to ANCA GN, particularly granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) is limited. Adult data suggests similar allograft survival post transplant to other causes of ESKD. We aimed to describe our experience of kidney transplantation in paediatric ANCA GN patients.

Methods: We performed a retrospective review of patients with ANCA GN who developed ESKD and were transplanted at the Hospital for Sick Children (HSC) between 2000 and 2012. All patients were diagnosed at HSC and followed until their transfer to an adult center.

Results: Since 2000 there have been 6 paediatric patients transplanted with ANCA GN (5 MPA). 5 patients were ANCA positive at diagnosis: 1 c-ANCA, PR3 positive and 4 p-ANCA MPO positive. Age at ANCA GN diagnosis was 10.4 ± 4.3 (Mean±SD) years (range 4.1 to 15.4). eGFR at diagnosis was 14.1 ± 6.2 ml/min/1.73m^2. Renal biopsy category was crescentic in 4 and sclerotic in 2 by the new histopathological classification. Initial treatments included: steroids 6 [100%], cyclophosphamide 4 [66.69%] and PLEX 1 [16.67%]. 2 patients had disease relapse within the first 6 months. 4 patients required dialysis at diagnosis (HD) and remained dialysis dependent. All 6 were dialysis dependent by 6 months post diagnosis. Time from ANCA GN diagnosis to kidney transplant (Mean±SD) was 31±12 months (range 17–48 months). All patients received induction therapy and maintenance immunosuppression with prednisone, mycophenolate mofetil, and tacrolimus. Median duration of follow up post transplantation was 3.5 years (range 1.25–6.9). eGFR at last follow up was 71.9 ± 34.7 ml/min/1.73m^2 (range 5.7–100.5). 1 patient lost her transplant to biopsy-proven, severe acute cellular rejection due to complete non-adherence to medications after 21 months of stable transplant function. No patient had recurrence of vasculitis.

Conclusion: Short-term patient and allograft survival in paediatric patients with ESKD secondary to ANCA GN is excellent despite aggressive disease, with no recurrence of vasculitis post transplant.

755

Survival Of Patients With ANCA-Associated Vasculitides In Chronic Dialysis In France From 2002 To 2011: Data From The National Rein Registry.
Manon Romeu[1], Cécile Couchoud Sr.[2], Jean-Christophe Delarozière[3], Laurent Chiche Sr.[4], Jean-Robert Harle[3], Bertrand Gondoin[3], Stéphane Burtey[3], Philippe Brunet[3], Yvon Berland[3] and Noémie Jourde-Chiche Sr.[5]. [1]Aix-Marseille Universite, APHM, Marseille, France, [2]agence de la biomédecine, paris, France, [3]APHM, Marseille, France, [4]Internal Medicine, CHU Marseille, Marseille, France, [5]Aix-Marseille Université - APHM, Marseille, France.

Background/Purpose: Despite dramatic outcome improvement in ANCA-associated vasculitides (AAV), renal involvement is still leading toend-stage renal disease (ESRD) in 20–30% of patients. This study evaluated the survival of AAV patients in chronic dialysis in France.

Methods: All patients starting chronic renal replacement therapy (RRT) secondary to AAV registered in the Renal Epidemiology and Information Network (REIN) registry, between January 1st 2002 and December 31st2011, were included in the study. Survival analysis, censored for renal transplantation, renal function recovery and lost to follow-up, was performed with Kaplan-Meier in AAV patients. AAV patients were compared to non-AAV patients in chronic dialysis matched for age, gender and main comorbidities.

Results: A total of 425 patients starting RRT were registered in the REIN registry (0.7% of incident patients in chronic RRT in France), comprising 166 (39%) patients with microscopic polyangiitis (MPA) and 259 (61%) patients with granulomatosis with polyangiitis (GPA). Renal disease was biopsy-proven for 307 (72%) of them. Within a median follow-up of 23 months, 58 (14%) patients received a renal allograft, 19 (4%) had a renal function recovery allowing dialysis withdrawal and 348 remained in dialysis. Median survival in dialysis was 5.35 years (95% CI, 4.4–6.3) and survival rates at 1, 3 and 5 years were respectively 83%, 65% and 49% in AAV patients, without difference between GPA and MPA. A total of 143 (41%) patients died, after a median of 16 months in dialysis. Causes of death were: cardiovascular (29%), infectious (20%), malnutrition (13%), malignancies (4%), AAV relapse (2%), other miscellaneous (14%) and unknown (18%). After Cox2 multivariate logistic regression, only 3 risk factors were independently associated with mortality in AAV patients: age (HR=1.05 per year, p<0.001), peripheral artery disease (HR=2.62, p=0.003) and the absence of autonomy (HR=2.43 p<0.001). Survival of AAV patients did not differ from that of the 792 non-AAV matched patients in chronic dialysis, but infectious mortality was higher in AAV patients (20% vs 8% p<0,001). The limitation of this study is the absence of registration of immunosuppressive regimen and non fatal AAV relapses in the REIN registry.

Conclusion: Survival of AAV patients in chronic dialysis, although poor, is comparable to the survival of non-AAV matched patients in dialysis, with a similar burden of cardio-vascular mortality, and a higher infectious mortality. This calls for cardio-vascular risk prevention and monitoring of vaccination status in this population.

756

Clinical Value Of Commonly-Measured Laboratory Tests In Eosinophilic Granulomatosis With Polyangiitis (Churg-Strauss).
Peter C. Grayson[1], Paul A. Monach[2], David Cuthbertson[3], Simon Carette[4], Gary S. Hoffman[5], Nader A. Khalidi[6], C. L. Koening[7], Carol A. Langford[8], Kathleen Maksimowicz-McKinnon[9], Christian Pagnoux[10], Philip Seo[11], Ulrich Specks[12], Steven R. Ytterberg[12] and Peter A. Merkel[13]. [1]National Institutes of Health, Bethesda, MD, [2]Boston University, Boston, MA, [3]University of South Florida, Tampa, FL, [4]UHN/MSH, Toronto, ON, [5]Cleveland Clinic Foundation, Cleveland, OH, [6]McMaster University, Hamilton, ON, [7]Salt Lake City Veterans Administration, Salt Lake City, UT, [8]Cleveland Clinic, Cleveland, OH, [9]Henry Ford Hospital, Detroit, MI, [10]Rheumatology, Mount Sinai Hospital, Toronto, Canada, Toronto, ON, [11]Johns Hopkins Vasculitis Center, Baltimore, MD, [12]Mayo Clinic, Rochester, MN, [13]University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Serial measurement of absolute eosinophil count (Eos), serum immunoglobulin E (IgE), erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP) is common practice in the care of patients with EGPA, yet the value of these tests as longitudinal biomarkers is largely anecdotal.

Methods: Subjects were enrolled in an observational EGPA cohort. Eos, IgE, ESR, and CRP were measured quarterly. BVAS/WG defined disease activity. Correlation among laboratory tests was derived using Spearman's rank order test. The association of tests with disease activity was assessed via GEE logistic regression, adjusting for repeated measures and medication use (prednisone, other immunosuppressants). Survival analysis was used to determine if laboratory tests were predictive of 3-month future flare risk. Analyses were stratified by ANCA status.

Results: Among 141 subjects, there were clinico-demographic differences according to ANCA status (**Table**). Out of 892 observations, the majority (74%) occurred while subjects were taking prednisone or other immunosuppressants. Correlations among Eos, IgE, ESR, and CRP were mostly low or non-significant (range r = −0.08 to 0.43) and differed by ANCA status and medication use. There were few significant, but clinically weak, associations with disease activity (Eos: OR=1.01 per 100 units, 95% CI 1.01–1.02 in both ANCA negative and positive subjects; CRP: OR=1.62 per 10 mg/L increase, 95%CI 1.57–1.67 in ANCA-negative subjects). When BVAS/WG ≥1 defined active disease, only Eos (HR=1.02 per 100 units, 95%CI 1.01–1.03) was predictive of flare. When BVAS/WG ≥3 defined active disease, only ESR was predictive of flare (HR=1.52 per 10 mm/hr increase, 95% CI 1.27–1.71).

Table. Clinical and Demographic Differences in EGPA cohort by ANCA status

Variable	Total	ANCA Negative	ANCA Positive
No. subjects	141	76 (54%)	65 (46%)
No. observations	892	490	402
Sex, female*	82 (58%)	53 (70%)	29 (45%)
Age at first observation, years (median, range)	55 (21–82)	51 (21–82)	57 (23–82)
Race, white	131 (93%)	72 (95%)	59 (91%)
Disease duration at first observation, years (median, range)	1.5 (0–29.8)	1.6 (0–21.7)	1.3 (0–29.8)
On prednisone* # observations	579 (65%)	348 (71%)	231 (57%)
On other medications,# # observations	423 (47%)	245 (50%)	178 (44%)
On either prednisone or other medications, # observations	659 (74%)	376 (77%)	283 (70%)
BVAS_WG	0: 766 (86%) ≥1: 99 (11%) ≥3: 33 (4%)	0: 414 (85%) ≥1: 56 (11%) ≥3: 17 (3%)	0: 352 (88%) ≥1: 43 (11%) ≥3: 16 (4%)
Eosinophil count, 10^3/mm (median, range)	262.0 (0–18,096)	276.0 (0–7,083)	229.4 (0–18,096)
Immunoglobulin E, mg/dL* (median, range)	60.0 (0–21,925)	38.4 (0–21,925)	85.0 (2–7,298)
ESR, mm/hr (median, range)	8.0 (1–94)	8.0 (1–72)	8.0 (1–94)
CRP, mg/L (median, range)	2.2 (0–203)	2.0 (0–98)	2.6 (0–203)

* Indicates statistically significant differences (p<0.01) between ANCA positive and ANCA negative subjects with EGPA. Categorical variables were assessed by Fisher's exact test and continuous variables were assessed by Wilcoxon rank sum test.
# Other medications= azathioprine, cyclophosphamide, methotrexate, or mycophenolate mofetil.

Conclusion: Eos, IgE, ESR, and CRP have limited value as longitudinal biomarkers of disease activity or predictors of flare in EGPA. Only Eos was consistently associated with disease activity but the association was quite weak. The relationship of these labs to each other and their value as biomarkers differed according to ANCA status. These findings question the routine use of these tests to guide therapy in EGPA and suggest that novel biomarkers of disease activity for EGPA are needed.

Impact Of Cardiac Magnetic Resonance Imaging On Eosinophilic Granulomatosis With Polyangiitis Outcomes: A Long-Term Retrospective Study On 42 Patients. Bertrand Dunogué, Pascal Cohen, Benjamin Terrier, Julien Marmursztejn, Denis Duboc, Olivier Vignaux and Loic Guillevin. Cochin University Hospital, Paris, France.

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) cardiomyopathy carries a poor prognosis, and is the main cause of 1st-year and long-term mortality. Morbidity due to chronic cardiac insufficiency is also a major concern. The need for complementary investigations, which may detect cardiac involvement earlier, is crucial to effectively treat these patients early, before the advent of more severe clinical manifestations and cardiac damage. Cardiac magnetic resonance imaging (CMRI) seems to be a sensitive tool to detect EGPA cardiac lesions (defined as late myocardial gadolinium enhancement) in symptomatic but also asymptomatic patients, thereby raising the questions of CMRI specificity and the type(s) of anomalies (active inflammatory and/or fixed fibrotic) detected. This study was undertaken to determine retrospectively the diagnostic and prognostic impacts of such lesions in a cohort of EGPA patients with or without signs of cardiomyopathy who had undergone systematic CMRI screening.

Methods: This retrospective analysis concerned a monocentric cohort of 42 EGPA patients: 25/42 male (59.5%); mean age at diagnosis: 46.5 years; 11/42 (26.2%) ANCA-positive, with a median EGPA duration of 0.42 years before the 1st CMRI screening.

Results: Among the 42 patients, 17 (40.5%), 15 (88.2%) of whom were ANCA-negative, were diagnosed with cardiomyopathy, independently of CMRI findings. CMRI revealed late myocardial gadolinium enhancement in 14/17 (82.4%) patients with cardiomyopathy vs. 11/25 (44%) without cardiomyopathy ($p=0.024$). Using the sole criterion of late myocardial gadolinium enhancement, CMRI sensitivity and specificity for diagnosing cardiomyopathy were, respectively, 82.4% (95% CI: 0.59–0.93) and 56% (95% CI: 0.37–0.73). Among patients with cardiomyopathy who underwent additional CMRI during follow-up (median follow-up: 4.6 years), 6/14 patients' CMRI-detected cardiac lesions had regressed under maintenance therapy, while those of 8/14 patients worsened or stabilized, despite treatment. No differences were found between non-cardiomyopathic patients with or without CMRI anomalies concerning subsequent EGPA cardiac manifestations and outcomes.

Conclusion: CMRI is a sensitive but non-specific method for detecting potential cardiomyopathic EGPA lesions. The diagnostic significance of late myocardial gadolinium enhancement in EGPA patients remains uncertain and should not be the only criterion for cardiomyopathy diagnosis. Furthermore, for patients with no other signs of cardiomyopathy, the CMRI-detected anomalies do not seem to adversely affect prognosis or outcome. However, longer follow-up is needed to assess this apparent absence of impact of CMRI lesions on cardiac outcome in asymptomatic patients.

Eosinophilic Granulomatosis With Polyangiitis (Churg-Strauss Syndrome)—Re-Analysis Of The French Vasculitis Study Group Cohort Using Different Disease Definitions and Cluster Analysis. Christian Pagnoux[1], Pascal N. Tyrrell[2], Chiara Baldini[3], Simon Carette[4], Jean-Francois Cordier[5], Loic Guillevin[6] and French Vasculitis Study Group FVSG[7]. [1]Division of Rheumatology, Mount Sinai Hospital, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]Rheumatology Unit, Pisa, Italy, [4]UHN/MSH, Toronto, ON, [5]Division of Pneumology, Hôpital Louis-Pradel, Hospices Civils de Lyon, Lyon 1, Lyon, France, [6]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France, [7]Service de médecine interne, Centre de Références des Vascularites, Université Paris Descartes, APHP, Hôpital Cochin, 75005 Paris, France., Paris, France.

Background/Purpose: Because only 25–40% of the patients are ANCA+ and biopsy is not always taken or helpful, EGPA diagnosis can be challenging. Previous cohort analyses identified several covariates associated with poor outcomes and suggested differences between ANCA+ and ANCA– patients. We reanalyzed the FVSG cohort using different definitions of EGPA and cluster analysis to try to identify other disease subsets.

Methods: FVSG-cohort patients were grouped using the following 4 EGPA definitions: 1) all 383 patients whose EGPA diagnoses met ACR criteria or 1994 Chapel Hill nomenclature according to referral physicians; 2) only the 59 patients with biopsy-proven vasculitides; 3) the 138 with biopsy-proven vasculitis and/or ANCA+; 4) the 267 patients with biopsy-proven vasculitis and/or ANCA+ and/or surrogate manifestations (purpura, gangrene, alveolar hemorrhage, mononeuritis multiplex (MNM), renal disease (glomerulonephritis and/or hematuria)). Exploratory hierarchical cluster analyses were performed on the entire cohort and each subgroup to determine the number of clusters. The parameters, all binary, included in these cluster analysis were: skin manifestations, sinusitis, cardiomyopathy (CM), renal disease, MNM. In subsequent steps, we also included ANCA test results (missing for 35 patients excluded from these cluster analyses). Then K-means nonhierarchical cluster analysis examined the characteristics of the clusters.

Results: Table 1 shows characteristics of the different patient subgroups.

	Definition 2	Definition 3	Definition 4	All others/ Undefined
n	59/383	138/383	267/383	116/383
Sex, (M/F, n)	30/29	74/64	141/126	58/58
Age at diagnosis (yrs)	51	51	51	49
Asthma	93%	94%	96%	80%
ENT manifestations	53%	54%	54%	34%
Lung infiltrate	37%	39%	42%	30%
Alveolar hemorrhage	5%	6%	6%	–
Skin manifestations	39%	41%	49%	16%
Purpura	31%	28%	32%	–
Mononeuritis multiplex	51%	53%	66%	–
CNS	5%	6%	6%	3%
Cardiomyopathy	9%	9%	19%	11%
Severe GI signs	7%	4%	6%	6%
Eye	7%	9%	8%	3%
Renal disease	25%	26%	28%	6%
BVAS at diagnosis	19.4 ± 6.8	21.10 ± 7.6	20.6 ± 7.9	12.0 ± 6.8
ANCA+	55%	82%	45%	–
(ANCA status missing, n)	(6)	(6)	(26)	(9)
Vasculitis relapse	36%	34%	30%	14%
Deaths	12%	7%	14%	6%

Cluster analysis of the entire cohort, not including ANCA, yielded 3 clusters:

- n=128, 89% with definite EGPA (definition 4), 29% ANCA+, 24% with renal disease, 66% with MNM, 27% with CM;
- n=160, 78% met definition 4, 38% ANCA+, 57% with MNM, 18% with CM, 16% with renal disease;
- n=95, only 29% met definition 4, 22% ANCA+, none with skin, renal, CM or MNM, meaning that 71% had undefined disease (others).

Without including ANCA and whichever the EGPA definition used, clusters differed mainly by their CM, MNM or skin-sign distributions. Including ANCA strongly influenced clustering results. Subgroup cluster analysis on the 241 patients with known ANCA status meeting definition 4, yielded 3 clusters:

- n=61, all ANCA+, with 41% ENT signs, 48% MNM, 25% renal disease, 7% CM, but no skin lesions, 31% vasculitis-relapse rate, 5% mortality;
- n=54, all ANCA–, with 89% MNM, 48% ENT signs, 22% CM, 22% renal disease, but no skin disease, 21% relapse rate, 13% mortality;
- n=126 with 37% ANCA+, 94% skin manifestations, 65% ENT signs, 60% MNM, 22% CM, 19% renal disease, 37% relapse rate, 16% mortality.

Conclusion: The results of this study suggest the need to establish rigorous EGPA definitions. Cluster analysis supported and strengthened findings from previous analyses, which showed the main subsets were identified by ANCA status.

Eosinophilic Granulomatosis With Polyangiitis (Churg–Strauss Syndrome): Comparison Of The Independent French Vasculitis Study Group and Italian–Pisa Patient Cohorts and Cross-Validation Of Cluster Analysis.

Chiara Baldini[1], Pascal N. Tyrrell[2], Manuela Latorre[3], Simon Carette[4], Nader A. Khalidi[5], Veronica Seccia[6], Loic Guillevin[7] and Christian Pagnoux[8]. [1]Rheumatology Unit, Pisa, Italy, [2]University of Toronto, Toronto, ON, [3]Pneumology Unit, Pisa, Italy, [4]UHN/MSH, Toronto, ON, [5]McMaster University, Hamilton, ON, [6]Unit of Otorhinolaryngology, Department of Neuroscience, University of Pisa, Pisa, Italy, Pisa, Italy, [7]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France, [8]Division of Rheumatology, Mount Sinai Hospital, Toronto, ON.

Background/Purpose: Previous analyses of the FVSG- and Pisa-cohort EGPA patients identified several covariates associated with poor outcomes and suggested differences between ANCA+ and ANCA– EGPA-patient subsets. Reanalysis of the FVSG cohort using more stringent (than the 1990 ACR criteria) EGPA definitions and clustering analysis identified 3 main clusters reinforcing the impact of ANCA status. We compared the FVSG and Pisa cohorts and aimed to cross-validate the FVSG-cohort cluster analysis results with Pisa-cohort data.

Methods: We first compared the main characteristics of patients from both cohorts, selecting only those patients with definite EGPA (biopsy-proven vasculitis, ANCA+ and/or surrogate clinical manifestations of vasculitis, i.e. mononeuritis multiplex, purpura, alveolar hemorrhage and/or renal disease [glomerulonephritis and/or hematuria]) and known ANCA status. Hierarchical cluster analysis of FVSG-cohort patients included 6 clustering parameters (cutaneous manifestations, sinusitis, cardiomyopathy, renal disease, mononeuritis multiplex, ANCA) and yielded 3 main clusters, further characterized using K-means nonhierarchical clustering methodology. The same cluster analysis was applied to the Pisa patients.

Results: Table 1 summarizes the main characteristics of both EGPA-patient cohorts with biopsy-proven vasculitis, ANCA+ and/or surrogate clinical vasculitis manifestations.

	Pisa patients N = 51	FVSG patients N = 241	P
Sex, (M/F, n)	24/27	132/109	0.32
Age at diagnosis (yr)	52	51	0.55
Asthma	100%	96%	0.14
ENT manifestations	86%	55%	< 0.01
Lung infiltrate	45%	44%	0.84
Alveolar hemorrhage	2%	6%	0.22
Skin manifestations	61%	49%	0.13
Purpura	49%	33%	0.02
Mononeuritis multiplex	61%	64%	0.72
CNS	4%	6%	0.52
Cardiomyopathy	12%	18%	0.26
Severe GI signs	8%	6%	0.58
Eye	12%	8%	0.37
Renal disease (n with GN)	6% (2)	21% (12)	0.01
BVAS at diagnosis	17.7 ± 7.7	20.8 ± 8.1	0.02
ANCA+	57%	45%	0.12
Vasculitis relapse	27%	32%	0.57
Deaths	6%	12%	0.18

Cluster analysis identified 3 clusters in the Pisa cohort:

- n=21, all ANCA+, with 86% ENT manifestations, 81% peripheral nerve involvement, 48% skin disease, 14%cardiomyopathy, 10% renal disease, 38% vasculitis-relapse rate, 12% died;
- n=14, all ANCA–, with 100% with peripheral nerve involvement, 72% ENT manifestations, 36% skin involvement, 7% cardiomyopathy, 7% renal disease, 29% relapsed, none died;
- n=16, 50% ANCA+, and 100% with ENT, 100% skin signs, 13% cardiomyopathy, but no renal disease and no peripheral nerve involvement, 13% relapsed, 7% died.

As for the FVSG cohort, the main feature distinguishing between clusters was ANCA status. Although, the intermediate ANCA+ (low but not null %) clusters in both cohorts had the lowest frequencies of renal disease, highest of skin disease and intermediate cardiomyopathy, distributions of other EGPA manifestations among clusters differed between the 2 cohorts.

Conclusion: Cluster analysis of 2 independent EGPA-patient cohorts demonstrated that ANCA status is the main parameter distinguishing disease subsets, as previously found with other statistical methods. These exploratory analyses exemplify the advantages and challenges of cluster-analysis methodology. Interpretation of results must be cautious, taking into account the methods used and sample size.

Cluster Analysis To Explore Clinical Subclassification Of Eosinophilic Granulomatosis With Polyangiitis (Churg–Strauss).

Thomas Neumann[1], Frank Moosig[2], Augusto Vaglio[3], Jochen Zwerina[4], Renato Alberto Sinico[5], Wojciech Szczeklik[6], Paolo Bottero[7], Phillip Bremer[2], Andrea Gioffredi[3], Barbara Sokolowska[6], Luca Di Toma[5], Federica Maritati[3], Julian Groβkreutz[1], Claus Kroegel[1], Matthieu Resche-Rigon[8] and Alfred Mahr[9]. [1]Jena University-Hospital, Jena, Germany, [2]University Hospital Schleswig Holstein and Klinikum Bad Bramstedt, Bad Bramstedt, Germany, [3]University of Parma, Parma, Italy, [4]Hanusch Hospital, Vienna, Austria, [5]Azienda Ospedaliera Ospedale San Carlo Borromeo, Milan, Italy, [6]Jagiellonian University Medical College, Krakow, Poland, [7]Magenta Hospital, Magenta, Italy, [8]Hopital Saint-Louis, Paris, France, [9]Department of Internal Medicine, Hospital Saint-Louis, Paris, France.

Background/Purpose: Results from descriptive studies of eosinophilic granulomatosis with polyangiitis (EGPA) suggest distinct clinical subclasses that may be determined by anti-neutrophil cytoplasmic antibody (ANCA) status. We used hierarchical cluster analysis to explore whether EGPA could be subclassified.

Methods: The study was based on patients with clinically diagnosed EGPA followed in 6 tertiary referral centers for vasculitis in Germany, Italy and Poland. Clinical data and ANCA results were collected retrospectively on a standardized case report form. A hierarchical cluster analysis (Ward's method) was performed using the following 12 input variables assessed at diagnosis or at relapse including the main symptoms and organ involvements (general symptoms, arthromuscular, mucocutaneous, ophthalmological, ENT, cardiovascular, gastrointestinal, renal and central nervous system involvement, peripheral neuropathy, non-fixed lung infiltrates) and ANCA positivity. The resulting clusters were described by their most prominent summary characteristics. The distribution of clinical variables was analyzed by ANCA status with chi-square test.

Results: The analyzed dataset included 362 EGPA cases diagnosed between 1984 and 2013. Median age at diagnosis was 50 years and 48% were males; ANCA were detected in 35%. The cluster analysis produced 3 clusters of respectively 158 (cluster 1), 74 (cluster 2) and 130 subjects (cluster 3). They were characterized as follows: cluster 1 by high proportion of renal involvement (43%) and positive ANCA serology (73%); cluster 2 by virtually absent renal involvement (4%) and no ANCA (0%); and cluster 3 by an intermediate phenotype with renal involvement (15%), positive ANCA (9%) and more frequent cardiovascular (57% vs. 33% and 38% for clusters 1 and 2, respectively) and gastrointestinal involvement (44% vs. 22% and 15%). Stratification of the 11 clinical input variables by ANCA status found that ANCA positivity was associated with more frequent arthromuscular involvement ($P = 0.045$), renal involvement ($P < 0.0001$), peripheral neuropathy ($P = 0.011$), constitutional symptoms ($P = 0.006$) while absence of ANCA was associated with more frequent cardiovascular involvement ($P = 0.005$).

Conclusion: Cluster analysis of EGPA, although reinforcing the link between ANCA status and renal, peripheral nervous system and cardiovascular involvement, does not suggest that this disease is composed of clearly separated and mutually exclusive subclasses.

Apremilast For The Treatment Of Behçet's Syndrome: A Phase II Randomized, Placebo-Controlled, Double-Blind Study. Gulen Hatemi[1], Melike Melikoglu[1], Recep Tunc[2], Cengiz Korkmaz[3], Banu Turgut Ozturk[2], Cem Mat[4], Peter A. Merkel[5], Kenneth Calamia[6], Ziqi Liu[7], Lilia Pineda[7], Randall M. Stevens[7], Hasan Yazici[1] and Yusuf Yazici[8]. [1]Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey, [2]Selçuk University, Konya, Turkey, [3]Eskisehir Osmangazi University, Eskisehir, Turkey, [4]Istanbul University, Cerrahpasa Medical Faculty, Dermatology, Istanbul, Turkey, [5]University of Pennsylvania, Philadelphia, PA, [6]Mayo Clinic, Jacksonville, FL, [7]Celgene Corporation, Warren, NJ, [8]NYU Hospital for Joint Diseases and New York University School of Medicine, New York, NY.

Background/Purpose: Mucocutaneous manifestations of Behçet's syndrome (BS) can be resistant to conventional treatment and at times disabling. Apremilast (APR), an oral phosphodiesterase 4 inhibitor, modulates inflammatory pathways. This study investigated the efficacy of APR in BS patients with active oral ulcers (OU).

Methods: This was a phase II, multicenter, randomized, placebo (PBO)-controlled study with an open-label extension. Patients with BS without major organ involvement but ≥2 OU were randomized to APR 30 mg BID or PBO for 12 weeks followed by a 12-week active-treatment period for all patients and a 28-day post-treatment observational follow-up. The primary endpoint was the number of OU at week 12. Secondary endpoints were the number of genital ulcers (GU) at week 12, efficacy over time (AUC for OU and GU, first 12 weeks), disease activity (BSAS, BDCAF), patient-reported outcomes (BDQOL, SF-36), and adverse events (AEs).

Results: 111 patients (mean age 34.5 ± 10.1 years, 69% women) were randomized (55 APR, 56 PBO) and 95 completed the treatment phase (50 APR, 45 PBO). Mean (±SD) number of OU at week 12 was 0.5 ± 1.03 with APR and 2.1 ± 2.58 with PBO ($P<0.0001$). The figure shows the mean number of OU over time. Notably, the beneficial effect of APR on OU started within 2 weeks. There was a sustained effect while on APR, but the effect disappeared shortly after APR was stopped at week 24. Improvement in OU pain (VAS) was significantly higher with APR (−44.7 ± 24.30 vs −16.0 ± 32.54; $P<0.0001$). At week 12, significantly more patients receiving APR had a complete response (OU-free) (71% [39/55], APR; 29% [16/56], PBO; $P<0.0001$). Among the limited number of patients with GU at baseline (n=16), 10/10 receiving APR had a complete response at week 12 vs 3/6 receiving PBO (p=0.036). The mean change from baseline in the BDCAF, BSAS and BDQOL scores were significantly higher in the APR group (APR vs PBO −1.5 ± 1.84 vs −0.1 ± 1.51; $P=0.0007$, −21.2 ± 17.9 vs −5.9 ± 18.2; $p<0.0001$ and −4.5 ± 7.61 vs −1.6 ± 5.3 $P=0.0397$ respectively). There were 2 serious AEs with APR (1 diplegia, 1 anal fissure and hemorrhoids) and 3 with PBO (2 disease flares, 1 fever episode). The diplegia in 1 patient was transient and was not thought to be related to APR.

Conclusion: APR was effective in the treatment of OU, the cardinal manifestation of BS, with an acceptable safety profile. There were also indications of efficacy in several secondary endpoints, including GU, a highly specific lesion for BS. Further trials are warranted to test the efficacy of APR for other manifestations of BS.

Inhibition Of TGF-Beta Signaling In Articular Chondrocytes Leads To OA-Like Pathological Defects and Pain-Related Behavior Change In Mice. Jia Li[1], Jie Shen[2], Shan Li[1], John Dickerson[1], Jeffrey Kroin[1], Hee-Jeong Im[1] and Di Chen[1]. [1]Rush University, Chicago, IL, [2]University of Rochester, Rochester, NY.

Background/Purpose: TGF-β signaling plays an important role in chondrocyte differentiation and osteoarthritis (OA) pathogenesis. However TGF-β downstream target genes and signaling mechanism in OA development remains poorly understood. In the present studies, we investigated TGF-β signaling in OA development.

Methods: *Tgfbr2* conditional knockout ($Tgfbr2^{Col2ER}$) mice were generated by breeding $Tgfbr2^{flox/flox}$ mice with *Col2-CreER* transgenic mice. Deletion of the *Tgfbr2* gene was achieved by administration of tamoxifen into 2-week-old $Tgfbr2^{Col2ER}$ mice. Changes in histology, gene expression and pain-related behavior were analyzed. *Tgfbr2*/*Mmp13* and *Tgfbr2*/*Adamts5* double KO mice were generated by breeding $Tgfbr2^{Col2ER}$ mice with $Mmp13^{flox/flox}$ mice and $Adamts5^{-/-}$ mice.

Results: Deletion of the *Tgfbr2* gene in articular chondrocytes resulted in up-regulation of *Runx2*, *Atf4*, *Mmp13*, *Adamts5* and *Col10* expression. Histological analysis showed articular cartilage degradation, increased chondrocyte hypertrophy in superficial zone, early osteophyte formation, and increased subchondral bone mass in 3-month-old $Tgfbr2^{Col2ER}$ mice. Loss of entire articular cartilage, formation of extensive osteophytes, and substantially increased subchondral bone mass were observed in 6-month-old $Tgfbr2^{Col2ER}$ mice. Histomorphometric analysis and evaluation with OARSI scoring system showed a significant decrease in articular cartilage area in $Tgfbr2^{Col2ER}$ mice. Significant reduction in spontaneous rearing activity and ambulation counts were also observed in 4-, 5-, 6-, 7-, and 8-month-old $Tgfbr2^{Col2ER}$ mice. To determine if up-regulation of *Mmp13* and *Adamts5* expression is responsible for $Tgfbr2^{Col2ER}$-induced OA development, we generated *Tgfbr2*/*Mmp13* and *Tgfbr2*/*Adamts5* double KO mice. Deletion of the *Mmp13* gene significantly alleviates OA-like pathological changes observed in 3- and 6-month-old $Tgfbr2^{Col2ER}$ mice. In contrast, deletion of the *Adamts5* gene only reversed OA-like phenotype in 3-month-old $Tgfbr2^{Col2ER}$ mice. These changes were confirmed by histomorphometric analysis and by evaluation with OARSI scoring system. We also investigated the signaling mechanism and found that inhibition of TGF-β signaling prevented Runx2 degradation. Runx2 directly bound to its binding site located in the proximal region of the *Mmp13* promoter and activated *Mmp13* transcription. ATF4 interacted with Runx2 and enhanced Runx2-induced *Mmp13* transcription.

Conclusion: In this study, we demonstrate that inhibition of TGF-β signaling in articular chondrocytes leads to a progressive OA-like phenotype in mice. *Mmp13* and *Adamts5* are critical downstream target genes of TGF-β signaling during OA development.

The Risk Of Myocardial Infarction In Systemic Sclerosis: A Population-Based Cohort Study. Iman Hemmati[1], Hyon K. Choi[2], Kamran Shojania[1], Eric C. Sayre[3] and J. Antonio Avina-Zubieta[4]. [1]University of British Columbia, Vancouver, BC, [2]Boston University School of Medicine, Boston, MA, [3]Arthritis Research Centre of Canada, Richmond, BC, [4]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC.

Background/Purpose: An increased risk of premature atherosclerosis has been well described in patients with rheumatoid arthritis and systemic lupus erythematosus. However, there is limited data on the risk of atherosclerotic diseases, myocardial infarction (MI) in patients with Systemic Sclerosis (SSc). Moreover, the scarce information has come from selected populations. To fill this knowledge gap, we estimated the risk of newly recorded MI events among incident cases with SSc compared to controls from the general population using physician billing and hospitalization databases that cover the entire population from our province (~ 5 million).

Methods: Our data included all visits to health professionals and hospital admissions covered by the comprehensive provincial medical services plan (from Jan1990 until Dec 2010) and all dispensed medication (from Sept 1995 to Dec 2010); for all individuals >= 18 years of age. We

conducted a matched cohort analysis among patients satisfying at least one of the following criteria: a) diagnosis of SSc on at least two visits within a two-year period between Jan 1996 and Dec 2010 by a non-rheumatologist physician; b) diagnosis of SSc on at least one visit by a rheumatologist or from a hospital. To increase specificity we excluded cases that were not confirmed by a rheumatologist if they were seen at a later point. Ten controls matched by birth year, sex and calendar year of follow-up were selected from the general population for each case. Newly recorded MI events from hospital or death certificate were recorded as an outcome. We estimated relative risks (RRs) comparing SSc with age-, sex- and entry time-matched comparison cohorts, adjusting for potential cardiovascular risk factors.

Results: Among 1,208 individuals with incident SSc (84% female, mean age of 56 yrs [SD 15.0]), 90 developed MI (incidence rate= 20.2 per 1000 person years) (Table 1). Compared with non-SSc individuals (N= 12,080), the age-, sex-, and entry-time-matched RR for MI was 3.8 (95% CI, 2.9 to 4.8). The risk was 9 times greater within the first year after the disease onset and progressively decreases over time. After further adjustment for angina, COPD, obesity, cardiovascular disease, diabetes, hormone replacement therapy, dyslipidemia, non steroidal anti-inflammatory drugs, Cox-2 inhibitors, number of hospitalizations and Charlson's comorbidity index at baseline; the RR remained similar (4.0, 95% CI, 3.1 to 5.3). These results persisted among men, women and different age groups (Table 1).

Table 1. Relative risk of incident MI according to Systemic Sclerosis status.

Incidence Rate Ratios of MI	SSc (n = 1,208)	Non-SSc (n = 12,080)
Cases, N	**90**	281
Incidence Rate/1000 Person-Years	**20.2**	**5.3**
Age-sex-entry time matched RRs (95% CI)	**3.8 (2.9–4.8)**	**1.0**
Multivariable RRs (95% CI)	4.0 (3.1–5.3)	1.0
Disease Duration		
< 1 year	**9.0 (5.8–13.9)**	**1.0**
1–4.9 years	**3.0 (2.0–4.4)**	**1.0**
5+ years	**1.6 (0.8–3.1)**	**1.0**
Female	4.1 (3.0–5.6)	**1.0**
Male	4.2 (2.2–7.9)	**1.0**
Age Group		
< 45	**3.0 (0.7–14.1)**	**1.0**
45–59	**5.2 (2.9–9.4)**	**1.0**
60–74	**3.5 (2.3–5.2)**	**1.0**
75 +	**5.4 (3.2–9.3)**	**1.0**

Conclusion: This large population-based study indicates an increased risk of MI in patients with SSc, especially within the first year of disease diagnosis. These findings support increased monitoring of MI complication and risk factors in those with SSc, particularly during the early phase of SSc diagnosis.

Inflammatory Disease Due To Dysregulated Nuclear Factor-κB Activation and Impaired Type I Interferon Response Resulting From a *De Novo* Human NEMO Hypomorphic Mutation. Alex Wessel[1], Amy Hsu[2], Jevgenia Zilberman-Rudenko[1], Raphaela Goldbach-Mansky[1], Richard M. Siegel[1] and Eric Hanson[1]. [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [2]Laboratory of Clinical Infectious Diseases, NIAID, Bethesda, MD.

Background/Purpose: The NF-kB family of transcription factors regulate innate and adaptive immunity, in addition to driving pro-inflammatory-disease states. The type I interferon response acts in parallel, and is mediated by IRF3 and IRF7 transcription factors. The IRFs are triggered by the RIG-I-like family of receptors (RLRs) in fibroblasts and Toll-like receptors (TLRs) in dendritic cells and macrophages. Both NF-kB activation and the Type I IFN response require the NF-kB essential modulator (NEMO) for normal function. The mechanisms by which NEMO is regulated to integrate various upstream signals to direct transcription in antiviral immune defense and inflammatory disease is unknown. We present the molecular mechanism by which a naturally occurring NEMO mutation associated with inflammatory disease leads to aberrant cell responses.

Methods: Genomic DNA and cDNA from dermal fibroblasts and peripheral blood cells from a patient with optic neuritis, panniculitis and physical characteristics consistent with NEMO mutation were analyzed to determine the genotype and effect on NEMO protein product. Patient cells were stimulated with TNF, anti-CD3/CD28,viral nucleic acid analogs, and RSV and HPIV3 infection. Gene expression profiling, cytokine production and biochemical analysis was performed to characterize and determine the mechanism of aberrant signaling produced by the mutant form of NEMO.

Results: We identified an individual with Ectodermal Dysplasia, a history of *in utero* cytomegalovirus exposure, and persistent inflammatory disease. Sanger sequencing revealed a *de novo* synonymous mutation in *IKBKG*, which encodes NEMO, the NF-kB essential modulator. The mutation results in an mRNA splicing defect which leads to the production of a mutant protein containing an in-frame deletion of 51 residues, lacking a previously identified TANK (TRAF family member-associated NFKB activator) interaction domain. Co-immunoprecipitation studies revealed that the mutant form of NEMO from patient T cells is unable to recruit the IRF3 kinase TANK-binding kinase-1 (TBK1), due to impaired association with TANK. Patient fibroblasts stimulated with the RLR ligand poly(I:C) led to impaired induction of IRF3 response genes *IFNB1*, *CCL5*, *CXCL10*, *IP10*, *OASL*, and *DDX58*. Consequently, dermal fibroblasts infected with RSV or hPIV3 demonstrated increased virus propagation relative to healthy control cells. Impaired gene expression occurred despite enhanced nuclear translocation of IRF3, suggesting that the mechanism of impaired activation is not a simple defect in nuclear localization of the transcription factor. In contrast to the impaired type I IFN response, canonical IKK activation and gene induction in dermal fibroblasts appeared relatively normal following TNF treatment.

Conclusion: These results illustrate a novel mechanism of autoinflammatory disease due to aberrant expression of an alternately spliced NEMO and deficient IRF3-mediated response.

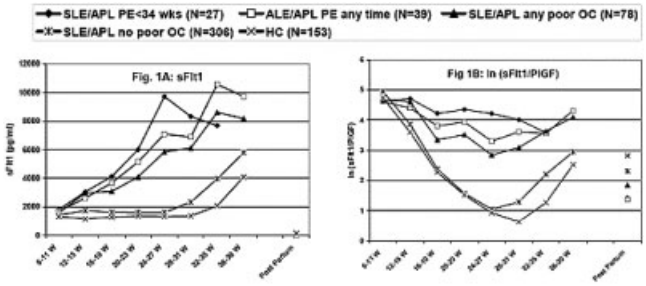
Angiogenic Factor Dysregulation and Risk Of Adverse Pregnancy Outcome In Lupus Pregnancies. Jane E. Salmon[1], Mimi Kim[2], Marta M. Guerra[1], Michael D. Lockshin[1], Ware D. Branch[3], Michelle Petri[4], Carl A. Laskin[5], Joan T. Merrill[6], Lisa R. Sammaritano[1], Jill P. Buyon[7] and S. Ananth Karumanchi[8]. [1]Hospital for Special Surgery, New York, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Univ of Utah, Salt Lake City, UT, [4]Johns Hopkins University School of Medicine, Baltimore, MD, [5]University of Toronto and LifeQuest Centre for Reproductive Medicine, Toronto, ON, [6]Oklahoma Medical Research Foundation, Oklahoma City, OK, [7]NYU School of Medicine, New York, NY, [8]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.

Background/Purpose: Pregnant women with lupus and APL are at increased risk for adverse outcomes, particularly preeclampsia (PE), yet identification of those destined for complications remains elusive. Dysregulation of angiogenic factors contributes to pathogenesis of placental insufficiency and preeclampsia. Placentally derived sFlt1 antagonizes proangiogenic proteins (placental growth factor, PlGF; VEGF) which are necessary for development of the placenta and for vascular homeostasis. We prospectively studied patients to determine whether levels of angiogenic factors early in pregnancy would predict outcomes.

Methods: The PROMISSE Study (**P**redictors of p**R**egnancy **O**utcome: Bio**M**arkers **I**n antiphospholipid antibody **S**yndrome and **S**ystemic **L**upus **E**rythematosus) enrolled 384 pregnant women with ≥4 ACR SLE criteria and/or APL and 153 healthy pregnant controls (HC). Subjects were evaluated and blood collected monthly beginning at <12 wks gestation. Exclusion criteria were multi-fetal pregnancy, prednisone >20mg/d, proteinuria >1gm/24hr, and creatinine >1.2 mg/dL. Poor pregnancy outcomes (OC) were defined as preeclampsia, fetal death, neonatal death, preterm delivery <36 wks because of IUGR or placental insufficiency, and/or growth restriction <5th %ile. Levels of angiogenic factors were measured by ELISA and compared between groups at each time point using Wilcoxon rank sum test. In addition, linear mixed effects models were fit to rank transformed data to estimate and compare rates of change in these factors over the entire gestational period.

Results: PE occurred in 10% of pregnancies (27 at <34 wks; 39 at any time) and other poor outcomes in 10%. Compared to SLE patients without poor OC, levels of sFlt1 (Fig 1A) and sFlt1/PlGF ratios were significantly higher as early as 12–15 wks in those destined for PE or other complications, and remained elevated through 31 weeks. The rate of increase in sFlt1 from 6 wks through 31 weeks was higher in patients with PE (<34 wks, any time) or non-PE OC compared to those without poor OC ($p < 0.0001$ all comparisons). In contrast, and consistent with impaired placental development, the rate of increase in PlGF was lower in those destined for poor OC ($p < 0.0001$ all comparisons). Ln sFlt1/PlGF ratios for those who developed PE were markedly and consistently higher throughout pregnancy compared to SLE patients without poor OC or HC ($p<0.0005$ all comparisons) (Fig 1B). Based on ROC analysis, a ln sFLT1/PlGF

ratio cutpoint of 4.14 at the 12–15 wk measure yielded 78% sensitivity and 73% specificity for PE < 34 wk.



Conclusion: We demonstrate that in pregnant SLE and/or APL patients, alterations in the balance of angiogenic factors early in pregnancy are strongly associated with subsequent PE and other poor outcomes. Absolute levels of sFlt1, ratio of sFLt1/PlGF and rate of change of angiogenic factors may be used to identify those at risk before 15 wks, allow early intervention and reveal novel targets for treatment.

Cholesterol Accumulation By Synovial Lining Macrophages Results In Ectopic Bone Formation During Experimental Osteoarthritis. Wouter de Munter[1], Arjen B. Blom[1], Monique M. Helsen[1], Birgitte Walgreen[1], Peter M. van Der Kraan[1], Leo A. Joosten[2], Wim B. van den Berg[3] and Peter L. van Lent[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Department of Medicine, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, [3]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: Synovial macrophages have previously shown to play a significant role in the etiopathology of experimental collagenase-induced osteoarthritis (OA). In addition to production of pro-inflammatory proteins such as S100A8/9 and IL-1 in early OA, synovial lining macrophages have also shown to play a crucial role in promotion of transforming growth factor-beta (TGFβ) mediated osteophyte formation. In an inflammatory milieu such as OA, accumulated low density lipoprotein (LDL) is oxidized, resulting in high intra-articular levels of oxidized LDL (oxLDL). OxLDL is taken up by macrophages via scavenger receptors, resulting in an more aggressive phenotype. In the present study we investigated whether LDL accumulation by either LDL-receptor deficiency ($LDLr^{-/-}$) or a cholesterol-rich diet leads to increased oxLDL uptake by synovial macrophages and affects synovial activation and osteophyte formation.

Methods: $LDLr^{-/-}$mice and their wild type (WT) controls received either a high cholesterol or control diet for 120 days. Experimental OA was induced by intra-articular injection of collagenase on day 84 and 86. Paraffin sections of OA knee joints were analyzed for cartilage destruction and osteophyte formation using the Pritzker score and image analysis, respectively. ApoB and S100A8 were detected using immunohistochemistry and synovial wash-outs were tested for active TGFβ using a TGFβ reporter gene assay and gene expression. Murine bone marrow derived macrophages were stimulated with 50 μg/mL oxLDL, after which supernatant was functionally tested for active TGFβ presence.

Results: Mice receiving a cholesterol-rich diet not only developed increased serum LDL cholesterol levels, but also showed enhanced ApoB expression in synovial lining macrophages. In line with that, $LDLr^{-/-}$ mice, which already had systemically high basal levels of LDL, showed a much higher accumulation of ApoB in the synovial lining after receiving a cholesterol-rich diet. Although increased LDL levels did not enhance thickening of the synovium, S100A8 expression within macrophages was markedly increased, reflecting an elevated activation status. Even though no effect of LDL accumulation on cartilage destruction was found, both a cholesterol-rich diet and $LDLr^{-/-}$ strongly increased cartilage and bone formation in ligaments with a fold change of 6.7 and 6.1, respectively. Moreover, an increase in osteophyte size was found at the margins of the tibial plateau (4.4 fold increase after a cholesterol-rich diet and 5.3 fold increase in LDLr deficient mice compared to WT mice). To elucidate the mechanism, we finally studied the presence of active TGFβ, which is crucial in driving osteophyte formation, in synovial wash-outs and culture supernatant of oxLDL stimulated macrophages. Using a TGFβ reporter assay, synovial wash-outs of $LDLr^{-/-}$mice and stimulation of macrophages with oxLDL showed an increased presence of functional TGFβ compared to controls (fold change of 1.4 and 2.9, respectively).

Conclusion: Both a cholesterol-rich diet and LDLr deficiency lead to increased synovial activation and ectopic bone formation in experimental OA. Uptake of oxLDL by synovial macrophages leads to activation, rather than production of TGFβ.

Zinc Finger Protein ZCCHC6 Is Highly Expressed In Osteoarthritic Cartilage and Regulate The Expression Of Interleukin-6 In Human Chondrocytes. Nahid Akhtar, Ahmad Arida and Tariq M. Haqqi. North East Ohio Medical University, Rootstown, OH.

Background/Purpose: Interleukin-1β (IL-1β) is the major cytokine involved in cartilage catabolism in osteoarthritis(OA) and induces the expression of pro-inflammatory cytokine IL-6. Members of cytoplasmic RNA nucleotidyl transferases superfamily catalyze the addition of nucleotides to the 3'end of mRNAs. However, the expression or role of RNA nucleotidyl transferases in regulating cytokine expression in OA is unknown. The aim of this study was to investigate whether RNA nucleotidyl transferase ZCCHC6 is expressed in OA cartilage and whether it is involved in the regulation of IL-6 expression in OA chondrocytes.

Methods: Chondrocytes were derived by enzymatic digestion of human cartilage obtained from OA patients (n=14) undergoing knee joint replacement. Chondrocytes were stimulated with IL-1β (5ng/ml) or treated with Actinomycin D (5 μg/ml) or NF-κB inhibitor SC514 (75 μM). Total RNA from grounded cartilage and from chondrocytes was purified using Qiagen RNeasy kit (Qiagen). Reverse transcription was performed using the Quantitect Reverse Transcription kit and the ZCCHC6 or IL-6 mRNA was quantified using TaqMan assays. SiRNA-mediated depletion of ZCCHC6 in human chondrocytes was used to study the effect on inflammatory cytokine expression using a cytokine array (Ray Biotech). Protein expression of IL-6 was studied using Western immunoblotting and by ELISA in culture supernatants. Data was analyzed using Origin 6.1 software package and $p<0.05$ was considered significant.

Results: Our results showed differential expression of nucleotidyl transferase ZCCHC6 in the damaged cartilage compared to unaffected cartilage. Higher expression of IL-6 (6.0-fold $\pm$ 1.44) in damaged cartilage compared to smooth cartilage (n=3; $p<0.05$) from OA patients was also observed. We further demonstrate that IL-1β stimulation resulted in significant increase in the expression of ZCCHC6 (11.3-fold $\pm$ 1.6) and the mRNA of the inflammatory cytokine IL-6 (4956-fold $\pm$ 40.6) in human chondrocytes (n=4; $p<0.05$). Similar increase in the protein expression of both ZCCHC6 and IL-6 was also observed. Depletion of ZCCHC6 significantly decreased the expression of IL-6 mRNA (~77–95%) and protein in IL-1β-stimulated human chondrocytes. Importantly, IL-6 mRNAs in IL-1β-stimulated human chondrocytes treated with ZCCHC6 siRNA had shorter poly-A tails (n=3; $p<0.05$). Cell supernatants from control or ZCCHC6 siRNA treated chondrocytes stimulated with IL-1β were analyzed using a cytokine array. A subset of cytokines including IL-6 was substantially decreased by loss of ZCCHC6. Our results also showed that the IL-1β-induced activation of NF-κB has no role in the regulation of ZCCHC6 expression in OA chondrocytes (n=3; $p<0.05$). Additionally, OA chondrocytes transfected with ZCCHC6 siRNA also showed a decrease (~99%) in constitutive IL-6 mRNA expression (n=3; $p<0.05$).

Conclusion: Taken together our results demonstrate that ZCCHC6 is highly expressed in damaged human cartilage from OA patients. Furthermore, ZCCHC6 modulates IL-6 expression in human chondrocytes at the post-transcriptional level by influencing cytokine mRNA stability. These

results identify ZCCHC6 as a possible therapeutic target for the treatment of OA.

Inhibition Of X-Box Binding Protein 1 (XBP1) Is Chondroprotective By Promoting Autophagy and Inhibiting Catabolic Responses. Ru L. Bryan[1], Robert Terkeltaub[2] and Ramon Serrano[3]. [1]VA Medical Center/ University of California San Diego, San Diego, CA, [2]VA Medical Ctr/ University of California San Diego, San Diego, CA, [3]VA Medical Center, San Diego, CA.

Background/Purpose: Chondrocyte stress responses to biomechanical injury and joint inflammation, and associated changes in differentiation and function, provide a foundation upon which cartilage injury and OA can be triggered and accelerated. Fundamental proteostasis responses by which cells normally resolve stress include the unfolded protein response (UPR), which restores equilibrium to the stressed ER via a reprogrammed proteome, rich in chaperones and protein folding catalysts. The UPR also regulates oxidative stress responses, inflammation, and cell fate including autophagy. Chondrocyte autophagy is impaired in biomechanical cartilage explant injury, and in aging and OA cartilage. Autophagy repairs damaged cell organelles and is anti-inflammatory, in part by degrading pro-IL-1beta. The UPR can promote autophagy and autophagy promotes normal UPR and mitochondrial functional. UPR-specific XBP1 alternative mRNA splicing generates the potent transcriptional activator XBP1s, which can exert either promote or inhibit autophagy or inflammation depending on cell type and context. In this study, we tested the hypothesis that XBP1 activation is noxious in chondrocytes by impairing autophagy.

Methods: We knocked down XBP1 expression in cultured normal human chondrocytes (passage 1) via siRNA transfection. After 48 hours, the XBP1 knockdown chondrocytes were subjected to SDS-PAGE/Western blot analysis for phosphorylation of the autophagy promoter AMPKα, expression of FOXO1, transglutaminase 2, and the autophagy proteins LC3, and p62. XBP1 knockdown chondrocytes were also treated with IL-1β for 18 hours, and nitric oxide (NO) production and MMP-3 release were measured from the conditioned media by Griess reaction method and Western blot, respectively.

Results: We observed markedly increased activation of XBP1 in human knee OA chondrocytes. In XBP1 knockdown human knee chondrocytes, we observed increased basal levels of expression of the autophagy promoter FOXO1, and increasing LC3 conversion from I to II, and decreased basal levels of expression of p62, indicating induction of autophagy. This was linked with increased basal level of phosphorylation of the autophagy promoter, anti-inflammatory mediator and metabolic super-regulator AMPK in the XBP1 knockdown chondrocytes. Conversely, IL-1β-induced release of NO and MMP-3 was significantly inhibited in the XBP1 knockdown chondrocytes. Last, basal expression of transglutaminase 2, which transduced inflammatory responses of IL-1β and chemokines in chondrocytes, was blunted in the XBP1 knockdown chondrocytes.

Conclusion: This study demonstrated increased UPR-specific XBP1 activation in human knee OA cartilage, and that XBP1 critically transduces noxious functions in chondrocytes, including impairment of autophagy, and pro-catabolic activities, mediated by regulation of AMPK and transglutaminase activity. These findings identify XBP1 as a novel target to limit OA progression.

Synovial Wnt and WISP1 Expression Induces Expression Of Cartilage-Degrading Metalloproteinases In The Synovium. Martijn H. van den Bosch[1], Arjen B. Blom[1], Sylvia W. Suen[1], Anke E. van Erp[1], Fons A. van de Loo[1], Esmeralda N. Blaney Davidson[1], Peter M. van der Kraan[1], Peter L. van Lent[1] and Wim B. van den Berg[2]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: Although many osteoarthritis (OA) patients show significant synovial involvement, consequences are largely unknown. Previously, we found strong upregulation of Wnts 2b and 16 and WISP1, a downstream protein of canonical Wnt signaling, in knee joints in two murine OA models. Wnt signaling has been implicated in OA incidence and modulation of the β-catenin pathway leads to OA-like changes in cartilage. However, the role of the synovium in the induction of OA pathology under the influence of Wnt signaling is unclear. Here we investigated the potential of Wnt signaling to increase the expression of cartilage-degrading enzymes in the synovium.

Methods: Pathway analysis of microarray data from the synovium of a collagenase-induced OA mouse model was done using DAVID software. *In vivo* synovial overexpression of genes from the canonical Wnt signaling pathway was achieved by intra-articular injection of adenoviral vectors. Joint pathology was assessed by histology at several time points after injection. Gene expression was analyzed by qPCR. Human OA synovial specimen were collected from joint replacement surgery and either stimulated or used for outgrowth of OA fibroblasts.

Results: Pathway analysis using DAVID showed that Wnt signaling was enriched in the synovium during experimental OA. To determine the effects of Wnt signaling on synovial tissue, we stimulated human OA synovial specimen with Wnt3a or WISP1, which resulted in increased expression of MMP3, MMP9 and MMP13, whereas expression of the MMP inhibitors TIMP1 and 3 was not altered. Next, we investigated which cell type in the synovium may cause the increased MMP expression. Stimulation of human synovial OA fibroblasts with Wnt3a increased the expression of both MMP3 and MMP13, whereas stimulation of these cells with WISP1 led to an upregulation of MMP3. Stimulation of human THP-1 cells with Wnt3a resulted in highly increased expression of MMP3, MMP9 and MMP13. Stimulation with WISP1 led to increased expression of MMP3. Expression levels of TIMP1 and TIMP3 were not altered. To determine if synovial overexpression of members of the Wnt signaling pathway leads to cartilage damage *in vivo*, we injected adenoviral vectors for Wnt8a, Wnt16 and WISP1 into murine knee joints. These vectors specifically target synovial cells, due to their size. 7 days after overexpression, we found a significant induction of OA pathology at the medial margin of the medial tibial plateau, a preferential site for damage in experimental OA. Lesions were found in 92% (n=12) of the knee joints after Wnt8a overexpression compared to 17% (N=12) for the control virus and 80% (N=5) for Wnt16 overexpression, but only 20% (N=5) for the control virus.

Conclusion: Canonical Wnts produced in the synovium may play an important role in OA pathology. Stimulation of human OA synovium with Wnts and WISP1 increases the expression of MMPs. Fibroblasts and macrophages showed comparable patterns of MMP induction. In addition, synovium specific overexpression of Wnt signaling members, as is found in experimental OA, induces cartilage damage *in vivo*. This underlines synovial Wnt/WISP1 expression to be a potential target for OA therapy.

Suppressor Of Cytokine Signaling-3 Is a Critical Regulator Of gp130 Cytokine Signaling In Articular Chondrocytes. Xiao Liu, Kate E Lawlor, Ben A Croker and Ian P Wicks. Walter & Eliza Hall Institute of Medical Research, Parkville, Australia.

Background/Purpose: Cartilage damage is a key feature of inflammatory and degenerative arthritis and an important determinant of patient outcomes. Chondrocytes are the only cells in articular cartilage and are critical for tissue homeostasis. Relatively little is known about how chondrocyte responses to cytokines are regulated. Suppressor of cytokine signaling-3 (SOCS-3) is a negative regulator of the IL-6 cytokine family, which utilizes the common gp130 signaling receptor, in other cell types. We investigated the impact of gp130 cytokines on cartilage and isolated chondrocytes and examined the impact of SOCS-3 deficiency on chondrocytes, *in vitro* and *in vivo*.

Methods: Conditional gene targeting was used to generate mice lacking SOCS-3 in chondrocytes by crossing mice with a floxed allele of *SOCS-3*, with mice transgenic for Cre recombinase driven by the type II collagen (*Col2a1*) promoter ($Socs3^{\Delta/\Delta col2}$ mice). Primary chondrocytes and femoral head cartilage explants were obtained from control and $Socs3^{\Delta/\Delta col2}$ mice. Cartilage explant cultures were stimulated with gp130 cytokines and aggrecanase activity measured using the 1,9-DMMB dye-binding assay and quantitative PCR. STAT1, STAT3 and STAT5 phosphorylation and cytokine/chemokine production in response to gp130 cytokines were measured by flow cytometry and multiplex bead array, respectively. The responses of littermate and $Socs3^{\Delta/\Delta col2}$ mice to intra-articular injections of

gp130 cytokines and to K/BxN serum transfer arthritis were assessed clinically and histologically.

Results: In wild-type articular chondrocytes, all gp130 cytokines activated JAK-STAT signaling and upregulated *Socs3* mRNA expression. Stimulation with Oncostatin M caused the most STAT phosphorylation. $Socs3^{\Delta/\Delta col2}$ cartilage explants and isolated chondrocytes stimulated with gp130 cytokines exhibited prolonged STAT1, STAT3 and STAT5 activation, enhanced *Adamts4* and *Adamts5* production and cartilage degradation. In addition, SOCS-3 deletion in chondrocytes increased the production of multiple inflammatory mediators (IL-6, G-CSF, CXCL1 and CCL2), including receptor activator of NF-kB ligand (RANKL). All features of joint pathology in the acute inflammatory arthritis model – exudate, synovitis, cartilage degradation and bone erosion - were exacerbated in $Socs3^{\Delta/\Delta col2}$ mice compared to $Socs3^{fl/fl}$ littermate controls (see figure). Total histological scores were 9.5 ± 0.78 vs. 6.0 ± 0.96 ($p=0.006$), for $Socs3^{\Delta/\Delta col2}$ and $Socs3^{fl/fl}$ mice, respectively. Furthermore, microarray analysis showed profound and selective effects on gene expression in response to gp130 cytokines, which were heightened in the absence of SOCS3.

Conclusion: Our findings highlight important biological effects of gp130 cytokines on cartilage and provide the first direct evidence for a key regulatory role of SOCS-3 in articular chondrocytes.

The S100A9 Inhibitor Paquinimod (ABR-215757) Reduces Synovial Activation, Osteophyte Formation and Cartilage Damage In Experimental Osteoarthritis. Rik Schelbergen[1], Arjen B. Blom[1], Tomas Leanderson[2], Helena Eriksson[3], Wim B. van den Berg[4] and Peter L.E.M. van Lent[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Lund University, Lund, Sweden, [3]Active Biotech AB, Lund, Sweden, [4]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: Synovial activation is present in a large subset of osteoarthritis (OA) patients and it is thought to play an important role in the development of OA pathology. Previously, we found that alarmins S100A8 and S100A9 are elevated in the synovium of OA patients and that high S100A8/A9 serum levels correlate with 2-year progression of the disease. Furthermore, in experimental OA these S100-proteins are involved in cartilage degradation and synovial activation. Paquinimod is a quinoline-3-carboxamide compound with immunomodulatory properties that is currently in clinical development for treatment of systemic sclerosis. It targets the S100A9 protein and disrupts the binding of S100A9 to RAGE and TLR-4.

In the current study we investigated the effect of the S100A9-blocking compound paquinimod on experimental osteoarthritis with different degrees of synovial activation.

Methods: Collagenase induced OA (CIOA) was induced by two times intra-articular injection of 1U collagenase and DMM was induced by transsection of the medial anterior meniscotibial ligament leading to destabilization of the medial meniscus (DMM), both in C57Bl6 mice. Paquinimod (3,75 mg/kg) was administered in the drinking water 4 days before induction of OA in both CIOA and DMM and refreshed twice a week. Synovial thickening and cellularity was measured using an arbitrary score from 0–3. OA-like cartilage pathology was scored using a modified Pritzker OARSI score. Osteophyte size was assessed by a blinded observer using imaging software.

Results: First, we assessed the effect of paquinimod on DMM development at day 56. Synovial activation in this surgical model is low, as are S100A8/A9 levels in the synovium. No differences were observed on osteophyte size between paquinimod-treated and non-treated animals at both medial tibia and medial femur. Furthermore, OA-like cartilage pathology was only significantly reduced by paquinimod-treatment at the medial femur (−64%), not at other surfaces and not in the total joint score (−16%).

Then, we treated collagenase-induced OA (CIOA) with paquinimod and evaluated the effects at day 42. In CIOA, synovial activation is high and S100A8/A9 levels in the synovium are significantly higher than those in DMM. Synovial activation was significantly reduced by paquinimod-treatment at the medial side of the patella-femur region (−57%). Osteophyte size was significantly reduced at the medial femur (66%) and cruciate ligaments (−67%). Finally, OA-like cartilage pathology in CIOA was significantly reduced after paquinimod treatment on the medial side of both tibia and femur (−47% and −75% respectively) as well as in the total joint score (−46%).

Conclusion: Paquinimod administered in the drinking water reduces synovial activation, osteophyte formation and OA-like cartilage pathology in CIOA. In contrast, in an experimental OA model where synovial activation is nearly absent (DMM), the effect of paquinimod is marginal.

Paquinimod could prove a very promising treatment for osteoarthritis patients with high synovial activation by blocking S100A9.

Neovascularization and CD15s Influence Long Distance Migration Of Synovial Fibroblasts From Patients With Rheumatoid Arthritis. Birgit Zimmermann[1], Sina Köppert[1], Stephanie Lefèvre[1], Stefan Rehart[2], Ulf Müller-Ladner[1] and Elena Neumann[1]. [1]Justus-Liebig-University of Gießen, Kerckhoff-Klinik, Bad Nauheim, Germany, [2]Markus-Hospital, Frankfurt, Germany.

Background/Purpose: Rheumatoid arthritis (RA) synovial fibroblasts (SF) are central cells of cartilage destruction and neoangiogenesis. RASF show an increased migratory potential in the synovium towards sites of cartilage degradation. In the SCID mouse model, RASF were able to migrate through the vascular system. The interaction of RASF with endothelial cells (EC) is important for RASF-mediated angiogenesis and migration. Vessel sprouting and EC activation are two key mechanisms induced by interaction of RASF and EC. In this study, the kinetics of vessel growth by RASF in the SCID mouse model was analyzed as well as the E-selectin ligand (CD15s) expression in the synovial membrane, a mechanism potentially involved in RASF adhesion to EC.

Methods: Using 5μm frozen sections RA and osteoarthritis (OA) synovium fluorescence double staining was performed with FITC-labeled anti-CD15s and Cy3-labeled anti-vimentin (fibroblast) antibodies. Medium of cultured RA- and OASF was replaced with RA serum or serum from healthy donors for 48h. Then, cells were stained for CD15s. SCID mouse model (implants n=3–7/time point): the ipsilateral site contained healthy cartilage together with 1.5×10^5RASF in a carrier matrix, the contralateral site contained cartilage without RASF. Neovascularization next to and into the implants was determined after 3 to 60 days. Implant images were taken, implants removed and angiogenesis analyzed by CD31 staining.

Results: CD15s signals were detectable in all RA tissues (n=12). In 67% CD15s signals were co-localized with vimentin, mainly located in sublining (50%) but also located in vessels (33%). After stimulation with RA serum, 80% of RASF (n=5) and 33% of OASF (n=3) showed an increased CD15s expression. Serum stimulation from healthy donors did not alter CD15s. Implant evaluation showed the early presence of truncated vessels (day 3–12) especially at the ipsilateral site which was reduced over time. Vessels in the murine skin close to ipsilateral implants increased in size and perfusion. Late during vascularization, very small vessels sprouted into the carrier matrix (day 9–60). Anti-CD31 staining showed that neoangiogenesis (<10 cell sizes) started at day 9 at both sites. Later (day 18), EC were detectable deep within the carrier matrix (>10 cell layers). Then (> day 27) the whole carrier matrix showed detectable EC signals. At this time the vessel lumen in the implants increased.

Conclusion: CD15s positive RASF were detectable in RA synovium and some of them located in vessels. RA serum increased CD15s expression by RASF which in turn allows RASF to adhere to EC. Implants co-implanted with RASF showed a stronger vessel formation at early time points then RASF-free implants. Vessel formation around and into implants showed an unexpected dynamics, starting with newly formed truncated vessels surrounding the implants especially at the ipsilateral site. Then these vessels disappear and EC invade into the implants, increasing over time. The perfusion of the surrounding vessels increases solely at the ipsilateral site. In summary, RASF

are actively involved in neovascularization showing distinctive pattern in vessel formation. In turn, vascularization allows RASF long distance migration.

Adioponectin-Induced p38 MAPK and AMPK Pathways In Rheumatoid Arthritis Synovial Fibroblasts Are Adiponectin Isoform Dependent. Kiran Khawaja[1], Klaus W. Frommer[1], Stefan Rehart[2], Ulf Müller-Ladner[1] and Elena Neumann[1]. [1]Justus-Liebig-University of Gieβen, Kerckhoff-Klinik, Bad Nauheim, Germany, [2]Markus-Hospital, Frankfurt, Germany.

Background/Purpose: Adiponectin, a C1q/tumour necrosis factor (TNF) homologue, was previously known to be secreted by adipocytes. Additionaly, it was found to be synthesized by other cells types like osteoblasts and synovial fibroblasts. Adiponectin levels were found to be high in synovial fluid of rheumatoid arthritis (RA) patients as compared to osteoarthritis patients, hence suggesting a role of adiponectin in the pathophysiology of the disease. Based on this, RA synovial fibroblasts (SF) are the key cells to secrete adiponectin in the synovium *in vivo*. At present, four different adiponectin isoforms are known, namely the globular, low molecular weight (LMW), middle molecular weight (MMW) and high molecular weight (HMW) form. Adiponectin acts by binding to its receptors AdipoR1, AdipoR2, and potentially PAQR3 and PAQR10, which leads to the activation of signaling cascades involving key molecules like AMPK, p38 MAPK, FAK, and ERK. The aim of the present study was to determine the adiponectin receptor expression in RASF and to elucidate the specificity of adiponectin isoforms mediating different signaling pathways in RASF.

Methods: AdipoR1, AdipoR2, PAQR3 and PAQR10 mRNA and protein expression were analyzed in RASF by real-time PCR, Western blotting, and immunocytochemistry. RASF were preincubated with serum-free medium for 30 min with or without signaling inhibitors. Stimulation of RASF was performed using the respective adiponectin isoforms, WT (wild type, contains all isoforms), LMW, globular and MMW/HMW enriched adiponectin isoform (each 10 μg/ml) for 10 min. Then a phosphorylation analysis of p38 MAPK, AMPK, and FAK by Western blotting was performed.

Results: Real-time PCR and Western blotting results showed that cultured RASF express AdipoR1, AdipoR2, and PAQR3 but not PAQR10. This was further confirmed by immunocytochemical analysis. With respect to signaling, phosphorylation of p38 MAPK increased by adiponectin isoform stimulation, with the strongest induction by the MMW/HMW enriched isoform. Similarly, the phosphorylation of AMPK increased in response to adiponectin isoforms and the effect was stronger with the MMW/HMW enriched isoform. On the contrary, although FAK was detectable, no induction or repression in FAK phosphorylation was observed in response to adiponectin isoform stimulation indicating that FAK does not play a role in adiponectin-mediated signaling. The increase in phosphorylation of AMPK was further enhanced by AMPK activator 5-aminoimidazole-4-carboxamide ribonucleoside (AICAR) and was reduced by AMPK inhibitor compound C. Compound C caused a further increase in the adiponectin isoform-induced enhanced phosphorylation of p38. Pre-treatment with p38 inhibitor SB203580 did not have any effect on the phosphorylation of AMPK.

Conclusion: Cultured RASF express the adiponectin receptors AdipoR1, AdipoR2 and PAQR3. Adiponectin signaling in RASF is mediated via the p38 MAPK and AMPK pathway but not FAK, and the effect is adiponectin isoform-dependent. The data suggest that the p38 MAPK pathway is a compensatory pathway for the AMPK pathway but not *vice versa*.

Citrullination Of ENA-78/CXCL5 Changes Its Receptor Affinity From CXCR2 To CXCR1 and Induces Monocyte Migration. Ken Yoshida, Alisa E. Koch, Ray A. Ohara, Phillip L. Campbell, M. Asif Amin, David A. Fox and Jeffrey H. Ruth. University of Michigan Medical School, Ann Arbor, MI.

Background/Purpose: We previously showed that citrullinated epithelial-derived neutrophil-activating peptide 78/CXCL5 (citENA-78/CXCL5) was significantly higher in rheumatoid arthritis (RA) synovial fluids (SFs) compared to osteoarthritis (OA) and other inflammatory rheumatic diseases (OD) SFs, and its concentration correlates with RA disease activity. Furthermore, we have shown that citrullination of ENA-78/CXCL5 results in conversion from a non-monocyte recruiting to a monocyte recruiting chemokine. We now examine the cellular receptors utilized by citENA-78/CXCL5 to induce monocyte migration in vitro.

Methods: Citrullination of ENA-78/CXCL5 was verified by *mass spectrometry* and Western blot analysis with anti-modified citrulline antibody (AMC). We initially performed polymorphonuclear *neutrophil*(PMN) chemotaxis assays to citENA-78/CXCL5 using a 48-well Boyden chamber system to determine if citrullination altered recruitment activity of ENA-78/CXCL5 for PMNs. Next, we performed monocyte chemotaxis assays to determine whether citENA-78/CXCL5 induced monocyte chemotaxis. Finally, we investigated whether cell recruitment could be inhibited by pertussis toxin (PTX), which is a G protein-coupled receptor antagonist, or with anti-CXCR1 and/or anti-CXCR2 blocking antibodies. For in vivo analysis, C57BL/6 mice were injected intra-articularly (i.a.) with non-cit or citENA-78/CXCL5 to induce inflammation. Immunofluorescence (IF) staining was performed on injected joint tissues using anti-F4/80 antibody, which is specific for monocytes/macrophages, to determine the number of recruited monocytes/macrophages to mouse joints.

Results: citENA-78/CXCL5 was recognized by AMC, while non-citENA-78/CXCL5 was not. Chemotaxis assays showed that citENA-78/CXCL5 induced less PMN migration compared to non-citENA-78/CXCL5, indicating that the binding affinity for PMN chemokine receptors was altered by citrullination of ENA-78/CXCL5. Monocyte chemotaxis assays showed that citrullinated ENA-78/CXCL5 significantly enhanced monocyte migration, while non-citENA-78/CXCL5 did not. PTX completely inhibited citENA-78/CXCL5-induced monocyte chemotaxis, indicating that citENA-78/CXCL5 is binding to a G-protein coupled receptor. Anti-CXCR1 and 2 antibodies both partially reduced the monocyte chemotaxis, and a combination of anti-CXCR1 and 2 antibodies completely inhibited monocyte chemotaxis. Lastly, IF staining showed that citENA-78/CXCL5 recruited more F4/80 positive monocytes/macrophages into mouse knee joints compared to non-citENA-78/CXCL5.

Conclusion: Our results show that citENA-78 induces monocyte migration via CXCR1 and CXCR2, and indicate that citrullination may increase the affinity of ENA-78/CXCL5 for CXCR1. Our data also shows that citENA-78/CXCL5 is a potent recruitment factor for monocytes, but a poor recruitment factor for PMNs. citENA-78/CXCL5 also induced more macrophage accumulation in synovium when injected into mouse knee joints compared to non-citENA-78/CXCL5. These results show that citrullination of ENA-78/CXCL5 can alter its receptor affinity and cellular recruitment properties.

Cytokine-Mediated Repression Of The Lncrna Hotair Enhances Intracellular Signaling and The Expression Of Adhesion Molecules In Synovial Fibroblasts. Michelle Trenkmann[1], Mojca Frank Bertoncelj[1], Matthias Brock[2], Christoph Kolling[3], Renate E. Gay[1], Beat A. Michel[4], Diego Kyburz[1], Lars C. Huber[2] and Steffen Gay[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Department of Internal Medicine, University Hospital Zurich, Zurich, Switzerland, [3]Schultess Clinic, Zurich, Switzerland, [4]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: Rheumatoid arthritis (RA) synovial fibroblasts (SF) are characterized by a stably activated phenotype which is, at least in part, because of the epigenetic inheritance of aberrations in gene expression. The histone methyltranferase EZH2 is upregulated in RASF thereby causing the epigenetic repression of specific target genes *via* methylation of histone 3 on lysine 27 (H3K27me3). Long noncoding RNAs (lncRNAs) have recently emerged as powerful regulators of gene expression, e.g. through the interaction with chromatin-associated proteins. In this regard, the lncRNA HOX transcript antisense RNA (HOTAIR) was found to associate with EZH2 and to regulate certain EZH2 target genes. Here we studied the function of HOTAIR in RASF.

Methods: SF were transfected using Lipofectamin 2000 (for siHOTAIR) or AMAXA Nucleofection (for plasmid DNA) and/or stimulated with 10ng/ml TNFα or 1ng/ml IL-1β. Gene expression was measured by quantitative real-time PCR (qPCR) and flow cytometry. Chromatin immunopre-

cipitation (ChIP) was performed with antibodies for histone 3 (H3), H3K27me3 or IgG control and precipitated chromatin was analyzed by qPCR. The activity of intracellular signaling pathways was determined by reporter gene assay (NF-κB; using the pGL4.32 vector and pRL_GAPDH as internal control) and Western blot (p38 phosphorylation).

Results: In OASF (n=13), the expression of HOTAIR was upregulated by 12.7-fold compared with RASF (n=9) (ΔCt 10.6±1.7 vs. 14.3±3.3, p=0.005). Stimulation of OASF (n=5) with TNFα or IL-1β potently decreased HOTAIR levels at 24h (by 65±8% and 50±9%) and 48h (by 52±31% and 49±27%) ($p<0.05$). ChIP analysis revealed increased levels of the repressive H3K27me3 mark at the HOTAIR promoter in RASF (ratio to H3: 0.51±0.35, OASF: 0.25±0.23; p=0.03) showing a strong inverse correlation with its expression (Spearman $R=-0.8725$, $p<0.0001$). Silencing of HOTAIR in OASF significantly increased the TNFα-induced activity of the NF-κB pathway (17±9-fold to 24±14-fold, n=13) whereas p38 phosphorylation was not significantly changed (n=8). In line with this, we found the expression of NF-κB target genes to be upregulated, namely intercellular adhesion molecule 1 (ICAM1) and vascular adhesion molecule 1 (VCAM1). At the mRNA level, ICAM1 and VCAM1 expression was increased after HOTAIR silencing (n=12) both under unstimulated (1.91±0.61- and 2.05±0.99-fold; $p\leq0.005$) as well as TNFα-induced conditions (from 53±23- to 72±43-fold and 4.77±3.39- to 6.31±4.2-fold; $p<0.005$) whereas under IL-1β only ICAM1 mRNA levels were elevated (from 11.9±5.4- to 15.5±6.8-fold; $p<0.005$). These data were confirmed for ICAM1 protein levels measuring its surface expression under TNFα stimulation (n=6, $p<0.01$).

Conclusion: Our data underline the role of the epigenetically repressed lncRNA HOTAIR in the activated phenotype of RASF. Silencing of HOTAIR increased the activity of the NF-κB signaling pathway and the expression of adhesion molecules suggesting a contribution to inflammatory cell infiltration into the joint and, thus, chronic inflammation in RA.

Tumor Necrosis Factor Alpha Modifies Chromatin Landscape and Amplifies Inflammatory Responses To Subsequent Stimuli In Synovial Fibroblasts. Angela Lee, Lionel B. Ivashkiv and George D. Kalliolias. Hospital for Special Surgery, New York, NY.

Background/Purpose: Fibroblast-like synoviocytes (FLS) cross-talk with macrophages (Mf) during the course of rheumatoid arthritis (RA). Our group has shown that TNFa, primarily Mf-derived within synovium, induces chromatin modifications and a sustained inflammatory program in FLS. Here we test the hypothesis that chronic TNFa modifies the chromatin landscape in FLS, amplifying responses to subsequent inflammatory stimuli.

Methods: FLS obtained from synovial tissues of patients with RA were chronically exposed to TNFa, then stimulated with interferons (IFNb or IFNg) and were assayed for gene expression by qPCR. NFkB signaling and chromatin modifications were evaluated using western blotting and ChIP assay.

Results: Chronic exposure (72h) of FLS to TNFa leads to super-induction of *CXCL10*, *CXCL11* and *CXCL9* upon subsequent stimulation with IFNb or IFNg (Figure 1A). Notably, these genes reside proximally within the same locus on chromosome 4. These chemokines have been linked to RA pathogenesis and a monoclonal antibody against CXCL10 has shown promising results in a clinical trial. The expression of other classic IFN-target genes upon IFN stimulation is not affected by pre-exposure to TNF (Figure 1B and data not shown), suggesting that the effect of TNF on the IFN-inducible transcriptional program in FLS is gene-specific. After 72h of TNF stimulation, FLS were washed to remove TNF and treated with infliximab (IFX) for 24h to neutralize any residual TNF in the system and then stimulated with IFN. Despite the abrogation of TNF signaling for 24h, the super-induction of *CXCL10*, *CXCL11* and *CXCL9* was retained (Figure 1C), suggesting that TNF has a sustained impact on FLS. In addition, it was observed that chronic TNF stimulation (72h) induces histone depletion, hyperacetylation of residual histones and induction of the active histone mark H3K27Ac at the *CXCL10* promoter (Figure 2A). Exposure of FLS to TNFa for 72h also induced nuclear localization and binding of p65 at the *CXCL10* promoter (Figure 2B) as well as expression of transcription factors STAT1, IRF1 and IRF7 (Figure 2C).

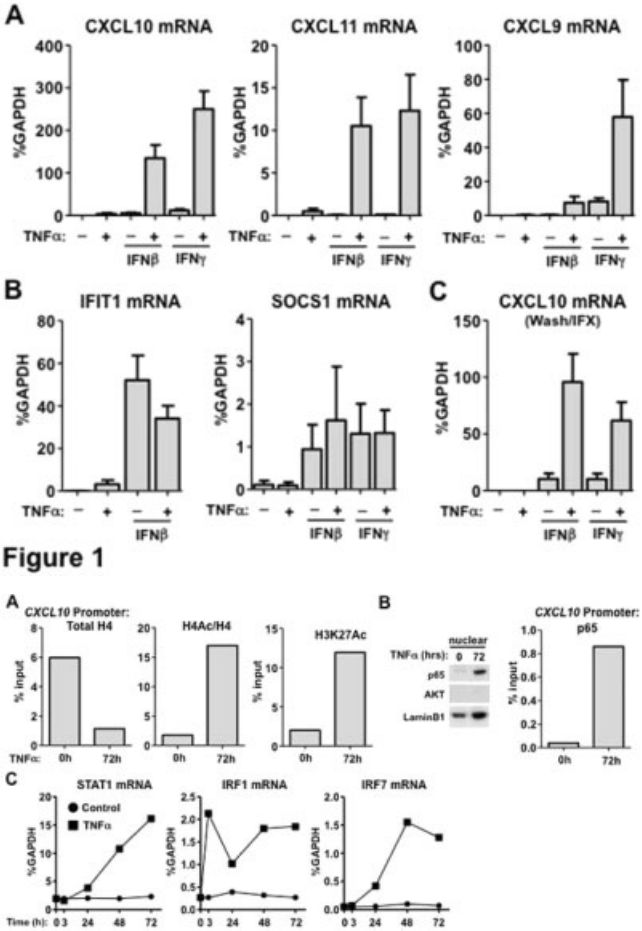

Figure 1

Conclusion: Chronic exposure of FLS to TNFa induces sustained chromatin activation at the *CXCL10* locus, allowing its super-induction upon subsequent IFN stimulation. Since this locus contains binding sites for TNFa-induced p65, STAT1 and IRFs, we will further investigate the potential implication of these transcription factors on the observed activation of chromatin in FLS.

A Unique Role For Galectin-9 In Angiogenesis and Inflammatory Arthritis. Martin O'Brien[1], Qiang Shu[2], Pei-Suen Tsou[3], William Stinson[4], Jeffrey H. Ruth[1], Takeo Isozaki[1], Alisa E. Koch[5], David A. Fox[1] and M. Asif Amin[1]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Michigan Medical School and Qilu Hospital of Shandong University, Ann Arbor, MI, [3]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI, [4]University of Michigan, Ann Arbor, MI, [5]VA Medical Service, Ann Arbor, MI.

Background/Purpose: Galectin-9 (Gal-9) is a mammalian lectin which contributes to T-cell autoimmunity and tumor biology. Here, we examined the contribution of Gal-9 in angiogenesis and inflammatory arthritis, two critical components involved in the pathogenesis of rheumatoid arthritis (RA).

Methods: To determine the role of Gal-9 in angiogenesis *in vitro*, we performed human dermal microvascular endothelial cell (HMVEC) chemotaxis in modified Boyden chambers and Matrigel tube formation assays. We employed the mouse Matrigel plug angiogenesis assay to examine the involvement of Gal-9 in angiogenesis *in vivo*. Inhibitors and siRNA to signaling molecules for Gal-9 were also tested in these assays. We performed a local model of inflammation by injecting Gal-9 in the knees of C57/Bl6 wild type (wt) mice. HMVECs were stimulated with Gal-9 in the presence or absence of chemical inhibitors and Western blots were performed to investigate the phosphorylation of signaling molecules. We also examined the expression of Gal-9 in RA synovial tissue (ST) sections by performing immunohistochemistry.

Results: Gal-9 significantly induced HMVEC migration at 1μg/mL and 2μg/mL ($P < 0.05$), while signaling inhibitors of Erk1/2, p38, and c-Jun inhibited Gal-9-mediated HMVEC migration ($P < 0.05$). Gal-9 increased HMVEC Matrigel tube formation *in vitro*, another facet of angiogenesis, which was significantly reduced by the signaling inhibitors of Erk1/2, c-Jun, and p38 ($P < 0.05$). We confirmed our data by using siRNA directed against signaling intermediates. To examine the role of Gal-9 in angiogenesis *in vivo*, we performed Matrigel plug angiogenesis assays in mice. Gal-9 induced significantly higher ($P < 0.05$) hemoglobin, an indirect measure of angiogenesis, compared to phosphate buffered saline (PBS) injected plugs. Gal-9-mediated angiogenesis was attenuated in the plugs containing Jnk inhibitor, suggesting the importance of Jnk in Gal-9 induced angiogenesis *in vivo*. We found a marked increase in inflammation when wt mouse knees were injected with Gal-9 compared to PBS, suggesting that Gal-9 is a potent proinflammatory mediator. Gal-9-stimulated HMVECs showed a time-dependent increase in Jnk and Erk1/2 phosphorylation. We also found that Jnk is upstream of Erk1/2, as siRNA directed against Jnk decreased Gal-9-activated Erk1/2 phosphorylation in HMVECs. Immunohistochemical staining showed markedly higher expression of Gal-9 in blood vessels in RA compared to osteoarthritis ST sections.

Conclusion: Gal-9 mediates angiogenesis *in vitro* and *in vivo* via Erk1/2 and Jnk pathways. Gal-9 increases mouse knee circumference when injected intraarticularly. Our data suggest a novel role of Gal-9 in angiogenesis and inflammatory arthritis. Gal-9 may be a potential therapeutic target for angiogenesis-dependent diseases such as RA.

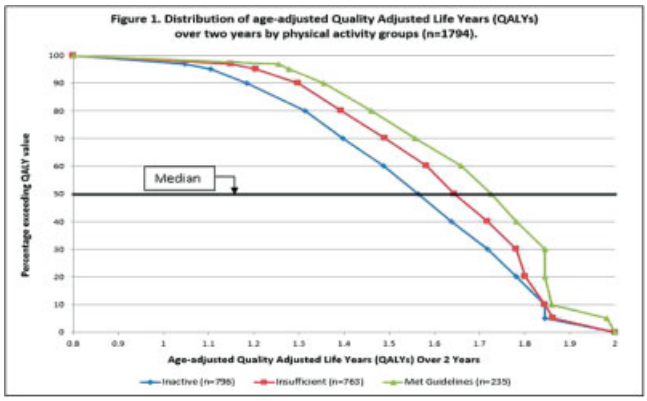
Relationship of Meeting Physical Activity Guidelines and Quality Adjusted Life Years. Kai Sun[1], Jing Song[1], Larry Manheim[1], C. Kent Kwoh[2], Rowland W. Chang[3], Pamela A. Semanik[1], Dorothy D. Dunlop[1] and Charles Eaton[4]. [1]Northwestern University, Chicago, IL, [2]University of Pittsburgh, Pittsburgh, PA, [3]Northwestern University Medical School, Chicago, IL, [4]Brown University, Providence, RI.

Background/Purpose: Regular physical activity is associated with reduced chronic disease burden and mortality. Recognizing the importance of physical activity, there are US federal guidelines for adults that also include persons with arthritis. Improving physical activity may be key to improving overall public health and reducing health care spending. Quality Adjusted Life Year (QALY) is a standard outcome measure used in cost-effectiveness analyses. We analyzed the data from the Osteoarthritis Initiative (OAI) to determine whether increasing levels of physical activity is correlated to larger QALY estimates.

Methods: Physical activity was measured using accelerometers and was classified as 1) Meeting Guidelines (≥150 moderate-to-vigorous [MV] minutes/week acquired in bouts ≥10 minutes); 2) Insufficiently Active (some but <150 MV bout minutes/week) or 3) Inactive (no bouts of MV activity lasting 10 minutes over the week). An SF6-D utility score (range 0–1) was derived from patient reported health status at baseline and 2 year follow-up. The QALY outcome was calculated as the area under utility curve over 2 years (range 0–2). Data were stratified by gender and body mass index (BMI). The relationship of physical activity levels to median QALY adjusted for sociodemographic factors (age, gender, race, education, income) and clinical/health factors (body mass index, medical comorbidity, smoking, presence of radiographic knee osteoarthritis, knee symptoms, and prior knee injury) was derived using median quantile regression.

Results: Median QALYs over 2 years were significantly higher with greater physical activity level in a stepwise fashion as shown by the cumulative frequency curve (figure). Relative to the Inactive group, the median QALYs of the Meeting Guidelines group was 0.162 (95% confidence interval (CI) 0.120–0.204) higher, and that of the Insufficiently Active group was 0.082 (95% CI 0.052–0.110) higher. After adjusting for sociodemographic and clinical/health factors, the differences in median QALYs continued to show a statistically significant linear trend with physical activity level. Similar findings were observed when the cohort was stratified by gender and BMI.



Conclusion: We found a strong graded relationship between greater physical activity and better QALYs. Moving individuals from the Inactive to Insufficiently Active group or from the Insufficiently Active to Meeting Guidelines group could be associated with a 0.08 increase in QALYs over 2 years. An intervention costing $4,000 or less that resulted in such physical activity gains would be cost effective using a $50,000 per QALY gain cutoff. Our analysis further supports the potential effectiveness and cost-effectiveness of interventions to promote physical activity even if recommended levels are not fully attained.

Low Cardiovascular Mortality Among Early Rheumatoid Arthritis Patients—A Nationwide Register Study 2000–2008. Anne M. Kerola[1], Tuomo Nieminen[2], Lauri J. Virta[3], Hannu Kautiainen[4], Kari Puolakka[5], Tuomas Kerola[6], Timo Pohjolainen[7] and Markku J. Kauppi[6]. [1]Medical School, University of Helsinki, Helsinki, Finland, [2]Division of Cardiology, Helsinki University Central Hospital, Helsinki, Finland, [3]Research Department, the Social Insurance Institution, Turku, Finland, [4]Unit of Primary Health Care, Helsinki University Central Hospital, Helsinki, Finland, [5]Department of Medicine, South Karelia Central Hospital, Lappeenranta, Finland, [6]Department of Internal Medicine, Päijät-Häme Central Hospital, Lahti, Finland, [7]ORTON Rehabilitation Centre, ORTON Foundation, Helsinki, Finland.

Background/Purpose: Increased cardiovascular (CV) mortality in established rheumatoid arthritis (RA) is a widely accepted threat, but in early RA or inception cohorts, growing evidence suggests no increased CV mortality. The aim of this study was to assess the CV mortality in early RA patients diagnosed in the 2000s, and to compare it with the general population.

Methods: All incident RA patients over 16 years of age diagnosed in 2000–2007 were identified from a Finnish nationwide register maintained by the Social Insurance Institution (M05 for RF positive and M06 for RF negative RA). Death certificate data were obtained from the National Population Registry until the end of 2008, and CV disease was identified as the primary cause of death by the ICD-10 codes I00–99. The number of CV deaths was calculated in subgroups according to sex, age, RF status, and calendar year. The cumulative incidence of CV deaths was assessed with adjustment for competing risks—that is, deaths due to causes other than CV disease. The expected number of CV deaths in each subgroup was calculated on the basis of CV death rates in the age- and sex-specific general population (data obtained from Statistics Finland), and a standardized mortality ratio (SMR) was calculated with 95% CIs.

Results: During the 8-year follow-up period, 14,878 new RA patients were identified (68% women, 63% RF positive). The mean age was 55.8 (SD 15.8) years in women and 57.5 (SD 13.9) years in men at the time of RA diagnosis. By the end of 2008, 501 patients had died of CV causes. Cumulative incidence analysis adjusted for competing risks showed that CV mortality at five/eight years after the diagnosis of RA was 2.6%/5.8% in women and 4.4%/8.4% among men (Figure 1). The SMR in the entire RA cohort was 0.57 (95% CI 0.52 to 0.62). The SMRs in subgroups according to sex and RF status varied from the lowest value of 0.43 among the RF negative women to 0.70 among the RF positive men (Table 1). Male sex and the presence of RF increased the risk of CV death: the sub-hazard ratios (sHR)

were 1.73 (95% CI 1.45 to 2.05, p<0.001) and 1.33 (1.10 to 1.60, p=0.003), respectively.

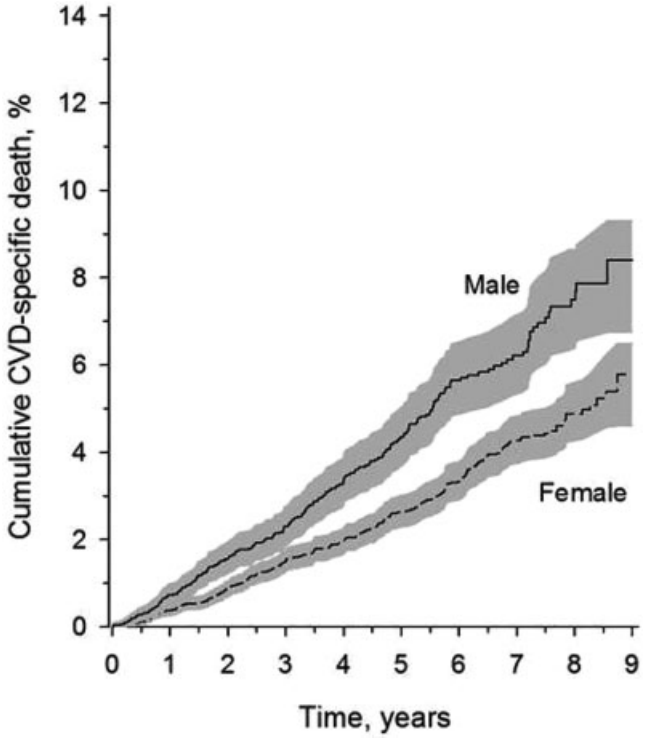

Figure 1. Estimated cumulative incidence functions for cardiovascular-disease-specific (CVD-specific) death among patients with RA.

Table 1.

	Number ofCV deaths	SMR (95% CI)
Total		
Men	214	0.63 (0.55 to 0.72)
Women	287	0.53 (0.48 to 0.60)
RF+		
Men	148	0.70 (0.60 to 0.83)
Women	198	0.60 (0.52 to 0.69)
RF−		
Men	66	0.51 (0.40 to 0.65)
Women	89	0.43 (0.35 to 0.53)

Conclusion: In this nationwide early RA cohort, CV mortality was substantially lower than in the age- and sex-specific general population. This reduction in CV deaths may reflect both the recent advances in the management of systemic inflammation and the improved recognition and treatment of CV risk factors in RA. With longer disease duration, this favorable CV prognosis may deteriorate.

Serious Infection Rates Among Patients With Systemic Lupus Erythematosus Receiving Corticosteroids and Immunosuppressants. Candace H. Feldman[1], Linda T. Hiraki[2], Francisco M. Marty[3], Wolfgang C. Winkelmayer[4], Jessica M. Franklin[5], Daniel H. Solomon[6], Seoyoung C. Kim[3] and Karen H. Costenbader[7]. [1]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Harvard School of Public Health, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Stanford University School of Medicine, Stanford, CA, [5]Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Boston, MA, [6]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA, [7]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Infections are among the leading causes of hospitalization and mortality in patients with systemic lupus erythematosus (SLE); approximately 50% have a serious infection during their disease course. We investigated rates of serious infections requiring hospitalization according to immunosuppressant use in a nationwide cohort of SLE patients.

Methods: We used the Medicaid Analytic eXtract (MAX) data system, with billing claims and demographic information for >24 million Medicaid enrollees from 47 states and Washington, DC, 2000–2006. We identified patients age 18–65 years with prevalent SLE (≥3 visits ≥30 days apart with ICD-9 codes of 710.0). We defined serious infections resulting in hospitalization using a method previously validated in an administrative database. We identified patients ever receiving immunosuppressants (IS; azathioprine, mycophenolate mofetil, cyclophosphamide, cyclosporine, tacrolimus), and corticosteroids (CS) and calculated incidence rates per 100,000 persons-years for bacterial (bacteremia, cellulitis, endocarditis, osteomyelitis, pneumonia, pyelonephritis, septic arthritis, listeriosis), fungal (pneumocystosis, candidiasis, cryptococcosis, aspergillosis, histoplasmosis) and viral (influenza, herpes zoster, cytomegalovirus) infections, occurring ≥7 days after receipt of the drug. We used Poisson regression to determine age, sex, and Medicaid enrollment duration-adjusted infection incidence rate ratios comparing SLE patients receiving no drugs to CS alone and IS and CS combined.

Results: We identified 43,351 patients with SLE. The mean age was 38 years (±12) and mean Medicaid enrollment duration was 3.3 person-years (±2.1). SLE patients were 98% female, 38% Black, 37% White, and 15% Hispanic. 18,659 (43%) patients received a CS alone and 13,913 (32%) received both a CS and an IS. During follow-up there were 13,986 serious bacterial infections: 23% bacteremia, 38% pneumonia and 24% cellulitis. There were also 47 cases of pneumocystosis, 382 cases of herpes zoster, and 114 cases of influenza all requiring hospitalization. The incidence rate for all infections was 1.2 times higher among those receiving a CS alone and combined with an IS, compared to those prescribed neither (**Table**). The incidence rate of viral infections was 2.4 times higher in patients receiving an IS and a CS combined and 1.3 times higher with a CS alone, compared to those prescribed neither.

Table. Incidence Rates of Serious Infections by Subtype among Patients with SLE, 2000–2006*

	Total Infections		Bacterial Infections		Fungal Infections		Viral Infections	
SLE Group	**IR**	**IRR**	**IR**	**IRR**	**IR**	**IRR**	**IR**	**IRR**
No IS or CS N=9197	102.05 (102.01–102.09)	1.0 (ref)	95.80 (95.76–95.84)	1.0 (ref)	3.65 (3.64–3.66)	1.0 (ref)	1.90 (1.90–1.91)	1.0 (ref)
CS Alone N= 18659	120.73 (120.71–120.75)	**1.20 (1.13–1.27)**	112.42 (112.40–112.44)	**1.19 (1.12–1.26)**	4.66 (4.65–4.66)	**1.30 (1.19–1.41)**	2.47 (2.47–2.54)	**1.31 (1.20–1.43)**
IS and CS N=13913	119.51 (119.48–119.53	**1.19 (1.12–1.26)**	109.06 (109.04–109.09)	**1.16 (1.09–1.22)**	5.10 (5.10–5.11)	**1.35 (1.23–1.47)**	4.62 (4.62–4.63)	**2.39 (2.15–2.65)**

*Crude incidence rates (IR) reported per 100,000 person-years with 95% CIs. Incidence rate ratios (IRR) with 95% CIs adjusted for age, sex and Medicaid enrollment duration.

Conclusion: In this large, diverse cohort, SLE patients receiving CS alone and both IS and CS combined had elevated incidence rates of serious infections requiring hospitalization, particularly viral infections. Further studies are needed to evaluate the causality of the observed associations accounting for patients' baseline infection risk and drug-specific effects.

Mortality Rates, Readmissions and Revascularisation Following a First Myocardial Infarction In Patients With Autoimmune Rheumatic Disease Compared With Controls. Sharon Van Doornum[1], Megan Bohensky[1], Mark Tacey[1], Caroline Brand[1], Vijaya Sundararajan[2] and Ian Wicks[3]. [1]The University of Melbourne, Melbourne, Australia, [2]University of Melbourne, Melbourne, Australia, [3]Royal Melbourne Hospital, Melbourne, Australia.

Background/Purpose: We have previously demonstrated increased case fatality following myocardial infarction (MI) in rheumatoid arthritis (RA) patients[1], however post-MI case fatality has not been inves-

tigated in other autoimmune rheumatic disease (AIRD). The primary aim of this study was to compare mortality rates following a first MI in patients with and without a diagnosis of AIRD. The secondary aims were to compare hospital readmission rates and post-MI revascularisation treatment.

Methods: This was a retrospective cohort study using two population-based linked databases. Cases of MI from 1 July 2001 to 30 June 2007 were identified using International Classification of Diseases (ICD) codes. AIRD status was identified from the index admission or any prior admission in the preceding 3 years using relevant ICD codes. Thirty-day and 1-year mortality rates were calculated from the date of index MI to the date of death (all-cause and cardiovascular causes of death) for patients with AIRD and patients without AIRD (controls). Adjusted odds ratios for mortality were calculated using a logistic regression model fitted with mortality as the outcome, AIRD status as the exposure and with adjustment for age, gender, socio-economic status, geographic location and relevant co-morbidities. Readmissions were defined as admission to hospital within 1 year of the index MI. Procedure codes for percutaneous transluminal coronary angioplasty (PTCA) and coronary artery bypass graft (CABG) up to 90 days after the index MI were identified to compare intervention rates.

Results: There were 79,390 individuals with a first MI, of whom 1,409 (1.8%) had AIRD. The 30-day all-cause mortality rate for patients with AIRD was 21.4% compared to 13.4% for controls ($p < 0.001$). At 1 year the AIRD group had an all-cause mortality of 38.6% compared to controls of 22.8% ($p < 0.001$). Adjusted odds ratios for mortality in the AIRD group and AIRD sub-groups are shown in Figure 1. Higher rates of readmissions at 30-days ($p=0.004$) and 1 year ($p=0.003$) were observed in the AIRD group compared to controls, but this was not sustained when considering only subsequent MIs as the cause of readmission. The 90-day rates of PTCA and CABG were significantly lower in the AIRD group compared to controls (PTCA: 15.7% vs 25.9%, $p < 0.001$ and CABG: 3.8% vs 8.7%, $p < 0.001$).

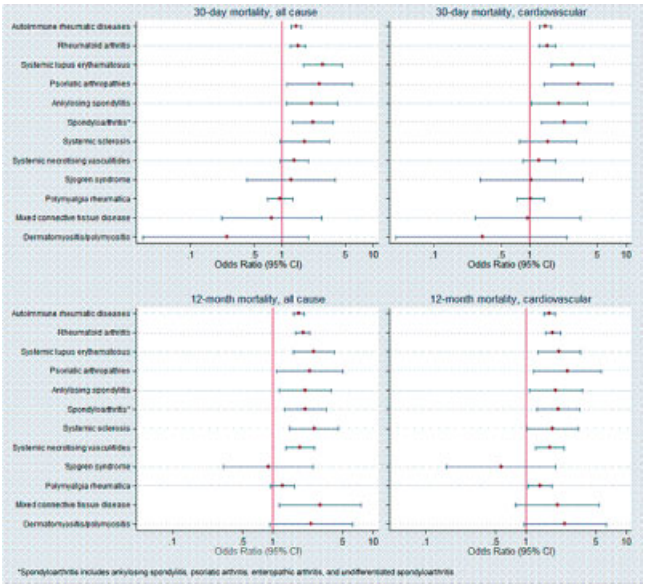

Figure 1. Mortality Risk for AIRD patients who experienced a first MI between 1 July 2001–30 June 2007

Conclusion: We identified a higher risk-adjusted mortality rate for AIRD patients overall and for the majority of patient subgroups at 30-days and 12 months after first MI. We also identified higher readmission rates and lower post-MI revascularisation rates in the AIRD group, suggesting gaps in the current treatment of cardiovascular disease for AIRD patients.

Rates Of Malignancies In Patients From 5 Rheumatoid Arthritis Registries Across The World. Johan Askling[1], Niklas Berglind[2], Stefan Franzén[2], Thomas Frisell[1], Christopher Garwood[3], Jeffrey D. Greenberg[4], Meilien Ho[5], Marie Holmqvist[1], Laura Horne[6], Kathy Lampl[6], Kaleb Michaud[7], Fredrik Nyberg[8], Dimitrios A. Pappas[9], George Reed[10], Eiichi Tanaka[11], Trung Tran[12], Suzanne Verstappen[3], Hisashi Yamanaka[11] and Deborah Symmons[3]. [1]Karolinska Institutet, Stockholm, Sweden, [2]AstraZeneca R&D Mölndal, Mölndal, Sweden, [3]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [4]NYU Hospital for Joint Diseases, New York, NY, [5]AstraZeneca R&D Alderley Park, Macclesfield, United Kingdom, [6]AstraZeneca R&D Wilmington, Wilmington, DE, [7]University of Nebraska Medical Center, Omaha, NE, [8]AstraZeneca R&D, Mölndal, Sweden, [9]Columbia University, New York, NY, [10]University of Massachusetts Medical School, Worcester, MA, [11]Tokyo Women's Medical University, Tokyo, Japan, [12]MedImmune LLC, Gaithersburg, MD.

Background/Purpose: The overall incidence of cancer in patients with rheumatoid arthritis (RA) is modestly elevated compared with the general population. The extent to which cancer rates in RA populations vary across cohorts and across patient subsets defined by disease activity or treatment is less known. Available data are often difficult to compare, since background malignancy rates may vary across the world, and due to methodological differences and population differences between studied RA cohorts. We investigated malignancy rates in 5 international RA registries from 4 continents, employing a standard set of analyses and standardizing rates to a common population.

Methods: Participating RA registries were CORRONA (USA), SRR (Sweden), NOAR (UK), CORRONA International (East Europe, Latin America, India) and IORRA (Japan). Within each registry, we analyzed a primary cohort of all RA patients from January 2000 to last available data of each register (2010–2013), and several subcohorts as defined by disease activity, treatment status, calendar time, duration of follow-up and prior comorbidity for sensitivity analyses. Malignancy rates with 95% confidence intervals were estimated, and were standardized for age, sex and, in 1 sensitivity analysis, also for HAQ, using the distributions from a typical RA trial program population.

Results: There was remarkable consistency in crude malignancy rates across registries (Table). Sex and age standardization reduced heterogeneity further, with standardized rates of malignancy excluding nonmelanoma skin cancer (NMSC) varying from 0.56 to 0.87 per 100 person-years (Table). Within each registry, rates were generally also consistent across the sensitivity analyses, which also differed little from the main analyses based on the full cohort (data not shown).

Table. Incidence of malignancies excluding NMSC, and of malignant lymphomas, in the primary cohorts (RA patients from Jan 1, 2000) from 5 RA registries

Registry	N	Events	PY*	Crude Incidence/ 100 PY	Standardized† Incidence/100 PY (95% CI)
Malignancies excluding NMSC					
CORRONA	24,176	694	74,751	0.93	0.64 (0.58–0.71)
SRR	18,527	1078	79,241	1.36	0.87 (0.80–0.94)
NOAR	1564	129	10,695	1.21	0.77 (0.60–0.99)
CORRONA-INT	2727	11	1812	0.61	0.56 (0.27–1.07)
IORRA	7770	241	33,582	0.72	0.65 (0.57–0.75)
Lymphoma					
CORRONA	24,176	62	75,655	0.08	0.06 (0.04–0.08)
SRR	18,527	82	81,459	0.10	0.06 (0.04–0.08)
NOAR	1564	10	10,931	0.09	0.09 (0.03–0.21)
CORRONA-INT	2727	1	1812	—‡	
IORRA	7770	23	33,951	0.07	0.06 (0.04–0.10)

* PY, person-years.
† Standardized according to the age and sex distribution in a typical RA clinical trial program.
‡ NA, not available. Too few events - incidence rates not calculated.

Conclusion: A consistent methodology and analysis with standardization of rates facilitated comparison across registries and demonstrated that in real world RA populations from different countries and with variations in RA management and comorbidity, rates of overall malignancy excluding NMSC and of lymphoma were surprisingly consistent across and within the cohorts.

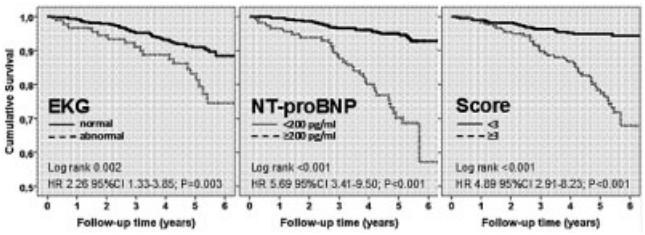
Outcome In Patients With Rheumatoid Disease: Simple Screening Tools Predict Cardiovascular Events and Death. Stefan Kleinert[1], Margret Breunig[2], Hans-Peter Tony[1], Martin Feuchtenberger[3], Marc Schmalzing[1], Christian Kneitz[4], Stefanie Lehmann[5], Christiane Angermann[1], Georg Ertl[1] and Stefan Störk[5]. [1]University Hospital Würzburg, Würzburg, Germany, [2]University Hospital Würzburg, Würzburg, Wuerzburg, Germany, [3]Kreiskliniken Altötting-Burghausen, Burghausen, Germany, [4]Hospital Südstadt, Rostock, Germany, [5]University of Würzburg, Würzburg, Germany.

Background/Purpose: Patients with rheumatoid disease (RD) have an increased mortality risk compared to the normal population, mainly due to cardiovascular (CV) disease. Only a proportion of this risk increase seems explained by traditional cardiovascular risk factors. It is therefore difficult to identify patients with RD at high risk. We identified patients at increased risk for CV diseases and mortality by a screening program that is suitable for clinical practice in rheumatology, and quantified long-term outcome.

Methods: 612 consecutive patients attending the rheumatology outpatient department of the University Hospital underwent a comprehensive CV risk assessment including medical history, patient questionnaires, ECG, and laboratory measurements including natriuretic peptides (NT-proBNP). Screening was regarded "positive" if any of the following was present: European CV disease risk assessment Score (SCORE) ≥3% or NTproBNP≥200 pg/ml or any pathological ECG pattern. Patients were followed for a median of 5.5 years.

Results: 312 subjects suffered from rheumatoid arthritis (RA; 80% female, mean age 54 yrs), and 260 from systemic autoimmune diseases (SAI; 77% female, mean age 51 yrs). Across all subjects, SCORE was ≥3% in 31%, 20% had a NTproBNP level ≥200 pg/ml, and 16% had a pathological ECG. All-cause mortality in RA/SAI was 6.2%/5.6%, respectively; frequency of cardiac events (ie, myocardial infarction, stroke, cardiac decompensation, resuscitation) was 5.8%/7.3%, respectively. The figure shows KM-plots for the 3 screening strategies, and unadjusted hazard ratios with 95%CI. In an age- and sex-adjusted multivariable model, only NTproBNP≥200 pg/ml conferred independent prognostic information with HR 2.8 (1.55–5.03; p<0.001) and an area under the ROC curve of 80%.



Conclusion: RD patients at high risk for death and CV events can be identified using simple screening tools. In patients with a SCORE ≥3% or NTproBNP ≥200 pg/ml are further diagnostics and closer long-term follow-up seem justified.

IgG4+ Plasmablasts Are A Novel Biomarker In IgG4-Related Disease. Mollie Carruthers[1], Hamid Mattoo[2], Zachary S. Wallace[1], Vinay Mahajan[2], Shiv Pillai[1] and John H. Stone[1]. [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: IgG4-related disease (IgG4-RD) is an immune-mediated disorder that responds to B cell depletion with rituximab (RTX). We detected IgG4+ plasmablasts in the sera of patients with IgG4-RD and observed a general correlation with disease activity. We examined the relationship between disease activity and IgG4+ plasmablast concentration more closely in eight patients treated with RTX.

Methods: This study was approved by the institutional review board and all subjects provided informed, written consent. All patients had histopathologic proof of their IgG4-RD diagnoses, and their clinical features were consistent with this diagnosis. Patients were selected for rituximab treatment based on previous refractoriness to glucocorticoids or disease activity at one or more organ sites. Rituximab (1000 mg) was administered in two doses at days 0 and 15. Absolute plasmablasts/ml were measured by flow cytometry, gated on IgG4+, CD38+, CD27+ and CD19 lo. Clinical visits and laboratory evaluations were performed at baseline and approximately 3 months later. One subject had the baseline plasmablast concentration measured 2 weeks after RTX, and another had the measurement at 5 months post-RTX treatment. The IgG4-RD responder index (IgG4-RD RI) was used to measure disease activity. Concentrations of plasmablasts before and after RTX were compared using a paired t-test.

Results: IgG4+ plasmablast concentrations decreased dramatically following RTX (Figure 1). The mean absolute IgG4+ plasmablast counts per ml before and after treatment were 3692 (range: 610 to 5772) and 422 (range: 1 to 156), respectively (p=0.004). The IgG4-RD RI declined in a similar fashion, from a mean of 13±4 to 3±2 (p=0.0001). Three patients had baseline serum IgG4 concentrations <140 mg/dl yet still had substantial blood plasmablast elevations, with a mean of 5279 PB/ml (range: 4530 to 5772). The mean serum IgG4 concentration also decreased significantly following RTX, from 284 mg/dl (range: 58 to 638) to 177 mg/dl (range: 47 to 387 mg/dl)(p=0.025).

Conclusion: The IgG4+ plasmablast level falls significantly 3 months after treatment with RTX, corresponding to improvements in disease activity in IgG4-RD. IgG4+ plasmablasts may be an important biomarker in IgG4-RD for diagnosis, serial assessment of disease activity, and a gauge for the need for treatment.

Ophthalmic Manifestations Of IgG4-Related Disease: A Single-Center Experience. Zachary S. Wallace, Vikram Deshpande and John H. Stone. Massachusetts General Hospital, Boston, MA.

Background/Purpose: IgG4-related disease (IgG4-RD) is an inflammatory disorder responsible for fibrosing, tumefactive lesions that can present in nearly any anatomic location. The orbital manifestations of IgG4-RD, termed IgG4-related ophthalmic disease (IgG4-ROD), include lacrimal gland involvement in most cases. However, the extraocular muscles, orbital soft tissues, sclera, and local nerves may also be affected. We review the orbital manifestations of IgG4-RD based on the experience at our center and characterize the natural history, pathology, and treatment of these IgG4-RD complications.

Methods: We identified 27 patients in our IgG4-RD Registry with orbital manifestations. Six cases were excluded because no pathology was available for review. All 21 cases included had histopathologically-confirmed IgG4-RD diagnoses. We then performed a retrospective medical records review.

Results: Patients with IgG4-ROD had a mean age of 50 years (range: 21–79) at the time of symptom onset and were approximately balanced with regard to gender distribution (male 57%, female 43%).The lacrimal gland, affected in 13/21 cases (62%) was the most commonly involved orbital structure. Dacryoadenitis typically led to proptosis. Most patients (71%) had bilateral ophthalmic disease as well as extra-orbital involvement. The salivary glands, abnormal in 40% of those with IgG4-ROD, comprised the most common site of extra-orbital disease. The average serum IgG4 concentration was 721 mg/dL (range: 28 to 4780; normal < 125). The mean serum concentration was higher in patients with bilateral disease and in those with extra-orbital manifestations. Among patients with dacryoadenitis, all were anti-Ro and anti-La negative. The histopathological and immunostaining features of every biopsy specimen were consistent with consensus criteria. Nine of 10 patients treated with rituximab responded to this therapy.

Conclusion: Ophthalmic involvement is a common manifestation of IgG4-RD and can affect nearly every anatomic structure of the orbit. Consideration of IgG4-RD and accurate diagnosis by biopsy have important implications for prognosis and treatment following the distinction of this condition from Sjögren syndrome (SjS), granulomatosis with polyangiitis (GPA, formerly Wegener's), sarcoidosis, lymphoma, infection, and other disorders. Rituximab holds promise as an effective steroid-sparing agent or therapy for steroid-resistant cases.

Antibodies Against Drp-4 and Macropain Subunit C2 As a Potential Marker Of Aosd. Niklas T. Baerlecken[1], Nils Pursche[2], Torsten Witte[3], Reinhold E. Schmidt[1], Marius Hoepfner[1], Frank Moosig[4], Wolfgang L. Gross[5], Eugen Feist[6] and Dirk Foell[7]. [1]Medical University Hannover, Hannover, Germany, [2]Medical University of Hannover, Hannover, Germany, [3]Medical University Hannover, Hanover, Germany, [4]University Hospital Schleswig Holstein and Klinikum Bad Bramstedt, Bad Bramstedt, Germany, [5]Medical University at Lubeck, Lubeck, Germany, [6]Charite University Hospital, Berlin, Germany, [7]University of Muenster, Muenster, Germany.

Background/Purpose: Making the diagnosis of adult-onset Still's disease (AOSD) is mainly based on the exclusion of inflammatory, infectious and malignant diseases. There are no specific clinical or laboratory findings for AOSD. Therefore, we aimed to identify new autoantibodies as diagnostic tools for AOSD.

Methods: As a screening procedure, we studied sera of 3 patients with AOSD using a protein array loaded with more than 28000 human recombinant proteins (imagenes biolifesciences, Berlin). Sera of patients with spondyloarthritis (SpA), rheumatoid arthritis (RA), eosinophilic granulomatosis with polyangiitis, granulomatosis with polyangiitis (GPA), HIV infection, B-NHL, chronic regional pain syndrome, giant cell arteritis (GCA), polymyalgia rheumatica (PMR), multiple sclerosis, osteoarthritis, Takayasu arteritis and sarcoidosis served as controls.

In the next step, we next established ELISAs in order to measure the respective autoantibodies in larger patient numbers.

Results: Using the protein array, we detected IgG antibodies against the two new autoantigens Macropain subunit C2 and DRP-4 in 2/3 AOSD patients, respectively, but in none of the 50 controls.

Using the ELISA, we measured autoantibodies binding to peptides of Macropain subunit C2 and Dihydropyrimidinase-related protein 4 (DRP-4) in the sera of patients with AOSD and other inflammatory disorders. The results are summarized in the table (AOSD* = patients with active AOSD before the onset of treatment, systemic JIA = systemic juvenile idiopathic arthritis, PsoA = psoriatic arthritis, BD = blood donors):

	AOSD (n=78)	AOSD* (n=39)	Systemic JIA (n=50)	SpA/ PsoA (n=58)	RA (n=66)	GPA (n=29)
MP + DRP-4	43%	56%	0%	19%	5%	10%
MP	54%	59%	0%	24%	9%	10%
DRP-4	43%	56%	3%	28%	8%	10%

	PMR/ GCA (n=60)	Sjögren's syndrome (n=29)	SLE (n=38)	febrile infections (n=63)	Malignant Disease (n=37)	BD (n=147)
MP + DRP-4	15%	0%	5%	18%	3%	1%
MP	22%	0%	11%	21%	3%	1%
DRP-4	20%	3%	8%	21%	5%	2%

Conclusion: The new autoantibodies against Macropain subunit C2 and DRP-4 are associated with AOSD and may be useful as a diagnostic tool of AOSD. In addition, these markers clearly differentiate AOSD from systemic juvenile idiopathic arthritis.

Serum Leucine-Rich Alpha-2 Glycoprotein As a Marker For Disease Activity In Adult-Onset Still's Disease. You-Jung Ha[1], Jung-Soo Song[2], Eun-Jin Kang[3], Sang-Won Lee[1], Yong-Beom Park[1], Soo-Kon Lee[1] and Sang Tae Choi[2]. [1]Yonsei University College of Medicine, Seoul, South Korea, [2]Chung-Ang University College of Medicine, Seoul, South Korea, [3]Busan Medical Center, Busan, South Korea.

Background/Purpose: Leucine-rich α2-glycoprotein (LRG) is a plasma protein which contains leucine-rich repeats. Though physiological functions of LRG have not been clarified yet, it has been reported that LRG could be a marker of granulocytic differentiation and its expression was up-regulated during neutrophil differentiation. Serum LRG levels were significantly elevated in some chronic inflammatory diseases such as ulcerative colitis and rheumatoid arthritis. However, there are no studies about the association between serum LRG level and disease activity and severity in patients with adult-onset Still's disease (AOSD). This study aimed to investigate whether the serum LRG level is elevated in AOSD patients and its correlation with disease activity and severity.

Methods: We enrolled 39 patients with AOSD and 39 age- and sex- matched healthy controls. Forty-five serum samples were obtained from patients with AOSD during active or inactive disease and were assayed for LRG by enzyme-linked immunosorbent assay (ELISA). Clinical and laboratory data related to disease activity were collected at the same time. Disease severity was determined by modified Pouchot's score.

Results: Serum LRG concentrations were significantly elevated in AOSD patients compared with healthy control (126.2 $\pm$ 40.9 ng/mL vs 22.4 $\pm$ 6.2 ng/mL, $p < 0.001$). Patients with active AOSD had a significantly higher LRG level than those with inactive disease (132.9 $\pm$ 34.6 ng/mL vs 67.1 $\pm$ 50.2 ng/mL, $p = 0.009$). Serum LRG showed modest correlation with C-reactive protein ($\gamma = 0.349$, $p = 0.029$), serum lactate dehydrogenase ($\gamma = 0.360$, $p = 0.031$) and ferritin ($\gamma = 0.533$, $p < 0.001$), but not with white blood cell counts or erythrocyte sedimentation rate. Serum LRG did not show correlation with AOSD systemic scores, reflecting disease severity. Serum LRG levels decreased significantly after treatment in all 6 active patients with AOSD who had follow-up evaluations ($p = 0.007$).

Conclusion: Serum LRG levels were increased in patients with AOSD and well correlated with disease activity measures. These findings suggest that plasma LRG may be a useful serologic marker for monitoring disease activity of AOSD.

Background/Purpose: Adult-onset Still's disease (AOSD) is frequently refractory to standard immunosuppressive drugs and it may require biological therapy. Tocilizumab (TCZ) has demonstrated efficacy in clinical isolated cases or in small series. We assessed the efficacy of TCZ in AOSD.

Methods: Multicenter study of 32 patients with AOSD from 20 hospitals diagnosed according to Yamagouchi's criteria (J Rheumatol 1992; 19:424). TCZ was used due to lack of efficacy to standard synthetic immunosuppressive drugs or lack of adequate response to at least 1 biologic agent.

Results: The 32 patients (24 women/ 8 men), had a mean age of 37.9±16.4 (range 16–74) and an average duration of AOSD of 5.6±5.0 years (range 0.1–17) before TCZ onset. In addition to steroids, they had previously received the following drugs: Methotrexate (29 patients), Anakinra (14), Etanercept (7), Adalimumab (6) and Infliximab (4). TCZ standard dose was 8 mg/k/iv/4 weeks.

At TCZ onset, the most frequent manifestations were joint (31 cases), cutaneous (17) and fever (19), along with increase of ESR or CRP (25 cases), anemia (14) or leucocytosis (18). Following TCZ clinical and analytical response was observed from the beginning (1st month) that was maintained over time **(TABLE)**.

	Basal	Month 1	Month 3	Month 6	Month 12
Joint manifestations, %	96.9%	68.8%	43.8%	25%	31.3%
Fever, %	59.4%	6.3%	6.3%	3.1%	3.1%
Cutaneous manifestations, %	53.1%	15.6%	12.5%	6.3%	6.3%
Leukocyte/mm3, mean ±SD	13650 ± 5978.4	8709 ± 4242.2	7898 ± 4188.7	7364 ± 3384.5	8630 ± 3709.5
ESR, mean±SD (mm/1st/hour)	49.8 ± 18,1	8.8 ± 10.8	5.9 ± 5.3	6.2 ± 5.7	8.0 ± 9.5
CRP, mg/dL mean±SD	23.2 ± 35.8	3.1 ± 6.0	0.8 ± 2.1	0.9 ± 2.7	0.8 ± 1.6
Prednisone dosage, mean±SD	15.2 ± 0.3	9.3 ± 7.0	6.0 ± 5.1	4.5 ± 5.4	4.8 ± 8.2
Prednisone dosage, median [IQR]	12.5 [7.5–20]	7.5 [5–15]	5 [2.5–10]	2.5 [0–7.5]	1.3 [0–7.5]

After a mean follow-up of 18.4 ±12.5 months, skin manifestations disappeared in 16 of 17 of the patients (94.1%), fever in 18 of 19 (94.7%) and joint manifestations in 25 of 31 (80.6%). In the laboratory findings, there was also improvement in most cases with normalization of the leucocytosis in 11 of 18 (61.1%) patients, anemia in 13 of 14 (92.9%), ESR in 18 of 24 (75 %), CRP in 22 of 25 (88%), hepatic enzymes (AST/ALT) in 3 of 4 (75 %) and ferritin seric levels in 11 of 14 (78.6%). The median [IQR] dose of prednisone was reduced from 15.1 [7.5–20] to 6.1 [0.0–7.5] mg/day.

Conclusion: In refractory AOSD, TCZ yields early and maintained clinical-laboratory improvement, even in cases that are refractory to other biologic agents. Although TCZ shows global efficacy, joint manifestations are more refractory than systemic manifestations.

Sirolimus Plus Prednisone For Erdheim-Chester Disease: A Pilot Trial. Davide Gianfreda[1], Federico Alberici[1], Maricla Galetti[2], Maria Nicastro[2], Carlo Buzio[1] and Augusto Vaglio[1]. [1]University of Parma, Parma, Italy, [2]Nephrology University of Parma, Parma, Italy.

Background/Purpose: Erdheim-Chester disease (ECD) is an extremely rare form of non-Langerhans cell histiocytosis. The pathogenesis of ECD is unclear: while most authors suggest the hypothesis of an inflammatory disease, others claim it is a neoplastic disorder. ECD often has a fatal course (3-year mortality 25–60%) and has no established treatment. Interferon-α is often used but it has severe toxicity and poor efficacy on CNS and cardiovascular lesions.

The mTOR inhibitor sirolimus (SRL) is an immunosuppressive drug with known anti-neoplastic properties. We tested the efficacy and safety of prednisone (PDN) and SRL in a series of patients with multisystemic, active ECD. We also assessed mTOR activity in patients' biopsies as a potential predictor of treatment efficacy.

Methods: We enrolled all patients with active, multisystemic ECD (either at first diagnosis or with progressive disease refractory to other treatments) referred to our Department between 2003 and 2011.

PDN was given at the initial dose of 0.75 mg/kg/day for 1 month, tapered to 2.5–5 mg/day over 6 months; SRL was given at a daily dose of 2–3 mg, with a target trough level of 8–10 ng/mL. If disease stabilization or remission was achieved, treatment was continued chronically.

Where available, frozen tissue biopsies were used to assess mTOR activity: for this purpose, the levels of phospho-p70S6K (Thr389) and phospho-mTOR (ser 2448) in total proteins extracted from the biopsies were determined by Western blotting.

Results: Nine consecutive ECD patients were enrolled; six were newly diagnosed and untreated, the remaining three were refractory to previous treatments (interferon-α, PDN and colchicine, PDN and cyclophosphamide). The median follow-up from diagnosis was 41 months (range 12–164). At the end of the follow-up, seven patients were alive and experienced quiescent disease; of the remaining two, one died 12 months after diagnosis because of progressive CNS involvement, and one 25 months after diagnosis because of small cell lung cancer.

One of two patients had a complete cardiac response (complete remission of pericarditis), 1/2 a complete response in the lungs and 2/5 a complete remission in cutaneous lesions. Partial responses were observed at the following sites: long bones in 2/8 cases, CNS in 1/2 cases, retroperitoneum-perirenal space in 5/7 cases, hypothalamic-pituitary axis in 1/4 cases, skin in 1/5 cases. One patient had a progression in retroperitoneal involvement.

Treatment-related toxicity was mild; only one patient had to stop treatment because of sirolimus-related pneumonia.

The three available biopsies (2 retroperitoneal, 1 skin) exhibited high levels of phospho-p70S6K and phospho-mTOR, confirming that the mTOR pathway is activated in ECD. Given the paucity of available frozen tissue samples, we could not evaluate whether mTOR activity was a predictor of response to SRL.

Conclusion: The combination of PDN and SRL is a potential treatment for multisystemic ECD; it usually induces disease stabilization and in some cases objective responses, and has a good tolerability. The mTOR pathway seems to be activated in ECD lesions; further studies are needed to explore whether phospho-p70S6K and phospho-mTOR tissue expression predict response to SRL therapy.

Background/Purpose: The double-blind, randomized placebo-controlled Trial of Early Aggressive Therapy in Polyarticular Juvenile Idiopathic Arthritis (TREAT) compared the ability of 2 aggressive treatment regimens to produce clinical inactive disease (CID) within 6 mos of starting therapy. An exploratory phase lasting up to 1 year from baseline determined if patients could achieve CID after switching to the more aggressive treatment arm (M-E-P: etanercept 0.8 mg/kg/wk, MTX 0.5 mg/kg/wk given subcutaneously, prednisolone 0.5 mg/kg/d tapered to zero by 17 wks) from the less aggressive arm (MTX: MTX as in the M-E-P Arm, placebo prednisolone, placebo etanercept), and achieve clinical remission on medication (CRM; 6 continuous mos of CID). The purposes of this analysis were to determine lapsed time on-therapy to the first occurrence, and sustainability of CID and if predictors of CID exist.

Methods: Eighty-five patients aged 2–17 yrs with active RF (+) or (−) polyarticular JIA (poly-JIA) less than 12 mos in duration (median 4.2 mos) were randomized to either M-E-P (N=42) or MTX (N=43) and assessed for CID using the Wallace Criteria at mos 1, 2, 4, 5, 6, 7, 8, 10 and 12 mos or discontinuation. Patients in either group who failed to achieve an ACR Pedi 70 at 4 mos, or CID at 6 mos were switched to open-label M-E-P for the remainder of the study. Descriptive measures, the Mann-Whitney U and Fisher's Exact tests were the chief statistical methods.

Results: CID was observed at least once in 30 (71%) of those who started on M-E-P and in 28 (65%) of MTX starts (17 of these 28 achieved CID only after switching to open-label M-E-P). Median number of days on aggressive therapy until the first occurrence of CID was 168.5 and 192 for those who started M-E-P and MTX groups respectively. M-E-P starts spent a median of 139.5 (42%) days of follow-up with CID, compared to a median of 79 (24%) days for MTX starts (p=0.016). M-E-P starts had CID at 117 of 347 (34%) follow-up visits while MTX starts had CID at 81 of 337 (24%) visits. When data were combined from the blinded and open-label (all patients receiving M-E-P) phases, CID was observed at 154 of 481 (32%) visits by patients on M-E-P, compared to 43 of 203 (21%) visits while receiving MTX alone.

Baseline characteristics were not statistically predictive of CID except for disease duration prior to enrollment. Patients with duration ≤3 mos at enrollment had CID at a median of 40% of visits, while those with disease >3 mos had CID for a median of only 11% of visits (p<0.0001).

Among 49 patients who achieved an ACR Pedi 70 at 4 mos, 42 (86%) attained CID, compared to 16 of 36 (44%) who failed to achieve the early response (p=0.0001). All 12 patients (9 M-E-P and 3 MTX) who achieved CRM met the ACR Pedi 70 at 4 mos.

Conclusion: Aggressive therapy given early in the disease course of poly-JIA results in a large proportion of patients achieving CID within 12 mos. There is a tendency for a combination of an anti-TNF agent, MTX and prednisolone to produce more sustainable CID than does high dose MTX monotherapy. A short disease duration prior to start of aggressive therapy and attainment of an ACR Pedi 70 by 4 mos are significant predictors of achieving sustained CID.

Efficacy and Safety Of Tocilizumab In Patients With Polyarticular-Course Juvenile Idiopathic Arthritis: 2-Year Data From Cherish. Hermine I. Brunner[1], Nicolino Ruperto[2], Zbigniew Zuber[2], Rubén J. Cuttica[3], Ricardo Xavier[2], Inmaculada Calvo[2], Nadina Rubio[2], Ekaterina Alekseeva[2], Vyacheslav Chasnyk[4], Jose Chavez[2], Gerd Horneff[3], Violetta Opoka-Winiarska[2], Pierre Quartier[2], Alberto Spindler[2], Caroline Keane[5], Kamal N. Bharucha[6], Jianmei Wang[5], Daniel J. Lovell[1], Alberto Martini[2] and Fabrizio De Benedetti[7]. [1]PRCSG, Cincinnati, OH, [2]PRINTO, Genoa, Italy, [3]Pediatric Rheumatology International Trials Organization (PRINTO)-Istituto Gaslini, Genova, Italy, [4]Saint-Petersburg State Pediatric Medical University, Saint-Petersburg, Russia, [5]Roche, Welwyn Garden City, United Kingdom, [6]Genentech, South San Francisco, CA, [7]IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy.

Background/Purpose: Efficacy and safety of tocilizumab (TCZ), an interleukin-6 receptor inhibitor, were previously demonstrated at week 40 of CHERISH, a phase 3 trial in patients with polyarticular-course juvenile idiopathic arthritis (pcJIA).[1] The purpose of this analysis was to investigate the efficacy and safety of TCZ over 104 weeks of treatment in pcJIA.

Methods: Patients 2–17 years old with ≥6 months' active pcJIA who failed methotrexate received open-label (OL) TCZ (weight ≥30 kg, 8 mg/kg [n=119]; weight <30 kg, randomized [1:1] to 8 [n=34] or 10 [n=35] mg/kg) every 4 weeks for 16 weeks. Patients with JIA American College of Rheumatology (ACR)30 response or better at week 16 entered a 24-week double-blind withdrawal period and were randomized (1:1) to placebo or continuation with TCZ. Patients with JIA ACR30 flare or who completed the withdrawal period entered an OL extension through week 104.

Results: One hundred eighty-eight patients entered the lead-in period, 166 entered the withdrawal period, 160 entered the OL extension period, and 155 completed 104 weeks. In patients who received TCZ throughout the study, JIA ACR responses and improvement in JIA ACR core components (Table) were maintained through week 104. The safety population comprised 188 patients with 307 patient-years (PY). Rates/100PY of adverse events (AEs) and serious AEs (SAEs) were 406.5 and 11.1, respectively; infections were the most common AE (151.4) and SAE (5.2). Alanine aminotransferase and aspartate aminotransferase elevations ≥3× upper limit of normal occurred in 6.4% and 2.7% of patients, respectively. Grade 3 neutropenia and grade 2/3/4 thrombocytopenia occurred in 5.9% and 1.6% of patients, respectively. Low-density lipoprotein cholesterol ≥110 mg/dL occurred in 16.2% of patients.

Table. JIA ACR50/70 Responses and Percentage Change From Baseline in Components,[a] mean ± SD

	All TCZ (N = 82)	
	Week 40	**Week 104**
JIA ACR70 responders,[b] n (%)	65 (79.3)	71 (86.6)
JIA ACR90 responders,[b] n (%)	41 (50.0)	58 (70.7)
ACtive joints (0–71)	−82.4 ± 24.9	−87.7 ± 27.1
Joints with limitation in ROM (0–67)	−73.5 ± 30.7	−81.3 ± 31.7
Patient global[c] (VAS 0–100 mm)	−62.5 ± 76.3	−75.4 ± 43.8
Physician global (VAS 0–100 mm)	−85.3 ± 16.8	−89.7 ± 23.7
CHAQ-DI (0–3)	−66.0 ± 44.7	−76.7 ± 34.7
ESR (mm/h)	−76.5 ± 22.0	−76.2 ± 27.3

[a] Patients who withdrew are excluded.
[b] Patients who withdrew due to nonsafety reasons are nonresponders. Patients who withdrew due to safety are included using last observation carried forward.
[c] Parent rated.
CHAQ-DI, Childhool Health Assessment Questionnaire Disability Index; ESR, erythrocyte sedimentation rate; ROM, range of motion; VAS, visual analog scale.
Crude incidence rates for ACS in the cohorts

Conclusion: Efficacy of TCZ was maintained through 2 years of treatment in patients with pcJIA, with no change in safety profile from that reported previously.[1]

Methotrexate Polyglutamates in Erythrocytes Are Associated With Lower Disease Activity in Juvenile Idiopathic Arthritis Patients. Maja Bulatovic Calasan[1], Ethan den Boer[2], Maurits C.F.J. De Rotte[2], S.J. Vastert[1], Sylvia Kamphuis[3], Robert De Jonge[2] and Nico M. Wulffraat[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands, [3]Eramus MC Sophia Children's Hospital, Rotterdam, Netherlands.

Background/Purpose: Methotrexate polyglutamates (MTX-PG) could be biomarkers of MTX response and adverse effects and could thus be used

as a therapeutic drug monitoring (TDM) tool to steer tailor-made therapeutic decisions. The aim of this study was to determine association of erythrocyte MTX-PG with disease activity and adverse effects in a prospective juvenile idiopathic arthritis (JIA) cohort.

Methods: One hundred thirteen JIA patients were followed from MTX start until 12 months. Erythrocyte MTX-PGs with 1 to 5 glutamate residues were measured at 3 months with tandem mass spectrometry. The outcomes were Juvenile Arthritis Disease Activity Score (JADAS)-27 and adverse effects. To determine associations of MTX-PGs with JADAS-27 at 3 months and during one year of MTX treatment, linear regression and linear mixed model analyses were used. To determine associations of MTX-PGs with adverse effects during one year of MTX treatment, logistic regression was used. Analyses were corrected for, JADAS-27 at baseline and co-medication.

Results: Median JADAS-27 decreased from 12.7 (IQR: 7.8–18.2) at baseline to 2.9 (IQR: 0.1–6.5) at 12 months. Higher concentrations of MTX-PG3 (β: −0.006, p=0.005), MTX-PG4 (β:−0.015, p=0.004), MTX-PG5 (β: −0.051, p=0.011) and MTX-PG3–5 (β: −0.004, p=0.003) were associated with lower disease activity at 3 months. Higher concentrations of MTX-PG3 (β: −0.005, p=0.028), MTX-PG4 (β: −0.014, p=0.014), MTX-PG5 (β: −0.049, p=0.023) and MTX-PG3–5 (β: −0.004, p=0.018) were associated with lower disease activity over one year. None of the MTX-PGs was associated with adverse effects.

Conclusion: In the first prospective study in JIA, long-chain MTX-PGs were associated with lower JADAS-27 at 3 months and during one year of MTX treatment. Erythrocyte MTX-PG could be a plausible candidate for therapeutic drug monitoring of MTX in JIA.

793

Efficacy and Safety of Adalimumab in Pediatric Patients With Enthesitis Related Arthritis. Rubén Burgos-Vargas[1], Shirley M.L. Tse[2], Gerd Horneff[3], Aileen L. Pangan[4], Kristina Unnebrink[5] and Jaclyn K. Anderson[6]. [1]Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico, [2]University of Toronto, The Hospital for Sick Children, Toronto, ON, [3]Asklepios Klinik Sankt Augustin, Sankt Augustin, Germany, [4]AbbVie Inc., North Chicago, IL, [5]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany, [6]AbbVie, North Chicago, IL.

Background/Purpose: Enthesitis related arthritis (ERA) is a subcategory of juvenile idiopathic arthritis (JIA) which primarily affects peripheral joints and entheses but also can involve the sacroiliac joints and spine. It causes long-term effects on both physical and quality aspects of a child's life. Adalimumab (ADA) has been previously demonstrated to be effective in polyarticular JIA. The purpose of this study was to evaluate the efficacy and safety of adalimumab compared to placebo in children and adolescents with ERA.

Methods: This is a phase 3, multicenter, randomized, double-blind (DB) study in patients (pts) aged ≥6 to <18 years (yr) with ERA (ILAR criteria) with active disease not responsive to ≥1 nonsteroidal anti-inflammatory drug and ≥1 disease-modifying antirheumatic drug. Active disease was defined as ≥3 active joints (swelling or loss of motion + pain/tenderness) and enthesitis in ≥1 location. Pts were randomized 2:1 to receive blinded ADA (24 mg/m^2 BSA up to 40 mg every other week (wk) [eow]) or placebo (PBO) for 12 wks followed by open-label (OL) ADA eow up to 144 wks. The primary endpoint was % change from baseline (BL) in the number of active joints with arthritis (AJC) at wk 12. Secondary variables assessed included enthesitis count (EC), tender and swollen joint counts, and American College of Rheumatology (ACR) Pediatric (Pedi) 30/50/70 responses. Results are summarized through 52 wks of treatment. Safety was assessed in terms of adverse events (AE).

Results: 46 pts were randomized (31 to ADA, 15 to PBO). No pts discontinued during the DB period; however, 7 pts early escaped to OL ADA. Mean age was 12.9±2.9 yrs. At BL, mean duration of ERA symptoms was 2.6±2.3 yrs; mean AJC was 7.8±6.6, and mean EC was 8.1±8.4. The % change from BL at wk 12 in AJC was greater in the ADA group vs. PBO (−62.6±59.5 vs −11.6±100.5, P=0.039). Most secondary variables showed numerically greater, but not statistically significant improvement at wk 12 in favor of ADA vs. PBO (Table). Treatment response was maintained with continued ADA therapy up to 52 wks (% change from BL at wk 52 in AJC, −88.7±26.1). During the DB period AE incidence rates were similar [ADA/PBO (%)]: any AE (67.7/53.3), serious AE (3.2/0, 1 pt in the ADA group [abdominal pain and headache]), and infectious AEs (29.0/20.0). Among pts who received at least 1 dose of ADA through wk 52, any AE, serious AEs, and infectious AEs were reported in 91.3%, 10.9%, and 76.1%, respectively. No deaths, TB, or malignancies were reported.

At Week 12		ADA (N=31)	PBO (N=15)
Change from Baseline[a] (mean ± SD)	# enthesitis sites (0-35)	−4.4 ± 6.2	−2.7 ± 5.0
	Tender joint count (0-72)	−7.9 ± 8.3	−4.5 ± 9.0
	Swollen joint count (0-68)	−3.5 ± 5.6	−2.4 ± 4.7
ACR Pedi Response[b] (n, %)	ACR Pedi30 responder	21 (67.7)	10 (66.7)
	ACR Pedi50 responder	20 (64.5)	7 (46.7)
	ACR Pedi70 responder	16 (51.6)	4 (26.7)

[a] LOCF. [b] NRI. SD, standard deviation.

Conclusion: ADA reduced the signs and symptoms of ERA at wk 12 and efficacy was sustained up to 52 wks. The safety profile observed in pediatric patients with ERA was consistent with that observed in children aged ≥4 years treated for polyarticular JIA.

Recent Trends In Medication Usage for the Treatment of Juvenile Idiopathic Arthritis and the Influence of TNF Inhibitors. Melissa L. Mannion, Fenglong Xie, Jeffrey R. Curtis and Timothy Beukelman. University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: The pharmacologic management of JIA has changed dramatically with the advent of tumor necrosis factor inhibitors (TNFi), but the impact of TNFi on medication usage in routine clinical practice has not been well-studied. Using national administrative claims from a large commercial U.S. health insurer, we investigated the use of medications in the treatment of JIA over the last 8 years. We examined medication use by calendar year, as well as medication use before and after new TNFi use among individual patients.

Methods: Using data from January 2005 through September 2012, we identified children <17 years old with > 1 physician diagnosis code consistent with JIA. In the analyses of medication use by year, only subjects with full medical and pharmacy benefits for the entire enrollment period of the calendar year were included. Use of TNFi, methotrexate (MTX), non-steroidal anti-inflammatory drugs (NSAID), and oral glucocorticoids (GC) was determined using pharmacy and infusion claims. Significant changes in medication usage over time were evaluated with the Cochran-Armitage test for trend. New TNFi users were defined by no receipt of any TNFi in the 6 months immediately prior to starting. New TNFi users were required to have a minimum of 6 months of follow-up after starting TNFi, and only the earliest episode of new TNFi use for each patient was included. Among prevalent users of NSAID and GC, we used paired t-tests to compare the number of filled prescriptions for NSAID and the cumulative mean daily GC dose (in prednisone equivalents) in the 6 months before and after new TNFi use.

Results: Including all years of the study, we identified 4,261 individuals with ≥1 JIA diagnosis code. Their median age was 11 years (IQR 7–14) and 64% were female. The proportion of TNFi users increased during the study period from 8.7% in 2005 to 22.3% in 2012 (p<0.0001). Over the same time period, the proportion of MTX users increased from 18.4% to 23.2% (p=0.02), the proportion of NSAID users decreased from 49% to 40% (p=0.02), and the proportion of GC users was relatively unchanged (19.8% to 16.1%; p=0.4). We identified 344 new users of TNFi (70% etanercept, 19% adalimumab, 10% infliximab). Among 194 prevalent NSAID users, the number of NSAID prescriptions decreased in the 6 months following new TNFi use (mean 2.8 prescriptions before versus 2.0 after; p<0.0001). Among 126 prevalent GC users, the cumulative mean daily dose was significantly reduced in the 6 months following new TNFi use (mean decrease 3.4 mg/day; p<0.0001). Many new TNFi users (195/344, 57%) had not filled a prescription for MTX in the previous 6 months. Of these without recent MTX use, only 11% (21/195) used MTX in the 6 months following new TNFi use. Overall, 38% (129/344) had any concurrent MTX use in the 6 months following new TNFi use.

Conclusion: TNFi use in the treatment of JIA increased 2–3 fold over the last 8 years with a concurrent smaller increase in MTX use. New use of TNFi was associated with a reduction in the number of NSAID prescriptions and mean daily GC dose. The relatively small proportion of patients with recent or concurrent use of MTX around the time of new TNFi use suggests that TNFi may be replacing, rather than complementing, MTX therapy in many patients.

795

Second TNF-Inhibitor Or Alternative Biologic In Juvenile Idiopathic Arthritis (JIA) Patients Failing a First TNF-Inhibitor. Kirsten Minden[1], Klaus Tenbrock[2], Gerd Horneff[3] and Hans-Iko Huppertz[4]. [1]pediatric rheumatology, Berlin, Germany, [2]University Aachen, Aachen, Germany, [3]Asklepios Klinik Sankt Augustin, Sankt Augustin, Germany, [4]Prof. Hess Childrens Hospital, Bremen, Germany.

Background/Purpose: Patients with incomplete response to initial anti-TNF treatment often are switched to other biologic treatments. However, little is known about the efficacy of switching to a second anti-TNF or a non-TNF biologic treatment since comparative clinical trials are lacking.

Methods: Data of the German BIKER registry were used to analyse treatment response after switching from a TNF-inhibitor to a second TNF-inhibitor or to a non-TNF-inhibitor biologic. Efficacy analyses were performed with the patients′ disease activity assessed by the Juvenile Arthritis Disease Activity Score (JADAS)-10 and functional status assessed by the Childhood Health Assessment Score-Disability Index (CHAQ-DI) as outcomes.

Results: 1725 JIA patients receiving Etanercept (ETA) as first biologic were identified in the BIKER registry. 279 patients received a second biologic, which was again a TNF-inhibitor in 219 (Adalimumab (ADA) 190, Infliximab (INF) 30, Golimumab (GOL) 5,) and a non-TNF inhibitor biologic in 60 cases (Abatacept (ABA) 16, Anakinra (ANA) 31, Tocilizumab (TOC) 13). Switchers more often had systemic JIA (15.1% vs 6.6%; $p<0.001$; Odd-R 2.5(1.7–3.7)) but less often enthesitis related arthritis (ERA) (9.7% vs.15. 9%; $p=0.008$, Odd-R 0.6 (0.4–0.9)) than non-switchers. Comparison of JADAS10 at last follow up to start of ETA gave a marked improvement of disease activity while a considerable residual disease activity persisted. 215 JIA patients had follow up forms after switching to a second biologic enabling the analysis of efficacy. After switching the biologic agent, a decrease of disease activity parameters could be observed in all cohorts. At last follow up, lowest JADAS10 (mean±SD) was reached in the patient cohort switching from ETA to ADA (6.2±6.1) followed by INF (9.7±9.9) and TOC (10.2±7.2). Patients on ABA had higher JADAS10 (12.5±10.2) at last follow up (table 1). Also the CHAQ-DI decreased in all cohorts. Lowest CHAQ-DI (mean±SD) was reached in patients switching from ETA to INF (0.21±0.52) or ADA (0.29±0.46), followed by TOC (0.4±0.67) and ABA (0.73±0.78). Follow-up data from few patients only switching to GOL and from patients switching to ANA (all but 3 systemic JIA) were not shown.

Switching from Etanercept to:	Time of analysis	JADAS-10	CHAQ-DI
Adalimumab N=163	first on ETA	17.1+/−7.4	0.72+/−0.70
	last on ETA	8.4+/−7.0	0.40+/−0.54
	first on ADA	9.9+/−8,0	0.37+/−0.52
	last on ADA	6.2+/−6.1	0.29+/−0.46
Infliximab N=19	first on ETA	19.4+/−8.0	1.03+/0.71
	last on ETA	10.9+/−9.5	0.44+/−0.58
	first on IFN	10.7+/−9.2	0.47+/−0.66
	last on IFN	9.7+/−9.9	0.21+/−0.52
Tocilizumab N=20	first on ETA	18.9+/−6.0	0.93+/−0.85
	last on ETA	9.4+/−7.5	0.67+/−0.76
	first on TOC	13.2+/−10.0	0.75+/−0.72
	last on TOC	10.2+/−7.2	0.40+/−0.67
Abatacept N=13	first on ETA	18.3+/−6.−3	0.68+/−0.56
	last on ETA	13.5+/−10.5	0.43+/−0.62
	first on ABA	17.4+/−6.5	0.57+/−0.51
	last on ABA	12.5+/−10.2	0.73+/−0.78

Conclusion: JIA patients failing ETA can successfully be switched to another biologic. Interestingly, switching within the class of biologics, from a first TNF- to a second TNF-inhibitor also gave favourable results.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Clinical Aspects I: Treatment Strategies in Rheumatoid Arthritis
Sunday, October 27, 2013, 2:30 PM–4:00 PM

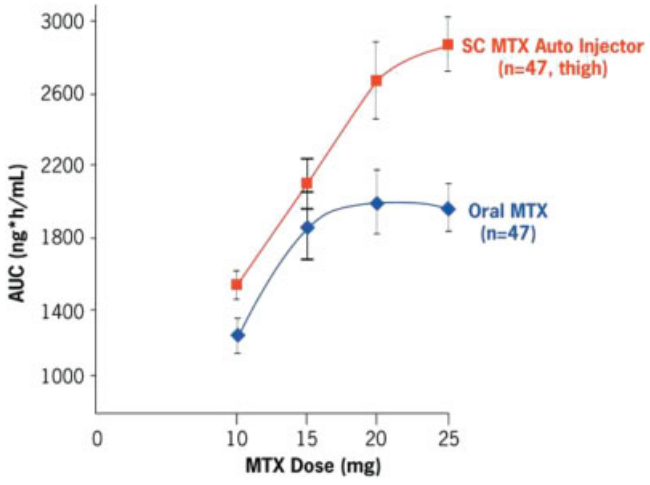
796

Drug Exposure Limitations of Oral Methotrexate (MTX) At Doses >15mgs May be Overcome By Using a Subcutaneous MTX Auto-Injector in Patients With Rheumatoid Arthritis (RA). Michael H. Schiff[1], Lee S. Simon[2], Bruce Freundlich[3], Jonathan Jaffe[4] and Kaushik J. Dave[4]. [1]University of Colorado, Denver, CO, [2]SDG LLC Consulting, West Newton, MA, [3]University of Pennsylvania, Philadelphia, PA, [4]Antares Pharma Inc, Ewing, NJ.

Background/Purpose: MTX is the cornerstone of RA therapy but absorption saturability limitations compromise oral MTX bioavailability (BA). Parenteral MTX exhibits a dose-proportional increase in exposure throughout the dosing range, possibly leading to better efficacy. Parenteral MTX is used by < 5% of U.S. clinicians due to lack of familiarity and availability and the challenges of self-injection. To address these issues, an investigational, single-use, self-administered SC MTX auto-injector (MTXAI) was developed with 10-, 15-, 20-, and 25-mg fixed doses. This study compares the relative BA of MTXAI vs oral MTX to demonstrate safety and tolerability of MTXAI in RA pts.

Methods: In this 12-week, open-label, crossover study, 49 adults with RA already receiving MTX for ≥3 months were given 10, 15, 20, or 25 mg MTX, based on their current dose and disease control, via random assignment (1:1:1) to oral MTX, MTXAI (abdomen), or MTXAI (thigh). Blood samples for PK analysis were collected predose and at 13 timepoints from 0.25 to 12 hours postdose and were analyzed by liquid chromatography-mass spectrometry. Mixed model analysis derived AUC, C_{max}, and T_{max} PK parameters. Dose-normalized parameter ratios were calculated. Safety was assessed by the incidence of treatment-emergent AEs (TEAEs), changes in safety laboratory parameters and vital signs, and administration site AEs.

Results: Mean age was 61 years; mean body mass index, 30.7 kg/m^2; and mean disease duration, 13 years; 63% of pts were female. PK analysis of MTXAI (thigh) vs. oral MTX showed that BA of MTXAI was consistently greater at all dose levels (Figure). MTXAI thigh and MTXAI abdomen PK measures were similar. Although oral MTX plateaued at 15 mg, MTXAI had no plateau, resulting in a higher exposure than comparable oral doses. Relative BA (AUC of MTXAI vs. oral MTX) at 10, 15, 20, and 25 mg were 121%, 114%, 131%, and 141%. Ratio of the dose-normalized AUC (0–24 h) and C_{max} of MTXAI vs. oral MTX were 127.61 (90%CI: 122.30–133.15) and 94.88 (90%CI: 87.95–102.37). Few TEAEs were reported with MTXAI; observed AEs were transient, manageable, and required no medical treatment. Two serious AEs were considered unrelated to treatment, including a death from a myocardial infarction in a 79-year-old man with cardiac history that occurred several weeks after the study. MTX and MTXAI were otherwise safe and well tolerated.



Conclusion: SC MTX delivered by auto-injector has a linear absorption compared to oral MTX, which plateaued at doses >15 mg. Pts receiving oral MTX with an inadequate clinical response may benefit from higher drug exposure levels by switching to SC MTX via MTXAI. This study confirms existing findings that higher systemic exposure to MTX is not associated with increased rates of AEs.

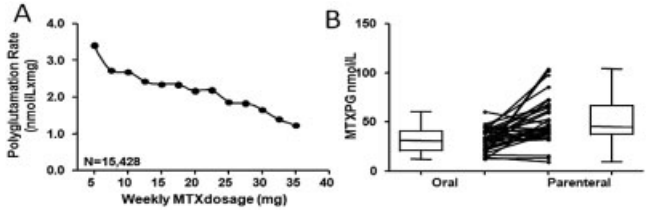
Methotrexate Exposure Assessment In Routine Clinical Rheumatology Practice: Effect Of Dosing and Route Of Administration On Polyglutamate Levels. Roy A. Kaplan[1], Brigid Freyne[2], Derren Barken[3] and Thierry Dervieux[3]. [1]Private Practice / Scripps Health, Encinitas, CA, [2]Private Practice, Murietta, CA, [3]Exagen Diagnostics, Vista, CA.

Background/Purpose: Large interpatient variability in Methotrexate (MTX) absorption and intracellular activation to methotrexate polyglutamates (MTXPGs) can explain, in part, the large spectrum of MTX response in patients with rheumatic diseases. We sought to identify the contributors to the large inter-subject variability in MTX exposure during the course of clinical care of patients with rheumatoid diseases.

Methods: Red blood cells (RBC) MTXPG levels were requested by treating physicians during the course of clinical care of patients with rheumatic diseases. Of all RBC MTXPG measurements performed, a total 15,428 measurements from 12,725 patients were available with weekly MTX dosing information as provided by the requesting physicians. In a subset of 2571 test results from 2261 patients the route of MTX administration (oral vs. parenteral) was provided. MTX RBC $MTXPG_3$ levels were measured in our accredited clinical laboratory using liquid chromatography and reported as nmol/L packed RBCs. A dose normalized polyglutamation rate defined as the amount of MTXPG produced per mg MTX administered (nmol/Lxmg) was calculated. To maintain patient privacy, all specimens were de-identified prior to the analysis. The statistical analyses consisted of multivariate linear regressions, and non parametric tests to assess differences between groups.

Results: There was a large interpatient variability in MTX polyglutamation. Median MTX dose administered was 17.5 mg/week (Interquartile [IQ] range: 15–20 nmol/L), median MTXPG levels were 36 nmol/L (IQ range: 21–54 nmol/L) and median MTX polyglutamation rate was 2.1 nmol/Lxmg (IQ: 1.2–3.0 nmol/Lxmg). The proportion of patients having undetectable MTXPG (<2 nmol/L), a potential indicator of non-adherence was 7.6%. Multivariate linear regression analysis revealed that lower MTX polyglutamation rates was associated with higher MTX dosage ($p<0.001$), lower patient age ($p<0.001$) and oral (vs. parenteral) administration of MTX ($p<0.01$) (Global $R^2=0.12$; $n=2571$). The impact of MTX dosing on MTX polyglutamation is highlighted in the Figure (panel A). In 31 patients who switched from oral to parenteral MTX without change in MTX dose (median 20 mg/week, range 15–25 mg), RBC MTXPG levels were determined 18 weeks (median) apart (range 8–65 weeks). The switch from oral to parenteral MTX was associated with a 1.4-fold increase in MTXPG levels (32 nmol/L [range 12–60 nmol/L] vs. 44 nmol/L [range 9–102 nmol/L]; $p<0.01$) (Figure, panel B).



Conclusion: These findings are consistent with the notion that MTX polyglutamation is a saturable process at higher MTX dosage. Switching from oral to parenteral administration of MTX produces higher levels of RBC MTX polyglutamates.

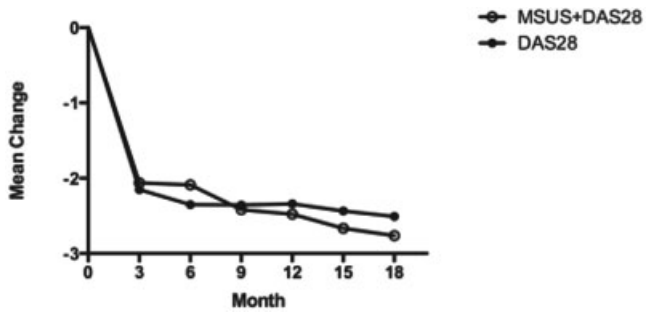
Targeting Ultrasound Remission In Early Rheumatoid Arthritis - Results Of The Taser Study. James Dale[1], Anne Stirling[2], Iain B. McInnes[1] and Duncan Porter[2]. [1]University of Glasgow, Glasgow, United Kingdom, [2]Gartnavel General Hospital, Glasgow, United Kingdom.

Background/Purpose: The TaSER study (NCT00920478) is an open label randomized clinical trial with blinded assessments of outcome. It was designed to test whether the efficacy of DAS28 driven treat-to-target DMARD strategies could be improved by the addition of regular musculoskeletal ultrasound (MSUS) disease activity assessment.

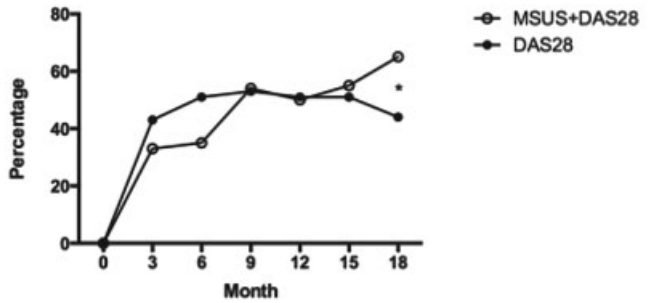
Methods: 111 untreated early UA/RA patients (symptom duration <1 year) were randomized to step-up DMARD escalation strategies guided by either DAS28 alone (target = DAS28<3.2) or DAS28+MSUS assessment of a limited joint set (target = PD signal in ≤1 joint). In the MSUS group, ultrasound assessment was undertaken in patients in LDAS, or moderate DAS but with minimal synovitis ($28SJC^2 1$). The follow-up period was 18 months. In the first 3 months both groups received identical treatment. Thereafter, treatment was escalated whenever the appropriate target was not achieved; through the addition of new DMARDs, DMARD dose optimisation, and/or IA/IM steroid. The sequence of DMARD escalation was: MTX □ MTX/SSZ/HCQ □ scMTX/SSZ/HCQ □ etanercept/scMTX/SSZ/HCQ.

Outcomes were assessed every 3 months by a metrologist who was blinded to randomization group. The primary clinical outcome was the mean improvement in DAS44. Secondary outcome measures included: mean improvement in ACR core set variables and DAS44 remission rate. Radiological outcomes included the MRI RAMRIS score and Total Sharp Score (results still to be analysed).

Results: 110 (99%) patients fulfilled 2010 ACR/EULAR RA classification criteria. Both groups were well matched for disease duration (median 4m), baseline DAS (4.4), ACPA+ve (60%) and HAQ (1.6 v 1.5). The DAS28 group contained a higher proportion of females (60% vs 78%, p 0.031). Both groups experienced significant improvements in DAS44 (mean change in DAS44 −2.51 [DAS28] vs −2.76 [MSUS]; 95%CI −0.84, 0.33; p 0.39) and HAQ (−0.79 v −1.06; 95%CI −0.57, 0.031: p0.08). The DAS28 group had a numerically higher rate of DAS44 remission after 3 months (43% v 33%; p=0.32). However, after 18 months, more patients in the MSUS groups had attained DAS44 remission (44% v 65%; p=0.046). There was no difference in DAS44, HAQ or ACR core set variables at any time point.



Graph 1. Mean change in DAS44 from baseline



Graph 2. Proportion of patients achieving DAS44 remission (* $p<0.05$)

Conclusion: Both groups exhibited similar, very robust improvements in clinical outcomes. MSUS disease activity assessment was not associated with improved clinical outcomes except a higher rate of DAS44 remission after 18 months.

Clinical and Radiological Outcomes Of Two Years Remission Steered Treatment In Early Arthritis Patients. L. Heimans[1], K.V.C. Wevers-de Boer[1], G. Akdemir[1], H.K Ronday[2], T.H.E. Molenaar[3], J. H. L. M. Van Groenendael[4], A.J. Peeters[5], I. Speyer[6], G. Collee[7], P.B. de Sonnaville[8], B.A. Grillet[9], T.W.J. Huizinga[1] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Haga Hospital, The Hague, Netherlands, [3]Groene Hart Hospital, Gouda, Netherlands, [4]Franciscus Hospital, Roosendaal, Netherlands, [5]Reinier de Graaf Gasthuis, Delft, Netherlands, [6]Bronovo Hospital, Den Haag, Netherlands, [7]MCH, The Hague, Netherlands, [8]Admiraal de Ruyter hospital, Goes, Netherlands, [9]Zorgsaam Hospital, Terneuzen, Netherlands.

Background/Purpose: To evaluate outcomes after 2 years of remission steered therapy in early arthritis patients.

Methods: 610 patients with early rheumatoid or undifferentiated arthritis (UA) were treated with methotrexate (MTX) and tapered high dose of prednisone. Patients in early remission (DAS<1.6) after 4 months, tapered prednisone to zero and when remission persisted after 8 months, also tapered MTX. Patients not in early DAS-remission were randomized to either MTX+hydroxychloroquine+sulphasalazine+prednisone (arm 1) or to MTX+adalimumab (arm2). Based on 4-monthly DAS evaluations, medication was restarted, increased or switched in case of no remission and tapered or stopped in case of remission. Proportions of DAS-remission, drug free remission (DFR) and radiological damage progression (increase Sharp-vanderHeijde Score ≥0.5) were analyzed separately for the treatment strategies and patients with RA and UA.

Results: 387 patients achieved early DAS-remission, 83 patients were randomized to arm 1 and 78 to arm 2 and 50 did not follow the protocol. After 2 years, 301/610 (49%) of all patients were in DAS-remission and 131/610 (21%) in DFR. Of the early remission group, 241/387 (62%) were in DAS-remission and 110/387 (28%) were in DFR. In arm 1, 22/83 (27%) were in DAS-remission compared to 24/78 (31%) in arm 2 (p=0.76), 7/83 (8%) were in DFR in arm 1 and 7/78 (9%) in arm 2 (p=0.90). Remission defined according to the proposed ACR/EULAR remission criteria was achieved in 138/610 (23%) patients; 117/387 (30%) in the early remission group, 2/83 (2%) in arm 1 and 14/78 (18%) in arm 2 (arm 1 vs. 2 p=0.001). There were no significant differences in DAS-remission rates between patients with RA (234/479, 49%) and patients with UA (64/122, 52%) (p=0.25). UA patients more often achieved DFR (41/122 (34%)) than RA patients (89/479 (19%), p<0.001). Over the first 2 years, DAS or HAQ were not significant different between arm 1 and 2 (mean difference (95%CI) DAS 0.01 (−0,2;0,2) and HAQ 0.1 (−0.1;0.2)).Of the total study population, 51/610 (8%) had radiological progression (increase SHS'0.5), in the early remission group 34/387 (9%) patients showed progression, in arm 1 9/83 (11%) and in arm 2 5/78 (6%) (p arm 1 vs. arm 2=0.31). Median (IQR) SHS progression in all groups was 0 (0-0).

	Early remission n = 387	Arm 1 n = 83	Arm 2 n = 78	p-value arm 1 vs. arm 2
Baseline				
Age in years, mean + SD	52 ± 14	49 ± 14	51 ± 14	0.20
Female, n (%)	240 (62)	64 (77)	58 (74)	0.68
ACPA positive, n (%)	225 (58)	40 (48)	37 (47)	0.99
RA(2010), n (%)	298 (77)	66 (80)	66 (85)	0.32
DAS, mean + SD	3.0 ± 0.8	3.6 ± 0.9	3.6 ± 1.0	0.91
HAQ, mean + SD	1.0 ± 0.7	1.4 ± 0.6	1.4 ± 0.6	0.47
Total SHS, median (IQR)	0 (0–0.5)	0 (0–0)	0 (0–0)	0.75
2 years				
DAS, mean + SD	1.3 ± 0.8	2.0 ± 0.7	1.9 ± 0.9	0.45
HAQ, mean + SD	0.4 ± 0.5	0.9 ± 0.7	0.8 ± 0.7	0.55
DAS-remission, n (%)	241 (62)	22 (27)	24 (31)	0.76
Drug free remission, n (%)	111 (29)	6 (7)	7 (9)	0.73
ACR/EULAR remission, n (%)	117 (30)	2 (2)	14 (18)	0.001
Total SHS, median (IQR)	0 (0–0.5)	0 (0–1.1)	0 (0–0)	0.12
SHS progression≥0.5, n (%)	34 (9)	9 (11)	5 (6)	0.31

Conclusion: Patients who achieved early remission after 4 months most often achieved (drug free) remission after 2 years. Patients in arm 1 and 2 achieved lower but comparable (drug free) DAS-remission rates, probably due to remission steered treatment adjustments. This may also explain negligible radiographic damage progression. These results suggest that there is a window of opportunity where effective anti-rheumatic therapy can induce lasting remission and non-progression.

A Strategy For Selecting Individuals With RA For Reduction Of Anti-TNF Therapy Using Combined Clinical and Ultrasound Assessment. Christopher R. Holroyd[1], Brian Davidson[1], Sarah Bennett[1], David Waghorn[1], Caron Underhil[1], Cyrus Cooper[2], Antonia Calogeras[1], Elaine M. Dennison[2], Nicholas C. Harvey[2], Ray Armstrong[1], Stephan Gadola[3] and Christopher J. Edwards[4]. [1]University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, [2]MRC Lifecourse Epidemiology Unit, Southampton, United Kingdom, [3]University of Southampton, Southampton, United Kingdom, [4]NIHR Wellcome Trust Clinical Research Facility, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom.

Background/Purpose: Reducing the dose of biological therapy may be possible for patients with rheumatoid arthritis (RA) who have achieved remission or low disease activity (LDA). However, patients in clinical remission may have synovitis detectable by ultrasound (US) and continue to accrue damage. We aimed to develop a strategy using both clinical and US assessment in a biologics review clinic to increase the likelihood of selecting the correct patients for biological therapy dose reduction, thereby minimising the chance of damage in those with subclinical synovitis.

Methods: All patients with RA (ACR criteria) receiving biologic therapies were reviewed in a biologics review clinic. At each appointment, patients underwent DAS28 assessment and US of their MCPs, PIP(2–5) and wrist joints (Esoate Mylab70). Synovitis was detected by power doppler (PDUS) and scored on a 0–3 semi-quantitative scale. PDUS remission was defined as a score of 0. Patients in clinical and US remission (DAS28<2.6 & PDUS=0) had the dose of anti-TNF therapy reduced by a third (adalimumab (ADA) to 40mg 3 weekly, etanercept (ETN) to 50mg every 10 days, infliximab (INF) reduced to 2mg/kg per infusion, certolizumab (CZB) reduced to 200mg every 3 weeks, golimumab (GOL) reduced to 50mg every 6 weeks). Patients were followed-up and if disease flared they were advised to ring a helpline to arrange an urgent clinic visit where a repeat DAS28 and US assessments were performed, and if needed the dose was increased back to baseline.

Results: 321 RA patients attended the clinic. All had fulfilled local requirements for biological therapy eligibility (including DAS28>5.1, and failed 32 non-biological DMARDs). Baseline demographics showed mean age 59.4 years, 75.4% female, mean time from diagnosis to first biological therapy 10.8years, mean pre-biologic DAS28 5.69, baseline biologic ADA 112, ETN 58, INF 41, GOL 5, CZB 5, rituximab 73, tocilizumab 25, abatacept 2. 179(55.8%) patients were receiving their first biological, 197(61.4%) received a biologic & methotrexate in combination. 101 (31.5%) patients were in DAS28 remission and 45 (15%) were in LDA. PDUS remission was present in 42.9% and of those in clinical remission 69(72.6%) had a PDUS score of 0. Biological reduction was agreed by 56(81.2%) patients and of these, 42(75%) have remained on a reduced dose at a mean of 8.7 months. 14 patients have flared and returned to baseline treatment at a mean of 5.9 months. Of patients flaring DAS28 score increased by mean 0.6. 11(78.6%) had a DAS28>2.6 and 50% had a PDUS=0.

Conclusion: A strategy using clinical assessment and US may increase the likelihood of correctly selecting patients with RA who could successfully reduce the dose of their biological therapy whilst maintaining

clinical and ultrasound remission. This strategy may minimize the risk of ongoing joint damage in those who reduce therapy.

Remaining Pain Is Common In Early RA Patients Treated With Methotrexate—Results From The EIRA Cohort and The Swedish Rheumatology Quality Register. Reem Altawil[1], Saedis Saevarsdottir[2], Sara Wedren[1], Lars Alfredsson[3], Lars Klareskog[2] and Jon Lampa[4]. [1]Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [2]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [3]Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden, [4]Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Although treatment with methotrexate is often efficient in decreasing inflammation and joint destruction in RA, several patients report remaining pain at follow-up (Taylor P et al, J Int Med Res 2010), and the potential discrepancy between decrease in inflammation and pain needs to be explored further. We investigated the frequency and possible predictors of remaining pain after 3 months treatment with MTX as the only DMARD treatment in early RA, with special focus on the patients who had a good clinical response to MTX.

Methods: The study base was cases reported to the Epidemiological investigation of RA (EIRA) cohort 1996–2009 who had follow-up data in the Swedish Rheumatology Quality Register (1996–2010), a total of 1241 patients (69% women). Disease activity was measured with the 28-joint based disease activity score (DAS28) and the EULAR response criteria were used to evaluate clinical response to treatment. The primary endpoint was 'remaining pain' at the 3 months follow-up visit, defined as pain according to a 100 mm visual analog scale above 20 mm (VAS pain >20 mm), which has earlier been stated as a cutoff for patient reported significant pain (Wolfe F et al, J Rheumatol 2007). The association between baseline parameters and remaining pain was evaluated by logistic regression and expressed as odds ratios (OR) with 95% confidence interval (95%CI), adjusted for age at onset/treatment start, gender and cigarette smoking status.

Results: Median VAS-pain was 54 mm at baseline and 25 mm at the 3 months follow-up visit. Remaining pain was observed in 57% of all patients at the 3 months follow-up. The frequency of EULAR good/moderate/no response was 40%/38%/22% respectively, and in these response groups, the frequency of remaining pain was 29%/70%/83% respectively. In the EULAR good responder group (n=421), remaining pain was associated with more disability at baseline (HAQ; adjusted OR 2.2, 95%CI=1.4–3.4 per unit increase) and less inflammation (erythrocyte sedimentation rate, ESR; adjusted OR 0.81; 95%CI=0.70–0.93 per 10 mm increase). In line with this, patients who were EULAR good responders and had a remaining pain at follow-up exhibited lower ESR ($p<0.02$) and higher HAQ ($p<0.02$) at baseline compared to patients with less pain. Moreover, increase in VAS pain during the treatment period was observed in 19% of the whole cohort and frequencies of increased pain in the response groups were 9%/15%/45% respectively.

Conclusion: Majority of early RA patients starting methotrexate monotherapy at diagnosis have remaining pain after 3 months. Further, almost 1/5 of the patients actually exhibit increase in VAS pain during treatment. Despite good response to methotrexate, almost a third of those patients have remaining pain, and in moderate responders, more than two thirds of the patients have remaining pain. Remaining pain despite a good response to MTX is associated with more disability and less inflammation at baseline. These results are in line with the hypothesis that a subgroup of early RA patients exhibits pain that is not inflammatory mediated and where non-RA causes and alternative treatment strategies can be discussed.

Tofacitinib, An Oral Janus Kinase Inhibitor: Analysis Of Malignancies Across The Rheumatoid Arthritis Clinical Program. X. Mariette[1], J. R. Curtis[2], E. B. Lee[3], B. Benda[4], I. Kaplan[5], K. Soma[5], R. Chew[5], J. Geier[6], L. Wang[5] and R. Riese[5]. [1]Paris-Sud University, Paris, France, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Seoul National University, Seoul, South Korea, [4]Pfizer Inc, Collegeville, PA, [5]Pfizer Inc, Groton, CT, [6]Pfizer Inc, New York, NY.

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). This analysis extended the evaluation of malignancies that occurred in the tofacitinib RA program from the Phase (P) 2, P3, and long-term extension (LTE) studies based on the data cut off of April 2013 (except where indicated).

Methods: Data were pooled from 6 randomized P2, 6 randomized P3 studies and 2 open-label LTE studies. Patients (pts) in P3 and LTE (LTE pts rolled over from the P2 and P3 studies) studies were treated with tofacitinib 5 or 10 mg twice daily; P2 included additional dosages.

Results: A total of 5674 patients (12669 pt-yr) received tofacitinib in the P2, P3 and LTE studies. One hundred and five pts receiving tofacitinib (all doses) reported malignancies (excluding non-melanoma skin cancer [NMSC]); the most common types of malignancies were lung and breast cancer. There were 10 lymphoma cases. The overall incidence rate (IR, events per 100 pt-yr) for all malignancies (excluding NMSC) and lymphomas were 0.83 (95% confidence interval [CI]: 0.69, 1.00) and 0.076 (0.04, 0.14), respectively. The IRs (95% CI) for all malignancies (excluding NMSC) broken down into 0–6, 6–12, 12–18, 18–24, 24–30, 30–36, 36–42, and >42 months based on exposure to study drug were 0.70 (0.44, 1.11), 0.62 (0.37, 1.05), 0.94 (0.59, 1.49), 1.04 (0.64, 1.66), 0.83 (0.47, 1.46), 1.00 (0.57, 1.76), 0.79 (0.36, 1.76), and 0.93 (0.46, 1.85), respectively. The standardized incidence ratios (SIRs) (95% CI) (as compared with the US Surveillance Epidemiology and End Result database) for all malignancies (excluding NMSC) and lymphomas were 1.07 (0.88, 1.30) and 2.58 (1.24, 4.74), respectively. The SIRs (95% CI) for lung and breast cancer were 1.93 (1.12, 3.09) and 0.71 (0.37, 1.24), respectively (data cut off April 2012). Thirty eight pts experienced NMSCs, for an IR of 0.45 (95% CI: 0.33, 0.62) (data cut off April 2012). By comparison, the IR of NMSC in patients treated with anti-TNF was 0.47 (0.37, 0.59) in a meta-analysis of randomized controlled trials[1] and ranged from 0.23 to 0.35 in a meta-analysis of registries.[2]

Conclusion: The malignancies that occurred in the tofacitinib RA program, including more than 12000 pt-yr of drug exposure, are consistent with the type and distribution of malignancies expected for patients with moderately to severely active RA. The IRs for all malignancies (excluding NMSC), lung cancer, breast cancer, and lymphomas are consistent with published estimates in RA patients treated with biologic and non-biologic DMARDs.[3–6]

The Risk Of Serious Infections In Patients Receiving Rituximab For Rheumatoid Arthritis: Results From The British Society For Rheumatology Biologics Register-Rheumatoid Arthritis. Lucía Silva-Fernández[1], Mark Lunt[1], Audrey S. Low[1], Kath D. Watson[1], BSRBR Control Centre Consortium[1], Deborah P. Symmons[1], Kimme L. Hyrich[2] and On behalf of the BSRBR[3]. [1]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Sciences Centre, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [3]British Society for Rheumatology, London, United Kingdom.

Background/Purpose: In the United Kingdom (UK), rituximab (RTX), an anti-CD20 monoclonal antibody, is currently used to treat patients with rheumatoid arthritis (RA) who have failed initial anti-tumor necrosis factor (TNF) therapy. There is a concern over whether B-cell depletion and potential resultant hypogammaglobulinaemia may result in an increased risk of serious infections (SI). The aim of this study was to determine if RTX influences the risk of SI when used in routine clinical practice.

Methods: The British Society for Rheumatology Biologics Register-RA is an ongoing national prospective cohort study of subjects with RA recently started on biologic therapy. To date, over 20000 subjects have been recruited. Patients who had failed a first anti-TNF and were switched to either a second anti-TNF or RTX between 2001–2012 were identified from the study cohort. All patients were followed by physician and patient questionnaires every six months for the first three years and annual physician questionnaires thereafter, in which data on drug therapy and serious adverse events were reported. Deaths were identified by flagging with UK National Health Service Information Centre. SIs were defined as those requiring intravenous antibiotics and/or hospitalization, or those resulting in death. Subjects were followed until 01/31/2013, first serious infection, death or treatment discontinuation allowing for a lag window (90 days after first missed dose of anti-TNF and 12 months following each course of RTX), whichever came first. The rates of SI in both cohorts (anti-TNF switched to another anti-TNF vs anti-TNF switched to RTX) were compared using Cox proportional hazards model adjusted using inverse probability of treatment weighting (IPTW) (see variables included in table).

Results: In total, 525 subjects experienced at least one SI (448 in 4048 anti-TNF treated subjects and 77 in 1433 RTX treated subjects) occurred during 14155 and 2621 person-years (pyrs) of observation respectively (incidence rate 31 versus 29 per 1000 pyrs) (Table). After adjustment using IPTW, there was a lower overall risk of SI for patients receiving rituximab than for those receiving a second anti-TNF: hazard ratio (HR) for RTX 0.50 (95% CI 0.33, 0.76). However, the median time to first SI was shorter in the RTX cohort. Analysis limited to patients who initiated their second biologic after RTX approval in 2006 gave similar results.

	Second anti-TNF (n=4048)	Rituximab (n=1433)
Age (years), mean (SD)	56.4 (12.3)	59.5 (11.8)
Gender: n (%) female	79.3	77
RA disease duration (years), Median (IQR)	14 (8, 21)	15 (9, 22)
DAS28 score at switch, mean (SD)	5.4 (1.5)	5.9 (1.3)
HAQ at switch, mean (SD)	1.9 (0.6)	1.9 (0.6)
Steroid use (%)	57	68
Past serious infection on initial anti-TNF therapy: n (%)	342 (8.5)	198 (19.9)
Follow-up (pyrs)	14155	2621
Median follow-up (pyrs; IQR)	2.7 (0.8, 6)	1.5 (0.8, 2.5)
Number of first serious infections	448	77
Median time to infection (years; IQR)	1.4 (0.4, 3.2)	0.5 (0.2, 1.4)
Crude incidence rate of SI per 1,000 pyrs (95% CI)	31 (28, 34)	29 (23, 36)
Unadjusted HR (95% CI)	Referent	0.62 (0.49, 0.80)
Age and gender adjusted HR (95% CI)	Referent	0.56 (0.44, 0.72)
Fully adjusted by IPTW HR (95% CI)*	Referent	0.50 (0.33, 0.76)

*IPTW HR adjusted by age, disease duration, Disease Activity Score (DAS)-28 score and Heath Assessment Questionnaire (HAQ) when initiating the second biologic, gender, smoking, use of steroids before switching to a second biologic, reason for stopping first anti-TNF, previous serious infection, number of prior disease modifying anti-rheumatic drugs (DMARDs) used before initiating biologic treatment, diabetes, lung involvement, heart disease, liver disease, renal disease, previous cancer, tuberculosis and year of starting first biologic drug.

Conclusion: The rate of SI in patients starting a second biologic is similar to that previously observed for a first anti-TNF therapy although our data suggest patients selected to switch to RTX may have a lower risk of SI compared to patients who switch to a second anti-TNF.

Tumour Necrosis Factor Inhibitors and The Risk Of Acute Coronary Syndrome In Rheumatoid Arthritis—a National Cohort Study. Lotta Ljung[1], Johan Askling[2], Solbritt M. Rantapää-Dahlqvist[1], Lennart T.H. Jacobsson[3] and The ARTIS Study Group[2]. [1]Umeå University, Umeå, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]Department of Rheumatology and Inflammation Research, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.

Background/Purpose: The high risk of ischemic heart disease (IHD) in patients with rheumatoid arthritis (RA) has been linked to inflammation and disease severity. Treatment with tumour necrosis factor inhibitors (TNFi) can modify cardiovascular risk factors and are often effective in reducing disease activity. The objective of the study was to evaluate the risk of acute coronary syndromes (ACS) in patients treated with TNFi for RA compared with the risk in bio-naïve RA patients and in the general population.

Methods: In the Swedish Biologics Register we identified a cohort of patients, with RA and no previous IHD, starting their first TNFi 2001–2010 (n=7,704, mean age 57.1 years, 75.9% women). Matched bio-naïve referents were randomly selected (3:1, n=23,112) from the underlying national cohort of all individuals with two or more outpatient diagnoses of RA (one of which at a dept. for Rheumatology or internal medicine) as identified in the National Patient Register. Furthermore, a matched comparator cohort (5:1, n=38,520) was randomly selected from the Population Register. Covariates were obtained from the Patient register (joint surgery, disease duration, and prevalent diagnoses of hypertension, diabetes, chronic pulmonary disease, infection, cerebrovascular disease and other atherosclerotic disease,) and Statistics Sweden (educational level and previous work disability). Three exposure windows were defined; *Actively on TNFi* – Until date of termination of TNFi therapy +90 days, *Short term exposure* – limiting the follow-up on TNFi to 2 years, and *Ever exposed to TNFi*. The outcome, incident ACS, was defined as a primary discharge diagnosis of myocardial infarction, or unstable angina, or myocardial infarction as the underlying cause of death. Incidence rates were calculated and Cox Proportional Regression models were utilized for risk estimations.

Results:

Crude incidence rates for ACS in the cohorts

	TNFi exposed RA pts (n = 7,704)		Bio-naive RA comparator (n = 23,112)		General population comparator (n = 38,520)	
Exposure window	ACS (n)	Crude IR per 1,000 pyar	ACS (n)	Crude IR per 1,000 pyar	ACS (n)	Crude IR per 1,000 pyar
Short term exposure	74	6.3 (5.0–8.0)	316	9.0 (8.0–10.0)	216	3.3 (2.8–3.7)
Actively on TNFi	137	5.7 (4.8–6.7)	476	8.6 (7.8–9.4)	394	3.3 (3.0–3.7)
Ever exposed to TNFi	221	6.8 (5.9–7.7)	680	9.0 (8.4–9.7)	602	3.6 (3.4–3.9)

The fully adjusted hazard ratios, HR (95%CI), for TNFi exposed compared with bio-naïve RA patients were for *Short term exposure* 0.78 (0.61–1.01), *Actively on TNFi* 0.73 (0.60–0.89), and *Ever exposed* 0.82 (0.70–0.95). Comparing the bio-naïve RA cohort with the general population fully adjusted models resulted in the HRs *Short term exposure* 2.27 (1.88–2.73), *Actively on TNFi* 2.10 (1.82–2.43), and *Ever exposed* 2.03 (1.80–2.29) for the risk of ACS. The corresponding HRs for the TNFi cohort compared with the general population referents were 1.65 (1.23–2.22), 1.50 (1.21–1.85), and 1.61 (1.36–1.92) respectively.

Conclusion: In this nation-wide, population-based, matched cohort study treatment with TNFi was associated with a modest reduction of the risk of ACS in patients with RA. Compared with the general population the risk of ACS in RA was increased, although less pronounced among the TNFi exposed patients. The decrease in risk could be attributable to the TNFi *per se,* or correspond to a higher degree of inflammatory control in the treatment group.

805

Good Response On Tumour Necrosis Factor Inhibitors Are Associated With a Decreased Risk Of Acute Coronary Syndromes In Patients With Rheumatoid Arthritis. Lotta Ljung[1], Lennart T.H. Jacobsson[2], Solbritt M. Rantapää-Dahlqvist[1], Johan Askling[3] and The ARTIS Study Group[3]. [1]Umeå University, Umeå, Sweden, [2]Department of Rheumatology and Inflammation Research, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [3]Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Inflammatory activity, as well as traditional cardiovascular risk factors, have been suggested to underlie the increased risk of coronary disease in patients with rheumatoid arthritis (RA). Treatment with tumour necrosis factor inhibitors (TNFi) may often effectively reduce disease activity in RA patients. The objective of the study was to evaluate whether level of response to TNFi in RA are associated with the risk of developing an acute coronary syndrome (ACS).

Methods: In the Swedish Biologics Register we identified a cohort of patients, with RA and no previous IHD, who had been on TNFi treatment > 2 months 2001–2010 (n=7,361). For each patient 5 matched referents were randomly selected from the Population Register. Information on inflammatory activity (ESR, CRP, DAS28, CDAI) for the patients was extracted from the register at start and from a visit 5 (±3) months after start of therapy. Data on the primary exposure, EULAR response at 5 months, was available in 4,931 (67%) individuals, mean age 57.1 years, 75.9% women. Covariates were extracted from the Patient register (prevalent hypertension, diabetes, chronic pulmonary disease, infection, and atherosclerotic disease, joint surgery, disease duration) and Statistics Sweden (educational level and work disability). The outcome, incident ACS, was defined as a primary discharge diagnosis of myocardial infarction or unstable angina, or myocardial infarction as the underlying cause of death. Incidence rates were calculated and Cox Proportional Hazard Regression models were utilized for risk estimations.

Results: A good EULAR response was observed in 37.8% (n=1866), a moderate response in 37.0% (n=1824) and no response in 25.2% (n=1241) of the patients. During the 1st year after the response evaluation 33 ACS were observed among the patients, and during year 1 and 2 after exposure 59 ACS were observed, resulting in crude incidence rates of (IR (95%CI)) 7.18 (5.10–10.10) and 6.90 (5.34–8.90) per 1,000 person-years, respectively. Among the general population comparators the corresponding IRs were 3.05 (2.42–3.86) and 3.37 (2.86–3.97). Relative risks for ACS among the response classes compared with non-responders and general population referents are presented in table.

Fully adjusted relative risks the year after evaluations for the secondary exposures were; ESR<20 vs. ESR≥20 HR 0.34 (0.16–0.74), $CRP^2$10 vs. CRP>10 HR 0.77 (0.38–1.54), DAS28 remission vs. non-remission HR 0.21 (0.05–0.88) and CDAI remission vs. non-remission HR 0.44 (0.06–3.27).

Conclusion: Good EULAR response after 5 months of treatment with TNFi in RA patients was associated with a significantly decreased risk of ACS, as was ESR<20 and DAS28 remission. In patients with good response on therapy no significant increase in the risk of ACS was detectable in comparison with the risk in general population during the 2 years after the evaluation.

806

Risk Of Cancer Recurrence Or New Tumors In RA Patients With Prior Malignancies Treated With Various Biologic Agents. Anja Strangfeld[1], Dagmar Pattloch[2], Peter Herzer[3], Edmund Edelmann[4], Silke Zinke[5], Martin Aringer[6], Joachim Listing[7] and Angela Zink[8]. [1]German Rheumatism Research Center, a Leipniz Institute, Berlin, Germany, [2]German Rheumatism Research Center, Berlin, Berlin, Germany, [3]University of Munich, Munich, Germany, [4]Rheumatologist, Bad Aibling, Germany, [5]Rheumatological Office, Berlin, Germany, [6]University Clinical Center Technical University of Dresden, Dresden, Germany, [7]German Rheumatism Research Center, Berlin, Germany, [8]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany.

Background/Purpose: If patients with rheumatoid arthritis (RA) have a history of malignancy, the choice of treatment is an important clinical question. The aim is to control disease activity with a minimum of risk for recurrence. During the past years we have observed in our register that rheumatologists tend to prefer rituximab over other biologic agents for the treatment of patients with prior malignancies. Our aim was to analyse the risk for recurrence or new tumors under different treatment regimens.

Methods: We used data from the German biologics register RABBIT which observes patients with RA from start of treatment with any approved biologic agent or with a nonbiologic (nb) DMARD. Only patients with a history of malignancy were included in our analysis. All data until 30st of October 2012 were used. Because of a possibly different risk for recurrences patients with prior lymphoma and skin cancer were looked at separately from patients with other malignancies.

Results: At time of the analysis 10,168 patients comprising 36,595 patient years of observation (PY) were included in the register. 367 patients (3.6%) had a history of cancer at time of enrollment. A remarkably high proportion of patients with prior malignancies (28%) were treated with rituximab. The mean time of observation in the register was 3 years for patients with prior lymphomas and 2.6 years for those with prior solid malignancies. The rates for recurrences or new incident tumors are shown in the table.

* antiTNF agents: adalimumab, etanercept, infliximab, certolizumab pegol, golimumab
§ other biologics: abatacept, anakinra, tocilizumab
# PY= patient years between enrollment (start of treatment) and new or recurrent malignancy or end of observation, whichever came first

Conclusion: Our data suggest that patients with a history of lymphomas, solid malignancies or skin cancer do not have higher recurrence rates when treated with rituximab in comparison to treatment with nbDMARDs. This finding is strengthened by the fact that the median time between prior solid malignancy and start of treatment was remarkably shorter in patients receiving rituximab than in all other treatments.

Perioperative Use Of Anti-Rheumatic Agents Does Not Increase Early Postoperative Infection Risks: A Veteran Affairs' Administrative Database Study. Zaki AbouZahr[1], Andrew Spiegelman[2], Maria Cantu[3] and Bernard Ng[4]. [1]Baylor College of Medicine, Houston, TX, [2]Michael E DeBakey Veteran Affairs Medical Center, Houston, TX, [3]Baylor College Of Medicine, Houston, TX, [4]Michael E. DeBakey VA Medical Center, Houston, TX.

Background/Purpose: Evidences for perioperative management of disease modifying anti-rheumatic drugs (DMARDs) and biologic agents (BA) are sparse, and limited mainly to methotrexate & specific surgeries (orthopedics). Such data may not be generalizable to other surgeries or DMARDs/BA. The use of administrative database is difficult here due to lack of validated methods to predict stopping of DMARDs/BA before surgery. Using novel techniques to predict stopping of DMARDs/BA, we used data from Veterans Affairs (VA) to compare infection risks of RA patients who stopped versus continued DMARDs/BA perioperatively over a 10-year period from 2000–2009.

Methods: We identified 6548 RA patients in VA administrative databases using validated algorithms & included only those on 1 DMARD or BA in the perioperative period. Those on multiple DMARDs/BA were excluded to simplify result interpretation.

We predicted drug stoppages by calculating × = medication stop date closest to the surgery - next start date. y = surgery date-stop date was used to determine if the drug was stopped before or after surgery. To validate this method, two

investigators independently reviewed clinic notes from the Houston VA facility for actual start or stop dates before or after surgery. A third investigator reviewed and resolved conflicting chart review results. ROC analyses were performed to obtain optimal x and y values to distinguish if DMARDs/BA were stopped and if it occurred before or after surgery.

The primary endpoints were wound infections within 30 days of surgery, according to the modified 1992 US Centers for Disease Control and Prevention criteria for postoperative infection, and other infections including pneumonia, UTI and sepsis. Propensity scores were used to match factors that may influence infection rates such as comorbidity scores, chronic steroid use, smoking, diabetes mellitus, etc.

Results: In the validation part of the study, ROC analyses found that $x \geq 33$ days best predicted stoppage of DMARD/BA (AUC=0.954) and $y \geq -11$ best predicted that DMARD/BA was stopped before surgery (AUC=0.846).

Risk of post-op general infection or wound infection in RA patients who stopped DMARDs/BA before surgery were not significantly different compared with those who did not stop these agents. Those who stopped BA after surgery had significantly higher odds of post-op wound (OR 13.7, p=0.014) and post-op general infections (OR 9.2, p=0.005) compared to those who did not stop BA. Similarly stopping DMARDs after surgery was associated with increased risk of post op wound infection (OR 3.08, p=0.000) and post op general infection (OR 1.68, p=0.024) compared with not stopping treatment. Treatment was stopped postoperatively likely because of post-operative infection.

Conclusion: Using our novel technique of identifying DMARDs/BA discontinuation, we showed that there was no significant difference in post-op infection risk whether stopping anti-rheumatic treatment preoperatively or not. Our results grouped all types of surgeries and different DMARDs/BA. Further analyses looking at different types of surgeries and individual DMARDs/BA will be helpful to evaluate possible differences in infection risks between individual DMARDs/BA in different types of surgeries.

Background/Purpose: Rheumatoid arthritis (RA) is a common autoimmune disease that is associated with a progressive loss of the joints induced by a chronic inflammation of the joint synovium. The production of anti-citrullinated peptide/protein antibodies (ACPA) is a common but not essential characteristic of RA patients, which is thought to be influenced by the genetic background. To date, the genetic background of ACPA negative patients (ACPA-) remains widely unknown. Therefore, our goal was to analyze the genetic risk factors that contribute to ACPA- RA.

Methods: We performed a large scale genome wide association study in three European cohorts comprising 1,148 ACPA- RA patients and 6,008 controls. Meta-analysis with previously published data was performed as follow-up for selected signals (reaching a total of 1,922 ACPA- RA patients and 7,087 controls). The HLA region underwent a specific imputation process which inferred the classical HLA alleles, polymorphic amino acid positions and SNPs. Finally, we recursively searched for models which better explained the association in the HLA region following a step-wise strategy.

Results: The combined analysis of the three cohorts identified a peak of association in the HLA-region and 34 non-HLA *loci* showed suggestive associations. These signals were selected for follow-up using meta-analysis with a previous report. The meta-analysis confirmed the association of the HLA region, a suggestive association in the *CLYBL locus* (rs9557321, $p = 5.82\times10^{-8}$) and two *tier 2* associations (rs518167 in *GRM5*; rs3790022 in the *RNASEH2B-FAM124A* region). In addition, we observed nominal associations in previously known susceptibility *loci*. In the case of the *TNPO3-IRF5* region, rs12531711 showed a remarkable risk association with ACPA-RA in the combined analysis ($p = 4.35\times10^{-5}$).

After the imputation in the HLA region, the most significant association corresponded to the HLA-DRB1 Leu67 variant (p-value $= 9.41\times10^{-10}$). Furthermore, we identified two additional independent amino acid signals: HLA-B Asp9 and HLA-DRB1 Thr181. Finally, we confirmed that the model including all the previously mentioned amino acid variants was the most parsimonious explanation and accounted for the observed genome-wide associations in this region.

Conclusion: The present report analyzed the genetic component of a large cohort of ACPA- RA patients compared to non-affected controls following a genome-wide strategy. Our results replicated previous findings in different *loci* and revealed a novel suggestive susceptibility factor, *CLYBL*. Moreover, we provided a deep insight into the influence of the HLA region in ACPA-RA. This study supported the existence of an ACPA- specific genetic component and highlighted the importance of comprehensive genetic analysis of large ACPA- RA cohorts.

IgM Rheumatoid Factor As a Potentiator Of Anti-Citrullinated Protein Antibody Mediated Inflammation In Rheumatoid Arthritis. Jeremy Sokolove[1], Danye Cheng[1], Dannette S. Johnson[2], Ted R. Mikuls[3] and William H. Robinson[4]. [1]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [2]Jackson VA and University of Mississippi Medical Center, Jackson, MS, [3]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [4]Stanford University School of Medicine, Stanford, CA.

Background/Purpose: The co-occurrence of rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) is well described in rheumatoid arthritis (RA), and has been associated with increased disease severity. However, the mechanisms underlying the potential interaction between these two distinct, but often co-existent, autoantibodies has not been well defined.

Methods: Multiplex cytokine profiles, plasma CRP levels, and disease activity scores (DAS28) were assessed in a cohort of 1,467 Veterans with RA (89% male). Patients were categorized into subgroups including double-negative (negative ACPA and RF; n=204), ACPA-positive (n=96), RF-positive (n=135), or double-positive (ACPA and RF positive; n=1031). Levels of each cytokine, CRP, and DAS28 score were compared between the double-negative, ACPA+, RF+, or double-positive subgroups using the Kruskal Wallis test with Tukey's multiple comparison post-test. Molecular interaction between ACPA and RF was investigated using an *in-vitro* immune complex (IC) stimulation assay in which IgG derived from RA patient sera was incubated with citrullinated fibrinogen (cFb) to form cFb-IC in the presence or absence of monoclonal IgM RF. The stimulatory capacity of these immune complexes to activate macrophages was assessed by measuring TNFa production.

Results: Compared with the double-negative subgroup, the double-positive subgroup (possessing ACPA and RF) exhibited significantly higher levels of DAS28, CRP, and multiple inflammatory cytokines including TNFa, IL-1b, IL-6, IL12p70, and IL-17A (all $P<0.001$). Notably, compared to the ACPA+/RF- subgroup, there was a similar increase in the levels of DAS28, CRP, and key inflammatory cytokines among the double-positive population (all $P<0.001$). *In vitro* stimulation of monocyte-derived macrophages by ACPA-immune complexes demonstrated significantly increased cytokine production with the addition of monoclonal IgM rheumatoid factor as compared to ACPA-immune complexes alone ($P=0.003$)

Conclusion: The combined presence of ACPA and IgM RF mediates increased proinflammatory cytokine production *in vitro*, and is associated with significantly increased systemic inflammation and disease activity in patients with RA. Compared to the double-negative subgroup, those with ACPA or RF alone demonstrated no increase in markers of inflammation or disease activity, while levels were consistently elevated among the double-positive subgroup. Our data suggest that the ability of IgM RF to enhance the capacity of ACPA-immune complexes to stimulate macrophage cytokine production is responsible for the increased level of inflammatory mediators and disease activity in double-positive individuals, thereby providing a mechanistic link by which RF enhances the pathogenicity of ACPA-ICs in RA.

Inducible Bronchus Associated Lymphoid Tissue In The Lung Is Associated With Seropositivity For Rheumatoid Arthritis-Related Autoantibodies In Subjects With and Without Clinically Diagnosed Rheumatoid Arthritis. M. Kristen Demoruelle, Adam W. Bagley, Mark C. Parish, David E. Heinz, V. Michael Holers, Carlyne D. Cool and Kevin D. Deane. University of Colorado School of Medicine, Aurora, CO.

Background/Purpose: Data suggest the lung may be a site of RA-related autoantibody (Ab) generation including findings of airways inflammation prior to onset of articular RA (Demoruelle 2012; Fischer 2012), and the presence of RA-related Abs in sputum but not blood in subjects at risk for future RA (Willis and Demoruelle 2013, in press). The mechanisms by which RA-related Abs may be generated in the lung are unknown; however, inducible bronchus-associated lymphoid tissue (iBALT) is known to form in the lung in response to inhaled antigens, can release Abs in the airways, and contains plasma cells generating RA-related Abs in RA (Rangel-Moreno 2006). Therefore, we hypothesize that iBALT formation is a mechanism by which RA-related Abs are generated in the lung, and aim to establish an association between iBALT and serum RA-related Abs.

Methods: We obtained stored blood and lung tissue from 48 subjects from the NIH Lung Tissue Research Consortium that includes subjects undergoing lung biopsy for clinical management of any underlying disease. Routine histologic staining of the lung was performed and interpreted in a blinded fashion by a trained pathologist. Lymphoid follicles consistent with iBALT and follicles with areas of inflammation organized into germinal centers (GCs) were quantified. Serum was tested for RA-related Abs: CCP2 (IgG, Axis-Shield), CCP3.1 (IgA/IgG, INOVA), and RF isotypes (IgM/A/G, INOVA). Differences in prevalence of positivity were compared using chi-squared/Fishers exact testing.

Results: Subjects with iBALT had similar rates of ever smoking (74% v. 64%, p=0.54), were younger (median age 60 v. 68, p=0.02), more often female (78% v. 44%, p=0.02), and more often had interstitial lung disease (ILD) (61% v. 8%, p<0.01) compared to subjects without iBALT. Nine subjects had a clinical diagnosis of RA; of these, 9 (100%) had airways disease or ILD, 9 (100%) were positive for ≥1 serum RA-related Ab, and 8 (89%) had iBALT. In the 39 subjects without RA, 35 (90%) had airways disease or ILD, 13 (33%) were positive for ≥1 serum RA-related Ab, and 15 (38%) had iBALT. In comparing all subjects, the prevalence of iBALT and GCs was associated with serum RA-related Ab positivity (Table).

Prevalence of serum RA-related autoantibody positivity in subjects with and without inducible bronchus-associated lymphoid tissue*

	iBALT present (N=23; 8 with RA)	iBALT absent (N=25; 1 with RA)	p-value	GC present (N=7; 5 with RA)	GC absent (N=41; 4 with RA)	p-value
CCP2 (+)	7 (30.4%)	0 (0%)	<0.01	4 (57.1%)	3 (7.3%)	<0.01
CCP3.1 (+)	8 (34.8%)	2 (8.0%)	0.03	4 (57.1%)	6 (14.6%)	0.03
CCP2 and/or CCP3.1 (+)	9 (39.1%)	2 (8.0%)	0.02	4 (57.1%)	7 (17.1%)	0.04
RF-IgA (+)	8 (34.8%)	2 (8.0%)	0.03	3 (42.9%)	7 (17.1%)	0.35
RF-IgM (+)	7 (30.4%)	2 (8.0%)	0.07	5 (71.4%)	4 (9.8%)	<0.01
RF-IgG (+)	7 (30.4%)	5 (20%)	0.51	3 (42.9%)	9 (22.0%)	0.34
Any RF isotype (+)	12 (52.2%)	6 (24.0%)	0.07	5 (71.4%)	13 (31.7%)	0.09

*48 subjects were included that had a variety of underlying diseases that resulted in a lung biopsy for clinical management including: 14 with interstitial lung disease (3 of which also had airways disease), 29 with emphysema and/or respiratory bronchiolitis, 1 with sarcoidosis, 2 with lung cancer, and 2 with normal lung tissue.

Conclusion: iBALT is associated with serum RA-related Abs in subjects with and without RA. While these pilot results are driven by subjects with diagnosed RA, when combined with the published data discussed above, this association suggests that iBALT may be a mechanism of RA-related Ab generation. Notably, iBALT can develop in response to inflammation, and given our prior findings of airways inflammation associated with RA-related Abs in absence of synovitis, iBALT may be a mechanism of RA-related Ab generation prior to synovitis in RA. Going forward we will expand these studies to additional subjects to evaluate the generation of RA-related Abs within iBALT, and factors (e.g. microbial) that may trigger iBALT and Ab development in subjects with and without classified RA.

Influence Of Smoking On Citrullinated Proteins and *Porphyromonas Gingivalis* In The Lung: A Priming Site For Autoimmunity In RA. Elena B. Lugli[1], Patrick Venables[2], Raquel Correia[3], Karin Lundberg[4], Ken Bracke[5] and Guy Brusselle[5]. [1]Kennedy Institute of Rheumatology, Oxford, United Kingdom, [2]University of Oxford, Oxford, United Kingdom, [3]Univerity of Oxford, Oxford, United Kingdom, [4]Rheumatology unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [5]Gent University, Gent, Belgium.

Background/Purpose: Anti-citrullinated peptide/protein antibodies (ACPA) may be detected in RA serum more than 10 years before onset of disease, suggesting that the autoimmune response begins outside the joint. Because smoking and periodontitis are risk factors for RA, it has been suggested that smoke inhalation or invasive infection with *Pophyromonas gingivalis* leads to citrullination of proteins in the lung. In this study, we examine human lung tissue by immunoblotting from 41 subjects with well-defined smoking status for the presence of citrullinated proteins, PAD2, PAD4 and *P. gingivalis* DNA.

Methods: Uninvolved tissue samples were dissected from lobectomy specimens from 41 subjects (10 never smokers, 10 COPD ex-smokers, 10 smokers without airflow limitation and 11 COPD smokers). The tissue was homogenised and examined by immunoblotting for the presence of citrullinated proteins with AMC. PAD2, PAD4, α-enolase, citrullinated α-enolase, vimentin and fibrinogen were detected using specific antibodies. Band intensities were scored quantitatively using a BioRad Quantity One Analysis Sofware or semi-quantitatively from 0–3 by two blinded observers. Recombinant proteins were used as positive controls and blots with secondary antibodies alone were carried out to exclude non-specific cross-reactivity. *P. gingivalis* was detected by nested PCR using primers spanning the PPAD gene.

Results: Citrullinated proteins were found in all lung tissues, both smokers and non-smokers. There was a trend towards increased citrullination in the lungs of the smokers with and without COPD but this did not reach statistical significance by either densitometry or semi-quantitative scoring of band intensities. There was a similar, but not significant, trend for increased expression of PAD2 amongst the smokers. PAD4 and the RA antigens, α-enolase, vimentin and fibrinogen, were observed in all lung tissue in comparable amounts regardless of disease and smoking status. There was also evidence of citrullination of α-enolase provided by co-migration of a ~50kDa

band recognised by AMC and an anti-citrullinated enolase antibody, and by 2D electrophoresis showing multiple isoforms of the antigen.

P. gingivalis DNA was detected most frequently in all the never smokers (100%) compared to the COPD ex-smokers (10%); smokers without COPD (10%); and least frequently in COPD smokers (0%) (Chi-square test, $p<0.001$).

Conclusion: We have demonstrated widespread citrullination of proteins in lung tissue from never smokers, with a slight increase with smokers. The inverse relationship between smoking and the detection of *P. gingivalis* DNA was initially surprising, but in keeping with previously published studies. These data support the hypothesis that the lung is a site for priming the ACPA response, though the mechanism is likely to be more complex than smoking inducing PAD enzymes or *P. gingivalis* infection.

Alveolar Bone Loss Is Associated With Disease Activity and ACPA Expression In Rheumatoid Arthritis. Ted R. Mikuls[1], Jeffrey Payne[2], Fang Yu[3], Geoffrey M. Thiele[3], Shawneen Gonzalez[2], Jeffrey Markt[4], Jeremy Sokolove[5], William H. Robinson[6], Richard J. Reynolds[7], Grant W. Cannon[8], David McGowan[9], Gail S. Kerr[10], Robert Redman[11], Andreas M. Reimold[12], Garth Griffiths[12], Mark Beatty[2], Marian Schmid[2], Paul Johnson[2], Debra Bergman[4], Bartlett C. Hamilton III[13], Alan R. Erickson[14] and James R. O'Dell[4]. [1]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [2]University of Nebraska Medical Center, Lincoln, NE, [3]Univ of Nebraska Med Ctr, Omaha, NE, [4]University of Nebraska Medical Center, Omaha, NE, [5]Stanford University, Palo Alto, CA, [6]Stanford University School of Medicine, Stanford, CA, [7]University of Alabama at Birmingham, Birmingham, AL, [8]Salt Lake City VA and University of Utah, Salt Lake City, UT, [9]George E. Wahlen VA Medical Center, Salt Lake City, UT, [10]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [11]Washington DC VA, Georgetown and Howard University, Washington, DC, [12]Dallas VA and University of Texas Southwestern, Dallas, TX, [13]University of Nebraska Medical Center and Omaha VA Medical Center, Omaha, NE, [14]Omaha VA and University of Nebraska Medical Center, LaVista, NE.

Background/Purpose: Periodontitis (PD) has been implicated in rheumatoid arthritis (RA) pathogenesis including the expression of anti-citrullinated protein antibody (ACPA). ACPA, in turn, have been shown to be robust predictors of radiographic progression in RA with recent evidence suggesting that ACPA targeting citrullinated vimentin could directly mediate disease-related bone damage. We sought to examine the relationship of alveolar bone loss (a feature of PD) with RA disease activity and autoantibody expression, including ACPA.

Methods: Panoramic radiographs were collected in RA patients and scored by two investigators (ICC 0.85) blinded to PD status. Patients were categorized into low, moderate, or high tertiles based on the mean bone loss across sites (up to 24 sites were examined per patient). PD was defined using a standardized periodontal exam and the criteria of Machtei et al (J Periodontol, 1990). ACPA concentrations were measured via 2ndgeneration ELISA (aCCP2) and by a bead-based multiplex antigen array on the BioPlex Platform, the latter to assess distinct antigen-specific ACPA. Associations of moderate and high bone loss (vs. low) with disease characteristics were examined using multivariable (MV) regression (covariates: age, gender, race, BMI, smoking, HLA-DRB1 SE, PD prednisone use, sicca symptoms, and others) identified through stepwise selection. Antigen-specific ACPA responses were compared across tertiles in aCCP2 positive patients using Significance Analysis of Microarrays (SAM) with separate analyses in ever and never smokers.

Results: RA patients (n = 274) were primarily male (63%), Caucasian (78%), ever smokers (62%), and had a mean age of 59 (±12) years. Approximately 1 in 3 patients (35%) had PD. Of those with PD, most had high (66%) and moderate (24%) levels of bone loss with fewer showing low bone loss (10%). Disease characteristics based on alveolar bone loss are shown (Table). Following MV adjustment, increased alveolar bone loss remained significantly associated with higher values of aCCP2, DAS-28-CRP, HAQ, tender joint counts, and joint space narrowing scores. Microarray analyses limited to aCCP2 positive patients demonstrated that ACPA targeting citrullinated vimentin and histone were significantly increased (q-value < 0.1%) in the moderate and high bone loss groups vs. low group, irrespective of smoking status.

Table. RA-related measures of disease activity & severity based on low, moderate, or high tertile of alveolar bone loss (unadjusted p-values shown)

	Low (n=88)	Moderate (n=85)	High (n=101)	P-Value
Tender joint count (0–28)	2.6 (4.8)	3.0 (4.2)	4.0 (4.9)	0.002
Swollen joint count (0–28)	3.0 (3.5)	3.4 (4.7)	4.2 (4.3)	0.041
DAS-28-CRP	2.4 (1.2)	2.6 (1.1)	3.0 (1.1)	<0.001
HAQ disability (0–3)	0.6 (0.7)	0.8 (0.7)	1.0 (0.7)	0.001
Pain (0–10)	2.7 (2.5)	3.0 (2.4)	3.9 (2.7)	0.007
Anti-CCP2, U/ml	145 (122)	162 (117)	203 (119)	0.007
RF, IU/ml	200 (519)	273 (465)	281 (490)	0.002
Total Sharp Score	13.2 (16.4)	18.1 (20.4)	25.8 (25.4)	0.003
Erosion Score	2.7 (4.7)	4.4 (7.8)	5.7 (8.7)	0.041
JSN Score	10.5 (13.3)	13.8 (14.5)	20.1 (19.3)	<0.001

Conclusion: Alveolar bone loss, a well-recognized feature of chronic PD, is strongly associated with increased RA disease activity. Furthermore, these results suggest that ACPA targeting, potentially of both vimentin and histones could represent potentially important links between RA and alveolar bone loss, providing novel insight into the disproportionate frequency of periodontal bone damage that has been reported in RA.

Citrulline Specific CD4+ T Cells Exhibit a Th1 Memory Phenotype In Rheumatoid Arthritis Subjects and Their Ex Vivo Frequency Is Influenced By Both Disease Duration and Biologic Therapy. Eddie James[1], Mary Rieck[1], Jennifer Pieper[2], John Gebe[3], Betty Yue[3], Megan Tatum[3], Charlotta Sandin[4], Lars Klareskog[5], Vivianne Malmström[6] and Jane Buckner[7]. [1]Benaroya Research Institute, Seattle, WA, [2]Karolinska Institutet, Rheumatology Unit, Stockholm, Sweden, [3]Benaroya Research Institute at Virginia Mason, Seattle, WA, [4]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [5]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [6]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [7]Translational Research Program, Benaroya Research Institute, Seattle, WA 98101, USA,, Seattle, WA.

Background/Purpose: Rheumatoid arthritis is thought to be a T cell mediated disease, based on its strong association with HLA class II alleles, clinical responsiveness to T cell directed therapies and the presence of CD4 T cells in rheumatoid joints. Understanding the character and antigen specificity of auto-reactive T cell responses in RA has been elusive, in part due to the limited identification of the most relevant epitopes and inability to interrogate responses directly ex vivo. The presence of ACPA in the serum of patients and association of these antibodies with HLA-DR4 alleles provides a clue to the specificity of pathogenic T cells and implicates their probable importance in the development and progression of RA.

Methods: We developed a panel of HLA-DR0401 tetramers, selecting citrullinated peptides from four different synovial antigens and verifying their immunogenicity in HLA-DR4 transgenic mice. This panel of tetramers was used to directly examine the frequency and cell surface phenotype of T cells specific for citrullinated peptides in subjects with DR0401 haplotypes using an ex vivo magnetic enrichment procedure.

Results: Citrullinated-antigen specific CD4 T cells were detectable in peripheral blood samples from both healthy subjects and RA patients. In comparison to healthy subjects, RA patients had significantly higher frequencies of citrullinated-antigen specific T cells ($p=0.0069$) and a greater proportion of these cells displayed a T_H1 memory phenotype ($p<0.0001$). Among RA subjects the frequency of citrullinated-antigen specific T cells was significantly higher within the first 5 years after disease onset ($p=0.0018$) and was decreased among patients on biologic therapies ($p<0.0001$) and this difference was seen irrespective of disease duration, indicating an independent effect.

Conclusion: This study represents the first evidence that the frequency and phenotype of citrullinated-antigen specific T cells vary with respect to important disease parameters and are therefore a potential biomarker in at risk

individuals and subjects with RA. These findings link the presence of ACPA in patient serum with T cells specific to citrullinated epitopes and suggest that the pathogenic T cells in established RA are of a Th1 lineage.

ACR Concurrent Abstract Session
Spondylarthropathies and Psoriatic Arthritis: Clinical Aspects and Treatment: Therapeutics and Outcomes in Psoriatic Arthritis
Sunday, October 27, 2013, 2:30 PM–4:00 PM

814

Results Of a Randomised Controlled Trial Comparing Tight Control Of Early Psoriatic Arthritis (TICOPA) With Standard Care: Tight Control Improves Outcome. Laura C. Coates[1], Anna R. Moverley[1], Lucy McParland[2], Sarah Brown[2], Howard Collier[2], Jennifer Law[2], Sarah R. Brown[2], Neil Corrigan[2], Nuria Navarro-Coy[2], Paul Emery[3], Philip G. Conaghan[1] and Philip S. Helliwell[1]. [1]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [2]Clinical Trials Research Unit, Leeds Institute of Clinical Trials Research, University of Leeds, Leeds, United Kingdom, [3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom.

Background/Purpose: The aim of this study was to assess the impact of tight control of early psoriatic arthritis (PsA) in a randomised-controlled trial (RCT) using a treat-to-target approach.

Methods: In this UK multicentre, open-label RCT, 206 patients with early DMARD naive PsA (<24 months symptom duration) were randomised 1:1 to receive either tight control (TC) (4 weekly review) or standard care (StdC) (12 weekly review) for 48 weeks. Patients assigned to the TC group followed a strict treatment protocol with escalation of therapy if minimal disease activity (MDA) criteria[1]were not met. All patients in the TC arm were started on methotrexate with rapid escalation to 25mg after 6 weeks if tolerated. After 12 weeks of therapy, patients were escalated to combination DMARDs if they had not achieved MDA. After a further 12 weeks, patients were either escalated to anti-TNF therapy if they had ≥3 tender and swollen joints (as per UK NICE guidelines) or to an alternative DMARD in combination with methotrexate if they were not in MDA but had <3 active joints. Patients assigned to the StdC group were treated by a rheumatologist with no set protocol and no limitations.

The primary outcome was ACR20 response at 48 weeks. Key secondary outcomes included ACR50 and 70, and PASI75 at 48 weeks. Treatment arms were compared using multivariate logistic regression adjusting for arthritis classification and centre. Missing ACR response component data was imputed using multiple imputation for the intention to treat (ITT) population.

Results: 206 patients were recruited from 8 UK centres from 2008–2012 with 101 randomised to TC and 105 to StdC. By week 48, 12 patients had withdrawn (5 TC, 7 StdC) and 12 lost to follow-up (6 TC, 6 StdC). Patients had a median age of 45 (range: 18–80), 52% were male and 71% presented with polyarthritis; these characteristics were similar across treatment arms. In the ITT population, there was significant evidence that the odds of achieving ACR20 at 48 weeks were greater in the TC arm compared to the StdC arm (odds ratio (OR): 1.91, 95% CI: 1.03, 3.55, p=0.0392). The odds of achieving ACR50 (OR: 2.36, 95% CI: 1.25, 4.47, p=0.0081) and ACR70 (OR: 2.64, 95% CI: 1.32, 5.26, p=0.0058) were also greater in the TC arm compared to the StdC arm. Results for patients with non-missing data are displayed below.

Outcome measure	Patients with all data available (N)	Tight Control	Standard Care
		N (%) achieving outcome	
ACR20	172	55 (61.8)	37 (44.6)
ACR50	170	44 (51.2)	21 (25.0)
ACR70	172	33 (38.4)	15 (17.4)
PASI75*	156	44 (58.7)	27 (33.3)
		Median improvement in score (range)	
Enthesitis*	145	2 (−12, 13)	1 (−8, 14)
LDI*	53	38 (0, 276)	58.5 (−6, 157)
mNAPSI*	110	3 (−18, 41)	2 (−22, 32)

* only evaluated if involvement at baseline

The most commonly reported adverse events (AEs) were nausea, liver function test abnormalities and infections (e.g. common cold). AEs were reported in 88% of patients, (97% TC vs 80% StdC). 33 serious AEs (SAEs) (25 TC, 8 StdC) were reported across 20 patients (14 TC, 6 StdC) during the course of the study. There were no deaths or unexpected SAEs.

Conclusion: Tight control of PsA disease activity using a treat-to-target approach significantly improves joint and skin outcomes for newly diagnosed PsA patients with no unexpected SAEs seen.

This study was funded by Arthritis Research UK and Pfizer.

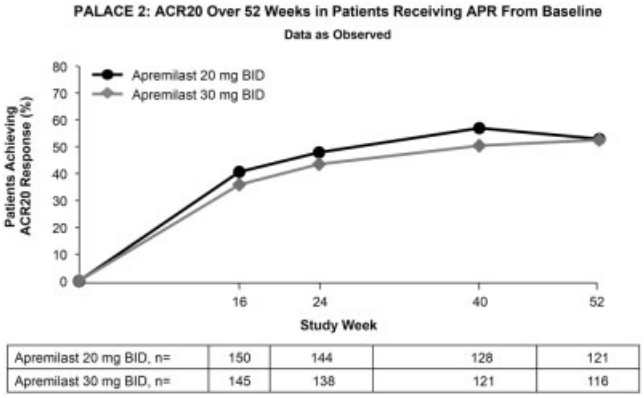
Long-Term (52-Week) Results Of a Phase 3, Randomized, Controlled Trial Of Apremilast, An Oral Phosphodiesterase 4 Inhibitor, In Patients With Psoriatic Arthritis (PALACE 2). Maurizio Cutolo[1], Gary E. Myerson[2], Roy M. Fleischmann[3], Frédéric Lioté[4], Federico Díaz-González[5], Filip Van den Bosch[6], Helena Marzo-Ortega[7], Eugen Feist[8], Kamal Shah[9], ChiaChi Hu[9], Randall M. Stevens[9] and Airi Poder[10]. [1]University of Genova, Genova, Italy, [2]Arthritis and Rheumatology of Georgia, Atlanta, GA, [3]Metroplex Clinical Research Center, University of Texas Southwestern Medical Center, Dallas, TX, [4]Hôpital Universitaire Lariboisière, Paris, France, [5]University of La Laguna, Hospital Universitario de Canarias, La Laguna, Spain, [6]Gent University Hospital, Gent, Belgium, [7]Leeds Musculoskeletal Biomedical Research Unit and University of Leeds, Leeds, United Kingdom, [8]Charite University Hospital, Berlin, Germany, [9]Celgene Corporation, Warren, NJ, [10]Clinical Research Centre Ltd, Tartu, Estonia.

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor, works intracellularly to modulate pro- and anti-inflammatory mediators. PALACE 2 compared the efficacy and safety of APR with placebo (PBO) in pts with active PsA despite prior DMARDs and/or biologics.

Methods: Pts were randomized 1:1:1 to PBO, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by baseline (BL) DMARD use. At wk 16, pts with <20% reduction from BL in swollen and tender joint counts qualified for protocol-defined early escape; those on PBO were re-randomized to APR20 or APR30 and those on APR remained on the initial APR dose. At wk 24, all remaining PBO pts were re-randomized to APR20 or APR30 through wk 52. Patients taking concurrent DMARDs were allowed to continue stable doses (MTX, sulfasalazine, leflunomide, or a combination).

Results: 484 pts were randomized and received ’1 dose of study drug (PBO, 159; APR20, 163; APR30, 162). At wk 16 (primary endpoint), a significantly greater proportion of pts treated with APR20 (38.4%; $P=0.0002$) and APR30 (34.4%; $P=0.0024$) achieved an ACR20 response vs PBO (19.5%). For those pts originally randomized to APR and completing 52 wks of study, improvements were maintained or increased over 52 wks for multiple endpoints, including: (1) ACR20 response of 52.9% (APR20) and 52.6% (APR30) (Figure); (2) HAQ-DI mean change from BL (SD) of −0.192 (0.573) for APR20 pts and −0.330 (0.509) for APR30 pts; (3) SF-36 Physical Functioning domain score mean change from BL (SD) of 5.05 (7.96) for APR20 pts and 6.35 (8.67) for APR30 pts; and (4), in these pts with BL BSA ≥3%, PASI-75/PASI-50 achievement of 27.1%/49.2% in APR20 pts and 39.3%/58.9% in APR30 pts. Pts randomized to APR at wks 16 and 24 demonstrated results consistent with those originally randomized to APR. APR was generally well tolerated. Adverse events (AEs) occurring in ≥5% of all pts exposed to APR through wk 52 were diarrhea, nausea, upper respiratory tract infection, headache, and nasopharyngitis. The majority of AEs were mild or moderate in severity and predominantly did not lead to discontinuation. Serious AEs (SAEs) occurred in 4.7% (APR20) and 5.1% (APR30) of pts as treated. No new safety findings were identified and the incidence of pts experiencing any AE was comparable over the 0–24 and 0–52 wk periods. No imbalance in the exposure-adjusted incidence rates of major adverse cardiac events, serious infections including systemic opportunistic infection, or malignancies between APR and PBO was observed. No cases of TB (novel or reactivation) were reported in the APR treatment groups; TB screening was not required per protocol.



Apremilast 20 mg BID, n=	150	144	128	121
Apremilast 30 mg BID, n=	145	138	121	116

Conclusion: Over 52 wks, APR demonstrated long-term efficacy in the treatment of PsA, including clinically meaningful improvements in signs and symptoms and physical function. APR had an acceptable safety profile and was generally well tolerated for up to 52 wks.

Apremilast, An Oral Phosphodiesterase 4 Inhibitor, Is Associated With Long-Term (52-Week) Improvements In Enthesitis and Dactylitis In Patients With Psoriatic Arthritis: Pooled Results From Three Phase 3, Randomized, Controlled Trials.

Dafna D. Gladman[1], Philip J. Mease[2], Arthur Kavanaugh[3], Adewale O. Adebajo[4], Juan J. Gomez-Reino[5], Jürgen Wollenhaupt[6], Maurizio Cutolo[7], Georg Schett[8], Eric Lespessailles[9], Kamal Shah[10], ChiaChi Hu[10], Randall M. Stevens[10], Christopher J. Edwards[11] and Charles A. Birbara[12]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]Swedish Medical Center and University of Washington School of Medicine, Seattle, WA, [3]University of California San Diego, San Diego, CA, [4]University of Sheffield, Sheffield, United Kingdom, [5]Hospital Clinico Universitario, Santiago, Spain, [6]Schön Klinik Hamburg Eilbek, Hamburg, Germany, [7]University of Genova, Genova, Italy, [8]University of Erlangen-Nuremberg, Erlangen, Germany, [9]University of Orléans, Orléans, France, [10]Celgene Corporation, Warren, NJ, [11]University of Southampton, Southampton, United Kingdom, [12]University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor, works intracellularly to modulate pro- and anti-inflammatory mediators. The PALACE 1, 2, and 3 trials compared the efficacy and safety of APR with placebo (PBO) in pts with active PsA despite prior DMARDs and/or biologics.

Methods: Pts were randomized 1:1:1 to PBO, APR 20 mg BID (APR20), or APR 30 mg BID (APR30) stratified by baseline DMARD use. At wk 16, pts with <20% reduction from baseline in swollen and tender joint counts qualified for protocol-defined early escape; those on PBO were re-randomized to APR20 or APR30 and those on APR remained on the initial APR dose. At wk 24, all remaining PBO pts were re-randomized to APR20 or APR30 through wk 52. Pts taking concurrent DMARDs were allowed to continue stable doses (MTX, sulfasalazine, leflunomide, or a combination). In order to increase the number of pts with pre-existing enthesopathy and/or dactylitis, data were pooled across PALACE 1, 2, and 3. Maastricht Ankylosing Spondylitis Enthesitis Score (MASES), ranging from 0–13, is the number of painful entheses out of 13 entheses. The dactylitis count, ranging from 0–20, is the number of digits on the hands and feet with dactylitis present; each digit is rated as 0 (no dactylitis) or 1 (dactylitis present).

Results: APR administration resulted in statistically significant and clinically meaningful improvement in ACR20 response (primary endpoint) in all 3 PALACE trials. In pts originally randomized to APR and with pre-existing enthesopathy (n=634) and/or dactylitis (n=428), APR was associated with improvements in the severity of enthesitis and dactylitis over the 52-wk period, as evidenced by reductions in MASES and dactylitis count. At wk 24, median changes in MASES were −21.1%, −40.0% (P=0.0789), and −50.0% (P=0.0167) in pts receiving PBO, APR20, and APR30, respectively. In those pts originally randomized to APR and completing 52 wks of study, median change in MASES was −66.7% with APR20 and APR30 (Table). A MASES score of 0, indicating no pain at any of the entheses assessed, was achieved by 41.4% of APR20 and 37.4% of APR30 pts. At wk 24, median changes in dactylitis count were −66.7%, −75.0% (P=0.2158), and −79.3% (P=0.0609) in pts receiving PBO, APR20, and APR30, respectively. At wk 52, both doses resulted in a median 100% decrease in dactylitis count. Dactylitis count decreased to 0 in 66.9% of APR20 and 65.9% of APR30 pts. Pts randomized to APR at wks 16 and 24 demonstrated results consistent with those originally randomized to APR. No new safety findings were identified and the incidence of pts experiencing any AE was comparable over the 0–24 and 0–52 wk periods.

Conclusion: Over 52 wks, APR continued to demonstrate efficacy in the treatment of PsA, including improvements in enthesitis and dactylitis. APR demonstrated an acceptable safety profile and was generally well tolerated for up to 52 wks.

Impact of APR on Enthesitis and Dactylitis at Week 52 in Patients Receiving APR From Baseline

MASES*	APR20 (n=307)	APR30 (n=327)
Baseline, median	4.0	4.0
Median percent change from baseline*	−66.7	−66.7
Proportion of patients achieving a score of 0§, %	41.4	37.4
Dactylitis count*	**APR20 (n=207)**	**APR30 (n=221)**
Baseline, median	2.0	2.0
Median percent change from baseline*	−100.0	−100.0
Proportion of patients achieving a score of 0‡, %	66.9	65.9

*In patients with pre-existing enthesopathy or dactylitis, the n reflects randomized patients; actual number of patients available for each end point may vary. Reductions in MASES and dactylitis count indicate improvement.
§MASES ranges from 0 to 13, with zero indicating no pain at any entheses assessed and 13 indicating the presence of pain at all entheses assessed.
‡Dactylitis count is the sum of scores for each of the 20 digits, with individual digits scored as 0=absence or 1=presence of dactylitis.

Clinical Response To Brodalumab, An Anti-Interleukin-17 Receptor Antibody, In Subjects With Psoriatic Arthritis.

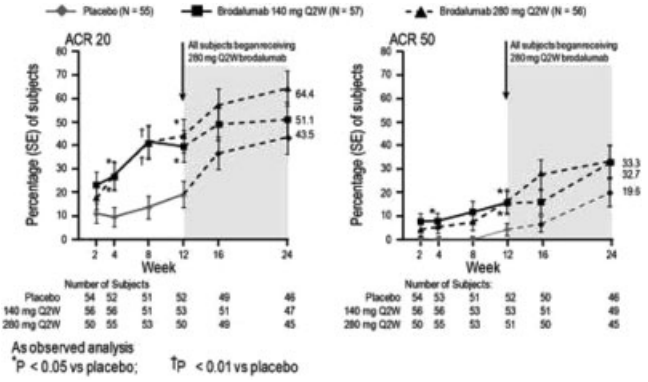
Mark C. Genovese[1], Philip J. Mease[2], Maria W. Greenwald[3], Christopher T. Ritchlin[4], André Beaulieu[5], Atul Deodhar[6], Richard Newmark[7], JingYuan Feng[7], Ngozi Erondu[7] and Ajay Nirula[7]. [1]Stanford University, Palo Alto, CA, [2]Swedish Medical Center and University of Washington School of Medicine, Seattle, WA, [3]Desert Medical Advances, Palm Desert, CA, [4]University of Rochester, Rochester, NY, [5]Faculty of Medicine, Laval University, Quebec, QC, [6]Oregon Health and Science University, Portland, OR, [7]Amgen Inc, Thousand Oaks, CA.

Background/Purpose: Psoriasis-associated skin and joint disorders are characterized by ongoing inflammation mediated by similar molecular pathways. IL-17 plays a potential role in the pathogenesis and ongoing inflammation of psoriatic disease. We sought to assess the efficacy and safety of brodalumab, a human anti-IL-17 receptor A monoclonal antibody, in patients with psoriatic arthritis (PsA).

Methods: Adults (age 18 to 75 years) with active PsA (Classification Criteria for Psoriatic Arthritis and ≥3 tender and ≥3 swollen joints) for ≥6 months were randomized to brodalumab (140 or 280 mg Q2W) or placebo. At week 12 subjects could enroll in an open-label extension (OLE) in which all subjects received 280 mg brodalumab. Outcomes based on available data up to week 24 from the ongoing study included American College of Rheumatology 20% response (ACR20), ACR50, and ACR70, changes in DAS 28 and ACR response components, and adverse events (AEs).

Results: At baseline, the majority of enrolled subjects (113 brodalumab and 55 placebo) were female (64%), white (94%), and rheumatoid factor negative (92%). Mean (SD) age, weight, and duration of PsA at baseline were 52 (12) years, 91 (21) kg, and 9 (8) years, respectively. 156 subjects entered in the OLE (52 prior placebo, 53 prior 140 mg, 51 prior 280 mg).

ACR20 was achieved at week 12 by 37% and 39% of subjects in the 140- and 280-mg brodalumab groups, respectively, compared with 18% of placebo subjects ($p < .05$) (Fig. 1). The percent of ACR20 responders (observed) increased at week 24 (44%, 51%, 64%, in prior placebo, prior 140 mg, and prior 280 mg groups, respectively) (Fig. 1). The percent of ACR50 responders (observed) across all groups increased from week 12 to week 24 (Fig. 1). There were improvements in other secondary endpoints such as DAS 28, CDAI, and several components of the ACR from baseline to week 12 that continued through week 24 in all treatment groups.



AEs were balanced among treatment groups and placebo, with 85% of subjects reporting an AE during the OLE. The most commonly reported adverse events were nasopharyngitis, arthralgia, psoriatic arthropathy, upper respiratory tract infection, and oropharyngeal pain. SAEs were reported in 11 subjects during the full study through data cutoff (double-blind phase and OLE). No deaths, clinically significant neutropenia (≥ Grade 2), or mycobacterial/fungal/opportunistic infections were reported in this study.

Conclusion: Brodalumab treatment was associated with significant clinical response with continued improvement from week 12 to 24. The benefit:risk profile supports continued evaluation of brodalumab for treatment of PsA.

HLA-B*0801 Is Strongly Associated With Asymmetrical Sacroiliitis and HLA-B*27 With Symmetrical Involvement In Psoriatic Arthritis: Results Of a Long-Term Follow-Up Study Examining Clinical and Genetic Predictors Of Radiographic Sacroiliitis. Muhammad Haroon[1], Agnes Szentpetery[1], Phil Gallagher[1], Robert Winchester[2] and Oliver FitzGerald[1]. [1]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]Columbia University, New York, NY.

Background/Purpose: Psoriatic arthritis (PsA) is characterised by involvement of both the appendicular and axial skeleton. Little is known about the clinical predictors of sacroiliitis (SI), especially regarding underlying patient's characteristics, life style, correlation with skin disease and with severity of psoriatic disease. The objectives of our study were: 1) To investigate the prevalence of SI in an ethnically homogenous cohort of established PsA, 2) to identify clinical and genetic predictors of SI in patients with PsA, 3) to describe different radiographic patterns of SI and their potential associations with clinical and genetic characteristics.

Methods: A cohort of 283 PsA patients, fulfilling CASPAR criteria, was included. Following informed consent, patients underwent a detailed skin and rheumatologic assessment including PASI, body surface area for Psoriasis (PsO), CRP, ESR, smoking, BMI status, alcohol intake, education status, family history of PsO and/or PsA, PsA duration, age of PsO/PsA onset, enthesitis, dactylitis, erosions, osteolysis, arthritis mutilans, clinically deformed joints, PsO and/or PsA requiring TNFi treatment, HAQ, DLQI, Bristol Rheumatoid Arthritis Fatigue Numeric Rating Scale (BRAF-NRS), and EQ5D. In addition, HLA-B*27 and B*080101 status was recorded, which we have recently shown are the key genetic markers of radiographic SI (www.rheumatology.org/education/annual/2012_abstract_supplement.pdf). Unilateral or bilateral grade 2 radiographic changes were required for inclusion as having SI. SI involvement was further defined as asymmetrical when radiographic scoring grades were discordant between the 2 SI joints and as unilateral when the opposite SI joint was completely uninvolved.

Results: 70 patients (25%) had radiographic SI; all either had present or past history of backache. Mean age of patients with SI was 51.6±11 years, and 53.5% were male. Unilateral SI was present in 14 patients (27%); bilateral SI in 38 patients (73%). Of those with bilateral involvement, SI was asymmetrical in 28 (73%) patients. HLA-B*0801 was significantly associated with asymmetrical SI, which included those with unilateral SI or asymmetrical bilateral involvement ($p=0.001$), and in striking contrast, HLA-B*2705 was significantly associated with bilateral symmetrical SI ($p=<0.001$). On backward step-wise multiple regression analysis, model predicted significant association of peripheral joint erosions (OR 1.91, $p=0.03$), PASI maximum (OR 1.05, $p=0.03$), younger PsA age of onset (OR 0.93, $p=<0.001$), presence of HLA-B*0801 (OR 2.9, $p=0.001$) and HLA-B*2705 (OR 2.39, $p=0.02$) with SI.

Conclusion: Twenty five percent of PsA patients developed SI on long-term follow up. PsA developing at younger age, severe skin PsO, peripheral joint erosions, HLA-B*0801 and HLA-B*2705 are clinical and genetic predictors for the development of SI. We report for the first time that there are two separate principal patterns of HLA antigens explaining 2 clinically distinct sub-types of radiographic SI.

Low Diagnostic Utility Of Candidate Definitions For a Positive MRI Of The Spine In Axial Spondyloarthritis. Ulrich Weber[1], Veronika Zubler[1], Zheng Zhao[2], Robert GW Lambert[3], Kaspar Rufibach[4], Stanley Chan[3], Susanne Juhl Pedersen[5], Mikkel Ostergaard[6] and Walter P. Maksymowych[3]. [1]Balgrist University Hospital, Zurich, Switzerland, [2]Department of Rheumatology, University of Alberta and PLA General Hospital, Beijing, PR China, Beijing, China, [3]University of Alberta, Edmonton, AB, [4]rePROstat, Basel, Switzerland, [5]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [6]Copenhagen Center for Arthritis Research, Glostrup, Denmark.

Background/Purpose: A recent consensus statement based on a systematic literature review by the Assessment of SpondyloArthritis International Society suggested the presence of ≥3 corner inflammatory lesions (CIL) or of several corner fat lesions (CFL) as candidate definitions for a positive MRI of the spine in axial spondyloarthritis (SpA) [1]. The goals of this study were to determine data-driven cut-off values for spinal CIL and CFL yielding a specificity ≥90%, and to evaluate their diagnostic utility in non-radiographic axial SpA (nr-axSpA) and ankylosing spondylitis (AS).

Methods: The study sample comprised 2 independent cohorts A/B of 130 consecutive patients with back pain ≤50 years newly referred to 2 university clinics, and 20 healthy controls (HC). Patients were classified according to clinical examination and pelvic radiography as having nr-axSpA (n=50), AS (n=33), or mechanical back pain (MBP; n=47). Spinal MRI were assessed by 4 blinded readers according to the standardized CanDen module. Readers recorded bone marrow edema and fat infiltration in the central and lateral compartment of 23 discovertebral units. We calculated cut-off values for CIL and CFL to obtain ≥90% specificity and the corresponding area under the curve (AUC) with confidence interval (CI). Finally, we tested the diagnostic

utility (mean sensitivity/specificity over 4 readers) of cut-off values for spinal MRI as proposed in the literature ('3 CIL [1] and ≥5 CFL [2]) for nr-axSpA and AS patients in both cohorts.

Results: In cohorts A/B, ≥3 CIL were reported in 43.4%/25.0% of nr-axSpA patients, 61.1%/42.7% of AS patients, and 25.0%/10.6% of MBP patients (and in 17.5% of HC in cohort A). Corresponding numbers for ≥5 CFL were 31.6%/43.5%, 47.2%/54.2%, and 32.1%/24.2% (and 23.8%). For cohorts A/B, the rounded lesion cut-offs to obtain ≥90% specificity were 3/2 CIL and 7/10 CFL, respectively. The corresponding AUC for CIL were 0.69 (CI 0.49–0.84) and 0.69 (CI 0.47–0.85) in the 2 cohorts, and for CFL 0.60 (CI 0.43–0.75) and 0.71 (CI 0.56–0.82), respectively. The diagnostic utility of the spinal thresholds of ≥3 CIL and of ≥5 CFL was low in both cohorts when comparing nr-ax SpA versus MBP.

Diagnostic utility of candidate definitions for a positive MRI of the spine in cohorts A/B

Lesion cut-off	Mean Sensitivity	Mean Specificity	Positive LR	Negative LR
nr-axSpA vs MBP				
≥3 CIL	0.43/0.25	0.75/0.89	1.74/2.36	0.75/0.84
≥5 CFL	0.32/0.44	0.68/0.76	0.98/1.80	1.01/0.75
≥7 CFL	0.21/0.34	0.86/0.82	1.47/1.86	0.92/0.81
≥10 CFL	0.12/0.21	0.89/0.90	1.11/2.13	0.99/0.88
AS vs MBP				
≥3 CIL	0.61/0.43	0.75/0.89	2.44/4.03	0.52/0.64
≥5 CFL	0.47/0.54	0.68/0.76	1.47/2.23	0.78/0.61
≥7 CFL	0.36/0.47	0.86/0.82	2.53/2.58	0.75/0.65
≥10 CFL	0.19/0.45	0.89/0.90	1.81/4.55	0.90/0.61

LR: Likelihood Ratio

Conclusion: In this controlled study, the definitions of a positive spinal MRI proposed in a recent consensus statement showed low diagnostic utility in nr-axSpA. While a cut-off of ≥2/≥3 CIL for a positive spinal MRI was optimal, the threshold for CFL was as high as 10.

CC-220: A Clinical Stage Immunomodulatory, Antifibrotic Drug For Systemic Sclerosis. Jörg HW Distler[1], Yongqing Wang[2], Pawel Zerr[3], Katrin Palumbo[4], Gerald Horan[5], Peter Schafer[5] and Bashar Kahaleh[2]. [1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]University of Toledo, Toledo, OH, [3]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [4]University of Erlangen-Nuremberg, Erlangen, Germany, [5]Celgene Corporation, Summit, NJ.

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune fibrotic disease in which B cells may play a crucial role in pathogenesis. CC-220 is an immunomodulatory drug with antifibrotic activity in early clinical development. CC-220 binds with high affinity to cereblon, part of the DCX (DDB1-CUL4–X-Box) ubiquitin ligase complex, and regulates ubiquitination of target proteins including key regulators of hematopoietic cell differentiation and activation. CC-220-treatment suppresses B cell proliferation, differentiation, Ig secretion, and cytokine production. In addition to its B cell suppressive properties, CC-220 has demonstrated antifibrotic activity both *in vitro* and *in vivo*. This combination of B cell suppressive and antifibrotic properties makes CC-220 an intriguing potential therapeutic for SSc. To better characterize its activity, we evaluated CC-220 in primary cells from SSc patients and in mouse models of scleroderma.

Methods: Primary dermal fibroblasts were isolated from both normal volunteers and SSc patients and cultured for 24 hours in presence of CC-220 or vehicle control. Gene expression was evaluated by quantitative RT-PCR. Dermal thickening was induced in mice by intradermal injection of bleomycin every other day for 3 weeks. CC-220 was orally administered at 30 mg/kg daily and skin samples were processed for histology, hydroxyproline analysis and quantitative RT-PCR. Tight skin-1 (Tsk) mice were similarly treated for 5 weeks.

Results: CC-220 had little to no effect on basal or TGFβ-stimulated expression of profibrotic genes in normal fibroblasts. However, in fibroblasts derived from SSc patients, CC-220 treatment induced a robust, dose-dependent normalization of the expression of key fibrotic mediators including COL1a1, α-SMA, PAI-1, FN and MMP1. We next wondered if this broad therapeutic effect, specific to the SSc fibroblasts, might be mediated by epigenetic mechanisms, so we measured expression of the DNA methyltransferase, Dnmt1. Dnmt1 is elevated in SSc fibroblasts, and CC-220 induced a dose-dependent decrease in expression, suggesting that CC-220 may mediate its antifibrotic activity, at least in part, via regulation of epigenetic modifiers.

To evaluate its antifibrotic potential *in vivo*, CC-220 was tested in a bleomycin-induced skin fibrosis model and in Tsk mice, a genetic model of scleroderma skin disease. In the bleomycin model, CC-220 treatment significantly prevented dermal thickening and inhibited expression of profibrotic genes in the skin, including COL1a1 and TGFβ1. In Tsk mice, CC-220 treatment resulted in highly significant decreases in dermal thickness and in skin collagen content as measured by hydroxyproline. Gene expression of COL1a1 and CTGF are elevated in the skin of Tsk mice and were significantly decreased by CC-220 treatment.

Conclusion: CC-220 potently regulates key profibrotic factors and has demonstrated antifibrotic efficacy *in vitro* and *in vivo*. The combined antifibrotic efficacy and B cell suppressive activity make it a promising candidate for treatment of SSc.

Activation Of The Signal Transducer and Activator Of Transcription 3 By Transforming Growth Factor-Beta Promotes Fibroblast Activation and Tissue Fibrosis. Barbora Sumova[1], Katrin Palumbo-Zerr[2], Clara Dees[3], Pawel Zerr[2], Oliver Distler[4], Georg Schett[3], Ladislav Senolt[5] and Joerg H. W. Distler[2]. [1]Department of Rheumatology of the First Faculty of Medicine, Institute of Rheumatology and Connective Tissue Research Laboratory, Prague, Czech Republic, [2]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]University of Erlangen-Nuremberg, Erlangen, Germany, [4]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [5]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic.

Background/Purpose: Systemic sclerosis (SSc) is characterized by uncontrolled activation of fibroblasts resulting in tissue fibrosis in which the TGFβ signaling plays a main role. Signal transducer and activator of transcription 3 (STAT3) is a transcription factor belonging to the family of seven proteins transmitting the signals from plasma membrane receptors to nucleus with subsequence modulation of gene transcriptions involved in angiogenesis, immune responses and metastasis. Nuclear translocation occurs upon phosphorylation by several receptors tyrosine kinases, particularly by Janus kinase 2 (JAK2). In the present study, we evaluated the role of STAT3 as a downstream mediator of TGFβ signaling pathway in the pathogenesis of SSc and analyzed the potential of STAT3 inhibition as a novel anti-fibrotic approach.

Methods: Activation of STAT3 in the human skin and in murine models was analyzed by IF staining for phosphorylated and thereby activated STAT3 (pSTAT3). Selective inhibitors of JAK2 and STAT3 and knockdown strategies were used to interfere with JAK2 and STAT3 signaling *in vitro* and *in vivo*. The anti-fibrotic potential of STAT3 inhibition was evaluated in two mouse models of SSc: bleomycin-induced fibrosis and fibrosis induced by overexpression of a constitutively active TGFβ receptor type I (TBR).

Results: Increased activation STAT3 signaling with accumulation of pSTAT3 in fibroblasts was observed in the skin of SSc patients and in murine models of SSc. Stimulation with TGFβ increased the expression of STAT3 protein and induced nuclear accumulation of pSTAT3 in cultured fibroblasts. Pre-incubation with specific JAK2 inhibitor abrogated the TGFβ induced induction of STAT3 as well as nuclear accumulation of pSTAT3, demonstrating that TGFβ activates STAT3 in a JAK2 dependent manner. Inactiva-

tion of STAT3 with the selective STAT3 inhibitor S3I-201 significantly reduced the stimulatory effects of TGFβ on the protein collagen level (−56%, p=0.05) and the mRNA level of *Col1a1* (−71%, p=0.0095) and *Col1a2* (−35 %, p=0.0095) and myofibroblast differentiation in cultured human fibroblasts. The same results were observed when STAT3 was inactivated by conditional knockout in murine fibroblasts. Moreover, treatment with S3I-201 (10 mg/kg) exerted potent anti-fibrotic effects in bleomycin- and TBR induced fibrosis. In the model of bleomycin induced fibrosis, treatment with the specific STAT3 inhibitor decreased dermal thickening by 33% (p=0.0009), hydroxyproline (HP) content by 51 % (p=0.001) and myofibroblast counts by 55 % (p=0.0009) Potent anti-fibrotic effects with reduced dermal thickening, decreased HP content and reduced myofibroblast counts were also observed in TBR induced fibrosis.

Conclusion: We characterize STAT3 as a novel downstream mediator of the profibrotic effects of TGFβ in SSc. We demonstrate that TGFβ activates STAT3 and that this activation is required for the profibrotic effects of TGFβ. Inhibition of STAT3 prevents fibroblast activation and shows potent antifibrotic effect in different preclinical models of SSc. These findings may have direct translational implications considering that several STAT3 inhibitors are currently in clinical trails.

Inhibition Of Casein Kinase II Reduces TGFβ Induced Fibroblast Activation and Ameliorates Experimental Fibrosis. Yun Zhang. Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany, Erlangen, Germany.

Background/Purpose: Casein kinase-2 (CK2) is a highly conserved serine/threonine kinase. CK2 is a tetramer composed of 2 catalytic subunits (α or α') and 2 β regulatory subunits, which are essential for cell viability. CK2 is discussed as a target for cancer therapy and is currently evaluated in clinical trials. Recently, we have shown that targeting of JAK2 might be an interesting molecular approach for the treatment of systemic sclerosis (SSc).

Methods: Activation of CK2, JAK2, and STAT3 in human skin and in experimental fibrosis were determined by immunohistochemical analysis. CK2 signaling was inhibited by the selective CK2 inhibitor 4, 5, 6, 7-Tetrabromobenzotriazole (TBB). The mouse models of bleomycin-induced and TGF-β receptor I (TBR)-induced dermal fibrosis were used to evaluate the anti-fibrotic potential of specific CK2 inhibition *in vivo*.

Results: Increased expression of CK2 was detected by immunohistochemistry in skin sections of SSc patients, particularly in fibroblasts. Inhibition of CK2 by TBB in cultured fibroblasts completely abrogated the stimulatory effects of TGFβ on collagen release (p<0.05). After TBB treatment, stress fiber formation and α-smooth muscle actin (α-SMA) expression in TGFβ-stimulated fibroblasts were significantly reduced by 97% (p=0.0064) and 69% (p=0.0280). Besides reduced fibroblast activation, western blot analyses showed complete normalization of the levels of phosphorylated JAK2 (pJAK2) in the cytoplasm and of phosphorylated STAT3 (pSTAT3) in the nucleus of TGFβ-treated fibroblasts upon preincubation with TBB (p=0.0004 and p=0.0214). In addition, treatment with TBB effectively prevented bleomycin-induced fibrosis in mice with decreased dermal thickness by up to 70% (p<0.0001) and efficient reductions in myofibroblast counts by up to 68% (p=0.0002). TBR-induced fibrosis in mice was strongly ameliorated by TBB with efficient reductions of dermal thickening by 75% (p<0.0001). Myofibroblast counts and hydroxyproline content also decreased by 59% and 40% (p<0.0001 and p=0.0193), respectively. In both murine models, we observed reduced pJAK2 and pSTAT3 expression as analyzed by immunohistochemistry.

Conclusion: We demonstrate that CK2 is activated in SSc and prove that inhibition of CK2 reduces canonical TGF-β signaling and prevents experimental fibrosis in different preclinical models. Considering the potent antifibrotic effects of CK2 inhibition, our study might have direct translational implications. These data provide first evidence that targeting CK2 may be a novel therapeutic approach for fibrotic diseases.

Activation Of Liver X Receptors Inhibits Experimental Fibrosis By Interfering With Interleukin-6 Release From Macrophages. Christian Beyer[1], Jürgen Beer[1], Katrin Palumbo-Zerr[1], Pawel Zerr[1], Alfiya Distler[1], Clara Dees[1], Louis E. Munoz[1], Gerhard Krönke[1], Oliver Distler[2], Steve Anderson[3], Georg A. Schett[4] and Joerg H. W. Distler[1]. [1]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Department of Rheumatology and Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [3]Lexicon Pharmaceuticals Inc., The Woodlands, TX, [4]University of Erlangen-Nuremberg, Erlangen, Germany.

Background/Purpose: Liver X receptors (LXRs) are orphan nuclear receptors with emerging roles in metabolic and autoimmune diseases. Here, we investigated the role of LXRs in experimental skin fibrosis and evaluated their potential as anti-fibrotic targets for systemic sclerosis (SSc) and other fibrotic diseases.

Methods: We studied the role of LXRs in bleomycin-induced skin fibrosis and in tight skin-1 (Tsk-1) mice, reflecting different subtypes of fibrotic disease. To dissect the role of both LXR isoforms in fibrosis, we generated LXRα- and LXRβ-knockout mice as well as LXR-α/β-double-knockout mice. To establish the mode of action of the anti-fibrotic effects of LXRs, we investigated the effects of LXRs on fibroblasts and macrophages.

Results: LXR activation by the LXR agonist T0901317 had potent anti-fibrotic effects in both bleomycin-induced skin fibrosis and Tsk-1 mice as assessed by skin thickness, hydroxyproline content, and the number of myofibroblasts. The anti-fibrotic activity of LXRs was particularly prominent in the inflammatory bleomycin-model in which LXR activation reduced skin thickening by up to 64%, the hydroxyproline content by up to 91% and the number of myofibroblasts by up to 91%.

LXRα-, β- and LXRα/β-knockout mice showed a similar response to bleomycin challenge as wildtype animals. In line with these results, low levels of the LXR target gene ABCA-1 in the skin of bleomycin-challenged and control mice suggested a weak baseline activation of the anti-fibrotic LXR signaling, which, however, could be specifically activated by T0901317. The specificity of T0901317 on LXRs was again reflected by the LXRα/β-knockout mice in which the LXR agonist lacked anti-fibrotic activity.

Of note, fibroblasts were not the direct targets of the anti-fibrotic effects of LXRs. By contrast, LXR activation inhibited macrophage infiltration in fibrotic tissue and decreased the release of the pro-fibrotic cytokine interleukin-6 from macrophages, resulting in reduced fibroblast activation and collagen release.

Conclusion: We identified LXRs as novel therapeutic targets for SSc and other fibrotic diseases, a yet unknown aspect of these nuclear receptors. Our data suggest that LXR activation might be particularly effective in patients with inflammatory disease subtypes. Activation of LXR interfered with the release of interleukin-6 from macrophages and, thus, inhibited fibroblast activation and collagen release.

Bosentan Improves Vascular Abnormalities In Endothelial Cell-Specific Fli1 Knockout Mice By Increasing The DNA Binding Ability Of Fli1 - a Possible Mechanism Explaining The Effect Of Bosentan On Scleroderma Vasculopathy. Kaname Akamata[1], Yoshihide Asano[1], Takashi Taniguchi[1], Takehiro Takahashi[1], Yohei Ichimura[1], Tetsuo Toyama[1], Maria Trojanowska[2] and Shinichi Sato[1]. [1]University of Tokyo Graduate School of Medicine, Tokyo, Japan, [2]Boston University, Boston, MA.

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disease characterized by initial vascular injuries and resultant fibrosis of skin and certain internal organs. Although there have been no established treatments against SSc, recent studies have demonstrated that bosentan, a dual endothelin receptor antagonist, reverses nailfold capillary changes in SSc patients. However, the molecular mechanism explaining this observation still remains unknown. Therefore, we herein investigated the mechanism underlying the reversal effect of bosentan on SSc vasculopathy by using endothelial cell (EC)-specific Fli1 knockout mice (Fli1 ECKO mice), which mimic the functional and morphological abnormalities characteristic of SSc vasculopathy.

Methods: Eight-week-old Fli1 ECKO mice were administered intraperitoneally with bosentan for 4 weeks. The expression levels of VE-Cadherin, PECAM1, a-SMA, and Fli1 were evaluated by immunohistochemistry. Vascular structure in the back skin was visualized by intravenously injected FITC-dextran. Vascular permeability was evaluated by the degree of Evans blue dye extravasation. The effects of bosentan on c-Abl, PKC-d, and Fli1 in human dermal microvascular ECs (HDMECs) were evaluated by immunoblotting.

Results: The structural and functional abnormalities, including stenosis of arterioles, dilation of capillaries, and increased vascular permeability, of small dermal blood vessels were improved by the administration of bosentan in Fli1 ECKO mice. Bosentan reversed the abnormal expression of various genes regulating EC-pericyte interaction, EC-EC interaction, and degradation of vascular basement membranes in dermal microvascular ECs isolated from Fli1 ECKO mice. In HDMECs, bosentan suppressed the activity of c-Abl and PKC-d, resulting in decreased phosphorylation levels of Fli1 at threonine 312. Consistent with the evidence that, when unphosphorylated, the DNA binding ability and the protein stability of Fli1 are increased, Fli1 protein levels were elevated along with the increase of its DNA binding, while Fli1 mRNA levels were not affected, after the exposure to bosentan in those cells.

Conclusion: Bosentan reverses the functional and morphological abnormalities of Fli1 ECKO mice at least partially by increasing the transcriptional activity and the protein levels of Fli1 through post-translational modification without affecting its mRNA expression. These results suggest that the efficacy of bosentan on SSc vasculopathy, in which Fli1 deficiency due to the epigenetic mechanism is deeply involved, is partly attributable to its reversal effect on Fli1 transcriptional activity and expression in SSc endothelial cells.

Activating Transcription Factor 3 Regulates Canonical Transforming Growth Factor Beta Signaling In Experimental Fibrosis. Tatjana Mallano[1], Katrin Palumbo-Zerr[1], Christian Beyer[1], Clara Dees[2], Jingang Huang[1], Tsonwin Hai[3], Georg A. Schett[2] and Joerg H. W. Distler[1]. [1]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]University of Erlangen-Nuremberg, Erlangen, Germany, [3]The Ohio State Biochemistry Program, The Ohio State University, Columbus, USA, Colombus, OH.

Background/Purpose: Activating transcription factor 3 (ATF3), a member of the activating transcription factor/cAMP-responsive element binding protein (ATF/CREB) family of transcription factors is induced by various types of cellular stress including oxidative stress. Here, we analyzed ATF3 as a downstream mediator of TGF- β signaling in fibroblast activation and tissue fibrosis in systemic sclerosis (SSc).

Methods: Activation of ATF3 expression in the skin and dermal fibroblasts was determined by real-time PCR, Western blot and immunohistochemistry. To investigate the role of ATF3 in fibrosis, ATF3 knock-out mice and wildtype littermates were evaluated in the mouse models of bleomycin-induced dermal fibrosis and dermal fibrosis induced by overexpression of a constitutively active TGF-β receptor I (TBR). The content was determined by haematoxylin-eosin and trichrome stainings, by immunohistostaining for aSMA and hydroxyproline assays respectively. In vitro cultured fibroblasts were used and measure collagen release by SirCol and study target genes by RT-PCR. Co-immunoprecipitation (Co-IP) and Smad reporter assay were performed to study physical and functional interactions between ATF3 and Smad3.

Results: An increased expression of ATF3 was detected in the upper layer of the dermis of SSc patients on fibroblasts double stained for ATF3 and anti-prolyl-4-hydroxylase ($p= 0.0016$). The overexpression of ATF3 persisted in cultured SSc fibroblasts with increases of 292% ($p= 0.043$). TGF-β induces ATF3 with an increase of 256% ($p= 0.01$). ATF3 knock-out fibroblasts were less sensitive to the pro-fibrotic effects of TGF-β with impaired induction of collagen mRNA and protein upon stimulation with TGF-β. In the model of bleomycin-induced fibrosis, dermal thickening was decreased by 70% ($p= 0.02$), the hydroxyproline content by 73% ($p= 0.035$) and the myofibroblast counts by 80% ($p= 0.0003$) in AFT3 knockout mice compared to wild type littermates. ATF3 knockout mice were also protected from TBR induced fibrosis with significant decreases in dermal thickening ($p= 0.003$), accumulation of collagen ($p= 0.001$) and myofibroblast differentiation ($p= 0.002$). Function studies demonstrated that ATF3 interacts with Smad3 to regulate the pro-fibrotic effects of TGF-β. Co-IP demonstrated that TGF-β induces binding of ATF3 to Smad3. Reporter study and analyses of the expression of classical Smad target genes such as PAI-1 demonstrated that the binding of ATF3 to Smad3 stimulates the transcriptional activity of Smad3. The activity in Smad3 reporter assays and the expression of PAI-1 upon stimulation with TGF-β were both strongly reduced in ATF3 knockout fibroblasts compared to control cells (decreases of 56 %, $p= 0.004$ and 85 %, $p= 0.02$, respectively).

Conclusion: We demonstrate for the first time a key-role of ATF3 in fibroblast activation and tissue fibrosis in SSc. Targeting of the ATF3 reduced the stimulatory effect of TGF-β on cultured fibroblasts by interfering with canonical Smad signaling. Moreover, knockdown of ATF3 protected from experimental fibrosis in different mouse models. Considering the potent anti-fibrotic effects observed in this study, ATF3 might be a candidate for molecular targeted therapies of SSc.

The Value Of History and Physical Examination Findings In The Diagnosis Of Symptomatic Meniscal Tear Among Middle-Age Subjects With Knee Pain. Jeffrey N. Katz, Yan Dong, John Wright, Stephanie Chen, Scott Martin, Laurel Donnell-Fink, Benjamin N. Rome and Elena Losina. Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Clinicians often rely on mechanical symptoms (e.g. clicking, catching, popping, giving way) and tests such as the McMurray sign in the diagnosis of symptomatic meniscal tear (MT). While the diagnostic value of these findings has been validated in younger patients with traumatic MT, there is limited data on the utility of the history and physical exam in the diagnosis of symptomatic MT in middle-age and older persons.

Methods: We enrolled patients $>$ 45 years old presenting with unilateral knee pain to 2 academic orthopedists. A research associate completed a standardized medical history and musculoskeletal physical exam. The history included mechanical symptoms and other items such as symptom duration and diffuse vs. localized location. The exam included identification of tender areas, motion, provocative tests and performance tests. The orthopedist, blind to this standardized assessment, rated his confidence that patients' symptoms were attributable to MT from 0 (certain the symptoms are NOT from MT) to 100 (certain that symptoms ARE from MT). We defined the primary outcome ("expert diagnosis of MT") as confidence $>$ 70. History and physical exam findings associated with this outcome ($p < 0.05$ or OR > 1.5 or < 0.75) in bivariate analyses were advanced to multivariate models. Findings associated in the model ($p < 0.05$) with expert diagnosis of MT were included in an additive index, with weights proportional to adjusted OR's. We calculated the proportion of subjects with particular index scores that had expert diagnosis of MT.

Results: The sample consisted of 80 persons who provided history and physical exam data. Median age was 62 years (range 47, 90) and 66% were female. 28% had expert diagnosis of MT. In bivariate analyses, none of the traditional mechanical symptoms (locking, clicking, catching, popping, giving way) were associated with expert's diagnosis of MT, nor was the McMurray test. History findings associated with expert diagnosis of MT included having localized pain (that the subject could point to with 1 finger) and pain present for $<$ 1 year. Physical exam findings associated with expert diagnosis of MT were joint line tenderness, absence of anserine bursa tenderness and knee pain with the step down test. These history and exam findings were aggregated into an additive index with 1 point for each positive feature and 1 subtracted for anserine bursal pain. 6% (1/17; 95% CI 0–17%) of subjects with -1 or 0 points had expert diagnosis of MT, while 21% (9/43; 95% CI 9–33%) of those with 1–2 points and 60% (12/20; 95% CI 38–82%) of those with 3–4 points had expert diagnosis of MT.

Conclusion: In this sample of middle-age and older subjects with knee pain, select history and physical findings identified subjects with low ($\sim$6%) risk of expert diagnosis of MT and a group with moderate risk of $\sim$60%. These findings suggest that the history and physical exam may be useful in the diagnosis of MT, but that emphasis on the "mechanical symptoms" traditionally thought to be associated with meniscal tear may not be useful in

determining whether those symptoms are attributable to MT in older patients with knee pain.

Cost-Effectiveness and Cost-Utility Of a One-Year Coaching Program For Healthy Physical Activity In Rheumatoid Arthritis. Nina Brodin[1], Malin Lohela Karlsson[2], Emma Swärdh[1] and Christina H. Opava[3]. [1]Karolinska Institutet, SE 14183 Huddinge, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]Karolinska Institutet, Huddinge, Sweden.

Background/Purpose: Economic evaluations of interventions, as a complement to the effect evaluation, intend to inform decision makers about whether an intervention provides good value for the money. Since resources in healthcare are scarce, there is an increased demand from decision makers for economic evaluations. Economic evaluations of non-pharmacologic care in RA are still not as commonly presented as evaluations of the costs related to medications, for example. At the CARE VI meeting, the importance of such evaluations was acknowledged. Thus, the aim of the present study was to describe cost-effectiveness and cost-utility of a one-year coaching program aimed at increasing daily physical activity in RA, previously studied in the Physical Activity in Rheumatoid Arthritis (PARA) study.

Methods: The protocol for the PARA study is available at http://www.controlled-trials.com/ISRCTN88886304/. Costs were collected and estimated retrospectively. The study was performed from 2000 to 2004 and all costs were deflated using gross domestic product with 2005 as a reference year. Cost-effectiveness was calculated based on the intervention cost per patient, with respect to health status (EuroQol visual analog scale, EQ-VAS) and activity limitation (Health assessment questionnaire, HAQ). To calculate cost utility, Quality adjusted life years (QALY) was used based on the EuroQol-5D.

Results: The cost of the one-year intervention program was estimated to €44 224 of which 65% were for treatment and 35% for education, project activities and administration. Estimated difference in total societal cost between the intervention (IG) and control (CG) was €372 per patient. ICER for one point (1/100) of improvement in EQ-VAS was estimated to €72. By offering the intervention exclusively to more affected patients (MO), both the effectiveness and cost-effectiveness were improved. The estimated ICER for a one-point improvement in EQ-VAS was €35 for MO in the IG compared to MO in the CG. By offering the intervention to MO in the IG only, and not to less affected patients (LE), an extra point of improvement in EQ-VAS would cost €21. An extra gain in QALY for this group would cost €3585 and for one extra point (1.0) of improvement in HAQ, the cost would be €1517.

Conclusion: The intervention resulted in improved effect on EQ-VAS for the intervention group with a cost of €72 per extra point. The result reveals that the cost per QALY and ICER for improvement in health status was lower in the subgroup with more affected patients (MO) in the IG compared to in the CG with the same level of disability. The cost per QALY and ICER for improvement in health status was even lower when comparing more affected patients (MO) to less affected patients (LE) within the IG. This indicates that from a societal perspective, it would be more cost-effective to offer this kind of intervention exclusively to more affected patients with RA, than to all patients with RA.

Psychosocial Determinants Of Total Knee Arthroplasty Outcomes 2 Years After Surgery. Aparna Ingleshwar[1], Maria A. Lopez-Olivo[2], Glenn C. Landon[3], Sherwin J. Siff[3], Andrea Barbo[4] and Maria E. Suarez-Almazor[5]. [1]The University of Texas, MD Anderson Cancer Center, Houston, TX, Houston, TX, [2]University of Texas. M.D Anderson Cancer Center, Houston, TX, [3]St. Luke's Episcopal Health System, Houston, TX, [4]MD Anderson Cancer Center, Houston, TX, [5]University of Texas MD Anderson Cancer Center, Houston, TX.

Background/Purpose: To explore potential psychosocial and demographic factors that influence Total Knee Arthroplasty (TKA) outcomes and satisfaction at 24 months.

Methods: A prospective cohort study was conducted. Outcome measures of interest were: WOMAC and SF-36 recorded at baseline and 24 months post-surgery, and SkiP, recorded at 24 months. Independent variables included: the Medical Outcome Study–Social Support Scale (MOS-SSS); Depression, Anxiety and Stress scale (DASS); brief COPE inventory; Health Locus of Control (MHLC); Arthritis Self-efficacy Scale (ASES) and the Life Orientation Test–revised (LOT). Spearman rank correlations between baseline predictors and outcomes at 24 months were calculated. Stepwise multiple linear regression was performed to determine the influence of various patient psychosocial domain characteristics at baseline, on the outcomes at 24 months. For each outcome, a model that considered the baseline outcome measure as one of the predictors and a model that did not consider this were run. Patient's age and sex were forced into all models.

Results: There were 178 TKA patients who had baseline and 24 month scores. Patients' mean age was 65±9 years; 65% were women. Results from the bivariate correlations between psychosocial and demographic characteristics, and outcomes at 24 months showed that; only problem-solving coping, emotional coping and the belief that others have control over one's health were not significantly correlated with any of the outcomes of interest ($p>0.05$). Regression analyses with baseline outcomes adjustment indicated that; older age, higher BMI, less tangible support, and lower optimism were associated with worse pain and function scores (total adjusted R^2: pain=0.15 and function=0.21). Older age, higher BMI and a greater number of comorbidities was associated with lower PCS domain scores (total adjusted R^2= 0.33); whereas being depressed ($p<0.001$) and having lower optimism ($p<0.001$) was associated with reduced MCS scores (total adjusted R^2= 0.43). Being employed ($p<0.001$) and less dysfunctional coping ($p=0.01$) was associated with greater satisfaction with knee procedure (total adjusted R^2: 0.12). Similar results were obtained in the models without baseline outcomes adjustment except for MCS component scores wherein; increased BMI ($p=0.04$), greater number of comorbidities ($p=0.03$), lower tangible support ($p=0.03$) and higher stress ($p=0.03$) was associated with lower MCS scores (total adjusted R^2= 0.43).

Conclusion: Psychosocial factors such as; level of tangible support, depression, problem-solving coping, dysfunctional coping and optimism were associated with pain, function and satisfaction in patients after TKA. Thus, in order to achieve clinical success following TKA, physicians must also consider their patients' psychosocial status. Further research is needed to study suitable intervention strategies targeting these identified psychosocial determinants.

Is The Severity Of Knee Osteoarthritis On MRI Associated With Outcome Of Exercise Therapy? Jesper Knoop[1], Joost Dekker[2], Marike van der Leeden[2], Martin van der Esch[1], J.P. Klein[2], David J. Hunter[3], Leo D. Roorda[1], Martijn P.M. Steultjens[4] and Willem F. Lems[2]. [1]Reade, centre for rehabilitation and rheumatology, Amsterdam, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands, [3]University of Sydney, Sydney, Australia, [4]Glasgow Caledonian University, Glasgow, Scotland.

Background/Purpose: To evaluate associations between severity of knee osteoarthritis (OA) on MRI and treatment outcome in knee OA patients treated with exercise therapy.

Methods: Ninety-five participants with knee OA in a 12-week exercise program had obtained 3.0 Tesla MRI scans of the knee joint, prior to treatment. MRI data were systematically assessed for OA severity of multiple features (cartilage loss, bone marrow lesions, osteophytes, effusion/synovitis, and meniscal abnormalities) according to the BLOKS scoring system. Regression analyses were performed to analyze associations between OA severity on MRI and outcome of exercise therapy, i.e. changes in activity limitations (WOMAC physical function; primary outcome), pain (NRS), and upper leg muscle strength, and treatment response (OMERACT-OARSI criteria).

Results: Improvements of on average 24%, 34%, and 21% in WOMAC physical function, NRS pain and upper leg muscle strength, respectively, after 12-week exercise therapy were found. Moderate-to-severe patellofemoral (PF) cartilage loss was significantly associated with less improvements in both activity limitations ($p=.01$) and upper leg muscle strength ($p=.04$), while moderate-to-severe PF osteophytes with less improvements in upper leg muscle strength ($p<.01$). Severity of other features on MRI were not found to be associated with treatment outcome.

Conclusion: Effectiveness of exercise therapy was found to be independent of OA severity on MRI, except for cartilage loss and osteophytes, both in the PF compartment. Our study suggests that all grades of OA severity on MRI can benefit from professionally supervised exercise therapy, although effects might be reduced in patients with advanced PF OA.

Ethnic Variations At Time Of Surgery and During Follow-Up In Patients Undergoing Total Knee Arthroplasty. Aparna Ingleshwar[1], Andrea Barbo[2], Glenn C. Landon[3], Sherwin J. Siff[3], Sofia De Achaval[4] and Maria E. Suarez-Almazor[5]. [1]The University of Texas, MD Anderson Cancer Center, Houston, TX, Houston, TX, [2]MD Anderson Cancer Center, Houston, TX, [3]St. Luke's Episcopal Health System, Houston, TX, [4]U.T. MD Anderson Cancer Center, Houston, TX, [5]University of Texas MD Anderson Cancer Center, Houston, TX.

Background/Purpose: Literature reports sizable improvements in pain and function in patients having undergone Total Knee Arthroplasty (TKA) procedure. However, significant disparities exist in the utilization of this procedure by racial groups. Hence, the aim of this study is to evaluate the role of race on TKA outcomes.

Methods: Patients were recruited from 2 orthopedic clinics. Outcomes measured included: i) WOMAC (Western Ontario and McMaster Universities Osteoarthritis Index) measuring pain, stiffness and function (higher scores=worse outcomes), ii) SF-36 measuring mental (MCS) and physical (PCS) health status. Scores at baseline, 6 and 24 months were generated and absolute change (Δ= Baseline score – 6/24 months score) was calculated. ANOVA was used to determine whether: scores at baseline, 6 and 24 months, independently, varied among the racial groups and; the absolute and percent change scores (at 6 and 24 months) varied among the racial groups. Multiple regression analysis was conducted to evaluate the association of race and other demographic characteristics with 6 and 24 months TKA outcomes; with and without controlling for baseline outcomes.

Results: 247 of 615 patients screened completed baseline of which 241 completed 6 months and 178 completed 24 months assessments. Of the 247; 162 (66%) were females, 114 (46%) were <65 years, 172 (70%) were White, 62 (25%) were African American and, 11 (4%) were Hispanic. Although African Americans compared to Whites had consistently greater pain and function WOMAC scores at all three time periods, this difference was statistically significant only pre-operatively (pain- 62 vs 52, $p<0.05$ and function- 62 vs 52, $p<0.05$). With respect to SF-36 scores: compared to Whites, Hispanics had significantly lower MCS scores (55 vs 48, $p<0.05$) only at 6 months, whereas, neither clinically nor statistically significant differences in PCS scores were observed between the two groups at any time period. In regards to absolute change: African Americans compared to Whites, experienced greater improvements in pain (Δ: 41 vs 33, NS) and function (Δ: 40 vs 20, $p<0.05$) which was not observed at 24 months. In spite of adjusting for age, gender, marital status, educational attainment and baseline outcomes; being Hispanic was still associated with lower MCS scores ($p=0.02$) at 6 months, and being African American was still associated with lower functional status at 24 months ($p=0.04$).

Conclusion: When compared to Whites, African American patients started out with a lower preoperative status. Yet, they achieved greater gains in pain and function than White patients, within 6 months. However, by 24 months these improvements leveled off such that no significant difference in change was observed between the two groups. Controlling for demographic characteristics and baseline outcomes, ethnicity was predictive of TKA outcomes such that; being Hispanic was associated with lower mental health at 6 months and being African American was associated with poorer functional status at 24 months. Further research is needed to explore potential behavioral and psychosocial determinants that explain reduced pain and functional outcomes in African American patients.

Relationships Between Clinical Outcome Measures and Gait Variables Before and After Total Hip Arthroplasty. Kharma C. Foucher[1] and Omar Behery[2]. [1]University of Illinois at Chicago, Chicago, IL, [2]Rush University Medical Center, Chicago, IL.

Background/Purpose: Inadequate clinical response in a substantial portion of total hip arthroplasty (THA) patients, [1] as well as gait deficits after THA [2] have been well-documented. However, the relationships between different types of outcome measures is not always obvious. A more detailed understanding of the relationships between clinical scores and gait variables could lead to new management strategies that would improve outcomes in both domains. The purpose of this study was to determine whether gait variables are related to clinical scores before or after THA, and whether changes in gait variables are related to changes in clinical scores.

Methods: From an IRB-approved repository, we identified 125 subjects (Age 61 $\pm$ 10 years; BMI 29 $\pm$ 5 kg/m^2; 62 Female, 63 Male) who had been evaluated before and 1 year after primary unilateral THA. Harris Hip Scores (HHS) were used to summarize clinical status (preop 57 $\pm$ 14, postop 91 $\pm$ 11). From standard gait analysis data, we selected 3D peak external hip moments and sagittal plane dynamic hip range of motion (HROM) from trials collected at each subject's self-selected normal walking speed. Pearson correlations revealed that speed was significantly correlated with several gait variables before or after surgery, and that change in speed was significantly correlated with change in HHS and gait variables ($R = 0.199$ to 0.660, p values ≤ 0.026). We therefore decided to use first order partial correlation coefficients to evaluate relationships between HHS and gait variables while controlling for speed.

Results: There were significant correlations between preop HHS and HROM ($R_{|speed} = 0.296$, $p = 001$), postop HHS and the peak external rotation moment ($R_{|speed} = 0.234$, $p=0.009$) and the change in HHS and the change in both HROM ($R_{|speed} = 0.252$, $p = 0.005$) and peak internal rotation moment ($R_{|speed} = 0.270$, $p = 0.002$). There were no other statistically significant relationships ($p \geq 0.158$).

Conclusion: To our knowledge, this is the first study linking specific gait variables to clinical outcome measures. After controlling for the relationship between walking speed and both clinical and gait variables, higher preop- and postop- clinical scores, or more clinical improvement, was associated with higher values of range of motion or hip rotational moments. Because the hip abductors play an important secondary role in maintaining rotational control during stance, we found the relationships between HHS and rotational moments particularly notable. It is possible that addressing subtle abductor dysfunction in the transverse plane could improve both gait and clinical outcomes for some patients. Future prospective studies, however, are needed to fully evaluate the time-course of clinical recovery and gait recovery.

Factors That Affect Tender and Swollen Joint Counts In Rheumatoid Arthritis. Christine L. Amity[1], Marisa Eckels[2], Kenneth N. Gold[3], Kelly A. Reckley[4], Niveditha Mohan[5], Stephen R. Wisniewski[6], Elizabeth A. Schlenk[7], Marc C. Levesque[7] and Terence W. Starz[8]. [1]Univ of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh Medical Center, Pittsburgh, PA, [3]Arthritis & Internal Medicine, Pittsburgh, PA, [4]University of Pittsburgh School of Medicine, Pittsburgh, PA, [5]Univ of Pittsburgh Arth Inst, Pittsburgh, PA, [6]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, [7]University of Pittsburgh, Pittsburgh, PA, [8]Arth & Internal Med Associates, Pittsburgh, PA.

Background/Purpose: Quantitative joint counts are used to determine rheumatoid arthritis (RA) disease activity and are increasingly important for routine clinical practice to optimize patient care. Several factors make quantitative joint assessments challenging. The purpose of this study was to determine how osteoarthritis (OA), fibromyalgia (FM), body mass index

(BMI), handedness and disease activity affect tender and swollen joint counts by examining their effects on the inter-rater reliability of tender and swollen joint counts in a usual care setting.

Methods: 72 RA patients (54 F, 18M) recruited from the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry underwent standardized 28-joint assessments performed by two registered nurses and two rheumatologists at a single clinic visit. A Manual Tender Point (TP) Survey to determine the presence of FM ($\geq$ 11/18 TPs) took place during the same visit. Hand X-rays within 1 year of the clinic visit were graded for the presence of OA by a blinded, independent rheumatologist. BMI and disease duration were obtained from registry data. Subjects were classified according to Clinical Disease Activity Index (CDAI) as being in remission-low (CDAI $\leq$ 10) or moderate-high (CDAI $>$ 10) disease activity. Intra-class correlations and 95% CIs were determined for tender and swollen joints, stratified by variables of interest.

Results: The overall agreement among raters was moderate for tender and swollen joints (ICC = 0.48 and ICC = 0.56, respectively). The agreement among raters for swollen joints was similar in subjects with and without OA, with disease duration $<$ or $\geq$ 3 years, with BMI $<$ or $\geq$ 30 and with remission-low or moderate-high disease activity (ICC = 0.17 to 0.56). For tender joints, agreement was also moderate between disease duration and BMI subgroups (ICC = 0.47 to 0.64). However there were significant differences in agreement for tender joints for subjects with OA versus without (ICC = 0.33 (0.12, 0.50) vs. ICC = 0.65 (0.55, 0.72), respectively), and for subjects in remission-low disease activity versus moderate-high (ICC = 0.13 (−0.03, 0.29) vs. ICC = 0.52 (0.39, 0.63), respectively).

Conclusion: Agreement between raters was only moderate for tender and swollen joint counts. The presence of OA and lower disease activity reduced inter-rater reliability significantly. These results indicate that new methods of assessing joint disease activity may be needed for many of the patients seen in usual care settings as opposed to clinical trials where subjects are generally younger, have less OA and higher levels of disease activity. Our future analyses will focus on the level of agreement between nurses and physicians, on the level of agreement at the individual joint level, and on multivariable analyses that incorporate all factors that may affect inter-rater agreement of tender and swollen joint counts.

Cardiovascular Diseases In Rheumatoid Arthritis: Can Early Treatment With Disease-Modifying Antirheumatic Drugs Alter The Risk? Rishi Desai[1], Jaya Rao[2], Richard Hansen[3], Gang Fang[2], Matthew Maciejewski[4] and Joel Farley[2]. [1]Brigham & Women's Hospital, Harvard Medical School, Boston, MA, [2]University of North Carolina, Chapel Hill, NC, [3]Auburn University, Auburn, AL, [4]Duke University, Durham, NC.

Background/Purpose: Atherosclerosis is known to be accelerated in rheumatoid arthritis (RA) patients resulting in an increased cardiovascular (CV) risk. Structural damage to joints occurs aggressively within the first few years of RA diagnosis, so it is possible that development of atherosclerosis may also be rapid during the early stages of RA. Little evidence exists on the association between use of disease-modifying antirheumatic drugs (DMARDs) and the risk of CV events in early RA patients. Our study evaluated this association in this previously understudied population.

Methods: A nested case-control study was conducted using data from a large US insurance claims database (2008–2010) representing commercial and Medicare supplemental plans. The population of interest was early RA patients, which included newly diagnosed RA patients with no medical claims indicating RA in the prior year. These patients were followed up for the outcome of a composite CV event including acute myocardial infarction, unstable angina, angina pectoris, chronic heart failure, other forms of chronic heart diseases, and cerebrovascular accident. Patients with the outcome were defined as cases on their event date. Twelve age-, sex-, and cohort entry month-matched controls were selected for each case using incidence density sampling. Seven mutually exclusive exposure categories were defined hierarchically: 1) no DMARD use, 2) past use of only non-biologic DMARDs, 3) current use of only non-biologic DMARDs, 4) past use of TNF-inhibitors, 5) current use of TNF- inhibitors, 6) past use of non-TNF biologics, and 7) current use of non-TNF biologics. Any use of these DMARDs in the period of 6 months prior to the event date was defined as current use and any use preceding that period was defined as past use. Duration of treatment was defined as a continuous variable representing cumulative days of use. Conditional logistic regression models were used to derive estimates for incidence rate ratios (IRR).

Results: Of the 15,951 RA patients of the base cohort, 466 cases of an incident CV event were identified during follow-up. Cases were matched with 5,592 controls. In our multivariate analyses adjusting for baseline factors as well as treatment history with medications, current use of TNF-inhibitors and current use of non-biologic DMARDs were found to be associated with a reduced risk of an incident CV events compared to no DMARD use (IRR 0.62 95% CI 0.40–0.98 & IRR 0.66 95% CI 0.48–0.89 respectively). Duration of use for both TNF-inhibitors and non-biologic DMARDs was found to be associated with a reduced risk of CV events in a linear manner (for each additional month of treatment, IRR 0.95 95% CI 0.90–1.00 & IRR 0.97 95% CI 0.94–1.00 respectively).

Conclusion: Treatment with TNF-inhibitors and non-biologic DMARDs may help in reducing the risk of incident CV events in patients newly diagnosed with RA compared to no treatment with DMARDs.

Table. Adjusted incidence rate ratios for a cardiovascular event in rheumatoid arthritis patients using various DMARDs

Exposure	n (cases)	n (controls)	Adjusted* IRR (95% CI)
DMARD use indicator			
No DMARD use	79	775	Ref.
Current TNF-I	39	518	0.62 (0.40–0.98)
Current nbDMARD	302	3879	0.66 (0.48–0.89)
Current other biologic	14	57	1.93 (0.96–3.87)
Past TNF-I	1	28	0.24 (0.03–1.85)
Past nbDMARD	28	323	0.68 (0.40–1.13)
Past other biologic	3	12	2.32 (0.61–8.84)
DMARD use duration indicators			
Each additional month of cumulative TNF-I use	–	–	0.95 (0.90–1.00)
Each additional month of cumulative nbDMARD use	–	–	0.97 (0.94–1.00)
Each additional month of cumulative other biologics use	–	–	1.06 (0.99–1.13)

Physical Activity Behavior In Patients With Arthritis. Gustavo J. Almeida and Sara R. Piva. University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: The physical activity (PA) guidelines issued by the US Health and Human Services (HHS) recommend that adults with arthritis should perform at least 150 min/week of PA at moderate or higher intensity spread in bouts of at least 10 minutes of PA. Although it has been extensively discussed that physical inactivity is a problem among adults with arthritis, relatively little is known about the pattern of their daily activities measured in real-time by an accelerometer-based monitor. The purposes of this study were (1) to characterize the time that adults with arthritis spent in daily activities of various intensity levels and (2) to examine whether adults with arthritis meet the PA recommendations from the HHS guidelines.

Methods: Adults with rheumatoid arthritis (RA) and with end-stage knee osteoarthritis post total knee replacement (TKA) participated in this cross-sectional study. The SenseWear Armband (Bodymedia, Pittsburgh, PA) was used to measure PA. Subjects wore the Armband for a period of 7 days, 24 hours a day. PA was characterized as the time spent per day in sedentary (0 to 0.99 metabolic equivalent [MET]), light (1 to 1.99 MET), lifestyle (2 to 2.99 METs) and moderate (3 METs and above) intensity activities. We also calculated the number of 10-minute bouts of moderate activity per day for each subject. Subjects who performed 15 bouts of moderate PA per week were considered to meet the HHS guidelines. Disability in subjects with RA was measured using the Health Assessment Questionnaire (HAQ) and in subject post TKA it was measured by the Western Ontario and McMaster

Universities Arthritis Index (WOMAC). Descriptive statistics were run for the demographics, biomedical and PA data.

Results: Complete data were obtained in 68 subjects post TKA and 100 subjects with RA. Descriptive statistics are depicted in the Table. In general, our sample consisted of mainly females who were well educated. Subjects post TKA appeared to be older and heavier than subjects with RA. In general, both groups presented with mild to moderate disability. The results indicated that around 16 hours a day were spent in sedentary, 3 hours in light, 2 hours in lifestyle, and 30 minutes in moderate activities. From the 30 minutes in moderate activity dispersed throughout the day, subject performed only 1 bout of 10 minutes of continuous moderate activity per day. Only 12% of subjects with RA and 12% of subjects post TKA met the HHS guidelines. Subjects post TKA had similar pattern of activities in comparison to subjects with RA.

Table. Demographic and biomedical characteristics and physical activity behavior of the study sample. Data are presented as mean ± standard deviation, unless otherwise indicated.

The Association Of Worsening Structural Disease With Trajectories Of Decline In Physical Function In Knee Osteoarthritis: Results From Two Cohort Studies. Daniel K. White[1], Tuhina Neogi[1], Jingbo Niu[1], Uyen Sa D.T. Nguyen[1], David T. Felson[1], Barton L. Wise[2], C.E. Lewis[3], Michael C. Nevitt[4], James Torner[5] and Yuqing Zhang[1]. [1]Boston University School of Medicine, Boston, MA, [2]UC Davis School of Medicine, Sacramento, CA, [3]University of Alabama, Birmingham City, Brimingham, AL, [4]University of California, San Francisco, San Francisco, CA, [5]University of Iowa, Iowa City, Iowa City, IA.

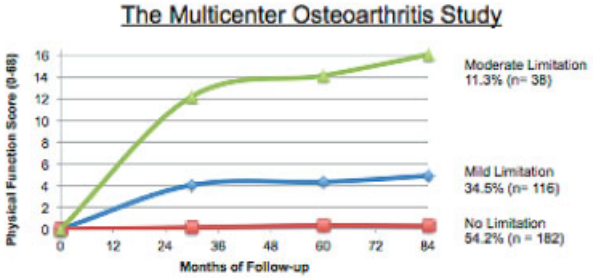
Background/Purpose: Knee osteoarthritis (OA) is the most common cause of functional limitation in older adults. It is not known, however, what proportion progress to a trajectory of functional decline and to what extent worsening of structural damage is associated with decline, particularly among initially well-functioning adults. We examined trajectories of physical function in adults with or at high risk of knee OA who started without functional limitation, and examined the relation of structural worsening to these trajectories.

Methods: We utilized data from the Osteoarthritis Initiative (OAI) and the Multicenter Osteoarthritis (MOST) to describe function trajectories over 48- and 84-months, respectively. Physical function was measured with the WOMAC physical function (PF) subscale (0–68) for each knee in OAI and each person in MOST. We included only participants with WOMAC-PF=0 (i.e., no functional limitation) at baseline. We used a group-based method (Proc Traj) to identify homogeneous clusters of developmental trajectories in MOST and OAI. We then examined the relation of worsening structural disease to the trajectory of subsequent functional decline. Since MOST had few high-functioning participants, we conducted this analysis in OAI only. Structural worsening was defined as any increase in Kellgren and Lawrence (KL) or joint space narrowing grade, or a new total knee replacement from 0- to 24-months. We examined the association of worsening structural disease (0- to 24-months) with trajectories of subsequent physical function (24- to 72-months) using multinomial logistic regression, adjusting for age, sex, body mass index, and baseline KL grades in OAI.

Results: Our study sample comprised 3,320 knees in OAI (age 63.3 ± 9.2 yrs, 53.4% female, BMI 27.4 ± 4.4 at 24-month visit) and 336 people in MOST (age 61.3 ± 8.0 yrs, 53.9% female, BMI 29.6 ± 4.8 at the baseline visit). We identified 3-trajectories in OAI and MOST (Figures). For OAI, the 1st trajectory, no limitation, had stable WOMAC-PF, with an average value < 1 at the last follow-up and included 65.6% of all knees. The 2nd trajectory, mild limitation, progressively worsened 1.0 unit/year to 4/68 at the last follow-up and included 24.8%. The 3rd trajectory, moderate limitation, progressively worsened 3.4 units/year to 13.7/68 at the last follow-up and included 6.3%. We observed similar trajectories in the MOST study. Worsening structural disease was associated with 1.6 to 1.8 times the odds of a trajectory of worsening function compared with those with no change in OAI (Table).

	No change in structural disease* [% (n)]	Worsening structural disease* [% (n)]	Adjusted** OR [95% CI]
No Limitation Knees = 2178	95.7 (2085)	4.3 (93)	1.0 [Reference]
Mild limitation Knees= 822	90.5 (744)	9.5 (78)	1.6 [1.0, 2.5]
Moderate limitation Knees= 320	87.8 (281)	12.2 (39)	1.8 [1.3, 2.5]

* Structural disease change was any worsening in KL grade, joint space narrowing, or a new TKR from the 0 to 24 month OAI visit. Functional trajectories started at the 24 month OAI visit.
**Adjusted for age, sex, Body Mass Index, and baseline KL grade



Conclusion: In initially well-functioning people with or at high risk of knee OA, a minority has progressive worsening of physical function, with worsening structural disease contributing to risk of this decline. Such findings

highlight the importance of addressing methods to maintain and improve function even among those with knee OA who are well-functioning.

Comprehensive Behavioral Intervention Compared To Standard Of Care Exercise Program After Total Knee Arthroplasty: A Pilot Randomized Trial. Sara R. Piva, Maria Beatriz Catelani and Gustavo J. Almeida. University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Although the overall outcome of total knee arthroplasty (TKA) is favorable, surgery alone fails to resolve many of the substantial functional limitations and physical inactivity that began long before the surgery. To improve these persistent limitations, exercise programs need to be performed at doses sufficiently high to promote sizable improvements in physical function (PF). In addition, physical activity (PA) promotion should be part of the rehab program. The aim of this study was to determine the effectiveness of comprehensive behavioral intervention (CBI) - that uses intense exercises and promotes activity participation - compared to a standard of care (SC) exercise program to improve PF and PA in patients after TKA.

Methods: Double blinded pilot randomized clinical trial. Patients who underwent unilateral TKA 3 – 6 months prior were assigned into 2 groups, the CBI or SC. Subjects in both groups completed 12 weeks of supervised exercise followed by 12 weeks of exercise program. Clinical outcomes were collected prior to (baseline) and after intervention (6 months). Self-reported PF was measured by the Western Ontario and McMaster Universities Arthritis Index- PF score (WOMAC-PF) and the PF subscale of the RAND-36. Patient-identified problem areas in daily functioning were measured by the Canadian Occupational Performance Measure (COPM), which considers both the importance and the satisfaction with the performance areas. Performance-based PF was measured by the chair-raise test, gait velocity, and the stair climbing test. An objective accelerometer-based monitor was used to quantify PA during light (2 to 2.99 metabolic equivalents – METs) and moderate intensities (above 3 METs). Changes between groups were compared using independent sample t-test or Wilcoxon according with data distribution.

Results: Sample included 44 subjects (70% female, age 68 ± 0.98 years, and BMI 30.0 ± 0.6 Kg/m2). Results are reported in the Table. Both groups reported improved PF. PF measured by the RAND-36 was statistically significant larger in the CBI than in the SC, whereas group differences in the WOMAC- PF did not reach significance. Both groups improved performance and satisfaction in the COPM. Subjects in the CBI group significantly improved in the Stair Climb test compared to the SC group. Group differences in gait velocity and chair-raise test were not significant. While not significant, subjects in the SC group decreased PA while the ones in the CBI increased PA.

Table Baseline and 6-month physical function and physical activity outcomes in the CBI and SC groups. Data represent mean ± SD or median (Q25; Q75).

	Group	Baseline	6 months	Change (6 mo – baseline)	Percentage Change	p-value
WOMAC – Physical Function*	SC	17.68 ± 2.21	12.8 ± 2.42	−5.35 ± 2.09	−30%	0.503
	CBI	19.09 ± 1.99	11.42 ± 1.50	−7.05 ± 1.34	−37%	
RAND-36 – Physical Function**	SC	66.14 ± 3.97	70.25 ± 5.41	6.75 ± 3.86	10%	0.037
	CBI	56.14 ± 4.80	76.05 ± 3.74	16.58 ± 2.30	30%	
COPM – Performance**	SC	36.38 ± 2.71	59.74 ± 5.74	23.18 ± 4.48	64%	0.360
	CBI	34.27 ± 3.16	63.34 ± 4.70	29.0 ± 4.39	85%	
COPM – Satisfaction**	SC	27.63 ± 3.26	56.70 ± 6.78	28.62 ± 5.50	104%	0.176
	CBI	22.36 ± 2.74	61.93 ± 5.37	39.15 ± 5.27	175%	
Chair-raise Test (sec)	SC	13.16 ± 0.68	13.74 ± 1.67	0.68 ± 1.53	5%	0.444
	CBI	14.26 ± 0.81	11.97 ± 0.63	−1.69 ± 0.40	−12%	
Gait Velocity (m/sec)	SC	1.106 ± 0.38	1.183 ± 0.06	0.06 ± 0.04	6%	0.679
	CBI	1.037 ± 0.04	1.147 ± 0.04	0.08 ± 0.03	8%	
Stair Climbing Test (sec)	SC	15.5 ± 0.997	15.59 ± 1.66	0.07 ± 1.47	0.5%	0.006
	CBI	19.03 ± 1.54	14.19 ± 0.98	−4.43 ± 1.00	−23%	
Light Intensity PA (min/d)	SC	123.5 (82.5; 176.8)	83.5 (42.0; 158.0)	−5.5 (−62.8; 14.0)	−5%	0.167
	CBI	99.5 (44.8; 157.5)	124.0 (61.0; 142.0)	12.0 (−26.0; 21.0)	12%	
Moderate Intensity PA (min/d)	SC	38.5 (18.3; 70.8)	33.0 (17.3; 61.8)	−1.0 (−25.3; 21.8)	−3%	0.999
	CBI	24.5 (9.3; 47.8)	34.5 (12.5; 47.7)	4.5 (−23.5; 12.0)	18%	

*Lower scores represent better function; ** Higher scores represent better function

Conclusion: Subjects in the CBI group experienced larger improvements in PF as measured by the RAND-36 and the stair climbing test. Although we observed a trend towards larger changes in COPM-satisfaction and light intensity PA in the CBI group, the negative results may be due to the small sample of this pilot study. Results indicate that the CBI may be a promising intervention for patients post TKA.

The Validity Of The Satisfaction With Appearance Scale and The Brief Satisfaction With Appearance Scale For Patients With Limited and Diffuse Systemic Sclerosis. Rina M. Sobel-Fox[1], Sarah D. Mills[1], Shadi Gholizadeh[1], Erin L. Merz[1], Philip J. Clements[2], Suzanne Kafaja[2], Vanessa L. Malcarne[3], Dinesh Khanna[4] and Daniel E. Furst[2]. [1]SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, CA, [2]David Geffen School of Medicine, UCLA, Los Angeles, CA, [3]Department of Psychology, San Diego State University, Psychology, San Diego, CA, [4]University of Michigan Medical School, Ann Arbor, MI.

Background/Purpose: The Satisfaction with Appearance Scale (SWAP) was originally developed to evaluate body image dissatisfaction (BID) among burn victims, and was later adapted for use in patients with systemic sclerosis (SSc). A short form of the measure (Brief-SWAP) was derived from the full version. Both measures yield factor-analytically derived subscales. Although both versions have been validated for use in SSc, their factor structures have never been compared for use with patients with limited versus diffuse SSc. Because these groups may have very different appearance issues, the purpose of the current study was to determine the comparability of the factor structures of 1) the SWAP and 2) the Brief-SWAP for patients with limited versus diffuse SSc.

Methods: Participants were adults participating in the UCLA Scleroderma Quality of Life Study with rheumatologist-diagnosed limited (n = 103) or diffuse (n = 82) SSc. The 14-item SWAP evaluated BID, and the six items that comprise the Brief-SWAP were taken from the full measure. Prior research has shown that the SWAP has four subscales evaluating Social Distress, Facial Features, Non-facial Features, and Perceived Social Impact; the Brief-SWAP has two subscales evaluating Social Discomfort and Dissatisfaction with Appearance. Multiple group confirmatory factor analysis was used to determine if the factor structures of the SWAP and the Brief-SWAP were the same for individuals with limited and diffuse SSc. Both statistical (chi squared [χ^2]), and descriptive (RMSEA, CFI, SRMR) indicators of model fit were considered. For RMSEA and SRMR, values $< .08$ and $< .05$ were considered to indicate acceptable and good model fit, respectively. For CFI, values $> .90$, and $> .95$ were considered to indicate acceptable and good model fit, respectively. A model was determined to fit well if at least two of the three descriptive fit indices met the criteria for acceptable model fit.

Results: For the 14-item SWAP, the four factors satisfactorily fit the data from persons with diffuse SSc (χ^2 [71, N = 82] = 120.271, $p < .001$; RMSEA = .092, CFI = .923, SRMR = .075), but not from persons with limited SSc (χ^2 [71, N = 103] = 199.547, $p < .001$; RMSEA = .133, CFI = .873, SRMR = .070), suggesting that the commonly used subscales might not be informative for persons with limited disease. In contrast, for the Brief-SWAP, fit indicators supported the two hypothesized factors for persons with either limited or diffuse disease. Interestingly, the variance in scores on the two factors was greater for persons with limited SSc. This indicated that severity of BID, as measured by the Brief-SWAP, varied more widely in persons with limited disease, versus those with diffuse disease, in the present sample.

Conclusion: The four-factor structure of the 14-item SWAP may not evaluate BID among patients with limited SSc as well as it does among patients with diffuse SSc. Conversely, the two-factor model of the Brief-SWAP, which evaluates Social Discomfort and Dissatisfaction with Appearance, was found to function equivalently across disease subtypes when measuring BID. Therefore, the two-factor structure of the Brief-SWAP can be confidently used to measure body image dissatisfaction in patients with either limited or diffuse SSc.

ACR Concurrent Abstract Session
Fibromyalgia, Soft Tissue Disorders and Pain: Diagnosis and Disease Epidemiology
Sunday, October 27, 2013, 4:30 PM–6:00 PM

838

Recommendations for the Classification and Diagnosis of Fibromyalgia Syndrome Provided By Independently Developed Evidence-Based Interdisciplinary Guidelines Spanning Three Continents. Mary-Ann Fitzcharles[1], Yoram Shir[1], Jacob N. Ablin[2], Dan Buskila[3], Howard Amital[4], Peter Henningsen[5] and Winfried Häuser[5]. [1]McGill University Health Centre, Montreal, QC, [2]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [3]Ben-Gurion University, Beer-Sheva, Israel, [4]Department of Medicine B, Center for Autoimmune Diseases, Sheba Medical Center, Tel-hashomer, Israel, [5]Klinikum Saarbrücken, Saarbrücken, Germany.

Background/Purpose: Fibromyalgia (FM), often disputed and challenged, has emerged as a clear cluster of symptoms and co-morbidities, characterized by subjective complaints without physical or biomarker abnormality. Areas of debate include classification, value of diagnostic label, tender point examination, and best clinical care setting. Recommendations in recent guidelines addressing these issues were examined for consistencies and differences.

Methods: Systematic searches from January 2008 to February 2013 of the US-American National Guideline Clearing House, the Scottish Intercollegiate Guidelines Network, Guidelines International Network and Medline for evidence-based guidelines for the management of FM were conducted. Inclusion criteria required that the guideline was commissioned by a scientific organisation, guideline group was interdisciplinary, systematic search strategy was outlined, criteria for classification of evidence and recommendations were stated and the process for establishing recommendations was outlined. Only guidelines addressing FM were accessed.

Results: The literature search yielded 24 citations (19 excluded for duplication, 1 without criteria for assigning evidence, 1 not scientific society commissioned) with three guidelines independently developed in Canada, Germany and Israel included. Recommendations concerning definition, classification, clinical diagnosis and general principles of care were based predominantly on expert consensus, with limited literature evidence. All three countries justified the need for guidelines based on high FM prevalence, controversies surrounding diagnosis/management, reduced health-related quality of life and high health care costs with unanimity for the following parameters: FM was defined by the 1990 ACR classification criteria; FM should be clinically diagnosed by a typical cluster of symptoms, following a composite history, physical examination, and selected laboratory tests, to exclude another somatic disease; diagnosis confirmation with 2010 ACR diagnostic criteria if desired; importance of assigning a diagnostic label; education regarding the nature of the disorder to include a biopsychosocial model, planned treatment strategy and expected outcome; recognition that FM is a continuum disorder; coexistence with another medical (e.g.) rheumatic condition and mental disorder. Differences between guidelines were reflected in the concept of FM as representing a clinical construct of pain and other symptoms, a functional somatic syndrome, or a central hypersensitivity syndrome identified by each, tender point examination replaced by examination for soft tissue tenderness by 2, care in the primary care setting by 2, and 1 discouraging focus on a triggering event.

Conclusion: Guidelines from three continents showed remarkable consistency regarding the clinical concept of FM, acknowledging the need to provide confidence in a clinical diagnosis, importance of assigning a diagnostic label, and acceptance that FM is neither a distinct rheumatic nor mental disorder, but a cluster of symptoms spanning a broad range of medical disciplines.

A Paradigm Change for Treatment Strategies for Fibromyalgia Syndrome Reflected By Recommendations of Recent Evidence-Based Interdisciplinary Guidelines Developed Independently in Three Countries. Jacob N. Ablin[1], Dan Buskila[2], Howard Amital[3], Mary-Ann Fitzcharles[4], Yoram Shir[4], Peter Henningsen[5] and Winfried Häuser[5]. [1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Ben-Gurion University, Beer-Sheva, Israel, [3]Department of Medicine B, Center for Autoimmune Diseases, Sheba Medical Center, Tel-hashomer, Israel, [4]McGill University Health Centre, Montreal, QC, [5]Klinikum Saarbrücken, Saarbrücken, Germany.

Background/Purpose: Although the ideal treatment for fibromyalgia (FM) remains elusive, the medical community requires direction in the care of these patients. The literature however abounds with copious reports of various treatments that drive health-care costs, but provide ever increasing confusion for patients and physicians. We have compared treatment recommendations for FM provided by recent evidence-based guidelines.

Methods: Systematic searches from January 2008 to February 2013 of the US-American National Guideline Clearing House, the Scottish Intercollegiate Guidelines Network, Guidelines International Network and Medline for evidence-based interdisciplinary guidelines on the management of FM were conducted. Inclusion criteria required that the guideline was commissioned by a scientific organisation, the guideline group was interdisciplinary, the systematic search strategy was outlined, criteria and process for classification of evidence and recommendations were stated.

Results: Three evidence-based interdisciplinary guidelines for the treatment of FM in Canada, Germany and Israel fulfilled inclusion criteria. All three guidelines emphasized a patient-tailored approach according to key symptoms. Non-pharmacologic strategies were the major positive first choice recommendation for all with emphasis on aerobic exercise, cognitive behavioural therapy and multicomponent therapy (exercise and psychological). Acupuncture, hypnosis/guided imagery and Tai Chi were recommended by the German and Israeli guideline, whereas the Canadian guidelines indicated only short term benefits for acupuncture, and categorized hypnosis/guided imagery and Tai Chi as psychological and exercise interventions respectively with some evidence for effect, but none were specifically recommended. Pharmacologic treatments were less enthusiastically recommended by all three groups. With the qualifier that drugs provide only modest effect, the Canadian and Israeli guidelines gave strong recommendation for the anticonvulsants (gabapentin and pregabalin) and serotonin noradrenaline reuptake inhibitors, whereas these drug categories received only weak recommendation by the German guideline. All groups cautioned about the side effects of drugs manifesting as symptoms of FM. Use of strong opioids was discouraged by all, with the Israeli and German guideline providing specific negative recommendation for many other drug categories including non-steroidal agents, systemic steroids, benzodiazepines, thyroid hormone replacement, amongst others. Although not providing specific negative treatment recommendations, the Canadian guidelines cited lack of evidence to support many treatments which would therefore constitute "off-label" use.

Conclusion: Recent evidence-based interdisciplinary guidelines concur on the importance of treatments tailored to the individual patient and further emphasize the necessity of self-management strategies which include exercise and psychological techniques. Contrary to popular perception, drug treatments were recommended with reservation regarding both efficacy and side effect profile.

Fibromyalgia, Somatic Symptoms, and Mental Illness In View Of The 2013 Diagnostic and Statistical Manual Of Mental Disorders. Frederick Wolfe[1], Brian T. Walitt[2], Robert S. Katz[3] and Winfried Häuser[4]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Washington Hospital Center, Washington, DC, [3]Rush Medical College, Chicago, IL, [4]Klinikum Saarbrücken, Saarbrücken, Germany.

Background/Purpose: Pain research conceptualizes fibromyalgia (FM) as a Physical or Somatic Symptom Disorder (PSD or SSD). However, the 2013 Diagnostic and Statistical Manual of Mental Disorders (DSM-5) identifies an SSD mental disorder (DSM-SSD) when there are findings of "positive symptoms (distressing somatic symptoms + excessive thoughts,

feelings, and behaviors in response to these symptoms)," whether or not the symptoms are "medically explained." FM is defined on the basis of somatic symptoms and concerns arose that DSM criteria would turn FM into a mental disease. We examined DSM mental illness in patients with rheumatoid arthritis (RA), including those with FM. We utilized RA patients to provide a large subject base and appropriate control subjects, and to avoid self-selection for severity.

Methods: We used the Patient Health Questionnaire-15 (PHQ-15), a validated assessment of somatic symptom severity, to operationalize the DMS-5 SSD definition. For mental illness Definition 1 a DSM-SSD positive individual had to have at least 2 "severe" symptoms ("bothered a lot") and a total PHQ-15 somatic symptom severity classification of "medium" (10–14) or "high" (>=15). A second, more restrictive definition (Definition 2) required the total PHQ-15 symptom severity classification to be high (>=15). We diagnosed FM according to the survey modified 2010 FM criteria.

Results: Of the 4718 RA patients, 22.1% were definition 1 DSM-SSD positive and 6.7% definition 2 positive (Table 1). When FM (+) patients were considered, 68.8% and 28.8% satisfied mental illness 1 and 2 definitions. 19.8% of RA patients also satisfied ACR2010 criteria. The probability of satisfying the mental illness definitions increased as a function of polysymptomatic distress (fibromyalgianess) (Figure 1). Persons who met either definition had more abnormal scores for all severity and outcome measures, including functional status, pain, quality of life, household income, etc.

	FM (−) (80.2%)	FM (+) (19.8%)	All
Mental illness 1 (%)	10.7	68.8	22.1
Mental illness 2 (%)	1.2	28.8	6.7
PHQ-15	5.6	12.3	6.9
Polysymptomatic distress	63.0	19.3	8.7

Conclusion: There are serious problems of face validity when mental illness is defined on the basis of "excessive thoughts, feelings, and behaviors" in response to somatic symptoms, as somatic symptoms form the basis of rheumatic diseases. In addition, somatic symptoms increase in number and severity with increasing pain, and no clear direction of causality can be discerned. If somatic symptoms are to be expected in rheumatic diseases, then it all comes down to "excessive", a term that cannot be reliably or validity defined. The high rates mental illness identified by the DSM-SSD definition in our study suggest the mental illness classification is invalid.

The Prevalence Of Fibromyalgia In The General Population – a Comparison Of The ACR 1990, 2010 and Modified 2010 Classification Criteria. Gareth T. Jones[1], Marcus Beasley[1], Fabiola Atzeni[2], Elisa Flüβ[1], Piercarlo Sarzi-Puttini[2] and Gary Macfarlane[1]. [1]University of Aberdeen, Aberdeen, United Kingdom, [2]Rheumatology Unit, L. Sacco University Hospital, Milan, Italy.

Background/Purpose: In 1990 the ACR published criteria for the classification of fibromyalgia (FM), based on widespread pain and tenderness. In 2010 new criteria were published which were based on widespread pain and somatic symptoms and explicitly excluded individuals that a clinician considered had a disorder that would otherwise explain the pain. Then, in 2011, the 2010 criteria were modified (hereafter referred to as the 2010m criteria) to allow their use in research, without the requirement of a clinical history or examination. To our knowledge, there have been no studies investigating the population prevalence of FM in a manner that allows comparison between the three sets of criteria. The aim of the current study was to determine the prevalence of FM in the general population and, specifically, to compare differences in prevalence, when using different criteria.

Methods: In the UK, 96% of the population are registered with a general practitioner providing an ideal population sampling frame. Postal questionnaires were sent to 4500 randomly selected individuals, aged >=25yrs, registered with a general practitioner in the Grampian region, Scotland (UK). The questionnaire included questions on pain and somatic symptoms, and on prior rheumatological diagnoses: osteoarthritis, rheumatoid arthritis, osteoporosis, SLE, scleroderma, ankylosing spondylitis and gout.

All participants with chronic widespread pain, or who met the 2010m FM criteria, were invited to attend a clinical research facility, as were a random sample of participants who did not meet these criteria. At the clinic, participants completed an additional questionnaire; and underwent a full examination by a rheumatologist, including clinical history and tender-point examination.

Using the information collected it was possible to classify participants according to each of the ACR 1990, 2010 and 2010m FM criteria. The population prevalence of each was determined by weighting back to the initial general practice sample, by the inverse of the sampling fraction.

Results: 1604 (36%) participants returned a questionnaire, 269 participants were invited, of whom 104 (39%) attended the clinical examination. Of these, 32 met at least one of the FM criteria (31%). Weighting back to the general population, the prevalence of FM using the ACR 1990, 2010 and 2010m criteria was 1.9% (95%CI: 0.8–3.1%); 1.2% (0.3–2.1%); and 5.3% (4.7–6.0%), respectively. The gender ratio (female: male) varied across criteria from 11.2 (1990) to 6.7 (2010) and 2.3 (ACR 2010m) and 56%, 29% and 48% of participants who met these criteria, respectively, also reported the prior diagnosis of another rheumatological condition.

Conclusion: This is the first study to produce population estimates of the prevalence of FM using the three different ACR classification criteria. Prevalence estimates are considerably higher, and a greater proportion of men are classified as having FM with the 2010m criteria in comparison to either of the criteria requiring clinician input (1990 and 2010). Further, depending on which set of criteria are employed, between one-third and one-half of participants who meet the criteria have coexistant other rheumatological disorders.

A Cytokine/Chemokine Multiplex Assay That Is Sensitive and Specific For Fibromyalgia Compared To Controls, Systemic Lupus Erythematosus, and Rheumatoid Arthritis. Daniel J. Wallace[1], Igor Gavin[2], Oleksiy Karpenko[2] and Bruce S. Gillis[2]. [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]University of Illinois College of Medicine at Chicago, Chicago, IL.

Background/Purpose: Fibromyalgia (FM) is a chronic pain and fatigue syndrome that affects about 6 million adults in the United States. The clinical diagnosis of FM has been based on subjective evaluations paired with the exclusion of other diseases. No confirmatory objective laboratory benchmark has been available. To investigate potential FM biomarkers, we previously determined whether cytokine/chemokine production is altered in FM patients by comparing their in vitro peripheral blood mononuclear cell (PBMC) cytokine/chemokine responses to mitogenic activators with matched healthy controls. A multiplex immunoassay (Luminex™) was used on PBMC supernatants. Based on a larger multiplex array exploratory pilot study, a custom panel of antibody-conjugated beads for eight cytokines/chemokines (IL-5, IL-6, IL-8, IFN-g, IL-10, MIP-1a, MIP-1b, MCP-1) was used. This panel was 93% sensitive for the diagnosis of FM. The current study was designed to address the specificity of the panel for FM vs SLE and RA.

Methods: After IRB informed consent, a total of 25 SLE and 25 RA patients, fulfilling ACR criteria, were recruited and compared with 101 FM patients and 91 controls. Peripheral blood was harvested and PBMC isolated by differential centrifugation on Ficoll. These cells were cultured overnight in medium alone or in the presence of mitogenic activators; PHA or PMA in combination with ionomycin. The supernatant cytokine/chemokine concentrations were determined using the Luminex multiplex immunoassay bead array technology. Data was ported to "R" statistical software for appropriate analysis. The standard curve was fitted with a 5-PL model and the concentrations of the analytes were quantified according to this curve. The two sided t-test was used to test whether the mean concentrations of each chemokine and cytokine were the same in every group. Each patient's profile was scored, as previously described, and ported to statistical software for appropriate analysis.

Results: Compared to FM, cytokine/chemokine levels from stimulated RA and SLE PBMC supernatants were significantly different ($p<0.002$). The concentrations of all cytokines except for IL-8 in RA were significantly lower in FM than in SLE or RA at 1% false discovery rate. In SLE and RA, 68% and 76%, respectively, tested negative for the FM profile. This was lower than

healthy controls at 89%. Concomitant corticosteroid use might explain this since in steroid naïve SLE and RA, the negative FM profile increased to 86% and 83%, respectively. There was no statistically significant difference at the 95% confidence level between the concentrations of chemokines and cytokines in SLE and RA patients except for MIP-1b ($p=0.042$), which was higher in the SLE cohort.

Conclusion: These data demonstrate that lowered cytokine/chemokine profiles from stimulated PBMC may represent a biomarker that is relatively sensitive and specific for FM compared to SLE and RA. It remains unclear if these differences are directly related to the pathogenesis of FM or if subsequent measurements will be useful in longitudinal outcome studies. This test may represent the first objective laboratory marker for an otherwise enigmatic and clinically defined rheumatic disease.

Endogenous Pain Modulation In The Ehlers-Danlos Syndrome, Hypermobility Type. Inge De Wandele. Ghent University, Ghent, Belgium.

Background/Purpose: The Ehlers-Danlos Syndrome (EDS) is the most prevalent heritable connective tissue disorder. More than 90% of individuals are classified as having the hypermobility type (EDS-HT). Patients typically demonstrate generalized severe joint hypermobility, associated with recurrent joint dislocations. Although pain is the number one complaint in EDS-HT, causing severe disability in daily life, the underlying pain mechanisms and the nature of pain are unknown. Therefore, this study aims to assess the nature of pain (nociceptive / neuropathic / dysfunctional pain) and the endogenous pain modulation in EDS-HT.

Methods: Patients with EDS-HT were compared with a healthy control group (CON), and a fibromyalgia group (FM). The latter was included, because FM has been the subject of a lot of research regarding endogenous pain modulatory deficits, and because of the large symptomatic overlap with EDS-HT. All patients filled out a Margolis Pain Diagram, the Pain Detect Questionnaire (PDQ) and questionnaires regarding cognitive-emotional sensitization (Pain Catastrophizing Scale - PCS, Hospital Anxiety and Depression Scale - HADS, Tampa Kinesiophobia Scale - TSK, Pain Vigilance and Awareness Scale – PVAQ). After a thorough anamnesis regarding medical history, the somatosensory system was evaluated. Thermal quantitative sensory testing was performed on the right trapezius and left tibialis anterior to determine the sensory thresholds for cold and warmth, and the pain thresholds for cold and heath. Next, pressure pain thresholds were examined on the right trapezius and quadriceps. Further, endogenous pain modulation was assessed by evaluating wind-up (WU), conditioned pain modulation (CPM) and exercise induced analgesia (EIA). WU was assessed by applying 10 pressure stimuli (at the pressure pain threshold) on the trapezius and quadriceps and by evaluating the subsequent increase in VAS score. CPM was induced by immersing the left hand into a 46° water bath and evaluating the subsequent decrease in VAS score (for a pressure stimulus at the pressure pain threshold). EIA was assessed by comparing the pressure pain threshold before and after a submaximal bicycle test (Aerobic Power Index Test).

Results: Regarding the nature of pain, the EDS-HT group showed characteristics of neuropathic pain, with 89.5% of patients being classified by the PDQ as having possible or probable neuropathic pain. In addition, the EDS-HT group also showed characteristics of dysfunctional pain. The Margolis pain diagram showed a more widespread pain in patients with EDS-HT ($p<0.001$). WU at the trapezius was significantly higher in patients with EDS-HT and FM compared to controls ($p=0.046$). EIA was significantly reduced at the quadriceps in EDS and FM ($p=0.041$). By contrast, CPM did not significantly differ between groups ($p=0.903$). Cognitive emotional sensitization was present in the EDS-HT group (significantly higher scores on the PCS, HADS and TSK compared to controls; $p<0.01$).

Conclusion: Patients with EDS-HT suffer from nociceptive, as well as neuropathic and dysfunctional pain. The endogenous pain modulation is disrupted by a reduced pain inhibition, which is comparable to FM.

Level and Determinants Of Health Related Quality Of Life In Childhood-Onset Systemic Lupus Erythematosus. Jordan T. Jones[1], Shannen L. Nelson[2], Janet Wootton[3], Brianna Liberio[4], Alexandria J. Greenler[1], Jennifer L. Huggins[1], Laura E. Schanberg[3] and Hermine I. Brunner[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Duke University Medical Center, Durham, NC, [4]University of Cincinnati College of Medicine, Cincinnati, OH.

Background/Purpose: Childhood-onset lupus (cSLE) is a chronic autoimmune disease and its effect on health-related quality of life (HRQoL) has not been systematically established, nor does certainty exist around what cSLE factors most impact HRQoL. Physician assessment of disease activity and disease activity measures exist, but are not inclusive. Chronic disease can impair developmental tasks achieved by adolescence, leading to functional disability. The *objectives* of this study were to document the degree of HRQoL impairment with cSLE and delineate HRQoL domains most affected by cSLE.

Methods: Two population-based cohorts of ALL cSLE patients (n= 86; 7 – 20 years) followed at two tertiary pediatric rheumatology centers were studied 3 times over a 12 month period. *Pediatric PROMIS™* Short Forms (Anger, Anxiety, Depression, Fatigue, Mobility, Upper Extremity, Pain Interference, Peer Relationships), Functional Disability Inventory [FDI; range 0 – 60], and the Child Health Questionnaire [CHQ]) were completed by patients and parents. Disease activity was measured by the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), and treating physicians completed a visual analog scale of cSLE activity (0–10; 0=inactive). Average PROMIS T-scores, CHQ physical function (PFS) and psychosocial summary scores (PSS) in healthy children are at 50 (SD 10), while a FDI score $\geq$ 13 signifies at least moderate functional disability.

Results: At enrollment 23% of the patients (mean age was 15.7 yrs [SD 2.44], average disease duration of 6 yrs, and SLEDAI score of 6.13 [SD 6.15])had at least moderate functional disability (FDI $\geq$ 13) . There was more than minimal pain (VAS $\geq$ 3) in 46% of the patients. A large proportion of cSLE patients had markedly decreased HRQoL (score $\leq$ 1 SD below mean of healthy; see Figure 1). The presence of functional disability correlated with decreased mobility, higher pain, and more fatigue (Pearson correlations; all $r > 0.69$). Conversely, none of the HRQoL measures correlated with the SLEDAI or MD-rated disease activity (all $r< 0.2$).

* Denotes < 0.001;

Conclusion: cSLE is often associated with decreased HRQoL, despite comprehensive treatment provided at tertiary pediatric rheumatology centers. Psychosocial aspects of heath are diminished, with depression being common and functional disability attributed to pain, fatigue, and mobility limitations. Traditional measures of cSLE activity do not capture HRQoL outcomes adequately which may limit achievement of optimal health outcomes with cSLE.

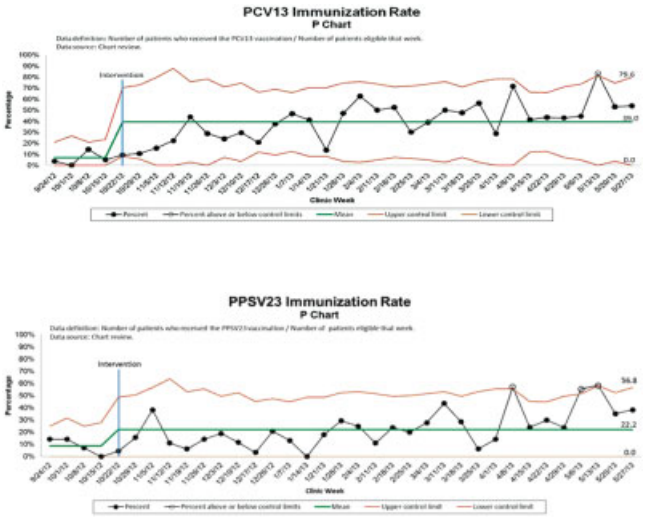
Improving Pneumococcal Vaccination Rate In The Pediatric Rheumatology Clinic. Julia G. Harris[1], Kristyn I. Maletta[2], Bixiang Ren[2] and Judyann C. Olson[3]. [1]Children's Hospital of Wisconsin, Milwaukee, WI, [2]National Outcomes Center, Children's Hospital of Wisconsin, Milwaukee, WI, [3]Medical College of Wisconsin, Milwaukee, WI.

Background/Purpose: This quality improvement project was conducted to increase pneumococcal vaccination rates in eligible Pediatric Rheumatology Clinic patients. *Streptococcus pneumoniae* is a leading cause of bacteremia, meningitis, pneumonia, sinusitis, and acute otitis media. Many patients in the Pediatric Rheumatology Clinic are at increased risk of pneumococcal disease secondary to a deficient immune system and/or immunosuppressive medications. Infections remain one of the leading causes of hospitalization and death in patients with certain rheumatic diseases. The Centers for Disease Control and Prevention recommends both the 13-valent pneumococcal conjugate vaccine (PCV13) and the 23-valent pneumococcal polysaccharide vaccine (PPSV23) for this high-risk population.

Methods: Baseline immunization rates were assessed for eligible clinic patients over a four week period. Eligible patients include children at least two years old and adults with systemic lupus erythematosus and patients currently on or starting an immunosuppressive medication. Interventions included a presentation to rheumatology providers and nurses, creation of clinic document with immunization algorithm, previsit planning, placing reminders on patient clinic forms, and sending letters to out-of-state patients. Chart reviews of eligible patients occurred throughout the study period. Control charts were established to portray change in immunization rate.

Results: The pre-intervention immunization rate for 90 eligible Pediatric Rheumatology Clinic patients was 6.7% for PCV13, 8.9% for PPSV23, and 0% for both vaccines. Data from 31 weeks were analyzed following the interventions for a total of 679 eligible patient visits and 265 separate patients. The average post-intervention immunization rate was 39.0% for PCV13, 22.2% for PPSV23, and 16.3% for both vaccines. These rates are statistically higher than the pre-intervention rates ($p<0.001$, $p=0.003$, and $p<0.001$, respectively). The final eight weeks of assessment showed a shift above the mean in pneumococcal rates for both PCV13 and PPSV23.



Conclusion: Pneumococcal vaccination is an important part of the care for systemic lupus erythematosus patients and pediatric rheumatology patients on immunosuppressive medications. Simple interventions through this quality improvement project led to a marked increase in pneumococcal vaccination rates in this vulnerable population.

Applying Choosing Wisely: Identifying Inefficiencies Of Antinuclear Antibody Subserology Testing In a Safety Net Health System. Lisa A. Davis[1], Barbara L. Goldstein[2], Vivian Tran[1], Angela Keniston[1], Jinoos Yazdany[3], Joel M. Hirsh[1], Amy Storfa[1] and Joann Zell[2]. [1]Denver Health and Hospital Authority, Denver, CO, [2]National Jewish Health, Denver, CO, [3]University of California, San Francisco, San Francisco, CA.

Background/Purpose: In 2013, the American College of Rheumatology participated in the American Board of Internal Medicine Foundation's Choosing Wisely® campaign, developing a Top 5 List of things physicians and patients should question. Among the top 5 items in rheumatology was "do not test ANA (antinuclear antibody) sub-serologies without a positive ANA and clinical suspicion of immune mediated disease." The goal of this study was to analyze ANA and sub-serology ordering patterns in a large safety net hospital, and to identify areas where there may be room for value improvement.

Methods: We identified all ANA and sub-serology testing and results at Denver Health, a large safety net hospital, between 1/1/2005 and 12/31/2011 via query of the electronic medical records. We included the following antibodies among the sub-serology testing: Ro (SSA), La (SSB), double stranded DNA, centromere, ribonuclear protein, Smith, Scl-70 and Jo-1. Finally, we identified the timing of the ANA and the sub-serologies, and using logistic regression, we identified predictors of the ANA and profile being sent simultaneously. Variables for logistic regression included demographics, insurance type and if the laboratory was sent by primary or specialty care.

Results: During the seven years, a total of 2800 ANA tests were ordered, of which 9.7% had multiple ANAs. Thus we analyzed 2662 index ANA studies. Of those patients with both an ANA and at least one sub-serology ordered at any time (n=339,) 46.7% (n=157) had these laboratory tests sent at the same patient encounter. A subspecialty care appointment predicted that the ANA and sub-serologies were sent concurrently (OR 8.41, 95% CI 5.46–12.96, p-value <0.0001). Only 4 individuals (1.5%) were found to have at least one positive sub-serology in the setting of a negative index ANA (see Figure).

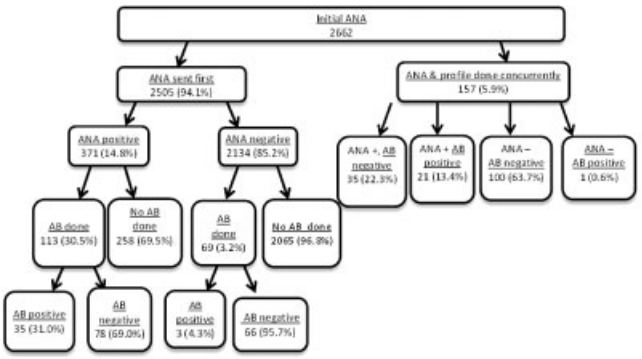

Figure. ANA and sub-serology ordering patterns between 2005–2011 at Denver Health (AB: at least one of the following was ordered: SSA, SSB, Smith, Centromere, Ribonuclear protein, Double stranded DNA, Jo-1 and Scl-70)

Conclusion: In this study, we showed that of the 2662 index ANAs, approximately 6% (157) of tests were accompanied by sub-serologies at the same patient encounter. A negative ANA predicted negative sub-serologies with rare exception in these patients. This brings into question the value of sending an ANA and sub-serologies simultaneously, which may not be cost effective or clinically indicated, and demonstrates an area for value improvement in rheumatology.

Do Rheumatologists (and Other Specialists) Practice What We Preach? A Study Of Serology Ordering Patterns With Attention To Subserologies When The Antinuclear Antibody By Enzyme Linked Immunosorbent Assay Is Negative; And The Clinical Significance Of These Positive Subserology Results.

David Bulbin[1], Alicia Meadows[1], Alfred E. Denio[1], H. Lester Kirchner[2], Sandi Kelsey[1] and Harold Harrison[1]. [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Health System, Danville, PA.

Background/Purpose: The American College of Rheumatology (ACR) was asked by the American Board of Internal Medicine to contribute to the "Choosing Wisely" campaign. The first recommendation from the ACR was: Don't test Antinuclear Antibody (ANA) subserologies without a positive ANA and clinical suspicion of immune-mediated disease. Rheumatologists likely presume that non-rheumatologists often use a "shotgun" approach when ordering ANA and subserologies. However, we wanted to look at how often physicians including rheumatologists used this "shotgun" approach that the ACR cautions against. We also investigated the clinical relevance of a positive subserology when the ANA is negative and the financial impact of such shotgun testing.

Methods: We conducted a retrospective study of the Geisinger integrated health system that examined ANA and subserology ordering practices of all physicians. Data from 2010–2012 was collected from the EPIC electronic health record and Sunquest lab system. We reviewed physician serology ordering rationale to determine the relevance of positive subserology when the ANA was negative. Subserologies included were DSDNA, Anti-Smith, RNP, SSA/SSB, SCL70 and JO1. We classified the reasoning for ordering a subserology prior to knowledge of ANA result as either justified or not justified. The subserology was justified if there was a high clinical suspicion of a specific systemic autoimmune inflammatory disease whose associated subserology is not included in the screening ANA (i.e. SSA/SSB. JO1 AB). Finally, we completed a 2010–12 cost analysis for unjustified subserology ordering.

Results: Of the 51 patients with negative ANA and a positive subserology, 41 had positive SSA/SSB, 7 Anti-Smith, 5 RNP, 2 SCL70, 0 JO1, and 0 DSDNA. 51% (26/51) of the patients had subserology orders placed by a rheumatologist at the same time as the ANA, prior to ANA results. 22% (11/51) had testing ordered by Neurologists and the other 27% (14/51) were ordered by primary physicians and other specialties. 75% of the patients had both ANA and subserology testing ordered concurrently. 75% of cases had unjustified reasoning for the subserology order. Positive subserologies when the ANA was negative did not have any clinical relevance. The cost analysis showed an average cost of tests ordered at $631.00 per patient totaling $32843 for all 51 patients. This was a small fraction of the total cost of all unjustified subserologies ordered, if one includes the NEGATIVE subserologies when the ANA was negative.

Conclusion: Rheumatologists do not always "practice what we preach." Rheumatologists ordered the majority of unjustified subserologies. We have demonstrated that there is significant waste of healthcare resources by the inappropriate ordering of subserologies, and that most of that waste is by rheumatologists. Positive subserologies when the ANA was negative did not have clinical importance. Of interest, we discovered that the ANA by Enzyme Linked Immunosorbent Assay (ELISA) assays and the subserology ELISA assays used by our lab were from two different manufacturers. The methodology difference could explain the positive subserology tests in patients with negative ANA's.

Human Papillomavirus Vaccine Uptake Among Children and Young Adults With Autoimmune Diseases.

Candace H. Feldman[1], Linda T. Hiraki[2], Joyce Lii[3] and Seoyoung C. Kim[3]. [1]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Harvard School of Public Health, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Autoimmune diseases such as lupus and inflammatory bowel disease are associated with increased rates of human papillomavirus (HPV), the most common sexually transmitted disease and the primary cause of cervical cancer. In 2006 and 2009 the U.S. Food and Drug Administration approved two 3-dose series HPV vaccines for use in 9–26 year-old females and males. Studies show the HPV vaccine to be safe and efficacious in patients with autoimmune diseases. We investigated whether HPV vaccine uptake is higher among those with autoimmune diseases compared to the general population.

Methods: Using a U.S. commercial insurance claims database from 2005–2012, we identified children and young adults age 9–26 with ≥12 months of continuous enrollment and ≥2 autoimmune disease diagnosis codes ≥7 days apart. We defined the index date as the calendar month and year of the second autoimmune disease diagnosis code. We matched these individuals by age, sex, and index date to randomly selected controls without any autoimmune disease diagnosis codes (1:4 ratio). We excluded individuals with a history of malignancy or organ transplant. Vaccination was defined as ≥1 HPV vaccine code (CPT 90649 or 90650) following the index date, after 2006. Baseline covariates for stratified analyses included age, sex, region, healthcare utilization and comorbidities. We also examined vaccine uptake in the 21 states that passed HPV-related legislation from 2008–2012, compared to states that did not. We obtained p-values comparing proportions of HPV vaccine uptake in the two cohorts.

Results: We identified 29,255 children and young adults with autoimmune diseases and 117,020 without. The mean age was 19 years (SD 5); 59% were female. The autoimmune disease cohort had a higher number of physician visits, abnormal pap smears, and sexually transmitted diseases (all p-values<0.01). Both cohorts had low percentages of HPV vaccine uptake overall, with 8.5% with autoimmune diseases and 9.1% without receiving ≥1 vaccine (p=0.34) (**Table)**. Among females, 13.1% with autoimmune diseases and 14.1% without received ≥1 vaccine (p<0.01); <5% of females in both groups completed a 3-dose series (p=0.57). Vaccinations were equally distributed geographically except for the Northeast which had a higher percent with autoimmune diseases receiving ≥1 HPV vaccine (p=0.02). In states with HPV-related legislation, 7.1% with autoimmune diseases and 7.5% without received ≥1 vaccine, compared to 6.5% with autoimmune diseases (p=0.04) and 7.4% without (p=0.5) in states without legislation.

Conclusion: HPV vaccine uptake is profoundly low among children and young adults both with and without autoimmune diseases despite its known efficacy. Heightened public health efforts are necessary for the general population and for those with autoimmune diseases given their increased risk of persistent HPV infection.

Table. HPV Vaccine Uptake Among Children and Young Adults in the U.S. With and Without Autoimmune Diseases*

	Autoimmune Disease Cohort* N=29,255	Non-autoimmune Disease Cohort N=117,020	p-value

Reasons For Failure To Obtain Influenza and Pneumococcal Vaccines Among Immunosuppressed Individuals With Systemic Lupus Erythematosus. Erica F. Lawson, Laura Trupin, Emily von Scheven, Edward H. Yelin and Jinoos Yazdany. UC San Francisco, San Francisco, CA.

Background/Purpose: Infection is the third-leading cause of death in individuals with systemic lupus erythematosus (SLE) in developed countries. Nearly half of those deaths are attributed to pneumonia, making vaccination against influenza and pneumococcus critical to prevention of mortality. Nonetheless, previous work has shown that a significant number of SLE patients fail to receive these vaccinations (Yazdany, 2010). The goal of this study was to better understand why individuals with SLE fail to receive influenza and pneumococcal vaccines.

Methods: Data derive from the 2009 cycle of the Lupus Outcomes Study (LOS), an annual longitudinal telephone survey of individuals with confirmed SLE. Subjects were included in the analysis if they had taken immunosuppressive medications in the past year and reported whether they had received influenza and pneumococcal vaccines. We assessed any prior receipt of pneumococcal vaccine and receipt of influenza vaccine in the past year. Subjects who did not receive a vaccine were asked whether their physician had recommended it. If the vaccine was recommended but not received, subjects were given itemized response options to elicit reasons for not receiving vaccination. We used bivariate statistics and logistic regression (adjusting for age, gender, race, insurance status, and physician specialty) to assess frequency and predictors of reported reasons for not obtaining influenza or pneumococcal vaccines.

Results: Among 508 subjects who received immunosuppressive medications, 485 reported whether they had received vaccines. Mean age (±SD) was 50 years (±12), 93% were female, and 40% were non-white. Nearly all had insurance coverage: 53% through employers, 40% with Medicare and 5% with Medicaid. Among subjects who did not receive the influenza vaccine (N=175), the most common reason was lack of doctor recommendation (45%), followed by efficacy or safety concerns (21%), and lack of time or motivation to obtain the vaccine (19%). Reasons for not receiving the pneumococcal vaccine (N=159) were similar, with lack of doctor recommendation the most common (85%), followed by lack of time (7%) and efficacy or safety concerns (4%). Subjects age 65 or older were more likely to receive a recommendation for pneumococcal vaccine than younger subjects (43% vs. 11%, p=0.02). Multivariate models to assess predictors of vaccine recommendation were not statistically significant.

Conclusion: The most common reason why individuals with SLE did not receive pneumococcal and influenza vaccines was that physicians failed to recommend them, follwed by concerns about safety and efficacy of vaccines and time constraints. Physicians were more likely to recommend pneumococcal vaccination for older subjects. Data suggest that increasing vaccination rates in SLE will require improved process quality at the provider level, as well as addressing patient concerns and barriers.

Salivary Gland Ultrasonography: A Highly Specific Tool For The Early Diagnosis Of Primary Sjögren's Syndrome. Nicoletta Luciano[1], Chiara Baldini[1], Gaia Tarantini[2], Rachele Pascale[2], Francesca Sernissi[1], Linda Carli[1], Francesco Ferro[1], Rosaria Talarico[1], Marta Mosca[3], Davide Caramella[2] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Department of Diagnostic and Interventional Radiology, University of Pisa, Pisa, Italy, [3]Rheumatology Unit, University of Pisa, Pisa, Italy.

Background/Purpose: Recently, Cornec D. et al. reported that salivary gland ultrasonography (SGUS) was characterized by a sensitivity of 65.8% and a specificity of 95.3%, in patients with primary Sjögren's syndrome (pSS) and a disease duration of ≤5 years, thus encouraging the use of SGUS for the early diagnosis of pSS. Aims of this study were:1) to validate SGUS diagnostic accuracy in a different cohort of patients with sicca symptoms duration of ≤5 years; 2) to correlate the SGUS score with minor salivary gland biopsy focus score (MSGB/FS) and unstimulated salivary flow rate measured by sialometry.

Methods: Patients with suspected pSS and symptoms duration of ≤5 years were consecutively enrolled in this study. The diagnosis of pSS was made according to the AECG criteria. SGUS was carried out by the same radiologist blinded to the diagnosis and the following US parameters were recorded: size, parenchymal echogenicity and inhomogeneity in the parotid and submandibular glands on both sides. A previously reported ultrasound scoring system (De Vita et al 1992, cut-off≥1) was used to grade the echostructure alterations of the salivary glands. Statistical analysis was performed using SPSS v16.

Results: This study included 50 patients with pSS and 57 with no-SS sicca symptoms. The mean age of the pSS group was lower than non-SS group (47(13) vs 53(12) yrs, p=0.006).No further differences between the two groups were observed with respect to gender, frequency and duration of dry-mouth and dry-eye related symptoms. Patients with pSS showed a significantly higher SGUS score in comparison with controls (mean (SD)=2.1 (1.8) vs 0.0 (0.4), p=0.000). The SGUS cut-off≥1 showed a sensitivity (SE) of 66%, a specificity (SP) of 98%, a positive predictive value (PPV) of 97% and a negative predictive value (NPV) of 73% for pSS diagnosis. An inverse correlation was observed between the SGUS score and the age of the patients (r=−26, p=0.006) with younger patients frequently presenting multiple hypoechoic areas. The SGUS score was also correlated with both the MSGB/FS (r=55, p=0.000) and the salivary flow rate (r=−40, p=0.000).

Conclusion: This study confirmed the good performance that SGUS for the early non-invasive diagnosis of pSS. Further research in larger international cohort of patients is mandatory in order to assess the role of SGUS in the diagnostic algorithm of pSS.

Salivary Gland Ultrasonography Improves The Diagnostic Performance Of ACR 2012 Classification Criteria For Sjögren's Syndrome, Even In The Early Stages Of The Disease. Divi Cornec[1], Sandrine jousse-Joulin[2], Thierry Marhadour[3], Jacques-Olivier Pers[1], Yves Renaudineau[1], Alain Saraux[4] and Valerie Devauchelle-Pensec[5]. [1]Brest Occidentale University, Brest, France, [2]Brest university medical school, EA 2216, UBO and CHU de la Cavale Blanche,, Brest, France, [3]CHU de la Cavale Blanche, Brest, France, [4]CHU Brest et Université Bretagne Occidentale, Brest, France, [5]Brest Occidentale university, Brest, France.

Background/Purpose: Recently published ACR classification criteria for primary Sjögren's syndrome (pSS) include only 3 objective tests: 1) a serological item: anti-SSA/SSB antibodies or [antinuclear antibody (ANA) titer ≥1:320 and rheumatoid factor (RF) positivity], 2) an Ocular Staining Score (OSS) ≥3, and 3) focus score ≥1 on salivary gland biopsy (SGB). None of these tests explore the function or the morphology of the salivary glands. In a recent study, we have shown that salivary gland ultrasonography (SGUS) has good diagnostic properties for SS.Our objective was to evaluate if SGUS could improve the diagnostic properties of ACR 2012 criteria.

Methods: The pSS Brittany cohort includes patients with suspected pSS (sicca symptoms, parotidomegaly or extraglandular manifestations suggestive of pSS). All patients had a standardized clinical and biological evaluation and a SGB. Ophtalmologic evaluation used fluorescein and lissamine green to assess the presence of keratoconjunctivitis sicca, allowing the subsequent calculation of the OSS. SGUS was performed on bilateral parotid and submandibular glands. Their echostructure was quoted on a scale between 0 and 4, as previously published. A SGUS score ≥2 was considered pathologic. The gold standard for the analysis was a clinical diagnosis of pSS performed by a group of experts, unaware of the of the SGUS score.

Results: 101 patients were included in this study (mean age 57.4±13.0 years, symptoms duration 6.7±6.1 years, 94.1% females). The diagnosis of pSS was made in 45 patients, and 34 patients fulfilled ACR criteria. Sensitivity (Se) and specificity (Sp) of the different items for the diagnosis of pSS were respectively: 60.0% and 96.4% for the serological item of ACR criteria; 82.2% and 82.1% for the focus score ≥1; 55.6% and 58.9% for the OSS ≥3; 60.0% and 87.5% for SGUS. ACR criteria displayed 64.4% Se and 91.1% Sp. We created a new criteria set including the 3 items of ACR criteria and SGUS; these criteria were considered positive for all patients fulfilling almost 2 of these 4 items. The adjunction of SGUS to ACR criteria increased their Se to 84.4%, for a similar 89.3% Sp. This improvement of ACR criteria diagnostic performance was also found when we restricted the analyses to patients with disease duration of less than 5 years.

Conclusion: The diagnosis properties of ACR classification criteria for pSS are notably improved by the addition of the SGUS score. SGUS should be included in future consensual classification criteria for pSS.

Systemic Lupus Erythematosous and Primary Sjogren's Syndrome May Display Joint Erosions On MRI As Well As Healthy Control, But Cannot Be Considered As Erosive Disease Such As Rheumatoid Arthritis: An MRI Observational Study Of 90 Subjects. Frédérique Gandjbakhch[1], Violaine Foltz[1], Jérôme Renoux[2], Nahalie Cozic[3], Nathalie Costedoat-Chalumeau[4], Damien Sene[5], Guillaume Mercy[6], Zahir Amoura[7], Jean-Charles Piette[7], Nathalie Morel[8], Pierre Bourgeois[9] and Bruno Fautrel[10]. [1]APHP, Pitié Salpétrière Hospital, Universite Paris 6, Paris, France, [2]Pitie-Salpetriere Hospital, Paris, France, [3]APHP, Pitie Salpetriere Hospital, department of statistics, Paris, France, [4]Hopital Cochin, Paris, France, [5]Hopital Lariboisière, Paris, France, [6]APHP, Pitie-Salpétrière Hospital, paris, France, [7]CHU Pitié-Salpêtrière, Paris, France, [8]Groupe Hospitalier Pitié-Salpétrière, Paris, France, [9]APHP, Pitie-Salpetriere Hospital, Paris 6, Paris, France, [10]Paris 6 – Pierre et Marie Curie University; AP-HP, Rheumatology, Pitié-Salpêtrière Hospital, - GRC-UPMC 08 – EEMOIS, Paris, France.

Background/Purpose: Recent studies tend to demonstrate presence of MRI erosion in Systemic Lupus Erythematosous (SLE) and primary Sjogren's syndrome (pSS). The objective of this study was to describe MRI characteristics (erosion and osteitis, i.e. bone marrow oedema) of patients with SLE and pSS without association with rheumatoid arthritis (RA) compared to "positive control",i.e. RA and "negative control" (sex/age-matched healthy controls).

Methods: pSS, SLE, RA and HC were prospectively included from 2 university departments (rheumatology and internal medicine) between 2009 and 2011. Inclusion criteria were: 1- for lupus and primary SS: disease duration >2 years, no association with RA defined as no arthritis, no ACPA, normal X rays of hand and feet. 2-for Healthy controls (HC): no history of tender or swollen joint or rheumatic disease. 3- for RA: established RA with duration>2 years. MRI of MCP2 to 5 and wrist of the dominant hand was performed for all subjects using a dedicated MRI (ESAOTE Cscan 0.2 Tesla) in coronal and axial plans using T1 and STIR sequences, without gadolinium injection, in order to evaluate erosion and osteitis according to the OMERACT definitions. Adaptation of the OMERACT definition for erosion was used in order to differenciate physiological cortical break, i.e. vascular foramen and erosion due to pathological process. MRIs were evaluated by 2 independent readers, blindly to clinical and radiographic data using RAMRIS scores for erosion and osteitis. Statistics were performed using SAS 9.3 software.

Results: 90 subjects were included prospectively in the study: 19 pSS, 21 SLE, 30 RA and 20 HC. 83 % of RA patients were erosive on Xrays, 86% and 72 % were RF and ACPA positive. All SLE and pSS patients had normal Xrays of hand and feet (inclusion criteria). All patients and HC had at least one cortical break seen in 2 plans on MRI of hand and wrist without statistical difference between the groups. Frequencies and scores for erosion and for osteitis were statistically different between RA and SLE/pSS while no statistical difference was seen between SLE/pSS and HC (Table). Sensitivity and specificity were respectively for erosion: 0.93 and 0.38, for erosion with grade ≥2: 0.4 and 0.88 and for osteitis: 0.77 and 0.78. A cut-off of RAMRIS erosion was determined at 9 and could discriminate SLE/pss and RA patients (AUC= 0.8007) with good sensitivity (0.68) and specificity (0.84).Erosions in wrist and MCP3 were frequent in all groups, while erosions in MCP2, MCP4 and MCP5 were more frequently observed in RA with statistical difference between the groups.

	RA (n=30)	Lupus (n=21)	SS (n=19)	HC (n=20)	SLE/pSS vs RA	SLE/pSS vs HC
Patient with at least one Cortical break, n(%)	30 (100%)	21 (100%)	19 (100%)	20 (100%)	NS	NS
Patient with at least one erosion, n(%)	28 (93%)	12 (57%)	13 (68%)	12 (60%)	0.004	1
Patient with at least one erosion ≥grade2, n(%)	22 (69%)	9 (43%)	7 (36%)	5 (25%)	0.019	0.39
Patient with at least one osteitis, n(%)	23 (77%)	3 (14%)	5 (26%)	5 (25%)	<.0001	0.74
Patient with at least one erosion and one osteitis, n(%)	22 (69%)	3 (14%)	5 (26%)	5 (25%)	<.0001	0.74
RAMRISerosion	21.6±10.34	13.02±5.59	11.56±5.73	10.69±4.54	0.0003	0.40
RAMRISosteitis	2.29±4.69	0.17±0.67	0.11±0.27	0.29±0.79	0.0005	0.63

Conclusion: MRI Cortical break are frequent in SLE and pSS as well as in HC. Erosions may be seen in SLE and pSS but can be distinguished from erosions of RA. Distinction of physiological cortical break and pathological

erosion may lead to better interpretation of MRI and further consensus on MRI definition of these 2 items should be to consider.

Capillaroscopy Compared With Color Doppler Ultrasound Of Digital Arteries For Distinguishing Primary From Secondary Raynaud's Phenomenon. Wolfgang A. Schmidt[1], Katharina Pagel[2], Bernd Schicke[3] and Andreas Krause[4]. [1]Med Ctr Rheumatology Berlin Buch, Immanuel Krankenhaus Berlin, Berlin, Germany, [2]Medical Ctr Rheumatol Berlin Buch, Immanuel Krankenhaus Berlin, Berlin, Germany, [3]Tumorzentrum Berlin, Berlin, Germany, [4]Immanuel Krankenhaus Berlin, Berlin, Germany.

Background/Purpose: Raynaud's phenomenon (RP) is commonly seen in rheumatology practice. Differentiating primary from secondary RP is important for disease management and prognosis. How does capillaroscopy compare to color Doppler ultrasound (US) of the finger arteries for distinguishing primary from secondary RP? How often do these imaging techniques detect abnormalities in nailfold arteries or finger arteries in patients with connective tissue diseases?

Methods: Consecutive patients with RP or with suspected connective tissue disease and healthy controls who presented within a 12-month period in a tertiary rheumatology referral center were examined.

Nailfold capillaroscopy of the 2nd to 5th fingers was done bilaterally with a Nikon Stereoscopic Zoom Microscope SMZ1000 including a camera control unit DS-Us, in search for scleroderma, dermatomyositis and other connective tissue disease patterns as previously described (Cutolo M, et al. Best Pract Res Clin Rheumatol 2008;22:1093–108).

Bilateral color Doppler US of the radial, ulnar, all common palmar and all proper digital arteries was performed after a hot water bath of the hands in search for occlusions and stenoses as previously described (Schmidt WA, et al. J Rheumatol 2008;35:1591–8). An Esaote MyLab Twice US machine, equipped with a 6–18 MHz linear probe, was used.

Capillaroscopy and US images were stored electronically. Both investigators were not aware of the results of the other examination. After diagnostic work-up the results of US and capillaroscopy were compared with the final diagnosis.

Results: Twenty healthy controls and 165 patients were included. Final diagnoses included primary RP (52 patients), systemic sclerosis (49 patients), myositis (15 patients), other connective tissue diseases such as SLE (13 patients), MCTD (12 patients), UCTD (10 patients), Sjögren's syndrome (4 patients) and vascular diseases such as vasculitis (5 patients), antiphospholipid syndrome (3 patients), and arteriosclerosis (2 patients). Table 1 shows the results.

Table 1.

Diagnosis	N	Consistent results of US and capillaroscopy	Only US positive	Only capillaroscopy positive	Kappa
Controls	20	100%	0%	0%	N.A.
Primary RP	52	71%	10%	19%	−0.10
Systemic sclerosis	49	88%	8%	4%	0.81
Myositis	15	67%	7%	27%	0.68
Other connective tissue diseases	39	80%	5%	15%	0.73
Vascular disease	10	50%	20%	30%	0.51
Total	185	79%	7%	14%	0.58

The highest rate of abnormalities was found in systemic sclerosis (capillaroscopy, 92%; US 96%). In myositis (87%; 67%) and other connective tissue diseases (82%; 72%) capillaroscopy more often displayed abnormal results than US. In primary RP, US and capillaroscopy were positive in 10% and 19% respectively. None of these patients showed abnormalities in both US and capillaroscopy.

Conclusion: Although capillaroscopy and US are assessing different anatomical structures, each technique helps distinguish primary from secondary RP. Abnormalities are particularly common in systemic sclerosis. Capillaroscopy is more sensitive in other connective tissue diseases. However, it is more frequently positive also in primary RP. The agreement between US and capillaroscopy is good to moderate.

Aortic Wall Thickness In Patients Without Aortitis: a Computed Tomography-Based Study Of 100 Patients. Afif Nakhleh, Irina Rukhkyan, Vladimir Wolfson, Itzhak A. Rosner, Majed Odeh and Gleb Slobodin. Bnai Zion Medical Center, Haifa, Israel.

Background/Purpose: Thickening of the aortic wall, probably the earliest CT sign of aortitis, is frequently missed as there are no accepted criteria for normal aortic wall thickness (AWT). Studies based on CT-assessed AWT in healthy persons and patients with prevalent co-morbidities are scarce, and do not allow determination of reference values for the definition of increased AWT necessary for the diagnosis of aortitis by CT. On the other hand, the substantial difference in the techniques of MRI and CT prevent the blind extrapolation of MRI-based definitions onto CT imaging. The present study was conducted to assess the relationship of CT-measured AWT with patient-related and disease-related factors in a large cohort of patients without aortitis.

Methods: CT scans of 100 consecutive patients without known aortic disease, hospitalized at the Bnai Zion Medical Center were reviewed and AWT measured at three levels: 1. thoracic descending aorta at the level of the bifurcation of the pulmonary artery; 2. abdominal aorta at the level of celiac artery origin; 3. abdominal aorta one slice below the level of the origin of renal arteries. Patients' charts were analyzed and demographic data and data on co-morbidities extracted. Correlations with measured AWT were calculated.

Results: By bivariate analysis, AWT had significant positive correlation with patient age ($r=0.68$, $p=0.000$; $r=0.6$, $p=0.000$; $r=0.62$, $p=0.000$, for 3 levels, respectively), the presence of arterial hypertension (2.11 ± 0.6 mm vs 1.7 ± 0.8 mm, $p=0.001$; 2.14 ± 0.8 mm vs 1.64 ± 0.5 mm, $p=0.004$; 2.05 ± 0.7 mm vs 1.51 ± 0.6 mm, $p=0.000$, for 3 levels, respectively) and calcifications of the aortic wall (2.24 ± 0.6 mm vs 1.63 ± 0.7 mm, $p=0.000$; 2.3 ± 0.8 mm vs 1.58 ± 0.5 mm, $p=0.000$; 2.16 ± 0.7 mm vs 1.52 ± 0.6 mm, $p=0.000$, for the 3 levels, respectively). The aortic wall had a tendency to be thicker in males (2.04 ± 0.8 mm vs 1.79 ± 0.6 mm, $p=0.089$; 2.00 ± 0.6 mm vs 1.85 ± 0.8 mm, $p=0.325$; 1.95 ± 0.7 mm vs 1.69 ± 0.7 mm, $p=0.071$, for the 3 levels, respectively) and in patients with known coronary artery disease (2.18 ± 0.6 mm vs 1.86 ± 0.7 mm, $p=0.04$; 2.11 ± 0.7 mm vs 1.76 ± 0.72 mm, $p=0.069$; 2.21 ± 0.6 mm vs 1.86 ± 0.76 mm, $p=0.073$, for the 3 levels, respectively), being independent on the presence of diabetes mellitus, hyperlipidemia or malignancies. Multivariate analysis showed significant positive correlation of AWT only with patient age and the presence of aortic calcifications ($p=0{,}000$ and $p=0.034$ for the thoracic descending aorta, $p=0.021$ and 0.001 for the upper abdominal aorta, $p=0.001$ and $p=0.005$ for the infrarenal abdominal aorta, respectively).

Table 1. AWT in different age groups

AWT in mm (median, range)	<50 years median 40.5 years (16 patients)	50–59 years median 54 years (11 patients)	60–69 years median 64 years (15 patients)	70–79 years median 74 years (33 patients)	≥80 years median 84.5 years (25 patients)
Level 1	1.3 (0.5–2.05)	1.4 (0.15–1.8)	1.65 (1.3–4.75)	2.05 (0.5–2.85)	2.38 (1.6–2.85)
Level 2	1.4 (0.5–1.75)	1.55 (0.2–1.7)	1.7 (1.25–5.95)	2.15 (0.75–3.0)	2.33 (0.7–3.05)
Level 3	1.2 (0.5–1.75)	1.4 (0.9–1.5)	1.5 (1.0–5.4)	2 (1.2–3.0)	2.1 (1.2–4.1)

Conclusion: The 'normal' range of AWT varies with age, and may also vary with co-morbidities. These data may serve as a reference and should be considered in interpretation of the CT-appearance of the aortic wall when assessing for aortitis.

Ultrasound Evaluation Of The Greater Trochanter Pain Syndrome: Bursitis Or Tendinopathy? Cristian Quiroz[1], Santiago Ruta[1], Javier Rosa[1], David A. Navarta[1], Ricardo Garcia-Monaco[2] and Enrique R. Soriano[3]. [1]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Radiology and Imagenology Department, Hospital italiano de Buenos Aires, Buenos Aires, Argentina, [3]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Argentina.

Background/Purpose: Greater trochanteric pain syndrome (GTPS) is a common clinical problem that may be caused by a variety of either

intra-articular o peri-articular pathologies. Inflammation of the trochanteric bursa has been postulated for a long time as the main cause of pain at trochanteric level. However, some studies have questioned the real involvement of the trochanteric bursa in the GTPS, and tendinopathy of the gluteus medius and/or minimus has been proposed as an important cause of this syndrome. The aim of the present study was to evaluate the prevalence of different US abnormal findings in patients with GTPS.

Methods: A retrospective analysis was carried out from the electronic medical records of consecutive patients complaining of a GTPS who underwent an US assessment of the greater trochanter between January 2011 and February 2013 at a Rheumatology Unit. US assessment was performed in all cases by the same experienced rheumatologist using a MyLab 70 XV (Esaote Biomedica, Genoa, Italy) machine equipped with a broadband 4–13 MHz linear probe. The presence or absence of the following US abnormal findings was investigated: 1) tendinopathy (tendinosis, calcific tendinosis and/or tendon tear) of the gluteus medius and/or minimus; 2) trochanteric bursitis (fluid distension). Additionally, we investigated if patients had also magnetic resonance imaging (MRI) evaluation of the hip within the 30 days before or after US evaluation.

Results: A total of 124 US examinations of the greater trochanter in 96 patients (28 underwent bilateral US evaluation) were included for the analysis. Eighty-seven patients (90.6%) were female and the mean age (SD) was 64.3 years (14.7). Sixty-eight (55%) US examinations were ordered by rheumatologists and the others by general practicioners, orthopedics and internal medicine consultants. Tendinopathy of the gluteus medius and/or gluteus minimus, as the only US abnormal finding, was detected in 62 out of 124 (50%) examinations. Bursitis, as the only US abnormal finding, was found in 5 out of 124 (4%) examinations. Eighteen (14.5%) US examinations showed a combination of both tendinopathy of the gluteus medius and/or gluteus minimus and trochanteric bursitis. Calcifications were found in 12 out of 80 (15%) tendinopathies. In 39 (31.5%) US examinations no abnormalities were detected. Twenty-five patients had also unilateral MRI evaluation of the hip. The unweighted kappa values between US and MRI for the detection of tendinopathy of the gluteus medius and/or gluteus minimus and trochanteric bursitis were 0,746 (95% CI: 0.477–1.014) and 0.715 (95% CI: 0.415–1.014), respectively.

Conclusion: Tendinopathy of the gluteus medius and/or minimus was the most frequent US abnormal finding in patients with GTPS. Trochanteric bursitis was less common and had associated tendinopathy in the majority of the cases. There was good agreement between US and MRI. These results support the role of pathology of the gluteus tendons as the major cause of pain in patients with GTPS.

Cost-Effectiveness Of Urate Lowering Strategies For The Management Of Gout. Eric Jutkowitz[1], Karen Kuntz[2], Laura T Pizzi[3] and Hyon Choi[4]. [1]University of Minnesota, Minneapolis, MN, [2]Division of Health Policy and Management, School of Public Health, University of Minnesota, Minneapolis, MN, [3]Thomas Jefferson University, Philadelphia, PA, [4]Boston University School of Medicine, Boston, MA.

Background/Purpose: The new 2012 ACR guidelines for the management of gout have provided updated recommendations; however, the employed method do not address the societal costs of the recommendations. We evaluated the cost-effectiveness of 5 first-line urate-lowering therapy (ULT) strategies (incorporating dose-escalation reflective of real practice) for the management of gout over a lifetime.

Methods: We developed a Markov model to calculate lifetime health benefits, costs, and incremental cost-effectiveness ratios (ICERs) of 5 ULT strategies: 1) no ULT, 2&3) allopurinol and febuxostat used as single therapy options, 4) allopurinol-febuxostat sequential therapy, and 5) febuxostat-allopurinol sequential therapy. We investigated two ULT dosing scenarios: 1) fixed dosing (febuxostat[80 mg daily]; allopurinol [300 mg daily]), 2) dose escalation (febuxostat [up to 120mg daily]; allopurinol [up to 800mg daily]). The fixed dosing scenario is reflective of recent randomized trials, whereas the dose-escalation scenario is reflective of real practice. Health states in the model reflected those that could occur during a gout patient's lifetime: controlled (serum urate acid (SUA) <6.0 mg/dl), or uncontrolled (SUA ≥ 6.0 mg/dl). Within each state we accounted for gout flares and ULT associated adverse events, including allopurinol hypersensitivity syndrome. Costs were evaluated from a payer perspective. Cost and utility estimates were obtained from the literature and discounted by 3% per year. Gout flares and ULT associated adverse events were associated with a disutility. Sensitivity analyses were conducted to evaluate the impact of parameter uncertainty.

Results: In both dosing scenarios (fixed and escalating), allopurinol as a single-line option was the least costly option (discounted lifetime cost = $12,004 and $10,477, respectively) and was more effective than no ULT (**Table**). In both dosing scenarios, allopurinol- febuxostat sequential therapy was more costly and more effective than allopurinol single therapy, with an ICER of $24,400/quality-adjusted life year (QALY) (fixed dosing) and $33,500/QALY (dose escalation). In both dosing scenarios, febuxostat -allopurinol sequential therapy had a cost-effectiveness ratio $>$$300,000/QALY, and febuxostat single therapy cost more and was less effective than febuxostat -allopurinol sequential therapy (dominated) (**Table**). The allopurinol- febuxostat sequential therapy result in the dose escalation scenario was sensitive to the cost of febuxostat and time spent on a given ULT without control.

Table. Costs, effectiveness,and cost-effectiveness of 5 ULT strategies for gout over a lifetime

Strategy	Fixed Dosing			Dose Escalation		
	Lifetime Costs	QALY (Yr)	ICER	Lifetime Costs	QALY (Yr)	ICER
Allopurinol Single Therapy	$12,004	12.813	Reference	$10,477	13.341	Reference
No ULT	$13,395	12.363	Dominated	$13,395	12.363	Dominated
Allopurinol-febuxostat sequential therapy	$27,578	13.451	$24,400	$19,142	13.599	$33,500
Febuxostat-allopurinol sequential therapy	$32,821	13.457	$873,800	$31,529	13.639	$309,700
Febuxostat Single Therapy	$35,938	13.413	Dominated	$35,257	13.380	Dominated

Notes: No ULT is dominated (costs more and is less effective) by allopurinol as an only treatment option.
Dominated strategies are excluded in the incremental cost-effectiveness ratio

Conclusion: Allopurinol single therapy is cost saving compared to no ULT. Allopurinol-febuxostat sequential therapy appears to be cost-effective as compared with allopurinol single therapy. Febuxostat single therapy and febuxostat-allopurinol sequential therapy are unlikely to be cost-effective.

Impact of Urate Lowering Therapy On Renal Disease Progression in Patients With Hyperuricemia. Gerald D. Levy[1], T. Craig Cheetham[2], Nazia Rashid[3] and Fang Niu[2]. [1]Southern California Permanente Medical Group, Downey, CA, [2]Kaiser Permanente, Downey, CA, [3]Kaiser Permanente Southern California, Downey, CA.

Background/Purpose: The relationship between elevated serum Uric Acid [sUA] and progression of chronic kidney disease is well established.[1–3] There are a several small studies on the impact of Urate Lowering Therapy (ULT) on renal progression or ESRD.[4–6] This large study evaluated patients with hyperuricemia and the impact of ULT on renal function.

Methods: This retrospective, database study identified 111,992 patients with a serum uric acid level (sUA) of $\geq$ 7mg/dl [Index Date (ID)] from January 1, 2002 to December 31, 2010. Patients with at least 12 months of Health Plan membership including drug benefit prior to ID were studied. All patients had at least one sUA and Glomerular Filtration Rate (GFR) level within the 6 months period prior to the ID and at least one sUA and GFR in the follow up period following the ID (follow up period). A $\geq$ 30% reduction in GFR, initiation of dialysis or a GFR $\leq$ 15 ml/min were defined as Outcome Events. All subjects were ULT naïve to allopurinol, probenecid and febuxostat in the 12 months before the ID. At ID, subjects were $\geq$18 years of age, without chronic kidney disease (CKD) 4 or 5, on dialysis, HIV, non-remission cancer, proteinuria, nephrolithiasis, or organ transplantation. Patients who met inclusion criteria were followed until they had an Outcome Event, disenrolled, died, the end of the follow up period or the conclusion of the study, 12/31/2011.. The cohort was subdivided into three groups: never treated (NT), ULT time on therapy of $<$80% ($<$80%) and time on therapy of $\geq$80%

(≥80%). Cox proportional hazards regression model was used to determine factors associated with renal function decline.

Results: A total of 16,186 patients met inclusion criteria with 11,192 NT patients, 3,902 with <80% and 1,092 with ≥80%. The ≥80% group tended to be older, male with more co-morbidities compared to NT or <80% groups. The ≥80% group received ULT earlier than <80% group with 43.5% compared to 16.9% starting within 2 weeks of ID and 94% compared to 41% starting within 4 months. Allopurinol accounted for 98.3% of ULT and deaths were equally represented amongst the groups at 1.2%. Factors associated with outcome events were age, female gender, hypertension, diabetes, congestive heart failure, previous hospitalizations, higher sUA at baseline and rheumatoid arthritis. Time on therapy of ≥80% was not associated with outcome events 1.07 (0.76–1.52, p=0.68) however those patients with a sUA <6mg/dL had a significant 37% reduction in events p=<0.0001 HR 0.63 (0.5–0.78). See Table 1.

Table 1. Cox Proportional Hazard Model for Risk Factors

Results After Statistical Analysis	Hazard Ratio	95% CI	p value
Age at Index	1.03	1.02–1.04	<0.0001
Gender: F vs M	1.49	1.25–1.78	<0.0001
Ethnicity			
Asian vs White	0.86	0.64–1.14	0.29
Black vs White	1.05	0.85–1.31	0.64
Hispanic vs White	0.94	0.71–1.24	0.65
Co-Morbities			
Hypertension	1.50	1.17–1.93	0.00
Obesity	0.96	0.79–1.18	0.71
Diabetes	1.96	1.64–2.35	<0.0001
Dyslipidemia	0.92	0.77–1.11	0.39
Cardiovascular Ds	1.15	0.93–1.42	0.21
Congestive Heart Failure	1.39	1.04–1.85	0.03
Osteoarthritis	1.05	0.86–1.29	0.62
Rheumatoid Arthritis	1.46	0.84–2.54	0.19
Concomitant medications			
NSAIDs	0.85	0.72–1.01	0.07
Colchicine	1.08	0.82–1.42	0.58
Corticosteroids	0.92	0.73–1.17	0.49
Patient characteristics			
Previous Hospitalizations	1.33	1.12–1.59	0.00
GFR at Baseline	1.01	0.99–1.01	0.12
sUA levels at Baseline	1.11	1.04–1.19	0.00
Gout Diagnosis at Index	1.00	0.81–1.24	0.99
Role of therapy and (sUA<6)			
<80% Time on Rx vs Never	1.27	1.05–1.55	0.01
≥80% Time on Rx vs Never	1.08	0.76–1.52	0.68
sUA at Goal vs Not at Goal	**0.63**	**0.5–0.78**	**<0.0001**

Conclusion: Serum Uric Acid is an independent risk factor for progressive renal function decline. Time on ULT was not associated with a reduction in renal disease progression, but in patients who achieved the ACR goal of sUA <6mg/dL[7] there was a 37% reduction in outcome events.

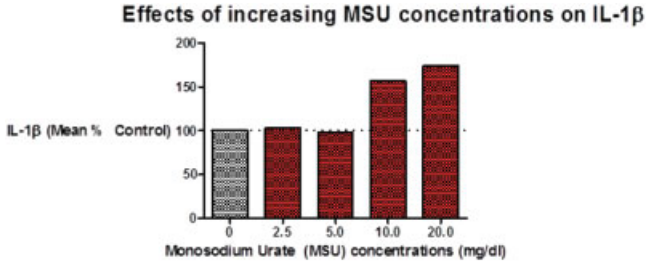
Monosodium Urate Crystal Induced Macrophage Inflammation Is Attenuated By Chondroitin Sulfate: Pre-Clinical Model For Gout Prophylaxis?

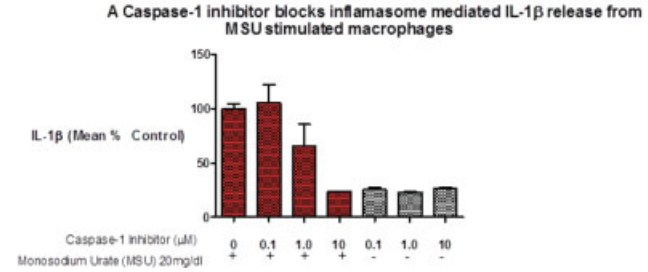
Eric W. Orlowsky[1], Thomas V. Stabler[1], Eulalia Montell[2], Josep Verges[2] and Virginia B. Kraus[1]. [1]Duke University Medical Center, Durham, NC, [2]Pre-Clinical R&D Area, Pharma Science Division, Bioibérica, Barcelona, Spain.

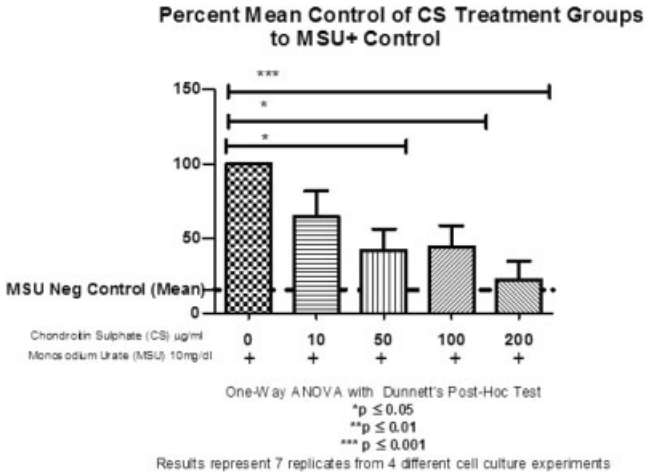
Background/Purpose: Gout is one of the most common forms of inflammatory arthritis and is characterized by acute episodes of joint pain. Monosodium urate (MSU) crystals are taken up by macrophages resulting in NLRP3 inflammasome activation and IL-1beta production. The ACR guidelines recommend a daily prophylactic agent, such as colchicine, NSAIDs or corticosteroids, to prevent acute gout flares at the time of initiation of urate-lowering therapy; however, all these agents are associated with possible intolerance or comorbidities. Chondroitin Sulphate (CS), a natural glycosaminoglycan of the extracellular matrix, has some clinical benefit in symptomatic osteoarthritis but has never been tested in gout. *In vitro*, CS has anti-inflammatory effects on chondrocytes and synoviocytes but its effect on macrophages is unknown. The purpose of our study was to evaluate the *in vitro* effects of CS on MSU-stimulated cytokine production of macrophages.

Methods: THP-1 monocytes were differentiated into mature macrophages using a phorbol ester followed by MSU crystal stimulation in the absence and presence (4 hours prior) of CS in a physiologically achievable range of concentrations (10–200μg/ml). Cell culture media was removed at 24h and analyzed by immunoassay for IL1β. The specificity of inflammasome activation by MSU crystals was tested with a caspase-1 inhibitor (0.01μM-10 μM). Lipopolysaccaride (LPS, 50μg/ml), a toll-like receptor activator, served as a positive control for IL-1 β production.

Results: MSU crystals ≥10mg/dll consistently increased IL-1β production by macrophages (Figure 1); this effect was inhibitable by the caspase-1 inhibitor confirming inflammasome activation as the source of this cytokine (Figure 2). Increasing levels of CS resulted in a significant dose-dependent inhibition of MSU stimulated IL-1β production from macrophages (Figure 3).







Conclusion: Increasing levels of CS attenuate MSU crystal induced macrophage inflammation, suggesting a possible role for CS in gout prophylaxis.

Knee Effusion: Sensitivity and Specificity Of Ultrasound For The Identification Of Calcium Pyrophosphate Crystals. Erika Catay[1], Santiago Ruta[1], Javier Rosa[1], David A. Navarta[1], Marina Scolnik[2], Ricardo Garcia-Monaco[3] and Enrique R. Soriano[4]. [1]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Rheumatology Section, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [3]Radiology and Imagenology Department, Hospital italiano de Buenos Aires, Buenos Aires, Argentina, [4]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Argentina.

Background/Purpose: Calcium pyrophosphate deposition disease (CPPD) is an important cause of arthritis mainly in elderly people. The final diagnosis is based on the identification of calcium pyrophosphate (CPP) crystals in the synovial fluid (SF).Our objective was to evaluate the sensitivity and the specificity of ultrasound (US) and conventional radiography for the detection of CPP crystals in patients with knee effusion.

Methods: Consecutive patients > 50 years old with knee effusion on clinical examination seen at the out-patient Rheumatology Unit who underwent aspiration of SF including microscopic investigation of SF samples, were included. In all patients, US and conventional radiography (CR) of the involved knee were performed after arthrocentesis. US examinations were carried out by a rheumatologist trained in this imaging technique who was blinded to all clinical and CR data. A MyLab 70 XV (Esaote Biomedica, Genoa, Italy) machine equipped with a broadband 4–13 MHz linear probe was used. US scanning technique was performed according to standard methods, including suprapatellar views (transverse and longitudinal) with knee in maximal possible flexion to assess femoral hyaline cartilage and lateral and medial longitudinal views with knee extended (as possible) to evaluate lateral and medial meniscal fibrocartilage, respectively. The following US abnormal findings were considered indicative of CPPD: 1) hyperechoic bands within the femoral hyaline cartilage layer; 2) hyperechoic sparkling spots in meniscal fibrocartilage. CR were read by an experienced rheumatologist blinded to all clinical and US data searching for radiological evidence of chondrocalcinosis. SF was analyzed by an experienced biochemist, blinded to clinical and imaging data, using plain light and polarizing light microscopy.

Results: A total of 75 knees were evaluated in the same number of patients [39 male; mean age (SD): 66.6 years (15.7)]. Twenty-four patients had previous diagnosis of primary knee osteoarthritis (OA), 15 rheumatoid arthritis, 10 CPPD (McCarty criteria), 8 psoriatic arthritis and 5 systemic lupus erytematosus. Thirteen patients had knee effusion without definitive diagnosis of any rheumatic condition. Analysis of synovial fluid revealed CPP crystals in 15 out of 75 (20%) examined knees from 9 patients with previous diagnosis of CPPD, 3 patients with previous diagnosis of primary knee OA and 3 patients without previous definitive diagnosis of a rheumatic condition.

Table shows the US and cr diagnostic test properties for the detection of CPP crystals using SF findings as the gold standard.

	Synovial fluid analysis		Sensitivity (95% CI)	Specificity (95% CI)	Positive predictive value (95% CI)	Negative predictive value (95% CI)
	Positive	Negative				
Ultrasound						
Positive	9	2	60% (32.33–83.57)	96.67% (88.45–99.50)	81.82% (48.24–97.18)	90.62% (80.69–96.46)
Negative	6	58				
Conventional radiology						
Positive	6	10	40% (16.43–67.67)	83.3% (71.47–91.69)	37.5% (15.29–64.53)	84.75% (73–92.76)
Negative	9	50				

Conclusion: US showed high specificity with good sensitivity to detect CPP crystals in patients with knee effusion. Compared with CR, US had better specificity and sensitivity. US may be used in daily rheumatologic practice when CPPD is suspected.

Diet-Induced Obesity Results In a Pro-Inflammatory Resting Environment With No Impact On Monosodium Urate Crystal-Induced Inflammation. Odette Shaw[1], Bregina Pool[2], Nicola Dalbeth[2] and Jacquie Harper[1]. [1]Malaghan Institute of Medical Research, Wellington, New Zealand, [2]University of Auckland, Auckland, New Zealand.

Background/Purpose: Obesity-related diseases, including gout, are associated with low-grade chronic inflammation. Although there is evidence that adipose resident macrophages have a pro-inflammatory M1-like phenotype, the impact of obesity on the inflammatory phenotypes of resident macrophage and infiltrating monocytes in other tissues is not clear. This study sought to determine if diet-driven obesity alters the inflammatory phenotype of non-adipose tissue resident macrophages and changes the inflammatory response to monosodium urate (MSU) crystals.

Methods: C57BlJ6 mice were fed normal chow containing 5.3% fat or high fat chow containing 23.5% fat for 12 weeks and then challenged with 3mg MSU crystals intraperitoneally (n=30 per group). Peritoneal lavage was carried out at 0, 8 and 18 hours. Peritoneal monocyte and neutrophil numbers were determined by flow cytometry and cytokine levels were quantified by ELISA. Purified resident peritoneal macrophages and 18 h MSU-recruited monocytes were stimulated *ex vivo* with MSU crystals and cytokine levels were measured.

Results: Mice receiving the high fat diet had higher weight, visceral adipose tissue, blood glucose and circulating insulin levels, compared to mice fed normal diet. The obese mice had significantly higher basal levels of the pro-inflammatory cytokine IL-6, the neutrophil and monocyte chemokines (KC and MCP-1 respectively) and the inflammatory differentiation factor GM-CSF in peritoneal fluid (Figure). This elevated inflammatory profile did not increase the numbers of peritoneal monocyte/macrophages or neutrophils in unchallenged obese mice compared to controls. Naïve, unstimulated resident macrophages from obese mice produced elevated levels of pro-inflammatory cytokines but produced less upon MSU crystal stimulation *ex vivo*. Consistent with this pattern, the elevated basal levels of peritoneal cytokines observed in obese mice decreased during MSU crystal-induced inflammation *in vivo* and there was a trend towards decreased MSU crystal-induced cell infiltration. IL-1b responses to MSU crystals were not different in the two groups.

Conclusion: Obesity induces a high basal pro-inflammatory environment outside the adipose tissue that may originate from the development of a GM-CSF-driven inflammatory resident macrophage phenotype. However, this phenotype does not translate into in an increased inflammatory response to MSU crystal stimulation. These data suggest that a heightened inflammatory background does not predict exacerbation of MSU crystal-induced inflammation.

Figure. NO FIGURE AVAILABLE. High fat diet increased basal cytokine levels but did not alter cytokine production following MSU-induced inflammation. Mice were fed on low fat (NFD) or high fat (HFD) diet for 12 weeks. Mice were then injected i.p. with MSU crystals for 8 or 18h. Mean (SEM) peritoneal lavage (A) IL-6, (B) KC, (C) MCP-1 and (D) GM-CSF.

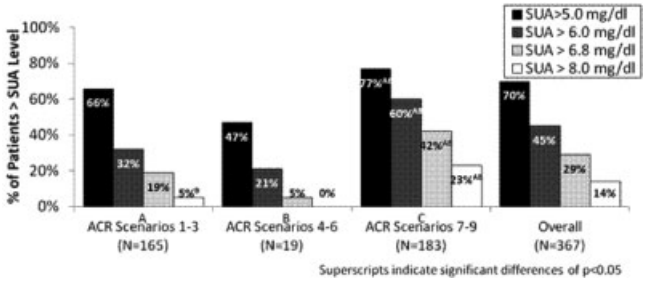
Many Gout Patients Treated By Rheumatologists Do Not Meet Established Treatment Goals Despite Long-Term Urate Lowering Therapy: Results Of a Gout Patient Encounter Survey. Max I. Hamburger[1], Michael H. Pillinger[2], Robert Sederman[3] and Gary Fernandez[4]. [1]Rheumatology Associates, Melville, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY, [3]C1 Consulting, LLC, Summit, NJ, [4]Savient Pharmaceuticals, Bridgewater, NJ.

Background/Purpose: In Oct 2012, the ACR published guidelines for the management of gout. These guidelines recommend pharmacologic treatment that results in a sufficient lowering of the serum urate level to durably improve signs and symptoms of gout, including palpable and visible tophi, with a target of <6 mg/dl at a minimum, and often <5 mg/dl. (Khanna et al. Arthritis Care & Research 2012; 64 10:1431–46.) The extent to which current practice among rheumatologists aligns with these guidelines is unknown, and the areas in which the guidelines may help improve gout treatment remain to be determined. Our purpose was to assess symptoms, treatment, and out-

comes among gout patients treated by US rheumatologists and identify any gaps in current practice per the new ACR recommendations.

Methods: We recruited a national sample of rheumatologists to report gout patient encounters prospectively between Jan 15 and Feb 22, 2013. Anonymous patient data collected included demographics, gout symptoms, rheumatologist assessment of control, gout medications and treatment changes. We applied the ACR working case "scenarios" used in the guideline process and grouped patients by increasing severity: ACR scenarios 1–3 (intermittent symptoms, no tophi), scenarios 4–6 (intermittent symptoms, ≥ 1 tophus) and scenarios 7–9 (Chronic Tophaceous Gouty Arthropathy). We defined "Higher Dose ULT" (Urate Lowering Therapy) as >300mg/day of allopurinol or ≥80 mg/day of febuxostat.

Results: 127 rheumatologists submitted 2,380 patient encounter forms. Patients were mostly male (79%) with mean age of 61 years. 68% of encounters were ACR scenarios 1–3, 4% were 4–6 and 28% were 7–9. 24% of patients were on Higher Dose ULT. Among those on Higher Dose ULT, 50% had an SUA >6 mg/dl, including 36% in ACR scenarios 1–3, 28% in 4–6 and 68% in 7–9. Despite elevated SUA levels, 45% of encounters did not result in a dose increase or change in ULT at the visit. Figure 1 shows that many patients have an SUA >6 mg/dl, even after 6 months on Higher Dose ULT.



Conclusion: Our results suggest that a high percentage of gout patients treated by rheumatologists are not at ACR recognized treatment goals, even after 6 months on Higher Dose ULT. The new ACR treatment guidelines recommend these patients should be considered for an increase in ULT dose or other treatment change, but no change was made in nearly 1/2 of encounters. These findings indicate gout management is currently suboptimal and inadequately aggressive for many patients. Further study is needed to determine the long-term impact of the new ACR treatment guidelines.

Ten-Year Incidence of Self-Reported Nonvertebral Fractures in 9,720 Japanese Patients With Rheumatoid Arthritis: A Prospective Observational Cohort Study. Kensuke Ochi[1], Takefumi Furuya[1], Eisuke Inoue[2], Katsunori Ikari[1], Atsuo Taniguchi[1], Hisashi Yamanaka[1] and Shigeki Momohara[1]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan.

Ten-Year Incidence of Self-reported Nonvertebral Fractures in 9,720 Japanese Patients with Rheumatoid Arthritis: A Prospective Observational Cohort Study

Background/Purpose: Although rheumatoid arthritis (RA) is a risk factor for osteoporosis and fracture, few studies have described the correlation between disease activity of RA and incidence of fracture in patients with RA. We previously reported that disease activity in our Institute of Rheumatology Rheumatoid Arthritis (IORRA) cohort improved significantly from 2001 to 2010; however, the change in the incidence of fractures in this period is unknown. This study aimed to investigate the change in the incidence of nonvertebral fractures between 2001 and 2010.

Methods: The IORRA is a prospective observational cohort study of Japanese RA patients at the Institute of Rheumatology, Tokyo Women's Medical University. A total of 9,720 patients (82% female; mean age, 56 years) with RA were enrolled in the IORRA cohort study from 2000 to 2010. Clinical parameters, including physician's assessment, patient's assessment, and laboratory data, were collected biannually in April and October. All participants self-reported the occurrence of a nonvertebral fracture within the previous 6 months and the fracture sites. Statistical analysis was performed using the *f*Ô test with a confidence interval of 95%.

Results: From 2001 to 2010, the percentage of patients with DAS28 remission increased from 7.8% to 39.7%, the mean score on the Japanese version of the health assessment questionnaire decreased from 0.82 to 0.65, prednisolone intake decreased from 51.4% (mean, 4.7 mg/day) to 41.3% (mean, 4.1 mg/day), and bisphosphonate intake increased from 5.0% to 23.4%. The incidence of nonvertebral fracture was 1.19% in 2001 and 1.79% in 2010, with no apparent change (mean, 1.78% [0.23%]; Figure 1). The incidence of fracture increased dramatically after the age of 45 years in women, while the increase was linear in men. The mean age of fracture (year) and the mean incidence of fracture (%) were 61.8 (12.7) and 0.36 (0.05) in the ribs, 65.9 (11.1) and 0.07 (0.03) in the pelvis, 66.8 (10.4) and 0.11 (0.04) in the shoulder, 67.4 (10.4) and 0.12 (0.04) in the wrist, 68.4 (9.4) and 0.18 (0.06) in the hip, and 62.5 (10.6) and 0.13 (0.04) in the ankle, respectively. Overall incidence of nonvertebral fracture was significantly higher in the autumn/winter than in the spring/summer ($p = 0.02$).

Conclusion: Despite the improvement in disease activity and functional disability, the incidence of nonvertebral fracture appears to show no apparent change between 2001 and 2010 in our patients with RA.

Romosozumab Administration Is Associated With Significant Improvements In Lumbar Spine and Hip Volumetric Bone Mineral Density and Content Compared With Teriparatide. H K Genant[1], S Boonen[2], M A Bolognese[3], C Mautalen[4], J P Brown[5], C Recknor[6], S Goemaere[7], K Engelke[8], Y-C Yang[9], M Austin[9], A Grauer[9] and C Libanati[9]. [1]UCSF & Synarc Inc., San Francisco, CA, [2]Leuven University Division of Geriatric Medicine, Leuven, Belgium, [3]The Bethesda Health Research Center, Bethesda, MD, [4]Centro de Osteopatias Medicas, Buenos Aires, Argentina, [5]CHU de Québec Research Centre and Laval University, Québec, QC, [6]United Osteoporosis Centers, Gainesville, GA, [7]Ghent University Hospital, Ghent, Belgium, [8]Synarc Germany, Hamburg, Germany, [9]Amgen Inc., Thousand Oaks, CA.

Background/Purpose: Sclerostin is an osteocyte-derived inhibitor of osteoblast activity. Romosozumab, a monoclonal antibody to sclerostin stimulates bone formation and decreases bone resorption. In a phase 2 study, romosozumab administered for 12 months increased areal bone mineral density (BMD) at the lumbar spine (LS) and total hip (TH) as measured by dual X-ray absorptiometry compared with placebo (Pbo), alendronate, and teriparatide (TPTD) in postmenopausal women with low bone mass. Here we describe the effect of romosozumab on LS and TH volumetric BMD (vBMD), and bone mineral content (BMC) as measured by quantitative computed tomography (QCT) in this trial.

Methods: This international, randomized, Pbo-controlled, phase 2 study enrolled postmenopausal women of 55–85 years with LS, TH, or femoral neck T-score ≤–2.0 and ≥–3.5. Measurements with QCT were performed at the "total" LS (mean of L1 and L2 entire vertebral bodies) and TH in subjects receiving Pbo, subcutaneous TPTD (20 μg QD), and romosozumab (210 mg QM). Percentage change from baseline in integral and cortical vBMD and BMC, and trabecular vBMD was evaluated at 12 months. The analyses included subjects with baseline and ≥1 post-baseline QCT measurements.

Results: Treatment with romosozumab resulted in significant increases in integral vBMD and BMC at the "total" LS and TH from baseline, and compared with Pbo and TPTD (Figure). TPTD and Pbo were similar at the TH, but not the LS. In the trabecular and cortical bone compartments, differences between romosozumab and TPTD were observed. Trabecular vBMD increased from baseline with both romosozumab and TPTD at the LS and TH (both $P<0.05$). These gains in trabecular vBMD were similar with romosozumab and TPTD at the LS (18.3% vs 20.1%, respectively), but

significantly larger with romosozumab at the TH (10.8% vs 4.2%, $P=0.01$). Cortical vBMD gains were larger with romosozumab compared with TPTD at the LS (13.7% vs 5.7%, $P<0.0001$) and TH (1.1% vs –0.9%, $P=0.12$). Cortical BMC gains were larger with romosozumab compared with TPTD at both the LS (23.3% vs 10.9%, $P<0.0001$) and TH (3.4% vs 0.0%, $P=0.03$).

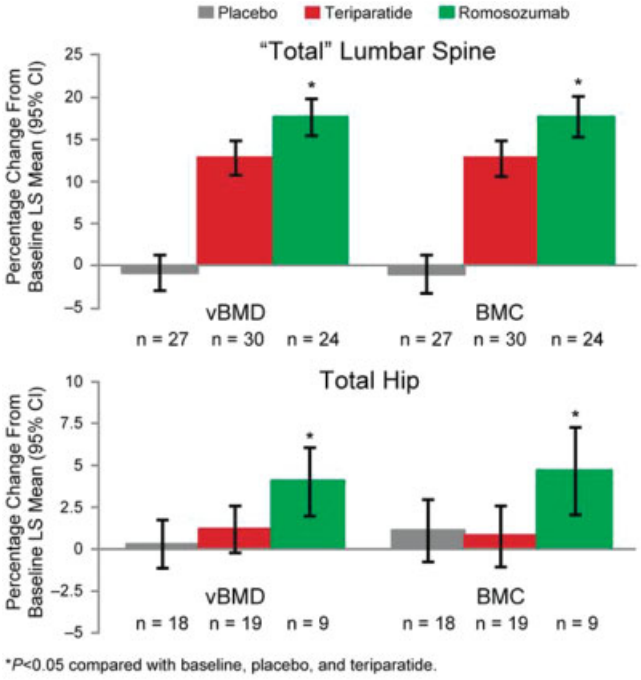

Figure. Percentage Change in Integral vBMD and BMC From Baseline at 12 Months.

Conclusion: Romosozumab significantly increased vBMD and BMC at the "total" LS and TH compared with Pbo and TPTD in postmenopausal women with low bone mass. The gains, observed in the trabecular and cortical compartments, support the continued clinical investigation of romosozumab as a potential treatment for women with postmenopausal osteoporosis with established BMD deficits and at increased fracture risk.

Further Reduction In Nonvertebral Fracture Rate Is Observed Following 3 Years Of Denosumab Treatment: Results With Up To 7 Years In The Freedom Extension. Jonathan D. Adachi[1], Serge Ferrari[2], Carol Zapalowski[3], Paul D. Miller[4], Jean-Yves Reginster[5], Ove Törring[6], Nadia Daizadeh[3], Andrea Wang[3], Cynthia O'Malley[3], Rachel B. Wagman[3] and E. Michael Lewiecki[7]. [1]McMaster University, Hamilton, ON, [2]Geneva University Hospital, Geneva, Switzerland, [3]Amgen Inc., Thousand Oaks, CA, [4]Colorado Center for Bone Research, Lakewood, CO, [5]University of Liège, Liège, Belgium, [6]Karolinska Institutet, Södersjukhuset, Stockholm, Sweden, [7]New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM.

Background/Purpose: Some antiresorptives reduce nonvertebral fracture incidence in the first 3 years of treatment; however, evidence for further reduction of nonvertebral fractures with prolonged therapy is limited. The effects of denosumab (DMAb) treatment for up to 10 years are being evaluated in the 3-year FREEDOM study and its 7-year extension. Here we compare the nonvertebral fracture rate during the first 3 years of DMAb with that in the following 4 years of treatment.

Methods: During the extension, all subjects received 60 mg DMAb Q6M. Here, long-term subjects received 7 years of DMAb (3 years in FREEDOM followed by 4 years in the extension); subjects from the cross-over group received 4 years of DMAb (3 years of placebo in FREEDOM followed by 4 years of DMAb in the extension). Nonvertebral fracture rates for the first 3 years of DMAb were compared with rates in the 4th year of DMAb in each group separately and combined. For the long-term group only, the nonvertebral fracture rate in the first 3 years of DMAb was also compared with the fracture rate during the subsequent 4 years. Adjusted rate ratios (95% CIs) between observational periods were computed via generalized estimating equation (GEE) Poisson regression.

Results: Of 5928 women eligible for the extension, 4550 (77%) enrolled (N=2343 long-term; N=2207 cross-over). In the long-term group, the nonvertebral fracture rate was 1.98 per 100 subject-years during years 1–3 of DMAb (FREEDOM). This rate decreased during year 4 (extension) to 1.43 (rate ratio=0.73; $P=0.096$), and the rate remained low at 1.45 during years 4–7 (rate ratio=0.74; $P=0.016$; Table). Similarly for the cross-over group, the fracture rate was 2.20 during years 1–3 of DMAb (extension) and decreased to 1.03 at year 4 (rate ratio=0.48; $P=0.004$). Combining the long-term and cross-over groups yielded a fracture rate of 2.08 during the first 3 years of DMAb (FREEDOM or extension) that decreased to 1.27 at year 4 (rate ratio=0.62; $P=0.002$).

Conclusion: Three years of DMAb treatment significantly reduced the nonvertebral fracture rate compared with placebo. When DMAb was continued for an additional 4 years, the fracture rate remained low and was significantly lower than that in the first 3 years of treatment. Contributing factors that might explain this observation include sustained reduction in bone resorption, continued gains in hip BMD and bone mass, decrease in cortical porosity, and increases in cortical/trabecular strength observed with DMAb treatment.

Vertebral Fractures In The 3 Year Period Following Steroid Initiation Among Children With Chronic Illnesses. Johannes Roth[1], Jinhui Ma[1], David A. Cabral[2], Peter B. Dent[3], Janet E. Ellsworth[4], Adam M. Huber[5], Kristin M. Houghton[6], Roman Jurencak[1], Bianca A. Lang[7], Maggie Larche[3], Claire MA Leblanc[8], Brian Lentle[6], MaryAnn Matzinger[1], Paivi M. Miettunen[9], Kiem Oen[10], Claire Saint-cyr[11], Rosie Scuccimarri[12], Nazih Shenouda[1], Leanne M. Ward[1] and The Canadian STOPP Consortium[13]. [1]University of Ottawa, Ottawa, ON, [2]BC Children's Hospital, Vancouver, BC, [3]McMaster University, Hamilton, ON, [4]University of Alberta, Edmonton, AB, [5]IWK Health Centre and Dalhousie University, Halifax, NS, [6]University of British Columbia, Vancouver, BC, [7]Dalhousie University, Halifax, NS, [8]McGill University, Montréal, QC, [9]University of Calgary, Calgary, AB, [10]University of Manitoba, Winnipeg, MB, [11]Université de Montréal, Montreal, QC, [12]Montreal Children's Hospital and McGill University, Montréal, QC, [13]National Pediatric Bone Health Working Group, Ottawa, ON.

Background/Purpose: To describe the pattern and frequency of incident vertebral fractures (VF) in glucocorticoid (GC)-treated children and to determine the clinical factors at baseline that are associated with incident VF.

Methods: In children with leukemia, rheumatic disorders and nephrotic syndrome, VF were assessed prospectively each year following GC initiation for 3 years, according to the Genant semi-quantitative method. An incident VF was defined as a new fracture in a previously normal vertebral body or worsening of an existing fracture. The 3-year cumulative VF incidence rate was then calculated. Multivariable Poisson regression was used to examine associations between the 3-year total number of incident VF and clinical factors *at baseline*, including diagnosis, age, gender, pubertal stage, height

and body mass index (BMI) Z-scores, calcium and vitamin D intake, physical activity, back pain, and lumbar spine (LS) bone mass density (BMD) Z-score. In addition, prevalent VF (at baseline) as well as cumulative GC exposure and the number of days in receipt of GC until the baseline visit were also assessed for their relationship with 3-year, incident VF.

Results: 404 children were enrolled at a median age of 6.2 years, range 1–17; 50% boys; 188 (46%) had leukemia, 136 (34%) rheumatic conditions, and 80 (20%) nephrotic syndrome. The baseline study visit occurred at a median of 18 days following steroid initiation (inter-quartile range 11–24 days). Forty-four (11%) children had VF at baseline, while 134 incident VF were detected in 55 children over the 3 years. Overall, 17% of children (95% CI 13–22) had at least one incident VF over the 3 years. The proportions of children with incident VF were as follows: Leukemia: 24% (95% CI 16–32); rheumatic disorders: 13% (95% CI 6–19); nephrotic syndrome 9% (95% CI 1–17). The annual proportion of children with incident VF peaked at 12 months and declined thereafter ($p=0.04$). Among those with incident VF, 24/55 children (44%) had 1 or more moderate or severe fracture. Most of the VF were new fractures in previously normal vertebral bodies (86%), compared to worsening of existing VF. In Poisson multivariable modeling assessing *baseline* clinical factors, the following were associated with higher, 3-year VF incident rates: the presence of VF at baseline (incidence Rate Ratio (RR) 6.3, 95% CI 3.2–12.4), female gender (RR 1.8; 95% CI 1.0–3.3), pre-pubertal status (RR 2.1; 95% CI 0.8–5.4), and lower BMD Z-scores (RR 1.4; 95% CI 1.1–1.7). Underlying diagnosis and back pain at baseline were highly correlated with these significant factors (co-linear). Other factors at baseline were not significantly associated with incident VF.

Conclusion: Within 3 years of steroid initiation, 17% of children had incident VF. VF incidence peaked at 12 months, and almost half of the VF were moderate or severe. Of the factors measured *at baseline*, prevalent VF were most strongly associated with incident VF over the ensuing 3 years. Female gender, pre-pubertal status and low BMD at baseline were also associated with 3-year incident VF (for every 1 standard deviation reduction in spine BMD Z-score, there was a 40% increased incident VF risk).

Use Of Non Steroidal Anti-Inflammatory Drugs Prevent Bone Loss In Patients With Early Inflammatory Back Pain: Results From The DESIR Cohort. Karine Briot[1], Simon Paternotte[1], Corinne Miceli-Richard[2], Maxime Dougados[3] and Christian Roux[1]. [1]Paris Descartes University, Paris, France, [2]Université Paris Sud, Le Kremlin Bicêtre, France, [3]Paris- Descartes University, Paris, France.

Background/Purpose: To assess the 2-year bone mineral density (BMD) changes at lumbar spine and hip in a large cohort of patients with early inflammatory back pain (IBP) suggestive of axial Spondyloarthritis (SpA), and to assess determinants of bone loss.

Methods: of the 708 patients of the DESIR cohort (IBP of less than 3 years duration suggestive of axial SpA), 265 (54% males, mean age 34.4 years) had BMD measurements at baseline and 2 years. Low BMD was defined as Z score ≤ -2 (at at least one site) and significant bone loss was defined by a decrease in BMD$\geq$0.03g/cm^2. Clinical, biological (erythrocyte sedimentation rate ESR and C reactive protein CRP, bone formation inhibitors markers (sclerostin and DKK-1 serum levels)), imaging (X-rays, spine and sacroiliac joints MRI) parameters and therapies were assessed. AntiTNF users were defined as those who received antiTNF at 2 years. The dependant variable of this study was the bone loss (decrease in BMD$>$ 0.03 g/cm2) at either lumbar spine or hip site. Independant variables included both the ones collected at baseline (age, gender, BMI, BASDAI, ADSAS CRP, ESR, CRP, HLA B27, current use of NSAIDS use, ASAS NSAIDs score, X-rays sacroiliitis, bone marrow oedema on sacroiliac or spine MRI, lean and fat masses, sclerostin and DKK-1) and 2-year longitudinal variables (BMI, BASDAI, ADSAS CRP, ESR, CRP, current NSAIDS use, ASAS NSAIDs score, lean and fat masses, intake of antiTNF). Parameters were tested in univariate and multivariate analyses; accuracy of models was measured by the area under the curve (AUC).

Results: Thirty nine patients (14.7%) patients had low BMD at baseline. 2-year BMD significantly changed from baseline at lumbar spine (+1.3 (6.4) %, p=0.02) and total hip (−0.3 (4.0) %, p=0.02). 95 patients (35.8%) had a 2-year significant bone loss (at lumbar spine or hip), 59 (22.4%) at lumbar spine and 46 (18.0%) at total hip. 187 (70.6%) had current use of NSAIDS at baseline and 89 (33.6%) received anti-TNF at 2 years (mean duration 5.7 (9.1) months). Significant 2-year lumbar spine bone loss was associated in multivariate analysis with age (OR=1.06 (1.00 – 1.12), p=0.017) (AUC= 0.608). In multivariate analysis, current use of NSAIDS at baseline (OR=0.38 (0.19–0.76), p=0.006) had a protective effect on hip bone loss (AUC= 0.608). In patients without anti-TNF treatments at 2 years (n=176): male gender was the only predictor of lumbar spine bone loss (OR= 2.4 (1.13–5.09), p=0.023) (AUC= 0.608). In these patients, current use of NSAIDS (OR= 0.09 (0.02 – 0.5), p= 0.006) and 2-year increase in BMI (OR= 0.55 (0.37–0.85), p=0.003) had protective effects on hip bone loss whereas 2-year increase in fat mass was associated with hip bone loss (OR=1.18 (1.02–1.42), p=0.046) (AUC=0.833).

Conclusion: Among patients with early IBP among whom a third received antiTNF during the follow-up, BMD are in the normal range and 35% have significant bone loss over 2 years. Current use of NSAIDS has a protective effect on hip bone loss in patients with or without antiTNF.

Reduced Hip Cortical Porosity Upon Denosumab Treatment: A Likely Mechanism Contributing To The Reduction Of Hip Fracture Risk In Women With Osteoporosis. R. M. Zebaze[1], C. Libanati[2], M. R. McClung[3], J. R. Zanchetta[4], D. L. Kendler[5], A. Høiseth[6], A. Wang[2], A. Ghasem-Zadeh[1] and E. Seeman[1]. [1]Austin Health, University of Melbourne, Melbourne, Australia, [2]Amgen Inc., Thousand Oaks, CA, [3]Oregon Osteoporosis Center, Portland, OR, [4]Instituto de Investigaciones Metabólicas, Buenos Aires, Argentina, [5]University of British Columbia, Vancouver, BC, [6]Curato Røntgen, Oslo, Norway.

Background/Purpose: Nonvertebral fracture risk is significantly influenced by cortical thickness, area, mass, and porosity because all of these contribute to bone strength. In particular, increased cortical porosity, a marker of structural decay, is associated with an exponential worsening in bone fragility. Cortical porosity is the result of unbalanced and accelerated intracortical remodeling upon Haversian canal surfaces which enlarge, coalesce, and fragment the cortex. Reducing remodeling will limit worsening of porosity but for individuals already at increased risk for fracture, reducing porosity is a preferred outcome. Using multi detector computer tomography (MDCT) hip images from the FREEDOM study, we previously reported that hip cortical mass and thickness improved over 3 years of denosumab (DMAb) administration and postulated that this could be explained by infilling of porosity in the inner cortical region adjacent to the medullary canal. Here, we used a subset of these images to evaluate changes in hip porosity.

Methods: FREEDOM was a 3-year, randomized, double-blind trial that enrolled postmenopausal women with a lumbar spine or total hip T-score <-2.5 but not <-4.0 at both sites. Women were randomly assigned to placebo (Pbo) or 60 mg DMAb every 6 months. Percentage porosity in both the compact and the trabecularized (outer and inner transitional zones) cortical volumes of the subtrochanter region were measured using StrAx1.0 software (Zebaze et al., *Bone* 2013) from MDCT hip images obtained at baseline and year 3 (Pbo, n=22; DMAb, n=28).

Results: Cortical porosity was larger as a function of proximity to the medullary canal; the percentage volume occupied by porosity at baseline was 72% in the inner transitional zone adjacent to the medullary compartment, 37% in the outer transitional zone, and 29% in the compact-appearing cortex. Cortical porosity correlated positively with serum CTX ($p=0.017$) and negatively with hip strength estimated using finite element analysis ($p=0.027$). DMAb reduced porosity compared with baseline and Pbo at year 3 across the entire cortex (Figure) and in each cortical sub-compartment, reaching treatment effect (DMAb–Pbo) improvements of –1.8% (inner transitional zone), –5.6% (outer transitional zone), and –7.9% (compact-appearing cortex) (all $p<0.001$).

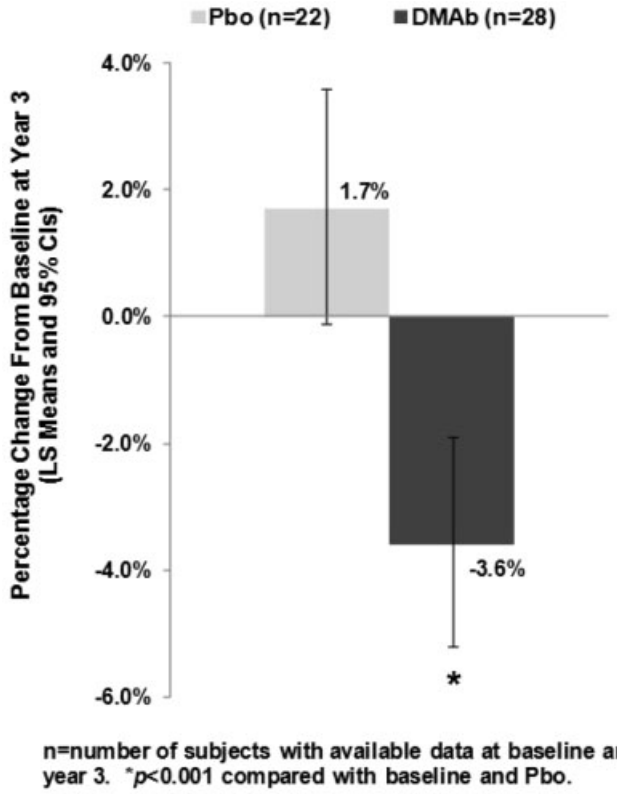

Figure. Percentage Change From Baseline at Year 3 in Cortical Porosity at the Hip

Conclusion: This is the first report of *in vivo* hip porosity changes in response to a pharmacological therapy. Since reductions in cortical porosity equate to increased mineralized bone matrix mass and both are relevant to strength, these improvements are expected to contribute to the observed reductions in nonvertebral fractures associated with DMAb administration.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Clinical Aspects II: Identifying Rheumatoid Arthritis in At-Risk Populations
Sunday, October 27, 2013, 4:30 PM–6:00 PM

868

Serum Immunoglobulin Free Light Chains and Rheumatoid Arthritis: A Population-Based Study. John M. Davis III[1], S. Vincent Rajkumar[1], Cynthia S. Crowson[1], Xiaoli Deng[2], Angela Dispenzieri[1], Dirk R. Larson[1], Terry M. Therneau[1], Eric L. Matteson[1], Robert A. Kyle[1], Jerry Katzmann[1] and Sherine E. Gabriel[1]. [1]Mayo Clinic, Rochester, MN, [2]Peking University Third Hospital, Beijing, China.

Background/Purpose: Serum immunoglobulin free light chains (FLCs) represent biomarkers of B-cell activation and have been associated with rheumatoid arthritis (RA) as well as all-cause mortality in the general population. The objective of this study was to evaluate the relationships of serum FLCs to pre-clinical disease, RA characteristics, and mortality in persons with RA compared to non-RA subjects.

Methods: A population-based study during the period of 1995 – 2003 was performed by cross-linking a large cohort in the general population with available serum FLC data with our established RA inception and prevalence cohorts. FLCs were measured using commercial immunonephelometric assays. The estimated glomerular filtration rate (eGFR) was estimated using the CKD-EPI formula. Levels of serum κ, λ, and total FLCs and their trends relative to RA incidence were compared between RA and non-RA subjects. Associations between RA disease characteristics and serum total FLCs were assessed using linear and logistic regression models, adjusting for age and sex. Among the population with normal κ-to-λ ratio (0.26 – 1.65), Cox models were used to determine the association between serum FLCs and mortality, adjusting for age, sex, serum creatinine, and the RA × FLC interaction variable.

Results: Among 16,609 subjects, 270 fulfilled criteria for RA at the time of the serum FLC measurement. The patients with RA were slightly older (mean age 67 vs. 65 years, $p<0.001$) and more frequently female (68% vs. 55%, $p<0.001$). The mean κ-to-λ ratio was similarly normal in both groups ($p = 0.9$), and there was no difference in the proportions of RA and non-RA subjects with an abnormal κ-to-λ ratio, which by definition indicates monoclonal gammopathy (3.3% vs. 4.1%, $p=0.48$). Significant elevations of κ, λ and total FLCs were observed in the RA compared to non-RA subjects (mean total FLCs: 4.2 vs. 3.3 mg/dL, $p<0.001$). These findings were not explained by any difference in the mean eGFR, which was similar between the groups (64.8 vs. 65.2 mL/min/1.73 m^2, $p=0.56$). Serum FLCs became elevated 3 – 5 years before the clinical onset of RA and remained elevated during follow-up (Figure). Total FLCs were associated with severe extra-articular manifestations (odds ratio = 3.64; 95% confidence interval [CI]: 1.26, 10.58) but not with rheumatoid factor or the sedimentation rate. Finally, total FLCs were associated with increased mortality in the RA population (hazard ratio = 1.07 per mg/dL; 95% CI: 1.03, 1.11), though the effect on mortality appeared to be attenuated in RA compared to non-RA subjects, perhaps due to treatment with immunosuppressive therapies or to other competing factors.

Conclusion: Serum FLCs are significantly elevated in patients with RA compared to the general population. The elevation of serum FLCs precedes the clinical onset of disease. Serum FLCs may be useful in monitoring B-cell activity and in assessing prognosis.

Anti-Carbamylated Protein Antibodies Are Present Prior To The Diagnosis Of Rheumatoid Arthritis and Predict Future Disease Onset. Ryan W. Gan[1], Leendert A. Trouw[2], Jing Shi[2], René E.M. Toes[2], Tom W. J. Huizinga[2], Gary O. Zerbe[3], Kevin D. Deane[4], Jess Edison[5], William R. Gilliland[5], Jill M. Norris[1] and V. Michael Holers[4]. [1]Colorado School of Public Health, Aurora, CO, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Colorado School of Public Health / University of Colorado Anschutz Medical Campus, Aurora, CO, [4]University of Colorado School of Medicine, Aurora, CO, [5]Walter Reed National Military Medical Center, Bethesda, MD.

Background/Purpose: Anti-cyclic citrullinated peptide-2 (CCP2) can be present in serum years before a diagnosis of rheumatoid arthritis (RA), and is highly specific (>95%) for the future onset of RA: however, its sensitivity for future RA is relatively low. Thus, novel autoantibodies (Abs) that are highly sensitive and specific for RA would be a valuable predictive tool. Recently, Shi and colleagues (Shi et al, *PNAS,* 2011) discovered that anti-carbamylated protein (anti-CarP) was not sensitive (43%), but highly specific (95%) for classified RA as well as present prior to the onset of classifiable RA in subjects with arthralgia but no inflammatory arthritis who were positive for CCP and/or rheumatoid factor (RF)(IgM) (Shi et al, *A&R*, 2013). Herein we utilized a unique sample set of military subjects to determine if serum anti-CarP antibodies are present before RA diagnosis, and compared the diagnostic accuracy of anti-CarP to other RA-related Abs.

Methods: Stored pre-diagnosis serum samples from military personnel were obtained from 82 RA cases and 82 controls matched on case age at diagnosis, sex, and race. We tested the pre-RA diagnosis samples from cases and controls for anti-CarP Fetal Calf Serum (FCS) and anti-CarP Fibrinogen (Fib), as well as RF by nephelometry, RF isotypes (IgM, IgG, and IgA), CCP2 (Axis-Shield), and CCP3.1 (Inova). The cutoffs for anti-CarP were determined using the mean +2 SD of log-transformed levels from 41 randomly selected military controls. The diagnostic accuracy of Abs for future RA were assessed in prediagnosis serum and logistic regression was used to determine the association between RA case status and antibody

positivity in prediagnosis serum, comparing RA cases to the 41 remaining controls.

Results: RA cases, cutoff controls, and controls had similar demographic characteristics. The diagnostic accuracy in prediagnosis serum for each Ab is presented in the Table. Anti-CarP FCS was 29.9% sensitive (SENS) and 95% specific (SPEC) for future RA; anti-CarP Fib was 17.9% SENS and 95.1% SPEC. There was a strong association between RF and/or CCP positive RA case status and anti-CarP FCS positivity in prediagnosis serum (OR: 8.3, 95% CI: 1.8–37.7, p<0.01); however, there was a non-significant association between seropositive RA case status and anti-CarP Fib positivity in prediagnosis serum (OR: 4.3, 95% CI: 0.9–20.8, p=0.07).

Table: Sensitivity and specificity for RA-related autoantibodies in prediagnosis serum samples, including only seropositive (RF and/or CCP positive) RA cases.

Antibody	Sensitivity (%) of 67 cases with RA	Specificity (%) of 41 controls	Positive Predictive Value (%)	Negative Predictive Value (%)
Anti-CCP 2	50.8	100.0	100.0	55.4
Anti-CCP 3.1	56.7	75.6	79.2	51.7
RF	52.2	85.4	85.4	52.2
RF IgM	55.2	87.8	88.1	42.9
RF IgG	25.4	82.9	70.8	40.5
RF IgA	55.2	87.8	88.1	54.5
Anti-CCP2 and/or ≥ 2 RF Isotypes	58.2	90.2	90.7	56.9
Anti-CarP FCS	29.9	95.1	90.9	45.3
Anti-Carp FCS and/or ≥ 2 RF Isotypes	49.3	85.4	84.6	50.7
Anti-CarP Fib	17.9	95.1	85.7	41.5
Anti-Carp Fib and/or ≥ 2 RF Isotypes	47.8	85.4	84.2	50.0

Conclusion: Our results suggest that anti-CarP antibodies, are present in RA cases before clinically apparent disease, and the presence of anti-CarP FCS is strongly associated with future onset of RA (Positive Predictive Value=90.9%). Identification of novel antibodies such as anti-CarP FCS can elucidate disease mechanisms and predict the onset of RA.

How To Predict That Early Arthritis Without Rheumatoid Factor and ACPA Becomes Rheumatoid Arthritis According To ACR/EULAR 2010 After a 3-Years Follow-Up? Results From The Espoir Cohort. Gaël Mouterde[1], Cédric Lukas[2], Nathalie Rincheval[3], Alain Saraux[4], Philippe Dieude[5] and Bernard Combe[6]. [1]Montpellier 1 University, Lapeyronie Hospital, Montpellier, France, [2]Lapeyronie Hospital, Montpellier, France, [3]Institut Universitaire de Recherche Clinique, Montpellier, France, [4]CHU Brest et Université Bretagne Occidentale, Brest, France, [5]Rheumatology departement & INSERM U699, Paris Diderot university, APHP, Bichat hospital, Paris, France, [6]Lapeyronie Hospital, Montpellier I university, Montpellier, France.

Background/Purpose: To describe disease course of patients without rheumatoid factor (RF) and anti-citrullinated protein auto-antibodies (ACPA) in an inception cohort of early arthritis patients. To determine baseline predictors of development of rheumatoid arthritis (RA) according to ACR/EULAR 2010 criteria at 3 years in these patients.

Methods: Patients presenting with synovitis of at least 2 joints for 6 weeks to 6 months were included in the multicenter French ESPOIR cohort. Following data were collected at baseline for those who were negative for IgM RF and ACPA (anti-CCP2): clinical and biological features of arthritis, HLA-DRB1* typing, socio economic factors, comorbidities, radiographs of hands, wrists, and feet (modified Sharp score). RA was defined according to the 2010 ACR/EULAR classification criteria (1) at any visit during the first 3 years of follow-up or by typical RA erosion (2). Alternative diagnoses were reported among patients who did not fulfill ACR/EULAR criteria. Logistic regression was performed to evaluate the association between RA diagnosis at 3 years and baseline variables.

Results: Of the 813 recruited patients, 406 (49.9%) were negative for both RF and anti-CCP2. They had the following characteristics: age 49±13 years, females 77%, mean disease duration: 102+/−50 days, median morning stiffness: 45mn [IQR 15 – 90], median pain at rest: 34/100 [IQR 12 – 58], median tender joint count (TJC) 6 [IQR 3 – 13], DAS28 4.95±1.3, HAQ score 0.93±0.68, CRP 18.6±34.2 mg/l. 70 (19.3%) patients had typical RA erosions on X-ray; 57 (14.1%) had antinuclear antibodies (ANA) and 39 (9.6%) were RF-IgA positive. 246/387 patients (63.6%) fulfilled ACR/EULAR 2010 criteria for RA at baseline and 269/374 (71.9%) at 3 years. In this seronegative cohort, diagnosis of RA at 3 years was associated with the following initial factors: symmetric involvement (OR=3 [1.41; 6.39], p=0.004), morning stiffness (>median: 45 min) (OR=2.48 [1.34; 4.57], p=0.004), pain at rest on a VAS (>median: 34/100) (OR=2.14 [1.14; 4.01], p=0.017), number of tender joints (>median: 6) (OR=3.51 [1.78; 6.92], p<0.001) and presence of feet erosions (OR=2.96 [1.19; 7.40], p=0.020). Presence of ANA (OR=0.38 [0.17; 0.87], p=0.021), transaminases elevation (OR=0.52 [0.28; 0.94], p=0.032) and living in the south of France (OR=0.45 [0.22; 0.90], p=0.024) had a protective effect against progression to RA. No association between extra-articular manifestations, HLA-DR3 and "seronegative RA" was observed. Among the 105 patients who did not fulfill ACR/EULAR 2010 criteria for RA at 3 years, 44 had another definite diagnosis: psoriatic arthritis (n=10), spondyloarthritis (n=7), erosive hand osteoarthritis (n=5), connective tissue disease and vasculitis (n=8), polymyalgia rheumatica or RS3PE syndrome (n=3).

Conclusion: Patients with early arthritis and without RF and ACPA are more prone to have RA at 3 years if they have inflammatory pain, symmetric involvement of numerous joints and typical feet erosions. Detection of ANA and transaminases elevation should suggest non RA diagnosis.

Do We Need To Lower The Cut Point Of The 2010 ACR/EULAR Classification Criteria For Diagnosing Rheumatoid Arthritis?! M. van der Ven[1], J.J. Luime[1], A.H. Gerards[2], C. Alves[1], P.J. Barendregt[3], D. van Zeben[4], M.H. de Jager[5], P.B.J. de Sonnaville[6], B.A. Grillet[7] and J.M.W. Hazes[1]. [1]Erasmus University Medical Center, Rotterdam, Netherlands, [2]Vlietland Hospital, Schiedam, Netherlands, [3]Maasstad Hospital, Rotterdam, Netherlands, [4]Sint Franciscus Gasthuis, Rotterdam, Netherlands, [5]Albert Schweitzer Hospital, Dordrecht, Netherlands, [6]Admiraal de Ruyter Ziekenhuis, Goes, Netherlands, [7]Zorgsaam Hospital, Terneuzen, Netherlands.

Background/Purpose: The 2010 ACR/EULAR classification criteria for rheumatoid arthritis (RA) were recently developed to facilitate the study of persons at earlier stages of the disease. Part of the patients in whom arthritis persists over time does not fulfil the ACR/EULAR 2010 criteria (≥6/10 points) at first consultation. Krabben et al [2013] showed that neither ACPA fine-specificity nor the Leiden prediction rule were able to identify these patients. The developers of the criteria suggest that there is a scope to use other cut points for different purposes. We used the 2010 criteria for diagnostic purposes and evaluated the effect of lowering the cut point to 5/10 points for diagnosing RA.

Methods: Clinical data used were from the Rotterdam Early Arthritis Cohort (REACH). This ongoing, prospective cohort study was set up in the greater Rotterdam area in July 2004. Demographic and clinical characteristics of each patient were recorded at baseline. For the present study we included patients with at least one joint with clinical synovitis as required for the implementation of the ACR/EULAR 2010 criteria (n=557). Outcome after one year was the use of methotrexate (MTX) or persistent disease defined as synovitis present at physical examination after 1 year and no other explanation for the synovitis was present. Sensitivity and specificity of the 2010 criteria for this outcome were determined at each cut point.

Results: Following implementation of the 2010 criteria we identified the undifferentiated arthritis patients (□6/10 points; n=328), the so-called 2010 UA patients. After 12 months follow-up 35% (n=115) of the 2010 UA patients (□6/10 points) used MTX (n=96) or had persistent disease (n=19). Table 1 shows the baseline characteristics of the cases (n=115) and the non-cases (n=213). 63% of the patients in the group with 5 out of 10 points of the 2010 criteria used MTX or had persistent disease. The area under the receiver operator characteristic curve (AUC) of the 2010 criteria for the use of MTX or persistent disease after 12 months was 0.78 (SE 0.02). Sensitivity and specificity for the cut point of 6 were 60% and 79% respectively. With the cut point of 5, sensitivity will increase to 73% and specificity will decrease to 70%. The patients that would be falsely diagnosed as having RA and start treatment when using the cut point of 5 included polyarthritis (n=18) and osteoarthritis (n=2).

Table 1. Baseline characteristics of 2010 UA patients who used MTX or had persistent disease after 1 year follow-up (case) and of those patients in whom arthritis did not persist over time (non-case).

	UA2010 case (n=115)	UA2010 non-case (n=213)
Women (%)	79 (69)	143 (67)
Age, years (mean, SD)	53 (15)	50 (16)
SJC (median, IQR)	5 (3–7)*	2 (1–4)*
TJC (median, IQR)	8 (4–12)*	4 (2–10)*
RF positive (%)	9 (8)	10 (5)
ACCP positive (%)	3 (3)	9 (4)
ESR (median, IQR)	21 (10–37)	13 (6–26)
CRP (median, IQR)	6 (3–31)	5 (2–16)
Morning stiffness, min (median, IQR)	60 (30–120)	45 (30–120)
DAS score (mean, SD)	4.5 (1.0)*	3.8 (1.1)*
Erosions (%)	13 (12)	9 (5)
Symptom duration, days (median,IQR)	95 (52–160)	90 (35–168)
HAQ (mean, SD)	0.9 (0.6)	0.8 (0.6)
Symmetry (%)		
*MCP	67 (58)	86 (41)
*PIP	54 (47)	72 (34)
*MTP	12 (10)	17 (8)
*Wrist	41 (36)	41 (19)

SD = standard deviation, IQR = interquartile range. Independent T-test or Wilcoxon-Mann-Whitney test was used for group comparisons for continuous variables. T-test was executed when variables are presented as mean. Wilcoxon-Mann-Whitney test was executed when variables are presented as median. Frequencies were compared using a Chi-square test. *p-value <0.001

Conclusion: By lowering the cut point of the 2010 criteria from 6 to 5 points, we were able to identify a substantial proportion of UA patients who develop RA within 1 year with higher sensitivity, but with the loss of some specificity. Hereby early treatment can be initiated, leading to optimal use of the window of opportunity.

Spontaneous Remission In Patients Fulfilling The 2010 Classification Criteria For Rheumatoid Arthritis: The Impact Of Duration Of Joint Swelling. Ellen Sauar Norli[1], Elisabeth Lie[2], Gina Hetland Brinkmann[3], Olav Bjørneboe[1], Halvor Nygaard[4], Anne Julsrud Haugen[3], Patrik Stolt[5], Cathrine Thunem[6], Tore K. Kvien[2] and Maria Mjaavatten[2]. [1]Martina Hansens Hospital, Gjettum, Norway, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Østfold Hospital Trust, Fredrikstad, Norway, [4]Revmatismesykehuset Lillehammer, Lillehammer, Norway, [5]Innlandet Hospital Trust, Brumunddal, Norway, [6]Betanien Hospital, Skien, Norway.

Background/Purpose: In 2010 the new ACR/EULAR classification criteria for rheumatoid arthritis (RA criteria) were published. The prospects for early diagnosis and treatment have increased over the past decades, partly driven by the theory of a window of opportunity. The theory even implies the possibility of preventing development of RA if aggressive treatment is started early. We wanted to study the 2-year outcome of patients with arthritis of less than 16 weeks duration who fulfilled the RA criteria at baseline, according to the duration of joint swelling at first visit.

Methods: 1084 patients (age 18–75 years) were included in the NOR-VEAC (Norwegian Very Early Arthritis Clinic) study from 2004 to 2010, i.e. before the RA criteria were implemented.

Patients with crystal arthritis, septic arthritis, osteoarthritis and arthritis due to trauma were excluded. 234 patients (21.6%) fulfilled the RA criteria at baseline. 202 of these had information about DMARD use and were included in the current study, and168 (83.2%) had 2-year follow-up data.

The relationship between spontaneous resolution of arthritis (defined as no swollen joints at last visit and never used DMARDs) and duration of joint swelling, as well as other factors, was examined. Duration was treated as a non-linear continuous variable as well as divided into categories. Mann-Whitney U, Fisher's exact and Chi-Square tests were used for the statistical analyses.

Results: Duration of joint swelling [median (25–75 percentiles)] was 64 (38–83) days, mean (SD) age 52 (14) years, 62% were females, 60% anti-CCP positive, and 69% anti-CCP and/or RF positive. 23/202 (11.4%) had spontaneous resolution of arthritis.

There was a statistically significant relationship between duration of disease and tendency of spontaneous resolution of arthritis (Mann-Whitney U p=0.01). In cases with very short (0–2 weeks) duration, the arthritis resolved without DMARDs in 9/23 patients (39.1%). The corresponding proportion for 2–6 weeks duration was 5/36 (13.9%), and for >6 weeks duration 9/143 (6.3%). The patients with resolving arthritis less often had positive anti-CCP (p<0.001),were more seldom current daily smokers (p=0.01) and had less RA criteria points (p=0.02). There were no significant differences between the groups with regard to sex (p=0.50), age (p=0.28), 68-swollen (p=0.34) and 28-tender (p=0.97) joint counts, SR (p=0.42), CRP (p=0.50), BMI (p=0.51), fatigue (p=0.93), joint pain (p=0.13), patient global (p=0.28), assessor global (p=0.37), HAQ (p=0.27) or distribution of mono-, oligo- and polyarthritis (p=0.62).

Conclusion: When the duration of joint swelling was very short, the arthritis resolved without initiation of DMARD treatment in a considerable proportion of patients who fulfilled the RA criteria at baseline. Patients with arthritis of more than 6 weeks duration experienced spontaneous resolution less frequently.

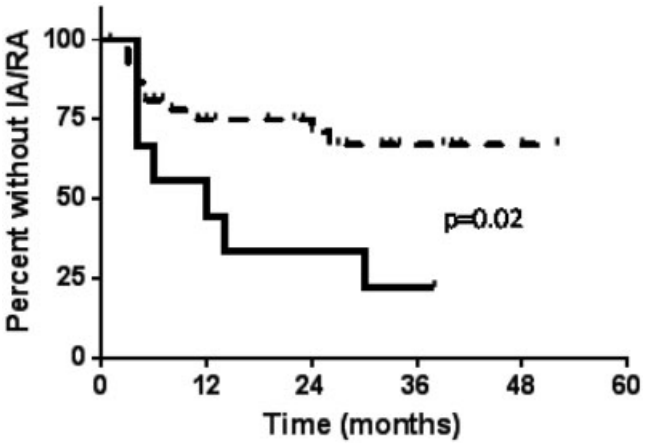
Health Fair Evaluations To Identify Subjects At-Risk For Future Inflammatory Arthritis and Rheumatoid Arthritis. Kristen E. Beck[1], M. Kristen Demoruelle[1], Christopher C. Striebich[2], Kaylynn Aiona[3], Marie L. Feser[4], Lezlie A. Derber[4], Stacey Brake[5], Jill Lysengen[6], Laura Rosseisen[6], Julia J. Rhiannon[1], Stuart M. Weisman[4], Jill M. Norris[3], V. Michael Holers[1] and Kevin D. Deane[1]. [1]University of Colorado School of Medicine, Aurora, CO, [2]University of Colorado Denver, Aurora, CO, [3]Colorado School of Public Health, Aurora, CO, [4]University of Colorado School of Medicine, Division of Rheumatology, Aurora, CO, [5]Health Fair, Denver, CO, [6]Arthritis Foundation, Great West Region, Denver Office, Denver, CO.

Background/Purpose: Multiple studies demonstrate that there is a preclinical period of rheumatoid arthritis (RA) when autoantibodies (Abs) including RF and anti-CCP are abnormal in absence of clinically apparent inflammatory arthritis (IA). Furthermore, RF and CCP abnormalities are highly predictive of future classifiable RA. However, most data regarding preclinical RA and prediction of future disease are derived from retrospective studies or referral clinics for symptomatic patients, and little is known from prospective community-based studies. Therefore, in a community health fair we identified and followed subjects with abnormalities of RA-related Abs in the absence of IA to evaluate predictive factors for development of IA/RA.

Methods: Volunteers were tested for serum anti-CCP3 (INOVA) at a Colorado health fair from 2008–2012. Subjects with CCP3 positivity (≥20 units) without IA by physical examination were invited for biannual follow-up that included assessment of demographic factors, environmental exposures, joint symptoms, joint examination by a trained study physician or nurse, and testing of CCP3 and CCP3.1 (INOVA), CCP2 (Axis-Shield), RF by nephelometry (Dade-Behring) and specific isotypes IgG/M/A (INOVA), C-reactive protein (CRP), and the shared eptiope (SE). The primary outcomes were the development of IA (≥1 swollen joint), and RA by 1987 and/or 2010 criteria at a research visit or clinical evaluation by a rheumatologist outside of the study.

Results: 7178 volunteers were initially evaluated, and 158 (2%) were CCP3(+) without IA; 47 of 158 (30%) invited subjects agreed to further study and were followed for a median of 27 months (range 1–52). Of these, 18/47 (38%) developed IA or RA all within 36 months: 10 with transient IA defined as ≥1 swollen joint(s) not present at an evaluation ~6 weeks later, and 8 with RA (7 by 1987 and 8 by 2010 criteria). The factor most strongly associated with the development of either IA or RA was CCP2 >3x normal plus positivity for any RF assay at any level (OR 5.5, 95% CI 1.2–25.3; sensitivity [SENS] 39%, specificity [SPEC] 90%, positive predictive value [PPV] 70%). This same Ab profile exhibited a stronger association with development of classified RA (OR 11.3, 95% CI 2.0–62.8; SENS 63%, SPEC 87%; PPV 50%). The timing of development of IA or RA is presented in the Figure. Age, sex, smoking, family history of RA, baseline joint symptoms, CRP and SE were not significantly associated with developing IA/RA.



Conclusion: A health fair evaluation using initial CCP3 testing is able to identify subjects at-risk for future IA or RA. In particular, during follow-up, CCP2 >3x normal and RF positivity were most strongly associated with development of IA or RA. This method of identifying subjects at risk for RA is useful for understanding the natural history of disease development, and may ultimately be used to identify candidates for RA prevention.

Sustained and Consistent Clinical Benefit With Intravenous Golimumab Therapy In Patients With Active Rheumatoid Arthritis Despite Methotrexate Therapy: Results Through 1-Year Of a Phase 3, Randomized, Multicenter, Double-Blind, Placebo-Controlled Trial. Clifton O. Bingham III[1], Rene Westhovens[2], Alan M. Mendelsohn[3], Lilianne Kim[3], Kim Hung Lo[3] and Michael E. Weinblatt[4]. [1]Johns Hopkins University, Baltimore, MD, [2]University Hospital KU Leuven, Leuven, Belgium, [3]Janssen Research & Development, LLC., Spring House, PA, [4]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: To report on sustainability and consistency of ACR component scores with intravenous (IV) golimumab (GLM) 2mg/kg+methotrexate (MTX) through wk52 in pts with active rheumatoid arthritis (RA).

Methods: 592 pts with active RA (≥6/66 swollen, ≥6/68 tender joints, C-reactive protein (CRP) ≥1.0mg/dL, rheumatoid-factor and/or anti-cyclic-citrullinated-peptide-antibody positive at screening) despite MTX ≥3 months (stable 15–25mg/wk, ≥4wks) participated in this multicenter, international, randomized, double-blind, placebo-controlled Phase 3 study. Pts were randomized (2:1) to IV GLM 2mg/kg or placebo (PBO) infusions at wks0&4 and q8w; pts continued stable MTX. PBO pts started GLM 2mg/kg at wk16 (early escape; <10% improvement in tender&swollen joints) or wk24 (crossover by design), so that all patients received GLM between wks 24–52.

Results: Significant and rapid clinical improvement in all ACR component scores was observed through wk24 (Table). Among pts with ≥20% improvement in ACR20 response or who achieved "good" or "moderate" response per 28-joint disease activity score employing CRP (DAS28-CRP) at wk24, approximately 80% maintained response through wk52. GLM+MTX treatment yielded sustained improvement across ACR components, including swollen and tender joint counts, pt assessments of pain and disease activity, physician assessment of disease activity, and the Health Assessment Questionnaire-Disability Index (Table).

Table. Median improvement in ACR components through 1-year

	PBO→GLM 2mg/kg + MTX	GLM 2 mg/kg + MTX
Randomized pts	197	395
Swollen joints (0–66)		
Baseline, median	12.0	12.0
% improvement at wk14/24/36/52	25.0%/27.3%/66.7%/81.8%	68.2%/75.0/77.8%/85.7%
Tender joints (0–68)		
Baseline, median	22.0	24.0
% improvement at wk14/24/36/52	12.8%/13.6%/57.9%/68.2%	61.5%/64.0%/66.7%/70.6%
Pt pain (0–10 cm VAS)		
Baseline, median	6.9	6.5
% improvement at wk14/24/36/52	7.4%/10.8%/30.0%/34.7%	38.1%/42.9%/41.5%/41.4%
Pt disease activity (0–10 cm VAS)		
Baseline, median	6.9	6.6
% improvement at wk14/24/36/52	7.3%/13.9%/31.1%/37.0%	37.1%/40.5%/40.0%/41.5%
Physician disease activity (0-1- cm VAS)		
Baseline, median	6.3	6.3
% improvement at wk14/24/36/52	14.5%/23.7%/54.0%/57.4%	52.1%/54.5%/59.7%/61.1%
HAQ-DI (0–3)		
Baseline, median	1.6	1.6
% improvement at wk14/24/36/52	6.7%/8.7%/26.7%/25.0%	28.6%/30.0%/31.3%/30.0%
Serum CRP (mg/dL)		
Baseline, median	1.7	2.0
% improvement at wk14/24/36/52	29.3%/21.4%/56.0%/57.3%	77.8%/76.8%/64.9%/65.8%

CRP=C-reactive protein, GLM=golimumab, HAQ-DI=Health Assessment Questionnaire-Disability Index, MTX=methotrexate, PBO=placebo

Conclusion: In pts with active RA despite MTX, IV GLM+MTX yielded sustained clinical improvement that was consistent across ACR components, with no new safety signals observed through 1-year.

Microrna Expression Profiles Associated With Response To Adalimumab and Methotrexate Versus Methotrexate: A Placebo-Controlled Clinical Trial. Sophine B. Krintel[1], Christian Dehlendorff[2], Merete L. Hetland[3], Kim Hørslev-Petersen[4], Klaus K. Andersen[2], Peter Junker[5], Jan Pødenphant[6], Torkell Ellingsen[7], Palle Ahlqvist[8], Hanne M. Lindegaard[9], Asta Linauskas[10], Annette Schlemmer[11], Mette Y. Dam[12], Ib Hansen[13], Hans Chr Horn[14], Anette Jørgensen[12], Johnny Raun[4], Christian G. Ammitzbøll[12], Mikkel Østergaard[15], Kristian Stengaard-Pedersen[12] and Julia S. Johansen[16]. [1]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark, [2]Danish Cancer Society Research Center, Copenhagen, Denmark, [3]DANBIO, Center for Rheumatology and Spine Diseases, Glostrup Univ Hospital, Glostrup, Denmark, [4]University of Southern Denmark, Graasten, Denmark, [5]University of Southern Denmark, Odense, Denmark, [6]Copenhagen University at Gentofte, Hellerup, Denmark, [7]Silkeborg Regional Hospital, Silkeborg, Denmark, [8]University of Southern Denmark, Vejle, Denmark, [9]Odense University Hospital, Odense, Denmark, [10]Vendsyssel Hospital, Hjørring, Denmark, [11]Aalborg University Hospital, Aalborg, Denmark, [12]Arhus University Hospital, Aarhus, Denmark, [13]Viborg Hospital, Viborg, Denmark, [14]Vejle Hospital, Vejle, Denmark, [15]Copenhagen University Hospital Glostrup, Copenhagen, Denmark, [16]Herlev Hospital, Herlev, Denmark.

Background/Purpose: The response to anti-TNF therapy varies widely between patients with rheumatoid arthritis (RA). MicroRNAs (miRNAs) are suggested to influence susceptibility to RA and disease severity. We aimed to investigate the association between miRNAs and treatment response in pre-treatment whole blood from 180 patients with early RA (treatment-naïve, disease duration <6 months) enrolled in the OPERA Study, a prospective, investigator-initiated, double-blinded, placebo-controlled study (1).

Methods: Patients were randomized 1:1 to methotrexate (MTX) 7.5 mg weekly (increased to 20 mg/week within two months) in combination with adalimumab (n=89) or placebo-adalimumab (n=91) 40 mg subcutaneously every other week. Both groups received intra-articular glucocorticoid injections (i.a. GC). Treatment response after 1 year was assessed according to EULAR response, DAS28(CRP) remission, and ACR/EULAR Boolean remission criteria. Expression of miRNAs was determined using TaqMan® Human MicroRNA LDA, A Card v2.0 (Applied Biosystems). Raw Cycle

threshold (CT) values of each miRNA were pre-processed using Quantile, 120 most expressed, and Rank normalizations. We performed interaction analyses to identify miRNAs associated differently with response to MTX + adalimumab and MTX + placebo-adalimumab. The overall test for no interaction between miRNAs and treatment was achieved by means of Kolmogorov-Smirnov. Potential predictive miRNAs were included in a multivariate model and backwards eliminated using the Bayesian Information Criterion. All effects were reported for a CT inter-quartile range increase.

Results: Kolmogorov Smirnov tests indicated interactions between miRNAs and treatment using EULAR response as outcome parameter (120 most expressed, p=0.008; Quantile, p=0.003; and Rank normalization, p=0.011). After backwards elimination, miR-22 and miR-886.3p demonstrated interaction with treatment using EULAR response as outcome parameter, Table 1. Nomograms suggested that in patients treated with adalimumab, the combination of low miR-22 and low miR-886.3p expression had the highest probability of EULAR good response (95%), whereas patients with high miR-22 and high miR-886.3p had the lowest probability of EULAR good response (65%).

Table 1. Multivariate estimated effects for 120 most expressed miRNAs, Rank, and Quantile normalization.

miRNA	Treatment	Normalization	OR	95% CI	p-value
miR-22	Adalimumab	120 most expressed	15.32	3.43–137.06	0.001
miR-22	Adalimumab	Rank	10.26	2.29–96.66	0.01
miR-22	Adalimumab	Quantile	12.18	2.30–140.45	0.01
miR-22	Placebo	120 most expressed	0.54	0.22–1.28	0.17
miR-22	Placebo	Rank	0.60	0.26–1.40	0.22
miR-22	Placebo	Quantile	0.71	0.29–1.80	0.46
miR-886.3p	Adalimumab	Rank	2.06	0.79–6.39	0.16
miR-886.3p	Adalimumab	Quantile	2.01	0.82–5.88	0.15
miR-886.3p	Placebo	Rank	0.33	0.11–0.78	0.02
miR-886.3p	Placebo	Quantile	0.40	0.14–0.97	0.06

Conclusion: In a one-year randomized, placebo-controlled, double-blind clinical trial of treatment-naïve patients with early RA, which compared adalimumab+MTX+i.a.GC with placebo+MTX+i.a.GC, we found that expression of miR-22 and miR-886.3p in pre-treatment whole blood was predictive of EULAR good response to adalimumab. Validation studies are needed to investigate the utility of these miRNAs as predictive biomarkers.

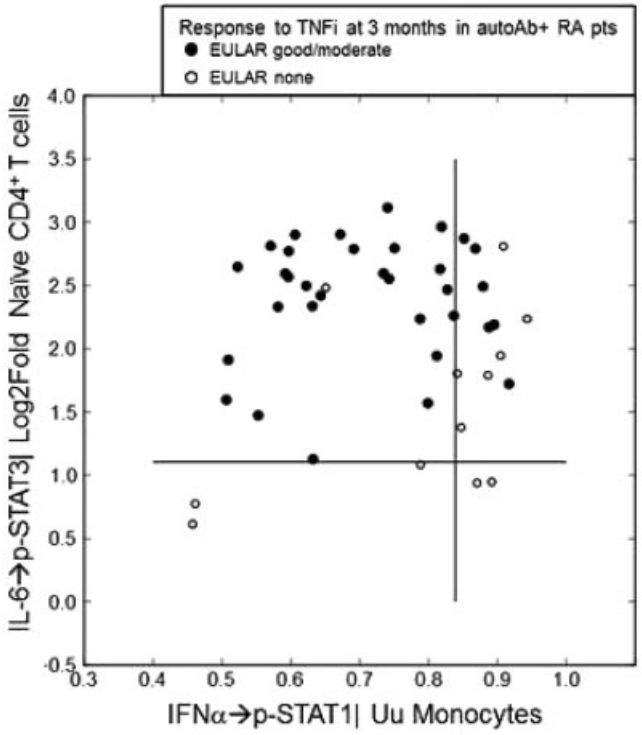
O'Dell[8], William H. Robinson[5], Nancy A. Shadick[7], E. William St Clair[9], Christopher C. Striebich[10], Geoffrey M Thiele[8], Peter K. Gregersen[4] and S. Louis Bridges Jr.[3]. [1]Nodality, Inc., South San Francisco, CA, [2]Johns Hopkins University, Baltimore, MD, [3]University of Alabama at Birmingham, Birmingham, AL, [4]The Feinstein Institute for Medical Research and North Shore-Long Island Jewish Health System, Lake Success, NY, [5]Stanford University, Palo Alto, CA, [6]University of Pittsburgh, Pittsburgh, PA, [7]Brigham and Women's Hospital/Harvard University, Cambridge, MA, [8]Omaha VA and the University of Nebraska Medical Center, Omaha, NE, [9]Duke Unversity Medical Center, Durham, NC, [10]University of Colorado Denver, Aurora, CO.

Background/Purpose: Biomarkers predictive of drug efficacy are lacking in rheumatoid arthritis (RA) and would be useful in clinical practice and clinical trials. Single cell network profiling (SCNP) is a multiparametric flow cytometry-based assay that measures induced changes in intracellular signaling proteins, providing a functional measure of pathway activity and immune networking in multiple cell subsets without physical separation. Induced signaling was measured in specific subsets of monocytes, B and T cells from RA patients (pts) initiating new treatment, and analyzed to build models to predict treatment response.

Methods: PBMCs from RA pts (n=87) starting TNF inhibitors (TNFi) were examined by SCNP of 42 nodes (combinations of modulator and intracellular readout) within 21 immune cell subsets. RA pts were a subset of ~200 from the Treatment Efficacy and Toxicity in Rheumatoid Arthritis Database and Repository (TETRAD). Blood samples were collected before initiating treatment with TNFi (adalimumab, etanercept, infliximab, golimumab). Clinical data included disease activity (DAS28) and EULAR response criteria at baseline, 3, 6, and 12 months. For the 53 evaluable patients, statistical analyses, including ordinal logistic regression and multivariate modeling, were performed to identify signaling profiles associated with response to TNFi after controlling for baseline DAS28 and age.

Results: Immune cell subsets from RA pts collected before initiating TNFi treatment exhibited heterogeneity in their induced intracellular signaling. Of note, T cell receptor (TCR) and IFNa modulation produced cell subset-specific signaling profiles that were associated with EULAR response at 3 months. Specifically, TCR→p-CD3z in CD4−CD45RA$^+$ T cells was weakest in pts that had a good EULAR response to TNFi (p=0.04). Similarly, donors with weak IFNa→p-STAT5 in B cells were more likely to have a good response to TNFi (p=0.007). In contrast, IL-6→p-STAT3 in naïve CD4$^+$ T cells was weakest in autoantibody (RF/ACPA)-positive (autoAb+) pts with no response (p=0.01). Although TNFa→p-p38 in monocytes was associated with baseline DAS28, this signaling was not predictive of TNFi response. Combining signaling nodes produced a model of TNFi response in autoAb+ donors defined by IL-6→p-STAT3 in naïve CD4$^+$ T cells and IFNa→p-STAT1 in monocytes with an area under receiver operating characteristic curve (AUC) of 0.91 in the full dataset, or 0.64 cross-validated.



Conclusion: These data provide the first evidence that measurement of peripheral blood immune cell function can: 1) identify patients likely to respond to TNFi, and 2) reveal the biology associated with TNFi response or lack thereof, thus providing information on therapeutic strategies. SCNP has revealed predictive biomarkers that, once replicated in future studies, may enable patient stratification in clinical practice and clinical trials.

Results From The RATE-RA Study: A Multicenter, Single-Arm Study To Evaluate The Safety Of Administering Rituximab At a More Rapid Infusion Rate In Patients With Rheumatoid Arthritis. Charles H. Pritchard[1], Maria W. Greenwald[2], Joel M. Kremer[3], Norman B. Gaylis[4], William Rigby[5], Steve Zlotnick[6], Carol Chung[6], Birgit Jaber[7] and William Reiss[6]. [1]Drexel University College of Medicine, Willow Grove, PA, [2]Desert Medical Advances, Palm Desert, CA, [3]Center for Rheumatology, Albany Medical College, Albany, NY, [4]Arthritis & Rheumatic Disease Specialties, Aventura, FL, [5]Geisel School of Medicine at Dartmouth, Lebanon, NH, [6]Genentech Inc., South San Francisco, CA, [7]F. Hoffmann-La Roche Ltd., Basel, Switzerland.

Background/Purpose: The FDA-approved dose of rituximab (RTX) in rheumatoid arthritis (RA) is 2 × 1000 mg IV infusions given 2 weeks apart (1 course), with recommended times of 4.25 hours (h) and 3.25 h for infusions 1 and 2, respectively. The objective of this analysis was to assess the safety of administering the second infusion of a RTX course and subsequent infusions at a more rapid rate over 2 h.

Methods: Patients (pts) with moderate-to-severe RA and an inadequate response to TNF inhibitors who were either RTX-naïve or RTX-experienced (up to 2 prior courses, last course 6–9 months before baseline) were eligible. All pts received methotrexate and were premedicated with IV methylprednisolone, antihistamines and analgesics prior to all RTX infusions. All pts received the first infusion (Infusion 1) on Day 1 over 4.25 h, the standard rate. The second infusion (Infusion 2) on Day 15 was over 2 h (Infusion 1 and 2 = course 1), as were both Infusions 3 and 4 (course 2) 6 months later. The primary endpoint was the incidence of infusion-related reactions (IRRs) during or within 24 h of Infusion 2 of course 1.

Results: The 351 enrolled pts had the following characteristics: RTX-naïve (n=306; 87.2%); RTX-experienced (n=45 of which 24 [6.8%] and 21 [6.0%] had received 1 or 2 prior RTX courses, respectively); mean age 55.5 (SD 11.5) y, with 19.7% of pts aged ≥65 y; and mean RA disease duration 12.5 (SD 9.7) y. The incidence of IRRs during or within 24 h of Infusion 1 was 16.2% (95% CI 12.5%, 20.5%) (none serious), consistent with that derived from historical clinical trial data (20.7%).[1] Infusion 2 was given to 337 pts (96.0%) over 2 hours; 333 completed the infusion and received the full 1000 mg dose, 4 pts did not complete the infusion (3 for AEs [none serious], 1 for another reason). Of these 333 pts, 5 (1.5%) required an infusion time >2.5 h. The incidence of IRRs for Infusion 2 (Figure 1, primary endpoint) was 6.5% (95% CI, 4.1%, 9.7%) (22 pts experienced a total of 30 events), similar to historical data for infusion 2 given at the standard rate (8.1%).[1] All IRRs for Infusion 2 were CTC grade 1 or 2 except two grade 3 (hypertension and headache), with no grade 4 events. The most commonly observed IRRs for Infusion 2 were nausea (1.2%) and chills (0.9%). Course 2 data indicate a low incidence of IRRs for Infusions 3 (secondary endpoint) and 4. No serious IRRs or SAEs were reported during or within 24 h of Infusions 1 and 2 (course 1) or Infusions 3 and 4 (course 2).

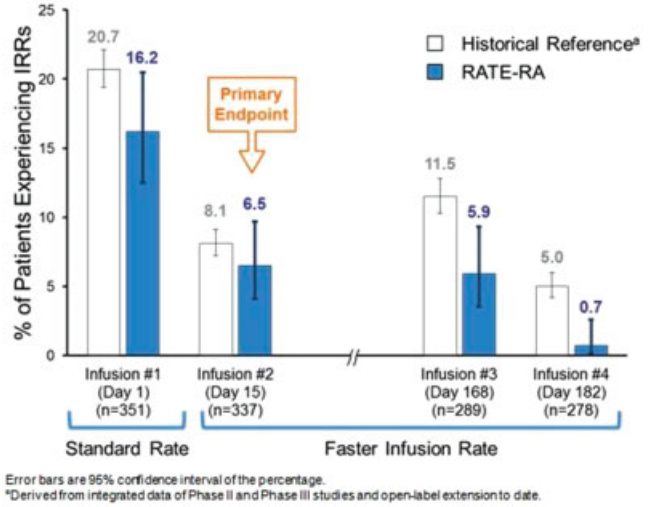

Figure. IRRs During or Within 24 Hours of Each RTX Infusion

Conclusion: The incidence of IRRs occurring during or within 24 h of the second infusion of RTX when administered at an increased 2 h rate is similar to the historical incidence. The incidence of IRRs for subsequent infusions is also similar to the historical incidence. The overall safety data were consistent with the known RTX safety profile. These data of RTX at a faster infusion rate provide clinically relevant information for HC providers and patients.

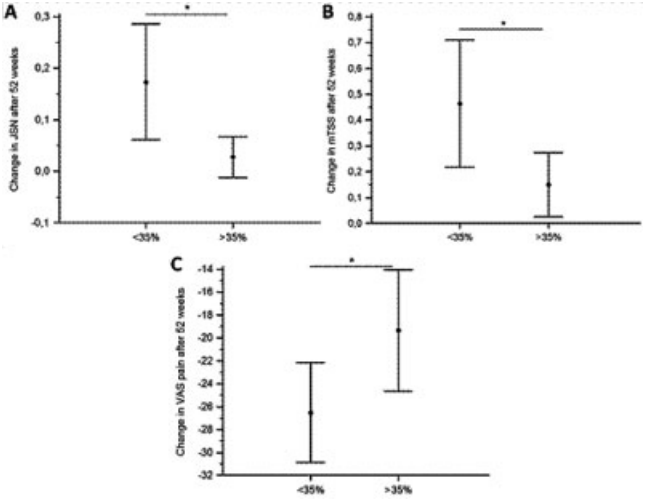
Responders To Tocilizumab Identified By Serological Measurement Of Connective Tissue Type I Collagen In Patients With Rheumatoid Arthritis. Anne Sofie Siebuhr[1], Anne C. Bay-Jensen[1], Diana J. Leeming[1], Adam Platt[2], Inger Byrjalsen[1], Claus Christiansen[3], Désirée van de Heijde[4] and Morten Asser Karsdal[1]. [1]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, [2]Roche Products Ltd, Welwyn Garden City, United Kingdom, [3]Center for Clinical and Basic Research and C4Pain, Aalborg, Denmark, [4]Leiden Univerisity, Leiden, Netherlands.

Background/Purpose: As biological treatments for rheumatoid arthritis (RA) are only effective in a subpopulation of patients and the treatment can have serious side effects, there is a need to identify patients who will benefit from a particular treatment. The serum Protein Fingerprint, type I collagen degradation mediated by MMP-cleavage (C1M), is a biomarker of connective tissue destruction. We investigated 1) whether baseline (BL) C1M levels were correlated with structural status, progression and pain, 2) how C1M changed with time and treatment with tocilizumab (TCZ) and 3) if C1M could be a potential early surrogate marker of treatment efficacy with TCZ.

Methods: LITHE biomarker study (n=585) was a 1-year phase III, double-blind, placebo (PBO)-controlled, parallel group study of TCZ 4 or 8 mg/kg every 4 weeks, in RA patients on stable doses of methotrexate (MTX). C1M was tested in serum from BL and week 2, 4, 16, 24 and 52. Spearman's correlations was analysed between BL level of C1M (log transformed) and clinical measures. The associations between BL serum C1M and change in JSN and mTSS were investigated in the PBO group by regressions analysis, including CRP, age, BMI, disease duration and BL JSN/mTSS. Change in C1M levels were studied as a function of time and treatment. Lastly, in patients receiving TCZ the level of change within 1-year in structural progression and pain were investigated in two groups based of the change in C1M level until week 16: 1; <35% change in C1M and 2; >35% change in C1M and analysed by Student's T-test.

Results: BL C1M was significantly correlated with change in JSN at week 24 (r=0.38 p<0.0001) and at week 52 (r=0.63, p<0.0001) and with changes in mTSS at 24 (r=0.21 p<0.012) and 52 weeks (r=0.58, p<0.0001). BL C1M was weakly negatively correlated with change in VAS pain at 24 weeks (r=−0.1, p<0.05). However, BL C1M was not correlated to BL JSN (rho=0.12) or mTSS (rho=0.14), but highly correlated with BL VAS pain (rho=0.3). Serum C1M was dose-dependently reduced by TCZ8 (p<0.0001) and TCZ4+MTX (p<0.05) as compared to PBO. Change in C1M at 16 weeks after treatment initiation in the TCZ groups was related to the level of radiographic changes over 1 year (p<0.05). Surprisingly, VAS pain had a negative relationship with change in C1M at 16 weeks.



Conclusion: MMP-mediated tissue degradation is imperative in joint destruction, as those patients with the highest levels of C1M were significantly more likely to progress in JSN and mTSS compared to those with a low level. Surprisingly, pain showed the reverse relationship with C1M. C1M may assist in identifying those patients that are rapid progressors. Interestingly, TCZ dose-dependently inhibited C1M level already after 2 weeks, suggesting almost immediate onset of joint protection. C1M may both be a surrogate marker of structural efficacy and enable prognostic identification of those patients that are in most need of treatment.

Serological Biomarkers Of Specific Mode Of Action For Early Identification Of Rheumatoid Arthritis Patients Who Respond To Anti-IL6 Or Anti-TNF Treatment. Anne C. Bay-Jensen, Natasja Stæhr Gudman, Anne Sofie Siebuhr, Claus Christiansen and Morten Asser Karsdal. Nordic Bioscience, Biomarkers and Research, Herlev, Denmark.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized debilitating joint destruction, if not treated aggressively in the patient in most need of treatment. Personalized health care is needed in RA, as response rates are low compared to the potential side effects and cost of treatment. Anti-IL6 and anti-TNF treatments are approved for treatment of RA patients, however with varying response rates. A unique class of serological biomarkers, which are measures of extracellular matrix turnover, also called protein fingerprint, may describe specific disease mode of actions. We investigated whether early measurement after treatment initiation could identify patients that would respond to either anti-IL6 or anti-TNF treatment.

Methods: Following tissue-specific biomarkers were measured in 800 RA patients treated with either methotrexate, tocilizumab, infliximab, entercept or adalimumab; VICM (citrullinated and MMP-degraded vimentin), C1M (MMP-degraded type I collagen), C3M (MMP-degraded type III collagen), CRPM (MMP-degraded CRP), C2M (MMP-degraded type II collagen), CTx (cathepsin K degraded type I collagen), osteocalcin (bone formation), and CRP (acute phase reactant). The baseline levels and changes in the biomarkers were investigated was investigated for each of the treatment groups. Logistic regression and classification and regression tree analysis were used to assess whether the markers alone or together could predict treatment response evaluated by DAS28 changes. Data was corrected for multiplicity.

Results: Methothraxate had a small effect on CRP, but not on any of the other markers. Tocilizumab significantly suppressed ($p<0.0001$) the level the connective tissue markers MMP3, VICM, C1M, C2M, C3M, CRPM and significantly increased ($p<0.05$) the level of the bone markers CTx and ostoecalcin. In contrast, cartilage degradation measured by C2M, was not inhibited anti-TNF treatment. A simple combination of the biomarkers (C1M, C3M, C2M, osteocalcin and CRPM) was able to double the DAS28 response rate of tocilizumab 27 to 54%. When including the change from baseline to 4 or 16 weeks in cartilage degradation or bone formation the rate was increased to 64%. Similar segregation could be reached for the anti-TNF group, however with a different set of markers; C1M, C3M, VICM and CRPM.

Conclusion: Distinct mode of action profiles were identified for each of the different treatment groups by measurement of the unique protein fingerprint markers. This may assist in identification of the patients, in any inflammatory disease, who respond most optimally to given interventions, with fewer AEs, and thus provide a stronger risk/benefit/cost value proposition to patients and payers.

ACR Concurrent Abstract Session
Systemic Lupus Erythematosus - Clinical Aspects and Treatment: Lupus Nephritis and Genetics
Sunday, October 27, 2013, 4:30 PM–6:00 PM

880

Role Of Urinary Podocyte Number and Urinary Podocalyxin Level As Biomarkers Of Glomerulonephritis In Systemic Lupus Erythematosus and ANCA-Associated Vasculitis. Hiroshi Kajiyama[1], Keiju Hiromura[2], Daisuke Ikuma[1], Hidekazu Ikeuchi[2], Hiroyuki Kurosawa[3], Yoshiaki Hirayama[3], Fumio Gondaira[3], Masanori Hara[4], Yoshihisa Nojima[2] and Toshihide Mimura[1]. [1]Saitama Medical University, Saitama, Japan, [2]Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan, [3]Denka Seiken Co. Ltd., Niigata, Japan, [4]Yoshida Hospital, Niigata, Japan.

Background/Purpose: Podocytes are glomerular visceral epithelial cells functioning as molecular sieves not to allow high molecular weight protein to leak from glomerular capillary wall. The decreased number of podocyte per glomerulus due to death or detachment from glomerular basement membrane leads to severe proteinuria, irreversible glomerulosclerosis and end stage kidney disease. Podocalyxin (PCX) is one of the podocyte markers, expressed on the apical cell membrane and shed in urine from injured podocytes. It has been reported that two different urine PCX-related biomarkers, urine numbers of PCX-positive cells (podocytes) and urine levels of PCX are associated with glomerular lesions, such as in IgA nephropathy and diabetic nephropathy. However, the role of these biomarkers in systemic lupus erythematosus (SLE) and ANCA-associated vasculitis (AAV) remain to be elucidated.

Methods: Urine numbers of podocytes (U-Pod) were determined by counting PCX-positive cells in sediments from urine samples. PCX staining was done by indirect immunofluorescent method. Urine levels of PCX (U-PCX) were measured by sandwich ELISA, normalized to urine creatinine levels. Patients with proteinuria (defined as more than 0.2 urine protein/creatinine ratio) and/or renal failure (defined as estimated GFR less than 60 mL/min/1.73m^2) were defined as KD(+), and patients who had neither proteinuria nor renal failure were defined as KD(−). Patients with SLE and AAV were recruited from our hospitals between October 2010 and March 2013. SLE-KD(+) (n=61), SLE-KD(−) (n=22), AAV-KD(+) (n=17) and AAV-KD(−) (n=6). Renal histology of lupus nephritis was classified according to ISN/RPS classification. Statistical analysis was done using Mann-Whitney test. $P<0.05$ was defined as statistical significance. Each value was described as mean ± standard deviation.

Results: U-Pod was significantly higher in the KD(+) group than in the KD(−) group both in SLE (7.9±24.9 vs 0.2±0.6 cells/mL, $P<0.0001$) and in AAV (0.7±1.0 vs 0.0±0.0 cells/mL, $P=0.0048$). However, there was not a statistical difference in U-Pod between the SLE-KD(+) group and the AAV-KD(+) group ($P=0.397$). In contrast, although U-PCX was significantly higher in the KD(+) group than in the KD(−) group in SLE (362.2±298.8 vs 128.9±113.5 μg/gCr, $P=0.0012$), U-PCX tended to be lower in the KD(+) group than in the KD(−) group in AAV (100.3±117.6 vs 206.3±169.5 μg/gCr, $P=0.06$). In addition, U-PCX was significantly higher in the SLE-KD(+) group than in the AAV-KD(+) group ($P<0.0001$). Among 36 patients with biopsy-proven lupus nephritis, U-Pod was significantly higher in patients with Class IV lesion (diffuse proliferative lesion) than in those without Class IV lesion (20.0±38.6 vs 0.7±0.6 cells/mL, $P=0.0025$). U-PCX tended to be higher in patients with Class V lesion (membranous lesion) compared to that in those without class V lesion (549.1±344.5 vs 347.8±274.0 cells/mL, $P=0.058$), although it did not reach statistical significance.

Conclusion: Our data suggest that podocyte injury estimated by U-PCX is more severe in lupus nephritis compared to AAV nephritis. In addition, the combination of U-Pod and U-PCX may predict the histological features of lupus nephritis.

Time To Renal Flare and Renal Disease Activity Over a 1 Year Period Is associated With Urinary TWEAK Levels In Patients With Systemic Lupus Erythematosus. Nicolas Wisniacki[1], Chris Stebbins[2], Jadwiga Bienkowska[3], Susan Gawlak[2], Donald Bennett[4], Yuhong Xiang[2], Andrea Dearth[5], Linda C. Burkly[2], Ann Ranger[5], Carrie Wager[2], Laurence S. Magder[6] and Michelle Petri[7]. [1]Biogen Idec, Maidenhead, United Kingdom, [2]Biogen Idec, Cambridge, MA, [3]Biogen Idec Inc., Cambridge, MA, [4]Biogen idec, Cambridge, MA, [5]Biogen Idec Inc, Cambridge, MA, [6]University of Maryland, Baltimore, MD, [7]Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: TNF-like weak inducer of apoptosis (TWEAK) is a member of the TNF superfamily that signals through its distinct, highly inducible receptor, FGF-inducible molecule 14 (Fn14) on renal epithelial and mesenchymal cell types. The TWEAK/Fn14 pathway mediates key pathologic processes involved in renal disease in SLE. Previous studies have demonstrated that lupus patients with active renal disease have higher levels of urinary TWEAK (uTWEAK) compared to those without active renal disease. Furthermore, uTWEAK levels correlated significantly with renal disease activity on the same day as assessed by the renal SLE Disease Activity Index (SLEDAI) scores. However, the value of uTWEAK to predict SLE disease activity during follow up is unknown. The aim of this study was to explore the ability of uTWEAK levels to predict SLE renal and non-renal disease activity in the subsequent year after measurement.

Methods: The SPARE study is a prospective, longitudinal, observational study conducted at single center. Consecutive adult patients attending the SLE clinic were eligible if they met the ACR Criteria for SLE. At baseline, uTWEAK levels were measured by ELISA and normalised with urinary creatinine. Patients within uTWEAK quartiles were compared with respect to the frequency of disease activity measured at clinic visits in the following year. Estimates of differences and p-values were based on generalized estimating equations (GEE) models to account for repeated visits from the same patient. Cox proportional hazards models were fit to time to first renal flare within the first year, adjusting for either log2-transformed or quartile of uTWEAK along with sex, race, complement (C3, C4), and dsDNA; p-values for uTWEAK were based upon the effect estimates. Renal flares were defined as increase in SLEDAI renal descriptors or doubling of urine protein/cr.

Results: 293 patients were included in the analysis: 91% were female; 59% Caucasian and 33% African American. The mean age was 46.2 (±12) years. Patients with higher uTWEAK at baseline were more likely to have renal SLEDAI, uPCR >0.5, PGA >1 and SLEDAI >3 during the follow-up year (Table 1). There were no differences in the non-renal SLEDAI score components or levels of anti-dsDNA and complement. The variables associated with time to first renal flare within one year of follow up included male gender, asian race, complement, dsDNA and uTWEAK. The median time (days) to renal flare declined with increasing quartile of uTWEAK (q1=323 / q2=195 / q3=183 / q4=141; p=0.05 for comparing hazard q4 to q1). In the model where log2-transformed uTWEAK was treated as a continuous variable, each 2-fold increase in uTWEAK corresponded to 1.34 times the instantaneous risk of having a flare in the first year (p=0.04).

Variable	Low uTWEAK Patient n=73 Visit n=310	Medium low uTWEAK Patient n=73 Visit n=294	Medium high uTWEAK Patient n=73 Visit n=300	High uTWEAK Patient n=74 Visit n=313	P-value	Adjusted P-value for race	Adjusted P-value for trend
PGA >1	13%	15%	16%	27%	0.099	0.135	0.0098
SLEDAI ≥3	22%	21%	27%	30%	0.42	0.24	0.044
urine protein/cr ≥0.5	5%	5%	12%	15%	0.12	0.20	0.012
Anti-dsDNA ≥ 10	24%	19%	21%	21%	0.90	0.91	0.62
C3 <79	7%	10%	16%	15%	0.15	0.20	0.12
C4 <12	8%	10%	14%	11%	0.62	0.70	0.62
ESR >20	58%	46%	50%	45%	0.30	0.58	0.66
Any SLEDAI Renal	3%	5%	9%	12%	0.013	0.016	0.0088
Any SLEDAI Musculoskeletal	2%	3%	2%	5%	0.40	0.38	0.14
Any SLEDAI Immunologic	32%	26%	31%	28%	0.85	0.82	0.85
Any SLEDAI Skin	31%	31%	28%	23%	0.53	0.92	0.84
Any SLEDAI Hematology	3%	5%	5%	4%	0.87	0.85	0.14

Conclusion: Shorter time to renal flare and increased renal disease activity over a 1 year period is associated with higher urinary TWEAK levels in patients with SLE

Association Of a Neutrophil Gene Signature Comprised Of Low Density Granulocyte (LDG)-Enriched Genes With Both Future Systemic Lupus Erythematosus Disease Activity and Poor Longterm Outcomes. Michelle Petri[1], Laurence S. Magder[2], Hong Fang[1], Jadwiga Bienkowska[3], Andrea Dearth[4], Norm Allaire[3] and Ann Ranger[4]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD, [3]Biogen Idec Inc., Cambridge, MA, [4]Biogen Idec Inc, Cambridge, MA.

Background/Purpose: Neutrophils and neutrophil death (NETosis) have a role in the pathogenesis of SLE. A neutrophil gene signature (NGS) exists in SLE, although its association with the clinical phenotype is unknown. We explored the association of a neutrophil gene signature comprised of genes significantly upregulated in low-density granulocytes (LDGs) with both future disease activity and long-term outcomes.

Methods: 292 SLE patients (91.1% female; 58.9% Caucasian, 33.9% African-American, mean age (SD) 46.5 (±11.9) years were included. Gene expression levels were assessed in peripheral blood RNA samples using microarray (Affymetrix). The LDG-associated gene signature was comprised of 8 genes reported in the literature to be significantly upregulated in LDGs relative to normal-density neutrophils. The LDG–associated NGS "score" was calculated for each patient based on the geometric mean of the expression levels (chip signal intensity) of the 8 genes in the signature. Three groups based on NGS scores were compared. GEE models (to account for repeated measures) were used.

Results: The mean LDG-associated NGS was somewhat lower in African Americans (mean=5.4) relative to Caucasians (mean=5.8) and other ethnicities (mean=6.4), p=0.0087. It was also somewhat higher in men than women (mean 6.2 vs. 5.7, p=0.067). The NGS was strongly associated with global disease activity over the next year, serologies (anti-dsDNA and low complement), and future organ-specific activity (renal, cutaneous and arthritis) (Table 1). An elevated LDG-associated NGS was also strongly associated with a history of poor outcomes (myocardial infarction, deep venous thrombosis, diabetes, malignancy).

Table 1. %visits with various types of disease activity over 1 year, by LDG-associated NGS tertiles

Variable	1st Tertile Neutrophil Patient n=97 visit n=406	2nd Tertile Neutrophil Patient n=98 visit n=395	3rd Tertile Neutrophil Patient n=97 visit n=409	P-value	Adjusted P-value for Ethnicity	Adjusted P-value for Trend
Physician Global Assessment >1	13%	17%	24%	0.057	0.045	0.0064
SLEDAI ≥2	48%	53%	62%	0.054	0.0034	0.0010
Urine Protein/Creatinine Ratio (≥0.5)	8%	7%	14%	0.16	0.11	0.037
Anti-dsDNA ≥ 10	9%	23%	32%	<0.0001	<0.0001	0.0006
C3 <79	9%	7%	19%	0.014	0.022	0.0012

Any SLEDAI Heme	6%	4%	4%	0.69	0.67	0.31

Table 2. Association between SLICC/ACR Damage Index and the LDG-associated NGS in SLE

Variable	Low Neutrophil (<5) (%, N=107)	Med Neutrophil (5–6) (%, N=92)	High Neutrophil (>6) (%, N=93)	Adjusted P-value for Ethnicity
Myocardial Infarction	0.0	6.5	5.4	0.0056
Deep Venous Thrombosis	1.9	0.0	6.5	0.016
Diabetes	4.7	6.5	14.1	0.024
Malignancy	2.8	12.1	15.2	0.0043

Conclusion: The LDG-associated NGS associates with SLE clinical and serologic activity over the next year. This is the first gene signature to be associated with myocardial infarction, deep venous thrombosis and malignancy. The NGS may be a promising biomarker of disease activity. Given that atherosclerotic disease is the major cause of death in late SLE, this gene signature may be the "missing link" in understanding how SLE accelerates atherosclerosis.

Montgomery[2], Wan-Fai Ng[16], Gunnel Nordmark[17], Patrick M. Gaffney[2], Katherine A. Siminovitch[15], Kathy L. Sivils[2], Slegen (International Consortium For The Genetics Of SLE)[18] and R. Hal Scofield[2]. [1]Cincinnati Children's Hospital Medical Center and the University of Cincinnati, Cincinnati, OH, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Haukeland University Hospital, Bergen, Norway, [4]U.S. Department of Veterans Affairs Medical Center, Oklahoma City, OK, [5]Bicêtre University Hospital, Le Kremlin Bicetre, France, [6]Stavanger University Hospital, Stavanger, Norway, [7]Queen Elizabeth Hospital, Adelaide, Australia, [8]King's College London, London, United Kingdom, [9]Karolinska Institutet, Stockholm, Sweden, [10]Medical University Hannover, Hanover, Germany, [11]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [12]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [13]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [14]University of Birmingham, Birmingham, United Kingdom, [15]Mount Sinai Hospital, Toronto, ON, [16]Newcastle University, Newcastle upon Tyne, United Kingdom, [17]Uppsala University, Uppsala, Sweden, [18]International Consortium For The Genetics Of Systemic Lupus Erythematosus, Cincinnati, OH.

Background/Purpose: Female preponderance is a hallmark of most autoimmune diseases, the mechanism for which is unknown. We hypothesize that this is a consequence of a gene dose effect from the X chromosome. Here we tested a prediction of the gene does hypothesis: that triple X (47,XXX, which is found in 1 in ~1,100 live female births) would be increased in female predominant diseases (e.g. Systemic Lupus Erythematosus [SLE], Sjogren's Syndrome [SS], Primary Biliary Cirrhosis [PBC] and Rheumatoid Arthritis [RA]) compared to diseases without a female predominance (e.g. sarcoidosis, granulomatosis with polyangiitis [GP]) or to healthy controls.

Methods: Chromosome X aneuploidies were identified using single nucleotide polymorphisms (SNP) array and confirmed by karyotyping, FISH, or quantitative PCR.

Results: 47,XXX was found in eight of 2,948 SLE patients and in three of 1,206 SS patients, but in none of the 4,976 controls, all female (OR≥28.64, 95% CI 1.65-∞, p=0.00037; and OR≥28.84, 95% CI 1.49-∞, p=0.00745; respectively). These data suggest that one female with SLE and one female with SS has 47,XXX of approximately every 391 female SLE cases and 351 SS female cases. In addition, we identified one individual with 47,XXX from 1,179 female cases with PBC and one from 943 female cases with Sarcoidosis. No individuals were identified with 47,XXX in 453 female cases with RA or 247 female cases with GP, providing no evidence in these underpowered samples that individual with a 47,XXX karyotype have an increased risk for PBC, RA, GP or Sarcoidosis (p>0.05 for each).

Conclusion: The 47,XXX karyotype is present in excess among females with either SLE or SS, consistent with the X chromosome gene dose hypothesis of pathogenesis. We estimate the prevalence of SLE and SS is ~2.5 and ~2.8 times higher than expected in individuals with 47,XXX when compared to 46,XX females and ~25 and ~39 times higher when compared to 46,XY males respectively. That Klinefelter's syndrome (47,XXY) males carry the same SLE disease risk as females with 46,XX karyotype further support the hypothesis that the X chromosome dose contributes to the sex-bias of SLE, independently of phenotypic sex and most hormone and cultural differences between male and female life.

Background/Purpose: Studies in murine models for SLE have shown that CTLA4Ig can ameliorate murine lupus nephritis. Moreover, the combination of CTLA4Ig plus intravenous cyclophosphamide (IVC) acts synergistically in mice to reverse lupus nephritis. The purpose of this study (the ACCESS Trial) was to determine whether these observations in mice could be translated into an effective treatment for lupus nephritis in people.

Methods: Subjects with biopsy-proven class III or IV lupus nephritis (with or without class V) and urine protein:creatinine ratio (UPCR) >1 were enrolled in the trial. All subjects received low-dose IVC (500 mg q 2 wks × 6) followed by azathioprine (2 mg/kg/d up to a maximum of 200 mg/dose), per the Euro-Lupus nephritis (ELN) regimen. Subjects were randomized 1:1 to receive either saline (n=68) or abatacept (ABA) (n=66) intravenously at weeks 0, 2, 4, and then every four weeks. ABA was dosed based on weight: <60 kg, 500 mg; 60–100 kg, 750 mg; >100 kg, 1 gm. In addition, subjects received oral prednisone beginning at 60 mg/d and tapered to 10 mg/d within 12 weeks. The primary outcome measure was complete response (CR) at 24 weeks, defined as: (i) UPCR <0.5; (ii) serum creatinine normal or, if abnormal, within 25% of baseline; and (iii) adherence to the steroid regimen. Partial response required a >50% improvement in UPCR and otherwise mirrored the CR criteria.

Results: A racially and ethnically diverse population of North American subjects was enrolled (39% African American and 40% Hispanic/Mestizo). The groups were well matched for baseline characteristics, including race, ethnicity, severity of nephritis, and biopsy class. At 24 weeks, the CR rate in the ABA group was 22/66 (33%) compared to 21/68 (31%) in the control group (p=0.85). Total response (CR+PR) was 59% in both groups (39/66 vs 40/68). Among African American subjects, 33% (9/27) of subjects in the ABA group achieved CR, compared to 16% (4/25) in the control group (p=0.20). Twice as many subjects in the ABA group experienced disappearance of anti-dsDNA Ab (24% vs 11%), but the difference was not statistically significant (p=0.22). Patient global assessment improved by 74% in the ABA group compared to 38% in the control group (p=0.051). There was no difference between the groups at week 24 in mean UPCR, anti-dsDNA and complement levels, BILAG score, SF-36 (physical and mental), frequency of serious adverse events (SAEs), or withdrawals (total or lupus-related). The rate of infectious SAEs was 0.3/yr in the ABA group compared to 0.2/yr in the control group (NS).

Conclusion: The ACCESS trial did not achieve its primary goal of demonstrating a benefit for ABA plus ELN compared to ELN alone at 24 weeks. However, it achieved an important secondary objective by providing the first systematic examination of the ELN regimen in a racially and ethnically diverse North American population. The response rate of >30% CR within 24 weeks in the ELN control group is higher than has been reported in prior lupus nephritis trials (including studies of mycophenolate mofetil and high-dose IVC), suggesting that the ELN regimen may have

broad applicability. Subjects in the ACCESS trial are still undergoing blinded evaluation to examine outcome at later time points.

Fatigue In SLE Is Associated With Upregulation Of Interferon-Alpha Related Gene Transcripts. Maureen A. McMahon, Jennifer M. Grossman, Bevra H. Hahn, Lori Sahakian, Isao Matsuura, Elaine Lourenco and Brian Skaggs. UCLA David Geffen School of Medicine, Los Angeles, CA.

Background/Purpose: Fatigue is a major complaint in at least 80% of SLE patients, and is often listed as the most disabling symptom of the disease; however, fatigue often does not improve significantly with standard treatments that reduce disease activity assessed by standard measures (SLEDAI). Defining altered biologic pathways in SLE patients with severe fatigue might provide clues to disease pathways that have not been previously identified – or have been identified but not appreciated for their importance in SLE fatigue. One possible pathway of interest is the IFNa pathway, well appreciated in SLE disease activity and recently identified as important in patients with chronic fatigue syndrome. We hypothesized that gene expression studies comparing patients classified by high fatigue scores and low disease activity and patients with low fatigue scores/low disease activity might identify new or previously underappreciated pathways of SLE pathogenesis.

Methods: We administered the Fatigue Severity Score (FSS) to a subset of SLE patients participating in a longitudinal SLE in atherosclerosis cohort study. Monocyte RNA was isolated from peripheral blood of 5 SLE patients with severe fatigue (defined as '6 on FSS) and 8 SLE subjects with mild fatigue ($\leq$ 4 on FSS), all of whom had low disease activity (SELENA-SLEDAI $\leq$ 4). Whole genome transcript analysis was performed using Affymetrix Human U133+2.0 chips. dChip software (Li lab, Harvard) was utilized to determine differentially expressed transcripts. The Database from Annotation, Visualization, and Integrated Discovery (DAVID) program (http://david.abcc.ncifcrf.gov) was utilized to examine if any functional groups of genes were altered. To examine whether a subset of IFNa-regulated genes were dysregulated, differentially expressed genes were entered into the Web-based database www.interferome.org. Differential transcript expression was confirmed by quantitative PCR.

Results: The mean FSS score in the high fatigue group was 6.7 $\pm$ 0.5 vs. 2.8 $\pm$ 0.8 in the low fatigue group. Approximately 300 transcripts were differentially expressed between the high and low fatigue groups (fold change $\geq$1.2 or $\leq$−1.2, p$\leq$0.05). Three gene families were significantly altered in this comparison: the immune response gene category (Benjamini corrected p-value 3.8 e-8), regulation of apoptosis (2.5 e-6), and response to virus (2.8 e-3). 35% of the dysregulated transcripts were IFNa-regulated genes (expected 'interferome' transcripts would be ~8%), and most were upregulated in patients with high fatigue. Dysregulation of five interferome genes was confirmed by qPCR analysis: ICAM1 (1.86-fold up, p=0.01), IRF1 (2.24-fold up, p=0.03), JAK2 (3.60-fold up, p=0.04), OAS-L (1.94-fold up, p<0.01), and TLR4 (2.63-fold up, p=0.01).

Conclusion: Upregulation of IFNa-regulated transcripts, already known to associate with SLE disease activity, appear to also associate with high fatigue in patients with low SLEDAI. Targeting IFNa pathways with specific therapeutic agents might be beneficial in patients suffering from fatigue, even in the absence of traditional high disease activity measurements.

Lupus Neutrophil Extracellular Traps Render High Density Lipoprotein Oxidized and proatherogenic. Carolyne K. Smith[1], Anuradha Vivekanandan-Giri[2], Jason S. Knight[3], Paul Ryan Thompson[4], Subramaniam Pennathur[2] and Mariana J. Kaplan[3]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Nephrology, Ann Arbor, MI, [3]University of Michigan Rheumatology, Ann Arbor, MI, [4]The Scripps Research Institute, Jupiter, FL.

Background/Purpose: Cardiovascular risk is significantly increased in systemic lupus erythematosus (SLE) patients. This phenomenon cannot be explained by the Framingham risk equation. Previous reports suggest that high density lipoprotein (HDL) becomes oxidized in autoimmune diseases such as rheumatoid arthritis and SLE. We previously demonstrated that phagocyte-derived myeloperoxidase (MPO) oxidizes HDL and renders the lipoprotein atherogenic by impairing reverse cholesterol transport. Neutrophil extracellular traps (NETs) are an innate antimicrobial mechanism wherein granulocytes extrude their chromatin and antimicrobial peptides, including MPO. Nitric oxide synthase (NOS) is also capable of generating the reactive nitrogen species required for HDL oxidation and is highly present in neutrophils. As a subset of lupus granulocytes termed low density granulocytes (LDGs) display an enhanced capacity to form NETs, we hypothesized that the MPO and NOS present in these structures may represent sources of HDL oxidation, thereby leading to vascular damage and acceleration of atherogenesis.

Methods: Two oxidation products, 3-chlorotyrosine and 3-nitrotyrosine were quantified by tandem mass-spectrometry (MS/MS) in plasma and HDL derived from healthy controls and lupus subjects. Site-specific nitration and chlorination of apoA-1 peptides were also quantified by MS/MS. Plasma MPO levels were determined. Isolated NETs from control neutrophils and LDGs were incubated with control, unoxidized HDL in the absence or presence of MPO- and/or NOS-specific inhibitors. The resulting levels of HDL oxidation were then quantified by MS/MS.

Results: Lupus subjects demonstrated higher levels of MPO, and altered HDL function. There was marked increase in 3-nitrotyrosine and MPO-specific 3-chlorotyrosine content in HDL from SLE subjects. Oxidative peptide mapping revealed site-specific unique oxidation signatures on apoA1 in lupus patients. NETs were significant inducers of HDL oxidation, and this phenomenon was enhanced in NETs isolated from LDGs compared to control neutrophils. HDL oxidation by NETs was blocked with incubation of NOS- and/or MPO-specific inhibitors *in vitro*.

Conclusion: Accelerated NET formation by LDGs leads to enhanced HDL oxidation and renders the lipoprotein proatherogenic. These observations further support the concept that aberrant NET formation in lupus leads to damage of the endothelium and promotes atherosclerosis.

Atherosclerosis and Cardiovascular Disease In Systemic Lupus Eryhematosus Are Related To An Inflammatory/Oxidative Status Linked To The Autoimmune Condition and The Clinical Activity Of The Disease. Effect Of Statins Treatment. Chary Lopez-Pedrera Sr.[1], Patricia Ruiz-Limon[1], Carlos Perez-Sanchez[1], M[a] Angeles Aguirre[1], Nuria Barbarroja[1], Tomás Cerdó-Ráez[2], Maria Laura Bertolaccini[3], Munther A. Khamashta[3], Antonio Rodriguez-Ariza[1], Yolanda Almaden[4], Husam Khraiwesh[5], Jose Antonio Gonzalez-Reyes[6], Jose Manuel Villalba[6], Eduardo Collantes[7] and M[a] Jose Cuadrado[8]. [1]IMIBIC-Reina Sofia Hospital, Cordoba, Spain, [2]Imibic, Córdoba, Spain, [3]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [4]Imibic, Códoba, Spain, [5]UCO, Córdoba, Spain, [6]University of Cordoba, Cordoba, Spain, [7]Hospital Reina Sofia, Cordoba, Spain, [8]The Rayne Institute, London, United Kingdom.

Background/Purpose: Atherosclerosis (AT) and cardiovascular disease (CVD) are enhanced systemic lupus erythematosus (SLE). Although there is evidence that statins have anti-inflammatory properties, their mechanism of

action remains incompletely understood. Aims: i) To determine if the proinflammatory SLE profile is related to their oxidative status, and associated to the autoimmune condition and the clinical disease activity; ii) to test the anti-inflammatory effectiveness of fluvastatin.

Methods: The study was conducted in 85 SLE patients and 62 healthy donors. Flow cytometry, ELISA and enzymatic assays were used to evaluate markers of inflammation and oxidative stress. Carotid-intimate media thickness (CIMT) was used as surrogate marker of AT. Microarray expression profiling was used in paired samples of SLE monocytes from 27 patients before and after of fluvastatin treatment.

Results: Increased TF and PAR2 levels were found in monocytes from SLE patients, which also displayed higher plasma levels of VEGF, IL-2, -6, -8, -17, -23, MCP-1, MIP1α and tPA. SLE monocytes displayed an altered mitochondrial membrane potential (MMP) and increased levels of peroxides, peroxynitrites, and antioxidant enzymes. Correlation and association studies demonstrated the existence of an interplay among parameters related to autoimmunity, oxidative stress and inflammation in the development of the disease and on the increased risk of athero-thrombosis in SLE patients. Real time RT-PCR showed that monocytes were major players in the altered expression of the above mentioned proinflammatory parameters.

The in vivo treatment of SLE patients with fluvastatin for one month led to a significant reduction in the activity of the disease and the levels of anti-dsDNA. Analysis of blood cells and serum showed that one month of fluvastatin treatment effectively attenuated SLEDAI and the lipid levels, and reduced the oxidative status and the vascular inflammation. Array studies on monocytes demonstrated that a total of 799 genes displayed significant changes in expression after 1 month of fluvastatin treatment. Many new target genes and pathways modulated by fluvastatin were uncovered. IPA analysis revealed a network of these genes involved in cholesterol and lipid metabolism, inflammation, oxidative stress and mitochondrial activity. Electron microscopy analysis of mitochondria in monocytes from fluvastatin treated SLE patients showed a significant increase in the number of mitochondria in that cells, pointing at an induced process of mitochondrial biogenesis. The increased expression of a set of genes involved in those processes (i.e. PGC1a, PPAR1a, NRF, Sirt-1) confirmed that hypothesis.

Conclusion: i) Several mediators of autoimmunity, inflammation, and endothelial dysfunction orchestrate in conjunction the pathophysiology of atherothrombosis in SLE ii) A redox-sensitive pathway seems to play a key role in the elicitation of that pathological processes. iii) Fluvastatin has significant anti-inflammatory effects on SLE monocytes, which may partly explain the beneficial pleiotropic effects of statins on cardiovascular disease in the setting of SLE.

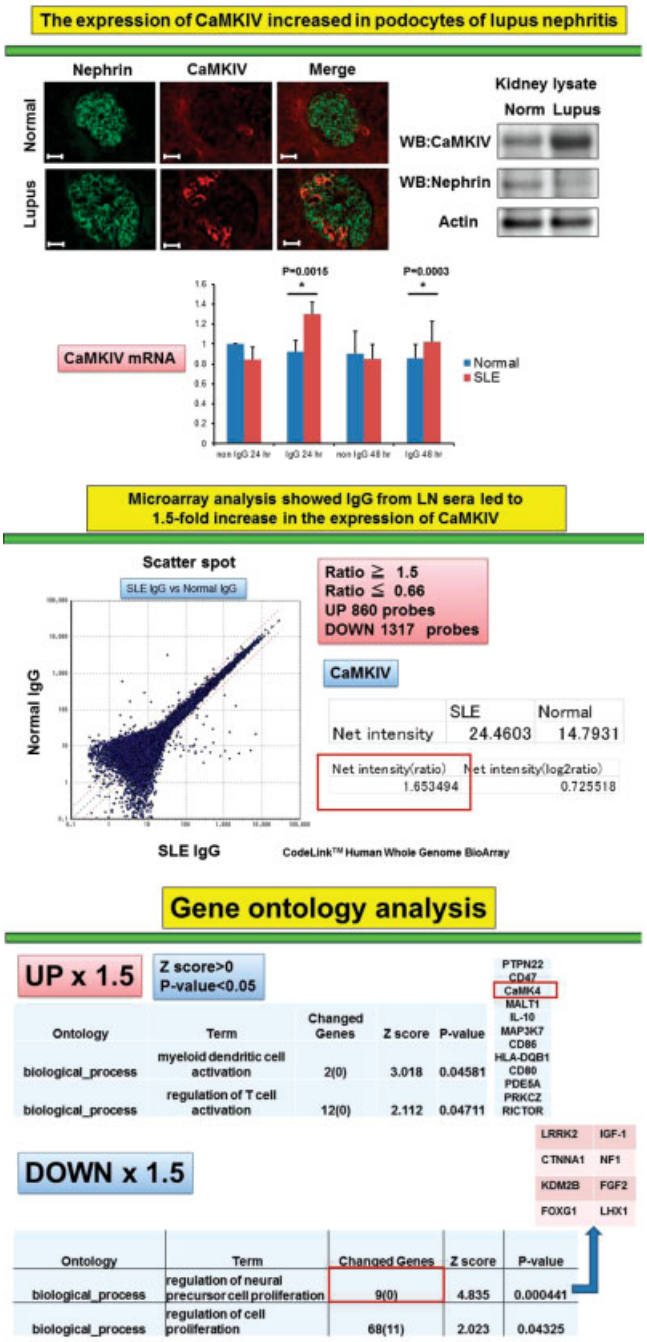
Role of Calcium/Calmodulin Kinase IV On Podocyte Function in Lupus Nephritis. Kunihiro Ichinose[1], Takeshi Ushigusa[2], Tomohiro Koga[3], George C. Tsokos[4] and Atsushi Kawakami[2]. [1]Unit of Translational Medicine, Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [4]BIDMC, Harvard Medical School, Boston, MA.

Role of calcium/calmodulin kinase IV on podocyte function in lupus nephritis

Background/Purpose: Kidney podocytes and their slit diaphragms settle the integrity of renal basement membrane and prevent urinary protein loss. T cell from patients with systemic lupus erythematosus display increased expression of calcium/calmodulin kinase IV (CaMKIV). Here we evaluated the expression of CaMKIV in kidney biopsy specimens from patients with lupus nephritis (LN) and in a human podocyte cell line (AB8/13) after exposure to IgG from sera of patients with LN

Methods: We examined the expression level of nephrin, a podocyte marker and CaMKIV in normal and LN kidney specimens by immunofluorescence staining. We cultured human podocytes with IgG purified from sera of normal individuals and LN patient for 24 hr and analyzed CaMKIV mRNA levels by real time PCR. We also performed microarray analysis to determine gene expression.

Results: Although the expression levels of nephrin were decreased, CaMKIV expression was found increased in podocytes of LN kidney biopsy specimens. The levels of nephrin and CaMKIV correlated in an inverse manner. Interestingly, culture of AB8/13 podocytes in the presence of IgG from LN sera led to 1.5-fold increase in the expression of CaMKIV mRNA. Gene array analysis revealed that the expression of genes related to the cell activation including CaMKIV increased significantly ($P<0.05$) and the regulation of neural precursor cell proliferation decreased significantly ($P<0.01$) in podocytes treated with IgG from LN patients.



Conclusion: Our data demonstrate increased expression of CaMKIV in LN podocytes which may represent the result of exposure to IgG. We suspect that increased CaMKIV expression may contribute to the inability of podocytes to maintain the integrity of glomerular basement membrane in LN patients.

Podocytes Take Up Adsdna Autoantibody Complexes. Anja Hillmann[1], Elisabeth Jung[1], Annika Engbers[1], Hedda Wardemann[2], Annett M. Jacobi[1] and Thomas Pap[1]. [1]University Hospital Münster, Münster, Germany, [2]Max Planck Institute for Infection Biology, Berlin, Germany.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease, resulting in inflammation and tissue damage in several organs. This autoimmune reaction is caused by autoantibodies, e.g. against dsDNA (adsDNAabs). Most patients with SLE develop joint pain and about 70% develop renal symptoms, partly with lupus nephritis leading to proteinuria. It is still unclear why the kidney and especially the postmitotic podocytes are involved in such a dramatic manner during SLE.

Methods: Antibodies were isolated from SLE-patients, cloned and produced recombinantly in HEK293 cells. Living podocytes were treated with equal amounts of adsDNAabs and control antibodies in time and concentration dependent experiments and examined by immunofluorescence and Western Blot. To investigate the uptake mechanism, antibodies were pretreated with DNaseI. To analyze the degradation mechanism, treated cells were incubated with e.g. Bafilomycin.

Results: adsDNAabs are taken up by cultivated podocytes selectively in a concentration and time dependent manner and turn up in cytosolic aggregates. After treatment of the antibodies with DNAseI, the uptake decreases significantly. In recovery experiments, we could show that these aggregates are eliminated over time in media without adsDNAabs. The aggregates co-localize with different autophagy related proteins. Western Blot analyzes show that autophagy is upregulated after treatment with adsDNAabs. The degradation of adsDNAabs is reduced in experiments under autophagy inhibiting conditions (treatment with Bafilomycin A) and number of aggregates after the inhibition of autophagy rises significantly up to twofold. The number of aggregates of podocytes treated with a control antibody or antibodies against other autoantigens (e.g. Ro) is almost zero.

Conclusion: Podocytes are postmitotic and highly complex cells. Loss of these cells leads to kidney injury and proteinuria. During lupus-nephritis, podocytes are destroyed. We could show that these cells take up adsDNAabs selectively in a complex with their target and are harmed by these antibody-aggregates. Our results indicate that the antibody-complexes in the cells are degraded via autophagy. This should be considered for future therapeutic approaches in lupus nephritis.

Quantitative Cell Distance Mapping In Human Nephritis Reveals Organization Of *In Situ* Adaptive Immune Responses. Marcus R. Clark, Vladimir M. Liarski, Natalya Kavernia, Maryellen L. Giger, Anthony Chang, Yahui Peng and Daniel F. Brandt. University of Chicago, Chicago, IL.

Background/Purpose: Inflammatory infiltrates contain multiple cell types that could interact in myriad ways to amplify *in situ* immune responses. However, there currently are no methods available to quantitatively assess such interactions in human tissue.

Methods: Therefore, we developed a novel computational approach which we term cell distance mapping (CDM) that, when coupled to confocal microscopy, enabled us to quantitatively assess the spatial relationships between different cell populations.

Results: When applied to human lupus nephritis (LuN), CDM revealed that T follicular helper (T_{FH})-like cells commonly infiltrated the renal tubulointerstitium with almost half in cognate pairs with B cells. Furthermore, in the absence of evident germinal center (GCs), the overall spatial organization of B cells and T_{FH} cells in LuN was similar to that observed in tonsil GC light zones. T_{FH}-like cells ($CD4^+ICOS^+PD\text{-}1^+$) were also observed in T cell-mediated renal transplant rejection (TCMR) cases. However, the T_{FH}-like cells in TCMR infrequently formed cognate pairs with B cells. Furthermore, the TCMR T_{FH}-like cells did not organize the B cells around them. Finally, while IL-21 expression was high in tonsil GC and LuN T_{FH}-like cells, it was barely detectable in the T_{FH}-like cells infiltrating the tubulointerstitium in TCMR.

Conclusion: These results suggest that even in areas of diffuse inflammation, CDM reveals cellular organizations and inter-cell interactions associated with *in situ* adaptive immunity. Furthermore, we propose that CDM can discriminate between functional and non-functional T_{FH} cells *in situ*.

Background/Purpose: Giant cell arteritis (GCA) is a polygenic inflammatory disease affecting medium- and large-sized blood vessels in people elder than 50-years old. Although it is clear that GCA has an important genetic component, very little is known about the genetic susceptibility to this vasculitis. In order to better understand the genetic association of the HLA region with this disease, we aimed to carried out for the first time a comprehensive fine-mapping of this genomic region to identify the causative variants and/or amino acids responsible for the GCA predisposition.

Methods: 556 biopsy-proven GCA patients and 1,951 controls from Spanish Caucasian ancestry were genotyped using the *Illumina Infinium Immunochip* genotyping platform. Subsequently, we isolated the genotyping data from the extended major histocompatibility complex (xMHC) region, located in chromosome 6, and used a previously validated imputation method to analyze the variation within the xMHC region of single-nucleotide polymorphisms (SNPs), classical HLA alleles and variable amino acids. For the imputation, we used the Beagle software and a reference panel comprised of 5,225 individuals of European origin with genotyping data of about 8,961 common SNPs and insertion-deletion polymorphisms across the xMHC region, and four digits genotyping data of the HLA class I and II molecules. Control quality filters were performed with the Eigensoft and Plink software.

Results: The accuracy reached after comparing 4 digit types with the corresponding imputed data was >90% for *HLA-DQA1*, *HLA-DRB1* and *HLA-B*. As expected, one of the highest association peaks was HLA-DRB1*0404 (P=1.97×10–11, OR=2.91, CI 95%=2.13–3.98), but HLA-DQA1*0301 was also firmly associated (P=4.81×10-09, OR=1.70, CI 95%=1.42–2.03). Consequently, different amino acid positions of both DRβ1 and DQα1 chains were strongly associated with disease predisposition ($P<5\times10$-8). However, the presence of a histidine in the position 13 of the DRβ1 molecule defined almost all the association of the HLA region with GCA. Only the addition of an arginine amino acid at position 56 of the

HLA-DQα1 chain improved marginally the model (likelihood-P=0.018). Both amino acids are located in the binding pocket of their corresponding molecule and, therefore, may interact with the antigen.

Conclusion: Our results show that one amino acid located at the binding pocket of the HLA-DRβ1 chain is responsible for almost all the HLA association with GCA.

Background/Purpose: The *PTPN22*/*CSK* signaling represents one of the common susceptibility pathways in autoimmunity. Considering that the genetic basis of giant cell arteritis (GCA), an autoimmune vasculitis of complex etiology, remains poorly understood, we decided to analyze whether variations within the *PTPN22* and *CSK* genes are associated with GCA predisposition and/or severity in a well-powered case/control cohort.

Methods: The study comprised a discovery cohort from Spanish Caucasian ancestry of 623 biopsy-proven GCA cases and 1,729 unaffected controls, and a replication Caucasian cohort from three different European countries (UK, Norway and Germany) consisting of 288 biopsy-proven GCA patients and 6,407 unaffected controls. Two non-synonymous functional *PTPN22* polymorphisms (rs24746601/R620W and rs33996649/R263Q) and two additional *CSK* variants that have been associated with systemic sclerosis (rs1378942) and systemic lupus erythematosus (rs34933034) were genotyped using TaqMan© probes. The statistical analyses were performed with Plink.

Results: A clear association of the *PTN22* classical polymorphism rs24746601/R620W with GCA was observed in the discovery cohort, which was maintained after FDR correction for multiple testing (corrected P=1.06E-04, OR=1.62, CI 95%=1.29–2.04). This association was further confirmed in the replication set of independent European cohorts, whose meta-analysis also reached statistical significance (P_{MH}=0.015, OR=1.38, CI 95%=1.07–1.77). A strong association signal was observed when the four European cohorts were combined (P_{MH}=2.00E-06, OR=1.51, CI 95%=1.28–1.79). The comparison between the analysed clinical phenotypes (*i.e*. polymyalgia rheumatica, visual ischemic manifestations, and irreversible occlusive disease) and the control set also yielded significant *P*-values for *PTPN22* R620W; however, no association was observed when the GCA cases positive and negative for each clinical characteristic were compared, suggesting that this *PTPN22* variant is associated with the whole disease. None of the other analyzed polymorphisms showed evidence of association either with the global disease or with the different phenotypes.

Conclusion: Our results clearly indicate that the autoimmune-disease associated *PTPN22* polymorphism rs24746601/R620W confers risk to develop GCA.

Association Between Human Leukocyte Antigen-B's Amino Acid Variation and Disease-Susceptibility To Takayasu's Arteritis. Hajime Yoshifuji[1], Chikashi Terao[1], Kosaku Murakami[1], Daisuke Kawabata[1], Koichiro Ohmura[1], Takao Fujii[1], Yasushi Kawaguchi[2], Hisashi Yamanaka[2] and Tsuneyo Mimori[1]. [1]Graduate School of Medicine, Kyoto University, Kyoto, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: HLA-B52 and HLA-B51 are frequently seen in Asian population and are almost identical except two amino acid residues(the 63rd and 67th), but HLA-B52 is related with susceptibility to Takayasu's arteritis (TAK) while HLA-B51 is related with susceptibility to Behçet's disease. To understand the mechanisms, we analyzed the variation of HLA-B amino acid sequences in TAK patients.

Methods: We collected DNA of 173 TAK patients from Kyoto University Hospital and Tokyo Women's Medical University Hospital, genotyped their HLA-B alleles, and compared them with those of 2000 healthy controls.

Results: HLA-B52 was strongly related with TAK susceptibility ($P < 0.000000000000001$), while HLA-B51 was not ($P = 0.39$). Analysis of HLA-B's amino acid variations revealed that 171H (histidine at 171st position) compared with 171Y was a risk factor ($P < 0.00000001$), and 67F compared with 67notF (S, Y, C or M) was a protective factor ($P < 0.0001$) of TAK susceptibility. Both the 171st and 67th amino acids are located at the groove of HLA-B protein, implying immune response is related to the pathogenesis. Both HLA-B52 and HLA-B51 have the TAK-susceptible 171H. While HLA-B52 has the TAK-susceptible 67S, HLA-B51 has the protective 67F. That is a plausible reason why HLA-B51 was not related with TAK susceptibility. Besides, we also searched for single nucleotide polymorphisms (SNPs) of non-HLA genes that related to TAK susceptibility and found several candidates of genes.

Conclusion: The difference of HLA-B's 67th amino acid residue was supposed to divide the susceptibilities to TAK or Behçet's disease. Further analyses are needed to know what kind of peptides show affinities to the HLA-B's groove.

Intermittent Fever, Immune Dysregulation, and Systemic Vasculopathy Due To Loss-Of-Function Mutations In Adenosine Deaminase2. Qing Zhou[1], Dan Yang[2], Andrey Zavialov[3], Amanda Ombrello[1], Hyesun Kuehn[4], Jae Jin Chae[1], Anton Zavialov[3], David Chin[1], Deborah Stone[1], Camilo Toro[1], Joshua Milner[5], Chyi-chia Lee[6], Edward Cowen[6], Fabio Candotti[1], Elaine Remmers[1], Susan Moir[5], Raman Sood[1], Shawn Burgess[1], Massimo Gadina[7], Sergio Rosenzweig[5], Michael Hershfield[8], Daniel L. Kastner[1], Manfred Boehm[2] and Ivona Aksentijevich[1]. [1]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, [2]National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD, [3]University of Turku, Turku, Finland, [4]Clinical Center, National Institutes of Health, Bethesda, MD, [5]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, [6]National Cancer Institute, National Institutes of Health, Bethesda, MD, [7]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, [8]Duke University Medical Center, Durham, NC.

Background/Purpose: We observed a syndrome characterized by intermittent fevers and livedoreticularis, systemic inflammation, hepatosplenomegaly, cytopenias, vasculopathy, and early-onset lacunar strokes in five unrelated patients. We suspected a genetic cause because the disorder presented in early childhood.

Methods: We performed whole-exome and candidate gene sequencing on the patients and their unaffected parents. Patient samples were analyzed by ELISA, immunoblotting, immunohistochemistry, flow cytometry, and cytokine profiling. Morpholino knockdowns in zebrafish embryos were used to study gene function.

Results: Our patients were compound heterozygous for 5 missense mutations(G47A, A109D, H112Q, R169Q, Y453C) anda 28kb genomic deletion in *CECR1* encoding adenosine deaminase2 (ADA2).All mutations are either novel or present at low frequency (<0.001) in several large databases, consistent with the recessive inheritance. The Y453C mutation was present in an NHLBI exomedatabase in 2 siblings who suffered from late-onset ischemic stroke. This finding indicatesthat heterozygous mutations in ADA2 might be associated with susceptibility to adult stroke.Computer modeling based on the crystal structure of the human ADA2 suggests that *CECR1* mutations either disrupt protein stability or impair ADA2 enzyme activity. Patients had at least a 10-fold reduction in blood ADA2, and dramatically reduced ADA2-specific adenosine deaminase activity in blood and $CD14^+$ monocytes. In contrast to patients with ADA1 deficiency and severe combined immunodeficiency, there was no accumulation of deoxyadenosine or its toxic metabolites in patients' blood suggesting new functional role of ADA2 addition to its enzyme activity. *cecr1b*knockdown caused intracranial hemorrhages in zebrafish embryossuggesting defects in vessel development.The intracranial hemorrhage phenotype was rescued with wild type human *CECR1* mRNA, but not by the R169Q mutant mRNA.Skin, liver, and brain biopsies from patients showed a diffuse vasculopathy, with evidence of impaired endothelial integrity and endothelial cellular activation.

Conclusion: Recessive mutations in *CECR1* cause ADA2 deficiency manifesting with diffuse vasculopathy, systemic inflammation, and early-onset stroke. Ex vivo experiments with patients' cells, in vitro cell culture studies, and animal model data suggest an important role for ADA2 in vascular and leukocyte development, consistent with its proposed role as a growth factor.ADA2 replacement with the fresh frozen plasma transfusions, enzyme therapies with recombinant ADA2, gene therapy, and hematopoietic stem cell transplantation are possible treatment options.

The Relative Risk Of Aortic Aneurysm In Patients With Giant Cell Arteritis Compared With The General Population. Joanna Robson[1], Amit Kiran[2], Joseph Maskell[3], Andrew Hutchings[4], Nigel K. Arden[5], Bhaskar Dasgupta[6], William Hamilton[7], Akan Emin[8], David Culliford[3] and Raashid A. Luqmani[2]. [1]Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, Botnar Research Centre, University of Oxford, Oxford, United Kingdom, [2]University of Oxford, Oxford, United Kingdom, [3]University of Southampton, Southampton, United Kingdom, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]Oxford NIHR Musculoskeletal Biomedical Research Unit, University of Oxford, Oxford, United Kingdom, [6]Southend University Hospital, Westcliff-on-sea, United Kingdom, [7]University of Exeter Medical School, Exeter, United Kingdom, [8]The Royal College of Surgeons of England, London, United Kingdom.

Background/Purpose: To evaluate the risk of aortic aneurysm in patients with giant cell arteritis (GCA) when compared with age, gender and location matched controls from the general population.

Methods: Parallel cohort study. General Practice Research Database (GPRD). 6999 men and women with giant cell arteritis (GCA). Non-GCA patients matched on a 6:1 ratio on the following three parameters: same GP practice, year of birth (+/− 3 years) and gender. A competing risk model using aortic aneurysm as the primary outcome and death as the competing risk, was used to determine the relative risk (subhazard ratio) between non-GCA and GCA subjects, after adjustment for cardiovascular risk factors.

Results: Comparing the GCA cohort with the non-GCA cohort, using a multivariable model with adjustment for BMI, smoking, alcohol, hyperlipidaemia, lipid lowering medication, hypertension, anti-hypertensives, diabetes, cardiovascular disease, cerebrovascular disease and peripheral vascular disease; the subhazard ratio for aortic aneurysm (95% CI) was 1.92 (1.52 to 2.41). Significant predictors of aortic aneurysm were as follows:being an ex-smoker 2.64 (2.03 to 3.43), current smoker 3.37 (2.61 to 4.37), previous prescription of anti-hypertensives 1.57 (1.23 to 2.01), previous history of diabetes 0.32 (0.19 to 0.56) and previous history of cardiovascular disease 1.98 (1.50 to 2.63). In a multivariable model of the GCA cohort alone, male gender 2.10 (1.38 to 3.19), smoking 3.79 (2.20 to 6.53), and diabetes 0.19 (0.05 to 0.77) were significant predictors of aortic aneurysm.

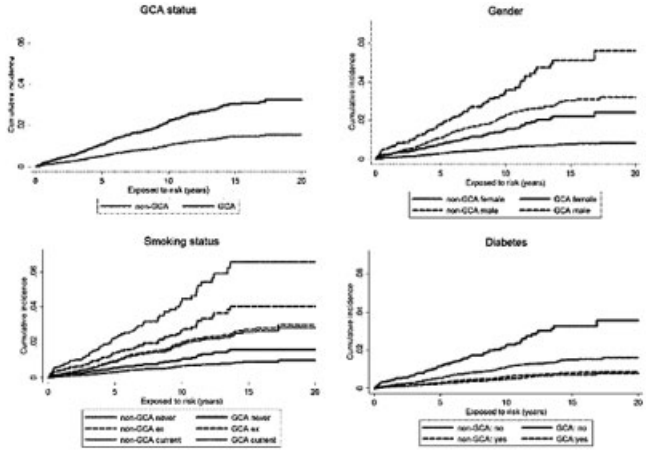

Figure 1. Cumulative incidence of AA events

Conclusion: This study demonstrates a two-fold increased risk of aortic aneurysm in patients with GCA. Other risk factors for aortic aneurysm, including male gender, age, and smoking, are important in patients with GCA and the general population. The message for clinicians and policymakers is therefore that the diagnosis of GCA should be considered within the context of the range of risk factors for aortic aneurysm, rather than acting as a prompt for a specific screening programme. This study also demonstrates for the first time the protective effect of diabetes in the development of aortic aneurysms in patients with GCA.

896

Increased Rho Kinase (ROCK) Activity In Temporal Artery Biopsies From Patients With Giant Cell Arteritis (GCA). Lindsay Lally[1], Navneet Narula[2], Alessandra B. Pernis[1], Wei-Ti Huang[1], Uzunma Udeh[1] and Robert F. Spiera[1]. [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medical College, New York, NY.

Background/Purpose: ROCKs are implicated in the pathogenesis of many vascular diseases. ROCK activation is associated with Th17 differentiation and production of Th17-associated cytokines, IL-17 and IL-21. Th17 cells and related cytokines are present in increased levels in the vascular inflammatory infiltrate in active GCA. ROCK activity in GCA is unknown. The aim of this study was to assess ROCK activity in temporal artery biopsy (TAB) specimens in GCA versus controls.

Methods: All TAB performed at a tertiary care center over a 5 year period were identified. Charts were reviewed for clinical information; included subjects had TAB specimens and clinical information available. Subjects were categorized according to 1990 ACR criteria and TAB status into 3 groups: GCA with positive TAB, GCA with negative TAB and age-sex-matched controls.

Paraffin-embedded temporal artery specimens were stained for Phospho-Ezrin/Radixin/Moesin (pERM), a surrogate of ROCK activity, using immunohistochemical (IHC) stain. IHC stained slides were reviewed by a pathologist blinded to clinical status. Three separate areas (endothelium, adventitia and vaso vasorum) were scored for intensity of staining on a scale of 0–2 for total possible composite score of 6. Primary outcome was biopsy pERM intensity score in subjects with GCA compared to controls.

Results: Nineteen subjects with GCA had positive TAB, 17 subjects had GCA with negative TAB and18 age-sex-matched controls were analyzed. Mean age was 77.9±9.1years and 81.4% were female (Table 1). Biopsy pERM intensity scores ranged from 2–6 with 28.3% scores ≤4 and 72.2% of scores >4 (high). 79.4% of high scores occurred in GCA subjects compared to controls (p=0.0033). Compared to controls, GCA subjects with either positive or negative TAB showed statistically significantly higher pERM intensity scores (p=0.035 and p=0.0083 respectively). Adjusting for comorbid diabetes, hypertension, prednisone use, and statin use, GCA subjects still had significantly higher pERM intensity scores compared to controls (OR 7.3; 95%CI 1.9–25.9, p=0.0046). High score for diagnosis of GCA had sensitivity of 86%, specificity of 55.6%. Comparing GCA with negative TAB to controls, high score had sensitivity of 90.4% and negative predictive value of 90.9%.

Table 1.

	GCA (n=36)			
	Biopsy Positive (n=19)	Biopsy Negative (n=17)	Control (n=18)	P value
Age, yr± SD	78.4±9.2	76.6±7.9	78.4±10.5	0.81
Female, n (%)	14 (74)	16 (94)	13 (72)	0.2
Prednisone Dose mg, mean±SD	55.6±17.9	50.6±17.1	47.2±27.2	0.5
Hypertension, n (%)	8 (44)	10 (59)	12 (67)	0.39
Diabetes, n (%)	1 (6)	6 (35)	4 (22)	0.11
Statin, n (%)	5 (28)	8 (47)	11 (61)	0.13
IHC score				0.0159
≤4	4 (21)	1 (6)	10 (56)	
>4	15 (79)	16 (94)	8 (44)	

Conclusion: Subjects with GCA had more intense pERM staining in TAB specimens compared to age and sex-matched controls regardless of whether TAB was positive or negative, independent of prednisone dose, statin use, or vascular comorbidities. In this population, high pERM staining score had a sensitivity comparable to what is reported as sensitivities of TAB routine histopathology itself and suggests it may be a useful adjunctive diagnostic tool especially in patients with suspected GCA and negative TAB. The ROCK pathway warrants further investigation in GCA as inhibition of this pathway is a potential therapeutic target.

Characterization Of Low Back Symptoms In a Community-Based Sample Of Older Adults: The Johnston County Osteoarthritis Project. Adam P. Goode[1], Kelli D. Allen[2], Timothy S. Carey[3] and Joanne M. Jordan[4]. [1]Duke University, Durham, NC, [2]Duke and Durham VA Medical Center, Durham, NC, [3]Cecil G. Sheps Center for Health Services Research University of North Carolina, Chapel Hill, NC, [4]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC.

Background/Purpose: The majority of research in low back pain has focused on the middle-aged segment of the population. As such, there is a gap in knowledge about low back pain among older adults (>=65 years). The purpose of these analyses is to describe differences in clinical characteristics between older adults with and without low back symptoms.

Methods: The sample for these analyses consists of 1,010 participants >=65 years of age who participated in the Johnston County Osteoarthritis Project from 2008–11. Participants had a mean age of 74.1 (SD 6.5), 69% were female, 29% were African American, and had mean body mass index (BMI) of 30.4 (SD 6.4). Low back symptoms were defined at clinical interview by "On most days do you have the symptoms of pain, aching or stiffness in your lower back?" General function was measured with the Health Assessment Questionnaire (HAQ) and, among those with reported low back symptoms, disease specific function with the Roland-Morris Low Back Pain Disability Questionnaire (RMDQ). The Centers for Epidemiological Questionnaire Scale (CES-D) was categorized at <16 or >=16 to represent mild depressive symptoms. Self-reported physical activity was measured as moderate (i.e., at least 10 minutes at a time, such as brisk walking, bicycling, vacuuming, gardening or anything else that causes small increases in breathing or heart rate) or vigorous (i.e., at least 10 minutes at a time, such as running, aerobics, heavy yard work, or anything else that causes large increases in breathing or heart rate). Lateral lumbar spine films were graded at each lumbar level in a semi-quantitative fashion (0–3) for disc space narrowing (DSN) and osteophytes (OST) according to the Burnett Atlas. Differences were determined by Chi-square tests.

Results: Fifty-nine percent (n=599) of older adults reported the presence of low back symptoms. The Table provides sample sizes, proportions and p-values for each clinical characteristic by low back symptom status. Among those with low back symptoms, self-reported general function (i.e., HAQ) was significantly (p<0.001) lower, depressive symptoms were significantly (p<0.001) greater and the reported mean RMDQ score was 7.6 (SD 6.9), indicating a perceived 31.7% disability. Those with low back symptoms were less likely (p=0.03) to report participation in weekly moderate physical activity. A similar finding was present with vigorous activity but not statistically significant. Particpants with low back symptoms had more severe DSN (p=0.04), whereas OST severity was similar between the groups.

Characteristic	No Low Back Symptoms	Low back symptoms	p-value
HAQ, n (%)			<0.001
0	114 (27.0%)	60 (16.2%)	
1	194 (45.9%)	118 (31.9%)	
2	115 (27.2%)	192 (51.9%)	
CES-D, n (%)			<0.001
<16	544 (93.8%)	334 (86.3%)	
>=16	36 (6.2%)	53 (13.7%)	
Moderate Physical Activity	423 (70.6%)	251 (64.0%)	0.03
Vigorous Physical Activity	72 (14.1%)	35 (10.6)	0.08
DSN, n (%)			0.04
0	117 (20.3%)	55 (14.4%)	
1	183 (31.7%)	115 (30.2%)	
2	150 (26.0%)	104 (27.3%)	
3	127 (22.0%)	107 (28.1%)	
OST, n (%)			0.10
0	45 (9.1%)	18 (5.3%)	
1	242 (49.0%)	160 (47.5%)	
2	142 (28.7%)	117 (34.7%)	
3	65 (13.2%)	42 (12.5%)	

Conclusion: These findings highlight the impact low back symptoms have across multiple health domains in older adults. Interventions to increase

physical activity have been shown to improve multiple outcomes among middle-aged adults, but the effectiveness is unknown in older adults. Clinical trials of physical activity are needed in this subgroup, which is particularly susceptible to declining general function.

898

Sex-Specific Employment Participation Restriction Across Occupational Groups Among Working-Age (18–64 years) U.S. Adults With and Without Arthritis. Kristina A. Theis[1] and Louise Murphy[2]. [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]CDC, Atlanta, GA.

Background/Purpose: Previous research has shown arthritis-attributable work limitation to be high (~30%) among U.S. adults with arthritis and for employment to be ~20% lower among adults with arthritis compared with those without arthritis. Women with arthritis typically are less likely to be employed than women without arthritis and all men. The purpose of this study is to estimate, for the first time, the overall and sex-specific prevalence of employment participation restriction (PR) among adults ≥18 years with and without arthritis and also to examine differences by occupational groups.

Methods: 2011 National Health Interview Survey (NHIS) data were analyzed (Adult Functioning and Disability Supplement and Sample Adult Core [n = 16,540; response rate = 63%]). NHIS is an annual, multistage probability survey by in-person interview designed to represent the U.S. civilian, non-institutionalized population. Arthritis diagnosis was identified by "Have you ever been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?" Several activities were queried with the root: "For each of the following activities, please tell me if you do the activity, don't do the activity, or are unable to do the activity." Employment PR was ascertained by a response of "unable to do" for the activity: "Working outside the home to earn an income." Five major occupational groups were categorized according to Bureau of Labor Statistics classifications: 1) management, professional, and related; 2) service; 3) sales and office; 4) natural resources, construction, and maintenance; 5) production, transportation, and material moving. Occupation among those who were working/had ever worked was classified based on their current/most recent job. Weighted proportions with 95% confidence intervals (CI) were calculated accounting for complex sample design (SAS 9.2).

Results: Overall, 5.9% (5.4–6.4) of respondents reported employment PR; the proportion was approximately four times higher among those with arthritis (17.5% [5.8 million]) compared with those without arthritis (3.5% [5.5 million]). For each occupational group, employment PR was 2.5–8 times greater among those with arthritis(Table). Among those with arthritis, the group with the greatest sex-specific difference was production, transportation, and material moving, with employment PR approximately double among women (32.0%) compared with men (14.9%).

Prevalence of Participation Restriction in Employment by Arthritis Status, Sex, and Occupational Group among Working-Age (18–64 year old) U.S. Adults, NHIS, 2011

	Men				Women			
	Arthritis		No Arthritis		Arthritis		No Arthritis	
Occupational Group	%	95% CI	%	95% CI	%	95% CI	%	95% CI
Management, professional, & related	6.8	3.8–9.7	N/A	–	9.7	6.8–12.6	1.5	0.9–2.2
Service	18.0	11.2–24.8	2.0	0.8–3.1	26.4	21.4–31.4	4.0	2.8–5.1
Sales & office	15.1	9.6–20.6	3.6	2.1–5.1	19.1	14.5–23.7	3.2	2.3–4.1
Natural Resources, construction, & maintenance	19.8	13.4–26.2	4.3	2.7–5.8	N/A	–	N/A	–
Production, transportation, & material moving	14.9	10.5–19.3	5.8	3.8–7.8	32.0	23.0–41.0	5.9	3.2–8.6

Conclusion: High prevalence of employment PR for people with arthritis across all occupational groups compared with their non-arthritis peers indicates greater employment PR burden; women have higher employment PR burden than men. Exploration of effective interventions to reduce employment PR, including potential differences in benefits by sex, is necessary to mitigate the negative effects of employment PR.

Foot Pain, But Not Foot Structure Or Foot Function, Are Associated With Self-Reported Physical Limitations: The Framingham Foot Study. Alyssa B. Dufour[1], Patricia P. Katz[2], Virginia A. Casey[3], Marian T. Hannan[1] and Hylton B. Menz[4]. [1]Hebrew SeniorLife & Harvard Medical School, Boston, MA, [2]University of California, San Francisco, San Francisco, CA, [3]Hebrew SeniorLife, Boston, MA, [4]La Trobe University, Bundoora, Victoria 3086, Australia.

Background/Purpose: The purpose of this cross-sectional study was to examine the relation between self reported physical limitations and foot pain, foot structure and foot function in older men and women of the Framingham Foot Study (FFS).

Methods: 1860 participants in the FFS completed the foot questionnaire, which included foot pressure measurements and questions on physical limitations. The presence of foot pain was defined (y/n) using the question "On most days, do you have pain, aching, or stiffness in either of your feet?" Foot structure and foot function were defined using standing and walking foot pressure scans from a Tekscan Matscan system, respectively. The modified arch index describes foot structure as planus, cavus or referent using sex-specific quintiles from the population distribution. The center of pressure excursion index measures dynamic foot function as pronated, supinated, or referent using sex-specific quintiles from the population distribution.

An overall physical limitations score was derived from items assessing difficulty (none vs. any [little, some, a lot, unable]) for 9 activities such as remaining balanced while standing; standing in one place; getting in/out of a car, a chair, or bed; putting on socks/stockings; and up/down 1 flight of stairs. We created an overall score by summing the number of tasks with limitations (range 0–9) and also a mean difficulty score across all levels of difficulty in the 9 items, range 0–4. Linear regression estimated the association between physical limitation score and foot pain, foot structure and foot function, adjusting for age, height, weight and sex.

Results: Of the 1860 participants, 55% were women and mean age was 65 yrs (SD=10.6). 37% had no physical limitation. The average overall physical limitations score was 2 (SD=2.4) and average mean difficulty score was 0.36 (SD=0.50). 27% reported foot pain, 34% were pronators, 27% were supinators, 24% had cavus foot and 29% had planus foot.

Those with foot pain reported more physical limitations than those without ($p<.0001$). Foot structure and foot function were not associated with the overall physical limitation score in adjusted models (Table). Remarkably similar results were seen for the mean difficulty score as seen with the overall physical limitations score.

Table. Least squares means (lsmeans) and p-values from a linear regression between the overall physical limitations score and foot pain, foot structure and foot function.

		Crude		Adju sted (age, height, weight, sex)	
	Raw means	lsmeans	p-value	lsmeans	p-value
Foot Pain	3.13	3.12	<.0001	3.03	<.0001
No Foot Pain	1.70	1.71	Ref	1.74	Ref
Foot Function					
Supinator	1.98	1.98	0.41	2.09	0.68
Pronator	2.16	2.16	0.60	2.13	0.44
Referent	2.08	2.09	Ref	2.04	Ref
Foot Structure					
Planus	2.48	2.48	<.0001	2.16	0.36
Cavus	1.86	1.86	0.48	2.08	0.73
Referent	1.95	1.96	Ref	2.04	Ref

Conclusion: Foot pain is strongly associated with self-reported physical limitations, but foot structure and foot function are not. Persons may adapt to their own foot structure and foot function so that it does not limit physical activity. Objective measures of physical limitations are needed to provide other insights into the links with foot pain.

Foot Symptoms Increase Odds Of Falling: The Johnston County Osteoarthritis Project. Yvonne M. Golightly[1], Marian T. Hannan[2], Alyssa B. Dufour[2], Amanda E. Nelson[3], Adam Dore[1] and Joanne M. Jordan[3]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Hebrew SeniorLife & Harvard Medical School, Boston, MA, [3]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC.

Background/Purpose: Foot symptoms (symptoms=pain, aching, and stiffness) are common in older adults and are associated with poorer physical function, but their contribution to risk of falling is understudied. The purpose of this cross-sectional study was to examine whether presence and severity of foot symptoms were associated with falls in a community-based cohort of African American and Caucasian men and women 50+ years old.

Methods: Of 1,690 Johnston County Osteoarthritis Project participants who completed questionnaires about falls from 2006–2010, complete data on foot symptoms, history of falls, and participant characteristics were available for 1,406 participants (mean age 68 ± 9 years, mean body mass index [BMI] 32 ± 7 kg/m^2, 66% women, 30% African American, 22.4% with <12 years of school). Falls (yes/no) were queried as: "In the last 12 months, have you had any falls of any type?" If they responded "yes", they reported the number of falls. Presence of foot symptoms (yes/no) was defined based on the question: "On most days, do you have pain, aching or stiffness in your left/right foot?" Foot symptom severity was recorded as none (referent), mild, moderate, or severe. Logistic regression models were used to estimate the association between foot symptoms and falls (defined two ways as ≥1 fall and ≥2 falls), adjusting for history of falls, age, BMI, gender, race, education (12+ years vs. <12 years) and other lower body symptoms at the low back, hip, or knee. Statistical interaction between foot symptoms and each covariate was examined, with a p-value of <0.10 for interaction considered statistically significant.

Results: Foot symptoms were reported by 341 (24.3%) participants, and symptoms were severe for 4.3% of participants, moderate for 10.7%, and mild for 9.3%. In the past 12 months, 26.9% of participants reported 1 or more falls and 10.5% reported 2 or more falls. 22.2% participants had a history of falls, and 60.1% had other lower body symptoms. Foot symptoms were associated with falls during the past 12 months (Table). Compared to those without foot symptoms, those with foot symptoms had 60% higher odds of sustaining at least one fall and 90% higher odds of sustaining at least 2 falls. The odds of falling increased with greater foot symptom severity (Table). There were no interactions between foot symptoms and any of the covariates.

Table. Odds ratios and 95% confidence intervals for the association between foot symptoms and falls during the past 12 months, adjusting for history of falls, age, BMI, race, gender, education, and other lower body symptoms.

Falls	Foot Symptoms	# of fallers/ n (%)	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
Any falls vs. no falls	Symptoms:			
	Yes	128/341 (37.5)	1.96 (1.57, 2.63)	1.62 (1.23, 2.15)
	No	250/1065 (23.5)		
	Severity:			
	None	250/1065 (23.5)	1.00	1.00
	Mild	44/131 (33.6)	1.65 (1.12, 2.43)	1.38 (0.92, 2.07)
	Moderate	54/150 (36.0)	1.83 (1.28, 2.63)	1.52 (1.04, 2.24)
	Severe	30/60 (50.0)	3.26 (1.93, 5.51)	2.68 (1.54, 4.68)
2 or more falls vs. 0 or 1 fall	Symptoms:			
	Yes	61/341 (17.9)	2.48 (1.74, 3.53)	1.92 (1.32, 2.80)
	No	86/1065 (8.1)		
	Severity:			
	None	86/1065 (8.1)	1.00	1.00
	Mild	22/131 (6.8)	2.30 (1.38, 3.82)	1.84 (1.09, 3.13)
	Moderate	26/150 (17.3)	2.39 (1.48, 3.85)	1.95 (1.18, 3.22)
	Severe	13/60 (21.7)	3.15 (1.64, 6.05)	2.00 (1.01, 3.98)

Conclusion: Foot symptoms were significantly associated with falls during the past 12 months, with odds increasing with greater severity of foot symptoms. Surprisingly, there were no interactions, especially by race or BMI. Fall prevention measures may target foot interventions specifically to reduce foot symptoms or to slow progression of symptom severity to prevent future falls.

Smokers and Overweight Persons Are At Increased Risk Of New Onset Of Severe Foot Pain and Persistent Severe Foot Pain In a Population Study. Alyssa B. Dufour[1], Hylton B. Menz[2], Arunima Awale[3], Thomas J. Hagedorn[3], Virginia A. Casey[3], Patricia P. Katz[4] and Marian T. Hannan[1]. [1]Hebrew SeniorLife & Harvard Medical School, Boston, MA, [2]La Trobe University, Bundoora, Victoria 3086, Australia, [3]Hebrew SeniorLife, Boston, MA, [4]University of California, San Francisco, San Francisco, CA.

Background/Purpose: Few studies have evaluated risk factors for patterns of foot pain in the general population, let alone over time. An understanding of the possible predictors is the first step towards evidence-based interventions. The purpose of this study was to examine risk factors for the onset and persistent of severe foot pain in men and women of the population-based Framingham Foot Study (FFS).

Methods: The longitudinal FFS included 648 participants who attended baseline (BL, 2002–5) and follow-up (FU, 2005–8) exams. The presence of foot pain at both BL and FU was queried using the question "On most days, do you have pain, aching, or stiffness in either of your feet?" If participants had foot pain, severity was then queried as mild, moderate or severe. We dichotomized pain severity into 2 pain groups: moderate/severe versus none/mild for each foot. Two separate analyses were done to examine 1) onset of moderate/severe pain versus none/mild pain and 2) persistent severe/moderate pain versus resolving severe/moderate pain. Two per-foot analyses using logistic regression and generalized estimating equations were used to examine the association between onset versus no foot pain and persistent versus resolving foot pain with potential risk factors (age, sex, body mass index (BMI), current smoking, knee pain, hip pain, and low back pain). Models were also examined by sex.

Results: At BL, average age was 65 years (range 36–86, SD=9), BMI was 29 kg/m^2 (SD=5), 51% were female and mean follow-up time was 3 years (range 1–6). 85% had no pain, 5% had onset, 7% had resolving, and 3% had persistent pain. Female sex and current smoking was associated with a 2–3 fold increased odds of onset of pain. Increased BMI was associated with a 16–20 fold increased odds of persistent versus resolving pain (Table).

Table. Odds ratios (OR) and 95% confidence intervals (CI) for the per-foot analysis between onset and persistent moderate/severe foot pain and risk factors in 648 participants (1296 feet)

	Onset (N_1=67 feet) vs. No Pain(N_0=1104 feet)			Persistent (N_1=40 feet) vs. Resolving (N_0=85 feet)		
	n/ N_1	OR (95% CI)	p-value	n/ N_1	OR (95% CI)	p-value
Age (10 yr incr)		1.23 (0.92,1.64)	0.16		1.06 (0.60,1.87)	0.84
Female sex	42/67	1.98 (1.03,3.82)	0.04	28/40	1.14 (0.41,3.18)	0.80
BMI 25–30 vs <25	27/67	1.26 (0.54,2.93)	0.59	16/40	20.67 (2.39,178.74)	0.01
BMI 30+ vs <25	25/67	1.24 (0.57,2.71)	0.59	23/40	16.31 (1.91,139.41)	0.01
Current smoking	14/67	2.76 (1.21,6.28)	0.02	6/40	2.92 (0.69,12.31)	0.15
Knee pain	23/67	1.26 (0.70,2.27)	0.45	15/40	1.11 (0.54,2.31)	0.78
Hip pain	9/67	0.67 (0.29,1.58)	0.36	7/40	0.52 (0.22,1.22)	0.13
Low back pain	29/67	1.69 (0.87,3.26)	0.12	29/40	1.66 (0.57,4.82)	0.35

In the sex-specific models, current smoking maintained its effect with onset pain, but was non-significant (OR_{men}=3.4, p=.07; OR_{women}=2.4, p=.11). The elevated odds of persistent pain remained for overweight (OR=14, p=.20) and obese men (OR=7, p=.10) but not for women. These non-significant results are not surprising given the small numbers in individual cells.

Conclusion: A larger study with longer follow-up is needed to identify risk factors and patterns of foot pain over time. Looking at foot disorders, in addition to pain, is also of interest. Nevertheless, in our study current smoking regularly appears to be linked with onset of moderate to severe foot pain, which is in agreement with common clinical observations that smokers develop more foot problems than non-smokers. Additionally, increased BMI was suggestively linked to persistent moderate to severe foot pain compared to those whose pain resolved.

The Effect Of Obesity On Physical Function: The Osteoarthritis Initiative Study. Jingbo Niu[1], Daniel K. White[1], David T. Felson[1], Michael C. Nevitt[2] and Yuqing Zhang[1]. [1]Boston University School of Medicine, Boston, MA, [2]University of California, San Francisco, San Francisco, CA.

Background/Purpose: Previous studies assessing relationship between obesity and physical function used linear regression model that assumes effects of obesity on physical function were the same across the distribution of outcome variable. However, if this assumption is not true, linear regression model may fail to reveal important associations and fail to identify persons who might be best targeted for obesity modification. Quantile regression provides a more complete picture of the relationship between obesity and physical function when both lower and upper or all quantiles are of interest. We used quantile regression to examine the distribution-specific effect of obesity on physical function.

Methods: The *Osteoarthritis Initiative* (*OAI*) Study is an observational study of people 45–79 years with or at high risk of knee osteoarthritis. Body Mass Index (BMI) was calculated from standardized assessments of height and weight and categorized into 3 groups: normal ($< 25 kg/m^2$), overweight ($25 - <30 kg/m^2$), and obese ($\geq 30 kg/m^2$). Physical function was measured with knee-specific WOMAC function (range: 0–68) at the 12-month visit. The knee with higher (worse) WOMAC function score was used to represent a person's function level. We performed sex-specific quantile regression models to assess association between BMI categories and WOMAC function percentiles from 30^{th} to 90^{th} with increase by 10^{th} adjusting for age, race, and CES-D score. We also performed a traditional linear regression model.

Results: 4,243 subjects (mean age 62.3, 58% women, 81% Whites, mean CES-D score 62.3) were included in analysis. In men, WOMAC function score among obese subjects was $>$ 6 units worse at the 70^{th}, 80^{th}, and 90^{th} percentile, but only 0.4 unit worse at the 30^{th} percentile compared with the score for those in a normal BMI category. Similarly, WOMAC function score among obese women was $>$ 9 units worse at the 70^{th}, 80^{th}, and 90^{th} percentile, but only 2.2 units worse at the 30^{th} percentile of WOAMC physical function score than score for those in a normal BMI category. A similar pattern was observed for subjects who were overweight though with attenuated effects (see table). Such findings were not revealed when using a linear regression approach.

Table. WOMAC function score and BMI categories (normal BMI as reference)

Mean/percentiles of WOMAC function score	Men		Women	
	overweight beta (95% CI)	obesity beta (95% CI)	overweight beta (95% CI)	obesity beta (95% CI)
mean	1.81 (0.60, 3.03)†	3.77 (2.50, 5.05)‡	1.94 (0.85, 3.02)‡	5.94 (4.83, 7.04)‡
30^{th}	0 (−0.13, 0.13)	0.42 (0.04, 0.79)*	0.13 (−0.04, 0.30)	2.20 (1.69, 2.72)‡
40^{th}	0.12 (−0.09, 0.34)	1.07 (0.66, 1.49)‡	0.60 (0.14, 1.06)*	3.85 (3.21, 4.49)‡
50^{th}	0.67 (0, 1.33)*	2.09 (1.22, 2.97)‡	1.05 (0.35, 1.75)†	5.10 (4.20, 6.01)‡
60^{th}	1.83 (0.81, 2.84)‡	4.25 (2.65, 5.84)‡	2.10 (0.98, 3.22)‡	6.98 (5.45, 8.50)‡
70^{th}	2.54 (1.01, 4.07)†	6.30 (4.20, 8.39)‡	3.22 (1.52, 4.93)‡	9.20 (7.26, 11.14)‡
80^{th}	3.46 (1.21, 5.71)†	8.01 (5.60, 10.42)‡	3.99 (2.00, 5.99)‡	10.49 (8.47, 12.52)‡
90^{th}	3.53 (−0.09, 7.15)	8.65 (4.59, 12.71)‡	5.21 (2.62, 7.81)‡	11.42 (8.52, 14.31)‡

*P-value <0.05, †P-value <0.01, ‡P-value <0.001

Conclusion: Using quantile regression model we demonstrated that the magnitude of association between obesity and physical function score was greater among subjects with worse physical function than those with better function. When research interest focuses on bounded outcomes, such as pain or function assessed with visual analogue scale, quantile regression models may provide more valuable insights into the relationships than methods that use single summary effect measure, such as difference in mean or median.

A Qualitative Study Of The Educational Needs Of Children With Scleroderma and Their Parents. Cindy F. Mendelson[1], Ana-Alicia Huerta[2], Jane Kastning[1], Bernadette Vargas[1] and Janet L. Poole[1]. [1]University of New Mexico, Albuquerque, NM, [2]Univeristy of New Mexico, Albuquerque, NM.

Background/Purpose: Scleroderma is a rare disease, especially in childhood. Skin changes can be physically disfiguring which can lead to lowered self-esteem, especially during the adolescent years when physical appearance is emphasized. No psycho-educational programs exist to help children and their families cope with disease management, prognosis and psychosocial issues. A qualitative interview study was conducted to determine the appropriate content, delivery methods and targeted audience to be included in a psycho- educational program for children with scleroderma and their parents

Methods: Participants were recruited through the Scleroderma Foundation (SF) website and at the annual conference. Participants completed consent and assent forms, a demographic questionnaire and the Childhood Health Assessment Questionnaire (CHAQ). Parents and children then participated in either focus groups (FG) or interviews. Two in person FG were convened at the SF annual conference; one with children and one with their parents, similarly two online FG were conducted, with children and parents who were unable to interview in person. Five child/parent interviews were also conducted: one in person and four via telephone. The telephone, in person, and FG interviews were audio recorded and transcribed. The documents from the online FG were downloaded for analysis.

Interview and FG questions centered on key information needed at time of diagnosis, desired content, format and target audience for a self-management program, managing questions from peers, and desired content on transition for pediatric to adult services. Data analysis was directed at identifying common themes. Key interview questions served as the initial organizing framework for data analysis Participants' responses to these questions were coded for key themes independently by the analysts and then reviewed for agreement. Differences were resolved by returning to the transcripts to reexamine the data jointly and discussing the data and themes until consensus was achieved.

Results: Eleven dyads (6 with jSSc, 5 with JLS) were included in the study. The majority of the children were female (90.9 %); all were White non-Hispanic. Mean age of the children was 14.5 years, their mothers was 46.5 years, the mean CHAQ disability score was 0.41. Analysis of the data revealed 8 themes: Lack of Scleroderma Information, Uncertain Future, Need for Internet Resources, Isolation, Disease Management, Health Professional Face to Face Time, Helping Explain to My Peers, and Self-Advocacy.

Conclusion: This is the first study to assess the educational needs of children with scleroderma and their parents. The psychosocial themes that emerged from this study are consistent with the low CHAQ disability scores and reflect children are affected psychologically and socially. Patient education for children with chronic diseases is valuable in helping the child and family cope with disease management, prognosis and psychosocial issues.

Worse Mental Health In Employed Adult Patients With Juvenile Idiopathic Arthritis (JIA): More Than Just A Job. Nadia E. Aikawa[1], Jms Gordo[2], R Krieger[3], LE Paula[4] and Claudia Goldenstein-Schainberg[5]. [1]Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina, Universidade de São Paulo, Sao Paulo, Brazil, [3]Universidade de Sao Paulo, Sao Paulo, Brazil, [4]Faculdade de Medicina, Universidade de São Paulo, Sao PAulo, Brazil, [5]Reumatologia, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: Work status and unemployment are significant future concerns among individuals with JIA, because roughly 20% patients enter adulthood with clinically active disease and disabled. Functional impairment allied to work condition may affect one's physical and mental health with an important impact in social relationships and economic aspects. Therefore we aimed to determine the employment rate and the prevalence of work disability among a cohort of adult patients with JIA from a tertiary rheumatology center and to determine possible associated risk factors.

Methods: Forty-three adult JIA patients according to 2004 revised ILAR criteria were enrolled in this cross-sectional study. Working status and labor activity were assessed through a self-administered questionnaire encompassing educational level, occupation, current/previous work, employment and withdrawal rate. Demographic data, JIA characteristics, clinical activity (DAS28>2.6), functional class (1991 ACR criteria), HAQ and SF-36 scores, therapeutic intervention, comorbidities, physical activity and sedentary status (WHO definitions) were recorded. The prevalence of work disability was calculated using 95% confidence interval, and compared to all parameters; quantitative variables were analyzed using Mann-Whitney or student test and qualitative variables by tests of association (chi-square test).

Results: Mean age of JIA patients was 29+7.4yrs (range 19–41) with mean JIA duration of 17.2+12.3yrs (range 3–33); 63% were males and 37% females. JIA subtypes were: 64% polyarticular (9/27= RF+), 11% oligoarticular, 9% systemic, 9% ERA, 2% extended oligoarticular, 2% psoriatic

arthritis. Serum RF was positive in 21%, ANA in 21% and 7% had uveitis. At the time of the study, 72% JIA patients (n=31) were employed whereas 28% (n=12) were not working. In the latter group, 83% (n=10) were prematurely retired due to JIA related disability. Further analysis comparing 31 patients currently working vs. 12 not working revealed similar age (25.3 vs. 29.5yrs, P=0.09), sex ratio, poly onset JIA (22 vs. 6 P=0.37), good education level >12 yrs at school (31 vs. 9, P=0.38), ACR functional class I (P=0.96), practice of regular physical activity (9 vs. 0, P=0.89) and singles (26 vs. 8, P=0.15). Both groups were also comparable for HAQ (0.62 vs. 0.59, P=0.47) and DAS 28 scores (2.51 vs. 2.07, p=0.64) with similar arthroplasty rate (8 vs. 4, p=0.42). Frequencies of hypertension (3 vs. 1, P=0.99), dyslipidemia (1 vs. 1, P=0.12), diabetes (1 vs. 0, P=0.99), depression (1 vs. 0, P=0.99) and smokers (3 vs. 1, P=0.99) were also alike in both groups. Unexpectedly, employed patients had a significantly higher SF 36 mental health component score (84.0 vs. 70.42, P = 0.01).

Conclusion: The present study provides evidence that disease related incapacity remains a matter of concern for adult JIA individuals with a high rate work disability and retirement. Worse mental health in employed patients is intriguing and may indicate that intense affirmative disability actions to remove possible disabling barriers and to adapt to restrictive environments are necessary. Moreover, further attention focused on enhanced strategies and policy for inclusion of JIA patients in the job market is urged.

Lupus and Reproductive Health Considerations: A Pilot Training For Reproductive Health Care Providers Serving Teens and Young Adults. Jillian A. Rose[1], Dariana M. Pichardo[2], Monica C. Richey[1], Josephine Isgro[3] and Roberta Horton[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital For Special Surgery, New York, NY, [3]Morgan Stanley Children's Hospital of New-York Presbyterian, Columbia University Medical Center, New York, NY.

Background/Purpose: Health disparities (our target communities continue to experience some of the highest rates of sexually transmitted disease and teen pregnancy in the country) related to reproductive health and lupus points to the need for sound interventions. Effective reproductive health care is crucial for teens/young adults with lupus given the multiple risk of pregnancy & high risk of sexual transmitted disease that often make medical management of lupus complex. As previously published, health professionals are often unprepared to counsel women with chronic illnesses about the potential adverse side effects of pregnancy and contraception on underlying disease. Providers may often hesitate to prescribe contraception to women with lupus due to concerns about the risk of lupus complications. Our national lupus support and education program is offered to people with lupus and their families in underserved Latino and African American communities. As part of our community service plan, we collaborated with a pediatric rheumatologist from an affiliated urban medical center, an internal rheumatology nurse practitioner and social worker to develop educational trainings to increase awareness of lupus and related treatment considerations among local reproductive health care providers in traditionally underserved areas.

Methods: Trainings were conducted at 3 reproductive health care centers that provide comprehensive care to culturally diverse teen/young adults. A 5-item post evaluation tool (Likert-scale and open-ended questions) was used to assess whether the program met its learning objective, and overall satisfaction

Results: A total of 85 health care providers attended the trainings, of which 67 completed evaluations. 94% strongly agreed/agreed that the training contributed to their professional learning and development; 85% strongly agreed/agreed that the training will enhance their work with clients. Participants reported that the training increased their understanding of contraception options and pregnancy management in lupus patients. All participants strongly agreed/agreed that their awareness/ understanding of this area of lupus has increased as a result of the traning; 76 % strongly agreed/ agreed that they would change their practice in some way as a result of the training; ie. "I will include calcium and vitamin D to medications for lupus patients". 98% strongly agreed/agreed that the program met its educational objectives and 94% strongly agreed/agreed that they were satisfied with the training. When asked to describe how this training contributed to their learning and further care of patients, themes focused on awareness of teen lupus related issues, pregnancy concerns, and appropriate contraception options. i.e., "I am better equipped to manage lupus patients in reproductive health/primary care setting."

Conclusion: This pilot program has allowed us to enhance awareness, and access to trusted reproductive health care services in the community for our lupus patients. In addition, it has helped to foster mutual collaborations that enhance awareness and understanding of lupus.

Longitudinal Patterns Of Depression In Lupus. Patricia P. Katz, Chris Tonner, Laura Trupin and Jinoos Yazdany. University of California, San Francisco, San Francisco, CA.

Background/Purpose: Depression is commonly reported in systemic lupus erythematosus (SLE), yet information is lacking about long-term patterns of depression. We examined a longitudinal SLE cohort to identify the proportions of individuals who were depressed at least once and who were persistently depressed over the 9-year observation period.

Methods: Data derive from the UCSF Lupus Outcomes Study (LOS), in which participants are interviewed by phone annually. Participants are recruited from medical and community settings, and all have confirmed SLE diagnoses. During each interview, the Center for Epidemiologic Studies Depression scale (CESD) is administered. We defined depression using two lupus-specific cut-points – a score of 20 was used to approximate any mood disorder, and a score of 24 to define probable major depressive disorder (MDD) (1) – and conducted separate analyses for each. Once individuals met a depression criterion, their CESD score was considered elevated until it dropped below the cut-point by 3 points (i.e., 0.5 standard deviation). Those whose CESD score remained within 0.5 SD of the cut-point (i.e., ≥ 17 for mood disorder, ≥21 for MDD) were classified as remaining depressed. Those whose CESD score dropped below 17 (or 21) were classified as remitting. In order to determine longitudinal patterns of depression, we included only individuals who had completed at least three annual interviews.

Results: Of 1008 individuals who participated in at least 3 annual interviews, mean age was 46 (± 13) years, 92% were female, and mean SLE duration was 12 (±9) years. 340 (34%) met the criterion for mood disorder and 256 (25%) met the criterion for MDD at the first interview. Among those who met the mood disorder criterion, 135 remained in this classification. An additional 220 individuals met the mood disorder criterion in a later interview; 44 of them remained in this classification once they met the criterion. In total, 560 (56%) were classified with a mood disorder in at least one interview, and179 (18%) were persistent in this classification once reaching it (Table). For MDD, 47% met the criterion in at least one interview, and 13% were persistent.

Table. Prevalence of mood disorder and major depressive disorder over time

	CESD ≥ 20: Any mood disorder % (n)	CESD ≥ 24: Major depressive disorder % (n)
Never depressed	44% (448)	53% (531)
Depressed at ≥1 interview	56% (560)	47% (477)
Remained depressed once meeting criterion	18% (179)	13% (128)
Depressed at all interviews	13% (135)	9% (89)

Conclusion: In this large cohort of individuals with lupus, over half met the criterion for a mood disorder and just under half met the criterion for major depressive disorder in at least one interview. Thirteen percent and 9% met these criteria in all interviews; 18% and 13% were persistently depressed once meeting the mood disorder or MDD criterion, respectively. Results underscore the high prevalence of depressive disorders in lupus, the persistence of such disorders in a sizable group of individuals, and the need for effective prevention and treatments.

The Role Of Social Relationships and Perceived Independence In The Employment Participation Of Young Adults With Rheumatic Disease.

Arif Jetha[1], Elizabeth M. Badley[2], Dorcas Beaton[3] and Monique A. Gignac[2]. [1]Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON, [2]Toronto Western Research Institute, University Health Network, Toronto, ON, [3]Scientist, Institute for Work & Health, Toronto, ON.

Background/Purpose: Participating in employment is an important milestone in the transition to adulthood for young people living with rheumatic disease and can be influenced by relationships with those closest to them including parents, spouses or friends. To date, little research has looked at social relationships and their impact on the work experiences of young adults living with rheumatic disease. This study aims at examining the nature of social relationships and their influence on perceived independence and participation in employment in young adults (18 to 30 years of age) living with systemic lupus erythematosus (SLE) and juvenile arthritis (JA).

Methods: 143 young adults (Mean age = 23.3, SD = 3.5,) with SLE (n = 78) and JA (n = 65) completed an online survey. In addition to collecting information on demographics, health (e.g. pain, fatigue, disease activity, activity limitations) and employment status, the Lubben Social Network Scale was administered to measure social contacts and perceptions of support using eight items (e.g. "How many relatives do you see or hear from at least once a month?"). Responses to items were provided on a 5-point scale (0 = none; 5 = nine or more) and a total score was produced. Participants were also asked about perceived overprotection that characterized their relationships with those closest to them (1 = not at all; 5 = a great deal). Seven items assessing independence were developed for the study and administered to participants (1 = not at all; 5 = a great deal). Bivariate analyses were conducted to examine the interrelationships between variables and multivariable log-Poisson analysis examined factors associated with employment.

Results: More than half of participants (59.4%) were employed at the time of the survey. 26% were students and the remaining were not working. Respondents indicated having a well-managed health condition with low average pain, fatigue, disease activity and HAQ-PROMIS scores. Participants reported moderate to high perceptions of independence (Mean = 3.6, SD = .60) and social support (Mean = 22.1, SD = 7.3) as well as low overprotection (Mean = 2.8, SD = 1.4). Despite low average scores, over one quarter (27.1%) reported 'quite a bit' to 'a great deal' of overprotection. At the bivariate level, perceived independence was related to greater social support and less overprotection ($p < .05$). At the multivariable level greater perceptions of independence were significantly associated with a greater likelihood of participating in employment (PR = 1.3, 95%CI 1.0–1.6). When controlling for psychosocial variables, health factors were not significantly related to being employed.

Conclusion: For young adults with rheumatic disease perceptions of independence play an important role in determining one's likelihood of participating in paid work and should be promoted. This study also showed that the role of others is more complex than simply providing support. Young adults experiencing less overprotection may have more opportunities for independence that may in turn foster employment. Future research needs to unpack the relationship between psychosocial factors and employment in greater detail.

Appearance Dissatisfaction, Social Discomfort, and Helplessness In Patients With Systemic Sclerosis.

Shadi Gholizadeh[1], Sarah D. Mills[1], Rina M. Sobel-Fox[1], Philip J. Clements[2], Suzanne Kafaja[2], Vanessa L. Malcarne[3], Dinesh Khanna[4] and Daniel E. Furst[2]. [1]SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, CA, [2]David Geffen School of Medicine, UCLA, Los Angeles, CA, [3]Department of Psychology, San Diego State University, Psychology, San Diego, CA, [4]University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: Systemic sclerosis (SSc) is a progressive, autoimmune disease with no known cure. It is related to a wide spectrum of adverse health outcomes including marked appearance changes (AC), particularly on the face, mouth, and hands. Despite the prevalence of AC among SSc patients, dissatisfaction with appearance is relatively unexplored in this group. Given that disease-related disfigurement can be unpredictable and uncontrollable, there is reason to hypothesize that AC may be associated with feelings of helplessness. Further, as there are personal (i.e., body image) and interpersonal (i.e., social relationships) aspects to AC, both were examined as correlates of helplessness. The present study examined the relationship between satisfaction with appearance and helplessness in patients with SSc

Methods: As part of the UCLA Quality of Life (QOL) Study, a sample of patients (N = 191) completed the Brief Satisfaction With Appearance Scale (Brief-SWAP) and the Arthritis Helplessness Index (AHI). The Brief-SWAP is a self-report measure comprised of two positively correlated subscales evaluating Dissatisfaction with Appearance and Social Discomfort. The AHI is a self-report measure designed to capture perceived loss of control among arthritic patients, and is comprised of two negatively correlated subscales - Internality and Helplessness.

Results: Hierarchical linear regression was utilized to examine the relationship between the Brief-SWAP and the AHI in two separate models controlling for disease severity using the modified Rodnan Skin Score. A significant main effect (p = .009) was found for social discomfort (e.g., comfort in the presence of strangers) as a statistical predictor of helplessness (e.g., my arthritis is controlling my life), such that greater social discomfort due to SSc-related AC was associated with greater feelings of helplessness. Dissatisfaction with appearance was not a significant predictor ($p > .05$) of helplessness. In the model predicting internality, neither social discomfort nor subjective dissatisfaction with appearance demonstrated significant main effects ($p > .05$) after controlling for disease severity. Age (M = 53.8; SD = 14.8) was examined as a potential moderator in both models, but no significant interaction effects were found.

Conclusion: Given the extent of AC among SSc patients, this is an area that deserves greater study in order to increase understanding of the spectrum of outcomes associated with body disfigurement. A limitation of this study is that the variance in age in the present sample was limited and may have precluded finding a significant age interaction effect. These findings suggest that social distress due to disease-related AC is associated with greater feelings of helplessness among SSc patients, while dissatisfaction with appearance is not. The findings further suggest that neither social distress nor dissatisfaction with appearance is associated with internality.

Diagnostic Autoantibody Signatures Of Rheumatoid Arthritis Patients Identified With a Bead-Based Assay Approach. Angelika Lueking[1], Petra Budde[1], Stefan Vordenbäumen[2], Carmen Theek[1], Heike Goehler[1], Martin Gamer[1], Peter Schulz-Knappe[1] and Matthias Schneider[3]. [1]Protagen AG, Dortmund, Germany, [2]Univ. Duesseldorf, Düsseldorf, Germany, [3]Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany.

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease typically characterized by chronic inflammation, accumulation of self-reactive B-cells and production of autoantibodies of which anti–cyclic citrullinated peptide (anti-CCP) antibodies and rheumatoid factor (RF) have diagnostic utility. 30% of RA patients remain sero-negative making the early diagnosis of RA more difficult. Our goal is to develop a novel autoantibody-based diagnostic test that allows to correctly diagnosing CCP-negative early RA patients.

Methods: We performed a large-scale screen of 5800 proteins in a total of 250 serum samples of patients with stable RA, patients with SLE and healthy volunteers. An automated bead-based Luminex xMAP technology enables to measure the reactivity of autoantibodies to up to 500 different antigens in one single serum sample. All proteins are produced from *E.coli*, are highly purified by affinity capturing, sequenced by mass spectrometry, and each protein is coupled in optimized concentration to individual color coded Luminex beads. Biostatistical analysis was performed using univariate as well as multivariate statistical algorithms.

Results: 144 novel antigens were identified in RA patients. The auto-antibody profile of RA patients is heterogeneous with some overlap between CCP-positive and CCP-negative patients. We therefore evaluated panels comprising five to ten antigens for identification of CCP-negative RA patients. One panel with six antigens showed a specificity comparable to CCP in CCP-negative patients. Another panel was able to detect about 60% of CCP-negative. Comparison to an active control group consisting of 100 SLE patients, an AUC was obtained of 0.78, with high a specificity of 0.86 and a lower sensitivity of 0.54.

Conclusion: CCP-negative RA patients can be identified based on specific set of autoantibodies. Further studies are currently conducted to validate the biomarker panels in early RA patients.

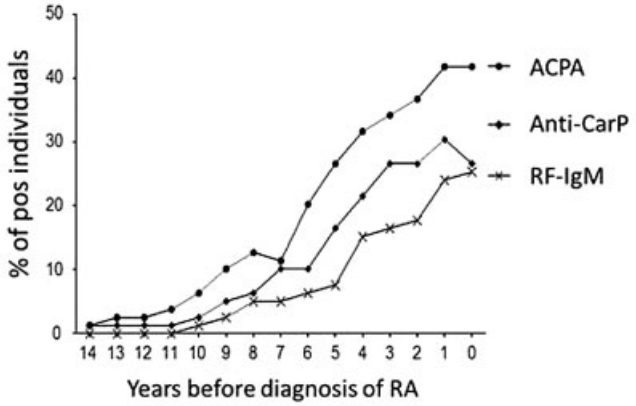
Anti-Carbamylated Protein Antibodies (Anti-CarP) Precede The Onset Of Rheumatoid Arthritis. Jing Shi[1], Lotte A. van de Stadt[2], E.W.Nivine Levarht[1], Tom W. J. Huizinga[1], Dörte Hamann[3], Dirkjan van Schaardenburg[2], René E.M. Toes[1] and Leendert A. Trouw[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [3]Sanquin Diagnostic Services, Amsterdam, Netherlands.

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) and IgM-Rheumatoid Factor (IgM-RF) are auto-antibodies that can be detected many years before the clinical diagnosis of Rheumatoid Arthritis (RA) [1]. Since ACPA and IgM-RF are known as predictive and prognostic markers of RA, it is conceivable that these antibodies play a pathogenic role in RA. In recent studies we discovered anti-carbamylated protein (anti-CarP) antibodies as a prognostic marker in RA [2]. In addition anti-CarP antibodies are associated with a conversion to RA in patients that suffer from arthralgia [3]. In this study we analyzed whether anti-CarP antibodies can also be detected prior to the onset of the symptoms of RA and which auto-antibody appears first over time.

Methods: Sera of 79 RA patients obtained prior to the onset of symptoms and 141 age and sex matched controls that were regular blood donors from Amsterdam, The Netherlands, were tested for the presence of anti-carbamylated fetal calf serum (Ca-FCS) antibodies, anti-cyclic citrullinated peptide 2 (CCP2) antibodies and RF-IgM. A median of 5 (IQR 4–6) sequential pre-RA sera, obtained at 1–6 year intervals was available for analysis.

Results: Anti-CarP antibodies were present in 27% of the serum samples that were drawn just prior to the diagnosis of RA of blood donors compared to 4% of the matched control samples. Anti-CarP antibodies were present in both ACPA positive and ACPA negative patients. Of the 79 individuals that developed RA, 42% were positive for anti-CCP2 antibodies and 25% for IgM RF.

Analysis of the longitudinal samples revealed that anti-CarP antibodies could be detected many years before the onset of symptoms (median 5 years) (Figure 1). Comparing the first appearance of the three autoantibody families revealed that both ACPA and anti-CarP antibodies appear (similarly) earlier in time as compared to IgM-RF.



Conclusion: Next to ACPA and IgM-RF also the newly identified anti-CarP antibodies appear many years before the onset of clinical symptoms of RA.

Neutralization Of Anti-Citrullinated Protein Antibodies - a Way To Go? Catia Cerqueira[1], Elena Ossipova[1], Monika Hansson[2], Linda Mathsson[3], Lars Klareskog[2], Johan Rönnelid[3] and Per Johan Jakobsson[2]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [2]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [3]Uppsala University, Uppsala, Sweden.

Background/Purpose: In a previous study, we have identified endogeneously citrullinated sites in fibrinogen from RA synovial tissue (Hermansson M. et al. Proteomics Clin Appl, 2010). Within the alpha chain, Arg573 and Arg591 were found citrullinated with an occupancy rate in the range of 1–2% and in the β-chain, Arg72 and Arg74 were also found citrullinated. In the present study, we demonstrate that citrullinated fibrinogen peptides are autoantigenic and can be used as probes for development of anti-citrullinated protein antibodies (ACPA) neutralizing compounds opening new opportunities for treatment of CCP positive RA patients.

Methods: The autoantigenic potential was investigated using the Phadia's ImmunoCAP ISAC® system. Citrullinated and unmodified fibrinogen peptides were immobilized onto a glass slide in an arrayed fashion and serum from 404 CCP positive and 532 CCP negative RA patients and 461 healthy controls from the EIRA cohort were tested. We also assayed the identified citrulline fibrinogen peptides for their ability to prevent purified ACPA (Ossipova E. et al. 2013, submitted) to bind to CCP (CCPlus® ELISA, Euro-Diagnostica AB). Peptides were individually or in combinations incubated with different ACPA pools and the blocking efficiency was expressed as percent of inhibition and IC50. Corresponding arginine peptides were used as controls.

Results: We found that 31% (87% are CCP positive) of patients were positive to Cit573 peptide. For the Cit591 peptide, the corresponding numbers were 10% (65%), for the Cit74 peptide 28% (68%) and for the Cit72 peptide 20% (68%). Interestingly, citrullinated 573 and Cit591 peptides revealed a maximum of 77% and 48% ACPA inhibition, respectively. When equally mixed, these peptides displayed an additive higher degree of ACPA neutral-

ization (84%). In contrast, Cit74 and Cit72 peptides reached a more modest maximum inhibition of 26% and 30%, respectively. This experiment was repeated using a different set of ACPA pool and then the efficiencies were lower for Cit573 (47%) but similar for Cit591 (51%). Logically, the efficiency of specific citrullinated compounds will depend on the individual ACPA specificities.

Conclusion: Here we demonstrate extensive autoantibody reactivity against in vivo citrullinated fibrinogen epitopes found in RA synovial membranes. These peptides can now be used as additional biomarkers for studies of ACPA sub-specificity profiles as recently reported (Brink M. et al. Arthritis Rheum, 2013). We also demonstrate that these citrullinated peptides can be used as neutralizing agents blocking a significant portion of ACPA binding to CCP. These results open novel possibilities for the design of personalized ACPA blockers preventing for instance the osteoclastogenesis and bone loss induced by ACPA (Harre U. et al. J Clin Invest, 2012).

B-Cell Responses To De Novo Identified Citrullinated Fibrinogen Peptides Are Associated With PTPN22 Risk Allele. Vijay Joshua[1], Loes Schobers[2], Lena Israelsson[1], Johan Rönnelid[3], Monika Hansson[4], Anca I Catrina[5], Ger JM Pruijn[2] and Vivianne Malmström[6]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [2]Department of Biomolecular Chemistry, Radboud University, Nijmegen, Netherlands, [3]Uppsala University, Uppsala, Sweden, [4]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [5]Rheumatology Unit, Department of Medicine, Karolinska Institute, Stockholm, Sweden, [6]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Antibodies against citrullinated proteins are common in patients with rheumatoid arthritis (RA) and appear prior to the onset of the disease [1]. Many of the citrullinated epitopes have been identified and studied to varying details. Using an unbiased approach via mass spectrometry, the levels of citrullinated (cit) fibrinogen (Fib) peptides were demonstrated to be elevated in the synovial fluid of RA patients compared to non-RA patients [2]. Here we aim to identify the presence of autoantibodies against these citrullinated peptides.

Methods: An in-house ELISA was established against 5 citrullinated fibrinogen epitopes (cit-Fib α-35, cit-Fib α-216, 218, cit-Fib α-263, 271, cit-Fib α-425,426 and cit-Fib β-60,72,74) and serum from a cohort of patients with established RA (n=347) and disease controls with psoriatic arthritis (PSA) or ankylosing spondylitis (AS) (n=268) were analyzed. Cut-off for the ELISA was set at 98 percentile, based on reactivity in a cohort of healthy controls (n=152). The RA patients were genotyped with regard to HLA-DR alleles and PTPN22 R620W. The RA cohort has previously been screened for anti-CCP2 antibodies and antibodies against cit-fibrinogen protein (cFib) [3].

Results: Autoantibodies against the different citrullinated fibrinogen epitopes were present in the following frequencies in the RA patients compared to the PSA/AS patients, cit-Fib α-35 (RA-20%, PSA/AS-2%), cit-Fib α-216,218 (13%, 2%), cit-Fib α-263,271 (21%, 2%), cit-Fib α-425,426 (17%, 2%) and cit-Fib β-60,72,74 (4%, 0%). The presence of autoantibodies against these epitopes was associated with the presence of anti-CCP2 antibodies and antibodies against whole cit-fibrinogen. No genetic association was found between the presence of HLA shared epitope and antibodies to the different cit-Fib epitopes, while an association was observed between the PTPN22 risk allele and positivity to cit-Fib α-35 and cit-Fib α-263,271.

Conclusion: Fibrinogen is readily citrullinated in the rheumatic joint and our data show that several of the citrullinated epitopes are targeted by autoantibodies in the context of RA, but not in PSA/AS. Our data further emphasizes that the anti-citrulline response is broad with many parallel immune responses. Association between the presence of these autoantibodies with the PTPN22 risk carriers suggest that cit-Fib reactive B-cells would normally be deleted during the B-cell tolerance check points [4].

High Throughput Epitope Mapping Of Autoantibodies In BXD2 Mice Reveals The Generation Of Autoantibodies Against Citrullinated Antigens At The Predicted Major Immunogenic Sites. Jennie Hamilton, Qi Wu, PingAr Yang, Hui-Chen Hsu and John D. Mountz. University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Increased polyreactive B cells have been identified in patients with systemic lupus erythematous (SLE) and rheumatoid arthritis (RA). Such autoantibodies (autoAbs) were also identified in BXD2 mice that spontaneously develop IgG Immune complex glomerulonephritis and erosive arthritis. Most naturally occurring polyreactive autoantibodies are primarily IgM, germline and low affinity. Pathogenic autoAbs including anti-citrullinated protein antibodies, however, evolve through somatic hypermutation and class-switch recombination, suggesting that antigen (Ag)-selected affinity maturation is required. The purpose of this study is to identify and characterize the dominant autoAbs and their epitopes in BXD2 mice to determine if pathogenic autoAbs indeed react to immunodominant epitopes of self antigens.

Methods: A PEPperPRINT Autoimmunity Microarray which covers 2,733 linear B-cell autoepitopes from the Immune Epitope Database (IEDB) was used to identify BXD2 autoepitopes. Top peptides were selected based on the strength of reactivity and concordance with predictions made by DiscoTope, a structure-based computational program that predicts discontinuous B cell epitopes from protein three dimensional structures.

Results: The dominant epitopes recognized by BXD2 autoantibodies are those commonly found in human SLE and RA patients. The strongest response was observed with peptides of the 60 and 65 kDa heat shock proteins. Serum was also strongly reactive against a variety of arginine-rich peptides, including several that show shared consensus sequence derived from antigens U1 small nuclear ribonucleoprotein (U1snRNP), 70 kDa and small nuclear ribonucleoprotein Sm D1 (snRNP Sm D1), and 52 kDa Ro protein. The array further revealed reactivity with several citrulline-modified peptides, including fibrinogen beta chain (PA[Cit]KQCSKEDGGGWWY and WYNZCHAANPNGA[Cit]YY) as well as glucose regulated protein 78 (GRP78) (ALSSQHQAA[Cit]IEIESFYE). X-ray crystallography information is available for these two Ags. DiscoTope analysis shows that citrullination occurs in the highly immunogenic sites and are the immunoreactive epitopes of BXD2 autoantibodies.

Conclusion: The present results suggest that BXD2 mice exhibit a high tendency to develop autoAbs against nucleosome proteins and stress response proteins. Such results are consistent with our recent report showing defective marginal zone macrophages in clearance of apoptotic self antigens in BXD2 mice. Although cross-reactivtive epitopes are found, BXD2 autoAbs also react to autoAg at the major immunogenic sites that exhibit protein citrullination, suggesting that specific Ag engagement and selection are involved in the formation of autoAb producing B cells. Tetramers against the dominant epitopes are currently being generated to evaluate the immune checkpoint loss that leads to the generation of these B cells.

Accentuated Expression Of RANKL In Switched Memory B Cells From Patients With Rheumatoid Arthritis. Yuri Hirosaki, Hiroaki Niiro, Shunichiro Ota, Naoko Ueki, Hirofumi Tsuzuki, Siamak Jabbarzadeh-Tabrizi, Kumiko Noda, Naoyasu Ueda, Naoyasu Ueda, Atsushi Tanaka, Masahiro Ayano, Sho Ueda, Satomi Hisamoto, Daisuke Oryoji, Mitsuteru Akahoshi, Yojiro Arinobu, Hiroshi Tsukamoto, Takahiko Horiuchi and Koichi Akashi. Department of Medicine and Biosystemic Science, Kyushu University Graduate School of Medical Sciences, Fukuoka, Japan.

Background/Purpose: Clinical efficacy of B-cell depletion therapy underscores a pathogenic role of B cells in autoimmune diseases such as rheumatoid arthritis (RA). In addition to generating pathogenic antibodies, B cells can function as potent effector cells by an Ab-independent mechanism. RANKL is a member of the tumor necrosis factor (TNF) family and plays a key role in osteoclastogenesis and inflammatory bone loss. A recent study suggested that B cells, but not T cells, are a major source of RANKL in the joints of patients with RA. In this study, we have elucidated underlying mechanisms of RANKL expression in B cells from normal subjects and RA patients, and determined the impacts on osteoclast differentiation.

Methods: Levels of RANKL mRNA and protein in B cells from peripheral blood of normal subjects and RA patients were evaluated using quantitative RT-PCR and flow cytometry, respectively. Highly pure B cell subsets were enriched using cell sorter. To validate the functional significance of osteoclast differentiation, B cells were co-cultured with osteoclast precursor cells and the formation of tartrate-resistant acid phosphatase (TRAP)-positive cells were assessed thereafter.

Results: In the absence of stimuli, human B cells only marginally expressed RANKL mRNA and protein. Combined stimulation of B cells with anti-Ig and anti-CD40, however, significantly induced RANKL expression. The experiments using signaling inhibitors suggested the involvement of several pathways in its expression. Among B cell subsets, switched-memory (CD27+IgD-) B cells, a normal counterpart of pathogenic B cells in the joints, expressed RANKL at the highest levels. Consistent with these findings, these subsets induced osteoclast formation as assessed by TRAP staining. Finally, switched-memory B cells from RA patients expressed RANKL at higher levels than normal subjects.

Conclusion: Our current findings shed the light on a pathogenic role of switched-memory B cells in bone damage associated with RA via production of RANKL, and regulation of RANKL expression in B cells may pave an avenue in developing a novel treatment for this devastating disease.

IL-6R Inhibition Reduces Activation Of Different Peripheral Memory B Cell Subsets In RA. Zafar Mahmood[1], Khalid Muhammad[1], Marc Schmalzing[2], Petra Roll[1], Kathrina Eckert[1], Thomas Dörner[3] and Hans-Peter Tony[2]. [1]University of Würzburg, Würzburg, Germany, [2]University Hospital Würzburg, Würzburg, Germany, [3]Charité university medecine/ German Rheumatism Research Centre Berlin (DRFZ), Berlin, Germany.

Background/Purpose: Enhanced B cell activity has been proposed as part of the pathogenesis of rheumatoid arthritis also based on the clinical experiences obtained by B cell targeted therapies able to modulate memory B cells. Human peripheral memory B cells can be distinguished by the phenotypic expression of CD27 and IgD defining three major B cell subpopulations: CD27+IgD+ pre-switch, CD27+IgD- post-switch and CD27-IgD- double negative memory B cells. We analyzed these different memory populations in RA and under IL6R blockade.

Methods: B cells from RA patients were phenotypically analyzed by 8 color flow cytometry at baseline, week 12 and week 24 under tocilizumab (TCZ) treatment. Memory B cell subsets were defined by CD27 and isotype surface expression. B cell activation was identified by surface staining with CD95 and intracellular Ki-67 staining. Mutation frequencies of VH gene rearrangements were analyzed by single B cell RT-PCR. Statistical analysis was performed using Mann Whitney U test.

Results: The Ig receptor mutational frequency was highest in class switched CD27+/IgD- memory B cells with 6.1±0.3% compared to CD27-/IgD- (3.5±0.2%) largely containing memory-like B cells and CD27-/IgD+ pre-switch memory B cells (4.1±0.2%). The phenotypically analyzed isotype profile in RA patients (n=40) and healthy donors (n=18) revealed that the memory B cell pool was a heterogeneous population of IgA, IgG and IgM expressing cells. The CD27-/IgD- B cell memory population showed a clear dominance of IgG followed by IgA and IgM (~70%, 20% and 10% respectively), whereas CD27+IgD- class switched B cells had an equal distribution of IgA and IgG. Under IL-6R inhibition by TCZ, the distribution of Ig isotypes remained stable at week 12 and 24. Surface and intracellular staining of B cells showed a significantly higher percentage of CD95 (14.0±1.4%, p=0.016) and Ki-67 expression (3.0±0.3%, p=0.041) in B cells of RA as compared to HD (CD95: 7.5±1.0% and Ki-67: 1.9±0.2% which was highest in post-switched memory B cells in RA (CD95: 38.4±2.1% and Ki-67: 8.1±1.0%). In post-switched memory B cells, IL-6R inhibition significantly decreased the expression of CD95 to 21.1±3.4 % and Ki-67 to 4.8±0.7% at week 12 with p=0.0004 and p=0.0081 respectively.

Conclusion: Our data suggest that the three major peripheral memory B cell populations, pre-, post-switch as well as CD27-/IgD- B cells harbour different numbers of mutations in their Ig receptors. These B cell subsets are activated in RA with enhanced CD95 and Ki-67 expression compared to healthy individuals and which can be reduced by IL-6R inhibition *in vivo.* The CD27-/IgD- B cell pool displays a significantly higher proportion of IgG bearing cells compared to post-switch B cells which is not modulated by IL-6R inhibition.

Role Of CD20+ B Cells As Antigen-Presenting Cells In Arthritis. Estefania Armas-Gonzalez[1], Ana Diaz-Martin[1], María Jesús Dominguez-Luis[1], Maria Teresa Arce-Franco[1], Ada Herrera-Garcia[1], Vanesa Hernandez[1], Alicia Usategui[2], Jose L. Pablos[2], Sagrario Bustabad[1] and Federico Diaz-Gonzalez[3]. [1]Hospital Universitario de Canarias, La Laguna. Tenerife, Spain, [2]Instituto de Investigación Hospital 12 de Octubre, Madrid, Spain, [3]University of La Laguna, Hospital Universitario de Canarias, La Laguna, Spain.

Background/Purpose: B cells participate in the pathogenesis of rheumatoid arthritis (RA) through a mechanism still not fully understood. In RA, B cells are believed to plays roles in: 1) the production of autoantibodies, 2) the release of proinflammatory cytokines, and 3) T-cell activation by acting as antigen-presenting cells. Objective: To study the potential involvement of B cells as antigen-presenting cell in the arthritis synovial microenvironment.

Methods: The presence of class II molecules (HLA-DR) and costimulatory molecules (CD86 and CD40) in CD20+ cells was studied by immunohistochemistry in biopsies of RA synovium. The surface-expression levels of CD27, class II molecules (HLA-DP, -DQ and -DR) and CD86 were analyzed by double-staining flow cytometry on CD20+ cells from peripheral blood (PB) and synovial fluid (SF) from 14 patients with RA and 12 with psoriatic arthritis (PA). The surface-expression levels of CD40 and CD20 on CD19+ and CD138- cells were studied in cells from both compartments by triple labeling. The expression of the interferon-induced protein, IFIT-4, which is involved in the differentiation into dendritic cells, was assessed by quantitative RT-PCR in immunoselected CD20+ cells from SF and PB of RA patients.

Results: Immunohistochemical studies showed that CD20+ B cells present in the RA synovial infiltrate express molecules involved in antigen presentation (HLA-DR) and costimulation (CD40 and CD86). In the patients included in this study the percentage of mononuclear CD20+ cells in SF (2.12±0.69%) was lower than in PB (7.44±0.62%). Flow cytometry analysis showed a significant increment in the expression levels of CD27 on B-cells from SF versus PB in both RA and PA patients, indicating that memory B cells are recruited into the inflamed synovium. CD20+ cells from SF showed an increased expression of HLA-DR and -DQ compared to PB in both RA and PA patients. HLA-DP was also elevated in SF with respect to PB in RA, although in PA, a significantly lower expression of HLA-DP was observed in SF with respect to PB. Surface expression of CD86 was higher in B cells from SF compared to those from PB in both pathologies. CD40 expression increased in SF compared to PB in PA patients; otherwise, a decrease was observed in SF with respect to PB in RA patients. Interestingly, a CD20 expression was lower in B cells (CD19+, CD138-) from SF in both RA (69.82±17.22%) and PA (54.44±15.66%) patients with respect to PB (considered 100%). Finally, qRT-PCR showed approximately a 5-fold increase in IFIT-4 mRNA content in B cells from SF compared to PB in RA patients

Conclusion: These data show that the B cells present in the synovial microenvironment express an antigen-presenting cell phenotype, which suggests that this cell type may participate in RA pathogenesis via antigen presentation.

B-Regulatory-, $CD19^{+}CD20^{+}CD24^{high}CD38^{high}$ -Cells Are Functionally Impaired In Patients With Rheumatoid Arthritis and Healthy First Degree Relatives Compared With Controls. Mikael Brink[1], Kristina Lejon[2], Lisbeth Ärlestig[3] and Solbritt Rantapää Dahlqvist[4]. [1]Umeå University, Umea, Sweden, [2]Umeå Universitet, Umeå, Sweden, [3]Umeå University, Umeå, Sweden, [4]Umeå University Hospital, Umeå, Sweden.

Background/Purpose: Rheumatoid arthritis (RA) is a complex disease with both genetic- and environmental risk factors. By studying first degree relatives (FDR) of RA patients which shares some of the genetic and

environmental risk factors, may shed light on the pathogenic mechanisms of RA. A subset of B-cells, identified by their IL-10 producing abilities, when stimulated with CD-40 the B-regulatory cells ($CD19^+CD20^+CD24^{high}CD38^{high}$) has been suggested to be less functional in expressing IL-10 in patients with Systemic lupus erythematosus compared with cells from healthy individuals. As a downstream protein of CD-40 stimulation, signal transducer and activator of transcription 3 (Stat-3) expression can be used as a pseudo- marker for IL-10 expression and response to CD-40 stimulation.

In FDR, regarded as high risk population we aim to analyze B-regulatory cells to investigate their Stat-3 response with and without CD-40 stimulation and compare it with healthy controls and RA- patients.

Methods: Mononuclear cell isolation was done with blood samples from 23 FDR and 26 RA patients and 11 control individuals from northern Sweden. Two million cells, either with or without anti-CD40-antibody stimulation was analyzed with LSRII flow cytometer (Becton-Dickinson, San Jose, CA) for Stat-3 expression in $CD19^+CD20^+CD24^{high}CD38^{high}$-cells (B-regulatory cells). Samples with a robust coefficient of variation in flow cytometry variables >150 was excluded for subsequent analyses. Anti-CCP2 antibody analysis was performed by ELISA (Euro-Diagnostica). HLA-DRB1 alleles were genotyped using polymerase chain reaction sequence-specific primers. Genotyping of the *PTPN22* 1858C/T polymorphism was performed using a Taqman instrument. Continuous data were compared by non-parametric analysis using the Mann-Whitney U-test for two groups and the Kruskal-Wallis test comparing several groups. For within-patient comparisons the Wilcoxon signed-rank test was used.

Results: Comparing the Stat-3 levels with and without CD-40 stimulation in B-regulatory cells on individual level, a significant increase was found in controls ($p=0.018$) while no change of significance was found in the FDR nor in the RA patients. No significant differences could be found in Stat-3 expression in B-regulatory cells when stratified for HLA-SE or *PTPN22* T-carrier. No significant difference could be found between the three studied populations (Controls/FDR/Patients) regarding; Stat-3 expression, relative cell number to parent ($CD19^+CD20^+$) or relative cell number to grandparent population, in neither CD40-stimulated nor unstimulated B-regulatory cells, respectively.

Conclusion: We have demonstrated that the B-regulatory cells of RA-patients and their FDR could be functionally impaired when measuring the Stat-3 response on CD40 stimulation, compared with healthy controls. HLA-SE and *PTPN22* 1858T genotype did not affect Stat-3 expression. This could indicate that defective B-regulatory cells play a role in the predisposition for RA.

Regulatory B Cells Suppress Skin Inflammation in a Murine Model of Psoriasis. Koichi Yanaba[1] and Shinichi Sato[2]. [1]The University of Tokyo, Tokyo, Japan, [2]University of Tokyo Graduate School of Medicine, Tokyo, Japan.

Background/Purpose: Psoriasis is a cutaneous disorder characterized by widespread erythematous plaques with adherent scales. Recent studies have revealed that both T helper (Th) 17 and Th1 cells play critical roles in disease development. Histologically, psoriasis is characterized by marked thickening of the epidermis with an inflammatory infiltrate predominantly composed of Th17 and Th1 cells. These infiltrated cells stimulate keratinocytes to produce cytokines, which further amplifies the inflammatory response.

The application of imiquimod occasionally leads to the development of psoriasis in humans. Imiquimod is a potent agonist for Toll-like receptors-7 and -8, and has been used therapeutically in the treatment of a variety of other skin disorders. In mice, the daily topical application of imiquimod induces the appearance of inflamed skin lesions resembling human psoriasis. This experimental method has therefore served as a convenient animal model of the disease.

B cells mediate multiple functions that influence immune and inflammatory responses. Recently, it has been demonstrated that B cells and specific B cell subsets can also negatively regulate immune responses in mice, validating the existence of regulatory B cells. A potent subset of regulatory B cells with a phenotype of $CD1d^{hi}CD5^+$ was recently found to regulate contact hypersensitivity and experimental autoimmune encephalomyelitis in an interleukin (IL)-10-dependent manner. This regulatory B cell subset is called B10 cells to distinguish them from other regulatory B cell subsets that may exist and to identify them as the predominant source of B cell IL-10 production. B10 cell subset is found within the spleen of naïve wild-type mice at 1–2% of the total B cell count, whereas CD19-deficient ($CD19^{-/-}$) mice have few, if any, B10 cells. At present, the contribution of regulatory B cells to imiquimod-induced skin inflammation is unclear. Therefore, we examined the importance of regulatory B cells in imiquimod-induced skin inflammation in $CD19^{-/-}$ and wild-type mice.

Methods: We treated $CD19^{-/-}$ and wild-type mice with imiquimod for 6 days and quantitatively evaluated the severity of skin inflammation.

Results: $CD19^{-/-}$ mice developed more severe skin inflammation, both clinically and pathologically, than wild-type mice. Splenic B10 cells entered the circulation and migrated to draining lymph nodes during imiquimod-induced skin inflammation, thereby suppressing interferon-g and IL-17 production. Remarkably, the adoptive transfer of spleen B10 cells from wild-type mice ameliorated skin inflammation, whereas either splenic B10 cells from $IL\text{-}10^{-/-}$ mice or non-B10 cells from wild-type mice were without effect.

Conclusion: IL-10-producing regulatory B10 cells regulated imiquimod-induced skin inflammation. Further studies are needed to determine the precise mechanisms by which regulatory B cells attenuate the severity of psoriasis. Nonetheless, the current results may provide new insights and therapeutic approaches for treating psoriasis.

B Cell Derived IFN-γ Contributes To The Negative Regulation Of T-Regulatory Cell Differentiation In Arthritis. Susan Olalekan, Yanxia Cao and Alison Finnegan. Rush University Medical Center, Chicago, IL.

Background/Purpose: Depletion of B cells using a monoclonal antibody against CD20 expressed on mature B cells has proven efficacious in patients with rheumatoid arthritis (RA). We have previously shown in our mouse model of RA, proteoglycan induced arthritis (PGIA), that depletion of B cells leads to enhanced T regulatory cell (Tregs) numbers and activity essential in the suppression of arthritis. This increase in Treg numbers and function correlated with a decrease in $CD4^+$ T cell IFN-γ production. In this study, we investigate the effects of B cells on the generation of Tregs and how IFN-γ contributes to this process.

Methods: An anti-CD20 mAb was used to deplete B cells in $FOXP3^{egfp}$ reporter mice 5 days after immunization intraperitoneally (i.p.) with a recombinant protein for the G1 domain of the human proteoglycan in adjuvant. Mice were sacrificed 4 days after B cell depletion. Naïve and memory $CD4^+CD25^-$ T cells based on CD62L expression were isolated from wild type (WT) and IFN-γ knockout ($IFN\text{-}\gamma^{-/-}$) mice and cultured under Treg differentiating conditions in the presence of proinflammatory cytokines IL-12 and IFN-γ. Flow cytometry was performed and Tregs were phenotyped as $CD4^+$ $Foxp3^+$ cells. ELISA was used to measure cytokine production. In the in vivo transfer model $CD4^+CD62L^+Foxp3^-$ T cell were sorted from transgenic animals and transferred into congenic animals that were later immunized and B cell depleted. Mixed bone marrow chimeras were created by transferring bone marrow cells from B cell deficient and $IFN\text{-}\gamma^{-/-}$ mice in a 1:1 ratio into irradiated recipients. These mice were later immunized i.p. with G1 in adjuvant 3 times at 3 week intervals. Paws were examined every other day for arthritis.

Results: We show that in vitro IFN-γ suppresses the differentiation of $CD4^+CD25^-CD62L^+$ T cells into $Foxp3^+$ Tregs. $CD4^+CD25^-CD62L^-$ T cells were resistant to Treg differentiation and this resistance correlates with copious IFN-γ production. Through an in vivo transfer model of transgenic T cells into congenic mice, we find that $CD4^+CD62L^+Foxp3^-$ T cells are converted into Tregs more effectively in B cell depleted mice as compared to the control group. To determine if IFN-γ is responsible for the suppression of Treg generation, we setup an in vitro Treg differentiation assay using WT and $IFN\text{-}\gamma^{-/-}$ $CD4^+CD25^-CD62L^+$ T cells in the presence of TGF-β and WT or $IFN\text{-}\gamma^{-/-}$ B cells. We find that $IFN\text{-}\gamma^{-/-}$B cells resulted in an increase in Treg differentiation in comparison to WT B cells. Chimeras with a specific deficiency in IFN-γ in B cells also show an increase in the percentage of Tregs.

Conclusion: Our findings demonstrate that B cell derived IFN-γ can negatively regulate the generation of Tregs in arthritis.

Fms-Like Tyrosine Kinase 3 Signaling Is Essential For Differentiation Of Antigen Specific Plasma Cells During Experimental Arthritis. Mattias Svensson, Kersti Månsson, Karin Andersson, Mats Bemark, Mikael Brisslert and Maria Bokarewa. University of Gothenburg, Gothenburg, Sweden.

Background/Purpose: Signaling through the tyrosine kinase receptor Flt3 plays an important role in early B-cell development. Mice lacking either Flt3 or its ligand (Flt3L) have reduced numbers of pre-B-cells in the bone marrow (BM) but normal numbers of mature B-cells in the periphery and normal serum levels of Igs. Flt3L is included in a predictive model for the development of rheumatoid arthritis (RA). We have previously shown that Flt3L is increased in RA patients and that interfering with Flt3 signaling during experimental arthritis reduces antibody production. In the present study we investigate how Flt3 signaling on activated B-cell affects terminal differentiation and antibody production during experimental arthritis.

Methods: C57/Bl6 mice deficient for Flt3L (FLKO) and their wild type (WT) counterparts were immunized with mBSA on day 0 and day 7. On day 21, arthritis was induced by an intraarticular injection of mBSA. Mice were sacrificed on day 14 or day 28 and splenocytes and bone marrow cells were isolated. B-cell populations were analyzed using flow cytometry and B-cell associated transcription factors by qPCR. Also, isolated splenocytes stimulated with either LPS or LPS+IL-4, were cultured for antibody and germ-line transcript measurements.

Results: mBSA immunization and LPS activation in vitro induced Flt3 expression on splenic B-cells. Flt3 expressing B-cells represented an activated population recognize by higher expression of MHCII, CD80, CD86 and CD40 when compared to B-cells not expressing the receptor. Lack of Flt3 signaling was associated with enlarged plasma cell population in spleen ($P=0.0014$) and bone marrow ($P = 0.016$), supported by high gene expression of transcription factors IRF4, Blimp1 and XBP1 essential for plasma cell maturation. FLKO mice had increased serum levels of IgM and impaired affinity maturation of mBSA specific IgG1 antibodies. The low IgG1 production by FLKO mice was supported by low formation of germ-line transcripts for IgG1. Stat6 activation (pStat6) controlling IgG1 switch was low FLKO mice compared to WT.

Conclusion: We show that antigen stimulation induces expression of Flt3 on mature B-cells during arthritis. Flt3 signaling is essential for differentiation of antigen specific plasma cells during experimental arthritis. Functional Flt3/Stat6 pathway regulates class switch recombination of IgG1.

Blocking The Complement Receptor 2 (CR2) Ligand-Receptor Interaction With a Novel Mouse Anti-Mouse CR2 Monoclonal Antibody Decreases Antigen-Specific Humoral Immune Responses and The Evolution Of Collagen-Induced Arthritis. Rosa Rodriguez[1], Liudmila Kulik[1], Joshua Thurman[1], Jonathan Hannan[1], Steve Tomlinson[2] and V. Michael Holers[1]. [1]University of Colorado School of Medicine, Aurora, CO, [2]Medical University of South Carolina, Charleston, NC.

Background/Purpose: The CR2/CD19 complex on B cells serves as a co-receptor for membrane IgM and amplifies B cell responses through physical associations of the bound antigen with the complement C3 activation fragment designated C3d. Prior studies have used *Cr2* −/− mice which lack CR2 expression; however, because the mouse CR2 protein is derived through an alternately spliced mRNA from the same gene as the complement receptor 1 (CR1) protein, a C3b/C4b receptor, one cannot discern whether the primary immune effect is due to deficiency of one or the other receptor, or whether compensatory mechanisms play important roles in the gene-targeted mice. To better understand the unique role of CR2 in autoimmune disease, while minimizing manipulation of CR1, we have generated a novel mouse monoclonal antibody (mAb), designated 4B2, to mouse CR2 that uniquely blocks the CR2/C3d interaction.

Methods: mAb 4B2 (IgG1) was generated in *Cr2*−/− mice by immunizing with recombinant mouse CR2 spanning the ligand-binding site within short consensus repeat domains 1–4 and fusion with the 653 myeloma cell line. A mouse model of collagen-induced arthritis (CIA) was used, and more recently a mouse model of lupus-like disease is being used to study the effects of blocking the CR2/C3d ligand-receptor interaction with mAb 4B2.

Mice were immunized twice with sheep red blood cells (SRBC) to evoke a primary and secondary antibody response in the presence or absence of a single pre-injection of mAb 4B2. Using the CIA model, the durability of the inhibitory effect of 4B2 was measured, and B cell levels were recorded. Immune responses to antigen were measured in CIA mice pretreated with 4B2, or control isotype mAb. In CIA, mice pre-treated with 4B2 or control mAb were injected with bovine type II collagen, and IgG2a antibodies to mouse and bovine type II collagen (mCII and bCII, respectively) were measured. Peripheral and splenic B and CD4+ T cells were measured as well as B cell subpopulations from spleen. Additionally, a clinical scoring system was used to evaluate arthritis.

Results: Mice pre-injected with 4B2 antibody demonstrated reduced levels of anti-SRBC IgG1 levels. Mice with CIA treated with 4B2 demonstrated a 6 week blockade of CR2 and significantly decreased anti-mCII and anti-bCII IgG2a. No anti-idiotype antibodies were generated to 4B2. Splenic B cell follicular, transitional, immature and marginal zone subpopulations were not changed. B and T cell hematopoietic changes were not seen. Clinical disease activity was substantially decreased in mice treated with mAb 4B2. Additionally, 4B2 is being used in studies of (NZBxNZW)F1 mice, which spontaneously develop lupus-like disease.

Conclusion: We have shown that the mouse monoclonal antibody to CR2, 4B2, is able to block CR2/C3d interaction and decrease immunological responses to model antigens as well as the development of CIA. Studies using 4B2 in (NZBxNZW)F1 mice are being undertaken to determine whether chronic blockade of the CR2/C3d interaction can be used as a therapeutic approach in lupus. Chronic inhibition of the CR2/C3d interaction can be further studied with this new tool as a potential therapeutic approach in other mouse models of autoimmune and inflammatory disease.

Role Of B Cells and/Or Autoantibodies In Pulmonary Manifestations Of Inflammatory Arthritis. Lisa K. Peterson[1], Jeremy Sokolove[2], Paul Jedlicka[3], Lauren J. Lahey[2], William H. Robinson[4] and Leonard L. Dragone[1]. [1]National Jewish Health, Denver, CO, [2]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [3]University of Colorado Denver, Aurora, CO, [4]Stanford University, Palo Alto, CA.

Background/Purpose: RA is a systemic condition affecting approximately 1% of the general population leading to progressive arthritis and extra-articular manifestations (ExRA), including interstitial lung disease (RA-ILD). RA-ILD is a major cause of morbidity and mortality due to its progression despite the use of therapies that effectively treat arthritis. These observations suggest that the articular and RA-ILD manifestations may have overlapping but unique features related to their pathogenesis, which could be identified and specific therapies started if biomarkers for RA-ILD were available. A significant obstacle to advancing our ability to predict the development of RA-ILD is the limited availability of relevant experimental mouse models that have a predictable kinetics of developing RA-ILD.

Methods: To enable mechanistic and biomarker studies, we created a mouse disease model based on SKG mice which develop inflammatory arthritis as well as ExRA manifestations upon zymosan exposure. Our model utilizes Double SKG Src-Like adaptor protein (SLAP)-Knockout mice (DSSKO) that are arthritis-resistant to the disease trigger (zymosan), yet develop progressive lung inflammation with histologic features of the clinical manifestations of RA-ILD that occurs with predictable kinetics. To examine the contributions of lymphocytes to the pulmonary manifestations associated with inflammatory arthritis using adoptive transfer and antibody-mediated cell depletion.

To identify autoantibodies associated with autoimmune lung disease in zymosan-treated DSSKO mice we performed arthritis autoantigen arrays on a well-characterized cohort of DSSKO mice with lung disease but without arthritis and SKG mice with arthritis but without lung disease. As a complement to this approach, generated B cell hybridomas and screened them against lung tissue lysates by ELISA and western blot. Specific autoantigens were then identified using mass spectrometry.

Results: Transfer of $CD4^+$ T cells from DSSKO mice into $RAG2^{-/-}$ mice induced arthritis in the absence of the lung disease. Thus, CD4+ T cells are not sufficient to induce lung disease. In contrast, B cell depletion studies using an anti-CD20 monoclonal antibody eliminated lung disease in DSSKO mice, implicating B cells and/or autoantibodies in lung disease pathogenesis.

In addition, DSSKO mice developed distinct profiles of anti-citrullinated antibodies compared to arthritis-prone (SKG) controls. DSSKO mice developed autoantibodies to several citrullinated antigens previously detected in the serum of humans with RA, though the exact relationship to RA-ILD pathogenesis is unknown.

Conclusion: B cells and/or autoantibodies are required for autoimmune lung disease in zymosan-treated DSSKO mice. DSSKO mice developed a distinct profile of autoantibodies to antigens that have been detected in the serum of humans with RA, but the relationship to RA-ILD pathogenesis is unknown. Therefore, identification of autoantibodies that develop during lung disease in DSSKO mice may reveal new biomarkers for RA-ILD. Identified autoantibodies could potentially also be used to determine their contribution to disease pathogenesis.

Redox Dependent Conformational Changes Of The Autoantigen La Are Responsible For Its Shuttling, Translocation and a Pathophysiological Role Of Anti-La Autoantibodies. Irene Michalk[1], Nicole Berndt[1], Claudia C. Bippes[1], Holger Bartsch[1], Stefanie Koristka[1], Claudia Arndt[1], Anja Feldmann[1], Biji T. Kurien[2], Robert Hal Scofield[3], A. Darise Farris[4], Judith A. James[5], Marc Cartellieri[1] and Michael Bachmann[1]. [1]Carl Gustav Carus TU-Dresden, Dresden, Germany, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation; Department of Medicine, University of Oklahoma Health Sciences Center; US Department of Veterans Affairs Medical Center, Oklahoma City, OK, [4]Oklahoma Medical Research Foun, Oklahoma City, OK, [5]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: Since their detection a pathophysiological role of antibodies (abs) to extractable nuclear autoantigens including anti-La abs has been controversially discussed. Stainings of anti-La abs point to an exclusive nuclear localization. However, we and others have also seen an intracellular shuttling and an occurrence on the cell surface. All conditions leading to a translocation of La onto the cell surface were later found to induce apoptosis. Therefore, a pathophysiological contribution of anti-La abs appears rather unlikely. And, even until today, the mechanisms underlying the shuttling and translocation of the autoantigen are still largely unclear.

Methods: Ten novel monoclonal abs (mabs) were established, characterized by epitope mapping and used for analysis of intra- and cell surface localization of La by immunoblotting, ELISA, epifluorescence microscopy and FACS. The observed redox dependent localization was confirmed by analysis of native and cystein mutant (GFP) La forms. In addition to mabs, human anti-La abs directed to redox dependent forms of La were isolated from autoimmune sera, tested for binding to cell surface La and induction of an ADCC using Chromium-release and FACS-based cytotoxicity assays.

Results: Reactivities of novel anti-La mabs were found to depend on reducing/non-reducing conditions when analyzed by immunoblotting or ELISA. The sensitivity to oxidation was lost when all three cystein residues present in La were mutated. Oxidation of native La protein or cystein mutants in which only one or two cystein residues were mutated leads to inter- and intra cystein disulfide bonds, and thereby to the formation of dimers and higher oligomers *in vitro* and *in vivo*. Oxidative stress results in oxidation of La and causes a separation from a redox dependent nuclear retention partner. Thereafter, La translocates to the cytoplasm and its reentry into the nucleus is blocked resulting in a cytoplasmic enrichment. Oxidation of La can occur in a cell type specific manner. E.g. LPS treatment causes a translocation only in cells expressing TLR4. Dying cells can release La. Released La binds strongly to the surface of neighbouring intact cells. The binding depends on the cell type and the oxidative status of the protein. Only oxidized La binds strongly to the surface of cells including to epithelial, endothelial, blood DCs and other APCs but not to NK- or T cells. Surface bound La is available for binding of anti-La abs, thereby mediating ADCC. Furthermore, it can bind nucleic acids including DNA which improves the binding of other autoantibodies such as anti-DNA abs. Such La/nucleic acid complexes can lead to maturation of DCs.

Conclusion: Under physiological conditions the shuttling of La is favoured to a nuclear localization. Redox dependent conformational changes of La alter this balance resulting in an enrichment of La in the cytoplasm. Dead cells release La which then binds to the surface of intact living cells in a redox dependent manner. Anti-La abs can bind to surface La and cause an ADCC. These redox dependent alterations explain why anti-La abs can become of pathophysiological relevance only under conditions causing acute phases of disease in autoimmune patients.

B Cell Subsets and Dysfunction Of Regulatory B Cells In IgG4-Related Diseases and Primary Sjögren Syndrome: The Similarities and Differences. Wei Lin[1], Lixia Jin[2], Wen Zhang[1], Hua Chen[1], QingJun Wu[1], Yunyun Fei[1], Yan Zhao[1], Xiaofeng Zeng[1] and Fengchun Zhang[1]. [1]Peking Union Medical College Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China, [2]Tsinghua University, Beijing, China.

Background/Purpose: IgG4 related disease (IgG4-RD) is a chronic, multisystem-involved autoimmune disease. Abnormally activated and differentiated B cells may play important roles. Regulatory B cells (Breg) are newly defined B cell subgroups with immunosuppressive functions. In this study, we investigated the differences of B cell subsets, the expressions of co-stimulatory molecules on B cells, and the function of Breg cells in the peripheral blood of patients with IgG4-RD, primary Sjögren's syndrome (pSS), and healthy donors.

Methods: We recruited 38 newly diagnosed IgG4-RD patients, 38 newly diagnosed pSS patients and 30 healthy volunteers were included as disease and healthy controls. To analyze B cell subsets and B cell activity, PBMCs were surface stained with CD19, CD24, CD38, BAFF-R, CD40, CD80 and CD86 mAbs and then detected by flow cytometry. The function of Bregs was tested by co-culturing of isolated CD19+CD24^{hi}CD38^{hi} Breg cells with purified CD4+CD25- effector T cells. Serum cytokines were measured by ELISA. Correlation of clinical data and laboratory findings were measured as well.

Results: Compared with pSS patients and healthy controls, IgG4-RD patients had a lower frequency of peripheral mature B cells and Breg cells. Interestingly, CD19+CD24-CD38hi B cell subsets were significantly higher in peripheral blood B cells from new-onset IgG4-RD patients than in pSS patients and healthy controls. The expression of BAFF-R and CD40 on B cells was significantly lower in IgG4-RD patients compared with those in pSS patients and healthy controls. Whereas, the expression of CD86 and CD80 on B cells was significantly increased in IgG4-RD patients compared with those in pSS patients and healthy controls. Unlike healthy B cells, CD19+CD24hiCD38hi Breg cells from pSS patients were lack of suppression function.

Conclusion: B cells in patients with IgG4-RD and pSS display a variety of abnormalities including disturbed B cell subpopulations, abnormal expression of key signaling molecules, co-stimulatory molecules. A significantly increased B cell subset, CD19+CD24-CD38hi B cells may play an important role in the pathogenesis of IgG4-RD.

B Cell Subset Phenotypes In Patients With Granulomatosis With Polyangiitis (Wegener's). Atul A. Khasnis[1], Carol A. Langford[2], L Calabrese[2], Julia M. Sugalski[3], Michael Lederman[3] and Donald D. Anthony[4]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Case Western Reserve University, Cleveland, OH, [4]Case Western Reserve University, Cleveland VA Medical Center, University Hospitals of Cleveland, Cleveland, OH.

Background/Purpose: B cells are pathogenic in granulomatosis with polyangiitis (Wegener's) (GPA). Rituximab (RTX), an anti-CD20 monoclonal antibody, is effective therapy however B cell reconstitution patterns after RTX are unknown. We present pilot data on B cell subsets in GPA patients compared to healthy controls in addition to GPA patients with active disease or remission as well as patients who are treated with RTX or non-biologic immunosuppression.

Methods: GPA patients were enrolled into: Group I (Active), Group II (Remission) and Group III (Controls). We have currently recruited 4 patients into Group 1, 13 patients into Group 2 and 5 patients in Group 3. Frozen

peripheral blood mononuclear cells were stained with isotype control, anti-CD19, anti-CD10, anti-CD20, anti-CD27, anti-CD38 and anti-CD21 antibodies. B cell subset frequencies were measured as CD19+ cell proportions that are CD10+CD27− (immature transitional - IT), CD10−CD21+CD27− (naive), CD10−CD21+CD27+ (resting memory - RM), CD10-CD21−CD27+ (mature activated - MA), CD10−CD21−CD27− (tissue like memory-TLM) and CD20-CD38+ (plasmablasts). Median proportions were compared using the Wilcoxon rank sum test with $P < 0.05$ considered significant.

Results: In all GPA subjects (n=17), we observed a decrease in total lymphopenia (P=0.03; 45.5 vs 66.2) and significantly decreased naïve B cell frequencies (P=0.04; 28.4 vs. 70.1) as compared to controls (n=5). GPA patients with active disease (n=4) had a significantly increased proportion of IT B cells (P=0.04; 27.85 vs. 0) compared to patients in remission. Patients in remission (n=13) who had received RTX had significantly decreased naïve B cell (P=0.03; 17.6 vs. 59.45) as compared to patients receiving non-biologic immunosuppression therapy (n=6). There were no statistically significant differences between other B cell subsets when comparing GPA patients with controls, active disease with remission, and comparing RTX with non-biologic immunosuppression.

Conclusion: Patients with GPA appear to have a skewed B cell profile compared to healthy controls and this is altered during active disease with a potentially increase in the IT B cell subset. Despite clinical remission observed with RTX, GPA patients continue to have lower frequencies of naïve B cells.

Table 1. B cell subset analyses comparing: 1) GPA patients with controls, 2) Active disease with remission and 3) patients in remission after RTX versus non-biologic immunosuppression

	GPA vs. controls			Active vs. remission			RTX vs. non-RTX		
Parameter**	GPA (n= 17)	Controls (n = 5)	p value	Active GPA (n = 4)	GPA in remission (n = 13)	p value	RTX group (n = 7)	Non-RTX group (n = 6)	p value
Total lymphocytes	45.50	66.2	**0.03**	39.45	53.00	0.41	53	50.35	0.94
CD19+ cells	0.70	6.43	0.16	8.52	0.70	0.62	0.15	2.17	0.23

Autoantibodies to the Th/To Complex Are the Most Common Antibodies in Systemic Sclerosis (SSc) Patients Without Other Autoantibodies. Michael Mahler[1], Jason Y.F. Chan[2], Edward K.L. Chan[2], Minoru Satoh[2], Marie Hudson[3], Murray Baron[4], James Wick[5] and Marvin J. Fritzler[5]. [1]INOVA Diagnostics, San Diego, CA, [2]University of Florida, Gainesville, FL, [3]McGill University, Montreal, QC, [4]Jewish General Hospital, Montreal, QC, [5]University of Calgary, Calgary, AB.

Background/Purpose: Antinuclear antibodies (ANA) play an important role in the diagnosis of systemic sclerosis (SSc) being present in about 80–90% of the patients. In the majority of ANA positive SSc patients, SSc-specific and SSc-associated antibodies can be detected (i.e. antibodies to centromere, Scl-70, RNA Pol-III, PM/Scl, Ro52/TRIM21 and U1RNP). However, in a significant portion of ANA positive SSc patients, no fine specificities can be detected when conventional diagnostic protocols are used. Several studies demonstrated limited sensitivity for the detection of autoantibodies (especially anti-nucleolar antibodies) using solid phase screening assays in SSc patients. Recently, it was found that anti-Rpp25 antibodies are an important autoantigenic component of the Th/To complex. However, it remains unknown how much anti-Th/To and anti-Rpp25 antibodies contribute to ANA positivity in SSc patients. Consequently, the present study aimed to define the prevalence of autoantibodies to Rpp25 in SSc patients without other SSc-specific or SSc-associated antibodies.

Methods: Sera from 874 Canadian SSc patients were tested for ANA and various SSc-specific and SSc-associated antibodies including antibodies to common extractable nuclear antigens (ENA) and to those contained in a SSc line immunoassay (Euroimmun, Germany). Samples without those antibodies (n=54, later referred to as ANA+/ENA-) were analyzed by immunoprecipitation (IP) analysis of proteins and RNAs and for anti-Rpp25 antibodies (n=51) by a chemiluminescent immunoassay (CIA, QUANTA Flash, INOVA Diagnostics, US) and Rpp25 ELISA (University of Florida, US).

Results: Anti-Th/To antibodies were the most common antibody in ANA+/ENA-negative SSc patients; being found in 18/54 (26%) of the patients as determined by IP. A total of 51 of these samples were available for additional testing by CIA and ELISA. Anti-Rpp25 antibodies were detected in 12 (23.5%, CIA) or 10 (19.6%, ELISA) of 51 patients when using the recently established cut-off values. ROC analysis showed similar discrimination between Th/To IP positive (n=18) and negative samples (n=33) by CIA and ELISA (AUC 0.89 *vs.* 0.86; $p=0.7491$). The positive percent agreements between IP and CIA or ELISA were 12/18 (66.7%, 95% Confidence interval 41.0–86.7%) or 10/18 (56.7%, 95% CI 30.8–78.5%), respectively. Negative percent agreements were 100% for both assays (95% CI 89.4–100.0%).

Conclusion: Autoantibodies to the Th/To autoantigen are important in SSc patients who have been considered to be negative for SSc-specific or SSc-associated antibodies by widely available commercial assays. Rpp25 has been confirmed as a major target of these anti-Th/To antibodies. Diagnostic assays for the detection of anti-Th/To and anti-Rpp25 antibodies hold promise to improve the diagnosis and management of SSc. Rpp25 might also help to improve solid phase screening assays for the detection of autoantibodies in SSc patients.

The Role of HIF-1 and HIF-2 During Angiogenesis and Metabolic Adaptation of Human Microvascular Endothelial Cells Towards Hypoxia. Martin Hahne[1], Cindy Strehl[1], Manuela Jakstadt[1], Paula Hoff[1], Timo Gaber[1], Gerd-Rüdiger Burmester[2] and Frank Buttgereit[3]. [1]Charité University Medicine, Berlin, Germany, [2]Charite University Hospital, Berlin, Germany, [3]Charité - Universitätsmedizin Berlin, Berlin, Germany.

Background/Purpose: Hypoxia is a feature of RA synovitis. In the present study, we focused on the two transcription factors Hypoxia inducible factor (HIF)-1 and (HIF)-2. These factors are known to regulate the cellular and metabolic responses to pathophysiologically reduced oxygen tension thereby promoting both angiogenesis and metabolic adaptation of endothelial cells. However, functional differences and similarities between these factors in these regards have not been investigated so far. Our aim was to knockdown either HIF-1α or HIF-2α in human microvascular endothelial cells (HMEC), respectively, in order to understand the differential impact of HIF-1 and HIF-2 on the angiogenic and metabolic transcriptome under hypoxic versus normoxic conditions.

Methods: Specific knockdown of either HIF-1α or HIF-2α was achieved using lentiviral-based shRNA technology. Angiogenic and metabolic transcriptome was studied by performing gene expression studies (Agilent Human Whole Genome 60K Microarrays) of (un-)transduced HMECs incubated under normoxia (18% O2) vs. hypoxia (1% O2) for 20h. Obtained data were analyzed by the classification of significantly regulated genes ($\geq$2-fold change, $p<0.01$) into angiogenic and metabolic processes using Panther database.

Results: In untransduced HMECs, we identified 73 angiogenesis related genes in 11 different pathways and 17 cellular metabolism related genes in 9 different pathways, respectively, which are differentially expressed under hypoxia vs. normoxia. Interestingly, in both HIF-1α and HIF-2α knockdown cells, hypoxia was still capable of inducing a differential gene expression pattern, but the effect was much less pronounced if compared with cells without knockdown.

Analysis of effects on *angiogenesis* related processes (VEGF pathway, HIF activation, EGFR pathway) showed that 74% of the differentially expressed genes are controlled by both HIF-1 and HIF-2. Another 14% of the regulated genes depend on the presence of HIF-1, among them the genes *GRB2*, *PDGFRB*, *PLD*, *WNT5A* and *MMP3.* The remaining 12% of regulated genes are under the control of HIF-2, among them the genes *DLL3*, *HSP27b2*, *NOTCH4*, *PKC* and *MMP1.*

The differentially regulated genes encoding proteins/enzymes involved in the *cellular metabolism* (i.e. glycolysis, ATP synthesis, TCA cycle) were found to be to 80% controlled by both HIF-1 and HIF-2, respectively. The remaining 20% are dependent on the presence of HIF-1, among them the genes *FOXJ1*, *FOXQ1* and *Cyt C.*

Conclusion: Both HIF-1α and HIF-2α are key regulators driving the adaptation of endothelial cells towards hypoxia with overlapping functions. However, they do differ in their capacity to regulate *cellular energy metabolism* and *angiogenesis*. This leads us to conclude that HIF-1α affects angiogenesis via indirect effects on cellular energy metabolism as indicated by the regulation of metabolic transcriptome to one fifth. In contrast, HIF-2α does influence angiogenesis more directly via regulating the synthesis of proangiogenic factors (as has been previously shown).These findings provide new insights into the divergent regulation of angiogenesis in inflamed (hypoxic) tissues by HIF-1 and HIF-2 and are, therefore, considered to be of clinical relevance in RA.

The Bioenergetic Role of HIF-1 and HIF-2 During Angiogenesis of Human Microvascular Endothelial Cells. Martin Hahne[1], Cindy Strehl[1], Manuela Jakstadt[1], Paula Hoff[1], Timo Gaber[1], Gerd-Rüdiger Burmester[2] and Frank Buttgereit[3]. [1]Charité University Medicine, Berlin, Germany, [2]Charite University Hospital, Berlin, Germany, [3]Charité - Universitätsmedizin Berlin, Berlin, Germany.

Background/Purpose: Hypoxia is a feature of inflamed tissues. The transcription factors Hypoxia inducible factor (HIF)-1 and (HIF)-2 regulate the cellular and metabolic responses to reduced oxygen tensions thereby promoting angiogenesis with implications on the pathogenesis of rheumatoid arthritis (RA). However, functional differences and similarities between these factors in regard to bionergetics have not been investigated so far. Our aim was to knockdown either HIF-1α or HIF-2α in human microvascular endothelial cells (HMEC) in order to investigate resulting effects on angiogenesis and bioenergetics under hypoxia vs. normoxia. In previous studies we showed that HIF-2α does directly influence angiogenesis via regulating the synthesis of proangiogenic factors. In this study we focused on the regulation of bioenergetics by HIF-1α and HIF-2α, respectively.

Methods: Specific knockdown of either HIF-1α or HIF-2α was achieved using lentiviral-based shRNA technology. Angiogenesis of transduced HMECs was studied by investigating both tubuli and node formation under hypoxic (<1% O2) versus normoxic (~18% O2) conditions.

Expression of genes involved in the metabolic response to hypoxia *(GAPDH, PGK, GLUT1, LDHA)* was quantified by realtime RT-PCR. The bioenergetic status of the cells was quantified via ATP/ADP measurements.

Results: Knockdown of HIF-1α resulted in a loss of both hypoxia induced node ($p<0.01$) and tubuli formation ($p=0.09$). Also HIF-2α knockdown was followed by a significant reduction of hypoxia induced formation of tubuli ($p<0.05$).

Focusing on bioenergetic aspects, we found hypoxia to significantly induce the gene expression of *PGK* ($p<0.001$), *LDHA* ($p<0.05$) and *GAPDH* ($p<0.05$) in control cells. Interestingly, knockdowns of HIF-1α and HIF-2α, respectively, did not affect the hypoxic induction of *PGK* and *LDHA* expression.

In both HIF-1α ($p=0.01$) and HIF-2α ($p=0.13$) knockdown cells, hypoxia was still capable of inducing *GAPDH*, but the effect was considerably less pronounced in HIF-1α knockdown cells. Hypoxia did not significantly up-regulate *GLUT1* (encoding the glucose transporter 1), neither in control nor in HIF-1α or HIF-2α knockdown cells.

However, the knockdown of HIF-2α resulted in significantly decreased expression levels of *GLUT1* under hypoxia ($p<0.01$).

We also found the ATP/ADP ratio to be similar in control, HIF-1α knockdown and HIF-2α knockdown cells under normoxia. Under hypoxia, however, HIF-1α knockdown cells showed a significantly reduced ATP/ADP ratio ($p<0.05$)–indicating that less ATP is available–compared to HIF-2α knockdown cells.

Conclusion: HIF-1α and HIF-2α are both key regulators of angiogenesis. However, they do differ in their potency to regulate cellular energy metabolism. We show here HIF-1α to affect angiogenesis via effects on cellular energy metabolism as indicated by the reduced expression of *GAPDH* and the diminished ATP/ADP ratio. In contrast, HIF-2α has rather modest effects on cellular energy metabolism but has been shown to affect angiogenesis directly via regulating the synthesis of proangiogenic factors. These findings provide new insights into regulation of angiogenesis in inflamed (hypoxic) tissues and are, therefore, considered to be of clinical relevance in RA.

Blockade Of TNFα Produced By TSLP-Primed CD1c Myeloid Dendritic Cells Skews T Cell Response To Th2 Activity In Rheumatoid Arthritis Patients. F.M. Moret, T.R.D.J. Radstake, J.W.J. Bijlsma, F.P.J.G. Lafeber and J.A.G. van Roon. University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Thymic stromal lymphopoietin (TSLP) is well known for its potent activation of myeloid dendritic cells (mDCs) to induce Th2-mediated immune responses. Additionally, TSLP and its receptor play a crucial role in promoting Th17-driven collagen-induced arthritis. Recently, we have shown that increased intra-articular TSLP concentrations in RA patients potently activate TSLPR-expressing mDCs from peripheral blood (PB) and synovial fluid (SF) of RA patients to secrete T cell attractant chemokines and to potently increase Th1, Th17 and Th2 activity. Since TNFα is a crucial pro-inflammatory and tissue-destructive mediator in RA, we assessed the capacity of TSLP to regulate TNFα production by CD1c mDCs and the effects of TNFα blockade in T cell regulation.

Methods: CD1c mDCs, isolated from PB or SF of RA patients, were primed with TSLP for 20 hours without or with anti-TNFα mAb and cytokine production was measured by multiplex immunoassay. Washed TSLP-activated mDCs primed without or with anti-TNFα mAb were added to autologous CD4 T cells in the absence of additional stimuli, cultured for 6 days and subsequently proliferation was measured. Additionally, T-cell cytokine production was measured by ELISA upon restimulation with ionomycin/PMA.

Results: Upon incubation with TSLP, mDCs from PB and SF potently stimulated TNFα production of autologous CD4 T cells as compared to unprimed mDCs (ratio T cell:DC 5:1, PB from 3498 to 9225 pg/ml, $p=0.001$ and SF from 8951 to 18415 pg/ml, $p<0.05$). TSLP significantly stimulated the production of TNFα by mDCs from PB and SF (PB from 99 to 378 pg/ml, $p<0.05$ and SF from 170 to 355 pg/ml, $p<0.05$). Blockade of TNFα during TSLP-priming of mDCs did not affect T-cell differentiating cytokine production but significantly decreased MIP1α and enhanced TARC production (MIP1a:TARC ratio, TSLP-mDCs versus anti-TNFα-TSLP-mDCs, ratio 40 vs. 3, $p<0.05$, respectively). Co-culturing TSLP-primed-mDCs that had been treated with anti-TNFα mAb together with T cells did not affect IFNγ and IL-17 production but significantly increased IL-4 production as well as the IFNγ:IL-4 ratio (TSLP-mDCs versus anti-TNFα-TSLP-mDCs, ratio 11 vs. 5, $p<0.05$, respectively).

Conclusion: TSLP induces TNFα production by CD1c mDCs and mDC-activated CD4 T cells of RA patients. Blockade of TNFα produced by TSLP-primed-mDCs results in the enhancement of Th2 activity by promoting Th2 attracting chemokine production and T cell skewing towards Th2 activity. Considering the inhibitory capacity of Th2 cells in RA, this suggests that TNFα blockade in RA patients contributes to reduced immunopathology by increasing the Th2-inducing potential of TSLP.

The Endocannabinoid Anandamide Modulates Adhesion, Proliferation and The Production Of Inflammatory Mediators In Rheumatoid Arthritis Synovial Fibroblasts By Activating CB_1, TRPV1, TRPA1 and Non-Cannabinoid Receptor Targets. Torsten Lowin, Angelika Graeber and Rainer H. Straub. Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, University Hospital of Regensburg, Regensburg, Germany.

Background/Purpose: In rheumatoid arthritis (RA), synovial fibroblasts (SF) secrete large amounts of IL-6, IL-8 and matrixmetalloproteinases (MMPs) which are crucial for cartilage destruction. RASFs are sensitive to the action of cannabinoids and they express cannabinoid receptors type I and II (CB_1 and CB_2), the vanilloid receptor (TRPV1) as well as endocannabinoid

degrading enzymes (FAAH and COX-2). Cannabinoids are regarded as antiinflammatory and since anandamide (AEA) is found in RA synovial fluid we investigated how this endocannabinoid affects adhesion, proliferation and production of inflammatory mediators of RASF.

Methods: Adhesion was assessed by the XCELL*igence* system. Proliferation was quantified by the amount of incorporated fluorescent dye into cellular DNA. MMP-3 and cytokines were detected by ELISA. Collagen II induced arthritis was used a s a mouse model of RA.

Results: AEA dose-dependently decreased IL-1β induced production of MMP-3, IL-6 and IL-8 in RASFs and OASFs under normoxic conditions (20% O_2). The efficacy of AEA was significantly enhanced by addition of the COX-2 inhibitor nimesulide. The effects of AEA were not inhibited by CB_1, CB_2 or GPR55 antagonists but were blocked by the TRPV1 antagonist capsazepine in RASFs but not OASFs. Under hypoxic conditions (1% O_2) and TNF stimulation, the effects of AEA on cytokine and MMP-3 production were blocked by TRPA1 and TRPV1 antagonists. In mixed synovial cell cultures however, AEA increased the production of TNF (100%) which was enhanced by inhibition of AEA degradation. Furthermore, AEA increased adhesion of OASFs and RASFs to fibronectin. Adhesion was modulated by CB_1, GPR55 and TRPV1 antagonists in OASFs but not in RASFs. Combined FAAH and COX-2 inhibition blocked the stimulatory effect of AEA on adhesion in OASF.Proliferation was decreased by AEA in RASFs and OASFs via a cyclooxygenase-2 but not via CB_1, CB_2 or TRPV1 dependent mechanism. Elevation of endogenous AEA by inhibition of its degradation showed beneficial effects in collagen-induced arthritis in mice.

Conclusion: In conclusion, AEA promotes an antiinflammatory phenotype of RASFs and OASFs by activating/desensitizing TRPV1 and TRPA1 under hypoxic conditions. Furthermore, COX-2 inhibition is necessary to fully exploit the therapeutic potential of AEA. This might be important in RA where low oxygen and abundant cytokine expression up-regulate COX-2 in the joint.

Effect Of Neutralizing IL-17A and IL-17F Antibodies On Host Resistance To Acute *Mycobacterium Tuberculosis* Infection In Mice In Comparison With Neutralizing TNF-α Treatment. Michael Kammüller[1], Franco Di Padova[1], Christian Antoni[2], Salah-Dine Chibout[1], Timothy Wright[3], Marie-Laure Bourigault[4], Noria Segueni[4], Stephanie Rose[4], Bernhard Ryffel[4] and Valerie Quesniaux[4]. [1]Novartis Institutes for Biomedical Research, Basel, Switzerland, [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [3]Novartis Pharma AG, Basel, Switzerland, [4]UMR7355 CNRS and University of Orleans, Orleans, France.

Background/Purpose: Antibodies targeting IL-17A or IL-17RA are in clinical trials for the treatment of several autoimmune diseases. However, these therapies, by blocking critical mediators of innate and adaptive immunity, may carry the risk of an increased susceptibility to infections. While *M. tuberculosis* infections can be an important complication of anti-TNFα therapies, the role of the Th17/IL-17 pathway in host resistance to this intracellular pathogen is less clear.

Methods: The effect of neutralizing IL-17A or IL-17F during acute *M. tuberculosis* infection was evaluated in a 4-week aerosol mouse model. *M. tuberculosis* (strain H37Rv, 1000 CFU) infected C57BL/6 mice were treated once per week i.p. with 0.5 mg (approximately 20 mg/kg) of anti-mouse IL-17A or F antibodies, 0.25 mg (approximately 10 mg/kg) of anti-mouse TNFα antibody, and respective isotype control antibodies, starting 1 day before the infection. Disease symptoms, lung and spleen weight, pulmonary bacterial burden and lung histopathology were assessed at day 28.

Results: IL-17A or IL-17F blockade like the isotype controls did not alter body, lung, and spleen weights, pulmonary bacterial burden and lung histopathology after 28 days. On the other hand, in mice treated with a neutralizing anti-TNFα antibody, body weight was drastically decreased, while lung and spleen inflammation and pulmonary bacterial burden were clearly increased by day 28. These changes were associated with a worsening of the microscopic observations in the lung with the anti-TNFα antibody. TNFα-deficient mice succumbed by day 28 to severe infection under these experimental conditions.

Conclusion: Overall, these results confirm the importance of TNFα in host resistance to *M. tuberculosis* infection, and highlight that anti-IL-17A or anti-IL-17F cytokine blockade for 4 weeks *in vivo* do not impair immunity in an acute mouse *M. tuberculosis* infection model.

Hypoxia and Signal Transducer and Activator Of Transcription 3 Signalling Interactions Regulate Pro-Inflammatory Pathways In Rheumatoid Arthritis. Wei Gao[1], Jennifer McCormick[2], Mary Connolly[3], Emese Balogh[3], Douglas J. Veale[1] and Ursula Fearon[2]. [1]Translational Rheumatology Research Group, Dublin, Ireland, [2]St. Vincent's University Hospital, Dublin 4, Ireland, [3]Translation Research Group, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland.

Background/Purpose: Signal Transducer and Activator of Transcription 3 (STAT3), a critical transcription activator in angiogenesis, plays a crucial role in the pathogenesis of Rheumatoid Arthritis (RA). Hypoxia and Notch signalling regulate angiogenesis, cell proliferation, invasion and survival. This study was to examine the effect of hypoxia on STAT3-induced pro-inflammatory pathways in RA.

Methods: Expression of phospho-STAT3 in synovial tissue and RA synovial fibroblasts (RASFC) was assessed by immunohistology/immunofluorescence. Primary RASFC and synoviocyte cell lines (K4IM) were cultured under 3% hypoxia and normoxia conditions±Stat3-siRNA, HIF-siRNA or WP1066 (potent STAT inhibitor). HIF1α, p-STAT3 and Notch-1IC (intracellular domain) protein expression were analyzed by Western blot. Functional mechanisms were quantified by invasion chamber, matrigel and wound repair assays. IL-6, IL-8, IL-10 and MMP-3 were quantified by ELISA. Notch-1 receptor, its DLL-4 ligand and downstream target genes (*hrt-1, hrt-2*) were quantified by Real-time PCR. Finally the effect of WP1066 on spontaneous secretion of pro/anti-inflammatory cytokines was examined in RA synovial explants *ex-vivo*.

Results: Increased p-STAT3 expression was demonstrated in RA synovium compared to healthy control ($p<0.05$) and 3% hypoxia induced nuclear translocation of p-STAT3 in RASFC. Hypoxia induced p-STAT3 and HIF1α expression, an effect blocked by Stat3-siRNA and WP1066. Hypoxia-induced cell invasion, migration and cytokine production were inhibited by Stat3-siRNA (all $p<0.05$) and WP1066 (all $p<0.05$). While HIF1α siRNA inhibited hypoxia-induced p-STAT3 expression, Stat3-siRNA also inhibited hypoxia-induced HIF1α. Furthermore hypoxia-induced Notch-1IC, DLL4, *hrt-1* and *-2* expression were significantly inhibited by STAT3 blockade ($p<0.05$). Finally, in RA synovial explant cultures *ex-vivo,* STAT3 blockade decreased spontaneous secretion of IL-6, IL-8 and MMP3 ($p<0.05$), and induced IL-10 ($p<0.05$).

Conclusion: This is the first study to provide evidence of a functional link between HIF1α, STAT3 and Notch-1 signalling in the regulation of pro-inflammatory mechanisms in RA, and further supports a role for STAT blockade in the treatment of RA.

Characterizing The Expression and Function Of CCL28 and Its Corresponding Receptor CCR10 In The Pathogenesis Of RA. Zhenlong Chen[1], Seung-jae Kim[1], Michael V. Volin[2], Suncica Volkov[1], William Swedler[1], Nadera J. Sweiss[1] and Shiva Shahrara[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]Chicago College of Osteopathic Medicine Midwestern University, Downers Grove, IL.

Background/Purpose: This study was conducted to determine the expression pattern and function of CCL28 and its corresponding receptor CCR10 in the pathogenesis of rheumatoid arthritis (RA).

Methods: Expression of CCL28 and CCR10 was examined in RA compared to osteoarthritis (OA) and normal (NL) synovial tissue (ST) and/or fluid (SF) by histological studies and real-time RT-PCR. Next, the factors

modulating CCL28 and CCR10 expression were identified in RA peripheral blood (PB) *in vitro* differentiated macrophages and endothelial cells by real-time RT-PCR. Based on the elevated expression of CCR10 on RA blood vessels, significance of CCL28 expressed in RA SF was evaluated on human endothelial progenitor cell (EPC) migration and tube formation. Finally, the mechanism by which CCL28 mediates angiogenesis was determined in knockdown CCR10 endothelial cells by Western blot analysis, endothelial chemotaxis and tube formation.

Results: We demonstrate that expression of CCL28 and CCR10 are markedly higher in RA and OA ST lining macrophages and sublining endothelial cells compared to NL ST. Consistently, comparable levels of CCL28 were expressed in RA and OA SF which were 4 to 33 fold greater than those detected in RA and NL serum. Since both CCL28 and CCR10 are mainly expressed in RA myeloid and endothelial cells, we asked whether their expression levels are regulated in a similar manner in these cells. Interestingly we found that expression of CCL28 and CCR10 was very responsive to stimulation in RA PB *in vitro* differentiated macrophages and was similarly enhanced by TNF-a (8–18 folds), IL-1b (6–32 folds) or IL-6 (12–18 folds) treatment. In contrast, concentrations of CCL28 and CCR10 were differentially regulated in endothelial cells. We show that while in endothelial cells, IL-1b (5 fold) or IL-17 (3 fold) were responsible for increasing CCL28 mRNA levels, CCR10 (11 fold) expression levels were modulated by TNF-a stimulation. We uncovered that CCL28 can strongly attract endothelial cells starting at 0.1 ng/ml, indicating that CCL28 (up to 3300 pg/ml expressed in RA SF) can contribute to migration of endothelial cells at a physiologically relevant concentration. We further document that ligation of SF CCL28 to endothelial CCR10 is involved in RA angiogenesis, as neutralization of CCL28 in RA SF or blockade of CCR10 on human EPCs significantly reduce RA SF induced endothelial migration and tube formation. To determine the mechanism by which CCL28 promotes RA angiogenesis, endothelial cells stimulated with CCL28 were examined for activation of MAPK and AKT pathways. We found that while ERK was phosphorylated by CCL28 stimulation in endothelial cells, JNK, p38 and AKT pathways were unaffected by this process. We further show that knockdown of endothelial CCR10 significantly reduces CCL28 mediated ERK phosphorylation as well as endothelial migration and tube formation compared to the control siRNA cells.

Conclusion: We found that CCL28 and CCR10 are coexpressed in RA ST blood vessels and as a result, ligation of RA SF CCL28 to endothelial CCR10 facilitates endothelial cell migration and tube formation through activation of ERK pathway. This study identifies for the first time the presence and function of CCL28 as a novel mediator of RA angiogenesis.

Interleukin-12B Is Up-Regulated By Decoy Receptor 3 In Specifically Rheumatoid Synovial Fibroblasts. Koji Fukuda[1], Yasushi Miura[2], Toshihisa Maeda[1], Shinya Hayashi[1] and Masahiro Kurosaka[1]. [1]Kobe University Graduate School of Medicine, Kobe, Japan, [2]Kobe University Graduate School of Health Sciences, Kobe, Japan.

Background/Purpose: Decoy receptor 3 (DcR3) is a secreted decoy tumor necrosis factor receptor and competitively binds and inhibits the TNF family including Fas-ligand (FasL), LIGHT, and TL1A. DcR3 is overexpressed in tumor cells and might benefit tumors by helping them to avoid cytotoxic and regulatory effects of the ligands. We previously reported that DcR3 overexpressed in rheumatoid synovial fibroblasts (RA-FLS) stimulated by TNFα protects the cells from Fas-induced apoptosis. We recently reported that DcR3 induces VLA-4 expression in THP-1 macrophages to inhibit cycloheximide-induced apoptosis, and that DcR3 binds to TL1A expressed on RA-FLS resulting in the negative regulation of cell proliferation induced by inflammatory cytokines. Therefore, DcR3 may regulate gene expressions in RA-FLS by binding to TL1A on RA-FLS as a ligand. In the present study, we studied interleukin (IL)-12B as one of the key molecules in DcR3-TL1A signaling in RA-FLS based on the genes expression profiles regulated by DcR3.

Methods: *Microarray assay.* Four individual lines of primary cultured RA-FLS were incubated with either recombinant human DcR3-Fc protein or control IgG1 for 12 hours. Gene expressions were detected by microarray assay and the profiles were analyzed. *Real-time polymerase chain reaction (real-time PCR).* RA and osteroarthritis (OA) -FLS were stimulated with various concentration of DcR3-Fc or control IgG1 for 12 hours. Further, RA-FLS were incubated with DcR3-Fc for 12 hours after overnight preincubation with anti-TL1A antibody. The relative expression levels of IL-12B mRNA were quantified by real-time PCR. *Western blotting.* RA-FLS was stimulated with DcR3-Fc or control IgG1 for 24 hours. The expression of IL-12B p40 protein in RA-FLS was investigated by western blotting.

Results: Microarray data analysis revealed that DcR3 up-regulates or down-regulates the expression of various genes n RA-FLS. Among the most significantly regulated 100 genes by DcR3, 45 genes were up-regulated and 55 genes were down-regulated. The profiles indicated that shared p40 subunit (IL-12B) of IL-12 and IL-23 was up-regulated by DcR3-Fc (fold change 1.65). Real-time PCR revealed that DcR3-Fc significantly increased the expression of IL-12B mRNA in RA-FLS in a dose dependent manner (113% with 10ng/ml, 135% with 100ng/ml, and 218% with 1000ng/ml) compared with control IgG1. In contrast, DcR3-Fc did not increase IL-12B mRNA in OA-FLS. Anti-TL1A antibody inhibited the up-regulation of IL-12B expression in RA-FLS induced by DcR3-Fc. Western blotting confirmed that IL-12B p40 protein in RA-FLS was increased when stimulated with DcR3-Fc.

Conclusion: IL-12 consisted of IL-12A (p35) and IL-12B induces Th1 immune responses. Meanwhile, IL-23 consisted of IL-23A (p19) and IL-12B is involved in the inflammatory pathway via IL-17. In this study, we revealed that DcR3 increased the expression of IL-12B in RA-FLS in a disease-specific fashion by binding to membrane-bound TL1A as a ligand. DcR3 may affect the pathogenesis of RA through IL-12B.

Adenosine A2A Receptor Activates The Pro-Fibrotic Wnt / β-Catenin Signaling In Human Dermal Fibroblasts. Miguel Perez-Aso[1] and Bruce N. Cronstein[2]. [1]New York University School of Medicine, New York, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Upon adenosine formation in stress conditions, the adenosine A_{2A} Receptor ($A_{2A}R$) activation promotes wound healing, but it is also detrimental in fibrotic conditions such as scarring, scleroderma and liver fibrosis. Although we have previously shown that the $A_{2A}R$ regulates scarring and fibrosis by fine-tuning the collagen1 to collagen3 balance in human dermal fibroblasts, the intracellular pathway leading to collagen production upon $A_{2A}R$ activation remains unclear. β-catenin is a central mediator of pro-fibrotic Wnt signaling in systemic sclerosis (Beyer et al. 2012) and the pro-fibrotic growth factor TGF-β1 targets the β-catenin pathway (Caraci et al. 2008). We therefore sought to determine whether $A_{2A}R$ stimulates Wnt / β-catenin signaling in human dermal fibroblasts.

Methods: Cells were stimulated for 24h with the specific $A_{2A}R$ agonist CGS21680, in the presence or absence of the $A_{2A}R$ antagonist SCH58211. β-catenin was knock-down with siRNA and collagen1, collagen3 and β-catenin expression were analyzed by western-blotting. Subcellular distribution of β-catenin was studied by cellular fractionation and confocal microscopy.

Results: The A2A agonist CGS21680 stimulated, in a dose-dependent fashion, a significant increase in β-catenin expression (increase over non-stimulated control: CGS21680 0.1μM 139.6$\pm$10.3%, $P<0.01$ n=5; 1μM 163.7$\pm$18.8%, $P<0.001$ n=3; 10μM 151.6$\pm$7.1%, $P<0.001$ n=5) and preincubation with the A2AR antagonist SCH21680 1μM prevented this effect (two-way ANOVA $P<0.01$, n=5). Subcellular fractionation after incubation with CGS21680 (1μM) showed a preferential increase of β-catenin in the nucleus, as assessed by Western Blot Analysis and confocal images demonstrate colocalization of the nuclear marker DAPI and β-catenin after A2AR stimulation. As expected, CGS21680 1μM stimulated an increase of both collagen1 (1.4 and 2.5 fold increase over control) and collagen3 (2.8 and 2.2 fold increase over control) but, interestingly, β-catenin knock-down prevented the CGS21680-mediated increase in collagen3, but not collagen1.

Conclusion: These results strongly support the hypothesis that activation of the A2AR leads to cross-talk with the pro-fibrotic Wnt / β-catenin signaling system. These findings suggest a mechanism for changes in the collagen1: collagen3 ratio in animal models of hypertrophic scars and scleroderma in which A2AR blockade or deletion prevents fibrosis and in which adenosine concentrations are dramatically increased.

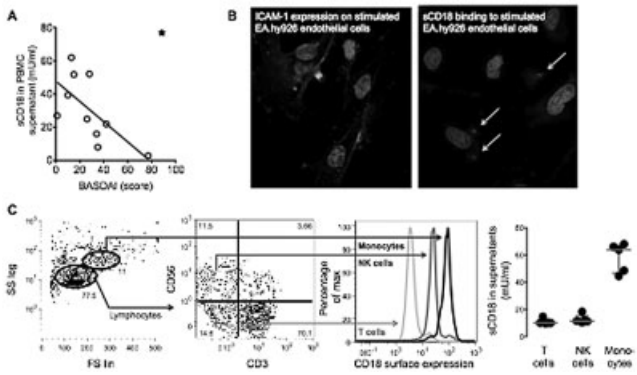
Decreased Plasma Levels Of Soluble CD18 Link Leukocyte Migration and Disease Activity In Spondyloarthritis. Tue W. Kragstrup[1], Babak Jalilian[2], Malene Hvid[2], René Østgård[2], Berit Schiøttz-Christensen[3], Anne G. Jurik[4], William H. Robinson[1], Thomas Vorup-Jensen[2] and Bent Deleuran[4]. [1]Stanford University School of Medicine, Stanford, CA, [2]Aarhus University, Aarhus, Denmark, [3]Private practice, Aarhus, Denmark, [4]Aarhus University Hospital, Aarhus, Denmark.

Background/Purpose: Spondyloarthritis (SpA) comprise a group of diseases characterized by inflammation of the entheses and joints of the axial skeleton primarily driven by innate immune cells such as monocytes, fibroblasts and granulocytes.(1) The family of CD18 integrins is pivotal in guiding leukocytes to sites of inflammation and has been shown to form soluble complexes in the blood (sCD18).(2) CD18 hypomorphic mice develop a disease resembling psoriatic arthritis, demonstrating that decreased CD18 expression can result in development of SpA-like disease.(3) Here, we investigated whether sCD18 plays a role in SpA disease pathogenesis.

Methods: The level of sCD18 in plasma from a well characterized study population with 84 SpA patients and age- and sex-matched healthy controls was analyzed with a time resolved immunoflourometric assay (TRIFMA). Shedding of CD18 from peripheral blood mononuclear cells was studied by using flow cytometry and TRIFMA. Binding of sCD18 to endothelial cells and fibroblast-like synovial cells (FLS) was studied by using confocal microscopy.

Results: Plasma levels of sCD18 were decreased in SpA patients compared with healthy volunteers ($P< 0.001$). The sCD18 levels exhibited an inverse correlation with the BASDAI ($P< 0.05$), the level of morning stiffness ($P< 0.05$), the BASMI ($P< 0.05$), the physician global assessment score ($P< 0.01$), and the sacroiliac MRI activity score ($P< 0.05$) in multiple regression models, including multivariate analysis to account for differences in CRP levels. Remarkably, this situation could be simulated in vitro. First, CD18 shedding from SpA PBMC correlated inversely with the BASDAI ($P< 0.05$), suggesting insufficient generation (Fig 1A). Second, sCD18 in plasma adhered to inflammation induced ICAM-1 on endothelial cells and FLS, indicating increased consumption (Fig 1B). Importantly, both ICAM-1 expression and CD18 shedding were increased by TNFα, suggesting that sCD18 plays a role in regulating leukocyte migration during the normal immune response. CD18 was primarily shed from monocytes, supporting the notion that alterations in innate immunity dominate the inflammatory processes in SpA (Fig 1C).



Conclusion: Taken together, the failure of SpA patients to maintain normal sCD18 levels may reflect insufficient CD18 shedding from monocytes to counterbalance the capture of sCD18 complexes to inflammation induced ICAM-1. This results in increased availability of ICAM-1 molecules on the endothelium and in the synovium facilitating increased leukocyte migration to the entheses and joints and increased inflammatory burden. In this way, our findings on sCD18 link leukocyte migration with SpA disease activity.

Inhibitor Of DNA Binding 1 Mediates Angiogenesis In Rheumatoid Arthritis By Recruitment Of Endothelial Progenitor Cells. Takeo Isozaki[1], Alisa E. Koch[1], M. Asif Amin[1], Ali S. Arbab[2], Gautam Edhayan[1], Christine M. Ha[1], Pei-Suen Tsou[3], Sean C. Friday[1], David A. Fox[3] and Jeffrey H. Ruth[1]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]Henry Ford Hospital and Medical Centers, Detroit, MI, [3]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: Endothelial progenitor cells (EPCs) are known to induce vasculoproliferative responses within rheumatoid arthritis (RA) synovial tissue (ST). Inhibitor of DNA-Binding 1 (Id1) is a transcription factor shown to be actively transcribed in only progenitor cells, making it a possible marker for identifying EPCs in neovascular responses in RA ST. We previously showed that Id1 is not only expressed in RA STs, but is also secreted and upregulated in RA synovial fluid (SF). The identification of Id1 in RA tissues indicates progenitor cells are active in the RA joint, and may serve as a potential target for limiting neovascularization in the RA ST. This study further examines the cellular sources, angiogenic and chemotactic potential, and cell signaling properties of Id1.

Methods: Severe combined immunodeficient (SCID) mice were implanted with RA ST and allowed to engraft for six weeks. Mice were injected i.v. with fluorescently dye-tagged EPC's while receiving simultaneous intragraft injections with either human Id1 (10 nM) or PBS. Another group of SCID mice grafted and injected similarly, received intragraft injections of RA SF immunodepleted with either non-specific IgG ("sham depleted"), or Id1 immunodepleted with a neutralizing antibody. For signal transduction analysis, human dermal microvascular endothelial cells (HMVECs) and EPCs were plated and stimulated with human Id1. Cell lysates were made and Western blot analysis was used to determine the kinetics of protein kinase expression. We also examined whether Id1 induces HMVECs to form blood vessels, measured as an increase in plug hemoglobin (Hb) concentration normalized to plug weight, using the mouse Matrigel plug angiogenesis assay. Finally, to determine the cells secreting Id1, we cultured monocytes, HMVECs, EPCs and fibroblasts and measured the supernatants for Id1 expression by ELISA.

Results: There was a significant increase in EPC migration to engrafted RA ST in the SCID mouse chimera to intragraft injections of Id1. Using the same RA ST SCID mouse chimera system, we found that intragraft injections of RA SF immunodepleted of Id1 resulted in a 50% reduction in EPC recruitment compared to mice injected similarly with sham depleted RA SF (*$p<0.05$). Cell signaling experiments to Id1 showed Jnk was upregulated in both HMVECs and EPCs, and P38 only in EPCs. We also show that Id1 induces *in vivo* blood vessel formation, and that inhibiting HMVEC associated Jnk with silencing RNA reverses Id1 induced HMVEC vessel formation in Matrigel plugs *in vivo*. Lastly, we show that monocytes and especially fibroblasts, but not HMVECs and EPCs, actively secrete Id1, indicating that mature fibroblasts may be a primary source of Id1 in RA SF.

Conclusion: Our data indicates that Id1 induces EPC recruitment in the RA ST SCID mouse chimera, and that by depleting RA SF of soluble Id1, we can attenuate EPC migration by 50%. Id1 was also found to be potently angiogenic in the mouse Matrigel angiogenesis assay, and activates Jnk signaling pathways in HMVECs and EPCs. Lastly, we found that fibroblasts actively secrete Id1 and may be a primary source for its expression in SF. These studies identify Id1 as both a regulatory transcription factor and a unique angiogenic target within the RA synovium.

A Disintegrin and Metalloprotease-17 (ADAM-17) Is Expressed In Rheumatoid Arthritis and Mediates Monocyte Migration. Takeo Isozaki, Nao Oguro, Shinya Seki, Yoko Miura, Sho Ishii, Hiroyuki Tsukamoto, Takahiro Tokunaga, Masayu Umemura, Hidekazu Furuya, Ryo Yanai, Sakiko Isojima, Kuninobu Wakabayashi, Nobuyuki Yajima, Yusuke Miwa and Tsuyoshi Kasama. Showa University School of Med, Shinagawa-ku Tokyo, Japan.

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized byinflammation and joint destruction. Migration of monocytes/macrophages into the synovium is important in a variety of vasculoproliferatine states in RA. A disintegrin and metalloprotease (ADAM) are a family of proteases that are responsible for the liberation of a variety of

types of cell surface expressed proteins. ADAM-17 has been shown to cleave a number of inflammatory mediators from the cell surface including CX3CL1 and CXCL16. In this study, we examined the expression of ADAM-17 in RA and the role it plays ininflammation.

Methods: ADAM-17 expression was determined in serumand synovial fluids from normal (NL) subjects, osteoarthritis (OA) patients and RA patients using enzyme linked immunosorbent assay. We also measured ADAM-17 in RA serum after treatment with tocilizmab (6, 12 and 24 week). To determine whether ADAM17 was expressed by THP-1 cells (human acute monocytic leukemia cell line)and whether it was regulated byphorbol 12-myristate 13-acetate (PMA), quantitative polymerase chain reaction (qPCR) was performed. In order to confirm the role of ADAM-17 in inflammation, we did THP-1 chemotaxis assay. To block the expression of ADAM-17, THP-1cells were transfected with siRNA against ADAM-17. After treatment with ADAM-17 siRNA, THP-1cell chemotaxis assay wasperformed towards RA synovial fluids and monocyte chemotactic protein-1 (MCP-1)/CCL2.

Results: ADAM-17 in RA serum (n=23) was significantly higher than NL serum (n=7) (mean ± SEM RA serum 2093 ± 538 pg/ml and NL serum 0 ± 0pg/ml). ADAM-17 in RA synovial fluids (n=10) was also significantly higher than OA synovial fluids (n=7) (mean ± SEM RA synovial fluids 1645 ± 952 pg/ml and OA synovial fluids 5±4 pg/ml). After treatment with tocilizmab, ADAM-17 in serum was significantly decreased [pre 486 ± 126pg/ml (n=21), 12 week 215 ± 114 (n=15) and 24 week 98 ± 98 (n=12); $p<0.05$ between pre and 12 week, pre and 24 week]. The expression of ADAM-17 messenger RNA (mRNA) in THP-1 cells was induced by stimulation withPMA after 1 hour (2.6 fold increased). ADAM-17 siRNA treated THP-1 cells had decreased migration compared with control siRNA treated THP-1 cells towards RA synovial fluids (6± 2number of cells migrated and 33 ± 12 number of cells migrated, $p<0.05$). ADAM-17 siRNA treated THP-1 cells had also decreased migration compared with control siRNA treated THP-1 cells towards MCP-1/CCL2 (27 ± 4 number of cells migrated and 146 ± 18 number of cells migrated, $p<0.05$).

Conclusion: These data show that ADAM-17 is overexpressed in RA, and is decreased after treatment. ADAM-17 is involved monocyte migration, and this study suggests that ADAM-17 may play a role in RA inflammation. ADAM-17 may be a potential target in inflammatory disease like RA.

Reduction Of Circulating Blood Neutrophils In Mice By Anti-IL-6R Alpha Monoclonal Antibody is Not Due To Apoptosis Or Blockade Of Neutrophil Differentiation. Ludmila Kelly, Vilma Decman and Dimitris Skokos. Regeneron Pharmaceuticals, Inc., Tarrytown, NY.

Background/Purpose: Blockade of IL-6/IL-6Rα signaling is associated with a reduction of circulating neutrophils in the blood of patients treated with anti-IL-6Rα mAb but the mechanism is unknown. Due to the lack of IL-6Rα mAb effect on neutrophils in naïve mice, we established a mouse model of dexamethasone (DEX)-induced neutrophilia to explore the impact of anti-IL-6Rα mAb on neutrophil distribution, differentiation and recovery in vivo.

Methods: Wild type C57Bl/6 or IL-6Rα$^{Hu/Hu}$/IL-6$^{Hu/Hu}$ mice were injected with anti-mouse (REGN844) or anti-human IL-6Rα mAb (REGN88, sarilumab), respectively. DEX was injected 2 hrs after mAb injection to induce a temporary increase of neutrophils in the periphery. Mice were euthanized 4 hrs after DEX injection, and blood, spleen, and bone marrow were evaluated for neutrophil levels by flow cytometry. Neutrophil apoptosis was assessed by active Caspase-3 staining in the above tissues. In another experiment, mice were injected with cyclophosphamide (CTX), resulting in temporary neutropenia. Recovery of neutrophils in peripheral blood in the presence or absence of IL-6Ra mAb was monitored for six days after CPM injection.

Results: Treatment of naïve C57Bl/6 mice with IL-6Rα mAb alone did not affect neutrophil levels in blood, spleen or bone marrow. We found that IL-6Rα mAb reversed the DEX effect in both mouse strains (Figure 1). This reversal was not associated with apoptosis as assayed by active Caspase-3 staining in spleen and bone marrow in C57Bl/6 mice. Furthermore, in IL-6Rα$^{Hu/Hu}$/IL-6$^{Hu/Hu}$ mice treated with CTX, neutrophil numbers in blood recovered to a comparable level in the presence of IL-6Rα mAb or hIgG1 isotype (Figure 2), indicating that differentiation and exit of neutrophils from bone marrow was not affected by IL-6Rα mAb treatment.

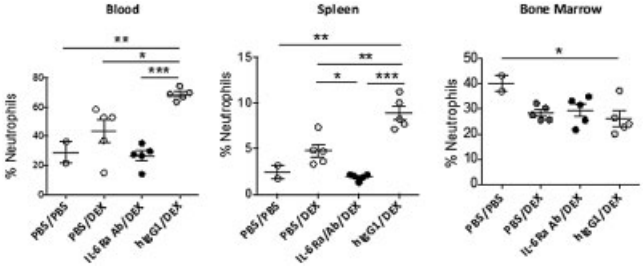

Figure 1. IL-6Ra antibody blocks the dexamethasone-induced neutrophilia in blood and spleen of IL-6$^{Hu/Hu}$/IL-6$^{Hu/Hu}$ humanized mice.

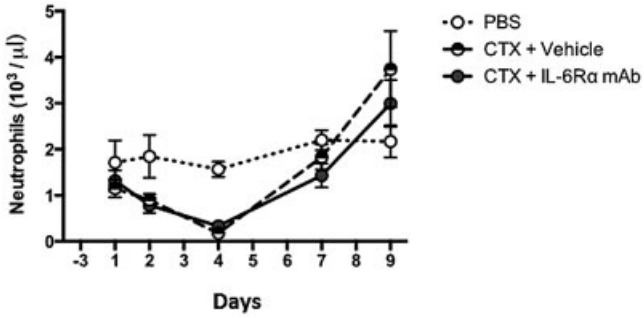

Figure 2. Il-6Rα mAb does not interfere with neutrophil recovery in blood after cyclophosphamide treatment in IL-6$^{Hu/Hu}$/IL-6$^{Hu/Hu}$ humanized mice (p=NS).

Conclusion: In a mouse model of DEX-induced neutrophilia, IL-6Rα mAb treatment negated the DEX effect in both C57Bl/6 and IL-6Rα$^{Hu/Hu}$/IL-6$^{Hu/Hu}$ mice. This effect was not associated with Caspase-3 mediated apoptosis, although alternative apoptotic pathways should be explored. IL-6Rα mAb did not prevent the recovery of neutrophils in blood following CPM treatment. These data suggest that the reduction in circulating neutrophil counts observed with IL-6Rα mAb treatment are not due to effects within the bone marrow and may be due to effects on neutrophil margination.

Novel Function Of Soluble Interleukin-6 Receptor As An Antagonist Of Interleukin-27-Mediated Anti-Inflammatory Responses. Misato Hashizume[1], Keiko Esaki[1], Keiko Yoshimoto[2], Hideto Kameda[2], Tsutomu Takeuchi[2] and Yoshihiro Matsumoto[1]. [1]Chugai Pharmaceutical Co., Ltd., Gotemba, Japan, [2]Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: The immunological roles of interleukin 27 (IL-27) have been reported in various rheumatic diseases, such as rheumatoid arthritis (RA), lupus, systemic sclerosis and psoriasis. The role of IL-27 in the immune response is not fully understood, although pro- and anti-inflammatory responses to IL-27 were reported. IL-27 is a heterodimeric cytokine composed of IL-27p28 and EBI3, which are analogous to IL-6 and soluble IL-6 receptor (sIL-6R) respectively, and exerts its biological activities through binding to IL-27 receptor which is composed of alpha subunit and gp130. Since IL-6 and IL-27 are similar in terms of their structures and the way of signaling pathway, we hypothesized that sIL-6R binds to IL-27. In this study, we investigated a possible role of sIL-6R in regulating IL-27 signaling.

Methods: Surface Plasmon Resonance (SPR) analysis was used to examine the binding of IL-27 to sIL-6R. CD14$^+$ cells were isolated from peripheral blood of RA patients. CD14$^+$ cells were incubated with IL-27, sIL-6R and anti-gp130 antibody for 30 minutes, and the expression of SOCS3, which is a negative regulator of inflammatory cytokine signaling, was measured by western blotting. MCP-1 was measured by ELISA in the culture supernatant of CD14$^+$ cells incubated with M-CSF, TNF-α, IL-27, sIL-6R, anti-IL-6 antibody, anti-IL-6R antibody (tocilizumab) and anti-gp130 antibody. The number of osteoclasts was counted after tartrate-resistant acid phosphatase staining in CD14$^+$cells cultured with RANKL and M-CSF in the presence of IL-27, sIL-6R and tocilizumab for 4 days.

Results: SPR analysis showed that binding curves were generated from experiments in which IL-27 was exposed to a high-density of sIL-6R coated on a sensor chip, showing that IL-27 bound to sIL-6R. IL-27 induced the expression of SOCS3 in $CD14^+$ cells, which was suppressed by the addition of sIL-6R to the culture. Neutralizing antibody to gp130O'Dell JR et al. Mir-34a In Rheumatoid Arthritis: Characterisation Of Elevated Synovial Expression and Association With Treatment Resistance. Clare E Tange[1], Stefano Alivernini[2], Derek S. Gilchrist[1], Lynn Crawford[1], Ashleigh-Ann Rainey[1], Derek Baxter[1], Iain B. Mcinnes[1] and Mariola Kurowska-Stolarska[1]. [1]University of Glasgow, Glasgow, United Kingdom, [2]Division of Rheumatology, Institute of Rheumatology and Affine Sciences, Catholic University of the Sacred Heart, Rome, Italy.

Background/Purpose: Cells of the monocyte/macrophage lineage are critical to RA pathogenesis: unravelling mechanisms underlying macrophage inflammatory gene expression should elucidate novel disease-associated pathways and thereby biomarkers and therapeutic targets. MicroRNA (miR) comprise small, non-coding RNA species that are key regulators of mammalian gene expression. We sought to define the expression and regulation of novel miR species that regulate RA macrophage biology.

Methods: Blood (PB; healthy controls & RA patients with defined treatment characteristics) or synovial fluid (SF; RA) CD14+ cells were purified using histopaque centrifugation & autoMACS bead separation. $CD14^+$ cells were matured with M-CSF or GM-CSF for up to 7 days, or stimulated with various TLR ligands. For T cell -macrophage interaction, $CD4^+$ T cells were cultured with TNF, IL-2, IL-6, prior to 24hr co-culture with M-CSF-matured $CD14^+$ cells. miR expression and copy number was variously quantified in cells or tissues via TLDA, validatory qPCR & *in situ* hybridisation with specific primers and DIG or FITC labelled probes, respectively.

Results: Prior TLDA elicited several dysregulated miRs in RA SF compared to PB $CD14^+$ cells, including miR-34a. Fold change and copy number PCR assays confirmed elevated miR-34a in RA SF cells ($n=10$; $p<0.01$). Crucially miR-34a was also elevated in PB $CD14^+$ cells from biologic-resistant RA patients compared to cDMARD good responders or matched healthy controls ($n=19$–30), associating miR-34a expression with chronic, treatment-resistance. miR-34a expression correlated with disease activity assessed by swollen joint count. *In situ* hybridisation demonstrated elevated miR-34a expression in RA compared with non-inflammatory and inflammatory OA synovial tissues ($n=6$); double fluorescent staining confirmed expression in lining and sub-lining layer CD68+ macrophages, plus adjacent cells of FLS morphology. miR-34a was rapidly upregulated during monocyte maturation induced by adherence, M-CSF or GM-CSF, but was not further enhanced by addition of TLR ligands (LPS, CLO97, PAM3, PolyIC, CpG). Similarly co-culture with RA derived SF (10%) enhanced miR-34a expression in monocytes. Finally, cognate interactions between CD4+ T cells and macrophages further enhanced miR-34a expression in the latter cells.

Conclusion: miR-34a expression is elevated in RA SF macrophages and in PB monocytes of treatment resistant RA patients where it correlates with clinical disease activity measures. miR-34a is upregulated by the maturation rich synovial microenvironment and by interactions with activated T cells. Putative miR-34a molecular targets include NOTCH1 rendering it a plausible novel immune regulator in synovitis.

CXCL13 Is a Marker Of Joint Involvement In Early Rheumatoid Arthritis. Stinne Greisen[1], Tue Rasmussen[1], Karen Schelde[1], Kristian Stengaard-Pedersen[2], Merete Lund Hetland[3], Kim Hørslev-Petersen[4], Bent Deleuran[5] and Malene Hvid[1]. [1]Aarhus University, Aarhus, Denmark, [2]Arhus University Hospital, Aarhus, Denmark, [3]The Danish Rheumatologic Database (DANBIO), Glostrup Hospital., Copenhagen, Denmark, [4]University of Southern Denmark, Graasten, Denmark, [5]Aarhus University Hospital, Aarhus, Denmark.

Background/Purpose: CXCL13 is central in the formation of lymphoid follicles in secondary and tertiary lymphoid tissue. It attracts CXCR5-expressing B cells and follicular helper T cells (T_{FH}). CXCL13 has previously been associated with disease in RA. We examined the role of CXCL13 and CXCR5 in early rheumatoid arthritis (eRA) and in a murine collagen induced arthritis (CIA) model.

Methods: CXCL13 was measured by ELISA in plasma from 76 treatment naïve eRA patients (disease $<$ 3 month), at baseline and after 6 months of treatment. Treatment was methotrexate (MTX) ($n=39$) or MTX + Adalimumab (ADA) ($n=37$). Clinical disease was assessed by: DAS28, VAS, CRP, no. of swollen joints (SJ28+40), SDAI, IgM-RF and ACPA. Healthy volunteers (HV) ($n=38$) were age and gender matched with eRA patients. Negative selected CD14+ cells from healthy blood donor buffy coats were cultured with GM-CSF (100 ng/ml) and IL-4 (40 ng/ml) to acquire monocyte derived dendritic cells (Mo-DC). At day 6 Mo-DC were stimulated with: LPS, CD40L, IL-21, TGFb, PD-1, CXCL13, OX40, TNFa, IL-22, LIGHT etc. Up regulation of CXCL13 and CXCR5 mRNA was evaluated by PCR with GAPDH as reference. CIA was induced in DBA/1 mice. Arthritis was scored according to the Mean Arthritis Score (MAS). Adoptive transfer was done with CXCR5+/− splenocytes from CIA mice to healthy DBA/1 mice, boosted with incomplete Freunds adjuvant. Mice were sacrificed at day 48, and paws embedded in paraffin were stained. Statistical correlations were assessed by Spearman's rho. Data are expressed as median (IQR).

Results: Treatment reduced CXCL13 plasma levels by 30% (baseline: 149.3 pg/ml (74.8 pg/ml–245.0 pg/ml vs. 6 months: 48.1 pg/ml (26.9 pg/ml–93.0 pg/ml), $p<0.001$). At 6 months CXCL13 levels were similar to levels observed in HV (50.3 pg/ml (29.2 pg/ml–92.7 pg/ml), $p=0.99$). Patients in the MTX group had 50% reduction in plasma CXCL13 compared with ADA ($p=0.015$). We observed correlation with baseline CXCL13 and disease parameters in both groups (VAS, SDAI and SJ28+40 (all $r=0.3$–0.4, all $p<0.05$)). CXCL13 mRNA expression in Mo-DC was only up regulated by TNFa, LIGHT and IL-22, whereas CXCR5 also was up regulated by PD-1 and CXCL13. Adoptive transfer of CXCR5+ splenocytes from CIA mice resulted in a more severe inflammation and cartilage destruction, compared with CXCR5- and total splenocytes. Adoptive transfer of similar cell types from healthy mice did not result in arthritis development in the recipient mice.

Conclusion: CXCL13 plasma levels were significantly elevated in eRA patients and decreased to levels comparable with HV within 6 months of treatment. Treatment with ADA resulted in a more prominent decrease in CXCL13 levels, supporting a close connection between TNF a inhibition and CXCL13 production, also supported by CXCL13 up regulation by TNFa. CXCL13 serves as a prominent marker of joint involvement, evaluated by the close association with number of swollen joints and the VAS score. The high degree of joint inflammation and destruction in mice receiving CXCR5+ cells, points to a memory development within this cellular subset, and considering the upregulation of CXCR5 by TNFa and CXCL13 the importance of these two chemokines in joint involvement is supported.

Synergism Between Granulocyte-Macrophage Colony Stimulating Factor and Interleukin-17 Causes Joint Damage Via The Production Of Interleukin-23, Receptor Activator Of NF-κB Ligand and S100A8. Annemarie E.M. Van Nieuwenhuijze[1], Fons A.J. Van de Loo[2], Birgitte Walgreen[1], Miranda B. Bennink[2], Monique M. Helsen[1], Liduine Van den Bersselaar[1], Ian P. Wicks[3], Wim B. Van den Berg[4] and Marije I. Koenders[4]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]Walter & Eliza Hall Institute of Medical Research, Melbourne, Australia, [4]Rheumatology Research and Advanced Therapeutics, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.

Background/Purpose: T helper-17 (Th17) cells are important mediators of inflammatory diseases, and are the main pathogenic cell type in many animal models of autoimmunity. Recent studies highlight a surprising role for T-cell derived granulocyte-macrophage colony stimulating factor (GM-CSF) in the pathogenicity of Th17 cells. We examined the mechanism by which interleukin 17 (IL-17) and GM-CSF contribute to cartilage- and bone damage of synovial joints during experimental arthritis, and provide a rationale for combination therapy in auto-inflammatory conditions.

Methods: Collagen-induced arthritis was elicited in DBA/1J mice. Neutralizing antibodies to IL-17 and/or GM-CSF were administered after onset of disease for 14 days. Arthritis progression was followed by macroscopic scoring of the paws (maximum score of 12 per mouse). In addition, the effect of local over-expression of IL-17 and/or GM-CSF was studied by adenoviral transfection in naïve knee joints. Knee- and ankle joints, synovial tissue and serum from both experiments were analyzed in detail for the presence of cytokines, chemokines, and matrix metalloproteinases (MMPs). Cartilage- and bone damage was determined by histological analysis.

Results: Combined therapeutic treatment of mice during arthritis ameliorated disease progression. Macroscopic joint inflammation was significantly reduced, from a total score of 5.6 ± 0.4 for mice treated with isotype control antibodies to 2 ± 0.6 for mice treated with combination therapy. Treatment with anti-IL-17 or anti-GM-CSF alone resulted in scores of 3.4 ± 0.5 and 3.5 ± 0.4, respectively. Anti-IL-17 specifically reduced the transcription of IL-23 in the synovium, whereas anti-GM-CSF inhibited production of MMPs, Receptor Activator of NF-κB Ligand (RANKL), and monocyte-chemotactic protein-1 (MCP-1, CCL2). Serum IL-6 was reduced in all treatment groups compared to control mice. To provide further insight in local additive or synergistic effects of IL-17 and GM-CSF, overexpression of IL-17, GM-CSF or the combination was achieved with adenoviral vectors. Inflammatory infiltrate and cartilage- and bone damage developed in all groups from day 1 after adenoviral transfer, with the most severe effect observed in the combination group. On day 7, partial destruction of joint architecture was apparent in knee joints after combined overexpression of IL-17 and GM-CSF. Overexpression of IL-17 alone caused a specific increase in synovial IL-6 production. Overexpression of GM-CSF alone induced IL-1β, S100A8 and MMP13 in synoviocytes. A strong synergistic effect of combined overexpression was seen on the production of the endogenous damage-associated molecular patterns (DAMP) ligand S100A8, the osteoclast activator RANKL and the Th17 differentiation factor IL-23.

Conclusion: We show that IL-17 and GM-CSF cause joint damage through synergistic effects on inflammatory mediators in synovial joints. In view of the moderate success of therapeutic IL-17 or GM-CSF blockade in rheumatoid arthritis, combined inhibition of IL-17 and GM-CSF might be an option for patients that do not fully respond to inhibition of the separate cytokines.

Mir-125a: A Novel Regulator Of IL-6 and TLR Driven Pathways In RA Pathogenesis. Ashleigh-Ann Rainey, Derek S. Gilchrist, Clare E Tange, Marina Frleta, Lynn Crawford, Derek Baxter, Iain B. Mcinnes and Mariola Kurowska-Stolarska. University of Glasgow, Glasgow, United Kingdom.

Background/Purpose: Molecular mechanisms driving disease initiation and chronicity in RA are incompletely understood. There is increasing interest in the role played therein by microRNAs–small RNA species that mediate post-transcriptional regulation of integrated pathways in mammalian cells. We recently profiled miRs in RA synovial fluid (SF) CD14+ macrophages in comparison to peripheral blood (PB) monocytes and identified dysregulation of miR-125a, which has not previously been associated with RA pathophysiology. Herein we aimed to characterise its expression and functional significance.

Methods: Matched PB & SF CD14+ cells were isolated from RA patients (n=10). Additional PB samples were obtained from RA DMARD good responders (n=17), recurrent non-responders (n=11) and matched healthy controls (n=17). Primary human monocytes and THP-1 cells were stimulated with TLR ligands (LPS, PAM3, PolyIC, CLO97) and differentiated using M-CSF or GM-CSF for up to 7 days. Copy number of miR-125a was evaluated using qPCR. Targeted pathways were identified using prediction algorithms (e.g. TargetScan) and transcriptional profiling of SF CD14+ cells. Direct molecular interactions were confirmed using luciferase reporters. miR-125a or control mimic were transfected into THP-1 cells and IL-6R expression was evaluated by flow cytometry.

Results: miR-125a was up-regulated in RA SF CD14+ macrophages compared to PB controls ($p=0.002$). Moreover, miR-125a was up-regulated in RA PB CD14+ monocytes compared with healthy controls, regardless of DMARD response status ($p<0.02$). Copy number of miR-125a in resting control PB monocytes was low. Extensive activation profiling revealed M-CSF, GM-CSF & 10% RA SF all induced miR125a expression at discrete time-points between 24h & 7ds. Of TLR ligands tested, only TLR4 agonism increased miR125a. Prediction algorithms identified members of the IL-6 signalling pathway (IL-6R, gp130) as potential targets of miR-125a. Luciferase reporter assays thereafter confirmed functional target interactions. Transfection of THP-1 cells with miR-125a but not control mimic reduced IL-6R membrane expression measured by FACS. miR-125a also targeted the negative regulators of TLR signalling, TNFAIP3 and IRF4, assessed by TargetScan and luciferase reporter. Commensurate with this IRF4 was down-regulated in RA PB monocytes (both DMARD good & recurrent non-responders) compared to healthy donors.

Conclusion: Inflammatory cytokines, maturation factors and articular DAMPs drive elevated miR-125a expression in monocyte/macrophage lineages. miR-125a, in turn represents a novel molecular pathway that cross regulates IL-6R and TLR pathway activation in RA macrophages. We conclude that miR-125a represents an intriguing molecular marker with therapeutic and biomarker potential.

945

Non-Canonical NF-Kappa B Signaling Enhances Angiogenesis In a Novel 3D Spheroid Model Of Rheumatoid Arthritis Synovial Inflammation. Chrissta X. Maracle, Ae-Ri Noort, Katinka P.M. van Zoest and Sander W. Tas. Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.

Background/Purpose: Angiogenesis plays a crucial role in rheumatoid arthritis (RA) synovitis and is regarded as a switch from acute to chronic inflammation. Previously, we have demonstrated that NF-kappaB inducing kinase (NIK) mediated non-canonical NF-kappaB signaling contributes to pathological angiogenesis in endothelial cells (EC). However, many of the current *in vitro* models of angiogenesis focus solely on EC and do not include interactions with other cell types. RA synovial fibroblasts (RASF) are important contributors to angiogenesis in synovial inflammation, and thus a model including both RASF and EC would more accurately represent the pathophysiology of RA angiogenesis.

Objective: To develop better *in vitro* models to study the interaction between RASF and EC and to further delineate the role of the non-canonical NF-kappaB pathway in pathological angiogenesis.

Methods: First, we utilized a 2 dimensional (2D) model to evaluate the effects of non-canonical NF-kappaB signaling on angiogenesis. RASF and human umbilical cord EC (HUVEC) were co-cultured in the presence or absence of lymphotoxin (LT), LIGHT, or growth factors (bFGF/VEGF). EC were visualized through immunohistochemical staining of CD31, which was semi-quantitatively scored. Next, we developed a novel 3 dimensional (3D) model in which HUVEC and RASF were labeled with green or orange cell tracker dye, respectively, and incubated overnight to form spheroids. Subsequently, the spheroids were harvested and plated in a collagen solution, and medium with or without LT, LIGHT or growth factors (bFGF/VEGF) was added. After 48 hours, spheroids were fixed and imaged through confocal

microscopy. Cumulative EC sprout length and the number of sprouts was quantified using Leica QWin Plus software.

Results: The 2D culture model revealed an increase in CD31 positive area under all stimulation conditions, with LIGHT inducing almost a 2-fold increase ($p<0.05$). Confocal analysis of the 3D model showed that spheroids containing HUVEC and RASF formed sprouts under all conditions and that LT and LIGHT caused significant increases ($p<0.05$) in cumulative sprout length. Interestingly, the total number of sprouts formed by each spheroid also increased significantly. Preliminary results indicate that siRNA-mediated knock-down of NIK in EC leads to a clear reduction in cumulative sprout length, as well as in total sprout numbers.

Conclusion: Both the 2D and 3D model demonstrate that activation of the non-canonical NF-kappaB pathway via LT and LIGHT enhances angiogenesis. However, in contrast to the 2D model, the 3D model allows visualization of actual blood vessel formation. Importantly, preliminary results demonstrate that the observed increase in angiogenesis is at least in part NIK-dependent. This suggests that NIK may be a novel therapeutic target to block pathological angiogenesis in RA, thereby halting disease progression. Of interest, it is also possible to incorporate immune cells in the 3D model to study their contributions to pathological angiogenesis in RA synovial inflammation, which makes this a valuable tool for future studies.

Interleukin-34 Regulates Angiogenesis and Cell Proliferation In Inflammatory Arthritis, This Effect Is Potentiated By Hypoxia. Emese Balogh[1], Mary Connolly[1], Monika Biniecka[1], Jennifer McCormick[2], Douglas J. Veale[2] and Ursula Fearon[2]. [1]Translation Research Group, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]St. Vincent's University Hospital, Dublin 4, Ireland.

Background/Purpose: Interleukin-34 (IL-34) is a cytokine implicated in macrophage differentiation, angiogenesis and osteoclastogenesis in inflammatory arthritis (IA). IA is characterized by synovial hypoxia, increased oxidative stress and altered angiogenesis. Our objectives was to investigate the role of IL-34 in the regulation of angiogenesis and hypoxia in IA.

Methods: Patients with active IA (RA n=18; PsA n=5) were recruited and underwent knee arthroscopies with a subgroup of (n=6) pre-post TNF-inhibitoric (TNFi) therapy investigations. Synovial tissue (ST) was collected and *in vivo*ST oxygen levels (tpO2) were measured. Synovial IL-34 expression was assessed by immunohistology (IHC) compared to control synovium. IL-34 expression was correlated to angiogenic marker (VEGF, Ang-2, Tie-2) expressions and proliferation marker expression (Ki67). Colocalisation of IL-34 with actin and vimentin was examined by dual-immunofluorescence (IF). IA fibroblast-like synoviocytes (IAFSCs, n=8) and human microvascular endothelial cells (HMVECs) were stimulated with IL-34 under normoxia and 3% hypoxia, then proliferation and tube formation assays were performed. IL-34 induced IASFC VEGF expression was measured by ELISA. Baseline mRNA levels of IASFCs were compared to osteoarthritic fibroblasts (OASFCs) by RT-PCR and followed up after TNFα stimulation. The effect of IL-34 on matrix metalloproteinase expression (MMP-2, MMP-9) was examined by zymography, IL-34 induced mononuclear cell (PBMC) adhesion to HMVECs was examined by adhesion assay.

Results: The baseline mean tpO_2 level was hypoxic at 25.94 mmHg (3.3%). IL-34 expression was observed through the synovium with higher expression in the vascular (VC) regions compared to the lining (LL) and sub-lining (SL). Expression levels were higher in any layers than in the healthy synovium ($p<0.05$). Synovial IL-34 expression correlated with VEGF ($r=0.60$, $p=0.011$), Tie2 ($r=0.50$, $p=0.021$), Ang2 ($r=0.70$, $p=0.013$) and Ki67 ($r=0.56$, $p=0.025$) and with macroscopic vascularity ($r=0.47$, $p=0.043$). Posttherapeuthic synovial IL-34 expression significantly decreased in SL and VC layers ($p=0.039$, $p=0.026$) with a simultaneous tpO_2increase from 20.9 to 23.2 mmHg. Baseline synovial IL-34 expression showed colocalisation with actin and vimentin. Basal IL-34 mRNA expression was higher in IASFCs than in OASFCs ($p<0.05$), the previous one was further potentiated by TNFα stimulation ($p<0.05$). IL-34 induced IASFC proliferation and HMVEC tube formation (all $p<0.05$), this effect was potentiated by 3% hypoxia ($p<0.05$). Furthermore IL-34 induced VEGF expression in IASFCs and stimulated PBMC adhesion to HMVECs as well as facilitated MMP-2 and MMP-9 expression in vitro.

Conclusion: IL-34 is strongly associated with synovial inflammation and promotes synovial angiogenesis and cell proliferation, an effect that is potentiated by hypoxia.

The Interleukin 33/miR29 Axis Regulates Differential Collagen Production In Tendinopathy. Dr Neal L Millar[1], Derek S. Gilchrist[1], Mariola Kurowska-Stolarska[2], Prof George AC Murrell[3] and Prof Iain B. McInnes[1]. [1]University of Glasgow, Glasgow, United Kingdom, [2]Institute of Infection, Immunity and Inflammation, College of Medical, Veterinary and Life Sciences University of Glasgow, Glasgow, United Kingdom, [3]Orthopaedic Research Institute, Sydney, Australia.

Background/Purpose: Tendon disorders comprise the commonest musculoskeletal clinical presentation and accordingly represent a significant unmet clinical need in rheumatology. Recent animal and human studies have highlighted a central role for inflammation and subsequent matrix remodeling in tendon pathophysiology. Interleukin-33 (IL-33) acting via its receptor ST2 is increasingly recognized as a critical endogenous tissue danger signal that can initiate inflammation.

We investigated the role of the IL-33/ST2 signaling pathway on tendon pathology in animal and human models of tendinopathy.

Methods: Fifteen torn supraspinatus tendon (established pathology) and matched intact subscapularis tendon (representing 'early pathology') biopsies were collected from patients undergoing arthroscopic shoulder surgery. Human tendon-derived primary cells were derived from hamstring tendon tissue obtained during hamstring tendon ACL reconstruction. The impact of microRNA 29 upon tenocyte biology ex vivo was measured using quantitative RT-PCR, collagen I/III ELISAs and luminex cytokine multiplexes.

Results: We show here that human and mouse tendons over express IL-33 when damaged, and drives tenocytes to undergo an early switch in collagen matrix production toward a collagen III phenotype. Moreover, administration of rh IL-33 in an in vivo model of tendinopathy results in reduced biomechanical tendon strength at early time points while neutralizing antibodies to IL-33 attenuates these changes. Furthermore we highlight a key regulatory role for the microRNA29 family in IL-33 induced collagen matrix changes through direct targeting of the soluble ST2 receptor and Collagen III. In particular we show that miR29a selectively targets Collagen III through distal polyadenylation sites.

Conclusion: For the first time we provide evidence that IL-33/miR-29 pathway orchestrates inflammatory and matrix responses following tissue injury, and thus may offer future strategies to treat tendon diseases.

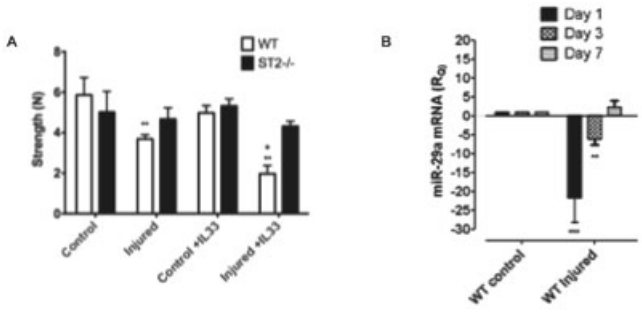

Figure 1. (A) rhIL-33 results in a significantly decreased load to failure in WT uninjured mice on Days 1 and 3 of the treatment protocol. More significantly WT injured mice had 45% less load to failure if treated with rhIL-33 on days 3 post injury with a 20% decrease in strength at 21 post injury compared to PBS injection alone. (B) miR29a levels in WT versus WT injured mice showing significant down regulation at early time points post injury which mirrored over expression of the IL33/ST2 axis.

Dual Neutralization Of TNF and IL-17 Provides Greater Efficacy In Collagen Induced Arthritis Through Regulation Of a Gene Transcription Program That Includes CXCL1 and CXCL5. Carolyn Cuff[1], Chung-Ming Hsieh[1], Suzanne Mathieu[1], Anwar Murtaza[2], Margaret Hugunin[1], Shaughn Bryant[1], Robert O'brien[1], Lisa Olson[1] and Jeffrey Voss[1]. [1]AbbVie Pharmaceuticals, Worcester, MA, [2]Broad Institute, Cambridge, MA.

Background/Purpose: Dual neutralization of TNF and IL-17 is hypothesized to provide greater efficacy in rheumatoid arthritis (RA) and inflammatory diseases compared to either monotherapy as these cytokines cooperatively up-regulate cytokines and metalloproteinases. Moreover, dual blockade has been reported to provide greater efficacy in mouse collagen induced arthritis (CIA) compared to either monotherapy. To better understand the mechanism of this apparent cooperativity, we conducted a series of experiments utilizing the mouse CIA model.

Methods: CIA was induced in DBA/1 mice according to standard method and animals were treated with vehicle, anti-TNF antibody (8C11, 12 mg/kg), anti-IL-17 (MAB421, 12 mg/kg), or both antibodies twice a week for 3 weeks beginning at the onset of disease. Affymetrix gene chips were used to measure RNA expression in the paw. PCR was used to analyze chemokine expression in fibroblast like synoviocyte (FLS) culture. ELISA and MSD were utilized to measure chemokines in paw homogenate on day 7 of disease.

Results: Neutralization of mouse TNF or IL-17 alone with antibodies resulted in a significant but partial inhibition of arthritic score (36% and 43% inhibition, respectively, $p < 0.05$). However, when the 2 cytokines were neutralized by administration of anti-TNF and anti-IL-17 mAbs, arthritic score was significantly reduced to a greater extent (60%; $p < 0.05$). Combination treatment was also more effective at preventing bone destruction vs anti-TNF alone as determined by micro-CT analysis (80% vs 42%, $p < 0.05$). Microarray analysis of paw RNA from mono or dual cytokine inhibition identified pathways that could account for the enhanced efficacy. Consistent with cooperative gene regulation observed in vitro, these data demonstrated that combination treatment regulated a unique subset of disease related genes that were not regulated by monotherapy. Among other molecules, the protein level of the chemokines CXCL1 and CXCL5 were inhibited in paw homogenates by the combination treatment (73% and 70% respectively, $p < 0.05$) whereas monotherapies had little effect. TNF and IL-17 concordantly regulated CXCL1 and CXCL5 mRNA expression in both mouse and human FLS cultures, indicating the cooperative regulation of mediators of arthritis by TNF and IL-17 may translate to human tissues.

Conclusion: These data provide a mechanistic basis for the increased efficacy achieved by dual blockade of TNF and IL-17 in mouse CIA and support the rationale for testing dual TNF/IL-17 blockade in the treatment of RA.

Targeting CD1c-Expressing Mdcs To Inhibit Tcell Activation and Thymus and Activation Regulated Chemokine (TARC)-Dependent Chemotaxis In RA. M.R. Hillen, F.M. Moret, F.P.J.G. Lafeber, C.E. Hack, T.R.D.J. Radstake and J.A.G. van Roon. University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Recently, we demonstrated strong Th1 and Th17 cytokine induction by $CD1c^+$ myeloid dendritic cells (mDCs) from synovial fluid and identified thymic stromal lympopoeitin (TSLP) as an important activator of these cells. CD1c-expressing mDCs and CD4 T cells are potent producers of Thymus and activation regulated chemokine (TARC), which is a chemotactic factor that attracts cells expressing CCR4, including CD4 T cells with Th2, Th17 and Treg phenotypes. TARC is known as a critical mediator in atopic diseases but is also present at sites of inflammation in autoimmune diseases. In synovial fluid (SF) of rheumatoid arthritis (RA) patients CCR4 is expressed on Th17 cells and mast cells that together are indicated to make up most IL-17 producing cells, suggesting that TARC plays an important role in attraction of IL-17 producing cells to the synovium. In addition, TARC can attract mDCs and fibroblasts. This study aimed to investigate if TARC is associated with RA pathogenesis and whether depletion of CD1c mDCs prevents production of high TARC concentrations.

Methods: TARC ELISA was performed on SF of 100 RA and 50 OA patients. Mononuclear cells (MC) were isolated from the blood of healthy controls (HC) and blood or SF of RA patients and juvenile idiopathic arthritis (JIA) patients. CD1c mDCs were isolated with MACS and stimulated with TSLP for 24 hours and TARC levels were measured in supernatants. Alternatively, CD1c-expressing cells were depleted from MC using MACS and TARC levels were measured upon stimulation with TSLP or IL-7.

Results: SF from RA patients contained significantly higher concentrations of TARC as compared to SF from OA patients (78.9 vs 9.2 pg/mL, $p<0.0001$). Isolated CD1c mDCs from the synovial fluid of RA patients produced TARC directly *ex vivo* and produced significantly higher TARC levels compared to paired mDCs from the blood (26.4 vs 1.2 pg/mL, $p<0.01$). CD1c mDCs and SFMCs from RA and JIA patients produced more TARC compared to paired PB counterparts when stimulated with TSLP (926 vs 128 pg/mL, $p<0.01$) (or IL-7, $p<0.01$). Moreover, depletion of CD1c cells from MC significantly reduced TARC production induced by stimulation with TSLP (mean inhibition 61%, $p=0.004$).

Conclusion: Increased TARC levels correlate with the percentages of CD1c-expressing mDCs present in RA SF; these mDCs produce enhanced TARC levels directly *ex vivo* and production is increased upon stimulation with TSLP. TARC production is markedly decreased when CD1c cells are depleted. Considering the strong potential of SF $CD1c^+$ mDCs to activate CD4 T cells and to induce Th1 and Th17 cytokine secretion as well as the potent attraction of a range of inflammatory cells by TARC, targeting CD1c mDCs could be a novel therapeutic approach in RA.

Changes In Circulating Visfatin Levels By Different Anti-Rheumatic Treatments: A Comparison Among Synthetic Disease Modifying Anti-Rheumatic Drugs, Tumor Necrosis Factor Blockade and B-Cell Depletion For Rheumatoid Arthritis. Hana Hulejová[1], Markéta Kuklová[2], Herman F. Mann[3], Mária Filková[4], Olga Kryštufková[5], Karel Pavelka[6], Ondrej Sglunda[4], Jiri Vencovsky[1] and Ladislav Senolt[1]. [1]Institute of Rheumatology, Prague, Czech Republic, [2]Institute of Rheumatology, Department of Experimental Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [3]Institute of Rheumatology, Prague, Prague, Czech Republic, [4]Institute of Rheumatology and Department of Rheumatology of the First Faculty of Medicine, Charles University in Prague, Czech Republic, Prague, Czech Republic, [5]Institute of Rheumatology, and Dept. of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, Prague, Czech Republic, [6]Department of Clinical and Experimental Rheumatology, Charles University, Prague, Czech Republic.

Background/Purpose: Visfatin is an insulin mimetic adipokine that has been originally described as a pre-B cell colony-enhancing factor. Association between elevated visfatin levels, disease activity and radiographic disease progression in rheumatoid arthritis (RA) were demonstrated, although the data are not consistent. The aim of this study is to investigate whether serum visfatin levels are affected by different treatments in various stages of RA.

Methods: Serum visfatin levels were determined by ELISA assay in patients with early RA (n=40) starting synthetic disease modifying anti-rheumatic drugs (DMARDs), in patients with established RA starting biologic DMARDs-adalimumab (n = 70) or rituximab (n = 31). Early RA was characterized as symptom duration £ 6 months. Fasting blood samples were collected from all patients at baseline and after three months of treatment. Visfatin levels were also evaluated in healthy controls (n=44). Disease activity was assessed based on DAS28 score. Serum levels of C-reactive protein (CRP), rheumatoid factors and anti-cyclic citrullinated peptides (anti-CCP) were measured.

Results: Baseline levels of visfatin were higher in patients with RA compared with healthy controls and correlated positively with CRP levels ($r = 0.456$, $p = 0.003$) and DAS28 ($r = 0.383$, $p = 0.015$) in patients with early RA, but not in patients with established disease. In addition, serum levels of visfatin significantly decreased after 3 months of treatment in patients with early RA (from 1.92 ± 1.17 to 0.99 ± 0.67 ng/ml; $p<0.0001$). Accordingly, in patients with established disease, treatment with adalimumab resulted in significant decrease of serum visfatin levels (from 2.27 ± 2.02 to 1.77 ± 1.66, $p < 0.05$), and treatment with rituximab resulted in significant decrease of serum visfatin levels (from 1.92 ± 1.66 to 0.94 ± 0.70, $p < 0.005$). The change of visfatin levels correlated positively with the change of CRP ($r = 0.393$, $p = 0.013$) and DAS28 ($r = 0.425$, $p = 0.007$) between baseline and 3 months in patients with early RA.

Conclusion: This study shows for the first time that circulating visfatin levels are decreased following synthetic as well as biologic DMARDs in various stages of RA; however, circulating visfatin is associated with disease activity only at early phase of the disease.

The Anti-IL-17A Monoclonal Antibody Secukinumab (AIN457) Inhibits Pro-Inflammatory Mediator Release From Human Primary Synoviocytes Costimulated With IL-17 and TNF. Christine Huppertz, Marija Curcic Djuric, Robert Hennze and Frank Kolbinger. Autoimmunity, Transplantation and Inflammatory Disease, Novartis Institutes for BioMedical Research, Novartis Pharma AG, Basel, SWITZERLAND, Basel, Switzerland.

Background/Purpose: Fibroblast-like synoviocytes (FLS) are targets of the pro-inflammatory IL-17 cytokines and a major source of inflammatory mediators in the inflamed synovium in rheumatoid arthritis (RA). We have determined the activity of IL-17A and IL-17AF (the heterodimer of IL-17A and IL-17F) to augment the effects of TNF or IL-1β on FLS derived from RA patients (RA-FLS) as described in a separate study. Since the newly developed anti-IL-17A antibody secukinumab has shown promise in various clinical trials including RA, we provide here further evidence how it interferes with IL-17 pathways by investigating the in vitro neutralizing activity of secukinumab on the release of key pro-inflammatory FLS products upon costimulation with TNF combined with IL-17A or IL-17AF and upon costimulation with IL-1β and IL-17A.

Methods: RA-FLS were stimulated for 18h with IL-1β (300 pM) combined with IL-17A, or with TNF (60 pM) combined with either IL-17A (30 pM) or IL-17AF (1 nM). Secukinumab or control antibody was given shortly before cytokine stimulation of RA-FLS. The release of IL-6, IL-8, CXCL-1 and CCL2 was determined by homogeneous time resolved fluorescence technology or AlphaLISA. RA-FLS cell lines were obtained from Cell Application Inc.

Results: While IL-17A was weak as a single stimulus, co-stimulation of primary human RA-FLS with IL-17A and TNF synergistically potentiated the effect of TNF on the release of the pro-inflammatory cytokines IL-6, IL-8 and CXCL-1 (Gro-α). Interestingly, CCL2 (MCP-1) release was not potentiated but was only dependent on TNF, indicating a different mechanism or regulation of this chemokine. Secukinumab potently inhibited the potentiated release of IL-6 induced by IL-17A/TNF costimulation at picomolar concentrations with an IC50 value of 0.14 $\pm$ 0.02 nM, but had no effect on basal TNF-induced release of IL-6. Similar results were obtained for the inhibition of IL-8 and CXCL-1 release. CCL2 release was not attenuated by secukinumab, which is in line with CCL2's dependency on the TNF pathway. As we had observed a lower potency of IL-17AF compared to IL-17A to co-stimulate mediator release, IL-17AF was administered at 34 higher concentrations to induce similar maximum IL-6 levels. The effect of secukinumab on IL-17AF/TNF stimulated mediator release were similar to those observed for IL-17A but were less potent, consistent with the lower binding affinity of secukinumab to IL-17AF and the higher IL-17AF cytokine levels required in the in vitro experiment. Combination of IL-1β with IL-17A showed no potentiating effect on pro-inflammatory cytokines. In line with this, there was no significant effect of secukinumab on mediator release from IL-17/IL-1β co-stimulated FLS.

Conclusion: The data show that secukinumab completely neutralizes the amplifying effect of IL-17 on TNF-stimulated RA synovial fibroblasts, one of the key target cells in rheumatoid arthritis. It is anticipated that this blockade contributes to the therapeutic effect of secukinumab seen in RA clinical trials.

CX3CR1 Deficiency Attenuates Imiquimod-Induced Psoriasis-Like Skin Inflammation By Predominant Infiltration Of M2 Macrophages. Sohshi Morimura, Makoto Sugaya and Shinichi Sato. The University of Tokyo, Tokyo, Japan.

Background/Purpose: CX3C chemokine receptor 1 (CX3CR1), a receptor for CX3CL1, has been identified as a key mediator of macrophage migration into injured tissue or inflammation sites. It has recently been reported that serum CX3CL1 levels were significantly elevated in patients with rheumatoid arthritis (RA). Psoriasis is a common skin condition that causes skin redness and irritation. Some patients with psoriasis suffer from arthritis, which is clinically similar to RA, suggesting that both psoriatic arthritis and RA *have* the same *underlying* immunological cause. Thus, we hypothesized that CX3CL1 and CX3CR1 also play important roles in the development of psoriasis. To elucidate the role of CX3CL1 and CX3CR1 in a mouse model of psoriasis, psoriasiform skin inflammation triggered by topical application of imiquimod, an agonist of Toll-like receptor (TLR) 7, was assessed in CX3CR1-deficinet mice and wild-type (WT) mice.

Methods: CX3CR1$^{-/-}$ and WT mice received a daily topical dose of 62.5 mg imiquimod cream (5%) on a shaved back and ears for 6 consecutive days. Erythema, scaling, and skin thickness were independently scored every day. Total RNA was isolated from ears 24 and 48 hours after the start of topical application and mRNA expression levels of cytokines were investigated. Furthermore, macrophages were harvested from peritoneal cavity of naive CX3CR1$^{-/-}$ and WT mice and cultured in the presence or absence of CX3CL1. Cytokine expression in macrophages was examined at mRNA levels by quantitative RT-PCR and at protein levels using enzyme-linked immunosorbent assay. We also investigated macrophage populations by checking expression of M1 and M2 macrophage markers.

Results: Imiquimod-induced skin inflammation assessed by erythema, scaling, and skin thickness was milder in CX3CR1$^{-/-}$ mice than WT mice. In inflamed skin, mRNA expression levels of IL-12/IL-23p40, IL-23p19, IL-12p35, IL-17A, IL-17F, IL-22, IL-1β, IL-6, TNFα, IL-36α, and IL-36γ were significantly decreased in CX3CR1$^{-/-}$ mice compared to WT mice. The number of macrophages harvested from peritoneal cavity of naive CX3CR1$^{-/-}$ mice were about one third of that of WT mice. The expression levels of IL-1β, IL-6, TNFα in macrophages of CX3CR1$^{-/-}$ mice were significantly lower than that of WT mice. Addition of CX3CL1 into the culture media, however, decreased expression of these cytokines in WT macrophages, suggesting that loss of interactions between CX3CL1 and CX3CR1 did not directly cause decrease in cytokine expression. In inflamed skin of CX3CR1$^{-/-}$ mice, MCP-1 (a M1 macrophage marker) mRNA expression levels were significantly lower, while mRNA levels of MRC-1, Arginase 1, and Ym1/2 (M2 macrophage markers) were significantly higher than in WT mice. Similar findings were observed in peritoneal macrophages, suggesting that difference in macrophage populations was one possible reason for different cytokine expression.

Conclusion: CX3CL1 and CX3CR1 play important roles for infiltration of M1 macrophages both in the skin and peritoneal cavity. Predominance of M2 macrophages in CX3CR1$^{-/-}$ mice may account for decreased expression of IL-1β, IL-6, and TNFα and milder imiquimod-induced skin inflammation.

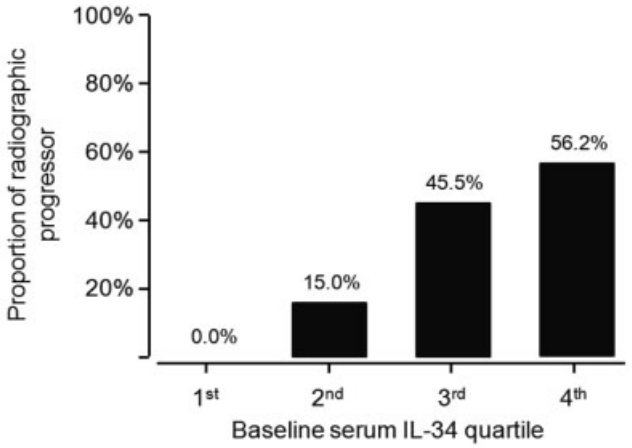
Baseline Serum Interleukin-34 Levels Predict Radiographic Progression In Rheumatoid Arthritis Patients. Sung Hae Chang[1], Byoung Youg Choi[1], Hyon Joung Cho[1], Hye Jin Oh[2], Eun Ha Kang[1], Yeong Wook Song[3] and Yun Jong Lee[1]. [1]Seoul National University Bundang Hospital, Seongnam-si, South Korea, [2]Seoul National University Hospital, Seoul, South Korea, [3]Seoul National University College of Medicine, Seoul, South Korea.

Background/Purpose: Interleukin-34 (IL-34), a novel cytokine playing a critical role in osteoclastogenesis, recently was reported that its expression increases in the synovial tissue and sera of patients with rheumatoid arthritis (RA). However, there has been no study on an association between IL-34 and RA-associated joint damage. We evaluated whether baseline serum IL-34 levels predict radiographic progression in RA patients.

Methods: Sera were obtained from consecutive patients with RA (n=100) and ankylosing spondylitis (AS, n=36). Fifty-nine gender- and age-matched healthy individuals served as controls. Synovial fluid (SF) samples were collected from another 18 patients with RA and 19 with osteoarthritis (OA). Clinical data were recorded at the time of sampling.

Radiologic damage was assessed according to the modified Sharp/van der Heijde score (SHS) at baseline and at follow-up (n=78), an average of 1.7 years later. The IL-34 concentrations were determined by an enzyme-linked immunosorbent assay.

Results: Serum IL-34 levels were significantly higher in patients with RA ($p=4.02 \times 10^{-4}$) or AS ($p=2.15 \times 10^{-5}$) than those in controls. RA patients showed significantly higher SF IL-34 levels in the SF samples than OA patients ($p=3.62 \times 10^{-5}$). In RA, serum IL-34 levels were significantly associated with rheumatoid factor positivity (p=0.011), current smoking status (p=0.002), ESR levels (r=0.258, p=0.010), and C-reactive protein levels (r=0.262, p=0.008). ¥ÄSHS/year was positively correlated with serum IL-34 levels (r=0.474, p=0.029). Moreover, baseline IL-34 level quartiles was an independent predictor for radiographic progression in RA patients (odds ratio 4.765 [95% CI 19.810–11.461], $p=4.89 \times 10^{-4}$, Figure 1).



Multivariate regression results for radiographic progression

Variables	Regression coefficients (β)	*p* values	Odds ratios [95% CI]
IL-34 quartiles	1.561	4.89×10^{-4}	4.765 [1.981, 11.461]
RF positivity	0.762	0.524	2.142 [0.206, 22.278]
WBC	0.000	0.156	1.000 [1.000, 1.001]
CRP	-0.009	0.613	1.565 [0.761, 3.220]

Figure 1. Proportions of patients with subsequent radiographic progression according to the quartiles of baseline serum IL-34 levels.

Conclusion: These results suggest that IL-34, a novel osteoclastogenic cytokine, play a role in RA-associated joint damage and it can be a biomarker for predicting the subsequent radiographic progression in RA patients.

Correlating The *In Vivo* Production Of IFNγ To Disease Parameters In TLR9-Induced Macrophage Activation Syndrome (MAS) In Mice. Vanessa Buatois[1], Laurence Chatel[1], Laura Cons[1], Sabrina Lory[1], Maureen Deehan[1], Jennifer Sims[2], Cristina de Min[1], Marie Kosco-Vilbois[1] and Walter Ferlin[1]. [1]NovImmune S.A., Geneva, Switzerland, [2]Integrated Biologix GmBH, Basel, Switzerland.

Background/Purpose: Cytokine release is the hallmark feature in mice given repeated injections of the TLR9 agonist, CpG-containing oligodeoxynucleotides (CpG-ODN), resulting in pathology resembling the human disease, MAS. However, an anti-IL-10 Receptor (R) monoclonal antibody (mAb) must be co-administered with CpG-ODN to induce more severe human MAS symptoms including hemophagocytosis (herein referred to as fulminant-MAS). Use of an anti-mouse IFNγ mAb, XMG1.2, has demonstrated the dependence of disease manifestation on this cytokine. This study exploits an *in vivo* principle that secreted IFNγ, in the presence of XMG1.2, produces a complex that has a relatively long-half-life and consequently allows cytokine accumulation in the serum which can be quantitated (Finkelman, 1999). An accumulation of complex, from body tissues into the serum, thus, is a reflection of the total IFNγ production of the cytokine in the body. Our *in vivo* results characterize and correlate the production of IFNγ to the clinical and laboratory parameters in murine models of MAS and fulminant-MAS.

Methods: C57BL/6 mice received i.p. injections of CpG-ODN on days 0, 2, 4, 7 and 9. Neutralizing IL-10R, mAb 1B1.3A at 200μg/mouse (days 0, 2, 4 & 6), and anti-mouse IFNg, mAb XMG1.2 at 100 mg/kg (days 1, 3 & 6) were administered *i.v*. Q-PCR was used to analyze inflammatory gene expression. Luminex multiplex technology was used to detect serum cytokines. Blood parameters were measured using a haematological counter. Serum concentrations of the cytokine-drug complex were determined by an ELISA method developed for purpose.

Results: TLR9 agonism resulted in a multi-phasic production of IFNγ evidenced by a spike in serum cytokine levels following each CpG-ODN injection. Therapeutic blockade of IFNγ by XMG1.2 reduced body weight loss, splenomegaly, normalized white blood cell counts, significantly reversed the decrease in other laboratory parameters (e.g. platelets, haemoglobin and red blood cells) and controlled hyperferritinemia. IFNγ measured from CpG-ODN mice co-treated with XMG1.2, which accumulated as a complex in the serum, reached steady state levels of 233 ng/ml. This represented a 200-fold increase over serum IFNγ levels measured in mice treated with CpG-ODN alone (1 ng/ml). Expression of IFNγ induced inflammatory genes demonstrated that spleen and liver are major sites of IFNγ production. Interestingly, although the fulminant-MAS model presented a more severe pathology, *in vivo* production of IFNγ production was determined to be equivalent in the two models. Nonetheless, blockade of IFNγ in mice with fulminant-MAS also improved key disease features including body weight loss, splenomegaly, anemia, hyper-cytokinemia, lymphopenia. Notably, XMG1.2 treatment also decreased the platelet loss in mice with fulminant MAS. Ongoing experiments are focused on determining how the blockade of IFNγ influences the consumptive anemia of inflammation observed in these mice.

Conclusion: The substantial production of IFNγ in tissues is intimately associated with the clinical and laboratory features in the CpG-induced model of MAS. These data support the potential therapeutic strategy for IFNγ neutralization in patients afflicted with this severe form of MAS.

Myeloid Deletion Of SIRT1 Aggravates Serum Transfer Arthritis But Ameliorate Collagen-Induced Arthritis. Sang-Il Lee[1], Yun-Hong Cheon[1], Won Seok Lee[2] and Ji-Min Kim[3]. [1]Gyeongsang National University School of Medicine, Jinju, South Korea, [2]Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Keimyung University School of Medicine, Daegu, South Korea.

Background/Purpose: SIRT1 plays a pivotal role in regulating the inflammatory response. Thus, we assessed the role of SIRT1 in K/BxN serum transfer arthritis as a model of inflammatory arthritis using a myeloid cell-specific SIRT1 knockout (mSIRT1 KO) mouse. To further understand how SIRT1 regulates autoimmunity, we also evaluated collagen-induced arthritis (CIA) using mSIRT1 KO mice.

Methods: mSIRT1 KO mice were generated by using the loxP/Cre recombinase system. K/BxN serum transfer arthritis and CIA were induced in mSIRT1 KO ($SIRT1^{loxP/loxP}$ LysM-$Cre^{+/+}$) and their age-matched littermate loxP control ($SIRT1^{loxP/loxP}$ LysM-$Cre^{-/-}$) mice. Arthritis severity was assessed by clinical and pathological scoring. The levels of inflammatory cytokines in the serum and joints were measured by ELISA and quantitative polymerase chain reaction. The migration, M1 polarization, cytokine production, osteoclastogenesis, and p65 acetylation were assessed in bone marrow-derived monocytes/macrophages (BMMs). The each subset of T cells and dendritic cells was analyzed by flow cytofluorometry in lymph node and spleen.

Results: The mSIRT1 KO mice showed more severe inflammatory arthritis accompanied by aggravated pathological findings than control in K/BxN serum transfer model. These effects were paralleled by higher levels of IL-1 and TNF-α and increased TRAP-positive osteoclasts and

F4/80$^+$ macrophages in the synovium of mSIRT1 KO mice. BMMs from the mSIRT1 mice displayed hyperacetylated p65 and increased NF-κB binding activity than control. However, unlike passive K/BxN arthritis, SIRT1 deficiency in CIA was associated with lower arthritic, radiographic, and pathologic severity. These effects were paralleled by lower levels of numerous inflammatory cytokines in the ankles and lymph nodes of mSIRT1 KO mice. In CIA, the proportion of Th1 and Th17 cells and CD80/86-positive dendritic cells was significantly decreased in mSIRT1 KO mice than controls.

Conclusion: Our study suggests that SIRT1 plays a complex role in regulating inflammation and adaptive immunity and, depending on the model, either enhances or suppresses rheumatoid arthritis.

The Role Of S100A4 As a Biological Marker Of Immune Response In Early Rheumatoid Arthritis. Lucie Andrés Cerezo[1], Klára Prajzlerová[1], Martina Remáková[1], Herman F. Mann[2], Michal Tomcík[1], Karel Pavelka[2], Jiri Vencovsky[1] and Ladislav Senolt[1]. [1]Institute of Rheumatology, Prague, Czech Republic, [2]Institute of Rheumatology, Prague, Prague, Czech Republic.

Background/Purpose: We have previously demonstrated that S100A4 is up-regulated in established rheumatoid arthritis (RA) and that S100A4 regulates apoptosis and synthesis of matrix degrading enzymes in synovial fibroblasts. The aim of the present study was to: 1) characterize whether S100A4 reflects disease activity and/or response to treatment in patients with early RA and 2) determine whether S100A4 regulates production of pro-inflammatory cytokines in mononuclear cells.

Methods: Serum samples were obtained from 59 patients with early RA (symptom duration ≤ 6 months) before and 3 months after treatment with disease modifying anti-rheumatic drugs (DMARDs) and also from 41 healthy individuals. Disease activity score (DAS28-CRP) was assessed at baseline and after 3 and 12 months. S100A4 levels were analyzed by ELISA. Peripheral blood mononuclear cells (PBMCs) and CD3+ T-cells isolated from patients with established RA were stimulated with S100A4, S100A8 and S100A12 proteins (each 1μg/ml). Production of interleukin IL-1β, IL-6 and tumor necrosis factor alpha (TNF-α) was measured by ELISA. Receptor for advanced glycation end products (RAGE) and Toll-like receptor-4 (TLR-4) signalling were examined. For signalling pathway blocking studies, inhibitors of MyD88, NFkB and MAP kinases p38, erk1/2, jnk were used. Activation of MAP kinases was determined by Western blotting.

Results: S100A4 serum levels were significantly higher in patients with early RA compared with healthy controls ($p<0.001$) and significantly decreased after 3 months of treatment ($p<0.001$).

Although S100A4 levels did not correlate with disease activity, in female patients, high S100A4 levels (>1000 ng/ml) at baseline predicted worse response to treatment (DAS28 ≥ 3.2) after 3 and 12 months of therapy (PPV 0.28, OR (95% CI) 2. 846 (1.837, 4.410), p= 0.006 and PPV 0.60, OR (95% CI) 2.700 (0. 992, 7.351), P=0.046). Interestingly, higher S100A4 levels (>1000 ng/ml) at 3 months predicted worse response to treatment (DAS28 ≥ 3.2) in all patients after 12 months (PPV=0.33, OR (95% CI) 2.36 (1.17, 4.74), p=0.04).

Stimulation of PBMCs with S100A4 significantly up-regulated production of IL-1β, IL-6 and TNF-α compared with unstimulated cells ($p<0.001$). Importantly, production of the cytokines was markedly enhanced in response to S100A4 compared with S100A8 and S100A12 proteins. Extracellular S100A4 induced production of the pro-inflammatory cytokines ($p<0.01$) also in CD3+ T-cells. Furthermore, enhanced production of pro-inflammatory cytokines in S100A4 stimulated PMBCs was at least partly mediated via TLR-4, but not RAGE, and by the activation of transcription factor NFkB and MAP kinases p38 and erk1/2.

Conclusion: This is the first study to demonstrate that S100A4 is elevated in patients with early RA and that S100A4 induces inflammatory response mediated by the TLR-4 signalling pathway in mononuclear cells. Taken together, we suggest that high levels of S100A4 may represent a potential biomarker of insufficient treatment response and/or therapeutic target for immune mediated diseases such as RA.

Serum Cytokine Changes In Rituximab-Treated Rheumatoid Arthritis Patients. Tamarah D. de Jong[1], Saskia Vosslamber[1], Wilco de Jager[2], Hennie G. Raterman[1], Alexandre E. Voskuyl[1], Kyra A. Gelderman[1] and Cornelis L. Verweij[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Although rituximab therapy is successful in the majority of rheumatoid arthritis (RA) patients, 30–40% of patients do not respond. The mechanism behind this is yet unknown, as B cell depletion generally takes place in all patients. This study aims to explore changes in serum cytokines during rituximab therapy in established RA patients.

Methods: Serum was collected from 18 established RA patients before and at 1, 3, 6, 9 and 12 months after start of rituximab therapy. A panel of 34 cytokines was measured by a multiplex immunoassay platform (Luminex). Rituximab responder status was determined by the change in disease activity score after 6 months; Patients with DDAS28>1.2 were considered responders.

Results: During rituximab therapy, CXCL13 showed a significant decrease in all patients (median 1.9-fold decrease (IQR 1.4–3.3)), irrespective of responder status. This pattern appeared to coincide with B cell depletion, suggesting that CXCL13 reflects B cell levels in the circulation.

No differences were observed between responders and non-responders after 1 and 3 months of therapy. However, at 6, 9 and 12 months, CXCL10 appeared to be regulated differently between responders and non-responders (R vs. NR, T6/T0 p=0.004, T9/T0 p=0.003, T12/T0 p=0.001). CXCL10 showed a relative increase compared to baseline in the non-responders and no increase or even a decrease in responders. The fold changes in CXCL10 correlated to the DDAS28 at 6 months, indicating that this reflects disease activity rather than a mechanistic effect of rituximab. Most strikingly, IL-12 was not detectable in most of the non-responders until 6 months, but showed a sudden increase after 9 months of therapy. This increase was not observed in the responders (R vs. NR T9/T6 p=0.030, Fisher's exact p=0.049). In contrast to CXCL10, no correlation was observed between DDAS28 and the fold change in IL-12.

Conclusion: This study shows that during rituximab therapy, cytokine changes occur in the patient serum, both related and unrelated to the clinical response. CXCL13 seems to reflect B cells levels in the circulation, whereas the dynamics of CXCL10 and IL-12 during therapy are regulated differently between responders and non-responders during rituximab treatment. These findings indicate different pharmacological effects of rituximab between responders and non-responders.

This research was supported by the Center for Translational Molecular Medicine (CTMM) and the Dutch Arthritis Foundation (TRACER).

Interleukin 10 Negatively Correlates With Glycoprotein VI-Related Platelet Activation In Rheumatoid Arthritis (RA): A Novel Potential Target Of Cardiovascular Morbidity In RA. Leann Bell[1], Anne M. Madigan[1], Paul A. MacMullan[1], Eimear Dunne[2], Paola M. Bagaglia[1], Laura J. Durcan[1], Dermot Kenny[2] and Geraldine M. McCarthy[1]. [1]Mater Misericordiae University Hospital, Dublin 7, Ireland, [2]RCSI, Dublin 2, Ireland.

Background/Purpose: Patients with rheumatoid arthritis (RA) die prematurely of cardiovascular disease (CVD). Platelet mediated thrombosis is a major cause of CVD. Platelets amplify inflammation in RA via the collagen receptor, glycoprotein (GP) VI. When platelets are activated, the GPVI receptor is shed and present in plasma as soluble GPVI (sGPIV). Since sGPVI is a marker of global platelet activation, we investigated whether sGPVI differs in patients with active RA in comparison with

patients with low RA disease activity. Moreover, since cytokines associated with disease activity in RA may effect platelet activation, we also assessed the relationship between sGPVI and plasma cytokine levels in this cohort.

Methods: We prospectively assayed blood samples from healthy donors (n=5), patients with active RA (n=13), and controlled RA (n=10), respectively. Disease activity assessment comprised of serological markers (ESR, CRP, fibrinogen), patient measures (VASDA), evaluator global assessment, and the DAS-28 score. Platelet activation was assessed by measuring sGPVI. Plasma was centrifuged at 720g and then 20000g to ensure that no platelets or platelet derived microparticles were present in the sample and sGPVI levels were measured by ELISA. Serum levels of tumor necrosis factor (TNF)α, interleukin (IL)1β, IL6, IL8, IL10, IL12p70 and interferon (IFN)δ were measured by multiplex ELISA and a Spearman's rank-order correlation was used to test significance.

Results: Mean plasma sGPVI was significantly higher in patients with active RA (14 $\pm$7ng/ml;(mean$\pm$SEM) $p<0.005$) compared to both stable RA (5$\pm$1ng/ml) and controls (5$\pm$2ng/ml) demonstrating that platelet activation occurs in active RA. Mean plasma IL-10 was significantly higher in stable RA patients (39$\pm$31 pg/ml; $p<0.005$) compared to both active RA and controls (15$\pm$8 and 2.24$\pm$0.33pg/ml respectively). There was no association with any measured cytokine and sGPVI levels apart from IL-10, which was negatively correlated with sGPVI in these 28, matched plasma samples (-0.432; $p \leq 0.045$).

Conclusion: Platelet hyper-reactivity in patients with active RA likely contributes to the associated adverse cardiovascular outcomes. sGPVI is a marker for platelet activation in active RA. The anti-inflammatory cytokine IL10, known to play a modulatory role in endothelial cell damage and platelet adhesion, may negatively regulate platelet activation in active RA. These effects of IL-10 could potentially be exploited in the management of RA.

Self-Perceived Efficacy of a Workshop On Musculoskeletal Clinical Anatomy. Miguel A. Saavedra[1], José E. Navarro-Zarza[2], J. Alvarez-Nemegyei[3], Juan J. Canoso[4], Robert A. Kalish[5], Pablo Villaseñor-Ovies[6] and Cristina Hernández-Díaz[7]. [1]Hospital de Especialidades, Centro Medico La Raza Instituto Mexicano del Seguro Social Mexico D.F., México D.F., Mexico, [2]Mexican Taskforce for the Advancement of Clinical Anatomy, Mexico, Mexico, [3]Instituto Mexicano del Seguro Social, Merida, Mexico, [4]ABC Medical Center and Tufts University, Mexico City, Mexico, [5]Tufts Medical Center, Boston, MA, [6]Hospital Angeles Tijuana, Tijuana, Mexico, [7]Instituto Nacional de Rehabilitación, Mexico City, Mexico.

Background/Purpose: Knowledge of musculoskeletal anatomy is suboptimal at many levels of rheumatology training and practice. In a recent practical anatomy pre-test administered prior to a clinical anatomy workshop rheumatology fellows, practicing rheumatologists and non-rheumatologists from 7 American countries (unpublished) scored a mean of less than 50% correct on a series of anatomic questions thought important to rheumatologic practice. We now report the results of a self-assessed competence questionnaire completed after our workshop took place.

Methods: The workshop on clinical anatomy consisted of a regional demonstration of anatomy, physical examination and simulated injections using clinical vignettes, anatomical drawings and attendee cross examination. The post-workshop questionnaire included the same twenty questions with the practical identification or demonstration of anatomic structures replaced by a self-assessment of competence. A five point Likert scale ranging from not competent to highly competent was used yielding a maximum score of 100. A total of 144 participants from 5 of the original 7 countries were asked to participate with 2 countries not included due to anticipated communication barriers. The initial request was sent one month after the workshop and monthly thereafter to a total of 3 requests. Comparison of self-assessment scores of anatomic competence between fellows, rheumatologists and other participants, as well as comparison of participants from the different countries, was calculated by ANOVA. Efficacy of the workshop was determined by the comparison of the pre-workshop (as assessed by instructors) and the post-workshop (self-assessed) scores by the t test for paired samples.

Results: The overall response rate was 74.3% (107 respondents, inter-country range 56–100). A significantly higher overall self-assessed competence score was noted after the workshop as compared to the pre-workshop score (74.7$\pm$13.1 v.s. 48.1$\pm$13.1; $p<0.0001$). Interestingly, marked score differences noted between countries in the pre-workshop tests (inter-country range: 42.8$\pm$20.5 to 62.7$\pm$15.8;) were no longer present in the post-workshop assessments (inter-country range 66.7$\pm$12.6 to 80.2$\pm$10.6). Likewise, whereas rheumatology fellows scored significantly higher in the pre-test assessment than non-rheumatologists, in the post-workshop self-assessment there were no significant differences in the scores of the three groups.

Conclusion: We found a uniformly high level of self confidence in the identification of key anatomical items following an intensive workshop in clinical anatomy despite significant differences between countries and between professional groups in the pre-workshop test. A limitation to our study is that scores from two dissimilar assessment methods, a practical clinical musculoskeletal anatomy pre-test and a self-rated competency assessment, were compared. Nonetheless based on these limited data we are optimistic that our clinical anatomy workshop can positively impact knowledge and skills in this important area for rheumatologists and that further assessment of the utility of our workshop is warranted.

Assessment and Promotion of a National Immunology Curriculum for Adult Rheumatology Residents. Dharini Mahendira[1], Shirley L. Chow[2], Sari Herman-Kideckel[3] and Heather McDonald-Blumer[4]. [1]St Michael's Hospital, University of Toronto, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]University of Toronto, North York, ON, [4]Division of Rheumatology, Mount Sinai Hospital; Osteoporosis Program, Toronto General Hospital, Toronto, ON.

Background/Purpose: Immunologic mechanisms play an integral role in understanding the pathogenesis and management of rheumatic conditions. Currently, there is limited access to standardized formal instruction in immunology for rheumatology trainees across Canada. This is despite the belief that a comprehensive immunology curriculum is essential for adult rheumatology trainees to meet the competencies mandated by the Royal College of Physicians and Surgeons of Canada. The goals of this project were (1) to describe the structure of current immunology curricula amongst adult rheumatology training programs across Canada and (2) to identify and compare the perceived learning needs of rheumatology trainees from the perspective of both the trainees and Program Directors.

Methods: Rheumatology trainees and Program Directors from adult rheumatology programs across Canada completed an online questionnaire. Information on student demographics, past immunology training and overall satisfaction with current immunology training was collected in an anonymous manner. All participants ranked a comprehensive list of immunology topics by order of perceived importance. A modified two step Delphi approach was implemented to obtain consensus on immunology topics.

Results: 15 Program Directors and 38 rheumatology trainees were contacted between March 2012 and May 2012. From this group, 42% of trainees and 66% of Program Directors responded, with a total 49% response rate. Of the rheumatology trainees, 67% had prior experience in immunology, consisting of undergraduate and graduate courses. Teaching format and formal teaching hours varied between sites. Notably, only 42% of Program Directors and 31% of trainees felt the current method of teaching immunology was effective. Results illustrate concordance between Program Directors and trainees for the highest ranked topics, which include innate immunity, adaptive immunity, and cells and tissues of the

immune system. However, there was discordance amongst other topics. Notably, diagnostic laboratory immunology and therapeutics were ranked higher by Program Directors as compared to trainees. Part two of the modified Delphi was conducted amongst Program Directors and completed by December 2012. Only six of the original twelve Program Directors participated in the second phase of the Delphi. The results of round two demonstrated consistency with topic ranking generated from round one.

Conclusion: There is a need to improve immunology teaching in rheumatology training programs. Results illustrate high concordance between many of the topics ranked by trainees and Program Directors. However, discordance is seen with other topics, including diagnostic immunology and therapeutics. To our knowledge, this is the first study to examine perceived immunology education needs of adult rheumatology trainees at a national level. It provides the groundwork for further development of immunology curricula for rheumatology trainees.

Electronic Learning Module Enhances Rheumatology Education. Malini Juyal[1], Avis Ware[1], John Houk[1] and Rina Mina[2]. [1]University of Cincinnati, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center/University of Cincinnati School of Medicine, Cincinnati, OH.

Background/Purpose: Electronic-learning (e-learning) has recently increased in use. Blended learning combines e-learning with traditional training. At the University of Cincinnati Division of Rheumatology, only traditional methods have been used for the education of resident and medical student rotators. Covering all aspects of basic rheumatology can be challenging in this short exposure time in addition, existing conventional teaching methods may not always allow the learners to retain and apply what they have learned.

The objective of this study was to determine if blended learning leads to better learning than traditional methods currently utilized during the four-week Rheumatology rotation for residents and students.

Methods: A digital CD module on Rheumatoid Arthritis (RA) was designed using Lectora® software following established methods, compliant with the learning industry standard SCORM (Sharable Content Object Reference Model). This included interactive links for a learner-directed process. Rotators were randomly allocated to two groups: 1) traditional and 2) blended. Both groups received comparable lectures and clinical exposure. The blended group also utilized the module. Performance was assessed using pre- and post-tests. The difference between the group scores was calculated using the Wilcoxon signed-rank test. The blended group also evaluated the CD module using five point Likert scales to determine, ease of use, navigation, and acceptability.

Results: In the traditional group, the median post-test score stayed the same (P-value=NS) versus the blended group, which increased by three and a half points (P-value=0.002) (Table 1). The pre-test scores for both groups were not statistically different. Learners with an interest in Rheumatology scored generally higher. The questionnaire revealed that 88% (N=15) thought they had a better understanding about RA than they did before using the module, 82% (N=14) of learners favored using the module, and agreed it was useful for future exams, and 94% (N=16) thought access to other rheumatology modules would be beneficial. There was no difference between the baseline scores of the two groups. Baseline characteristics were also similar, regarding age, sex and level of training.

Table 1. Difference Between Pre and Post-Test Scores

	Traditional Group (No Module, N=8)		
Variable	**Median**	**Range**	**P-value**
Pre-test Scores	31	20–35	NS
Post-test Scores	31	28–39	
	Blended Group (With Module, N=19		
Pre-test Scores	30	23–36	0.002
Post-test Scores	33.5	26–40	

Conclusion: In this pilot study, blended learning resulted in improved learning for residents and medical students during the rheumatology rotation. Implementation of this module will likely enhance trainee learning in the Rheumatology rotation.

Disclosure: M. Juyal, None; **A. Ware**, None; **J. Houk**, None; **R. Mina**, None.

Background/Purpose: Patients with rheumatoid arthritis (RA) are at an increased risk of developing numerous comorbid conditions that affect both mortality and RA outcome.

Objectives: To evaluate the impact of a nurse-led program on comorbidity (cardiovascular disease [CVD], infection, cancer and osteoporosis) management in RA.

Methods: *Design:* Prospective, randomized, controlled, open-label, six-month trial between March 2011 and December 2012.

Setting: Outpatient clinic.

Participants: Patients aged 18 to 80 years with non-active RA for at least three months (ACR criteria).

Intervention: After written informed consent was obtained, the study treatment was randomly allocated (i.e. either comorbidity evaluation by a nurse or using a self-assessment program). *Study treatment:* Data was collected by a nurse as recommended by the French Society of Rheumatology (SFR). In the event of inconsistencies, the patient was informed. A report summarizing the program results was prepared by the nurse and sent to the patient's attending physician and rheumatologist.

Outcome variables: Number of actions taken for comorbidities, in line with the recommendations, in the six months following the program. The actions taken into account for CVD were: introduction of lipid-lowering or anti-platelet therapy, smoking cessation, blood pressure measurement, purchase of a sphygmomanometer, weight loss, creatinine measurement, nephrological consultation; for infection: vaccinations; for cancer: mammography, Pap smears, digital rectal examination and/or consultation with a urologist, fecal occult blood testing, colonoscopy and consultation with a dermatologist; and for osteoporosis: DEXA scan, increased alimentary calcium uptake, initiation of calcium and/or vitamin D supplementation and/or anti-osteoporosis medication, Increased physical activity and alcohol discontinuation.

Results: The 970 recruited patients, 488 of whom were assigned to the active group and 482 to the control group, did not differ in terms of baseline characteristics. During the six-month follow-up, the number of actions taken per patient was statistically higher in the comorbidity group: 4.54+2.08 vs. 2.65+1.57 ($p<0.001$); incidence rate ratio (IRR): 1.78 (1.61–1.96). This increase in actions taken concerned CVD (IRR: 1.44 [1.30–1.61]), infection (IRR 1.81 [1.43–2.30]), cancer (IRR: 1.65 [1.40–1.94]) and osteoporosis (IRR 3.45 [2.91–4.09]).

Conclusion: This study demonstrates the short-term benefit of a nurse-led program on RA comorbidity management.

Trial registration: NCT #0131652.

Redesign Of a Rheumatology Curriculum For Internal Medicine Residents: Results Of Needs Assessment Survey. Susan F. Kroop[1], Cecilia P. Chung[2] and Charlene M. Dewey[3]. [1]Vanderbilt University Medical School, Nashville, TN, [2]Vanderbilt University, Nashville, TN, [3]Vanderbilt University School of Medicine, Nashville, TN.

Background/Purpose: We plan to improve internal medicine (IM) resident competence in caring for patients with rheumatologic disease and increase resident interest in rheumatology as a career. To achieve this goal, we conducted a needs assessment to help inform curriculum revisions to enhance our rheumatologic ambulatory curriculum.

Methods: After interviewing IM and Rheumatology faculty we constructed a 16-item online self-assessment resident survey tool. This tool assessed confidence (0=not confident, 100=extremely confident) in performing a rheumatologic history, exam and common rheumatology procedures (knee injection and aspiration, and shoulder and trochanteric bursa injection), ordering and interpreting rheumatologic labs (ESR, CRP, RF, CCP, ANA), and caring for patients with osteoarthritis, rheumatoid arthritis, systemic lupus erythematosus, and fibromyalgia. Additional questions included demographics, interest in rheumatology as a topic and career, and current career choice. Between February and May, 2013, we invited categorical PGY1 residents, just prior to the onset of their one week rheumatology ambulatory block, and all PGY3 residents to complete the Web-based survey. The results from the resident surveys were analyzed via two-sample Wilcoxon rank-sum (Mann-Whitney) test. IRB-approval and consent was obtained prior to completing the survey.

Results: Eighty-six percent (19/22) PGY1 IM residents and 70% (6/37) of PGY3 IM residents responded. Twenty-three of 45 residents (51%) were females. Twelve (27%) residents planned careers in General IM vs. 33 (73%) in IM subspecialties. There was no significant difference in any self-assessed confidence ratings when analyzed by gender or career plans. Table 1 summarizes the results. Overall PGY3 residents self-assessed their confidence ratings higher than PGY1s in all categories. There was no difference in interest in rheumatology between the PGY1 and PGY3 groups but there was significantly less interest in rheumatology as a career in the PGY3 group (p=0.002). Self-rated confidence in joint procedures was consistently lower for both groups compared to history, exam, lab interpretation and patient care.

Table 1. Self rated confidence survey results of PGY1 and PGY3 IM residents Feb-May 2013; Visual analogue scale (0–100).

Self-rated confidence in performing:	PGY1 (median, IQR)	PGY3 (median, IQR)	P value	95% Confidence Interval of difference in medians
Rheumatology History taking	50 (27–64)	65 (50–76)	0.014	−4, −27
Rheumatologic exam	30 (18–52)	59 (37–65)	0.005	−6, −32
Knee injection	10 (2–35)	34 (17–50)	0.006	−6, −33
Knee aspiration	12 (2–20)	42 (30–62)	<0.001	−17, −42
Shoulder injection	5 (1–13)	19 (2–34)	0.041	0, −21
Trochanteric bursa injection	5 (0–14)	20 (6–34)	0.019	−1, −22
Self-rated confidence in ordering and interpreting:				
ESR	63 (50–69)	72 (61–81)	0.004	−5, −25
CRP	59 (48–68)	73 (64–84)	<0.001	−7, −25
ANA	50 (32–59)	62 (50–76)	0.011	−5, −30
RF	55 (39–64)	65 (56–71)	0.032	−1, −21
CCP	57 (38–84)	70 (61–88)	0.161	5, −29
Self-rated confidence in care of patient with:				
OA Care	53 (44–75)	68 (64–75)	0.023	−2, −22
RA Care	43 (28–52)	59 (35–66)	0.011	−3, −26
Gout Care	64 (49–80)	82 (73–85)	0.001	−5, −26
SLE Care	31 (22–51)	50 (38–67)	0.006	−7, −27
Fibromyalgia Care	31 (19–42)	56 (38–74)	<0.001	−12, −38
Self-rated interest in:				
Topic of Rheumatology	62 (56–73)	60 (36–72)	0.260	−4, 21
Career in Rheumatology	49 (29–58)	17 (0–38)	0.002	11, 35

Conclusion: Our results suggest we need to enhance training of procedural skills in our ambulatory curriculum. Further study on factors that influence a resident to consider rheumatology as a career is needed. Encouragement and support for rheumatology as a career should be given early and throughout training.

Disclosure: S. F. Kroop, None; **C. P. Chung**, None; **C. M. Dewey**, None.

The "Mini-Residency" In Musculoskeletal Care: An Efficient and Effective Mixed Method Model For Continuing Professional Education. Michael J. Battistone[1], Andrea M. Barker[1], Marissa Grotzke[1], J Peter Beck[1], Robert Z. Tashjian[1], Timothy A. Huhtala[1], Grant W. Cannon[1] and Patrice Kennedy[2]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]Salt Lake City VA, Salt Lake City, UT.

Background/Purpose: The societal burden of musculoskeletal (MSK) disease is amplified by the limited number of subspecialists. Developing knowledge and skills of primary providers is projected to be cost-effective in addressing this. The George E. Wahlen VA Salt Lake City Health Care System (VASLCHCS) has established an interprofessional "mini-residency" in MSK care to serve this purpose.

Methods: The mini-residency, held on the campus of VASLCHCS, is a one-week immersive experience. Content is introduced in didactics, reinforced in hands-on sessions with peer teaching and technologically enhanced simulations, and applied in the clinic in supervised patient encounters. Course evaluation was informed by Kirkpatrick's model of assessing educational effectiveness, and Phillip's concept of return on investment. Outcome measures included a post-course survey (5-point scale; 1 = "not at all satisfied"; 5 = "extremely satisfied"), qualitative comments in telephone interviews, and the number of joint injections performed after training.

Results: Thirteen of the first fourteen participants completed course evaluations (93% response rate).

Participant Satisfaction (Kirkpatrick Level 1)	• 97% agreed or strongly agreed across all satisfaction items (mean =4.67); all respondents (100%) strongly agreed they would recommend the MSK Mini-residency to others (mean=5.00).
Learning/Skill Acquisition (Kirkpatrick Level 2)	• 100% agreed or strongly agreed across all learning items.
Application/Job Impact	• 100% indicated the training was able to affect practice outcomes.
	• 100% felt trained and more comfortable performing a full shoulder and knee examination.
(Kirkpatrick Level 3)	• 100% are more comfortable performing MSK procedures.
	• Respondents indicated they conducted more thorough exams and had had fewer referrals

Credentials of Participants	States Represented	Number of Injections Performed In 6 Months Following Training
MD (11), NP (9), PA (3)	CO, GA, ID, MN, MT, UT, VA, WA, WI, WY	385 total
		Average per provider = 30
		Range 0–120; s.d. = 42

Conclusion: An interprofessional "mini-residency" in musculoskeletal care is an effective model of continuing medical education. This program is highly rated, results in an expanded scope of practice for most participants, and providers who participated in this course report an increase in the numbers of joint injections they perform in their primary care settings.

966

Less Is More? A Targeted Intervention Results In Substantial Improvement In rheumatologists' Ordering Of Anti Nuclear Antibodies (ANA) In Patients With Rheumatic Complaints. Nienke Lesuis[1], Ester Piek[1], Hatice Demirel[1], Ronald F. van Vollenhoven[2] and Alfons A. den Broeder[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), the Karolinska Institute, Stockholm, Sweden.

Background/Purpose: Anti-Nuclear Antibodies (ANA) are found both in patients with (non-)rheumatic diseases and in healthy controls[1]. ANA testing is useful in the diagnostic process of Systemic Lupus Erythematodus (SLE), Systemic Sclerosis (SSc), Mixed Connective Tissue Disease (MCTD), Sjögren Syndrome (SS), Polymyositis (PM) and dermatomyositis (DM)[1,2]. Laboratory tests in general, are often used inappropriate which leads mainly to overuse of tests.[3] This was recently recognized by the American College of Rheumatology and the ANA is now included in the top 5 list of 'things physicians and patients should question'.[4] Therefore we aimed to assess the

characteristics of ANA testing by rheumatologists in patients visiting the rheumatology outpatient clinic of the Sint Maartenskliniek (SMK) and Maartenskliniek Woerden (MKW), the Netherlands, before and after a targeted educational intervention.

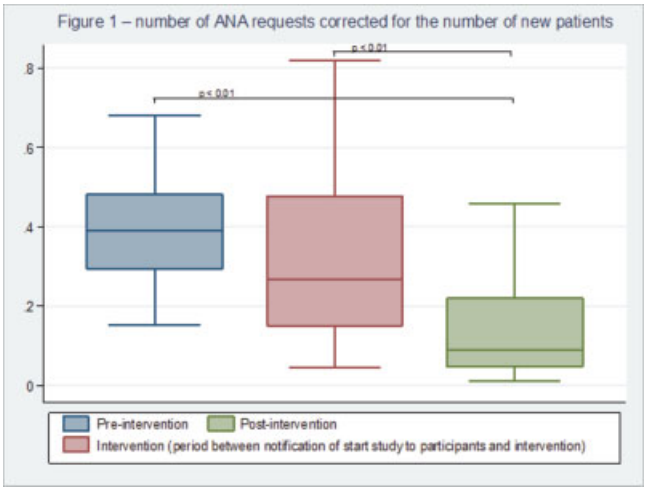
Methods: The characteristics (number, result, final diagnosis) of all ANA tests conducted by rheumatologists between 1-1-2010 and 31-1-2012 (25 months) were compared with the ANA tests done in the four months after the intervention. For fair comparison, the absolute ANA count was corrected for the number of new patients seen at the outpatient clinic in the same period. The intervention consisted of a one-hour, group training in which the individual ordering behavior from the pre-intervention period was given, followed by general background information on ANA test characteristics and the correct use of ANA testing. Directly afterwards all rheumatologists received individual information on their own ANA orders in comparison with their colleagues.

Results: All rheumatologists working in both the pre- and post-intervention period at the outpatient clinic participated (n=20). The characteristics of the ANA tests they ordered pre- and post-intervention are summarized in table 1. At both locations a large decrease in the number of ANA tests was seen after the intervention; when corrected for number of new patients seen the decrease was 77% (figure 1).

Table 1. ANA characteristics before and after the targeted intervention

	SMK & MKW (n=20)	
Characteristic	**Pre-intervention**	**Post-intervention**
Number of ANAs	3702	187
Number of unique patients	3615	185
Number of ANAs per new patient (median; p27–p75)	0.39; 0.29–0.48	0.09; 0.05–0.22
Mean age patients (year; SD)	52 ± 16	47 ± 16
Women (%)	75	81
Most frequent final diagnosis*		
1	UAM	UAM
2	RA	RA
3	FMS	FMS
ANA associated disease** (%)	6	7
Negative ANAs (%)	71	67

* UAM, undifferentiated arthralgia/myalgia; RA, rheumatoid arthritis; FMS, fibromyalgia; OA, osteoarthritis
** SLE, SSc, PM, DM, MCTD and SS



Conclusion: The finding that our single session intervention resulted in a sizable reduction in number of ANA's requested, while inter-individual variation and final diagnoses remained unchanged, suggests that excessive usage of ANA tests was reduced without a reduction in appropriate use of the ANA test.

'Bending' Ethical Norms To Serve Patients' Interests: Tensions In Medical Professionalism. C. Ronald MacKenzie[1], Inmaculada de Melo-Martin[2], Michele Meltzer[3] and Elizabeth A. Kitsis[4]. [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medical College, New York, NY, [3]Jefferson Universtiy, Philadelphia, PA, [4]Albert Einstein College of Med, Bronx, NY.

Background/Purpose: The rheumatic diseases are a common cause of short and long-term disability. Affecting all sectors of the population, they diminish wellbeing, affect quality of life, and have a significant social impact. In spite of the benefits of early treatment and ever more effective therapies, access to rheumatologic services is often inadequate, involving long wait times, and difficulties finding providers; moreover the cost of effective therapy renders treatment unaffordable for many. A just system would mitigate these impediments to care, but in unjust context physicians might find themselves in situations of ethical conflict. We herein focus on the effects that the current practice context has on how rheumatologists' view their ethical responsibilities.

Methods: A survey consisting of 14 closed-ended and 2 open-ended questions, was developed, pilot tested, and sent electronically to 5,500 members of the ACR in the United States. A second email requesting participation was sent to increase the response rate. Reported herein are the results of the open-ended component.

Results: A pressing ethical issue for many rheumatologists is their perceived need to 'bend' ethical norms and compromise ethical principles in order to serve their patients' interests. In the survey physicians report ways in which they see themselves as 'bending' ethical standards and presented justifications as to why they do so. Examples include, 'embellishment' of symptoms to help patients obtain prior authorization; downcoding to help the less fortunate; stretching the truth to obtain drugs and testing; and label patients with certain diagnosis that they do not have so as to obtain coverage for medications or physical therapy. The ethical implications of these challenges for the physicians' sense of integrity, their responsibilities towards their patients, and the impact on justice in the health care system are considered.

Conclusion: The results of our questionnaire indicate that, in the context of inadequate access to care, rheumatologists wrestle with ethical dilemmas concerning how to fulfill their responsibilities to their patients. As the delivery of medical care takes places in a particular social context, the extent to which the context involves unjust conditions forces healthcare practitioners to struggle with ethical conflicts, making trade-offs that are often not sufficiently recognized. In order to provide solutions to the resultant ethical and professional challenges faced daily by physicians, an awareness of this problem and its consequences is necessary.

Success Of Educational Intervention In Improving The Management Of Rheumatoid Arthritis. Nimish Mehta and Ronald Viggiani. Medscape, LLC, New York, NY.

Background/Purpose: In many patients with rheumatoid arthritis (RA), the disease is not adequately controlled and only a minority of patients attain the goal of consistent remission or low disease activity. Underlying clinical practice gaps and educational needs were identified and a study was conducted to determine if an online educational intervention specifically designed to address the identified practice gaps could improve knowledge and competence of rheumatologists with respect to evidence-based management of patients with RA.

Methods: A cohort of practicing rheumatologists participated in an innovative educational intervention that used a problem-based learning model and short-branching technology. Clinical decision questions included at 3 critical points in each of the 2 case vignettes provided tailored feedback and clinical consequences related to the specific answer selected. Learners who did not make the correct decision on the first attempt were allowed a second opportunity to make a decision. Each case also included knowledge assessment questions pre- and post-intervention. The education launched on August 31 2012 and data were collected through November 13, 2012 (76 days). A paired 2-tailed t-test was used to assess differences in mean scores between knowledge assessment questions pre- and post-education. Pearson's $\chi 2$ statistic was used to measure changes in responses to individual questions. For

the consequence-based clinical decision questions a test of proportions was used to determine the effectiveness of the feedback provided for incorrect first attempts. P value of less than .05 indicates statistical significance.

Results: A total of 456 rheumatologists participated in the activity during the data collection period and 146 (who answered all questions) were included in the analysis. Evaluation of the knowledge assessment questions demonstrated statistically significant improvements (n = 146; $P < .05$), with an overall large effect size of 0.829. Improvements post-guidance in specific clinical decisions were as follows:

- 52% improvement post education in determination of the level of RA disease activity objectively using a predefined metric ($P = .01$).
- In a patient who developed new or worsening symptoms consistent with heart failure while receiving treatment with anti-TNF agents, 38% more rheumatologists recommended evaluation with transthoracic echocardiogram post education ($P = .01$).
- Post education, 62% more rheumatologists correctly identified Clinical Disease Activity Index as the validated metric that incorporates both patient- and clinician-derived data ($P = .001$).
- 76% improvement in switching to correct biologic therapy for a patient with RA who developed CHF while receiving treatment with an anti-TNF agent and had to discontinue methotrexate due to adverse effects ($P = .07$).

Conclusion: Statistically significant improvement in knowledge and competency of rheumatologists who completed the educational intervention was demonstrated in a number of areas. Technology-enhanced educational interventions utilizing consequence-based feedback can significantly impact rheumatology practices in the management of patients with RA.

969

Increasing Rheumatology Exposure To Internal Medicine Residents: 3 Year Analysis Of A Web-Based Image Of The Month. Steven J. Katz University of Alberta, Edmonton, AB.

Background/Purpose: A previous study has demonstrated a web based Image of the Month can increase rheumatology exposure for internal medicine residents over 1 year with minimal additional manpower or financial resources. It remains unclear whether or not this effect would persist over a longer duration, or in the transition from junior to senior resident. This study examines this question with an analysis of 3 years' experience of the web based Image of the Month.

Methods: An Image of the Month webpage was established in July 2010 on the www. EdmontonRheumatology.com website, a site representing rheumatologists in Edmonton, Alberta, Canada. Each month, a rheumatologist was responsible for posting a new image with a question which could be answered and submitted online by University of Alberta Internal Medicine residents. At the end of each month, a token book prize was awarded randomly to a correctly submitted respondent.

Results: The Image of the Month webpage has posted images monthly for 35 months since July 2010. There was no cost to implement the program as the website already existed and there was pre-existing funding for the book prize. The rheumatologist required no more than 15 minutes monthly to administer the contest. The webpage had 2517 visits (average 72 visits/month) between July 2010 and May 2013. Resident participation was constant over time ($p>0.05$), with 46/80 (57.5%) residents participating in 2010/11, 49/85 (57.6%) in 2011/12, and 59/92 (64.1%) in 2012/13, with each resident participating on average 3.6, 4.2, and 3.2 times/year respectively. Rheumatology exposure was also improved consistently ($p>0.05$), as there were 35/80 (43.8%) residents in 2010/11 who did not complete a rheumatology rotation but participated in the Image of the Month, 34/85 (40%) in 2011/12, and 40/92 (43.5%) in 2012/13. There was a small decrease in participation as residents transitioned from a junior to senior level, as the 2010/11 first year resident cohort went from 25 participants to 20 in their second and third years of residency, while the 2011/12 first year cohort went from 20 to 19 participants in their second year of residency.

Conclusion: The Image of the Month webpage successfully improves rheumatology exposure to internal medicine residents with minimal resources required. Further, increased exposure remains persistent over time as most residents continue to participate as they gain seniority. Further study is necessary to determine the impact this exposure may have on the musculoskeletal clinical skills of internal medicine residents.

Disclosure: S. J. Katz, None;

Incorporating The Health Literacy Universal Precautions Toolkit Quick Start In Academic Rheumatology Practices: Carolina Fellows Collaborative. Adam Dore[1], John Dye[2], Lara Hourani[3], Betsy Hackney[1], Lisa G. Criscione-Schreiber[2], Faye N. Hant[4], Kenneth S. O'Rourke[5], Beth L. Jonas[1] and Leigh F. Callahan[6]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Duke University School of Medicine, Durham, NC, [3]Medical University of South Carolina, Charleston, SC, [4]Medical Univ of South Carolina, Charleston, SC, [5]Wake Forest School of Medicine, Winston-Salem, NC, [6]University of North Carolina, Chapel Hill, NC.

Background/Purpose: Gaps in health literacy (HL) are associated with increased medication errors, higher health care costs, and inadequate care of chronic medical conditions. Previous studies have shown a large number of rheumatology patients have low HL. To address this, a Health Literacy Universal Precautions Toolkit (HLUPTK) has been developed for rheumatology practices (HLUPTK-R), including a Quick Start for patient encounters. The Quick Start consists of 3 tools: encouraging questions, the teach-back method, and brown-bag medication review. The purpose of this project is to evaluate the implementation of the HLUPTK-R Quick Start into academic rheumatology practices in the Carolina Fellows Collaborative (CFC).

Methods: At the winter meeting of the CFC, the HLUPTK-R Quick Start was introduced to participants through a 20 minute presentation and included an overview of HL. Prior to the presentation, the participants were asked to complete a questionnaire to evaluate their awareness of HL. After the presentation, participants were given paper and electronic versions of the HLUPTK-R Quick Start and asked to incorporate the Quick Start techniques into their rheumatology practice. Eight weeks later, the participants completed a second questionnaire which assessed their impression of the presentation and experience with incorporating the techniques into their practice.

Results: Eighteen participants filled out the pre-questionnaire and were present for the HLUPTK-R Quick Start and HL presentation. Sixteen participants (89%) knew what HL was prior to the presentation, with 10 having learned about HL during their residency training (56%). No participants stated they had previously learned about HL during their fellowship training. Only 6 participants (33%) believed their practice was currently promoting HL for their patients. The post-assessment questionnaire was returned by 13 participants (72%), all of whom incorporated HLUPTK-R Quick Start techniques into their practice. Ten (77%) of those who returned the post-questionnaire agreed that their knowledge of HL was improved and agreed that incorporating the HLUPTK-R Quick Start techniques made a positive impact on patient care. All 13 participants believed the Quick Start techniques were helpful in their practice. The encouraging questions technique was used by all participants who returned the post-questionnaire (13), 8 (62%) used the teach-back method, and 5 (39%) used the medication review technique. Seven participants (39%) thought incorporating the HL techniques added time to the patient's visit. However, all 7 thought the extra time was "worth-while". Lastly, all 13 participants stated they would continue to support interventions to promote HL in their practice.

Conclusion: By introducing the HLUPTK-R Quick Start to rheumatologists of the CFC, we were able to raise awareness and knowledge of HL. A majority of the participating rheumatologists used HL techniques into their practice, believed it was beneficial for their patients, and would support interventions to benefit HL in their practice. We advocate widespread dissemination of the HLUPTK-R Quick Start into rheumatology training programs.

A Needs Assessment and Review Curriculum Of Content Of Teaching On Systemic Lupus Erythematosus. Mo Yin Mok, Yi Lo and Chak Sing Lau. University of Hong Kong, Hong Kong, Hong Kong.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease that is more common among Asians compared with Whites but the prevalence of SLE is significantly low compared with common chronic medical diseases in westernised city like Hong Kong.

This study aimed to evaluate medical student knowledge on SLE and their feedback on teaching on SLE related topics at a medical school in Hong Kong.

Methods: Senior medical students were recruited to complete a self administered questionnaire regarding learning, teaching and subjects regarded as important in SLE.

Results: A total of 124 (109 MBBS IV, 15 MBBS V) medical students from the University of Hong Kong were recruited. Majority of students acquired knowledge on SLE from standard sources provided by curriculum teaching including lectures (98.4%), textbook (96.7%), patient contact (86.1%) and problem based learning sessions (64.8%). A significant proportion of students (77.0%) also obtained knowledge from internet and e-learning. An addition of 36.4% of students also preferred learning from extra-curricular sources including education leaflets from professional societies, family contact and television program. Most students regarded knowledge on clinical presentations (45.4%), diagnosis (49.6%) management and treatment (76.5%) as the most fundamental knowledge an average doctor should know more about SLE. Renal disease was considered most important (36.7%) among all organ involvement in SLE teaching. Only 8.4% of students regarded epidemiology and pathogenesis as essential but overall importance of subjects on epidemiology and pathogenesis, management and complications ranked 4.0/5, 4.3/5 and 4.2/5 respectively. These senior medical students graded their confidence in knowledge in SLE as 3.4/5. In general, the quality (3.9/5) and quantity (3.5/5) of teaching regarding SLE is good. Majority (85.1%) of students preferred to be taught by rheumatologists where as only 15.8% regarded rheumatology nurse as important sources.

Conclusion: Majority of students were satisfied with current curriculum teaching and valued clinical management with higher priority than epidemiology and pathogenesis among the taught subjects. Extra-curricular sources of learning including information from professional societies and rheumatology nurse may be considered as adjunct to teaching.

Retrospective Self-Assessment Of Pre-Course Competency: A Useful Tool For Musculoskeletal Curriculum Assessment In a Multi-Center, Interprofessional Cohort. Michael J. Battistone[1], Andrea M. Barker[1], J Peter Beck[1], Marissa Grotzke[1], Timothy A. Huhtala[1], Jorie Butler[2], Amy C. Cannella[3], David I. Daikh[4], Meika A Fang[5], Antonio A. Lazzari[6], Pedro Roldan[7], Joan Marie Von Feldt[8] and Grant W. Cannon[1]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]Salt Lake City VA, Salt Lake City, UT, [3]Omaha Veterans Affairs Hospital and University of Nebraska Medical Center, Omaha, NE, [4]University of California, San Francisco, San Francisco, CA, [5]VA Greater Los Angeles Healthcare System, Los Angeles, CA, [6]Boston VA Medical Center, Boston, MA, [7]Leesburg VA CBOC, Leesburg, FL, [8]Univ of Pennsylvania/Philadelphia VAMC, Philadelphia, PA.

Background/Purpose: Value of traditional pre- and post-course assessments is uncertain. Having learners re-evaluate pre-course competency after a course may be a more useful tool for curriculum evaluation. This project explores whether "retrospective" self-assessments provide a more useful measure of program effectiveness than traditional pre- and post-course assessments.

Methods: The Department of Veterans Affairs created a program in musculoskeletal care for primary providers. To date, this has involved 130 participants across six national sites. Prior to the course, providers used a 5-point Likert scale to rate proficiency in approaching shoulder, knee, and back pain. Curriculum included focused didactics and small group hands-on practice sessions with simulated patients for shoulder and knee exams. In contrast, back pain was addressed through a single didactic session. After the program, providers retrospectively rated pre-course proficiency on the same dimensions, as well as post-course proficiency. Paired t-tests compared mean prospective and retrospective assessments.

Results: Post-course ratings were higher than pre-course ratings across all items. Retrospective ratings of pre-course competency in assessing shoulder and knee pain were significantly lower than initial, prospective pre-course ratings. In contrast, retrospective ratings for competency with back pain were not significantly lowered.

	Mean Pre-course Ratings		Mean Paired Difference	Mean Post-course Ratings	Pre-Post Change	
	Prospective	Retrospective	(SEM; p)		Post-Pro	Post-Retro
Shoulder Pain						
I can examine and diagnose shoulder pain without MRI	3.1	2.7	0.3 (0.09; 0.001)	4.7	1.6	2.0
I can evaluate patients effectively	3.2	2.8	0.3 (0.08; <0.001)	4.8	1.6	2.0
I can develop a appropriate plan	3.3	3.0	0.2 (0.09; 0.011)	4.7	1.4	1.7
I understand when to order imaging	3.4	3.1	0.3 (0.09; 0.003)	4.8	1.4	1.7
I understand when to refer	3.6	3.3	0.2 (0.08; 0.007)	4.7	1.1	1.4
Knee Pain						
I can examine and diagnose knee pain without MRI	3.2	2.9	0.3 (0.08; 0.01)	4.7	1.5	1.8
I can evaluate patients effectively	3.3	3.0	0.2 (0.07; 0.01)	4.7	1.4	1.7
I can develop an appropriate plan	3.5	3.1	0.3 (0.08; 0.01)	4.6	1.1	1.5
I understand when to order imaging	3.6	3.2	0.2 (0.08; 0.03)	4.7	1.1	1.5
I understand when to refer	3.7	3.3	0.3 (0.09; 0.01)	4.7	1.0	1.4
Back Pain						
I can identify patients with low back for whom MRI is appropriate	3.8	3.6	0.04 (0.09; 0.65)	4.5	0.7	0.9
I can develop a reasonable management plan	3.8	3.7	0.01 (0.09; 0.91)	4.5	0.7	0.8
I understand when to refer	3.8	3.7	0.07 (0.09; 0.42)	4.6	0.8	0.9

Conclusion: Lower retrospective pre-course ratings were seen only in course elements that involved multiple methods of instruction. Multi-modal skill acquisition may lead to a more critical assessment pre-course proficiency. Incorporating retrospective pre-course self-assessment may distinguish educational programs that most effectively teach new skills.

973

Basic Musculoskeletal Ultrasound Curriculum Among Internal Medicine Residents: A Pilot Study. Gaurav Gulati[1] and David George[2]. [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]The Reading Hospital and Medical Center, West Reading, PA.

Background/Purpose: Musculoskeletal Ultrasound (MSKUS) is becoming an important component of rheumatology practice. Given increasing appreciation of bedside ultrasound, residency programs are beginning to include ultrasound training in their curriculum. Time and resources are barriers to implementation. We performed a pilot study to assess the feasibility of incorporating introductory MSKUS education into an Internal Medicine (IM) Residency Program.

Methods: A limited MSKUS curriculum for IM residents was created, with knee ultrasound as focus of our pilot study. After IRB approval, participants were recruited and consented. Educational program included reading material; two one hour lectures on anatomy, biophysics and pathology; and a 30 min hands on practicum. A pre and post test for medical knowledge was performed, and a minimum 80 % score was required to proceed.

Residents then received individual technique training on two knees, with identification of effusion as principal objective. They were supervised for cognitive and technical skill by experienced rheumatology faculty.

An Observed Structured Clinical Exam (OSCE) was performed. Each resident performed MSKUS on two patient knees. Residents were assessed for proper probe placement, machine use and identification of knee effusion. In addition, they were tested on five still images. Feedback questionnaires were completed by residents and faculty. Analysis was performed using paired t-test for pre and post tests and survey results were collated.

Results: All fifteen enrolled residents completed their training but twelve could complete the OSCE. Pre and post results [TABLE 1] demonstrated significant improvement in knowledge for all three curricular components ($p < 0.001$). Final OSCE scores ranged from 7 to 10 on a 10 point scale. Faculty evaluated all residents' cognitive and technical skills as excellent or good. All participants rated reading material, orientation and supervision as great or good on the four point Likert scale. Program was thought to be a valuable learning experience by all participants. Although 66.7% participants thought the exposure to patients before OSCE was adequate, others suggested 3 to 20 additional supervised procedures. Based upon resident performance and faculty time commitment, faculty rated overall learning experience as good.

Table 1. Outcomes Data Analysis (Paired t-test)

Variable	Pretest Values Mean	Pretest Values SD	Posttest Values Mean	Posttest Values SD	p-value
Pre-Post Total (20)	6.45	1.62	17.48	1.13	<0.001
Biophysics (12)	3.88	1.32	11.13	0.63	<0.001
Pathology (4)	0.97	0.90	3.07	0.68	<0.001
Anatomy (4)	1.60	0.92	3.28	0.50	<0.001

Conclusion: Our study was a pilot project to assess incorporating introductory MSKUS training into an IM Residency training program, addressing feasibility, perceived value, and observed competence. Based upon our preliminary results, the curriculum is a feasible and time efficient addition to training and was considered valuable by both faculty and residents. Further studies are needed to assess methods to reinforce core training for all residents, offer advanced curriculum for a subset of interested residents, and assure MSKUS for IM residents complements their ultrasound training in other subspecialties.

974

Medical Student Perceptions Of Point-Of-Care Ultrasound In Musculoskeletal Education. Minna J. Kohler[1], Joshua Rempell[2] and Margaret Seton[2]. [1]Massachusetts General Hospital/Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Point-of-care ultrasound (POC US) is increasingly being incorporated into clinical care among rheumatologists and other specialties to expedite diagnosis and assist in needle and vascular access guidance for improved accuracy and patient safety. POC US is also emerging as an educational tool for medical students for better understanding of anatomy, physiology, pathology, physical diagnosis skills, and problem-based learning. A survey of students was performed to document student-perceived value in the use of POC US as an educational tool and to assess student interest in rheumatology after POC US exposure.

Methods: We describe our experience incorporating POC US into a 2nd year medical student musculoskeletal (MSK) pathophysiology course to introduce basic concepts of arthritis, tendinitis, and crystal-induced arthropathies. A 40 minute case-based lecture describing the use of MSK US in the care of rheumatology patients was provided followed by a 1.5 hour hands-on US session. Instructors guided students (1:5 ratio) to use portable US equipment to scan patients with osteoarthritis, tendinitis, gout, and pseudogout. Anatomic and pathologic findings on US were identified while patients simultaneously described their clinical symptoms. Seven Likert scale formatted questions were administered to survey students after completion of the US teaching session.

Results: Thirty students were surveyed by email. 24(80%) students responded. Among those who responded, prior awareness of US use in rheumatology was reported: 14(58.3%) were somewhat aware of US being used in rheumatology and thought it is used in other specialties, 2(8%) were minimally aware and had not seen it used in other specialties, and 8 (33%) were not aware at all of US use. Twenty-two (91.7%) felt that the hands-on US session added a great deal of value to the course, while 2(8.3%) felt it somewhat added value to the course. All students desired more hands-on US exposure; additionally 4(16.7%) were interested in learning more US by class lectures, and 2(8.3%) desired more class lectures and online didactics. The effects of US exposure on increasing understanding of concepts and increasing interest in rheumatology are shown in the Table.

Table.

Effect of Hands-on US Exposure	N (%)
Better understanding of anatomy	22 (91.7%)
Better understanding of pathology	20 (83.3%)
Better understanding of physical exam skills	12 (50.0%)
Better understanding of physiology	2 (8.3%)
Raised consideration for pursuing rheumatology as a specialty	4 (16.7%)
Wanted to learn more about rheumatology but uncertain what specialty to pursue	14 (58.3%)
Wanted to learn more about rheumatology but wants to pursue another specialty	4 (16.7%)

Conclusion: Hands-on POC US teaching in medical student MSK education is highly valued by students. Exposure to MSK US increased their understanding of anatomy, pathology, and physical exam skills, increased their desire to learn, and additionally increased their interest in learning more about rheumatology as a potential specialty to pursue.

975

Outcomes-Based Program Evaluation Of a Musculoskeletal Ultrasound Curriculum. Hitasha Singh[1] and Karina D. Torralba[2]. [1]University of Southern California, Los Angeles, CA, [2]University of Southern California Keck School of Medicine, Los Angeles, CA.

Background/Purpose: The Los Angeles County-University of Southern California Rheumatology fellowship program has incorporated musculoskeletal ultrasound (MSUS) in its curriculum since 2009. The following teaching approaches have been used: 1) 8-hour correlative history-physical exam-MSUS didactic and hands-on scanning workshop, 2) twice monthly cadaver-based procedural simulation, and 3) weekly MSUS clinic. We aimed to evaluate the effectiveness of this curriculum in the acquisition and utilization of MSUS-knowledge and skills (MSUS-KS).

Methods: Program evaluation was done through: 1) Likert-scale based survey of current and past fellows (2010–2013, (N=15)), noting satisfaction with organization and content, confidence, and MSUS-KS utilization, 2) written feedback from 3 faculty members regarding challenges faced, 3) MSUS-clinic utilization review via sampling of 50 cases referred and seen by fellows since 2010 (reasons for referral, interventions, patient outcomes); and 4) review of competency-based electronic portfolios (ePFs) for learning evidences. Ultrasound School of North American Rheumatologists (USSONAR) fellow program participation was also considered. Descriptive statistics were used to analyze data.

Results: 11/15 fellows responded to the survey (6 current, 5 graduates; 4 were USSONAR participants). There was a favorable response towards organization and content of the workshop-didactic sessions, and clinic. Suggested improvements included: limiting simulations to once monthly, correlative dissection; and disease-specific (i.e. synovitis) didactics. Immediate feedback from faculty was useful. 10/11 agreed with understanding MSUS indications and limitations, and had an improved understanding of clinical anatomy. There was at least 50% neutral-disagree responses regarding confidence in using MSUS, ability to identify pathology; and amongst graduates, regarding application of MSUS-KS in practice. Faculty cited a learning curve, striking a balance between developing their own MSUS-KS while also achieving confidence and competency in teaching this field. ePFs showed documentation through procedure logs and journal article reviews; USSONAR fellows had more number of evidences. Referrals to MSUS clinic were mainly by fellows sending patients from continuity clinics, and majority were for rheumatoid arthritis disease activity evaluation. 38% of patients had management changes as a result of MSUS findings. 20 patients underwent MSUS-guided injection; 80% had symptom relief at follow-up.

Conclusion: This program evaluation indicates feasibility in the usage of these various teaching approaches as part of a MSUS curriculum. Faculty development and learner participation are vital towards successful implementation; USSONAR participation can complement learning. Feedback can be used to improve curricular content and organization, and assessment. Measures are needed ensure lifelong learning. Although this study involved a limited number of fellows in one program, it provides a realistic view of how to incorporate MSUS into a fellowship curriculum.

976

Experiential Learning In Musculoskeletal Ultrasound. Hitasha Singh[1] and Karina D. Torralba[2]. [1]University of Southern California, Los Angeles, CA, [2]University of Southern California Keck School of Medicine, Los Angeles, CA.

Background/Purpose: The Los Angeles County Medical Center-University of Southern California Rheumatology fellowship program has incorporated MSUS in its curriculum since 2009. Apart from didactics with hands-on workshops, cadaver-based simulation, a weekly 4-hour musculoskeletal ultrasound clinic (MSUSc) was incorporated with an early rheumatoid arthritis (ERA) clinic to teach knowledge and skills (MSUS-KS). The MSUSc was also established to address MSUS needs of patients which could not feasibly be done during other clinics. The objective of this study was to

assess the utilization of a dedicated MSUSc by fellows as part of curricular program evaluation.

Methods: A sampling of 50 charts seen at the MSUSc July 2009-May 2013 was done. Charts were reviewed mainly for: reasons for referral, pre-existing diagnoses, anatomic sites evaluated, intervention (synovitis evaluation, guided injection) and outcomes (pain resolution, diagnosis change) were noted. A Likert-scale based survey by current and graduate fellows was done to determine effectiveness of MSUSc teaching, and effectiveness of the overall curriculum. Review of electronic portfolios (ePFs) was done to assess evidences of learning.

Results: Majority of the patients were seen within a week's time from date of referral from a fellow continuity clinic. The most common pre-clinic diagnoses were: RA (35), psoriatic arthritis, OA (2 each), gout, pseudogout, vasculitis, mixed connective tissue disease, entrapment neuropathy (1 each), and tendinopathy (3). Majority of referrals were for initial diagnostic evaluations (29), treatment monitoring (10), mass evaluation (1), therapeutic injections without prior attempt (9). Of cases referred for initial diagnostic evaluation, 9 were injections without prior attempts, 8 were diagnostic scans followed by injection based on scan findings. Scans for RA initial diagnostic ultrasound were more common and included fingers (15), wrist (11), knee (11), and elbow joints (7). Majority of scans for synovitis showed positive power Doppler (23). Of 11 tendinopathy evaluations, positive doppler (3), and tendon tears (3) were noted. Of 20 patients that had injections, 80% reported pain relief. Overall 38% of patients had a change in treatment based on the ultrasound findings or procedure.

Of 15 fellows surveyed, 11 responded. 90% were agreeable regarding MSUSc provision of adequate patients, and efficient opportunities for procedures. All noted better understanding of MSUS indications and limitations. There were 50% neutral-disagree responses regarding overall confidence in doing MSUS, pathology identification. Immediate attending feedback and self-directed learning were cited as MSUSc advantages. All ePFs showed mainly procedure logs and journal article reviews as evidence of MSUS learning with most of procedures done during MSUSc.

Conclusion: This is an initial attempt to assess the effectiveness of learning MSUS-KS through various teaching approaches including experiential learning in a MSUSc and its applicability towards patient care. Feedback obtained from fellows can be used to improve curricular content and guide proper competency-based assessments.

Development Of a Tool To Assess Internal Medicine Residents' Confidence In Their Musculoskeletal Examination Skills. Lisa G. Criscione-Schreiber[1], Eric Schreiber[2], Murat Arcasoy[3] and Kenneth S. O'Rourke[4]. [1]Duke University Health System, Durham, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]Duke University School of Medicine, Durham, NC, [4]Wake Forest School of Medicine, Winston-Salem, NC.

Background/Purpose: Published literature shows that internists have poor confidence in their ability to perform the musculoskeletal (MSK) exam. Confidence is an important self-assessment; lack of confidence drives individuals towards improvement efforts, but lack of confidence in physical exam skills can yield reliance on expensive imaging modalities and over-referral to specialists. Therefore, educators should develop effective interventions to teach the MSK exam and determine those efforts' effects on practitioners' confidence. There are no published validated surveys to assess confidence in performing a comprehensive MSK exam.

Methods: We designed a pilot MSK exam confidence survey based on a previously validated 15-item MSK student assessment for confidence in knee and shoulder exams. Our survey included 10 multi-item questions designed to measure confidence in several examination tasks for the knees, back/spine, shoulders, and hands/wrists. Confidence was measured on a 10-point Likert Scale (1=not at all confident to 10=very confident). The pilot survey was administered to internal medicine residents at Duke University before a didactic session on performing the MSK exam. We performed psychometric analyses of the instrument. Survey responses were analyzed in two dimensions: 1) the joint area in which confidence was assessed, and 2) specific task confidence (taking a pain history, assessing for swelling or range of motion, using information gained to make diagnoses or guide medical decision making, ability to perform provocative maneuvers).

Results: 19 surveys were collected (14 PGY1 residents, 4 PGY2, 1 PGY4). Only PGY1 responses were analyzed; 3 incomplete surveys were not analyzed. The discrimination for the entire test was 0.726 (joint domain R values 0.5–0.75), which is very good. The reliability was also high; Cronbach's alpha for all scored items was 0.975 (joint domain values 0.906–0.925). For response analysis, confidence was highest for knee examination (mean 6.34) and lowest for hands (mean 5.92). In task domains, participants were most confident in assessing range of motion of joints (mean 7.71) and least confident in their ability to use the joint exam to guide medical decision making (5.05), identify and name deformities (5.182), use the joint exam to make diagnoses (5.27), and perform provocative diagnostic maneuvers (5.295). Extremes of confidence were rarely endorsed, giving an item frequency distribution that was highly skewed towards the center (overall item mean 6.016).

Conclusion: We established content and internal structure validity for a 10-question multi-item survey to assess residents' confidence in their ability to perform a comprehensive musculoskeletal examination. Confidence was relatively similar among joint areas and varied more based on MSK exam task. Based on these results, we have modified the survey, contracting response options to 6 with a descriptive rather than numerical Likert scale to improve validity. Testing of this modified survey is ongoing. Future directions include validation by testing the relationship of measured confidence to actual performance of a comprehensive MSK exam.

978

Inter-Professional Training Programs For Primary Care Providers Can Successfully Educate Practitioners With Dramatically Different Educational and Training Background Through a Common Mini-Residency Training Program. David I. Daikh[1], Michael J. Battistone[2], Andrea M. Barker[2], Andy L. Avins[3], Marissa Grotzke[2], Meika A Fang[4], Antonio A. Lazzari[5], Amy C. Cannella[6], Pedro Roldan[7], Joan Marie Von Feldt[8] and Grant W. Cannon[2]. [1]San Francisco VA Medical Center and University of California, San Francisco, San Francisco, CA, [2]Salt Lake City VA and University of Utah, Salt Lake City, UT, [3]San Francisco VA Medical Center, San Francisco, CA, [4]VA Greater Los Angeles Healthcare System, Los Angeles, CA, [5]Boston VA Medical Center, Boston, MA, [6]Omaha Veterans Affairs Hospital and University of Nebraska Medical Center, Omaha, NE, [7]Leesburg VA CBOC, Leesburg, FL, [8]Univ of Pennsylvania/Philadelphia VAMC, Philadelphia, PA.

Background/Purpose: Musculoskeletal (MSK) problems present frequently during outpatient visits to primary care providers. Training in the diagnosis and care of MSK disease varies based on the specific discipline and on the degree of emphasis placed on these problems by training programs. Providers may also have different learning styles and post-training experiences that influence their comfort and competence with MSK problems. We examined the impact of prior training and experience on providers' perceived level of competence before and after participation in a novel intensive 3 day MSK "mini-residency" training program including physicians (MD), physician assistants (PA) and nurse practitioners (NP) from six VA health systems across the country.

Methods: Providers engaged in a three-day intensive, multi-method training program that included specific training in the approach to common shoulder and knee problems. Participants were surveyed regarding training and clinical experience with MSK problems. We compared experience with self-reported competency and performance in observed structured clinical examinations (OSCE) of the shoulder and knee.

Results: Participants had significant heterogeneity in their educational and training experience with MSK disease.

	Professional School Education (%)		Residency Training (%)		Post-training Experience (%)	
Discipline	≤6 hrs	>12 hrs	≤ 6 hrs	>12 hrs	<5 yrs	>10 yrs
MD	42.5	29.7	49.1	33.6		
NP/PA	68.4	23.1	46.4	25.0	19.2%	50.0%
OSCE Rating (maximum 5.0)						
Shoulder	4.53	4.62	4.60	4.56	4.77	4.57
Knee	4.15	4.17	4.26	4.08	4.41	4.07

95.4% of 109 participants reported that they frequently see common MSK conditions in practice. However, there were no significant differences in their confidence level in the evaluation and management of common MSK conditions prior to taking the course, or in specific self-reported baseline competencies based on these differences in training or experience. Providers exhibited significant improvements in post-course evaluations, with no significant differences in improvement in self-rated competencies or in objective skill assessments across education, experience, or practice specialty.

Surprisingly, providers with less than 5 years post-training experience performed better on the post-course OSCE than those with 10 or more years ($p = 0.022$ and 0.017 for shoulder and knee, respectively).

Conclusion: Providers have widely varying education and training in MSK problems. Higher performance in OSCE among providers recently completing training may reflect easier acceptance of a systematic physical examination approach or greater comfort with the OSCE format. Despite differences in prior training and experience, participation in a focused, structured, multi-method training experience can lead to improved MSK competency, even among experienced clinicians from varied backgrounds.

Disclosure: D. I. Daikh, None; **M. J. Battistone**, None; **A. M. Barker**, None; **A. L. Avins**, None; **M. Grotzke**, None; **M. A. Fang**, None; **A. A. Lazzari**, None; **A. C. Cannella**, None; **P. Roldan**, None; **J. M. Von Feldt**, None; **G. W. Cannon**, None.

979

Southern Hemisphere Educational Partnership For Pediatric Arthritis and Rheumatological Diseases (SHEPPARD): An International Educational Program. Ricardo A. G. Russo[1], Marìa M. Katsicas[2], Kate Webb[3] and Christiaan Scott[3]. [1]Hospital de Pediatria Garrahan, Buenos Aires, Argentina, [2]Hospital de Pediatrìa Garrahan, Buenos Aires, Argentina, [3]Red Cross War Memorial Children's Hospital, Cape Town, South Africa.

Background/Purpose: Cooperation and collaboration between developing countries can be mutually beneficial and create the basis for a longstanding, Third World-centered educational program aimed at increasing the pediatric support for Pediatric Rheumatology (PR). The objective of this presentation is to describe a binational (Argentina-South Africa), bicontinental, educational program aimed at increasing the pediatric support for PR in developing countries with similar health problems.

Methods: This is an ongoing program aimed at combining the expertise from 2 centers in different developing countries to deliver a program in professional education. This program was approved and supported by an ILAR educational grant. Its objectives are: 1) To provide pediatricians with education and training in the management of patients with juvenile rheumatic diseases to facilitate early diagnosis, referral and follow up 2) To develop permanent communication means for bidirectional contact between local teams and specialized centers. 3) To establish an integrated South Africa-Argentina (SA-A) teaching modality, adapted to the needs of these developing countries. Strategies used were: selection of 6 pediatricians working in underserved areas of SA-A based on availability and interest in the field; 3 months-long rotations in Pediatric Rheumatology centers in Cape Town and Buenos Aires; supervised patient-centered education and personalized training of pediatricians where they applied to a 10-item curriculum-based program; visiting professorships to those areas for education of basics of PR for pediatricians through patient-based teaching sessions and interactive discussions; periodic, problem-based, SA-A teleconference rounds where expertise in clinical, epidemiological and educational aspects of PR from both centers were shared and promoted new developments in patient care and professional education. A tailored educational program included specific competency-based educational goals for each trainee as well as community-based epidemiological research and team-based, patient-oriented care adapted to the specific local needs of the trainee′s setting. Post-training assessment of trainees' skills and knowledge was performed through multiple choice tests and Objective Structured Clinical Examination, as well as trainees′ satisfaction through a structured survey.

Results: Six pediatricians (3 in Argentina and 3 in South Africa) received a comprehensive training according to the educational program. They were successfully evaluated and returned to their local setting, where they are currently involved in the care of children and adolescents with rheumatic conditions. Visiting professorships resulted in the delivery of basics of PR to over 200 pediatricians in different cities of underserved areas of SA-A. All trainees expressed high degree of satisfaction with their experience. Their activities are periodically monitored through combined trainer-trainee case discussions.

Conclusion: This project developed an ongoing, successful educational strategy that may be used as a model for training in PR in other regions of the developing world. Evaluation of the impact of the program on care delivery will follow.

Promoting Critical Appraisal Self-Efficacy and Peer Connectivity With An Epidemiology Curriculum For Rheumatology Trainees. Juliet Aizer[1], Jessica Berman[2], Anne R. Bass[1], Stephen A. Paget[1] and Lisa A. Mandl[3]. [1]Hospital for Special Surgery Weill Cornell Medical College, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [3]Hospital for Special Surgery, New York, NY.

Background/Purpose: Self-efficacy and peer connectivity are important in career choice, productivity, and persistence. Applying adult, critical, and social learning theory, we broadened a traditional journal club format into an Epidemiology Curriculum for Rheumatology trainees, to foster critical appraisal self-efficacy and peer support in clinical research.

Methods: Rheumatology faculty at a single center developed learning objectives with input from trainees. All year 1 adult and pediatric rheumatology trainees, as well as those in years 2 and 3 of the clinical/translational research track participated. The group met 27 times from 9/2012–6/2013.

Clinically relevant, methodologically important articles were reviewed in 19 sessions. Participants joined facilitators to critique articles through questions on study design, chance, bias, confounding, generalizability and significance. Participants identified knowledge gaps, reflected on related clinical and research experiences, suggested alternative methodologic approaches, and debated implications. Faculty facilitated 16 sessions. With faculty support, 3rd year trainees each facilitated 1 session. Each of 5 2nd year trainees had one session to present their own research in progress. Challenges were highlighted and solutions sought through peer consultation followed by reflection and follow up to address barriers.

Baseline and year-end questionnaires examined trainees' experience, critical appraisal skills, attitudes, behaviors and suggestions. Perspectives on curriculum format/content were also captured mid-year and year-end. The primary outcome was change in critical appraisal self-efficacy.

Results: 12 trainees participated; all had experience in clinical research. 75% had taken epidemiology courses. After exposure to the curriculum, the proportion of participants reporting "a lot" of confidence in their "ability to critically evaluate study design" increased from 16% to 58%, ($p=0.09$, Fisher Exact Test). Self-efficacy regarding ability to evaluate bias, statistics and quality of a study increased by 17%, 8%, and 17%, respectively.

17% reported more thorough reading habits. 33% reported an increase critically evaluating study results.

Participants considered the epidemiology curriculum worthwhile, with positive personal impact. Participants highlighted the importance of a comfortable learning environment and clinical relevance in article selection.

Participants presenting research in progress attributed revision of study aims, hypotheses, protocols, and analyses to the curriculum. Participants developed timelines to achieve the goals of research dissemination. Peers' perspectives and solutions were considered valuable. Research discussions enhanced participants' sense of peer connectivity and likelihood to discuss research.

Conclusion: Although small numbers preclude statistically significant results, application of adult, critical, and social learning theory in an Epidemiology Curriculum for Rheumatology trainees has the potential to promote self-efficacy related to critical appraisal, peer connectivity, and clinical research project development.

981

Competency and Confidence In Musculoskeletal Medicine For The First Graduating Class Of a New Medical School. Shazia Bég University of Central Florida, Orlando, FL.

Background/Purpose: Musculoskeletal problems are among the most common patient complaints in the United States. Despite this, studies show that medical students and interns are not adequately prepared in these topics. The University of Central Florida College of Medicine (UCF) is a new medical school with an integrated curriculum that graduated its charter class of in May 2013. At UCF a four week module that includes topics in rheumatology and orthopedics is taught in the second year. The purpose of this study was to test the UCF charter class on basic topics in musculoskeletal medicine to assess their competence in this area and compare it to the national average and to their juniors who have had an improved curriculum.

Methods: A basic-competency examination in musculoskeletal medicine has been previously validated and used since 1999 by various medical schools. It has 25 short-answer questions covering topics seen in primary care settings. This exam was taken by UCF second year medical students (M2) during their musculoskeletal module and by UCF fourth year medical students (M4) just before their graduation. A Likert-Scale questionnaire was administered to M4 class to rate their self-confidence in musculoskeletal physical examination skills. M4 students were asked if they had taken an elective in orthopedics or rheumatology (MSK). The exam was scored anonymously according to a standardized answer key.

Results: A total of 79 second-year (M2) and 35 fourth-year (M4) medical students took the quiz. The mean score for the M2 class was 80% (sd=10.9), M4 class was 58% (sd=13.1). The pass rate using 60% cut off was 96.2% for M2 and 54.3% for M4 ($p<0.001$). The pass rate using 73% cut off was 82.3% for M2 and 8.6% for M4 ($p<0.001$). The pass rate for UCF M2 and M4 classes was higher than the national average pass rate of 18% for medical school graduates using the same exam in 1998. Using the 60% cut off for the M4 class, those who had taken an MSK elective had a pass rate of 76.5% compared to 33.3% in those who did not take such an elective ($p=0.01$). For the M4 class, confidence level in physical exam skills was as follows: back exam: poor=5.7%, fair to good=94%; shoulder exam: poor=25.7%, fair to good= 74.3%; knee exam: poor=17.1%, fair to good=82.8%. M4 students who had an MSK elective were more confident in back exam ($p=0.014$) compared to those who did not take an elective, but there was no significant difference between shoulder ($p=0.85$) and knee ($p=0.39$) exam confidence levels between the two groups, although the trend was towards more confidence in the group that had taken an MSK elective.

Conclusion: Pass rate using a validated musculoskeletal exam for the UCF graduating class was better than the national average but was still poor overall. Pass rate was significantly better in the second year class who had the improved curriculum. M4 students who had taken a MSK elective had significantly higher pass rates and trended towards having higher confidence in physical exam skills compared to those who had not taken such an elective. Musculoskeletal medicine education needs to be improved in all four years of undergraduate medical education to increase confidence and performance in the real world where there is a high demand for these skills.

982

Preferred Strategies For Delivering Treatment Information To People With Rheumatoid Arthritis, Osteoarthritis and Osteoporosis. Maria A. Lopez-Olivo[1], Robert Volk[2], Maria Jibaja-Weiss[3] and Maria E. Suarez-Almazor[4]. [1]University of Texas. M.D Anderson Cancer Center, Houston, TX, [2]UT MD Anderson Cancer Center, Houston, TX, [3]Baylor College of Medicine, Houston, TX, [4]University of Texas MD Anderson Cancer Center, Houston, TX.

Background/Purpose: To explore the perceptions of people with rheumatoid arthritis (RA), osteoarthritis (OA), and osteoporosis (OP) regarding their preferred delivery methods for obtaining treatment information.

Methods: Six focus groups and 18 cognitive interviews were conducted with patients recruited from publicly funded clinics (1 per disease in English and Spanish) and 2 focus groups and 4 cognitive interviews to rheumatologists. In general, patients had low health literacy and were multiethnic. Patients with RA were at least 18 years old and had a diagnosis of RA; patients with OA were 50 or older and had a diagnosis of knee OA (unilateral or bilateral). We included only female patients with OP that were at least 50 years old and at least 3 years post-menopausal.

Results: Content analyses revealed that the preferred media for patients obtaining treatment information were a) passive sources, (i.e., TV and DVDs) and b) active sources (i.e., workshops and classes). The preferred messengers were patients affected by the disease and physicians (specifically rheumatologists). Real life stories and testimonials narrating both successful outcomes with treatment adherence and complications of no adherence were preferred. There was discrepancy by the best method to receive information between patients and providers. Physicians stated that the preferred delivery method to provide information was written material (brochures, booklets and pamphlets). There were diverse perspectives about the key treatment messages to share with people with these conditions. The 3 key messages preferred by most patients and physicians were: 1) understanding the condition, 2) complications of non-adherence, and 3) side-effects.

Conclusion: The methods, key messages, and messengers identified in this study illustrate the need of combined efforts from consumer organizations and health providers for more adequate ways to effectively deliver treatment information to individuals with lower levels of education experiencing these chronic conditions.

Disclosure: M. A. Lopez-Olivo, None; **R. Volk**, None; **M. Jibaja-Weiss**, None; **M. E. Suarez-Almazor**, None.

983

Teaching Musculoskeletal Care Through An Inter-Disciplinary and Inter-Professional Clinical Training Program Successfully Provides Trainees With Knowledge and Skills Required To Deliver Excellent Musculoskeletal Care. Grant W. Cannon[1], Andrea Barker[1], J Peter Beck[1], Jeffery Berdan[1], Marissa Grotzke[1], Timothy A. Huhtala[1], Patrice Kennedy[2], Phillip Lawrence[2], JoAnn Rolando[1] and Michael J. Battistone[1]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]Salt Lake City VA, Salt Lake City, UT.

Background/Purpose: While musculoskeletal (MSK) complaints are some of the most common reasons for primary care and specialty visits, little time is dedicated to this important topic in training curricula. To address this critical need, we developed an inter-disciplinary and inter-professional program involving primary care (PC), rheumatology (RHE), orthopaedic surgery (OrS), endocrinology (END), and physical medicine specialists (PM&R) to train physicians and associated health professionals in MSK care.

Methods: Through funding from the Office of Academic Affiliations (OAA) of the Department of Veterans Affairs (VA), we developed an intensive week of training that combines didactics, simulations, and clinical experiences to establish a Center of Excellence (COE) for patient centered MSK care. A significant component of this experience is an inter-disciplinary clinic for evaluation of patients with complex MSK disorders. During COE clinic visits, patients are seen by a team of specialists including trainees, attending physicians, and advanced practice clinicians in the specialties listed above. The trainees and practitioners of this inter-professional and inter-disciplinary team evaluate patients and implement a comprehensive management plan. Faculty assess trainee competence through direct observation in clinical experiences and an objective structured clinical exam (OSCE).

Results: To date, 40 physician trainees (30 PC, 3 RHE, 1 OrS, 1 END, 5 PM&R) and 8 associated health trainees (4 DNP, 2 PA, 1 Physical therapist, 1 Pharmacist) have been involved in COE training. A review of the first 140 patients seen in the COE MSK inter-disciplinary clinic documents a rich clinical training opportunity with an average of 2.4 ± 1.5 complaints per visit, and patients being seen by 2.8 ± 1.2 disciplines. The chief MSK complaint by patients was classified according to the following areas (OrS, RHE, END, PC); however, as noted, the vast majority of patients had multiple MSK diagnoses.

	Chief Complaint	Co-Morbid Conditions	Most common diagnoses
OrS	73%	91%	Osteoarthritis, shoulder, knee & spine complaints
RHE	22%	38%	Rheumatoid arthritis, gout, other MSK diseases
END	4%	49%	Osteoporosis, vitamin D deficiency
PC	1%	26%	Fibromyalgia, chronic pain

Trainees reported high satisfaction with the intensive training and COE MSK clinic. Self-assessment of knowledge and skills for several of the key elements evaluated for physician trainees is listed below.

Competency Assessment	Pre-course	Post-course	Change
Comprehensive shoulder and knee pain evaluation	16.7%	100%	83.3%
Manage shoulder and knee pain	11.1%	94.4%	83.3%
Manage gout	22.2%	94.4%	72.2%
Indication for joint injection	5.6%	94.4%	88.9%
Shoulder/Subacromial injection using simulation	27.8%	100.%	72.2%
Knee aspiration using simulation	50.0%	94.4%	44.4%
Perform joint aspirations and injections on patients	23.5%	100.%	76.5%
Diagnose and manage patients with osteoporosis	35.3%	100%	64.7%

There was marked improvement in MSK knowledge and skills in all areas of training with reported improvement in clinical competence confirmed on OSCE.

Conclusion: The COE in MSK disease provides a comprehensive training program in MSK disease. The employment of an inter-disciplinary and inter-professional training model gives trainees the unique opportunity to learn to manage patients with MSK disease in a rich collaborative setting.

984

Development and Usability Testing Of The Arthritis Health Journal: An Online Tool To Promote Self-Monitoring In People With Rheumatoid Arthritis. Erin Carruthers[1], Paul M Adam[2], Hilary Horlock[3], Linda C. Li[4], Anne F. Townsend[1], Charles H Goldsmith[5], Beverly Mitchell[3] and Diane Lacaille[6]. [1]Arthritis Research Centre of Canada, Richmond, BC, [2]Mary Pack Arthritis Centre, Vancouver, BC, [3]Provincial Health Services Authority, Vancouver, BC, [4]University of British Columbia, Vancouver, BC, [5]Simon Fraser University, Burnaby, BC, [6]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC.

Background/Purpose: Patient passports have been used in chronic diseases to promote the active involvement of patients in their care, and have led to better treatment and health outcomes. In rheumatoid arthritis (RA), the 'Treat to Target' approach emphasizes the importance of regular assessment and modifying therapy until the target (remission or low disease activity) is reached. Active involvement of RA patients in monitoring their own disease activity could facilitate this approach by providing early warning when targets are not being met. The Arthritis Health Journal (AHJ) is a patient-centered online tool that helps patients track symptoms, monitor disease activity and develop action plans. This study aims to evaluate user satisfaction with the AHJ and to identify usability issues that will help refine the tool.

Methods: Development of the AHJ was guided by a series of semi-structured interviews with patients and rheumatologists. The tool consists of six sections: 1) symptom and exercise log; 2) disease activity assessment; 3) mood assessment; 4) medical information; 5) goals and action plans; 6) health reports.

Two iterative cycles of usability testing were conducted with people with RA using the concurrent think-aloud protocol, in which participants are asked to verbalize their thoughts while performing a set of tasks. Sessions were audio-recorded and field notes were taken. The System Usability Scale (SUS) was used to evaluate the usability of the tool (min-max=0–100; higher=more user friendly) and simple content analysis was performed to identify issues and refine the tool.

Results: Usability testing was conducted with nine participants with RA–five in the first iteration and four in the second iteration. Mean (SD) RA duration was 11y (12.6); mean (SD) age was 51.6y (10.2). All participants were female and most (89%) were college or university educated. Mean (SD) daily internet use was 4h (2.2). The tool's overall usability was good, with a mean (SD) SUS score of 84.7 (7.7).

Participants responded positively to the content and design of the AHJ, reporting particular satisfaction with the ability to view patterns over time and relationships between symptoms and other aspects of their disease or management. Graphical representation of results was viewed as an effective method of displaying these patterns.

Aspects of the interface that were modified after the first iteration led to improved satisfaction in the second iteration. Ensuring font types, sizes and colours were easy to read was essential to user satisfaction. Participants rarely read text or instructions, so long blocks of text were replaced with simple and succinct instructions, and key points were emphasized to ensure important details were understood. Particularly, instructions regarding time frame in analog scale questions (e.g. in the past week) tended to be ignored or go unnoticed, until questions were reformatted in the second iteration to more clearly emphasize the time frame.

Conclusion: Direct observation methods provided valuable insight into the use of online tools to promote active involvement of patients in their care. While general satisfaction was high, usability testing revealed important issues that warranted improvement to refine the prototype.

985

Efficacy Study Of Multimedia To Educate Rheumatoid Arthritis Patients. Julie A. Unk. Washington Univ School of Med, St. Louis, MO.

Background/Purpose: The level of health literacy varies among rheumatoid arthritis (RA) patients in their ability to understand and act upon information presented in a clinic appointment. The purpose of this randomized trial was to improve patient clinician communication in the rheumatology office by assessing the efficacy of multimedia compared to a handout for RA patients with the goals of improving patients' scores on the self reported Medication Adherence Questionnaire (MAQ) at one month post intervention. Scores of the Brief Illness Perception Questionnaire (BIPQ), Health Assessment Questionnaire (HAQ), and program evaluation were also assessed.

Methods: 200 RA patients in a Midwestern rheumatology outpatient clinic were recruited over 10 months. All participants provided informed consent. They were randomized 1:1 to receive a handout or a 15 minute audio visual Power Point program. At baseline all participants completed a demographics questionnaire, MAQ-5 questions, BIPQ-8 questions, and HAQ identified only by study number. Participants randomized to the handout group took the document home to read. Participants randomized to the multimedia group were shown the program while in the office and sent home with a handout and CD copy of the program. At baseline all participants were sent home with the 3 follow up questionnaires (MAQ, BIPQ, and HAQ) and program evaluation to complete and mail back. At one month all participants were called and reminded to complete and return the forms. Study data were entered and managed using the Research Electronic Data Capture tool (REDCap).

Results: The multimedia group had significant improvement in the MAQ score of skipped doses ($p=0.006$) and experienced significantly fewer physical and emotional symptoms compared to the handout group ($p=0.03$, $p=0.03$ respectively). Both groups had improvement in MAQ and BIPQ scores. No change was seen in the HAQ scores of either group. Upon program evaluation both groups equally reported a better understanding of rheumatoid arthritis.

Conclusion: Multimedia was superior to handout to educate RA patients about adherence to medications which resulted in improved physical and emotional symptoms. Healthcare providers should use multimedia to educate RA patients about causes of disease, RA effects on the body, treatments for RA, self-care strategies, and resources to access more information about their disease. Multimedia can be used as a tool to address health literacy and improve patient clinician communication.

Participant and Educator Feedback Informs Delivery Of An Interprofessional Inflammatory Arthritis Education Program Using Telemedicine In Rural Communities. Carol Kennedy[1], Kelly Warmington[2], Carol Flewelling[1], Rachel Shupak[3], Angelo Papachristos[4], Caroline Jones[4], Dorcas Beaton[5], Sydney C. Lineker[6] and Denise Linton[1]. [1]St. Michael's Hospital, Toronto, ON, [2]Hospital for Sick Children, Toronto, ON, [3]St. Michaels Hospital, Toronto, ON, [4]St Michael's Hospital, Toronto, ON, [5]Scientist, Institute for Work & Health, Toronto, ON, [6]The Arthritis Society, Toronto, ON.

Background/Purpose: Telemedicine-based approaches to healthcare service delivery are known to improve access to care, as well as the efficiency, quality and timeliness of healthcare service provision in sparsely populated areas. Arthritis care providers working in rural communities recognized that patients with inflammatory arthritis had limited access to appropriate patient education and could benefit from the Prescription for Education (RxEd) program (a one-day education session for adults with inflammatory conditions delivered by an interprofessional team of specialized arthritis care providers).

The one-day program was adapted to include the use of interactive videoconferencing as a method of delivery. Adaptive strategies for educators

(local presenters and rural site clinical leads) included two workshops (Telemedicine Best Practices and Adult Education Principles; Improved Public Speaking) designed to optimize the instructive value of the videoconferencing technology.

The objectives of this presentation are: 1) To explore the feasibility of and participant satisfaction with the use of telemedicine to deliver the RxEd program in rural communities; 2) To use process outcome data to inform improvements in the delivery of future sessions.

Methods: Participants included adults with inflammatory arthritis attending the RxEd program locally or at one of four rural sites (remote). Participants completed course evaluations immediately post-program. Educators completed post-program reflective logs (including qualitative perceptions of videoconferencing technology, interaction between sites, small group learning activities). In addition, a debriefing meeting was held (RxEd educators, telemedicine coordinators, researchers) to discuss collected data and identify delivery modifications to be implemented in future sessions.

Results: Forty-nine persons (12 local; 37 remote, across 4 sites) attended the inaugural RxEd Telemedicine session. Forty-three completed the post-program course evaluation (12 local; 31 remote). Preliminary findings indicate that remote participants were satisfied with the quality of the videoconference (% responding with 'agree' or 'strongly agree'): could hear presenter (97%), could see who was speaking at remote sites (83%), could see slides (87%), adequate facilitation of interaction between sites (90%), could hear discussion between sites (73%).

Educators' post-program reflection logs (n=9) captured feedback about the quality of the videoconferencing, interaction between sites, and small group learning activities. Many of the concerns identified by the educators were consistent with participant feedback. Suggested improvements included: the use of two screens where possible and direct frontal camera angles; equality of interaction with remote sites; slide modifications to improve readability on screen and in handouts; and slight changes in program delivery.

Conclusion: Findings from this pilot session confirm that it is feasible to extend the RxEd program to rural communities using telemedicine. Several areas for improvement of the Telemedicine delivery have been identified and will be addressed where possible.

Improving Access To Subspecialty Care For Underserved Communities: A Rheumatology Patient Navigator Pilot Intervention. Candace H. Feldman[1], Gregory A. Culley[2], Erika Brown[3], Chanele R. Assencoa[2], LeRoi S. Hicks[4] and Daniel H. Solomon[5]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Family Health Center of Worcester, Inc., Worcester, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]UMass Memorial Medical Center, Worcester, MA, [5]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA.

Background/Purpose: Early and sustained access to rheumatology care can improve access to disease-modifying medications and reduce disparities in outcomes. In one state, more than one-half of community health center (CHC) medical directors felt that their predominantly low-income, underserved patients required better access to rheumatology care. We pilot tested an intervention that utilized a patient navigator- a layperson trained to provide a range of education, advocacy and care coordination services- to improve access to rheumatology and musculoskeletal care.

Methods: We partnered with a CHC that cares for over 30,000 patients each year, 95% with income levels below 200% of poverty. The CHC medical director identified an affiliated community health worker to serve as the patient navigator. We developed a rheumatology/musculoskeletal disease curriculum to train the navigator and provided comprehensive patient resources and pamphlets for distribution. We identified established patients with rheumatic and musculoskeletal diseases by ICD-9 code, and primary care providers (PCPs) confirmed whether each patient would benefit from the navigator's assistance. All patients requiring a new rheumatology appointment were also referred to the navigator. We conducted semi-structured interviews with patients to assess need and tracked all navigator services provided.

Results: Of the 695 patients initially identified by ICD-9 code with possible rheumatic and musculoskeletal diseases, 125 were referred to the navigator; 29 also required new rheumatology appointments. On average, 5 new referrals (range 2–10) were received weekly. After 3 months, 31 (28%) patients were actively working with the navigator, 81 (72%) patients' PCPs were actively in communication with the navigator, and 62/81 (77%) of these patients were in the process of being engaged (outreach attempts made or waiting for appointments to be scheduled). Two of the 125 (2%) patients declined participation. Among the 31 actively engaged patients, navigator's services included direct coordination of appointments and repeated reminders prior to the visit (n=26, 84%), facilitation of communication between providers (n=31, 100%), transportation arrangements (n=7, 23%), financial services including provisions for affordable medications (n=4, 13%), coordination of live interpreters (n=2, 6%), and organization of senior services (n=2, 6%). Of the 29 patients scheduled to see rheumatologists, 14/17 (82%) successfully kept their appointments and 12 appointments are upcoming.

Conclusion: This CHC-based rheumatology navigator pilot demonstrates the feasibility and acceptability of subspecialty navigators to improve access to care for underserved patients. Further research is needed to assess the effectiveness and costs of the patient navigator.

988

Lupus Education For Providers Serving The Asian American Community: Hospital For Special Surgery's LANtern® (Lupus Asian Network) Initiative. My-Lan N. Tran[1], Roberta Horton[2], Michael D. Lockshin[2] and Arthur Yee[2]. [1]Hospital for Special Surgery, New York City, NY, [2]Hospital for Special Surgery, New York, NY.

Background/Purpose: Lupus affects Asian Americans 2–3 times more than their white counterparts, with studies demonstrating health disparities in severity and outcomes. Our hospital's national support and education program for Asian Americans with lupus and their loved ones, as part of our community service plan initiative, piloted a collaborative effort to raise awareness about lupus as an Asian American health concern with community providers in healthcare and social services.

Methods: Our program identified and formulated collaborative partnerships with three key stakeholders with longstanding histories of servicing a lower socioeconomic and immigrant population within the Asian American community. We coordinated and delivered specifically designed professional education for medical practitioners in primary care, pediatrics, obstetrics-gynecology, and psychiatry, in addition to programs for health professionals in women's health and mental health, and social services providers. Post-program measures assessed the degree to which these programs contributed to professional learning, enhanced clinical practice, increased interest to learn more about lupus, and overall degree of satisfaction. We also launched an *e-News* publication as a forum for professionals serving the Asian American community.

Results: A total of 10 lupus education programs and 2 *e-News* publications were delivered in 2010–2012. Seven of these programs were for healthcare providers on lupus topics relevant to their professional interests and areas of practice. Of the 94 evaluations completed, 98% strongly agreed/agreed that the presentations contributed to their professional learning, and 96% strongly agreed/agreed that the content would enhance their clinical practice. Responses to open-ended questions underscored how the presentations contributed to their care of lupus patients, for example, "to use helpful clinical pearls in future clinical assessment", and "awareness of subtle presentation of the disease, early diagnosis, treatment and maintenance would result in better outcome."

For the 3 programs tailored for social service providers, the 63 evaluations submitted reflected that 97% strongly agreed/agreed that their awareness of lupus had increased as a result of these presentations. Regarding what was most learned, responses included "what lupus is, and how much of an impact it is to patients and family", and "lupus can affect anyone and differently."

The pilot issue of our e-News was sent to 150 recipients; the 2nd issue reached > 400 interested professionals, an increase of 266%.

Conclusion: Early identification and appropriate treatment of lupus may significantly influence its progression and impact. To our knowledge, this is the first initiative directed toward increasing knowledge of lupus for

providers serving the Asian American community. Our professional education, with topics specifically relevant to providers' areas of practice, yielded a positive impact in potential care outcomes. The increase in our e-News reach also demonstrated an interest among providers in learning more about lupus as an Asian American health issue, as well as the potential power of this form of messaging.

Disclosure: M. L. N. Tran, None; **R. Horton**, None; **M. D. Lockshin**, None; **A. Yee**, Pfizer, Abbvie, Abbott, 6.

989

Reproductive Counseling Program For Lupus Patients At The Systemic Lupus Erythematosus-Antiphospholipid Syndrome Center Of Excellence At Hospital For Special Surgery. Katherine Kim[1], Alana B. Levine[2], Monica C. Richey[2], Nadine H. Spring[2], Elizabeth Schulman[3], Lisa R. Sammaritano[2], Shari E. Gelber[4] and Jane E. Salmon[2]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgey, New York, NY, [4]New York Presbyterian Hospital, New York, NY.

Background/Purpose: Maternal exposure to mycophenolate mofetil (MMF) during pregnancy is associated with increased risks of first trimester pregnancy loss and congenital malformations. Responding to this observation, the Food and Drug Administration (FDA) mandated a risk evaluation and mitigation strategy (REMS) for MMF in October 2012. MMF is currently used to treat a variety of conditions including systemic lupus erythematosus (SLE) and lupus nephritis. The HSS SLE-APS Center of Excellence (COE) serves a large number of female patients of child-bearing potential. Based on these facts, we developed a survey to better understand the reproductive counseling needs of our cohort. The objectives were: a) To understand SLE patients' pregnancy intentions and assess their current patterns of contraceptive use. b) To assess the level of contraceptive and reproductive counseling offered by the HSS SLE-APS COE and determine the need for and patient interest in contraceptive and reproductive patient education.

Methods: An anonymous, 9-question paper survey was offered to patients of the HSS SLE-APS COE from December 2010 to September 2011. Survey questions assessed attitudes about pregnancy, patterns and type of contraceptive use, prior pregnancy and contraceptive counseling by healthcare providers, and patients' interest in participating in new reproductive health educational programs offered by the COE.

Results: Sixty-six patients completed the survey; 53 (80%) were female. 23 (35%) patients could recall a discussion with COE healthcare providers regarding contraceptive use; 22 (33%) remembered such a conversation about pregnancy. 56% were interested in participating in a contraception class and 53% were interested in a pregnancy class (Table 1).

Table 1.

Pregnancy Intentions (n=66)	
Pregnant	4 (6%)
Trying to become pregnant	4 (6%)
WouldnÂ't mind becoming pregnant	13 (20%)
Trying to avoid pregnancy	29 (44%)
Not possible to become pregnant	18 (27%)
Haven't considered pregnancy	2 (3%)
Contraceptive use (n=66)	
Never	13 (20%)
Rarely	6 (9%)
Sometimes	11 (17%)
Most of the time	8 (12%)
Always	14 (21%)
Not applicable	14 (21%)
Contraceptive type (n=34)	
None	56%
Barrier	35%
Estrogen/progesterone pill	3%
Progesterone only pill	3%
Progesterone injection	3%

Conclusion: Our survey demonstrated a striking deficiency in recall of contraceptive and reproductive counseling by patients in our COE. Over half of survey participants were interested in a formal educational program on these topics. Based on data from this survey and the FDA's mandate, the SLE-APS Center of excelence now offers a personalized, one-on-one, patient education session taught by a registered nurse for SLE patients taking MMF. Similar sessions for patients receiving cyclophosphamide, methotrexate, and azathioprine are being developed.

Disclosure: K. Kim, None; **A. B. Levine**, None; **M. C. Richey**, None; **N. H. Spring**, None; **E. Schulman**, None; **L. R. Sammaritano**, None; **S. E. Gelber**, None; **J. E. Salmon**, None.

990

Utilizing Facebook Chats To Convey Health Information To Lupus Patients At The Systemic Lupus Erythematosus-Antiphospholipid Syndrome Center Of Excellence At Hospital For Special Surgery. Nadine H. Spring[1], Elyse Bernstein[1], Su Jin Kim[1], Monica C. Richey[1], Jessica Rowshandel[2] and Jane E. Salmon[1]. [1]Hospital for Special Surgery, New York, NY, [2]SLE Lupus Foundation, New York, NY.

Background/Purpose: The SLE-APS Center of Excellence at Hospital for Special Surgery (HSS) uses Facebook chats as a means to increase awareness, reach a wider audience, allow for interaction between patients and health care providers, and answer patients' questions about lupus. To date, three chats have been completed. These lupus Facebook chats help to educate patients about their disease and the importance of maintaining relationships with their rheumatologists.

Objective: To determine whether collaboration with a disease-specific foundation increases patient awareness of and participation in lupus Facebook chats.

Methods: Three chats have been completed. The first two were promoted through advertising and promotion on the HSS's Facebook and Twitter accounts, targeted pitching of lupus bloggers and awareness groups, word of mouth, and by flyers. For the third chat, HSS collaborated with the S.L.E. Lupus Foundation and they used similar advertising. Participants were instructed to like the HSS Facebook page and post their questions. A panel of rheumatologists, an obstetrician-gynecologist, social workers, physical therapists, nutritionists, and a rheumatology nurse practitioner responded to as many questions as possible over one hour. Remaining questions were distributed to the experts for answers and turned into a blog series on "HSS on the Move" (www.hss.edu/onthemove).

Results: The first chat (May 2012) focused on lupus and medications. 2,280 users saw the chat post, with 60 questions and comments from 20 users. Promotional Facebook posts before the chat were shared 247 times. HSS reported 14 twitter mentions and five retweets. The HSS page received 30 new likes on the day of the chat, and 21 users liked the chat post. The second chat (October 2012) discussed lupus, pregnancy, and reproductive health. There were 2,203 people who saw the chat with 25 questions and comments from 12 users. The promotional Facebook posts were shared 81 times and eight users retweeted. The HSS page received 34 new likes the day of the chat. In May 2013, HSS collaborated with the SLE Lupus Foundation for the third chat on lupus and general health. 6,624 people saw the chat. The HSS Facebook page received 332 new likes on the day of the third chat. The month's daily average was 34 likes. The chat post drew 78 likes. There were 123 participants representing six countries and 28 States. Participants posted 162 questions and comments with 61 answered during the hour. The promotional Facebook posts before the chat (from HSS and the S.L.E. Foundation) were shared 288 times. The S.L.E. Lupus Foundation tweeted an additional 18 times in promotion of the chat.

Conclusion: Participation level was higher when the topics were more general. Lower participation in the second chat may relate to the private nature of the topic and concerns of privacy. Collaboration with the SLE Lupus Foundation increased patient awareness of the chat and participation. This experience suggests that partnering with disease-specific community organizations can enhance delivery of health education programs. More data from participants are needed to determine how they learned about the chat, why they joined, and how to increase comfort in asking difficult questions in an open forum.

991

Utilization Of An Informational Needs Assessment To Develop An Education Program For Patients With Ankylosing Spondylitis (AS) and Related Axial Spondyloarthritis (SpA). Rita Kang[1], Rebecca Morton[1], Christopher Hawke[2], Laura A. Passalent[2], Robert D. Inman[3], Dinny Wallis[2], Joan Blair[2], Alison Lake[1], Heather Sloman[1], Marc Doucet[4], Debra MacGarvie[1] and King Wong[4]. [1]University Health Network-Toronto Western Hospital, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON, [3]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON, [4]University Health Network, Toronto, ON.

Background/Purpose: The effectiveness of education programs for patients with arthritis has been well documented. Despite this, there has been minimal investigation into patient education specifically for ankylosing spondylitis (AS) and axial spondyloarthritis (SpA). The current evidence suggests that only 40% of patients with AS are being referred for education. AS patient education programs have demonstrated positive effects with respect to mobility, function, self efficacy, and depression, however many of these effects are not sustained over the long term. Effective patient education programs are built on carefully executed needs assessments.

The objective of this study was to identify what patients with AS and SpA feel their current informational needs are. In addition, the method of preferred information access was also assessed, i.e. group classes vs. pamphlet etc. This information will be used to develop a comprehensive interprofessional patient education program for patients with AS and SpA attending the Toronto Western Hospital Spondylitis Clinic, Toronto, Ontario, Canada.

Methods: Patients with AS and SpA were emailed a link with an Informational Needs Assessment Survey. This included five multiple choice sections: 1. Demographics, 2. Disease, Diagnosis and Prognosis, 3. Management, 4. Relationships, 5. Emotions and an open ended question at the end of the survey. Descriptive statistics and bivariate analyses were used for data analysis. Qualitative statistical methods were utilized to address the open ended question section.

Results: The response rate was 32.1%, of which 66.1% were male. The sample group was primarily older adults, with 22.3% between the ages of 31 to 40, 23.2% between the ages of 41 to 60. The sample group was well educated, with 50.0% completing college or university and 24.1% completing graduate school. The average number of years since diagnosis was 11 years. Of those who completed the survey, 21 (19.4%) were newly diagnosed (diagnosed between 2010–2012) and 87 (80.6%) were diagnosed earlier than 2010. The Disease, Diagnosis and Prognosis and Management sections were found to be the most important informational needs. In addition: website, on-line audio/ video and E-learning were cited as the most useful ways to receive information in all five sections. Qualitative analysis indicated three major themes concerning patients including medication/pain, fatigue/activity/work and long term prognosis.

Conclusion: Based on the needs assessment, it was determined to develop an e-learning module for this patient population followed by self-management focused face-to-face sessions. It is anticipated this unique education program for patients with AS and SpA will be a successful model using best practice in patient education.

Promise Of Behavioral Economics: Delay Discounting and Physical Activity In Patients With Musculoskeletal Diseases. Elena Losina[1], Yan Dong[1], Stephanie Chen[1], Ran Schwarzkopf[2], Laurel Donnell-Fink[1], David Lerner[1] and Jeffrey N. Katz[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]University of California Irvine Medical Center, Orange, CA.

Background/Purpose: Despite strong evidence that physical activity (PA) is associated with better quality of life, less pain and better functional status in persons with musculoskeletal diseases, uptake of PA in this population is low. PA is also associated with delayed rewards, which people tend to value less than immediately tangible benefits. Behavioral economics studies document that preference for smaller immediate rewards, as compared with larger delayed rewards – defined as delay discounting – is related to obesity, substance abuse and drug dependence. We sought to examine the relationship between delay discounting and uptake of PA in patients with musculoskeletal diseases.

Methods: We conducted a cross-sectional study among patients attending an arthritis clinic in a tertiary medical center. Patients completed a questionnaire in which they were asked to choose between pairs of hypothetical monetary rewards in which one reward (e.g. $100) is offered immediately and an alternative, larger reward is offered after a time delay (e.g. $200 after one year). The amounts of the rewards ranged from $100 to $50,000 and the time frames ranged from no delay to a delay of 10 years. The delay discounting factor (DDF) was derived using a hyperbolic function and divided into quartiles. We assessed engagement in PA with the Yale Physical Activity Scale, using the overall Activity Dimensions Summary Index (ADSI) as well as the Vigorous Activity and Leisurely Walking indices. We conducted a multivariate regression analysis to establish the association between delay discounting and PA scores, adjusted for age, sex, BMI and race.

Results: The analysis is based on 172 study subjects with a mean age of 56 years (SD 14). 69% were female, the mean BMI was 29 (SD 7), and 34% were obese (BMI>30 kg/m^2). The primary reasons for seeing a rheumatologist were back pain (46%), osteoarthritis (29%) and rheumatoid arthritis (23%). The average value of ADSI was 49 (SD 29). Mean values of both vigorous and walking PA indices were 3 (range 0–12). After adjusting for age, sex, obesity and race, a greater extent of delay discounting (greater preference for immediate rewards) was statistically significantly associated with lower overall PA ($p=0.0168$), as well as lower vigorous ($p=0.0032$) and walking ($p=0.0370$) activity indices (less engagement in physical activity). Adjusted least squared means for ADSI ranged from 38 in the highest quartile of DDF to 54 in the lowest quartile of DDF. Corresponding adjusted means for vigorous PA ranged from 3.4 for the lowest quartile of DDF to 1.7 for the highest quartile of DDF. A similar trend was observed for walking.

Conclusion: Delay discounting, characterized by preference for smaller immediate rewards rather than larger delayed rewards, is associated with lower levels of PA among persons with musculoskeletal conditions. These data provide rationale and support for the development of incentives-based interventions, built on the principals of behavioral economics, to increase the perception of immediate rewards associated with PA among persons affected by musculoskeletal diseases. Such interventions may serve as a means of improving engagement in PA in persons affected by these conditions.

An Analysis Of Healthcare Resource Utilization Among Patients Undergoing Total Knee Arthroplasty In The United Kingdom. Mireia Raluy[1], Michael Schoenfeld[2], Dimitra Lambrelli[1], Meng Wang[1], Ning Wu[3], Shih-Yin Chen[3] and Russel Burge[2]. [1]United BioSource Corporation, London, United Kingdom, [2]Eli Lilly and Company, Indianapolis, IN, [3]United BioSource Corporation, Lexington, MA.

Background/Purpose: Elective total knee arthroplasty (eTkA) is among the most commonly performed surgical procedures. The typical reasons for eTkA are pain and decreased quality of life (QoL) from osteoarthritis. These patients can be at risk of various clinical complications, mobility impairment, muscle weakness, decreased ability to perform daily activities. The purpose of this study was to assess the patient characteristics, healthcare resource use, and costs among eTkA patients in large UK-based general practitioner and hospital databases.

Methods: The Clinical Practice Research Datalink (CPRD) linked to the Hospital Episode Statistics (HES) was used to estimate resource use in adult eTkA patients. Inclusion criteria: patients had no GP visits or inpatient stays with OPCS (4.6) procedure codes suggesting eTkA (W-40, 41, 42) in 7 days to 1 year prior to index date (hospital stay for eTkA) with at least 1 year of computerized data pre- and post-index hospitalization. Elective TKA related medical costs (British Pound Sterling, 2012) were calculated by multiplying resource units by official publicly available costs from the NHS perspective.

Results: This study included 12,737 patients with mean age of 71 years, of whom approximately 26% were within 18–65 years of age. Pre-index, opioids (53%), NSAIDs (48%), and acetaminophen (34%) were the most common medications, followed by oral steroids (24%) and antidepressants (17%). Nearly all patients had osteoarthritis (98.6%). Other common comorbidities were pulmonary disease (22.4%), cancer (14%), renal disease (13.9%), and osteoporosis (6.8%). The Charlson Comorbidity Index (mean score was 1.3. For the index hospitalization, average length of stay was 6.2 days and average costs (standard deviation [SD]) were £5,397 (2,459). After index hospitalization the majority of patients (97.5%) were discharged to their place of residence and 1.6% were discharged to another NHS hospital. During their index hospitalization the majority of patients (98.0%) were treated by trauma and orthopedics; almost one-fourth (23.8%) were treated by general medicine. The mean (SD) total healthcare cost in the pre-index period was £2,507 (4168), driven mainly by inpatient costs that were £1,858. Average outpatient costs were £592 and pre-index pharmacy costs were £57. During the post-index follow up, mean (SD) overall cost was £2068 (6519), with average inpatient costs of £1,526.

Conclusion: This study described resource utilization, pain medications usage, and costs among patients undergoing eTkA in the UK. These estimates may provide a better understanding of the ubiquitous economic burden of this condition.

The Economic Burden Of Osteoarthritis In Americans: Analysis From a Privately Insured Population. Susanne X. Wang[1], Arijit X. Ganguli[1], Dendy Macaulay[2], William Reichmann[3], Jeroen Medema[1] and Mary A. Cifaldi[1]. [1]AbbVie Inc., North Chicago, IL, [2]Analysis Group, Inc., New York, NY, [3]Analysis Group, Inc., Boston, MA.

Background/Purpose: Osteoarthritis (OA) is the most common form of arthritis and leading cause of working age disabilities. Over 27 million US adults have clinical OA, and different types of burdens exist based on the disease stages and locations. The burden of OA by joint location, age, or comorbidity has not been well studied. The objective of this study was to assess the excess healthcare resource use and costs attributable to OA by joint location, age, and comorbidity in a privately insured population.

Methods: 428,084 OA patients aged 18+ were selected from a US-based employer claims database (1999–2011). Controls were selected from the same database by matching OA patients 1:1 by age, gender, index date, and follow-up, to patients who never had OA in their claims histories. Descriptive analyses were used to compare baseline characteristics and study period medical resource use and costs, inflated to 2011 USD using annual medical CPI data (Bureau of Labor Statistics). Statistical comparisons were made using McNemar's test for categorical variables and the Wilcoxon signed-rank test for continuous variables.

Results: Among all the OA patients studied, 181,379 had a primary claim of knee OA; 48,617 had hip OA; 29,340 had hand OA; and 30,549 had spine OA. The average age of OA patients was 63 years and 59% were female. At baseline, OA patients tended to have a greater comorbidity burden than controls ($P< 0.001$). The occurrence of the 4 most common comorbidities between the OA group and controls were hypertension (45% vs 30%, respectively), cardiovascular disease (16% vs 9%, respectively), diabetes (16% vs 10%, respectively), and depression (8% vs 4%, respectively). OA patients aged 18+ incurred total annual medical costs of $8,644 vs $2,273 in controls ($P< 0.001$). 20% of all OA patients had at least 1 primary joint arthroplasty, 1% had a revision joint arthroplasy, and 2% had arthrodesis. The cost per surgery ranged from $16,000 to $25,000. On average, a hip arthroplasty cost $18,425 and a knee arthroplasty cost $17,433. Annual pharmacy cost was $2,179 for OA patients and $1,096 for controls. OA-related healthcare costs are summarized by joint locations, age, and comorbidity in **Table 1**.

Table 1. OA-Related Mean Cumulative One-Year Costs by Joint Location, Age, and Comorbidity

Subgroup	Total Medical*	Inpatient	Outpatient	Physical or Occupational Therapy	Pharmacy
Overall	$ 8,644	$3,533	$4,921	$265	$2,179
Joint location					
Knee	$ 9,466	$4,178	$5,093	$292	$2,086
Hip	$12,478	$7,473	$4,818	$295	$2,047
Hand	$ 6,705	$1,505	$5,004	$221	$2,256
Age group, y					
18–44	$10,857	$3,398	$7,070	$440	$1,794
45–64	$12,799	$5,400	$7,144	$395	$2,258
65+[†]	$ 3,510	$1,429	$2,002	$ 84	$2,156
Comorbidity					
Hypertension	$ 8,917	$3,855	$4,857	$232	$2,519
CVD	$10,844	$4,993	$5,575	$157	$3,150
Diabetes	$10,815	$4,709	$5,859	$242	$3,358

CVD=cardiovascular disease; OA=osteoarthritis.
* Total medical costs are equal to the sum of inpatient, outpatient, and emergency room costs.
[†] Costs for 65+ may be underestimated because payments observed here are supplements to Medicare.

Conclusion: Patients with OA incur greater medical and pharmacy costs than those without OA. The burden of OA varies substantially by joint location. Surgical procedures are the most significant cost among all categories, and therefore is also the main driver of the total cost. In contrast, pharmacy costs are rather small due to no disease-modifying OA drug (DMOAD) available. Hand OA had lower cost than knee and hip due to lack of DMOAD and effective surgery. In summary, OA presents a great disease and economic burden. The current treatment options are limited to generic symptom-modifying drugs and late-stage surgical management of the disease, but the latter is only available for certain joints.

Quality Of Life, Productivity Impairment, Disease Severity and Health Care Costs In Relation To Functional Impairment In Psoriatic Arthritis Patients In The Czech Republic. Jiri Stolfa[1], Liliana Sedova[1], David Suchy[2], Jiri Klimes[3], Milan Vocelka[3] and Tomas Dolezal[3]. [1]Charles University Prague, Prague, Czech Republic, [2]University hospital Plzen, Plzen, Czech Republic, [3]Charles University, Prague, Czech Republic.

Background/Purpose: Our aim was to describe the QoL, productivity impairment, clinical indicators and health care costs in relationship to functional status described by Health assessment questionnaire (HAQ) in Psoriatic arthritis patients. This relationship is highly important to justify the investment into health care.

Methods: We have organized a prospective multicentre non-interventional observational study with Psoriatic arthritis (PsA) patients in 4 specialized centres for treatment of rheumatic diseases in the Czech Republic. There is 3 years of follow-up planned with 6 months period between each time point observation. The data presented here comes from the first visit, where demographics, clinical, QoL data and productivity were directly collected from patients. Health care consumption was assessed retrospectively reviewing individual patient's medical record (with 6 or 12 months recall period from the first visit). Clinical data were described by DAPsA, QoL measured by EuroQol questionnaire (EQ-5D), work impairment by Work Productivity and Activity Impairment (WPAI) in relationship to HAQ categories. Validated Czech versions of all questionnaires were used. Patients are stratified according to their HAQ in 6 categories, i.e. 0–0.5>, 0.5–1.0>, 1.0–1.5>, 1.5–2.0>, 2.0–2.5>, 2.5–3.0>. Within health care consumed, we focus on medication (classical DMARDs, corticosteroids and biological drugs), out-patient & in-patient care, complement and instrumental examination and out-of pocket money. Health care expenditures are annualized and presented as an average costs per patient. Patients are analysed as the whole cohort and specifically by the presence of biologic treatment.

Results: We have already included 164 patients with PsA, 63 on biological drugs, mean patient age was 57.3 years, mean time from diagnoses of PsA was 25.9 years, 52% were female. With higher

functional impairment, described by HAQ, there is an increase in age, time from diagnoses, percentage of work impairment and also decrease in work-active patients. There is also deterioration in clinical impairment (DAPsA) and QoL observed with worse functional status. There is almost the same height of total costs in each HAQ category in the cohort of patients treated with biologics, as these drugs are the biggest costs driver. However, there is a cost increase in the category with highest HAQ in the cohort not treated with biologics. See results table, where all values are presented as mean values, n.a.-not applicable.

Patients on biologic drugs

Whole cohort of patients

HAQ category	HAQ	No.	Age	Time from Dx(Years)	% women	Costs (EUR)	% of work-active	WPAI %	DAPsA	EQ-5D
0–0.5>	0.2	79	53.6	23.8	41.8%	4,264	72.2%	15.5%	8.5	0.803
0.5–1.0>	0.9	34	59.1	26.3	61.8%	4,407	44.1%	25.7%	11.6	0.679
1.0–1.5>	1.3	30	58.9	27.5	56.7%	4,486	16.7%	43.2%	16.6	0.554
1.5–2.0>	1.8	10	62.7	29.3	40.0%	10,302	10.0%	50.0%	21.2	0.510
2.0–2.5>	2.4	6	66.7	37.8	83.3%	6,796	16.7%	0.0%	28.5	0.378
2.5–3.0>	2.8	5	72.2	23.6	100.0%	1,218	0.0%	n.a.	24.8	0.216
Mean/total	**0.80**	**164**	**57.3**	**25.9**	**51.8%**	**4,657**	**48.2%**	**23.7%**	**12.6**	**0.680**

Conclusion: Patients with worse functional impairment (based on HAQ) revealed impairment of their QoL, work productivity and revealed also worse clinical outcomes. We present total health care costs according to the functional impairment. The findings attributed to higher HAQ impairment (i.e. HAQ $>$ 2.0) must be interpreted with caution because of lower number of patients in these categories.

Predictors and Modeling of Costs in Rheumatoid Arthritis. Jonas Eriksson[1], Thomas Frisell[2], Johan Askling[3] and Martin Neovius[1]. [1]Clinical Epidemiology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]Karolinska University Hospital, Stockholm, Sweden.

Background/Purpose: Costs in RA are substantial with 2–3 times higher mean annual costs than in the general population, but with a skewed cost distribution.[1] As a first step in identifying potential high cost patients, our aim was to identify predictors of costs, and assess the accuracy of prediction models in prevalent and incident RA patients using data from nationwide Swedish registers.

Methods: A prevalent cohort of RA patients ≥18y on Jan 1, 2010, was identified from the Swedish National Patient Register (requiring ≥2 visits listing RA) and the Swedish Rheumatology Quality Register, and followed until Dec 31, 2010. From the same registers, patients with the 1st visit listing RA in 2009, with a 2nd visit within one year, were identified to the incident cohort, and were followed for 1 year. Costs for inpatient care, nonprimary outpatient care, prescription drugs, and work loss, as well as explanatory variables, were retrieved from national registers. A linear regression model was used in a training set including 90% of the prevalent patients, and validated in the remaining 10%. The corresponding proportions in the smaller incident cohort were 50%/50%.

Results: 21,682 prevalent RA patients 18–64y were identified. The model included sex, age, time since register identification with RA, rheumatoid factor, hospital admission days and days of work loss the previous year, and any hospital admission/outpatient visit for chronic obstructive pulmonary disease, ischemic heart disease, and diabetes mellitus the previous 3 years. Predictions from the linear regression model performed well at the middle and higher end of the cost distribution, but poor in the lower cost segments (R^2=0.79; Figure).

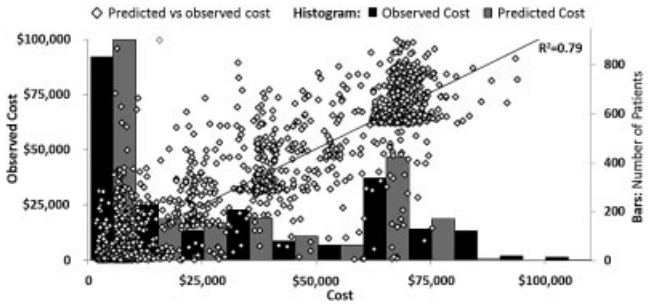

Figure. Scatter plot and histogram of predicted vs observed costs in working age prevalent RA (n=2168)

For the working age incident cohort (n=1378), the same variables were included plus annual income. Also this model performed better in the middle and higher cost segments than in the lower cost end of the distribution (R^2=0.59).

In both models work loss days was the strongest predictor, where 1 more day of work loss the previous year was associated with a $165 (95%CI 163–166) higher annual cost in prevalent patients and $145 (95%CI 133–157) higher in incident patients. For patients ≥65y, a linear regression model including available variables from national data sources resulted in poor cost prediction (R^2<0.15).

Conclusion: Reasonable prediction of annual costs in working age prevalent and incident RA patients was possible, while a satisfactory prediction model in older patients may need additional explanatory variables.

Does Biologic Treatment For Rheumatoid Arthritis Offset Health Care Costs In Patients With Rheumatoid Arthritis? An Instrumental Variable Approach Using Administrative Data. Nick Bansback[1], Eric Fu[2], Daphne Guh[2], Huiying Sun[2], Wei Zhang[2], Diane Lacaille[3] and Aslam H. Anis[1]. [1]University of British Columbia, Vancouver, BC, [2]Centre for Health Evaluation and Outcome Sciences, Vancouver, BC, [3]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC.

Background/Purpose: Expenditure on biologic therapies for rheumatoid arthritis (RA) accounts for the highest pharmaceutical spending in many western healthcare systems. Given their clinical benefit with marked reduction in symptoms and prevention of joint damage, biologics are expected to lead to reduced treatment related costs, such as joint surgeries or physician visits. Despite over a decade of routine use, there is currently no direct evidence supporting an association between biologic use and subsequent reductions in healthcare utilization. The objective of this study was to estimate the impact of biologic treatment compared to DMARDs on other healthcare utilization using instrumental variable (IV) techniques to control for confounding by indication.

Methods: From a population-based cohort of all patients with a rheumatologist diagnosis of RA identified from administrative data, we selected patients that mimick eligibility for reimbursement for biologics between 2003–2007 based on DMARD use history and having 3-year follow-up under the care of rheumatologists since eligibility. Patients receiving biologics in the first follow-up year form the treatment group whereas others who never received biologics throughout the follow-up form the control group. The data contains patient-level information on hospitalizations, physician visits (including investigations and procedures), and prescription medications. Since disease severity is known to be associated with treatment received and healthcare use, but is not directly captured in administrative data, conventional risk-adjustment

approach might not adequately adjust for this confounding by indication. We use an IV based on the prescribing rheumatologist's preference for biologic use at the time of treatment assignment to address the issue of unobserved confounder.

Results: The final analysis included 314 and 486 patients in the biologic and DMARD groups, respectively. As expected, conventional multivariable regression adjusting for observed confounders, but not necessarily for confounding by indication, did not attribute biologic use with cost offsets. The IV analysis results suggest that RA-related costs in the biologic group, compared to the DMARD group, in the 2- and 3-year follow up periods, was 22.5% (95% CI: −21.0%–90.0%) and 48.3% (2.0%–115.6%) more for physician visits but 45.9% (−63.7%–82.1%) and 32.7% (−97.4%–77.0%) less for medications excluding biologics or DMARD, whereas the odds ratios of hospitalization were 2.308 (0.44–12.00) and 3.64 (0.71–18.68), respectively. A similar pattern was observed for total resource utilization.

Conclusion: While RCTs are the gold standard for determining causal relationships, such studies would be infeasible to investigate this important question. Through the use of established econometric methods and a population-based administrative dataset, this study finds no signal that biologic use offsets health care costs in the short-term. Limitations include large confidence intervals common in IV studies, and follow-up of 3 years, which may be too short to observe cost savings from joint replacement prevention.

998

Adequacy Of Drug Coverage and Cost-Sharing For Medicare Beneficiaries With Rheumatoid Arthritis. Jinoos Yazdany[1], R. Adams Dudley[2], Randi Chen[3] and Chien-Wen Tseng[4]. [1]University of California, San Francisco, San Francisco, CA, [2]University of California San Francisco Philip R. Lee Institute for Health Policy Studies, San Francisco, CA, [3]Pacific Health Research and Education Institute, Honolulu, HI, [4]University of Hawaii and Pacific Health Research and Education Institute, Honolulu, HI.

Background/Purpose: Biologic and non-biologic disease-modifying anti-rheumatic drugs (DMARDs) significantly reduce pain, disability and mortality in rheumatoid arthritis (RA). We evaluated how well RA drugs are covered by Medicare Part D plans, and what copays are typically required.

Methods: We conducted a cross-sectional analysis of all Medicare Part D stand-alone plans' and Medicare Advantage plans' formularies (n=2,737) in 50 states and Washington D.C. using the January 2013 Centers for Medicare and Medicaid Services (CMS) Prescription Drug Plan Formulary and Pharmacy Network Files. Special Needs Plans (n=643) were excluded since they target subgroups of beneficiaries (e.g. institutionalized, chronic/disabling conditions, dually eligible for Medicaid) and may have specialized formularies. We used the default maintenance dose given by Epocrates©. To calculate the national average of the percentage of plans covering a drug and account for the fact that plans cover varying geographic regions, we first calculated the percentage of plans covering a drug in each county, averaged these percentages across all counties in the state, and then averaged across all 50 states and Washington D.C. We also examined prior authorization requirements and calculated the mean copays for each drug across all states.

Results: All plans covered at least 1 biologic DMARD, but 91% of formularies required providers to first obtain prior authorization (PA) for covered drugs. Across biologic DMARDs, coverage (with PA) ranged from 29% (anakinra) to 100% (adalimumab, etanercept, infliximab, rituximab; **see Table)**. In addition, the vast majority of plans (87%) charged a percentage co-insurance, requiring patients to pay on average 30% of drug costs. Thus, mean copays for biological DMARDs ranged from $255 to $650 per month. In contrast, for five non-biologic DMARDs (methotrexate, leflunomide, sulfasalazine, minocycline, hydroxychloroquine), nearly all plans provided coverage without requiring a PA. For these non-biologic DMARDs, approximately 90% of plans charged a fixed dollar copayment (range $5 to $11 per month); **see Table**.

Table Coverage for Rheumatoid Arthritis Drugs in U.S. Medicare Part D Plans.

Drug	Plans covering drug *(%)*	Plans covering drug without prior authorization *(%)*	Plans Charging Percent Co-insurance *(%)*	Mean Co-insurance *(%)*	Average Copay *Mean (SD) ($)*
Biologic					
Abatacept	54	4	100	30.1	601 (22)
Adalimumab	100	7	100	30.0	583 (12)
Anakinra	40	4	100	29.9	517 (19)
Certolizumab	59	1	100	29.6	650 (16)
Etanercept	100	7	100	30.0	547 (11)
Golimumab	42	1	100	29.6	580 (17)
Infliximab	100	7	100	30.0	255 (5)
Rituximab	100	8	87	29.5	611 (25)
Tocilizumab	40	1	99	29.7	335 (14)
At least 1 biologic DMARD	100	9	87	30.3	275*
Non-biologic					
Azathioprine	100	34	10	18.1	7 (1)
Cuprimine	60	60	59	30.6	83 (6)
Cyclophosphamide	94	2	20	27.4	32 (3)
Cyclosporine	100	12	22	25.1	34 (2)
Hydroxychloroquine	100	100	10	18.1	5 (1)
Leflunomide	100	100	13	19.3	11 (1)
Methotrexate	100	85	13	19.8	5 (1)
Minocycline	100	94	10	18.1	7 (1)
Sulfasalazine	100	100	10	18.1	5 (1)
At least 1 non-biologic DMARD	100	100	11	18.2	4*

*mean copay of least expensive drug covered.

Conclusion: Although most health plans serving Medicare beneficiaries cover at least one biologic DMARD, nearly all require a PA and charge a percent coinsurance. Medicare beneficiaries with RA who require biologic therapies can expect very high mean copays regardless of which Part D plan they choose, likely posing a significant financial barrier for many patients.

Cost Consideration For Biologics For Patients With Rheumatoid Arthritis In a Pharmacy Benefit Management Setting. Ning Wu[1], Yuan-Chi Lee[1], Neel Shah[2] and David J. Harrison[2]. [1]United BioSource Corporation, Lexington, MA, [2]Amgen Inc., Thousand Oaks, CA.

Background/Purpose: Of the seven biologics FDA-approved for the treatment of moderate to severe rheumatoid arthritis (RA) as of August 2011, etanercept, adalimumab, certolizumab, and golimumab were subcutaneously (SC) administered; abatacept, infliximab, and rituximab were intravenous (IV) infusions. Utilization of these agents is often controlled by Pharmacy Benefits Managers (PBMs) using various methods which can affect dosing in clinical practice, gaps in therapy, treatment persistence and switching, and in turn the costs. This study describes the annual cost of biologics per treated patient with RA using administrative claims from a PBM.

Methods: The Medco Database was used to identify adults (18–63 years) with a claim for etanercept, adalimumab, infliximab, abatacept, rituximab, golimumab, or certolizumab between July 1, 2008 and August 31, 2011 preceded by ≥180-days of enrollment. The first claim for biologics was used to define the index agent and date. Patients had to be continuously enrolled for ≥360 days post-index and have a diagnosis of RA between 180 days before and 30 days after the index date. Patients with other conditions for which some of these agents are indicated (e.g. psoriasis, psoriatic arthritis, ankylosing spondylitis, Crohn's disease, ulcerative colitis, non-Hodgkin's lymphoma, or chronic lymphocytic lymphoma) were excluded. Annual cost per treated patient equaled total dose for the index biologic and all other biologics taken in the post-index period multiplied by wholesale acquisition cost (WAC) as of June 1, 2013, plus the costs associated with administrations, calculated as number of infusions multiplied by the 2013 Medicare Physician Fee Schedule costs.

Results: In the 4,736 patients with RA in this study, etanercept (40.3%), adalimumab (27.9%), and infliximab (19.0%) were the most frequently prescribed biologics followed by abatacept (7.1%), rituximab (3.7%), golimumab (1.2%), and certolizumab (0.7%). Mean age was 51.2 years (SD 9.1) and 78.5% were female. Among the three most commonly prescribed biologics, the annual cost per treated patient was lowest for patients on etanercept ($21,706), followed by infliximab ($22,030) and

adalimumab ($23,150). Among the other agents, cost per treated patient was highest for certolizumab ($21,630), followed by golimumab ($20,526), abatacept ($17,386), and rituximab ($16,571).

Conclusion: Of the three most frequently prescribed biologics for RA, the annual cost per treated patient was the lowest for etanercept. Cost may be an additional consideration when choosing biologic treatments for RA.

Comparison Of The Cost-Effectiveness Of The Treatment Strategies With and Without Biological Response Modifiers For Patients With Recently Diagnosed Rheumatoid Arthritis Following A Clinical Guideline For Treatment Selection. An Tran-Duy[1], Annelies Boonen[1], Wietske Kievit[2], Piet L.C.M. van Riel[2], Mart A.F.J. van de Laar[3] and Johan L. Severens[4]. [1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]Medisch Spectrum Twente & University of Twente, Enschede, Netherlands, [4]Erasmus University Rotterdam, Rotterdam, Netherlands.

Background/Purpose: In clinical practice, management of rheumatoid arthritis (RA) is characterized by a sequence of drugs which is determined based on patient characteristics, notably disease activity and treatment history. However, existing cost-effectiveness models do not reflect this clinical process of treatment decisions. In the last decade, biologic response modifiers (BRMs) became available in the treatment of RA. While these drugs show large efficacy in trials, they are expensive. This study aimed at quantifying the cost-effectiveness of the treatment strategy including BRMs (Strategy B) compared with the treatment strategy without BRMs (Strategy A) following a formal guideline for treatment of recently diagnosed RA.

Methods: A discrete event simulation model was developed to simulate life-time health utility and costs of individual patients using a societal perspective. Treatment effect on DAS28 and time to events were estimated using Dutch observational studies (DREAM and Nijmegen Inception cohorts). Long-term progression of HAQ was quantified using a linear mixed model. Health care and sick leave costs were estimated using two-part models. Health utilities (EQ-5D) were predicted using a mixture model with adjusted limited dependent variable. Treatment decisions were based on the recommendations of the Dutch Society for Rheumatology for treatment of RA. A number of 10,000 theoretical patients were tracked individually until death. For uncertainty analysis of the model outcomes, Monte Carlo simulations were performed with 1,000 sets of parameters sampled from the probability distributions. SAS, R and Delphi were used for data analysis and model development.

Results: The recommended treatment selection based on DAS28 and treatment history was well simulated. Incremental cost per quality-adjusted life year gained (ICER) in Strategy B compared with Strategy A was €124,095. At willingness-to-pay thresholds above €119,167 per QALY, Strategy B dominated Strategy A in terms of cost-effectiveness but the probability that the Strategy B is cost-effective never exceeded 0.87.

Conclusion: Incorporation of the treatment decisions based on a clinical guideline in a cost-effectiveness model for RA is feasible, which makes the model more realistic. Our model can be used as a tool to assess the effects of changes in clinical practice of RA management on disease progression of patients and on the corresponding incremental cost-effectiveness.

Long-Term Effectiveness and Cost Per Effectively Treated Patient With Biologics Used In Rheumatoid Arthritis. Vernon F. Schabert[1], Jason Yeaw[2], Jonathan Korn[2], Caroleen Quach[3], David J. Harrison[4], Huifeng Yun[5], George Joseph[6], David H. Collier[4] and Jeffrey R. Curtis[7]. [1]IMS Health, Alexandria, VA, [2]IMS Consulting Group, Alexandria, VA, [3]University of North Carolina at Chapel Hill, Gillings School of Public Health, Chapel Hill, NC, [4]Amgen Inc., Thousand Oaks, CA, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Former Amgen Employee, Thousand Oaks, CA, [7]University of Alabama at Birmingham, School of Public Health, Birmingham, AL.

Background/Purpose: Previous work compared one-year cost per effectively treated patient with biologics for rheumatoid arthritis (RA) using a published, claims-based algorithm.[1] Longer term comparisons are important since RA requires lifetime treatment. Using the same algorithm, treatment effectiveness (as a proxy for low disease activity or remission) and cost per effectively treated patient in the second year of biologic treatment for patients who met effectiveness criteria at the end of the first year was estimated.

Methods: Data were obtained from the IMS PharMetrics Plus™ database, comprising adjudicated medical and pharmaceutical claims for 150 million enrollees (40 million annually). The first-year cohort included patients with RA aged 18–63, initiating biologic treatment with etanercept, adalimumab, infliximab, or abatacept between Jan 1, 2007 and Dec 31, 2010, without diagnoses for other approved indications for these biologics or any biologic use for RA in the 6 months before initiation. Patients had to be continuously enrolled for 6 months before and 12 months after initiation; the subset of patients whose initial biologic was classified as "effective" by the algorithm and who were enrolled for a second year were included in this analysis. The algorithm defined lack of effectiveness as: medication possession ratio (MPR) $<80\%$ (or fewer infusions than specified on US label), increase in biologic dose or frequency, switching biologics, adding new non-biologic Disease Modifying Anti-Rheumatic Drugs, initiation or increase of glucocorticoid dose, or >1 parenteral or intra-articular injection. Cost was based on patient and health plan paid amounts for biologic drugs and drug administration from the claims.

Results: Of 16,011 patients in the initial cohort, 1,999 met eligibility criteria for the second-year effectiveness analysis: etanercept (n=994), adalimumab (n=620), infliximab (n=229), and abatacept (n=156). Mean age was 50.8 (SD 8.9), 71.8% were female. In the second year, 44.9% of abatacept, 47.4% of adalimumab, 47.2% of etanercept, and 45.4% of infliximab patients met criteria for effectiveness. Second-year cost per effectively treated patient as defined in the algorithm was $48,176 for abatacept, $37,082 for adalimumab, $37,306 for etanercept, and $36,954 for infliximab. From the prior study, comparable results were (31.0% and $50,141 etanercept, 28.6% and $56,941 adalimumab, 20.2% and $114,089 infliximab, 28.6% and $73,516 abatacept)[1].

Conclusion: Despite similar effectiveness in the second year, cost per effectively treated patient was lower for TNF blockers (etanercept, adalimumab, and infliximab) than for abatacept.

Measuring Economic Value of Morning Stiffness; Consistency Over 1 Year. Risto Tuominen. University of Turku, Turku, Finland.

Background/Purpose: Economic evaluation of health care activities requires often measuring clinical symptoms and their changes also in monetary terms. Patients with rheumatoid arthritis (RA) may experience morning stiffness (MS), which varies over time, reflecting both short-term fluctuation in symptoms and long-term disease progression. A method that has been successfully applied to measure symptoms of RA is contingent valuation, and particularly its form called Willingness-To-Pay approach (WTP). In this method, patients are asked the maximum amount they would be willing to pay in order to reach a certain health status. In earlier studies patients with more severe symptoms have been willing to pay higher amounts than those with less symptoms. However, it is not known whether the fluctuation in symptoms is reflected in the amounts produced by WTP method. In order to serve as a useful method for monetary valuation of symptoms, WTP approach should produce values which reflect also the changes in symptoms.

The aim of this study was to determine the within-patient variation in duration of MS over 1 year, and the corresponding monetary equivalents assigned to its changes using WTP methodology.

Methods: The sample (n=100) comprised patients with RA from Turku University Hospital, Finland. All patients were interviewed twice by a trained interviewer using the same interview, 1 year apart. Patients estimated duration of MS in minutes. They were also asked to estimate how much they would be willing to pay on a daily basis if MS could be reduced by 25%, 50%, 75% and 100%. Weighted average of the monetary assessment for MS reduction was computed. Statistical evaluation was based on paired samples t-test, one way analysis of variance and linear regression model.

Results: After 1 year, there was a highly significant reduction in average MS duration from 44.7 minutes to 41.4 minutes ($p<0.001$); duration was reduced in 34.7% of patients, unchanged in 34.7% and prolonged in 30.6%. Weighted group average WTP for MS duration reduction was € 13.75 in the first interview and € 14.26 a year later ($p<0.001$). Changes in MS duration were reflected in within-patient WTP estimates. Among patients with reduced MS, weighted average WTP was reduced by € 18.46, in patients with unchanged duration, weighted average WTP increased by € 4.89, and in patients with increased duration of MS, weighted average WTP increased by € 13.46 ($p<0.05$). This pattern was statistically significant ($p<0.05$) for hypothetical reduction in MS duration of 50%, 75% and 100%, but not for 25% reduction in MS duration. Changes in duration of MS explained significantly ($p<0.05$) the variation in change of WTP for reduction, also when level of income was simultaneously controlled ($R^2=0.325$).

Conclusion: Duration of MS varied considerably over the 1 year follow-up. WTP estimates and their changes corresponded closely to changes in MS duration. WTP method can be considered a valid method to evaluate the impact of morning stiffness in patients in monetary terms.

Cost-Effectiveness Analysis Of Two Rituximab Based Therapeutic Regimens For Longstanding Rheumatoid Arthritis. Luca Quartuccio[1], Rossella Di Bidino[2], Matteo Ruggeri[3], Domenico Biasi[4], Franco Schiavon[5], Leonardo Punzi[6], Silvano Adami[4], Americo Cicchetti[3] and Salvatore De Vita[1]. [1]Rheumatology Clinic, DSMB, University of Udine, Udine, Italy, [2]HTA Unit, "A. Gemelli" Teaching Hospital, Rome, Italy, [3]Faculty of Economics, Catholic University of the Sacred Heart, Rome, Italy, [4]Rheumatology Clinic, University of Verona, Verona, Italy, [5]Rheumatology Clinic, University of Padova, Padova, Italy, [6]University of Padova, Rheumatology Unit, Padova, Italy.

Background/Purpose: Socioeconomic costs of rheumatoid arthritis (RA) are very high. Biologic therapies with different biologic targets are now available for moderate to severe RA, and these drugs increased the overall direct costs of RA. Thus, therapeutic strategies to improve the cost-effectiveness of the biologics are welcome. Rituximab (RTX) is generally administered intravenously 1 g × 2 (day 1- day 15, regimen 1) and the retreatment is scheduled at the time of clinical relapse. A more intensive regimen has been proposed: 1 g × 2 (day 1- day 15, regimen 2) every six months, following the "treat to target" approach (1). The aim of this study is to compare the cost-effectiveness of two regimens of RTX administration in longstanding RA patients.

Methods: An observational retrospective study was conducted in three Centers. One hundred and two patients suffering from moderate to severe longstanding RA (disease duration more than two years) were enrolled. 47 followed regimen 1, while 55 patients were treated with regimen 2. All the patients were followed for at least one year. A cost effectiveness analysis (CEA) based on a Markov Model were conducted on the basis of sample data collected and scientific literature. Markov Model represented natural evolution of RA and was composed by four states: Treatment, Response, Relapse, and Death. An hypothetical cohort of 300.000 populated the model and was followed till death adopting a societal perspective. Pharmaceutical, direct health, and indirect costs were estimated as well as health quality. Univariate and probabilistic sensitivity analysis (PSA) were done. CEA was conducted for the whole sample of patients and for a subgroup of them (those with rheumatoid factor and/or anti-cyclic citrullinated peptide).

Results: Results for the overall sample show at 10–20–30 year that regimen 1 is less costly and associated with an higher QoL compared to regimen 2. PSA at 10 years estimated a probability of 94.20% for regimen 1 to be cost-effective given a willingness to pay of 30000 € /QALY. The subanalysis in seropositive patients showed that regimen 1 is more cost-effectiveness than regimen 2. PSA at 10 years estimated a probability of 90% for regimen 1 to be cost-effective given a willingness to pay of 30000 € /QALY. Significant differences in the baseline HAQ and DAS 28 scores were estimated ($p<0.0001$, and $p=0.002$, respectively, Mann Whitney U test), although both groups of patients showed a median baseline high disease activity and disability [regimen 1 vs regimen 2: 1.5 (0.5–2.75) vs. 2.7 (0.375–3) for HAQ, and 5.9 (3.5–8.4) vs. 5.0 (2.9–7.0) for DAS28]. At 12 month, the difference in the HAQ scores persisted ($p=0.0004$), while there was no difference in the DAS28 ($p=0.86$).

Conclusion: In longstanding RA, a less intensive regimen of RTX with retreatment at clinical relapse seems to be at least equivalent of the more intensive regimen with retreatment every six months. RTX regimen choice may be oriented by the clinical judgment on the balance between the disease activity and the level of disability, and the evaluation of the irreversible/reversible component ratio in the HAQ score. A similar evaluation in patients with early disease is required.

1005

Generalization and Extrapolation Of Treatment Effects From Clinical Studies In Rheumatoid Arthritis. Sandhya C. Nair[1], Wietske Kievit[2], R W Janse[3], Johannes WJ Bijlsma[4], Floris Lafeber[5], Jaap Fransen[2] and P.M.J. Welsing[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]Medical student, Utrecht, Netherlands, [4]University Medical Centre Utrecht, Utrecht, Netherlands, [5]UMC Utrecht, Utrecht, Netherlands.

Background/Purpose: Randomized clinical trials (RCTs) are accepted as the 'gold standard' to evaluate the efficacy/effectiveness of treatment. However, generalizing results from RCTs to daily practice poses a challenge with treatment effectiveness often being different. Pragmatic clinical trials have been posed as a solution. The objective was to identify whether pragmatic clinical trials are indeed generalizable to clinical practice and investigate how efficacy estimates from RCTs can be translated into effectiveness estimates for daily practice populations.

Methods: Data from pragmatic clinical trials of the Utrecht Rheumatoid Arthritis Study Cohort and the observational Nijmegen inception cohort study with comparable inclusion criteria (RA < 1 year disease duration and no prior DMARD use) were used. Patient characteristics were compared between the studies. The treatment effectiveness of MTX and Hydroxychloroquine both compared to the so-called Pyramid approach were compared between the pragmatic trials and observational data using a modified comprehensive cohort design analysis. Change from baseline in DAS28 and HAQ and EULAR good- and moderate response both at 6 months were the outcomes studied in the regression analyses. To study extrapolation of the treatment effect from Phase II/III clinical trials to clinical practice, published results from recent clinical trials evaluating biological treatment compared to control therapy were used. A metaregression analysis was performed to study the influence of population and treatment characteristics on ACR50% response at 6 months. Relative risk (RR) and risk difference (RD) were studied as outcome.

Results: Age, higher disease activity and response to treatment were higher in patients included in the pragmatic trial as compared to daily practice and rheumatoid factor positive patients were lower. DAS28 and HAQ generally improved more in trial patients as compared to daily practice. Using EULAR response as outcome, the relative effect of treatment (relative risk) was not found to be different. For extrapolating RCT results, glucocorticoid use, disease duration and co treatment with DMARD increased the RR in the study. Higher values of baseline DAS28 and HAQ decreased RD and the use of corticosteroids increased RD.

Conclusion: Pragmatic clinical trials might be directly generalizable only regarding relative treatment effects. In extrapolating RCT results to daily practice, population characteristics associated with disease activity, disease duration and treatment history or co-treatment need to be taken into account, regardless whether the treatment effect is expressed absolute or relative. Extrapolations of RCT results could also considerably impact costs-effectiveness results.

1006

One-Year Change Of Employment and Work Productivity In Patients With Systemic Lupus Erythematosus From The Southeastern United States. Deepak Sree[1], S. Sam Lim[1], Hong Kan[2], Priti M. Jhingran[2], Charles T. Molta[3], Gaobin Bao[1] and Cristina Drenkard[1]. [1]Emory University, Atlanta, GA, [2]GlaxoSmithKline, Research Triangle Park, NC, [3]GlaxoSmithKline, King of Prussia, PA.

Background/Purpose: Different factors influence employment and work productivity in systemic lupus erythematosus (SLE) patients, including disease activity, cognitive impairment, comorbidities, education, and psychosocial factors. Previous studies have mostly been done in predominantly White SLE populations. This study assesses work loss and factors that impact change in work productivity over a 1-year period in patients with SLE who are primarily Black.

Methods: GOAL is a prospective cohort of SLE patients who provide patient-reported measures at least annually. It is derived primarily from the Georgia Lupus Registry, a population-based registry established in metropolitan Atlanta, Georgia. Data were collected in 2 Waves (2011–12 and 2012–13). We assessed demographic and disease factors associated with work loss over 1 year. Change in work productivity was measured in patients using the Work Productivity and Activity Impairment (WPAI) tool. Three measures were used to examine the change in WPAI: % of work time missed, % of overall work productivity impairment, and % of impairment to perform daily activities. Demographic and disease factors assessed at Wave 1 were evaluated as potential predictors of 1-year change in WPAI outcomes.

Results: Of 511 SLE patients employed at disease diagnosis, 252 aged 18–64 remained employed at the time of the Wave 1 survey and 225 completed the WPAI questionnaire. One-hundred-seventy-three patients who were employed at Wave 1 responded to the Wave 2 survey. Of them, 153 (88%) continued to be employed. Lower education attainment (p=0.01), worse physical health (p=0.002) and greater disease activity (p=0.04) were significantly associated with work loss over 1 year, while living with a partner tended to be a protective factor (p=0.09). One-hundred-thirty-six patients who were employed for 2 consecutive years responded to Waves 1 and 2 WPAI surveys. Their mean disease duration and education level were 13 years and 16 years, respectively; 95% were female and 65% were Black.

* Mean of % change ±SD: negative values indicate improvement

Conclusion: SLE has a profound impact on employment. In patients having endured more than one decade of disease, the majority become unemployed. Education, physical health and disease activity are associated with short-term work loss, while social support tends to be protective. In those who remain employed, lower education attainment is the only factor predictive of 1-year work productivity impairment. Although not statistically significant, there was a trend towards Black race being negatively associated with work productivity. Patients who live with a partner have better daily life activities performances than those who are single, divorced or widowed. Notably, disease factors do not impact 1-year changes in work productivity. Further research is needed to better understand the pathways through which education, social support and disease status impact short-term work loss and productivity in SLE.

Dose Of Corticosteroid, Risk Of Adverse Events and Healthcare Resource Utilization In Systemic Lupus Erythematosus. Wei-Shi Yeh[1], Shih-Yin Chen[2], Kathleen McCarty[1], Qian Li[2], Yuan-Chi Lee[2] and Nathalie Franchimont[1]. [1]Biogen Idec Inc., Weston, MA, [2]United BioSource Corporation, Lexington, MA.

Background/Purpose: Gluco-corticosteroids (GCs) are frequently used to treat autoimmune disease and their chronic use has long been known to cause adverse events (AEs). The purpose of this study was to examine the relationship between dose of GCs, risk of AEs, and healthcare resource utilization (HRU) in patients with systemic lupus erythematosus (SLE).

Methods: This retrospective study used a US commercial insurance claims database from January 2007 through December 2011. SLE patients were identified using ICD-9 CM code 710.0 from ≥2 outpatient or 1 inpatient claims. Use of oral GCs was examined for 12 months from the date of first observed SLE diagnosis (index date). Patients receiving ≥60 days of GCs were categorized based on their average daily oral dose of prednisolone (or equivalent) as follows: low (≤7.5mg), medium (7.5mg<dose≤15mg), and high (>15mg) dose groups. A cohort of SLE patients who did not receive any oral GCs was selected as the reference group. Potential AEs associated with chronic GCs were identified from literature and a total of 36 conditions were examined. HRU of outpatient/emergency department (ED) visits, hospitalizations, prescriptions, and total health costs were examined for 12 months post index date. Rates of AEs were compared with the reference group using Chi-square tests. Trend tests of dose response were conducted for dichotomous variables using Cochran-Armitage test and for continuous variables fitted via generalized linear regression.

Results: We identified 46,785 commercially-insured SLE patients with no GCs use and 5,221, 4,965, and 4,136 patients with low, medium, and high dose of GCs, respectively. Their mean age was 46.8, 47.0, 45.1, and 42.8 years and the proportion of males was 9.2, 9.7, 10.8, and 13.3%, respectively. Some but not all steroid-related AEs were observed at a higher frequency among GCs users than non-users. A positive dose-relationship was observed for myopathy, atherosclerosis, hypertension, heart failure, Cushingoid syndrome, and bacterial infection (all $P<0.05$). Among the patients receiving GCs, the proportion of patients having ED visit (29.7, 37.7, and 47.0%, $P<0.01$) and hospitalization (18.3, 24.8, and 42.8%, $P<0.01$) increased significantly with the dose of GCs. Similar trends were observed in annual average number of non-ED outpatient visits (25.0, 28.8, and 34.5, $P<0.01$) and non-steroid prescriptions and refills (42.9, 48.3, and 51.4, $P<0.01$). The annual average total health costs for the low, medium, and high dose groups of GCs users were $21,815, $27,635, and $45,339, respectively ($P<0.01$).

Conclusion: Higher dose of GCs is associated with more AEs and greater HRU in SLE. Although the association may be confounded by SLE disease severity, this finding highlights the value of future effective SLE treatments with steroid-tapering effect.

Longitudinal Analysis Of Direct Medical Costs For Systemic Sclerosis Patients: A Population-Based Study. Natalie McCormick[1], Carlo A. Marra[2], Eric C. Sayre[3] and J. Antonio Avina-Zubieta[4]. [1]University of British Columbia, Vancouver, BC, [2]Univ of British Columbia, Vancouver, BC, [3]Arthritis Research Centre of Canada, Richmond, BC, [4]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC.

Background/Purpose: Patients with systemic sclerosis (SSc) have considerable morbidity which may be associated with high health resource utilization.

Studies on health use and costs are scarce and the few available have short follow-up from clinic-based samples. To address this knowledge gap, we have estimated the longitudinal health care costs of cases with SSc. We measured physician visits, hospitalizations, and dispensed medication data that cover the entire SSc population of our province.

Methods: Data Source: Universal coverage is a feature of our healthcare system and administrative data captures *all* funded health services (outpatient visits, tests and hospitalizations) and *all* dispensed medications from 1996 through 2010 (regardless of funding source).

Cases: A population-based cohort of SSc was identified using the following algorithm: **a)** diagnosis of SSc on at least two visits within a two-year period between Jan 1990 and Dec 2010 by a non-rheumatologist physician; **b**) diagnosis of SSc on at least one visit by a rheumatologist or from hospitalization. To increase specificity we excluded cases that were not confirmed by a rheumatologist if they were seen at a later point.

Cost Calculation: Costs for outpatient services and prescriptions were summed directly from paid claims. Case-mix methodology was used to cost hospitalizations. Costs are reported in 2010 Canadian dollars.

Results: We identified 1,456 SSc cases (82% female, mean (SD) age of 55.3 (±14.9) years) contributing 7,824 total patient-years (PY). Over 15 calendar years the cumulative costs for SSc cases totalled **$83,507,123** and averaged $10,673 per-PY with $2,475 (23%) from outpatient services, $5,360 (50%) from hospitalizations, and $2,837 (27%) from prescription medications. Cases who were hospitalized at least once over the period averaged 1.9 (±3.0) admissions per-PY.

After adjustment to 2010 dollars, annual mean per-PY costs increased by 8%, from $9,513 in 1996 to $10,261 in 2010. Mean per-PY outpatient costs decreased by 14% and hospital costs by 15% (see table). In contrast, mean per-PY prescription costs increased by 109% (from $1,740 in 1996 to $3,641 in 2010), and the mean number of prescriptions per-PY increased by 56% (from 29 to 46).

	Mean Per-Patient-Year Costs (2010 Canadian dollars)				Mean Per-Patient-Year Dispensed Prescriptions
Year	Overall	Outpatient	Hospital	Medication	
1996	$ 9,513	$2,714	$5,059	$1,740	29
1997	$11,657	$2,851	$6,901	$1,905	30
1998	$11,396	$2,680	$6,741	$1,975	31
1999	$11,329	$2,550	$6,784	$1,995	31
2000	$11,111	$2,369	$6,789	$1,953	32
2001	$ 9,411	$2,479	$4,969	$1,963	34
2002	$10,363	$2,598	$5,549	$2,216	34
2003	$11,906	$2,512	$6,782	$2,612	35
2004	$10,446	$2,398	$4,970	$3,078	36
2005	$11,050	$2,456	$5,662	$2,933	37
2006	$10,322	$2,480	$4,502	$3,341	40
2007	$10,933	$2,467	$5,240	$3,226	43
2008	$ 9,895	$2,375	$4,067	$3,453	43
2009	$11,048	$2,389	$5,206	$3,453	45
2010	$10,261	$2,333	$4,287	$3,641	46
Overall	**$10,673**	**$2,475**	**$5,360**	**$2,838**	**38**
Fifteen-Year %-Change	**8%**	**−14%**	**−15%**	**109%**	**56%**

92% of the cohort's cumulative healthcare costs came from the 67% of SSc cases (n=977) that were hospitalized at least once. These cases had a substantially larger increase in prescription drug costs over the 15 years (by 193%, $1,791 to $5,253 per-PY) than never-hospitalized cases (by 42%, $1,283 to $1,824).

Conclusion: This is the first longitudinal and population-based study assessing the direct medical costs of patients with SSc. As outpatient and hospital costs decrease, medication use and costs continue to rise. Given there are no specific disease modifying anti-rheumatic drugs for SSc, our results suggest the long-term costs of SSc cases may be driven by ongoing complications and comorbidities of this disease.

Association Of Depressive Symptomatology and Life and Job Satisfaction In Patients With Rheumatoid Arthritis. Jutta G. Richter[1], Dr. Ralph Brinks[2], Thomas Muth[1], Mia Vidakovic[1], Tobias Koch[1], Peter Angerer[1] and Matthias Schneider[3]. [1]Heinrich-Heine-University, Duesseldorf, Germany, [2]Univ. Duesseldorf, Duesseldorf, Germany, [3]Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany.

Background/Purpose: Life satisfaction (LS) has become an important outcome measure in healthcare, is a relevant indicator of job satisfaction, and might be influenced by depression. The objectives of the study were to investigate life and job satisfaction and the influence of self-reported depressive symptomatology (DS) in patients (pts) with rheumatoid arthritis (RA) to consider these aspects in future treatment concepts.

Methods: Self-administered questionnaires (Qs) were applied to RA pts and controls (c) not suffering from rheumatic diseases. General life satisfaction Q (FLZ) captured ten domains of satisfaction (see Table 1). Scores are expressed as age & sex standardized stanines (a method of scaling test scores on a normalized nine-point standard scale with a mean of 5 and a standard deviation of 2). DS was measured by the German long version of the Center for Epidemiological Studies Depression Scale (ADSL). A separate Q assessed self-reported clinical data. Ethics approval was obtained.

Results: 267 pts (85.0% female (f)) and 177 c (90.3% f) contributed data. Pts' mean age was 47.7±10.0 (c 42.8±9.8) years, mean disease duration 9.0+8.0 years, mean HAQ 1.1±0.5 (c 0.4±0.1). 85.5% self-reported at least one comorbidity (range 0–8, c 45.2%, range 0–4). In pts 81.7% received at least one immunosuppressive medication (range 0–6), 43.8% steroids < 7.5mg, 9.0% steroids >7.5mg and 61.4% NSAIDS.

Pts' mean general LS was 236.7±39.6 (c 263.9±31.7, p<1e-15), mean satisfaction with health was significantly lower in pts (26.3±8.6; c 38.6±7.2, p<1e-15). In the FLZ subscales job & profession, finances, self, sexuality and friends pts scored significantly lower than c. Pts' ADS-L score was 18.2±10.7 (c 9.8±6.8, p<1e-15). 27.1% pts and 4.6% c (p<1e-9) scored >23 on the ADS-L which is indicative of depression.

A logistic regression calculated the association between LS (sub-)scale-stanines and DS. Table 1 depicts odds ratios (OR). If the health stanine increases by one unit, a person's risk with respect to an outcome of DS decreases by a factor of 0.409. For RA pts it increases by an additional factor of 1.710. In all FLZ-scales RA pts had a higher risk of DS. Highest OR was detected in the job & profession subscale.

Table 1. Logistic regression: FLZ-(sub-)score-stanine, group affiliation, self-reported depressive symptomatology (0 in the p-value column means $p < 10^{-16}$)

	Stanine			RA vs controls		
FLZ (Sub-)Score	OR	95%-ci	p-value	OR	95%-ci	p-value
Health	0.409	0.392–0.426	5.18e-10	1.710	1.627–1.796	0
Job & profession	0.581	0.571–0.590	2.68e-09	8.536	5.596–13.021	0

Friends and relatives	0.645	0.636–0.654	2.09e-07	6.406	4.528–9.063	0
Home	0.733	0.723–0.744	0.000322	8.479	5.711–12.589	0
General LS	0.446	0.433–0.459	2.44e-11	3.357	2.414–4.668	6.06e-13

Unrestricted grants Ministry of Innovation, Science, Research and Technology of the German State North Rhine-Westphalia, Deutsche Rheuma-Liga e.V., German LE Self-Help Community, Hiller Foundation

Conclusion: RA pts showed low satisfaction in 10 areas of LS and significantly more pts were indicative of depression. Significant ORs were detected in all FLZ scales, domains that are potentially modifiable. The high OR in the job and profession subscale indicates that beside DS social and job related satisfaction issues should predominantly targeted. Apart from already established (QoL) assessments (e.g. HAQ, SF36) routine care and further clinical studies might gain from additional assessments of LS and ADSL as outcome parameters.

1010

Association Of Depressive Symptomatology and Life and Job Satisfaction In Patients With Systemic Lupus Erythematosus. Jutta G. Richter[1], Thomas Muth[1], Ralph Brinks[2], Mia Vidakovic[1], Tobias Koch[1], Peter Angerer[1] and Matthias Schneider[3]. [1]Heinrich-Heine-University, Duesseldorf, Germany, [2]Univ. Duesseldorf, Duesseldorf, Germany, [3]Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany.

Background/Purpose: Life satisfaction (LS) has become an increasingly important outcome measure in healthcare, is a relevant indicator of job satisfaction and might be associated with depression. The objectives of the study were to investigate life and job satisfaction and the association of self-reported depressive

symptomatology (DS) in patients (pts) with systemic lupus erythematosus (SLE) to consider these aspects in future treatment concepts and studies.

Methods: Self-reported questionnaires (Qs) were applied to SLE pts and controls (c) not suffering from rheumatic diseases. General life satisfaction Q (FLZ) captured ten domains of satisfaction (see Table1). According to Q's analysis, scores are expressed as age and sex standardized stanines (a method of scaling test scores on a normalized nine-point standard scale (1–9) with a mean of 5 and a standard deviation of 2). DS was measured using the German long version of the Center for Epidemiological Studies Depression Scale (ADS-L). A separate Q assessed self-reported clinical data. Ethics committee approval had been obtained.

Table 1. Logistic regression: FLZ-(sub-)score-stanine, group affiliation, self-reported depressive symptomatology (0 in the p-value column means $p < 10^{-16}$)

	Stanine			SLE vs controls		
FLZ (Sub-)Score	**OR**	**95%-ci**	**p-value**	**OR**	**95%-ci**	**p-value**
Health	0.462	0.446–0.478	6.32e-09	2.245	2.033–2.480	0
Job and profession	0.674	0.664–0.685	8.06e-06	9.396	6.314–13.982	0
Finances	0.695	0.686–0.705	1.87e-05	8.549	5.983–12.214	0
Leisure	0.666	0.657–0.675	1.7e-06	7.483	5.281–10.604	0
Partner/relationship	0.808	0.799–0.818	0.0053	7.644	5.278–11.070	0
Children	0.708	0.695–0.723	0.000623	8.193	4.366–15.373	5.77e-11
Self	0.500	0.489–0.511	6.8e-11	6.710	4.618–9.748	0
Sexuality	0.687	0.677–0.697	1.17e-05	6.146	4.468–8.455	0
Friends and relatives	0.636	0.627–0.644	3.23e-08	7.960	5.510–11.500	0
Home	0.711	0.700–0.722	0.000143	8.933	5.938–13.439	0
General LS	0.483	0.471–0.495	7.92e-11	4.260	3.065–5.920	0

Results: 252 pts (95.6% female (f)) and 177 controls (90.3% f) contributed data. Patients' mean age was 40.1±9.4 (c 42.8±9.8) years, mean disease duration 10.5±7.3 years, mean HAQ 0.8±0.4 (c 0.4±0.1). 86.0% reported at least one comorbidity (range 0–10, c 45.2%, range 0–4). 77.4% received at least one immunosuppressive medication (range 0–3). 40.5% were on steroids <7.5mg, 16.3% on steroids >7.5mg, 34.0% took NSAIDS.

The mean general LS of pts was 237.8±39.6 (c 263.9±31.7, p<4e-10). Except in partner/relationship pts scored significantly lower in all FLZ-subscales compared to c. Pts mean ADS-L Score was 18.1±11.0, c 9.8±6.8 (p<6e-16). 30.0% pts and 4.6% c (p<3e-10) scored >23 on the ADS-L which is indicative of depression.

A logistic regression model calculated the association of LS (sub-)scale-stanines and DS. Table 1 depicts odds ratios: If the health stanine increases by one unit, a person's risk with respect to an outcome of DS decreases by a factor of 0.462. For pts, it increases by an additional factor of 2.245. In comparison to c, SLE pts had a higher risk of DS in all FLZ (sub)scales.

Conclusion: SLE pts showed reduced satisfaction in 10 areas of life and significantly more pts were indicative of depression. Significant ORs were detected in all FLZ scales, domains that are potentially modifiable. The very high OR in the job and profession subscale indicates that beside depression social and job related satisfaction issues should predominantly targeted. Besides from already established (QoL) assessments (e.g. HAQ, SF36) routine care and further clinical studies might gain from the additional assessment of LS and DS as outcome parameters.

1011

Psychiatric and Cardiovascular Comorbidities As Causes Of Work Disability Among Individuals With Rheumatoid Arthritis. Anne M. Kerola[1], Tuomo Nieminen[2], Markku J. Kauppi[3], Hannu Kautiainen[4], Tuomas Kerola[3], Lauri J. Virta[5], Timo Pohjolainen[6] and Kari Puolakka[7]. [1]Medical School, University of Helsinki, Helsinki, Finland, [2]Division of Cardiology, Helsinki University Central Hospital, Helsinki, Finland, [3]Department of Internal Medicine, Päijät-Häme Central Hospital, Lahti, Finland, [4]Unit of Primary Health Care, Helsinki University Central Hospital, Helsinki, Finland, [5]Research Department, the Social Insurance Institution, Turku, Finland, [6]ORTON Rehabilitation Centre, ORTON Foundation, Helsinki, Finland, [7]Department of Medicine, South Karelia Central Hospital, Lappeenranta, Finland.

Background/Purpose: A remarkable proportion of rheumatoid arthritis (RA) patients stop working before the normal age of retirement. Initial research data suggests that comorbidities, with depression in particular, may increase work disability (WD) rates in RA. The aim of this study was to determine the contribution of psychiatric and cardiovascular (CV) comorbidities to WD among RA patients.

Methods: All incident, non-retired patients with RA (aged 18–64 years, RA diagnosed in 2000–2007) were identified from a Finnish nationwide register maintained by the Social Insurance Institution. From another register maintained by the Finnish Centre for Pensions, data on WD in the RA cohort as well as the entire Finnish population was obtained up until December 31, 2008. The data included all permanent disability pensions and WD periods which had continued for at least one year at the end of the follow-up. The incidence of WD caused primarily by CV diseases, psychiatric disease, and RA was analyzed. The primary cause of WD was identified by the ICD-10 codes I00–99 for CV diseases, F20–69 for psychiatric diseases, and M05 or M06 for RA as the first (i.e. the most important) diagnosis in the register.

Results: We identified a cohort of 7,831 patients with RA who were available for work full-time (71% women, mean age 46 [SD 11]). During the follow-up (median 4.0 years, IQR 2.2–6.3), 1,095 (14.0%) patients became disabled for work. In two out of three cases, the primary cause was RA, whereas psychiatric diseases constituted the second-most important cause (Table). After adjusting for competing risks, 12.0% (95% CI 11.5 to 12.4), 1.3% (1.2 to 1.5), and 0.5% (0.4 to 0.6) of the RA patients lost their capacity for work primarily due to RA, a psychiatric comorbidity, or a CV disease, respectively (Figure). A CV cause was more frequent among men, but no difference was found between the sexes in psychiatric causes. Compared with the overall Finnish population, the age- and sex-specific standardized incidence ratios of WD due to CV or psychiatric comorbidities were 1.75 (95% CI 1.23 to 2.51) and 0.99 (95% CI 0.80 to 1.23), respectively.

Table. Primary causes of work disability according to ICD-10 disease class.

	Male n (%)	**Female n (%)**	**All n (%)**
Total	414	681	1095
M00–M99	321 (77.5)	552 (81.1)	873 (79.7)
** of which M05 or M06 (RA)*	**277 (66.9)*	**462 (67.8)*	**739 (67.5)*
Mental and behavioral disorders F00–F99	27 (6.9)	64 (9.4)	91 (8.3)
** of which F20–F69*	**23 (5.6)*	**59 (8.7)*	**82 (7.5)*
I00-I99	16 (3.9)	14 (2.1)	30 (2.7)
Other	50 (12.1)	51 (7.5)	101 (9.2)

M00–M99 Diseases of the musculoskeletal system and connective tissue.
F00–F99: Mental and behavioral disorders.
F20–F69: Schizophrenia, schizotypal and delusional disorders.
Mood disorders; neurotic, stress-related, and somatoform disorders; behavioral syndromes associated with physiological disturbances and physical factors; disorders of adult personality and behavior.
I00–I99 Diseases of the circulatory system.

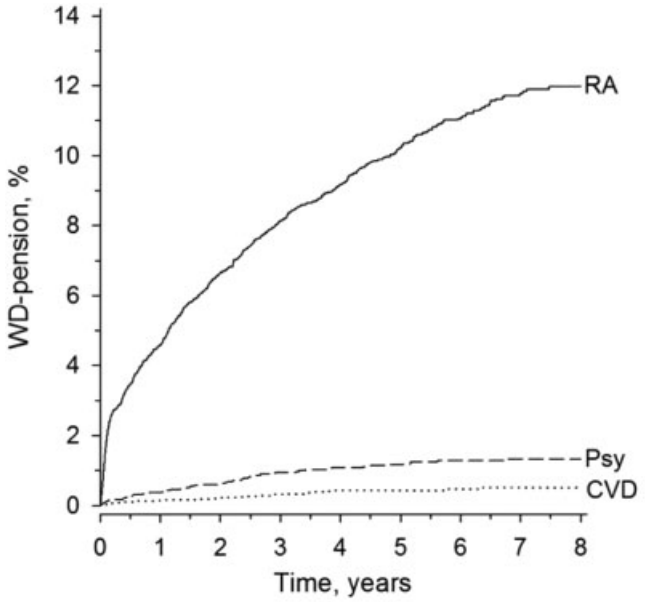

Figure. Competing risk-adjusted cumulative incidence functions for work disability (WD) due to rheumatoid arthritis (RA) as well as psychiatric (Psy) and cardiovascular diseases (CVD) after the diagnosis of RA.

Conclusion: In this cohort of RA patients from 2000–2007, psychiatric or CV comorbidities were the primary causes of WD much less frequently than RA itself. This may, however, represent only a part of their overall contribution to WD, as they may enhance the devastating impact of RA on working capacity without being the leading cause of WD. The risk of WD due to CV disease is higher in RA than in the general population, but psychiatric comorbidities do not appear to cause WD beyond the population level in early RA.

Disease Severity, Quality Of Life, and Productivity Loss Among Patients With Ankylosing Spondylitis In Germany. Jürgen Braun[1], Herbert Kellner[2], Regina Max[3], Markus Rihl[4], Elmar Schmitz-Bortz[5], Hendrik Schulze-Koops[6], Silke Zinke[7], Tao Fan[8], Qian Ding[8] and Ramon Lyu[8]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Centre for Inflammatory Joint Diseases, Munich, Germany, [3]University of Heidelberg, Heidelberg, Germany, [4]German Society for Rheumatology Association, Traunstein, Germany, [5]Rheumatism Practice in Hattingen, Hattingen, Germany, [6]University of Munich, Munich, Germany, [7]Rheumatological Office, Berlin, Germany, [8]Merck & Co., Inc, Whitehouse Station, NJ.

Background/Purpose: Ankylosing Spondylitis (AS) is a chronic, inflammatory form of arthritis that primarily affects the spine, which can cause significant pain and lead to bone ankylosis, deformities in the spine, and peripheral joint damage over time. Diminished quality of life, reduced productivity, and unemployment associated with AS present a significant burden to patients and society. The purpose of this study is to describe disease severity and morbidity in terms of patient-reported quality of life (QoL) and productivity loss and explore factors associated with productivity loss in patients with AS in Germany.

Methods: A multi-center observational study using 12-month retrospective chart review, with prospective paper-based questionnaires at the index visit and 3 months thereafter was conducted. Patients completed Short-form 36 (SF-36), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), and Work Productivity and Activity Impairment (WPAI). Physicians completed the Bath Ankylosing Spondylitis Metrology Index (BASMI) and current disease activity. Descriptive analyses of QoL, utility values derived from SF-36 domains, disease activity, and work productivity impairment were performed. Adjusted multivariate regression was used to explore the variables associated with productivity loss.

Results: A total of 106 patients in 15 AS care centers across Germany were recruited. The majority of patients were men (75%), with a mean age of 46.5 ± 13.2 years and time since diagnosis of 14.6 ± 10 years. The main disease manifestation was inflammatory spinal pain (37%), followed by spinal deformities (27%) and hyperkyphosis (21%). Two-thirds of patients had co-morbidities including hypertension (28%), arthritis (25%), and psoriasis (15%). The main treatment was biological drugs in 72 patients (68%), followed by NSAIDs (53%) and Immunosuppressants (21%).

Physician evaluated the current disease activity with a mean of 2.8 ± 2.1. The mean of BASMI was 3.9 ± 1.8 at index visit, with the highest limitations in lumbar flexion at mean of 5.5 ± 2.7 and lateral spinal flexion at a mean of 4.5± 2.6.

The SF-36 summary means of physical health and mental health were 43.8 ± 8.9 and 46.9 ± 11.7. The lowest mean in the 8 domains was general health with 50.2 ± 19, followed by vitality with 52.7 ± 20.7 and bodily pain with 53.3 ± 24.4. The mean of SF-36 utility values was 0.7 ± 0.1.

Among 76 employed patients, 80% of the patients reported a mean of 2 ± 4 hours/week missed work due to AS at the index visit. Two-thirds of patients reported means of 26% of impairment while working and 31% of activity impairment due to AS. Limitation in physical functioning and BASDAI can explain 68% of productivity loss (Adjusted $R2=0.6765$, $P<0.0001$).

Conclusion: German AS patients had lower QoL and experienced substantial sick leave or impairment while working due to AS conditions. Productivity loss was significantly associated with limitation in physical functioning and BASDAI score.

Estimating the Monetary Value of annual Productivity Gained in Early Active RA Patients Receiving Etanercept Plus Methotrexate: Results From the Prize Study. Wei Zhang[1], Nick Bansback[2], Huiying Sun[1], Ronald Pedersen[3], Sameer Kotak[4] and Aslam H. Anis[1]. [1]Centre for Health Evaluation and Outcome Sciences, Vancouver, BC, [2]University of British Columbia, Vancouver, BC, [3]Pfizer Inc, Collegeville, PA, [4]Pfizer Inc., New York, NY.

Background/Purpose: Determining the effect of treatment on work productivity of subjects with rheumatoid arthritis (RA) is an important topic given that most sufferers develop the disease between 35 to 50 years of age and many experience functional loss that translates into reduced productivity and work disability. The Valuation of Lost Productivity (VOLP) is a validated instrument developed to estimate productivity impacts from a societal perspective according to the human capital (economic) approach to measuring worker productivity. The VOLP was included in the PRIZE trial: a phase IV, 121-week, prospective, 3-phase (open-label followed by randomized double-blind, and tapering/observational phases), parallel-group, multicenter, outpatient study.

Objective: To assess productivity changes (gains), as measured by the VOLP, in phase 1 of the PRIZE trial.

Methods: In Phase 1, MTX- and biologic-naïve patients with early, active RA (symptom onset ≤12 months from enrollment; DAS28 >3.2) received open-label ETN50/MTX for 52 weeks. The VOLP was completed approximately every 13 weeks. The changes in three main VOLP outcomes from baseline to week 52 were measured: 1) 3-month paid work productivity gains, the sum of increased worked hours after adjusting for absenteeism, presenteeism and employment status changes; 2) 7-day unpaid work productivity impact; 3) Total 3-month monetary productivity gains as the sum of paid and unpaid work productivity gains. Productivity impacts included direct impact of a worker's own productivity as well as the spillover effect when team productivity is impacted and/or substitute worker productivity is considered. Bootstrapping methods were used to test the changes in VOLP outcomes.

Results: A total of 196 patients were employed at baseline and had at least one scheduled follow-up visit. The average age was 46 years and 68% were female. The patients had a high disease activity (DAS28=5.91) and moderate functional disability (HAQ=1.22). The paid work loss was about 111.7 hours in the past 3 months at baseline and decreased to 60.1 hours at week 52, with a gain of 33.43 hours per 3 months. Similarly, the gain in unpaid work was about 4 hours per week. Total costs of lost productivity in the past 3 months were €3,483 at baseline and were reduced to €843 at week 52, with total monetary gains of €1322 per 3 months. All the three main VOLP outcomes were improved significantly over the 52 weeks.

Outcomes	Week0	Week52	Gains†	P value†
Employed (N)	**196**	**143**		
Paid work productivity loss in the past 3 months (N)	**162**	**135**		
Paid work loss, hours (SD)	111.71 (116.84)	60.11 (140.91)	33.43(164.41)	0.035
Unpaid work productivity loss in the past 7 days (N)	**167**	**143**		
Unpaid work loss, hours (SD)	6.27 (11.11)	1.79 (5.86)	4.22(12.33)	0.001
Total costs of lost productivity in the past 3 months (N)	**141**	**124**		
Total costs, € (SD)	3483.48 (8482.03)	842.77 (2242.33)	1322.42 (4378.08)	0.017

Bolded values are the numbers of non-missing values used to generate the outcomes below.
† for patients whose outcomes at week 0 and week 52 were both observed.

Conclusion: Combination therapy with ETN50/MTX was associated with a significant productivity gain for patients with early RA who were still observed at week 52.

Test-Retest Reliability Of Five Global Measures Addressing At Work Limitations/Productivity Loss In Patients With Rheumatological Conditions. Sarah Leggett[1], Annelies Boonen[2], Diane Lacaille[3], Dorcas Beaton[4], Bruno Fautrel[5], Ailsa Bosworth[6], Catherine Hoffstetter[7], Sabrina Dadoun[5], Carlo Alberto Scirè[8], Sofia Hagel[9], Mihai Bojinca[10], Carina Mihai[11], Antje Neuen[12], Pam Rogers[13], Denise Linton[14], Ingemar Petersson[15] and Suzanne Verstappen[16]. [1]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC, [4]Scientist, Institute for Work & Health, Toronto, ON, [5]APHP, Pitié-Salpêtrière University Hospital, Paris, France, [6]National Rheumatoid Arthritis Society, Maidenhead, United Kingdom, [7]Patient partner, Toronto, ON, [8]Epidemiology Unit -Italian Society for Rheumatology, Milano, Italy, [9]Lund University and Skåne University Hospital, Lund, Sweden, [10]"Dr. I. Cantacuzino" Hospital, Bucharest, Romania, [11]Carol Davila University of Medicine and Pharmacy & Cantacuzino Hospital, Bucharest, Romania, [12]University Hospital Maastricht, Internal Medicine, Division of Rheumatology, Maastricht, Netherlands, [13]Arthritis Research Centre, Vancouver, BC, [14]St. Michael's Hospital, Toronto, ON, [15]Lund University, Department of Orthopedics, Clinical Sciences Lund, Lund, Sweden, [16]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom.

Background/Purpose: There are a number of single item global measures available to explore at-work productivity loss (presenteeism) in patients with rheumatological conditions. However, test-retest data are not available for all these measures and comparison data are lacking. The purposes of this study were i) to test-retest five at-work productivity loss global measures, including: Work Productivity Scale–Rheumatoid Arthritis (WPS-RA), Work Productivity and Activity Impairment Questionnaire (WPAI), Work Ability Index (WAI), Quality and Quantity questionnaire (QQ),and WHO Health and Performance Questionnaire (HPQ), ii) to explore the correlations between the 5 measures, and iii) to investigate the association between the 5 scales and disease activity.

Methods: In this international study 50 patients with a diagnosis of inflammatory arthritis or osteoarthritis in paid employment were recruited from 7 countries (United Kingdom, Sweden, France, The Netherlands, Romania, Italy, and Canada). At baseline and 2 wk follow up, participants completed the five 10-point global measures (WPAI; *0=no effect on work–10=completely prevented from working,* WPS-RA; *0=no interference–10=complete interference,* WAI; *0=unable to work–10=work ability at its best,* QQ; *0= practically nothing/very poor quality–10=normal quantity/very good quality,* HPQ; *0=worst performance–10=top performance).* VAS general well-being was also recorded at 2 wks. Test-retest reliability was assessed applying intra-class correlation (ICC) statistics. ICCs of 0.75 and 0.95 are generally regarded as good at respectively group and individual level. Spearman correlations were calculated to determine the association between the two week global scores and between each scale with the VAS general well-being score.

Results: 54% of the study population was female; mean age was 44 (SD 10.2) yrs and median symptom duration 9.5 [IQR 5–15] yrs. Median VAS general well-being was 28 [IQR 12–55]. 72% of the study population had a non-manual occupation. ICC correlations were moderate at a group level: WPAI (r=0.65), WPS-RA (r=0.66), WAI (r=0.81), QQ-quantity (r=0.70), QQ-Quality (r=0.68) and HPQ (r=0.62). The correlations between the 5 at-work productivity measures ranged from good (WPS-RA vs WPAI, r=0.92) to moderate (QQ-quality and QQ-quantity with all 4 other measures) (see table). Correlations between each of the individual measures and VAS general well-being were low to moderate.

Table. Spearman correlations between 5 at-work productivity loss measures and VAS general well-being

	WPAI	WPS-RA	WAI	QQ–Quantity	QQ–Quality	HPQ-question C	VAS well-being
WPAI	1						
WPS-RA	0.92	1					
WAI	−0.68	−0.70	1				
QQ–quantity	−0.58	−0.59	0.57	1			
QQ–quality	−0.58	−0.60	0.38	0.75	1		
HPQ-question c	−0.71	−0.71	0.73	0.63	0.54	1	
VAS well-being	0.56	0.66	−0.62	−0.37	−0.40	−0.60	1

Conclusion: Overall, test-retest results of the 5 existing at-work productivity loss measures and the correlation between these 5 measures were moderate. The latter probably reflecting differences in concepts, recall periods, and references used in these measures. The moderate association between the global at-work productivity measures and VAS general well-being suggests that the impact of arthritis on work is only partly captured by generic health measures.

Quality Of Life, Productivity Impairment, Disease Severity and Health Care Costs In Relation To Functional Impairment In Ankylosing Spondylitis Patients In The Czech Republic. Liliana Sedova[1], Jiri Stolfa[1], David Suchy[2], Andrea Smrzova[3], Jiri Klimes[4], Milan Vocelka[4] and Tomas Dolezal[4]. [1]Charles University Prague, Prague, Czech Republic, [2]University hospital Plzen, Plzen, Czech Republic, [3]University hospital Olomouc, Olomouc, Czech Republic, [4]Charles University, Prague, Czech Republic.

Background/Purpose: Our aim was to describe the quality-of-life (QoL), productivity impairment, clinical indicators and health care costs in relationship to functional status described by Bath Ankylosing Spondylitis Functional Index (BASFI) in Ankylosing spondylitis (AS) patients. This relationship is highly important to justify the investment into health care.

Methods: We have organized a prospective multicentre non-interventional observational study with AS patients in 4 specialized centres for treatment of rheumatic diseases in the Czech Republic. A three-year follow-up is planned with 6 months period between each time point observation. The data presented here comes from the first visit, where demographics, clinical, QoL and productivity data were directly collected from patients. Health care consumption was assessed retrospectively reviewing individual patient's medical record (with 6 or 12 months recall period from the first visit). Clinical data were described by ASDAS-CRP, QoL measured by EuroQol questionnaire (EQ-5D), work impairment by Work Productivity and Activity Impairment (WPAI) with respect to BASFI categories. Validated Czech versions of all questionnaires were used. Patients are stratified according to their BASFI in 10 categories. Within health care consumed, we focus on medication (classical DMARDs, corticosteroids and biological drugs), out-patient & in-patient care, complement and instrumental examination and out-of pocket expenses. Health care expenditures are annualized and presented as an average costs per patient. Patients are analysed as the whole cohort and specifically by the presence of biologic treatment.

Results: We have already included 225 patients with AS, 200 on biological drugs, mean patient age was 43.4 years, mean time from diagnoses of AS was 13.8 years, 24.4% were female. With higher functional impairment, described by BASFI, there is trend in age increase, increase in time from diagnosis, percentage of work impairment and also decrease in percentage of work-active patients. There is also deterioration in clinical impairment (ASDAS-CRP) and QoL observed with worse functional status. There is almost the same height of total costs in each BASFI category as 89% of all patients are treated with biologics, which are the most important costs driver. See results table, where all values are presented as mean values, na-not applicable.

Patients on biologic drugs

BASFI category	BASFI	No.	Age	Time from Dx (years)	% women	Costs (EUR)	% of work active	% WPAI	ASDAS-CRP	EQ-5D

2–3>	2.5	37	46.2	14.7	18.9%	12,303	73.0%	25.2%	2.1	0.724
3–4>	3.4	26	46.3	17.4	30.8%	10,534	69.2%	24.9%	2.3	0.664
4–5>	4.5	22	44.0	17.0	27.3%	12,370	59.1%	33.2%	2.0	0.656
5–6>	5.4	19	48.9	19.3	21.1%	9,528	47.4%	37.3%	2.6	0.621
6–7>	6.6	7	42.4	7.7	14.3%	12,621	57.1%	47.5%	2.6	0.665
7–8>	7.4	6	49.3	14.5	0.0%	8,134	50.0%	68.9%	3.3	0.608
8–9>	8.5	9	50.0	22.4	11.1%	8,684	11.1%	40.0%	3.7	0.444
9–10>	9.3	2	46.0	13.5	0.0%	12,479	50.0%	95.3%	3.0	0.521
Mean/total	2.9	225	43.4	13.8	24.4%	11,286	70.2%	22.7%	2.0	0.734

Conclusion: Patients with worse functional impairment revealed more significant impairment of their QoL, work productivity and revealed also worse clinical outcomes. We present total health care costs according to the functional impairment. The findings attributed to higher BASFI impairment (BASFI > 6.0) and to patients not treated with biologics should be interpreted with caution because of lower number of patients in these categories.

Presenteeism Predicts Sick Leave Better Than Basdai and/Or BASFI In A Longitudinal Cohort Of Patients With Ankylosing Spondylitis (EASIC). Thien Thi Vinh Nguyen[1], An Tran-Duy[2], Frank Heldmann[3], Juergen Braun[3], Herbert Thijs[1] and Annelies Boonen[2]. [1]Hasselt University, Hasselt, Belgium, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Rheumazentrum Ruhrgebiet, Herne, Germany.

Background/Purpose: Sick leave (SL) is a critical socioeconomic consequence of ankylosing spondylitis (AS). This study aimed at exploring the role of presenteeism relative to BASDAI and BASFI in predicting SL in patients adequately treated with the TNF-α inhibitor infliximab using longitudinal data analysis.

Methods: The EASIC database is an open label extension of the ASSERT trial and includes 103 patients with AS from six European countries that were treated with infliximab. Demographic, clinical and work-related data were collected at baseline and every six months over a 2-year period. Sick leave represented the number of non-working days in the last six months. Presenteeism represented the AS impact on productivity of patients at work and is measured as a single item (0: no effect; 10: strong effect). We fitted a number of statistical models, including standard/zero-inflated Poisson/Negative Binomial (NB) fixed/mixed effects models. Based on exploratory data analysis and expert opinion, covariates considered in the models included time, gender, baseline age, disease duration, BASDAI, BASFI, BASMI, presenteeism and work-status (part-/full- time), and pair-wise interactions between them. Model selection was based on Akaike information criterion (AIC), Bayes information criterion (BIC) and likelihood ratio test. SAS 9.2 was used for data analysis.

Results: Of all patients (n=103), 84% had full-time job; 86% were male; mean (SD) age was 41 (9.6); mean monthly presenteeism ranged from 2 to 3; mean (SD) BASDAI and BASFI were 3.2 (1.7) and 3.5 (1.4), respectively. Of patients with paid jobs, 35% had SL > 0 with a mean (SD) of 8 (10) days over two years. The ratio of the deviance of Poisson regression to its degrees of freedom indicated overdisperson, suggesting that the standard Poisson models were not appropriate. The likelihood ratio tests comparing the NB models with the Poisson models were significant (p-value < 0.001) in favor of the NB over the Poisson models. Because the overdispersion was due to excess of zero, the zero-inflated NB (ZIBN) models were considered better than the standard NB models. AIC resulting from the ZINB fixed model was smallest, suggesting that the ZINB fixed effect model was the best choice.

In the first part of the best fitting ZINB fixed effect model (which predicts the probability of having zero day of SL), the intercept and the only slope for presenteeism at 6 months (PRES.LAG6) in the past were significantly different than zero. In the second part (which predicts the number of non-zero SL), the intercept and only slopes for time and PRES.LAG6 were significantly different than zero. An increase of one unit in presenteeism yielded an increase by 29% in the expected SL.

Conclusion: In patients with adequately controlled AS, our findings show that presenteeism is a better predictor for SL over time than BASDAI and/or BASFI. Limitations of this study include small sample size, short follow-up time and the absence of work-related factors among the predictors.

Methodology Of Determining An Appropriate Look-Back Period To Identify Autoimmune Rheumatic Disease In a Study Of Post-Myocardial Infarction Mortality. Mark Tacey, Megan Bohensky and Sharon Van Doornum. The University of Melbourne, Melbourne, Australia.

Background/Purpose: Hospital administrative datasets offer an opportunity to study the relatively rare occurrence of auto-immune rheumatic diseases (AIRD). Under-coding is a known limitation however. "Look-back" periods can be used to compensate for under-coding within the ("index") admission of interest by identifying AIRD codes in preceding admissions for each patient. However if the timespan of the dataset is fixed, increasing the look-back period to identify more AIRD patients reduces the duration of the primary analysis period (Figure 1). This study aimed to examine the effect of different look-back periods for identifying AIRD patients in an evaluation of the relationship between AIRD status and mortality following myocardial infarction (MI).

Methods: This study utilises a population-based hospital admission dataset with data available from 1 July 1998 to 30 June 2007. MI and AIRD status were identified using relevant International Classification of Diseases (ICD) codes. Six scenarios were defined for ascertainment of AIRD status (A to F: Figure 1), ranging from no look-back to a 5 year look-back period. Thirty-day and 1-year mortality rates were calculated from the date of the index MI. A logistic regression model was fitted with mortality as the outcome, AIRD status as the exposure and adjustment for relevant covariates. We compared the relationship between AIRD status and post-MI mortality for each scenario.

Results: As the duration of the look-back period increased (progressing from scenario A to F), the prevalence of AIRD increased from 0.7% (n=632 of 86,841 patients: scenario A) to 2.2% (n=998 of 45,447 patients: scenario F). The number of patients identified with MI decreased from scenario A to F due to the progressive reduction in the duration of the primary analysis period. Adjusted odds ratios for all-cause mortality for the AIRD group are shown in Figure 2. When no look-back period was used, no significant relationship between AIRD and 30-day mortality was identified (OR = 1.13, 95%CI 0.90–1.42). As the look-back period increased, a statistically significant relationship was obtained with an increase in the odds ratio, before stabilising with a look-back period of 3 years or longer in duration.

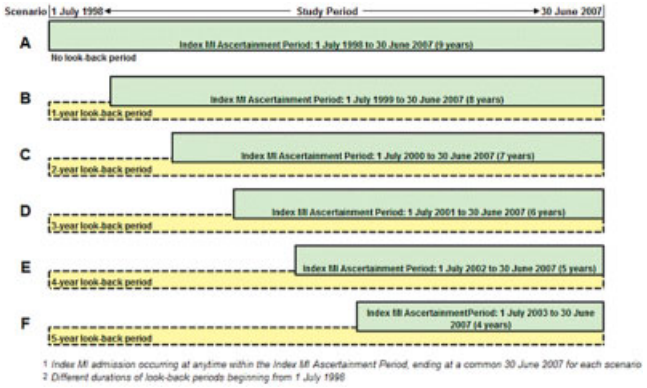

Figure 1. Index MI ascertainment and look-back period scenarios

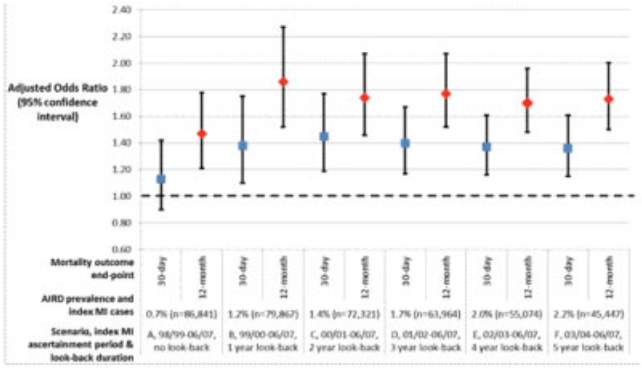

Figure 2. Adjusted Odds Ratio for 30-day and 12-month mortality for AIRD patients

Conclusion: Using a look-back period to identify AIRD status changed the significance of our findings. Based on the dataset in question, there is no advantage of extending the look-back period beyond a duration of three years, with an analysis period of six years.

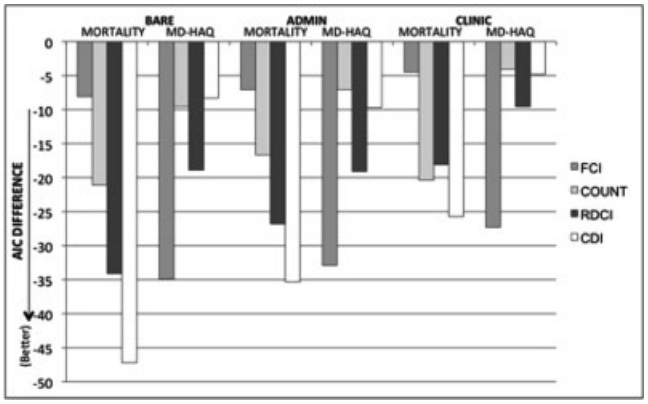
Comparison Of Comorbidity Indexes In a Clinical and Administrative Rheumatoid Arthritis Cohort: A Case For The Rheumatic Diseases Comorbidity Index. Bryant R. England[1], Harlan Sayles[1], Ted R. Mikuls[2], Dannette S. Johnson[3] and Kaleb Michaud[4]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [3]Jackson VA and University of Mississippi Medical Center, Jackson, MS, [4]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: Quantifying comorbidities contribution to disability and mortality is important for assessing prognosis and standardizing cohorts in rheumatic disease research. A comorbidity index has been developed specifically for individuals with rheumatic diseases. We compared the Rheumatic Diseases Comorbidity Index (RDCI) with the Charlson-Deyo index (CDI) and Functional Comorbidity Index (FCI) using a nationwide cohort of RA patients.

Methods: The RDCI, range 0–9, combines 11 comorbidities: lung disease, hypertension, MI, stroke, heart disease, cancer, fracture, diabetes, depression, GI problem and ulcer. The predictive value of the RDCI, CDI, FCI, and a generic comorbidity count (COUNT) for outcomes of functional disability and mortality were tested in the Veterans Affairs RA registry by access to administrative ICD9 diagnosis codes. Functional disability was measured by MD-HAQ. Comorbidity indices were fixed at baseline values and patient visits were limited to first visits within each of twenty-one six-month phases from January 2003 to March 2013. Best fit via Cox proportional hazard for mortality and Generalized Estimating Equations for disability models was determined by the Akaike Information Criterion (AIC) where a lower AIC signifies a better model fit. Indices were compared in three models: a bare model [age, sex, and race]; an admin model [bare+ visit frequency, BMI, prednisone, and MTX]; and clinic model [admin+ ESR, nodules, RF+, and patient activity scale].

Results: Each index improved the fit of all models (see Figure). Comorbidity indices decreased AIC most in the bare model and least in the clinic model. CDI decreased AIC most in the mortality analysis while performing worst in MD-HAQ. FCI decreased AIC the most in MD-HAQ analysis but performed worst in mortality. RDCI performed well in both mortality and MD-HAQ analysis.



Conclusion: The RDCI quantifies the contribution of comorbidity to both MD-HAQ and mortality well, while other indices were better predictors of only one outcome. In the first study that compares comorbidity indices with administrative data such as ICD9 codes, RDCI performed well and shows promise for future use in observational studies obtaining data from electronic medical records. Furthermore, we demonstrate when choosing a comorbidity index, the outcome of interest and the variables within the model should guide index selection.

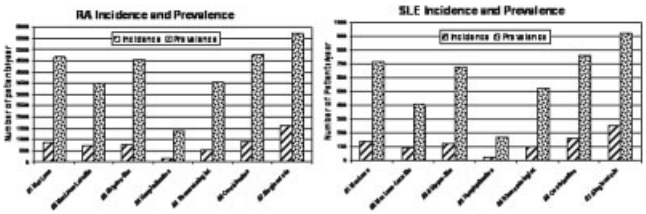
The Impact Of Diagnostic Decision Rules Used In Administrative Healthcare Databases On The Frequency Of Rheumatoid Arthritis and Systemic Lupus Erythematosus. John G. Hanly, Kara Thompson and Chris Skedgel. Dalhousie University and Capital Health, Halifax, NS.

Background/Purpose: To compare the incidence and prevalence of rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) in administrative databases using different diagnostic decision rules.

Methods: A retrospective cohort study was performed using administrative health care data from a population of 1 million people with access to universal healthcare. Information was available on hospital discharges and physician billings over a 13 year period. Each RA and SLE case was matched 4:1 by age and gender to randomly selected controls. Seven decision rules, validated against the diagnosis confirmed by a rheumatologist, were used to identify RA and SLE cases and to examine the incidence and prevalence of both diseases.

Results: The overall accuracy of the decision rules for RA cases varied between 68.9–82.9% with a kappa statistic between 0.26–0.53. The sensitivity varied from 20.7–94.8% and the specificity between 62.5–98.5%. For SLE the overall accuracy of the decision rules varied between 88.2–95.6% with a kappa statistic between 0.53–0.86. The sensitivity varied from 41.0–86.6% and the specificity between 92.4–99.9%. The number of incident cases per year was between 176–1610 (0.02–0.17% population) for RA and between 29–255 (0.003–0.027% population) for SLE. The number of prevalent cases per year was between 1384–5722 (0.15–0.61% population) for RA and between 172–920 for SLE (0.018–0.098% population).



Conclusion: The performance of decision rules for the identification of incident and prevalent RA and SLE cases in administrative healthcare databases is variable and should be considered when compareing results across studies.

Application Of a Novel Measure Of Socioeconomic Status Using Individual Housing Data In Rheumatology Research. Young Juhn, Sherine E. Gabriel, Cynthia S. Crowson, Jennifer Rand-Weaver and Elizabeth Krusemark. Mayo Clinic, Rochester, MN.

Background/Purpose: We recently developed and validated an index of socioeconomic status (SES) termed HOUSES (HOUsing-based index of SocioEconomic Status) to address unavailability of SES measures in routinely used data sources for clinical research concerning health disparities. While HOUSES has been associated with various childhood health outcomes, whether HOUSES is associated with adult health outcomes is unknown. Our objective was to assess whether HOUSES (a measure of SES) is associated with risk of and mortality after rheumatoid arthritis (RA).

Methods: We conducted a population-based case-control study among all residents of a geographically-defined area with RA who were identified using 1987 American College of Rheumatology criteria for RA from January 1, 1988 to December 31, 2007. HOUSES was formulated based on z-score for four real property data (housing value, actual square footage, and numbers of bedrooms and bathrooms) and analyzed in categorical (quartiles) and continuous variables. Self-reported educational level and pertinent risk factors for RA were obtained. Logistic regression was used to examine the association between HOUSES and risk of RA. Cox models were used to examine the association between HOUSES and mortality rate during the follow-up after RA adjusting for age, gender, index year of RA, comorbid conditions known to be associated with risk of RA, and therapy for RA.

Results: There were 650 eligible patients who developed RA during the study period and 1:1 matched controls without RA; 604 of RA (93%) and 564 of controls (87%) were successfully geo-coded to real property data. Of these 604 subjects, 418 (69%) were female; the mean age (±SD) was 56±15.6 years, the mean follow-up was 7.7±5.1 years. HOUSES was associated with risk of developing RA (mean±SD: 0.5±3.8 for controls vs. −0.2±3.1 for RA cases, p=0.003) (odds ratio: 1.06 per 1 unit decrease in HOUSES; 95%CI: 1.02–1.09). This association persisted after adjustment for smoking status and body mass index. Cumulative mortality rates at 15 years following RA were 33% (95%CI: (27–39), 27% (21–33), 24% (18–30), and 25% (19–31) for patients in the first (lowest SES), second, third, and fourth quartiles (highest SES) of the HOUSES

index, respectively. The lowest quartile of HOUSES was significantly associated with increased mortality after RA compared to higher quartiles of HOUSES (HR: 1.74; 95%CI: 1.10–2.74; p-value=0.017) adjusting for RA characteristics, comorbidities and RA therapies. The association between HOUSES and mortality after RA was not explained by other known risk factors for mortality after RA. RA therapy such as disease modifying drugs including biologics were not associated with HOUSES nor accounted for the association between HOUSES and mortality after RA.

Conclusion: Lower SES (as measured by HOUSES) is associated with increased risk of RA and mortality after RA. To reduce the gap in differential mortality after RA among individuals with different SES, clinicians or health care systems need to consider their preventive and therapeutic strategies in the patients' social context.

Initiation Of Biologic Therapy: The Patient Perspective. Amir Goren[1], Susan C. Bolge[2], Duncan Brown[3], Roxanne Meyer[4] and Seth Ginsberg[5]. [1]Kantar Health, New York, NY, [2]Janssen Scientific Affairs, LLC, Horsham, PA, [3]Kantar Health, New York, NY, [4]Janssen Scientific Affairs, LLC, Horsham, NY, [5]Creaky Joints, New York, NY.

Background/Purpose: Current guidelines for the treatment of rheumatoid arthritis (RA) recommend that patients who are not adequately responding to treatment with disease modifying anti-rheumatic drugs (DMARDs), most often methotrexate, initiate treatment with biologic therapy. However, from the patient perspective, there may be many other factors which influence this decision. This study describes the experience of patients who are considering biologic therapy to manage their RA.

Methods: Study patients were recruited through two sources: the patient advocacy organization, CreakyJoints, and the Lightspeed Research consumer panel. Patients were U.S. adults (aged ≥18), diagnosed with RA, and currently treated by a rheumatologist with DMARDs. Patients had no history of biologic use but had discussed biologic therapy with their physician. Data were collected directly from patients through a self-administered, web-based questionnaire.

Results: Among the 243 patients who completed the study, the mean (SD) time that elapsed since discussions about biologic therapy began was 1.3 (1.8) years over a mean (SD) of 2.7 (2.6) office visits. Rheumatologists were most likely to initiate the discussion (54%), but 23% of patients reported initiating it. A majority of patients (>73%) reported discussing the following aspects of biologic therapy either somewhat or in detail: ability to improve well-being or daily functioning; ability to improve mobility or range of motion; ability to slow or stop joint damage; potential side effects; how treatment is taken/administered; and frequency of administration. However, fewer than 39% of patients reported discussing the subcutaneous injection experience, the intravenous infusion experience, or financial and treatment support programs. Most patients believe they are the primary decision maker: 25% make the final decision about treatment and 49% make the final decision after considering their rheumatologist's recommendation. When making treatment decisions, 74% of patients reported that they consider both their current and future situations, though 15% only consider the present and 10% only consider the future.

Conclusion: Patients with RA are active participants in the process of initiating biologic therapy. Rheumatologists should actively engage their patients in the shared-decision making process for initiating biologic therapy. As demonstrated by previous research, effective communication between patients and providers may have a positive impact on patient satisfaction and adherence to therapy.

Openness To and Preference For Biologic Therapy Among Patients With Rheumatoid Arthritis Prior To Biologic Initiation: Patient and Prescriber Perspectives. Susan C. Bolge[1], Duncan Brown[2], Amir Goren[3], Roxanne Meyer[4] and Seth Ginsberg[5]. [1]Janssen Scientific Affairs, LLC, Horsham, PA, [2]Kantar Health, New York, NY, [3]Kantar Health, New York, NY, [4]Janssen Scientific Affairs, LLC, Horsham, NY, [5]Creaky Joints, New York, NY.

Background/Purpose: Currently two modes of administration are available for biologic therapies used to treat rheumatoid arthritis (RA): subcutaneous injection (SQ) and intravenous infusion (IV). Patient preference for mode of administration may be among the factors influencing choice of therapy. The purpose of this study was to explore openness to and preference for biologic therapy among patients with RA prior to biologic initiation from the perspectives of both patients and prescribers.

Methods: Data were collected online from both patients and prescribers through self-administered questionnaires. Patients were U.S. adults (aged ≥18), diagnosed with RA, currently treated by a rheumatologist with disease modifying anti-rheumatic drugs (DMARDs), and with no history of biologic use but had discussed biologics with their physician. Prescribers were board certified rheumatologists, practicing for 2–25 years, spent ≥50% of their time in a clinical setting seeing ≥50 RA patients per month, and were not government employees or employed by or consultants to pharmaceutical companies. A total of 243 patients were recruited through the patient advocacy organization CreakyJoints (n=101) and a consumer panel (n=142); 103 prescribers were recruited through a physician panel.

Results: Among all study patients, 53% were open to both SQ and IV therapies, 16% were open only to SQ, 14% were open only to IV, and 16% were open to neither. However, prescribers believed that 41% of patients are open to considering both SQ and IV therapies, 34% are open only to SQ, 13% are open only to IV, and 12% are open to neither. When asked about preference for SQ vs. IV therapy, 22% of patients had no preference, while 49% preferred SQ and 28% preferred IV. Prescribers believed that 31% of patients have no preference, while 52% prefer SQ and 16% prefer IV. Patient openness to and preference for SQ vs. IV therapy was further influenced by frequency of administration, time to complete an infusion, and site of care.

Conclusion: More patients may be open to both SQ and IV biologic therapy and more patients may prefer IV biologic therapy than rheumatologists currently believe. Rheumatologists are well positioned to guide the shared-decision making process with patients to ensure that patients are provided with information about all appropriate biologic therapy options and that patient preferences are considered when making prescribing decisions.

Modeling The Benefit Risk Profiles Of a New Janus Kinase Inhibitor Tofacitinib Compared Tottumour Necrosis Factor Inhibitor Biologic Treatments Incorporating Conjoint Derived Patient Preference Weights. Michael P. Ingham[1], Shannon Cartier[2], Raphael J. DeHoratius[3], Jack McGowan[3] and Eric Sabot[2]. [1]Janssen Scientific Affairs, LLC, Horsham, PA, [2]Optum, Eden Prairie, MN, [3]Janssen Services, LLC, Horsham, PA.

Background/Purpose: Tofacitinib (Tofa) was recently approved in the U.S. There are no data comparing the benefit risk profile of Tofa to tumor necrosis factor inhibitors (TNFi). This analysis included a conjoint survey of rheumatology patients' preferences, followed by a benefit-risk assessment combining multiple benefits and risks associated with Tofa vs. TNFi.

Methods: The patient preference study investigated 10 attributes, Patient cost, ACR20, Oral vs Injection vs Infusion, Injection site/infusion reactions, Nausea, Herpes Zoster, Malignancies, and Cholesterol elevation. Attribute "levels" were assigned from pivotal trial data, meta-analyses, FDA documents and prescribing information. Levels encompassed a plausible range of values. Each patient was asked to complete a preference selection for 15 choice tasks, based on a randomized design using a 5-attribute partial profile. A Multi-Criteria Decision Analysis (MCDA), a tool from the EMEA risk-benefit project, was used to assess the overall benefit-risk profile, incorporating differences in outcomes and using the conjoint survey to weight each attribute's relative importance. The base case profile identified Tofa as having a less robust ACR20 response, higher incidence of malignancy and herpes zoster risk, greater impact on cholesterol, lower levels of injection site/infusion reactions and oral vs injection/infusion.

Results: 386 patients had evaluable data from the conjoint preference study. 71% were female and median age was between 60 and 64. Fifty-one patients (13%) were bio-naïve. Attributes that showed the greatest impact on preference perception between top and bottom levels included out-of-pocket costs, injection site reactions, dose interval/mode and impact on cholesterol. There was little difference between injection site reactions levels of none and 4/100 patient years (PY), as well as between dose interval/mode of oral at 730 doses per year and injections at 12 times per year. For dose interval/mode, the least preferred option was injections 26–52 times per year. Based on base case profiles assigned to individual products, 42% of patients would choose golimumab, 34% an oral DMARD and 24% infliximab. If all Tofa risk

attribute differences vs TNFi were removed, 53% would choose Tofa, 28% golimumab and 19% infliximab. Etanercept and Adalimumab preferences were sensitive to rate of injection site reactions. The MCDA estimated a greater combined score for TNFi compared to Tofa, indicating that from a patient perspective TNFi are a more favorable treatment option overall. A major contributing factor to this outcome was the relative importance that patients placed on risk attributes which favored the TNFi profile.

Conclusion: Patients appear sensitive to relatively small changes in tolerability and safety profiles of rheumatology treatments. Benefit and risk profiles can have significant mitigating influence over patient preferences related to convenience of treatment. This reinforces the need for full and clear disclosure to patients of the benefit and risks of treatments in RA and the importance of patient involvement in treatment decisions, since lack of preference can have an impact on adherence.

Mapping The Health Assessment Questionnaire On a Preference Based Utility Measure In a Large Canadian Rheumatoid Arthritis Cohort: Results From The Ontario Best Practices Research Initiative. Mark Tatangelo[1], George A. Tomlinson[2] and Claire Bombardier[1]. [1]University of Toronto, Toronto, ON, [2]Toronto General Hospital, Toronto, ON.

Background/Purpose: mANMClinical trials are limited in demonstrating the cost effectiveness of biologic therapies, as these studies often do not collect measures required for economic analysis. Thus we sought to provide a validated algorithm, allowing utility scores to be estimated using mapping (also known as "cross-walking") of the Health Assessment Questionnaire Disease Index (HAQ-DI) onto a standardized utility measure (EQ-5D).

Methods: We studied 5971 patient visits for 1911 patients included in the Ontario Best Practices Research Initiative, a clinical registry of RA patients followed in routine care (2008–2013). Data were collected every 6 months and include patient demographics, socioeconomic status, clinical variables, disease activity measures, and HAQ-DI and EQ-5D. Each patient's EQ-5D score was converted to a utility value using a Canadian tariff. EQ-5D utility values were then predicted from HAQ-DI scores using a linear random effects model. HAQ-DI scores were entered as predictors in the model. Random effects for each patient were fitted for intercepts and slopes for the effect of HAQ-DI. Linearity was assessed by fitting non-parametric estimate calculated by mean EQ-5D grouped by HAQ scores.

Results: The estimated fixed effect change in EQ-5D for each point of the HAQ-DI scores is −0.15 (SE=0.0027, P<0.001), with a $RMSE$= 0.099, and R^2=0.68. Examination of the residual plots suggested mild departures from normality with slightly smaller variance for large EQ-5D values (Figure 1). EQ-5D health utility scores showed a ceiling effect, with 1621 observations achieving a utility value of 1 (perfect health).

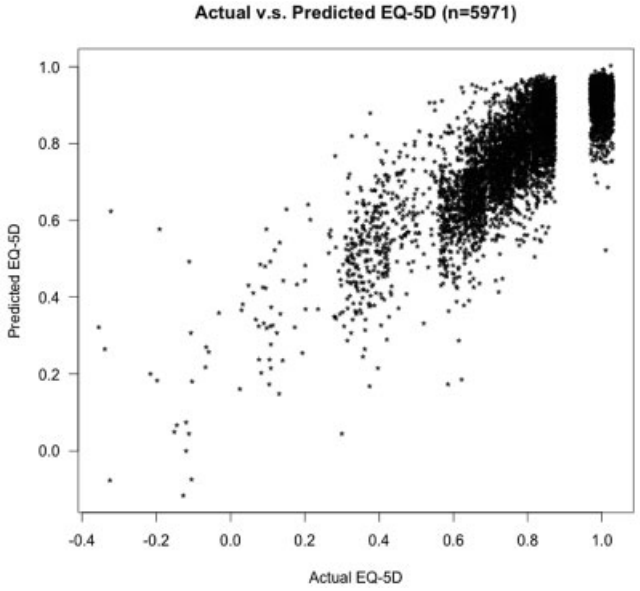

Figure 1.

Conclusion: Preference based utility values like the EQ-5D can be estimated using measures such as the HAQ. These results are important because they allow for accurate prediction of average utility values from functional measures included in current clinical trials. This model will allow for economic analyses of the benefit of biologic rheumatic drugs in Quality Adjusted Life Years that are meaningful to payers. Future analysis will use each HAQ item to predict EQ-5D utility score, and external validation of the algorithm.

Impact Of Basing Rheumatoid Arthritis Disease Activity Measurement and Treatment Recommendations On Patient Instead Of Physician Joint Assessments. Yomei Shaw[1], Daisy Bang[2], Heather Eng[1], Stephen R. Wisniewski[1], Mark S. Roberts[1] and Marc C. Levesque[2]. [1]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Current guidelines recommend treatment for rheumatoid arthritis (RA) be informed by a measure of disease activity such as the Disease Activity Score-28 (DAS28-CRP), which includes physician assessments of tenderness and swelling in joints. We explored the impact of basing disease activity measurement and treatment recommendations for RA patients on patient joint assessments rather than physician assessments.

Methods: 364 RA subjects enrolled in the Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry and their physicians performed independent and blinded exams of 28 joints for tenderness and swelling during routine clinic visits. Subjects assessed their own joints assisted by a web-based tool that provided illustrations and instructions. We measured discrepancies in the DAS28-CRP, disease activity categories and treatment recommendations (following American College of Rheumatology (ACR) guidelines for therapy adjustment) when based on patient vs. physician assessments. Treatment recommendations were compared with actual treatment decisions for 342 subjects.

Results: Mean DAS28-CRP scores based on patient assessments were higher than when based on physician assessments (mean ±SD, 3.49 ±1.50 vs. 3.02 ±1.25; p<0.0001). In 56% of 364 cases, the patient and physician-based DAS28-CRP led to categorization in the same disease severity level; in 44% of cases the patient and physician-based scores led to discrepant categorizations. In 84% of cases the physician and patient-based scores would yield the same recommendation regarding therapy adjustment, but in 16% of cases they would yield different recommendations. When evaluating actual decisions against treatment recommendations based on ACR guidelines (n=342), only 8.77% of patients actually adjusted therapy, compared to 33.33% and 39.18% recommended to adjust therapy according to physician and patient DAS28-CRP, respectively (Table 1). Actual rates of therapy adjustment were low among those subjects recommended to adjust therapy (16.7% when assessed by physician DAS28-CRP and 14.9% when assessed by patient DAS28-CRP (Table 1)).

Table 1. Physician- and patient-DAS28-CRP based treatment recommendations versus actual decisions (n = 342)

		Actual decisions		
		Therapy adjusted (n = 30, 8.77%)	Therapy not adjusted (n = 312, 91.23%)	Row total (%) (n = 342, 100%)
Physician-DAS28-CRP-based treatment recommendation	Recommended to adjust therapy (n, row %)#	19 (16.7%)	95* (83.3%)	114 (33.33%)
	Not recommended to adjust therapy (n, row %)	11* (4.8%)	217 (95.2%)	228 (66.67%)
Patient-DAS28-CRP-based treatment recommendation	Recommended to adjust therapy (n, row %)*	20 (14.9%)	114* (85.1%)	134 (39.18%)
	Not recommended to adjust therapy (n, row %)	10* (4.8%)	198 (95.2%)	208 (60.82%)

* Undertreated, *Overtreated.
# Both physician and patient-DAS28 based recommendations were significantly different from actual decisions (p < 0.0001), but not significantly different from each other (p = 0.1307).

Conclusion: Although discrepancies in disease severity categorization occurred frequently (44% of the time), discrepancies in RA treatment recommendations arose less frequently (16% of the time) as a result of differences in patient and physician joint exams. Regardless of whether

treatment recommendations were based on patient or physician joint exams, actual treatment decisions often appeared to be inconsistent with disease severity, primarily because therapy was often not adjusted despite > 3 months of moderate to high disease activity. Further research will explore disease and health-related outcomes associated with miscategorizing disease severity and under-treating RA patients.

1027

Factors Associated With Decisions To Adjust Therapy For Rheumatoid Arthritis Patients In Moderate To High Disease Activity. Yomei Shaw[1], Chung-Chou H. Chang[2], Heather Eng[1], Ilinca D. Metes[2], Stephen R. Wisniewski[1], Mark S. Roberts[1] and Marc C. Levesque[2]. [1]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: The American College of Rheumatology (ACR) recommends treating rheumatoid arthritis (RA) to the target of low disease activity or remission with traditional and biologic disease-modifying anti-rheumatic drugs (DMARDs). However, significant numbers of RA patients do not receive care consistent with these recommendations. Previously, we found that age, race, physician age, current use of a biologic, Disease Activity Score-28 joint (DAS28-CRP), and RA duration were significantly associated with decisions to adjust DMARD therapy for RA patients with moderate to high disease activity. Here, we present an update to our findings with new covariates added to the analysis, including income and comorbidities, which were adjusted for to prevent confounding bias in the effects of age and race.

Methods: Data was drawn from the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Research (RACER) observational registry (2010–13) on visits where patients had moderate to high disease activity for at least 3 months. Therapy adjustment was defined as adding, switching, or increasing the dose of oral or biologic DMARD therapy. To assess this binary outcome, a generalized linear model with logit link was used. Generalized estimating equations (GEE) with clustering by patient were used to account for correlation between different visits for each patient. Variables significant in univariable GEE analyses (Wald test on coefficient has $p<0.2$) were entered into a multivariable model, then backwards selection was used to choose the final model by removing variables with $p>0.05$. The model controlled for patient demographic and disease characteristics: age, race, gender, RA duration, DAS28-CRP, Short Form 12 (SF12) physical and mental components, Health Assessment Questionnaire (mdHAQ), and two new variables (income and Charlson comorbidity index).

Results: There were 562 visits for 255 patients with moderate to high disease activity for at least 3 months. Therapy was adjusted at 23.1% of visits. The odds ratios (OR; [95% CI]) of adjusting therapy were decreased by longer disease duration (0.965; [0.943,0.987]), physician age (0.955; [0.932,0.978]), current use of biologic therapy (0.394; [0.240,0.648]), and lower DAS28-CRP (0.640; [0.455,0.900]). Age and race were no longer significant.

Conclusion: In the RACER observational cohort, 76.9% of RA patients with moderate/high disease activity for at least 3 months did not have DMARD therapy adjusted. Physician age, duration of RA, lower DAS28, and current use of biologic therapy decreased the likelihood of therapy adjustment. The fact that age and race were no longer significant upon the addition of Charlson comorbidity index and income to the model suggests that these new variables may partially explain the previously observed effects of age and race. These results can be used to improve treat-to-target strategies in clinical practice. Our future research will explore how other factors such as prior use of DMARDs/corticosteroids, insurance coverage, and risk aversion may influence treatment decisions for RA patients with moderate/high disease activity.

Development Of Patient-Reported Outcomes Measurement Information System (PROMIS®) Gastrointestinal (GI) Symptoms Item Bank. Dinesh Khanna[1], Lin Chang[2], Gil Y. Melmed[3], Roger Bolus[4], Puja Khanna[1], Ron Hays[5] and Brennan Spiegel[5]. [1]University of Michigan Medical Center, Ann Arbor, MI, [2]David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA, [3]Cedar-Sinai Medical Center, Los Angeles, CA, [4]Research Solutions Group, Encinitas, CA, [5]University of California, Los Angeles, Los Angeles, CA.

Background/Purpose: The National Institutes of Health PROMIS® roadmap initiative is a cooperative research program designed to develop, evaluate, and standardize item banks to measure patient-reported outcomes (PROs) across different medical conditions as well as the US population (www.nihpromis.org). PROMIS includes items banks that assess self-reported physical, mental, and social health. The aim of this study was to develop GI Symptoms measures applicable to patients with GI illness and the general population.

Methods: A systematic review was conducted to find relevant articles assessing PROs in GI diseases and a conceptual model was proposed for different GI symptoms scales (Spiegel et al Am J Gastroentrol 2011). The individual items from extant instruments were grouped based on different symptoms. This was complemented by 12 focus groups including 102 patients with GI conditions to evaluate their symptoms. New items were developed based on extant items and input from the focus group participants followed by cognitive debriefing in 28 patients with GI conditions. Preliminary items were administered to the patients (irritable bowel syndrome (IBS), inflammatory bowel disease (IBD), systemic sclerosis (SSc), and other common GI disorders) and the US General Population (GP, based on 2010 census data). Patients were recruited from academic, Veterans Affairs, and private practices and completed the survey predominantly on the web using SurveyMonkey® software and the US GP using the Cint®. Items were finalized based on psychometric analyses including categorical confirmatory factor analyses and item response theory modeling to estimate item thresholds and discrimination parameters.

Results: 102 items were developed after qualitative analysis (N=130 patients) and administered to 865 patients with GI conditions and 1177 participants from the US GP. Patients were older (mean age 48 vs. 45 years), more educated (86% vs. 62% with >=some college degree), and reported greater moderate to very-severe overall GI symptoms in the past 1 week (57% vs. 26%). Patients' self-reported GI conditions included IBS (40%), GERD (33%), IBD (28%), chronic constipation (24%), SSc (16%), and other GI conditions. Confirmatory factor analyses provided support for 8 scales: Gastroesophageal reflux (13 items), disrupted swallowing (7 items), diarrhea (5 items), bowel incontinence/soilage (4 items), nausea and vomiting (4 items), constipation (9 items), belly pain (6 items), and gas/bloat/flatulence (12 items). All scales are calibrated using the two-parameter IRT graded response model and scored on a T-score metric with a mean of 50 and SD of 10 in the U.S. general population.

Conclusion: Using NIH PROMIS framework, we have developed a 60-item GI Symptoms scale that can be used for clinical care and trials.

Quality Of Life In Rheumatoid Arthritis: Cross-National Comparison Study Between US and South Korea. Yoon-Kyoung Sung[1], Kazuki Yoshida[1], Femke H.M. Prince[1], Michelle A. Frits[1], Jung-Yoon Choe[2], Won Tae Chung[3], Jisoo Lee[4], Eun-Mi Koh[5], Dae-Hyun Yoo[6], Simon M. Helfgott[1], Nancy A. Shadick[1], Michael E. Weinblatt[1], Sang-Cheol Bae[6] and Daniel H. Solomon[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Catholic University of Daegu School of Medicine, Daegu, South Korea, [3]Dong-A University Hospital, Busan, South Korea, [4]Ewha Womans University Mokdong Hospital, Seoul, South Korea, [5]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [6]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea.

Background/Purpose: Quality of life (QOL) is a well-established outcome for rheumatoid arthritis (RA) trials. To perform trials with QOL as an outcome involving many countries, it is valuable to compare QOL measures

across countries. The objective of this study was to compare health-related quality of life (HRQOL) of rheumatoid arthritis (RA) patients between United States (US) and South Korea.

Methods: Two year follow-up data on health and HRQOL measured with EuroQoL-5 dimension (EQ-5D) between 2009 and 2011 were compared between US-based (BRASS) and Korean-based (KORONA) cohorts. A total of 1,166 subjects (187 from BRASS and 979 from KORONA) were included in this study to compare the cross-sectional differences in QOL in 2009 and the longitudinal two-year change through 2011. We performed multivariate linear regression analyses to identify factors associated with QOL and its changes in each cohort.

Results: The mean (standard deviation) of EQ-5D score (1.0 being the best possible score) of BRASS subjects was 0.82 (0.16) and that of KORONA subjects was 0.69 (0.25) ($P < 0.01$) at baseline in 2009 (see table). Disease activity score (DAS) 28 ($P<0.01$) and modified health assessment questionnaire (MHAQ) score ($P<0.01$) were inversely associated high QOL in both cohorts. Income level ($P<0.01$) was positively and the number of comorbidities ($P<0.01$) was negatively associated with QOL only in KORONA (see table). Mean changes in QOL were not different between cohorts ($P=0.17$). Only changes in DAS28 and MHAQ during 2 years were significantly associated with the change in QOL in both cohorts.

Table. Multivariate linear regression analyses of predictors for utility score in 2009 and change until 2011

	EQ-5D in 2009				ΔEQ-5D between 2009 and 2011

*P<0.05; BRASS, Brigham Rheumatoid Arthritis Sequential Study; KORONA, KORean Observational study Network for Arthritis; OR, odds ratio; CI, 95% confidence interval; HAQ, health assessment questionnaire

Conclusion: In this cross-national comparison study, changes in QOL and predictors for QOL were comparable between US-based BRASS and Korean-based KORONA, in spite of the differences in baseline characteristics and QOL level in each population.

Readability of Participant Information and Consent Forms for Rheumatology Clinical Trial Participants. Stephen Hall[1], Gail Grant[2] and Christina Meyer[2]. [1]Melbourne Rheumatology, Melbourne, Australia, [2]emeritus research, melbourne, Australia.

Background/Purpose: To determine the readability of written information (Participant Information and Consent Forms [PICS]) provided to clinical trial participants prior to enrolment into a clinical trial. General recommendations for reading age are that reading materials should be at educational level of year 8 or below

Methods: PICS over a time frame 2003–2013 from a dedicated clinical trials site were assessed for reading age. 81 industry derived PICs for musculoskeletal studies, 4 investigator initiated PICS and 3 non–drug study PICS were reviewed using a number of validated reading age tools -Flesch Reading Ease; Gunning FOG; Flesch-Kincaid Grade Level; The Coleman Liau Index; The SMOG Index; Automated Reading Index; Linsear Write Formula readability scores-to estimate readability of specific subsections. Specific sub-sections of the PICs from industry sponsored studies were reviewed–confidentiality/privacy section and the Risk Section.

Results: Only 4% of documents conformed to a recommended reading age of year 8 or below. The majority of documents had high reading ages with 93–96% pitched at year 10 or greater. 34–70% required reading levels of college graduate or postgraduate. A study of a small number of non-industry studies demonstrated similar results

Conclusion: Current information materials provided to potential clinical trial participants fall far short of recommended readability levels potentially compromising the process of informed consent. Further attention needs to be paid to this aspect of clinical trials

Health Literacy Predicts Discrepancies Between Traditional Written Rheumatoid Arthritis Patient Assessments and Verbally-Administered Assessments. Joel M. Hirsh[1], Lisa A. Davis[2], Itziar Quinzanos[3], Angela Keniston[1] and Liron Caplan[4]. [1]Denver Health and Hospital Authority, Denver, CO, [2]Univ. of Colorado Sch. of Medicine, Aurora, CO, [3]University of Colorado School of Medicine, Aurora, CO, [4]Denver Veterans Affairs Medical Center, Denver, CO.

Background/Purpose: Patient assessments of disease activity (PtGA) and general health (GH) measured by visual analog scale (VAS) are widely used in rheumatoid arthritis (RA) clinical practice and research. These require comprehension of the question's wording and the translation of disease activity onto a written VAS, which is problematic for patients with poor vision, limited health literacy (HL), and others unable to complete forms due to hand deformities or neurologic or muscular disorders. The objective of this study was to validate verbally-administered versions of patient assessments and identify factors that might explain discrepancies between verbal and written measures.

Methods: We enrolled RA patients at the Denver Health rheumatology clinic in our study. Subjects completed the traditional written PtGA and GH and one of the verbal assessments. Subjects provided a verbal numeric response after reading the question, having the question read to them in person, or hearing the question over the phone. Spearman correlations comparing written and verbal assessments were determined. Multivariate logistic regression was performed to explain any discrepancies.

Results: Our subjects (n=300) were predominantly female, unmarried and currently unemployed. This cohort was diverse, consisting of approximately half non-white and 58% Hispanic. Limited HL was a common finding as 28% of patients had either inadequate or marginal HL. The verbally administered instruments showed good, but not excellent, correlation with traditional written VAS forms (Spearman coefficients 0.59 to 0.74; $p<0.001$ for all correlations). Approximately one-third of patients provided verbal PtGA and GH responses that were discrepant by more than 2 standard deviations with their PtGA-VAS and GH-VAS, respectively. Twenty-three percent of subjects were unable to complete the one of the VAS assessments without assistance. HL predicted missing written data and discrepancies between verbal and written assessments ($p<0.05$ for all correlations, see Table).

Table. Final multivariate logistic regression models predicting: 1) odds of a discrepancy between verbally-administered and written patient assessments; and 2) odds of a missing patient assessment score.

Variable	Odds Ratio	Std. Err.*	p-value	95% CI	
Odds of a verbally-administered PtGA and traditional written PtGA-VAS discrepancy					
S-TOFHLA comprehension score	0.959	0.012	0.001	0.936	0.983
Odds of a verbally-administered GH and traditional written GH-VAS discrepancy					
S-TOFHLA numeracy score	0.940	0.028	0.042	0.887	0.998
Odds of a missing PtGA value					
S-TOFHLA comprehension score	0.899	0.021	0.000	0.859	0.941
Age (years)	0.952	0.018	0.011	0.917	0.989
Odds of a missing GH value					
S-TOFHLA comprehension score	0.965	0.010	0.001	0.946	0.985

* Std. Err = standard error; CI = confidence interval; PtGA = patient global assessment, as utilized in disease activity score with 28 joint count (DAS28); VAS = visual analog scale; S-TOFHLA = short test of functional health literacy in adults; GH = global health assessment, as utilized in multi-dimensional health assessment questionnaire (MDHAQ).

Conclusion: Verbally-administered PtGA and GH are appropriate for use in population based-studies and randomized control trials, where the results are important for the cohort as a whole. Providers should use verbal versions of PtGA and GH with caution while caring for individual patients unable to complete traditional written version. Limited HL is widely prevalent and a barrier to obtaining patient-oriented data.

Shared Decision-Making In The Choice Of Biologic Medication: The Patient Perspective. Susan C. Bolge[1], Helen Eldridge[2] and Michael P. Ingham[1]. [1]Janssen Scientific Affairs, LLC, Horsham, PA, [2]Janssen Services, LLC., Titusville, NJ.

Background/Purpose: There has been increasing focus on the importance of patients participating in the treatment decision-making process with their physicians. Previous research has demonstrated that effective physician-patient communication, a key component of shared decision-making, has a positive impact on patient satisfaction and adherence to therapy.[1] The purpose of the study is to understand the patient role in decisions about mode of administration when initiating biologic therapy.

Methods: In November 2011 through March 2012, semi-structured telephone interviews were conducted with 405 patients diagnosed with rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis, currently using biologic therapy administered through subcutaneous injection (SQ), and residing in the United States. In August through September 2010, a similar study was conducted among a broader group of immunology patients currently using biologic therapy administered through intravenous infusion (IV), of which 209 were diagnosed with a rheumatology condition. The purpose of both studies was to better understand the patient experience with biologic therapies.

Results: Among rheumatology patients currently using SQ biologic therapy, only 45.2% were offered an IV option prior to initiating SQ therapy. However, most SQ patients reported that they themselves made the decision to use a SQ therapy either independently (24.6%) or in partnership with their physician (56.8%). Only 15.3% of patients reported that their physician made the decision independently. Among rheumatology patients currently using IV biologic therapy, slightly more than half (54.1%) were also offered a SQ option prior to initiating IV therapy. As was the case with current SQ users, most current IV users reported that they themselves most greatly influenced the decision to use an IV therapy either independently (15.0%) or in partnership with their physician (44.2%), while 32.7% of patients reported that their physician most greatly influenced the decision.

Conclusion: While many patients report being active decision makers, most often in partnership with their physician, patient decisions are quite frequently based on only a subset of the available biologic options. For patients to be active participants in the shared-decision making process, they need to understand both SQ and IV options. Rheumatologist offices are well positioned to ensure that patients are provided the information and options needed to fully engage in the shared decision-making process.

Psychological status correlates of disease activity and sleep quality in patients with Ankylosing Spondylitis: A case-control study. Mingcan Yang[1], Yutong Jiang[1], Zhiming Lin[2], Zetao Liao[3], Qiuxia Li[4], Yanli Zhang[1] and Jieruo Gu[5]. [1]Third affiliated hospital of Sun Yat-sen University, Guangzhou, China, [2]third affiliated hospital of Sun Yat-sen Universtiy, Guangzhou, China, [3]THIRD AFFILIATED HOSPITAL OF SUN YAT-SEN UNIVERSIT, Guangzhou, China, [4]The Affiliated Third Hospital of Sun Yat-san University, Rheumatology, Guangzhou, China, [5]Third Affiliated Hospital of Sun Yat-sen University, Guang-Zhou, China.

Background/Purpose: The objective of this study was to compare psychological status and sleep quality between the patients with AS patients and healthy controls, and to discover the correlation between anxiety, depression and sleep disturbances, to evaluate the associated factors of disease specific variables in AS patients and to detect independent factors contributing to psychological variables.

Methods: A nationwide face-to-face epidemiological investigation was performed in multiple centers of China. The demographic data, clinical symptoms/signs and psychological assessment data including Zung self-rating anxiety scale (SAS), Zung self-rating depression scale (SDS) and the Pittsburgh Sleep Quality Index questionnaire (PSQI) were collected using questionnaires. Mann-Whitney U test and t test was used in independent groups for parametric variables, whereas the Spearman correlation analysis and multiple stepwise regression analysis were used to assess correlation between parametric variables.

Results: 683 AS patients by the revised New York criteria for AS and 697 age-, sex-, education- matched healthy controls were enrolled in the study. (1) Compared with healthy controls, AS patients suffered from more severe psychological disorders and sleep disturbance ($P<0.001$), and the prevalence rate of comorbidity of anxiety- depression-sleep disorders was significantly higher (32.3%vs. 2.4%, $p<0.001$) . (2) Spearman rank correlation analysis found the following variables to be significantly associated with the SAS score: disease duration, morning stiffness and duration, overall pain, back pain, BASDAI, BASFI, SDS score and all components of the PSQI score positively and years of education negatively ($P<0.05$). The SDS score were significantly associated with degree and duration of morning stiffness, overall pain, back pain, BASDAI, BASFI, SAS and all components of the PSQI score positively, and years of education negatively($P<0.05$). (3) In multiple regression analysis, SAS and SDS contributed most to each other, with standardized coefficients of 0.674 and 0.598 respectively. Meanwhile SAS ($P=0.000$) and SDS ($P=0.031$) contributed significantly to sleep disorder.

Conclusion: A large number of AS patients were reported to have anxiety, depression, sleep disturbance. Various psychological abnormalities factors influence one another, there is anxiety-depression-sleep disorders comorbidity phenomenon. Psychological abnormalities factors associated with disease activity in AS patients, there was physical-psychological comorbidity phenomenon.

1034

The Part Of Function (Health assessment Questionnaire) In The SF-6D and EQ-5D Utility Measures Varies Over Time In Early Arthritis (ESPOIR cohort): Questionable Validity Of Deriving Quality Adjusted Life Years From HAQ. Cécile Gaujoux-Viala[1], Anne-Christine Rat[2], Kossar Hosseini[3], Rene-Marc Flipo[4], Francis Guillemin[3] and Bruno Fautrel[5]. [1]EA 2415, Montpellier I University, Nîmes University Hospital, Rheumatology Department, Nîmes, France, [2]Université de Lorraine, Nancy, F-54000, France; Inserm, CIC-EC CIE6, Nancy, F-54000, France; CHU de Nancy, Clinical Epidemiology and Evaluation Department, Nancy, F-54000, France; CHU de Nancy, Rheumatology department, Nancy, France, [3]CHU Nancy, Clinical Epidemiology and Evaluation, Université de Lorraine, Paris Descartes University, APEMAC, EA 4360, Nancy, France, [4]Hopital R Salengro CHRU Lille, Lille, France, [5]Paris 6–Pierre et Marie Curie University; AP-HP, Rheumatology, Pitié-Salpêtrière Hospital,-GRC-UPMC 08–EEMOIS, Paris, France.

Background/Purpose: There is growing emphasis on the cost-effectiveness of treating early arthritis (EA). As few studies directly record the utility measures needed for economic analyses, mapping is often used. Health Assessment Questionnaire (HAQ) is 'converted' into utility using regression. The use of such transformed data by regulatory bodies which determine drug availability raises concern as it involves mathematical transformation between measures which may not be clinically equivalent and with potentially variable interrelationships over time.

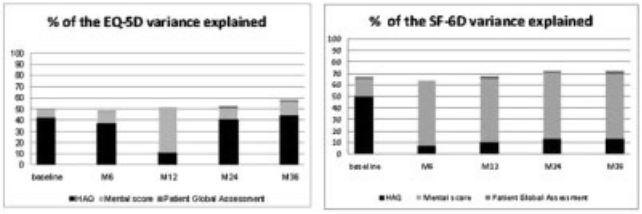
We aimed 1) To assess characteristics associated with SF-6D and EQ-5D utility measures in EA 2) To check whether these associations are stable over 3 years.

Methods: - *Patients:* included in the French nationwide cohort of EA ESPOIR (at least 2 swollen joints for less than 6 months and suspicion of RA).

- *Data available:* SF-6D and EQ-5D utility measures were longitudinally assessed in 813 patients with EA (at baseline, 6 months, 1, 2 and 3 years). Bio-clinical variables and X-rays were also recorded.

- *Analysis:* The determinants of SF-6D and EQ-5D utility measures at each time-point were assessed by multivariate linear regressions in 618 EA patients followed over 3 years. Partial R-squares were used to assess the relative importance of variables to the variation in EQ-5D and SF-6D scores.

Results: At baseline, SF-6D was essentially determined by function, HAQ explaining 50.2% of the variance, whereas after 6 months, SF-6D was essentially determined by mental status (the Arthritis Impact Measurement Scale 2–Short Form) (55.8 to 57.6% of the variance) and the HAQ represented only 7.3 to 13.2%. At each time-point, EQ-5D was essentially determined by function, HAQ explaining 36.9 to 44.2% of the variance, except at 1 year, it was essentially determined by mental status, explaining 40.8% of the variance and the HAQ only 11% (figure).



Conclusion: The major impact of functional ability and mental status, and the variability of the utility determinants over time in addition of the bimodal distribution of the EQ-5D raise concerns about mapping to estimate utilities from clinical instruments. Evaluation of treatment cost-utility should not be based on utility data transformed from HAQ.

Psoriatic Arthritis and Mortality-a Nationwide Study. Thorvardur Jon Love[1], Thor Aspelund[2], Alexis Ogdie[3], Joel M. Gelfand[4], Hyon K. Choi[5], Vilmundur Gudnason[2] and Bjorn Gudbjornsson[6]. [1]Landspitali University Hospital, Reykjavik, Iceland, [2]The Icelandic Heart Association, Kopavogur, Iceland, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Pennsylvania., Philadelphia, PA, [5]Boston University School of Medicine, Boston, MA, [6]Faculty of Medicine, University of Iceland, Reykjavik, Iceland.

Background/Purpose: Psoriatic arthritis is an inflammatory arthritis that causes significant morbidity. While a study from a single research clinic in Canada published in the 1990′s suggested an increased mortality rate compared to that seen in the general population, two recent studies from the UK reported no increased mortality, one based on a single center similar to the Canadian study, and the other based on a sample from the general population. We have performed a study of the mortality rate among all known cases of psoriatic arthritis diagnosed since 1971 in Iceland compared to the general population of the same country.

Methods: We used a list of all known patients in Iceland with a diagnosis of psoriatic arthritis assembled in 2002–2003 for a cross-sectional study of psoriatic arthritis in Iceland. The list includes both those patients who were still alive in 2002, as well as those who had died before the study began. This list has been validated by examining close to 200 patients, showing that about 85% had active disease in 2003 and more than 80% fulfilled the CASPAR criteria applied post-hoc. Using national identification numbers and the Icelandic national mortality database we were able to determine the year of death for all individuals who died before end of year 2012, making death ascertainment complete. Using data on age- and sex stratified 1-year survival for the Icelandic population available for each year starting in 1971 we were able to compare the survival of patients with psoriatic arthritis to the expected survival of the age- and sex-matched population starting the year that each psoriatic arthritis diagnosis was made.

Results: The list of psoriatic arthritis patients contained 346 individuals and data on the date of diagnosis of psoriatic arthritis was available for 340. Of these, 293 were diagnosed in 1971 or later and could be used for comparison to the population statistics, with 6747 patient years of follow-up. The mean age at the time of diagnosis was 42.3 years (95%CI 40.1–44.4), with 57 diagnosed in the 1970′s, 98 diagnosed in the 1980‘s, 137 diagnosed in the 1990′s and 1 diagnosed in 2001. This is equivalent to an incidence rate of 3.8 (2.9–5.0), 5.7 (4.6–7.0), and 7.2 (6.1–8.6) incident cases per year per 100.000 individuals age 18 or older for each of the three whole decades included in the study.

Out of 107 men with psoriatic arthritis, 28 had died by the end of 2012, and the same was true for 42 of 186 women with psoriatic arthritis. The age- and sex-specific expected number of deaths updated annually based on year of diagnosis was 27 men and 39 women. The age- and sex-standardized mortality ratio of psoriatic arthritis patients compared to the general population was 1.06 (95% CI 0.84–1.13), p=0.64.

Conclusion: There was no increased death rate among psoriatic arthritis patients compared to the general population.

The Independent Impact Of Depression On Incident Myocardial Infarction In Psoriatic Disease: A Population-Based Cohort Study. Lindsay C Burns[1], Jan P. Dutz[1] and Hyon K. Choi[2]. [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada, Richmond, BC.

Background/Purpose: Psoriasis (PsC) and psoriatic arthritis (PsA) represent common, lifelong inflammatory diseases of the skin and joints (respectively) that are associated with substantial cardiovascular and psychiatric morbidity. Considering that depression is associated with deleterious cardiovascular outcomes, we investigated the potential long-term impact of depression on myocardial infarction (MI) risk in this patient population.

Methods: Our analysis employed linked administrative health data, including physician visits, hospital admissions, and death records from Apr 1991 to Mar 2006, and all dispensed medications from Apr 1996 to Mar 2006, for the entire adult (≥18 years) population of British Columbia, Canada (4.1 million individuals). Inclusion in our incident PsC/PsA exposure cohort required one of the following: 1) ≥2 ICD-9 physician diagnostic codes specific for PsC/PsA within a 2 year period between Apr 1996 and Mar 2006; 2) ≥1 specific ICD-9 diagnostic code from a dermatologist (for PsC), a rheumatologist (for PsA), or from hospital. Five unexposed, general population controls were matched to each PsC/PsA case by age, sex, and follow-up time (index date). Individuals with diagnoses of PsC, PsA, or MI prior to the baseline were excluded. Depression was defined by physician or hospital diagnosis, and MI was defined by hospitalization or death certificate. We used Cox proportional hazards models to estimate the independent impact and potential effect modification of depression in psoriatic disease compared to matched controls, adjusting for age, sex, comorbidities, health resource utilization, and socioeconomic status.

Results: Among 10,041 cases of incident PsC/PsA (51% male, mean age of 49 years), 268 incident MI events occurred (incidence = 5.8 per 1,000 person-years [PY]). The incidence of depression in PsC/PsA was 3.4 per 1,000 PY and the corresponding 10-year prevalence estimate was 21.6%. Individuals with PsC/PsA were more likely to be depressed (adjusted OR, 1.26) than controls. Incident depression increased the risk of incident MI by 80% in PsC and PsA (adjusted RR, 1.8; 95% CI, 1.3–2.5). Further, depression was found to modify the risk of MI in psoriatic conditions such that an increased risk was only observed among psoriatic individuals with depression (RRs = 1.6, $P<0.01$ vs. 1.1, *ns*).

Conclusion: These population-based data suggest that depression is a prevalent and independent risk factor for MI among patients with PsC and PsA. Moreover, our findings suggest that depression acted as a major effect modifier in the context of PsC and PsA, such that PsC and PsA only led to an increased risk of MI among individuals with depression. These data underscore the need to actively screen for depression among PsC and PsA patients and closely monitor cardiovascular health in this high-risk group to improve long-term survival.

Main Effects of PsC/PsA and Incident Depression on Risk of MI

Parameter	RR (95% CI)*
PsC/PsA cohort (ref, matched controls)	1.14 (0.97–1.34)
Incident depression	1.80 (1.29–2.51)

Effect of PsC/PsA on Risk of MI According to Prevalent Depression Strata

Parameter	RR (95% CI)*
PsC/PsA cohort (ref, matched controls)	
With depression	1.58 (1.24–2.03)
Without depression	1.14 (0.97–1.35)

*All RRs adjusted for age, sex, Charlson Comorbidity Index, socioeconomic status, history of hospitalizations, chronic obstructive pulmonary disease, obesity, alcoholism, liver disease, cerebrovascular accidents, hypertension, sepsis, varicose veins, peripheral vascular disease, congestive heart failure, chronic renal disease, inflammatory bowel disease, malignant neoplasms, trauma, and fractures, assessed in the year prior to the index date

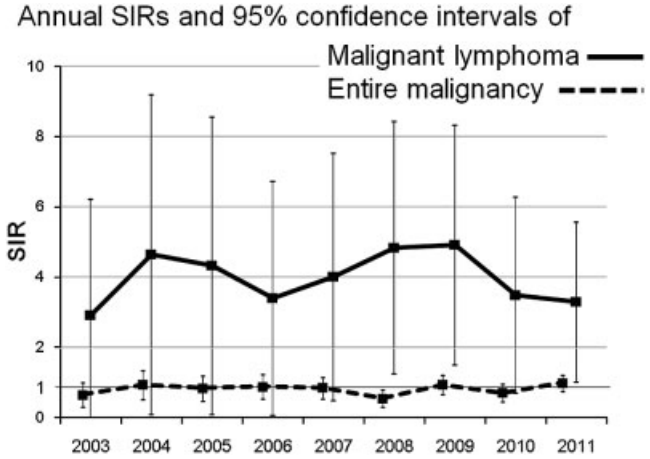
Incidence Of Malignancy In Patients With Rheumatoid Arthritis From a Japanese Large Observational Cohort (NinJa). Atsushi Hashimoto[1], Noriyuki Chiba[2], Jinju Nishino[3], Toshihiro Matsui[4] and Shigeto Tohma[1]. [1]Sagamihara Hospital, National Hospital Organization, Sagamihara, Japan, [2]Morioka National Hospital, NHO, Iwate, Japan, [3]Nishino Clinic, Orthopedics and Rheumatology, Tokyo, Japan, [4]National Hospital Organization Sagamihara Hospital, Kanagawa, Japan.

Background/Purpose: Patients with rheumatoid arthritis (RA) die mainly of cardiovascular/cerebrovascular diseases, respiratory diseases, infections, or malignancies. In recent years, the ratio of infections and respiratory diseases associated with RA as causes of deaths has been decreasing, whereas that of malignancies increasing. A possible reason is recent changes in RA therapy, namely, elevated dose of methotrexate (MTX) or popularized biologics. Incidence of malignancies varies depending on studies because it is strongly affected by regional or racial differences among cohorts. This study is to disclose incidence and risk of malignancy in Japanese patients with RA.

Methods: Data from RA patientsregistered in a nationwide Japanese cohort database (**NinJa:** National Database of Rheumatic Diseases by iR-net in Japan) from 2003 to 2011 were used. To adjust difference of population composition and compare the incidence of malignancy between RA patients and general population, standardized incidence rates (SIRs) were calculated. An SIR is a ratio between actually obtained number of malignancies from the cohort and expected number estimated using incidence of age- and sex-matched Japanese population.

Results: In 9 years the cohort comprised of 55003 patient-years (80% females and 18% males) yielded 444 malignancies, which contained 300 (69%) females and 137 (31%) males, including 6 patients with multiple malignancies. Most frequent malignancy was lung cancer (n=71) followed by gastric (n=59) and breast cancer (n=53). SIR for entire malignancies was 0.96 (95% confidence interval 0.87–1.05), which was consistent with that in the general population. SIRs for malignant lymphoma (ML) in both sexes (SIR 4.01) and bladder cancer in females (SIR 2.80) were significantly higher, whereas several malignancies including rectal cancer in both sexes (SIR 0.49), colon cancer in females (SIR 0.89), or liver cancer in both sexes (SIR 0.28) had significantly lower SIRs. Number of patients on MTX therapy and their dose of MTX have been increasing, while annual SIRs for entire malignancies and ML remained steady (figure).



Conclusion: RA patients had no higher incidence for entire malignancies but should be cared for several malignancies including ML.

Impact Of Biological Treatment On Overall Mortality and On Incidence Of Second Cancers In Arthritis Patients-A Follow-Up Study From The Danish Danbio Registry. Lene Dreyer[1], Lene Mellemkjær[2], Inger Marie Jensen Hansen[3] and Merete Lund Hetland[4]. [1]Copenhagen University Hospital at Gentofte, Copenhagen, Denmark, [2]Danish Cancer Society Research Center, Copenhagen, Denmark, [3]OUH Svendborg Hospital, Svendborg, Denmark, [4]The Danish Rheumatologic Database (DANBIO), Glostrup Hospital., Copenhagen, Denmark.

Background/Purpose: It is largely unknown whether it is safe to treat arthritis patients with a previous malignancy with biologics. Only a few studies have address the question of whether therapy with biologics influences the malignancy rate and mortality in patients with prior cancer and the results are conflicting. We aimed to study 1) the overall mortality and 2) the incidence of second cancers in arthritis patients treated with or without biologics after a primary cancer diagnosis.

Methods: A total of 23,233 arthritis patients (RA:15,286, PSA:3196, MB: 2189, other:2562) registered in the nationwide DANBIO database between January 2000 and Dec 2011 were included and linked to the Central Population Register (information on dates of death or emigration) and the Danish Cancer Registry (identification of all cancer cases). Follow-up for death and second cancer started at the date for diagnosis of the primary cancer or at entry in DANBIO whatever came latest. Information on recurrence of cancers was not available. Hazard Ratio (HR) for death and second cancer among arthritis patients ever receiving biologics compared with patients never receiving biologics were calculated using Cox proportional hazard models, adjusted for age, sex and calendar time.

Results: A total of 2972 patients with a primary cancer were identified. Of these, 262 had been treated with biologics *before* the primary cancer diagnosis, 501 *after* and 244 *both* before and after, while 1965 cancer cases *never* had received biologics. The first biological treatment given *after* the primary cancer diagnosis among 745 patients were: adalimumab(25%), etanercept(23%), infliximab(29%), rituximab(16%) and other(7%). Among the 2972 cancer patients, HR for death in patients *ever* treated with biologics compared to *never* treated was slightly increased: 1.26(95%CI: 1.04–1.53). The same was observed among the non-cancer patients HR 1.38(95%CI 1.16–1.64) (data not shown). An increased risk for overall mortality including (HR 1.49) and excluding (HR 1.50) non-melanona skin cancer were observed in patients treated with biologics only before first cancer diagnosis. An increased risk of developing a second cancer was observed in arthritis patients treated with biologics *both* before and after primary cancer diagnosis, when non-melanoma skin cancers were excluded from the calculations (HR= 5.29), table.

Risk of death and second cancer in arthritis patients treated with biologics (bio) after a primary cancer.

Type of first cancer	Outcome	Bio treatment	Events	Person-years	HR (95% CI)
All types	Death				
		Never bio	300	4155	1 (ref)
		Bio only *after* first cancer	59	1765	0.96 (0.70–1.32)
		Bio only *before* first cancer	111	457	1.49 (1.16–1.91)
		Bio *both* before and after first cancer	32	614	0.83 (0.56–1.21)
All types excluding non-melanoma skin cancer[1]	Death				
		Never bio	257	2924	1 (ref)
		Bio only *after* first cancer	41	1024	1.07 (0.73–1.56)
		Bio only *before* first cancer	118	365	1.50 (1.18–1.93)
		Bio *both* before and after first cancer	27	236	0.95 (0.63–1.44)
All types	All types of second cancer				
		Never bio	51	3793	1 (ref)
		Bio only *after* first cancer	22	1610	1.30 (0.76–2.25)
		Bio only *before* first cancer	9	454	1.19 (0.55–2.60)
		Bio *both* before and after first cancer	12	598	1.52 (0.79–2.94)
All types excluding non-melanoma skin cancer[1]	All types excluding non-melanoma skin cancer				
		Never bio	47	2584	1 (ref)
		Bio only *after* first cancer	13	885	1.66 (0.82–3.36)
		Bio only *before* first cancer	8	338	0.47 (0.21–1.04)
		Bio *both* before and after first cancer	19	240	5.29 (2.98–9.40)

[1] Arthritis patients with non-melanoma skin cancer before entry in DANBIO but diagnosed with another cancer type after entry were included in the analysis.

Conclusion: Arthritis patients treated with biologics had a slightly increased mortality (≈30%) compared to patients never treated with biologics, and this increase was independent of whether they got cancer or not. Treatment with biologics *after* a primary cancer was associated with an increased risk for a second cancer.

Risk Of High-Grade Cervical Dysplasia In Women With Systemic Inflammatory Diseases. Seoyoung C. Kim[1], Robert J. Glynn[1], Edward Giovannucci[2], Sonia Hernandez-diaz[3], Jun Liu[1], Sarah Feldman[1], Elizabeth W. Karlson[4], Sebastian Schneeweiss[1] and Daniel H. Solomon[5]. [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard School of Publich Health, Boston, MA, [3]Harvard School of Public Health, Boston, MA, [4]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [5]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA.

Background/Purpose: Human papillomaviruses (HPV) are causes of high-grade cervical dysplasia and cervical cancer. Persistent HPV infection, the major risk factor for cervical cancer, is associated with several factors including HPV genotypes, age, coexisting infection, and immune function. Several prior studies suggested that the risks of any cervical dysplasia and HPV infection were increased in immunocompromised patients including those with HIV, organ transplantation, and systemic inflammatory diseases (SID). The objective of this study was to assess the risk of high-grade cervical dysplasia, a surrogate endpoint for cervical cancer, in women with SID including inflammatory bowel diseases (IBD), rheumatoid arthritis (RA), psoriasis, and systemic lupus erythematosus (SLE).

Methods: Using U.S. commercial insurance claims data (2001–2012), we conducted a population-based cohort study to examine the incidence rates (IR) of high-grade cervical dysplasia in women with SID including inflammatory bowel disease (IBD), rheumatoid arthritis (RA), psoriasis, and systemic lupus erythematosus (SLE). To have comparable health care utilization with the SID cohort, we selected women with hypertension as the non-SID cohort, matched on age and index date with a 4:1 ratio. The index date was defined as the dispensing date of the first immunomodulating drug after ≥ 2 diagnoses of one of the SID and the first anti-hypertensive drug after ≥2 diagnoses of hypertension for non-SID women. High-grade cervical dysplasia was defined by a validated claims-based algorithm with a positive predictive value of ’81%. Crude and multivariable Cox models estimated the hazard ratios (HR) of high-grade cervical dysplasia in SID versus non-SID women. Separate Cox models were used to calculate HRs for IBD, RA, psoriasis, and SLE subcohorts compared to the non-SID. Our full model was adjusted for age, smoking, prior abnormal cervical dysplasia or sexually transmitted diseases, comorbidities, medications, and health care utilization.

Results: Over the mean follow-up of 2.1 years, the IR of high-grade cervical dysplasia per 100,000 person-years was 94.2 among women with SID (n=133,333) and 73.4 in non-SID women (n=533,332). The fully adjusted HRs were 1.12 (95% CI 0.92–1.35) for all SID combined compared to non-SID. For the SID subcohorts, the fully adjusted HR was significantly increased in women with RA (1.46, 95% CI 1.07–2.01) and SLE (1.49, 95% CI 1.01–2.19), but not among those with IBD (1.06, 95% CI 0.78–1.44) or psoriasis (0.96, 95% CI 0.73–1.26). (**Table**) In women with baseline immunosuppressive use and with prior abnormal Papanicolaou smears, our results were unchanged.

Table. Hazard ratios (95% confidence intervals) for high-grade cervical dysplasia

Adjustment	SID* (n=133,333)	IBD (n=25,176)	Psoriasis (n=34,665)	RA (n=58,979)	SLE (n=14,513)	Non-SID* (n=533,332)
N, outcome	259	59	58	102	40	818
Unadjusted	**1.28 (1.11–1.47)**	**1.50 (1.16–1.96)**	1.11 (0.85–1.45)	1.13 (0.92–1.38)	**1.90 (1.38–2.6)**	Referent
Partial[a]	**1.24 (1.07–1.44)**	1.18 (0.90–1.55)	0.98 (0.77–1.31)	**1.38 (1.12–1.71)**	**1.61 (1.17–2.23)**	Referent
Full[b]	1.12 (0.92–1.35)	1.06 (0.78–1.44)	0.96 (0.73–1.26)	**1.46 (1.07–2.01)**	**1.49 (1.01–2.19)**	Referent

* age and index date-matched, [a] adjusted for age, comorbidity score, and no. of prescription drugs. [b] further adjusted for HPV risk factors, comorbidities, medications, health care utilization and preventive health care use.
The likelihood ratio test of the global null hypothesis showed no significant heterogeneity between the SID subcohorts (p=0.1).

Conclusion: Our study showed that RA and SLE were associated with a 1.5-times increased risk of high-grade cervical dysplasia after adjusting for potential confounders, although the absolute risk was generally low.

Use Of TNF Inhibitors Is Associated With a Reduced Risk Of Diabetes In RA Patients. Siri Lillegraven[1], Jeffrey D. Greenberg[2], George W. Reed[3], Katherine C. Saunders[4], Jeffrey R. Curtis[5], Leslie R. Harrold[6], Marc C. Hochberg[7], Dimitrios A. Pappas[8], Joel M. Kremer[9] and Daniel H. Solomon[10]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]NYU Hospital for Joint Diseases, New York, NY, [3]CORRONA, Inc., Worcester, MA, [4]CORRONA, Inc., Southborough, MA, [5]University of Alabama at Birmingham, Birmingham, AL, [6]University of Massachusetts Medical School, Worcester, MA, [7]University of Maryland, Baltimore, MD, [8]Columbia University, College of Physicians and Surgeons, New York, NY, [9]Center for Rheumatology, Albany Medical College, Albany, NY, [10]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA.

Background/Purpose: Inflammation may contribute to diabetes risk, and some studies indicate that certain DMARDs might be associated with a reduced risk of diabetes. Most studies in RA have not included confirmed diabetes cases, information about disease activity, BMI and DMARD utilization. The objective of the present study was to assess the association between DMARD exposure and incident diabetes in a large multi-center observational cohort of RA patients.

Methods: The study population consisted of RA patients followed in CORRONA, a longitudinal multi-center cohort. Five mutually exclusive DMARD treatment categories were defined: 1) TNFi, incl. combinations with nonbiologic (nb) DMARDs 2) Other biologic (b) DMARDs, incl. combinations with nbDMARDs 3) Methotrexate, MTX without concomitant bDMARDS or hydroxychloroquine (HCQ) 4) HCQ without concomitant bDMARDs or MTX, and 5) Other nbDMARDs (e.g. LEF, CsA, SSZ), without concomitant TNFi, MTX or HCQ. Patients who did not attend at least one follow-up visit, who had a diagnosis of diabetes at index date of the DMARD regimen, did not receive the DMARD treatments of interest or who had other arthritic diagnoses were excluded. Incident cases of diabetes were confirmed through case ascertainment based on medical records and patient interviews. Incidence rates (IR) and incidence rate ratios (IRR) were calculated. Cox regression models were fitted to estimate the risk of incident diabetes, adjusting for propensity score (including variables such as age, BMI, steroid use and CDAI). The comparison group for all analyses was “Other nbDMARDs”.

Results: We identified 21775 eligible treatment regimens-9880 TNFi regimens, 1756 other bDMARD, 7441 MTX, 1496 HCQ and 1202 other nbDMARD regimens. The mean (SD) age at start of treatment was 58(13) years, mean disease duration 10(10) years and mean CDAI 13.4(12.4). 76% were women and 30% used oral steroids. The mean duration of the treatment regimens ranged from 1.5–2.4 years, and 82 incident cases of diabetes of interest were confirmed. The IRs, IRRs and results from Cox regression models are presented in the table. Diabetes development was significantly reduced in patients receiving TNFi compared to patients receiving other nbDMARDs (e.g. LEF, CsA, SSZ). Use of HCQ, MTX, and other bDMARDs also trended toward a reduced risk, but confidence intervals did not exclude the null. Similar results were found in models adjusted directly for BMI, and in models adjusting for propensity score quintiles. Higher steroid dosages were associated with an increased risk of diabetes in separate models.

	DM IR, cases per 1000 person-years (95% CI)	Crude IRR	HR (95% CI) Propensity score adjusted model	P-value for Cox regression model
TNFI	1.46 (1.03, 2.00)	0.47 (0.21, 1.07)	0.35 (0.13, 0.91)	0.03
Other bDMARDs	1.53 (0.51, 3.63)	0.50 (0.15, 1.70)	0.44 (0.08, 2.57)	0.36
MTX	2.08 (1.45, 2.29)	0.68 (0.30, 1.54)	0.67 (0.44, 1.02)	0.34
HCQ	1.29 (0.43, 3.07)	0.42 (0.12, 1.44)	0.45 (0.13, 1.53)	0.21
Other nbDMARDs	3.07 (1.37, 6.03)		Ref	

Conclusion: After controlling for variables such as BMI, disease activity and steroid use, RA patients treated with TNF inhibitors had a reduced risk for development of diabetes.

Non-Differential Reporting Of Myocardial Infarction To a National Observational Drug Safety Study Using Linked Data: Linkage Of The British Society For Rheumatology Biologics Register For Rheumatoid Arthritis and The Myocardial Ischaemia National Audit Project. Audrey SL Low[1], Deborah P. Symmons[2], Mark Lunt[3], Louise K. Mercer[1], Christopher Gale[4], Kath Watson[1], British Society for Rheumatology Biologics Registers (BSRBR) Control Centre Consortium[1], William G. Dixon[5], Kimme L. Hyrich[6] and On behalf of the BSRBR[7]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Science Centre, Manchester, United Kingdom, [3]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [4]Department of Cardiology, York Teaching Hospital NHS Foundation Trust, York, United Kingdom, [5]The University of Manchester, Manchester, United Kingdom, [6]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Sciences Centre, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [7]British Society for Rheumatology, London, United Kingdom.

Background/Purpose: The BSRBR-RA was established to compare the long term safety of anti tumour necrosis factor (TNFi) drugs with non-biologic drugs (nbDMARD) in subjects with rheumatoid arthritis (RA). Serious adverse events (SAEs) are identified by physician and patient reporting as well as linkage to the national death register. We used myocardial infarction (MI) as an example to explore whether there is differential under-reporting of SAEs to BSRBR between treatment groups by linking BSRBR-RA to the Myocardial Ischaemia National Audit Project (MINAP). MINAP aims to collect data on all hospitalisations with MI in England and Wales.

Methods: This analysis was limited to subjects living in England and Wales. BSRBR and MINAP were linked using deterministic matching with combinations of these parameters: first and last names, birthdate, postcode, unique National Health Service number and sex. Events from both datasets were matched by subject using a 30-day window. Matched and unmatched events were verified using the American Heart Association/European Society of Cardiology criteria for MI. Deaths from MI (reported as the underlying cause of death using ICD-10 via death register linkage) were also included as verified MIs. Age, sex, treatment group, MI phenotype, whether the subjects received cardiology care at the same hospital as their rheumatology care and location of deaths due to MIs were explored as possible reasons for non-overlap between datasets using descriptive statistics. The risk of MI was compared between subjects receiving nbDMARDs and ever-exposed to TNFi using a Cox regression model, adjusted for deciles of propensity scores (PD) (Table) using i) MIs verified from BSRBR only and ii) all MIs verified from either BSRBR or MINAP. Subjects were censored at first MI, death, last physician follow-up or 04/20/2010, whichever came first.

Results: In total, 310 verified MIs were recorded during the observation period, of which 75% were captured in BSRBR-RA, 64% captured in MINAP and 39% were captured in both datasets (Table). A fifth of the BSRBR-RA-only MIs was deaths due to MI occurring outside hospital and therefore could not have been captured by MINAP. There were no differences in the age, sex, treatment group, site of MI care or MI phenotype between matched and unmatched MIs. When additional MIs from MINAP were included in the analysis, the adjusted risk estimate for MI in subjects receiving TNFi compared to nbDMARD did not differ to estimates obtained using MIs from BSRBR-RA only: BSRBR-only MIs; hazard ratio (HR) 0.56 (95%CI 0.35, 0.91); including MINAP MIs: HR 0.59 (95%CI 0.40, 0.88).

Table.

	BSRBR-RA-only MIs	Matched BSRBR-RA-MINAP MIs	MINAP-only MIs	p-value*
Number of verified MIs	112	120	78	-
Median age at MI, years (IQR)	67 (59,73)	65 (58,72)	68 (62, 74)	0.09
Female gender, n (%)	70 (63)	74 (62)	44 (56)	0.67
Proportion of subjects receiving TNFi at time of MI, n (%)	64 (57)	67 (56)	41 (53)	0.09
Proportion of subjects with ST elevation MI, n (%)	Data not collected by BSRBR-RA	63 (53)	33 (42)	0.63
Proportion of subjects treated for MI at a different hospital for MI care to rheumatology care, n (%)	Data not collected by BSRBR-RA	71 (59)	40 (51)	0.28
Number of deaths from MI verified by death certificate using ICD-10	44	5	0	-
Deaths from MI occurring outside hospital, n (%)	21 (48)	0	0	0.04

*Chi-squared test for categorical variables, Kruskal-Wallis test for continuous variables. Variables in PD: age, gender, disease duration, DAS28, HAQ score, steroid use, number of previous nbDMARDs, entry year to study, hypertension, diabetes, smoking, chronic lung disease, aspirin, statin, NSAID/COX2-inhibitor use, all at baseline.

Conclusion: A degree of under-reporting of MIs exists in BSRBR but is non-differential between nbDMARD and TNFi subjects. The additional 78 (25%) MIs from MINAP did not alter the risk estimate but increased its precision. Our findings suggest linkage with other datasets is an important method of increasing event capture and enriching data for analysis.

Comparison Of Medication Usage Following Myocardial Infarction In Patients With Autoimmune Rheumatic Disease Versus Controls. Sharon Van Doornum[1], Mark Tacey[1], Megan Bohensky[1], Caroline Brand[2], Vijaya Sundararajan[3] and Ian Wicks[4]. [1]The University of Melbourne, Melbourne, Australia, [2]The Royal Melbourne Hospital, Melbourne, Australia, [3]University of Melbourne, Melbourne, Australia, [4]Royal Melbourne Hospital, Melbourne, Australia.

Background/Purpose: We have previously demonstrated that RA patients have higher post-myocardial infarction (MI) case fatality than controls [1] and that treatment with secondary prevention medications is lower in RA patients than matched controls [2]. More recently we have demonstrated that post-MI case fatality is also higher in the larger group of patients with autoimmune rheumatic disease (AIRD) such as lupus, spondyloarthritis, scleroderma and systemic necrotising vasculitis [manuscript in preparation]. The aim of this study was to compare the utilization of lipid-lowering agents (statins), beta-blockers (BB) and angiotensin converting enzyme inhibitors (ACE-I) following MI in patients with AIRD compared to patients without AIRD.

Methods: A retrospective cohort study utilising a population-based dataset containing statewide hospital admission data linked with medication utilisation data. Data were available from 1 July 2001 to 30 July 2009. Cases of MI were identified from hospital admission data based on relevant International Classification of Diseases (ICD) codes. AIRD status was identified from the index MI admission or any admission in the preceding 5 years using relevant ICD codes. Relevant co-morbidities including cardiovascular risk factors were identified using ICD codes from the index MI admission. Adjusted odds ratios (OR) for post-MI treatment with each of the specified medications in AIRD patients compared to non-AIRD patients were estimated using a logistic regression model with adjustment for age, gender, socio-economic status, geographic location and relevant co-morbidities.

Results: There were 21,126 individuals with an index MI, of whom 518 (2.5%) were identified as AIRD patients. The rate of statin use within 12 months post MI for patients with AIRD was 52.7% compared to 69.8% for patients without AIRD ($p<0.001$). A decreased rate of BB and ACE-I use was also identified for AIRD patients compared to non-AIRD patients (BB: 49.4% vs 55.6 %, $p<0.005$ and ACE-I: 50.2% vs 58.3%, $p<0.001$). The adjusted OR for statin use within 12 months post MI for AIRD patients was 0.57 (95% CI: 0.45–0.73). The adjusted ORs for usage of BB and ACE-I in AIRD patients within 12 months of the MI were reduced but not statistically significant after adjustment for covariates (BB: OR = 0.86, 95% CI: 0.69–1.08 and ACE-I: OR = 0.84, 0.68–1.03).

Conclusion: Treatment with statins in the 12 months following MI is significantly lower for patients with AIRD, even after adjustment for potential confounders. Lower rates of usage of BB and ACE-I were also found, although these differences were not statistically significant after adjustment for relevant co-variates.

Musculoskeletal Hospital Admissions Among Patients Treated For Rheumatoid Arthritis Between 1999 and 2010 Compared With The General Population In The Netherlands. I D Bezemer[1], L M A Houweling[1], E Alemao[2], F J A Penning-van Beest[1] and M Hochberg[3]. [1]PHARMO Institute for Drug Outcomes Research, Utrecht, Netherlands, [2]Bristol-Myers Squibb, Princeton, NJ, [3]University of Maryland, Baltimore, MD.

Background/Purpose: Advances in treatment for RA may have resulted in a decrease in musculoskeletal hospital admissions. This study aimed to assess the trends in hospital admissions among patients receiving treatment for RA in the past decade compared with the general population.

Methods: Patients with RA in the PHARMO Database Network treated with any disease-modifying antirheumatic drug (DMARD) between 1999 and 2010 were identified. Population controls were randomly matched 2:1 to patients with RA by age and sex. Patients and controls were followed from the first DMARD dispensed and the matched index date, respectively, until death, end of study period or end of database registration, whichever occurred first. Musculoskeletal hospital admissions and procedures were assessed during follow-up. Incidence rates (IRs) of the first musculoskeletal hospitalization after the index date were calculated and compared using Cox proportional hazards regression.

Results: Between 1999 and 2010, 24,762 patients with RA treated with DMARDs were identified. The IR of musculoskeletal admissions per 100 person years (pt-yrs) decreased from 10.4 (95% CI] 9.4, 11.5) in 1999 to 3.2 (95% CI 2.9, 3.5) in 2010, while the reference population IR was stable at 1.3 per 100 pt-yrs. The largest improvement among patients with RA occurred around 2003; the period in which biologic DMARDs (bDMARDs) were introduced. Therefore, a second comparison was made between 2078 patients with RA (8%) treated with bDMARDs (index date=first bDMARD dispensed) and 4156 patients with RA (17%) treated only with conventional DMARDs, matched by age, sex and timing of first DMARD dispensed (any) in the database. Between 2003 and 2010, the IR of musculoskeletal hospital admissions per 100 pt-yrs decreased from 27.1 (95% CI 20.4, 35.2) to 7.8 (95% CI 6.0, 9.9) among bDMARD users and from 9.9 (95% CI 7.4, 12.9) to 3.2 (95% CI 2.6, 4.1) among the matched conventional DMARD users. Also, the IR of musculoskeletal procedures per 100 pt-yrs decreased from 4.3 (95% CI 2.7, 6.3) to 1.8 (95% CI 1.3, 2.4) among bDMARD users and from 1.6 (95% CI 0.7, 2.9) to 0.7 (95% CI 0.4, 1.1) among the matched conventional DMARD users. Compared with the general population, bDMARD users in 2010 remained six times more likely to be hospitalized for a musculoskeletal event (hazard ratio 6.5 [95% CI 4.2, 10.0]).

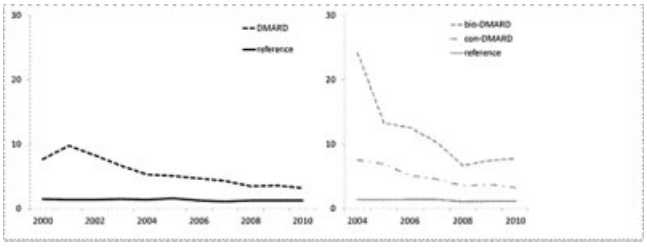

Figure. IRs per 100 pt-yrs of musculoskeletal hospital admissions among DMARD users and matched references.

Conclusion: The IR of musculoskeletal hospital admissions among patients in the Netherlands treated for RA decreased from 1999 to 2010. The largest reduction occurred during the period when bDMARDs were introduced. However, the rates have stabilized in recent years and hospital admission rates in 2010 remained twice as high for patients with RA as the general population, and six times higher in patients receiving bDMARDs.

Temporal Associations Of Prevalent Depression With The Different Domains Of Rheumatoid Arthritis Disease Activity. Alan Rathbun, Leslie R. Harrold and George Reed. University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Depression (DEP) is a common psychiatric comorbidity of rheumatoid arthritis (RA), yet little is known of its temporal effect on disease activity and symptoms. The study aim was to evaluate how the lifetime prevalence of DEP influenced longitudinal changes in the different domains of RA disease activity.

Methods: RA patients with self-reported DEP data and ≥ 1 follow-up visit were identified from a national observational cohort of > 34,000 individuals (The Consortium of Rheumatology Researchers of North America; CORRONA). Linear mixed models estimated the association between the lifetime prevalence of DEP and changes in disease activity over 2-years. Outcomes were the clinical disease activity index (CDAI), tender and swollen joint counts (TJC and SJC), patient and physician global assessment (PGA and EGA), patient-reported pain, health assessment question (HAQ), C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR). To account for potential confounders, patients with and without prior DEP were matched (1:1) using a propensity score. Propensity score models incorporated covariates selected a priori and were the following: baseline disease severity, gender, race, ethnicity, age, health insurance, marital status, employment, alcohol use, smoking, exercise, BMI, and composite comorbidity. The matching was performed separately for each outcome measure. Model based estimates of disease activity were generated and trends over time between the two groups tested.

Results: The rates of change by DEP status were significantly different for the CDAI, TJC, PGA, EGA, pain, and HAQ. Patients without prior DEP had greater decreases in disease activity. Baseline, 1-year, and 2-year CDAI estimates in those without prior DEP were: 15.7 [14.7–16.6], 11.4 [10.5–12.4], and 7.2 [6.1–8.3]; compared to patients with prior DEP: 15.8 [14.8–16.7], 12.9 [11.9–13.8], and 10.0 [8.9–11.1]. The component measures displayed similar trends. Also, this effect was greater for the patient-reported outcomes. Baseline, 1-year, and 2-year PGA estimates in those with no prior DEP were: 3.7 [3.5–3.8], 3.1 [2.9–3.2], and 2.5 [2.3–2.7]; and in patients with prior DEP: 3.7 [3.5–3.8], 3.6 [3.4–3.7], and 3.4 [3.2–3.6]. In contrast, baseline, 1-year, and 2-year EGA estimates in patients without prior DEP were: 2.7 [2.6–2.9], 2.0 [1.8–2.1], and 1.2 [1.0–1.4]; and in those with prior DEP: 2.7 [2.5–2.9], 2.1 [1.9–2.3], and 1.5 [1.3–1.7]. Similar results were obtained for the TJC, a measure assessed via the patient and physician, when compared to the SJC, which is evaluated solely by clinicians.

Table 1. Model based estimates of disease activity by lifetime depression status at baseline, 1 year, and 2 years, among propensity score matched samples.

Prior Depression	Variable	N	Baseline	Year 1	Year 2
No	CDAI***	4250	15.66 [14.69–16.63]	11.43 [10.46–12.39]	7.19 [6.11–8.28]

Under Reporting Of Cataracts In Randomised Controlled Trials Investigating The Use Of Systemic Glucocorticoids In Patients With Rheumatoid Arthritis. Rachel J. Black and William G. Dixon. The University of Manchester, Manchester, United Kingdom.

Background/Purpose: Oral glucocorticoid (GC) therapy is used in more than half of patients with rheumatoid arthritis (RA). Cataracts are a recognised treatment-related side effect of GC use. However, the magnitude of the risk, its relationship with dose, or whether screening for cataracts should be undertaken in patients on GC therapy is not clear. The aim of this study was to determine the incidence of cataracts in the active and placebo arms of RCTs of systemic GC therapy in patients with RA. Because of early concerns about possible under-reporting in the trials, a second aim was to compare the observed incidence in the RCTs to the incidence of cataracts in the general population.

Methods: Twenty two RCTs of systemic GC therapy in patients with RA were reassessed to identify incident cataracts in the placebo and treatment arms. The number of person years at risk (pyr) and the resultant incidence rates/ 1000pyr were calculated for the combined RCT population, then for the GC and control groups separately. The incidence rate ratio for GC use was calculated using Poisson regression. Two large observational studies (The Beaver Dam Eye Study and The Blue Mountains Eye Study) reporting the incidence of cataract in the general population were identified. Both studies reported the age and gender-specific cumulative incidence of cataracts over 5 years and 10 years. The mean of the incidence rates across the two studies was used to generate a general population incidence rate for the age-specific strata. Indirect standardisation was used to calculate the expected number of cases in the RCTs, were the RCT patients to have had the same incidence rate as the general population. A standardised incidence ratio was then calculated using the number of observed and expected cases.

Results: In the 22 RCTs, there were 2250 patients with a mean age of 56 years (weighted by duration of follow up), contributing 3764pyr. There were 13 cases of cataract reported in 3 of the 22 RCTs, giving an overall incidence rate of 3.5 per 1000pyr. The RCTs contributed 1884pyr to the GC group and 1880pyr to the control group. There were 7 cases of cataract reported in the GC group and 6 in the control group, generating incidence rates of 3.7 and 3.2 / 1000pyr in the GC and control group, respectively. The incidence rate ratio for GC use was 1.16 (95%CI 0.39–3.46). Using the general population incidence for patients aged 55–64 years of 46.7 per 1000pyr, the expected number of cataracts was 176. This generates a standardised incidence ratio of 0.07 (95%CI 0.03–0.21).

Conclusion: The incidence of cataracts was 16% higher in GC-treated compared to control patients with RA using all available RCTs. However the lack of precision (wide confidence intervals) due to small numbers means that this calculation is inconclusive. The observed number of cataracts was around 15 times lower than expected in both arms, suggesting huge under-reporting. Such under-reporting results in low confidence of any measured risk from these studies emphasising the need for well designed observational studies and better reporting of steroid-side effects in future RCTS.

Comparison Of The Incidence Of Influenza Like Illness In Pregnant Women With Rheumatoid Arthritis and Women Without Rheumatoid Arthritis Who Receive An Influenza Vaccination. Yunjun Luo, Diana L. Johnson, Ronghui Xu and Christina D. Chambers. University of California, San Diego, La Jolla, CA.

Background/Purpose: Influenza infection poses significant risk to pregnant women, therefore it is recommended that all pregnant women be vaccinated. However, it is unknown whether the protective effect of influenza vaccine is the same for pregnant women with rheumatoid arthritis (RA) as it is for pregnant women without autoimmune disease.

Methods: Data were obtained from an ongoing prospective cohort study of pregnancy outcome among women in the U.S. and Canada. We included women enrolled between 2009 and 2012 who either had a current diagnosis of RA or were healthy women without autoimmune disease. All women had completed multiple standard maternal telephone interviews during pregnancy that contained structured questions on the receipt of influenza vaccination and the occurrence of a diagnosis of influenza-like illness (ILI) during pregnancy. Using time varying vaccine exposure during pregnancy, and adjusting for the timing of the flu season during pregnancy, we estimated the hazard ratio (HR) and its 95% confidence interval (CI) for ILI in a Cox regression model comparing women who reported receipt of an influenza vaccine some time in pregnancy to women without vaccine during pregnancy. We addressed the potential differential effect of influenza vaccination on risk of ILI by testing an interaction term in the model (influenza vaccination by RA status). For those women who were vaccinated, only ILI reported subsequent to vaccination was included as an event.

Results: There were 1,233 subjects available for analysis: 825 women received influenza vaccine during pregnancy and 408 women did not receive vaccine; 245 women had RA and 988 women were without autoimmune disease. Among RA subjects, 144 (58.8%) were vaccinated and among subjects without autoimmune disease, 681 (68.9%) were vaccinated. Nine (3.7%) of the women with RA and 55 (5.6%) of the women without autoimmune disease reported a diagnosis of ILI at some time in pregnancy. Six (4.2%) vaccinated RA women and 28 (4.1%) vaccinated women without autoimmune disease reported ILI at some time in pregnancy. The adjusted HR for ILI in women vaccinated vs. women not vaccinated was 1.19 with 95% CI of 0.64, 2.24. The interaction term for vaccine exposure and autoimmune disease was not statistically significant ($p = 0.16$).

Conclusion: We found no evidence of a difference in the incidence of ILI after vaccination is pregnant women with RA compared to women without autoimmune disease.

Rates Of Hospitalized Infections In Rheumatoid Arthritis Patients From 5 Rheumatoid Arthritis Registries Across The World. Hisashi Yamanaka[1], Johan Askling[2], Niklas Berglind[3], Stefan Franzén[3], Thomas Frisell[2], Christopher Garwood[4], Jeffrey D. Greenberg[5], Meilien Ho[6], Marie Holmqvist[2], Laura Horne[7], Eisuke Inoue[1], Kathy Lampl[7], Kaleb Michaud[8], Dimitrios A. Pappas[9], George Reed[10], Deborah Symmons[4], Eiichi Tanaka[1], Trung Tran[11], Suzanne Verstappen[4] and Fredrik Nyberg[12]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Karolinska Institutet, Stockholm, Sweden, [3]AstraZeneca R&D Mölndal, Mölndal, Sweden, [4]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [5]New York Hospital for Joint Disease, New York, NY, [6]AstraZeneca R&D Alderley Park, Macclesfield, United Kingdom, [7]AstraZeneca R&D Wilmington, Wilmington, DE, [8]University of Nebraska Medical Center, Omaha, NE, [9]Columbia University, New York, NY, [10]University of Massachusetts Medical School, Worcester, MA, [11]MedImmune LLC, Gaithersburg, MD, [12]AstraZeneca R&D, Mölndal, Sweden.

Background/Purpose: Rheumatoid arthritis (RA) patients are at increased risk of infection due to both RA itself and immunomodulating treatments. Infection rates are often difficult to compare across studies, since the rates may vary across the world, and due to methodological and demographic differences between studied populations or cohorts. We investigated rates of hospitalized infection in 5 RA registries from 4 continents, employing a standard set of analyses and standardizing rates to a common population.

Methods: Participating registries were CORRONA (USA), SRR (Sweden), NOAR (UK), CORRONA International (East Europe, Latin America, India) and IORRA (Japan). The definition of hospitalized infections was harmonized as much as possible across registries. Within each registry, we analyzed a primary cohort of all RA patients from January 2000 to last

available data of each registry (2010–2013), and several subcohorts for sensitivity analyses, defined by disease activity, treatment status, calendar time, duration of follow-up and prior comorbidity. Rates were standardized for age, sex and, in 1 sensitivity analysis, also for HAQ, using the distributions from a typical RA trial program population.

Results: There was relatively high consistency in rates across registries, and sex/age standardization increased consistency further (Table 1). Generally, the primary cohorts provided the lowest or close to lowest rate (Table 2). In most registries, the highest rates were seen in subcohorts (either biologic naïve or with prior biologic treatment) with only 18 months follow-up after treatment change (Table 2). Additional standardization for HAQ score according to a trial patient distribution led to increased rates in all registries (Table 2).

Table 1. Incidence of hospitalized infection in the primary cohorts (RA patients from Jan 1, 2000) from 5 RA registries

Registry	N	Events	PY*	Crude Incidence/ 100 PY	Standardized† Incidence/100 PY (95% CI)
CORRONA	19,537	701	43,473	1.61	1.30 (1.18–1.42)
SRR	18,527	1909	76,855	2.48	1.62 (1.52–1.72)
NOAR	1564	231	10,366	2.23	1.56 (1.30–1.88)
CORRONA-INT	2727	28	1812	1.55	1.51 (0.99–2.24)
IORRA	10,255	690	59,680	1.16	1.14 (1.05–1.25)

† Standardized according to the age and sex distribution in a typical RA clinical trial program.
* PY, person-years.

Table 2. Incidence of hospitalized infections in the primary cohorts and selected sensitivity analyses from 5 RA registries.

Standardized incidence* per 100 person-years (with 95% confidence intervals)				
CORRONA	SRR	NOAR	CORRONA-INT	IORRA
Main analysis, primary cohort followed from Jan 1, 2000				
1.30 (1.18–1.42)	1.62 (1.52–1.72)	1.56 (1.30–1.88)	1.51 (0.99–2.24)	1.14 (1.05–1.25)
Sensitivity analysis A: Standardization for HAQ score in addition to sex and age, primary cohort				
1.90 (1.64–2.21)	2.03 (1.85–2.23)	1.86 (1.51–2.28)	2.17 (1.29–3.55)	1.84 (1.60–2.13)
Sensitivity analysis B: Subcohort of biologics-naïve patients followed from treatment change for 18 months (nested within primary cohort)				
3.03 (2.09–4.30)	2.11 (1.79–2.49)	2.67 (1.35–4.89)	NA†	1.00 (0.78–1.28)
Sensitivity analysis C: Subcohort of previously biologics-treated patients followed from treatment change for 18 months (nested within primary cohort)				
1.70 (1.25–2.30)	3.50 (2.75–4.43)	-‡	-‡	-‡

* Standardized according to the age and sex distribution (and in Sensitivity Analysis A also HAQ score) in a typical RA clinical trial program.
† Not available. Too few events - incidence rates not calculated.
‡ Too small cohort for reliable analysis.

Conclusion: This study constitutes the first attempt to compare the incidence of hospitalized infections internationally using existing RA cohorts. Consistent methodology, outcome definitions and analysis with standardization of rates facilitated comparison across registries. In most registries there is evidence of higher infection rates initially after starting treatment. The main analysis may be a good averaged estimate of risk over the longer term but may underestimate short-term risk. HAQ standardization appears useful to further address potential bias due to differences between registries and a typical trial population. Remaining differences between registries may reflect true regional differences in risk factors, populations and health care, although residual population and methodological differences are possible.

Generalizability Of a U.S. Rheumatoid Arthritis Registry: A Comparison Of Participants' Vs. Non-Participants' Characteristics. Jeffrey R. Curtis[1], Lang Chen[2], Huifeng Yun[2], Leslie R. Harrold[3], Jeffrey D. Greenberg[4] and Joel M. Kremer[5]. [1]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Massachusetts Medical School, Worcester, MA, [4]New York Hospital for Joint Diseases, New York, NY, [5]Center for Rheumatology, Albany Medical College, Albany, NY.

Background/Purpose: Observational registries provide a valuable complement to clinical trials yet might suffer from limited generalizability referent to the desired population of interest. We compared characteristics of older patients enrolled in a large U.S. rheumatoid arthritis (RA) registry compared to RA patients treated by non-participating rheumatologists throughout the U.S.

Methods: We used national data from the U.S. Medicare program from 2006–2010 and linked it to the Consortium of Rheumatology Researchers of North America (CORRONA) registry. Linkage was accomplished using deterministic methods on multiple non-unique identifiers and achieved $>$ 96% accuracy. RA patients were identified in Medicare on the basis of having at least one ICD-9 diagnosis code for RA (714.X) from a rheumatologist. Demographics, comorbidities, and drug utilization were examined in Medicare data during the most recent consecutive 12 month period with full fee-for-service coverage including pharmacy benefits. Characteristics of CORRONA RA patients were compared to characteristics of RA patients of non-CORRONA rheumatologists. Differences were quantified as standardized mean differences (SMDs), with values $<$ 0.1 considered clinically irrelevant.

Results: A total of 620,111 RA patients in Medicare treated by 3,834 non-CORRONA rheumatologists were identified and their characteristics compared with 5,643 RA patients treated by 282 CORRONA rheumatologists (Table). Mean age and sex were similar; CORRONA patients were more likely to be recruited in the Northeast and West. The prevalence of common comorbidities was comparable. During the 12m observation period, CORRONA RA patients were more likely to use biologics (22 vs. 12%) and somewhat less likely to use oral glucocorticoids (33 vs. 38%). Health services utilization was similar between CORRONA and non-CORRONA RA patients.

Table. Characteristics of Older RA Patients Enrolled in CORRONA vs. RA Patients of Non-CORRONA Rheumatologists

Patient Characteristic	CORRONA Patients	Non-CORRONA Patients	Standardized Mean Differences
Age, years	72.3 (9.9)	72.7 (11.1)	0.03
Female sex, %	74.6	73.8	0.02
Caucasian race	89.5	85.2	0.18
Region, %			
Northeast	30.2	17.4	0.038
Midwest	25.1	23.4	0.303
West	12.7	15.9	0.091

Number of physician visits, mean ± SD	13.9 ± 10.2	14.2 ± 10.9	0.02
Any hospitalization, %	26.2	28.9	0.06

Conclusion: Despite some differences in regional geographic representation, older RA patients enrolled in CORRONA were generally similar in their characteristics to older RA patients of other rheumatologists not participating in CORRONA, although were more likely to receive biologic therapies. Based upon these findings, results from this U.S. registry may be generalizable to a national U.S. RA population.

Formal Education Level Explains Variation In Rheumatoid Arthritis (RA) Core Data Set Measures and Indices In Korean Patients At Higher Levels Of Significance Than Age, Sex, and Duration Of Disease. Sung-Hoon Park[1], Isabel Castrejón[2], Jung-Yoon Choe[1], Seong-Kyu Kim[1], Hwajeong Lee[1], Sang Gyu Kwak[1] and Theodore Pincus[2]. [1]Catholic University of Daegu School of Medicine, Daegu, South Korea, [2]NYU Hospital for Joint Diseases and New York University School of Medicine, New York, NY.

Background/Purpose: Poor health is associated with low socioeconomic status (SES), with higher prevalence, greater severity and earlier mortality of many diseases, including rheumatoid arthritis (RA). However, a variable describing SES is not included in many clinical research reports, in contrast to age, sex and duration of disease, which are almost always included as potential confounders of differences between patients in clinical status, treatment responses and outcomes. The most easily measured SES variable is formal education level (EDUC), which has been interpreted as an available surrogate for patient actions and attitudes that may affect health. We analyzed the possible significance of EDUC, age, sex and duration of disease to explain variation in RA Core Data Set variables and 4 RA indices, in a cohort of Korean RA patients seen in usual care.

Methods: MDHAQ and all 7 RA Core Data Set measures were collected in 397 consecutive patients with RA seen in a Korean setting by 4 rheumatologists. Patients were classified in 3 EDUC categories: <7 years (elementary school, n=76; mean age 62.9 years), 7–12 years (high school, n=228; mean age 55.8), and >12 years (college, n=93; mean age 42.9). Possible associations with EDUC were analyzed for each of the 7 RA Core Data Set measures and 4 RA indices: DAS28, SDAI, CDAI and RAPID3 [an index of only the 3 patient self-report Core Data Set measures found on an MDHAQ: physical function, pain and patient global estimate of status (PATGL)]. The data were analyzed by multivariate generalized linear model (GLM) with a log link, and a Poisson distribution was applied to examine difference in 7 Core Data Set measures among EDUC, adjusted for age, sex and disease duration, and by regressions for each Core Data Set variable, with EDUC, age, sex and disease duration as independent variables.

Results: Patients with lower EDUC had higher scores, indicating greater severity, for all Core Data Set measures, statistically significant for tender joint count (TJC), physical function, pain, PATGL and ESR, and all 4 indices–DAS28, SDAI, CDAI and RAPID3–adjusted for age, sex and disease duration ($p < 0.01$; data not shown). No significant differences were seen for swollen joint count (SJC), physician global estimate (DOCGL) or CRP. In a series of regressions, EDUC was the only significant variable to explain variation in TJC, pain, PATGL, DOCGL, SDAI, CDAI and RAPID3. EDUC and disease duration explained variation in DAS28 significantly, and only disease duration explained variation in ESR. None of the 4 independent variables was significant to explain variation in SJC, physical function, or CRP.

Table. Beta coefficient (p value) of regressions including 4 possible independent variables to explain variation in ACR Core Data Set measures and composite indices

Dependent variables	Independent variables			
	Age	Sex	Disease duration	EDUC
TJC	<0.001 (0.999)	0.475 (0.483)	0.289 (0.292)	−0.130 (0.034)
SJC	−0.009 (0.331)	−0.004 (0.989)	0.130 (0.239)	−0.021 (0.430)
Physical function	0.016 (0.097)	0.129 (0.633)	0.012 (0.256)	−0.051 (0.053)
Pain	−0.008 (0.621)	0.559 (0.196)	−0.001 (0.957)	−0.140 (0.001)
PATGL	−0.017 (0.232)	0.681 (0.091)	0.011 (0.505)	−0.016 (0.007)
DOCGL	−0.018 (0.048)	0.259 (0.300)	−0.014 (0.163)	−0.072 (0.003)
ESR	−0.206 (0.109)	1.351 (0.709)	0.504 (0.001)	−0.539 (0.123)
CRP	−0.010 (0.341)	0.272 (0.346)	0.001 (0.917)	−0.027 (0.326)
DAS28	−0.010 (0.153)	0.181 (0.363)	0.021 (0.009)	−0.059 (0.002)
SDAI	−0.054 (0.231)	1.684 (0.184)	0.040 (0.436)	−0.365 (0.003)
CDAI	−0.044 (0.294)	1.411 (0.233)	0.039 (0.418)	−0.337 (0.003)
RAPID3	−0.009 (0.798)	1.369 (0.156)	0.022 (0.567)	−0.297 (0.002)

Conclusion: Significant associations of low EDUC with greater disease severity according to most RA Core Data Set measures and 4 indices were seen in 397 Korean RA patients. EDUC was more likely than age, sex or duration of disease to explain variation in most Core Data Set measures and RA indices. EDUC should be included in all clinical databases.

Population-Based Analysis Of Treatment Patterns For Recently Diagnosed Rheumatoid Arthritis Patients In The United States. Martin M. Crane[1], Boyka Stoykova[2], Julie Priest[1], Nasha Wang[1], Henry Krzywy[1] and Rahul Ganguly[1]. [1]GlaxoSmithKline, Durham, NC, [2]GlaxoSmithKline, Uxbridge, United Kingdom.

Background/Purpose: As treatment paradigms for rheumatoid arthritis (RA) continue to evolve, population-based studies can help assess which strategies are being used in "real-world" practice for the complete spectrum of clinical RA. This approach can also relate therapy to the consumption of other health-care resources such as RA-related surgery or hospitalization which are fundamental for RA economic models. Herein we describe treatment patterns in RA patients newly diagnosed in 2009 and followed for two years.

Methods: A retrospective cohort analysis of adults (age ≥20) with complete medical and pharmacy insurance claims from 1 Jan 2008 to 31 Dec 2011 was used. "Incident RA" required a primary diagnosis at two separate visits 30 days apart in 2009 and no prior claims for RA. Databases employed were the Marketscan Commercial Claims and Encounters (CCAE) and Medicare Supplemental and Coordination of Benefits (MSCB) databases from Truven Health Analytics. Information on demographics, co-morbidities and treatments including conventional (cDMARD) and biologic (bDMARD) therapy and sequencing thereof was obtained for the entire follow-up period. Selected results were informally compared to a similar analysis in 2006 [Arth Rheum 2010;62(Suppl10):18].

Results: There were 8.02 million persons who met study criteria from which 8,507 RA cases were newly diagnosed in 2009. Incidence was 1.06/1000 persons at risk (1. 5 in females; 0.57 in males). 18% of incident patients received a bDMARD in year one (versus 21% in 2006) and 67% a cDMARD. Among the former, TNF inhibitors were the most commonly prescribed (94%). Over two years of follow-up, 23% of patients were prescribed bDMARDs but 22% of them were subsequently switched to a different biologic. A total of 26% of patients did not receive a DMARD over the two years (as compared to 28% in 2006). Corticosteroids were given to 77% of patients during the 2-year follow-up.

Treatment patterns over the 24 months after RA diagnosis were as follows (Table 1):

Table 1.

				bDMARDs								
	No Tx	cDMARDs	NSAIDs/ Cox2/CS	ETA	ADA	INF	CER	GOL	ABA	RTX	TOC	Total
0–12 months	827 (9.7%)	5,718 (67%)	6,767 (80%)	699 (45%)	532 (34%)	279 (18%)	47 (3%)	61 (3.9%)	102 (6.6%)	41 (2.6%)	NA	1,552 (18%)
0–24 months	520 (6.1%)	6,020 (71%)	7,361 (87%)	927 (47%)	734 (37%)	358 (18%)	100 (5%)	110 (5.6%)	189 (9.5%)	82 (4.1%)	35 (1.8%)	1,981 (23%)

ETA-etanercept, ADA - adalimumab, INF - infliximab, CER - certolizumab pegol, ABA - abatacept, RTX - rituximab, TOC - tocilizumab.

Of patients who used bDMARDs, 78% had only one, 17% had two, 4% had three, and 1% had four different biologics over the study period. The most common first line biologic was ETA (45%), followed by ADA (27%), and INF (22%), while second line biologic choices were ADA (43%), INF (22%), and ABA (13%).

Conclusion: The majority of newly diagnosed patients received anti-rheumatic therapy. The proportion of cDMARDs and bDMARDs were similar in 2006 and 2009. Switching among biologics was not uncommon. There were 26% (versus 28% in 2006) who had not received anti-rheumatic treatment over the two years of follow-up.

Sociodemographic, Health System, and Community Characteristics Associated With Initiation Of Biological Dmards In RA. Edward H. Yelin[1], Chris Tonner[2], Seoyoung C. Kim[3], Jeffrey N. Katz[3], John Z. Ayanian[3] and Daniel H. Solomon[4]. [1]UC San Francisco, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA, [3]Brigham and Women's Hospital, Boston, MA, [4]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA.

Background/Purpose: The use of biologic DMARDs for RA has improved outcomes, but it is unknown whether there are disparities in

initiation of these agents by sociodemographic, medical, health system, and community characteristics.

Methods: We analyzed data from the UCSF Rheumatoid Arthritis Panel for the years 1999 through 2011. Panel participants are drawn from a random sample of Northern California rheumatologists, with enrollments in 1982/1983, 1985, 1989, 1999, and 2003. Principal data collection is by a structured annual phone survey. We used Cox regression to estimate the effect of individual- and community-level characteristics on the first initiation of a biological DMARD. Individual-level characteristics include sociodemographics (age, gender, race, ethnicity, marital status, formal education, annual household income), medical (HAQ, # painful and # swollen joints and # comorbid conditions, Geriatic Depression Score, and use of oral steroids, non-biological DMARDs, and NSAIDS), and health system (having any health insurance, including for medications; HMOs vs. fee-for-service; and # of rheumatologist visits in prior year). Community-level characteristics include # of rheumatologists per capita, presence of a federally qualified health center in local area, and living in area of concentrated poverty.

Results: 527 persons were in the RA Panel in 1999. 83% were female, 83% whites, 7% Hispanics, 41% ≤ high school, and 38% had household income < 30,000/year. Mean (Std) age was 61 (14), RA duration was 20 (11) years, and HAQ score was 1.1 (0.7). Among the 527 persons, 20% had initiated biological therapy by 2000, 40% by 2005, and 43% by 2011. In fully adjusted Cox regression models that include all medical characteristics, younger age [Hazard Ratio (HR) for ages 19–54 =1.89 (95%CI 1.24, 2.87); HR for 55–69=1.25 (0.84,1.87)], Hispanic ethnicity [HR 2.02 (1.05, 3.86], household incomes >$30,000/year [HR1.61 (1.12, 2.32)], being married or with a partner [HR 1.39 (1.00, 1.92)], and living in a rural setting [HR 1.96 (1.28, 2.99)] were associated with a higher probability of initiating a biologic DMARD. The following characteristics were associated with a lower probability: having no [HR 0.18 (0.08, 0.40)] or only 1–4 rheumatology visits in the year prior to interview [HR 0.60 (0.45, 0.81)] and living in an area with Federally qualified health centers [HR 0.63 (0.41, 0.96)]. After adjustment, no medical characteristics were associated with initiation of a biologic DMARD.

Conclusion: These results indicate that many sociodemographic and community characteristics influence the initiation of biologic DMARDs, suggesting attention to these characteristics to improve access to such treatment.

Glucocorticosteroids and Mortality Risk In Rheumatoid Arthritis-Results Of a Population Based Study. Diane Lacaille[1], J. Antonio Avina-Zubieta[1], Eric C. Sayre[2], Michal Abrahamowicz[3] and John Esdaile[1]. [1]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC, [2]Arthritis Research Centre of Canada, Richmond, BC, [3]McGill University, Montreal, QC.

Background/Purpose: Glucocorticosteroids (GC) are frequently used in the management of rheumatoid arthritis (RA). Due to their metabolic and immunosuppressive effects, they could increase the risk of mortality, yet suppression of disease activity, a known predictor of premature mortality, could also reduce the risk of mortality in RA. We evaluated the association between exposure to GC and risk of mortality in RA, using a population-based incident RA cohort with administrative health data.

Methods: Using administrative billing data, we assembled a population-based cohort including all incident RA cases between 01/1996 and 03/2006, followed until 03/2010. Cases with GC use prior to RA onset were excluded. Administrative data were obtained on all medications since 09/1995; MD visits, hospitalizations, and tests since 01/1990. The Cox proportional hazard model (PHM) was used to estimate risk of death associated with GC exposure. Time analyzed was from index RA date to death or end of follow-up. GC exposure was defined as any dispensed prescription for oral GC during follow up, and was measured using three time-dependent exposure variables, in separate models, representing current dose (in mg prednisone equivalent), past cumulative dose and past cumulative duration of exposure . We used propensity scores (PS) to control for the observed differences between GC users and non-users, calculated at the time of initiating GC, using markers of RA severity, as well as co-morbidities increasing risk of death. Variables for which there was residual imbalance across PS quintiles were also included as covariates in the model. PHM analyses were also adjusted for age, gender, calendar year of inclusion, PS, as well as time-dependent variables representing exposure to RA medications that could influence mortality risk (MTX, biologics and NSAIDs).

Results: Our sample includes 18,215 incident RA cases (mean (SD) age: 57.2(17.1), 66.5% females) providing a mean of 7.1 years and a total of 128,799 person-years of follow-up, with 5,326 RA cases (29.2%) exposed to GC. We observed 2,881 deaths. Exposure to GC was associated with an increased risk of death in all models (Table 1). Female gender, current MTX and biologic use, and later calendar year of inclusion were associated with a reduced risk of death; whereas age, smoking, Charlson comorbidity score and markers of RA severity were associated with an increased risk of death. Limitations of our study are those inherent to observational study, including possible effect of residual or unmeasured confounding, and selection bias from non-random allocation of treatment.

Table 1.

Model	GC exposure measurement	Risk of all cause mortality aHR (95% CI)	p value
1	Current dose (per 5 mg)	1.22 (1.21;1.24)	<0.0001
2	Cumulative dose (per 1 gm)	1.11 (1.10;1.12)	<0.0001
3	Cumulative duration (per 1 yr)	1.30 (1.26;1.35)	<0.0001
4	Current dose (5mg)	1.22 (1.20;1.24)	<0.0001
	Cumulative duration (1 yr) in same model	1.26 (1.22;1.31)	<0.0001 <0.0001

Conclusion: In a population-based cohort, exposure to GC was associated with a significant increase in mortality. Given the increased mortality risk of RA, this has important implications for health care providers and people with arthritis.
