Results: 461 subjects were randomized (placebo, n=157; atacicept 75 mg, n=159; atacicept 150 mg, n=145). The primary endpoint was not met in the atacicept 75 mg arm (flare rate 57.9% vs 54.1% among controls; OR 1.15, p=0.54). Treatment was discontinued in the 150 mg arm after enrollment of 145 subjects due to two fatal pulmonary infections (pneumococcus and leptospirosis). The flare rate in the 150 mg arm was 36.6% vs 54.1% in the placebo arm (OR 0.48, p=0.002). Time to first new flare was significantly longer in the 150 mg arm vs placebo (HR 0.62, p=0.02). Improvements were seen with atacicept 75 mg and 150 mg in SF-36 physical and mental summary scores exceeding the minimal clinically important difference (MCID=2.5) at Week 52 (atacicept 75 mg=3.14, 2.64; 150 mg=4.26, 3.46; placebo=2.00, 1.33). Adverse events (AEs) due to infection were similarly distributed in the placebo and treatment arms during treatment and during the 24-week follow-up period (Table). Serious AE (SAE) rates, and SAE rates due to infection, were also similar in the placebo, 75 mg, and 150 mg groups (5.8%, 7.0%, and 5.6%, respectively) throughout the treatment and follow-up period. There were no deaths during the follow-up period.

Table. Proportion of subjects experiencing at least one adverse event (safety population)

	Placebo (n=154)		Atacicept 75 mg (n=157)		Atacicept 150 mg (n=144)	
	Week 52	(24-week follow-up)	Week 52	24-week follow-up	Week 52	24-week follow-up
Adverse events*	117 (76.0)	48 (31.2)	130 (82.8)	59 (37.6)	116 (80.6)	50 (34.7)
Serious adverse events*	21 (13.6)	9 (5.8)	23 (14.6)	11 (7.0)	20 (13.9)	8 (5.6)
Infections*	80 (51.9)	27 (17.5)	93 (59.2)	32 (20.4)	79 (54.9)	28 (19.4)
Serious infections*	7 (4.5)	4 (2.6)	6 (3.8)	7 (4.5)	10 (6.9)	2 (1.4)

*All data are n (%).

Conclusion: The primary endpoint was not met in the atacicept 75 mg arm compared with placebo. Two fatal infections in the 150 mg arm caused sufficient concern to terminate this arm prematurely. *Ad-hoc* analysis of those subjects who had received 150 mg atacicept (either by reaching 52 weeks or by withdrawing during the 52-week treatment period) showed a reduced risk of SLE flares, and increased time to flare. Clinically meaningful improvements in quality of life were observed in both atacicept arms compared to controls. Total SAEs were similar between groups. Fewer subjects in all groups experienced AEs during the 24-week follow-up period than during the 52-week treatment period. Taken together, these findings show signals suggestive of risk as well as efficacy for atacicept. Future studies will be needed to further clarify the balance between risk and benefit and to identify subsets of subjects in whom the benefits may outweigh the risks.

Background/Purpose: "Lupus headache" is controversial and is included in validated measures of global SLE disease activity. We examined the frequency and characteristics of "lupus headache" in a large, prospective, inception cohort of SLE patients and the association with global disease activity and health related quality of life.

Methods: An international network of 30 academic medical centers enrolled patients within 15 months of SLE diagnosis. Annual assessments were performed for 19 neuropsychiatric (NP) syndromes as per the ACR case definitions. This included 5 types of headache using the International Headache Society (IHS) criteria. Additional data were demographic and clinical variables, SLE global disease activity (SLEDAI-2K), which includes "lupus headache" as a standalone variable, SLICC/ACR damage index (SDI) and self-report mental (MCS) and physical (PCS) component summary scores of the SF-36. Statistical analysis used linear regression models with generalized estimating equations to account for within patient correlation.

Results: Of the 1732 enrolled patients 89% were female. Race/ethnicity was Caucasian (48%), African (16%), Asian (16%), Hispanic (16%) and other (4%). At enrollment the mean (±SD) age was 34.6±13.4 years, disease duration was 5.6±4.8 months and followup was 3.8±3.1 years. Twenty-six (1.5%) patients had "lupus headache" at 27 (0.36%) of 7523 assessments. Concurrent classification using the IHS headache case definitions were: migraine (13), tension headaches (8), intractable non-specific headaches (5), cluster headaches (1) and intracranial hypertension (1). Two patients had 2 types of headache and in 5 (18.5%) of 27 assessments there were concurrent NP events. "Lupus headache" was reported at both enrollment (n=14) and follow-up (n=13) assessments, in patients from all racial/ethnic groups in 15 of 30 (50%) sites located in 8 of 11 countries (USA, Canada, UK, Spain, South Korea, Mexico, Sweden and Iceland). The estimated mean (±SE) SLEDAI-2K scores, without including "lupus headache" variable, for visits with no headache (n=6019), a non-lupus headache (n=1330) and both a non-lupus and "lupus headache" (n=27) were 3.8±0.08, 3.6±0.18 and 7.2±1.40 respectively (p=0.034). Concurrent SF-36 MCS scores were 47.8±0.28, 42.6±0.56 and 39.4±2.41 (p<0.001) and PCS scores were 42.6±0.30, 38.1±0.53 and 32.4±1.76 (p<0.001). SLEDAI-2K scores, without including "lupus headache" variable, for patients with and without "lupus headache" were 7.2±1.40 vs 3.7±0.08 (p=0.035). In 5/26 (19.2%) patients "lupus headache" was the sole contributor to the SLEDAI-2K score. Concurrent SF-36 MCS and PCS scores for patients with and without "lupus headache" were 39.4±2.41 vs 46.8±0.27 (p=0.002) and 32.4±1.76 vs 41.7±0.28 (p<0.001) respectively.

Conclusion: "Lupus headache", although infrequent, was associated with higher global disease activity and a lower HRQoL. It was not reproducibly aligned with a uniform IHS classification of headache (e.g. intractable headache). The lack of consistency in diagnosing "lupus headache", even by experienced clinicians, indicates a need to better define "lupus headache" and to reach consensus on whether it is truly a standalone manifestation of NPSLE.

Blood-Brain Barrier Damages and Intrathecal Synthesis Of Anti-NMDA Receptor NR2 Antibodies In Diffuse Psychiatric/Neuropsychological Syndromes In Systemic Lupus Erythematosus. Shunsei Hirohata[1], Yoshiyuki Arinuma[1] and Taku Yoshio[2]. [1]Kitasato University School of Medicine, Sagamihara, Japan, [2]Jichi Medical University, School of Medicine, Shimotsuke-shi, Tochigi-ken, Japan.

Background/Purpose: Neuropsychiatricmanifestations in SLE are difficult complication that may cause substantialimpairment of quality of life as well as disability. Among a variety of neuropsychiatric manifestations in SLE, acute confusional state (ACS) in diffusepsychiatric/neuropsychological syndromes (diffuse NP-SLE) is the most seriousone. Recent studies have demonstrated that cerebrospinal fluid (CSF) anti-NMDAreceptor NR2 antibodies (anti-NR2) are associated with diffuse NP-SLE, especially ACS. However, the precise mechanism of elevation of CSF anti-NR2remains uncertain. There are 2 mechanisms for the elevation of CSF IgG, including transudation through the damaged blood-brain barrier and intrathecalsynthesis. The current studies therefore examined the blood-brain barrierfunction and intrathecal synthesis of anti-NR2 in NP-SLE.

Methods: Pairedserumand CSFsamples were obtained from 85 SLE patients whosatisfied the 1982 ACR revised criteria when they showed activeneuropsychiatric manifestations (59 patients with diffuse NP-SLE and 26patients with neurologic syndromes [focal NP-SLE]) as well as from 26 control patients with non-inflammatory neurologicaldiseases. IgG anti-NR2 were measured by ELISAusing synthetic peptide containing the extracellular ligand-binding domain ofNR2. Albumin was also quantitated by ELISA. Blood-brain barrier function andintrathecal synthesis of anti-NR2 were evaluated by Q albumin (CSF albumin x1,000/serum albumin) and by CSF anti-NR2 index ([CSF anti-NR2 × serumalbumin]/[serum anti-NR2 × CSF albumin]), respectively.

Results: CSF anti-NR2levels were significantly elevated in diffuse NP-SLE compared with those infocal NP-SLE or in control patients. Q albumin as well as CSF anti-NR2 indexwas also significantly elevated in diffuse NP-SLE compared with those incontrol patients. CSF anti-NR2 levels and Q albumin were significantly higherin ACS than in non-ACS diffuse NP-SLE (cognitive disorder, mood disorder, anxiety disorder and psychosis), whereas there was no significant difference inCSF anti-NR2 index between both groups (Figure). Finally, CSF anti-NR2 levelswere significantly correlated with Q albumin (r=0.3628, p=0.0083), but not withserum anti-NR2 (r=0.0366, p=0.7807) in patients with diffuse NP-SLE.

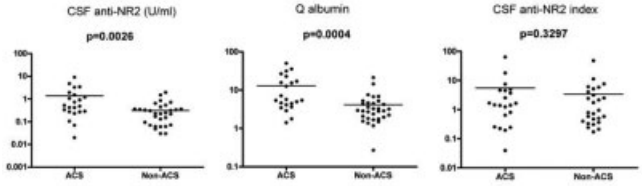

Figure. CSFanti-NR2 levels, Q albumin and CSF anti-NR2 index in patients withacute confusional state and in those with non-acute confusional state ofdiffuse NPSLE

Conclusion: Theseresults demonstrate that CSF anti-NR2 were elevated by both transudationthrough the damaged blood-brain barrier and intrathecal synthesis. Moreover, thedata indicate that the severity of the damages of blood-brain barrier, whichallows transudation of higher concentrations anti-NR2 into the central nervoussystem, play a crucial role in the development of ACS, a more serious form of diffuseNP-SLE.

Cognitive Dysfunction, Depression and Anti N-Methyl-D-Aspartate Receptor Antibodies and Anti- Ribosomal P In Systemic Lupus Erythematosus Patients In Argentina. Graciela Gómez, Judith Sarano, Maria de los Angeles Gargiulo, María Victoria Collado, Lorena Suarez, Daniel Fadel, Alexandra Panopulos and Marina Khoury. Instituto de Investigaciones Medicas Alfredo Lanari, Buenos Aires, Argentina.

Background/Purpose: Cognitive dysfunction (CD) and depression (D) are common manifestations of neuropsychiatric systemic lupus erythematosus (SLE) and they have been linked to antibodies (abs) like ribosomal P (anti-P), phospholipids and to the NR2 subunit of human N-Methyl-D-Aspartate receptor (anti NR2-NMDAR). The aim of the study was to describe the frequency of neurocognitive dysfunction and depression in patients with SLE and to assess their association with anti-NR2, anti-P and anticardiolipins (aCL) abs.

Methods: Patients who fulfilled the ACR classification SLE criteria were recruited in this cross-sectional study. Demographic and clinical information was obtained during the interview. Anti NR2-NMDAR isotype IgG was determined by commercial ELISA (Cis Biotech, Inc), cut off value=2ng/ml, anti-DNAds, aCL IgG/IgM by ELISA, anti-P by Lineal Immunoassay. Psychiatric evaluation, DSM IV, A-HAM and Depression Beck scales were applied. The ACR tests were applied to evaluate CD.Cognition was assessed in 4 domains:(1) attention, (2) memory, (3) executive skills and (4) language. Individual tests were: Trail Making Test Part A (1) and Part B (2), Digit symbol (2), Clock Drawing Test (2), SPAN (2), Rey-Osterrieth Complex figure test (3), Rey Auditory Verbal learning test (3), immediate and delayed logical memory(3), semantic Fluency (4). Z-scores (representing standard deviations [SD] from the tests standardization sample mean) were generated for each test. Overall mean z-scores were then determined for each subject in each of the four domains, method used by Diamond (A&R 2006).CD was defined as a mean z score worse than −1.0 in at least one domain. Statistical analyses: data are presented as mean ±SD and percentages. Fisher exact test for categorical variables. Alpha=0.05.

Results: 50 SLE patients, mean age 46±13 yrs, female 96%, white 76%, *mestizos* 20%, disease duration 18±12 yrs, SLEDAI ≤ 4 66%, SLICC ≤ 1 68%. Antibodies to NR2 52% (7/26 strong positive), anti-P 12%, aCL IgG 18%, aCL IgM 20%.Global CD 82%,depression 56% and anxiety 56%. Analyzing by groups (table 1) no significant differences with age (p=0,30) or disease duration(p=0,76) were observed.

	Without CD and D n= 3 (6%)	Only CD n=19 (38%)	With CD and D n=22 (44%)	Only D n=6 (12%)	p value
NR2-NMDA (n=7)	0	3	1	3	0,056
anti-P (n=6)	0	1	3	2	0,26
a-CL Ig G (n=9)	0	2	7	0	0,21
a-CL Ig M(n=10)	0	3	7	0	0,30

Conclusion: We found cognitive dysfunction and depression in our patients with SLE. Although the differences among the groups were not statistically significant, there was higher frequency of anti NR2 in depression and higher frequency of aCL and anti-P in cognitive dysfunction. These antibodies did not appear in patients without depression or cognitive impairment. No association was found between CD and NR2 abs, perhaps due to abs levels that may fluctuate over time or to methodological differences in abs assay detection. These findings would requiere a great number of patients to assess the possible association between these antibodies and these manifestations of neuropsychatric SLE.

Electroclinical Correlates and Outcome Of Status Epilepticus In Systemic Lupus Erythematosus. Jamal Mikdashi[1], Tricia Ting[2] and Allan Krumholz[3]. [1]University of Maryland School of Medicine, Baltimore, MD, [2]University of Maryland. School of Medicine, Baltimore, MD, [3]University fo Maryland school of Medicine, Baltimore, MD.

Background/Purpose: Predictors of seizures and epilepsy in systemic lupus erythematosus (SLE) patients are well described but descriptions of status epilepticus (SE) have thus far been limited to isolated case reports. The purpose of this study is to determine the electro-clinical characteristics as potential predictors of long-term outcome of SE in SLE.

Methods: This is an observational study of consecutive SLE patients with SE, enrolled out of the Maryland Lupus cohort that consists of 1138 SLE patients. Demographic, clinical features, laboratory data, brain magnetic resonance imaging (MRI) studies and video electroencephalography (EEG) were examined during SE event. Outcome was determined at 12 months following SE event. Seizure not related to SLE were excluded.

Results: In this SLE population, 78 (6.9%) of all patients had seizures related to SLE, and of these 7 (9.0%) had SE. At the SE events, patients [mean age 21.4 years, 72 % women, 72 % African American, and a mean duration of SLE of 6.5 years] presented with cutaneous vasculitis (57%), arthritis (43 %), psychosis (29 %), nephritis (14 %) and ischemic stroke (14 %). Convulsive SE was observed in 6 patients (3 generalized, 3 complex partial with secondary generalized) and non-convulsive SE in 1. Prolonged electrographic seizure activity (1–3 days) with continuous slowing and multifocal spikes in the bifornatal and temporal regions, associated with refractory complex partial and generalized seizures were observed in 5 patients. EEG seizures resolved abruptly in 2 patients. In addition to immunotherapy, multiple anti-epileptic drugs were needed to control SE in all patients.

All SE patients had a symptomatic structural lesion with probable etiologic significance with increased T2/FLAIR hyperintensity in the front-temporal and posterior cortex, and hypointense lesions in the regions of the amygdyla –hippocampal complex, thalamus and basal ganglia areas. Restricted weighted sequence images demonstrated restricted diffusion in the corresponding cortical regions of the frontal and temporal lobes in two patients. Two patients had normal initial brain MRI, but abnormal lesions were identified using functional FDG-PET scanning.

A favorable clinical and EEG response was recognized in all SLE patients with SE, with improvement in consciousness and survival. Recurrent seizure events were observed in 3 patients following the SE event, while recurrent SE events were observed in one patient who developed mesial temporal sclerosis overtime. Poor functional and cognitive outcome observed in 3 (43 %) patients, was associated with prolonged SE event, presence of cortical and subcortical structural lesions on brain MRI that correlated with the recorded EEG abnormality. No mortality among the SE patients was observed.

Conclusion: Overall, SLE patients with SE seem to have a favorable clinical outcome. Patients with prolonged SE events with a greater cortical-subcortical lesion burden on brain MRI have poor physical and cognitive function on long-term outcome. Identifying the pathogenic role of specific SLE related autoantibodies/cytokines in relation to brain structural lesions of SLE patients with SE is needed.

1596

Relationship Between IgG Anti-NR2 Glutamate Receptor Antibodies and Depressive/Anxiety Symptoms In Patients With Systemic Lupus Erythematosus. Chi Chiu Mok[1], Kar Li Chan[1] and Betty Diamond[2]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Feinstein Institute for Medical Research, Manhasset, NY.

Background/Purpose: To study the relationship between anti-NR2 glutamate receptor antibodies (anti-NR2) and depressive/anxiety symptoms in patients with systemic lupus erythematosus (SLE).

Methods: Consecutive Chinese patients who fulfilled >=4 ACR criteria for SLE were recruited. Depressive/anxiety symptoms were assessed by the validated Chinese version of the Hospital Anxiety and Depression scale (HADS) (0–21 points). Serum samples were taken at 10am in the morning for the assay of anti-NR2 antibodies (in-house ELISA using peptide adsorbed to plate and serum diluted 1:100, developed with an anti-human IgG antibody). Disease activity of patients recruited was assessed by SLEDAI and physicians' global assessment (PGA), whereas organ damage since SLE diagnosis was assessed by the ACR/SLICC damage index (SDI). Correlation among anti-NR2 titer, age, sex, HADS-depression score, HADS-anxiety score, SLEDAI, PGA and SDI in various systems was studied by linear regression models.

Results: 285 SLE patients were studied (95% women; age 38.9±12.6 years; SLE duration 9.0±7.0 years). At the time of study, 57 (20%) patients had clinically active SLE (SLEDAI>5); and 106 (37%) patients had organ damage (SDI score>=1). The mean SLEDAI was 3.9±4.6 and the mean PGA was 0.36±0.66. Forty-four (15%) patients had HADS-anxiety score of >10 and 28 (9.8%) of patients had HADS-depression score of >10. Anti-NR2 antibodies were present in 154 (54%) patients, defined as titers of greater than the mean+2SD (standard deviation) of healthy controls. Strongly positive values of anti-NR2 (defined as mean+4SD of controls) were found in 90 (32%) patients. Linear regression revealed that anti-NR2 reactivity correlated with SLEDAI score (Beta 0.25; $p<0.001$), PGA score (Beta 0.31; $p<0.001$), mean SLEDAI in the preceding 12 months (Beta 0.18; $p=0.003$), C3 level (Beta −0.25; $p<0.001$), HADS-depression score (Beta 0.14; $p=0.022$) and HADS-anxiety score (Beta 0.14; $p=0.023$), adjusted for age and sex. There was no relationship between anti-NR2 titers and anti-dsDNA titer, total SDI damage score (Beta 0.09; $p=0.14$), neuropsychiatric damage (Beta 0.06; $p=0.32$) or SDI scores in other systems.

Conclusion: Anti-NR2 antibodies are prevalent in patients with SLE. Anti-NR2 reactivity correlated with disease activity and depressive/anxiety symptoms in SLE patients.

Autonomic Dysfunction In Systemic Lupus Erythematosus Patients With Previous Neuropsychiatric Involvement. Yang Gao, Sheung Wei Li, Lai Heung Chau, Chak Sing Lau and Mo Yin Mok. University of Hong Kong, Hong Kong, Hong Kong.

Background/Purpose: Autonomic dysfunction has increasingly been described to be associated with central nervous system (CNS) disorders and has been attributed to damage of the central autonomic network. In this study, we examined autonomic function among systemic lupus erythematosus (SLE) patients with previous neuropsychiatric involvement (NPSLE) compared to those without NPSLE.

Methods: SLE patients with previous CNS involvement including seizure, acute confusion state and stroke (NPSLE), age-, sex- and disease duration- matched SLE patients (non-NPSLE) and age- and sex- matched healthy subjects were evaluated by standardized tests on sympathetic and parasympathetic functions of the cardiovascular system. Symptoms of autonomic dysfunction were screened by questionnaire.

Results: 96.0% of NPSLE and non-NPSLE patients reported one or more autonomic symptoms (24/25 for both groups) compared with 37.5% (6/16) of healthy subjects ($p<0.001$). Patients with NPSLE had more complaints over urinary frequency (48% vs. 20%, $p=0.04$) and incomplete voiding (48% vs. 12%, $p=0.005$) than non-NPSLE patients. They had significantly lower heart rate response to standing compared with healthy controls (1.12±0.12 vs. 1.26±0.11, $p=0.003$ by post hoc Tukey's test) but not with non-NPSLE patients (1.17±0.11, $p=0.44$). NPSLE patients also had significantly smaller heart rate variation during deep breathing compared with non-NPSLE patients (13.1±5.3 vs. 19.5±6.1 bpm, $p=0.01$ by post hoc Tukey's test). Linear

regression analysis showed NPSLE as predictive factor for smaller heart rate variability during deep breathing (p=0.02) after adjustment for age. However, NPSLE was not found to have more autonomic dysfunction than non-NPSLE patients when Ewing's criteria were applied.

Conclusion: NPSLE patients were found to have smaller heart rate variation during deep breathing compared with non-NPSLE patients but the frequency of autonomic dysfunction was similar in both groups.

1598

Cognitive Dysfunction, a Non-Inflammatory Neuropsychiatric Syndrome In Systemic Lypus Erythematosus. Juanita Romero-Díaz[1], Alí Duarte-García[2], Sandra Juarez-Arellano[3], Alba Cicero-Casarrubias[1], Hilda Fragoso-Loyo[4], Luis Llorente[5] and Jorge Sánchez-Guerrero[6]. [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Tufts Medical Center, Boston, MA, [3]Instituto Nacional de Ciencias Medicas y Nutricion S.Z., Mexico city, Mexico, [4]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico, [5]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubirán, Mexico City, Mexico, [6]Mount Sinai Hospital and University Health Network, Toronto Canada, Toronto, ON.

Background/Purpose: Cognitive dysfunction (CD) affects 15 – 60% of SLE patients; nevertheless, its pathogenesis and predisposing factors are unknown.

Objective: To identify factors associated with CD in SLE, focusing on clinical manifestations, neuropsychiatric syndromes (NPSLE), disease activity, inflammation, treatment, and co-morbidities.

Methods: Patients and methods: A random sample of 100 ambulatory patients from a prospective cohort of SLE of recent-onset (<12 months) at enrollment, participated. At entry into the cohort, patients have a standardized medical history with emphasis in atherosclerosis and NPSLE, physical examination, and laboratory tests (chemical analyses, lipids, homocystein, hsCRP, autoantibodies, complement, etc.). Every 3–6 months, patients are seen for medical care, and disease activity (SLEDAI-2K), medications use/dose are assessed. Every year, information is up-dated; including damage accrual (SLICC-DI), co-morbidities, cardiovascular risk-factors, NPSLE, and a blood sample is drawn. Clinical information is stored in a database containing demographic, anthropometric, lifestyle habits, medical family history, obstetric variables, and lupus information. Two rheumatologists perform all assessments.

At screening for CD, participants were assessed using: Trail Making test, Digit Span, California Verbal Learning test, Rey-Osterrieth complex figure test, the Stroop Color-Word test, WAIS III letter-number sequencing, Animal naming test, Controlled Oral Word association, WAIS-R/III digit symbol substitution test, Grooved pegboard test, and WAIS-R/III similarities. Tests were grouped in 7 cognitive domains: memory, attention/executive function, visuospatial, motor, psycho-motor speed, language, and problem solving. An expert neuropsychologist applied and graded the cognitive tests. Cognitive Dysfunction was defined as at least −2 SD in 2 or more cognitive domains. A nested analysis of autoantibodies, cytokines and chemokines in serum and cerebrospinal fluid (CSF) was conducted among 10 patients with moderate/severe CD and 30 patients without CD.

Results: At enrolment into the cohort, mean age of patients was 25.9 (8.2) years, and SLE duration 5.3 (3.7) months. At screening for CD, mean age was 32.6 years, 93% females, SLE duration 6.2 years. CD was diagnosed in 16 (16%) patients, since age 24 years and from 1.2 years of diagnosis. Patients with CD had lower education 9 vs.12 years (p=0.006), higher BMI 26.7 vs. 24.3 (p=0.03), tested positive of IgG aCL antibodies (50% vs. 18%, p=0.009), and were older (35 vs. 31 years, p=0.09). They had had other NPSLE more often (50% vs. 27%, p=n.s.) and their median number was higher (2.5 vs. 1, p=0.04). No difference was observed in other variables including disease activity, anti-dsDNA antibodies, C3, C4, or treatment.

No difference in autoantibodies, cytokines and chemokines was observed in serum and CSF in the nested analysis, except for higher levels of MCP-1 in CSF (886.1 vs. 515.8, pg/mL, p=0.04) among patients with CD.

Conclusion: Cognitive dysfunction is a non-inflammatory NPSLE syndrome. Lower education, higher BMI, presence of IgG aCL antibodies, and previous NPSLE syndromes influence its onset.

High Proportion Of Intrathecal Ro52 SSA Antibodies In Neuropsychiatric Lupus Patients – Relations To Neuropsychiatric Manifestations. Johanna Estelius, Liisa Hopia, Vijole Dzikaite-Ottosson, Magnus LA. Andersson, Elisabet Svenungsson and Jon Lampa. Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Neuropsychiatric (NP) manifestations in Systemic Lupus Erythematosus (SLE) are often associated with significant impact on quality of life and work capability. The underlying mechanisms behind NPSLE are still largely unknown. Here, we aimed to investigate the associations between the occurrence of Ro52 SSA autoantibodies and manifestations of NPSLE.

Methods: Presence or absence of SSA antibodies were detected with a non-quantitative in-house Ro52 ELISA in serum and cerebrospinal fluid (CSF) samples from a cohort of unselected SLE patients displaying neuropsychiatric features, collected between 2005 and 2011. Sensitivity of the assay was tested against confirmed Ro52 negative and positive individuals in serum. All SSA serum negative patients were also SSA negative in CSF indicating specificity of the assay. Blood brain barrier (BBB) permeability was calculated with the serum/CSF albumin ratio, and a ratio < 5.7 – 9 (age related) was considered to associate with an intact BBB.

Results: 55 NPSLE patients (mean age 50, 93% women) with paired serum and CSF samples were included in the analysis. Out of these, 40% (n=22) tested positive for SSA in serum. 64% (n=14) of SSA serum positive patients were also SSA positive in CSF (double positive), leaving 8 patients SSA positive in serum only (single positive). The distribution of major clinical NP manifestations in the total group of NPSLE patients was as follows (overlapping data): seizures 27% (n=15), headache 46% (n=25), cognitive dysfunction 31% (n=17), mood disorder or depression 11% (n=6) and stroke 11% (n=6). In the SSA double positive group this distribution was 29% (seizures), 29% (headache), 57% (cognitive dysfunction), 29% (mood disorder or depression) and 7% (stroke) respectively. There was a tendency that double positive patients had higher frequency of cognitive dysfunction than the other groups (57% (double positive) vs. 25% (single positive) and 31% (total)), however, this did not reach statistical significance. No clear differences were found between the groups concerning the other NP manifestations, distribution of ACR SLE criteria, age, disease duration, presence of brain lesions, cortisone treatment or smoking.

Conclusion: Presence of serum SSA autoantibodies in 40% of the NPSLE patients is in line with previous reports; however, our finding of high prevalence of double serum- and CSF SSA positivity in NPSLE patients was unexpected and indicates either facilitated passage over the BBB or intrathecal production of these autoantibodies. Our assay did not allow quantitative comparisons, but patients with confirmed intact BBB showed similar relation in SSA serum vs. CSF positivity, thus excluding BBB breakage as a main factor for detection of intrathecal SSA in this context. Moreover, intrathecal SSA tended to associate with cognitive dysfunction. Altogether, our results indicate the possibility of SSA antibodies interacting with cerebral functions, which may be in line with previous reports showing that other lupus-associated autoantibodies, i.e. anti-dsDNA antibodies, may cross react with neuronal N-metyl-D-aspartat (NMDA) receptors affecting neuron function and viability.

Anti-Ribosomal P Protein Antibodies Exacerbate Long-Term Prognosis In Patients With Diffuse Neuropsychiatric/Neuropsychological Syndromes In Systemic Lupus Erythematous. Yoshiyuki Arinuma[1], Hirotoshi Kikuchi[2], Eisuke Ogawa[1], Tatsuhiko Wada[1], Tatsuo Nagai[1], Sumiaki Tanaka[1] and Shunsei Hirohata[1]. [1]Kitasato University School of Medicine, Sagamihara, Japan, [2]Teikyo University School of Medicine, Tokyo, Japan.

Background/Purpose: Systemic lupus erythematous (SLE) is a chronic inflammatory disease characterized by the expression of a variety of autoantibodies. Although the comprehensive survival from the disease has been improved in recent decades, neuropsychiatric manifestations in SLE (NPSLE) still remain one of the difficult complication. However, the factors that influence the long-term mortality in patients with NPSLE, especially diffuse neuropsychiatric/neuropsychological syndromes (diffuse NPSLE), have not been fully elucidated. Anti-ribosomal P protein antibodies (anti-P) are detected in 12–16% of patients with SLE, and have been shown to be

associated with diffuse NPSLE. The aim of this study is to clarify the effects of various autoantibodies, including anti-P, on the overall mortality in patients with diffuse NPSLE.

Methods: Fifty-eight patients with diffuse NPSLE (9 males and 49 females, ages 38.6 ± 17.0 years [mean ± SD]) who had been admitted to Kitasato University Hospital and to Teikyo University Hospital from 1992 to 2012 were exhaustively collected for the study. The medical charts were reviewed for various clinical parameters. The relationship of various serum autoantibodies with overall mortality was analyzed.

Results: Of 58 patients, 12 patients [20.7%] died during the observation periods (2322 ± 2250 days [mean ± SD]) including 6 patients from SLE itself, 5 patients from infections and 1 patient from aortic aneurysm. The 5-year, 10-year and 15-year mortality rates based on the Kaplan-Meier method were 17.9%, 22.0% and 30.7%, respectively. The overall mortality was neither correlated with age nor with the duration of SLE at the onset of diffuse NPSLE. Among various autoantibodies in the sera, the presence of anti-P, but not that of anti-DNA, anti-Sm or anti-cardiolipin (CL) antibodies, at the onset of diffuse NPSLE, significantly increased the hazard ratio for death of the patients (p=0.0447). Moreover, on the Kaplan-Meier analysis, the survival rate was lower in patients with positive anti-P than those with negative anti-P at the onset (p=0.0711).

Table. Logistic regression analysis of effects of various autoantibodies on the death in patients with diffuse NPSLE

autoantibodies	HR	95% CI	p	n
anti-DNA	0.923	0.244–3.616	0.906	57
anti-Sm	0.785	0.204–3.107	0.722	54
anti-CL	1.333	0.171–7.405	0.754	43
anti-P	4.909	1.0954–26.729	0.0447	47

HR = hazard ratio. CI = confidence interval.

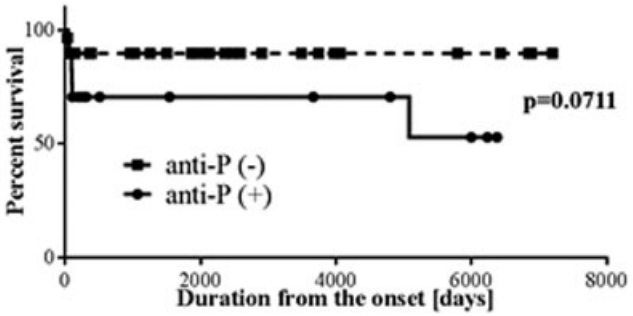

Figure. The effect of anti-P on the survival in patients with diffuse NPSLE.

Conclusion: These results indicate that the presence of anti-P in the sera is a significant risk factor for the poor prognosis of diffuse NPSLE.

1601

The Presence Of IgG-Immune Complexes In The Cerebrospinal Fluids Is Associated With Central Neurocychiatric Manifestatin But Not With Intrathecal Production Of Proimmflammatory Cytokines/Chemokines Such as Interferon-α In Systemic Lupus Erythematosus. Taku Yoshio[1], Hiroshi Okamoto[2], Kazuhiro Kurasawa[3], Yoshiaki Dei[4], Shunsei Hirohata[5] and Seiji Minota[6]. [1]Jichi Medical University, School of Medicine, Shimotsuke-shi, Tochigi-ken, Japan, [2]Minami-Otsuka Clinic, Tokyo, Japan, [3]Dokkyo Medical University, Mibu-machi, Shimotsuga-gun, Tochigi-ken, Japan, [4]Saiseikai Utsunomiya Hospital, Utsunomiya-shi, Tochigi-ken, Japan, [5]Kitasato University School of Medicine, Sagamihara, Japan, [6]Jichi Medical University, Shimotsuke, Tochigi, Japan.

Background/Purpose: IgG-Immune complexes (IC) formed by CSF autoantibodies in patients with neuropsychiatric syndromes of systemic lupus erythematosus (NPSLE) has reported to stimulate the production of interferon (IFN)-α, IL-8, IP-10, MCP-1 in a bioassay containing plasmacytoid dendritic cells and a source of antigens. The pathological roles of these cytokines/chemokines in the CSF has been reported in patients with NPSLE. These results suggest that IgG-IC in the CSF may have pathogenic roles in central NPSLE.

We investigated whether IgG-IC are present in the CSF of patients with central NPSLE and correlated with cytokines/chemokines such as IFN-a levels in the CSF.

Methods: 50 SLE patients, of whom the CSF samples were obtained, were enrolled. Of 50 SLE patients, 29 had central NPSLE and the reminder 21 did not have central NPSLE. The levels of IgG-IC in the CSF samples were measured by ELISA kits. The levels of IL-6, IL-8, IP-10, MCP-1, and G-CSF in the CSF samples were measured by Bio-Plex Pro Assays. IFN-α in the CSF samples were measured by ELISA kits. Antiribosomal P protein antibody (anti-P) titers in the CSF samples were measured by ELISA using recombinant ribosomal P0 protein as the antigen.

Results: CSF IgG-IC levels in 29 patients with central NPSLE were significantly higher than in 21 patients without central NPSLE (mean ± SD, median [range]; 3.75 ± 4.80 μg/ml, 1.28 [0.09 – 18] vs. 1.01 ± 1.40 μg/ml, 0.49 [0.09 – 6.38]; p = 0.047). The CSF levels of IL-6, IL-8, IP-10, MCP-1, and G-CSF and CSF anti-P titers in 29 patients with central NPSLE were significantly higher than those in 21 patients without central NPSLE, respectively (275.1 ± 595.9 pg/ml, 17.4 [1.9 – 2882.2] vs. 11.6 ± 12.8 pg/ml, 5.0 [1.3 – 45.2]; p = 0.007, 482.5 ± 1697.6 pg/ml, 99.2 [17.7 – 9233.7] vs. 58.5 ± 81.2 pg/ml, 31.0 [6.3 – 366.8]; p = 0.004, 8988.0 ± 15406.2 pg/ml, 3248.2 [228.7 – 76941.5] vs. 2988.3 ± 4126.9 pg/ml, 1137.8 [427.6 – 15765.1]; p = 0.034, 555.7 ± 481.0 pg/ml, 387.6 [35.6 – 2008.5] vs. 284.3 ± 161.5 pg/ml, 265.1 [55.6 – 664.6]; p = 0.021, 71.5 ± 156.0 pg/ml, 33.4 [0.81 – 779.4] vs. 15.5 ± 24.8 pg/ml, 3.9 [0 – 102.7]; p = 0.009 and 6.90 ± 9.36 CSFU/ml, 2.6 [0 – 31.0] vs. 3.75 ± 9.25 CSFU/ml, 0.95 [0.14 – 41.3]; p = 0.021). Unexpectedly, CSF IFN-α levels in patients with central NPSLE were not significantly higher than in patients without central NPSLE (13.1 ± 58.9 pg/ml, 0 [0 – 314.0] vs. 0.17 ± 0.75 pg/ml, 0 [0 – 3.4]; p = 0.565). Discriminant analysis showed the most significant association between IgG-IC levels in the CSF and the presence of central NPSLE (P = 0.02). However, CSF IgG-IC levels in these patients were not significantly correlated with CSF levels of any of the studied cytokines/chemokines. The significant positive association between CSF IgG-IC levels and CSF anti-P titers was not observed in these patients.

Conclusion: The intrathecal IgG-IC might have important roles in the pathogenesis of central NPSLE. But the intrathecal IgG-IC was not associated with the intrathecal production of cytokines/chemokines studied in this study.

Autoantibodies, Cytokines and Chemokines In Serum and Cerebrospinal Fluid Of SLE Patients With Cognitive Dysfunction. Hilda Fragoso-Loyo[1], Alí Duarte-García[2], Sandra Juárez-Arellano[3], Alba Cicero-Casarrubias[4], Juanita Romero-Díaz[4], Luis LLorente-Peters[1] and Jorge Sánchez-Guerrero[5]. [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico, [2]Tufts Medical Center, Boston, MA, [3]Instituto Nacional de Ciencias Medicas y Nutricion S.Z., Mexico city, Mexico, [4]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [5]Mount Sinai Hospital and University Health Network, Toronto Canada, Toronto, ON.

Background/Purpose: The nature and pathogenesis and cognitive dysfunction (CD) in patients with SLE is unkown. To determine the presence and levels of autoantibodies, cytokines and chemokines in serum and cerebrospinal fluid (CSF) of SLE patients with CD.

Methods: 40 patients participating in a larger study of CD in SLE were analyzed. All patients are active members in a prospective cohort of SLE of recent-onset at enrollment. At entry into the cohort, patients have a standardized medical history, and laboratory tests. Every 3–6 months, patients are seen for medical care, and disease activity (SLEDAI-2K), medications use/dose are assessed. Every year, information is up-dated; including damage accrual (SLICC-DI), co-morbidities, cardiovascular risk-factors, NPSLE, and a blood sample is drawn. All patients were screened for CD using: Trail Making test, Digit Span, California Verbal Learning test, Rey-Osterrieth complex figure test, the Stroop Color-Word test, WAIS III letter-number sequencing, Animal naming test, Controlled Oral Word association, WAIS-R/III digit symbol substitution test, Grooved pegboard test, and WAIS-R/III similarities. Tests were grouped in 7 cognitive domains: memory, attention/executive function, visuospatial, motor, psycho-motor speed, language, and problem solving. Cognitive Dysfunction was defined as at least −2 SD in 2 or more cognitive domains.

In all patients a blood and CSF sample were drawn and the following autoantibodies were measured: NMDA, nucleosomes, ribosomal-P, ds-DNA, b_2-glycoprotein-I IgG and IgM, anticardiolipin IgG and IgM. Cytokines [Interferon-alpha(IFN- a), Interleukin-6 (IL-6)] and chemokines [monocyte chemoattractant protein-1 (MCP-1), gamma interferon inducible protein-10 (IP-10), Interleukin-8 (IL-8), and CCL-19] were analyzed by luminometry. Results are expressed as pg/mL.

Results: CD was diagnosed in 10 patients. Patients with CD had median age of 33 years (24 – 57), disease duration 7.0 years, and SLEDAI-2K score 5 (0 – 14) at CD assessment and did not differ from patients without CD.

No difference in autoantibodies, cytokines and chemokines was observed in serum between patients with and without CD.

In CSF, no difference in the levels of autoantibodies and cytokines was observed; however, MCP-1 was significantly higher among patients with CD [886.1 (374.9 – 1439.7) vs. 515.8 (3.2 – 1958.2) pg/mL, p=0.04]. No difference was observed with other chemokines.

Conclusion: The levels of autoantibodies, cytokines, and chemokines in serum and CSF do not differ between patients with or without CD. Although the levels of MCP-1 in CSF were higher in patients with CD, they do not reach the levels observed in inflammatory NPSLE manifestations. These results support that CD is a non-inflammatory NPSLE manifestation.

1603

Sustained Reductions In Circulating B Cell Populations and Immunoglobulin G Levels With Long-Term Belimumab Treatment In Patients With Systemic Lupus Erythematosus. Herbert Struemper[1], William Freimuth[2], Christi Kleoudis[3], Thi-Sau Migone[4], David Roth[3] and William Stohl[5]. [1]GlaxoSmithKline, Research Triangle Park, NC, [2]Human Genome Sciences, Inc., Rockville, MD, [3]GlaxoSmithKline, King of Prussia, PA, [4]Igenica, Burlingame, CA, [5]University of Southern California Keck School of Medicine, Los Angeles, CA.

Background/Purpose: Belimumab treatment in autoantibody-positive systemic lupus erythematosus (SLE) patients for up to 76 weeks results in sustained reduction in several circulating B cell subsets, including naïve and activated B cells, as well as in serum immunoglobulin (Ig) levels. The purpose of the present analysis was to examine long-term changes in B cell subsets and IgG beyond 76 weeks through 172 weeks of continued belimumab treatment.

Methods: B cell, B cell subset and IgG data were collected in the Phase 3 Study BLISS-76 (NCT00410384; N=819) and in its US extension study (NCT00724867; N=268). All B cell subsets were measured at baseline, Weeks 8, 24, 52, 76, 100, 124, 148 and 172. Subjects randomized to 1 mg/kg or 10 mg/kg cohorts in BLISS-76 received bi-weekly doses of belimumab for the first month followed by dosing every 4 weeks thereafter. Placebo subjects, who chose to enter the extension study, received 10 mg/kg belimumab every 4 weeks starting at Week 76. Subjects in all cohorts received standard of care SLE agents (eg. corticosteroids, immunosuppressants, and/or antimalarials).

Results: Most B cell subsets in peripheral blood showed a rapid initial decline over the first 24 weeks followed by a comparatively slower decline or sustained suppression. Memory B cells were an exception and roughly doubled by Week 8, followed by a slow and sustained decline through Week 172. Beyond 76 weeks of treatment, B cell reductions either stabilized (naïve and plasma B cells), or continued to gradually decrease (CD19+ /CD20+ B cells, memory cells, plasmacytoid B cells) leading to net reductions of about 80–90% for naïve, activated, and plasmacytoid B cells, 70–75% for CD19+/CD20+ B cells and 50–60% for plasma cells after 172 weeks of continued belimumab dosing. Over 172 weeks, a 20–30% reduction in IgG levels was observed. Only 1 completer (10 mg/kg) experienced a shift from no to Grade 3 hypogammaglobulinemia (HGG; <400 mg/dL). Of all belimumab treated subjects, 3 subjects (0.5%) experienced a Grade 3/4 HGG shift. Development of Grade 3/4 HGG was not associated with severe infections.

Results for 1 and 10 mg/kg groups in the timing and magnitude of the response were similar for most measures. Results for placebo patients, who received 10 mg/kg at Week 76, confirmed the response patterns observed for patients who received belimumab at Week 0.

Response in Week 172 completers:

Response parameter	Median % change from baseline (N) Placebo → 10 mg/kg	1 mg/kg	10 mg/kg
$CD20^+$ B cells	−69.3 (57)	−74.3 (63)	−72.2 (46)
$CD19^+$ B cells	−69.2 (65)	−70.6 (68)	−72.2 (51)
$CD20^+/CD27^+$ memory B cells	−16.7 (57)	−35.6 (63)	−37.7 (46)
$CD20^+/CD27^-$ naïve B Cells	−79.4 (57)	−79.7 (63)	−81.6 (46)
$CD20^+/CD69^+$ activated B cells	−90.8 (68)	−89.9 (80)	−85.5 (54)
$CD20^+/CD138^+$ plasmacytoid B cells	−88.6 (61)	−89.8 (70)	−87.9 (50)
$CD20^-/CD138^+$ plasma B cells	−64.1 (61)	−47.2 (70)	−57.9 (51)
IgG	−19.6 (65)	−23.4 (69)	−26.2 (53)

Conclusion: Treatment of SLE patients with belimumab for 172 weeks results in substantial, but subtotal, declines in circulating B cell subsets. These declines are associated with a modest decline in IgG levels and do not appear to be associated with development of severe infections.

1604

Effects Of Chronic Treatment With Blisibimod, An Inhibitor Of B Cell Activating Factor, On Renal and Inflammation Biomarkers In Patients With Systemic Lupus Erythematosus: Observations From The Placebo-Controlled Pearl-SC and Open-Label Extension Studies. Richard A. Furie[1], Matthew Thomas[2], Alvina Chu[3], Renee S. Martin[3], Colin Hislop[3] and Morton A. Scheinberg[4]. [1]The Feinstein Institute for Medical Research and North Shore-Long Island Jewish Health System, Lake Success, NY, [2]Health and Research Centre, Trivandrum, Kerala, India, [3]Anthera Pharmaceuticals Inc, Hayward, CA, [4]Rheumatology Hospital Abreu Sodre Pesquisa Clínica, São Paulo, Brazil.

Background/Purpose: To evaluate the effects of subcutaneously-administered blisibimod on renal and inflammation biomarkers in patients with SLE during the phase 2b clinical trial PEARL-SC (NCT01162681) and the ensuing open-label extension (OLE) study (NCT01305746).

Methods: 547 patients with serologically-active SLE and SELENA SLEDAI ≥6 were randomized to receive placebo or blisibimod. Per SELENA-SLEDAI definitions, 76 subjects (13.9%) had renal involvement at baseline. In the PEARL-SC study, subjects received blinded study drug for up to 52 weeks (with a median of 37 weeks) or until the last subject completed 6 months of therapy. A total of 382 subjects enrolled in the OLE study and received blisibimod. Here we report the effects of blisibimod in subjects who initiated blisibimod therapy in the PEARL study (N=277), evaluating changes on renal and inflammation biomarkers in the combined PEARL and OLE studies through March 2013. In addition, we report blisibimod effects on renal biomarkers in 2 renal subgroups defined as (i) baseline proteinuria equivalent ≥0.5 g/24hr (determined from random spot urinary protein:creatinine ratio, N=41), or (ii) baseline proteinuria equivalent to ≥1g/24hr (N=25).

Results: Compared with baseline, decreases in proteinuria were observed with blisibimod from Week 12 through Week 52 in the subgroup of subjects with proteinuria equivalent ≥1 g/24hr at enrollment (Figure 1A). Similarly decreases in proteinuria were observed in subjects with proteinuria equivalent ≥0.5 g/24hr through Week 44. When compared with response in the patients randomized to receive placebo in PEARL-SC, there was a tendency toward greater decreases in mean GFR in the patients receiving placebo compared with blisibimod at Week 24 in both renal subgroups, eg mean ΔGFR =1.4 and −3.0 mL/min [N=36,37], for blisibimod and placebo respectively in the ≥0.5 g/24hr subgroup.

Consistent with a durable pharmacological effect, decreases in anti-double-stranded DNA (dsDNA) antibodies, and increases in complement C3 and C4 compared with baseline were observed through 52 weeks of blisibmod therapy (Figure 1B, C and D).

Blisibimod was safe and well-tolerated at all dose levels with no meaningful imbalances in serious adverse events or infections between blisibimod and placebo in the PEARL-SC study, and continued to be well-tolerated through the OLE study.

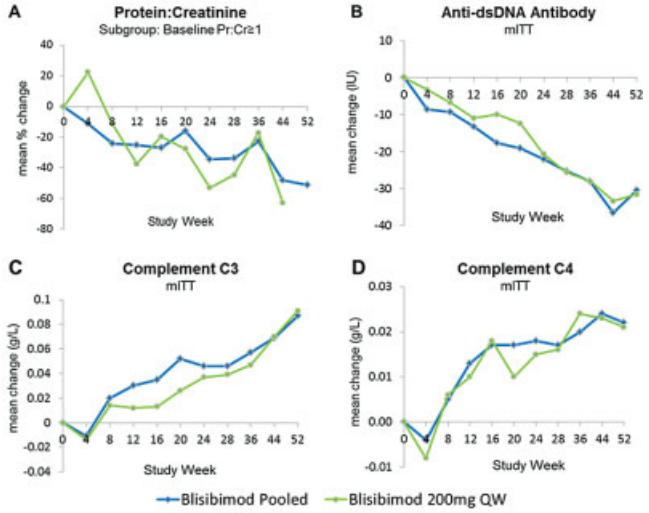

Figure 1. Effect of Blisibimod on Proteinuria and SLE biomarkers.

Conclusion: These data demonstrate that blisibimod induces pharmacological effects on proteinuria and SLE biomarkers that are consistent with BAFF-mediated inhibition of B cells and plasma cells, without adversely impacting the risk of infection in patients with SLE. These data support further evaluation of blisibimod in patients with SLE and other B cell-mediated diseases.

Post-Marketing Experience With Belimumab In U.S. Lupus Centers: Data From The Lupus Clinical Trials Consortium, Inc. (LCTC) National Patient Registry. Jinoos Yazdany[1], Doruk Erkan[2], Jorge sanchez-Guerrero[3], Bevra H. Hahn[4], Alana B. Levine[2], Galina Marder[5], W. Joseph McCune[6] and Ellen M. Ginzler[7]. [1]University of California, San Francisco, San Francisco, CA, [2]Hospital for Special Surgery, New York, NY, [3]Mount Sinai Hospital and University Health Network, Toronto Canada, Toronto, ON, [4]UCLA David Geffen School of Medicine, Los Angeles, CA, [5]North Shore Long Island Health System, Great Neck, NY, [6]University of Michigan, Ann Arbor, MI, [7]SUNY-Downstate Medical Center, Brooklyn, NY.

Background/Purpose: Much of the published experience with belimumab in lupus patients has derived from clinical trials. We examined the non-sponsored experience with belimumab in routine clinical practice among 15 U.S. lupus centers participating in a national patient registry, the Lupus Clinical Trials Consortium, Inc. (LCTC).

Methods: The LCTC registry consists of consecutively enrolled adults with SLE from U.S. centers, each contributing approximately 100 patients. Patients who received at least one belimumab infusion after enrollment in the registry between March 2011, the date of FDA approval, and April 2013 were analyzed. We investigated clinical characteristics, indications for belimumab, and reasons for discontinuation. We calculated changes in SELENA-SLEDAI, physician global assessment, glucocorticoid dose, and serological parameters between baseline and follow-up at 6 months and 1 year for those maintained on the drug.

Results: Among 1189 patients followed for 27,469 months (mean 23.2 months), 68 patients started belimumab (5.7%). Mean treatment duration was 13.2 months (SD 6.7). Three centers started no patients on the drug, and the remaining started between 1–5 patients. In the 68 treated patients, mean age was 39.1 years (SD 12), 94% were female, 41% Caucasian, 47% Black and 12% Hispanic. Mean disease duration was 10.7 years (SD 8). Mean SELENA-SLEDAI at drug initiation was 4.4 (SD 4.3, range 0–22). 30 patients (44%) had a positive dsDNA upon starting belimumab and 15 (22%) had low complements. The mean physician global assessment was 1.4 on a scale of 0–3 (SD 0.7). 56 patients (82%) were on glucocorticoids, with a mean prednisone dose of 14.6 mg (SD 23). 27% received azathioprine, 31% mycophenolate mofetil, 15% methotrexate, and 75% an anti-malarial. The most common reasons for belimumab initiation were arthritis (52%), mucocutaneous disease (19%), and serositis (8%). 12 patients received the drug solely for maintenance, and 4 solely for steroid-sparing. After 898 person-months of follow-up, 18 patients discontinued belimumab (4 for adverse events/intolerability, 3 lack of efficacy, 3 no longer needed it, 3 patient preference, and 1 for insurance reasons). Response at 6 months and 1 year for those maintained on belimumab is shown in the Table.

Table. Serological and lupus progression characteristics at treatment initiation, 6 months, and 12 months following belimumab administration among 68 patients.

	Belimumab initiation	Six month follow-up	One year follow-up
N	**68**	**58**	**44**
Mean SELENA-SLEDAI (N)	**68**	**58**	**44**
Mean ± SD	4.40±4.32	3.09±3.41*	2.30±2.79**
Mean physician global assessment (N)	**62**	**51**	**37**

Prednisone equivalent dose (N)	**55**	**45**	**33**
Mean ± SD	17.8±23.7	14.4±15.6	16.0±27.9
C3 (N)**	**64**	**54**	**40**
Mean ± SD	22.8±28.5	23.7±32.2	31.5±42.2*
Low (%)	60 (93.8)	49 (90.7)	34 (94.4)
Returned to normal from prior 6 months	–	2/47 (4.3)	2/36 (5.6)
C4 (N)**	**63**	**54**	**41**
Mean ± SD	7.1±9.2	7.6±11.5	9.1±13.8
Low (%)	51 (81.0)	45 (83.3)	32 (94.1)
Returned to normal from prior 6 months	–	1/39 (2.6)	2/34 (5.9)
Anti ds-DNA (N)**	**62**	**41**	**26**
Positive (%)	30 (48.4)	22 (53.7)	13 (50.0)
Became negative from last follow-up (%)	–	1/20 (5.0)	1/12 (8.3)

P values are two-tailed and represent results of paired t-tests.
* $p < 0.05$, ** $p < 0.01$,
**C3, C4, and anti-dsDNA results reflect available data collected +/−3 months of each time point examined.
Note: Because the components of the British Isles Lupus Assessment Group Index (BILAG) was not collected, the BILAG it is not presented here and the SLE responder Index or SRI could not be calculated

Conclusion: Since the approval of belimumab, 5.7% of patients enrolled in the LCTC registry have received the drug in routine clinical practice. Utilization was similar across centers; the primary indications were arthritis and mucocutaneous disease. After 6 and 12 months, there were statistically significant improvements in SELENA- SLEDAI and physician global assessment. There was no statistically significant steroid-sparing effect. 65% of patients remained on belimumab by one year.

Overview Of The Safety Of Epratuzumab In Systemic Lupus Erythematosus. Daniel J. Wallace[1], Josep Ordi-Ros[2], C. Michael Neuwelt[3], Kenneth Kalunian[4], Michelle A. Petri[5], Slawomir Jeka[6], Ronald F. van Vollenhoven[7], Brian Kilgallen[8], Sabine Bongardt[9], Caroline Gordon[10] and Vibeke Strand[11]. [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Vall De Hebron General Hospt, Barcelona, Spain, [3]East Bay Rheumatology Research Institute, San Leandro, CA, [4]UCSD School of Medicine, La Jolla, CA, [5]Johns Hopkins University School of Medicine, Baltimore, MD, [6]2nd University Hospital in Bydgoszcz Medical College of Nicolaus Copernicus University, Bydgoszcz, Poland, [7]The Karolinska Institute, Stockholm, Sweden, [8]UCB Pharma, Raleigh, NC, [9]UCB Pharma, Brussels, Belgium, [10]University of Birmingham, Birmingham, United Kingdom, [11]Stanford University, Palo Alto, CA.

Background/Purpose: The efficacy and safety of epratuzumab, a monoclonal antibody targeting CD22, has been evaluated in patients with moderate-to-severe systemic lupus erythematosus (SLE). A pooled analysis of epratuzumab adverse event (AE) data from open-label extension (OLE) studies in SLE is provided.

Methods: AE data were pooled from 2 completed OLE pilot studies (015 and SL0002 [NCT00113971]), and 4 completed and on-going long-term OLE studies (SL0006 [NCT00383513], EMBLEM™ OLE [NCT00660881],

SL0012 [NCT01408576] and SL0027 [NCT01534403]. Data are presented for epratuzumab at a total monthly dose of 2400 mg (dose used in Phase III studies). These analyses are presented as event rates (AEs/100 patient-years [pt-yrs]) and as the proportion of pts experiencing each AE. Malignancies classified as serious AEs are reported.

Results: As of 15 April 2013 in OLE studies, 488 pts with moderate-to-severe SLE had received a total of 726 pt-yrs of exposure to epratuzumab. The overall rate of AEs, serious AEs (SAEs) and infusion reactions per 100 pt-years was 457.6, 21.1 and 23.1 respectively (Table). 40 patients (8.2%) withdrew due to AEs. The most common AEs (≥10% incidence for all epratuzumab dose group) were upper respiratory tract infection (17.0%), urinary tract infection (13.9%) and headache (12.3%). The most common SAEs (≥3 pts) were worsening of SLE (1.8%), cholelithiasis (0.6%), pneumonia (0.6%), sepsis (0.6%), depression (0.6%) and dyspnea (0.6%). The most common serious infections were pneumonia and sepsis (0.6 and 0.4 per 100 pt-yrs respectively). Malignancies were reported in 3 pts; 1 CNS lymphoma, 1 squamous cell CA and 1 patient experienced basal cell CA, breast CA and lip neoplasm. There were 6 deaths; 5 with known causes: bilateral lobal pneumonia, pneumonia/septic shock/acute respiratory failure, chronic heart failure, polydrug overdose, stroke. In 1 case cause was unknown.

Table. Overall summary of AEs with epratuzumab in OLE studies

	Epratuzumab (total monthly dose of 2400 mg) n=488
Total treatment exposure, pt-years	726.0
Any AE, rate per 100 pt-years	457.6
Any AE, n (%)	322 (66.0)
AE leading to discontinuation, n (%)	40 (8.2)
SAEs, rate per 100 pt-years	21.1
SAE, n (%)	91 (18.6)
Serious infectious events, rate per 100 pt-years	4.0
Serious infectious events, n (%)	24 (4.9)
Infusion reactions, rate per 100 pt-years	23.1
Infusion reactions, n (%)	53 (10.0)

Conclusion: Epratuzumab at a total monthly dose of 2400 mg was well tolerated. These data, based on >700 pt-years of exposure, support the ongoing development of epratuzumab for treatment of SLE.

Two Year Follow-Up On Biologics Use In 13 Centers- Data From The International Registry For Biologics In Systemic Lupus Erythematosus. Ronald F. van Vollenhoven[1], Melinda Mild[2], Søren Jacobsen[3], S. Bernatsky[4], Daniel J. Wallace[5], Sang-Cheol Bae[6], Manuel Ramos-Casals[7], Francisco J. García-Hernández[8], R. Ramsey-Goldman[9], Andrea Doria[10], Marta Mosca[11], Michelle A. Petri[12], M Ayala-Gutiérrez[13], J.G. Hanley[14] and for The SLICC group[15]. [1]Unit for Clinical Therapy Research, Inflammatory Diseases (CliniTRID), the Karolinska Institute, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]Department of Rheumatology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [4]McGill UHC/RVH, Montreal, QC, [5]Cedars-Sinai Medical Center, Los Angeles, CA, [6]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [7]Hospital Clínic, Barcelona, Spain, [8]Hospital Virgen del Rocío, Sevilla, Spain, [9]Northwestern University Feinberg School of Medicine, Chicago, IL, [10]University of Padova, Padova, Italy, [11]Rheumatology Unit, University of Pisa, Pisa, Italy, [12]Johns Hopkins University School of Medicine, Baltimore, MD, [13]Hospital Carlos Haya, Malaga, Spain, [14]Division of Rheumatology, Halifax, NS, [15]Department of Medicine, the Karolinska Institute, Stockholm, Sweden.

Background/Purpose: Only one biologic agent has been approved for use in SLE, but some are used off-label in various settings. To obtain systematic information regarding this, members of the SLICC group initiated the International Registry for Biologics in SLE (IRBIS). The entire registry contains data from 28 centers. Here, data are presented from 13 centers for which two-year follow-up was available on patients for whom a biologic was initiated in 2010–2011. The purpose with this study was to analyse the use of biologics in SLE, and assess the results achieved over the first two years after initiation.

Methods: IRBIS investigators provided retrospective data on all patients treated with a biologic for SLE at their center in 2010–2011. Standardized case report forms were used to collect demographic, disease-specific and treatment data at the time of biologic initiation and at yearly follow-ups.

Results: In the entire cohort, 455 patients were treated with rituximab (84%), belimumab (10%), epratuzumab (5%), and anti-tumor necrosis factor agents (abatacept, etanercept and adalimumab, each <1%). The major organ manifestations leading to biologic treatment were lupus nephritis (LN, 44%), hematological (17%), musculoskeletal (16%), skin disease (10%), CNS (4%) and other (9%). Reasons for choosing the biologic were disease-control (73%), steroid-sparing (5%) or both (23%). At biologic initiation mean disease duration (±SD) was 9.5±7.9 years, and mean age was 42.2±12.5. Most patients (91%) were female. Prior to biologic treatment, most patients (91%) had been treated with one or more immunosuppressives (ISs). Just over half (57%) had used 1–2 ISs, 21% had used three, and 13% had used 4–6 ISs.

At two-year follow-up (n=120), SLE disease activity (SLEDAI) and corticosteroid (CS) dose were significantly lower versus baseline (SLEDAI: 9.4±5.3 to 3.1±2.5; CS dose: 10.7±13.9 to 4.8±5.9 mg; mean±SD paired analyses, p<0.0001 for both comparisons). SLICC damage-index remained unchanged.

At baseline, concomitant CS was used in 91% of patients compared to 61% at follow-up. There were six deaths, none attributed to the biologic. In almost half of patients (48%) there was at least one adverse event reported over the indicated follow-up period, of which 5% were attributed to the biologic agent. Serious adverse events included 6 infections, 4 opportunistic infections, posterior reversible encephalopathy syndrome (3), allergic reactions (4).

Conclusion: Rituximab was the biologic used most commonly in this international cohort of patients who were started on biologics in 2010–2011. Biologics were used for a range of SLE manifestations. At two-year follow-up both lupus activity and concomitant corticosteroid dosage had decreased significantly and corticosteroids had been discontinued in 30% of patients.

A Phase I Single-Dose Crossover Study To Evaluate The Safety, Tolerability, Pharmacokinetics, Pharmacodynamics, and Clinical Efficacy Of AMG 811 (anti-IFN-gamma) In Subjects With Discoid Lupus Erythematosus. Victoria P. Werth[1], David Fiorentino[2], Stanley B. Cohen[3], David Fivenson[4], Chris Hansen[5], Steve Zoog[6], Greg Arnold[6], Christine Wang[6], Michael Boedigheimer[6], Andrew Welcher[6], James Chung[6], Barbara Sullivan[6] and David A. Martin[7]. [1]Philadelphia Veterans Affairs Medical Center, Philadelphia, PA, [2]Stanford University School of Medicine, Redwood City, CA, [3]Metroplex Clinical Research Center, Dallas, TX, [4]David Fivenson, MD, Dermatology, PLLC, Ann Arbor, MI, [5]University of Utah School of Medicine, Salt Lake City, UT, [6]Amgen, Thousand Oaks, CA, [7]Amgen, Seattle, WA.

Background/Purpose: Discoid Lupus Erythematosus (DLE) is the most common form of chronic cutaneous LE (CCLE) and develops in up to a quarter of SLE patients. DLE inflammation typically involves hair follicles and the epidermis leading to scaring, atrophy, telangiectasias and/or dyspigmentation. Patients with DLE have an IFN signature in the blood and the skin, and the level of gene expression correlates with cutaneous disease activity. Skin biopsies of DLE lesions show elevated mRNA levels of interferon gamma and provide rationale for a therapeutic trial of AMG 811, a human IgG1 monoclonal antibody that selectively neutralizes human IFN-g.

Methods: This multi-center, randomized, double-blind, placebo-controlled, two-period, crossover study in which 16 subjects with DLE received AMG 811 and placebo in one of two sequences [ie, AMG 811 followed by placebo (n=9) on day 85 or placebo followed by AMG 811 on day 85 (n=7)]. The primary objectives were to evaluate the safety, tolerability and immunogenicity of a single subcutaneous (SC) dose of AMG 811. Secondary objectives focused on the single-dose pharmacokinetic (PK) profile of AMG 811 and changes from baseline in the Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) score following a single SC dose of either AMG 811 or placebo. Adverse events, safety laboratory tests and disease activity were assessed. Serum AMG 811 concentrations were measured by ELISA, and anti-AMG 811 antibodies were measured by an immunoassay. Skin biopsies were obtained from lesional and non-lesional areas pre-dose and from lesional areas on day 15 and 57. T cell and macrophage infiltrate in the skin was quantitated by laser scanning cytometry. Whole blood and skin RNA and serum proteins were analyzed by microarray and ELISA, respectively.

Results: During the study all but one DLE subject (9/9 AMG 811 and 6/7 placebo) experienced treatment-emergent adverse events. AMG 811 displayed linear pharmacokinetics and no immunogenicity to AMG 811 was observed. Changes in the CLASI scores were similar between subjects that received AMG 811 and placebo over the first 85 days, and there was no beneficial effect on disease activity seen in placebo subjects receiving AMG 811 on day 85. IFN-g modulated genes were elevated in both blood and lesional skin, indicating the presence of an interferon signature. In blood AMG 811 led to a dose dependent modulation of the expression of genes previously shown to be modulated by AMG 811 in subjects with SLE. Histopathology and RNA transcript analysis revealed substantial intra- and inter-subject heterogeneity between skin biopsies from DLE subjects at baseline and following AMG 811 treatment. The number of CD3+ T cells and CD68+ macrophages were elevated in the lesional skin compared to non-lesional and there was no apparent reduction following AMG 811.

Conclusion: AMG 811 demonstrated acceptable safety and favorable PK profiles in this single dose study of DLE subjects but there was no apparent clinical benefit. Evidence of a pharmacodynamic effect in the blood (e.g. inhibition of IFN-g) was apparent; however, heterogeneity in skin samples prevented definitive conclusions about the effects of AMG 811 in diseased skin.

AMG 811 (anti-IFN-gamma) Treatment Leads To a Reduction In The Whole Blood IFN-Signature and Serum CXCL10 In Subjects With Systemic Lupus Erythematosus: Results Of Two Phase I Studies. David A. Martin[1], Andrew Welcher[2], Michael Boedigheimer[2], Zahir Amoura[3], Alan Kivitz[4], Jill P. Buyon[5], Jorge Sanchez-Guerrero[6], Juanita Romero-Diaz[7], Alla Rudinskaya[8], Kevin M. Latinis[9], S Cohen[10], Cynthia Aranow[11], Mike Damore[2], Winnie Sohn[2], Kit Chiu[2], Christine Wang[2], Naren Chirmule[2], Barbara Sullivan[2] and James Chung[2]. [1]Amgen, Seattle, WA, [2]Amgen, Thousand Oaks, CA, [3]CHU Pitié-Salpêtrière, Paris, France, [4]Altoona Center for Clinical Research, Duncansville, PA, [5]NYU School of Medicine, New York, NY, [6]Mount Sinai Hospital, University Health Network, Toronto, ON, [7]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [8]Danbury Hospital, Danbury, CT, [9]Latinis Rheumatology, Leawood, KS, [10]Metroplex Clinical Research Center, Dallas, TX, [11]The Feinstein Institute, Manhasset, NY.

Background/Purpose: Interferon-gamma (IFN-g) is a major pro-inflammatory cytokine that modulates the function of several important populations of immune cells including B cells, T cells, and macrophages. Several lines of evidence from animal models and in humans suggest increased levels of Type I and/or Type II IFN are associated with inflammatory disorders including systemic lupus erythematosus (SLE). Although some information is available on the effect of blocking Type I IFNs from human trials in SLE, little is known about the role of Type II. AMG 811 is a human IgG1 monoclonal antibody that selectively targets and neutralizes human IFN- g. The safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of single and multiple dose administration of AMG 811 was assessed in SLE subjects. The studies were not powered to assess efficacy.

Methods: Mild, stable SLE subjects were administered AMG 811 or placebo in single (SD) (n=26) or multiple doses (MD) (n=28) ranging from 2 mg to 180 mg SC or 60 mg IV. Adverse events, laboratory tests and disease activity were assessed. Serum AMG 811 concentrations were measured using an enzyme-linked immunosorbent assay, and anti-AMG 811 antibodies were measured using an immunoassay. Whole blood immunophenotyping parameters were measured by flow cytometry. Whole blood RNA and serum proteins were analyzed pre- and post-dosing by microarray and ELISA, respectively.

Results: In the SD cohorts there were no withdrawals due to adverse events and few adverse events were reported by more than a single subject receiving either AMG 811 or placebo. In the MD cohorts the number of subjects reporting treatment emergent adverse events was similar between placebo (7/8) and AMG 811 (18/20). AMG 811 displayed linear pharmacokinetics and properties consistent with a typical IgG1 antibody. Immunogenicity to AMG 811 was low in both SD (1/18) and MD (none observed) cohorts. There were no detectable changes in expression of MHC I or II on circulating immune cells following AMG 811 treatment. AMG 811 led to a dose dependent and reversible modulation of the expression of many genes associated with IFN-g signaling and that are differentially expressed in lupus patients. The list of impacted genes and the magnitude of modulation following AMG 811 treatment in SLE subjects suggests that the lupus 'interferon signature' is not solely derived from Type 1 IFNs. Levels of several serum proteins were elevated at baseline relative to healthy individuals, including CXCL10 (IP-10), which has been associated with increased disease activity and to correlate with future SLE flare. Treatment with AMG 811 led to dose-related and reversible reduction in CXCL10 in both single- and multiple-dose settings.

Conclusion: AMG 811 demonstrated acceptable safety and favorable PK profiles in single and multiple dose studies in mild SLE subjects. AMG 811 administration impacted IFN-associated gene expression. AMG 811 reduced serum CXCL10 levels in a dose and concentration dependent manner. No impact of AMG 811 on disease activity was observed in these mild, stable SLE patients. These data support further evaluation of AMG 811 as a therapeutic for SLE, including subjects with active lupus nephritis.

Lymphoablation Including B Cell Depletion and Autologous Hematopoietic Stem Cell Transplantation Leads To Long Remissions In Treatment-Resistant Systemic Lupus Erythematosus Patients. Sarfaraz A. Hasni[1], Gabor G. Illei[2], Nikolay P. Nikolov[3], Francis Hakim[4], Susan Leitman[4], James E. Balow[5], Howard A. Austin[6], Juan Gea-Banacloche[4], Unsong Oh[7], Paulo Muraro[8], Claude Sportes[9], Peter E. Lipsky[10], Ronald Gress[9], Steve Pavletic[9] and Amrie Grammer[10]. [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [2]NIDCR/NIH, Bethesda, MD, [3]NIDCR, NIH, Bethesda, MD, [4]NCI, NIH, Bethesda, MD, [5]National Institutes of Health, Bethesda, MD, [6]NIDDK/NIH, Bethesda, MD, [7]NINDS, NIH, Bethesda, MD, [8]NINDS/NIH, Bethesda, MD, [9]NCI/NIH, Bethesda, MD, [10]NIAMS/NIH, Bethesda, MD.

Background/Purpose: Over the past two decades, approximately 200 patients with severe systemic lupus erythematosus(SLE) have received autologous hematopoietic stem cell transplants (autoHSCT). More than half of these patients achieved clinical remission, but the duration of clinical benefit is variable and not well defined. We report long term clinical outcomes of eight refractory SLE patients in whom B cell depletion was combined with a reduced intensity T cell lymphoablative conditioning regimen before autoHSCT.

Methods: Eight patients were enrolled with active SLE despite prior treatment with IV cyclophosphamide (CYC): 2 had transverse myelitis, 1 retinal vasculitis and 5 WHO Class IV nephritis. Stem cell mobilization consisted of 2,000 mg/m^2 CYC, 750 mg/m^2 rituximab (RTX) and G-CSF.

The conditioning regimen consisting of 750 mg/m^2 RTX, 4.8 g/m^2 CYC and 120 mg/m^2 fludarabine was followed by CD34+ selected stem cell infusion and G-CSF.

All immunosuppressive medications and hydroxychloroquine were discontinued at the start of mobilization and steroids were rapidly tapered off after the transplant. Clinical response was evaluated by organ specific response criteria. Disease activity indices (SLEDAI and SLAM) were used to assess overall lupus activity. The primary endpoint was complete response (CR) at 24 months defined as no lupus activity and no treatment for lupus (including HCQ and steroids).

Immune depletion and reconstitution was followed by multiparameter flow cytometry.

Results: Of the 8 patients, there were 2 early infectious deaths (one from diffuse alveolar damage associated with coronavirus infection, one from mycobacterial meningoencephalitis) at 6 and 5 months post autoHSCT, respectively in subjects with no signs of active SLE. Four patients have had no disease activity in the 7 years of follow up and continue to have SLEDAI of 0 since 3 months after auto-HSCT. Two patients had lupus flares (at 6 and 18 months post-HSCT) which was subsequently well controlled requiring only modest doses of immunosuppressive medications (one on prednisone <10 mg/day and one on daily azathioprine). Six patients had no evidence of serological disease activity post autoHSCT, whereas one early response patient and one patient who flared at 6 months continued to have positive ANA and anti-SSA antibody with negative anti-ds-DNA antibody.

In responding patients, autoHSCT resulted in a loss of memory B cells and plasma B cells and recovery of naïve T and B cell populations in the first year after transplant. Notably, in contrast, the patient who flared at 6 months had an early reappearance of circulating plasma cells that preceded the flare.

Conclusion: The novel regimen that included B cell depletion, modified immunoablation and autoHSCT resulted in sustained medication free remission in one half of the refractory SLE patients and a marked reduction in disease activity in another quarter. There were 2 (25%) deaths from infection, although these patients had no evidence of active SLE at the time of death. Whereas long term remission of SLE activity appears possible with this approach, additional studies are required to assess risk: benefit ratio and the appropriate patient population to treat.

1611

Off-Label Use Of Rituximab For Systemic Lupus Erythematosus in Europe: Limited Use Mostly In Refractory Patients. Ronald F. van Vollenhoven[1], Melinda Mild[2], Andrea Doria[3], T. Dörner[4], Gianfranco Ferraccioli[5], Frederic Houssiau[6], T.W.J. Huizinga[7], David A. Isenberg[8], László Kovács[9], Guillermo Ruiz-Irastorza[10], Danilo Squatrito[11], Alexandre Voskuyl[12], Marta Mosca[13], G D Sebastiani[14], Murat Inanç[15], Gabriella Szücs[16], Søren Jacobsen[17], A. Castro[18] and for The IRBIS-EMA group[19]. Background/Purpose: Rituximab (Rituxan, Mabthera; RTX) has not been approved for use in SLE, but uncontrolled observations have suggested efficacy in some patients and the medication can be used off-label in many European countries. We previously reported that based on data from the IRBIS registry and additional data from investigators, between 0.5 and 1.3% of European patients with SLE have been treated, off-label, with RTX. The objective for this study was to compare characteristics of SLE patients treated off-label with RTX to those of SLE patients treated with conventional, non-biological immunosuppressives (ISs) at the same specialty centers.

Methods: Investigators participating in the International Registry for Biologics in SLE (IRBIS), which was initiated by the SLICC group, provided the data for this study. Data previously submitted to the IRBIS registry by 28 centers in 11 European countries were complemented with additional clinical information from the participating sites. Comparator patients had been started on any conventional IS but were not necessarily naïve for this.

Results: 175 patients were analyzed; 103 were treated off-label with RTX and 72 with a conventional IS. The most frequently used ISs were mycophenolate mofetil (43%) and azathioprine (33%). For both groups, about 90% were female, 90% were Caucasians and 85% were non-smokers. Organ manifestations leading to treatment with RTX were lupus nephritis in 58%, hematological lupus in 16%, musculoskeletal manifestations in 11%, skin disease in 6%, CNS lupus in 7%, and other manifestations in 7%. For patients started on conventional ISs the corresponding percentages were 53%, 11%, 22%, 6%, 7%, and 6%. These distributions were not statistically different. Reason for treatment initiation with RTX was mainly disease control while steroid sparing was frequently the main reason for conventional ISs. At treatment initiation mean disease duration ($\pm$SD) was 9.1$\pm$7.0 for RTX-treated patients and 4.1$\pm$6.6 for patients on ISs ($p<0.0001$) and mean ages were 41.2$\pm$12.5 and 36.1$\pm$11.3, respectively ($p=0.007$). There were significant differences between the groups for SLEDAI scores (12.2$\pm$7.0 vs. 9.4$\pm$7.0; $p=0.001$) and SLICC damage index (1.6$\pm$3.4 vs. 0.57$\pm$1.0, $p=0.014$).

Conclusion: Both RTX and conventional ISs are mostly used for lupus nephritis, and no other specific organ manifestation was more likely to be treated with RTX. However, patients started on RTX were somewhat older, had significantly longer disease duration, higher disease activity and more damage compared to patients started on conventional ISs only. These data support the view that RTX is used for selected patients with later-stage, more severe SLE.

Rituximab For Treatment Of Refractory Auto-Immune Hepatitis. Chadi Rakieh, Edward M. Vital, Paul Emery and Michael Martin. Division of Rheumatic and Musculoskeletal Disease, Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, LTHT, Leeds, United Kingdom, Leeds, United Kingdom.

Background/Purpose: Auto-immune hepatitis (AIH), also known as lupoid hepatitis, is a chronic progressive disease of unknown aetiology. First-line therapy consists of corticosteroids alone or in combination with azathioprine. Cyclophosphamide, mycophenolate mofetil (MMF), and tacrolimus have also been used but some patients do not respond or experience toxicity. Rituximab is effective in other connective tissue diseases. The aim of this study was to evaluate the efficacy and safety of rituximab in patients with refractory AIH.

Methods: We conducted a prospective open-label single centre trial in patients with seropositive biopsy-proven AIH resistant to conventional therapy including high dose corticosteroids and multiple immunosuppressants. Two infusions of rituximab 1000 mg two weeks apart were given, each preceded by 100mg methylprednisolone. Response was assessed at month 3 using biochemical parameters including alanine transaminase (ALT), bilirubin, and immunoglobulin G (IgG). B cell subsets were enumerated using highly sensitive flow cytometry with a lower limit of detection. Repeat cycles were given if the disease flared up with rising liver enzymes.

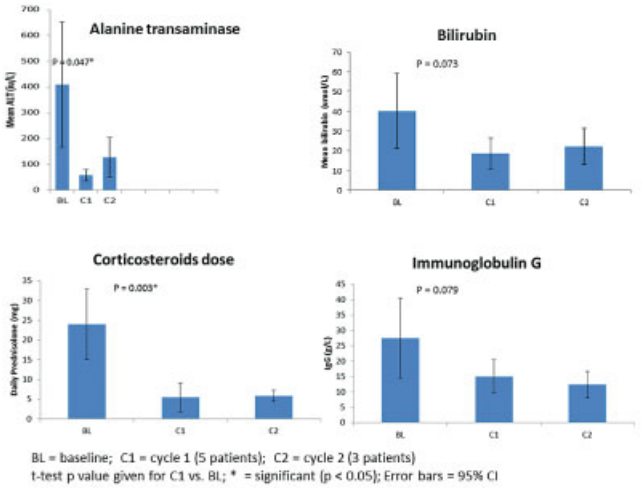
Results: Between November 2007 and January 2013, 5 patients (3 females) with refractory AIH were treated with rituximab. Mean age was 25 years. Median follow-up duration was 26 months. All patients were positive for antinuclear antibody (ANA), 3 for anti-smooth muscle antibody (SMA), and 3 for anti-double stranded DNA. All of the patients achieved good response with marked improvements in clinical symptoms and laboratory

abnormalities. Significant reductions were observed in the mean values of ALT and daily prednisolone dose after cycle 1 with trends to improvement in other parameters. Three patients to date required another cycle of rituximab after 18, 20, and 60 months and maintained good response. All patients exhibited B cell depletion by conventional flow cytometry (0.01×10^9 cells/L), although complete B-cell depletion ($<0.0001 \times 10^9$cells/L) was seen in just 3 of the 8 cycles given; this did not appear to impact on the therapeutic outcome. One serious adverse event possibly related to treatment was observed; a patient, who had previously suffered from inflammatory bowel disease, developed a large bowel perforation six weeks after starting rituximab and stopping tacrolimus.

Biochemical outcomes and prednisolone dose before and after rituximab

Outcomes Means (SD)	Baseline N = 5	Cycle 1: month 3 N = 5	t-test p value vs. baseline	Cycle 2: month 1 N = 3
ALT (iu/L)	409 (273)	53 (23)	0.047*	128 (95)
Bilirubin (μmol/L)	40 (21)	18.6 (9)	0.073	22.6 (13)
IgG (g/L)	28 (13)	15 (5.4)	0.079	12.4 (2.5)
Albumin (g/L)	35.2 (8)	39.8 (4.4)	0.294	40 (1.7)
Prednisolone (mg/day)	24 (8.9)	5.5 (3.7)	0.003*	5.8 (1.5)
CRP (mg/L)	15.8 (18)	4 (5.5)	0.200	6.6 (11.5)

SD = standard deviation; ALT = alanine transaminase; CRP = C-reactive protein; IgG = immunoglobulin G; * = si?????????



BL = baseline; C1 = cycle 1 (5 patients); C2 = cycle 2 (3 patients)
t-test p value given for C1 vs. BL; * = significant (p < 0.05); Error bars = 95% CI

Anti-Malarial Drugs (hydroxychloroquine and quinacrine) Decrease The Production Of Interferon-Alfa Initiated By TLR-9 Agonist. Ou Jin[1], Xi Zhang[2], Qiuxia Li[3], Lingkai Fang[3], Hongyue Huang[3], Chengcheng Hou[3], Zetao Liao[4], Qiujing Wei[3], Zhiming Lin[1], Dongfang Lin[3] and Jieruo Gu[5]. [1]third affiliated hospital of Sun Yat-sen Universtiy, Guangzhou, China, [2]The Affiliated Third Hospital of Sun Yat-san University, Guangzhou, China, [3]The Affiliated Third Hospital of Sun Yat-san University, Rheumatology, Guangzhou, China, [4]THIRD AFFILIATED HOSPITAL OF SUN YAT-SEN UNIVERSIT, Guangzhou, China, [5]Third Affiliated Hospital of Sun Yat-sen University, GuangZhou, China.

Background/Purpose: Toll-like receptor 9 (TLR-9) plays an important role in initiating innate immunity. The recognition of self DNA fragments by TLR-9 may results in the production of interferon-α, a central cytokine in the pathogenesis of Systemic lupus erythematosus (SLE). Anti-malarial drugs such as hydroxychloroquine (HCQ) and quinacrine (Qn) are commonly used in the treatment of SLE. Some studies imply that anti-malarial drugs may influence TLR pathway, though detail mechanisms are still under study. In this study, we want to evaluate the influence of anti-malarial drugs (HCQ and Qn) on the initiation of IFN-α production through TLR-9 pathway, combinded with or without glucocorticoid.

Methods: Freshly isolated PBMCs of healthy donors were stimulated with the TLR-9 agonist CpG oligodeoxynucleotides (CpG-A ODN)-2216, then incubated with different kinds of anti-malarial drugs (HCQ and Qn or both) and/or different doses of glucocorticoid (hydrocortisone: 10^{-6}M (low dose), 10^{-5}M (median dose), 10^{-4}M (high dose), 10^{-3}M (pulse dose)). The changes in the expression of IFN-α were detected by real time PCR.

Results: (1). Hydroxychloroquine or quinacrine alone or combined together significantly inhibited the production of IFN-α initiated by ODN 2216 (Qn (p=0.047), HCQ (p=0.047), Qn and HCQ (p=0.046)). (2). When combined with low (10^{-6}M), median (10^{-5}M), or high (10^{-4}M) dose of hydrocortisone, HCQ or Qn or both significantly revised the elevation of IFN-α caused by ODN 2216 ((low dose: Qn (p=0.017), HCQ (p=0.017), Qn & HCQ (p=0.017), median dose: Qn (p=0.034), HCQ (p=0.032), Qn & HCQ (p=0.036), high dose: Qn (p=0.028), HCQ (p=0.024), Qn & HCQ (p=0.028)), which cannot be decreased by glucocorticoid (each p>0.05). (3). When combined with pulse dose (10^{-3}M) hydrocortisone which could promote the expression of IFN-α to some extent, anti-malarial drugs (HCQ, Qn alone or both) could not significantly down-regulate the expression of IFN-α stimulated by ODN 2216.

Conclusion: (1). Anti-malarial drugs hamper the production of IFN-α by TLR-9 recognition of nucleotides (ODN 2216), which is the critical cytokine in the pathogenesis of lupus. (2). The combination with anti-malarial drugs (HCQ, Qn alone or both) seem to be a good choice to help low, median, high dose glucocorticoid to achieve a better disease control by inhibiting IFN-α, which cannot be decreased by glucocorticoid. (3). When combined with pulse dose glucocorticoid, anti-malarial drugs (HCQ, Qn alone or both) could not down-regulate the expression of IFN-α stimulated by TLR-9 agonist.

Hydroxychloroquine Reverse The Elevation Of Interferon-Alfa Initiated By TLR-9 Agonist Which Irresponsive To Glucocorticoid. Ou Jin[1], Xi Zhang[2], Lingkai Fang[3], Qiuxia Li[3], Hongyue Huang[3], Zhiming Lin[1], Zetao Liao[4], Dongfang Lin[3], Chengcheng Hou[3] and Jieruo Gu[5]. [1]third affiliated hospital of Sun Yat-sen Universtiy, Guangzhou, China, [2]The Affiliated Third Hospital of Sun Yat-san University, Guangzhou, China, [3]The Affiliated Third Hospital of Sun Yat-san University, Rheumatology, Guangzhou, China, [4]THIRD AFFILIATED HOSPITAL OF SUN YAT-SEN UNIVERSIT, Guangzhou, China, [5]Third Affiliated Hospital of Sun Yat-sen University, GuangZhou, China.

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by chronic stimulation of the innate immune system by endogenous nucleic acids through toll-like receptors (TLRs) pathway, which results in the elevation of interferon-alfa (IFN-α). Though glucocorticoid have been widely used to treat autoimmune diseases for their strong anti-inflammatory effects, a recent research has found that TLRs recognition of self nucleic acids hampers the effects of glucocorticoid in lupus. Hydroxychloroquine has been reported to block the TLRs. We want to evaluate whether hydroxychloroquine and/or glucocorticoid influence the production of IFN-α stimulated by TLR-9 agonist in human peripheral blood mononuclear cells (PBMCs). Moreover, we want to explore whether hydroxychloroquine influences the expression of signal proteins in the TLR-9 pathway.

Methods: Freshly isolated PBMCs of healthy donors were stimulated with the TLR-9 agonist, CpG oligodeoxynucleotides (CpG-A ODN)-2216, then treated with hydroxychloroquine and/or different doses of glucocorticoid (hydrocortisone: low dose (10^{-6}M), median dose (10^{-5}M), high dose (10^{-4}M), pulse dose (10^{-3}M)). The changes in the expression of IFN-α and signal proteins (TLR7, TLR9, MyD88, AP-1, IKK-α, NF-κB) in PBMCs were detected by real time PCR.

Results: (1) Hydroxychloroquine significantly reversed the elevation of IFN-α caused by ODN 2216 (p=0.005), and in low dose (p=0.017), median dose (p=0.01) and high dose (p<0.001) of glucocorticoid, while could not significantly down-regulate the expression of IFN-α stimulated by ODN 2216 in pulse dose of glucocorticoid (p=0.05). (2) Hydroxychloroquine had no effects on the expression of TLR7, TLR9, MyD88, AP-1, IKK-α and NF-κB in PBMCs stimulated by ODN 2216. (3) Pluse dose of glucocorticoid could increase the production of IFN-α stimulated by ODN 2216 to some extent. (4) Pluse dose of glucocorticoid could significantly elevate the expression of TLR9 (p=0.016), IKK-α (P=0.025) and NF-κB (P<0.001) in the TLR pathway.

Conclusion: (1) Hydroxychloroquine hampers the critical pathogenesis of SLE that the IFN-α expression elevates in PBMCs through TLR-9 recognition of nucleotides, which is irresponsive to glucocorticoid alone. This result suggests that combination with hydroxychloroquine may help glucocorticoid to achieve a better disease control. (2) Hydroxychloroquine does not significantly influence signal proteins (TLR7, TLR9 MyD88, AP-1, IKK-α and NF-κB) in the TLR pathway, which implies its weak influence in innate immunity. (3) The side-effects of pluse dose glucocorticoid in the elevation of IFN-α may related to the elevated expression of TLR9, IKK-α and NF-κB in PBMCs stimulated by ODN 2216.

Type I Interferons As a Serum Biomarker Of Subclinical Atherosclerosis In Pediatric Systemic Lupus Erythematosus Patients.
Smriti Mohan[1], Julie Barsalou[2], Timothy J. Bradley[2], Cameron Slorach[2], Lawrence Ng[3], Deborah M. Levy[4], Earl D. Silverman[2] and Mariana J. Kaplan[5]. [1]University of Michigan, Ann Arbor, MI, [2]The Hospital for Sick Children, University of Toronto, Toronto, ON, [3]The Hospital for Sick Children, Toronto, ON, [4]The Hospital for Sick Children and University of Toronto, Toronto, ON, [5]University of Michigan Rheumatology, Ann Arbor, MI.

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disorder with a marked increase in cardiovascular (CV) morbidity and mortality due to premature atherosclerosis, distinct from what is predicted by the Framingham risk equation alone. This risk may be increased in pediatric-onset SLE (pSLE) due to the younger age of disease onset, greater disease severity, and longer disease burden seen in pSLE. Type I interferon (IFN) levels are elevated in SLE and have been shown to play a prominent role in premature vascular damage in adult patients and in animal models of SLE. We hypothesized that serum type I IFN activity may also be an independent predictor of subclinical atherosclerosis and endothelial dysfunction in pSLE.

Methods: A cross-sectional analysis of a pSLE cohort was performed. The following markers of subclinical atherosclerosis and endothelial dysfunction were measured in 132 pSLE patients and 138 healthy controls using standardized protocols: carotid intima-media thickness (CIMT), flow-mediated dilatation (FMD) of the brachial artery, and aortic pulse wave velocity (PWV). Serum samples from the pSLE patients were assayed to quantify type I IFN serum activity, using a previously validated bioassay in which HeLa cells were incubated in the presence of pSLE or age- and gender-matched healthy control sera. HeLa RNA was then isolated and real-time quantitative PCR was performed to quantify the expression of 5 type I IFN-inducible genes (*MX1, C1orf-29, IFIT1, PRKR*, and *IFI44*) and the housekeeping gene *HPRT1*. Principal component analysis was used to establish the association between individual type I IFN-inducible genes and markers of subclinical atherosclerosis and endothelial dysfunction.

Results: Females accounted for 89% of pSLE patients; mean age was 14.8 $\pm$ 2.7 years. Disease duration at time of vascular tests was 2.1 $\pm$ 2.1 years, with a wide range spanning 2 months to 13.25 years. Mean CIMT was 0.41 $\pm$ 0.05 mm, mean FMD was 8.2% $\pm$ 3.94%, and mean aortic PWV was 5.45 $\pm$ 1.0 m/s. These results did not differ from the healthy control population. Four type I IFN-inducible genes were found to be significantly elevated in pSLE patients when compared with controls: *MX1* (8-fold higher), *C1orf-29* (3-fold higher), *PRKR* (2-fold higher), *and IFI44* (2-fold higher). There was no correlation between type I IFN serum activity and markers of subclinical atherosclerosis and endothelial dysfunction in pSLE patients.

Conclusion: Serum type I IFN activity is increased in pSLE patients, but we found no association between serum type I IFN activity and markers of subclinical atherosclerosis and endothelial dysfunction in pSLE. These results are in contrast to the association which has been shown in adult SLE patients. Further study including longitudinal assessments is needed to evaluate if change in type I IFN activity over the duration of disease predicts progression of atherosclerosis and/or development of CV events in pSLE.

Interferon Regulatory Factors 3 and 5 As Key Elements Of The Interferon Signature On Plasmacytoid Dendritic Cells From Systemic Lupus Erythematosus Patients.
Diana Gómez-Martín[1], Karina Santana-de Anda[2], Adriana Elizabeth Monsivais-Urenda[3], Sandra Rajme-Lopez[4], Luis Aparicio-Vera[4], Jorge Alcocer-Varela[1] and Roberto González-Amaro[3]. [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubirán, Mexico City, Mexico, [3]Facultad de Medicina. UASLP, San Luis Potosí, Mexico, [4]Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubirán, Mexico city, Mexico.

Background/Purpose: Plasmacytoid dendritic cells (pDC) are considered the main source of type-I interferon (IFN-I). The interferon signature has been widely associated to systemic lupus erythematosus (SLE). Among these over-expressed genes, interferon regulatory factors (IRF) have been proposed as key regulators of the increased IFN-I production in SLE patients and murine models. Many genetic association studies have found association between many IRF-5 polymorphisms with increased susceptibility to SLE in different ethnic groups, however these studies have been done with total mononuclear cells, which may not reflect specific DC alterations. The aim of the present study was to address the expression of IRF-3 and 5 on different DC subsets from SLE patients, as well as their association to IFN-I production.

Methods: In this work we included 35 patients with SLE (20 with SLEDAI=0, 15 with SLEDAI>6) according to the classification criteria of the American College of Rheumatology as well as 35 healthy age and gender matched controls. Peripheral blood mononuclear cells were isolated by density gradient. Monocytes were purified by positive selection with magnetic beads. mDC were generated by culturing monocytes for 6 days in presence of GM-CSF, IL-4 and for 2 additional days in presence of LPS to induce maturation. The expression of CD80, CD86, HLA-DR, CD40 was evaluated by flow cytometry. IRF3 and IRF5 expression was assessed by qPCR, flow cytometry and western blot in mDC and pDC from peripheral blood and monocyte derived DC. IFN-I serum levels were measured by ELISA. Data were analyzed by the Student t test. In all cases, an informed consent was obtained, and the ethics committee approved this study.

Results: We found increased expression of IRF-3(4331.6$\pm$794 vs 2400.8$\pm$225.9, p=0.038) and 5 (2724.6$\pm$335.9 vs 1785$\pm$115.2, p=0.031) by flow cytometry (mean fluorescence intensity) on pDCs from SLE patients vs healthy controls. This finding was associated to increased IFN-I serum levels in SLE patients vs healthy controls (160.2$\pm$21 vs 106.1$\pm$14, p=0.036). We found as well that monocyte derived DC from SLE patients showed decreased levels of CD40 after maturation with LPS. However no other differences were observed on the other DC phenotype markers. Interestingly, differences between IRF-3 and 5 expression were restricted to pDC subset. Moreover, these findings were present regardless of disease activity.

Conclusion: Our findings suggest that increased levels of IFN-I in SLE patients are associated to increased expression of IRF-3 and 5, which is restricted to pDC subset. Furthermore, the abnormal expression of these factors might be an intrinsic defect in SLE, since it is present regardless of disease activity.

Toll-Like Receptor 3 Plays a Role In Loss Of Tolerance To The Ro/SSA Auto-Antigen In Systemic Lupus Erythematosus. Julie Ducreux[1], Christine Galant[1], Julie Verbeeck[1], Pierre Coulie[2], Benoît Van den Eynde[2], Frédéric A. Houssiau[1] and Bernard Lauwerys[1]. [1]Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Brussels, Belgium, [2]Institut de Duve, Université catholique de Louvain, Brussels, Belgium.

Background/Purpose: Toll-like Receptor (TLR)7 and TLR9 play a role in the pathogenesis of systemic lupus erythematosus (SLE) by inducing Interferon (IFN)-α and IFN-induced genes expression. However, recent data indicate that other agonists inside the type I IFN system could be involved in the pathogenesis of the disease. In the present study, we described the presence of IFN-β in cutaneous lesions of patients with SLE, an observation that led us to investigate the role of TLR3 in the disease.

Methods: IFN-β evaluation in SLE skin biopsies versus controls was performed by immunohistochemistry. The variations in the genomic sequence of the *TLR3* gene were first explored in a population of Western-European SLE patients versus age- and gender-matched healthy controls, using 8 Tag SNP from the HapMap database. In addition, the distribution of *TLR3 rs3775291* alleles and genotypes were assessed in two independent populations of Western- and Southern-European SLE patients (n = 197 and 282, respectively) and controls (n = 262 and 291, respectively). Functional experiments were performed on peripheral blood mononuclear cells (PBMC) and monocyte-derived dendritic cells (moDC) generated from PBMC of healthy individuals categorized according to their *TLR3 rs3775291* genotype. Anti-Ro/SSA- specific T cells were derived from PBMC of healthy individuals by repeated stimulations with autologous Ro/SSA-pulsed moDC.

Results: We found a positive IFN-β immunostaining in skin lesions of SLE patients, compared to controls. This result prompted us to evaluate the potential role of TLR3 in the pathogenesis of the disease. Out of the 8 *TLR3* Tag SNP, 2 are significantly associated with SLE in Western-European anti-Ro/SSA antibody (Ab)-positive patients. None of these intronic SNP have a functional impact. However, one of them is in linkage disequilibrium with *rs3775291*, a SNP that encodes an amino-acid substitution in the ligand-binding pocket of TLR3. We found a positive association between *rs3775291* and susceptibility to SLE in patients with anti-Ro/SSA Ab, in two independent populations of SLE patients and controls. We confirmed that the rs3775291 major allele, which is enriched in anti-Ro/SSA Ab-positive patients, is associated with increased TLR3 responses to stimulation. In addition, moDC from individuals homozygous for the susceptibility *TLR3 rs3775291* allele are more susceptible to UV-induced apoptosis, thereby resulting in the release of larger amounts of the Ro/SSA autoantigen in response to UV irradiation. UV exposure of dendritic cells from individuals homozygous for the susceptibility *TLR3 rs3775291* allele also results in higher interleukin-6 secretion, and cell surface expression of MHC II molecules and CD86. Finally, we found that UV exposure of Ro/SSA-pulsed moDC from individuals homozygous for the susceptibility *TLR3 rs3775291* allele leads to a higher activation of auto-reactive autologous CD4+ T cells.

Conclusion: *rs3775291*, a functional SNP in the *TLR3* gene, is associated with susceptibility to SLE in anti-Ro/SSA Ab-positive patients, and facilitates loss of tolerance to the Ro/SSA auto-antigen through increased maturation of moDC after UV exposure.

Chromatin Binding In SLE Patients Correlates With The Intensity Of Apoptotic Binding By 9G4+ B Cells. Asiya Seema Chida[1], Quan-Zhen Li[2], Chandra Mohan[2], Youliang Wang[1], Scott Jenks[3], Louise Hartson[1] and Ignacio Sanz[4]. [1]Emory University Medical Center, Atlanta, GA, [2]University of Texas Southwestern Medical Center, Dallas, TX, [3]Emory University School of Medicine, Atlanta, GA, [4]Emory University, Atlanta, GA.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a multi-organ autoimmune disease characterised by production of autoantibodies to multiple nuclear antigens, some of which are highly specific for SLE including anti-ds DNA, anti-Smith and anti-nucleosome antibodies. IgG antibodies expressing the 9G4 idiotype, encoded by the framework-1 hydrophobic patch (HP) of VH4–34, are specifically expanded in SLE and provide a unique model to understand the participation of different autoantigens in the pathogenesis of this disease. 9G4 autoreactivity may be directed against different lupus antigens and accounts for a significant fraction of anti-apoptotic cell binding (APCB), of lupus serum. Here we sought to understand the contribution of anti-nucleosome reactivity to APCB.

Methods: A panel of 9G4+ monoclonal antibodies was generated from IgD-CD27+ memory cells of SLE patients. APCB was determined by flow cytometry. Positive and negative binders for Apoptotic binding were tested for anti-Chromatin reactivity by ELISA. Three representative antibodies with strong APCB activity were also tested against a glomerular proteome antigen microarray.

Results: Our preliminary data demonstrate a strong correlation of apoptotic binding with chromatin by ELISA. Out of 37 9G4+ monoclonals tested 10 were positive for apoptotic binding and out of these 10, 9 were positive for chromatin ($p=<0.001$; fisher exact test). Glomerular microarray analysis identified reactivity with Chromatin, histones H2A, H2B, H3 and H4 in different patterns for the individual antibodies. This assay also identified interesting patterns of polyreactivity against of other lupus antigens including Riboprotein P1, but not P0 or P2, U1-RNP and Sm. Of note, these patterns reflected the reactivity of the patients serum. Levels of reactivity against chromatin, H2A, H2B, H3, and U1-Sn-RNP-68 correlated with disease activity.

Conclusion: SLE-specific 9G4 antibodies recognize nucleosomal antigens (chromatin and individual histones) and may be polyreactive against components of the snRNP complex. Both these types of antigens are expressed at high density on apoptotic cells which are highly immunogenic sources of self-antigens in SLE at least in part due to deficient clearance. Detailed structural, antigenic and functional studies of our mAbs should shed significant light into the triggering of these autoimmune responses and the role of different antigens in the shaping and selection of the autoimmune B cell memory compartment. Determination of 9G4 antibodies against apoptotic cells and/or nucleosomal antigens might provide a useful test for the diagnosis and monitorization of SLE.

***In Vitro* Assessments Of Mesenchymal Stem Cells From Lupus Patients To Predict Suppressive Function *In Vivo*.** Erin Collins[1], Fei Gu[2] and Gary S. Gilkeson[1]. [1]Medical University of South Carolina, Charleston, SC, [2]Division of Rheumatology and Immunology, Medical University of South Carolina, Charleston, SC.

Background/Purpose: Broad immune suppression by mesenchymal stem cells (MSCs) make them an attractive candidate as a cell therapy for autoimmune diseases, such as systemic lupus erythematosus (SLE). MSCs can be derived from various sources and vary slightly depending on the source of origin. Currently the source of MSCs that will be most effective in ameliorating SLE is unknown. Moreover, *in vivo* studies have suggested that lupus derived MSCs are not as effective as MSCs from non-diseased sources. In this study we assess the suppressive capabilities of MSCs from different sources *in vitro*.

Methods: To determine the suppressive efficacy of human MSCs we harvested MSCs from healthy donor umbilical cords, bone marrow, and lupus patient bone marrow (n=3–4 of each). Peripheral blood mononuclear cells (PBMCs) were isolated from healthy individuals and used immediately for cell culture. PBMCs were labeled with CFSE for detection of suppression. PBMCs (5×10^5) were then stimulated with 1μg/ml αCD3/CD28 and co-cultured with varying dilutions of MSCs. Co-cultures were incubated for 72 hours before cells were collected for flow cytometry and qPCR analysis. MSC activation was assessed by stimulating 1×10^5 MSCs with varying concentrations of IFNγ and incubating for 24 hours. Expression of MSC activation/suppressive markers was assessed by qPCR.

Results: In comparison to MSCs from healthy donors, lupus MSCs were able to suppress PBMCs equally well. Only a modest decrease in suppression was seen when lupus MSCs were diluted 1:40 (MSC:PBMC), when compared to healthy MSCs. We next examined the expression of markers that are important for suppressive MSCs. Our data showed increased expression of IDO1, CFH, TGFβ and IL6 in lupus MSCs compared to healthy MSCs during PBMC co-culture. To determine whether lupus MSCs were more readily activated for suppression, we activated the various MSCs with graded doses of IFNγ. We found that IDO1 and CFH were upregulated in a dose dependant manner similarly in both lupus and healthy MSCs. However, lupus MSCS had higher expression of IL6, TGFB and T cell attractant chemokines (CXCL9 and CXCL10) when compared to healthy MSCs.

Conclusion: Our results indicate that lupus MSCs are equally as suppressive as healthy MSCs *in vitro*. Additionally, certain standard suppressive markers are up regulated in lupus MSCs. Although our *in vitro* assessments do not show that lupus MSCs are defective, these results do not correlate with *in vivo* studies showing reduced capacity of lupus MSCs to mediate disease. Moreover, our studies suggest that different *in vitro* evaluations need to be utilized to determine *in vivo* effectiveness of MSCs.

Characterization Of a Jamaican Lupus Cohort: Proinflammatory Biomarkers and Disease Activity. Rohan Willis[1], Monica Smikle[2], Karel de Ceulaer[3] and Silvia S. Pierangeli[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]University of the West Indies, Kgn 7, Jamaica, [3]University of the West Indies, KIngston, Jamaica.

Background/Purpose: Systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) are related systemic autoimmune diseases associated with proinflammatory prothrombotic biomarkers/cytokine (PPM) and antiphospholipid antibodies (aPL). Reports also suggest that low 25-hydroxy vitamin D (25OH-VD) levels are associated with disease activity in SLE. There is an increased prevalence and severity of SLE in Black and Afro-Caribbean patients (pts) but few data highlighting 25OH-VD and PPM levels in this population. We sought to determine which cytokines and oxidative stress markers are elevated in a unique population of Jamaican (JA) SLE pts.

Methods: A total of 47 patients (mean age 43.3 ± 11.9yrs) satisfied ACR classification criteria for definite or incomplete SLE; the BILAG index was used to measure disease activity. Two groups of controls served as comparison for PPM. ELISAs were used to measure anti-dsDNA, aPL (anticardiolipin (aCL), anti-β_2-glycoproteinI (aβ_2GPI) and APhL®), 25OH-VD, IgG anti-oxLDL/β_2GPI antibodies (IgG aOXLβ-Ab) and oxLDL/β2GPI antigen-complex (OXLβ-Ag). Interferon (IFN)-α, Interleukin (IL)1b, IL6, IL8, inducible protein (IP)10, tumor necrosis factor (TNF)-α, vascular endothelial growth factor (VEGF), and soluble CD40 ligand (sCD40L) levels were determined by the MILLIPLEXMAP human cytokine/chemokine assay in the serum of patients and controls. Pearson's correlation and the Kruskal-Wallis test were used to evaluate PPM levels in SLE patients and controls.

Results: A third of patients (14/47,29.8%) had at least one positive aPL and 5/47 (10.6%) had isolated IgA anti-β2GPI positivity. Most PPM were significantly elevated in SLE patients vs controls (Table 1). Only 6.4% (3/47) patients had positive IgG aOXLβ Ab levels but all of these patients had extremely elevated aPL. IgG aOXLβ Ab was significantly correlated with IgG aCL (r0.854, $p<0.001$), IgG APHL (r0.940, $p<0.001$) and IgG aβ_2GPI (r0.978, $p<0.001$) while OXLβ-Ag was associated with IgA aβ2GPI (r.316, $p=0.031$). Disease activity was significantly correlated with both dsDNA (r0.341, $p=0.020$) and IP10 (r0.362, $p=0.013$) and these 2 markers were also correlated (r0.490, $p<0.001$). Most patients (34/47, 72.3%) had below normal 25OH-VD levels and patients with 25OH-VD deficiency had higher mean IFN-α levels compared to those with normal levels (49.9 vs 3.6 pg/ml, $p=0.05$).

Table 1. Proinflammatory markers in SLE patients vs controls

Marker	JA SLE patients median	Controls median	P value
IL6 (pg/mL)	1.7	0.0	<0.001
IL1β (pg/mL)	0.0	0.0	0.108
TNFα (pg/mL)	7.1	0.0	<0.001
IP10 (pg/mL)	226.7	96.2	<0.001
sCD40L (pg/mL)	232.3	16.4	<0.001
IFNα (pg/mL)	4.5	0.0	0.162
VEGF (pg/mL)	154.6	88.3	0.031
OXLβ Ag (U/mL)	14.5	2.8	<0.001

Conclusion: Jamaican SLE patients have a high rate of aPL positivity, particularly IgA anti-β_2GPI, associated with oxidative stress markers and this may be an underlying reason for the increased prevalence of severe disease in Afro-Caribbean patients. IFN-inducible cytokines appeared to drive disease activity on the background of dsDNA activity, which is unsurprising. IFN activity was also associated with low 25OH-VD.

T Helper 17 Cells and Interferon Type I: Partners In Crime In SLE? Odilia B.J. Corneth, Zana Brkic, Cornelia G. van Helden-Meeuwsen, Radboud J.E.M. Dolhain, Naomi I. Maria, Sandra M.J. Paulissen, Nadine Davelaar, Jan Piet van Hamburg, Paul L. Van Daele, Virgil A. Dalm, Martin van Hagen, Marjan A. Versnel and Erik Lubberts. Erasmus Medical Center, Rotterdam, Netherlands.

Background/Purpose: A hallmark of systemic autoimmune diseases, such as systemic lupus erythematotsus (SLE), is the increased expression of interferon (IFN) type I inducible genes, the so-called IFN type I signature. Recently, a novel T helper 17 subset (Th17 cells), which produces IL-17A, IL-17F, and IL-22, has also been implicated in autoimmune diseases. We investigated a possible link between these two pro-inflammatory immune pathways in SLE.

Methods: 25 SLE patients and 15 healthy controls (HC) were included. SLE patients were divided into an IFN type I signature negative (n=9) and positive (n=16) group as assessed by mRNA expression of IFN type I inducible genes. Peripheral expression of Th17 cytokines IL-17A, IL-17F and IL-22 by CD4+CCR6+ memory T cells was measured by flow cytometry and compared between IFN type I signature positive and negative patients and HC.

Results: Increased fraction of IL-17A and IL-17A/IL-17F double producing CCR6+ cells was found in IFN type I positive patients compared with IFN type I negative patients and HC. The expression of IL-17A and IL-17F within CCR6+ cells correlated significantly with IFN scores. In addition, we found a significant correlation between BAFF and IL-21 producing CCR6+ cells.

Conclusion: Here we show for the first time a correlation between IFN type I activation and expression of the Th17 cytokines in SLE patients. These data give new insight into the pathogenesis of SLE with possible implications for treatment.

Deep-Sequencing Reveals Class-Specific Urinary Micrornas In Human Lupus Nephritis. Beatrice Goilav[1], Iddo Z. Ben-Dov[2], Irene Blanco[3], Olivier Loudig[3], Dawn M. Wahezi[4] and Chaim Putterman[3]. [1]Children's Hospital at Montefiore, Bronx, NY, [2]The Rockefeller University, New York, NY, [3]Albert Einstein College of Medicine, Bronx, NY, [4]Children's Hospital Montefiore, Bronx, NY.

Background/Purpose: Lupus nephritis (LN), particularly, ISN/RPS class IV LN, is associated with significant morbidity and mortality. microRNAs (miRs) are small, non-coding RNAs that regulate translation. Previous studies report changes in miR expression in kidney tissue, urine and PBMCs that correlate with LN disease activity. However, LN class-specific miRs have not been previously described.

Using deep-sequencing, we aimed to identify class-specific miRs in urine from adult and pediatric patients with biopsy-proven LN.

Methods: Cell-free urine from adult (n=25) and pediatric (n=8) female patients with ISN/RPS class III, IV (proliferative) and class V LN were obtained at time of active disease and during remission. Total RNA was used to prepare small RNA cDNA libraries for sequencing. Multiplexing through sample-specific 3' adapters was applied to limit batch effects and cost. Sequence reads were mapped to the human genome and small RNA databases. miRs were quantified by relative read abundance. qRT-PCR was used for quantitative validation.

Results: We had specimens from adult patients with distinct class III, IV, and V LN and pediatric patients with class III and IV. Samples from pediatric patients with class V LN were mixed with another class LN. We obtained reproducible miR profiles. In a paired-sample analysis we compared miR abundance in adult and pediatric active vs inactive LN, proliferative vs non-proliferative LN, class IV vs class III LN, active class III vs inactive class III LN, active class IV vs inactive class IV LN, and adult active class V vs inactive class V LN. In this analysis, we found significant changes in miR-324, -320, -200c (adult), -375 (pediatric), -200c, -30a, and -671*, respectively. All changes had a p value of <0.001, except for miR-30a ($p=0.0011$). Changes in miR abundance ranged from −11.8-log fold change to 11.3-log fold change.

Conclusion: In this study, we detected significant changes in miR abundance related to specific LN classes. Given that the prognosis of class IV LN is significantly worse than that of class III, identifying miRs that are associated with class IV LN is an important step in biomarker discovery of this particular aggressive form of LN. Identification of target genes of these miRs may open a venue for the discovery of new pathogenic pathways in this devastating disease.

Differential Methylation Of Interferon-Related Genes Is Associated With Anti-dsDNA Autoantibody Production In Systemic Lupus Erythematosus. Sharon A. Chung[1], Joanne Nititham[2], Kimberly E. Taylor[1], Emon Elboudwarej[3], Hong L. Quach[3], Lisa F. Barcellos[3] and Lindsey A. Criswell[2]. [1]University of California, San Francisco, San Francisco, CA, [2]University of California, San Francisco, Rosalind Russell Medical Research Center for Arthritis, San Francisco, CA, [3]University of California, Berkeley, Berkeley, CA.

Background/Purpose: DNA methylation studies in systemic lupus erythematosus (SLE) have shown that SLE patients have less methylation in genes regulating the immune response compared to unaffected individuals. We conducted this study to determine if differences in methylation are associated with specific SLE manifestations, and focused on anti-dsDNA autoantibody production since it indicates more severe disease.

Methods: Genomic DNA from peripheral blood leukocytes was isolated from 326 women with SLE of European descent who never smoked. Approximately 48% of the SLE cases were anti-dsDNA autoantibody positive. Using the Illumina HumanMethylation450 Beadchip, the methylation status of 484,740 CpG sites across the genome was characterized in all SLE cases. For analysis, the cases were divided into discovery (n=186) and replication datasets (n=140). Wilcoxon rank sum tests were used to identify sites whose methylation status showed evidence of association with anti-dsDNA autoantibody production. Significantly associated sites in the discovery dataset were examined for association in the replication dataset. Linear and logistic regression was used to adjust for estimated leukocyte cell proportions, age, disease duration, batch effects, and population substructure (assessed by principal component analysis of previously generated genotype data).

Results: Statistically significant associations between anti-dsDNA autoantibody production and methylation status were identified for 18 sites using the discovery dataset ($p<1.0E–07$ with Bonferroni correction) and were replicated ($p<0.0028$, corrected for 18 sites). All associated sites were less methylated in anti-dsDNA positive SLE cases compared to anti-dsDNA negative SLE cases. These 18 sites represent 12 genes, and the most significantly associated sites were in *IFIT1*, *MX1*, and *RSAD2*. For the top 3 associated sites, the adjusted mean difference in methylation between anti-dsDNA positive and negative SLE cases and the adjusted odds ratio for anti-dsDNA autoantibody production if a subject's methylation level was below the median are presented in Table 1. Of note, 7 of 12 associated genes identified are either interferon inducible or involved in the interferon signaling pathway, including the 3 genes shown in Table 1.

Table 1. The top 3 methylation sites associated with anti-dsDNA autoantibody production.

Site	Gene	Adjusted mean difference in methylation[1] (95% CI)	p	Adjusted OR for anti-dsDNA autoantibody[2] (95% CI)	p
cg05696877	*IFI44L*	−15% (−19% to −11%)	9.8E–13	7.2 (4.0–13.1)	5.4E–11
cg21549285	*MX1*	−18% (−23% to −13%)	1.7E–12	6.5 (3.6–11.9)	4.1E–10
cg10959651	*RSAD2*	−4.8% (−6.2% to −3.5%)	7.7E–12	7.2 (4.0–12.8)	4.2E–11

[1] difference < 0 indicates that methylation levels were lower in the anti-dsDNA positive group
[2] OR for anti-dsDNA autoantibody if a subject's methylation level was below the median

Conclusion: This study suggests that differential methylation is associated with specific SLE manifestations in addition to disease susceptibility. Among SLE cases, additional hypomethylation of interferon-related and other genes is associated with anti-dsDNA autoantibody production. Thus, the extent of hypomethylation for critical genes may influence disease severity in SLE.

Lupus Risk Alleles With High Ethnic Variability Worldwide Are Associated With Renal Disease In Hispanic Patients. Belinda Waltman[1], Kimberly E. Taylor[2], Joanne Nititham[2] and Lindsey A. Criswell[2]. [1]University of California, San Francisco, San Francisco, CA, [2]University of California, San Francisco, Rosalind Russell Medical Research Center for Arthritis, San Francisco, CA.

Background/Purpose: Systemic lupus erythematosus (SLE) disproportionately affects minority patients. Non-European ancestry is associated with more severe disease, and conversely, European ancestry is associated with a lower risk of developing renal disease in SLE. Large genetic studies have identified 58 single nucleotide polymorphisms (SNPs) that influence risk of SLE. Separately, the Human Genome Diversity Project (HGDP) has characterized the allele frequency of 650,000 SNPs in 938 people from 53 different populations worldwide. We hypothesized that SLE SNPs with the greatest allele frequency differences across populations compared to Europeans could identify risk alleles that are associated with severe disease manifestations.

Methods: We analyzed the frequency distribution of the 58 SLE SNPs across populations in the HGDP database grouped into 6 geographic regions; 50 SNPs or proxies had available data. For each SNP, we determined the maximum absolute difference (max diff) in mean frequency between each region and Europe. SNPs were selected whose max diff was greater than 4 standard deviations of the distribution of intra-European frequencies. We tested these SNPs in our multiethnic cohort of 1588 SLE patients for severe disease outcomes (renal disease by ACR renal criterion, severe renal disease including severe forms of lupus nephritis on biopsy or end-stage renal disease, and production of double-stranded DNA antibodies) stratified by ethnicity: Caucasian, African American, Hispanic, and Asians. Logistic regression was performed for these 3 outcomes, adjusting for disease duration and gender.

Results: The max diff approach identified 19 SNPs; 13 had been genotyped in our SLE collection. Analysis identified a strong association between renal disease and Hispanic ethnicity: the number of these 13 risk alleles cumulatively increased the risk of renal disease among Hispanic patients (OR=1.2 per allele, p=0.006). Three of the 13 SNPs were individually associated ($p \leq 0.05$) with renal disease or severe renal disease. The strongest single allele associations were rs2205960/TNFSF4 (OR=2.2, p=0.0014 for renal disease), rs2736340/BLK (OR 2.1, p=0.006 for severe renal disease and OR 1.6, p=0.05 for renal disease) and rs9888739/ITGAM (OR 1.8, p=0.04 for renal disease). In HGDP data, the Central/South American region was the first or second greatest max diff compared to Europeans for these alleles.

Conclusion: Using worldwide genetic ancestry data, we identified SLE risk SNPs with high allele frequency variability across populations, postulating that these variants might influence severe disease phenotypes. Indeed, in a multiethnic SLE cohort, these 13 SNPs cumulatively increased the risk of renal disease in Hispanics, and 3 of these 13 alleles were individually associated with renal disease outcomes. This approach may be useful for identifying genetic variants that influence disease severity in SLE.

Prolactin-Induced Interferon Regulatory Factor 1 Activation and Histone H4 Hyperacetylation In Monomac-6 Cells Correlating With Changes Seen In Monocytes From Systemic Lupus Erythematosus Patients. Yiu Tak Leung[1], Lihua Shi[2], Kelly Maurer[2], Li Song[2], Michelle Petri[3] and Kate Sullivan[2]. [1]University of Pennsylvania, Philadelphia, PA, [2]The Children's Hospital of Philadelphia, Philadelphia, PA, [3]Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: Epigenetic changes have been described in systemic lupus erythematosus (SLE) and offer a potential explanation for the chronicity of disease and missing heritability. Therapies targeting the epigenome will require a greater understanding of the cellular pathways regulating the epigenetic changes. We previously found a global increase in histone H4 acetylation (H4ac) in monocytes of SLE patients as compared to controls using tiling arrays. Transcription factor motif analysis found 63% of genes with increased H4ac had potential interferon regulatory factor (IRF) 1 binding sites within the 5kb upstream region. IRF1 is highly inducible by prolactin, a hormone implicated in the pathogenesis of SLE: hyperprolactinemia has been reported in 15–33% of SLE patients as compared to 0.4–3% of controls. Prolactin upregulation of IRF1 can lead to H4ac in Nb2 T cells, representing

a potential pathological pathway in SLE. Prolactin-induced IRF1 activation in MonoMac-6 (MM6) cells was examined, with the aim to identify IRF1 interactions with specific histone acetyltransferases (HATs) and histone deacetylases (HDAC) leading to pathological H4ac in SLE.

Methods: Flow cytometry for acetylated H4 lysines: K5, K8, K12, K16 were run on the Accuri C6 with isotype controls. H4ac was defined in monocytes from 20 controls and 24 SLE patients, as well as in unstimulated and prolactin-stimulated MM6 cells. Real-time quantitative reverse transcription polymerase chain reaction (qRT-PCR) evaluated HAT/HDAC expression in monocytes from 10 SLE patients and 4 controls. IRF1 activation by prolactin in MM6 cells was studied by immunofluorescence microscopy and western blot analysis.

Results: Flow cytometry data found significantly increased H4K5, H4K8, H4K12, and H4K16 acetylation ($p = 0.03, 0.01, 0.004, 0.02$) in SLE monocytes compared to controls. H4K5 and H4K16 acetylation were also increased in MM6 cells stimulated by prolactin concentrations comparable to pregnancy (200 ng/mL) and prolactinoma levels (2000 ng/mL).

Immunofluorescence microscopy showed translocation of IRF1 from the cytoplasm to the nucleus in prolactin-stimulated MM6 cells by 1 hr, demonstrating IRF1 activation. This was supported by western blots of MM6 nuclear extracts showing IRF1 increase at 1–2 hrs of prolactin stimulation.

Potential mechanisms were examined. qRT-PCR studies of HAT/HDAC expression patterns found decreased HDAC3 and HDAC11 expression in SLE monocytes ($p = 0.19$ and 0.16). HDAC3 deacetylates all H4 lysine acetyl groups, preferentially H4K5 and H4K12. PCAF, a HAT that places H4K5, H4K8, and H4K16 acetylation marks, had significantly ($p = 0.001$) higher expression in SLE monocytes than in controls. IRF1 was overexpressed and H4ac at target genes defined by ChIP assays. Overexpression led to increased H4ac at known IRF1 targets.

Conclusion: These data demonstrate that prolactin stimulation of monocytes induces IRF1 activation and a pattern of acetylated H4 that corresponds to the changes seen in monocytes of SLE patients. This helps to explain the known association of prolactinomas with SLE. The identification of candidate HATs that associate with IRF1 in the context of prolactin stimulation may provide for potential therapeutic targets in SLE.

1626

Genetic Alterations In Abnormal Neutrophils Isolated From Human Systemic Lupus Erythematosus Patients. Namrata Singh[1], Kayla Martin[1], Mariana J. Kaplan[2], Philip L. Cohen[3] and Michael F. Denny[1]. [1]Temple University, Philadelphia, PA, [2]University of Michigan Rheumatology, Ann Arbor, MI, [3]Temple University School of Medicine, Philadelphia, PA.

Background/Purpose: Human SLE patients have an abnormal population of neutrophils called low density granulocytes (LDGs). LDGs express the surface markers of mature neutrophils, yet their nuclear morphology resembles an immature cell. A similar discrepancy in maturation status is observed in myelodysplasias, suggesting a disruption in neutrophil development in the LDGs. Because disruption of neutrophil development is frequently associated with genomic alterations, we compared genomic DNA isolated from autologous pairs of LDGs and normal-density neutrophils for genetic changes.

Methods: Somatic alterations were detected by cytogenetic microarray analysis of genomic DNA from LDGs and neutrophils from 13 female SLE patients, as well as neutrophil samples from 9 healthy female donors. Autologous pairs of SLE LDGs and neutrophils were processed and analyzed together to minimize variability. Variations present in both samples are consistent with inheritance, while alterations found exclusively in the LDG sample suggest somatic alterations. While copy number alterations are associated with repair of DNA strand breaks, a different type of genomic alteration is associated with defects in the correction of DNA replication errors. Microsatellite instability (MSI) is a characteristic of replication error-prone cells. MSI was assessed at 6 mononucleotide markers.

Results: Control neutrophils had an average of 7.76 chromosomal alterations per genome, similar to the average of the SLE neutrophils value of 8.77 alterations per genome, in contrast, the autologous SLE LDGs had 18.77 alterations per genome. The increased frequency of copy number alterations was comprised of both an elevation in the number of deletions and duplications. Copy number alterations were prevalent in 6 of the 13 patients and occurred preferentially on certain chromosomes with the majority of the alterations restricted to the × chromosome, and chromosomes 19, 17, and 8. These elevations in copy number alterations were accompanied with an increase in large genome-wide losses of heterozygosity in these same SLE patients. The enhanced level of copy number alterations and losses of heterozygosity are consistent with DNA strand break repair in LDGs. Microsatellite instability (MSI) was also detected in the LDGs of three patients, suggesting impaired correction of replication errors. Two patients displayed MSI in greater than one marker, and one patient had MSI and increased copy number alterations. No correlations between genomic instability or MSI and immunosuppressive drugs, disease activity or disease manifestations were apparent.

Conclusion: LDGs had elevated levels of genetic alterations consistent with accumulated genetic damage or genomic instability. Copy number alterations were more prevalent on certain chromosomes and restricted to discrete chromosomal intervals, suggesting an increased propensity for damage within these intervals and/or that these alterations confer a selective advantage. The pro-inflammatory environment in SLE patients may promote accumulation of these genetic alterations, alternatively a genetic predisposition toward impaired mechanisms of DNA repair may facilitate the apparent genomic instability in the LDGs.

1627

Typing TREX1 Gene In Patients With Systemic Lupus Erythematosus. Micaela Fredi[1], Marika Bianchi[2], Laura Andreoli[3], Gaetano Grieco[2], Ivana Olivieri[4], Simona Orcesi[4], Elisa Fazzi[5], Cristina Cereda[2] and Angela Tincani[3]. [1]Rheumatology Chair, University of Brescia and Pavia, Brescia, Italy, [2]Laboratory of Experimental Neurobiology, C. Mondino National Institute of Neurology Foundation, Pavia, Italy, [3]Rheumatology Unit, University of Brescia, Brescia, Italy, [4]Child Neurology and Psychiatry Unit C. Mondino National Institute of Neurology Foundation, Pavia, Italy, [5]Child Neurology and Psychiatry Unit, Mother-Child Department, Civil Hospital, University of Brescia, Brescia, Italy.

Background/Purpose: An increased expression of type I interferon regulated genes (IFN signature) has been reported in patients (pts) with Systemic Lupus Erythematosus (SLE) and it is involved in the pathogenesis of the disease. Raised level of IFN-α in the cerebral spinal fluid are found in pts with Aicardi-Goutières syndrome (AGS), a rare genetic encephalopathy characterized by calcification of basal ganglia, abnormalities in white matter and chronic cerebrospinal fluid lymphocytosis. One of AGS-causing mutations is located in the Trex1 gene chromosome3. Subsequent studies demonstrated that up to 2% of pts with SLE had pathogenic mutations in Trex1. The enzymatic function of TREX1protein is still not clear, but 3′ Repair exonuclease (Trex1) is the most abundant mammalian 3′->5′ DNA exonuclease with specificity for ssDNA. The loss or reduction of Trex1 activity may result in the accumulation of double-stranded DNA degradation intermediates that could trigger autoimmune activation. A recent study (1) described significant associations between a risk haplotype made by common single nucleotide polymorphisms (SNPs) of Trex1 and closely linked ATRIP gene in European SLE pts with neurologic manifestations, especially seizures.

Methods: 51 SLE pts were screened for Trex1 gene. Genomic DNA was extracted by automatic extraction and stored at −20°C. Trex1 gene was amplified and automatically sequenced (Genetic Analyzer 3130xl, Applied Biosystems). Each fragment was sequenced on both strands. Alignments were viewed using Sequencher 4.8. PolyPhen2 pathogenicity prediction software was used to determine possible pathogenic significance of the not previously described mutation. NM_033629.2 (isoform b-short isoform) was used to report novel variation. Clinical and serological data were collected from clinical charts.

Results: A novel heterozygous variant (NP_338599.1 p.Asp130Asn) was identified in one patient affected by SLE. Trex1 missense variation was classified as probably damaging by PolyPhen2 (score 1/1). This change was absent in 150 control samples sequenced. We also reported mutations of SNP rs11797 in 33 pts and the rs3135944 variation in only 1 patient. We searched for clinical or serological differences among pts with the wildtype rs11797 and the pts with the mutations. No significant associations were found. We reported a high prevalence of neuroSLE manifestations in pts who had rs11797 mutations: among the 8 pts who had clinical features of neuroSLE, 1 was homozygous for the major allele, 2 had heterozygous mutations for these SNP and 5 had homozygous mutations. The distribution of mutations of rs11797 were similar between pts and controls, but the homozygous mutations of rs11797 was significantly more frequent in the pts with neuroSLE than in the controls (p=0,00013;OR=11,5).

Conclusion: Although we analyzed a small number of SLE patients, we found a probably novel pathogenic variation (1,96% of pts) of TREX1. Homozygous mutations of rs11797 was significant more frequent in SLE patients with neurologic manifestations than in controls.

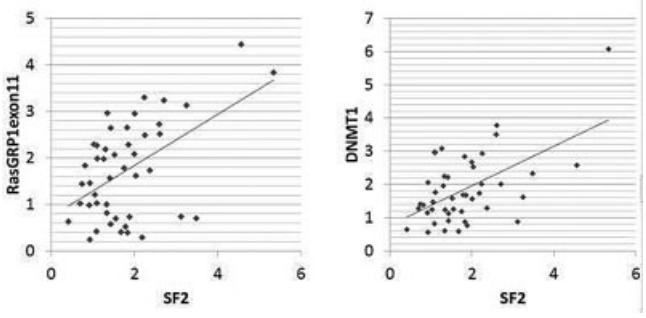
Decreased Levels Of Splicing Factor 2/Alternative Splicing Factor (SF2/ASF) Correlate With Lower Transcript Levels Of The RasGRP1 Normal Isoform In Lupus T Cells. Takashi Kurita[1], Shinsuke Yasuda[1], Vaishali R. Moulton[2], Michihito Kono[1], Hideyuki Koide[1], Kenji Oku[1], Toshiyuki Bohgaki[1], Olga Amengual[1], Tetsuya Horita[1], George C. Tsokos[2] and Tatsuya Atsumi[1]. [1]Hokkaido University Graduate School of Medicine, Sapporo, Japan, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.

Background/Purpose: Down-regulation of MAP kinase pathway has been recognized in T cells from patients with SLE that results in hypomethylation of DNA. RasGRP1 is an intracellular signaling protein highly expressed in T cells and activates the Ras signaling pathway downstream of TCR engagement. RasGRP1 deficient mice develop late-onset lymphoproliferative autoimmune syndrome. Previously we reported that defective (alternatively spliced) RasGRP1 transcripts correlate with lower levels of RasGRP1 protein in SLE T cells (Yasuda S et.al. J Immunol 2007). Splicing factor 2/Alternative Splicing factor (SF2/ASF) is a member of the serine arginine family of splicing proteins that binds pre-mRNA to regulate alternative splicing. For instance, SF2/ASF binds to the 3'UTR of CD3 zeta and enables normal splicing of this signaling protein. (Moulton V et.al. J Biol Chem. 2010). The purpose of this study is to determine the relationship between aberrant splicing of RasGRP1 and SF2/ASF expression in SLE T cells.

Methods: Forty-five SLE patients and eighteen healthy subjects were included in this study. T cells were collected from peripheral blood of each subject and RNA was isolated. Expression levels of SF2/ASF, normally spliced RasGRP1 and DNMT1 transcripts were assessed by real time quantitative PCR. RNA electrophoretic mobility shift assays (EMSA) and immunoprecipitations (IP) were performed to confirm the direct binding of SF2 to RasGRP1 pre-mRNA. RasGRP1 exon11 RNA oligonucleotides end-labeled with biotin and recombinant SF2/ASF phosphate mimic were used in these experiments.

Results: Expression levels of SF2/ASF transcripts were significantly lower in SLE patients compared with healthy subjects ($p=0.001$, t-test). In patients with SLE, expression levels of SF2/ASF correlated with those of normally spliced RasGRP1 and DNMT1 ($r=0.517$, $p=0.023$ [RasGRP1]; $r=0.557$, $p=0.013$ [DNMT1], Figure). EMSA and IP studies suggested that SF2/ASF binds directly to RasGRP1 exon 11 RNA.



Conclusion: SF2/ASF binds to RasGRP1 mRNA and controls its expression. Low SF2/ASF levels in SLE T cells correlate with the expression levels of RasGRP1 and DNMT1. We propose that SF2/ASF regulates the alternative splicing of important genes in SLE T cells including RasGRP1 and CD3 zeta.

Functional Effect Of NR1H3 (LXRA) Promoter Polymorphisms In Korean Patients With Systemic Lupus Erythematosus. Ja-Young Jeon[1], Hyoun-Ah Kim[1], Ju-Yang Jung[1] and Chang-Hee Suh[2]. [1]Ajou University School of Medicine, Suwon, South Korea, [2]Ajou University Hospital, Suwon, South Korea.

Background/Purpose: Liver × receptor alpha (LXRA, NR1H3) and beta (LXRB, NR1H2) can influence macrophage biology by modulation of lipid metabolism and by effects on innate immunity. The recent studies have reported that LXRs are involved in regulation of inflammation and immune responses. In our previous data, we have identified five polymorphisms (−1851 T>C, −1830 T>C, −1003 G>A, −840 C>A and −115 G>A) including one novel SNPs (−1003 G>A) in the *NR1H3* gene. Especially, the −1830 T>C promoter polymorphism was significantly different in genotype analysis and clinical manifestations. This study evaluated the functional effect of the *NR1H3* promoter polymorphism on systemic lupus erythematosus.

Methods: The promoter activity was analyzed by luciferase reporter assay in Hep3B cells and COS-7 cells. To investigate the effects of the stimulation, we used a functional assay of transcriptional activity and B cell proliferation assay with lipopolysaccharide, GW3965 and T0901317. The mRNA expression of *NR1H3* gene according to the genotype was analyzed by RT-PCR and quantitative real-time PCR. To investigate whether the genetic polymorphism changed a transcription factor binding, we performed an electrophoretic mobility shift assay (EMSA).

Results: Luciferase activity of the constructs containing −1830 C was lower than that of the constructs containing −1830 T ($p=0.009$). Moreover, promoter activity of the −1830 C was less enhanced compared to that of the −1830 T in GW3965 and T0901317 treated cells ($p=0.034$ and $p<0.001$, respectively). Proliferation of −1830 TC type was increased compared to that of −1830 TT type in basal, GW3965 and T0901317 treated B cells from SLE patients ($p=0.011$, $p=0.040$ and $p=0.017$, respectively). The −1830 TC type B cells displayed lower *NR1H3* mRNA expression level than the −1830 TT type B cells in both SLE and NC. Moreover, *NR1H3* expression level significantly different between genotypes in real-time PCR. In both SLE and NC, the −1830 TC type was an approximately 1.8-fold decrease than the −1830 TT type. EMSA using nuclear extracts prepared from Hep3B cells revealed a specific band with the −1830 T probe, but not with the −1830 C probe. We performed a competition assay using GATA-3 probes, and found that the shifted band corresponding to the −1830 T probe was completely competed for by the unlabeled GATA-3 probe. The −1830 T specific band was also competed by anti-GATA-3 antibodies but not supershifted.

Conclusion: These results suggest that the *NR1H3* gene −1830 T>C promoter polymorphism may be involved in regulation of *NR1H3* expression.

Association Of TREM-Like Transcript-1 With Systemic Lupus Erythematosus. Yerania Rodríguez-Navedo[1], Karina Vilá -Rivera[1], Mariely Nieves-Plaza[2], Martha Ricaurte[3], A. Valance Washington[3] and Luis M. Vilá[1]. [1]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Puerto Rico, Río Piedras Campus, San Juan, PR.

Background/Purpose: Recent studies suggest that a platelet α-granule protein named TREM-like transcript-1 (TLT-1) is a key molecule in modulating the inflammatory response. TLT-1 has been proposed to be an inhibitor of the inflammatory gene activator TREM-1 and its soluble ligand, thus preventing overactivation of the immune cellular response and sustained inflammation. TLT-1 plasma levels are markedly elevated in infectious disorders such as sepsis and dengue to counterbalance the inflammatory response. The role of TLT-1 in systemic lupus erythematosus (SLE) is unknown. Thus, the aims of this study were to assess TLT-1 plasma levels in SLE patients and healthy individuals, and to determine the factors associated with TLT-1 levels among SLE patients.

Methods: A cross-sectional, case-control study was performed in 46 SLE patients (per American College of Rheumatology [ACR] criteria) and 28 healthy individuals. Data on demographic parameters, clinical manifestations (ACR and non ACR lupus manifestations), disease activity (as per the Systemic Lupus Activity Measure [SLAM]), health-related quality of life (using the Lupus Patient Reported Outcome [LupusPRO] questionnaire), comorbidities, pharmacologic treatment, and damage accrual (as per the Systemic Lupus International Collaborating Clinics/ ACR Damage Index)

were gathered. Plasma TLT-1 levels were measured by ELISA. Student's t test (or Wilcoxon signed-rank test, as appropriate) and Pearson's correlation coefficient test were used for statistical analysis.

Results: The mean (standard deviation [SD]) age for SLE patients and healthy individuals was 45.5 (11.8) and 37.3 (12.1) years respectively; 93% of SLE patients and controls were females. The mean disease duration (SD) of SLE patients was 10.7 (4.1) years. SLE patients had lower mean (SD) levels of plasma TLT-1 than controls (9.0 [7.2] vs. 18.6 [22.3] ng/ml, p=0.008). A negative correlation was observed between TLT-1 levels and the SLAM (r = −0.278, p 0.064) and some domains of LupusPRO (lupus symptoms [r = −0.388, p = 0.055], cognition [r = −0.442, p = 0.027], physical health [r = −0.382, p = 0.060], desires/goals [r = −0.435, p = 0.030]). SLE patients receiving corticosteroid treatment had higher mean (SD) levels of TLT-1 than those not taking corticosteroids (11.1 [8.8] vs. 6.9 [4.6] ng/ml, p = 0.014).

Conclusion: Plasma levels of TLT-1 were lower in SLE patients compared to healthy individuals. Among SLE patients a negative correlation was observed for disease activity and some domains of the LupusPRO. Given that TLT-1 has anti-inflammatory properties, deficiency of this protein could have an important role in the pathogenesis of SLE.

Transcription Activation-Like Effector Nuclease-Mediated Enhancer Knockout Influences *TNFAIP3* Gene Expression and Mimics a Functional Phenotype Associated With Systemic Lupus Erythematosus. Shaofeng Wang[1], Feng Wen[1], Bo He[2] and Patrick M. Gaffney[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]The University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background/Purpose: Emerging technologies for precise, targeted genome editing provide new opportunities for the functional elucidation of causal genetic variants and genomic elements without the confounding effects of correlated variants. Transcription Activation-Like Effector Nucleases (TALENs) represents an efficient tool to mediate site-specific genome modification in human cell lines. Previously, we described the influence of systemic lupus erythematosus (SLE)-associated functional variants (rs148314165, rs200820567; collectively referred to as TT>A) on *TNFAIP3* gene expression. The TT>A variants, which lie 42-kbs downstream of the *TNFAIP3* promoter, are located in a putative enhancer and were recently proposed as causal variants responsible for genetic association of SLE in the region of *TNFAIP3*. In this study, we generated a TT>A enhancer knockout in human cell lines to further characterize the role of the enhancer in regulating *TNFAIP3* gene expression.

Methods: The genomic DNA sequence surrounding the TT>A enhancer was scanned for potential TALEN target sites using TALEN Targeter 2.0. A modified TALEN Golden Gate assembly system was then used to generate RVD repeat arrays, which were then subcloned into the expression vectors pCS2TAL3DD and pCS2TAL3RR. TALENs were expressed in HEK293T cells by transient transfection, and single-cell clones were isolated. Targeted cell clones were selected based on high-resolution melt analysis of PCR amplicons from each cell clone. Sanger sequencing was performed to determine the sequence of the targeted allele. Protein expression of A20 and mRNA expression of *TNFAIP3* were determined by Western blot and RT-qPCR assay, respectively. Chromatin conformation capture (3C) assay was performed to determine the interaction frequency between the TT>A enhancer and the *TNFAIP3* promoter.

Results: We assembled RVD repeat arrays targeting the TT>A enhancer, generated TALEN constructs, and expressed TALENs in HEK293T cells. Using high-resolution melt analysis, we identified an engineered HEK293T cell that carries a 26-bp deletion at the TT>A enhancer, which leads to alteration of NF-κB binding sites predicted using the UniProbe database. Assessing the effect of the mutant TT>A enhancer on the expression of *TNFAIP3* at the protein and transcript level, we demonstrated low-level expression of *TNFAIP3* mRNA and A20 protein in the mutant cell line. Follow up allele-specific 3C assay with the engineered cells demonstrated significantly fewer interactions with the *TNFAIP3* promoter as a result of the mutant allele. This is consistent with the naturally occurring SLE-associated TT>A polymorphism, in which the risk allele reduces gene expression of *TNFAIP3*.

Conclusion: The SLE-associated TT>A enhancer plays an important role in regulating gene expression of *TNFAIP3*. By generating an engineered TT>A enhancer mutant HEK293T cell line, we have characterized the influences of the mutated enhancer on *TNFAIP3* gene expression. These results suggest that TALEN-mediated genome editing has potential to be used for the identification and characterization of complex disease-associated causal variants.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, heterogeneous autoimmune disorder characterized by inflammation, loss of tolerance to self-antigens, and dysregulated interferon responses. Although >40 loci have been associated with SLE, a substantial portion of the genetic risk has not been explained. Previous work has shown that the genetic architecture and associated loci differ among ancestral populations. In this study, we performed a genome-wide association scan to identify genes associated with SLE in Korean subjects.

Methods: Genotyping was performed using Illumina OMNI-express arrays with ~700,000 variants. Standard best practice quality control measures were applied for Hardy-Weinberg proportions, missing and differential missing genotypes data, genetic outliers determined by principal component (PC) analysis. Only SNPs with minor allele frequencies >1% are reported. After quality control filtering, a total of 1174 Korean SLE cases and 4248 population controls were available for analysis. SNP-SLE association was tested using logistic regression model adjusting for PC. Inference is the additive genetic model unless there was significant (P<0.05) departure from additivity, then dominant additive and recessive examined. Bioinformatic analysis was done using HaploReg ver. 2.0.

Results: Ten regions outside the HLA exceeded the genome-wide significance threshold of P<5×10E–8. Of these, 9 regions replicated previously identified SLE risk loci: *TNFSF4, STAT1-STAT4, TNFAIP3, IKZF1, HIP1, IRF5, BLK, WDFY4, and ETS1*. The novel associated locus was between *FCHSD2* and *P2RY2* on 11q14. (rs11235667, P=1×10E–8, odds ratio = 0.59, 95% CI= 0.50–0.71). No additional SNP was significant after adjusting for rs11235667 via logistic regression. Bioinformatics analysis reported that rs11235667 is a strong enhancer in B lymphoblastoid cell lines. Chromatin immunoprecipitation followed by sequencing experiments done by the ENCODE project found POL2 and YY1 proteins cross-linked to this region. Moreover, sequence prediction methods indicate that rs11235667 can alter the binding motif for the FOXa family of transcription factors.

Conclusion: We have identified a novel association in the region of *FCHSD2-P2RY2* and confirmed associations with 9 previously-associated SLE regions outside the HLA in Korean subjects. Although *FCHSD2* (FCH and double SH3 domains 2) has no known function, variants in this region are associated with Crohn's disease in Japanese subjects. P2RY2 (purinergic receptor P2Y, G-protein coupled, 2) is known to be involved in cell proliferation, apoptosis, and inflammation. In rheumatoid synoviocytes, IL-6

has been shown to increase the expression of *P2RY2*. Ongoing studies are seeking to replicate the *FCHSD2-P2RY2* association in additional samples.

Sub-Phenotype Mapping In Systemic Lupus Erythematosus Identifies Multiple Novel Loci Associated With Circulating Interferon Alpha. Silvia Kariuki[1], Yogita Ghodke[2], Jessica M. Dorschner[2], Beverly Chrabot[1], Jennifer A. Kelly[3], Betty P. Tsao[4], Robert P. Kimberly[5], Marta E. Alarcon-Riquelme[6], Chaim O. Jacob[7], Lindsey A. Criswell[8], Kathy L. Sivils[3], Carl D. Langefeld[9], John B. Harley[10], Andrew D. Skol[1] and Timothy B. Niewold[2]. [1]University of Chicago, Chicago, IL, [2]Mayo Clinic, Rochester, MN, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]David Geffen School of Medicine University of California Los Angeles, Los Angeles, CA, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Oklahoma Medical Research Foundation, Center for Genomics and Oncological Research Pfizer-University of Granada-Junta de Andalucia, Oklahoma City, OK, [7]University of Southern California Keck School of Medicine, Los Angeles, CA, [8]University of California, San Francisco, Rosalind Russell Medical Research Center for Arthritis, San Francisco, CA, [9]Wake Forest University Health Sciences, Winston-Salem, NC, [10]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a phenotypically heterogeneous complex disease. Our previous work has documented significant genetic heterogeneity, with some well-validated risk factors demonstrating strong sub-group effects. Approximately 50% of patients have high circulating levels of interferon alpha (IFN-α), and many lines of investigation support IFN-α as a heritable and primary causal factor in human SLE. This study aims to genetically map the serum IFN-α trait in SLE patients, allowing for novel genetic discovery in this heterogeneous disease.

Methods: GWAS data were obtained from 450 European ancestry SLE cases who were genotyped as part of the Systemic Lupus Erythematosus Genetics (SLEGEN) study. Genotypes were generated on the Illumina Infinium HumanHap 300 genotyping platform, and principal component analysis was used to correct for population stratification. Sera were obtained from each of these subjects, and IFN-α activity was measured using a sensitive and specific reporter cell assay. Associations between genome-wide SNP markers and serum IFN-α were detected using logistic regression conditioned on the principal components to control for structure. IFN-α activity was studied as a categorical trait. Patients with IFN-α levels 2SD above the mean of healthy controls were designated as high IFN-α, and the remainder as low IFN-α.

Results: Top novel associated loci in the GWAS screen include multiple SNPs in the C7orf57, PRKG1, ANKRD44, and PNP loci. Interestingly, three of the 5 top SNPs are missense SNPs. Strong association signals were also detected in chromosomes 12 and 14. Genome-wide imputation using SNPs from the 1000 Genomes Project did not yield additional significant association signals beyond those identified by the directly genotyped SNPs.

Conclusion: These novel loci have not been previously associated with SLE in case-control analyses. This supports the concept that studying pathogenic subgroups within the complex disease SLE will be important in our efforts to fully map disease susceptibility. These loci could provide novel therapeutic targets in the IFN-α pathway and assist in personalizing therapy in this disease.

Genome-Wide Transcriptional Profiling Of Isolated Immune Cell Populations From SLE Patients With Different Ancestral Backgrounds. Shruti Sharma[1], Zhongbo Jin[2], Elizabeth Rosenzweig[1], Swapna Rao[1], Kichul Ko[1] and Timothy B. Niewold[2]. [1]University of Chicago, Chicago, IL, [2]Mayo Clinic, Rochester, MN.

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex multi-system autoimmune disease of uncertain etiology. Different ancestral backgrounds demonstrate different clinical manifestations and autoantibody profiles. Whole blood gene expression studies in SLE have demonstrated a prominent type I interferon (IFN) signature. Presumably different cell types will exhibit different patterns of gene expression, and in this study we sorted major immune cell populations from PBMC and examined genome-wide transcription patterns in cell subsets and in different ancestral backgrounds.

Methods: Peripheral blood was collected from 21 African-American (AA) and 21 European-American (EA) SLE patients, 5 AA controls, and 5 EA controls. $CD4^+$ T-cells, $CD8^+$ T-cells, monocytes and B cells were purified by flow sorting. Each cell population from each subject was run on an Illumina HumanHT-12 V4 expression BeadChip array. The raw data were filtered to exclude the non-detected genes. Quantile normalization and Log2 transformation were applied prior to between-group comparisons. Differentially expressed genes (DEGs) were determined by comparing cases and controls of the same ancestral background, and then DEG lists were compared between cell types and between ancestral backgrounds. Because IFN-related gene expression differed between cell types, we also developed a novel metric to encompass IFN-induced gene expression more globally and comprehensively than pathway analyses, generating a quantitative metric.

Results: While we observed approximately 1000 DEGs in each cell type that was isolated, the overlap in DEG lists between different cell types was very modest (<1%), supporting the idea that different transcripts are upregulated in different cell types. Typically between 5 to 10% of DEGs were shared when comparing the same cell type in different ancestral backgrounds (for ex. CD20 AA vs. CD20 EA). Interestingly, gene expression profiles different cell types from the same subject exhibited individualized patterns on unsupervised hierarchical clustering, supporting some cell-type independent inter-individual variations. Quantitative measurement of global IFN-induced gene expression revealed that AA subjects demonstrated more concordance across all studied cell types in IFN-induced gene expression. In EA subjects, a subset of patients demonstrated increased IFN-induced gene expression in all lymphocyte populations but not monocytes, and another subgroup demonstrated IFN-induced gene expression in monocytes and B-cells but not in CD4 or CD8 T-cells.

Conclusion: We find fascinating differences in gene expression between different immune cell populations and between ancestral backgrounds in SLE patients. It seems that the IFN signature is relatively diverse, affecting different cell populations in different ways, and behaving differently in EA vs. AA patients. These data may impact efforts to target this pathway therapeutically.

1635

Identification Of Novel Genetic Associations Within Major Histocompatibility Complex (MHC) Class I and Class II In Systemic Lupus Erythematosus (SLE) Patients: An Examination Of Epitopes Of Early Autoimmunity. Gerard Dumancas[1], Chee Paul Lin[1], Indra Adrianto[1], Jennifer A. Kelly[1], Stuart B. Glenn[1], Jourdan Anderson[1], John B. Harley[2], Timothy J. Vyse[3], Robert P. Kimberly[4], Marta E. Alarcon-Riquelme[5], Carl D. Langefeld[6], Betty P. Tsao[7], Lindsey A. Criswell[8], Chaim O. Jacob[9], Patrick M. Gaffney[1], Kathy Sivils[1], Judith A. James[1] and Courtney Montgomery[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Divisions of Genetics and Molecular Medicine and Immunology, King's College London, London, United Kingdom, [4]University of Alabama at Birmingham, Birmingham, AL, [5]Oklahoma Medical Research Foundation, Center for Genomics and Oncological Research Pfizer-University of Granada-Junta de Andalucia, Oklahoma City, OK, [6]Wake Forest University Health Sciences, Winston-Salem, NC, [7]David Geffen School of Medicine University of California Los Angeles, Los Angeles, CA, [8]University of California, San Francisco, Rosalind Russell Medical Research Center for Arthritis, San Francisco, CA, [9]University of Southern California Keck School of Medicine, Los Angeles, CA.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by autoantibody production, multiple organ involvement, strong genetic predisposition and specifically, to be associated with Class II alleles within the Major Histocompatibility Complex (MHC). Immunochemistry studies have shown that specific antibodies often occur years before clinical diagnosis and accrue new specificities through preclinical and clinical phases of SLE. More specifically, specific epitopes appear to

be unique to SLE patients early in the course of disease evolution, even compared to other rheumatic diseases. The goal of our study was to better characterize the role of the genes within the MHC by assessing genetic association between antibodies to early epitopes of SmB', SmD1 and 60kD Ro (termed here GMR, GRx4 and Ro169, respectively) in 703 SLE European-American (EA) and 557 African American (AA) SLE cases. We also assessed genetic association with autoantibodies directed against the parent lupus autoantigens, Sm and 60kD Ro, in both races.

Methods: Standardized ELISA assays tested serum samples for binding of SmB': amino acid sequence PPPGMRPP (GMR); SmD1: Glycine Arginine repeat sequence (GRx4); 60kD Ro: amino acids 169–180 (Ro169). Levels of anti-Sm and anti-Ro60 were determined by Bio-Rad Bioplex2200 ANA testing. All data are semi-quantitative and only measured in SLE patients. This is in contrast to previous studies, which assessed genetic association of the dichotomous trait, positive versus negative by immunodiffusion asays.

We evaluated $>$ 50,000 SNPs within the MHC in both EA and AA samples. SNP data were collected from Affymetrix Genome-Wide Human SNP Array 5.0, Illumina iSelect Infinium II, and Immunochip and imputed with IMPUTE2. Quality control included removing of SNPs with call rate $<$90%, minor allele frequency $<$0.01 and Hardy-Weinberg proportion tests $P < 0.001$.

Results: Autoantibodies against the GRx4) yielded a novel association within the Class I region, with the most significant SNP near TRIM40/TRIM15 in EAs ($P < 5 \times 10^{-7}$) and near TRIM39 in AAs ($P < 5 \times 10^{-5}$). The Ro169 was also strongly associated in EAs at this location ($P < 5 \times 10^{-5}$). Autoantibodies against the GMR showed no association with Class I genes but was significant for Class II ($P < 5 \times 10^{-4}$, nearest DQB1) in the same race. Both Sm and 60kd Ro autoantibody responses were also significantly associated within the Class I region ($P < 5 \times 10^{-5}$ and $P < 5 \times 10^{-4}$, respectively) in the EAs. 60kD Ro was also highly significant ($P < 5 \times 10^{-8}$) within the Class II region at DRB1, DQB1 and DQA1 in EAs. Further conditional analysis showed the driving effect to be within HLA-DQA1. The AA sample was significant for DQB1 and DQA1 ($P < 5 \times 10^{-6}$) for the 60kD Ro epitope.

Conclusion: Our genetic study of the MHC region identified novel association between autoantibody responses against some of the earliest epitopes of lupus, their parent proteins and Class I variants. We further confirmed and more specifically characterized association between Class II variants and 60kd Ro. These findings and other investigations into the genetic mechanisms underlying early lupus autoimmunity will give significant insight into disease etiology.

Pro-Inflammatory HDL and Subclinical Atherosclerosis Are Associated With Altered Expression Of Epigenetic and Oxidative Stress-Related Gene Transcripts In SLE. Brian Skaggs, Bevra H. Hahn, Jennifer M. Grossman, Elaine Lourenco, Isao Matsuura, Lori Sahakian and Maureen A. McMahon. UCLA David Geffen School of Medicine, Los Angeles, CA.

Background/Purpose: Premature atherosclerosis is widely recognized as a significant co-morbid condition of systemic lupus erythematosus (SLE), but exact mechanisms are unknown. Although traditional cardiovascular risk factors correlate with subclinical atherosclerosis in cohort studies, they are unable to fully account for the increased risk. Longer SLE duration correlates with higher risk for cross-sectional and longitudinal progression of atherosclerosis, suggesting that chronic inflammation and/or oxidative stress could be SLE-specific factors contributing to accelerated atherosclerosis. Plasma pro-oxidant, pro-inflammatory HDL (piHDL) is also closely linked to presence and progression of plaque in SLE and can abnormally activate monocytes, the major immune cell type involved in atherosclerosis. Recent data have linked oxidative stress to epigenetic aberrations in non-autoimmune subjects with atherosclerosis, and we wanted to examine whether these mechanisms could partially explain the risk of premature atherosclerosis in SLE.

Methods: Patients were recruited from a pre-existing cohort to study atherosclerosis in SLE. Carotid ultrasound was performed to determine the presence or absence of subclinical atherosclerosis (plaque). HDL status was determined by a fluorometric assay examining oxidation of human LDL in the presence of patient HDL. RNA was isolated from freshly isolated primary monocytes from 51 SLE patients subdivided into three groups: a) plaque+piHDL+ (LPP, n=15), b) plaque-piHDL+ (LPN, n=18), and c) plaque-piHDL- (LNN, n=18). Whole-genome monocyte expression analysis was performed using Affymetrix Human U133+2.0 chips. dChip software (Li lab, Harvard) was utilized to determine differentially expressed transcripts between the three groups. Clustering was performed and graphed using Cluster and TreeView (Eisen lab, UC Berkeley). Confirmation of significantly altered transcript levels was determined using quantitative PCR.

Results: Expression of 385 genes was significantly altered between the LPP and LNN groups (fold change $\geq$1.2 or ≤ -1.2, $p \leq 0.05$, false discovery rate 6.8%). The majority of the differentially-expressed genes were downregulated in LPP (vs. LNN). A large proportion of genes were involved in histone acetylation, DNA methylation, and oxidative stress (14% of the total; $<$5% expected). Multiple methyltransferases (MT) were downregulated in LPP subjects, including DNMT1. The presence of piHDL correlates with lower MT, acetyltransferase, and oxidative stress transcripts, as many of the same transcripts were downregulated in the LPN group (vs. LNN). Conversely, the antioxidants peroxiredoxin2 (PRDX2) and superoxide dismutase 2 (SOD2) were upregulated in LPN and LPP groups versus LNN. Unsupervised clustering placed almost all samples into their piHDL/plaque subgroups.

Conclusion: The presence of piHDL correlates with dysregulation of multiple epigenetic and oxidative stress-related transcripts in circulating monocytes of SLE patients. Further epigenetic and biochemical experiments will determine the role of lipid and protein oxidation in the initiation of premature atherosclerosis in SLE.

IKZF1 Modulates PP2Ac Expression Through An Intronic Binding Site. Kamalpreet Nagpal[1], Katsue S. Watanabe[2] and George C. Tsokos[1]. [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama, Japan.

Background/Purpose: Protein phosphatase 2A (PP2A) is a highly conserved and ubiquitous serine/threonine phosphatase. We have previously shown that mRNA and protein, as well as the activity of the catalytic subunit (PP2Ac) of PP2A are increased in T-cells of SLE patients as compared to healthy controls. This increased expression and activity of PP2A plays a central role in the molecular pathogenesis of SLE, including reduced production of the cytokine IL-2. Although the control of PP2Ac expression has been the focus of many studies, many aspects of its regulation still remain poorly understood. In this study, we identify the transcription factor Ikaros (*IKZF1*) as a novel regulator of PP2Ac expression.

Methods: CD3 (+)ve T-cells from healthy individuals were transfected with Ikaros expression plasmid using AMAXA nucleoporation. RNA and protein were isolated and Real-Time PCR and western blotting were used to analyze gene expression. Biotinylated oligos spanning the putative Ikaros binding site or a non-specific control oligo were used in pull-down assays followed by western blotting with Ikaros specific antibody to examine the binding of Ikaors. EMSA with Jurkat cells nuclear protein extract and radio-labeled oligos was used to confirm this binding. Binding of endogenous Ikaros to the PP2Ac intron region was validated by ChIP using a commercially available kit.

Results: An online *in-silico* transcription factor search identified the transcription factor Ikaros as having a binding site in the first intron of *PPP2AC* gene. To examine this binding, biotinylated oligos spanning this region in the intron were used in a pull-down assay with nuclear proteins extracted from Jurkat cells. As compared to the control oligo, the specific oligo exhibited significant binding to Ikaros. EMSA with radio-labeled oligos as well as ChIP assays in primary T-cells further validated the binding of Ikaros to this region. Exogenous expression of Ikaros in T-cells led to diminished PP2Ac expression. Conversely, siRNA enabled knockdown of Ikaros enhanced the expression of PP2Ac, suggesting that Ikaros acts as a

suppressor of PP2Ac gene expression. We also attempt to delineate the mechanism of Ikaros mediated PP2Ac gene suppression. We report that Ikaros recruits the histone deacetylase HDAC1 as well as DNA methyltransferase DNMT1 to this intronic site, thus mediating epigenetic alterations leading to reduced gene expression.

Conclusion: We show for the first time that the transcription factor Ikaros can regulate the gene expression of PP2Ac by binding to a site in the first intron. Ikaros seems to mediate this suppression by modulating chromatin modifications at this site. Our study thus identifies a novel means of control of PP2A, a critical molecule involved in lupus pathogenesis.

Concurrent Autoimmune Disease and Autoantibodies In a Large, Multi-Racial Cohort Of First Degree Blood Relatives Of SLE Patients. Julie M. Robertson[1], Benjamin F. Bruner[2], Rufei Lu[1], Joel M. Guthridge[1], John B. Harley[3] and Judith A. James[4]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Harding University, Searcy, AR, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Oklahoma Medical Research Foundation and University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background/Purpose: First degree relatives (FDRs) of SLE patients have an increased risk of developing autoantibodies and/or autoimmune disorders. Between 20% and 40% of FDRs develop autoimmune diseases. FDRs with a family history of SLE have 6 fold higher risk of developing SLE and a 4 fold higher risk for developing a non-SLE autoimmune disease. Previous studies have estimated that about 30% of FDRs develop anti-nuclear antibodies (ANA). This study is the first to examine the prevalence of autoimmune disease and autoantibody development in a large, multi-racial group of FDRs of lupus patients.

Methods: Clinical and demographic (age, sex, and self-reported race) information from individuals in the Lupus Family Registry and Repository was obtained for 1,092 FDRs of SLE patients, including information regarding diagnosed autoimmune disorders and symptoms of clinical autoimmune rheumatic diseases by connective tissue disease screening questionnaire (CSQ). Serum samples from European-American (EA, n=680), African-American (AA, n=264), and Hispanic (Hisp, n=148) individuals were examined for 13 common autoimmune rheumatic disease autoantibodies using a multiplexed bead-based assay. Autoantibody prevalence and association with non-SLE rheumatic disease and non-rheumatic disease was evaluated using Fisher's exact tests and Kruskal-Wallis tests for continuous data.

Results: Among the 403 families included in the study, 134 reported autoimmune disease in FDRs (33%). In the 1092 FDRs, 172 (15.8%) reported a rheumatic autoimmune disease while 65 (5.96%) reported a non-rheumatic autoimmune disease. The most common autoimmune disease reported was rheumatoid arthritis (RA, n= 83, 7.6% of FDR). No ethnic differences were observed in the development of non-lupus autoimmune disorders in FDRs. ANA positivity was detected in 34.3% EA, 37.1% AA, and 32.4% Hisp FDRs out of all FDRs tested. Anti-Sm/nRNP antibodies were more prevalent in African-American FDRs with a rheumatic autoimmune disease ($p<0.05$) compared to EA and Hisp individuals with rheumatic autoimmune disease. Anti-nRNP A antibodies are significantly increased in EA FDRs with a rheumatic autoimmune disease compared to a EA FDRs with a non-rheumatic autoimmune disease or no autoimmune disease. Anti-chromatin, Sm, Sm/nRNP, and 60kD Ro antibodies trend towards being increased in AA FDRs with a non-lupus rheumatic autoimmune disease compared to AA individuals with a non-rheumatic autoimmune disease or no autoimmune disease. In Hisp FDRs, antibodies against chromatin, nRNP A, and 60kd Ro are significantly more prevalent ($p<0.05$) in Hisp FDRs with.

Conclusion: First degree blood relatives of SLE patients have an increased risk for developing autoimmune disease and autoantibodies. In this large, multi-racial cohort, 21.7% of the FDRs report a non-SLE autoimmune disease and about 30% have detectible ANA. Racial differences in autoantibody prevalence are observed in FDRs of lupus patients with autoantibodies against chromatin, 60kD Ro, and Sm/nRNP being the most common autoantibody specificities.

Oscar E. Alende, Mar del Plata, Argentina, [18]Hospital San Juan Bautista, Catamarca, Argentina, [19]Instituto de Investigaciones Biomédicas de la Universidad Nacional Autónoma de México, and Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico, [20]Childrens Hospital, Cincinnati, OH, [21]University of Southern California, Los Angeles, CA, [22]University of Southern California Keck School of Medicine, Los Angeles, CA.

Background/Purpose: Systemic lupus erythematosus (SLE), a chronic autoimmune disease with a strong genetic component, exhibits a 9:1 female to male ratio and disproportionate impact on individuals of admixed ancestries in the Americas. We performed a genome-wide association scan on individuals from Latin America and the United States enriched for Amerindian while admixed with European ancestry.

Methods: A total of 4516 individuals were genotyped, 2906 for the Illumina Human Quadv1 (OMNI1) and data from1610 out-of-study controls for the OMNI2.5 Bead array was obtained yielding, 996,672 SNPs for final analysis (580,483 SNP were on both BeadArrays). After quality control filters were applied, a total of 3710 individuals were kept for genetic association analysis. The final inflation factor was 1.00 using the 2 first principal components (PC). Principal component analysis revealed 2 differentiated populations that corresponded to a South American (individuals from Argentina, Chile and Peru; $N = 875$), and a North American group composed of individuals from Mexico, and Hispanics and Native Americans from the United States ($N = 2835$). SNP-SLE association was tested using logistic regression model adjusting for PC. Results for the additive model are reported.

Results: One novel genetic association was identified in chromosome 10, between *INA*, *USMG5* and *PDCD11* (rs4917385, $P_{value} = 7.48 \times 10^{-8}$, min FDR p-value=0.00099, OR=0.75, CI=0.67–0.84). Several known lupus susceptibility loci were replicated. Overall, the strongest effect was that of *TNPO3-IRF5* locus, followed by the HLA class II region. Regions previously associated in Europeans that were associated for the first time in individuals with enriched Amerindian ancestry were *TNFSF4*, *NCF2*, *NMNAT2*, *JAZF1*, *FAM167A-BLK*, and *PTTG1-MiR146a*. Regions previously associated in Asians and associated for the first time in individuals with enriched Amerindian ancestry were *SLC15A4* and *WDFY4*.

Conclusion: We identify a new locus for SLE in chromosome 10. Our data show the major importance of genes outside the HLA in the susceptibility for lupus in this population and provide support for loci previously found in Asians and Europeans.

Methotrexate Treatment Affects Effector, But Not Regulatory T Cells in Juvenile Idiopathic Arthritis. Maja Bulatovic Calasan, S.J. Vastert, Rianne C. Scholman, Frederik Verweij, Mark Klein, Nico M. Wulffraat, Berent J. Prakken and Femke van Wijk. University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: The balance between regulatory (Treg) and effector T cells (Teff) is crucial for immune regulation in juvenile idiopathic arthritis (JIA). How methotrexate (MTX), the cornerstone treatment in JIA, influences this balance *in vivo* is poorly elucidated. The aim of this study was to investigate quantitative and qualitative effects of MTX on Treg and Teff in JIA patients during MTX treatment.

Methods: Peripheral blood samples were obtained from JIA patients at MTX start and 3 and 6 months thereafter. Treg numbers and phenotype were determined by flow cytometry and suppressive function in allogeneic suppression assays. Teff proliferation upon stimulation with anti-CD3, activation status and intracellular cytokine production were determined by flow cytometry. Effector cell responsiveness to suppression was investigated in autologous suppression assays. Effector cell cytokines in supernatants of proliferation and suppression assays and in plasma were measured by cytokine multiplex assay.

Results: MTX treatment in JIA did not affect Treg phenotype and function. Instead, MTX treatment enhanced, rather than diminished, $CD4^+$ and $CD8^+$ T cell proliferation of JIA patients after 6 months of therapy, independent of clinical response. Effector cells during MTX treatment were equally responsive to Treg-mediated suppression. MTX treatment did not attenuate Teff activation status and their capacity to produce IL-13, IL-17, TNFα and IFNγ. Similarly to Teff proliferation, plasma IFNγ concentrations after 6 months were increased.

Conclusion: This study provides a novel insight that MTX treatment in JIA does not attenuate Teff function but conversely, enhances T cell proliferation and IFNγ plasma concentrations in JIA patients.

Bispecific Antibodies For Redirection Of Human Regulatory T Cells To Surface-Inducible Autoantigen La/SS-B. Stefanie Koristka[1], Marc Cartellieri[1], Claudia Arndt[1], Anja Feldmann[1], Irene Michalk[1], Claudia C. Bippes[1], Nicole Berndt[1], Anne Hermsdorf[1], Slava Stamova[1], Biji T. Kurien[2], Robert Hal Scofield[3], A. Darise Farris[4], Judith A. James[5], Holger Bartsch[1] and Michael Bachmann[1]. [1]Carl Gustav Carus TU-Dresden, Dresden, Germany, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation; Department of Medicine, University of Oklahoma Health Sciences Center; US Department of Veterans Affairs Medical Center, Oklahoma City, OK, [4]Oklahoma Medical Research Foun, Oklahoma City, OK, [5]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: Adoptive transfer of regulatory T cells (Tregs) represents a promising strategy for treatment of auto- and alloimmunity. However, it is difficult to obtain therapeutically relevant numbers of antigen-specific Tregs. Bispecific antibodies (bsAb) are promising tools for a target-specific redirection of polyclonal Tregs. BsAb are composed of two different antigen binding moieties facilitating the cross-linkage of two different cell types. E.g. T cells redirected by bsAb to tumor cells result in an eradication of tumor cell as shown in various *in vitro, in vivo* and first clinical trials. Recently, we reported that bsAb can also be used for redirection of Tregs leading to the search of potential target structures in inflamed tissues. Many pathological immune-mediated conditions, e.g. autoimmune diseases, graft rejection or GvHD are associated with massive cell death. Recently, we established a cell culture system allowing us to unequevocally show that the nuclear autoantigen La is released from dying cells and tightly binds to neighbouring living intact cells. Therefore, we wanted to learn if La can be used as inducible surface target for redirection of subpopulations of T cells including Teff and Tregs via bsAbs.

Methods: In order to induce cell death, cultured human cells were irradiated with UV. After irradiation human cells were cocultured with untreated murine cells. Human La released and bound to the surface of co-cultured murine cells was stained with three different anti-human La specific mabs (SW5, 5B9, 7B6). These mabs recognize well defined epitopes either in the N- (SW5, 5B9) or C-terminus (7B6) of La. Alternatively, recombinant human La was added to cultured human cells. Cell surface bound La was used for redirection of sorted Tregs via two novel bispecific anti-CD3-anti-La abs. The effects of sorted redirected Tregs on activation, cytokine release, killing efficacy, and proliferation of immune effector T cells were estimated by FACS.

Results: Two novel fully humanized bsAb targeting La and the CD3 complex of T cells were established and their capability to redirect Teff and Tregs to surface bound La was tested. Both CD4+ and CD8+ Teff redirected to surface bound La resulted in an efficient killing of target cells while highly enriched sorted Tregs were not able to mediate cytotoxicity. In contrast, the cross-linkage of Tregs with La-decorated target cells resulted in activation of both freshly isolated and expanded human Tregs. Moreover, such bsAb-activated Tregs displayed a potent suppressive capacity and negatively influenced proliferation, expansion and cytokine production of autologous CD4+ and CD8+ Teff cells.

Conclusion: Our results indicate that La released and tightly bound to the surface of living cells are accessible for abs and can therefore be used as inducible surface target for redirecting of T cell (sub)populations via bsAb. While redirected effector T cells mediate cell death Tregs can attenuate Teff cell-mediated inflammatory immune responses and tissue destruction and may therefore be useful for a site-specific recruitment of Tregs into inflamed tissues for the treatment of GvHD, autoimmunity or transplant rejection.

CD25+CD39+ Regulatory T Cells Are Enriched At The Site Of Inflammation Of Patients With Rheumatoid Arthritis and Impaired In Suppressing IL-17A Secretion. Jessica Herrath[1], Karine Chemin[2], Inka Albrecht[1], Anca Catrina[2] and Vivianne Malmström[3]. [1]Karolinska University Hospital, Department of Medicine, Solna, Unit of Rheumatology, Stockholm, Sweden, [2]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Regulatory T cells (Tregs) are important for the maintenance of self-tolerance and are implicated in the origin of autoimmunity. Despite enrichment of Tregs in joints of rheumatoid arthritis (RA) patients, local inflammation persists and becomes chronic. Recently, CD39 expression has been described on FOXP3+ Tregs and suggested to be a novel mechanism of Treg suppression by producing anti-inflammatory adenosine together with CD73. Interestingly the capacity of CD39+ Treg to suppress Th17 responses is impaired in multiple sclerosis. Whether this defect is a general feature found in autoimmune diseases is currently unknown. In this study, we first aimed to better characterize the CD39+ Treg compartment in blood and synovial fluids from RA patients. We then further addressed their capacity in suppressing T effector cell responses, especially Th17 responses.

Methods: Multi-parameter flow cytometry was used to assess the *ex vivo* frequencies of FOXP3+CD39+ and FOXP3+CD39- Tregs in blood of healthy controls (n=11) and RA patients (n=15) as well as at the site of inflammation of RA (n=15) and spondylarthropathy patients (n=10). In addition, the differential suppressive capacity of synovial CD39+ and CD39- Tregs was investigated by conventional co-culture systems (n=6). Proliferation and cytokine secretion was measured by thymidine incorporation and luminex, respectively.

Results: FOXP3+CD39+ Tregs were enriched at the site of inflammation ($p=0.0007$) whereas synovial FOXP3+CD73+ Tregs were reduced compared to the circulation ($p<0.001$). The same pattern for CD39 and CD73 expression was also seen for the total population of synovial CD4+ T cells, ($p<0.0001$). Furthermore, synovial CD25+CD39+ Tregs were able to suppress proliferation of T effector cells ($p=0.0313$) in contrast to their CD39- counterparts that proliferated instead ($p=0.026$). Finally, cytokine suppression was exerted by the CD25+CD39+ Treg subset (and not by CD39-) for many cytokines but not for IL-17A.

Conclusion: Our data suggest that FOXP3+CD39- and FOXP3+ CD39+ Tregs are distinct subsets with different functions as exemplified by synovial CD39- T cells that proliferate *in vitro* and secrete pro-inflammatory cytokines instead of suppressing them. CD39- Tregs could represent plastic Tregs that converted to IL-17 producers under inflammatory conditions. Furthermore, we demonstrate that, in synovial fluid, CD39+ Treg are impaired in suppressing IL-17A secretion, a cytokine that may contribute to disease pathogenesis. This finding could partly explain why accumulation of Tregs is seen at the site of inflammation without facilitating remission.

1643

***Ex Vivo* Suppression Of RA Effector T Cells (Teff) By Mapc Media Is Synergistic With Treg.** Gali Malul[1], David Soler[2], Donald D. Anthony[3], Hillard M. Lazarus[2], Nicholas Lehman[4], Thomas McCormick[2], Julia M. Sugalski[5], Anthony E. Ting[4] and Nora G. Singer[6]. [1]MetroHealth Medical Center, Cleveland, OH, [2]Case Medical Center, Cleveland, OH, [3]Case Western Reserve University, Cleveland VA Medical Center, University Hospitals of Cleveland, Cleveland, OH, [4]Athersys, Inc., Cleveland, OH, [5]Case Western Reserve University, Cleveland, OH, [6]Director, Division of Rheumatology, MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH.

Background/Purpose: Use of mesenchymal/multipotent stem cells (MSCs/MAPCs) is an emerging immune modulatory therapeutic strategy promising for a number of human diseases. Multipotent adult progenitor cells (MAPC) are adherent cells isolated from adult bone marrow and have strong anti-inflammatory and immunomodulatory properties. MultiStem®, a cGMP manufactured MAPC product, is in Phase II clinical use for treatment of ischemic strokeand ulcerative colitis. We are interested in treating new onset Rheumatoid Arthritis (RA) patients with MAPC to induce immune regulation and tolerance. In the present study our goal was to demonstrate the potential for of MAPC-based therapy in new onset RA. To that end, we characterized the effect of MAPC conditioned media on RA effector T-cell (Teff) and T-regulatory (Treg) function *ex vivo*. We hypothesized that Treg function and number might improve following treatment with MAPC conditioned media. We evaluated RA Teff function in the presence of cytokine stimulated conditioned media (CCM) that was generated following co-culture with MAPC.

Methods: Active sero-positive RA subjects (RF+ or CCP+) with DAS28 scores varying from 4.5–5.8 were recruited. Teff and Treg were obtained (flow sorted) from seropositive RA patients off therapy, and 6 weeks after start of therapy with methotrexate. Treg were CD4+CD25^{hi} cells and Teff were CD4+CD25 ^{low}. To measure the effect of conditioned MAPC media and Treg on Teff responses, suppression assays were performed; RA and healthy donor (HD) Teff were incubated with CCM with or without Treg and proliferation was measured at 5– 6 days by dye dilution method and flow cytometry. The dilution of CCM to growth media (GM) ranged from a high of 7/8 to a low of 1/8 (GM is media prior to addition of cytokines or culture with MAPC).

Results: Cytokine stimulated MAPC conditioned media (CCM) alone suppressed Teff proliferation in a dose dependent fashion. Maximal suppression by CCM was observed with 7/8 CCM/GM and ranged from 48 to 80% (median 57%) suppression. Treg also suppressed Teff in a dose dependent fashion; 50% suppression of Teff proliferation was observed with Treg (no CCM) at a Treg:Teff ratio of 1:1. Combining Tregs (1:1 Treg:Teff) and CCM (CCM:GM 1:1) led to 86% suppression of Teff. Dose dependent suppression was observed with varying Treg numbers and/or CCM dilution. The possibility that Treg proliferation occurred was excluded by stimulating Treg alone with beads, and measuring proliferation as described for Teff.

Conclusion: Potent suppression of RA Teff by combining MAPC conditioned media and Treg is demonstrated. This strongly suggests that MAPC will offer therapeutic value in RA and may act in synergy with Treg. To what extent MAPC therapeutic effects *in vivo* are mediated by increases in Treg number and/or function is an open question. Studies testing MAPC therapeutically in RA should be accompanied by studies to understand mechanism.

Circulating CD4+CD161+ T Lymphocytes Are Increased In Seropositive Arthralgia Patients But Decreased In Patients With Newly Diagnosed Rheumatoid Arthritis. Paulina Chalan, Bart-Jan Kroesen, Kornelis S.M. van der Geest, Minke G. Huitema, Wayel H. Abdulahad, Elisabeth Brouwer and Annemieke M.H. Boots. University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: Improved understanding of the immune events discriminating between seropositive arthralgia and clinical synovitis is of key importance in rheumatology research. Ample evidence suggests a role for Th17 cells in rheumatoid arthritis (RA). We hypothesized that CD4+CD161+ T-cells representing Th17 lineage cells may be modulated prior to or after development of clinical synovitis. Therefore, in a cross-sectional study, we investigated the occurrence of CD4+CD161+ T-cells in seropositive arthralgia patients who are at risk for developing RA and in newly diagnosed RA patients. In a prospective study, we evaluated the effect of methotrexate treatment on circulating CD4+CD161+ T-cells. Next, we assessed if these cells can be detected at the level of the RA joints.

Methods: Whole blood from healthy controls (n=20), ACPA and/or RF seropositive arthralgia patients (n=26) and newly diagnosed, DMARD-free RA patients (n=35), was analyzed by flow-cytometry using anti-CD4, -CD8, -CD45RO, -CCR7, -CD161 fluorochrome-conjugated antibodies. Next, CD4+CD161+ T-cells were prospectively assessed in 26 and 12 RA patients at 3 and 6 months after MTX treatment, respectively. Paired samples (peripheral blood and synovial fluid, n=11) and enzyme-digested synovial tissue cells (n=4) from late-stage RA patients were analyzed for the same markers. T-cell cytokine production potency (IL-17, IFNγ and TNFα) was assessed in peripheral blood mononuclear cells and in synovial fluid mononuclear cells.

Results: Precursor Th17 lineage cells were found to be increased in seropositive arthralgia patients. In contrast, circulating CD161+CD4+ T-cells were decreased in newly diagnosed RA patients. The decrease in CD4+CD161+ T-cells correlated inversely with C-reactive protein ($r = -0,43$ and $p = 0.02$) and with the swollen joint count 66 ($r = -0,41$ and $p = 0.03$). Methotrexate treatment led to normalization of CD4+CD161+ T-cells and reduced disease activity. CD4+CD161+ T cells were readily detected in synovial tissue from both early and late stage rheumatoid arthritis. In addition, synovial fluid was found to be enriched for CD4+CD161+ T-cells compared to blood. Late stage synovial fluid CD4+CD161+ T-cells showed skewing towards the Th1 phenotype as evidenced by increased IFN-γ expression.

Conclusion: The changes in peripheral numbers of CD4+CD161+ T-cells in seropositive arthralgia and early RA and the enrichment of these cells at the level of the joint predict a role for CD4+CD161+ T-cells in the early immune events leading to clinical synovitis. Our findings may add to the development of RA prediction models and provide opportunities for early intervention.

Alterations In Circulating T Follicular Helper Cells and T Regulatory Cells In Autoimmune Rheumatic Diseases Treated With B Cell Depletion Therapy: Rituximab. Pamela M.K Lutalo[1], Yuan Zhao[1], Lee Meng Choong[2], Shirish Sangle[2], Jo Spencer[1] and David P. D'Cruz[2]. [1]Peter Gorer Department of Immunobiology, School of Medicine, King's College London, London, United Kingdom, [2]Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom.

Background/Purpose: Granulomatosis with polyangiitis (GPA) and systemic lupus erythematosus (SLE) are autoimmune rheumatic diseases which develop due to failure of immune self-tolerance. T follicular helper cells have been linked with autoimmunity, where they are thought to reduce B cell survival threshold. In contrast, T regulatory cells can suppress autoimmune responses.

Hypothesis:GPA and SLE patients have low T regulatory (T_{REG}) cell frequencies and high circulating T follicular helper (cT_{FH}) cell frequencies during severe, active disease. B cell depletion therapy may correct disease-associated changes of cT_{FH} and T_{REG} frequencies in treatment responsive patients.

Methods: A longitudinal study of GPA and SLE patients treated with rituximab, an anti-CD20 monoclonal antibody.

Fluorochrome labelled antibody cell staining (FACS) flow cytometry of peripheral blood mononuclear cells was analysed for $CD4^+$ $CD25^{high}CD127^{low}$ T_{REG} cells, $CD3^+CD4^+CXCR5^{high}PD1^{high}$ cT_{FH} cells and B lymphocyte subsets pre-rituximab and at 1 month, 3 months and 6-months post-rituximab.

The Birmingham Vasculitis Activity Score (BVAS) and SELENA-SLEDAI score were used to measure disease activity in GPA and SLE patients.

Statistical analysis was done using GraphPad Prism 5.

Results: Mean age of GPA patients 47 years (25–67), SLE patients 38years (18–64) and healthy controls (HC) 44 years (23–65).

cT_{FH}%$CD4^+$ lymphocytes in HC mean=0.24%, GPA pre-rituximab=0.68% [p=0.02] and SLE pre-rituximab=0.69% [p=0.0001]. GPA 3-months post-rituximab mean cT_{FH}=0.24% [p=0.02], GPA 6-months post-rituximab mean=0.42% [p=0.01] compared to GPA pre-rituximab. SLE 3-months post-rituximab mean cT_{FH}=0.34% [p=0.006], SLE 6-months post-rituximab mean cT_{FH}=0.39% [p=0.09] compared to SLE pre-rituximab.

T_{REG}%$CD4^+$ lymphocytes in HC mean=8.42%, GPA pre-rituximab=5.06% [p=0.001] and SLE pre-rituximab=8.25% [p=0.95].GPA 3-months post-rituximab mean T_{REG}=7.96% [p=0.04], GPA 6-months post-rituximab mean=6.74% [p=0.1] compared to GPA pre-rituximab. SLE 3-months post-rituximab mean T_{REG}=12.15% [p=0.03], SLE 6-months post-rituximab mean T_{REG}=9.68% [p=0.04] compared to SLE pre-rituximab.

GPA pre-rituximab mean BVAS=16, 3-months post-rituximab=3 [$p < 0.0001$] and 6-months post-rituximab=7 [p=0.06]. BVAS shows a positive correlation with cT_{FH} cell frequencies r=0.51 [p=0.004] and negative correlation with T_{REG}cell frequencies r=−0.45 [p=0.01].

Mean SELENA-SLEDAI score pre-rituximab=14, 3-months post-rituximab=4 [p<0.0001] and 6-months post-rituximab=3 [p=0.0003].

SELENA-SLEDAI scores show a positive correlation with cT_{FH} cell frequencies r=0.50 [p=0.005] and negative correlation with T_{REG}cell frequencies r=−0.51 [p=0.004].

Conclusion: The frequencies of cT_{FH} are higher in severe, active GPA and SLE compared to health, whilst the frequencies of T_{REG} are only lower in GPA compared to health. cT_{FH} and T_{REG}frequencies were similar to those in healthy controls following successful treatment with rituximab.

An Altered Frequency Of Circulating Follicullar T Helper Cell Counterparts and Their Subsets Is Associated With Increased Circulating Plasmablasts In Seropositive RA Patients. Irene Arroyo-Villa[1], M. Belén Bautista-Caro[1], Alejandro Balsa[1], Pilar Aguado[1], Alejandro Villalba[1], Chamaida Plasencia[1], Amaya Puig-Kröger[2], Emilio Martín-Mola[1] and Maria Eugenia Miranda-Carus[1]. [1]Hospital La Paz-IdiPaz, Madrid, Spain, [2]Hospital Gregorio Marañon, Madrid, Spain.

Background/Purpose: Follicular T helper (Tfh) cells, a CD4 T helper subset localized in lymphoid organs, help B cell differentiation and function. Circulating CD4 T cells expressing CXCR5 together with ICOS and/or PD-1 are considered as counterparts of Tfh, can function as B cell helpers, and can be subdivided into three subpopulations based on the expression of CCR6 and/or CXCR3: CXCR5+CXCR3+CCR6- (Tfh-Th1), CXCR5+CXCR3-CCR6+ (Tfh-Th17) and CXCR5+CXCR3-CCR6- (Tfh-Th2). Only Tfh-Th17 and Tfh-Th2, as opposed to Tfh-Th1, seem to display functional properties of Tfh cells. An altered proportion of these subpopulations has been associated with autoimmune diseases. Terefore, our objective was to study the frequency of circulating Tfh and Tfh cell subsets together with the frequency of circulating plasmablasts (CD19+CD20-CD27+CD38high B cells) in patients with Rheumatoid Arthritis (RA).

Methods: Peripheral blood was drawn from healthy controls (n=27) and RA patients (n=27). After isolation by Ficoll- Hypaque gradient, PBMCs were stained with antibodies to CD3, CD4, CXCR5, ICOS, PD-1, CCR6, CXCR3, CD19, CD20, CD27, and CD38, and examined by flow cytometry. The percentages of CXCR5+CXCR3+CCR6- (Tfh-Th1), CXCR5+CXCR3- CCR6+ (Tfh-Th17) and CXCR5+CXCR3-CCR6- (Tfh/Th2) cells were calculated after gating for CD3, CD4 and CXCR5+. The percentage of CD20-CD38high cells was calculated after gating for CD19+ and CD27+.

Results: The frequency of circulating CXCR5+ cells gated for CD4+ T cells was not different among the studied groups. In contrast, RA patients demonstrated an increased frequency of CD4+CXCR5+ICOS+PD-1+ cells. Furthermore, in RA patients, the frequency of Tfh-Th1 cells was significantly decreased and the frequency of Tfh-Th17 and Tfh-Th2 cells was significantly increased as compared with controls. Subsequently, the ratio (Tfh-Th17+Tfh-Th2)/Tfh-Th1 was increased in RA patients. When examining seropositive (RF+ and/or ACPA+) and seronegative RA patients (RF- and ACPA-) separately, it was evident that the above described alterations were only apparent in seropositive RA. That is, seropositive but not seronegative RA patients demonstrate a higher proportion of Tfh subsets bearing a phenotype associated with B cell helping capacity. At the same time, the frequency of circulating plasmablasts was increased in seropositive but not in seronegative RA. Interestingly, there was a significantly positive correlation between the percentage of circulating plasmablasts and the frequency of CXCR5+ICOS+PD-1+CD4+ T cells. In addition, the frequency of circulating plasmablasts showed a positive correlation with the ratio (Tfh-Th17+Tfh-Th2)/Tfh-Th1.

Conclusion: Seropositive, but not seronegative RA patients, demonstrate an increased frequency of circulating Tfh counterparts (CXCR5+ICOS+PD-1+CD4+ T cells) and altered proportions of circulating Tfh subpopulations, with overrepresentation of subsets bearing a phenotype associated with B cell helping capacity. At the same time, an increased proportion of circulating plasmablasts is apparent in seropositive RA patients.

PD-$1^+$$CD45RB^{lo}122^{lo}$ Autoantibody-Inducing CD4 T Cells (*ai*CD4 T cells) As a Key In The Pathogenesis Of Systemic Lupus Erythematosus (SLE). Yumi Miyazaki, Ken Tsumiyama and Shunichi Shiozawa. Kyushu University Beppu Hospital, Beppu, Japan.

Background/Purpose: We found that systemic lupus erythematosus (SLE) was induced experimentally by repeatedly immunizing the mice normally not prone to autoimmune diseases by any exogenous antigen so far examined (Tsumiyama K. *et al.* PLoS ONE 4(12):e8382, 2009). We have then proposed a novel 'self-organized criticality theory' that takes place when host's immune system is overstimulated by repeated exposure to antigen to levels that surpass the immune system's stability limit, i.e., self-organized criticality. The autoreactive lymphocyte clones, which we name autoantibody-inducing CD4 T cells (*ai*CD4 T cells), are newly generated *via de novo* T cell receptor (TCR) revision from thymus-passed non-autoreactive clones at peripheral lymphoid organs. They not only stimulated B cells to generate varieties of autoantibodies but also helped final differentiation of CD8 T cell into cytotoxic T lymphocyte (CTL) *via* antigen cross-presentation to induce tissue injuries identical to SLE. We further showed that the transfer of $CD45RB^{lo}122^{lo}$ CD4 T cell of repeatedly-immunized mice could did induce autoantibodies in the naïve recipients, indicating that *ai*CD4 T cell seemed to belong to $CD45RB^{lo}122^{lo}$ CD4 T subpopulation. To identify the phenotype of *ai*CD4 T cell in more detail, we here performed microarray analysis and cell transfer assay to show that *ai*CD4 T cell belongs to PD-1^+ $CD45RB^{lo}122^{lo}$CD4 subpopulation.

Methods: BALB/c mice were repeatedly immunized with ovalbumin (OVA). To investigate gene expression profiles of *ai*CD4 T cell, we performed microarray analysis (Whole Mouse Genome Microarray; Agilent Technologies) of $CD45RB^{lo}122^{lo}$ CD4 T cell after immunization 12x with OVA. We also studied protein expression on $CD45RB^{lo}122^{lo}$ CD4 T cell by flow cytometric analysis. $CD45RB^{lo}122^{lo}$CD4 T cells were isolated additionally referring to PD-1 expression, and these fractionated cells were adoptively transferred into naïve recipients. Autoantibodies in sera of recipient mice were measured 2 weeks after cell transfer.

Results: Upon repeated immunization 12x with OVA, varieties of autoantibodies including RF, anti-Sm and anti-dsDNA antibodies were generated. Under microarray analysis, we compared the gene expression profile between $CD45RB^{lo}122^{lo}$ CD4 T cell and the rest of CD4 T cell subsets after immunization 12x with OVA. We found that gene expression of programmed cell death 1 (PD-1) was increased x2 in the $CD45RB^{lo}122^{lo}$ CD4 subset. Simultaneously, surface expression of PD-1 protein was also significantly increased in this subset: The PD-1^+ cell was concentrated up to 25.2 ± 6.3% in $CD45RB^{lo}122^{lo}$ CD4 T subset versus 7.5 ± 2.4% in $CD45RB^{hi}$ and/or $CD122^{hi}$ CD4 T subset ($P < 0.001$). Adoptive cell transfer from 12x immunized mice showed that RF and anti-dsDNA antibody in the transferred

recipients with PD-1^{+}CD45RB^{lo}122^{lo} CD4 T cell were 36.3 ± 336.0 U/ml and 0.5 ± 0.007 AU, whereas those with PD-1^{-}CD45RB^{lo}122^{lo} CD4 T cell were 12.6 ± 2.9 U/ml and 0.4 ± 0.002 AU, respectively ($P < 0.05$ and $P < 0.05$). These results indicated that PD-1^{+}CD45RB^{lo}122^{lo}CD4 T cells were capable of inducing autoantibodies in the naïve recipients.

Conclusion: The *ai*CD4 T cell that induces SLE belongs to a PD-1^{+}CD45RB^{lo}122^{lo} CD4 subpopulation.

Assessment Of Cytomegalovirus-Specific T Cell Responses Upon Initiation Of Immunosuppression In Patients Suffering From Rheumatic Diseases As Novel Approach For Functional Immune Monitoring. Emmanuelle Le Bras[1], Sandra Weigand[2], Ludwig Deml[3], Dagmar Halbritter[4], Boris P. Ehrenstein[2], Wolfgang Hartung[2] and Martin Fleck[1]. [1]University Medical Center of Regensburg, Regensburg 93053, Germany, [2]Asklepios Clinic Bad Abbach, Bad Abbach, Germany, [3]Lophius Biosciences GmbH, Regensburg 93053, Germany, [4]University Medical Center of Regensburg, 93042 Regensburg, Germany.

Background/Purpose: The management of immunosuppressive therapies is challenging, as physicians are confronted with difficulties to keep the balance between immunosuppression on one hand and raised risk of infection on the other hand. Currently, there is no standardized immune monitoring established helping to guide immunosuppression. Therefore, CMV-specific T cell responses were analyzed before and after initiation of immunosuppression in patients with newly diagnosed rheumatic diseases to assess the immune network in a functional fashion.

Methods: PBMC were isolated from treatment naive patients and at different time points following initiation of immunosuppression using a ficoll-separation protocol, and stimulated utilizing a novel urea-activated-CMV-tegument phosphoprotein 65 (pp65, T-Track® CMV, Lophius Biosciences, Germany). Protein specific T cell responses were analyzed and quantitated by ELISPOT detecting IFN-γ secreting cells. In addition, FACS-analyses have been performed simultaneously to observe phenotypic changes in PBMC subpopulations utilizing characteristic surface markers.

Results: 23 treatment naive patients suffering from newly diagnosed rheumatic diseases were included in this study (RA: 11, PMR: 7, SpA: 3, connective tissue diseases: 3). In total, 14 of the 23 patients (60,8%) had a positive IgG-CMV-serology and were further analyzed. A CMVpp65-specific T cell response could be observed in 5 of these 14 CMV-positive patients (35,7%) allowing for monitoring of the T cell function. There was a decrease of more than 80% of IFN-γ secreting cells 8–19 days (mean 10,6; SD ± 4,7) following initiation of immunosuppression (cumulative glucocorticoid dosage median: 405 mg) in 4 (80%) of these patients demonstrating substantial impairment of the specific immune response leading to a diminished T cell function. In contrast, no or only a minimal decrease in IFN-γ secreting cells could be observed in 1 (20%) patient despite immunosuppressive therapy. Phenotypic analyses revealed an increase (mean +26%) of the effector-memory CD4+-T-cell population in all patients, as well as a rise (mean +22%) of the central memory CD4+-T-cells. Moreover, there was a decrease of CD8+-T cells (mean −23,7%) as well as NK cells (mean −46%), whereas a substantial increase (mean +70%) could be observed in the memory B-cell subpopulation. From the CMV-positive patients, 8 could be followed-up. Clinically relevant infections occurred in 3 patients. 2 of these patients presented with an impaired pp65 specific T cell response already before initiation of immunosuppression, whereas a dramatic decrease of −86% in IFN-γ secreting cells could be observed in one patient 12 weeks following initiation of immunosuppression, who developed a respiratory infection.

Conclusion: The present results demonstrate a substantially impaired function of the specific immune system in a subgroup of patients following initiation of immunosuppression. We propose that these patients have a higher risk for infection and that utilization of the novel Elispot-assay based on urea-activated CMV-pp65 has the potential to guide immunosuppression as a valuable tool for functional immunmonitoring.

The Route Of T Cell Priming Determines The Requirement For IL-23 In The Development Of Arthritis. Alison Finnegan, Yanxia Cao and Susan Olalekan. Rush University Medical Center, Chicago, IL.

Background/Purpose: Rheumatoid arthritis is a very heterogeneous disease and distinct molecular mechanisms may underlie the disease process. IL-23 is an important cytokine for the expansion of Th17 cells and in the development of a number of autoimmune diseases. IL-23 is a heterodimeric cytokine composed of p19 and p40 subunits. IL-12, an important cytokine for differentiation of Th1 cells, is composed of p40 and p35. We have reported in proteoglycan-induced arthritis (PGIA) that the route of antigen exposure, intraperitoneal (i.p.) versus subcutaneous (s.c.), determines the Th1/Th17 phenotype respectively of the T cells involved in arthritis. In this study, we assess the contribution of IL-23 to the development of PGIA induced by i.p. or s.c. immunization.

Methods: Wild type (WT), p19$^{-/-}$ and p40$^{-/-}$ female BALB/c mice (>3 months of age) were immunized i.p. or s.c. with 50 ug recombinant G1 domain of human PG in adjuvant dimethydioctadecy ammonium bromide (DDA) 3 times at 3-week intervals. Paws were examined every third day for arthritis assessed based on the intensity of erythema and swelling on a score of 1–4. ELISA measured cytokines from CD4^{+}T cells and spleen cells re-stimulated in vitro with PG. T cell intracellarular cytokines were assessed by flow cytometry.

Results: In p19$^{-/-}$ mice, arthritis severity was significantly reduced in s.c. immunized mice, but only mildly reduced in i.p. immunized mice. In p40$^{-/-}$ mice, arthritis was significantly reduced in both i.p. and s.c. immunized mice. Levels of IL-17 were suppressed in splenocytes and inguinal lymph nodes (LN) from p19$^{-/-}$ mice either s.c. or i.p. immunization. However, IFN-γ levels were reduced only in p19$^{-/-}$ mice after s.c. immunization. To determine if suppression of IFN-γ was an early event after T cell priming we assess splenocyte responses early after immunization on day 9, IFN-γ was not suppressed in p19$^{-/-}$ mice. In p40$^{-/-}$ mice, IFN-γ and IL-17 responses were reduced after id or i.p. immunization.

Conclusion: The present results demonstrate that IL-23 plays a critical role in the development of arthritis after s.c. immunization and a minor role after i.p. immunization. Since p40 is a shared subunit of IL-12 and IL-23 reduction in arthritis after i.p. or s.c. follows the requirement of IL-12 in Th1 responses after i.p. immunization and the requirement for IL-23 in Th17 responses after s.c. immunization. These data suggest that activation of T cells in different compartments or routes of antigen exposure could affect the dominance of a Th1 versus a Th17 response.

Autophagy May Contribute To Glucocorticoid Resistance In Patients With Myositis By Maintaining T Lymphocytes Homeostasis In The Muscles. Mei Zong[1], John Jörholt[2], Julia Winter[2], Eva Lindroos[3], Helena E. Harris[2] and Ingrid E. Lundberg[1]. [1]Rheumatology Unit, Department of Medicine, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [2]Karolinska University Hospital, Solna, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology Unit, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden., Stockholm, Sweden.

Background/Purpose: Infiltrating T cells is a typical histopathologic feature in muscles of patients with myositis and these cells are also believed to play important roles in the disease development. In contrast to macrophages which can be reduced after glucocorticoid (GC) treatment, T cells often persist after treatment. The explanation for these persisting T cells after treatment even with high doses of GC is still unclear. Autophagy helps cells to survive under variable cellular stresses. In this context the effects of endogenous, cytosolic high mobility group box 1 (HMGB1) protein is of interest as HMGB1 can induce autophagy by binding Beclin1 (an upstream protein initiating autophagy) and thereby contribute to cell survival. In this study, we investigated whether autophagy initiated by HMGB1-Beclin1 binding can contribute to T cell survival in the muscles of patients with myositis, and whether this homeostasis of T cells can contribute to the GC resistance.

Methods: Muscle biopsies were obtained from poly- and dermatomyositis patients with no or limited clinical response to GC and from patients with good response to GC. Biopsies were investigated by immunohistochemistry for macrophages (CD163, CD68), T cells (CD3), HMGB1 and Beclin1. Computer image analysis was performed for each marker. Co-localization of HMGB1, Beclin1 and T cells was done by consecutive section staining and was confirmed by double fluorescence staining.

Results: Both HMGB1 and Beclin1 expression was detected in muscle tissue of patients with myositis; furthermore, the expression co-localized to the infiltrating T cells as demonstrated by consecutive section staining and double fluorescence staining. Moreover, the expression of HMGB1 and Beclin1 correlated strongly ($p=0.002$, $R=0.8$). In five patients who were good responders, the number of T cells in the muscles was decreased after treatment, and simultaneously the HMGB1 and Beclin1 expression was decreased. Analyses are ongoing on the non-responders. According to our hypothesis in these patients T cells will not be reduced after treatment and HMGB1 and Beclin1 expression will maintain at high levels too.

Conclusion: Markers of autophagy are present in the invading T cells in muscle tissue of myositis patients. Autophagy initiated by HMGB1-Beclin1 binding may contribute to T cell survival in the muscles of patients with myositis. And this homeostasis in T cells could be a factor that contributes to the GC resistance.

Rheumatoid Arthritis Synovial IL-21+CD4+ T Cells Specifically Induce Matrix Metalloproteinase Production By Fibroblast-Like Synoviocytes. Maria C. Lebre[1], Pedro L. Vieira[2], Saïda Aarrass[1], Thomas Newsom-Davis[2], Paul Peter Tak[3] and Gavin R. Screaton[2]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Imperial College London, London, United Kingdom, [3]Academic Medical Center/University of Amsterdam, Department of Clinical Immunology and Rheumatology & GlaxoSmith-Kline, Amsterdam, Netherlands.

Background/Purpose: IL-21 is a cytokine produced by activated CD4+ T cells and T follicular helper cells (TFh) that has been implicated in several autoimmune diseases including rheumatoid arthritis (RA). IL-21 regulates antibody production by B cells and induces osteoclastogenesis, mechanisms that contribute to rheumatoid arthritis (RA) pathology. Importantly, IL-21R blockade ameliorates arthritis in mice. Here we investigated the functional characteristics of synovial CD4+IL-21+ T cells in RA.

Methods: Matched peripheral blood (PB) and synovial fluid (SF) from 13 RA and 6 psoriatic arthritis (PsA) patients, and PB of 17 healthy control (HC) subjects were stimulated with PMA/Ionomycin/brefeldin A and intracellular cytokine production assessed by FACS. STAT3-dependent IL-21 production by SF CD4+ T cells was investigated by using a STAT3 specific inhibitor (WP1066). The effects of IL-21 were evaluated on cytokine and matrix metalloproteinase (MMP) release by RA synovial biopsies. In addition, the capacity of sorted RA SF IL-21+ or IL-21-CD4+ T cells in mediator release by fibroblast-like synoviocytes (FLS) was evaluated in co-cultures. IL-21, IL-6 and MMP-1 and MMP-3 concentrations were assessed by ELISA.

Results: The frequency of both SF IL-21+CD4+ or IL-21+TNF-a+CD4+ T cells in RA was significantly higher compared to PsA ($p=0.0140$ and $p=0.0038$, respectively). STAT3-specific inhibitor blocked significantly the production of IL-21 by SF CD4+ T cells. Synovial IL-21+CD4+ T cells did not phenotypically fit the TFh cell paradigm in that they did not co-express CXCR5 and ICOS. The levels of SF IL-21 were associated with CRP, MMP-1 and MMP-3. Related to this, IL-21 selectively induced MMP-1 and MMP-3 secretion by RA synovial biopsies. Sorted SF IL-21+CD4+ T cells induced specifically the release of MMP-1 and MMP-3 by FLS compared to medium (both $p<0.0001$) or IL-21-CD4+ T cells ($p=0.0035$ and $p=0.0088$, respectively). This induction was specific since the capacity of IL-21+ and IL-21- CD4+ T cells to induce IL-6 production by FLS was similar.

Conclusion: The results of this study support the notion that RA IL-21-producing CD4 T cells are involved in promoting joint destruction by inducing MMP release and might be a therapeutic target in RA.

Characterization Of T Cell Phenotype and Function In a Double Transgenic (Collagen-Specific TCR /HLA-DR1) Humanized Model Of Arthritis. Seunghyun Kim[1], Bo Tang[2], Sarah Hammond[1], DL Cullins[1], David Brand[3], EF Rosloniec[1], John M. Stuart[4], Arnold E. Postlethwaite[1], AH Kang[1] and Linda Myers[1]. [1]University of Tennessee Health Science Center, Memphis, TN, [2]St. Jude Children's Research Hospital, Memphis, TN, [3]VA Medical Center, Memphis, TN, [4]VA Medical Center, University of Tennessee Health Science Center, Memphis, TN.

Background/Purpose: T cells orchestrate joint inflammation in rheumatoid arthritis (RA), yet they are difficult to study due to the small numbers of antigen-specific cells. The goal of this study was to characterize the phenotypic and functional changes that occur in autoimmune T cells following the induction of pathological events in a humanized model of arthritis.

Methods: We developed a double transgenic mouse containing both the HLA-DR1 transgene and an HLA-DR1-restricted CII (263–273)-specific TCR in order to more closely mimic the human immune responses that occur in RA.

Results: *In vitro*, CII-specific T cells demonstrated an increased ability to proliferate in response to the CII immunodominant peptide and the cells altered their phenotype to become predominately $CD62L^{low}$ and $CD44^{high}$ "activated" T cells. Functionally, the CII-specific T cells produced increased levels of Th1, Th2, and Th17-type cytokines in comparison to controls from HLA-DR1 single transgenic animals, when challenged with CII peptide. Following immunization with CII/CFA, these mice develop an accelerated arthritis compared to single transgenic HLA-DR1 mice. Histology confirmed that the double transgenic mice had greater pannus formation and cartilage destruction when compared to arthritic DR1 mice. On the other hand, when the mice were treated orally with the analog peptide A12, the arthritis was significantly suppressed, despite the fact that >90% of the CD4+ T cells express the TCR Tg. In the A12-treated mice, IL-2, IFN-γ, and IL-17 production dropped and high levels of IL-10 and IL-4 were produced.

Conclusion: These data suggest that the model will be useful to study T cell directed therapies as well as the mechanisms of autoimmune diseases.

HLA-B27 and KIR3DL2 Interactions Promote The Differentiation and Survival Of Proinflammatory T Cells In Spondyloarthritis. A. Ridley, I. Wong-Baeza, H. Hatano, J. Shaw, H. Al-Mossawi, P. Bowness and S. Kollnberger. University of Oxford, Oxford, United Kingdom.

Background/Purpose: T helper 17 (Th17) cells are a subset of pro-inflammatory CD4+ T cells implicated in a number of inflammatory arthritides including the Spondyloarthritides (SpAs). Ankylosing Spondylitis (AS), the commonest spondyloarthropathy, is genetically associated with HLA-B27 (B27) and IL-23 receptor polymorphisms, however the link remains unexplained. We have previously shown KIR3DL2+ CD4+ T cells are expanded in the peripheral blood of individuals with AS. In addition to classically folded heterotrimers, HLA-B27 can form β2m-free homodimers (B272). B272, as well as free heavy chains, are able to interact with KIR3DL2. The aim of this study was to investigate whether KIR3DL2 expression was induced by activation of CD4+ T cells and to investigate the consequence of co-culturing HLA-B272-expressing cells with KIR3DL2+ CD4+ T cells.

Methods: Production of cytokines by PMA/ionomycin stimulated-peripheral blood mononuclear cells (PBMCs) was investigated by intracellular cytokine staining (ICS). KIR3DL2 expression by PMA/ionomycin stimulated-naïve CD4+ T cells was investigated by flow cytometry (FACS). Expression of Bcl-2, RORC and T-bet by naïve CD4+ T cells was investigated using qPCR after co-culture with SEB stimulated-HLA-B272-expressing cells, or control HLA-expressing cells.

Results: KIR3DL2+ CD4+ T cells from AS patients are enriched for production of IL-17 ($p<0.0001$, $n=16$) and IL-17/IFNγ ($p=0.002$, $n=8$), as compared to KIR3DL2- CD4+ T cells. KIR3DL2+ CD4+ T cells from AS patients produce more IL-17 than KIR3DL2+ CD4+ T cells from HLA-B27- healthy controls ($p=0.013$). Naïve CD4+ T cells express KIR3DL2

de novo by FACS after activation (p=0.02, n=3). Co-culture of naïve CD4+ T cells with HLA-B272-expressing cells further increased KIR3DL2 expression and increased expression of the anti-apoptotic molecule Bcl-2. Time-dependant alterations in RORC and T-bet expression were observed.

Conclusion: Expression of KIR3DL2 on naïve CD4+ T cells can be induced by activation. Co-culture of naïve CD4+ T cells with HLA-B272-expressing cells preferentially promotes the survival of KIR3DL2+ CD4+ T cells and promotes a Th17 (and Th1) transcriptional profile. SpA KIR3DL2+ CD4+ T cells are enriched for production of IL-17 and for dual production of IL-17 and IFNγ, consistent with the theory that AS is a Th17 or a Th17/1 driven disease.

Interferon Type I and T Helper 17: A Dangerous Liaison In Primary Sjögren's Syndrome? Zana Brkic, Sandra M.J. Paulissen, Cornelia G. van Helden-Meeuwsen, Naomi I. Maria, Odilia B.J. Corneth, Nadine Davelaar, Jan Piet van Hamburg, Paul L. Van Daele, Virgil A. Dalm, Martin van Hagen, Erik Lubberts and Marjan A. Versnel. Erasmus Medical Center, Rotterdam, Netherlands.

Background/Purpose: The T helper 17 (Th17) cell subset, which produces IL-17A, IL-17F, IL-22 and IL-21, has been implicated in the pathogenesis of primary Sjögren's syndrome (pSS). The aim of this study was to elucidate a possible link between the Th17 system and another key-player in the pathogenesis of pSS− Interferon (IFN) type I.

Methods: IFN type I signature was assessed by mRNA expression of IFN type I inducible genes. Th cell populations were analyzed by flow cytometry in peripheral blood of 12 pSS patients positive (IFN+) and 12 patients negative (IFN-) for the IFN type I signature and 12 healthy controls (HC). Cytokine expression by memory Th cells (CD4+ CD45RO+) cells and memory CCR6+ Th cells (CD4+CD45RO+ CCR6+) cells was assessed.

Results: Th17 (defined as CD4+CD45RO+CCR6+CCR4+CXCR3-CCR10-) and Treg cell percentages were significantly increased in IFN+ patients compared with IFN- patients and HC. This was accompanied by a significant decrease in Th1 cells in IFN+ patients compared to HC. IL-22 and IL-21 production by memory Th cells and memory CCR6+ cells was higher in IFN+ patients. Interestingly, Th17 cell percentage was significantly correlated with presence of anti-SSA antibodies, hypergammagloblulinemia and elevated expression of monocyte B cell activating factor (BAFF), all three previously found in IFN type I signature positive patients.

Conclusion: Here we show for the first time a relation between two key players of pSS pathogenesis − IFN type I and the Th17 pathway. This study brings new insights in the pathogenesis of pSS, having possible implications for future treatment.

Enothelin-1 Plays a Role In The Pathogenesis Of Reversible Cerebral Vasoconstriction Syndrome. Tariq Hammad[1], Leonard H. Calabrese[1], Ken Uchino[2], Seby John[2], Mark Stillman[2], Stewart Tepper[2], Colin O'Rourke[1], Allison Janocha[1], Serpil Erzurum[1] and Rula Hajj-Ali[2]. [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland, OH.

Background/Purpose: Cerebral vasoconstriction is thought to be the underlying pathogenetic mechanism of Reversible Cerebral Vasoconstriction Syndromes (RCVS). However, mediators of the syndrome at molecular levels have not been elucidated. We aim in this proposal to assess the role of Endothelin-1 (E-1), a potent vasoconstrictor, in the pathogenesis of RCVS.

Methods: Seven patients with RCVS, recruited from the Cleveland Clinic prospective RCVS registry were included. Five peripheral blood samples were collected during the cerebral vasoconstrictive acute attack (group 1) and four samples after complete resolution of the vascular abnormalities and resolution of the symptoms (group 2). Further, E-1 levels were measured from 10 healthy controls of similar races and genders, who were then matched to group 1 using a one-to-one Greedy matching algorithm based on age. Plasma E-1 levels were measured using Quantikine Endothelin-1 enzyme-linked immunosorbent assay kit (from R& D Systems) according to the user manual. Average E-1 levels for patients was compared to the average E-1 levels for matched healthy patients using mixed effects modeling to account for matched group clustering.

Results: During the acute vasoconstrictive attack, average plasma E-1 level differs significantly between the patients and the healthy controls (p = 0.002). Mean plasma E-1 levels for RCVS patients (group 1) was estimated to be about 1.2 pg/ml (95% CI 0.6 pg/ml – 1.7 pg/ml) higher as compared to the healthy controls. Paired samples from the same patients (during the acute attack and after resolution) were available from two patients (4 samples). In these patients, there was a trend for plasma E-1 level to decline to the average level of healthy controls (2.7 to 1.6 and 2.8 to 1.2) when comparing acute attack to the resolution phase levels. Average plasma E-1 levels of all patients in group 2 (the resolution phase, n=4) was 1.41pg/ml similar to the average plasma healthy control group.

Conclusion: Plasma Endothelin-1 (E-1) levels are significantly elevated in RCVS patients during the vasoconstrictive acute attack as compared to healthy controls, with a trend to decline after resolution of the vasoconstriction. These results suggest a potential role of E-1 in the pathogenesis of RCVS.

Vessel Wall Characteristics Using High Resolution Magnetic Resonance Imaging In Reversible Cerebral Vasoconstriction Syndrome and Central Nervous System vasculitis. Rula Hajj-Ali[1], Seby John[1], Tariq Hammad[2], Emmanuel Obusez[2], Ken Uchino[1], Stephen Jones[2], Ferdinand Hui[3], Russell Cerejo[2] and Leonard H. Calabrese[2]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic, Cleveland, OH.

Background/Purpose: Distinguishing between reversible cerebral vasoconstriction syndrome (RCVS) and central nervous system (CNS) vasculitis is often a diagnostic dilemma. High-resolution-3-Tesla Magnetic Resonance Imaging with contrast (HR-MRI) is a non-invasive method which has an added value to the vascular imaging by defining the intracranial vessel wall characteristics (enhancement and thickening). We have explored the utility of HR-MRI in distinguishing RCVS from CNS vasculitis.

Methods: A retrospective analysis of all patients with a diagnosis of RCVS or CNS vasculitis that underwent HR-MRI at our institution was performed. Inclusion criteria for RCVS included acute thunderclap headache with no aneurysmal subarachnoid hemorrhage, normal cerebrospinal fluid and reversible multifocal intracranial vessel stenosis. The CNS vasculitis group included patients with primary CNS vasculitis diagnosed according to the Calabrese criteria, and one patient with Varicella Zoster CNS vasculitis. Images were reviewed by two radiologists, Demographics, clinical presentation, laboratory testing, imaging studies and outcomes were collected.

Results: Twenty-six patients met inclusion criteria with 13 patients in each group. Median age was 52 and 42 in the RCVS and the vasculitis groups respectively. Females represented the majority in the RCVS groups 85 % (11/13) and only 15% (2/13) in the vasculitis group. In the RCVS group 77% (10/13) had wall thickening, only 31 % (4/13) had minimal wall enhancement. In the vasculitis group 92% (12/13) had vessel wall enhancement as well as wall thickening.

Conclusion: Findings of enhancement of the intracranial vessel wall by HR-MRI occurred mainly in the CNS vasculitis group as compared to the RCVS group. The enhancement in RCVS group was very minimal. HR-MRI may be a useful tool in differentiating RCVS from CNS vasculitis, in the acute presentation. Further studies with larger number of cases are needed to confirm the utility of HR-MRI in the diagnosis of cerebral arteriopathies.

Systematic Review Of Amyloid Beta-Related Angiitis: A Treatable Cause Of Vasculitis Affecting Central Nervous System. Abhijeet Danve and Atul Deodhar. Oregon Health and Science University, Portland, OR.

Background/Purpose: Amyloid β-related angiitis (ABRA) is a rare type of Central Nervous System Vasculitis (CNSV), which complicates Cerebral Amyloid Angiopathy (CAA). Data about clinical features, management and outcomes of ABRA are scant. It is important to differentiate this treatable disease from primary CNSV and other irreversible neurological disorders.

Methods: We searched the OVID Medline database for relevant articles between 1946 to 2012 using the key words "Cerebral amyloid angiopathy", "vasculitis" "inflammatory CAA" "Amyloid Beta-Related Angiitis". Data from major case series and reviews as well as individual case reports was extracted. We found total 98 patients who were reported in the literature. Two case reports were in other languages and data was unavailable for 2 other patients. Demographics, clinical features, lab and imaging findings, treatment and follow up was extracted for 94 patients and is summarized descriptively.

Results: Patients with mean age of 67 years presented acutely (54%) or subacutely (46%) with cognitive or behavioral changes of variable severity (71%), focal deficits (51%), seizures (36%) and headache (35%). More than 2 features were present in 77%. Prior malignancy was reported in 10 patients and associated autoimmune disease (e.g. autoimmune thyroiditis, autoimmune hepatitis, RA and pernicious anemia) in 11. ESR and CRP were elevated in 14 /47 (29.7%); 70% patients (12/17) had ApoE genotype e4/e4 CSF showed elevated protein in 71% (42/59) and lymphocytic pleocytosis in 44% (26/ 59) and abnormalities normalized after treatment in 2/2 patients. Brain MRI was abnormal in 97.4 % (75/77) and typically showed asymmetrical bilateral white matter hyperintensity on T2W and FLAIR (88%), cortical microbleeds in 87% (21/24) on SWI and minimally enhancing mass like lesions (26%). Post treatment MRI showed improvement in 38/47 (80%) patients. Brain biopsy confirmed diagnosis in 97.8% (92/94) patients which showed transmural inflammation with deposition of A β-amyloid in vessels in 80% and pervasculitis in 20% patients. Of 73 patients who received corticosteroids 78% showed either partial or complete clinical improvement. Cyclophosphamide (34%), azathioprine (6.6%), methotrexate (2%) and mycophenolate (2%) were also used successfully in conjunction with steroids. Relapse occurred in 26% of 57 patients, either after reduction or cessation of therapy and responded well after retreatment.

Primary Central Nervous System Vasculitis: Treatment and Course. Carlo Salvarani[1], Robert D. Brown Jr.[2], Teresa J. H. Christianson[2], John Huston III[2], Kenneth Calamia[3], Caterina Giannini[2] and Gene G. Hunder[2]. [1]Arcispedale S Maria Nuova-IRCCS, Reggio Emilia, Italy, [2]Mayo Clinic, Rochester, MN, [3]Mayo Clinic, Jacksonville, FL.

Background/Purpose: To determine the response to therapy and long-term outcome of PCNSV we reviewed all cases of PCNSV seen over a 29-year period.

Methods: The cohort included 163 consecutive patients diagnosed with PCNSV at Mayo Clinic Rochester over a 29-year period (1983 through 2011). The diagnosis was based on findings of brain or spinal cord biopsy, cerebral angiography, or both. Biopsy specimens were reviewed by a neuropathologist and angiograms by a neuroradiologist. Information about clinical findings, laboratory, radiologic imaging, type of, duration of, and response to treatment, number of relapses, functional status at followup, and cause of death were completed for all cases.

Results: In 75 patients, glucocorticoids (GCs) were the only initial therapeutic agents. In 66 intravenous pulse GC doses (median: 5 pulses of methylprednisolone [1 gm/pulse]) were administered before oral GCs were started. The median initial oral prednisone dose was 60 mg/day. The median duration of prednisone therapy was 10 months, and 75% were treated for 19 months or less. In 69 patients cyclophosphamide (CYC) (49 had daily oral doses, 23 had intermittent intravenous pulses) and prednisone were the only initial treatment. The median initial dose of oral CYC was 150 mg/day and the median duration of therapy was 7 months. The median dose of intravenous pulse CYC was 1 gm/month. Other initial treatments included CYC alone (2) azathioprine (median initial dose 100 mg/day) and GCs (6), mycophenolate mophetil and GCs (3), rituximab and GCs (1), plasma-exchange, CYC and GC therapy (2), and infliximab (1). Four patients received no specific therapy. In the 75 treated with GCs only, a favorable response was observed in 83%. In those with CYC plus GCs, 76% responded favorably. 44 patients had relapses that led to a change in therapy. The frequency of relapses were significantly lower in the patients treated with CYC compared to those treated with GCs alone (18% vs 39%, $p = 0.006$). The median follow-up duration of the 163 patients was 12 months (range: 0–13.7 years). Age- and sex-adjusted survival of the patients with PCNSV was significantly reduced compared to the estimated survival of the US white population ($p < 0.001$). 25 patients died during follow-up. The cause of death was cerebral infarction in 10 patients. Univariate Cox proportional hazards model was used to assess survival and findings at diagnosis: older age at diagnosis (HZ 1.4) and cerebral infarction at MRI (HZ 4.4) were associated with poor survival, while gadolinium enhanced cerebral lesions or meninges at MRI (HZ 0.20) with better survival. Univariate logistic regression analysis was used to assess association of findings at diagnosis with Rankin score outcomes. Older age (HZ 1.4) and MRI evidence of cerebral infarction (HZ 3.7) at presentation were associated with a high disability score at last

follow-up (Rankin score of 4–6), while patients with gadolinium enhanced cerebral lesions or meninges had lower disability at follow-up (HR 0.35).

Conclusion: Most patients with PCNSV showed a favorable response to therapy. Recognition of findings at diagnosis associated with poor outcomes may aid decisions regarding initial therapy.

Background/Purpose: Childhood Inflammatory Brain diseases are potentially life-threatening diseases leading to severe neurological deficits if not treated. The spectrum of childhood inflammatory brain diseases is rapidly expanding, and recent evidence shows the presence of inflammatory markers in previously thought to be vasculopathies, such as Moyamoya. We reviewed all pediatric patients enrolled in the international BrainWorks database.

Methods: All pediatric patients enrolled through a BrainWorks center were identified in the BrainWorks database. Patients were eligible for inclusion if predetermined information at the baseline visit was available. This included, information on demographic information, such as age at diagnosis and gender, diagnosis at enrollment, clinical, laboratory, neuroradiology and if applicable brain biopsy.

Results: In total 370 (190 boys, 180 girls) children were enrolled in BrainWorks with complete dataset at baseline. The mean age at diagnosis was 9.33 years (boys 9.67 years, girls 9.07 years). The diagnosis included were; Non-progressive large vessel CNS vasculitis n=108 (68 boys, 40 girls, mean age 8.15 years), Small vessel CNS vasculitis n = 76 (26 boys, 50 girls, mean age 11 years), Progressive large vessel CNS vasculitis n=25 (17 boys, 8 girls, mean age 10.3 years), NMDAR-encephalitis n=42 (15 boys, 27 girls, mean age 9.9 years), secondary CNS vasculitis due to underlying systemic disease n=33 (16 boys, 17 girls), and Moyamoya n=33 (18 boys, 15 girls). Other diagnosis included CNS vasculitis due to infection n=20, ADEM n=5, MS n=2, Rasmussen n=2, and other vasculopathies/vasculitis (n-21).

Focal deficits at presentation were more commonly seen in patients with large vessel CNS vasculitis and infantile Moyamoya, while diffuse deficits were seen more in children with small vessel CNS vasculitis and NMDAR encephalitis. Seizures were seen in all inflammatory brain diseases, but were more frequently present in NMDAR encephalitis and small vessel CNS vasculitis (80% and 61%) compared to the large vessel CNS vasculitis subtypes and Moyamoya.

Conclusion: Childhood inflammatory Brain diseases encompasses many different diagnosis. The most frequent diagnosis are the different subtypes of childhood CNS vasculitis, however NMDAR encephalitis and Moyamoya are increasingly recognized and diagnosed.

IDIBAPS, Barcelona, Spain, [34]Med Ctr Rheumatology Berlin Buch, Immanuel Krankenhaus Berlin, Berlin, Germany, [35]University of Genoa, Genova, Italy, [36]Innsbruck Medical University, Innsbruck, Austria, [37]Arcispedale S Maria Nuova-IRCCS, Reggio Emilia, Italy, [38]Southend University Hospital, Essex, United Kingdom.

Background/Purpose: To explore similarities and differences between rheumatologists (rheum), general practitioners (GP) and patients (pt) regarding the relevance of outcome parameters in polymyalgia rheumatica (PMR).

Methods: This study was part of the ACR/EULAR project for the development of guidelines for PMR. A candidate list of outcome parameters was identified by literature review and input from the guideline development group (GDG) involving rheum, GP and pt. The candidate item list contained 119 outcome measures including symptoms, physical examination findings, laboratory parameters, imaging, composite outcome measures, drug related adverse effects, functional status, quality of life and PMR related complications. A survey-based grading of the candidate outcomes was performed using SurveyMonkey®. We invited 43 rheum (15 with a special interest in PMR), 87 GP (all UK) and 43 pt (all UK) to rate each item based on its relative importance for clinical decisions on a 1–9 point scale (1–3 not important, 4–6 important, but not critical and 7–9 critical). We excluded the rating of a group if >33% of responders marked an item with "don't know".

Results: Thirty-eight rheum (88%; 100% of those with special interest in PMR), 15 (17%) GP and 41 (95%) pt responded. Only 6 (5.0%) parameters were deemed as critical (score ≥7) by all groups [remission, relapse, duration of glucocorticoid (GC) therapy, discontinuation of GC therapy, development of GCA, osteoporosis].

General symptoms such as fatigue, malaise, sleep disturbances, depression or anxiety were more frequently rated as critical by pt (37.5–71.8%) than by rheum (0–26.3%, all p-values ≤0.01). Appraisal of fatigue and malaise was similar by GPs and rheum whereas sleep disturbance, depression and anxiety were similarly graded by GP and pt. Among laboratory and imaging parameters no significant differences between groups were observed mainly because several parameters were marked "don't know" by a high proportion of pt and GP. GP (57.1%) considered healthcare resource use more relevant than rheum (26.3%, p=0.038) whereas a high proportion of pt did not know about this parameter. Functional status, impact on pt's career, quality of life, mobility, self-care and usual activities were rated higher by pt (54.8–84.6%) than by rheum (23.7–44.7%, all p-values <0.01). Quality of life, impact on pt's career, self-care and usual activities were also more relevant for GP (71.4–92.9%) than for rheum (all p-values <0.05).

Conclusion: These data demonstrate a higher relevance of general symptoms, functional status and quality of life to patients with PMR compared with rheumatologists. Ratings of outcome parameters from patients and general practitioners were less discordant than those from patients and rheumatologists.

Obese Polymyalgia Rheumatica Patients Experience More Pain and Disability and Need Higher Doses Of Glucocorticoids. Marco A. Cimmino[1], Bhaskar Dasgupta[2], Cynthia S. Crowson[3], Michael Schirmer[4], Christian Dejaco[5], Carlo Salvarani[6] and Eric L. Matteson[3]. [1]University of Genoa, Genova, Italy, [2]Southend University Hospital, Westcliff-on-Sea, United Kingdom, [3]Mayo Clinic, Rochester, MN, [4]Innsbruck Medical University, Innsbruck, Austria, [5]Medical University Graz, Graz A-8036, Austria, [6]Arcispedale S Maria Nuova-IRCCS, Reggio Emilia, Italy.

Background/Purpose: Obesity is not only a risk factor for osteoarthritis but also for rheumatoid arthritis (RA). In obese RA patients, disease incidence is higher and response to treatment poorer. This paper is concerned with an evaluation of the clinical characteristics at onset and of the outcome of polymyalgia rheumatica (PMR) in obese vs. non-obese patients.

Methods: 83 patients with newly diagnosed PMR from the clinical cohort studied to obtain the ACR/EULAR criteria were studied. Weight and height were obtained and the BMI calculated. Obesity was defined as a BMI≥30 kg/m^2.

Results: The mean BMI was 26.1± 3.4, with BMI ≥ 30 found in 12 patients (14.5%). The two groups were comparable in terms of age (71.6±10.5 vs 72.6±8.1 years; p=0.53), sex (59% and 58% women, respectively; p=0.96), duration of morning stiffness (190±200 vs 206±219 minutes; p=0.42), and localization of involvement. Obese patients had a higher shoulder VAS (76.6±26.1 vs 58.8±25.5; p=0.03), global pain VAS (76.4±23.7 vs 58.7±24.9; p=0.025), PMR VAS (82.3±21.9 vs 60.6±24.3; p=0.004), fatigue VAS (71.8±28.1 vs 53.7±27.2; p=0.03), and modified HAQ (1.7±0.6 vs 1.2±0.6; p=0.005). They also showed a decreased physical component of the SF36 (31.6±6.3 vs 35.7±7.1; p=0.048).

The mean dose of prednisone was not different at treatment onset between obese (16.6±7 mg) and non-obese (15.1±5.6 mg) patients (p=0.98). At the end of follow-up, the clinical and laboratory features of both obese and non-obese patients significantly improved. However, during the first 6 months of treatment obese patients needed a higher mean daily dose of prednisone in comparison with the non obese ones (8.5±3.2 mg vs 6.2±5.2 mg; p=0.021). BMI was negatively correlated with percent improvement of PMR VAS at 6 months (Spearman r= −0.24; p=0.046), indicating that higher BMI was associated with a lower percent improvement.

Conclusion: Our results support the view that the burden of PMR is higher in obese vs. non obese patients. This fact may be related to the poorer quality of life seen usually in obese individuals as well as to the increased amount of cytokines produced by the adipose tissue. However, ESR and CRP were not different in the two groups of patients, although the categorical nature of these variables (normal/abnormal) may have hampered the evaluation of possible differences.

The outcome of PMR at 6 months was not different in obese vs. non-obese patients but the former needed a significantly higher cumulative dose of prednisone. The more intuitive interpretation of this finding is that prednisone dose should be adjusted to weight because of the larger volume of distribution in obese patients. Alternatively, the increased inflammation possibly associated with obesity would need more GC.

In conclusion, obesity affects both severity of symptoms and GC utilization. BMI should be considered by clinicians when interpreting symptoms of their PMR patients and deciding their GC doses. (for the European League Against Rheumatism-American College of Rheumatology PMR classification criteria study group).

Lower Tissue Expression Of IL 6 In Patients With Giant Cell Arteritis Presenting With a Cranial Ischaemic Compication. Lorraine O'Neill[1], Jennifer McCormick[1], Danielle Molloy[1], Douglas J. Veale[1], Conor Murphy[2], Geraldine M. McCarthy[3], Ursula Fearon[1] and Eamonn S. Molloy[1]. [1]St. Vincent's University Hospital, Dublin 4, Ireland, [2]Royal Victoria Eye and Ear Hospital, Dublin, Ireland, [3]Mater Misericordiae University Hospital, Dublin 7, Ireland.

Background/Purpose: Giant Cell Arteritis (GCA) is a granulomatous systemic vasculitis with a prediliction for the aorta and it's extracranial branches. The majority of the morbidity associated with GCA is related to its ischaemic complications of acute visual loss and stroke. It has previously been shown that patients with cranial ischaemic complications (CICs) due to GCA have lower temporal artery IL 6 expression and circulating levels of IL 6 than patients without CICs.[1]

The current study aimed to extend these previous observations by:

1. Comparing the spontaneous release of IL 6 from cultured temporal artery explants of patients with GCA and CICs to those without CICs.
2. Investigating the association between spontaneous release of IL 6 from the explant cultures and the presence of intimal hyperplasia and luminal occlusion on histopathology.

Methods: Patients with suspected GCA underwent a temporal artery biopsy and had serum biomarkers assayed at baseline.

TAB sections were sent for review to a histopathologist who was blinded to the clinical presentation.

Additional sections were cultured for 24 hours and IL 6 expression in the supernatants quantified by ELISA.

Temporal artery explants from 7 patients with GCA (3 TAB positive, 4 TAB negative & 1 patient with a documented CIC) were embedded in matrigel, stimulated with recombinant IL 6 at concentrations of 20 ng/ml and 40 ng/ml and myofibroblast outgrowths observed over a 3 week period.

Results: 30 patients had a temporal artery biopsy (TAB) that was positive for GCA. 25 had a negative or inconclusive TAB but met ACR classification criteria for GCA and were therefore included in the analysis.

11/55 (20%) patients presented with an ischaemic complication attributable to GCA.

Baseline demographics were similar between those with CICs and those without. Other than their presenting CICs, there was no difference in any of the other clinical manifestations of GCA between both groups.

Cumulative steroid dose pre biopsy was higher in those presenting with a cranial ischaemic complication than those without ($p = 0.015$) However, there was no correlation observed between cumulative steroid dose and expression of IL 6 in explant cultures.

There was a trend both towards a lower baseline CRP and IL 6 in those with CICs than those without but this was not statistically significant. (Mean CRP 33 g/L vs 49 g/L and mean IL 6 17.23 pg/ml vs 31.83 pg/ml).

Patients with CICs had significantly lower levels of of IL 6 in explant supernatants when compared to those without CICs (Mean 8.66 ng/ml/mg biopsy weight vs 18.92 ng/ml/mg biopsy weight, $p < 0.01$).

This lower tissue IL 6 production was significantly associated with both intimal hyperplasia ($p < 0.03$) and luminal occlusion ($p < 0.01$) on histopathology.

In addition, rIL 6 induced myofibroblast outgrowths at concentrations of 20 ng/ml but had a significant inhibitory effect at 40 ng/ml.

Conclusion: The study confirms the association between lower levels of IL 6 expression in patients with CICs than those without. The inhibitory effect on myofibroblast outgrowths at higher concentrations of IL 6 merits further investigation given the known involvement of myofibroblasts in the development of intimal hyperplasia and occlusion.

B Cells Revisited In Giant Cell Arteritis. Kornelis S.M. van der Geest, Wayel H. Abdulahad, Gerda Horst, Caroline Roozendaal, Abraham Rutgers, Annemieke M.H. Boots and Elisabeth Brouwer. University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: Giant cell arteritis (GCA) is a primary vasculitis affecting large to medium-sized arteries. Ample evidence suggests that dendritic cells, T cells and monocytes/macrophages contribute to the immunopathology of GCA. Previous reports showed that B cells are not predominant cells in temporal arteries of GCA patients (*Cid et al. AR 1989*). However, a high prevalence of various auto-antibodies in serum of GCA patients is suggestive of B cell activation in GCA (*Baerlecken et al. ARD 2012; Regent et al. ART 2011; Schmits et al. Clin Exp Immunol 2002*). Furthermore, emerging data indicate that B cells can modulate immune responses of T cells and monocytes by producing IL-10 and TNF-α (*Lund et al. Nat Rev Immunol 2010*). In the current study, we assessed the distribution of defined B cell subsets, including IL-10+ regulatory B cells and TNF-α+ effector B cells, in GCA patients before and after glucocorticoid (GC) treatment.

Methods: B cells were analyzed in peripheral blood of 15 newly-diagnosed GCA patients. In addition, we studied 40 age-matched, healthy controls (HCs) and 28 disease controls, including 17 polymyalgia rheumatica (PMR) patients and 11 rheumatoid arthritis (RA) patients. In a prospective, longitudinal study design, 39 samples were obtained from GCA and PMR patients who were in remission after 2 and 12 weeks of treatment with GCs. Serum levels of BAFF were determined. Flow cytometric staining of B cells for intracellular TNF-α and IL-10 was performed after 4 hours of stimulation with PMA and calcium ionophore in the presence of brefeldin A.

Results: Circulating B cells were decreased in newly-diagnosed GCA and PMR patients, but not in RA patients, compared to HCs. Following 2 and 12 weeks of GC treatment, B cell numbers normalized in GCA and PMR patients. This normalization was neither attributable to repopulation by immature-transitional B cells from the bone marrow, nor to compensatory hyperproliferation in the blood. Instead, already existing mature B cell subsets seemed to be mobilised towards the circulation of treated GCA and PMR patients. In particular the circulating pool of unswitched and switched memory B cells was expanded after GC treatment. B cell numbers inversely correlated with ESR, CRP and serum levels of the B cell growth factor BAFF. In newly-diagnosed GCA patients, TNF-α+ effector B cells but not IL-10+ regulatory B cells were decreased. Following treatment, numbers of TNF-α+ effector B cells and IL-10+ regulatory B cells were normal in GCA patients.

Conclusion: Our data indicate that B cells, including TNF-α+ effector B cells, are redistributed during active GCA and PMR. Following treatment, mature B cells subsets, in particular memory B cells, are mobilized to the circulation. In accordance with the high prevalence of various auto-antibodies reported in GCA and PMR, our data further suggest that activation of B cells occurs during the active stages of both diseases. Additional studies on the pro-inflammatory and regulatory role of B cells in GCA and PMR are ongoing.

Negative Temporal Artery Biopsies: Pathologic Findings Of Patients With Biopsy-Negative Giant Cell Arteritis Compared To Those Of Patients Without Arteritis. Francesco Muratore[1], Alberto Lo Gullo[1], Alberto Cavazza[1], Giuseppe Germanò[1], Luigi Boiardi[1] and Carlo Salvarani[2]. [1]Arcispedale S Maria Nuova, IRCCS, Reggio Emilia, Italy, [2]Arcispedale S Maria Nuova-IRCCS, Reggio Emilia, Italy.

Background/Purpose: Temporal artery biopsy (TAB) showing transmural inflammation is considered the gold standard for the diagnosis of giant cell arteritis (GCA). A negative TAB does not rule out GCA, and a diagnosis of biopsy-negative GCA was reported in 5–25% of patients. In the absence of active mural inflammation (negative TAB), other structural changes in the wall of TA are often present and some of those have been described as "healed" or quiescent arteritis, but if these histological changes are expression of GCA is still debated. The aim of this study is to evaluate if there are histopathological features of negative TAB that allow to differentiate patients with GCA from those without.

Methods: 42 consecutive patients with negative TAB were retrospectively selected. All patients underwent TAB for suspected GCA between January 2009 and December 2012. Demographic, clinical and laboratory data at presentation and at each follow up visit were collected. A pathologist with expertise in vasculitis blinded to clinical data and final diagnosis reviewed all 42 negative TABs. Histopathologic features evaluated were: the presence of a focal medio-intimal scar with medial attenuation, intimal hyperplasia, fragmentation of inner elastic lamina (IEL), calcification, adventitial fibrosis and neoangiogenesis.

Results: After a median follow-up period of 177 days (interquartile range 38, 508), 20 of the 42 patients had a final diagnosis of GCA, while in the remaining 22 patients GCA was excluded (9 had polymyalgia rheumatica, 4 non arteritic anterior ischemic optic neuropathy, 3 fibromyalgia, 2 non-specific elevation of inflammatory markers, 1 fever of unknown origin, 1 rheumatoid arthritis, 1 ANCA associated vasculitis, 1 osteoarthitis). 1990 ACR classification criteria for GCA were satisfied in 13 of the 20 patients with GCA (65%) and in none of the 22 non-GCA patients. 12 patients (60%) with GCA and 14 patients (64%) with non-GCA were on steroid therapy when TAB was performed ($p > 0.05$). The mean prednisone dose was (mg+ SD) 23.75 +12.95 for GCA patients and 13.57 +11.67 for non-GCA patients ($p = 0.05$). Mean duration of prednisone treatment was (days+SD) 30.58+44.23 for GCA patients and 144.36+162.24 for non GCA patients ($p < 0.05$). A focal medio-intimal scar with medial attenuation was found in 15% of GCA vs 14% of non-GCA patients ($p > 0.05$). Intimal hyperplasia was present in 45% vs 59%, fragmentation of IEL in 80% vs 91%, calcification in 30% vs 18%, adventitial fibrosis in 10% vs 5% and neoangiogenesis in 10% vs 9% of GCA vs non-GCA patients respectively (all p NS). 4 patients with GCA had visual loss. A focal medio-intimal scar with medial attenuation was not observed in these 4 patients, intimal hyperplasia was observed in 2, fragmentation of IEL in all 4, calcification in 2, adventitial fibrosis in 1 and neoangiogenesis in 1. Histological findings of GCA patients with visual loss were similar to those of patients with non-GCA.

Conclusion: The histological features of negative TAB evaluated in this study do not allow to differentiate between GCA and non-GCA patients. These data suggest that in the absence of mural active inflammation, other histological changes of the TA wall are not specific for GCA.

Serum S100A8/S100A9 and S100A12 As a Marker Of Disease Activity In Giant Cell Arteritis. Jason Springer[1], Dirk Holzinger[2], Gary S. Hoffman[3], Paul A. Monach[4], Thomas Hamilton[5], Carol A. Langford[5], Dirk Foell[6], David Cuthbertson[7], Colin O'Rourke[5], Simon Carette[8], Nader A. Khalidi[9], Carol McAlear[10], Christian Pagnoux[11], Philip Seo[12], Kenneth J. Warrington[13], Steven R. Ytterberg[13], Thomas Vogl[14], Peter A. Merkel[10], Johannes Roth[14] and Rula Hajj-Ali[3]. [1]University of Kansas Medical Center, Kansas City, KS, [2]University Muenster, Muenster, Germany, [3]Cleveland Clinic Foundation, Cleveland, OH, [4]Boston University, Boston, MA, [5]Cleveland Clinic, Cleveland, OH, [6]Department of Pediatric Rheumatology and Immunology, University of Münster, Münster, Germany, [7]University of South Florida, Tampa, FL, [8]UHN/MSH, Toronto, ON, [9]McMaster University, Hamilton, ON, [10]University of Pennsylvania, Philadelphia, PA, [11]Division of Rheumatology, Mount Sinai Hospital, Toronto, ON, [12]Johns Hopkins Vasculitis Center, Baltimore, MD, [13]Mayo Clinic, Rochester, MN, [14]University of Muenster, Muenster, Germany.

Background/Purpose: The S100 proteins (S100A8/9 complex and S100A12) are calcium binding proteins expressed during myeloid differentiation. S100 proteins are phagocyte-specific proteins that have been demonstrated to be markers of early recruited phagocytes in various inflammatory disorders. We previously demonstrated that gene expression of the S100A8/A9 and S100A12 are significantly elevated in temporal arteries in patients with giant cell arteritis (GCA), compared to controls. Furthermore, serum concentrations of S100A8/A9 and S100A12 arehigher in patients with GCA compared to healthy controls. We aimed to assess the association of S100 proteins in disease activity in GCA and their value in predicting disease activity as compared to standard inflammatory markers (CRP and ESR).

Methods: Fifty-nine patients with GCA were selected from the Vasculitis Clinical Research Consortium Longitudinal Study of GCA. Mean age was 72.3 and 44 (75%) were female. Serum concentrations of S100A8/A9 complex and S100A12 were measured by ELISA in 106 samples at times of active or inactive disease. Data on ESR and CRP values were available for 100 and 94 samples, respectively. Mixed effects model, accounting for repeat measurements, was used to compare S100A8/A9 or S100A12 levels between active and inactive disease. ROC curves were created to compare the utility of CRP and ESR, S100 proteins or a combination of all markers in predicting disease activity.

Results: Estimated mean serum S100A8/9 was significantly higher during active disease (1446 ng/mL) vs. inactive disease (1096 ng/mL), p=0.003. Mean serum S100A12 was also significantly higher during active disease (163 ng/mL) vs. inactive disease (117 ng/mL), p=0.016. The AUC for the combination of S100 proteins and standard markers of inflammation was higher than the AUC for either alone (Figure 1).

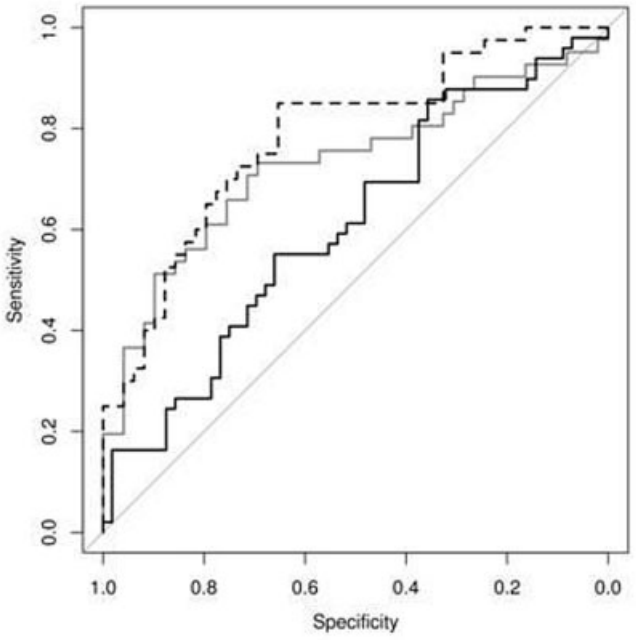

Figure 1. Estimated ROC curves for prediction of disease activity in patients with GCA. The grey line is for predictions based on CRP and ESR (AUC = 0.73). The black line is for predictions based on S100A12 and S100A8/9 (AUC = 0.61). The dashed line is the model involving all measurements (AUC = 0.79).

Conclusion: Serum S100A8/A9 and S100A12 are both significantly elevated during active disease in GCA. The combination of S100 proteins measurements with ESR and CRP enhanced the predictive value of disease activity in GCA.

1668

Does Fibrinogen Have a Role In The Assessment Of Patients With Giant Cell Arteritis? Lorraine O' Neill[1], Eoghan M. McCarthy[2], Anne M. Madigan[2], Geraldine M. McCarthy[2], Eamonn S. Molloy[1], Ursula Fearon[1], Douglas J. Veale[1] and Conor Murphy[3]. [1]St. Vincent's University Hospital, Dublin 4, Ireland, [2]Mater Misericordiae University Hospital, Dublin 7, Ireland, [3]Royal Victoria Eye and Ear Hospital, Dublin, Ireland.

Background/Purpose: Giant cell arteritis (GCA) in the most common systemic vasculitis in patients over 50 years of age. Considerable difficulties exist in the evaluation of patients with GCA. Accurate clinical assessment can be challenging due to the wide spectrum of clinical presentations. Temporal artery biopsy is negative in a substantial minority of patients.

The traditional biomarkers ESR and CRP are non-specific and can be negative.

Therefore development of better disease biomarkers is needed for diagnosis in GCA.

Plasma Fibrinogen has already been demonstrated in Polymyalgia Rheumatica to accurately identify those patients with quiescent disease, to be at least as useful as CRP and ESR for diagnosis of active disease and more specific for confirmation of response to treatment than either ESR or CRP.

Aim: The aim of this study was to evaluate the utility of plasma Fibrinogen in the assessment of patients with GCA.

Methods: Patients presenting with suspected new-onset GCA were prospectively enrolled. Plasma fibrinogen, ESR and CRP were assayed at baseline and 3 months following initiation of steroid therapy.

Biomarkers were also assayed in 25 age and sex matched controls attending with osteoarthritis (OA).

Demographic data and categorical variables were assessed using Fischers Exact Test. Receiver operator curves (ROC), predictive values, and likelihood ratios were calculated for all biomarkers measured. Spearman rank correlation coefficient was used to directly compare Fibrinogen, ESR and CRP.

Results: 68 patients with suspected GCA were recruited. 30 patients had positive temporal artery biopsies and of the 38 with negative biopsies, 25 met ACR criteria for GCA and were included in the ananlysis.

Plasma Fibrinogen levels were significantly elevated in patients with GCA when compared with OA controls. (Mean 4.9 g/L vs. 3.05 g/L, $p = 0.0017$). Fibrinogen levels were also significantly elevated in patients with GCA who were biopsy positive when compared to those patients fulfilling ACR criteria for GCA but who were biopsy negative (Mean 6.05 g/L vs 3.75 g/L, $p = < 0.01$) No correlation was observed between Fibrinogen and any clinical variable observed.

Fibrinogen levels also demonstrated a response to therapy. (Mean of 4.9 g /L at baseline vs. 3.5 g/L at 3 months, $p = 0.04$) Baseline Fibrinogen levels correlated with baseline ESR ($r = 0.6946$, $p < 0.0001$) and CRP ($r= 0.6951$, $p < 0.0001$. ROC analysis revealed Fibrinogen to be a less sensitive but more specific marker of GCA than CRP (Sensitivity of 67% vs. 82% and Specificity of 100% vs. 80% respectively) with comparable specificity to ESR above a cut off for ESR >30 mm/hr.

Values above the upper limit of normal for Fibrinogen (4 g/L) were associated with a positive likelihood ratio of 15.18 for GCA.

Conclusion: Plasma fibrinogen levels are elevated in patients with GCA, respond to glucocorticoid therapy and correlate with serum ESR and CRP levels. This data suggests that fibrinogen may be a more specific marker for GCA than CRP. Further research is required to define the utility of fibrinogen in assessment of disease activity in patients with GCA.

The Birmingham Vasculitis Activity Score As a Measure Of Disease Activity In Patients With Giant Cell Arteritis. Tanaz A. Kermani[1], David Cuthbertson[2], Simon Carette[3], Gary S. Hoffman[4], Nader A. Khalidi[5], Curry L. Koening[6], Carol A. Langford[7], Kathleen McKinnon-Maksimowicz[8], Carol McAlear[9], Paul A. Monach[10], Philip Seo[11], Kenneth J. Warrington[12], Steven R. Ytterberg[12], Peter A Merkel[13] and Eric L. Matteson[12]. [1]University of California Los Angeles, Los Angeles, CA, [2]University of South Florida, Tampa, FL, [3]UHN/MSH, Toronto, ON, [4]Cleveland Clinic Foundation, Cleveland, OH, [5]McMaster University, Hamilton, ON, [6]Salt Lake City Veterans Administration, Salt Lake City, UT, [7]Cleveland Clinic, Cleveland, OH, [8]University of Pittsburgh, Pittsburgh, PA, [9]University of Pennsylvania, Philadelphia, PA, [10]Boston University, Boston, MA, [11]Johns Hopkins Vasculitis Center, Baltimore, MD, [12]Mayo Clinic, Rochester, MN, [13]University of Pennsylvania and VA Medical Center, Philadelphia, PA.

Background/Purpose: To evaluate the performance of the Birmingham Vasculitis Activity Score (BVAS), a validated tool for assessment of vasculitis disease activity, in a cohort of patients with GCA.

Methods: Patients with GCA enrolled in a prospective, multicenter, longitudinal study were included. All subjects were followed with serial standardized clinical assessments. Symptoms attributable to vasculitis, BVAS, and physician global assessments (PGA) (scale 0–10) were available at each visit. Patients with a BVAS >0 at any visit, or those with symptoms of active vasculitis, were included. Manifestations of active vasculitis captured under the "Other" category of BVAS were scored as 0. Spearman's rank correlation was used to explore the association of BVAS with other measures of disease activity including PGA, physician rated disease activity (low, moderate or high), erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP).

Results: During a mean (SD) follow-up of 2.3 (1.6) years, symptoms of active GCA were present in 236 visits in 136 subjects (100 female, 74%). Median (range) of BVAS1 (new or worse symptoms) was 1 (0–11), median (range) of BVAS2 (persistent symptoms) was 0 (0–5), and median (range) PGA was 4 (0–9) during the 236 episodes of active disease. In 32 encounters (14%), both BVAS1 and BVAS2 were 0. Clinical manifestations sorted by organ systems on BVAS are displayed in Table 1. Several vascular and ischemic symptoms attributed to active GCA on standardized history forms were captured in the "Other" category and did not contribute to the composite scores on BVAS, including diplopia (4 episodes, 2%), temporal artery tenderness (43 episodes, 18%), carotidynia (16 episodes, 7%), jaw/tongue claudication (65 episodes, 28%), upper extremity claudication (34 episodes, 15%), and lower extremity claudication (12 episodes, 5%).

Table 2 contains correlations of BVAS and other measures of disease activity. BVAS1 correlated with PGA and disease activity while BVAS2 was negatively correlated with both. Neither BVAS subscore correlated with ESR or CRP.

Table 1. Frequency of clinical manifestations in 236 encounters of giant cell arteritis with active disease during observation, as captured by the Birmingham Vasculitis Activity Score (BVAS). BVAS items are arranged by organ systems.

BVAS items (by organ system)	New/worse symptoms*	Persistent symptoms*
General (N=193)		
Malaise	57	17
Myalgia	51	7
Arthralgia/arthritis	49	17
Headache	94	9
Fever (<38.5 degrees Celsius)	4	2
Fever (>38.5 degrees Celsius)	2	1
Weight loss (≥2 kilograms)	24	1
*Median (range) BVAS for category	1 (0–3)	0 (0–2)
Cutaneous (N=1)		
Ulcer	1	0
*Median (range) BVAS for category	0 (0–4)	0 (0–0)
Mucous membranes/eyes (N=34)		
Mouth ulcers	0	1
Blurred vision	29	1
Sudden vision loss	12	0
*Median (range) total BVAS for category	0 (0–6)	0 (0–2)
Ear, Nose, and Throat (N=1)		
Sinus involvement	0	1
*Median (range) total BVAS for category	0 (0–0)	0 (0–1)
Chest (N=9)		
Persistent cough	8	1
*Median (range) total BVAS for category	0 (0–2)	0 (0–1)
Cardiovascular (N=2)		
Congestive heart failure	0	2
*Median (range) BVAS for category	0 (0–0)	0 (0–2)
Abdominal (N=1)		
Severe abdominal pain	1	0
*Median (range BVAS for category)	0 (0–3)	0 (0–0)
Renal (N=0)		
*Median (range) BVAS for category	0 (0–0)	0 (0–0)
Nervous system (N=4)		
Organic confusion/dementia	2	0
Stroke	1	0
Sensory peripheral neuropathy	0	1
*Median (range) BVAS for category	0 (0–9)	0 (0–3)
Other N=85	63	22

N=total number with any clinical manifestation in that organ system
*Values are number of patients with symptoms except for median BVAS scores.

Table 2. Correlations of BVAS with other parameters used to assess disease activity in GCA.

	BVAS1	p-value	BVAS2	p-value	PGA	p-value
PGA	0.45	<0.001	−0.20	0.002	–	
ESR	0.02	0.78	−0.13	0.06	0.09	0.18
CRP	0.06	0.39	−0.02	0.73	−0.003	0.98
Disease activity*	0.43	<0.001	−0.17	0.01	0.91	<0.001

BVAS= Birmingham Vasculitis Activity Score; BVAS1= score for new/worse disease activity; BVAS2= score for persistent disease activity;
GCA= Giant cell arteritis;
PGA= physician global assessment; ESR= erythrocyte sedimentation rate;
CRP= C-reactive protein.
*rated by evaluating physician as low, medium or high.

Conclusion: The BVAS has limited utility in GCA. BVAS1, but not BVAS2, correlates positively with PGA. Several patients in this study with active GCA had a BVAS of 0. Items in 7 of the 9 organ systems on BVAS are not applicable to most patients with active GCA and important symptoms attributable to GCA often fall into the "Other" BVAS section and are not captured in the composite score. Modification of the BVAS with retention of a set of general items and inclusion of large-vessel vasculitis disease-specific items may provide more accurate disease assessment in GCA.

Large Vessel Vasculitis: Estimating Disease Activity In Patients With Inflammatory Thoracic Aortic Aneurysms. Alison Clifford, Tiffany M. Clark, Douglas Johnston, Gosta Pettersson, Eric Roselli, E. Rene Rodriguez, Edward Soltesz, Lars Svensson, Carmela Tan and Gary S. Hoffman. Cleveland Clinic Foundation, Cleveland, OH.

Background/Purpose: Thoracic aortic aneurysms due to large vessel vasculitis may be a sign of ongoing inflammation or the sequelae of previous damage to the arterial wall. Ongoing inflammation in the aorta is usually estimated indirectly using clinical features, inflammatory markers and imaging characteristics. Whether these surrogates accurately reflect inflammation within the vessel wall is not known.

Methods: We retrospectively reviewed the clinical, laboratory and imaging data for patients in whom aortitis was histologically demonstrated at the time of reconstruction for thoracic aortic aneurysms (May 2011-December 2012). ACR classification criteria were used to define vasculitis subtype. Pre- and post-operative assessments of disease activity were estimated using the NIH criteria for active disease.

Results: Among 126 consenting study patients who underwent repair of thoracic aortic aneurysms, 14 (11%) had histological features of aortitis. Thirteen specimens (93%) had persistent inflammatory infiltrates, and 1 had features of healed aortitis. Seven patients met criteria for Giant Cell Arteritis, 2 for Takayasu's arteritis, 4 for Isolated Aortitis, and 1 for Sarcoidosis. Median duration of disease prior to surgery was 35.5 months (range 0–180). At the time of surgery, only 2 of 10 patients (20%) with known systemic disease met criteria for active disease, while the remaining 8 (80%) were felt to be in clinical remission, yielding a sensitivity of 22% and specificity of 100% for the NIH criteria for determining active disease. When assessed over 1 year pre-operatively, 5 of 10 patients (50%) met criteria for active disease, increasing the sensitivity of NIH criteria to 44%. Post-operatively, only 1 of 13 (7%) patients met criteria for active disease. Two patients developed new vascular lesions during follow-up, at median of 3 months post-operatively, and 2 patients died.

Pt	Age, Sex	Presentation and Treatment (Rx)	Indication for Surgery	Diagnosis	Aneurysm size at surgery (cm)

14	30, M	2007: Sweats, weight loss, headache, ESR 80, MRA: TAA (ascending & descending) stenoses R common carotid, L subclavian, celiac & L renal arteries, L common carotid artery aneurysm. Rx: prednisone, AZA, MTX, Adalimumab	Aneurysm size	TAK	5.3

Abbreviations: Rx=treatment, CT=computerized tomography, MRA=magnetic resonance angiogram, TAA=thoracic aortic aneurysm, CHF=congestive heart failure, AI=aortic insufficiency, PMR=polymyalgia rheumatica, IA=isolated aortitis, GCA=Giant Cell Arteritis, TAK=Takayasu's arteritis, MTX=methotrexate, AZA=azathioprine, TA=temporal artery

Conclusion: At the time of surgery only 20% of patients with aortitis met criteria for active disease based on indirect clinical features, while 93% demonstrated ongoing inflammation on biopsy, indicating that indirect estimates of thoracic aortic inflammation are insensitive in patients with aneurysms. These findings emphasize the need for improved markers for assessing disease activity in patients with large vessel vasculitis.

Cardiovascular Risk At Incidence Of Giant Cell Arteritis: A Population Based Retrospective Cohort Study. P. Deepak Udayakumar, Arun K. Chandran, Cynthia S. Crowson, Kenneth J. Warrington and Eric L. Matteson. Mayo Clinic, Rochester, MN.

Background/Purpose: Many systemic inflammatory rheumatic conditions are associated with increased cardiovascular (CV) risk. We aimed at assessing the CV risk at incidence of giant cell arteritis (GCA).

Methods: We retrospectively reviewed a population-based incidence cohort of GCA patients diagnosed between 1950 and 2009 based on American College of Rheumatology 1990 GCA classification criteria. We also included patients ' 50 years of age with elevation of erythrocyte sedimentation rate or C-reactive protein and computed tomography, magnetic resonance imaging or positron emission tomography evidence of large vessel vasculitis involving ascending aorta and its branches. We compared this cohort with age, sex and calendar year matched cohort from the same population. All subjects were longitudinally followed through all available community medical records until death, migration or April 30, 2013. Data was collected on all documented episodes of acute coronary syndrome (ACS) events prior to GCA incidence/index date and CV risk factors at GCA incidence/index date. Chi-square tests were used to compare characteristics between GCA and non-GCA cohort.

Results: We identified 245 patients in GCA cohort and 245 age, sex and calendar year matched patients in non-GCA cohort. At GCA incidence, 107 (44%) GCA subjects were on antihypertensives as opposed to 127 (52%) non-GCA subjects (p=0.08). Mean high density lipoprotein (HDL) was higher in GCA cohort [61.5 mg/dl; standard deviation (SD) 17.1] than non-GCA cohort (55.3 mg/dl; SD 17.9) (p=0.034). Mean triglycerides was lower in GCA cohort (124.2 mg/dl; SD 59.6) than non-GCA cohort (148.8 mg/dl; SD 77.5) (p=0.029). Mean low density lipoprotein (LDL) and total cholesterol were not different between the two cohorts. 23 (9.6%) subjects were on lipid lowering medication in GCA cohort as opposed to 39 (16.1%) in non-GCA cohort (p=0.032). No difference was noted in smoking status, obesity or chronic kidney disease between the two cohorts. Diabetes mellitus was present in 17 (6.9%) GCA subjects and 40 (16.3%) non-GCA subjects (p=0.001). Mean overall Framingham 10 year cardiovascular risk score was 30% (SD 19) in GCA subjects and 34% (SD 23) in non-GCA subjects (p=0.096) at incidence/index date. Positive family history of premature ACS was less frequent in GCA (2 of 26 subjects; 13%) than non-GCA cohort (10 of 32 subjects; 48%) (p=0.024). Occurrence of acute coronary syndrome (ACS) prior to GCA incidence/index date was similar between the two cohorts: 18 episodes (7.4%) in GCA cohort versus 17 episodes (6.9%) in non-GCA cohort (p=0.86).

Conclusion: Multiple cardiovascular risk factors are more favorable at incidence of GCA when compared to non-GCA subjects of similar age and gender. Anti-hypertensives and lipid lowering medications are less frequently used in GCA subjects at incidence. Framingham 10 year cardiovascular risk may be lesser at GCA incidence although this did not achieve statistical significance in our study. As GCA is a disease that almost exclusively affects the elderly, there may be a component of healthy cohort bias causing this effect.

Serious Cardiovascular Events Risk Factors In Giant Cell Arteritis. A Population-Based Study In The French Apogee Cohort. Grégory Pugnet[1], Laurent Sailler[2], Guillaume Moulis[3], Jean-Pascal Fournier[4], Robert Bourrel[5], Jean-Louis Montastruc[6] and Maryse lapeyre-Mestre[6]. [1]Toulouse University Hospital, University of Toulouse, INSERM UMR 1027, Toulouse, France, [2]Toulouse University Hospital, Toulouse, France, [3]Toulouse University Hospital, Clinical Pharmacology Department, University of Toulouse, UMR INSERM-UPS 1027, Toulouse, France, [4]Toulouse University, INSERM UMR 1027, Toulouse, France, [5]Caisse Nationale de l'Assurance Maladie échelon régional, Midi-Pyrénées, Toulouse, France, [6]Toulouse University Hospital, INSERM U1027, University of Toulouse, France, Toulouse, France.

Background/Purpose: No population-based study has assessed serious cardiovascular events (sCVE) risk factors in Giant Cell Arteritis (GCA). The aim of our study was to identify risk factors associated with sCVE occurrence in GCA in the general population.

Methods: The APOGEE cohort includes most incident GCA patients of the Midi-Pyrénées County, south of France from January 2005 to December 2008. GCA patients are identified in the French National Health Insurance System (FNHIS) database by their international classification of diseases code, 10th version (M31.5: "GCA with polymyalgia rheumatica (PMR)" or M31.6: "GCA without PMR"). Incident cases are defined by a continuous glucocorticosteroids (GCs) course lasting for at least 6 months, and no previous exposure to GCs during the 6 preceding months. For each case two controls matched on gender and age were randomly selected in the FNIHS database. New CVE were identified by analyzing comprehensive data on drugs' reimbursement, diagnostic procedures, hospital stays and new cardiovascular diseases registered in the database. Serious CVE were defined as CVE leading to hospitalization > 24 hours or death. Serious CVE identified was: cerebrovascular disease, coronary disease, peripheral arterial disease, congestive heart failure and atrial fibrillation. Follow-up ended in April 2011. We used a multivariate Cox proportional hazards model to identify independent predictors of the first sCVE in the whole population and in GCA patients.

Results: The cohort included 103 patients (80 women, mean age 74.8 ± 9 years, mean follow-up 48.9 ± 14.8 months) and 206 controls. At study entry, there was no difference between cases and controls for cardiovascular co-morbidities except for diabetes mellitus, which was more prevalent in controls ($p<0.01$). Serious CVE occurred more frequently in GCA patients (15.5% vs. 7.8%, p= 0.014). Independent risk factors for sCVE occurrence were GCA (HR= 1,99 [1.02–3.9]; p< 0.05), age over 77 (HR= 4.31 [1.78–10.45]; p=0.001), a previous history of diabetes (HR= 2.54 [1.19–5.41]; p=0.02) or chronic heart failure (CHF) (HR= 8.24 [1.89–35.84]; p=0.005). Independent risk factors for sCVE occurrence in the GCA cohort were age over 77 (HR= 7.07 [2.04–24.47]; p= 0.002) and a previous history of CHF (HR= 8.15 [1.86–35.72]; p= 0.005). Exposure to statins for more than 18 months decreased the risk of sCVE occurrence in the whole cohort (HR= 0.26 [0.06–1.11]; p= 0.07) and in the GCA cohort (HR= 0.35 [0.11–1.09] p= 0.071).

Conclusion: GCA is an important independent cardiovascular risk factor and statins may prevent sCVE occurrence. Older GCA patients with a previous history of CHF have a very high risk of developing serious cardiovascular complication and should be monitored closely.

1673

Risk Of Myocardial Infarction In Patients With Giant Cell Arteritis: A Population-Based Study. Neda Amiri[1], Hyon K. Choi[2], Eric C. Sayre[2], Kamran Shojania[2] and J. Antonio Avina-Zubieta[3]. [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada, Richmond, BC, [3]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC.

Background/Purpose: Involvement of large arteries leading to stenosis is well-documented in giant cell arteritis (GCA), but limited data are available on the risk of coronary events. We estimated the risk of newly diagnosed MI events among incident cases with GCA compared to controls from the general population. We also explored time trends for MI since GCA diagnosis.

Methods: Our data included all visits to health professionals and hospital admissions covered by the comprehensive provincial medical services plan from January 1, 1990 until December 31, 2010 for all individuals. We conducted a matched cohort analysis among patients satisfying the following criteria: **a)** 40 years of age or older; **b)** new diagnosis of GCA on at least 2 visits within a 2-year period between Jan 1996 and Dec 2010; and **c)** use of oral glucocorticoids between 1 month before and 6 months after the diagnosis date. Ten non-GCA controls matched by birth year, sex, and calendar year of follow-up were selected from the general population for each case. Our outcome was risk of **incident MI events** based on hospitalization records or death certificate. We estimated the relative risks (RRs) of MI compared with the matched non-GCA comparison cohort, adjusting for history of angina, COPD, obesity, cardiovascular disease, diabetes, hormone replacement therapy, dyslipidemia, non-steroidal anti-inflammatory drug use, COX-2 inhibitor use, number of hospitalizations, and Charlson Comorbidity Index at baseline.

Results: Among 835 individuals with incident GCA (74% female, mean age of 75 years), 109 developed MI (incidence rate = 49.8 per 1000 person years) (**Table 1**). Compared with non-GCA individuals, the age-, sex-, and entry time-matched RRs were 3.3 (95% CI; 2.6–4.1). After adjusting for covariates, the RR remained similar (3.0; 95% CI, 2.3–4.1) (**Table 1**). The risk of developing an MI was highest in the first year following diagnosis of GCA and decreased over time, with no increased risk observed after 5 years.

Table 1. Risk of Incident MI according to GCA Status

	GCA (n = 834)	Non-GCA (n = 8,340)
Incidence Rate Ratios of MI		
MI events, N	109	401
Incidence Rate/1000 Person-Years	49.8	15.1
Age-, sex-, and entry time-matched RRs (95% CI)	3.3 (2.6–4.1)	1.0
Overall	**6.8 (4.8–9.7)**	**1.0**
< 1 year disease duration	6.8 (4.8–9.7)	1.0
1–4.9 years disease duration	2.4 (1.7–3.3)	1.0
5+ years disease duration	1.4 (0.5–3.2)	1.0
Multivariable RR (95 % CI)		
Overall	3.0 (2.3–4.1)	1.0
Females	2.9 (2.0–4.1)	1.0
Males	3.5 (2.0–6.2)	1.0

Conclusion: This large population-based study indicates a substantially increased risk of MI among GCA patients. The risk was 7 fold higher than that observed in non-GCA controls within the first year of the disease, suggesting that a high level of inflammation or associated therapy at the time of GCA diagnosis may be the culprit. These findings support the need for increased screening for MI and managing cardiovascular risk factors in GCA, particularly in the period following diagnosis.

Acute Coronary Syndromes In Patients With Giant Cell Arteritis: A Population Based Retrospective Cohort Study. P. Deepak Udayakumar, Arun K. Chandran, Cynthia S. Crowson, Kenneth J. Warrington and Eric L. Matteson. Mayo Clinic, Rochester, MN.

Background/Purpose: Acute coronary syndrome (ACS) is one of the leading causes of death in the general population. We aimed at assessing the occurrence of ACS in patients with giant cell arteritis (GCA).

Methods: We retrospectively reviewed a population-based incidence cohort of patients with GCA diagnosed between 1950 and 2009 based on American College of Rheumatology 1990 GCA classification criteria. We also included patients ≥ 50 years of age with elevation of erythrocyte sedimentation rate or C-reactive protein and computed tomography, magnetic resonance imaging or positron emission tomography evidence of large vessel vasculitis involving ascending aorta and its branches. We compared this cohort with age, sex and calendar year matched cohort from the same population. All subjects were longitudinally followed through all available community medical records until death, migration or April 30, 2013. Data was collected on all documented episodes of ACS including Thrombolysis in Myocardial Infarction (TIMI) score. Cox models were used to compare the development of ACS between GCA and non-GCA cohort.

Results: We identified 245 patients in the GCA cohort and 245 age, sex and calendar year matched patients in the non-GCA cohort. No difference between the two cohorts was noted in overall ACS events [hazard ratio (HR) 0.74; confidence interval (95% CI) 0.44, 1.26]. No difference was noted in different types of ACS such as unstable angina [HR 0.41; 95% CI (0.16, 1.09)], non-ST elevation myocardial infarction (NSTEMI) [HR 0.85; 95% CI (0.39, 1.85)] and ST elevation myocardial infarction (STEMI) [HR 1.03; 95% CI (0.41, 2.62)]. Age at first ACS event after index date was similar in both cohorts. Time from index date to first ACS event was also similar in both cohorts. Overall TIMI scores for unstable angina and NSTEMI were similar in both cohorts. 10 of 26 GCA subjects (38%) underwent coronary angiography as opposed to 19 of 32 non-GCA subjects (59%) (p=0.11). Revascularization procedures including percutaneous coronary intervention (PCI) and coronary artery bypass graft (CABG) were done less frequently in GCA [5 of 26 (19%)] than non-GCA subjects [16 of 32 (50%)] (p=0.015). Median length of hospital stay of first ACS event after index date was similar in both cohorts (4.5 vs 4 days). Post ACS complications including cardiogenic shock, persistent rest angina despite intervention, ventricular septal defect, mitral regurgitation and sustained ventricular arrhythmias were similar in both cohorts. 6 of 26 GCA subjects who had ACS experienced 10 recurrent events during 83 person-years of observation after the first episode as opposed to 6 of 32 non-GCA subjects who experienced 17 recurrent events during 138 person-years (rate ratio 1.00; 95% CI 0.44, 2.10).

Conclusion: There is no overall increased risk of acute coronary syndromes in patients with giant cell arteritis. Revascularization procedures are done less frequently in patients with giant cell arteritis. Overall length of hospital stay is not different in patients with giant cell arteritis who develop acute coronary syndrome.

Infections Requiring Or Acquired During Hospitalizations In Patients With Giant Cell Arteritis - a Population Based Retrospective Cohort Study. P. Deepak Udayakumar, Arun K. Chandran, Cynthia S. Crowson, Kenneth J. Warrington and Eric L. Matteson. Mayo Clinic, Rochester, MN.

Background/Purpose: There is a general impression that the patients with giant cell arteritis (GCA) on glucocorticoid therapy are at higher risk for infections. We aimed to assess the occurrence of infections requiring or acquired during hospitalizations in patients with GCA.

Methods: We retrospectively reviewed a population-based incidence cohort of GCA patients diagnosed between 1950 and 2009 based on American College of Rheumatology 1990 GCA classification criteria. We also included patients ≥ 50 years of age with elevation of erythrocyte sedimentation rate or C-reactive protein and computed tomography, magnetic resonance imaging or positron emission tomography evidence of large vessel vasculitis involving ascending aorta and its branches. We compared this cohort with age, sex and calendar year matched cohort from the same population. All subjects were longitudinally followed through all available community medical records until death, migration or April 30, 2013. Data was collected on all documented episodes of infection requiring or acquired during hospitalization after the GCA incidence/index date. Infection rates were calculated using person-year methods.

Results: We identified 245 patients in the GCA cohort and 245 age, sex and calendar year matched patients in the non-GCA cohort. Baseline characteristics including mean age, sex and length of follow up were similar between the two groups. 74 GCA (134 episodes) and 79 non-GCA (153 episodes) subjects had infections requiring, or acquired during hospitalizations [Rate ratio (RR) 0.94; 95% confidence interval (CI) 0.74, 1.18]. 67 subjects (107 episodes) in GCA cohort and 63 subjects (110 episodes) in non-GCA cohort required hospitalization secondary to an infection [RR 1.04; 95% CI (0.80, 1.36)]. Pneumonia [RR 0.76; 95% CI (0.48, 1.17)], urinary tract infections [RR 0.81; 95% CI (0.43, 1.47)], skin and soft tissue infections [RR 0.83; 95% CI (0.36, 1.87)] accounted for the majority of infections requiring hospitalizations and had similar occurrence in both cohorts.

9 episodes of infections requiring hospitalization occurred in the first 6 months in GCA cohort as opposed to 5 in non-GCA cohort [RR 1.85; 95% CI (0.67, 6.01)]. Urinary tract infections accounted for the majority of infections requiring hospitalization in the first 6 months after GCA incidence [RR 3.93; 95% CI (0.85, 56.52)].

No difference between the two cohorts was noted in overall infections acquired during hospitalizations [RR 0.68; 95% CI (0.41, 1.08)]. Median length of hospital stay was 5 days and median duration of antibiotic use was 10 days in each cohort among infection episodes requiring hospitalizations.

Conclusion: There is no overall increased risk of infections requiring or acquired during hospitalizations in patients with giant cell arteritis on glucocorticoid therapy. There may be an increased risk of infections requiring hospitalization, especially of the urinary tract in the first six months after GCA incidence although this did not achieve statistical significance in our study. Overall length of hospital stay and duration of antibiotic use is not different in patients with GCA requiring hospitalization because of infection.

Statins Do Not Influence Occurrence Or Prednisone Requirement Of Giant Cell Arteritis. A French Population-Based Cohort Study. Grégory Pugnet[1], Laurent Sailler[2], Robert Bourrel[3], Jean-Louis Montastruc[4] and Maryse Lapeyre-Mestre[4]. [1]Toulouse University Hospital, University of Toulouse, INSERM UMR 1027, Toulouse, France, [2]Toulouse University Hospital, Toulouse, France, [3]Caisse Nationale de l'Assurance Maladie échelon régional, Midi-Pyrénées, Toulouse, France, [4]Toulouse University Hospital, INSERM U1027, University of Toulouse, France, Toulouse, France.

Background/Purpose: Statins are widely prescribed to reduce the risk of cardiovascular ischemic events, but also present immunoregulatory effects promoting a shift from a TH-1 to a TH-2 immune response. The aim of our study was to investigate the potential relationship between exposure to statins, GCA occurrence and prednisone requirement in the general population.

Methods: The cohort includes incident GCA patients of the Midi-Pyrénées County, south of France from January 2005 to December 2008. Incident GCA cases were selected in the French National Health Insurance system database. For each patient, two age- and paired- controls were selected in the same database. Endpoints were GCA occurrence, cumulative prednisone doses and time until maintenance of low prednisone doses (LPD) (i.e < 5 mg prednisone per day for at least 6 months). Statin exposure was measured during the 6 months before the date of first prednisone prescription and as a time-dependent co-variable during the course of GCA for cases and controls. Patients were followed up to April 2011.

Results: The study included 103 patients (80 women, mean age 74.8 ± 9 years, mean follow-up 48.9 ± 14.8 months) and 206 controls. Twenty-eight (27.2%) patients versus 45 (21.8%) controls had a sustained exposure to statins before the index date (adjusted OR = 0.70 [0.4–1.2], p = 0.22). A total of 81 patients reached a maintenance of LPD during the follow-up period: respectively 48%, 70%, 85% and 89% at 2, 3, 4 and 5 years of follow-up. The mean time necessary to reached a maintenance of LPD was 24.3 ± 11.2 months. Their mean cumulative prednisone dose at this time was 11.4 ± 6.1 g. Statin exposure at diagnosis was associated with a higher rate of remission, however this effect was not present when statin exposure was treated as a time-dependent covariate (adjusted HR =1.06 [0.81–1.40], p> 0.05). Cumulative prednisone doses did not differed according to statin exposure.

Conclusion: We found no influence of statin therapy on the occurrence of GCA or on prednisone requirement in a French population-based GCA cohort.

May Giant Cell Arteritis Be Characterized By Different Clinical Entity and Long-Term Outcome? Rosaria Talarico[1], Chiara Stagnaro[1], Claudia Ferrari[1], Anna d'Ascanio[1], Chiari Tani[1], Chiara Baldini[1], Marta Mosca[2] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Rheumatology Unit, University of Pisa, Pisa, Italy.

Background/Purpose: Giant cell arteritis (GCA) represents the most common primary vasculitis of the elderly, that affect large and medium-sized arterial vessels. Growing data shown that almost one-third of the patients with GCA develop serious peripheral vascular complications during long-term follow up, and it seems that unrecognized extra-cranial involvement may be even more common.

The primary aim of this study was to explore if there are different clinical entities in a cohort of patients with GCA (i.e. symptoms compatible with cranial GCA and large-vessel GCA); a secondary aim was to evaluate long-term outcome of GCA patients with at list 5 years of follow-up.

Methods: Two hundred and ten GCA patients (34 males and 176 females, mean ± SD age 77±8 years) were retrospectively studied. Clinical symptoms at disease onset and during the follow-up, time delay until diagnosis, as well as laboratory findings at the time of diagnosis, therapeutic approach were retrospective evaluated. In order to characterized the different disease entities, overall clinical symptoms were evaluated by means of a spectrum analysis. Moreover, we evaluated long-term outcomes in patients with a minimum follow-up of 5 years. We have defined as disease flare any further clinical manifestation compatible with the clinical spectrum of GCA and/or an increase of ESR ≥ 40 mm/hour, not otherwise justifiable, that required higher doses or new introduction of GC therapy.

Results: The most frequent clinical manifestations presented at the onset included: new onset headache and/or scalp pain 77%, constitutional symptoms 46%, jaw claudicatio 36%, vision loss 34%, abnormal temporal artery on examination 32%, dizziness 29%, neuropsychiatric symptoms 29%, cough not otherwise justifiable 10%, cerebrovascular accidents 6% and hearing loss 5%. Irreversible blindness was reported in 7% of patients, mainly due to a latency period between onset and treatment of ≥ 2 months. Temporal artery biopsy was performed in 160/210 of patients, resulting positive in 58%. Globally, about 26% of subjects (55, M/F: 9/46, mean ± SD age 71±7 years) was characterized by a clinical profile compatible with extra-cranial GCA. In all case, extra-cranial involvement was confirmed by (18)F-fluorodeoxyglucose (FDG) positron emission tomography (PET) and/or

angiography. Moreover, patients who presented symptoms compatible with large-vessel GCA were characterised by a more relapsing course compared with patients with cranial involvement GCA profile.

Conclusion: According literature data, our results confirm that GCA may be composed by more than one single entity. Extra cranial involvement due to GCA must be must be promptly recognized, because it probably may require a different prognostic and therapeutic approach.

How Similar Are Extracranial Giant Cell Arteritis and Takayasu Arteritis? Tanaz A. Kermani[1], Cynthia S. Crowson[2], Francesco Muratore[3], Jean Schmidt[4], Eric L. Matteson[2] and Kenneth J. Warrington[2]. [1]University of California Los Angeles, Los Angeles, CA, [2]Mayo Clinic, Rochester, MN, [3]Arcispedale S Maria Nuova, IRCCS, Reggio Emilia, Italy, [4]CHU Nord, Amiens, France.

Background/Purpose: The clinical and radiographic features of giant cell arteritis (GCA) with extracranial (large-vessel) involvement can be similar to those of Takayasu arteritis (TAK) with age often being used to differentiate these two forms of large-vessel vasculitis. The aim of this study was to compare clinical and imaging characteristics of GCA and upper extremity (UE) arterial involvement with TAK.

Methods: A cohort of patients with TAK diagnosed between 1984 and 2009, and, a cohort of patients with GCA and UE arterial involvement (based on imaging) diagnosed between 1999 and 2008 have been assembled. Comparisons were performed using Kruskal-Wallis and Chi-square tests.

Results: The TAK cohort consisted of 125 patients (91% female); mean age (±SD) at diagnosis 30.9 (±10) years. The cohort of patients with GCA and UE involvement comprised of 120 patients (80% female); mean age (±SD) at diagnosis 67.8 (±7.5) years. Mean onset of symptoms prior to diagnosis was significantly longer in TAK (3.2 years) compared to GCA (0.5 years), $p<0.001$. Fever was more common in patients with TAK (29% compared to 15% with GCA, $p=0.01$). Headache frequency was similar in both groups (33% GCA versus 45% TAK, $p=0.06$). UE claudication was present in 63 patients (53%) with GCA compared to 49 patients (40%) with TAK, $p=0.04$. Lower extremity claudication was reported in 11 patients (9%) with GCA compared to 22 patients (18%) with TAK, $p=0.05$. UE blood pressure discrepancy was present in 65% with TAK versus 28% with GCA, $p<0.001$. Absent pulses were noted in 72% of the TAK cohort compared to 53% of the GCA cohort, $p=0.002$; while any bruit was present in 74% TAK and 38% GCA, $p<0.001$.

Imaging findings are in the **Table**. Involvement of the thoracic aorta, abdominal aorta, carotid arteries, innominate artery, mesenteric artery and left renal artery was more frequently observed in TAK (Table). Among patients with luminal changes of the thoracic aorta, stenotic/occlusive lesions were predominant in TAK (81% compared to 0% in GCA), whereas aneurysmal disease was more common in GCA (100% compared with 19% in TAK $p<0.001$). Similar findings were noted in the abdominal aorta. In other arterial beds, stenotic or occlusive changes were the most frequent type of lesion observed in both GCA and TAK ($p>0.05$).

Table. Distribution and type of arterial lesions in GCA compared to TAK.

Artery	GCA Total number with any lesion/total number with imaging of area (%)	TAK Total number with any lesion/total number with imaging of area (%)	p-value
Thoracic aorta	13/117 (11)	26/109 (24)	0.01
Abdominal aorta	4/69(6)	21/93 (38)	<0.001
Right carotid	10/118 (8)	46/107 (43)	<0.001
Left carotid	11/118 (9)	53/107 (50)	<0.001
Right vertebral	13/115 (11)	14/107 (13)	0.69
Left vertebral	13/115 (11)	20/107 (19)	0.11
Innominate	5/117 (4)	27/105 (26)	<0.001
Right subclavian	57/116 (49)	40/103 (39)	0.126
Left subclavian	65/117 (56)	68/103 (66)	0.11
Right axillary	42/113 (37)	16/39 (41)	0.67
Left axillary	53/115 (46)	20/39 (51)	0.57
Mesenteric	11/65 (17)	31/88 (35)	0.01
Right renal	7/65 (11)	19/89 (21)	0.08
Left renal	3/65 (5)	17/89 (19)	0.01
Right iliac	3/64 (5)	12/87 (14)	0.07
Left iliac	2/64 (3)	12/87 (14)	0.03

Conclusion: Despite some similarities, patients with UE involvement from GCA differ from TAK in clinical and imaging characteristics. Stenotic/occlusive disease was the most frequent type of arterial lesion in both groups at the primary branches of the aorta. However, the type of aortic involvement differed between the two forms of large-vessel vasculitis. Aortic aneurysms were more common in GCA while stenotic changes of the aorta were more common in TAK suggesting different pathophysiologic mechanisms or vascular response to injury.

Clinical Implications Of Antiphospholipid Antibodies In Takayasu's Arteritis. Natasha Jordan, Holy Bezanahary and David P. D'Cruz. Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom.

Background/Purpose: Takayasu's arteritis (TA) is a granulomatous inflammation of unknown origin involving the aorta and its major branches. Association and implication of antiphospholipid antibodies (aPL) in the TA disease process remain controversial. The aim of this research was to ascertain if aPL positivity or the presence of Antiphospholipid Syndrome (APS) were predictive of a worse clinical outcome in TA.

Methods: Clinical data was retrospectively collected on 22 TA patients over an 11 year period (2001–2012). All patients fulfilled the ACR criteria for TA. Patients were categorised into 2 groups: a diagnosis of TA alone or a diagnosis of TA with either persistently positive anticardiolipin antibodies and/or lupus anticoagulant or a concurrent clinical diagnosis of APS. Those with APS met the Sapporo classification criteria.

Screening for lupus anticoagulant was performed using the dRVVT (dilute Russell's viper venom time) assay in accordance with standard methods. Confirmatory tests used a combination of mixing studies and correction with phospholipid. IgG and IgM anticardiolipin antibodies were measured using a standardized ELISA. Since anti-beta-2-glycoprotein-1 antibodies were not routinely measured clinically during the early stages of the study, they were not included in the analysis.

Adverse clinical outcomes included cerebrovascular accident (CVA),transient ischaemic attack (TIA), loss of vision, vascular lesions (carotid, femoral, renal coronary or other vessels) requiring stenting, angioplasty or other surgical intervention, aortic valve replacement, end-stage renal failure or death.

Results: 59% of patients had TA without aPL (n=13) and 41% had TA with a persistently positive aPL or a concurrent diagnosis of APS (n=9). Overall 7 significant vascular complications occurred in TA patients without aPL including 1 CVA, 1 TIA, 1 carotid endarterectomy and 4 angioplasty/stenting procedures. 8 such events occurred in TA patients with aPL/APS including 2 CVAs, 1 carotid endarterectomy, 1 aortic valve replacement and 4 angioplasty/stenting procedures. No patients developed end-stage renal failure or loss of vision. There were no deaths in this study cohort.

Conclusion: Persistently positive aPL and APS are present in a significant proportion of TA patients. Our concern was that these individuals may have a worse clinical outcome in terms of vascular complications. This study has shown that this is not the case and that vascular complications and need for intervention are equal in TA patients regardless of aPL positivity.

Predictivity Of Serum Biomarkers For Disease Activity In a Prospectively Followed-Up Takayasu Arteritis Cohort: Is Serum Amyloid A Protein Better Than Conventional Acute Phase Markers? Ahmet Omma, Burak Erer, Nilufer Alpay, Nuray Gurel Polat, Ahmet Gul, Murat Inanc, Lale Ocal and Sevil Kamali. Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey.

Background/Purpose: Takayasu arteritis (TA) is a chronic vasculitis with an indolent course. Reliable diagnostic and activity markers have not yet been demonstrated. We aimed to evaluate the predictivity of conventional acute phase proteins (ESR, CRP) and other non-conventional inflammation and endothelial activity markers such as serum amilod A (SAA) protein, interleukin-6 (IL-6) and von Willebrand factor (vWF) in a TA cohort, prospectively followed-up.

Methods: Fourty-eight TA patients diagnosed according to ACR 1990 criteria and followed-up ≥ 6 months, 37 patients with granulomatosis with

poliangiitis (GPA) diagnosed according to ACR 1990 criteria and 28 healthy controls (HC) were included into the study. Demographic and clinical features of TA, GPA and HCs were recorded into a predefined protocol. ESR, CRP, SAA, IL-6 and vWF levels were analysed initially in all groups and at 3rd, 6th, 12th months visits in TA and GPA groups. Westergreen method for ESR, nephelometric assay for CRP, SAA and ELISA method for IL-6 and vWF were used. Disease activity was evaluated by Kerr criteria for TA and BVAS2003 for GPA. TA and GPA cohorts were stratified to the subgroups according to the activity. Comparisons were performed by Mann Whitney U test in subgroups. ROC curve analysis was used to identify the sensitivity and specificity of laboratory parameters for predicting activity.

Results: Mean age and disease duration were found as 40±13 yrs, 121±115 mo for TA, 47±13 yrs, 65±42 mo for GPA and mean age was 38±9 for HCs. Females were significantly high in TA cohort (%) when compared to GPA (%) (p<0,001). The percentage of active disease was 40%, 31%, 35%, 29% for TA and 32%, 19%, 11%, 13% for GPA at initial 3rd, 6th and 12th months, respectively. ESR, CRP and SAA levels were significantly high in active TA at the initial, 3rd, and 6th months visits (41±20 vs 21±12, p=<0.001 for ESR, 20±20 vs 6±10 p=<0.001 for CRP, 23±23 vs 12±29, p=0.001 for SAA at initial visit, 41±19 vs 24±17, p=0.002 for ESR, 26±28 vs 6±8, p= 0.004 for CRP, 38±59 vs 12±17, p=0.02 for SAA at the 3rd visit, 41±17 vs 24±12, p= <0.001 for ESR, 16±18 vs 4±5, p= 0.01 for CRP, 22±30 vs 10±16, p=0.002 for SAA at the 6th visit). SAA was the only marker that demonstrate the significance between subgroups at the 12th month (12±10 vs 8±11, p= 0.007). In active GPA subgroup, SAA and vWF at the 3rd visit and vWF at the 6th visit were found significantly high compared to inactive patients. Sensitivity and specificity were found as 88–70%, 79–84% for ESR levels of 35 mm/h, 83–65%, 86–84% for CRP levels of 5–8 mg/L 72–50%, 90–80% for SAA levels of 10–11 mg/L at the initial and 6th months visits in TA cohort. At the 12th month visit, SAA levels of 9 mg/L, was the only marker reaching the significant sensitivity (45%) and spesificity (83%) for predicting activity.

Conclusion: In a well established and prospective cohort of TA, SAA has found to be a comparable sensitivity and specificity with ESR and CRP for predicting activity. It's been observed that sensitivity of ESR, CRP had a trend towards to decrease in time which could be related to the decreasing activity during the follow-up. SAA was the only laboratory parameter which maintained its specificity in contrast to conventional biomarkers.

Assessment of Patients With Takayasu's Arteritis in Routine Clinical Follow-Up With Indian Takayasu Clinical Activity Score 2010(*ITAS2010*). Fatma Alibaz-Oner and Haner Direskeneli. Marmara University, School of Medicine, Istanbul, Turkey.

Background/Purpose: ITAS2010 (Indian Takayasu Clinical Activity Score) is a new composite index developed to assess clinical activity in Takayasu's arteritis (TAK), which is weighted for vascular items. In this study, we aimed to investigate the effectiveness of ITAS2010 in the routine clinical follow-up of patients with TAK.

Methods: Patients (n=33, mean age:40.9±12,4 years, F/M:30/3) classified according to ACR criteria for TAK were enrolled. ITAS2010 forms were filled cross-sectionally at baseline for all clinical features and 2 follow-up visits prospectively, with intervals of at least 4–6 months, by including only new or worsening symptoms within the past 3 months(1).

Results: ITAS2010 was similar at baseline for both active and inactive patients [12 (5–20) vs 10 (0–19), respectively]. There was no correlation between ITAS2010 and acute phase reactants (APRs) in this visit. Similarly, change according to PGA was not reflected in ITAS in the second visit [1,15 (0–6) vs 1,4 (0–3), respectively]. Only in the third visit ITAS2010 score was observed to be significantly higher in active [1,62 (0–7)] patients compared to inactives [0,45 (0–3)](p=0,001). The total agreement between ITAS2010 and PGA was 60% (kappa: 0,096, p=0,43) and between ITAS2010 and *Kerr et al*. was 74% (kappa: 0,18, p=0,035). The total agreement between PGA and *Kerr et al*. was 71% (kappa: 0,26, p=0,005). Twelve patients were evaluated with imaging in the follow-up period (4 with PET, 8 with MR-Angiography). When we added an extra score on ITAS2010 for high APRs or positive imaging (vascular progression with radiology or increased uptake on major vascular structures with PET), the total agreement between ITAS2010 and PGA increased to 74% (kappa: 0,499, p<0,001), whereas ITAS2010 and *Kerr et al*. decreased to 51% (kappa: 0,102, p=0,06).

Conclusion: The agreement between PGA and ITAS2010 was observed to be limited in our study. However, when we combined ITAS2010 with APR or imaging, our results improved. ITAS2010 had a significant discriminatory value according to disease activity in only the third visit in our routine follow-up. These results suggest that ITAS2010 may be valuable in the long-term follow-up of patients with TAK, especially if combined with biomarkers and imaging.

Patients With TAKAYASU'S Arteritis Having Persistent ACUTE PHASE Response Usually Have An Increased MAJOR Vessel Uptake By 18F-FDG-PET/CT. Fatma Alibaz-Oner[1], Fuat Dede[1], Tunc Ones[2], H. Turgut Turoglu[1] and Haner Direskeneli[1]. [1]Marmara University, School of Medicine, Istanbul, Turkey, [2]Marmara University, School of Medicine, ISTANBUL, Turkey.

Background/Purpose: 18F-fluorodeoxyglucose positron emission tomography (18F-FDG PET/CT) is a sensitive imaging tool for large-vessel vasculitis. Although not uniformly accepted, an increased uptake by 18F-FDG PET/CT in large-vessels is accepted to be a sign of active disease in Takayasu's arteritis (TAK). In this study, we aimed to investigate the value of 18F-FDG-PET/CT for clinical assessment in a subset of TAK patients having a persistent acute phase response (APR) without any signs or symptoms of clinical disease activity.

Methods: We studied 12 patients with TAK (mean age: 39.2±14.8 years, F/M: 10/2, disease duration: 5.4 years). Patients were clinically inactive (according to the definition of activity by *Kerr et al*), while categorized as having "persistent" disease activity by physician's global assessment due only to APR. All patients were under immunosupressive treatments including corticosteroids. The severity of large-vessel 18F-FDG uptake was graded using a four-point scale from grade 0 (no uptake present) to grade III (high-grade: uptake higher than liver). Any uptake in major vessels with a grade ≥2 was accepted to be "active."

Results: Mean ESR was 55.5 (30–86) mm/h and mean CRP was 29.6 (7.7–90) mg/L. Active vasculitic lessions were observed by 18F-FDG-PET/CT in 8 of 12 (66%) of the study group, with a mean number of 2.6 (1–4) active vascular lesions. Arcus aorta was involved in 25%, ascending aorta in 20%, right brachiocephalic artery in 20%, descending aorta in 15%, abdominal aorta in 10% and left and right subclavian arteries in 5% each of the investigated vessels. A step-up treatment change was decided in 7 patients according to 18F-FDG-PET/CT results.

Conclusion: We observed increased 18F-FDG uptake in the majority of TAK patients with an increased APR, but clinically silent disease. 18F-FDG-PET/CT showed the presence and localisation of active vascular inflammation in the aorta and its branches. Although specificity of observed lesions are not clear, 18F-FDG-PET/CT imaging may influence physician's assessment of clinical activity and treatment choices in TAK.

High Prevalence Of Metabolic Syndrome In Takayasu Arteritis: An Increased Cardiovascular Risk and Lower Adiponectin Serum Levels. Thiago Silva[1], Mauricio Levy-Neto[2], Rosa M. R. Pereira[3] and Eloisa Bonfa[4]. [1]Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [4]Universidade de Sao Paulo, São Paulo, Brazil.

Background/Purpose: The prevalence of Metabolic Syndrome (MetS) tends to be high among rheumatic patients, and cardiovascular disease is the leading cause of death in these conditions. The aim of this study is to determine the prevalence of MetS in Takayasu Arteritis patients (TA) and its association with risk factors and adipokines levels.

Methods: A cross sectional study was conducted in 45 consecutive TA women with 47 age- and body mass index (BMI)-matched healthy controls.

Results: The prevalence of MetS (IDF/AHA criteria) was higher in TA compared to controls (33.34 vs. 8.51%, $p=0.003$). TA patients had higher frequency hypertension ($p< 0.001$), dyslipidemia ($p=0.001$), insulin ($p=0.021$), HOMA-IR ($p=0.024$), apoliprotein E ($p=0.029$), resistin ($p=0.018$) and CRP ($p<0.001$) compared to healthy subjects, with similar levels of adiponectin and PAI-1 ($p>0.05$). Further analysis of TA patients with and without MetS revealed a higher frequency of overweightness/obesity (66.66 vs. 26.66%, $p=0.022$), Framingham score ≥ 1 ($p=0.032$), and lower adiponectin levels (20.37 ± 21.16 vs. 38.64 ± 22.62ug/ml, $p=0.022$) in the former group. No differences were found regarding disease duration, activity, glucocorticoid use, resistin and PAI-1 levels in these two groups of TA patients ($p>0.05$).

Conclusion: A high prevalence of MetS was observed in TA patients and this comorbidity seems to identify a subgroup of overweight/obese patients with high cardiovascular risk without a significant association with disease status. Further longitudinal studies are necessary to observe the impact of controlling this modifiable risk factor in the quality of life and survival of TA patients.

Early Combination Immunosuppression and Serial Non-Invasive Imaging Improves Outcome In Takayasu Arteritis. Taryn Youngstein, Michael Quinn, James Peters and Justin C. Mason. Hammersmith Hospital, Imperial College London, London, United Kingdom.

Background/Purpose: Takayasu arteritis (TA) affects the aorta and its branches, pre-disposing to stenoses and aneurysmal dilatation. While morbidity remains high, evidence for efficacy of immunosuppressive therapy is relatively limited. The purpose of this study was to analyze our use of combined immunosuppression with serial non-invasive imaging, to show that early intervention and detailed monitoring improves outcome.

Methods: A longitudinal study of case notes, imaging studies and outcome data in 110 patients seen with TA from 2000–2013.

Results: All TA sub-types were found, with a mean of 3 arteries involved (range 1–9). 89% were female, with mean age at diagnosis 31.5 yrs. ^{18}FDG-CT-PET was used for detection of active disease at diagnosis and identified pre-stenotic disease. Ultrasound, magnetic resonance (MRA) and CT angiography (CTA) aided diagnosis, and also revealed pre-stenotic lesions. Combined immunosuppression was initiated at diagnosis, with 90% prescribed prednisolone, plus methotrexate (43%), azathioprine (37%), mycophenolate mofetil (9%) or cytoxan (10%). TNFa and IL-6R antagonists were used effectively in 9 patients with refractory disease. 10% had burnt out disease and were not immunosuppressed. Serial MRA was used for monitoring, revealing stable disease in 82% and sensitively detecting new stenoses/aneurysms in 9.8% of patients, many of whom had no change in ESR/CRP or clinical exam. Subsequent treatment escalation prevented progression, and MRA revealed improved arterial stenoses in 9 patients (8.2%). Echocardiography and cardiac MRI identified silent myocardial injury in 22%. MRA also aided management decisions, allowing accurate steroid titration and low maintenance doses (<10mg/d) to be safely achieved. Low dose prednisolone was continued for 38.2 ± 27.2 mths to optimize disease activity control, with no osteoporotic fractures and <2% steroid-induced diabetes detected. Cross-sectional analysis (2013) revealed a mean prednisolone dose of 3.22 ± 4.97 mgs. 50% had stopped prednisolone, 41.4% were receiving '10mg and 8.6% >10mg/d. Two deaths were recorded, both unrelated to complications of TA or its treatment.

Conclusion: Our analysis suggests that non-invasive imaging aids early diagnosis, and that prednisolone with an immunomodulator controls disease activity and can prevent and occasionally reverse stenoses. Serial MRA allows accurate monitoring of arterial anatomy and facilitates targeted titration of therapy and steroid-sparing, improving outcome and minimizing side-effects. Arterial imaging is also essential due to the relative insensitivity of ESR/CRP in assessing disease activity, and their complete suppression by novel therapies, particularly tocilizumab.

Long-Term Use Of Tocilizumab For The Treatment Of Giant Cell Arteritis. Sebastian Unizony[1], John Stone[1] and Brian Keroack[2]. [1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [2]Maine Medical Center, Tufts University Medical School, Maine, ME.

Background/Purpose: A sizeable percentage of giant cell arteritis (GCA) patients experience disease relapse upon glucocorticoid (GC) tapering, and a clearly effective GC-sparing alternative has not been identified. Interleukin (IL)-6 contributes to the pathogenesis of GCA and represents a target for therapy.

Methods: Retrospective study of 12 relapsing GCA patients treated the IL-6 receptor (IL-6R) antagonist tocilizumab (TCZ). Clinical outcomes evaluated were number of flares, ability to taper GC without disease exacerbation and safety.

Serum levels of the T-helper (T_H)1-, T_H17- and regulatory T cell-related cytokines IL-17, IFN-γ, IL-12, IL-6, IL-21, IL-22, IL-23, IL-1β, TNF-α and IL-10 were analyzed by Luminex in a group of patients who achieved remission on TCZ with or without low dose GC (n = 5), and compared with those of a group whose disease was controlled with GC monotherapy (n = 5).

Results:

Baseline characteristics: The mean follow-up of this cohort since diagnosis was 37 months (range 17–70). The mean duration of the disease at the time of TCZ initiation was 19.5 months (range 4–53). Eight subjects had failed at least one immunosuppressant (i.e., methotrexate), and four had contraindications for the use of GC.

Clinical response and GC-sparing effects: TCZ (4 mg/Kg, n = 3 and 8 mg/Kg, n = 9) was given in monthly infusions for a mean period of 16 months (range 5–26). Before and during IL-6R blockade, the patients experienced an average of 2.7 (95% CI 2–3.5) and 0.6 (95% CI 0–1.2) disease exacerbations per year, respectively (P = 0.0006). The mean daily prednisone dose of the cohort decreased from 24 mg (95% CI 15–33.5) at the time of TCZ initiation to 7 mg (95% CI 0.7–14) by the time of last evaluation (P = 0.01). On TCZ, 7 subjects maintained disease remission for a mean time of 17.5 months (range 8–26), and 5 patients flared after an average of 11 months of therapy (range 2–24). The mean prednisone dose at the time of flare in these 5 patients was 4.5 mg/day. One subject relapsed after TCZ discontinuation. Currently, 6 patients are taking ≤5 mg/day of prednisone and 3 patients are off GC. As expected, inflammatory markers normalized and IL-6 levels significantly increased in all patients receiving TCZ.

Safety: Adverse events attributable in part to TCZ included leucopenia (n = 5), transaminitis (n = 8), and pneumonia (n = 1). Autopsy on one patient who died from an unrelated cause revealed persistent vasculitis.

Cytokine analysis: There was a non-statistically significant difference in the serum cytokine concentrations measured by multiplex bead-based Luminex assays. Patients whose disease was maintained in remission on TCZ with or without low dose GC (mean prednisone dose 5 mg/day) tended to have lower levels of IL-12, IFN-γ, and IL-17, and higher levels of IL-10 than subjects in remission with GC monotherapy (mean prednisone dose 16 mg/day). IL-1β and IL-6 increased during IL-6R blockade. IL-21, IL-22, and IL-23 were not detected in the majority of cases, and the concentration of TNF-α was similar in both groups.

Conclusion: TCZ led to a significant reduction in the flare rate and GC requirement of a group of patients with highly relapsing GCA. A randomized-controlled trial of TCZ for the treatment of GCA is currently ongoing.

Tocilizumab In Refractory Takayasu Arteritis: a Case Series and Updated Literature Review[2]. Noemie Abisror[1], Arsene Mekinian[1], Christian Lavigne[2], Marie Anne Vandenhende[3], Michael Soussan[4] and Olivier Fain[1]. [1]Internal Medicine, Jean Verdier Hospital, Bondy, France, [2]Internal Medicine, Angers, France, [3]Internal Medicine, Bordeaux, France, [4]Nuclear Medicine, Avicennes Hospital, Bobigny, France.

Tocilizumab in refractory Takayasu arteritis: a case series and updated literature review.

Background/Purpose: The aim of this study is to analyze the efficacy and tolerance of tocilizumab in patients with Takayasu arteritis (TA).

Methods: We retrospectively studied patients with TA (ACR and/or *Ishikawa's* criteria): 5 French multicenter cases and 39 from the literature. Clinical, biological, radiological disease activity and treatment were analyzed before tocilizumab, during the follow-up and at the last available visit.

Results: Forty four patients (median age 26 years [3–65]) were included in the present study: 5 patients from the 3 French university hospitals and 39 cases from the literature review. Median follow-up after initiation of tocilizumab was 15 months [8–33]. Clinical and biological activities significantly decreased within 3 months, similarly to steroid amount (from 15 mg/day [5–75] at baseline to 10 mg/day [2–30] at 6 months; $p<0.05$) and steroid-dependence rate. Even radiological activity did not significantly decreased at 6 months, significant decrease of arterial FDG uptake was noted at 6 months. Median duration of tocilizumab treatment was 9 months [3–180]. At the last visit, tocilizumab was continued in 17/32 patients (53%), and was discontinued in the 15 remaining cases because of the remission (n=5), relapse (n=3), persistent radiological activity (n=3), cutaneous rash (n=2), severe infections (n=1) and the absence of tocilizumab financial support (n=1). No death related to tocilizumab treatment was noted.

Table 1. Characteristics of patients with TA from personal data (n=5) and literature review (n=39).

Number of evaluable patients	Baseline assessment (N=44)	3 months after beginning tocilizumab (N=30)	6 months after beginning of tocilizumab	Last visit N=44
Tocilizumab treatment	44	28 (93%)	12/15 (80%)	17/32 (53%)
Delay from baseline (months)	–	3 [2–3]	6 [4.5–6]	15 [8–33]
Clinical response				
Tocilizumab efficacy (by physician)	–	13/14 (93%)	14/18 (78%)	33/44 (75%)
Disease clinical activity	41/42 (98%)	1/14 (7%)*	3/18* (17%)*	7/34 (26%)*
Laboratory data				
Biological activity	28/29 (97%)	2/15* (13%)	2/19*(11%)	7/34 (26%)
ESR (mm/hour)	42 [8–88]	4 [0–63]	5 [0–41]*	4 [0–41]*
C-reactive protein (mg/l)	21 [8–126]*	0 [0–13]	0.5 [0–124]*	0 [0.5–17]*
Radiological data				
Radiological activity	15/22 (68%)	3/9* (33%)	5/15** (33%)	–
PET FDG vascular uptake	9/9	–	3/7* (43%)	–
SUV max	3.8 [1,3–5,3]	–	–	–
Tocilizumab associated steroids	27/30 (90%)	27/30 (90%)	8/13 (62%)	18/22 (82%)
Steroids (prednisone; mg/day)	15 [5–75]	10 [7–30]*	10 [2–30]*	5 [0–30]*

Values are medians with ranges or frequencies with percentages. ESR: erythrocyte sedimentation rate; Steroid-dependence: prednisone ≥20 mg/day; PET FDG: positron emissions tomography with fluorodesoxyglucose.
* $p<0.05$ versus baseline
** $p=0.05$

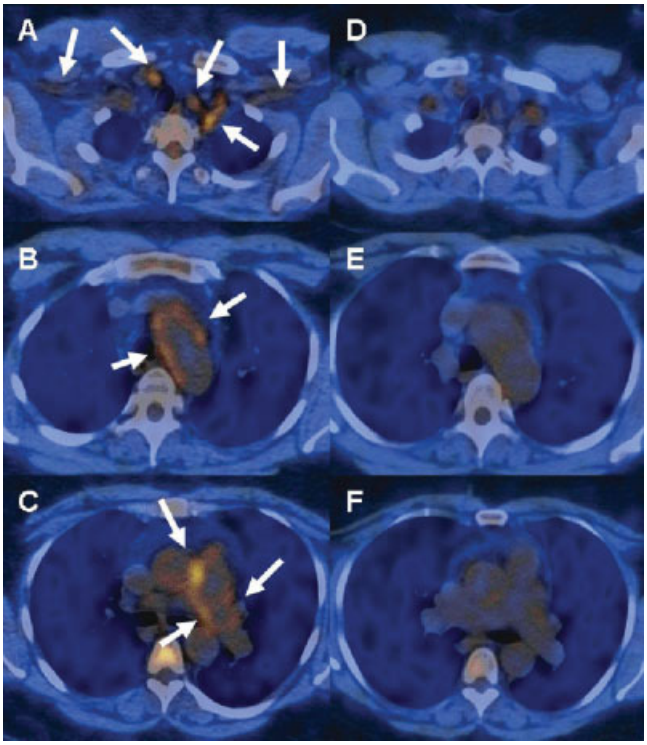

Figure 1. PET-FDG uptake before tocilizumab treatment (A, B, C) and after 6-month tocilizumab (D, E, F) in patient with Takayasu arteritis. A and D: FDG uptake in cervical and subclavians arteries; B and E: FDG uptake in aortic arch; C and F: FDG uptake in pulmonary arteries.

Conclusion: This study show the efficacy of tocilizumab in terms of clinical, biological and radiological response, as well as steroid-sparing agent. Only well-designed studies could definitely address the efficacy of tocilizumab in TA.

Villajoyosa, Villajoyosa, Spain, [12]Hospital Universitario de Bellvitge, Barcelona, Spain, [13]Consorcio Hospital General Universitario. Valencia, Valencia, Spain, [14]University Hospital Virgen Macarena. Sevilla, Sevilla, Spain, [15]Hospital Universitario Juan Canalejo. La Coruña, La Coruña, Spain.

Background/Purpose: Aortitis can occur alone or associated with other conditions. It is often refractory to standard immunosuppressive therapy. IL-6 has been implicated in the mechanisms leading to aortitis. Tocilizumab (TCZ) is a humanized monoclonal anti-IL6 receptor (IL-6R) antibody. Our aim was to assess the efficacy and side-effects of TCZ in patients with refractory inflammatory aortitis.

Methods: Multicenter study of 13 patients diagnosed of inflammatory aortitis due to different underlying conditions. The diagnosis of aortitis was based on imaging (CT angiography, MR angiography, PET and/or echocardiogram).

Results: Patients (12 women/1 man) had a mean age ±SD of 50.69±21.93 years (table). The underlying conditions were: Takayasu arteritis (TKY) (6 cases), giant cell arteritis (GCA) (5 cases), relapsing polychondritis (RP) (1 case) and idiopathic aortitis (1 case).

TCZ was the first biological drug in all patients with GCA, and in the case of idiopathic aortitis but in only 1 of 6 patients with TKY. In the remaining cases anti-TNF inhibitors had previously been prescribed. TCZ standard dose was 8 mg/k/iv/4 weeks.

After a median [interquartile 25–75 range (IQR)] follow-up of 13 [11–18] months most patients experienced clinical improvement and a reduction of ESR (from 46±37 mm/1st h to 6±4 mm/1st h in the last visit). Patients also had clinical improvement. At TCZ onset, 15% of patients had polymyalgia rheumatica and 31% fever. After 3 months on TCZ therapy, these manifestations had disappeared. Also, constitutional syndrome observed in 31% of patients at TCZ onset, improved following this therapy (16% at 3 months), and disappeared completely after 6 months of treatment. In addition, a reduction in the dose of corticosteroids was achieved (prednisone or equivalent dose: from 28±17 mg/day at TCZ onset to 4±3 mg/day in last visit).

TCZ was relatively safe; only in 1 patient TCZ had to be discontinued because of neutropenia.

Case	Age/ Sex	Underlying disease	Previous synthetic and/or biologic immunosuppressive drugs	Prednisone dose or equivalent (at TCZ onset) mg/ d	Prednisone dose or equivalent (at last visit) mg/d	CRP/ESR* (at TCZ onset)	CRP/ESR* (at last visit)	Follow-up with TCZ (months)	Serious side effects

Does The Treatment With Anti-Coagulants and Anti-Platelets Protect Giant Cell Arteritis Patients From Visual Manifestations? Andreas P. Diamantopoulos, Helene Hetland, Glenn Haugeberg, Dag Magnar Soldal and Geirmund Myklebust. Hospital of Southern Norway Trust, Kristiansand, Norway.

Background/Purpose: Visual manifestations such as diplopia, amaurosis fugax or blindness occur in up to half of the giant cell arteritis (GCA) patients. Some studies have shown that the use of warfarin or aspirin reduces the ischemic complications in GCA patients. Low dose aspirin is recommended by EULAR in all patients with GCA. The aim of this study was to calculate the number of GCA patients who receive low-dose aspirin after the diagnosis is made and examine whether the use of anti-coagulant or anti-platelets really protects against visual ischemic complications.

Methods: GCA patients diagnosed for the period March 2010 through May 2013 were identified retrospectively. All the patients have a positive ultrasound (halo sign) of the temporal vessels and/or large vessels (carotid, axillary) and met the American College of Rheumatology classification criteria. Initial use of aspirin or warfarin was documented. Initiation of aspirin treatment in the patients after the diagnosis was made was also registered. A chi-squared test was used for group comparison and statistical significance was defined as $p<0.05$.

Results: Fifty-one patients were diagnosed with GCA during the inclusion period. Thirteen patients suffered from visual manifestations (6 from permanent visual loss in one or both eyes). In this group, 2 patients had been on warfarin and 4 on aspirin. The corresponding numbers for the group without visual manifestations were 6 patients on warfarin and 5 on aspirin. No significant differences in visual manifestations were observed between the two groups, neither for those on warfarin ($p=0.97$) nor for those on aspirin ($p=0.15$). The number of patients who received aspirin after the diagnosis of GCA was recorded and include 11 patients (33%). Three of 7 GCA patients with visual manifestations who were not on anti-coagulation or anti-platelet treatment before diagnosis, received aspirin as a supplementary therapy.

Conclusion: In our study, which included only a small number of patients with GCA, the use of anti-coagulants or anti-platelets was not protective against visual manifestations. This is in contrast with previous published studies. Only 33% of GCA patients received anti-platelet treatment after the diagnosis of GCA was made. Further studies are warranted to clarify the role of anti-platelet treatment in GCA.

Antiplatelet Agents Decrease Ischemic Complications In Systemic Large Vessel Vasculitides: A Meta-Analysis. James Jeong[1] and Lillian J. Barra[2]. [1]Schulich School of Medicine & Dentistry, Western University, London, ON, [2]Schulich School of Medicine and Dentistry, Western University, London, ON.

Background/Purpose: Large Vessel Vasculitides (LVV) consist of Giant Cell Arteritis and Takayasu's Arteritis, which are chronic systemic autoimmune diseases characterized by inflammation of large blood vessels leading to ischemic complications. The objective of this study is to determine the effectiveness of antiplatelet agents at reducing ischemic events in patients with LVV.

Methods: We performed a random effects meta-analysis examining antiplatelet (AP) and/or anticoagulant therapy (AC) and ischemic events in large vessel vasculitis (LVV). Severe ischemic events were defined as stroke, ischemic ocular manifestations and claudication symptoms. Any ischemic event included jaw claudication in addition to the above manifestations.

Results: Seven studies met inclusion criteria. The primary study outcome was the risk of severe ischemic events in patients treated with AP/AC versus no treatment expressed as an odds ratio (OR). The risk of any ischemic event was a secondary outcome. When accounting for baseline atherosclerotic risk factors, AP/AC was protective for severe ischemic events: OR 0.20 (95% CI 0.12–0.32); as well as for any ischemic events: OR 0.33 (95% CI 0.13–0.81). Subgroup analyses established *a priori* were also performed comparing i) AP and AC therapy alone ii) ischemic events reported at baseline and follow-up. AP alone had a protective effect on ischemic events when compared to no treatment when controlling for cardiovascular risk factors (OR 0.21, 95% CI 0.09–0.50). AC did not appear to decrease ischemic events; however, there were only 2 studies that reported on AC separately from AP. On follow-up, a protective effect for AP/AC therapy was observed (OR 0.18 (95% CI 0.04–0.83)).

Conclusion: Antiplatelet therapy significantly decreases ischemic events in patients with LVV. However, in most cases, the treatment was initiated prior to the diagnosis of vasculitis. Available studies do not address whether initiating antiplatelet therapy at the time of LVV diagnosis is beneficial.

Impaired Vitamin D Receptor Signaling Upregulates Transforming Growth Factor Beta (TGFβ) Signaling In Systemic Sclerosis. Pawel Zerr[1], Stefan Vollath[1], Katrin Palumbo-Zerr[1], Michal Tomcik[2], Jingang Huang[1], Alfiya Distler[1], Christian Beyer[1], Clara Dees[3], Oliver Distler[4], Georg Schett[3] and Joerg H. W. Distler[1]. [1]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [3]University of Erlangen-Nuremberg, Erlangen, Germany, [4]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: Vitamin D receptor (VDR) is a member of the nuclear receptor superfamily. Its ligand, 1,25-$(OH)_2$D, is a metabolically active hormone derived from vitamin D_3. Activated VDR binds to specific VDR elements in the promoters of target genes to regulate their expression. The levels of vitamin D_3 have been shown to be significantly decreased in patients with systemic sclerosis (SSc). However, the functional consequences remain unknown. Our aim was to find a potential link between impaired VDR signaling and fibrosis.

Methods: VDR expression was analyzed by real-time PCR, Western Blot and IF. VDR agonist paricalcitol was used in in *vitro* and in *vivo* experiments. Collagen synthesis was quantified in fibroblasts overexpressing or lacking VDR. Interaction of VDR and Smad3 was shown by Co-IP. VDR was analyzed in two different mouse models of SSc: bleomycin-induced dermal fibrosis and mice overexpressing a constitutively active TGFβ receptor I (TBR).

Results: VDR mRNA levels were reduced by 78 % in skin of SSc patients compared to healthy individuals ($p = 0.02$). Similar decreases were observed on the protein level. VDR mRNA and protein levels were also decreased in the bleomycin-induced (33 %; $p = 0.01$) and the TBR-induced fibrosis (45 %; $p = 0.03$). Chronic stimulation with TGFβ strongly decreased VDR mRNA and protein levels in fibroblasts. VDR knockdown fibroblasts showed significantly increased levels of Col1a1 mRNA (+216 %; $p = 0.002$) and collagen protein (+165 %; $p = 0.01$) compared to TGFβ stimulated controls. In contrast, VDR overexpression inhibited the pro-fibrotic effects of TGFβ with decreased Col1a1 mRNA levels, collagen release and prevented differentiation into myofibroblasts. Co-IP showed that paricalcitol stimulated the formation of high affinity complexes of VDR and active, phosphorylated Smad3 in fibroblasts. Reporter assays confirmed that binding of VDR to phosphorylated Smad3 impaired the transcriptional activity of phosphorylated Smad3. Moreover, potent anti-fibrotic effects of paricalcitol were observed in different mouse models of SSc. Mice treated with paricalcitol were less sensitive to TBR induced dermal fibrosis with reduced dermal thickening (−46%, $p = 0.01$), myofibroblast counts (−69%, $p = 0.001$) and hydroxyproline content (−77%, $p = 0.02$). Paricalcitrol also significantly ameliorated bleomycin-induced fibrosis.

Conclusion: We demonstrate that VDR is a crucial regulator of TGFβ/Smad signaling. Pharmacological activation of VDR inhibits TGFβ signaling and reduces fibrosis. Impaired VDR signaling with reduced levels of its ligand vitamin D_3 may thus contribute to hyper-active TGFβ signaling and aberrant fibroblast activation in SSc. These findings may have direct clinical implications, considering the higher binding affinity and the less calcaemic effects with more prolonged administration of paricalcitol compared to the natural ligand and the potent anti-fibrotic

effects, the good tolerability and the availability of VDR agonists in clinical trials.

The STAT1 Signaling Pathway In Giant Cell Arteritis. Bjorn Hartmann[1], Joyce Liao[2], Michael H. Weisman[3], Kenneth J. Warrington[4], Jorg J. Goronzy[1] and Cornelia M. Weyand[1]. [1]Stanford University School of Medicine, Stanford, CA, [2]Stanford University, Palo Alto, CA, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]Mayo Clinic, Rochester, MN.

Background/Purpose: In giant cell arteritis (GCA), CD4 T cells, macrophages and multinucleated giant cells form granulomatous lesions in the walls of medium and large arteries. A plethora of innate and adaptive cytokines are produced within the vasculitic infiltrates, but it is not known whether a hierarchy of cytokines exists that initiates and sustains vessel wall damage, drives intimal hyperplasia and promotes persistent immune activation. Most cytokines function by triggering JAK/STAT signaling pathways in target cells to regulate gene programs that drive cellular activation, differentiation, and survival, all critical in the maladaptive response of the inflamed artery and the acute phase response underlying systemic inflammation.

Methods: To induce experimental GCA, NOD.Cg-*Prkdc*^{scid} *Il2rg*^{tm1Wjl}/SzJ mice (NSG) mice were engrafted with human medium-sized arteries and reconstituted with PBMC from patients with biopsy-proven GCA. Following induction of vasculitis, chimeras were treated with either dexamethasone (15 mg/kg) or tofacitinib (4 mg/kg) or both for 5 days. Explanted artery grafts or temporal artery biopsies from patients with GCA were analyzed for gene expression profiles by RT-PCR. Plasma was harvested from GCA patients and from untreated or treated reconstituted chimeras and cytokines were quantified by ELISA.

Results: To identify signaling pathways involved in vasculitis, we screened temporal artery biopsy samples and plasma from GCA patients for induction of signal transducer and activator of transcription (STAT) activity. STAT-1 transcripts were abundantly expressed in tissue lesions. The major inducer cytokine of STAT-1, IFN-γ, was 10-fold higher in GCA patients than in age-matched controls. To examine the relevance of STAT-1 signaling, we compared the effects of two classes of immunosuppressive agents (corticosteroids and the JAK/STAT-inhibitor tofacitinib, CP-690,550, a potent kinase inhibitor for JAK3 > JAK1 > JAK2) in experimentally induced vasculitis in 7 independent experiments. Dexamethasone primarily suppressed innate immunity with inhibition of dendritic cell activation (P = 0.005), IL-6 and IL-1β expression in the vascular lesions. Conversely, dexamethasone spared adaptive immunity and left IFN-γ-producing T_H1 unaffected (P = 0.98). The kinase inhibitor effectively prevented T cell accumulation in the vessel wall and suppressed IFN-γ production (P = 0.03) and signaling. JAK/STAT inhibition reduced blood levels of IFN-γ in the chimera mice by 65% (P = 0.004). The underlying mechanism involved a reprogramming of T cell trafficking, barring vasculitic T cells from arterial wall infiltration.

Conclusion: STAT-1 signaling is a key pathogenic pathway in GCA, is sustained by excessive activity of the adaptive cytokine IFN-γ and persists despite suppression of innate immunity. Retention of vasculitic T cells in the vessel wall is a major determinant of vasculitic activity and emerges as a novel therapeutic target.

Characterization Of Changes In Gene Expression and Inflammatory Proteins In Systemic Juvenile Idiopathic Arthritis Patients On Canakinumab Therapy. Nanguneri. R Nirmala[1], Nico Wulffraat[2], Hermine Brunner[3], Pierre Quartier[4], Riva Brik[5], Liza McCann[5], Huri Ozdogan[5], Lidia Rutkowska-Sak[5], Rayfel Schneider[3], Valeria Gerloni[5], Liora Harel[6], Maria Terreri[3], Kristin Houghton[3], Rik Joos[5], Daniel Kingsbury[3], Jorge M. Lopez-Benitez[3], Arndt Brachat[7], Stephan Bek[7], Martin Schumacher[7], Marie-Anne Valentin[7], Hermann Gram[7], Ken Abrams[8], Alberto Martini[5], Nicolino Ruperto[5] and Daniel J. Lovell[3]. [1]Novartis Institutes for Biomedical Research, Cambridge, MA, [2]Pediatric Rheumatology International Trials Organization (PRINTO)-Istituto Gaslini, Genova, Italy, [3]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati, OH, [4]Necker-Enfants Malades Hospital, Paris, France, [5]Paediatric Rheumatology International Trials Organization (PRINTO), Genova, Italy, [6]Schneider Children's Medical Center, Tel Aviv University, Petach Tikvah, Israel, [7]Novartis Institutes for Biomedical Research, Basel, Switzerland, [8]Novartis Pharmaceuticals Corporation, East Hanover, NJ.

Background/Purpose: Interleukin (IL)-1β plays a key role in the pathogenesis of systemic juvenile idiopathic arthritis (SJIA). Canakinumab (CAN), a selective, fully human, anti-IL-1β monoclonal antibody, has been shown to be efficacious in the treatment of SJIA. Here we present the analysis of changes in peripheral blood gene expression and inflammatory proteins in SJIA patients (pts) on CAN therapy and report the identified baseline biomarkers that predict clinical response to CAN treatment.

Methods: Levels of inflammatory biomarkers (IL-6; total IL-18) and gene expression profiles of active SJIA pts (aged 2 to <20 yrs) before and during CAN treatment enrolled in 2 phase III trials were analyzed.

Results: Gene Expression: Transcriptional changes upon CAN treatment at Day 3 were assessed. When applying cut-offs of ≥2 fold and p≤0.05, no transcript passed this filter for placebo-treated pts (n=9) or for CAN treated pts (n=11) that were ACR30 (adapted pediatric ACR) non-responders at Day 15, while 171 probesets passed the filter for pts (n=52) showing ≥ACR30 response. Pts who showed strong transcriptional changes also showed a strong ACR response (≥ACR50) at Day 15, while pts with <ACR50 at Day 15 showed a much weaker transcriptional response at Day 3. Strongly repressed genes included many known inflammation- and innate immunity-related genes (eg, TLR1, TLR4, TLR5, TLR6, TLR8), including several members of the IL-1β signaling pathway, such as IL-1β, IL1R1, IL1R2 and IL1RAP. A set of transcripts was identified for which high baseline expression levels predicted a subgroup of strong (≥ACR50) responders at Day 15. However, another subgroup of strong responders was indistinguishable from weak responders (≤ACR30) based on baseline transcript levels.

Protein markers: IL-6 protein levels were strongly reduced by Day 3 (4.7 × and 4.4 × with p=0.002 and 0.0001, n=20 and n=51 for the 2 trials), and at Day 29 (12.5 × and 8.1 × with p=0.01 and 0.00005, n=20 and n=65) while total IL-18 levels remained largely unchanged until Day 29 (n=22 and n=76) and showed a moderate reduction only at Day 57. For IL-6, stronger reduction at Day 3 and Day 29 was observed for pts who showed stronger ACR response at Day 15. Only 3 baseline samples were available from pts who developed macrophage activation syndrome during the studies.

Conclusion: CAN treatment resulted in a rapid, strong reduction of many pro-inflammatory leukocyte transcripts and serum IL-6. Compared with IL-6, IL-18 protein levels were reduced upon treatment much later and less strongly. About two thirds of pts with a strong treatment response (≥ACR50) were characterized by a set of leukocyte transcripts with high baseline levels and strong reduction upon CAN treatment. However, the remaining one third of CAN strong responders did not show these characteristic transcriptional patterns, suggesting some heterogeneity at the molecular level in SJIA pts showing strong response to CAN treatment.

Initial Triple DMARD Therapy Is More Efficient Than Methotrexate Monotherapy In Recent Onset Rheumatoid Arthritis; 1-Year Data Of a Randomized Clinical Trial (tREACH). P.H.P. de Jong[1], J.M.W. Hazes[1], K.H. Han[2], A.M. Huisman[3], D. van Zeben[3], P.A. van der Lubbe[4], A.H. Gerards[4], B. van Schaeybroeck[5], P.B. de Sonnaville[6], M.V. Krugten[7], J.J. Luime[1] and A.E.A.M. Weel[2]. [1]Erasmus University Medical Center, Rotterdam, Netherlands, [2]Maasstad Hospital, Rotterdam, Netherlands, [3]Sint Franciscus Gasthuis, Rotterdam, Netherlands, [4]Vlietland Hospital, Schiedam, Netherlands, [5]Albert Schweitzer Hospital, Dordrecht, Netherlands, [6]Admiraal de Ruyter hospital, Goes, Netherlands, [7]Admiraal de Ruyter Hospital, Vlissingen, Netherlands.

Background/Purpose: Recommended treatment for DMARD naïve patients is methotrexate (MTX) with or without glucocorticoids (GCs). Triple DMARD therapy however is not recommended, because well proven evidence of superior efficacy is suggested to be lacking. Furthermore possible drug toxicities might influence the physician's choice of induction therapy. Therefore, our aim is to compare one-year clinical efficacy of: (1) triple DMARD therapy vs. MTX mono-therapy and (2) oral GCs bridging therapy vs. 1 dose of intramuscular (im) GCs in patients with early RA.

Methods: The one-year data of single-blinded randomized clinical trial in patients with recent-onset arthritis (tREACH) were used. Patients were included who had a high probability (> 70%) of progressing to persistent arthritis, based on the prediction model of Visser. The Visser algorithm and 2010 criteria for RA have similar discriminative abilities to identify patients at risk of persistent arthritis at 1 year. Patients were randomized into 3 induction therapy strategies: (A) triple DMARD therapy (MTX 25 mg + sulfasalazine (SASP) 2 gr. + hydroxychloroquine (HCQ)) 400 mg with im GCs (Depomedrol 120mg), (B) triple DMARD therapy with an oral GCs tapering scheme (starting 15 mg) and (C) MTX with oral GCs similar to B. Treatment strategies were 'tightly controlled', with patients being examined every 3 months and treatment decisions based upon the original DAS thresholds for low disease activity. We investigated following response parameters over time: DAS, HAQ, using the area under the curve (AUC). We also looked at radiographic progression after 12 months of therapy, medication usage and adverse events.

Results: A total of 281 patients were included in the high probability stratum and randomly assigned to (A) (n=91), (B) (n=93) or (C) (n=97). Patients were mostly females (68%) with an average symptom duration of 166 days (95% CI: 156 – 177). At baseline 267 (95%) of patients fulfilled the 2010 criteria for RA, 216 (77%) patients were ACPA positive and 48 (16%) patients had erosions. Over time disease activity and functional ability were respectively −2·39 (−4·77 to −0·00, 95%CI) and −1·67 (−3·35 to 0·02, 95%CI) lower in patients with triple DMARD therapy compared with MTX mono-therapy. After 3 months, less treatment failure occurred in the triple DMARD therapy groups, resulting in the prescription of 50% fewer biologicals. This difference remained over time. No differences were seen between both GC bridging therapies. Respectively 15%, 30%, and 18% of patients in arm A, B, and C had radiographic progression after 1 year. No differences in serious adverse events were seen.

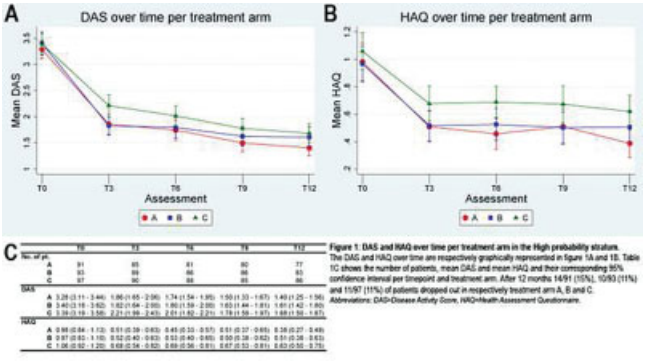

Figure 1. DAS and HAQ over time per treatment arm in the High probability stratum. The DAS and HAQ over time are respectively graphically represented in figure 1A and 1B. Table 1C shows the number of patients, mean DAS and mean HAQ and their corresponding 95% confidence interval per timepoint and treatment arm. After 12 months 14/91 (15%), 10/93 (11%) and 11/97 (11%) of patients dropped out in respectively treatment arm A, B, and C. Abbreviations: DAS=Disease Activity Score, HAQ=Health Assessment Questionnaire.

Conclusion: In patients with early RA triple DMARD therapy is superior to MTX mono-therapy even after 12 months of therapy. Furthermore both intramuscular and oral GCs can be used as bridging therapy.

A Randomised Trial Of A Brace For Patellofemoral Osteoarthritis Targeting Knee Pain and Bone Marrow Lesions. David T. Felson[1], Matthew J. Parkes[1], Andrew D. Gait[1], Elizabeth J. Marjanovic[1], Mark Lunt[2], Charles E. Hutchinson[3], Laura Forsythe[1], Timothy F. Cootes[1] and Michael Callaghan[1]. [1]University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [3]University of Warwick, Coventry, United Kingdom.

Background/Purpose: Patellofemoral (PF) braces have been shown to increase contract area in this joint, decreasing focal stress and may also correct patellar malalignment. Bone marrow lesions (BMLs) are lesions in the subchondral bone of osteoarthritis (OA) knees on MRI that are caused in part by focal stress in the joint. Because BML size correlates with knee pain severity, because they predict structural progression and because recent evidence suggests, unlike cartilage, that their volumes fluctuate substantially in as little as 6 weeks, BML's may be a good outcome to test short term structure modification in OA trials. We performed a trial testing the efficacy of the BIOSKIN patellar tracking Q brace (Ossur, inc).

Methods: Eligible subjects had to have pain daily of >=40/100 for the last 3 months during a PF activity and on examination had tenderness over patellar facet or a positive patellar compression test. X-rays had to show KL grade 2 or 3 PFOA which was worse than tibiofemoral disease. At baseline, subjects were randomly allocated to immediate or 6 weeks provision of the brace; the trial lasted 6 weeks. Subjects with other forms of arthritis were excluded as were those ineligible for MRIs or with impaired renal function. Gadolinium MRIs were acquired on a 1.5 T MRI at baseline, and at 6 weeks. Postgadolinium fat suppressed sagittal and PD weighted axial images were used for BML's which were manually segmented (blinded to sequence and to treatment) at all time points. The primary symptom outcome was the change in pain at 6 weeks (0 – 100 VAS scale) during the PF painful activity in the more symptomatic knee and the primary structural outcome was BML volume in the PF joint of that knee (patella and trochlea). We also examined tibiofemoral (TF) BML volumes as a control untreated region. Analyses used multiple linear regression with an ITT approach.

Results: We randomised 126 subjects age 40–70 years (mean age 55.5 years (SD 7.5 years); 72 females (57.1%). Mean pain score at baseline was 64.6. Ninety of the 125 with MRI scans (72%) had PF BML's at baseline. Subjects wore the brace for a mean of 7.4 hrs/day. Six subjects withdrew during the RCT (an additional 2 did not attend one session, and therefore had only one MRI). Compared with the control group, the brace group had both a significant reduction in PF-related knee pain and a decrease in the volume of BML's in the PF but not in the TF joint (see Table).

RANDOMISED TRIAL RESULTS

Variable	NO BRACE GROUP	BRACE GROUP	Between Groups Difference	
Change @ 6 weeks In:	Mean change (95% CI)	Mean change (95% CI)	Mean difference in change (95% CI)	p
PRIMARY Symptom OUTCOME: Nominated VAS (0 – 100)	−1.29 (−6.39, 3.80)	−18.16 (−23.88, −12.44)	16.87 (9.30, 24.43)	<0.001
Primary Structural Outcome: BML Volume in PF joint (in mm^3)	102.66 (−292.80, 498.12)	−554.92 (−964.02, −145.82)	−657.58 (−1226.57, −88.59)	0.02
Secondary Structural Outcome: BML Volume in TF Joint (in mm3)	1.79 (−492.67, 496.26)	198.08 (−313.44, 709.60)	196.29 (−515.15, 907.73)	0.59

Conclusion: A patellofemoral brace is efficacious for treatment of PF OA reducing both symptoms and BML volumes in the targeted compartment. BML's may be a responsive outcome measure in OA trials.

Ustekinumab Is Effective In Inhibiting Radiographic Progression In Patients With Active Psoriatic Arthritis: Integrated Data Analysis Of Two Phase 3, Randomized, Placebo-Controlled Studies. Iain B. McInnes[1], Christopher T. Ritchlin[2], Proton Rahman[3], Lluis Puig[4], Alice B. Gottlieb[5], Michael Song[6], Bruce Randazzo[6], Shu Li[6], Yuhua Wang[6], Alan M. Mendelsohn[6] and Arthur Kavanaugh[7]. [1]University of Glasgow, Glasgow, United Kingdom, [2]University of Rochester, Rochester, NY, [3]Memorial University, St. Johns, NF, [4]Universitat Autònoma de Barcelona, Barcelona, Spain, [5]Tufts Medical Center, Boston, MA, [6]Janssen Research & Development, LLC., Spring House, PA, [7]University of California San Diego, San Diego, CA.

Background/Purpose: We describe the effect of ustekinumab (UST), an IL-12/23 p40 inhibitor, on inhibition of progression of structural damage in patients with active psoriatic arthritis (PsA) at wk24 and wk52 in the PSUMMIT 1 and PSUMMIT 2 trials.

Methods: Adult PsA patients with active disease (≥5 SJC and ≥5 TJC; CRP≥0.3mg/dL [ULN 1.0 mg/dL]) despite DMARD and/or NSAID therapy (PSUMMIT 1, n=615; PSUMMIT 2, n=132) or previously treated with DMARD and/or NSAID, and prior anti-TNFα therapy (PSUMMIT 2, n=180) were randomized to UST45mg, 90mg, or PBO at wks 0, 4, and q12wks, thereafter. At wk16, patients with <5% improvement in TJC & SJC entered blinded early escape [EE] (PBO→UST45mg; UST45mg→90mg; 90mg→90mg). No concomitant DMARDs with the exception of MTX (approximately 50% of patients in each study) were permitted. Radiographs of hands and feet were taken at wks 0, 24, and 52 regardless of EE status, or at the time of study drug discontinuation (unless radiographs were completed within the prior 8wks). Erosions and joint space narrowing (JSN) were evaluated by independent readers blinded to treatment, patient IDs and image time sequence using PsA modified van der Heijde-Sharp (vdH-S) method (total score ranging from 0–528). The major secondary endpoint of change from baseline in total vdH-S scores at wk24 was analyzed based on a pre-specified integrated data analysis using data combined from both studies. Imputation of missing data was done using linear extrapolation or median change of 0.

Results: Baseline disease characteristics including total vdH-S, TJC, SJC and CRP were comparable between PSUMMIT 1 & 2. In the integrated analyses, both UST 45 mg and 90 mg treated patients demonstrated a significant difference in change from baseline in total vdH-S scores at wk24 vs PBO (Table). Moreover, continued inhibition was demonstrated through wk 52; patients randomized to PBO who initiated UST at wk16 or 24 demonstrated slowing of radiographic progression by wk52 (mean change in total vdH-S wk24 to wk52 of 0.08). These observations were reproduced when PSUMMIT 1 was evaluated alone. In PSUMMIT 2, a demonstrable effect of UST on inhibition of structural damage progression could not be discerned; these results may have been impacted by missing radiographic data, especially among PBO-treated patients (23% missing radiographs).

ACR Concurrent Abstract Session
Epidemiology and Health Services Research II: Epidemiology in Systemic Lupus Erythematosus and Rheumatoid Arthritis
Monday, October 28, 2013, 2:30 PM–4:00 PM

1696

Prevalence and Incidence of Systemic Lupus Erythematosus in a Population-Based Registry of American Indian and Alaska Native People in the United States, 2007–2009. Elizabeth D. Ferucci[1], Janet Johnston[2], Jasmine Gaddy[3], Lisa Sumner[4], James Posever[4], Tammy L. Choromanski[1], Caroline Gordon[5], S. Sam Lim[6] and Charles G. Helmick[7]. [1]Alaska Native Tribal Health Consortium, Anchorage, AK, [2]Univeristy of Alaska Anchorage, Anchorage, AK, [3]Oklahoma City Area Indian Health Service, Oklahoma City, OK, [4]Phoenix Indian Medical Center, Phoenix, AZ, [5]University of Birmingham, Birmingham, United Kingdom, [6]Emory University, Atlanta, GA, [7]Centers for Disease Control and Prevention, Atlanta, GA.

Background/Purpose: Estimates of the prevalence and incidence of systemic lupus erythematosus (SLE) have varied widely but have consistently been high in women and minority populations. The goal of this registry was to determine the prevalence and incidence of SLE in the US American Indian/Alaska Native (AI/AN) population.

Methods: This population-based registry was developed as a public health surveillance project within the Indian Health Service (IHS), in partnership with the Centers for Disease Control and Prevention (CDC). The denominator was individuals: 1) included in the IHS active clinical population in 2007, 2008, and/or 2009 (2 or more visits to an IHS clinic in the past 3 years, at least one of which must be to a core medical clinic); and 2) residing in a community in one of 3 specified regions (Alaska, Phoenix, and Oklahoma City IHS Areas). Potential SLE cases were identified based on International Classification of Diseases, Ninth Revision (ICD-9) codes for SLE or related connective tissue diseases in the IHS National Data Warehouse, a central repository for clinical and administrative data. Detailed medical record abstraction was performed for each potential case. Cases were defined as individuals with documentation of 4 or more of the ACR classification criteria for SLE. Prevalence and 95% confidence intervals (CI) were calculated for 2007 overall and by region, sex, and age. Age-adjusted rates were calculated using the standard projected 2000 US population. Person-time incidence rates were calculated over the years 2007–2009 overall and by region, sex, and age.

Results: Prevalence of SLE in 2007 and incidence from 2007–2009 are presented in the Table, including unadjusted and age-adjusted rates with 95% confidence intervals (CI). Age-specific prevalence rates by sex are shown in the Figure. The prevalence was highest in women, the age group 60–69, and the Phoenix Area of IHS. The groups with the highest incidence were women, those in the age group of 40–49, and the Phoenix Area of the IHS.

Table. Prevalence (2007) and Incidence (2007–2009) of SLE in the IHS lupus registry

	Prevalence (per 100,000 people)		Incidence (per 100,000 person-years)	
	Unadjusted (95% CI)	Age-adjusted (95% CI)	Unadjusted (95% CI)	Age-adjusted (95% CI)
Overall	134.5 (119.8–151.0)	177.7 (157.1–200.2)	5.9 (4.2–8.0)	7.4 (5.1–10.4)
Sex-specific				
Female	215.4 (190.3–243.7)	270.6 (237.5–307.0)	8.4 (5.8–11.8)	10.4 (6.6–14.6)
Male	35.7 (25.5–49.8)	53.8 (36.2–77.1)	2.7 (1.3–5.2)	ND
Region-specific				
Alaska	110.2 (92.8–130.8)	148.7 (123.8–177.3)	4.8 (2.9–7.5)	6.1 (3.4–10.2)
Phoenix	177.8 (149.2–211.8)	247.5 (204.5–297.3)	8.1 (5.0–12.6)	10.7 (6.2–17.5)
Oklahoma	126.9 (88.9–179.1)	138.2 (92.6–199.5)	4.3 (1.1–11.7)	ND

* ND: not determined due to small number of cases.

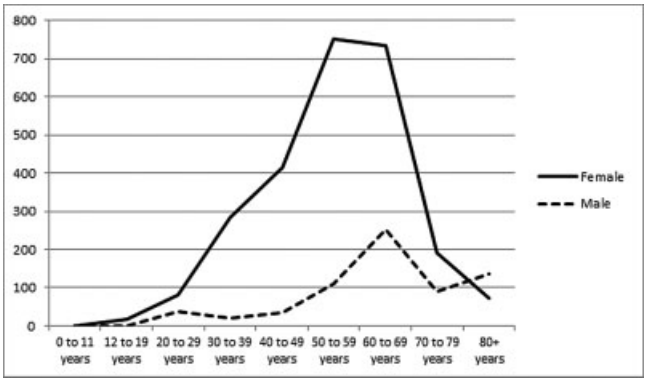

Figure. Age-specific prevalence of SLE (2007) in the IHS lupus registry

Conclusion: The first population-based lupus registry in the US AI/AN population has demonstrated high prevalence and incidence of SLE in the IHS active clinical population, especially in women. Our estimates are consistent with higher rates in minority populations, and are on the higher bound of previous estimates in the AI/AN population.

Are Patients With Rheumatoid Arthritis Still At An Increased Risk Of Tuberculosis and What Is The Role Of Biological Treatment? Elizabeth V. Arkema[1], Jerker Jonsson[2], Eva Baecklund[3], Maud Rutting[4], Judith Bruchfeld[1], Nils Feltelius[4] and Johan Askling[5]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Swedish Institute for Communicable Disease Control, Solna, Sweden, [3]Uppsala University Hospital, Uppsala, Sweden, [4]Swedish Medical Products Agency, Uppsala, Sweden, [5]Karolinska University Hospital, Stockholm, Sweden.

Background/Purpose: Anti-TNF therapy is a risk factor for clinical tuberculosis (TB), which has led to pre-treatment screening and increased vigilance. The extent to which these measures have reduced or removed the TB risk - with or without biological treatment - and how such risks differ between individual biologics remains less clear. We therefore sought to estimate the risk of TB in patients with rheumatoid arthritis (RA) 2002–2011 with and without exposure to biological therapy and to directly compare the risks between biological therapies.

Methods: Data from the Swedish National Population Registers, TB Register and the Swedish Biologics Register were used to conduct a prospective population-based national cohort study (2002–2011). We estimated the rate of TB in the general population (N=173,333), in a cohort of patients diagnosed with RA unexposed to biological therapy (N=37,770) and in a cohort of patients with RA exposed to biologicals (abatacept, adalimumab, certolizumab, etanercept, golimumab, infliximab, rituximab, tocilizumab, N=10,803). Cox models adjusting for age, sex, country of birth, education, history of diabetes, chronic obstructive pulmonary disease and cancer were used to estimate hazard ratios and 95% confidence intervals (HR; 95%CI). We estimated the risk of TB in the biological-exposed RA population compared to the unexposed, with particular attention to risks by calendar and follow-up time, and risks associated with individual biologics.

Results: Compared to the general population, RA patients *not* exposed to biologicals had a 4-fold increased risk of TB (HR 4.4 (95%CI 2.7, 7.1) 30 RA, 37 general population TB cases). We identified 19 TB cases with RA who were exposed to a biological before TB diagnosis (etanercept, infliximab, adalimumab or rituximab). The rate of TB in the biological-exposed RA population has decreased since 2002. Individuals with RA who were exposed to any biological had a multivariable-adjusted HR of 4.7 (95%CI 2.5, 9.0) compared to biological-naïve patients. The HR comparing etanercept-exposed patients to biological-naïve was 1.8 (95%CI 0.5, 6.4). The HRs for adalimumab and infliximab compared to etanercept were 3.8 (95%CI 1.0, 14.8) and 2.6 (95%CI 0.6, 11.0) respectively. One case was exposed to rituximab (HR 0.9 95%CI 0.1, 10.6).

Table. Incidence rates and hazard ratios of tuberculosis comparing biological-naïve to biological-exposed patients with RA, overall and stratified by calendar year of follow-up and total follow-up time.

Overall	Biological-Naive RA	Biological-Exposed RA	Hazard Ratio* (95% CI)
TB Cases/Person-years (py)	30/219,571	19/48,337	
Overall IR, per 100,000 py (95% CI)	13.7 (9.6, 19.6)	39.3 (25.1, 61.6)	4.7 (2.5, 9.0)
IR (95% CI) by Calendar Year			
2002–2006	16.8 (10.3, 27.5)	60.5 (32.6, 112.5)	9.5 (3.9, 22.9)
2007–2011	12.6 (7.5, 21.4)	21.0 (10.9, 40.3)	2.5 (1.0, 6.2)
IR (95% CI) by Follow-up Time			
<5 y	14.4 (9.3, 22.3)	48.3 (30.0, 77.7)	7.0 (3.4, 14.5)
≥5 y	15.0 (8.1, 27.9)	8.2 (2.0, 32.8)	1.4 (0.3, 7.1)
Drug-Specific Analysis			
Etanercept † IR (95% CI)		15.8 (5.1, 48.9)	1.0 (ref)
Infliximab † IR (95% CI)		67.2 (33.6, 134.4)	2.6 (0.6, 11.0)
Adalimumab † IR (95% CI)		61.1 (29.2, 128.3)	3.8 (1.0, 14.8)
Rituximab † IR (95% CI)		29.0 (4.1, 206.0)	0.9 (0.1, 10.6)

*Comparing biological-exposed to biological-naïve, Adjusted for age, sex, country of birth, education, cancer, diabetes, copd. In drug-specific analysis, comparing each drug to etanercept exposure.
†Exposure from date of initiation until start of next biologic.
RA Rheumatoid Arthritis; TB Tuberculosis; IR Incidence Rate; CI Confidence Interval; PY Person Years; HR Hazard Ratio.

Conclusion: The risk of TB in patients with RA is increased compared to the general population. In the past decade, the risk of TB has decreased possibly due to the introduction of pre-treatment screening but remains higher than in RA patients unexposed to biologicals. Between drug comparisons showed that the lowest risk is among those exposed etanercept, but etanercept still carries an increased risk compared to biological-unexposed. The majority of cases observed over the 10 years of follow-up occurred in biological-naïve RA patients.

Sex-Related Differences and Trends In Mortality Of Juvenile-Onset Systemic Lupus Erythematosus (SLE) In The United States Over The Last Forty Years, 1971–2010. Eric Y. Yen[1], Jennifer M.P. Woo[2] and Deborah K. McCurdy[1]. [1]Mattel Children's Hospital, University of California at Los Angeles, Los Angeles, CA, [2]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA.

Background/Purpose: To date, SLE-specific mortality studies in children and adolescents are few. Estimations of mortality in adult cohorts of SLE patients have shown that male patients often demonstrate increased mortality, suggesting worse disease severity and prognosis in males. However, these studies are limited because they estimate mortality over a finite period rather than over the lifetime of a cohort of subjects. In this study, we analyzed SLE-specific mortality data for all children and adolescents in the United States over the past 40 years and estimated the sex difference in mortality rates over their lifetime.

Methods: We studied mortality data from the National Center for Health Statistics (NCHS) from the period of 1971–2010, divided into 4 cohorts based on 10 year periods. NCHS states that over 99% of all deaths in the United States are registered. We examined death certificates for all

children and adolescents ages 0–19 years old with systemic lupus erythematosus (ICD10: M32.0, ICD9: 710.0, ICD8: 734.1) listed as the underlying cause of death. Age groups, crude mortality rates per 100,000 persons (=number of deaths/population*100,000), and adjusted crude mortality rates (thus removing the effect of sex difference in SLE prevalence) were calculated. We utilized previously published data of SLE prevalence in children according to sex as the standard population for our adjusted crude mortality calculation (=crude mortality rate/prevalence of SLE per 100,000 in females and males).

Results: Of the 3,130,638,696 mortality records examined, 716, 415, 343, and 310 SLE-specific mortalities for ages 0–19 were identified during the periods of 1971–80, 1981–90, 1991–00, 2001–10 respectively. Crude mortality rate per 100,000 children has decreased over the last forty years from 1971 to 2010 (Fig 1). The absolute numbers of deaths attributed to SLE decreased from 610 (female, 85%) and 106 (male, 15%) cases during 1971–80 to 253 (female, 82%) and 57 (male, 18%) cases during 2001–10. For all years, SLE-specific deaths were significantly greater among females than males. After adjusting for the increased SLE prevalence in females, the sex difference in mortality between females and males diminished (Fig 2).

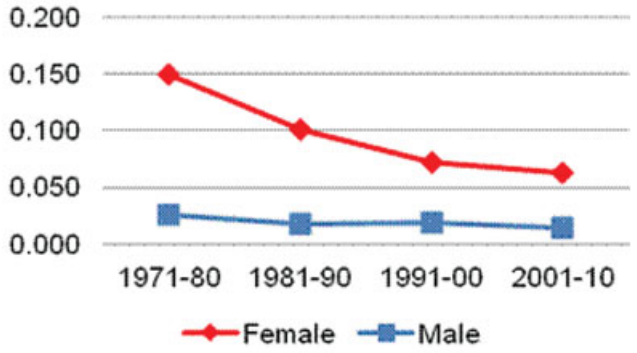

Fig. 1. SLE Crude Mortality Rate per 100,000 Children Ages 0–19 years from 1971–2010.

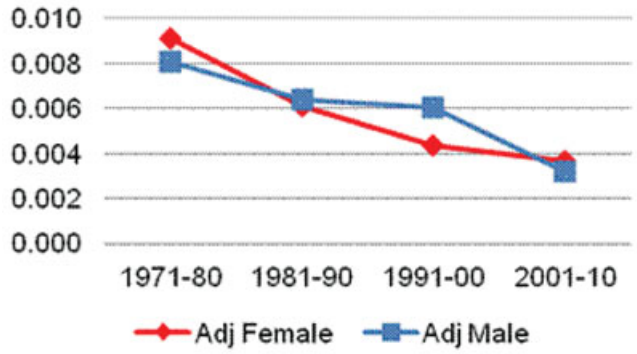

Fig. 2. Adjusted SLE Crude Mortality Rate per 100,000 Children Ages 0–19 years from 1971–2010.

Conclusion: Mortality rates from juvenile-onset SLE appear to be declining in children and adolescents over the past 40 years. Although females still account for 82% of the total deaths due to SLE in children from 2001–2010, the overall mortality rates in males are comparable to females after correcting for increased prevalence of SLE in females.

Development Of Systemic Lupus Erythamatosus Among "Possible Systemic Lupus Erythamatosus" Patients Seen In Consultation: Long-Term Follow-Up. May Al Daabil, Bonnie L. Bermas, Tabatha Norton, Hsun Tsao, Patricia Ho, Joseph F. Merola, Peter H. Schur, Elena M. Massarotti and Karen H. Costenbader. Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Rheumatology consultation to rule out SLE is common. However, in a substantial proportion of patients, SLE can be neither confirmed nor ruled out at initial visit. We followed a cohort of patients seen in consultation and thought to have possible SLE, through their most recent visits, to examine factors associated with developing SLE.

Methods: Our Lupus Center Registry contains data on 5,032 patients who have received billing codes for SLE (ICD-9 710.0) and rheumatologist reviews for ACR Criteria for Classification. Within the registry, we identified patients: ages 18–60, seen first from January 1, 1998 to December 31, 2008; thought to have possible SLE by a board certified rheumatologist at initial visit; < 4 SLE ACR criteria at that visit; and > 2 visits > 3 months apart. Extensive review of medical records through May 15, 2013 collected: visit dates, SLE manifestations, ACR criteria, autoimmune disease serologies, prescriptions, and final diagnoses per rheumatologists. Fisher's exact and t-tests were employed to assess differences between patients with and without definitive SLE diagnoses. Multivariable logistic regression models were used to identify independent predictors of definite SLE.

Results: We identified 181 patients meeting inclusion criteria. At initial visit, mean age was 38.4 (SD 12.1) years, mean number of SLE ACR criteria was 2.6 (SD 0.9); 173 (95%) were female and 124 (68%) were white. Mean follow-up was 6.2 (SD 4.3) years. 136 (75%) of patients were prescribed hydroxychloroquine at some point. At last visit, 42 (23%) were diagnosed with SLE; 34 (19%) were thought not to have SLE, and the remaining 105 (58%) were thought still to have possible SLE. In univariable models, significantly higher proportions of patients with final definite SLE than those with possible SLE had positive ANAs, anti-dsDNA, arthritis and renal involvement, but fewer had neurologic involvement (**Table**). Definite SLE patients were also slightly younger (37 vs. 39 years) and were more likely to be non-white. A higher proportion of those with definite than with possible SLE had arthritis, anti-dsDNA and nephritis, and received hydroxychloroquine. In multivariable models, arthritis (OR 2.9, 95% CI 1.3–6.9), anti-dsDNA (OR 2.9, 95% CI 1.3–6.5) and renal involvement (OR 12.4 95% CI 1.1–135.8) were independent predictors of definite SLE. The most common diagnoses among those without ultimate SLE were fibromyalgia, Sjogren's syndrome, MCTD and cutaneous lupus. Overall, 34 (18%) were also diagnosed with autoimmune thyroid disease.

Table. Characteristics at Last Follow-up of Patients seen for Possible SLE between 1998–2008

Clinical	Definite SLE N= 42	Possible SLE N= 105	p value*	Not SLE N= 34	p value**
Mean Follow up years (±SD)	5.8 ± 3.4	5.6 ± 4.1	0.75	8.3 ± 5.0	**0.02**

MCTD	0 (0%)	0 (0%)	0.55	3 (8.8%)	0.09
RA	0 (0%)	0 (0%)	0.55	1 (2.9%)	0.45
Scleroderma/ Myositis	0 (0%)	3 (2.7%)	0.55	2 (5.4%)	0.19
Sjogren's Syndrome	3 (6.7%)	3 (2.9%)	0.35	6 (17.6%)	0.28

γ Two patients diagnosed with SLE fulfilled < 4 ACR criteria: one developed WHO class IV nephritis and the other developed transverse myelitis.
* p-value for Definite SLE vs. Possible SLE.
** p-Value for Definite SLE vs. Not SLE.
t-tests for continuous and Fisher's exact for categorical variables.

Conclusion: Among patients with possible SLE at initial consultation, almost 25% were diagnosed with definite SLE within 6 years and 75% received hydroxychloroquine regardless of ultimate diagnosis. Arthritis, anti-dsDNA and renal disease were independent predictors of SLE. A better means of accurately identifying those who will progress to definitive SLE among those presenting with possible SLE is necessary.

Which Are The Most Common Disease Modifying Antirheumatic and Biologic Treatment Pathways For Rheumatoid Arthritis Patients? Sofia Pedro[1], Frederick Wolfe[1], James O' Dell[2] and Kaleb Michaud[3]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]University of Nebraska Medical Center, Omaha, NE, [3]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: While guidelines and cost effectiveness analyses assume limited pathways for RA treatment, there is little known about what occurs in clinical practice. We sought to determine the most common RA treatment pathways over the past decade.

Methods: Enrolled patients provided historical and at least 1 year of prospective treatment use in an open US observational cohort from 1998 through 2012. Treatment groups included 5 DMARDs – methotrexate (MTX), hydroxychlorine (HCQ), leflunomide (LEF), sulfasalazine (SUL), and other DMARDs (OTD) – and 6 biologics – etanercept (ETA), infliximab (INF), adalimumab (ADA), abatacept (ABA), rituximab (RIT), and other biologics (OTB). We implemented sequential data mining, a technique only recently used in the field of medicine, to uncover the most frequent treatment sequences at 1% support (at least 1% of patients had the sequence). Frequent sequences can then be used to obtain association rules, a *happens-after* statement of the form A→B, given a "confidence" threshold for the probability of taking drug B after drug A. We constrained sequences to only describe consecutive and new therapeutic changes, which were presented as association rules expressed by support, confidence, lift (confidence of a rule divided by the support of the consequent) and coverage (total probability of transiting to all consequents and not switching). **Results** were further obtained within contrasted subsets defined by calendar year, age, and disease duration.

Results: With 11 RA drug groups, there were over 7448 drug pathways of the 10,119 eligible RA patients with an average of 5.6 (4.5) years of observation/patient. After implementing the 1% support and confidence thresholds, only 24 pathways remained. Most participants (54.3%) did not switch therapy and were primarily on MTX (37.1%), HCQ (14.3%), and combination MTX + HCQ (9%). Among switchers, the modal treatment pathway was MTX then switch to another DMARD (9.3% of total) or an anti-TNF biologic (9.1%) (See Table). Before 2006, patients tended to switch from MTX to an anti-TNF biologic whereas during and after 2006, non anti-TNF agents appear. This was similar for high duration patients (>5 years), whereas non anti-TNF biologics never made the use-threshold for low duration patients. The transition from MTX to anti-TNF was more frequent in patients with longer disease duration than for early RA patients. ETA was a common choice for patients <65 years whereas INF was more common for patients >65 years.

Table. Support of the Left hand side (LHS) of the rules (L(%)), Confidence (%) and Lift of the right hand side (RHS); probability of staying in the LHS (S(%)) and coverage (C(%))

LHS	L (%)	RHS (Support (%) (Confidence (%)) Lift) ADA	S ETA	C HCQ	INF	LEF	MTX	OTD	SUL	(%)	(%)
{ETA}	18	1.5 (8.3) 1.0			1.6 (8.9) 0.6	1.2 (6.9) 0.4	1.1 (6.3) 0.1			56	87
{HCQ}	20					1.3 (6.6) 0.4	3.4 (17.3) 0.4	1.0 (5.1) 0.4	1.1 (5.5) 0.7	54	89
{LEF}	18		2.8 (15.5) 0.9		2.3 (12.8) 0.9					45	74
{MTX+ HCQ}	9		1.2 (12.7) 0.7			1.5 (15.4) 0.9				49	77
{MTX}	46	1.5 (3.3) 0.4	3.8 (8.3) 0.5	2.8 (6.1) 0.3	4.2 (9.2) 0.6	4.7 (10.3) 0.6		1.6 (3.4) 0.3	1.3 (2.9) 0.4	53	97
{OTD}	13		1.0 (8.0) 0.4			1.5 (11.5) 0.6	1.2 (9.5) 0.2			50	79
{SUL}	8					1.0 (12.6) 0.7	1.1 (13.7) 0.3			43	69

Conclusion: By using sequential data mining in a large dataset, we have estimates of the idiosyncratic and myriad drug pathways taken by US RA patients. While our results provide evidence of the recent ACR RA treatment guidelines in practice, only 38.1% of switching patients were in the modal pathway. Future health models of patient treatment need to account for this heterogeneity.

Identification of Multiple Genetic Susceptibility Loci in Takayasu's Arteritis. Guher Saruhan-Direskeneli[1], Travis Hughes[2], Patrick S. Coit[2], Joel M. Guthridge[3], Judith A. James[3], Peter A. Merkel of behalf of the Vasculitis Clinical Research Consortium[4], Haner Direskeneli on behalf of the Turkish Takayasu Study Group[5] and Amr H. Sawalha[2]. [1]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [2]University of Michigan, Ann Arbor, MI, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]University of Pennsylvania, Philadelphia, PA, [5]Marmara University, Faculty of Medicine, Istanbul, Turkey.

Background/Purpose: Takayasu's arteritis is a rare inflammatory disease of large arteries. The etiology of Takayasu's arteritis remains poorly understood, but genetic contribution to the disease pathogenesis is supported by the confirmed genetic association with *HLAB*52*. Genomic studies in Takayasu's arteritis have not been previously performed.

Methods: We genotyped ~200,000 genetic variants in two ethnically divergent Takayasu's arteritis cohorts from Turkey (339 patients and 516 controls) and North America (112 patients and 599 controls) using a custom designed genotyping platform (Immunochip). Additional genetic variants and the classical HLA alleles were imputed and analyzed.

Results: We identified and confirmed two independent susceptibility loci within the HLA region ($r^2<0.2$): *HLA-B*/*MICA* (rs12524487, OR= 3.29, $P= 5.57\times10^{-16}$), and *HLADQB1*/ *HLA-DRB1* (rs113452171, OR= 2.34, $P= 3.74\times10^{-9}$, and rs189754752, OR=2.47, $P= 4.22\times10^{-9}$). In addition, we identified and confirmed a novel genetic association between Takayasu's arteritis and the *FCGR2A*/*FCGR3A* locus on chromosome 1 (rs10919543, OR= 1.81, $P= 5.89\times10^{-12}$). The risk allele in this locus results in increased mRNA expression of *FCGR2A*. We also established the genetic association between *IL12B* and Takayasu's arteritis (rs56167332, OR= 1.54, $P= 2.18\times10^{-8}$). An association with an additional locus on chromosome 21q22 downstream of *PSMG1* did not pass the threshold for genome-wide significance and requires replication ($P=4.39\times10^{-7}$).

Conclusion: We established multiple genetic susceptibility loci for Takayasu's arteritis with a genome-wide level of significance including two independent susceptibility loci in the HLA region, and disease susceptibility loci in *FCGR2A*/*FCGR3A* and *IL12B*.

High Density Genotyping Of Immune-Related Disease Genes Identifies 7 New Susceptibility Loci For Behçet's Disease. Masaki Takeuchi[1], Nobuhisa Mizuki[2], Akira Meguro[2], Michael J. Ombrello[3], Colleen Satorius[1], Yohei Kirino[2], Tatsukata Kawagoe[2], Duran Ustek[4], Ilknur Tugal-tutkun[5], Emire Seyahi[6], Yilmaz Ozyazgan[6], Shigeaki Ohno[7], Atsuhisa Ueda[2], Yoshiaki Ishigatsubo[2], Ahmet Gül[5], Daniel L. Kastner[1] and Elaine Remmers[1]. [1]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, [2]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [3]National Institute of Arthritis Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [4]Institute of Experimental Medicine, Istanbul University, Istanbul, Turkey, [5]Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey, [6]Cerrahpasa Faculty of Medicine, Istanbul University, Istanbul, Turkey, [7]Hokkaido University Graduate School of Medicine, Hokkaido, Japan.

Background/Purpose: Genome-wide association studies have revealed susceptibility genes for many genetically complex diseases. The Immunochip is a custom array with 196,524 markers in 186 loci selected

from analysis of 12 autoimmune diseases. It enables dense genotyping of established immune disease-associated loci as well as genotyping of additional suggestive variants identified in immune diseases. Behçet's disease (BD) is a systemic vasculitis that manifests with oral ulcers, uveitis, skin inflammation, genital ulcers and inflammation in other organs. Although *HLA-B*51*, *IL10*, *IL23R*, *CCR1*, *STAT4*, *KLRC4*, and *ERAP1* have been reported to be susceptibility genes in previous studies, the pathogenesis of BD remains unclear. The purpose of this study was to perform dense genotyping of loci associated with immune diseases to identify novel susceptibility loci for BD.

Methods: In this study, 2014 Turkish BD patients and 1826 controls were densely genotyped using the Immunochip. Samples with call rate > 0.95 and markers with call rate > 0.95, minor allele frequency > 0.01, and Hardy-Weinberg equilibrium P value > 0.00001 were included. Samples from related individuals with identity by descent pi-hat > 0.18 were excluded and principal components were used to evaluate population stratification. For novel loci with association test P value $< 5\times10^{-6}$, additional SNPs in the region were imputed using 1000 Genomes data as the reference panel. Imputed SNPs with info > 0.8 were included in the comprehensive association analysis. $P < 5\times10^{-8}$ and $P < 1.67\times10^{-8}$were considered thresholds for genome-wide significance in the basic allele test analysis and the three model (additive, dominant, recessive) genotypic analysis, respectively.

Results: The basic allele association test confirmed 2 loci, *IL10* and *CCR1*, previously associated with BD and identified 4 novel loci, *IL1A-IL1B*, *SCHIP1-IL12A*, *IRF8,* and *PTPN1*, which exceeded genome-wide significance. In addition, the *FUT2* locus showed dominant model genome-wide significance in the three model genotypic analysis. Imputation data provided 2 additional novel loci with genome-wide significance, *RIPK2* and *EGR2*.

Conclusion: This immunochip dense-genotyping study identified 7 new BD susceptibility loci. These results have greatly expanded the list of genes with common variants that influence BD susceptibility. Some of these new loci implicate important pathways, such as the IL-1 pathway, which may help explain BD pathogenesis and suggest therapeutic targets.

Mapping The Shared and Distinct HLA Alleles For Seropositive and Seronegative Rheumatoid Arthritis. Buhm Han[1], Stephen Eyre[2], Dorothee Diogo[1], John Bowes[3], Yukinori Okada[1], Leonid Padyukov[4], Robert M. Plenge[1], Lars Klareskog[4], Jane Worthington[3], Peter K. Gregersen[5], Paul de Bakker[6] and Soumya Raychaudhuri[1]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [3]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [4]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [5]Feinstein Institute for Medical Research, Manhasset, NY, [6]University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Investigators have long speculated that the two subtypes of rheumatoid arthritis (RA), anti-citrullinated protein autoantibody positive (ACPA+) and negative (ACPA-), have distinct underlying genetic factors. The MHC region is the strongest genetic risk factor to ACPA+ RA, but plays a much more modest role in ACPA− RA. To understand the similarities and differences between these two disease subtypes, we fine-mapped and compared MHC associations.

Methods: Using densely genotyped SNP data consisting of 7,222 ACPA+ RA cases, 3,339 ACPA- RA cases, and 15,870 controls from six different cohorts (Eyre et al., *Nat Gen*, 2012), we imputed and tested HLA alleles in the two RA subtypes separately.

Results: We mapped associations to ACPA+ RA using forward search conditional analysis and confirmed previously published associations at amino acid sites at positions 13 ($P < 10^{-705}$), 71, and 74 in *HLA-DRB1*, position 9 in *HLA-B*, and position 9 in *HLA-DPB1*. In addition, we identified a novel association at position 77 in *HLA-A* ($P=1.7\times10^{-8}$) located in the peptide binding groove implicating antigen presentation as the major mechanism by which MHC variation confers risk. Then in parallel we mapped associations to ACPA- RA. We recognized that ACPA- RA associations to the MHC might be confounded due to the inclusion of misclassified samples that are actually ACPA+ RA (false negative testing) or ankylosing spondylitis. We developed a novel statistical approach that estimates the proportion of misclassified samples and regresses out their effects. Using this approach we observed that each cohort consistently contained 3–9% of cases that likely had ankylosing spondylitis, and a variable number of cases that likely had ACPA+ RA. Controlling for misclassification effects, we identified the amino acid residues at position 13 in *HLA-DRB1* as strongly associated with risk (Omnibus test $P=1.2\times10^{-16}$). Serine conferred the highest risk (OR= 1.28, $P=5.7\times10^{-13}$); in stark contrast serine conferred protection to ACPA+ disease (OR=0.4). We also observed a shared association to the presence of an aspartate in position 9 in *HLA-B* ($P=1.3\times10^{-15}$, OR=1.38) with a more modest effect size than for ACPA+ disease (OR=2.1).

Conclusion: Our analysis is the first to define specific amino acid sites for ACPA- RA, and demonstrates a distinct genetic basis for ACPA+ and ACPA- RA in the MHC region. Our analysis also underscores the importance of phenotypic classification for accurate fine-mapping.

Genetic Associations In Anterior Uveitis Implicate T-Cell Co-Stimulation and Other Immune Pathways. Philip Robinson[1], Dorith Claushuis[2], Paul Leo[1], Pamela Mukhopadhyay[3], P. Wordsworth[4], Michael H. Weisman[5], Walter P. Maksymowych[6], Proton Rahman[7], Robert Inman[8], Alex Hewitt[9], Tammy M. Martin[10], James T. Rosenbaum[11], Dennis Wakefield[12], John D. Reveille[13] and Matthew A. Brown[14]. [1]University of Queensland Diamantina Insititute, Brisbane, Australia, [2]The University of Queensland Diamantina Institute, Brisbane, Australia, [3]The University of Queensland Diamantina Insititute, Brisbane, Australia, [4]University of Oxford, Oxford, United Kingdom, [5]Cedars-Sinai Medical Center, Los Angeles, CA, [6]University of Alberta, Edmonton, AB, [7]Memorial University, St. Johns, NF, [8]University of Toronto and Toronto Western Hospital, Toronto, ON, [9]University of Western Australia, Perth, Australia, [10]Oregon Health & Science Univ, Portland, OR, [11]Oregon Health and Science University, Portland, OR, [12]University of New South Wales, Sydney, Australia, [13]University of Texas Health Science Center at Houston, Houston, TX, [14]University of Queensland Diamantina Institute, Brisbane, Australia.

Background/Purpose: Anterior uveitis (AU) complicates a number of autoimmune diseases including ankylosing spondylitis (AS), Behcet's disease and sarcoidosis. It is highly heritable and HLA-B27 is the major risk factor. Functional data has suggested that AU is a T-cell mediated disease. Genes including MHC class II molecules and cytokine genes have been associated with AU. A linkage study has reported suggestive linkage at chromosome 9p21-9p24, but no non-MHC gene has been definitively associated with AU. Our aim was to use an immune focused micro-array to better characterise the genetic variants associated with AU.

Methods: Cases of AS with AU (n = 1,422), cases of AS without AU (n = 2,339), AU cases alone (n = 289) and healthy controls (HC) (n = 10,000) were recruited. The Illumina Immunochip microarray was used to genotype 190,000 autoimmune related SNPs across the genome selected for their previous identification in autoimmune phenotypes or for fine mapping of association signals already identified. Analysis was completed with the linear mixed model FaST-LMM. We report here the analysis of all AU cases compared to HC. Classical MHC alleles were imputed from genotyping data using the programme HLA*IMP.

Results: Multiple regions previously reported to be associated with AS were significantly associated. In addition, in this analysis, one rare haplotype (minor allele frequency in controls = 0.0003) spanning the genes *CCL19*, *CCL21* and *CCL27* was associated with AU at genome wide significance ($P = 2.6 \times 10^{-9}$, OR = 11.4). Taqman genotyping of the lead SNP in this haplotype was completely concordant with array genotype. Five other loci implicating *RGS21* (9.5×10^{-7}, OR 1.2), *CD28-CTLA4* (9.4×10^{-7}, OR = 1.2), *POP7* (1.6×10^{-6}, OR = 1.3), *WFDY4* (7.9×10^{-6}, OR = 1.2) and *CLECL16A* (6.4×10^{-6}, OR = 1.3)

were associated at a suggestive level of significance ($P < 1 \times 10^{-5}$). *HLA-B27* was strongly associated ($P = 1 \times 10^{-320}$, OR = 5.0). Conditioning on HLA-B*27, a protective association with HLA-B*07 was observed ($P = 1.2 \times 10^{-6}$, OR = 0.71).

Conclusion: Multiple SNPs implicating T cell function and co-stimulation, as well as complement and chemokine pathways were associated with AU. These findings indicate that whilst the genetic risk factors for AS and AU are similar, additional genetic risk variants influence the risk of developing AU that are not involved in AS itself.

Fine-Mapping Major Histocompatibility Complex Variation Associated With Ankylosing Spondylitis Susceptibility. Adrian Cortes[1], International Genetics of Ankylosing Spondylitis Consortium (IGAS)[2], Paul de Bakker[3] and Matthew A. Brown[4]. [1]The University of Queensland Diamantina Insititute, Brisbane, Australia, [2]University of Queensland Diamantina Institute, brisbane, Australia, [3]University Medical Center Utrecht, Utrecht, Netherlands, [4]University of Queensland Diamantina Institute, Brisbane, Australia.

Background/Purpose: Ankylosing spondylitis (AS) is a common, highly heritable, inflammatory arthritis. Thus far, 27 susceptibility loci have been identified in and outside the MHC in populations of European and Asian ancestry. The HLA-B*27 allele is the major genetic risk factor to AS and its role in disease aetiology remains elusive to this date. Potential mechanisms include disorders of the antigenic presentation function of HLA Class I proteins, or on abnormal intracellular effects unique to the HLA-B*27 protein variant. Prior studies have suggested that other HLA-B alleles and MHC genes are involved in AS-susceptibility. In this study we aim to better define the MHC associations of AS and to identify functional and potentially causal variants to shed light on the mechanisms by which the HLA-B*27 molecule confers risk to disease.

Methods: We successfully genotyped 7,264 MHC polymorphic SNPs in 9,069 AS affected individuals and 13,578 healthy controls of European descent using the Illumina Immunochip microarray, designed for immunogenetic studies. High-density genotype data was then followed by imputation of HLA Class I and II classical alleles and residues at polymorphic amino acid positions of HLA Class I and II proteins. Association to disease susceptibility was assessed by logistic regression correcting for population structure.

Results: As expected, strong association was observed with SNPs in the HLA-B locus (P-value $< 1 \times 10^{-320}$). Analysis of HLA-B alleles revealed other non-HLA-B*27 alleles affecting susceptibility to AS of moderate effect size (HLA-B*40:01, OR=1.13; *40:02, OR=1.59; *51:01, OR=1.36; *07:02, OR=0.77; *57:01, OR=0.73; all P-value$<5\times10^{-8}$). After controlling for the associated haplotypes in HLA-B we observed independent association signals with SNPs in the HLA-A locus (rs2975033, P-value $= 4.94 \times 10^{-10}$, OR = 1.22), which tagged the classical allele HLA-A*02:01 (P-value $= 7.95 \times 10^{-10}$, OR = 1.22), and in HLA-DRB1 (rs1126513, P-value $= 5.12 \times 10^{-8}$, OR = 1.22). Analysis of polymorphic amino acid positions demonstrated that the most significant polymorphisms in the HLA-B and HLA-DPB1 loci were amino acid residues located in the binding pocket of these molecules. We have previously shown that AS is associated with *ERAP1* polymorphisms only in HLA-B*27 carriers, which we confirm here. Additionally, we show that amongst HLA-B*27 negative cases, *ERAP1* variants are AS-associated in HLA-B*40:01-positive but not –negative subjects, indicating that *ERAP1* variants also interact with HLA-B*40:01.

Conclusion: This study has identified susceptibility alleles in MHC Class I and II loci. The identification of multiple HLA-B alleles affecting AS susceptibility and the interaction between *ERAP1* variants and the HLA-B alleles *27:02, *27:05 and *40:01 suggests that these alleles all operate by similar mechanisms to induce AS, and further supports antigen presentation as the molecular mechanism by which HLA-B*27 confers risk to disease. The presence of associated polymorphism in both HLA Class I and II loci suggests that antigen presentation to both $CD4^+$ and $CD8^+$ T lymphocytes are important in AS pathogenesis and/or tissue specificity.

Background/Purpose: A major challenge in human genetics is to devise a systematic strategy to integrate disease-associated variants with diverse genomic and biological datasets to provide insight into disease pathogenesis and guide drug discovery. Here, we demonstrate one such strategy for a common autoimmune disease with no known cure, rheumatoid arthritis (RA).

Methods: We performed a trans-ethnic genome-wide association study (GWAS) and *in silico* and *de novo* replication studies in a total of >100,000 subjects of European and Asian ancestries (29,880 RA cases and 73,758 controls), by assessing ~10 million autosomal and X-chromosomal single nucleotide polymorphisms (SNPs). Using the RA risk loci obtained from the GWAS meta-analysis, we conducted an integrative analysis with a variety of biological resources: functional annotation of SNPs (missense or non-coding); cis-eQTL analysis for peripheral blood mononuclear cell (PBMC)/T cells/monocytes; H3K4me3 histone peak overlap; trans-ethnic and functional fine-mapping of candidate causal alleles; pleiotropy analysis with other human complex traits; and others. Armed with these biological insights or RA, we constructed *in silico* pipeline to prioritize biological candidate genes from the RA risk loci, and evaluated their connections to target genes for approved RA drugs.

Results: We discovered 42 novel RA risk loci at a genome-wide level of significance ($P < 5\times10^{-8}$), bringing the total to 101. The common alleles at these RA risk loci revealed: a shared genetic architecture among individuals of European and Asian ancestry; most risk alleles alter gene expression with fewer alleles altering protein structures; two-thirds of loci had pleiotropic effects on other traits, especially disorders of the immune system and inflammatory biomarkers; an overlap with genes that contribute to human primary immunodeficiency (PID) and hematological cancer somatic mutations; and specific cell types (e.g. overlap with H3K4me3 peaks in $CD4^+$ regulatory T cells) and molecular pathways (e.g., T cell, B cell, cytokine signaling) that contribute to RA pathogenesis. We also demonstrated that biological candidate RA risk genes were significantly enriched in overlap with genes that are the target of approved therapies for RA (e.g., *TNF* and *IL6R*), and further suggested that drugs approved for other indications may be repurposed for the treatment of RA (e.g., CDK4/CDK6 inhibitors used in cancers).

Conclusion: This comprehensive genetic study sheds light on fundamental pathways and genes that contribute to RA pathogenesis, and provides empirical evidence that the genetics of RA can provide important information for drug discovery efforts.

Can People With Rheumatoid Arthritis Self Monitor Their Disease Activity? Noura AL Osaimi[1], Erin Carruthers[2], Charles H Goldsmith[3], Paul M Adam[4] and Diane Lacaille[5]. [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada, Richmond, BC, [3]Simon Fraser University, Burnaby, BC, [4]Mary Pack Arthritis Centre, Vancouver, BC, [5]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC.

Background/Purpose: In rheumatoid arthritis (RA) the target for treatment is clinical remission or minimal disease activity. Active involvement of patients in monitoring their own disease activity could enhance treatment by providing an early warning when targets are not met, indicating the need for a visit to evaluate treatment. The objective of this study is to determine if patients can self-monitor their RA disease activity and accurately identify whether they have reached the target of low disease activity or remission.

Methods: RA disease activity states from patient self-reported data and rheumatologist evaluation were compared. All consecutive RA patients presenting for follow-up to seven participating rheumatologists were invited to participate. Consenting patients filled out a questionnaire and performed a self-report joint count. Rheumatologist joint count and lab values (CRP) were obtained from rheumatologists' charts.

RA disease activity indices (CDAI, SDAI and RAPID-4) were used to calculate disease activity, categorized into remission, low, moderate or high, according to published cut points. In patient versions of the CDAI and SDAI, physician global scores were replaced with the patient global score. Because change in treatment is recommended with moderate or high disease activity, we created two categories: remission or low vs. moderate or high. We also compared agreement across the four categories. Patient-derived and rheumatologist-derived activity states were compared using percent perfect agreement, as well as Cohen's kappa for two category comparisons, and weighted kappa, which weighs how close the agreement is to perfect agreement, for four category comparisons.

Results: We recruited forty-nine RA patients [mean (SD) RA duration: 9.9(12.3) years; mean (SD) age: 57.7(15.4) years; 76% female]. Results suggest moderate to good agreement between patient and rheumatologist assessment of disease activity state when comparing patient-derived with rheumatologist-derived CDAI and SDAI, and when comparing RAPID-4 self-report assessment with rheumatologist CDAI and SDAI.

Two Category Comparison – Remission or Low vs. Moderate or High

Comparison	% perfect agreement	Cohen's Kappa (95% CI)
Patient vs. rheumatologist CDAI	75.5%	0.51* (0.27;0.75)
Patient vs. rheumatologist SDAI	79.6%	0.59* (0.36;0.82)
RAPID4 vs. rheumatologist CDAI	79.6%	0.59* (0.36;0.82)
RAPID4 vs. rheumatologist SDAI	79.6%	0.59* (0.36;0.82)

Four Category Comparison – Remission vs. Low vs. Moderate vs. High

Comparison	% perfect agreement	Weighted Kappa (95% CI)
Patient vs. rheumatologist CDAI	51%	0.66** (0.51;0.81)
Patient vs. rheumatologist SDAI	61%	0.75** (0.64;0.87)
RAPID4 vs. rheumatologist CDAI	47%	0.69** (0.56;0.81)
RAPID4 vs. rheumatologist SDAI	49%	0.69** (0.56;0.82)

*values in 0.5–0.6 interval represent moderate agreement, all $p < 0.001$.
**values in 0.6–0.8 interval represent good agreement; all $p < 0.001$.

Conclusion: There is moderate to good agreement between patient self-assessment and rheumatologist assessment of disease activity, with little difference between instruments used. These results suggest that patients are able to assess their own disease activity, which may be helpful in guiding the need for physician visit and medication adjustments.

Rheumatoid Arthritis Patient Cardiovascular Disease Prevention Experiences: Qualitative Analysis and Implications. Christie M. Bartels[1], Sarah Tweddell[2], Barbara Bowers[3], Elizabeth Jacobs[2] and Tonya Roberts[3]. [1]University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]UW School of Medicine and Public Health, Madison, WI, [3]UW School of Nursing, Madison, WI.

Background/Purpose: Although rheumatoid arthritis (RA) increases cardiovascular disease (CVD) risk, RA patients receive less CVD preventive care than peers. We previously showed gaps in lipid testing and hypertension diagnosis despite more clinic visits in RA patients compared to peers. This qualitative study aimed to examine the processes by which RA patients experience CVD preventive care in order to inform patient-centered interventions to close these gaps.

Methods: Ten adult RA patients were recruited from 3 local rheumatology clinics for interviews to evaluate CVD preventive care experiences beyond clinical documentation. Interviews were recorded, transcribed, dual coded and team reviewed using NVivo software to facilitate grounded theory analysis and interpretation (Strauss 1994).

Results: Interviewed RA patients were 70% female, ages 23–81 (mean 57). Most RA patients were unaware of increased CVD risk while all patients were aware of RA medication side effects. Those who had experienced CVD risk management described two processes by which they received CVD preventative care: 1) identifying risk and 2) action (Figure 1). The number of steps and likelihood of actions were related to the physician who identified risk. Primary care physicians were not specifically described as identifying RA-CVD risk, but ***if*** they identified traditional CVD risks were most likely to actively manage them. However, many patients described rarely seeing their PCP, which is consistent with national reports. Rheumatologists more often identified RA-specific risk, but rarely provided active CVD risk treatment or monitoring. Therefore, a particularly concerning finding was that 60% of participants perceived their rheumatologist as their main provider, since the reliance on this provider may delay or decrease treatment likelihood. A few participants alternatively described steps in which they themselves identified

RA-specific risk and self-advocated care (Fig 1. O's). Overall, most patients had no preference about who managed CVD risks, expecting that blood pressure or cholesterol would be addressed. Future work should examine actual rheumatologist and PCP CVD risk identification and actions, and provider perceptions to inform future interventions. Optimizing roles may include RA patient activation (O) and rheumatologist communication/co-management (Δ) to catalyze CVD risk identification and management.

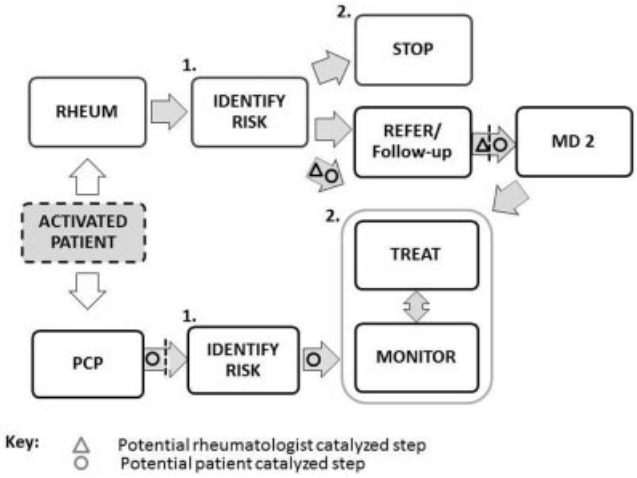

Figure 1. Process of how RA patients receive CVD preventive care.

Conclusion: Patients with RA do not report receiving consistent CVD preventive care. Most described their rheumatologist as their main doctor and noted infrequent PCP visits, though rheumatologists were less likely than PCP's to actively manage CVD risks. This suggests that RA patient activation, rheumatologist communication/co-management and advocating regular PCP care should be studied as potential interventions to close CVD-preventive care gaps in RA.

Folic Acid Prescription Among Older Adult Methotrexate Initiators Is Poor. Gabriela Schmajuk[1], Jinoos Yazdany[2], Yinghui Miao[3], David I. Daikh[2] and Michael Steinman[3]. [1]UCSF/San Francisco VA Medical Center, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA, [3]San Francisco Veterans Affairs Medical Center, San Francisco, CA.

Background/Purpose: Methotrexate (MTX) is the most commonly used disease modifying agent for rheumatoid arthritis (RA), although liver enzyme (LFT) elevations limit its use in some patients. Folic acid has been shown in a randomized controlled trial to dramatically reduce the incidence of elevated LFTs in patients taking MTX (van Ede et al, 2001). Although national guidelines recommend universal folic acid use for MTX users, the prevalence of folic acid prescription among MTX users in an older, population-based cohort of patients with rheumatic diseases is unknown.

Methods: We used national Veterans Health Administration (VHA) data to assess (1) folic acid prescription among new users of low-dose (< 40 mg/weekly), oral MTX and (2) predictors of not being prescribed folic acid. We created a national cohort of incident MTX users $\geq$ age 65 using linked medical, pharmacy, and laboratory data from the VHA during fiscal years 2007–2008. Patients were included if they had a new, $\geq$ 28-day supply of MTX dispensed and evidence of continuous use of VHA services. We excluded subjects who may have obtained care outside of the VHA by removing those with any encounter billed to Medicare. Folic acid prescription through the VHA pharmacy was assessed up to 30 days after the first MTX dispensation. We examined patients for elevated LFTs (AST or ALT $\geq 1.5 \times$ upper limit of normal) during the 6 months after the first MTX dispensation. We used multivariate regression to estimate (1) the relative risk of not being prescribed folic acid among different subgroups, and (2) the odds of LFT elevations among patients not prescribed folic acid, in both cases adjusting for demographic and clinical factors (sex, age, race, comorbid conditions, MTX dose, baseline LFT levels, # of specialty visits, and # of outpatient medications).

Results: Out of 717 new MTX users, 27% were not prescribed folic acid through the VHA pharmacy within 30 days of MTX initiation. Our cohort was mostly male (97%), white (87%), mean age 71.4 (SD 6.4), and carried a diagnosis of rheumatoid arthritis or psoriasis/psoriatic arthritis (57% and 22%, respectively). 52% of patients had a rheumatologist visit before the first MTX prescription was dispensed. Patients not followed by rheumatologists were 20% less likely (RR 0.8, 95% CI (0.7, 0.9)) to be prescribed folic acid compared with patients with a rheumatologist visit prior to their first MTX prescription, even after adjusting for the other factors listed above. Notably, patients who were not prescribed folic acid were significantly more likely to have LFT elevations after starting MTX in both univariate (9.7% vs. 5.0%, $p = 0.02$) and multivariate (OR 2.2, 95% CI (1.1, 4.2)) analysis.

Conclusion: Many new oral MTX users were not prescribed folic acid, and these patients were significantly more likely to have elevated LFTs. Rheumatologists were more likely to prescribe folic acid than other providers. Improving folic acid prescription, especially in an older adult cohort, has the potential to significantly reduce the incidence of LFT abnormalities and may allow more widespread and persistent use of MTX, an effective and inexpensive medication for RA and other rheumatic diseases.

Identification Of Factors Associated With Agreement Between Rheumatoid Arthritis Electronic Medication Lists and Prescribed Disease Modifying Treatment Plans. Ilinca D. Metes[1], Heather Eng[2], June Feng[2], G.K. Balasubramani[2], Stephen R. Wisniewski[2] and Marc C. Levesque[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA.

Background/Purpose: Federal government programs incentivize the use of Electronic Health Records (EHR) including accurate medication lists. The accuracy of a patient's EHR medication list is essential for understanding the efficacy of treatment plans and reducing adverse events. However, studies indicate that many EHR medication lists are inaccurate. Therefore, it was our aim to determine the level of agreement and to determine the factors associated with agreement between a RA patient's EHR medication list and their disease modifying treatment plan.

Methods: Subjects (n = 1,029) were drawn from the University of Pittsburgh RA Comparative Effectiveness Research (RACER) registry (2010–13). For each outpatient visit (n = 5,236) a "Gold Standard" medication list (encompassing oral disease modifying anti-rheumatic disease modifying drugs (DMARDS), biologics, and corticosteroids) was created using retrospective (n = 4,251) and prospective (n = 985) data collected through chart review of physician notes and/or patient interviews. The "Gold Standard" was compared to the EHR medication list and the measure of agreement was determined using Cohen's kappa coefficient. Patient, physician and clinic characteristics were compared between visits where medications matched vs visits where medications did not match using chi square for categorical variables and t-tests or Wilcoxon signed rank tests for continuous measures. To evaluate the characteristics associated with drug matches, a longitudinal regression model using a generalized estimating equation (GEE) method was used to account for repeated observations within a patient.

Results: Comparison of the "Gold Standard" and EHR medication lists resulted in 8,124 true positive, 95,984 true negative, 638 false positive, and 1,829 false negative medication matches. Retrospective (kappa = 0.86) and prospective (kappa = 0.85) data was combined to give an overall kappa = 0.86, with oral DMARDS having a kappa = 0.89, biologics a kappa = 0.85, and corticosteroids a kappa = 0.78. Based on the GEE, the odds ratio (OR; 95% CI) of oral DMARD, biologic and corticosteroid medication matches was decreased by having a longer prescription list (0.94; 0.93–0.96), a high % decrease in medications compared to the last visit (0.97; 0.97–0.98), having high RA disease activity by the RAPID3 (0.38; 0.29–0.51), CDAI (0.32; 0.25–0.42), or DAS28 (0.76; 0.72–0.81), and having more comorbidities as measured by the Charlson (0.90; 0.83–0.97).

Conclusion: For RA patients in a usual care setting, there was a high level of agreement between their disease modifying drug treatment plan and their EHR medication list, with the level of agreement differing

slightly between oral DMARDs, biologics and corticosteroids. A longer medication list, a high % decrease in overall medications since the last visit, being in high disease activity by the RAPID3, CDAI, or DAS28, and having more comorbidities as measured by the Charlson increased the likelihood of drug discrepancies. Using these results, our future research will focus on reducing discrepancies in the EHR medication list by implementing targeted interventions.

1713

Disparity In Biologic Therapy In Ethnic Minorities With Rheumatoid Arthritis: Can It All Be Due To Lack Of Access To Drug? Gail S. Kerr[1], Ted R. Mikuls[2], Christopher J. Swearingen[3], Chunqiao Luo[4] and Yusuf Yazici[5]. [1]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [2]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [3]Pediatric Biostatistics, University of Arkansas for Medical Sciences, Little Rock, AR, [4]University of Arkansas for Medical Sciences, Little Rock, AR, [5]NYU Hospital for Joint Diseases and New York University School of Medicine, New York, NY.

Background/Purpose: Ethnic disparities in the administration of DMARDs exist, but the impact of differing health care systems on access in ethnic minorities treated by rheumatologists, is unknown. The Veterans Affairs RA (VARA) registry and Ethnic Minority RA Consortium (EMRAC) are prospective databases but, EMRAC patients receive RA therapies primarily through private insurance/Medicare/Medicaid coverage, while VA patients have unrestricted access. We compared these cohorts to evaluate the role of medication access in RA treatment discrepancies.

Methods: Both registries collect demographic data, RA disease severity (nodules, erosions, RF, ACPA), and activity (MDHAQ, pain, patient/MD global scores, TJC, SJC, ESR, CRP, CDAI, DAS28 and RAPID3) measures. To establish comparability between registries, equivalence tests were estimated for demographic, clinical, disease activity measures. To estimate differences in prednisone, DMARD, biologic use between health care systems, Chi-square tests of independence were used. Both equivalence tests and medication use differences between ethnic groups (Caucasians vs non-Caucasians) were examined. Finally, multivariable logistic regression was used to estimate differences in biologic use between race and health care systems adjusting for age, education, disease duration, and RAPID3.

Results: 1959 VARA and EMRAC 1083 patients were analyzed. Both cohorts had equivalent age, education and RAPID3 scores, but lacked equivalency for disease duration (VARA 13.5 + 12.2, EMRAC 10.2 +10.2 years) and MD global scores (VARA 2.0 + 2.6, EMRAC 3.1 + 2.3). VARA had more males (91%, EMRAC 15%) and Caucasians (77%, EMRAC 42%). Prednisone and DMARD use were more frequent in VARA patients (38% vs 31%, $p<0.001$; 71% vs 66%, $p=0.006$, respectively). Biologic use was reported in 422 (22%) of VARA subjects (Caucasian 21%, non-Caucasian 22%), lower than in the 391 (36%) EMRAC subjects (Caucasian 45%, non-Caucasian 33%, ($P<0.001$). While there was no difference in biologic use between non-Caucasians in each cohort (non-Caucasian 28% vs Caucasian 26%, $p=0.285$), there was interaction between ethnicity and health care systems. Caucasian EMRAC subjects had a 60% increased odds of biologic use vs non-Caucasian subjects regardless of health care system (OR=1.59, P=0.007), and a 47% increased odds compared to Caucasian VARA subjects (OR=1.5, P=0.024), adjusting for age, education, disease duration and RAPID3 score. Biologic use was not different between other ethnicity and health care system comparisons. Because of the inter-dependency between gender prevalence and health care system, gender could not be modeled in the logistic regression.

Conclusion: Comparisons of two different health care administrative systems suggest non-Caucasian RA patients with unrestricted access to treatment do not achieve similar frequency of biologic use as Caucasian patients with insurance coverage, despite comparable disease activity. However, there is no difference in biologic use amongst ethnic minorities between health care systems. Reasons for these findings require further evaluation in order to accurately assess RA treatment outcomes in diverse ethnic populations.

Grey-Scale and Power Doppler Findings Of Lower Extremity Entheses In Healthy Children. Clara Lin[1] and Diana Milojevic[2]. [1]University of California-San Francisco, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA.

Background/Purpose: The aim of our study is to describe the grey-scale and Power Doppler findings in lower extremity entheses in healthy children ages 5–18 years.

Methods: Healthy patients, ages 5–18 years, were recruited for the study. Demographics, weight, and BMI were collected. Grey-scale and Power Doppler ultrasound was performed on 3 entheseal sites bilaterally, the proximal patellar ligament insertion (PPL), distal patellar ligament insertion (DPL), and Achilles tendon insertion (AT). Entheseal thickness and presence and intensity of Doppler signal (DS) were recorded. Differences in entheseal thickness and DS between contra lateral sites in the each subject were evaluated. Entheseal quality (fibrillar pattern, bony changes, and tendon/ligament contour) was also evaluated.

Results: 702 entheses were examined in 117 children ages 5–18 years with a mean age of 10.44±3.66 years. There was large variability in entheseal thickness and DS in children. Age had a weak positive correlation with thickness (R^2=0.13–0.26). Weight had the strongest correlation to thickness (R^2=0.26–0.35). Using linear regression models with generalized estimating equations techniques, multivariate analysis demonstrated that entheseal thickness at all 3 sites increases by 0.02 mm for every additional kilogram of weight (n=104, 95% CI= 0.02–0.03 mm, p= <0.0001). Using the same model, multivariate analysis demonstrated that entheseal thickness of all 3 entheseal sites is 0.25 mm larger in males than females (n=87, 95% CI= 0.02–0.47, p=0.03), and entheseal thickness in Hispanics is 0.32 mm smaller compared to non-Hispanic Whites (n=87, 95% CI=−0.60-−0.03, p=0.03). Entheseal thickness in bilateral sites correlated well with each other (Pearson's correlation coefficient=0.8–0.94), but there is some degree of variability; a difference below 27.85%, 25.88%, and 17.54% between bilateral PPL, DPL, and AT thickness, respectively, falls within the 95thpercentile of the healthy pediatric population in this study. DS was seen in 14% of all entheses in 45.3% of subjects. DS was most commonly seen in the DPL (31%). Presence and intensity of DS varied between contra lateral sites of an individual; however, DS is typically seen in the same location of each enthesis. Entheseal attachment changed with age from a completely cartilaginous to completely bony attachment. The patellar ligament contour evolved with age from a curved contour to a linear contour that is parallel to the skin surface.

Conclusion: Weight is the best predictor of entheseal thickness; however there is a large degree of variability. Contra lateral entheseal sites are comparable in thickness, and a difference below 27.85%, 25.88%, and 17.54% between bilateral PPL, DPL, and AT, respectively, falls within the 95th percentile of the healthy pediatric population in this study. DS is seen in entheses of healthy children, most commonly in the DPL, and may not be symmetric in presence or intensity in bilateral sites. Entheses in children have a homogeneous fibrillar pattern of the tendon/ligament without bony changes, and the patellar ligament contour changes with age.

Detection Of Enthesitis In Children With Enthesitis-Related Arthritis: Dolorimeter Examination Compared To Ultrasonography. Pamela F. Weiss[1], Nancy Chauvin[2], Andrew J. Klink[3], Russell A. Localio[4], Chris Feudtner[5], Diego Jaramillo[2], Robert A. Colbert[6], David D. Sherry[3] and Ron Keren[3]. [1]The Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, PHILADELPHIA, PA, [3]Children's Hospital of Philadelphia, Philadelphia, PA, [4]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [5]Division of General Pediatrics, Children's Hospital of Philadelphia; University of Pennsylvania Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA, [6]NIAMS NIH, Bethesda, MD.

Background/Purpose: To evaluate the distribution of enthesitis and accuracy of physical examination (PE) for the detection of enthesitis in children, using ultrasound with power Doppler (USD) as the gold standard.

Methods: We performed a prospective cross-sectional study of 30 enthesitis-related arthritis (ERA) subjects and 30 controls. The following tendon insertion sites were assessed by standardized PE with a dolorimeter and USD: common extensor on lateral humerus epicondyle, common flexor on mediaal humerus epicondyle, quadriceps at superior patella, patellar ligament at inferior patella, Achilles, and plantar fascia at calcaneus. Abnormal tendon appearance was defined as loss of fibrillar pattern, regions of hypoechogenicity, or fusiform thickening. The cortical bone insertion was assessed with power Doppler in long and transverse imaging planes, and graded as: 0, absent; 1, minimal (1 spot); 2, moderate (2 spots); 3, severe (>3 spots). Since minimal power Doppler findings have been previously identified in normal children, positive findings were defined as grade 2 or above.

Results: Median age of the ERA subjects was 13 years (IQR: 11,15). Sixty percent were male and 30% were HLA-B27+. Abnormal findings were detected most commonly by USD at the insertions of the quadriceps (30%; N= 18/60 sites), common extensor (12%; N=7/60), and Achilles (10%; N=6/60) tendons, which are different than the most common sites of enthesitis in adults with spondyloarthropathy. Fifty-seven percent (N=17/30) of ERA subjects had an abnormal USD at 1 or more entheses and 33% (N=10/30) at 2 or more entheses. Abnormal USD findings were detected in control subjects at 2% (N=1/60) of common extensor tendon insertions and at none of the remaining insertion sites. The intra-and inter-rater reliability of USD (kappa) were 0.78 (95% CI: 0.63, 0.93) and 0.81 (95% CI: 0.67, 0.95), respectively. Tenderness detected by standardized dolorimeter exam had poor positive predictive value (average, range across entheses) for USD-confirmed enthesitis. Tenderness occurred most commonly at the insertions of the patellar ligament (80%; N=48/60 sites), quadriceps (78%; N= 47/60 sites), and common extensor tendons (55%; N=33/60 sites). Eighty-seven (N=26/30) percent of subjects had tenderness at 3 or more entheses and 57% (N=17/30) at 6 or more entheses. Inter-rater reliability of dolorimeter exam for detection of enthesitis was low (kappa 0.49, 95% CI: 0.33, 0.65). In comparison to controls, ERA subjects reported more pain and had lower pain thresholds at every site, including control sites (all p-values <0.001).

Conclusion: Tenderness detected by standardized dolorimeter exam overestimated USD-confirmed enthesitis in children with ERA. Compared to USD, PE for the detection of enthesitis in children has poor accuracy and reliability. The significantly decreased pain threshold of ERA subjects at all sites likely contributed to the limited accuracy of PE. Future research is warranted regarding the utility of USD for identifying enthesitis at JIA diagnosis, accurately predicting disease progression, and guiding therapeutic decisions.

Childhood-Onset Systemic Lupus Erythematosus With Clinical Neurocognitive Dysfunction Have Lower Nodal Density and Connectivity On Diffusion Tensor Imaging. Jordan T. Jones[1], Mark DiFrancesco[1], Ahmad I. Zaal[2], Marisa S. Klein-Gitelman[3], Darren Gitelman[4], Jun Ying[5] and Hermine I. Brunner[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Damascus University-Children's Hospital, Damascus, Syria, [3]Children's Memorial Hospital, Chicago, IL, [4]Northwestern University, Chicago, IL, [5]University of Cincinnati, Cincinnati, OH.

Background/Purpose: Neurocognitive dysfunction (NCD) is common in childhood-onset systemic lupus erythematosus (cSLE), and often difficult to detect with current resources. Diffusion tensor imaging (DTI) is a magnetic resonance imaging technique, which allows the calculation of various measures of tissue microstructural integrity, and structural connectivity via evaluation of white matter tracts. The objectives were to use DTI to investigate specific anatomic changes in the brain in cSLE patients with and without NCD in comparison to controls, and to assess the potential of these measures for use as imaging biomarkers.

Methods: Formal neuropsychological testing using the cSLE Neurocognitive Battery (Ross et al, 2010) was done to measure cognitive ability and identify NCD in cSLE. DTI was performed in cSLE patients with NCD (cSLE-NCD; n = 6), without NCD (cSLE-noNCD; n = 9) and healthy controls (n = 14). DTI was acquired on a 3 Tesla scanner at 2mm isotropic resolution for 32 gradient directions using an echo-planar imaging protocol with TR/TE = 8800/88 ms and a b-factor of 1000 s/mm^2. DTI data were processed using FSL 4.1 (http://www.fmrib.ox.ac.uk/fs/) including eddy current correction. Diffusion tensors were calculated using the Diffusion Toolkit (http://trackvis.org/blog/tag/diffusion-toolkit/), determining the principal diffusion direction per voxel throughout the white matter. This resulted in a 3D map of fiber streamlines (FS). Structural connectivity between two brain regions was defined as the number of FS with an endpoint in each of those regions. Fiber density was defined as the number of FS passing through a region regardless of endpoints. The entire brain was divided into 116 distinct regions using a standard anatomical atlas (Tzourio-Mazoyer et al, 2002). A binary matrix summarized structural network architecture by setting a connectivity threshold at > 20 FS. Group comparisons were made for density and probability of connection to each region individually and across the entire brain.

Results: A significant decrease in density was observed for the cSLE-NCD group vs. controls (p = 0.002) or cSLE-noNCD (p= 0.001). No difference in density was found between controls and cSLE-noNCD. Connectivity over the entire brain and individual regions followed a similar pattern of significant decrease for the cSLE-NCD group.

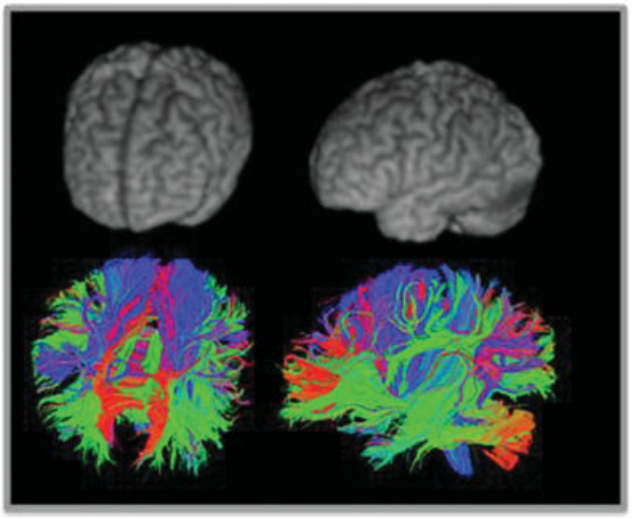

Figure 1. Tractography in single subject

Conclusion: Based on DTI, neurocognitive deficits in cSLE are associated with loss of fiber density and interregional connectivity that suggest breakdown of structural network integration. These results complement our previously reported functional and volumetric findings (DiFrancesco et al, 2013; Gitelman et al, 2013), suggesting that cSLE-NCD is associated with measurable changes in grey and white matter. If confirmed in larger cohorts, DTI abnormalities may be used as imaging biomarkers of cSLE-associated NCD.

1717

Do Bone Marrow Edema (BME) Lesions In The Sacroiliac Joint (SIJ) Change Into Fatty Lesions Over a 3-Month Period In Patients With Axial Spondyloarthritis (axSpA)? Manouk de Hooge[1], Rosaline van den Berg[1], Victoria Navarro-Compán[1], Monique Reijnierse[1], Floris van Gaalen[1], Karen Fagerli[2], Robert Landewé[3], Maikel van Oosterhout[4], Roberta Ramonda[5], Tom Huizinga[1] and Désiréé van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Academic Medical Center, Amsterdam, Netherlands, [4]GHZ Hospital, Gouda, Netherlands, [5]University of Padova, Padova, Italy.

Background/Purpose: BME lesions may change into fatty lesions in the SIJ over time. In one study significant changes of fatty lesions in the SI joints were observed over 1 year in patients with axSpA[1]. It is unknown if similar results are found with a shorter follow-up period. Therefore we investigate whether BME lesions in the SIJ seen on MRI change into fatty lesions over a 3-month period in patients with axSpA.

Methods: Patients with back pain (≥3 months, ≤2 years, onset <45 years) from the 5 participating centres of the SPondyloArthritis Caught Early (SPACE)-cohort were included. All patients fulfilling the ASAS axSpA criteria underwent MRI-SI at baseline (MRI-SI-baseline) and after 3 months (MRI-SI-3months). MRI-SI-baseline and MRI-SI-3months were scored by 2 well-calibrated readers independently, blinded for time point, for the presence

of BME and fatty lesions on STIR and MRI T1-weighted images viewed simultaneously. BME and fatty lesions were defined present if 1 lesion was seen on ≥2 consecutive slices or if >1 lesion were seen on a single slice. The scores of baseline and 3 months were compared on quadrant level (Q) and the sum of all quadrants (8 total) was calculated to obtain patient scores. Scores of the readers are reported separately.

Results: Only axSpA patients with MRI-SI-baseline and MRI-SI-3months were included for this analysis (n=83, number of Q=664). In 62/83 patients (74.7%) reader 1 indicated the presence of BME or fatty lesions at any time point, reader 2 indicated this in 60/83 patients (72.3%). Readers agreed in 73/83 patients (88%) on the presence of lesions at any time point. Reader 1 indicated no lesions at baseline or follow-up in 410/664 Qs (61.7%) and in 131/664 Qs (19.7%) the type of lesions did not change over time. In 123/664 Qs (18.5%) lesions occurred, disappeared or changed from one type to another. In total, there were 34/664 Qs (5.1%) in which fatty lesions occurred, and 29/664 Qs (4.4%) in which fatty lesions disappeared. In only 3/664 Qs (0.5%) BME lesions on MRI-SI-baseline turned into FAT lesions on MRI-SI-3months. In the same amount of Qs the opposite thing is happening; FAT lesions change into BME lesions over time. The results of both readers show similar trends (see table).

		3 months		
	No lesions	**BME**	**FAT**	**BME & FAT**
Reader 1				
Baseline				
No lesions	410	17	22	1
BME	28	58	3	8
FAT	15	3	52	11
BME & FAT	7	4	4	21
		3months		
Reader 2				
Baseline				
No lesions	395	19	11	0
BME	32	79	4	6
FAT	4	5	56	9
BME & FAT	3	2	14	25

Conclusion: We find a lot of volatility of BME and fatty lesions over 3 months time. It is common for both lesions to occur without a previous lesion or disappear completely without leaving a mark, but it is uncommon to see BME lesions turn into fatty lesions over a period of 3 months. This observation casts serious doubts on the value of fatty lesions as a surrogate for previous inflammation.

Reading Of The Sacroiliac Joints On Plain Radiographs: Agreement Between Clinical Practice and Trained Central Reading Of The DESIR-Cohort. Rosaline van den Berg[1], Grégory Lenczner[2], Antoine Feydy[3], Désirée van der Heijde[1], Monique Reijnierse[1], Alain Saraux[4] and Pascal Claudepierre[2]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Henri Mondor Teaching Hospital, AP-HP, Créteil, France, [3]Paris Descartes University, Côchin Hospital, APHP, Paris, France, [4]Université Brest Occidentale, Brest, France.

Background/Purpose: In daily practice, radiologists/rheumatologist judge sacroiliac (SI) joints on X-rays (X-SI). However, reliable identification of radiographic sacroiliitis is difficult. Consequently, large inter- and intra-observer variations have been reported, even after specific training[1]. In cohorts and clinical trials the reading is usually done by ≥1 trained readers. However, in the DEvenir des Spondylarthropathies Indifferenciées Récentes (DESIR)-cohort, X-SIs at inclusion were first read by the local radiologist/rheumatologist, then by centralized read. We compared the local (by multiple readers in various centers) to centralized read (by a few trained readers) on sacroiliitis yes/no.

Methods: Patients (pts) aged 18–50 with inflammatory back pain (IBP; ≥3 months, ≤3 years) from 25 participating centers were included in the DESIR-cohort (n=708). Available baseline X-SIs were read by local radiologists/rheumatologists with access to clinical data, according to a method derived from the modified New York (mNY) criteria[2]. Grade 2 and 3 from the mNY were pooled together in 1 combined grade 'DESIR-2'. Local sacroiliitis was defined by at least unilateral grade ≥DESIR-2. Next, 2 well-calibrated centralized readers independently read all X-SIs according to the original mNY, blinded for clinical data. In case of disagreement, an experienced radiologist was adjudicator. An X-SI was marked positive if 2/3 readers agreed on bilateral ≥2 or unilateral ≥3. Agreement between the 2 centralized readers, and between the local and centralized read was calculated (Kappa; % agreement).

Results: Pts with complete X-SI data (n=689) were included in this analysis. Inter reader agreement between the 2 centralized readers is moderate (Kappa 0.54), while percentage agreement (84.3%) is good (table). The low Kappa can partially be explained by the high numbers of normal X-SIs. However, the adjudicator needed to read 108/689 X-SIs (15.7%) because of disagreement among the 2 centralized readers. Comparison between the centralized and the local read shows similar levels of agreement (table). Overall, more X-SIs are read positive by local readers (n=184) than by centralized readers (n=145). In 77 pts, X-SI was read positive by local readers but negative by centralized read; in 38 pts it was the other way around.

	Reader 2	
	modified New York +	**modified New York −**
Reader 1		
modified New York +	96	58
modified New York −	50	485
Kappa (95% CI)/ Agreement (%)	0.54 (0.46–0.62)	84.3
	Centralized score (2/3)	
	modified New York +	**modified New York −**
Local score		
DESIR mNY +	107	77
DESIR mNY −	38	468
Kappa (95% CI)/ Agreement (%)	0.54 (0.47–0.62)	83.3

Conclusion: Agreement between the centralized and local read, but also the inter reader agreement between the 2 centralized readers, is moderate, thereby showing that early detection of sacroiliitis on X-SIs is a challenge. In patients with recent onset IBP, trained readers do not perform better than local rheumatologists/radiologists in recognizing sacroiliitis on X-SI, suggesting that the role of X-SI as diagnostic criterion for axSpA should be re-evaluated.

High Reliability Was Found for Ultrasound Scoring of Osteophytes in Patients With Hand Osteoarthritis Using An Atlas As Reference; An Omeract Initiative. Hilde B. Hammer[1], Alexander Mathiessen[1], Annamaria Iagnocco[2], Emilio Filippucci[3], Frédérique Gandjbakhch[4], Marion C. Kortekaas[5], Ingrid Möller[6], Esperanza Naredo[7], Richard J. Wakefield[8], Philippe Aegerter[9] and Maria-Antonietta D'Agostino[10]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]University La Sapienza, Rome, Italy, [3]Università Politecnica delle Marche, Ancona, Italy, [4]APHP, Pitié Salpétrière Hospital, Universite Paris 6, Paris, France, [5]Leiden University Medical Center, Leiden, Netherlands, [6]Instituto Poal de Reumatologia, Barcelona, Spain, [7]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [8]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals, Leeds, United Kingdom, [9]Versailles-Saint Quentin en Yvelines University- APHP, Ambroise-Paré Hospital, Boulogne-Billancourt, France, [10]Ambroise Paré Hospital, and Versailles Saint Quentin en Yvelines University, Boulogne-Billancourt, France.

Background/Purpose: Ultrasound (US) is a sensitive method for detecting osteophytes (OP) in hand osteoarthritis (HOA). To improve the reliability of scoring OP, an US atlas has recently been published including representative OP images of finger joints scored semi-quantitatively 0 to 3 [1].

As an OMERACT exercise we wanted to explore the reliability of OP scoring of finger joints in dynamic examinations of HOA patients with use of an US atlas as reference.

Methods: One sonographer with limited experience (AM) and one experienced sonographer (HBH) had developed an US atlas of OP in HOA

[1]. Together with 8 experienced sonographers a dynamic reliability exercise was performed on scoring of OP in finger joints in patients with HOA. To gain consensus on the scoring method, a reliability test on static images was performed previous to the study, including images of each of the 15 joints to be examined (CMC1, MCP 1–5, PIP 1–5 and DIP 2–5). The images were scored individually by all the sonographers twice (several weeks apart and in a new order the second time) using the US atlas as reference, and the results collected by e-mail showed high reliability (kappa values >0.9). During the dynamic reliability exercise in patients, 5 high-end US machines (GE logic E9) were used and a paper version of the US atlas was available for the sonographers. In 10 HOA patients (5 patients examined each day for two days, all women, median (range) age 74.5 (53–77) years, all fulfilling the ACR criteria) 30 joints were examined twice with at least 3hrs interval. The intra-and inter-examiner reliability was explored by use of kappa statistics (Cohen and Light's). The prevalence of observed lesions and the percentage of exact agreement (PEA) on a 4 levels (0–3) scale and the percentage of close agreement (PCA, ' 1 score difference) were also calculated.

Results: Good to excellent intra-examiner reliability was found for all sonographers with median (range) weighed kappa values 0.80 (0.68–0.89). The prevalence of OP scores was quite evenly distributed (mean values score 0 =20%, score 1= 26%, score 2= 21% and score 3=33%). The inter-examiner reliability was also good, with mean weighted kappa 0.66 (95%CI 0.63–0.68) the first day and 0.67 (95%CI 0.65–0.70) the second day. There was high agreement between first and second OP scoring (table; PEA=Percentage exact agreement, PCA=Percentage close agreement).

	Rater 1	Rater 2	Rater 3	Rater 4	Rater 5	Rater 6	Rater 7	Rater 8	Rater 9	Rater 10
PEA	86	85	85	78	78	77	75	75	75	66
PCA	99	100	99	99	99	98	100	98	98	97

Conclusion: The present study shows that using a reference US atlas resulted in very good intra-and inter- observer reliability for dynamic scoring of OP images in patients with finger joint OA. This suggests that US could be developed as a future tool for trials on HOA patients.

Risk Of Cardiovascular Disease and Use Of Xanthine Oxidase Inhibitors For Gout. Seoyoung C. Kim, Sebastian Schneeweiss, Niteesh Choudhry, Jun Liu, Robert J. Glynn and Daniel H. Solomon. Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Hyperuricemia and gout are associated with an increased risk of hypertension and cardiovascular disease (CVD) such as myocardial infarction (MI) and stroke. Xanthine oxidase inhibitors (XOI), allopurinol and febuxostat, are the main therapy to treat gout patients with hyperuricemia. Little is known whether treating hyperuricemia with a XOI has any effect on CVD risks. We examined the risk of CVD in gout patients initiating a XOI drug compared to untreated hyperuricemic patients.

Methods: We conducted a population-based cohort study combining two U.S. commercial insurance claims databases (2003–2012). Among adult patients with a diagnosis of gout, initiators of XOIs were identified. Serum uric acid levels at baseline were available in 15% of XOI initiators. Patients with hyperuricemia defined as the serum uric acid level ≥6.8 mg/dl were identified as a reference. For both groups, patients were required to have no use of XOIs in the 180-day baseline period. Patients with a history of malignancy were excluded. For primary 'as treated' analysis, patients were followed from the index date, the first receipt of XOI or the first high uric acid level measured after the 180-day baseline period, up to 180 days. Secondary 'as treated' analyses included the entire follow-up time from the index date. We calculated incidence rates (IR) of CVD including MI, coronary revascularization, stroke, and heart failure, based on inpatient and/or outpatient diagnosis and procedure codes. To control for baseline demographic factors, comorbidities, medications, and health care utilization, a propensity score (PS) matching with a 1:1 ratio was used. Cox proportional hazards models stratified by the PS matched pair compared the risk of CVD in XOI initiators vs. the hyperuricemic group.

Results: There were a total of 43,269 PS-matched pairs. Baseline comorbidities, medication use, and health care utilization were well-balanced between the groups. Mean age was 52.5 years and 86% male for both groups. Common comorbidities include hypertension (56%), hyperlipidemia (50%), diabetes (19%), CVD (9%), obesity (7%) and chronic kidney disease (7%). Use of systemic steroids at baseline was common (20%). The mean (SD) serum uric acid level was 8.6 (1.7) mg/dl in XOI initiators and 8.1 (3.0) mg/dl in the hyperuricemia group. The IR per 1,000 person-years was 8.03 (95% CI 6.63–9.72) for MI and 57.69 (95% CI 53.70–61.98) for composite CVD in XOI initiators, 1.13 times higher compared with the hyperuricemia group (**Table**). In secondary analyses not limited to the first 180 days of follow-up, CVD risks in XOI initiators were increased similarly to the main results (**Table**).

Table. Risk of cardiovascular diseases (CVD) associated with initiation of xanthine oxidase inhibitors: PS-matched 'as treated' analysis

	Xanthine oxidase inhibitor group (n=43,269)					Hyperuricemia group (n=43,269)

A Prediction Tool for Incident Gout Among Those With Hyperuricemia. Liseth Siemons[1] and Eswar Krishnan[2]. [1]University of Twente, Enschede, Netherlands, [2]Stanford University, Palo Alto, CA.

Background/Purpose: The most common form of inflammatory arthritis observed in men is gout, a condition characterized by hyperuricemia and deposition of uric acid crystals in joints and surrounding tissues. It leads to unpredictable, severe attacks of acute joint inflammation, extreme pain, swelling, disability, and diminished physical and mental wellbeing. Gout affects millions of people and its prevalence is increasing. Hyperuricemia is considered a necessary, but insufficient, precursor of gout. Hence, additional risk factors have been identified, but collecting information on them all is too time-consuming. Therefore, this study aimed to develop an easy-to-use prediction tool for identifying patients with asymptomatic hyperuricemia at high risk for developing gout.

Methods: The tool was developed using data of 8,951 patients with uric acid levels >6 mg/dl from the Multiple Risk Factor Intervention Trial (MRFIT). The risk model was built using backward stepwise Cox regression analysis including 7 candidate variables and was externally validated in a nationally representative cross sectional sample from the US National Health and Nutrition Examination Survey (NHANES). Risk factors with a p-value <0.05 were retained and model accuracy was evaluated with receiver operating characteristic curve analyses by examining area under the curve (AUC) values. A simplified prediction tool was made for clinical convenience and to stratify patients into risk groups to discriminate between people at low, moderate and high risk of gout. Hazard and odds ratios were calculated for each risk stratum and logistic regression analyses were performed to determine the agreement between predicted and observed probabilities of having gout.

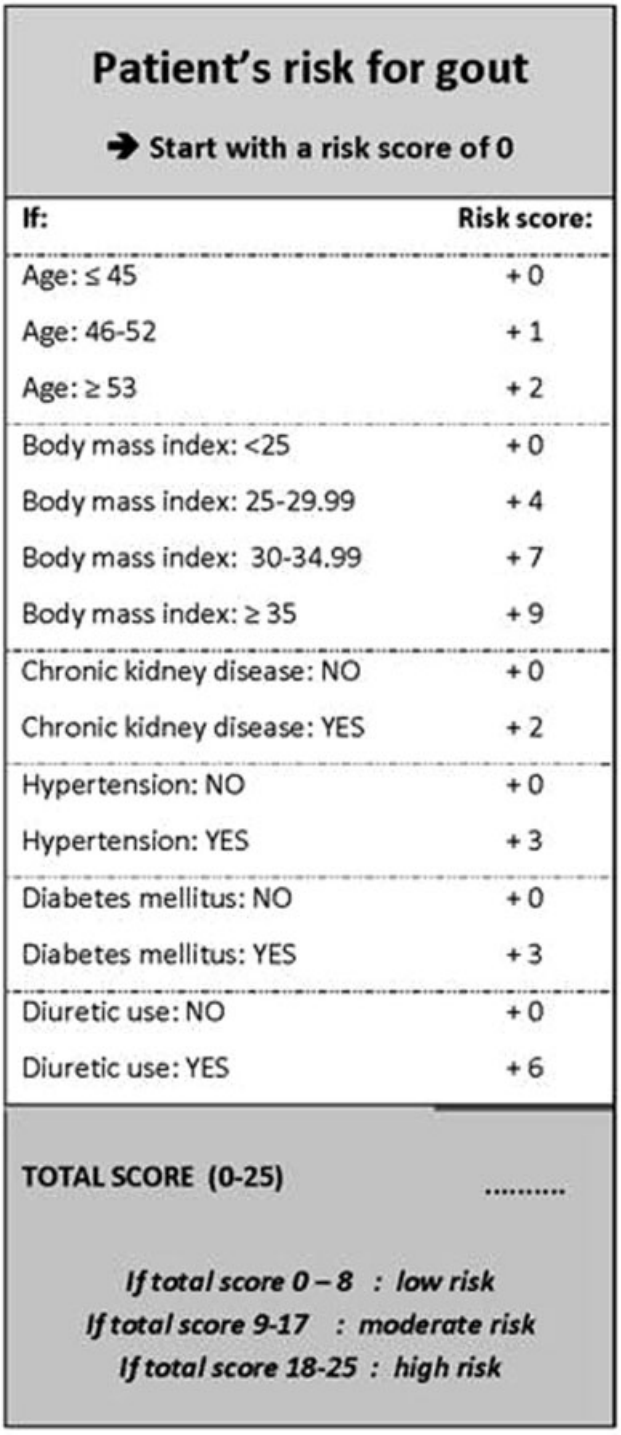

Figure 1. Scoring chart for determining a patient's risk for developing gout.

Results: 1,705 patients (19%) developed gout during the study. Gout patients reported more health complaints than non-gout patients, showing higher prevalence rates of chronic kidney disease, hypertension, and metabolic syndrome. They were also older and more likely to be obese, to smoke, and to use diuretics. Age, body mass index, chronic kidney disease, hypertension, diabetes, and diuretic use were all significant predictors for developing gout and were included in the final model (AUC value: 0.6420) which was externally validated on the NHANES data (AUC value: 0.7139). The resulting simplified prediction tool (Figure 1) discriminated well between patients from different risk strata. Hazard and odds ratios of the distinct strata showed increasing risks or odds on gout when moving from the lowest to the highest risk group and the agreement between observed and predicted probabilities of having gout was generally high.

Conclusion: The prediction tool is relevant for clinical practice since it helps physicians identifying asymptomatic hyperuricemia patients at high risk for developing gout.

Does Starting Allopurinol Prolong Acute Treated Gout? Erica Hill[1], Jay B. Higgs[1], Karen Sky[2], Michelle Sit[3] and Angelique N. Collamer[4]. [1]San Antonio Military Medical Center, Fort Sam Houston, TX, [2]US Department of Veterans Affairs, Alaska VA Healthcare System, Anchorage, AK, [3]David Grant Medical Center, Travis AFB, CA, [4]Langley AFB Hospital, Langley AFB, VA.

Background/Purpose: Gout is a common cause of morbidity in the US population. Traditionally, allopurinol is not initiated during an acute episode to avoid prolonging the painful gouty attack. The 2012 ACR guidelines for management of gout suggested that urate-lowering therapy could be started during an acute gout attack, provided that effective acute management was instituted. These recommendations were based on "consensus opinion of experts, case studies, or standard of care." We conducted a 28-day, placebo-controlled, double-blind study of allopurinol initiation in patients receiving treatment for acute gout.

Methods: Pre-study power analysis suggested 32 subjects to detect a two-day difference in days to resolution (DTR) of acute gout with a power level of 0.8. Exclusion criteria included GFR $<$ 50cc/min, AST/ALT or alkaline phosphatase $>$ 1.25 times normal. The treating physician determined therapy for the acute gout attack. Standard prophylaxis, with colchicine or NSAIDs, was prescribed. Patients were assessed at five visits over 28 days. The primary endpoint was DTR of acute gout, using separate Likert scales for patient rated involved joint pain and physician exam. Secondary measures included MHAQ, physician global assessment, side effects of therapy, per protocol (completer) analysis, serum uric acid, CBC, and CMP at two and four weeks. The intent to treat analysis included any patient who took at least one pill; we assigned 28 days DTR to allopurinol dropouts and actual DTR or last study day to placebo.

Results: Thirty-six patients were randomized to 19 placebo and 17 allopurinol. One allopurinol patient dropped out before taking one pill, and was excluded from analysis. Three placebo and two allopurinol patients dropped out before day 28. The intent to treat analysis showed a statistically insignificant 4.5 days longer DTR in the allopurinol group that was reduced to two days in the per protocol analysis. Both groups had similar patient rated Likert pain scores at enrollment and at day 28. The acute gout attack resolved in all patients by the end of the study.

	Treatment Group		
	Placebo	**Allopurinol**	**P-value[1]**
ITT[2]: Days to Resolution			0.13
N	19	16	
Mean (SD)	12.53 (7.73)	17 (8.53)	
SEM	1.77	2.13	
Median [IQR]	14 [4, 20]	17.5 [13, 23]	
Min, Max	3, 24	3, 28	
PP[3]: Days to Resolution			0.5
N	16	14	
Mean (SD)	13.44 (7.78)	15.43 (7.92)	
SEM	1.95	2.12	
Median [IQR[4]]	14 [7, 21]	15 [12, 22]	
Min, Max	3, 24	3, 28	

[1] Wilcoxon test
[2] ITT [N=35]: Intent-to-treat group. Analysis of all patients as randomized at beginning of study.
[3] PP [N=30]: Per-protocol group. Analysis of patients that followed protocol.
[4] IQR: InterQuartile Range

Conclusion: There is no difference in DTR or Likert pain scales between allopurinol and placebo groups treated for acute gout. This supports the new ACR guidelines expert consensus that allopurinol may be initiated in acute gout, providing the acute attack is appropriately managed.

Lesinurad, An Inhibitor Of The Uric Acid Transporter URAT1 and a Potential Therapy For Gout, Requires URAT1 Phenylalanine 365 For High Affinity Inhibition. Philip K. Tan[1], David Hyndman[2] and Jeffrey N. Miner[2]. [1]Ardea Biosciences, San Diego, CA, [2]Ardea Biosciences, Inc., San Diego, CA.

Background/Purpose: Gout is caused by a lack of efficient excretion of uric acid, resulting in hyperuricemia and the formation of crystal deposits of uric acid. The renal uric acid transporter URAT1 is important for regulating serum uric acid levels, and URAT1 inhibitors reduce serum uric acid levels and are used as gout therapies. Here, we define a molecular interaction of a novel URAT1 inhibitor lesinurad, under clinical evaluation in patients with gout.

Methods: HEK-293T cells transiently expressing chimeric URAT1 mutants were used to measure cell-based uric acid transport activity in the presence of lesinurad and other URAT1 inhibitors. A binding assay was also developed using membrane preparations from transfected cells and radiolabeled RDEA3170, a high-affinity URAT1 inhibitor also in development for gout. Binding was measured after incubation with lesinurad and other URAT1 inhibitors.

Results: Lesinurad inhibits the uric acid transport activity of human URAT1 (hURAT1) at a 20-fold higher potency compared to rat URAT1 (rURAT1), with IC_{50}'s of 3.36 and 74.84 μM, respectively. Chimeras containing portions of the rat and human genes identified a single residue, hURAT1 phenylalanine 365, located within transmembrane segment 7, as crucial for the higher affinity interaction with lesinurad. This residue is a tyrosine in rURAT1. In particular, the single chimeric point mutant hURAT1-Tyr365 shows a significantly reduced sensitivity for inhibition by lesinurad (IC_{50} = 47.76 μM) compared to wild type hURAT1, while the converse point mutant rURAT1-Phe365 displays a significantly enhanced sensitivity (IC_{50} = 6.82 μM) compared to wild type rURAT1. Phe365 is also important for the interaction with hURAT1 to other commercially available inhibitors benzbromarone, probenecid, and sulfinpyrazone. Lesinurad, the other URAT1 inhibitors, as well as salicylate and nicotinate which are known URAT1 inhibitors at high concentrations all bind competitively at the inhibitor binding site. Among URAT1 orthologs, Phe365 occurs only in human, apes, and certain monkeys, whereas a tyrosine residue occurs in all other animals. Consistent with in vitro inhibition of URAT1, lesinurad treatment results in an increased fractional excretion of uric acid and a decrease in serum uric acid.

Conclusion: Lesinurad inhibits hURAT1 through an interaction that involves a critical residue, Phe365. The gain-of-function phenotype of rURAT1-Phe365 suggests that Phe365 directly binds to lesinurad. Phe365 is also important for the interaction with other URAT1 inhibitors, and this residue likely forms part of an inhibitor binding site within the transporter channel of URAT1.

The Role Of Low-Grade Inflammation In The Association Between Uric Acid and Atherosclerosis: The Codam Study. José M.A. Wijnands[1], Annelies Boonen[2], Pieter C. Dagnelie[1], Marleen M.J. van Greevenbroek[1], Carla J.H. van der Kallen[1], Isabel Ferreira[1], Casper G. Schalkwijk[1], Edith J.M. Feskens[3], Sjef van der Linden[2], Coen D.A. Stehouwer[2] and Ilja C.W. Arts[1]. [1]Maastricht University, Maastricht, Netherlands, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Wageningen University, Wageningen, Netherlands.

Background/Purpose: Uric acid may be involved in the atherosclerotic process by increasing the level of low-grade inflammation. The aims of this study were: 1) to investigate if uric acid was associated with ankle-brachial index (AAIx), carotid intima media thickness (c-IMT), and prevalent cardiovascular disease (CVD); 2) the extent to which any such association(s) could be explained by low-grade inflammation; and 3) whether these associations were different in subjects with normal (NGM) compared to disturbed (DGM) glucose metabolism. A difference between these subgroups may exist because of the influence of insulin and glucose on uric acid excretion.

Methods: We studied 530 subjects (60.6% men; mean age 58.9 $\pm$ 6.9 yrs; 52.6% NGM) with an increased risk of CVD from the Cohort on Diabetes and Atherosclerosis Maastricht (CODAM) Study. Cross-sectional associations between uric acid and CVD, AAIx and c-IMT, and the mediating role of low-grade inflammation therein, were analyzed with logistic and linear regression analyses in the total population and stratified according to glucose metabolism status. Inflammation markers (hs-CRP, TNF-α, IL-6, IL-8, SAA, sICAM-1, haptoglobin, ceruloplasmin) were standardized and combined into an average inflammation score.

Results: After adjustment for potential confounders (gender, age, BMI, waist, alcohol, smoking, physical activity, hypertension, total:HDL cholesterol, triglycerides, fasting glucose and insulin, eGFR, diuretics) plasma uric acid concentration, expressed per SD (81.3 μmol/L), was positively associated with CVD in subjects with NGM (OR=1.66, 95%CI 1.06–2.58), but not with DGM (OR=0.82, 0.56–1.22; p for interaction=0.065). Uric acid was positively associated with c-IMT in the total population (β=0.027, 95%CI 0.010–0.045) and in subjects with NGM (β=0.030, 95%CI 0.007–0.054). Although the beta coefficient was similar, uric acid was not significantly associated with c-IMT in subjects with DGM (β=0.023, 95%CI −0.004–0.050; p for interaction=0.164). There was no association between uric acid and AAIx in any of the groups. Uric acid was positively associated with low-grade inflammation in the total population (β=0.073, 95%CI 0.012–0.133) and in DGM (β=0.115, 95%CI 0.026–0.203), but not in NGM (β=0.042, 95%CI −0.044–0.128, p for interaction=0.975). The significant associations between uric acid and CVD or c-IMT were not attenuated when adding low-grade inflammation to the models.

Conclusion: We found evidence of modest associations between uric acid and CVD and c-IMT, but these were not explained by low-grade inflammation. The data suggest the effect of uric acid may be different in subjects with NGM and DGM.

Survivin Inhibition Disturbs Bcl-6 and Blimp-1 Control Of Lymphocyte Maturation and Alleviates Antigen-Induced Arthritis. Mattias Svensson[1], Karin Andersson[1], Malin Erlandsson[2], Ing-Marie Jonsson[2] and Maria Bokarewa[1]. [1]University of Gothenburg, Gothenburg, Sweden, [2]Göteborgs University, Göteborg, Sweden.

Background/Purpose: Survivin is a proto-oncogene known to regulate cell division and apoptosis. In patients with rheumatoid arthritis, survivin has emerged as an independent predictor of severe disease recognised by the progressive joint damage and resistance to anti-rheumatic treatment.

Objectives: In the present study we assessed if inhibition of survivin is sufficient to reduce arthritis and joint damage in experimental autoimmune models of rheumatoid arthritis.

Methods: Survivin production was inhibited by a lentiviral construct, which coded for shRNA (shSurv) suppressing survivin gene. shSurv was provided as a single injection (106-107 particles/mouse) on the day of first immunization or on the day of clinical onset of arthritis. Five independent experiments were performed. Each experiment contained the control group received non-targeting transduction particles.

Results: Intra-articular and intra-peritoneal delivery of shSurv resulted in a pronounced inhibition of survivin in spleen and in bone marrow. Inhibition of survivin, early at immunization and later at clinical signs of arthritis, significantly alleviated clinical and histological signs of arthritis and production of antigen-specific antibodies. Also, it reduced cartilage- and bone destruction in the inflamed joints in microCT. Survivin inhibition was inversely correlated to an increase of transcription repressors Bcl-6 and Blimp-1. In consistence with overexpression of Blimp-1, shSurv mice had low levels of IL-2, suppressed proliferation response and increased populations of the effector CD4+ and CD8+ cells, followed by high IL-6 and IL10 production. shSurv mice had increased populations of Tregs (CD4+Foxp3+) and Th2 cells supported by high mRNA of Foxp3 and GATA3, and high release of IL-10 and IL-4. Inhibition of survivin was associated with a sequential impairment of Bcl-6 functions and small follicular T and B cell populations, and poor affinity maturation of antigen-specific antibodies.

Conclusion: We show that survivin is the essential regulator of molecular and cellular events in the pathogenesis of arthritis. It enhances synovial proliferation and aggressive growth and participates in the mounting of antigen-dependent T and B cell responses. Importantly, survivin regulates the Bcl-6 dependent events attracting attention to the important role of this duo in the pathogenesis of rheumatoid arthritis.

Novel Selective Inhibitors Of Nuclear Export Attenuate Inflammation and Prevent Bone Mineral Density Loss In Multiple Preclinical Models Of Rheumatoid Arthritis. Mwanasha Hamuza[1], Yosef Landesman[1], Boris Klebanov[1], Michael Kauffman[1], Sharon Shacham[1], Judith Endres[2], David A. Fox[2] and Dilara McCauley[1]. [1]Karyopharm Therapeutics Inc., Natick, MA, [2]University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: Exportin 1 (XPO1; also called chromosome region maintenance 1, CRM1) is a key protein that controls the export of ~220 cargo proteins and several mRNAs out of nucleus. Novel Selective Inhibitors of Nuclear Export (SINE) are oral XPO1 inhibitors that activate multiple tumor suppressor proteins and are currently in clinical development for a variety of cancers. SINE also force the nuclear retention of various cargos that play key roles in inflammation including the proteins IkB, COMMD1, FOXO, PPARγ, NRF2, RXRγ, as well as COX2 mRNA. Here, we report the *in vitro* effects of SINE on RA cells and their oral activity *in vivo* in the Collagen Induced Arthritis (CIA) and Collagen Antibody Induced Arthritis (CAIA) RA models.

Methods: The effects of SINE on fibroblast-like synoviocytes (FLS) were tested *in vitro* by 1. Time-lapse imaging to quantify the anti-proliferative effects of SINE on RA FLS cell lines. 2. Quantifying anti-proliferative effects of SINE on activation of T-cells by bacterial superantigen presented by FLS. 3. Measuring SINE inhibition of cytokine secretion by FLS stimulated by cytokine-activated T-cells. Cytokines in culture supernatants were analyzed by Luminex assay. In the CAIA model, study animals were treated with vehicle, dexamethasone or various oral doses of the SINE KPT-355 on days 4, 6, 8 and 10. In the CIA model, study animals received vehicle, dexamethasone, or KPT-355 from day 11 to day 28 on QoD or QD regimens. A standard clinical scoring system was used to quantify the clinical symptoms of arthritis in both models. In the CIA model, the levels of cytokines and pro-inflammatory markers were measured in the synovial fluid using a Luminex assay and ELISA. Bone erosion within the paws was quantified with 3D micro-tomodensitometry. Histopathology was conducted on the hind paws of rats using H&E staining.

Results: SINE inhibited RA FLS proliferation (IC_{50} ~10nM) as well as T cell responses to bacterial superantigen presented by FLS that had been pretreated with IFN-γ. SINE showed minimal cytotoxicity to these cells. SINE blocked the secretion of IL-6, IL-8 and other cytokines by FLS in a dose dependent manner (IC_{50}~100nM). In both CIA and CAIA models, KPT-355 SINE treated animals had significantly lower disease scores compared to the vehicle treated animals. In the CIA model, peak clinical scores were 1.4±0.542 with KPT-355 compared to 8.5±0.707 with the vehicle. In the CAIA model peak clinical scores were 0.56 ± 0.29 with KPT-355 compared to 7.44 ± 0.85 with vehicle. Histological analyses of SINE treated animals showed significant reduction in the degeneration of articular cartilage and inflammation in the joint spaces. KPT-355 also significantly reduced the levels of IL-1β *(p=0.0262)*, IL-6 *(p=0.0253)*, MCP-1 *(p=0.0008)* and CRP *(p=0.0003)* in the synovial fluid. Micro-CT data showed that SINE significantly prevented bone mineral density loss.

Conclusion: These studies demonstrate that SINE display potent anti-inflammatory activity, joint sparing activity, and protection from bone mineral density loss in established models of rheumatoid arthritis, justifying further development of SINE for RA.

Amelioration Of Collagen-Induced Arthritis By Modulation Of Inhibitory Apoptosis Stimulating Protein Of p53 To Activate Transcription Factor p73. Chrong-Reen Wang, Shih-Yao Chen, Ai-Li Shiau, Yuan-Tsung Li, Chia-Tse Weng, I-Ming Jou, Ming-Fei Liu and Chao-Liang Wu. College of Medicine, National Cheng Kung University, Tainan, Taiwan.

Background/Purpose: Our previous studies have demonstrated p53 mutations competent for the inactivation of wild type p53 in synovial fibroblasts (SF) from either rheumatoid arthritis patients or collagen-induced arthritis (CIA) rats; however, the pathogenic role of p73 (a transcription factor belonging to the p53 family) remains to be explored in rheumatoid joints. The 37 amino acid (37AA) peptide, a hybrid small peptide corresponding to p53 residues, inhibits the binding of p73 with inhibitory apoptosis stimulating protein of p53 (iASPP), thus activating p73 and further inducing apoptosis in p53-null cells.

Methods: Male Sprague-Dawley rats were immunized with bovine type II collagen with Freund's adjuvant on days 0 and 7 to induce arthritis, and SF were isolated from CIA rats. CIASF were transfected with adenoviral vectors encoding 37AA gene (Ad37AA), and then subjected to TUNEL, colorimetric WST-8 and real-time RT-PCR analyses to examine apoptotic status, cell viability and expression levels of p53 upregulated modulator of apoptosis (PUMA, a downstream target gene of p73), respectively. The association status of iASPP with p73 in Ad37AA-transfected CIASF was identified by immunoprecipitation with anti-iASPP, followed by immunoblot with anti-p73 antibodies. Serial expression levels of iASPP on synovium from rats were investigated by immunohistochemical (IHC) staining before and after the induction of arthritis. The therapeutic effect of Ad37AA on CIA rats were examined by intra-articular (i.a.) injection of 5×10^7 plaque-forming units into ankle joints on day 12, and evaluated by articular index and histological analyses including H&E staining and a specific surface marker of SF. Furthermore, expression levels of PUMA and IL-6 on CIA synovium were examined by immunoblot and enzyme-linked immunosorbent assay, respectively.

Results: Increased apoptosis status with reduced cell viability was found in Ad37AA-transfected CIASF as compared with control vector or mock-treated counterpart. There were significantly increased expression levels of PUMA on days 4 and 6 after the Ad37AA transfection. Decreased levels of associated p73 with iASPP were identified in Ad37AA-trasfected CIASF as compared with control vector-treated cells. Serial synovium sections revealed higher expression of iASPP in synovial lining layer after the induction of arthritis. Articular indexes of Ad37AA-injected joints were significantly smaller as compared with control vector or phosphate-buffered saline-treated ankles. There were significantly lower histological scores with milder synovial hyperplasia and bone erosion in Ad37AA-injected joints as compared with control groups. Notably, Ad37AA-treated synovium revealed up-regulation of PUMA, lower numbers of SF and decreased concentrations of IL-6.

Conclusion: These data demonstrate amelioration of CIA in rats by i.a. gene transfer of a small peptide corresponding to p53 residues via induction of apoptosis in CIASF through p73 activation. Such findings implicate a pathogenic role of p73 and the enhancement of p73-dependent pathway as a potential therapeutic strategy in rheumatoid joints.

Cell Cycle Regulation Therapy Combined With Cytokine Blockade Enhances Anti-Arthritic Effects Without Increase Of Immune Suppression. Tadashi Hosoya, Hideyuki Iwai, Yu Yamaguchi, Nobuyuki Miyasaka and Hitoshi Kohsaka. Department of Medicine and Rheumatology, Tokyo Medical and Dental University, Tokyo, Japan.

Background/Purpose: The pathogenesis of rheumatoid arthritis (RA) is characterized by infiltration of immune cells to the synovial tissues and their hyperplasia. Aim of the current therapeutic strategies of RA is blockade of proinflammatory cytokines or inhibition of immune cell activity. Anti-tumor necrosis factor and interleukin (IL)-6 biological agents have been proven more effective than conventional oral anti-rheumatic drugs. However, they cannot induce complete remission in all patients and render treated patients susceptible to infections. Combination treatments with other molecular targeting drugs failed to enhance anti-rheumatic effects but increased adverse effects. To explore non-immunosuppressive treatment, we have focused on proliferation of synovial fibroblasts as a target pathological process. We have revealed that cell cycle regulation of synovial fibroblasts by cyclin-dependent kinase (CDK) inhibition ameliorated animal models of RA without inhibiting immune responses. A small molecule CDK4/6 inhibitor (smCDKI) has been tolerated clinically as an anti-cancer drug with the toxic effect being transient myelosuppression. The present studies were carried out to discern if smCDKI under toxic doses enhances the anti-arthritic effect of cytokine blockade and reduces their adverse effects in treating collagen induced arthritis (CIA).

Methods: DBA/1J mice were immunized with bovine type II collagen (CII) emulsified in complete Freund's adjuvant. Arthritis score and peripheral blood counts of the CIA mice treated with different doses of smCDKI were assessed. The arthritis score, radiographic score and histological score of the mice treated with smCDKI alone, with anti-IL-6 receptor antibody (IL-6R-Ab) or etanercept (ETN) alone, or with combination of smCDKI and cytokine blockade were assessed. Serum anti-CII antibodies were quantified with

enzyme-linked immunosorbent assay. CII specific proliferation of T cells derived from draining lymph nodes was assessed with thymidine incorporation assay.

Results: The smCDKI monotherapy suppressed arthritis, radiographic and histological scores of CIA dose-dependently. The therapeutic effects were observed without myelosupression. Both of IL-6R-Ab and ETN monotherapies were also effective. Their efficacy was further enhanced in the all scores when combined with smCDKI administration. Of note, the combination of smCDKI and ETN suppressed arthritis almost completely. Serum anti-CII antibody levels and CII-specific T cell proliferation were comparable among all the treated and control groups.

Conclusion: This is the first report demonstrating that combination of molecular targeting therapies exerted synergistic effects without increase in immune suppression. The smCDKI treatment combined with the anti-cytokine treatment might be more effective than anti-inflammatory monotherapy without increasing infection risks in treating RA. We hope that development of smCDKI as an anti-rheumatic drug will help to increase the remission induction rate in RA treatment without inducing infections.

Novel Role For Ly6C$^-$ Monocyte Subsets and Joint Macrophages In Mouse Model Of Rheumatoid Arthritis. Alexander Misharin[1], Carla M. Cuda[2], Rana Saber[1], Angelica K. Gierut[3], G. Kenneth Haines III[4], Steffen Jung[5] and Harris R. Perlman[1]. [1]Northwestern University, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Northwestern Med Faculty Found, Chicago, IL, [4]Yale University, New Haven, CT, [5]Weizmann Institute, Rehovot, Israel.

Background/Purpose: Monocytes and macrophages play a key role in the pathogenesis of rheumatoid arthritis. However, role of the individual subsets of monocytes and macrophages in the initiation, perpetuation and/or resolution of arthritis is unknown.

Methods: To uncover their role we utilized multiple strategies to deplete selective subsets of monocytes and macrophages in the K/BxN serum transfer arthritis mouse model: clodronate-loaded liposomes, diphtheria toxin and CD11b-DTR mice, aCCR2 antibody, adoptive transfer of monocytes.

Results: We found that contrary to the current dogma monocytes, and not neutrophils were necessary for initiation of arthritis. Moreover, we found that only non-classical Ly6C$^-$ monocytes were required for induction of arthritis, while classical Ly6C$^+$ monocytes were dispensable. Further, we identified that naïve mouse joint contains heterogeneous population of macrophages, which differ in their origin, turnover and function, namely tissue-resident macrophages and bone marrow-derived macrophages. Selective depletion of the tissue-resident macrophages accelerated development of arthritis, while depletion of bone marrow-derived macrophages had no effect on arthritis. While blood monocytes were necessary for initiation and development of arthritis, they were not necessary for its resolution. In contrast, tissue macrophages were crucial for the resolution, since their depletion delayed resolution of arthritis and was associated with increased histological joint damage.

Conclusion: These data suggest that unlike other models (myocardial infarction, infectious diseases) resolution of arthritis does not require second wave of monocyte recruitment into the joint, but rather dependent on a molecular rheostat within macrophages, which controls the switch of their phenotype from "proinflammatory/classically activated" to a "wound healing/regulatory". Phagocytosis of apoptotic neutrophils (efferocytosis) is potentially one of the mechanisms controlling this switch.

Treatment Of Innate Immune Arthritis With a Toll-Like Receptor 7 Agonist Requires Type I Interferon. Maripat Corr[1], Tomoko Hayashi[2], Dennis A. Carson[2], Howard Cottam[3] and Joshua Yang[2]. [1]Univ of California-San Diego, La Jolla, CA, [2]UCSD School of Medicine, La Jolla, CA, [3]ucsd School of Medicine, La Jolla, CA.

Background/Purpose: We previously demonstrated that repeated administration of the low molecular weight Toll-like receptor (TLR) 7 agonist (1V136) substantially reduces arthritic inflammation in mice. Here we investigated the mechanisms contributing to this potent anti-inflammatory effect using the K/BxN passive transfer model of murine arthritis.

Methods: The following mutant strains were given arthritis with 150ul K/BxN serum intraperitoneally (ip) and treated with daily subcutaneous (s.c.) injections of vehicle or 150nmol 1V136: C57BL/6, *Tlr7*$^{-/-}$, *Ifnar1*$^{-/-}$, *kit*$^{W\text{-}sh}$ (Wsh), Pretty2, and *Stat1*. Bone marrow chimeric mice were generated by irradiating C57BL/6 and *Tlr7*$^{-/-}$ mice with 10Gy and injecting these recipients with 10^7 donor bone marrow cells (BM). To assess the effects on vascular permeability mice were injected with 150ul K/BxN serum i.p. and 1mg/kg Evans blue dye intraveniously. After sacrifice the paws were removed and incubated in formamide overnight and the absorbance of the supernatant at 600nm was measured. Complete blood counts were performed by the UCSD Animal Care Program Diagnostic Laboratory.

Results: The joint swelling and arthritis scores of K/BxN serum transferred arthritis was significantly reduced by daily injections of 150nm 1V136 s.c. in C57BL/6 (WT) mice (AUC 6.6 drug treated vs. AUC 0.38 vehicle treated, $P<0.001$). Radiation bone marrow chimeric mice were tested and in WT BM>WT mice paw swelling in 1V136 treated mice was significantly less than vehicle treated controls (AUC 3.3 vs 7.4, $P<0.01$), but not in the TLR7 BM>TLR7 mice (AUC 6.7 vs 7.1, $P>0.05$). In mixed chimeras the drug was effective in the WT BM>TLR7 mice (AUC 4.9 vs 7.4, $P=0.03$), but not in the TLR7 BM>WT (AUC 6.2 vs 7.0, $P>0.05$). These data suggested that TLR7 is necessary for the activity of the compound. Mice that were defective in STAT1 and type I IFN signaling were refractory to 1V136 treatment, implicating these molecules effector molecules in the mechanism of this drug treatment. The data using BM chimeric mice suggested that radiosensitive cells were primarily involved in the beneficial effects of 1V136. A single dose of 1V136 reduced plasma extravasation in the joints of mice that received K/BxN sera. Plasma extravasation in immune complex reactions is associated with mast cell degranulation and neutrophil recruitment. Two strains of mast cell deficient mice were tested: Pretty2 and kit$^{W\text{-}sh}$ mice. The kit$^{W\text{-}sh}$ mice were refractory to treatment (AUC 7.3 vs 5.6, $P>0.05$), but the Pretty2 mice responded to 1V136 (AUC 2.2 vs 7.5, $P<0.05$). In the Pretty 2 strain the c-kit mutation is also associated with a low level of circulating neutrophils. A single dose of 1V136 significantly decreased the circulating white blood cells in WT mice ($10.6+0.22$ vs $3.9+0.44$, $P<0.01$), but not IFNAR1 null mice ($11.77+0.7$ vs $10.8+0.5$, $P<0.05$). There was no effect in the platlet counts.

Conclusion: The joint inflammation and vascular permeability observed in the passive serum transferred arthritis were significantly attenuated by 1V136 treatment. The drug requires TLR7 on bone marrow derived cells, and an intact type I interferon pathway to be fully effective.

Efficacy and Safety Of Subcutaneous Administration Of Tabalumab, An Anti-B Cell Activating Factor Monoclonal Antibody, In Rheumatoid Arthritis: Results From a Phase 3 Multicenter, Randomized, Double-Blind Study. Mark C. Genovese[1], Gregg J. Silverman[2], Paul Emery[3], Ramesh Gupta[4], Anne Gill[5], Wendy J. Komocsar[5], Melissa Veenhuizen[5], Li Xie[5], Pierre-Yves Berclaz[5] and Chin Lee[5]. [1]Stanford University, Palo Alto, CA, [2]NYU School of Medicine, New York, NY, [3]University of Leeds, Leeds, United Kingdom, [4]Private Practice, Memphis, TN, [5]Eli Lilly and Company, Indianapolis, IN.

Background/Purpose: Tabalumab is a monoclonal antibody that neutralizes membrane-bound and soluble B cell activating factor (BAFF). These interim analyses evaluated the efficacy and safety of 2 different subcutaneous (SQ) dosing regimens of tabalumab in RA patients (pts).

Methods: 1004 pts (ITT population) were enrolled in this phase 3, multicenter, randomized, double-blind study that evaluated 2 different SQ tabalumab doses (120 mg every 4 wks [120/Q4W] or 90 mg every 2 wks

[90/Q2W]) vs. placebo over 24 wks. At wk 0, pts received an SQ loading dose that was 2 times the planned treatment dose (ie, 240 mg, 180 mg, or placebo). Eligible pts included those with or without background DMARDs having a Patient's Global Assessment of Disease Activity ≥20/100 mm. Prespecified efficacy analyses were based on a subset of pts (n=849) with ≥5/68 tender and ≥5/66 swollen joints at baseline; the primary endpoint was ACR20 at 24 wks in this subset.

Results: At baseline, the ITT population comprised mostly women (79%) who were seropositive (77%) with a mean age of 51 yrs, RA diagnosis of 6 yrs, and mean DAS28-CRP of 5.3±1.2; these baseline characteristics were similar to that of the efficacy population. For the efficacy population at wk 24, no significant differences in the percentage of pts who achieved ACR20 (NRI; range: 32%–34%) and ACR50 (NRI; range: 12%–13%), and no differences in mean DAS28-CRP (mLOCF; 4.6±1.5 to 4.7±1.5), mean HAQ-DI (mLOCF; range: 1.2±0.7 to 1.3±0.7), or percent with moderate/good EULAR28 response (mLOCF; range: 47%–50%) were observed. Efficacy results were similar between the efficacy and ITT populations. Discontinuation rates due to an AE were similar across all groups (range: 2%–4%) as were incidences of TEAEs (range: 58%–64%) and SAEs (range: 2%–4%). For the 120/Q4W, 90/Q2W, and placebo groups, incidences of events of interest were infection (23%, 26%, and 22%, respectively), injection-site reaction (6%, 10%, and 3%, respectively), and allergy/hypersensitivity reaction (2%, 5%, and 5%, respectively). Major adverse cardiovascular events were reported in two 120/Q4W pts and one 90/Q2W pt. Three deaths occurred (two 120/Q4W pts and one 90/Q2W pt). Changes in CD3-CD20+ B cells seen in the 120/Q4W and 90/Q2W groups were generally consistent with prior phase 2 results. Over the 24-wk treatment period, decreases in IgM, IgA, and IgG were also observed in both tabalumab groups vs. placebo (Table).

Table. Measures of Biologic Activity

	120 mg Q4W N=320[a]/379[b]	90 mg Q2W N=316[a]/371[b]	Placebo N=213[a]/250[b]
CRP (mg/L)[a]			
Baseline	13.3±21.1	12.1±16.2	11.7±15.2
Change at wk 24	−0.2±18.3	−0.5±14.0	−0.6±13.8
CD3-CD20+ B cells (cells/μL)[a]			
Baseline	214.2±146.1	213.2±129.9	223.4±129.0
Change at wk 24	−43.2±306.2*	−67.4±117.8*	3.5±98.5

Baseline	12.5±3.7	12.5±3.6	12.5±3.7
Change at wk 24	−0.8±1.8*	−0.8±1.8*	0.1±1.9

Data are mean±SD.
[a]Based on efficacy population.
[b]Based on safety population (N=1000) who received ≥1 dose.
**P≤0.05 vs. placebo.*

Conclusion: Tabalumab administration had biologic activity demonstrated by changes in B cells and immunoglobulins, but no significant changes in CRP were observed. Despite showing improvements in efficacy measures with intravenous and SQ treatment in three phase 2 trials, no clear clinical benefit and no new, unexpected safety findings were observed for the tabalumab doses evaluated in this larger phase 3 study. Post-hoc analyses to help understand the disparity in responses between phase 2 and phase 3 are planned.

Early and Sustained Improvement In Pain and Physical Function As Measured By Visual Analog Scale and Short Form-36 Physical Component Summary Score In Rheumatoid Arthritis Patients Treated With Mavrilimumab, An Investigational Anti-GM-CSFR-Alpha Monoclonal Antibody, In a Phase 2a Study.

Gerd-Rüdiger Burmester[1], Tsutomu Takeuchi[2], Olga Barbarash[3], Duncan Porter[4], Didier Saurigny[5], David Close[5], Alex Godwood[5], Yoojung Yang[6] and Ancilla W. Fernandes[6]. [1]Charite University Hospital, Berlin, Germany, [2]Keio University School of Medicine, Tokyo, Japan, [3]SIH Kemerovo Regional Clinical Hospital, Kemerovo, Russia, [4]Gartnavel General Hospital, Glasgow, United Kingdom, [5]MedImmune, Ltd, Cambridge, United Kingdom, [6]MedImmune, LLC, Gaithersburg, MD.

Background/Purpose: Rheumatoid arthritis (RA) is associated with significant pain and loss of physical function. We evaluated self-reported pain and physical function in adults patients with moderate-severe, active RA treated with mavrilimumab in combination with MTX in a 3-mo phase 2a, double-blind, placebo-controlled, ascending dose study.

Methods: Eligible patients had moderate-severe RA (DAS28-CRP ≥3.2) of ≥3 mos duration, were DMARD-IR on stable MTX (7.5–25 mg/wk), and positive for auto-antibodies ACPA and/or RF. 192 and 92 patients were randomized to subcutaneous mavrilimumab (10–100mg) and placebo, respectively, given every other wk for 12 wks. The primary endpoint was proportion of patients achieving a ≥1.2 decrease from baseline in DAS28-CRP at wk 12. Pain visual analog scale (VAS) and Short Form-36 physical component summary (SF-36 PCS) score were used to assess pain and physical function. The proportion of responders using minimal clinically important differences was assessed. In a post-hoc analysis, relationships between pain, physical function, and DAS28-CRP were examined using linear regression.

Results: At its highest dose, mavrilimumab 100mg (M100mg) met the primary endpoint vs placebo (difference, 35.5%; p<.001) at wk 12. In addition, following a single dose at wk 2, M100mg demonstrated a statistically significant improvement in the proportion of pain responders compared to placebo (difference, 16.7%; p=.034). This improvement was maintained until 4 wks after the last dose at wk 16 (difference, 24.7%; p=.007). At the first assessment of physical function (SF-36 PCS) at wk 4, M100mg demonstrated a statistically significant improvement in the response rate compared to placebo (difference, 26.7%; p=.004) (Table). This improvement was maintained to the final assessment at wk 12. The relationship between improvements in pain, physical function, and DAS28-CRP showed that, on average, a patient achieving a minimally important improvement in pain following 12 wks of M100mg also had an improvement of 5.71 (95% CI 4.04, 7.38) in the SF-36 PCS and 1.66 (95% CI −1.91, −1.41) in the DAS28-CRP score. Lower doses of mavrilimumab (10mg, 30mg, and 50mg) generally did not yield statistically significant improvements over placebo for these 3 endpoints, except for 30mg (n=49) in DAS28-CRP as early as wk 6 (difference, 25.2%; p=.004). All doses combined (n=192) achieved a response in DAS28-CRP as early as wk 4 (difference, 13.9%; p=.015).

Table. Responder Analysis[1] (%) of Patient-Reported Outcomes and DAS28-CRP at Wks 4 and 12

	Wk 4					Wk 12				
	M100mg (N=47)	PBO (N=92)	Difference	95% CI	*p*-value	M100mg (N=47)	PBO (N=92)	Difference	95% CI	*p*-value
Pain VAS	46.8	26.1	20.7	3.8, 37.4	0.022	55.3	33.7	21.6	4.2, 38.2	0.018
SF-36 PCS	70.2	43.5	26.7	9.1, 42.7	0.004	70.2	40.2	30.0	12.3, 45.3	0.001
DAS28-CRP[2]	42.6	17.4	25.2	9.2, 41.3	0.002	68.1	32.6	35.5	17.8, 50.6	<0.001

CI, confidence interval; DAS28-CRP, Disease Activity Score 28 – C-reactive Protein; M100mg, mavrilimumab 100mg; PBO, placebo
[1]Minimal clinically important difference: VAS, 20mm; SF-36 PCS, 3.1; DAS28-CRP, 1.2
[2]The mean baseline DAS28-CRP was 5.33 and 5.43 in M100mg and placebo groups, respectively.

Conclusion: Treatment with mavrilimumab 100mg resulted in an early onset and sustained improvement in pain relief and physical functioning as measured by VAS and SF-36 PCS, respectively, in moderate-severe RA patients. These findings are consistent with improvement in the disease activity (DAS28-CRP) and support further investigation of the blockade of the GM-CSF receptor with mavrilimumab in Phase 2b studies conducted in both DMARD-IR and TNF-IR patients.

Background/Purpose: A therapeutic strategy based on the selective delivery of an immuno-regulatory cytokine to the sites of inflammatory disease has been developed. DEKAVIL is an 'armed antibody', composed of the human F8 antibody (specific to the EDA domain of fibronectin, a marker of angiogenesis) fused to the human anti-inflammatory cytokine interleukin-10 (IL10), enabling delivery and accumulation of the cytokine specifically at sites of disease. This 'targeting' approach increases the therapeutic index of IL10. A Phase Ib clinical trial is now on-going, which features the administration of weekly doses of DEKAVIL, in combination with MTX, to patients with RA who have previously failed at least one line of anti-TNF therapy. Objectives of the study are to establish the MTD, safety and tolerability, to obtain preliminary information on efficacy and to assess the PK behavior. Here, we report the results obtained in 14 patients studied to date.

Methods: Cohorts of 3–6 patients with active RA were assigned to receive escalating doses of DEKAVIL (6, 15, 30, 60, 110, 160 and 210 μg/kg respectively) in combination with 15mg of MTX. The treatment is given as once weekly sc injection for up to 8 weeks. Standard safety evaluations performed on days 1 through 28 were used to determine the dose limiting toxicity. Response was assessed after 4 and 8 weeks of treatment according to ACR and EULAR (DAS28) criteria. The PK profile and formation of human anti-fusion protein antibodies are measured using standard methods.

Results: Responses are summarized in the attached table. All 3 patients in the first cohort (6 μg/kg) achieved ACR 50 response, accompanied by a 'good' EULAR response. In cohort 2 (15 μg/kg), patient 5 enjoyed an ACR 70 response, whereas patients 4 and 6 did not reach ACR20 despite achieving 'moderate' EULAR response. In cohort 3 (30 μg/kg) patient 8 achieved an ACR70. This was particularly striking as it was prolonged and at a late evaluation time point. Patient 7 did not achieve any ACR response, and patient 9 achieved an ACR20 response. In cohort 4 (60 μg/kg) Patient 11 achieved an ACR50 at EOT, which improved to an ACR70 response at a late evaluation time point, demonstrating an extended response period. Patient 10 achieved an ACR20 and patients 12 and 13 did not respond. In cohort 5 (110 μg/kg) patient 14 achieved an ACR20 at week 5. Trends of swollen/tender joints and DAS28 score also showed improvement. Excellent tolerability was observed, since no grade >2 adverse drug reactions were reported. A very low signal from human anti-fusion protein antibodies was occasionally detected. Several patients are still being treated and followed-up.

Conclusion: The promising safety data, together with preliminary positive signs of activity, suggest that the targeted delivery of IL10 to the site of inflammation may be beneficial to patients with RA. The extended activity periods indicate the possibility for a long lasting therapeutic potential.

1735

A Phase IIb Study Of The Efficacy and Safety Of Subcutaneous Clazakizumab (anti-IL-6 monoclonal antibody) With Or Without Methotrexate In Adults With Moderate-To-Severe Active Rheumatoid Arthritis and An Inadequate Response To Methotrexate. M Weinblatt[1], P Mease[2], E Mysler[3], T Takeuchi[4], E Drescher[5], A Berman[6], M Zilberstein[7], J Xing[7] and P Emery[8]. [1]Brigham and Women's Hospital, Boston, MA, [2]Swedish Medical Center and University of Washington, Seattle, WA, [3]Organización Médica de Investigación, Buenos Aires, Argentina, [4]Keio University, Tokyo, Japan, [5]Csolnoky Ferenc Hospital, Veszprém, Hungary, [6]Centro Médico Privado de Reumatología, Tucuman, Argentina, [7]Bristol-Myers Squibb, Princeton, NJ, [8]University of Leeds, Leeds, United Kingdom.

Background/Purpose: Clazakizumab (claza) is a humanized anti-interleukin-6 (IL-6) monoclonal antibody that potently neutralizes IL-6 signaling. This study evaluated the safety and efficacy of subcutaneous claza with or without MTX versus placebo (pbo) or adalimumab (ada).

Methods: Patients with moderate-to-severe RA and an inadequate response to MTX were randomized equally to receive pbo + MTX; 25, 100 or 200 mg claza + MTX; 100 or 200 mg claza without MTX; and ada 40 mg every other week + MTX for 24 weeks. The primary endpoint was ACR 20 response rate at Week 12. Key secondary endpoints at Week 24 were ACR 20, ACR 50 and ACR 70 response rates, Health Assessment Questionnaire-Disability Index (HAQ-DI) improvements and remission defined as Disease Activity Score (DAS)28 (C-reactive protein, CRP) <2.6, Clinical Disease Activity Index (CDAI) <2.8 and Simplified Disease Activity Index (SDAI) <3.3.

Results: 418 patients were randomized and received treatment. Baseline characteristics were balanced across the arms; 82% female, mean age 50 years, mean duration of RA 5.9 years, mean DAS28 (CRP) 5.94, and 80% rheumatoid-factor positive. The primary endpoint was met; ACR 20 response rates were statistically significantly higher in all claza arms versus pbo + MTX. All claza treatment groups were associated with improved ACR 20/50/70 response rates, HAQ-DI and remission versus pbo + MTX through Week 24. Rates of remission per DAS28 (CRP) <2.6, SDAI <3.3 and CDAI <2.8 were numerically higher in the claza + MTX arms compared with ada + MTX. Treatment with claza in combination with MTX resulted in higher response rates than monotherapy. However, no clear dose response for efficacy was noted. The rates of serious adverse events ranged from 8.3 to 13.3% in claza arms versus 3.3% for pbo + MTX and 5.1% for ada + MTX. Rates of serious infections were similar as reported for all claza arms and ada versus none in pbo. Claza was associated with mostly mild injection-site reactions, few of which led to discontinuation. As expected based on its mode of action, claza treatment was associated with increased transaminases (mainly in combination with MTX), increased lipids and hemoglobin, and decreased polymorphonuclear neutrophils and platelets.

	Pbo + MTX (n=61)	Claza 25mg + MTX (n=59)	Claza 100mg + pbo (n=60)	Claza 100mg + MTX (n=60)	Claza 200mg + pbo (n=59)	Claza 200mg + MTX (n=60)	Ada + MTX (n=59)

DAS 28 (CRP) <2.6, % (95% CI)	13.1 (4.6, 21.6)	49.2 (36.4, 61.9)	28.3 (16.9, 39.7)	41.7 (29.2, 54.1)	35.6 (23.4, 47.8)	41.7 (29.2, 54.1)	23.7 (12.9, 34.6)
CDAI remission, % (95% CI)	1.6 (0.0, 8.8)	15.3 (6.1, 24.4)	6.7 (1.8, 16.2)	20.0 (9.9, 30.1)	6.8 (1.9, 16.5)	20.0 (9.9, 30.1)	8.5 (1.4, 15.6)
SDAI remission, % (95% CI)	4.9 (1.0, 13.7)	18.6 (8.7, 28.6)	6.7 (1.8, 16.2)	20.0 (9.9, 30.1)	6.8 (1.9, 16.5)	23.3 (12.6, 34.0)	8.5 (1.4, 15.6)
HAQ-DI mean change from baseline (SE)	–0.6 (0.1)	–0.7 (0.1)	–0.7(0.1)	–0.8 (0.1)	–0.6 (0.1)	–0.7 (0.1)	–0.7 (0.1)

Conclusion: Claza as monotherapy or in combination with MTX demonstrated efficacy in controlling the signs and symptoms of RA. At Week 24, remission rates with claza + MTX trended higher than with ada + MTX. Its safety profile was consistent with the known pharmacology of IL-6 blockade. Claza is a promising future treatment for RA that warrants further investigation.

A Randomized, Controlled, Multicenter, 2-Arm, Parallel-Group, Double-Blind Study To Demonstrate The Equivalence Of CT-P10 To Innovator Rituximab With Respect To Pharmacokinetic Profile In Patients With Rheumatoid Arthritis. Dae-Hyun Yoo[1], Won Park[2], Slawomir Jeka[3], Fidencio Cons Molina[4], Pawel Hrycaj[5], Piotr Wiland[6], Wolfgang Spieler[7], Jan Brzezicki[8], Eun Young Lee[9], Francisco G. Medina-Rodriguez[10], Pavel Shesternya[11], Sebastiao Radominski[12], Marina Stanislav[13], Volodymyr Kovalenko[14], Dong Hyuk Sheen[15], Mie Jin Lim[2], Jung-Yoon Choe[16], Sung Young Lee[17], Seung-Cheol Shim[18] and Chang-Hee Suh[19]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Inha University Hospital, Incheon, South Korea, [3]Clinic of Rheumatology and Connective Tissue Diseases University Hospital No 2 in Bydgoszcz Collegium Medicum UMK in Torun, Bydgoszcz, Poland, [4]Centro de Investigacion en Artritis y Osteoporosis SC, Mexicali, Mexico, [5]Poznan University of Medical Sciences, Poznan, Poland, [6]Medical University of Wroclaw, Wroclaw, Poland, [7]ZeFOR GmbH Zentrum für Forschung, Zerbst, Germany, [8]Wojewodzki Szpital Zespolony Oddzial Reumatologiczny, Elblag, Poland, [9]Division of Rheumatology, Department of Internal Medicine, Seoul National University, Seoul, South Korea, [10]Centro de Investigación Farmacológica y Biotecnológica, Mexico City, Mexico, [11]Krasnoyarsk State Medical University, Krasnoyarsk, Russia, [12]CETI Centro de Estudos em Terapias Inovadoras Ltda, Curitiba, Brazil, [13]Russian Academy of Medical Science, Moscow, Russia, [14]National Scientific Center, Kiev, Ukraine, [15]Eulji University Hospital, DaeJeon, South Korea, [16]Daegu Catholic University Medical Center, Daegu, South Korea, [17]CELLTRION, Inc., Incheon, South Korea, [18]Chungnam National University Hospital, Daejeon, South Korea, [19]Ajou University Hospital, Suwon, South Korea.

Background/Purpose: CT-P10 was developed as a biosimilar candidate to innovator rituximab (RTX), an anti-CD20 monoclonal antibody. This trial is a phase I study to demonstrate the equivalence of the pharmacokinetic (PK) profile of CT-P10 with RTX in patients with active rheumatoid arthritis (RA) who had an inadequate response or intolerant to previous antitumor necrosis factor (TNF) agents. Equivalence will be concluded if the 90% Confidence Intervals (CI) for the ratios of the geometric means of AUC_{0-last} and C_{max} between the CT-P10 and RTX groups are within 80%– 125%. The pharmacodynamics (PD), efficacy, and overall safety of both treatments were also evaluated.

Methods: One hundred and fifty-four patients with active RA were randomized 2:1 to receive 2 infusions (1000 mg, IV each) of either CT-P10 (n=103) or RTX (n=51) with a 2-week interval between infusions, both co-administered with weekly methotrexate and folic acid. The primary endpoints were area under the serum concentration-time curve from time '0' to time of last quantifiable concentration (AUC_{0-last}) and maximum serum concentration (C_{max}) (after second infusion) of the CT-P10 and RTX groups. ACR response, EULAR response, B-cell kinetics, immunogenicity and safety parameters were also evaluated up to week 24.

Results: The geometric means were 7870.84 day-μg/mL and 8010.39 day-μg/mL for AUC_{0-last} and 465.94 μg/mL and 477.52 μg/mL for C_{max} in the CT-P10 and RTX groups, respectively. The ratios (%) of the geometric means of AUC_{0-last} and C_{max} between the CT-P10 and RTX groups were 98.3% (90% CI: 89.6, 107.8) and 97.6% (90% CI: 92.0, 103.5), respectively.

The geometric mean area under the curve (AUC) of B-cell count, a comparative PD parameter, was 20.8 cells/μL for the CT-P10 group and 20.4 cells/μL for the RTX group. The ratio (%) of the geometric means of AUC for B-cell count was 102% (90% CI: 98, 106). ACR20/50/70 response rates at week 24 were 63.0%/37.0%/16.0% in the CT-P10 group and 66.7%/31.3%/14.6% in the RTX group. The proportions of patients who had a moderate or good response at week 24 were 76.8% and 79.1% for EULAR (ESR) response and 82.1% and 83.7% for EULAR (CRP) response in the CT-P10 and RTX groups, respectively.

The proportions of patients with a positive anti-drug antibody at week 24 were 17.6% (18/102) for the CT-P10 group and 17.6% (9/51) for the RTX group. A total of 166 and 88 treatment-emergent adverse events were reported for the CT-P10 and RTX groups, respectively. Serious adverse events were reported in 16.7% of CT-P10 and 17.6% of RTX patients. Infections were reported in 23.5% of CT-P10 and 25.5% of RTX patients. Infusion reactions were reported in 16.7% of CT-P10 and 19.6% of RTX patients.

Conclusion: CT-P10 and RTX were equivalent in terms of AUC_{0-last} and C_{max} in patients with active RA. Clinical efficacy for ACR20/50/70 and EULAR response rates and PD for B-cell kinetics were comparable between the two treatment groups. CT-P10 was well tolerated with a safety profile comparable to that of RTX up to week 24.

1737

Association Of *HLA-DRB1* Alleles With Clinical Responses To The Anti-Interleukin−17A Monoclonal Antibody Secukinumab In a Cohort Of Patients With Active Rheumatoid Arthritis: An Exploratory Phase 2 Biomarker Study. Gerd R Burmester[1], Patrick Durez[2], Galina Shestakova[3], Yue Li[4], Amanda Wang[5], Steve Lewitzky[5], Irina Koroleva[5], David Lee[4] and Wolfgang Hueber[4]. [1]Charité-Universitätsmedizin Berlin, Free University and Humboldt University of Berlin, Berlin, Germany, [2]Université Catholique de Louvain, Brussels, Belgium, [3]Kaluga State Pedagogical Tsiolkovsky University, Kaluga, Russia, [4]Novartis Pharma AG, Basel, Switzerland, [5]Novartis Pharma AG, Cambridge, MA.

Background/Purpose: The shared epitope (SE) may play a functional role in RA via Th17/interleukin (IL)-17 polarization (Holoshitz et al. *FEBS Lett* 2011;585:3619–26). Two phase 2 studies of secukinumab in RA suggested that *HLA-DRB1*04* allelic group and the SE could be candidate biomarkers for treatment with secukinumab. In this study, validation in an independent cohort was sought for candidate markers of response.

Methods: In a randomized, double-blind, placebo-controlled trial, patients with RA (2010 criteria), TJC ≥ 6, SJC ≥ 6, CRP > 10 mg/L, who were biologic-naive and DMARD incomplete responders or DMARD naive, were randomized 2:1 to secukinumab 6×10 mg/kg i.v. or placebo every other week (wk). Associations of treatment effect of secukinumab vs. placebo with *HLA-DRB1*04* (primary endpoint), *HLA-DRB1*SE* and protein markers RF and anti-CCP were assessed at wk 12 in 96 evaluable patients, using change from baseline in DAS28-CRP by ANCOVA, or ACR20 response by logistic regression.

Results: At baseline, 46 (72%) on secukinumab and 23 (72%) on placebo were taking concomitant DMARDs; 16% were RF/anti-CCP negative. Frequency of *HLA-DRB1*SE* and **04* was 72% and 47%, respectively. ACR20 responses at wk 12 were 87.9% for secukinumab compared to 25.0% for placebo. Change from baseline in DAS28-CRP differed significantly as early as wk 2 and continued through wk 12 (Fig 1). For change from baseline in DAS28-CRP, *HLA-DRB1*SE* status demonstrated a significant association with response to secukinumab vs. placebo (p=0.007), but the *HLA-DRB1*04* allelic group and *HLA-DRB1*0401* did not (Fig 2). Among protein markers, RF but not anti-CCP was significantly associated with both DAS28-CRP (RF p=0.022, anti-

CCP p=0.124) and ACR20 response (RF p=0.013, anti-CCP p=0.228). The small number of *HLA-DRB1*SE* non-carriers within the CCP/RF-positive subcohort precluded assessment of associations in this subgroup. Two SAEs were reported, necrotizing vasculitis and ovarian adenoma, both leading to early secukinumab discontinuation.

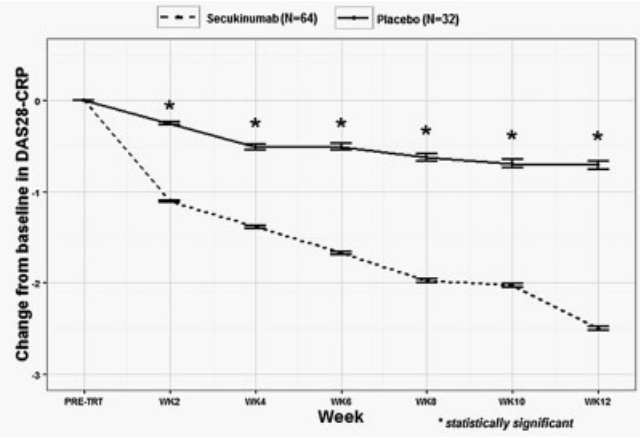

Figure 1. Secukinumab 6×10mg/kg i.v. compared to placebo for change from baseline in DAS28-CRP responses. *All p-values at post-baseline visits are <0.0005 from mixed-effects model for repeated measurements.

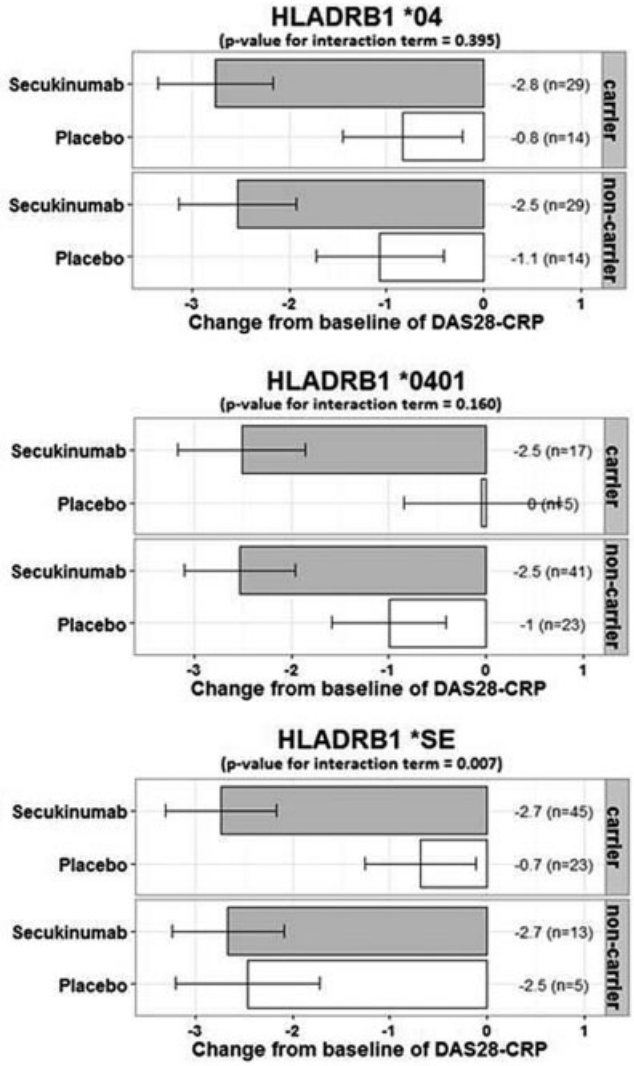

Figure 2. Biomarker associations with clinical response to secukinumab vs. placebo treatment in DAS28-CRP at week 12.

Conclusion: Secukinumab was associated with improvements in efficacy outcomes compared with placebo. *HLA-DRB1*SE* was associated with response to secukinumab vs. placebo. However, these associations are driven by lack of placebo response in carriers vs. non-carriers. Notable differences in genetic ancestry and disease activity suggest potential confounder effects. Additional studies with enhanced power are needed to confirm contributions of SE and other markers to anti-IL-17A responsiveness.

Epratuzumab Maintains Improvements In Disease Activity For Over 2 Years In Patients With Moderate-To-Severe Systemic Lupus Erythematosus: Results From An Open-Label Long-Term Extension Study.

Megan E. B. Clowse[1], Frederic Houssiau[2], Michelle A. Petri[3], Brian Kilgallen[4], Kenneth Kalunian[5], Vibeke Strand[6], Sabine Bongardt[7], Caroline Gordon[8] and Daniel J. Wallace[9]. [1]Duke University Medical Center, Durham, NC, [2]Université catholique de Louvain, Brussels, Belgium, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]UCB Pharma, Smyrna, GA, [5]UCSD School of Medicine, La Jolla, CA, [6]Stanford University, Palo Alto, CA, [7]UCB Pharma, Brussels, Belgium, [8]University of Birmingham, Birmingham, United Kingdom, [9]Cedars-Sinai Medical Center, Los Angeles, CA.

Background/Purpose: Epratuzumab is a monoclonal antibody targeting CD22. In EMBLEM™ (dose-ranging phase IIb study), epratuzumab produced clinically relevant improvements in disease activity in patients with moderate-to-severe systemic lupus erythematosus (SLE).[1] The open-label extension (OLE) of EMBLEM™ (NCT00660881) reports long-term data on the efficacy of epratuzumab.

Methods: Patients from any EMBLEM™ arm completing 12 weeks blinded treatment and those who discontinued due to lack of efficacy but completed ≥8 weeks were eligible. In the OLE, all patients received 1200mg epratuzumab at weeks 0 and 2 of repeating 12-week cycles. Evaluation visits were at weeks 4 and 8 of each cycle. Efficacy endpoints included British Isles Lupus Assessment Group (BILAG) improvement, SLE Disease Activity Index (SLEDAI) score, Physician Global Assessment (PGA) and combined treatment response (defined as BILAG improvement without worsening, no SLEDAI worsening, no PGA worsening, relative to EMBLEM™ baseline [BL]). Observed data are reported to week 108 of OLE (last timepoint when >50% of patients reported data for BILAG). The last visit, which refers to the last available value for each subject regardless of timing, is also presented.

Results: 203 patients participated in the EMBLEM™ OLE: 95% female (n=192), 78% Caucasian (n=158), mean±SD age 39±11 yrs. 35 (17%) and 168 (83%) received placebo and epratuzumab (various doses) respectively for 12 weeks in EMBLEM™. Median (range) duration of epratuzumab exposure was 845 (75–1185) days. BILAG improvements were observed between EMBLEM™ BL and week 108 of OLE. Median BILAG total score decreased by 64%. Median (range) BILAG total score was 25.0 (12–61) at EMBLEM™ BL, 14.0 (0–57) at OLE screening, 9.0 (0–52) at week 48, 9.0 (0–52) at week 96 and 9.0 (0–52) at week 108. Last visit value was 10.0 (0–72). At week 108, 60.3% of on-going patients responded to treatment, according to combined treatment response criteria (Table). Median (range) SLEDAI total score was 12.0 (6–39) at EMBLEM™ BL, 10.0 (0–34) at OLE screening, 6.0 (0–30) at week 48, 5.0 (0–22) at week 96, 4.0 (0–24) at week 108 and last visit value was 8.0 (0–32). At week 108, 94.0% (109/116) had no worsening in SLEDAI. Median (range) PGA total score was 50.0 (9–90) at EMBLEM™ BL, 31.0 (0–96) at OLE screening, 18.0 (0–81) at week 48, 19.0 (0–73) at week 96, 17.5 (0–69) at week 108 and last visit value was 25.0 (0–94). At week 108, 97.4% (113/116) had no worsening in PGA. Corticosteroid use decreased with long-term epratuzumab use.

Table: Change in BILAG grade among subjects with BILAG grade A or B at EMBLEM™ baseline

	BILAG grade at EMBLEM™ baseline	BILAG grade (shift) at EMBLEM™ OLE screening			BILAG grade (shift) at week 108 of EMBLEM™ OLE			
Body system	A/B (Severe/ moderate disease) n	A/B (Severe/ moderate disease) n (%)	C (Stable disease) n (%)	D (Inactive disease) n (%)	N	A/B (Severe/ moderate disease) n (%)	C (Stable disease) n (%)	D (Inactive disease) n (%)
Musculoskeletal	183	101 (55.2)	48 (26.2)	34 (18.6)	106	27 (25.5)	31 (29.2)	48 (45.3)
Mucocutaneous	166	97 (58.4)	40 (24.1)	29 (17.5)	93	31 (33.3)	21 (22.6)	41 (44.1)
Cardiorespiratory	69	45 (65.2)	3 (4.3)	21 (30.4)	41	13 (31.7)	0 (0)	28 (68.3)
Neuropsychiatric	50	32 (64.0)	5 (10.0)	13 (26.0)	27	12 (44.4)	1 (3.7)	14 (51.9)
Constitutional	44	7 (15.9)	3 (6.8)	34 (77.3)	20	1 (5.0)	2 (10.0)	17 (85.0)
Renal	25	12 (48.0)	10 (40.0)	3 (12.0)	13	4 (30.8)	4 (30.8)	5 (38.5)

Conclusion: Epratuzumab was associated with sustained improvements in disease activity in patients with moderate-to-severe SLE. Responder rates were sustained beyond 2 years or increased during open-label treatment, particularly in patients previously treated with placebo.

Sustained British Isles Lupus Assessment Group-Measured Improvement In Moderately-and-Severely Affected Body Systems In Patients With Systemic Lupus Erythematosus By Epratuzumab: Results From An Open-Label Extension Study. Kenneth Kalunian[1], Megan E. B. Clowse[2], Frederic Houssiau[3], Michelle A. Petri[4], Brian Kilgallen[5], Caroline Gordon[6], Vibeke Strand[7], Sabine Bongardt[8] and Daniel J. Wallace[9]. [1]UCSD School of Medicine, La Jolla, CA, [2]Duke University Medical Center, Durham, NC, [3]Université catholique de Louvain, Brussels, Belgium, [4]Johns Hopkins University School of Medicine, Baltimore, MD, [5]UCB Pharma, Raleigh, NC, [6]University of Birmingham, Birmingham, United Kingdom, [7]Stanford University, Palo Alto, CA, [8]UCB Pharma, Brussels, Belgium, [9]Cedars-Sinai Medical Center, Los Angeles, CA.

Background/Purpose: Epratuzumab is a monoclonal antibody targeting CD22. In EMBLEM™ (a dose-ranging phase IIb study), epratuzumab produced clinically relevant improvements in disease activity in patients with moderate-to-severe systemic lupus erythematosus (SLE).[1] The open-label extension (OLE) of EMBLEM™ (NCT00660881) reports long-term data on the efficacy of epratuzumab. The improvement in British Isles Lupus Assessment Group (BILAG) 2004 index according to body systems is reported.

Methods: Patients from any EMBLEM™ arm completing 12 weeks' blinded treatment and patients who discontinued due to lack of efficacy but completed ≥8 weeks were eligible. In the OLE, all patients received 1200mg epratuzumab at weeks 0 and 2 of repeating 12-week cycles. Data are reported to week 108, the last time point when more than 50% of patients reported data for BILAG improvement. Independent central readers determined BILAG grades for all 9 systems. Data for the BILAG improvement component of the combined index in body systems for which a sufficient number of patients entering the OLE (≥20) had baseline disease activity to assess response are reported. Observed case analysis are presented.

Results: Improvements from BILAG A/B scores to BILAG C or D were observed following 12 weeks of epratuzumab treatment (EMBLEM™ OLE screening) in all body systems (Table). In the musculoskeletal body system 44.8% of patients with BILAG A/B at EMBLEM™ baseline improved to BILAG C or D at EMBLEM™ OLE screening. This was 41.6%, 34.7%, 36.0%, 84.1% and 52.0% in the mucocutaneous, cardiorespiratory, neuropsychiatric, constitutional and renal body systems respectively. The percentage of patients with an improvement in baseline BILAG A/B scores to BILAG C or D was further increased up to week 108 in the EMBLEM™ OLE. At week 108 the proportion of patients with BILAG C or D exceeded 60% in the musculoskeletal, mucocutaneous, cardiorespiratory, constitutional and renal systems (observed data) (Table).

Table: Change in BILAG grade among subjects with BILAG grade A or B at EMBLEM™ baseline

	BILAG grade at EMBLEM™ baseline	BILAG grade (shift) at EMBLEM™ OLE screening			BILAG grade (shift) at week 108 of EMBLEM™ OLE			
Body system	A/B (Severe/ moderate disease) n	A/B (Severe/ moderate disease) n (%)	C (Stable disease) n (%)	D (Inactive disease) n (%)	N	A/B (Severe/ moderate disease) n (%)	C (Stable disease) n (%)	D (Inactive disease) n (%)
Musculoskeletal	183	101 (55.2)	48 (26.2)	34 (18.6)	106	27 (25.5)	31 (29.2)	48 (45.3)
Mucocutaneous	166	97 (58.4)	40 (24.1)	29 (17.5)	93	31 (33.3)	21 (22.6)	41 (44.1)
Cardiorespiratory	69	45 (65.2)	3 (4.3)	21 (30.4)	41	13 (31.7)	0 (0)	28 (68.3)
Neuropsychiatric	50	32 (64.0)	5 (10.0)	13 (26.0)	27	12 (44.4)	1 (3.7)	14 (51.9)
Constitutional	44	7 (15.9)	3 (6.8)	34 (77.3)	20	1 (5.0)	2 (10.0)	17 (85.0)
Renal	25	12 (48.0)	10 (40.0)	3 (12.0)	13	4 (30.8)	4 (30.8)	5 (38.5)

Conclusion: Treatment with epratuzumab provided BILAG improvements in disease activity in all affected body systems. Improvements were sustained and enhanced with long-term treatment. Within specific body systems, most patients had symptom reduction or absence of active disease with treatment.

12-Month Outcomes Associated With Belimumab In Patients With Systemic Lupus Erythematosus In Clinical Practice Settings: The Observe Study. Christopher E. Collins[1], Maria Dall'Era[2], Alan Oglesby[3], Michael B. McGuire[4], Ramesh Pappu[3], Hong Kan[3] and Charles T. Molta[5]. [1]Washington Hospital Center, Washington, DC, [2]University of California, San Francisco, San Francisco, CA, [3]GlaxoSmithKline, Research Triangle Park, NC, [4]Medical Data Analytics, Parsippany, NJ, [5]GlaxoSmithKline, King of Prussia, PA.

Background/Purpose: Large-scale clinical trials have demonstrated the clinical efficacy of belimumab in patients with systemic lupus erythematosus (SLE). We examined clinical outcomes associated with 12 months of belimumab treatment in clinical practice settings in the United States (US).

Methods: This is a multi-center retrospective chart review from community-based rheumatology practices that treated >10 SLE patients annually and had >5 yrs of practice experience (OBSErve; GSK117295). Physicians randomly identified adult SLE patients who had received ≥8 infusions of belimumab as part of their usual care. Data were collected for the 6 months prior to belimumab initiation (baseline), for the first 6 months after initiation and for Months 6–12; data included demographics, disease characteristics, disease activity assessment scores (where available), and concomitant medications. The primary outcome measure was physician impression of change in SLE disease manifestations.

Results: This interim analysis at 12 months included 384 patients (female: 89.8%; mean age: 41.8 [standard deviation: 12.3] years; Caucasian: 51.6%; African-American: 25.5%; Hispanic: 16.7%; Other: 6.3%) enrolled by 60 rheumatologists from 21 states. During the 6–12 month follow-up period, 43 patients (11.2 %) discontinued belimumab. The most common reasons for discontinuation were patient request (37.2%), medication not effective (27.9%), lack of patient compliance (20.9%), disease progression (18.6%), loss of insurance/reimbursement (7.0%) and loss to follow-up or death (7.0%).

During Months 0–6, physicians' impression of change in SLE disease showed improvements of <20%, ≥20%, ≥50% and ≥80% in 10.7%, 88.3%, 47.1% and 11.2% of patients, respectively; no change was reported for

0.5% of patients, and 0.5% were considered to have worsened. Continued improvements were observed during Months 6–12 when improvements of <20%, ≥20%, ≥50% and ≥80%, beyond those observed at Month 6, were reported in 16.1%, 70.8%, 30.2% and 10.2% of patients, respectively; no change was reported for 9.9% of patients and 3% were considered to have worsened.

Overall, 297/384 patients (77.3%) received concomitant steroids at baseline; 104/297 patients (35.0%) were able to discontinue steroids altogether at 12 months. The mean steroid dose (prednisone equivalent) among steroid users at baseline and 12 months was 19.4 mg/day and 8.4 mg/day, respectively. During the 12 month period, 6 patients initiated steroid treatment.

For the 96 (25%) patients with SELENA-SLEDAI scores at 12 months, mean score was 12.5 at baseline, 6.0 at 6 months, and 5.1 at 12 months (59.2% reduction from baseline). From baseline to 12 months, mean Physician Global Assessment scale scores improved by 58.7% (n=100) and Patient Global Assessment scale scores improved by 61.5% (n=78).

Conclusion: Overall, physicians reported continued improvement in clinical outcomes and reduction in steroid use over 12 months of treatment with belimumab 10 mg/kg plus usual care, among patients receiving ≥8 belimumab infusions.

Correlation Of The Interferon Gene Signature With Systemic Lupus Erythematosus Disease Activity Is Dependent On The Associated Level Of The BAFF Gene Transcript. Michelle Petri[1], Laurence S. Magder[2], Hong Fang[1], Julie Czerkowicz[3], Andrea Dearth[3], Jadwiga Bienkowska[4], Norm Allaire[4], Patrick Cullen[3], Alice Thai[3] and Ann Ranger[3]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD, [3]Biogen Idec Inc, Cambridge, MA, [4]Biogen Idec Inc., Cambridge, MA.

Background/Purpose: The interferon alpha (IFN) gene signature is frequent in SLE (~50% of patients) and important in pathogenesis. However, multiple studies have found that the IFN signature does not predict flares. In SLE peripheral blood, the level of the B-cell activating factor (BAFF) transcript is highly associated with the IFN signature. We asked whether an association of the interferon gene signature with disease activity depended on the level of the BAFF transcript.

Methods: 292 patients (59% Caucasian, 34% African-American, 92% female, mean age 46 ±12 years) were enrolled in a prospective observational study. At baseline, gene expression levels were assessed in peripheral blood RNA samples using microarray (Affymetrix) and select transcripts validated with qPCR. The IFN signature "score" was calculated based on the geometric mean of the expression levels (chip signal intensity) of 16 IFN-induced genes and divided into low, medium and high groups. Patients were divided in subgroups based on BAFF and IFN signatures. Subgroups were compared with respect to frequency of clinical events in the next year. P-values were calculated using generalized estimating equations (SAS 9.2).

Results: Table 1 shows the strong correlation of the IFN signature with BAFF gene expression. Of those individuals with a high level of BAFF mRNA, 97% also had a high IFN signature.

Table 1. Number (%) of SLE Patients with Each Level of IFN Signature, by BAFF Levels

		IFN signature		
		Low	Medium	High
BAFF mRNA	Low (n=91)	77 (85%)	7 (8%)	7 (8%)
	Medium (n=88)	38 (43%)	8 (9%)	42 (48%)
	High (n=93)	1 (1%)	2 (2%)	90 (97%)

Because there were only 17 patients with medium IFN, they were pooled together with high IFN in Table 2 below.

Table 2. Proportion of Visits with Various Disease Manifestations, by IFN within BAFF Subgroups over 1 Year

	Low BAFF		Medium BAFF		High BAFF			
Disease activity	Low IFN (n=77) (304 total visits)	High IFN (n=14) (67 total visits)	Low IFN (n=38) (159 total visits)	High IFN (n=50) (210 total visits)	Low IFN (n=1) (4 total visits)	High IFN (n=92) (381 total visits)	P-value for association between IFN and item, controlling for BAFF	P-value for association between BAFF and item, controlling for IFN
Physician global assessment >1	8%	3%	24%	20%	0%	26%	0.37	0.0008
SLEDAI ≥2	34%	27%	55%	65%	0%	69%	0.55	0.0002
Urine protein/cr (≥0.5)	3%	0%	13%	14%	0%	14%	0.83	0.012
Anti-dsDNA ≥ 10	7%	7%	7%	37%	0%	36%	0.0070	0.074
C3 <79 mg/dl	3%	0%	4%	20%	20%	21%	0.018	0.028
C4 <12 mg/dl	3%	0%	7%	18%	0%	20%	0.14	0.023
ESR >20	32%	45%	50%	62%	0%	61%	0.053	0.068
SLEDAI Arthritis	1%	3%	6%	3%	0%	5%	0.84	0.29
SLEDAI Skin	19%	23%	29%	36%	0%	36%	0.28	0.19
SLEDAI Heme	3%	5%	2%	6%	0%	6%	0.27	0.88

In those patients with low or medium BAFF gene expression, there was no association between the IFN signature and global disease activity measures (such as PGA, SLEDAI). Thus, controlling for BAFF, the IFN signature was not related to global measures of disease activity (p=0.37 for PGA, p=0.55 for SLEDAI).

Conclusion: In this study, we found that the association of the IFN signature with SLE global disease parameters is dependent on the BAFF gene expression (with which it is closely correlated). The IFN gene signature, however, is associated with serologic activity (high anti-dsDNA and low complement), controlling for BAFF. These results may shed light on confusing data from anti-IFN clinical trials.

Effects Of Blisibimod, An Inhibitor Of B Cell Activating Factor, On Serum Immunoglobulins and Infection Risk In Patients With Systemic Lupus Erythematosus: Observations From The Placebo-Controlled Pearl-SC and Open-Label Extension Studies. Richard A. Furie[1], Matthew Thomas[2], Alvina Chu[3], Renee S. Martin[3], Colin Hislop[3] and Morton A. Scheinberg[4]. [1]The Feinstein Institute for Medical Research and North Shore-Long Island Jewish Health System, Lake Success, NY, [2]Health and Research Centre, Trivandrum, Kerala, India, [3]Anthera Pharmaceuticals Inc, Hayward, CA, [4]Rheumatology Hospital Abreu Sodre Pesquisa Clínica, São Paulo, Brazil.

Background/Purpose: To evaluate the effects of subcutaneously-administered blisibimod (A-623, AMG 623), an inhibitor of B-cell activating factor (BAFF), on IgG, IgM and infection risk in patients with systemic lupus erythematosus (SLE) during the phase 2b clinical trial PEARL-SC (NCT01162681) and the ensuing open-label extension (OLE) study (NCT01305746).

Methods: 547 SLE patients with anti-double-stranded DNA or anti-nuclear antibodies and SELENA-SLEDAI score ≥6 at baseline were enrolled into the PEARL-SC study, and randomized 1:1 to receive placebo or blisibimod administered at 1 of 3 dose levels, 100 mg weekly (QW), 200 mg QW, or 200 mg every 4 weeks. In the PEARL-SC study, subjects received blinded study drug for up to 52 weeks (with a median of 37 weeks) or until the last subject completed 6 months of study drug therapy. A total of 382 subjects enrolled in the OLE study and received blisibimod. The efficacy, safety and tolerability of blisibimod in the combined studies were evaluated through March 2013 using clinical evaluations, adverse event reporting and laboratory data.

Results: Consistent with the effects of blisibimod on inflammation biomarkers reported previously (total B cell counts, C3, C4), significant decreases in immunoglobulins IgG and IgM were evident in patients in the pooled blisibimod group compared with placebo from Week 8 through Week 52 (percent changes with blisibimod vs placebo in IgG= −14.1% vs −3.9%, and IgM= −34.6% vs −9.3%, p≤0.003, N=94 at Week 52). Similarly, significant decreases in anti-dsDNA antibody titers were observed with blisibimod from Week 4 through Week 52 (−23.5% vs 7.9%, p=0.008, N=90 at Week 52). The effects of blisibimod 200mg QW were similar to

those observed in the pooled blisibimod group. In addition, after the end of the placebo-controlled study, IgG, IgM, and anti-dsDNA levels continued to be lower compared with pre-treatment levels through Week 80 (changes in IgG= −10.7%, IgM= −34.6%, N=31; change in anti dsDNA= −26.6%, N=20).

There was no difference between treatments in the numbers of subjects reporting infections: placebo 62.0% and blisibimod 58.2%. Furthermore, the mean concentrations of IgG in patients who reported infections were similar between the pooled placebo group (14.6–16.2 g/L) and the pooled blisibimod group (12.9–16.6 g/L).

Blisibimod was safe and well-tolerated at all dose levels with no meaningful imbalances in serious adverse events or infections between blisibimod and placebo. Amongst the commonly-reported AEs, imbalance was observed only with injection site reactions (200mg QW blisibimod=15%, matched placebo=7%), but these were not serious or severe and did not result in discontinuation of treatment. During the placebo-controlled study, critically low IgG levels (<4g/L) were observed in 1/280 subjects in blisibimod group compared with 0/266 subjects on placebo.

Conclusion: In patients with SLE, blisibimod induces pharmacological effects on immunoglobulins that are consistent with a BAFF-mediated inhibition of B cells and plasma cells, without adversely impacting the risk of infection. These data support further evaluation of blisibimod in patients with SLE and other B cell-mediated diseases.

Administration Of AMG 557, a Human Anti-B7RP-1 (ICOSL) Antibody, Leads To The Selective Inhibition Of Anti-KLH IgG Responses In Subjects With SLE: Results Of a Phase 1 Randomized, Double-Blind, Placebo-Controlled, Sequential, Rising, Multiple-Dose Study.

Barbara Sullivan[1], Wayne H. Tsuji[2], Vishala L. Chindalore[3], Thomas D. Geppert[4], Alla Rudinskaya[5], Patricia Pardo[6], Alan Kivitz[7], C. Michael Neuwelt[8], Meggan Mackay[9], R. John Looney[10], J. Carter Thorne[11], Marilee Andrew[2], Greg Arnold[1], Michael Boedigheimer[1], Kit Chiu[1], Cherie Green[1], Arunan Kaliyaperumal[1], Christine Wang[1], Andrew Welcher[1] and James Chung[1]. [1]Amgen, Thousand Oaks, CA, [2]Amgen, Seattle, WA, [3]Anniston Medical Clinic PC, Anniston, AL, [4]Metroplex Clinical Research Center, LLC, Dallas, TX, [5]Danbury Hospital, Danbury, CT, [6]MRA Clinical Research, Miami, FL, [7]Altoona Center for Clinical Research, Duncansville, PA, [8]East Bay Rheumatology Research Institute, San Leandro, CA, [9]Feinstein Institute for Medical Research, Manhasset, NY, [10]University of Rochester, Rochester, NY, [11]Southlake Regional Health Centre, Newmarket, ON.

Background/Purpose: The interaction of inducible costimulator (ICOS) with its ligand, B7-related protein-1 (B7RP-1 or ICOSL), plays a role in T cell differentiation, cytokine production, and T cell dependent help for B cells. Blockade of the B7RP-1/ICOS pathway may be efficacious in treating SLE and other autoimmune diseases. AMG 557 is a human IgG2 monoclonal antibody that binds to B7RP-1, inhibiting its interaction with ICOS. Safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of multiple dose administration of AMG 557 were assessed in SLE subjects.

Methods: Fifty-six subjects with mild, stable SLE received multiple doses of AMG 557 or placebo in a 3:1 ratio ranging from 6 mg to 210 mg SC (every 2 weeks × 7 doses). Subjects received an intradermal injection of the neoantigen keyhole limpet hemocyanin (KLH) on days 57 and 85 (1 mg, Biosyn™). Adverse events, safety laboratory tests and disease activity were assessed. Serum AMG 557 concentrations and anti-AMG 557 binding and neutralizing antibodies were measured during the study. B7RP-1 target occupancy (TO) and an immunophenotyping panel selected for SLE and the ICOS pathway were measured in whole blood (WB) by flow cytometry. Serum protein and WB RNA biomarkers associated with SLE were measured by ELISA and microarray, respectively. Measurement of serum anti-KLH IgG and IgM antibodies was conducted by a flow cytometric bead array assay.

Results: The tolerability of multiple doses of AMG 557 up to 210 mg SC was acceptable. Most adverse events were grade 1 and 2 and no grade 3 adverse events were attributed to AMG 557. Serious adverse events were reported for 5 subjects (12%) who received AMG 557 and 2 subjects (14%) who received placebo. Serum AMG 557 exposure increased greater than dose-proportionally from 6 – 70 mg SC and approximately dose-proportionally from 70 – 210 mg SC. No subjects tested positive for neutralizing anti-AMG 557 antibodies. Mean TO was greater than 50% in the 18 mg dose group (and above) and was greater than 90% from days 71 – 141 in the 140 mg group and from days 5 – 169 in the 210 mg group. A significant reduction in anti-KLH IgG response was observed in the subjects treated with AMG 557 compared to subjects treated with placebo ($p = 0.0044$). No difference in anti-KLH IgM response was observed between the AMG 557 and placebo groups. A consistent effect of AMG 557 on SLE disease activity or SLE biomarkers was not observed.

Conclusion: Multiple doses of AMG 557 up to 210 mg SC demonstrated an acceptable safety profile. AMG 557 showed dose-proportional PK above the 70 mg dose level. Binding of AMG 557 to B7RP-1 was dose-related, reversible, and reached maximum observed levels in the 140 mg SC and greater dose groups. Significant and selective reduction in the anti-KLH IgG response was observed with AMG 557 treatment, without reduction in the anti-KLH IgM response, demonstrating a pharmacodynamic effect of multiple doses of AMG 557 in subjects with SLE and consistent with the biology of the ICOS pathway. No impact on disease activity was observed in these mild, stable SLE patients. These data support further evaluation of AMG 557 in SLE.

Identifying Trajectories of Lung Function Change Over Time in Scleroderma.

Ada Man[1], Todd Davidyock[1], Laura Western[2], Michael Ieong[1], Yuqing Zhang[1] and Robert W. Simms[1]. [1]Boston University School of Medicine, Boston, MA, [2]University of Maryland, Baltimore, MD.

Background/Purpose: Interstitial lung disease (ILD) is a leading cause of scleroderma (SSc) mortality, yet little is known about how changes in lung function over time varies among patients with SSc. We sought to identify trajectories of change in % predicted forced vital capacity (% pFVC) and their associated clinical variables in SSc patients over a 12-year period.

Methods: FVC values were obtained from serial pulmonary function tests performed as part of clinical care in SSc patients at Boston University Medical Center from January 2000-August 2012. SSc diagnoses were confirmed and clinical data obtained by chart review. Patients with ≥3 FVC values were included. We described the trajectories of % pFVC change over time using a group-based mixture model (SAS Proc Traj) that identifies relatively homogenous clusters of % pFVC change within a study population. Baseline demographic and clinical variables were examined for association with the identified trajectories of change using multivariable polytomous regression.

Results: In 253 SSc patients (1613 FVC values) we identified 4 trajectory groups of % pFVC change over time: fast decline (13%), slow decline (21%), improving (45%), and normal stable (21%) (Figure). Mean

baseline % pFVC was lowest in the fast decline (56.5±16) and highest in the normal stable group (100±11.9). At baseline, the fast decline group had the highest proportion of males, African-Americans, patients with diffuse subtype, overlap features, anti-Scl70 positivity, ILD, pulmonary hypertension, myositis, and cyclophosphamide use. The normal stable group had the highest proportion of anti-centromere positive patients. In the multivariable model, younger age at baseline and at diagnosis, male sex, ILD and cyclophosphamide use were significantly associated with fast decline. Diffuse subtype was inversely associated with being in the normal stable group. Pulmonary hypertension was non-significantly associated with fast decline.

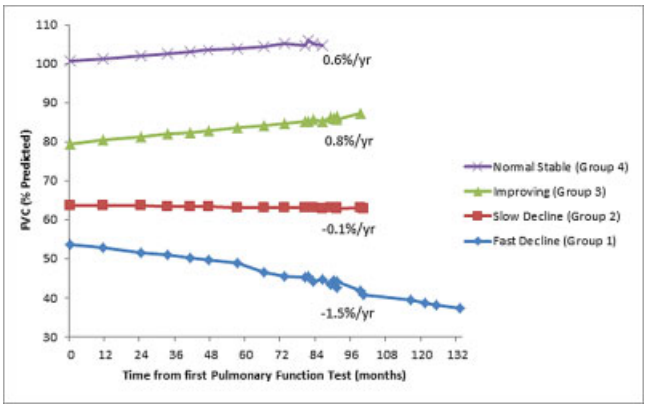

Figure. FVC Trajectories

Conclusion: SSc patients receiving standard care in a tertiary care setting presented 4 distinct trajectories of %pFVC change, with approximately 1/3 of them experiencing % pFVC decline over time. As expected, low % pFVC and ILD at baseline were associated with fast decline. Younger age, younger age at diagnosis and male sex were also associated with fast decline and are factors not consistently noted in previous studies. The identification of distinct trajectories of lung function in SSc confirms what has been anecdotally observed and allowed us to estimate the proportions of such groups. Studying risk factors according to group-based modeling may have advantages over traditional methods and may be useful in future studies of biomarkers and other patient centered outcomes.

Prediction Of Pulmonary Complications In Systemic Sclerosis - Model Development and Validation. Svetlana I. Nihtyanova[1], Benjamin E. Schreiber[2], Voon H. Ong[3], John G. Coghlan[4], Athol U. Wells[5] and Christopher P. Denton[1]. [1]Royal Free and University College Medical School, London, United Kingdom, [2]National Pulmonary Hypertension Service, London, United Kingdom, [3]The Royal Free and University College Medical School, London, United Kingdom, [4]The Royal Free Hospital NHS Foundation Trust, London, United Kingdom, [5]Department of Radiology, London, United Kingdom.

Background/Purpose: Pulmonary complications contribute substantially to systemic sclerosis (SSc) associated morbidity and are the most frequent disease-related cause of death. We explore predictors of clinically significant pulmonary fibrosis (csPF) and pulmonary hypertension (PH) in a large single-centre cohort of unselected SSc patients.

Methods: The study cohort consisted of consecutive patients with disease onset between 1995 and 1999. Multivariable Cox regression was used for model building. Continuous variables were categorised and risk points, based on the β values associated with the predictor variables were calculated. Internal validation of the model was done in an independent second cohort of consecutive SSc subjects with disease onset between 2000 and 2003.

Results: A total of 398 SSc patients, 146 with diffuse cutaneous (dc)SSc and 252 with limited cutaneous (lc)SSc, formed the predictor model derivation cohort, while 279 (130 dcSSc, 149 lcSSc) were used for model validation. Frequency of csPF was very similar in the derivation cohort (22% of lcSSc,42% of dcSSc) and the validation cohort (21% of lcSSc and 40% of dcSSc). Cumulative frequency of PH was slightly lower in the validation cohort (9% in lcSSc and 10% in dcSSc) compared to the derivation cohort (17% of lcSSc and 12%of dcSSc), potentially reflecting a shorter follow-up period.

In a multivariable analysis, significant positive predictors of csPFwere dcSSc subset (HR 1.77, p=0.027), age at onset (HR 1.02, p=0.031) and anti-topoisomerase I antibody (ATA), which was time-dependent, therefore we used its interaction term with disease duration in years (HR 1.16, p=0.001). Significant negative predictors were forced vital capacity (FVC) (HR 0.97, p=0.003), carbon monoxide diffusing capacity (DLCO) (HR 0.97, p=0.006), and anti-centromere antibodies (ACA)(HR 0.19, p=0.003). The final model using categorised variables and risk points is shown in Table1. The AUC for the model using risk points was 0.81. Risk score was calculated for all patients from the validation cohort and the AUC was 0.82.

For the PH prediction model the variables that demonstrated significant association in a multivariable analysis were age (HR 1.03, p=0.026), DLCO (HR 0.94, p<0.001), creatinine (HR 1.004, p=0.026), ATA (HR 0.41, p=0.04), anti-RNA polymerase antibody (HR 3.23, p=0.023), anti-U3RNP antibody (HR 3.92, p=0.017) and presence of renal crisis (SRC) within the first 5 years of disease (HR 0.004, p=0.009). In addition, there was one significant interaction in the model between SRC and DLCO (HR 1.08, p=0.019). Details of the model using categorical variables and risk points are presented in Table 1. The model using risk scores had AUC 0.79 which was replicated in the validation cohort.

Table 1. Multivariable analysis with categorical variables and risk score points for survival, pulmonary fibrosis and pulmonary hypertension

	Variables	β	HR	95.0% CI for HR		p-value	Points
Pulmonary fibrosis	DcSSc	0.526	1.692	1.052	2.721	0.03	1
	Age>55 years	0.306	1.358	0.866	2.127	0.182	1
	FVC 65–80%	0.542	1.719	1.005	2.939	0.048	1
	FVC<65%	1.157	3.18	1.765	5.727	<0.001	2
	DLCO≤55%	1.108	3.027	1.752	5.231	<0.001	2
	ACA	−1.728	0.178	0.061	0.519	0.002	−3
	ATAxT (5 years)	0.707	2.028	1.291	3.186	0.002	1
Pulmonary hypertension	Age>55years	0.565	1.759	0.991	3.124	0.054	1
	DLCO 55–65%	1.247	3.481	1.161	10.442	0.026	1
	DLCO<55%	2.492	12.089	4.591	31.83	<0.001	2
	Creatinine>85μmol/L	0.43	1.538	0.805	2.939	0.192	0
	ATA	−0.926	0.396	0.172	0.915	0.03	−1
	ARA	0.681	1.975	0.839	4.649	0.119	1
	AFA	1.155	3.175	1.192	8.454	0.021	1
	SRC5y	1.541	4.668	0.847	25.715	0.077	2
	SRC5y*DLCO 55–65%	−1.526	0.217	0.015	3.097	0.26	−2
	SRC5y*DLCO<55%	−2.754	0.064	0.006	0.674	0.022	−3

Conclusion: We present predictive models that could be used as clinical tools in unselected SSc cases for patient risk stratification and could facilitate cohort enrichment for event driven studies.

Pericardial Effusions Are Not a Poor Prognostic Factor In Systemic Sclerosis Patients With Pulmonary Hypertension. Elana J. Bernstein[1], Jessica K. Gordon[1], Wei-Ti Huang[1] and Virginia D. Steen[2]. [1]Hospital for Special Surgery, New York, NY, [2]Georgetown University Medical Center, Washington, DC.

Background/Purpose: Pulmonary hypertension (PH) (defined as a mean pulmonary arterial pressure ≥ 25 mmHg on right heart catheterization) is a leading cause of death in patients with systemic sclerosis (SSc). Pericardial effusions (PEf) have been shown to be a poor prognostic indicator in patients with idiopathic pulmonary arterial hypertension (PAH). The World Health Organization (WHO) classifies PH into 5 groups based on etiology. SSc patients most commonly fall into groups 1 (PAH), 2 (PH due to left heart disease), and 3 (PH due to lung disease or hypoxemia). Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma (PHAROS) is a multicenter, prospective registry of SSc patients with PH (SSc-PH) or at high risk for the development of PH. The aim of this study was to compare the survival of SSc-PH patients with PEf

to the survival of SSc-PH patients without PEf, and to describe the frequency and associations of PEf in SSc-PH patients.

Methods: This is a prospective cohort study of 260 SSc-PH patients who were enrolled in the PHAROS registry between 2006 and 2012. Statistical analysis was performed using the Kaplan-Meier method and chi-square test.

Results: The mean age of subjects was 60 years (± 11); 81.6% were female, 65.0% had limited cutaneous (lc) SSc, 29.5% were anti-centromere antibody (ACA) positive, and 65.8% had WHO group 1 PH. The mean duration of follow-up in PHAROS was 2.3 years (± 1.9) (see Table). The 3-year cumulative survival rate was 74.8%. Fifty-nine (22.7%) patients died during the course of follow-up. Forty-eight percent of all SSc-PH patients had a PEf at some point in their disease course – 53.0% in group 1, 37.2% in group 2, and 39.5% in group 3 (p=0.086). There was no statistically significant difference in survival between the SSc-PH patients with PEf and those without across the entire cohort, or when analyzing WHO groups 1, 2, and 3 separately. Patients with ACA were statistically significantly more likely to have had a PEf than patients with anti-Scl-70 antibody or other SSc-specific autoantibodies (58% vs. 31% vs. 47%, respectively, p<0.04). The frequency of PEf was not statistically significantly different between patients with lcSSc and diffuse cutaneous SSc; between patients of different races; or between patients who died from SSc-related causes and those who died from non-SSc-related causes.

Table. Characteristics of SSc Patients in PHAROS

Characteristics	SSc Patients (N=260)
Age – yr, mean ± SD	60.4 ± 11.3
Duration of follow-up – yr, mean ± SD	2.3 ± 1.9
Female sex – no. (%)	200/245 (81.6)
White race – no. (%)	184/244 (75.4)
Limited cutaneous SSc – no. (%)	165/254 (65.0)
WHO group 1 (PAH)	171/260 (65.8)
WHO group 2 (PH due to left heart disease)	45/260 (17.3)
WHO group 3 (PH due to lung disease or hypoxemia)	44/260 (16.9)
Pericardial effusion – no. (%)	121/252 (48.0)
Anti-centromere antibody – no. (%)	71/241 (29.5)
Anti-Scl-70 antibody – no. (%)	33/241 (13.7)
Deceased – no. (%)	59/260 (22.7)

Conclusion: Unlike in idiopathic PAH, there was no difference in survival between SSc-PH patients with PEf and those without. Thus, although PEf are common in SSc patients as a whole (19% in SSc patients at high risk for PH) – and even more common in SSc-PH patients – they are not a poor prognostic sign in SSc patients with WHO groups 1, 2, or 3 PH. SSc-PH patients with ACA were more likely to have PEf than those with anti-Scl-70 or other SSc-specific autoantibodies. The clinical significance of this association will continue to be examined via long-term follow-up of this cohort.

Plasma MCP-1 and IL-10 Levels Predict Long-Term Progression Of Interstitial Lung Disease In Patients With Early Systemic Sclerosis. Minghua Wu, Claudia Pedroza, Gloria Salazar, Xiaodong Zhou, John D. Reveille, Maureen D. Mayes and Shervin Assassi. University of Texas Health Science Center at Houston, Houston, TX.

Background/Purpose: The currently available clinical markers are not reliable predictors of long-term progression of systemic sclerosis (SSc) related interstitial lung disease (ILD). SSc patients have a distinct cytokine profile but the predictive significance of these cytokines for long-term progression of ILD has not investigated in early SSc cohorts. Herein, we examine the predictive significance of 11 key cytokines for progression of ILD and survival in a large early SSc cohort.

Methods: The plasma levels of 9 key Th1/Th2 cytokines (IL-6, MCP-1, TNF-α, IL-8, IL-5, IL-12, IL-10, IL13, and IL1β) and two interferon inducible chemokines (IP-10 and ITAC) were determined in the baseline samples of 266 SSc patients enrolled in the GENISOS cohort. The primary outcome was decline in forced vital capacity (FVC% predicted) over time. A total of 1016 FVC measurements fulfilled the American Thoracic Society criteria and were included in the analysis. The mean follow-up time was 4.4 years. The predictive significance for long-term change in FVC was investigated by a joint analysis of longitudinal measurements (sequentially obtained FVC% predicted) and survival data. This approach allows inclusion of all FVC measurements and accounts for dependency on survival. The primary cultured skin fibroblasts from SSc patients (n=10) and matched controls (n=10) were stimulated with MCP-1 for 24 and 48hrs and measured TGF- β1 protein levels by ELISA.

Results: Diffuse skin involvement was present in 156 patients (59%) and mean disease duration at enrollment was 2.5 years. After adjustment for age, gender, and ethnicity, MCP-1 and IL-10 were significant predictors of ILD progression. MCP-1 predicted faster decline in FVC% predicted (b=−0.57, 95% CI: −1.11–−0.04, p=0.032) while IL-10 predicted a slower decline in FVC% (b=0.26, 95% CI: 0.06–0.46, p=0.01) and had a protective effect. The predictive significance of MCP-1 and IL-10 did not change substantially in a multivariable that included both cytokines in addition to age, gender, and ethnicity (b=−0.64, p=0.014 and b=0.26, p=0.008, respectively).

The other investigated cytokines did not have independent predictive significance for ILD progression. Importantly, IL-6 did not predict faster decline in FVC% predicted (p=0.35).

Plasma MCP-1 was also predictive of poorer survival (HR: 1.93, 95% CI: 1.04 – 3.58, p= 0.032) while IL-10 did not predict survival.

MCP-1 and IL-10 levels were also determined in plasma from 97 age-, gender-, and ethnicity-matched unaffected controls. Patients had higher MCP-1 and IL-10 levels than unaffected controls (p= 0.001and p=0.002, respectively).

In-vitro experiments with skin fibroblasts showed stimulation of TGF-β1 protein production with MCP-1 in patients and control fibroblasts, confirming the profibrotic effect of this cytokine.

Conclusion: MCP-1 is an important pro-fibrotic cytokine that predicts faster ILD progression and poorer survival in SSc while IL-10 predicts a slower ILD progression supporting the previously in-vitro studies indicating an anti-fibrotic effect of this cytokine. These findings can have important implications for drug and biomarker development in SSc related ILD.

Autoantibodies To RuvBL1 and RuvBL2: A Novel Systemic Sclerosis-Related Antibody Associated With Diffuse Cutaneous and Skeletal Muscle Involvement. Kenzo Kaji[1], Noreen Fertig[2], Thomas A. Medsger Jr.[2], Takashi Sathoh[3], Kana Hoshino[3], Yasuhito Hamaguchi[1], Minoru Hasegawa[1], Mary Lucas[2], Andrew Schnure[2], Fumihide Ogawa[4], Shinichi Sato[5], Kazuhiko Takehara[1], Manabu Fujimoto[1] and Masataka Kuwana[3]. [1]Kanazawa University Graduate School of Medical Sciences, Kanazawa, Japan, [2]University of Pittsburgh, Pittsburgh, PA, [3]Keio University School of Medicine, Tokyo, Japan, [4]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [5]The University of Tokyo, Tokyo, Japan.

Background/Purpose: Detection of serum autoantibodies is useful in diagnosis, disease subgrouping, and prediction of subsequent organ involvement and prognosis in patients with systemic sclerosis (SSc). Currently, SSc-related autoantibodies consisted of at least 9 specificities, which are identified in ~80% of the entire SSc population, suggesting the possibility that other autoantibodies remain undiscovered. In this study, we have identified a novel SSc-related antibody against a complex consisting of RuvBL1 and RuvBL2 (RuvBL1/2) and evaluated its clinical correlations.

Methods: We first analyzed 316 consecutive patients with SSc, 290 disease controls including, patients with SLE, PM, DM, RA, interstitial lung disease alone, or autoimmune hepatitis, and 50 healthy subjects (Kanazawa cohort). Autoantibody specificities were analyzed using RNA and protein immunoprecipitation assays. Autoimmune targets were affinity-purified using patients' sera and subjected to liquid chromatography-mass spectrometry. SSc patients in two additional cohorts (Keio and Pittsburgh) were also included in analysis for evaluating prevalence and clinical correlations.

Results: By protein immunoprecipitation assay, 6 SSc sera (1.9%) reacted with doublets with molecular weights around 50 kDa. This antibody specificity was not detected in any sera obtained from a total of 290 disease controls or 50 healthy controls. Liquid chromatography-mass spectrometory of the partially purified autoantigen and additional immunoblots-based analysis revealed that this antibody specificity recognized RuvBL1/2, which is involved in many important cellular processes, such as transcription and DNA repair. Anti-RuvBL1/2 antibody was also found in 4 (1.5%) of 272 consecutive SSc patients in the Keio cohort, and in 5 (1.1%) of 463 consecutive SSc patients in the Pittsburgh cohort. In all three cohorts, SSc in overlap was the predominant disease subset in patients with anti-RuvBL1/2 ($P < 0.0001$). Diffuse skin thickening was more common in patients with anti-RuvBL1/2 in general and in those with SSc in overlap, compared to those without ($P < 0.04$). In terms of organ involvement, skeletal muscle involvement was frequent in patients with anti-RuvBL1/2 than those without ($P < 0.0003$). When we examined potential differences in clinical correlations between anti-RuvBL1/2 and other SSc-related antibodies associated with inflammatory myopathy, such as anti-PM-Scl and anti-Ku, age at onset was older and the proportion of males was higher in patients with anti-RuvBL1/2 than in those without ($P = 0.0001$ and 0.002, respectively). In patients with anti-RuvBL1/2, diffuse skin thickening was more prevalent ($P = 0.004$), the maximum mRSS in patients with diffuse cutaneous involvement was greater ($P = 0.001$), and dermatomyositis rashes were less common ($P = 0.01$), compared to patients with anti-PM-Scl or anti-Ku.

Conclusion: We have identified a novel SSc-related antibody reactive with a RuvBL1/2 complex, which is associated with a unique combination of clinical features, including myositis overlap and diffuse cutaneous involvement.

Treatment Strategies and Outcomes In Patients With Systemic Sclerosis and Acute Myocardial Infarction. Priya Prakash, Dhaval Kolte, Sahil Khera, Jagadish Khanagavi, Marjan Mujib, Chandrasekar Palaniswamy, Farrah Gutwein, Sachin Sule, Wilbert S. Aronow, William H. Frishman and Julia Ash. New York Medical College, Valhalla, NY.

Background/Purpose: Systemic Sclerosis (SSc) is associated with an increased risk of cardiovascular diseases, including acute myocardial infarction (AMI). However, whether SSc influences treatment choice and in-hospital outcomes in patients with AMI remains unknown.

Methods: We used the 2002–2010 Nationwide Inpatient Sample databases to identify all patients aged ≥18 years with the principal diagnosis of AMI using International Classification of Diseases, Ninth Edition, Clinical Modification (ICD-9-CM) code 410.xx. Secondary diagnosis of SSc was confirmed with ICD-9-CM code 710.1. Patients with rheumatoid arthritis (714.0–714.2), systemic lupus erythematosus (710.0), dermatomyositis (710.3) and polymyositis (710.4) were excluded. Multivariable logistic regression was used to compare treatment choice and outcomes between AMI patients with and without SSc.

Results: From 2002–2010, among 5,966,599 patients with AMI, 3,890 (0.07%) had SSc. Patients with SSc were more likely to be younger, women, white and had a lower prevalence of smoking, dyslipidemia, obesity, hypertension, diabetes, known coronary artery diseases, carotid artery diseases, and a higher prevalence of congestive heart failure, peripheral vascular disease, chronic kidney disease, pulmonary circulation disorders, atrial fibrillation, atrioventricular block, deficiency anemia, chronic blood loss anemia, hypothyroidism and coagulopathy. SSc patients were more likely to receive medical therapy alone (OR 1.20, 95% CI 1.10–1.32, p<0.001) and thrombolysis (OR 1.47, 95% CI 1.12–1.92, p=0.005), and less likely to receive coronary artery bypass grafting (CABG) (OR 0.55, 95% CI 0.45–0.68, p<0.001), as compared to those without SSc. Utilization of percutaneous coronary intervention was similar in AMI patients with and without SSc (OR 0.97, 95% CI 0.88–1.06, p=0.486). Overall risk-adjusted in-hospital mortality was higher in patients with SSc (OR 1.60, 95% CI 1.40–1.84, p<0.001), as compared to those without SSc. Patients with SSc had less cardiogenic shock (OR 0.50, 95% CI 0.39–0.64, p<0.001), more gastrointestinal bleeding (OR 1.65 95% 1.38–1.97, p<0.001), and longer average length of stay (5.9±7.1 versus 5.1±6.1 days, p<0.001). Incidence of acute stroke was similar in AMI patients with and without SSc (OR 0.85, 95% CI 0.61–1.17, p=0.321).

Conclusion: In patients with AMI, SSc is associated with an increased use of medical therapy alone and thrombolysis, and lesser use of CABG. Compared to patients without SSc, SSc patients with AMI have higher in-hospital mortality, more gastrointestinal bleeding, less cardiogenic shock and longer length of stay.

Background/Purpose: To evaluate short and long-term response to biological therapy in uveitis associated to Behçet's syndrome refractory to standard systemic treatment.

Methods: Multicenter study of 124 patients followed in uveitis units from 38 hospitals. All of them presented inadequate response to conventional therapy with corticosteroids and at least 1 systemic immunosuppressive drug.

The degree of ocular inflammation was evaluated according to "The Standardization of Uveitis Nomenclature (SUN)" (Am J Ophthalmol 2005; 140: 509–516) and macular thickness by optical coherence tomography (OCT). Comparisons were made between baseline and 1st week, 1st month, 6th month, 1st year, 2nd year, 3rd year and 4thyear. Statistical analysis was

performed using the software STATISTICA (StatSoft Inc. Tulsa, Oklahoma, USA). **Results** were expressed as mean±SD for variables with a normal distribution, or as median [25th-75th interquartile range (IQR)] when they were not normally distributed. The comparison of continuous variables was performed using the Wilcoxon test.

Results: We studied 124 patients/221 affected eyes (68 men/56 women) with a mean age of 38.6±10.4 years (range 10–67). HLA-B51 was positive in 66.1%. Besides oral steroids and before biologic therapy onset patients had received methylprednisolone i.v. boluses (34 patients), cyclosporine A (CyA) (102), methotrexate (MTX) (62) or azathioprine (AZA) (66). Anti-TNF drugs were the first choice biological agents; Infliximab (IFX) in 77 cases (62%) and adalimumab (ADA) in the remaining 47 cases (38%). They were used in 25 cases as monotherapy or in combination with: CyA (52 cases), MTX (27), AZA (17), mycophenolate (1), tacrolimus (1) or cyclophosphamide (1). The IFX regimen more frequently used were 5 mg/kg /i.v./every 4–8 weeks and ADA 40 mg/sc/EOW. In cases of refractory uveitis or intolerance to a 1stbiologic other agents were used; namely: Golimumab (4 cases), Tocilizumab (1 case), rituximab (1 case) and etanercept (1 case). The mean follow-up of anti-TNF therapy was 35.9±20.3 months. Visual acuity (VA), Tyndall, vitritis and OCT showed a rapid and statistically significant improvement at the 1^{a} week. From biological onset to 2 years mean improvement was observed in VA from 0.5±0.3 to 0.7±0.3 ($p<0.01$); tyndall from a median [IQR] of 1 [0–2] to 0 [0–0] ($p<0.01$) and vitritis, from a median [IQR] of 1 [0–2] to 0 [0–0] ($p<0.01$). At baseline, 50 patients, (80 eyes) had macular thickening (OCT>250μ) and 35 patients (49 eyes) had cystoid macular edema (CME) (OCT>300μ). The CME improved from 420±119.5 microns to 282.5±55 microns at 2 years ($p<0.01$).

The more severe side-effects observed were milliary tuberculosis and fatal lymphoma (in one case each).

	Basal active patients, N/ active eyes (%)	**1 week** active eyes (%)	**1 month** active eyes (%)	**6 months** active eyes (%)	**1 year** active eyes (%)	**2 years** active eyes (%)	**3 years** active eyes (%)	**4 years** active eyes (%)
Anterior inflammation (Tyndall)	80/57 %	51%	32.3%	19.3%	9.2%	11.7%	5.7%	6.1%
Vitritis	96/64.4%	58.4%	42.8%	24.6%	16.9%	13.9%	9.4%	5.8%
Choroiditis	28/17.6%	15.1%	12.1%	4.1%	2.5%	1.7%	0%	0%
Retinitis	45/30.7%	24.5%	14.3%	2.8%	0.5%	0.6%	1.1%	0%
Retinal vasculitis	89/61.1%	56.5%	34.8%	15.7%	7.1%	9.7%	8.2%	2.3%
Macular thickness ≥ 250 microns	55/61.4%	62.2%	56.5%	48.3%	43.5%	50%	27.3%	37.5%

Conclusion: Biological therapy, especially IFX and ADA, yields short and long-term efficacy and has a relatively safety profile in uveitis refractory to standard systemic treatment of Behcet's syndrome.

Ethnicity-Related Differences In Behçet's Disease In a French Multiethnic Country. David Saadoun[1], Mathieu Resche Rigon[1], Bertrand Wechsler[2], Du Le Thi Huong[3], Jean-Charles Piette[4] and Patrice P. Cacoub Sr.[4]. [1]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [2]CHU Pitié-Salpêtrière, Paris, France, [3]Groupe Hospitalier Pitié-Salpétrière, Paris, France, [4]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France.

Background/Purpose: It has been suggested that Behçet's disease (BD) varies in its phenotypic expression in different ethnies and in different countries indicating that both environmental and genetic factors play a role in the aetiology of the condition. However, most of the evidence supporting these propositions arises from observational case series, which are subject of many sources of bias.

Objective. The present study was undertaken to investigate potential any ethnicity-related differences in the phenotype and prognosis of BD patients in a French multiethnic country.

Methods: We analyzed the phenotype and prognosis of 769 consecutive patients [median (IQR) age at diagnosis of 30.9 (24.9–37.2) years with 535 (69.6%) male] fulfilling the international criteria of classification for BD, in the 3 largest ethnic groups of our cohort [European (n=369), North African (n=350) and sub Saharan African (n=50)].

Results: Sub Saharan African BD patients had a higher frequency of arterial involvement (28% vs 13.2% vs 10.3%, p=0.004), a higher frequency of CNS involvement (48% vs 32.3% vs 29.5%, p=0.035), a higher frequency of cardiac involvement (16% vs 7.1% vs 4.3%, p=0.007), a higher rate of death (12% vs 6% vs 3.5%, p=0.029) and a lower frequency of HLA B51 allele (29.4 % vs 49.2% vs 55.8%, p=0.009) compared to those from north Africa and Europe, respectively. The 15-year mortality rate was of 19% in sub Saharan Africa's BD patients compared to 9% and 6% in those from north Africa and Europe, respectively (p=0.015). Logistic regression analysis showed that male gender (HR: 4.94, CI: 1.53–16.43), and arterial involvement (HR: 2.51, CI: 1.07–5.90) were independently associated with mortality.

Conclusion: In a French multiethnic country, sub Saharan African BD patients exhibited a worse prognosis which is likely related to their vascular phenotype.

Behçet′s Disease Activity: An Important Factor For Immunogenicity Of Unadjuvanted Influenza A/H1N1 Vaccine. Leandro L. Prado[1], Carla G.S. Saad[1], Julio C. B. Moraes[1], Ana Cristina Medeiros Ribeiro[1], Nadia E. Aikawa[1], Clovis A. Silva[1], Claudia G Schainberg[1], Percival D Sampaio-Barros[1], Alexander R. Precioso[2], Maria A. Ishida[3], Eloisa Bonfa[4] and Celio Goncalves[1]. [1]Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [2]Instituto Butantan, São Paulo, Brazil, [3]Instituto Adolfo Lutz, São Paulo, Brazil, [4]University of Sao Paulo, Rheumatology Division, São Paulo, Brazil.

Background/Purpose: Routine annual influenza vaccination is the most effective method for preventing influenza virus infection and its complications. Influenza vaccine is recommended for all persons aged 6 months and older who do not have contraindications to vaccination. Despite those recommendations, there are no studies evaluating influenza vaccination influences on clinical manifestations in Behçet′s Disease (BD). Our objective is to evaluate short-term safety and efficacy of influenza A/California/7/2009/H1N1-like virus single vaccination and the potential deleterious effect of the vaccine in BD patients compared to healthy controls.

Methods: Eighty-five BD patients and 85 gender/age-matched healthy controls were evaluated before and 21-days after vaccination with unadjuvanted influenza A/H1N1-like virus regarding seroprotection/seroconversion, factor increase in geometric mean titre (FI-GMT), C-reactive-protein (CRP) levels and side effects. Brazilian BD Current Activity Form (BR-BDCAF) was used to assess BD activity.

Results: Seroconversion rate was significantly lower in BD patients compared to controls (69 vs. 83%, p=0.04). Similar rates of seroprotection (71 vs. 83%, p=0.06) and FI-GMT (p=0.96) were found. Interestingly, BD patients without seroconversion had significantly higher mean BR-BDCAF scores (6.0 ±4.1 vs. 3.8 ±4.3, p=0.009), with a significantly increased rate of active BD in this group (73 vs. 39%, p=0.003). Disease duration and glucocorticoid, immunosuppressors or TNF-blockers therapies did not affect seroconversion (p>0.05). Regarding side effects, patients had significantly increased rate of mild and transient reactions, such as fever (7 vs. 0%, p=0.02), headache, (27 vs. 12%, p=0.02), arthralgia (24 vs. 0.2%, p<0.001) and myalgia (25 vs. 9%, p=0.004). Moderate and severe side effects were not reported.

Conclusion: This is the first study to indicate appropriate influenza A/H1N1 vaccine safety and efficacy in BD, reinforcing its recommendation. Disease activity impaired humoral response to vaccination. Further studies are necessary to determine if a second dose would increase seroconversion rates in these patients.

An Outcome Survey Of 40 Patients With Budd-Chiari Syndrome Due To BEHÇET'S Syndrome Followed By A Single Center. Emire Seyahi, SerdaL Ugurlu, Erkan Caglar, Fatih Kantarci, Abdullah Sonsuz, Sebahattin Yurdakul and Hasan Yazici. Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey.

Background/Purpose: Budd-Chiari syndrome is a rare complication of BS with a frequency of < 1 %, and carries a high mortality rate. In a previous survey out of 14 Behcet patients with BCS, 10 (60 %) had died with a mean survival of 10 months (1). We assessed the outcome in a cohort of 40 BS patients with BCS diagnosed and followed by a single center between 1977 and 2012.

Methods: We reviewed records of about 8000 patients with BS who were registered at the multidisciplinary clinic at Cerrahpasa Medical Faculty between July 1977 and December 2012 (study closure). We identified 40 (37 M/ 3 F) patients who were diagnosed with BCS. The outcome of 40 patients was evaluated between September and December 2012. Attempts were made to contact every patient in this cohort by telephone calls or home visits. All thus contacted were called back to the outpatient clinic for a clinical evaluation, blood tests and hepatic Doppler USG. Hepatic Doppler USG specifically analyzed hepatic veins patency, intrahepatic collateral formation, caudate lobe hypertrophy, hepatomegaly, splenomegaly, and portal vein dilatation. Survival data were assessed by Kaplan-Meier analysis.

Results: A total of 40 BS patients with BCS were surveyed. The mean age of the patients at diagnosis of BS was 28.7 ± 8.6 years, and the mean age at the onset of BCS was 30.3 ± 8.5 years. A total of 35 patients received immunosuppressive treatment (cyclophophamide n= 31; azathioprine n =4) after being diagnosed with BCS. Only 2 patients had surgical interventions. One patient had percutaneous transluminal angioplasty another transjugular intrahepatic portosystemic shunting. Fifteen patients received anticoagulant treatment. Apart from this, 3 patients were treated with thrombolytic treatment which was ineffective. Additionally, 17 patients received diuretics. By the end of the study, we had the outcome information in all patients: 20 patients (19 M/1F) (50 %) had died, while the remaining 20 were alive. Of these, 17 could be re-evaluated in the clinic. Among the patients who had died, the median survival time was 8 months (IQR: 4– 54 months). The causes of mortality were mainly due to hepatic failure (n =17) (85 %). Additionally, one had died due to myocardial infarction, another due to suicide and another with unknown cause. Postmortem study was available in one patient. Mortality rate among patients diagnosed between 1977–2000 (10/15, 67 %) was somewhat higher (Log rank P= 0.75). compared to those diagnosed between 2001–2012 (10/25, 40 %), however, the difference did not reach statistical significance in the survival analysis. Final hepatic USG among 17 patients who survived showed occlusion in one ore more hepatic veins in 12, caudate lobe hypertrophy in 8, splenomegaly in 3, and portal vein dilatation in 3. It was noted that all 17 patients had multiple intrahepatic veno-venous collaterals with good drainage.

Conclusion: BCS due to BS still caries serious mortality. Mortality rate perhaps tend to decrease after 2000. Formation of intrahepatic veno-venous collaterals seem to be the only factor important in the survival.

Safety and Efficacy Of Peg-IFNa/Ribavirin/Protease Inhibitor Combination In 34 Patients With HCV-Mixed Cryoglobulinemia Vasculitis. David Saadoun[1], Stanislas Pol[2], Vincent Thibault[3], Gilles Pialoux[4], François Blanc[5], Lucile Musset[6], Alexandre Karras[7], Olivier Decaux[8], Jean-Marc Ziza[9], Olivier Lambotte[10] and Patrice Cacoub Sr.[11]. [1]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [2]Hepatology, Cochin Hospital, Paris, France, [3]Virology, Pitié-Salpétrière, Paris, France, [4]hôpital Tenon, Paris, France, [5]hôpital Montpellier, Montpellier, France, [6]Laboratoire d'immunochimie, Pitié- Salpêtrière, Paris, France, [7]Hôpital Européen Georges Pompidou, APHP, Paris, France, [8]Rennes University Hospital, Rennes, France, [9]Croix Saint Simon Hospital, Paris, France, [10]Hopital Kremlin Bicêtre, Kremlin Bicêtre, France, [11]CHU Pitié-Salpêtrière, Paris, France.

Background/Purpose: The standard of care treatment of patients presenting a HCV-mixed cryoglobulinemia (MC) vasculitis includes Peg-IFNa plus Ribavirin, w/wo Rituximab. Thirty to 40% of patients are non-responders or relapsers to such combination.

Objective: To analyze the safety and efficacy of a Peg-IFNa/// Ribavirin/Protease inhibitor combination in HCV-MC vasculitis.

Methods: Open label, prospective, cohort study including 34 patients with HCV-MC vasculitis. Peg-IFNa//Ribavirin was associated to Telaprevir [375 mg three times daily for 12 weeks, 19 patients (56%) or Boceprevir (800 mg three times daily, 15 patients (44%) for 44 weeks] for 48 weeks.

Results: Mean age 58.9 years, 50% women, and 30/34 (88%) had HCV genotype 1. Twenty eight (83%) patients received previous antiviral therapy with Peg-IFNa//Ribavirin and the remaining 6 were naïve of antiviral therapy. Of the 28 patients with HCV-MC vasculitis previously treated with Peg-IFNa/Ribavirin, 16 (57.1%) were non-responders, 5 (17.8%) were partial responders and 7 (25.1%) were relapsers. Mean HCV RNA level was 5.7 Log copies/mL, mean ALT level was of 49.85 IU/mL and severe liver fibrosis (i.e. Metavir score 3 and 4) was noted in 14 (41.1%) cases. Twenty six patients had a type II MC and 7 had a type III. Main HCV-MC manifestations included purpura (n=21), polyneuropathy (n=19), arthralgia (n=14), and kidney involvement (n=9). The mean serum cryoglobulin and C4 rheumatoid factor levels were of 0.8 g/l and 0.10 g/l, respectively. Nineteen (55.9%) patients showed a complete clinical response of MC vasculitis and 15 (44.1%) were partial responders at the end of follow up. Sustained virological response (i.e. at week 60) could be assessed in 27/34 HCV MC patients and was achieved in 15 (55.5%) cases. All 34 patients experienced at least one treatment side effect including grade 3 anemia in 32%, grade 3 neutropenia in 6%, infection in 30%, pruritus in 35% and skin eruption under Telaprevir (6%). Antiviral therapy discontinuation was required in 12 (35.3%) patients for virological non-response (n=8), virological relapse (n=3) and depression (n=1).

Conclusion: Peg-IFNa///Ribavirin/protease inhibitor combination represents an effective new therapeutic option in HCV-MC vasculitis. Such therapeutic regimen should be administered cautiously considering the high rates of side effects.

Genetic Association Of Mitochondrial DNA Polymorphisms With Behçet's Disease In a Korean Population. Mi-Hye Kwon[1], Chung-Il Joung[1] and Jiwon Hwang[2]. [1]Konyang university hospital, Daejeon, South Korea, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea.

Background/Purpose: Behcet's disease (BD) is an inflammatory multisystemic disorder. Although precise etiopathogenesis should be elucidated, BD is known to be multifactorial and accumulating data suggest genetic mechanisms for the development of disorder. Variations in genomic DNAs have been investigated vigorously, while studies on mitochondrial DNAs (mtDNAs) are limited. Association between BD and mtDNA alteration is not well known yet, and there is one report about the association of m.709G>A in an Iranian population. This study was performed to investigate the potential association of mitochondrial single nucleotide polymorphisms (mtSNPs) and haplotypes with BD in a Korean population. To identify candidate mtSNPs, our group sequenced complete mtDNA genomes of patients with BD and normal controls and compared the frequency of mtSNPs.

Methods: Blood sample was collected from 20 patients and 10 healthy controls. Complete mtDNA genomes were sequenced using GeneChip® Human Mitochondrial Resequencing Array 2.0(MitoChip v2.0) (Affymetrix, Santa Clara, CA). Raw data (CEL files) were analyzed with GeneChip Sequence Analysis Software (GSEQ 4.1) and revised Cambridge reference sequence (rCRS) was used as reference sequence. Haplotypes were searched with sequences in the hypervariable region 1 and 2 with mtDNA manager (http://mtmanager.yonsei.ac.kr/). Chi square or Fisher's exact test were used to analyze the association of of mtSNPs between groups and to investigate possible association between clinical characteristics and mtSNPs. (SPSS ver. 18.0).

Results: We sequenced 16545 nucleotides from total of 16569 mitochondrial DNA nucleotides for each individual due to experimental method. With a quality score (QS) of 9, a total of 64 nucleotides were discordant with those of rCRS, and among them 6 discordant nucleotides were observed in all of the patients and healthy controls showing ethnic characteristics. m.200A>G, m.16129G>A, and m.16304T>C were more frequently observed in the patient group, while, m.150C>T was more frequent in the control group although statistically not significant. By Fisher's exact test, m.16182A>C, m.16183A>C, and m.16189T>C were associated with uveitis (p= 0.041, 0.022, and 0.014 respectively). None of the haplotypes we searched were associated with BD risk statistically, but B4a were more frequently observed in the patient group.(3 versus 0)

Conclusion: We report the first association study between BD and mitochondrial SNPs in a Korean population. In the present study, m.200A>G, m.16129G>A, m.16304T>C and m.150C>T could be novel candidate mtSNPs in BD in a Korean population.

Trends In Incidence and Mortality In Rheumatoid Arthritis and Systemic Autoimmune Rheumatic Diseases In Quebec, Canada: A Population-Based Study. Sonia Jean[1], Philippe Gamache[2], Marie Hudson[3], Louis Bessette[4], Paul R. Fortin[5], Gilles Boire[6] and Sasha Bernatsky[7]. [1]National Institute of Public Health of Quebec, Quebec, QC, [2]National institute of public health of Quebec, Quebec, QC, [3]McGill University, Montreal, QC, [4]Centre Hospitalier Universitaire de Québec, pavillon CHUL, Sainte-Foy, QC, [5]Centre de Recherche du Chu de Québec et Université Laval, Quebec City, QC, [6]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [7]Research Institute of the McGill University Health Ctre, Montreal, QC.

Background/Purpose: Health administrative data (HAD) are a potentially efficient to conduct population-based research and are increasingly used to develop chronic disease surveillance indicators. Examining trends in incidence and mortality over time can assist in monitoring disease burden and evaluating the effectiveness of treatment. The aim of this study was to explore time trends in incidence and mortality for rheumatoid arthritis (RA) and selected systemic autoimmune rheumatic diseases (SARD).

Methods: Using case definitions for HAD available in Quebec, Canada, 2 population-based cohorts for RA and SARD (1996–2010) were defined. To identify incident cases, a period of 5 years (1996–2000) was used to exclude prevalent cases. Age and sex-specific incidence rates were calculated using the number of incident cases as the numerator and the counts of population eligible for health insurance registry as the denominator. Age-standardized incidence rates (SIR) were calculated using the 2001 age-structure of the Quebec population. Health insurance registry file was also used to identify deaths among 2 cohorts and, for each year, mortality rates in each cohort were compared with mortality rates in the general population using standardized mortality rate ratios (SRR). Joinpoint and negative binomial regression analyses were used to test for linear change in incidence rates and SRR.

Results: Prevalence of RA and SARD in 2009 were estimated at 1100.7 and 529.8 per 100,000 persons, respectively. For RA, 69.2% of cases were females, while for SARD, this percentage was 73.5%. The linear trends in SIR did not show significant change over the study period (RA p-value=0.3613, SARD p-value 0.0510) (Fig. 1 and 2). The mortality rate in RA and SARD patients was significantly higher than the expected rate in general population (2009: RA SRR=1.32, SARD SRR=1.95), and no significant improvement was observed (Fig. 3).

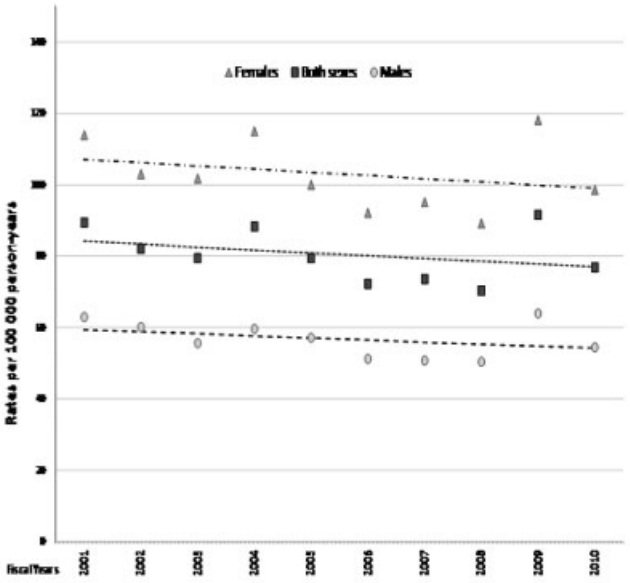

Figure 1. SIR for RA, Quebec, 2001–2010

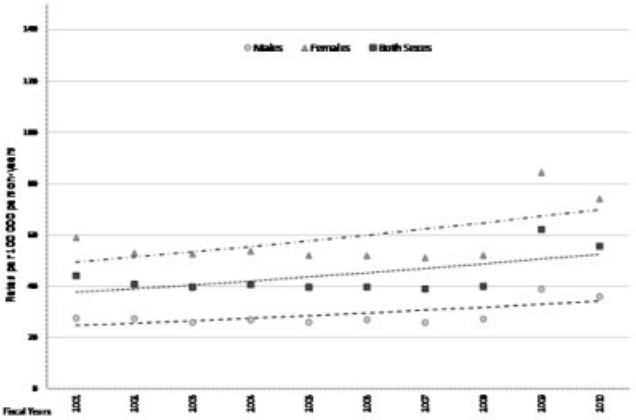

Figure 2. SIR for SARD, Quebec, 2001–2010

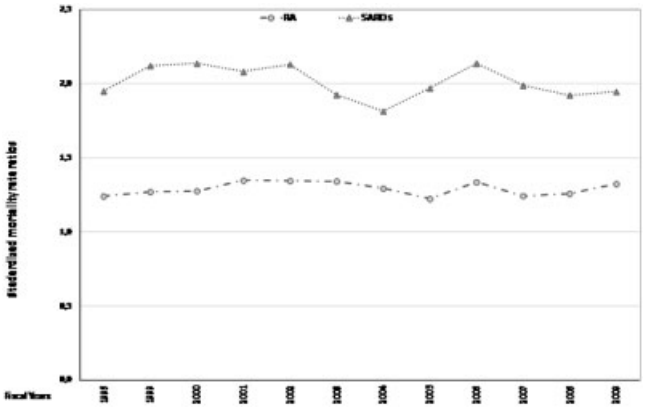

Figure. 3 SRR, Quebec, 1998–2009

Conclusion: No secular trends in SIR of RA and SARD were observed over time. The mortality was substantially higher in RA and SARD compared to general population, and remained so over the study period. This suggests further efforts are needed to optimize long-term outcomes in these diseases.

Does Foot Pain Mediate The Effect Of Knee Osteoarthritis and Risk Of Indoor and Outdoor Falls In Older Men and Women? Uyen Sa D.T. Nguyen[1], Yuqing Zhang[1], Jingbo Niu[1], Robert H. Shmerling[2], Douglas P. Kiel[3], Suzanne G. Leveille[4], Carol A. Oatis[5] and Marian T. Hannan[3]. [1]Boston University School of Medicine, Boston, MA, [2]Beth Israel Deaconess Med Ctr, Boston, MA, [3]Hebrew SeniorLife & Harvard Medical School, Boston, MA, [4]University of Massachusetts-Boston, Boston, MA, [5]Arcadia University, Glenside, PA.

Background/Purpose: Knee osteoarthritis (OA), foot pain, and falls are common in older adults and limit mobility. We previously showed that knee OA increases the risk of indoor falls for men and outdoor falls for women. Because foot pain often accompanies knee OA and women report more foot pain than men, understanding whether the increased risk of falls in subjects with knee OA is mediated through foot pain can help us better target interventions to reduce falls. We examined the associations of knee OA with foot pain and falls, and assessed the extent that foot pain may mediate the association between knee OA and the risk of falls, and whether this varies by sex.

Methods: This study included 764 participants from the MOBILIZE Boston Study, a population-based cohort of older adults. Knee OA was assessed at baseline using the ACR clinical criteria. Falls data were prospectively collected using monthly calendars, with phone follow-up to assess location of falls. The presence of foot pain was assessed at baseline. Using negative binomial regression, we examined the sex-specific association of knee OA with the risk of indoor falls and outdoor falls adjusting for confounders. We applied a counterfactual approach of mediation analysis using logistic regression and marginal structural modeling to estimate the direct (through mechanisms excluding foot pain) and indirect (through the foot pain mechanism) effects to determine the extent that foot pain mediates the associations between knee OA and falls.

Results: Among study participants (486 women and 278 men, mean age: 78 years, mean BMI: 27.3), 25% had clinical knee OA. The proportions with foot pain were 35.8% in men with and 14.4% in men without knee OA; foot pain was reported by 33.6% and 24.5% of women with and without OA. Over an average of 2.2 years, 43% in men with and 35% in men without foot pain had ≥ 1 indoor falls while 39% and 36% of the women with and without foot pain had ≥ 1 outdoor falls. The adjusted rate ratio (RR) and 95% confidence interval (CI) for the total effect of knee OA (i.e., including both direct and indirect effects) on risk of indoor falls in men was 1.58 (95% CI: 0.99, 2.52), and on risk of outdoor falls in women was 1.70 (95% CI: 1.21, 2.40). The effect of knee OA on risk of indoor falls in men mediated by foot pain was 0.93 (95% CI: 0.73, 1.32) and on risk of outdoor falls in women was 1.00 (95%CI: 0.81, 1.25).

Table. The Association between Knee OA and Rate of Indoor and Outdoor Falls and Whether the Effect is Mediated through Foot Pain, by Men and Women

		Rate Ratio (95% CI)				
				Effect Mediated through Foot Pain Using Marginal Structural Modeling[2]		
	Falls	Unadjusted	Total Effect,[1] Adjusted for Confounders	Direct Effect	Indirect Effect	% mediated
Men	Indoor	1.39 (0.83, 2.32)	1.58 (0.99, 2.52)	1.58 (1.14, 2.18)	0.98 (0.73, 1.32)	0%
Women	Outdoor	1.64 (1.15, 2.34)	1.70 (1.21, 2.40)	1.70 (1.33, 2.16)	1.00 (0.81, 1.25)	0%

[1]Total Effect (TE) is the effect of OA that includes mechanisms with and without foot pain and is adjusted for age, BMI, use of medications (anti-depressants, anti-psychotics, anti-hypertensives, and sedatives), no. of co-morbidities (high blood pressure, stroke, heart disease, diabetes, ulcer/stomach disease, kidney disease, anemia, cancer/skin cancer, rheumatoid arthritis), and history of falls
[2]The effect of knee OA on risk of falls weighted by the probability of having foot pain conditioned on knee OA status and confounders as stated above: (a) Direct Effect (DE) is the effect of knee OA on risk of falls not through foot pain, adjusting for covariates; (b) Indirect Effect (IE) is the effect of OA mediated by foot pain on risk of falls, adjusting for covariates; (c) % mediated by foot pain, e.g., [RR(TE)-RR(DE)]/[RR(TE)-1].

Conclusion: Despite the increased risk of falls in people with OA and a strong association of knee OA and foot pain, there is no evidence that knee OA increases the risk of falls through foot pain in older men and women. The counterfactual method of mediation analysis reduces potential confounding and selection bias that occur with the conventional method of including a potential mediator in a model as a covariate. Future studies should explore other possible mechanisms through which knee OA affects the risk of indoor and outdoor falls differently for men and women.

Low Literacy Decision Aid Enhances Knowledge and Reduces Decisional Conflict Among Diverse Population Of Adults With Rheumatoid Arthritis: Results Of a Pilot Trial. Jennifer Barton[1], Laura Trupin[2], Gina Evans-Young[3], John B. Imboden[1], Dean Schillinger[3], Victor M. Montori[4] and Edward H. Yelin[1]. [1]University of California, San Francisco, San Francisco, CA, [2]UC San Francisco, San Francisco, CA, [3]UCSF, San Francisco, CA, [4]Mayo Clinic, Rochester, MN.

Background/Purpose: Vulnerable populations with rheumatoid arthritis (RA) have poorer outcomes and report suboptimal shared decision-making communication. Patient involvement in the choice of disease modifying anti-rheumatic drugs (DMARDs) for RA may result in improved adherence and better outcomes. Our objective was to test the efficacy of an RA decision aid tool, developed for low literacy and non-English-speaking patients, to improve knowledge and enhance patient involvement in treatment decisions.

Methods: We conducted a pilot trial to test the utility of the decision aid, a set of 5 issue cards which described 12 DMARDs by frequency and mode of administration, time to onset of action, cost, side effects and contraindications. Patients at 2 university-affiliated rheumatology clinics faced with a possible medication change were enrolled consecutively into one of three arms: Arm 1 – existing medication summary guide (usual care) provided pre-clinic visit; Arm 2 – low literacy RA guide provided pre-visit; Arm 3 – low literacy guide provided pre-visit and decision aid used during visit. Immediately post-visit and during a telephone interview 3 months post-visit, subjects completed an RA knowledge questionnaire and the low-literacy version of the Decisional Conflict Scale (DCS; range 0–100; higher scores reflect more conflict). At 3 months, subjects were also asked about self-reported medication adherence. All materials were available in English, Spanish, and Chinese. DCS, knowledge, and adherence were compared by arm using linear (for DCS) or logistic regression with adjustment for gender immediately post-visit and 3 months.

Results: Of 166 patients enrolled, 88% were female, mean age 59±12; 87% were non-white; 54% spoke a language other than English; and 66% had not graduated high school. There were no statistically significant differences by study arm for education, language, or race/ethnicity; however, there were differences by gender (p=0.02). Compared with the existing guide (Arm 1, n=58), patients who received the low literacy guide plus decision aid (Arm 3, n=60), were more likely to have adequate RA knowledge (OR 3.1, 95% CI 1.4–7.0) immediately post-visit; a difference not seen at 3 months (Table). Among patients who reported a medication change during the visit, Arm 3 patients reported lower decisional conflict compared to those in Arm 1 post-visit (mean DCS 11 vs. 24, p =0.05) and at 3 months (17 vs. 32, p<0.05). Self-reported adherence did not differ by study arm at 3 months.

Conclusion: An innovative, multi-lingual, low literacy decision aid tool effectively reduced decisional conflict among vulnerable patients with RA faced with choices about DMARDs. The decision aid and medication guide also enhanced RA-specific knowledge immediately post-visit. Future studies are needed to assess the impact of the decision aid on health outcomes in vulnerable populations.

Decisional conflict, RA knowledge, and medication adherence by study arm immediately post-visit and 3-months

The Effect Of Knee Replacement On Self-Reported Participation and Gait Speed: The Multicenter Osteoarthritis Study and The Osteoarthritis Initiative. Jessica L. Maxwell. Boston Univ Sargent College, Boston, MA.

Background/Purpose: Little research has explored participation outcomes, defined as involvement in life situations, among persons following total knee replacement (TKR). Since confounding by indication is likely in a study of TKR outcomes, we examined whether participation restriction (PR) differed among persons following TKR compared to a propensity-score matched group with symptomatic knee osteoarthritis (SxOA). Research has found differences in results between self-reported and performance measures; and, as gait speed is strongly associated with disability, we also explored whether it differs by TKR status using the same methods.

Methods: Subjects with SxOA were selected from The Multicenter Osteoarthritis (MOST) Study and the Osteoarthritis Initiative (OAI). We generated a propensity score for each subjects' odds of having a TKR based on their values of 17 TKR-associated ($p<0.2$) variables (e.g. sex, medication use, comorbidities, living situation, pre-TKR participation). Within each cohort using a greedy matching method, we matched 1 subject with SxOA, defined as radiographic evidence of knee OA and report of frequent knee pain over the last 30 days, with 1 subject with a TKR by their propensity scores. The clinic visit falling $\geq$ 1 year after the TKR date for each matched pair was used as the index visit. Participation was measured using the Late Life Disability Instrument (LLDI); and PR was defined using a previously established cut-point of $<$ 69/100 on the Instrumental Limitation subscale of the LLDI. Gait speed was calculated using the time required to ambulate 20 m on a straight walkway (m/s). Slow gait speed was defined as speed $<$ 1.0 m/s. We compared the proportion of subjects with PR and slow gait speed among the TKR and non-TKR SxOA subjects using chi square analyses. We evaluated the association between TKR status (yes/no) and PR, and TKR status and gait speed, using logistic regression.

Results: There were 258 and 247 matched pairs with post-index date PR and gait speed data, respectively. Table 1 presents the proportions of subjects with these data in each group, as well as estimates of association. The proportion with PR among the non-TKR subjects was 10% higher than that for the TKR subjects, and the proportions of subjects reporting PR was considerably higher than the subjects demonstrating slow gait speed. Having a TKR was associated with decreased odds of PR but not with slow gait speed.

Table. Proportions and odds ratios of participation restriction and slow gait speed by TKR status among propensity-score matched subjects.

	% PartRestrict	OR (95% CI)	% Slow Gait Speed	OR (95% CI)
TKR group	33	0.65 (0.5, 0.9)	17	1.1 (0.7, 1.7)
SxOA group	43	reference	16	reference
p-value	0.02		0.7	

Conclusion: In this study, TKR subjects had two-thirds the risk of participation restrictions compared with demographically and clinically similar subjects not undergoing TKR, although there was no effect of TKR on gait speed.

Relationships Between Driving Distance, Rheumatoid Arthritis Diagnosis, and Disease-Modifying Anti-Rheumatic Drug Receipt. Jennifer M. Polinski[1], M. Alan Brookhart[2], John Z. Ayanian[1], Jeffrey N. Katz[1], Seo Young Kim[1], Chris Tonner[3], Edward H. Yelin[3] and Daniel H. Solomon[4]. [1]Brigham and Women's Hospital, Boston, MA, [2]University of North Carolina, Chapel Hill, NC, [3]University of California, San Francisco, San Francisco, CA, [4]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA.

Background/Purpose: Disease-modifying antirheumatic drugs (DMARDs) are recommended for all patients with rheumatoid arthritis (RA). Some studies estimate that almost half of patients with RA do not receive DMARDs. Distance to the nearest rheumatologist, a proxy for access to care, may explain some variability. We hypothesized that patients with RA living further from a rheumatologist would be less likely to receive an RA diagnosis and to receive DMARDs.

Methods: We obtained a list of US rheumatologists from the American College of Rheumatology. Medicare patients with Parts A, B, and linked prescription data from CVS Caremark were eligible. We calculated driving distance from patients' homes to the nearest rheumatologist. Using multivariable logistic regression, we assessed relationships between driving distance and RA diagnosis, defined using procedures for claims data, and between driving distance and DMARD receipt in 365 days of follow-up. Secondary outcomes included receipt of $\geq$1 biologic DMARD, combination DMARD use ($\geq$2 DMARDs for $\geq$60 days) and majority of time on DMARDs (days supply of $\geq$1 DMARD for $\geq$50% of days). In one set of analyses, distance was divided into quartiles: 0–2, 2.1–5.0, 5.1–15.9, $\geq$16 miles. In a second, we used pre-defined categories: 0–15, 15.1–30, 30.1–60, $\geq$60 miles.

Results: 26,590 patients had diagnosed RA. Compared to the first quartile, increased distance was associated with decreased odds of RA diagnosis: second quartile, OR=0.96 (95% CI, 0.80–1.16); third=0.88 (0.72–1.07); fourth=0.72 (0.56–0.93), p for trend=0.0099. Similar results were observed using pre-defined distance categories. Among those with RA, increased driving distance was associated with increased odds of any DMARD receipt across quartiles: second=1.15 (1.06–1.25); third=1.41 (1.29–1.54); fourth=1.32 (1.18–1.46), p for trend=0.0012. There was no relationship between pre-defined categories and any DMARD receipt: 15.1–30 miles=1.09 (0.99–1.19); 30.1–60=1.03 (0.91–1.16); $\geq$60.1=1.06 (0.91–1.23), p for trend=0.4506. Similar results were observed for combination DMARD use, but not for biologic DMARD receipt or majority of time on DMARDs (Table).

Table. Relative odds of DMARD use at 365 days, comparing the 2 approaches to define driving distance

	Quartiles of driving distance			Pre-defined categories of driving distance		
	2.1–5.0 miles	**5.1–15.9 miles**	**≥ 16 miles**	**15.1–30 miles**	**30.1–60 miles**	**≥ 60.1 miles**
Receipt of any DMARD	1.15 (1.06–1.25)	1.41 (1.29–1.54)	1.32 (1.18–1.46)	1.09 (0.99–1.19)	1.03 (0.91–1.16)	1.06 (0.91–1.23)
		p for trend: 0.0012			p for trend: 0.4506	
Receipt of a biologic DMARD	1.02 (0.87–1.19)	1.05 (0.89–1.24)	1.00 (0.81–1.22)	0.96 (0.80–1.15)	1.08 (0.86–1.35)	1.07 (0.80–1.43)
		p for trend: 0.8037			p for trend: 0.6010	
Receipt of combination DMARDs	1.09 (0.93–1.28)	1.17 (1.00–1.37)	1.23 (1.02–1.49)	1.11 (0.95–1.31)	1.16 (0.95–1.42)	1.07 (0.83–1.39)
		p for trend: 0.0837			p for trend:0.4036	
Majority of time on DMARDs	1.17 (1.07–1.28)	1.41 (1.29–1.55)	1.33 (1.19–1.49)	1.07 (0.97–1.18)	1.08 (0.95–1.22)	1.04 (0.89–1.22)
		p for trend: 0.0026			p for trend: 0.4456	

Conclusion: Increased driving distance to a rheumatologist was associated with decreased odds of RA diagnosis. Among those with diagnosed RA, the odds of DMARD use rose as distance increased from <2 to 16 miles, but not beyond, suggesting that urban residents who live closer to a rheumatologist may have other barriers to DMARD use.

The Link Of Foot Structure and Foot Function With Falls: The Johnston County Osteoarthritis Project. Yvonne M. Golightly[1], Marian T. Hannan[2], Howard J. Hillstrom[3], Alyssa B. Dufour[2], Amanda E. Nelson[4], Adam Dore[1] and Joanne M. Jordan[4]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Hebrew SeniorLife & Harvard Medical School, Boston, MA, [3]Hospital Special Surgery (HSS), New York, NY, [4]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC.

Background/Purpose: Nearly 1/3 of older adults experience at least one fall annually in the United States. Foot type (static and dynamic arch height) is related to how people walk, but the relationship to falls is unclear. Prior studies have shown differences in foot type by race with a lower arch height more common in African Americans than Caucasians. The purpose of this cross-sectional study was to evaluate the association of static foot structure and dynamic foot function with falls in a community-based study of Caucasian and African American men and women 50+ years old.

Methods: Participants in the Johnston County Osteoarthritis Project were queried: "In the last 12 months, have you had any falls of any type?" If they answered "yes", the number of falls was reported. Tekscan Matscan foot pressure scans were used to determine foot structure (modified arch index [MAI]) during standing and foot function (center of pressure excursion index [CPEI]) while walking. Foot structure (high arch $\leq$0.030, low arch $\geq$0.164, referent $>$0.030 and $<$0.164) and foot function variables (pronated $\leq$7.3, supinated $\geq$21.0, referent $>$7.3 and $<$21.0) were defined *a priori* (based on quintiles from population data), and the most extreme foot type for each participant was used in analyses. Logistic regression models were used to

estimate the association between foot types and falls (defined two ways as ≥1 fall and ≥2 falls), adjusting for the covariates of age, body mass index [BMI], gender, and race. Statistical interaction between foot types and each covariate was examined, and $p<0.10$ was considered statistically significant.

Results: Of the 1690 participants with complete falls data, 1571 participants had foot structure data and 1490 had foot function data (mean age 68 ±9 years, mean BMI 31 ± 7 kg/m^2, 67% women, 30% African American). 25% of participants reported 1+ falls in the past 12 months and 8% reported 2+ falls. Although not statistically significant ($p=0.06$), the odds of 2+ falls were 40% lower among participants with high arches compared to referent (Table). The interaction between low arches and race was $p=0.05$, and thus results were stratified by race. African Americans had a lower occurrence of falls than Caucasians. Among African Americans, those with low arches had a 75% higher odds of 1+ falls compared to referent, although these results were of borderline significance ($p=0.07$). Foot function was not associated with falls (Table).

Table. Associations between foot type and falls, adjusting for age, BMI, gender, and race

Falls definition	Foot Structure (MAI)	Total Sample N=1571		African American N=479		Caucasian N=1092		
		# of fallers/n (%)	Adjusted OR (95% CI)	# of fallers/n (%)	Adjusted OR (95% CI)	# of fallers/n (%)	Adjusted OR (95% CI)	p for interaction

Falls definition	**Foot Function (CPEI)**	**Total Sample N=1490**		**African American N=431**		**Caucasian N=1029**		
		# of fallers/n (%)	Adjusted OR (95% CI)	# of fallers/n (%)	Adjusted OR (95% CI)	# of fallers/n (%)	Adjusted OR (95% CI)	p for interaction
1 + (Any falls vs. no falls)	Referent	172/700 (24.6)	1.00	38/193 (19.7)	1.00	134/507 (26.4)	1.00	
	Pronated	83/314 (26.4)	1.06 (0.78, 1.44)	22/103 (21.4)	1.12 (0.61, 2.05)	61/211 (28.9)	1.06 (0.74, 1.52)	0.850
	Supinated	108/446 (24.2)	1.05 (0.79, 1.39)	26/135 (19.3)	0.99 (0.57, 1.73)	82/311 (26.4)	1.07 (0.77, 1.49)	0.878
2 + (2 or more falls vs. <2 falls)	Referent	58/700 (8.3)	1.00	15/193 (7.8)	1.00	43/507 (8.5)	1.00	
	Pronated	27/314 (8.6)	1.02 (0.63, 1.65)	9/103 (8.7)	0.94 (0.39, 2.30)	18/211 (8.5)	1.05 (0.58, 1.88)	0.877
	Supinated	36/446 (8.1)	1.03 (0.66, 1.59)	10/135 (7.4)	0.92 (0.40, 2.15)	26/311 (8.4)	1.04 (0.63, 1.77)	0.937

Conclusion: These cross-sectional results indicate a possible protective relationship between high arches and falls and among African Americans a positive association between low arches and falls. Future studies are needed to longitudinally examine the role of foot type in falls and to test the effectiveness of interventions for modifying foot type (e.g., orthotics) for fall prevention in populations.

Endogenous IL-22 Regulates Th1 Responses and Plays a Pathogenic Role After the Onset of Arthritis. Shivali Justa, Xiaoqun Zhou and Sujata Sarkar. University of Arizona, Tucson, AZ.

Background/Purpose: IL-22,belongs to the IL-10 family of cytokines and is primarily produced by CD4 T, NK and LTi cells. IL-22 plays a dual role depending on the context of the disease model under study, it is protective in inflammatory bowel disease, hepatitis, myocarditis, ulcerative colitis and pathogenic in psoriasis. IL-22 knock-out mice have a reduced incidence of arthritis, while neutralization of IL-22 after onset of arthritis in IL-1 receptor antagonist knock-out mice had limited effect on joint inflammation, additionally, administration of IL-22 prior to onset of joint inflammation is associated with reduced arthritis. These findings are suggestive of a nuanced role of IL-22 in the regulation of inflammation.

Methods: CIA was induced in DBA1 mice following immunization with collagen and complete Freund's adjuvant. Arthritic mice with clinical scores of ≥ 1 and with arthritis duration of 4 days were randomized to receive anti-IL-22 or RatIgG antibody and disease progression was assessed by clinical scoring and histopathology. IL-22, IL-17 and IFN-g responses were measured by ELISA and flowcytometry. Anti-collagen antibodies were analyzed by ELISA. Expression of IL-22R1 in CD4T, CD19+ and CD11c+ cells was elucidated by flowcytometry and real time PCR.

Results: There was a significant expansion of collagen specific IL-22 responses during arthritis and IL-22 producing cells were discrete from IL-17 or IFN-g producing cells. Neutralization of IL-22 after onset of joint inflammation resulted in significantly reduced severity of arthritis and was accompanied by increase in collagen specific IFN-g responses, a modest reduction of anti-collagen IgG2a antibodies, and unaltered Th17 or IL-10 responses. To corroborate our findings, both intracellular and secreted levels of IFN-γ and IL-17 were measured and similar results were observed. CD4+T cells from arthritic mice showed increase surface expression of IL-22R1(13.3%) in comparison to naïve mice (1.50%) or mice from the initiation phase (1.97%). Flowcytometrically, IL-22R1 was detectable in CD19+ cells, however, the expression levels were similar in naïve mice, mice from initiation phase or arthritic mice. In-vitro, CD4T cells from arthritic mice when co-cultured with antigen presenting cells in the presence or absence of IL-22, suppressed or induced IFN-g respectively. In another in-vitro set up, CD19 cells from arthritic mice when cultured in the presence of recombinant IL-22, showed significant suppression of anti-collagen IgG1 and augmentation of IgG2a responses. *These* in *vitro results* are in *agreement* with our in *vivo findings* suggesting that IL-22R1 expression in T and B cells is functionally active and associated with IFN-g regulation in T cells or pathogenic anti-collagen IgG2a antibody production from B cells. Our results shows that IL-22R1 may be induced on immunocytes during inflammatory state thus enabling them to respond to IL-22.

Conclusion: Endogenous IL-22 suppresses Th1 responses and is pathogenic after onset of arthritis. IL-22R1 is upregulated in CD4 T cells during arthritis and regulates IFN-g in T cells.

IL4–10 Synerkine: A Novel Immunoregulatory Drug To Prevent Immunopathology In Rheumatic Diseases. Sarita Hartgring[1], Cristine Steenlouws[2], C.E. Hack[2], Martin De Smet[2], Floris Lafeber[2] and J.A.G. van Roon[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]UMC Utrecht, Utrecht, Netherlands.

Background/Purpose: A considerable percentage of patients shows a limited response to biologics targeting one specific inflammatory mediator, largely because of redundancy of these mediators. An attractive alternative is inhibition of multiple proinflammatory mediators and induction of immunoregulatory activity by regulatory cytokines such as IL4 and IL10. Many studies demonstrated the strong capacity of IL4 and IL10 as stand alone drugs to inhibit inflammation and tissue-destructive responses in animal and human in vitro models. Clinical results of these cytokines, however, have been disappointing, possibly because of poor bioavailability that is mainly due to their low molecular weight and rapid renal clearance. We have executed a feasibility study to develop IL4 and IL10 as one biologic, preserving distinct characteristics of each molecule plus improving bioavailablity by increasing the molecular size. Our objective was to develop and test the anti-inflammatory properties of an IL4/IL10 fusion protein; IL4–10 synerkine.

Methods: IL4–10 synerkine was expressed in human HEK293 cells. Biochemical properties of IL4–10 synerkine were determined by western blot, size exclusion chromatography, and ELISA. Functional properties were studied by measuring the capacity of IL4–10 synerkine to regulate production of pro-inflammatory cytokines and their inhibitors, as well as proinflammatory and regulatory T cell activity, and expression Fcγ and Fcϵ receptors (FcγRI, IIa, IIb, III and FcϵR). In addition, blocking IL4 receptor and IL10 receptor strategies were performed to confirm the specific activities of IL4 and IL10.

Results: IL4–10 synerkine appeared as a glycosylated dimeric protein with a molecular size of ~70kDa. ELISA as well as immunoblotting confirmed that the IL4–10 synerkine indeed consisted of IL10 and IL4 subunits. In whole blood assays IL4–10 synerkine dose-dependently inhibited multiple pro-inflammatory cytokines, which was almost complete at 20 ng/ml (IL1β, TNFα, IL6 and IL8, all $p<0.001$). This effect was dependent on interaction with IL10R and IL4R. Oppositely, the synerkine significantly induced production of IL1RA and preserved sTNFR levels. In addition, IL4–10 synerkine strongly inhibited Th1 and Th17 cytokine secretion, while maintaining FoxP3 expression and FoxP3-expressing CD4 T cells. Finally, while IL4 up regulated FcϵR expression and IL10 up regulated expression of activating FcγRs on monocytes (all $p<0.001$), both Fcϵ and FcγR expression were largely down regulated to control levels in the presence of IL4–10 synerkine (all at least $p<0.01$).

Conclusion: The IL4–10 synerkine is a novel anti-inflammatory drug that shifts multiple proinflammatory pathways towards immunoregulation. The increased molecular mass predicts better bioavailabilty in humans than the wild-type molecules, which potentially enhances its clinical efficacy. The strong and improved inhibitory activities of IL4–10 synerkine (as compared to IL4 or IL-10 monotherapy and combination therapy) that were observed in several animal models for inflammatory pain underscores the potential for treatment of inflammatory and possibly degenerative rheumatic diseases.

Binding Of Apoptotic Fetal Cardiocytes By Anti-Ro Antibodies Stimulates uPA/uPAR-Dependent Macrophage Infiltration and M2 Type Phenotype. Paraskevi Briasouli[1], Savvas Pavlides[2], Leslie Gold[3], Mark Halushka[4] and Jill P. Buyon[5]. [1]New York University Medical Center, New York, NY, [2]New York University Medical Center, new York, NY, [3]new York University Medical Center, new York, NY, [4]John Hopkins PAthology, Baltmore, MD, [5]NYU School of Medicine, New York, NY.

Background/Purpose: Organ injury induced by antibodies characteristic of Sjogren's Syndrome and Systemic Lupus Erythematosus, while varied in the adult and fetus, may share in common a link between apoptosis and ultimate fibrosis. In congenital heart block (CHB), surface binding of maternal anti-Ro antibodies to apoptotic cardiocytes decreases their removal by healthy cardiocytes, increases uPAR-(urokinase plasminogen activator receptor) dependent uPA activation, plasmin activity and stimulation of TGFbeta signaling. Immunological staining of CHB hearts reveals extensive TGFbeta in the septal region and macrophage infiltration with intense uPA expression. Since TGFbeta mediates chemotaxis of macrophages and stimulates urokinase expression, this study evaluated the hypothesis that anti-Ro binding to apoptotic cardiocytes exploits the plasmin-mediated activation of TGFbeta to trigger macrophage infiltration and polarization to a fibrosis- associated M2 phenotype.

Methods: Chemotaxis, immunoblot and immunofluoresence assays were used.

Results: A thin membrane chemotaxis assay showed directed migration of calcein-labeled THP-1 macrophages towards supernatants from co-cultures of healthy cardiocytes and apoptotic cardiocytes incubated with IgG fractions from mothers whose sera contain anti-Ro antibodies and who had a child with CHB (opsonized apo-CHB-IgG) compared to co-cultures of healthy cardiocytes and apoptotic cardiocytes incubated with control IgG (apo-nl-IgG) (80% migration CHB-IgG vs 39% migration nl-IgG; $p=0.05$; $n=3$). The effect was similar to that induced by TGFbeta and dependent on both TGFbeta and plasmin activity since supernatants of cocultures of healthy cardiocytes with apo-CHB-IgG in the presence of either aprotinin (10 μg/mL) or TGFbeta inhibitor SD543423 1μM did not induce macrophage migration. Similar results were obtained with supernatants of healthy cardiocytes cultured with apoptotic cardiocytes incubated with affinity purified anti-Ro60 (67% migration AP60-IgG vs 30% migration nl-IgG). Immunofluoresence revealed increased surface uPA expression only on macrophages incubated with supernatants of co-cultures of healthy cardiocytes with apo-CHB-IgG. Furthermore real time PCR confirmed that the increased uPA was due to de novo mRNA expression To evaluate whether the macrophages were polarized towards a pro-fibrotic M2 phenotype, surface CD206 was assessed and increased expression of CD206 was only observed following exposure to supernatants from co-cultures of healthy cardiocytes and apo-CHB-IgG. Immunoblot analysis of THP-1 macrophages showed that IRF4 but not IRF5 knockdown, mediator of M2 and M1 macrophage associated transcriptional program respectively, led to reduced uPA expression when incubated with supernatants from cocultures of healthy cardiocytes and apo-CHB-IgG.

Conclusion: These data suggest that binding of anti-Ro antibodies to apoptotic cardiocytes by virtue of increased uPAR-dependent uPA activity triggers TGFbeta mediated macrophage infiltration and polarization towards a profibrotic M2 phenotype amplifying a cascade of events that promote myofibroblast transdifferentiation and scar.

Complement Component C5a Permits The Co-Existence Of Pathogenic Th17 Cells and Type I Interferon In Lupus. Marc C. Levesque, Sudesh Pawaria, Kelly Maers and Partha Biswas. University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Systemic lupus erythematosus (SLE) is a type I interferon (IFN-I)-driven autoimmune disorder with exaggerated B and T-helper (Th) cell responses. Th17 cells, a recently identified T-helper cell subset, have been strongly implicated in the pathogenesis of SLE. Since IFN-I suppress the generation and expansion of Th17 cells in an IL-27-dependent manner, it is unclear how pathogenic Th17 cells are generated in SLE in the presence of an environment characterized by high IFN-I levels.

Methods: To test whether C5a has any impact on IFN-I-induced IL-27 production, bone marrow derived macrophages (BMDM) from wild type (WT) mice were treated with IFN-a in the presence or absence of C5a. Supernatants of BMDM treated with IFN-a ± C5a or IFN-a ± anti-IL-27 Ab were used to differentiate naïve $CD4^+$ T cells in the presence of Th17 skewing conditions. Similarly, BMDM from $MRL.Fas^{lpr}$ mice were stimulated with a TLR7/8 agonist (IFN-I inducer) in the presence or absence of C5a. To assess the *in vivo* consequence of C5aR activation on Th17 responses, we used the pristane induced lupus model and evaluated the development of lupus nephritis, number of Th17 cells and production of IL-27 in secondary lymphoid organs and kidney in WT and $C5aR^{-/-}$ mice ($n=5$). We measured the expression of IRF-1 in $MRL.Fas^{lpr}$ macrophages in response to TLR7/8 agonist stimulation. Finally, we measured serum C5a and IL-27(p28) levels by ELISA and the frequency of Th17 cells in peripheral blood from 22 SLE patients. Results obtained from the serum ELISAs and Th17 assays were used to determine correlations between serum C5a versus IL-27, serum IL-27 and the percentage of peripheral blood Th17 cells and serum C5a and the percentage of Th17 cells. To further validate our mouse model studies in human subjects with SLE, we treated macrophages from healthy donors with serum from SLE patients in the presence or absence of neutralizing anti-C5a Ab.

Results: Activation of C5aR on macrophages blocked IFN-I-mediated IL-27 production ($p < 0.0001$) and permitted the differentiation of Th17 cells. Similar findings occurred in lupus-prone mice and C5a exhibited a negative impact on TLR7 mediated synthesis of IL-27 ($p < 0.001$). Consequently, $C5aR^{-/-}$ mice were protected from lupus nephritis and showed increased IL-27 expression ($p < 0.001$) and reduced numbers of Th17 cells in the secondary lymphoid organs and kidney ($p < 0.001$ for spleen and lymph nodes; $p < 0.05$ for kidney). Furthermore, activation of the PI3K-Akt pathway was required for inhibiting IFN regulatory factor-1(IRF-1) mediated transcription of the *IL-27(p28)* gene. In support of these mouse model studies, we found that serum from SLE patients significantly inhibited IFN-I-induced IL-27 production ($p < 0.001$), and the level of serum C5a directly correlated with the Th17 frequency in the SLE peripheral blood ($r = 0.74$; $p = 0.001$).

Conclusion: In this report, we demonstrated the negative regulation of IFN-I induced IL-27 production by C5a via the C5aR on macrophages. Our findings highlight a potential mechanism that explains how Th17 cells can develop despite strong IFN-I responses in SLE. Thus therapeutic strategies to block C5aR activation may be beneficial for controlling pathogenic Th17-mediated inflammation in SLE.

Role Of IL33 In The Inflammation Of Takayasu Arteritis. David Saadoun[1], Marlène Garrido[2], Julien Gaudric[3], Cloé Comarmond[4], Michele Rosenzwacjg[5] and Patrice Cacoub[6]. [1]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [2]Pitié-Salpétrière, Paris, France, [3]Department of Vascular surgery GHPS, Paris, France, [4]Hôpital Pitié Salpétrière, Paris, France, [5]Department of Immunology GHPS, Paris, France, [6]Hopital Pitié-Salpétrière, Paris, France.

Background/Purpose: Interleukin (IL)-33, a member of the IL-1 cytokine family, is a recently described novel activator of endothelial cells, which promotes adhesion molecules and proinflammatory cytokine expression in the endothelium and angiogenesis and vascular permeability. Unlike, the other IL-1 family members, IL-33 primarily induces T-helper (Th)2 immune responses and the polarisation of macrophages.

Objective: To analyse the role of IL-33 and its receptor ST2 in the pathogenesis of Takayasu arteritis (TA).

Methods: Thirty three TA patients fulfilling the ACR criteria, with active disease (aTA) or inactive disease (iTA) and 10 age-matched controls (HD) were included. We performed quantitative measurement of IL-33, analysis of cell surface markers and cytokine production by flow cytometry and Luminex. Immunohistochemical analysis of inflamed aorta from patients with TA was performed.

Results: Increased level of serum (mean ± SEM; 155 ± 69.5 vs 32.9 ± 19.6 pg/ml, respectively, p=0.040) and culture supernatants IL-33 (14.6± 3.3 vs 2.9 ±1.8 pg/ml, respectively, p=0.013) was observed in TA patients compared to HD. Level of IL-33 correlated with disease activity in TA patients (25.4± 6.5 in aTA vs 7.5 ±2.6 pg/ml in iTA, p=0.021) and with the NIH score (r^2=0.3009, p=0.0009). IL-33 level dropped in active TA patients (n=10) that become inactive (20.1± 6.7 vs 4.2 ±1.2 pg/ml, p=0.031). IL-33 was mainly produced by eosinophils, basophils, and mast cells and in a lesser extent by macrophages and CD8+ T cells. ST2 (i.e. the IL-33 receptor) was mainly expressed by eosinophils and mast cells and much weaker by macrophages and neutrophils. IL-33 and ST2 were overexpressed in the inflamed arteries of TA patients and colocalized with endothelial cells and T cells, respectively. Stimulation of purified CD4+ T cells with IL-33 increased Th2 cells.

Conclusion: These findings open new perspectives for the role of IL-33 in the pathogenesis of TA.

Gender, Race, and Soluble Mediators Distinguish Blood Relatives Who Develop Incomplete Lupus Or Classified SLE In The Lupus Autoimmunity In Relatives (LAUREL) Study. Melissa E. Munroe[1], Kendra A. Young[2], Jill M. Norris[2], Joel M. Guthridge[1], Diane L. Kamen[3], Timothy B. Niewold[4], Gary S. Gilkeson[3], Michael H. Weisman[5], Mariko L. Ishimori[5], Daniel J. Wallace[5], David R. Karp[6], John B. Harley[7] and Judith A. James[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Colorado School of Public Health, Aurora, CO, [3]Medical University of South Carolina, Charleston, SC, [4]Mayo Clinic, Rochester, MN, [5]Cedars-Sinai Medical Center, Los Angeles, CA, [6]UT Southwestern Medical Center, Dallas, TX, [7]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background/Purpose: Identifying populations at risk of SLE is essential to curtail inflammatory damage and identify individuals for prevention trials. Healthy blood relatives (FDRs) of lupus patients have increased risk of SLE. Some FDRs have autoantibodies and SLE clinical features, but do not meet the required <4 ACR classification criteria (incomplete lupus, ILE), while others remain unaffected. The goal of this study is to determine factors that distinguish previously healthy FDRs who subsequently develop ILE or SLE.

Methods: This study re-enrolled 436 FDRs of SLE patients who previously enrolled in a genetics study (mean time to followup = 6.3 yrs) and did not meet SLE classification criteria (144 with 0 criteria, 251 with 1–2 criteria, and 41 met 3 criteria) to determine evolution of SLE symptoms and classified disease. FDRs provided clinical and demographic information, and completed the SLE-specific portion of the CTD Screening Questionnaire (CSQ) at baseline (BL) and follow-up (FU). Medical records were reviewed for ACR classification criteria. BL and FU plasma samples were assessed for autoantibody production (ANA, anti-dsDNA, aCL, Ro, La, Sm, nRNP, and ribosomal p antibodies) and for 52 soluble inflammatory mediators (BLyS, APRIL, cytokines, chemokines, and shed TNF receptors). Samples were compared among ILE participants, FDRs who transitioned to SLE, and race/gender/age (± 5 years) matched FDRs who remained unaffected (2:1 ratio of unaffected: ILE/SLE).

Results: 56 FDRs transitioned to SLE (≥ 4 ACR criteria) and 34 were considered as ILE (cumulative ACR criteria = 3) at FU. Matched, unaffected FDRs (n=180) had significantly lower CSQ scores ($p \leq 0.0001$) at BL and FU than those with ILE or classified SLE. Initial analysis revealed a number of soluble mediators that positively correlated with the number of cumulative ACR criteria, including BL levels of MIP-1β, MCP-1, MCP-3, and Eotaxin, as well as SCF ($p \leq 0.01$). TNF superfamily member BLyS positively ($p < 0.0001$) correlated with cumulative ACR criteria, while APRIL ($p = 0.008$) and regulatory mediator TGF-β ($p = 0.002$) negatively correlated with ACR criteria. We then determined factors that differentiated FDRs with ILE or classified SLE at FU. FDRs who transitioned to SLE had significantly higher rate of arthritis and serositis ($p < 0.01$) at BL and higher levels of SCF and MCP-3 ($p < 0.02$) at BL. For FDRs who met fewer than 3 ACR criteria at BL (n = 49 with ILE or SLE at FU), FDRs with ILE at FU (n = 19) were more likely to be female ($p = 0.0002$) and had significantly higher levels of APRIL ($p < 0.04$). For FDRs with ILE at BL (n = 41), FDRs who remained at ILE (n = 15) were more likely to be European-American ($p < 0.0001$) and had significantly lower levels of MCP-3, SCF, and shed TNFRII ($p < 0.03$) than FDRs who transitioned to SLE. BL age and time between BL and FU were not significant factors in distinguishing FDRs with ILE or transition to SLE.

Conclusion: FDRs of known SLE patients demonstrate elevated inflammatory mediators that correlate with cumulative ACR criteria, distinguishing unaffected FDRs from those with ILE or who transition to SLE. Soluble mediators, as well as gender and race, distinguished FDRs with ILE or who transitioned to SLE.

Value Of Arthroscopic Partial Meniscectomy In Treatment Of Symptomatic Patients With Meniscal Tears and Knee Osteoarthritis: Is More Research Warranted? Elena Losina[1], A. David Paltiel[2], Elizabeth Dervan[1], Yan Dong[1], Kurt P. Spindler[3], Lisa A. Mandl[4], Morgan Jones[5], John Wright[1] and Jeffrey N. Katz[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Yale School of Public Health, New Haven, CT, [3]Vanderbilt University, Nashville, TN, [4]Hospital for Special Surgery, New York, NY, [5]Cleveland Clinic, Cleveland, OH.

Background/Purpose: Arthroscopic partial meniscectomy (APM) is often offered to patients with symptomatic meniscal tear (MT). Recent trials in symptomatic patients with MT and knee OA (MT + OA) revealed similar pain relief in persons treated with APM and those treated with physical therapy (PT) and then referred for APM if pain persisted. We assessed expected costs and outcomes of alternative surgical and non-surgical strategies for patients with MT+OA. We examined the value of further research in this population and its likely impact on treatment decisions and their outcomes.

Methods: We used data from the Meniscal Tear in OA Research (MeTeOR) multicenter RCT (mean age 58, 76% Kellgren-Lawrence (KL) grade<3, 24% KL3) to estimate input parameters for a Markov state-transition computer simulation model. The model estimates long-term clinical and economic outcomes of management of MT+OA. We considered 3 strategies: 1) PT only, 2) APM, 3) PT with referral for APM, if PT did not relieve pain. We performed the analysis over a 10-year timeframe and considered short-term pain relief, subsequent pain onset (due to OA) and pain resolution. Transition probabilities were derived from MeTeOR and stratified by KL grade and time from treatment initiation. Pain relief 3 months after APM was 69% (95% CI: 59%-79%) among those with KL<3 and 51% (95% CI: 36%–66%) among those with KL3. Pain relief following APM among those who failed PT was worse (58% for KL<3 and 25% for KL3). Pain relief from PT alone was 49% (95% CI: 39%–58%) for KL<3 and 34% (95% CI 19%–50%) for KL3. Costs of PT ($680/3 month) and pain control ($215/quarter) were derived from MeTeOR and costs of APM ($2,800) from the Medicare Fee Schedule. We performed a probabilistic sensitivity analysis to examine the impact of parameter uncertainty on our finding. To estimate the value of further research, we assessed the expected value of partial perfect information (EVPPI), related to pain-based model parameters. We used willingness to pay (WTP) thresholds from $50k to $144K/QALY to denote programs as "cost-effective".

Results: PT alone led to quality-adjusted life expectancy of 6.96 years with costs of $4,116. Delayed APM (in those who failed PT) led to 7.009 QALYs with costs of $8,130, yielding an incremental cost-effectiveness ratio (ICER) of $80,300/QALY. Immediate APM produced both higher costs ($9,556) and lower QALYs (7.008). In persons with KL<3, the estimated ICERs were $42,200/QALY for delayed APM and $106,400/QALY for immediate APM. In persons with KL3, neither APM-based strategy had favorable cost-effectiveness. Accounting for uncertainty in parameter estimates, in persons with KL<3, the probability of immediate APM being cost-effective ranged from 35% if WTP=$50K to 50% if WTP=$144K. The EVPPI that would result from reducing uncertainty in likelihood of pain relief and subsequent development and resolution of pain was estimated at $2,700/person.

Conclusion: APM-based strategies are unlikely to be cost-effective for MT+OA, even in those with less advanced OA. However, this conclusion is sensitive to assumptions regarding short- and long-term pain relief. Given the prevalence of this condition, more research on pain parameters is warranted.

Direct and Indirect Costs For Patients With Systemic Lupus Erythematosus In National Cohorts In Sweden. Andreas Jönsen[1], Anders A. Bengtsson[1], Christine Bengtsson[2], Iva Gunnarsson[3], Johanna Gustafsson[3], Frida Hjalte[4], Dag Leonard[5], Susanne Pettersson[3], Solbritt Rantapää Dahlqvist[6], Lars Rönnblom[7], Christopher Sjöwall[8], Katarina Steen Carlsson[4], Elisabet Svenungsson[3], Minna Willim[9] and Ola Nived[10]. [1]Lund University, Lund, Sweden, [2]Rheumatology, Umeå, Sweden, [3]Karolinska Institutet, Stockholm, Sweden, [4]Health Economy, Lund, Sweden, [5]Department of Medical Sciences, Section of Rheumatology, Uppsala University, Uppsala, Sweden, [6]Umeå University Hospital, Umeå, Sweden, [7]Section of Rheumatology, Uppsala University, Uppsala, Sweden, [8]Linköping University, Linköping, Sweden, [9]Lund University, Malmö, Sweden, [10]Rheumatology, Lund, Sweden.

Background/Purpose: To study direct and indirect costs for patients with Systemic Lupus Erythematosus (SLE) ín five defined cohorts with nationwide spread in Sweden, and to find potential predictors of cost.

Methods: All 1029 prevalent and incident cases of clinically confirmed SLE, all with at least 4 ACR classification criteria, being alive between January 1st 2003 and December 31st2010 and followed in cohorts in five out of seven university hospitals in Sweden were included. Demographics, date of diagnosis, follow up period, phenotype, disease activity (SLEDAI), organ-damage (ACR/SLICC DI), quality of life (EQ5D) and costs for SLE specific therapy was collected when available from the databases of the rheumatology units. The database at the National Board of Health and Welfare provided all costs for in-patient admissions, out-patient specialist visits and all drug prescriptions from July 2005, and from the Swedish Social Insurance Agency data was obtained about sick leave and disability pensions. The data merge was done within these National Institutions and the cost analysis at the Swedish Institute for Health Economics. All costs are expressed in 2011 price level.

Results: Eighty-eight percent were females and the mean age in 2010 was 52 years with mean disease duration of 17.7 years and approximately 75 percents of the patients were below retirement age (65 years) at the end of the study period in 2010. Annual mean inpatient days were 3.1–3.6. Annual median outpatient specialist physician visits were 6.0–7.5. Annual net sick leave days decreased from 129.8 to 95.1 during the study period. The average total annual costs in SEK 2011, was per SLE patient 208 555 SEK (=$ 33 102) of which 70 percent were indirect costs, the corresponding costs for the subgroup with nephritis was 245 523 SEK (=$ 38 970). The mean annual cost for outpatient pharmaceuticals per SLE patient was 12 888 SEK (=$ 2 046), while the annual cost for more expensive inpatient pharmaceuticals constituted only between 10 and 20 percent of the total cost for pharmaceuticals. Predictors for total costs were increasing age from the age of 40, explained by an increase in indirect costs. Total costs increased with 39 percent for every additional point in ACR/SLICC DI and with 51 percent for patients with a SLEDAI score above 3 (All p<0.01). The EQ5D decreased with increasing SLEDAI (p<0.01). By extrapolation of the study-data the total cost for SLE in Sweden in 2011 can be estimated to 1.125 billions SEK (=$ 178 millions).

Conclusion: The average annual cost for each SLE patient in Sweden is $ 33 102, with indirect costs representing approximately 70 percent and cost for pharmaceuticals only 7 percent of total costs. Significant and independent predictors of costs are increasing age, acquired organ damage and disease activity.

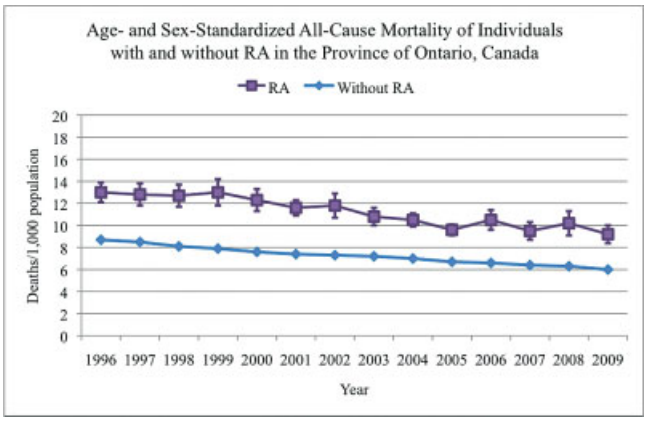
All-Cause Mortality For Patients with Rheumatoid Arthritis In a Universal Public Health Care System. Jessica Widdifield[1], J. Michael Paterson[1], Sasha Bernatsky[2], Bindee Kuriya[3], J. Carter Thorne[4], Simon Hollands[1] and Claire Bombardier[5]. [1]Institute for Clinical Evaluative Sciences, Toronto, ON, [2]McGill University, Montreal, QC, [3]Mount Sinai Hospital, University of Toronto, Toronto, ON, [4]Southlake Regional Health Centre, Newmarket, ON, [5]University of Toronto, Toronto, ON.

Background/Purpose: Studies evaluating trends in rheumatoid arthritis (RA) mortality over time have produced inconsistent results. Our aim was to estimate all-cause mortality in RA between 1996–2009, assess changes in mortality over time, and to compare mortality rates in RA with the general population.

Methods: We studied all residents in Ontario, Canada's most populous province (N~13 million). Patients with RA were identified using the Ontario RA administrative Database (ORAD), a population-based research cohort generated from administrative data using a validated RA case definition. Linking to vital statistics data, we estimated annual all-cause mortality in RA by dividing the number of deaths among RA patients by the number of RA patients in each year. To compare mortality rates over time, we standardized for age and sex using the 2001 Ontario census population estimates. Age specific and age-and-sex standardized all-cause mortality estimates are expressed as the number of deaths per 1,000 RA patients for each year of the study period. The age-and-sex-standardized all-cause mortality estimates were compared in terms of relative percentage change between 1996 and 2008. We compared changes in mortality over time in RA patients, to estimates of mortality in the general population, over the same period. Finally, standardized mortality ratios (SMRs) were calculated, which provides the ratio of the mortality rate in RA patients versus the age and sex matched general population mortality.

Results: Age-and-sex standardized all-cause mortality ranged from 13.0 deaths per 1,000 RA patients (95%CI 12.2,13.9) in 1996 to 9.2 deaths per 1,000 RA patients (95%CI 8.4,10.0) in 2010. In 2008, the age-standardized rate for RA females was 8.8 deaths per 1,000 (95%CI 8.0,9.6) compared to 12.1 deaths per 1,000 (95%CI 10.3,14.2) in males, and rates were higher among males than females in all age groups. Age-specific all-cause mortality in RA patients increased with increasing age. Comparing RA mortality trends to the general population (Figure),

since 1996, all-cause mortality decreased for RA by a relative 21.4%, with a smaller decrease (13.4%) in the general population. The SMRs for RA patients in 2000, 2004, and 2008 were 1.50 (95% CI 1.43–1.57), 1.43 (95%CI 1.37–1.50), and 1.41 (95%CI 1.35,1.47) respectively.



Conclusion: All-cause mortality for patients with RA has decreased over the past decade but remains elevated compared to the general population. Our results suggest 40–50% more deaths among RA patients compared to the general population. SMR estimates over the past decade do suggest the mortality gap may be slowly narrowing.

1771

Cost-Effectiveness Of Different Treatment Sequences Including Adalimumab In The Treat-To-Target Framework For Early Rheumatoid Arthritis In Germany. Malte Wolff[1], Zheng-Yi Zhou[2], James Signorovitch[2], James W. Shaw[3] and Arijit Ganguli[3]. [1]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany, [2]Analysis Group, Inc., Boston, MA, [3]AbbVie Inc., North Chicago, IL.

Background/Purpose: The 2012 German rheumatoid arthritis (RA) treatment guidelines recommend sequential use of disease-modifying antirheumatic drugs (DMARDs) in a treat-to-target (T2T) framework. Biologics are recommended for patients not responding to two conventional DMARDs or with high disease activity and indicators for poor prognosis while on initial DMARD therapy. The objective of this study was to assess the cost-effectiveness of three T2T strategies for achieving and maintaining remission among early RA patients in Germany.

Methods: A Markov model was developed to evaluate the costs and outcomes of three T2T strategies (A, B, C) among early RA patients over a 20-year time horizon from a German societal perspective. Four health states (i.e., remission and low, moderate, and severe disease activity) were defined based on the Disease Activity Score 28 joints (DAS28). At the beginning of each cycle (every 6 months), patients not achieving remission switched to the next treatment. The treatment strategies are: (A) first-line adalimumab (ADA) + methotrexate (MTX); (B) first-line MTX monotherapy, followed by a hybrid approach with ADA + MTX for patients with high disease activity and one DMARD + MTX for patients with low or moderate disease activity after MTX failure; and (C) (current recommended treatment sequence): ADA + MTX after 2 conventional DMARDs. Transition probabilities were estimated using efficacy data from randomized controlled trials. Both direct medical costs (i.e., drug and administration, monitoring, medical, and adverse event costs) and indirect costs (productivity loss) were considered; costs inputs were derived from public data or literature based on the 2012 German treatment guidelines. Utility inputs were estimated based on the OPTIMA trial. Incremental cost-effectiveness ratios (ICERs) comparing Arm A or B vs. C were computed as incremental costs per quality-adjusted life year (QALY) gained. Univariate sensitivity analyses were performed.

Results: At 20 years, Arm A led to an additional 7.8% of patients in remission and 0.280 additional QALY gained compared to Arm C; while Arm B vs. C yielded an additional 0.5% of patients in remission and 0.027 QALY gained. The incremental costs for Arms A and B vs. C over 20 years were €12,135 and €989, respectively, resulting in ICERs of €43,404 per QALY gained for Arm A vs. C and €37,206 for Arm B vs. C as well as ICERs of €9,003 per additional year in remission for Arm A vs. C and €10,609 for Arm B vs. C. Results were robust in univariate sensitivity analyses. Most scenarios (86% for A vs. C and 99% for B vs. C) yielded an ICER below an assumed willingness-to-pay threshold of €50,000 per QALY with exceptions of excluding indirect costs for both comparisons and a shorter time horizon for Arm A vs. C.

Conclusion: In a T2T framework in early RA, strategies starting with ADA + MTX and starting with MTX monotherapy followed by early switching to ADA + MTX for patients with high DAS28 were cost-effective compared with the current recommended treatment sequence with ADA + MTX use after two conventional DMARDs.

Better Cost-Effectiveness and Worker Productivity In Triple DMARD Therapy Versus Methotrexate Monotherapy In Early Rheumatoid Arthritis; Cost-Utility Analysis Of The Treach Trial. P.H.P. de Jong[1], A.E.A.M. Weel[2], J.J. Luime[1], P.J. Barendregt[2], A.H. Gerards[3], P.A. van der Lubbe[3], M.H. de Jager[4], P.B. de Sonnaville[5], D. van Zeben[6], B.A. Grillet[7] and J.M.W. Hazes[1]. [1]Erasmus University Medical Center, Rotterdam, Netherlands, [2]Maasstad Hospital, Rotterdam, Netherlands, [3]Vlietland Hospital, Schiedam, Netherlands, [4]Albert Schweitzer Hospital, Dordrecht, Netherlands, [5]Admiraal de Ruyter hospital, Goes, Netherlands, [6]Sint Franciscus Gasthuis, Rotterdam, Netherlands, [7]Zorgsaam Hospital, Terneuzen, Netherlands.

Background/Purpose: In the treatment in the Rotterdam Early Arthritis Cohort (tREACH) trial we showed that treatment goals were attained faster and maintained with less treatment intensifications within the initial triple DMARD therapy (iTDT) groups as opposed to the initial methotrexate (MTX) mono-therapy (iMM) group. Medication costs are just 20–50% of the total costs. Furthermore the policy for covering prescribed drugs by health insurance companies and governments is more and more influenced by cost-effectiveness. Therefore, our aim is to investigate which initial treatment regimen has the lowest costs per Quality Adjusted Life Year (QALY).

Methods: The one-year data of the tREACH trial were used. Patients were included who had a high probability (> 70%) of progressing to persistent arthritis, based on the prediction model of Visser. The Visser algorithm and 2010 criteria for RA have similar discriminative abilities to identify patients at risk of persistent arthritis at 1 year. Patients were randomized into 3 induction therapy strategies: (A) iTDT (MTX 25 mg/week + sulfasalazine 2 grams/day + hydroxychloroquine 400mg/day) with intramusculair glucocorticoids (GCs) (depomedrol 120mg), (B) iTDT with an oral GCs tapering scheme (starting 15 mg) and (C) iMM with oral GCs similar to B. We used a treat-to-target approach, with patients being examined every 3 months and treatment decisions based upon the original DAS thresholds for low disease activity. Data on QALYs, direct and indirect cost were used. Direct costs are the costs of treatment and medical consumption, whereas indirect costs are costs due to loss of productivity (i.e. sick leave and unemployment).

Results: A total of 281 patients were randomly assigned to strategy (A) (n=91), (B) (n=93) or (C) (n=97). Average QALYs (ideally 1) for treatment strategy A, B and C are given in table 1. Direct and indirect costs per QALY were higher in the iMM group compared with the iTDT groups (table 1). The difference in direct costs was due to ~40% more biological usage, from 3 months up to 1 year. Less unemployment, long-term sickness and reduction in contract hours caused the difference in indirect costs (table 2). Total costs per QALY differed significantly between treatment arm B and C (p=0.012, table 1).

Table 1: QALYs and (specified) average cost per QALY after 1 year of follow-up

	A. MTX + SASP + HCQ + im GCs (n=91)	B. MTX + SASP + HCQ + oral GCs (n=93)	C. MTX + oral GCs (n=97)

Table 2: Loss of productivity and costs during the first year of therapy, stratified for initial treatment regimen.

	A. MTX + SASP + HCQ + im GCs (n=91)	B. MTX + SASP + HCQ + oral GCs (n=93)	C. MTX + oral GCs (n=97)
Unemployment change*	-1 (-2%)	-4 (-8%)	+6 (+11%)
Loss of productivity			
Sick leave			
o Occurrence	47 (89%)	43 (81%)	46 (81%)
o Long term sickness††	10 (19%)	5 (9%)	17 (30%)
o Days absent, *median(IQR)*	3 (1 – 8)	5 (1 – 11)	4 (1 – 8)
Reduction contract hours			
o Occurrence	17 (32%)	20 (38%)	22 (39%)
o Decrease in hours, *median(IQR)*‡	18 (4 – 37)	5 (1 – 11)	29 (10 – 36)

Results shown are number (%) unless stated otherwise.
†Long term sickness is defined as absence from work longer than 160 days (Dutch friction period)
*p=0.015 and p=0.015 for respectively A vs. C and B vs. C.
†p=0.0076 B vs. C.
‡p=0.0007 B vs. C.
Abbreviations: GCs, glucocorticoids; HCQ, hydroxychloroquine; MTX, methotrexate and SASP, sulfasalazine.

Conclusion: iTDT had the lowest costs per QALY compared with iMM. Furthermore iTDT has significant better worker productivity. This underlines once again why iTDT instead of iMM is preferred as first choice in very early RA.

The Contribution Of Environmental Factors To Familial Risk Of Rheumatoid Arthritis By Serologic Phenotypes Among Women In a Longitudinal Cohort Study. Jeffrey A. Sparks[1], Chia-Yen Chen[2], Linda T. Hiraki[3], Susan Malspeis[1], Karen H. Costenbader[1] and Elizabeth W. Karlson[1]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Harvard School of Public Health, Boston, MA, [3]Brigham and Women's Hospital, Harvard School of Public Health, Boston, MA.

Background/Purpose: Familial risk of RA is composed of shared genetic and environmental factors. Previous studies exploring familial risk of RA have not incorporated environmental factors or stratified RA by serologic status. We aimed to estimate the familial risk for all, seropositive, and seronegative RA adjusting for known RA environmental risk factors.

Methods: We conducted a prospective study of family history and RA among a subset of 121,700 women followed since 1976 in the Nurses' Health Study. In 2008, 74,024 participants provided information about family history (FH) of RA or lupus by affected first-degree relative (FDR). RA cases were validated by medical record review according to the 1987 ACR criteria for RA classification. RA serologic status was defined as +RF or ACPA by chart review or laboratory measurement. Cox proportional hazards models were performed to estimate the hazard ratio (HR) and 95% confidence interval (CI) for RA phenotypes (all, seropositive, and seronegative) by affected FDR. Cox regression models were performed for any FH and environmental factors previously shown to be associated with RA (cigarette smoking pack-years, alcohol consumption, parity, breastfeeding duration, body mass index, alcohol intake, menopause, hormone use, menses regularity, and age at menarche) for each RA phenotype.

Results: In 2,082,926 person-years of follow-up in the Nurses' Health Study, we validated 532 RA cases (311 seropositive and 221 seronegative) among 74,024 women that provided information on FH. Any FH of RA or lupus in FDRs was reported in 143 (27%) cases and 6,856 (9%) non-cases. Any FH was associated with all RA (HR 3.76, 95% CI 3.10–4.57), seropositive RA (HR 4.03, 95% CI 3.14–5.17), and seronegative RA (HR 3.98, 95% CI 2.93–5.42) (**Table 1**). RA risk was greatest for those with parental FH. After adjusting for environmental factors, any FH remained significantly associated with all RA (HR 3.66, 95% CI 3.01–4.45), seropositive RA (HR 3.93, 95% CI 3.06–5.06), and seronegative RA (HR 3.84, 95% CI 2.82–5.23) (**Table 2**). After adjusting for FH, smoking >10 pack-years, overweight body mass index, and breastfeeding duration ≥12 months all remained significantly associated with RA.

Table 1. Age-adjusted hazard ratios for family history of RA or lupus by first-degree relatives (FDR: parent, sibling, or offspring) and RA phenotypes (all, seropositive, and seronegative) in the Nurses' Health Study (n=74,024).

Regular	1.0 (Ref)	1.0 (Ref)	1.0 (Ref)
Irregular	1.13 (0.88–1.45)	1.21 (0.88–1.66)	1.04 (0.69–1.56)

[1]Adjusted for age, cigarette smoking pack-years, WHO body mass index category, alcohol intake, parity, breastfeeding duration, menopausal status, hormone use, age at menarche, and menses regularity.
[2]Adjusted for age and any family history of RA of lupus in first-degree relatives.

Conclusion: In this large prospective cohort, women with a first-degree relative with RA or lupus had a four-fold increase in risk of RA compared to those with no family history. This association was similar for seropositive and seronegative RA and remained significant after adjusting for RA environmental risk factors, suggesting that familial RA risk is not fully explained by known environmental factors.

ACR Concurrent Abstract Session
Muscle Biology, Myositis and Myopathies I: Insights into Mechanisms of the Idiopathic Inflammatory Myopathies
Monday, October 28, 2013, 4:30 PM–6:00 PM

1774

Sepsis Is The Leading Cause Of Hospital Mortality In Dermatomyositis/Polymyositis: Data From a Population-Based Study. Sara Murray[1], Laura Trupin[1], Chris Tonner[1], Matthew Cascino[1], Gabriela Schmajuk[1], Mary Margaretten[1], Jennifer Barton[1], Patricia P. Katz[1], Edward H. Yelin[2] and Jinoos Yazdany[1]. [1]University of California, San Francisco, San Francisco, CA, [2]UC San Francisco, San Francisco, CA.

Background/Purpose: Dermatomyositis (DM) and polymyositis (PM) are debilitating inflammatory myopathies with five-year mortality rates estimated to be 33%. However, the leading causes of inpatient mortality in these conditions have not been fully explored. In this study, we used a multi-state sample from the Healthcare Cost and Utilization Project (HCUP) to evaluate the sociodemographic and clinical predictors of inpatient mortality in patients with DM/PM.

Methods: Using the 2009 HCUP State Inpatient Databases for California, New York, Florida, Washington, and Utah, we performed a retrospective study of individuals >18 years of age who met a validated administrative definition of DM/PM. The primary outcome was death during hospitalization. Principal diagnoses were determined according to Clinical Classification Software (CCS) codes and variables for interstitial lung disease (ILD), infection, malignancy, and cardiovascular disease (CVD) were generated based on any primary or secondary ICD–9 code falling within these respective diagnostic categories. A modified Charlson Index was calculated excluding the above diagnoses. Logistic regression was used to investigate the relationship between inpatient mortality and sociodemographic characteristics (age, gender, race, income), admission characteristics (length of stay, weekend admission), and associated diagnoses (ILD, infection, malignancy, CVD).

Results: 3,300 admissions with PM/DM were identified and inpatient mortality was 3.9% (128 deaths). Subjects had an average age of 60 years (SD 17), 68% were female, 62% had DM and 38% had PM. In unadjusted analyses, age (65 years in those who died vs. 60 years in those who survived), weekend admission (27% vs. 19%), length of stay (17 vs. 7 days), more comorbidities (Charlson score of 1.4 vs. 1.3), ILD (22% vs. 12%), infection (76% vs. 36%), malignancy (21% vs. 9%), and CVD (51% vs. 29%) were all associated with mortality. Leading principal diagnoses in subjects who died were septicemia (24%), respiratory failure (17%), pneumonia (9%), aspiration pneumonitis (9%), and acute cerebrovascular disease (5%). In adjusted logistic regression, age (OR 1.09, 95% CI 1.02–1.17), weekend admission (OR 1.5, 95% CI 1.0–2.3), length of stay (OR 1.05, 95% CI 1.03–1.07), ILD (OR 2.0, 95% CI 1.2–3.1), infection (OR 4.3, 95% CI 2.8–6.5), malignancy (OR 3.2, 95% CI 1.9–5.2), and CVD (OR 2.4, 95% CI 1.6–3.5) were independently associated with mortality (see Table).

Table. Adjusted logistic regression of predictors of inpatient mortality in patients with polymyositis and dermatomyositis in a multi-state population-based sample.

	OR (95% CI)	*P*
Age (per 5 years)	**1.09 (1.02–1.17)**	**<0.05**
Female	1.3 (0.8–1.9)	0.2
Race (reference: white)		
Black	1.3 (0.8–2.1)	0.4
Hispanic	0.9 (0.5–1.6)	0.7
Asian/Pacific Islander	1.7 (0.8–3.8)	0.2
Other	2.0 (0.8–4.9)	0.2
Low Income	0.9 (0.6–1.4)	0.7
Weekend Admission	**1.5 (1.0–2.3)**	**<0.05**
Length of Stay (per 2 days)	**1.05 (1.03–1.07)**	**<0.001**
Modified Charlson Index	0.89 (0.78–1.01)	0.08
Dermatomyositis (reference polymyositis)	1.0 (0.7–1.5)	0.9
Interstitial Lung Disease	**2.0 (1.2–3.1)**	**<0.01**
Infection	**4.3 (2.8–6.5)**	**<0.001**
Malignancy	**3.2 (1.9–5.2)**	**<0.001**
Cardiovascular disease	**2.4 (1.6–3.5)**	**<0.001**

Conclusion: Among hospitalized patients with DM/PM, infection, CVD and factors associated with the disease process (ILD, malignancy) were leading causes of mortality. Sepsis was the leading cause of death in these patients, suggesting that additional attention to infection prevention in both the inpatient and outpatient settings may significantly improve outcomes.

Use Of "Computer-Aided Lung Informatics For Pathology Evaluation and Rating" Software In High-Resolution Computed Tomography In Patients With Idiopathic Inflammatory Myopathy and Interstitial Lung Disease. Katelynn Wilton[1], Brian Bartholmai[2], Sanjay Kalra[2], Cynthia S. Crowson[2], Helen Khun[2] and Floranne C. Ernste[3]. [1]Mayo Clinic College of Medicine, Rochester, MN, [2]Mayo Clinic, Rochester, MN, [3]Mayo Clinic Rochester, Rochester, MN.

Background/Purpose: The idiopathic inflammatory myopathies (IIM) are associated with interstitial lung disease (ILD), characterized by parenchymal abnormalities on high-resolution computed tomography (HRCT). We determined the radiologic progression of IIM patients with ILD using a novel lung parenchymal scoring system, "Computer-Aided Lung Informatics for Pathology Evaluation and Rating" (CALIPER) software to record abnormalities on HRCT.

Methods: We conducted a retrospective study of dermatomyositis (DM) and polymyositis (PM) patients at a large academic institution in 2003–2011. We collected HRCT and PFT data at IIM diagnosis and 1, 3, and 5 years. HRCT images were anatomically scored using CALIPER: total volume of normal parenchyma, low attenuation areas (mild, moderate, and severe subclasses) and interstitial abnormalities (ground glass opacities, honeycombing, and reticular densities). Definition of improvement (DOI) for ILD was a $\geq$ 10% increase in total lung capacity (TLC), $\geq$ 15% increase in diffusing capacity (DLCO), and normalization of oxygen during exercise between baseline and 1 year. Spearman correlations, two group and paired t-tests were performed.

Results: We identified 172 patients with IIM and ILD (62% female; mean age 51 years; mean follow-up 4.1 years). Of those, 59 had DM, 84 had PM, 22 had anti-synthetase syndrome, and 7 were unknown. HRCT images revealed ILD in 95% of patients. Main ILD types were nonspecific interstitial pneumonia (59%), cryptogenic organizing pneumonia (23%), and usual interstitial pneumonia (9%). At year 1, improvement occurred in HRCT scans ($n = 58$) in percentage of reticular densities from $7 \pm 6\%$ to $5 \pm 6\%$ ($p < 0.001$) and interstitial abnormalities from $20 \pm 16\%$ to $17 \pm 16\%$ ($p = 0.049$), and a trend in improvement in DLCO ($n = 80$) from 56.2 ± 18.1 to 58.8 ± 16.6 percent predicted ($p = 0.053$). Baseline to year 3, improvement occurred ($n = 34$) in reticular densities ($p = 0.011$) but no difference in PFT values ($n = 64$). At year 1, 22 patients met DOI; within these, there was improvement in DLCO ($n = 22$): 46.8 ± 10.8 to 62.5 ± 12.8 ($p < 0.001$) and TLC ($n = 12$): 65.9 ± 15.4 to 73.9 ± 13.4 ($p = 0.004$). Subgroup analysis bytreatment, prednisone (group 1; $n = 43$), prednisone + other immunosuppressant (group 2; $n = 65$), other immunosuppressant (group 3; $n = 18$), and none (group 4; $n = 40$) revealed no differences in PFTs at baseline; but, in group 4 there were more interstitial abnormalities at baseline ($p = 0.050$). Baseline to year 3, group 4 worsened in interstitial abnormalities ($p = 0.036$). Progression from normal lung (green) to ground glass opacities (yellow) and reticular fibrosis (orange) also occurred despite treatment (See Figure).

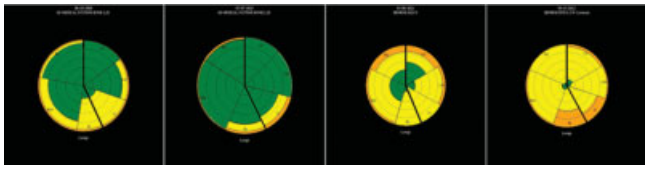

Figure. CALIPER in ILD.

Conclusion: IIM patients with ILD improve in reticular densities, low attenuation areas, and interstitial abnormalities. Progression of ILD was observed in patients without treatment. CALIPER aids in tracking ILD over time.

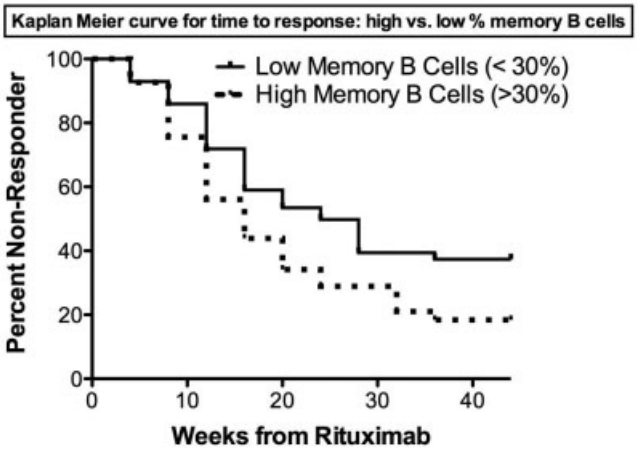
Peripheral Blood Memory B Cell Numbers Predict Clinical Response Following Rituximab Treatment Of Adult and Childhood Myositis. Rohit Aggarwal[1], Chester V. Oddis[1], Erich R Wilkerson[1], Diane Koontz[1], Ilinca D. Metes[1], Ann M. Reed[2], Dana P. Ascherman[3] and Marc C. Levesque[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Mayo Clinic, Rochester, MN, [3]University of Miami Miller School of Medicine, Miami, FL.

Background/Purpose: B cell subset numbers, especially lower memory B (Bmem) cells, predict clinical responsiveness to rituximab in several diseases including pemphigus and rheumatoid arthritis (RA). The Rituximab in Myositis (RIM) trial enrolled 200 refractory myositis subjects (76 dermatomyositis (DM), 76 polymyositis (PM), 48 juvenile dermatomyositis (JDM)). Our aim was to determine whether the numbers and relative percentage of peripheral blood B cell subsets at baseline and after rituximab predicted clinical responses in refractory myositis.

Methods: Using flow cytometry, we analyzed total B cell numbers and B cell subset (transitional/naïve/switched and unswitched Bmem/ and plasmablast) percentages at baseline, 8, 24 and 32 or 36 weeks after rituximab. We assessed 71 "responders" who met the study definition of improvement (DOI) without experiencing subsequent disease worsening and compared them to 35 "non-responders." The DOI was defined as 20% improvement in at least 3 of 6 core set disease activity measures, including MD and subject global disease activity, manual muscle testing (MMT), physical function, muscle enzymes,

and extramuscular disease activity. We used Mann-Whitney tests to determine the association of B cell subsets with response. Cox proportional hazard models were used to determine if B cell subsets predicted a better (i.e. shorter) time to response post rituximab. Spearman correlations assessed the relationship of changes in MMT and MD global post rituximab to changes in Bmem and plasmablast subsets.

Results: 97% of RIM subjects depleted their B cells to <5/ul following rituximab. There was no difference in total B cell numbers, total and % B cell subsets, or the ratios of transitional and naive:Bmem cells between responders and non responders at any time-point. There was no correlation between change in B cell subsets and the change in MD global disease activity or MMT. However, among myositis autoAb positive subjects (N=80; 58 responders, 22 non-responders), there was a significantly higher percentage of Bmem cells in responders at week 8 [median (IQR): 30.6% (17.8–45.9) vs. 21.3% (12.8–26); p = 0.009], mainly due to a higher percentage of switched Bmem cells. The total number of Bmem cells at week 8 showed a similar trend (p=0.02). The percentage of Bmem cells at week 8 was also associated with a shorter time to response (p=0.008; Figure 1), mainly due to switched memory B cells in autoAb positive subjects (p=0.004). Similar trends between clinical responsiveness and Bmem cell numbers were seen in the overall cohort as in the PM, DM, and JDM subsets but not statistically significant.



Conclusion: In contrast to RA, a higher percentage of Bmem cells at week 8 was associated with clinical responsiveness in autoAb positive myositis patients post rituximab. This suggests the presence of a subpopulation of Bmem cells in myositis associated with a favorable response following B cell depletion.

Antibodies Against TIF1-Gamma In Cancer Associated Myositis May Precede Cancer Symptoms and Persist After Cancer Removal. Ingrid E. Lundberg[1], Lara Dani[1], Maryam Dastmalchi[2], Maria Angeles Martinez[3], Moises Labrador-Horrillo[4] and Albert Selva O'Callaghan[4]. [1]Rheumatology Unit, Department of Medicine, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [2]Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [3]Sant Pau Hospital, Barcelona, Spain, [4]Vall d'Hebron General Hospital, Barcelona, Spain.

Background/Purpose: Antibodies against TIF1-gamma have been detected in patients with cancer associated myositis (CAM) but it is not known whether the antibodies precede the diagnosis of cancer or if the antibodies persist after successful treatment of a malignancy. We aimed to analyse levels of TIF1-gamma antibodies in longitudinally collected sera taken before cancer diagnosis and after treatment of the malignancy in patients with CAM.

Methods: From our local myositis register including 170 myositis patients we found 56 cases of CAM. Serum samples and clinical data were available from 54 patients with CAM. Serum levels of anti-TIF1gamma antibody were tested by ELISA using a commercially available purified recombinant protein (OriGene, Rockville, MD).

Results: Sera from 16 (29.6%) patients (13 females and 3 males) were positive for anti-TIF1gamma antibodies in at least one serum sample. Their mean age was 63.6 years. Of the 16 positive patients 12 had developed cancer within 3 years from myositis diagnosis, 4 after 3 years. Serum samples taken before cancer diagnosis were available from 15/54 patients and four of them were positive for anti-TIF1-gamma. Of the 16 anti-TIF1-gamma positive cases, four had sera available before cancer diagnosis and three of them were positive before cancer diagnosis. One of these patients had detectable anti-TIF1gamma antibodies up to 5 years before cancer diagnosis. Of the 16 patients positive for anti-TIF1-gamma, 12 patients had died at time of our study, 7 within 1 year from cancer diagnosis. The 7 patients who died within one year had a mean antibody level of 1976 +/− 304 au, the 5 patients who died after more than 1 year had a mean antibody level of 1036 +/− 555 au (p=0.003). Four patients were still alive at time of the investigation, between 2–13 years after cancer treatment. They were all in remission from cancer disease. Two patients became negative for anti-TIF1-gamma antibodies, these two patients were among the patients in remission at follow up.

Conclusion: Anti-TIF1-gamma antibodies can be detected before cancer diagnosis and may thus become a helpful marker to alert for cancer in patients with myositis. The levels of anti-TIF1-gamma antibodies seem to be a prognostic marker for survival in CAM.

Physical Interactions Between Histidyl-tRNA Synthetase and Endogenous/Exogenous Alarmins Enhance Immunogenicity In a Model Of Antigen-Induced Myositis. Irina Fernandez[1], Lisa Harlow[1], William Ridgway[2] and Dana P. Ascherman[1]. [1]University of Miami Miller School of Medicine, Miami, FL, [2]University of Cincinnati, Cincinnati, OH.

Objective: To assess the biological interplay between histidyl-tRNA synthetase (HRS) and different endogenous/exogenous ligands capable of generating signals through MyD88-dependent receptor systems in idiopathic inflammatory myopathy.

Background/Purpose: Recent immunohistochemical and array-based studies of human muscle tissue implicate Toll-like receptor (TLR)- and other MyD88-dependent signaling pathways in the pathogenesis of idiopathic inflammatory myopathy. Our model of HRS-induced myositis replicates many of these observations, demonstrating that intramuscular immunization of mice with bacterially produced HRS fusion proteins preferentially triggers muscle inflammation (relative to other bacterially generated control proteins) via partially redundant MyD88-dependent signaling cascades. However, the biophysical properties endowing HRS with this unique signaling capacity remain undefined.

Methods: Binding interactions between eukaryotically expressed HRS and ligands of TLR2 (FSL-1), TLR4 (LPS), or RAGE (HMGB1) were assessed via standard solid phase ELISA following co-incubation of soluble HRS or TLR/RAGE ligands with defined concentrations of pre-bound substrate antigen. As an alternative method for detection of HRS-TLR ligand complex formation, HRS and specified ligands were pre-incubated in solution for 2 hours prior to plating in BSA-blocked ELISA wells and subsequent probing with anti-HRS serum. The ability of these complexes to signal via defined TLRs was assessed through stimulation of TLR-transfected HEK23 cells and measurement of resulting IL-8 production.

Results: ELISA-based experiments demonstrated that both human and murine HRS expressed in a eukaryotic system bound HMGB1 in dose-dependent fashion. Similarly, the TLR2 ligand FSL-1 formed complexes with baculovirus-expressed HRS that inhibited subsequent binding of HRS to BSA-blocked ELISA wells. LPS also readily formed complexes with baculovirus-expressed HRS, as evidenced by diminished ELISA-based binding of these complexes relative to HRS alone. Comparative ELISAs employing a biotinylated LPS/streptavidin-HRP probe system and various substrate antigens demonstrated that HRS bound LPS with 10–100 fold greater affinity/aviditiy than did ovalbumin or control autoantigens such as baculovirus-expressed Ro52. Corresponding to these heightened interactions with the TLR ligands LPS and FSL-1, complexes of HRS-LPS and HRS-FSL-1 synergistically activated HEK293 cells transfected with TLR4 and TLR2, respectively—producing levels of IL-8 which significantly exceeded those induced by HRS or ligand alone.

Conclusion: HRS preferentially binds various ligands of innate immune receptors with high affinity, resulting in synergistic activation of TLR2- and TLR4-mediated signaling pathways that likely contribute to human idiopathic inflammatory myopathy as well as our model of HRS-induced myositis. Of note, these findings support a more general paradigm in which autoantigens such as HRS bind endogenous/exogenous alarmins to activate innate immune signaling cascades that enhance immunogenicity and prime subsequent adaptive autoimmune responses.

A Randomized Controlled, Clinical, Histological and mRNA Profiling Pilot Study Of Endurance Exercise In Myositis. Li Alemo Munters[1], Ingela M. Loell[2], Joan Raouf[3], Maryam Dastmalchi[4], Eva Lindroos[5], Christina Ottosson[6], Yi-Wen Chen[7], Annemarie F van Delden[6], Mona Esbjörnsson[8], Marina Korotkova[9], Helene Alexanderson[10], Kanneboyina Nagaraju[7] and Ingrid E. Lundberg[2]. [1]Rheumatology Unit, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Department of Medicine, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology Unit, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden, [4]Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [5]Rheumatology Unit, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden., Stockholm, Sweden, [6]Rheumatology Unit, Karolinska University Hospital Solna, Karolinska Institutet, Stockholm, Sweden., Stockholm, Sweden, [7]Research Center for Genetic Medicine, Children's National Medical Center, Washington DC, USA., Washington DC, DC, [8]Karolinska Institutet, Huddinge, Sweden, [9]Rheumatology Unit, Department of Medicine, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden, [10]Division of Physiotherapy, Karolinska Institutet, Huddinge, Stockholm, Sweden.

Background/Purpose: This pilot study is a hypothesis-driven exploratory part of a larger randomized controlled trial evaluating effects of a supervised 12-week endurance exercise program (EG) compared to a non-interventional control group (CG) in patients with established polymyositis (PM) and dermatomyositis (DM). The aim was to determine the potential mechanisms underlying the beneficial effects of endurance exercise.

Methods: A subgroup of 15 patients with paired baseline and 12 week follow-up muscle biopsies (EG n=7 and CG n=8) were included in the analysis. mRNA expression profiling and immunohistochemistry analysis of biopsies from vastus lateralis muscle were used to determine molecular changes associated with the changes in clinical assessments. Clinical assessments consisted of: Maximal oxygen uptake (VO_2 max) and cycling time to exhaustion at 65% of VO_2 max. Lactate levels in the vastus lateralis muscle were measured with microdialysis directly after the cycling. Clinical disease activity was assessed according to the International Myositis Assessment and Clinical Studies Group (IMACS) criteria.

Results: Patients in the EG clinically improved compared to the CG in cycling time ($p<0.01$) and VO_2 max ($p<0.05$), whereas lactate levels at exhaustion were decreased or unchanged. A majority of the patients in the EG were responders with reduced disease activity compared to the CG ($p<0.05$). These clinical changes were accompanied with down-regulation in genes related to inflammation and ER-stress, such as Eukaryotic translation initiation factor 2C, 4 (−2.6, $p<0.01$) and Cell adhesion molecule with homology to L1CAM (−1.6, $p<0.01$); and up-regulation in genes related to capillary growth, cytoskeletal remodeling, muscle hypertrophy, mitochondria biogenesis and protein synthesis, such as Toll-like receptor 7 (1.7 fold, $p<0.01$), Fms-related tyrosine kinase 3 ligand (4.3 fold, $p<0.01$), Insulin-like growth factor 1 receptor (1.4, $p<0.001$), Insulin receptor (1.3, $p<0.001$). The CG displayed non- synchronized regulation of genes, although up-regulation in genes related to type 1 interferon and apoptosis was determined. No significant changes were displayed in the number of T-cells and macrophages in the EG nor in the CG. The EG but not the CG showed a higher number of capillaries per mm^2 in the follow up biopsy.

Conclusion: Our data showed that endurance exercise in patients with PM and DM may induce genes involved in muscle growth and remodeling as previously reported in healthy individuals. In addition, the exercise suppressed inflammation and ER-stress accompanied with reduced clinical disease activity in the patients. The findings suggest that endurance exercise may be beneficial by activating the muscle growth program which overwrites the muscle atrophy process, and suppressing the inflammation responses in parallel in the patients' muscles.

Background/Purpose: The RAndomized Placebo Phase Study Of Rilonacept in the Treatment of Systemic Juvenile Idiopathic Arthritis (RAPPORT) is a multicenter controlled trial using a 4 week randomized placebo phase. The study design reasons that if a treatment is effective, subjects who begin active treatment earlier will respond sooner, on average, than subjects who begin active treatment later. Rilonacept is a fusion protein consisting of human cytokine receptor extracellular domains of both receptor components required for IL-1 signaling: the IL-1 Type I receptor and the IL-1 receptor accessory protein as well as the Fc portion of human IgG1.

Methods: RAPPORT consisted of a double-blind phase (weeks 0–4), a treatment phase (weeks 4–24) and an open label Long Term Extension phase (24 weeks −21 months). The primary endpoint was time to response, using adapted JIA ACR 30 response criteria requiring absence of fever for 2 weeks and meeting pre-specified criteria for tapering of corticosteroids during the first 12 weeks of the study. We randomized 71 children with at least 2 active joints from 20 sites 1:1 to 2 arms of the study. The rilonacept arm subjects received rilonacept (4.4mg/kg loading dose followed by weekly 2.2mg/kg subcutaneously) and placebo arm subjects received placebo for 4 weeks followed by loading dose of rilonacept at week 4 followed by weekly maintenance doses. After week 14, corticosteroids were dosed according to the treating physician.

Results: The time to response was shorter in the rilonacept arm (median 4 weeks; range 2–10 weeks) than in the placebo arm (median 6 weeks; range 2–12 weeks) (Chi-square 7.235; p=0.007). Twenty-six of 35 (79%) patients in the rilonacept arm and 13 of 33 (39%)in the placebo arm met ACR Pediatric 30 response criteria at week 4 (p=0.004); 21/35 (60%) in the rilonacept arm vs. 10/33 (30%) in the placebo arm met ACR pediatric 50 response criteria (p=0.015); 14/35 (40%) vs. 4/33 (12%) met ACR pediatric 70 criteria (p=0.013). Adverse events were similar in the two arms of the study (Table). Four subjects developed elevations in liver transaminases of ≥ 2 times the upper limit of normal (all while on rilonacept); 2 subjects developed elevations ≥5 times the upper limit of normal. In one, the

elevations resolved but recurred on re-challenge and was deemed an SAE. One subject developed EBV induced macrophage activation syndrome.

Table. Adverse Events

Variable	Double-Blind Phase		Treatment Phase		LTE Open-Label Phase
	Rilonacept (N=36)	Placebo (N=35)	Rilonacept (N=35)	Placebo (N=33)	Rilonacept (N=40)
ADVERSE EVENTS

Pyrexia	0	0	1 (3%)	0	0
Varicella	0	0	1 (3%)	0	0
Viral upper respiratory tract infection	0	0	0	0	1 (3%)
INFECTIONS					
No. of events	2	2	25	29	37
No. of events per patient-year	0.7	0.8	1.9	2.7	1.0
Patients with an event - no. (%)	2 (6%)	2 (6%)	16 (46%)	20 (61%)	14 (35%)

[1] The most frequently reported events were defined as events that occurred in at least 10% of all patients during the entire study.

Conclusion: This is the first double-blind, randomized, placebo-controlled trial of rilonacept to demonstrate efficacy in sJIA. Rilonacept treatment was relatively safe. Significant elevations in aspartate aminotransferase levels were rare but occurred more often in subjects receiving rilonacept than in those on placebo.

1781

Clinical Variation In Children With Mutations In *MEFV*. Karyl S Barron[1], Amanda K. Ombrello[2], Ivona Aksentijevich[3], Anne Jones[3] and Daniel L. Kastner[3]. [1]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, [2]National Human Genome Research Institute, National Institute of Health, Bethesda, MD, [3]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

Background/Purpose: As a referral clinic for children with periodic fevers, we see a wide variety of clinical presentations. While genetic testing is usually helpful in determining clinical course and possible treatment options, we have seen a wide variation in clinical presentation in those patients found to have a genetic mutation in one of the genes linked to periodic fever syndromes. Familial Mediterranean fever (FMF) is usually regarded as an autosomal recessive inherited disorder due to mutations in the *MEFV* gene; however we have seen a number of symptomatic children who carry only one identifiable mutation in *MEFV*. In this study, we aim to characterize the clinical presentations of children with a variety of mutations in *MEFV*.

Methods: Patients were evaluated at the National Institutes of Health. Clinical and laboratory information were collected at each visit. Genetic testing for mutations in *MEFV* was performed by GeneDx. Genomic DNA was PCR-amplified for analysis of exons 2, 3, and 10 of the *MEFV* gene. Patients were evaluated for age at onset (months), duration of episode (days), frequency (weeks), and presence or absence of fever, abdominal pain, chest pain, rash, adenopathy, oral ulcers, or sore throat associated with flares. Patients were considered as meeting the criteria for PFAPA (Periodic Fever with Aphthous Ulcers, Pharyngitis, and Adenopathy) Syndrome if they had a history of periodic fever and 2 of the following: adenopathy, oral ulcers or sore throat.

Results: 82 children with mutations in *MEFV* were evaluated: 14 had 2 exon 10 mutations, 7 had 2 exon 10 mutations + E148Q, 18 had a single exon 10 mutation, 7 had a single exon 10 mutation + E148Q, 12 had a single E148Q mutation, 9 had a single K695R mutation, and 15 had P369S/R408Q ± E148Q.

We found no significant difference in any of the factors when children with one exon 10 mutation were compared with children with two exon 10 mutations. Children heterozygous for only E148Q were similar to those with a single exon 10 mutation with the exception that a higher percentage of E148Q heterozygotes met criteria for PFAPA (42% vs. 6%, P=.015). Similarly, children heterozygous for K695R had a significantly longer duration of episode (4 days vs. 2.6, P=.01) and higher frequency of adenopathy (89% vs. 39%, P=.014), oral ulcers (67% vs. 17%, P=.009), sore throat (56% vs. 11%), and meeting criteria for PFAPA (78% vs. 6%, P<.009) when compared to children with one mutation in exon 10. Children with P369S/R408Q ± E148Q were similar to those heterozygous for an exon 10 mutation, with the exception of longer duration of episode (4 vs. 2.6 days, P=.027). While most children with one or two exon 10 mutations responded to therapy with colchicine, there was a trend for need for additional treatment options in patients with E148Q, K695R or P369S/R408Q heterozygosity.

Conclusion: A clinical presentation similar to that of PFAPA was more common in patients heterozygous for either E148Q or K695R mutations of *MEFV*. While this is not an unexpected finding in patients with E148Q, it is surprising that patients with mutations in amino acid 695 do not follow the pattern of severe disease seen historically in patients with mutations in amino acid 694.

Chronic Atypical Neutrophilic Dermatosis With Lipodystrophy and Elevated Temperatures (CANDLE): Clinical Characterization and Initial Response To Janus Kinase Inhibition With Baricitinib. Gina A. Montealegre Sanchez[1], Adam L. Reinhardt[2], Paul Brogan[3], Yackov Berkun[4], Diane Brown[5], Peter Chira[6], Ling Gao[7], Dawn C. Chapelle[1], Nicole Plass[1], Hanna Kim[1], Michael Davis[1], Adriana Almeida de Jesus[1], Yin Liu[1], Yan Huang[1], Colleen Hadigan[8], Theo Heller[9], Zlotogorski Zlotogorski[10], John J. O'Shea[1], Chyi-chia Lee[11], Suvimol C. Hill[12], Kristina Rother[9], Massimo Gadina[1] and Raphaela T. Goldbach-Mansky[1]. [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD, [2]Children's Hosp of Omaha/UNMC, Omaha, NE, [3]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy, [4]Hadassah Medical Center, Mount Scopus, Jerusalem, Israel, [5]Children's Hospital Los Angeles, Los Angeles, CA, [6]Indiana University School of Medicine, Riley Hospital for Children, Indianapolis, IN, [7]University of Arkansas for Medical Sciences, Little Rock, AR, [8]National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD, [9]National Institute of Diabetes and Digestive Kidney Diseases, NIH, Bethesda, MD, [10]Department of Dermatology, Hadassah-Hebrew University Medical Center, Jerusalem, Israel., Jerusalem, Israel, [11]National Cancer Institute, National Institutes of Health, Bethesda, MD, [12]NIH Clinical Center, Bethesda, MD.

Background/Purpose: CANDLE, a novel autoinflammatory syndrome presents with attacks of fever, annular cutaneous plaques, persistent periorbital edema, arthritis, lymphopenia and lipodystrophy since early childhood. CANDLE is caused by mutations in *PSMB8* and other proteasome associated genes. Elevated serum IP-10 (CXCL10) levels and gene expression studies show a prominent "interferon (INF) signature", and successful *in vitro* blocking studies with small molecules that inhibit Janus kinases (JAKs)

signaling, raised the questions whether IFN could be a therapeutic target in CANDLE.

Objectives: The primary objective of this compassionate use study is to determine whether the treatment with the JAK1 and JAK2 inhibitor (baricitinib/Eli Lilly) allows a reduction in daily oral corticosteroid of at least 50%. The secondary objective is to determine whether treatment with baricitinib results in the reduction of the mean Autoinflammatory Diary Score (ADS) to below 0.5.

Methods: CANDLE patients with an ADS >0.5 who take at least 0.15mg/kg/day of oral prednisone are eligible. Paired t-test were used to compare baseline to last clinic visit data.

Results: We enrolled eight CANDLE patients, 62% males, 75% Caucasians, 37% Hispanics. Mean age at disease onset was 5 (SD±6) weeks. Most patients presented with annular lesions/periorbital erythema (88%), fever (85%) and failure to thrive (38%). At enrollment all patients had characteristic areas of lipodystrophy and joint contractures, growth delay (87%), increased intra-abdominal fat deposition (83%), and dyslipidemia (75%). Seven patients presented with anemia at baseline, mean of 11.6 g/dL, often also associated with thrombocytopenia and/or lymphopenia (the latter only patients not homozygous for *PSMB8*). MRI-confirmed myositis was present in 75% of patients. Other findings include: presence of basal ganglia calcifications (71%), peripheral calcinosis (25%), conjunctivitis/episcleritis (50%), pancreatic abnormalities (25%) and epididymitis (25%).

All patients were followed for at least 2 weeks (mean 8 months). The mean dose of baricitinib is 5 mg/day (SD±3), The mean daily autoinflammatory diary score at baseline of 1.33 dropped to 0.25 at the time of their last visit ($p<0.05$). The mean total prednisone dose of 17 mg/day (SD±7) dropped by 58% to 7 mg/day (SD±4) (~0.47 mg/kg/day), ($p<0.05$). Myositis improved in 4 out of the 5 patients and signs of bone marrow immunosuppression resolved in all patients, with improvement on Hgb, PLT and ALC counts. All other immunosuppressive medications were discontinued. Three SAEs were reported (rotavirus and CANDLE related severe neutropenia).

Conclusion: Preliminary data in eight patients with CANDLE treated with baricitinib are encouraging and suggest that targeting interferon signaling with a JAK1, JAK2 inhibitor may be a potential therapeutic regimen for CANDLE and possibly other IFN mediated autoinflammatory disorders but further data is needed.

Canakinumab Treatment In Active Hyper-IgD With Periodic Fever Syndrome. Juan Ignacio Aróstegui[1], Inmaculada Calvo[2], Jordi Anton[3], Angel Robles[4], Jordi Yagüe[1], Ruth Viana[5], Lillian Tseng[6] and Ken Abrams[6]. [1]Hospital Clinic Barcelona, Barcelona, Spain, [2]Hospital La Fe, Valencia, Spain, [3]Hospital Sant Joan de Deu, Barcelona, Spain, [4]Hospital La Paz, Madrid, Spain, [5]Novartis Farmacéutica, S.A., Barcelona, Spain, [6]Novartis Pharmaceuticals Corporation, East Hanover, NJ.

Background/Purpose: Hyper-IgD with periodic fever syndrome (HIDS) is a recessively inherited autoinflammatory disease due to biallelic *MVK* mutations. It is characterized by 4–6 days-long acute inflammatory episodes, which typically start during infancy and recur every 4–6 weeks. Previous studies suggested IL-1 blockade as a potential therapy. However, little information is available about the efficacy and safety of the fully human anti-IL-1b monoclonal antibody canakinumab (CAN) in active HIDS.

Methods: The present study is a multicenter, open-label, and single treatment arm study with a 6-month treatment period (TP) with CAN and a max. 6-month follow-up period (FP). Inclusion criteria were age ≥2 yr. old, biallelic *MVK* mutations, and active disease defined by ≥3 acute flares in the 6-month historical period (HP, period in which patients did not receive drugs other than symptomatic treatment with NSAIDs and/or steroids) and C-reactive protein (CRP)>10 mg/L. The CAN dose in the TP was 4 mg/kg (max. 300mg) Q6-wks, with a dose up-titration to 6mg/kg (max. 450mg) if a flare occurred during the first 6-weeks. The primary objective was to assess the efficacy of CAN to reduce the flare rate during the TP compared with the HP. Secondary objectives included evaluation of changes in key disease features, disease control during TP, time to flare after the last CAN dose and safety.

Results: Nine patients (6 F, 3 M) from 3 centers were included. Median age was 17.3 yr (5–29 yr) and median disease duration since diagnosis was 4.1 yr (1–25 yr). The median of number of flares/patient with CAN reduced from 5 (3–12) during HP to 0 (0–2). During FP 7/9 patients flared, with a median of 110 days (62–196 days) after the last CAN dose. At baseline, physicians rated 6 and 3 patients as having no or poor disease control, respectively. At day 4 of TP, all patients were rated as having good/excellent disease control. At baseline, 8/9 patients had moderate/severe fever, 8/9 had mild/moderate lymphadenopathy, 5/9 had mild/moderate abdominal pain and 4/9 had mild/moderate apthous ulcers. From day 4 of TP onwards, no patient referred fever or abdominal pain, and only one patient had mild to moderate lymphadenopathy and apthous ulcers. At baseline, the median plasma levels of CRP and serum amyloid A (SAA) were elevated (CRP: 117.7 mg/L and SAA: 688.5 mg/L; normal values ≤10 mg/L in both cases). At day 15 of TP both plasma levels normalized (CRP: 0.8 mg/L; SAA: 2.6 mg/L) and were maintained. At least one adverse event (AE) was detected in 8 patients, most of them being of mild (76%) or moderate (18%) severity. Respiratory tract infections were the most common AE detected. Two patients reported a serious AE, one patient with an acute inflammatory flare leading to hospitalization, and another one had a gastrointestinal bleed and peritonitis separately (this patient was on peritoneal dialysis from amyloidosis induced by renal failure). No AEs led to CAN discontinuation.

Conclusion: CAN in active HIDS markedly reduced the rate of acute flares, and a sustained good/excellent disease control was observed. Most AEs registered were mild/moderate and all of them were manageable. Further studies are needed to better define CAN treatment in active HIDS.

Effectiveness Of First Line Use Of Recombinant IL-1RA Treatment In Steroid naïve Systemic Juvenile Idiopathic Arthritis: Results Of a Prospective Cohort Study. S.J. Vastert[1], Wilco de Jager[1], Bo Jan Noordman[1], Dirk Holzinger[2], Wietse Kuis[1], Berent J. Prakken[1] and Nico M. Wulffraat[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]University Muenster, Muenster, Germany.

Background/Purpose: To perform a prospective cohort study with recombinant IL-1RA (Anakinra, rIL-1RA) as first-line therapy in newly onset sJIA.

Methods: Patients fulfilled the ILAR criteria for sJIA. RIL-1RA (2 mg/kg) was started as first-line therapy and patients were monitored clinically and immunologically. The protocol contained a stop strategy when in remission at 3 months.

Results: We included 20 consecutive newly onset sJIA patients and started rIL1-RA as first line treatment (in steroid naive patients). Mean follow-up was 32 months (range 12–54). After 3 months, 85% of patients showed ACRPed90 responses and 75% (15/20) were in remission on rIL-1RA alone. After 1 year, 85% of patients (17/20) displayed ACRPed90 responses / clinically inactive disease. 65% of patients (13/20) achieved this on rIL-1RA alone. However, 7/20 patients (35%) required therapy besides rIL1-RA because of persistent disease activity. Following our stop strategy, 11/15 (73%) patients with clinically inactive disease at 3 months, could stop rIL-1RA within the first year.

After two years, (n=14), 86% (12/14) of patients showed ACRPed90 responses / disease remission, either on (n=4) or off (n=8) medication. After three years (n=11), 91% of patients (10/11) showed ACRPed90 responses / disease remission, either on (n=2) or off (=8) medication.

Conclusion: This is the first prospective study describing rIL-1RA as first-line therapy in sJIA. We observed excellent clinical responses in nearly all patients within three months. The majority of responding patients could stop rIL-1RA within 1 year with preserved remission during follow-up. Approximately one-third of patients needed concomitant therapy to maintain clinical response. IL-18 and S100A proteins seem candidate biomarkers for guiding tapering.

Disclosure: S. J. Vastert, Novartis Pharmaceutical Corporation, 5; **W. de Jager**, None; **B. J. Noordman**, None; **D. Holzinger**, None; **W. Kuis**, None; **B. J. Prakken**, None; **N. M. Wulffraat**, Roche, Pfizer, 2, Novartis Pharmaceutical Corporation, 5.

Structural Determinants Of Low Vertebral Strength In Pediatric Systemic Lupus Erythematosus. Jon M. Burnham[1], Babette S. Zemel[1], David C. Lee[2], Tony M. Keaveny[3] and Mary Beth Leonard[1]. [1]The Children's Hospital of Philadelphia and the Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [2]O.N. Diagnostics, LLC, Berkeley, CA, [3]University of California, Berkeley, CA and O.N. Diagnostics, LLC, Berkeley, CA.

Background/Purpose: Children with systemic lupus erythematosus (SLE) are at high risk for bone fragility. Studies in pediatric SLE using two-dimensional lumbar spine (LS) dual X-ray absorptiometry (DXA) demonstrate deficits in areal bone mineral density (aBMD). However, the bone structural abnormalities that lead to vertebral compression fractures are unknown. Vertebral volumetric density (vBMD), structure, and compression strength can be estimated using finite element analysis (FEA) of three-dimensional spine quantitative computed tomography (QCT) scans. We performed a cross-sectional study using QCT FEA to assess: 1) LS strength deficits in pediatric SLE and 2) structural determinants of deficits, including vertebral geometry and cortical and trabecular density.

Methods: Participants with SLE were 5–21 years of age and had SLE for at least 1 month. Controls were matched by sex, race (black vs non-black), and Tanner stage. QCT scans of the second lumbar vertebra (L2) were acquired on a Siemens Sensation 64 scanner. FEA strength and density parameters were calculated using VirtuOst 1.2 (ON Diagnostics, Berkeley, CA). DXA scans of L1–4 were obtained using a Hologic QDR 4500A bone densitometer (Apex Software v3.3). Height, body mass index (BMI), fat mass index (FMI), lean mass index (LMI) and LS aBMD Z-scores were generated using reference data from our institution. Multivariable linear regression was used to identify covariates independently associated with L2 strength.

Results: Participants with SLE (n=23, 91% female, 48% black) had a mean age of 14.1 years and significantly lower height Z-scores (−0.05 vs 0.76, p=0.02) and LMI Z-scores (−0.78 vs 0.07, p=0.006). BMI- and FMI Z-scores did not differ between SLE and controls. The median disease duration was 2.1 years (range: 0.3 to 5.8). In SLE, prednisone was prescribed in 74% (median 7.5 mg/day, range: 0–20), hydroxychloroquine in 91%, and immunosuppressants in 74%. LS aBMD Z-scores were lower in SLE (−0.89 vs 0.72, p<0.001). In controls, L2 strength was greater at higher Tanner stages (p≤0.001), adjusting for age and race (both p>0.5). The L2 strength distribution according to SLE and Tanner stage is shown (Figure). In SLE, L2 strength was 21% lower (6844 vs 8688 Newtons (N), p=0.006). The trabecular compartment strength was 26% lower (3659 vs 4913 N, p=0.003), while the cortical compartment strength was 16% lower (3186 vs 3777 N, p=0.04). Further, the inner trabecular vBMD was 18% lower (156 vs 191 mg/cm^3, p<0.001), and the cortical vBMD was 9% lower (293 vs 322 mg/cm^3, p=0.03). The strength attributable to differences in geometry alone was similar to controls (2643 vs 2840 N, p=0.18).

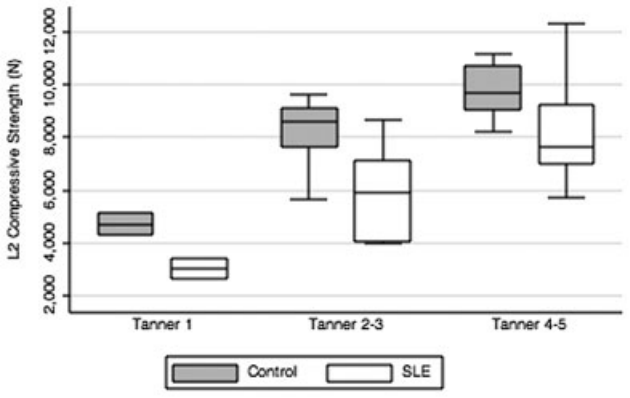

Figure. L2 strength according to Tanner stage.

Conclusion: In the first pediatric study to use vertebral FEA, we found substantial L2 vertebral strength deficits in pediatric SLE. These deficits were not driven by differences in geometry but by the lower cortical and primarily, trabecular bone density.

91% Of Early RA Patients Are Positive For Serum 14–3–3η Or Its Auto-Antibodies. Walter P. Maksymowych[1], Dirkjan van Schaardenburg[2], Désirée van der Heijde[3], Robert Landewé[4], Gilles Boire[5], Maarten Boers[6], Vivian P. Bykerk[7], Edward C. Keystone[8], Katherine A. Siminovitch[9], Mairead Murphy[10] and Anthony Marotta[10]. [1]University of Alberta, Edmonton, AB, [2]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Academic Medical Center, Amsterdam, Netherlands, [5]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [6]VU University Medical Center, Amsterdam, Netherlands, [7]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [8]Mount Sinai Hospital, University of Toronto, Toronto, ON, [9]Mount Sinai Hospital, Toronto, ON, [10]Augurex Life Sciences Corp, North Vancouver, BC.

Background/Purpose: Current serological markers such as RF and ACPA are useful for early diagnosis and perhaps for screening people at risk, but there remains a high unmet need for biomarkers that are present in the earliest stages of RA. The 14–3–3η serum protein is an early complementary marker to RF/ACPA and generates a specific anti-14–3–3η auto-antibody response to the native protein, that can also be measured for diagnosis. This study documents the expression of 14–3–3η auto-antibodies, their diagnostic utility and their complementarity to the 14–3–3η protein in early RA diagnosis.

Methods: 14–3–3η auto-antibody levels were measured on the Meso-Scale-Discovery electro-chemiluminescent platform in 873 patients; 254 with early RA, 324 with established RA and 295 controls. RA patients had a rheumatologist-confirmed diagnosis and early RA patients were DMARD-naïve. Controls included 10 each of psoriasis, ulcerative colitis, type 1 diabetes, and SLE, 9 with Crohn's; 5 each of Sjogren's, scleroderma, multiple sclerosis, gout and osteoporosis; 65 ankylosing spondylitis, 50 osteoarthritis and 106 healthy subjects. RA patient and control samples were provided by the co-authors, representing multiple international centers. Serum 14–3–3η protein levels were previously determined in these subjects with a positive diagnostic cut-off of > 0.19 ng/ml. Two-tailed t-tests and Mann-Whitney u-tests were used to compare differences in autoantibody levels between early RA, established RA and controls groups. Post-hoc ROC curves were generated and diagnostic utility was estimated by area under the curve (AUC) analysis.

Results: Median 14–3–3η auto-antibody levels were significantly higher in early RA subjects at 536 U/ml (154–3011) compared to established RA (223 U/ml, 64–2058), healthy (234 U/ml, 123–919), OA (258 U/ml, 125–1421) and all controls (264 U/ml, 96–1421), p values were < 0.0001 for early RA and each group. The ROC AUC for early RA versus healthy and all controls was 0.92 (95%CI 0.89 to 0.95; p <0.0001) and 0.85 (95%CI 0.82 to 0.89; p <0.0001), respectively. A best cut-off of 380 U/ml was determined based on the optimal specificity (93%) and sensitivity (77%) point on the ROC curve. The corresponding PPV and NPV were 0.97 and 0.63 and LR+ and LR- were 11.6 and 0.25. In early RA, 61% were positive for the 14–3–3η protein, 77% were positive for 14–3–3η auto-antibodies, 67% for RF and 67% for ACPA. 75% of the early RA patients were positive for either RF or ACPA and 81% for at least one of RF, ACPA or 14–3–3η. Especially notable, was that 91% of early RA patients were positive for either the 14–3–3η protein or its auto-antibodies, capturing 63% of RF/ACPA seronegative patients. A low Pearson correlation of r=−0.06 between the 14–3–3η protein and its auto-antibody titres in early RA further reinforces their high complementarity.

Conclusion: 14–3–3η biomarkers, alone and in combination with RF and ACPA identify a large proportion of Early RA patients, potentially allowing for earlier intervention and more favorable clinical outcomes.

1787

Does Age At Disease Onset Influence Disease Activity and Function In Rheumatoid Arthritis Patients? Results From The Ontario Best Practices Research Initiative (OBRI) Registry. Thanu Nadarajah[1], Binu Jacob[1], Pooneh Akhavan[2], Bindee Kuriya[3], Edward C. Keystone[3] and Claire Bombardier[1]. [1]University of Toronto, Toronto, ON, [2]Mount Sinai Hospital/ University of Toronto, Toronto, ON, [3]Mount Sinai Hospital, University of Toronto, Toronto, ON.

Background/Purpose: The population of elderly individuals with rheumatoid arthritis (RA) is increasing. The aim of this study was to assess whether age at disease onset affects disease activity and functional outcome in patients with RA. We hypothesized that patients with elderly-onset RA (EORA) would have more severe disease and higher disability compared to younger-onset RA (YORA) patients.

Methods: All patients enrolled in the Ontario Best Practices Research Initiative (OBRI), a clinical registry of early and established RA patients followed in routine care, were included in the study (N= 1981). Patients were categorized as EORA if their disease onset was ≥ 60 years of age (N=1516) and as YORA if disease onset occurred before 60 years (N=465). Outcomes assessed were disease activity (measured by Disease Activity Score 28 [DAS28]) and function (assessed by Health Assessment Questionnaire [HAQ]) at entry into the registry. Differences between two groups were compared using chi-square test and t-test. Separate linear regression models, adjusted for gender and disease duration were performed, with $p < 0.05$ considered statistically significant.

Results: The mean (SD) age of patients was 57.4 (12.9) years. The mean (SD) disease duration in the group was 8.5 (9.4) years. EORA patients were less likely to be rheumatoid factor and anti-citrullinated protein antibody positive ($p<0.05$). At entry into the registry, EORA patients were more likely to be on disease-modifying agents (79.4% vs. 66.1%, $p<0.001$) and steroids (27.4% vs. 22.9%, $p=0.05$), and less likely to be taking biologic therapy (12.1% vs. 25.7%, $p<0.001$) compared to YORA patients. Mean DAS28 scores were significantly higher among EORA patients compared to those with YORA (4.6 vs. 4.3, $p=0.002$). In a stratified analysis, this association was seen for those with early disease (< 2 years) but not for longer disease duration (Table 1). There was a non-significant trend towards higher HAQ scores among EORA patients compared to YORA patients. In a regression analysis with disease duration as a continuous variable, there was a significant association between EORA and higher disease activity and greater disability ($p<0.05$).

Table 1. Mean DAS28 and HAQ scores at entry into OBRI, stratified by age at disease onset and disease duration

	Mean DAS28 score			Mean HAQ score		
Disease Duration	Age at disease onset <60 years	Age at disease onset ≥ 60 years	P value (adjusted for disease duration)	Age at disease onset <60 years	Age at disease onset ≥ 60 years	P value (adjusted for disease duration)
< 2 years	4.47	4.92	0.001	1.07	1.18	0.098
2 – 5 years	4.18	4.25	0.65	1.14	1.12	0.743
>5 years	4.35	4.35	0.99	1.23	1.41	0.054

Conclusion: Research in the area of EORA has produced mixed results in terms of disease activity and functional disability. Our study demonstrates that older age at disease onset is associated with greater disease activity and functional disability at entry into OBRI. Disease duration appears to influence these outcomes. Further study is required to evaluate which components of the DAS28 may differ among EORA vs. YORA and what drives these potential differences. Furthermore, evaluating the role of factors including comorbidities is necessary to understand the reasons for higher disease activity and poor functional outcome among patients with EORA.

The Multi-Biomarker Disease Activity Test (Vectra® DA) Estimates Risk Of Radiographic Progression For Patients With Rheumatoid Arthritis From The Leiden Early Arthritis Clinic. Wanying Li[1], DJ Haney[1], Guy Cavet[1], Thomas W. Huizinga[2], Eric H. Sasso[1] and A. H. M. van der Helm-van Mil[2]. [1]Crescendo Bioscience Inc., South San Francisco, CA, [2]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: The multi-biomarker disease activity (MBDA) blood test assesses disease activity in patients with rheumatoid arthritis (RA) using a validated algorithm to provide a score of 1 to 100. The Leiden Early Arthritis Clinic (EAC) has enrolled a population-based cohort of subjects within 2 years of RA diagnosis for long-term care. In a prior study of Leiden EAC patients receiving non-biologic-DMARDs (median RA duration 4.6 yrs.), the MBDA score was significantly better than DAS28-CRP for predicting radiographic progression. We now provide in-depth analyses of the relationship between MBDA score and radiographic progression, and the ability of MBDA score to add value to other measures for predicting radiographic progression.

Methods: This retrospective study evaluated 271 clinic visits by 163 RA patients (1987 ACR criteria) of the Leiden EAC. Clinical and blood test data were obtained at each visit, with radiographs taken then and 1 year later. At first visit, patients were receiving only DMARDs and <5% received an anti-TNF subsequently. MBDA biomarkers (VCAM-1, EGF, VEGF-A, IL-6, TNF-RI, MMP-1, MMP-3, YKL-40, leptin, resistin, SAA, CRP) were measured for each visit. Radiographic progression was assessed as change in Sharp van der Heijde score (DSHS) over one year. The association between MBDA score and radiographic progression was assessed by AUROC, by logistic quantile regression curves, and by relative risk (RR) vs. MBDA ≤25 for DSHS > 0, 3 or 5 units/yr. Frequency of DSHS >3 across MBDA categories (low: ≤29; moderate 30–44; high: >44) was assessed within categories of DAS28-CRP, CRP (≤1,1–3 and >3 mg/dL) or serologic status (sero+: RF+ and/or CCP+; sero-neg: both negative), with p-values adjusted for multiple testing.

Results: Characteristics of the 271 patient visits included median age 55 yrs., 67% female, 66%/69% RF+/anti-CCP+, median SHS 25, median MBDA score 41. The 75th and 90th quantile regression lines indicating risk of progression increased non-linearly with increasing MBDA score (AUROC = 0.72/0.77 for DSHS >3 or >5, $p < 0.001$). The increase was most prominent between groups with MBDA scores of 40–44 and 45–49. Risk increased within the high MBDA category (RR (95% CI) = 7.2 (2.4–22.6)/18.1 (6.5–29.1) for DSHS >3 or >5 for MBDA ≥60). Within categories of DAS28-CRP or CRP, and for sero-neg and sero+ patients, the low/high MBDA score subgroups had significantly lower/higher rates of progression, respectively.

Frequency of Radiographic Progression (ΔSHS >3) by Category of MBDA Score and DAS28-CRP, CRP, or Serologic Status

		MBDA Score			
	N	Low (≤29)	Moderate (>29–≤44)	High (>44)	P-value
DAS28-CRP					
Low (≤2.7)	113	8% of 37	22% of 51	44% of 25	0.008
Moderate (>2.7–≤4.1)	95	15% of 13	19% of 36	30% of 46	0.454
High (>4.1)	63	0% of 6	6% of 18	56% of 39	<0.001
CRP mg/dL					
Low (≤1)	158	9% of 53	21% of 85	50% of 20	0.003
Moderate (1–3)	80	0% of 3	5% of 20	37% of 57	0.013
High (>3)	33	NP	NP	48% of 33	NA
Serologic Status					
Positive	200	11% of 38	24% of 72	46% of 90	<0.001
Negative	70	6% of 18	3% of 32	30% of 20	0.016

NP, no patients in that category; NA, not applicable

Conclusion: In DMARD-treated patients with established RA, radiographic progression increased non-linearly with increasing MBDA score. High MBDA score was associated with increased progression even when DAS28-CRP or CRP were low, and regardless of serologic status. Low MBDA score was associated with infrequent progression. Thus, the MBDA score may help identify patients at risk for rapid radiographic progression and may add useful information to other assessments.

In Early Rheumatoid Arthritis, The 12 Individual Biomarkers That Comprise The Multiple Biomarker Disease Activity Score Relate Differentially To Clinical Response and Radiographic Progression: Results From a Randomized Trial. Karen Hambardzumyan[1], Saedis Saevarsdottir[1], Rebecca Bolce[2], Kristina Forslind[3], Sofia Ernestam[4], Ingemar F. Petersson[5], Pierre Geborek[5], David Chernoff[2], Douglas J. Haney[2], Eric H. Sasso[2] and Ronald F van Vollenhoven[1]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Crescendo Bioscience Inc., South San Francisco, CA, [3]Section of Rheumatology, Department of Medicine, Helsingborg General Hospital, Helsingborg, Sweden, [4]Karolinska University Hospital, Huddinge, Sweden, [5]Lund University, Lund, Sweden.

Background/Purpose: In early rheumatoid arthritis (eRA), clinical and radiographic predictors would be very useful for optimizing available therapies. Individual biomarkers and their combinations, such as the multibiomarker disease activity (MBDA, Vectra DA) test, can be considered for these purposes. In the SWEFOT study, patients with eRA (symptom duration < 1 year) were started on methotrexate (MTX); at 3 months, responders (DAS28 < 3.2) continued MTX monotherapy and were followed in regular care, whereas non-responders were randomized into triple DMARD therapy or the addition of infliximab group.

The objective of this study was to assess the 12 individual biomarkers that comprise the MBDA score at baseline (BL) as predictors of clinical response at 3 months and radiographic progression at 1 year in eRA.

Methods: Analyses were performed for patients from the SWEFOT trial who had BL and 3-month data of DAS28 (based on ESR), the MBDA score (which has been validated to assess disease activity in RA patients) and the 12 individual biomarkers at BL; and for a subset of patients who also had radiographs at BL and 1 year (assessed using the Van der Heijde modified Sharp score [SHS]). Patients with DAS28 > 3.2 at 3 months were considered clinical non-responders, and patients with a change in SHS > 0 as radiographic progressors ("radiological non-responders"). Group comparisons of biomarkers were performed by Mann-Whitney U test.

Results: The results are summarized in the table below. Clinical non-responders had significantly higher BL values for CRP and IL-6 compared to responders. TNF-R1 and VCAM-1 were significantly lower for non-responders, while other biomarkers and the MBDA did not differ. The patients who progressed radiographically had, at BL, significantly higher MBDA scores, inflammatory biomarkers (CRP, SSA and IL-6), MMP-1, MMP-3 and TNF-R1, as well as a trend towards higher VEGF.

Biomarkers at BL (mean±SEM)	clinical responders (n=112)	clinical non-responders (n=190)	P value	Radiographic non-progressors (n=116)	Radiographic progressors (n=120)	P value
CRP	45.8±6.22	65.5±5.42	0.048	48.2±6.39	73.35±6.84	<0.001
SAA	38.3±5.04	41.9±3.49	N.S.	33.9±4.31	48.6±4.73	0.004
IL-6	82.7±9.01	114.2±10.36	0.051	89.83±11.68	121.7±13.33	0.002
TNF-R1	2.05±0.06	1.8±0.04	0.002	1.85±0.05	2.01±0.06	0.047
MMP-1	12.1±0.94	13.9±0.71	N.S.	12.4±0.87	14.4±0.86	0.038
MMP-3	76.9±8.55	90.21±6.5	N.S.	73.4±8.26	97.64±8.21	0.010
YKL-40	103.5±9.93	106.9±6.44	N.S.	115.4±11.3	107.9±7.35	N.S.
Leptin	12.8±1.17	15.1±1.09	N.S.	16.3±1.81	13.32±1.13	N.S.
Resistin	7.23±0.26	7.31±0.21	N.S.	7.23±0.28	7.3±0.21	N.S.
EGF	196.05±12.1	187.9±8.29	N.S.	195.2±9.7	182.6±11.65	N.S.
VEGF	474±27.99	469.34±22.7	N.S.	437.4±27.24	511.2±29.12	0.069
VCAM-1	0.74±0.019	0.66±0.012	<0.001	0.67±0.016	0.72±0.018	N.S.
MBDA	57±1.3	59.6±1.14	N.S.	55.7±1.4	63.3±1.19	<0.001

Conclusion: In eRA patients treated initially with MTX, some individual biomarkers at BL may help identify those patients who are less likely to achieve DAS28 < 3.2 after 3 months of MTX therapy. Other biomarkers, as well as the MBDA score, may identify patients at higher risk for radiographic progression during the first year of therapy. These results suggest that biomarkers can differentially predict aspects of disease course in eRA.

Serum Amyloid A Levels Model Rheumatoid Arthritis Disease Activity Better Than C-Reactive Protein Levels Especially During Treatment With Anti-Tumor Necrosis Factor α Therapy (Etanercept). Ilinca D. Metes[1], Douglas W. Chew[1], Aarat M. Patel[1], G.K. Balasubramani[2], Jeffrey R. Curtis[3], S. Louis Bridges Jr.[3], Stephen R. Wisniewski[2], Larry W. Moreland[1] and Marc C. Levesque[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, [3]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: C reactive protein (CRP) levels have been used extensively to model disease activity in rheumatoid arthritis (RA). However, TNF antagonist therapy (and likely therapy with other biologics) reduce CRP levels, even without associated reductions in RA disease activity. Serum amyloid A (SAA) also models RA disease activity and has been suggested as a better biomarker for RA disease activity. We previously showed that TNF antagonist therapy lowered both SAA and CRP levels to a greater extent than oral disease modifying anti-rheumatic drugs (DMARDs) after adjusting for disease activity. However, TNF antagonists, compared to oral DMARDs, decreased CRP levels more than SAA levels. Our aim was to compare the effect of etanercept (ETN) and/or oral DMARD therapy on serum SAA versus CRP levels, and to determine whether SAA levels model RA disease activity better than CRP levels, especially during treatment with a TNF antagonist.

Methods: Samples were analyzed from RA subjects (n = 755) in the Treatment of Early RA (TEAR) study, a randomized, double-blind, comparative effectiveness trial. In the TEAR trial, early RA subjects with less than 2 years of disease duration were randomized to receive either combination ETN/methotrexate (MTX) therapy (n = 244), MTX/hydrochloroquine/sulfasalazine (triple oral) therapy (n = 132) or MTX monotherapy (n = 379). MTX monotherapy subjects with a DAS28-ESR > 3.2 after 6 months were stepped up to either ETN/MTX (n = 205) or triple oral therapy (n = 93). Serum samples and clinical data were collected when treatment was initiated and at 24, 48 and 102 week follow up visits. We used Spearman correlation coefficients (rho) to determine the overall relationship between SAA and CRP levels, and mixed effects models to determine the fit between 1) SAA levels and DAS28-ESR and 2) CRP levels and DAS28-ESR, for subjects treated with ETN/MTX and subjects treated with oral DMARDs, while correcting for baseline SAA and CRP levels, respectively. Akaike information criterion (AIC) and parameter estimates were used to determine model fit, with ΔAIC > 10 used as strong evidence for one model fitting better than another.

Results: At the baseline visit, SAA levels were only moderately correlated with CRP levels (rho = 0.42), and the SAA and CRP correlation was similar regardless of treatment or study visit (rho range 0.35 to 0.62). Across all subjects and time points, models of the DAS28-ESR using SAA levels were better than models using CRP; the ΔAIC between the models was 305. The model of DAS28-ESR using SAA was associated with a ~6 fold better fit vs. the CRP model for subjects treated with ETN/MTX, and a ~5 fold better fit vs. the CRP model for subjects treated with oral DMARDs (ΔAIC = 159 vs. ΔAIC = 137, respectively).

Conclusion: The lack of a strong correlation between SAA and CRP levels coupled with their different modeling of RA disease activity suggests that SAA levels may be a better biomarker for RA disease activity than CRP, especially during treatment with TNF antagonists.

Reaching The Target Of Low Disease Activity At 6 Months Predicts Better Long-Term Functional Outcome In Patients With Early Rheumatoid Arthritis. Pooneh Akhavan[1], Bindee Kuriya[2], Edward C. Keystone[2], Juan Xiong[3], Janet E. Pope[4], Gilles Boire[5], Diane Tin[6], Boulos Haraoui[7], Carol A. Hitchon[8] and Vivian P. Bykerk[9]. [1]Early Rheumatoid Arthritis Program, Mount Sinai Hospital and University of Toronto, Toronto, ON, [2]Mount Sinai Hospital, University of Toronto, Toronto, ON, [3]Mount Sinai Hospital, Toronto, ON, [4]St Joseph Health Care, London, ON, [5]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [6]Southlake Regional Health Centre, Newmarket, ON, [7]Centre Hospitalier de l'Université de Montréal, Montreal, QC, [8]University of Manitoba, Winnipeg, MB, [9]Mount Sinai Hospital/University of Toronto, Toronto, ON.

Background/Purpose: Current clinical practice guidelines recommend remission, and if not possible, low disease activity (LDA) as the treatment target in

rheumatoid arthritis (RA). Patients should also be assessed frequently to facilitate achieving this target as early as possible. It has been previously shown that reaching LDA at 1 year is associated with better long-term functional and radiographic outcomes in an early RA cohort that enrolled patients prior to the introduction of T2Tconcept and the widespread use of biologics[1]. Our objective was to assess the predictive validity of reaching LDA at an earlier time point (6 mo), the desired goal in current guidelines, on future disability.

Methods: Data from Canadian early ArThritis Cohort (CATCH) including patients with early RA (symptom duration ≤ 12 mo) were used. Patients with at least two years of follow-up were included. The outcome was HAQ-DI at 2 years and the main predictor was LDA at 6 mo, measured by Clinical Disease Activity Index. Linear regression analysis was used for assessment of the impact of LDA (y/n) on HAQ at 2 years adjusting for potential confounders including baseline LDA, HAQ, age, sex, ESR, RF, use of DMARDs, steroids and biologics. We included baseline and 6-mo LDA interaction in the model and as it was not significant, removed it. As an exploratory analysis, we added the socioeconomic status (SES), pain and fibromyalgia to the model.

Results: A total of 833 patients were analyzed. Baseline characteristics included: female (75%), mean+sd age 53.3+14.2 years, symptom duration 5.9(2.9) months, HAQ 1.1(0.7), swollen joint count 8.1(6.2), tender joint count 8.7(6.7), ESR 27.9 (23.0), CDAI 27.5(14.8). More than 90% received DMARDs. Methotrexate was used in 74%, steroids in 52% and biologics in only 3% at baseline. CDAI improved to 12.0(6.2) at 6 mo and HAQ to 0.52(0.6) at 2 yrs. 389 patients (56%) were in LDA at 6 months.

In the multivariate analysis, LDA at 6 mo was a significant predictor of lower HAQ at 2 yrs ($p<.0001$) (Table). Among additional covariates added in the exploratory analysis, only the presence of fibromyalgia at baseline was associated with higher HAQ at follow-up.

Table. Multivariate analysis result. Outcome HAQ at 2 years

Predictor	Estimate	p-value
LDA at 6 mo	−0.27	<.0001
LDA at baseline	0.016	0.83
Age (year)	0.005	0.004
Sex	0.253	<.0001
Symptom duration	0.012	0.12
HAQ*	0.332	<.0001
Rheumatoid Factor	0.078	0.12
DMARD use*	0.017	0.83
Corticosteroid use*	0.071	0.13
Biologics use*	−0.001	0.99

*at BSL

Conclusion: LDA as early as 6 mo predicts less future disability. This provides further evidence to support current guidelines recommending early LDA as a desired treatment goal where remission is not possible. Considering that remission is only achieved in a minority of early RA patients, LDA appears to be a more feasible target.

Inhibition Of Chemokine Receptors CCR1 and CCR6 As Promising Therapies For Autoimmune Diseases Such As Rheumatoid Arthritis and Psoriasis. Daniel Dairaghi[1], Penglie Zhang[2], Manmohan Leleti[2], Robert Berahovich[2], Karen Ebsworth[2], Linda Ertl[2], Shichang Miao[1], Zhenhua Miao[2], Lisa Seitz[2], Joanne Tan[2], Matthew Walters[2], Yu Wang[2], Jay Powers[2], Thomas J. Schall[1] and Juan C. Jaen[1]. [1]ChemoCentryx, Inc., Mountain View, CA, [2]ChemoCentryx, Mountain View, CA.

Background/Purpose: Chemokines are key regulators of leukocyte activation and recruitment to sites of inflammation. Of particular relevance in rheumatoid arthritis (RA), the chemokine receptors CCR1 and CCR6 are thought to drive monocyte/macrophage and Th17 cell recruitment, respectively, into RA joints. We recently demonstrated the clinical benefit of our first-generation CCR1 antagonist (CCX354) in a Phase 2 trial in RA patients (Tak (2012)). Meanwhile, CCR6 is thought to be a key factor for Th17 cell activity in RA and psoriasis. To date, no therapeutic agents targeting CCR6 have progressed into clinical evaluation. Our objective is to identify orally active small molecules that selectively target either CCR1 or CCR6 and possess overall profiles suitable for clinical development.

Methods: The *in vitro* potency of CCX9588 (CCR1 antagonist) was assessed by inhibition of CCL15-mediated chemotaxis of THP-1 cells and human blood monocytes. The *in vitro*potency of CCX9664 (CCR6 antagonist) was assessed by inhibition of CCL20-mediated chemotaxis and binding using CCR6-expressing cell lines and CD4-positive human PBMC. CCX9588 and CCX9664 were assessed for their ability to block CCR1 or CCR6-mediated chemotaxis towards RA synovial fluids. The ability of a CCR6 antagonist to inhibit dermal inflammation in preclinical models of psoriasis-like disease was assessed in mice with the imiquimod and IL-23 models.

Results: CCX9588 potently blocks CCR1-mediated chemotaxis with an IC_{50} of 0.1 nM (THP-1 cells). In 100% human serum, CCX9588 blocks CCR1-mediated chemotaxis with an IC_{50} of 0.7 nM (THP-1 cells) and 0.2 nM (human monocytes). CCX9588 also completely blocks the monocyte-chemotactic activity displayed by human RA synovial fluid samples. CCX9664 potently blocks CCR6-mediated chemotaxis of CD4-positive human PBMC (IC_{50}: 24 nM). CCR6-mediated chemotactic activity of RA synovial samples was completely inhibited by CCR6 antagonists. CCX9664 significantly reduced dermal manifestations of disease in two preclinical psoriasis-like models, one induced by topical application of imiquimod and the other by dermal injections of IL-23. Both CCX9588 and CCX9664 are highly selective for CCR1 and CCR6, respectively, when tested against a wide screen of chemokine and chemoattractant receptors.

Conclusion:

CCR1: The novel second-generation CCR1 antagonist CCX9588 is about 20 times more potent on human CCR1 than the structurally distinct first-generation molecule CCX354. This new CCR1 antagonist (CCX9588) remains equally selective for CCR1 and orally bioavailable in preclinical species (Dairaghi (2011)) and was shown to block CCR1-mediated chemotaxis of human blood monocytes towards RA synovial fluid samples.

CCR6: Several chemical lead series were identified using a proprietary high-throughput screening format. Optimization of one of these series resulted in advanced molecules such as CCX9664. This molecule is highly potent on human and mouse CCR6 and displays properties conducive to its use for the treatment of diseases such as RA and psoriasis.

Oskira-1: A Phase III, Multicenter, Randomized, Double-Blind, Placebo-Controlled Parallel-Group Study Of 2 Dosing Regimens Of Fostamatinib In Rheumatoid Arthritis Patients With An Inadequate Response To Methotrexate. Michael Weinblatt[1], Mark C. Genovese[2], Meilien Ho[3], Sally Hollis[3], Krystyna Rosiak-Jedrychowicz[4], Arthur Kavanaugh[5], David Millson[3], Gustavo Leon[6], Millie Wang[3] and Désiréé van der Heijde[7]. [1]Division of Rheumatology, Brigham & Women's Hospital, Boston, MA, [2]Stanford University, Palo Alto, CA, [3]AstraZeneca R&D Alderley Park, Macclesfield, United Kingdom, [4]Przychodnia Neuromedyka, Zyrardów, Poland, [5]University of California, San Diego, La Jolla, CA, [6]Instituto de Ginecología y Reproducción-Cirugía Mínimamente Invasiva, Surco, Peru, [7]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Fostamatinib (Fosta) is an oral SYK inhibitor. This 52-wk study (NCT01197521) compared Fosta vs placebo (PBO) + methotrexate (MTX) in patients (pts) with active RA despite MTX.

Methods: Adult pts on MTX were randomized (1:1:1) to Fosta (100 mg bid for 52 wks [Group A, n = 310] or 100 mg bid for 4 wks then 150 mg qd [Group B, n = 304]) or to PBO for 24 wks then Fosta 100 mg bid (Group C, n = 304). Non-responders at Wk 12 could leave the study and enter an active extension study. Co-primary endpoints were the proportion of pts achieving ACR20 response at Wk 24 and the change from baseline to Wk 24 in modified total Sharp score (mTSS). Secondary endpoints evaluated efficacy, safety and tolerability up to 52 wks.

Results: Demographic and baseline characteristics were well balanced across groups. Fosta Groups A and B had significantly more pts achieving ACR20 at Wk 24 vs PBO (Table, $p < 0.001$; $p = 0.006$, respectively), with 18.2% of Fosta pts achieving ACR20 as early as Wk 1 (vs 4.9% PBO). Fosta Groups A and B did not show a significant difference in mTSS at Wk 24 ($p = 0.25$; $p = 0.17$, respectively [Table]) vs PBO. The percentages of pts who did not progress (mTSS change ≤ 0.5) in Groups A, B and C were 80.7%, 77.6% and 79.5%. Key secondary efficacy endpoints were consistently favorable for Fosta Groups A and B vs PBO (Table), with better results at the higher dose, but were not tested statistically due to failure of the mTSS co-primary endpoint.

In the 24-wk PBO-controlled period, the most frequently reported AEs in pts in Groups A, B and C were hypertension (15.9%, 15.1%, 3.9%), diarrhea (13.9%, 15.1%, 3.9%) and nausea (4.2%, 6.9%, 3.6%). Serious AEs occurred in 2.9%, 4.9% and 1.6% of pts. AEs leading to discontinuation occurred in 5.2%, 9.2% and 2.6% of pts, the most frequent being diarrhea, hepatic enzyme increase, hypertension and ALT increase. Elevated BP ($\geq$ 140/90 mmHg) was observed in 44.2%, 41.6% and 19.3% of pts at $\geq$ 1 visit.

Overall exposure up to 52 wks was 111 patient-years (PY) for PBO and 569 PY for Fosta. There were 9 adjudicated CV events: 2 on PBO, and 7 on Fosta (5 in Group B, 2 in Group C). One pt on PBO died (0.9/100 PY; pulmonary embolism) and 5 died while on Fosta (0.9/100 PY; 2 in Group B [sepsis/renal failure; gastroenteritis/hypovolemic shock/cardiorespiratory failure] and 3 in Group C [septic shock/interstitial lung disease; circulatory collapse; acute renal failure/cardiorespiratory arrest]). There were 5 malignancies, all on Fosta (0.9/100 PY; 2 × non-melanoma skin cancer; 1 × gastric, renal or thyroid cancer), over 52 wks.

Table. Patient discontinuations, primary and key secondary endpoints at or up to Wk 24*

Endpoint*	Group A Fosta 100 mg bid + MTX (n = 310)	Group B Fosta 100 mg bid + MTX for the first 4 wks then 150 mg qd + MTX (n = 304)	Group C PBO + MTX (n = 304)
Patients discontinuing treatment up to Wk 24	76 (24.4%)	81 (26.5%)	(116) 37.9%
Change from baseline in mTSS score at Wk 24	0.45 (N=285)	1.29 (N=277)	0.13 (N=278)
ACR20 at Wk 24	152 (49.0%)	135 (44.4%)	104 (34.2%)
ACR50 at Wk 24	81 (26.1%)	56 (18.4%)	30 (9.9%)
ACR70 at Wk 24	32 (10.3%)	17 (5.6%)	6 (2.0%)
ACR20 at Wk 1		112 (18.2%)	15 (4.9%)
DAS28-CRP < 2.6 at Wk 12	32 (10.3%)	24 (7.9%)	6 (2.0%)
DAS28-CRP < 2.6 at Wk 24	41 (13.2%)	26 (8.6%)	15 (4.9%)
HAQ-DI reduction ≥ 0.22 at Wk 24	170 (54.8%)	153 (50.3%)	107 (35.2%)

*Pts who withdrew for any reason, including non-response at Wk 12, or had an increased MTX dose, had any DMARD initiated or received parenteral steroids in the prior 8 wks were considered non-responders at Wk 24. Non-responders at Wk 12 could be transferred to an extension study to receive Fosta 100 mg bid, however, the treatment arm to which they were initially randomized remained blinded for the duration of the study.

Conclusion: In this phase III study both Fosta regimens achieved statistical improvements in ACR20 response rate at 24 wks vs PBO in pts treated with MTX but did not show a significant difference in mTSS. The overall level of response with Fosta was not as large as observed in the phase ll (TASKi) program. Safety and tolerability findings were consistent with the profile observed in earlier studies.

The Jak Inihibitor Tofacitinib Suppresses Synovial Jak-Stat Signalling In Rheumatoid Arthritis. D. L Boyle[1], N. Wei[2], A. K. Singhal[3], D. R. Mandel[4], P Mease[5], A. Kavanaugh[1], R. Shurmur[6], J. Hodge[7], Z. Luo[8], S. Krishnaswami[8], D. Gruben[8], S. H. Zwillich[8], K. Soma[8], J. D. Bradley[8] and G. S. Firestein[1]. [1]UCSD School of Medicine, La Jolla, CA, [2]Arthritis Treatment Center, Frederick, MD, [3]Southwest Rheumatology Research LLC, Mesquite, TX, [4]Office of David R Mandel MD, Inc., Mayfield Village, OH, [5]Seattle Rheumatology Associates, Seattle, WA, [6]Associated Internal Medicine Specialists, Battle Creek, MI, [7]Pfizer Inc, Collegeville, PA, [8]Pfizer Inc, Groton, CT.

Background/Purpose: Tofacitinib is a novel oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). The specific JAK-STAT (signal transducer and activator of transcription) pathways affected by tofacitinib in different tissues and the downstream effects on gene expression in situ are unknown. Phase 3 studies ORAL Scan[1] (A3921044 NCT00847613) and ORALStart[2] (A3921069 NCT01039688) have shown that tofacitinib reduces the progression of joint destruction; however, the underlying mechanisms are unknown. The effects of tofacitinib on synovial histopathology, gene expression, and signaling were studied and correlated with clinical response. We also evaluated the relationship of synovial, blood and urine biomarkers with inflammation and structural damage.

Methods: A randomized, double-blind, Phase 2a clinical trial (A3921073; NCT00976599) of seropositive RA patients (pts) with inadequate response to methotrexate compared tofacitinib 10 mg twice daily for 28 days (15 pts) with placebo (PBO; 14 pts). Synovial biopsies were performed on Days −7 and 28. Biopsies were analyzed by immunohistochemistry (IHC), quantitative real-time polymerase chain reaction (qPCR), and synovial tissue extracts by enzyme-linked immunosorbent assay. Clinical response was determined by disease activity score (DAS)28–4 ESR and EULAR response criteria on Day 28 in study A3921073 and at 4 months in an open label long term extension study (A3921024; NCT00413699).

Results: Tofacitinib led to EULAR moderate to good responses (11/14 pts), while PBO was ineffective (1/14 pts) on Day 28. Tofacitinib significantly reduced synovial gene expression of the matrix metalloproteases MMP1 and MMP3 ($p<0.05$) and chemokines CCL2, CXCL10, and CXCL13 ($p<0.05$). Changes in synovial phosphorylation of STAT1 and STAT3 predicted 4-month clinical responses (correlations of 0.755 and 0.874, respectively), significantly ($p=0.0018$ and $p<0.0001$). Tofacitinib significantly decreased plasma IP-10 ($p<0.005$) which is a mediator of osteoclastogenesis[3]. Urine CTX-II, an indicator of MMP-mediated type II collagen turnover and cartilage damage[4], was reduced by tofacitinib (LS mean change −122.93) compared to PBO (LS mean change −6.2) ($p=0.08$). No changes were observed in synovial inflammation scores or immune cell lineages using IHC, e.g. CD20, CD3, CD68, or qPCR.

Conclusion: The data suggest that tofacitinib modulates synovial immune and inflammatory responses. Modulation of certain JAK STAT pathways correlates with clinical response, e.g. STAT1 and STAT3-dependent IL-6, and interferon signaling. Biomarkers including MMP-3[4], IP-10[3] and urinary CTX-II[4] which are associated with an increased risk of joint damage in RA are reduced by tofacitinib. This study provides insights into the mechanism of tofacitinib's clinical efficacy and preservation of cartilage and bone.

An Active Metabolite Contributes To The Pharmacodynamics and Efficacy Of GLPG0634, a Selective JAK1 Inhibitor. Florence Namour. Galapagos SASU, Romainville, France.

Background/Purpose: GLPG0634 is an orally-available, selective inhibitor of Janus kinase 1 (JAK1). Through inhibition of signaling pathways for cytokines involved in rheumatoid arthritis (RA), non-selective JAK inhibitors have shown long-term efficacy in treating RA but also dose-limiting side effects. Selective inhibition of JAK1 may result in an acceptable safety profile while maintaining clinical efficacy. Based on GLPG0634's moderate pharmacokinetic (PK) half-life, both once-daily (QD) and twice-daily (BID) dosing regimens have been explored in humans. QD dosing of GLPG0634 in humans has shown highly encouraging pharmacodynamic (PD) properties and early efficacy in RA in two 4-week Phase 2a studies/ Evaluate the PK, PD and efficacy of GLPG0634 and its main metabolite in healthy volunteers and patients with active RA.

Methods: GLPG0634 was dosed in healthy volunteers (N=30) at doses of 50 and 100 mg BID and 200, 300 and 450 mg QD for 10 days. In Phase 2a studies, RA patients (n=98) received doses of 100 mg BID and from 30 to 300 mg QD for 28 days, added on to a background therapy of methotrexate. The PK of GLPG0634 and its active major metabolite was evaluated. The PD was evaluated in whole blood from healthy volunteers using *ex vivo* IL-6 induced phosphorylation of STAT1 (pSTAT1) in CD4+ cells for JAK1 activity and GM-CSF induced pSTAT5 in CD33+ cells for JAK2. JAK inhibition and selectivity of the metabolite were evaluated *in vitro*.

Results: The PK for GLPG0634 following BID and QD dosing showed dose-proportionality and a mean half-life of 7 h. A major metabolite was found that showed plasma levels in humans well exceeding those of GLPG0634 and a half-life ranging from 21 to 27 h. This metabolite was found to be active with a similar selectivity for JAK1 inhibition in human whole blood as parent GLPG0634. Its overall potency as a kinase inhibitor was 10 to 20-fold lower. In healthy volunteers, IL-6 induced pSTAT1 was inhibited for the entire 24 h dosing period, including at 24 h after the last dose for QD dose regimens. No relevant inhibition of JAK2 activity was observed at any dose level. While plasma levels of parent GLPG0634 were low beyond 12 hours from the last intake, those for its active metabolite remained high. The PK profile in RA patients for GLPG0634 and its metabolite were similar to that in healthy volunteers. A QD and BID regimen for a 200 mg daily dose showed a similar high level of efficacy following 4-week treatment in RA. QD dosing was found efficacious for doses of 75 mg onwards, with mean decreases in DAS28(CRP) ranging from 1.7 to 2.8 (placebo 0.3 to 1.2), and high baseline CRP levels normalizing within 7 to 14 days.

Conclusion: The results of these studies suggest that the 24-hour maintained JAK1 inhibition and the observed clinical efficacy of QD dosing of GLPG0634 is supported by an active metabolite. The long half-life of this metabolite provides a lasting effect, though at a lower level of JAK1 inhibition than GLPG0634. The lower potency may be compensated by the high exposure. The major active metabolite supports longer lasting effects of GLPG0634 and reduces fluctuations in JAK1 inhibition. This may allow for QD dosing in a therapeutic setting, adding to dosing convenience for patients.

12-Week Results Of a Phase 2b Dose-Ranging Study Of Baricitinib, An Oral JAK1/ JAK2 Inhibitor In Japanese Patients With Rheumatoid Arthritis On Background Methotrexate Therapy. Yoshiya Tanaka[1], Kahaku Emoto[2], Mika Tsujimoto[2], Douglas E. Schlichting[3] and William Macias[3]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Eli Lilly Japan K.K., Kobe, Japan, [3]Eli Lilly and Company, Indianapolis, IN.

Background/Purpose: Baricitinib (formerly LY3009104/INCB028050), a novel, oral inhibitor of JAK1 and JAK2 in the JAK-STAT signaling pathway, has been evaluated in a 12-week blinded phase 2b study in Japanese patients (pts) with moderate to severe rheumatoid arthritis (RA) with inadequate response to methotrexate (MTX).

Methods: Japanese RA pts, based on the 2010 ACR/EULAR criteria, with active symptoms (at least 6 swollen and 6 tender joints based on the 66/68 joint assessment) on stable MTX (6 to 16 mg/week) were randomized 2:1:1:1:1 to receive placebo (PBO) or 1of 4 once-daily baricitinib doses (1, 2, 4, or 8 mg), respectively, for 12 weeks. The primary objective was to evaluate the efficacy of baricitinib as assessed by the combined proportion of pts in the 4- and 8-mg dose groups who achieved an ACR20 response compared to PBO over 12 weeks.

Results: Of the 145 pts randomized and treated, 77% of the combined 4- and 8-mg (67% of the 4-mg and 88% of the 8-mg dose) groups achieved ACR20 responses compared with 31% of PBO-treated pts ($p \leq 0.001$) by the end of 12 weeks. Significant differences versus placebo ($p < 0.05$) were observed in the proportion of patients achieving ACR20 and ACR50 in a dose-dependent manner at Week 12 (Table1). Similarly, greater proportions of pts were judged as disease remission by DAS28CRP<2.6, SDAI≤3.3, and HAQ-DI≤0.5 in the 4- and 8-mg dose groups compared to PBO (Table 1). Over 12 weeks in the PBO and combined baricitinib groups, there were similar incidence rates of adverse events (AEs) (53% vs 55%, respectively). Most AEs were mild. There were no opportunistic infections and no deaths. Serious AEs were reported in 2 pts. Decreases in hemoglobin were small (Table 2). This was probably due to the iron supplements that were allowed during the study. Small increases in serum creatinine were seen (Table 2). Several bone metabolic markers and systemic inflammatory markers such as serum TNF-alpha and IL-6 were evaluated. Some bone markers showed dose-dependent changes from baseline. In P1NP and osteocalcin, significant decreases compared to PBO were observed only in the 4- or 8-mg group ($p < 0.05$), but not in the 1- or 2-mg group at Week 12.

Table 1. Selected Efficacy Endpoints at Week 12

Efficacy	PBO (N=49)	1 mg QD (N=24)	2 mg QD (N=24)	4 mg QD (N=24)	8 mg QD (N=24)
% ACR20*	31	67***	83***	67***	88***
% ACR50*	8	33***	46***	50***	54***
% DAS28CRP<2.6**	22	29	33	38	42
% SDAI≤3.3**	8	4	29***	17	17
% HAQ-DI≤0.5**	45	50	54	63	83***

1-sided Fisher's exact test. *non-responder imputation; **last observation; ***$p < 0.05$ vs. PBO. Abbreviations: ACR20/50 = American College of Rheumatology 20/50 responder index; DAS28CRP = Disease Activity Score 28 using C reactive protein; HAQ-DI= Health Assessment Questionnaire - Disability Index; PBO=Placebo; QD=Once-daily; SDAI=Simplified Disease Activity Index.

Table 2. Summary of Laboratory Data at Week 12: Change from Baseline

Median (Min, Max)	PBO	1 mg QD	2 mg QD	4 mg QD	8 mg QD
Hemoglobin (mmol/L)	−0.125 (−1.18, 1.06)	0.130 (−0.94, 2.54)	−0.090 (−1.42, 0.93)	0.000 (−1.30, 0.50)	−0.190 (−1.12, 1.06)
Neutrophil count (109/L)	−0.250 (−2.44, 4.76)	−0.320 (−2.94, 1.71)	−0.595 (−6.66, 1.36)	−1.120 (−6.98, 2.14)	−0.480 (−5.28, 1.22)
Creatinine (mmol/L)	0.0 (−13, 10)	4.0 (−3, 11)	3.0 (−5, 13)	5.0 (−2, 17)	5.0 (−5, 23)
HDL cholesterol (mmol/L)	−0.050 (−0.59, 0.36)	0.130 (−0.37, 0.49)	0.100 (−0.88, 0.83)	0.160 (−0.62, 0.85)	0.250 (−0.39, 0.70)
LDL cholesterol (mmol/L)	−0.050 (−0.72, 0.70)	0.130 (−0.54, 0.78)	0.255 (−1.19, 1.68)	0.310 (−0.44, 1.17)	0.465 (−2.23, 1.32)

Abbreviations: HDL=high-density lipoprotein; LDL=low-density lipoprotein; PBO=placebo; QD=once daily.

Conclusion: Clinical efficacy of baricitinib against PBO was demonstrated in this Phase 2b study of baricitinib in combination with background MTX in Japanese pts with moderate to severe RA over 12 weeks. Baricitinib was well tolerated. Safety signals observed over 12 weeks were consistent with previous studies of baricitinib in non-Japanese pts with RA.

A Randomized, Dose-Ranging, Placebo-Controlled, 84-Day Study Of INCB039110, a Selective Janus Kinase-1 Inhibitor, In Patients With Active Rheumatoid Arthritis. Monica Luchi, Rosanne Fidelus-Gort, Diane Douglas, Haifeng Zhang, Robert Flores, Robert Newton, Peggy Scherle, Swamy Yeleswaram, Xuejun Chen and Victor Sandor. Incyte Corporation, Wilmington, DE.

Background/Purpose: To characterize the safety and efficacy of INCB039110, a novel and selective JAK1 inhibitor, in patients with active RA.

Methods: This phase 2, multicenter study (NCT01626573) was conducted in two parts in the United States. Part 1 consisted of an initial 28-day treatment period in an independent group of patients with active RA and identified a dosing range of INCB039110 that was evaluated in part 2. In part

2, presented here, patients with active RA (≥ 6 tender/≥ 4 swollen joints out of 28 examined) and CRP ≥ 6 mg/L were randomized to placebo (PBO) or INCB039110 at daily oral doses of 100 mg BID, 300 mg QD, 200 mg BID or 600 mg QD. Patients could be on stable doses of methotrexate, hydroxychloroquine, corticosteroids (< 10 mg/day) and/or sulfasalazine. Other concurrent DMARDs/biologics were excluded. The primary analysis was at the end of an 84-day PBO controlled period.

Results: Of the 60 planned patients, 40 patients have completed the Day 84 visit and were included in this analysis. Seven patients discontinued treatment. Mean age across treatment groups was 53.2 yrs and 73% were female. Mean disease duration was 9 yrs. Approximately 90% were on background DMARDs and approximately 33% had been previously treated with biologics.

Response rates at Day 84 for ACR and DAS28 CRP and mean percent change from baseline in DAS28 CRP are shown in the table.

Table. Efficacy parameters at Day 84

		INCB039110			
	PBO N=8	100 mg BID N=8	300 mg QD N=9	200 mg BID N=8	600 mg QD N=7
ACR20, n (%)	3 (38%)	4 (50%)	4 (44%)	4 (50%)	7 (100%)
ACR50, n (%)	2 (25%)	3 (38%)	4 (44%)	3 (38%)	5 (71%)
ACR70, n (%)	1 (13%)	2 (25%)	2 (22%)	1 (13%)	4 (57)
DAS28 CRP, Mean % change*	−23% (n=7)	−45% (n=5)	−49% (n=6)	−44% (n=7)	−47% (n=7)
DAS28 CRP < 2.6, n (%)	0	2 (25%)	3 (33%)	2 (25%)	3 (43%)

*Change from baseline in patients with DAS28 CRP assessment at Day 84.

Responses were observed as early as the first assessment (14 days), demonstrating a rapid onset of action. Similar ACR responses were achieved with INCB039110 regardless of background therapy or previous biologic experience.

There were no grade 3 or grade 4 AEs and no dose relationship for treatment-related AEs. One patient experienced a grade 2 ALT elevation. One patient experienced an unrelated serious AE of rib fracture. There were no serious or opportunistic infections. A dose-related increase in LDL was noted. There was no change in HDL to LDL ratio.

Conclusion: INCB039110 given once or twice daily over 84 days was generally well tolerated and demonstrated rapid and clinically meaningful responses in patients with active RA.

ACR Concurrent Abstract Session
Spondylarthropathies and Psoriatic Arthritis: Clinical Aspects and Treatment: Therapeutics and Outcomes in Spondyloarthritis
Monday, October 28, 2013, 4:30 PM–6:00 PM

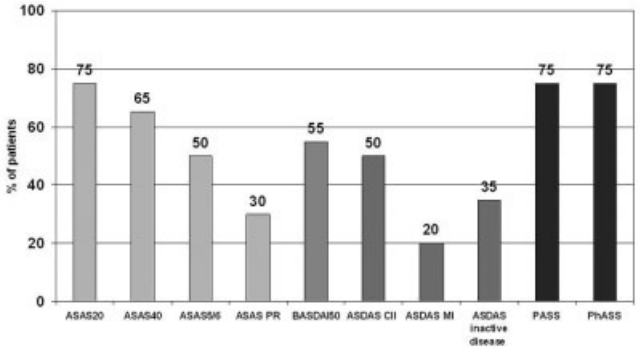
1798

Ustekinumab For The Treatment Of Patients With Active Ankylosing Spondylitis: Results Of a 28-Week, Prospective, Open-Label, Proof-Of-Concept Study (TOPAS). Denis Poddubnyy[1], Johanna Callhoff[2], Joachim Listing[2] and Joachim Sieper[1]. [1]Charité Universitätsmedizin Berlin, Berlin, Germany, [2]German Rheumatism Research Center, Berlin, Germany.

Background/Purpose: In contrast to other inflammatory rheumatic diseases, such as rheumatoid arthritis, the therapeutic options in ankylosing spondylitis (AS) with predominant axial manifestations are limited and confined to non-steroidal anti-inflammatory drugs (NSAIDs) and, if this treatment fails, to tumour necrosis factor α blockers. Ustekinumab – a fully human monoclonal antibody against interleukin (IL)-12 and −23 – has been shown to be effective in psoriasis and is currently in phase 3 trials in psoriatic arthritis and Crohn's disease. The purpose of the current study was to investigate the short-term efficacy and safety of ustekinumab in patients with active AS.

Methods: In this prospective, open-label, proof-of-concept clinical trial (ClinicalTrials.gov identifier NCT01330901), ustekinumab in a dose of 90 mg was administered subcutaneously at baseline, week 4 and week 16 in 20 patients with active AS. Eligible patients were required to have a diagnosis of AS according to the modified New York criteria and an active disease defined as a BASDAI score of ≥ 4 despite previous NSAIDs treatment. The primary study endpoint was the proportion of patients with ASAS40 response at week 24.

Results: At week 24, ASAS40 response was reached by 65% of the patients. ASAS partial remission and a ≥50% improvement of the BASDAI were achieved in 30% and 55% of the patients, respectively. Most of the other outcome parameters also showed a clear and significant improvement (figure, table). There was no reduction of serum C-reactive protein level in the whole group, however, a clear CRP reduction occurred in the ASAS40 responder group (−1.1±7.5 mg/l) vs. the non-responder group (+3.3±3.5 mg/l), p = 0.008. Overall, ustekinumab was well tolerated: only one serious adverse event (AS worsening) was observed, there were no adverse events leading to study discontinuation, no cases of serious infections, malignancies or deaths.



ASAS PR = ASAS partial remission, ASDAS CII = ASDAS clinically important improvement (change score ≥1.1 from baseline), ASDAS MI = ASDAS major improvement (change score ≥2.0 from baseline), PASS = patient acceptable symptom state, PhASS = physician acceptable symptom state.

Figure. Response rates to ustekinumab at week 24 in patients with active AS in the TOPAS trial (n = 20).

Table. Changes in the clinical and laboratory parameter over 24 weeks in patients with active AS (n = 20) treated with ustekinumab in the TOPAS trial.

Parameter	Baseline	Week 24	p-value*
ASDAS (mean ± SD)	3.0 ± 0.6	2.0 ± 1.1	0.001
BASDAI, points NRS (mean ± SD)	5.3 ± 1.5	3.0 ± 1.8	<0.001
BASFI, points NRS (mean ± SD)	5.3 ± 1.9	3.0 ± 2.3	<0.001
BASMI (mean ± SD)	1.6 ± 1.4	1.2 ± 1.3	0.016
Patient global, points NRS (mean ± SD)	6.3 ± 1.6	3.3 ± 2.3	<0.001
General pain, points NRS (mean ± SD)	6.5 ± 1.6	3.3 ± 2.4	<0.001
Nocturnal pain, points NRS (mean ± SD)	6.5 ± 1.9	3.3 ± 2.4	<0.001
EQ-5D (mean ± SD)	0.6 ± 0.2	0.8 ± 0.1	<0.001
ASQoL (mean ± SD)	9.4 ± 3.1	5.1 ± 4.0	<0.001
ASAS NSAIDs intake score (mean ± SD)	68.7 ± 37.9	33.3 ± 33.6	0.008
CRP, mg/l (mean ± SD)	5.9 ± 5.5	6.4 ± 7.1	0.760

*Paired-samples t-test

Conclusion: In this prospective, open-label, proof-of-concept clinical trial, ustekinumab treatment seems to be effective with a significant reduction of signs and symptoms of active AS. For comparison, the ASAS40 response rates in similarly designed AS trials with methotrexate [1], abatacept [2], or anakinra [3] were 10%, 13%, or 20%, respectively.

Background/Purpose: Previous reports of RAPID-axSpA have demonstrated the efficacy and safety of certolizumab pegol (CZP), a PEGylated Fc-free anti-TNF, in patients (pts) with axial spondyloarthritis (axSpA) including pts with ankylosing spondylitis (AS, meeting modified New York criteria) and pts with no sacroiliitis on X-ray (non-radiographic axSpA, nr-axSpA), to Week (Wk) 24.[1] We report clinical efficacy and safety of CZP in axSpA pts to Wk48.

Methods: The ongoing RAPID-axSpA trial (NCT01087762) is double-blind and placebo (PBO) controlled to Wk24 and dose-blind to Wk48.[1] Pts fulfilled ASAS criteria[2] and had active axSpA, including both AS pts and nr-axSpA pts. Pts originally randomized to CZP (200mg Q2W or 400mg Q4W, following 400mg loading dose at Wks 0, 2, 4) continued on their assigned dose in dose-blind phase; PBO pts entering dose-blind phase were re-randomized to CZP loading dose followed by CZP 200mg Q2W or CZP 400mg Q4W after Wk24 or, for non-responders Wk16. We present efficacy data for all pts originally randomized to CZP and imaging outcomes for all pts included in the imaging sub-study (MRI set). Endpoints included ASAS20 and ASAS40 responses, ASAS PR and ASDAS outcomes. Also included were BASDAI, BASFI, BASMI-linear, total spine pain, fatigue, ASQoL, SPARCC and ASspiMRI-a. Outcomes are presented at Wk24 and Wk48. NRI was used for categorical measures and LOCF for quantitative measures. Safety sets consists of all pts treated with CZP at any stage of the 48-wk trial.

Results: 325 pts were randomized, of which 218 received CZP from Wk0. Of pts randomized to CZP at baseline (BL), 93% completed Wk24 and 88% Wk48. ASAS20, ASAS40 and ASAS PR were maintained from Wk24 to 48 (Table) and improvements from BL in BASDAI, BASFI, BASMI-linear, ASDAS and ASDAS-ID were also maintained to Wk48 (Table). Reductions in pain, fatigue and ASQoL were also observed between Wk24 and Wk48 (Table). In the MRI sub-study (CZP N=104), reduction of inflammation, as measured by SPARCC and ASspiMRI-a, was maintained to Wk48. Similar improvements were seen with both dosing regimens and in both AS and nr-axSpA subpopulations (Table). In the safety set (N=315), adverse events (AEs) occurred in 248 pts (78.7%; event rate per 100 pt-yrs=419.5), serious AEs in 25 (7.9%). Serious infections occurred in 10 (3.2%) pts, including suspected tuberculosis in 3 (1.0%) of which 1 was confirmed (from Mexico). No deaths or malignancies were reported.

Presented data are mean values except where otherwise stated. [a] AS patients fulfilled modified New York criteria; [b] For the Full Analysis Set of patients originally randomized to CZP; [c] Numeric Rating Scale (NRS) scale; 0 = no pain, 10 = most severe pain. [d] NRS scale; 0 = no fatigue, 10 = severe fatigue. ASAS20: assessment of Axial SpondyloArthritis international Society 20% response criteria; ASAS40: assessment of Axial SpondyloArthritis international Society 40% response criteria; ASAS PR: assessment of Axial SpondyloArthritis international Society Partial Remission criteria; ASDAS: Ankylosing Spondylitis Disease Activity Score; ASDAS-CII: ASDAS Clinically Important Improvement; ASDAS-MI: ASDAS Major Improvement; ASDAS-ID: ASDAS Inactive Disease criteria; PROs: Patient-Reported Outcomes; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BASFI: Bath Ankylosing Spondylitis Functional Index; BASMI-linear: Bath Ankylosing Spondylitis Metrology Index-linear; ASQoL: Ankylosing Spondylitis Quality of Life scale; MRI: Magnetic Resonance Imaging; SPARCC: SPondyloArthritis Research Consortium of Canada SIJ score for inflammation; ASspiMRI-a: Berlin modification of AS spine MRI score for disease activity in the spine.

Conclusion: In the RAPID-axSpA trial, improvements observed over 24 wks in clinical efficacy, patient-reported and MRI outcomes were sustained over 48 wks in both CZP dosing regimens. Similar sustained improvements in clinical, patient-reported and MRI outcomes were observed in both AS and nr-axSpA subpopulations. The safety profile was in line with that observed for CZP in RA.

Persistent Fatty Lesions In The Vertebrae In Ankylosing Spondylitis Favor Subsequent New Syndesmophytes: Imaging Results Of a Phase III, Randomized, Placebo-Controlled Study. Kay-Geert A. Hermann[1], Xenofon Baraliakos[2], Jürgen Braun[2], Stephen Xu[3] and Benjamin Hsu[3]. [1]Charité Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]Janssen Research & Development, LLC., Spring House, PA.

Background/Purpose: In ankylosing spondylitis (AS), it is hypothesized that stepwise pathologic changes in the spine begin with active inflammation, then fatty degeneration (Fat), leading to syndesmophyte formation. Using data from the golimumab (GLM) AS study (GO-RAISE), we assessed how fatty and inflammatory lesions detected by MRI related to subsequent syndesmophytes and bridging on x-ray.

Methods: In GO-RAISE, 356 patients with definite AS, BASDAI >4, and back pain score >4 were randomized to SC GLM 50mg, 100mg, or PBO q4wks. All patients were to have lateral view radiographs of the cervical and lumbar spine performed at baseline (BL), wks104 and 208. At MRI substudy sites, serial spine MRI scans in the sagittal plane were acquired using 1.5T scanners with T1 and short tau inversion recovery (STIR) sequences at BL, wk14, and wk104 for 98 patients. Two imaging readers blinded to treatment and image order independently evaluated anterior and posterior vertebral corners on x-rays for syndesmophytes/bridging. Blinded MRI reads were done using ASspiMRI-a scoring of active inflammation (Infl) in vertebral units (VU), with notation of lesional location by VU quadrant (upper, lower × anterior, posterior); and the modified ASspiMRI-c scoring method to assess structural changes including presence of Fat in each of the 23 VU. This analysis focused on percentage of vertebral corners with new syndesmophytes/bridging visible on x-ray at wk 104 and 208, and how this percentage varied by presence or absence of prior Infl or Fat lesions in the corresponding VU quadrants at BL and wk14.

Results: There were 91 patients in the substudy representing over 1200 VU (cervical, lumbar) with evaluable Fat data by MRI at BL and wk14 and corresponding vertebral corner x-ray data at wk104 and 208. Of VU with Fat at wk14, more frequently there was also Fat at BL and Fat persisting to

wk104, and Infl lesions were more frequently absent at BL than present. Overall, as assessed by both readers individually and concordantly, the percentage of corners with new syndesmophytes at wk 104 or 208 was greater in VU where Fat was persistently present at both BL and wk14, compared to those where Fat was only present at wk14. New syndesmophytes were significantly more likely to develop in VU with Fat at both BL and wk14 than those that did not have persistent fat (odds ratios for wk208 syndesmophyte/ bridging, Reader 1, 3.27; Reader 2, 2.42). The combined presence at BL of Fat and Infl lesions in a VU quadrant appeared to further increase the chance of new syndesmophytes developing at the corresponding vertebral corner ([Reader #1] 7.9% and 2.5% of corners with new syndesmophytes at wk104 for VU with BL Fat+Infl/ wk14 Fat *vs*. BL Fat-no Infl/ wk14 Fat, respectively, and [Reader #2] 4.4% and 2.7%, respectively). Conversely, for VU without Fat or Infl at BL but wk14 Fat present, only 0–1.5% of corners developed new syndesmophytes later.

Conclusion: This detailed analysis of spine MRI and radiographs at the vertebral level supports the hypothesis that in AS, fatty degeneration and active inflammation within vertebral unit favors progression toward subsequent syndesmophyte growth and ankylosis.

Relationship Between MRI and Clinical Remission In Patients With Non-Radiographic Axial Spondyloarthritis After Two Years Of Adalimumab Therapy.

Désiréé van der Heijde[1], Walter P. Maksymowych[2], Joachim Sieper[3], Robert Lambert[4], Matthew A. Brown[5], Suchitrita S. Rathmann[6], Jaclyn K. Anderson[7] and Aileen L. Pangan[6]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]University of Alberta, Edmonton, AB, [3]Charité Universitätesmedizin, Berlin, Germany, [4]University of Alberta Hospital, Edmonton, AB, [5]University of Queensland Diamantina Institute, Brisbane, Australia, [6]AbbVie Inc., North Chicago, IL, [7]AbbVie, North Chicago, IL.

Background/Purpose: Adalimumab (ADA) is currently approved in the EU for the treatment of severe non-radiographic axial spondyloarthritis (nr-axSpA), in patients (pts) with an elevated CRP and/or positive MRI who have had an inadequate response to, or are intolerant to NSAIDs. Reduction of sacroiliac joint (SIJ) and spine inflammation on MRI has been previously reported after 12 wks of ADA compared to placebo in the ABILITY-1 study. The objective of this analysis was to determine the efficacy of ADA in improving inflammation on MRI in pts with nr-axSpA and the relationship between MRI and clinical remission.

Methods: ABILITY-1 is an ongoing phase 3, randomized, controlled trial in pts with nr-axSpA who had an inadequate response, intolerance, or contraindication to NSAIDs. A 12-wk double-blind period of ADA 40 mg every other week (eow) or placebo (PBO) was followed by an open-label period in which pts could receive ADA 40 mg eow for up to an additional 144 wks. MRI of the SIJ and spine were done at baseline (BL), wks 12, 52 and 104, and were read using the SPARCC scoring system (6 discovertebral unit method for the spine) by 2 independent readers who were blinded to time sequence. Mean reader scores were used. This *post hoc* analysis evaluated the efficacy of ADA in improving MRI inflammation at wks 52 and 104 in the overall population and in the MRI+/CRP+ subpopulation (pts who had positive BL MRI [SPARCC score ≥2 for either the SIJ or spine] or elevated BL CRP). Clinical remission was defined by ASDAS inactive disease (ASDAS ID, ASDAS <1.3) and MRI remission by SPARCC score <2.

Results: 142 (69 ADA, 73 PBO) of the total efficacy population (N=185) were in the MRI+/CRP+ subpopulation. MRI obtained at wks 52 and 104 showed sustained mean improvements with long-term ADA therapy in SPARCC SIJ and spine scores for the overall population (wk 52 n=149, –3.7 and n=148, –1.2; wk 104 n=131, –3.8 and n=130, –1.4) and for the MRI+/CRP+ subpopulation (wk 52 n=116, –4.6 and n=115, –1.7; wk 104 n=102, –4.8 and n=101, –2.0). The table presents MRI and clinical remission rates among pts who had a positive MRI at BL (SPARCC score ≥2 for either the SIJ or spine). Of the 46 pts who were in ASDAS ID at wk 104, 33 (72%), 35 (76%) and 26 (57%) had MRI remission of the SIJ, spine or both SIJ and spine respectively.

Table. Patients with baseline MRI Scores ≥2 for SI joint or Spine Achieving MRI and Clinical Remission at Weeks 52 and 104

ASDAS Inactive Disease Status	SPARCC SI Joint Score		SPARCC Spine Score		SPARCC SI Joint and Spine Scores	
	<2 n	≥2 n	<2 n	≥2 n	SI Joint and Spine <2 n	SI Joint or Spine ≥2 n
Week 52				**N=101**		
In ASDAS inactive disease	37	10	32	15	26	21
Not in ASDAS inactive disease	39	15	28	26	21	33
Week 104				**N=88**		
In ASDAS inactive disease	33	13	35	11	26	20
Not in ASDAS inactive disease	33	9	19	23	18	24

N = patients who are MRI+ at baseline (MRI SPARCC score ≥2 for SI joint or spine) and with available ASDAS and MRI data. ASDAS, Ankylosing Spondylitis Disease Activity Score.

Conclusion: In ABILITY-1, ADA therapy of up to 2 yrs in nr-axSpA pts resulted in reduction of inflammation on MRI. The majority of pts in clinical remission were noted to also have MRI remission. However, resolution or absence of inflammation on MRI did not always correspond to clinical remission.

1802

A Major Clinical Response To Anti-Tumor Necrosis Factor Agents Is Associated With a Reduced Development Of Fatty Changes In The Spine Of Patients With Ankylosing Spondylitis.

Xenofon Baraliakos[1], Frank Heldmann[1], Joachim Listing[2], Johanna Callhoff[2] and Jügen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]German Rheumatism Research Center, Berlin, Germany.

Background/Purpose: Fatty changes (FC) on T1-weighted magnetic resonance images (MRI) have been described in the spine of patients with ankylosing spondylitis (AS). Such lesions were recently found to be related to syndesmophyte development in AS patients treated with anti-TNF agents. While TNF blockers have been shown to reduce inflammatory changes seen on STIR MRI sequences, their effect on the course of FC has not been studied in detail to date. To study the course of FC in patients with AS under anti-TNF therapy and analyse which clinical parameters are associated with the occurrence of FC.

Methods: MRI of AS patients participating in the EASIC study who had received infliximab for 2 years were blindly for the time point of examination. Presence or absence of FC was recorded for all vertebral edges (VEs) at baseline, after 24 weeks and after 2 years of treatment. Spinal radiographs at baseline and 2 years were scored by the mSASSS. Relative risk (RR) calculations were performed based on generalized estimation equations (GEE model). Poisson variation and $\chi 2$ test was used to compare MRI findings between time points.

Results: Complete sets of MRI were available of 73 patients (mean age 40.5±10.5 years, 86.3% male, HLA-B27+: 83.6%, mean BASDAI 6.5±1.4, mean disease duration 10.0±8.4 years) resulting in a total of 1,948 VEs at each time point. At baseline, FC were found in 619 VEs (31.8%). After 24 weeks of infliximab therapy, regression of FC was seen in 19 VEs (3.1%), while new FC had appeared in 133/1,329 VEs (10.0%). After 2 years, regression of FC was observed in 35/619 VEs (5.7%) and new FC were seen in 215 VEs (16.2%), while 4/1,948 VEs (0.3%) showed both regression and development to FDL at different time points. Increased inflammatory activity at baseline was significantly associated with development of FC: 34% of VEs with inflammation vs. 12.9% of VEs without (p<0.0001). Baseline mSASSS scores increased the risk of FC: RR 1.03, 95% CI: 1.01–1.04 (p=0.0003),

while a major treatment response (50% BASDAI improvement) was associated with lower risk: RR=0.85, 95% CI: 0.76–0.95 (p=0.005). Being female lowered the risk for FC by 22%: RR: 0.88, 95% CI: 0.59–1.32, p=0.544), and younger age also had some influence: RR: 0.97, 95% CI: 0.93–1.00 (p=0.0327).

Conclusion: This study confirms that FC develop in AS patients treated with TNF blockers and that inflammation may be one source of that. However, the most important finding of this analysis is that a good response to TNF blockers was associated with significantly lower risk to develop FC. Whether this leads to a decrease in new bone formation over time remains to be seen.

1803

Is Site Of Back Pain Related To Location Of Inflammatory and Structural Lesions On MRI In Patients With Chronic Back Pain? Manouk de Hooge[1], Rosaline van den Berg[1], Floris van Gaalen[1], Victoria Navarro-Compán[1], Monique Reijnierse[1], Karen Fagerli[2], Maureen C. Turina[3], Maikel van Oosterhout[4], Roberta Ramonda[5], Tom Huizinga[1] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [4]GHZ Hospital, Gouda, Netherlands, [5]University of Padova, Padova, Italy.

Background/Purpose: Pain has found to be related to inflammatory lesions in thoracic, lumbar and sacroiliac joints (SIJ) sites and to structural lesions in the SIJ site in the DESIR cohort. Our aim was to evaluate if localisation of back pain, as indicated by patients, is related to location of BME lesions seen on MRI (in spine (MRI-spine) or sacroiliac joints (SIJ) (MRI-SI)) in patients with chronic back pain.

Methods: Chronic back pain patients (≥3 months, ≤2 years, onset <45 years) recruited from 5 participating centres were included in the SPondylo-Arthritis Caught Early (SPACE)-cohort. Pain was indicated by patients at different sites (thoracic, lumbar, buttock, total spine). Patients underwent MRI-spine and MRI-SI. On MRI-spine anterior/posterior BME and fatty lesions suggestive of spondylitis were scored when visible on ≥2 consecutive slices. For any other structural lesion (erosions or syndesmophytes), suggestive of spondylitis, presence on ≥ 1 slice was sufficient. On MRI-SI, BME, fatty lesions, sclerosis and erosions, suggestive of spondylitis, were scored when ≥1 lesion was present on ≥2 consecutive slices or >1 lesion on 1 slice. Presence of ankylosis on ≥1 slice was scored. MRIs were scored independently by 3 blinded, well calibrated readers. Agreement of 2/3 readers was used. Association between pain site and BME location was assessed by logistic regression analysis adjusted for gender, HLA-B27 and age at onset of back pain resulting in adjusted Odds Ratios (OR).

Results: In 296 patients, data of the location of pain, MRI-spine (n=293) and MRI-SI (n=288) was available. Mean age at pain onset was 28.9 years, 35.1% male, 38.5% HLA-B27+ and 41.9% fulfilled the ASAS axSpA classification criteria. The prevalence of pain and lesions is shown in the table. The ORs of pain and MRI lesions at same site for the different patient group are shown in the table. Pain in the thoracic site was significantly associated with BME lesions at the same site in the whole patient group. Similar ORs were found in the no-SpA and axSpA subgroups, though not significant due to the lower amount of patients. Pain was significantly associated with fatty and any structural lesions in the buttock/SIJ site in the axSpA supgroup (see table).

Prevalence of pain and lesions

	Back pain	BME lesions	Fatty lesions	Any structural lesion
Cervical	ND	5 (1.7%)	9 (3%)	16 (5.4%)
Thoracic	108 (36.5%)	52 (17.6%)	45 (15.2%)	80 (27%)
Lumbar	244 (82.4%)	65 (22%)	33 (11.1%)	59 (19.9%)
Buttock/SIJ	100 (33.8%)	67 (22.6%)	36 (12.2%)	49 (14.2%)
Total spine	10 (3.4%)	0	4 (1.4%)	8 (2.7%)
Any site in the spine	296 (100%)	95 (32.1%)	60 (25%)	101 (34.1%)

Odds ratios of pain at the same site

	OR (CI) all patients (n=296)	OR (CI) axSpA patients (n=124)	OR (CI) no-SpA patients (n=172)
BME lesions			
Thoracic site	*2.07 (1.08–3.95;p<0.03)*	2.11 (0.87–5.15)	2.54 (0.91–7.05)
Lumbar site	1.39 (0.65–3.11)	1.26 (0.47–3.40)	1.75 (0.37–8.35)
Buttock/SIJ site	0.63 (0.34–1.16)	0.55 (0.23–1.28)	0.27 (0.06–1.28)
Fatty lesions			
Thoracic site	1.10 (0.54–2.24)	1.23 (0.49–3.06)	1.13 (0.35–3.62)
Lumbar site	0.62 (0.26–1.51)	0.76 (0.23–2.44)	0.38 (0.92–1.60)
Buttock/SIJ site	1.06 (0.49–2.30)	*3.71 (1.15–11.96; p<0.03)*	0.57 (0.25–1.28)
Any structural lesion			
Thoracic site	1.23 (0.71–2.14)	1.20 (0.53–2.70)	1.49 (0.67–3.32)
Lumbar site	0.99 (0.47–2.15)	0.74 (0.27–2.01)	1.08 (0.29–4.07)
Buttock/SIJ site	1.62 (0.95–2.78)	*5.10 (1.45–17.92; p<0.01)*	0.56 (0.25–1.27)

Conclusion: The localisation of pain in the spine (thoracic, lumbar, buttock or total spine), as indicated by the patient, is significantly related to the location of BME lesions in thoracic site in patients with chronic back pain. In addition, in the subgroup with axSpA patients there is a significant relation between buttock pain and any structural lesions seen on MRI-SI.

ACR Concurrent Abstract Session
Systemic Lupus Erythematosus - Clinical Aspects: Non-biologic Disease-modifying Antirheumatic Drugs
Monday, October 28, 2013, 4:30 PM–6:00 PM

1804

Effect of Mycophenolate On the White Blood Cell Count and the Frequency of Infection in Systemic Lupus Erythematosus. Ananta Subedi[1], Hong Fang[2] and Michelle Petri[2]. [1]Good Samaritan Hospital, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: Leukopenia is a common manifestation of SLE. Addition of immunosuppressive therapy is of concern, in that it could worsen leukopenia; increase the risk of infection, or both. The aim of this study was to analyze the effect of mycophenolate on the white blood cell count and the rate of infection in SLE patients.

Methods: Three hundred patents within the Hopkins Lupus Cohort who were on mycophenolate mofetil were included in the study. SLE patients served as their own control (before and after mycophenolate mofetil). The white blood cell count and rate of infection were compared on the day mycophenolate was started with the white blood cell count and rate of infection at the next visit. Statistical analysis was performed using the paired t-test.

Results: At the time of the analysis, three hundred patients in the cohort were taking mycophenolate mofetil. The study population included 43% Caucasians, 47% African-Americans and 10% other ethnicities. There was a slight but not statistically significant increase in the white blood cell count (6.65±3.34 vs. 7.02±3.28, P= 0.075), after starting mycophenolate. Patients with a baseline white blood cell count less than 3,000/mm^3 did have a statistically significant increase in the white blood cell count after starting mycophenolate mofetil (2.49±0.46 vs. 4.83±2.66, P= 0.0007). In the multivariate model for factors associated with the white blood count, mycophenolate use was not statistically significant (Table 1). We also found a statistically significant increase in the rate of bacterial infection (but not viral infection) after starting mycophenolate mofetil (5% vs. 9%, P= 0.032, Table 2).

Table 1. Factors Associated with the White Blood Cell Count Adjusted for Ethnicity and Prednisone dose.

Variable	Effect on white blood cell Count	p-value
Ethnicity		
African-American vs. Caucasian	−0.91±0.33	0.0049
Other ethnicity vs. Caucasian	−0.52±0.51	0.31
Prednisone (per mg/d)	0.07±0.01	<0.0001
Mycophenolate mofetil (before vs. after)	0.20±0.18	0.28

Table 2. Frequency of Infection Before and During the Use of Mycophenolate mofetil.

Variable	Before mycophenolate mofetil (%)	After mycophenolate mofetil (%)	Adjusted p-value*
Infection (viral or bacterial)	14	18	0.087
Viral infection	10	10	0.17
Bacterial infection	5	9	0.032

* p-value adjusted for prednisone dose.

Conclusion: Leukopenia does not worsen with mycophenolate. However, mycophenolate does increase the rate of bacterial (but not viral) infection.

Hydroxychloroquine Levels Identify Four Distinct Subsets of Systemic Lupus Erythematosus Patients. Michelle Petri, Hong Fang and William Clarke. Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: Hydroxychloroquine is used for both its effect on SLE disease activity (cutaneous and arthritis) and for its preventive roles (reduction in flares, renal damage, thrombosis). HCQ blood levels have been predominantly used to identify nonadherence; to date, they have not correlated well with disease activity.

Methods: 357 SLE patients (mean age 44.7, 94% female, 45% Caucasian, 45% African-American, and 10% other ethnicity) had hydroxychloroquine blood levels measured (therapeutic 500–1500 ng/mL in whole blood) and same day assessment of global disease activity by Physician Global Assessment (PGA, 0 to 3 VAS) and SELENA-SLEDAI.

Results: 53 (15%) had 0 level, meaning complete nonadherence. 110 (31%) had levels between 15–500 ng/mL indicating partial adherence. 167 (47%) had therapeutic levels. Surprisingly, 27.8% had supratherapeutic levels. This supratherapeutic group was appropriately dosed for weight, age, and renal function.

Table 1. Effect of Hydroxychloroquine level on Clinical Characteristics (as categorical variables)

Demographic Characteristics	HCQ <15 (N=53)	HCQ (15–500) (N=110)	HCQ (500–1500) (N=167)	HCQ ≥1500 (N=27)	Adjusted P-Value§	Adjusted P-value for therapeutic (≥500) vs non-therapeutic levels§

§Comparison between among different HCQ groups; adjusted for age, ethnicity, and gender.

Conclusion: Hydroxychloroquine blood levels remain important in assessing adherence, but they are disappointing in not being correlated with current disease activity (by PGA or SLEDAI). In fact, the identification of the "supratherapeutic" group explains this paradox, as they had greater PGA, SLEDAI, and prednisone use. Several hypotheses (patients increasing HCQ dose on their own for disease activity vs genetic differences in metabolism of HCQ) could explain a "supratherapeutic" group. Our data also indicate that nonadherence should be subdivided into two groups: complete nonadherence (15%) and partial nonadherence (31%), as the clinical implications are quite different.

Association Between Hydroxychloroquine Exposure and Incidence Of Diabetes Mellitus In Systemic Lupus Erythematosus. Michelle Petri[1] and Laurence S. Magder[2]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD.

Background/Purpose: Diabetes mellitus is one of the SLICC/ACR Damage Index items and a recognized risk factor for cardiovascular disease and renal failure. In rheumatoid arthritis, hydroxychloroquine is protective against diabetes. We examined the incidence of and risk factors for diabetes in SLE.

Methods: For each month of follow-up for a patient in a large single-site clinical SLE cohort, we calculated the proportion of previous months in the cohort that hydroxychloroquine was prescribed. We then determined the rate of incident diabetes in groups defined by hydroxychloroquine exposure and other patient characteristics. Diabetes was defined based on the SLICC/ACR Damage Index.

Results: The analysis was based on 1944 SLE patients. They were 93% female. They were 55% Caucasian, 37% African American, and 8% other ethnicity. At the start of follow-up there were 632 (33%) under 30 years of age, 803 (41%) between 30 and 44, 408 (21%) age 45–59, and 101(5%) 60 or older. The mean age was 37.5 years. The mean duration of follow-up per patient was 6.6 years. 682 (35%) were followed for less than 3 years, 413 (21%) were followed for 3–6 years, 258 (13%) were followed for 6–9 years, and 591 (30%) were followed for 9 or more years.

There were 59 incident cases of diabetes out of 12,802 person-years of follow-up (rate=4.6/1000).

Table 1 shows the rates of incident diabetes in subgroups defined by demographic and medication variables. The last column shows the rate ratios found after performing a multivariable regression adjusting for all other variables in the table. In the unadjusted analysis hydroxychloroquine appears protective (RR for >75% vs. <25%=0.5, p=0.012). After adjustment, there is still some evidence of a protective effect (RR=0.6, p=0.067).

[1]Refers to percentage of prior months of cohort follow-up in which hydroxychloroquine was prescribed.
[2] Refers to the mean daily dose of prednisone during prior months of cohort follow-up
[3] Adjusting for all variables in the table

Conclusion: In univariate analysis, hydroxychloroquine appears protective. However, after adjustment, while the estimated RR did not change, the result was no longer statistically significant (RR=0.6, p=0.066). This is likely due to the fact that there is a strong association between hydroxychloroquine and year (it is being used much more frequently in recent years) and also a strong relationship between year and incidence of diabetes. This results in a loss of power to detect an effect of hydroxychloroquine as the regression model is trying to tease out which of the two (hydroxychloroquine vs year) are the true predictors. Although the evidence is modest (p=.066), our data are consistent with previous findings of lower rates of diabetes among those who use hydroxychloroquine.

Do We Know How and When To Taper and Stop In Immunosuppressants In Lupus Patients? Zahi Touma, Murray B. Urowitz, Dominique Ibanez and Dafna Gladman. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: After achieving low disease activity or remission, immunosuppressant therapies might be stopped in lupus patients, but information on whether and how this should be done is scarce.

Our aim was to determine if tapering and withdrawing immunosuppressants in patients in remission is associated with flare.

Methods: Analysis on all patients seen in The Lupus Clinic from 1987–2012 was conducted: 1) patients in clinical remission (no activity in the clinical SLEDAI-2K descriptors and absence of proteinuria, thrombocytopenia and leukopenia), 2) ≥ 25% taper of the immunosuppressant and 3) prednisone ≤7.5mg/day.

Flare was defined as: 1) any increase in the dosage or introduction of new immunosuppressant or 2) start or any increase of prednisone dosage.

4 groups were identified (Figure 1):

A: Flare after tapering and while still on immunosuppressant.

B: No flare but still on tapering immunosuppressant dose at last visit.

C: Flare after stopping immunosuppressant.

D: No flare after stopping immunosuppressant to last clinic visit or at 2 years.

Success was defined as no flare at last clinic visit if still on immunosuppressant (B) or no flare within 2 years following stopping the immunosuppressant (D).

Results: Of the 1678 lupus patients registered, 204 tapering episodes in 179 patients were identified. 162 were female with age 39.0±13.3 and lupus duration 11.2±8.5 years at tapering.

Of the 204 tapering episodes 124 (61%) were successful (B and D). Immunosuppressant was stopped in 101 episodes (C and D) (table 1).

Group A and B did not reach the point of completely stopping immunosuppressant. 55 of these 103 (53.4%) flared. In group C and D 25 of 101 (24.7%) flared. In group C the time to flare was 1.7±1.0 years. In group D, all patients stopped immunosuppressant at 1.7±1.8 years and did not flare with a mean time from tapering to censoring of the data at 3.3±1.8 years (table 2).

Table 1. 204 tapering episodes

	AZA	MTX	MMF	P values
Number of patients	109	37	39	
Number of episodes N=204	123	42	39	
Flare (% episodes)	53 (43.1%)	17 (40.5%)	10 (25.6%)	X^2=0.15
Completely stopped immunosuppressants (episodes) N (C+D)=101	58 (47.2%)	25 (59.5%)	18 (46.2%)	X^2=0.34

Figure 1. Grouping of patients

Table 2. Mean time to event results (years)

Group	Time to stop event	Time to stop immunosuppressant	Time stop immunosuppressant to event
A n=55	1.5±1.2	N/A	N/A
B n=48	2.1±2.5	N/A	N/A
C n=25	1.7±1.0	0.9±0.9	0.8±0.5
D n=76	3.3±1.8	1.7±1.8	1.6±0.6

Conclusion: Our results suggest that successful tapering and discontinuation of immunosuppressants is possible in about 1/2 of clinically stable patients. In 1/4 a subsequent flare occurred. Future research may identify which patients are most likely to successfully discontinue immunosuppressants and define an appropriate algorithm for immunosuppressant tapering.

Impact Of Baseline Disease Severity and Treatments On Outcomes In Clinical Trials Of SLE: Results From The Soccit Program. Kenneth C. Kalunian[1], Mimi Kim[2], Timothy W. Behrens[3], Sabine Bongardt[4], Paul Brunetta[5], Paola Daly[6], Nathalie Franchimont[7], Richard Furie[8], Matthew Linnik[9], Bevra H. Hahn[10], Leslie M. Hanrahan[11], Jan L. Hillson[12], Jane Salmon[13], Neil Solomons[14] and Joan T. Merrill[15]. [1]UCSD School of Medicine, La Jolla, CA, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Genentech, Inc, South San Francisco, CA, [4]UCB Pharma, Brussels, Belgium, [5]Genentech, So San Francisco, CA, [6]Lupus Foundation of America, Washington DC, DC, [7]Biogen Idec Inc., Weston, MA, [8]North Shore-LIJ Health System, Lake Success, NY, [9]Lilly Research Laboratories, La Jolla, CA, [10]UCLA David Geffen School of Medicine, Los Angeles, CA, [11]Lupus Foundation of America, Washington, DC, [12]Bristol-Myers Squibb, Seattle, WA, [13]Hospital for Special Surgery, New York, NY, [14]Vifor Pharma, New York, NY, [15]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: The Lupus Foundation of America Collective Data Analysis Initiative was established to evaluate SLE clinical trial design, using data collected from multiple studies. To evaluate the impact of baseline disease characteristics and background treatments on trial endpoints, we evaluated the effects of baseline disease severity and background medications on flare rates in non-nephritis patients.

Methods: Data from 186 SLE patients receiving standard-of-care (SOC) but no investigational agents were compiled from 3 multicenter non-nephritis Phase 2 or 3 trials. A flare (referred to as "any flare") was defined as either >/= 1 new BILAG A or >/= 2 new B scores; a severe flare was defined as the occurrence of >/= 1 new BILAG A organ score since the previous visit. Treatments compared were: azathioprine, mycophenolate mofetil (MMF), methotrexate, and other including treatments such as antimalarials or low dose prednisone alone.

Results: Those with severe disease at baseline (at least one BILAG A) were more likely to experience any flare as well as a severe flare. At baseline, mean BILAG composite scores for MMF patients was 26.2 (SD 8.2) vs 22.1 (8.5) for all other patients (p=0.01). MMF-treated patients with severe disease at baseline had the highest rate of any flare and severe flare. Flare rates in other SOC groups did not differ when compared to each other (data not shown).

Table 1. Any Flare** Stratified by Baseline Disease Severity and Background Drug

Background drug	Baseline disease severity	Total person-years	Total number of any flares	Rate of any flare	P-value†
MMF	No BILAG A	11.7	12	1.03	reference
	At least one A	19.3	46	2.39	**0.01**
Other drugs	No BILAG A	48.3	44	0.91	reference
	At least one A	51.3	72	1.40	**0.02**

** Defined as >/= 1 new BILAG A **or**>/= 2 new B scores any new A or 2+ new Bs since last visit.
† By fitting a Poisson regression model to the total number of flares and the total person-years for each background drug group.

Table 2. Severe Flare* Stratified by Baseline Disease Severity and Background Drug:

Background drug	Baseline disease severity	Total person-years	Total number of severe flares	Rate of severe flare	P-value†
MMF	No BILAG A	11.7	4	0.34	reference
	At least one A	19.3	36	1.87	**0.0013**
Other drugs	No BILAG A	48.3	21	0.43	reference
	At least one A	51.3	59	1.15	**<0.0001**

* Defined as >/= 1 new BILAG A since last visit.

Conclusion: Previously, we reported MMF to be associated with increased response rates based on a BILAG assessment, which may have been confounded by increased protocolized steroid use in studies contributing the majority of MMF-treated patients. We now report that in non-nephritis trials, patients entered on MMF had greater baseline disease, suggesting that treatment with MMF might define a sicker subset of patients. Our new data further indicate a higher propensity for all flares and severe flares in those on MMF at baseline despite increased response rates after high steroid use, consistent with the hypothesis that those more ill patients who do not respond to protocol therapy, are more likely to flare than other patients. Trial results could be confounded, then, by inconsistencies between endpoints defining response and endpoints relying more heavily on flare.

Topline Results Of The Biomarkers Of Lupus Disease (BOLD) Study: Clinical and Mechanistic Perplexities Of Lupus Treatment Trials Can Be Mitigated By Eliminating Background Immune Suppressants. Joan T. Merrill[1], Frederick W. Immermann[2], Tianhui Zhou[3], Margot O'Toole[4], Maryann Whitley[5], Andrew A. Hill[5], Ying Zhang[5], David von Schack[5], Padmalatha S. Reddy[5], Jaime L. Masferrer[4], Stan Kamp[6], Joel M. Guthridge[1], Aikaterini Thanou[1], Paul Wu[5], Theresa Paradis[5], William M. Mounts[5], Judith A. James[1] and Sudhakar T. Sridharan[2]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Pfizer Inc, Collegeville, PA, [3]Bristol Myers Squibb, Princeton, NJ, [4]independent consultant, Cambridge, MA, [5]Pfizer Inc, Cambridge, MA, [6]Oklahoma Medical Research Foundation, Oklahoma CIty, OK.

Background/Purpose: The BOLD study was designed to test the discriminatory capacity and safety of a trial design eliminating background **immune suppressants (IS)** in SLE patients (pts) with active, non-organ threatening disease.

Methods: 103 active pts (SLEDAI >/= 6 and/or >/= 2 BILAG B or 1 A) were evaluated at ***baseline (BV)*** for effects of IS on immunologic variables, then 41 pts entered a prospective phase with depomedrol injections to improve disease, withdrawal of background IS, and serial biomarker samples until flare. Designation of ***improving visits (IV)*** and ***flare visits (FV)*** were weighted by clinical opinion and confirmed by BV vs IV: universal decreases in SLEDAI, BILAG, PGA, CLASI, and joint counts (all $p<0.0001$), IV vs FV: universal increases (all $p<0.0013$).

Results: The regimen was well tolerated. Of 48 adverse events only one was serious (bleeding ulcer) and resolved. 40/41 pts flared within 24 weeks. All flares improved within 6 weeks with treatment. **Median (95% CI) Days to flare (DTF) was 56 (40–76).** This was influenced by baseline disease activity and amount of steroid given. *BILAG >/= 17* **DTF 40** (29–72) vs *BILAG < 17* **DTF 71** (43–91) (log rank p= 0.043), *depomedrol </= 240mg + BILAG >/= 17* **DTF 38** (22–76) vs *depomedrol >/= 320mg + BILAG < 17* **DTF 91** (40–107). Baseline (withdrawn) IS had no impact on DTF. 47% of pts had elevated type I interferon signature (IFN HI) defined by a novel 11 gene panel we have reported (1). 38% of Caucasians were IFN HI vs 50% Asians, 69% Native Americans and 65% African Americans (Cauc vs others: p=0.012). IFN HI pts were more likely to have antibodies to dsDNA (p=0.001) SSA/Ro (p=0.0007) RNP (p=0.0001) and Sm (p=0.01), had higher circulating BLyS (p=0.00018) and IL23 (p=0.02) but not increased CR3 membrane expression. The table below illustrates potential differences between IFN HI and LOW pts in the impact of different IS on fold expression of non-IFN RNA [e.g. Increase **(INCR)** or Decrease **(DECR),** blank cells indicate no differences.

Mechanistic Impact of Background Treatments Commonly Allowed in Lupus Trials Evaluated By Underlying IFN Signature: Fold Increase or Decrease in RNA Expression

	All Pts (n=103) vs healthy controls		Pts on AZA vs Pts on no IS		Pts on MMF vs Pts on no IS		Pts on MTX vs Pts on no IS	
Gene product	IFN HI	IFN LOW	IFN HI	IFN LOW	IFN HI	IFN LOW	IFN HI	IFN LOW
BLyS/TNFSF13B (p value)	INCR 2.43 (0.0001)				INCR 1.36 (0.018)			
IL23A (p value)	DECR 1.29 (0.04)	DECR 1.24 (0.09)	INCR 1.57 (0.029)					
CR3/ITGAM (p value)			DECR 1.27 (0.04)			DECR 1.69 (0.006)		
LGALS3BP (p value)	INCR 2.93 (0.0001)						DECR 2.77 (0.0009)	
IgE Receptr (p value)	DECR 2.13 (0.0001)			INCR 1.95 (0.053)	INCR 2.28 (0.02)		INCR 2.20 (0.051)	INCR 3.43 (0.0008)

This exploratory, biomarker analysis was not corrected for multiple comparisons.

Conclusion: The BOLD treatment regimen is safe in pts without organ threatening disease and confirms the feasibility of an efficient trial design, ensuring low placebo response rates after brief baseline steroid intervention. This allows consideration of immediate rescue treatment at time of non-response without obfuscating the endpoint, and solves the problem of conventional trials requiring year-long stability of ineffective IS. Less background IS may also decrease infection risk. All outcome measures (BILAG, SLEDAI, PGA, CLASI) performed robustly in this simplified protocol, consistent with clinician-determined improvement and flare. With improved understanding of individual treatment effects on immune targets in key patient subsets, IS might be more strategically selected for studies of sicker pts and withdrawn entirely for stable pts, improving the discriminatory capacity of lupus trials while illuminating the optimal use of medications in clinic.

Background/Purpose: New classification criteria for systemic sclerosis (SSc) have recently been developed. In this study, we aimed to assess the sensitivity of this classification in the patients in the Canadian Scleroderma Research Group (CSRG) cohort.

Methods: SSc patients are included in the CSRG cohort if they have a diagnosis of SSc according to a rheumatologist. The 1980 Preliminary Classification Criteria for systemic sclerosis and the new ACR/EULAR classification criteria were applied. The sensitivity of each criterion in diagnosing SSc was calculated and compared across different socio-demographic and clinical categories.

Results: A total of 1115 SSc patients were included in the study. The majority were females (86%). Overall, the sensitivity of the new criteria was higher (98.4%) than that of the 1980 criteria (87.7%). This pattern was consistent among a number of sub-groups. The new criteria detected 691 (97.5%) of the limited SSc patients whereas the 1980 criteria detected only 572 (80.7%) of limited SSc patients. Both criteria detected 100% of patients with diffuse SSc. Ninety nine percent of anti-centromere (ACA) positive patients were detected by the new criteria, whereas the sensitivity of the 1980 criteria was 78.6% in this category. The sensitivities of new and 1980 criteria were 98.1% and 92.2% respectively in negative ACA category. In patients with disease duration ^{2} 3 years, the sensitivity of the new criteria was 98.8% whereas the sensitivity of 1980 criteria was 87.2%. In patients with disease duration > 3 years, the sensitivities of new and 1980 criteria were 98.3% and 87.9% respectively. When we compared the sensitivities according to age at disease onset, we found that the new criteria had a higher sensitivity than the 1980 criteria, 98.6% and 88.8% respectively, for age of onset of ^{2} 50 years and 98% and 85.8% respectively for age of onset > 50 years. The sensitivity of the new criteria were much higher than the 1980 criteria in the ACA positive and disease duration ^{2} 3 years group, 96.9% versus 67.7%, respectively. For patients with disease duration > 3 years and positive ACA, sensitivities were 99.3% versus 81.2% for new and 1980 criteria, respectively. In patients with negative ACA and disease duration ^{2} 3 years, the sensitivity of the new criteria was 99.4% while the sensitivity of 1980 criteria were 95%. Ninety eight percent of patients with negative ACA and disease duration > 3 years were detected using the new criteria, compared with 91.3% for the 1980 criteria in the same group.

Comparison of new ACR/EULAR and 1980 classification criteria for SSc

		New criteria		1980 criteria	
	N total	N	%	N	%
Entire cohort	1115	1097	98.4%	978	87.7%
Limited	709	691	97.5%	572	80.7%
Diffuse	405	405	100.0%	405	100.0%
Anti-centromere	359	355	98.9%	282	78.6%
Not anti-centromere	668	655	98.1%	616	92.2%
Disease duration ≤3 yrs	250	247	98.8%	218	87.2%
Disease duration > 3 yrs	862	847	98.3%	758	87.9%
Male	155	155	100.0%	147	94.8%
Female	960	942	98.1%	831	86.6%
Disease onset ≤ age 50	715	705	98.6%	635	88.8%
Disease onset > age 50	395	387	98.0%	339	85.8%
Anticentromere AND Disease duration ≤ 3 yrs	65	63	96.9%	44	67.7%
Anticentromere AND Disease duration > 3 yrs	293	291	99.3%	238	81.2%
(NOT anticentromere) AND Disease duration ≤ 3 yrs	159	158	99.4%	151	95.0%
(NOT anticentromere) AND Disease duration > 3 yrs	508	496	97.6%	464	91.3%

Conclusion: Overall, the new classification criteria for SSc are substantially more sensitive than the 1980 criteria. This applies to both sexes, recent or longstanding disease and either young or older subjects. The improvement in sensitivity is most striking, however, in limited SSc or in those with ACA and especially in those with recent onset ACA positive disease.

Validation Of The ICD-CM-9 Code For Systemic Sclerosis Using Updated ACR/EULAR Classification Criteria. Aaliya Yaqub[1], Lorinda Chung[2], David Fiorentino[3] and Eswar Krishnan[4]. [1]Stanford Univ Medical Center, Stanford, CA, [2]Stanford University Medical Center, Palo Alto, CA, [3]Stanford University School of Medicine, Redwood City, CA, [4]Stanford University, Palo Alto, CA.

Background/Purpose: Systemic sclerosis (SSc) is a rare autoimmune disease associated with substantial morbidity. Epidemiologic studies using large administrative databases often rely on the accuracy of International Classification of Diseases-Clinical Modification-9 (ICD-CM-9) codes for case definitions of medical conditions such as SSc. A previous study of 89 hospitalized patients at a

tertiary care center found that the accuracy of ICD-CM-9 code 710.1 for determining true cases of SSc that met the 1980 ACR criteria was 45%. We sought to determine the accuracy of the ICD-CM-9 code of 710.1 for identifying cases of SSc using a large outpatient cohort of well-characterized patients.

Methods: This was a retrospective analysis of the medical records of all patients evaluated at Stanford Hospital and Clinics from 2005–2012 who have an associated ICD-CM-9 code of 710.1. True cases of SSc were defined as any of the following: a) Fulfill the 1980 American College of Rheumatology (ACR) classification criteria for SSc; b) Have at least 3 of 5 of the CREST (calcinosis, Raynaud's, esophageal dysmotility, sclerodactyly, telangiectasias) features; OR c) Fulfill preliminary ACR/European League Against Rheumatism (EULAR) revised criteria for the classification of SSc.

Results: 432 patient records were reviewed. Mean age was 57±14.5 years, 84% were female, 51% Caucasian. 21% had diffuse cutaneous disease, 66% had limited disease, and 3% were characterized as SSc sine sclerosis. 238 (55%) patients met the 1980 ACR criteria, 292 (68%) patients met CREST criteria, and 297 (69%) patients met the revised ACR/EULAR criteria. The accuracy of ICD-9-CM code 710.1 for determining true cases of SSc by any of the three classification criteria was 77%. The ICD-CM-9 code for SSc was accurate 71% of the time when the 1980 ACR criteria were applied, and 75% of the time when the CREST or ACR/EULAR revised criteria were applied.

Table 1. Clinical Characteristics of 432 Systemic Sclerosis Patients by Criteria

Classification Criteria	Percentage of patients affected
1980 ACR Criteria:	
Major criterion:	
Proximal diffuse (truncal) sclerosis (skin tightness, thickening, non-pitting induration)	42%
Minor criteria:	
• Sclerodactyly (only fingers and/or toes)	63%
• Digital pitting scars or loss of substance of the digital finger pads (pulp loss)	25%
• Bilateral basilar pulmonary fibrosis	29%
Patients who met the major criterion or 2 minor criteria:	55%
CREST Criteria	
Calcinosis	12%
Raynaud's Phenomenon	82%
Esophageal dysmotility	60%
Sclerodactyly	63%
Telangiectasias	49%
Patients who met 3 of 5 CREST criteria:	68%
Revised ACR/EULAR Criteria	
Skin thickening of the fingers	
puffy fingers	25%
whole finger distal to MCP	47%
Fingertip lesions	
digital ulcers	28%
pitting scars	21%
Abnormal nailfold capillaries	33%
Pulmonary involvement	
Pulmonary hypertension	20%
Interstitial lung disease	29%
Autoantibody profile	
Positive ANA	62%
Positive scl-70 Ab	11%
Positive anti-centromere Ab	20%
Patients who scored ≥ 9 points in the revised ACR/EULAR criteria:	69%

*Raynaud's, telangiectasia percentages already noted above.

Conclusion: We found an acceptable accuracy rate of 77% for the ICD-CM-9 code 710.1 for determining true cases of SSc according to any of 3 different classification schemes. Our study supports the validity of this ICD-CM-9 code for identifying cases of SSc for epidemiologic studies using administrative databases.

Adverse Events In Connective Tissue Disease-Associated Pulmonary Arterial Hypertension Compared To Idiopathic Pulmonary Arterial Hypertension. Rennie L. Rhee[1], Nicole B. Gabler[1], Amy Praestgaard[1], Peter A Merkel[2] and Steven M. Kawut[1]. [1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania and VA Medical Center, Philadelphia, PA.

Background/Purpose: Whether the risk of treatment-related adverse events (AEs) in patients with pulmonary arterial hypertension (PAH) differs based on diagnosis, either connective tissue disease (CTD-PAH) or idiopathic (IPAH), is unknown.

Methods: This study compared the occurrence of AEs and serious AEs (SAEs) among patients with CTD-PAH vs IPAH enrolled in clinical trials of new therapies for PAH. A pooled analysis was conducted using de-identified, patient-level data from 11 randomized double-blind placebo-controlled trials of therapies for PAH submitted to the US Food and Drug Administration. These trials ranged from 3–4 months in duration. Therapies studied included endothelin receptor antagonists (ERA), phosphodiesterase-5 inhibitors (PDE-5i), and prostacyclin analogues.

Results: The study sample included 2,581 participants: 562 with CTD-PAH, including 28% with diffuse systemic sclerosis, 26% with limited systemic sclerosis, 13% with systemic lupus erythematosus, and 11% with mixed connective tissue disease, and 1,426 patients had IPAH. Patients with CTD-PAH were older, more likely to be female, and had a shorter 6-minute walk distance at baseline (Table). Patients with CTD-PAH had a higher rate of AEs (13.6 [95% CI, 9.4 – 17.9] additional events per 100 patient-years, $p < 0.001$) and had a greater risk of having at least 1 SAE (OR 1.55 [95% CI 1.18 – 2.03], $p = 0.002$) compared to patients with IPAH, after adjustment for age, race, and sex, and treatment assignment (drug or placebo). A sub-analysis of AE types showed that patients with CTD-PAH were more likely to have an infection compared to patients with IPAH (OR 1.46 [1.06 – 2.01], $p = 0.020$). In ERA trials, diagnosis modified the relationship between treatment and the occurrence of at least 1 AE (p for interaction = 0.026, OR in CTD-PAH 0.55 [95% CI 0.25–1.22], OR in IPAH 1.54 [95% CI 0.92–2.59]). In PDE-5i trials, diagnosis modified the relationship between treatment and rate of AE (p for interaction = 0.005, IRR in CTD-PAH 0.76 [95% CI 0.69–0.87], IRR of IPAH 0.96 [95% CI 0.88–1.04]).

Table. Characteristics of Study Participants

	CTD-PAH (n = 562)	IPAH (n = 1,426)	p-value
Age, years	55 ± 14	48 ± 15	< 0.001
Female sex, No. (%)	492 (88)	1,061 (74)	< 0.001
Race, No (%)			
Whit	460 (83)	1,157 (82)	0.473
Black	38 (7)	64 (4)	0.035
Other	56 (10)	196 (14)	0.026
BMI, kg/m^2	26.1 ± 5.8	27.6 ± 6.2	< 0.001
World Health Organization functional class, No (%)			
I-II	226 (41)	583 (41)	0.897
III-IV	328 (59)	835 (59)	0.897
Baseline hemodynamics			
Right atrial pressure, mmHg	8.2 ± 5.2	9.3 ± 5.7	< 0.001
Pulmonary arterial pressure, mmHg	46 ± 12	56 ± 15	< 0.001
Cardiac output, L/min	4.2 ± 1.4	4.2 ± 1.4	0.447
Cardiac index, L/min/m^2	2.4 ± 0.8	2.3 ± 0.8	0.001
Pulmonary capillary wedge pressure, mmHg	9 ± 4	9 ± 4	0.483
Pulmonary vascular resistance, Woods units	9.9 ± 6.0	12.5 ± 7.1	< 0.001
Baseline 6-minute walk distance, meters	322 ± 85	343 ± 81	< 0.001

Data are presented as mean ± standard deviation unless otherwise indicated otherwise.

Conclusion: Patients with CTD-PAH are at a higher risk of experiencing AEs and SAEs in clinical trials of therapy for PAH compared to patients with IPAH, independent of age and other potential confounders. Patients with CTD-PAH may have had less drug-associated AEs. Understanding the difference in risks of AEs for this specific population may inform the design of future trials and bring greater awareness to patients and clinicians on the safety of therapy for PAH.

Evaluation Of The Effect Of Sildenafil On The Microvascular Blood Flow and On The Endothelial Progenitor Cells In Patients With Early Systemic Sclerosis: A Randomized, Double-Blind, Placebo-Controlled Study. Fernando V. Andrigueti, Pâmela C.C. Ebbing, Maria I. Arismendi and Cristiane Kayser. Universidade Federal de São Paulo, São Paulo, Brazil.

Background/Purpose: Phosphodiesterase-5 inhibitors have been successfully used for the treatment of Raynaud's phenomenon (RP) in patients with systemic sclerosis (SSc). However, no study has evaluated the effect of these drugs in patients with early disease as well as on the number of endothelial progenitor cells (EPC) in SSc. The present study aimed to evaluate the effects of oral Sildenafil on the digital microvascular blood flow by means of Laser Doppler Imaging (LDI), in clinical features of RP, and in serum EPC levels in women with early SSc.

Methods: A randomized double-blind placebo controlled trial was conducted. Forty-one patients with RP secondary to SSc with less than 4 years of diagnosis (ACR criteria or LeRoy's criteria for Early SSc), were randomly assigned to receive oral sildenafil 100mg/day (21 patients, mean age 47.2±10.9 years) or placebo (20 patients, mean age 41.6±13.3 years) for 8 weeks. Patients were evaluated at baseline (T0), after 8 weeks of treatment (T1), and 2 weeks after the end of the treatment (T2). The primary outcome was changes in finger blood flow (FBF) measured using LDI (Moor LDI-VR) before and for 30 minutes after cold stimulus (CS). FBF values were expressed in arbitrary perfusion units (PU). Secondary endpoints included serum levels of EPCs, frequency and duration of RP attacks, RP severity, and Raynaud's Condition Score. EPCs were quantified by flow cytometry and identified by the co-expression of CD34, CD133 and vascular endothelial growth factor receptor type 2 (VEGFR2). The trial was registered on ClinicalTrials.com under the identifier NCT01347008.

Results: Basal FBF were similar between sildenafil and placebo groups (213.1±87.9 versus 256.0±119.5 PU, respectively; p=0.20) as well as in the different time-points after CS at T0. There was a significant increased in basal FBF in sildenafil group (FBF 260.0±108.0 PU; p=0.02), with no significant difference in placebo group (FBF 261.4±137.0 PU; p=1.00) after 8 weeks. There was also a significant increase in FBF values after CS in sildenafil group after 8 weeks of treatment (p<0.05), with no change in the placebo group. EPCs serum levels were similar between sildenafil and placebo groups before treatment (161.0±103.7 versus 156.6±97.5/10^6 lymphomononuclear cells, respectively; p=0.89). There were no significant changes in EPCs levels after treatment in both groups. There was a significant improvement in the duration of RP in the sildenafil group, as well as on RP severity after 8 weeks of treatment (p=0.010, p=0.031; respectively). All parameters returned to their basal values at T2. There was no significant difference in any clinical parameter evaluated in the placebo group along the study.

Conclusion: Oral Sildenafil showed to improve digital blood flow and RP symptoms in early SSc after 8 weeks of treatment, and may be a good therapeutic option for RP treatment in these patients.

1814

The Risk Of Pulmonary Embolism and Deep Venous Thrombosis In Systemic Sclerosis: A Population-Based Cohort Study. J. Antonio Avina-Zubieta[1], Iman Hemmati[2], Eric C. Sayre[3], Kamran Shojania[2] and Hyon K. Choi[3]. [1]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC, [2]University of British Columbia, Vancouver, BC, [3]Arthritis Research Centre of Canada, Richmond, BC.

Background/Purpose: Data on the risk of pulmonary embolism (PE) and deep venous thrombosis (DVT) in patients with systemic sclerosis (SSc) is lacking. To fill this knowledge gap, we estimated the risk of newly recorded PE and DVT among incident cases of SSc compared to controls from the general population using physician billing and hospitalization databases that cover the entire population of the province of British Columbia (~ 5 million).

Patients and Methods: Our data included all visits to health professionals and hospital admissions from Jan 1990 until Dec 2010 and all dispensed medication from Sept 1995 to Dec 2010 for all individuals ≥ 18 years of age. We conducted a matched cohort analysis among patients satisfying at least one of the following criteria: **a)** diagnosis of SSc on at least two visits within a two-year period between Jan 1996 and Dec 2010 by a non-rheumatologist physician; **b)** diagnosis of SSc on at least one visit by a rheumatologist or from a hospital. To increase specificity, we excluded cases that were not confirmed by a rheumatologist if they were seen at a later point. Ten controls matched by birth year, sex, and calendar year of follow-up were selected from the general population for each case. Our outcomes were newly recorded PE and DVT events from outpatient visits, hospital, or by death certificate. For nonfatal events, we required the use of anticoagulant medications within six-months of the PE and DVT events as part of our outcome definition. We estimated relative risks (RRs) comparing SSc with age-, sex- and entry time-matched comparison cohorts, adjusting for potential cardiovascular risk factors.

Results: Among 1,284 individuals with incident SSc (83% female, mean age of 57 yrs [SD 15.0]), 21, 17, and 35 developed PE, DVT or both, respectively (incidence rates= 4.4, 3.6, and 7.5 per 1000 person years, respectively) (**Table**). Compared with non-SSc individuals (N= 12,080), the age-, sex-, and entry-time-matched RRs for PE, DVT, or both were 4.2, 4.6, and 4.7 respectively ($P<0.05$ for all). The risks were greatest within the first year after disease onset and progressively attenuated with time for all outcomes. The RRs were also significantly larger among men. After further adjustment for baseline obesity, hormone replacement therapy, dyslipidemia, Cox-2 inhibitors, Charlson's comorbidity index, alcoholism/liver disease, hypertension, sepsis, varicose veins, inflammatory bowel disease, trauma, fractures, surgery, glucocorticoids, and oral contraceptives, the RRs remained similar (**Table**).

Table. Risk of Incident PE, DVT or DVT or PE according to SSc Status

	SSc n = 1,284	Non-SSc n = 12,840
Incidence Rate Ratios of PE		
PE events, N	21	61
Incidence Rate/1000 Person-Years	4.4	1.1
Age-,sex-, and entry time-matched RRs (95% CI)	4.2 (2.4 – 6.9)	1.0
< 1 year of disease duration	10.3 (3.4 – 31.5)	1.0
1–4.9 years of disease duration	3.4 (1.4 – 7.4)	1.0
5+ years of disease duration	2.6 (0.7 – 7.7)	1.0
Multivariable RR (95% CI)	4.0 (2.3 – 7.0)	1.0
Females	2.9 (1.4 – 5.8)	1.0
Males	8.8 (2.8 – 27.3)	1.0
Incidence Rate Ratios of DVT		
PE events, N	17	45
Incidence Rate/1000 Person-Years	3.6	0.8
Age-,sex-, and entry time-matched RRs (95% CI)	4.6 (2.5 – 8.2)	1.0
< 1 year of disease duration	9.2 (3.1 – 26.8)	1.0
1–4.9 years of disease duration	3.2 (1.1 – 8.2)	1.0
5+ years of disease duration	3.1 (0.6 – 11.2)	1.0
Multivariable RR	4.7 (2.5 – 8.5)	1.0
Females	4.9 (2.5 – 9.6)	1.0
Males	3.9 (0.9 – 16.3)	1.0
Incidence Rate Ratios of PE or DVT		
PE or DVT events, N	35	91
Incidence Rate/1000 Person-Years	7.5	1.6
Age-sex-entry time matched RRs (95% CI)	4.7 (3.1 – 7.0)	
< 1 year of disease duration	8.6 (3.9 – 18.5)	1.0
1–4.9 years of disease duration	4.1 (2.1 – 7.5)	1.0
5+ years of disease duration	2.9 (1.0 – 7.2)	1.0
Multivariable RR	4.3 (2.8 – 6.7)	1.0
Females	3.7 (2.3 – 6.1)	1.0
Males	8.5 (3.4 – 21.1)	1.0

Conclusion: This large population-based study is the first to demonstrate an increased risk of PE and DVT in patients with SSc, especially among men and within the first year of disease diagnosis. These findings support the need of increased monitoring of VTE complications and risk factors in those with SSc.

Asymmetric Dimethylarginine Levels In The Early Detection Of Systemic Sclerosis-Related Pulmonary Arterial Hypertension. Vivek Thakkar[1], Wendy Stevens[1], David Prior[1], Joanne Sahhar[2], Janet E. Roddy[3], Jane Zochling[4], Peter Nash[5], Peter Youssef[6], Susanna Proudman[7] and Mandana Nikpour[8]. [1]St Vincent's Hospital, Melbourne, Australia, [2]Monash Medical Centre, Clayton, Australia, [3]Royal Perth Hospital, Perth, Australia, [4]Menzies Research Institute Tasmania, Hobart, Australia, [5]Nambour Hospital, Sunshine Coast, Australia, [6]Royal Prince Alfred Hospital, Sydney, Australia, [7]Royal Adelaide Hospital, Adelaide, Australia, [8]University of Melbourne, Fitzroy, Australia.

Background/Purpose: Pulmonary arterial hypertension (PAH) is a major cause of mortality in systemic sclerosis (SSc), and alterations in nitric oxide (NO) metabolism and endothelial cell function are implicated in the pathogenesis of SSc-PAH. Asymmetric dimethlyarginine (ADMA) is a novel biomarker of endothelial cell dysfunction. In this study, the clinical utility of ADMA as a screening biomarker for incident SSc-PAH was evaluated.

Methods: ADMA levels were measured in 15 consecutive treatment-naive subjects with newly-diagnosed SSc-PAH, and compared with 30 SSc-controls without PAH. ADMA levels were assayed using high performance liquid chromatography with solid phase extraction. N-terminal pro-brain natriuretic peptide (NT-proBNP) levels were measured in the same subjects. Logistic regression models were used to evaluate the independent association of ADMA with PAH. Important correlations of ADMA were assessed using Spearman's rank correlation coefficient (rho). The optimal cut-points of ADMA and NT-proBNP that maximised desired test properties for screening were determined.

Results: The PAH group had significantly higher mean ADMA levels than the control group (0.76 ± 0.14 μM versus 0.59 ± 0.07 μM; $p < 0.0001$). ADMA levels remained significantly associated with PAH after the adjustment for specific disease characteristics, cardiovascular risk factors and other SSc-related vascular complications (all $p < 0.01$). An ADMA level ≥ 0.694 μM had a sensitivity of 86.7%, specificity of 90.0% and AUC of 0.86 for diagnosing PAH. An NT-proBNP level ≥ 209.8ng/mL had a sensitivity of 93.3%, specificity of 100% and AUC of 0.94 for diagnosing PAH. A 'purely' biomarker based screening model that combined an NT-proBNP ≥ 209.8ng/mL and/or ADMA ≥ 0.694 ng/mL resulted in a sensitivity of 100% and specificity of 90% for the detection of SSc-PAH.

Conclusion: ADMA may be an important screening biomarker for SSc-PAH. A composite 'purely' biomarker-based screening algorithm, using NT-proBNP in combination with ADMA, may achieve an excellent sensitivity (and also specificity) for the non-invasive identification of SSc-PAH.

Exercise Therapy Reduces Pain Sensitivity In Patients With Knee Osteoarthritis: A Randomized Controlled Trial. Marius Henriksen[1], Louise Klokker[1], Thomas Graven-Nielsen[2], Cecilie Bartholdy[1], Tanja Schjoedt Joergensen[3], Elisabeth Bandak[1], Bente Danneskiold-Samsøe[4], Robin Christensen[4] and Henning Bliddal[1]. [1]The Parker Institute, Copenhagen University Hospital at Frederiksberg, Copenhagen F, Denmark, [2]Aalborg University, Aalborg, Denmark, [3]The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Copenhagen F, Denmark, [4]The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, Frederiksberg, Denmark.

Background/Purpose: Exercise has beneficial effects on pain in patients with knee osteoarthritis (OA), yet the underlying analgesic mechanisms are ambiguous. A deeper understanding of the analgesic mechanisms of exercises in knee OA is imperative to optimize the exercise paradigm in clinical management of OA. The purpose of this study was to investigate the effects of a 12 week therapeutic exercise program on pressure pain sensitivity in patients with knee OA.

Methods: This was a randomized trial with blinded outcome assessors (NCT01545258). Participants were randomly assigned (1:1) to 12 weeks of facility-based neuromuscular exercise therapy (ET), 3 sessions per week supervised by trained physical therapists, or a no attention control group (CG). To assess pressure pain sensitivity, we used cuff pressure algometry, with an inflatable tourniquet cuff mounted on the calf of the most symptomatic leg. The co-primary outcomes were pressure pain thresholds (PPT unit: kPa) and temporal summation (TS) of pressure pain. TS was assessed by continuous recordings of pain (100 mm electronic visual analog scale (VAS)) during sustained (6 minutes) noxious pressure stimulation at PPT+25%. TS was quantified as the area under the time-VAS curve (unit: mm*s). Higher PPT and lower TS, respectively, represent less pressure pain sensitivity. Secondary outcomes included patient reported pain using the KOOS questionnaire, with higher scores representing less pain. According to the protocol, the analyses were based on the 'Per-Protocol' population (defined as participants following the protocol). Analysis of covariance adjusting for the level at baseline was used to determine differences between groups (95% confidence intervals) in the changes from baseline at week 13.

Results: 60 participants were randomized to ET (n= 31) or CG (n=29). In the ET group, six participants were lost to follow-up; in the CG five were lost and one violated the protocol (exercise outside study). Thus per protocol population included 48 participants (25 ET/23 CG). At baseline, the average PPTs were; ET: 18.1 kPa (SD 6.1), and CG: 19.1 kPa (6.8). At follow-up the PPT increased in the ET group by 1.94 kPa corresponding to a group difference in the change from baseline of 3.06 kPa (95% CI: 0.17 to 5.95; P=0.04) favoring ET. Accordingly, the ET group was stimulated at higher pressure levels in the sustained noxious pressure experiment at follow-up. The TS decreased in the ET group by 1,641 mm*s, giving a group differences in TS change of 2,608 mm*s (95%CI: 458 to 4,758; P= 0.019) favoring ET. After 12 weeks exercise, there was a statistically significant difference between groups in regard to KOOS pain of 6.8 points (95% CI 1.2 to 12.4; P= 0.0179) in favor of ET (corresponding to an effect size of 0.71).

Conclusion: A 12-week supervised neuromuscular exercise program reduces the pressure pain sensitivity, seen as a higher PPT and lower TS at follow-up in the ET group, in adjunct to a clinically relevant effect on pain estimated by KOOS. These results indicate that neuromuscular exercise therapy has beneficial effects on basic pain mechanisms, and further exploration of this effect may provide basis for optimized treatment.

The Clinical Burden Of Generalized Osteoarthritis Represented By Activity Limitations and Health Related Quality Of Life: A Cross-Sectional Study. Nienke Cuperus[1], Thea Vliet Vlieland[2], Elien Mahler[1], Clarinda Kersten[1], Thomas Hoogeboom[3] and Els van den Ende[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]University Medical Center Leiden, Leiden, Netherlands, [3]CAPHRI school for public health and primary care, CCTR centre for Care Technology Research, Maastricht University, Maastricht, Netherlands.

Background/Purpose: A growing body of evidence shows that generalized osteoarthritis (GOA) is fairly common, however research and clinical practice recommendations are mainly focused on a specific localization of osteoarthritis (OA). As a consequence the clinical burden of GOA is largely unknown. More insight into the clinical burden of GOA is needed in order to improve its management and to develop treatment tailored to the patients' needs and problems. Therefore the aim of this study was to determine the clinical burden of GOA in terms of activity limitations and health related quality of life (HRQoL).

Methods: Baseline data from a randomized controlled trial (RCT) comparing two non-pharmacological treatment programmes for patients with GOA were used. GOA was defined as having musculoskeletal complaints in >2 joint groups and having >1 objective signs of OA in >1 joint. In addition, patients had to be limited in performing daily activities (HAQ-DI score > 0.5). Patients clinically diagnosed with GOA by a rheumatologist and referred to multidisciplinary treatment completed self-reported questionnaires to assess socio-demographics, joint involvement (self-report and objective), activity limitations (HAQ-DI) and HRQoL (SF-36 physical (PCS) and mental

component summary (MCS) norm based scores). Patients were asked to report the three most important activity limitations due to GOA and to rate its severity on a visual analogue scale. Reported activity limitations were linked to the International Classification of Functioning, Disability and Health (ICF) using established linking rules.

Results: In total, 147 patients (85% female) participated in this study with a mean (SD) age of 60 (8) years. Hundred-fifteen patients (78%) reported musculoskeletal complaints in ≥ 4 joint areas. Self-reported and objective signs of OA were most common in the hands (n = 125; 85%) and knees (n = 121; 82%). Patients with GOA were moderately to severely limited in performing daily activities reflected by a mean (SD) HAQ-DI score of 1.27 (0.50). "Much difficulty" with activities such as shopping or doing chores were reported by more than half of the patients. Patients with GOA experience a markedly reduced HRQoL on the physical domain reflected by a mean (SD) PCS score of 32 (8), which is comparable with the impact of Rheumatoid Arthritis on HRQoL. Activities concerning mobility and domestic life were most frequently reported as being important activity limitations, in particular walking (Table 1).

Table 1. The ten most frequently reported, self-perceived activity problems with corresponding ICF codes and corresponding mean (SD) severity scores in 147 patients with Generalized Osteoarthritis (GOA).

ICF code	Activity	N (%)	Mean (SD) severity (0–10)
d450	Walking	71 (48)	6.7 (2.1)
d415	Maintaining a body position	46 (31)	6.4 (2.4)
d410	Changing basic body position	41 (28)	7.1 (1.8)
d640	Doing housework	35 (24)	6.9 (1.7)
d455	Moving around (climbing stairs)	35 (24)	6.5 (2.0)
d430	Lifting and carrying objects	30 (20)	6.1 (2.0)
d440	Fine hand use	25 (17)	6.5 (2.0)
d650	Caring for household objects	24 (16)	7.3 (1.7)
d920	Recreation and leisure	22 (15)	6.1 (2.2)
d475	Driving	20 (14)	6.2 (2.9)

Conclusion: The results of this study suggest a high clinical burden at least in selected patients with GOA in terms of activity limitations and HRQoL. According to the results it is conceivable that non-pharmacological treatment targets for patients with GOA may focus especially on the physical domain of HRQoL and on mobility limitations (walking in particular) as these activities are the most important for patients.

Automated Telephone-Linked Communication: A Novel Approach To Enhance Long-Term Adherence To Resistance Training Exercise Among People With Knee Osteoarthritis. Kristin Baker[1], Aileen Ledingham[1], Michael P. Lavalley[2], Julie J. Keysor[1] and David T. Felson[3]. [1]Boston University Sargent College, Boston, MA, [2]Boston University, Boston, MA, [3]University of Manchester, Manchester, United Kingdom.

Background/Purpose: Knee Osteoarthritis (OA) is one of the most common chronic musculoskeletal conditions and is a leading cause of disability. Strengthening exercise is well known to improve pain and physical function, but benefits decline as adherence to exercise ceases. Participation drops precipitously when trainer initiated instruction and social support for exercise are withdrawn. We have developed a dynamic automated telephone calling system, Boston Osteoarthritis Strengthening telephone linked-communication (BOOST TLC), to empower and motivate people with knee OA to adhere to strengthening exercise after participating in a class.

TLC is an automated, interactive conversation system that speaks with a recorded human voice. During the conversation the system asks questions, comments on the users' responses and educates and counsels them. TLC stores the users' answers in a database used to direct current and future TLC conversations. The system is run by a scheduling protocol with the ability to receive and make calls. The purpose of this abstract is to describe 1) the content of the BOOST TLC system we developed, and 2) the methods of an ongoing randomized controlled clinical trial to examine long-term exercise adherence.

Methods: We designed the BOOST TLC to 1) assess adherence to strengthening exercise in the previous 2 weeks 2) provide feedback on current adherence vs. the goals previously set in the last call 3) negotiate and set new adherence goals 4) provide education and counseling to improve adherence.

The BOOST TLC education and counseling content is derived from social cognitive theory, in which self-efficacy is a central concept, and decision-making theory, an individual's evaluation of the pros and cons of exercise. The system addresses reasons for low self-efficacy and ways to increase it, and provides education on the benefits of strengthening exercise and overcoming common barriers to exercise. In addition the BOOST TLC system utilizes the users' self-reported exercise adherence information to detect and provide special counseling to those that lapse (>3 weeks of no exercise), providing information on behavioral and cognitive strategies to help users recover from a lapse and prevent future lapses.

Subjects (N=100) with painful knee OA will be recruited from the community, participate in a 6-week strengthening class twice a week, randomized to BOOST TLC or control, and followed for 2 years. The BOOST TLC will receive biweekly calls for 6 months and monthly calls for the remaining 18 months. Data includes self-report questionnaires on pain and physical function, timed physical function tasks and isokinetic muscle strength.

Results: To date, 62 subjects are enrolled. Table 1 describes the study population.

Baseline demographics (n=62)

Gender N (%)	
Male	9 (15)
Female	53 (85)
Race and Ethnicity N (%)	
White	38 (61)
Black	16 (26)
Hispanic	1 (2)
Asian	3 (5)
Mix	1 (2)
Other	1 (2)
Refused	2 (3)
Age (years)	66.7 (7.6)
BMI	30.7 (6.4)
Worst WOMAC pain (0–20)	7.2 (3.4)
WOMAC physical function (0–68)	20.0 (9.9)
Observed physical function	
Timed up and go (seconds)	8.1 (1.8)
Stair climb (seconds)	16.0 (7.1)
Comorbidities N (%)	
Heart disease	7 (11%)
Chronic respiratory conditions	7 (11%)
Diabetes	9 (14%)

Conclusion: TLC is a low-cost approach for continued exercise instruction and counseling that has the potential to improve exercise adherence in people with knee OA.

1819

Effectiveness Of Pilates Method For The Treatment Of Chronic Mechanical Neck PAIN. Luciana A. Cazotti[1], Anamaria Jones[1], Diego Roger Silva[1], Luiza H. C. Ribeiro[1] and Jamil Natour[2]. [1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo, São Paulo, Brazil.

Background/Purpose: The neck pain comes from multifactorial origin and affects approximately 70% of individuals at some point in their lives being considered a frequent problem of disability. Pilates is a method of physical conditioning that has been widely used to improve posture and develop body sense. Although the symptoms of neck pain are common in the population, no study has investigated the effects of the Pilates method as a possible treatment for neck pain. The aim of this study is to assess the effectiveness of the Pilates method on pain, function and quality of life in patients with chronic mechanical neck pain.

Methods: Sixty-four patients with diagnosis of chronic mechanical neck pain for more than three months were selected to this study. Patients with symptoms of pain in the cervical spine, between the occipital and the first thoracic vertebra, both genres, age between 18 and 65 years were included. Patients with fibromyalgia, previous traumatic lesions in the spine, infections

and inflammation in the spine, cervical pain radiating to upper limbs, patients that practice of physical activity started or altered in the last 3 months, visual deficiency not corrected by glasses, diseases of the central nervous system were excluded. The patients were randomized into two groups: Pilates and control. The Pilates group (PG) realizes the drug treatment and two sessions per week of Pilates for twelve weeks. The control group (CG) realizes the drug treatment and remained on the waiting list for Pilates. Regarding drug treatment both groups were instructed to use 750mg acetaminophen every 6 hours if there is pain. Both groups were assessed for pain (VAS), function (Neck Disability Index - NDI), quality of life (SF-36), acetaminophen consumption. The evaluations were made by a blinded assessor at baseline (T0), 45 days (T45), 90 days (T90) and 180 days (T180) after baseline.

Results: Thirty-two patients were randomized to each group. The groups were homogeneous at baseline with respect to demographic and clinical characteristics, only the Body Mass Index (BMI) was not homogeneous among the groups (p = 0,023), with the GP showing higher BMI than the CG. The analysis between groups over time (ANOVA) show a statistical difference for pain (p <0,001), function (p <0,001) and quality of life [physical functioning (p = 0.019), pain (p <0,001), general health (p = 0,022), vitality (p <0.001), mental health (p = 0,012)] always with best results for the GP. Regarding medication GP consumed less analgesic than the CG (p = 0,037).

Conclusion: we conclude that the Pilates method is effective for the treatment of chronic mechanical neck pain for relive pain; improve function and quality of life and reduce analgesic consumption.

Assessing 24-Hour Physical (In)Activity and Sleep In People With Early Rheumatoid Arthritis. Christopher Feehan[1], Eric C. Sayre[2], Erin Carruthers[2] and Lynne M. Feehan[3]. [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada, Richmond, BC, [3]Arthritis Research Centre of Canada and University of British Columbia, Vancouver, BC.

Background/Purpose: For people with inflammatory arthritis, the health benefits of physical activity (PA) and negative impact of sedentary lifestyle are clear. However, it is unclear how daily physical (in)activity and sleep may be affected in people with early rheumatoid arthritis (RA) (1). The purpose of this study was to examine measures of daily PA and sleep in people with early RA, compared to age and gender matched peers.

Methods: We recruited 30 adults diagnosed with RA in the past year and 30 age and gender matched healthy volunteers. Physical activity and sleep were measured with SenseWear Mini™ (SW) accelerometers worn over the triceps of the dominant arm for 6 days. We fit a multivariate analysis of variance model with RA status as the independent variable and a dependent variable of minutes spent in 8 categories [night - sleep; day - off body, sedentary (< 1.6), light [1.6, 3), 3, 4, 5 and ≥ 6 MET activities] across 24-hours. Overall difference (Multivariate Wilks' Lambda F-test) and post hoc differences (F-tests / Least Square Mean) in sleep and PA intensity were examined. Differences in four PA behaviours [Bouted (≥10 minutes) Moderate to Vigorous PA (MVPA, ≥ 3 METs), Intensity of Bouted MVPA, Bouted (≥ 20 minutes) Sedentary time and Overall Sleep (night + day)] were also examined with paired Student T-tests.

Results: Average age 53 y (21–73 y). Females - 24 of 30 / group**.** 3 RA / NRA pairs excluded [non-adherence (n=2), mechanical failure (n=1)]. Mean SW wear time 5.8 d (SD: 0.02) RA Participants: 73% RF or anti-CCP positive. Time since diagnosis 8 m (SD: 5). Health Assessment Questionnaire [Disability Index: Mean 0.6 (SD: 0.6), Pain VAS_{100}: Mean 21 (SD: 16)]; Tender & Swollen Joints: Mean 3 (SD: 3). Sleep and PA Intensity Comparisons (Table 1): People with early RA had a significantly different (p = 0.03) overall pattern of nighttime sleep and daytime physical (in)activity. The primary differences were significantly fewer minutes of higher PA intensity (≥ 4 METs, Mean Diff: 37m, P < 0.03), as well as a tendency for more nighttime sleep (Mean Diff: 17m, p = 0.26) and more daytime sedentary (Mean Diff: 37m, p=0.33) and light physical activity (Mean Diff: 15m, p = 0.39). PA Behavior Comparisons (Table 1): RA participants spent significantly less time in bouted MVPA (Mean Diff: −65m, p = 0.01) at a lower intensity (Mean METs: RA 3.5 vs. NRA 4.1, p = 0.01). RA participants also accumulated significantly more overall sleep (Mean Diff: 29m, p = 0.02).

Table 1. Summary of Average Daily Sleep and Physical Activity (PA) Intensity and Selected PA Behaviours in People Living With and Without Rheumatoid Arthritis (RA).

Sleep and PA Intensity Comparison: (n=54, 27 Pairs)

Post hoc Component Examined	RA [LS Mean (95% CI)]	Non-RA [LS Mean (95% CI)]	P value
Nighttime Sleep (Min)	454 (432, 476)	437 (415, 459)	0.27
Off-body Time (Min)	29 (18, 39)	28 (17, 38)	0.91
Sedentary (< 1.6) METs (Min)	642 (588, 695)	605 (551, 659)	0.33
Light PA [1.6, 3) METs (Min)	207 (183, 231)	192 (168, 216)	0.39
3 METs (Min)	78 (49, 107)	111 (82, 140)	0.11
4 METs (Min)	25 (14, 35)	47 (37, 58)	0.004
5 METs (Min)	4 (0.2, 8)	13 (9, 17)	0.002
6+ METs (Min)	2 (−2, 5)	8 (4, 11)	0.02

Selected PA Behaviour Comparison: (n=54, 27 Pairs)

PA Behaviour Examined	RA [Mean (SEM)]	Non-RA [Mean (SEM)]	*Difference (RA–Non-RA) [Mean (SEM)]	P value
Bouted (≥ 10 min) MVPA (Min)	72 (19)	137 (18)	−65 (25)	0.01
Average Intensity of MVPA (METs)	3.5 (0.2)	4.1 (0.1)	−0.6 (0.2)	0.01
Bouted (≥ 20 min) Sedentary (Min)	393 (32)	359 (29)	33 (42)	0.43
Overall (Night + Day) Sleep (Min)	482 (10)	453 (11)	29 (12)	0.02

*Negative value indicates RA less than Non-RA.

Conclusion: People living with recently diagnosed RA have markedly different patterns of sleep and physical (in)activity than age and gender matched healthy peers. These findings suggest that people living with early RA would benefit from education and support to enhance physical activity related health behaviours.

Benefits Of Progressive Muscle Strengthening Using a Swiss Ball In Patients With Ankylosing Spondylitis: A Randomized Controlled Trial. Marcelo Souza[1], Fabio Jennings[1], Hisa Morimoto[1] and Jamil Natour[2]. [1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo, São Paulo, Brazil.

Background/Purpose: Ankylosing spondylitis (AS) is a systemic inflammatory disease that affects the physical capacity of patients globally. Exercises are recommended to the management of patients with AS, although the benefits of specific exercise programs are not yet well defined.

Objective: To evaluate the effectiveness of a progressive muscle strengthening program using a Swiss ball in improving functional capacity, muscle strength, disease activity, mobility and quality of life of patients with AS.

Methods: Sixty patients were randomized to intervention group (IG) or to control group (CG), with 30 patients in each group. Eight exercises were done by GI with free weights on a Swiss ball, 2 times per week for 16 weeks. Loads were reassessed and increased every 4 weeks. The GC continued drug therapy without any exercise, on a waiting list. The evaluations were performed by a blinded evaluator immediately before randomization and at 4, 8, 12 and 16 weeks after initiation of the study. Functional capacity were evaluated using the BASFI (Bath Ankylosing Spondylitis Functional The Index), HAQ-S (Health Assessment Questionnaire for Spondyloarthropathies), the 6-minute walk test and the Time Up and Go test. Muscle strength was assessed by the 1-repetition maximum (1 RM) test. Disease activity was measured by BASDAI (The Bath Ankylosing Spondylitis Disease Activity Index) and by dosage of ESR and C-reactive protein. The BASMI (The Bath Ankylosing Spondylitis Metrologyl Index) was used to assess spinal mobility and the SF-36 questionnaire to assess quality of life. Patients were also evaluated by Likert scale for satisfaction. In addition, the amount of analgesic and non-steroidal anti-inflammatory used was controlled.

Results: The groups were homogeneous at baseline for clinical and demographic characteristics. There was a statistically significant difference between the two groups in the improvement of strength in IG compared to the CG for the muscles used in the exercises: abdominal (p =

0.003), unilateral stroke ($p = 0.02$), squat ($p = 0.01$), triceps ($p = 0.021$) and reverse crucifix ($p = 0.02$). The IG also improved the 6-minute walk test ($p = 0.005$) at week 16 compared with the CG. We also found a statistically significant difference between groups in the Likert scale at all times ($p < 0.001$) with IG showing greater treatment satisfaction. We found no differences between groups in other variables and there was no worsening of disease activity in IG.

Conclusion: The progressive muscle strengthening using a Swiss ball is effective in improving muscle strength and walking performance in patients with AS. The exercise program has shown good tolerance assessed by patient satisfaction without deleterious effects on disease activity.

Oleanolic Acid Acetate Inhibits Osteoclast Differentiation By Downregulating Phospholipase Cγ^2–calcium ion oscillation-Nuclear Factor Of Activated T Cell c1 Signaling, and Suppresses Bone Loss In Mice. Chang-Hoon Lee[1], Myeung Su Lee[1], Won Seok Lee[2], Wan-Hee Yoo[2], Ju-Young Kim[3], Jae-Min Oh[3] and Yong-Geun Jeong[4]. [1]Department of Internal Medicine, School of Medicine, Wonkwang University, Iksan, Chonbuk, South Korea, [2]Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea, [3]Department of Anatomy, School of Medicine, Wonkwang University, Iksan, South Korea, [4]Division of Rheumatology, Department of Internal Medicine, Changwon Fatima Hospital, Changwon, South Korea.

Background/Purpose: we first isolated oleanolic acid acetate (OAA), a triterpenoid compound, from *Vigna angularis*(azuki bean) to discover anti-bone resorptive agents. Many studies have identified and described the various medicinal effects of *V. angularis*extract, but the pharmacological effect is not known. Therefore, we investigated the effect and mechanism of OAA in receptor activator of nuclear factor-kB ligand (RANKL)-induced osteoclast differentiation and bone resorption.

Methods: *V. angularis* was obtained from an herbal medicine store (Jeonbuk, Korea). The plant material (10 kg) was dried, ground to a fine powder, and extracted with 95% ethanol at 70°C. The extracts were filtered through a 0.45-mm filter and concentrated under reduced pressure to yield the ethanol extracts, which were further extracted with ethyl acetate. we treated primary BMMs with various concentrations of OAA in the presence of RANKL and M-CSF. Expression of c-Fos, NFATc1, TRAP and OSCAR were determined by RT-PCR and Western blot analysis. we used a retrovirus to overexpress NFATc1 and the CA form of NFATc1 (CA-NFATc1) in BMMs and examined the effect of OAA on the MAPKs and Ca^{2+} responses in the presence of RANKL. To investigate whether OAA affects bone-resorbing activity, mature osteoclasts were cultured on hydroxyapatite-coated plates. Finally, We investigated the *in vivo* effects of OAA with an experimental animal model of bone erosion. Mice were intraperitoneally injected with LPS with or without OAA. The mice were sacrificed 8 days after the first LPS injection, and the left femurs underwent micro-CT analyses.

Results: Interestingly, OAA significantly inhibited phospholipase Cγ2 (PLCg2) phosphorylation, calcium ion (Ca^{2+}) oscillation, and nuclear factor of activated T cell c1 (NFATc1) expression in RANKL-stimulated BMMs, but did not affect RANKL-induced mitogen-activated protein kinase. OAA also inhibited the bone-resorbing activity of mature osteoclasts. Furthermore, mice treated with OAA demonstrated marked attenuation of lipopolysaccharide-induced bone erosion based on micro-computed tomography and histologic analysis of femurs.

Conclusion: Taken together, the results suggested that OAA inhibited RANKL-mediated osteoclastogenesis via PLCg2–Ca^{2+}-NFATc1 signaling *in vitro* and suppressed inflammatory bone loss *in vivo*.

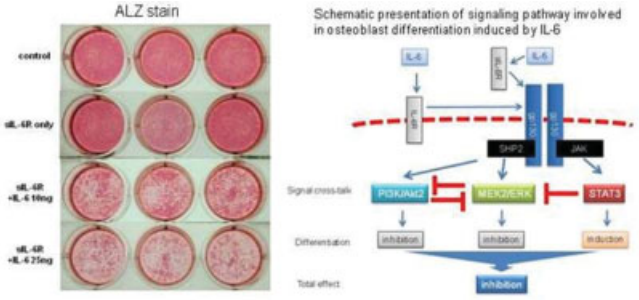
1823

IL-6 Suppresses Osteoblast Differentiation Through The SHP2/MEK2 and SHP2/Akt2 Pathways *In Vitro*. Shoichi Kaneshiro[1], Kosuke Ebina[1], Kenrin Shi[1], Chikahisa Higuchi[1], Hideki Yoshikawa[1], Jun Hashimoto[2] and Makoto Hirao[3]. [1]Osaka University Graduate School of Medicine, Suita, Japan, [2]Osaka-Minami Medical Center, Kawachinagano City, Japan, [3]Osaka Minami Medical Center, Osaka, Japan.

Background/Purpose: Interleukin-6 (IL-6), a potent inflammatory cytokine, plays a key role in the pathogenesis of rheumatoid arthritis (RA), including osteoporosis not only in inflamed joints but possibly also in whole body. Since increase of bone formation markers is recognized in RA patients treated with tocilizumab, a humanized anti- IL-6 receptor antibody, IL-6 could be thought to have negative effect on osteoblast differentiation. However, previous reports regarding the effects of IL-6 on osteoblast differentiation *in vitro* are not consistent. IL-6 activates two major intracellular signaling pathways, SHP2/MEK/ERK and JAK/STAT3, and can also lead to the activation of additional signaling cascade involving PI3K/Akt. The purpose of this study was to clarify the effect of IL-6 on osteoblast differentiation *in vitro*, with consideration of intracellular signaling pathways. Cross-talk between these pathways was also investigated.

Methods: Osteoblast differentiation was induced in murine MC3T3-E1 osteoblastic cells and primary calvarial osteoblasts with or without addition of IL-6 (soluble IL-6 receptor was used to enhance the effect of IL-6). Osteoblast differentiation was assessed by alkaline phosphatase (ALP) activity, mineralization and expression of osteoblastic gene. We examined which signaling pathways were activated by IL-6 and their effects on the differentiation were assessed by using each specific inhibitor and each knockdown.

Results: IL-6 significantly reduced ALP activity, mineralization and expression of osteoblastic gene, in a dose-dependent manner, which indicates a negative effect of IL-6 on osteoblast differentiation. Signal transduction study demonstrated that IL-6 activated not only two major signaling pathways, SHP2/MEK/ERK and JAK/STAT3, but also SHP2/PI3K/Akt2 signaling pathway. The negative effect of IL-6 on osteoblast differentiation was restored by inhibition of MEK as well as PI3K, while it was enhanced by inhibition of STAT3. Knockdown of MEK2 and Akt2 transfected with siRNA enhanced ALP activity and gene expression of Runx2. These results indicate that IL-6 negatively regulates osteoblast differentiation through SHP2/MEK2/ERK and SHP2/PI3K/Akt2 pathways, while it effects positively through JAK/STAT3. Moreover, STAT3 inhibitor enhanced IL-6-induced phosphorylation of ERK. MEK inhibitor enhanced IL-6-induced phosphorylation of Akt. PI3K/Akt inhibitor enhanced IL-6-induced phosphorylation of ERK. IL-6-induced ERK and Akt signaling pathways, both of which are downstream of SHP2, could negatively regulate each other reciprocally.



Conclusion: IL-6 could negatively regulate osteoblast differentiation through SHP2/MEK2/ERK and SHP2/PI3K/Akt2 pathways, while it effects positively through JAK/STAT3. Inhibition of MEK2 and Akt2 signaling in osteoblasts might be of potential use in the treatment of osteoporosis in RA.

1824

ONO-4059 - A Novel Small Molecule Dual Inhibitor Of Bruton's Tyrosine Kinase (Btk) and Tec Kinase- Suppresses Osteoclastic Bone Resorption and Inflammation. Yuko Ariza, Toshio Yoshizawa, Yoshiko Ueda, Shingo Hotta, Tomoko Yasuhiro, Masami Narita, Yutaka Shichino and Kazuhito Kawabata. Ono Pharmaceutical Co., Ltd., Osaka, Japan.

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by leukocyte infiltration, synoviocyte hyperplasia and osteoclastogenesis, leading to erosion of the joints and cartilage, which results in stiffness, pain and swelling, making it difficult to perform daily activities. Osteoclasts are responsible for bone erosion in RA and both Bruton's tyrosine kinase (Btk) and Tec kinase have essential functions in osteoclast differentiation. ONO-4059 is a highly potent and dual oral Btk/Tec inhibitor with an IC_{50} in the sub-nmol/L range. Previous studies with ONO-4059 demonstrated that ONO-4059 significantly inhibits the macrophage colony-stimulating factor (M-CSF) and receptor activator of nuclear factor-κB ligand (RANKL)-driven osteoclast defferentiation. The treatment with ONO-4059 also resulted in a dose-dependent inhibition of arthritis severity and bone damage in a mouse collagen induced arthritis (CIA) model (ACR 2012). To assess the effects of ONO-4059 on bone resorption, we examined the RANKL-induced bone loss *in vivo*. In addition, the regulation of proinflammatory cytokines and MMPs in the joints of arthritic mice validating qRT-PCR was performed in another CIA model.

Methods: Female C57BL/6 mice were injected intraperitoneally with 1 mg/kg of sRANKL on days 0, 1 and 2. ONO-4059 was administered orally, twice a day in three groups of animals, at doses of 3 mg/kg, 10 mg/kg and 30 mg/kg 1 hr before the every sRANKL injection. After the last sRANKL injection, all of the mice were sacrificed and underwent peripheral quantitative computed tomograghy (pQCT) analysis. To further characterize the effect of ONO-4059 in a RANKL-induced model, the serum bone resorption markers were measured by ELISA. Gene expression profiles were determined by qPCR using samples taken from the ankle in CIA model.

Results: The injection of sRANKL resulted in a decrease in trabecular bone volume with the increase of serum TRACP5β and CTX-1. Treatment with ONO-4059 resulted in a dose-dependent suppressioin of RANKL-induced bone loss with the inhibition of TRACP5β and CTX-1. The inhibition rate of Bone Mineral Density (BMD) of ONO-4059-treated animals was 55% ($P<0.05$), 87% ($P<0.001$) and 88% ($P<0.001$) for the 3, 10 and 30 mg/kg dose groups respectively. In CIA model, MIP-1α, IL-1β, KC, IL-6, RANKL and MMP-3 production in joints of arthritic mice, as measured by determining relative arthritic/sham ratios, was significantly higher (from 5 to 20 fold), while the 3 mg/kg dose of ONO-4059 almost completely inhibited such production.

Conclusion: Btk and Tec are required for osteoclast differentiation and activation based on the genetic evidence obtained from Btk and Tec double deficient mice. Dual Btk/Tec inhibitor, ONO-4059 may be a novel therapeutic target for RA to suppress bone erosion and inflammation.

Osteoclast Progenitors, Fibroblast-Like Cells and Draining Lymph Node Cells Induce Catecholaminergic-To-Cholinergic Transition Of Sympathetic Nerve Fibers Under Healthy Conditions But Not In Highly Inflamed Arthritic Tissue. Hubert Stangl[1], Dominique Muschter[2], Susanne Graessel[2] and Rainer H. Straub[1]. [1]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, University Hospital of Regensburg, Regensburg, Germany, [2]Division of Experimental Orthopedic Surgery, University Hospital of Regensburg, Regensburg, Germany.

Background/Purpose: Sympathetic nerve fibers innervate bone and tissue adjacent to joints. They play an important role in bone and tissue homeostasis. Under certain conditions, sympathetic nerve fibers can change their phenotype from catecholaminergic to cholinergic (see innervation of sweat gland and periosteum). This can be important because anti-inflammatory effects of acetylcholine have been described which is mainly mediated by the α7nicotinic acetylcholine receptor. We asked whether this transition could also occur in the joint during collagen-induced arthritis (CIA) in mice or during rheumatoid arthritis (RA) and osteoarthritis (OA) in humans.

Methods: Arthritic limbs from 30 immunized C57Bl/6J mice were collected at distinct time points covering all stages of the disease. Sections of mouse limbs and synovial tissue samples obtained from 30 OA and 12 RA patients were stained for tyrosine hydroxylase (TH, noradrenergic fibers), and for vesicular acetylcholine transporter (VAChT, cholinergic fibers). For co-culture experiments, sympathetic ganglia were obtained from newborn mice and double-stained for TH and VAChT after a co-culture period of two to three days with osteoclast progenitors attained from the femoral and tibial bonemarrow as well as lymphocytes obtained from the draining lymph nodes and fibroblast-like cells isolated from the paws of adult mice.

Results: In mouse joint area, an increase in the ratio of cholinergic to catecholaminergic nerve fibers appeared at day 35 after immunization. Most of the nerve fibers were located in joint-adjacent skin or muscle tissue, and only very few were detected in synovial tissue or near erosions. In human tissue sections, we were able to show cholinergic fibers in the synovial tissue of four OA patients but in none of the RA patients. Co-cultures of sympathetic ganglia and osteoclast progenitors as well as lymphocytes and fibroblast-like cells obtained from healthy mice showed more catecholaminergic-to-cholinergic transition when compared to experiments with the respective cells from arthritic mice.

Conclusion: In men and mice, catecholaminergic-to-cholinergic transition is possible in less inflamed tissue of the joint but not in highly inflamed arthritic tissue.

Immune Complex Formation By Adalimumab Contributes Significantly To Its Inhibitory Effect On TNF-Enhanced Human Osteoclast Development Even In The Absence Of Fc Receptor Binding. Bohdan P. Harvey and Zehra Kaymakcalan. AbbVie Bioresearch Center, Worcester, MA.

Background/Purpose: TNF-alpha (TNFa) has been shown to contribute to osteoclastogenesis independently and in conjunction with M-CSF or RANKL, two key cytokines involved in osteoclast development. Both TNFa and RANKL have been concomitantly detected in the synovial fluid of RA patients. We have previously demonstrated that TNF enhances the kinetics of RANKL-induced human osteoclastogenesis and that its effects are mitigated more effectively by the anti-TNF biologic adalimumab as compared to etanercept. Based on these findings, we sought to determine the mechanism that was responsible for this difference and to identify the TNF-receptor that is predominantly involved in TNF-enhanced osteoclastogenesis.

Methods: Primary human osteoclast precursors (OCP) were exposed to various combinations of M-CSF, RANKL and TNFa (100 ng/mL) +/− increasing equimolar concentrations of adalimumab (ADA) [whole, F(ab′)2 or Fab], etanercept (ETN) [whole or Fc-deficient (pepsin digested) molecule] or certolizumab pegol (CZP) for up to 6 days. Prior to adding to the cells, the biologics were pre-incubated with the TNFa for 30 min. To artificially generate large immune complexes (IC), polyclonal anti-human IgG Fc-specific F(ab′)2 antibody (20 μg/mL) was added to the preformed TNF:biologic complexes. To determine contribution of individual TNF receptors to TNF-mediated osteoclast development, OCP were treated with 50 μg/mL anti-human TNF-RI or -RII blocking antibodies prior to the addition of TNF. Osteoclast differentiation was determined by the presence of large multinucleated cells positive for tartrate-resistant acid phosphatase (TRAP) and by TRAP5b activity. Resorptive activity was assessed by measuring the release of cross-linked C-telopeptide of type I collagen (CTX-I) from human bone.

Results: Each of the biologics as whole molecule was able to reduce TNF-enhanced osteoclast development; however, both CZP and ADA were more effective at lower concentrations as compared to ETN (9.6, 14.4 and >130 nM, respectively). The F(ab')2 of ADA inhibited osteoclast activity to the same level as the whole IgG demonstrating that the Fc domain was not contributing to the inhibitory effects of the biologic. Following the cross-linking of the biologics with anti-human IgG to generate artificially large IC, the inhibitory effect of ADA improved two-fold, whereas etanercept suppressed osteoclast development to levels comparable to non-cross-linked ADA, suggesting that IC formation by ADA contributes to its ability to block TNF-enhanced osteoclastogenesis. As to which receptor mediates the effect of TNF on human OCP, blocking TNF-RI curtailed TNF-dependent development demonstrating that the effective anti-TNF biologics are restricting TNF access to TNF-RI.

Conclusion: The mechanistic feature that distinguishes ADA from ETN in its ability to more effectively inhibit TNF-enhanced osteoclastogenesis is its TNF binding mode. Surprisingly, the Fc domain of ADA does not contribute to its suppressive function. Overall, our results may provide a mechanistic explanation for the sustained potency of adalimumab in preventing bone erosion due to chronic TNF exposure.

The Intraarticular Injection Of An Inhibitor Of Complex V Of Mitochondrial Respiratory Chain Induces a Pathological Response In Rat Knee Joints. Carlos Vaamonde-García[1], Jesus Loureiro[1], Eduardo López-Peláez[2], Alberto Centeno-Cortés[2], Romina R. Riveiro-Naveira[1], M. Noa Valcárcel-Ares[1], Francisco J. Blanco[3] and Maria J. López-Armada[1]. [1]Aging and Inflammation Research Lab, INIBIC-CHU A Coruña, A Coruña, Spain, [2]Experimental Surgery Unit, CHU A Coruña, A Coruña, Spain, [3]Osteoarticular and Aging Res. Lab. CIBER-BBN. INIBIC- University of A Coruña, A Coruña, Spain.

Background/Purpose: A decline of mitochondrial function has been described in OA chondrocytes and RA synoviocytes. Recent ex vivo findings support a connection between mitochondrial dysfunction and activation of inflammatory and destructive pathways in these cells. The aim of this study was to investigate in an in vivo articular model if the intraarticular injection of oligomycin, an inhibitor of mitochondrial function, induces a destructive and inflammatory response in rat knee joints.

Methods: 24 female wistar rats (180–220g) were divided into three study groups: Healthy (no intraarticular injection); Lipopolysaccharide (LPS)-

treated, positive control (left joint injected with: LPS 10mg and right joint with vehicle); and Oligomycin (OLI)-treated (left joint injected with Oligomycin 20mg and right joint with vehicle). Three intraarticular injections were carried out at 0, 2 and 5 days. Rats were sacrificed at day 6, hind paws were collected and joint tissues were obtained. Measurement of joint diameters on stimulis- and control-injected paws was performed at days 0 and 6. Histopathologic lesions were evaluated by hematoxilyn-eosin (H&E) and masson trichromic stain sections in synovial tissue and by safranin O staining in cartilage. ROS production by dihydroethidium (DHE) staining was evaluated. By RT-PCR, CINC-1, IL-1**b**, CCL-2 and TNF-**a** gene expression was analyzed in extracted cartilage. And by immunohistochemical staining, IL-8, equivalent of CINC-1, expression was localized in the joint tissue.

Results: OLI-treated hind paws significantly increased the joint diameter (0.9 ± 0.1 mm, $n=8$, $p<0.05$, vs vehicle-injected joints), similarly to LPS-treated (2 ± 0.3 mm, $n=8$, $p<0.05$, vs vehicle-injected joints). In relation, histological evaluation of synovial tissue by H&E staining revealed that joints treated with mitochondrial inhibitor present greater synovial lining hyperplasia, proliferation of subsynovial tissue and infiltration of a marked number of inflammatory cells while the right control synovial only contained a moderate synovial proliferation and inflammation (3.3 ± 0.1 vs. 2.1 ± 0.2, respectively, $n=8$, $p<0.001$, vs vehicle-injected joints). Besides, a higher increment in ROS production was detected in synovial tissue from OLI-injected knees than observed in vehicle-injected counterparts. Immunohistochemical studies on IL-8 also showed a greater expression in synovial tissue from OLI-injected joints versus those from vehicle-injected joints, coinciding with a strong neutrophils infiltration. In relation to cartilage, when the loss of matrix in this tissue by safranin O staining was evaluated no differences were observed. We also failed to detect modulations in IL-8 immunoperoxidase staining in cartilage. By contrast, when CINC-1 mRNA expression was analyzed in this tissue, a significant increment in OLI-injected joints was detected ($n=8$, $p<0.05$ vs. vehicle-injected joint), similar to those LPS-treated.

Conclusion: The data seems to support that a loss of mitochondrial function in the joint could participate in rheumatoid pathology through generating an inflammatory response in the articular tissue, contributing to the perpetuation of joint injury.

In Vivo Cartilage-Specific Deletion Of Ephrin-B2 In Mice Results In Developmental Locomotory Defects Associated With Hip Bone Abnormality. Gladys Valverde-Franco[1], Bertrand Lussier[2], David Hum[1], Jiangping Wu[3], Jean-Pierre Pelletier[1], Mohit Kapoor[1] and Johanne Martel-Pelletier[1]. [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [2]Department of Clinical Sciences, Faculty of Veterinary Medicine, University of Montreal, Saint-Hyacinthe, QC, [3]Laboratory of Immunology, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC.

Background/Purpose: The ephrins and their related receptors comprise the largest subfamily of receptor protein-tyrosine kinases and have been implicated in mediating developmental events. We have previously demonstrated that a member of the ephrin family, ephrin-B2, plays a role in knee joint pathology associated with osteoarthritis (OA). Specifically, we have shown a deregulation in the production of the receptor EphB4 and its specific ligand ephrin-B2 in human subchondral bone and cartilage, and in vitro activation of this system or in vivo overexpression of EphB4 positively impacts the pathological process of OA. The aim of this study was to comprehensively delineate the in vivo role of ephrin-B2 in musculoskeletal growth and development using cartilage-specific ephrin-B2 knockout mice.

Methods: Cartilage-specific ephrin-B2 knockout (ephrin-B2KO^{CRE}) mice were generated using the LoxP-Cre system. The effect of ephrin-B2 genetic deletion was evaluated on bone development using a combination of techniques including macroscopic, histologic, morphometric, radiological, densitometer, and micro-computed tomography (micro-CT). Analyses were performed on postnatal days 0, 15, and 21 (P0, P15, P21), on 8-week-old cartilage-specific ephrin-B2KO^{CRE}mice, and in littermates with no Cre as controls.

Results: Data showed that the ephrin-B2KO^{CRE} mice exhibited developmental defects leading to abnormal locomotory patterns. Ephrin-B2KO^{CRE} mice at P15 exhibited reduced weight ($p<0.002$) and length ($p<0.01$) and, most importantly, limping and dragging of limbs apparent from the time they started to walk (about 2–3 weeks of age). Interestingly, the hip of ephrin-B2KO^{CRE} mice displayed abnormalities associated with smaller pelvic width ($p<0.03$) and hip bones ($p<0.01$), as well as reduced acetabular rim length ($p<0.05$) and angle ($p<0.05$). In addition, ephrin-B2KO^{CRE} mice had significantly smaller femur ($p<0.03$) and tibia length ($p<0.01$) and reduced bone mineral density in the total skeleton ($p<0.02$), femur ($p<0.03$) and spine ($p<0.04$). Micro-CT analyses revealed that the distal femur and proximal tibia in ephrin-B2KO^{CRE}mice had a significantly decreased bone volume/tissue volume (BV/TV; $p<0.03$, $p<0.02$), trabecular thickness (TbTh; $p<0.02$, $p<0.02$), and trabecular separation (TbS; $p<0.03$, $p<0.05$).

Conclusion: This study was the first to show that in vivo ephrin-B2 is essential for normal bone growth and development and that conditional cartilage-specific ephrin-B2 deficiency leads to significant alterations in hip bones resulting in developmental locomotory defects. The changes in the long bones are probably a secondary effect of the hip loading force abnormalities.

1829

Carboxypeptidase B2 Down-Regulates Osteoclast Activation In Inflammation. Jason Jungsik Song[1], Sang-Won Lee[1], Yong-Beom Park[1], Soo Kon Lee[1], Lawrence Leung[2] and William H. Robinson[2]. [1]Yonsei University College of Medicine, Seoul, South Korea, [2]Stanford University School of Medicine, Stanford, CA.

Background/Purpose: Carboxypeptidase B2 (CPB2) is well established to play an anti-fibrinolytic role by removing C-terminal lysine residues from fibrin, thereby preventing its cleavage by plasmin. CPB2 also removes arginine/lysine residues from other proinflammatory substrates such as C5a, and SDF-1a. Previously we demonstrated that CPB2 plays a major role to down regulate synovial inflammation in collagen induced arthritis by down-regulating C5a (Song et al, 2011 JCI). However, its mechanism to prevent bone erosion in RA is unknown. We investigate the molecular mechanism how CPB2 prevents bone erosion.

Methods: LPS induced osteoclast (OC) activation model was performed by injection of LPS on *cpb2*$^{-/-}$ and *cpb2*$^{+/+}$ mice. On day 8, femur was collected for microCT and histology. OC precursor (OCP) population in bone marrow was evaluated by FACS. OC differentiation was evaluated by TRAP staining on OCP ex vivo culture. OCP migration was measured by transwell migration assay with C5a and SDF-1a with or without CPB2 treatment. C5a receptor expression in bone marrow was measured by FACS.

Results: As compared to wild-type (WT) mice, CPB2 deficient mice exhibited significantly more severe osteoclast activation measured by microCT after LPS injection (bone volume/total volume *cpb2*$^{-/-}$ 4.3 ± 0.3 vs *cpb2*$^{+/+}$ 7.7 ± 0.3, $p< 0.01$). There is increased OCP population in bone marrow of *cpb2*$^{-/-}$ mice (Gr1 low, CD11b high population; *cpb2*$^{-/-}$ 40% vs *cpb2*$^{+/+}$ 25.2%). There are more TRAP positive multinuclear cells from bone marrow of *cpb2*$^{-/-}$ mice as compared to *cpb2*$^{+/+}$ mice (130.6 ± 4.2 vs 107.3 ± 3.5, $p<0.01$). OCP chemotaxis was decreased by CPB treatment on C5a and SDF-1a. C5a receptor expression is increased in CPB2 deficient mice.

Conclusion: These results suggest that CPB2 plays a critical role in osteoclast migration and activation in inflammation and that this effect could be in part mediated by its down-regulation of C5a and SDF-1a. CPB2 deficient mice demonstrate more osteoclast activation in response to LPS challenge. We also demonstrated that SDF-1a, a known chemotactic factor for OCP, is a novel substrate of CPB2. Studies are underway to investigate the role of CPB2 on osteoclast activation in human rheumatoid arthritis.

Adenosine A_{2A} Receptor (A2AR) Diminishes Wear Particle (UHMWPE)-Mediated Osteolysis, Increases Bone Formation and Regulates Expression Of Axonal Guidance Proteins (AGP) By Macrophages, Osteoclasts (OC) and Osteoblasts (OB). Aranzazu Mediero[1], Tuere Wilder[1], Miguel Perez-Aso[2] and Bruce N. Cronstein[3]. [1]NYU School of Medicine, New York, NY, [2]New York University School of Medicine, New York, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Communication between OC and OB is critical for maintenance of bone homeostasis; both OC and OB release regulatory

messengers. Among these signaling molecules are semaphorin 3A and 4D (sema3A and sema4D). During inflammatory osteolysis bone destruction is regulated by RANKL, M-CSF, TNF, among others. A2AR ligation diminishes osteolysis and expression of RANKL, M-CSF and TNF. We therefore asked whether A2AR activation modulates OB-OC crosstalk by regulating sema3A and sema4D or their receptors PlexinA1/Neuropilin1 and PlexinB1, respectively, in a model of inflammatory osteolysis.

Methods: 1cm midline sagittal incisions were made over calvaria in 6–8 wk old C57Bl/6 mice. Calvaria were exposed to 20μl of PBS containing 3mg of UHMWPE followed by daily injections of either vehicle or CGS21680 (A2AR agonist) 1μM (n=4 each) for 14 days. XenoLight Rediject Bone Probe was injected IV and fluorescence of calvaria measured (IVIS) to assay bone formation. Sema3A/PlexinA1/Neuropilin1 and Sema4D/PlexinB1 expression were studied by RT-PCR and Western Blot in primary bone marrow-derived OC and OB in the presence/absence of CGS21680 and ZM241385 (A2AR antagonist) 1μM each.

Results: XenoLight imaging revealed a 52.5±6% reduction in bone formation after exposure to UHMWPE ($p<0.001$, n=5) and CGS21680 completely reversed this effect (11±5% increased compare to control, p=NS, n=5). In UHMWPE-exposed calvaria there was a decreased number of cells expressing Sema3A and PlexinA1 but not Neuropilin1, effects largely reversed by CGS21680. In contrast, Sema4D/PlexinB1 expressing cells, primarily macrophages and OC, were increased in UHMWPE-exposed calvaria and CGS21680 reversed these changes as well. In marrow cell cultures RANKL induced a 2.5±0.1 fold increase in Sema4D mRNA ($p<0.001$,n=4) which was blocked by CGS21680 ($p<0.001$,n=4). In contrast, PlexinA1 mRNA was enhanced by CGS21680 (9.3±0.7 fold increase vs 4.9±0.6 for RANKL, $p<0.001$,n=4) but Neuropilin1 mRNA was unchanged. Sema3A mRNA increased 3.5±0.5 fold during OB differentiation and CGS21680 enhanced this to 8.7±0.2 fold, $p<0.001$,n=3); PlexinB1 mRNA was increased 2 fold during OB differentiation and was not altered by CGS21680 exposure. Similar changes were observed in protein expression and secretion.

Conclusion: UHMWPE-induced inflammatory osteolysis involves both bone destruction and reduction of new bone formation. $A_{2A}R$ stimulation diminishes secretion of inflammatory mediators and also regulates expression of AGP that likely contribute to inflammatory osteolysis and reduction in bone production.

1831

Study Of Serum Levels Of Osteocalcin (s-OC) On Patients With Diffuse Idiopathic Skeletal Hyperostosis (DISH) and Ankylosing Spondilitis (AS). Mariela Geneva-Popova[1], Stojan Andreev[2], Pavel Pavlov[1], Daniel Ilev[1] and Stanislava Popova[1]. [1]Medical University, Plovdiv, Plovdiv, Bulgaria, [2]MHAT Tokuda, Sofia, Bulgaria.

Background/Purpose: Osteocalcin (bone Gla protein), one of the basic markers for bone matabolism, has not been thoroughly studied on patients with DISH and AS. It is a specific product of the osteoblasts, in bones it connects with hydroxyapatite and in the presence of calcium it plays the role of a promoter of the accumulation of calcium in the bone matrix. That's how osteocalcin takes part in the regulation of bone ossification.

The aim of the study is to estimate the serum levels of osteocalcin on patients with DISH and AS.

Methods: s-OC is estimated on 55 patients with DISH, 25 patients with AS, 50 patients with spondylosis and 15 particularly healthy people aged 55–65, 10 particularly healthy people aged 20–25. The measuring of the s-OC is done by ELISA „sandwitch" method, with a kit of eBioscience, Austria. The statistic processing is done with SPSS 19 programme ($p<0.001$).

Results: The average measurements of s-OC of patients with DISH and AS are higher in comparison with the results of patients with spondylosis and healthy people, regardless of their age ($p<0.05$) (table 1).

Table 1. Results of average measurements of s-OC of patients with DISH, spondylosis, AS, young and old controlled in ng/ml

	Number of patients			
Disease	**Min**	**Max**	**Referent measurments**	
DISH	55	6.37 ± 0.619	0.80	23.90
Spondylitis	50	1.19 ± 0.024	0.70	1.90
AS	23	7.27 ± 1.80	0.40	41.50
Young people	10	1.22 ± 0.236	0.50	3.20
Old control group	15	1.78 ± 0.226	1.20	3.60

Conclusion: s-OC is significantly increased on patients with DISH and AS in comparison with the results of patients with spondylosis and healthy people, but it is really hard to explain the reason why at the present moment. Hypothetically, this might be a result as a sequence of events, based on which is damage of the spinal cord (stimulation of inflammatory proteins, on-going osteoporosis, compresion fractures, hyperinsulinemia which is a result from metabolic disorders, etc.), the endurance of the vertebrae is decreased and the body increases the production of osteocalcin from the osteoblasts to form compensatory more bone substance. That's how the organism adapts to the new changes.

Measuring the levels of serum osteocalcin can be used for early diagnose of DISH due to a difference between the serum levels on patients with DISH and spondylosis, with which differential diagnose is mostly done.

1832

Discovery of MicroRNAs in the Regulation of Inflammation and Bone Erosion in Rheumatoid Arthritis. Ellen M. Gravallese[1], Yukiko Maeda[1], Nicholas Farina[2], Paul Fanning[3] and Jane Lian[2]. [1]University of Massachusetts Medical School, Worcester, MA, [2]University of Vermont College of Medicine, Burlington, VT, [3]University of Massachusetts Medical School, worcester, MA.

Background/Purpose: Focal articular bone erosion in rheumatoid arthritis (RA) is mediated by osteoclasts and repair of erosion by osteoblasts is uncommon, despite the use of potent anti-inflammatory therapies. TNF treatment of primary calvarial osteoblasts from Wnt reporter (Top-gal) mice suppresses Wnt signaling activity in these cells, altering a pathway critical for osteoblast differentiation and function. Additional mechanisms inhibiting bone formation likely contribute to the persistence of articular erosion in this disease. We have shown in an animal model of RA that in the setting of resolving inflammation, repair of articular bone erosion can occur, accompanied by alterations in expression of components of the Wnt signaling pathway. MicroRNAs (miRNAs) are important regulators of skeletal remodeling and several miRNAs, including miR-23b and miR-155, have been shown to play a role in RA pathogenesis. Since miRNAs can regulate both inflammation and bone remodeling, we hypothesized that they might play a regulatory role in bone erosion in RA.

Methods: To address the potential role of miRNAs in these pathogenic events, we used a modification of the serum transfer model of RA for the study of bone erosion development and repair in which inflammation is induced, then allowed to resolve. We performed Fluidigm high-throughput expression profiling of 750 miRNAs in pooled synovial samples from non-arthritic and arthritic mice (peak inflammation, day 10), as well as mice with resolving inflammation (day 21). We also performed gene array (Affymetrix) analysis in these same RNA samples. We analyzed and compared gene and miRNA array expression, and performed gene ontology analyses to identify important pathways.

Results: We performed a principle component analysis that revealed three distinct sets of miRNAs with expression patterns that were significantly different between synovium from non-arthritic mice and mice with peak inflammation and resolving inflammation. We then compared miRNA and gene expression patterns and found 796 up-regulated genes in arthritic compared with non-arthritic synovium that are predicted targets of down-regulated miRNAs (1.5 fold or >). Relevant pathways from gene ontology analysis included extracellular matrix organization, cell cycle, inflammation, and blood vessel and bone development. We also found 639 genes to be down-regulated that are predicted targets of up-regulated miRNAs (1.5 fold or >) in arthritic compared with non-arthritic synovium. Gene ontology analysis included genes in the TGFβ signaling pathway and genes regulating skeletal development. Finally, expression of several miRNAs was significantly altered

during the resolution phase compared with peak inflammation, and some of these miRNAs may also regulate skeletal pathways.

Conclusion: In this murine model of bone erosion development and repair, we have identified miRNAs and associated genes whose relative expression is altered according to stage of inflammation/erosion. Further study of these miRNAs and regulated pathways may prove fruitful for elucidating mechanism and developing therapeutic strategies for bone remodeling.

1833

Combination Of TNF and IL-6 Induces Osteoclast-Like Cells With Bone-Resorption Activity Both *In Vitro* and *In Vivo*. Kazuhiro Yokota, Kojiro Sato and Toshihide Mimura. Saitama Medical University, Saitama, Japan.

Background/Purpose: Although TNF inhibitors suppress bone destruction in patients with rheumatoid arthritis (RA), TNFα stimulation alone does not directly induce osteoclasts, bone-resorbing cells. With the assumption that the combination of TNFα and IL-6 induces differentiation of osteoclast-like cells, we examined the effect of the combination on bone marrow-derived monocytes/macrophages (BMMs) and on intracellular signaling pathways.

Methods: BMMs were cultured with macrophage-colony stimulating factor (M-CSF), TNFα, IL-6, and receptor activator of nuclear factor κB ligand (RANKL). The activities of nuclear factor-κB (NF-κB), c-Fos, and nuclear factor of activated T-cells cytoplasmic 1 (NFATc1) were analyzed using an ELISA-based system, western blot analysis and immunostaining. *In vivo* administration of the cytokines into the supracalvariae of mice was performed. The effects of osteoprotegerin (OPG), the decoy receptor for RANKL, the NFAT inhibitor tacrolimus, anti-IL-1β antibody, ERK inhibitors and a novel JAK inhibitor tofacitinib were examined. The effects of RNAi for c-Fos and the genetic ablation of Stat3 were also evaluated.

Results: The combination of TNFα and IL-6 induced the differentiation of tartrate-resistant acid phosphatase (TRAP)-positive multinucleated osteoclast-like cells in a RANKL-independent manner. The osteoclast-like cells resorbed dentin slices in a manner similar to osteoclasts induced by RANKL. Activity of c-Fos and NFATc1 was significantly upregulated by TNFα and IL-6 used in combination compared to TNFα or IL-6 alone. The differentiation of osteoclast-like cells was completely inhibited by tacrolimus but not by OPG or anti-IL-1β antibody. In addition, silencing of c-Fos significantly decreased the expression level of NFATc1 mRNA and the number of osteoclast-like cells. Most interestingly, we observed no significant difference in the induction of osteoclast-like cells derived from conditional Stat3-knockout mice and control mice. In contrast, ERK inhibitors clearly exerted an inhibitory effect on the differentiation of osteoclast-like cells compared to that of osteoclasts induced by RANKL. Thus, the JAK-ERK signaling pathway is likely to regulate the differentiation of osteoclast-like cells. On the other hand, the number of TRAP-positive cells on the calvariae was significantly higher in mice administered with TNFα plus IL-6 than in mice administered with PBS, IL-6 or TNFα alone. Furthermore, tofacitinib suppressed the differentiation of osteoclast-like cells *in vitro*, and decreased the number of TRAP-positive cells and inhibited bone resorption induced by the combination of TNFα and IL-6 *in vivo*.

Conclusion: The combination of TNFα and IL-6 is a potent mediator of bone resorptive osteoclast-like cells even in the absence of RANKL. These results suggest that TNF inhibitors might suppress bone destruction by inhibiting the differentiation of osteoclast-like cells induced by the combination of TNFα and IL-6.

Abnormal Collagen Fibers Deposition In The Synovial Joints Is a Characteristic Of The Temporal Evolution Of The Diabetic rats' Model Induced By Streptozotocin. Priscila C Andrade[1], Ana Paula P. Velosa[1], Jymenez Morais[1], Edwin R. Parra[2], Cláudia Goldeinstein-Schainberg[1], Vera L. Capelozzi[2] and Walcy R. Teodoro[1]. [1]University of Sao Paulo School of Medicine, São Paulo, Brazil, [2]University of Sao Paulo School of Medicine, Sao Paulo, Brazil.

Background/Purpose: Diabetes is a causative factor in joint diseases and amplifies the damage induced by other agents as well. According to an accepted hypothesis, damaged joint tissue in diabetes is caused by an excess of advanced glycation end products, which forms covalent cross-links within collagen (COL) fibers and alters their structure and function. In this context the remodeling process of the collagen fibers in different structures in the joint probably is the trigger of the joints disorders observed in these patients. The main of this study was to analyze the synovial collagen fibers in the rat diabetic joints induced by streptozotocin and their correlation with the temporal evolution of the diabetes.

Methods: Twenty diabetic Wistar rats (2.5 months of age and 200–250g) induced by infusion of streptozotocin (35mg/kg) were divided in two groups. The first group (G1=10) was euthanized after 2 weeks of induction and the second group (G2=10) after 2 months of diabetic induction. The control (C1=10 and C2=10) groups received only saline infusion. The experimental protocol complies the rules adopted by the Brazilian College of Animal Experimentation (COBEA) and was approved by the internal Ethics Committee of the University of São Paulo Medical School, protocol # 10501/13. After the euthanasia, weight, blood glucose and plasmatic anti-carboximetilisin (ACML) analysis were performed. The synovial tissues of the knee were included in paraffin and histological sections were stained with Hematoxylin and Eosine. 4-hydroxyproline analysis, picrosirius red stained, immunofluorescence and image analysis were used to evaluated the amount of total collagen and the COL I, COL III and V in the synovial tissues.

Results: Blood glucose was statistical significant increases in the diabetic groups when compared with control groups ($p<0.005$). In contrast, the weight of the diabetic animals decreased when compared with the control groups ($p<0.001$). Increased quantities of collagen was observed by 4-hydroxyproline analysis in G2 group when compared to C2 ($p<0.005$) group. Similar situation was observed between G1 and C1 but without statistical significance. The morphology analysis showed a substitution of the sub-synovial layer fat by fibrotic tissue in the diabetic groups with important deposition of collagen fibers around small vessels. Indeed, the histomorphometry analysis showed an increased amount of coarse collagen fibers (22.70 $\pm$ 8.20) with a reduction of fine collagen fibers in G2 (16:29 $\pm$ 6:10%) when compared with C2 (14:45 $\pm$ 5:39%, 21:39 $\pm$ 6.14, respectively, $p<0.05$) group. Similar situation was observed between G1 and C1 but without statistical significance. The COL I, III and V analysis showed a statistical increased of these fibers in G2 when compared with C2. Between G1 and C1 this increase was observed but without significance.

Conclusion: The morphologic changes observed in the synovial tissues from diabetic rats and the increased amount of the collagen fibers deposition in this structure reinforce the idea that the collagen fibers deposition and remodeling are part of the pathogenic pathway progression in the joint from diabetic patients.

Dynamic Visualization Of Monocyte Migration In 3D Synovial Micromass Tissue Cultures. Clemens Scheinecker[1], Ruth Byrne[1], Karolina Dalwigk[1], Anastasiya Hladik[1], Gunter Steiner[1], Josef S. Smolen[2] and Hans Peter Kiener[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria.

Background/Purpose: Monocytes (Mo) are among the first hematopoietic cells to migrate into the inflamed synovial tissue of arthritic joints. Monocyte migration appears to be associated with the expanding synovial lining network of fibroblast-like synovial cells (FLS). Whether cognitive interaction between Mo and FLS is required for an orchestrated migratory behavior has not been analyzed so far. We analyzed Mo migratory activity under inflammatory conditions in regard to cell-cell interactions with FLS.

Methods: Human FLS were prepared from synovial tissues obtained as discarded specimens following joint arthroplasty. $CD14^+$ Mo were isolated from peripheral blood by magnetic bead sorting. FLS and Mo were labeled with fluorescent membrane dyes and cultured in spherical extracellular matrix micromasses with an average size of 1.5 mm for up to two weeks. For stimulation experiments, micromasses were cultured in medium containing 10 ng/ml of tumor necrosis factor (TNF). At different time-points cell migration was monitored in individual micromasses by real-time confocal microscopy.

Results: Cell migration could be subdivided into three successive phases of cell movement. Phase I (day 1–3 of culture) was characterized by the

formation of the synovial lining layer. Mo in close contact with FLS appeared sessile. On average 20% of Mo were in no apparent contact with FLS and displayed a mobile and seeking behavior. During phase II (day 3–7) already >95% of Mo were in contact with FLS. The majority of Mo remained sessile whereas a fraction of Mo displayed a directed cell movement with an impressive maximum speed of up to 15 mcm/min. In addition the formation of Mo cell clusters was observed. The rapid Mo migration finally ceased during phase III (day 7–14). The addition of TNF i) increased the frequency and size of Mo cell clusters during phase II two and ii) prolonged the mobility of Mo into phase III.

Conclusion: The 3D synovial tissue culture system allows to monitor and analyzed subtle migration patterns of Mo in relation to the organized synovial lining architecture. Ongoing experiments address molecular mechanism(s) of Mo – FLS interaction in order to identify potential targets for future therapeutic intervention in arthritis.

Suppression Of HDAC5 Expression By Inflammatory Cytokines Is Required To Promote CXCL Chemokine Production In RA FLS. Chiara Angiolilli[1], A.M. Grabiec[1], P.A. Kabala[1], Paul-Peter Tak[2], D. Baeten[1] and Kris A. Reedquist[1]. [1]Department of Clinical Immunology and Rheumatology Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center / currently also GlaxoSmithKline, Amsterdam, Netherlands.

Background/Purpose: Histone deacetylases (HDACs) are important regulators of gene expression and protein function in the immune system. HDAC inhibitors (HDACi) display anti-inflammatory properties in animal and in vitro models of rheumatoid arthritis (RA), as well as initial safety and efficacy in the treatment of systemic onset juvenile idiopathic arthritis1, 2.However, as most of the currently available HDACi display little selectivity or specificity for class I (HDAC 1–3, 8) and class II (HDAC 4–6, 9, 10) HDACs, the role of specific HDACs in RA is unclear.

We examined the relationship between HDAC expression and inflammation in RA synovial tissue and fibroblast-like synoviocytes (FLS).

Methods: RNA was isolated from arthroscopic synovial biopsies from 19 RA patients. MMP-1, TNFα, IL-6, and HDAC 1–10 expression was measured by quantitative PCR (qPCR). RA FLS were stimulated with IL-1β, TNFα and LPS and HDAC expression was measured by qPCR. RA FLS were transduced with adenovirus encoding control GFP or GFP-HDAC5, or transfected with control siRNA or siRNA targeting HDAC5. Effects of HDAC5 modulation on RA FLS gene and protein expression were analyzed by custom qPCR array and ELISA, respectively.

Results: Positive correlations were observed between RA synovial tissue expression of TNFα and HDAC1 (R=0.651, P=0.003) HDAC2 (R=0.523, P=0.022) and HDAC3 (R=0.570, P=0.011) and between MMP-1 and HDAC1 (R=0.501, P=0.029) and HDAC2 (R=0.512, P=0.025). A significant negative correlation was observed between synovial tissue expression HDAC5 and IL-6 (R=−.477, P=0.039), as well as HDAC5 and clinical parameters of disease activity (CRP: R=−0.664, P= 0.007; ESR: R=−0.556, P=0.013: DAS28: R=−0.567, P=0.011). HDAC5 mRNA expression was significantly and selectively reduced after RA FLS stimulation with TNFα and IL-1β, but not LPS. Of 84 genes regulated in RA FLS by IL-1β or TNFα, mRNA expression of CXCL9, CXCL10, and CXCL11, as well as CXCL10 protein, were selectively upregulated following silencing of HDAC5 expression. Conversely, mRNA expression of these chemokines was suppressed by overexpression of HDAC5 in RA FLS.

Conclusion: RA synovial expression of HDAC 1 and 2, but not class II HDACs, positively correlates with local inflammatory mediators, while HDAC5 expression negatively correlates with IL-6 mRNA expression and with disease activity parameters. HDAC5 mRNA is decreased after inflammatory stimulation, and silencing of HDAC5 leads to an increase of CXCL chemokine expression in RA FLS, an effect reversed by HDAC5 overexpression. Our results suggest an involvement of HDAC5 in the regulation of a specific subset of IL-1β induced CXCL chemokines RA FLS.

Three-Dimension Culture Of Mesenchymal Stem Cells With Nano-Fiber Scaffold Induces Chondrogenesis and Osteogenesis. Kunihiro Yamaoka[1], Koshiro Sonomoto[1], Xiangmei Zhang[1], Masahiro Kondo[1], Shunsuke Fukuyo[1], Makoto Satake[2], Hiroaki Kaneko[2], Kazuhisa Nakano[1], Yosuke Okada[1] and Yoshiya Tanaka[1]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Integrative Technology Research Institute, Teijin Limited, Tokyo, Japan.

Background/Purpose: Development of biologics has made remission a realistic treatment goal in treatment of rheumatoid arthritis (RA). However, once bone or cartilage is destructed treatment tool aiming joint repair do not exist. On that note, treatment strategy for established RA is requisite. We have previously shown that mesenchymal stem cells (MSCs) suppress osteoclastogenesis and also differentiate into osteoblasts under the presence of inflammation. Therefore, in addition to its immunosuppressive effect, we believe that MSCs is a useful tool to develop treatment aiming joint repair. We have evaluated the applicability of poly-lactic fiber (Nano-fiber) scaffold.

Methods: MSCs from healthy donor, osteoarthritis (OA) or RA was seeded onto Nano-fiber (Nano-MSCs) and cultured in MSCs growth media (MSCGM) or osteoblast induction media (OIM) for 7~56 days. Differentiation markers for osteoblasts (RUNX2, Osteocalcin, meneralization), osteocytes (Dmp-1, MEPE) and chondrocytes (SOX9, Type II collagen, COL10A1, proteoglycan production) were evaluated.

Results: Healthy Nano-MSCs culture in OIM for 28 days induced runt-related gene 2 (RUNX2) expression and mineralization with positive Safranin O staining suggesting that Nano-hMSC induced osteoblastogenesis and chondrogenesis in parallel. When healthy Nano-MSCs was cultured in MSCGM, Safranin O positive cells and chondrocyte markers were detectable from day 14. Mineralization and osteocyte marker expression were observed on day 56 with osteocyte-like shape under the scan electron microscopy. Similar results were observed with MSCs from RA and OA patients. However, MSCs seeded onto culture flask with MSCGM did not express any of these differentiation markers. The non-canonical wingless-type MMTV integration site (Wnt) signaling pathway was suggested to play a role in these phenomena.

Conclusion: Our results suggest that MSCs simutaneously differentiate into chondrocytes, osteoblasts and osteocytes when seeded onto Nano-fiber scaffold without specific stimulation for differentiation. Since Nano-fiber is bioabsorbable, its use in combination with MSCs would be a useful tool for regeneration of destructed joints in RA and OA patients.

The Use Of Three-Dimensionally Printed β-Tricalcium Phosphate/ Hydroxyapatite To Understand The Regulation Of Adenosine Receptors In Osteoclast Formation and Promotion In Bone Regeneration. Stephanie Ishack[1], Aranzazu Mediero[1], Tuere Wilder[1], John Ricci[2] and Bruce N. Cronstein[3]. [1]NYU School of Medicine, New York, NY, [2]NYU Dental School, New York, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Bone defects resulting from trauma or infection need timely and effective treatments to replace damaged bone. Using specialized three-dimensional (3-D) printing technology, combined with bioactive molecules, we can design custom 3-D scaffolds for bone repair. The Hydroxyapatite (HA)/Beta-Tri-Calcium Phosphate (b-TCP) scaffold components provide mechanical strength, conduct bone throughout the scaffold and remodel over time. Adenosine, acting via adenosine receptors (A_1, A_{2A}, A_{2B} and A_3), plays a critical role in regulating bone metabolism. Dipyridamole (DIPY) increases local adenosine levels by blocking cellular uptake of adenosine and stimulates bone regeneration. We tested the capacity of dipyridamole, hypothesize that with a bioactive filler, such as DIPY, these scaffolds may successfully regenerate bone over critical sized bone defects in an *in vivo* model.

Methods: 15% HA:85% b-TCP scaffolds were designed using Robocad software, fabricated using a 3-D Robot, and sintered at 1100°C for 4h. SEM

and microCT were used to examine structural aspects on pre/post-sintering, while XRD, FT-IR and ICP were used to evaluate porosity, crystalline phase quantification, and Ca:P ratio, respectively. Vehicle, BMP-2 and combination drug scaffolds (calcium sulfate + drug, calcium sulfate + drug in solution, collagen + drug in solution) were implanted in C57B6 mice with 3mm critical size defect for 2 weeks. DIPY release from scaffold was assayed *in vitro* spectrophotometrically over time. MicroCT and histological analysis were conducted to determine the degree of new bone formation and remodeling.

Results: Qualitative microstructural evaluation using SEM showed a broader pore/particle size distribution for materials sintered. The x-ray diffraction (XRD), Fourier transform infrared spectroscopy (FT-IR) and inductive coupled plasma (ICP) results showed substantial deviations in the original 15/85% HA/b-TCP formulation with the detection of ~10%calcium pyrophosphate. Also, as sintering temperature was increased, lower amounts of the HA (5% HA: ~95% b-TCP) phase was observed. DIPY release assays showed a constant 10^{-6}M release of the compound for a period of 10 days. Quantitative and qualitative results from microCT showed similar and significant bone formation and remodeling in HA/b-TCP- DIPY and HA/b-TCP-BMP-2 scaffolds (p=NS) when compared to vehicle 2 weeks after surgery. Histological analysis showed increased bone formation and osteoconduction in HA/b-TCP- DIPY scaffolds.

Conclusion: Results from the *in vitro* and *in vivo* studies demonstrate that HA/b-TCP- DIPY scaffolds are highly biocompatible and can rapidly and successfully regenerate and remodel bone in critical size defects.

Osteoclastogenesis Is Enhanced By Synovial Fluid Derived Anti-Citrullinated Proteins Antibodies In Rheumatoid Arthritis. Akilan Krishnamurthy[1], Heidi Wähämaa[2], Vijay Joshua[1], Catia Cerqueira[3], Elena Ossipova[3], Nancy Vivar Pomiano[1], Karin Lundberg[3], Vivianne Malmström[4], Per-Johan Jakobsson[1], Lars Klareskog[1], Georg Schett[5], Jimmy Ytterberg[6] and Anca I Catrina[1]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [2]Rheumatology unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden, [3]Rheumatology unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [4]Rheumatology unit, Karolinska University Hospital, Karolinska Institutet, STockholm, Sweden, Stockholm, Sweden, [5]University of Erlangen-Nuremberg, Erlangen, Germany, [6]Rheumatology Unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden.

Background/Purpose: Anti citrullinated modified vimentin antibodies isolated from peripheral blood (PB) of RA patients induce osteoclasts (OC) formation from PB derived monocytes of healthy individuals. Recently dendritic cells have been proposed as potent precursor of osteoclasts. We aimed to characterize dendritic cells derived osteoclastogenesis in ACPA+ RA and to explore the effect of anti-CCP2 antibodies containing a large array of anti-citrulline specificities on dendritic cells mediated osteoclastogenesis.

Methods: SF (n=26) samples were collected from RA patients. Total IgG were isolated first on Protein G and than on CCP2 affinity columns. CD14+ monocytes were isolated from (PB) of ACPA+ RA patients and cultured in the presence of GM-CSF and IL-4 to generate dendritic cells (DC) or M-CSF to generate macrophages (MΦ). DC's and MΦ were further differentiated to OC in the presence of RANKL and M-CSF, with or without ACPA IgG or flow through control IgG (at a final concentration of 100 ng/ml). OC were counted as multinucleated (more than 3 nuclei) TRAP+ cells. In parallel cultures were grown on osteoassay surfaces and resorbed area was quantified by computer assisted image analysis. Proteomic analysis and western blot to identify citrullinated proteins were performed on different stages of differentiation of dendritic cells derived osteoclasts.

Results: Osteoclastogenesis from DC was as efficient as osteoclastogenesis from MΦ of ACPA+ RA patients. ACPA IgG increased RANKL-driven osteoclastogenesis from both DC (from a median of 193 OC/well, interquartile variation of 86–308 in controls to a median of 418 OC/well, IQR 317–447) and MΦ (from a median of 238 OC/well, IQR 55.5–378.5 to a median of 333.5, IQR 88.8–489.3). These changes were paralleled by an increase of bone resorption areas by ACPA IgG in both the dendritic assay (from a median of 6.8%, IRQ 1.6–18.9 to a median of 10.3%, IQR 2.3–38.4) and the monocyte assay (from a median of 4.9%, IRQ 1.9–8.5 to a median of 6.9, IQR 2.7–10) No significant increase in either osteoclasts numbers or resorption areas was observed with the control flow through IgG. Interestingly when OC precursors were obtained from healthy donors, ACPA were only able to promote dendritic driven but not monocyte driven osteoclastogenesis. Similar to our previous findings in monocytes-derived osteoclasts we found a significant time dependent increase in native vimentin levels during dendritic-derived osteoclast maturation with identification of citrullinated vimentin peptides in the matured but not immature osteoclasts. Western Blotting using ACPA IgG also confirmed presence of citrullinated proteins in matured osteoclasts.

Conclusion: SF derived ACPA IgG with broad specificities enhance RANKL-driven osteoclastogenesis. While citrullinated vimentin is a potential target in mature osteoclasts, the exact contributions of each distinct ACPA specificities remains to be determined.

Increased Expression of BAFF Receptor On Monocytes Is a Contributory Factor of Hypergammaglobulinemia in Patients With Primary Sjögren's Syndrome. Keiko Yoshimoto[1], Maiko Tanaka[1], Masako Kojima[1], Hideko Ogata[1], Eriko Ishioka[1], Ayumi Nishikawa[1], Katsuya Suzuki[1], Hideto Kameda[1], Tohru Abe[2] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Saitama Medical School, Kawagoe-shi Saitama, Japan.

Background/Purpose: BAFF (B cell stimulation factor belonging to TNF family) is a cytokine which is mainly produced by monocytes, dendritic cells and T cells. We have been investigating the possible involvement of BAFF in the pathogenesis of primary Sjögren's syndrome (pSS) because BAFF plays a pivotal role in the proliferation, differentiation and survival of B cells. In our previous study, we found that BAFF robustly increased IL-6 production by pSS peripheral monocytes, and the expression level of a BAFF receptor (BAFF-R) was significantly elevated in pSS monocytes compared to that of normal monocytes. These data collectively suggest that the elevated expression of BAFF-R on monocytes is involved in activation of monocytes to promote IL-6 production. Since IL-6 promotes the differentiation of B cells, our findings may provide clues to elucidate the mechanism of the development of pSS. On the other hand, it is well known that pSS is often accompanied by hypergammaglobulinemia (HγG). However, the molecular and cellular mechanism underlying HγG is unknown. In the present study, we focused on this abnormality and investigated the possible involvement of monocytes producing IL-6 in the development of HγG.

Methods: Peripheral monocytes were cultured with or without peripheral B cells and stimulated with soluble BAFF (sBAFF) in vitro. IL-6 production by monocytes and IgG production by B cells were measured by ELISA. FACS analysis of whole blood samples was employed to analyze the expression of BAFF-R.

Results: The serum level of IgG and the proportion of BAFF-R positive monocytes ($BR^+/CD14^+$) were elevated in pSS patients as compared to those in normal individuals. Remarkably, the $BR^+/CD14^+$ ratio was positively and significantly correlated with the serum IgG level. In addition, pSS monocytes produced a significantly higher amount of IL-6 than normal monocytes upon stimulation with sBAFF in vitro, and the $BR^+/CD14^+$ ratio was positively and significantly correlated with the amount of IL-6 produced by pSS monocytes. Stimulation of co-culture of B cells and monocytes with sBAFF drastically enhanced IgG production by B cells in vitro, whereas the stimulation showed only marginal effects on IgG production when B cells were cultured in the absence of monocytes.

Conclusion: The data in the present study collectively suggest that the abnormal expression of BAFF-R on monocytes is responsible for the overproduction of IgG by B cells in pSS patients. IL-6 produced by monocytes may be involved in the differentiation of B cells to produce IgG. We presume that aberrations of monocytes may underlie the development of hypergammaglobulinemia in pSS patients.

1841

BAFF Induces Production of Matrix Metalloproteinase-9 By Peripheral Monocytes in Patients With Primary Sjögren's Syndrome Through a Signaling Pathway That Involves NF-Kb and PI3 Kinase. Keiko Yoshimoto[1], Maiko Tanaka[1], Masako Kojima[1], Hideko Ogata[1], Eriko Ishioka[1], Ayumi Nishikawa[1], Katsuya Suzuki[1], Hideto Kameda[1], Tohru Abe[2] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Saitama Medical School, Kawagoe-shi Saitama, Japan.

Background/Purpose: B cell activating factor of the TNF family (BAFF) regulates proliferation, differentiation and survival of B cells, and plays a pivotal role in the development of primary Sjögren's syndrome (pSS). In our previous study, we found that IL-6 production was significantly enhanced in pSS monocytes upon stimulation with BAFF. We also found that the expression level of a BAFF receptor (BAFF-R) was significantly elevated in pSS monocytes compared to that of normal monocytes. These data collectively suggest that the elevated expression of BAFF-R on monocytes is involved in activation of monocytes to promote IL-6 production. Matrix metalloproteinase-9 (MMP-9) is one of the enzymes involved in pathogenesis of autoimmune diseases. In this study, we explored possible involvement of BAFF and BAFF-R in the expression of MMP-9 in pSS monocytes.

Methods: The expression levels of BAFF-R and MMP-9 in peripheral monocytes of pSS patients (n = 19) and age matched normal individuals (n = 14) were analyzed by FACS. The cells were cultured in vitro in the presence or absence of recombinant human soluble BAFF (rhsBAFF) for 96 hrs, and the amounts of IL-6 and MMP-9 in the culture supernatants were measured by ELISA. The expression level of MMP-9 was also analyzed by quantitative PCR. Signal transduction pathways were investigated by exposing rhsBAFF-stimulated pSS monocytes to several inhibitors against NF-κB (BAY11–7082 and BAY11–7085) and PI3 kinase (LY294002).

Results: Quantitative PCR and FACS analyses revealed that stimulation of pSS moncytes with rhsBAFF drastically enhanced the expression of MMP-9 compared to that of normal monocytes. ELISA showed robust enhancement of MMP-9 production by pSS monocytes. Remarkably, the amount of MMP-9 was positively correlated with the expression level of BAFF-R on pSS monocytes, suggesting that BAFF-signaling is involved in the production of MMP-9 by pSS monocytes. Moreover, the elevated production of MMP-9 was significantly suppressed by specific inhibitors against NF-κB and PI3 kinase in a dose dependent manner.

Conclusion: The present study suggests that the BAFF signaling pathway is involved in the production of MMP-9 by pSS monocytes. The study also suggests that NF-κB and PI3 kinase are involved in the pathway.

Pathophysiological Effects Of Free Fatty Acids On Key Cells Of Arthritis. Klaus W. Frommer[1], Andreas Schäffler[2], Stefan Rehart[3], Angela Lehr[3], Ulf Müller-Ladner[1] and Elena Neumann[1]. [1]Justus-Liebig-University of Gieβen, Kerckhoff-Klinik, Bad Nauheim, Germany, [2]Justus-Liebig-University of Giessen, Giessen, Germany, [3]Markus-Hospital, Frankfurt, Germany.

Background/Purpose: Although obesity, a known risk factor for arthritic diseases, increases mechanical stress on joints, it appears not to be the only factor being responsible for joint damage. Free fatty acid (FFA) levels, which are increased in obese compared to non-obese individuals, may therefore also play a role in different forms of arthritis. In this respect, continuously elevated FFA levels have already been linked to inflammatory cardiovascular and metabolic diseases. To test our hypothesis that FFA play role in arthritic diseases, we investigated the effect of FFA on key effector cells of arthritis.

Methods: Rheumatoid arthritis (RA) synovial fibroblasts (SF), osteoarthritis (OA) SF, psoriatic arthritis (PsA) SF, human macrovascular (HUVEC) and microvascular (HBdMEC) endothelial cells as well as human primary chondrocytes (HCH) and RA osteoblasts (OB) were stimulated *in vitro* with different saturated and unsaturated FFA within their physiological range of concentrations. FFA-induced protein secretion was determined by immunoassays. Fatty acid translocase (FAT) was inhibited by sulfosuccinimidyl oleate sodium (SSO). TLR4 signaling, which can contribute to driving arthritis, was inhibited intracellularly and extracellularly.

Results: FFA dose-dependently enhanced the secretion of the proinflammatory cytokine IL-6, the chemokines IL-8 and MCP-1, as well as the matrix-degrading enzymes MMP-1 and MMP-3 in all SF types (e.g. for RASF with lauric acid [100 μM] IL-6: 9.1-fold increase; IL-8: 14.9-fold increase; MCP-1: 2.4-fold increase; pro-MMP1: 5.1-fold increase; MMP-3: 83.6-fold increase). There was also a high dependency on the cell population. The effects on RASF were not significantly different between saturated and unsaturated FFA of variable lengths as opposed to HCH, in which saturated FFA induced a strong synthesis of IL-6 (up to 11.6-fold increase), while unsaturated FFA only had a weak effect (between 1.2- and 3.9-fold increases). OB increased IL-6 secretion to a similar degree as SF when stimulated with saturated and unsaturated FFA (100 μM). Endothelial cells, HUVEC and HBdMEC, responded only to higher concentrations of FFA (100 μM), lower concentrations of FFA (10 μM) did not induce a significant response in IL-6 secretion. Blocking fatty acid transport into the cell almost completely abrogated the effect of palmitic acid on IL-6 secretion. Both intracellular and extracellular TLR4 signaling inhibition blocked the palmitic acid-induced IL-6 secretion of RASF.

Conclusion: The data show that FFA not only play a role as high energy source in metabolism but also as contributors to articular inflammation and degradation in arthritis. Therefore, elevated FFA levels (as for example occurring in obesity) may be another element in the multifactorial pathogenesis of arthritic diseases. Additionally, in SF, TLR4 signaling is necessary for FFA-induced gene expression.

Treatment With Staphyloccocal Protein A Which Is Immuno-Modulatory In The Murine Collagen Arthritis Model, Does Not Increase Infection Severity In Murine Listeria Or Candida Challenge Models, In Contrast To Anti-TNF Treatment. Edward Bernton[1] and Valerie Lowe[2]. [1]Protalex Inc., Summit, NJ, [2]Washington Biotechnology, Inc., Baltimore, MD.

Background/Purpose: PRTX-100 is a highly-purified GMP staphylococcal protein A (SpA) that is currently in Phase I trials in patients with active rheumatoid arthritis (RA). SpA has diverse activities in vitro and in vivo: forming immune complexes with IgG, SpA induces a "suppressor" phenotype in murine and human macrophages; IP or IV administration reduces disease severity in the murine CIA model. SpA can also inhibit activation of human monocyte-derived macrophages by LPS and gamma-IFN. SpA binds to Vh3 B-lymphocytes, and relocates with them to lymphoid tissues. Since anti-cytokine biologic DMARDS, in particular anti-TNF products, have been shown to increase patient susceptibility to pathogens such as listeria, fungi and TB, we compared the effects of SpA treatment to that of etanercept and anti-mouse TNF in murine models of Listeria and Candida infection.

Methods: For Listeria challenges, groups of 15 Balb/C mice were treated ip with either 10 mL/kg of 0.1% BSA, 15 mg/kg of etanercept, 50 or 250 μg/kg of SpA, or 0.2 mL of rabbit anti-mouse TNF antisera. After 4 hours mice were administered 5 $\times$ 10$\hat{1}$0 CFU of L. monocytogenes orally. Mice were then re-treated with drugs every 48 hours $\times$ 2. Weights and mortality were recorded daily. On Days 3, 5, and 8, five mice/group were sacrificed for spleen cultures and CFU counts. For Candida challenges, groups of 15 female CD-1 mice received the same treatments. Four hours after the first treatments they were injected IV with 2 $\times$ 10$\hat{6}$ CFU of Candida albicans. Daily weights and mortality were recorded. On days 3, 5, and 8, five mice/group were sacrificed for kidney cultures and CFU counts.

Results: Mean values for weights, bacterial load: *Listeria challenge – BSA:* 20% mortality.10% weight loss at Day 4 was regained by Day 6.

Anti-TNF: 21% weight loss on Day 5, 100% lethality by Day 6. *Etanercept:* 17% weight loss by Day 5, maintained through to end of study; no mortality. Spleen bacterial counts were higher ($p<0.05$) than with BSA treatment at Day 5. SpA, 25 or 250 μg/kg; no mortality, weight loss similar to BSA-treated mice. Lower bacterial counts at Day 5 than seen following etanercept or anti-TNF treatment. *Candida challenge – BSA:* 17% weight loss by Day 5 and 10% mortality by Day 8. *Anti-TNF:* 23% weight loss on Day 5 with 100% mortality by Day 6. Kidney yeast counts higher ($p<0.05$) than BSA group on days 3 and 5. *Etanercept:* 30% weight loss by Day 7 and 60% mortality by Day 8. Mean kidney counts higher ($p<0.05$) than BSA group at days 3, 5, and 8. *SpA groups:* weight loss similar to BSA group. Kidney counts not significantly different at days 5 and 8 from BSA group; no mortality by Day 8.

Conclusion: In contrast to etanercept or anti-TNF treatment, repeated injections of SpA at 50 or 250 μg/kg did not affect disease severity or pathogen load in these challenge models with bacterial or fungal intracellular pathogens.

Rheumatoid Arthritis, Sjogren's Syndrome and Systemic Lupus Erythematosus Patients Have a Distinct Spectrum Of Serum Anticytokine Autoantibodies. Sarthak Gupta[1], Ioanna P. Tatouli[2], Lindsey B. Rosen[1], Sarfaraz A. Hasni[3], Richard M. Siegel[3], Steven M. Holland[1], Haralampos M. Moutsopopoulos[2] and Sarah K. Browne[1]. [1]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, [2]School of Medicine, National University of Athens, Athens, Greece, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD.

Background/Purpose: Anticytokine autoantibodies are pathogenic in many hematologic, pulmonary and infectious diseases. However, the prevalence and significance of anticytokine autoantibodies in rheumatic conditions is poorly characterized. We comprehensively evaluated anticytokine autoantibodies in Rheumatoid Arthritis (RA), Sjogren's Syndrome (SS) and Systemic Lupus Erythematosus (SLE).

Methods: Bio-Plex Pro Magnetic COOH beads (Bio-Rad Laboratories, Inc) were coupled with commercially available cytokines. Sera from patients with RA, SS, and SLE were compared to normals for autoantibodies against 24 cytokines. Data were acquired on a Bio-Plex 100 instrument and analyzed using Prism, version 6.0. Values above the 99th percentile for the normal controls were classified as positive.

Results: Forty-two percent of RA (Fig. 1), 21% of SS (Fig. 2), and 25% of patients with SLE (Fig. 3) tested positive for anticytokine autoantibodies. Those with RA had mostly anti-TNFa and anti-TNFb antibodies, while SS patients had autoantibodies against Interleukin (IL)-1a, IL-4, IL-6 and IL-12. SLE patients had antibodes against GM-CSF, M-CSF, interferons (IFNs) types I, II and III and IFNg-induced Protein 10 (IP-10).

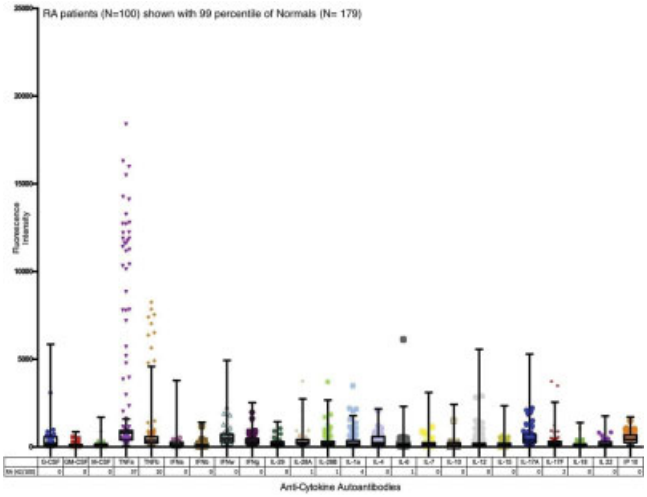

Fig. 1

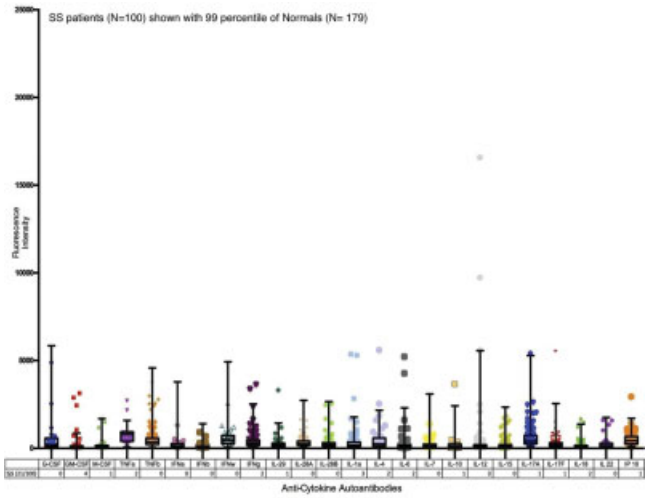

Fig. 2

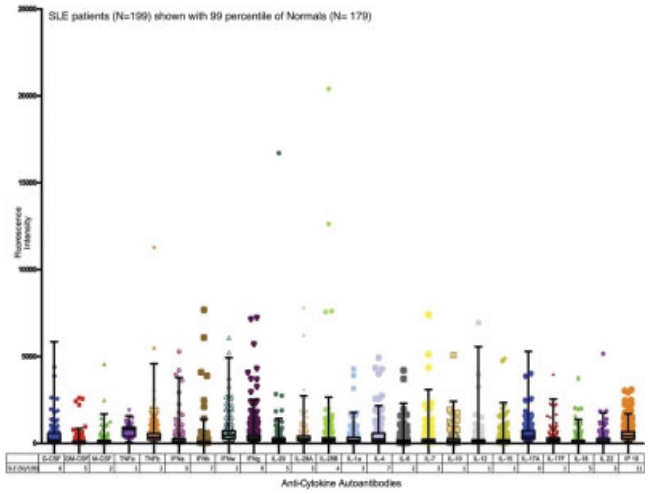

Fig. 3

Conclusion: RA, SS, and SLE had distinct spectra of anticytokine autoantibodies. Those in RA were mostly against TNFa and TNFb, probably due to monoclonal biologics; SS patients did not have many autoantibodies to TNFs or IFNs; SLE had the broadest range of autoantibodies, including those against types I and II IFNs as well as GM-CSF, M-CSF, IL-4, IL-7, IL-18 and IP-10. We confirmed autoantibodies against types I and II IFNs, GM-CSF, TNFa, TNFb, IL-1α, IL-6, IL-10, IL-12 as previously described. However, antibodies to M-CSF, IL-7, IL-17 and IL-22 have not been previously identified in rheumatologic conditions. Anti-type III IFNs (IL-29, IL-28A, IL-28B), anti-IL-4 and anti-IP-10 autoantibodies are newly recognized. These data confirm that anticytokine autoantibodies are a significant presence in autoimmune diseases and extend to more cytokines than previously appreciated. The clinical and pathophysiologic roles of these autoantibodies may teach us more about etiology and pathogenesis of rheumatic diseases.

Soluble Type I Interferon Receptor 2 Is Elevated By Interferon Treatment and In Certain Autoimmune Diseases. Taher Fatakdawala, Michael Skawinski, Jonathan Ferriera, Tara Stauffer and Thomas Lavoie. PBL Assay Science, Piscataway, NJ.

Background/Purpose: The Type I Interferon (IFN) receptor is a heterodimer of chain 1 (IFNAR1) which is required for signaling, and chain 2 (IFNAR2) which binds tightly to IFN. Soluble forms of IFNAR2 can be produced by proteolytic cleavage or production of an alternatively spliced

transcript. Soluble IFNAR2 can be found in serum and urine however its role and regulation are poorly understood. Studies have suggested that sIFNAR2 may be elevated in multiple sclerosis (MS) patients, advanced cancer patients and hepatitis C infected patients. We have examined the sIFNAR2 in healthy donors and a small set of autoimmune patients, to determine its suitability as a member of a biomarker panel for autoimmune diseases.

Methods: Healthy donor and autoimmune Sera and plasma were commercially sourced. sIFNAR2 and IFN-Beta were determined by single analyte ELISA. IP-10 and inflammatory cytokines were determined by multiplex ELISA. IFN activity was determined by a reporter gene assay. 30 male and 30 female normal donor, 59 MS, 67 Systemic Lupus, 16 Rheumatoid Arthritis (RA), 11 Sjogren's and 10 Scleroderma samples were examined. Significance of observed differences was determined by 2-tail t-test using Welsh's correction.

Results: The average sIFNAR2 levels are 2.6±0.7 ng/ml with no difference observed between male (n=30) and female healthy donors (n=30). MS patients on IFN therapy (n=29) had significantly (p=0.0002) higher levels of sIFNAR2 than healthy donors. Those on other therapies (n=24) were not different from the healthy population but were significantly different than the MS patients on IFN therapy (p=0.0001). IFN-Beta mass was measurable in 86% of those patients treated with IFN. IP-10 levels in these patients correlated with IFN dose (r=0.747) while sIFNAR2 did not. sIFNAR2 levels showed no correlation with treatments such as vitamin-D, copaxone or natalizumab. Systemic Lupus patients (n=67) had elevated sIFNAR2 (p=<0.0001). Rheumatoid arthritis (n=16), Sjogren's (n=11) and Scleroderma patients were not significantly different from normal.

Conclusion: Only subsets of autoimmune patients show elevated sIFNAR2 levels. Although evidence of Type I IFN activation has been observed in RA, Sjogren's and Scleroderma patients the intensity is thought to be less than that observed for MS patients on IFN-therapy and Systemic Lupus. These data are consistent with a model where long term IFN signaling above a certain threshold leads to elevated sIFNAR2.

1846

Mitochondrial Dysfunction Induces An Inflammatory, Tissue-Degrading, and Angiogenic Response In Normal Human Synoviocytes. M. Noa Valcárcel-Ares[1], Romina R. Riveiro-Naveira[1], Jesus Loureiro[1], Carlos Vaamonde-García[1], Laura Hermida-Carballo[1], Francisco J. Blanco[2] and Maria J. López-Armada[1]. [1]Aging and Inflammation Research Lab, INIBIC-CHU A Coruña, A Coruña, Spain, [2]Osteoarticular and Aging Res. Lab. CIBER-BBN. INIBIC- University of A Coruña, A Coruña, Spain.

Background/Purpose: Tissues affected with inflammatory arthritis (IA) are subjected to great levels of oxidative stress. Synoviocytes from IA patients present a higher rate of mitochondrial DNA mutagenesis and mitochondrial dysfunction than those from healthy donors. In this work, we studied the role of mitochondrial dysfunction in the inflammatory, tissue-degrading and angiogenic response in human synoviocytes, as those are pivotal processes occurring in IA.

Methods: Mitochondrial dysfunction was induced in normal human synoviocytes with the ATPase inhibitor oligomycin (OLI). Antimycin (AA) and paraquat (PQ) were also used. Mitochondrial polarization was evaluated by TMRM staining; and cytosolic and mitochondrial superoxide production by DHE and mitoSOX staining, respectively. Cyclooxygenase-2 (COX-2), interleukin (IL)-8, metalloproteinase (MMP)-1, MMP-3 and vascular endothelial growth factor (VEGF) mRNA expression were evaluated by RT-PCR. COX-2 protein expression was tested by flow cytometry whereas prostaglandin E_2 (PGE_2), IL-8, and MMP-1/3 levels were assayed by ELISA. In order to establish the role of ROS production, the general and mitochondria-targeted ROS scavengers N-acetylcysteine (NAC) and mitoTEMPO, respectively, were employed. The involvement of NF-kappaB was evaluated by using the inhibitor BAY. Also p65 translocation to the nucleus and NF-kappaB binding activity were assayed by immunofluorescence and EMSA, respectively. The protecting effect of the natural antioxidant resveratrol (RSV) was tested.

Results: OLI induced mitochondrial depolarization and mitochondrial and cytosolic ROS production. OLI-treated synoviocytes showed an increased inflammatory response (as determined by COX-2, PGE_2, and IL-8 expression) as well as a tissue-degrading phenotype confirmed by an increase in MMP-1/3 expression and an angiogenic potential (as evaluated by VEGF mRNA expression and tube formation assay). Besides, in the presence of IL-1β (one of the key pro-inflammatory mediators in IA affected tissues) synoviocytes with mitochondrial dysfunction exhibit a synergic effect regarding the expression of COX-2, PGE_2, and IL-8, as well as MMP-1/3 as compared with healthy synoviocytes. When the role of ROS was investigated, we found that NAC and mitoTEMPO significantly reversed the inflammatory response. Involvement of NF-kappaB was confirmed when the inflammatory response was reduced after incubation with BAY; besides, p65 translocation to the nucleus and NF-kappaB binding activity were found in synoviocytes treated with OLI and IL-1β + OLI. AA and PQ showed a similar effect on the inflammatory response. Finally, RSV clearly prevented inflammation, MMP production and the angiogenic response.

Conclusion: The present study confirms the implication of mitochondria in the proinflammatory, tissue-degrading and angiogenic response in human synoviocytes. Also mitochondrial dysfunction sensitizes these cells amplifying the effect of IL-1β. The responses of synoviocytes with dysfunctional mitochondria are mediated at least in part by mitochondrial ROS production and NF-kappaB activation. RSV has proven to be effective in controlling the deleterious effect of mitochondrial dysfunction.

Certolizumab-Pegol Induces Reverse Signaling Through Membrane TNF Via Calcineurin Activation In Human Monocytes. Relevance In Inflammation. Jean-Frederic Boyer[1], Michel Baron[1], Delphine Nigon[2], Arnaud L. Constantin[2], Alain G. Cantagrel[1] and Jean-Luc Davignon[3]. [1]INSERM CNRS UMR 1043, Paul Sabatier University Toulouse, Toulouse, France, [2]Purpan University Hospital, Toulouse Cedex 9, France, [3]Purpan University Hospital, Toulouse, France.

Background/Purpose: Reverse signalling seems to play a role in the mode of action of anti-TNF-α agents but this pathway and its relevance are poorly understood. CD36 is a scavenger receptor implicated in the phagocytosis of senescent cells at the end of the inflammatory process. We previously demonstrated that TNF-α inhibitors increase CD36 expression in human monocytes and our results suggest a reverse signalling pathway. Casein kinase 1 phosphorylation of serine localized in the intra-cytoplasmic tail of membrane TNF-α (tmTNF) has been reported to play a role in reverse signalling. Our aim was to clarify the pathway engaged in reverse signalling induced by certolizumab-pegol and its relevance on TNF receptor (TNFR) and TLR4 signalling.

Methods: Human monocytes were isolated from peripheral blood mononuclear cells of healthy donors by plastic adherence or negative selection. The consequence of dephosphorylation of tmTNF in CD36 induction was assessed using a specific casein-kinase 1 inhibitor D4476. We searched for a putative phosphatase using cyclosporine A, a specific inhibitor of calcineurin phosphatase. An inhibitor of the endopeptidase SPPL2b, ZLL-2 ketone, was used to asses intra-membrane proteolysis of tm-TNF. CD36 and expression was analyzed by RT-qPCR and flow cytometry. IL-1 expression was induced by LPS and analysed by RT-PCR and western blot. Experiments were done at least 3 times in duplicate. Data were analyzed by Wilcoxon test matched-pairs signed-rank test and Student's paired t-test.

Results: Certolizumab-pegol and D4476 used separately respectively increased the expression of CD36. The association of both compounds potentiated this increase (p=0.02). This suggested the role of casein kinase I in the down-regulation tmTNF. The calcineurin inhibitor cyclosporine strongly inhibited the induction of CD36 observed with certolizumab-pegol (p=0.02), However, the inhibitor of intra-membrane clivage of tmTNF, ZLL-2, did not modify the induction of CD36 induced by certolizumab-pegol (p=0.2). Moreover a transfection of TNF-α linked with GFP in its intracytoplasmic tail failed to show any nuclear translocation in presence of certolizumab-pegol. These data demonstrated the absence of intramembrane proteolysis in reverse signalling induced by anti-TNF-α. IL-1 expression induced by LPS was significantly decreased by certolizumab-pegol, and this effect was inhibited by the calcineurin inhibitor cyclosporine A. Furthermore, TNFR2 did not play a role in the reverse signalling induced by tmTNF.

Conclusion: Certolizumab-pegol induced reverse signalling in human monocytes through tm-TNF. This resulted in increased CD36 expression,

down-modulation of IL-1 production induced byTLR4, but had no effect on TNFR2 signalling. Dephosphorylation of tmTNF as well as calcineurin activation were involved in certolizumab-pegol-induced reverse signalling. Taken together, these results suggest a role of reverse signalling in the regulation of inflammation by anti-TNF-α.

Human Gingiva-Derived Mesenchymal Stromal Cells Inhibit Graft-Versus-Host Disease Through CD39 and IDO. Song Guo Zheng[1], Maogeng Chen[1], Dong Dong Chen[2], Jian Gu[1] and Yi Shen[3]. [1]University of Southern California Keck School of Medicine, Los Angeles, CA, [2]Zhoushan Hospital at Zhejiang Province, Zhoushan, China, [3]Shanghai East Hospital at Tongji University, Shanghai, China.

Background/Purpose: We recently have reported that human-derived gingival mesenchymal stem cells (GMSC) have strong capacity to suppress immune responses and T cell-mediated collagen-induced arthritis, however, it is unclear whether these cells can suppress human T cell-mediated diseases. In this project, we have developed a humanized animal model to investigate the interventional role of human GMSC in xeno-GVHD model, which is a best animal model to study human cell therapy prior to clinical trial.

Methods: Human gingival tissues were gained from discard samples from the patients who underwent dental operation. GMSC were isolated and grown from gingival tissues and cultured in α-MEM with 10%FBS for 3–6 generations. GMSC were harvested and added to human CD25 depleted CD3+ T cells for the co-culture with 0.025ng/ml anti-human CD3 antibody for in vitro suppression test. To determine the relative molecular mechanisms, various inhibitors and antagonists were added to the cultures. In vivo, sub-lethally irradiated NOD mice were given 2×10^7 peripheral blood mononuclear cell (PBMC) intravenously (IV) without (PBMC group) or with 2×10^6 GMSC (PBMC + GMSC group), while other NOD mice received 2×10^6 nTreg (PBMC + nTreg group) or 2×10^6 human fibroblast cell (PBMC + Fibroblast) for the controls. The levels of cytokines and IgG in mouse serum were measured by ELISA. Mice weight was measured twice a week and survival was monitored.

Results: We showed that GMSCs potently suppress the proliferation of human PBMC in vitro independent of cell contact. GMSC also suppress Th1, Th2 and Th17 cell differentiation. Co-transfer of human PBMC and GMSC significantly suppress IFN and IgG production, maintained weight and prolonged the mouse survival. In contrast, the adoptive transfer of human fibroblast cells did not suppress xeno-GVHD. Moreover, we demonstrated that GMSCs suppress xenogenic response of human PBMCs via CD39 and IDO signals.

Conclusion: Human GMSCs can suppress human immune responses and immune system-mediated diseases, offering a pre-clinical option to be used for modulating GVHD and other autoimmune diseases.

Proteomic Analysis Of Connexin 43 Reveals Association With Proteins Dysfunctional Related With Osteoarthrosis. Patricia Fernández-Puente[1], Raquel Gago-Fuentes[1], Paula Carpintero-Fernández[2], Jesús Mateos[2], Maria Dolores Mayan[3] and Francisco J. Blanco[4]. [1]These authors contribute equally to this work, A Coruña, Spain, [2]Osteoarticular and Aging Research Group. Rheumatology Division, Biomedical Research Center (INIBIC). Hospital Universitario A Coruña, Xubias de Arriba 84, 15006, A Coruña, Spain, [3]Correspondence to: Ma.Dolores.Mayan.Santos@sergas.es and fblagar @sergas.es, A Coruña, Spain, [4]Osteoarticular and Aging Res. Lab. CIBER-BBN. INIBIC- University of A Coruña, A Coruña, Spain.

Background/Purpose: Human adult articular cartilage is composed of a dense extracellular matrix and specialized cells called chondrocytes. The chondrocytes are found to their own lacuna and remain in resting stage refraining form proliferation but displaying a moderate metabolic activity to maintain their surrounding matrix during the whole adult life. We have previously found that human adult chondrocytes express the gap junction (GJ) protein connexin 43 and chondrocytes in tissue have long cytoplasmic arms that physically connect two distant cells. The interaction of proteins with the C-terminal tail of Cx43 directly modulates different cellular activities such as cell growth and proliferation.

Methods: Chondrocytes were isolated by sequential digestion with trypsin-EDTA and Collagenase. Isolated cells from healthy and cartilage from osteoarthritis (OA) patients were maintained for stable short-term cell culture in DMEM supplemented with primocin and 15% FCS. Co-immunoprecipitation (IP) experiments were performed to identify the proteins that interact with the C-Terminal tail of Cx43. In-gel digestion of immunoprecipitated proteins separated by SDS-PAGE were analysed using the nano-liquid chromatography (Nano-LC, Eksigent) coupled to mass spectrometry (MALDI-TOF/TOF, Applied Biosystem). The identification of proteins was performed using ProteinPilot™ 3.0 Software. Samples were evaluated by SDS-PAGE followed by Western blotting with specific antibodies.

Results: A total of 123 were identified, of which 68 proteins were represented by at least two unique peptides. 118 proteins were specific to the Cx43 IP, not identified in the control IP performed without antibody. Identified interactors show significant enrichment for Gene Ontology (GO) processes directly linked with cytoskeleton dynamics (vimentin, a/b-tubulin or profiling-1), metabolic pathways (enolase, aldolase or GAPDH), nuclear activity (histones, nucleolin and other nucleoar proteins) and translation (several ribosomal and ribosomal-related proteins). IHC experiments showed that chondrocytes from OA patients in cartilage contain higher levels of Cx43 in the nucleus, the cytoplasm and membrane. However Cx43 was only found in the membrane of healthy chondrocytes in tissue. GO terms of proteins identified in OA samples showed an enrichment of Cx43-interactors related with cell adhesion, calmoduling binding, nucleolus or cytoskeleton related proteins in OA samples regards to healthy. However the mitochondrial proteins SOD2 or ATP5J2 were only identified in samples from healthy donors.

Conclusion: Mass-spectrometry results revealed novel functional Cx43 interactors involved in human disease and OA development emphasizing the importance of Cx43-interactions for normal development and physiology. Besides IHC experiments suggest that Cx43 interacts with nuclear and translational components especially in OA cartilage. The interaction of Cx43 with mitochondrial proteins may be involved in ischemic preconditioning as occur in other cell types.

The Bromodomain Protein Inhibitor I-BET151 Suppresses Inflammatory and Matrix Degrading Properties Of Rheumatoid Arthritis Synovial Fibroblasts. Kerstin Klein[1], Renate E. Gay[1], Christoph Kolling[2], Lih-Ling Lin[3], Steffen Gay[1] and Caroline Ospelt[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Schultess Clinic, Zurich, Switzerland, [3]Pfizer, Cambridge, MA.

Background/Purpose: Bromodomain proteins (BRD) contain conserved acetyl-lysine binding domains that specifically recognize ϵ-N-lysine acetylation motifs, a key event in the reading process of epigenetic marks. Recently, a functional role of the BET bromodomain proteins BRD2, BRD3, and BRD4 in inflammation was described and BET inhibitors were shown to inhibit the expression of pro-inflammatory cytokines and chemokines in LPS-stimulated macrophages (Nicodeme et al., Nature. 2010). Our objectives were to evaluate the expression of the BET proteins BRD2, BRD3 and BRD4 in rheumatoid arthritis synovial fibroblasts (RASF) and to investigate the effects of the BET protein inhibitor I-BET151 on expression levels and functional properties of RASF.

Methods: The mRNA expression levels of BRD2, BRD3 and BRD4 in RASF and osteoarthritis synovial fibroblasts (OASF) were verified by quantitative Real-time PCR. RASF were treated with the inflammatory cytokines TNF-α (10 ng/ml), IL1β (1 ng/ml) and the Toll-like receptor (TLR) ligands Pam3 (100 ng/ml), pIC (10 μg/ml), and LPS (100 ng/ml) in presence or absence of I-BET151 (1 μM, R&D Systems) for 24h. The mRNA expression levels and secretion rates into cell culture supernatants of MMP1, MMP3, IL6, IL8 and CCL5 were evaluated by quantitative Real-time PCR and ELISA. Rates of proliferation and migratory properties of RASF before and after I-BET151 treatment were investigated using a BrdU-based proliferation assay and scratch assays, respectively.

Results: BRD2 (delta Ct: OASF: 5.93 $\pm$ 0.22; RASF: 5.47 $\pm$ 0.47; $p<0.01$) and BRD3 (delta Ct: OASF: 7.94 $\pm$ 0.67; RASF: 7.27 $\pm$ 0.56; $p<0.01$) mRNA levels were slightly increased in RASF (n=20) compared to OASF (n=10). On the other hand, BRD4 mRNA levels were similar in

OASF and RASF (delta Ct: OASF: 4.94 ± 0.26; RASF: 4.95 ± 0.36). Treatment of RASF (n=12) with I-BET151 significantly reduced basal IL6 mRNA levels ($p<0.001$), as well as the mRNA expression levels of IL6, IL8, MMP1, MMP3 and CCL5 after stimulation with cytokines and TLR ligands ($p<0.05$). Furthermore, basal IL6 and IL8 secretion rates were decreased after I-BET151 treatment of RASF (n=10–12) by 75.9% ($p<0.01$) and 39.4% ($p<0.01$), respectively. Both, IL6 and IL8 secretion rates remained decreased after I-BET151 treatment of RASF (n=9–12, $p<0.01$) after stimulation with cytokines and TLR ligands between 53.6 and 79%. Whereas I-BET151 significantly reduced MMP1 secretion rates only after TNF-α (71.5%, $p<0.01$), IL1β (75.6%, $p<0.01$) and pIC (32.8%, $p<0.05$) (n=12), MMP3 levels in supernatants (n=12) were reduced after stimulation with all cytokines and TLR ligands by 29.5–82.2% ($p<0.05$). CCL5 secretion was reduced in I-BET151 treated RASF (n=6) by 51.3–67.2%, depending on the stimuli. Furthermore, rates of proliferation were reduced by 61.4 ± 14.3 % ($p=0.0625$) in RASF (n=5) treated with I-BET151, whereas migratory properties of RASF (n=2) were not affected.

Conclusion: Our results demonstrate that I-BET151 is a strong suppressor of the inflammatory, matrix degrading and proliferating properties of RASF and suggest a therapeutic potential of blocking the recruitment of BET proteins to promoters of target genes in RA.

Adenosine 2A Receptor Promotes Collagen Production By Human Fibroblasts Via Smad2/3-Independent Pathways Involving Cyclic AMP and AKT. Miguel Perez-Aso[1], Patricia Fernandez[2], Aranzazu Mediero[3], Edwin SL Chan[1] and Bruce N. Cronstein[4]. [1]New York University School of Medicine, New York, NY, [2]National Cancer Institute, NIH, Bethesda, MD, [3]NYU School of Medicine, New York, NY, [4]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Activation of Adenosine 2A Receptors ($A_{2A}R$) promotes fibrosis and collagen synthesis. However, the underlying mechanism by which $A_{2A}R$ stimulate collagen synthesis is still unclear. Previous reports indicate that cAMP, principal effector of the $A_{2A}R$, inhibits Transforming Growth Factor β1-induced collagen synthesis and has been proposed as an anti-fibrotic mediator.

Methods: Primary Human Dermal Fibroblasts (NHDF) were stimulated with increasing concentrations of the $A_{2A}R$ agonist CGS21680 or the direct adenyl cyclase (AC) activator forskolin, and results were compared to the well-known profibrotic agent TGF-β1. cAMP intracellular levels and proliferation were measured and collagen1 (Col1), collagen3 (Col3), MAPK and Smad2/3 expression were assessed by western blotting. The role of MAPK and Smads in regulating collagen synthesis was studied by use of specific inhibitors and knock-downs with siRNA.

Results: $A_{2A}R$ stimulation with CGS21680 elicited a modest cAMP increase (150.3±11% of control; $P<0.01$, n=5) which stimulated both Col1 (194.3±28% of control; $P<0.01$, n=8) and Col3 (178.4±9.8% of control; $P<0.001$, n=10) synthesis, but higher cAMP concentrations resulting from direct activation of AC by forskolin (15688±7038% of control; $P<0.01$, n=3) inhibited Col1 production (41±2% inhibition; $P<0.001$, n=3). Surprisingly, Col3 expression was increased at maximal cAMP levels (218.7±38.5% of control; $P<0.05$, n=3). Similar to Col1 expression, fibroblast proliferation increased following physiologic increases in cAMP levels induced by $A_{2A}R$ stimulation (164.7±20.8% of control; $P<0.05$, n=4) but was inhibited by greater cAMP increases resulting from forskolin incubation (26±2% inhibition; $P<0.05$, n=3). The $A_{2A}R$-mediated increase of Col1 and Col3 was mediated by an AKT-dependent pathway as shown in a dose-response of CGS21680 in the presence of two AKT inhibitors LY294002 and wortmannin (two-way ANOVA Col1: $P<0.001$, n=5 for both inhibitors; Col3: LY294002 $P<0.001$, n=5 and wortmannin $P<0.01$, n=4) while Col3, but not Col1, expression was dependent on p38MAPK activation (p38 inhibitor SB20358: two-way ANOVA $P<0.01$, n=3) and repressed by ERK (ERK1/2 siRNA: two-way ANOVA $P<0.05$, n=4). Transforming Growth Factor β1 strongly induced phosphorylation of Smad2 (426.3±136% of control; $P<0.001$, n=3) and Smad3 (1530.3±268% of control; $P<0.001$, n=3) and increased Col3 expression was prevented by Smad3 depletion (after Smad3 silencing: control *vs* CGS21680 P=non significant, n=3), whereas CGS21680 did not induce phosphorylation of either Smad2 (P=non significant, n=3) or Smad3 (P=non significant, n=3), and Smad2/3 knockdown did not prevent CGS21680-induced Col1 or Col3 increases.

Conclusion: Our results indicate that cAMP is an all-or-none intracellular switch for collagen production via the non-canonical Smad2/3-independent AKT-dependent pathway, which provides an attractive explanation for the paradox that $A_{2A}R$ induces pro-fibrotic signals via cAMP in dermal fibroblasts.

Adenosine A2A Receptors (A2AR) Promote Scarring By Repressing Mir-29a. Ross C. Radusky[1], Miguel Perez-Aso[1], Andrew G. Franks Jr.[2], Bruce N. Cronstein[3] and Edwin SL Chan[1]. [1]New York University School of Medicine, New York, NY, [2]New York University, New York, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: We have previously demonstrated that the nucleoside adenosine stimulates collagen production and induces dermal fibrosis *in vitro* and *in vivo*. Recent studies have demonstrated the presence and significance of microRNAs in various disease conditions and, in fibrosing conditions, diminished levels of miR-29a are found in the skin and other organs that have undergone fibrosis. We therefore determined whether adenosine A2AR stimulation regulates the expression and levels of miR29a in skin at fibrotic sites.

Methods: In this investigation, human dermal fibroblasts were treated with the A2AR specific agonist (CGS21680). Changes in miR-29a, collagen1 and collagen3 expression were analyzed by real-time PCR. An *in vivo* model of hypertrophic scarring previously described (Perez-Aso et al. 2012) was used to analyze the impact of A2AR pharmacological blockade with the specific A2AR antagonist ZM241385 on miR-29a expression in the skin: 12mm incisional wounds were splinted to promote chronic scarring in a total of 32 C57BL/6 mice. Mice were topically treated with either the A2AR antagonist or vehicle (3% carboxymethylcellulose and 7.4% DMSO) alone as a control. Scar progression was quantified using trichrome staining for collagen deposition.

Results: In *in vitro* studies A2AR stimulation with increasing concentrations of CGS21680 (0.01, 0.1 and 1μM) reduced the expression of miR-29a (table 1) and the A2AR agonist CGS21680 (1μM) stimulated an increase of both collagen1 and collagen3 (table 2). *In vivo* investigation yielded parallel results. Trichrome stains revealed that collagen deposition in the scar was reduced by topical application of the A2AR antagonist ZM241385 (2.5mg/ml). Changes in miR-29a expression in the scar were analyzed at the end of the investigation. Scarring decreased miR-29a expression by 46.3±4.8%; ($P<0.001$ *vs* unwounded skin, n=7) and A2AR blockade with the antagonist ZM241385 stimulated a dramatic increase of miR29a (191.7±4.8% of unwounded skin; ZM241385 *vs* vehicle $P<0.01$, n=7).

Table 1.

CGS21680 (μM)		0.01		0.1		1
miR-29a inhibition (%)	28.3	57.5	32.9	50.5	11.1	46

Table 2.

Collagen 1 (% of control)	143.3	252.3
Collagen 3 (% of control)	282.2	218.9

Conclusion: The findings of the present work indicate that A2AR activation represses miR-29a *in vitro* and, in a similar fashion, *in vivo*. These findings indicate that targeting A2AR may be a novel therapeutic target in scleroderma that mediates its action, at least in part, by diminishing miR29a, in promoting wound healing and preventing pathologic fibrosis such as that observed in hypertrophic scarring or scleroderma.

Functions Of Aminopeptidase N/CD13 *In Vitro* On Rheumatoid Arthritis Synovial Cells. Rachel Morgan[1], Nilofar Behbahani-Nejad[1], Judith Endres[2] and David A. Fox[3]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Medical Center, Ann Arbor, MI, [3]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: Aminopeptidase N (CD13, EC 3.4.11.2) is a metalloproteinase expressed on the surface of fibroblast like synoviocytes (FLS) that is also found in soluble form in serum and synovial fluid. We have shown that CD13 can be released from FLS in culture, and that CD13 is higher in amount and activity in Rheumatoid arthritis (RA) synovial fluids compared to osteoarthritis (OA). Recombinant human CD13 (rhCD13) can act as a chemokine for cytokine activated T cells (Tck), and it has been previously suggested but not proven that CD13 may contribute to the T cell chemotactic activity of synovial fluid. The goal of this study was to determine potential functions of CD13 in the RA joint by examining its effects on migration of T cells and FLS.

Methods: Tck were generated using IL-6, TNFα, and IL-2. Tck chemotaxis was measured using an under agarose system. Synovial fluids were immunodepleted with 591.1D7.34 (an anti-CD13 antibody developed in our laboratory) bound to agarose beads. FLS cell growth and migration were measured using an Incucyte (Essen Biosciences) imaging system. Growth was measured by confluence and migration by relative wound density. FLS were grown in 20% CMRL and switched to 10% media for assays.

Results: Pertussis toxin treatment of the Tcks prior to chemotaxis significantly reduced positive chemotaxis toward 200ng/ml rhCD13 either with a fibronectin coating ($p=0.047$) or without ($p=0.00096$), and also inhibited migration toward SDF/CXCL12 and TARC/CCL17 positive controls. Immunodepletion of synovial fluids significantly reduced chemotaxis across an uncoated surface compared to mock depleted fluids, Chemotactic Index (CI=Ln # of cells toward the chemokine – Ln # of cells toward media control) was 0.56 ± 0.21 versus -0.045 ± 0.21 $p=0.047$ pre- versus post-immunodepletion. Immunodepletion of CD13 reduced CI across a fibronectin coating, from 1.12 ± 0.43 to 0.31 ± 0.50, however it was not statistically significant. Addition of 200ng/ml rhCD13 to the depleted synovial fluids partially restored the depleted activity. Treatment of FLS with anti-CD13 mAbs 1D7 or WM15 (50ng/ml) or the chemical inhibitors, bestatin (100μM) or actinonin (10μM) significantly decreased FLS confluence at time points from 24–120hours. CD13 inhibitors were also able to significantly decrease FLS migration in a wound healing assay. Actinonin (10μM) and 1D7 (25ng/ml) both slowed migration so that wound healing was significantly lower at 48hr, while WM15 (25ng/ml) showed a significant difference by 24hr. Bestatin, however, had no significant effect on FLS migration. Addition of rhCD13 was not able to further increase cell growth or wound healing beyond FLS alone.

Conclusion: Together this data demonstrates multiple pathways by which CD13 may contribute to RA pathogenicity. CD13 significantly contributes to the chemotactic ability of synovial fluids for a population of T cells similar to those found in the RA joint. This process is mediated through a G-protein coupled receptor. Increased levels of CD13 in the RA joint may also contribute to synovial tissue hyperplasia by increasing FLS proliferation and migration.

The Involvement Of Mast Cells In The Development Of Lung Fibrosis Via Modulating Pulmonary Fibroblast Immune Function. Shinjiro Kaieda[1], Morihisa Tajiri[2], Masaki Okamoto[2], Naomi Yoshida[2], Hiroaki Ida[2], Tomoaki Hoshino[2] and Takaaki Fukuda[3]. [1]Kurume University School of Medicine, kurume, Japan, [2]Kurume University School of Medicine, Kurume, Japan, [3]Kurume University Medical Center, Kurume, Japan.

Background/Purpose: Idiopathic pulmonary fibrosis (IPF) is an interstitial lung disease of unknown etiology; the most critical event in the evolution of fibrosis is the appearance of activated myofibroblasts. Mast cells (MC) mediate a variety of inflammatory and fibrotic conditions, but their role in IPF is unclear. We examined whether MCs play a critical role in the development of pulmonary fibrosis.

Methods: Lung tissue was examined using histology and immunohistochemistry. Bioptic material was obtained from the involved lung tissue of 18 IPF patients. As control samples, we used 8 noncancerous lung sections from patients who had undergone surgery for lung cancer. We used immunohistochemistry to identify and quantify tryptase-positive MCs, prolyl-4-hydroxylase β-positive fibroblasts, and alpha-smooth muscle actin (α-SMA)-positive myofibroblasts. Co-culture of human mast cell line 1 (HMC-1) with pulmonary fibroblasts was performed in a transwell system. Fibroblasts cultured with HMC-1 cells for 7 days were cytospun and expression of α-SMA, a marker of myofibroblast differentiation, was examined by immunohistochemistry. α-SMA gene (Acta2) expression in fibroblasts, and IL-6, TGF-β, and bFGF in HMC-1 cells and fibroblasts were evaluated by RT-qPCR.

Results: MCs were significantly more numerous in IPF than control lung tissue. MCs were usually in close proximity to pulmonary fibroblasts and myofibroblasts. Up-regulation of α-SMA in fibroblasts during co-culture with MCs was confirmed by immunohistochemistry; Acta2 mRNA was also significantly elevated. In co-cultures of fibroblasts and HMC-1 cells, IL-6, TGF-b, and bFGF expression increased in the HMC-1 cells and IL-6 and TGF-b expression increased in the fibroblasts. These observations suggest an amplification loop is generated between MCs and fibroblasts, enhancing production of pro-fibrotic factors.

Conclusion: These findings suggest a novel role for MCs in the development of lung fibroblasts via induction of myofibroblast differentiation. An amplification loop between MCs and fibroblasts enhances production of pro-fibrotic factors including TGF-b and bFGF, which may contribute to myofibroblast differentiation and activation.

IL-6 Promotes Systemic Bone Loss Via Upregulation Of S1PR2 In Osteoclast Precursors In a Mouse Collagen-Induced Arthritis Model. Keisuke Tanaka, Misato Hashizume, Hiroto Yoshida, Miho Suzuki and Yoshihiro Matsumoto. Chugai Pharmaceutical Co., Ltd., Gotemba, Japan.

Background/Purpose: Systemic bone loss is a hallmark of rheumatoid arthritis (RA). Inflammatory cytokines such as interleukin-6 (IL-6) promote bone resorption by osteoclasts. Recent studies have shown that sphingosine-1-phosphate (S1P) controls the migration of osteoclast precursors (OCPs) between the blood and bone marrow, in part via S1P receptor 1 (S1PR1) and S1PR2 expressed on the surface of OCPs. It has been reported S1PR1 directs positive chemotaxis along an S1P gradient, and S1PR2 inhibits S1PR1 function and mediates negative chemotaxis in the direction of S1P. The purpose of this study was to investigate whether IL-6 regulates the expression of S1PR1 and S1PR2 and whether it has any influence on the localization of OCPs during the course of bone loss.

Methods: DBA/1J mice were immunized with bovine type II collagen (Day 0 and Day 21), and anti-mouse IL-6 receptor antibody (MR16-1) was administered intraperitoneally on the same days. On Day 14 or Day 35, femurs were excised and the trabecular bone volume of the distal femur was analyzed using micro-computed tomography. The percentage of OCPs ($CD11b^{+}Gr\text{-}1^{low+med}$) in the tibial bone marrow was measured by flow cytometry. S1PR1 and S1PR2 mRNA expression in OCPs from immunized mice was measured by real-time PCR. For in vitro study, OCPs were isolated from normal DBA/1J mice bone marrow by using a cell sorter, and were stimulated with IL-6. S1PR1 and S1PR2 mRNA expression in these OCPs was measured by real-time PCR. S1P-directed chemotaxis of OCPs was evaluated by using a transwell plate.

Results: Trabecular bone volume was significantly lower in immunized mice than in non-immunized control mice on Day 35. Treatment of immunized mice with MR16-1 inhibited trabecular bone loss. The percentage of OCPs in tibial bone marrow was significantly higher and the mRNA expression of S1PR2 in OCPs was significantly higher in immunized mice than in control mice on Days 14 and 35. S1PR1 mRNA expression in OCPs from immunized mice did not differ from expression in non-immunized control mice. In MR16-1 treated mice, the percentage of OCPs and S1PR2 mRNA expression were each decreased compared with that in immunized mice on Day 14 but not on Day35. IL-6 induced S1PR2 mRNA expression in OCPs in a dose-dependent manner but did not induce S1PR1 mRNA expression. IL-6 stimulation significantly decreased S1P-directed chemotaxis of OCPs.

Conclusion: These results demonstrate that IL-6 increases the percentage of OCPs in tibial bone marrow by upregulating S1PR2, and thereby plays a crucial role in systemic bone loss induced by inflammation.

Potentiating Effects Of IL-17A, IL-17AF, IL-17F In Combination With TNF But Not With IL-1beta In Human Primary Fibroblast-Like Synoviocytes From Rheumatoid Arthritis Patients. Christine Huppertz[1], Marija Curcic Djuric[1], Robert Hennze[1], Friedrich Raulf[1], Frank Kolbinger[1], Anis Mir[1] and David Lee[2]. [1]Autoimmunity, Transplantation and Inflammatory Disease, Novartis Institutes for BioMedical Research, Novartis Pharma AG, Basel, SWITZERLAND, Basel, Switzerland, [2]Novartis Pharma AG, Basel, Switzerland.

Background/Purpose: The pro-inflammatory cytokine interleukin-17A (IL-17A) activates fibroblast-like synoviocytes (FLS) and other mesenchymal cells via the IL-17RA/RC receptor. FLS are a major source of inflammatory cytokines, chemokines and growth factors in the inflamed synovium in rheumatoid arthritis (RA) and thus contribute to disease perpetuation. Since the macrophage products TNF and IL-1β play an important role in the pathogenesis of RA, we wanted to better understand if IL-17 cytokines augment the effects of TNF or IL-1β on FLS derived from RA patients (RA-FLS) in modulating the expression of inflammatory FLS products and IL-17RA and RC expression. Furthermore, we compared the co-stimulatory effects of IL-17A, the founding member of the IL-17 cytokine family, with the less characterized but closely related cytokines IL-17AF and IL-17F.

Methods: The ability of IL-17A, IL-17-AF and IL-17F to co-stimulate mediator expression in comparison to single TNF or IL-1β stimulation was determined in criss-cross titrations of RA-FLS, and a panel of pro-inflammatory mediators including IL-6, IL-8, CXCL-1, CCL2, PGE2 and GM-CSF was determined by protein (18h) or mRNA levels (RT-PCR or Affymetrix chips analyses, upon 2, 6, 18 or 24h stimulation). Basal IL-17RA and RC expression and the effects of cytokine stimulation on receptor expression were measured by flow cytometry and quantitative RT-PCR. RA-FLS cell lines were obtained from Cell Application Inc.

Results: When tested as single stimulus *in vitro*, IL-1β was the most potent cytokine to induce the release of IL-6 and other mediators, followed by TNF. IL-17 cytokines caused only minor elevation over basal levels if used alone. Combination of IL-1β and IL-17A showed no potentiating effect on either protein or mRNA levels of IL-6, IL-8, CXCL-1, CCL2, PGE2/Cox2 and GM-CSF. In contrast, combining IL-17A with TNF, resulted in significant potentiation of IL-6, IL-8, CXCL-1, PGE2 and GM-CSF. Interestingly, this potentiation is selective as CCL2 (MCP-1) release was only dependent on TNF, indicating a different mechanism for regulation of the latter. The closely related cytokine IL-17F and the heterodimer IL-17AF showed strikingly different potencies for co-stimulation of RA-FLS with TNF, with ranking IL-17A> IL-17AF>IL-17F. To further explore the underlying mechanism of potentiation of TNF+IL-17, we examined IL-17 receptor expression on RA-FLS. Interestingly, cytokine stimulation did not upregulate the expression of IL-17RA or IL-17RC.

Conclusion: Our data show that IL-17 cytokines synergistically potentiate the effects of TNF on RA-FLS to release pro-inflammatory mediators. All three IL-17 cytokines have pro-inflammatory effects but differ in the respective potencies (IL-17A>IL-17AF>IL-17F). Combination of IL-1β and IL-17 showed no potentiation but was only additive.

1857

Identification Of SOX5 and SOX6 As Potent Regulators Of *RANKL* Expression Contributing To Bone Erosion In Rheumatoid Arthritis and Experimental Arthritis Model. Wenfeng Tan[1], Xiaoke Feng[2], Lingxiao Xu[3], Ke Gan[1], Fang Wang[3], Miaojia Zhang[4], Hui Wu[5] and Betty P. Tsao[6]. [1]the First Affiliated Hospital of Nanjing Medical University, Nanjing, China, [2]the First Affiliated Hospital of Nanjing Medical University, China, Nanjing, China, [3]the First Affiliated Hospital of Nanjing Medical University, Nanjing, CHINA., Nanjing, China, [4]Department of Rheumatology, Jiangsu Provincial People's Hospital, Nanjing, China, [5]David Geffen School of Medicine University of California Los Angeles, Los Angeles, CA, [6]UCLA School of Medicine, Los Angeles, CA.

Background/Purpose: We previously reported a *RANKL*promoter SNP confers an elevated promoter activity after stimulation via binding to a SOX family transcription factor SOX5 and is associated with younger age at onset of rheumatoid arthritis (RA). Here, we examine the expression of SOX family in RA patients and to elucidate their potential role in RA pathogenesis.

Methods: SOX expression levels in PBMC, plasma, and synovium were tested using RT-PCR, ELISA and immunohistochemistry. RNA interference and immunoprecipitation were used to determine the role of SOX5 and 6 on cytokine mediated *RANKL*expression. Effect of SOX5 and 6 on bone erosion was analyzed using collagen-induced arthritis (CIA) model.

Results: Among the 9 *SOX* family genes, expression of *SOX5* and *SOX6* were robust in 42 RA PBMC and 20 RA synovium smples. Compared to 40 osteoarthritis (OA) and 40 healthy controls (HC) samples, increased expression of *SOX5* and *6* were observed consistently in PBMC ($p<0.05$, respectively), plasma ($p=0.0002$,$p=0.0378$, respectively) and synovium ($p=0.0205$,$p<0.0001$, respectively) from RA patients. Both SOX5 and 6 could be co-immunoprecipitated with Mab specific to RANKL upon TNFα and IL6 stimulation of rheumatoid fibroblast-like synoviocytes MH7A. An increase in RANKL expression was observed in MH7A after TNFα and IL6 treatment. Transfectiom with SOX5 and/or SOX6-shRNA significantly downregulated cytokine-mediated RANKL upregulation in MH7A. Intra-articular injection of lentivirus expressing shRNA for SOX5 and/or 6 gene silenced RANKL expression, suppressed arthritic development, and markedly ameliorated bone erosion inDAB/1mice of a CIA model.

Conclusion: These findings identify SOX5 and 6 as potential targets for inhibition *RANKL* expression and preventing bone erosion in RA.

1858

Investigating The Role Of IL-22 In The Pathogenesis Of Familial Mediterranean FEVER. Dilek Keskin[1], Goksal Keskin[1], Ali Inal[2] and Lale Ozisik[2]. [1]DYB Research and Training Hospital, Ankara, Turkey, [2]MD, Ankara, Turkey.

Background/Purpose: Familial mediterranean fever (FMF) is a familial disease characterized by recurrent episodes of febrile serositis, peritonitis, arthritis andpleuritis. Many studies have been performed as an attempt to understand the basis of the inflammatory attacts in FMF. During the acute attacts, neutrophil accumulation, elevations in acute phase reactant levels, several non specific immunological abnormalities and increased several proinflammatory cytokines, such as IL-1, IL-8, IL-6 and TNF-alpha have been described.

Th 17 cells are a new class of T-cells involved in a wide range of inflammatory disease. Th17 cells are characterized by production of IL-22 and are known to be key participants in various inflammatory disease, such as, BD, crohn'disease, sarcoidosis. IL-22 acts synergistically with TNF alpha, IL-1 beta or IL-17 and induces acute phase reactants. These findings indicate that IL-22 represents a novel type of immune mediator that is produced by immune cells which regulates tissue protection and homeostasis. So the aim of this study was to investigate the role of serum IL-22 levels in patients with FMF.

Methods: Fifty-seven patients with FMF and 18 healthy controls (8 female, 10 male; mean age 33.7 $\pm$ 2.9 years) were enrolled in this study. Thirty-nine patients were in active stage (17 female, 22 male, mean age; 31.7 $\pm$ 3.1 years, mean disease duration 6.3 $\pm$ 2.8 years) and 18 patients were in inactive stage (9 female,9 male, mean age; 34.7 $\pm$ 4.9 years, mean disease duration; 8.1 $\pm$ 4.3 years). Serum IL-22 levels were determined by ELISA.

Results: In active patients, the mean ESR was 41.9 $\pm$ 8.2 mm/h, the mean serum CRP level was 28.6 $\pm$ 6.8 mg/L and the mean serum fibrinogen level was 514.3 $\pm$ 88.3 mg/dl. In inactive patients, the mean ESR was 18.3 $\pm$ 4.7 mm/h, the mean serum CRP level was 2.4 $\pm$ 1.6 mg/L and the mean serum fibrinogen level was 197.3 $\pm$ 62.9 mg/dl. The mean serum IL-22 levels were 56.4 $\pm$ 8.5 pg/ml in patients with FMF and 21.7 $\pm$ 3.9 pg/ml in healthy controls. The mean serum IL-22 levels were 73.5 $\pm$ 7.9 pg/ml in active patients and 38.2 $\pm$ 8.3 pg/ml in inactive patients.

According to this result; serum IL-22 levels were significantly high in patients with FMF compared to healthy controls ($p<0.001$). Serum IL-22 levels were significantly high in active patients compared to inactive patients and healthy controls ($p<0.001$ and $p<0.001$ respectively).

In active FMF patients, although the mean serum IL-22 level was correlated with the mean serum fibrinogen level ($r=0.508$ $p=0.027$) and serum CRP level ($r=0.482$, $p=0.039$), the mean serum IL-22 level was not correlated with ESR ($r=0.334$, $p=0.085$).

Conclusion: The high levels of serum IL-22, in active and inactive patients with FMF suggest that IL-22 may play a significant role of in the pathogenesis of FMF.

1859

OX40$^+$ T Cells and OX40L$^+$ B Cells Accumulate In The Inflamed Joints and OX40 Signalling Is Skewed Towards Autoreactivity. Julie Kristine Laustsen[1], Tue Rasmussen[2], Malene Hvid[2] and Bent Deleuran[3]. [1]Aarhus University, Aarhus N, Denmark, [2]Aarhus University, Aarhus, Denmark, [3]Aarhus University Hospital, Aarhus, Denmark.

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by the presence of autoantibodies and autoreactive T cells, leading to synovitis and joint destruction. The TNF-family members OX40 and OX40L are crucial for the generation of memory T cells, which can lead to persistence of immunity, but also autoreactivity. Both molecules exist in soluble isoforms and sOX40 has been suggested to be antagonistic to the membrane bound isoform. Signals through the OX40 receptor leads to AKT phosphorylation, thereby leading to increase of anti-apoptotic signals and maintenance of the memory response, while signals through the OX40L are mediated by ERK, which upregulates survival signals in a similar manner. Objectives of the study was to investigate the bioactivity and levels of OX40 and OX40L in RA

Methods: Paired PBMCs and SFMCs from 12 RA patients were compared with PBMCs from 6 healthy volunteers (HV). Cells were stained with anti-OX40 and anti-OX40L and the cell markers CD4 and CD45RO and analysed by flow cytometry. To determine the activation pathways, cells were stimulated with sOX40 and sOX40L in a time dependent setup, followed by intracellular staining with anti-AKT and anti-ERK antibody. Phosphorylation status were analysed by phosphoflow.

Results: In the blood, increased expression of OX40 observed by memory T cells (CD4+CD45RO+) from RA patients (11.7% (5.8%-13.30%)) compared with HV (4.9% (2.8%-6.0%)), $p<0.05$. Furthermore, OX40+ memory T cells accumulated in the SF of RA patients (17.0% (11.6%-30.3%) $p<0.01$). B cells from SFMC expressed significantly more OX40L (11.8% (3.2%-25.5%)) compared with the PBMCs (2.8% (0.8%-4–8%)) from RA patients and from HV (2.4% (1.6%-3.1%)) (All $p<0.05$).The unstimulated CD4+ T cells from SFMCs and PBMCs from RA patients had significantly elevated AKT phosphorylation compared with PBMCs from HV ($p<0.01$). When stimulated with CD3 alone, the CD4+ T cells from RA patients had increased AKT phosphorylation, whereas the CD4+ T cells from HV had decreased phosphorylation. When stimulated with CD3 and sOX40L together, cells from HV more than doubled their AKT phosphorylation, while the increase in AKT phosphorylation was very modest in RA patients; however, the MFI remained elevated in RA patients through all time points. The ERK phosphorylation of RA B cells was not increased upon sOX40 stimulation, indicating that bi-directional signaling in RA B cells is absent.

Conclusion: Cells expressing OX40 and OX40L accumulate in the inflamed joints of RA patients. This supports an on-going local activity of the adaptive memory responses in RA. Further, CD4+ T cells from RA patients have significantly higher AKT phosphorylation compared with HV, and thus, have up regulated anti-apoptotic signals. The absence of B cell response after sOX40 stimulation could support the antagonistic effects of this molecule.

Novel Proinflammatory Microvesicles That Carry LL-37 In Patients With Cutaneous Lupus. Ming-Lin Liu[1], Muhammad Bashir[2], Meena Sharma[1], Honghui Xu[2], Kevin Williams[3], Cynthia O. Anyanwu[4], Joyce Okawa[2] and Victoria P. Werth[5]. [1]University of Pennsylvania, Philadelphia, PA, [2]Philadelphia V.A. Hospital, Philadelphia, PA, [3]Temple University School of Medicine, Philadelphia, PA, [4]Philadelphia Veterans Affairs Medical Center, Philadelphia, PA, [5]University of Pennsylvania School of Medicine, Philadelphia, PA.

Background/Purpose: Cutaneous lupus erythematosus (CLE) refers to variants of lupus erythematosus (LE) with exclusively or predominantly skin manifestations. CLE is associated with accumulation of autoantibodies and infiltration of inflammatory cells in the skin. The underlying trigger for autoimmunity in CLE has not been definitively identified. Apoptosis, which generates apoptotic bodies and apoptotic blebs, the latter also known as membrane microvesicles (MVs), have been proposed to play a central role in autoimmune diseases, particularly when normal mechanisms for clearance of apoptotic cells, bodies and MVs are impaired. We and others have shown that apoptotic MVs exert pro-inflammatory properties. The role of MVs in CLE has not been studied. In addition, tobacco smoking has emerged as a risk factor for CLE, particularly severe and refractory forms, but the underlying mechanisms are unclear. Our recent publications showed that exposure of human monocyte/macrophages to tobacco smoke extract (TSE) provokes apoptosis and the release of potent, biologically active MVs. LL-37 is a cathelicidin antimicrobial peptide with proinflammatory properties that has been described as a soluble molecule or released with neutrophil *extracellular* traps (*NETs*), and is involved in autoimmune diseases. In the current study, we hypothesized a role for MVs in CLE in the transport of LL-37, a cathelicidin antimicrobial peptide with proinflammatory properties.

Methods: Blood and skin biopsy samples were collected from CLE patients and healthy control subjects. Platelet-free plasma was isolated by sequential centrifugation. Freshly harvested skin samples were rinsed with PBS, and then minced into small pieces in DMEM for later analysis of MVs. Cultured human HL-60 neutrophils, THP-1 monocytes, and peripheral blood monocytic ce lls (PBMCs) were treated without or with tobacco smoke extract (TSE), and then the cells were examined by fluorescent microscopy, and the cells and supernatants were analyzed with flow cytometry.

Results: We found that skin lesions of CLE patients contain MVs that carry LL-37. Flow cytometry analysis using cell-specific markers revealed that LL-37-positive MVs in CLE skin lesions are largely of neutrophil origin. In plasma, we found increased concentrations of circulating total- and LL-37-positive MVs in CLE patients, compared to healthy controls. Most importantly, we found that MVs isolated from the plasma of CLE patients can stimulate TNFα release from PBMCs. In addition, exposure of human HL-60 neutrophils, THP-1 monocytes, or PBMCs isolated from healthy volunteers to TSE significantly increased their production of total- and LL-37-positive MVs. Treatment of PBMCs or THP-1 monocytes with TSE induced the redistribution of LL-37 to the cell surface, a prerequisite for export of this molecule on membrane MVs.

Conclusion: Our studies indicate for the first time that extracellular LL-37 can be carried by MVs. These LL-37-positive MVs are present in skin lesions and the circulation of patients with CLE. Microvesicles in CLE can stimulate cytokine release from nearby inflammatory cells and may thereby contribute to cutaneous inflammation.

Neurotrophins Are Involved In Vascular Remodeling Of Giant Cell Arteritis. Kim Heang Ly[1], Alexis Régent[2], Elsa Molina[3], Sofiane Saada[3], Philippe Sindou[3], Claire Le Jeunne[4], Antoine Brezin[5], Veronique witko-Sarsat[2], Philippe Bertin[6], Francois Labrousse[1], Pierre-Yves Robert[1], Anne-Laure Fauchais[7], Elisabeth Vidal[7], Luc Mouthon[8] and Marie-Odile Jauberteau[3]. [1]Limoges University Hospital, Limoges, France, [2]Institut Cochin, INSERM U1016, CNRS UMR 8104, Université Paris Descartes, Paris, France, [3]Limoges Medical School, Limoges, France, [4]Hotel-Dieu Hospital, AP-HP, Paris, Paris, France, [5]Service d'ophtalmologie, hôpital Cochin, AP-HP, Paris, France, [6]Hôpital Dupuytren, Limoges, France, [7]Department of Internal Medicine A, Dupuytren Hospital, Limoges University Hospital, Limoges, France, [8]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France.

Background/Purpose: Giant cell arteritis (GCA) is a large-vessels vasculitis. Hhistopathological findings show cellular infiltrates, internal elastic lumina disruption and intimal hyperplasia leading to luminal stenosis. Platelet-derived growth factor (PDGF) stimulates vascular smooth muscle cells (VSMC) migration from the media to the intima initiating intimal hyperplasia. Neurotrophins (NTs) and their receptors (NTRs) belong to a family of growth factors, described in nervous system. They include the nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3). NTR include: the selective tropomyosin receptor kinase (Trk), TrkA for NGF, TrkB for BDNF and TrkC for NT-3, and a non-selective receptor p75NTR and a co-receptor, which is almost associated with p75NTR, called sortilin. NTs and NTRs are involved in cardiovascular development, blood vessel growth and VSMC functions. We hypothesized that NTs and NTRs are involved in the vascular remodeling stage of GCA.

Methods: We included consecutive patients who underwent temporal artery biopsy (TAB) for a suspicion of GCA. We develop an enzymatic digestion method to obtain VSMC from TAB (TASMC). TASMC from six GCA patients and 10 controls were used to study NT and NTR involvement in vascular remodeling of GCA.

Results: NGF, BDNF and sortilin were significantly overexpressed in GCA patients (n=22) compared to controls (n=21). NT-3 and p75NTR were only expressed in GCA patients. An overexpression of TrkB receptor was noted in GCA patients with ischemic complications. NT-3, TrkB, TrkC and sortilin trancripts were overexpressed (increase upper fivefold levels) in TASMC from GCA patients compared to controls. NTs stimulated TASMC proliferation, similarly to FCS (10%) at day 3 in both groups, this effect tended to disappear at day 4. The p75NTR blocking alone tend to decrease cell proliferation at day 3, especially in GCA patients TASMC (p=0.053). TASMC from GCA patients were significantly able to migrate in presence of exogenous BDNF in comparison to those from controls after a 24-hour exposure. Only cells from GCA were able to significantly invade matrigel chambers in presence of 10% FCS and exogenous PDGF. NGF sera concentrations were significantly higher in 30 patients with proven GCA compared to 48 controls (177 +/− 67.6 pg/mL vs 145.5 +/− 66 pg/mL, p=0.04).

Conclusion: Herein, we report for the first time, the expression and functions of NTs and their receptors, potentially involved in vascular remodelling in GCA. It is worth noting that NGF, BDNF and sortilin are significantly overexpressed in different histological layers of TA in GCA patients compared to those of controls. In addition, TrkB staining was significantly higher in TA of GCA patients with cranial ischemic events. BDNF enhances TASMC migration by binding to TrkB and p75NTR receptor. Our results provide new insight concerning NTs and their receptors in the vascular remodelling stage of GCA pathogenesis. Their overexpression could contribute to intimal hyperplasia by facilitating VSMC migration from media to intima. However further studies will be conducted to elucidate signalling pathways that allow VSMC migration in order to define new therapeutic approach in patients with GCA

Target-Directed Development Of a Proposed Biosimilar Etanercept, GP2015: Comparability Of *In Vitro* Target Binding and Pre-Clinical Efficacy and Pharmacokinetics. Antonio da Silva[1], Ulrich Kronthaler[1], Cornelius Fritsch[2], Johann Poetzl[3], Adelheid Rohde[4], Anastassia Papandrikopoulou[1], Hans-Peter Hofmann[5] and Jan Marinus Visser[1]. [1]Sandoz Biopharmaceuticals / HEXAL AG, Holzkirchen, Germany, [2]Novartis Pharma AG, Basel, Switzerland, [3]Sandoz Biopharmaceuticals/Hexal AG, Oberhaching, Germany, [4]Sandoz Biopharmaceuticals/Hexal AG, Kundl, Austria, [5]Sandoz Biopharmaceuticals/Hexal AG, Holzkirchen, Germany.

Background/Purpose: Biosimilars are copy versions of existing biologic medicines that have lost patent exclusivity and are approved via stringent regulatory pathways. Biosimilars are designed to be similar to their reference medicinal product (originator) and can contribute to savings for health care systems that can be used to treat more patients or fund novel therapies. Development of a biosimilar involves extensive characterization of the originator product and a target-directed iterative development process to ensure a product is highly similar to the reference medicinal product. During this process, product specific post-translational properties were engineered into GP2015, a proposed biosimilar etanercept (p75TNF-R IgG1 Fc-fusion protein), to ensure similarity in functional/structural relationships with the approved reference medicinal product etanercept. At *in vitro* level, we show comparable binding affinities of both products to TNFα and FcR, as well as functional inhibition of TNFα and LTα. Data from pre-clinical models confirm *in vivo* comparability for the proposed biosimilar etanercept GP2015, in terms of PK and efficacy.

Methods: By employing surface plasmon resonance, the binding of GP2015 to TNFα and to a panel of Fc-receptors that may impact on pharmacokinetics and effector functions, was determined and compared. Bioactivity of GP2015 was measured as functional neutralization of TNFα or TNFβ in an NFκB-dependent luciferase reporter gene assay. *In vivo* efficacy was assessed in a human TNF transgenic mouse model of polyarthritis. Comparative pharmacokinetics (PK) was assessed in a single dose study in rabbits (8 mg/kg) and a multiple dose (10 s.c. administrations of 15 mg/kg over 4 weeks) study in cynomolgus monkeys.

Results: Comparative *in vitro* binding data of GP2015 and the reference medicinal product showed comparable high-affinity binding to TNFα, and similar binding affinities to the tested panel of Fc receptors within the pre-established values for the reference product. Biological neutralization of TNFα- and LTα-mediated cellular responses also displayed an overlapping pharmacological potency over a wide dose-response range. Preclinical evaluation in the polyarthritis TNFα transgenic mouse model showed similar clinical and histological response to treatment with either product when tested at a therapeutic sensitive dose. Single and multiple dose pre-clinical studies further demonstrated comparable systemic C_{max}, T_{max} and AUC of the two compounds.

Conclusion: This non-clinical similarity exercise confirms that GP2015 and the reference medicinal product are pharmacologically highly-similar with regard to target binding, anti-TNFα biological activity and PK exposure. Future clinical trial(s) are needed to provide evidence of similar efficacy and safety of GP2015 to that of the originator product.

SLE Disease Activity In The Mucocutaneus, Vascular and Hematologic Systems Is Associated With An Increase In Plasma Type I Interferon Activity. Elena Gkrouzman, Mikhail Olferiev, Margaret Robotham, Mari Lliguicota, Wei-Ti Huang, Elzbieta E. Jacek, Kyriakos A. Kirou and Mary K. Crow. Hospital for Special Surgery, New York, NY.

Background/Purpose: Type I interferon (IFN-I) has been implicated in SLE pathogenesis, and cross-sectional studies have shown that IFN-I pathway activation is associated with multiple disease manifestations. To identify those clinical and laboratory features most significantly associated with high IFN-I activity, we retrospectively evaluated IFN-I in plasma samples collected longitudinally from SLE patients.

Methods: Plasma samples as well as clinical and laboratory patient data were collected longitudinally from 60 patients meeting ACR criteria for SLE. On average, 9 visits (range 2–20) per patient and 568 data points were collected. WISH cells were stimulated with either recombinant IFN-I standard, healthy donor or SLE plasma for 5 hours. Quantification of biological response was performed by qPCR using IFIT1 as the target and HPRT1 as the reference gene. A linear mixed effect model was used to build regression models and correlate IFN-I activity of plasma across all patient visits with various clinical and laboratory parameters measured longitudinally. In total, 50 laboratory and clinical variables were analyzed.

Results: The longitudinal analysis identified that visits with high IFN-I activity correlated significantly with high disease activity determined by both SLEDAI ($p<0.01$) and BILAG scores ($p<0.05$). The rise in IFN-I activity often corresponded to lupus flares ($p<0.05$). Visits of SLE patients with hematologic ($p<0.01$), mucocutaneus ($p<0.01$) or vascular ($p<0.05$) activity (according to BILAG 2000 components) were associated with an increase in IFN-I levels. Among serologic parameters, a significant increase in antibody titer against dsDNA ($p<0.01$) and erythrocyte sedimentation rate ($p<0.01$) corresponded to higher IFN-I activity. Decreases in complement component 3 ($p<0.01$), white blood cell count ($p<0.01$), and absolute neutrophil count ($p<0.01$) were also associated with high IFN-I level.

Conclusion: The measurement of IFN-I activity in SLE patient plasma represents an important experimental parameter with possible clinical implications. The WISH assay, which measures the biological activity of IFN-I, was used to establish relationships between high interferon activity and multiple clinical manifestations in a longitudinal retrospective study. Our longitudinal analysis supports a significant association of high IFN-I activity with elevated disease activity, particularly in the mucocutaneous, vascular and hematologic systems.

Immunologic Markers and Molecular Mechanisms Associated With Increased Systemic Lupus Erythematosus Activity In Patients Not Taking Immunosuppressive Medications. Mikhail G. Dozmorov[1], Cory Giles[1], Krista M. Bean[1], Nicolas Dominguez[1], Jonathan D. Wren[1], Joan T. Merrill[1], Judith A. James[2] and Joel M. Guthridge[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation and University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background/Purpose: The course of systemic lupus erythematosus (SLE) is characterized by exacerbations (or flares) and remissions of disease activity. Predicting which patients are likely to develop high disease activity (flare more) after remission have been generally limited to assessing autoantibodies, complement products and select serum cytokine levels, such as BLyS. The goal of this study is to identify immunologic markers and molecular mechanisms associated with flare intensity in SLE patients no longer taking immunosuppressive medications.

Methods: As part of the Biomarkers of Lupus Disease (BOLD) study, 41 patients with ACR Classification Criteria for SLE, with moderately severe, but not organ-threatening disease activity, (SLEDAI $>$ 6 and/or BILAG $>$ 2 B or 1 A) were enrolled, background immunosuppressants (IS) stopped, intramuscular steroids given until disease suppression and then serially followed until clinical disease flare. In addition to autoantibody levels and extensive immunophenotyping, 52 soluble inflammatory mediators, including cytokines, chemokines, and soluble receptors, using either xMAP multiplex technology or sandwich ELISA (BLyS and APRIL), were measured. Gene expression profiling, with globin depletion, was performed on the subset of patients with available whole blood RNA samples.

Results: Hierarchical clustering of longitudinal SLEDAI profiles identified two distinct subgroups of SLE patients. After improvement, 17 patients demonstrated higher disease activity ("flare more" group), in contrast with 15 patients showing more moderate flare activity ("flare less" group) ($p=0.007$). At the baseline visit, SLE patients from the "flare more" group overexpressed 133 genes (including HLA-DQB1, CXCL5, IL15RA, CD74, and ELK1) and showed decreased expression of 104 genes, including CLEC12A, MAX, FCAR, IL4R, IL25. The patterns of differentially expressed genes were suggestive of active IFNg signaling (z-score$=2.1$) and inhibited CD28 signaling (z-score$=-2.4$). The "TNF alpha/NFkB signaling" was the most overrepresented pathway ($p=0.003$).

SLE patients who flared more had higher baseline plasma levels of Eotaxin (CCL11, $p=0.03$), and MCP-1 (CCL13, $p=0.03$) and TRAIL (TNFSF10, $p=0.04$) increased at the flare visit. They also exhibited decreased monocyte ($p=0.03$) and neutrophil ($p=0.04$) counts at the baseline visit, and decreased CD80 ($p=0.04$) at the flare visit. On the contrary, CD4+ T cells counts were increased ($p=0.05$) at baseline visit in the "flare more" group.

Conclusion: SLE patients who will flare more after withdrawal of ineffective immunosuppressants and transient amelioration of disease with steroid treatment have gene expression, cytokine protein levels and immunophenotyping biomarker signatures indicative of 1.) abnormal antigen presentation signaling manifested by decreased co-stimulatory signals, (CD80, CD28), 2.) chemoattraction of eosinophils and monocytes, and 3.) potential activation of NFkB signaling through TRAIL binding, antagonizing cell death and promoting inflammation.

Complement Activation and Anaphylatoxin Generation In Response To Staphylococcal Protein A Exposure: Ex Vivo and In Vivo Human Studies. Edward Bernton[1], Antonio Polley[2], Susan Zondlo[2], Lynne Mitchell[3] and Dennis Hourcade[3]. [1]Protalex Inc., Summit, NJ, [2]QPS Holdings LLC, Newark, DE, [3]Washington University School of Medicine, St. Louis, MO.

Background/Purpose: PRTX-100, a highly-purified GMP staphylococcal protein A (SpA), is currently in clinical trials treating patients with active rheumatoid arthritis (RA). It has been reported that binding of SpA to rabbit Vh3 IgM antibodies could deplete complement hemolytic activity and release C3a. Furthermore, complement activation is a postulated mechanism for dosing reactions seen in several patients after overly-rapid injection of SpA. We therefore looked at ex vivo effects of: 1. Adding SpA to pooled normal serum using a highly-sensitive modified CH50 assay; and 2. Adding SpA to fresh healthy donor blood on production of stable metabolites of C3a, C4a, and C5a, which are anaphylatoxins and known vasoactive and immunomodulatory mediators. Additionally, these analytes were measured in plasma from RA patients, before and after dosing with SpA.

Methods: *CH50 studies:* Pooled normal donor serum was incubated with various concentrations of SpA or positive controls and then assayed for residual complement activity (measured as CH50). *Whole blood studies:* Heparinized blood was incubated at 37 °C with 0, 250, 500, or 2000 ng/mL of SpA or with zymosan as a positive control. At 15 and 60 minute intervals, samples were evaluated using a multiplexed cytometric bead array (CBA) assay to quantify C3a, C4a, C5a stable metabolites. *Patient studies:* EDTA/Futham plasma samples were obtained before and after the first and fifth infusion with SpA, and frozen for CBA analysis of anaphylatoxins. Sequential groups of 6 patients were infused weekly with 1.5, 3.0, 6.0, or 12 μg/kg of SpA.

Results: In the CH50 study, 3 replicate experiments were performed adding serial two-fold dilutions of SpA from 4000 to 125 ng/mL. All CH50 values averaged between 85% and 108% of serum incubated without SpA, with no SpA dose response observed. CH50 values at 4000 ng/mL SpA were 114, 106, and 98% of the serum control. Incubation with a complement-activating nanoparticle reduced hemolytic activity to undetectable levels ($<$ 5% of serum control). Using whole blood from 3 donors, and the CBA assay, C3a increased a maximum of 2.5-fold with SpA addition, compared to no addition. The mean increase with zymosan addition was 332-fold. For C4a the maximum increase was 2.3-fold compared with a mean 99-fold for zymosan addition. For C5a the maximum increase was 2.3-fold that seen for control, compared with a mean 213-fold increase with zymosan addition. Data for pre- and post-infusion samples for 47 infusions in the first 28 patients dosed, showed 7/28 had 3-fold or greater increase in C3a (range 3 to 14 fold) but only 2/28 had a 2-fold or greater increase in C4a (range 2.4 to 2.7 fold). The mean of the ratio between pre- and post-dose values was 2.1, 1.0, and 1.1 for C3a, C4a, and C5a respectively. The maximum fold increases were 14.0, 2.7, and 3.0 respectively.

Conclusion: Ex vivo experiments do not demonstrate activation of complement in serum or whole blood by SpA at concentrations of up to 4000 ng/mL (serum) or 2000 ng/mL (blood). One quarter of patients experienced a 3-fold or greater increase in C3a after SpA treatment, which was not associated with any dosing symptoms. C4a and C5a were unaffected by treatment.

1866

Primary Human Cell BioMAP® Profiling Of Methotrexate, Tocilizumab, Adalimumab, and Tofacitinib Reveals Different Mechanisms Of Action With Distinct Phenotypic Signatures. Seng-Lai Tan[1], Alison O'Mahony[2], Ellen L. Berg[2], Kandeepan Ganeshalingam[3] and Ernest H. Choy[4]. [1]Hoffmann-La Roche, Nutley, NJ, [2]BioSeek, South San Francisco, CA, [3]F. Hoffmann-La Roche, Basel, Switzerland, [4]Cardiff University School of Medicine, Cardiff, United Kingdom.

Background/Purpose: Proinflammatory cytokines cause joint inflammation and destruction in patients with rheumatoid arthritis, as exemplified by the therapeutic success of inhibiting tumor necrosis factor alpha (TNFα) by adalimumab (ADA) and inhibiting interleukin-6 receptor (IL-6R) by tocilizumab (TCZ). Such biologic agents and small molecule inhibitors, including methotrexate (MTX) and the recently approved tofacitinib (TOF), a Janus kinase inhibitor, have diverse and potentially overlapping biological effects. The purpose of this study was to use the human primary cell–based BioMAP platform to identify similar and discriminating biological activities of TCZ, ADA, MTX, and TOF.

Methods: BioMAP systems model complex signaling networks in primary human cell types and have been used extensively to validate compounds and targets, identify mechanisms of action and potential toxicities, and determine phenotypic signatures.[1] TCZ, ADA, MTX, and TOF were profiled across a panel of 14 cell-based BioMAP systems containing early-passage primary human cells cultured alone or with different stimulus combinations. Compounds were profiled at concentrations that would cover their reported clinical plasma exposure for the respective approved dosing regimen. To examine the effects of compounds on IL-6 *trans*-signaling, parallel experiments were conducted in the presence of exogenous soluble IL-6R (sIL-6R). Compound-mediated perturbations of protein-based and clinically relevant biomarker readouts and other cellular events (eg, proliferation, cell cytotoxi-

city) were used to generate a biological activity plot (ie, BioMAP profile) that served as a multisystem signature of the activity for each compound.

Results: TCZ significantly inhibited the expression of P-selectin (4H system), IL-8 (Sag system), TNFα (BT and HDFSAg systems), IP-10 and IL-17A (HDFSAg system), and CD69 (LPS and Mphg systems), consistent with anti-inflammatory and immunomodulatory effects. In general, little overlap was reported in the BioMAP profiles for TCZ, ADA, MTX, and TOF. TOF disrupted IL-17F, but not IL-17A, production in the HDFSAg system and showed dose-dependent selectivity; the phenotypic signatures of TOF at clinically relevant doses (<1 μM) were distinct from those at higher concentrations. sIL-6R induced additional activities in the BioMAP, including inflammation-related, novel immunomodulatory and tissue/matrix remodeling effects. Importantly, TCZ, but not ADA or TOF, completely blocked all sIL-6R–related activities at concentrations corresponding to clinical plasma exposure levels.

Conclusion: TCZ, ADA, MTX, and TOF have markedly unique BioMAP signatures, indicating that these compounds exert different mechanisms of action. IL-6 signaling in BioMAP required the presence of sIL-6R for functional *trans*-signaling, which was fully reversed by TCZ but not by ADA or TOF at clinically relevant concentrations. The relevance of these findings requires confirmation in clinical studies.

1867

Profiling Cytokine Production Of B Cells From SLE Patients Upon TLR9 Stimulation. Julia Sieber[1], Capucine Daridon[2], Simon Fillatreau[3] and Thomas Dörner[4]. [1]Charité University Medicine, Berlin, Germany, [2]Charité University Medicine / German Rheumatism Research Centre Berlin (DRFZ), Berlin, Germany, [3]German Rheumatism Research Center Berlin (DRFZ), Berlin, Germany, [4]Charité university medecine/ German Rheumatism Research Centre Berlin (DRFZ), Berlin, Germany.

Background/Purpose: Beyond their antibody producing function, B cells have been shown to be potent antigen-presenting and cytokine-producing cells. In systemic lupus erythematosus (SLE), B cells have been reported to be hyper-reactive, but it is not entirely known how cytokine production changes. An important signaling mechanism in B cell hyper-reactivity is Toll-like receptor 9 (TLR-9), which is up-regulated in B cells from patients with active SLE. Therefore, the aim of this study was to profile the cytokine production by B cells upon TLR-9 activation and to compare healthy donors (HD) to SLE-patients. In addition, the capacities of B cells to produce cytokines were put in relation with disease activity (SLEDAI) and serum autoantibody titers.

Methods: Untouched B cells from 19 SLE-patients and 13 HD were purified from peripheral blood mononuclear cells and were stimulated *in vitro* using CpG for 48 hours. The culture supernatants were harvested and then tested for 28 cytokines and chemokines by Bio-Plex. The cytokine responses upon stimulation were compared between both groups and correlated with the SLEDAI and anti-dsDNA titers for SLE-patients.

Results: 24 out of 28 cytokines/chemokines measured were significantly up-regulated upon TLR-9 stimulation compared to un-stimulated B cells ($p<0.05$). Although B cells from SLE patients showed a trend to produce less cytokine than B cells from HD, no significant differences were observed. However, the amount of IL-2, IL-4, IL-7, IL-12p70, IL13, IL-15, IL-17A, Eotaxin, Basic FGF, G-CSF, GM-CSF, IFN-γ, IP-10, MIP-1α, and VEGF produced by B cells from SLE-patients inversely correlated with their SLEDAI ($p<0.05$) and even more (additionally IL-1β, IL-1ra, MIP-1β and TNF-α) with their anti-dsDNA antibody titers. Interestingly, the more $CD27^+$ memory B cells were in the cells culture from SLE-patients, the more IP-10 and TNF-α were produced.

Conclusion: This study highlighted unknown perturbations of cytokine/chemokine production by B cells in active SLE upon TLR-9 stimulation with an inverse correlation of cytokines/chemokines produced by B cells with SLEDAI and anti-dsDNA titers. Most prominent were pro-inflammatory mediators as IP-10, MIP-1α, TNF-α, and VEGF. This suggests that the known enhanced B cell proliferation and differentiation upon TLR9-stimulation possibly results in a diminished cytokine production.

Chemokine Expression In Systemic Lupus Erythematosus. Eoghan M. McCarthy[1], Joan Ní Gabhann[2], Siobhán Smith[2], Ruth Lee[3], Gaye Cunnane[4], Michele Doran[4], Donough G. Howard[3], Paul G. O'Connell[3], Grainne M. Kearns[3] and Caroline Jefferies[2]. [1]Mater Misericordiae University Hospital, Dublin 7, Ireland, [2]Royal College of Surgeons in Ireland, Dublin, Ireland, [3]Beaumont Hospital, Dublin 9, Ireland, [4]St James's Hospital, Dublin, Ireland.

Background/Purpose: Systemic lupus erythematosus(SLE) is a systemic autoimmune disease characterised by the deregulated activation of T and B lymphocytes, production of autoantibodies and the formation of immune complexes causing tissue damage. Chemokines which are normally involved in leucocyte chemotaxis have been associated with tissue injury in SLE via leucocyte infiltration. We sought to assess the relationship between serum levels of a number of chemokines and disease activity, damage scores and clinical profiles in Caucasian SLE patients.

Methods: Serum levels of the following chemokines were determined by ELISA – CXCL10, CXCL13, CCL17 and CXCL8. Demographic data, disease activity as per SLEDAI and damage scores (SLICC) at baseline and 5 year follow-up were recorded. Active disease was defined as a SLEDAI score $>$ 6. Categorical variables were analyzed using Fisher's exact test and continuous variables by unpaired *t*-tests. The Mann-Whitney test was used in instances of non-normality.

Results: 45 patients were recruited**.** Serum levels of CXCL10, CXCL13, CCL17 and CXCL8 were higher in SLE patients than controls (Table 1).

	Patient(pg/ml) IQR range	Control(pg/ml) IQR range	P-Value
CXCL10	234.6 [85.49;499]	84.76 [46.59;107.3]	0.001
CXCL13	311.6 [131.4;545.8]	64.99 [43.49;444.4]	0.01
CCL17	117.2 [69.21;181.3]	32.93 [18.49;171.2]	0.0097
CXCL8	6.13 [4.52;10.43]	1.7 [1.27;1.985]	0.0001

Significantly higher levels of CXCL10 were observed earlier in disease course as well as in those patients with active disease (493.5pg/ml v 94.2 pg/ml, $p=0.0045$) and those who suffered damage over the 5 year follow up period (407.1pg/ml v 94.2pg/ml, $p=0.006$). CCL17 and CXCL8 were also higher in patients with active disease [CCL17 (211.7pg/ml v 108.2pg/ml, $p<0.0001$), CXCL8 (9.784pg/ml v 5.576pg/ml, $p=0.0199$)]. CXCL13 levels failed to show an association with disease activity.

Regarding clinical involvement CXCL10 levels were higher in those with CNS involvement (649.7pg/ml v 151.7pg/ml, $p = 0.02$) whilst higher levels of CCL17 were observed in those with both renal involvement (146.8pg/ml v 113.4pg/ml, $p = 0.046$) and serositis (166.8pg/ml v 108.8pg/ml, $p = 0.039$) as part of their ACR diagnostic criteria. Of note CXCL10 and CXCL8 levels were also elevated in those with immunological involvement.

When each of the chemokines was analysed with respect to antibody profile higher levels of CXCL8 were seen in patients who were La +ve versus La -ve (11.16pg/ml v 5.9pg/ml, $p = 0.04$). None of the other chemokines assayed demonstrating an association with an antibody signature.

Finally a strong correlation was seen between CXCL10 and CXCL13 levels in SLE patients (Spearman $r = 0.711$, $p < 0.001$) indicating the importance of the interferon pathway to their induction. Both CXCL8 and CCL17 levels failed to show a correlation with any of the other chemokines measured suggesting that these chemokines are driven by distinct mechanistic pathways in SLE.

Conclusion: Chemokines play an important role in the pathogenesis of SLE with CXCL10, CXCL8 and CCL17 levels all reflecting disease activity. In addition CXCL10 levels are higher in CNS involvement whilst we have demonstrated enhanced CCL17 levels in those with patients renal involvement.

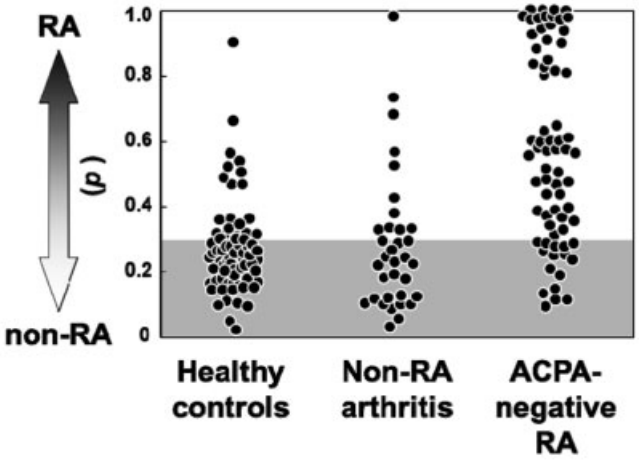
Serum Cytokine/Chemokine Profiles Are Useful For Evaluating Pathological Conditions Of Rheumatoid Arthritis and Diagnosing Anti-CCP Antibody-Negative Patients. Hitoshi Uga[1], Takahiro Okazawa[1], Yoshiaki Miyamoto[1], Takehiro Hasegawa[1], Jun Saegusa[2], Goh Tsuji[3], Sho Sendo[3], Akio Morinobu[2], Shunichi Kumagai[2] and Hirokazu Kurata[1]. [1]Sysmex Corporation, Kobe, Japan, [2]Kobe University Graduate School of Medicine, Kobe, Japan, [3]Shinko Hospital, Kobe, Japan.

Background/Purpose: The diagnosis of anti-CCP antibody (ACPA) negative rheumatoid arthritis (RA) are known to be difficult and delayed as compared with ACPA-positive RA. This study was designed to evaluate serum levels of cytokines/chemokines and to establish a new discriminating system of ACPA-negative RA patients from non-RA arthritic patients and healthy controls.

Methods: A total of 174 RA patients (mean DAS28-CRP = 2.67; 104 ACPA-positive and 70 ACPA-negative patients) diagnosed according to the ACR/EULAR 2010 classification criteria for RA, 33 non-RA arthritic (NRA) patients including seronegative spondyloarthropathy (SNSA), and 76 sex-matched healthy controls (HC) were included. By using a chemi-luminescence immunoassay, twenty-eight cytokines/chemokines, including IFN-γ, TNF-α, IL-1β, IL-4, IL-6, IL-8, IL-10, IL-17A, IL-17F, IL-23, CCL20, CXCL13, TGF-β1, were measured in the sera of the above populations. **Results** were analyzed by Mann-Whitney U-test. Discriminant analysis was performed using multiple logistic regression analysis.

Results: Our study revealed that (1) several cytokines/ chemokines, including IFN-γ, TNF-α and novel cytokines were upregulated in RA patients as compared with in healthy controls. (2) Multiple logistic regression analysis revealed that the combinations of three to five cytokines/chemokines could clearly discriminate not only ACPA-positive but also ACPA-negative RA patients from NRA patients as well as RA patients from HC (Figure 1); ACPA-negative RA: 70, NRA: 33, HC:76).



Conclusion: Our study using a chemi-luminescence immunoassay led to the identification of cytokine/chemokine profiles useful in the differential diagnosis of ACPA-negative RA from non-RA arthritis.

B-Cell Activating Factor (BAFF) and Pregnancy Outcomes. Hindi E. Stohl, Lisa Korst, Richard H. Lee and William Stohl. University of Southern California Keck School of Medicine, Los Angeles, CA.

Background/Purpose: Pregnancy often exacerbates systemic rheumatic diseases, and systemic rheumatic diseases often lead to adverse obstetric outcomes. Both rheumatic disease activity and adverse obstetrical outcomes are associated with alterations in B cells. To date, circulating levels of BAFF, a vital B cell survival factor, have not been serially evaluated in pregnancy. Accordingly, we assessed maternal and cord blood serum levels of BAFF and evaluated whether first-trimester BAFF levels are associated with adverse pregnancy outcomes.

Methods: Blood samples were collected from pregnant women with non-anomalous singleton intrauterine pregnancies receiving care at a single medical center. Participants were classified as "healthy" (n = 33), "medical disease" (n = 34), or "rheumatic disease" (n = 5) based on the presence/ absence of medical or rheumatic conditions. Age-matched non-pregnant women (n = 5) served as controls. Pregnant participants had blood samples collected at least once per trimester, at delivery, and postpartum. Additionally, cord blood was collected at delivery. Non-pregnant subjects had a single blood draw. Samples were assayed for BAFF by ELISA. Levels in women who developed spontaneous abortion (SAB; pregnancy loss prior to 20 weeks gestation), hypertensive disorders of pregnancy (HDP), or preterm delivery (PTD) were compared with levels in women without these adverse events.

Results: Median BAFF levels between "healthy" and "medical disease" participants did not differ significantly, whereas levels were elevated in women with rheumatic conditions ($p=0.04$). Median (interquartile range) first, second, and third trimester, cord blood, and postpartum BAFF levels (ng/ml)in women without rheumatic diseases were 0.63 (0.45–3.95), 0.53 (0.45–1.02), 0.59 (0.45–1.03), 1.95 (0.61–4.54), and 0.76 (0.45–1.41), respectively. In women with rheumatic conditions, levels were 0.76 (0.69–2.02), 0.78 (0.544–0.99, 0.60 (0.45–0.99), 1.14 (0.70–2.07), and 0.74 (0.45–0.97), respectively. Second and third trimester BAFF levels were significantly decreased compared to first trimester and postpartum BAFF levels ($p<0.01$ for each) in the women without rheumatic diseases, whereas levels did not significantly differ across trimesters among women with rheumatic conditions. Cord blood levels for all women were significantly elevated compared with any trimester level ($p<0.001$ for each). In contrast to the decrease in BAFF levels seen in women in the second trimester without HDP, BAFF levels increased between the first and second trimester in women who developed HDP ($p<0.01$). First trimester BAFF levels were not significantly associated with HDP ($p=0.26$) or PTD ($p=0.82$), whereas a trend towards significance was noted with SAB ($p=0.051$).

Conclusion: Elevated first-trimester BAFF levels may be associated with SAB. Moreover, the loss of the normal decline in BAFF levels between the first and second trimesters may be associated with the development of HDP. Additional subjects and samples are being collected and analyzed to confirm these initial observations. If confirmed, serum BAFF may be a useful biomarker in the management of pregnancy.

Progranulin Directly Binds To The CRD 2 and CRD3 Of TNFR Extracellular Domains. Jinlong Jian[1], Shuai Zhao[1], Qingyun Tian[1], Elena Gonzalez Gugel[1], Jyoti Mundra[1], Sardar MZ Uddin[1], Ben Liu[2], Brendon Richbourgh[1], Ryan Brunetti[1], Gerald Chan[3], Carolyn Green[4] and Chuanju Liu[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]NYU Hospital for Joint Diseases, New York Univerity, NY, [3]Atreaon, Boston, MA, [4]Atreaon, Boston, NY.

Background/Purpose: We previously reported that Progranulin (PGRN) bound to TNF receptors (TNFR) and was therapeutic in inflammatory arthritis (Tang, W., et al, *Science*, 2011). PGRN is highly cysteine-rich glycoprotein, and contains a number of internal disulfide bonds, which are critical for maintaining the proper folding and confirmation of this protein. The objective of this project is 1) to determine whether PGRN also form a complex with TNFR in immune cells, and whether PGRN affects the binding of TNFα to immune cells, 2) to compare the effects of folding of PGRN on its binding to TNFR and Sortilin, a neuronal receptor known to interact with PGRN as well, and 3) to dissect and identify the domains of TNFR required for PGRN interaction.

Methods: Co-Immunoprecipitation (CoIP) assay and TNF-α blocking assay with flow cytometry were performed to examine the association of PGRN and TNFR in immune cells and its inhibition of TNF binding to cell surface; Various protein-protein interaction assays, including Solid phase binding, Surface Plasmon Resonance, yeast-two hybrid and GST pull-down, were performed to compare the binding activity of various sources of PGRN, to determine the effects of folding of PGRN to TNFR, and to identify the domains of TNFR responsible for binding to PGRN; Differentiation of bone marrow-derived macrophages were used to measure the biological activity of PGRN with ELISA and real-time PCR.

Results: Our previous study showed that PGRN bound to TNFR in chondrocytes. Here we found that PGRN also associated with TNFR2 in splenocytes in a Co-IP assay, and PGRN blocked the binding of TNFα to splenocytes in a dose-dependent manner.

Proper folding and modification of PGRN appear to be essential for its binding to TNFR, as DTT treatment, which is known to disturb the formation of disulfide bonds in PGRN and in turn affects its folding, abolished its binding to TNFR. Interestingly, the binding of PGRN to Sortilin was actually enhanced by DTT treatment. This is probably due to the fact that the C-terminal last three amino acids (DLL) of PGRN, known to be required for Sortilin binding, are exposed in the unfolded PGRN and become more easily accessible to Sortilin. Additionally, in vitro direct protein interaction assays, including Solid phase and Surface Plasmon Resonance, and cell-based functional assays revealed 1) that some commercial PGRNs are of poor quality, and that 2) the selection of chips in Surface Plasmon Resonance is important for demonstrating the high affinity binding of PGRN to TNFR.

Yeast two hybrid assays with numerous deletion mutants of TNFR extracellular domain demonstrated that CRD2 and CRD3 of TNFR are important for the interaction with PGRN, similar to its binding to their canonical ligand TNFα. This finding was confirmed with in vitro GST pulldown and solid phase assay with recombinant proteins.

Conclusion: These findings provide the molecular basis underlying PGRN-mediated anti-inflammatory activity in various autoimmune diseases and conditions.

Gene-Body Mass Index Interactions Are Associated With Methotrexate Toxicity in Rheumatoid Arthritis. Stella Aslibekyan[1], Jin Sha[1], David T. Redden[1], Larry W. Moreland[2], James R. O'Dell[3], Jeffrey R. Curtis[1], Ted R. Mikuls[4], S. Louis Bridges Jr.[1] and Donna K. Arnett[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Nebraska Medical Center, Omaha, NE, [4]Omaha VA and University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: Response to methotrexate (MTX) therapy in rheumatoid arthritis (RA) is highly heterogeneous, with both genetic and environmental factors contributing to the efficacy and toxicity of the drug. However, known predictors account for a small proportion of observed variability, and interactions between genetic and environmental factors, in particularly the body mass index (BMI) have not been extensively studied.

Methods: Using data from the Treatment of Aggressive Rheumatoid Arthritis (TEAR) trial (n=755), we fit logistic regressions to test for associations between 3,127 genetic markers selected based on their biological significance and the odds of MTX toxicity, adjusting for age, sex, race, active smoking, BMI, and interactions between genetic variants and BMI. The cohort was randomly split into discovery and replication sets. Genetic variants that reached nominal statistical significance in the discovery phase were subsequently tested in the replication subset.

Results: We observed statistically significant, replicated interactions between BMI and a variant in CMYA5 (cardiomyopathy 5), a known RA susceptibility gene (P=0.005 for discovery, 0.04 for replication), as well as with a variant located near the chemokine (CCL2 and others) gene cluster (P= 0.005 for discovery, 0.05 for replication). Among carriers of at least one copy of the minor allele at either locus, the estimate of BMI effect on MTX toxicity was fourfold higher compared to wild type individuals. Both genetic variants also had significant, replicated main effects on toxicity.

Conclusion: We have identified and replicated interactions between two biologically plausible genetic variants and BMI in models of methotrexate toxicity. Our findings lay the groundwork for developing more accurate and complete algorithms of MTX response prediction in RA.

Use Of Mendelian Randomization Associates Increased Serum Urate Caused By Genetic Variation In Uric Acid Transporters With Improved Renal Function. Tony R. Merriman[1], Tanya Flynn[1], Janak de Zoysa[2], Nicola Dalbeth[3] and Kim Hughes[1]. [1]University of Otago, Dunedin, New Zealand, [2]Waitemata District Health Board, Auckland, New Zealand, [3]University of Auckland, Auckland, New Zealand.

Background/Purpose: Hyperuricemia is the central risk factor for gout. In observational studies hyperuricemia also predicts the development and progression of chronic kidney disease independent of other measured risk factors. The use of xanthine oxidase inhibitors coincides with improved renal function – whether this is due to reduced serum urate or some other physiological mechanism remains unresolved. We applied Mendelian randomization to the question – is increased serum urate, determined by genetic modulation of renal excretion, detrimental to renal function?

Methods: Data from the Atherosclerosis Risk in Communities (n=5237) and Framingham Heart (n=3033) studies were used. Mendelian randomization uses genetic variants known to be causal of a modifiable exposure (serum urate in this study) to test for association of that exposure with an outcome (renal function in this study). Mendelian randomization by the two stage least squares method was conducted with serum urate as the exposure, a genetic risk score (based on variants from 5 urate transporters; *SLC2A9, ABCG2, SLC17A1, SLC22A11, SLC22A12*) as the instrumental variable and serum creatinine (SCr) or estimated glomerular filtration rate (eGFR) as the outcome. All analysis was done using STATA 8.0 and analyses adjusted for possible confounding variables.

Results: Increased serum urate genetic risk score associated with improved renal function in men (SCr P=0.023, eGFR P=0.045) but not women (SCr P=0.73, eGFR P=0.42) (Table). Analysis of individual genetic variants revealed that the effect size associated with serum urate did not correlate with the effect size associated with renal function in the Mendelian randomization model.

Table. Mendelian randomization analysis of SU against eGFR/SCr.

	Ordinary Least Square Regression			Two Stage Least Square		
	Beta	SE	P	Beta	SE	P
SCr						
All	37.12	2.00	2.65E-75	−16.54	10.48	0.12
Males	38.51	3.01	1.11E-36	−41.65	18.38	0.023
Females	36.84	2.69	8.42E-42	4.29	12.38	0.73
eGFR						
All	−37.67	2.32	1.87E-58	8.87	11.96	0.46
Males	−35.85	3.15	1.97E-29	38.00	18.94	0.045
Females	−37.17	3.43	5.75E-27	−12.71	15.70	0.42

Ordinary least square regression: Beta is the change in SCr/eGFR attributed to a unit change in serum urate (left).
Two stage least square: Beta is the change in SCr/eGFR caused by a unit change in serum urate attributed to the genetic risk score (right).

Conclusion: Contrary to the established relationship of increased serum urate with reduced renal function, increase in serum urate caused by genetic variation in uric acid transporters results in improved renal function. The single variant analysis suggests that the renal protection could be mediated by the activity of renal transporters in increasing serum urate levels. These results justify further research into the mechanism of renal function protection mediated by xanthine oxidase inhibitors.

Genome-Wide Profiling Identifies Significant Differences Between The T-Lymphocyte and B-Lymphocyte Methylomes In Healthy Individuals. John Glossop[1], Nicola Nixon[1], Richard Emes[2], Kim Haworth[3], Jonathon Packham[1], Peter Dawes[1], Anthony Fryer[3], Derek Mattey[3] and William Farrell[3]. [1]Haywood Rheumatology Centre, Stoke-on-Trent, United Kingdom, [2]University of Nottingham, Sutton Bonnington, United Kingdom, [3]Keele University, Stoke-on-Trent, United Kingdom.

Background/Purpose: Multiple reports now describe changes to the DNA methylome in a variety of autoimmune disorders, such as rheumatoid arthritis. In many cases, these studies have analysed methylation in mixed cell populations from whole blood. However, the cellular heterogeneity inherent

in these approaches may preclude the identification of cell type-specific methylation differences, which may in turn bias identification of disease-specific changes in methylation. To address this possibility, we used genome-wide DNA methylation profiling to identify differences within matched pairs of T-lymphocytes and B-lymphocytes isolated from the blood of healthy individuals.

Methods: Peripheral blood samples were collected from 10 healthy female donors (all Caucasian non-smokers). T- and B-lymphocyte populations were isolated from each individual using magnetic beads and genomic DNA was extracted. Sodium bisulphite converted DNA was hybridised to HumanMethylation450 BeadChips to establish quantitative genome-wide DNA methylation at more than 450,000 CpG sites. Methylation status at individual CpGs was reported as a β-value on a continuous scale ranging from 0 (unmethylated) to 1 (completely methylated). Array processing and identification of differential methylation was performed using NIMBL software. Pyrosequencing was used to validate array data.

Results: Genome-wide methylation was initially determined by analysis of LINE-1 sequences and was significantly higher in B-lymphocytes than matched T-lymphocytes (69.8 vs. 65.2%, $p \leq 0.01$). Pairwise analysis identified 679 CpGs, representing 250 genes, which were differentially methylated between T-lymphocytes and B-lymphocytes. Approximately half of the sites (326; 48%) displayed β-value differences of at least 0.5, and a similar number were associated with a CpG island. The majority of the sites (76.6%) were hypermethylated in B-lymphocytes compared with T-lymphocytes. Pyrosequencing analysis of selected candidate CpGs/genes confirmed the array data in all cases. Hierarchical clustering revealed perfect segregation of the samples into two distinct clusters based on cell type. Differentially methylated genes showed enrichment for biological functions/pathways associated with leukocytes and T-lymphocytes.

Conclusion: Matched pairs of T- and B-lymphocytes from healthy individuals possess intrinsic differences in DNA methylation within a restricted set of functionally-related genes. These data provide a foundation for investigating DNA methylation in diseases in which these cell types play important and distinct roles.

A Dense Mapping Of Human Leukocyte Antigen Region For Study Of Interaction With Smoking In The Development Of Rheumatoid Arthritis. Xia Jiang[1], Henrik Källberg[1], Lisbeth Ärlestig[2], Solbritt M. Rantapää-Dahlqvist[2], Lars Klareskog[3], Leonid Padyukov[3] and Lars Alfredsson[4]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Umeå University, Umeå, Sweden, [3]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [4]Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden.

Background/Purpose: Rheumatoid arthritis (RA) is believed to have a multifactorial etiology, involving both genetic and environmental components, and can be divided into two major subsets according to the presence/absence of anti-citrullinated protein/peptide antibodies (ACPA). Smoking is the most established environmental risk factor. Despite progress from genome-wide association studies (GWAS), identified genetic variants only explain a small proportion of RA occurrence. Hypothetically, gene-environment interaction could add etiologic understanding of the disease. The aim of current study is to investigate large scale gene-environment interaction between smoking and SNPs selected of interest from an inflammatory point of view, for each of the two major RA subsets.

Methods: We analyzed data from the Swedish EIRA case-control study using logistic regression models. Smoking history was collected through questionnaires. An ever smoker was defined as a person who had ever smoked cigarettes before the index year, while a never smoker was defined as a person who had never smoked cigarettes. Genetic information was obtained from a custom made Illumina Immunochip scan. Interaction between smoking and 133648 genetic markers that passed quality control were examined for the two RA subsets (1590 ACPA positive cases, 891 ACPA negative cases; compared with 1856 matched controls). Attributable proportion (AP) due to interaction together with 95% confidence intervals (CIs) was evaluated for each smoking-SNP pair. We performed replication in a separate case-control study from northern Sweden, Umeå. In order to further validate the results we also performed interaction analysis using GWAS data on the EIRA individuals.

Results: In ACPA positive RA, 102 SNPs were significantly interacting with smoking after Bonferroni correction, all SNPs located in the HLA region (one in HLA class I region, the rest in HLA class II region) and displayed high linkage disequilibrium (LD); 51 of them were replicated in the Umeå study. No additional loci besides from chromosome 6 turned up in the GWAS validation. After adjusting for *HLA-DRB1* shared epitope (SE), 15 SNPs remained significant for ACPA positive RA, with 8 of them being replicated. For ACPA negative RA, no SNP passed threshold for significance. Through functional prediction and pathway annotation, 10 candidate genes/regions were identified for ACPA positive RA, with dominance on antigen presentation pathways (*HLA-DOB, HLA-DQA1, HLA-DQA2, HLA-DRA, HLA-DRB1, HLA-DRB5, TAP2*).

Conclusion: Our study presents the most explicit picture to date, with regard to the patterns of gene-smoking interaction in ACPA positive/negative RA, suggesting contrasting etiology of the two subsets. Except for HLA-DR, the study additionally unambiguously linked RA risk to the class I HLA, implicating the function of CD8+ T cells in RA pathogenesis.

1876

Potential Chondrogenic Biomarkers For Cell-Based Therapy Monitoring In Osteoarthritis. Beatriz Rocha[1], Valentina Calamia[1], Vanessa Casas[2], Lucia Lourido[1], Carolina Fernandez-Costa[1], Patricia Fernandez-Puente[1], Jesus Mateos[1], Montserrat Carrascal[2], Francisco J. Blanco[1] and Cristina Ruiz-Romero[3]. [1]Osteoarticular and Aging Research Laboratory, Proteomics Unit-Associated Node to ProteoRed-ISCIII, INIBIC-CHUAC, A Coruña, Spain, [2]Laboratorio de Proteómica CSIC/UAB, Barcelona, Spain, [3]CIBER-BBN, INIBIC-CHUAC, A Coruña, Spain.

Background/Purpose: Chondrogenesis occurs as a result of mesenchymal stem cells (MSCs) condensation and chondroprogenitor cell differentiation. Following chondrogenesis, the chondrocytes remain as resting cells to form the articular cartilage. A major challenge for the osteoarthritic (OA) cartilage repair by stem cell-based approach is the understanding of this multi-step process. In this work, we have analyzed the extracellular protein expression profile of human bone marrow MSCs (hBMSCs) of osteoarthritic patients and control donors undergoing chondrogenesis, in order to compare the mechanisms involved in the cartilage extracellular matrix (ECM) remodeling that occurs during chondrogenic differentiation process.

Methods: hBMSCs isolated from 3 OA patients and controls were grown with different isotope variants of lysine and arginina (Arg6, Lys4 for the control population and Arg10, Lys8 for the OA population) during 4–6 weeks, until achievement of full labeling. The labeled populations were then subjected to differentiation in 3D cultures (micromasses) supplemented with chondrogenic inducers for 14 days. Proteins in the conditioned media from the two cell populations were combined, separated by 1D-SDS-PAGE and subjected to in-gel trypsin digestion using an automatic digestor. The resulting peptide mixtures were analyzed by nanoLC coupled on-line to an LTQ-Orbitrap XL mass spectrometer and quantified using the MaxQuant software.

Results: Real-Time PCR assays showed a relevant difference in the gene expression of collagen type II in the normal donors when compared to the OA patients. Moreover, the chondrocyte phenotype was confirmed in both cases by the proteoglycan immunostainings such as aggrecan and chondroitin-6-sulfate after 14 days in chondrogenesis. Using the proteomic approach, we compared the extracellular protein profiles of OA and normal hBMSC at the same time of differentiation. Among the 531 proteins quantified, 56 had significantly altered levels. 35 proteins displayed consistently higher levels in the OA samples compared to normal donors. Many of these proteins are cartilage specific proteoglycans such as hyaluronan and proteoglycan link protein 1, aggrecan core protein or lumican as well as some proteins with a well-known role in the pathogenesis of OA like COMP or MMP3. On the other hand, 21 proteins exhibited a significantly reduced abundance in OA patients when compared to controls. Interestingly, we detected several proteins which belong to the tenascin protein family, like tenascin-X which accelerates collagen fibril formation. We also found WISP2 decreased at day 14, suggesting a lower activity of the Wnt signaling pathway in OA cells.

Conclusion: The identification and quantification proteins secreted by OA and normal hBMSC enhance our knowledge on the extracellular

regulation of this process and allow the identification of extracellular markers of chondrogenesis. Moreover, the lower expression of some of them in OA patients (like tenascin-X or WISP2), suggest their putative role for the molecular monitorization of the chondrogenesis in cell therapy-based approaches for cartilage repair.

A Neutrophil Signature Comprised Of Low Density Granulocyte (LDG)-Enriched Genes Is Associated With Organ-Specific Disease Activity In Systemic Lupus Erythematosus. Michelle Petri[1], Hong Fang[1], Jadwiga Bienkowska[2], Andrea Dearth[3], Norm Allaire[2] and Ann Ranger[3]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Biogen Idec Inc., Cambridge, MA, [3]Biogen Idec Inc, Cambridge, MA.

Background/Purpose: The neutrophil gene signature (NGS) has recently gained interest due to new understanding of the role of neutrophils and NETosis in SLE pathogenesis. We explored the association of a neutrophil gene signature comprised of genes significantly upregulated in low-density granulocytes (LDGs) with both global and organ specific disease activity in SLE patients.

Methods: Of 292 SLE patients, 91.1% were female; 58.9% Caucasian, 33.9% African-American, and 7.2% other ethnicities. Mean age (standard deviation) at baseline was 46.0 (±11.9) years. Gene expression levels were assessed in peripheral blood RNA samples using microarray (Affymetrix). The LDG-associated gene signature was comprised of 8 genes significantly upregulated in LDGs relative to normal-density neutrophils. The LDG-associated signature "score" was calculated based on the geometric mean of the expression levels (chip signal intensity) of the 8 genes in the signature. The patients were divided into three roughly equal sized groups based on neutrophil signature "scores", and the groups compared with respect to same-day disease activity. Adjusted p-values were calculated using generalized linear models controlling for ethnicity (SAS 9.2).

Results: The NGS was high (>6) in 31.9% (N=93), medium (5–6) in 31.5% (N=92), and low (<5) in 36.6% (N=107) of patients. The LDG-associated NGS was associated with same day global activity measured both by the physician global assessment >1 (on a 0 to 3 VAS) and by SLEDAI ≥2. It was associated with renal activity by VAS, arthritis by SLEDAI, anti-dsDNA, low complement, and alopecia. It was negatively associated with the hematologic VAS.

Table 1. Association between same-day disease activity and neutrophil signature in SLE

Variable	Low Neutrophil (<5) (% patients N=107)	Med Neutrophil (5–6) (% patients N=92)	High Neutrophil (>6) (% patients N=93)	Adjusted *P*-value for Ethnicity	Adjusted *P*-value for Ethnicity, Low/Med vs High
Physician's global assessment >1	11.2	16.3	30.1	0.003	0.0011
Rash >0	27.1	33.7	33.3	0.19	0.093
Joints >0	25.2	32.6	37.6	0.15	0.12
Serositis >0	0.9	1.1	2.2	0.65	0.36
Neurologic >0	0	2.2	3.2	0.078	0.14
Renal >0	14.0	12.0	28.0	0.0085	0.0024
Hematologic >0	24.3	13.0	9.7	0.0096	0.020
SELENA SLEDAI ≥2	47.7	60.9	65.6	0.012	0.015
Hematuria	0.9	0	3.2	0.091	0.062
Proteinuria	5.6	4.4	10.8	0.18	0.072
Arthritis	0	1.1	6.5	0.0073	0.0023
Low complement	12.2	13.0	24.7	0.066	0.020
Anti-dsDNA	10.3	26.1	31.2	0.0005	0.011
Rash	2.8	7.6	7.5	0.21	0.47
Alopecia	18.7	23.9	28.0	0.011	0.0030
Mucous membrane	3.7	3.3	3.2	0.95	0.77
Pleurisy	1.0	1.1	2.2	0.65	0.36
Platelet<100	2.8	2.2	1.1	0.62	0.35
WBC<3	2.8	1.1	3.2	0.50	0.45

Conclusion: The LDG-associated gene signature was strongly associated with both global and organ-specific activity, being positively associated with arthritis and renal disease. Subsetting patients by neutrophil gene signature may be helpful in clinical trials of new biologics in SLE. In those patients with renal and musculoskeletal activity, LDGs may be a promising therapeutic target.

Proteomics Analysis Of Cartilage Secretome: A Powerful Tool For The Discovery Of OA Biomarkers. Lucía Lourido, Valentina Calamia, Patricia Fernández-Puente, Jesus Mateos, Beatriz Rocha, Carolina Fernández-Costa, Francisco J. Blanco and Cristina Ruiz-Romero. Osteoarticular and Aging Research Laboratory, Proteomics Unit-Associated Node to ProteoRed-ISCIII, INIBIC-CHUAC, A Coruña, Spain.

Background/Purpose: Osteoarthritis (OA) is characterized by the progressive loss of cartilage structural extracellular matrix (ECM) components, mainly collagenous and non-collagenous proteins. The release of these proteins from the tissue can vary according to the stage of the disease. Characterization of molecular differences between cartilage subtypes will provide a background for better understanding OA onset and progression. The aim of this study was to perform a quantitative proteomics approach to identify and quantify those proteins released from normal (N) and OA human articular cartilages.

Methods: Tissue explants were obtained from the dissection of 4 N and 4 OA cartilages, both from femoral heads and tibial condyles. Among the OA samples, we differentiated the wounded zones (WZ) from those corresponding to the area adjacent to the lesion, or unwounded zones (UZ). The study was approved by the local ethical committee. Cartilage shavings from each donor were cut into 6 mm discs and five discs/donor were placed into 96 wells plates and incubated during 6 days (37 °C/5% CO2). The conditioned media from each condition were collected and their proteins were digested with trypsin. Each peptide mixture was labelled with different isobaric tags using the iTRAQ reagents (ABSciex). Then, labelled peptides of the different conditions were mixed, desalted and separated by liquid chromatography (LC). The resulting fractions were grouped and resolved by reversed-phase nano-LC coupled to mass spectrometry (MS). The identification and relative quantification of the proteins was carried out with Protein Pilot 3.0 software.

Results: A mean of 206 cartilage secreted proteins was identified. Measurement of the different iTRAQ tags intensities allowed the relative quantification of almost all of them. Globally, we found 35 secreted proteins with statistically significant differences in abundance ($p \leq 0.05$) between the different OA zones (WZ and UZ) when compared with N samples: 26 were increased and 9 were decreased. We classified them in 3 sets of proteins: a group of 5 proteins (CILP, CILP2, CHI3L1, SPP1, PLA2G2A) were increased specifically in UZ samples (early OA biomarkers), a group of 6 proteins (APOA1, HSPG2, CRTAC1, COL12A1, COL15A1, PRG4) were increased only in WZ samples (late OA biomarkers) and finally a group of 15 proteins were modified in both OA zones. Although some of these proteins, like CHI3L1 and PRG4, have a previously reported putative biomarker value for OA, most of them are novel candidates of the disease onset (the first group) and progression (the second and third groups). Interesting when we compared these results with those obtained from cartilage tissue extracts analysis we found that most of the proteins increased in OA cartilage secretomes (like BGN, HAPLN1, APCS, TNC, TGFBI) are decreased in cartilage proteomes and viceversa.

Conclusion: We have identified a characteristic profile of proteins released from N and OA cartilages. We describe a panel of cartilage ECM proteins with potential biomarker value. This panel will be further explored in biological fluids (synovial fluid and serum) for the development of early diagnosis and/or anti-OA therapy monitoring strategies.

Major Histocompatibility Complex Class I Molecules Contribute To Behçet's Disease Risk Through Both Innate and Adaptive Immune Interactions. Michael J. Ombrello[1], Yohei Kirino[2], Paul de Bakker[3], Ahmet Gül[4], Elaine F. Remmers[2] and Daniel L. Kastner[2]. [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [2]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, [3]University Medical Center Utrecht, Utrecht, Netherlands, [4]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey.

Background/Purpose: Behçet's Disease (BD) is a complex genetic disease of unknown etiology that is characterized by inflammatory lesions of the eyes, skin, and oro-genital mucosa. The class I major histocompatibility complex (MHC) molecule, *HLA-B*51* (*B*51*), is the strongest known genetic

risk factor for BD. Associations between BD and a range of other factors within the extended MHC locus (xMHC) have also been reported, however strong linkage disequilibrium across the xMHC has complicated the confident disentanglement of other BD risk factors from *B*51*.

Methods: We examined a combination of directly obtained and imputed single nucleotide polymorphism (SNP) genotypes, directly obtained *HLA-B* locus types, and imputed classical *HLA* types and polymorphic HLA amino acid residues for association with BD in 1190 BD cases and 1257 controls. Genotypes from 2832 xMHC SNPs were extracted from a genome wide SNP array, and these data were used as the basis for SNP imputation with reference data from the 1000 Genomes Project. *HLA-B* types were determined using a sequence specific oligonucleotide-based assay. We used imputation to infer classical HLA types and the identities of polymorphic amino acid residues in each classic HLA molecule. Stepwise logistic regression and conditional analyses were performed using genotype probabilities produced by imputation.

Results: SNP mapping of the xMHC identified two regions, the *HLA-B/MICA* region and the region between *HLA-F* and *HLA-A*, as independently and significantly associated with BD after respective regression analyses ($p < 1.7E-08$). Haplotype analysis of the *HLA-B/MICA* region identified a common BD-associated haplotype that included *B*51* and 48 BD-associated SNPs, yet an identical SNP haplotype that lacked *B*51* conferred no risk of BD. We found that *HLA-B*51*, *-B*15*, *-B*27*, *-B*57*, and *-A*26* each contributed to BD risk independently, while *HLA-B*49* and *-A*03* were each protective against the development of BD. Regression analyses of polymorphic amino acid residues identified independent associations between BD and nine MHC class I amino acid residues, including one that conferred risk in both HLA-A and HLA-B. The majority of the BD-associated residues clustered around the MHC class I antigen binding groove, however one residue was located in the signal peptide of HLA-B. The BD-associated risk variant, threonine, at position −21 in the signal peptide has been previously shown to produce enhanced NK cell activation and cytotoxicity by reducing inhibitory NK ligand expression, when compared to the protective variant, methionine.

Conclusion: There are multiple MHC class I antigens, including *B*51*, that independently affect BD susceptibility. Nine MHC class I amino acid residues influence BD risk, eight of which map to the antigen binding groove and imply adaptive immune involvement. One BD-associated residue is within the HLA-B signal peptide, a known point of cross-talk between the innate and adaptive immune systems, where it leads to reduced protection from NK cytotoxicity. Together, our data indicate that MHC class I molecules influence BD risk through both innate and adaptive immune mechanisms.

Global Gene Expression Profiles Reveal Genetic Signatures Of Kawasaki Disease and Disease Outcome. Long Truong Hoang[1], Chiea Chuen Khor[1], Ahmad Nazri Mohamed Naim[1], Ling Ling[1], Chisato Shimizu[2], Martin L. Hibberd[1] and Jane C. Burns[2]. [1]Genome Institute of Singapore, Singapore, Singapore, [2]UC San Diego, School of Medicine, La Jolla, CA.

Background/Purpose: Kawasaki Disease (KD) is a self-limited vasculitis of unknown etiology that predominantly affects children younger than 5 years. The inflammation associated with KD affects the arterial wall and leads to coronary artery aneurysms (CAA) in 25% of untreated KD children, making KD the most common cause of acquired heart disease in children in developed countries. Genetic predispositions are thought to influence the risk of aneurysm formation, and several gene expression profiling studies for KD were performed to describe KD-specific signatures. However, the lack of power due to limited sample size precluded definitive identification of transcriptomic signatures specific to KD. In this study, we aim to identify the gene expression signatures associated with acute KD by investigating the global gene expression profiles in large number of samples collected in paired-blood samples from acute and convalescent phases. We also investigated the transcript abundance in patients with different IVIG treatment status and different CAA outcomes.

Methods: Illumina gene expression microarray was used to characterize gene expression profiles of 171 KD patients with paired blood samples from the acute and convalescent phase of KD. Quantitative RT-PCR was used to validate the findings of the microarray. A detailed clinical and hematological data was also collected for all the patients. A generalized linear model was used to indentify differentially abundant transcripts between acute and convalescent samples, as well as between IVIG response status and CAA outcomes.

Results: Our data suggest that the complement and coagulation cascades, Toll-like receptor signaling and innate immune related responses were the most prominent pathways that were up-regulated in acute KD patients, while CD8 T cell receptor pathway such was less abundant in acute patients. Toll-like receptors (TLR2, 5 and 8), FCGR1 (A and B), FCRG2 (A and B), CD3, CD4, CD8 and CD28 were amongst the most significant transcripts. We also observed and validated 24 transcripts that were differentially expressed between IVIG responsive and IVIG-resistant KD patients which could play a pivotal role in the disease pathogenesis. These include LILRA5, IL18R1, IRAK3, SORT1 and BMX.

Conclusion: We proposed the potential genetic signatures of acute KD and signatures of IVIG treatment outcomes. The functions of these markers will be further discussed.

HLA-DRB1 Rheumatoid Arthritis Susceptibility Amino Acids Define Haplotypes Associated With Radiological Outcome. Sebastien Viatte[1], Annie Yarwood[2], Buhm Han[3], Soumya Raychaudhuri[3], Deborah P. M. Symmons[4], Jane Worthington[5] and Anne Barton[6]. [1]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, Centre for Musculoskeletal Research, Institute of Inflammation and repair, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [4]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [5]Arthritis Research UK Epidemiology Unit, The University of Manchester and Rheumatoid Arthritis Consortium for Immunochip (RACI), International Consortium, United Kingdom, [6]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) is a systematic autoimmune disease caused by the interplay between environmental and genetic risk factors. The major genetic determinants of RA susceptibility comprise a group of alleles of the HLA DRB1 gene, which encode a similar amino-acid (aa) motif in the peptide binding groove of the beta chain and are collectively referred to as the shared epitope (SE). Several studies investigated different classifications of HLA-DRB1 alleles and their association with disease susceptibility. Recently, we reported a new classification system based on 3 HLA-DRB1 aa independently associated with RA susceptibility. We demonstrated that HLA-DRB1 haplotypes defined solely by aa at positions 11, 71 and 74 can be hierarchically classified regarding their effect size on RA susceptibility, ranging from risk to protective haplotypes. The impact of this classification on the prediction of radiological outcome in RA has not been studied so far.

Aims: To test whether the RA risk hierarchy within HLA-DRB1 haplotypes also associates with radiological outcome.

Methods: The Norfolk Arthritis Register (NOAR) is a primary care based inception cohort of patients with inflammatory polyarthritis (IP). Radiographs of the hands and feet were performed at baseline, year 1 and year 2 for some patients, and systematically at year 5 for all patients and scored using the Larsen technique. The HLA region of a subset of NOAR patients was densely genotyped using a custom Illumina® Infinium® array (ImmunoChip), imputed and HLA-DRB1 aa at positions 11, 71 and 74 were derived. In order to incorporate multiple records per patient over time and to fit the non-normal distribution of Larsen scores, Generalized Linear Latent and Mixed Modelling (GLLAMM) with discrete random effects and three latent classes was used to assess the association between Larsen score and HLA-DRB1 haplotypes longitudinally.

Results: 1685 NOAR patients had at least one x-ray available and 4-digit HLA-DRB1 typing with a total of 2796 x-rays. Of these, 482 were genotyped on the ImmunoChip platform. HLA-DRB1 haplotypes based on positions 11, 71 and 74 were grouped in 3 haplotype categories, based on their known effect on disease susceptibility (risk, neutral or protective). Preliminary multivariate haplotype group analysis showed a correlation between known effect sizes for susceptibility and effect sizes for severity. The protective group of HLA-DRB1 haplotypes on RA susceptibility

(Ser-Lys-Arg or Ser-Glu-Ala at 11, 71, 74, corresponding to HLA-DRB1*03:01, *11:02, *11:03, *13:01, *13:02) is protective for the development of radiological damage as well, independently of the SE.

Conclusion: Susceptibility HLA-DRB1 haplotypes define severity haplotypes as well. Protective HLA-DRB1 haplotypes on radiological severity were also identified. Since the effect size of HLA-haplotypes is likely to outweigh the effect of non-HLA single nucleotide polymorphisms in the prediction of disease outcome, our findings may be relevant in stratifying patients into different risk categories prior to the initiation of treatment.

1882

Characterizing The C-Type Lectin Domain Family 4, Member C Gene (*CLEC4C*) Expression In Peripheral Blood From Rheumatoid Arthritis Patients. Annie Yarwood[1], Joanna Cobb[2], Kate McAllister[1], Joanne Barnes[1], Ernst R. Dow[3], Michelle A. Penny[3], Robert W. Hoffman[3] and Anne Barton[4]. [1]Arthritis Research UK Epidemiology Unit, Centre for Musculoskeletal Research, Institute of Inflammation and repair, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [2]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Science Centre, Central Manchester Foundation Trust, Manchester, United Kingdom, [3]Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN, [4]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom.

Background/Purpose: A previous hypothesis-seeking study examining baseline phenotypic expression of mRNA in a Phase 2 clinical trial of tabalumab (also known as LA294 or LY2127399) suggested that expression of the gene *CLEC4C* might serve to help stratify patients for their clinical response to tabalumab. CLEC4C-expressing cells appear to mediate their immunoregulatory effects through direct cell-cell contact or indirectly through the production of cytokines including TGF-beta and IL-10 and appear to influence T regulatory cells via these mechanisms. We hypothesize that this immunoregulatory cell may have a role in pathogenesis of RA and may influence drug treatment response. The primary aim of our study was to characterise the phenotypic expression of the gene *CLEC4C*, as measured in peripheral blood among a well characterised cohort of rheumatoid arthritis patients receiving different therapies.

Methods: Total RNA was extracted from whole blood and converted to cDNA. A total of 322 samples were available for analysis, consisting of four groups: 1) 93 healthy controls 2) 72 RA patients with recent onset disease receiving methotrexate 3) 85 RA patients who have failed methotrexate and are receiving a TNFi 4) 72 RA patients who had failed at least one TNFi due to lack of efficacy and were receiving another biologic. Quantitative real time PCR was carried out to measure the expression of *CLEC4C* and three reference genes. *CLEC4C* expression was normalised and quantified using the delta CT method. Linear regression was used to correlate expression with treatment group.

Results: A significant difference in CLEC4C expression was observed between sample groups ($p=2.5\times10^{-5}$). CLEC4C expression was significantly higher in healthy individuals compared to all RA patients ($p=8.9\times10^{-6}$). All patient groups showed lower expression when compared to healthy controls and this difference is greatest in patients treated with biologic therapies including TNFi (Table 1).

Table 1. Linear regression results comparing CLEC4C expression in patients and healthy controls

Group	Coefficient	Standard error	P value	95% confidence interval	
Controls	Reference	—	—	—	—
MTX	−0.0018	0.0006	0.007	−0.0032	−0.0005
TNFi	−0.0027	0.0007	9.89×10^{-5}	−0.0040	−0.0013
Other Biologic	−0.0027	0.0007	0.00036	−0.0042	−0.0012

Conclusion: Differences in expression of *CLEC4C* were found between RA patients and age- and sex-matched healthy controls with statistically significant higher levels of expression of *CLEC4C* seen in healthy controls. Among RA patients the highest levels of CLEC4C were seen in the RA patients who had been treated only with methotrexate and were biological naive; lowest levels of *CLEC4C* in those treated with one or more biologic agent including TNFi. These results suggest that stratification for *CLEC4C* expression may be valuable to assure balance between patient subgroups in clinical trials in that difference in baseline *CLEC4C* expression could be a source of unanticipated bias influencing trial outcome. Finally, determining the biologic basis for these observed differences in *CLEC4C* gene expression among different subgroups of patients, based upon prior treatment, may help advance our understanding of disease pathogenesis in RA.

1883

Fine Mapping and Expression Of a Locus Overlapping 3 Types Of Inflammatory Arthritis. Kathryn J. A Steel[1], Anne Hinks[1], Annie Yarwood[2], Stephen Eyre[3], Edward Flynn[3], Paul Martin[1], Anne Barton[3] and Wendy Thomson[4]. [1]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Sciences Centre, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, Centre for Musculoskeletal Research, Institute of Inflammation and repair, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [3]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [4]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Science Centre, Manchester, United Kingdom.

Background/Purpose: In a recent fine-mapping study using the Immunochip array, the *RUNX1* region was strongly associated with rheumatoid arthritis (RA $p=5\times10^{-10}$), juvenile idiopathic arthritis (JIA $p=1\times10^{-8}$) and psoriatic arthritis (PsA $p=6\times10^{-4}$). In each disease the SNP rs9979383 confers disease protection with odds ratios ranging from 0.8–0.9. This SNP maps approximately 290kb upstream of *RUNX1*, indicating that it may be involved in regulation of gene expression. *RUNX1* encodes a transcription factor highly expressed during chondrogenesis, which has also been shown to interact with the regulatory T cell marker *FOXP3*. Unlike many loci on the Immunochip, variation in the *RUNX1* region is not well covered, therefore further fine mapping is required.

Methods: As rs9979383 lies between two points of high recombination, SNPs between these points were selected for fine mapping. 42 common (MAF>0.05) tag SNPs ($r^2>0.9$) from the Utah residents (CEPH) with Northern and Western European ancestry (CEU) 1000 genomes July 2010 release were selected. 2255 RA cases and 1877 healthy controls from the United Kingdom Rheumatoid Arthritis Genetics Group (UKRAG) were genotyped using the Sequenom iPlex MassARRAY platform. SNPs and samples which reached >90% success rate were included in the analysis. Allelic association testing was performed using PLINK v.1.07 and functional annotation of SNPs was performed using ASSIMILATOR. To determine if rs9979383 represents an expression quantitative trait locus (eQTL), Taqman genotyping and gene expression assays were performed in 75 healthy controls from the national repository healthy volunteers study. *RUNX1* expression was normalised to 2 endogenous controls (*ACTNB* and *GAPDH*) and linear regression performed in STATA v.11.2.

Results: In the UKRAG cohort, association with rs9979383 was replicated ($p=0.02$, OR = 0.9, CI 95% 0.82–0.98) with an odds ratio of 0.9, identical to the previous RA study. No other SNPs in the region showed evidence for association. Functional annotation of this SNP indicates that it lies within a region of open chromatin with transcription factor binding potential, making it an ideal candidate for gene expression studies. In whole blood, RUNX1 expression was not correlated with genotype at rs9979383 in healthy controls ($p=0.92$) indicating that rs9979383 may alter expression of another gene or that this eQTL may only be present at a cell specific level.

Conclusion: The results indicate that the *RUNX1* association is localised to r99793983 (or SNPs in high LD) in RA but the association requires confirmation in independent JIA and PsA cohorts. Although no eQTL was observed in whole blood in healthy controls, cell specific whole transcriptome studies are currently underway to determine whether this SNP is an eQTL. Combined with the fine mapping this will inform further investigations of the role of the *RUNX1* region in the common pathogenesis of inflammatory arthritis.

Autoantibody Specificities and Type I Interferon Pathway Activation In Idiopathic Inflammatory Myopathies. Saskia Vosslamber[1], Louise Ekholm[2], Anna Tjarnlund[2], T.D. de Jong[1], Lenka Plestilova[3], Martin Klein[4], Peter J. Charles[5], A.E. Voskuyl[1], Irene Bultink[1], Michiel Pegtel[1], J Vencovsky[6], Ingrid E. Lundberg[2] and Cornelis L. Verweij[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Rheumatology Unit, Department of Medicine, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [3]Institute of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [4]Institute of Rheumatology, Prague, Prague, Czech Republic, [5]Kennedy Institute of Rheumatology, Oxford, United Kingdom, [6]Institute of Rheumatology, Prague, Czech Republic.

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are rare autoimmune diseases characterized by proximal muscle weakness and muscle inflammation. IIM are associated with several autoantibodies, which are believed to play a role in its pathogenesis. Recent studies showed involvement of an activated type I IFN pathway in a subset of patients. Here we studied the possible relationship between autoantibody specificity and type I IFN pathway activation.

Methods: Ninety-four IIM patients, diagnosed with polymyositis (PM) (n=46), dermatomyositis (DM) (n=42), or inclusion body myositis (IBM) (n=6), 47 patients with systemic lupus erythematosus (SLE) and 43 healthy controls (HC) were included. Autoantibody profiles were assessed using lineblots. A whole blood IFN score was determined in all patients and healthy controls by measuring and averaging expression levels of 29 IFN response genes using BioMark™Dynamic Arrays. Type I IFN bioactivity in serum of 47 IIM patients was determined using a bioassay. The role of IFNα as an interferogenic trigger was determined using neutralizing antibodies in sera of a subset of 25 patients.

Results: The IFN signature was present in 45% of IIM patients, irrespective of diagnosis. The IFN score was associated with disease activity for patients diagnosed with DM but not PM or IBM. In IIM patients with a mono-specific autoantibody profile, an association between the presence of an IFN signature and autoantibodies against RNA binding proteins, such as Jo-1, Ro60, SRP and U1RNP, was observed, whereas the absence of an IFN signature is associated with autoantibodies not directed against RNA-binding proteins, such as Ro-52, and PMScl. Moreover, we observed an association between the presence of an IFN signature and patients with multi-specific autoantibody profiles compared to patients with a mono-specific autoantibody profiles or patients without autoantibodies ($p = 0.038$ and $p=0.002$, respectively). The IFN score correlated with type I IFN pathway-bioactivity (n=47) (r 0.4243, p= 0.0057), which could be partly blocked by neutralizing antibodies directed against IFNα and the type I IFN receptor.

Conclusion: Overall, our findings indicate involvement of IFNα in the type I IFN activity in IIM and suggest a relationship between the presence of anti-RNA-binding protein autoantibodies and the IFN signature in IIM. This hints towards a role for RNA as trigger of type I IFN activity in IIM similarly as has been observed for SLE.

A Weighted Genetic Risk Score Using All Known Susceptibility Variants To Predict Rheumatoid Arthritis Risk. Annie Yarwood[1], Buhm Han[2], Soumya Raychaudhuri[1], John Bowes[1], Mark Lunt[3], Dimitrios A. Pappas[4], Joel M. Kremer[5], Jeffrey D. Greenberg[6], Robert M. Plenge[2], Jane Worthington[3], Anne Barton[7] and Stephen Eyre[3]. [1]Arthritis Research UK Epidemiology Unit, Centre for Musculoskeletal Research, Institute of Inflammation and repair, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [4]Columbia University, College of Physicians and Surgeons, New York, NY, [5]Center for Rheumatology, Albany Medical College, Albany, NY, [6]New York Hospital for Joint Diseases, New York, NY, [7]NIHR Manchester Musculoskeletal BRU, Central Manchester Foundation Trust and University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom.

Background/Purpose: Recent advances in the identification of loci associated with susceptibility to complex disease have led to methods being developed that incorporate this information into genetic screening models to identify individuals at high risk of disease. Here we present the first risk prediction model including all 46 known genetic loci associated with rheumatoid arthritis (RA) in Caucasian populations.

Methods: Weighted genetic risk scores (wGRS) were created using odds ratios from 45 RA susceptibility SNPs and a HLA-DRB1 tag SNP or imputed HLA amino acids (HLA-DRB1 amino acids 11, 71, 74 and amino acids 9 at HLA-DPB1 and HLA-B). The wGRS were tested in 11,370 RA cases and 15,536 healthy controls of known genotype from the UK, USA, Sweden, Netherlands and Spain, all cases were Caucasian, over the age of 18 and satisfied 1987 ACR criteria for RA modified for genetic studies. The risk of developing RA was assessed using logistic regression by dividing the wGRS into quintiles. The ability of the wGRS to discriminate between cases and controls was assessed by receiver operator curve (ROC) analysis and discrimination improvement tests. As several of the RA susceptibility loci included in the wGRS were identified in the cohort used in this study, the wGRS were tested in an independent European cohort of 2206 RA cases and 1863 healthy controls for validation. Validation samples were from the Consortium of Rheumatology Researchers of North America (CORRONA) registry and the Informatics for Integrating Biology and the Bedside (I2B2) centre.

Results: Individuals in the highest risk group showed significantly increased odds of developing anti-CCP positive RA compared to the lowest risk group (AUC 0.77, OR 18.00 95% CI 13.67–23.71). 4347 individuals were classed as high risk when all susceptibility factors were included in the model, interestingly this included 10.13% of our control population. The wGRS was validated in an independent cohort which showed similar results (AUC 0.78, OR 18.00 95% CI 13.67–23.71). The AUC was improved by replacing the HLA-DRB1 tag SNP with imputed HLA variation at HLA-DRB1, HLA-DPB1 and HLA-B (wGRStag AUC 0.70, wGRSfull AUC 0.77) (in CCP positive individuals). Integrated discrimination improvement tests showed an increase in sensitivity and specificity of 9% and net reclassification tests showed that including all variation in the HLA over a HLA tag SNP improves the probability of correctly identifying a high risk individual to 69.20% from 64.21% and showed an overall reclassification improvement of 58.54% between models. Comparing the full model (in CCP positive individuals) to a model containing only imputed variation at the HLA and gender showed that the addition of the susceptibility SNPs to the model only slightly improved the ROC AUC (0.74 to 0.77 respectively).

Conclusion: We have shown that in RA, even when using all known genetic susceptibility variants, prediction performance remains modest; whilst this is insufficiently accurate for general population screening, it may prove of more use in targeted studies. Our study has also highlighted the importance of including HLA variation in risk prediction models.

1886

Differential Methylation Related To Response To Etanercept In Patients With Rheumatoid Arthritis. Amy Webster[1], Darren Plant[2], Mark Lunt[1], Stephen Eyre[1], Edward Flynn[1], Paul Martin[3], A. G. Wilson[4], A. W. Morgan[5], John Isaacs[6], Jane Worthington[1] and Anne Barton[1]. [1]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]NIHR Manchester Musculoskeletal BRU, Central Manchester Foundation Trust and University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom, [3]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Sciences Centre, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [4]Genomic Medicine, The University of Sheffield, Sheffield, United Kingdom, [5]Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, [6]National Institute for Health Research, Newcastle Biomedical Research Centre, Newcastle Hospitals Foundation Trust and Newcastle University, Newcastle Upon Tyne, United Kingdom.

Background/Purpose: The introduction of biologic drug therapies targeting specific components of the inflammatory response represents a huge advance in the treatment of rheumatoid arthritis (RA). Despite this, up to 40% of patients fail to respond well to these therapies. Ideally, clinicians would like to identify patients who are likely to respond to therapy as early as possible in the disease course, making identification of reliable biomarkers of response an important area of research. Recent studies suggest that epigenetic control

of gene expression may be important in RA; we have therefore hypothesized that epigenetic changes such as aberrant DNA methylation patterns may provide useful biomarkers of response to biologics.

Objectives: To identify a DNA methylation signature indicative of response to TNF-blockade therapy in patients with RA.

Methods: Patients were recruited from the Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS) longitudinal cohort. Patients (n=72) were selected based on having an extreme response phenotype after 3 months of treatment with etanercept; 36 were good responders defined as having an endpoint DAS28<2.6, and 36 were poor responders defined as having an improvement of <0.6 or between 0.6–1.2 with an endpoint DAS28 of >5.1. Whole blood DNA from each patient, sampled before initiation of etanercept therapy, was bisulfite converted and an epigenome wide association study was conducted using the HumanMethylation450 BeadChip (Illumina). A detection threshold was applied and probes with a detection p-value of greater than 0.01 were removed. Differentially methylated positions between responders and non responders were identified by linear regression following quantile normalisation.

Results: 4 CpG sites showed differences between responders and non-responders to etanercept passing a false discovery rate of 0.05 with a ($p \leq 10^{-7}$): cg04857395, cg16426293, cg03277049, cg14862806. While none of the 4 CpG sites mapped to obvious candidate genes, the most differentially methylated probe mapped to exon 7 of *LRPAP1,* which is highly expressed in mononuclear cells. Statistical adjustment for whole blood cell composition did not qualitatively alter the results.

Conclusion: This is the first methylome wide investigation of treatment response to TNF blockade therapy in RA and, while further well powered studies are required, these preliminary data identify methylation biomarkers of response.

1887

Interleukin-1 Receptor Antagonist (IL-1Ra) Plasma Levels Predict Radiographic Progression Of Symptomatic Knee Osteoarthritis Over 24 Months. Mukundan Attur[1], Alexander Statnikov[2], Jonathan Samuels[2], Svetlana Krasnokutsky[1], Jeffrey D. Greenberg[1], Zhiguo Li[2], Leon Rybak[2], Constantin F. Aliferis[2] and Steven B. Abramson[2]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]NYU Langone Medical Center, New York, NY.

Background/Purpose: Osteoarthritis is multi-factorial complex degenerative joint disease that leads to permanent joint damage. We and others have shown elevated levels of inflammatory and anti-inflammatory mediators in OA. Furthermore, polymorphism in IL-1RN gene has been shown to predict radiographic severity and progression in OA. There is currently great interest in the field of OA to identify biomarkers that identify patients at higher risk for disease progression and to identify biomarkers that can lead to new drug targets. This study was designed to test the hypothesis that plasma levels of IL-1Ra predict radiographic knee OA severity and progression and to examine IL-1Ra interactions with other biomarkers and confounding covariates.

Methods: 178 SKOA patients (mean age 62.5 + 10.5, mean BMI 26.7 ± 3.5) fulfilling ACR criteria for knee OA were recruited as part of an NIH-funded prospective study. Patients were followed longitudionally for 24 months with standard semi-flexed radiographs taken at 0 and 24 months, scored for overall KL grade and joint space width (JSW) by the same radiologist. SKOA patients (n=111) with medial OA and baseline JSW >0 completed the two year study. The blood samples collected at baseline were assayed for IL-1Ra by ELISA. For radiographic severity, biomarkers were evaluated between KL scores of 1, 2 with those with scores of 3, 4. Progression was defined as a change in medial JSW between baseline and 24 month radiographs of the signal knee, defined as the more symptomatic knee by the WOMAC pain scale.

Results: The mean plasma IL-1Ra level in SKOA subjects was 318.6 ± 205.8 pg/ml. Our data indicate that plasma IL-1Ra levels predicted higher risk for disease severity (KL grade), with an area under the curve (AUC) under receiver operating characteristic curve of 0.699 (p=0.0006). We found no significant association of IL-1Ra with WOMAC or VAS pain scores. In the 24-month longitudinal study we examined IL-1Ra in patients with JSN < 0 mm (*non-progressors*, 35% of cohort) and those with JSN > 0.6mm (*fast-progressors,* 38% of cohort). Baseline IL-1Ra was significantly elevated in fast-progressors (p= 0.0142) relative to non-progressors. After adjustment for BMI, age and gender, plasma IL-1Ra approached significance as a predictor of fast progression (p=0.0586). In order to determine the dependence of IL-1Ra on covariates (BMI, age, gender) we performed causal graph analysis [FCI algorithm, Spirtes et al 2000)] of continuous JSN. FCI allows discovering causality from observational data and identifying hidden confounding covariates. This method has been proven to be correct (i.e., to identify underlying causal structures that are consistent with the data) under broad distributional assumptions. Based on this analysis, plasma IL-1Ra plays a causal role and positively influences JSN independent of BMI, age and gender.

Conclusion: These findings suggest that plasma IL-1Ra is a candidate biomarker of radiographic progressive JSN. The analysis also suggests that IL-1Ra elevations are associated with causal events in OA disease progression. These observations will be further validated in a larger cohort of SKOA patients.

Transcriptional Regulation Of Peptidylarginine Deiminase Type IV: Implications For Rheumatoid Arthritis. Ali Abbas, Kevin Le, Virginia Pimmett, David A. Bell, Ewa Cairns and Rodney P. DeKoter. Schulich School of Medicine and Dentistry, Western University, London, ON.

Background/Purpose: High titers of anti-citrullinated protein/peptide antibodies (ACPA) have been detected in sera of rheumatoid arthritis (RA) patients, implicating citrullinating enzymes in the pathogenesis of RA. Peptidylarginine Deiminase Type IV (PAD4) is a member of the PAD family of citrullinating enzymes and has been linked to RA. Therefore, our aim was to determine how transcription of *PAD4* is regulated in the human myeloid lineage.

Methods: The *PAD4* transcription start site and promoter was located by 5' RACE and phylogenetic comparisons of the area identified a 200 bp conserved region. Bioinformatics analysis predicted the presence of a NFκB binding site and this was tested by luciferase assays. RT-qPCR was used to quantify *PAD4* expression in HL-60 cells treated with TNF-α to activate the canonical NFκB pathway. Finally, chromatin immunoprecipitation (ChIP) was used to determine NFκB enrichment at the *PAD4* promoter.

Results: The human *PAD4* promoter showed high biological activity. Interestingly, mutation of the predicted NFκB binding site significantly increased activity in human cell lines. *PAD4* mRNA was reduced in response to TNF-α treatment. Finally, the p50 subunit of NFκB was more highly enriched than p65 at the *PAD4* promoter.

Conclusion: We characterized the *PAD4* promoter and demonstrated that the p50 subunit of NFκB binds to the *PAD4* promoter upon NFκB activation. Our results suggest that the p50 subunit of NFκB may play a role in the repression of *PAD4* transcription during inflammation.

Genome-Wide Association Study Of Knee Radiographic Osteoarthritis In African-American Populations. Youfang Liu[1], Michelle S. Yau[2], Laura Yerges-Armstrong[2], M C. Hochberg[3], Braxton D. Mitchell[2], Rebecca D. Jackson[4], Jordan B. Renner[5], David Duggan[6] and Joanne M. Jordan[7]. [1]Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of Maryland School of Medicine, Baltimore, MD, [3]University of Maryland, Baltimore, MD, [4]Ohio State University, Columbus, OH, [5]University of North Carolina at Chapel Hill, Chapel Hill, NC, [6]TGen, Pheonix, AZ, [7]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC.

Background/Purpose: Few SNPs and susceptibility genes have been identified in previous genome-wide and candidate gene association studies for knee radiographic osteoarthritis (OA). Nearly all studies have been conducted in European Caucasian and Asian populations with few data published on genetics of knee OA in African-Americans. For this reason we have performed a genome-wide association study (GWAS) of knee OA in African Americans.

Methods: In total, 1217 African-American participants from two cohorts, the Johnston County Osteoarthritis Project (JoCo, 590 subjects) and the Osteoarthritis Initiative (OAI, 627 subjects), were included in the analysis. This sample size provides 80% power to detect odds ratios of 1.55–1.70 for minor allele frequencies ranging from 0.10–0.50. Knee OA cases were defined as having a Kellgren-Lawrence (KL) grade of 2 or higher in at least one knee, whereas controls were defined as having KL grade of 0 or 1 in both knees. Genome wide genotyping was completed using the Illumina 2.5M platform for OAI and Illumina Infinium 1M-Duo array for JoCo. Imputation was conducted with Minimach using the combined 1000 Genome CEU and YRI reference panels. Single marker analysis was conducted using logistic regression with adjustment for age, sex, body mass index (BMI) and principal components. We combined GWAS results from the two data sets using the meta-analyses as implemented in the METAL software program.

Results: No SNP reached the significant level at 10e-8. However, we identified 24 SNPs with P-value less than 5×10−6. Among the 24 SNPs, three are located in the coding regions of genes (*FLJ2052*, *RRAGD* and *ATP8A2*). *FLJ 2052* codes a hypothetical protein, whose biological function is unknown. *RRAGD* (Ras-Related GTP Binding D) codes a monomeric guanine nucleotide-binding protein. By binding GTP or GDP, small G proteins act as molecular switches in numerous cell processes and signaling pathways. *ATP8A2*(ATPase Class I Type 8A Member 2) codes a member of ATPase. It is well known that ATPases import and export many of the metabolites necessary for cell metabolism. However, the molecules carried by ATP8A2 are unknown. None of these genes has been implicated in OA development in Caucasian populations.

	N_samples	Age Mean (sd)	BMI Mean (sd)	Sex %women
JoCo_AA				
Case	293	63.98 (10.78)	34.70 (8.76)	68.94
Control	297	58.55 (9.63)	30.14 (6.27)	61.95
All	590	61.24 (10.57)	32.40 (7.93)	65.42
OAI_AA				
Case	449	59.63 (8.37)	31.92 (4.58)	69.71
Control	178	57.38 (8.25)	29.04 (4.59)	61.24
All	627	58.99 (8.39)	31.10 (4.76)	67.30

CHR	POS	SNP	Gene	Allele1	Allele2	Direction	Study	Beta	SE_Beta	P-value
5	16608874	rs890824	FLJ2052	t	c	—	META	—	—	3.93E-06
							JoCo	−0.7948	0.2234	0.000374
							OAI	−0.5875	0.1972	0.002898

							JoCo	−0.6490	0.2142	0.002448
							OAI	−0.7592	0.2167	0.00046
13	26095937	rs34622730	ATP8A2	a	g	++	META	—	—	4.34E-06
							JoCo	0.4618	0.1509	0.002212
							OAI	0.5141	0.1498	0.000599

Conclusion: We identified three genes associated with knee OA with P-value < 5×10−6 in African Americans. *RRAGD* and *ATP8A2* are both involved in various cell processes and signaling pathways. Further analysis, including pathway analysis, will be performed to determine if these biological pathways or protein networks have a role to play in knee osteoarthritis.

Chemokine Receptor Polymorphisms On Chromosome 3 Are Associated With Anticitrullinated Protein Antibody Specificities In African Americans With Rheumatoid Arthritis. Richard J. Reynolds[1], Maria I. Danila[2], Jeremy Sokolove[3], William H. Robinson[4], Doyt L. Conn[5], Beth L. Jonas[6], Leigh F. Callahan[7], Larry W. Moreland[8], Richard D. Brasington[9], Edwin A. Smith[10], Peter K. Gregersen[11] and S. Louis Bridges Jr.[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Univ of Alabama-Birmingham, Birmingham, AL, [3]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [4]Stanford University School of Medicine, Stanford, CA, [5]Emory Univ School of Medicine, Atlanta, GA, [6]University of North Carolina at Chapel Hill, Chapel Hill, NC, [7]University of North Carolina, Chapel Hill, NC, [8]University of Pittsburgh, Pittsburgh, PA, [9]Washington Univ School of Med, St. Louis, MO, [10]Med Univ of South Carolina, Charleston, SC, [11]Feinstein Institute for Medical Research, Manhasset, NY.

Background/Purpose: ACPA antibody specificities to citrullinated autoantigens (e.g., histones, vimentin, fibrinogen) are associated with the preclinical phase of RA and may predict the onset of synovitis. However, it is not known whether individual antibody response to different citrullinated peptides has a genetic basis. Here we report that non-HLA polymorphisms known to be associated with autoimmune disease are associated with ACPA specificities in African-Americans with RA.

Methods: 449 (RF+ or anti-CCP+) African-American RA patients genotyped on the Immunochip array (~200K SNPs from a variety of autoimmune diseases) were analyzed. 90% individual and 98.5% SNP call rates were used as quality control thresholds. Using a custom Bio-Plex™ bead-based autoantibody assay platform, we measured autoantibodies targeting different RA associated citrullinated autoantigens: vimentin, fibrinogen, histone 2A (H2A), histone 2B (H2B), and apolipoprotein A1 (Apo A1). Linear regression was used to fit models of ln (ACPA Ab) conditional on sex, disease duration, proportion European admixture and minor allele copies for ~167K markers that met quality control.

Results: In addition to an association with the MHC region (known to be associated with ACPA+ RA), we found additive allelic effects on anti-citrullinated H2A (anti-cit H2A) indicating a strong association in a non-MHC region on chromosome 3 (Figure 1). For anti-cit H2A and anti-cit H2B there were 43 and 48 associations, respectively, with p value < 0.001 between 45.9 and 46.4 Mb. The association signal with strong LD support was verified for both anti-cit H2A (Figure 2) and anti-cit H2B. The strongest SNP association was rs4683166 (MAF = 0.45) for both anti-cit H2A (p-value= 1.5e-05) and anti-cit H2B (p-value = 1.0e-05), and indicated an increasing relationship of minor alleles (G) and Ab concentration. In addition, rs4683166 was associated with anti-cit vimentin (p=0.0045), and anti-cit ApoA1 (p=0.024), but not anti-cit fibrinogen (p=0.15). rs4683166 was not associated with RA suceptibility (p-value = 0.18 for difference in MAF between 662 RA cases and 876 African-American controls).

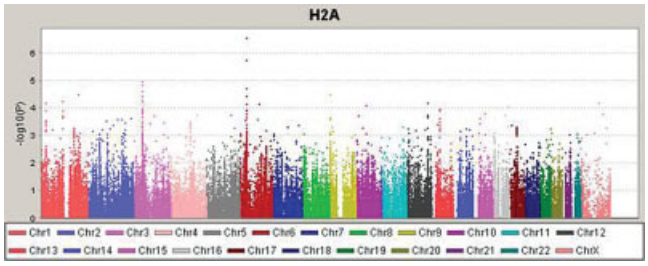

Figure 1. Manhattan plot of loci associated with serum anti-cit H2A levels.

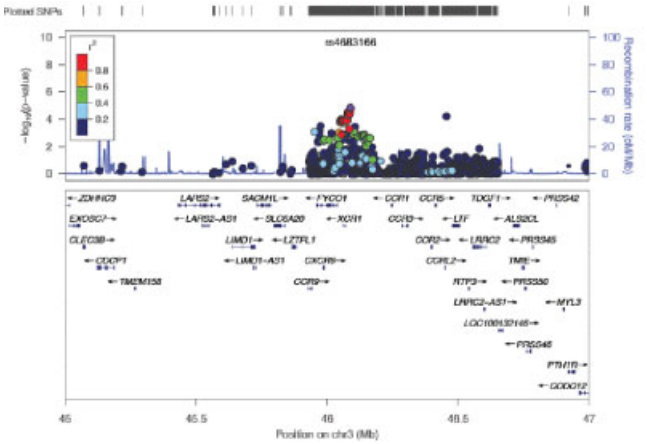

Figure 2. Zoomplot indicating the strongest chr 3 association signal.

Conclusion: The presence of antibodies to citrullinated autoantigens appears to have a strong non-MHC association near the XCR1 chemokine receptor on human chromosome 3. These results suggest there may be a significant genetic basis for disease specific antibodies in RA.

Proteomic Profile Of Tears: Can It Help To Diagnose Juvenile Arthritis - Associated Uveitis Prior To The Clinical Signs Of Joints Inflammation.
Vyacheslav Chasnyk[1], Sergei Nekhai[2], Alla Hynes[3], Tatiana Ammosova[2], Yuri Obukhov[2], Ekaterina Gaidar[4], Anatolyi Kononov[4], Margarita Dubko[1], Elena Serogodskaia[4] and Tatiana Nikitina[4]. [1]Saint-Petersburg State Pediatric Medical University, Saint-Petersburg, Russia, [2]Howard University, Washington, DC, [3]Eye Care Physicians and Surgeons, Winchester, VA, [4]Saint-Petersburg State Pediatric Medical University, St. Petersburg, Russia.

Background/Purpose: Approximately 6% of all cases of uveitis arise in children (Nguyen, Foster, 1998). One of the common causes of uveitis is Juvenile Idiopathic Arthritis (JIA). Up to 20% of JIA children have uveitis (Kesen et al., 2008) and often uveitis is the initial clinical manifestation of JIA, the delay of arthritis can be estimated at years which complicates treatment for uveitis and lead to blindness. During the last years the number of proteins identified in tears increased from 200 (Herber et al., 2001) of only 17 (Zhou et al., 2003) different molecular weights (MW) to 491 (de Souza et al., 2006) and 80 chemokines, cytokines, and growth factors (Sack et al., 2005). Objective: to reveal protein markers of JIA-associated uveitis in tears using high-resolution mass-spectrometry.

Methods: Patients with uveitis were examined by ophthalmologists and rheumatologists and the standard clinical protocol was used to diagnose the disease. Tear samples drawn from 13 JIA-patients and 3 healthy subjects were analyzed. Tears were collected on a filter paper, digested with trypsin and the peptides were purified on Zip tips. The samples were loaded to nano C18 column attached to Shimadzu nano LC coupled in-line to LTQ Orbitrap XL tandem mass spectrometer (Thermo Fischer Scientific, GA, USA). The mass spectra of the peptides were detected with a data-dependent 4-event scan method (a survey FT-MS parent scan followed by sequential data-dependent FT-MS/MS scans on the three most abundant peptide ions from the parent scan). Proteins were identified from the mass spectra results with Proteome Discoverer software for protein database search using the International Protein Index (IPI) Human Protein Database (version 1.79). Quantification was conducted using SIEVE.

Results: About 3000 proteins were detected in tears. Among those, 236 proteins (MW 7.4 – 466 kDa) were chosen as candidates for early diagnosis of the JIA-associated uveitis. Besides the rheumatoid factors RF-ET12, RF-IP14, RF-IP24, cytokines and T-cell receptor alpha-chain, we identified anti-CD40 single-chain antibody fragment A49, inhibiting protein CD40 which is a member of the TNF-receptor superfamily, lipocalin-1 precursor, associated with immune response and prostaglandin synthesis, clusterin inhibiting the cytolytic reaction of complement components, anti-TNF-alfa antibody light chain Fab fragment, protein phosphatase, regulatory subunit 15B, which plays a role in cell progression, apoptosis and regulation of membrane receptors and channels, DMBT/8kb.2 protein, which takes part in the interaction of tumor cells and the immune system.

Conclusion: Our pilot study demonstrates the benefits of high resolution mass- spectrometry for analysis and development of molecular signatures which can be used in future diagnostics. Earlier it was shown that induced anterior uveitis in the eyes of rats can be described in terms of proteins drawn from the anterior chamber (Sobn et al., 2000), which result is close to our terms of description. Our results support the suggestion that it is possible to identify protein markers of JIA-associated uveitis in tears prior to the clinical signs of arthritis.

High-Throughput Immunoglobulin G Fab Glycosylation Profiling Reveals Differential Glycosylation On Fab and Fc.
Albert Bondt[1], Yoann Rombouts[2], Maurice H.J. Selman[2], Radboud JEM Dolhain[1] and Manfred Wuhrer[2]. [1]Erasmus University Medical Center, Rotterdam, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Rheumatoid arthritis is known to improve during pregnancy, and a flare of disease activity is observed after delivery (1). N-glycosylation of the constant region (Fc) of immunoglobulin (Ig) G has been associated with these observations (2). However, glycosylation of the antigen binding fragment (Fab) of IgG might also play a role. Fab glycosylation has been suggested to influence affinity to antigen, and antibody half-life (3, 4). Analysis of Fab glycosylation is challenging because of the hypervariable properties of IgG Fab. Here we describe a newly developed highly specific method for the analysis of Fab N-glycosylation.

Methods: Sera were collected three times during pregnancy and three times after delivery from healthy individuals participating in a prospective cohort study on Pregnancy induced Amelioration of Rheumatoid Arthritis (PARA-study). IgG was affinity purified from the sera using IgG-Fc (Hu) beads. Using FabRICATOR® enzyme IgG was cleaved in two ½ Fc portions and a $F(ab')_2$ portion. Fc and $F(ab')_2$ were separated, and glycans were released followed by automated MALDI-TOF measurement to establish the levels as well as patterns of glycosylation.

Results: In healthy pregnant individuals Fc and Fab show distinct glycosylation patterns (Figure 1). Levels of galactosylation and sialylation are higher on Fab compared to Fc (±94% vs. ±60% and ±60% vs. ±15%, respectively). However, while major changes occur in these features on IgG Fc during pregnancy, the levels appear to be stable at the Fab portion. On the other hand, fucosylation and bisecting N-acetylglucosamine do not change drastically on the Fc portion with pregnancy, while pronounced lowered levels of both glycosylation features are observed during pregnancy in these individuals.

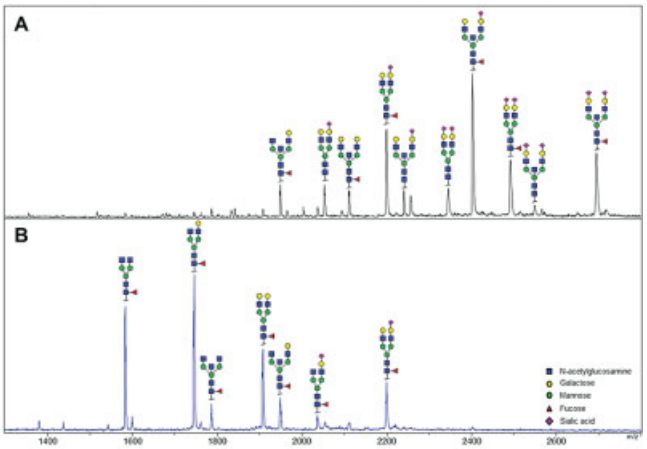

Figure 1. Typical IgG Fab (**A**) and Fc (**B**) spectra showing distinguishable AA-labeled glycans

Conclusion: Data obtained from serum of healthy pregnant individuals reveals differential glycosylation on Fab compared to Fc. Fab and Fc were found to show distinct glycosylation changes with pregnancy. In the near future we will apply this method to RA patient sera to identify whether Fc or Fab glycosylation could be a bigger effector in the improvement of RA during pregnancy.

Altered DNA Methylation Profiles In Individuals With Osteoarthritis.
Kathryn A Bailey[1], Daniel Rojas[2], Nikhil Umesh[1], Lisa Smeester[1], Tristan De Buysscher[3], Jordan B. Renner[4], Joanne M. Jordan[5] and Rebecca C. Fry[1]. [1]Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Curriculum in Toxicology, Univeristy of North Carolina at Chapel Hill, Chapel Hill, NC, [3]Center for Bioinformatics, University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, [5]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC.

Background/Purpose: Major risk factors associated with osteoarthritis (OA) development include age, joint stress/injury, obesity, and genetic

predisposition. In recent years, the role epigenetic processes that may be associated with OA have been of increasing interest both as factors implicated in disease development and as powerful diagnostic tools. Here, we set out to identify 5-methyl cytosine DNA methylation patterns associated with OA in participants of the Johnston County Osteoarthritis Project (JoCo OA), an ongoing study of North Carolinians of over 20 years.

Methods: Genomic DNA was isolated from peripheral blood mononuclear cells (PMNCs) collected from 20 Caucasian, non-smoking, non-drinking women from the JoCo OA cohort. Methylated regions of PMNC 5-methyl cytosine DNA were isolated and amplified using the Methylated CpG Island Recovery Assay (MIRA) and subsequently hybridized to Affymetrix® Human Promoter 1.0R arrays. Controlling for known confounders (e.g. age and body mass index (BMI)), we compared the promoter DNA methylation profiles of >14,000 promoter regions of genes from women with knee OA (n=8) to women without knee OA (n=12) using regression analysis. Differentially methylated genes were analyzed for associated biological functions, diseases, canonical pathways and molecular networks.

Results: A total of 68 genes were identified that had statistically significant differences in promoter DNA methylation levels in women with knee OA compared to women without knee OA. Most of these genes (n=61) showed hypomethylation in their promoter regions in individuals with knee OA. Analyses of associated biological functions, pathways and molecular networks revealed an enrichment of genes involved in varied cellular functions including tissue development, metabolism, and inflammation (Table). Several of these genes have prior associations with OA, namely connective tissue growth factor (*CTGF*), eyes absent homolog 4 (*Drosophila*)(*EYA4*), growth hormone receptor (*GHR*), and homeobox A2 (*HOXA2*).

Table. Most significant biological functions, canonical pathways and molecular networks associated with differentially methylated genes in individuals with OA.

Biological functions	***p*-value**
Embryonic development	5.77×10^{-6}–3.58×10^{-2}
Organismal development	5.77×10^{-6}–3.58×10^{-2}
Tissue development	5.77×10^{-6}–3.58×10^{-2}
Auditory and vestibular system development and function	1.63×10^{-5}–3.31×10^{-2}
Organ morphology	1.63×10^{-6}–3.58×10^{-2}
Canonical pathways	***p*-value**
PRPP biosynthesis I	8.37×10^{-3}
Tetrapyrrole biosynthesis II	8.37×10^{-3}
Glycogen biosynthesis II	1.67×10^{-2}
NF-kB activation by viruses	1.67×10^{-2}
Heme biosynthesis II	1.82×10^{-2}
Molecular network functions	***p*-value**
Hematological disease, nutritional disease, tissue morphology	$<10^{-40}$
Cellular assembly and organization, cellular function and maintenance, cell cycle	$<10^{-32}$
Cellular growth and proliferation, auditory and vestibular system development and function, embryonic development	$>10^{-27}$
Connective tissue disorders, developmental disorder, hereditary disorder	$<10^{-12}$
Molecular transport, RNA trafficking, RNA post-translational modification	$<10^{-10}$

Conclusion: We identified genes in PBMCs with altered promoter DNA methylation levels associated with knee OA in this pilot study. Expanding these analyses to include more individuals from the JoCo OA cohort will determine if these DNA methylation profiles may serve as biomarkers of OA and/or provide insight into the role epigenetic alterations may play in OA development.

Association Of Alleles and Amino Acids Of The Major Histocompatibility Complex Class I Chain-Related Gene A With Psoriatic Disease. Remy Pollock, Fawnda Pellett, Renise Ayearst, Fatima Abji, Dafna Gladman and Vinod Chandran. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: We previously reported associations between alleles of the major histocompatibility complex class I chain-related gene A (*MICA*) and psoriatic disease that were independent of *HLA-B* despite their tight linkage disequilibrium. In a larger cohort of patients, we sought to investigate the association with *MICA* alleles and determine if associations are evident at the amino acid level.

Methods: Caucasian psoriatic disease patients [786 PsA patients satisfying CASPAR criteria and 358 psoriasis patients without arthritis (PsC)], and 717 unaffected controls were recruited from a large cohort. *MICA* and *HLA-B* allelic typing was performed by PCR-SSO. Univariate logistic regressions were performed using *MICA* and *HLA-B* alleles as predictor variables for psoriatic disease compared to controls, and PsA compared to PsC. Multivariate logistic regressions used significant *MICA* alleles with significant *HLA-B* alleles as covariates. *MICA-HLA-B* haplotypes were estimated using the EM algorithm and differences between subject groups were analyzed using SNP & Variation Suite 7 software. *MICA* alleles were converted into amino acids at each polymorphic site of the mature MICA protein and analyzed for differences between groups.

Results: PsA patients were 58% male, mean age (s.d.) at diagnosis of psoriasis 28 (14.4) years, age at PsA diagnosis 36 (13.0) years, and PASI 5.3 (8.1). Psoriasis patients were 55% male, mean age at diagnosis of psoriasis 30 (16.6) years, and PASI 5.3 (4.9). Controls were 43% male. *MICA**002:01, *004, *007:01, *008:01, *009:01, *010:01, *016, *017, and *027 were associated with psoriatic disease compared to controls, and *MICA** 007:01 and *017 were associated with PsA compared to PsC in univariate analyses ($p<0.05$). After adjusting for *HLA-B* alleles, only *MICA**016 was independently associated with psoriatic disease (OR=2.1, $p<0.01$), and *MICA** 007:01 with PsA (OR=3.2, $p=0.04$). Haplotypes *MICA** 016-*B**3501 (OR=3.2, $p<0.01$), *MICA**017-*B**5701 (OR=2.5, $p<0.01$) and *MICA**002:01-*B**3801 (OR=6.5, $p<0.01$) were among those increased in psoriatic disease compared to controls. Haplotype *MICA**007:01-*B**2705 (OR=4.1, $p<0.01$) was increased in PsA compared to PsC, while haplotypes *MICA**017-*B**5701 (OR=0.54, $p<0.01$) and *MICA**008:01-*B** 1302 (OR=0.42, $p<0.01$) were decreased. Methionine at amino acid position 129 (M129), which is present in *MICA**002:01, *007:01 and *017, was associated with psoriatic disease compared to controls (OR=1.9, $p<0.01$), and was strongly associated with amino acids G206, W210, S215, C36, and K173. Arginine at position 91 (R91), which is unique to *MICA** 017, was decreased in PsA compared with psoriasis patients (OR=0.57, $p<0.01$).

Conclusion: We confirmed the HLA-B-independent association of *MICA**016 with psoriatic disease, and found a new association between *MICA**007:01 and PsA. *MICA* alleles containing the M129 amino acid are associated with psoriatic disease, while the *MICA**017 allele containing the R91 amino acid are protective against PsA in psoriasis patients. Further genetic and structural studies are needed to understand the significance of these findings.

Identification Of Aberrant Pathways In Osteoarthritis Using RNA-Seq. Kathleen M. Fisch[1], Masahiko Saito[2], Ryuichiro Akagi[1], Stuart Duffy[1], Andrew I. Su[1] and Martin K. Lotz[1]. [1]The Scripps Research Institute, La Jolla, CA, [2]Toho University Sakura Medical Center, Sakura, China.

Background/Purpose: Osteoarthritis (OA) is a prevalent joint disease that is characterized by the destruction of articular cartilage, although the disease process affects all joint tissues. Understanding the biology of joint homeostasis and the mechanisms of disease will increase our understanding of OA, particularly as it relates to aging. This long-term study aims to integrate genomic, epigenetic, transcriptomic and proteomic data on both normal and OA joint tissues to build a multidimensional molecular profile for OA and aging. The first phase of this project explores the gene expression profiles of articular cartilage from normal and OA human knee joints. In this study, we identified differentially expressed genes between normal and OA articular cartilage using RNA-sequencing (RNA-seq) to discover key biological pathways that are dysregulated in OA.

Methods: We extracted total RNA from full-thickness articular cartilage from 10 human donors (5 normal and 5 severe OA) using the Ambion RNAqueous Kit and prepared RNA libraries for sequencing using the NuGen Encore Complete RNA-Seq DR Multiplex System. Sequencing was performed on an Illumina HiSeq 2000 (single-end, 100bp reads). Raw data were checked for quality using FASTQC, and the raw FASTQ files were aligned to the human genome (hg19) using TOPHAT2. Aligned transcripts were assembled with CUFFLINKS2 and differentially expressed (DE) transcripts were determined using CUFFDIFF2 with a false discovery rate q-value of 0.05, fragment bias correction and upper quartile normalization. We con-

ducted a signaling pathway impact analysis using the Bioconductor packages SPIA and Graphite with the KEGG, Reactome, BioCarta and National Cancer Institute/Nature Pathway Interaction Databases (NCI/NPID) to identify potential functional pathways dysregulated in OA.

Results: A total of 2,180 DE genes were discovered between OA and normal human cartilage. Of these DE genes, 1,428 were significantly up-regulated in OA and 752 were significantly down-regulated in OA (Table 1). The five DE genes with the largest fold-change that were up-regulated in OA include COL1A1, THY1, TGFBI, CLDN7, and SLPI. The five DE genes with the largest fold-change that were down-regulated in OA include ADM, CHPF2, HILPDA, SERPINA10 and NRF1. Signaling pathway impact analysis revealed 11 significantly perturbed pathways in OA (Table 2).

Table 1. Gene/Isoform Expression Summary

Genes	Normal	OA
Total Genes expressed	28,554	28,711
Normal Only	1,388	
OA Only		1,545
Up-regulated		1,428
Down-regulated		752
Known Isoforms	**Normal**	**OA**
Total Known Isoforms expressed	55,997	54,268
Normal Only	5,099	
OA Only		3,370
Up-regulated		961
Down-regulated		267
Potentially Novel Isoforms	**Normal**	**OA**
Novel Isoforms Expressed	13,100	12,683
Normal Only	851	
OA Only		434
Up-regulated		3,252
Down-regulated		3,755

Genes, known isoforms and novel isoforms expressed in normal and OA articular cartilage. Expression determined by CuffDiff, after Benjamini-Hochberg correction. Up−/− Down regulated genes are those where there is a 2-fold or greater difference that is significantly differentially expressed. The fold change is the ratio of OA FPKM to normal FPKM.

Table 2. Pathways identified as significantly dysregulated in Osteoarthritis by signaling pathway impact analysis.

Arthritis Associated Sequence Alterations Within a Genetic Susceptibility Region Of Mouse Chromosome 3; A Genomic Region Which Is Syntenic With a Prominent Non-MHC Locus In Rheumatoid Arthritis.

Andras Vida[1], Timea Besenyei[2], Beata Tryniszewska[1], Timea Ocsko[1], Zoltan Szekanecz[3], Tibor A. Rauch[1], Katalin Mikecz[1] and Tibor T. Glant[1]. [1]Rush University Medical Center, Chicago, IL, [2]University of Debrecen, Debrecen, Hungary, [3]University of Debrecen Medical and Health Sciences Center, Debrecen, Hungary.

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease that results in inflammatory destruction of synovial joints in affected patients. The involvement of genetic and epigenetic factors in RA is recognized, but not well understood. Using proteoglycan (PG)-induced arthritis (PGIA), an autoimmune mouse model of RA, previously we identified a genomic region in mouse chromosome 3 (mChr3) which was associated with PGIA susceptibility independently of MHC. The goals of the present study were (i) to generate MHC-matched PGIA-susceptible and -resistant interval-specific congenic (IVSC) strains in order to narrow this genomic region to a size that can be sequenced by next generation sequencing (NGS) methods, and (ii) to identify disease-associated genomic alterations/mutations (e.g., nucleotide insertions or deletions: "indels") within this region in PGIA-susceptible and resistant IVSC mice.

Methods: IVSC strains were created by intercrossing MHC-matched PGIA-resistant DBA/2 and PGIA-susceptible BALB/c strains, which resulted in IVSC offspring carrying partially overlapping DBA/2 genomic segments within mChr3 on a full BALB/c background. Heterozygous mice with the same narrow genomic intervals were mated and homozygous offspring were tested for susceptibility to PGIA. On the basis of arthritis incidence and severity in IVSC mice, a 21 Mbp region of Chr3 (99.4–120.4 Mbp) was selected, and sequenced by NGS in parent and IVSC mice (n=16). All sequence alterations were compiled into a database and analyzed using GeneSpring NGS software (Agilent) and Microsoft Visual Studio program scripts.

Results: The sequenced 21 Mbp genomic region of mChr3 contained a total of 164,380 nucleotide changes (mutations) in DBA/2 and BALB/c as compared to the corresponding core (reference) C57BL/6 genomic sequences. Of these mutations, 42% were unique to BALB/c and 21% were unique to DBA/2. However, less than 1% of the mutations were located within protein coding (exonic) regions. All missense exonic mutations were predicted to have negligible or no effect on RNA or protein sequences, and no nonsense mutation was found. A total of 4,429 mutations were located within the region containing the *Ptpn22* and *Cd2* genes and their flanking sequences, which have been reported to harbor RA-associated SNPs on human Chr1. However, a number of indels found in the intergenic regions *Ptpn22* and *Cd2* loci of mChr3 were predicted to create or eliminate binding sites for potentially important transcription factors.

Conclusion: We have identified arthritis-associated sequence alterations within a genomic region of mChr3 containing the *Ptpn22* and *Cd2* genes in mice, which region is syntenic with a prominent RA susceptibility locus on human Chr1. Although the majority of the mutations are located within non-coding sequences, they may alter the binding of transcription factors or epigenetic modulators to promoter regions, thus affecting the transcription of the neighboring genes. Our finding warrant further genetic, epigenetic, and functional studies on this arthritis-associated locus in mice and humans.

1897

Algorithms Using Genome-Wide SNP Analysis For Prediction Of Progression Of Joint Space Narrowing Or Erosion In Rheumatoid Arthritis Patients Using Data From Multiple Medical Cohorts.

Tsukasa Matsubara[1], Satoru Koyano[2], Yoshitada Sakai[3], Keiko Funahashi[2], Takako Miura[1], Kosuke Okuda[1], Takeshi Nakamura[1], Akira Sagawa[4], Takeo Sakurai[5], Hiroaki Matsuno[6], Tomomaro Izumihara[7] and Eisuke Shono[8]. [1]Matsubara Mayflower Hospital, Kato, Japan, [2]Research Institute of Joint Diseases, Kobe, Japan, [3]Kobe University, Kobe, Japan, [4]Sagawa Akira Rheumatology Clinic, Sapporo, Japan, [5]Inoue Hospital, Takasaki, Japan, [6]Matsuno Clinic for Rheumatic Diseases, Toyama, Japan, [7]Izumihara Rheumatic and Medical Clinic, Kagoshima, Japan, [8]Shono Rheumatology Clinic, Fukuoka, Japan.

Background/Purpose: Although not yet fully possible, ideally, since patients with rapidly progressing joint space narrowing/erosion exist, predicting progression of joint space narrowing/erosion would be pivotal in establishing treatment strategy for individual RA patients. Also, it is important to distinguish the effectiveness between TNF biologics and non-TNF biologics in joint space narrowing progression-type/erosion progression-type patients for determining the best treatment strategy. We developed SNP algorithms with an aim of enabling prediction of progression of joint space narrowing/erosion by means of genome-wide SNP analysis using multiple medical cohorts.

Methods: One-hundred twenty-four RA patients with disease duration of 5 years or less from 6 different hospitals were enrolled. All patients were treated with biologics after the using DMARDs. We defined patients with

rapid progression of joint space narrowing and with rapid progression of erosion by the ratio between joint space narrowing/erosion score in each patient. Twenty-five patients had joint space narrowing/erosion score of ≧ 5 (rapid progression of joint space narrowing), 99 had joint space narrowing/erosion score of < 5 (slow progression of joint space narrowing), 21 had an erosion/joint space narrowing score of ≧1 (rapid progression of erosion), and 103 had erosion/joint space narrowing score of < 1 (slow progression of erosion). Case-controlled analyses between 278,347 SNPs and progression of joint space narrowing/erosion (rapid vs. slow) were examined by Fisher's exact tests. We selected 10 SNPs closely associated with progression of joint space narrowing/erosion ($p < 0.0001$). We then scored a relationship between each SNP and progression of joint space narrowing/erosion, the estimated total score of the 10 SNPs (estimated scoring in each SNP was as follows: homo allele in the majority in rapid progression group: +1 point, hetero allele: 0 point, and homo allele in the majority of slow progression group: −1 point), and examined relationships between the rapid and slow group, and the total score.

Results: Accuracy ((true positive+true negative)/total), specificity (true negative/(false positive+true negative)) and sensitivity (true positive/(true positive+false negative)) of the algorithm for distinguishing the rapid progressing joint space narrowing group from the slow progressing group ranged from 80–88%. Accuracy, specificity and sensitivity of the algorithm for distinguishing the rapid progressing erosion group from the slow progressing group ranged from 86–95%. It is therefore suggested that this SNP algorithm may enable the prediction of rapidly progressing joint space narrowing/erosion. Though neither effectiveness of TNF-biologics nor non-TNF biologics correlated to the score of erosion progression-type and/or joint space narrowing progression-type patients ($p > 0.05$), with progressive type of erosion, tocilizumab treatment tended to be effective.

Conclusion: This highly accurate algorithm using SNP analysis may be useful in initially diagnosing rapid progression of joint space narrowing and/or erosion, and, in this way, may contribute to establishing a treatment strategy for individual RA patients.

1898

Repression Of Wolf-Hischhorn Syndrome Candidate-1 (WHSC1) Contributes To The Osteoarthritis-Inducing Cartilage Loss Of Functions. Francisco Espinoza[1], Yves-Marie Pers[2], Paul Chuchana[3], Jean Marc Brondello[4] and Christian Jorgensen[2]. [1]INSERM U844, MONTPELLIER, France, [2]Inserm U844, CHU saint-Eloi, Université Montpellier 1, CHU Lapeyronie, Montpellier, France, [3]INSERM U844, Montpellier, France, [4]UM1, Montpellier, France.

Background/Purpose: Accumulation of senescent $p16^{INK4A}$-positive cells within numerous tissues through out life span contributes to the onset of several age-related disease such as intervertebral disc degenerescence or osteoarthritis (OA). These cells are believed to induce tissue degenerescence and age-dependent loss of functions through the establishment of one senescence-associated secretory phenotype (SASP) including pro-inflammatory cytokines (e.g IL-6, IL-8) and hypertrophic-associated matrix degrading enzymes (e.g MMP1/13 and ADAMTS5). Understanding the molecular mechanism in particular epigenetic regulators leading to the establishment of such deleterious secretome, is a next challenge. Here, we investigate the role and the regulation of the histone H3K36Me2 methyltranferase, WHSC1 (NSD2/MMSET) in cartilage loss of functions in OA.

Methods: We used primary human OA chondrocytes, specific siRNA interference, western-blot, transient transfection, IL-1b treatment, RT-qPCR, Elisa and statistical analysis.

Results: We found that WHSC1 mRNA expression is reduced in OA senescent-like cartilage compared to healthy donors. WHSC1 mRNA and protein levels are as well reduced in human primary chondrocytes following IL-1b chronic treatment. By a loss of function experiment based on specific siRNA against WHSC1, we found an up-regulation of MMP1, MMP13 and ADAMTS5 mRNA accumulation but not pro-inflammatory cytokines (IL-8, IL-6) in primary chondrocytes. As result, WHSC1-depleted chondrocytes show a reduced expression in Aggrecan and a slight increase production in GAG.

Conclusion: Our preliminary data demonstrate that WHSC1 impacts articular homeostasis maintenance by repressing part of the senescence-associated secretome induced in OA. Further experiments are required in particular for understanding how WHSC1-dependent epigenetic regulation of these hypertrophic-associated matrix-remodeling factors, occurs.

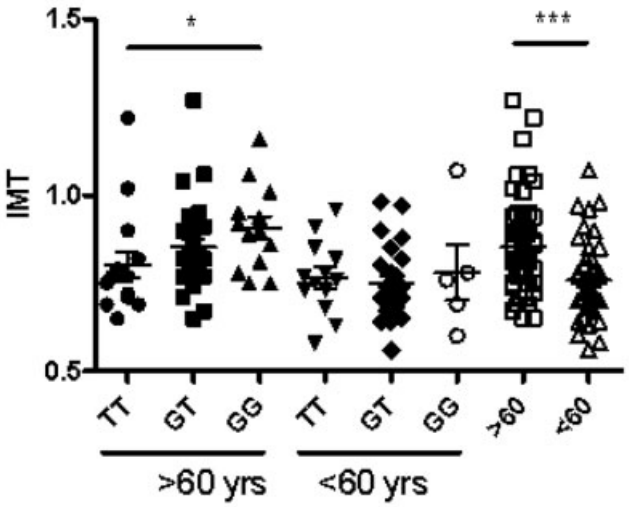
1899

Interferon Regulatory Factor 5 Gene Variant rs2004640 Is Associated With Carotid Intimal Medial Thickness In Rheumatoid Arthritis Patients. Saskia Vosslamber, Alper M. van Sijl, Carina Bos, A.E. Voskuyl, Michael T. Nurmohamed and Cornelis L. Verweij, VU. University Medical Center, Amsterdam, Netherlands.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory joint disease which is associated with an increased cardiovascular (CV) risk.. An important process in atherogenesis is cell growth and hyperplasia. Interferons (IFNs), especially IFNβ, are known inhibitors of vascular smooth muscle cell proliferation and intimal hyperplasia. Interferon regulatory factor 5 (*IRF5*) is a major regulator of IFN production and genetic variants in *IRF5* are known to stimulate the consecutive production of type I IFNs. In the current study, we investigate the effect of *IRF5* gene variants on preclinical atherosclerosis, measured with carotid intima media thickness (cIMT) in RA patients.

Methods: Peripheral blood DNA was obtained in a subgroup of 101 RA patients from the CARRÉ study. *IRF5* SNPs rs2004640 was determined using Taqman Genotyping assay. cIMT was determined by B-mode ultrasonography. Linear regression analyses were used to investigate the association between cIMT and *IRF5* genotypes, adjusted for demographic and cardiovascular factors (age, sex, cholesterol blood pressure and smoking).

Results: RA patients carrying the rs2004640 T-allele have significant lower cIMT compared to homozygote G-allele carriers ($P<0.005$). This effect is stronger when patients are homozygous for the T allele compared to the wildtype allele ($P<0.005$). Age was shown to be an effect-modifier for the association and the strongest association between cIMT and rs2004640 was seen in patients older than 60. Linear regression analysis in patients older than 60 showed that the rs2004640 TT-genotype was associated with lower cIMT (regression coefficient −0.107 (C.I. −0.205; −0.008), $p=0.035$) which remained significant after adjustment for demographic and cardiovascular risk factors (regression coefficient −0.111 (C.I.−0.202; −0.02), $p=0.020$).



Conclusion: We demonstrate for the first time that the *IRF5* gene variant rs2004640, which is associated with enhanced type I IFN activity, is associated with preclinical atherosclerosis in RA patients, independent of cardiovascular risk factors. The genetic variant of *IRF5* rs2004640 T-allele, which leads to enhanced type I IFN levels, is related to lower cIMT in RA. As reduced activity of IFN-beta is highly associated with both atherosclerosis and inflammation, these results might implicate IFN as an important cytokine responsible for the increased rate of CV disease in RA.

Background/Purpose: Nowadays, the advances of novel proteomic technologies are encouraging research projects for generating reliable diagnostic biomarkers for primary Sjögren's syndrome (pSS) to be used in both clinical settings and in clinical trials. Aim of this study was to identify the most significant salivary biomarkers in pSS using proteomic methods and to correlate pSS patients' salivary proteomic profile to the different histological and immunological aspects of the disease.

Methods: Salivary samples from patients affected by pSS, and sex- and age-matched healthy volunteers (HC) were consecutively collected from May 2012 to February 2013. The ProteinChip System, Series 4000 Personal Edition (Ciphergen Biosystems, Inc) was used to perform SELDI-TOF-MS. The cation exchange array CM10 (Bio-Rad) was selected. Chips were read on a Ciphergen Express Data Manager – Personal Edition (version 3.5). SELDI-TOF-MS data were analyzed by using Mann-Whitney non-parametric test for univariate analysis coupled with a classification and regression tree (CART) algorithm in the multivariate setting. Only significant variables ($p<0.05$) at the univariate analysis were included in the CART algorithm.

Results: Unstimulated whole saliva samples were collected from 72 consecutive unselected female patients with pSS and from 29 sex- and age-matched HC**.** A total of 75 peaks were detected at the SELDI-TOF-MS. We found that 25 peaks were significantly different in the pSS patient group with respect to HC ($P<0.05$). Among these 25 peaks, the selected CART tree indentified 7149 m/z, 7192 m/z, 13507 m/z, 13714 m/z, 16547 m/z, 24059 m/z as best independent biomarkers able to discriminate between pSS and HC with a sensitivity of 96%, a specificity of 70% and a global cross validated error of 29%. Peaks of 7192 m/z, 24059 m/z and two further peaks of 28674 m/z and 33285 m/z were also significantly different in the group of pSS patients with parenchymal inhomogenicity at the salivary gland ultrasonography. Furthermore, in pSS patients with high focus score at the minor salivary gland biopsy and in pSS patients positive for anti-Ro/SSA antibodies, peaks of 4205 m/z and 22232 m/z and peaks of 3502 m/z and 4808 m/z were differently expressed, respectively.

Conclusion: This study supports the use of high throughput technologies to approach the challenge of the discovery of new, accurate diagnostic biomarkers for pSS and its clinical subsets.

Genetic Variants In *OPG* and *ANKH* Are Associated With Severity Ofankylosis In Ankylosing Spondylitis In a Korean Cohort. Il-Hoon Sung[1], Tae-Hwan Kim[1], Young Bin Joo[1], So-Young Bang[2], Seunghun Lee[3], Kyung-Bin Joo[4], Proton Rahman[5], Darren D. O'Rielly[5] and Robert Inman[6]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Hanyang University Guri Hospital, Guri, South Korea, [3]Hanyang University College of Medicine, Seoul, South Korea, [4]Hanynag University, Seoul, South Korea, [5]Memorial University, St. Johns, NF, [6]University of Toronto and Toronto Western Hospital, Toronto, ON.

Background/Purpose: Spinal ankylosis, which represents the most severe radiologic change in ankylosing spondylitis (AS), is associated with permanent work disability as well as decreased quality of life. Clinically, male sex, younger age at symptom onset, smoking, and elevated C-reactive protein level have been identified as factors associated with radiologic severity. However, genetic factors associated with radiologic severity remains elusiveal though AS is thought to be largely genetically determined. Thus, weset out to investigate which polymorphisms among genes involved in bone formation was associated with radiologic severity. Particular emphasis was placed on genes involved in WNT/β-catenin pathway and their respective antagonists or agonists. We also set out to investigate possible genetic-environmental interactions which could also impact AS radiologic severity.

Methods: A total of 417 Korean AS patients were enrolled and were classified into two groups based on the radiologic severity as defined by mSASSS: (1) Severe ankylosis (2) Control AS. Severe ankylosis was defined in the cases which had two intervertebral adjacent bridges (mSASSS score 2 at each site) and/or fusion (mSASSS score 3 at each site) in the lumbar spine or cervical spine. Control AS was defined in the cases which had no or only 1 syndesmophytes or bridging. There were 148 patients in the first group and 259 patients in the second. A total of 366 single nucleotide polymorphisms within 52 genes were genotyped using the Sequenom MassARRAY® system (iPLEX GOLD). Odds ratios (OR) and 95% confidence interval (95% CI) were analysed by logistic regression controlling for age and disease duration as covariates to identify the genetic predictors of radiologic severity.

Results: SNP *rs1032128* (in *OPG* or *TNFRSF11B*) and *rs2453327* (in *ANKH*) showed the most significant associations with severe ankylosis($P=6.49\times10^{-4}$, OR = 0.56, 95%, and $P=1.08\times10^{-3}$, OR = 1.72, respectively) after adjusting age and disease duration. In multivariate analyses, smoking(OR = 1.87, 95% CI 1.19–2.95) was significantly associated with severity ofankylosis. The combination of smoking and SNP *rs1032128 A* increased the risk of ankylosis 4.56-fold (95% CI 2.104–9.889) comparing to that of nonsmoker and SNP *rs1032128G*,and the combination of smoking and SNP *rs2453327* Tincreased the risk of ankylosis 2.89-fold(95% CI 1.586–5.277) comparing to that of nonsmoker and SNP *rs2453327* C.

Conclusion: Genetic polymorphisms in the bone-related genes *OPG* and *ANKH*demonstrate a significant association with severity of ankylosis in Korean AS, and theseassociationsareenhancedin smoker.

1902

Characterization Of HLA-DRB1 Distribution By 3rd Hypervariable Region Sequence In Systemic Sclerosis and Control Populations. Coline, A. Gentil[1], Hilary S. Gammill[1], Christine, T. Luu[1] and J. Lee Nelson[2]. [1]Fred Hutchinson Cancer Research Center, SEATTLE, WA, [2]Fred Hutchinson Cancer Rsch, Seattle, WA.

Background/Purpose: HLA class II genes are associated with a wide spectrum of autoimmune diseases. Specific alleles at the DRB1, DQA1 and DQB1 loci are associated with systemic sclerosis (SSc) risk and/or clinical characteristics such as autoantibody profile. HLA nomenclature, particularly for the HLA-DRB1 locus, evolved utilizing serological typing reagents resulting in "a language of HLA" with initial grouping based primarily on antibody recognition of the HLA molecule. However, the third hypervariable region (3rd HVR) is the important site for T cell recognition, and the T cell perspective may be more important for autoimmune diseases including SSc. We therefore conducted an analysis based on the different amino acid sequences of the 3rd HVR (aa 67–74) irrespective of the HLA allele group. We sought to test the hypotheses that 1) overall charge of the amino acids in the 3rd HVR (positive, neutral or negative) differs for SSc patients compared to controls and 2) 3rd HVR charge differs for maternally-inherited vs. paternally-inherited HLA-DRB1 alleles.

Methods: We studied 254 control women and 133 women with SSc. HLA genotyping for DRB1 was performed by a PCR sequence-specific oligonucleotide probe method. Family studies were conducted to determine which HLA haplotype was maternally- or paternally-inherited. The data were then categorized according to which of 24 different 3rd HVR sequences was encoded by each allele. Next the 3rd HVR sequences were grouped according to whether they resulted overall in a positive, neutral or negative charge. Analyses were done by chi square.

Results: The overall distribution of the 3rd HVR sequences was significantly different in the SSc compared to the control population ($p=0.0005$), a difference primarily driven by enrichment of the FLED sequence present in the DRB1*1104 allele among the SSc population ($p=0.001$). No difference was observed for the overall 3rd HVR charge comparing the two populations. However, interestingly, among SSc patients, 3rd HVR charge differed by maternal vs. paternal haplotype ($p=0.0001$), a difference not seen among controls.

Conclusion: We observed a significant difference in the distribution of HLA-DRB1 alleles when classified according to the 3rd HVR, and especially an enrichment of the FLED sequence among SSc patients compared to

controls. This result indicates a possible role for 3rd HVR amino acid sequences in SSc. Polymorphism of amino acid sequences in the 3rd HVR can result in overall differences in charge. Our surprising observation of a significantly skewed distribution of 3rd HVR charge in maternal vs. paternal HLA haplotype in SSc patients but not in controls suggests a potential epigenetic effect that could contribute to SSc pathogenesis.

***PIK3CD* Overexpression In The Synovial Membrane Of Rheumatoid Arthritis Patients Is Associated With Response To Anti-TNF Therapy.** Antonio Julià[1], Gabriela Ávila[1], Raquel Celis[2], Raimon Sanmarti[3], Julio Ramirez[4], Sara Marsal[1] and Juan D. Cañete[5]. [1]Vall d'Hebron Hospital Research Institute, Barcelona, Spain, [2]Hospital Clínic, Barcelona, Spain, [3]Hospital Clínic of Barcelona, Barcelona, Spain, [4]Hospital Clinic, Barcelona, Spain, [5]Hospital Clínic de Barcelona, Barcelona, Spain.

Background/Purpose: The mechanisms by which Rheumatoid Arthritis (RA) patients do not respond to TNF blockade are still poorly characterized. The goal of this study is to identify in synovial tissue (ST) of RA patients the genes that best characterize the profile of response to anti-TNF, therapy by using whole genome gene expression analysis.

Methods: Whole genome expression analysis of >21,000 genes was performed using Illumina WG-6 BeadChip microarrays in ST obtained by arthroscopy of RA patients before starting anti-TNF therapy. The clinical response was determined after 20 weeks of therapy using the EULAR criteria. The genes most significantly associated with the anti-TNF response were validated by quantitative RT-PCR. Changes in ST protein expression induced by anti-TNF therapy were quantified by immunochemistry and Digital Image Analysis.

Results: Eleven RA patients were included and a total of 135 genes were found to be differentially expressed between responders and non-responders after multiple test correction. The functional analysis of the overexpressed genes in the non-responder group (n=76 genes) identified a highly significant enrichment of genes expressed in peripheral blood CD14+ monocytes (similarity score Kappa=1.00, P=3.56e-5). We validated by RT-PCR the genes showing the most significant differential expression: *PIK3CD* (P= 7.11E-18) and *CX3CL1* (P=7.39E-12). Synovial tissue expression of PIK3CD protein before and after 5 months of anti-TNF therapy showed a significant reduction (P=0.035) only in those patients with a positive clinical response.

Conclusion: Our findings suggest that *PIK3CD* could be a useful biomarker of response to TNF blockade.

Gene Expression In Whole Blood Predicts The Abatacept–Methotrexate Combination Responsiveness In Rheumatoid Arthritis: Preliminary Results From The Power Doppler Ultrasonography IM101–179 Study. T Lequerré[1], C Derambure[1], MA D'Agostino[2], M Hiron[3], P Gaudin[4], C Gaillez[5], M Le Bars[5] and O Vittecoq[1]. [1]Rouen University Hospital & Inserm U905, Rouen, France, [2]AP-HP Ambroise Paré Hospital, Boulogne-Billancourt, France, [3]Rouen University Hospital & Inserm, Rouen, France, [4]CHU Hôpital Sud, Grenoble, France, [5]Bristol-Myers Squibb, Rueil Malmaison, France.

Background/Purpose: The overall response rate (defined as low disease activity [LDA] related to DAS28[CRP]) to abatacept associated with MTX was 57.1% at 6 months in the 6-month open-label abatacept Power Doppler Ultrasonography (PDUS; IM101–179) study in patients with RA and inadequate response to MTX.[1–3] The objective of this exploratory analysis was to identify potential predictors of response to the abatacept–MTX combination by whole blood gene expression profiling in order to optimize treatment choice.

Methods: 104 patients with active RA and inadequate response to MTX were treated with abatacept + MTX at the approved doses. Whole blood in Paxgene tubes was collected for each RA patient at baseline. At 6 months, RA patients were categorized as responders if DAS28 was ≤3.2 (LDA) and non-responders if DAS28 was >3.2. Baseline RNAs from a first set of RA patients (n=44) were hybridized to a whole human genome 4 × 44K microarray Agilent slide to identify a gene combination able to separate responders and non-responders with the GeneSpring GX software. A *t*-test with false discovery rate correction for multiple testing ($p<0.05$) was used to determine mRNAs differentially regulated between responders and non-responders. This gene combination was validated with a second set of RA patients (n=32) by qRT-PCR.

Results: Among these 104 RA patients, 28 were excluded from the following analysis because of missing clinical data (n=13), poor integrity of whole blood mRNA (RIN< 7) (n=6), low concentration rate for reverse transcription (n=7), qRT-PCR failures (n=2). Responders (n=45) and non-responders (n=31) had similar baseline characteristics.[1] In a first set of 44 enrolled RA patients (25 responders and 19 non-responders), 87 mRNAs identified by microarray analysis were expressed as a function of the response to treatment and an unsupervised hierarchical clustering almost perfectly separated these responders from non-responders. The informativeness of 12 of these 87 transcripts (selected with the lowest p-value), as measured by qRT-PCR, was re-assessed in a second set of 32 RA patients (20 responders and 12 non-responders). The combined levels of these 12 transcripts properly classified 23 out of 32 patients with a sensitivity of 80%, a specificity of 66.7%, a positive predictive value of 80%, and a negative predictive value of 66.8%. This combination enriched with more genes is in progress in order to better classify the second set of RA patients.

Conclusion: Our gene profiling results obtained by a non-invasive procedure have generated a list of 12 candidate genes that were associated with a response to abatacept combined with MTX in this study. This combination of genes needs to be further validated in other RA studies to support their utility as a potential diagnostic assay for predicting abatacept response in an effort to personalize treatment for RA.

1905

Protein Profiles Of Peripheral Blood Mononuclear Cells As a Biomarker For Behcet's Disease. Manae Kurokawa[1], Takuya Yoshioka[2], Toshiyuki Sato[1], Kouhei Nagai[1], Nobuko Iizuka[1], Mitsumi Arito[1], Yukiko Takakuwa[2], Hiromasa Nakano[2], Seido Ooka[2], Naoya Suematsu[1], Kazuki Okamoto[1], HIroshi Nakamura[3], Noboru Suzuki[2], Shoichi Ozaki[2] and Tomohiro Kato[1]. [1]St. Marianna University Graduate School of Medicine, Kawasaki, Japan, [2]St. Marianna University School of Medicine, Kawasaki, Japan, [3]Nippon Medical School, Bunkyo-ku, Japan.

Background/Purpose: To investigate the pathophysiology of Behcet's disease (BD) and find biomarker candidates for the disease, we analyzed protein profiles of peripheral blood mononuclear cells (PBMCs).

Methods: Proteins, extracted from PBMCs, were comprehensively analyzed in 16 patients with BD, 16 patients with rheumatoid arthritis (RA), and 16 healthy control subjects (HC) by 2-dimensional differential gel electrophoresis (2D-DIGE). Differently expressed proteins were identified by mass spectrometry.

Results: In total, 563 protein spots were detected. Intensity of 25 and 115 spots showed at least 1.2-fold intensity difference between the BD and HC groups and between the BD and RA groups, respectively ($p<0.05$). We completely discriminated between the BD and HC groups and between the BD and RA groups by multivariate analysis of intensity of 23 and 35 spots, respectively. The protein spots with significantly different intensity and also selected by the multivariate analysis included proteins functionally related to cytoskeleton, transcription/translation, T cell activation, bone turnover, regulating apoptosis, and microbial infection. Interestingly, intensity of only 3 protein spots provided area under the receiver operating characteristic curves (AUROC) of 0.922 for discrimination between the BD and HC groups. Similarly, intensity of 2 protein spots provided AUROC of 0.883 for discrimination between the BD and RA groups.

Conclusion: PBMC protein profiles, especially those of the 3 and 2 proteins, would be candidate biomarkers for BD. The identified PBMC proteins may play important roles in the pathophysiology of BD.

Comparison Of Decision Rules For Identifying Patients With Systemic Lupus Erythematosus (SLE) In Administrative Healthcare Databases. John G. Hanly, Kara Thompson and Chris Skedgel. Dalhousie University and Capital Health, Halifax, NS.

Background/Purpose: Identification of SLE cases in administrative healthcare databases is used to estimate disease frequency, healthcare utilization and cost. The optimal methodology for achieving this is unclear. Our aim was to validate and compare a range of decision rules that can be applied to administrative databases to identify patients with SLE.

Methods: The study was conducted at a single academic medical center. Administrative health care data from a geographic area with approximately 1 million people who had access to universal healthcare was utilized. A retrospective cohort study was performed through the Population Health Research Unit at our institution and utilized data from existing administrative databases. These included information on hospital discharges and physician billings over a 10 year period. Each SLE study subject was matched by age and gender to 4 randomly selected control subjects in the same datasets but without a diagnosis of SLE or other connective tissue diseases. A total of 7 decision rules, some derived from previous studies, were applied to the administrative data to identify SLE cases. The sensitivity, specificity, overall accuracy, positive (PPV) and negative (NPV) predictive values of these rules was compared to the diagnosis of a rheumatologist in the academic medical center determined by chart review.

Results:

Decision Rule	Sensitivity (95% CI)	Specificity (95% CI)	Accuracy (95% CI)
#1 MacLean	81.5 (77.2, 85.3)	96.6 (95.5, 97.4)	93.6 (94.3, 96.5)
#2 MacLean/Lacaille	51.5 (46.3, 56.7)	98.1 (97.2, 98.7)	88.7 (87.4, 90.5)
#3 Shipton	79.6 (75.2, 83.6)	96.5 (95.5, 97.4)	93.1 (93.8, 96.0)
#4 Hospitalization	41.0 (36.0, 46.2)	99.9 (99.6, 100.0)	88.2 (85.2, 88.7)
#5 Rheumatologist	83.4 (79.2, 87.0)	98.7 (97.9, 99.2)	95.6 (94.9, 96.9)
#6 Combination	85.3 (81.2, 88.7)	98.0 (97.1, 98.6)	95.4 (95.3, 97.3)
#7 Single admin	86.6 (82.7, 89.9)	92.4 (90.7, 93.7)	91.3 (95.4, 97.4)

Decision Rule	PPV (95% CI)	NPV (95% CI)
#1 MacLean	85.6 (81.5, 89.1)	95.4 (94.3, 96.4)
#2 MacLean/Lacaille	86.9 (81.7, 91.0)	89.0 (87.4, 90.5)
#3 Shipton	85.1 (80.9, 88.7)	95.0 (93.8, 96.0)
#4 Hospitalization	99.4 (96.4, 100.0)	87.1 (85.5, 88.7)
#5 Rheumatologist	95.0 (90.8, 96.3)	96.0 (94.8, 96.9)
#6 Combination	91.4 (87.9, 94.1)	96.4 (95.3, 97.3)
#7 Single admin	74.1 (69.7, 78.1)	96.5 (95.4, 97.4)

Conclusion: The performance of decision rules for the identification of SLE cases in administrative healthcare databases is variable and should be considered when comparing data across studies. This variability may be used to advantage in study design when, for example, either sensitivity or specificity is the most critical issue for different population health research questions.

1907

Acceptability Of Various Technology-Based Communication Modalities In a Rheumatology Clinic. Lisa A. Davis[1], Phat Luong[2], Sushmitha Bobba[2], Hannah Dischinger[2], Itziar Quinzanos[3] and Liron Caplan[2]. [1]Denver Health and Hospital Authority, Denver, CO, [2]Denver Veterans Affairs Medical Center, Denver, CO, [3]University of Colorado School of Medicine, Aurora, CO.

Background/Purpose: Technological advances have diversified the communication modalities of patients and healthcare providers. These include conveying information through telephone, internet portals, short-message service (SMS, "texting"), and electronic mail (email). The acceptability and preference for the use of these methods, however, likely varies by patient population. In order to assess the technology use and preferences of the U.S. veterans in our clinic, we administered an anonymous survey.

Methods: A convenience sample of patients in our rheumatology clinic at the Denver Veterans Affairs Medical Center completed a brief survey printed on paper. This survey assessed their access to technology, speed of responding to messages, barriers to technology use, and acceptability of various technologies as a means of communicating with their healthcare providers (0 to 10 Likert scale). Linear regression was used to explore the relationship of age and gender to the acceptability of each communication modality.

Results: The mean age of subjects (n=50) was 56 years, 84% were male, and 96% spoke English as their primary language. A majority had access to a computer (84%) and possessed an email address (78%). Similarly, 84% possessed a mobile phone; of those who possessed a mobile phone, 57.4% and 66.7%, respectively, had internet and texting ability. Of those who had texting, 28.2% found the cost of texting prohibitive for communicating with healthcare providers. The acceptability of various modalities (a score of at least 5 on the 10 point scale) as a means of contact with their healthcare providers was as follows: telephone call (80%), email (56%), internet-based portal (54%) and texting (42%). In a linear regression predicting the level of acceptability of each technology for communicating with the healthcare provider, only age was associated with texting. For every 10 years increase in age, the acceptability of texting declined by 1.4 points (95% CI −2.2 to −0.5, p-value 0.002).

Table 2. Use and preference of technology in US veterans in a rheumatology clinic

Variable	Cohort n	Cohort mean, %	Cohort with specified equipment* n	Cohort with specified equipment* mean, %
Age (mean)		56.2		
Gender, male (M)	42	84.0		
Primary language (%)				
English	48	96.0		
Spanish	2	4.0		
Access to a computer (%)	42	84.0		
Currently possesses an email address (%)	39	78.0	39	92.9
Frequency of email use (%)				
No email	9	18.0		
Once a month or less	7	14.0	5	12.8
Once a week	6	12.0	6	15.4
Most days	6	12.0	6	15.4
Everyday	11	22.0	11	28.2
Several times a day	11	22.0	11	28.2
How quickly patient responds to email (%)				
No email	9	18.0		
Weekly	4	8.0	4	10.3
Every few days	13	26.0	12	30.8
Daily	11	22.0	11	28.2
Every few hours	11	22.0	10	25.6
Every few minutes	2	4.0	2	5.1
Currently possesses a mobile phone (%)	42	84.0		
Internet access on mobile phone (%)	27	54.0	26	61.9
Current texting capability, (%)	32	64.0	32	76.2
Cost of texting prohibitive, (%)	11	22.0	6	18.8
How quickly patient responds to texts (%)				
Do not text	20	40.0	3	9.4
Weekly	1	2.0	1	3.1
Every few days	2	4.0	1	3.1
Daily	3	6.0	3	9.4
Within a few hours	9	18.0	9	28.1
Within a few minutes	15	30.0	15	46.9
Average rating on Likert scale (mean)				
Email	50	4.9	39	6.1
Text	50	3.8	32	5.7
Web portal	50	4.4	42	5.2
Phone call	50	7.1		
Wish to be contacted by doctor's office (Likert scale >=5) (%)				
Email	28	56.0	28	71.8
Text	21	42.0	21	65.6
Web portal	27	54.0	27	64.3
Phone call	40	80.0		

* The mean or % among those subjects with the specified equipment. For example, the "frequency of email"item only includes responses from those subjects with email, rather than the cohort as a whole.

Conclusion: Many of our patients have access to various communication modalities. Individual veterans display preferences for each of the modalities, but the majority wishes to communicate with their healthcare providers via telephone. Age only predicts the acceptability of texting, where increasing age was associated with less enthusiasm for this form of communication.

Quality Of Life and Adherence To Treatment In Patients Managed In Nursing Clinics In Rheumatology. Santiago Muñoz-Fernández[1], Pablo Lazaro[2], Antonio Javier Blasco[2], Sandra Fortea Gracia[3], Laura Cano-García[4], Jose A. Roman Ivorra[5], Raquel Almodóvar González[6], José Santos Rey Rey[7], Teresa Navío-Marco[8] and Mercedes Cabañas[2]. [1]Hospital Universitario Infanta Sofía, San Sebastián de los Reyes (Madrid), Spain, [2]Advanced Techniques in Health Services Research (TAISS), Madrid, Spain, [3]Hospital de Sagunto, Sagunto, Spain, [4]Hospital Regional Universitario Carlos Haya, Málaga, Spain, [5]Hospital Universitario y Politécnico La Fe, Valencia, Spain, [6]Hospital Universitario Fundación Alcorcón, Madrid, Spain, [7]Complejo Hospitalario de Toledo, Toledo, Spain, [8]Hospital Universitario Infanta Leonor, Madrid, Spain.

Background/Purpose: Nursing clinics in rheumatology (NCR) are organizational models in the field of nursing care. However, little is known about the NCR outcomes. The purpose of this research is to evaluate differences between centers with and without NCR in patients' quality of life and treatment adherence.

Methods: Cross-sectional study carried out in rheumatology departments of 39 Spanish public hospitals from July to December 2012. The minimum requisites that the department must have to be defined as NCR were: 1) A nursing office, but not necessarily every day of the week; 2) at least one specialist nurse, at full or part time; 3) nurse appointment book; and 4) a dedicated telephone. Patients inclusion criteria were: 1) older than 18 years; 2) diagnosed of rheumatoid arthritis (RA) or ankylosing spondylitis (AS); 3) treated with at least one DMARD or a biologic; and 4) signing the informed consent. Data were collected through a survey with case report forms (CRF) completed by rheumatologists and patients. Sociodemographic, disease characteristics, treatment, quality of life and adherence variables were collected. The EuroQol-5D (EQ-5D) and Morisky-Green test were used to assess the quality of life and adherence to treatment, respectively. Regional and hospitals research and ethics committees approved the project protocol and CRFs.

Results: Twenty one centers were NCR and 18 were no-NCR. The NCR centers included 181 patients (142 RA and 39 AS) and the no-NCR centers included 212 patients (160 RA and 52 AS). There were no statistically significant differences between NCR and no-NCR patients in: age [mean±SD, years] (53.2±11.8 vs. 56.3±13.5), gender [male, %] (29.8 vs. 38.7), rheumatic disease [RA, %] (78.5 vs. 75.5), years diagnosed (10.6±8.8 vs. 9.5±8.9), treatment [only biologics, only DMARDs, both %] (23.8, 39.2, 37.0 vs. 23.6, 46.7, 29.7, respectively), DAS-28 (2.87±1.28 vs. 2.97±1.19) and HAQ (0.81±0.68 vs. 0.88±0.68) in patients with RA, and BASDAI (3.44±2.41 vs. 3.68±2.31) and BASFI (3.15±2.78 vs. 3.85±2.60) in patients with AS. No statistical differences were observed between NCR and no-NCR in EQ-5D index (0.68±0.21 vs. 0.66±0.21) and EQ-5D Visual Analogue Scale (64.6±21.0 vs. 64.5±20.5). Patients from NCR have a better adherence to treatment than the no-NCR patients [adherent patients, %] (79.0 vs. 69.3; p=0.03).

Conclusion: Patients managed in rheumatology departments with NCR have clinical characteristics, treatment patterns and quality of life similar to patients managed in centers without NCR, however, they have better adherence to treatment.

Interpretation Of Patient Reported Outcomes Measurement Information System (PROMIS) By Rheumatologists. Vivek Nagaraja, David A. Fox, Sheeja Francis, Ora Singer, Puja Khanna, Timothy Laing, Rory Marks, Seetha U. Monrad, Vladimir M. Ognenovski, Kristine Phillips and Dinesh Khanna. University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: The National Institutes of Health Patient Reported Outcomes Measurement Information System (PROMIS¨) roadmap initiative is a cooperative research program designed to develop, evaluate, and standardize item banks to measure patient-reported outcomes (PROs) across different medical conditions as well as the US population (www.nihpromis.org). It has comprehensive items banks that assess physical, mental, and social well-being. The aim of this study was to assess the interpretation of PROMIS report by rheumatologists at the University of Michigan (UM) Hospital.

Methods: Four focus group discussions consisting of eleven rheumatologists were held at UM Health System. The panelists were first presented with an overview of PROMIS process followed by a series of patient reports With a focus on the evaluating which report was feasible to use in day-to-day practice and clinically meaningful, the following questions were asked by: (i) What do you think of this report? (ii) Do you understand what this report is communicating? (iii) Is there anything you would change about this report to make this better?

Results: All the rheumatologists agreed on the following suggestions: (i) Representation of the item scores as thermal graphs or "heat map" was easier to interpret (ii) Provide average scores for the U.S. population and rheumatology patients, (iii) Provide both average and percentile scores, and (iv) Provide pictorial depiction of most bothersome symptom and urgency for referral. Based on these discussions, we modified the PROMIS heat map (Figure 1) to include: (i) average scores for rheumatologic disorders (bold square), (ii), an open diamond to indicate the individual scores of the patients, and (iii) thickness of the diamond indicates the severity of these symptoms in the patient with an urgency for intervention (thicker equates to greater urgency).

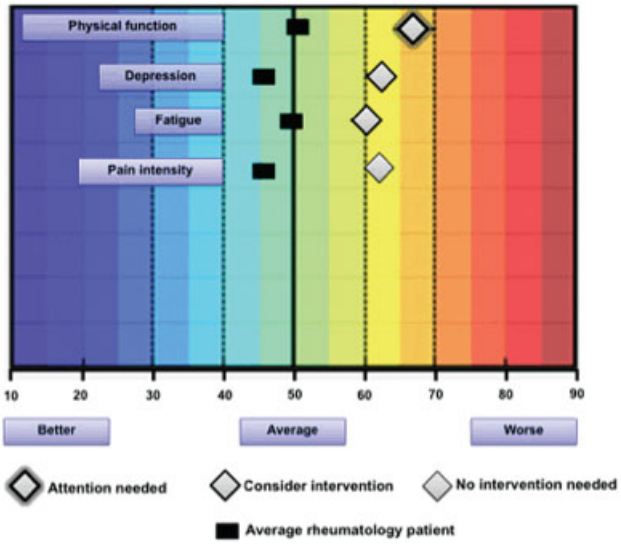

Figure 1. Format of PROMIS report after incorporating the suggestions

Conclusion: This presents the first step to assess feasibility of incorporating PRO in rheumatology practice at UM. The PROMIS report card when integrated with the electronic medical record can contribute towards meaningful use. It may improve patient satisfaction and physician-patient relationship. Our long-term goal is to integrate PROMIS into a busy academic practice and assess its effectiveness.

Validation Of The Mayo Hip Questionnaire: Validity and Sensitivity To Change. Jasvinder A. Singh[1], Cathy Schleck[2], W. Scott Harmsen[3] and David Lewallen[4]. [1]University of Alabama, Tuscaloosa, AL, [2]Mayo Clinic College of Medicine, Rochester, MN, [3]Mayo Clinic, Rochester, MN, [4]Mayo Clinic college of medicine, Rochester, MN.

Background/Purpose: Mayo Hip questionnaire has previously been shown to have face, content and test-retest reliability. Our objective was to assess the validity and responsiveness of the Mayo Hip Questionnaire.

Methods: We used data from the Mayo Clinic Total Joint Registry to assess the validity of Mayo Hip questionnaire, by including patients who underwent primary total hip arthroplasty (THA) between 1993–2005 and responded to the baseline and 2-year post-primary THA Mayo Hip questionnaire. Mayo hip questionnaire assesses the domains of pain, function and mobility; reliability and construct validity has been previously established. It generates a total score clinical score ranging 0–80 (Excellent result is 72–80 points, good is 64–71 points, fair is 56–63 points, and poor is less than 55 points). Convergent/divergent validity was examined with the association of select demographics (age, gender, number of joints involved) at baseline with Mayo hip scores using linear regression analyses. Minimally Clinically Important Difference (MCID) and Really Important Difference (RID) were calculated corresponding to "somewhat better now" and "much better now", respectively in response to patient-reported anchor at 2-years- Compared to your condition before the surgery, how would you rate your hip now? For discriminant ability, we calculated a) effect size by taking the change in respective score from baseline to 2-years and dividing the result by the standard deviation at baseline and b) the standardized response mean, defined as the mean change in the patient score with improvement at 2-years divided by the SD of the changed scores.

Results: For primary THA, there are 2,311 hips with both a baseline and a 2-year data. The sample consisted of 1,097 males (47.5%)and 1,214 females (52.5%). The mean age at surgery (SD) is 64 (13), median was 66 (range, 15–92). Age and gender were significantly associated Mayo Hip score at 2-years post-THA ($p<0.001$); and the number of joints involved was not associated ($p=0.98$). MCID was 24.8 and RID threshold was 37.1. Effect size at 2-years was large, 2.26 and the Standardized Response Mean was 2.25.

Conclusion: The Mayo Hip questionnaire is a valid and sensitive outcome measure for patients undergoing primary THA. This study provides further validation of this previously validated scale. Further validation in revision THA and in more diverse populations will provide more support to its validation as an outcome instrument.

1911

How Are Actual Patterns Of Care For a Health System In Rheumatology In Comparison With Validated Quality Measures? Susan Mathew, Tarun S. Sharma, Oscar Quintero, Olga Bailey, Debra Webb, Eric D. Newman and Androniki Bili. Geisinger Medical Center, Danville, PA.

Background/Purpose: The American College of Rheumatology (ACR) in 2008 and 2012 published guidelines for the use of disease modifying anti-rheumatic drugs (DMARD) and biologics in rheumatoid arthritis (RA) in an attempt to improve quality and decrease variability in RA care. In addition, in 2012, a unique population management program for RA was initiated in our institution, an academic tertiary center, designed to improve quality and safety while reducing cost of care in RA. The aim of the present project was to characterize the variability in RA care provided in the rheumatology practice in our institution, according the ACR and local measures.

Methods: Data on 80 consecutive patients with newly diagnosed RA between 1/1/2010 and 8/1/2011 with at least 18 month follow-up period were extracted through the electronic health records (EHR). RA diagnosis was made based on ICD-9 code 714.0 by a rheumatologist. Additional data were extracted by manual review of the EHR by four of the authors. The primary objective was to measure practice patterns in RA care and DMARD use according to selected quality measures. Secondary objective was to compare the actual vs. perceived RA care rendered by rheumatologists. For that purpose, we used a survey with questions regarding DMARD use in RA that had been administered earlier to all staff rheumatologists and fellows as part of our population management program. The results of this survey were termed "perceived" care. This was compared to the actual RA care delivered by these providers, based on data extracted from the EHR, termed "actual" care.

Results: Results are shown in Table 1. We achieved >60% in disease activity and functional measures, DMARD use and PPD before starting a biologic, but <50% in obtaining a disease activity measure in at least 50% of the visits, and administering pneumococcal and influenza vaccinations in patients on DMARDs. MTX median starting dose was 12.5 (min 7.5, max 20) mg/weekly; switch from oral to injectable MTX was only 9%, although physician perception was 20%; and, the median time patients were treated with MTX prior to starting a biologic was 6 (min 1, max 6) months with physician perception being 4 months.

Table 1. Actual and Perceived Patterns of RA care

Category	Process	National Guideline or Quality Measure	Actual (N = 80) median or %	Actual (N = 80) variability	Perceived median	Perceived variability
RA Care	Disease Activity (CDAI ≥1) measured atleast once	Y	70%		n/a	
	Disease Activity (CDAI >50% visits)	Y	43%		n/a	
	Function (MDHAQ) measured atleast once	Y	66%		n/a	
	Hand Xrays measured in 1st 6 months	N	59%		90%*	(0,100)
	Feet Xrays measured in 1st 6 months	N	31%		50%*	(0,100)
	Sed Rate measured at baseline	N	76%		n/a	
	Time between visits	N	3 months	(1,6)	1.5*	(1,3)
DMARD Use	Any DMARD use	Y	88%		n/a	
	MTX start dose	N	12.5	(7.5, 20)	15	(7.5, 15)
	Switch from oral to subq MTX	N	9%		20%*	(5, 60)
	MTX dose before biologic	N	15	(0, 20)	20*	(17.5, 20)
	Time on MTX before biologic	N	6 months	(0, 23)	4	(3, 9)
DMARD Safety	MTX Baseline Lab tests	Y	93%		n/a	
	MTX Interval between lab tests	Y	3 months	(1,6)	2	(1,3)
	PPD before Biologic	Y	78%		n/a	
	Influenza vaccine	Y	48%		n/a	
	Pneumococcals Vaccine	Y	48%		n/a	
	CXR before MTX	N	65%		n/a	

CDAI: clinical disease activity index; DMARD: disease modifying anti rheumatic drug; RA: Rheumatoid arthritis; MDHAQ: modified Health Assessment Questionnaire; MTX, Methotrexate; PPD: purified protein derivative for TB, *$p<0.009$.

Conclusion: Our results showed there is need for improvement in several selected measures in RA care. Improvement in quality should aim to increase the routine collection of disease activity measures, greater use of injectable MTX and vaccinations. Cost reduction should aim to reduce variability in MTX use prior to starting biologics in terms of both time and dosages and in laboratory monitoring. There were also differences in the perception of rheumatologists about the care they deliver and the actual care that is delivered. Results of this study will be used as a benchmark for ACR measures and our population management program, in order to examine ways to reduce variability and improve quality in the care provided to RA patients.

1912

Do Persons With SLE In Poverty Rate Interactions With Providers and Health Plans Differently? Edward H. Yelin[1], Chris Tonner[2], Laura Trupin[2] and Jinoos Yazdany[2]. [1]UC San Francisco, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA.

Background/Purpose: We previously showed that poverty is associated with the quantity, type, and technical quality of care in SLE.[1] Here we assess whether poverty is associated with ratings of interpersonal aspects of care about providers and health plans.

Methods: We analyzed data from the UCSF Lupus Outcomes Study (LOS), a national sample of persons with SLE interviewed annually using a structured telephone survey. The survey includes batteries from the Consumer Assessment of Health Plans (CAHPS) developed by the Agency for Healthcare Research and Quality and the Interpersonal Processes of Care Scales (IPC) developed by Stewart, et al. (Health Serv Res 2007; 42: 1235–1256) for respondents to rate care along six dimensions of interpersonal processes of care about providers (patient-provider communication, shared decision-making, and trust in provider) and health plans (promptness/timeliness of care, care coordination, and

assessment of health plan). Scores in the CAHPS and IPC items were transformed to a uniform 0 (lowest) −100 (highest) rating scale. Ratings on the six dimensions were regressed on whether respondents had household income ≤ 125% of the Federal poverty level for their household size with and without the following covariates: demographics (age by category, race/ethnicity, language spoken at home), presence and source of health insurance (public, employer, other), HMO vs. fee-for-service coverage, specialty of main SLE provider, and health status (BILD index of damage, SLAQ index of activity, and CESD index of depressive symptoms).

Results: In 2012, the LOS included 793 respondents living in 40 states. Mean (SD, range) age was 52 years(13, 20–86), duration of SLE was 19 years(9, 1–55), SLAQ was 11(8, 0–47) and BILD was 2.1(2.1, 0–13); 93% were female, 42% non-white, 19% ≤ high school, and 16% met the study definition of poverty. For the six dimensions evaluated, highest ratings were for patient/provider communication (90, 95%CI: 89,91), trust in provider (89, 95%CI:88,90), while lowest ratings were for shared decision-making between patient and provider (43, 95%CI:41,46). In bivariate analysis, poverty was associated with significantly lower ratings of patient-provider communication, trust in provider, timeliness of care, and evaluation of health plan. In multivariate analysis, poverty was not associated with any dimension of care.

Ratings of Six Dimensions of Care by Poverty Status

	Provider			Health Plan		
	Pt/Provider Commun.	Shared Decisions	Trust	Promptness/ Timeliness	Care Coord.	Evaluation Heath Plan
	ratings 0–100 (95% CI)					
All	90 (89, 91)	43 (41, 46)	89 (88, 90)	74 (72, 76)	77 (74, 79)	81 (80, 82)
Bivariate model	*		*	*		*
POVERTY	86 (84, 89)	40 (34, 46)	86 (82, 89)	68 (63, 73)	71 (65, 77)	75 (71, 79)
Not POVERTY	91 (90, 92)	44 (41, 46)	90 (88, 91)	75 (73, 77)	78 (75, 81)	82 (81, 84)
Multivariate model						
POVERTY	88 (84, 92)	37 (27, 47)	87 (82, 93)	67 (59, 74)	75 (65, 85)	75 (70, 80)
Not POVERTY	89 (86, 92)	43 (35, 52)	88 (83, 92)	69 (62, 75)	75 (67, 83)	79 (75, 83)

* $p<0.05$ for difference by poverty status

[1] Arthritis Care Res 2010; 62: 888–895; J Gen Int Med 2012; 27: 1326–1333.

Conclusion: Unlike objective measures of quantity, type, and technical quality of care, after adjustment, poverty is not associated with subjective assessments of interpersonal processes of care about providers and health plans.

1913

Expectations RA Patients Have For Their Treatment - A Comparison Of Clinical Results For Biologic and Disease-Modifying Anti-Rheumatic Drug Treated Patients Using Multiple Medical Cohorts. Tsukasa Matsubara[1], Hiroaki Matsuno[1], Tomomaro Izumihara[1], Yuichi Takahashi[1], Akira Sagawa[1], Motohiro Oribe[1], Eisuke Shono[1], Kensuke Kume[1], Masanori Adachi[1], Yuichi Nishioka[1], Nobumasa Miyake[1], Keisuke Hashimoto[1], Toshikaki Miyamoto[1], Shigeto Kiyokawa[1], Tomohiko Yoshida[1], Syoichi Kondo[1], Yoshiki Shiohira[1], Takanori Azuma[1], Yukio Sato[1], Masaaki Yoshida[1], Kenji Mannami[1], Akihiko Nakamura[1], Yasuhiko Hirabarashi[1], Keiko Funahashi[2] and James E. Middleton[3]. [1]Japanese Clinician's Biologic Research Group, Kobe, Japan, [2]Matsubara Mayflower Hospital, Kato, Japan, [3]Research Institute of Joint Diseases, Kobe, Japan.

Background/Purpose: Treat to Target (T2T) primary principal - "The treatment of rheumatoid arthritis must be based on a shared decision between patient and rheumatologist". Japan uses T2T, but its impact on patients is not yet clear. To better understand T2T implementation, a large scale survey was conducted using a multi-cohort study.

Methods: A survey was given to 4489 RA outpatients in multiple facilities in Japan; contents included; age, gender, medical history, and comments on; 1) things to know before administration, 2) expectations of medication, 3) disappointment with medication, 4) anxiety switching medication 5) biologics experience, 6) goals for treatment, 7) satisfaction level, 8) questions and expectation of doctors, 9) treatment fees, 10) impression of biologics, 11) injections, 12) desires for the future. For further analysis the total results from respondents were divided into 2 groups; Biologics (BG), 1728 patients, and DMARDs Group (DG), 2264 patients.

Results: Eighty-two point five percent of the respondents were female and 27% had disease duration of 10–20 years. Usage; DG 80% BG, 35%. For 'expectations of medication', 35% responded with 'assured improvement of the condition' while 22% responded 'reduced destruction or deformation of joints'; no difference between groups. In BG more patients (22%) hoped for long-lasting efficacy than in DG (14%). 'Experience of disappointment' was 22% in total, but the rate of BG was twice that of DG; reason for disappointment for BG was lack of efficacy, however, for DG it was adverse events. The reason for 'anxiety when switching' was mainly 'adverse events' and 'efficacy' in both groups, but 'diminishing efficacy' showed a higher rate in BG, related with the reason for disappointment. In both groups the 'goals for treatment' was mostly 'the improvement of QOL' and 'reduced destruction/deformation of joints', but 'reduced destruction/deformation of joints' for BG were 1.5 times that of DG. BG wanted more information about future treatment. In DG, 70% were willing to spend up to ¥10,000 a month, as opposed to 30% in BG, suggesting BG understood the cost of biologics. For injections, many in both groups, responded 'troublesome' or 'frightening', but the image was higher for self-injection, especially in DG, but, half the respondents in BG chose 'convenient'.

Conclusion: Expectations for medication in terms of assured improvement of conditions and prevention for joint destruction, were confirmed with results of a single-institution study 2 years ago. But, rate of 'long-lasting efficacy of drugs' was higher in BG this time. Data indicated BG showed these tendencies after secondary failure, which was also suggested in both studies. The patients in BG, due to knowledge of prevention of joint destruction, have higher treatment goals than DG. The comparison between 2 groups indicated once patients experience high efficacy, they can tolerate self-injection and higher fees. We should be aware that what Japanese RA patients are expecting is assured improvement of condition including prevention from joint destruction and long-lasting efficacy. Our study indicates steady implementation of T2T while patients are receiving good education, clearly understanding 3 standards for remission of RA.

1914

Patient and Physician Perspectives On Family Planning and Pregnancy Issues In Systemic Inflammatory Diseases: Mind The Gap! Megan E. B. Clowse[1], Eliza Chakravarty[2], Daphnee S. Pushparajah[3], Sarah Mertens[3] and Caroline Gordon[4]. [1]Duke University Medical Center, Durham, NC, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]UCB Pharma, Brussels, Belgium, [4]University of Birmingham, Birmingham, United Kingdom.

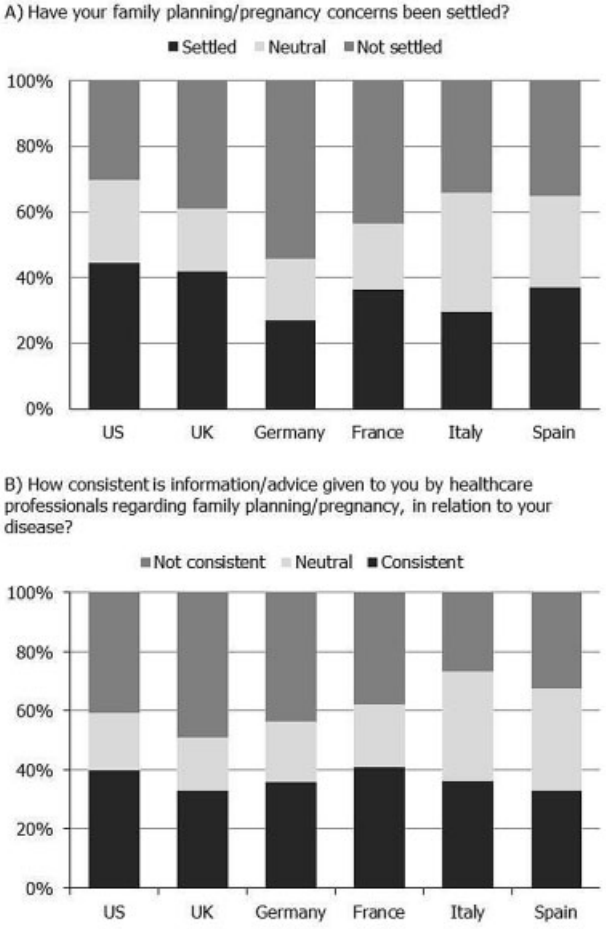
Background/Purpose: Autoimmune and inflammatory diseases often affect women of reproductive age and can impact pregnancy outcomes. This patient (pt) group has important concerns about family planning and pregnancy (FPP), however little research has been undertaken into whether such concerns are adequately addressed in current clinical practice. The aim was to identify FPP issues for female pts of child-bearing age and to assess whether current clinical practice routinely provides adequate support to alleviate these concerns.

Methods: Two online surveys were undertaken to identify FPP issues for both pts and physicians. The surveys were designed to gauge whether there is a gap in the communication by examining the frequency of dialogue on these topics between physicians and pts, alongside assessment of pt satisfaction regarding these discussions. Physician survey was designed to elicit both spontaneous (open-ended questions) and prompted (closed questions) responses: rheumatologists were surveyed in Germany (N=50), France (N=50), Italy (N=50) and the USA (N=100) while

gastroenterologists were surveyed in the USA (N=100). Pt survey was targeted at premenopausal women (aged 20–45 years of age; N=969) and delivered in USA, UK, Germany, France, Italy and Spain.

Results: 32–56% of physicians spontaneously reported having discussed FPP with their female pts of child-bearing age across all countries surveyed. When prompted, the majority of rheumatologists (74–92%) and gastroenterologists (74%) reported having discussed conception/pregnancy with female pts; however, less than half reported discussing FPP with their pt's treating GP/gynaecologist. Even though physicians report discussing FPP with their female pts, the majority of pts report their concerns relating to FPP are not adequately addressed/settled during their medical appointments (Figure 1A); although responses did vary across countries. Furthermore, only 30–40% of pts considered advice/information to be consistent across multiple healthcare professionals (Figure 1B). Female pts receiving medication for their condition were more concerned about FPP than those not receiving medication (63% vs 32%, respectively), and <5% reported discussing FPP when their condition was stable enough to become pregnant.

Figure 1: Settlement of patient concerns and consistency of advice received by patients from healthcare professionals



Conclusion: Female pts who suffer chronic inflammatory disease have important FPP concerns. The majority of pts, however, do not feel that their FPP concerns are adequately addressed in current clinical practice and report that they receive inconsistent advice from the various healthcare professionals who manage different aspects of their care. There is a clear need for provision of up-to-date and consistent information/support to female pts suffering inflammatory diseases, including the key importance of disease control when/before planning pregnancy.

Approaches and Challenges To Reducing Wait Times For Total Hip and Knee Replacement. Aileen M. Davis[1], Cheryl Cott[2], Rose Wong[3], Michel Landry[4], Linda C. Li[5], Allyson Jones[6], Cy Frank[7], Sydney C. Lineker[8], Louise Bergeron[9], Rhona McGlasson[10], Gillian A. Hawker[11], Dianne P. Mosher[12], Susan B. Jaglal[13], Richard Birtwhistle[14], Sherry Bar[15] and Elizabeth M. Badley[16]. [1]Division of Health Care and Outcomes Research, Toronto Western Research Institute, University Health Network, Ontario, ON, [2]Divison of Health Care and Outcomes Research, Toronto Western Research Institute, University Health Network, Toronto, ON, [3]Division of Health Care & Outcomes Research, Toronto Western Research Institute, University Health Network, Toronto, ON, [4]Department of Community and Family Medicine, Physical Therapy Division, Duke University Medical Center, Durham, NC, [5]Arthritis Centre of Canada, Richmond, BC, [6]University of Alberta, Edmonton, AB, [7]Alberta Bone and Joint Institute and Department of Surgery, University of Calgary, Calgary, AB, [8]The Arthritis Society, Toronto, ON, [9]Canadian Arthritis Patient Alliance, Ottawa, ON, [10]Bone and Joint Canada, Toronto, ON, [11]Women's College Research Institute, University of Toronto, Toronto, ON, [12]University of Calgary, Calgary, AB, [13]Department of Physical Therapy, University of Toronto, Toronto, ON, [14]Centre for Studies in Primary Care and Family Medicine and Community Health and Epidemiology, Queen's University, Kingston, ON, [15]British Columbia Ministry of Health Services, Victoria, BC, [16]Toronto Western Research Institute, University Health Network, Toronto, ON.

Background/Purpose: Due to obesity, the growing prevalence of hip and knee osteoarthritis and boarder indications for hip and knee replacement, there is increasing pressure on developed countries to provide total joint replacement (TJR) in a timely manner. In Canada, reduction of wait times for TJR was a priority in the 2004 Health Accord (at that time it was not uncommon for waits to exceed 100 weeks) and, as a result, provinces instituted various strategies to reduce the wait. This work describes the approach taken by three provinces to achieve a target 26 week wait from patient/surgeon decision for surgery to surgery for 90% of people.

Methods: This research used a policy case study approach with review of government documents, non-governmental organization reports and published literature for Federal and Provincial policy and descriptions of programs/models of care related to TJR implemented by British Columbia (BC), Alberta (AB) and Ontario (ON). Additionally, one-on-one interviews (n=28) were conducted with policy makers, individuals in key leadership roles, program directors and managers to further understand provincial approaches. Transcribed interviews were analyzed thematically for activities targeted at reducing TJR wait times conducted within each province.

Results: Arthritis prevalence (15–16% over age 15) and health human resources (4 orthopaedic surgeons per 100,000 population) were similar across provinces with each challenged to provide service in low density regions. Although all provinces implemented efficiencies through standardized care pathways and processes to improve operating room access, there were different approaches relating to access to surgical consultation (e.g. referral central intake, triage and who conducted it based on availability, scope of practice, and how programs/providers were funded). AB focused on a case manager who also aided the patient in system navigation; ON focused on rehabilitation professionals working in advanced practice roles for triage; and, BC implemented a variety of approaches, driven by local champions and context. A provincial platform to drive change was critical for success, as were evidence-informed experts who had the authority to make decisions and champion change, and financial resources to support change, program implementation and sustainability. All provinces decreased wait times but, as shown in table 1 (fourth quarter data from fiscal 2012/13), at a provincial level and in the majority of institutions, challenges continue in meeting target wait times.

	Province	Number of primary joint replacements	Wait time (number of weeks for 90%)	Hospitals meeting target	Trend 2010 to 2013
Knee	BC	1255	32.8	12/29	–
	AB	1599	39.1	5/13	+
	ON	8903*	33.1	24/56	+
Hip	BC	1833	37.5	14/29	–
	AB	971	38.9	6/13	+
	ON	–	27.1	33/56	NA

*combined hip and knee

Conclusion: Although sharing common elements in approach, provincial TJR wait time strategies were variable. Despite reductions results have varied across the provinces. This raises questions of whether benchmarks are attainable and how such strategies will be sustained in times of fiscal constraint and rising demand for TJR.

1917

Falls Among Hospitalized Orthopedic Patients: A Prospective Case-Control Study. Lisa A. Mandl, Wei-Ti Huang, Jaimie Lee, Tina Bailey, Danielle Edwards, Patricia Quinlan, Mayu Sasaki and Steven K. Magid. Hospital for Special Surgery, New York, NY.

Background/Purpose: This study evaluated rates and predictors of falls among adult orthopedic in-patients at a musculoskeletal specialty hospital.

Methods: Researchers prospectively studied falls from 5/2/10–5/1/12. Two controls were matched to every fall on age, post-operative day (POD), type of orthopedic procedure, and each assigned the index time that their case fell. Data were collected via chart review and patient questionnaire. Medical record data for controls was abstracted from last note prior to the index time or first note after. Differences between cases and controls were compared using t-test or chi-square test, as appropriate. A multivariate logistic regression was performed to identify predictors of falls.

Results: There were 169 falls during the study timeframe. The fall rate was 0.65 of in-patient orthopedic admissions; 1.67 falls/1000 in-patient days. The average age of cases was 68.4 yrs, (SD 12.7), 55% were women, mean BMI was 29.4, (SD 6.5), and average POD was 2.9 (SD 2.5). One patient fell twice. 39.5% of falls occurred in total knee replacements (TKR), 23.3% in total hip replacements (THR), 25.8% in spine procedures, 9.6% in lower extremity procedures and 1.8% in upper extremity procedures. 92% of falls occurred in the patients' room. Neither a known history of falls nor wearing a "falls risk" bracelet was associated with falling. Fallers were less likely to use a crutch or cane, more likely to use a walker, and more likely to be in a single occupancy room. Cases walked significantly fewer feet and required significantly more physical therapy (PT) ambulation assistance than controls. 31% of falls involved using the bathroom. Of 168 first falls, 28 (17%) resulted in injuries, most of which were minor. 8 falls (4.8%) resulted in 10 serious adverse events (AEs), including 4 dehiscence/return OR, 3 transfer to a higher level of care, 2 dislocations and 1 fracture. There we no deaths or intracranial/epidural bleeds.

In a logistic regression controlling for significant univariate predictors (single room occupancy, confusion, being assigned canes/crutches, using a walker or needing physical therapy assistance to ambulate) the only predictors of falls were confusion (OR 2.6; 95% CI 1.4–4.8) and using a walker (OR 28.6; 95% CI 6.5–125.0). Being in a double occupancy room was borderline protective against falling (OR 0.55; 95% CI 0.3–1.003). Among TKR, having a femoral block trended towards being associated with falls (p-value=0.057). There were no significant predictors of AEs.

Table 1. Comparisons of Patients Who Fell vs. Controls*

Characteristic	Fall Cases (n = 168)	Controls (n = 317**)	P-value
Sex			
Female	92 (55%)	179 (56%)	0.72
Distance (feet) able to ambulate with assistive device	48.9 (SD = 66.5)	64.4 (SD = 86.8)	0.049
Room Size†			
Double room	124 (80%)	262 (89%)	0.011
Single, or Double-Single	31 (20%)	33 (11%)	
Chart documented confusion	34 (20%)	29 (9%)	<0.001
Assigned a cane or crutches at fall/index time	162 (96%)	278 (88%)	0.0016
Walker used during fall/index time	142 (85%)	325 (99%)	<0.001
Ambulation Assistance by Physical Therapist			0.005
Max or Moderate	24 (15%)	33 (11%)	
Minimal	39 (25%)	97 (31%)	
Contact Guard	56 (35%)	84 (27%)	
Supervision or independent	13 (8%)	57 (19%)	
Not Tested	27 (17%)	37 (12%)	
Recorded prior history of falling	58 (36%)	82 (26%)	0.09
Patient wearing a yellow risk bracelet	45 (28%)	60 (19%)	0.13
Pre-operative urinary issues (incontinence, nocruria, urgency/frequency)	49 (30%)	84 (27%)	0.62

* Controls were assigned index time and date based on the time and date their matched case itself
** 2:1 controls could not be identified for 14 cases
† double room = two beds and two patients; a single room = one bed and one patient; double-single rooms size of a double room with one bed and one patient.

Conclusion: The rate of falls and AEs in this patient population was low. This large series identifies confusion and using a walker as being predictive of falling among orthopedic in-patients. Larger studies are needed to confirm these results, and to inform fall prevention strategies in this rapidly growing group of patients.

1918

Adoption Of New Electronic Medical Records May Inhibit Documentation Of Physician Quality Reporting System. Minzi Chen, William E. Davis, Austin Fraser, Jerald M. Zakem, Eve Scopelitis, Kismet Collins, MD, Tamika A. Webb-Detiege and Robert Quinet. Ochsner Medical Center, New Orleans, LA.

Background/Purpose: Lower back pain (LBP) is a common complaint in the general population and accounts for 2.5% of all outpatient office visits. Critical assessment and documentation of the clinical features of LBP are essential for accurate diagnosis and proper care. Medicare has established physician quality reporting system (PQRS) guidelines for back pain. An incentive is given to clinicians who successfully report 3 or more PQRS measurements for a minimum of 50–80% applicable Medicare Part B FFS patients from January 1 to December 31. Clinicians not compliant with reporting system will receive a service penalty that will be applied in 2015. Electronic medical records (EMR) are promoted as tools for performance improvement. We investigated the impact of education and conversion to a comprehensive EMR (EPIC) on physicians' documentation and compliance with the quality reporting system guidelines.

Methods: We initiated a performance improvement project by retrospectively reviewing 100 charts (20 from each of 5 clinicians) for Medicare PQRS guidelines for low back pain. Content of the PQRS documentation assessed includes initial comprehensive assessment using standardized assessment tools for pain, functioning status, warning signs, prior treatment response and employment status, physical examination including straight leg raise and neurological exam, advice for normal activities, and advice against bed rest. Results were reviewed with the clinicians, in conjunction with a didactic review of the PQRS guidelines. A comprehensive EMR system (EPIC) was launched shortly after the first chart review. Subsequently, 100 (20 from each of 5 physicians) charts were reviewed to measure change in documentation. An additional plan-do-study-act cycle was performed after working with the software development team to embed PQRS measurement guidelines within the EMR system.

Results: The overall percentage for prior lecture documentation was 36.75%, post lecture and EMR/EPIC system implementation was 19.59%. The compliance rate for pre-lecture comprehensive initial assessment was 34%, physical exam 46%, advice for normal activity 55%, and advice against bed rest 12%. The post-lecture/EMR comprehensive initial assessment was 23.3%, physical exam 27.5%, advice for normal activity 23.95%, and advice against bed rest 3.61%. Documentation declined significantly after education and EPIC implementation. A standard template for documentation ("smartphrase") was developed to facilitate physician documentation. The impact of this EMR enhancement on documentation is being measured and will be reported.

Conclusion: Initial implementation of the EMR had a significant *negative* impact on physician documentation of back pain for PQRS reporting in spite of physician education. An electronic template with built in PQRS guidelines may improve physician documentation and quality of care.

1919

Rheumatology-Ophthalmology Collaborative Uveitis Units May Improve The Diagnostic Approach Of This Pathology: Experience From a Uveitis Unit In a Secondary Spanish Hospital. Elena Aurrecoechea[1], Ana Diez del Corral[2], Angel de la Mora[2], Jaime Calvo-Alén[3] and Ernesto Romera[4]. [1]Hospital Sierrallana. Torrelavega, Torrelavega, Spain, [2]Ophthalmology Unit Hospital Sierrallana, Torrelavega, Spain, [3]Hospital Universitario Sierrallana, Torrelavega, Spain, [4]Hospital Sierrallana Torrelavega, Torrelavega, Spain.

Background/Purpose: Uveitis is defined as an intraocular inflammation, and may be associated to a systemic disease, it has a worldwide distribution, and it is a significant cause of blindness. As such the creation of Uveitis Units with the association of Rheumatologists and Ophthalmologists is highly recommended. The aim of this study is analyze the Etiology of the Uveitis diagnosed in the first three years of this unit and share our experience.

Methods: This study includes 125 patients, new and long standing, with Uveitis examined in the last three years. All patients were evaluated by the Ophthalmologist and the Rheumatologist including a detailed history and examination. A questionnaire about family and medical history were given (a Spanish translation from uveitis.org questionnaire), and guided by the evaluation a blood test, chest ray, OCT, retinal angiography or other test were ordered as needed.

Results: The most common form of uveitis was anterior uveitis (67.2%) and the most common diagnoses were Idiopathic (44%), Ankylosing spondylitis (17.8%), Herpes (14.3%), HLA-B27 (9.5%), Fuchs Heterochromic Iridocyclitis(3.5%).

The second most common uveitis type was posterior uveitis (16.8%) and the most common diagnoses were toxoplasmosis (42.9%), Serpiginous choroidopathy (23.8%), idiopathic (23.8%), Tuberculosis (4.8%) and Vogt Koyanagi Harada disease (4.8%).

Panuveitis was diagnosed in 8.8% of the cases and the most frequent causes were idiopathic (54%), Behçet's disease (18.8%), Endophthalmitis (9%), and Toxoplasmosis (9%).

The less frequent type of uveitis was intermediate uveitis with 7.2% of the diagnoses, most of the cases were idiopathic (66.6%), but sarcoidosis (11%), syphilis (11%), and multiple sclerosis (11%) were other etiologies found.

There were no eyes with final visual acuity worse than 20/200 in these 3 years with non-infectious uveitis.

Anterior Uveitis	67.2%	Intermediate Uveitis	7.2%	Posterior Uveitis	16.8%	Panuveitis	8.8%
Idiopathic	44%	*Idiopathic*	66.6%	Toxoplasmosis	42.9%	*Idiopathic*	54.4%
Ankylosing Spondylitis	17.8%	Multiple Sclerosis	11%	Serpiginous choroidopathy	23.8%	Behçet's disease	18.8%
Herpes	14.3%	Syphilis	11%	Idiopathic	23.8%	Endophthalmitis	9%
HLA-B27+	9.5%	Sarcoidosis	11%	Tuberculosis	4.8%	Toxoplasmosis	9%
Fuchs heterochromic Iridocyclitis	3.5%			VKH	4.8%		
Psoriasis	2.4%						
Sarcoidosis	2.4%						
AIJ	2.4%						
TINU	1.2%						
IBD	1.2%						
Rheumatoid arthritis	1.2%						

Conclusion: This secondary center based study shows the type and etiology of uveitis in our population, and how a multidisciplinary approach can improve the rate of diagnosis and prognosis for patients permitting a ready access to new and better treatments in an effective way, leading to a satisfying experience for the Rheumatologist and Ophthalmologist alike.

1920

Determining The Vaccination Rates Of American College Of Rheumatology Recommended Vaccines Among Veterans With Rheumatoid Arthritis – A Quality Indicator. Puneet Bajaj, Melinda Collins and Ranjan Roy. VA Medical Center, Northport, NY.

Background/Purpose: American College of Rheumatology (ACR) guidelines recommends the administration of killed vaccines [pneumococcal, influenza and hepatitis B (HepB)], recombinant human papillomavirus (HPV) vaccine and live attenuated herpes zoster (HZV) vaccinations prior to therapy with DMARDs or biologic agents. HepB vaccination is indicated if hepatitis risk factors are present. Rheumatoid arthritis (RA) patients already on a DMARD or a biologic agent, vaccination with pneumococcal, influenza, HepB and HPV vaccine should be administered as indicated. RA patients already on a DMARD (non biologics) may be vaccinated with HZV vaccine.

Objective: The question addressed in this quality improvement project was to ascertain whether veterans with RA at our VA Medical Center (VAMC), are being vaccinated as per ACR guidelines.

Methods: A retrospective chart review was performed. Patients were identified using clinic encounters with an associated ICD9 code for RA (714.0, 714.2) in the Computerized Patient Record System (CPRS) at our VAMC, from January 1, 2011 through April 23, 2013. Charts were searched using several keywords, for documentation of these vaccinations, either offered or received.

Results: A total of 330 RA patients were identified, of which 251 were included. Out of the 79 patients excluded, 59 did not have a definitive diagnosis of RA and 20 had insufficient records. The mean age was 74 years, 92% males and 88% Caucasian. Among the included patients 54.5% had been treated with methotrexate, 35.8% hydroxychloroquine, 65% corticosteroids, 15% sulfazalazine, 6.7% leflunamide, 1.6% azathioprine and 38.6% with a biologic agent. Out of the patients who had been on a DMARD or biologic agent, 95.6% were either offered or received influenza vaccine, 93% pneumococcal vaccine, and 20.5% HZV vaccine. In addition, 1.5% had received Hep B vaccine. HPV vaccine was not indicated as per the vaccination guidelines due to age limitations. In a subset analysis, 53.4% of the patients either received or were offered influenza vaccine in each of the last three years (2010, 2011, 2012), 24% patients in two of the last three years, 17.5% patients only once and the remaining 5.1% were not offered the vaccine.

Conclusion: At our center, documented pneumococcal vaccination rates were high but annual influenza and HZV vaccination rates were suboptimal.

The low HZV vaccination rate could be due to some patients already on biologic agents prior to the vaccine approval in 2006 and initial difficulties in obtaining the vaccine. Annual influenza vaccination rates were less than desired. This could be due to missed annual follow ups, unavailable documentation of vaccination administered outside the VAMC & patients who had expired. HepB vaccination rate was also low; however, analysis regarding the presence of hepatitis risk factors was not performed.

Limitations of our analysis were unavailability of vaccination data prior to 1999 before CPRS was implemented and difficulty in obtaining data from outside the VA.

Better adherence to vaccination guidelines and documentation is required. This may be achieved through interventions such as physician and nursing staff education, and use of clinical reminders in CPRS.

1921

Ask The Rheumatologist: Evaluating The Use Of a Patient Centered Web Based Service. Steven J. Katz. University of Alberta, Edmonton, AB.

Background/Purpose: Previous studies have demonstrated growing and significant patient use of the internet as a health resource. Yet, many web based resources have been shown to have poor quality, or lack the information being sought. An Ask the Rheumatologist service was established as an enhancement of a local rheumatology website. This study aims to examine the characteristics of the users of this service over its first year in operation and whether it can be a means to creating a dynamic website.

Methods: An Ask-the-Rheumatologist webpage was established on the www.EdmontonRheumatology.com website in January 2012., a site representing rheumatologists in Edmonton, Alberta, Canada. Each submitter provided a first name, city/country, and his/her question. The webpage explicitly states responses will not be provided for those questions that address specific patient care issues. A descriptive evaluation of the questions submitted between January and December 2012 was undertaken, examining the number of webpage visits, number of questions submitted, number of answers posted, gender and location of submitters when provided, general category of question, and whether or not the answer to the question could be found at least partially elsewhere on the website.

Results: The Ask the Rheumatologist webpage was visited 1484 times in 2012. 61 questions were submitted by 48 females, 10 males, and 3 who could not be identified. 29 questions were submitted from Edmonton, 21 from other Canadian centers, and 11 from other centers around the world. 33 submitters identified having a rheumatic disease themselves, with the

most common being rheumatoid arthritis (N=12), followed by fibromyalgia (N=4) and systemic lupus (N=4). 29 submitters included their personal experience. were most common (N=16), followed by disease treatment (N=14), investigations and natural treatment options (N=5), genetics and pregnancy (N=2). 11 questions were deemed inappropriate, most commonly because of a request to see a rheumatologist. Answers to 22 questions (36%) asked could be at least partially found elsewhere on the website. 31 questions (51%) were selected with answers posted throughout the year on the webpage.

Conclusion: An Ask the Rheumatologist webpage was a well used service upon its introduction. It provided answers to specific patient concerns, and in half the cases, provided information that was otherwise not available on the website, thereby allowing the site to adapt to user needs. By doing so, it provides another means to optimize care and education for those with rheumatic diseases.

1922

Determinants Of Patient Satisfaction In An Academic Rheumatology Practice. Abhijeet Danve, Jennifer H. Ku, Helena Pang, Thien Hoang, Alana Ralston, Dongseok Choi and James T. Rosenbaum. Oregon Health and Science University, Portland, OR.

Background/Purpose: Patient satisfaction has emerged as an important measure of physician performance and criterion for compensation in the US. Factors contributing to patient satisfaction are incompletely understood especially in chronic rheumatic diseases. The aim of this study was to identify various factors associated with patient satisfaction.

Methods: This was a cross-sectional study conducted at Oregon Health & Science University's rheumatology clinic. Consented patients' satisfaction of their clinic visit was measured on a 0 to 10 numerical rating visual analogue scale, anchored by 10 verbal descriptions ranging from extremely dissatisfied to extremely satisfied. We collected demographic and clinical data including diagnosis; size of problem list; depression (identified by documentation or antidepressant use in absence of other indications); use of narcotics, biologic agents, or steroid injections; investigations like blood tests, x-rays, or MRI; or hospitalization in past 1 year. The impact of characteristics like attending physician versus physician in training, provider's gender, new versus follow up visit, wait time, number of telephone and email encounters was studied. Statistical analysis was performed using descriptive statistics and quantile regression.

Results: We enrolled 300 patients between January and June of 2013. Mean age was 50 years (s.d. 15.2); 74.3% were female; 92% were white. Common diagnoses included lupus/MCTD (n=49, 16.3%), fibromyalgia (42, 14.0%), seronegative arthritides (39, 13.0%), rheumatoid arthritis (35, 11.7%), vasculitides (26, 8.7%), osteoarthritis (20, 6.7%) and others (89, 29.7%). In the univariate analysis, female gender (regression coefficient [rc] 4.62; 95% CI 0.52, 8.71; $p=0.03$) and follow-up visits (rc 8.01; 95% CI 6.74, 9.44; $p<0.01$) were associated with higher satisfaction. Afternoon appointments (rc −5.20; 95% CI −8.73, −1.67; $p<0.01$), female providers (rc −7.50; 95% CI −9.54, −5.48; $p<0.01$), use of narcotics (rc −4.62; 95% CI −8.8, −0.44; $p=0.03$) or an MRI in the past year (rc −5.78; 95% CI −10.83, −0.72; $p=0.03$) were associated with lower patient satisfaction. At multivariate analysis, an MRI in the past year (rc −4.42; 95% CI −5.86, −0.44; $p=0.02$) and afternoon appointments (rc −3.15; 95% CI −5.86, −0.44; $p=0.02$) remained significantly associated with lower satisfaction. Other factors like age, race, diagnosis, presence of fibromyalgia, depression, obesity, biologic use, steroid injections and quality of life did not affect satisfaction.

Conclusion: Patient satisfaction is playing an increasing role in patient centered outcomes and physician reimbursement. Accordingly, it is critical to understand what drives satisfaction.

We found that female gender, follow-up visits, male providers and morning appointments were associated with higher satisfaction. Contrary to our expectations, use of narcotics and an MRI in the past year had a negative influence on satisfaction when controlling for covariates. Interestingly, diagnosis of fibromyalgia, obesity, depression, steroid injections and use of biologic agents did not affect satisfaction. The validation of these results should be tested in other practices.

1923

A Study To Determine Patient Satisfaction With a Nurse-Led Injection Clinic In Rheumatology. Margaret Saldanha[1], Kathleen Brown[1], Dawn Heap[1], Cynthia Mech[1], Melissa Deamude[1], Kathy Kislinsky[1], Debbie McClory[2], Alpesh Shah[3] and William G. Bensen[4]. [1]Rheumatology Health Team, St. Joseph's Hospital Hamilton, Hamilton, ON, [2]Rheumatology Health Team Hamilton, Hamilton, ON, [3]Rheumatology Health Team, Dr. Bensen's Rheumatology Clinic, Hamilton, ON, [4]St. Joseph's Hospital and McMaster University, Hamilton, ON.

Background/Purpose: There is a widening care gap in Canada between patients who need Rheumatology care and the capacity of the system to deliver that care in a timely manner. At St. Joseph's Hospital and McMaster University in Hamilton we have developed several models of team-based care with trained rheumatology nurses.

One successful team -based model has been a nurse managed injection clinic treating patients with inflammatory arthritis or soft tissue pain. All patients fill out a health check questionnaire and authorize their consent before receiving injections, ensuring patient safety. Nurses use a set of directives written by the rheumatologist as guidelines for the clinic with a Rheumatologist always present on site.

This clinic, run twice weekly, allows immediate access and assessment of patients with flares or potentially needing steroid injections. Currently this clinic administers nearly 100 injections per week. The purpose of this study was to assess patient perspectives on how they view this team -based model as compared to a traditional MD model which historically would cause a delay of treatment by 8–10 weeks before an assessment of their disease was possible.

Methods: A cross-sectional study sampling 217 consecutive patients who attended the nurse-led injection clinic was conducted at Dr. Bensen's Rheumatology Practice in Hamilton, Canada from May 2013 to June 2013. Patients were given a structured self-administered questionnaire to determine their satisfaction with the steroid injection clinic run by the nurses. Those that have English as a second language were excluded as well as anyone who wasn't able to understand and follow directions on the questionnaire. Efficacy and relevance was assessed by patients answering eight qualitative questions.

Results: The results of this study indicated that patients were offered timely access to care at critical times when they were experiencing a flare of disease symptoms. 83% of patients responded that their pain was better managed in this clinic. 96% of patients affirmed that they were able to be seen within 2 weeks of their onset of symptoms. All patients surveyed felt comfortable discussing their health issues with the nurse and felt confident in the nurse's assessment and injection techniques. Overall the patients reported that because of this nurse led injection clinic model their quality of life living with a rheumatologic condition improved.

Conclusion: Our results show that a nurse run steroid injection clinic is both valued by patients for pain and inflammation management and is readily available. This demonstrates a high degree of satisfaction with the nurse run program and they feel very strongly that without this clinic their pain management would not be optimal. Without this clinic, patients indicated that they would seek treatment elsewhere, mostly with their family doctors, emergency rooms, or walk-in clinics, resulting in further congestion in an already overwhelmed healthcare system. This study determined that nurse run steroid injection clinics are both needed and valued by our patients in Hamilton, Canada.

1924

Cleveland Clinic Dual Energy X-Ray Absorptiometry Registry, A Web-Based Tool Designed For Efficient Collection Of Bone Density and Osteoporosis Related Clinical Risk Factor Data. Chad L. Deal, Gregory J. Strnad, Robert A. Overman and Boris Bershadsky. Cleveland Clinic, Cleveland, OH.

Background/Purpose: A patient registry is an organized system that collects uniform data to allow evaluation of specific outcomes for a population with a particular disease. They can enable observation of the natural history of disease, clinical/cost effectiveness, treatment, quality of care, and factors that influence prognosis and outcomes. Osteoporosis research using administrative claims lacks clinical characteristics including bone mineral density (BMD) and fracture risk. To fill this gap a dual energy x-ray

absorptiometry (DXA) registry was established at the Cleveland Clinic (CCF) in 2009.

Methods: The CCF DXA Data Entry System is a web-based intranet tool designed to capture data important to patient care and osteoporosis research. The system receives real-time scheduling messages from the electronic medical record, generates an online data collection form for each DXA bone density scan appointment, and pre-loads them with patients' demographic information.. DXA technologists log in from any workstation connected to the intranet and are guided through a data entry page for each appointment that helps to ensure complete and accurate data collection. Data on bone density (T and Z-scores, g/cm2), self-reported osteoporosis treatment, and FRAX® clinical risk factors are recorded. From 2009 through 2012, data on a total of 35,373 patients were entered into the registry, which represents 83.6% of the eligible population (4.3% missing data, 12.1% refused) and are stored in a secure SQL Server database and have been successfully linked with 99.1% of patients' medical record data using Explorys Inc. proprietary software. In 2013, FRAX®10-year risk of major osteoporotic fracture and hip fracture was computed for all registry subjects.

Results: The registry includes 28,095 postmenopausal women, 5,079 men ≥50, 1,549 premenopausal women, and 650 men <50. Of these, 11.9% of postmenopausal women, 9.6% of men ≥50, 4.8% of premenopausal women, and 6.5% of men <50 have now had a 2nd DXA. To date we have investigated the relationship between registry data (FRAX®clinical risk factors and bone mineral density) and initiation of drug therapies per NOF guidelines, evaluated the frequency of DXA in organ transplant patients, and the rate of osteoporosis therapy in glucocorticoid treated subjects, among other projects. We found that 62.4% of rheumatologists and 52.2% of non-rheumatologists had started osteoporosis therapy within 365 days after their patient had a T-score ≤ 2.5, that 78% of patients on glucocorticoids had osteoporosis therapy initiated within 6-months, and that 42.5% of patients with a T-score <−2.5 had a follow-up DXA within 3-years. Ongoing projects includes evaluation of premenopausal women (n= 176) and men <50 (n= 161) with Z-score ≤ 2.0 (low bone mass for age), glucocorticoid users, effect of BMI and vitamin D on BMD, changes in BMD over time, and possible interventions for patients with a T-score ≤−2.5 who do not report osteoporosis therapy.

Conclusion: The CCF DXA Registry has enrolled 35, 373 patients with approximately 10–15,000 new patients each year. This large and longitudinal registry offers opportunities to monitor quality indicators, assess patient care, and conduct observational and interventional research.

Disclosure: C. L. Deal, None; **G. J. Strnad**, None; **R. A. Overman**, None; **B. Bershadsky**, None.

1925

Patient Satisfaction with an Associate Teaching Hospital Clinical Trial Unit In North-East London. Genevieve Casey[1], Carey Tierney[2], Hasan Tahir[2], Simon Donnelly[2] and Judith Bubbear[2]. [1]Barts and the London Medical School, London, United Kingdom, [2]Barts Health NHS Trust, London, United Kingdom.

Background/Purpose: Compared to patient satisfaction with general medical care little is known about patient satisfaction within clinical trials. Clinical trials are a time and resource demand for patients without necessarily a guarantee of receiving the active compound. Given the importance in developing new therapies and medicines, and outcomes overall we were keen to examine patient satisfaction within the unit we run and thoughts and experiences with regard to clinical trials.

Whipps Cross University Hospital is an Associate Teaching Hospital in North-East London serving a population of around 400,000 with a commercially run research unit. Our unit currently runs 14 trials and sees 20–30 patients each week. The clinical trials mainly test biological therapies in autoimmune rheumatic diseases.

Methods: We could not find a validated satisfaction survey for patients in clinical trials. We modified a survey by Madsen et al. using clinical trials with inflammatory bowel disease. The survey had 21 questions. Every patient attending the unit at least 3 times was surveyed from April - June 2013.

Results: 38 surveys were completed. Patient satisfaction with clinical trials and the research unit is positive. 71% reported a very positive attitude towards these trials, 79% indicated they would participate again and 79% would recommend a friend or family member to participate.

81% of respondents felt it was 'always' necessary to examine new drugs using a clinical trial design, 31% were 'hesitant' about randomization and 48% about blinding. 53% said it was 'very important' to them to recognise staff at each visit and 74% indicate this aspect influences their attitudes towards clinical trials 'a lot'.

One respondent reported the trial was 'too time consuming', two that they 'could have used more time' and the remainder felt time allocation was 'OK'.

Getting the 'new' drug, being closely monitored, having a 'good relationship' with doctors/nurses, and helping future patients, were all 'very important' motives for participating in the trial with the majority of the respondents.

Conclusion: Our results are similar to those reported by Madsen et al. The attitudes towards blinding and randomization could perhaps be addressed by providing more education about the necessity of blinding and randomization prior to trial participation.

Madsen et al identified having a single physician design their trials results in high patient satisfaction. Our survey also shows participants value recognising the same staff at each visit and may be undervalued by trial designers in a busy setting.

Overall, patient satisfaction with clinical trials was high and clinicians should feel confident when referring patients for inclusion in clinical trials.

Validation Of The Hospital For Special Surgery Knee Questionnaire: Convergent Validity, Responsiveness and Sensitivity To Change. Jasvinder A. Singh[1], Cathy Schleck[2], W. Scott Harmsen[3] and David Lewallen[4]. [1]University of Alabama, Tuscaloosa, AL, [2]Mayo Clinic College of Medicine, Rochester, MN, [3]Mayo Clinic, Rochester, MN, [4]Mayo Clinic college of medicine, Rochester, MN.

Background/Purpose: Hospital for Special Surgery (HSS) Knee questionnaire has previously been shown to have construct validity. Our objective was to further assess the validity and responsiveness of HSS Knee Questionnaire.

Methods: We used data from the Mayo Clinic Total Joint Registry to assess the validity of HSS Knee questionnaire, by including patients who underwent primary total knee arthroplasty (TKA) between 1993–2005 and responded to the baseline and 2-year post-primary TKA HSS Knee questionnaire. HSS Knee questionnaire combines pain, function, range of motion and muscle strength to derive a total score. Convergent/divergent validity was examined with the association of select demographics (age, gender, number of joints involved) at baseline with HSS Knee scores using linear regression and correlation analyses. Minimally Clinically Important Difference (MCID) and Really Important Difference (RID) were calculated corresponding to "somewhat better now" and "much better now" patient responses, respectively to the question at 2-years- Compared to your condition before the surgery, how would you rate your knee now? For discriminant ability, we calculated effect size by taking the change in respective score from baseline to 2-years and dividing the result by the standard deviation at baseline.

Results: For primary TKA, there were 5,280 knees with both a baseline and a 2-year data. The sample consisted of *2,375* males (45%) and 2,905 females (55%). The mean age at surgery (SD) is 68 (10), median age was 69 (range, 17–93). Male sex, body mass index, Deyo-Charlson index and the number of lower extremity joints involved were significantly associated with HSS scores ($p<0.001$). HSS correlated highly with knee society score (KSS; correlation coefficient 0.52, $p<0.001$) and KSS function (0.65, $p<0.001$). Age was not significantly associated ($p<0.34$). MCID and RID thresholds were 8.29 and 25.97 respectively. Effect size was 2.95 at 2-years and the standardized response mean was 1.85. HSS score at 2-years in the lowest category had odds ratio of 5.15 (95% confidence interval: 2.73,9.71; $p<0.001$) for revision of index TKA 2-years or later after primary TKA. Preoperatively only 0.03% and 0.1% were at the floor and ceiling, respectively. At 2-years, 0% and 17% scores were the floor and ceiling, respectively.

Conclusion: The HSS Knee questionnaire is a valid and sensitive outcome measure for patients undergoing primary TKA. Further validation in independent patient samples will improve its usability in more patient populations.

Assessing Adherence To Choosing Wisely® Recommendations Regarding Antinuclear Antibody and Antinuclear Antibody Subserology Testing In An Urban Community Health System. Adam Carlson[1], Jinoos Yazdany[1], Kara Lynch[2] and Laura Trupin[1]. [1]UC San Francisco, San Francisco, CA, [2]San Francisco General Hospital, San Francisco, CA.

Background/Purpose: As part of the American Board of Internal Medicine's Choosing Wisely Campaign®, the ACR published recommendations in 2013 advising clinicians against ordering anti-nuclear antibody (ANA) subserologies in the absence of a positive ANA and a clinical suspicion for an underlying immune mediated disease. Subserology testing for SSA and Jo-1 was considered a reasonable exception this rule. Previously published guidelines also recommend against obtaining serial ANAs. In this study, we sought to assess the current practice patterns for ordering ANAs and ANA subserologies at an urban community hospital and its affiliated outpatient clinics.

Methods: Laboratory data was compiled for all patients who underwent testing for an ANA or any of several ANA subserologies (dsDNA, Smith, RNP, SSA, SSB, Scl-70, Centromere, and Jo-1) at the San Francisco General Hospital clinical laboratory between January 2012 and January 2013. All ANAs were measured by immunofluorescence, and all subserologies were measured by enzyme linked immunosorbant assay. Data were analyzed to generate descriptive information regarding the frequency and origin of ANA and ANA subserology ordering

Results: A total of 2514 patients underwent testing for either an ANA or an ANA subserology during the study period. A total of 2350 patients underwent initial ANA testing of whom 123 (5.2%) underwent serial ANA evaluations. Repeated ANA tests were ordered either from primary care clinics or on inpatient services and not from subspecialty clinics (Table 1). A positive initial ANA (defined as a titer >1:40) was found in 524 (23%) patients, and a negative initial ANA was found in 1810 (77%) patients. Of those patients whose initial ANA was negative, 117 (6%) went on to have a subserology checked. From this group, 58 (50%) patients were tested for SSA and 12 (10%) were tested for Jo-1. ANA subserologies were therefore ordered inappropriately in 47 (2%) patients whose initial ANA was negative. Over a one year period, 170 (7%) patients with an initial ANA test underwent subsequent ANA or ANA subserology testing that was counter to current recommendations.

Table 1. Initial and serial ANA testing between 2012 and 2013 in an urban community hospital health system.

Clinical Setting	Initial ANA N=2350	Serial ANA N=123
Primary Care	1832 (78%)	77 (63%)
Specialty Outpatient	402 (17%)	0
Emergency Department/Urgent Care	44 (2%)	0
Inpatient hospitalization	255 (11%)	46 (37%)

Conclusion: Inappropriate ANA and ANA subserology testing were relatively infrequent in our safety net health system, which provides care to poor and medically indigent patients. Serial ANA testing was three times more common than inappropriate subserology testing. Measures aimed at reducing repeated ANAs ordered from primary care clinics and on inpatient services would likely be most efficacious in reducing unnecessary testing.

1928

Outcomes Of The Fast-Track Pathway In Giant Cell Arteritis: A Sight Saver. Pravin Patil[1], Win Win Maw[1], Katerina Achilleos[1], Christian Dejaco[2], Mark Williams[3], Tochukwu Adizie[4], Dimitrios Christidis[5], Frances Borg[1] and Bhaskar Dasgupta[4]. [1]Southend University Hospital, Westcliff-on-sea, United Kingdom, [2]Medical University Graz, Graz A-8036, Austria, [3]Southend University Hospital, Westcliff on sea, United Kingdom, [4]Southend University Hospital, Westcliff-on-Sea, United Kingdom, [5]Southend University Hospital, Westcliffe on sea, United Kingdom.

Background/Purpose: Giant cell arteritis (GCA) is a medical emergency, with permanent visual loss occurring in about 20–30% of patients. We have identified that delayed recognition, multiplicity of referral routes and absence of a standard pathway of care increases the complications rate in GCA. We report our experience of developing and implementation of a fast-track referral pathway (FTP) to reduce the incidence of sight loss in GCA.

Methods: All patients with suspected GCA seen between Jan 2012 to Dec 2012 were enrolled into a FTP. Patients were started immediately on high dose glucocorticosteroids (GC) by the referring doctor and seen by a rheumatologist within one working day. We compared data from the FTP with that of a longitudinal cohort of suspected GCA patients seen through standard referral routes between January 2009 and December 2012. A logistic regression method was used to investigate the effect of several variables on sight loss.

Results: GCA was diagnosed in 46 (56.8%) patients in the standard pathway and in 33 (58.9%) in the FTP. As shown in table 1, complete sight loss was more commonly observed in standard compared to FTP [n=17 (37.0%) versus 3 (9.1%), p=0.005 in univariate and p=0.007 in multivariate analysis adjusting for clinical risk factors of sight loss]. There was no difference in the staring dose of GC or the number of patients receiving intravenous GC in both groups.

In the standard pathway, a higher proportion of GCA patients were referred to other specialties before rheumatology [n=11 (23.9%) vs. n=5 (15.2%), p=0.34]. The majority of patients in FTP were seen within a day of presenting to general practitioner compared to a median time of 3.0 (1.0–71.0 days) in the standard pathway (p=0.068). Interestingly, a significantly lower number of patients who subsequently lost sight presented with headache [n=13 (65.0%)] compared to those who did not lose sight [57 (98.3), p<0.001].

Table 1. Types of sight loss in conventional and fast track pathways

Type of sight loss	GCA–conventional (n=17)	GCA–fast track (n=3)
Partial, monocular¥	6 (35.3)	1 (33.3)
Complete, monocular¥	8 (47.1)	2 (66.7)
Partial, binocular¥	0	0
Complete, binocular¥	3 (17.6)	0

¥ n (percentage)

Conclusion: Implementation of a GCA fast track pathway led to a reduction of permanent sight loss in newly referred GCA patients. The effect is explained by a reduction of the delay in treatment of GCA as well as by other, difficult to measure factors including increased awareness of GCA by public and general practitioners and reduction in the multiplicity of referral routes to rheumatology clinic. We recommend adoption of the FTP as a standard of care for GCA.

1929

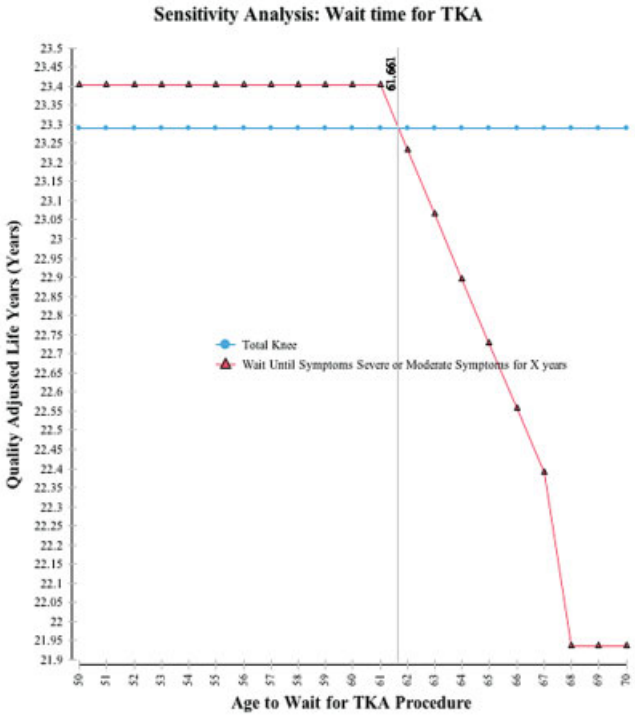
Timing Of Total Knee Arthroplasty: A Decision Analysis. Darena Tulanont[1], Haily Vora[1], Roopa Akkineni[2] and Daniel A. Albert[1]. [1]The Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, NH, [2]Dartmouth-Hitchcock Medical Center, Lebanon, NH.

Background/Purpose: Total Knee Arthroplasty (TKA) reduces pain and restores mobility. However, replacement joints have limited durability and patients have to weight the benefits of having a knee replacement versus its lifespan, especially since revision arthroplasty has a higher complication rate and poorer outcomes. The objective of this study is to determine the trade-off between undergoing TKA versus delaying TKA and thereby reducing the chance of revision.

Methods: A Markov state-transition model was constructed to assess wait-times in patients undergoing TKA. The model estimated the quality-adjusted-life-years (QALYs) for patients undergoing TKA at age 50 versus waiting until moderate or severe symptoms occur. The model simulated a hypothetical cohort of patients 50-years and older. The Western Ontario and McMaster Universities Arthritis Index (WOMAC) was used to classify mild, moderate and severe symptom levels. Probabilities and quality adjustment measures were extracted from published literature. Sensitivity analyses were performed on utilities for pain and wait time to undergo TKA. The model was simulated over the lifetime of an individual.

Results: Compared to waiting until age 65, performing TKA at age 50 regardless of symptoms is the preferred strategy [22.73 QALYs versus 23.29 QALYs]. However, sensitivity analysis demonstrates that waiting is preferred for mild pain when utility is greater than 0.85; and moderate pain when utility is greater than 0.72. In patients with severe pain TKA is always favored over waiting. For a 50-year old patient with mild pain the natural history of

osteoarthritis suggests progression to moderate or severe pain. Thus, our model indicates that patients presenting with mild pain will wait an average of 11.7 years (age 61.7 years; 23.40 QALYs) for TKA in order to maximize expected utility.



Conclusion: TKA is the preferred strategy in individuals with severe knee pain. For patients having mild pain, it is preferable to wait until moderate or severe pain develops.

Patients' Response To a Sleep Question and Disease Activity In Multiple Rheumatic Conditions. Sapna Sangani[1] and Martin J. Bergman[2]. [1]Mercy Catholic Medical Center, Lansdowne, PA, [2]Drexel University College of Medicine, Philadelphia, PA.

Background/Purpose: Sleep disturbances can have an impact on the quality of life of any individual. Research studies have shown a significant association between sleep disturbances and a number of chronic inflammatory conditions, including Asthma and Crohn's disease. This study aims to determine the significance of sleep disturbances in patients diagnosed with various rheumatic conditions, and its association with disease activity levels.

Methods: All patients with any rheumatologic diagnosis attending a single rheumatology practice were asked to complete a MDHAQ. The MDHAQ includes sections regarding function, pain, patient global estimate, a patient self-reported joint count, fatigue, exercise, AM stiffness and a brief psychological profile. The MDHAQ includes 3 psychological profile queries, including "Over the past week, were you able to get a good night's sleep?" The responses are 0–3 which stand for, 0=without difficulty, 1= with some difficulty, 2= with much difficulty, 3=unable to do. RAPID3 is an index of the 3 patient-reported outcome measures: physical function, pain and patient global estimate. RAPID3 can be calculated from a MDHAQ in less than 10 seconds. Patients are then characterized into disease activity categories ("remission", "low disease activity", "moderate disease activity", "high disease activity"), according to established criteria. Using a random visit for each patient, linear regression models were determined using the composite score value as the dependent variable, and "sleep" as the independent variable, to determine possible interactions between "sleep"score and disease activity scores. All statistical analyses were performed using Stata v12.

Results: We analyzed data on total of 786 patients diagnosed with a non-overlapping rheumatic disease and who had completed the MDHAQ survey. The number of patients diagnosed with a particular rheumatic disease is shown in the table below. The rheumatic conditions studied are Rheumatoid Arthritis (RA), Osteoarthritis (OA), Fibromyalgia, SLE, Psoriatic Arthritis (PsA), Spondyloarthropathies, and Gout. A "linear" worsening of RAPID3 was seen with each increment of sleep variable.

Table.

Rheumatic conditions	Observation	Sleepinc=0 (p-value)	Sleepinc=1 (p-value)	Sleepinc=2 (p-value)	Sleepinc=3 (p-value)	R-squared
Rheumatoid Arthritis (RA)	195	5.38 (<0.01)	10.69 (<0.01)	15.45 (<0.01)	17.40 (<0.01)	0.33
Osteoarthritis (OA)	232	9.31 (<0.01)	11.38 (<0.01)	15.73 (<0.01)	17.98 (<0.01)	0.17
Fibromyalgia	52	9.96 (<0.01)	13.51 (<0.01)	18.39 (<0.01)	19.79 (<0.01)	0.25
SLE	53	4.54 (0.003)	8.4 (<0.01)	13.91 (<0.01)	12.16 (0.008)	0.23
Psoriatic Arthritis (PsA)	60	5.34 (<0.01)	10.35 (<0.01)	16.24 (<0.01)	19.77 (<0.01)	0.42
Spondyloarthropathies	113	4.82 (<0.01)	10.04 (<0.01)	16.96 (<0.01)	20.16 (<0.01)	0.52
Gout	81	5.20 (<0.01)	9.82 (<0.01)	17.10 (<0.01)	21.05 (<0.01)	0.37

Conclusion: Interestingly, patients affected by a myriad of chronic inflammatory rheumatic diseases perceive significant sleep disturbances, at any given point of time during the course of their disease process. Patients with worse sleep scores are less likely to be in low disease activity as measured by RAPID3. Interventions in chronic rheumatic diseases are often targeted to impact symptoms of joint pain / function. Further interventions may be needed to improve strategies designed for the improvement of psychological profile, especially sleep disorders.

Models Of Care For Arthritis: Drivers, Facilitators and Barriers To Their Development and Implementation. Aileen M. Davis[1], Cheryl Cott[2], Rose Wong[3], Michel Landry[4], Linda Li[5], Allyson Jones[6], Cy Frank[7], Sydney C. Lineker[8], Louise Bergeron[9], Gillian A. Hawker[10], Dianne P. Mosher[11], Vandana Ahluwalia[12], Michel Zummer[13], Susan B. Jaglal[14], Rhona McGlasson[15], Richard Birtwhistle[16], Sherry Bar[17] and Elizabeth M. Badley[18]. [1]Division of Health Care and Outcomes Research, Toronto Western Research Institute, University Health Network, Ontario, ON, [2]Divison of Health Care and Outcomes Research, Toronto Western Research Institute, University Health Network, Toronto, ON, [3]Division of Health Care & Outcomes Research, Toronto Western Research Institute, University Health Network, Toronto, ON, [4]Department of Community and Family Medicine, Physical Therapy Division, Duke University Medical Center, Durham, NC, [5]Arthritis Centre of Canada and Department of Physical Therapy, University of British Columbia, Vancouver, BC, [6]University of Alberta, Edmonton, AB, [7]Alberta Bone and Joint Institute and Department of Surgery, University of Calgary, Calgary, AB, [8]The Arthritis Society, Toronto, ON, [9]Canadian Arthritis Patient Alliance, Ottawa, ON, [10]Women's College Research Institute, University of Toronto, Toronto, ON, [11]University of Calgary, Calgary, AB, [12]Past President, Ontario Rheumatology Association, Brampton, ON, [13]Ch Maisonneuve-Rosemont, Montreal, QC, [14]Department of Physical Therapy, University of Toronto, Toronto, ON, [15]Bone and Joint Canada, Toronto, ON, [16]Centre for Studies in Primary Care and Family Medicine and Community Health and Epidemiology, Queen's University, Kingston, ON, [17]British Columbia Ministry of Health Services, Victoria, BC, [18]Toronto Western Research Institute, University Health Network, Toronto, ON.

Background/Purpose: Management of arthritis is a growing concern given disease prevalence and limited health care resources. In the context of a larger project investigating innovative models of care (MOC) delivery for people with arthritis, this study sought to identify the drivers, facilitators and barriers to the MOC development and implementation in British Columbia (BC), Alberta (AB) and Ontario (ON), Canada.

Methods: This study used embedded case methodology, with triangulation of documents from peer-reviewed literature, reports, working papers of MOC, health human resources (HHR), etc.; population/administrative data regarding utilization of care; and, semi-structured, one-on-one stakeholder interviews with health planners, decision-makers, program managers, and care providers. Thematic analysis using a constant comparative approach was used to identify drivers, facilitators and barriers to models/innovative processes of providing care.

Results: 79 key informants interviews (BC=24, AB=22, ON=33) of which 28 (BC=9, AB=10, ON=9) were in-depth interviews related to drivers, facilitators, and barriers were conducted between 2009 and 2012. In addition to traditional primary care to specialist referral, MOC identified included community-based direct access to services, multi-disciplinary and inter-disciplinary care. Various processes were implemented to enhance access and care provision: therapists with skills in arthritis assessment and management were embedded in primary care; specialty multi-disciplinary musculoskeletal clinics were established to interface with primary care; therapists with advanced arthritis skills practiced in triage roles to expedite priority referrals for the rheumatologist; and, health professionals traveled to smaller communities to provide service and/or utilized telehealth. For both inflammatory (IA) and non-IA, MOC developed were driven and facilitated by local factors including a local champion and the willingness of local providers to work together. In BC, this was further influenced by centralized control of resources. In AB, provincial chronic disease management policy and resources facilitated care for people with non-IA, although the resources were not viewed as sufficient to meet need. For IA services, barriers included challenges with primary care identification of need for and access to a rheumatologist; limited HHR and skill sets, particularly in rural/remote communities (this also posed challenges in providing multi-disciplinary care); and, geographically dispersed and small populations. For non-IA services, lack of recognition as a priority in local, regional, and provincial jurisdictions and limited community resources and chronic disease management resources also were barriers.

Conclusion: MOC varied greatly and local factors drove care provision for people with arthritis. Policies that facilitate arthritis management as a priority at local, regional and provincial levels, greater collaboration and linkages with community resources and increased health providers with the necessary skill sets are required to address current barriers to care for people with arthritis.

1932

Shared Decision Making In Early Knee Osteoarthritis: Perspectives Of Older Adults With Overweight and Obesity and Health Care Providers. Alicia Zbehlik[1], Mary Meinke[2] and Stephen Bartels[1]. [1]The Center for Aging Research, The Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, NH, [2]The Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, NH.

Background/Purpose: Knee osteoarthritis (KOA) is the most common form of mobility disability in the United States yet those at highest risk—older adults with overweight and obesity—continue to have unmet needs regarding their KOA care. People with early KOA receive arthroscopic surgery proven to have no benefit and receive little information regarding exercise and weight loss that may modify the course of their disease. Although shared decision making (SDM) and decision aids (DAs) are effective strategies to reduce unnecessary procedures by guiding patients to make informed decisions incorporating their personal values, SDM and DAs are not widely used. To our knowledge, studies have not simultaneously compared patient and provider preferences of multiple decision making tools in early KOA. Our study examines three DAs for early KOA: (1) Osteoarthritis Option Grids, (2) the "Managing Early-Stage Knee Osteoarthritis" booklet, and (3) "What are my options for managing hip or knee osteoarthritis?: A stepped decision aid." Evaluating DA preferences of both patients and providers will serve as a first step to build and implement a system of effective early KOA care that supports lifestyle modification for older adults who are overweight or obese.

Methods: This on-going study employs a cross-sectional, qualitative design using focus groups of patients and providers. We recruit English-speaking participants by flier, word of mouth, and referral. The patient group (n=35) inclusion criteria are: a) Body Mass Index =>/25 kg/m^2; b) age =>/ 60 years, and; c) the diagnosis of KOA or a positive screen for knee OA on The Knee and Hip OA Screening Questionnaire. The provider group (n=35) is recruited through word of mouth and by email invitation. Providers that care for adults with OA in an academic or community setting are included. Plan is for five focus groups per target population, or until thematic saturation is reached. Each group uses a semi-structured format and lasts 60 to 90 minutes. The taped sessions are de-identified by a transcriptionist. Transcripts are coded and for the generation of themes by two researchers using a qualitative data analysis software program.

Results: Preliminary results from patient focus groups conducted during May 2013 show emerging themes include costs of care, lack of information about treatment options, and challenges in communicating with providers. Patients demonstrated an interest in SDM and DAs, but had little prior exposure to the tools. They also commented on the granularity and visual presentation of evidence, the lack of details regarding exercise options available, and the logistics of distributing DAs. Participants were enthusiastic about shared medical appointments. Patients gravitated towards the booklet format, but appreciated the unique characteristics of all the decision aids. They felt the DA's would be useful before, during, and after a clinic appointment and would assist with provider communication.

Conclusion: Preliminary results indicate that patients respond to a variety of early KOA decision aids and are eager to engage providers in shared decision making. Patients are concerned about costs of care, a theme not incorporated into any of the decision aids.

1933

Crowdsourcing Using The Audience Response System To Solve Medical Problems: A Pilot Study. Antoine G. Sreih[1] and Fadi Aldaghlawi[2]. [1]The University of Pennsylvania, Philadelphia, PA, [2]Weiss Memorial Hospital, chicago, IL.

Background/Purpose: When faced with unclear diagnostic or therapeutic uncertainties, patients often seek further clinical opinions. Similarly, when in doubt, physicians seek expert opinions to assist with clinical care and minimize errors. The audience response system (ARS) has been traditionally used to test knowledge and improve the educational experience. However, ARS can be used to solicit crowd opinion (crowdsourcing) for specific medical questions. In this proof-of-concept pilot study, we sought to examine the ability of professional crowds to correctly answer difficult medical questions using the ARS.

Methods: This study analyzed data on answers to questions based on clinical vignettes administered during the 2009, 2010, and 2011 ACR/ARHP scientific meetings for which the ARS was used. Questions were considered evidence-based or expert-based. All questions were multiple-choice format. The crowd chose the answers independently and anonymously using remote control panels. Questions were considered answered correctly if the majority of the crowd chose the correct answer. To minimize the influence of the speaker on the crowd, only questions administered prior to any medical discussion were used for this study. As a validation group and to determine if physicians other than rheumatologists were able to answer correctly, 10 randomly chosen ACR/ARHP questions were administered using the ARS during medical Grand Rounds at 2 academic institutions. The percentage of correct answers was calculated. Chi- square test was used to analyze the data.

Results: 93 ARS questions were administered during three consecutive ACR/ARHP scientific meetings. 21 questions were excluded because they either had unknown answers (12 questions) or were administered following medical discussions (9 questions). A total of 72 questions were included in the study, of which 59 had evidence-based and 13 had expert-based answers. The number of multiple-choice answers for each question ranged from 2 to 8 choices, with 97% having at least 4 choices. Vasculitis was the most common topic covered (19%) followed by rheumatoid arthritis (16%). 41 of 59 evidence-based questions (70%) were answered correctly ($p<0.0001$), and 8 of 13 expert-based questions (62%) were answered similarly to what an expert would answer ($p<0.0001$). The mean percentage of people answering correctly was 59 $\pm$ 18 %. The mean difference in percentage between the correct answer and the next best answer was 37 $\pm$ 26 %. 23 of 72 (32%) questions were answered incorrectly. Of those, the correct answer was the second best answer in the majority of questions (66%). For the validation groups, 7/10 (70%) and 9/10 (90%) questions from each institution were answered correctly, mirroring the results seen at the ACR/ARHP meetings.

Conclusion: Regardless of their specialty, professional crowds as a whole are able to answer difficult clinical questions and solve clinical vignettes using the ARS. Their answers frequently match evidence and expert answers. In the age of crowdsourcing and wide Internet use, professional crowds may serve as a source for solving difficult clinical questions.

1934

Scores On The Multidimensional Health Assessment Questionnaire (MDHAQ) For "Walk 2 Miles Or 3 Kilometers," "Poor Sleep," and "Participate In Recreation," Are Higher, Indicating Poorer Status, Than Scores For 8 Activities Derived From The Health Assessment Questionnaire (HAQ). Kathryn Gibson[1], Sung-Hoon Park[2] and Theodore Pincus[3]. [1]Liverpool Hospital and University of New South Wales, Sydney, Australia, [2]Catholic University of Daegu School of Medicine, Daegu, South Korea, [3]NYU Hospital for Joint Diseases and New York University School of Medicine, New York, NY.

Background/Purpose: The HAQ *[Arthritis Rheum 1980;23:137]* has been used in almost all rheumatoid arthritis (RA) clinical trials conducted over the last two decades, and provides scores for the 3 patient self-report components of the RA Core Data Set: physical function, pain, and patient global estimate. However, RA patients now have significantly better clinical status than in previous decades *[Arthritis Rheum 2005;52:1009],* and some patients who experience functional disability score "0" on the HAQ, suggesting "normal" function. Furthermore, psychosocial issues remain important barriers to optimal outcomes. The MDHAQ includes 13 queries in the user-friendly HAQ format, 8 activities of daily living (ADL) from (and identical to) the HAQ, and 5 items not found on the HAQ: 2 complex activities, "walk 2 miles or 3 kilometers" and "participate in recreation and sports as you would like;" as well as 3 queries concerning poor sleep, anxiety and depression. Some of the unique MDHAQ items have been documented to recognize problems in patients with normal HAQ scores, but the traditional HAQ continues to be widely used in most clinical research. We analyzed mean scores for each of the 13 MDHAQ items in an Australian rheumatology setting.

Methods: All patients are asked to complete an MDHAQ in the reception area while waiting to see the physician. The MDHAQ queries 13 items: ability to perform 8 ADL from the HAQ (see Table, A-H), 2 complex activities ("walk 2 miles or 3 kilometers" and "participate in recreation and sports as you would like"), and 3 psychological items: "get a good night's sleep," "deal with anxiety," and "deal with depression." The patient-friendly HAQ format provides 4 response options: without any difficulty=0, with some difficulty=1, with much difficulty=2, and unable to do=3. The first 112 completed MDHAQs from 118 patients (3 patients had language barriers and 3 refused) were analyzed for the mean scores of 13 MDHAQ items, all scored 0–3, in 3 groups: all patients (n=112), RA patients (n=44) and patients with other diagnoses (n=68). Median levels of the 13 items were compared in the 3 groups; statistical significance of differences was analyzed using 2×2 Wilcoxon signed rank tests.

Results: Highest scores, >1 on a 0–3 scale, were seen for 3 of the 13 items: "walk 3 kilometers," "participate in recreation and sports as you would like," and "poor sleep." Similar patterns were seen in all patients, and subgroups of RA and other patients. Scores for 3 of the 5 MDHAQ items not found on the HAQ were significantly higher than scores for the other 10 items in all patients and "other" patients, and than 9 of 10 other items in RA patients ($p < 0.001$).

Table. Mean scores for 13 items on MDHAQ (0–3 score range)

Questionnaire item	All Patients (n=12)	RA (n=44)	Other Diagnoses (n=68)
A. Dress yourself	0.64	0.60	0.66
B. Get in and out of bed	0.51	0.42	0.58
C. Lift full cup/glass to your mouth	0.13	0.21	0.07
D. Walk outdoors on flat ground	0.44	0.40	0.47
E. Wash/dry your entire body	0.50	0.51	0.49
F. Bend down to pick up clothing off floor	0.81	0.60	0.94
G. Turn on taps/faucets	0.55	0.63	0.51
H. Get in and out of car/bus	0.89	0.89	0.90
I. Walk 2 miles or 3 kilometers	1.54	1.66	1.45
J. Participate in recreation/sports	1.31	1.26	1.34
K. Sleep	1.30	1.05	1.47
L. Anixety	0.69	0.51	0.74
M. Depression	0.70	<0.001*	<0.001

* $p<0.001$ except for K vs H ($P=0.125$), using Wilcoxon signed rank tests.

Conclusion: The MDHAQ recognizes patient problems that are not captured by the HAQ, which may be of value in clinical management and to document improvement over time. The MDHAQ might be considered for usual clinical care as well as for clinical trials.

Validation Of The Cutaneous Dermatomyositis Disease Area and Severity Index: Characterizing Severity and Assessing Responsiveness To Clinical Change. Cynthia O. Anyanwu[1], David Fiorentino[2], Lorinda Chung[3], Yanli Wang[4], Kathleen J. Propert[4] and Victoria P. Werth[5]. [1]Philadelphia Veterans Affairs Medical Center, Philadelphia, PA, [2]Stanford University School of Medicine, Redwood City, CA, [3]Stanford University Medical Center, Palo Alto, CA, [4]University of Pennsylvania, Philadelphia, PA, [5]University of Pennsylvania School of Medicine, Philadelphia, PA.

Background/Purpose: Translational research and clinical trials necessitate validated outcome measures to reliably assess disease progression and treatment efficacy. The Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI), a disease-specific and skin-based outcome measure, was developed for use in clinical trials and longitudinal patient assessment. The reliability and validity of this instrument have been established.[1] The goal of this study is to assess responsiveness of this tool and characterize severity and clinical response of cutaneous dermatomyositis (DM) using the CDASI.

Methods: In this two-center prospective database study the skin of patients with clinical or histologic evidence of DM was evaluated. Patients were evaluated using clinical instruments including the CDASI, a physician global assessment (PGA) 5-point Likert scale measuring disease severity (none, mild, moderate, severe, extremely severe), a PGA 0 – 10 cm visual analog scale (VAS) of disease severity and a PGA 3-point Likert scale that captured change in disease severity since the last visit (improved, worse, no change). The severity analysis compared CDASI scores for patients with mild disease to those with moderate and severe disease according to the PGA 5-point Likert. The PGA 3-point Likert and PGA VAS were used to evaluate responsiveness. Clinical response was defined as a rating of "improved" on the PGA 3-point Likert or a change in VAS scores of at least 2 cm. Statistical analysis included logistic regression models using generalized estimating equations to account for correlation among patients. A receiver operating characteristic curve was used with each model to determine cutoffs.

Results: A total of 199 patients from two sites completed up to 12 study visits each. Study participants were 79% female and 78% Caucasian. Disease subtype was classified as classic in 65% of patients and skin predominant in 35%. Separate site-specific analyses were performed due to interactions between study site and score in both the severity and responsiveness analyses. Baseline CDASI scores at the two sites range from 0 to 47 (median 17) and 0 to 48 (median 21). Data collected at one site resulted in a cutoff of 19 to differentiate mild from moderate and severe disease while at the second site CDASI scores of 14 or less characterized mild disease. Compared to the PGA VAS, the PGA 3-point Likert may be a less reliable measure of clinical response. Using a PGA VAS to assess responsiveness we found that improvement in CDASI scores of 4 or 5 indicates a clinically significant change.

Conclusion: Inter-rater variations in the use of the external PGA Likert and VAS gold measures may account for the differences between sites. The above results suggest that the CDASI is a valid and responsive tool for the evaluation of cutaneous dermatomyositis but randomized controlled trials are needed to confirm these results.

Quality Of Care In Patients At Risk For Pulmonary Involvement: Assessment Of Pulmonary Screening In Systemic Sclerosis and Myositis Patients In a General Rheumatology Clinic. Michael G. Indelicato[1], Janet E. Lewis[2], Vincent J. Giuliano[1] and Donald L. Kimpel[2]. [1]University of Virginia, Charlottesville, VA, [2]University of Virginia School of Medicine, Charlottesville, VA.

Background/Purpose: As a quality assessment tool to evaluate patient care in a general Rheumatology Clinic, we determined the frequency of screening for pulmonary hypertension and interstitial lung involvement in a subset of patients at high risk. Involvement of the respiratory system is common in Systemic Sclerosis (SS) and Polymyositis/Dermatomyositis (PM/DM). Interstitial Lung Disease (ILD) and Pulmonary Arterial Hypertension (PAH) can lead to significant morbidity. These complications are now

the leading cause of death in systemic sclerosis. The prevalence of pulmonary involvement in PM/DM is variable, but has been reported to be close to 50%. ILD is a negative prognostic factor in these patients. General medical opinion is that Pulmonary Function Tests (PFTs) are suitable as a screening tool, but that a High Resolution Computed Tomography (HRCT) scan is crucial for the initial diagnosis of ILD. In addition, an echocardiogram is recommended to evaluate for PAH. However, there are no uniform guidelines for screening and the frequency with which these studies should be repeated. Published data suggests that screening assessments are not done routinely, so to establish a baseline for quality of care,we determined the frequency of pulmonary evaluation in our clinic population.

Methods: All patients were seen in our outpatient Rheumatology clinic from January 1, 2010 to December 31, 2011. Patients were identified based on diagnosis codes, and diagnoses confirmed by chart review. Charts were reviewed to determine if screening for ILD and PAH had been performed within 24 months of the index visit. ILD was classified by FVC < 70% or suggestive findings on CT imaging. If PAH was suggested by either decreased DLCO on PFTs or increased RVSP on echocardiogram, a right heart catheterization (RHC) was needed to confirm the presence of PAH.

Results: Of the 91 patients categorized, 44 had a diagnosis of SS, while 47 carried a diagnosis of PM/DM. Of the 44 patients with SS, nearly all patients were screened for ILD with PFTs (38/44, 86%) and PAH with echocardiogram (40/44, 91%). 16 had ILD and 10 had PAH. A total of 4 patients had both ILD and PAH. All 10 patients with PAH were confirmed with RHC. All patients with ILD had a HRCT at baseline. Of the 47 patients with PM/DM, about 61% (29/47) of the patients were screened for ILD with PFTs and just 28% (13/47) were screened for PAH with echocardiogram. 18 had ILD, while only 1 had PAH, confirmed on RHC. The 1 patient with PAH, also had ILD. All patients with ILD did have a HRCT obtained at baseline.

Conclusion: In our SS patients, 86% and 91% or our patients were screened for ILD and PAH respectively. For patients with PM/DM, although our screening percentage for ILD was lower compared to the SS group, the high frequency of ILD noted in PM/DM patients in prior studies suggests that routine screening is warranted. Only 28% of our PM/DM patients were screened for PAH. The association of PAH with PM/DM is not as well documented, however it remains good practice that patients with progressive dyspnea despite optimal treatment for ILD, should undergo evaluation for PAH. Future studies will assess the ongoing screening patterns, and address the rate of disease progression and the incidence of new onset ILD or PAH in this patient population.

The Role Of Rural Residence In Low Back Pain. Elizabeth G. Salt[1], Yevgeniya Gokun[1], Heather Bush[1] and Leslie J. Crofford[2]. [1]University of Kentucky, Lexington, KY, [2]Vanderbilt University, Nashville, TN.

Background/Purpose: Low back pain (LBP) affects 67% to 84% of persons residing in industrialized countries.[1] With an estimated 2% of the workforce being compensated for work days lost to back injuries, LBP is responsible for the more lost workdays and disability claims than any other health condition.[2,3] The combined direct and indirect costs have been estimated to be $90 billion annually.[3]

Of Kentucky's 29,886 occupational injuries (2010–2011), 28% were low back injuries.[4] Ninety-two of Kentucky's 120 counties are designated as medically underserved populations; 71 of these 92 counties are designated as rural areas (2013 USDA Rural/Urban Continuum Codes).[5] We aim to report the percentage of women who report LBP per Kentucky county, compare rates of LBP in rural versus urban counties, and report predictors of LBP.

Methods: We extracted data (county of residence, self-reported LBP, and demographics) from the Kentucky Women's Health Registry, a database with over 16,000 women participants, and used descriptive statistics, two-sample t-tests with unequal variances, and multiple linear regression modeling during data analysis. Data was weight-adjusted based on the percentage of the county population represented in the database.

Results: Approximately 27.3% (standard deviation (SD)=6%; range=9–46%) (median=27%; mode=27%) of those women residing in an urban county reported LBP; 33.5% of women residing in a rural area reported LBP (SD=9.3%; range=17–64%) (median=33%; mode=35%). Of all Kentucky women, 31.7% (SD=8.9%; range=10–64%) (median=31%; mode=27%) reported having low back pain (Table 1). Using two-sample t-tests, those women who lived in a rural area were significantly more likely to report LBP when compared to those women residing in an urban area ($p<.0001$). Predictors of LBP using multiple linear regression modeling (residence, disability status, body mass index (BMI), physical activity, and age), were rural residence and BMI. Women residing in a rural county were 5.1% more likely to report LBP compared to urban counties ($p=0.0016$) and for every 5 unit increase in BMI, there was a 9.1% increase in the likelihood of reported LBP ($p=0.0005$).

Table 1. LBP per rural/urban continuum code.

	N	% reporting LBP	Std. Deviation
1.00	14	29.7%	.06
2.00	11	26.8%	.03
3.00	10	24.4%	.07
4.00*	2	29.5%	.01
5.00*	4	27.8%	.04
6.00*	19	35.0%	.08
7.00*	24	29.9%	.07
8.00*	11	31.0%	.07
9.00*	25	38.2%	.12
Total	120	31.7%	.09

*Rural area- 2013 USDA Rural/Urban Continuum Codes.

Conclusion: Study findings suggest that women with increased BMI who reside in a rural area are significantly more likely to report LBP; thus a significant health disparity has identified.

Disclosure: E. G. Salt, None; **Y. Gokun**, None; **H. Bush**, None; **L. J. Crofford**, None.

1938

A Description Of Therapies Used For Low Back Pain. Elizabeth G. Salt, Yevgeniya Gokun and Jeffery Talbert. University of Kentucky, Lexington, KY.

Background/Purpose: An estimated 67% to 84% of persons residing in industrialized countries suffer from low back pain (LBP), and 2% of all workers are compensated for work days lost to back injuries.[1–3] Of the 29,886 occupational injuries reported in Kentucky in 2010–2011, 28% were low back injuries.[4] The combined direct and indirect costs of LBP have been estimated to be 90 billion U.S. dollars annually.[3] An estimated 13% of direct costs are spent on primary care and pharmacy services.[1] Many pharmaceuticals such as opioids have only "fair" evidence to support their use. Yet the number of opioid analgesic prescriptions for LBP have increased dramatically – In 1998, 16% of all opioid prescriptions were written for LBP, while 40% of opioid prescriptions were written for LBP in 2004.[2,3] In the Clinical Guidelines for the Diagnosis and Treatment of LBP, Chou and colleagues[2] recommend treating patients who fail self-care with proven non-pharmacologic therapies (ex. cognitive behavioral therapy) stating the level of evidence to support this therapy as "good."[2] We will report the treatments provided to patients with the diagnosis of LBP using a private insurance dataset which represents a sample of 15 million patients annually across the US.

Methods: We extracted de-identified patient health claims data from persons residing in Kentucky with the diagnosis of LBP or related terms using ICD-9 codes (ex. 724.2 (lumbago)) along with treatments received using CPT codes (ex. 97001 (physical therapy evaluation)) and medication records from January 1, 2007 to December 31, 2009. Descriptive statistics were used to report the percentage of patients receiving the various treatments for LBP.

Results: Approximately 25% of patients with LBP received a service administered by a physical therapist (ex. evaluation, iontophoresis). Approximately 16% received exercise therapy and only 6% received psychological services. Similarly, despite the frequency in which occupation affects LBP, less than 1% of patients received occupational therapy (Table 1).[2] Yet,

approximately 55% of patients filled a prescription for an opioid analgesic (Table 2).

Table 1. Therapies among patients with the diagnosis of LBP in Kentucky (N=15,335).

Assessing The Increasing Costs To Manage Patients With Gout By State. Aaron Davis[1] and Jason Wreath[2]. [1]Goutchoices.com, San Clemente, CA, [2]Symphony Health, Phoenix, AZ.

Background/Purpose: Gout is a chronic progressive disease and worldwide prevalence is increasing. After over 40 years with limited and inexpensive treatments several new and more expensive treatment options are available. Although gout treatment guidelines are well established, variances in treatment patterns exist. The objective was to identify the rate of gout by state and estimate the budget impact of treating patients with chronic urate lowering and acute gout treatments.

Methods: Estimates from NHANES were used to project the rate of gout by state and compared to Symphony Health Solutions' ProMetis longitudinal patient data. Symphony Health Solutions' PHAST database provides destailed estimates of chronic and acute pharmaceutical treatments for gout. Looking at prevelance rates across states and treatment estimates between 2007 and 2012 costs by state by yearare estimated and presented in constant dollars using published wholesale acquisition costs for drugs.

Results: In 2011 gout is estimated to impact 9.2 million individuals based on NHANES estimates. Total gout pharmaceutical spend in the 2012 data was $1.038 billion, a 918% increase since 2007. Total number of prescriptions for gout rose 27% over the same time period. The costs of gout treatments vary: allopurinol at less than a dollar a day, febuxostat $2,250 per year; and pegloticase has the potential to cost as much as $100,000 per year. Acute and prophylaxic treatment colchicine now costs between $4.94 and $9.88 per day. Four states were identified accounting for approximately 30% of all pharmaceutical spending on gout; California, Florida, Texas and New York. Although colchicine does not treat the underlying urate burden found in patients with gout it accounted for over 55% of the total drug spend for patients with gout in in 2012; up from less than 20% in 2007. Among urate lowering therapies, febuxostat accounted for 60% of pharmaceutical costs, yet, allopurinol accounted for 93% of all fills across the U.S. State-by-state differences were seen in the utilization of urate lowering therapies, with higher colchicine prescribing leading to increased drug expenditure within certain states. Hawaii (1377%), South Carolina (1324%) and Georgia (1274%) have been most affected by increasing gout treatment costs, driven primarily by colchicine prescribing.

Conclusion: With an aging population and increasing rates of obesity, the rate of gout will continue to rise in the US. Recently launched drugs have increased the drug spend on gout. Forthcoming and likely expensive treatments will further add to the pharmaceutical budget impact of gout in the coming years. Reviewing treatment patterns within geographies will identify opportunities for gout education; including early identification, lifestyle management, treating the underlying cause of the disease vs. symptoms and utilization of effective generic medications. Early identification and treatment with effective generic medications will offer savings to the health care system.

1940

The Development Of A National Systemic Sclerosis Service In Ireland Incorporating A National Registry. Mairead Murray[1], Emese Balogh[2] and Douglas J. Veale[3]. [1]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]Translation Research Group, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [3]St. Vincent's University Hospital, Dublin 4, Ireland.

Background/Purpose: Systemic Sclerosis (SSc) is a rare autoimmune connective tissue disease with an increasing burden for health care systems. National SSc registries have proven to be useful internationally to capture and track patient information in chronic diseases, such an example is the irish SSc registry running from 2011. The objective of our study was to characterize disease trends in the Irish SSc cohort.

Methods: A standard proforma was devised to capture relevant data fields for both the Irish Registry and European Scleroderma Trials and Research Group Registry (EUSTAR). Physical and functional assessments were carried out and captured. SSc cases in the Irish and EUSTAR database entered from March 2011-June 2012 were analysed in the following subsets (n= 67): limited (lcSSc), diffuse (dcSSc), and overlap/undifferentiated (Other) disease in comparison with each other.

Results: Mean±SD patient age was 57.41±13.22 years with disease onset of 13.95±10.19 years. LcSSc patients were older than dcSSc and Other counterparts (p=0.021). Beside the expected female predominance in each group, there were more male patients in the dcSSc vs any other groups (p=0.018). The onset of Raynaud's Phenomenon was the shortest in dcSsc with 9.6+7.4 yrs (lcSSc: 15+10.8, Other: 15+10.4) and other SSc related symptoms also presented earlier in this subset with 6.13+5.9 yrs (lcSSc: 9.5+9.1, Other: 9.28+7.5 yrs). Gastrointestinal involvement was similar in each group (66.7%, 62%, 55%). DcSSc group was more frequently affected by cardiovascular (40% vs 25.8% vs 15%), lung (42.9% vs 16.7% vs 36.4 %) and musculoskeletal involvement (60% vs 20% vs 50%, p=0.0015) than lcSSc and Other subsets. The dcSSc group also manifested higher modified Rodnan skin scores (mRSS) than their counterparts (p<0.001). Comparing dcSSc with lcSSc based on a background of lung fibrosis, pulmonary arterial hypertension (PAH) was greater in the diffuse group (13.3% vs 9.7%, p=0.0015) as well as digital ulcer occurrence (13.3% vs 6.5%). LcSSc showed less frequent capillaroscopic scleroderma pattern (70% vs 100%) and aScl70 positivity (10.3% vs 58.3%, p<0.0001), however ACA positivity was higher compared to dcSSc (57.1 vs 25.0 %, p=0.002).

Conclusion: This is the first snapshot of disease characteristics of systemic sclerosis patients participating in the Irish SSc registry and EUSTAR. The continued enrolment of all SSc patients onto a national registry will facilitate the improvement in disease classification of the different subsets in the Irish population. A specialist nurse dedicated to SSc patients has been vital for information gathering to facilitate future research into this complex, challenging disease.

Imaging Atherosclerotic Plaque Inflammation In RA: Methodology and Initial Findings In a Single Centre Cohort. Sarah Skeoch[1], Penny Hubbard[2], Heather Williams[2], Dongxiang Xu[3], Sun Jie[3], Niranjan Balu[3], Wei Zhang[3], Jacqueline James[4], Thomas Hatsukami[3], Chun Yuan[3], M. Yvonne Alexander[5], Paul Hockings[6], John Waterton[7] and Ian N. Bruce[4]. [1]Arthritis Research UK Epidemiology Unit and NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [2]University of Manchester, Manchester, United Kingdom, [3]University of Washington, Seattle, WA, [4]Central Manchester University Hospitals Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, [5]Healthcare Science Research Institute, Manchester Metropolitan University, Manchester, United Kingdom, [6]Astra Zeneca, Mölndal, Sweden, [7]Astra Zeneca, MACCLESFIELD, United Kingdom.

Background/Purpose: Chronic inflammation in RA may contribute to an unstable atherosclerotic plaque phenotype. Dynamic contrast enhanced MRI (DCE MRI) can be used to image carotid plaque neovascularisation and vascular permeability. Contrast agent distribution into the plaque, measured via the transfer constant (K^{trans}), correlates with macrophage content and microvessel density on non-RA carotid endarterectomy specimens. Positron emission tomography with fludeoxyglucose (^{18}F) (FDG-PET) can be used to quantify inflammation in carotid plaque and also correlates well with macrophage content. We aimed to employ these imaging techniques to assess plaque inflammation, for the first time, in RA.

Methods: RA patients, aged 40–65 years old were recruited and underwent a clinical and serological evaluation of RA disease and cardiovascular risk. All patients were screened for carotid plaque using B-mode Doppler ultrasound (US). Patients with plaque >2mm thickness had a carotid DCE MRI on a 3 Tesla scanner. Images were analysed by 2 blinded readers at the Vascular Imaging Laboratory, University of Washington, using a semi-automated analysis software package (Cascade; University of Washington, Seattle, WA). Patients with no history of cancer or recent infection underwent a carotid FDG-PET-CT scan. Plaque was localised using MR and CT then FDG uptake in the region of interest (ROI) was measured by calculating the standardised uptake value (SUV^{max}).

Results: 57 patients were screened, of whom 29 (51%) had ultrasound evidence of carotid plaque and 12 (21%) had a plaque >2mm. 2 MR scans were incomplete (1 due to pain, 1 due to claustrophobia) so MRI data were avail-
able on 10 patients; 5 patients also had FDG-PET-CT. The median (IQR) age and disease duration of the 10 patients undergoing imaging was 57 (55,59) and 9 (2, 20) years respectively. The median (IQR) DAS28 score was 5.15 (4.69, 6.55) and all patients were seropositive. No patients had a history of cerebrovascular disease.

On MRI, plaque >2mm thick was confirmed in 6 (60%) cases. The median (IQR) vessel stenosis was 54.5 (42,70)% and contrast enhancement was seen in all 6 cases (see figure 1), with a median K^{trans} value of 0.046 (0.023, 0.105)min^{-1}. Preliminary analysis of PET images demonstrated uptake in all cases with a median (IQR) SUV^{max}= 2.22 (1.67, 2.95). There was no significant correlation between imaging and clinical parameters.

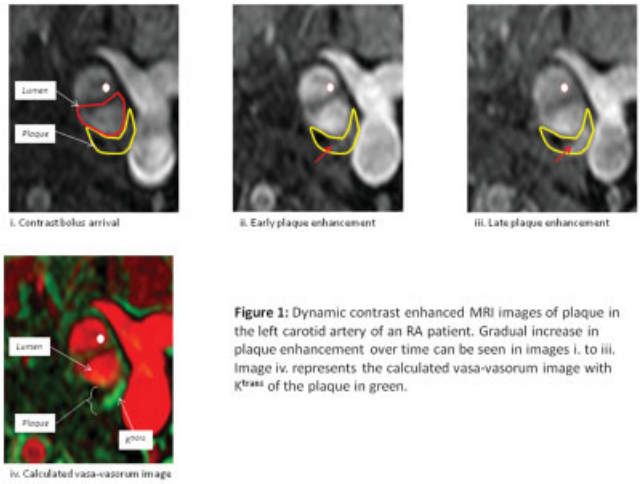

Figure 1: Dynamic contrast enhanced MRI images of plaque in the left carotid artery of an RA patient. Gradual increase in plaque enhancement over time can be seen in images i. to iii. Image iv. represents the calculated vasa-vasorum image with K^{trans} of the plaque in green.

Conclusion: Our preliminary study shows that atherosclerotic plaque inflammation can be detected using both 3T MRI and PET in RA patients. The discrepancy between MRI and US findings may be due to measurement error on US or flow artefact on MRI. A larger sample size and a comparator cohort will enable us to further determine the characteristics of atherosclerotic plaque inflammation in RA patients.

Ultrasound Shows Tenosynovitis to be Frequently Present as Well As Sensitive to Change in RA Patients On Biologic Medication. Hilde B. Hammer. Diakonhjemmet Hospital, Oslo, Norway.

Background/Purpose: Ultrasound (US) (grey scale (GS) and power Doppler (PD)) is a sensitive tool for examination of tenosynovitis in patients with rheumatoid arthritis (RA). The extensor carpi ulnaris (ECU) and tibialis posterior (TP) tendons have been shown to be frequently inflamed in RA patients and improve during treatment. Even so, only few of the US joint scores include these tendons in disease assessments. The present objective was to examine by US the frequency of involvement of the ECU and TP tendons as well as explore their sensitivity to change during biologic medication.

Methods: A total of 108 RA patients (aged mean (SD) 52.6 (12.9) years, 87% women, disease duration 7 (6) years, 84% anti-CCP positive)

were consecutively included when starting biologic treatment (infliximab (n=17); etanercept (n=36); adalimumab (n=9); certolizumab (n=2); golimumab (n=5); rituximab (n=26); tocilizumab (n=8); abatacept (n=5)) and examined bilaterally by US of the ECU and TP tendons at baseline and after 1, 2, 3, 6 and 12 months (performed by HBH on Siemens Acuson Antares Excellence version, with standard setting throughout the study). Tenosynovitis was scored semi-quantitatively 0–3 for presence of GS and PD pathology. The frequencies of tendon involvement at baseline (percentage of patients) as well as the sum scores of GS and PD at all examinations were calculated, and the changes in US sum scores from baseline were explored by paired samples T-test.

Results: The distribution of GS and PD scores of the ECU and TP tendons are shown in table 1. The sum GS and PD scores decreased significantly from baseline to all of the follow-up examinations ($p \leq 0.001$) as illustrated in figure 1.

Percentages of patients with tenosynovitis at baseline.

	Extensor carpi ulnaris				Tibialis posterior			
	Grey scale		Power Doppler		Grey scale		Power Doppler	
	Right	Left	Right	Left	Right	Left	Right	Left
Score 0	67	56	81	80	62	67	76	77
Score 1	18	21	7	9	19	15	11	10
Score 2	14	16	11	8	15	9	11	7
Score 3	1	7	1	3	4	9	2	6

Conclusion: More than one third of the patients had GS synovitis and more than one fifth of the patients had PD activity in the ECU and/or TP tendons at baseline, and both GS and PD sum scores decreased significantly during biologic medication. The frequent involvement of the ECU and TP tendons as well as their sensitivity to change during treatment, support the inclusion of these tendons in models of joint scoring of RA patients on biologic medication.

Background/Purpose: To develop the first ultrasound (US) scoring system of tendon rupture in rheumatoid arthritis (RA) and assess its intra- and inter-observer reliability.

Methods: We undertook a Delphi consensus process on US defined tendon damage and US scoring system of tendon damage in RA among 35 rheumatologists expert in musculoskeletal US from 16 countries. Then, we assessed the intra- and interobserver reliability of US in scoring tendon damage on B-mode. Twelve patients with RA with symptoms of hands or feet were recruited. Twelve rheumatologists expert in musculoskeletal US consecutively performed a blind and independent US examination for tendon damage in B mode of five wrist extensor compartments and one ankle tendon of each patient bilaterally in two rounds. Intra- and inter-observer reliability were assessed by kappa coefficients. Reliability of tendon compartments was assessed by ICC.

Results: Five men and seven women were included. Median age was 66.5 years, range 36–74. Rheumatoid factor positivity was present in 8 patients (67%), anti-CCP+ in five (42%). Median DAS28 was 3.79, range 2.41–5.6. A three-grade semiquantitative scoring system was agreed for scoring tendon damage in B-mode, where grade 0 stands for normal tendon, grade 1 for partial rupture, and grade 2 for complete tendon rupture, respectively. Overall, 3456 investigations of tendon compartments were carried out. US scoring showed the following prevalences: grade 0 (N=2652, 76.7%); grade 1 (N=727, 21%), and grade 2 (N=77, 2.3%). The mean intra-observer reliability for tendon damage scoring was excellent (kappa value 0.91). The mean interobserver reliability assessment showed good kappa values (kappa value 0.75). The most reliable tendons were the extensor digiti minimi, the extensor carpi ulnaris, and the tibialis posterior.

Conclusion: US is a reproducible tool for evaluating tendon damage in RA. In addition, this study supports a novel reliable US scoring system for tendon rupture. The scoring system should at least include the extensor digiti minimi, the extensor carpi ulnaris, and the tibialis posterior tendons.

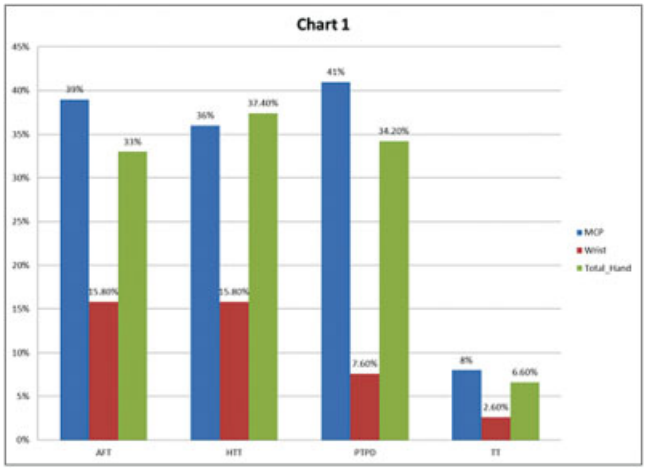
1944

Ultrasound Characteristics Of Extensor Tendon Abnormalities and Peritendinous Fluid In Rheumatoid Arthritis. Laurie Ann Ramrattan and Gurjit S. Kaeley. University of Florida, Jacksonville, FL.

Background/Purpose: Rheumatoid arthritis (RA) is synonymous for involving synovial lined structures such as joints and tendon sheaths. Alterations in the extensor tendons overlying the metacarpophalangeal (MCP) joints which do not have synovial sheaths and which do not normally communicate with the joint recess have been observed with sonography but have not been clearly characterized. We report findings from a sonographic pilot study regarding changes in the MCP extensor tendons in patients with RA. These findings will lead to further study of the etiology and importance of these findings.

Methods: A retrospective cross-sectional study was done on 26 RA patients who had ultrasounds (US) of their hands between June 2010 and April 2012. Scans of the dorsal wrist and dorsal and volar 2nd- 5th MCP joints had been recorded in these patients. Esaote MyLab 70 ultrasound machine was used with a 12–18MHz LA 435 probe. The studies were re-read by GSK and B-mode and Power Doppler (PD) joint activity were scored. Changes in the extensor tendons were examined for the presence of B-Mode ultrastructural changes and PD. B- mode changes included anechoic fluid around the tendons (AFT), hypoechoic tissue around the tendon (HTT), tendon thickening (TT), tendon rupture (TR) and tendon calcifications (TC). The presence of vascularity around the tendon-Peritendon power doppler (PTPD) was recorded dichotomously. Joint erosions and tenosynovitis was also recorded.

Results: 26 patients, 77% were women, mean age of 56 years, mean body mass index of 31 and mean duration of disease 159 months were studied. PTPD and AFT were the highest findings, 41% and 39% respectively, observed around the extensor tendons at the level of the MCP. At the wrist, distal to the retinaculum, AFT and HHT were the dominant findings in 15.8 % of hands. TT was the least common finding, being found in 8% of hands at the MCP and 2.6% at the wrist. Joint erosions were noted in 50% of hands at the wrist. One patient had PD signal around the annular hood of the extensor tendon complex. B-Mode and Power Doppler were scored semiquantitatively from 0–3. Levels of activity were stratified in the following tertiles, 0–0.9, 1–1.9 and 2–3.The overall level of disease activity was high. Forty- four percent of patients had B-Mode score (BMS) in the upper tertile at the MCPs and 88% had a BMS in the upper tertile at the wrist. Twenty- eight percent of the patients had a Power Doppler score (PDS) in the upper tertile at the MCPs, and 67% at the wrist. Although the greatest joint activity was noted at the wrist, the extensor tendons at the MCPs displayed the greatest frequency of pathological changes.



Conclusion: Significant changes at the dorsal extensor tendon of the MCP joints were AFT, HTT, PTPD and TT. Although these findings have been reported in the past, they have not been fully characterized. Further studies are needed to define the etiology and significance of these findings.

1945

Comparison Of Selected Joint Evaluation With Comprehensive Assessment In Musculoskeletal Ultrasonography For Detection Of Synovitis In Rheumatoid Arthritis. Ryusuke Yoshimi, Atsushi Ihata, Yosuke Kunishita, Daiga Kishimoto, Reikou Kamiyama, Kaoru Minegishi, Maasa Hama, Yohei Kirino, Yukiko Asami, Atsuhisa Ueda, Mitsuhiro Takeno, Ichiro Aoki and Yoshiaki Ishigatsubo. Yokohama City University Graduate School of Medicine, Yokohama, Japan.

Background/Purpose: Musculoskeletal ultrasonography (US) is recognized as a useful tool for the diagnosis and monitoring of rheumatoid arthritis (RA), though a standard procedure has not been established. Scanning all joints is ideal but not practical for routine examinations. Therefore, it is important to determine which joints should be examined. Here we investigated the optimal number and combination of joints to be assessed by power Doppler (PD) US in daily practice for RA.

Methods: PDUS were performed in 24 joints, including all PIP, MCP, bilateral wrist and knee joints in 234 patients with RA. PD signals were scored semiquantitatively from 0 to 3 in each joint, and total PD score-24 was calculated by summing them up as comprehensive assessment. We examined correlations of total PD score-24 with individual joint PD scores and the sum PD scores of 8 sets of arbitrarily selected joint combinations. The sensitivity and negative predictive value (NPV) of the individual sets of selected joint examination for the detection of active synovitis were also evaluated.

Results: Positive PD signals were more frequently found in bilateral wrist, knee, MCP 2 and 3 joints than the other joints. The individual PD scores of these 8 joints also showed higher correlation coefficients with total PD score-24 ($r_s \geq 0.4$). There was no significant laterality in PD scores except for PIP 4 joints ($P = 0.037$). In wrist, the PD score was significantly lower in each region (radial, medial or ulnar region) as compared to that from the assessment of whole joint ($P = 7.6 \times 10^{-7}$, 9.8×10^{-3} and 1.2×10^{-4}, respectively). Among the sum PD scores of the 8 sets of selected joint combinations, that of the combination of 8 joints (total PD score-8), including bilateral MCP 2, 3, wrist, and knee joints, showed the highest sensitivity and NPV (Table 1; 98.1% and 96.2%, respectively). Discrepancy between the comprehensive 24 joint assessment and the selected 8 joint assessment was found in only 3 of 234 patients including 76 patients in US remission. Moreover, total PD score-8 showed very high correlation with the total PD score-24 (Table 1 and Figure 1; $r_s = 0.97$, $P < 0.01$). Comparison with other sets of joint combinations revealed that the wrist and knee joints had the stronger impacts on the correlation and the other parameters.

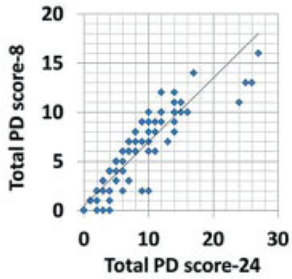

Figure 1 Total PD score-8 correlates well with total PD score-24.

Table 1. Sensitivities, NPVs and correlation coefficients of the different joint combinations for the detection of active synovitis

Joint combination	Sensitivity (%)	NPV (%)	Correlation coefficient (r_s)[a]
Bilateral MCP 2, 3, wrists & knees[b]	98.1	96.2	0.97
Bilateral MCP 2, wrists & knees	97.5	95.0	0.96
Bilateral wrists & knees	96.8	93.8	0.93
Bilateral MCP 2, 3 & wrists	88.0	80.0	0.89
Bilateral wrists	86.1	77.6	0.84
Bilateral knees	38.0	43.7	0.55
All MCPs	34.8	42.5	0.69
All PIPs	22.8	38.4	0.52

[a]Spearman's rank correlation coefficients between total PD score-24 and sum PD scores of the different joint combination ($P < 0.01$ for all the correlations). [b]Total PD score-8.

Conclusion: This study suggests that US examination in the selected 8 joints, including the bilateral wrist, knee, MCP 2 and 3 joints, is simple and efficient enough for making the diagnosis, monitoring disease activity, and judging imaging remission of RA in daily practice.

Can Satisfactory Reliability Of The 7-Joint Ultrasound Score Be Attained By Inexperienced Readers In a Single Calibration Exercise? Results From The Biodam Program. Marina Backhaus[1], Stephanie G. Werner[1], Sarah Ohrndorf[4], Shafeeq Alraqi[2], Sean Crowther[3], Sukhvinder Dhillon[3], Navjot Dhindsa[4], Arthur J. Fernandes[5], Oliver M. FitzGerald[2], Hilde B. Hammer[6], Christophe Hudry[7], Sandrine Jousse-Joulin[8], Robert GW Lambert[3], Maggie Larche[9], Anouck Remy-Moulard[10], Lene Terslev[11], Ramin Yazdani[12], Rana Dadashova[13], Joel Paschke[13] and Walter P. Maksymowych[3]. [1]Charite University Hospital, Berlin, Germany, [2]St. Vincent's University Hospital, Dublin, Ireland, [3]University of Alberta, Edmonton, AB, [4]University of Manitoba, Winnipeg, MB, [5]Universite de Sherbrooke, Sherbrooke, QC, [6]Diakonhjemmet Hospital, Oslo, Norway, [7]Hopital Cochin, Paris, France, [8]CHU de la Cavale Blanche, Brest, France, [9]McMaster University, Hamilton, ON, [10]Hopital Peyronie, Montpellier, France, [11]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [12]St. Clare's Mercy Hospital, St. John's, NF, [13]CaRE Arthritis, Edmonton, AB.

Background/Purpose: While ultrasound assessment of patients with RA using the 7-joint score (US7) demonstrates reliability in the hands of experienced readers it is unclear to what degree this has external validity, and whether satisfactory calibration can be attained over the course of a single calibration exercise conducted over one day at a single location. We aimed to assess the feasibility and impact on inter-reader reliability of a one-day structured program of training based on an eCRF designed to provide real-time feedback on reader reliability during the process of scanning.

Methods: Six patients with rheumatoid arthritis were examined by 12 sonologists from 6 countries and 12 centers in 6 rater pairs who performed the US7 score (1). The US7 score includes the clinically dominant wrist, the second and third metacarpophalangeal (MCP) and proximal interphalangeal joints, and the second and fifth metatarsophalangeal (MTP) joints, which were evaluated for synovitis (SYN), tenosynovitis/paratenonitis (TS), and erosions (ER) from the dorsal side and palmar/plantar aspects by gray-scale (GS) and power Doppler (PD) ultrasound. Additional lateral scans were performed at the MCP2 and MTP5 joints. Scores were entered into an eCRF custom designed to provide immediate calculation of reliability data (eCaRe-US reliability). Training of readers focused on the most discrepant features observed in exercise 1. All reader pairs repeated

the examination in different patient order. Mean (SD) weighted kappa values, mean (SD) per cent agreement rates, inter-observer intra-class correlation (ICC) for summed scores (SYN, TS, ER) were calculated.

Results: Improvement in reliability was mainly observed in assessment of SYN-GS and PD. Primary regions of improvement in SYN-GS were dorso-median and ulnar wrist (k 0.31 to 0.54 and 0.17 to 0.34), PIP2 and 3 dorsal (k 0.03 to 1 and 0.13 to 1), MCP2 and 3 palmar (k 0.04 to 0.37 and 0.06 to 1.0), and MTP5 dorsal (k 0.06 to 1.0). Improvement in detection of SYN-PD was mainly observed in the wrist. Regions where reliability was not improved were MCP2 dorsal, PIP2 and 3 palmar, and MTP2 dorsal. Erosion assessment was lengthy and considered challenging for routine practice.

	Ex	SYN-GS	SYN-PD	TS-GS	TS-PD	ER
% agree	1	39.8 (25.9)	75.6 (25.9)	60.0 (19.0)	80.0 (13.9)	67.8 (24.0)
	1	48.7 (41.6)	73.1 (26.0)	53.3 (32.1)	80.0 (18.3)	nd
kappa	1	0.12 (0.10)	0.53 (0.47)	0.40 (0.22)	0.40 (0.42)	0.29 (0.35)
	2	0.47 (0.40)	0.45 (0.43)	0.31 (0.31)	0.30 (0.41)	nd
ICC	1	0.63	0.53	0.60	0.45	0.55
	2	0.84	0.77	0.56	0.37	nd

Conclusion: Substantial enhancement of reliability for detection of synovitis by ultrasound may be observed with limited calibration of inexperienced readers. We have identified specific regions that require more intensive calibration, specifically, MCP2 dorsal, PIP2 and 3 palmar, and MTP2 dorsal.

1947

The 7-Joint Ultrasound Score Is a Feasible Tool For Evaluating Joint Inflammation In Rheumatoid Arthritis Patients. Experience Among Rheumatologists With Basic Or Intermediate Level Of Ultrasound Training. Jana Hurnakova[1], Jakub Zavada[2], Herman F. Mann[2], Ladislav Senolt[1], Martin Klein[1], Petra Hanova[1], Sarka Forejtova[1], Marta Olejarova[1], Olga Ruzickova[1], Olga Sleglova[1] and Karel Pavelka[1]. [1]Institute of Rheumatology, Prague, Prague, Czech Republic, [2]1st Faculty of Medicine, Charles University, Prague, Prague, Czech Republic.

Background/Purpose: Musculoskeletal ultrasound plays an increasingly important role in monitoring disease activity and therapy response. German US-7 score is a recently introduced ultrasound scoring index to assess soft tissue changes and bone erosions in patients with RA[1]. US7 score has been shown to be a viable method to monitor disease activity when performed by skilled ultrasonographers.

Our aim was to investigate the value of the German US7 score among non-experts users in daily rheumatologic practice.

Methods: One hundred patients with rheumatoid arthritis (81 females, 19 males; 25 with early and 75 with long-standing arthritis) treated with conventional DMARDs (N=84 patients) and/or biologics (N=12 patients) were enrolled. At each visit (baseline, after 3 and 6 months), clinical (TJC, SJC, DAS28), laboratory (CRP, FW) and ultrasound assessments were performed in blinded manner. Distinct pathologic features detected by ultrasound examination were assessed by eight physicians in seven joint areas (wrist, second and third metacarpophalangeal and proximal interphalangeal, and second and fifth metacarpophalangeal joints) of the clinically dominant hand and foot according to the German US7 score. Synovitis and tenosynovial vascularity due to inflammation were scored according to a 4-point semiquantitative scale (0–3) in Grey Scale (GS) and Power Doppler (PD). Tenosynovitis (GS) and erosions were scored binary (on a yes or no basis). All values are shown as mean±SD. Followed parameters and correlations were statistically analysed as a change from baseline to second follow-up using Spearman′s correlation coefficients. P values less than 0.05 were considered as statistically significant.

Results: In this study, serum levels of C-reactive protein decreased from 7.13±8.69 at baseline to 5.71±6.6 mg/l after 6 months and DAS28 changed from 3.78±1.65 at baseline to 3.14±1.43 after 6 months. Similarly, total synovitis score in GS decreased from 7.42±6.66 at baseline to 5.05±5.29 after 6 months, synovitis score in PD decreased from 4.16±5.14 at baseline to 2.74±3.10 after 6 months. Significant correlations between change in DAS28 and synovitis improvement in GS ($R=0.371$, $p<0.001$), PD ($R=0.448$, $p<0.001$) and tenosynovitis in PD ($R=0.348$, $p<0.0016$) over 6 months were observed. Furthermore, synovitis in GS correlated significantly with synovitis in PD ($R=0.445$, $p<0.001$).

Conclusion: Our results show, that the German US-7 scoring system correlates well with clinical disease activity assessment even in the hands of non-expert users and thus, is a feasible tool for use in daily practice. It may be suggested that the decrease in all investigated parameters during the study period might be due to the implementation of ultrasound as a part of disease activity control influencing the treatment strategy.

1948

Power Doppler Ultrasound 7-Joint Score Vs. Simplified Disease Activity Index In Rheumatoid Arthritis Associated With Fibromyalgia. Rafael Chakr[1], Marina Behar[1], José A. Mendonça[2], Daniela Cervantes[1], Nizele Calegaro[1], Nicole Andrade[1], Iuri Siqueira[1], Daniel Zanchet[1], Andrese Gasparin[1], Penélope Esther Palominos[1], Charles Kohem[3], Odirlei Andre Monticielo[1], Claiton Brenol[4], Ricardo M. Xavier[1] and João Carlos T. Brenol[1]. [1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]Pontifical Catholic University of Campinas / Institute of Clinical Research – IPECC, Campinas, Brazil, [3]Brazilian Registry of Spondyloarthritis, São Paulo, Brazil, [4]Universidade Federal do Rio Grande do Sul, Porto Alegre RS, Brazil.

Background/Purpose: Fibromyalgia (FM) falsely increases rheumatoid arthritis (RA) disease activity clinical composite scores, such as the simplified disease activity index (SDAI), recently incorporated into ACR/EULAR definitions of remission in RA clinical trials (1–3). Allegedly, an objective assessment tool such as ultrasound is less prone to overestimation. The power Doppler (PDUS) US7 (0 to 39) semiquantitatively measures synovial neoangiogenesis as an objective estimation of RA disease activity. Our goal is to investigate whether PDUS US7 performs better than SDAI in disease activity evaluation among RA patients with FM.

Methods: A matched case-control study of RA women with FM (cases) and without FM (control) selected participants from a University-based arthritis clinic. Controls were matched for RA duration and rheumatoid factor positivity. Subjects with concomitant diseases potentially causing arthritis were not included. SDAI and PDUS US7 were calculated by a blinded assessor. Student′s *t* test of paired means and Pearson′s correlation coefficient were done for between groups comparisons. All participants signed informed consent.

Results: Thirty six cases (age = 55 ± 12.9 years, FIQ = 54.5 ± 21.1) and 36 controls (age = 55 ± 12.1 years) presented statistically different SDAI (30.6 ± 14.2 vs. 16.3 ± 10.3, $P<0.001$) but similar PDUS US7 (5.9 ± 4.2 vs. 5.8 ± 3.1, $P>0.05$). SDAI and PDUS US7 showed weak correlation among cases ($r = 0.18$, $P>0.05$) and moderate correlation among controls ($r = 0.62$, $P<0.05$). Arbitrarily considering PDUS US7 as the "gold standard" for RA disease activity assessment, SDAI had six times more false moderate/high individuals among cases as compared to controls (specificity of 54% in cases and 89% in controls).

Conclusion: PDUS US7 does not seem to be falsely increased by FM among RA patients, as opposed to SDAI. Longitudinal studies are necessary to clarify if ultrasound-based treatment decision decreases adverse events and costs in patients with RA and FM.

1949

Assessment Of Wrist Joint Inflammation In Patients With Rheumatoid Arthritis By Quantitative Two- and Three-Dimensional Power Doppler Ultrasonography. Hsin-Hua Chen. National Yang-Ming University, Taipei, Taiwan.

Background/Purpose: To assess the intra-operator and inter-operator reliability of two-dimensional (2D) and three-dimensional (3D)-power Doppler ultrasonography (PDUS) computer-aided quantification data for wrist joint vascularity.

Methods: This is a single-center, cross-sectional outpatient study using convenience sampling. Patients fitting the1987 ACR classification criteria for rheumatoid arthritis having at least one painful swollen wrist at the rheumatology clinic of Taichung Veterans General Hospital regardless of their DAS28 scores were enrolled. 2D- and 3D-PDUS examinations of swollen wrist joints were performed using a high-resolution, real-time ultrasound equipment (Phillips iU22 intelligent 3D ultrasound system, USA) with two transducers sequentially. One is a 5–13 MHz broadband linear array transducer (volumetric transducer) that is able to do a 2D scan and an automatic volume scan. The other is a "hockey stick", 7–15 MHz broadband linear transducer. The participants underwent three consecutive 2D PDUS assessment using the "hockey stick" linear transducer and the volumetric transducer, and three consecutive 3D PDUS assessment using the volumetric transducer in a dark room at room temperature (25βC) within 30 minutes of clinical evaluation by two sonographers (HH Chen and KL Lai). The vascular software, QLAB, provided by the Philips performed quantification analyses, including the area/volume, vascularization index (VI), flow index (FI) and vascularization flow index (VFI) for 2D- and 3D-PDUS respectively. Inter-operator and intra-operator reliability of computer-aided quantification are assessed by calculating intra-class correlation coefficients (ICCs).

Results: A total of 60 wrists in 48 RA patients were evaluated. The intra-operator ICCs of area, VI, FI, and VFI for 2D PDUS were 0.966, 0.952, 0.933 and 0.947 assessed by the "hockey stick" linear transducer, and were 0.972, 0.979, 0.814 and 0.979 assessed by the volumetric probe. The intra-operator ICCs of volume, VI, FI, and VFI for 3D-PDUS were 0.939, 0.965, 0.871, and 0.964. The inter-operator ICCs of area, VI, FI, and VFI for 2D-PDUS were 0.971, 0.968, 0.884, and 0.962 assessed by the "hockey stick" linear transducer, and were 0.977, 0.974, 0.837, and 0.973 assessed by the volumetric transducer. The inter-operator ICCs of volume, VI, FI, and VFI for 3D-PDUS were 0.388, 0.983, 0.874, and 0.983. The mean $\pm$ SD 2D VFI obtained by the "hockey stick" linear transducer was significantly higher than that obtained by the volumetric transducer (12.58 ± 8.57 vs. 10.66 ± 8.11, $p = 0.008$).

Conclusion: The present study demonstrates good intra-operator and inter-operator reliabilities of both 2D- and 3D-PDUS computer-aided quantification data for wrist joint vascularity in patients with RA. The 7–15 MHz "hockey stick" linear transducer detects greater Doppler signals than the 5–13 MHz volumetric transducer.

1950

Relationship Between Radiographic Joint Space Narrowing, Sonographic Cartilage Thickness and Anatomy In Rheumatoid Arthritis and Control Joints. Peter Mandl[1], Gabriela Supp[1], Gabor Baksa[2], Daniel Aletaha[3], Reka Kurucz[4], Dora Niedermayer[2], Helga Radner[3], Paul Studenic[3], Peter V. Balint[4] and Josef S. Smolen[5]. [1]Medical University of Vienna, Vienna, Austria, [2]Semmelweis University, Budapest, Hungary, [3]Medical University Vienna, Vienna, Austria, [4]National Institute of Rheumatology and Physiotherapy, Budapest, Hungary, [5]Medical University of Vienna and Hietzing Hospital, Vienna, Austria.

Background/Purpose: To validate ultrasound (US) for measuring cartilage thickness, by evaluating cartilage thickness on cadaver specimens of metacarpophalangeal (MCP) joints by US and conventional measurement. To correlate cartilage thickness measured by US with joint space narrowing (JSN) and joint space width (JSW) as assessed on conventional radiographs in MCP joints of patients with rheumatoid arthritis (RA).

Methods: Forty-three consecutive patients with RA were evaluated by US at our outpatient clinic. Bilateral MCP joints of 35 consecutive patients, who had hand x-rays taken within the last 12 months and additionally cadaver specimens of MCP 2–5 joints (n=12) were assessed by ultrasonography and histology. The cartilage layer of the metacarpal heads and proximal phalangeal bases of digits 2–5 were assessed bilaterally using a 15 Mhz linear transducer (GE Logic E9) from dorsal longitudinal and transverse views in midline, with the joints in 90° flexion. Cartilage thickness was measured in mm with an integrated caliper on static images. Both JSW and JSN were evaluated on conventional posterior-anterior radiographs. JSW was quantified as the shortest distance between the subchondral bone plates along the force-bearing axis of the joint using a standard measurement tool of the applied picture archiving and communication system; while JSN was evaluated using the van der Heijde modified Sharp scoring method (vdHS). Ankylosed or luxated joints were not included. Metacarpal cartilage thickness (MCT) of cadaver MCP joints was evaluated using a stereoscopic magnifying loupe and digitised image software. Cartilage thickness was correlated with x-ray findings using Spearman's or Pearson's correlation. Intra- and interobserver reliability of US and agreement between US and anatomic measurement were assessed by estimating the intraclass correlation coefficient (ICC).

Results: Agreement (ICC) between US and anatomic measurement of MCT on cadaver specimens of MCP joints (n=12) was 0.62 while the smallest detectable difference was 0.028 mm. Intra- and interobserver reliability of the US measurement of MCT in patients was 0.77 and 0.62 respectively. In the clinical group mean age was 63.1 ± 11.3 years, mean disease duration was 10.6 ± 7.8 years, mean CDAI was 7.76 ± 7.1; 82.9% were female and 54.1% were rheumatoid factor positive. US measurement of MCT of MCP 2–5 in patients was 0.38+/−0,17 mm. MCT of individual joints of the left and right hand correlated with individual MCP JSN ($r = -0.799$ and -0.702, respectively; $p<0.01$) and individual MCP JSW ($r=0.588$ and 0.401, respectively; $p<0.01$). The sum score of MCS for MCP joint 2–5 correlated with total MCP JSW ($r=0.771$, $p<0.01$), total JSN ($r=-0.412$, $p<0.05$), sum erosion score of the vdHS ($r=-0.500$, $p<0.01$) and the total vdHS ($r=-0.576$, $p<0.01$). No significant correlation was found between phalangeal cartilage thickness and JSN.

Conclusion: Both JSW and JSN by radiography indeed represent cartilage thickness at least in MCP joints. US is a validated tool for measuring MCT. When radiographic scoring is not available, US measurement of MCT might be a feasible alternative to depict cartilage damage in patients with RA. Phalangeal cartilage thickness has no added value beyond the measurement of MCT.

The Spring Ligament Window: A Unique Sonoanatomic View Into a Complex Rheumatoid Joint. Joanne Kitchen[1], I. Moller[2], Maribel Miguel-Perez[3] and David A. Bong[4]. [1]Instituto Poal de Reumatolgia, Barcelona, Spain, [2]Instituto Poal, Barcelona, Spain, [3]University of Barcelona, Barcelona, Spain, [4]Instituto Poal de Reumatologia, Barcelona, Spain.

Background/Purpose: The calcaneonavicular or spring ligament (SL) is a group of 3 stout non-elastic fibrocartilaginous bands in the medial mid-foot that is important in maintaining the long arch of the foot & is an integral component of the articular socket for the head of the talus. In its entirety this socket is referred to as the "acetabulum pedis" of the talocalcaneonavicular(TCN) joint & is analogous to the acetabulum of the hip allowing a wide range of motion: gliding, rotation, inversion & eversion. There is also a synovial gliding layer externally where it effaces the overlying posterior tibialis tendon (PTT) sheath. The SL provides a "window" (SLW) to assess synovial disease with direct visualization of articulating surfaces & a prominent tendon sheath. High frequency musculoskeletal ultrasound (MSUS) visualization of the SL has been described in both normal subjects & patients with non-rheumatic mid-foot disorders. This study aims to evaluate the joint-ligament complex in cadaveric specimens & to utilize MSUS to view the TCN joint & measure the ligament in controls & rheumatoid arthritis (RA) patients.

Methods: MSUS (GE P6 machine, 5–16MHz transducer) was performed on 4 fresh cadaveric feet. The SLW was obtained in long-axis over the articulating cartilaginous surface of the medial aspect of the head of

the talus by fixing the distal end of the vertically oriented probe over the sustentaculum tali & rotating the proximal end of the probe counterclockwise from vertical until the medial aspect of the talar head was visualized. The transverse diameter of the SL at the midpoint of the interface of the talar cartilage & the articulating portion of the ligament was measured. This axis of the probe was marked on the cadaver foot surface & the refrozen specimen was cut with a band saw along this axis. Specimens were examined & measured with calipers, by two physicians blinded to each other's findings.

Healthy controls & RA patients underwent MSUS while supine with the ankle in a neutral position. The SLW was visualized as described above. Thus, the view obtained included the sustentaculum tali, the PTT, the sharp bony acoustic medial border of the talus with its distinct anechoic cartilage surface & the overlying hyperechoic fibrillar ligament. The spring ligament diameter was measured.

Results: The medial aspect of the TCN joint was easily identified with MSUS in cadaver, healthy & rheumatoid feet through the SLW using the technique described above & offered a unique view into the interior joint. The mean transverse diameter of the cadaveric ligament was 0.55cm (Range = 0.475 – 0.625cm) by MSUS & 0.58cm (Range = 0.47 – 0.7cm) by caliper anatomic measurement (n = 4). There was no significant difference between MSUS & anatomic measurement (p = 0.767). In RA patients (n = 28) mean transverse diameter by MSUS was 0.384cm (Range = 0.21 – 0.6cm) & in healthy controls (n = 10) it was 0.39cm (Range = 0.35 – 0.47cm), with no significant difference between groups (p = 0.392).

Conclusion: The SLW should be considered as part of the routine MSUS examination in rheumatic diseases affecting the foot & offers a unique intra-articular perspective.

1952

The Value Of An Automated Ultrasound System In The Detection Of Synovitis. Ruediger Mueller[1], Mathias Gruenke[2], Joerg Wendler[3], Florian Schuch[3], Karina Hofmann-Preiss[4], Ina Boettger[4], Ruediger Jakobs[5], Hendrik Schulze-Koops[6] and Johannes von Kempis[1]. [1]Kantonsspital St. Gallen, St. Gallen, Switzerland, [2]Medizinische Klinik IV, University of Munich, Munich, Germany, [3]Schwerpunktpraxis Rheumatologie, Erlangen, Germany, [4]Institut für bildgebende Diagnostik und Therapie, Erlangen, Germany, [5]Siemens AG, Erlangen, Germany, [6]University of Munich, Munich, Germany.

Background/Purpose: The detection of joint swelling caused by synovitis is important for the diagnosis and assessment of inflammatory arthritis. Ultrasound (US) and MRI have proven to be more sensitive and reliable than physical examination, but a comprehensive examination of affected joints with these techniques is time consuming and expensive. The automated breast volume scanner (ABVS) was developed to acquire serial B-mode pictures of the female breast and these data can be analysed in all three dimensions.

Objectives: To analyse the value of automated grey scale B mode US employing the ABVS system in detecting synovitis of the finger joints compared to manual ultrasound and physical examination, using MRI as gold standard.

Methods: 19 consecutive patients suffering from rheumatoid (n=15) or psoriatic (n=4) arthritis with at least one swollen finger joint were included. Automated and manual US were conducted using the ACUSON S2000™. The ABVS transducer was equipped with a linear array used with a frequency of 11 MHz. Each automatic sweep of the scanner generated 15.4 × 16.8 × 2.5 cm volume data sets. The system was set to perform an automatic scanning time of 65 s per scan with a slice thickness of 0.5 mm. The dorsal and palmar side of each hand were scanned separately. Multiplanar reconstruction enabled examination of the images at multiple levels for the presence of synovitis.

Results: Automated US detected 12.0, manual ultrasound 14.2, MRI 13.4, and clinical examination 4.1 swollen joints on average, respectively, per patient. The inter-observer reliability of both assessors for automated and manual US, MRI, and physical examination, was 66.9%, 72.7%, 95.1%, and 88.9%, respectively. A double assessor detection of joint swelling with MRI was used as gold standard. For the other methods, single observer detection was chosen. 84.3% of the joints classified as positive on MRI were confirmed by automated ultrasound, 85.5% on manual US, and 36.0 on physical examination. This translated into a sensitivity of 83.5%, 85.5%, and 36.0% for the three methods, respectively.

Conclusion: Automated US is a simple and time sparing option for the effective detection of synovitis in patients with inflammatory arthritis.

1953

The Progression of Cartilage Damage in Rheumatoid Arthritis: A Three Year Prospective 3T- Magnetic Resonance Imaging Study Examining Predictive Factors. Fiona M. McQueen[1], Alexandra McHaffie[2], Andrew Clarke[2], Arier Lee[1], Quentin Reeves[2], Barbara Curteis[1] and Nicola Dalbeth[2]. [1]University of Auckland, Auckland, New Zealand, [2]Auckland District Health Board, Auckland, New Zealand.

Background/Purpose: Cartilage damage impacts on patient disability in RA. The aims of this MRI study were to investigate cartilage damage over 3 years and determine predictive factors.

Methods: 38 RA patients and 22 controls were enrolled at t=0 (2009). After 3 years, clinical and MRI data were available in 28 patients and 15 controls. 3T MRI scans were scored for cartilage damage, bone erosion, synovitis and osteitis. A model was developed to predict cartilage damage from baseline parameters.

Results: Inter-reader reliability for the Auckland MRI cartilage score (AMRICS) (1) was high for status scores (ICC 0.90 [0.81–0.95]) and moderate for change scores (ICC 0.58 [0.24–0.77]). AMRICS scores were highly correlated with the OMERACT MRI joint space narrowing (jsn) and XR jsn scores (r =0.96, p<0.0001 and 0.80, p<0.0001 respectively). AMRICS change scores were greater for RA patients than controls (p = 0.06 and p = 0.04 for the 2 readers) (Figure 1). Using linear regression, the baseline MRI cartilage score was the strongest predictor of the 3 year MRI cartilage score but synovitis and osteitis scores were also predictive (R2 = 0.67, 0.37 and 0.39 respectively). Baseline radial osteitis predicted increased cartilage scores at the radiolunate and radioscaphoid joints, (p = 0.0001 and 0.0012 respectively) and synovitis at radioulnar, radiocarpal and intercarpal-carpometacarpal joints also influenced 3 year cartilage scores (p values of 0.001, 0.04 and 0.01 respectively). Using multiple linear regression with outcome of cartilage damage at 3 years the optimal model predicted 76% of the variance of the 3-year AMRICS (R2 = 0.76), the strongest component being the baseline cartilage score (R2 = 0.67). The baseline MRI erosion score was also predictive but to a lesser degree (R2 = 0.47). When the outcome of bone erosion score was used, the strongest predictor was baseline erosion score (R2 = 0.87, p < 0.0001), while baseline cartilage score was less predictive (R2 = 0.49, p = 0.01). These data would support the hypothesis that some patients favour one damage pathway over the other so that those who develop erosions tend to erode further (E-progressors) while those who damage cartilage continue preferentially in that manner (C-progressors) (Figure 2).

1) McQueen FM et al. *Ann Rheum Dis* 2010;**69:** 1971–75.

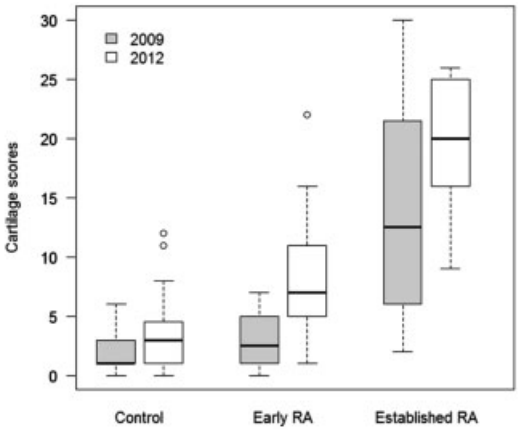

Figure 1. Progression of cartilage scores over 3 years in controls and RA

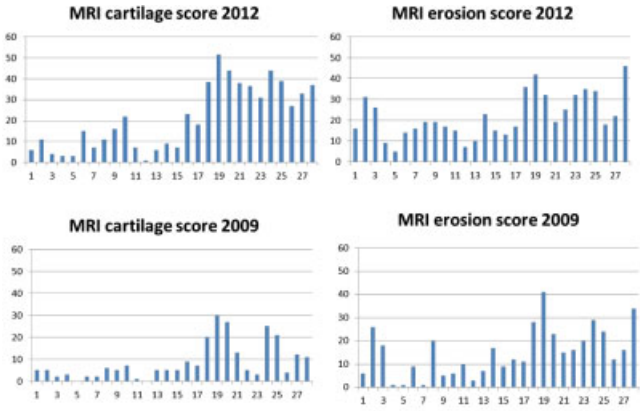

Figure 2. MRI cartilage and erosion scores at baseline and 3 years showing each patient as a bar.

Conclusion: MRI cartilage damage progression is preceded by osteitis and synovitis but is most influenced by pre-existing cartilage damage suggesting primacy of the cartilage damage pathway in certain patients.

1954

Advantages Of a Combined Rheumatoid Arthritis Magnetic Resonance Imaging Score (RAMRIS) For Hand and Feet: Does The Ramris Of The Hand Alone Underestimate Disease Activity and Progression? Dr. Philipp Sewerin[1], Dr. Christian Buchbender[1], Dr. Stefan Vordenbäumen[1], Dr. Axel Scherer[1], Dr. Falk Miese[1], Dr. Ralph Brinks[2], Dr. Hans-Jörg Wittsack[1], Prof. Dr. Gerald Antoch[1], Prof. Dr. Matthias Schneider[2] and Prof. Dr. Benedikt Ostendorf[1]. [1]Univ. Duesseldorf, Düsseldorf, Germany, [2]Univ. Duesseldorf, Duesseldorf, Germany.

Background/Purpose: To evaluate a combined rheumatoid arthritis magnetic resonance imaging score (RAMRIS) for hand and foot (HaF-score) in rheumatoid arthritis (RA).

Methods: Magnetic resonance imaging (MRI) of the dominant hand and foot of 26 consecutive, ACPA positive RA patients before and 6 months after initiation of methotrexate was obtained. RAMRIS of the hand was complemented by corresponding scoring of the foot (MTP I-V; HaF-score). DAS28 and a tender and swollen joint count of the joints scored in MRI were recorded. Changes in these scores (Δ) were assessed.

Results: ΔHaF-score correlated significantly with ΔDAS28 (r = 0.835, 95%-CI 0.661–0.923). Correlations to ΔDAS28 were best for changes in the synovitis subscore (0.695) and bone marrow edema (0.754). Correlations to ΔDAS28 were significantly better for of the ΔHaF-score than ΔRAMRIS (0.662, 0.369–0.835, p=0.0361). All patients with at least moderate response (EULAR criteria, n=11) had continuing disease activity on MRI without improvement in the HaF-score, including five cases with new erosions, three of them at the feet. Similarly, 12 patients had an improved joint count without improvement of the HaF-score. 6 of these discrepant findings were attributable to the foot. No patient fulfilled SDAI remission criteria.

Conclusion: The HaF-score identifies patients with continuing disease activity despite clinical response that would have been missed by consideration of the traditional RAMRIS or the DAS28 alone. Response as opposed to remission may be an insufficient goal in RA as all patients showed continuing disease activity, especially at the feet.

1955

Biochemical MRI With Gagcest (Glycosaminoglycan Chemical Exchange Saturation Transfer Imaging) Of Finger Joint Cartilage In Rheumatoid Arthritis. Dr. Philipp Sewerin[1], Dr. Christoph Schleich[2], Prof. Dr. Benedikt Ostendorf[1], Dr. Stefan Vordenbäumen[1], Prof. Dr. Gerald Antoch[1], Prof. Dr. Matthias Schneider[2] and Dr. Falk Miese[1]. [1]Univ. Duesseldorf, Düsseldorf, Germany, [2]Univ. Duesseldorf, Duesseldorf, Germany.

Background/Purpose: Rheumathoid arthritis (RA) predominantly involves finger joints. Cartilage damage promotes synovitis and has previously been shown to be predictive for bone erosions. gagCEST has recently been demonstrated to visualize biochemical alterations of cartilage in knee joints of patients following cartilage repair surgery as well as in intervertebral discs without using contrast agents. The purpose of our study was to test the feasibility of gagCEST imaging in finger joint cartilage in healthy volunteers and patients with RA to assess cartilage damage as a first step of bone destruction in RA patients.

Methods: Six healthy volunteers (mean age 33; range: 21–45 years) and four patients with ACPA and rheumatoid factor positive rheumatoid arthritis (age 58; range: 52–64 years, 2 men, 2 women, mean DAS28 4,8) were examined at a 3T MR scanner (Siemens Magnetom Trio) using two loop coils (4 cm diameter), one fixed on the palmar, the other on the dorsal side of the second metacarpophalangeal joint (MCP). For gagCEST imaging, CEST effects were prepared by a train of Gaussian RF pulses followed by signal readout with a 3D RF spoiled GRE sequence. The CEST curves were calculated for each pixel and were shifted for the water resonance to appear at 0 ppm of the Z-Spectrum. The CEST effect of the cartilage was measured with the glycosaminoglycan saturation transfer [ST = CEST (+1.3 ppm) – CEST (−1.3 ppm)/CEST (+1.3 ppm)]. Joint space width (JSW) as a morphologic feature of cartilage integrity was measured.

Results: Cartilage ST values were significantly lower in patients with seropositive rheumatoid arthritis compared to healthy volunteers (13.58 ± 6.11 vs. 27.38 ± 4.52; p=0.011). Cartilage CEST curves showed a decrease of CEST effect between 1.2 and 2.2 ppm, which corresponds to the resonance frequency of hydroxyl protons of glycosaminoglycans. There was no significant difference in JSW between healthy volunteers and RA patients.

Conclusion: gagCEST imaging revealed alterations in finger cartilage of seropositive RA patients compared to healthy controls in the absence of cartilage thinning. gagCEST is a potentially useful biomarker for imaging cartilage loss as a first step of inflammation and bone destruction in RA patients.

1956

The Effect Of Initial Methotrexate Therapy On Cartilage Composition In Early Rheumatoid Arthritis: Follow-Up With Biochemical MRI Of Finger Cartilage. Dr. Philipp Sewerin[1], Dr. Falk Miese[1], Dr. Hans-Jörg Wittsack[1], Dr. Stefan Vordenbäumen[1], Dr. Christoph Schleich[2], Prof. Dr. Gerald Antoch[1], Prof. Dr. Matthias Schneider[2] and Prof. Dr. Benedikt Ostendorf[1]. [1]Univ. Duesseldorf, Düsseldorf, Germany, [2]Univ. Duesseldorf, Duesseldorf, Germany.

Background/Purpose: To test for initial status and subsequent recovery of cartilage glycosaminoglycane content in metacarpophalangeal joints (MCP) in patients with early rheumatoid arthritis (eRA) undergoing Methotrexate (MTX) therapy with delayed Gd(DTPA)2-enhanced MRI of the cartilage (dGEMRIC).

Methods: MCP II and III in 19 patients with eRA (disease duration less than 3 month) and 13 healthy volunteers were examined (eRA patients: 13 females, six males, mean age 51 years, range 25–69; eRA 6 months follow-up patients: 7 females, one male, mean age 48 years, range 33–68; healthy volunteers: ten females, three males, mean age 51 years, range 25–66). All eRA patients received methotrexate (MTX, monotherapy, 15mg subcutaneously). Laboratory parameters collected at baseline and follow-up were: ESR, CRP (mg/dl), DAS28. Remission was defined as DAS28<2,6. dGEMRIC was acquired using the variable flip angle techique (VFA). dGEMRIC index was measured in phalangeal and metacarpal cartilage of MCP II and III with manually drawn region-of-interest evaluation. Cartilage thickness was determined as a conventional measure of cartilage integrity. Statistical analysis used non-parametric Mann-Whitney-U-Test to test for significant differences between the groups.

Results: dGEMRIC index was significantly decreased in MCP-joints of eRA patients compared to healthy subjects at T0 (healthy volunteers: MCP II 488 ms ± 90 ms, MCP III 523 ms ± 100 ms; eRA patients: MCP II 414 ms ± 119 ms (p<0.05), MCP III 415 ms ± 132 ms (p<0.05)). Cartilage thickness was not significantly different between the groups. Following initial MTX therapy, remission (DAS28<2,6) was achieved in six out of eight patients. Mean increase of dGEMRIC index was 12 ms ± 180 ms (n.s.).

Conclusion: In therapy naive early RA, there was a decrease in cartilage glycosaminoglycane content in metacarpophalangeal joints in comparison to healthy controls in the MCP joints II und III. Glycosaminoglycane content as assessed with dGEMRIC of normal appearing finger cartilage did not significantly change after a six month MTX monotherapy despite clinical remission

(based on DAS28) and could be a hint for silent progression. dGEMRIC may be a possible tool for studies on cartilage protection in RA therapy.

1957

Correlation Of Structural Abnormalities Of The Wrist and Metacarpophalangeal Joints Evaluated By High-Resolution Peripheral Quantitative Computed Tomography, 3 Tesla MRI and Conventional Radiographs In Rheumatoid Arthritis. Chan Hee Lee[1], Waraporn Srikhum[2], Andrew J. Burghardt[1], Warapat Virayavanich[3], Thomas M. Link[1], John B. Imboden[1] and Xiaojuan Li[1]. [1]University of California, San Francisco, San Francisco, CA, [2]Thammasat University, Pathumthani, Thailand, [3]Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.

Background/Purpose: Early detection of joint inflammation and tissue damage are critical for patient management in rheumatoid arthritis (RA). High-resolution peripheral quantitative computed tomography (HR-pQCT) is an emerging modality for the assessment of bone damage in RA, including erosions and deterioration of bone microarchitecture. The goal of this study was to examine the correlation of structural changes evaluated by HR-pQCT, 3 Tesla (T) MRI and conventional radiographs (CR) in RA.

Methods: In sixteen RA patients, HR-pQCT of the second and third metacarpophalangeal joints (MCP) as well as the wrist joints, 3 T MRI of the wrists joint and CR of both hands and feet were performed. Ten patients had 1 year follow-up CR. CRs were graded according to the Modified Sharp/ van der Heijde Score (MSS). Bone erosions were evaluated in HR-pQCT and MRI for number, grade and maximum dimension. Bone marrow edema pattern (BMEP) was quantified from MRI for volume, signal intensity and lesion burden using in-house developed software. Spearman's rank correlation coefficients between MSS by CR, bone erosion by HR-pQCT, bone erosion and BME by MRI were calculated.

Results: Fifteen patients (93.8%) had evidence of erosions in HR-pQCT. MRI erosions and BME were found in 13 patients (81.3%). Baseline total MSS was significantly correlated with HR-pQCT erosion measures, MRI erosion measures and MRI BMEP volume ($r = 0.59 – 0.90$, $p < 0.05$). The erosion detection sensitivity of MRI was 85.7% (42/49) and CR was 60.9% (53/87) when HR-pQCT was considered as a reference method. In the 10 patients who had both baseline and one year follow up CRs, the mean difference between baseline and follow up MSS (delta MSS) was 1.2. There was no significant correlation between delta MSS and HR-pQCT/MRI erosion measures at baseline, but a trend was observed toward a correlation between delta MSS and MRI BMEP volume and burden.

As a result of inflammation, initially BMEP will develop without erosion (stage 1). After this stage, early erosion will develop, which can be very small and can be identified only on HR-pQCT, which is the most sensitive modality for the detection of erosion but no on other modalities such as MRI and CR (stage 2). As the disease progresses, the size of erosion becomes larger and can be detected by both HR-pQCT and MRI (stage 3). Finally, the erosion is becoming large enough to be shown by all 3 modalities, CR, HR-pQCT and MRI (stage 4).

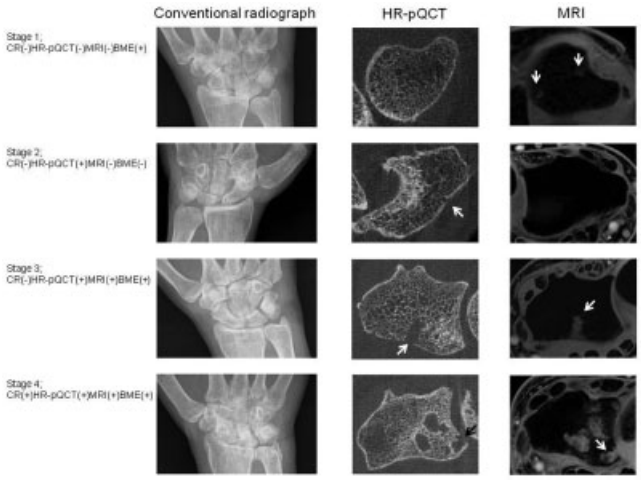

Figure 1. The stages of erosion by HR-pQCT, MRI and CR in RA hands.

Conclusion: HR-pQCT detects more and smaller bone erosions compared to MRI and CR. In addition, 3 T MRI can also provide quantitative measurement of BMEP. From the erosion findings by HR-pQCT, MRI and CR, and the BME observation by MRI, we may suggest the stages of erosion in RA, shown in Figure 1. The combination of HR-pQCT and MRI is a powerful mean to evaluate joint inflammation and bone damage, and MRI BMEP potentially could predict disease progression in patients with RA.

1958

Does Evaluation Of Hand Bone Loss By Digital x-Ray Radiogrammetry Within The First 3 Months After Diagnosis Of Rheumatoid Arthrits Identify Patients At Risk For Radiological Progression? Ewa H. Berglin[1] and Solbritt M. Rantapaa-Dahlqvist[2]. [1]Institution of Public health and clinical medicine/ Rheumatology, University of Umeå, Umeå, Sweden, [2]Institution of Public health and clinical medicine/ Rheumatology, University of Umeå, Umeå, Sweden, Umea, Sweden.

Background/Purpose: To evaluate the usefulness of assement of hand bone loss in prediction of radiological progression in patients with early rheumatoid arthritis (RA).

Methods: Patients with early RA (< 12 months of symptoms) were consequtively included in the study and treated according to the Swedish guidelines. Hand bone mineral density (BMD) was measured with digital x-ray radiogrammetry (DXR) at inclusion and after 3 months and the difference between the two assessments was related to clinical measurements and to the radiological outcome (Larsen score) at one year follow-up.

Results: Sixty-eight patients (71% females) with disease duration of (mean (SD)) 5.28 (2.79) months were included. The BMD decreased significantly for the whole cohort from (mean, (SD)) 0.571(0.0918) to 0.567 (0.0933) g/cm^2 ($P = 0.0001$). Seventeen percent of the patients had a decrease of > 2.50 mg/cm^2/month which was regarded as considerable bone loss (CBL). The level of C-reactive protein (CRP) at inclusion was significantly higher among patients with CBL compared with patients with less bone loss ($P=0.007$). Female patients with DAS28 above 2.6 at 3 months had significantly higher rate of bone loss (mean (SD) 1.745 (1.715) vs 0.667 (1.530) mg/cm^2, $P = 0.038$) and a significantly higher increase in Larsen score between inclusion and 1 year mean (SD) 0.94 (1.211) vs 2.08 (2.060), $P = 0.029$ than female patients with DAS28< 2.6. Mean value (SD) of Larsen score at inclusion was 5.5 (5.53) and 7.1 (6.00) at 1 year ($P < 0.0001$). There was a tendency, although not statistically significant, of greater difference in Larsen score between inclusion and 1 year in patients with CBL compared with patients with less bone loss (data not shown).

Conclusion: Hand bone loss was significant already at 3 months after diagnosis of RA. It was related to measures of inflammation and with a trend suggesting a relationship with radiological progression

Extremity MRI Scans of the Hand and the Diagnosis of Inflammatory Arthritis: Findings in Patients With a Clinical Diagnosis of RA, Non-Inflammatory Arthritis and Fibromyalgia. Robert S. Katz[1], Hannah Bond[2] and Anthony Farkasch[2]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL.

Background/Purpose: Low field extremity MRI has been utilized to evaluate patients for inflammatory arthritis and to follow their progress on immunosuppressive and biologic therapy. The interpretation is performed by radiologists experienced in evaluating extremity MRI scans, but how often do the findings agree with the clinical evaluation? The purpose was to evaluate hand and wrist pain to determine whether patients have changes of inflammatory arthritis and are good candidates for immunosuppressive or biologic therapy.

Methods: We analyzed our rheumatology office practice patients who had extremity MRI of the hand and wrist performed in 2010 through 2012. All patients received low field MRI evaluations of the wrist and hand, using an Esoate.2 Tesla C Scanner. We compared the patient's clinical diagnosis to the MRI findings. The MRI radiologists assessed whether synovitis was present and its intensity and location, the presence of osteitis; bone erosions and joint space narrowing.

Results: Mild synovitis was frequently reported in patients with fibromyalgia. Erosions were occasionally seen in fibromyalgia patients, but they were almost always solitary or a few small erosions whereas, as expected, in rheumatoid arthritis the synovitis was more intense and the erosions were more frequent and more extensive. Osteitis was reported in RA and OA patients and helped distinguish their MRI scans from those with fibromyalgia.

Clinical Diagnosis	Number of Patients	Interpreted as Rheumatoid Arthritis	Interpreted as Inflamatory Arthritis	Interpreted as Neither Rheumatoid or Inflamatory Arthritis	Outcome
Rheumatoid arthritis	47	11 (23.4%)	2 (4.3%)	34 (72.3%)	72.3% were under read
Osteoarthritis	17	2 (11.7%)	1 (5.9%)	14 (82.4%)	82.4% matched the clinical diagnosis of non-inflamatory
Fibromyalgia	84	12 (14.0%)	4 (5.0%)	68 (81.%)	19% were over read
Systemic Lupus Erythemosus	11	2 (18.2%)	0	9 (81.8%)	
Other (PMR, Derm)	2	0	0	2 (100.0%)	

Conclusion: We conclude that MRI scans of the extremities are helpful in evaluating patients with hand pain, but caution is necessary to avoid over-interpretation of mild findings, especially mild synovitis and small and rare erosions. Patients with inflammatory arthritis had moderate to severe synovitis that was present in more locations (the MCP joints, PIP joints, and the carpal joints) than patients with the clinical diagnosis of non-inflammatory arthritis, or fibromyalgia. However, a few patients thought originally to have fibromyalgia were considered for treatment of inflammatory arthritis based on the MRI findings. Mild synovitis without gadolinium is difficult to evaluate accurately. 72.3% of patients with RA were not interpreted as consistent with this diagnosis indicating either effective treatment or under interpretation of MRI findings.

The MRI scans of patients with fibromyalgia and non-inflammatory arthritis are frequently reported as abnormal. Mild changes on extremity MRI can be seen in patients with fibromyalgia and should not lead to a change of diagnosis. The same applies to those with non-inflammatory arthritis. Generally, a distinction can be made compared to those with inflammatory arthritis based on the intensity and widespread distribution of the synovitis, the number and size of erosions, and the presence of osteitis.

Over-interpretation and under interpretation of extremity MRI by experienced radiologists is common.

Combination Of Magnetic Resonance Imaging-Proven Osteitis With 2010 RA Classification Criteria Improves The Diagnostic Probability Of Early Rheumatoid Arthritis Whose Disease Duration Less Than 6 Months. Mami Tamai[1], Junko Kita[2], Yoshikazu Nakashima[2], Ayako Nishino[2], Takahisa Suzuki[2], Yoshiro Horai[2], Akitomo Okada[3], Tomohiro Koga[2], Shin-ya Kawashiri[2], Naoki Iwamoto[2], Kunihiro Ichinose[2], Kazuhiko Arima[2], Satoshi Yamasaki[4], Hideki Nakamura[2], Tomoki Origuchi[2], Masataka Uetani[2], Aya Fukushima[2], Kiyoshi Aoyagi[2], Katsumi Eguchi[5] and Atsushi Kawakami[2]. [1]Unit of Translational Medicine, Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Japanese Red Cross Nagasaki Genbaku Hospital, Nagasaki, Japan, [4]Hiroshima University Hospital, Hiroshima, Japan, [5]Sasebo City General Hospital, Sasebo, Nagasaki, Japan.

Background/Purpose: In the articles describing the 2010 rheumatoid arthritis (RA) classification criteria, it is stated that additional evidence of joint injury from imaging techniques such as magnetic resonance imaging (MRI) may be used for confirmation of the clinical findings. MRI is able to detect synovitis, tenosynovitis, osteitis and bone erosion. Among these, osteitis, is supposed to be the best surrogate MRI feature for differentiating RA from other rheumatic diseases. This study is undertaken to investigate whether MRI-proven osteitis improves the diagnostic performance of the 2010 RA classification criteria among early arthritis patients.

Methods: All of early arthritis patients, whose disease duration at entry less than 6 months, were recruited in the present study from Nagasaki University Early Arthritis Cohort. Patients whose diagnoses were compatible with rheumatic diseases other than RA or obvious to plain radiographic erosion at entry, were excluded. All of the subjects underwent physical examination, blood tests, and gadolinium-diethylenetriamine pentaacetic acid (Gd-DTPA)-enhanced MRI on the same day. Gold-standard RA was defined as the patients receiving disease-modifying antirheumatic drugs during the first year. The diagnostic performance of the 2010 RA criteria with or without the finding of MRI-proven joint injury was investigated.

Results: One hundred sixty-four patients, whose median disease duration at entry was 2 months, were recruited. The median values for age, CRP (mg/l), prevalence of rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (ACPA) at examination were 54 years, 2.0, 40.2% and 34.1%, respectively. The 2010 RA classification criteria classified RA with a sensitivity of 62.4%, a specificity of 83.1%, a positive predictive value (PPV) of 82.9%, a negative predictive value (NPV) of 62.8%, accuracy of 71.3%. Osteitis was the most specific MRI finding in gold-standard RA. We have proposed a decision-tree algorithm that involves initially applying the 2010 RA classification criteria, and if the patients do not fulfill 2010 RA classification criteria, the MRI-proven osteitis rule is introduced. The tree algorithm has been shown to differentiate patients more efficiently than the 2010 RA classification criteria alone, exhibiting a sensitivity of 79.6%, a specificity of 76.1%, a PPV of 81.3%, a NPV of 74.0%, accuracy of 78.0%.

Conclusion: The present data indicate that the combination of MRI-proven osteitis with the 2010 RA classification criteria improves the diagnostic probability of RA at an early stage.

The Diagnostic Utility Of Musculoskeletal Ultrasound In Early Arthritis – a Probabilistic (Bayesian) Approach. Hamed Rezaei[1], Erik af Klint[1], Yogan Kisten[1] and Ronald F. van Vollenhoven[2]. [1]The Karolinska Institute, Stockholm, Sweden, [2]Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), the Karolinska Institute, Stockholm, Sweden.

Background/Purpose: While musculoskeletal ultrasound examination (MSUS) is used increasingly in the work-up of patients with inflammatory joint disease, the exact diagnostic utility has not been established. We sought to apply a prospective, probabilistic (Bayesian) approach to quantify the diagnostic utility of MSUS.

Methods: All patients referred to our clinic for evaluation of arthritis were eligible, unless a prior diagnosis was indicated or a certain diagnosis could be made based on the information in the referral letter. Patients were assessed by history and physical examination including joint examination, laboratory testing including acute-phase reactants, RF, and ACPA, and plain x-ray of hands, wrists and feet if clinically indicated. A diagnostic assessment was then performed by the responsible physician where the probability of a) any inflammatory joint disease and b) rheumatoid arthritis was given on a 5-point scale ranging from unlikely (0–20% probability) to very likely (80–100% probability). Subsequently, an ultrasound examination of the wrist, MCP, PIP 2–5 in both hands, MTP 2–5 in both feet and also symptomatic joints was performed by HR and the results of the examination presented to the responsible physician. The latter then assessed the diagnostic probabilities again, using the same scale. The proportions of patients with maximal and minimal diagnostic certainty pre-test and post-test were compared by Fisher exact test.

Results: 67 patients were included, 52 were female, average (SD) age 47.9 (16.5) years. Symptom duration 8.9 (4.0) months, 15 patients were positive for RF and 12 for ACPA. The pre-test and post-test probability distributions for (any) inflammatory joint disease and for RA are given in the table. The final diagnoses in these patients were RA (15), other inflammatory joint diseases (21), non-inflammatory joint disease (31).

With regard to a diagnosis of (any) inflammatory joint disease, the proportion of patient for whom diagnostic certainty was maximal (<20% OR >80% likelihood) was 20/67 (29.9%) before MSUS and 42/67 (62.7%) after MSUS (p=0.0002). With regard to a diagnosis of RA, the proportions were 21/67 (31.3%) pre-test and 39/67 (58.2%) post-test (p=0.003). Parallel reductions were seen in the proportions of patients with greatest diagnostic uncertainty (40–60% likelihood), from 24/67 (35.8%) to 10/67 (14.9%) (p=0.0093) and from 17/67 (25.3%) to 4/67 (6.0%) (p=0.0035), respectively.

	any inflammatory disease (n patients in group)		rheumatoid arthritis (n patients in group)	
Diagnostic probability	Pre-test	Post-test	Pre-test	Post-test
<20%	4	14	12	27
20–40%	14	10	26	17
40–60%	24	10	17	4
60–80%	9	5	3	7
>80%	16	28	9	12

Conclusion: In this probabilistic (Bayesian) analysis, musculoskeletal ultrasound when added to routine physical and laboratory examination greatly increased the diagnostic certainty in patients referred for the evaluation of arthritis.

1962

The Value Of the 2010 ACR/EULAR Rheumatoid Arthritis Classification Criteria For The Prognosis Of Early Arthritis: Evaluation Of Erosion Development With Ultrasonography. Nevsun Inanc, Fatma Alibaz-Oner, Meryem Can, Pamir Atagündüz and Haner Direskeneli. Marmara University, School of Medicine, Istanbul, Turkey.

Background/Purpose: The 2010 ACR/EULAR Rheumatoid Arthritis(RA) classification criteria was developed to diagnose the early arthritis patients who will progress destructive disease and to start early treatment. We aimed to investigate the value of these classification criteria for the prognosis of early arthritis patients with the evaluation of the longitudinal ultrasonographic(US) examination for the development of erosions.

Methods: The study included patients presenting with at least one swollen joints to "Early arthritis Clinic" between 2009 and 2012. The patients having symptom duration less than 24 months were recruited to the study. Clinical evaluation(tender/swollen joint counts, DAS28 and HAQ scores) and US examination of erosion at 2nd MCP, 5th MCP, 2nd PIP ulnar styloid and 5th MTP joints were performed prospectively at the lateral approach longitudinally and transversally for the determination of the erosion at baseline and 12months.

Results: A total of 71 patients (F/M:53/18) were recruited to the study. The mean age was 38.2± 14.2, mean symptom duration was 6.4 (0–24) months. At baseline assessment, 46.5% (n:33) of patients were classified as RA according to 2010 ACR/EULAR criteria and others were diagnosed as undiffererentiated arthritis(UA) after excluding other possible diagnosis.

At baseline, higher percentage of patients whom was diagnosed as RA according to 2010 ACR/EULAR criteria (44 % vs 23%, p= 0.072) were found to have erosive changes with the US examination. Furthermore, a tendency was observed for the progression of erosive disease, in terms of increased number of erosive joints, in patients diagnosed according to 2010 criteria vs patients diagnosed as UA (32% vs 10 %, p=0.072) at follow-up. Positive RF was also determined as a predictor of erosions by US (35% vs 11%, p=0.053).

Conclusion: Among patients with early arthritis fulfilling the 2010 ACR/EULAR RA criteria had erosive disease at diagnosis and increased frequency of erosions during the follow-up. Early evaluation of the joints by US can be used for the early detection of erosive patients which may predict the prognosis of RA.

1963

Ultrasonography Is Helpful For Optimizing The Diagnosis Of Early Rheumatoid Arthritis. Maasa Hama, Darisuren Tsolmon, Kaoru Minegishi, Ryusuke Yoshimi, Yohei Kirino, Atsuhisa Ueda, Mitsuhiro Takeno, Ichiro Aoki and Yoshiaki Ishigatsubo. Yokohama City University Graduate School of Medicine, Yokohama, Japan.

Background/Purpose: 2010 ACR–EULAR criteria enable us to make diagnosis of early rheumatoid arhtiritis (RA) with no erosion revealed by X-ray. However, the criteria potentially possess two critical issues. One is that some seronegative patients with polyarthritis may be excluded from RA even if they met 1987 ACR criteria. The other is that seropositive patients with arthralgia may be included in RA even in absence of synovitis, if "no synovitis" is not appropriately proven. In this study we assessed the roles of ultrasonography (US) in the diagnosis of early rheumatoid arthritis when the new criteria were applied clinically.

Methods: We retrospectively examined 122 undiagnosed patients who first visited our hospital from 2009 to 2011 due to joint symptoms without any previous therapies except for NSAIDs. The patients who started to receive anti-rheumatic therapy during the one-year observation period were categorized into the RA group. At the study entry, 10 joints (second proximal interphalangeal, second and third metacarpophalangeal joints, wrists and knees) were assessed by US using gray-scale (GS) and power Doppler (PD) scoring.

Results: Fifty and 72 patients were divided into RA group and non-RA group, respectively. Fulfillment of the 2010 ACR-EULAR criteria in the RA group was 70% at the first visit and 96% at the end of study. When applying US synovitis to □esynovitis' in the scoring system of the 2010 criteria in addition to routine works, sensitivity of the criteria in RA diagnosis increased from 70% to 82% at the first visit. According to ROC analysis, diagnostic findings of US in early RA are the presence of more than 1 joint with GS score.

Table. ROC analysis of each US parameter in differentiation of RA from non-RA.

	AUC	Cut off value	Youden Index	sensitivity (%)	specificity (%)
No. of GS≥1 joints	0.735	4	0.373	72	65.3
No. of GS≥2 joints	0.76	1	0.481	80	68.1
No. of PD≥1 joints	0.753	1	0.458	68	77.8
Sum of GS score of 10 joints	0.766	5	0.427	76	66.7
Sum of PD score of 10 joints	0.754	1	0.444	68	76.4
tenosynovitis	0.608	1 (+)	0.444	34	87.5
synovitis in wrist	0.706	1 (+)	0.412	62	79.2

Conclusion: US contributes to making early diagnosis of RA, especially in patients having no clinically apparent arthritis and seronegative patients. It is also useful to determine the optimal initiation of anti-rheumatic therapy.

1964

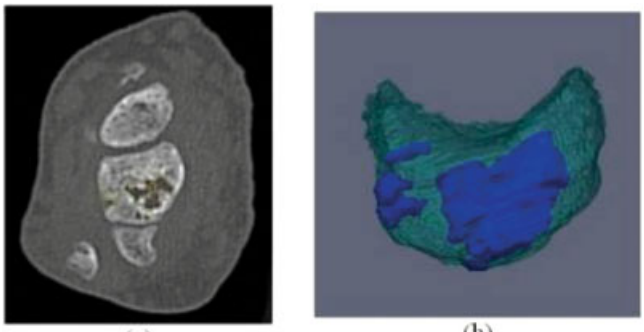
Quantitative Erosion Volume Measurement From Computed Tomography. Jeffrey W. Duryea[1], Daniel H. Solomon[2], Bing LU[3], Ruby Russell[1], Roger Han[1], Ellen M. Gravallese[4] and Jonathan Kay[5]. [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA, [3]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [4]UMass Memorial Medical Center, Worcester, MA, [5]UMass Memorial Medical Center and University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Rheumatoid arthritis (RA) causes two key structural changes that are visible on plain radiographs: narrowing of the joint space width (JSN) and erosion of the juxta-articular bone. Hand radiography is a low-cost and widely available tool to assess RA and is used extensively in clinical studies. However, plain radiography provides only a two-dimensional (2D) projection of structures that have a complex three-dimensional (3D) shape. Highly accurate quantification of erosion size will become increasingly important to use in longitudinal

studies of RA treatment and may also be useful to monitor drug therapy in routine patient care. Computed tomography (CT) provides superb imaging of bone margins and, as a 3D modality, it is ideal to measure erosion volume.

Methods: We have developed a semi-automated software method to segment (outline) the margins of erosions in 3D, from high-resolution CT scans of the hand and wrist, and to calculate erosion volume. A reader operates the software and guides the computer to segment the erosions on each CT slice. Figure 1 illustrates a CT slice with erosion (a) and its 3D rendering (b). The method was validated using CT scans of both hands and wrists from 5 subjects (10 hands) with moderate to severe RA. Each hand was scanned twice during a single session, after repositioning subjects between scans. The repositioning reproducibility for the 10 hands was quantified using intra-cluster correlation (ICC), the root-mean square standard deviation (RMSSD), and the coefficient of variation (CoV) (Table). For each scan, we measured the erosion volume of the total hand and wrist, as well as for two sub-regions: sub-region 1 included the radius, ulna, carpal bones and carpometacarpal (CMC) joints and sub-region 2 included the PIP, MCP, and DIP joints.

Results: See table. The total erosion volume for the 10 hands ranged from 34.5 mm^3 to 1,492.4 mm^3. The ICC values demonstrate excellent correlation. The RMSSD and CoV suggest that this technique should be capable of detecting erosion volume change on the order of 20 to 30 mm^3 or 4–7 percent.



(a) (b)

	Total	Subregion 1	Subregion 2
Intra-cluster correlation	1.00	0.99	0.97
Root Mean Square, Standard Deviation (mm^3)	22.9	17.3	30.1
Coefficient of variation	5.3%	4.0 %	7.0%

Conclusion: Our semi-automated high-resolution CT method reproducibly detects and quantifies the volume of juxta-articular erosions in RA and can be applied to studies of RA treatment to detect longitudinal changes in erosion volume.

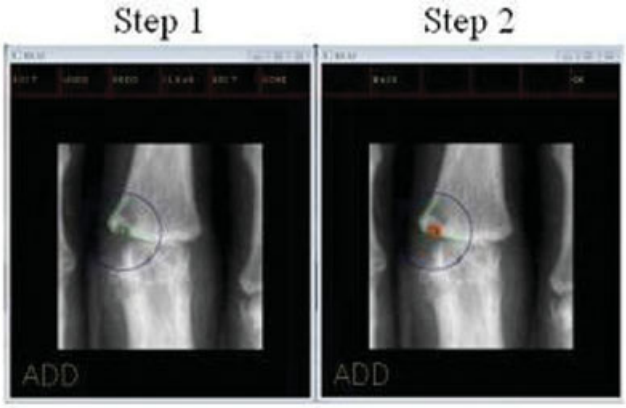
1965

Performance Of a Computer-Based Method To Measure Erosions In Rheumatoid Arthritis: A Longitudinal Study. Jeremy Wortman[1], Stacy Smith[1], Frederick Wolfe[2] and Jeffrey W. Duryea[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]National Data Bank for Rheumatic Diseases, Wichita, KS.

Background/Purpose: To describe the methodology of a novel computer-based technique for outlining erosions on plain radiographs in rheumatoid arthritis (RA) patients, and assess the responsiveness and correlation with the Sharp erosion score.

Methods: A sample of 112 patients with mild to severe rheumatoid arthritis, for whom serial (baseline and one follow-up) bilateral hand radiographs were available, was obtained from the National Databank for Rheumatic Diseases. A radiologist, blinded to time point, used the software to outline the erosions at each MCP and PIP joint. Severely diseased joints were excluded. The computer-based method partially automates the process of outlining erosions on hand radiographs, and calculates erosion area (see figure). For 99 subjects, the total Sharp erosion score for the MCP and PIP joints of digits 2 to 5 was available. Because all radiographs were acquired prior to the advent of DMARDS, we expected radiographic damage to increase with time. Therefore, the chronological order of serial radiographs was used as the standard to assess performance. The percent change and standardized response mean (SRM) were used to quantify responsiveness, and linear regression established the correlation with the Sharp score.

Results: 78% of subjects showed an increase in erosion area over time, and 5% showed no change. Changes in the computer-based and Sharp methods were highly correlated ($r = 0.75$, $p < 0.01$). The SRM was 0.46. The reader time was approximately 0.6 minutes per hand radiograph.



Conclusion: The computer-based method is fast and can accurately assess progression of disease in patients with RA. The high correlation of the software measure with the Sharp score suggests it can be used as a surrogate for this measure.

1966

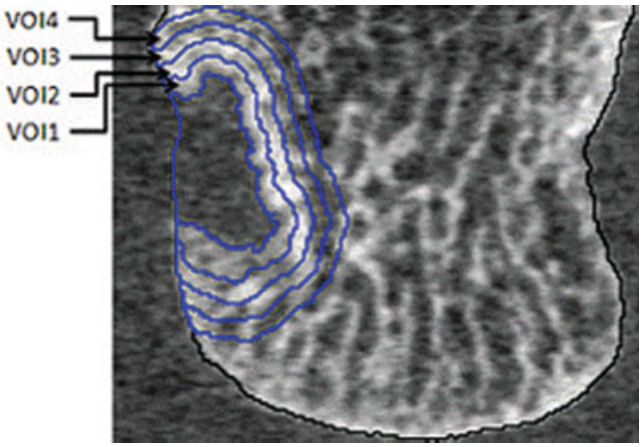
Longitudinal Quantification Of Bone Erosions In Patients With Rheumatoid Arthritis Using High-Resolution Computed Tomography. Dominique Toepfer, Stephanie Finzel, Oleg Museyko, Georg Schett and Klaus Engelke. University of Erlangen-Nuremberg, Erlangen, Germany.

Background/Purpose: Diagnosis and monitoring of patients with rheumatoid arthritis (RA) is based on radiographs or MRI, therefore the sensitivity to detect small changes of bone erosions is limited. We developed a fully 3D automated method for precise quantification of longitudinal changes of erosion size and shape in high resolution peripheral quantitative computed tomography (HR-pQCT) images of the metacarpophalangeal (MCP) joints.

Methods: HR-pQCT images of the second to fourth MCP joint from 17 RA patients were acquired on an XtremeCT scanner (Scanco, Switzerland) with an isotropic voxel size of 82μm. Patients were scanned at baseline and after 1.1±0.6 years. In order to reduce precision errors baseline (BL) and follow-up (FU) datasets were 3D rigidly registered using the periosteal surfaces to ensure identical segmentation of the cortical breaks. Erosions were then segmented independently in both BL and FU data. We evaluated change in volume, surface area, and sphericity (a measure between 0 and 1 for how closely the erosion resembles a sphere). We also dilated each erosion surface to obtain 4 concentric volumes of interest (VOIs 1–4, see figure), in which BMD was measured. The patients were treated using either Methotrexate (MTX, N=10, mean age±SD 55.8±19 years, 2 males) or tumor necrosis factor inhibitors (TNFi, N=7, 45.5±12.8 years, 1 male) and group differences were also analyzed.

Results: 37 Erosions were analyzed in both BL and FU. % change in erosion volume correlated significantly ($p<0.01$) in all 4 VOIs with % change in BMD. Spearman's rho were −0.58 (VOI1), −0.64 (VOI2), −0.62 (VOI3) and −0.45 (VOI4). % differences (Mean±SD) between the

two treatment groups were 14.3±51.3, 13.8±44.7 and −2.7±10 in the MTX group (21 erosions) for volume, surface area and sphericity, respectively, and −11±31.5, −8.9±27.6 and 3.9±17.9 in the TNFi group (16 erosions). % BMD changes in VOIs 1 to 4 were −0.6±11.2, 0.6±12.2, −0.1±9.8 and −0.6±7.8 in the MTX group and 7.7±18.5, 10.7±23.5, 8.6±16.8 and 5.8±12.4 in the TNFi group. These differences were not significant, probably due to the small sample size.



Conclusion: We developed an automated, precise and fully 3D framework for longitudinal evaluation of changes in bone erosions in HR-pQCT images. Under treatment changes in erosion volume negatively correlated with BMD changes in the vicinity of the erosion. The loss of periarticular bone mass as a sign of inflammatory activity in RA has already been suggested in radiographic studies; interestingly, BMD did not further decrease (MTX) or increased (TNFi) after one year. However, it is still unclear, whether this is of predictive value for monitoring of disease activity. A limitation of the HR-pQCT technique are motion artifacts due to long scan times (~8min), impairing image quality.

1967

Computer-Aided and Manual Quantifications Of MRI Synovitis, Bone Edema, Erosion and Semi-Quantitative Cartilage Loss In Rheumatoid Arthritis. Haitao Yang[1], Julien Rivoire[2], Michael Hoppe[2], John B. Imboden[2], Thomas M Link[2] and Xiaojuan Li[2]. [1]The First Affiliated Hospital of Chongqing Medical University, Chongqing, China, [2]University of California, San Francisco, San Francisco, CA.

Background/Purpose: Early diagnosis and early detection of therapeutic response within the so called "window of opportunity" in rheumatoid arthritis (RA) are essential for superior clinical and functional outcome. Magnetic Resonance Imaging (MRI) is the only modality for allowing simultaneous assessment of all the structural changes involved in RA such as synovitis, cartilage damage, bone marrow edema pattern, bone erosion and tendonsynovitis. Fast and reliable MRI quantitative methods are significant to evaluate disease activity and assist management for RA patients.

The objectives of this study were to investigate the reliability of multiple computer-aided and manual quantifications for MRI synovitis, bone marrow edema pattern, erosion and semi-quantitative cartilage loss of wrists with RA.

Methods: Wrist imaging was performed with 3T MRI in 16 patients with RA and 3 healthy controls. Computer-aided semiautomatic quantifications for synovitis volume and perfusion (maximum enhancement (E) and steepest slope (S)), bone marrow edema pattern (BMEP) volume, signal intensity and perfusion (E and S), and erosion dimension were measured using in-house developed software, and compared with the OMERACT-RAMRIS classification. In addition a semi-quantitative MRI wrist cartilage loss score system was developed. Intra-Class Correlation (ICC) coefficients were calculated to examine intra- and inter-operator reproducibility; Spearman correlation coefficients were calculated between MRI quantifications, RAMRIS, and radiographic Sharp van der Heijde score.

Results: The intra- and inter-observer ICC were 0.97 and 0.89 for synovitis volume quantification, respectively. The intra- and inter-reader ICC for erosion dimension measurement were 0.91 and 0.93, respectively. The synovitis volume, BMEP volume and signal intensity, and erosion dimension were significantly correlated with the corresponding RAMRIS sub-scores (r from 0.727 to 0.900). Regarding perfusion, no significant correlation was found between synovitis perfusion, BMEP perfusion and RAMRIS scores except for between synovitis E, synovitis volume and synovitis RAMRIS ($r = 0.928$, $p = 0.002$; $r = 0.798$, $p = 0.017$), and between synovitis and BMEP perfusion E ($r = 0.900$, $p = 0.037$). The intra- and inter-reader ICC of the MRI cartilage loss score were 0.98 and 0.99 respectively. The MRI cartilage loss score was significantly correlated with the hand Sharp van der Heijde joint space narrowing score ($r = 0.635$, $p = 0.008$).

Conclusion: Multiple computer-aided and manual quantitative methods can be used to quantify MRI pathologies in RA and showed excellent reliability compared with RAMRIS. The quantitative methods have the potential to be more sensitive for detecting early and subtle changes than conventional scoring systems, and thus may be helpful with early diagnosis and providing critical monitoring after treatment.

A Novel, Feasible and Reliable Method Of Radiographic Scoring Of Rheumatoid Arthritis. Priyanka Vashisht[1], Harlan Sayles[2], Ted R. Mikuls[3] and Alan R. Erickson[4]. [1]Creighton University Medical Center, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE, [3]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [4]Omaha VA and University of Nebraska Medical Center, LaVista, NE.

Background/Purpose: Radiographs of the hands and feet are used to evaluate the disease course of rheumatoid arthritis (RA) with several scoring systems previously described. However, most of them are time-intensive, require specialized expertise and are thus not practical for use in routine clinical care. We assessed a novel method of radiographic scoring using the VARA (Veterans Affairs RA) registry. The goal of our study was to compare radiographic scores using the 'VARA method' with a well-established scoring method (Sharp score) and to assess the correlations and agreement between these two approaches.

Methods: The study was done on a multi-center database of veterans with RA. A total of 198 patients were studied. Bilateral hand radiographs were read by an experienced rheumatologist trained in the Sharp scoring method and radiographic scores were calculated independently by the Sharp and VARA methods. The simplified VARA method involves assessments for the presence of erosions and joint space narrowing in 3 joint regions of the hand- including wrist, metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints. The same individual joints are also evaluated for the Sharp score. For VARA scoring, the presence of erosion or narrowing each gives a score of 1 and absence gives a score of 0. The maximum erosion and narrowing score for each hand is 3 each and minimum score is 0. Thus, the range for the total cumulative VARA score is 0 to 6 while the range in Sharp score is 0 to 314.

Correlations of the two systems were examined by calculating non-parametric Pearson correlations while formal agreement for the two approaches in capturing the presence of erosions and narrowing were assessed through calculation of a kappa coefficient. A sub-analysis was done to estimate time needed to complete the scoring for each individual set of radiographs.

Results: Of the RA patients examined (n=198), there were moderate and highly statistically significant correlations between the VARA and Sharp scores ($r = 0.66$, $p < 0.001$ for erosion score and $r = 0.68$, $p < 0.001$ for narrowing score). The average time needed for VARA scoring is 3.3 minutes, whereas time for the Sharp score is 7–9 minutes. Additionally, there is near perfect agreement between the 2 methods with highly significant p-values in the detection of any erosion or any joint space narrowing (kappa = 0.984 for erosion and kappa = 1.00 for narrowing; p-value < 0.001).

Conclusion: The VARA method demonstrates significant correlations with the standard radiographic Sharp scoring method. The average calculation time decreases by 2/3rd when VARA method is adopted and it appears to provide a meaningful quantitative measure of global joint involvement in RA at a single point of time. Potential disadvantages of this novel scoring method include limitations in sensitivity that may preclude its use in identifying small changes in disease progression over a period of time.

Nevertheless, the VARA method is a very practical method of radiographic scoring and may be particularly useful for observational studies and in clinical practice where quantitative assessments of joint damage at a single time point are needed.

1969

Ankle Joint Involvement In Rheumatoid Arthritis. An Ultrasound Study Using High Resolution- and Colour Doppler Ultrasound. Mohammed Alsuwaidi[1], Boris P. Ehrenstein[1], Martin Fleck[2] and Wolfgang Hartung[1]. [1]Asklepios Clinic Bad Abbach, Bad Abbach, Germany, [2]University Medical Center of Regensburg, Regensburg, Germany.

Background/Purpose: Despite a pivotal role for RA patients mobility, the ankle joints are frequently neglected, and omitted in activity scoring systems including DAS 28. In addition, only few studies have assessed pathologies detected by ultrasonography of the ankle in symptomatic RA patients (1). Therefore, the type and degree of involvement of the ankle joints were evaluated in established RA patients regardless of symptomatology or duration of illness utilizing standardized high resolution musculoskeletal ultrasound (MSUS) including colour Doppler ultrasonography (CDUS).

Methods: A total number of 89 ankle joints of 45 consecutive RA patients fulfilling the ACR/EULAR classification criteria 2010 were examined using MSUS (*Logic E9, GE Healthcare, Buckinghamshire, GB with* a *ML6–15 linear probe with 6–15 MHz*) and CDUS according to the EULAR MSUS guidelines (2). In addition, the talonavicular, the intertarsal- and the tarso-metatarsal joints were investigated. Furthermore, ankle pain (VAS score 0–10) and loss of function were recorded for each patient individually.

Results: 45 RA patients (32 female, 13 male) with a median age of 61 years (range 28–81) and a disease duration of 5 years (0–43 range) were enrolled in our study. The median DAS28 was 5,0 (range 0,8 −7,8). Ankle pain was recorded for 27 patients, whereas 18 patients were completely asymptomatic regarding the ankles. Overall, the predominant pathology was arthritis of the tibiotalar and/or talonaviclar joint in 64% of the patients (29 out of 45), followed by tenosynovitis of the flexor tendons in 44% of the patients (20 out of 45). Pathologic B-mode findings were observed in 85% of the symptomatic patients (23/27), however, also 61% of the asymptomatic patients (11/18) exhibited pathologic B-mode findings (p=0.06). CDUS activity was higher in the subgroup of symptomatic patients with 33% (9/27) compared to 17% of asymptomatic patients (3/18) (p=0.13), for detailed information table 1.

Pathologies Joints	Arthritis only tibiotalar	Arthritis tibiotalar and talonavicular	Arthritis only talonavicular	Tenosynovitis (M. tibialis posterior +/− or M. flexor digitorum)	CDUS positive Arthritis or Tenosynovitits
All ankles (n = 89)	29	16	1	20	12
Symptomatic patients (n = 27)	17	12	1	15	9
Asymptomatic patients (n = 18)	12	4	0	5	3

Conclusion: Most frequent pathologies detected by MSUS were arthritis of the tibiotalar and talonavicular joint, followed by tenosynovitis of the flexor tendons. Pathologic findings are also common in asymptomatic patients with RA, whereas CDUS activity is predominately observed in symptomatic patients.

1970

The Utility Of Fluorescence Optical Imaging For Detecting Clinically Silent Synovitis Of The Hands and Wrists. Yogan Kisten[1], Noémi Györi[2], Hamed Rezaei[1], Anna Karlsson[2], Carolina Romanus[2], Ronald van Vollenhoven[3] and Erik af Klint[1]. [1]The Karolinska Institute, Stockholm, Sweden, [2]Unit for Clinical Therapy Research Inflammaroty Diseases (ClinTRID) Department of Medicine, the Karolinska Insitute, Stockholm, Sweden, [3]Unit for Clinical Research Therapy. Inflammatory Diseases (ClinTrid), Karolinska Institute, Stockholm, Sweden.

Background/Purpose: The detection of subclinical synovial inflammation ("silent synovitis") would be of critical importance for the detection of rheumatoid arthritis (RA) in its earliest pathophysiological stage ("pre-RA"), and it has been suggested that ultrasound (US) with power Doppler (PD) can be a useful technology to achieve this. Fluorescence optical imaging (FOI,"Rheumascan") is a novel imaging modality for the hands based on the use of an intravenous fluorescence dye that allows imaging of the hands with increased optical signal in areas of high perfusion and/or capillary leakage. Here, we investigated whether FOI could be used in lieu of US/PD for ascertaining subclinical syovitis in the hands and wrists.

Methods: A total of 748 joints of the bilateral hands and wrists, including 3 wrist joints, 5 MCPs, 5 PIPs, and 4 DIPs in 22 patients (15 female, 7 male) aged between 19 and 84 years old, with inflammatory arthritis (RA:9, JIA, gout psoriatic arthritis, SLE, and other diagnoses, 1–2 each) were examined clinically, by US and FOI. Joints were considered clinically inflamed when both swollen and tender, and non-inflamed otherwise. Ultrasound was considered positive for synovitis if both thickening on grey scale and Doppler signal were present. FOI was considered positive by visual inspection of the images.

Results: Out of 748 joints, 71 (9%) were considered inflamed by clinical examination and 677 were not. Of the clinically non-inflamed joints, exactly 100 were inflamed by US. Of these joints, 80 were inflamed by FOI and 20 were not. Thus, the sensitivity of FOI for detecting sub-clinical synovitis when defined as a positive US in the absence of clinical inflammation was 80%. Out of the 577 joints that were non-inflamed clinically and non-inflamed by ultrasound, 26 had inflammation by FOI, yielding a specificity of 95%.

Conclusion: Under the assumption that US can correctly identify sub-clinical synovitis in clinically non-inflamed joints (using the combination of clinical examination and US as the "gold standard"), the sensitivity of FOI for detecting subclinical synovitis in the hands and wrists is 80% and the specificity 95%. These metrics suggest that it may be a useful tool in the setting of identifying patients with very early synovial inflammation of the hands and/or wrists.

1971

The Four Finger Examination Technique Is Superior To The Standard Two Finger Technique To Detect Metacarpal Phalangeal Joint Swelling In Rheumatoid Arthritis - A Validation By Power Doppler Ultrasound. Mohammed Omair[1], Pooneh Akhavan[1], Ali Naraghi[1], Deborah Weber[2], Shikha Mittoo[1], Melissa Weber[2], Juan Xiong[3] and Edward C. Keystone[1]. [1]Mount Sinai Hospital/University of Toronto, Toronto, ON, [2]Mount Sinai Hospital, Toronto, ON, [3]Mount Sinai Hospital, University of Toronto, Toronto, ON.

Background/Purpose: Swollen joints (SJs) are a strong clinical predictor of radiographic progression in rheumatoid arthritis (RA). The metacarpal phalangeal joints (MCP) SJs are particularly relevant since they are the earliest joints demonstrating radiographic progression. Thus, more sensitive detection of less obvious SJs is important for improved assessment of disease activity.

A novel four finger (FF) examination technique was developed to be more sensitive than the two finger (TF) technique in the detection of less clinically apparent joint swelling.

Methods: To compare the sensitivity of the FF vs. TF technique to detect synovitis by ultrasound (US). We compared the FF vs. TF examination technique in 180 MCPs in 18 RA patients. The population was comprised of 94.4% females, mean age of 55.8 years and mean disease duration of 19.9 yrs. Patients were examined twice on the same day by 4 rheumatologists; 2 performed FF and 2 used the TF technique. SJs

were determined by palpation defined by being either (1) ballotable or (2) spongy (non-ballotable swelling). TJs were also assessed. We evaluated the agreement between the SJ/TJ examination techniques with US using grey scale, power Doppler (PD) positivity, or the presence of an effusion.

Results: Consistent with previous literature, the inter-observer agreement (IA) using Kappa statistics was poor to moderate for both SJ techniques. We therefore evaluated only joints in which there was agreement between the 2 examiners for each SJ technique. With the TF and FF techniques respectively, there were 115 & 134 SJs in which there was agreement for the joints being ballotable and 99 & 122 SJs for being spongy. The Kappa agreement between FF and TF techniques respectively, for ballottement by PD was 0.55 vs 0.27; by grey scale 0.35 vs. 0.12, and by effusion: 0.18 vs. 0.08. For SJ detected by being spongy, the relationship between FF and TF was the same, but the Kappas were lower. The agreement between TJs and US was extremely poor with mean Kappas for the 4 examiners for PD of 0.07; for grey scale: 0.06 and for effusion: −0.08.

Conclusion: The results of this study demonstrate that for MCPs, the FF technique is more sensitive than the TF technique for detection of synovitis as determined by US and therefore a better examination technique for clinical decision making. Of significance, the data provide strong support for the importance of detecting SJs (rather than TJs) as a prognostic guide for structural damage in RA.

1972

Erosion Case Definition and Scoring Reliability Exercise Using a New Outcome Measurement Tool, High-Resolution Peripheral Quantitative Computed Tomography, In Rheumatoid Arthritis. Cheryl Barnabe[1], Dominique Toepfer[2], Hubert Marotte[3], Ellen-Margrethe Hauge[4], Andrea Scharmga[5], Roland Kocijan[6], Sebastian Kraus[2], Kresten K. Keller[4], Joost de Jong[5], Jeroen Williams[5] and Stephanie Finzel[2]. [1]University of Calgary, Calgary, AB, [2]University of Erlangen-Nuremberg, Erlangen, Germany, [3]Inserm U1059, Saint-Etienne, France, [4]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark, [5]Maastricht University, Maastricht, Netherlands, [6]Academic Teaching Hospital of Medical University Vienna, Vienna, Austria.

Background/Purpose: High-resolution peripheral quantitative computed tomography (HR-pQCT) is a novel imaging instrument for bony damage in rheumatoid arthritis (RA). Agreement on a case definition for pathologic erosions is required given the sensitivity of HR-pQCT for detecting cortical bone disruptions. The reliability of erosion detection and measurement between readers is crucial to evaluate with this new technology, as HR-pQCT is undergoing validation as an outcome measurement tool.

Methods: HR-pQCT images of the 2nd and 3rd metacarpophalangeal joints of RA patients and control subjects were used in an iterative process to achieve consensus on a case definition for erosions. This case definition was applied by 10 independent readers to score 82 joints. Each surface (radial, ulnar, palmar, dorsal) of the proximal phalanx and metacarpal head were characterized for image quality, the presence of a cortical break, the appearance of the cortical defect (physiological or pathological) and a total count of the number of pathologic erosions. Pathologic erosions were further characterized in 2 perpendicular planes for their maximum width and depth.

Results: The case definition of erosion was based on the size and shape of the defect so as to eliminate physiological (eg vessel channel) defects. Of the 656 surfaces analyzed in the reliability exercise, 6 (0.9%) were felt to be of inadequate quality for analysis by the 10 readers and were removed. Inter-reader reliability for erosion detection was excellent with a kappa score of 0.9024 ($p<0.0001$), with higher kappa scores between experienced readers. Images with discrepant scoring by more than 2 readers were reviewed as a group a second time, with resolution of all cases except for 2 which were lower quality images with multiple bony pathologies overlapping each other(eg vessel channels with superimposed osteophytes masquerading as erosions). Erosion size ranged from 0.16 to 0.89 mm in maximal width and 0.028 to 0.801 mm in maximal depth, with up to 6.3% variability in measurement between readers.

Conclusion: We have devised a new case definition for erosions visualized with a novel sensitive imaging tool. Inter-reader reliability for erosion detection and measurement is high, yielding promise to use HR-pQCT as an outcome measurement tool for bony damage.

1973

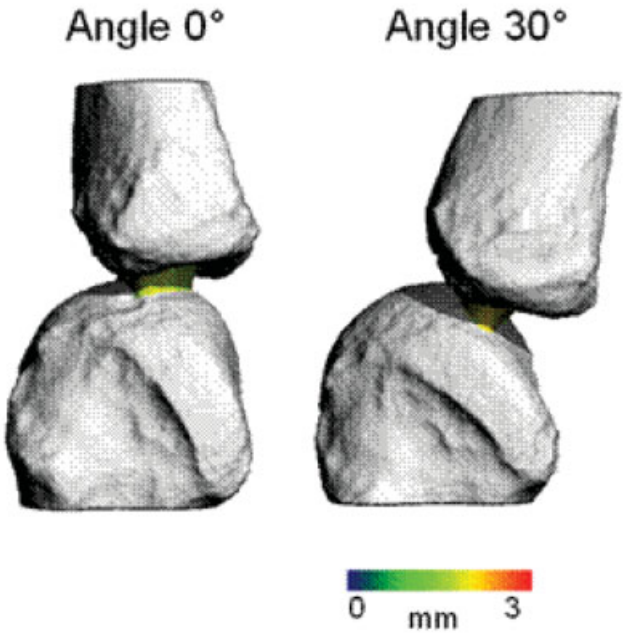
Importance Of Hand Positioning In 3D Joint Space Morphology Assessment. Stephanie Boutroy[1], Elodie Hirschenhahn[1], Emile Youssof[2], Hervé Locrelle[2], Thierry Thomas[2], Roland Chapurlat[3] and Hubert Marotte[2]. [1]INSERM U1033 and University of Lyon, Hôpital Edouard Herriot, Lyon, France, [2]INSERM U1059 and University Hospital, Hôpital Nord, Saint-Etienne, France, [3]INSERM UMR 1033 and University of Lyon, Hôpital Edouard Herriot, Lyon, France.

Background/Purpose: Precise quantification of joint space morphology (JSM) is an important factor for early diagnosis and monitoring of disease activity and therapeutic responses in rheumatoid arthritis (RA). Patients with active RA usually present painful, stiff and swollen joints and have difficulties in stretching their joints. Positioning of these patients is a major concern for accurate assessment as it is responsible for an important variability in cross-sectional and longitudinal studies.

We have developed a method to characterize 3D JSM of the metacarpophalangeal (MCP) joint by high resolution peripheral quantitative computed tomography (HR-pQCT). We assessed the impact on JSM of measurements performed with a 0° and a 30° flexion of the MCP joints, which we assume would be convenient for most active RA patients.

Methods: We performed HR-pQCT on the second metacarpophalangeal (MCP) joints of twelve *ex vivo* hands (3 men, 3 women, mean age = 77±9 yrs) and developed an automated algorithm to compute joint space volume (JSV), mean, minimal and maximal joint space width (JSW, JSW.MIN, JSW.MAX), as well as its distribution (JSW.SD) and asymmetry (JSW.AS, ratio of JSW.MAX over JSW.MIN). MCPs were scanned with a 0° and a 30° degree angle, with an inclined custom cast. The effects of different hand positioning were assessed by paired t-test.

Results: Angles between metacarpal and phalangeal bones were retrospectively verified on the reconstructed 3D images, with mean values of 5.2±4.5° (ranging from 0° to 12°) and 29.5±3.7° (ranging from 25° to 35°).



Positioning markedly impacted the mean and maximum values of joint space width. JSW was 16.4% thicker (2.00±0.38 vs. 1.72±0.30 mm; p=0.001) and JSW.MAX was increased by 12.5% (2.32±0.34 vs. 2.07±0.34 mm; p=0.001) when measured at 30° compared to 0° respectively. Its impact was less marked on joint space volume (64±22 vs. 59±17 mm^3; 8.9%; p=0.29), minimum joint space width (1.28±

0.22 vs. 1.18±0.31 mm; 8.7%; p=0.23) and asymmetry of joint space width (1.85±0.30 vs. 1.68±0.42; 10.2%; p=0.09), at 30° compared to 0° respectively. The heterogeneity of the joint space width (JSW.SD) was not affected by hand positions (0.22±0.09 vs. 0.21±0.08 mm; p=0.88).

Conclusion: This study suggests that positioning remains a major concern even with a 3D quantification of JSM. On the basis of active RA patient comfort, the use of a fixed-inclined cast would probably be the most appropriate method to accurately follow-up disease activity.

1974

Assessing Validity Of Low Field Magnetic Resonance Imaging (MRI) for Joint Inflammation and Damage In Wrist/Hand Rheumatoid Arthritis (RA) - A Systematic Literature Review (SLR). OM Troum[1], OL Pimienta[1], TG Woodworth[2], O Morgacheva[2], V Ranganath[3] and D E Furst[2]. [1]Keck School of Medicine, University of Southern California, Los Angeles, CA, [2]David Geffen School of Medicine, University of California, Los Angeles, CA, [3]David Geffen School of Medicine, UCLA, Los Angeles, CA.

Background/Purpose: Radiographic scoring of erosions and joint space narrowing (JSN) of the hand/wrist is standard to evaluate RA joint damage for regulatory approval of DMARDs; however, MRI has demonstrated its superiority in assessing joint inflammation and damage in clinical trials. MRI field strength impacts feasibility, image quality and cost. Measurement methods using high field (hf) ≥1.0 tesla (T) MRI requires large machines and specialized space. Low field (lf) <1.0T MRI has also demonstrated utility in clinical trials and is easily performed in a clinical office setting. We report the results of an SLR examining Outcome Measures in Rheumatology Clinical Trials (OMERACT) RA MRI scoring (RAMRIS) validation for lf images of RA wrist/hand.

Methods: We searched PubMed with Cochrane hedge for articles from 1970 to Aug 2012 using search terms enabling relevant data extraction. Data included: demographics/RA features in adults, MRI field strength (<1.0 T), wrist/hand images assessing ≥1 joint feature: synovitis, bone marrow edema (BME)/osteitis, erosions, JSN, tenosynovitis, in addition to measurement method and validity evidence. We applied OMERACT validity definitions: face, criterion, content, construct, also assessing reliability, responsiveness, discrimination, and feasibility. Quality was determined by Cochrane Handbook criteria, adapted for imaging research.

Results: 35 lf MRI articles met criteria for extraction. RAMRIS was most often used, as with our previous SLR evaluating ≥1.0T MRI. Altogether, 16 articles using <1.0T/RAMRIS were analyzed, seeking validated MRI measures: 0.2T (13 articles, including 3 RCTs), 0.6T (2 articles), and 0.3T (1 article). 5 articles compared lf to high field (hf) MRI. Table 1 shows lf MRI validation data. There is indirect criterion validity for synovitis and erosions: 2 articles compared lf to hf MRI for synovitis and 2 others for erosions. One study provided good erosion score correlation between lf MRI and computed tomography, and another one with x-ray. Validating data with 0.2T included prediction of x-ray progression, sensitivity to change by 4 weeks, and intra/inter reliability for synovitis, BME, and erosions. Data currently lacking include discrimination for synovitis, BME, erosions, construct discriminant for erosions, and validation for JSN or tenosynovitis.

Table 1. Number of articles providing validity data for RAMRIS measurement with lf MRI

Validity Feature	Content	Construct Discriminant	Construct Convergent	Responsiveness to change	Intra-rater reliability	Inter-rater reliability	Discrimination
Definition	Measures across age range, disease duration, treatments	Correlation with clinical assessment of joint status	Correlation between scores - same health component- 2 different instruments	Sensitivity to change	Within reader ICCs	≥2 readers ICCs	Differentiates between treatment groups
Synovitis	+7	+3	+2	+4	+3	+4	0
Osteitis/BME	+4	+1	+4	+3	+3	+2	0
Erosions	+7	0	+3	+5	+4	+3	0
JSN	0	0	0	0	0	0	0
Tenosynovitis	+1	0	0	0	0	+1	0

Conclusion: Using a rigorous PRISMA-compliant SLR to examine low field MRI/RAMRIS of the RA wrist/hand, we found 0.2T MRI is partially validated to measure synovitis, BME/osteitis, and erosions. To finalize validation, evidence for discrimination between treatment groups for synovitis, BME, erosions, and discriminant construct validity for erosions are needed.

1975

Cardiovascular Risk Stratification In Rheumatic Diseases: Carotid Ultrasound Is More Sensitive Than Coronary Artery Calcification Score To Detect Subclinical atherosclerosis In Patients With Rheumatoid Arthritis. Francisco Ortiz-Sanjuán[1], Alfonso Corrales[2], José Antonio Parra[3], Carlos González-Juanatey[4], Montserrat Santos[1], Javier Rueda[1], Ricardo Blanco[2], Vanesa Calvo-Río[1], Javier Loricera[1], Javier Llorca[5] and Miguel A González-Gay[1]. [1]Hospital Universitario Marqués de Valdecilla. IFIMAV. Santander. Spain, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain, [3]Radiology Division, Hospital Universitario Marqués de Valdecilla, Santander, Spain, [4]Cardiology Division, Hospital Lucus Augusti, Lugo, Spain, [5]School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), Santander, Spain.

Background/Purpose: Rheumatoid arthritis (RA) is a disease associated to accelerated atherogenesis leading to increased incidenceof cardiovascular (CV) mortality. Adequate stratification of the CV risk in patients with RA is still far from being completely established. Several validated noninvasive imaging techniques may be useful to determine subclinical atherosclerosis, such as the assessment of carotid intima-media thickness (cIMT) and the presence of plaques by carotid ultrasonography (US) and the assessment of coronary artery calcification (CAC) by the Multi-Detector Computed Tomography (MDCT). Objective: To determine the ability of CAC Score (CACS) and carotid US to detect subclinical atherosclerosis in patients with RA.

Methods: A set of 104 consecutive RA patients without history of CV events was studied to determine CACS, cIMT and carotid plaques. The Systematic Coronary Risk Evaluation (SCORE) modified according to the EULAR recommendations (mSCORE) was also assessed.

Results: The mean disease duration was 10.8 years, 72.1% had rheumatoid factor and/or anti-CCP positivity and 16.4% extra-articular manifestations. Nine were excluded because they had type 2 diabetes mellitus or chronic kidney disease. CV risk was categorized in the remaining 95 RA patients according to the mSCORE as follows (Table 1): low (n=21), moderate (n=60) and high/very high risk (n=14). Most patients with low mSCORE (16/21; 76.2%) had normal CACS (zero), and none of them CACS>100. However, a high number of patients with carotid plaques was disclosed in the groups with CACS 0 (23/40; 57.5%) or CACS 1–100 (29/38; 76.3%). Seventy-two (75.8%) of the 95 patients fulfilled definitions for high/very high CV as they had mSCORE ≥5% or mSCORE <5% plus one of the following findings: severe carotid US findings (cIMT>0.9 mm and/or plaques) or CACS>100 (Table 2). A CACS>100 showed sensitivity similar to mSCORE (23.6% versus 19.4%). In contrast, the presence of severe carotid US findings allowed identifying most patients that met definitions for high/very high CV risk (70/72; sensitivity 97.2% [95% CI: 90.3–99.7]).

Table 1. SCORE risk, mSCORE risk im 95 RA patients without CV events. EULAR mSCORE according to the CACS>100, cIMT > 0.90 mm and carotid plaques

	SCORE	mSCORE	mSCORE CACS	mSCORE Carotid US cIMT	mSCORE Carotid US	mSCORE Carotid US cIMT >0.90 mm and/or carotid plaques n=70 (%)
Cardiovascular Risk	n	n	CACS >100 n = 17 (%)	>0.90 mm n=14 (%)	Carotid plaques n=69 (%)	
Low (<1%)	21	21	0/21 (0.0)	0/21 (0.0)	7/21 (33.3)	7/21 (33.3)
Moderate (≥1% and <5%)	63	60	12/60 (20.0)	8/60 (13.3)	51/60 (85.0)	51/60 (85.0)
High (≥ 5% and <10%)	9	10	4/10 (40.0)	5/10 (50.0)	8/10 (80.0)	9/10 (90.0)
Very High (≥10%)	2	4	1/4 (25.0)	1/4 (25.0)	3/4 (75.0)	3/4 (75.0)
High plus Very High	11	14	5/14 (35.7)	6/14 (42.8)	11/14 (78.6)	12/14 (85.7)

Table 2. Sensitivity of high/very high CV risk in RA patients without CV events, using EULAR mSCORE, carotid US findings (cIMT>0.90 mm or plaques) or CACS >100

Gold standard	n=72/95
mSCORE >5%	n=14 of 72 19.4% (95% CI:11.1–30.5)
CACS >100	n=17 of 72 23.6% (95% CI:14.4–35.1)
cIMT >0.90 mm and/or carotid plaques	n=70 of 72 97.2% (95% CI: 90.3–99.7)
mSCORE >5% or mSCORE <5% plus CACS >100	n=26 of 72 36.1% (95% CI:25.2–48.3)
mSCORE >5% or nSCORE <5% plus one of the following: cIMT >0.90 mm or carotid plaques	n=72 of 72 100% (95% CI:95.0–100)

Note: Gold Standard for high/very high cardiovascular risk: a) mSCORE ≥5% or b) mSCORE <5% plus one of the following: severe carotid US findings (cIMT>0.90 mm or carotid plaques) or CACS>100

Conclusion: Carotid US is more sensitive than CACS for the detection of subclinical atherosclerosis in RA.

1976

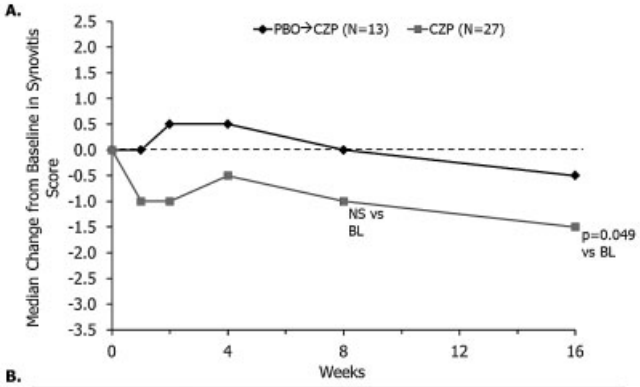
Magnetic Resonance Imaging-Assessment Of Early Response To Certolizumab Pegol In Rheumatoid Arthritis: A Randomized, Double-Blind, Placebo-Controlled Phase IIIb Study Applying Magnetic Resonance Imaging At Week 0, 1, 2, 4, 8 and 16. Mikkel Ostergaard[1], Lennart Jacobsson[2], Christopher Schaufelberger[3], Michael Sejer-Hansen[4], Johannes Bijlsma[5], Anna Dudek[6], Maria Rell-Bakalarska[7], Fabienne Staelens[8], Robert Haake[9], Britt Sundman-Engberg[10] and Henning Bliddal[11]. [1]Copenhagen Center for Arthritis Research, Glostrup, Denmark, [2]Section of Rheumatology, Malmö, Sweden, [3]Sahlgrens' Hospital, Göteborg, Sweden, [4]Rheumatology Clinic, Copenhagen, Denmark, [5]University Medical Center, Utrecht, Netherlands, [6]Medica Pro Familia, Warsaw, Poland, [7]Rheuma Medicus, Warsaw, Poland, [8]UCB Pharma, Brussels, Belgium, [9]UCB Pharma, Raleigh, NC, [10]UCB Pharma, Stockholm, Sweden, [11]Department of Rheumatology, Frederiksberg, Denmark.

Background/Purpose: The OMERACT rheumatoid arthritis (RA) magnetic resonance imaging (MRI) scoring system (RAMRIS) is a validated scoring system for assessment of synovitis, bone edema and bone erosion. Previous studies have reported that TNF inhibitors improve RAMRIS scores, but it is not known how early this occurs. The rapid clinical efficacy of certolizumab pegol (CZP), a PEGylated Fc-free anti-TNF, in RA has been reported.[1] This study aimed to identify the first time point of a MRI-verified response to CZP in RA patients.

Methods: MARVELOUS (NCT01235598) is a Phase IIIb multicenter, randomized, double-blind (DB), placebo (PBO)-controlled (during initial 2 weeks) study. Eligible patients were randomized (2:1) to receive either CZP Q2W (400mg at Wks 0–4, then 200mg every 2 weeks to Wk16) or PBO at Day 0, then CZP Q2W (400mg Wks 2–6, then 200mg every 2 weeks to Wk16). Contrast enhanced MRI of one hand and wrist was acquired at Baseline (Wk0) and Wks 1, 2, 4, 8 and 16. Primary endpoint was change from Wk0 in OMERACT RAMRIS synovitis score in the CZP group. The first significance test was conducted at Wk16 and continued to earlier time points if prior test proved significant. All MRIs were analyzed by an experienced reader, blinded to subject identity, study treatment and time point; all six time points were read simultaneously. Change in bone edema, bone erosion and clinical parameters were secondary outcomes. LOCF imputation was used for synovitis and observed data for other outcomes. Safety variables were also assessed, including AEs, and laboratory parameters.

Results: 40 pts were randomized and treated: CZP group n=27 and PBO–CZP n=13. During the DB phase, 4 patients discontinued treatment (1 PBO, 3 CZP). In the CZP group a significant reduction from baseline in synovitis score was reported at Wk16 (median change= −1.5, p=0.049) (Figure A); reductions in synovitis score were not significant at Wk8, precluding further testing of earlier time points. In the CZP group, bone edema score was also significantly reduced at Wk16 (−2.5, p=0.031) (Figure B), whereas there was no significant change from Wk0 in bone erosion score. For all RAMRIS parameters (synovitis, bone edema, bone erosion), very good intra-reader reliability (intra-class correlations >0.90) was observed. Most AEs were mild or moderate, with low incidence of withdrawals due to AEs. There were no serious infections or deaths.

Figure: A. Median change from baseline in synovitis score; B. Synovitis and bone edema scores.



B.

Outcome	CZP (N=27) Week 1	Week 2	Week 4	Week 8	Week 16
CFB Synovitis Score (estimated using Hodges-Lehmann median) (95% CI)	-1.0 (-2.5,0.0)	-1.0 (-2.0,0.5)	-0.5 (-1.5,0.5)	-1.0 (-3.0,0.0; NS)	-1.5 (-3.0,0.0; p=0.049)
CFB Bone Edema Score (estimated using Hodges-Lehmann median) (95% CI)	-1.0 (-2.5,1.0)	0.0 (-1.5,1.0)	-1.0 (-2.5,0.0)	-1.0 (-3.0,1.0; NS)	-2.5 (-5.0,0.0; p=0.031)

For CZP change from BL, the first significance test was conducted at Wk16, and continued to earlier time points if prior test proved significant. Once a non-significant result was obtained no further testing was allowed. BL: Baseline; CFB: Change from Baseline; CI: Confidence Interval; CZP: Certolizumab Pegol; NS: Non-Significant; PBO: Placebo

Conclusion: In this first study with multiple MRIs following initiation of biological therapy, CZP successfully reduced the OMERACT RAMRIS synovitis and bone edema score as measured by MRI as early as Wk16, despite small sample size and the technical challenges of reading 6 time points simultaneously. This study documents the effect of CZP and provides essential information on the optimal timing of MRI and sample sizes for subsequent larger clinical trials.

1977

Remission At 3 Or 6 Months and Radiographic Non-Progression At 12 Months In Methotrexate-Naïve Rheumatoid Arthritis Patients Treated With Tofacitinib Or Methotrexate: A Post-Hoc Analysis Of The ORAL Start Trial. V. Strand[1], D. van der Heijde[2], R. Landewe[3], E. B. Lee[4], B. Wilkinson[5], S. H. Zwillich[5], J. Bradley[5], C. Mebus[5], B. Benda[6] and D. Gruben[5]. [1]Stanford University, Palo Alto, CA, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Academic Medical Center / University of Amsterdam, Amsterdam, Netherlands, [4]Seoul National University, Seoul, South Korea, [5]Pfizer Inc, Groton, CT, [6]Pfizer Inc, Collegeville, PA.

Background/Purpose: Tofacitinib is a novel, oral Janus kinase (JAK) inhibitor for the treatment of RA. The importance of "treat to target" in RA to attain remission and subsequently prevent structural damage is established.

Objectives: To examine the relationship between attainment of clinical remission at Months (Mo) 3 or 6 with inhibition of radiographic progression at Mo 12 in methotrexate (MTX)-naïve patients (pts) in the Phase 3, 24-mo ORAL Start trial (NCT01039688). Pre-planned interim 1-year analyses, including primary efficacy endpoints, were reported previously.[1]

Methods: 952 pts were randomized 2:2:1 to tofacitinib 5 mg BID, 10 mg BID or MTX. Endpoints included remission defined by DAS28-4(ESR) <2.6, SDAI ≤3.3, CDAI ≤2.8 and ACR-EULAR Boolean-based criteria by

observed data and van der Heijde modified Total Sharp Score (mTSS) linear extrapolation; the definition of non-progression was change from baseline in mTSS ≤0.5. Rates were calculated for radiographic non-progression at Mo 12 by remission at Mo 3 or 6.

Results: Across all definitions of remission, rates at Mo 3 and 6 were lower with MTX (3–8% and 11–14%; N=186) than tofacitinib 5 (29–46% and 37–49%; N=371) and 10 mg BID (39–64% and 73–84%; N=395). The positive predictive values of remission by various criteria at Mo 3 or 6 for radiographic non-progression at Mo 12 are presented in the table. Across all definitions of remission, a high proportion of pts receiving tofacitinib 10 mg BID in remission at Mo 3 and 6, respectively, had no radiographic progression at Mo 12 (94–95% and 89–92%). For pts receiving tofacitinib 5 mg BID, 69–80% were in remission at Mo 3 and had no radiographic progression at Mo 12, according to the stringency of the definition utilized, which increased to 78–85% for Mo 6 remission. 83–100% of the few patients on MTX in remission at Mo 3 or 6 had no radiographic progression at Mo 12. The proportion of pts who failed to achieve radiographic non-progression at Mo 12 following remission at Mo 3 and 6 (not shown in table) were: tofacitinib 5 mg BID, 18–31% and 15–22%; tofacitinib 10 mg BID, 5–15% and 7–14%; MTX, 0–36% and 7–38%, respectively. Among the patients who did not achieve remission at Mo 3 and 6 (not shown in table), more pts receiving tofacitinib still achieved radiologic non-progression than with MTX (tofacitinib 5 mg BID, 80–83% and 82–84%; tofacitinib 10 mg BID, 85–94% and 85–92%; MTX, 63–100% and 60–93%).

	Tofacitinib 5 mg BID (N=371) (n/N) % [95% CI]	Tofacitinib 10 mg BID (N=395) (n/N) % [95% CI]	Methotrexate (N=186) (n/N) % [95% CI]
Remission Criteria^ at Month 3 to Positively Predict Nonprogression@ in mTSS at Month 12			
DAS28-4(ESR)	**(36/46)**78.3% [63.6,89.1]	**(60/64)**93.8% [84.8,98.3]	**(8/8)**100.0% [63.1,100.0]
SDAI	**(28/35)**80.0% [63.1,91.6]	**(51/54)**94.4% [84.6,98.8]	**(4/4)**100.0% [39.7,100.0]
CDAI	**(26/33)**78.8% [61.1,91.0]	**(42/44)**95.5% [84.5,99.4]	**(5/6)**83.3% [35.9, 99.6]
ACR-EULAR Boolean	**(20/29)**69.0% [49.2,84.7]	**(37/39)**94.9% [82.7,99.4]	**(3/3)**100.0% [29.2,100.0]
Remission Criteria^ at Month 6 to Positively Predict Nonprogression@ in mTSS at Month 12			
DAS28-4(ESR)	**(41/49)**83.7% [70.3,92.7]	**(70/78)**89.7% [80.8,95.5]	**(12/13)**92.3% [64.0, 99.8]
SDAI	**(37/44)**84.1% [69.9,93.4]	**(77/84)**91.7% [83.6,96.6]	**(13/14)**92.9% [66.1, 99.8]
CDAI	**(35/41)**85.4% [70.8,94.4]	**(72/78)**92.3% [84.0,97.1]	**(12/13)**92.3% [64.0, 99.8]
ACR-EULAR Boolean	**(29/37)**78.4% [61.8,90.2]	**(68/73)**93.2% [84.7,97.7]	**(10/11)**90.9% [58.7, 99.8]

^Remission definitions: DAS28-4(ESR), Disease Activity Score for 28-joint counts and erythrocyte sedimentation rate <2.6; SDAI, simplified disease activity index ≤3.3; CDAI, clinical disease activity index ≤2.8; ACR-EULAR Boolean requires ≤1 swollen and ≤1 tender joint, Patient Global (0–10) ≤1, C-Reactive Protein (mg/dL) ≤1.
@Nonprogression in modified Total Sharp Score (mTSS) (change ≤0.5) at Month 12, imputed using linear extrapolation.

Conclusion: These results indicate that clinical remission within 3 or 6 months of treatment initiation has limited value in predicting radiological non-progression at Mo 12 in MTX-naïve RA pts treated with tofacitinib. This may be due to the high proportion of pts achieving radiological non-progression with tofacitinib treatment overall, in that pts who do not achieve remission criteria at Mo 3 or 6 may still benefit from structure preservation through Mo 12.

The Effect Of Certolizumab On Lymphatic Volume and Flow In Rheumatoid Arthritis Patients With Acute Flare. Homaira Rahimi, Vaseem Chengazi, Gregory Dieudonne, Edward M. Schwarz and Christopher T. Ritchlin. University of Rochester, Rochester, NY.

Background/Purpose: Episodic flare occurs in rheumatoid arthritis (RA) but the mechanisms of this process are not well understood. Our prior reports on MRI analysis of joints in murine arthritis models showed expanded volume and increased contrast enhancement in the popliteal node draining inflamed knees prior to arthritic flare. In the expanded node, B cells translocate to paracortical sinuses, the node suddenly collapses and there is loss of efferent lymphatic drainage and rapid onset of synovitis. Two models of flare dependent on disease duration were identified. In acute flare, joint inflammation overwhelms the lymphatics and can be effectively treated with anti-inflammatories (i.e. anti-TNF). However, mice with chronic arthritis that flare lack an efferent lymphatic pulse and are unable to normalize lymphatic function or mediate arthritic flare. To examine if similar lymph node (LN) volume and lymphatic function is altered in adult RA patients, we performed MRIs of affected joints and LN and measured lymphatic flow in RA patients with acute flare, before and after certolizumab therapy.

Methods: Eight RA patients with active flare of a single wrist or knee underwent 3T pre and post contrast MRIs at baseline and 18 weeks after certolizumab. LN volumes of the popliteal or epitrochlear nodes were quantified. A subset of 3 patients underwent radiocolloid Technetium sulfur tracing (RTS) to assess lymphatic flow in the affected and unaffected extremity. RTS studies were read by a radiologist blinded to the extremity with joint flare.

Results: Of eight patients, all had improvement in disease activity score (DAS) and all six of eight with LN noted on MRI had alterations of total LN volume (Table 1.) Of those six patients, all but one had a decrease in total LN volume. Three patients underwent RTS and MRI. Patient 1 had foot- inguinal transit time (tt) of 15min to the affected extremity that increased after treatment to 65min (normal tt is 60min), showing normalization of lymphatic flow after treatment. Patient 2 had foot -inguinal tt of 15min to the affected extremity that increased after treatment to 24min, showing deceleration in lymphatic flow. Patient 7 had long standing disease and markedly decreased lymphatic flow (hand-axillary tt >75 min, normal tt is 30min) prior to treatment that did not change with therapy; no nodes were visible on MRI pre or post treatment.

Table 1.

Patient	Disease Length (yr)	LN Volume (mm^3) Pretreat	LN Volume (mm^3) Posttreat	DAS 0 mo	DAS 6 mo	ΔLN volume	ΔDAS
1	0.5	1309	891	6.14	5.13	−0.32	−0.17
2	8	4613	3037	4.93	3.45	−0.34	−0.30
3	7	3701	2124	6.41	4.07	−0.43	−0.37
4	1	5126	6601	3.94	2.45	+0.32	−0.38
5	6	622	464	5.26	2.1	−0.36	−0.60
6	0.5	134.9	742	5.23	4.35	−0.45	−0.17
7	17	0	0	3.7	1.81	0	−0.51
8	10	0	0	5.34	4.87	0	−0.09

Conclusion: LN volume and lymphatic flow are altered in response to anti-TNF therapy. Specifically, total LN volume decreased with certolizumab and patients with shorter disease duration appear to improve lymphatic flow, whereas patients with long-standing disease may not normalize lymphatic flow. Thus, similar to murine inflammatory arthritis, there may be an early versus chronic model of arthritic flare in which lymphatic function is a key factor and treatment response may depend on how severely lymphatic function is compromised.

Occupational Balance Questionnaire: From People's Perspectives To A Patient Reported Outcome. Mona Dür[1], Gunter Steiner[1], Michaela Stoffer[1], Alexandra Kautzky-Willer[1], Veronika Fialka-Moser[1], Clemens Dejaco[1], Birgit Prodinger[2], Alexa Binder[3], Josef S. Smolen[4] and Tanja A. Stamm[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Swiss Paraplegic Group, Nottwil, Switzerland, Notwill, Switzerland, [3]Hospital Goettlicher Heiland, Vienna, Austria, [4]Medical University of Vienna and Hietzing Hospital, Vienna, Austria.

Background/Purpose: Occupational balance is one of the foundations on which occupational therapy is based. Occupational balance is defined diversely and mainly derived from the perspective of occupational therapists.

Empirical evidence for occupational balance, as well as instruments to assess occupational balance based on qualitative analysis is scarce. The aim of the present project was to develop a questionnaire on occupational balance and explore measurement properties in the data of people with and without chronically autoimmune diseases.

Methods: The study consisted of three parts: a development of the occupational balance questionnaire based on a qualitative study, an exploration of its internal consistency and content validity conducted with Rasch analysis, and a suggestion for a revised version. Findings of the Rasch analysis and patient feedback were used to develop a revised version of the questionnaire. A German version was designed first which was translated back and forward into an English version according to the standard procedure by three native speakers. Patients were involved into item generation. This study was a part of a larger study, named the GOBI study – Gender, Occupational balance and Immunology.

Results: We developed seven questionnaire items based on the analysis of the life stories of 90 people with and without chronic autoimmune diseases (table 1). The inclusion of people's perspectives into item generation, contributes to the content validity of the questionnaire. The Rasch analysis of the data from 251 people, 132 patients with rheumatoid arthritis, 43 patients with systemic lupus erythematous and 76 healthy people showed a person separation index of 0.51. These findings indicate questionable internal consistency and that occupational balance might not be a unidimensional construct. Consequently, a revised version was developed with the involvement of 10 further patients and 10 healthy people.

Table 1. Items of the revised occupational balance questionnaire

Nr.	Item
1	How often do you find your activities of daily living too simple?
2	How often do you find your activities of daily living too difficult?
3	Do you generally receive enough appreciation for activities of daily living?
4	How much is your health affected by your activities of daily living?
5	Do you get enough rest and sleep?
6	Do your daily activities provide sufficient alternations between active and non-active actions, such as an alteration to posture or physical position, perhaps between sitting and standing?
7	How well can you adapt your activities of daily living to changed living conditions, such as a changed state of health, a change of profession, or a change in the family circle?
8	Could you take sufficient care of yourself while caring for another (such as a family member, loved one, etc.)?

Conclusion: To our knowledge, this is one of the first studies, developing a patient reported outcome measure for occupational balance using qualitative research, the involvement of patients into item generation, and an exploration of internal consistency and construct validity in quantitative data. In this study we found seven underlying dimensions of occupational balance on which we based the questionnaire items. The findings of the Rasch analysis resulted in a need of a revised version which needs to be validated in further research.

1980

Validation Of The Fox-Walk Test In People With Rheumatoid Arthritis. Birgitta Nordgren[1], Cecilia Fridén[1], Eva Jansson[2], Ted Österlund[3], Wilhelmus Johannes Andreas Grooten[1], Christina H. Opava[2] and Anette Rickenlund[2]. [1]Karolinska Institutet, SE 14183 Huddinge, Sweden, [2]Karolinska Institutet, Huddinge, Sweden, [3]Karolinska University Hospital, Huddinge, Sweden.

Background/Purpose: Aerobic capacity tests are important to evaluate exercise programs and to encourage individuals to a physically active lifestyle. Maximum aerobic tests in a laboratory setting are expensive and not always feasible for people with RA. Therefore several self monitoring submaximal tests have been developed. The Fox-walk test was designed to make it possible for healthy individuals to monitor their aerobic capacity themselves. The test is performed on tracks of different lengths and are located at several public places throughout Sweden and some other European countries. The test has earlier been shown to be reliable in people with RA. The aim of our study was to validate the Fox-walk test against measured maximum oxygen uptake (measured VO_{2max}) in people with RA.

Methods: Twenty seven subjects (81% female), mean (SD) age 62 (8.1) diagnosed with RA since 17.2 (11.7) years, activity limitation with the Stanford Health Assessment Questionnaire, (HAQ) 0.412 (0.421) and DAS 28, 2.44 (0.82) participated in the study. The subjects performed the measured VO_{2max} (Alpha version 4.5, Jaeger, KFA-2028-01) and a 774 m Fox-walk test track within one week. To estimate VO_{2max}, the walking time was recorded and age, gender, BMI, the height of the person and the topography of the track was taken into account.

Results: Mean (SD) for the measured VO_{2max} and the Fox-walk test was 33.2 (7.8) ml/kg/min and 44.2 (7.1) respectively. There was a significant difference between the two tests ($p<0.0001$). The correlation between the two tests was moderate, $r = 0.52$, ($p = 0.006$) and showed an overestimation of aerobic capacity in the Fox-walk test compared to the measured VO_{2max} test.

Conclusion: Since our earlier study showed high reliability of the Fox-walk test and the present study showed a moderate correlation compared to the measured VO_{2max} test, it could be recommended as an easy way to monitor aerobic capacity without supervision from health professionals. However, most people were overestimated in the Fox-walk test and the formula could possibly be adjusted to people with RA.

1981

Developing International Consensus Definitions Of Improvement For Adult and Juvenile Dermatomyositis and Polymyositis. Saad Feroz[1], Nicolino. Ruperto[2], Jiri Vencovsky[3], Peter A. Lachenbruch[1], Brian Erman[4], Adam Huber[5], Brian M. Feldman[6], Ingrid E. Lundberg[7], Angela Pistorio[8], Howard Rockette[9], Frederick W. Miller[1], Rohit Aggarwal[9], Lisa G. Rider[1], for The ACR-EULAR Myositis Response Criteria Project Group[1], Angelo Ravelli[10], Clarissa Pilkington[11] and Sheila K. Oliveira[12]. [1]NIEHS, NIH, Bethesda, MD, [2]PRINTO, IRCCS G. Gaslini, Genoa, Italy, [3]Institute of Rheumatology, Department of Clinical and Experimental Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [4]SRA International, Research Triangle Park, NC, [5]IWK Health Centre, Halifax, NS, [6]Hospital for Sick Children, Toronto, ON, [7]Rheumatology Unit, Department of Medicine, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [8]PRINTO, Genoa, Italy, [9]University of Pittsburgh, Pittsburgh, PA, [10]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy, [11]Great Ormond Street Hospital, London, United Kingdom, [12]Instituto de Pediatria e Puericultura Martagão Gesteira (IPPMG) da Universidade Federal do Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil.

Background/Purpose: IMACS and PRINTO have developed preliminary core set activity measures and definitions of improvement (DOIs). However, these were developed from small and partially retrospective data sets. The current project will develop and further validate DOIs for adult and juvenile dermatomyositis (DM) and polymyositis (PM), and the first definition of major clinical improvement for use in therapeutic trials.

Methods: A repository of 8 natural history studies and 8 clinical trials in DM/PM was used to create 270 adult and 299 pediatric patient profiles consisting of core set activity measures on two visits. Clinical experts completed a questionnaire on their experience with the core set measures and care of myositis patients. Experts, randomized into survey groups based on experience, rated the degree of improvement in patient profiles.

Results: Sixty-six adult specialists (39 rheumatologist, 11 neurologists, 7 dermatologists, 7 other), saw an average of 82 adult DM/PM patients and practiced an average of 18.6 years. Fifty-two percent of adult experts had experience with 5 of 6 core set measures. Sixty-nine pediatric specialists, primarily rheumatologists, saw an average of 28 juvenile DM patients and practiced an average of 19.7 years. Forty-nine percent had experience with all core set measures and 34% had experience with 7 or 8 of 9 measures. Adult and pediatric experts had participated in an average of 1.5 trials utilizing IMACs measures; pediatric experts participated in 1 trial using PRINTO measures. Patient profiles indicated a moderate degree of activity (median MD global activity of 2 and 5, Patient/parent global activity of 5 and 4.9, MMT-8 score of 70 and 54, Extra-Muscular global activity of 1.7 in adult and 5.0 in pediatric profiles). Profiles varied in their degree of improvement based on the IMACS preliminary DOI (52% adult and 77% of pediatric profiles met DOI20%, 18% adult and 54% of pediatric profiles met DOI60%, and 48% adult and 23% of pediatric profiles were not improved by the DOI). Four-hundred-seven DOIs have been drafted to be tested for sensitivity and specificity, based on the number of measures and the degree of change corresponding to consensus clinical improvement, and inclusion of FDA's recommendation to incorporate patient-reported outcomes. Additional DOIs will be created by logistic regression analysis of the ratings of patient profiles.

The top performing DOIs will be externally validated with data from 4 randomized controlled trials.

Conclusion: A DOI for minimal and major clinical response will be developed and fully validated for adult and juvenile DM/PM using large natural history and clinical trial datasets. These internationally accepted consensus DOIs should facilitate new trials and enhance development of future therapies for myositis patients.

Development and Validation Of Medication Assessment Tools Specific For Rheumatoid Arthritis. Louise Grech[1], Bernard Coleiro[1], Anthony Serracino Inglott[2], Lilian M. Azzopardi[2], Victor Ferrito[2] and Andrew A. Borg[1]. [1]Mater Dei Hospital, Msida, Malta, [2]University of Malta, Msida, Malta.

Background/Purpose: Medication assessment tools can be defined as evidence-based instruments intended for the evaluation of prescribing trends and monitoring of adherence to established guidelines. Medication assessment tools have been specifically designed and implemented in the management of heart failure, coronary artery disease, asthma, diabetes mellitus and pain management in cancer. The objective of the study was to develop and validate medication assessment tools specific for rheumatoid arthritis (RA) in order to provide a systematic and standardised instrument ensuring evidence based practice in RA management.

Methods: Guidelines, recommendations and standards on RA and its management as set out by the American College of Rheumatology (ACR), the European League against Rheumatism (EULAR), the British Society for Rheumatology (BSR) and the National Institute for Clinical Excellence (NICE) were used to develop the Rheumatoid Arthritis Medication Assessment Tool (RhMAT). The summary of product characteristics for each drug included in the RhMAT were used as reference criteria. The medication assessment tool was designed in the form of a table bearing in mind that the tool will be used in a busy clinic where time can be limited. The RhMAT was validated by an expert panel who assessed the practicality, presentation, robustness and validity of the tool according to the data provided.

Results: The developed RhMAT was designed in the form of a table consisting of 11 separate sections dealing with general criteria for RA, use of analgesics, methotrexate, sulphasalazine, hydroxychloroquine, leflunomide, gold injections, general prebiologic screening, biologic therapy, use of glucocorticoids, remission cases. Table1 is an extract from the RhMAT and outlines part of the methotrexate section.

Table 1. Extract from "RhMAT"

Methotrexate	N/A	Yes	No justified	No unjustified	Insufficient Data	Comments	Reference
1 Used as first line DMARD in the absence of contraindications							
2 Pre-treatment screening including Chest X ray, CBC, ESR, CRP, LFTs, U&Es, Creatinine have been completed							
3 Regular monitoring according to monitoring protocol schedule including mouth ulcers, nausea and vomiting and dyspnoea							
4 Contraindications namely pregnancy, breastfeeding, active local or systemic infection, bone marrow suppression excluded							
5 The patient has been prescribed methotrexate at a dose that is unambiguously expressed as a *ONCE A WEEK* administration							

The expert panel validating the developed RhMAT consisted of 3 consultant rheumatologists, 2 academic pharmacists, an academic science professor and a rheumatology nurse specialist. Following the expert panel review one of the statements was split into 2 separate statements to increase specificity. This was repeated for another statement.

Conclusion: Medication assessment tools have been shown to be effective instruments providing a one-atop measure which can be used both as a clinical audit tool as well as a tool which supports best practice for a number of chronic diseases. The developed RhMAT is a comprehensive, user-friendly checlist tool designed to be used in a busy adult rheumatology out-patient clinic ensuring safer prescribing of rheumatological drugs.

1983

Prevalence Of Birefringent Crystals In Three Inflammation-Prone Tissues. Jane Park, Divya Soman, Martine P. Roudier and Peter A. Simkin. University of Washington, Seattle, WA.

Background/Purpose: When serum is hyperuricemic, so too are all interstitial fluids other than CSF and sweat. Anecdotally, urate crystals deposit as grossly visible tophi in many non-articular organs, including cardiac valves, but no microscopic studies of crystal prevalence have been done at those sites. Are the tophi unique, or are they the tip of a crystalline iceberg? Evidence from new imaging modalities including dual energy CT and ultrasound suggest that they may be surprisingly common.

Just as urate crystals drive gouty arthritis, such deposits may be a factor in extraarticular inflammation. Higher urate levels within prostatic secretions have correlated with symptoms of chronic prostatitis, and a single placebo-controlled study found that allopurinol decreased prostatic urate secretion and improved subjective pain. In addition, gout and hyperuricemia are now accepted as independent risk factors for coronary artery disease and all-cause mortality, and allopurinol use may lead to decreased mortality. The cardiac risk has been attributed to hyperuricemia, but the possibility of arterial urate crystals has not been considered. If present, such crystals could cause intimal inflammation leading to coronary thrombosis. To investigate this possibility, we used polarizing microscopy to examine tissues from 3 sites of enigmatic inflammation: coronary arteries, cardiac valves, and prostates.

Methods: Tissues were: 1. Alcohol-fixed and H&E stained coronary arteries (left anterior descending, right coronary, and circumflex) from 50 explanted hearts collected from 2000–2003. 2. Twenty-three alcohol-fixed, unstained aortic valves from replacement surgery done in 2011–2013. 3. Frozen, unstained, non-malignant regions of 40 consecutive prostatectomies for cancer in 2012–2013. Clinical data regarding gout and hyperuricemia were unavailable or incomplete for all subjects.

Results:

Tissue	Source	Gender	Age	N	Number of positive specimens	% positive
Coronary	Explant	M + F	Any	50	6	12%
Prostate	Cancer surgery	M	61.2 ± 7.2	40	19	47.5%
Aortic valve	Explant	M + F	62.3 ± 17.0	23	1	4.3%

Conclusion: We have observed birefringent crystals, primarily negatively so, in 12% of coronary arteries, 48% of prostates, and 4% aortic valves examined thus far. Alcohol fixation, rather than formalin which is known to dissolve urate crystals, and polarizing microscopy are necessary in order to recognize urate crystals in pathologic tissues.

"Gouty arteritis" should be considered as a possible factor in ischemic heart disease. We hope these tools will be applied by pathologists conducting autopsies on patients who have suffered fatal myocardial infarctions. In addition, if our preliminary findings are confirmed within the prostate, further studies will be indicated with urate lowering agents and anti-inflammatory drugs known to be effective in gouty arthritis.

1984

Impact Of Educational Attainment On Health-Related Quality Of Life and Healthcare Utilization Among Veterans With Gout. Cleopatra Aquino-Beaton[1], Jay E. Persselin[1], Ari Weinreb[1], Meika A Fang[1], Jasvinder A. Singh[2], Erin Duffy[3], David Elashoff[4], Puja Khanna[5] and Dinesh Khanna[6]. [1]VA Greater Los Angeles Healthcare System, Los Angeles, CA, [2]University of Alabama, Tuscaloosa, AL, [3]University of California Los Angeles, Los Angeles, CA, [4]UCLA Department of Medicine Statistics Core, Los Angeles, CA, [5]Ann Arbor VA, Ann Arbor, MI, [6]University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: Gout is a debilitating, chronic disease that requires ongoing treatment and effective self-management. Successful gout treatment depends on multiple factors, including educational attainment. Adequate health literacy enables patients with chronic illnesses, including gout, to better manage their disease and overall health. Evidence suggests that higher health literacy and education may be associated with better self-care and personal health management. Gout is associated with poor health-related quality of life (HRQoL) and greater healthcare utilization (HCU) among US Veterans. However, there is little research on the impact of educational attainment on HRQoL and HCU.

Methods: 186 gout patients with varying levels of educational attainment were recruited in rheumatology and primary care clinics at the West Los Angeles, CA and Birmingham, AL VA facilities. Patients' clinical status, HRQoL, and HCU were assessed every 3 months for a 12-month period. Educational attainment was self-reported at baseline and patients were categorized into two education levels: 1) No post-high school education and, 2) post-high school (some college, college degree, or graduate school education). HRQoL were measured using the SF-36, HAQ-DI and Gout Impact Scales (GIS) of the Gout Assessment Questionnaire (GAQ). Patients and physicians independently scored the severity of gout on a 0–10 scale. HCU was assessed with the UCSD Health Care Utilization Questionnaire. Demographics, clinical characteristics, HRQoL and HCU of patients with and without post-high school education were compared using Wilcoxon rank sum and Fisher exact tests. P-values less than 0.05 were considered significant.

Results: There were 46 patients with no post-high school education and 138 patients with education beyond high school; 2 patients did not provide their education. Patients with post-high school education were significantly younger than their counterparts, but there was no difference between groups with respect to race, ethnicity or gender (Table). The clinical characteristics, patient severity scores, SF-36, HAQ-DI and GIS scores did not differ between educational attainment groups. However, physician scores for severity of gout were higher for patients with no post-high school education compared to those with higher education. Patients with post-high school education reported a significantly higher frequency of medical office visits (MD, DO, or NP), phone calls to physician or medical staff, and urgent care visits (triage center or emergency department) during the 3-month period prior to baseline.

Patient Characteristics by Educational Attainment

		No Post-High School Education N=46	Post-High School Education N=138	p-value
Age (Years)	Mean(SD)	69.9 (9.6)	62.8 (10.8)	0.0001
Gender (Male)	N (%)	45 (97.8%)	135 (97.8%)	0.99
Race:				
Caucasian	N (%)	32 (69.6%)	73 (52.9%)	0.08
African American	N (%)	9 (19.6%)	51 (37.0%)	
Other	N (%)	5 (10.9%)	14 (10.1%)	
Hispanic or Latino Ethnicity	N (%)	7 (18.9%)	13 (10.7%)	0.18
Tophi Diagnosed	N (%)	11 (25.6%)	24 (18.7%)	0.34
Serum Urate Level	Mean (SD)	8.3 (3.6)	8.3 (3.4)	0.72
Number of Charlson Comorbidities	Mean (SD)	3.0 (2.4)	3.5 (2.2)	0.58
ACR Functional Class:				
I & II	N (%)	19 (76.0%)	69 (85.2%)	0.29
III & IV	N (%)	6 (24.0%)	12 (14.8%)	
Recent Gout Attack (<4 weeks)	N (%)	24 (52.2%)	79 (58.5%)	0.20
Patient Severity Assessment (0–10)*	Mean (SD)	6.0 (3.0)	5.6 (3.2)	0.50
Physician Severity Assessment (0–10)*	Mean (SD)	3.9 (2.9)	2.8 (2.6)	0.05
SF-36 Physical Component Summary	Mean (SD)	37.4 (12.5)	38.8 (9.4)	0.45
SF-36 Mental Component Summary	Mean (SD)	47.2 (13.8)	42.9 (13.9)	0.07
HAQ-DI Composite Score (0–3)*	Mean (SD)	0.8 (0.6)	0.8 (0.6)	0.63
Average GIS Score (0–100)*	Mean (SD)	53.0 (19.6)	55.5 (19.8)	0.49
Healthcare Utilization over 3 Months Number of:				
Visits to MD, DO, or NP	Mean (SD)	2.4 (2.6)	4.4 (4.7)	0.0006
Phone calls to MD or medical staff	Mean (SD)	0.7 (1.7)	2.0 (3.3)	0.0002
Triage, urgent care, or ER visits	Mean (SD)	0.3 (0.6)	0.7 (1.0)	0.02
Home-healthcare visits	Mean (SD)	0.2 (0.9)	0.7 (2.8)	0.22
Days as inpatient	Mean (SD)	0.6 (2.1)	2.3 (11.1)	0.10
Outpatient surgeries or procedures	Mean (SD)	0.3 (1.0)	0.3 (0.8)	0.96

*Higher score= worse HRQoL

Conclusion: VA patients with lower educational attainment had significantly higher physician severity scores, utilized fewer outpatient and urgent care services despite similarities in clinical characteristics and HRQoL as their more educated peers.

1985

Prescription Patterns Of Colchicine Before and After Food and Drug Administration Approval. Eswar Krishnan[1], Jasvinder A. Singh[2] and Linjun Chen[1]. [1]Stanford University, Palo Alto, CA, [2]University of Alabama, Tuscaloosa, AL.

Background/Purpose: Colchicine, a commonly used drug, had never been subjected to rigorous safety and efficacy studies prior to 2009, when under Hatch-Waxman ACT (1984) and the Unapproved Drug Initiative, the Food and Drug Administration approved a proprietary version of colchicine (Colcrys®) for treatment of acute gout flare. The approved dose was much lower than that used traditionally. One assumption for the FDA approval of colchicine was that proprietary versions of the previously unapproved products would enhance patient safety by encouraging more rational prescribing practices. The goal of this study was to test this assumption using clinical data.

Methods: The data used for the present study was retrieved from the STRIDE (Stanford Translational Research Integrated Database Environment) database that includes electronic medical record data from 15 million clinical encounters with 1.6 million unique patients. After validating diagnosis of gout by chart review we identified 970 records of gout utilizing colchicine from 2006 to 2012. High-dose colchicine (HDC) and very-high-dose colchicine (VHDC) prescriptions were defined as more than 1.8 mg/day and 3.0 mg/day respectively. Factors associated with HDC and VHDC were analyzed using logistic regression models. Although Colcrys ® was approved in June 2009 we assumed that the earliest time for discernible impact to be January 1, 2010.

Results: Before and after 2010, the mean age and mean serum creatinine were similar, while the proportion of women and mean serum uric acid were statistically different (Table). The proportion of patients using HDC/VHDC decreased from 11.7%/8.6% before 2010 to 4.0%/3.7% after 2010, representing an unadjusted odds ratio of 0.3 (0.2, 0.6)/0.4 (0.2, 0.8) and age-sex-adjusted odds ratio of 0.3 (0.2, 0.6)/0.4 (0.2, 0.8). The utilization of high-dose colchicine has been declining steadily even before the introduction of Colcrys®, while the utilization of very-high-dose colchicine declined after 2007 and was steady through 2007 to 2009 and then declined after 2010(Figure). In multivariable logistic regressions that adjusted for age, sex and renal function, the odds ratio for HDC/VHDC 2010–2012 compared to the preceding years (2006–2009) was 0.4 (0.2, 0.6)/0.5 (0.2, 0.9).

	2006–2009	2010–2012
Mean Age in years (SD)	65.7 (17.8)	67.3 (14.8)
Proportion of women*	17.9%	23.4%
Mean serum creatinine in mg/dL (SD)	1.3 (1.0)	1.4 (1.4)
Mean serum uric acid in mg/dL (SD)*	7.3 (2.8)	6.4 (2.5)

SD: standard deviation; * Statistically different ($p<0.05$)

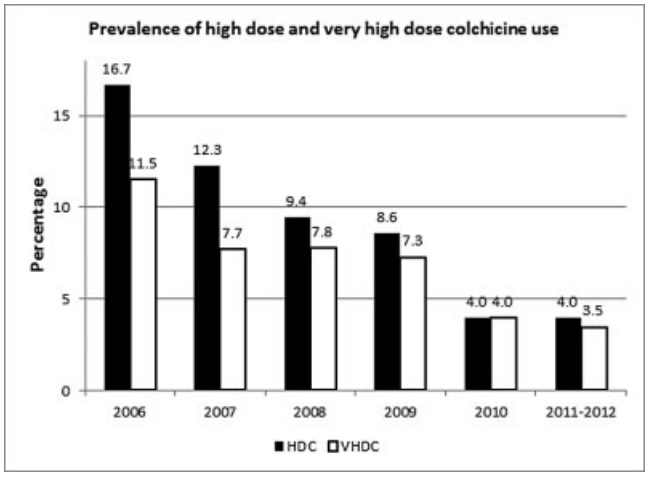

Figure.

Conclusion: Colchicine dosing has been declining over time. Statistically this is unrelated to the approval of Colcrys® under the FDA Unapproved Drug Initiative.

1986

Colchicine Use and The Risk Of Myocardial Infarction Among Gout Patients: Results From a Community-Based, Informatics-Driven Retrospective Cohort Study. Daria B. Crittenden[1], Binita Shah[2], Steven P. Sedlis[2], Christopher J. Swearingen[3], Eric S. Wagner[4], Yvette M. Henry[4], Peter B. Berger[4], Bruce N. Cronstein[1] and Michael H. Pillinger[1]. [1]NYU School of Medicine, Division of Rheumatology, New York, NY, [2]NYU School of Medicine, Division of Cardiology, New York, NY, [3]Pediatric Biostatistics, University of Arkansas for Medical Sciences, Little Rock, AR, [4]Geisinger Health System, Cardiovascular Center for Clinical Research, Danville, PA.

Background/Purpose: Gout patients have an increased risk of myocardial infarction (MI). Since atherosclerosis and plaque rupture are inflammatory processes, anti-inflammatory gout medications might also reduce MI. Colchicine inhibits inflammatory cells implicated in gout and MI; our prior study suggests that colchicine might reduce MI in gout patients (Crittenden, J Rheum 2012). To further assess the effect of colchicine on risk of MI, we performed a retrospective cohort study of patients in the Geisinger Health System, a large community-based health care system.

Methods: We analyzed Geisinger's electronic records and identified all patients in the Geisinger Health Plan with ICD-9 codes for gout on at least two different encounters between 2001–12. Patients were separated into 2 groups: chronic ($>$ 30 days; n=628) and no colchicine (controls; n=2436) use. Patients with $>$ 0 but $\leq$ 30 days of use were excluded from analysis. For patients in each cohort, we set the index date as 1st colchicine use or 1st gout diagnosis date (colchicine and controls, respectively). For colchicine users, we defined a colchicine lapse as any period of non-use $\geq$ 2 weeks after medication cessation, to account for the kinetics of colchicine elimination. The primary outcome was MI during the study period. Demographic and baseline clinical features were compared between the 2 groups using equivalence tests (20% margin). Difference in frequency of MI between groups was estimated using Chi-square test and logistic regression adjusting for age, diabetes, heart failure, prior MI, and length of follow-up.

Results: Of the 3064 patients who met the inclusion criteria, 2316 (76%) were male and 3010 (98%) were white. The 2 groups were equivalent with regard to age, sex, hypertension, hyperlipidemia, allopurinol use (45 vs 43%), and mean serum urate (7.8 vs 8.0 mg/dL). Forty-eight MIs were reported during the study period; 35 (1.4%) in the control group vs 5 (0.8%) among active colchicine users (OR=1.78, P=0.22), and 8 (1.3%) during colchicine lapse or after its final discontinuation. The odds of MI were larger in the control vs colchicine group using logistic regression, though the effect lessened over time (OR at 6 months = 2.29 [P=0.263] at 2 years = 1.35 [P=0.609]). In contrast, the MI incident rate/1000 person-years of exposure was higher in the colchicine group (6.3 vs 2.3, P=0.064), probably relating to a much longer follow-up (i.e. denominator) for the control group (14,996 vs 796 person-years). Among colchicine users overall, the incidence rate of MI during periods of active use was lower than during lapse periods (6.3 vs 11.2/1000 person-years [P=0.324]).

Conclusion: Active colchicine users demonstrated trends toward a reduced incidence of MI and reduced odds of MI in the first 2 years of observation vs controls. Colchicine users also had a reduced risk of MI during periods of active use vs lapse. In contrast, MI person-year incidence rate was higher among the colchicine users vs controls, possibly a consequence of the much longer observation period in the control group. Overall, the number of MI events was unexpectedly low, limiting our ability to draw conclusions; additional studies are needed to clarify the potential cardioprotective effect of colchicine.

LIVER Outcomes In Gout Patients Treated With Febuxostat and Altered LIVER Function TESTS. Fernando Perez-Ruiz and Ana M. Herrero-Beites. BioCruces Health Institute, Baracaldo, Spain.

Background/Purpose: patients with significantly altered liver function test (LFTs) at screening do not qualify for clinical trials. Therefore, scarce data are available on the impact on altered LFTs with febuxostat. To assess whether febuxostat has an impact in LFTs in patients with altered LFTs at baseline, compared with patients with normal LFTs.

Methods: prospective follow-up of a cohort of patients initiating febuxostat for hyperuricemia of gout. ASAT, ALAT, and GGT were measured at baseline and at 3–6–12 months during follow-up. Child-Plough stage $>$ 1 were not included. General characteristics of patients were obtained at entrance in the cohort, including parameters of gout severity, previous urate-lowering therapy, ethanol intake, hyperlipidemia, renal function impairment, and diabetes. Altered LFTs were defined as ASAT/ALAT $>$ 1.5 or GGT $>$ 2.5 upper normal limit (UNL). Liver ultrasonography was obtained prior to febuxostat in patients with altered LFTs at baseline and in those who developed altered LFTs during follow-up.

Results: 86 patients included, 83, 69, and 59 patients with data at 3, 6, and 12 months of follow-up, respectively, 96% with previous failure or intolerance/adverse events to at least one urate-lowering drug. General comorbidities: 47% renal function impairment (11% CKD 4–5), 29% ethanol intake $>$ 20 g/day, 70% hypertension, 50% hyperlipidemia, 22% diabetes, 40% on diuretics, and 26% heart failure; 35% on the upper stratum of the Kaiser Permanent Pyramid of complexity. Of 23 (27%) patients with altered LFTs at baseline (ASAT, ALAT, and GGT were altered in 4, 9, and 18 % respectively), diseases were: 1 von Gierke Disease, 1 liver transplantation, 1 hemochromatosis, 2 alcoholic cirrhosis, 3 stasis liver due to heart failure, and 9 fatty liver. Six patients had altered LFTs but normal ultrasonography. Altered LFTs at baseline were more prevalent in patients with previous high ethanol intake (14/25 vs. 12/61, 56% vs. 19%, respectively; p$<$0.05).

No patient withdrew due to altered liver function test. Three patients developed sustained altered LFTs, ultrasonography showing lithiasis, fatty liver, and iron overload and four patients showed normalization of LFTs during follow-up. There was no significant change in paired means in any LFTs but a descent of ASAT/ALAT at 6 months and of GGT at 6 and 12 months (Table).

	ASAT 0/3	ASAT 0/6	ASAT 0/12	ALAT 0/3	ASAT 0/6	ASAT 0/12	GGT 0/3	GGT 0/6	GGT 0/12	P
All	29 ± 15	29 ± 15	29 ± 15	35 ± 26	36 ± 28	34 ± 25	68 ± 71	63 ± 59	64 ± 61	All NS
	30 ± 19	29 ± 17	27 ± 15	36 ± 31	37 ± 31	32 ± 29	66 ± 75	56 ± 45	61±57	
Normal LFTs	23 ± 7	23 ± 7	23 ± 6	27 ± 13	27 ± 13	27 ± 13	35 ± 20	37 ± 20	38 ± 21	All NS
	25 ± 11	25 ± 14	24 ± 13	31 ± 27	31 ± 27	29 ± 31	35 ± 23	39 ± 28	41 ± 37	
Altered LFTs	45 ± 20	48 ± 18	45 ± 19	55 ± 38	60 ± 40	55 ± 39	146 ± 88	132 ± 70	141 ± 75	*<0.05
	40 ± 27	40 ± 20	35 ± 17*	51 ± 39	51 ± 37	38 ± 22*	140 ± 101	101 ± 52**	119±64***	<0.01

Conclusion: in this prospective cohort of patients with severe gout but not liver insufficiency, patients with altered LFTs, including patients including chronic liver disease, showed no signal of worsening of LFTs compared to patients with normal LFTs at baseline. There was even an improvement in LFTs in the long-term in patients with previously altered LFTs.

1988

Self-Reported Gout, Comorbidities and Healthcare Resource Utilization Data From The 2012 United States National Health and Wellness Survey. Jasvinder A. Singh[1], Kathy Annunziata[2] and Puja Khanna[3]. [1]University of Alabama, Tuscaloosa, AL, [2]Kantar Health, Princeton, NJ, [3]University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: Hyperuricemia and gout are associated with major cardiovascular and metabolic comorbidities. Recently published data on comorbidities and gout epidemiology in the US have been drawn from the 2007–2008 National Health and Nutrition Examination Survey (NHANES),[1,2] thus underscoring the need for current information. Here we present data from the subscription-based 2010–2012 National Health and Wellness Survey (NHWS; Kantar Health).

Methods: The NHWS is an Internet-based survey of adults aged ≥18 years providing self-reported information on treatment, healthcare attitudes and behaviors, disease and demographic characteristics (N=71,157). Mean values were weighted/projected to match gender, age, and race in accordance with current US Census Bureau data. NHWS members were recruited from

the Lightspeed Research panel, whose members were recruited through e-mail and Web site advertisements, and other panels. All participants provided informed consent and were nominally compensated.

Results: The majority of respondents were men (77%) and mean time since gout diagnosis was 12.3 years. Close to half of these patients (42%) were age 65 years or older. A large proportion of gout patients were unaware of their serum uric acid (sUA) levels (71%); 17% reported sUA below 6 mg/dL and 13% reported sUA >6 mg/dL. Gout was classified as mild in 52%, moderate in 33% and severe in 15%. Table 1 shows key comorbidities and healthcare utilization for the NHWS cohorts with and without gout; Table 2 displays trends over time. Respondents with gout had significantly higher utilization of inpatient, outpatient, and emergency room services and were hospitalized more often than respondents without gout. The overall prevalence of gout in the 2012 NHWS was 2.4%, slightly higher than that reported by the NHWS in 2011 (2%) and 2010 (1.7%) but lower than that reported using NHANES 2007–2008 (3.9%).

Table 1. Characteristics of Gout vs No Gout Populations

	Total Sample 2012	US Adults No Gout	US Adults w/ Gout	US Adults w/ Gout and Rx	US Adults w/ Gout, No Rx
NHWS sample	N=71,157	n=69,161	n=1996	n=1347	n=649
Total projected to US population	230.3M	224.7M	5.6M	3.7M	1.9M
% Men	48	48	77	79	72
Mean age (years)	46.4	46.1	60.4	61.6	58
Pain	34	34	53*	51	56
Self-Reported Comorbidities (% of sample)					
Hypertension	26	25	66	69	60
Hypercholesterolemia	25	24	56*	59	51**
Diabetes	10	10	30*	33	24**
Arthritis other than gout	20	20	52*	54	47**
Healthcare Resource Utilization (% of sample with 1 or more visits)					
Visited GP in past 6 months	47	47	69*	72	63**
Visited HCP in past 6 months	72	72	90*	93	84**
Visited ER in past 6 months	12	12	17*	18	15
Hospitalized in past 6 months	7	6	11*	13	8**
Mean Healthcare Resource Utilization					
Mean # visits in past 6 months	3.4	3.3	5.6*	6.0	4.7**

* Denotes statistical significance vs the sample with no gout.
** Denotes statistical significance vs gout with Rx.

Table 2. Medication Usage and Treatment Patterns Over Time

	2010	2011	2012
% With Gout on Rx	68%	66%	66%
Allopurinol	NA	NA	75%
Febuxostat	NA	NA	7%
Patient Attitudes			
% with gout who consult HCP when ill	38%	36%	35%
% with gout who prefer self-treatment with OTC products	23%	20%	19%
Resource Utilization			
% visited GP in past 6 months	NA	67%	69%
% visited any HCP in past 6 months	93%	90%	90%
Mean # visits in past 6 months	6.3	6	5.6
% visited ER in past 6 months	22%	19%	17%
% hospitalized in past 6 months	16%	13%	11%

Conclusion: Current data from the NHWS demonstrated a higher incidence of comorbidities and gout when compared to NHANES III. This difference could be attributed to mode of survey administration (Internet vs home-based) along with the growing epidemic of obesity. Trends from 3 years showed modest reductions in healthcare utilization over time that are promising and have implications for gout-related healthcare cost.

1989

Determinants Of Functional Disability In Patients With Gout: Longitudinal Analysis From a Multicentre Observational Study Of The Italian Society For Rheumatology.

Carlo Alberto Scirè[1], Maria Manara[1], Greta Carrara[1], Marco A. Cimmino[2], Marcello Govoni[3], Fausto Salaffi[4], Leonardo Punzi[5], Carlomaurizio Montecucco[6], Marco Matucci-Cerinic[7] and Giovanni Minisola[8]. [1]Epidemiology Unit -Italian Society for Rheumatology, Milano, Italy, [2]University of Genoa, Genova, Italy, [3]Section of Rheumatology - Department of Clinical and Experimental Medicine - University of Ferrara, Ferrara, Italy, [4]Rheumatology Unit - Polytechnic University of the Marche, Jesi, Italy, [5]University of Padova, Padova, Italy, [6]University and IRCCS Policlinico S. Matteo Foundation, Pavia, Italy, [7]University of Florence, Azienda Ospedaliera Careggi, Florence, Italy, [8]Rheumatology Unit, San Camillo-Forlanini Hospital, Rome, Italy.

Background/Purpose: Gout is the most prevalent arthritis and significantly impacts on function. Beside the influence of concurrent comorbidities, identifying disease-related prognostic factors may help to improve management and prevent disability. This study primarily aims to evaluate the independent association of disease-related factors with functional disability over time in patients with gout.

Methods: This is prospective analysis of a multicentre cohort study including a random sample of patients with prevalent clinically diagnosed gout from 30 rheumatology centres across Italy (KING Study, promoted by SIR, NCT01549210) recruited between June 2011 and January 2012. All patients underwent full clinical evaluation, including general health variables (socio-demographics, life-styles, comorbidities and treatments), and gout-related variables (diagnosis, duration, pattern of disease, previous and current treatment, VAS pain and patient global, joint examination, tophi burden and serum uric acid (sUA) levels). Primary outcome was defined as persistency of or worsening of functional disability (according to the following HAQ classes: absent= 0–0.5; mild= 0.5–1; moderate= 1–2; severe= 2–3). The relationship between predictors and outcomes was modelled using logistic models, and results presented as crude and adjusted odds ratios (OR) and 95%CI. Generalised linear models explored longitudinal association between gout-related variables and functional outcome. Missing data were imputed using switching regression on 10 datasets.

Results: A total of 446 patients were included in the analyses. M:F ratio was 9:1 M:F, mean (SD) age 63.9 (11.6) years and median (IQR) disease duration 3.8 (1.5–10.1) years; 92% fulfilled ACR preliminary classification criteria for gout, 19.9% had tophaceous gout; mean (SD) sUA level was 6.3(1.7), and 81% were on treatment with xantine-oxidase inhibitors (68% allopurinol and 13% febuxostat).

Factors associated with worse functional outcome after 12 months are reported in Table.

	12-month functional outcome		
Gout-related variables	Crude OR [95% CI]	Adj OR [95% CI]$^{\mu}$	Adj OR [95% CI]$^{\#}$
Disease duration (>5yrs)	2.13 (1.32–3.44)	2.17 (1.31–3.57)	1.94 (1.16–3.27)
Number of attacks last year	1.07 (1.01–1.14)	1.08 (1.01–1.16)	1.06 (0.99–1.14)
Attacks last month	2.44 (1.48–4.01)	2.87 (1.70–4.87)	2.75 (1.59–4.76)
Presence of tophi	2.06 (1.20–3.54)	1.87 (1.06–3.29)	1.62 (0.90–2.92)
Number of swollen joints (66)	1.31 (1.19–1.46)	1.30 (1.17–1.44)	1.26(1.14–1.40)
Number of tender joints (68)	1.23 (1.15–1.32)	1.22 (1.14–1.31)	1.19 (1.11–1.27)
Serum Uric Acid (>6mg/dl)	1.67 (1.01–2.77)	2.11 (1.22–3.63)	1.95 (1.10–3.45)
Urate lowering treatment	1.06 (0.57–1.97)	1.01 (0.52–1.94)	0.84 (0.43–1.65)
Current NSAID or colchicine	3.02 (1.78–5.12)	2.99 (1.72–5.18)	2.88 (1.63–5.10)
Previous steroid	2.38 (1.43–3.96)	2.20 (1.28–3.77)	1.90 (1.08–3.37)

$^{\mu}$ *adjusted for age and gender.*
$^{\#}$ *adjusted for age, gender, comorbidities*

Variations over time of the following gout-related variables associated with statistically significant variation on HAQ score: swollen and tender joint count, VAS pain and patient global, number of attacks. Tophi and sUA showed only a marginal association.

Conclusion: disease-specific variables independently impact on function over time, suggesting that stricter control of the disease may improve the excess of disability observed in gout.

1990

Treatment Of ACUTE Gout In The Emergency Department Evaluated According To The 2012 American College Of Rheumatology Guidelines. Naomi Schlesinger[1], Tina Chang Young[2], Diane C. Radvanski[3], Dirk Moore[4] and Robert Eisenstein[5]. [1]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [2]UMDNJ/School of Public Health, Piscataway, NJ, [3]Robert Wood Johnson Medical School, New Brunswick, NJ, [4]UMDNJ - School of Public Health, Piscataway, NJ, [5]UMDNJ- Robert Wood Johnson Medical School, New Brunswick, NJ.

Background/Purpose: Acute gout attacks account for a substantial number of emergency department (ED) visits. Our aim was to record acute gout treatment in the ED and evaluate the treatment according to the 2012 American College of Rheumatology (ACR) guidelines (Khanna D et al. *Arthritis Care Res.* 2012; 64:1447–61).

Methods: Retrospective chart review of consecutive patients with acute gout seen in the ED 1/01/2004 - 12/31/2010. Patients included if their diagnosis field included the word gout. Variables included: age, years of gout, number of attacks/year, comorbidities, medications and involved joints.

Descriptive and summary statistics were performed on all variables. Subgroup analysis, sensitivity analysis and exploratory data performed where applicable.

Results: 541 acute gout patient visits recorded in the ED over 7 years. Mean patient age: 54 (range 20–96); 79% were men. 118 (22%): first attack. 75%: attack duration ≤ 3 days. Most commonly affected: lower extremity joints.

Of the 541 visits, 355 (66%) given drug treatment in the ED; 186 (34%) not given a medication during their visit. Medications given: NSAIDs: 56 % (n=198): (toradol 19% (n=69); indomethacin 19% (n=66); Ibuprofen 14% (n=49); naproxen 3% (n=11)); opiates 54% (n=190); colchicine 9% (n=32); prednisone 9% (n=32). 154 (28%) not given drugs during visit received prescriptions. 6% (n=32) given no drugs during visit nor did they receive a prescription.

An anti-inflammatory drug given during 44% (n=239) of visits. 75% (n=408) given an anti-inflammatory drug prescription. 40% (n=216) given an anti-inflammatory drug during visit and a prescription. 110 (20%) not given an anti-inflammatory drug during visit nor a prescription.

35% (n=190) given an opiate (oxycodone/acetaminophen) during the ED visit and 52% (n=282) a prescription.

Monotherapy given during 74% (n=262) of visits.

During 13.4% (n=72) of visits patient reported being on colchicine prophylaxis. Patients on colchicine prophylaxis significantly more likely to receive colchicine for their acute attack than those not on prophylaxis (p=0.005).

Conclusion: According to the ACR guidelines, first-line anti-inflammatory drugs for the treatment of acute gout include oral colchicine, NSAIDs and corticosteroids, yet during 56% of acute gout ED visits, anti-inflammatory drugs not given. The ACR guidelines propose treatment be continued for 7–10 days yet only 40% given anti-inflammatory drugs in the ED and prescriptions. We suggest that 60% did not receive optimal treatment for acute gout. The ACR guidelines suggest that colchicine is not recommended when attack occurred in a patient on colchicine prophylaxis yet patients on chronic prophylaxis significantly more likely to receive colchicine for their acute attack. Opiates commonly given in the ED for acute gout; however, analgesia alone does not treat gouty inflammation (not addressed in guidelines). Combination of colchicine and NSAIDs suggested for severe and unresponsive attacks by ACR guidelines, yet in 76% of patient visits receiving combination therapy, an opiate was combined with an NSAID or prednisone.

Further studies are needed for development of evidence-based guidelines tailored to the ED to help improve treatment of acute gout in the ED.

1991

Gout In Ambulatory Care Settings In The US: 1993–2009. Eswar Krishnan and Linjun Chen. Stanford University, Palo Alto, CA.

Background/Purpose: Gouty arthritis (gout) is primarily cared for in ambulatory care settings. Yet, there are few nationally representative data on ambulatory health care utilization of this condition. The goal of this study is to analyze the quantity of visits for gout and its trends in the US between 1993 and 2009.

Methods: We combined the data from National Ambulatory Medical Care Surveys (NAMCS) and National Hospital Ambulatory Medical Care Surveys (NHAMCS) from 1993 to 2009 where the unit of analysis was the outpatient visit. Gout visit was defined as a visit with physician-prescribed gout diagnosis, or a visit associated with a prescription of allopurinol or colchicine. Patients younger than 20 or older than 90 were excluded. Data were analyzed using SVY suite of commands in STATA. Time trends were tested using Poisson regressions.

Results: For men, the annual number of visits for gout increased from 2.9 million at 1993 to 8.9 million at 2009; for women, it increased from 1.2 million to 3.2 million. The total number of visits for gout increased from 4.1 million at 1993 to 12.1 million at 2009. The increase of gout visits was highly significant (p<0.001) (Figure 1). When examined as a proportion of all ambulatory care visits, the proportion of gout visits increased from 13.0 per 1000 (10.0‰, 17.2‰) to 25.5 per 1000 (21.0‰, 31.1‰) among men and 3.2 per 1000 (2.0‰, 5.1‰) to 5.8 per 1000 (4.4‰, 7.7‰) among women (Figure 2). The increase was evident in all age groups but was large only among the 60+ age group. Overall, in age-gender adjusted Poisson regressions the 2006–2009 time period was associated with a relative risk for 1.6 (1.4, 1.9) compared to the 1993–2005 time period.

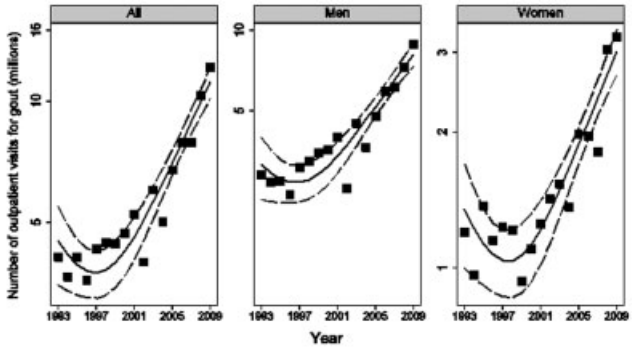

Figure 1.

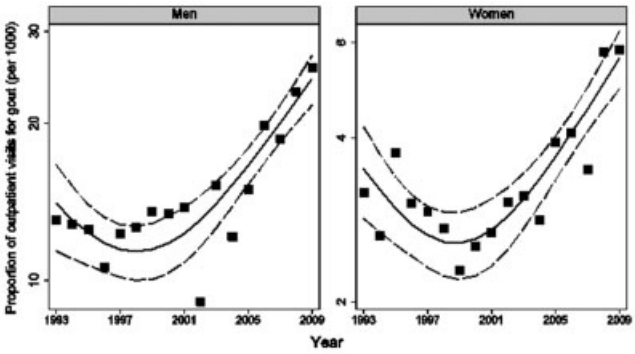

Figure 2.

Conclusion: The frequency of gout increased over three fold between 1993 and 2009, and most of the increase occurred after 2005. The gout awareness campaign funded by the industry could be the explanatory factor.

1992

Trends In Outpatient Treatment Of Gout In The US: From 1993 To 2009. Eswar Krishnan and Linjun Chen. Stanford University, Palo Alto, CA.

Background/Purpose: Gouty arthritis (gout) is primarily managed in the community by primary care providers. Relatively little is known about the treatment patterns as well as time trends in general population settings.

Methods: We combined the data from National Ambulatory Medical Care Surveys (NAMCS) and National Hospital Ambulatory Medical Care Surveys (NHAMCS) from 1993 to 2009. Presence of a physician determined diagnosis of gout or prescription of allopurinol/colchicine was

considered to signify a gout visit. We assessed the prescription of gout medications classified as allopurinol, colchicine, oral corticosteroids, any Non-Steroidal Anti-inflammatory drugs (NSAIDs) and Non-Coxib NSAIDs. We also studied the prescription pattern of aspirin as a 'control' group. Time trends were analyzed using weighted logistic regression models.

Results: Time trends in the use of medications are shown in the Figure. The trends for colchicine and steroids were not statistically significant. In logistic regressions that adjusted for age and sex, each advancing year was associated with a significant increase in the use of allopurinol with an odds ratio of 1.02 ((1.00,1.05), p=0.048) and the use of aspirin with an odds ratio of 1.09 (1.05,1.12). The use of Non-Coxib NSAIDs decreased with a yearly odds ratio of 0.96 (0.94, 0.99). There were no significant trends in other medications. The estimate of visits with concurrent prescriptions of allopurinol and probenecid was negligible. Overall, the combination of colchicine and any one of the NSAIDs were prescribed in 3.5 million (2.4 to 4.6 million) gout patients, representing 3.6% (2.6%, 4.8%) of all gout visits. The proportion of such combinations increased from 2.0% (1.2%, 3.3%) in the 1993–2000 period to 4.3% (3.1%, 6.1%) in the 2001–2009 period. In unadjusted logistic regression this change represented an odds ratio of 2.4 (1.3, 4.5) and in age-sex adjusted logistic regression the odds ratio was unchanged. Combination of NSAIDs and steroids was rare, and was prescribed in 1.7% gout visits (1.1%, 2.8%). These proportions were similar in the 1993–2000 and 2001–2009 periods: 1.3% (0.6%, 2.8%) and 1.9% (1.1%, 3.5%) respectively.

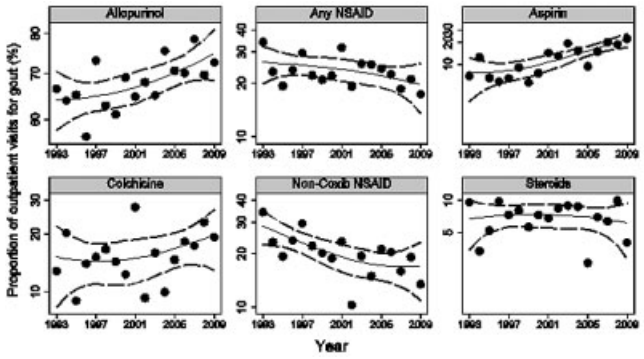

Figure.

Conclusion: Distinct trends of gout medication use were observed signifying decrease in NSAIDs and increase in allopurinol. The utilization of colchicine and steroids has remained steady over time. Combination of different classes of anti-inflammatory therapies was infrequent.

1993

Geographic Variations Of Gout Epidemiology In The United Kingdom: A Nationwide Population Study. Chang-Fu Kuo[1], Michael Doherty[2], Matthew J. Grainge[2] and Weiya Zhang[2]. [1]Chang Gung Memorial Hospital, Taipei, Taiwan, [2]University of Nottingham, Nottingham, United Kingdom.

Background/Purpose: To examine geographic variations of gout prevalence, incidence and management in the United Kingdom.

Methods: We used the Clinical Practice Research Data-link (CPRD) to estimate the prevalence, incidence of gout, consultation rate for gout, percentage under urate-lowering treatment (ULT) and time to first prescription of ULT in each of 13 areas in the United Kingdom: North East, North West, Yorkshire & The Humber, East Midlands, West Midlands, East of England, South West, South Central, London, South East Coast, Northern Ireland, Scotland and Wales.

Results: Overall prevalence of gout was 2.51% (95% CI, 2.50%μ2.52%) and incidence was 1.87 (95% CI, 1.83–1.91) per 1000 person-years in the UK in 2012. The prevalence and incidence vary throughout the country (Figure 1). The highest prevalence was in North East (3.11% [3.00%–3.23%]) and Wales (2.98% [2.93–3.03]); the highest incidence as also in these 2 regions (2.30 [95% CI, 2.26–2.35] and 2.20 [95% CI, 2.15–2.24] per 1,000 patient-years respectively). Among prevalent gout patients in 2012, only 50,453 patients (43.6%) were under medical attention (with at least one consultation with a gout diagnosis or a prescription containing ULT). Management of gout in terms of percentage given ULT also varies between regions, partially in line with the variation of prevalence (Table 1). In general only one-third of prevalent cases were given ULT, and only one quarter of incident cases received ULT within one year from diagnosis.

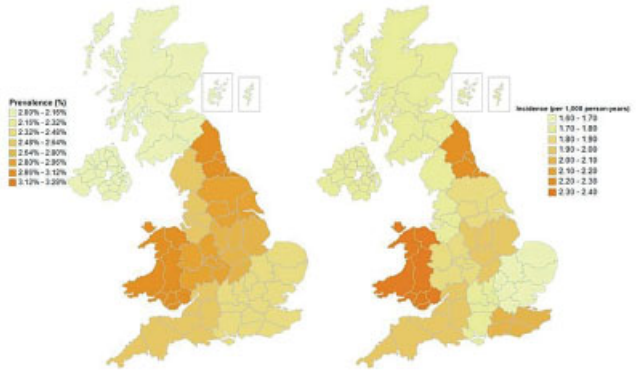

Figure 1. Geographic variations in the prevalence and incidence of gout

Table 1. Regional variation in gout management of gout in the United Kingdom in 2012

Area	Prevalent cases		Incident cases	
	Consulted	Treated by ULT	ULT by 6 months	ULT by 12 months
Overall	43.8%	31.1%	16.1%	23.3%
North East	36.4%	37.7%	16.6%	20.2%
North West	43.2%	31.8%	19.2%	26.7%
Yorkshire & The Humber	39.0%	24.9%	8.6%	16.0%
East Midlands	44.5%	25.7%	6.6%	10.3%
West Midlands	38.2%	27.5%	14.4%	20.6%
East of England	44.1%	32.3%	14.7%	21.8%
South West	37.1%	29.6%	11.4%	18.3%
South Central	44.2%	26.0%	12.6%	17.9%
London	43.9%	35.1%	18.0%	28.0%
South East Coast	37.7%	30.6%	17.0%	23.9%
Northern Ireland	46.7%	29.3%	18.0%	24.7%
Scotland	65.9%	37.8%	22.1%	30.1%
Wales	44.7%	30.7%	15.1%	21.1%

Conclusion: A regional variation of gout prevalence and incidence in the UK was observed. Only a minority of people with gout receive ULT and this aspect of gout management also varied between regions, suggesting a need for further education of general practitioners with respect to understanding of gout and its mangement.

1994

Performance Of Gout Impact Scale Of The Gout Assessment Questionnaire In a Longitudinal Observational Study Of Patients With Gout. Puja Khanna[1], Cleopatra Aquino-Beaton[2], Jasvinder A. Singh[3], Erin Duffy[4], David Elashoff[5] and Dinesh Khanna[6]. [1]University of Michigan Medical Center, Ann Arbor, MI, [2]VA Greater Los Angeles Healthcare System, Los Angeles, CA, [3]University of Alabama, Tuscaloosa, AL, [4]University of California Los Angeles, Los Angeles, CA, [5]UCLA Department of Medicine Statistics Core, Los Angeles, CA, [6]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: Gout Assessment Questionnaire (GAQ2.0) is a validated disease-specific measure used to evaluate patient reported outcomes in gout studies. The objective was to evaluate the correlates of Gout Impact Scale (GIS) of GAQ2.0 and change over time in a prospective cohort of patients.

Methods: 186 gout patients were recruited in a 9-month longitudinal study at 2 VA centers where data on HRQOL using SF36 v2 (higher score

denotes better health), Health Assessment Questionnaire, HAQ-DI (0–3, higher score indicates worse function) and GIS (higher score denotes greater impact of disease) was administered. The GIS has 5 domains: gout concern overall, gout medication side effects, well-being during attack, unmet gout treatment needs, and gout concern during attack; GIS scores range from 0 to 100, where a higher score indicates worse health. Demographics, education level, acute flare frequency, Charlson comorbidities (CCI), serum urate (sUA), serum creatinine, functional class, and patient and physician rating of the severity of gout on a 0–10 scale, were assessed. Spearman Correlations were calculated between baseline GIS domains scores and SF-36 PCS & MCS, HAQ-DI Score, CCI, sUA, and age. Multivariate linear regression was used to assess demographic and clinical predictors of total GIS score at baseline. Paired Wilcoxon sign rank tests were used to assess change in GIS between baseline and last visit. P-values <0.05 were considered significant.

Results: Mean age (SD) of patients was 64.6 (10.9) years, they were predominantly male (98%); 57% Caucasian, 32% African American, 13% Hispanic, and 94% who graduated high school. Mean sUA was 8.3 mg/dL (3.4), physician assessment of gout severity was 3.1 (2.7) and patient gout-severity assessment was 5.7 (3.1). Moderate negative correlations were noted between SF-36 PCS and GIS scores ($r=-0.29$) and well-being during attack ($r=-0.39$); whereas SF 36 MCS showed higher correlation with GIS domains ranging from 0.35–0.43, all $p<0.001$. HAQ-DI was significantly correlated with GIS, ($r=0.32$, $p<0.001$). Average GIS scores correlated with age ($r=0.4$, $p<0.001$). GIS score was significant higher than those with self-reported recent attack of gout within $^{2}3$ months from baseline compared to those without a recent attack. Younger age and experiencing an attack within last 3 months were predictive of higher total GIS score in multivariate linear regression analyses. A significant decrease in GIS scores was observed from baseline to 9-month period in the domains (Table).

Domains of GIS	Change from Month 9 to baseline, N=148, Mean (SD)
Gout Concern Overall	−8.7 (21.7)***
Gout Medications Side Effects	−2.0 (22.5)
Unmet Gout treatment Need	−4.0 (18.8)**
Well Being During Attack	−6.6 (19.5)***
Gout Concern During Attack	−4.1 (19.6)*
Total GIS	−3.3(13.3)***

*P<0.05; **p<0.01; *** p<0.001

Conclusion: GIS is a disease-specific measure that adequately captures the impact of gout over time. This study provides comprehensive validity of GIS in gout that meets the OMERACT filters.

1995

Serum Homocysteine Related To Decreased Renal Function In Chronic Gouty Patients. Jung-Soo Song, Jin Su Kim and Sang Tae Choi. Chung-Ang University College of Medicine, Seoul, South Korea.

Background/Purpose: Homocysteine is a non-essential amino acid formed by the conversion of methionine to cysteine. Hyperhomocysteinemia is a risk factor for cardiovascular events by inducing reactive oxygen species and impairing endothelial function. Gout is also associated with several comorbidities including cardiovascular disease (CVD). Hyperhomocysteinemia and gout are both related to CVD, however, there are few reports about serum homocysteine levels in gout patients and the results reveal discrepancies. In this study, we investigated whether or not homocysteine levels are elevated in patients with chronic gout and which factors are associated with elevated homocysteine levels.

Methods: 91 male patients with chronic gout and 97 age-matched healthy male controls were included in this study, and the averages of age were 51.19 ± 15.08 and 51.57 ± 17.01 years old, respectively. Serum homocysteine, uric acid (UA), blood urea nitrogen (BUN), creatinine (Cr) and other laboratory findings were tested for all participants. Serum homocysteine levels were measured by a competitive immunoassay using direct chemiluminescent (Siemens Centaur Immunoassay Systems, USA). The estimated glomurular filtration rate (eGFR) was calculated using modification of diet in renal disease (MDRD) formula, then the stages of chronic kidney disease (CKD) were classified according to eGFR levels.

Results: The chronic gout group were not significantly different from the control group in serum uric acid levels (6.15 ± 2.23 mg/dL vs 5.82 ± 1.22 mg/dL, $p = 0.214$). However, the patients with chronic gout showed much higher serum homocysteine levels than healthy controls (13.96 ± 4.05 μmol/L vs 12.67 ± 3.51 μmol/L, $p = 0.022$). Serum homocysteine levels were not different between the groups that are treated with allopurinol and with benzbromarone. The patients at stages 1 or 2 of CKD had significantly lower serum homocysteine levels than the patients at stage 3 of CKD (12.99 ± 4.81 μmol/L, 13.17 ± 2.97 μmol/L, and 17.45 ± 4.68 μmol/L, $p < 0.001$). In patients with chronic gout, serum homocysteine levels showed the positive correlations with serum BUN and Cr levels, and the negative correlation with eGFR and systolic blood pressure ($r = 0.429$, $p < 0.001$; $r = 0.435$, $p < 0.001$; $r = -0.413$, $p < 0.001$; $r = -0.251$, $p < 0.025$, respectively). However, serum homocysteine levels are uncorrelated with serum uric acid levels or cholesterol profiles. In multiple linear analyses, serum homocysteine level was affected by eGFR ($\beta = -0.385$, $p < 0.001$), however, was not affected by the serum uric acid level.

Conclusion: Serum homocysteine levels were higher in the male patients with chronic gout than in the healthy male controls. Hyperhomocysteinemia in gouty patients could be related not with serum uric acid levels, but with decreased renal function.

Racial/Ethnicity Differences In Health-Related Quality Of Life (HRQOL), Functional Ability and Health Care Utilization In Gout Patients. Aseem Bharat[1], Jasvinder A. Singh[2], Puja Khanna[3], Cleopatra Aquino-Beaton[4], Jay E. Persselin[4], Erin Duffy[5], David Elashoff[6] and Dinesh Khanna[7]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama, Tuscaloosa, AL, [3]University of Michigan Medical Center, Ann Arbor, MI, [4]VA Greater Los Angeles Healthcare System, Los Angeles, CA, [5]University of California Los Angeles, Los Angeles, CA, [6]UCLA Department of Medicine Statistics Core, Los Angeles, CA, [7]University of Michigan, Ann Arbor, MI.

Background/Purpose: Due to limited/no data for race/ethnicity, our objective was to assess whether HRQOL functional ability and health care utilization in gout patients differs by race/ethnicity.

Methods: This prospective cohort study included 186 veterans with gout (predominantly male) recruited at Veterans Affairs (VA) rheumatology and primary care clinics at the West Los Angeles, CA and Birmingham, AL facilities. We assessed HRQOL (with short-form 36 and the Gout Impact Scales (GIS) of the Gout Assessment Questionnaire (GAQ)); functional ability with Health assessment questionnaire-disability index (HAQ-DI); and health care utilization (patient self-reported University of California at San Diego (UCSD) Health Care Utilization Questionnaire) every 3 months for a 9-month period. Comparisons were made using the student's t test or the chi-square, Wilcoxon rank sum test or Fisher exact test, as appropriate.

Results: Race/ethnicity data were available for 167 patients, 107 Caucasian and 60 African-American. The cohort mean age was 64.6 years, 98% were men, 13% Hispanic or Latino, 6% did not graduate high school, 21% had gouty tophi, the mean serum urate was 8.3.

Compared to Caucasians, African-American gout patients were younger (61.1 vs. 67.3 years, $p=0.0003$), had higher serum urate (9.6 vs. 7.9 mg/dl, $p=0.005$), but similar patient (6.0 vs. 5.4, $p=0.27$) and physician assessment (3.3 vs. 2.9, $p=0.53$) of gout severity.

HRQOL Differences: African American patients with gout had lower scores on SF-36 mental health, role emotional, social functioning domains and MCS (but not PCS) relative to White patients ($P \leq 0.04$ for all; table 1).

On the GIS, African American scored higher in the areas of gout concern overall, unmet treatment need, well-being during attacks, concern during attacks, and overall average GIS (Table 2), but not medication side effects.

Functional limitation: Compared to Caucasians, African American had higher/worse HAQ scores overall and lower scores in 5 of the 8 activity domains of Dressing & Grooming, Arising, Eating, Walking, and Grip, indicating more difficulty with these tasks (Table 1).

Table 1. SF-36 (Higher score indicates better health) and HAQ scores (Higher score indicates worse health)

SF-36 T-Score Values	White N=107 Mean (SD)	African American N=60 Mean (SD)	T-test p-value
Physical Functioning (PF)	37.3 (12.1)	34.1 (12.4)	0.12
Role Limitation Physical (RP)	37.5 (12.4)	33.8 (12.1)	0.06
Pain (BP)	42.6 (12.2)	39.6 (12.6)	0.13
General Health (GH)	43.3 (5.1)	43.5 (4.9)	0.82
Emotional Well-being (MH)	46.3 (12.6)	40.8 (12.9)	0.008
Role Limitation Emotional (RE)	40.6 (16.0)	31.3 (17.0)	0.0005
Social Functioning (SF)	41.5 (12.3)	37.3 (12.8)	0.04
Energy Fatigue (VT)	45.8 (11.3)	45.2 (8.4)	0.71
Physical Health Component (PCS)	38.7 (10.4)	38.1 (10.0)	0.72
Mental Health Component (MCS)	46.2 (14.2)	39.5 (12.9)	0.003

HAQ	White N=105 Mean (SD) [Median (IQR)]	African American N=60 Mean (SD) [Median (IQR)]	Wilcoxon rank sum p-value
Dressing & Grooming	0.58 (0.74) [0.00 (1.00)]	0.87 (0.70) [1.00 (1.00)]	0.005
Arising	0.68 (0.69) [1.00 (1.00)]	0.98 (0.89) [1.00 (2.00)]	0.04
Eating	0.31 (0.67) [0.00 (0.00)]	0.52 (0.65) [1.00 (1.00)]	0.01
Walking	0.73 (0.81) [1.00 (1.00)]	1.10 (1.02) [1.00 (2.00)]	0.03
Hygiene	0.70 (0.89) [0.00 (1.00)]	0.80 (0.92) [1.00 (1.00)]	0.41
Reach	0.81 (0.82) [1.00 (1.00)]	0.82 (0.70) [1.00 (1.00)]	0.70
Grip	0.44 (0.72) [0.00 (1.00)]	0.95 (0.90) [1.00 (1.50)]	0.0001
Activities	1.10 (0.99) [1.00 (2.00)]	1.33 (1.13) [1.00 (2.00)]	0.23
HAQ Composite Score	0.67 (0.55) [0.63 (1.00)]	0.93 (0.68) [0.88 (1.13)]	0.02

Table 2. GIS by Race (Higher score indicates worse health)

GIS	White N=107 Mean (SD) [Median (IQR)]	African American N=60 Mean (SD) [Median (IQR)]	Wilcoxon rank sum p-value
Concern Overall	64.3 (27.9) [75.0 (50.0)]	73.6 (24.6) [75.0 (37.5)]	0.04
Medication Side Effects	48.8 (27.6) [50.0 (37.5)]	54.6 (28.9) [50.0 (50.0)]	0.16
Unmet Treatment Need	33.9 (18.6) [25.0 (16.7)]	41.4 (20.3) [33.3 (33.3)]	0.01
Well Being During Attack	51.1 (26.2) [52.3 (47.7)]	61.5 (25.5) [64.8 (36.4)]	0.01
Concern During Attack	50.0 (25.2) [50.0 (50.0)]	60.4 (26.5) [62.5 (43.8)]	0.01
Average GIS Score	50.8 (18.9) [51.6 (28.1)]	60.3 (19.6) [62.5 (32.3)]	0.004

Conclusion: This is the first prospective cohort study to show that African-American patients with gout have significantly worse emotional, social, and mental wellbeing/HRQOL and functional ability than Caucasians. Further research is needed into the determinants of this poorer HRQOL and function to target interventions to modifiable mediators of this relationship.

1997

Health Care Utilization In Gout Patients: A Prospective Multicenter Cohort Study. Jasvinder A. Singh[1], Aseem Bharat[2], Puja Khanna[3], Cleopatra Aquino-Beaton[4], Jay E. Persselin[4], Erin Duffy[5], David Elashoff[6] and Dinesh Khanna[7]. [1]University of Alabama, Tuscaloosa, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Michigan Medical Center, Ann Arbor, MI, [4]VA Greater Los Angeles Healthcare System, Los Angeles, CA, [5]University of California Los Angeles, Los Angeles, CA, [6]UCLA Department of Medicine Statistics Core, Los Angeles, CA, [7]University of Michigan, Ann Arbor, MI.

Background/Purpose: Because of the chronic nature of the disease, gout is associated with more co-morbidities, poor health-related quality of life (HRQoL) and more healthcare utilization (HCU). Therefore, the cost of care associated with gout management is rising. There is lack of evidence that describes the predictions of health care utilization in patients with gout. The objective of this study is to assess health care utilization and its predictors in patients with gout.

Methods: We conducted a prospective cohort study of 186 veterans with gout (predominantly male) recruited at Veterans Affairs (VA) rheumatology and primary care clinics at the West Los Angeles, CA and Birmingham, AL facilities. We assessed overall health care utilization with the patient self-reported University of California at San Diego (UCSD) Health Care Utilization Questionnaire and gout-specific health care utilization on the Gout Assessment Questionnaire (GAQ) every 3 months for a 9-month period. We collected data including patient demographics, education level, comorbidity, serum urate (in mg/dl) and patient and physician rating of the severity of gout on a 0–10 scale, HRQOL assessment with SF-36, and the Gout Impact Scales (GIS) of the GAQ and functional ability assessed with Health Assessment Questionnaire-Disability Index (HAQ-DI), were assessed. Comparisons were made using the student's t test or the chi-square, Wilcoxon rank sum test or Fisher exact test, as appropriate. Zero-inflated Poisson regression was used to assess potential predictors of gout-related HCU.

Results: The cohort mean age was 64.6 years, 98% were men, 13% Hispanic or Latino, 6% did not graduate high school, the mean serum urate was 8.3, mean physician gout severity assessment was 3.1 and mean patient gout severity assessment was 5.7. Mean Deyo-Charlson score was 3.1.

Overall health care Utilization: There were a mean of 3.9 visits to the health care provider in the past 3 months and 1.7 telephone calls to the provider or medical staff (Table). 17% had 1 or more inpatient visits in the past 3 months, 41% had 1 or more ER/urgent care/triage center visits and 16% with any outpatient procedure or surgery (Table).

Gout-specific health care utilization: During the past year, patients had a mean of 1.5 visits to rheumatologist, 2 visits to primary care doctor (Table). 7% had 1 or more inpatient visits in the past year related to gout, 26% had 1 or more ER visits related to gout and 33% with any urgent care/walk-in visit related to gout (Table).

	Patients with at least one visit/call N			Patients with at least one visit/call %			Number of visits/calls Mean (SD)		
Healthcare Utilization	Total N=186	BHAM N=74	LA N=112	Total N=186	BHAM N=74	LA N=112	Total N=186	BHAM N=74	LA N=112
Overall HCU, prior 3 months:									
Number of visits to MD, DO, or NP	163	63	100	92%	88%	95%	3.9 (4.3)	2.8 (2.5)	4.6 (5.1)
Number of phone calls to MD or medical staff	85	32	53	48%	44%	50%	1.7 (3.1)	1.4 (2.3)	1.9 (3.5)
Number of times to a triage, urgent care center, or emergency room	74	31	43	41%	43%	40%	0.6 (0.9)	0.6 (0.9)	0.6 (1.0)
Number of home visits by healthcare provider	16	6	10	9%	8%	9%	0.6 (2.4)	0.5 (1.9)	0.6 (2.8)
Number of days as inpatient	31	11	20	17%	15%	19%	1.8 (9.6)	0.6 (1.6)	2.7 (12.3)
Number of outpatient surgeries or procedures	27	15	12	16%	23%	12%	0.3 (0.9)	0.4 (1.1)	0.2 (0.7)
Gout related HCU, prior year:									
Rheumatologist	97	20	77	53%	28%	70%	1.5 (2.0)	1.2 (2.4)	1.7 (2.4)
Primary Care Doctor	128	57	71	71%	79%	66%	2.0 (1.9)	2.0 (1.5)	2.0 (1.5)
Nurse Practitioner or Physician's Assistant	53	8	45	31%	12%	43%	0.8 (1.6)	0.2 (0.7)	1.2 (0.7)
Walk-in or Urgent Care Clinic	57	21	36	33%	31%	34%	0.7 (1.5)	0.6 (0.9)	0.8 (0.9)
Emergency Room at a hospital	45	22	23	26%	31%	22%	0.4 (0.8)	0.4 (0.8)	0.4 (0.8)
Hospital Over-night Stay	17	5	12	10%	7%	11%	0.7 (7.5)	0.1 (0.4)	1.1 (0.4)

Conclusion: This cohort study is the first prospective cohort study to examine health care utilization in patients with gout. We have described patterns of health care utilization by patients with gout in the U.S. Future studies need to examine whether modifiable predictors of utilization can be targeted to reduce the overall and gout-related utilization in patients.

1998

The Risk Of Subsequent Attacks In Patients With Incident Gout: A Population-Based Study. Nour Zleik, Clement J. Michet, Helen Khun, Cynthia S. Crowson, Eric L. Matteson and Tim Bongartz. Mayo Clinic, Rochester, MN.

Background/Purpose: While there appears to be consensus that non-pharmacological uric acid lowering therapies (diet and lifestyle modifications) should be initiated in every patient presenting with gout, there is much less agreement as to when urate lowering drugs should be considered. Expert opinion ranges from starting uric acid lowering therapy after the first attack of gouty arthritis through a more cautious approach where therapy is only started in patients with more than 3 attacks per year. We aimed to assemble a population based cohort of patients with newly diagnosed gout to determine the risk of additional flares after an initial gout attack and explore the role of various demographic, clinical and laboratory predictors that may aid the clinician in quantifying this risk.

Methods: We examined a population-based incidence cohort of patients with gout, diagnosed according to the New York, Rome or ACR preliminary criteria in Rochester, Minnesota, between Jan 1st 1989 and Dec 31st 1992. All subjects were followed longitudinally through their complete community medical records, until death, migration or July 1st 2012. We used descriptive statistics to delineate the frequency and number of subsequent flares of gouty arthritis in our cohort. In addition, we utilized a conditional frailty model (accounting for multiple flares per subject) to explore risk factors of subsequent flares after an initial diagnosis of gout.

Results: 158 patients with incident gout were identified among Rochester residents within the 4 year time period. Subjects were followed for a mean (SD) of 13.4 (8.5) years. The majority of patients were male (73.4%) and the mean age (SD) at gout onset was 59.2.0 (17.8). Isolated podagra was the most common form of joint involvement at disease onset (74.7%) and the mean (SD) serum uric acid level was 8.1 (1.6) mg/dl. 111 patients (70.3%) developed at least 1 subsequent flare, with a total of 381 subsequent flares during the entire follow-up period. Patients with the highest risk of subsequent flares had an initial joint involvement other than first MTP joint (odds ratio 1.5, 95% CI 1.1, 2.2) and a high serum uric acid level at baseline (OR 1.35, 95% CI 1.2, 1.5). Age, gender, BMI, alcohol consumption, lipid levels and starting uric acid lowering therapy were not significant predictors of subsequent flare risk.

Conclusion: The majority of patients in our population-based cohort did develop at least one subsequent flare after a initial diagnosis of gout, with a 20-year cumulative incidence of more than 80 percent. Joint involvement other than the first MTP1 joint and the serum uric acid level were significant predictors of subsequent flare risk and should be taken into account when deciding on the timing of starting uric acid lowering therapy.

1999

Hospitalization and Flare Risk In Patients With Established Gout: A Population-Based Study. Nour Zleik, Clement J. Michet, Helen Khun, Cynthia S. Crowson, Eric L. Matteson and Tim Bongartz. Mayo Clinic, Rochester, MN.

Background/Purpose: Hospitalization of patients with gout may be associated with an increased risk of arthritic flares, due to administration of IV fluids, discontinuation of established uric acid lowering therapies and other medication changes. While previous studies have suggested an association of gouty arthritis and hospitalization, the absolute flare risk has not been identified. We aimed to assemble a population based cohort of patients with newly diagnosed gout to determine the risk of flares with future hospitalizations and explore the role of various predictors that may be associated with an increased risk of in-hospital gout flares.

Methods: We examined a population-based incidence cohort of patients with gout, diagnosed according to the New York, Rome or ACR preliminary criteria between Jan 1st 1989 and Dec 31st 1992. All subjects were followed longitudinally through their complete community medical records, until death, migration or July 1st 2012. Hospitalizations of each subject were recorded and hospital records were evaluated for a possible flare of gouty arthritis. Person-year methods were used to calculate the rate of flares of gouty arthritis during hospitalizations and out-of-hospital. In addition, we utilized a conditional frailty model (accounting for multiple flares per subject) to explore risk factors of in-hospital gout flares.

Results: 159 patients with incident gout were identified within the 4 year time period. Subjects were followed for a mean (SD) of 13.4 (8.5) years. The majority of patients were male (73.4%) and the mean age (SD) at gout onset was 59.2.0 (17.8). 107 patients (67%) did have at least 1 hospitalization, with a total of 382 hospitalizations during the entire follow-up period. 12 of these 382 hospitalizations were complicated by a flare of gouty arthritis during a total of 1548 hospital days (4.2 total person-years) compared to 370 out-of hospital flares during 2117 person-years of follow-up. The rate of flares during hospitalization was 7.7 per 1000 person-years compared to 0.5 per 1000 person-years out-of-hospital. Hospitalization was associated with a significantly increased risk of gout flares (Rate Ratio: 16.8; 95% CI: 8.8, 27.7).Various possible predictors of gout flares during hospitalization were evaluated, including discontinuation of established uric acid lowering therapy, administration of IV fluids, ICU admission, use of diuretics and reason for admission. None of these factors could be identified as a statistically significant predictor of in-hospital flares.

Conclusion: Hospitalization does represent a significant risk factor for flares of gouty arthritis in patients with a prior diagnosis of gout. Future studies will have to clarify if there are patient subgroups that are at particular risk and if inpatient care related measures can help to prevent arthritic flares during hospitalization.

2000

Changes In The Prevalence Of Gout In The United States General Population Between 1960 and 2010: The National Health and Nutrition Examination Surveys. Eswar Krishnan and Linjun Chen. Stanford University, Palo Alto, CA.

Background/Purpose: Despite the widely shared impression that the prevalence of gouty arthritis (gout) has increased over time in the US few population data are available.

Methods: We compared the age-gender specific prevalence proportions of self-reported gout from the 1959–1962 and 2009–2010 cycles of National Health and Nutrition Examination Surveys (NHANES). Using mid-period Census data we estimated and compared population-prevalence rates. Age, sex and risk factor adjusted changes were assessed using Poisson regressions.

Results: The estimated number of cases of gout in the US increased from about 1.1 million in 1960 to 8.1 million in 2010. The proportion of respondents with gout in NHANES increased from 1.1% to 3.7% whereas the unadjusted population-based prevalence of gout increased from 6 per 1000 to 26 per 1000. The increased prevalence was evident among all adults, men and women but was statistically significant and of larger magnitude among those 65 years and older (Figure 1, 2). The proportion of women in the population with gout remained unchanged at 31%. The mean age of the prevalent gout among adults (age>=18) increased from 54 years to 61 years among men and 57 years to 65 years among women. The age-sex adjusted prevalence rate ratio was 2.9 (2.1, 4.1). In Poisson regressions adjusted for age and waist circumference, the prevalence rate ratio decreased to 1.57 (1.18, 2.11). When men and women were studied separately in these regressions, the increase in prevalence was evident among men with rate ratio 1.77 (1.20, 2.60) but not among women with rate ratio 1.16 (0.74, 1.80). When hypertension and diabetes were added to the above model, the prevalence rate ratio was 1.86 (1.28, 2.71) for men and 1.21 (0.81, 2.11) for women.

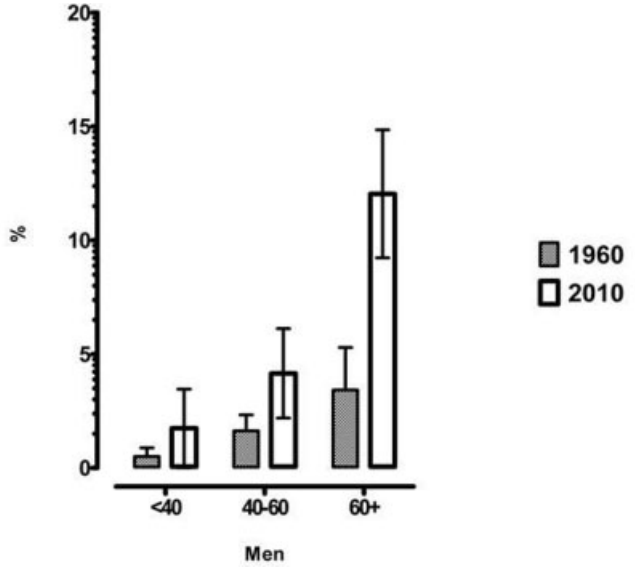

Figure 1.

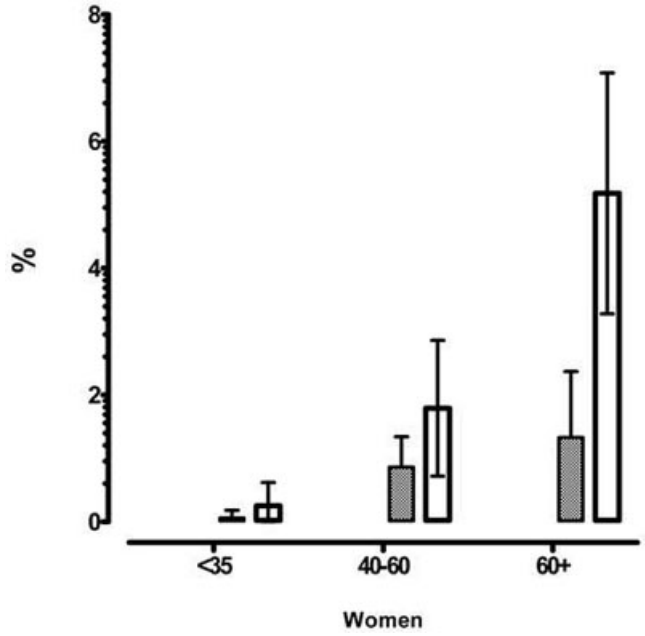

Figure 2.

Conclusion: The population burden of illness from gout has increased substantially in absolute and relative terms in the past 50 years. Both genders and all age groups witnessed increasing rate, the highest rise being evident in men older than 65 years. This increase was explained entirely by increase in abdominal adiposity among women. Among men, however, increased prevalence of abdominal adiposity, hypertension, diabetes, increasing population age only partly explained the increase. At least some of the observed increase could be due to greater disease awareness as the case definition was based on self-report.

2001

Kaiser Permanent Pyramid In Patients With Gout: The Most Severe Gout Is Associated To The Most Complex Patients. Fernando Perez-Ruiz, Ana M. Herrero-Beites and Amaya Martinez-Galarza. BioCruces Health Institute, Baracaldo, Spain.

Background/Purpose: gout is well known to be associated with comorbid conditions; the *Kaiser Permanente Pyramid* (KPP) identify high risk people (two higher strata) in the population, in order to support them in an individualized and multidisciplinary management, respectively, to avoid admissions. This study intends to evaluate whether severity of gout is also associated with higher KPP.

Methods: prospective cohort of follow-up of gout patients in whom KPP distribution was endorsed by the health system in the patients electronic file from Sept 2012. Comorbid conditions known to be cardiovascular risk factors (hypertension, glomerular filtration, diabetes, hyperlipidemia, vascular events), were recorded in the patientsx record file at baseline. In addition, evaluation of the severity of gout according to the number of flares (previous year), joint distribution, presence of subcutaneous tophi, and X-ray abnormalities related to gout, along with acute kidney injury related to the previous use of NSAIDs were also recorded at baseline evaluation.

Results: 256 patients, 92.2% men, 77% crystal and 11% hs-ultrasound based diagnosis, have been evaluated using the KPP. KPP higher strata included 132 (51.5%) of all the patients: 72 (28.1%) considered as high risk /disease care patients and 60 (23.4%) as very complex/case management patients. Comorbidities associated with gout were much more prevalent in the two higher strata of KPP (Table), but also showed that polyarticular distribution, presence of tophi, and X-ray abnormalities were more prevalent in these patients. Interestingly, previous acute kidney injury attributed to NSAIDs was ten-fold in these high-risk patients compared to low-risk patients.

KPP	Age (yr)	Women (%)	Onset (yr)	FGR (ml/min)	HT (%)	DM (%)	HLP (%)	VE (%)	Flares (yr)	Poly (%)	Tophi (%)	X-ray (%)	AKI (%)
0–1 N=124	55 ± 11	4.0	8.4 ± 8.4	53 ± 26	36	7	55	11	4 ± 4	37	35	46	1.6
2–3 N=132	67 ± 11**	11.4**	7.3 ± 7.1	89 ± 24**	73	30**	55	56**	4 ± 6	58**	46*	70**	15.9**

Conclusion: Patients with the highest clinical complexity according to Kaiser Permanente Pyramid also showed the most severe gout, indicating that these complex-severe patients could well deserve specific rheumatologic or even multidisciplinary management.

2002

Prophylactic Duration and Serum Uric Acid Level Are Associated With Gout Flare During Urate Lowering Treatment. Hyo-Jin Choi[1], Chan Hee Lee[2], Sang Tae Choi[3], Jung-Soo Song[3], Hyoun-Ah Kim[4], Chang-Hee Suh[5], Hoyeon Joo[6], Ki Chul Shin[7] and Hanjoo Baek[1]. [1]Gachon University Gil Hospital, Incheon, South Korea, [2]NHIC Ilsan Hospital, Goyang-si, South Korea, [3]Chung-Ang University College of Medicine, Seoul, South Korea, [4]Ajou University School of Medicine, Suwon, South Korea, [5]Ajou University Hospital, Suwon, South Korea, [6]Inha University Hospital, Incheon, South Korea, [7]Seoul National University College of Medicine, Seoul, South Korea.

Background/Purpose: To evaluate the clinical factors on gout flare during urate lowering treatment

Methods: We retrospectively examined data derived from 228 patients who had been treated with urate lowering agent more than six months after stopping prophylactic medication at multicenter rheumatology clinics. Demographic data (age, sex, disease duration, tophi and comorbidity), clinical and laboratory features including presence of gout flare during only urate lowering treatment, kinds and dose of urate lowering agents, serum uric acid, fasting glucose, lipid profile and creatinine clearance were collected at the initiation of urate lowering treatment and at the six months after stopping prophylaxis.

Results: Mean age of patients was 51.3 years, mean disease duration was 28.9 months, and mean body mass index was 27.5. Male to female ratio was 225:3. Starting urate lowering agents were allopurinol 84.6%, febuxostat 0.9%, and uricosuric agents 14.5%. Seventy-seven patients among 228 cases (33.8%) had experienced at least 1 gouty attack during only urate lowering therapy. Mean duration of prophylactic medication was shorter in flare group (9.1 months) than in non- flare group (11.3 months, $p=0.042$). At the time of stopping prophylaxis, mean serum uric acid level was 6.2 mg/dL (6.5 mg/dL vs. 6.0 mg/dL, $p=0.071$). According to the duration of prophylactic treatment ($<$ 6months, $\geq$6months), there were more frequent flares in the $<$ 6 months group than $\geq$ 6 months group (41.7% vs. 25.7%, $p=0.012$). At the time of stopping prophylaxis, mean serum uric acid level was 6.8 mg/dL vs. 5.6 mg/dL, $p=0.000$ respectively.

Conclusion: Prophylactic duration more than six months and target serum uric acid level (<6mg/dL) at the time of stopping prophylaxis are favorable factors for recurrent gout flare during urate lowering treatment

2003

Outcome Of Gout Patients Placed On Febuxostat After Failing To Reach Serum Urate Target With Allopurinol. Hind Hatoum[1], Dinesh Khanna[2], Aki Shiozawa[3], Swu-Jane Lin[4], Kasem Akhras[5] and Puja Khanna[6]. [1]University of Illinois at Chicago, chicago, IL, [2]University of Michigan, Ann Arbor, MI, [3]Takeda Pharmaceuticals International, Inc, Deerfield, IL, [4]University of Illinois at Chicago, Chicago, IL, [5]Formerly of Takeda Pharmaceuticals International, Inc, Deerfield, IL, [6]University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: The 2012 American College of Rheumatology (ACR) gout guidelines recommends allopurinol or febuxostat as first-line urate-lowering therapy (ULT). Purpose of this study was to compare outcomes in ULT-treated patients who were initiated and maintained on either allopurinol or febuxostat. In addition to outcomes of those switched to febuxostat after failing to reach target serum urate (sUA) ≤ 6mg/dL on allopurinol.

Methods: Centricity Electronic Medical Record database of ambulatory care by GE was used. Patients ≥18 years of age, with newly diagnosed with gout (ICD-9, 274.xx) on or after 2005, and initiated on allopurinol or febuxostat were included. Study index date was defined as date of first initiated ULT in patients with at least 6 months of data pre- and post study index. Patients were followed to date of last record. Primary study endpoint was reaching target sUA <6mg/dL within 6 months from index date. Descriptive statistics and bivariate analyses were performed on proportions of patients who reached target sUA among groups of allopurinol-throughout, febuxostat-throughout, or allopurinol-switched-to-febuxostat.

Results: Study cohort consisted of 16,366 patients who used allopurinol throughout, 884 patients used febuxostat throughout, 505 patients switched to febuxostat after failing targeted sUA with allopurinol. Within 6 months after switching to febuxostat, 36.8% of 505 patients who failed to reach target sUA on allopurinol achieved the goal sUA <6mg/dL. The proportion of allopurinol-switched-to-febuxostat who reached target sUA level was significantly higher than that among the allopurinol-throughout patients (36.8 vs. 28.9%, p=0.001), however, significantly lower than that among the febuxostat-throughout patients (36.8% vs. 46.0%, p=0.003, Figure). The 6-month average sUA after switching was 5.4 mg/dL, representing 39% reduction from the mean value of 8.6 mg/dL at time of switch. At the end of available records, 244/505 (48.3%) reached target. For these patients who reached target sUA, the mean (SD) days to switch from allopurinol was 197 (165 days), and the mean days of febuxostat treatment after the switch was 111 (137 days). The only significant difference between those who reached or did not reach sUA target was that the former group was significantly older (Table).

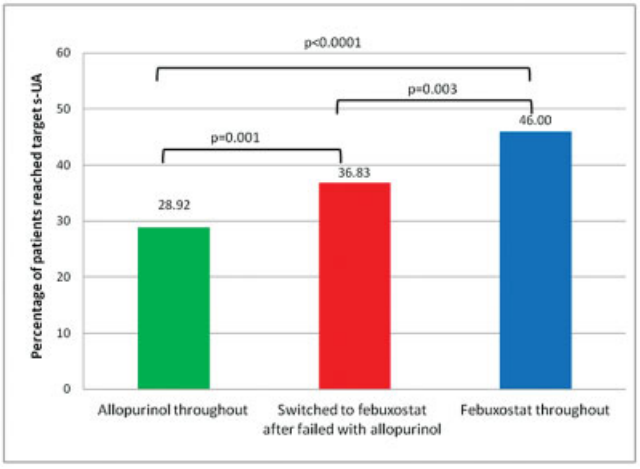

Figure 1. Proportion of patients reached sUA goal in 6 months of initiating ULT or switching.

Table 1. Bivariate analyses comparing between allopurinol patients who reached or did not reach sUA goal after switched to febuxostat

Variable	Did not reach goal after switch (N = 261)	Reached goal after switch (N = 244)	P value
Age, mean (SD)	61.84 (14.21)	65.02 (12.57)	0.0083
CCI, mean (SD)	0.45 (0.96)	0.38 (0.87)	0.3840
Gender, n (%)			
Female	79 (30.27)	91 (37.30)	0.0949
Race, n (%)			0.2098
Asian	4 (1.53)	4 (1.64)	
Black	29 (11.11)	19 (7.79)	
Hispanic	3 (1.15)	3 (1.23)	
Unknown	119 (45.59)	94 (38.52)	
White	106 (40.61)	124 (50.82)	
Gout diagnosis year, n (%)			0.8442
2005	6 (2.30)	4 (1.64)	
2006	5 (1.92)	6 (2.46)	
2007	19 (7.28)	16 (6.56)	
2008	35 (13.41)	30 (12.30)	
2009	92 (35.25)	77 (31.56)	
2010 & 2011	104 (39.85)	111 (45.49)	
BMI group, n (%)			0.3827
Underweight	0 (0)	1 (0.49)	
Normal	14 (6.39)	19 (9.22)	
Pre-obese	42 (19.18)	45 (21.84)	
Obese	163 (74.43)	141 (68.45)	
Baseline eGRF, ml/min, n (%)			0.3621
<15	0 (0.00)	3 (1.55)	
15≈<30	23 (12.11)	30 (15.46)	
30≈<60	105 (55.26)	102 (52.58)	
60≈<90	49 (25.79)	44 (22.68)	
>90	13 (6.84)	15 (7.73)	
Baseline serum UA level group, n (%)			0.3398
<6 mg/dL	2 (1.16)	4 (2.38)	
>=6–<7 mg/dL	8 (4.62)	12 (7.14)	
>=7–<8 mg/dL	19 (10.98)	22 (13.10)	
>=8–<9 mg/dL	39 (22.54)	46 (27.38)	
>=9 mg/dl	105 (60.69)	84 (50.00)	
Baseline Tophi diagnosis, n (%)	5 (1.92)	3 (1.23)	0.7256

Conclusion: Proportion of patients reaching target sUA levels varied significantly in patients utilizing ULT. Those who switched from allopurinol to febuxostat did significantly better than those who stayed on allopurinol in reaching target sUA but worse than those who started on febuxostat from the beginning.

2004

Kidney Disease Is An Independent Risk Factor For Incident Gout. Weiqi Wang[1], Vidula Bhole[2] and Eswar Krishnan[3]. [1]Stanford University, Palo Alto, CA, [2]EpiSolutions Consultancy Services, Thane, India, [3]Stanford University, Palo Alto, CA.

Background/Purpose: Even though the prevalence of chronic kidney disease (CKD) has been shown to be dispoportionarely high among those with gout, there have been scant data on temporal relationship between the two.

Methods: We analyzed data from the Framingham heart study (FHS) spanning 52 years from 1948 to 2000, over 26 study visits. Gout was defined as X-ray identified gout or physician diagnosed gout or usage of any gout medication or self-reported gout or presence of individual gout history. CKD was defined as physician diagnosed CKD or presence of CKD history. Hypertension was defined as systolic blood pressure >= 140 mm Hg or diastolic blood pressure >= 90 mm Hg or usage of anti-hypertensive medications. The alcohol and tobacco usage were self-reported. Diabetes and BMI was defined according to FHS official review. Statistical analyses were performed using Cox proportional hazard regression models, where the dependent variable was the time to incident gout. All covariates that entered the multivariable models (CKD, sex, age, BMI, hypertension, diabetes, usage

of alcohol and tobacco) were treated as time varying in the regression models. Missing values were addressed by multiple imputations.

Results: There were 5079 participants that were included, among whom 815 had CKD. At the baseline the proportion of men was 45.17%. Overall there were 414 incident cases of gout during the follow up. The incidence rate per thousand person-years of gout in the CKD group was 4.37 and in the non-CKD group was 2.53. The unadjusted and age adjusted hazard ratio of CKD were 1.48 (95% confidence interval 1.15–1.90) and 1.48 (1.15–1.90) respectively. In multivariable Cox models, CKD was associated with a hazard ratio of 1.68 (1.23–2.29).

Conclusion: CKD is a risk factor for gout, independent of gender, increasing age, obesity, hypertension, diabetes, usage of tobacco and alcohol.

2005

Predictors Of Outcomes In Tophaceous Gout- Results From a Prospective Cohort At The Veterans Affairs. Puja Khanna[1], Cleopatra Aquino-Beaton[2], Jasvinder A. Singh[3], Erin Duffy[4], David Elashoff[5] and Dinesh Khanna[6]. [1]Ann Arbor VA, Ann Arbor, MI, [2]VA Greater Los Angeles Healthcare System, Los Angeles, CA, [3]University of Alabama, Tuscaloosa, AL, [4]University of California Los Angeles, Los Angeles, CA, [5]UCLA Department of Medicine Statistics Core, Los Angeles, CA, [6]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: Tophaceous gout is a chronic inflammatory arthritis that causes debilitating acute attacks and associated with exponential resource utilization. Our objective was to define predictors of tophaceous gout in a prospective cohort.

Methods: 112 veterans with gout were recruited from rheumatology and primary care clinics at a single VA facility and followed for a total of 4 visits 3 months apart. Joint counts and presence of tophus was assessed by providers. HRQOL was evaluated with SF-36 v2, Health assessment questionnaire-disability index (HAQ-DI), and Gout Impact Scale (GIS) of $GAQ_{2.0}$. Patient demographics, duration of gout, Charlson comorbidities (CCI), serum urate (sUA), and patient and physician rating of the severity of gout on a 0–10 scale were assessed. Comparisons were made using the student's t test or the chi-square, Wilcoxon rank sum test or Fisher exact test, as appropriate, p-value < 0.5 was considered statistically significant. Age, race, physician severity score, functional class, disease duration, alcohol use, and number of comorbidities were considered as predictors of having tophaceous gout in univariate and multivariate logistic regression models.

Results: Patients diagnosed with tophaceous gout (N=35) were similar to patients without tophaceous gout (N=74) with respect to age, gender, race, alcohol use, duration of gout, polyarticular involvement, sUA and number of Charlson comorbidities, serum creatinine, and sUA (Table). Physician gout severity scores were significantly greater among patients with tophaceous gout; however, there was no difference in patient severity scores between groups. SF-36 scores indicated that the tophaceous group had worse physical functioning (p =0.04), bodily pain (p=0.07), total PCS scores (p=0.07), and gout concern overall domain of GIS (p=0.07). Physician severity score was the only significant predictor of outcomes identified after controlling for age, race, physician severity score, functional class, disease duration, alcohol use, and number of comorbidities.

Table 1. Patient Characteristics, Non-Tophaceous and Tophaceous

		Total Cohort N=112	Non-Tophaceous N=74	Tophaceous N=35	p-value
Age (Years)	Mean (SD)	65.7 (11.2)	65.5 (12.1)	66.5 (9.8)	0.68$^{\alpha}$
Gender (Male)	N (%)	106 (97.3)	72 (97.3)	34 (97.1)	0.99$^{\beta}$
Race					
Caucasian	N (%)	76 (67.86)	47(63.51)	26 (74.29)	0.29$^{\beta}$
African American	N (%)	17 (15.18)	15 (20.27)	2 (5.71)	
Other	N (%)	19 (16.96)	12 (16.22)	7 (20.00)	
Alcohol Use	N (%)	39 (35.1)	27 (36.5)	11 (32.4)	0.75$^{\epsilon}$
Duration of Gout	Mean (SD)	13.9 (12.9)	12.7 (12.3)	15.7 (14.0)	0.31$^{\gamma}$
Polyarticular Involvement (>3 joints)	N (%)	37 (36.3)	22 (32.4)	14(45.2)	0.22$^{\epsilon}$
# of Comorbidities (CCI)	Mean (SD)	3.9 (2.5)	3.6 (2.3)	4.5(2.6)	0.12$^{\gamma}$
Physician Severity Score	Mean (SD)	3.0 (2.5)	2.3 (2.1)	4.4(2.9)	<0.0001$^{\alpha}$
Patient Severity Score	Mean (SD)		6.0 (2.9)	6.5 (3.4)	0.44$^{\alpha}$
Radiographic evidence of erosion or tophi	N (%)	35 (70.0)	16 (53.3)	19 (95.0)	0.002$^{\beta}$
Serum Urate	Mean (SD)	7.5 (1.9)	7.8 (2.0)	7.1 (1.6)	0.09$^{\gamma}$
Serum Creatinine	Mean (SD)	1.4 (0.9)	1.5 (0.9)	1.3 (0.5)	0.60$^{\gamma}$

α=T-test; β=Fisher Exact test; γ=Wilcoxon test;ϵ=Chi-square test

Conclusion: Physicians rated tophaceous gout patients as having more severe disease. Surprisingly, conventional predictors of tophaceous gout such as disease duration, kidney disease, and sUA were similar in tophaceous and non-tophaceous groups. This may be reflective of the VA population that has a higher burden of urate even in the non-tophaceous patients.

2006

Uric Acid Level Is Not An Independent Predictor Of Cardiovascular Diseases In Gout Patients With Treatment; Long-Term Follow-Up Data In Single Tertiary Center In South Korea. Seulkee Lee[1], Eun-Jung Park[2], Jinseok Kim[2], Chan Hong Jeon[3], Hyungjin Kim[1], Jaejoon Lee[4], Eun-Mi Koh[1] and Hoon-Suk Cha[4]. [1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Jeju National University Hospital, Jeju, South Korea, [3]Soonchunhyang University College of Medicine, Bucheon, South Korea, [4]Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, South Korea.

Background/Purpose: Hyperuricemia and gout are closely related conditions that are prevalent worldwide. A possible link between hyperuricemia and cardiovascular diseases (CVD) has been a debated clinical topic for many decades. In particular, no study showed long-term cumulative effect of serum uric acid on CVD in gout patients with treatment.

The aim of this study is to evaluate the cardiovascular outcomes and determined cumulative impact of long-term uric acid level on CVD in gout patients with uric acid lowering treatment.

Methods: All patients who had first visit for gout at Samsung Medical Center between 1995 and 2002 and follow-up until December 2012 or expired during follow-up period were included and retrospective analyzed. Demographics, laboratory data and cardiovascular outcomes were evaluated. Mixed effect model and multi-variable analysis were used to determine the cumulative effect of long-term, repeated uric acid level on CVD.

Results: Two-hundred seventy-three patients with gout were observed. Of these, 49 (17.9 %) patients developed at least one of the CVD during follow-up period. Seven of the 49 patients showed two different kinds of CVD. Twenty-nine cases of coronary heart disease (CHD) or congestive heart failure (CHF), 24 cases of cerebral infarction or transient ischemic attack (TIA) and 4 cases of peripheral arterial occlusive diseases (PAOD). Mean age of diagnosis of gout was 45.4 and mean follow-up duration was 11.5 years. Baseline characteristics between patients with or without CVD showed no significant difference except incidence of hypertension. The cumulative effect of long-term uric acid level on CVD did not showed statistical significance according to mixed effect model ($P = 0.13$) and also multivariable analysis after adjusting confounding factors ($P = 0.07$). Chronic kidney disease (CKD), duration of gout and hypertension were risk factors for CVD in gout patient with uric acid lowering treatment by multi-variable analysis ($P = 0.01$, $P = 0.01$ and $P= 0.01$, respectively)

Conclusion: Our data demonstrated a long-term cumulative effect of uric acid may a cause for factors that are in the causal pathway for CVD rather than an independent predictor for CVD in gout patients with uric acid lowering treatment. CKD, duration of gout and hypertension were found to be the sole predictors for CVD in gout patients with treatment.

2007

Using Natural Language Processing and Machine Learning To Identify Gout Flares From Electronic Clinical Notes. Chengyi Zheng[1], Nazia Rashid[2], T. Craig Cheetham[3], Yi-Lin Wu[3] and Gerald D. Levy[4]. [1]Kaiser Permanente Southern California, Pasadena, CA, [2]Kaiser Permanente Southern California, Downey, CA, [3]Kaiser Permanente, Downey, CA, [4]Southern California Permanente Medical Group, Downey, CA.

Background/Purpose: Gout flares are the most common manifestation of gout. Gout flares are not well documented by diagnosis codes and are not adequately captured when conducting retrospective database analyses. Recently, in 2009, a code for acute gouty flare (ICD9 – 274.01) became available, but has yet to be widely adopted. We implemented a computer based method to automatically identify gout flares using Natural Language

Processing (NLP) and Machine Learning (ML). NLP aims to understand human languages and facilitates the utilization of the information in the free text. Machine Learning is aimed to train a computer system from data and then used to make decisions on new data.

Methods: A retrospective review was conducted between 1/1/2007 to 12/31/2010 from Kaiser Permanente Southern California Region. Patients > 18 years, with a diagnosis of gout (ICD9 274.xx) and on urate-lowering therapy were identified. 599,317 notes for 16,519 patients were retrieved. A training dataset of 1,264 notes was created by selecting 100 random patients. A Rheumatologist reviewed these notes to classify each note as gout flare or not. 1,192 notes from another 100 random selected patients were created and independently reviewed by two Rheumatologists to create the gold standard. A list of key words and phrases were used in the NLP algorithm which was used to capture different aspects of gout flares. The NLP results were used as features of the ML system which helped to achieve better specificity without significant loss in sensitivity. Both NLP+ML algorithms were developed using the training dataset then applied to all of the notes. Gout flares were also identified using claims data as proposed in published literature, which was then compared to the gold standard as well.

Results: Out of the 599,317 notes, the NLP system identified 49,415 notes as gout flare. ML system further classified them into 18,869 positive and 30,546 negative cases. Flares occurred within 30 days are merged. For the 16,519 patients, the NLP+ML system identified 1,402 patients with >= 3 flares, 5,954 with 1–2 flares, and 9,163 with no flare. Our method significantly identified more flare cases (18,869 vs. 7,861) and patients (7,356 vs. 5,458) compared to the method using the claims data.

On task of identifying flare for each note, our method achieved sensitivity of 84.8% and specificity of 92.2%. On task of identifying patients who had flares, our method had sensitivity of 98.5% and specificity of 96.4%. On task of identifying patients who had 3 or more flares, our method had sensitivity of 93.5% and specificity of 84.6%. The NLP+ML method is consistently better than the claims data approach and it even out-performed the two rheumatologist reviewers on task of identifying patients with gout flares.

Conclusion: A combination of NLP and ML is able to accurately and efficiently identify patients with gout flares. This is the first successful use of a computer controlled algorithm to identify gout flares from the clinical notes. It demonstrates that NLP could be a valuable tool to identify populations of patients who experience gout flares for more intensive therapy, ultimately getting them to serum urate goal, and help reducing overall costs associated to gout flares.

2008

Assessing Treat To Target In Gout Patients With and Without Tophi. Leslie R. Harrold[1], Carol Etzel[2], Bruce Schechter[3], Raymond L. Malamet[3], Vanessa Cox[4] and Jeffrey D. Greenberg[5]. [1]University of Massachusetts Medical School, Worcester, MA, [2]UT MD Anderson, Houston, TX, [3]Savient Pharmaceuticals, Inc., Bridgewater, NJ, [4]CORRONA, Inc, Southborough, MA, [5]NYU Hospital for Joint Diseases, New York, NY.

Background/Purpose: Little is known regarding the differences in characteristics between patients with tophaceous gout compared to those without tophi. We examined these differences in a national cohort of gout patients.

Methods: Patients enrolled by their rheumatologist within the Consortium of Rheumatology Researchers of North America (CORRONA) gout registry between 11/1/12 and 5/12/13 were included. All gout patients were eligible for enrollment regardless of disease severity, disease activity or medication use. Data was gathered at the time of routine clinical visits from patients and their treating rheumatologists including demographics, gout characteristics, comorbid conditions, current treatments, laboratory results and physical exam findings, including presence of tophi. Specifically we examined medication use and successful compliance with respect to target treatment goals (e.g., gouty flares and serum urate levels).

Results: There were 54 rheumatologists across the US who enrolled 524 gout patients who were predominately men (79%), with a mean age of 64 years (±13.6), disease duration of 10 years (± 9.6), and maximum uric acid level of 9 (±2.1) at the time of diagnosis. Associated cardiovascular disease was common in both those with tophi (n=116) and those without (n=407) (73% vs. 65%, p=0.12). Patients with tophi were more likely to have chronic kidney disease (29% vs. 14%, p=0.001). There was a trend towards a greater prevalence of diabetes mellitus in patients with tophi (25% vs. 19%, p=0.192) In addition, those with tophi, more often had to avoid the use of nonsteroidal anti-inflammatory drugs for acute gouty flares (33% vs. 20%, p<0.01). While use of urate-lowering therapy was common in those with tophi (60% allopurinol, 28% febuxostat, 5% pegloticase and 3% probenecid), only 58% of patients had achieved a SUA ≤6mg/dl (39% <5mg/dl). Both those with and without tophi had active disease with a mean of 4 and 3 gout flares respectively in the prior 12 months.

Conclusion: Most of the gout patients had active disease and not reached target SUA levels. Those with tophi are more likely to have chronic kidney disease and were less likely to be able to tolerate commonly prescribed medications to treat gouty flares.

2009

Outcome Of Allopurinol Or Febuxostat Treatment In Gout Patients Naïve To Urate-Lowering Therapy. Puja Khanna[1], Hind Hatoum[2], Swu-Jane Lin[3], Aki Shiozawa[4], Kasem Akhras[5] and Dinesh Khanna[1]. [1]University of Michigan Medical Center, Ann Arbor, MI, [2]University of Illinois at Chicago, chicago, IL, [3]University of Illinois at Chicago, Chicago, IL, [4]Takeda Pharmaceuticals International, Inc, Deerfield, IL, [5]Formerly of Takeda Pharmaceuticals International, Inc, Deerfield, IL.

Background/Purpose: In the US, 3.9% (8.3 million) of the population have self-reported gout, and 21.4% (43.3 million) have hyperuricemia. The 2012 ACR guidelines recommend febuxostat or allopurinol as first line urate-lowering therapy (ULT). In this study, outcomes in ULT-naïve patients in community clinics were investigated based on prescriptions patterns for allopurinol or febuxostat.

Methods: Centricity Electronic Medical Record database of ambulatory care by General Electric was used. Patients (≥18 years of age), newly diagnosed with gout (ICD-9, 274.xx) on or after 2005 and initiated on allopurinol or febuxostat were included. Study index date was defined as date of first initiated ULT in patients with at least 6 months of data pre- and post study index. Study groups consisted of patients first prescribed either ULT. Patients were followed to date of last record. Primary study endpoint was reaching target serum urate (sUA) of <6mg/dL in 6 months from index. Descriptive statistics and bivariate analyses were performed. Logistic regressions compared the likelihood to reach target sUA after either ULT accounting for several relevant covariates such as age, gender, baseline sUA and Charlson co-morbidity index (CCI).

Results: 17,199 (93.5%) patients started on allopurinol and 1190 (6.5%) patients started on febuxostat were enrolled. Overall study cohort had a mean age of 63.7±13.3 (standard deviation, SD), with 69.4% male, and 79.7% white. Mean follow-up duration from index to last record was 541.5±237.9 days. No significant differences between 2 ULT-treated groups were found for age, CCI, gender, race, or in having hypertension. Febuxostat group was more likely to have lower estimated glomerular filtration rate (eGFR; 46.4% vs 34.7% with <60 ml/min), higher overall mean baseline sUA (68.8% vs 68.0% with >=8 mg/dL), and twice as many with tophi (1.68% vs 0.88%), all p<0.05. Among the overall study cohort, 10,871 patients (59.1%) had sUA level after initiating ULT. 59.12% of the patients had documented sUA levels after initiation of ULT. Patients who had sUA measurement post study index date included 10,119 (93.1%) in the allopurinol and 752 (6.9%) in the febuxostat groups. Proportions reaching target were 29.2% in the allopurinol group and 42.2% in the febuxostat group (p<0.05) at 6-month follow-up. At 2 years post initiating ULT, 58.2 % of the patients in the febuxostat and 48.4% in the allopurinol treated groups reached target sUA levels (p<0.05).

Conclusion: Among ULT naïve patients, those starting with febuxostat had higher baseline sUA, higher tophi and worse eGFR than those starting with allopurinol. In spite of their more advanced or severe gout, febuxostat treated patients were significantly more likely to achieve target sUA at 6 months. Since more than 40% of the patients did not have documented sUA levels after initiation of ULT and doses were not factored into the analysis, the generalizability of the study results is hindered. Also study duration may have impacted the reported findings.

Background/Purpose: Erdheim-Chester disease (ECD) is a rare non-Langerhans form of histiocytosis characterized by an infiltration of foamy CD68+ CD1a- histiocytes. More than 500 cases of this disease have been reported since its first description in 1930.

Methods: The aim of this study was to describe a single-centre series of 96 consecutive ECD patients hospitalized at least once between 1992 and 2013 in the departement of internal medicine of Pitié-Salpêtrière hospital, Paris, France.

The geographic origin of patients referred to our tertiary care centre is international: 75 are french residents, while 21 patients come from Germany, UK, Eire, Belgium, Spain, Portugal, Israel, Norway and South Africa.

Results: Patients were 75 men and 21 women. Median age at diagnosis was 54.6 years (5–81 yr). In the present series the mean diagnostic delay is 2 yr (0–35yr). Mean follow-up between diagnostic and last news is 37.3 months (1.63–376 months). Fifty-five patients (56%) had peri-renal. Forty patients (42%) had a peri-aortic sheathing of the whole aorta ("coated aorta"), 33 (34%) a pericardial involvement, 29 (30%) a coronary involvement, 20 (21%) a reno-vascular hypertension, 34 (35%) a pseudotumoral infiltration of the right atrium. Twenty-two patients (23%) had an exophthalmos, 24 (25%) a xanthelasma often in peri-orbital spaces, 29 (30%) a diabetes insipidus, and 38 (40%) an involvement of the central nervous system (CNS), among which 17 (18%) with a cerebellar involvement. Twenty-one patients (22%) had hydronephrosis, 35 (36%) a pulmonary involvement, often asymptomatic. Seventy-four patients (80%) had high C-reactive protein values.

Eighty-seven patients (91%) have been treated with interferon alpha (IFNα) or Pegylated IFNα, with high doses when facing CNS and/or cardiac involvements. Twenty-two patients died (23%). We were able to identify a $BRAF^{V600E}$ mutation among 27 of the 53 patients (51%) among which tissue samples were exploitable. Seven of these patients with multisystemic ECD, refractory and/or intolerant to IFNα, have been treated with BRAF inhibitors (vemurefenib) with spectacular and sustained responses.

Conclusion: We report the world largest's monocentric series of ECD patients. The prognosis, which largely depends on the presence of CNS involvement, is variable. First line of treatment remains IFNα, which use is associated with improved survival in ECD is an independent prognostic factor of survival of ECD. Nevertheless, long-term therapy with IFNα may be poorly tolerated, and the place of BRAF inhibition, particularly for $BRAF^{V600E}$ mutated patients with life-threatening forms of the disease, should be studied in larger scale.

Osseous Sarcoidosis: Clinical Presentation, Treatment, and Outcomes. Experience From a Large Tertiary Care Academic Hospital. Jeffrey A. Sparks[1], Jakob I. McSparron[2], Christopher H. Fanta[2] and Jonathan S. Coblyn[2]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Sarcoidosis is a systemic inflammatory disease characterized by the formation of non-caseating granulomas. Osseous involvement in sarcoidosis is a rare manifestation and has infrequently been reported. The distribution of lesions, clinical presentation, treatment strategies, and outcomes of patients with osseous sarcoidosis are unclear. We have reviewed our experience with osseous sarcoidosis to better characterize these clinical features.

Methods: Potential cases of osseous sarcoidosis seen at a large tertiary care academic hospital by the Division of Rheumatology, Immunology and Allergy and the Division of Pulmonary and Critical Care Medicine were identified through directed inquiry and electronic health record queries. Cases were defined as having pathologic evidence of non-caseating granulomas on bone biopsy or evidence of osseous lesions on imaging attributable to sarcoidosis by the radiologist, treating clinician, and reviewer. Characteristics of the clinical presentation, treatment, and outcomes were obtained from thorough medical record review.

Results: We identified 19 cases of osseous sarcoidosis (9 with biopsy-proven disease and 10 with diagnosis based on imaging and clinical presentation). Osseous lesions were detected by imaging during the initial presentation for sarcoidosis in 11 of 19 cases (58%). In those who had a prior established diagnosis of sarcoidosis, the mean duration of sarcoidosis before osseous detection by imaging was 4.8 years. The mean duration between detection of lesions on imaging and definitive clinical diagnosis in those who had a bone biopsy was 344 days. Other systemic features of sarcoidosis were present in 18 out of 19 cases (95%). Hilar lymphadenopathy was present in most cases (16 out of 19, 84%). Symptoms were present in 10 out of 19 cases (53%) and consisted mostly of low back pain, arthralgias/arthritis, and soft tissue swelling. Lesions were detected by magnetic resonance imaging (13 cases) and positron emission tomography (8 cases). All patients had more than one bone involved. Most patients (89%) had axial involvement, primarily in the pelvis and lumbar spine, and required no specific treatment if lesions were discovered incidentally. A minority of cases (9/19, 47%) were treated specifically for osseous sarcoidosis, mostly with prednisone and hydroxychloroquine. Two cases required multiple medications, including anti-tumor necrosis factor therapy, for refractory symptomatic osseous sarcoidosis. At last follow-up, 16 out of 19 (84%) patients were asymptomatic from osseous lesions.

Conclusion: We have identified the largest series of osseous sarcoidosis and characterized its clinical presentation, treatment, and outcomes. Patients with osseous sarcoidosis had multiple bones affected and generally had other systemic manifestations of sarcoidosis. A minority of patients required treatment of their osseous sarcoidosis for relief of symptoms and most patients were symptom-free at last follow-up.

2012

Gender Influences On Organ Manifestations In a New Orleans Sarcoidosis Population. Adam Janot[1], McCall Walker[2], Mary Yu[1], Harmanjot K. Grewal[3], Matthew R. Lammi[4] and Lesley Ann Saketkoo[5]. [1]Louisiana State University Health Sciences Center, New Orleans, LA, [2]LSUHSC School of Medicine, New Orleans, LA, [3]Lousiana State University Health Sciences Center, New Orleans, LA, [4]Louisiana State University Health Sciences Center, Pulmonary and Critical Medicine, New Orleans, LA, [5]LSU HSC - New Orleans, Sections of Rheumatology and Pulmonary Medicine, New Orleans, LA.

Background/Purpose: Sarcoidosis is a multi-organ disease in which pulmonary manifestations predominate. The skin, eyes, heart, gastrointestinal tract (GI), reticuloendothelial, renal and nervous systems are also commonly involved. Prior studies have shown a gender association with organ-specific manifestations. Male gender is associated with more severe radiographic abnormalities and female gender with more frequent extra-pulmonary manifestations (EPM). We conducted a survey of gender-based differences in organ-specific manifestations of sarcoidosis.

Methods: A retrospective chart review on patients seen in clinics from a single institution from 2006–2012 with biopsy-proven sarcoidosis and a diagnosis >1 year were included. Data were collected on sex, smoking status, EPM (cutaneous, ocular, cardiac, neurologic, GI, and renal), chest radiographs and pulmonary function testing (PFT).

Gender differences between EPMs and pulmonary sarcoidosis (defined as chest radiographic findings consistent with hilar adenopathy and pulmonary fibrosis) were calculated. Differences in forced vital capacity (FVC), total lung capacity (TLC), and diffusion capacity of lung for carbon monoxide (DLCO) were calculated using a t-test for the mean. PFTs were stratified by time of diagnosis in five year intervals. PFT results were averaged if more than one test was done in a five year period.

Results: Of 511 charts reviewed, 156 patients (50 Male, 106 Female) met inclusion criteria. Ocular sarcoidosis (OS) was more frequent in males (M=28.0%, F=10.4%, p=0.005) with an odds ratio of 3.35(95% CI 1.40 to 8.08). Gender was not a significant risk factor for other EPMs, nor for all EPMs combined.

The presence of pulmonary sarcoidosis was not associated with gender. PFTs showed significant gender difference (Table 1). Males demonstrated worse FVC (M=69.0 ± 0.71% predicted, F=82.2 ± 20.35% predicted, p=0.03) and TLC (M=63.0 ± 0.71% predicted, F=78.86 ± 16.37% predicted, p=0.003) at 5–10 years post diagnosis. DLCO was significantly lower in females compared to males at 10–15 years post diagnosis (M= 72.0 ± 4.24% predicted, F=55.33 ± 15.17% predicted, p= 0.02). There was no significant difference in smoking status between male and female groups with pulmonary sarcoid (p=0.11).

Table 1. Percent Predicted FVC, TLC, and DLCO at 5 year intervals from time of diagnosis

Time of PFT relative to diagnosis	0–5 years			5–10 years			10–15 years		
PFT	FVC	TLC	DLCO	FVC	TLC	DLCO	FVC	TLC	DLCO
Males	77.2 ± 16.9 n=22	69.8 ± 15.8 n=22	64.3 ± 18.0 n=22	69.0 ± 0.7 n=2	63.0 ± 0.7 n=2	59.0 ± 12.7 n=2	92.7 ± 11.0 n=3	77.5 ± 9.2 n=2	72.0 ± 4.2 n=2
Females	79.0 ± 18.0 n=39	77.9 ± 15.6 n=36	62.2 ± 25.9 n=36	82.2 ± 20.4 n=14	78.9 ± 16.4 n=14	66.6 ± 21.1 n=14	86.2 ± 19.9 n=9	76.2 ± 10.7 n=9	55.3 ± 15.2 n=9
p-value	0.71	0.06	0.72	0.03	0.003	0.55	0.51	0.88	0.02

Conclusion: Male gender is an independent risk factor for OS. Though gender was not associated with radiographic sarcoidosis, when controlled for smoking, a difference in increased severity of restrictive lung disease was suggested in a very small group of males at 5–10 year post diagnosis. Interestingly, females demonstrated a lower diffusion capacity at 10–15 years after diagnosis; the implications for underlying pulmonary vascular disease with disease duration are unclear.

Biologic Therapy In Refractory Uveitis Of Sarcoidosis. Multicenter Study Of 16 Patients. Javier Loricera[1], Vanesa Calvo-Río[1], Ricardo Blanco[2], Marina Mesquida[3], Alfredo M. Adan[3], JM Herreras[4], A Aparicio[5], MJ Moreno Ramos[6], MJ Moreno Martínez[6], LF Linares Ferrando[6], M Hernández Martínez[6], D Peitado-Lopez[7], Miguel Cordero-Coma[8], Jl García Serrano[9], Norberto Ortego[9], O Maíz[10], A Blanco[10], Juan Sánchez-Bursón[11], S González-Suárez[12], Alejandro Fonollosa[13], Montserrat Santos-Gómez[1], F. Ortiz-Sanjuán[1] and Miguel Angel González-Gay[1]. [1]Hospital Universitario Marqués de Valdecilla. IFIMAV. Santander. Spain, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain, [3]Hospital Clínic of Barcelona, Barcelona, Spain, [4]Hospital Universitario, IOBA. Valladolid, Valladolid, Spain, [5]Hospital de Toledo., Toledo, Spain, [6]Hospital Clínico Universitario Virgen de la Arrixaca. Murcia, Murcia, Spain, [7]Hospital Universitario La Paz Madrid, Madrid, Spain, [8]Hospital de León, León, Spain, [9]Hospital San Cecilio. Granada, Granada, Spain, [10]Hospital Donosti San Sebastian, San Sebastián, Spain, [11]Hospital de Valme. Sevilla, Sevilla, Spain, [12]Hospital Cabueñes, Gijón, Gijón, Spain, [13]Hospital de Cruces. Bilbao, Bilbao, Spain.

Background/Purpose: Uveitis related to sarcoidosis is a potentially severe complication. Corticosteroids are the first line of treatment. In refractory cases or in those with unacceptable side effects, traditional synthetic immunosuppressive drugs are used. TNF-α has been implicated in the pathogenesis of sarcoidosis. Our aim was to evaluate both short and long-term response to anti-TNF therapy in uveitis associated to sarcoidosis refractory to standard systemic treatment.

Methods: Multicenter study of 16 patients followed in the uveitis units from 12 hospitals. All of them presented inadequate response or intolerance to conventional therapy with corticosteroids and at least 1 systemic synthetic immunosuppressive drug.

The degree of ocular inflammation was evaluated according to "The Standardization of Uveitis Nomenclature (SUN) Working Group" (Am J Ophthalmol 2005; 140: 509–516), and macular thickness by optical coherence tomography (OCT). Results were expressed as mean± SD for variables with a normal distribution, or as median [25th-75th interquartile range (IQR)] when they were not normally distributed. Comparison of continuous variables was performed using the Wilcoxon test.

Results: We studied 16 patients/ 27 affected eyes (7 men, 9 women) with a mean age of 38.4±17.2 years (range 13–76). Angiotensin-Converting Enzyme (ACE) was elevated at 56.2% of patients. We observed bilateral hilar lymphadenopathy (56.2%), lung parenchymal involvement (43.7%), peripheral lymph nodes (37.5%) and involvement of other organs (56.2%). In 31.2% of patients the diagnosis was confirmed by a biopsy. The most frequent pattern of ocular involvement was bilateral chronic relapsing panuveitis and the most characteristic findings were Mutton-fat keratic precipitates and snowballs in vitreous. Besides oral corticosteroids and before the onset of biologic therapy patients had received i.v. boluses of methylprednisolone (1 patient), methotrexate (MTX) (12), cyclosporine A (CyA) (5), or azathioprine (AZA) (3). The first biologic agent used was: infliximab (IFX) in 7 cases (43.7 %) and adalimumab (ADA) in 9 cases (56.3 %). They were used in 3 cases as monotherapy and in the remaining cases in combination with: MTX (10), AZA (2) and Mycophenolate mofetil (1). IFX 5 mg/kg /i.v./every 4–8 weeks and ADA 40 mg/sc/2 weeks were the most patterns of administration. During the follow-up, due to intolerance, IFX was successfully switched to golimumab in 2 cases. The mean duration of follow-up after the onset of anti-TNF therapy was 27.7±16.8 months. Overall, improvement was observed after 2 years of therapy: Baseline results versus results after 2 years of biologic therapy were the following: Visual acuity (VA): baseline 0.6± 0.3; after 2 years: 0.8±0.2; p=0.03; Tyndall from a median [IQR] of 1 [0–3] to 0 [0–2] (p=0.017) and vitritis, from a median [IQR] of 0 [0–3] to 0 [0–1] (p=0.03). At baseline, 6 patients, (9 eyes) had macular thickening (OCT>250μ) and 6 patients (7 eyes) had cystoid macular edema (CME) (OCT>300μ). CME improved from 372±58.3 microns to 241±1.4 microns at 2 years (p=0.17).

Conclusion: Anti-TNF therapy seems effective in patients with uveitis secondary to sarcoidosis refractory to conventional immunosuppressive therapy.

2014

Cigarette Smoking and Male Sex Are Independent Risk Factors For Ocular Sarcoidosis. Adam Janot[1], Dörte Huscher[2], McCall Walker[3], Harmanjot K. Grewal[4], Mary Yu[1], Matthew R. Lammi[5] and Lesley Ann Saketkoo[6]. [1]Louisiana State University Health Sciences Center, New Orleans, LA, [2]Charité University Hospital and German Rheumatism Research Centre, a Leibniz Institute, Berlin, Germany, [3]LSUHSC School of Medicine, New Orleans, LA, [4]Lousiana State University Health Sciences Center, New Orleans, LA, [5]Louisiana State University Health Sciences Center, Pulmonary and Critical Medicine, New Orleans, LA, [6]LSU HSC - New Orleans, Sections of Rheumatology and Pulmonary Medicine, New Orleans, LA.

Background/Purpose: Sarcoidosis is a multi-organ system granulomatous disease of unknown origin with an incidence of 1–40/100,000. Though pulmonary manifestations are predominant, ocular morbidity is characteristic. Ocular Sarcoidosis (OS) affects 25–50% of patients with sarcoidosis and can lead to blindness. To date, no studies have sought to determine risk factors for OS.

Methods: A retrospective chart review was conducted at a single institution with inclusion criteria of biopsy-proven sarcoidosis with a duration of >1 year and a documented smoking status. Variables collected were ages at time of diagnosis (of any organ) and at time of chart review, race, sex, smoking status, quantity of tobacco exposure, and presence (or history) of OS. Disease duration is defined as the difference of age at diagnosis and age time of chart review. Group comparisons were done by t-test and by

Mann-Whitney tests where applicable. Univariate and multivariate regression analysis were done to identify independent risk factors.

Results: Of 269 charts reviewed, 109 patients met inclusion criteria. Characteristics of patients with and without OS are shown in table 1. In the OS group, the portion of smokers (71.4%) was significantly higher than in the group without OS (42.0%, p=0.027). There was no significant difference (p=0.605) in the median number of pack years between smokers with OS (13 [7, 28]) and those without OS (16.5 [7, 25]). Furthermore, the OS group consisted of more male patients (57.1% versus 26.1%, p=0.009). Median disease duration of sarcoidosis was also higher in patients with OS (10 years versus 4 years, p=0.031).

Through multivariate regression analysis, tobacco exposure (OR=5.24, p=0.007, 95% CI 1.58–17.41) and male sex (OR=7.48, p=0.002, 95% CI 2.152–26.006) were found to be independent risk factors for the development of OS.

Table 1. Characteristics of patients with and without OS

	No OS (n=88)	With OS (n=21)	p-value
Sex			
Female	65 (73.9%)	9 (42.9%)	0.009
Male	23 (26.1%)	12 (57.1%)	
Age at onset of sarcoidosis (median, IQR)	41 (35, 49)	43 (33, 49)	0.863
Disease duration (median, IQR)	4 (2, 12)	10 (4, 15)	0.031
Race			
Black	78 (88.6%)	19 (90.5%)	1.000
White	5 (5.7%)	0	
Hispanic	0	1 (4.8%)	(black vs. all other)
Middle Eastern	1 (1.1%)	0 (0.0%)	
Unknown	4 (4.5%)	1 (4.8%)	
Smoking Status			
Never smoker	51 (58.0%)	6 (28.6%)	0.027
Ever smoker	37 (42.0%)	15 (71.4%)	
Pack years of ever smokers (median; IQR)	13 (7, 28)	16.5 (7, 25)	0.605

Conclusion: Male sex and tobacco exposure (regardless of pack years) are independent risk factors for development of OS. Disease duration did not withstand multivariate analysis in this moderately sized group. However, screening for OS should not remit in patients with known sarcoidosis until defined in larger prospective populations.

2015

Sarcoid Arthritis In World Trade Center Exposed New York City Firefighters Presenting As a Unique Clinical Subset. Konstantinos Loupasakis[1], Jessica Berman[2], Michelle S Glaser[3], Nadia Jaber[4], Rachel Zeig-Owens[4], Mayris P Webber[4], Michael D Weiden[4], Anna Nolan[4], Kerry J Kelly[4] and David J Prezant[5]. [1]Hospital for Special Surgery Weill Cornell Medical College, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [3]Montefiore Medical Center, Bronx, NY, [4]Bureau of Health Services Fire Department of New York, Brooklyn, NY, [5]Montefiore Medical Center Albert Einstein College of Medicine, Bronx, NY.

Background/Purpose: Sarcoidosis is a multisystem disease characterized by the formation of non-caseating granulomas with lungs being predominantly affected and the joints in up to 40%. Acute joint manifestations occur in 25–40% of patients and are often self-limited with only 1–4% of patients developing a more chronic arthritis, requiring more aggressive therapy, due to persistence or progression. We previously reported an increased incidence of sarcoidosis among Fire Department of the City of New York (FDNY) firefighters prior to 9/11/01 and an even higher incidence after World Trade Center (WTC) exposure. We now describe a series of FDNY firefighters who developed sarcoidosis following WTC rescue/recovery work with severe chronic polyarthritis as a significant component of their disease.

Methods: All FDNY WTC-exposed firefighters with polyarticular sarcoidosis are followed jointly by the WTC Health Program at FDNY and the Rheumatology Division at the Hospital for Special Surgery (HSS). Patient demographics, WTC-exposure information, smoking status, date of diagnosis, and pulmonary findings were obtained from FDNY's WTC database. Joint findings (symptoms, duration, distribution of joints involved, treatments, and response) were obtained from HSS chart review.

Results: 11 male firefighters developed polyarticular arthritis after WTC-exposure; 2 had been diagnosed with sarcoidosis pre-9/11/01. All were never smokers and arrived at the WTC-site within 2 weeks after 9/11/01. Their median age was 37.7 years (IQR = 31.6–40.8), with a median of 6.9 years (IQR=4.4–13.2) of FDNY firefighting service pre-9/11/01. All had biopsy-proven pulmonary sarcoidosis, 9 by transbronchial or mediastinal lymph node biopsy, 1 by liver and bone biopsy and 1 by Kveim testing. All had normal pulmonary function tests at presentation. Duration from WTC-exposure to diagnosis of pulmonary sarcoidosis was 7.7 years (IQR=5.8–9.5). Polyarticular arthritis was part of the initial presentation in 9 patients who developed sarcoidosis post-9/11/01. In 2 patients with pre-9/11/01 sarcoidosis, polyarticular arthritis occurred after WTC exposure, 5 and 10 years after their initial diagnosis. Polyarthritis was symmetrical, involving large joints (n=1), small and large joints (n=10) and ankles (n=10). All had normal ESR and CRP; negative anti-CCP and Quantiferon or PPD. Only one had a positive RF and all but two had normal ACE levels. All required additional disease modifying agents for steroid sparing (stepwise progression from hydroxychloroquine->methotrexate->TNF-blocking agent). Adequate disease control was obtained with hydroxychloroquine (n=1); methotrexate (n=3); and anti-TNF agents (n=6).

Conclusion: Chronic polyarthritis appears to be an important manifestation of sarcoidosis in FDNY firefighters with sarcoidosis and WTC-exposure. Their arthritis appears to be chronic and most have not responded adequately to oral DMARDs, generally necessitating the addition of anti-TNF agents. Further studies are needed in order to determine the generalizability of these findings to other groups with varying levels of WTC-exposure or with non-WTC environmental/occupational exposures.

2016

Inflamamatory Myositis-Increased Incidence In Fire Department Of New York Firefighters After World Trade Center Exposure. Basit Qayyum[1], Michelle S Glaser[2], Nadia Jaber[3], Rachel Zeig-Owens[2], Mayris P Webber[3], Anna Nolan[3], Kerry J Kelly[3] and David J Prezant[4]. [1]New York University School of Medicine, New York, NY, [2]Montefiore Medical Center, Bronx, NY, [3]Bureau of Health Services Fire Department of New York, Brooklyn, NY, [4]Montefiore Medical Center Albert Einstein College of Medicine, Bronx, NY.

Background/Purpose: Inflammatory myositis (IM) is extremely rare in white middle-aged males. Incidence rates in males ranging from 0.25 to 5 per million. We describe a series of Fire Department of the City of New York (FDNY) firefighters who developed IM following World Trade Center (WTC) exposures.

Methods: FDNY WTC-exposed firefighters with IM are followed jointly by the WTC Health Program at FDNY and the Rheumatology Division at the New York University, School of Medicine. Patient demographics, WTC-exposure information, smoking status, diagnoses (including date of diagnosis), and pulmonary findings were obtained from FDNY's WTC database. Findings (symptoms, duration, muscles involved, treatments, and response) were obtained from chart review.

Results: Seven firefighters developed IM after WTC-exposure. Duration from WTC-exposure to IM diagnosis was 4.6 years (IQR=1.5–6.2). The average annual incidence rate was 9.2 per million. No cases had been reported at FDNY pre-9/11/01 (15 year prior database search). All were white males who arrived at the WTC-site within two weeks after 9/11/01. Three cases are never smokers, while four cases are ever-smokers. None had a family history of IM or autoimmune disease. Their median age on 9/11/01 was 45.5 years (IQR = 43.2–55.6), with a median of 20 years (IQR=15.8–31.0) of FDNY firefighting service pre-9/11/01. All presented with bilateral proximal muscle weakness and pain most noticeable in the pelvic girdle and quadriceps, and elevated creatine kinase. None had skin involvement; one patient developed interstitial lung disease (anti-Jo antibodies) and died two years after lung transplantation; and one patient had inclusion body myositis (IBM) on muscle biopsy. All but two patients responded to corticosteroids and methotrexate with dramatic improvement and one patient had complete resolution without need for maintenance medication. Two patients (one with anti-Jo antibodies and one with IBM) required monthly intravenous immunoglobulin.

Conclusion: The incidence of IM appears to be increased in male FDNY firefighters after WTC-exposure, however further studies are needed to confirm this. Additionally, studies are needed in order to determine the generalizability of these findings to other groups with varying levels of WTC-exposure or with non-WTC environmental/occupational exposures.

Hyper Ferritinemia Suggests a High Frequency Of Macrophage Activation Syndrome In a Large Adult Severe Sepsis Cohort: A Role For Anakinra?
Bita Shakoory[1], Joseph A. Carcillo[2] and Steven Opal[3]. [1]Temple University, Philadelphia, PA, [2]University of Pittsburg Medical Center, Pittsburgh, PA, [3]Brown University, Providence, RI.

Background/Purpose: Inreased ferritin levels are protective during infection whereas but very very high level are associated with MAS in rheumatologic disease cTo determine frequency of macrophage activation syndrome (MAS) in a sepsis cohort defined by using ferritin level (> 2,000), and to compare outcome, organ involvement and response to anakinra in sepsis across levels of Ferritinemia.

Methods: Remaining sera and data from "interleukin-1 receptor antagonist trial in severe sepsis: a phase III, randomized, double-blind, placebo-controlled, multicenter trial" (Opal, et. al. Crit Care Med. 1997 Jul;25(7): 1115–24.) was analysed. Ferritin was measured in the remaining sera of de-identified subjects from this study (levels beyond 6,000 were not further diluted). Subgroups were defined based on serum ferritin ranges (0–499, 500–999, 1000–1999, above 2000 μg/L). Post hoc statistical analysis included: descriptive statistics, rank test, ANOVA, Cox regression.

Results: Sera and data were available for ferritin measurement in 120/756 original study cohort (ages 22–85; 41.6% women). Demographics and 28-day outcome with or without anakinra in the ferritin subgroups are shown in Table. The Ferritin subgroup 500–999 had higher 28 day survival than other subgroups (18/21, 85.7%)(p <.05?), which was decreased with anakinra (100% alive in placebo vs. 82.4% with anakinra). The Ferritin subgroup >2000 (24/29, 24.2%) showed lower 28-day survival, which was increased with anakinra (40% with placebo vs. 57.9% with anakinra).

Ferritin Range	Group N (%) (Total 120)	Age Range	Woman (%)	28 Day Alive	28 Day Alive	
					Anakinra	Placebo
0–499	42 (35.0)	25–85	18/42 (42.9)	27 (64.3)	17/27 (62.9)	10/15 (67.7)
500–999	21 (17.5)	22–83	7/21 (33.3)	**18 (85.7)**	**14/17(82.4)**	**4/4 (100)**
1000–1999	28 (23.3)	22–81	15/28 (53.6)	18 (64.3)	16/25 (64.0)	2/3 (67.7)
2000	29 (24.2)	28–76	10/29 (34.5)	**15 (51.8)**	**11/19(57.9)**	**4/10 (40)**

Conclusion: As hypothesized, an increased Ferritin 500–1000 showed a protective inflammatory response in adult severe sepsis patients, whereasvery high Ferritin levels > 2,000 μg/L may signify immune dysregulation and concurrent MAS (25% of adult severe sepsis patients). Given the high mortality of unrecognized MAS in adults with rheumatic diseases (up to 64% reported) further stuies are warranted both evaluating ferritin in the diagnosis of, and anakinra in the treatment of severe sepsis associated MAS (Ferritin > 2,000).

2018

Hemophagocytic Lymphohistiocytosis As a Clinical Syndrome Of Autoimmune Diseases, Haematology, Oncology and Infectious Diseases.
César Antonio Egües Dubuc, Vicente Aldasoro Cáceres, Miren Uriarte Ecenarro, Carlos Meneses Villalba, Nerea Errazquin Aguirre, Iñaki Hernando Rubio, Olga Maiz Alonso, Jorge Cancio Fanlo, Esther Uriarte Isacelaya and Joaquin Belzunegui Otano. Donostia University Hospital, San Sebastián, Spain.

Background/Purpose: Hemophagocytic Lymphohistiocytosis (HLH) is a severe and acute inflammatory syndrome usually fatal without treatment. HLH includes a spectrum of diseases produced by the proliferation and activation of T-cells and macrophages. The macrophage activation syndrome (MAS) is a variant of secondary HLH that occurs in autoimmune diseases.

Methods: A retrospective search was performed by reviewing medical reports with HLH diagnosed between December 2008 and June 2013 at the Donostia University Hospital, Spain. Inclusion criteria were to meet the diagnostic criteria for HLH and had a bone marrow biopsy with hemophagocytic cells. The qualitative variables were: etiologies, triggers, treatments, causes of death and causes of admission in Intensive Care Unit (ICU); and the dichotomous were: sex, fever, organomegaly, mortality and ICU admission. The quantitative variables were: age, laboratory findings, diagnosis delay (days from the admission to the bone marrow biopsy), hospital and ICU stay. The quantitative variables were showed with median and interquartile range (IR).

Results: Thirteen patients (7 men) with median age of 54 years (IR 34–61) were studied. Table 1 shows demographic characteristics, aetiologies, triggers, hospital stay, diagnosis delay, treatments and mortality of patients with diagnosis of secondary HLH. The diagnostic delay median was 14 days (IR 9–18) and the median hospital stay was 38 days (RI 30–61). Patient 9 continued at the end of this paper. Six patients were admitted to the I.C.U. (patients 3, 4, 6, 7, 8 and 9), the main cause of diagnosis admission was multi-organ dysfunction syndrome (MODS). The overall mortality rate was 30.1%, died 3 due MODS (patients 6, 7 and 8) and 1 due massive haemoptysis (patient 11). The only clinical criterion common to all patients was fever. Patient 12 was the only one without organomegaly. The diagnostic criteria and other laboratory data of each patient are given in table 2. All patients had at least one bone marrow biopsy with hemophagocytics cells; patient 3 also had hemophagocytics cells in the ascitic fluid.

Table 1. Demographics caracteristics, aetiologies, triggers, evolution, treatments and final resolution of patients with secondary HLH in at Donostia University Hospital.

Hb: hemoglobin (mg/dl). Plt: platelets (ul). Neu: neutrophils (/ul). Tg: triglycerides (mg/dl). Fbr: fibrinogen (mg/dl). Fer: Ferritin (ng/ml). GOT Glutamic oxalacetic transaminase (mg/dl). GPT: Glutamic-pyruvic transaminase (mg/dl) LDH: Lactate dehydrogenase (IU/l). TB: Total bilirubin (mg/dl). INR: International normalized ratio TP: Total proteins (g/dl). ALP: Alkaline phosphatase (mg/dl). GGT: Gamma glutyl transferase (IU/L). NA: No test performed.

Conclusion: 1) Hemophagocytics cells not only can be found in bone marrow, lymph nodes and spleen, but also in other pathological body fluids such as ascitic fluid, being a simpler method that could be performed before the biopsy or in doubt of it.

2) The mortality may be influenced by the aetiology and trigger of the HLH, the delay in diagnosis and the delay of immunosuppressive treatment. Patients with hematologic diseases had worse prognosis.

2019

Kikuchi-Fujimoto disease: Features and Outcome Of 91 Patients In France. Guillaume Dumas[1], Virginie Prendki[2], Julien Haroche[3], Patrice Cacoub[4], Zahir Amoura[3], Lionel Galicier[5], Olivier Meyer[6], Christophe Rapp[1], Christophe Deligny[7], Bertrand Godeau[8], Elisabeth Aslangul[9], Olivier Lambotte[10], Thomas Papo[11], Jacques Pouchot[12], Mohamed Hamidou[13], Gilles Grateau[14], Eric Hachulla[15], Thierry Carmoi[16], Robin Dhote[17], Magdalena Gerin[18], Arsene Mekinian[18], Fréderique Charlotte[4], Dominique Farge[5], Thierry Molina[9] and Olivier Fain[18]. [1]Hôpital d'Instruction des Armées Bégin, Saint Mandé, France, [2]Hôpitaux Universitaires de Genève, Genève, Switzerland, [3]Hôpital Pitié-Salpêtrière, AP-HP, UPMC Univ Paris 06 & French National Reference Center For Systemic Lupus and Antiphospholipid Syndrome, Paris, France, [4]Hopital Pitié-Salpétrière, Paris, France, [5]Hopital St Louis, AP-HP, Paris, France, [6]Bichat University Hospital, Paris, France, [7]Centre hospitalier Universitaire de Fort de France, Fort de France, Martinique, [8]University of Paris, AP-HP, Hôpital Mondor Créteil, Creteil, France, [9]hôpital Hotel Dieu, AP-HP, Paris, France, [10]Hopital Kremlin Bicêtre, Kremlin Bicêtre, France, [11]University Paris-7, INSERM U699, APHP, Bichat Hospital, Paris, France, [12]Hôpital Européen Georges Pompidou, AP-HP, Paris, France, [13]Nantes University Hospital, Nantes, France, [14]Hopital Tenon, Paris, France, [15]University Hospital Lilles, Lille CEDEX, France, [16]Hôpital d'Instrcution des Armées du Val de Grace, Paris, France, [17]Avicenne University Hospital, Bobigny, France, [18]Hôpital Jean Verdier, AP-HP, Bondy, France.

Background/Purpose: Kikuchi Fujimoto disease (KFD) constitutes a rare cause of cervical lymphadenitis, usually reported in Asia. Data about this disease are scarce in Europe. The primary endpoint of this study was to describe KFD epidemiology in France. Secondary endpoints were to analyze more specifically the most severe expression of this disease, and forms associated with systemic lupus erythematosus (SLE).

Methods: Retrospective observational study of KFD cases diagnosed in thirteen hospitals in France, between January 1989 and January 2011.

Results: 91 patients were included. 70 (77%) were female with a mean (+/− SD) age of 30+/−10.4 years. 33% of patients came from Europe, 32% from Africa or the Caribbean, 15.4% from Maghreb and 13% from Asia. Eighteen patients presented a history of systemic disease, eleven of them having systemic lupus erythematosus. Cervical lymphadenitis was present in 90% of the cases, and generalized lymphadenomegaly in 52%. Hepatomegaly and splenomegaly were found in 14.8% of the patients, and deep-seated lymphadenitis in 18% of them. Adenitis was associated with fever in 67%, asthenia in 74.4%, weight-loss in 51.2% of the total number of patients. Regarding extra-nodal manifestations we can list cutaneous involvement (32.9%), arthralgia and myalgia (34.1%), and more rarely aseptic meningitis (n=2) or hemophagocytic lymphohistiocytosis (n=3). Laboratory findings brought up lymphopenia for 63.8% of the patients and inflammatory syndrome for 56.4% of them. Anti-nuclear (ANA) and anti ds-DNA antibodies were detected in respectively 45.2% and 18% of tested patients. A viral infection was diagnosed for 8.8% of the studied cases. Corticosteroid treatment was used in the treatment of 32% of the patients, hydroxychloroquine in 17.6% and intravenous immunoglobulins in a total of 3 patients. Even though good prognosis was observed, relapse occured for 21% of the patients. Considering the 33 patients presenting with ANA, systemic lupus erythematosus was diagnosed concomitantly in 10 cases, and within the next year in 2 cases. 6 patients did not develop SLE and 6 patients were lost to follow up (median (Q1-Q3) follow up of 19 [3–39] month).

Weight loss, arthralgia, cutaneous involvement and ANA were associated with SLE ($p<0.05$). Male sex and lymphopenia were factors associated with severity of the disease ($p<0.05$).

Conclusion: KFD not exclusively occurs in Asian population. Associated SLE must be investigated. A prospective study is warranted to determine risk factors for SLE in patients with KFD.

2020

Clinical Characteristics In Japanese Patients With IgG4-Related Disease. Kazu Hamada, Yoshinori Taniguchi, Yoshiko Shimamura, Koji Ogata, Kosuke Inoue, Taro Horino, Yoshitaka Kumon, Kahori Hirose, Masamitsu Hyodo and Yoshio Terada, MD. Nankoku, Japan.

Background/Purpose: IgG4-related disease (IgG4-RD) is the new entity, which is a multisystem and fibroinflammatory condition. It is characterized by progressive scarring and dysfunction of affected organs and tissues including the pancreas, hepatobiliary tree, kidneys, salivary glands, retroperitoneum and lungs, etc. New diagnostic imaging methods for IgG4-RD have been sought. Recent several reports showed that FDG-PET/CT scans accurately, and safely identifies the multiple organs' involvements in IgG4-RD patients. To evaluate clinical characteristics, including laboratory and FDG-PET/CT findings, of Japanese patients with IgG4-RD.

Methods: The clinical symptoms, laboratory, pathological and FDG-PET/CT findings of Japanese patients with IgG4-RD (n=13) were assessed. Several laboratory data of IgG4-RD with multiple organs' involvements (n=6), IgG4-RD with limited organ's involvement (n=7) and ANCA-associated vasculitis, one of hyper-IL-6 syndromes, (n=10) were comparatively examined. All data are presented as mean ± SD.

Results: IgG4-RD patients (mean age 68±11; male/female 10/3) had xerostomia and bilateral submandibular glands enlargement. As complication, 3 had bronchial asthma, 2 had chronic thyroiditis and 1 had ulcerative colitis. FDG-PET/CT imaging revealed enlargement and increase of FDG accumulation of the bilateral submandibular glands, mediastinal lymph node, lung, spleen, kidney, periaorta and prostate. Interestingly, a part of these organs was asymptomatic. Follow-up FDG-PET/CT after steroid treatment, with no symptoms, showed a significant decrease in FDG accumulation in IgG4-RD lesions. The serum IgG4 level was 847±711 mg/dl (normal 8–135 mg/dl). Four cases with hypocomplementemia and elevated immunocomplex of 13 IgG4-RD cases revealed renal involvements (tubulointerstitial nephritis), and moreover, these 4 cases also had interstitial lung involvements. Notably, cholinesterase (ChE) and total cholesterol (T-cho) levels in IgG4-RD cases with multiple organs' involvements (n=6) significantly decreased from these levels in IgG4-RD with limited organ's involvement (n=7) and ANCA-associated vasculitis (n=10) ($p<0.05$).

Conclusion: When we diagnose IgG4-RD, it is important to differentiate hyper-IL-6 syndrome. FDG-PET/CT imaging and measuring serum ChE and T-cho levels might help us not only to evaluate widespread lesions and monitor disease activity in IgG4-RD, but also to differentiate other disorders. We must investigate further cases of IgG4-RD in order to elucidate its pathophysiology and mechanisms of development.

2021

The Proportion Of IgG4-Related Aortitis In Patients Diagnosed As Chronic Inflammation Of Aorta In Pathology. Bon San Koo[1], Bin Yoo[1], Chang-Keun Lee[1], You Jae Kim[1], Seokchan Hong[1], Yong-Gil Kim[1], Wook Jang Seo[2] and Kyung joo Ahn[3]. [1]University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, [2]Seoul Veterans Hospital, Seoul, South Korea, [3]KEPCO medical center, Seoul, South Korea.

Background/Purpose: The purpose of our study was to identify the proportion of IgG4-related aortitis in patients diagnosed with chronic inflammation of aorta in pathology and evaluate histological and clinical characteristics of IgG4-related aortitis.

Methods: We searched electronic medical records of pathologic reports including description of chronic inflammation in aorta specimen. Forty-seven patients had chronic inflammation of aorta and immunostaining of IgG4 were performed on all biopsy specimen of aorta. If IgG4 positive plasma cell counts were more than 50 per high power field (HPF) and IgG4/IgG ratio were more than 40% with dense lymphoplasmacytic infiltration, fibrosis, or obliterative phlebitis, the patient classified as IgG4-related aortitis.

Results: Total 47 patients who had chronic inflammation in pathologic specimen of aorta were identified which consisted of 29 idiopathic aortitis, 6 takayasu's arteritis, 6 behcet's disease, 3 infection, 3 graft failure patients. Among 29 idiopathic aortitis patients, three patients (10.3%) were classified as IgG4-related aortitis patients. The mean IgG4 positive plasma cell counts of IgG4-related aortitis and idiopathic aortitis were 120.0 ± 52.0 and 7.1 ± 11.7, respectively. One patients had thoracic aortic aneurysm and two patients had abdominal aortic aneurysm. The mean age of IgG4-related aortitis and idiopathic

aortitis was 67.0 ± 2.0 and 54.7 ± 15.5 years, respectively (p=0.086). The sex ratio was all male (100%) in IgG4-related aortitis and 19 male in idiopathic aortitis (65%). In one IgG4-related aortitis patient, chronic pancreatitis with atrophy was observed. All IgG4-related aortitis patients underwent surgical treatement with no immunosuppressant. There was no recurrence of IgG4-related aortitis during follow-up period (45.3 ± 28.7 months).

Conclusion: The ratio of IgG4-related aortitis patients was 10% in patients which were diagnosed as idiopathic aortitis in the past. Although the small number of IgG4-related aortitis was found, the old and male patient who had chronic inflammation of aorta with no secondary cause might be related to IgG4-related disease.

Disclosure: B. S. Koo, None; **B. Yoo**, None; **C. K. Lee**, None; **Y. J. Kim**, None; **S. Hong**, None; **Y. G. Kim**, None; **W. J. Seo**, None; **K. J. Ahn**, None.

2022

The Comparison Between IgG4-Related Retroperitoneal Fibrosis and Idiopathic Retroperitoneal Fibrosis. Bon San Koo[1], Bin Yoo[1], Chang-Keun Lee[1], Yong-Gil Kim[1], You Jae Kim[1], Seokchan Hong[1], Wook Jang Seo[2] and Kyung joo Ahn[3]. [1]University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, [2]Seoul Veterans Hospital, Seoul, South Korea, [3]KEPCO Medical Center, Seoul, South Korea.

Background/Purpose: The purpose of our study was to identify the ratio of IgG4-related retroperitoneal fibrosis (RPF) which were diagnosed as idiopathic RPF and investigate histological and clinical characteristics of IgG4-related RPF.

Methods: We retrospectively reviewed the medical records of 41 RPF patients in a tertiary care medical center between January 2000 and January 2013. We identified 20 pathologies which were obtained from biopsy or surgery. Immunostaining of IgG4 and histopathologic examination was performed in all surgical pathologies according to 2012 consensus statement on the pathology of IgG4-related disease. Clinical characteristics were also compared between IgG4-related RPF and idiopathic RPF.

Results: In a total 20 RPF cases, more than 30 IgG4 positive plasma cells were identified in 10 cases with dense lymphoplasmacytic infiltrate, storiform fibrosis, or obliterative phlebitis (IgG4 related RPF), but a few (°Å5) IgG4 positive or IgG4 negative cases were also identified in 10 cases (idiopathic RPF). Among 10 IgG4-related RPF, highly suggestive and probable features of IgG4 related RPF in histology were shown in 8 cases and 2 cases, respectively. In comparison between IgG4 related and idiopathic RPF, recurrence rate of IgG4-related RPF (60%) was higher than that of idiopathic RPF (10%) (p=0.032) (figure 1). Initial and 3 month cumulative steroid dosages were not different between two groups.

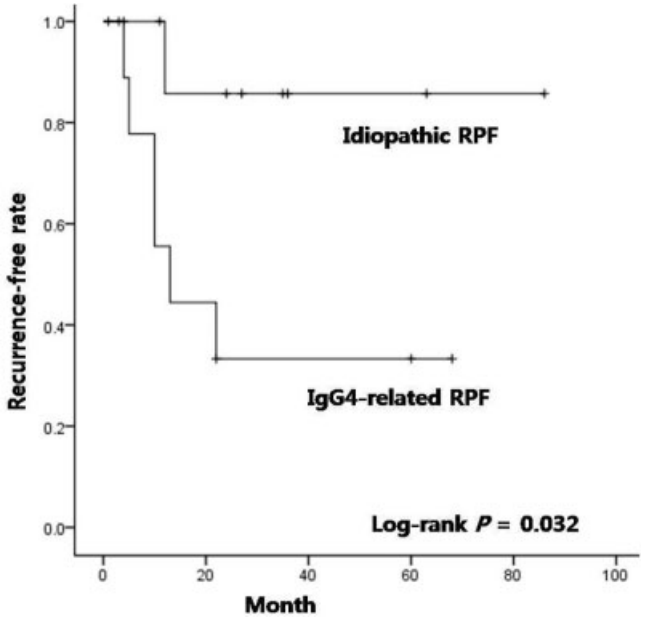

Figure 1. The recurrence-free rate of IgG4-related and idiopathic retroperitoneal fibrosis

Conclusion: We found that IgG4 related RPF according to 2012 consensus statement on the pathology of IgG4-related disease was 50% of the patients who had been diagnosed as idiopathic RPF in the past. We suggested that more aggressive therapy might be considered in IgG4-related RPF to reduce recurrence rate initially.

2023

IgG4-Related Midline Destructive Lesion: Expanding The Spectrum Of Organ Involvement In IgG4-Related Disease. Emanuel Della Torre[1], Donald Krause[2], Vikram Deshpande[1], Vinay Mahajan[3], Hamid Mattoo[3], Shiv Pillai[1] and John Stone[3]. [1]Massachusetts General Hospital, Boston, MA, [2]St. Joseph's Hospital, Bangor, ME, [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Midline destructive lesion (MDL) is a fibroinflammatory condition involving the nose, paranasal sinuses, and palate with relentless erosion through contiguous facial structures. A variety of historical terms, including "lethal midline granuloma", have been used to describe MDL. The characteristic lesion is an ulcerative process that occurs in the nose and palate associated with epithelium and cartilage loss, leadingultimately to functional deformity. MDL may occur in a variety of inflammatory, neoplastic, and infectious disorders, but the diagnosis remains elusive in a significant proportion of idiopathic cases. We report three patients with MDLwhose cases were marked by clinical, serological, and histopathological features diagnostic of IgG4-related disease (IgG4-RD).

Methods: We evaluated three patients with MDL involving the soft palate and uvula. Two patients also had nasal septal perforations. We investigated the clinical and radiological features of each case, performed flow cytometry on peripheral blood to determine the concentration of IgG4+ plasmablasts, and reviewed the histopathology, performing immunostaining for IgG and IgG4.

Results: The three patients, one man and two women, were aged 54, 38, and 27, respectively. All three patients were heavy, current tobacco smokers. One patient had a remote history of intranasal cocaine use but had not used cocaine for six years before the onset of her palatal and nasal symptoms. Onset of symptoms was subacutein all patients and, in view of the extent of the tissue destruction, the lesions appeared (in retrospect) to have occurred with remarkably little symptomatology. The processes began as small ulcers in the soft palate that evolved slowly into palatal perforations. The onset and progression of nasal septal perforation was equally subacute and subclinical.

Two patients had obtained prostheses to plug their soft palate defects, facilitate speech, and prevent nasal regurgitation of liquids and food. The third patient had remnants of food within her nasal cavity. Physical examination demonstrated a hypernasalspeechquality and florid palatal and nasal septal lesions. The uvulae were absent in all three cases. There were no obvious sites of disease beyond the soft palate and nasal cavity, but diagnostic imaging is awaited presently in one patient. Infections, malignancies, and autoimmune disorders were excluded by extensive serological, microbiological, and histopathological examinations.

The serum IgG4 concentrations were normal in all three patients (96, 119, and 11 mg/dL, respectively; normal < 121 mg/dL)(the third patient had been treated with rituximab). However, all three patients had substantial elevations of IgG4+ plasmablastin blood, with concentrations of 85,200/ml, 3835/ml, and 7351/ml, respectively (normal < 300/ml). Pathologyin all three cases showedtypical histopathological features of IgG4-RD: a diffuse lymphoplasmacytic infiltratewith an abundance of IgG4-positive plasma cells, a mild to moderate tissue eosinophilia, storiform fibrosis, and obliterative phlebitis.

Conclusion: IgG4-RD is a cause of midline destructive lesions involving the soft palate, uvula, and nasal septum.

Elevated IgG4+ Plasmablasts In Patients With Active, Untreated IgG4-Related Disease. Zachary S. Wallace[1], Vinay Mahajan[2], Mollie Carruthers[1], Hamid Mattoo[2], Shiv Pillai[1] and John H. Stone[1]. [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: IgG4-delated disease (IgG4-RD) is an immune-mediate condition responsible for inflammatory lesions that can affect nearly every organ. Diagnosis is challenging as it relies upon classic histopathology and immunohistochemical findings as well as careful pathology interpretation

and clinicopathologic correlation. No single finding, including the IgG4+ plasma cell infiltrate or the serum IgG4 concentration, is diagnostic. Paramount is the ability to distinguish IgG4-RD from clinically similar conditions such as malignancies. A biomarker to identify patients with active disease would improve diagnosis and may help distinguish subtypes. Here we describe the clinical characteristics of patients with active, untreated IgG4-RD and an elevated IgG4+ plasmablast level.

Methods: This study was approved by the institutional review board and all subjects provided informed, written consent. All patients had histopathologic proof and clinical features consistent with their IgG4-RD diagnoses. Nineteen IgG4-RD patients with active, untreated disease were evaluated and their blood sample findings were compared with those of ten healthy controls. Patients' disease activity was scored by the IgG4-RD Responder Index (RI) where an RI>/= 3 is regarded as active disease. Flow cytometry was used to measure absolute plasmablast count per ml by gating peripheral blood for $IgG4^+$, $CD19^{low}CD20^-CD38^+CD27^+$. Serum IgG4 levels were measured by nephelometry. Student's t-tests were used to compare the groups.

Results: The mean age of the IgG4-RD group was 58 years (range: 41–77 years) and 14 (74%) were male. Nine of the IgG4-RD patients had at least 3 organs involved; the remainder had active IgG4-RD in only 1 or 2 organs. The mean IgG4-RD RI was 11.2 (range: 3–36). The mean ages of the healthy controls was 42.5 years, six of whom were males. All of the IgG4-RD patients had an elevated IgG4+ plasmablast concentrations (normal <500 /ml; mean: 14,316 /ml; range: 732–85,208 /ml). In contrast, the mean plasmablast concentration among healthy controls was 63/ml (range: 1–156/ml; p=0.02). Among IgG4-RD patients, eight (42%) had normal serum IgG4 concentrations (nl< 135mg/dL; mean: 58.3 mg/dL; range: 5.3–123 mg/dL). The mean IgG4+ plasmablast concentration did not differ significantly according to the presence or absence of an elevated serum IgG4 concentration (means =14,249/ml & 13,169/ml, respectively; p=0.94). Patients with a normal serum IgG4 concentration were more likely to have single organ disease as well as lower inflammatory markers; in contrast, patients with an elevated serum IgG4 concentration were more likely to have 3 or more organs involved (64% vs. 25%, p=0.10) and abnormal inflammatory markers (p<0.05 for C3 & CRP; p=0.15 for ESR & C4). The serum plasmablast concentration correlated with the number of organs affected by IgG4-RD (R^2= 0.80).

Conclusion: IgG4-RD appears to be associated with an elevated blood concentration of IgG4+ plasmablasts. This finding may be highly specific for IgG4-RD and may be superior in sensitivity to the serum IgG4. Further investigations of serum IgG4+ plasmablast concentrations in IgG4-RD and other immune mediated conditions are appropriate.

Distinctive Expression Profiles Of Long Intergenic Non-Coding RNA Between Polymyalgia Rheumatica and Rheumatoid Arthritis Might Contains Helpful Suggestions For Understanding and Discriminating These Diseases. Yoshinobu Koyama[1], Motohiko Tanino[2], Hirokazu Shiraishi[3], Shuji Nagano[3], Toshiyuki Ota[3] and Toshie Higuchi[1]. [1]Okayama Red Cross General Hospital, Okayama, Japan, [2]DNA Chip Research Inc., Yokohama, Japan, [3]Iizuka Hospital, Iizuka, Japan.

Background/Purpose: There are many clinical similarities between polymyalgia rheumatica (PMR) and rheumatoid arthritis (RA). It has been reported that the specificity for discriminating PMR from RA was up to 70% with using 2012 EULAR/ACR provisional classification criteria. The recent technology of microarrays had made it possible to reveal the expression profiles of non-coding RNAs together with protein-coding RNAs (pcRNAs). So far, the differences of these expression profiles between PMR and RA have not been elucidated. In this study, we tried to identify the gene expression signature that may distinguish PMR from RA.

Methods: The study included 71 RA, 17 PMR and 11 osteoarthritis (OA) patients. Peripheral blood was drawn from the patients who were newly diagnosed. The samples were prepared and subjected to RNA extraction. Messenger RNA levels were then measured with using Agilent whole human genome 60K, and the log-transformed raw intensity data were normalized with a quantile algorithm. Based on the differences in gene expression among RA, PMR and OA by ANOVA, differentially expressed genes (DEGs) were selected, and then subjected to a hierarchical clustering with assessment of the statistical robustness. In order to discriminate RA from PMR, we also performed discriminant analysis with using DEGs selected by t-test.

Results: The hierarchical clustering showed major 3 clusters with using expression profiles of 556 pcRNAs selected from top1000 DEGs. OA samples were aggregated in the edge of 1st cluster, while PMR samples were distributed among RA samples. In the top 100 DEGs between RA vs. OA, OA vs. PMR and PMR vs. RA, the long intergenic non-coding RNAs (lincRNAs) accounted for 7%, 9% and 26% respectively. In the comparison of PMR with RA, 86% of the 26 lincRNAs were upregulated in PMR. With using top 49 DEGs containing both pcRNAs and lincRNAs, PMR is differentiated from RA with retrospective accuracy of 98.9% by discriminant analysis. The accuracy was also calculated as 94.3% with leave-one-out (LOO) cross-validation. Meanwhile, with using only 14 lincRNAs, it was calculated as 92.0% for retrospective accuracy and as 86.4% for LOO cross-validation. In comparison with pcRNAs, performance of the discriminant analysis with using lincRNAs was better, if the number of applied genes was same. When the 26 lincRNAs were selected, expression profile-based hierarchical clustering of all samples showed major 3 clusters. Although PMR and OA samples were distributed in RA samples, most of PMR and OA samples were segregated into 1st and 2nd clusters respectively; while 3rd cluster was consist only of RA samples. Analysis of clinical characteristics suggests that the averages of RF/CCP titers of patients in the 3rd cluster were significantly lower as compare with RA patients in other clusters.

Conclusion: The similarity of gene expression profile between PMR and RA would give us the explanation of the difficulty in the differential diagnosis. However, if genes are selected properly, evaluation of expression profiles might be a promising tool for the diagnosis. Although we are only beginning to understand the nature and extent of the involvement of lincRNAs in diseases, our results inspire us to investigate about lincRNAs in rheumatic diseases.

2026

Initial Dose Of Prednisolone For Japanese Patients With Polymyalgia Rheumatica. Akiko Aoki, Hiroshi Oka and Mitsuyuki Nakamura. Tokyo Medical University Hachioji Medical Center, Tokyo, Japan.

Background/Purpose: Polymyalgia rheumatica (PMR) is a common inflammatory condition of elderly persons. Clinical symptoms respond to low-dose glucocorticoids, but treatment is often required for several years. The recent UK guideline and a systematic review reported the adequate initial dose of prednisolone (PSL) was 15 or 20 mg daily. PSL doses as mg/kg body weight (PSL/BW) might be too large in lighter-build patients. Majority of PMR patients in Japan are smaller and lighter than the patients in Western countries.

We evaluated the initial doses of PSL and clinical course of the Japanese patients.

Methods: This was a retrospective study in a single hospital. We studied 15 patients with a diagnosis of PMR according to modified Bird's criteria (CRP positive instead of ESR>40). They presented to our hospital from April 2011 to April 2013. Patients who had the following symptoms were excluded; recent temporal or occipital pain, tender, swollen temporal artery, jaw claudication, and impairment of vision.

The patients were divided into 2 subgroups based on the initial PSL/BW: less than 0.3 mg/kg PSL (group L) and more than 0.3 mg/kg (group H). Remission was defined as the absence of symptoms more than one month after the withdrawal of PSL. Relapse was defined by the recurrence of clinical symptoms accompanied by serum CRP elevation, requiring PSL increase. We collected the demographic and clinical data from the medical records.

Statistical significance of differences between two groups of patients was determined by Mann-Whitney U test and chi-squared test. Analyses were performed using JMP ver9.

Results: The median follow-up was 14 months (range 2 to 18 months). Among the 15 patients, ten were women. Nine of 10 women and 1 of 5 men were weighing less than 50 kg. PSL Initial doses were 15 mg in 7 patients, 5mg in 5 patients, 20mg in 2 patients, and 5mg in 1 patient. The mean PSL/BW was 0.29 mg/kg/day. Eight patients belonged to group L, the other to group H. There was no significant difference in follow-up months, sex, age, BW, and serum CRP at diagnosis between two groups. In addition, the clinical course, including the relapse and PSL withdrawal rate, were similar in two groups.

Table. Characteristics of 15 patients and comparisons of outcome between 2 groups

			group L (<0.3mg/kg)	group H (>or=0.3mg/kg)	
		n=15	n=8	n=7	p
Follow-up period (months)	median (IQR)	14 (10,17)	13 (5,16)	14 (10,18)	0.6
Women	n (%)	10 (67%)	5 (63%)	5 (71%)	0.7
Age at diagnosis (years)	median (IQR)	75 (71,81)	80 (72,83)	72 (69,78)	0.1
Body weight at diagnosis (kg)	median (IQR)	44 (40,52)	50 (40,55)	44 (40,45)	0.2
PSL initial (mg/day)	median (IQR)	15 (10,15)	15 (10,15)	15 (15,20)	0.004*
Initial PSL dose per body weight (PSL/BW)	mean (SD)	0.29 (0.09)	0.22 (0.05)	0.37 (0.04)	<0.01*
Serum CRP (mg/dl) at diagnosis	median (IQR)	7.9 (4,12.7)	7.5 (3,13)	7.9 (4,13)	1
Days until first dose reduction of PSL	median (IQR)	38 (28,59)	51 (37,61)	35 (28,38)	0.08
Days until tapering to PSL 7.5 or 8 mg	median (IQR)	62 (40,103)	50 (35,61)	70 (63,150)	0.1
More than one relapse	n (%)	10 (67%)	5 (62%)	5 (71%)	0.7
PSL withdrawal	n (%)	4 (27%)	3 (38%)	1 (14%)	0.3

Conclusion: Initial dose of PSL/BW < 0.3mg/kg was equally effective to that of PSL/BW >0.3mg/kg. Calculating the initial PSL dose by BW might be more appropriate for especially elderly low-body weight women in Japan without deteriorating their prognosis.

Treatment Of Refractory Adult-Onset Still's Disease With Abatacept: Report Of Five Cases. Hye Jin Oh[1], Myung Jae Yun[2], Kyong Rok Kim[2], Sang Hyun Joo[2], Jae Myung Lee[2], Jin Kyun Park[2], Eun Bong Lee[2], Yeong Wook Song[1] and Eun Young Lee[2]. [1]Seoul National University Hospital, Seoul, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, South Korea.

Background/Purpose: Adult onset Still's disease (AOSD) is a rare disorder of unknown etiology and systemic inflammatory disorder characterized by spiking fever, arthritis, evanescent rash and leukocytosis. Up to 80% of patients with AOSD were controlled with non-steroidal anti-inflammatory drugs, corticosteroid, disease-modifying antirheumatic drugs (DMARDs), particularly methotrexate. Some AOSD patients do not response to conventional DMARDs or biologic therapy including tumor necrosis factor-α inhibitor. Abatacept, cytotoxic lymphocyte antigen 4 (CTLA4) immunoglobulin, is a biologic agent which blocks the co-stimulation of T-lymphocytes and currently is approved for use in rheumatoid arthritis. Therefore we report the use of abatacept in the treatment of five patients with AOSD manifested by severe polyarthritis unresponsive to treatment with corticosteroid, methotrexate, TNF-α inhibitors or tocilizumab.

Subjects & Methods: Four female and one male patients with the diagnosis of AOSD according to the Yamagushi criteria of 1992 were treated with abatacept. Median disease duration of those patients was 5.7 years. They do not response to glucocorticoid, disease-modifying antirheumatic drugs including methotrexate, and TNF-α inhibitor treatment before abatacept. Two patients of them were treated with tocillizumab but, we discontinued the agents due to the uneffectiveness or infusion reaction. After administering two 500mg infusions of abatacept 2 weeks apart initially, abatacept was administered every 4 week. Clinical efficacy and adverse events, changes in the values of routine laboratory parameters were evaluated at each visit.

Results: The major symptom is the polyarthritis in four patients and fever and myalgia in one. One patient improved remarkably in tender joint counts and swollen joints (17à6, 9à 0) after 6 months treatment with abatacept. Another two patients showed no change in joint counts but, there is the improvement of systemic symptoms. Also in one patient with systemic symptom, fever and myalgia resolved after abatacept treatment. ESR and CRP were declined in three patients, but did not changed in the other two patients. AOSD patients have received abatacept treatment for between seven and thirteen months. Throughout this period all patients have no serious adverse event including infection and some benefits from this treatment, with improvement in their clinical symptoms, joint counts, and serological disease activity.

Conclusion: Abatacept was administered in five patients with AOSD failing traditional DMARDs, anti-TNF-α and anti-IL-6 therapies, with some beneficial outcome. These our data suggest the potential therapeutic benefit of abatacept treatment in AOSD.

Efficacy and Safety Of Biologic Agents In Adult-Onset Still's Disease: A Long-Term Follow-Up Of 19 Patients At a Single Referral Center. Giulio Cavalli[1], Stefano Franchini[2], Alvise Berti[2], Corrado Campochiaro[2], Barbara Guglielmi[2], Maria Grazia Sabbadini[2], Elena Baldissera[3] and Lorenzo Dagna[1]. [1]San Raffaele Scientific Institute, Milan, Italy, [2]Vita-Salute San Raffaele University, Milan, Italy, [3]Vita-Salute San Raffaele University, Milano, Italy.

Background/Purpose: No data comparing the long-term outcome of Adult-Onset Still's Disease (AOSD) patients treated with different biological drugs is currently available. We evaluated the efficacy and safety of different biological agents in a cohort of 19 AOSD patients followed-up at a single referral center, and compared the results with the current knowledge.

Methods: Nineteen Italian AOSD patients were treated with biological agents and followed-up at our institution for at least 24 months between 1998 and 2013. For each case we retrospectively evaluated disease course, efficacy of treatment, and potential adverse effects. Efficacy was evaluated as 'Complete response' (CR: absence of articular and systemic manifestations, normalization of inflammatory indexes, >50% reduction in the corticosteroid dosage), 'Partial response' (PR: clinical improvement without normalization of inflammatory markers, nor >50% reduction in the dose of steroids), or 'Treatment failure' (TF: persistence/worsening of disease manifestations, persistent elevation of inflammatory markers, or need for an increased dose of corticosteroids despite 2 months of treatment). We compared our data with the current literature on the topic.

Results: Nineteen patients with AOSD refractory to conventional therapies were administered biological agents. The average duration of follow-up after initiation of biologic agents was 5 years. Overall, the different biologic drug regimens induced an improvement of systemic and articular manifestations in 17 (89%) patients. Anakinra was used in all 19 patients; etanercept, tocilizumab and adalimumab were used in 6, 4, and 1 patient, respectively. Fifteen patients responded to anakinra (79%; CR 68%; PR 11%). A minority of patients (4 out of 19, 21%) did not respond to anakinra; three of them (16%) responded to tocilizumab, and one (5%) responded to adalimumab. Etanercept was used unsuccessfully in six patients. A decrease in the dose of corticosteroids and immunosuppressants was possible in all patients (discontinuation: 56%; >25% reduction: 44%). A reduction in the dose of the immunosuppressive drugs was possible in 14 patients (74% of the cohort; discontinuation, 21%; reduction 53%). Three patients experienced herpes zoster reactivation while on treatment.

Conclusion: Biological agents represent a pivotal therapeutic resource for AOSD patients refractory to conventional treatment and display a good safety profile. IL-1 blockade with anakinra represented the mainstay of treatment. Both anakinra and tocilizumab treatments were more effective than TNF-α blockers. IL-6 blockade may be more effective than IL-1 blockade in a group of patients with chronic articular involvement. Most of the patients in whom treatment with biologics proved poorly effective had already developed irreversible structural damages before the biologic treatment was started. It is thus conceivable that a more prompt initiation of biological agents could be beneficial in patients with severe AOSD.

2029

Exposure-Response Modeling Of Canakinumab In The Avoidance Of Flares In Children With Systemic Juvenile Idiopathic Arthritis. Yuan Xiong[1], Wenping Wang[1], William Ebling[1], Haiying Sun[1], Olivier Luttringer[2], Ken Abrams[1], Nicola Ruperto[3] and Hermine Brunner[4]. [1]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [2]Novartis Pharma AG, Basel, Switzerland, [3]Istituto Gaslini, Genova, Italy, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background/Purpose: Canakinumab (CAN), a fully human selective anti-IL-1β monoclonal antibody, has been shown to be efficacious in systemic juvenile idiopathic arthritis (SJIA), resulting in significantly longer times to flare vs. placebo (PBO).[1] The objectives of the study were to 1) To explore the relationship between SJIA flare reduction and CAN exposure (4mg/kg/ every 4 weeks) with consideration of patient baseline characteristics using a discrete hazard (flare) simulation model. 2) To predict the effects of body weight-tiered CAN dosing regimens at 1 to 6 mg/kg every 4 weeks on SJIA flare rates compared with PBO.

Methods: Plasma concentrations were modeled for patients treated with CAN (n=50) or PBO after CAN treatment (n=50) and used to predict flare risk by a validated and qualified simulation of the CAN exposure-flare hazard relationship. The model considered both PBO and CAN treatments and multiple covariates, including baseline steroid dose, heterogeneity of the population with respect to disease severity (which had a varying influence on risk of an early flare), and declining CAN concentrations over time due to washout in patients on PBO (after receiving CAN). The final simulation model was also used to explore the dose-response relationship between SJIA flare hazard and CAN dose in a simulated trial (1000 simulations), that modeled 700 patients randomized to 1 of 7 treatment arms: PBO, 1 mg/kg, 2 mg/kg, 3 mg/kg, 4 mg/kg, 5 mg/kg, and 6 mg/kg (all every 4 weeks) of CAN.

Results: The final simulation model successfully re-produced the Kaplan-Meier curves observed in the phase III program, with significant differences in flare hazard ($p<0.001$) between treatment arms. Higher CAN plasma concentrations were associated with lower flare hazard. Differences in the corticosteroid dose at baseline, age, gender, body weight, daily steroid usage, and level of adapted ACR response to CAN were not significant predictors of flare risk. Based on simulation, the probability of flare (90% CI) over 12 months was 63% (55%, 71%) for the PBO arm. CAN at 4mg/kg/every 4 weeks reduced the flare rate over PBO by 39% (28%, 49%), consistent with the clinical data observed. Based on simulation, CAN at 1, 2, 3, 4, 5, and 6 mg/kg every 4 weeks was associated with annual flare rates of 37% (28%, 47%), 30% (24%, 38%), 26% (21%, 33%), 24% (19%, 30%), 22% (17%, 27%), and 21% (16%, 26%), respectively. Relative to the approved CAN dose, the model predicted a change in flare probability of +13%, +6%, +2%, −2%, and −3% for the 1, 2, 3, 5, and 6 mg/kg every 4 weeks doses, respectively.

Conclusion: The simulations support 4 mg/kg every 4 weeks as the appropriate dose for preventing SJIA flare events. Doses greater than 4 mg/kg provide only marginal gain in flare reduction over 12 months, while doses less than 4 mg/kg relatively increase the risk of experiencing a flare.

Comparative Immunogenicity Of Tumor Necrosis Factor Inhibitors: Impact On Clinical Efficacy and Tolerability In The Management Of Autoimmune Diseases: A Systematic Review and Meta-Analysis.

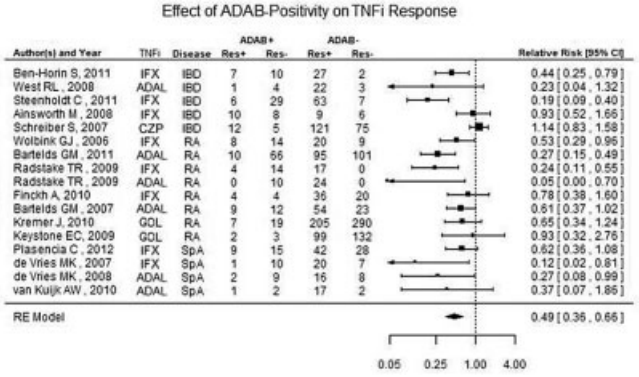
Sarah Thomas[1], Nabeel Borazan[2], Lewei Duan[3], Nashla Barroso[3], Sara Taroumian[1], Banjamin Kretzmann[4], Ricardo Bardales[4] and Daniel E. Furst[1]. [1]University of California, Los Angeles, Los Angeles, CA, [2]Rheumatology UCLA, Los Angeles, CA, [3]David Geffen School of Medicine, University of California School of Medicine, Los Angeles, CA, [4]University of California Los Angeles, los angeles, CA.

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) are a mainstay in the treatment of rheumatoid arthritis (RA), as well as the management of spondyloarthritis (SpA) and inflammatory bowel disease (IBD). Unfortunately, a significant portion of patients taking these drugs require escalating doses to achieve response, while others lose response altogether. This may be due to the development of antibodies against TNFi.

Objectives: To examine the immunogenicity of TNFi (adalimumab (ADAL), infliximab (IFX), etanercept (ETA), golimumab (GOL), and certolizumab pegol (CZP)) in RA, SpA, IBD, and to examine the potential effect of anti-drug antibodies (ADAB) on the loss of clinical response through a systematic literature review (SLR) and meta-analysis.

Methods: A comprehensive literature search using 3 databases (Pubmed, Web of Science (WOS), and the Cochrane library) was conducted to identify studies examining the immunogenicity of TNFi in autoimmune diseases from 1966 and December 1, 2012. Studies eligible for inclusions required that they be in English, be randomized controlled trials, observational studies or case reports of more than 5 patients, and that patients were 18 years of age or older. Studies were excluded if they were strictly genetic with no clinical correlate, if the patients had concomitant cancer within 5 years of the study, or if the patients had a renal disease requiring dialysis. Double extraction was followed by a third extraction for disagreements. Random effect models were generated for the meta-analysis of the 48 studies to estimate the effects of ADAB on TNFi response.

Results: A total of 8861 patients from 48 studies matching the inclusion/exclusion criteria were examined. Trial durations were from 8 to 522 weeks. Overall, ADAB were detected in 18% [95% CI (0.14–0.23)] of the patients. 30% of those taking IFX developed ADAB [95% CI (0.23–0.37)], compared to 23% [95% CI (0.18–0.29)] for ADAL, 4% [95% CI (0.00–0.08)] for GOL, 4% [95% CI (0.08–0.16)] for ETA, and 6% [95% CI (0.02–0.11)] for CZP. The use of concomitant immunosuppressives (IS) (methotrexate (MTX), 6-mercaptopurine, azathioprine, and others) reduced ADAB formation in all patients by 31% [relative risk (RR) 0.69, 95% CI (0.59–0.81)]. Figure 1 shows that ADAB reduced clinical response by 51% overall, although most of the data derived from IFX (8 articles) and ADAL (6 articles). Under the random effect model, the summary effect for infliximab was RR 0.46 [95% CI (0.3–0.69)]; for ADAL the RR was 0.35 [95% CI (0.2–0.58)]; both estimates are statistically significant.



Conclusion: All five TNFi are associated with anti-drug antibodies. Concomitant immunosuppresives reduced ADAB. ADAB are associated with a reduced clinical response.

Goethe-University, Frankfurt/Main, Germany, [5]University of Düsseldorf, Düsseldorf, Germany, [6]University Medical Center of Regensburg, Regensburg, Germany, [7]Hospital Bad Bramstedt, Bad Bramstedt, Germany, [8]University Hospital Tuebingen, Tuebingen, Germany, [9]University Hospital Münster, Münster, Germany, [10]Hospital Südstadt, Rostock, Germany, [11]Roche Pharma AG, Grenzach-Wyhlen, Germany, [12]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Munich, Germany, [13]University of Munich, Munich, Germany, [14]University Hospital Hamburg Eppendorf, Hamburg, Germany.

Background/Purpose: Autoimmune diseases are characterized by high morbidity and lead frequently to physical disability and loss of income. They are the third most important disease group following cardiovascular and tumour diseases. Beyond clinical studies the GRAID registry evaluates primarily safety aspects of the use of all biological therapies in clinical routine off-label settings.

Methods: Following GRAID1, GRAID2 is a retrospective, non-interventional multicentre registry using online data collection starting 2010. Whereas GRAID1 included only rituximab therapies, in GRAID2 all patients with an initial off-label-treatment with biologics since August 2006 can be enrolled. The retrospective documentation comprises case history, diagnosis, course of disease including safety and global efficacy.

Results: While GRAID1 included 370 patients, the interim analysis of GRAID2 is based on additional 125 patients (mean age 47.4 years; 62.4% female) refractory to conventional therapies covering 119.2 patient years (py) of biologics therapy up to now. As in GRAID1 the most frequent diagnosis was systemic lupus erythematosus (SLE; GRAID1 23.0%, GRAID2 20.0%). Further diagnoses in GRAID2 were ANCA associated vasculitides (AAV; 16.0%), overlap syndromes (8.0%), arthritis (non-RA/ankylosing spondylitis/psoriasis arthritis; 7.2%), fever syndromes (6.4%), progressive systemic sclerosis (3.2%), Sjögren's syndrome (3.2%), macrophage activation syndrome (3.2%), polymyalgia rheumatica/cranial arteritis (2.4%), poly-/dermatomyositis (1.6%) and cryoglobulinaemic vasculitis (0.8%). Other main diagnoses were found in 28.0%. Main pre-treatments comprised steroids (69.6%) and azathioprine (50.4%). Most frequent biologics used were rituximab (71.2%), tocilizumab (12.0%), infliximab (8.0%), anakinra (3.2%), adalimumab (1.6%) and certolizumab (0.8%). In SLE and AAV rituximab was the only therapy used and in overlap syndromes it was most frequently used (90.0%). In arthritis and fever syndromes tocilizumab was applied most frequently (55.6% and 50.0%, resp.). After 6–7 months, data were available for 21/89 rituximab patients incl. 13 patients (61.9%) with general symptoms as clinical manifestation: Complete remission found in 3/13 patients (23.1%), partial remission in 4/13 patients (30.8%) and no substantial change in 6/13 patients (46.2%). After first application the tolerability of biologics was assessed as "very good"/"good" by physicians in 92.8% of patients. Altogether, 110 adverse events (AEs) occurred in 44 patients incl. 20 infections in 17 patients representing a rate of 16.8/100 py. 4 serious infections were reported, representing a rate of 3.4/100 py. In total, 12 serious AEs were reported in 8 patients. 2 patients (1.6%) died (pneumonia fungal and leukaemia).

Conclusion: GRAID1 has shown that off-label therapy with rituximab can be effective and well-tolerated in several autoimmune diseases. As data on off-label use are valuable to get data on therapeutic options for patients in urgent need, GRAID2 continues to collect data of a broader range of biologics and autoimmune diseases. Up to now, the data indicate benefits for the patients as well and safety results corresponding to GRAID1.

How Does Age At Onset Influence Autoimmune Rheumatic Diseases?
Jenny Amaya-Amaya, Juan-Camilo Sarmiento-Monroy, Nicolás Molano-González, Mónica Rodríguez-Jiménez, Rubén-Darío Mantilla, Adriana Rojas-Villarraga and Juan-Manuel Anaya. School of Medicine and Health Sciences, Universidad del Rosario. Center for Autoimmune Diseases Research (CREA), Bogotá, Colombia.

Background/Purpose: Age at onset of disease (AOD) refers to the time period at which a patient experiences the first sign (s) and symptom(s). AOD varies among autoimmune diseases (ADs) and has been related to prognosis in some of them. Genetic, epigenetic, and environmental factors may influence the AOD. The objective was to evaluate the influence of AOD on the clinical course and outcome in adult patients (> 17 years) with autoimmune rheumatic diseases, namely rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and Sjögren's syndrome (SS).

Methods: This was a cross sectional analytical study in which 1,082 consecutive adult patients fulfilling international criteria for RA (n=517), SLE (n=271), and SS (n=294) were included. Information on patients socio-demographic and cumulative clinical and laboratory data were obtained by interview, standardized report form, physical examination and chart review. Early AOD was categorized according to the *lower quartile*of AOD in every AD (i.e., 17–34 years in RA, 17–23 years in SLE, and 17–35 years in SS). Data were analysed by Fisher's exact test, Chi square and Kruskal–Wallis test.

Results: There were significant differences between important demographic and clinical variables according to AOD (Table). Early AOD was associated with a more severe clinical course in RA and SLE. No relevant differences between early-SS and late-SS were observed. Late-AOD was associated with environmental exposure in RA and SLE.

Disease	*Early-AOD*	*Late-AOD*
RA	Female Higher educational level Higher joint involvement Extraarticular manifest	Environmental exposure Cardiovascular disease Higher body mass index Higher waist to hip ratio
SLE	Cutaneous involvement Antiphospholipid antibodies Renal compromise	Environmental exposure
SS	Cutaneous vasculitis	

Conclusion: Our findings support the hypothesis of an influence of AOD on illness course in patients with ADs. Early-onset traits are more sensitive to genetic influence while late-onset to environmental variation. These results may serve to design better strategies aimed to discover the etiological factors of ADs.

2033

Mortality Prognostic Factors Of Patients With Systemic Autoimmune Diseases Admitted To An Intensive Care Unit.
Pamela Inés Doti[1], Sara Fernandez[2], Emmanuel Coloma[1], Ona Escoda[1], Ignasi Rodiguez-Pintó[1], Pedro Castro[2], Gerard Espinosa[1] and José María Nicolás[2]. [1]Department of Autoimmune Diseases, Hospital Clínic, Barcelona, Barcelona, Spain, [2]Medical Intensive Care Unit, Hospital Clínic, Barcelona, Barcelona, Spain.

Background/Purpose: To identify mortality prognostic factors of patients with systemic autoimmune diseases (SAD) admitted in a medical intensive care unit (ICU).

Methods: Retrospective observational study including all patients with SAD admitted to a medical ICU of a tertiary referral centre between January 1999 and December 2012. Only patients with the diagnosis of SAD according to accepted criteria made prior to ICU admission or during hospitalization were selected. Patients with short term irreversible disease and those with an ICU stay less than 48 hours were excluded. The reason for ICU admission, clinical follow-up, immunosuppressive treatment received before ICU admission, and outcome were collected. Mortality prognostic factors were identified through logistic regression analysis.

Results: Seventy patients accounting for 75 ICU admissions (48 [68.6%] women) with mean (SD) age of 54 (19.3) years were included. Five patients were admitted twice. Twenty-three (30.7%) patients had systemic lupus erythematosus (SLE) (mean SLE Disease Activity Index [SLEDAI] at ICU admission 8.2 (5.6) [range 0–20]); 23 (30.7%) had systemic vasculitis (mean Birmingham Vasculitis Activity Score [BVAS] 14.5 (9.3) [range 0–33]); 7 (9.3%) systemic sclerosis; 7 (9.3%) dermatomyositis, and 5 (6.7%) had Sjögren′s syndrome. The reasons for ICU admission were infection in 26 (34.7%), followed by autoimmune disease flare-up in 17 (22.7%). Other complications related or not with the SAD were present in 26 (34.7%) patients. The mean Acute Physiology and Chronic Health Evaluation (APACHE II) at admission was 16.5 (6.5) (range 5–31). At the end of follow-up, 29 (41.4%) patients had died, 10 (14.2%) during the stay at ICU, 7 (10%) during hospitalization, and 12 (17.1%) after hospital discharge. A logistic regression model showed that multiorgan failure (respiratory failure [p=0.032], renal failure [p=0.017]), and the need of renal replacement therapy [p=0.007] were risk factors associated with increased mortality. In addition, corticosteroid therapy [p<0.005] and the need of intravenous immunoglobulin treatment [p<0.005] during the stay at ICU, and the use of cyclophosphamide in the previous six months [p=0.016] of ICU admission, were also risk factors associated with increased mortality.

Conclusion: The most prevalent SAD admitted to a medical ICU were SLE and systemic vasculitis being infections the main reason for admission. The presence of respiratory and renal failure, the need of renal replacement therapy, the need of corticosteroid or intravenous immunoglobulin during the stay in ICU and the use of cyclophosphamide before the admission were factors associated with increased risk of mortality.

2034

Does Mixed Connective Tissue Disease Or Sharp's Syndrome Really Exist? Anne Barbarini[1], Christelle Sordet[1], Emmanuel Chatelus[1], Rose-Marie Javier[1], Joelle Goetz[1], Francois Lefebvre[2], Jacques-Eric Gottenberg[1], Thierry Martin[3] and Jean Sibilia[1]. [1]Strasbourg University Hospital, Strasbourg, France, [2]Strasbourg University Hospital, strasbourg, France, [3]IBMC, Strasbourg, France.

Background/Purpose: The existence of Mixed Connective Tissue Disease (MCTD) has often been discussed in literature and its diagnostic criteria are very heterogeneous. Anti-U1-RNP antibodies are not specific, but their presence is obligatory for the diagnosis of MCTD. To determine whether MCTD exist as a distinct entity, we analyse their frequency in a group of anti-U1-RNP positive patients and their diagnostic evolution rate at the end of follow-up. We studied the predictive value of some clinical and biological factors for diagnostic transformation.

Methods: We have selected retrospectively 103 patients from January 2006 to May 2011. The only inclusion criterion was the presence of anti-U1-RNP antibodies. We have studied medical information at the time of first presentation, at each visit and at the last follow-up visit. The selected patients were classified into one group of connective tissue disease if they fulfilled the following classification criteria: ARA for Rheumatoid Arthritis (RA), ACR for Systemic Lupus Erythematous (SLE), Leroy and Medsger for Systemic Scleroderma (SS), American and European criteria for Sjögren's Disease (SD), Bohan and Peter for myopathies, Alarcón-Segovia for MCTD. Patients fulfilling more than one or respectively none of the connective tissue disease criteria were classified as Overlap Syndrome (OS) or Undifferentiated Connective Tissue Disease (UCTD) respectively. The initial diagnosis was reviewed after each visit. Anti-U1-RNP antibodies were detected by immune-dot or radial immune-diffusion. We used Student's test or Fisher's test for statistical analyze ($p \leq 0.05$).

Results: 103 patients were anti-U1-RNP positive. 98 patients had a diagnosis of a connective tissue disease at the initial presentation and were followed up between January 2006 and May 2011: 20 UCTD, 10 MCTD, 5 OS, and 63 defined connective tissue diseases (48 SLE; 7 SD, 5 SS; 3 RA). The diagnosis of MTCD was rare (10.2% at first presentation and only 5.1% at the end of follow-up). 60% of the initial MCTD's have evolved into 2 SLE and 4 OS in a medium delay of 7.3 years [2–16] by the end of follow-up. No predictive factors for diagnostic evolution were identified ($p > 0.05$). Anti-U1-RNP antibodies were associated with a high proportion of SLE (49%) and OS (26%) at the end of follow-up. Visceral complications were frequently observed in our patient group (54%).

Conclusion: MCTD is probably an intermediate stage towards an evolution into a well-defined connective tissue disease. We underline the importance of a systematic and long follow-up for all anti-U1-RNP positive patients which are at high risk to develop more than one connective tissue disease and visceral complications over time.

2035

Description Of 142 Cases Of Relapsing Polychondritis Followed In a Single Center Since 2000. Jeremie Dion[1], Nathalie Costedoat-Chalumeau[1], Damien Sene[2], Judith Cohen-Bittan[3], Gaëlle Leroux[3], Camille Francès[4] and Jean-Charles Piette[3]. [1]Hopital Cochin, Paris, France, [2]Hopital Lariboisière, Paris, France, [3]CHU Pitié-Salpêtrière, Paris, France, [4]Hopital Tenon, Paris, France.

Background/Purpose: Relapsing polychondritis (RP) is a rare condition characterized by recurrent inflammation of cartilaginous tissues and systemic manifestations. Data on prognosis available from the latest large series published in 1986 indicate a 5- and 10-year survival after diagnosis of 74% and 55%, respectively [1]. The purpose of this study is to describe a recent series of patients with RP.

Methods: 142 patients with a diagnostic of RP according to Michet's criteria were included in this monocentric retrospective study. All the patients were seen at least once since 2000. The median year of diagnosis was 2002 (1974 to 2011).

Results: 56 men (39%) and 86 female (61%) were included. The mean age at first symptoms was 43.5±15 years, and was higher for men (47±15 vs 41±15 p=0.02). The median delay of diagnosis was 1 year (1 to 25). The mean number of initial symptoms was 1.85±1, and main first symptoms consisted of nasal or auricular chondritis (59%), joint (32%), ophthalmologic (18%), general (15%) or cutaneous (15 %) manifestations. During a median evolution of 11 years (1 to 41), all the patients presented chondritis: auricular in 89%, nasal in 63%, laryngeal in 43%, chondrocostal in 40%, and tracheobronchial in 22%. Nasal and ear deformations occurred in 15 and 10% respectively. Other manifestations were articular in 69%, ophthalmological in 56% (episcleritis or scleritis in 41%, uveitis in 13%, keratitis in 4%), cochleovestibular in 34%, (deafness in 27% and vestibular syndrome in 20%), cardiac in 27% (including aortic valve insufficiency in 17% and cardiac surgery in 5%), cutaneous in 30% and neurological in 11%.

A concomitant hematological disease was present in 14%: myelodysplasic syndrome in 8% and others in 6%. Myelodysplasic syndrome affected only men in our series ($p=8\times10^{-6}$), and was associated with older age (63 vs 41years; $p=4\times10^{-6}$) and cutaneous involvement (p=0.0001). Deep vein thrombosis occurred in 11% of the patient.

58% of the patients had an inflammatory syndrome during disease's flares with a median CRP level of 80 mg/l (10 to 379 mg/l). Antinuclear antibodies were found in 20%, anti-neutrophil cytoplasmic antibodies in 10%, rheumatoid factor in 13% (17/129).

An autoimmune disease was associated in 22% (including Sjogren syndrome in 9%, autoimmune thyroiditis in 6%, systemic lupus erythematosus in 4%).

Corticosteroids were used in 94%, methotrexate in 49%, dapsone in 38%, colchicine in 32%, azathioprine in 25%, mycophenolate mofetil in 19%, cyclophosphamide in 17%, TNF-alfa inhibitors in 11%, rituximab in 7%, anakinra in 3% and autologous stem cell transplantation in 2%.During the evolution, 18% were hospitalized for an infection and 13% were transferred in Intensive Care Unit.

To avoid selection bias, we studied the survival in the 87 patients who had a diagnosis of RP after 2000. After a median follow up of 7 years, the 5- and 10-years survival after diagnosis were of 95% and 91%, respectively.

Conclusion: Compared with previous studies, the prognosis of RP has greatly improved.

Disclosure: J. Dion, None; **N. Costedoat-Chalumeau**, None; **D. Sene**, None; **J. Cohen-Bittan**, None; **G. Leroux**, None; **C. Francès**, None; **J. C. Piette**, None.

2036

Biologic Therapy For Relapsing Polychondritis: Old and New Efficacy Indices. Mattia Baldini, Patrizia Aiello, Mirta Tiraboschi, Maria Grazia Sabbadini and Elena Baldissera. Ospedale San Raffaele and Università Vita-Salute San Raffaele, Milano, Italy.

Background/Purpose: The inflammatory milieu in affected tissues from Relapsing Polychondritis (RP) is rich in TNF-α, IL-1-β and IL-6. Cytokine-targeted biologic therapies has therefore been proposed in patients with active disease despite conventional treatment (steroids + DMARDs). Given the rarity of the disease, no randomized controlled trial has been published yet; moreover, different outcomes are considered in each study. Recently, an international study group published Relapsing Polychondritis Disease Activity Index (RPDAI). We report our experience on the efficacy of biologic therapy in RP evaluating both conventional indexes and the RPDAI.

Methods: The efficacy of each drug has been assessed considering the reduction of ESR, CRP, steroid dose and RPDAI at two time points (6 months, 12 months).

Results: From 2004 on 8 RP patients have been treated with biologic therapies. Anti-TNF (i.e. etanercept, n=4; infliximab, n=1; golimumab, n=1) or anakinra were used as 1st line biologics in 6 and 2 patients, respectively. In the anti-TNF group: 2 patients (both on etanercept) achieved long-term remission (mean follow-up 54 months and one could discontinue the drug without disease flare), while 4 were switched to anakinra (n=2) or to another anti-TNF (n=2) after a mean of 25 months because of efficacy loss (n=3) or intolerable injection-site reaction (n=1). Both patients on 1st line anakinra therapy were switched to etanercept after a mean of 17 months because of efficacy loss. Among the patients on 2nd line biologic therapy, 2 (out of 4) from the anti-TNF group (on etanercept and adalimumab, respectively) and 1 (out of 2) from the anakinra group achieved long-term remission (mean follow-up 43 months). Tocilizumab was successfully used as a 3rd line agent after anti-TNF (n=2) or anakinra (n=1) failure (mean follow-up 7.5 months). In total, 17 biologic therapies have been used in 8 patients. Anti-TNF agents (n=9), and in particular etanercept (n=6) were the most used biologics, followed by anakinra (n=4), and tocilizumab (n=3). At 6 months, tocilizumab was effective in 100% of cases (n=3), anakinra in 50%, ant-TNF in

12% (etanercept in 40%). At 12 months, anti-TNF were effective in 67% (etanercept in 60%) and anakinra in 50% (no follow-up at 12 months is yet available for tocilizumab), RPDAI and ESR variation from baseline were the best indicators of efficacy at 12 months. Interestingly, RPDAI and steroid dose variation at 6 months were the best predictors of the outcome at 12 months.

Conclusion: Cytokine-targeted drugs are promising therapies for RP resistant to conventional therapy. Variations at 6 months in ESR levels and RPDAI score may be predictors of the long term efficacy of anti-TNF and anakinra.

2037

Isolated Anti-Ro52 Antibody – Significance and Clinical Association. Yogesh Singh[1], Pravin Patil[2], Hilary Longhurst[3], Garry Clarke[3] and Bhaskar Dasgupta[4]. [1]Southend university hospital, Westcliff-on-sea, United Kingdom, [2]Southend University Hospital, Westcliff-on-sea, United Kingdom, [3]Southend University Hospital, Westcliff on sea, United Kingdom, [4]Southend University Hospital, Westcliff-on-Sea, United Kingdom.

Background/Purpose: Antibodies against Ro-52 (TRIM21) have been described in patients with a broad spectrum of autoimmune diseases. Anti-Ro52 antibodies are the most common immunological markers detected in the idiopathic inflammatory myopathies. The significance and clinical association of isolated anti-Ro52 anti-body is not well known.

Methods: This is a retrospective study of patients who had isolated Ro52 positivity on ENA screen. Patients were identified from the immunology laboratory records. Search was limited to year 2009 to 2012. Medical records of patients with isolated Ro-52 were reviewed for clinical details.

Results: Thirty eight patients had isolated anti-Ro52 antibody positivity on ENA screen. The median age was 68 years and 26 were female. ANA was positive in 28 (73%). The prevalence of pulmonary manifestations in presence of anti-Ro52 antibodies was high (9/38, 23%). One patient had an undifferentiated connective tissue disease with interstitial lung disease, 4 had idiopathic pulmonary fibrosis, 2 with malignancy (bronchogenic −1, lung metastases – 1) and remaining 2 patients had suspected malignancy (bronchogenic).

Clinical manifestations of autoimmune diseases were observed only in 21 (55%) patients with Ro 52 positivity (Table 1). A severe form of ITP requiring splenectomy was seen in 2 patients. It was associated with present or past malignancy in 8 (18%) patients and out of these 3 had an underlying auto-immune disease. In another 3 patients malignancy was strongly suspected based on clinical features, imaging findings but histological confirmation could not be obtained due to untimely demise of these patients.

Table 1. Disease association with anti-Ro52 antibody

Systemic autoimmune disease (N=11)	Organ specific autoimmune disease (N=6)	Malignancy (N=9 malignancies in 8 patients)	Suspected malignancy (N=3)	Others (N=13)
Rheumatoid arthritis-2	AIH-2	**Current malignancy**	Brochogenic-2	Stroke-2
Scleroderma myositis overlap-1	Coeliac disease-1	Prostate-1	Lymphoma-1	Chronic diarrhea-1
LcSSc with ITP-1	Pernicious anemia-1	Malignant melanoma-1		General weakness-1
Primary Sjogren's-1	PBC-1	Gastric-1		Secondary pulmonary hypertension-1
Antiphosphilipid syndrome-1	ITP-1	Colon-1		Sepsis-1
Polymyalgia rheumatica-1	Idiopathic pulmonary fibrosis-4	Bronchogenic-1		Alcoholic cirrhosis of liver-1
Dermatomyositis-1		Breast-1#		Elevated ALP-1
UCTD-1		**Previous malignancy**		Generalized tingling-1
GPA-1		Endometrial-1$		
PsA-1		Ovarian-1*		
		Hodgkin's disease-1*		

Patient with GPA had previous breast cancer which was treated, now presented with lung metastases.$ Previous history of endometrial cancer, now presented with stroke.* In the patient with PsA, previous history of treated ovarian cancer and Hodgkin's disease. UCTD – undifferentiated connective tissue disease, GPA – granulomatous polyangiitis, PsA – Psoriatic arthritis, AIH – Autoimmune hepatitis, PBC – Primary biliary cirrhosis, ITP – Idiopathic thrombocytopenia, ALP – Alkaline phosphatase

Conclusion: Ro 52 antibody is commonly seen in non-autoimmune disorders. Presence of isolated anti-Ro52 antibody is associated with pulmonary involvement. It may represent the primary site for loss of tolerance and generation auto-antibodies. It can be seen in conditions other than autoimmune diseases. In our cohort anti-Ro52 was seen in association with malignancy. The role of Ro52 antibody as anti-cancer immune response should be studied further.

2038

Congenital Heart Block Related With Maternal Autoimmune Diseases: Descriptive Analysis Of a Series Of 17 Cases. Pamela Inés Doti[1], Ona Escoda[1], Sergi Cesar-Diaz[2], Narcís Masoller[3], Irene Teixidó[3], Josep Maria Martinez[3], Georgia Sarquella-Brugada[2] and Gerard Espinosa[1]. [1]Department of Autoimmune Diseases, Hospital Clínic, Barcelona, Barcelona, Spain, [2]Arrhythmia Unit, Cardiology Section, Hospital Sant Joan de Déu, Barcelona, Barcelona, Spain, [3]Maternal Fetal Medicine Department, Hospital Clínic, Bacelona, Barcelona, Spain.

Background/Purpose: To describe the clinical characteristics of maternal autoimmune-mediated fetal congenital heart block (CHB) in a cohort of pregnant women from an Autoimmune Diseases Pregnancy Clinic.

Methods: Retrospective observational study of all women presenting with CHB in our Autoimmune Diseases Pregnancy Clinic from January 1997 to December 2012. In addition, outcome of live newborn with CHB is also described.

Results: Thirteen patients accounting for 17 episodes of CHB were identified. One patient had three episodes and two patients had two episodes each one. The mean (SD) age was 31.3 (5.3) years. Six (46.2%) patients had Sjögren's syndrome and the remaining 7 (53.8%) were asymptomatic carriers of auto-antibodies. All patients had anti-Ro antibodies and 10/12 (83.3%) had anti-La antibodies. Anti-Ro52 antibody was positive in the 4 women in which it was performed. The mean gestational age at the time of CHB was 21.8 (2.9) weeks (range 18–28). Complete cardiac block (CCB) was detected in 12 (70.6%) fetuses and second-degree CHB in 5 (29.4%). During pregnancy, 4 of them progressed to CCB whereas the remaining changed to first-degree CHB. Severe complications were detected in 5 fetuses (3 hydrops fetalis, 2 fetal growth restriction). Regarding the maternal treatment at diagnosis, only 2 were receiving low-dose corticosteroids, associated with hidroycloroquine and azathioprine in each one, respectively.

Six cases of CHB were treated with dexamethasone, two with ritodrine and one with the association of dexamethasone, ritodrine and terbutaline. Despite the pharmacological intervention, pregnancy was interrupted in 9 (52.9%) cases. Finally, there were 8 newborns (7 males [87.5%]) with mean age at delivery of 37.2 (1.5) weeks (range 34.5–39).

Elective cesarean was the preferred technique of delivery in all cases. Seven out of 8 (87.5%) newborns were diagnosed of symmetric intrauterine growth restriction. In two cases, Apgar test at first minute was less than 7, because of severe oligohydramnios and meconium aspiration syndrome. Apgar test at 5 and 10 minutes was 9 in all cases.

All newborns were diagnosed of CCB, except one who had first-degree CHB. Half of newborns needed temporal endovascular pacemaker within the 24 hours of life. Two cases showed heart failure signs. A definitive epicardial pacemaker was placed in all cases within 2 weeks of life. Of the remaining patients without a neonatal pacemaker requirement, two needed a pacemaker due to chronotropic and electric insufficiency, at 4 and 14 years old, respectively. Two patients didn't need a pacemaker due to a good ventricular rate without symptoms and first-degree CHB. One case of CCB with a pacemaker died due to congestive cardiac insufficiency related to a dilated cardiomyopathy (4 months old). Currently, mean age of the 7 living patients is 7 years (range 2–16).

Four women with previous CHB received intravenous immunoglobulins in a subsequent pregnancy being ineffective in two of them.

Conclusion: CHB is a severe complication related to anti-Ro/La antibodies. Therapy is ineffective and most of the surviving patients will require neonatal pacemaker.

2039

Micro and Nanoparticles As Possible Causative-Prognostic Co-Factors Of Mixed Cryoglobulinemia Syndrome. Erica Artoni[1], Gian Luca Sighinolfi[1], Daniele Campioli[2], Marco Sebastiani[1], Dilia Giuggioli[1] and Clodoveo Ferri[1]. [1]University of Modena and Reggio Emilia, Modena, Italy, [2]Azienda Ospedaliera - Policlino di Modena, Modena, Italy.

Background/Purpose: We previously demonstrated that patients affected by membranoproliferative glomerulonephritis and mixed cryoglobulinemia syndrome (MCs) show the presence of circulating micro and nanoparticles (MPs and NPs) as possible causative/prognostic co-factors. This pilot study aimed to evaluate the possible role of occupational/environmental agents in

the etiopathogenesis of MCs by investigating the patients' exposure to both MPs and NPs.

Methods: We investigated 20 consecutive HCV-positive MCs patients without renal involvement compared to 10 healthy, sex-/age-matched volunteers. All subjects completed a questionnaire concerning demographic data, dietary and smoking habits, prosthesis implants, air pollution, occupational and medical history. Environmental Scanning Electron Microscopy (ESEM) has been employed to detect inorganic MPs and NPs and to evaluate their presence in subjects with and without MCs. Energy Dispersive X-ray Spectroscopy (EDS) microanalysis was used to chemically characterize the elemental composition of the particles. Blood serum samples were spotted on metal free cover slips in a sterile environment. The complex of particles (MPs and NPs) was quantified using the number of spots (NS) containing inorganic particles in a fixed mapping area for each sample. Levels of NS were assessed statistically with Mann-Whitney U test.

Results: Patients displayed higher serum levels of MPs/NPs particles (NS 36.67 ± 18.18, $p < 0.0003$), compared to controls (NS 5.62 ± 6.25), independently of smoking habits. A direct correlation between the presence of particles and patients occupational exposure, environmental pollution and prosthesis implants was found. EDS microanalysis revealed that the particles have complex compositions, which includes several elements like Si, Fe, Al, Ti, Zn, Cu, Mn, and Ni.

Conclusion: The ESEM analyses were a valuable tool to detect particulate matter in the serum samples. The complex of MPs/NPs particles was greater in MCs patients than in healthy subjects. These preliminary data suggest that, in addition to HCV infection, particulate complex might represent an environmental co-factor in the etiopathogenesis of MCs.

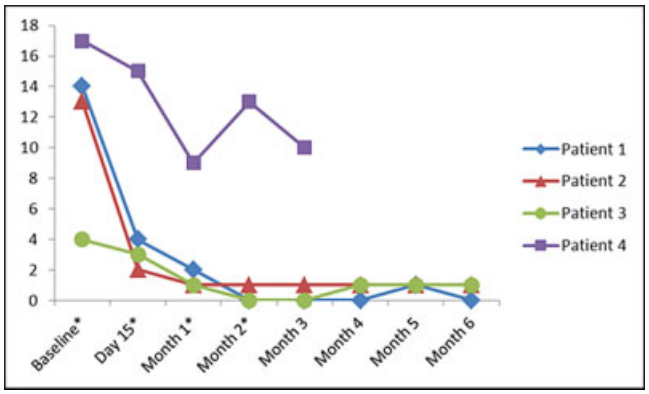
Pilot Study Of Abatacept In Patients With Refractory Autoimmune Chronic Urticaria. Clifton O. Bingham III[1], Marilyn Towns[1] and Susan J. Bartlett[2]. [1]Johns Hopkins University, Baltimore, MD, [2]McGill University, Montreal, QC.

Background/Purpose: Associations between chronic urticaria (CU) with autoantibodies and other autoimmune conditions have implicated T cells in CU initiation and/or propagation. Many patients (pts) have symptoms that require chronic corticosteroids (CCS) and/or immunomodulatory therapies. We conducted an investigator-initiated pilot study to assess the safety and potential efficacy of abatacept (ABA) in pts with CU.

Methods: Pts with refractory CU were enrolled in an open-label study of intravenous (IV) ABA (750–1000 mg per body weight) administered at baseline, 2 wk, 4 wk, and 8 wk (clinicaltrials.gov NCT00886795). Pts had required previous CCS and failed other immunomodulators. If symptoms improved, sequential tapering of CCS and/or antihistamines was permitted. Outcomes included Dermatology Life Quality Index (DLQI), urticaria severity score, number of hives, interference with sleep and daily activities, MD and Pt assessments of response, and SF-36. Safety was carefully monitored during infusions; adverse events were recorded using the OMERACT Rheumatology CTCAE v2.0. Funding and study drug were provided by BMS, who had no role in study conduct, data analysis, or decision to submit abstract.

Results: Four pts (2M/2F) were enrolled (32–51 yo; urticaria duration: 3–29 yr). Prior immunomodulatory therapies included sulfasalazine (SSZ), hydroxychloroquine (HCQ), methotrexate, azathioprine, adalimumab, mycophenolate, and cyclosporine. At baseline 2 pts were on CCS, 1 was on SSZ, and 1 was on HCQ, continued per protocol. All pts improved from their baseline clinical state by 3 months (mo), in terms of most pt-reported outcomes and in MD-reported variables. Three pts had complete urticaria resolution. One pt improved from baseline but remained symptomatic and exited at 3 mo. For all pts there was considerable improvement in DLQI (Figure). In 3 pts, background medications were tapered (CCS elimination in 1; antihistamine tapering in 3). Two pts continue to do well off ABA, requiring only periodic non-sedating antihistamines for intermittent pruritus (Time since last ABA infusion 7 mo and 24 mo). One pt had recurrent urticaria approximately 3 mo after last ABA infusion, with response rapidly recaptured with SQ ABA administered outside the study. ABA infusions were well-tolerated with no worsening urticaria, angioedema, or anaphylaxis. Upper respiratory infections (mild) were consistent with ABA studies for other indications.



DLQI over time (MID in CU 2.24–3.1). Timing of Abatacept infusions indicated with *.

Conclusion: A 2 mo intervention with IV ABA led to improvement in 4 pts with immunomodulatory therapy-resistant CU. For 3 pts there was a rapid and complete response; in the 4th there was a clinically detectable improvement. Limitations are the small number of pts and open-label design. These results suggest a fundamental role for T cells in CU pathogenesis.

Pregnancy Outcomes In Women Exposed To Golimumab. Amy G. Lau[1], Michael Clark[1], Diane D. Harrison[1], Anja Geldhof[2], Riikka Nissinen[2] and Marilyn Sanders[1]. [1]Janssen Research & Development, LLC., Horsham, PA, [2]Janssen Biologics Europe, Leiden, Netherlands.

Background/Purpose: Rheumatologic conditions and inflammatory bowel disease can affect women of childbearing potential. Golimumab (GLM) is approved for rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS), and ulcerative colitis (UC). GLM should be used during pregnancy only if clearly needed. For RA and some PsA patients, GLM is administered with methotrexate (MTX), an agent with teratogenic and abortifacient properties. To characterize pregnancy outcomes in patients treated with GLM, data obtained from maternal exposure to GLM are presented.

Methods: This dataset includes individual patient cases reported to the manufacturer through 06 April 2013. Cases retrieved included prospectively reported (ie, pregnancy outcome not known when first reported) and retrospectively reported (ie, pregnancy outcome known when first reported) maternal exposures to GLM for all approved indications during pregnancy or within 2 months prior to conception, and a reported pregnancy outcome. Cases originated from various sources, including spontaneous reporting, clinical studies, and registries.

Results: Forty pregnancy reports with reported outcomes (24 RA; 1 PsA; 5 AS; 10 UC) were identified (32 prospective, 8 retrospective). Of these 40 pregnancies, 30 were reported from clinical trials. Average maternal age was 33.2 years. Of the 40 pregnancy reports, 19 (47.5%) resulted in live births, 13 (32.5%) resulted in spontaneous abortion, 7 (17.5%) resulted in induced abortion, and 1 (2.5%) resulted in ectopic pregnancy (Table). One spontaneous prospectively reported patient case (2.5%) reported a congenital anomaly with an unspecified birth defect resulting in intrauterine death and an induced abortion. Of the 13 reports with a pregnancy outcome of spontaneous abortion, 4 (30.8%) patients received MTX concomitantly with GLM, as compared to 3 out of 19 (15.8%) reports in the GLM exposed pregnancies resulting in live births. In the 1 pregnancy with a congenital anomaly, the patient had used MTX, but the timing of MTX use was not available.

Table. Summary of pregnancy outcomes in patients treated with GLM for RA, PsA, AS, and UC

Pregnancy Outcome	RA, PsA, AS, and UC Patient Cases		
	Count (%)	Congenital Anomaly	MTX[a]
Live birth	19 (47.5)	0	3
Spontaneous abortion	13 (32.5)	0	4
Elective/Induced abortion	6 (15.0)	1	2
Abortion planned	1 (2.5)	0	0
Ectopic pregnancy	1 (2.5)	0	1
Total	**40**	**1**	**10**

a: Patient received MTX at the time of conception/during pregnancy.
KEY: AS=Ankylosing spondylitis; MTX=Methotrexate; PsA=Psoriatric arthritis; RA=Rheumatoid arthritis; UC=Ulcerative colitis.

Conclusion: This review of pregnancy outcomes after GLM exposure in utero reported 1 congenital anomaly in a small number (40) of pregnancies; the rate of congenital anomalies was consistent with the background rate. Out of the 40 pregnancies, 32.5% reported spontaneous abortions. Of those pregnancies, 30.8% of the patients received MTX, an agent which is contraindicated in pregnant women due to its teratogenic and aborifacient properties. Limitations of this analysis included the lack of a direct comparison group, the variable amount of data available in the reports, and the possible bias towards reporting more negative outcomes in retrospective cases.

Pregnancy Outcomes In Women With Rheumatologic Conditions Exposed To Infliximab. Sirisha Kalari[1], Fredrik Granath[2], Chun-Yuan Guo[1], Diane D. Harrison[1], Gabriella Bröms[2], Anja Geldhof[3], Riikka Nissinen[3], Marilyn Sanders[1], Mika Gissler[4], Lars Pedersen[5], Henrik Toft Sorensen[5] and Helle Kieler[2]. [1]Janssen Research & Development, LLC., Horsham, PA, [2]Karolinska Institutet, Stockholm, Sweden, [3]Janssen Biologics Europe, Leiden, Netherlands, [4]National Institute for Health and Welfare, Helsinki, Finland, [5]Aarhus University Hospital, Aarhus, Denmark.

Background/Purpose: RA, AS, and PsA are approved indications for infliximab (IFX). In the US, IFX is a pregnancy Category B drug. For RA and some PsA patients, IFX is administered with MTX, an agent with teratogenic and abortifacient properties. To characterize pregnancy outcomes in rheumatology patients treated with IFX, data available to the manufacturer through spontaneous reporting and through a pregnancy registry are presented.

Methods: Data from the Company safety database on individual, spontaneously reported pregnancies worldwide through Feb 23, 2013 were analyzed. The analysis focused on prospectively reported (ie, pregnancy outcome not known when first reported) cases of maternal IFX use for RA, AS, or PsA during pregnancy or within 2 months prior to conception and a known pregnancy outcome. In addition, data through Dec 31, 2010 from a Company-sponsored pregnancy registry study, undertaken to address health authority post-marketing commitments for IFX-exposed pregnancies, were analyzed; data were obtained from national medical registries in Sweden, Denmark and Finland. Maternal characteristics and pregnancy outcomes (births beyond 22 weeks of gestation) were analyzed among RA, AS, and PsA patients exposed to IFX or non-biologic systemic therapy during pregnancy or within 3 months prior to conception.

Results: 56 prospective reports (37 RA; 12 AS; 6 PsA; 1 RA&AS) of IFX exposure during pregnancy were identified. Mean maternal age was 31 years. 76.8% resulted in a live birth. Birth defects were reported for 3 live births: intestinal malrotation (1), hypospadias (1), and cardiac/coronary artery perforation (1). Of the 56 reports, MTX use was reported in 10 (8 RA), including the hypospadias case; it is possible that additional RA patients may have been exposed to MTX during their pregnancy. 23.2% of the pregnancies resulted in an induced (7) or spontaneous abortion [SAB] (6); 4 of the latter had MTX exposure. In the registry study, 27 IFX-exposed pregnancies were identified (18 RA; 5 AS; 4 PsA). Mean maternal age was 31.2 years. Birth defect was reported in 1 of the 27 IFX-exposed infants (atrial septal defect/metatarsus varus) and in 133 of the 1,974 infants exposed to non-biologic systemic therapy.

Conclusion: Review of pregnancy outcomes after IFX exposure in utero showed that 76.8% of spontaneous, prospectively reported pregnancies with known outcomes resulted in live births. The most frequently identified congenital anomalies were cardiovascular defects, the most common birth defect in the general population. While there did not appear to be an increased rate of birth defects compared to the general population, the rates in both datasets were based on small study populations. Additionally, the use of MTX, an agent contraindicated in pregnant women, was reported in more than half of the SABs. Spontaneous reporting is limited by the lack of a direct comparison group, the variable amount of data provided, and a possible reporting bias towards more serious cases. The registry study was limited to the Nordic population and data only included births from 22 weeks of gestation onwards.

Perinatal Exposure To Traditional and Biologic Disease Modifying Antirheumatic Drugs In Rheumatic Diseases: A Systematic Review Of Congenital Outcomes. Corisande Baldwin[1], Sharan Rai[2], J. Antonio Avina-Zubieta[3] and Mary De Vera[2]. [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada, Richmond, BC, [3]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC.

Background/Purpose: Despite the high incidence of rheumatic diseases during reproductive years, little is known about the perinatal impact of traditional and biologic disease modifying antirheumatic drugs (DMARDs). Systematic reviews of the evidence, which are widely based on case reports and cross-sectional studies, are scarce; only one exists on the use of methotrexate in pregnancy. Our objective was to systematically review the evidence on the perinatal use of traditional and biologic DMARDs on congenital malformation outcomes in babies born to women with rheumatic diseases.

Methods: We conducted a systematic search of MEDLINE (1946-), EMBASE (1974-), and INTERNATIONAL PHARMACEUTICAL ABSTRACTS (1970-) databases for peer-reviewed articles. Inclusion criteria were: 1) study sample that included women with rheumatic disease; 2) use of traditional and/or biologic DMARDs during pregnancy; and 3) congenital malformation outcome(s) reported. To ensure wide capture, we did not set limits on study design. We extracted information on study design, data source, number of exposed pregnancies, type of DMARD, type of exposure (single DMARD or combination), number of live births, and number of congenital malformations reported. While not the focus of our review, we extracted data on other perinatal outcomes in live births including prematurity and birthweight.

Results: We identified 1,141 articles and report on 53 that met eligibility criteria. We divided studies according to those with no unexposed comparison groups (case report [21], case series [17], cross-sectional [5], and surveys [3]) and observational studies and trials with unexposed comparators (cohort study [6] and controlled trial [1]). With respect to the former group, most studies reported primarily on single DMARD exposures with cyclophosphamide and methotrexate most widely studied among traditional DMARDs and etanercept and adalimumab among biologics. For traditional DMARDs, eligible studies reported 176 pregnancies among women with rheumatic diseases, 134 live births, and 12 malformations. For biologics, eligible studies included 11 pregnancies with rheumatic disease, 11 live births, and 1 malformation. Studies that included a comparator group were limited to traditional DMARDs, namely hydroxychloroquine, and report no differences between groups. Overall, data on DMARDs and congenital malformations are largely limited, particularly with biologics. We also identified the need for better reporting in terms of identifying patients with rheumatic disease, directly attributing medication exposures to patients, and delineating timing of medication use to pregnancy course.

Conclusion: This is the first systematic review on the use of both traditional and biologic DMARDs during pregnancy among women with rheumatic diseases, with focus on congenital malformations. Findings confirm the limited number of studies in this area. As controlled trials in this patient population are unlikely, systematic reporting and reviewing of medication exposures and perinatal outcomes provides a valuable resource for synthesizing evidence on the use of DMARDs among women with rheumatic diseases during pregnancy.

Birth Outcomes In Childbearing Women Treated With Thiopurines: A Meta-Analysis. Zeinab F. Saleh, Raveendhara R. Bannuru, William F. Harvey and Timothy E. McAlindon. Tufts Medical Center, Boston, MA.

Background/Purpose: The thiopurines azathioprine (AZA) and 6-mercaptopurine (6-MP) are effective treatments for many rheumatic and autoimmune conditions. These medications have a category D classification from the US FDA. In humans, few studies have evaluated their safety in pregnancy, and most of them have focused on women with Inflammatory Bowel Disease (IBD). We performed an updated meta-analysis to study their effect on birth outcomes for any indication, not only IBD.

Methods: We searched Medline and the Cochrane database from inception to May 2013 for articles reporting birth outcomes in all women who took thiopurines within 3 months prior to conception and/or during pregnancy.

Outcomes of interest were incidence of congenital abnormalities (CAs), low birth weight (LBW; <2,500 g) and/or preterm birth (PTB; <37 weeks gestation). We calculated the Relative Risk (RR) for each outcome. Data were combined using a random effects model, and heterogeneity was assessed using an I^2 score.

Results: Fifteen case-control studies met inclusion criteria. We could not identify any study exclusively including patients with rheumatic conditions. A total of 1184 pregnancies were exposed to thiopurines, and 5955 disease-matched pregnancies were not exposed. There were 13 studies reporting on CAs, 10 on LBW, and 15 on PTB. Analysis of the studies that reported thiopurine exposure indicated an association with increase in CAs, but did not reach statistical significance (RR 1.35; 95% CI 0.99–1.85; I^2 = 0%). No statistically significant difference was found for LBW (RR 1.17; 95% CI 0.63–2.18; I^2 = 79%). Similarly, there was no significant increase of PTB (RR 1.28; 95% CI 0.88–1.86; I^2 = 69%).

Table 1. Characteristics of included studies

Study	Study design	Thiopurine	Indication	Thiopurine exposed pregnancies (N)	Disease-matched pregnancies unexposed to thiopurine (N)**
Casanova, 2013	RC	AZA or 6-MP	IBD	187	318
Perales-Puchalt 2012	RC	AZA	KT	8	16
Mahadevan 2012	PC	AZA or 6-MP	IBD	279	326
Coelho 2011	PC	AZA or 6-MP	IBD	86	129
Shim 2011	RC	AZA or 6-MP	IBD	19	74
Cleary 2009	RC	AZA	IBD	324	1739
Langagergaard 2007	RC	AZA or 6-MP	Any indication*	65	174
Norgard 2007	RC	AZA or 6-MP	IBD	26	880
Schramm 2006	RC	AZA	AIH	14	28
Dejaco 2005	PC	AZA or 6-MP	IBD	33	35
Francella 2003	RC	6-MP	IBD	39	92
Heneghan 2001	RC	AZA	AIH	15	20
Kallen 1998	RC	AZA	Any indication*	33	2104
Haugen 1994	RC	AZA	KT	35	11
Pahl 1993	RC	AZA	KT	21	9

*: includes IBD, rheumatic diseases, Myasthenia Gravis, Interstitial lung disease, glomeruloneprhitis and others.
** disease-matched pregnancies were either on other immunosuppressant or on no medication.
RC: Retrospective Cohort; PC: Prospective Cohort; AZA: Azathioprine; 6-MP: 6-Mercaptopurine. IBD: Inflammatory Bowel Disease; KT: kidney Transplant; AIH: Autoimmune Hepatitis

Conclusion: We found that thiopurine use at the time of conception and/or during pregnancy in women with autoimmune conditions is not associated with CAs, LBW or PTB. There was a positive association with increased risk of congenital malformations, but this might be due to potential confounders, such as disease activity or use of other immunosuppressants. Overall, the results are reassuring, but welcome larger prospective studies reporting more data on disease activity during pregnancy. Interestingly, although only 2 trials included patients with rheumatic diseases, it is reassuring that all 15 studies used the same doses of thiopurines that rheumatologists use in practice. These results could be helpful in discussing therapy with patients considering pregnancy.

Disclosure: Z. F. Saleh, None; **R. R. Bannuru**, None; **W. F. Harvey**, None; **T. E. McAlindon**, None.

2045

Long QT and Hydroxychloroquine; A Poorly Recognised Problem In Rheumatology Patients. Andra Negoescu[1], Andrew Thornback[2], Eugene Wong[2] and Andrew J. Ostor[2]. [1]Rheumatology Research Unit, Addenbrooke's Hospital, Cambridge, United Kingdom, [2]Addenbrooke's Hospital, Cambridge, United Kingdom.

Background/Purpose: Hydoxychloroquine (HCQ) is widely used for the treatment of rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) with a side-effect profile including myopathy and cardiotoxicity. Acute HCQ poisoning has been reported to cause a prolonged QT interval, hypokalaemia and a prolonged QRS complex. RA itself is an independent risk factor for cardiovascular (CV) disease and a recent study has shown that patients are 40% more likely to develop atrial fibrillation. Our objective was to determine if alterations in cardiac conductivity with HCQ is appreciated and whether patients should undergo monitoring ECGs.

Methods: A retrospective analysis of our electronic medical records was undertaken to determine whether patients had had an ECG prior to, and at least 6 months after, starting HCQ and whether there had been a resultant change in the QT interval. Only resting standard 12-lead ECGs with both QT and QTc interval values measured were used. A past history of cardiac disease, arrhythmias or other medications know to prolong the QT interval were documented. The threshold for diagnosis of long QT syndrome was a QTc interval of 450 ms.

Results: 1537 patients currently taking HCQ were identified. 102 patients were found to have had ECGs before, and at least 6 months after, starting HCQ therapy. Of these only 19 patients had suitable ECGs for analysis. This comprised 16 females and 3 males, with a mean age of 62.5 years (range 19–87). CV risk factors included hypertension (n=7), obesity (n=5), ischaemic heart disease (n=4), deep vein thromboses (n=3) and cerebral vascular accidents (n=3). Known diagnoses of arrhythmias included atrial fibrillation (n=2), supraventricular tachycardia (n=1) and an unspecified arrhythmia (n=1). The patients had been on HCQ therapy for a mean of 3.6 years (range 1.3–9.2) and were receiving either 200 mg (n=4) or 400 mg (n=15) per day. The initial ECGs had a mean QTc interval of 424 ms (range 377–584). The post HCQ ECGs had a mean QTc interval of 449 ms (range 387–620). The mean change in QTc was 25 ms (range 66–143). Overall 4 patients had a long QTc prior and 8 patients after initiation of HCQ therapy (table 1). 8 patients were also taking ≥1 medication known to prolong the QT interval.

Table 1.

Patient	QTc Change	Years on HCQ	Cumulative Dose
1	−66	5.0	733
2	143	1.8	277
3	7	7.2	1058
4	62	1.2	199
5	9	2.8	297
6	28	2.4	219
7	−49	1.6	246
8	47	5.8	637
9	31	4.5	669
10	40	3.4	503
11	90	2.4	370
12	42	2.1	317
13	8	5.6	825
14	20	2.1	323
15	−6	9.2	1313
16	57	4.5	336
17	47	2.3	353
18	−38	1.8	281
19	0	3.6	269
Average	**25**	3.6	485

Conclusion: The appreciation of potential drug-induced arrhythmias in Rheumatology patients to date has not been well described. Our analysis showed a trend in prolongation of the QTc following treatment with HCQ. As we examined only a surrogate outcome, namely a change in QTc interval, we were unable to determine whether this was clinically relevant. It is difficult to distinguish whether the ECG changes observed were due to HCQ or due to other factors. Nevertheless as only a small number of patients had ECGs we have highlighted the under-recognition of this particular problem. In order to truly determine HCQ as a culprit, a prospective study is required in this area.

Lower-Dose Indomethacin Submicron Particle Capsules' Efficacy In Acute Pain: Results From Two Phase 3 Studies. Roy D. Altman[1], Allan Gibofsky[2], Mark Jaros[3] and Clarence Young[4]. [1]UCLA, Los Angeles, CA, [2]Hospital for Special Surgery, New York, NY, [3]Summit Analytical, Denver, CO, [4]Iroko Pharmaceuticals, Philadelphia, PA.

Background/Purpose: Indomethacin is used to treat acute gouty arthritis and other acute pain conditions but, like other NSAIDs, is associated with dose-related gastrointestinal, cardiovascular, and renal complications. A US Food and Drug Administration Public Health Advisory recommended that physicians use NSAIDs at "the lowest effective dose for the shortest duration consistent with individual patient treatment goals." A challenge with using existing NSAIDs at lower doses is achieving efficacy. New, submicron particle NSAIDs with enhanced absorption are under investigation to evaluate efficacy at lower doses than commercially available NSAIDs. We report the results of two phase 3 studies that evaluated investigational, lower-dose indomethacin submicron particle capsules compared with placebo in patients with acute pain following elective surgery.

Methods: Two phase 3, multi-center, randomized, double-blind studies enrolled patients 18 to 65 years of age undergoing bunionectomy with

osteotomy and internal fixation under regional anesthesia. Patients with a pain intensity rating of ≥40 mm/100-mm by Visual Analog Scale following surgery received indomethacin submicron particle capsules (40 mg three times daily [TID] or twice daily [BID], or 20 mg TID), or placebo. One study included celecoxib (400 mg loading dose followed by 200 mg BID). The primary endpoint was the overall (summed) pain intensity difference measured by Visual Analog Scale over 48 h.

Results: Overall, 835 patients were enrolled in both studies with >350 patients in each study. In study 1, all doses of indomethacin submicron particle capsules provided significantly better analgesia than placebo ($P \leq 0.046$). While celecoxib led to some pain control, it did not achieve statistical significance compared with placebo ($P = 0.103$; **Table**). In study 2, indomethacin submicron particle capsules 40 mg TID ($P = 0.034$) and BID ($P = 0.023$) provided significantly better analgesia than placebo (**Table**). In both studies, adverse events were generally similar across treatment groups and included nausea, localized post-procedural edema, dizziness, and headache.

Table.

	Indomethacin Submicron 40 mg TID	Indomethacin Submicron 40 mg BID	Indomethacin Submicron 20 mg TID	Celecoxib 200 mg BID, 400 mg loading dose	Placebo
			Study 1		
n	93	91	91	93	94
SPID-48					
Least squares mean ± SE	509.6 ± 91.9	328.0 ± 92.9	380.5 ± 92.9	279.4 ± 91.9	67.8 ± 91.4
P-value vs placebo	<0.001	0.046	0.017	0.103	
			Study 2		
n	94	93	92	N/A	94
SPID-48					
Least squares mean ± SE	598.5 ± 105.7	623.0 ± 106.2	342.8 ± 106.8	N/A	280.9 ± 105.8
P-value vs placebo	0.034	0.023	0.680	N/A	

TID, three times daily; BID, twice daily; SPID-48, overall (summed) pain intensity difference measured by Visual Analog Scale over 48 h; SE, standard error; N/A, not available.

Conclusion: Investigational, lower-dose indomethacin submicron particle capsules provided effective analgesia in two phase 3 studies in patients with acute pain following elective surgery. Indomethacin submicron particle capsules are a potentially promising lower-dose option for patients with acute pain.

Lower-Dose Indomethacin Submicron Particle Capsules' Combined Safety From Two Phase 3 Studies In Patients With Acute Pain Following Elective Surgery. Allan Gibofsky[1], Roy D. Altman[2], Clarence Young[3], Daniel Solorio[4] and Jennifer Nezzer[5]. [1]Hospital for Special Surgery, New York, NY, [2]UCLA, Los Angeles, CA, [3]Iroko Pharmaceuticals, Philadelphia, PA, [4]Iroko Pharmaceuticals, LLC, Philadelphia, PA, [5]Premier Research, Philadelphia, PA.

Background/Purpose: Indomethacin is prescribed to treat acute pain and inflammation but, like other NSAIDs, is associated with dose-dependent gastrointestinal, cardiovascular, and renal adverse events (AEs). A US Food and Drug Administration Public Health Advisory recommended that physicians use NSAIDs at "the lowest effective dose for the shortest duration consistent with individual patient treatment goals." The efficacy of new, submicron particle NSAIDs with enhanced absorption is being evaluated at lower doses than commercially available NSAIDs. We present safety and tolerability data from two phase 3 studies evaluating the analgesic efficacy and safety of investigational, lower-dose indomethacin submicron particle capsules in patients with acute pain following elective surgery.

Methods: Two phase 3, randomized, multi-center, double-blind studies enrolled patients 18 to 65 years of age undergoing bunionectomy with osteotomy and internal fixation under regional anesthesia. Patients with a pain intensity rating of ≥40 mm/100-mm Visual Analog Scale following surgery received indomethacin submicron particle capsules (40 mg three times daily [TID] or twice daily [BID], or 20 mg TID), or placebo. One study included celecoxib (400 mg loading dose followed by 200 mg BID). Safety assessments included an overall summary of AEs by severity and seriousness.

Results: The pooled safety population included 835 patients. AEs were similar across treatment groups (**Table**). The most common AEs were nausea, post-procedural edema, headache, dizziness, vomiting, post-procedural hemorrhage, and constipation. There were no severe cardiovascular, gastrointestinal, or renal AEs. One serious AE, deep vein thrombosis, occurred in the indomethacin submicron particle capsules 40 mg BID treatment group and was determined by the investigator to be unrelated to the study drug. Seven patients withdrew from the trials due to an AE. AEs leading to withdrawal included one case each of uvulitis, angioedema, pyrexia, anxiety, and nausea, and 2 cases of urticaria.

Adverse Event	Indomethacin Submicron 40 mg TID (n = 187) n (%)	Indomethacin Submicron 40 mg BID (n = 184) n (%)	Indomethacin Submicron 20 mg TID (n = 183) n (%)	Combined Indomethacin Submicron (n = 554) n (%)	Celecoxib 200 mg BID, 400 mg loading dose (n = 93)[a] n (%)	Placebo (n = 188) n (%)
Any AE	131 (70.1)	148 (80.4)	137 (74.9)	416 (75.1)	68 (73.1)	142 (75.5)
Nausea	62 (33.2)	60 (32.6)	63 (34.4)	185 (33.4)	30 (32.3)	67 (35.6)
Post-procedural edema	44 (23.5)	40 (21.7)	48 (26.2)	132 (23.8)	25 (26.9)	60 (31.9)
Headache	29 (15.5)	25 (13.6)	20 (10.9)	74 (13.4)	5 (5.4)	21 (11.2)
Dizziness	28 (15.0)	26 (14.1)	18 (9.8)	72 (13.0)	7 (7.5)	32 (17.0)
Vomiting	14 (7.5)	19 (10.3)	21 (11.5)	54 (9.7)	3 (3.2)	21 (11.2)
Post-procedural hemorrhage	9 (4.8)	20 (10.9)	9 (4.9)	38 (6.9)	8 (8.6)	11 (5.9)
Constipation	7 (3.7)	9 (4.9)	11 (6.0)	27 (4.9)	3 (3.2)	9 (4.8)

AE, adverse event; BID, twice daily; TID, three times daily. [a]Only study 1 had a celecoxib treatment arm.

Conclusion: Indomethacin submicron particle capsules were generally well-tolerated in two phase 3 studies in patients with acute pain following elective surgery. Based on emerging efficacy data, investigational, lower-dose indomethacin submicron particle capsules represent a potentially promising lower-dose option for treating acute pain.

Risk Factors For Glucocorticoids-Induced Diabetes In Patients With Rheumatic Diseases. Takayuki Katsuyama[1], Sayaka Aoki[2], Ken-ei Sada[1], Yuriko Yamamura[1], Haruki Watanabe[1], Eri Katsuyama[1], Mariko Narazaki[1], Noriko Tatebe[1], Koichi Sugiyama[1], Katsue S. Watanabe[1], Hiroshi Wakabayashi[1], Tomoko Kawabata[1], Jun Wada[2] and Hirofumi Makino[1]. [1]Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama, Japan, [2]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.

Background/Purpose: Since the efficacy of glucocorticoids for various rheumatic diseases was reported, glucocorticoids are still one of the important therapeutic agents in the current treatment of autoimmune disease. However, various adverse effects of glucocorticoids have been recognized and glucocorticoids-induced diabetes mellitus (GC-DM) is one of the critical systemic adverse effects of glucocorticoids. We conducted a single center retrospective cohort study to reveal risk factors for GC-DM.

Methods: We enrolled inpatients with newly diagnosed rheumatic disease from April 2006 to February 2013 in our department. Patients with previously diagnosed DM, defined as hemoglobin A1c (HbA1c) more than or equal to 6.5% or fasting plasma glucose (FPG) more than or equal to 126 mg/dl on admission, were excluded from the study. Each patient's baseline data included age, sex, underlying disease, smoking history, body mass index (BMI), family history of DM, FPG, HbA1c, eGFR, cholesterol, and triglyceride. We also collected the information of initial treatment including the maximum and the cumulative dosage of glucocorticoids and the concomitant use of methylprednisolone pulse therapy in four weeks. Primary end point of this study is the development of DM defined as fasting glucose not less than 126 mg/dl and/or postprandial glucose not less than 200 mg/dl at least twice after the initiation of glucocorticoids. We compared the characteristics and treatment status between GC-DM group and non DM group using paired *t* test and a Chi-square test. In order to identify independent risk factors for GC-DM, the extracted variables in the univariate analysis were entered into multivariate analysis using the logistic regression model.

Results: 26 male and 49 female patients (60.2± 17.1 years of age) consisting of 30 with systemic vasculitis, 15 with myositis and 11 with systemic lupus erythematosus were enrolled in the present study. The mean maximum dosage of glucocorticoids was 0.76 mg/kg/day and 20 patients (26.7 %) received methylprednisolone pulse therapy. 46 of 75 patients (61.6 %) developed GC-DM within 4 weeks. All patients with GC-DM showed the rise in postprandial blood glucose levels, while FPG levels of most patients were within normal range. The mean age and HbA1c levels at onset were significantly higher in GC-DM group than that in non-DM group (66.6 vs. 50.1 years p=0.002, 5.85 vs. 5.54 % p=0.034, respectively). No difference was found between two groups with the mode and dose of glucocorticoids. The patients with vasculitis developed GC-DM more frequently than those with SLE (73.3 % vs. 27.3 % p=0.006) while the mean age at disease onset is older in patients with vasculitis than those in patients with SLE (68.7 vs. 36.6 years p=0.008). In multivariate analysis, older age (more than or equal to 65 years) and higher levels of HbA1c (> 5.9%) were detected as independent risk factors for GC-DM (Odds ratio; 4.28 and 5.24, respectively).

Conclusion: Under the treatment with moderate or high dose of glucocorticoids, monitoring the postprandial glucose level is recommended particularly in patients with older age or higher levels of HbA1c for monitoring the development of GC-DM.

2049

Comparison Of Corticosteroid Plus Lidocaine Or Lidocaine Alone In Patients Receiving Celecoxib For The Treatment Of Acute Shoulder Or Trochanteric Bursitis: A Randomized, Double-Blind, Placebo Controlled Trial. Muhammad Imran[1], Haritha Narla[2], Jo A. Wick[3] and Herbert B. Lindsley[3]. [1]Kansas University Medical center, Kansas city, MO, [2]Kansas university Medical Center, kansas city, MO, [3]Kansas University Med Ctr, Kansas City, KS.

Background/Purpose: Bursitis is a self-limiting disorder in the majority of patients and typically responds to conservative measures. However, corticosteroid injections may be necessary in recurrent cases. The purpose of this study is to determine the efficacy of corticosteroid injection of methylprednisolone acetate with lidocaine versus lidocaine alone, in addition to celecoxib for subdeltoid and greater trochanteric bursitis in a randomized, double blind, placebo controlled trial.

Methods: 30 patients in our rheumatology clinic with acute or recurrent subdeltoid or trochanteric bursitis were randomized into an experimental group [n=15, 4 subdeltoid and 11 trochanteric bursitis] and a control group [n=15, 4 subdeltoid and 11 trochanteric bursitis]. Subjects with subdeltoid bursitis in the experimental group received methylprednisolone acetate (long acting) 80 mg (1.0 ml) plus lidocaine 20 mg (2.0 ml) into the subdeltoid bursa. The control group received lidocaine 20mg (2.0 ml) plus normal saline (1.0 ml). Subjects with trochanteric bursitis in the experimental group received methylprednisolone acetate (long acting) 120 mg (1.5 ml) plus lidocaine 30 mg (3.0 ml); the control group received 30 mg lidocaine plus normal saline (1.5 ml). Each group also received celecoxib 600 mg for the first day (a 400 mg initial dose followed by 200 mg later in the day) then 200 mg BID for 13 days. All subjects were treated for 14 days.

The primary end point was improvement of VAS (visual analog score) for bursal pain; secondary end points included improvement of VAS for fatigue, sleep, and global function; and bursal tenderness by palpation.

VAS for bursal pain, fatigue, sleep, and global function was scaled from 0 to 10 and bursal tenderness was scaled from 0 to 4.

Results: 30 subjects completed the study with 15 subjects in each group. The primary end point was met, periarticular corticosteroid significantly reduced VAS for bursal pain in experimental group compared to controls). The secondary end points also were met, improvement trends were noted for fatigue, sleep and global function; and bursal tenderness by palpation.

	Treatment Group			*Control Group*		
Variables	Day 0 [Mean SD]	Day 14 [mean (SD)]	% improvement	Day 0 [Mean SD]	Day 14 [mean (SD)]	% improvement
Bursal Pain	6.3 (2.2)	2.3 (2.2)	63	6.6 (2.3)	5.4 (3.0)	18
Fatigue	7.0 (3.2)	4.3 (3.4)	38	6.0 (2.9)	5.5 (3.2)	25
Sleep	6.9 (2.5)	3.0 (2.8)	56	6.3 (2.7)	4.3 (3.3)	31
Global Function	5.8 (2.5)	2.1 (2.0)	63	5.8 (2.2)	4.3 (2.1)	25
Bursal Tenderness (left shoulder)	1.9 (1.2)	1.4 (0.78)	26	2.0 (1.10)	1.75 (1.20)	12
CRP (mg/dl)	0.6 (0.4)	0.6 (0.5)	0	0.6 (0.4)	1.2 (2.3)	−100

Conclusion: Three of four VAS outcomes exceeded 50% improvement in the experimental group, whereas with the control group no VAS outcomes exceeded (31%). Periarticular corticosteroid plus lidocaine in addition to full dose of celecoxib enhances short term benefits of treatment for bursitis.

Arthralgia Occurring Under Aromatase Inhibitor Treatment For Breast Cancer. A Prospective Study. Daniel Wendling[1], Helene Letho-Gyselinck[1], Xavier Guillot[2], Clément Prati[3] and Xavier Pivot[2]. [1]Minjoz University Hospital, Besancon, France, [2]CHRU Besançon, Besançon, France, [3]CHU J Minjoz, Besancon, France.

Background/Purpose: Treatment with third generation aromatase inhibitors (AI) is associated with occurrence of arthralgia, with an incidence ranging from 25 to 45 %. In these patients, arthralgia may also be related to other conditions such as osteoarthritis, common tendinitis or auto immune diseases.

The aim of this study was to study patients treated with AI and reporting arthralgia, and comparing patients with new onset to patients with pre existing arthralgia and exacerbation under AI, to look for associated etiologic factors.

Methods: Patients followed in a tertiary oncology center for breast cancer treated with AI and reporting arthralgia were prospectively screened for rheumatologic clinical evaluation, as well as biologic (ESR, CRP, RF, ANA, ACPA) or imaging (X-Rays of symptomatic regions) investigation. Type of cancer, duration, treatment, type of AI, duration of AI treatment. Patients were divided in two groups: patients with new onset of arthralgia under AI, and patients with pre existing and exacerbation of arthralgia under AI. The two groups are compared using t test for quantitative variables (significance: p less than 0.05).

Results: Seventy five women were included, mean age (SD): 64.8 (9.2) years, time from cancer diagnosis: 34 (25) months. Adjuvant chemotherapy and/or radiotherapy were noted in respectively 52 and 64 cases. AI was Anastrozole (n = 6), Letrozole (55), Exemestane (14). Mean duration AI treatment since onset or exacerbation of arthralgia: 179 (224) days. Mean number of painful joints: 7.6 (9.7); locations (number of patients):shoulder 36, elbow 22, wrist 25, MCP 27, PIP 26, knee 26, MTP28. Mean ESR: 29 (25)mm/h; CRP: 3 (7.6) mg/l). New onset arthralgia: n = 38; pre existing and exacerbation of arthralgia: n = 37. No statistical differences were found between these two groups for type of cancer, presence of chemotherapy or radiotherapy, presence of metastases, duration and type of AI treatment, VAS pain, number and distribution of tender joints, ESR, CRP, ANA, RF, ACPA positivity, and radiographic findings. Positive lymph nodes and radiographic signs of rotator cuff dysfunction were statistically more frequent in the pre existing and exacerbation group. Some specific diagnoses were done after evaluation: 2 CREST syndrome (one in each group), 1 RA and 1 Sjögren syndrome in the new onset symptom group.

Conclusion: Arthralgia under AI treatment is frequent. Our study argues for an absence of specificity of these arthralgia, without particular difference between new onset or exacerbation of pre existing arthralgia, auto immune disease seem more frequent in the new onset symptom group, and thus possibly related to anti aromatase therapy.

2051

Characteristics and Comparison Of Patients With Cystic Fibrosis With and Without Arthritis. Heather O. Tory[1], Karen Herlyn[2], David Zurakowski[3], Angela S. Pizzo[4], Robert P. Sundel[5] and Peter A. Merkel[6]. [1]Boston Children's Hospital, Boston, MA, [2]University Hospital Schleswig-Holstein, Lübeck, Germany, [3]Boston Children's Hospital, Boston, MA, [4]Mercy Hospital, Portland, ME, [5]Boston Children's Hospital and Harvard Medical School, Boston, MA, [6]University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Cystic Fibrosis (CF) is a common genetic mutation in Caucasian populations. Many patients have musculoskeletal complaints and 12% develop arthritis, including CF arthropathy (CFA), a poorly

understood entity of episodic mono or polyarthritis, and other inflammatory arthropathies. Prior studies have been limited to small patient cohorts showing no clear association with disease severity or complications, or specific laboratory results. Thus, diagnostic criteria are not well defined and the pathogenesis remains unclear. The goal of this study was to compare disease characteristics and laboratory findings between patients with CF with and without arthritis from a large cohort.

Methods: Patients with CF seen at 2 tertiary care hospitals over a 6 year period were screened for musculoskeletal symptoms via questionnaire or referral. Patients with symptoms underwent a comprehensive evaluation including chart review, medical history and physical examination by a rheumatologist, laboratory testing and pulmonary function testing. Patients were diagnosed with arthritis if they had physician documented evidence of joint effusion, warmth, or limited range of motion. Age- and gender-matched control patients with CF without arthritis were also evaluated. Comparisons between cases and controls were made by univariate and multivariate logistic regression analyses to identify independent markers of arthritis.

Results: The study cohort consists of 25 patients with CF and arthritis and 72 without arthritis. Demographic features were similar with no differences in the presence of disease complications (**Table 1**). Univariate analysis did find a higher percentage of rheumatoid factor (RF) positivity in patients with arthritis compared to patients without arthritis (18% vs. 3%, p = 0.04), with no other between group differences (**Table 2**). Regression analysis suggested this association held (p=0.05) after controlling for other markers of disease severity (age, IgG level, and FEV1).

Table 1. Comparison of demographic features and disease complications between groups

Patient Characteristics	Cystic Fibrosis Patients with Arthritis (n=25)	Cystic Fibrosis Patients without Arthritis (n=72)	p value
Demographic features			
Female, no. (%)	14 (56)	38 (53)	0.82
Age at visit, median (range) in years	25.1 (4.6–55.9)	26.6 (5–43.8)	0. 93
Body mass index, mean (SD) kg/m^2	19.6 (3.9)	20.6 (3.6)	0.33
Family history of autoimmunity, no. (%)	0 (0)	4 (6)	0.57
Complications of cystic fibrosis, no. (%)			
Allergic bronchopulmonary aspergilosis	2 (10)	8 (12)	1
Bowel obstruction	8 (35)	14 (20)	0.17
Diabetes mellitus/pancreatic	8 (35)	20 (29)	0.61
Hepatitis/cirrhosis	6 (26)	7 (10)	0.08
Hepatobiliary/gallbladder	4 (17)	9 (13)	0.73
Malabsorption/intestinal	19 (83)	57 (83)	1
Nasal polyps	16 (70)	34 (49)	0.15
Pulmonary	23 (100)	62 (90)	0.19

Table 2. Comparison of laboratory features among groups

Laboratory Features	Cystic Fibrosis Patients with Arthritis (n=25)	Cystic Fibrosis Patients without Arthritis (n=72)	p value
Albumin, g/dL	3.9 (0.5)	3.9 (0.53)	0.83
ALT, units/L	28.8 (18.8)	37.3 (31.4)	0.21
Amylase, units/L	39.8 (23.6)	51.1 (32.9)	0.13
ANA present, no. (%)	3 (14)	13 (22)	0.54
AST, units/L	27.2 (17.5)	32.5 (24.3)	0.33
CH50, units/mL	232 (63)	206 (58)	0.15
Cholesterol, mg/dL	151 (50)	141.2 (43)	0.40
Immune complexes, median (IQR)	11.5 (5.8, 15)	9 (3, 12)	0.21
Creatinine, mg/dL	0.82 (0.38)	0.83 (0.26)	0.93
CRP, median (IQR) mg/dL	5.7 (3, 14.4)	3.1 (3, 18)	0.71
Cryoglobulin present, no. (%)	1 (5)	3 (5)	1
ESR, mm/hr	26.9 (21.6)	24 (23.1)	0.60
FEV1, % predicted	62.5 (26.2)	63.5 (29.8)	0.89
FVC, % predicted	75.5 (22.6)	78.8 (25.6)	0.61
Glucose, mg/dL	114 (59)	120 (81)	0.76
Hematocrit, %	38 (4)	39 (4)	0.23
IgG, mg/dL	1258 (441)	1383 (554)	0.33
Platelet, cells/uL	284 (110)	304 (92)	0.37
Rheumatoid factor present, no. (%)	4 (18)	2 (3)	0.04
Total bilirubin, mg/dL	0.45 (0.21)	0.47 (0.58)	0.84
Triglyceride, mg/dL	131 (94)	110 (63)	0.27
White blood cell, 103-cells/uL	9.4 (2.3)	9.7 (3.3)	0.75

Data are mean (SD) unless otherwise indicated. IQR = interquartile range.

Conclusion: In this largest cohort to date, patients with CF and arthritis were more likely to have a positive RF compared to patients without arthritis, suggesting that the pathophysiology may be related to accumulation of antigenic immune markers. There were no other differences, indicating that the etiology and spectrum of disease may vary and requires additional exploration, including genotype evaluation and longitudinal follow-up.

2052

The Prevalence and Pattern Of Self Reported Joint Symptoms In Cystic Fibrosis. Carl Orr[1], Cormac McCarthy[1], Johan Meurling[1], Paul G. O'Connell[2], Cedric Gunaratnam[1] and Noel G McElvaney[1]. [1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]Beaumont Hospital, Dublin 9, Ireland.

Background/Purpose: Arthritis in cystic fibrosis (CF) can be very incapacitating, and it is mainly of three types: CF arthritis, hypertrophic osteoarthropathy, and arthritis due to co-existent conditions and drug reactions [1]. Episodic arthritis occurring in patients with cystic fibrosis has been recognised [2]. However, although joint manifestations are common in children with cystic fibrosis (CF), they have received little attention in adults [3]. The prevalence of joint pain in the CF patients has been reported variously as: 12.9% [4], 2–8.5% of patients [3] and 4.5% in patients aged over 10 [5]. Our experience suggested that the prevalence may be higher than that previously reported.

Methods: Rheumatic symptoms and signs of 55 adult patients with CF (age 18 to 63 years) were determined by questionnaire and phone interview. The questionnaire was designed to elicit the pattern of joint problems, as well as to determine features of definite inflammatory problems which included joint swelling, difficulty with function (e.g. making a fist) and morning stiffness lasting greater than 1 hour.

Results: 63.6% (35/55) reported ever having experienced joint pain, but only 37.1% of those who reported experiencing pain at any point said that it had affected important activities in their lives. 16.4% (9/55) reported more than one hour of morning stiffness in their joints. 30.9% (17/55) reported joint swelling or difficulty making a fist.

In those that reported pain, 60% (21/35) reported wrist pain, with 42.9% (9/21) of these patients reporting wrist swelling. 16.4% (9/55) of the total cohort had experienced both wrist pain and swelling.

In those that reported pain, 57.1% (20/35) reported hand pain, with 60% (12/20) reporting swelling and 65% (13/20) having difficulty making a fist. Inflammatory symptoms (difficulty making a fist or hand swelling) were reported in 80% (16/20) of those with hand pain.

Knee 80% (28/35), ankle 60% (21/35) and foot 31.4% (11/35) pain were cited by those reporting pain.

Symmetrical disease in time was reported in 48.6% (17/35) patients.

Conclusion: The prevalence of joint symptoms by self-report in our CF cohort far exceed that reported in previous studies. The age of the cohort would suggest that joint pain is being reported more commonly in patients with CF than in subjects of similar age who do not have CF.

The reported symptoms of swelling and morning stiffness suggest that the problems may be inflammatory in up to 30% of patients with CF.

No definite pattern of involvement could be identified in this study.

Efficacy Of Intermittent Intra-Venous Cyclophosphamide and Cyclosporin A Combination Therapy For Rapidly Progressive Interstitial Lung Disease With Dermatomyositis Associated With Anti-Melanoma Differentiation-Associated Gene 5 Autoantibody Titer. Noriko Sasaki, Shinji Sato, Shinichi Nogi, Naofumi Chinen, Kiri Honda, Eiko Saito, Chiho Yamada and Yasuo Suzuki. Tokai University School of Medicine, Isehara, Japan.

Background/Purpose: Anti-Melanoma Differentiation-Associated Gene 5 (MDA5) autoantibody is present specifically in patients with dermatomyositis (DM), especially those with few or no muscle manifestations (clinically amyopathic dermatomyositis: CADM). It is strongly associated with rapidly progressive interstitial lung disease (RP-ILD). Recently, an association between anti-MDA5 antibody titer measured by enzyme-linked immunosorbent assay (ELISA) and disease activity has been reported in addition to its diagnostic utility for CADM with RP-ILD. However, the relationship between antibody titer and efficacy of intermittent intra-venous cyclophosphamide and cyclosporin A combination therapy had not been reported.

Methods: 7 patients with CADM and RP-ILD positive for anti-MDA5 antibody by RNA and protein immunoprecipitation assay who were seen at our University between 2011 and 2012 were retrospectively evaluated for anti-MDA5 antibody and lung involvement. Anti-MDA5 antibody titers were determined by a previously established ELISA. Patients received combination therapy consisting of intermittent intra-venous cyclophosphamide (0.5 g/m^2/month), cyclosporin A (2–4 mg/kg/day) and high dose corticosteroid (1 mg/kg/day orally, then tapering gradually) including pulse therapy (1,000 mg/day for 3 days) over 24–48 weeks. Associations between anti-MDA5 titer and the change in high resolution computed tomography (HRCT) findings after improvement of lung involvement or outcome were analyzed. HRCT findings were evaluated by alveolar and interstitial score proposed by Kazerooni et al.

Results: The combination therapy was effective for all 7 CADM and RP-ILD patients and none of them died during follow-up. There was no correlation between the mean alveolar score and the mean titer of anti-MDA5 antibody before treatment ($r=-0.36$; $P=0.44$). The mean titer of anti-MDA5 antibody significantly decreased after treatment (130.8 units vs. 15.3 units, $P=0.016$, cut-off level = ~15 unit). In parallel with the reduced antibody titer, respiratory symptoms improved in all patients and the mean alveolar score significantly decreased after treatment (10.9 vs. 7.6, $P=0.012$), whearas no changes were seen in the mean interstitial score. After improvement of RP-ILD, anti-MDA5 titer remained under the cut-off level over time in 5 of 7 (71%) patients.

Conclusion: These results emphasize the clinical importance of using anti-MDA5 antibodies to monitor disease activity of lung involvement and to evaluate the response to treatment in patients with DM and RP-ILD.

Efficacy and Safety Of Low-Intensity Resistance Training Combined With Vascular Occlusion In Polymyositis and Dermatomyositis. Melina Mattar[1], Luiz A. Perandini[1], Thalita Dassouki[2], Samuel K. Shinjo[1], Bruno Gualano[3], Hamilton Roschel[3], Fernanda R. Lima[4] and Ana Lucia S. Pinto[1]. [1]University of Sao Paulo, Rheumatology Division, LACRE, Sao Paulo, Brazil, [2]Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [3]University of Sao Paulo, School of Physical Education and Sport, Sao Paulo, Brazil, [4]University of Sao Paulo, Rheumatology Division, Sao Paulo, Brazil.

Background/Purpose: Previous studies have demonstrated that low-intensity resistance training combined with vascular occlusion (VO) improves muscle strength to the magnitude of traditional high-intensity resistance training in healthy subjects. We, therefore, aimed to determine whether low-intensity resistance training combined with VO is safe and effective to improve muscle strength, functional capacity and quality of life in patients with polymyositis (PM) and dermatomyositis (DM).

Methods: Thirteen patients (4 PM and 9 DM according to Bohan and Peter's criteria, 1975) from the Outpatient Myopathy Unit of our tertiary Center, with complete clinical response to the treatment (age: 45.6±8.8 years; disease duration: 5.4±2.9 years; body mass index (BMI): 31.0±6.6kg/m^2; VO_2max: 23.3±6.9mL/kg/min) were submitted to a 12-week supervised exercise program that consisted of resistance exercises at low-intensity [30% of one repetition maximum (1RM)] combined with VO (70% of the total occlusion pressure of the tibial posterior artery). Clinical questionnaires [36-item short form health survey (SF-36), the health assessment quality (HAQ) and the visual analogue scale (VAS)], muscle strength (1RM of leg press and leg extension), functional capacity [time stands (TS) and timed up and go (TUG) tests] and serum muscle enzymes were assessed before (PRE) and after (POST) the exercise program. The pharmacological treatment remained unchanged at least three months prior to study entry and throughout the protocol.

Results: Comparison of pre- and post-exercise intervention revealed that all patients had significant improvements in muscle strength (leg-press: 128±62 *vs*. 155±78kg, $P=0.001$; leg-extension: 37±10 *vs*. 46±13kg, $P=0.001$) and muscle function (TS: 13±2 *vs*. 15±2, $P=0.001$; TUG: 6.9±1.1 *vs*. 6.6±1.0s, $P=0.002$). Additionally, improvement in quality of life, as measured by the SF-36 (Physical component: 41.6±7.2 *vs*. 50.0±7.4, $P=0.001$; Mental component: 42.7±13.0 *vs*. 56.0±10.1, $P = 0.008$), HAQ (1.58±1.98 *vs*. 0.60±0.62, $P=0.007$) and VAS (VAS patient: 4.6±2.9 *vs*. 1.6±1.2cm, $P=0.024$; VAS physician: 2.7±1.2 *vs*. 1.2±0.6cm, $P=0.001$). Of note, no change in serum levels of creatine kinase (195±76 *vs*. 224±171IU/L, $P=0.944$) and aldolase (3.9±1.5 *vs*. 3.1±1.6IU/L, $P=0.265$).

Conclusion: The present work provides novel evidence that a low-intensity resistance training program combined with VO is safe and effective in improving muscle strength, functional capacity, and quality of life in PM and DM patients.

Killer T Cell Inhibition By CD226 Blockade For Treatment Of Inflammatory Myopathy. Hitoshi Kohsaka[1], Nao Tateishi[1], Shinya Hirata[2], Kazuko Shibuya[3], Akira Shibuya[3] and Nobuyuki Miyasaka[4]. [1]Department of Medicine and Rheumatology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Kumamoto University School of Medicine, Kumamoto, Japan, [3]Department of Immunology, University of Tsukuba, Ibaraki, Japan, [4]Tokyo Medical and Dental University, Tokyo, Japan.

Background/Purpose: Current treatment strategy of polymyositis/dermatomyositis calls for administration of high dose glucocorticoids and additional immunosupressants when necessary. These options are based largely on successful experiences in treatment of other systemic autoimmune disorders. This is partly because no appropriate animal models were available for basic and preclinical studies. We have developed a new polymyositis model, C-protein induced myositis (CIM) of mice, and disclosed that muscle-reactive killer CD8 T cells and activation of muscular innate immunity are both critical therapeutic targets specific for myositis. To develop a new treatment that addresses specific pathology, CD226 (DNAM-1), which expressed on T cells to promote killer cell function upon interaction with its ligands, was investigated as a candidate therapeutic target.

Methods: Expression of CD112 and CD155, both of which are ligands of CD226, was studied with RT-PCR and immunostaining. In vitro effects of CD226 ligation on CD8 T cells were studied by stimulating mouse splenic CD8 T cells with monoclonal anti-CD226 antibodies (Tx42) and anti-CD3 antibodies immobilized onto microtiter wells. IFNγ in the culture supernatants was quantified with specific ELISA. Mice were immunized with recombinant skeletal muscle C-protein fragments/complete Freund's adjuvant for CIM induction and treated with intact Tx42, F(ab')2 of Tx42, or controls. Treatment was initiated before or after the myositis onset.

Results: C2C12 myoblasts and C2C12-derived myotubes expressed CD155 but not CD112 at the mRNA and protein levels. Mouse muscle tissues expressed CD155 mRNA. In vitro treatment of splenic CD8 T cells with immobilized Tx42 augmented IFNγ secretion when the T cells were stimulated with anti-CD3 antibodies. The augmentation was more obvious when the CD3 antibody concentration was low. CIM was ameliorated when immunized mice were treated with F(ab′)2 of Tx42 both in preventive and therapeutic protocols. Intact Tx42 was not effective in either protocol.

Conclusion: Muscles express CD155, which is a ligand of CD226. Blockade of CD226 with Tx42 F(ab')2, but not with intact Tx42, suppressed CIM. In vitro agonistic effects of immobilized Tx42 in CD8 T cell activation suggested that abrogation of Fc mediated cross-linking by F(ab')2 preparation is essential for the therapeutic effects of the anti-CD226 antibodies. Killer cell inhibition by CD226 blockade should be a new therapeutic approach that addresses specific pathology of polymyositis and possibly dermatomyositis.

Use Of Biologics In Polymyositis and Dermatomyositis – A National Register Study. John Svensson[1], Anna Tjärnlund[2], Balsam Hanna[3], Sara Magnusson Bucher[4], Johan Askling[1], Ingrid E. Lundberg[5] and Maryam Dastmalchi[6]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Solna, Karolinska Institutet, Stockholm, Stockholm, Sweden, [3]Sahlgrenska University Hospital, Gothenburg, Sweden, [4]Örebro University Hospital, Örebro, Sweden, [5]Rheumatology Unit, Department of Medicine, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [6]Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Biologics have been used off-label in treatment of refractory polymyositis (PM) and dermatomyositis (DM). In this study we aimed to describe the use of biologics in patients with PM and DM based on national registries in Sweden.

Methods: Patients were identified by linking the national patient care registers, listing all in-patients and out-patient visits seen by specialists to the prescribed drug register, the Swedish Rheumatology Quality register (SRQ) and the Swedish Myositis Network (SWEMYONET). To retrieve information on demographics, effectiveness and safety we used information in SRQ, SWEMYONET and patient records. Effectiveness was based on an overall assessment of clinical outcome in the patient records, serum levels of creatine phosphokinase (CPK) and prednisolone dose. Clinical data were collected at start of treatment, at last follow up within 12 months or at discontinuation of biological treatment. Therapies stopped within 3 months were excluded from effectiveness evaluation. Safety was evaluated by the number of patients stopping treatment due to adverse events within 12 months.

Results: 63 patients treated with at least one biologic (36 PM, 27 DM, mean age 60 (12), 45 women, 18 men) were identified at 11 different centers between 2001 and 2011. All identified cases were refractory to previous medication with mean 2.5 (1.3) DMARDS beings used prior to start of biologic therapy. Multiple biological treatments were common with 7 patients treated with 2 different biologics and 7 patients treated with 3 different biologics.

Rituximab (RTX) was the most often used biological agent (Table 1). No new treatment with anakinra (ANA) had been started after 2009 and no new treatment with TNF-inhibitors (TNFi) had been started after 2003. One treatment with tocilizumab was identified in 2011 but was stopped after 2 months due to a lung infection.

Table 1. Demographics and outcome measures of biologics in PM and DM

	rituximab	abatacept	anakinra	TNF-inhibitors*
n	42	13	15	13
PM:DM	1.0:1	1.2:1	2.0:1	3.3:1
F:M	1.8:1	5.5:1	4.0:1	2.3:1
Disease duration, years median (range)	4.0 (0.2–35)	7.7 (0.6–35.9)	8.2 (3.5–28.8)	7.4 (1–12.3)
Follow up, months median (range)	6.6 (3.6–12.7)	9.6 (5–12.9)	5.9 (3.1–10.9)	6.1 (3.2–12.4)
Treatment duration, months median (range)	12.0 (0–103.4)	18.5 (1.8–53.1)	6.0 (0.8–30.8)	4.3 (0–75.5)
Stopped due to side effects n(%)	5 (11.9%)	1 (7.7%)	7 (46.7%)	4 (30.1%)
Overall responder** n(%)	27 (69.2%)	8 (66.7%)	4 (36.4%)	2 (22.2%)
CKP-25%*** n(%)	10 (62.5%)	3 (50.0%)	1 (20.0%)	0 (0.0%)
CPK, μkat/L median (range)				
Before	8.4 (0.6–111.6)	7.4 (0.33–39.3)	3.7 (1.2–30.9)	1.9 (1.2–12.6)
After	1.8 (0.4–147.6)	6.6 (1.2–31.4)	4.0 (1.2–28.3)	2.0 (1.2–16.8)
Daily prednisone dose, mg median (range)				
Before	10.0 (0–80)	10.0 (2.5–100)	7.5 (0–50)	11.3 (0–15)
After	10.0 (0–30)	8.1 (0–15)	8.8 (0–20)	10.0 (0–20)

PM = polymyositis, DM = dermatomyositis, F = female, M = male, CPK = creatinine phospokinase
* 1 etanercept, 12 infliximab, **According to patient records, ***Number of patients having a ≥25% decrease of CPK if serum levels at start of treatment > Upper limit of normal.

No statistical difference could be found for any of the biologics when comparing CPK level and prednisolone dose before and after treatment. 3 patients stopped their treatment due to disease remission. They were all treated with RTX. The most common adverse events leading to discontinuation were infections, and for ANA local injection reaction.

Conclusion: We found an increasing use of RTX and ABA in patients with PM and DM. In this population we found an overall favorable response to RTX and ABA in 65% of patients but less often to ANA and TNFi. A reduction of elevated CPK levels was observed more often after RTX and ABA treatment compared to ANA and TNFi treatment. RTX and ABA seemed to be well tolerated by patients.

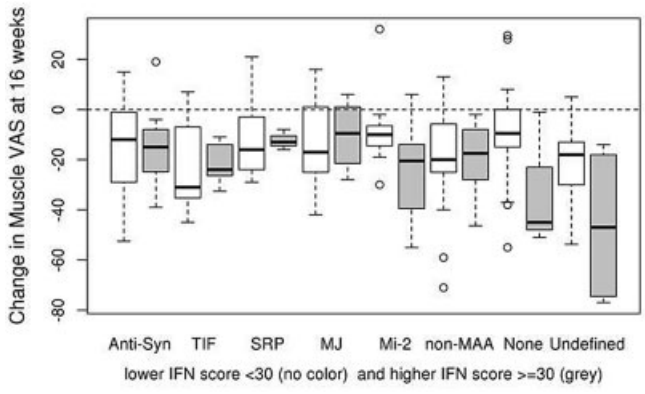
2057

Biomarker and Serologic Predictors Of Clinical Improvement After B Cell Depletion In Refractory Adult and Juvenile Dermatomyositis (DM) and Adult Polymyositis (PM) - The RIM (Rituximab in Myositis) Trial. Ann M. Reed[1], Cynthia S. Crowson[1], Molly S. Hein[1], Consuelo Lopez de Padilla[1], Helen Khun[1], Rohit Aggarwal[2], Dana P. Ascherman[3], Marc C. Levesque[2] and Chester V. Oddis[2]. [1]Mayo Clinic, Rochester, MN, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Miami Miller School of Medicine, Miami, FL.

Background/Purpose: The aim of this study was to examine the longitudinal utility of a biomarker signature in conjunction with myositis autoantibodies (autoAbs) as biomarkers of disease outcome in refractory myositis patients treated with B cell depletion (BCD).

Methods: In the RIM Trial, all subjects received 1 gram of rituximab on 2 consecutive weeks. Using start of treatment as baseline, serum samples (n=177) were analyzed at 0, 8, 16, and 24 weeks after BCD with multiplexed sandwich immunoassays (Meso Scale Discovery) to quantify type-1 IFN-regulated and other pro-inflammatory chemokines and cytokines. Biomarker scores were generated based on a priori assignment from literature review for serum levels from the following pathways: type-1 IFN-inducible (IP-10, I-TAC, MCP1), Th1 (IFNγ, TNFα, IL2), Th2 (IL4, IL5, IL10, IL12, IL13), Th17 (IL6, IL17, IL1b) and regulatory cytokines (IL10 and TNFa). Biomarker scores are defined as the normalized sum of cytokine/chemokine levels adjusted to a 100-point scale. Myositis autoAbs (anti-synthetase (anti-syn) n=28, TIF1-g n=19, Mi-2 n=25, SRP n=21, MJ n=18, non-myositis associated (non-MAA) n=24, unidentified autoantibody n=9, and no autoantibodies n=33) determined by immunoprecipitation at baseline, were correlated with outcome measures. Kruskal-Wallis rank sum test was used for comparisons.

Results: The mean (SD) values for muscle disease and physician global disease activity VAS scores (0–100 mm) were 46 (22) and 49 (19). IFN scores (median values) were higher at baseline in patients with anti-syn; (43), TIF1-g (31) and Mi-2 (30) compared with other autoAb groups ($p<0.001$). No significant improvement in biomarker scores was detected at 8 weeks. However, at 16 weeks after BCD anti-syn and Mi-2 autoAb (+) patients and non-MAA had a greater improvement in IFN scores (−6.7, −6.1 and −7.2 $p<.001$) while TIF1-g (+) patients worsened by 7.0. The change in IFN score at 16 weeks correlated with percent change in muscle ($r=0.27$, $p<0.001$) and physician VAS ($r=0.16$, $p=0.06$). High IFN scores at baseline (>30) demonstrated the greatest clinical improvement based on global and muscle VAS among patients in certain autoAb groups (e.g., Mi-2, none and "undefined") (IFN score-autoAb interaction $p=0.075$; Figure).



Regulatory scores were higher at baseline in patients with anti-syn (31) and non-MAA (32) vs. other groups (p=0.01). Regulatory score improved at 16 weeks in anti-syn (−5.8) and Mi-2 (−3.4) and non-MAA (−7.2, p=0.028). Th1 scores decreased in the anti-syn, Mi-2, non-MAA and to a lesser extent in the TIF-g group at 16 weeks (p=0.039) with the greatest improvement at 24 weeks (p=0.014) suggesting a longer time to improvement if the Th1 score is elevated. Th17 remained unchanged.

Conclusion: Biomarker signatures in conjunction with autoAbs prior to treatment help guide response to BCD in refractory myositis. In addition, biomarker and clinical response is greatest at 16 weeks after BCD.

Evidence For Immunotherapy In Polymyositis and Dermatomyositis: A Systematic Review. Erin Vermaak[1] and Neil J McHugh[2]. [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]Department of Pharmacy and Pharmacology, University of Bath, Bath, United Kingdom.

Background/Purpose: Dermatomyositis (DM) and polymyositis (PM) are rare chronic inflammatory disorders of muscle. The morbidity and mortality associated with these conditions remains significant despite treatment, which typically begins with high-dose corticosteroids. Second-line agents are commonly used in clinical practice, however there are no clear evidence-based guidelines directing their use. We systematically assessed the evidence for immunotherapy in DM and PM.

Methods: Relevant studies were identified through Ovid Medline and PubMed database searches. Bibliographies of relevant studies were scrutinized for other potentially relevant citations, and research registers of ongoing trials and international conference proceedings were examined to identify research in progress or data as yet unpublished. Randomized controlled trials and experimental studies without true randomization (quasi-randomized) including adult patients with definite or probable DM or PM were evaluated. Trials involving patients with possible, early or mild disease were excluded, as were those where diagnostic certainty was unknown or diagnostic criteria had not been specified. Any type of immunotherapy was considered. Improvement in muscle strength was the primary outcome. Secondary outcomes included improvements in patient and physician global scores, physical function and muscle enzymes. Studies not assessing these outcomes were excluded. Using predetermined criteria, the two authors independently selected trials for inclusion and then assessed these for quality.

Results: 1697 citations were retrieved. 13 trials were identified as potentially relevant, 3 were excluded after full text review. 2 further trials were identified after hand-searching reference lists. 12 studies were selected for full analysis, including a total of 522 participants. Differences in trial design and quality, and variable reporting of baseline characteristics and outcomes made direct comparison impossible. Although no one treatment can be recommended on the basis of this review, improved outcomes were demonstrated with a number of agents including methotrexate, azathioprine, ciclosporin and intravenous immunoglobulin. Plasmapheresis and leukapheresis were of no benefit. Biologics were well tolerated but were not demonstrated to be of benefit.

Study	Intervention	Conclusion
Bunch *et al* 1980	Pred + AZA vs. Pred + Placebo	No additional benefit with AZA at 3 months
Hollingworth *et al* 1982	ALG + AZA vs. Pred	NS trend toward benefit with ALG + AZA
Miller *et al* 1992	PEX vs. Leukapheresis vs. Sham apheresis	PEX/Leukapheresis of no benefit
Dalakas *et al* 1993	IVIg vs. Placebo	IVIg beneficial in refractory DM
Villalba *et al* 1998	MTX + AZA + Pred vs. IV MTX + Pred	NS trend toward benefit with MTX + AZA
Vencovsky *et al* 2000	CsA + Pred vs. MTX + Pred	MTX and CsA equivalent, but MTX better tolerated
Coyle *et al* 2008	IFX vs. Placebo	IFX is well tolerated, but has limited efficacy
Van de Vlekkert *et al* 2010	Pred vs. Dex	Dex not superior to Pred, but fewer side effects
The Muscle Study Group 2011	Pred +ETAN vs. Pred + Placebo	No additional benefit with ETAN, but has steroid-sparing effect
Miyasaka *et al* 2011	IVIg vs. Placebo	IVIg of no benefit in cortico-steroid-refractory PM/DM
Choy *et al* 2011	Pred vs. Pred + MTX vs. Pred + CsA vs. Pred + MTX + CsA	Adding immunosuppressants to corticosteroid therapy offers no additional benefit
Oddis *et al* 2013	Ritux early vs. Ritux late	No significant difference between groups, but 83% met DOI

ALG, anti-lymphocyte globulin; AZA, azathioprine; CsA, ciclosporin; Dex, dexamethasone; ETAN, etanercept; IFX, infliximab; IV, intravenous; IVIg, intravenous immunoglobulin; MTX, methotrexate; NS, non-significant; PEX, plasma exchange; Pred, prednisolone; Ritux, rituximab.

Conclusion: More high quality randomized controlled trials are needed to establish the role of second-line agents, in particular biologics, in the treatment of DM and PM.

2059

Mortality In Polymyositis and Dermatomyositis: A Single Centre Study. Erin Vermaak[1], Gavin Shaddick[2] and Neil J McHugh[3]. [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]University of Bath, Bath, United Kingdom, [3]Department of Pharmacy and Pharmacology, University of Bath, Bath, United Kingdom.

Background/Purpose: PM and DM are rare chronic inflammatory disorders of muscle, and data on long-term prognosis and outcomes are lacking. Previous studies have reported 5-year survival rates of 60–75% and standardized mortality ratios (SMRs) ranging from 1.75 to 2.92. Through a better understanding of mortality and its causes, those at increased risk of premature death can be identified and treated accordingly, thereby improving management of these conditions, and therefore also outcomes. The aim of this study was to determine whether the mortality of a cohort of patients with polymyositis (PM) and dermatomyositis (DM) is significantly different from that of the general UK population, and whether the presence or absence of myositis-specific and myositis-associated autoantibodies influences mortality.

Methods: Patients entered onto the myositis database at our tertiary referral centre were included. Information on patient deaths was collected retrospectively. The National Health Service (NHS) Strategic Tracing Service was used to establish which patients had died and which were still alive. Date and cause of death was confirmed by death certificate from the Registry of Births, Marriages and Deaths. Standardized mortality ratios (SMR) were calculated by matching the patient data to single-year, 5-year age-banded England and Wales data from the Office of National Statistics.

Results: Out of 86 patients with PM and DM (57 PM, 65 female), there were 21 deaths – 15 female and 6 male. The SMR for the total cohort was 2.20 (95% CI 1.36–3.36), for PM was 2.12 (95% CI 1.16–3.56) and for DM was 2.38 (95% CI 0.96–4.90). SMRs were higher in females compared with males overall and in the PM subgroup, however the SMR was higher in males with DM compared with females. There was a trend towards higher death rates in those without myositis-specific or myositis-associated autoantibodies (OR 2.11, 95% CI 0.68–7.43). The leading causes of death were infection (33%), malignancy (28.6%) and cardiovascular disease (23.8%).

Conclusion: Patients with PM and DM are at 120% increased risk of mortality; and infections, cardiovascular disease and malignancy account for the majority of deaths. Females, in particular those with PM, and autoantibody-negative patients are at higher risk of death. Early identification and aggressive management of infections, thorough cardiovascular evaluation, and targeted malignancy screening may improve outcomes in these conditions.

2060

Influence Of Anti-Ro/SSA Autoantibodies On Cinical Characteristic Of a Cohort Of Myositis Patients. Simone Barsotti[1], Rossella Neri[1], Valentina Iacopetti[2], Chiara Baldini[1], Nicoletta Luciano[1], Antonio Tavoni[3], Anna d'Ascanio[1] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Internal medicine, Barga, Italy, [3]Immunoallergology unit, Pisa, Italy.

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of acquired diseases, characterized by immunoflogistic processes primarily involving the skeletal muscle. Myositis-associated antibodies are frequently detected in IIM patients' sera, particularly in those with overlap syndromes; more specifically, the clinical relevance of anti-Ro/SSA has not been fully elucidated. Aim of this study is to establish the prevalence of Ro/SSA in a single centre cohort of patient with IIM followed in our Rheumatology Unit and to investigate their influence on the IIM clinical expression.

Methods: Clinical charts of patients diagnosed as IIM according with Bohan e Peter criteria and followed between 1974 and 2012 were retrospectively examined. Antibodies antiRo/SSA were determined by counter-immunoelectrophoresis. Epidemiological, clinical, laboratory, instrumental and histological features of the patients were collected.

Results: a total of two hundred and forty six patients affected by IIM were identified; 21 (8.6%) were positive for anti-Ro/SSA antibodies. The anti-Ro/

SSA positivity was associated with xerostomia 12/21 ($p<0.001$) and xerophthalmia 14/21 ($p<0.001$). A biopsy of accessory salivary glands was performed in 10 patients resulting positive in 9/10; moreover a strict association with an overlapping Sjögren's Syndrome (IIM/SS) diagnosed according to AECG criteria was found in 11/21 cases ($p=0.000$). The anti-Ro/SSA positivity was also associated with patients' reported "dysphagia" in IIM patients ($p=0.035$) and with the use of intravenous immunoglobulins ($p<0.001$). By contrast, no differences were found in the prevalence of abnormalities at the oesophagus x-ray examination between anti-Ro/SSA positive and negative patients. No differences were also found between the two groups regarding: sex, age, subset of disease (polymyositis, dermatomyositis, inclusion body myositis), muscular or cutaneous involvement, pulmonary fibrosis, incidence of neoplasm, creatinine phosphokinase or other muscular necrosis enzyme, association with anti-Jo-1 autoantibodies.

Conclusion: In IIM patients the positivity for the anti-Ro/SSA antibodies is associated, as attended, with secondary SS. The increased prevalence of subjective dysphagia reported by patients positive for anti-Ro/SSA might be partially related to the oral dryness which may worsen the IIM oesophageal involvement.

Further prospective studies are required to elucidate the pathogenic mechanisms of dysphagia in IIM patients and the therapeutic implication of our findings.

Good Inter-Rater Reliability Of Myositis Experts In Assessing Clinical Improvement. Rohit Aggarwal[1], Nicolino. Ruperto[2], Brian Erman[3], Saad Feroz[4], Jiri Vencovsky[5], Adam Huber[6], Sheila K. Oliveira[7], Angela Pistorio[8], Clarissa Pilkington[9], Angelo Ravelli[10], Brian M. Feldman[11], Howard Rockette[1], Frederick W. Miller[4], Peter A. Lachenbruch[4] and Lisa G. Rider[4]. [1]University of Pittsburgh, Pittsburgh, PA, [2]PRINTO, IRCCS G. Gaslini, Genoa, Italy, [3]National Institute of Health, Bethesda, DC, [4]NIEHS, NIH, Bethesda, MD, [5]Institute of Rheumatology, Prague, Czech Republic, [6]IWK Health Centre, Halifax, NS, [7]Instituto de Pediatria e Puericultura Martagão Gesteira (IPPMG) da Universidade Federal do Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil, [8]PRINTO, Genoa, Italy, [9]Great Ormond Street Hospital, London, United Kingdom, [10]Istituto Giannina Gaslini, Genova, Italy, [11]Hospital for Sick Children, Toronto, ON.

Background/Purpose: IMACS and PRINTO have developed preliminary core set activity measures and definitions of improvement (DOIs) for adult or juvenile dermatomyositis (DM) and polymyositis (PM). Our aim was to evaluate the inter-rater reliability and consensus among myositis experts rating patient profiles on clinical improvement, given core set measures and their change.

Methods: Fifteen adult and 15 juvenile myositis profiles using IMACS core-set measures (baseline and follow up) were evaluated by 30 adult and 29 pediatric myositis experts. PRINTO profiles on the same 15 juvenile DM patients were also evaluated. by 29 pediatric experts. Experts rated improvement on each profile as a) Likert scale: no improvement or worsening, minimal, moderate and major improvement, b) on the degree of improvement (0–10 scale). Percent agreement, kappa, Cronbach's α, analysis of variance, and intra-class correlation (ICC) were used to determine overall inter-rater reliability, as well as that of different groups of myositis experts (adult (N=30) vs. pediatric specialists (N=29), more vs. less experienced, rheumatologist (N=50) vs. non-rheumatologist (N=9), North American (N=30) vs. other location (N=29)).

Results: Consensus (≥70%) on minimal clinically significant improvement was reached on all profiles. Eleven of 15 adult DM/PM profiles, 12/15 IMACS and 12/15 PRINTO juvenile DM profiles were rated as at least minimally improved. For all profiles, different group of raters reached the same consensus on at least minimal improvement. There was substantial agreement among all individual raters (kappa 0.64) and very high agreement between different group of raters for minimal and major clinical improvement (Table 1). The agreement between PRINTO and IMACS profiles on the same patients was poor (Table1), primarily because there was a difference in the consensus as to whether the patient improved or not in 4 juvenile profiles. Results were not explained by geographical differences between North American and European evaluators or by a better familiarity of PRINTO members with PRINTO measures. ICC was high for all raters (0.82) as well as different group of raters (Table1). Cronbach's α for all profiles was very high (≥0.98) for improvement on the Likert scale and in the degree of improvement (0–10 scale). There was no difference in degrees of improvement rated by different group of myositis experts. However, IMACS profiles had a different degree of improvement as compared to the PRINTO profiles from the same pediatric patients.

Table 1. Inter-rater reliability among various groups myositis experts on clinical improvement

Groups	Minimal Improvement		Major Improvement		Improvement on Likert scale	Degree of improvement
	% agreement	Kappa	% agreement	Kappa	ICC	ICC
Adult (n=30) vs. Pediatric (n=29)	93.3%	0.83	93.3%	0.83	0.82	0.81
North American(n=30) vs. Other location (n=29)	100%	1.0	93.3%	0.84	0.82	0.81
More vs. less experienced	93.3%	0.83	93.3%	0.84	0.82	0.82
Rheumatologist (n=50) vs. Non-rheumatologist (n=9)	90%	0.74	96.6%	0.93	0.82	0.81
IMACS (n=15) vs. PRINTO (n=15) pediatric profiles	73.3%	0.16	60%	0.25	0.80	0.79

Conclusion: Inter-rater reliability among myositis experts was excellent in assessing minimal and major improvement in patient profiles. The agreement between ratings in IMACS and PRINTO profiles was poor. These results will aide in the development of new DOIs for minimal and major clinical response for myositis.

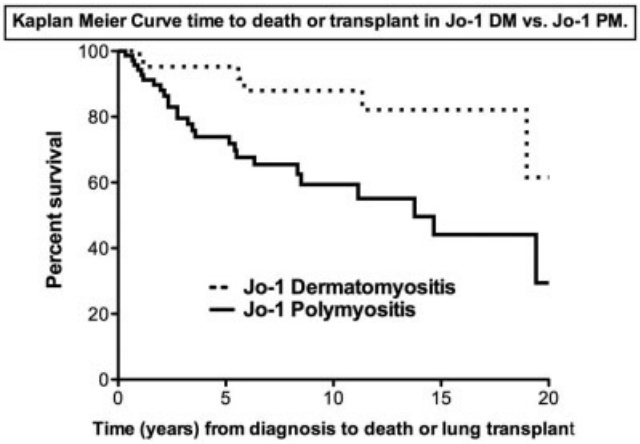
Clinical Features and Outcome In Polymyositis Vs. Dermatomyositis Patients With The Anti-Jo-1 Autoantibody. Rohit Aggarwal, Diane Koontz, Zengbiao Qi and Chester V. Oddis. University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: The clinical characteristics of dermatomyositis (DM) patients possessing the anti-Jo-1 autoantibody (autoAb) are not well known. We analyzed the clinical features and prognosis of Jo-1+ DM patients (Jo-1 DM) compared to Jo-1+ polymyositis (Jo-1 PM) patients.

Methods: Jo-1+ patients were identified from a prospectively collected computer and serum database of adult myositis (n=856) patients seen from 1985 to 2012. Anti-Jo-1 was detected by immunoprecipitation and immunodiffusion in our research laboratory and probable or definite PM and DM were defined using Bohan and Peter criteria. Amyopathic and hypomyopathic DM was included in the DM cohort as per Sontheimer criteria. Designation of overlap syndrome and undifferentiated connective tissue disease (UCTD) was based on clinical diagnosis. Demographics, clinical and laboratory features were compared between Jo-1 DM and Jo-1 PM. Chi-square and t-tests were used for comparison. Survival (time to death) and pulmonary survival (death or transplant) was compared between the two groups from diagnosis using log rank test.

Results: 140 Jo-1+ patients in our cohort had available clinical data. 31% (44/140) were diagnosed as DM including 4 amyopathic DM and 11 hypomyopathic DM, 53% (74/140) had PM and 16% (22/140) had overlap or UCTD. There was no difference in gender (female 78% vs. 65%), age at diagnosis [mean (SD) years: 43.7 (12.8) vs. 47.1 (12.7)] or ethnicity (Caucasians: 87% vs. 88%) in Jo-1 DM vs. Jo-1 PM. All Jo-1 DM patients (except 3) had classic DM rashes including a heliotrope rash or Gottron papules or sign. Among DM rashes, Gottron papules, Gottron sign, heliotrope, other DM rashes (V-rash or shawl sign), periungual erythema, mechanics hands and periorbital edema were seen in 26%, 55%, 24%, 26%, 31%, 67% and 14%, respectively. There was no difference in Jo-1 DM vs. Jo-1 PM in the following CTD features: arthritis (46 %) vs. 44%), fever (31% vs. 52%), Raynaud (38% vs. 36%), dysphagia (21% vs. 19%), cardiac (4% vs. 3%) or primary pulmonary hypertension (5% vs. 3%). Mechanics hands were more common in Jo-1 DM as compared to Jo-1 PM (67% vs. 17%, $p=0.001$). Pulmonary involvement was very common and similar in both groups (89% vs. 95%) mostly due to pulmonary fibrosis (84% vs. 92%). Dyspnea (76% vs. 72%) or O_2 supplementation (19% vs. 37%) was common in both groups as was muscle involvement (similar peak CK, proximal weakness and peak muscle disease activity (VAS) on the MDAAT). Significantly ($p<0.01$)

fewer Jo-1 DM patients died [13.6% (6/44) vs. 33.3% (24/72)] as compared to Jo-1 PM. Cumulative survival and pulmonary survival (death or transplant) from diagnosis was significant better in patients with Jo-1 DM vs. Jo-1 PM ($p < 0.004$).



Conclusion: One-third of Jo-1+ patients have DM. Jo-1 DM and Jo-1 PM have similar clinical characteristics except for the rashes of DM and mechanic hands. DM Jo-1 patients had a better prognosis than Jo-1 PM.

Identification Of Autoantibodies To Tyrosyl–Transfer RNA Synthetase Associated With Anti-Synthetase Syndrome. Yuko Okamoto[1], Yasuhiro Katsumata[1], Yasushi Kawaguchi[1], Koji Tahara[2], Kaori Ito[2], Hiroaki Hattori[2], Takahisa Gono[1], Kae Takagi[1], Masanori Hanaoka[1], Yuko Ota[1], Hidenaga Kawasumi[1] and Hisashi Yamanaka[1]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]BML, Saitama, Japan.

Background/Purpose: Autoantibodies directed against the aminoacyl transfer RNA (tRNA) synthetases are associated with myositis, arthritis, Raynaud's phenomenon, mechanic's hands, fever, and interstitial lung disease, clinically referred to as the anti–synthetase syndrome. A preliminary report has described the detection of an autoantibody to tyrosyl–tRNA synthetase (TyrRS) in only one patient with features of anti–synthetase syndrome. In addition, it has also been reported that TyrRS can be split into two fragments with distinct cytokine activities. We aimed to identify further patients with anti–TyrRS autoantibodies using other assays than previously reported methods and elucidate their clinical significance.

Methods: Multiple assays were performed to detect anti–TyrRS antibodies in the sera of patients with active polymyositis/dermatomyositis patients. First, recombinant human TyrRS protein coupled with a His-tag was expressed in *Escherichia coli*. Autoantibodies against the recombinant human TyrRS in sera of patients with polymyositis/dermatomyositis were quantified by employing solid phase direct enzyme–linked immunosorbent assay (ELISA). Second, the recombinant human TyrRS was electrophoresed and transferred to PVDF membranes. Western blot was performed with the serum samples and anti–human IgG secondary antibodies. Third, TyrRS–transfected HeLaS3 cells were immunoprecipitated with sample serum. Then, the antibody–protein complex captured with μMACS™ Protein G MicroBeads was loaded onto a μColumn. The eluted immunoprecipitates were subjected to the SDS–polyaclylamidegel electrophoresis, and western blotted with rabbit anti–TyrRS polyclonal antibodies. In addition, the titer of anti–TyrRS antibodies was evaluated by ELISA before and after treatment among the patients with positive anti–TyrRS antibodies at the initial evaluation. Control sera were obtained from normal healthy control subjects. The clinical features of the patients with positive anti–TyrRS antibodies were analyzed. This study was approved by the ethics committee of our institution, and the principles of the Helsinki Declaration were followed throughout the study.

Results: Sera from three patients with polymyositis/dermatomyositis showed significantly high O.D. values in ELISA, significant bands of 59 kDa protein of TyrRS at the same place as anti–His tag antibody in Western blot, and significant bands at the same place as the recombinant human TyrRS in immunoprecipitation assay. These data strongly suggest that these sera had autoantibodies to TyrRS. These patients had myositis, interstitial lung disease, arthritis, Raynaud's phenomenon, and fever. In two of the three patients, anti–TyrRS antibody titers decreased as clinical diseases were ameliorated following treatment.

Conclusion: This study reconfirmed the presence of anti–TyrRS antibody in the setting of the anti–synthetase syndrome and strengthens the association of anti–synthetases with these conditions.

An Autoimmune Myositis-Overlap Syndrome Associated With Autoantibodies To Nuclear Pore Complexes - Description and Long-Term Follow-Up Of The Anti-Nup Syndrome. Catherine Isabelle[1], Marie-Christine Dabauvalle[2], Marvin J. Fritzler[3], Ira N. Targoff[4], Rose Goldstein[5], Yves Troyanov[1], Michel Gagné[1], Jean-Pierre Raynauld[1] and Jean-Luc Senécal[1]. [1]Division of Rheumatology, Centre Hospitalier de l'Université de Montréal, Montreal, QC, [2]University of Würzburg, Würzburg, Germany, [3]University of Calgary, Calgary, AB, [4]Oklahoma Medical Research Foun, Oklahoma City, OK, [5]McGill University, Montreal, QC.

Background/Purpose: Autoimmune myositis encompasses various myositis-overlap syndromes, each one being identified by the presence of serum marker autoantibodies. We describe a novel myositis-overlap syndrome in four patients characterized by the presence of a unique immunological marker, autoantibodies to nuclear pore complexes.

Methods: Clinical features and sera were collected from French Canadian patients followed prospectively since 1984 at the Connective Tissue Disease Clinic, Centre Hospitalier de l'Université de Montréal. Reactivity with nuclear pore complexes was identified by indirect immunofluorescence on HEp-2 cells displaying a positive ANA with a distinct punctate peripheral (rim) fluorescent pattern of the nuclear envelope, and confirmed by immunoelectron microscopy.

Results: In a cohort of 100 French Canadian patients with autoimmune myositis, sera from 4 (4%) patients displayed a high titer ANA with a fluorescent pattern characteristic of nuclear pore complexes. Clinically, these four patients shared a clinical phenotype characterized by prominent myositis in association with erosive, anti-CCP positive and rheumatoid factor positive arthritis, trigeminal neuropathy, mild interstitial lung disease, Raynaud phenomenon and weight loss. The myositis was typically chronic, relapsing and refractory to corticosteroids alone, but remitted with the addition of a second immunomodulating drug. There was no clinical or laboratory evidence of liver disease. The prognosis was good with 100% long-term survival. The nuclear pore complex fluorescent ANA pattern was not observed in sera from 393 adult patients with systemic sclerosis (n=112), mixed connective tissue disease (n=35), systemic lupus (n=94), rheumatoid arthritis (n=45), or other rheumatic diseases (n=107) nor was it observed in 62 normal adults.

Autoantibodies to nuclear pore complexes were predominantly of IgG isotype. No other IgG autoantibody markers for defined connective tissue diseases or overlap syndromes were present, indicating a selective and highly focused immune response. In three patients, anti-nuclear pore complex autoantibody titers varied in parallel with myositis activity, suggesting a pathogenic link to pathophysiology. The nuclear pore complex proteins, i.e. nucleoporins (nup), recognized by these sera were heterogeneous and included Nup358/RanBP2 (n=2 patients), Nup90 (n=1), and Nup62 (n=1). Taken altogether the data suggested that nup autoantigens themselves drive the anti-nup autoimmune response. Immunogenetically, the four patients shared the DQA1*0501 allele associated with increased susceptibility for autoimmune myositis.

Conclusion: We report a novel subset of autoimmune myositis in our population of French Canadian patients with connective tissue diseases. This syndrome is recognized by the presence of a unique immunologic marker, autoantibodies to nuclear pore complexes that react with nups, consistent with an "anti-nup syndrome".

2065

The Prevalence and Clinical Usefulness Of Anti-NXP-2 Autoantibodies In Chinese Patients With Idiopathic Inflammatory Myopathies. Xin Lu[1], Guochun Wang[2], Qinglin Peng[2], Kai Yuan[2] and Hanbo Yang[2]. [1]China-Japan Friendship Hospital, Beijing, China, Beijing, China, [2]China-Japan Friendship Hospital, Beijing, China.

Background/Purpose: To determine the sera levels of anti-NXP-2 antibodies and their clinical association in Chinese patients with idiopathic inflammatory myopathies(IIM).

Methods: Sera from 198 Chinese patients with IIM including 15 Juvenile dermatomyositis (JDM), 133 dermatomyositis(DM) and 50 polymyositis (PM), other connective tissue diseases(CTD) including 70 systemic lupus erythematosus (SLE), 60 rheumatoid arthritis (RA), 25 systemic sclerosis(SSc), 46 primary Sjogren's syndrome(PSS), 10 mixed connective tissue disease(MCTD) and 60 healthy controls were measured by enzyme linked immunosorbent assay. The positive sera were further examined by immunoprecipitation assay. We analyzed the distribution of these autoantibodies in each groups and evaluated the association between autoantibodies and clinical features of IIM.

Results: The positive rate of anti-NXP-2 autoantibodies in IIM patients was 5%, patients with JDM 20%, DM 3.7% and PM 4%, respectively. The positive rate of anti-NXP-2 autoantibodies were statistical differences within JDM, DM and PM groups($P=0.043$). There was no positive for the antibodies from patients with other CTD as well as healthy controls. Anti-NXP-2-positive patients had significantly younger age compared with anti-NXP-2-negative patients($t=-2.09, P<0.05$). The incidence of calcinosis in the anti-NXP2-positive patients was significantly higher than that in the negative patients($P<0.01$).There were no statistical differences between positive and negative groups for gender, duration, arthritis, rash, dysphagia, myalgia, myasthenia, Raynaud's phenomenon, interstitial lung disease and concomitant with cancer($P>0.05$). In laboratory examination, the sera levels of aspartate aminotransferase, IgA, complement C3 were significantly increased in anti-NXP-2-positive patients than those in anti-NXP-2-negative patients($P<0.05$). However, there was no significantly statistical differences between two groups for sera levels of creatine kinase, lactate dehydrogenase, hydroxybutyrate dehydrogenase, alanine aminotransferase, γ-glutamyltranspeptidase, erythrocyte sedimentation rate, C-reactive Protein and the positive rate of tumor markers ($P>0.05$). Among the three anti-NXP-2-positive JDM patients, two patients showed calcinosis and myasthenia, one of them who died 10 months later had increasing level of anti-NXP-2 autoantidodies, severe myasthenia and rapid progress.

Conclusion: This study first reported the sera levels of anti-NXP-2 autoantibodies in Chinese patients with IIM and other CTD. We found that anti-NXP-2 autoantibodies only exist in patients with IIM. Anti-NXP-2 autoantibodies were associated with young-onset IIM and calcinosis.

2066

Distinct Arthropaties In Patients With Anti-Aminoacyl tRNA Synthetase Antibodies: Utility Of Autoantibody Profiles In Discrimination. Yuko Kaneko, Hironari Hanaoka, Michito Hirakata, Tsutomu Takeuchi and Masataka Kuwana. Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Arthritis is observed frequently in patients with anti-aminoacyl transfer RNA synthetase (ARS) autoantibodies and is usually not destructive like rheumatoid arthritis (RA). Despite several case reports with anti-ARS antibodies and with deforming arthritis, there is a controversy as to whether this is associated with anti-ARS antibody itself or concomitant RA. Moreover, previous reports focusing on articular involvement have been limited to anti-Jo-1 antibody, and it is still unclear whether arthropathies are common among anti-ARS antibodies. The aim of this study is to clarify the characteristics of arthropathies associated with anti-ARS antibody, focusing on structural damage and autoantibody profiles.

Methods: Fifty-six patients with anti-ARS antibodies were enrolled in this study from consecutive patients who visited Keio University Hospital between1983 and 2011, based on joint symptoms and availability of hand X-rays. Their clinical characteristics, anti-cyclic citrullinated peptide (anti-CCP) antibody, rheumatoid factor (RF), and hand X-ray findings were retrospectively examined.

Results: The anti-ARS specificities in 56 patients enrolled included Jo-1 in 28, EJ in 9, OJ in 1, PL-7 in 7, PL-12 in 5, and KS in 6. At the time of X-ray evaluation, the mean age was 57.6 years and the mean disease duration from onset of joint symptoms was 9.4 years. RF and anti-CCP antibody were positive in 25 (45 %) and 16 (29 %), respectively. Significant X-ray changes were found in 20 patients (36%). According to the patterns of X-ray findings garnered with cluster analysis, the patients were divided into two groups; Group A of 12 patients (21%) mainly with erosions and ankylosis, and Group B of 8 (14%) with the subluxations and periarticular calcinosis. When we compared the characteristics of these two groups, Group A showed the significantly higher rates of positive RF and anti-CCP with any anti-ARS specificities than Group B (83% versus 38%, and 75% versus 13%, respectively), consistent with the serologic features of RA. In contrast, all patients in group B were positive for anti-Jo-1 antibody independent of RF or anti-CCP.

Conclusion: Autoantibody profiles, including RF, anti-CCP, and individual anti-ARS specificity, are useful in classifying anti-ARS-associated arthropathies into a comorbid RA and a peculiar anti-Jo-1-related arthropathy.

Autoantibodies Associated With Inflammatory Myopathy and Other Systemic Autoimmune Rheumatic Diseases In Sera From Breast Cancer Patients. Monica Vázquez-Del Mercado[1], Adrian Daneri-Navarro[2], Beatriz Teresita Martín-Márquez[3], Raul Vargas Ramirez[4], Diego Velasco-Sanchez[5], Jason Y.F. Chan[6], S. John Calise[6], Edward K.L. Chan[6] and Minoru Satoh[6]. [1]Universidad de Guadalajara, Guadalajara, Jalisco, México, Mexico, [2]Laboratorio de Inmunología, CUCS, Universidad de Guadalajara, Guadalajara, Mexico, [3]Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético, Guadalajara, Mexico, [4]Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético,, Guadalajara, Mexico, [5]1. Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético, CUCS, Universidad de Guadalajara, Guadalajara, Mexico, [6]University of Florida, Gainesville, FL.

Background/Purpose: Various autoantibodies have been reported in cancer patients, however, results are inconsistent. In dermatomyositis (DM), striking association between autoantibodies to p155/140 (transcription intermediary factor (TIF) 1gamma/alpha) and malignancy has been documented in several recent studies, however, whether this autoantibody specificity can also be found in malignancy without DM is not known. In the present study, anti-TIF1gamma/alpha and other specificities found in systemic autoimmune rheumatic diseases (SARD) were examined in breast cancer patients.

Methods: 152 unselected breast cancer patients were enrolled to the study. Clinical information was collected from medical record and serum autoantibodies were tested by immunoprecipitation (IP) of ^{35}S-methionine-labeled K562 cell extract and anti-Ro52 and -TIF1gamma ELISA. Immunofluorescence antinuclear antibodies (ANA) using HEp-2 slide were also tested.

Results: By IP, anti-TIF1gamma/alpha was found in 2 cases and anti-PM-Scl was found in one case among myositis-specific autoantibodies. Interestingly, no other myositis-specific autoantibodies, scleroderma specific anti-topoisomerase I and –RNA polymerase III, or SLE-specific anti-Sm or ribosomal P antibodies were found. Among autoantibodies associated with SARD but not specific for particular diagnoses, anti-Su/Argonaute 2 (Ago 2) was found in 3% (4/152), anti-Ro60 in 4% (6/152) by IP and anti-Ro52 was positive in 6% (9/152) by ELISA. Anti-U1RNP or anti-Sm was not found, however, interestingly, rare autoantibodies specific for U5RNP were found in 2 cases. A case with anti-TIF1gamma/alpha also had anti-Ro60 and Su/Ago2 but all other cases had only one specific autoantibodies listed above. As a whole, 14.5% (22/152) of breast cancer patients had autoantibodies associated with SARD. Although autoantibody specificities that are generally common in SARD and occasionally found in healthy individuals, such as anti-Ro60, Ro52 and Su were the most common, 2 cases of anti-TIF1gamma/alpha and anti-U5RNP seems significant because other disease-specific autoantibodies were not detected. Among 152 breast cancer patients, 6 had rheumatoid arthritis (RA) and one had ankylosing spondylitis but none had polymyositis/dermatomyositis, scleroderma or SLE. All specific autoantibodies detected were not associated with the presence of rheumatic diseases except one case of RA with anti-Ro52.

Conclusion: Although the specificities that are generally common in SARD (anti-Ro60, Ro52 and Su) were most common, unique specificities such as anti-TIF1gamma/alpha and anti-U5RNP was found in sera from breast cancer patients.

2068

Comparison Of Radioimmunoprecipitation Versus Antigen Specific Assays For Identification Of Myositis Specific Autoantibodies In Dermatomyositis Patients. Eun Ha Kang[1], Eun Young Lee[2], Yun Jong Lee[3], Eun Bong Lee[4] and Yeong Wook Song[2]. [1]Seoul National University Bundang Hospital, Seongnam-si, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University, Seoul, South Korea, [3]Rheumatology, Seoul National University, Seoul, South Korea, [4]Seoul National University College of Medicine, Seoul, South Korea.

Background/Purpose: To confirm the antigen specificities of autoantibodies that precipitate 140 kDa (anti-p140) or 155/140 kDa polypeptides (anti-p155/140) on radioimmunoprecipitation (RIP) in Korean patients with dermatomyositis (DM).

Methods: Forty nine sera from patients who had been diagnosed as having inflammatory myopathy according to Bohan and Peter criteria were examined using RIP. Subsequently, 17 serum samples of DM patients who were found to have either anti-p140 ($n = 9$) or anti-p155/140 antibodies ($n = 8$) were examined using enzyme-linked immunosorbent assay (for anti-MDA5 antibodies) and immunoblotting (for anti-MJ/NXP-2 and anti-TIF-1γ antibodies).

Results: Seven out of nine anti-p140 antibody positive patients were found to have anti-MDA5 antibodies. The rest two had anti-MJ/NXP-2 antibodies with no interstitial lung disease (ILD). The association of anti-MDA5 antibody with rapidly progressive ILD was found to be significant (4/8 vs. 0/41, $p = 0.0003$). All eight anti-p155/140 antibody positive patients were found to have anti-TIF-1γ antibodies, showing a significant association between anti-TIF-1γ antibody and cancer-associated DM (5/8 vs. 6/41, $p = 0.009$). Anti-TIF-1γ and anti-MDA5 antibodies were simultaneously detected in one patient with anti-p155/140 antibody, who suffered HIV infection and non-Hodgkin's lymphoma.

Conclusion: Although radioimmunoprecipitation still looks to be a good screening tool, confirmation with antigen-specific assays seems mandatory. The associations between anti-MDA5 antibody and rapidly progressive ILD and between anti-TIF-1γ antibody and cancer-associated DM were confirmed in Korean patients with DM.

Serum Interferon-α Is a Biomarker To Reflect The Disease Activity In Patients With Anti-Melanoma Differentiation-Associated Gene 5 (MDA5) Antibody-Positive Dermatomyositis. Yoshiro Horai[1], Tomohiro Koga[1], Keita Fujikawa[2], Ayuko Takatani[1], Ayako Nishino[1], Yoshikazu Nakashima[3], Takahisa Suzuki[3], Shin-ya Kawashiri[1], Naoki Iwamoto[3], Kunihiro Ichinose[3], Mami Tamai[3], Hideki Nakamura[3], Hiroaki Ida[4], Yuji Ishimatsu[5], Hiroshi Mukae[6], Yasuhito Hamaguchi[7], Manabu Fujimoto[7], Masataka Kuwana[8], Tomoki Origuchi[1], Shigeru Kohno[5] and Atsushi Kawakami[3]. [1]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]Isahaya Health Insurance General Hospital, Isahaya, Japan, [3]Unit of Translational Medicine, Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [4]Kurume University School of Medicine, Kurume, Japan, [5]Department of Molecular Microbiology and Immunology, Nagasaki University School of Medicine, Nagasaki, Japan, Nagasaki, Japan, [6]Department of Respiratory Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan, Kitakyushu, Japan, [7]Kanazawa University Graduate School of Medical Sciences, Kanazawa, Japan, [8]Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: The pathogenesis of anti-melanoma differentiation-associated gene 5 (MDA5) antibody (Ab)-positive dermatomyositis (DM), which often complicates rapidly progressive interstitial lung disease (RPILD), is thought to be associated with double-stranded RNA virus infection. Some serum factors, including interferon-a (IFN-a), are found to be elevated in these patients. Recent investigations have reported that high serum ferritin and the titer of anti-MDA5 Ab are poor prognosis factors in patients with anti-MDA5 Ab-positive DM. The aim of this study is to clarify the clinical importance of measurement of serum type I IFNs in patients with anti-MDA5 Ab-positive DM.

Methods: The study population consisted of 30 patients (22 females and 8 males) with DM: Ten patients were anti-MDA5 Ab-positive whereas the remaining 20 were anti-MDA5 Ab-negative, respectively. All of the 10 anti-MDA5 Ab-positive sera were also positive with anti-clinically amyopathic dermatomyositis (CADM) 140kDa polypeptide Abs detected by immunoprecipitation assay. Clinical diagnosis of DM was made by either Sontheimer's criteria for CADM or Bohan and Peter's criteria for classical DM. Serum IFN-a, IFN-b, interleukin 18 (IL-18), ferritin and the titer of anti-MDA5 Ab at initial visit were measured by each enzyme-linked immunosorbent assay (ELISA). Clinical characteristics, such as the diagnosis of CADM or classical DM and the presence of RPILD, were confirmed by medical records and the associations of IFNs with the other variables were examined. All of the patients gave their informed consent to be subjected to the protocol that was approved by the Institutional Review Board of Nagasaki University.

Results: Eleven patients were diagnosed as CADM whereas the remaining 19 patients as classical DM, respectively. RPILD was confirmed in 10 patients. The presence of CADM and RPILD as well as serum concentrations of IFN-a and ferritin were significantly higher in anti-MDA5 Ab-positive DM patients as compared with anti-MDA5 Ab-negative DM patients. However, there was no difference in serum concentrations of IFN-b and IL-18 between the two patients groups. Furthermore, clear positive correlations were found between IFN-a and the titer of anti-MDA5 Ab ($r = 0.54$, $p = 0.0037$) and between IFN-a and ferritin ($r = 0.49$, $p = 0.0086$), respectively.

Conclusion: Serum IFN-α level is high in anti-MDA5 Ab-positive DM patients presenting clinical characteristics with CADM and RPILD. Considering good correlations of IFN-a with the titer of MDA5 Ab and ferritin, serum IFN-α is considered as a biomarker to reflect the disease activity in patients with anti-MDA5 Ab-positive DM.

Cytokine Profiles In Polymyositis and Dermatomyositis Complicated With Anti-Melanoma Differentiation-Associated Gene 5 Antibody-Associated Interstitial Lung Disease Or Anti-Aminoacyl tRNA Synthetase Antibody-Associated Interstitial Lung Disease. Takahisa Gono, Yasushi Kawaguchi, Hirotaka Kaneko, Yasuhiro Katsumata, Masanori Hanaoka, Sayuri Kataoka, Hidenaga Kawasumi, Kae Takagi, Hisae Ichida, Sayumi Baba, Yuko Okamoto, Yuko Ota and Hisashi Yamanaka. Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Polymyositis (PM)/dermatomyositis (DM) are often complicated with interstitial lung disease (ILD). In PM/DM, complication with ILD is associated with anti-aminoacyl-tRNA synthetase (ARS), including Jo-1 Ab or anti-melanoma differentiation-associated gene 5 (MDA-5) Ab. Clinically amyopathic DM (CADM) patients with anti-MDA-5 Ab have frequent complications with rapidly progressive (RP) ILD, especially in East Asia, where it is classified as acute interstitial pneumonia and reflects diffuse alveolar damage upon pathological examination. In contrast, chronic ILD is frequently observed in anti-ARS Ab-associated PM/DM, which responds well to treatment with corticosteroids. The response to treatment and the mortality rate are different between anti-MDA-5 Ab-associated ILD (anti-MDA-5-ILD) and anti-ARS Ab-associated ILD (anti-ARS-ILD). The differences in pathophysiology between these two Ab-associated ILD subsets remain unknown. Therefore, we investigate various serum cytokines in patients with PM/DM with ILD, and then clarify the differences in pathophysiology between anti-MDA-5-ILD and anti-ARS-ILD.

Methods: We evaluated the serum cytokine profiles of 38 patients with PM/DM and compared the cytokine profiles of 17 patients without ILD (non-ILD subset) and 21 patients with ILD (ILD subset), as well as the anti-MDA5-ILD and anti-ARS-ILD subsets. The levels of serum cytokines, including IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-17, TNF-α, IFN-α, IFN-γ, and interferon γ-inducible 10-kd (IP-10), were measured by multiplex assay. In addition, serum was obtained from 15 healthy controls (HCs).

Results: Serum IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, TNF-α, IFN-α, IFN-γ and IP-10 were significantly higher in PM/DM patients than HCs. Moreover, the levels of IL-4, IL-6, IL-8, IL-10, TNF-α and IP-10 were significantly higher in the ILD subset than the non-ILD subset. By multivariate analysis, TNF-α was the most significant cytokine (P = 0.0006, odds ratio 1.4, CI 1.1–2.2) associated with PM/DM with ILD. Regarding to the comparison between 10 patients with anti-MDA-5-ILD and 11 patients with anti-ARS-ILD, IL-8 level was significantly higher in the anti-MDA-5-ILD subset than the anti-ARS-ILD subset. Lower levels of IL-4 and higher levels of IL-10 and IFN-α were found in the anti-MDA-5-ILD subset than those in the anti-ARS-ILD subset. By multivariate analysis, IL-8 was the most cytokine that was most significantly associated with anti-MDA-5-ILD (P = 0.0006, odds ratio 1.5, confidence interval [CI] 1.1–3.0). In addition, the IL-4 level was inversely associated with anti-MDA-5-ILD (P = 0.01, odds ratio 0.8, CI 0.6–0.98). Moreover, the ratio of serum IL-4 to IFN-γ, which may reflect a balance between T helper 1 (T_H1) and 2 (T_H2) cells, was lower in anti-MDA-5-ILD (median value 0.16) than in anti-ARS-ILD (median value 2.0).

Conclusion: TNF-α is an especially important in contributing to ILD in PM/DM. Serum IL-8 levels and the balance between IL-4 and IFN-γ may contribute to the differences in pathophysiology between chronic ILD (anti-ARS-ILD) and RP-ILD (anti-MDA-5-ILD).

Adipokines Contribute To The Inflammatory Response In Adult and Juvenile Myositis. Molly S. Hein[1], Cynthia S. Crowson[1], Helen Khun[1], Consuelo Lopez de Padilla[1], Erik J. Peterson[2], Emily Baechler[3] and Ann M. Reed[1]. [1]Mayo Clinic, Rochester, MN, [2]University of Minnesota Medical School, Minneapolis, MN, [3]University of Minnesota, Minneapolis, MN.

Background/Purpose: Recently adipokines have been implicated for their role in regulating immune and inflammatory responses in autoimmune disease. To test the hypothesis that adipokines are predictive of dermatomyositis (DM) disease activity and inflammatory response, we analyzed blood cell gene expression of four adipokines, adiponectin (ADIPOQ), visfatin (NAMPT), leptin (LEP), and resistin (RETN) in juvenile (JDM) and adult (DM) patients.

Methods: For this study PAXgene vacutainers were collected for 14 DM, 23 JDM, and for adult (n = 5), and pediatric (n = 6) non-inflammatory controls. The IMACS core set myositis disease activity measure for physician global visual analog scale (Global VAS) scores (0–10 cm) was collected for myositis cases at time of blood draw. Total RNA was isolated with on-column DNase treatment according to manufacturer's protocol (PreAnalytiX). The expression levels of ADIPOQ, NAMPT, LEP, RETN, IL6, and housekeeping genes GAPDH, B2M, and ACTB were generated using a custom RT^2 Profiler PCR Array. Genes were first normalized to the mean of three housekeeping genes. Relative quantification of gene expression was then normalized to the mean of adult and pediatric controls respectively Wilcoxon tests and Spearman Correlation methods were used for analysis.

Results: The mean(range) age(years) and gender are as follows: JDM 9.7(3.7–17.1) (65% female), DM 50.1(23.0–72.8)(79% female), pediatric controls 12.4(8.2–16.5)(50% female), adult controls 39.8(25.2–61.4)(60% female). DM and control groups were Caucasian. The JDM group can be described as follows; 68.2% Non-Hispanic, 9.1% African American, 4.5%, American Indian, 4.5% Indian, 4.5% Middle Eastern, 4.5% Pacific Islander, and 4.5% unknown. In this population 79% of DM and 35% of JDM cases were receiving prednisone or an equivalent. Median BMI in the DM group was 25.9(19.7 – 51.2) and 17.2(13.8 –30.0) in JDM (median percentile 65.5(range 2–99)).

LEP, RETN, and NAMPT, all adipokines thought to promote inflammation were consistently up-regulated in all myositis cases compared to all controls, p=0.036, p=0.046 and p=0.013 (Table 1). ADIPOQ, known to have both anti- and pro- inflammatory effects in RA and SLE, did not appear to be dysregulated in the cases. p=0.400(Table 1). Increased RETN correlated with elevated disease activity represented by Global VAS in our myositis population (r=0.39, p=0.017). The magnitude of change in gene expression still held when groups were separated into juvenile and adult categories however statistical significance was not reached.

Table 1. Relative Quantification of Adipokines in DM and JDM

Gene	Control N=11	DM/JDM N=37	P value
LEP	−0.2 (1.0)	0.4 (0.6)	0.036*
RETN	−0.2 (0.8)	0.7 (1.3)	0.046*
ADIPOQ	−3.6 (3.6)	−5.0 (2.7)	0.400
NAMPT	−0.4 (1.3)	0.9 (1.3)	0.013*

Conclusion: Elevated adipokines levels in JDM and DM may serve as beneficial biomarkers that allow a practitioner to better monitor disease activity and potentially predict disease flares.

Decreased Number Of Circulating NK Cells and Dramatic Lack Of IFN-Gamma Production In Patients With Antisynthetase Syndrome. Baptiste Hervier[1], Yves Allenbach[1], Fleur Cohen-Aubart[1], Micheline Pha[2], Lenaig Mescam-Mancini[3], David Saadoun[1], Alexis Mathian[1], Olivier Benveniste[1] and Vincent Vieillard[2]. [1]Pitié-Salpêtrière Hospital, APHP, Paris, France, [2]INSERM UMR-S 945, UPMC, Paris, France, [3]University hospital, Grenoble, France.

Background/Purpose: Antisynthetase syndrome (ASS) is a rare autoimmune myositis associated with interstitial lung disease (ILD) and characterized by specific anti-tRNA-synthetase autoantibodies (ARS). To date, the pathogenesis of ASS remains largely unknown and the involvement of innate immune cells, such as Natural Killer (NK) cells is poorly described. The aim of this study was to conduct the first extensive analysis of the phenotype and functional properties of NK cells in ASS.

Methods: This monocentric study included 14 ASS patients (woman/man=13, median age 51, range 29–77) and 7 healthy controls (w/m=6, median age 30, range 22–42). Patients were divided into 2 groups, based on their ASS activity: active myositis (myalgia/muscle weakness with elevated creatine-kinase) or deteriorating ILD (> 10% decrease in lung vital capacity) leading to disease-modifying antirheumatic drug use, distinguished patients with active (n=6) *vs* inactive (n=8) ASS. NK cell phenotype was performed by flow cytometry after staining with an appropriate antibody cocktail: CD16, CD57, CD69; Natural Cytotoxicity Receptors (NKp30 and NKp44); pan-KIR, NKG2A-C-D and ILT2. Assessment of NK cell functions was performed spontaneously or after an interleukin-12 and −18 overnight stimulation, in the presence of K562 target cells, at a 1/1 ratio. Degranulation was evaluated by CD107a detection, and production of TNFα and IFNγ was measured by specific intracellular-staining. Comparisons between patient groups were performed using the Mann-Whitney test; a p-value < 0.05 was considered significant.

Results: Myositis and ILD occurred each in 12/14 patients (median time from onset: 4 years, range 1–22) and the distribution of ARS was anti-Jo1 (n=9), anti-PL12 (n=4) and anti-PL7 (n=1). Patients (n=12) were receiving stable doses of steroids (n=10, median 10 mg/d, range 5–20) and/or immunosuppressive drugs, including Methotrexate (n=5), Mycophenolate Mophetil (n=3) or Hydroxychloroquine (n=3). Patients with ASS had a normal percentage of NK cells among circulating lymphocytes (9.6 ± 6.4%) but a dramatically low absolute count: 89 ± 73/mm^3 (*vs* controls: 221 ± 100/mm^3, p=0.02). NK cells from ASS patients were indistinguishable from those of controls in term of the cell-surface expression of NK receptors. However, NKp30, a receptor involved in NK cell-Dendritic cell crosstalk, was decreased in active ASS patients as compared to both inactive patients and controls (50.3 ± 25.7% vs 80.6 ±11.2% and 85.4 ± 7.4, p=0.03 and 0.01, respectively).

Functional activities revealed no differences between ASS patients and controls, regarding both spontaneous degranulation capacities (29.7 ± 13.4% *vs* 21.8 ± 9.4%, p=0.14) and intracellular-TNFa production after stimulation (4 ± 4.4% *vs* 6,2 ± 6.4%, p=0.25). Conversely, IFNg production was dramatically decreased after stimulation in ASS patients *vs* controls (12.7 ± 14.0% *vs*31.3 ± 12.9%, p=0.01) and seemed not related to treatments.

Conclusion: Although quantitatively decreased, NK cells mainly displayed a normal phenotype in ASS. However, NK cells from patients with ASS had a significantly decreased capacity to produce IFNg, suggesting that they may play an immune regulatory role in favor of a TH2/TH1 imbalance.

Clinical and Prognostic Factors Associated With Survival In Mexican Patients With Idiopathic Inflammatory Myopathies. Angeles Shunashy Galindo-Feria[1], Jorge Rojas-Serrano[2] and Andrea Hinojosa-Azaola[1]. [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico.

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of autoimmune diseases, with low prevalence and 5-year survival of 70–95%. Previous studies in Mexican IIM patients suggest differences compared to other ethnic groups in clinical presentation, response to treatment, prognosis and autoantibodies. The aim of this study was to estimate the survivor function of IIM Mexican patients and identify factors associated to mortality.

Methods: This is a retrospective cohort study including patients with Dermatomyositis (DM) and Polymyositis (PM) according to Bohan and Peter's criteria, seen at a tertiary care center from January 1985 to January 2012. Baseline demographic, clinical variables, comorbidities, systemic manifestations and muscular strength were registered. The time to death, last medical evaluation or loss of follow up was obtained. Censoring time was established as the last medical visit. Univariate and multivariate Cox regression analysis were done to analyze factors associated with mortality. All analysis were two tailed, alpha was set at 5%.

Results: 304 DM and 71 PM patients were included, 70% female. At baseline evaluation, patients with DM were younger ($p<0.005$) and PM patients had higher CPK levels ($p<0.004$). DM patients had lower survivor function than those with PM during the first 4 years of follow up (log Rank test, $p<0.041$, Fig. 1). Respiratory failure secondary to pneumonia was the principal cause of death in DM patients (26/56, (46%)). Miscellaneous causes were responsible of death in PM patients. In univariate analysis, the variables associated with mortality during the first 4 years of disease in DM patients were: Age at onset (HR 1.03, 95% CI 1.01–1.05, $p<0.001$), cancer (HR 2.58, 95% CI 1.33–5.04, $p<0.02$), muscular strength (HR 0.60, 95% CI 0.45–0.80, $p< 0.002$), hemoglobin (HR 0.78, 95% CI 0.68–0.89, $p<0.0001$), serum albumin (HR 0.33, 95% CI 0.23–0.42, $p<0.001$), creatinine (HR 1.88, 95% CI 1.08–3.27, $p<0.03$), platelet count (HR 0.99, 95% CI 0.990–0.999, $p<0.04$), ever use of methotrexate and azathioprine (RM 0.19, 95% CI 0.09–0.40, $p<0.0001$). In the multivariate analysis, age at onset (HR 1.03, 95% CI 1.01–1.06, $p<0.002$), cancer (HR 2.55, 95% CI 1.1–6.4, $p<0.05$) and muscular strength (HR 0.54, 95% CI 0.34–0.84, $p<0.006$) were independent factors associated with mortality. In patients with PM, the only variable associated with mortality was cancer (HR 8.22, 95% CI 1.5–44.98, $p<0.02$).

Conclusion: Patients with DM had lower survival rate during the first 4 years of disease than patients with PM. Respiratory failure secondary to pneumonia was the main cause of death in DM patients. Factors associated to mortality differed in DM and PM. In DM patients, age of disease onset, cancer, and level of muscle strength were associated with mortality; in PM patients only cancer was associated.

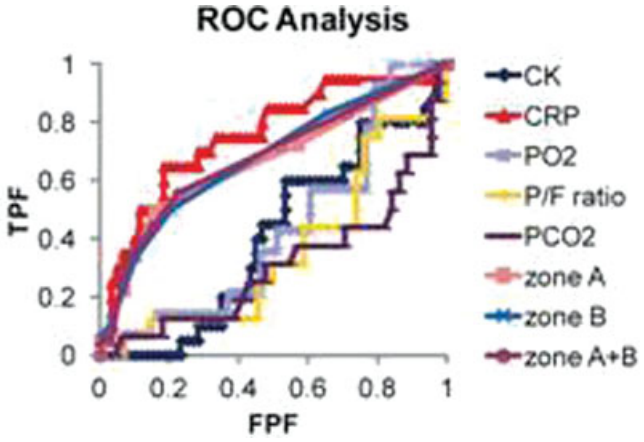
The Analysis Of Prognostic Factors In Patients With Inflammatory Myopathies and Amyopathic Dermatomiositis Complicated With Interstitial Lung Disease. Maasa Hama, Yumiko Sugiyama, Yohei Kirino, Yosuke Kunishita, Daiga Kishimoto, Reikou Kamiyama, Kaoru Minegishi, Ryusuke Yoshimi, Yukiko Asami, Atsuhisa Ueda, Mitsuhiro Takeno, Ichiro Aoki and Yoshiaki Ishigatsubo. Yokohama City University Graduate School of Medicine, Yokohama, Japan.

Background/Purpose: Because interstitial lung disease (ILD) is one of the most critical manifestations and can be lethal in inflammatory myopathies (IM), especially amyopathic dermatomiositis (ADM), it is important to determine prognostic factors for survival. We investigated clinical features which are associated with fatal events in IM patients having ILD.

Methods: We retrospectively analyzed clinical features, laboratory and HRCT findings, pulmonary function, and therapeutic regimens with clinical outcomes in 144 patients who were diagnosed with IM at the two hospitals of Yokohama City University from 1993 to 2012. Diagnoses of IM and clinical ADM were made according to Bohan and Peter criteria and modified Sontheimer's criteria, respectively. DM patients who did not met the ADM criteria were categorized as myopathic DM (MDM). The distribution and extent of ILD lesions were evaluated based on the percentage of the lung parenchyma involved in each of the four-divided lung zones (A to D) from upper to lower.

Results: HRCT showed ILD lesions in 83 of 144 IM patients (58%); polymyositis (PM) 18, MDM 40, ADM 25. Routine malignant screening detected cancers in 13 (16%). Twenty patients (24%) including 2 PM, 13 MDM and 5 ADM died during follow-up period (median 49 mo. (0.5–235 mo.)) due to respiratory failure (11 patients), infection (6), and malignancy (5). Of them 12 died within 7 months after the diagnosis. The levels of serum CK, P (PaO2)/F (FiO2) ratio, and PCO2 before therapy were significantly lower in non-survivors than survivors (CK; 817±1235 vs. 1809±2773, $p=0.03$, P/F ratio; 344±92.6 vs. 398±87, $p=0.04$, PCO2; 36.2±5.2 vs. 38.8±3.9, $p=0.04$). Moreover, high CRP (non-survivors 4.65±6.94, survivors 1.15±2.56 ($p=0.04$)) and high ILD scores in the upper lung field (Zone A; 1.5±1.2, 0.8±0.9 ($p=0.01$), Zone B; 1.8±1.4, 1.0±1.0 ($p=0.01$), Zone A+B; 3.3±2.5, 1.8±1.9 ($p=0.01$), respectively) were closely associated with lethal events (Figure). All of 9 patients who required mechanical ventilatory support died. Intensive combination immunosuppressive therapies with PSL, IVCY, and calcineurin inhibitors were conducted in 20 patients including 10 MDM, and 10 ADM patients with lower CK and hypocapnia, because they were likely to progress fatal respiratory failure rapidly as clinically ADM associated ILD. Of them, 8 non-survivors, who showed lower CO2 level at the diagnosis than survivors (32.9±3.0 vs. 36.4±4.1, $p=0.076$), died within short term from diagnosis (median 2 mo. (1–51 mo.)) because of respiratory failure (5 patients) and/or infection (4 patients).



Conclusion: The present study revealed that some MDM patients as well as ADM patients developed lethal ILD especially when low CK, high CRP, hypocapnia, and expanded upper lung field lesions were found. More rapid and intensive therapies including prophylactic procedures against infections are necessary to manage IM associated ILD before type I respiratory failure progresses.

Analysis Of The Associations Between Serum Ferritin and Cytokines In Pulmonary Disease Activity With Polymyositis/Dermatomyositis. Hidenaga Kawasumi, Takahisa Gono, Yasushi Kawaguchi, Yasuhiro Katsumata, Masanori Hanaoka, Sayuri Kataoka, Kae Takagi, Hisae Ichida, Sayumi Baba, Yuko Okamoto, Yuko Ota and Hisashi Yamanaka. Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Polymyositis (PM) / dermatomyositis (DM) is occasionally complicated by interstitial lung disease (ILD), and ILD is a prognostic factor in PM/DM. We previously reported that high levels of serum ferritin are associated with the severity and prognosis of ILD in patients with PM/DM. Hyperferritinemia could be associated with a cytokine storm in rapidly progressive ILD associated with PM/DM. The reason for the serum ferritin increase in ILD with PM/DM is unknown. We investigated the associations between the serum ferritin levels and various cytokines in patients with PM/DM.

Methods: This retrospective study included 38 patients admitted to our hospital with PM/DM. Among 38 patients, PM/DM was a complication of ILD in 21 patients. Serum cytokines (IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-17, TNF-α, INF-α, INF-γ and IP-10) were measured by a multiplex assay. Global disease activity and the disease activity of ILD were evaluated by the Myositis Intention to Treat Activity Index (MITAX) and the pulmonary visual analogue scale (Pulmonary VAS), which the International Myositis Assessment and Clinical Studies Group has proposed and recommended, respectively. We analyzed the associations between the disease activity, serum ferritin and cytokines.

Results: The MITAX was significantly correlated with the following: ferritin (r_s=0.53), IL-6 (r_s=0.61), IL-8 (r_s=0.37), IL-10 (r_s=0.44), TNF-α (r_s=0.58) and IP-10 (r_s=0.47). The Pulmonary VAS was significantly correlated with the following: ferritin (r_s=0.62), IL-8 (r_s=0.45), IL-10 (r_s=0.46), TNF-α (r_s=0.45) and IP-10 (r_s=0.33). The serum ferritin levels were significantly correlated with IL-6 (r_s=0.40), IL-8 (r_s=0.57), IL-10 (r_s=0.50) and TNF-α (r_s=0.34). To clarify the degree to which these cytokines contribute to the ferritin levels, we performed a multiple linear regression analysis. IL-6 (t=3.6, p=0.0010), IL-8 (t=4.8, $p<0.0001$) and IL-10 (t=5.7, $p<0.0001$) were significantly associated with the ferritin levels.

Conclusion: Serum ferritin was correlated with the pulmonary disease activity and with global disease activity in PM/DM. IL-6, IL-8 and IL-10 were significant factors that contributed to the serum ferritin levels. The regulation of these cytokines might be a possible treatment strategy for ILD with PM/DM.

2076

Oxidation Products Of Arachidonic Acid and Linoleic Acid Are Increased In High Density Lipoprotein From Patients With Dermatomyositis and Polymyositis. Christina Charles-Schoeman, Yuen Yin Lee, Ani Shahbazian, David Meriwether, Geraldine Navarro, John D. FitzGerald and Srinivasa T. Reddy. UCLA David Geffen School of Medicine, Los Angeles, CA.

Background/Purpose: Oxidation products of arachidonic acid and linoleic acid including hydroxyeicosatetraenoic acids (HETEs) and hydroxyoctadecadienoic acids (HODEs), respectively, play an important role in the pathogenesis of atherosclerosis and have been associated with endothelial cell activation. HETEs and HODEs contribute to the oxidation of low density lipoprotein (LDL) and their accumulation in high density lipoprotein (HDL) impairs HDL function, which increases risk of vascular damage. The current work evaluated the levels of HETEs and HODEs in HDL isolated from patients with dermatomyositis (DM) and polymyositis (PM) since vascular damage is implicated in the pathogenesis of both muscle and lung disease in DM/PM patients.

Methods: HDL was isolated by ultracentrifugation from plasma of 12 DM patients, 12 PM patients and 12 healthy controls. 5-HETE, 12-HETE, 15-HETE, 9-HODE, and 13-HODE levels in HDL were measured by mass spectrometry as described previously (Imaizumi et al. *Drug Metab Lett.* 2010; 4(3): 139–48). HDL's anti-inflammatory function was measured by a cell free assay as described previously (Charles-Schoeman et al. *Arthritis Rheum.* 2009; 60(10): 2870–9). Lipoprotein cholesterol levels were determined by standard methods.

Results: 5-HETE, 15-HETE, 9-HODE and 13-HODE levels were significantly increased in HDL from patients with PM compared to healthy controls (see Table). 5-HETE was also significantly increased in HDL from DM patients compared to controls and was significantly correlated with the HDL inflammatory index (r = 0.41, p=0.01); higher HDL-associated 5-HETE was associated with worse anti-oxidant capacity of HDL. Myositis patients with interstitial lung disease (ILD) (n=14) had higher 13-HODE, 12-HETE, and 5-HETE levels in HDL compared to myositis patients without ILD (n=10) (p values= 0.05, 0.06, and 0.13 respectively). Patients with moderate to severe ILD suggested by the diffusing *capacity* of the *lungs* for carbon monoxide (*DLCO*) <50% of predicted also showed trends for higher HDL-associated 5-HETE, 12-HETE, and 13-HODE levels compared to ILD patients with less severe disease (DLCO >50%) (see Table). 5-HETE and 12-HETE levels were inversely correlated with DLCO, r = −0.58 (p=0.02) and r = −0.49 (p=0.05), respectively.

	Healthy Control (n=12)	Polymyositis (n=12)	Dermatomyositis (n=12)

13-HODE (pg/75μg HDL-C)	481 ± 279	263 ± 236

	ILD (DLCO >50) (n=6)	ILD (DLCO ≥ 50) (n=7)
5-HETE (pg/75μg HDL-C)	64867 ± 24687	53143 ± 21244
12-HETE (pg/75μg HDL-C)	1117 ± 658	542 ± 466
13-HODE (pg/75μg HDL-C)	567 ± 319	357 ± 192

All values mean ± standard deviation. *p value ≤ 0.05 compared to controls.
Note: Recent DLCO value not available for one patient with known ILD.

Conclusion: Oxidation products of arachidonic acid and linoleic acid are increased in HDL from patients with PM and DM compared to healthy controls. Increased 5-HETE in HDL was associated with impaired HDL anti-oxidant function and was inversely associated with DLCO in patients with myositis. Our results suggest that therapeutic agents such as apoA-I mimetic peptides, which bind oxidized fatty acids and reduce vascular damage and lung injury in animal models, may warrant further investigation in DM/PM patients.

Inflammatory Lung Disease a Potential Risk Factor For Onset Of Inflammatory Myopathies. Ingrid E. Lundberg[1], Sevim Barbasso Helmers[2] and Lars Alfredsson[3]. [1]Rheumatology Unit, Department of Medicine, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [2]Institute of Environmental Medicine, Unit of Cardiovascular Epidemiology, Karolinska Institutet, Stockholm, Sweden, [3]Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Although the etiology of inflammatory myopathies is unclear, there are data indicating that myositis occurs as a result of complex interactions between genes and environmental/life style factors.

The aim of this study was to assess the association between lung disease and the risk of developing inflammatory myopathies, myositis.

Methods: In this population-based case-control study, 179 incident adult myositis cases diagnosed between 1995 and 1997 were identified from the Swedish inpatient registry. Verification of diagnosis was performed through patient records. The analysis was based on responses from a questionnaire on exposures to environmental factors from 100 cases that were alive and fulfilled the inclusion criteria and from 402 randomly selected population controls matched to cases on birth of date, gender and residency. Exposure was based upon self-reports of preceding inflammatory lung disease (pneumonia, tuberculosis or sarcoidosis). The association between inflammatory lung disease and risk of developing myositis was evaluated by calculating odds ratio (OR) together with 95% confidence interval (CI) by means of logistic regression.

Results: There was a suggestive association between preceding inflammatory lung disease and diagnosis of myositis: adjusted OR = 1,5 (CI (95%) = 0.9–2.6). The number of cases and controls that reported inflammatory lung disease *(i.*e. pneumonia, tuberculosis or sarcoidosis) was 42 (42%) and 112 (28%), respectively. Overall recorded signs of ILD were found in 16% of the cases, mainly based on results from chest radiography. Out of 12 cases with ILD, nine (75%) had reported inflammatory lung disease in the questionnaire, while the corresponding frequency for cases without ILD was 36%. The median duration between the lung disease and first symptom of myositis was 30 years.

Conclusion: Subjects with a history of a preceding inflammatory lung disease had an increased risk to develop myositis compared to those without such disease. Inflammatory lung disease could thus be a potential risk factor for onset of inflammatory myopathies, in particular for the subset of patients with ILD, or it may be a parallel phenomenon.

2078

Pulmonary Hypertension In Anti-Jo1 Syndrome. Nilofar Syed, Ruchi Yadav, Colin O'Rourke and Soumya Chatterjee. Cleveland Clinic, Cleveland, OH.

Background/Purpose: Antisynthetase syndrome is characterized by fever, myositis, interstitial lung disease (ILD), inflammatory arthritis, mechanic's hands, and Raynaud phenomenon. The most commonly reported form of antisynthetase syndrome has been associated with anti-Jo1 antibody and ILD is a major determinant of prognosis. However, the presence of pulmonary hypertension (PH) in anti-Jo1 syndrome had not been systematically evaluated in the past.

Methods: We conducted a retrospective chart review of patients with anti-Jo1 syndrome. Patients were evaluated both for ILD and/or PH. ILD was diagnosed on the basis of high resolution CT (HRCT) scan of lungs and PH had to be confirmed on right heart catheterization (RHC). The pattern and severity of ILD on HRCT scan was graded by a radiologist and each lung lobe was individually quantified with a score from 1 to 4 according to percentage of lobar involvement. A score of 1 represented <25% lobar involvement, 2: ≥ 25% but < 50%, 3: ≥ 50 % but < 75%, and 4: ≥ 75% involvement. Summation of individual lobar scores provided the overall ILD severity score. Fibrosis (reticular and honeycomb scores) and inflammation indices (ground glass opacity and mixed score) were also calculated *(Ooi et al. Acta Radiologica. 2003)*.

Results: We identified 116 patients with positive anti-Jo1 antibody, of which 13 were found to have RHC-confirmed PH and were included in this study. All 13 patients also had ILD. Mean age at diagnosis of antisynthetase syndrome was 51 years and mean age at diagnosis of pulmonary hypertension was 58 years. Of the 13 patients, 8 had mild PH (mean pulmonary artery pressure (mPAP): 25–40 mmHg), 4 had moderate PH (mPAP: 41–55 mmHg), and 1 had severe PH (mPAP: >55 mmHg). The predominant type of lung injury observed in these patients was inflammation, not fibrosis. For the same degree of ILD severity (Figure 1), there was significant variability in the severity of PH, indicating that PH in anti-Jo1 syndrome is not solely secondary to ILD, but is also a result of an independent inflammatory and/or fibro-proliferative process affecting the pulmonary microvasculature. The correlations between mPAP and overall ILD severity, inflammation index, or fibrosis index were not statistically significant.

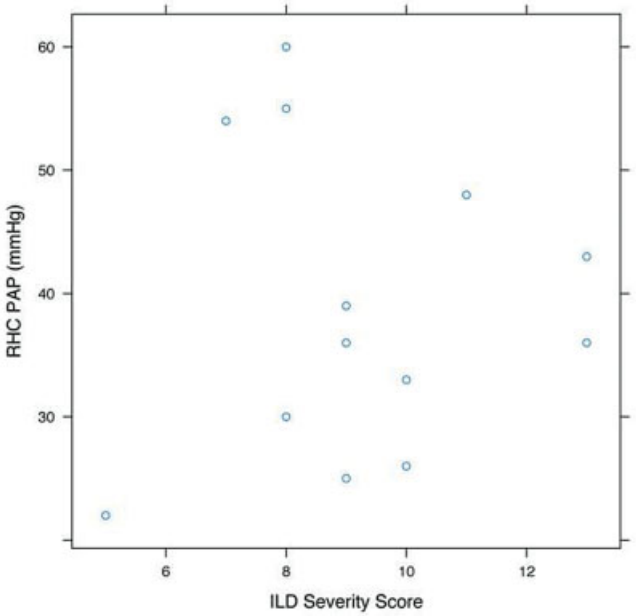

Figure 1.

Conclusion: Our findings suggest that chronic hypoxic pulmonary vasoconstriction or vascular obstruction/destruction associated with progressive ILD are not the sole mechanisms in the pathogenesis of PH in anti-Jo1 syndrome. It is likely that an obliterative pulmonary vasculopathy (possibly resulting from proliferation of endothelial and vascular smooth muscle cells) co-exists and plays an important role in the pathogenesis. Therefore, it may be appropriate to consider routine screening of anti-Jo1 syndrome patients at the onset of disease and periodically thereafter, in order to have maximum impact of vasoactive therapy on the outcome.

2079

Serum Interferon α, β and Interleukin-18 Are Associated With Disease Activity Of Rapidly Progressive Interstitial Lung Disease In Patients With Clinical Amyopathic Dermatomyositis. Shinji Sato, Noriko Sasaki, Shinichi Nogi, Naofumi Chinen, Kiri Honda, Eiko Saito, Chiho Yamada and Yasuo Suzuki. Tokai University School of Medicine, Isehara, Japan.

Background/Purpose: It is well known that rapidly progressive interstitial lung disease (RP-ILD) in patients with dermatomyositis (DM) is associated with poor outcome. Previous findings suggested that interferon alfa (IFNα), interferon beta (IFNβ) and interleukin-18 (IL-18) might play an important role in the pathogenesis of DM (including the DM subtype clinically amyopathic dermatomyositis, CADM) and RP-ILD. The aim of this study was to determine whether levels of IFNα, IFNβ, IL-18 and other cytokines were associated with disease activity in CADM and RP-ILD.

Methods: Serum samples and clinical data were collected from 28 patients diagnosed as having DM with or without RP-ILD (14 with RP-ILD, 9 with chronic ILD and 5 without ILD), 4 other connective tissue diseases (CTD) and 4 normal healthy controls (NHC). Serum IFNα, IFNβ, IL-18 and other proinflammatory cytokines were quantified by commercially-available enzyme-linked immunosorbent assay (ELISA) kits over the disease course and related to disease activity.

Results: IFNα was detected in 7 of 28 (25%) DM serum samples before treatment. All 7 patients who had high IFNα concentration were diagnosed as CADM and RP-ILD. IFNα decreased significantly and was no longer detectable after treatment which reduced symptoms (33.8 pg/ml vs. 0.0 pg/ml, P=0.019). In contrast, no IFNα was detected in any sera from DM without RP-ILD, other CTD or NHC. Sera from 14 of 28 (50%) patients with DM had high IFNβ in contrast to only 1 of 8 (13%) with other CTD and NHC. Nine of 14 (64%) sera with IFNβ before treatment were from CADM with RP-ILD patients. As with IFNα, IFNβ levels of 7 CADM and RP-ILD patients who responded to therapy and survived decreased significantly after improvement of pulmonary symptoms (108.9 pg/ml vs. 38.3 pg/ml, P=0.027). IL-18 was detected in all sera from DM with or without RP-ILD as well as other CTD and NHC before treatment. Serum IL-18 levels in CADM with RP-ILD, as well as in DM without RP-ILD, decreased significantly, parelleling symptom improvement (70.2 pg/ml vs. 25.0 pg/ml, P=0.017). Serum IL-17A, IL-23 and BAFF were not detected in any DM patient or NHC.

Conclusion: These results suggest that serum IFNα, IFNβ and IL-18 levels might be involved in the pathogenesis of RP-ILD and CADM, and might represent a useful biomarker of disease activity.

Pregnancy Outcomes In Adult Patients With Dermatomyositis and Polymyositis. Lorinda Chung[1], David Fiorentino[2], Shufeng Li[3] and Eliza Chakravarty[4]. [1]Stanford Univ Medical Center, Palo Alto, CA, [2]Stanford University School of Medicine, Redwood City, CA, [3]Stanford University School of Medicine, Stanford, CA, [4]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: Dermatomyositis (DM) and polymyositis (PM) are autoimmune inflammatory myopathies that frequently affect females of child-bearing potential. Small studies have indicated that active disease during pregnancy may result in intra-uterine growth restriction (IUGR) and fetal loss. We sought to assess pregnancy outcomes of adult DM and PM patients compared with the general obstetric population using a U.S. hospitalization dataset.

Methods: We used the Nationwide Inpatient Sample (NIS) (1993–2007) to estimate the number of obstetric hospitalizations and deliveries among women > 18 years of age with DM and PM. Controls were from the general obstetric population hospitalized in 2007. Pregnancy outcomes included length of hospital stay (LOS), hypertensive disorders including preeclampsia and eclampsia (HTN), premature rupture of membranes (PROM), IUGR, and cesarean delivery (C-section). Multivariate regression analyses were performed using maternal age, race/ethnicity, antiphospholipid antibody syndrome (APLA), diabetes mellitus, renal failure, and interstitial lung disease (ILD) as covariates.

Results: We compared 4.1 million deliveries in the general obstetric population to 459 that occurred in women with DM and 404 in women with PM. Patients with DM and PM were slightly older than controls (28±6 years vs 27±6 years, p<.0001), and more were African American than controls (DM 30% vs 15%, p=.002; PM 46% vs 15%, p <.0001). Renal failure and ILD were more common in both the DM and PM groups, while diabetes and APLA were more common in DM compared with controls. In univariate analysis, LOS was significantly longer in the DM and PM groups compared with controls (3.8±3.5 in DM and 4.9±6.3 in PM vs. 2.7±2.7 days in controls, p<.0001 for both) (Table). In multivariate analyses, DM (OR 1.6, 95%CI 0.9–2.9) and PM (OR 2.4, 95%CI 1.5–3.9) were associated with an increased odds of HTN compared with controls, though this did not reach statistical significance in the DM group. Interestingly, DM was associated with a decreased odds of IUGR (OR 0.7, 95%CI 0.6–0.9). There were no differences in rates of PROM or C-section in the DM or PM patients compared with controls.

Table 1. Obstetric Outcomes by Diagnosis

Group	LOS (d, mean±SD)	p-value vs. control	HTN (%)	p-value vs. control	PROM (%)	p-value vs. control	IUGR (%)	p-value vs. control	C-section (%)	p-value vs. control
DM	3.8 ± 3.5	<.0001	17.3	0.0004	5.3	0.37	1.7	0.92	25	0.33
PM	4.9 ± 6.3	<.0001	24.2	<.0001	4.6	0.55	4.6	0.02	27.3	0.7
CONTROL	2.7 ± 2.7		8.8		3.6		1.8		28.9	

Conclusion: Our data suggest that patients with DM and PM may be at increased risk of preeclampsia and eclampsia. We did not find an increased risk for IUGR in these patients. Vigilant monitoring of blood pressure may be advisable in pregnant patients with DM and PM.

Role Of Muscle Persistent CD28null T Cells In Glucocorticoid Therapy Resistance In Myositis Patients. Jayesh Pandya, Ingela M. Loell, Mohammad Shahadat Hossain, Mei Zong, Sukanya Raghavan, Ingrid E. Lundberg and Vivianne Malmström. Rheumatology Unit, Department of Medicine, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Polymyositis (PM) and dermatomyositis (DM) are characterized by infiltration of T cells and macrophages in skeletal muscle tissue. Conventional immunosuppressive treatment has limited effects on infiltrating cells. In this context, CD28null T cells are interesting, which display properties of proinflammatory killer cells and are suggested to be resistant to apoptosis *in vivo*. Recently, it was found in our lab that after conventional glucocorticoid treatment, the relative number of regulatory T cells (Treg) was unchanged or decreased, while the CD28null T cell proportion was mainly increased in muscle tissue of myositis patients. (Loell et al; ACR 2011, *Arthritis Rheum 2011;63 Suppl 10:233)*. This leads to our working hypothesis that CD28null T cells are resistant to immunosuppression mediated by glucocorticoids in the setting of myositis. An additional explanation could be a lack of sensitivity in the CD28null population towards Treg mediated suppression.

The aim of this study was to investigate the clinical relevance of persistent CD28null T cells in myositis patients treated with glucocorticoids and to further evaluate immunosuppressive effects of both glucocorticoids and Treg on CD28null T cells *in vitro*.

Methods: Immunohistochemistry for CD3, FOXP3 and CD28null surrogate marker CD244 was performed on muscle tissue obtained from 14 patients with PM/DM, treated with glucocorticoids and additional immunosuppressive drugs for 8 (4–16) months. For clinical evaluation, muscle performance was measured by Functional Index at biopsy time points. Post treatment 5 years follow up for disease activity was done by Myositis Intention To Treat Activity Index (MITAX). *In vitro* immunosuppression assays were performed on anti-CD3 activated PBMCs from 6 myositis patients and 6 healthy donors. To quantify % suppression, reduction in CD69 (early T cell activation marker) on activated T cells upon glucocorticoid and Treg addition was measured by flow cytometry.

Results: At group level, patients improved in Functional Index measurement. However, patients with Functional Index <75% post treatment were found to display higher level of CD244+(CD28null) T cells (median 14,cells/mm^2, *p=0.01*) in post treatment muscle biopsies compared to those with high Functional Index (>75%) (median 1 cell/mm^2). Patient disease activity MITAX correlated with the number of CD244+ cells/mm^2 post treatment (Rho=0.74, p=0.04). In *in vitro* immunosuppression assays, CD4+CD28null T cells displayed lower sensitivity towards glucocorticoid-mediated suppression (median suppression: patients 46.8%, healthy 51.6%) compared to CD28+ counterparts (68.5%, 80.7%) in both myositis patients and healthy donors. CD4+CD28null T cells were also less sensitive than CD28+ counterparts towards Treg mediated suppression (median: 18% versus 57.2%). No clear trend could be observed in CD8+ compartment.

Conclusion: Above *in vivo* and *in vitro* findings suggest that poor outcome from the glucocorticoid therapy in myositis patients is linked to persistence of CD28null T cells in muscle tissue, which are relatively resistant to both glucocorticoid and Treg mediated immunosuppression.

Interferon-Regulated Chemokine and Innate Cytokine Scores Identify Refractory Myositis Patients That Respond Better To Rtuximab Therapy. Consuelo Lopez de Padilla[1], Cynthia S. Crowson[1], Molly S. Hein[1], Helen Khun[1], Rohit Aggarwal[2], Marc C. Levesque[2], Dana P. Ascherman[3], Chester V. Oddis[2] and Ann M. Reed[1]. [1]Mayo Clinic, Rochester, MN, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Miami, Miami, FL.

Background/Purpose: Serum cytokines play an important role in the pathogenesis of myositis by initiating and perpetuating various cellular and humoral autoimmune processes. The aim of this study was to measure interferon (IFN)-inducible chemokines, Th1, Th2, Th17, innate, and regulatory cytokines in patients with refractory idiopathic inflammatory myositis (IIM) to identify a biomarker signature to predict responsiveness to rituximab.

Methods: In a randomized, placebo-phase trial (Rituximab in Myositis (RIM)), 200 refractory IIM subjects received 1 gm of rituximab on 2 consecutive weeks – weeks 0/1 (Early) or weeks 8/9 (Late). Serum samples were collected at baseline, 8, and 16 weeks following treatment. Multiplexed sandwich immunoassays (Meso Scale Discovery) were used to measure IFN-regulated chemokines and other pro- and anti-inflammatory cytokines specific to differentiation of specific T cell and innate pathways. Cytokine scores were computed for **Th1** (IFNy, TNFα, and IL2), **Th2** (IL4, IL5, IL10, IL12, and 1L 13), **Th17** (IL6, IL17, IL1β), **innate** (IFNα, MCP-1, MCP-2, MIG, MIP-1β, IP-10, I-TAC, IL18), **IFN-regulated chemokine** (I-TAC, IP-10, MCP-1), and **regulatory** (IL10, TNFα) factors. IMACS core set myositis disease activity measures (physician global, patient global, MMT, HAQ, muscle enzyme, and extramuscular visual analog scale (VAS) scores (0–100 mm) and Myositis Disease Activity global VAS were collected at each visit. Changes in IFN chemokine and cytokines and VAS scores between time points were calculated, and were correlated using Spearman methods.

Results: We analyzed data available for 177 myositis subjects (mean age (SD)/disease duration (SD) 37(19)/5(7) years, 73% female, 70% Caucasian. The mean (SD) values for muscle disease activity and physician global disease activity VAS scores were 46(22) and 49(19) cm, respectively. Increased levels of Th2, Th17 and innate cytokines were observed 16 weeks after the start of treatment (p = 0.05, p = 0.02, p < 0.001, respectively), while the levels of regulatory cytokines were reduced (p < 0.001). IFNCK, Th1, Th2, Th17, innate, and regulatory cytokine scores at baseline were positively correlated with physician global VAS at the start of treatment (r=0.20 [P=.01], r=0.29 [P<.001], r=0.16 [P=.03], r=0.18 [P=.02], (r=0.19 [P=.01], and (r=0.19 [P=.01], respectively); while Th1, Th2, and Th17 cytokine scores correlated positively with muscle disease activity VAS at the start of

treatment (r=0.22 [P=.003], r=0.17 [P=0.02], (r=0.22 [P=.003], respectively). Higher baseline IFNCK and innate cytokine scores were predictive of better response in physician global VAS at 16 weeks after treatment (r= −0.167 [P=.03], (r= −0.15 [P=.05], respectively). In addition, baseline IFNCK, innate and regulatory cytokine scores correlated with muscle improvement on the MDAAT at 8 weeks ([r= −0.19, P=.01], [r= −0.20, P=.01], [r= −0.21, P=.005] respectively) while baseline IFNCK and innate cytokine scores correlated with muscle improvement at 16 weeks ([r= −0.17, P=.03], [r= −0.16, P=.04], respectively).

Conclusion: IFNCK and innate cytokine scores before treatment may help to identify rituximab responsiveness in refractory myositis patients.

Environmental Factors Associated With Disease Flare In Juvenile and Adult Dermatomyositis. Gulnara Mamyrova[1], Lisa G. Rider[2], Olcay Jones[3], Alison Ehrlich[4], Lauren M. Pachman[5], Robert Nickeson[6], Lisa G. Criscione-Schreiber[7], Frederick W. Miller[2], Lawrence K. Jung[8] and James D. Katz[1]. [1]George Washington University, Washington, DC, [2]NIEHS, NIH, Bethesda, MD, [3]Walter Reed National Military Medical Center, Bethesda, MD, [4]The George Washington University, Washington, DC, [5]Division of Pediatric Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, [6]All Children's Hospital, St Petersburg, FL, [7]Duke University School of Medicine, Durham, NC, [8]Children's National Medical Center, Washington, DC.

Background/Purpose: To assess environmental factors in relationship to increased disease activity (flare) in juvenile and adult dermatomyositis (DM).

Methods: An online survey was conducted for juvenile and adult DM patients from the US and Canada who were ≥1 year from diagnosis. Patients were recruited through myositis clinics and by a patient support group. The survey examined: exposures during the 6 months prior to disease flare, if the patient experienced a flare within the past 2 years, or in the past 6 months, if the patient did not have a flare. Exposures assessed included smoking, sun exposure, infections, medications, vaccines, stressful life events, and sport activities. Differences were evaluated by Chi-square and Fisher's exact tests.

Results: Of 210 participants meeting probable or definite Bohan and Peter criteria (164 juvenile and 46 adult DM patients), 134 (63.8%) (103 juvenile and 31 adult DM) experienced a flare and 76 (36.2%) (61 juvenile and 15 adult DM) participants did not experience a disease flare within the past 2 years. For those reporting a disease flare, the mean duration to flare was 13 months for JDM and 10 months for DM. Eighty percent of patients with a flare were female vs. 70% of those without flare; 85% were Caucasian. Patients with flare were less often 0–5 years of age compared to those who did not flare (2.2% vs. 15.8%, p=0.0004). Patients with a disease flare more often reported that their myositis worsened after sun exposure (44.4% vs. 28.6%, p=0.03, OR=1.99, 95% CI: 1.1–3.7), but the use of photoprotective measures was similar between both groups. Infections were more frequently recorded in the preceding 6 months in those who flared vs. those who did not, including UTI (10.2% vs. 0.0%, p= 0.005, OR=16.4, CI: 0.96–280.2) and gastroenteritis (16.5% vs. 5.8%, p=0.04, OR=3.2, CI: 1.1–9.8). Patients who flared more frequently used NSAIDs (63.4% vs. 36.8%; p=0.0003, OR=3.0, CI: 1.7–5.3) or blood pressure medicines (12.7% vs. 3.9%, p=0.049, OR=3.5, CI: 1.0–12.5). HPV vaccine was more frequent in those who flared vs. those who did not (8.2% vs. 0.0%, p=0.032, OR=10.0, CI: 0.6–175.5). Patients who flared tended to experience more frequent serious financial difficulties compared to those who did not (17.2% vs. 7.9%, p= 0.06, OR=2.4, CI: 0.9–6.2), but other stressful life events did not differ. Patients with a flare more often exercised 1–5 times a week (74.7% vs. 57.7%, p=0.06, OR=2.2, CI: 1.02–4.6). There was no difference in smoking exposure between the two groups.

Conclusion: Sun exposure, certain infections, medications, and vaccines, which have been associated with illness onset, may also play a role in disease flares in patients with adult and juvenile DM.

2084

Increasing Incidence Of Immune Mediated Necrotizing Myopathy In A Single Center. Martin Klein[1], Herman F. Mann[1], Josef Zámecník[2] and Jiri Vencovsky[3]. [1]Institute of Rheumatology, Prague, Prague, Czech Republic, [2]2nd Medical School and University Hospital Motol, Charles University, Prague, Czech Republic, Prague, Czech Republic, [3]Institute of Rheumatology, Prague, Czech Republic.

Background/Purpose: Immune mediated necrotizing myopathy (IMNM), characterized histologically by predominant myofiber necrosis with minimal or no inflammatory infiltrate and clinically by response to immunosuppressive therapy, is a relatively newly recognized category of idiopathic inflammatory myopathy (IIM). IMNM itself is a heterogeneous group with some cases associated with presence of anti-SRP, anti-HMGCR or, less frequently, antisynthetase antibodies. The relative frequency of IMNM compared to other IIM subtypes and the temporal pattern of its incidence is not known.

Methods: We have performed a retrospective evaluation of muscle biopsy results, clinical and laboratory data including antibody associations of all patients newly diagnosed with IIM in the Institute of Rheumatology between the year 2004 and February 2013. All biopsies were interpreted by a single experienced pathologist, results were subcategorized as necrotizing myopathy (NM), polymyositis (PM), dermatomyositis (DM), non-specific myositis (N-SM) or non-classifiable (NC).

Results: A total of 315 biopsies were performed, with 206 obtained from patients who fulfilled Bohan and Peter criteria for IIM (definite or probable category). 20 cases were histologically classified as NM, all of them were IMNM based on history, biopsy and clinical features. In the remaining 186 biopsies 24 were subcategorized as PM, 39 as DM, 77 as N-SM and 46 as NC. There were no IMNMs diagnosed between 2004 and 2007, subsequently 2–3 cases of IMNM per year were seen during the period of 2008 to 2011 with a sudden increase to 9 cases (36% of all biopsies) in the year 2012. This trend was confirmed in the first two months of 2013 (Figure 1). Three IMNM patients were positive for anti-SRP antibodies, two were anti-Jo1 positive, one had anti PM-Scl antibodies, one had isolated anti-Ro52 positivity and two were ANA positive with no identifiable antibody. Interestingly anti-CCP antibodies, considered highly specific for rheumatoid arthritis (RA), were detected in two IMNM patients. Anti-HMGCR antibodies were not tested. Nine patients with IMNM (45%) had no detectable autoantibodies (all of them diagnosed in or after 2011), six of them were exposed to statins before developing IMNM. Only two other patients had a history of statin use (one anti-Jo1 positive diagnosed in 2008 and one with anti-CCP diagnosed in 2012).

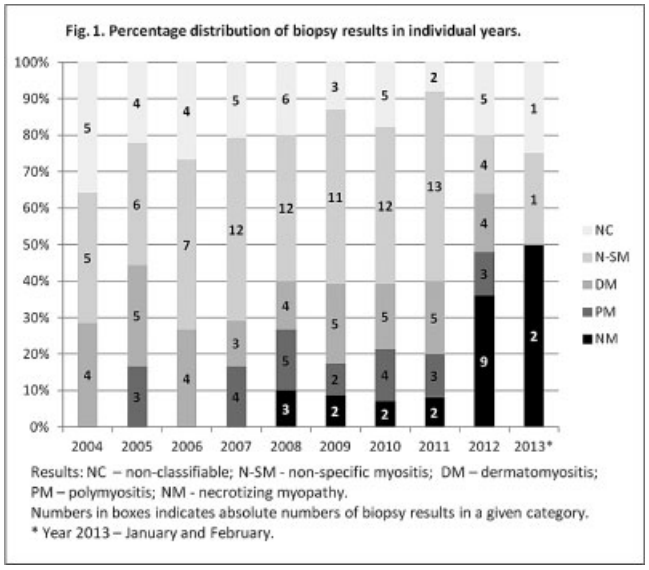

Figure 1.

Conclusion: We have observed an increasing incidence of immune mediated necrotizing myopathy, which cannot be explained by changes of referral pattern or biopsy reporting. There has been an increasing number of statin exposed IMNM patients since 2011.

Identification Of Clinical Features and Risk Factors Associated With Calcinosis In Adult Patients With Dermatomyositis. Antonia Valenzuela[1], Lorinda Chung[2], Livia Casciola-Rosen[3], Antony Rosen[3] and David Fiorentino[4]. [1]Stanford University School of Medicine, Palo Alto, CA, [2]Stanford University Medical Center, Palo Alto, CA, [3]Johns Hopkins University, Baltimore, MD, [4]Stanford University School of Medicine, Redwood City, CA.

Background/Purpose: Prior studies have estimated that 20% of adult dermatomyositis (DM) patients suffer from calcinosis. Although calcinosis is related to persistent disease activity, poor treatment adherence, and therapy refractoriness in juvenile DM (JDM) patients, risk factors for calcinosis in the adult DM population have not been extensively studied. Antibodies to nuclear matrix protein 2 (NXP-2) have been associated with calcinosis in JDM patients but only one study has shown a trend for this association in adult DM. We aimed to determine the prevalence of calcinosis and to identify associated clinical features in a large cohort of adult DM patients.

Methods: This is a cross-sectional study of 126 patients diagnosed with DM at Stanford University Medical Center between 01/2006 and 01/2013. Calcinosis was defined as the presence of calcium deposition in the skin and/or subcutaneous tissues as determined by physical examination and/or radiography. Logistic regression was used to obtain odds ratios (OR) relating calcinosis to various clinical features using both univariate and multivariate analyses.

Results: 94% of patients had DM-specific or myositis-specific autoantibodies (against NXP-2, transcription intermediary factor-gamma (TIF-g), melanoma differentiation antigen 5 (MDA-5), sumoyl activating enzyme (SAE1/2), Mi-2, or Jo-1). A total of 14 (11%) patients had calcinosis. In univariate analysis, longer disease duration (OR=1.1, 95%CI 1.01–1.3, p=0.03), digital ulcers (OR=9.8, 95%CI 2.9–33.6, p=0.0003), interstitial lung disease (OR=6.5, 95%CI 1.9–22.2, p=0.003), autoantibodies to MDA-5 (OR=5.1, 95%CI 1.4–17.8, p=0.01) and antibodies to Ro52 (OR=3.5, 95%CI 1.1–11.0, p=0.04) were positively associated with calcinosis while autoantibodies to TIF-g were negatively associated with calcinosis (OR=0.19, 95%CI 0.04–0.91, p=0.04). The association between anti-NXP-2 and calcinosis reached statistical significance only in multivariate analysis (OR=7.6, 95%CI 1.5–39.2, p=0.01), while MDA-5 and TIF-g were no longer significantly associated in these models. Because of the known association between MDA-5 and digital ulcers, we evaluated a multivariate model excluding digital ulcers, and found that MDA-5 positivity was highly predictive of calcinosis (OR=6.9, 95%CI 1.8–27, p=0.005). Digital ulcers were strongly associated with calcinosis in all multivariate models, independent of the underlying autoantibody present (Table 1).

Table 1. Predictors of calcinosis in multivariate analyses.

	OR	95%CI	p-value
Multivariate model 1			
Disease duration	1.2	1.04–1.38	0.01
Digital ulcers	23.1	4.74–112	<0.001
NXP-2	7.6	1.48–39.2	0.01
Multivariate model 2			
Disease duration	1.17	1.04–1.33	0.01
Digital ulcers	12.8	2.12–77.2	0.005
MDA-5	1.19	0.17–8.04	0.85
Multivariate model 3			
Disease duration	1.16	1.03–1.3	0.01
MDA-5	6.9	1.76–27	0.005
Multivariate model 4			
Disease duration	1.16	1.03–1.33	0.01
Digital ulcers	13.9	3.31–58.6	0.0003
TIF-g	0.24	0.04–1.25	0.09

Conclusion: Calcinosis was a relatively uncommon clinical feature in our cohort of DM patients. We found an association between calcinosis and anti-NXP-2 autoantibodies as well as a novel association with digital ulcers. A common vascular mechanism may underlie the development of both calcinosis and digital ulcers in patients with DM.

Defining The Prevalence and Associated Risk Factors For Calcinosis In Adult Dermatomyositis Patients. Jessie Werner[1], Jason Liebowitz[2], Andrew L. Mammen[3] and Lisa Christopher-Stine[4]. [1]University of Maryland School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins, Baltimore, MD, [4]Johns Hopkins University, Baltimore, MD.

Background/Purpose: Calcinosis is known to be associated with junvenile dermatomyositis, but the prevalence and risk factors associated with the development of calcinosis in adult dermatomyositis (DM) patients is unknown. We sought to quantify this burden by estimating the prevalence of calcinosis by patient self- report, and identifying associated risk factors for calcinosis in adult DM patients.

Methods: After obtaining IRB approval, a standardized telephone interview and retrospective chart review of 50 consecutive adult DM patients evaluated between 5/1/97 and 1/1/13 at a single tertiary care center was conducted. Variables collected included: self-reported anatomic location of calcinosis if present; laboratory data including myositis specific antibodies (MSAs); signs and symptoms of dermatomyositis; calcinosis treatment history; and immunosuppressant agents used. Patients were separated into 2 groups – those who developed calcinosis over the course of their disease and those who did not.

Results: Of the 50 patients, 76% were female, 19 (38%) developed calcinosis over their disease course (89% of whom were female), and 84% had at least one positive MSA. MDA5 was the only MSA which was significantly associated with calcinosis. The mean time between symptom onset and diagnosis of dermatomyositis was 16 months. The mean time between the diagnosis of dermatomyositis and development of calcinosis was 21 months. Patients with calcinosis scored lower on the SF-36v2 compared to patients without calcinosis (39.52 vs. 44.17; p=0.055). Furthermore, patients with calcinosis scored higher (indicating a higher degree of difficulty performing activities of daily living) compared to patients without calcinosis (0.93 vs. 0.69; p=0.096) on the Stanford Health Assessment Questionnaire Disability Scale (HAQ). Calcinosis patients also reported worse joint pain (4.0 vs. 3.06 on a 10 point scale).

Conclusion: Calcinosis is a common complication of adult dermatomyositis patients. Calcinosis risk factors included the specific MSA, MDA5. Patients with calcinosis have more difficulty performing activities of daily living, experience more joint pain, and rate their physical health worse than patients who do not have calcinosis.

Utility and Reliability Of Digital Nailfold Capillaroscopy In Children With Juvenile Dermatomyositis: Three Methods. Gabrielle A. Morgan[1], Adam Ostrower[1], Chiang-Ching Huang[2] and Lauren M. Pachman[1]. [1]Ann & Robert H. Lurie Children's Hospital of Chicago Research Center, Chicago, IL, [2]Department of Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL.

Background/Purpose: Nailfold Capillaroscopy (NFC) is a non-invasive assessment of the nailfold area of the fingers which aids in the diagnosis of Juvenile Dermatomyositis (JDM) by providing images where the number of capillary end row loops/ mm (ERL) can be both visualized and counted. Previous studies documented that ERL numbers are usually decreased at diagnosis and often change over time. Although many NFC studies employ non-digital methods of photo capture and analysis, new digital tools are well adapted for NFC photography, but their reliability is unknown. The objective of this study was to explore the utility and reliability of digital methods of NFC in children with JDM.

Methods: First, the relationship between the Disease Activity Score (DAS) and end row capillary loops (ERL) was explored. 109 untreated children with JDM (78% females, 92% White or Hispanic, mean age 6.7 ± 3.4 years, mean duration of untreated disease 11.2 ± 16.9 months) had DAS and NFC obtained at diagnosis (IRB# 2012–14858), using the non-digital method. To assess the standardization of the digital method, 12 randomly selected treated patients with JDM (42% Female, mean age 14.8± 6.4 years, White or Hispanic) were enrolled (IRB# 2011–14651). NFC was performed on 8 fingers on each of the 12 patients, using three methods, by the same experienced investigator; there were 2 readers. The first method, freeze frame video microscopy (FFVM), produced photos that were printed and not digitally stored. For each method, the NFC were analyzed by counting the ERL per mm, which were then averaged. DermLite II ProHR (DL) (portable) and Leica Z6APO stereomicroscope (LS) (stationary) served as the two digital methods for image acquisition. These photos were analyzed with Adobe Photoshop CS5 using the same ERL formula. All 288 images were evaluated by each of the two investigators, one very experienced in NFC analysis (R1), and one a novice (R2).

Results: Untreated children with JDM had a significant negative correlation between skin DAS and ERL (p=.0027), which was not found for muscle DAS and ERL (p= 0.43). Both digital methods, DL and LS, were quite reliable in

terms of quantification of the number of ERL, compared with the FFVM, when read by R1 (r_c= 0.833, r_c=.846, Concordance Correlation Coefficient). R2's reliability was low using both digital methods (DL r= 0.436, LS r= 0.543). This lack of concordance between the readers was further documented when DL was compared to LS (R1 r_c= 0.832, R2 r_c= 0.41). The data from both the experienced and the novice investigators were concordant using the FFVM images (r_c= 0.834); however, the inter-rater reliability was poor when R1 and R2 were compared for the digital methods (DL r_c= 0.676, LS= 0.577).

Conclusion: NFC can be used in the clinical setting to assess skin associated vascular changes in JDM, providing the ERL number at diagnosis and over time to assess the vasculopathy. FFVM is more easily interpreted by a novice, but digital methods pose a challenge to the novice. However, when read by an experienced investigator, the results from both methods are highly concordant. We speculate that this new, easily accessible technology may allow NFC to become a standard of care for children with JDM.

The Percentage Of Th17 Cells Correlates with the Expression Of Microrna-206 In Patients With Dermatomyositis. Xinyi Tang and Shengjun Wang. Department of Immunology, Jiangsu University, Zhenjiang, China.

Background/Purpose: DM (dermatomyositis) is a subtype of inflammatory myopathies, which is a rare autoimmune disease of skeletal muscle. Although the pathogenic mechanism of DM is still unclear, it was considered as a CD4+T cells driven disease. It was reported that IL-17, a key cytokine of Th17 cells, has been detected in the inflammatory infiltrates of patients with DM. But there is no study focusing on the alteration of Th17 cells in the peripheral blood of patients with DM. In addition to RORC, Kruppel-like factor 4 (KLF4), a transcription factor of cell differentiation, stem cell properties, and malignant transformation, is another positive regulator of Th17 differentiation.

Methods: Thirteen patients with DM were included in this study. The diagnosis was based on commonly accepted clinical and laboratory criteria. Peripheral blood samples were obtained from all patients. The serum concentrations of CK and LDH is by biochemistry test. Healthy subjects were included, ranging from 32 to 50 year old. All of the control subjects were free of a history of DM diseases. All samples were taken in accordance with the regulations and approval of the Affiliated People's Hospital of Jiangsu University.

Results: We analyzed the proportion of Th17 cells in PBMCs of DM patients by flow cytometry. The percentage of Th17 cells was significant increased in PBMCs from patients with DM compared with healthy controls. qRT-PCR analysis displays an enhanced expression of IL-17mRNA in the PBMCs from DM patients, with lower expression in healthy controls. To further document the state of Th17 cells in DM patients, we analyzed the expression of RORC mRNA, which plays a considerable role in differentiation of human Th17 cells. As expected, the expression of RORC mRNA in PBMCs from DM patients is significant higher than that from healthy controls. We found that there was a positive correlation between the percentages of Th17 cells and serum level of CK, but not with level of LDH. This result demonstrated that the percentage of Th17 cells could reflect the severity of DM in some extent. In addition, we found that DM patients have significant increased serum concentration of IL-6 and TGF-βin comparison with healthy controls. In addition, serum concentrations of IL-1$\beta$is higher in DM patients compared with healthy controls, but this difference did not reach statistical significant. To further analyze the influential factor of Th17 cells enhancement in DM patients, we considered searching the miRNA which may influence the enhancement of Th17 cells. KLF4 is one of the targets of miR-206, and an inverse relationship between miR-206 and KLF4 in human has been confirmed. After acquired the increased expression of KLF4 mRNA in PBMCs of DM patients, we verified the decreased expression of miR-206 in PBMCs and serum of DM patients.

Conclusion: Our data collectively suggest that there is an enhanced frequency of Th17 lymphocytes in DM patients, the augmented expression of KLF4 mRNA may cause by the attenuated expression of miR-206, and the high level of KLF4 mRNA evokes the proportion of Th17 cells in DM patients. And besides the potential role of proinflammatory cytokines, the attenuated expression of miR-206 may regulate the percentage of Th17 cells in DM patients in some extend.

Downregulation Of Mir-10a Is Associated With Increased Von Willebrand Factor Antigen, Disease Activity Score and Earlier Diagnosis In Children With Untreated Juvenile Dermatomyositis. Dong Xu[1], Akadia Kachaochana[1], Gabrielle A. Morgan[1], Chiang-Ching Huang[2] and Lauren M. Pachman[1]. [1]Ann & Robert H. Lurie Children's Hospital of Chicago Research Center, Chicago, IL, [2]Department of Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL.

Background/Purpose: We previously reported (Arthritis Rheum 2012;64 Suppl 10:1670) that miRNA array studies of diagnostic muscle biopsies obtained from untreated children with Juvenile Dermatomyositis (JDM) identified 19 differentially expressed miRNAs in JDM muscle compared to healthy orthopedic controls. Downregulation of miR-10a and miR-10b headed the list with fold changes of −1.96, adjusted p=0.0028, and fold change of −1.62, adjusted p value= 0.0027, respectively. miR-10a and miR-10b are located on separate chromosomes (2 and 17) and regulate the NFκB pathway which controls the synthesis of inflammatory mediators. We confirmed that plasma levels of IL-6, IL-8, TNF-α, MCP-1, VCAM-1, but not IL-1β, were elevated in untreated JDM compared to controls. The purpose of the present study was to determine association of the miR-10a and miR-10b downregulation in the muscle with customary clinical and laboratory findings in untreated children with JDM.

Methods: After obtaining informed consent, 24 children: 11 with a short duration of untreated disease (DUD) of less than 3 months and 13 with a long DUD of greater than 3 months were enrolled; 17 were girls. Of the 24, 19 were White and 5 were Hispanic. The children were enrolled at the time of diagnosis and their clinical and diagnostic laboratory data examined in relation to the expression levels (qPCR) of miR-10a and miR-10b in the diagnostic muscle biopsy. The clinical variables considered were disease activity scores (DAS, skin, muscle, total score), nailfold capillary end row loop number (ERL) and the blood level of von Willebrand factor antigen (vWF:Ag), DUD, and the presence of the TNF-α−308 A allele. Healthy orthopedic patients donated muscle from the trunk or proximal limbs as controls.

Results: Of note, decreased miR-10a, but not miR-10b, was associated with: a short DUD of less than 3 months, p=0.014; the presence of the A allele at the promoter region of TNF-α−308, p=0.006; an elevated DAS Total, p=0.03; and increased vWF:Ag level, p=0.004. There was no association of either decreased miR-10a or miR-10b with loss of ERL.

Conclusion: Downregulation of miR-10a, but not miR-10b, was associated with increased vWF:Ag, indicating damaged endothelial cells, and a more severe disease onset with a higher DAS, contributing to earlier diagnosis and a shorter DUD. We conclude that miR-10a downregulation is a critical factor in JDM pathophysiology and speculate that it may be a potential therapeutic target early in the disease course.

The Effects of Commercially Available Footwear On Foot Pain and Disability in People With Gout: A Feasibility Study. Keith Rome[1], Sarah Stewart[1], Alain Vandal[2], Peter J. Gow[3], Peter J. McNair[1] and Nicola Dalbeth[4]. [1]AUT University, Auckland, New Zealand, [2]Counties Manukau District Health Board, Auckland, New Zealand, [3]Middlemore Hospital, Auckland, New Zealand, [4]University of Auckland, Auckland, New Zealand.

Background/Purpose: The non-pharmacological management goals for people with foot-related rheumatic diseases are pain management, preservation of foot function and patient mobility. One of the therapeutic components that may achieve these goals is footwear. To date, no clinical trials have examined the impact of footwear as an intervention for people with gout. The aim of this study was, first, to determine the factors that are important to people with gout in their choice of walking shoes, and thereafter to determine whether those chosen shoes could reduce foot pain and musculoskeletal disability in people with gout over 8 weeks.

Methods: Thirty-six people with gout participated in a randomised, single-blind, crossover trial, followed by an 8-week prospective observational study. Four walking shoes were included into the trial based upon cost and footwear characteristics (Helix Viper, Dunlop Apollo, Dunlop Asteroid, ASICS Cardio Zip). Perceived comfort and footwear acceptability were determined for each shoe; participants selected a shoe for the observational study. The primary outcome of the crossover trial was perceived comfort of the footwear. The primary endpoint of the observational study was foot pain visual analogue scale.

Results: The Cardio Zip shoe was selected by 21/36 (58%) participants. The Cardio Zip was reported as comfortable by 81% and well-fitting by 62% participants ($p=0.004$ and 0.03 compared with other shoes respectively). Compared with baseline, scores at 8-weeks decreased in foot pain ($p=0.03$), general pain ($p=0.012$), Health Assessment Questionnaire (HAQ)-II ($p=-0.016$) and Leeds Foot Impact Scale (LFIS) impairment subscale ($p=0.03$). No significant differences were observed in other patient reported outcomes including patient global assessment, LFIS activity subscale, and Lower Limb Task Questionnaire subscales (all $p>0.10$). We observed significant differences between participants' own shoes and the Cardio Zip for foot pain ($p=0.002$), general pain ($p=0.001$), HAQ-II ($p=0.002$) and LFIS impairment subscale ($p=0.004$) after 8 weeks. The other three shoes did not improve pain or disability.

Conclusion: Footwear with good cushioning, motion control and adequate width may reduce foot pain and disability in people with gout.

Adaptation and Preliminary Testing of An Arthritis Walking Program to Reduce Joint Pain for Elderly Breast Cancer Survivors On Aromatase Inhibitor Therapy. Kirsten A. Nyrop[1], Betsy Hackney[1], Rebecca J. Cleveland[1], Mary Altpeter[1], Hyman Muss[2] and Leigh F. Callahan[3]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of North Carolina, Chapel Hill, NC.

Background/Purpose: Joint pain/stiffness/achiness (arthralgia) is a common side-effect among postmenopausal women with breast cancer (BC) who are hormone receptor positive (HR+) for whom standard adjuvant endocrine treatment includes an aromatase inhibitor (AI). AI discontinuation due to side-effect severity is an estimated 20–32%. There is a need for effective alternative or adjunctive approaches to arthralgia management that enable BC survivors to remain on AI therapy while optimizing as pain-free a life as possible. This study investigates the feasibility of adapting and testing an evidence-based self-directed 6-week physical activity program (PA) for adults with arthritis – Arthritis Foundation's *Walk With Ease (WWE)* – among female BC survivors age 65+ on AIs who report joint pain.

Methods: ***Design:*** *Mixed methods design:* (a) semi-structured interviews (qualitative) to adapt the *WWE* program and (b) one-arm pre-post pilot test (quantitative) to gather preliminary data on program impact. Initial sample of 10 BC survivors completed questionnaires and interviews about barriers and facilitators to moderate intensity PA; findings were used to develop an insert (*WWE-Breast Cancer*) for the *WWE* workbook. New sample of 20 was recruited to participate in the *WWE* program, complete pre- and post-intervention questionnaires, and complete a post-intervention interview to refine the *WWE-Breast Cancer* insert. ***Recruitment:*** BC survivors age 65+ were recruited through the oncology clinic of a university-affiliated hospital. ***Eligibility:*** age 65+; Stage I-III breast cancer; currently on AI therapy; self-reported joint pain/stiffness; physician permission to engage in PA; English speaking. ***Measures:*** (1) walking – number of days per week and number of minutes per walk, and (2) visual analog scales (VAS) for joint pain, fatigue and stiffness. ***Statistics:*** t-test evaluation of changes in mean values.

Results: Total sample (N=30) – mean age 70 (range 65–87), 90% Caucasian, 30% < high school degree. Within the walking sample (N=20): 100% would recommend *WWE* to other breast cancer survivors experiencing joint pain or stiffness; 100% thought they had learned how joint pain or stiffness could be lessened by physical activity, and how to safely engage in moderate-intensity physical activity; 90% thought *WWE* had motivated them to become more physically active, and how to overcome physical and mental barriers to walking; and 90% were fairly to extremely confident they would continue walking. At 6 weeks, all three walking measures showed significant improvements: number of times increased by 1.9 (effect size = 0.68, $p<0.001$), number of minutes increased by 8.8 (effect size = 0.48, $p<0.05$), and total minutes per week increased by 62.6 (effect size = 0.53, $p<0.001$). Mean joint pain decreased 10% ($p=0.63$), fatigue decreased 19% ($p=0.31$), joint stiffness decreased 32% ($p=0.07$).

Conclusion: A moderate-intensity self-directed walking program is feasible for elderly breast cancer patients on AI therapy who have joint pain. The program significantly increased total walking time per week over a 6 week period and was perceived as informative and motivational.

Strengthening Exercises Using A Swiss Ball Improve Symptoms and Muscle Performance Of Patients With Fibromyalgia: A Randomized Controlled Study. Josiander Arakaki Sr., UNIFESP, sao paulo, Brazil.

Background/Purpose: Fibromyalgia (FM) is a disorder characterized by chronic widespread pain, fatigue and reduced muscle strength. Exercise is fundamental to the treatment of FM and muscle strengthening programs have shown evidence of effectiveness in improving the symptoms of the syndrome.

Methods: Sixty patients classified with FM were selected and randomized into two groups: intervention group (IG) that conducted strengthening exercises using a Swiss ball, and control group (CG) that performed stretching exercises. The trainings were conducted three times per week, lasting 40 minutes, for 12 weeks. The IG (n = 30) performed 8 strengthening exercises using a Swiss ball with the aim of recruiting the major muscle groups: lateral raise (deltoid), simultaneous threads (biceps), squat (quadriceps), *French* triceps (triceps), abdominal (rectus abdominis), unilateral stroke (latissimus dorsi), crucifix (pectoralis major) and reverse crucifix (rhomboid and trapezius). The CG (n = 30) performed stretching exercises of the same muscle groups exercised by IG. The outcome measures were: VAS (visual analogue scale) for pain; one repetition maximum (1RM) test to assess muscle strength; FIQ (Fibromyalgia Impact Questionnaire) to assess the impact of the disease; and SF-36 (Short Form Health Survey) to assess quality of life. All participants underwent an evaluation at the beginning and after 6 and 12 weeks of training.

Results: The two groups were homogeneous regarding demographic and clinical characteristics at baseline. The IG showed statistically significant improvement ($p<0.05$) in VAS and FIQ compared to GC in T6 and T12. In addition, the IG showed improvement of muscle strength in almost all prescribed exercises compared to the control group. Both groups improved general quality of life, but without significant differences between groups. No adverse events were reported in both groups.

Conclusion: The treatment of fibromyalgia with strengthening exercises using a Swiss ball determined improvement in pain, quality of life related to disease and muscle strength compared with the stretching exercises without deleterious effects.

2093

A Comparison Of Performance On The Keital Functional Test By Persons With Rheumatoid Arthritis and Systemic Sclerosis. Janet L. Poole, Amy New and Christina Garcia. University of New Mexico, Albuquerque, NM.

Background/Purpose: Mobility is necessary for participation in all areas of daily life including self-care, work and leisure. In rheumatic conditions such as rheumatoid arthritis (RA) and systemic sclerosis (SSc), mobility can be compromised due to decreased joint motion, muscle weakness and pain in the lower extremities. While the lower extremity impairments in RA have been studied, less attention has been paid to lower extremity involvement in persons with SSc. Therefore the purpose of the study is to compare lower extremity impairments in persons with RA, SSc and healthy controls.

Methods: Fifty eight persons with RA, 64 persons with SSc and 30 healthy controls were evaluated with the Keital Functional Test (KFT), a performance based test of functional joint motion and strength that has been shown to be an important predictor of disability and mortality in people with RA. Only the 15 items from the KFT that related to lower extremity function in an upright position were used. There are specific ordinal scoring criteria for each item. Scores for 11 items range from 0 (no limitation) to 2 (impossible).

Two items (rise from a chair and walk 30 minutes) range from 0 (no problem) to 6 (impossible) while two other items (going up and down stairs) are scored from 0 (7 seconds, no rail) to 5 (impossible). Demographic information on age, disease duration, gender, employment status and health status was also collected. Analysis of variance compared the three groups on item scores and total scores on the KFT.

Results: There were no significant differences between the 3 groups for any of the demographic variables except for perceived health status (p =.001) and employment status (p =.001). Perceive health was significantly better in the HC group and significantly more HC were working full time compared to the RA and SSc groups. On the KFT, there were significant differences between the HC group and RA and SSc groups for 5 items and the total score: rising from a chair (p =.007), squatting (p =.001), walking 30 meters (p = 001), walking downstairs (p = 001), walking upstairs (p = 001), and the total score (p = 001). There were no significant differences for 7 items: standing on heels, standing on the right leg, standing on the left leg, placing right foot on chair for hip and knee flexion, placing left foot on chair, placing right heel on chair for hip flexion and knee extension, and placing left heel on chair. All 3 groups scored significantly different from each other for external rotation of the right hip (p = 001) in that the HC group has the highest external rotation and the SSc group had the least. For external rotation of the left hip, there was only a significant difference between the RA and HC group.

Conclusion: The results show that persons with RA and SSc have greater lower extremity involvement than HC and suggest areas that could be targeted for intervention. The results also show that persons with SSc do have lower extremity impairments which have not been examined, other than walking speed and time, in other studies.

Do Exercise Interventions For Total Hip Arthroplasty Have Therapeutic Validity? A Sensitivity Analysis Of Trials Included In a Cochrane Systematic Review. Marie D. Westby[1], Shirin Kazemi[2] and Dina L. Jones[3]. [1]University of Alberta, Edmonton, AB, [2]Mary Pack Arthritis Program, Vancouver, BC, [3]West Virginia University, Morgantown, WV.

Background/Purpose: Therapeutic exercise is the most common element of rehabilitation after total hip arthroplasty (THA). To elicit a training effect, interventions must be performed at sufficient doses (frequency, intensity, time, type) as recommended by the American College of Sports Medicine (ACSM). Evaluating the quality of primary studies' interventions is not part of Cochrane review methodology. Yet, judging an intervention's likelihood of providing a training effect would inform the assessment of clinical heterogeneity and interpretation of results. Hoogeboom *et al.* developed a 9-item CONsensus on Therapeutic Exercise aNd Training (CONTENT) scale to assess the therapeutic validity (i.e., quality) of exercise interventions. Thus, the purpose of this study was to 1) assess the therapeutic validity of exercise interventions included in a systematic review of post-acute physical therapy after THA; and 2) determine if they meet ACSM guidelines.

Methods: The methodological quality and results of the Cochrane review were previously presented. This study included trials from the review that focused on exercise interventions. Two researchers (MW & SK) independently extracted data on ACSM exercise dose and overall duration, and applied the CONTENT scale to assess therapeutic validity. Each of the 9 items were rated 'yes' or 'no' and 'meeting' or 'not meeting' ACSM guidelines. Studies scoring ≥6 were considered to have high therapeutic validity. Disagreements between raters were resolved through discussion and a tie-breaker (DJ) when necessary. Frequency counts and proportions were calculated to determine the number of CONTENT and ACSM items met. We calculated Cohen's kappa (*k*) coefficient with 95% confidence intervals for individual and overall CONTENT items to determine strength of agreement between raters. Kappa coefficients ≥ 0.60 represented good agreement.

Results: Of the 14 trials in the Cochrane review, 11 were exercise interventions of strength training alone (n=3), neuromotor training alone (n=2), and both (n=6). Overall, there was substantial agreement between the 2 raters (*k* 0.71 [CI 0.56, 0.86]) with absolute agreement on 86 of 99 (87%) CONTENT items. Perfect agreement was obtained on items addressing patient selection and exercise intensity and lowest agreement (*k* 0.23 [CI 0.40, 0.86]) for exercise monitoring/progression. Two interventions were therapeutically valid (Table 1). No interventions met the ACSM criteria. The details most often missing were exercise type and intensity.

Table 1. Therapeutic validity scores and ACSM criteria met by each study

ACSM Criteria - Bolded letter means criteria met: **F**=frequency, **I**=intensity, **T**=timing, **T**=type, **D**=duration of intervention. *=intensity not applicable for neuromotor exercise.

Conclusion: This is one of the few analyses conducted to address therapeutic validity of exercise interventions. Post-THA exercise interventions have low therapeutic validity and fail to meet ACSM exercise prescription criteria for health benefits. The conclusions of individual trials, and our and other systematic reviews of THA exercise interventions should be interpreted with caution.

Hand Exercises Significantly Improved Activity Performance, Grip Strength and Pain In Women With Hand Osteoarthritis - Results From a Randomised Controlled Trial. Toril Hennig[1], Liv Haehre[1], Vivian Tryving Hornburg[1], Petter Mowinckel[2], Ellen Sauar Norli[1] and Ingvild Kjeken[2]. [1]Martina Hansens Hospital, Gjettum, Norway, [2]Diakonhjemmet Hospital, Oslo, Norway.

Background/Purpose: Even if hand exercises is regarded as a core treatment for individuals with hand osteoarthritis (HOA), the evidence for the effect is limited. The main aim of this study, therefore, was to evaluate the effect of a hand exercise program in women with HOA.

Methods: In this observer blinded, randomised controlled trial ((ISRTCN79019063), 40 women with HOA received information and instruction in hand exercises (E-group), and 40 women received information only (control (C)-group). The exercise program followed the American College of Sports Medicine recommendations for developing muscular strength and flexibility in older frail adults, and included a warm-up period, two exercises to maintain/increase flexibility of the MCP, PIP and DIP joints, one exercise to strengthen the thumb extensors and abductors to maintain thumb web space and increase thumb stability, one exercise to increase grip strength, and a stretching exercise to prevent thumb adduction deformities. E-group participants recorded date, duration of the exercise session and pain following exercising in a diary, and received eight follow-up telephone calls during the three month study period.

Primary outcome was activity performance measured by the Patient Specific Functional Scale (PSFS) on a 0–10 scale (10=good performance). Secondary outcomes included measures of grip strength, joint mobility, thumb web space, pain, disease activity, stiffness and fatigue. Analysis of covariance was used to estimate between group differences at three months follow-up, with scores at three months as dependent variable, taking baseline values as covariates.

Results: Seventyone participants (mean age 60.8, SD 7.0) completed all assessments. Median number (min, max) of exercise sessions in the E-group in the study period was 37 (26, 43), and median time used pr session was 23.6 minutes (10.4, 42.0).Hand exercises was associated with significant improvement in the PSFS score (adjusted mean difference in change between groups 1.4, p<0.001).Concerning secondary outcomes, hand exercises significantly predicted improvement in fatigue, (mean adjusted differences in change between groups −1.1, p=0.05), in joint pain (−1.1, p=0.02), in grip strength in right (53.5 N, p<0.001) and left (44.6 N, p<0.001) hand, in thumb web

space of the right (0.6, p=0.018) and left (0.7, p=0.007) hand, and in the FIHOA activity performance score (−3.2, p<0.001).

While measures of joint mobility in general were stable in the E-group, there was a trend towards deterioration in the C-group, with a significant increase in flexion deficit of 5.4 mm in the right hand (p=0.009).

Conclusion: Hand exercises is well tolerated and significantly improves activity performance, grip strength and pain in women with HOA.

2096

Impaired Shoulder-Arm Mobility and Muscle Function In Patients With Systemic Sclerosis. Helene Alexanderson[1], Fia Bringby[2], Annica Nordin[3], Lena Björnådal[3], Elisabet Svenungsson[4] and Carina Boström[5]. [1]Division of Physiotherapy, Karolinska Institutet, Huddinge, Stockholm, Sweden, [2]Capio Arthro Clinic, Stockholm, Sweden, [3]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [4]Karolinska Institutet, Stockholm, Sweden, [5]Division of Physiotherapy, Karolinska Institutet Huddinge, Stockholm, Sweden.

Background/Purpose: Patients with systemic sclerosis (SSc) have reduced hand function and self-reported limitations in daily activities. Few studies have explored limitations in shoulder-arm mobility and muscle function, or if there are differences in physical function between diffuse cutaneous (dcSSc) and limited cutaneous (lcSSc) SSc. The purpose of this study was to describe objectively assessed shoulder-arm mobility, lower extremity muscle function and muscle endurance in SSc and evaluate possible differences between lcSSc and dcSSc.

Methods: 121 consecutive patients with Systemic sclerosis were included in this cross sectional study. Shoulder-arm mobility were examined using the Shoulder Function Assessment Scale (SFA) including 5 tasks (each task scored between 1–6 with maximum score 30, where 6 and 30 = no limitation), lower extremity muscle function was measured by Timed stands test (TST) and muscle endurance in shoulder- and hip flexors were assessed by the Functional Index 2 (FI-2) (maximal number of repetitions, 60 = 100%).

Results: Mean age was 61 (SD + 16) years, 83% were female, and median disease duration was 9 Q1-Q3 (4–15) years. 96 patients had lcSSc and 25 had dcSSc. The SFA score in the whole patient group were 27 (25–29) and 28 (26–29) on the right and left side respectively. Patients with dcSSc had median SFA "hand to back" score 5 (4–6) and median "hand to seat" score of 5 (4–6) compared to patients with lcSSc with corresponding median values of 6 (4–6) and 6 (5–6) respectively (p<0.01-p<0.05). 50% of both patients with lcSSc and patients with dcSSc had lower muscle function assessed by the TST compared to age- and gender matched reference values but there were no differences in TST between the two patient groups. There was also no difference in FI-2 scores between dcSSc and lcSSc. The whole group had 40 (28–83) % and 38 (32–72) % of maximal FI-2 shoulder flexion score on the right and left sides, and 40 (23–63) % and 37 (23–62) % of maximal FI-2 hip flexion score on the right and left sides. Preliminary reference values for the FI-2 indicate that healthy individuals aged 40–65 years perform in mean 100 % of maximal score with a range of 50–100%.

Conclusion: Patients with SSc have mild limitations in shoulder-arm mobility, although patients with dcSSc were more limited in specific tasks than patients with lcSSc. Patients with SSc have reduced muscle function compared to reference values. These results highlights the importance of assessing shoulder-arm mobility and muscle function as well as a need for further research to identify exercise interventions to target these limitations.

Evaluation Of An Advanced Practice Physiotherapist Role in Rheumatology. Chandra Farrer. University of Toronto, Toronto, ON.

Background/Purpose: Arthritis affects 4.6 million Canadians and is the leading cause of disability in Canada. Many Canadians do not have access to a family physician. There are currently 353 rheumatologists practicing in Canada. Of these, 44% are 55 and older. The need for arthritis care in Canada, in the context of limited health human resources, has led to evolving models of care. Extended practice roles for physiotherapists, occupational therapists and nurses have been implemented to address access to care and wait times and thereby decrease the burden of illness. Within our setting, the Advanced Practice Physiotherapist role has expanded to ordering x-rays, laboratory tests and more recently to intra-articular joint injections of the knee and shoulder. The purpose of this study is to evaluate the impact of the Advanced Practice Physiotherapist role in Rheumatology clinics.

Methods: Patient Volumes, wait times, and diagnosis information was collected from April 2009 using patient service information. Volumes of patients, seen by the Advanced Practice Physiotherapist, requiring x-ray, laboratory tests and intra-articular joint injection were also collected. Patient satisfaction was collected from April 2009-Sept 2009 on consecutive patients.

Results: The Advanced Practice Physiotherapist had 1711 total patient visits. Wait times in the clinic have trended downward, while overall clinic volumes have remained stable. Diagnosis classification are: Osteoarthritis (40.33%), Inflammatory Arthritis (37.58%), non-articular rheumatism (14.32%), other (4.32%) and chronic pain (3.51%).Patient's reported being "extremely satisfied" or "very satisfied" with the Advanced Practice Physiotherapist skills/knowledge, recommendations for care, explanation of assessment results and answers given to questions. Intra-articular joint injections have been required for 7.89% of visits, laboratory tests 23.38% of visits and x-rays 16.19% of visits.

Conclusion: The Advanced Practice Physiotherapist role has evolved since April 2009 by gradually expanding the scope of practice to ordering x-rays, laboratory tests and more recently intra-articular joint injections. There has been a positive trend towards decreasing wait times while maintaining overall Rheumatology clinic volumes. Patient satisfaction with the role has been high. Further research is needed to demonstrate efficacy of intra-articular joint injections performed by the advanced practice physiotherapist as this is a new endeavour for our clinic. Cost effectiveness and efficiency of the model need to be addressed in future.

What Elements Of Physical Therapy Interventions Contribute To Improved Outcomes Following Total Knee Arthroplasty. Joshua K Johnson[1], Traci E DeWan[1], Kelly L Donahue[1], Wenjun Li[2], Patricia D. Franklin[2] and Carol A. Oatis[1]. [1]Arcadia University, Glenside, PA, [2]University of Massachusetts Medical School, Worcester, MA.

Background/Purpose: Functional outcomes are variable among patients following total knee arthroplasty (TKA). Evidence is lacking to support best practices in rehabilitation to optimize functional outcomes. The purpose of this research was to determine associations of post-operative function defined by standardized patient report and objective PT evaluation with timing, amount, and content of physical therapy (PT) services in TKA patients.

Methods: We requested 142 and received 91 outpatient (OP) and 27 home care (HC) PT records for patients participating in a randomized behavioral trial for patients who had received a unilateral primary TKA, had completed the 6-month study assessment and their post-TKA PT rehabilitation. PT researchers performed a retrospective review of PT intervention data from 37 facilities, recording intervention type, frequency and dosage data for each subject during their terminal course of PT services. Performance outcomes measured at 6 month post TKA included flexion range of motion (ROM), timed stair climb (TSC) and WOMAC physical function (PF). Linear regression models assessed associations between PT intervention frequency and content (i.e., open and closed chain (CC) exercises and progressions) and 6 month outcomes, with and without adjusting for gender, age, baseline physical component score of SF-36, WOMAC PF, and number of comorbid conditions.

Results: 91 records, including 74 (81%) OP and 17 (19%) HC from 37 facilities, contained complete exercise information. Number of PT interventions, number of CC interventions and progressions and number of CC exercises per visit were associated with improved TSC (p <.05) with coefficients ranging from -.45 to -.99. Number of CC progressions was also associated with improved ROM (1.41; p<.01). Earlier initiation of OC exercises was associated with improved WOMAC PF scores. Adjusted coefficients revealed similar associations between the number of progressions of CC exercises and improved TSC (p <.05) and knee flexion ROM (p <.01), between number of CC exercises per PT visit and ROM and between OC exercises and WOMAC PF. Number of PT visits did not predict outcomes. An increased number of passive interventions predicted poorer ROM outcomes (p <.01).

Conclusion: Preliminary data suggest that the number and progressions of CC exercises used per visit and over the episode of care contribute to improved objective performance outcomes following TKA. Timing of exercise initiation contributes to improved patient-reported outcomes. Content, dosage and timing of PT exercises rather than number of visits appear to be predictive of performance outcomes. Further research is needed to clarify the role of PT content, dosage and intensity in optimizing functional outcomes following TKA.

Global Postural Reeducation To TREAT Chronic LOW Back PAIN: Randomized, Controlled Trial. Priscila Almeida Lawand[1], Imperio Lombardi Jr[2], Carla Caires Sardim[1], Luiza H. C. Ribeiro[1], Anamaria Jones[1] and Jamil Natour[3]. [1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [2]Universidade Federal de Sao Paulo, Santos, Brazil, [3]Universidade Federal de São Paulo, São Paulo, Brazil.

Background/Purpose: Low back pain (LBP) is a major cause of physical limitations and absenteeism at work throughout the world. A number of studies have demonstrated the effectiveness of therapeutic exercises on reducing pain symptoms and improving function in patients with chronic LBP. Global Postural Reeducation (GPR) technique theoretically consists of a reestablishment of the balance in the myofascial tension of different chains of muscles. GPR is based on the notion that a shortened muscle creates compensations in other proximal or distal muscles. One systematic review assessed the use of GPR for different conditions of the musculoskeletal system and found only one RCT that demonstrated a significant improvement in functional capacity in patients with ankylosing spondylitis. However, there are no previous randomized, controlled, clinical trials assessing the effectiveness of GPR on chronic LBP. The purpose of this study were to assess the effectiveness of global postural reeducation (GPR) on pain, function, quality of life and depressive symptoms in patients with chronic LBP.

Methods: Sixty-one patients with chronic LBP were randomly allocated to either the GPR group or a control group. Patients in the GPR group underwent one weekly 60-minute session of GPR for a period of 12 weeks. The control group remained on the waiting list under clinical treatment, with no physical intervention. Pain, function capacity, quality of life and depressive symptoms were assessed using a visual analog scale (VAS), the Roland-Morris questionnaire (RMQ), the Medical Outcomes Study Short-Form 36-Item Health Survey (SF-36) and the Beck Inventory, respectively. The evaluations were performed by a blinded examiner at baseline, three months and six months after the initial evaluation and the data were analysis using an intention to treat approach.

Results: The GPR group demonstrated significant improvements in pain ($p<0.001$) and function ($p<0.001$) as well as the domains: pain ($p=0.047$), emotional aspects ($p=0.008$), limitation in physical functioning ($p=0.040$), vitality ($p=0.003$) and mental health ($p=0.034$) of the SF-36.

Conclusion: Based on the findings, GPR proved to be effective regarding pain, function and some domains of quality of life in chronic LBP patients.

A Scoping Review On Leisure Activity Expectations After Total Hip Or Knee Arthroplasty Due To Arthritis. Dina L. Jones and Nirupama Semmalidinne. West Virginia University, Morgantown, WV.

Background/Purpose: It is important that patient expectations are met after total hip (THA) or knee (TKA) arthroplasty in order to maximize outcomes and satisfaction. Although patients state that return to leisure activities is a priority, few studies have focused on their expectations for return to these activities. We conducted a scoping review to determine: 1) the types of studies that have been conducted on leisure activity expectations after THA/TKA, 2) how expectations have been measured, 3) if expectations are met, and 4) if expectations can be modified.

Methods: Scoping reviews are used to determine the extent, range, and nature of the scientific literature when experimental studies are lacking. This review was conducted using the 6-stage framework of Arksey and O'Malley (identify research question, identify relevant studies, select studies, chart data, report results, and consultation). The review included cohort and experimental studies of patients, aged 18 years or more, who received primary THA/TKA due to arthritis, and included a pre-operative assessment of leisure activity expectations and data on if they were met or modified. Electronic database searches (e.g., MEDLINE, CINAHL) were conducted by a medical librarian. The studies were independently screened for eligibility by 2 researchers during 3 rounds of review (title, abstract, and full-text). A descriptive analytical method was used to summarize the data according to published methods. Cohen's kappa coefficient with 95% CI was used to determine inter-rater agreement.

Results: Of the 242 articles identified, 169 titles, 60 abstracts, and 15 full-text articles were screened for eligibility. The rater agreement for each round was 0.47 (CI 0.32, 0.63), 0.61 (CI 0.35, 0.86), and 1.0 (CI 1, 1), respectively. The review included 5 studies. Four studies used a cohort design to determine if expectations were met after surgery (follow-up between 1 and 5 years). Only 1 randomized controlled trial attempted to modify expectations prior to surgery using an educational class with hip- or knee-specific information. Expectations were measured by questionnaire (self- or phone-administered) and presented as an overall score (summation of Likert scale responses) or in MET-hours per week. Only 1 study measured the expected dose (frequency, intensity, time, type) of activity. Expectations exceeded post-operative ability at 5 years in 1 study, and were not met in another. Two studies estimated that expectations were met in 10% to 43% of patients. The randomized controlled trial reported that expectations could be modified.

Conclusion: This scoping review demonstrated that few studies focused on patient expectations for leisure activity after THA/TKA, and even fewer attempted to modify expectations. Expectations were not consistently met, but they are capable of being modified. Future studies should assess the expected dose of activity that patients expect to achieve to ensure that they will be active enough to maintain health. More studies are needed to test educational interventions in patients undergoing joint replacement. Educating patients about appropriate activity expectations could improve the health and activity levels of this population.

Barriers To Improving Physical Activity In Patients With Systemic Lupus Erythematosus: The Activity and Nutrition Trial In Lupus To Energize and Renew (ANTLER) Pilot Study. Linda S. Ehrlich-Jones[1], Grace E. Ahn[2], Christine Pellegrini[3] and Rosalind Ramsey-Goldman[3]. [1]Rehabilitation Institute Chicago, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Northwestern University Feinberg School of Medicine, Chicago, IL.

Background/Purpose: Current literature indicates that exercise is safe and effective in improving fatigue, depression, aerobic capacity, and health-related quality of life in systemic lupus erythematosus (SLE). Only 28% of SLE patients self-report that they meet the US government public health goal of at least 150 minutes/week of moderate to vigorous intensity physical activity (PA). Some barriers to PA for patients with SLE include fatigue, exposure to sunlight, pain, depression, sleep disturbance and hematologic and bony abnormalities predisposing to bleeding and fracture. We assessed barriers to PA as well as goals to improving PA before and after a behavioral intervention in a group of patients with SLE.

Methods: In a mixed-methods pilot study of 8 SLE adults, we identified barriers to increasing their PA using the Arthritis Comprehensive Treatment Assessment. In addition, we identified goals they would like to achieve over the next 6 weeks to increase their PA. All participants completed the Motives for Physical Activity Measure-Revised (MPAM-R), a questionnaire to assess the strength of five motives for participating in PA, at baseline and completion of the study. Individual coaching sessions were held at baseline and 6 weeks with a healthy lifestyle coach (exercise physiologist or occupational therapist) to review their barriers to PA and the achievement of their goals at the end of the study. Participants were also offered 3 group educational sessions highlighting PA, healthy nutrition and motivation to behavior change.

Results: The sample consisted of 6 women and 2 men, mean age 47 years (SD=7.75) and included 50% African-American, Asian and Caucasian (25% each). Sixty-two percent were married. At baseline, 8 participants participated in an individual coaching session; 7 completed the 3 group educational sessions and the individual session at the end of the study. At the baseline visit, 6 participants identified feeling tired or

washed out, 5 identified motivation and 4 identified pain as barriers to doing PA. PA goals included: going to the gym (treadmill, elliptical, swimming and strength training), doing yoga or Zumba classes. Post-intervention, 4 participants stated an increase in their level of satisfaction with their PA. Fatigue, pain and motivation continued to be barriers to increasing PA. Mean MPAM-R subscale change scores for enjoyment (4.01), social (2.18), and appearance (1.56), all increased post-intervention, while change scores for competence (−0.48) and fitness (−0.57) remained relatively the same.

Conclusion: Fatigue, pain and motivation appear to be the most common barriers to increasing PA in this pilot study. Enjoyment, appearance and social motives for PA appeared to increase post intervention. A larger clinical trial is needed to confirm these findings.

The Effect Of a Novel System Of Insoles Using Styrene Foam Beads On Foot Deformities In RA Patients. Yoshitada Sakai[1], Akira Hashiramoto[2], Yoshiko Kawasaki[2], Takaichi Okano[2], Takahiro Takeda[3], Naomi Yagi[3] and Yutaka Hata[3]. [1]Kobe University Graduate School of Medicine, Kobe, Japan, [2]Kobe University Hospital, Kobe, Japan, [3]Graduate School of Engineering, University of Hyogo, Himeji, Japan.

Background/Purpose: Foot deformities in RA patients decrease their ADL and QOL because of pain and corns.

Custom-made insoles are often prescribed for the patients with these deformities, however, the effect of these is not enough, because of their difficulties of casting and adaptation. Previous study showed that casting by footprint has the difficulty of the reflection of the plantar pressure change by foot motion at walk.

Therefore, we developed a novel system of insoles using styrene foam beads for deformities of foot, and analyzed the gait of the RA patients with foot deformities wearing our novel insoles.

Methods: Eight RA patients (all females, average age: 65.1±8.4 years old) with foot deformities were enrolled in this study. All patients met the classification criteria of the American College of Rheumatology 1987 or the 2010 rheumatoid arthritis classification criteria.

The novel insoles were made by styrene foam beads, deaerated by pressure, and memorize the plantar shapes (Tatsuno Cork Kogyo Co., Ltd, Tatsuno, Japan).

The novel insoles were inserted into slippers (Grizzly Michel, HAFLINGER, Goslar, Germany).

We compared their gaits with bare feet, our novel insoles or low rebound slippers (DAISO Industries Co., Ltd., Saijo, Japan) using a mat type load distribution sensor (Allow industry, Japan).

The parameters of our analysis were visual analog scale (VAS) of the general gait impression (including pain and ease to walk, best: 0mm, worst: 100mm), gait speed, step length, width of center of gravity during gait, and max load of sole pressure. Gate parameter data were converted %Bare-feet, and statistical analysis were performed using Kruskal-Wallis test.

Results: The data of VAS during their gaits and max load of sole pressure were significantly decreased by using the our novel insoles compared with bare feet (Bare-feet 64.6±28.6, Low rebound slippers(LRS) 48.3±25.7, Our insole 18.1±12.5). The data of gait speed, step length and max load of sole pressure were significantly increased compared with bare feet (Step length: Bare 100%, LRS 109.0±0.1%, Ours 109.8±0.1%. Gait Speed: Bare 100% LRS 106.0±0.1%, Ours: 107.1±0.1% Max load: Bare 100%, LRS 55.8±0.1, Ours 51.1±0.1%). The width of center of gravity during gait was significantly decreased by using the novel insole compared with low rebound slippers (Bare100%, LRS 109.0±0.1%, Ours 95.5±0.1%).

Conclusion: In this study, we investigated the gait analysis of RA patients with foot deformity and pain using our novel insoles. The gait parameters were improved using our insoles, and pain is decreased. In addition, from the comparison of low rebound slippers, our insole could contribute the compatibility of gait stability and reducing pain.

The limitation of this study is no investigation of the long time follow up and the durability of insoles.

Our novel insoles may be useful for the treatment of foot deformities in RA patients.

Relationships Between Self-Efficacy, Outcome Expectancy, and Outcomes In Older Adults With Osteoarthritis Of The Knee and Hypertension: Baseline Results. Elizabeth A. Schlenk, Deborah Crowley-Lisowski, Sarah Twerski, Alice Fallon, Alyssa Sartore, Susan Sereika, Joan Rogers, G. Kelley Fitzgerald and C. Kent Kwoh. University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Staying Active with Arthritis (STAR), an intervention guided by Bandura's Self-Efficacy Theory, is being investigated in an ongoing clinical trial of an individually delivered, home-based, 6-month lower extremity exercise and fitness walking program with older adults with osteoarthritis of the knee and hypertension treated with anti-hypertensive medication. We hypothesized that at baseline, self-efficacy and outcome expectancy (perceived therapeutic efficacy) would be related to relevant outcomes being measured in the STAR Study.

Methods: A descriptive correlational design was used for this study (N=107). Belief measures included McAuley's Self-Efficacy Scales for Exercise and Barriers to Exercise; Lorig's Arthritis Self-Efficacy Scales for Pain, Function, and Other Symptoms; and Perceived Therapeutic Efficacy Scale for arthritis (PTES-A) and hypertension (PTES-H). Outcome measures included systolic (SBP) and diastolic (DBP) blood pressure; 6-minute walk; Short Physical Performance Battery (SPPB); WOMAC Scales for Knee Function and Pain; SF36 Bodily Pain (BP) Scale, Physical Component Score (PCS), and Mental Component Score (MCS); Brief Fatigue Inventory (BFI); and quadriceps strength (QS) by MicroFET2 dynamometer. Multiple regression analyses were performed to identify significant independent predictors of the outcomes. Significance level was set at.05.

Results: Participants were on average 65 (SD=8) years of age, 73% (n=78) female, 76% (n=81) white, 42% (n=45) married, and 47% (n=50) employed, with 77% (n=81) having more than a high school education and 54% (n=48) having a family income <$50,000. There were no significant group differences in demographics or outcomes so the intervention and attention control groups were combined. Multiple regression analyses found that Exercise Self-Efficacy predicted 6-minute walk (p=.038) and SPPB (p=.022). Arthritis Self-Efficacy Pain was related to SBP (p=.002) and DBP (p=.001). Arthritis Self-Efficacy Function was predictive of DBP (p=.015), 6-minute walk (p<.0001), SPPB (p<.0001), PCS (p=.003), MCS (p=.021), and right (p=.030) and left (p=.020) knee QS. Arthritis Self-Efficacy Other Symptoms was associated with SBP (p=.032), DBP (p=.001), WOMAC Function (p=.008), WOMAC Pain (p=.023), SF-36 BP (p=.021), MCS (p<.0001), and BFI (p=.008). PTES-A predicted SBP (p=.031), WOMAC Function (p=.028), and WOMAC Pain (p=.035). PTES-H was related to WOMAC Pain (p=.019).

Conclusion: At baseline, Exercise Self-Efficacy predicted performance-based functional status as anticipated. Arthritis Self-Efficacy Pain was positively related to SBP and DBP, contrary to expectation. Arthritis Self-Efficacy Function and Other Symptoms predicted most outcomes in expected directions. Outcome expectancy predicted fewer outcomes. Future plans include examining the effect of the STAR intervention on self-efficacy and outcome expectancy and the extent to which self-efficacy and outcome expectancy act as mediators between the STAR intervention and outcomes.

2104

Exercise For Ankylosing Spondylitis: It's Still Important. Janet Millner[1], John Barron[2], Kirsty Beinke[3], Rachael Butterworth[4], Briony Chasle[5], Lindsay Dutton[6], Margaret Lewington[7], Errol Lim[4], Tony Morley[8], Jennie O'Reilly[9], Kathryn Pickering[10] and Jane Zochling[1]. [1]Menzies Research Institute Tasmania, Hobart, Australia, [2]Eastwood Physiotherapy, Adelaide, Australia, [3]Adelaide West Pilates Physiotherapy, Adelaide, Australia, [4]BJC Health, Sydney, Australia, [5]South East Sydney Area Health Service, Sydney, Australia, [6]Royal Perth Hospital, Perth, Australia, [7]Hydrohealth, Brisbane, Australia, [8]Physio Plus, Lismore, Australia, [9]Physiotherapy, Melbourne, Australia, [10]Curtin University, Perth, Australia.

Background/Purpose: Previous systematic reviews [1] and international consensus [2] have agreed that exercise is beneficial in ankylosing spondylitis (AS), and this concept is widely supported by patient groups.

However, there is a paucity of information to guide exercise prescription. There is a need for more information about different types of exercise, how long, to what intensity and how often it should be performed for maximal improvement. Results from studies on spa therapy and hospital in-patients may not be directly transferrable to other countries where most exercise therapy is prescribed on an outpatient basis. Finally, improvements in disease management with biological medication have raised questions about the relevance of exercise as a core component of management. This collaborative project, combining evidence with expertise, was therefore established to develop practical recommendations to guide Australian exercise prescription for individuals with AS.

Methods: Ten Physiotherapists participated in discussion rounds, to determine a set of eight key topic areas, using modified Delphi methodology. A systematic literature review was conducted for each topic, and a range of evidence analysed for level, quality and relevance to the clinical question and local setting. Ten recommendations were developed, based on the integration of available evidence and expert opinion. The importance of the recommendations was validated by surveying both patient and health professional groups.

Results: A total of 202 papers were allocated to the key topic areas, the majority being surveys, cohort and case-controlled studies. Effect sizes were calculated for 20 randomised controlled trials, the range being 0.12–4.96. Exercise recommendations were developed for the following areas: assessment/evaluation; monitoring of exercise prescription; safety; biological therapy; ankylosing spondylitis-specific exercise; physical activity levels; setting; dosage and compliance. The average Strength of Recommendation was 9.0/10 (range 8.79–9.3) for patients and 9.5/10 (range 9.2–9.8) for health professionals. Valuable patient feedback was obtained regarding the relationship between health professional assessment / monitoring and compliance/ dosage.

Conclusion: Although insufficient evidence was found to recommend one type of exercise over another, the group concluded that other factors, such as targeted exercise, safety, dosage and compliance were of equal priority, and that exercise prescription remains important (and is additive) for those patients also receiving biological therapy. Widespread dissemination of the recommendations will support appropriate exercise prescription as a key component for optimal patient outcomes.

Differences In Spinal Mobility Measures In Relation To Disease Duration and Between Subgroups With Axial Spondyloarthritis.

Elisabeth A. Mogard[1], Elisabet Lindqvist[1], Stefan Bergman[2] and Ann B. I. Bremander[1]. [1]Lund University, Lund, Sweden, [2]Spenshult Research and Development Center, Halmstad, Sweden.

Background/Purpose: Spinal mobility is a core domain for research and clinical practice in Ankylosing Spondylitis (AS) but less studied in undifferentiated SpA (USpA). Our objective was to study the change of commonly used spinal mobility measures stratified on disease duration in patients with AS and differences in these measures in AS vs. USpA.

Methods: Patients with AS or USpA were identified from a cohort attending a specialist clinic. A cross sectional studie were the first measures of spinal mobility for each patient recorded during 1999 to 2012 were analyzed. Disease duration was split into tertiles, (<17 years (G1), 18–30 years (G2) and >31 years (G3)). Differences between AS G1/G2/G3 were calculated with Kruskal-Wallis. Differences between AS and USpA were controlled for sex and disease duration (ANCOVA).

Results: 126 patients with AS vs. 57 with USpA were included in the study, mean (SD) age 48.4 (13.7) vs. 41.6 (11.4) years and 23% vs. 46% were women. In AS, lumbar, and thoracic measures, vital capacity and the BASMI composite score were the first measures to deteriorate in relation to disease duration (G1 vs. G2, $p<0.035$). Late in the disease all measures had deteriorated (G1 vs. G3, $p<0.036$). Patients with USpA presented better scores in lumbar, hip and thoracic spinal measures ($p<0.05$), data controlled for sex and disease duration. In early disease (<17 years) also cervical measures ($p<0.05$) were less affected compared to patients with AS.

Conclusion: The first measures to significantly change during the disease course in AS were the lumbar and thoracic mobility measures and the BASMI score. As expected, patients with USpA were less affected in mobility than patients with AS.

Aquatic Exercise Training For Fibromyalgia: A Systematic Review.

Julia Bidonde[1], Angela J. Busch[1], Sandra Webber[2], Candice Schachter[1], Adrienne Danyliw[3], Tom Overend[4], Rachel Richards[5] and Tamara Rader[6]. [1]University of Saskatchewan, Saskatoon, SK, [2]University of Manitoba, Winnipeg, MB, [3]Health Quality Council, Saskatoon, SK, [4]Western Universtiy, London, ON, [5]North Shore Sports Medicine Clinic, North Vancouver, BC, [6]University of Ottawa, Ottawa, ON.

Background/Purpose: Fibromyalgia (FM) is a chronic pain condition leading to reduced physical function. Exercise training is recommended for people with FM. We examined randomized controlled trials (RCTs) to evaluate benefits and harms of aquatic exercise training (AQ) in adults with FM.

Methods: We searched 9 electronic databases. Selection criteria included full text publication of an RCT of AQ for adults diagnosed with FM, and provision of between-group outcome data. Studies were excluded if exercise in water was <50% of the full intervention. Pairs of reviewers independently screened and selected articles, assessed risk of bias, and extracted data on 24 outcomes in 4 domains: wellness, symptoms, physical fitness and adverse effects. Discordance was resolved through discussion. Benefits and harms of the interventions were evaluated using standardized mean differences (SMD) and 95% CI, with meta-analysis carried out when applicable.

Results: We screened 1856 citations, 766 abstracts, and 156 full-text articles. Fourteen RCTs examined AQ with a total of 820 participants. AQ was compared to control (9 studies) and to land exercise (5 studies). Risk of bias was rated low for randomization, incomplete outcome data, selective reporting, other bias, and blinding of outcome assessors. Allocation concealment, and blinding of participants and care providers were rated as unclear or high risk. Differences (SMD [95% CI]) between the AQ vs control were: multidimensional function −0.55 [−0.83, −0.27], self-reported physical function −0.44 [−0.76, −0.11], pain −0.53 [−0.76, −0.31], stiffness −1.08 [−2.05, −0.11], strength 0.63 [0.20, 1.05], and cardiovascular submaximal function 0.56 [0.27, 0.85] all favouring AQ ($p < 0.05$). Attrition was similar in AQ and control groups. Adverse effects were poorly reported, with no serious adverse effects reported. Differences (SMD [95%CI] for AQ compared to land exercise were: strength −0.74 [−1.44, −0.04] favoring land, and sleep −0.75 [−1.32, −0.17] favoring AQ. Older participants with longer disease duration and less pain/impact of disease at baseline responded better to AQ than their counterparts. Greater exercise frequency, accumulated pool time, and length of program were also associated with better results

Conclusion: Low to moderate quality evidence suggests that AQ is beneficial for improving wellness, symptoms and fitness and that no serious adverse effects result from the intervention. Very low to moderate quality evidence suggests that there are no differences in benefits between AQ and land exercise except in muscle strength (evidence favoring land) and sleep (one study favoring aquatic).

Disclosure: J. Bidonde, None; **A. J. Busch**, None; **S. Webber**, None; **C. Schachter**, None; **A. Danyliw**, None; **T. Overend**, None; **R. Richards**, None; **T. Rader**, None.

Benefitial Effects Of a Simple Stretching Exercise Program For Patients With Ankylosing Spondylitis: A Randomized Controlled Trial.

Andréa L. Gallinaro[1], Carla G.S. Saad[1], Claudia Goldenstein-Schainberg[1], Percival D sampaio-Barros[1], Julio C. B. Moraes[1], Hamilton Roschel[2], Ana Lucia S. Pinto[1] and Celio R. Gonçalves[1]. [1]Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [2]Universidade de São Paulo, Faculdade de Educação Física e Esporte, São Paulo, Brazil.

Background/Purpose: Static and dynamic stretching exercises are applied in Ankylosing Spondylitis (AS) patients to preserve and restore

the axial mobility. However, there are no data regarding a specific rehabilitation program including solely stretching in patients with low/moderate disease activity. We, therefore, assessed the efficacy of a stretching program on mobility, functional capacity and disease activity of AS patients.

Methods: Forty sedentary AS patients with low/moderate disease activity according to Ankylosing Spondylitis Disease Activity Scores (ASDAS <2.1) and with stable medication during at least 3 months prior to study entry were included. AS patients were randomly assigned to receive a simple stretching supervised exercise program or no exercise (control group). Exercise group sessions were performed twice a week, for sixteen weeks. This supervised program comprised of 30 minutes of outdoor dynamic and static stretching exercises for the spine and limbs, using only a chair. Mobility, disease activity and functional capacity parameters were evaluated blinded for treatment, at baseline and after 16 weeks.

Results: At study entry patients had mean ± SD age of 47.1 ± 11.5 years, mean disease duration of 17.6 ± 10 years and mean BASMI of 4.7 ± 2.1. All patients were receiving anti-inflammatory drugs and 30% were using anti-TNF therapy. Thirty nine AS patients completed this trial. Patient's attendance of 14.8 ± 8.3 sessions was registered. Comparing baseline to 16 weeks, the exercise group presented significant improvement in mobility dimensions such as Pavelka's trunk rotation [1.4 (0.9) vs. 2.2 (1.8) cm, $p=0.03$], cervical rotation [43.9 (23.5) vs. 53.9 (22.3) degrees, $p=0.012$], tragus-coronoid distance [12.2 (3.7) vs. 9.3 (2.0) cm, $p=0.0001$], mento-coronoid distance [13.7 (5.4) vs. 9.6 (2.3) cm, $p=0.03$], minor intermaleolar distance [0.9 (1.3) vs. 0.2 (0.5) cm, $p=0.01$] and trunk lateral flexion [7.5 (5.1) vs. 9.5 (5.7) cm, $p=0.03$]. Exercise group also had improvement in total BASMI ($p=0.004$). In contrast, comparing control group at baseline vs. 16 weeks, no difference was observed in all mobility parameters assessed and a significant worsening was observed in BASFI ($p=0.02$), BAS-G ($p=0.006$) and ASDAS ($p=0.03$).

Conclusion: Our findings provide novel evidence that a simple stretching program has a significant beneficial mobility effects on AS patients with long disease duration and low/moderate disease activity (ClinicalTrials.gov, number NCT01690273).

2108

Pre- and Postoperative Physical Therapy In Total Hip and Knee Replacement Surgery: A Multi Center Study. Wilfred FH Peter[1], Claire Tilbury[2], Rutger Tordoir[3], Suzan Verdegaal[3], Ron Onstenk[4], Menno Benard[5], Stephan Vehmeijer[5], Enrike van der Linden-van der Zwaag[2], Eric Vermeulen[2], Rob Nelissen[2] and Thea Vliet Vlieland[6]. [1]Reade, center for rehabilitation and rheumatology, Amsterdam, Nicaragua, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Rijnland Hospital, Leiderdorp, Netherlands, [4]Het Groene Hart Hospital, Gouda, Netherlands, [5]Reinier de Graaf Hospital, Delft, Netherlands, [6]Leids University Medical Center, Leiden, Netherlands.

Background/Purpose: Physical therapy shown to be effective after Total Hip and Knee Arthroplasty. Less evidence is available for preoperative physical therapy in Total Hip and Knee. Little is known on what the actual characteristics, frequency and duration of physical therapy after Total Hip and Knee in daily practice are. The aim of the study was to describe the extent and content of pre- and postoperative physical therapy before and after Total Hip and Total Knee surgery.

Methods: To 1005 patients in 4 hospitals who received Total Hip and Knee in 2011 were sent a survey in 2012 regarding physical therapy (referral, setting, frequency, duration, content and satisfaction) before and after surgery, sociodemographic characteristics and health status.

Results: 522 patients (282 Total Hip en 240 Total Knee) responded (52%). 210 (40%) received preoperative physical therapy and 514 (98%) postoperative physical therapy (no differences between Total Hip en Total Knee). Total knee patients had significant higher average Body Mass Index, significant more co morbidity, and significant lower level of physical functioning compared with Total Hip patients.

More patients were referred by the orthopedic surgeon after surgery (77%) than before surgery (36%) and for Total Knee than for Total Hip. The most consistently reported exercise modalities ($>$ 60% of patients) were preoperatively aerobic exercise and walking stairs, and postoperatively aerobic exercises, muscle strengthening exercises, range of motion exercises, walking stairs, rising/sitting and gait training.

Both before and after surgery significant more Total Knee patients reported receiving strengthening exercises (55% before, 65% after) and passive Range of Motion exercises (51% before, 60% after) compared to Total Hip patients (32% before, 57% after and 36% before, 37% after, respectively).

Total Hip and Knee patients who received physical therapy in secondary care before physical therapy in primary care were older and had a lower level of physical functioning compared to patients who only received physical therapy in primary care.

Total Hip and Knee patients were more satisfied with physical therapy after than before surgery.

Conclusion: A considerable number of patients received physical therapy before Total Hip and Knee surgery. There is a great variation of provided treatment modalities after, but particularly before surgery. Differences between hip and knee patients were reported by patients. These results indicates that more research into the potential benefits of physical therapy for specific groups of patients undergoing Total Hip or Knee surgery and into effective treatment modalities is needed. Distinction should be made between hip and knee patients.

2109

Quality Indicators For Physical Therapy Management In Hip and Knee Osteoarthritis and Rheumatoid Arthritis. Wilfred FH Peter[1], Emalie Hurkmans[2], Philip van der Wees[3], Erik Hendriks[4], Rob de Bie[4], Leti van Bodegom-Vos[1] and Theodora P.M. Vliet Vlieland[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]University of Applied Sciences, Vienna, Austria, [3]Radboud University, Nijmegen, Netherlands, [4]University of Maastricht, Maastricht, Netherlands.

Background/Purpose: Physical therapy is recommended in several guidelines on the management of osteoarthritis and rheumatoid arthritis. Currently, no specific quality indicators for physical therapy in patients with Osteoarthritis and Rheumatoid Arthritis are available. The aim of this study was to develop quality indicators for the physical therapy management of patients with Osteoarthritis and Rheumatoid Arthritis.

Methods: The first concept quality indicators were derived from the recommendations included in two recent Dutch physical therapy evidence based practice guidelines for Osteoarthritis and Rheumatoid Arthritis, according to guidelines for the development of quality indicators.

Two multidisciplinary expert group (Osteoarthritis and Rheumatoid Arthritis) of 19 persons were composed containing patients; 1 patient representative from the Dutch Arthritis association; physical therapists; general practitioners; rheumatologists; orthopaedic surgeon; rehabilitation physician; occupational therapist; and researchers. Using Delphi rounds, the expert group could suggest other topics for the set of indicators, and then scored all topics with respect to relevance (score range 0=not at all relevant to 9=extremely relevant) and feasibility of measuring. Potential topics were selected if a score of >6 was obtained by $>75\%$ of the experts regarding aspect representing good quality of physical therapy care. Indicators with scores 5 or 6 were again entered into a Delphi round and selected for the final set based on comments of the expert arguments. Selected quality indicators were then combined and reformulated by the project group.

Results: In Osteoarthritis an initial set of 23 indicators were selected. Based on relevance score >6 eleven indicators were first selected. Based on experts' comments 3 indicators were rejected, and the remaining 9 indicators were partly combined and reformulated into 6 items, resulting in a final set of 17 indicators for physical therapy in Osteoarthritis.

For physical therapy in Rheumatoid Arthritis an initial set of 27 indicators were selected. Based on relevance sore > 6 ten indicators were first selected. After comments of the experts 3 items were rejected, and 14 items were partly combined and reformulated into 7 indicators for the final set, resulting in a final set of 17 quality indicators for physical therapy in Rheumatoid Arthritis.

Both quality indicator sets containing 16 process indicators (regarding initial assessment, treatment and evaluation) and one outcome indicator.

The majority of multidisciplinary experts in Osteoarthritis and Rheumatoid Arthritis stated the final indicators were measurable, and data should preferably conducted by consulting (electronic) patient files.

Conclusion: Two sets of 17 quality indicators for physical therapy management in Osteoarthritis and Rheumatoid Arthritis were developed and made suitable to measure quality of physical therapy care in daily clinical practice. The clinimetric properties reliability and discriminative power need to be investigated in future research.

2110

Who Will Achieve Individually Set Goals After Arthritis Team Rehabilitation? Sofia Hagel[1], Elisabet Lindqvist[1] and Ann B. I. Bremander[2]. [1]Lund University and Skåne University Hospital, Lund, Sweden, [2]Lund University, Lund, Sweden.

Background/Purpose: To study goal achievement among patients with chronic inflammatory arthritis after arthritis rehabilitation performed in multidisciplinary team rehabilitation programs.

Methods: 146 consecutive patients with rheumatoid arthritis (RA) and spondylarthritis (SpA), age 18 years or older, completing arthritis rehabilitation for 5 days or more at 2 rheumatology specialist units were included in this study. At admission and discharge the patients were evaluated with measures on functioning (HAQ), self efficacy (ASES), psychological health (Hopkins Symptom Checklist – HSCL-25), pain and fatigue (NRS) and on health related quality of life (HRQoL) as captured by the EQ-5D and the SF-36. Comorbidity and social demographics was also reported. The patients, in cooperation with the health professionals, set individual goals for their rehabilitation period. At discharge the patients reported if the goal was achieved completely, partially or not at all.

Non parametric statistical analyses were performed and Chi2 and Kruskal-Wallis analyses were used to study the relationship between goal achievement and baseline and change variables.

Results: 108/146 patients reported whether goals were achieved or not, and were included in further analyses. 76% were females and 55% had RA. At baseline median age was 54 years (IQR 17), median HAQ 0.88 (IQR 0.88), median HRQoL as captured by the EQ-5D 0.62 (IQR 0.57) and median psychological wellbeing according to HSCL-25 1.62 (IQR 0.68). The patients reported median fatigue 6.0 (IQR 4.0) and median pain 5.0 (IQR 3.0) when entering the rehabilitation program that lasted for median 18 days (IQR 2).

58/108 patients (54%) rated their goal to be completely achieved, 40 patients (37%) reported partial goal achievement while 10 (9%) patients had not achieved their goal. Positive reporting of having followed the recommendations (compliance) during the rehabilitation period was obtained from 100 (93%) of the patients.

Change after intervention and compliance did not affect reports of goal achievement after rehabilitation. Females reported goal achievement more often than men did ($p=0.019$). Those not achieving their goals reported less psychological wellbeing (HSCL-25, $p=0.011$) at admission together with reports of worse pain (SF-36bp, $p=0.011$).

Conclusion: 54% of the included patients reported complete goal achievement after arthritis team rehabilitation. Neither change after intervention nor compliance affected patients' reports of goal achievement. Female patients were more prone to achieve their goals while patients experiencing less psychological wellbeing or more pain at baseline were less prone to report goal achievement.

Disclosure: S. Hagel, None; **E. Lindqvist**, None; **A. B. I. Bremander**, None.

2111

The Impact Of Centralized Pain On Long-Term Analgesic Response To Lower Extremity Joint Arthroplasty: A Prospective, Observational Cohort Study. Chad M. Brummett[1], Andrew Urquhart[2], Brian Hallstrom[2], Alex Tsodikov[3], David A. Williams[4] and Daniel J. Clauw[5]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Michigan Health System, Ann Arbor, MI, [3]School of Public Health, University of Michigan, Ann Arbor, MI, [4]Univ of MI Hlth System-Lobby M, Ann Arbor, MI, [5]University of Michigan, Ann Arbor, MI.

Background/Purpose: In cross-sectional studies, depression and pain in other locations have been reported as predicting poorer outcomes following total knee and hip arthroplasty. These factors may be better explained by a common pathophysiology of aberrant central pain processing as is seen in conditions like fibromyalgia. We hypothesized that patients with altered central pain processing would be less likely to report pain improvement after lower extremity joint arthroplasty.

Methods: Patients were preoperatively phenotyped using validated self-reported, including the Brief Pain Inventory, PainDETECT, WOMAC, Hospital Anxiety and Depression Scale, Catastrophizing, health information (opioid use, ASA Status, BMI, primary anesthetic), and demographics. Participants also completed the American College of Rheumatology (ACR) survey criteria for fibromyalgia as a surrogate of centralized pain, which is a measure of widespread pain and an assessment of symptoms such as fatigue or trouble thinking. Patients were re-assessed using the same preoperative phenotype at 6-months postoperatively. Data were analyzed using R 2.15.2. A linear model was used to regress the change in pain responses at surgical site and overall on a set of covariates including the baseline pain value.

Results: 598 of the 851 patients approached agreed to participate (70.3%). A total of 454 patients completed the 6-month outcome follow-up (75.9%) and were included in the outcome analyses. Preoperatively, patients with higher fibromyalgia survey scores were significantly younger, more likely to be female, less educated, more likely to be on disability or unemployed, and more likely to be taking preoperative opioids ($p < 0.05$ for each comparison). Patients with higher scores on the fibromyalgia survey also reported higher pain severity overall and at the surgical site, higher WOMAC scores, and had a more negative psychological profile ($p < 0.0001$ for each comparison). When adjusting for other covariates, patients with higher preoperative pain and educational status showed more improvement in overall pain (Table 1). Higher fibromyalgia survey scores, higher BMI, use of opioids preoperatively, and African American race were independently predictive of less improvement in pain overall. Similar results were obtained when regressing for the change in surgical site pain.

Table 1. Regression model for 6-month change in overall body pain.

	Estimate (regression coefficient)	SE	p-value
(Intercept)	−0.078	0.54	0.88
Pain in Surgical Site	0.93	0.044	<0.00001
Advanced education	−0.59	0.26	0.021
Fibromyalgia Survey Score	0.14	0.02	<0.00001
African American race	1.48	0.55	0.0087
Body Mass Index	0.029	0.015	0.045
Preoperative use of opioids	0.49	0.19	0.012

The composite score of the pain severity questions for the BPI were used to assess the change in overall body pain from baseline to 6-mo after surgery. Independent predictors of outcome are noted in the table. Covariates with a negative estimated indicate a reduction or improvement in pain overtime, while covariates associated with poor outcomes have a positive estimate. In addition to previously described predictors of arthorplasty outcome, the fibromyalgia survey score (measure of cantralised pain) independently predicted poorer outcomes in pain with a 0.14 decrease in change in pain (0–10 scale) for every 1 point increase on the fibromyalgia survey measure (0–31 scale). SE = standard error.

Conclusion: In this large, prospective, observational cohort study, the ACR survey criteria for fibromyalgia differentiated patients preoperatively and was independently predictive of poorer long-term outcomes when

assessing both the change in the surgical site and overall body pain. Altered central pain processing may explain some of the variance in outcomes previously described in lower extremity joint arthroplasty. This simple, validated, self-report measure may add value in selecting appropriate candidates for arthroplasty.

2112

Hip and Knee Arthroplasty In Patients With Rheumatoid Arthritis: Results From The Australian Orthopaedic Association National Joint Replacement Registry: 2003 To 2011. Andrew Lim[1], Stephen Graves[2], Yen Liu[2], Lionel Schachna[1] and Russell R. Buchanan[1]. [1]Austin Health, Melbourne, Australia, [2]Australian Orthopaedic Association National Joint Replacement Registry, Adelaide, Australia.

Background/Purpose: Total Joint Replacement in rheumatoid arthritis (RA) patients is a marker of disease severity. Whilst the rate of total hip (THA) and total knee arthroplasties (TKA) are increasing in Australia, this may not be the case for those patients with rheumatoid arthritis. Currently, there are no published data examining the rates of hip and knee joint replacement surgery, revision rates and mortality following total joint arthroplasty in rheumatoid arthritis over time in Australia. The aim of the study was to determine if the rate of THA and TKA undertaken for RA in Australia has changed since 2003. A secondary aim was to assess the outcome of both THA and TKA undertaken for RA versus Osteoarthritis (OA) during the study period.

Methods: The Australian Orthopaedic Association National Joint Replacement Registry (AOANJRR) collects validated data on all THA and TKA procedures throughout Australia. Registry data include patient demographics, diagnosis, prosthesis type and features, method of fixation and surgical technique. Patient specific outcomes are determined by linking the primary procedure to any subsequent revision or death. Data collection commenced in 1999 and full national data collection was achieved in mid-2002. All hospitals in Australia that perform joint replacement surgery contribute to this registry. A Chi-Square test was used to compare the distribution of RA and OA in THA and TKA. Kaplan-Meier estimates of survivorship and Cox Proportional hazards models were used to compare revision rates and mortality.

Results: The proportion of both THA and TKA undertaken for RA decreased significantly between 2003 and 2011, THA; 1.74% vs 0.84% (chi^2=71.9, p<0.0001) and TKA; 2.38% vs 1.15% (chi^2=135.7, p< 0.0001).

There was no significant difference in the overall rate of revision for primary THA undertaken for RA and OA (HR=1.20, 95CI, 0.98–1.48, p=0.074) but revision rates were higher for dislocation in RA (HR=2.36, 95CI, 1.68–3.31, p<0.001). There is a significantly higher rate of mortality in RA following THA (HR=2.03, 95CI, 1.76–2.33, p<0.001).

There was a significantly lower rate of revision for primary TKA undertaken for RA compared to OA after 9 months (9mths-2yrs: HR=0.38, 95CI, 0.25–0.58, p<0.001, 2–2.5yrs: HR=0.27, 95CI, 0.10–0.72, p=0.009 and 2.5+yrs: HR=0.67, 95CI, 0.48–0.93, p=0.016). TKA for RA has a significantly higher rate of mortality than patients with OA in TKA (HR=2.07, 95CI, 1.84–2.32, p<0.001).

Conclusion: A reduction in the total numbers of THA and TKA in RA patients across Australia has occurred over the last 9 years. The lesser numbers may be the result of improvements in disease control but further studies are needed to clarify. Outcomes of both THA and TKA undertaken for RA appear different when compared to OA.

Glucosamine–Chondroitin Sulfate Reduces Pain, Disability and Non-Steroidal Anti-Inflammatory Drug consumption In Patients With Chronic Low Back Pain: A Large, Community-Based, Pilot, Open Prospective Study. Gurkirpal Singh[1], Liudmila Alekseeva[2], Valeriy Alekseev[3] and Evgeny Nasonov[4]. [1]ICORE, Woodside, CA, [2]State Institute of Rheumatology of Russian Academy of Medical Sciences, Moscow, Russia, [3]First Moscow State Medical University, Moscow, Russia, [4]State NII of Rheumatology of Russian Academy of Sciences, Moscow, Russia.

Background/Purpose: The Global Burden of Diseases, Injuries, and Risk Factors Study 2010 identified low back pain as the leading cause of Years Lived with Disability (YLD) worldwide. In 2010, low back pain (LBP) accounted for over 83 million YLDs, and was the number one cause of YLD in all developed countries in the world (1). LBP continues to create diagnostic and therapeutic challenges due to its unclear etiology and multiple interventions of uncertain efficacy. Significant proportion of LBP may be attributed to osteoarthritis (OA) and degenerative changes in the spine (2). Glucosamine-chondroitin sulfate (GCS) combination is widely used in the treatment of OA, despite conflicting evidence of its efficacy; however there are few prospective scientific investigations of its therapeutic merits in the management of LBP.

Objective: To study the efficacy and safety of GCS in the community management of LBP in a large-scale open pilot prospective observational study.

Methods: We enrolled patients between 40 and 65 years of age who had LBP for at least 12 weeks with a pain intensity >3 on a 0–10 point visual analogue scale (VAS). Major exclusion criteria were the presence of fibromyalgia, degenerative spondylolisthesis, and alcohol and/or drug abuse. All patients were treated with ARTRA (combination of glucosamine hydrochloride 500 mg and chondroitin sulfate 500 mg in tablet form; Unipharm Inc.) at a dose of 1 tab bid for the first month and then 1 tab daily for the next two months. The primary endpoint was pain intensity (at rest and movement) as measured on a 0–10 point VAS. Secondary endpoints included the Oswestry Disability Index, patient global assessment of efficacy (0–5 scale) and NSAID consumption.

Results: We present results from a planned interim analysis of the study in the first 2,344 patients (mean age 52.1 years, 67% women). Patients reported an improvement in pain at rest from mean (+ SD) of 5.2 + 2.6 at study entry to 1.4+1.6 at 3 months (p<0.01). Pain at movement decreased from 6.7+1.7 to 2.3 +1.8 (p<0.01). The Oswestry disability index improved by almost 75%, from 20.8+9.4 to 5.7+6.3 (p<0.01) at 3 months. NSAIDs were used by 63.5% of patients at study entry; at 3 months of treatment, only 6.7% of patients required NSAIDs for pain control. An adverse event (AE) was reported by 156 (6.7%) patients (mostly gastrointestinal in origin, such as nausea, abdominal pain and dry mouth) but only 2 patients deemed the AE to be severe enough to discontinue therapy.

Conclusion: Although open and uncontrolled, this pilot, community-based efficacy and safety study shows dramatic reductions in pain and disability, and in particular, a 90% reduction in NSAID consumption in patients with LBP treated with GCS. With its benign safety profile, GCS therapy deserves serious evaluation in the management of LBP in a prospective randomized double-blinded clinical trial.

Hip Fracture Risk Factors To One Year and In-Hospital Mortality, a Prospective Cohort In South Brazil. Tiango Aguiar Ribeiro[1], Melissa Orlandin Premaor[1], João Alberto Larangeira[1], Michel Luft[1], Luiz Giulian Brito[1], Leonardo Waihrich Guterres[1] and Odirlei Andre Monticielo[2]. [1]Federal University of Santa Maria (UFSM), Santa Maria, Brazil, [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Background/Purpose: Hip fractures is considered one of the most common and serious injury in the elderly life and have been associated with increased morbidity and mortality. Several risk factors are associated with these elevated rates of mortality, such as the surgical delay, ASA score, type of fracture, gender and comorbidities. The aim of this study was to define risk factors for death one year after hip fracture and in-hospital stay in a public university hospital.

Methods: The study design was a prospective cohort study from April 2005 to April 2011 and it was realized in a tertiary public university hospital. Subjects were followed since the admission until hospital discharge and an appointment was scheduled in one year time. ASA score, gender, fracture type, comorbidities, date of birth, date of admission to

hospital and discharge were collected. The statistic analyze was performed using SPSS 18.0. To attribute one year mortality risk factors a Cox's Regression analyze was performed and to define in-hospital mortality risk factors a Logistic Regression was used. Significant findings was considered those with a p-value=0.05. The survival time was analyzed by Kaplan Meier curves and Long-Rank test was made to identify differences between gender groups, ASA groups and fracture type groups.

Results: 450 patients were initially included on this study. 7.1% lost their follow up. 418 subjects were included in final analysis. Of whom, 4.3% have died in-hospital and 15.3% died at one year time. Female gender represents 76.1% (318) and male corresponds to 23.9% (100). The mean age of patients was 79.82±7.26 years. The mean of time to surgery was 7.1±5.4 days with an IQR (Interquartile Range) from 3–9 days. In-hospital stay mean time was 12.2±11.5 days with and IQR from 6–14 days. The variables that were significant in the univariate Cox's analyze were time to surgery, ASA score, Ischemic Heart Disease and in-hospital stay. The risk factors to one year mortality were ASA scores and time to surgery. In the Logistic Regression the in hospital death risk factors were ASA score and age. The overall survival time was 330.3±4.6 SE days (Standard Error). Differences in the survival time was observed in ASA groups (between ASA group 1 – ASA I to II – and ASA group 2 – ASA III to V).

Conclusion: ASA score is a useful tool to evaluate the clinical status of patient and to reduce in-hospital and one year mortality. Moreover, surgical delay is a risk factor that has potential to be modified.
