Characterization Of Histidyl-tRNA Synthetase Specific Th Cell Response In Blood and Broncheoalveolar Lavage (BAL) Of Myositis Patients. Inka Albrecht[1], Eddie James[2], Maryam Fathi[3], Maryam Dastmalchi[1], Jessica Herrath[1], Vivianne Malmström[4] and Ingrid E. Lundberg[5]. [1]Karolinska University Hospital, Department of Medicine, Solna, Unit of Rheumatology, Stockholm, Sweden, [2]Benaroya Research Institute, Seattle, WA, [3]Karolinska Institutet, Department of Medicine, Respiratory Medicine Unit, Stockholm, Sweden, [4]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [5]Rheumatology Unit, Department of Medicine, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Idiopathic inflammatory myopathy is a rare chronic inflammatory disease that is associated with the presence of autoantibodies pointing to a contribution of adaptive immune responses to disease manifestation. One of the most frequent myositis-specific autoantibodies is raised against histidyl-tRNA synthetase (Jo1). This autoantibody can be detected in 20% of myositis patients and is associated with interstitial lung disease (ILD). ILD may precede myositis symptoms implicating that the autoimmune reaction may start in the lungs. The release of Jo1 and fragments thereof into the extracellular milieu is believed to trigger both activation of T cells by antigen-presenting cells and influx of CCR5 expressing cells e.g. dendritic cells and Th1 lymphocytes. So far, there is only limited knowledge about Jo1-reactive T cells in myositis patients.

Methods: A candidate T cell epitope was predicted from the N-terminal part of the Jo-1 protein. In order to identify and characterize Jo1 antigen-specific Th cells, we stimulated peripheral blood (n=9) and BAL cells (n=3) of myositis patients with either recombinant Jo1 protein or the 13aa peptide covering the predicted epitope. Subsequently, $CD3^+CD4^+$T cells were analyzed for up-regulation of CD40L by flow cytometry at day 5. In addition, T cells were examined for effector functions by measuring expression of intracellular cytokines. Finally we compared the phenotype of T cells in blood and BAL (n=4) by staining for Th1 associated chemokine receptors.

Results: Stimulation of cells from blood and BAL with Jo1 protein caused a high up-regulation of CD40L on $CD3^+CD4^+$ T cells. Thus, Jo1-specific $CD4^+$T cells can be detected in both blood and BAL fluid of myositis patients. Upon activation, Jo1-specific T cells mainly show Th1 effector functions as evident by IFNg expression.

Stimulation of cells with the 13aa peptide corresponding to our novel candidate T cell epitope also resulted in a high up-regulation of CD40L.

Moreover, Jo1-reactive T cells are highly enriched in the BAL fluid. Those antigen-specific T cells have a highly pronounced Th1 phenotype as around 60% produce IFNg in response to antigen stimulation compared to only 10% IFNg responders in the corresponding blood samples. Interestingly, BAL T cells were all (100%) positive for CXCR3 and CCR5, two chemokine receptors specifically expressed on Th1 cells. In contrast, $CD4^+$T cells derived from blood only showed 20% positivity for CCR5 and CXCR3 expression, respectively.

Conclusion: In this study, we were able to demonstrate presence of Jo1-reactive $CD4^+$ T cells in inflammatory myopathies and thus provide evidence that those T cells do react with epitopes on this autoantigen. Jo1 reactive $CD4^+$ T cells are also present in the lung and show here pronounced Th1 effector functions. Moreover, we were able to identify a novel T cell epitope of the histidyl-tRNA synthetase. This will open up new ways for studying disease mechanisms and might provide novel starting points for therapeutic intervention.

Rituximab For The Treatment Of IgG4-Related Disease: A Prospective Clinical Trial. Mollie Carruthers[1], Mark Topazian[2], Arezou Khosroshahi[3], Thomas Witzig[4], Judith Oakley[1], Philip Hart[4], Lauren Kelly[1], Lori Bergstrom[4], Suresh Chari[4] and John Stone[5]. [1]Massachusetts General Hospital, Boston, MA, [2]Mayo Clinic, Rochester, MA, [3]Emory University School of Medicine, Atlanta, GA, [4]Mayo Clinic, Rochester, MN, [5]Massachusetts General Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: IgG4-related disease (IgG4-RD) is a multiorgan, fibro-inflammatory disorder. An open label pilot trial of rituximab (RTX) in IgG4-RD conducted at twocentershas enrolled 29 of the targeted 30 patients. We report preliminary results on28 patientsfollowed for a minimum of one month.

Methods: The trial was approved by institutional review boards at the Massachusetts General Hospital and Mayo Clinic. All patients had histopathologically-proven diagnoses of IgG4-RD, includingat least two out of the three major featuresoflymphoplasmacytic infiltrate, storiform fibrosis, and obliterative phlebitis AND immunoperoxidase staining >10 IgG4+ plasma cells per HPF and a >40% IgG4/IgG ratio. All patients had active disease, based on the IgG4-RD Responder Index (IgG4-RD RI). Patients were treated with RTX(1000 mg) times two doses (days 0 and 15) but not treated with maintenance RTX. Patients received methylprednisolone 100 mg with each RTX dose. Trial visits were performed at 1, 3, 5, 6, 8, 10, and 12 months after the first rituximab infusion. The primary outcome was defined by three measures: 1) disease response (decrease of responder index of ≥2 points from baseline); 2) no disease flares before month 6; and, 3) no glucocorticoids between months 2 and 6. Complete remission was defined as an IgG4-RD RI disease activity score of zero.

Results: The organ system involvement among patients in the trial spanned the full spectrum of IgG4-RD, including the orbits, salivary glands, hypopharynx, lungs, lymph nodes, pericardium, pancreas, biliary tree, retroperitoneum, kidney, prostate, and others. The mean IgG4-RD RI at baseline was 12.7 (range: 5 – 36).The mean serum IgG4 concentration was 534 mg/dL (normal < 121; range: 22 – 4780), but 12 patients (43%) had normal values at baseline. Prednisone was used concomitantly with RTX at baseline for remission induction in only 2 of the 28 patients. Twenty-six of the 28 patients followed for at least one month and 22 of 24 followed for three months achieved steroid-free achieved disease responses (93% and 92% at these two timepoints, respectively). Among the

23 patients completing six months of follow-up to date, 20 (87%) have achieved the primary outcome. Only 2 of the 28 patients required an increase in prednisone dose after Month 1. Two patients were hospitalized during the study, one for Legionnaire's disease (pre-baseline infection) and the other for a cold agglutinin-mediated autoimmune hemolytic anemia. No serious adverse events related to rituximab were reported.

Conclusion: Rituximab has promise as a safe, effective treatment for IgG4-RD.Excellent disease responses have been observed to date despite the absence of concomitant glucocorticoid use in this trial.

Silent Ischemic Heart Disease In Patients With Primary Antiphospholipid Syndrome. Antonio R. Cabral[1], Gregoria Gómez-Hernández[2], Martha Morelos-Guzmán[3], Tatiana Rodriguez-Reyna[4], Carlos Alberto Núñez-Alvarez[5] and Jorge Vazquez-Lamadrid[3]. [1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubirán, Mexico, Mexico, [2]Instituto Nacional De Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico, [3]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico, [4]National Institute of Medical Sciences and Nutrition, Mexico City, Mexico, [5]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.

Background/Purpose: Premature atherosclerosis in PAPS is still a matter of debate.

Patients and Methods: To determine the prevalence of ischemic heart disease in PAPS patients. *Inclusion criteria:* Patients ≥18 years of age included in the Patients Registry of the Department of Immunology and Rheumatology from our Institution with the diagnosis of PAPS (Sydney and Alarcón-Segovia et al classifications criteria). All patients gave their written informed consent. *Exclusion criteria:* creatinine >1.5 mg/dl, BP persistently >150/90 in spite of treatment, diabetes mellitus (I or II), dyslipidemia, SLE, positive anti-dsDNAcd (ELISA), positive antinucleosome antibodies (ELISA), asthma and/or pregnancy. All patients had a coronary CAT scan both at rest and under stress myocardial perfusión with adenosine (140 μg/kg/min for 3 minutes) with a 64 channel tomograph (G.E Milwaukee, USA). We also determined new aCL (IgG, IgA e IgM), anti-β_2GP-I (IgG, IgM e IgA), anti-dsDNA and anti-nucleosomes (all by ELISA). Lipid profile and serum creatinine were also newly determined. Our study was approved by the IRB of our Institution.

Results: We studied 24 patients (15 women) with PAPS with a mean age of 29 ± 9.8 years at time of study and 9.5 ± 5.5 years of disease duration. None of them had a history of coronary symptoms. We found that 14/24 patients (58%) had abnormal myocardial perfusion under stress with adenosine, 95% of them with normal coronary arteries. No valvular abnormalities were found. Only one patient (4%) had a previous EKG with ischemic abnormalities. The BMI for the whole group was 26.1 ± 4.5 kg/m^2 and 54% had history of cigarette consumption (TI= 9.7 ± 3.2). aCL y anti-β_2GP-I (any isotype) were positive in 86 and 96% of cases, respectively. We confirmed that no patient had positive anti-DNA, antinucleosomes nor hyperlipidemia.

Conclusion: We found no direct evidence of epicardial coronary atherosclerosis with aPL in PAPS patients, even after 10 years of follow-up. We also show a high prevalence of abnormal myocardial perfusión (58%) in PAPS patients with normal epicardial coronary arteries. Our study suggests silent myocardial ischemia perhaps due to endothelitis and/or microthrombosis in patients with primary antiphospholipid syndrome.

The Association Between Antiphospholipid Antibodies and Related Clinical Outcomes: A Critical Review Of The Literature. Cecilia B. Chighizola[1], Laura Andreoli[2], Alessandra Banzato[3], Guilherme Ramires de Jesus[4], Guillermo J. Pons-Estel[5], Doruk Erkan[6] and On Behalf of APS Action[7]. [1]Istituto Auxologico Italiano, University of Milan, Cusano Milanino, Italy, [2]Rheumatology Unit, University of Brescia, Brescia, Italy, [3]Department of Cardiac Thoracic and Vascular Sciences, University of Padua, Padua, Italy, [4]Department of Obstetrics, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [5]Department of Autoimmune Diseases, Institut Clìnic de Medicina i Dermatologia, Hospital Clìnic, Barcelona, Spain, [6]Hospital for Special Surgery, New York, NY, [7]APS ACTION, New York, NY.

Background/Purpose: AntiPhospholipid Syndrome Alliance For Clinical Trials and InternatiOnal Networking (APS ACTION) is an international network that has been created to design and conduct APS clinical trials. A basic need of APS ACTION was to accurately assess the relationship between antiphospholipid antibodies (aPL) and the different aPL-associated outcomes, i.e., pregnancy morbidity (PM, comprising pregnancy loss [PrL], early PrL, late PrL, intrauterine growth restriction [IUGR], pre-eclampsia [PEC], severe PEC, eclampsia [EC], and HELLP syndrome), stroke (ST), myocardial infarction (MI), and deep venous thrombosis (DVT).

Methods: The search for "aPL" and multiple keywords regarding the outcomes of interest was completed in PubMed. A total of 117 full-text papers assessing the rate of aPL positivity in patients and controls were retrieved; 97 of these studies statistically investigated the relationship between aPL and clinical outcomes. We analyzed the reported association between aPL and the clinical outcomes for each criteria test (anticardiolipin antibodies [aCL], anti-β_2-glycoprotein-I antibodies [a$\beta_2$2GPI], and lupus anticoagulant test [LA]), and then for all three criteria tests combined.

Results: The table reports the number of studies, median number of patients [IQR], and the association between aPL and related outcomes based on different aPL tests. There was a 25–100% association between aPL and clinical outcomes depending on the aPL type and outcome analyzed. However, the literature was impinged by several limitations including: a) only 12% of the studies used the three available criteria aPL tests; b) 4% used a cut-off conforming to international guidelines (low-titer cut-off was used in 22% and medium-titer cut-off in 8%); c) the sample sizes were rather small, with 64% including less than 100 patients; d) only 19% of the studies confirmed that aPL was persistent; and e) 57% of the studies did not have a prospective design.

OUTCOME (# of studies) (Median # of patients [IQR])	aCL (+) Association (N (+)/N, %)	ab2GPI (+) Association (N (+)/N, %)	LA (+) Association (N (+)/N, %)	Overall aPL (+) Association (N (+)/N, %)
PM				
- PrL (n: 9) (114 [48.25–213.75])	**7/8** (88%)	**3/4** (75%)	**7/7** (100%)	**8/9** (89%)
- Early PrL (n: 3) (113 [113–137])	**2/3** (66.6%)	**1/2** (50%)	–	**2/3** (67%)
- Late PrL (n: 7) (96 [26–158])	**6/8** (75%)	**2/3** (67%)	**5/6** (83%)	**5/7** (71%)
- IUGR (n: 3) (22 [14–36])	**1/3** (33%)	–	**0/1** (0%)	**1/3** (33%)
- PEC (n: 12) (87.5 31.75–216.75])	**5/11** (46%)	**0/1** (0%)	**3/5** (60%)	**5/12** (42%)
- Severe PEC (n: 8) (41.4 23.75–74.75])	**5/7** (71%)	**1/2** (50%)	**4/4** (100%)	**6/8** (75%)
- EC (n: 4) (25 [14–25.5])	**0/3** (0%)	–	**0/1** (0%)	**1/3** (25%)
- HELLP (n: 3) (44.5 [25.5–59.75])	**1/3** (33%)	**0/2** (0%)	**0/1** (0%)	**2/3** (67%)
ST (n: 21) (116.5 [81–189.25])	**15/21** (71%)	**2/4** (50%)	**6/9** (67%)	**10/21** (48%)
MI (n: 24) (90 [34–167])	**12/22** (55%)	**5/7** (71%)	**3/5** (60%)	**12/24** (50%)
DVT (n: 21) (122 [92–317])	**8/19** (42%)	**4/6** (67%)	**7/11** (64%)	**10/21** (48%)

Conclusion: The positive association between aPL and clinical outcomes included in the Updated Sapporo APS Classification Criteria is not supported by every study, the association is particularly weak for early PrL, IUGR, PEC, EC and HELLP Syndrome. Given the limitations of the literature, well-designed general population studies as well as large scale APS registries are warranted to further investigate the relationship between aPL and related manifestations. We hope that APS ACTION will help improving upon existing aPL/APS literature.

Ovarian Reserve In Women With Primary Antiphospholipid Syndrome. Lucas Yamakami[1], Paulo Serafini[2], Daniel B. Araujo[3], Eloisa Bonfá[4], Elaine P. Leon[4], Edmund C. Baracat[4] and Clovis A. Silva[5]. [1]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [2]MD; PhD, Sao Paulo, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil, [4]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [5]University of São Paulo, São Paulo, Brazil.

Background/Purpose: Aging, smoking, obesity and surgery have been found to influence the quantity and quality of primordial follicles in ovaries and, ultimately, the ovarian reserve. Other conditions such as autoimmune oophoritis, ovarian ischemia and hemorrhage may also result in diminished ovarian reserve. Female primary antiphospholipid syndrome (PAPS) patients are susceptible to these complications but there is no systematic study assessing this ovary abnormality.

Methods: We screened 85 female patients between 18 to 40 years old with APS. Of these, 67 patients were excluded due to association with other autoimmune diseases (n=42), contraindication or unwillingness to stop hormonal contraceptive (n=21), current pregnancy or breastfeeding (n=3) and previous ovarian surgery (n=1). Therefore, a cross sectional study was conducted in 18 PAPS patients. Control group included 24 healthy volunteers recruited in primary care services according to the same inclusion and exclusion criteria. Complete ovarian function was assessed on the early follicular phase of the menstrual cycle, blinded to the other parameters of ovarian function. Ovarian reserve was assessed by: FSH, luteinizing hormone (LH), estradiol, anti-Müllerian hormone (AMH) and antral follicle count (AFC) in patients without hormonal contraception for at least 12 consecutive months. Anti-corpus luteum antibody (anti-CoL) was detected by immunoblot technique.

Results: Arterial thrombosis, venous thrombosis and pregnancy morbidity were observed in 17%, 83% and 33% of the PAPS patients, respectively. Lupus anticoagulant, anticardiolipin and anti-β2-GPI were detected in 67%, 83% and 11% of these patients. The mean of current age was similar between PAPS and controls (33.0 $\pm$ 5.0 vs. 30.4 $\pm$ 7.0 years old; p=0.189). Body mass index, smoking and the remaining demographic features were similar in both groups (p>0.05). Regarding ovarian reserve tests, the frequencies of low and very low AFC were significantly higher in PAPS patients compared to controls (56% vs. 22%, p=0.042; 37% vs. 9%, p=0.045, respectively). Trends to higher frequencies of reduced, low and negligible AMH levels were found in PAPS patients (p=0.08; p=0.07 and p=0.07; respectively). FSH, LH and estradiol were similar in PAPS patients and controls (p>0.05). Anti-CoL was solely observed in two PAPS patients (11% vs. 0%; p=0.177), one presented reduced ovarian reserve.

Conclusion: The present report was the first to identify a high prevalence of diminished ovarian reserve in PAPS patients reinforcing the need of fertility counseling and family planning. Further study is necessary regarding the mechanisms by which PAPS causes ovarian impairment, as well as the most appropriate fertility treatment for these patients.

Low Vitamin D Is Associated With Increased Risk of Venous Thrombosis in Systemic Lupus Erythematosus, Regardless of Lupus Anticoagulant Status. Michelle Petri and Hong Fang. Johns Hopkins University School of Medicine, Baltimore, MD.

Background/Purpose: Vitamin D deficiency is common in SLE. Vitamin D deficiency is also associated with activation of Tissue Factor. In cross-sectional studies, vitamin D deficiency is more common with APS and thrombosis. We determined whether vitamin D deficiency was associated with thrombosis in SLE.

Methods: 1131 SLE patients had a measure of 25-OH vitamin D. Twenty-seven% had a history of any thrombosis, 15% arterial thrombosis (defined as stroke, myocardial infarction, digital gangrene or other arterial thrombosis), and 17% venous thrombosis (defined as DVT or PE, or other venous thrombosis).

Results: Table 1 shows that low 25-OH vitamin D (<32 ng/ml) was associated with all thrombosis and with venous thrombosis, but not with arterial thrombosis.

Table 1. Association of 25-OH vitamin D level with thrombosis.

Variable	Number (%) with the characteristic: Vitamin D <32 (n=667)	Vitamin D ≥32 (n=464)	Adjusted p-value
All thrombosis	199 (30%)	105 (23%)	0.0017*
Arterial thrombosis	107 (16%)	63 (14%)	0.43**
Venous thrombosis	130 (19%)	59 (13%)	0.0004*
Same-day lupus anticoagulant	111 (17%)	62 (14%)	0.089§

*Adjusted for age at last assessment, ethnicity, gender, and history of lupus anticoagulant (LAC).
**Adjusted for age at last assessment, ethnicity, gender, history of LAC, history of hypertension, and history of hypercholesterolemia.
§Adjusted for age at last assessment, ethnicity, and gender.
Vitamin D deficiency was not associated with any gene signature (interferon, BAFF, neutrophil, or plasma cell).

Conclusion: Vitamin D deficiency in SLE is associated with venous (but not arterial thrombosis) in adjusted analyses that controlled for other risk factors, including lupus anticoagulant. Vitamin D deficiency is not associated with the interferon gene signature. Given that vitamin D deficiency is associated with Tissue Factor expression and that it is already known to be associated with thrombosis in antiphospholipid patients, this is another rationale for vitamin D measurement and supplementation in SLE. Clinical trials, already underway, in the general population may shed further light on the anti-thrombotic potential of vitamin D.

Disclosure: M. Petri, None; **H. Fang**, None.

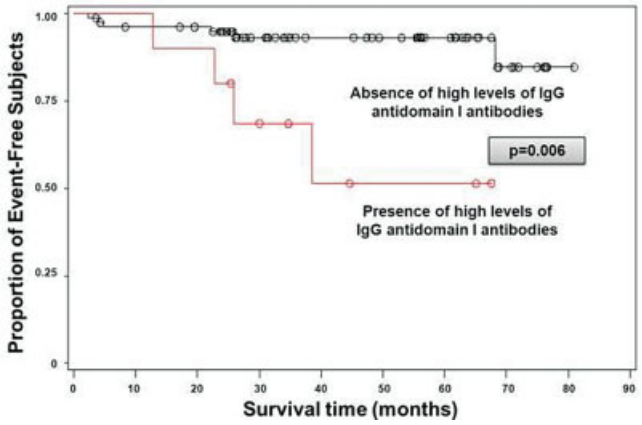
Background/Purpose: Our objective was to prospectively determine the prognostic significance of laboratory variables regarding thrombotic events during follow-up, including novel assays IgG antibodies directed against domain I of β_2-glycoprotein I (antiDI) and IgG anti-phosphatidylserine-prothrombine (antiPS-PT) antibodies in patients with systemic lupus erythematosus (SLE) and/or antiphospholipid antibodies (aPL).

Methods: We performed a prospective cohort study in a French University Hospital and tertiary care center. Consecutive patients with SLE and/or aPL without ongoing anticoagulant treatment were enrolled. The outcome was the time to the first incident thrombotic event. Blood

was drawn at baseline. ELISA antiDI and antiPS-PT antibodies assays were performed together with traditional assays (lupus anticoagulant, anticardiolipin and anti-β_2-glycoprotein I antibodies).

Results: Ninety-two patients (median age 40 years [interquartile range IQR: 29–58]; 74 women) were followed-up for a median duration of 35 months (IQR: 26–62; 320 patient-years). Thrombosis during follow-up occurred in 11 patients (2 strokes, 1 myocardial infarction, 1 splanchnic arterial thrombosis, 2 pulmonary embolisms, 2 deep vein thromboses, 3 small vessels thromboses). Triple positivity, high levels of antiDI and of antiPS-PT antibodies were found in 17, 10 and 13 patients respectively. In univariate analysis, high levels of antiDI (HR=6.41 [CI95%; 1.72–23.89], p=0.006) and antiPS-PT antibodies (HR=3.62 [CI95%, 1.06–12.37], p=0.04) were significantly predictive of incident thrombotic event while triple positivity did not reach statistical significance (HR=3.09 [CI95%; 0.90–10.66], p=0.07). In multivariate analysis (stepwise method), high levels of antiDI antibodies remained the only laboratory variable significantly predictive of incident thrombotic events overtime.



Conclusion: High levels of IgG antibodies directed against the domain I of the β_2-glycoprotein I are significant predictors of thrombosis in patients with aPL and/or SLE.

Therapeutic Effect Of β2GPI and Its Synthetic derivative Loaded Tolerogenic Dendritic Cells In Experimental Antiphospholipid Syndrome, Is Associated With miRNA 23b, 142-3p and 221 Expression and Tregs Upregulation. Miri Blank[1], Silvia S. Pierangeli[2], Honorio Torres-Aguilar[3] and Yehuda Shoenfeld[4]. [1]Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel-Hashomer, affiliated to Sackler Medical School, Tel Aviv University, Ramat Gan, Israel, [2]University of Texas Medical Branch, Galveston, TX, [3]National Center for Blood Transfusion, Mexico City, Mexico, [4]Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Affiliated to Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Tel-Aviv, Israel.

Background/Purpose: The importance of beta-glycoprotein I (beta2GPI)-specific CD4+ T cells in the development of pathogenic processes in patients with antiphospholipid syndrome (APS) and APS mice models is well established. Tolerogenic dendritic cells (tDCs) have the potential to control the outcome of autoimmunity by modulating the immune response. Previously we showed that human tDCs induced with IL-10 and TGFbeta1, loaded with beta2GPI ameliorated effector/memory CD4+ T cells response in patients with APS in-vitro (Ann Rheum. Dis 2012). The aim of this study was to uncover the mechanisms that define the tolerogenic effect of beta2GPI or beta2GPI synthetic derivatives specific tDCs on experimental APS.

Methods: tDCs were generated *in-vitro* from naïve mice bone marrow cells in the presence of TGFbeta and IL-10, cDCs were supplemented with GM-CSF. All the DCs were LPS maturated, pulsed with beta2GPI or beta2synthetic derivatives control peptide and candidin and phenotyped by FACS. miRNA expression were defined by RT-PCR and MAPKs by MAPKs protein-arrays. beta2GPI T cell response to tDCs and cDCs by CFSC and FACS analyses. The tDCs and cDCs were subjected subcutaneously into mice with experimental APS induced by beta2GPI. $CD4^+CD25^+FOXP3^+$ Treg cells were analyzed by FACS. Adoptive transfer experiments were conducted by passive transfer of Tregs from the tDCs –injected mice to APS mice. Cytokine expression of IFNgamma, IL-17, TGFbeta and IL-10 by RT-CR.

Results: tDCs expressed miRNA 23b, 142-3p and 221, whereas cDCs were characterized in expression of miRNA 146a and miRNA155. tDCs specific to beta2GPI and its synthetic derivative were able to decrease b2GPI response manifested by decreased beta2GPI T cell response by 75%–87% while cDCs did not show any significant response, $p<0.001$. Moreover, we were able to show inhibition of circulating anti-beta2GPI antibodies titers ($p<0.002$) and inhibition of fetal loss by 67% was documented in tDCs recipient APS mice in comparison to 8% in the cDCs recipient mice, $p<0.02$. Enhanced expression of CD4+CD25+FOXP3+Tregs by 21% in tDCs injected mice in comparison to 5% in the cDCs injected APS mice was exemplified by FACS. Reduced expression of IFNgamma and L-17 by 5.2 times and enhanced expression of TGFbeta and IL-10 by 6.8 fold was illustrated by RT-PCR. A significant amelioration of all the above parameters were noticed as well in the Treg transferred-APS recipient mice (e.g decreased beta2GPI T cell response, circulating anti-beta2GPI antibodies, and IFNgamma/IL-17). tDCs uploaded with beta2GPI had beneficial effect on the therapeutic properties than the beta2GPI synthetic derivatives, $p>0.05$.

Conclusion: beta2GPI tDCS have the potential to ameliorate experimental APS by upregulation of Tregs and proinflammatory cytokines. beta2GPI tDCS may offer a novel approach for developing personalized therapy for APS patients.

Performance Of Prediction Models For Rheumatoid Arthritis Serologic Phenotypes Among Women Using Family History, Genetics and Environmental Factors. Jeffrey A. Sparks[1], Chia-Yen Chen[2], Xia Jiang[3], Linda T. Hiraki[4], Lars Klareskog[5], Lars Alfredsson[3], Karen H. Costenbader[1] and Elizabeth W. Karlson[1]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Harvard School of Public Health, Boston, MA, [3]Karolinska Institutet, Stockholm, Sweden, [4]Brigham and Women's Hospital, Harvard School of Public Health, Boston, MA, [5]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Family history (FH) of autoimmunity, genetics, and environmental factors have been associated with RA. The area under the receiver operating characteristic curve (AUC) can measure the ability of prediction models to discriminate between cases and controls. We aimed to evaluate the performance of prediction models for RA based on family history, genetics, and environmental factors.

Methods: We developed RA prediction models in a nested case-control study within Nurses' Health Study (NHS) and replicated in women in the Epidemiological Investigation in RA (EIRA) study. NHS cases were validated by chart review and matched to controls by age, menopausal status and post-menopausal hormone use. EIRA new-onset RA cases were matched to controls by age and region. All cases were Caucasian and satisfied the 1987 ACR criteria for RA classification. FH data were obtained from questionnaires (NHS) and registries (EIRA). Serologic status was defined by +RF/ACPA for NHS and by +ACPA for EIRA. Weighted genetic risk scores were calculated for cases and controls based on 39 genetic markers associated with RA in prior studies. Logistic regression models were used to calculate the AUC and 95% confidence intervals (CI) for seropositive/ACPA+ RA and seronegative/ACPA- RA. Model components were based on family history (FH, first-degree relative with RA or lupus in NHS and RA in EIRA), environmental (E: age, smoking pack-years, body mass index, alcohol intake, education, and parity), genetic factors (G), and HLA shared epitope-smoking interaction (GEI). Analyses stratified by FH were performed using models based on E, G, and GEI components.

Results: We analyzed 492 cases and 501 controls in NHS women and 1,244 cases and 971 controls in EIRA women with FH data. The complete model (FH+E+G+GEI) for seropositive/ACPA+ RA had an AUC of 0.71 (95% CI 0.67–0.75) in NHS and 0.78 (95% CI 0.76–0.80) in EIRA (**Table 1**). For women with +FH, the complete model (E+G+GEI) had an AUC of 0.85 (95% CI 0.77–0.92) for seropositive RA in NHS and an AUC of 0.85 (95% CI 0.78–0.92) for ACPA+ RA in EIRA (**Table 2**). For seronegative/ACPA- RA with +FH, E+G+GEI models had an AUC of 0.85 (95% CI 0.63–0.72) in NHS and an AUC of 0.80 (95% CI 0.69–0.91) in EIRA.

Table 1. Areas under the receiver operating characteristic curves (AUC) for RA prediction models using family history (FH), environment (E), genetics (G), and gene-environment interaction (GEI) in the Nurses' Health Study (NHS) and the Epidemiologic Investigation of RA (EIRA) study.

E	0.82 (0.74–0.90)	0.78 (0.68–0.87)	0.67 (0.62–0.71)	0.61 (0.55–0.66)
G	0.63 (0.52–0.75)	0.64 (0.52–0.75)	0.58 (0.54–0.63)	0.58 (0.53–0.62)
E+G	0.84 (0.77–0.92)	0.79 (0.70–0.88)	0.68 (0.64–0.72)	0.62 (0.57–0.67)
E+G+GEI	0.85 (0.77–0.92)	0.85 (0.77–0.92)	0.68 (0.64–0.73)	0.63 (0.58–0.68)

	EIRA AUC (95% CI)			
	+FH		**-FH**	
Models	**ACPA+ RA**	**ACPA- RA**	**ACPA+ RA**	**ACPA- RA**
E	0.77 (0.68–0.86)	0.78 (0.67–0.90)	0.69 (0.67–0.72)	0.65 (0.62–0.68)
G	0.74 (0.65–0.84)	0.57 (0.44–0.71)	0.71 (0.69–0.73)	0.53 (0.50–0.56)
E+G	0.84 (0.76–0.91)	0.80 (0.69–0.92)	0.77 (0.75–0.79)	0.65 (0.62–0.68)
E+G+GEI	0.85 (0.78–0.92)	0.80 (0.69–0.91)	0.77 (0.75–0.79)	0.66 (0.63–0.69)

E models: age, cigarette smoking pack-years, body mass index, alcohol intake, education, and parity
G models: weighted genetic risk scores based on 39 RA associated markers
GEI models: HLA shared epitope-cigarette smoking interaction

Conclusion: We have developed and replicated prediction models for RA in women using family history, environment, and genetics. These models had higher discrimination for seropositive/ACPA+ RA and performed best in stratified analysis for those with family history. For women with family history of RA or lupus, environmental and genetic data may be able to predict the development of RA.

Interactions Between Cigarette Smoking, Body Mass Index and Inflammatory Cytokine Levels In Determining The Risk Of Developing Rheumatoid Arthritis. Elizabeth V. Arkema[1], Susan Malspeis[2], Bing Lu[2], Linda T. Hiraki[3], Elizabeth W. Karlson[4] and Karen H. Costenbader[5]. [1]Harvard School of Public Health, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Harvard School of Public Health, Boston, MA, [4]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [5]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: Smoking and high body mass index (BMI) are risk factors for RA. Both are associated with increased systemic inflammation, with elevated C-reactive protein, interleukin (IL)-6, and tumor necrosis alpha (TNFα). We and others have previously reported that circulating plasma levels of IL-6 and TNFRII (a proxy for TNFα) are elevated years prior to RA onset. We hypothesized that there may be modification of the relationship between plasma levels of IL6 and TNFRII and the future risk of RA according to an individual's BMI and smoking history.

Methods: We conducted a nested case-control study using stored plasma samples from the Nurses' Health Study (NHS) and Nurses' Health Study II (NHSII), prospective cohort studies of U.S. female nurses. Cases were women diagnosed with RA at least 3 months after blood draw. We identified 3 controls for each case randomly chosen from subjects with stored blood, matched on year of birth, race, menopausal status/postmenopausal hormone use, time of day, blood draw fasting status and menstrual cycle timing. Smoking (pack-years) and BMI were obtained from the questionnaire cycle prior to blood collection. IL6 and TNFRII were measured by ELISA. Multivariable logistic regression models were used to calculate odds ratios (OR) and 95% CIs for RA risk associated with a 1 unit increase in log-TNFRII or log-IL6, adjusting for matching factors, alcohol intake, and menstrual regularity. We tested for multiplicative and additive interactions between cytokine levels, and smoking (never or $<$ 10 vs. $\geq$ 10 pack years) and BMI $<$25 (normal weight) vs. $\geq$25 kg/m2 (overweight).

Results: Among 62,439 women followed in the NHS cohorts with stored blood, incident RA was confirmed in 196 subjects, who were matched to 588 healthy participants. Mean age at RA diagnosis was 60.1 years (10.0 SD), 54% RF or anti-CCP seropositive. Mean duration until RA diagnosis was 7.6 years (4.5 SD). A significant association between IL6 and future RA risk was found (**Table**). The OR for TNFRII was elevated but non-significant. We observed a significant multiplicative interaction between TNFRII and BMI (p=0.02). The relationship between plasma TNFRII cytokine elevation and future RA risk was stronger among women with higher BMI than those of normal weight. We did not detect any significant additive or multiplicative interactions between IL6 and BMI, or IL6 or TNFRII and smoking.

Table. Odds Ratios for RA among Women in the Nurses' Health Studies Blood Cohort

	Odds Ratio (95%CI)
Smoking ($\geq$ 10 pack-years vs.$<$ 10 pack-years)	**1.78 (1.25, 2.52)**
BMI ($\geq$25 kg/m2 [overweight]) vs. $<$25 [normal weight])	**1.55 (1.11, 2.17)**
TNFRII	
TNFRII- per one unit increase	1.42 (0.78, 2.56)
Interaction between TNFRII and BMI (overweight vs. normal)	
RERI*	0.24 (−0.37, 0.85)
ROR**	**4.11 (1.29, 13.09)**
Interaction between TNFRII and Smoking ($\geq$ 10 pack-years vs. $<$ 10 pack-years)	
RERI*	−0.11 (−2.95, 2.73)
ROR**	1.65 (0.52, 5.29)
IL6	
IL6- per one unit increase	**1.32 (1.04, 1.68)**
Interaction between IL6 and BMI (overweight vs. normal)	
RERI*	0.24 (−0.48, 0.97)
ROR**	1.08 (0.68, 1.74)
Interaction between IL6 and Smoking ($\geq$ 10 pack-years vs. $<$ 10 pack-years)	
RERI*	0.89 (−0.17, 1.95)
ROR**	1.43 (0.88, 2.33)

TNFRII and IL6 were log-transformed in all models.
* RERI=additive interaction, relative excess risk due to interaction
** ROR= multiplicative interaction, ratios of odds ratios

Conclusion: In this large prospective cohort study of women with blood collected up to 14 years prior to the diagnosis of RA, a multiplicative interaction was found between high BMI and elevated TNFRII level in increasing the risk of RA. This suggests that BMI and TNFα elevation may belong to the same biologic pathway in RA pathogenesis.

Dipeptidyl Peptidase-4 Inhibitors In Type 2 Diabetes May Reduce The Risk Of Autoimmune Diseases. Seoyoung C. Kim[1], Sebastian Schneeweiss[1], Robert J. Glynn[1], Michael Doherty[1], Allison Goldfine[2] and Daniel H. Solomon[3]. [1]Brigham and Women's Hospital, Boston, MA, [2]Joslin Diabetes Center, Boston, MA, [3]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA.

Background/Purpose: Dipeptidyl peptidase-4 inhibitors (DPP4i), such as linagliptin, saxagliptin, and sitagliptin, are oral glucose-lowering drugs for type 2 diabetes mellitus (T2DM). DPP4 is a transmembrane glycoprotein widely expressed in various cells including fibroblasts, T lymphocytes, and macrophages, and has a co-stimulatory function in the immune response. Altered levels of DPP4 activity were noted in patients with autoimmune diseases (AD) such as rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), inflammatory bowel disease (IBD), psoriasis, and multiple sclerosis (MS). The objective of this study was to estimate the incidence rate (IR) of systemic AD such as RA, SLE, psoriasis, MS, and IBD in patients with T2DM initiating a DPP4i drug compared to those initiating non-DPP4i oral hypoglycemic agents.

Methods: We conducted a population-based cohort study using commercial insurance claims data (2005–2011). Among patients aged ≥40 years with T2DM, two mutually exclusive exposure groups were selected: 1) DPP4i combination therapy (DPP4i and at least 1 other oral non-DPP4i drugs) and 2) non-DPP4i combination therapy (2 or more oral non-DPP4i drugs). Patients with a diagnosis of systemic AD, HIV, and cancer, and use of insulin-containing drugs or immunosuppressive drugs at baseline were excluded. Incidence rates (IRs) were calculated for RA, other AD and composite AD. RA and other AD were defined with ≥2 diagnosis codes that were ≥7 days apart and ≥1 prescription for disease-specific immunosuppressive drugs or steroids. Propensity score (PS)-matched Cox regression models compared the risk of RA or AD in DPP4i initiators compared to non-DPP4i initiators, controlling for baseline demographic factors, comorbidities, medications, and health care utilization. Sensitivity analyses matched on PS compared DPP4i combination therapy initiators separately to sulfonylurea combination therapy initiators and to thiazolidinediones combination therapy initiators.

Results: We included 58,275 patients starting DPP4i combination therapy 1:1 PS-matched to those starting non-DPP4i combination therapy. Risks of RA and other AD were significantly lower in the DPP4i group vs. non-DPP4i with the HR of 0.64 (95% CI 0.45–0.91) for RA, 0.53 (95% CI 0.39–0.73) for other AD, and 0.57 (95% CI 0.45–0.73) for composite AD (**Table**). In sensitivity analysis, the risk of other AD and composite AD was significantly reduced in initiators of DPP4i combination therapy compared to sulfonylurea combination therapy and thiazolidinediones combination therapy, but the risk of RA was not.

Table. Risk of autoimmune diseases associated with type 2 DM treatments: PS-matched 'as treated' analysis

	DPP4i (n=58,275)				Non-DPP4i (n=58,275)			
Outcome	Cases	Person-years (PY)	IR* (95% CI)	HR	Cases	Person-years (PY)	IR* (95% CI)	HR
RA	47	39,379	1.19 (0.88–1.59)	**0.64 (0.45–0.91)**	87	48,665	1.79 (1.43–2.21)	Ref
Other autoimmune diseases	59	39,361	1.50 (1.14–1.93)	**0.53 (0.39–0.73)**	129	48,615	2.65 (2.22–3.15)	Ref
Composite: RA or other autoimmune diseases	105	39,325	2.67 (2.18–3.23)	**0.57 (0.45–0.73)**	214	48,539	4.41 (3.84–5.04)	Ref

*Per 1,000 PY
The logistic model for PS includes age, sex, comorbidities, smoking, obesity, non-DM medications, number of DM meds, number of primary and specialist visits, and other health care utilization.

Conclusion: In this large cohort of T2DM patients, initiating DPP4i combination therapy was associated with a decreased risk of incident RA or other AD compared to those initiating non-DPP4i combination therapy. These results suggest possible pharmacologic pathways for reducing the incidence of AD.

Antibodies To Citrullinated Enolase, Fibrinogen, and Vimentin Are Associated With Markers Of Endothelial Dysfunction In First-Degree Relatives Of Patients With Rheumatoid Arthritis: The Studies Of The Etiology Of Rheumatoid Arthritis. Jan M. Hughes-Austin[1], Kendra A. Young[2], Kevin D. Deane[3], Michael H. Weisman[4], Jane H. Buckner[5], Ted R. Mikuls[6], James R. O'Dell[7], Richard M. Keating[8], Peter K. Gregersen[9], Jeremy Sokolove[10], William H. Robinson[11], V. Michael Holers[3] and Jill M. Norris[2]. [1]University of California, San Diego, La Jolla, CA, [2]Colorado School of Public Health, Aurora, CO, [3]University of Colorado School of Medicine, Aurora, CO, [4]Cedars-Sinai Med Ctr, Los Angeles, CA, [5]Benaroya Research Institute, Seattle, WA, [6]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [7]University of Nebraska Medical Center, Omaha, NE, [8]The University of Chicago, Chicago, IL, [9]Feinstein Institute for Medical Research, Manhasset, NY, [10]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [11]Stanford University School of Medicine, Stanford, CA.

Background/Purpose: Among rheumatoid arthritis (RA) patients, antibodies to citrullinated protein antigens (ACPA) have been detected in atherosclerotic plaques. In particular, antibodies to citrullinated fibrinogen (cit-fib) have been associated with prevalent coronary artery calcium (*Sokolove, Arth Rheum 2013*). In the absence of RA, ACPA have been associated with cardiovascular disease (CVD) (*Cambridge, Atherosclerosis 2013*), suggesting that ACPA themselves may directly contribute to accelerated CVD recognized in RA. Therefore, we hypothesized that among RA-free first-degree relatives (FDRs) of patients with RA, ACPA are associated with markers of endothelial dysfunction, an indicator of initial vascular injury in CVD.

Methods: From the Studies of the Etiology of RA (SERA) (a multicenter prospective study of preclinical RA), 113 FDRs who had been positive for any of 5 RA-related antibodies (Abs): rheumatoid factor (RF), RF isotypes – IgM, IgG, IgA, or anti-cyclic citrullinated peptide (anti-CCP2) on at least one of their visits, and 100 FDRs who had never been Ab positive were selected, frequency matched on age, sex, and field center site. In cross-sectional testing of single samples obtained at the baseline exam, the following were measured: endothelial activation/injury markers: soluble intracellular adhesion molecule-1 (sICAM), soluble vascular cell adhesion molecule-1 (sVCAM) and E-selectin; and a panel of 15 ACPA (using Bio-Plex bead-based assay). ACPA were dichotomized as positive/negative based on cut-offs in 200 RA patients and 98 blood bank controls, and were developed using receiver operating characteristic (ROC) curves giving >90% specificity. Soluble VCAM was analyzed as a continuous variable; sICAM and E-selectin were log-transformed to approximate normality and were analyzed in log units. ANCOVA was used to evaluate associations between ACPA positivity and markers of endothelial dysfunction, adjusting for age, sex, race, body mass index, pack-years of smoking, and high sensitivity C-reactive protein.

Results: Among 193 FDRs with complete data and presented in detail in Table 1, sICAM was significantly higher in FDRs who were positive for ACPA to cit-enolase compared with those who were negative, with anti-cit-vimentin showing similar magnitude and marginal significance. sVCAM was significantly higher in those who were positive for antibodies to cit-fibrinogen and cit-vimentin. No significant associations were observed between ACPA and E-selectin.

Vimentin (58–77) cit3 cyclic	8 (4)	**0.32 (0.17)**	0.05	204.17 (83.4)	0.02	0.31 (0.18)	0.09

*adjusted for age, sex, race, BMI, pack-years of smoking and high sensitivity C-reactive protein

Conclusion: In FDRs without classified articular RA, sICAM and sVCAM were higher in those who were ACPA positive. While cit-fib and cit-vimentin have been implicated in subclinical CVD in RA, and antibodies to a-enolase have been associated with vasculitis, our findings support the potential role of these ACPA in the initial insult in the development of CVD, even in the absence of clinical RA.

Omega-3 Supplement Use Is Associated With a Reduced Risk Of Anti-Cyclic Citrullinated Protein Positivity In a Population Without Rheumatoid Arthritis, But At Risk For Future Disease. Ryan W. Gan[1], Kendra A. Young[1], Gary O. Zerbe[2], M. Kristen Demoruelle[3], Michael H. Weisman[4], Jane H. Buckner[5], Peter K. Gregersen[6], Ted R. Mikuls[7], James R. O'Dell[8], Richard M. Keating[9], Michael J. Clare-Salzler[10], Kevin D. Deane[3], V. Michael Holers[3] and Jill M. Norris[1]. [1]Colorado School of Public Health, Aurora, CO, [2]Colorado School of Public Health / University of Colorado Anschutz Medical Campus, Aurora, CO, [3]University of Colorado School of Medicine, Aurora, CO, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]Benaroya Research Institute, Seattle, WA, [6]Feinstein Institute for Medical Research, Manhasset, NY, [7]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [8]University of Nebraska Medical Center, Omaha, NE, [9]The University of Chicago, Chicago, IL, [10]University of Florida, College of Medicine, Gainesville, FL.

Background/Purpose: Rheumatoid arthritis (RA) is characterized by systemic inflammation and circulating autoantibodies, which can be present in serum years prior to RA diagnosis and can define higher risk for future development of classified disease. In particular, the anti-cyclic citrullinated protein (anti-CCP) autoantibody is specific for RA, and its presence is strongly associated with future disease onset. While dietary intake of anti-inflammatory omega-3 (n-3) fatty acids *may* protect against development of RA and decrease the need for drugs to treat RA symptoms, the exact roles that n-3 fatty acids play prior to disease onset is unknown. We investigated the relationship between anti-CCP positivity and n-3 fatty acids, as measured by n-3 supplement use and erythrocyte membrane levels, in a population without RA, but increased risk for future RA.

Methods: The Studies of the Etiology of RA (SERA) is a multisite study of a cohort of first-degree relatives of RA probands (FDRs) and a cohort enriched with the HLA-DR4 genetic variant, both of which are RA-free, but at-risk for future RA. A nested case-control design was employed, with 30 cases defined as positive for anti-CCP2 autoantibody (Axis-Shield), and 48 controls always negative for any RA-related autoantibodies, frequency matched on age at study visit, sex, race, and study site. Antibody status, self-reported n-3 supplement use, and erythrocyte membrane levels of n-3 fatty acids (a biomarker for long-term fatty acid status measured by GC-MS) were obtained from a single cross-sectional visit. Logistic regression was used to assess the association between n-3 supplement use and CCP2 positivity, and test the association between a 1SD increase in membrane n-3 levels and CCP2 positivity. Mediation analyses assessed the percent of the association between self-report n-3 supplement use and CCP2 positivity mediated by membrane levels.

Results: Demographic characteristics were similar between CCP2 positive cases and controls. Subjects with CCP2 positivity were less likely than controls to self-report n-3 supplement use (OR: 0.14; 95% CI: 0.03–0.68). In addition, CCP2 positive subjects had lower erythrocyte membrane levels of certain n-3 fatty acids when compared to controls (Table). In mediation analyses, membrane n-3s explained ~9% of the association between supplement use and CCP2.

Table. The association between anti-CCP2 positivity and increasing levels of erythrocyte membrane n-3 fatty acids. Odds ratios reported correspond to a 1 SD increase in erythrocyte membrane n-3 fatty acid levels.

	Odds Ratio	95% CI	p-value
Self-Reported Use of n-3 Supplement*	0.14	0.03–0.68	0.01
Erythrocyte Membrane n-3			
Total n-3 fatty acid*	0.48	0.26–0.87	0.02
ALA(18:3n-3)*	0.90	0.56–1.45	0.67
EPA(20:5n-3)*	0.58	0.30–1.11	0.10
DPA(22:5n-3)*	0.65	0.40–1.05	0.67
DHA(22:6n-3)*	0.53	0.31–0.92	0.02
EPA + DHA*	0.51	0.29–0.92	0.03
EPA + DHA + DPA*	0.48	0.26–0.88	0.02

* Each row represents a separate model (i.e. the fatty acid variables are not adjusted for each other).

Conclusion: CCP2 positivity is inversely associated with self-reported n-3 supplement use and increasing levels of erythrocyte membrane n-3 fatty acid concentrations. These data suggest intake of longer chain n-3 fatty acids (EPA+DHA) may reduce the likelihood of developing anti-CCP2 antibodies, and potentially, the future development of RA. Only a small percentage of the association between n-3 supplement use and CCP2 positivity is explained by increasing levels of membrane n-3 fatty acids, suggesting other beneficial mechanisms, yet to be explored.

Physical Activity, Adiposity, and The Risk Of Gout In Women: The Nurses Health Study. Hyon K. Choi[1], Lindsay C Burns[2], Yuqing Zhang[1], Sharan Rai[3] and Gary Curhan[4]. [1]Boston University School of Medicine, Boston, MA, [2]University of British Columbia, Vancouver, BC, [3]Arthritis Research Centre of Canada, Richmond, BC, [4]Harvard Medical School, Boston, MA.

Background/Purpose: There is a remarkable, increasing disease burden of gout and its associated cardiovascular (CV)-metabolic comorbidities in the US. While the benefits of physical exercise on CV-metabolic outcomes have been shown to extend beyond weight loss, such an independent impact on the risk of gout is unknown. We evaluated the potential impact of physical activity on the risk of incident gout in a large prospective cohort of women in the Nurses Health Study.

Methods: We examined the relation between physical activity, body mass index, and the risk of incident gout in 94,389 female participants with no history of gout at baseline. We used the American College of Rheumatology criteria to ascertain gout. Cox proportional hazards models were used to estimate the relative risk (RR) of incident gout after adjusting for the following variables in a time-varying manner: age, total energy intake, alcohol, body-mass index, use of diuretics, history of hypertension, history of chronic renal failure, and daily mean intake of meats, seafood, dairy foods, coffee, and total vitamin C.

Results: During 26 years of follow-up, we documented 846 confirmed incident cases of gout. An increasing level of physical activity was independently associated with a decreasing risk of gout. The multivariate relative risks (RRs) of gout were 1.00, 0.99, 0.90, 0.81, and 0.75 (95% CI, 0.58 to 0.97) (P for trend < 0.001) for physical activity levels from the lowest to the highest quintile (Table). In contrast, compared with BMI < 21, the multivariate RRs of gout were 1.71, 1.81, 2.91, 5.00, 6.77 (95% CI, 4.60 to 10.0) (P for trend < 0.001) for BMI categories of 21–22.9, 23–24.9, 25–29.9, 30–34.9, and ≥ 35, respectively. These findings persisted in subgroup analyses stratified by major factors such as intake of alcohol, dairy products, and sugary soda (all P values for interaction > 0.05).

Table 1. Relative Risk of Incident Gout According to Physical Activity

Physical Activity (hr/wk)	0	0.03–0.50	0.51–1.50	1.51–3.74	≥3.75	*P* for trend
No. of Cases	249	257	104	138	98	–

Multivariate* + BMI-adjusted RR (95% CI)	1.0	0.99–0.78, 1.26)	0.90–0.73, 1.11)	0.81–0.64, 1.03)	0.75–0.58, 0.97)	0.012

Table 2. Relative Risk of Incident Gout According to BMI

Body Mass Index (kg/m^2)	< 21	21–22.9	23–24.9	25–29.9	30–34.9	≥35	*P* for trend
No. of Cases	33	75	99	304	248	173	–
Person-Years	322346	419510	441973	678320	262748	120362	–
Age Adjusted RR (95% CI)	1.0	1.80 (1.20, 2.71)	2.07 (1.40, 3.08)	3.80 (2.65, 5.45)	7.81 (5.42, 11.2)	12.8 (8.83, 18.7)	< 0.001
Multivariate* RR (95% CI)	1.0	1.70 (1.13, 2.57)	1.82 (1.22, 2.70)	2.94 (2.05, 4.23)	5.14 (3.55, 7.45)	7.07 (4.81, 10.4)	< 0.001
Multivariate* + Physical Activity-adjusted RR (95% CI)	1.0	1.71 (1.13, 2.58)	1.81 (1.22, 2.69)	2.91 (2.02, 4.18)	5.00 (3.45, 7.26)	6.77 (4.60, 10.0)	< 0.001

Abbreviations: RR= Relative Risk; CI = confidence intervals
* Adjusted for age, total energy intake, menopause, use of hormonal replacement, diuretic use, history of hypertension, and intake of alcohol, sugar-sweetened soft drinks, coffee, total meats, seafood, dairy foods, and total vitamin C

Conclusion: Our findings provide prospective evidence that increased physical activity is independently associated with a decreased risk of incident gout among women, beyond its impact on adiposity. In contrast, increased adiposity was independently associated with an increased risk of incident gout. These findings support the fundamental role of increased physical activity and weight control in the prevention of gout.

Quality Of Care Predicts Disease Outcomes Among Patients With Systemic Lupus Erythematosus. Jinoos Yazdany[1], Laura Trupin[1], Patricia P. Katz[1], Gabriela Schmajuk[1] and Edward H. Yelin[2]. [1]University of California, San Francisco, San Francisco, CA, [2]UC San Francisco, San Francisco, CA.

Background/Purpose: Although measures to assess quality of care in systemic lupus erythematosus (SLE) are available, their relationship to long-term disease outcomes is unknown. Using a prospective, longitudinal cohort study, we examined the associations between high quality care and risks of increased SLE disease activity and damage.

Methods: Data derive from a longitudinal study of individuals with SLE, the UCSF Lupus Outcomes Study (LOS). Participants were followed from 2009 through 2012, responding to yearly telephone surveys. The primary outcomes in this study were clinically meaningful increases (>0.5 standard deviations) in 1) disease activity, defined as greater than or equal to 4 points on the Systemic Lupus Activity Questionnaire (SLAQ) between the 1st and 4th year of observation, and 2) disease damage, defined as greater than or equal to 2 points on the Brief Index of Lupus Damage (BILD) over the same time period. Both SLAQ and BILD have been validated for self-report in telephone surveys. Our primary independent variable was performance on 13 previously validated SLE quality measures, with a pass rate of greater than or equal to 85% (corresponding to the top quintile of performance, with pass rate defined as proportion of eligible recommended services received) considered indicative of high quality care. Using multivariable logistic regression, we examined the relationship between higher performance on quality measures and disease outcomes, adjusting for baseline disease activity and damage, age, gender, race/ethnicity, education, insurance source, health care utilization, specialties of providers seen, number of eligible quality measures, and follow-up time.

Results: Among 737 participants, the mean age at baseline was 50 years (SD 13), 93% were female, 63% were white; 41% had college degrees, and 15% had poverty-level incomes. Respondents were eligible for a mean of 5 quality measures (SD 2, range 2–11). There were 155 participants who had a clinically meaningful increase in SLAQ and 162 with an increase in BILD. In our models, we found no statistically significant relationship between performance on quality measures and changes in SLAQ score. However, receiving higher quality SLE care was significantly protective against increased disease damage (adjusted OR 0.4, 0.2–0.7; Table), even after adjusting for covariates, including baseline damage, disease activity, sociodemographic characteristics, insurance, health care utilization and number of eligible quality measures.

Table. Longitudinal relationship between higher performance on SLE quality measures and disease activity and damage, with adjustment for other health services and sociodemographic factors.

Characteristic	Increase in SLAQ by 4 or more points OR (95% CI)	Increase in BILD by 2 or more points OR (95% CI)
Higher performance (at least 85% fulfillment of eligible quality measures)	0.9 (0.5, 1.4)	**0.4 (0.2, 0.7)**
Eligible services in baseline year	.	.
2–3	Ref	Ref
4–6	1.2 (0.8, 1.9)	1.1 (0.7, 1.8)
7–11	1.6 (0.9, 2.9)	**1.9 (1.0, 3.6)**
Number of health care visits in baseline year (range 1–41)	1.0 (1.0, 1.0)	**1.0 (1.0, 1.1)**
Baseline BILD score	**1.2 (1.1, 1.3)**	**1.1 (1.0, 1.1)**
Baseline SLAQ score	**0.9 (0.9, 1.0)**	**1.1 (1.0, 1.1)**
Disease duration, per 10 years	0.9 (0.7, 1.1)	**1.9 (1.5, 2.5)**

BILD=Brief Index of Lupus Damage, SLAQ=Systemic Lupus Activity Questionnaire.
The model is also adjusted for age, sex, race/ethnicity, education, health insurance source and type, and the providers seen during the baseline year (rheumatologists vs. generalists).

Conclusion: In this community-based cohort of individuals with SLE, we illustrate for the first time a strong link between processes of care, defined by SLE quality measures, and the subsequent accumulation of disease damage, an important outcome. This suggests that improving quality of care has the potential to reduce accumulated damage in SLE even in advance of the development of new treatment options.

Moving Towards Personalized Healthcare: A Patient Reported Outcome Based Algorithm Can Aid Rheumatologists and Patients In Monitoring Rheumatoid Arthritis In Daily Clinical Practice. Jos Hendrikx[1], Jaap Fransen[1], Alessandro Toniolo[2] and Piet L.C.M. van Riel[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Pfizer Pharmaceuticals, Rome, Italy.

Background/Purpose: Several Patient Reported Outcome (PRO)-based instruments to measure disease activity in Rheumatoid Arthritis (RA) exist, though an evidence base for their use in monitoring strategies is lacking. The objective of this study was to evaluate alerts generated by a PRO-based algorithm for monitoring patients with RA in the second year follow-up after diagnosis.

Methods: The algorithm (figure 1) monitors an easily attainable, equally weighted PRO-score of VAS general health, VAS disease activity and VAS pain. Red flags are generated in two instances:

1. the target level of disease activity is not met (set at a Patient Acceptable Symptom State value of 40mm)
2. change in disease activity (current level versus best moving average of 3 past visits) surpasses the early alert threshold (set at a Minimal Important Change value of 20mm)

Three consecutive red flags trigger an alert to the physician.

Data from patients with complete second year follow-up, included consecutively in the Nijmegen Early RA cohort between 2003–2011, were used. Weekly PRO-scores were interpolated, with addition of a random error component, based on the empirical individual patient data during the second year follow-up after diagnosis. Alerts were evaluated against DMARD/Biologic medication escalation registered in daily clinical practice. Escalation was defined as an increase in dose/frequency or start of new drug. Analyses were stratified according to DAS28 level at 12 months.

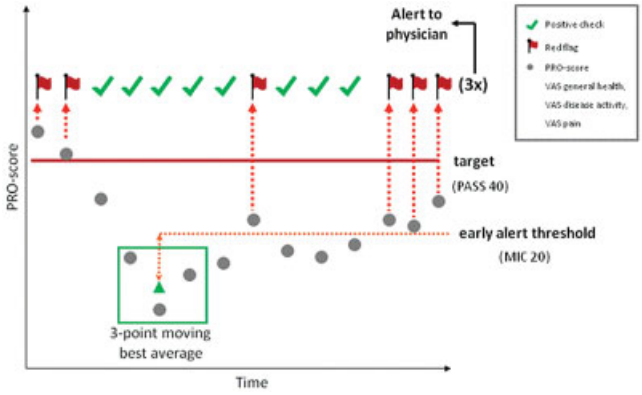

Figure 1. Preliminary PRO-based algorithm

Results: Data of 158 patients with RA were available for analysis. An overview of the algorithm performance is shown in table 1. The Negative Predictive Values (NPVs) represent the proportion of visits without medication escalation in all cases that the algorithm did not generate an alert. Overall, in 92.5% of visits where the algorithm did not generate an alert medication was also not escalated.

Table 1. preliminary algorithm results

	Visits	PPV	NPV	Sens	Spec	A priori chance of escalation
Total	693	14.0	92.5	55.7	61.5	10.1
	Stratified according to $DAS28_{12\ months}$					
DAS_{28} <2.6	277	6.0	95.9	38.5	70.5	4.7
DAS_{28} ≤3.2 & ≥2.6	101	16.7	95.4	66.7	67.4	8.9
DAS_{28} <5.1 & >3.2	282	18.3	86.8	54.5	55.0	15.6
DAS_{28} ≥5.1	33	13.8	100	100	13.8	12.1

PPV: Positive Predictive Value, NPV: Negative Predictive Value, Sens: Sensitivity, Spec: Specificity

Conclusion: The high NPVs indicate that, when using the algorithm, the chance of missing patients in need of medication escalation is very low. These findings provide evidence that an off-site monitoring system could aid in optimizing the number and timing of face-to-face consultations of patients with their rheumatologists. Further investigation into the optimal PRO-score, measurement frequency and algorithm parameter values to be used for off-site monitoring is warranted.

Evaluation Of Osteoporosis Medication Starts In Patients Based On T-Score and FRAX® Absolute Fracture Risk Model In a Large Health Care System. Robert A. Overman and Chad L. Deal. Cleveland Clinic, Cleveland, OH.

Background/Purpose: The National Osteoporosis Foundation (NOF) 2008 guidelines recommend treatment for postmenopausal women (PMW) and men ≥ 50 if the T-score is ≤−2.5 at the hip or spine and in patients with osteopenia (T-score −1.0 to −2.5) if the WHO FRAX® 10-yr fracture risk is ≥3% for hip or ≥20% for major osteoporotic fractures. We evaluated treatment initiation in patients after DXA and compared treatment by rheumatologists to non-rheumatologists.

Methods: The Cleveland Clinic DXA registry was linked with the patient's electronic medical record using Explorys Inc. PMW and men ≥50 in the registry between 7/2009 and 12/2012, who were anti-osteoporosis medication (AOP) naïve, and had at least one office visit in the years pre and post-DXA were included. New use of AOPs; bisphosphonates, teriparatide, denosumab, raloxifene, calcitonin, and estrogen started within 90, 180, and 365 days post-DXA were collected through 2/2013. Subjects who did not exceed each post-DXA time period were not included in the analysis. Subjects were stratified into 6 groups based on T-score (osteoporosis or osteopenia); FRAX® 10-yr risk of major osteoporotic fracture or hip fracture, ≥20% and/or ≥3% (high-risk) or <20% and <3% (low-risk); and treatment by a rheumatologist or non-rheumatologist. Results are presented as % difference in treatment starts. Group comparisons were made using chi-square with p≤0.05 demonstrating statistical significance.

Results: Study subjects had a mean age of 70.9 (SD 10.5) and 80.8% (3456/4280) were female. The difference in treatment starts at 90, 180 and 365 days after initial DXA for rheumatologists and non-rheumatologists are presented in Table 1. The groups were osteoporosis at either spine or hip and FRAX® high-risk; osteoporosis and FRAX® low-risk; osteopenia and FRAX® high-risk. Rheumatologists were compared to non-rheumatologists. Treatment would be recommended for all 6 groups based on NOF guidelines. Rheumatologists started significantly more patients on AOP than non-rheumatologists at 180 and 365 days in patients with osteoporosis and FRAX ® high-risk, and at all-time points in patients with osteopenia and FRAX® high-risk. The greater number of AOP starts in rheumatologists indicate closer adherence to NOF guidelines for treatment.

Table 1. Percentage of osteoporosis treatment naïve patients started on osteoporosis therapy by Rheumatologists v Non-Rheumatologists based on time periods post-DXA

Treatment Initiation	Osteoporosis and FRAX® High-Risk (Rheum)	Osteoporosis and FRAX® High-Risk (Non-Rheum)	% diff	Osteoporosis and FRAX Low-Risk® (Rheum)	Osteoporosis and FRAX® Low-Risk (Non-Rheum)	% diff	Osteopenia and FRAX® High-Risk (Rheum)	Osteopenia and FRAX® High-Risk (Non-Rheum)	% diff
% within 90 Days (n/group n)	42.4 (70/165)	40.3 (546/1355)	2.1	32.4 (24/74)	42.4 (378/891)	−10.0	24.1 (58/241)	17.3 (269/1554)	6.8*
% within 180 Days (n/group n)	55.6 (85/153)	48.6 (613/1262)	7.0	45.7 (32/70)	51.2 (429/838)	−5.5	32.2 (75/233)	21.9 (316/1440)	10.3**
% within 365 Days (n/group n)	67.2 (90/134)	54.9 (594/1082)	12.3**	58.3 (35/60)	58.7 (423/721)	−0.4	40.5 (81/200)	27.8 (340/1225)	12.7**

Subjects who contributed at least the period days to the analysis were included in percentages for each row
Rheum = subjects who had at least one visit with a rheumatologist in the year before and after DXA
Non-Rheum = subjects not seen by a Rheumatologist in the year before and after DXA
FRAX® High-Risk = 10-yr risk of hip fracture ≥3% and/or 1-yr risk of major osteoporotic fracture ≥20%
FRAX® Low-Risk = 10-yr risk of hip fracture <3% and 10-yr risk of major osteoporotic fracture <20%
% diff = the difference in percent treated by rheumatologists vs. a non-rheumatology physician
*: p≤0.05 **: p≤0.01.

Conclusion: Rheumatologists started AOP therapy significantly more often in patients who would be recommended for therapy based on NOF guidelines. However, only 67.2% of rheumatology and 54.9% of non-rheumatology FRAX® high-risk with osteoporosis patients were started on AOP by 1-yr. In FRAX® high-risk with osteopenia patients only 40.5% of those treated by a rheumatologist and 27.8% of those not treated by a rheumatologist were started on therapy at 1-yr. These data indicate a care gap in osteoporosis treatment in both physician groups which needs to be addressed to improve quality of care.

Disclosure: R. A. Overman, None; **C. L. Deal**, None.

Efficiency Gains For Rheumatology Consultation From An Electronic Referral System In a Safety Net Health System. Meghan M. Scheibe[1], John B. Imboden[2], Gabriela Schmajuk[2], Mary Margaretten[2], Jonathan D. Graf[2], Alice Chen[2], Edward H. Yelin[2] and Jinoos Yazdany[2]. [1]California Pacific Medical Center, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA.

Background/Purpose: Rheumatology care is a scarce resource in some settings. Health information technology holds promise in increasing the quality and efficiency of rheumatology referrals, but little information about its use for these purposes is available. The aim of this study was to determine the proportion of electronic referrals that are appropriate for pre-consultation exchange as well as to assess potential efficiency gains in a safety net health system.

Methods: The Electronic Referral System (eReferral) allows two-way electronic communication between referring and specialty providers for new patient referrals. Once a referral is initiated, several possible outcomes may result: either the patient is scheduled in rheumatology clinic, the consult is deemed not appropriate for rheumatology, more information is requested from the referrer to gauge the appropriateness of the consultation, or the question is answered entirely within the eReferral system without scheduling a clinic visit. The latter 3 constitute "pre-consultation exchange." We performed a retrospective study of a random sample of eReferrals for ambulatory rheumatology consultation between 2007–2012. A sample of approximately 10% of eReferrals (n=257) was reviewed. The primary clinical question and disposition for these referrals was recorded. Using a blinded adjudicated, structured review performed independently by two rheumatologists, we rated each eReferral for pre-consultation exchange using the categorization above.

Results: Between 2007–2012, 2383 eReferrals were sent to rheumatology. Of the 257 referrals examined in more detail, the top reasons for consultation are shown (Table). 156 (61%) eReferrals were rated as appropriate for pre-consultation exchange. The primary reasons pre-consultation exchange was recommended were: additional testing was needed to clarify or expedite the consultation request (37%), the clinical question was unclear (14%), or the consult was deemed not appropriate for rheumatology consultation (10%). Referrals for pain were most likely to be rated as appropriate for pre-consultative exchange and those for crystal arthropathies were the least likely (Table). Following the exchange, 49 (32%) eReferrals were able to be resolved without a clinic visit.

Table. Appropriateness of Rheumatology eReferrals for Pre-consultation Exchange in a Safety Net Setting.

Diagnosis	N (%) Top Reasons for eReferral	N (%) eReferrals recommended for immediate scheduling	N (%) eReferrals deemed appropriate for pre-consultation exchange
Potential inflammatory arthritis	42 (17%)	15 (35%)	27 (65%)
Rheumatoid arthritis	35 (14%)	15 (43%)	20 (57%)
Pain	31 (13%)	2 (6%)	29 (94%)
Systemic lupus erythematosus	20 (8%)	9 (45%)	11 (55%)
Crystal Arthropathy	17 (7%)	11 (65%)	6 (35%)

Conclusion: We evaluated eReferral, an innovative program designed to improve the quality and efficiency of specialty referrals. Over half of the referrals to rheumatology were rated as appropriate for pre-consultative exchange. In addition, one-third of the referrals were able to be resolved without a clinic visit, suggesting that using an iterative referral system that facilitates communication between referrers and specialists has the potential to improve the triage and efficiency of new patient visits in a busy

rheumatology practice, particularly in settings where rheumatologists are a scarce resource.

Implementing a Personalized Health Plan To Improve Therapeutic Outcomes In Veterans With Gout. Astrud Lorraine Leyva[1], Una E. Makris[2] and Salahuddin Kazi[1]. [1]UT Southwestern Medical Center, Dallas, TX, [2]UT Southwestern Medical Center, VA Medical Center, Dallas, TX.

Background: Gout is a chronic crystal-induced arthritis that predominantly occurs among men with rising prevalence with advancing age. Patients with uncontrolled gout present with recurrent flares leading to unanticipated clinical encounters, i.e. phone calls, ER visits, and/or hospitalization. Given the patient population at the Dallas VAMC, it is appropriate to evaluate novel strategies for improving gout management. Outcomes in gout may be improved by eliciting goals of care from the patient.

The Dallas VA has adapted a personalized health plan (PHP) derived from Duke University's Integrative Medicine program that assesses patients' desired goals in 8 different domains, initially tested in diabetic patients. The purpose of this study is to pilot the PHP to facilitate achieving goal uric acid <6mg/dL in patients with uncontrolled gout.

Methods: We recruited consecutive patients at the VA rheumatology clinic with uncontrolled gout, defined by uric acid > 6mg/dL AND ≥ 1 acute gout flare(s) from July to September 2012. This project was reviewed by the VA IRB and considered to be a quality improvement project.

The initial interview focused on formulating a goal (congruent with gout management). Patients selected a goal, indicating their starting and desired status using a numerical scale (1–10). Continuous reinforcement was achieved by weekly phone calls (ALL). Uric acid levels were evaluated at baseline and at the end of the study period. An exit interview was conducted after 3 months; which included open ended questions regarding feedback for the PHP (see Table 1). Clinical encounters over 1 year were evaluated for trends and compared to non-PHP patients using a student's t-test.

Results: Thirty-six veterans meeting study criteria were approached; 13 agreed to participate and completed the 3 month study. Participants' average age was 59 ± 8.9 years, 5/13 were Non-Hispanic White, 7/13 African-American and 1/13 Hispanic. All but one selected a goal to increase physical activity or adjust diet. At completion of the study, 1 patient achieved his desired goal; 3/13 remained at the same level; 9/13 did not achieve, but approached, the goal, as seen in Table 1. 10/13 patients had a reduction in uric acid level, of which 8/10 reached the goal of ≤6mg/dL. Clinical encounter data did not significantly differ between PHP participants and non-participants.

Table 1.

Patient	Age	Race	Goal Pre → Post [desired]	Pre/Post Uric Acid	Quotes illustrating feedback for PHP
1	66	NHW	Increase physical activity 2 → 2 [10]	7.5/7.7	"Would have to change my expectation with 8, a little lower. I'd have a better chance of success with lower expectation"
2	73	H	Improve diet 3 → 5 [8]	12.6/6.1	"Makes me more aware to stay healthy and I'm eating better than I had been"
3	56	AA	Improve diet 7 → 10 [10]	4.3/4.1	"Having a doctor calling me and taking time to show their concern is really good"
4	57	NHW	Improve diet 4 → 5 [8]	8.0/6.0	"The weekly phone calls helped by re adjusting medications as problems came up"
5	43	AA	Stop alcohol use 3 → 8 [10]	12.7/10.9	"The program is a good reminder to stop drinking and source of education"
6	65	AA	Increase physical activity 3 → 4 [10]	8.6/5.3	"Having someone to talk to on a regular basis was good. Provided encouragement and answer questions as they come up"
7	60	AA	Increase physical activity 6 → 7 [10]	6.2/5.6	"How many doctors call you and ask if you are doing ok? It made me accountable to get out of bed."
8	45	AA	Increase physical activity 4 → 4 [10]	6.8/7.7	"Helpful to have someone concerned about you calling every week"
9	68	NHW	Increase physical activity 7 → 8 [10]	7.8/5.9	"Helps me stay an track"
10	65	NHW	Improve diet 6 → 8 [10]	8.5/5.6	"The program may be better calls were every 2 weeks"
11	53	AA	Increase physical activity 5 → 5 [10]	11.0/10.4	"Constant reminder to keep on working on my goal and to stay on medications"
12	53	NHW	Increase physical activity 5 → 7 [10]	8.4/5.9	"I like hearing from the doctor every week."
13	63	AA	Improve diet 5 → 6 [10]	6.8/4.1	"The depression is bad." The phone calls "it's like an uplift". "I have a better understanding of what gout brings on."

NHW = non-Hispanic white, AA = African American, H = Hispanic

Conclusion: This pilot study suggests that Veterans had a positive response to the gout PHP. Veterans indicated satisfaction with physician follow-up phone calls; however, this may not be feasible in a "real world" setting. Future studies evaluating the efficacy of the PHP in gout patients should include a control group, utilize technology for continuous reinforcement, measure unanticipated clinical encounters, and lastly, extend the duration of follow-up to allow behavioral, physical activity, or psychosocial change.

Fast-Track Pathway In Giant Cell Arteritis: A Cost-Effectivenss Analysis. Katerina Achilleos[1], Pravin Patil[1], Win Win Maw[1], Laura Bown[2], David Halsall[2], Charles Dobson[2], Christian Dejaco[1], Frances Borg[1], Sunil Gupta[3] and Bhaskar Dasgupta[1]. [1]Southend University Hospital, Westcliff-on-sea, United Kingdom, [2]National Health Service England, Leeds, United Kingdom, [3]Clinical Commissioning Group, Southend-on-sea, United Kingdom.

Background/Purpose: With incidence of 2.2 per 10,000 patient years, it is estimated that 12,000 new cases of Giant Cell Arteritis (GCA) are diagnosed every year in the UK of whom 20% lose sight permanently. This has significant implications on personal, social care and socioeconomic costs. A fast-track GCA pathway was introduced in 2012 aimed at reducing multiple referral routes, delayed review and treatment and improving outcomes. We report the cost effectiveness of this pathway.

Methods: A retrospective data analysis of 138 patients investigated for GCA (Jan 2009-Dec 2012), comparing costs of fast-track pathway (57 patients; Jan – Dec 2012) with the conventional referral route (81 patients; pre 2012) using the incremental cost effectiveness ratio (ICER). Data was collected from patient records, general practice and pathology databases along with telephone questionnaires. Direct costs included: GP appointments, investigations such as blood tests, scans and biopsies, outpatient appointments (Rheumatology, Eye Clinic and Neurology), A&E attendances, Inpatient stays, readmissions, drugs for treatment of GCA. Costing data for treatment and diagnosis costs was gathered from Reference Costs 2011/12, Prescription Cost Analysis 2012, and Unit Costs of Health and Social Care 2012. QOL was measured in 66 patients using the EQ5D. Health gains from diagnosis and treatment of GCA were quantified using Quality Adjusted Life Years (QALY's).

Results: The fast-track pathway has seen a reduction in number of GP appointments and cost of diagnosis and treatment. The difference in QALYs between patients with and without sight loss due to GCA was 0.2. Each patient that didn't lose vision gained on average 2.6 QALY's. The average cost of diagnosing and treating a patient with suspected GCA in the conventional pathway was ≤2,600, whilst in the fast-track; this was ≤1,675, a difference of ≤925 per patient. The ICER of implementing the fast-track pathway is -≤1,950 per QALY. Thus, there is an average cost saving to the NHS of ≤925 for each patient treated for suspected GCA.

Table 1. Patients with sight loss and the costs of treatment/diagnosis in the conventional and fast-track pathway

	Total number of patients suspected of having GCA	Total number of patients diagnosed with GCA	Number of patients with Sight loss	Average cost of diagnosis and treatment
Conventional pathway	81	46	17 (37%)	≤2,600
Fast-track pathway	57	33	3 (9%)	≤1,675

Conclusion: The fact-track pathway leads to a reduction in irreversible sight loss and is associated with reduced diagnosis and treatment costs. It results in 2.6 QALY's gained for each patient that does not suffer sight loss, suggesting that the fast-track pathway is more cost effective than the conventional pathway for management of early GCA. The ICER of implementing the fast-track pathway is -≤1,950 per QALY with an average cost saving to the NHS of ≤925 for each patient. Our results do not include the small educational/refresher costs and are preliminary but indicate that the Fast track GCA pathway should be 'rolled out' globally.

A Randomized, Double-Blind, Dose Ranging Study Comparing FX006, An Intra-Articular (IA) Sustained-Release Formulation Of Triamcinolone Acetonide (TCA), To An Approved Injectable Suspension Of TCA In Patients With Osteoarthritis (OA) Of The Knee.

Neil Bodick[1], Joelle Lufkin[1], Christina Willwerth[1], Pierre Lachance[2], Gregory Jasey[3], Anil Gupta[4], Anthony Chris[5], Marc Russo[6], Michael O'Mahony[7], Sam Henein[8], Louise Murdoch[9], Ferdinandus de Looze[10], David Hunter[11] and Michael Clayman[1]. [1]Flexion Therapeutics, Burlington, MA, [2]Clinique St-Louis (Recherche) Inc, Quebec, QC, [3]North Walkerville Orthopaedic Associates, Windsor, ON, [4]Anil K. Gupta Medicine Professional Corporation, Toronto, ON, [5]Aim Health Group, Waterloo, ON, [6]Hunter Clinical Research, Broadmeadow, Australia, [7]London Road Diagnostic Clinic and Medical Centre, Sarnia, ON, [8]SKDS Research Inc., Newmarket, ON, [9]Emeritus Research, Malvern East, Australia, [10]AusTrials Pty Limited, Sherwood, Australia, [11]Royal North Shore Hospital, St. Leonards, Australia.

Background/Purpose: FX006 is a novel sustained-release formulation of TCA in poly(lactic-co-glycolic) acid microspheres intended to maintain therapeutic concentrations in the joint up to 3 months following IA injection. In patients (pts) with OA of the knee, FX006 was compared to an approved injectable suspension of TCA (TCA IR) to identify a dose of FX006 to move forward into Phase 3.

Methods: Pts with baseline average daily pain intensity (ADP) of ≥5 to ≤9 on an 11 point Numeric Rating Scale (NRS) ranging from 0 (no pain) to 10 (pain as bad as you can imagine) were randomized (1:1:1:1) and treated with a single IA injection of FX006 (containing 10, 40 or 60 mg of TCA) or 40 mg of TCA IR. Pts were evaluated at 7 visits over 12 wks for efficacy, safety and PK. Primary endpoint: change from Baseline to each of Wks 8, 10 and 12 in the weekly mean of ADP. Secondary endpoints: time to onset of pain relief, WOMAC (pain, stiffness and function), responder status, and global impression of change.

Results: Pts (228) were randomized and treated (FX006 10 mg, n=58, FX006 40 mg, n=59, FX006 60 mg, n=60; TCA IR, n=51). Treatment arms were well balanced across demographic and baseline characteristics (mean baseline ADP: 6.5). FX006 40 mg was superior to TCA IR on weekly mean of ADP at Wk 5 to Wk 10 ($p<0.05$) (average pain reduction −0.9) (Figure 1). The 40 mg dose also demonstrated significant improvement over TCA IR ($p<0.05$) in secondary outcomes at Wk 8 (Table 1). Time to onset of pain relief was the same for FX006 40 mg and TCA IR. The 10 mg dose produced effects that were consistently improved relative to TCA IR but of lessor magnitude than those of the 40 mg dose. The 60 mg dose did not produce an improvement relative to the 40 mg dose. There were no related SAEs. AEs were generally mild and unrelated to study drug. Local knee-related AEs, lab assessments, ECGs and vital signs were unremarkable and similar across all treatments. Plasma PK across the FX006 doses were linear and dose-dependent. Peak plasma concentrations achieved with TCA IR were 10× of that seen with FX006 40 mg.

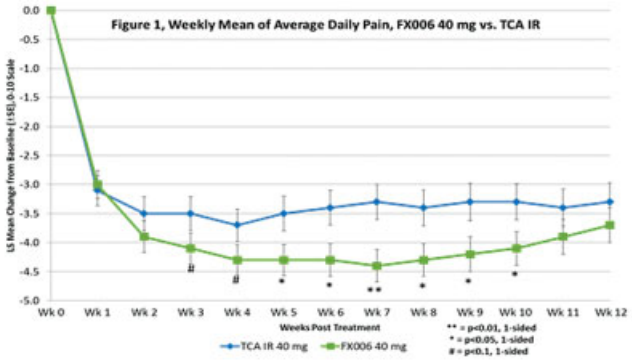

Table 1. Secondary efficacy endpoints at Week 8 comparing FX006 40 mg vs. TCA IR 40 mg

WOMAC A (pain) (0–4 Likert scale)	FX006 40 mg (n=59)	TCA IR 40 mg (n=51)

Treatment Of Knee Osteoarthritis Patients With Strontium Ranelate Reduces The Loss Of Cartilage Volume and Bone Marrow Lesions As Assessed By Magnetic Resonance Imaging: Data From The Phase III Strontium Ranelate Efficacy In Knee Osteoarthrtis Trial. Johanne Martel-Pelletier[1], Camille Roubille[1], Jean-Pierre Raynauld[1], François Abram[2], Marc Dorais[3], Philippe Delorme[1] and Jean-Pierre Pelletier[1]. [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [2]Imaging Research & Development, ArthroLab Inc., Montreal, QC, [3]StatSciences Inc., Notre-Dame de l'Île Perrot, QC.

Background/Purpose: This study aimed to evaluate in a subpopulation of osteoarthritis (OA) patients from the SEKOIA Phase III trial the disease-modifying (DMOAD) effect of strontium ranelate (SrRan) on the changes in knee OA cartilage volume and bone marrow lesions (BML) using magnetic resonance imaging (MRI).

Methods: Patients with knee OA (n=300) received placebo (n=112) or SrRan at 1 g/day (n=113) or at 2 g/day (n=105). The study included all randomised patients who received at least one dose of treatment and had at least two MRI examinations. MRI was performed at baseline and at 12, 24, and 36 months. The changes in cartilage volume loss and BML were assessed in the global knee and subregions. Missing values were imputed and the analyses were adjusted according to Bonferroni.

Results: Data showed no between-group differences at baseline with regard to demographics, clinical symptoms, or imaging characteristics. Treatment with SrRan at 2 g/day significantly decreased cartilage volume loss on the tibial plateau as early as 12 months (p=0.002), which persisted up to 36 months (p=0.003). The urinary CTX-II was found to be significantly decreased in both SrRan groups at 36 months. At baseline, the BML were detected mainly in the medial compartment where they were found at increased prevalence in the femur compared to the plateau. At 36 months, SrRan treatment at both 1 and 2 g/day significantly reduced the BML score change in the medial compartment (p=0.002 and p=0.001, respectively). Interestingly, patients treated with SrRan 2 g/day showed no increase in BML score in the medial femur, central condyle or plateau, and those treated with SrRan 1g/day showed no increase in the medial central condyle or plateau, while an increase (39%, 40%, and 17%, respectively) in BML score was found in the placebo group. In those patients with BML at baseline, SrRan 2 g/day significantly (p=0.023) decreased the cartilage loss at 36 months in the medial plateau.

Conclusion: In knee OA patients, treatment with SrRan 2 g/day was found to have a beneficial effect on both cartilage and subchondral bone by significantly reducing the cartilage volume loss in the tibial plateau and the progression of BML in the medial compartment. In turn, the decrease in BML in the medial tibial plateau was associated with a marked and significant reduction in cartilage volume loss at SrRan 2 g/day. These results from the MRI study support the DMOAD effect of SrRan reported using X-rays.

Does Change In Femorotibial Cartilage Thickness Differ Between Acutely Anterior-Cruciate Ligament Injured Knees Treated With and Without Reconstructive Surgery. Wolfgang Wirth[1], Felix Eckstein[1], Martin Hudelmaier[1], Stefan Lohmander[2] and Richard Frobell[3]. [1]Paracelsus Medical University, Salzburg, Austria, [2]Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, [3]Lund University, Lund, Sweden.

Background/Purpose: An ACL tear is a serious knee injury, involving chronic alterations in joint biomechanics. The risk of developing knee OA after an ACL tear is elevated, but the driving mechanisms are not known. We tested the hypothesis that surgical reconstruction of an acute ACL tear would influence change in femorotibial cartilage thickness over the first five years after injury.

Methods: In a treatment RCT (the KANON-trial), 121 young (32 women, mean age 26.1 years) active adults with an acute ACL tear in a previously un-injured knee received similar rehabilitation. Baseline sagittal MR images were available for 117 participants, with year 2 and year 5 follow-up for each 112 of the 121 participants. 59 of those underwent an early ACL reconstruction (ACLR), 29 had a delayed ACLR, and 29 were treated with rehab alone. Cartilage thickness (ThC) was measured manually with blinding to time point and treatment using a dedicated software (Chondrometrics GmbH, Ainring, Germany). Primary outcome was the mean change in ThC for the entire femorotibial joint (FTJ); secondary outcomes were mean change in ThC for the medial and the lateral femorotibial compartments (MFTC/LFTC), the subregion with the largest ThC loss (ordered value 1 = OV1) and gain (OV16). ThC changes were analyzed using the t-test (crude differences) and analysis of covariance (differences with adjustment for age, sex & BMI).

Results: The cartilage thickness change over 5 years in the FTJ did not differ significantly between knees treated with early ACLR (+148μm, 95%CI: [+38, +258]μm), with delayed ACLR (+174 [+42, +306]μm), or with rehabilitation alone (+121 [−3,+246]μm, crude/adjusted p≥0.56/0.65). In addition, no significant differences were found for the periods between BL→Y2 and Y2→Y5. The change in FTJ ThC was largely driven by change in MFTC ThC (early ACLR: +132 [+77, +187] μm, delayed ACLR: +128 [+40, +216] μm, rehab alone: +82 [+19, +146] μm), but without significant differences between treatment groups over the entire 5 year period (p≥0.28/0.20) or for the sub-periods (p≥0.19/0.20). Smaller changes, not significantly different between treatment groups (p≥0.60/0.70), were observed in LFTC (early ACLR: +16 [−53, +85] μm, delayed ACLR: +46[−25, +116] μm, rehab alone: +39 [−46, +124] μm).

OV 1 was significantly more negative and OV 16 was significantly more positive over 5 years in knees treated with early ACLR than in knees treated with rehab alone (OV1: p=0.04/0.03; OV16: p=0.02/0.01). These differences were predominantly driven by changes occurring between BL→Y2 with OV1 being significantly more negative in knees with early (p=0.01/0.01) or delayed ACLR (p=0.04/0.04) compared to knees treated with rehab alone. No other significant differences were found for any period.

Conclusion: Change in mean femorotibial cartilage thickness over a five year period after acute ACL injury did not differ between knees treated with early or delayed ACL reconstruction or knees treated with rehabilitation alone. An early ACL reconstruction may induce greater magnitudes of subregional cartilage thickness change as compared to knees treated with rehabilitation alone but the clinical relevance of such change remains to be determined.

The Relationship Between Toe-Out Angle During Walking and Risk Of Medial Knee Osteoarthritis Incidence: The Multicenter Osteoarthritis Study. K. Douglas Gross[1], Yuqing Zhang[2], Emily K. Quinn[1], Michael C. Nevitt[3], Neil A. Segal[4], Cora E. Lewis[5] and David T. Felson[2]. [1]Boston University, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]University of California, San Francisco, San Francisco, CA, [4]University of Iowa, Iowa City, IA, [5]University of Alabama, Birmingham, Birmingham, AL.

Background/Purpose: A previous study suggests a linear relationship between increased toe-out angle during walking and reduced risk of medial knee OA progression. Yet, gait lab findings indicate that both highly positive (toe-out) and negative (toe-in) angles can reduce medial knee load. The relationship of these angles with medial knee OA incidence has not been studied. We assessed the dose-response relationship of toe-out angle during walking with 2-year risk of incident medial knee OA.

Methods: The NIH-funded Multicenter Osteoarthritis Study (MOST) includes adults aged 50–79 years that have or are at risk of knee OA. Among 60-month participants, mean toe-out angle was measured during 4 self-paced walking trials using a 4.9 meter GAITRite walkway (14-day

retest ICC = 0.95). Readers scored medial joint space narrowing (JSN) on semiflexed knee x-rays using OARSI grades (weighted $\kappa = 0.81$). Among knees with medial JSN grade 0 at 60 months, incident cases had medial JSN ≥ 1 and $>$ lateral JSN grade at 84 months. With the middle quintile as a reference, logistic regression estimated the relative odds of medial OA incidence in each case-based quintile of toe-out angle while adjusting for age, BMI, walking speed, sex, race, clinic site, and non-independent knees of a single subject. We used a quadratic spline to smooth the curve and obtain a clear picture of the dose-response relationship. In sensitivity analysis, knees with pain during the walking exam were excluded.

Results: 1112 participants (mean age 66.6 +/− 7.6 yrs, BMI 29.6 +/− 5.3 kg/m^2, walking speed 1.19 +/− 0.19 m/sec, 61.1% female, 88.0% white, 55.7% Iowa clinic) contributed 1856 knees with a mean toe-out angle of 6.7 +/− 5.4° (range −11.0, 30.0°). After adjustments, the relative odds of incident medial knee OA had an n-shaped relationship with toe-out angle (p for trend < 0.01), such that the highest (9.8 to 30.0°) and lowest (−11.0 to 2.7°) quintiles had 11–25% reduced odds compared to the middle quintile (5.1 to 7.5°) (see table and figure). Results were unchanged in sensitivity analysis (p for n-shaped trend = 0.03).

	Toe-In −11.0, 2.7°	⟵ 2.8, 5.0°	5.1, 7.5°	7.6, 9.7° ⟶	Toe-Out 9.8, 30.0°	p for n shape trend
# knees	424	289	356	284	503	
% incident	3.3%	3.5%	3.9%	6.7%	3.4%	
Adj OR*	0.89	0.89	1.00	1.69	0.75	0.01
(95% CI)	(0.41, 1.92)	(0.38, 2.06)	(ref)	(0.85, 3.36)	(0.36, 1.60)	

*Adjusted for age, BMI, walk speed, sex, race, clinic, and non-independent knees

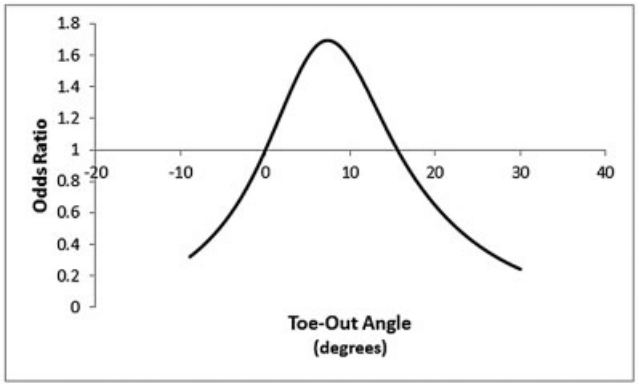

Figure. Quadratic spline depicting relative odds of medial knee osteoarthritis incidence by continuous measurement of toe-out angle during walking.

Conclusion: These results suggest that both highly positive (toe-out) and negative (toe-in) angles during walking are protective against medial knee OA incidence. Clinical trials should determine if gait training to alter toe-out angle is effective in preventing medial OA onset in at-risk knees.

Associations Between Popliteal Artery Wall Thickness and Knee Structure In Adults Without Clinical Knee Disease: A Prospective Cohort Study. Yuanyuan Wang[1], Diaz Novera[1], Anita Wluka[1], Jessica Fairley[1], Graham Giles[2], Richard O'Sullivan[3], Andrew Teichtahl[1] and Flavia Cicuttini[4]. [1]Monash University, Melbourne, Australia, [2]University of Melbourne, Melbourne, Australia, [3]Epworth Hospital, Melbourne, Australia, [4]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3004, Australia.

Background/Purpose: There is evidence for a vascular contribution to the pathogenesis of osteoarthritis. The aim of this study was to examine the association between popliteal artery wall thickness, previously shown to be associated with risk of generalized osteoarthritis, and knee structural changes in an asymptomatic cohort.

Methods: 297 adults with no significant knee pain, injury, or history of clinical knee disease were recruited. Participants underwent knee magnetic resonance imaging at baseline and 2 years later. Popliteal artery wall thickness, knee cartilage volume and bone marrow lesions (BML) were assessed.

Results: Of 278 participants with valid popliteal artery wall thickness measurement, 254 (91.4%) completed the follow-up. After adjusting for age, gender, body mass index and tibial bone area, increased popliteal artery wall thickness was associated with reduced medial tibial cartilage volume (B = −6.7, 95% CI −12.9, −0.6, p = 0.03) and increased rate of medial tibial cartilage volume loss (B = 0.06, 95% CI 0.01, 0.12, p = 0.03). There was a trend for medial tibiofemoral BML getting worse in relation to increased popliteal artery wall thickness (odds ratio 1.07, 95% CI 0.99, 1.15, p = 0.07). No significant associations were observed in lateral tibiofemoral compartment.

Conclusion: Increased popliteal artery wall thickness was associated with adverse changes in knee structure, as evidenced by reduced medial tibial cartilage volume, increased rate of cartilage volume loss and a trend for BML worsening over 2 years. These findings suggest an association between vascular pathology and early knee structural changes, supporting the hypothesis that vascular health may play a role in the development of knee osteoarthritis.

Mortality In Clinically Relevant Osteoarthritis and Rheumatoid Arthritis Compared With The General Population. Aleksandra Turkiewicz[1], Tuhina Neogi[2], George Peat[3] and Martin Englund[1]. [1]Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, [2]Boston University School of Medicine, Boston, MA, [3]Research Institute for Primary Care & Health Sciences, Keele University, Keele, United Kingdom.

Background/Purpose: There is strong evidence in support of increased mortality in patients with rheumatoid arthritis (RA), while the relation is more controversial in osteoarthritis (OA). Our aim was to assess mortality rates in patients with clinically relevant OA and RA, respectively, compared with those in the general population who have sought health care to minimize confounding.

Methods: We used a cohort study design within the Skåne Health Care Register in Sweden, which is a legislative, mandatory register based on physicians' International Classification of Diseases (ICD) 10 diagnostic codes. The register covers all primary and specialist health care as well as hospitalizations in southern Sweden (population 1.3 million). The Swedish population register contains information about vital events (births, deaths) and changes in residential address. We identified all patients aged ≥45 years having received the diagnosis of knee OA (ICD-10: M17), hip OA (M16), hand OA (M18, M15.1, M15.2, M19.0D, M19.1D, M19.2D), or RA (M05, M06) during 1999 to 2006. For RA patients we required at least two health care visits with the specific code registered, with at least one from a specialist in rheumatology or internal medicine. For OA we required at least one visit with the specific code registered. For the reference population aged ≥45, we required at least one visit with any diagnostic code (90% of the population had sought care during the period). Using the population register we followed all subjects from Jan 1st 2007 until relocation outside of the region, death, or Dec 31st 2011. We calculated mortality rates using the Cox proportional hazard model adjusted for age and sex, disposable income, marital status, and highest level of education reached (provided by Statistics Sweden). In a sensitivity analysis, we considered subjects who received a diagnosis of pain in a joint (M25.5, location unspecified) at age 55 or older as OA subjects in addition to the definition above.

Results: The hazard ratio of death for RA patients compared to general population was 1.58 (95% CI: 1.35–1.84). Patients with knee, hip or hand OA did not have increased risk of mortality compared with the general population, adjusted for age, sex and socioeconomic variables (Figure). The risk of death remained similar when OA in any joint (i.e., any combination of knee, hip, or hand) was assessed, or when pain in a joint at age ≥55 was additionally considered as OA. Effect estimates were similar in men and women (Table).

	Knee OA n=26 825	Hip OA n=14 557	Hand OA n=7 279	RA n=4 838	Reference population n=511 115
Age, mean (SD)	69.5 (11.8)	72.6 (10.8)	65.8 (10.2)	67.3 (11.0)	63.2 (12.3)
Women, n (%)	15 820 (590	8 449 (58)	5 666 (78)	3 459 (72)	269 118 (53)
Person time, years	122 982	65 498	34 532	21 399	2 386 221
Deaths, n	4 166	2 771	660	1 002	56 373
Mortality rate, per 100 000 person-years	3 388	4 231	1 911	4 682	2 362
HZ (95% CI)—adjusted for age, marital status, income and highest level of education reached					
Men	0.89 (0.79–1.00)	0.97 (0.85–1.10)	0.89 (0.65–1.21)	1.36 (1.04–1.79)	
Women	0.90 (0.82–0.98)	0.90 (0.80–1.01)	0.95 (0.79–1.15)	1.71 (1.41–2.06)	

Conclusion: We found no evidence of increased risk of mortality over 5 years in patients with doctor-diagnosed knee, hip or hand OA, compared with the general population, while increased mortality in RA was confirmed.

Vitamin D Deficiency Is Common and Associated With Increased C-Reactive Protein In Children With Lupus: An Atherosclerosis Prevention In Pediatric Lupus Erythematosus Substudy. Angela B. Robinson[1], Vin Tangpricha[2], Eric Yow[3], Reut Gurion[1], Grace McComsey[1] and Laura E. Schanberg[4]. [1]Rainbow Babies and Children's Hospital / Case Medical Center, Cleveland, OH, [2]Emory University School of Medicine, Atlanta, GA, [3]Duke Clinical Research Institute, Durham, NC, [4]Duke University Medical Center, Durham, NC.

Background/Purpose: Epidemiologic associations suggest vitamin D may play a role in inflammation and progression of atherosclerosis. Using frozen serum, carotid intima medial thickness (CIMT) measurements, and other data from the Atherosclerosis Prevention in Pediatric Lupus Erythematosus (APPLE) trial, we assessed associations between 25-hydroxyvitamin D [25(OH)D] and measures of systemic lupus erythematosus (SLE) disease activity and cardiovascular risk.

Methods: Participants in the 3-year APPLE trial were randomized to placebo or atorvastatin and CIMT progression was measured. Serum collected at baseline and 1 year was used to measure 25(OH)D levels. Logistic regression models for vitamin D deficiency [25(OH)D levels < 20 ng/mL] at baseline were constructed to evaluate univariable and multivariable associations with baseline variables. Variables collected as part of the APPLE trial included (1) known risk factors for vitamin D deficiency, (2) SLE-specific factors including duration of illness, disease activity, high sensitivity C-reactive protein (hsCRP), and proteinuria, and (3) traditional cardiovascular risk factors including fasting lipids and baseline CIMT.

Results: 201/221 APPLE subjects had available samples and were included in the analysis; 61/201 (30%) had vitamin D deficiency at baseline. There was no change in 25(OH)D levels after 1 year of atorvastatin or placebo. In univariable analysis, baseline 25(OH)D deficiency was associated with season ($p < 0.01$), minority status ($p < 0.01$), body mass index ($p = 0.04$), duration of SLE ($p < 0.01$), SLICC damage index ($p = 0.04$), hsCRP ($p < 0.01$), mean-max IMT ($p = 0.01$), LDL-cholesterol ($p = 0.03$), and timed urine protein ($p = 0.03$). In multivariable modeling, vitamin D deficiency was associated with age, latitude, season, minority status, proteinuria, and hsCRP (see Table).

Table. Logistic modeling of vitamin D deficiency (25OHD $<$ 20ng/mL)

	Odds ratio	95% CI	P-value
Age	1.28	1.09, 1.50	0.002
Latitude	0.87	0.76, 0.99	0.034
Season			
1st quarter	2.83	0.87, 9.23	0.084
2nd quarter	1.23	0.45, 3.36	0.685
3rd quarter	0.57	0.19, 1.75	0.327
Minority status	17.47	5.22, 58.48	<0.001
Log timed urine proteinuria	2.47	0.96, 6.34	0.060
Log hsCRP	1.40	1.07, 1.83	0.015

Conclusion: Vitamin D deficiency is common in pediatric lupus and is independently associated with elevated hsCRP, a marker of inflammation which predicts higher general cardiovascular disease risk. Observed association differences between univariable and multivariable modeling may be related to confounding or loss of power and requires further study. The association between vitamin D deficiency and hsCRP is novel in the SLE population and suggests that vitamin D deficiency may independently contribute to heightened inflammation and cardiovascular risk in this population.

Phase 2 Trial On Triptorelin For Ovary Protection In Childhood-Onset Systemic Lupus Erythematosus. Rina Mina[1], Andreas Reiff[2], Clovis A. Silva[3], Patricia Vega Fernandez[4], Gloria C. Higgins[5], Lisa F. Imundo[6], Marisa S. Klein-Gitelman[7], Calvin Williams[8], Carol A. Wallace[9], Nadia E. Aikawa[10], Shannen L. Nelson[11], Jun Ying[12], Susan R. Rose[13] and Hermine I. Brunner[14]. [1]Cincinnati Children's Hospital Medical Center/University of Cincinnati School of Medicine, Cincinnati, OH, [2]Children's Hospital Los Angeles, Los Angeles, CA, [3]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [4]Cincinnati Children's Hospital Medica Center, CINCINNATI, OH, [5]Nationwide Childrens Hosp, Columbus, OH, [6]Morgan Stanely Children's Hospital of New York-Presbyterian, Columbia University Medical Center, New York, NY, [7]Children's Memorial Hospital, Chicago, IL, [8]Medical College of Wisconsin, Milwaukee, WI, [9]Seattle Childrens Hosp & Research Institute, Seattle, WA, [10]Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [11]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [12]University of Cincinnati, Cincinnati, OH, [13]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [14]PRCSG, Cincinnati, OH.

Background/Purpose: Gonadotoxicity is a known side effect of cyclophosphamide (CYC) therapy in childhood-onset systemic lupus erythematosus (cSLE). Gonadotropin releasing hormone (GnRH) agonists, such as triptorelin, can induce complete ovarian suppression (COS), which makes ovaries resistant to CYC gonadotoxicity. The aims of this research are to determine (1) the dose of triptorelin sufficient for reliable

COS in cSLE patients receiving CYC, and (2) the safety profile of triptorelin in cSLE.

Methods: This double-blind, placebo-controlled, dose-escalation RCT (phase I/II) recruited cSLE patients from 7 international centers (NCT00124514). All patients were female, aged ≤ 21 years and Tanner breast stage ≥ 2. They were randomized in a 4:1 fashion to receive either intramuscular triptorelin [μg/kg/dose: 25 (T1), 50 (T2), 75 (T3), 100 (T4)] or placebo every 4 weeks during CYC induction. The primary efficacy endpoint was the monthly dose of triptorelin that resulted in maintenance of COS which was defined *a priori* as (A) basal level of Follicle Stimulating Hormone (FSH) < 2 mIU/ml and of Luteinizing Hormone (LH) < 1 mIU/ml; or (B) FSH < 3 mIU/ml and of LH < 2 mIU/ml during GnRH Stimulation Testing (GAST). FSH and LH levels were drawn at the expected trough levels of triptorelin (27 days post administration). The triptorelin dose was escalated by 25% or at least 20 μg/kg until maintenance of COS was achieved (maximum=150 μg/kg/dose). Adverse events (AE) were graded according to the National Cancer Institute Common Toxicity Criteria, Version 2.

Results: Twenty-nine females were randomized (Placebo=6, T1= 9, T2=8, T3=5, T4=1). Of those who received triptorelin, 4 patients did not complete the study due to CYC discontinuation or withdrawal of consent. As expected, none of those in the placebo group achieved COS. A dose of 75 and 110 μg/kg maintained COS in 75% and 90% of the patients, respectively. There was no relationship between the triptorelin dose and the patients' age, Tanner stage, global disease activity, renal and hepatic function. None of the patients in T3 and T4 arms needed dose escalation of triptorelin while the converse is true for majority of patients in T1 and T2. AE were mild and the most common were hot flashes (24%), headache (14%), and insomnia (10%). Serious AE included hospitalization due to dehydration (Placebo=1), worsening of SLE disease activity (Placebo=1), and cutaneous vasculitis (T3=1).

Conclusion: This interim analysis supports that higher doses of triptorelin than previously suggested are needed for COS in adolescent females with cSLE who require CYC. Doses of intramuscular triptorelin at 110 μg/kg induce continuous COS between injections given every 28 days in almost all females, and thus likely provide ovarian protection. These high doses of triptorelin appear well tolerated.

Increased Pulse Wave Velocity In Juvenile Idiopathic Arthritis Patients Compared To Controls From The General Population. Hanne A. Aulie[1], Anne Marit Selvaag[1], Vibke Lilleby[1], Oyvind Molberg[1], Anders Hartmann[2], Hallvard Holdaas[2] and Berit Flato[1]. [1]Department of Rheumatology, Oslo University Hospital, Rikshospitalet, Oslo, Norway, [2]Department of Nephrology (and specialised Endocrinology), Oslo University Hospital, Rikshospitalet, Oslo, Norway.

Background/Purpose: The aim of this study was to compare markers of subclinical cardiovascular disease (CVD) in adults with juvenile idiopathic arthritis (JIA) and controls, and assess the relation between arterial properties and JIA characteristics, received therapy, and traditional cardiovascular risk factors.

Methods: Eighty-seven JIA patients (median age 38.4 years), with persistently active disease at least 15 years after disease onset, registered by longitudinal follow-up, were reexamined after median 29 years and compared to 87 matched controls from the Norwegian population register. Pulse wave velocity (PWV), a direct measure of large arterial stiffness and augmentation index (AIx), a marker of arterial stiffness and wave reflection, were estimated. Linear regression analyses adjusted for age and gender were used to analyze the associations between arterial stiffness and traditional cardiovascular risk factors as well as disease characteristics. Linear multiple regression analyses were performed to identify predictors of arterial stiffness.

Results: PWV, systolic and diastolic blood pressures (SBP and DBP) were significantly higher in patients than controls (table). In patients, increased PWV was mainly related to DBP ($p < 0.001$), but was also associated with higher SBP ($p<0.001$), glucose ($p=0.001$), and pulse rate ($p=0.003$), lower high density lipoprotein cholesterol ($p=0.050$), and male gender ($p=0.013$). Higher AIx was determined by increased DBP ($p<0.001$), age ($p = 0.039$), female gender ($p < 0.001$), daily smoking ($p=0.024$), high sensitivity C- reactive protein (CRP) ($p=0.014$), and physician's global assessment of disease activity ($p=0.001$). Furthermore, AIx was associated with longer duration of active disease ($p=0.012$), higher CRP area under the curve ($p=0.006$), less vigorous physical activity ($p=0.004$), joint erosions ($p=0.016$), and therapy with prednisolone ($p<0.001$), nonsteroidal anti-inflammatory drugs ($p=0.036$), and methotrexate ($p=0.015$). Hypertension, daily smokers, and insulin resistance were more frequent in patients than controls ($p=0.039$, $p=0.043$ and $p=0.034$ respectively), but the traditional cardiovascular risk factors were more extensively related to increased AIx in controls.

Table.

	n	JIA patients	Controls	P (paired t-test)
Systolic blood pressure (mmHg)	87	119.4 ± 14.5	115.7 ± 9.8	0.050
Diastolic blood pressure (mmHg)	87	75.7 ± 10.3	72.7 ± ±8.2	0.029
Pulse (beats/ minute)	87	62.7 ± 10.7	61.8 ± 9.7	0.564
Pulse wave velocity (PWV) (m/s)	78	7.2 ± 1.0	6.9 ± 0.8	0.035
Augmentation index (AIx)	79	14.5 ± 10.8	12.0 ± 12.2	0.154

Conclusion: JIA patients with long-term active disease experienced increased arterial stiffness assessed by PWV. Traditional cardiovascular risk factors and the degree of disease activity and severity, treatment factors and physical activity influenced the arterial stiffness measured by PWV and AIx in these patients.

2677

Disease Progression Into Adulthood In Patients With Juvenile Idiopathic Arthritis – a Longitudinal 30 Year Follow-Up Study. Anne Marit Selvaag, Hanne Aulie, Vibke Lilleby and Berit Flatø. Department of Rheumatology, Oslo University Hospital, Rikshospitalet, Oslo, Norway.

Background/Purpose: The aim of the study was to assess disease activity and health status in a previously studied cohort of patients with juvenile idiopathic arthritis (JIA) 30 years after disease onset and reveal predictors of active disease.

Methods: A total of 254 patients with JIA, first referred to our hospital from 1980 to1985, were reexamined clinically after median 15 years of disease duration, and by mailed questionnaires after median 23 years. These patients were invited to attend the present study. All patients were assessed by questionnaires, and those with signs of active disease after 15, 23 and/or 30 years were invited to a clinical reexamination. Health status was measured by HAQ and SF-36, and disease activity by the clinical version of the juvenile arthritis disease activity score (cJADAS). Logistic regression analyses were used to assess predictors of persistently active disease and an unacceptable symptom state (cJADAS > 4.5).

Results: One hundred and seventy-one patients (67%) were included in the study. They were examined after a median of 30 (range 21–40) years of disease duration, median age 39 (range 28–45) years, 74% females.

After 30 years, 101 patients (59%) were in clinical remission off medication, 12 (7%) were in remission on medication and 58 (34%) had persistently active disease. Thirty-seven of 57 patients (65%) with active disease at 15 years follow-up had active disease at 30 years follow-up, and 20 patients (35%) went into remission on/off medication. Eighty-four of 97 patients (87%) in remission off medication at 15 years were in remission at 30 years follow-up. Patients in remission on medication at 15 years (n=17) tended to flare (n=9) or go into remission off medication (n=6).

The cJADAS score was median 1.9 for the total study group, and 43% (n=73) of the patients had a cJADAS score ≤ 1.0, 10 % (n=16) had cJADAS from 1.1 to 2.0, 18% (n=30) had cJADAS from 2.1 to 4.5, and 30% (n= 50) had cJADAS > 4.5.

Predictors of persistently active disease at 30 years follow-up were: being diagnosed with a JIA subgroup other than persistent oligo articular and systemic JIA (OR 4.1, 95%CI 1.5–11.5), being DR1 positive (OR 8.3, 95%CI 2.3–30.3), a short total time in remission (OR 9.0, 95% CI 3.0–26.7), and not being in remission at 15 years follow-up (OR 13.7, 95%CI 4.9–38.4). R^2=65%. Predictors of a cJADAS score > 4.5 at 30 years follow-up were physician's global score of disease activity at 15 years (OR 2.4, 95%CI 1.7–3.5) and daily smoking (OR 2.5, 95%CI 1.1–5.9). R^2=23%.

We compared disease activity at 15 years with that of 30 years follow-up for 90 patients. There were significant improvements in physicians global assessment of disease activity ($p=0.003$), number of active joints ($p=0.010$), ESR ($p=0.041$) and CRP ($p<0.001$), but no significant change in patient's global assessment, number of joints with limitation of motion, HAQ, or SF-36.

Conclusion: The overall remission rates were stable between 15 and 30 years. After 30 years, a third of the JIA patients had an unacceptable symptom state and a third was not in remission on or off medication. Physician's assessment of disease activity and inflammatory markers improved over the years, but patient reported disability and health status did not change.

Medically Significant Infections Are Increased In Patients With Juvenile Idiopathic Arthritis Treated With Etanercept. Results From The British Society For Paediatric and Adolescent Rheumatology Etanercept Cohort Study. Rebecca Davies[1], Taunton R. Southwood[2], Lianne Kearsley-Fleet[1], Mark Lunt[1], Kimme L. Hyrich[3] and on Behalf Of The BSPAR Etanercept Cohort Study[1]. [1]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]Institute of Child Health, University of Birmingham and Birmingham Children's Hospital, Birmingham, United Kingdom, [3]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Sciences Centre, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom.

Background/Purpose: The association between anti-TNF therapy and increased rate of infection are widely documented in adults with rheumatoid arthritis. Findings in children with juvenile idiopathic arthritis (JIA) have been less consistent and limited by small sample size and restricted follow up times. Dutch and German national registers documented low rates of serious infection (SI) in etanercept (ETN) treated patients with JIA, although one analysis has suggested more frequent SIs when ETN was used in combination with methotrexate (MTX). The aims of this analysis were (1) to compare rates of serious infection in JIA patients treated with ETN vs. MTX and (2) to compare the rates between ETN-MTX combination and ETN monotherapy.

Methods: To 31/5/2013, 677 ETN and 182 biologic-naive MTX control patients had been recruited to the BSPAR Etanercept Cohort Study, a UK national register established in 2004 to monitor the safety and effectiveness of ETN in children with JIA. All patients were followed by regular hospital questionnaires. Serious infections were defined as any infection regarded as medically significant by the patient's clinican. This on-drug analysis followed all patients until first SI, death, treatment discontinuation or last follow-up date, whichever came first. Cox proportional hazards models were used to compare rates of SI between cohorts. Adjustments were made for potential confounders including age, gender, co-morbidities, oral steroid use, disease duration, ILAR category (systemic versus non-systemic) and disease severity, using a propensity score stratified into deciles (PD). Missing baseline data were accounted for using multiple imputation.

Results: The ETN cohort were older (mean 10.6 v 7.8 years), with longer disease duration (4.6 v 1.2 years), and had a higher proportion of children with systemic arthritis (15% v 4%). Disease activity was similar between the cohorts. The mean duration of follow up was 2.4 years in the ETN cohort, and 2.6 years in the MTX cohort. A total of 120 first SI's were reported (99 ETN, 21 MTX). Patients on ETN had higher rates of SI than controls (PD adjusted HR 2.03 (1.12, 3.65)). The risk of SI did not differ between patients receiving ETN as monotherapy and those receiving ETN in combination with MTX (PD adjusted HR 1.24 (95 % CI 0.83, 1.86)) (Table).

Table. Patient characteristics and incidence of serious infection.

	MTX registered	On ETN	On ETN monotherapy	On ETN & MTX in combination
Subjects (n)	182	677	..	..
Exposure (person-years)	466	1498	827	671
Total serious infection, n	21	134	67	67
First serious infection, n	21	99	47	52

Incidence Rates Of Serious Infections and Infection Subtypes Among Pediatric Systemic Lupus Erythematosus Patients Enrolled In Medicaid, According To Medication Use. Linda T. Hiraki[1], Candace H. Feldman[2], Mary Beth Son[3], Jessica M. Franklin[4], Michael A. Fischer[4], Daniel H. Solomon[5], Seoyoung C. Kim[6], Wolfgang C. Winkelmayer[7] and Karen H. Costenbader[8]. [1]Brigham and Women's Hospital, Harvard School of Public Health, Boston, MA, [2]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]Children's Hospital Boston, Boston, MA, [4]Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Boston, MA, [5]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA, [6]Brigham and Women's Hospital, Boston, MA, [7]Stanford University School of Medicine, Stanford, CA, [8]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: We investigated incidence rates of serious infections and infection subtypes among children with SLE enrolled in Medicaid, the U.S. health insurance program for low-income children and parents.

Methods: We identified all children aged 3 to <18 years with SLE (≥3 ICD-9 codes of 710.0, each >30 days apart) in the Medicaid Analytic eXtract (MAX) from 2000–2006. This dataset contains all outpatient and inpatient Medicaid claims for enrollees in 47 U. S. states and the District of Columbia. Filled prescriptions were documented and patients were classified as ever/never users of corticosteroids (CS) and immunosuppressants (IS). We identified serious infections from hospital discharge diagnosis codes for all infections, and for specific subtypes of infections (bacterial, fungal and viral). We calculated incidence rates (IR) per 1000 person-years for number of infections ≥7 days following first prescription. Incidence rate ratios (IRR) (95% CI) were calculated comparing: 1) receipt of neither CS nor IS, 2) receipt of CS alone and 3) receipt of both CS and IS. We employed Poisson models, adjusted for age, sex and duration of enrollment in Medicaid.

Results: Of the 4,068 children identified with SLE. A total of 839 serious infections occurred in 457 children during 8,854 person-years. 2.9% of the children had ≥3 infections during their Medicaid enrollment. (**Table**) Incidence rates for all serious infections requiring hospitalization varied between 43 and 109 per 1000 children per year. Among children with SLE receiving CS alone, incidence rates were approximately twice as high for both all infections and for bacterial infections, and 5.2 times higher for viral infections, compared to those children not receiving CS or IS. Among children receiving both CS and IS, overall serious infection incidence rates were approximately 2.5 times higher, bacterial infections were 2.3 times higher, and viral infections were 7.5 times higher, compared to children not receiving either medication. Fungal infection incidence rates did not appear to be increased among users of CS or IS.

Table. Incidence Rates and Incidence Rate Ratios for Serious Infections among Children with SLE enrolled in Medicaid, 2000–2006

	All Infections		Bacterial Infections		Fungal Infections		Viral Infections	
	IR (95%CI)	IRR (95% CI)	IR (95% CI)	IRR (95% CI)	IR (95%CI)	IRR (95% CI)	IR (95%CI)	IRR (95% CI)
SLE								
No CS* or IS n=763**	43.6 (43.2, 44.0)	1.0 (ref)	37.9 (37.5, 38.2)	1.0 (ref)	3.6 (3.5, 3.7)	1.0 (ref)	2.1 (2.1, 2.2)	1.0 (ref)
CS* alone n=1211	86.5 (86.2, 86.8)	**1.97 (1.55, 2.53)**	71.2 (70.9, 71.5)	**1.90 (1.49, 2.41)**	3.7 (3.7, 3.8)	0.98 (0.71, 1.35)	11.2 (11.1, 11.3)	**5.16 (3.37, 7.90)**
CS* and IS n=1872**	109.0 (108.8, 109.2)	**2.48 (1.92, 3.22)**	88.5 (88.3, 88.7)	**2.32 (1.79, 3.00)**	4.4 (4.3, 4.4)	1.25 (0.92, 1.70)	15.7 (15.6, 15.8)	**7.51 (4.32, 13.06)**

Incidence rate ratios (IRRs) adjusted for age, sex and Medicaid enrollment duration. Incidence rates (IRs) and IRRs reported per 100,000 person years.
*CS: Corticosteroids: oral/IV prednisone, methylprednisolone, dexamethasone, hydrocortisone, prednisolone, cortisone.
**IS: Immunosuppressants: mycophenolate mofetil, oral/IV cyclophosphamide, azathioprine, cyclosporine, tacrolimus. Hydroxychloroquine not included.
Bacterial infections: cellulitis, endocarditis, pneumonia, pyelonephritis, septic arthritis, osteomyelitis, bacteremia, listerosis.
Fungal infections: systemic candidiasis, cryptococcosis, aspergillosis, histoplasmosis, pneumocystic carinii, .
Viral infections: cytomegaloviral disease, influenza, herpes zoster, varicella zoster.

Conclusion: We observed significant variation in incidence rates of serious infections among children with SLE. Those children with SLE who were receiving CS alone or in combination with IS, had much higher rates of bacterial and viral infections, compared to those children receiving neither CS nor IS. Viral infection rates were over 5 times higher among the children receiving these mediations than among those who were not.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Clinical Aspects IV: Comorbidities in Rheumatoid Arthritis
Tuesday, October 29, 2013, 2:30 PM–4:00 PM

2680

Risk of Subsequent Infection among Rheumatoid Arthritis Patients Using Biologics. Huifeng Yun[1], Fenglong Xie[1], Elizabeth S. Delzell[1], Lang Chen[1], Emily Levitan[1], James Lewis[2], Kenneth G. Saag[1], Timothy Beukelman[1], Kevin L. Winthrop[3], John Baddley[1], Paul M. Muntner[1] and Jeffrey R. Curtis[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Pennsylvania, Philadelphia, PA, [3]Oregon Health & Science University, Portland, OR.

Background/Purpose: Much has been written about infections associated with biologic agents in patients with rheumatoid arthritis (RA). However, less is known about the risk of subsequent infections in RA patients who resume biologic therapy after a serious infection. To compare the subsequent risk of hospitalized infections associated with specific biologic agents among RA patients previously hospitalized for infection while receiving anti-TNF therapy.

Methods: Using Medicare data from 2006–2010 for 100% of beneficiaries with RA, we identified patients who were hospitalized with infection while on anti-TNF agents and who had US Medicare fee-for-service hospital, physician and prescription drug coverage continuously in the 6 months before the hospitalization discharge date and throughout follow up. Follow-up began 60 days after hospital discharge and ended at the earliest of subsequent infection, loss of Medicare coverage or after 18 months. We determined biologic exposure on each person-day during follow-up and treated exposure as time varying. Confounding was controlled through a person-specific infection risk score that was separately derived among new users of anti-TNF and non-biologic DMARDs. We calculated the incidence rate of subsequent hospitalized infection for each biologic and used cluster adjusted Cox regression to evaluate the association between specific biologics and subsequent infection, controlling for the decile of the infection risk score, types of anti-TNF use, steroid use during baseline, non-biologic DMARD use during baseline and coexisting biologic exposures.

Results: During follow-up of 10,794 hospitalized infections while exposed to anti-TNF therapy, we identified 7,807 person-years of exposure to target biologics and 2,666 subsequent hospitalized infections; of this exposure time 4% was on abatacept, 2% on rituximab and 94% on anti-TNFs, including 23% on etanercept, 18% on adalimumab and 53% on infliximab. Abatacept users had the lowest crude incidence rate of subsequent infection, and etanercept users had the highest. After adjusting for infection risk score decile, the original anti-TNF medication and other potential confounders, abatacept (hazard ratio (HR): 0.80, 95% CI: 0.64–0.99) and etanercept (HR: 0.83, 95% CI: 0.72–0.96) users had significantly lower risks of infection compared to infliximab users.

Table. Number of events, crude incidence rates (IRs) and adjusted Hazard Ratios (HR) for subsequent hospitalized infection by biologic*

Biologic Exposure	Events	PYs†	IR/100 PYs	Crude HR (95% CI)	Adjusted HR (95% CI)‡
Abatacept	88	333	26.5	0.88 (0.71–1.09)	0.80 (0.64–0.99)
Rituximab	38	133	28.5	0.93 (0.68–1.28)	0.85 (0.62–1.18)
Etanercept	661	1,831	36.1	1.07 (0.98–1.17)	0.83 (0.72–0.96)
Adalimumab	497	1,423	34.9	1.03 (0.93–1.14)	0.92 (0.79–1.07)
Infliximab	1382	4,087	33.8	1.0 (ref)	1.0 (ref)

*Biologic exposure was defined as the days' supply field from filled prescriptions to which was added a 30-day 'extension' period.
† Person years.
‡Adjusted for the decile of disease risk score, types of anti-TNF use before the index hospitalization, steroid dose during baseline, methotrexate use during baseline, infection type for the index hospitalization and concurrent biologic exposures during follow up.

Conclusion: Among RA patients who experienced a hospitalized infection while on anti-TNF therapy, the risk of subsequent hospitalized infection was lower for abatacept and etanercept than for other commonly prescribed biologic therapies.

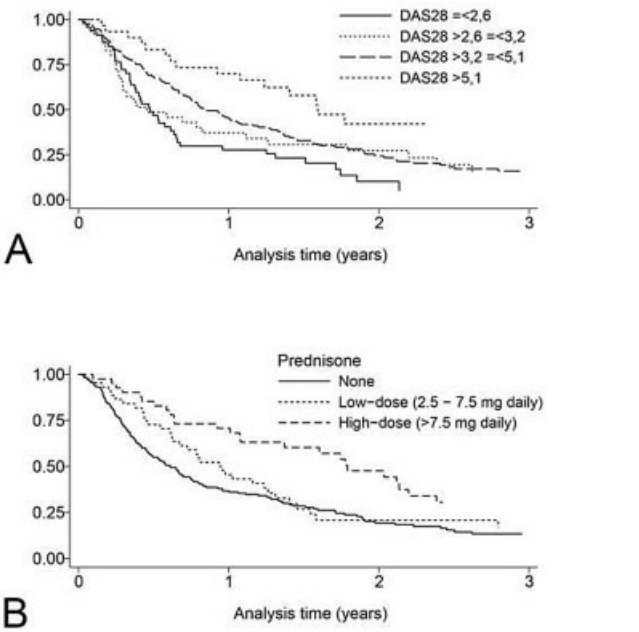
Reduced Fertility In Women With Rheumatoid Arthritis: Influence Of Disease Activity and Medication Use. Jenny Brouwer, Johanna MW Hazes, Joop SE Laven and Radboud JEM Dolhain. Erasmus University Medical Center, Rotterdam, Netherlands.

Background/Purpose: Many female rheumatoid arthritis (RA) patients who try to conceive have a time to pregnancy (TTP) longer than 12 months. During this period RA often cannot be treated optimally. As a result, a longer TTP may result in higher chance of permanent joint damage, with a negative impact on social roles. Thus far, no studies on possible causes of the prolonged TTP in RA patients have been reported. In order to optimize care for these women, we aimed to identify clinical factors associated with a prolonged TTP in RA patients.

Methods: From 2002 until 2010, a nationwide prospective cohort study on pregnancy in RA patients (PARA study) was performed. Women with RA according to the 1987 American College of Rheumatology (ACR) criteria were included preconceptionally or during first trimester. All preconceptionally included women were actively trying to become pregnant. To study the effect of various disease characteristics and medications on the TTP, we performed a multivariable Cox regression analysis.

Results: Two-hundred-forty-five patients were included. The mean age was 31.3±3.9 years. The TTP was longer than 12 months in 42% of patients, of whom 40 women(16%) had not gotten pregnant during the follow up period. A longer TTP was related to various variables. Hazard ratios for occurrence of pregnancy were 0.96 (95%CI 0.92–1.00) per year increase in age; 0.52 (0.38–0.70) for nulliparity; 0.81 (0.71–0.93) per

point increase in disease activity score (DAS28); 0.61 (0.45–0.83) for preconceptional prednisone use; and 0.66 (0.46–0.94) for non-steroidal anti-inflammatory drug (NSAID) use. Eighty-five patients used prednisone during the preconceptional period. The impact of prednisone use on TTP was dose-dependent, with a significant longer TTP when the daily dose was higher than 7.5 mg. TTP was not affected by smoking, disease duration, rheumatoid factor, anti-citrullinated protein antibodies, past methotrexate use, and preconceptional sulfasalazine use.



Survival curves showing the time to pregnancy (TTP) in RA patients with (**A**) various levels of disease activity, and (**B**) with different prednisone dosages. If women had not become pregnant at the last time of contact, the TTP was considered censored at the date of the last visit.

Conclusion: TTP in female RA patients is longer if patients are older or nulliparous, have higher disease activity scores, use NSAIDs or use prednisone in a daily dose higher than 7.5 mg daily. Treatment strategies during the preconceptional period should try to maximize suppression of disease activity, taking account of possible negative effects of NSAIDs use and use of higher doses of prednisone.

Incidence Trends and Predictors Of Orthopedic Surgery In Patients With Rheumatoid Arthritis – Results From a Well Defined Population. Korosh Hekmat[1], Lennart Jacobsson[1], Jan-Åke Nilsson[1], Minna Willim[1], Martin Englund[2], Ingemar F. Petersson[3] and Carl Turesson[1]. [1]Lund University, Malmö, Sweden, [2]Lund University, Lund, Sweden, [3]Musculoskeletal Scienes, Department of Orthopedics, Clinical Sciences, Lund, Sweden.

Background/Purpose: Orthopedic surgery is used effectively in many patients with severe rheumatoid arthritis (RA). The aim of modern pharmacologic treatment is to prevent joint destruction and reduce the need for orthopedic surgery. Our purpose was to investigate trends in the incidence as well as predictors for such procedures in a population-based sample of patients with RA.

Methods: The study was based on a dynamic cohort of all known patients from a defined geographical area with a clinical diagnosis of RA who fulfilled the 1987 American College of Rheumatology criteria for RA. A total of 2342 patients (68.7% women) were included. Questionnaires were sent to the RA patients in the register in 1997, 2002, 2005 and 2009(response rates 62–74 %) including visual analogue scales (VAS) for general health and pain and the health assessment questionnaire (HAQ). This register was linked to a regional health care register, which contains information on all inpatient and outpatient procedures in the area, to the national population register to add information on vitality and residential address, and to a regional register of patients with arthritis treated with biologics, which covers >90% of such patients in the region. The total follow-up was calculated for each calendar year from 1998 through 2011, and the annual incidence rate of orthopedic surgery procedures was estimated. The incidence rate for 1998–2001 was compared to those of 2002–2006 and 2007–2011. The impact of demographics and patient reported outcomes on the risk of future orthopedic surgery was analyzed using Cox proportional hazard models.

Results: The incidence of all orthopedic surgery procedures during the whole study period was 82,3/1000 person-years (95 % confidence interval (CI) 78,7–86,0). The incidence of all procedures declined significantly over time, with a decrease also for large joint surgery and small joint surgery (hand, wrist, foot and ankle surgery), when studied separately (Table). There was a decline in hip surgery, but not in knee surgery (Table). The incidence of large joint surgery was reduced already in 2002–2006 compared to 1998–2001, whereas a decline in small joint surgery was apparent only in the final period (2007–2011).

Female sex was a predictor of orthopedic surgery [age adjusted hazard ratio (HR) 1.50; 95 % CI 1.23–1.83). Greater disability, measured by HAQ, was associated with a higher rate of orthopedic surgery (HR per standard deviation 1.37; 95 % CI 1.25–1.50 adjusted for age, sex and duration of RA), and similar, although weaker, associations were observed for VAS pain and VAS global.

Table. Incidence of orthopaedic surgery procedures per 1000 person-years (95% CI)

	1998–2001	2002–2006	2007–2011	P for trend
Any orthopedic surgery	94.6 (87.3–102.2)	82.6 (76.7–88.8)	71.8 (66.1–77.8)	<0.001
Hip surgery	27.8 (23.9–32.0)	16.5 (14.0–19.4)	17.6 (14.8–20.7)	<0.001
Knee surgery	12.3 (9.8–15.3)	13.2 (10.9–15.8)	12.9 (10.6–15.6)	0.759
Any small joint surgery	43.8 (38.9–49.0)	43.4 (39.2–47.9)	30.5 (26.9–34.5)	<0.001
Any large joint surgery	48.5 (43.4–54.0)	37.9 (33.9–42.1)	39.3 (35.1–43.8)	0.009

Conclusion: The overall incidence of orthopedic surgery declined over time which coincides with increasing use of more intensive pharmacological treatment including the use of biologics. The decrease in large joint surgery predated that of small joint surgery. Improved management may reduce the need for orthopedic interventions in patients with RA.

Application Of a Multi-Biomarker Disease Activity (Vectra® DA) Score For Assessing Rheumatoid Arthritis Patients With Fibromyalgia Or Low C-Reactive Protein. Yvonne C. Lee[1], James Hackett[2], Claire Alexander[3], Michelle A. Frits[1], Christine K. Iannaccone[1], Nancy A. Shadick[1], Michael E. Weinblatt[1], Oscar Segurado[3] and Eric H. Sasso[3]. [1]Brigham and Women's Hospital, Boston, MA, [2]Hackett & Associates, Inc., San Diego, CA, [3]Crescendo Bioscience Inc., South San Francisco, CA.

Background/Purpose: Clinical assessment of rheumatoid arthritis (RA) may be challenging if patients have fibromyalgia (FM) or if C-reactive protein (CRP) is low (≤1 mg/dL). A multi-biomarker disease activity (MBDA) blood test has been developed to assess RA disease activity with a score (range: 1–100) that is calculated using a validated algorithm for 12 serum protein biomarkers (VCAM-1, EGF, VEGF-A, IL-6, TNF-RI, MMP-1, MMP-3, YKL-40, leptin, resistin, SAA, CRP). The present study evaluated the role of the MBDA score for assessing disease activity in a cohort of established RA patients, including patients with concomitant FM or low CRP.

Methods: 208 RA patients from a prospective observational cohort were randomly selected for a substudy of pain in RA. For the present cross-sectional study, DAS28-CRP components, the Widespread Pain Index (to diagnose FM by a modified version of the 2010 ACR Diagnostic Criteria for FM), and the MBDA (Vectra‰ DA) score were evaluated for

the initial substudy visit. 198 patients with non-missing baseline MBDA score and DAS28-CRP components were included. Measures of disease activity were compared between patients with RA+FM vs. RA without FM using: t-test or Wilcoxon rank sum tests; multivariate adjustment for age, sex, race, BMI, RF-positivity and non-biologic DMARD use by linear regression or poisson regression (for SJC, TJC); and cumulative probability plots. CRP was compared to MBDA scores by cross-classification.

Results: Characteristics of the overall group (N=198) included: mean age 58.1 years, 84.8% female, 15.9 years mean duration RA, and 61.6%/60.6% taking a non-biologic/biologic DMARD. Patients with RA+FM (N=25) vs. RA alone (N=173) had similar CRP levels, MBDA scores and swollen joint counts (SJC), whereas the 25 RA+FM patients had significantly greater unadjusted values for patient global assessment (PGA) (median 50 vs. 15, $p<0.001$), DAS28-CRP (mean 3.6 vs. 2.8, $p<0.01$) and tender joint counts (TJC) (median 4.0 vs. 1.0, $p=0.04$). Multivariate adjustment gave similar results, but with a larger p-value for TJC ($p=0.30$). CRP levels were ≤1, >1 to 3, or >3 mg/dL in 93%, 6%, and 1% of the 198 subjects, respectively. Among those with low CRP (≤1 mg/dL), MBDA scores were low (≤29) in 51%, moderate (30–44) in 36% and high (>44) in 13%, with similar findings seen in the RA+FM and RA-alone groups. For those with low CRP, the TJC and SJC increased across low to high MBDA categories, suggesting that MBDA differentiated levels of joint inflammation when CRP was low.

Table 1. Disease activity measures for RA patients who met 2010 ACR diagnostic criteria for FM versus those who did not.

Disease Activity Index	RA + FM (N = 25)	RA without FM (N = 173)	Unadjusted P-value[1]	Adjusted P-value[2]
MBDA score	33	32	0.65	0.86
C-reactive protein (mg/dL)	2.0	1.6	0.84	0.72
Swollen joint count	1.0	1.0	0.38	0.40
Tender joint count	4.0	1.0	0.04	0.30
Patient global assessment	50	15	<0.001	<0.001
DAS28-CRP	3.6	2.8	<0.01	<0.01

Values for disease activity measures are unadjusted for covariates and are medians, except for MBDA score and DAS-28, which are means.
[1]P-values for unadjusted means by t-test; for unadjusted medians by Wilcoxon test.
[2]P-values for multivariate (covariate-adjusted) analysis.

Conclusion: Patients with RA+FM, vs. those with RA alone, had similar MBDA scores and CRP values, but significantly greater DAS28-CRP, mostly due to greater PGA. However, MBDA score differed from CRP because MBDA score detected moderate or high disease activity in nearly half of patients with low CRP (≤1 mg/dL). Further study is needed to determine the clinical meaning of discordance between CRP and MBDA scores.

Impact Of Anti-Rheumatic Treatment On Immunogenicity Of Pandemic H1N1 Influenza Vaccine In Patients With Arthritis. Meliha C. Kapetanovic[1], Lars-Erik Kristensen[2], Tore Saxne[3], Teodora Aktas[4], Andreas Mörner[4] and Pierre Geborek[3]. [1]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund University, Lund, Sweden, [2]Department of Clinical Sciences, Section of Rheymatology, University Hospital of Skåne, Lund, Sweden, [3]Lund University, Lund, Sweden, [4]Vaccinology Unit, Department of Diagnostics and Vaccinology, Swedish Institute for Communicable Disease Control, Solna, Sweden, Solna, Sweden.

Background/Purpose: An adjuvanted pandemic H1N1 influenza (pH1N1) vaccine (Pandemrix®) was reported as highly immunogenic resulting in seroconversion in 77–94% of adults after administration of a single dose. The aim of the present study was to investigate impact of different anti-rheumatic treatments on antibody response to pH1N1 vaccination in patients with rheumatoid arthritis (RA) and spondylarthropathy (SpA).

Methods: Patients with arthritis (n=291; mean age 57 years, 64% women) participated. Hemagglutination inhibition (HI) assay was performed on blood samples drawn before and after a mean (SD) of 8.3 (4) months following vaccination. A positive immune response i.e. seroconverstion was defined as negative prevaccination serum and post-vaccination HI titer ≥40 or a '4-fold increase in HI titer. There were 7 treatment groups: 1) RA on methotrexate (MTX); 2) RA on anti-TNF monotherapy; 3) RA on anti-TNF+MTX; 4) RA on other biologics (abatacept, rituximab, tocilizumab); 5) SpA on anti-TNF monotherapy; 6) SpA on anti-TNF+MTX and 7) SpA on NSAIDs/analgesics. Predictors of positive immune response were studied using logistic regression analysis.

Results: The percentage of patients with positive immune response in the different treatment groups were: 1) 42% 2) 53% 3) 43% 4) 20% 10%, 50% 5) 76% 6) 47% and 7) 59%, respectively. RA patients on rituximab had significantly lower ($p<0.001$) and SpA on anti-TNF monotherapy significantly better response rates compared to other treatment groups (p 0.001–0.033). Higher age ($p<0.001$) and current smoking predicted impaired immune response ($p=0.025$). Antibody titers 3–6 months after vaccination were generally lower compared to those within first 3 months but no further decrease in titers were observed 6–22 months after vaccination.

Conclusion: Rituximab treatment severely reduced antibody response to pH1N1 influenza vaccine. All other treatments groups showed lower although acceptable antibody response. Serological immunity seems to be stable for 22 months in the current patient population, with the exception of rituximab (and possibly abatacept) treated patients.

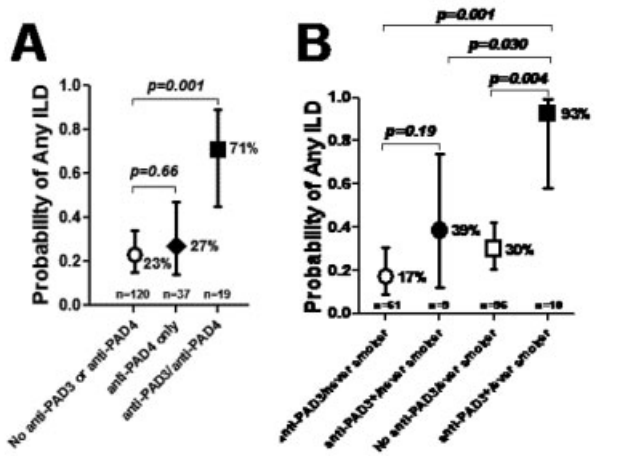
Anti-Peptidylarginine Deiminase 3/4 Cross-Reactive Antibodies Are Associated With Radiographic Interstitial Lung Disease In Rheumatoid Arthritis, An Effect Potentiated By Smoking. Jon T. Giles[1], Erika Darrah[2], Sonye K. Danoff[2], Cheilonda Johnson[2], Felipe Andrade[3], Antony Rosen[2] and Joan M. Bathon[4]. [1]Columbia University, College of Physicians & Surgeons, New York, NY, [2]Johns Hopkins University, Baltimore, MD, [3]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [4]Columbia University, New York, NY.

Background/Purpose: Antibodies targeting citrullinated proteins (ACPA) are implicated in the pathogenesis of interstitial lung disease (ILD) in rheumatoid arthritis (RA). Citrullinated proteins and the enzymes that catalyze citrullination, the peptidylarginine deiminases (PADs), are detected in RA-ILD lung tissue and in the lungs of heavy smokers. A subset of RA patients demonstrates cross-reactive antibodies against PADs 3 and 4 that have been shown to lower the calcium threshold required for PAD activation, an effect potentially relevant to the pathogenesis of RA-ILD. We sought to explore the association between anti-PADs and radiographic RA-ILD.

Methods: RA patients participating in a study of subclinical cardiovascular disease underwent multi-detector computed tomography (MDCT) of the chest with interpretation by a pulmonary radiologist for ILD features. A semi-quantitative ILD Score (ILDS; range 0–32) was calculated. Concurrent serum samples were assessed for antibodies against PAD by immunoprecipitation of S^{35}-labeled PAD3 and 4.

Results: Among the 176 RA patients studied [60% female, 86% Caucasian, mean age 59±9 years, 11% current smokers, median RA duration=8 years, median DAS28=3.7], any CT-ILD was observed in 58 (33%). Anti-PAD3/4 cross-reactive antibodies were detected in 19 (11%) and 37 (21%) had antibodies directed against PAD4 alone. In univariate analysis, the frequency of any CT-ILD among those with anti-PAD3/4 was 68%, vs. 27 and 29% among those with anti-PAD4 only and neither reactivity, respectively (crude OR=5.39; $p=0.001$ for the comparison of anti-PAD3/4 vs. no anti-PAD). The association was stronger after adjustment for relevant demographic and RA disease/treatment confounders

(Fig 1A: adjusted OR=7.22; p=0.001). Anti-PAD3/4 antibodies were significantly associated with all CT-ILD predominant patterns (i.e. ground glass, honeycombing, etc. . .) and quantitative ILD scores were significantly higher for the anti-PAD3/4 vs. the no anti-PAD group (median ILD score 2 vs. 0 units, respectively; p=0.020). The association of anti-PAD3/4 antibodies with CT-ILD was stronger in ever smokers than never smokers. Among never smokers, the adjusted frequency of any ILD was 39 vs. 17%, respectively, for those with vs. without anti-PAD3/4 (Fig 1B, never smokers: OR=3.01; p=0.19) compared with 93 vs. 30%, respectively, for ever smokers with vs. without anti-PAD3/4 (Fig 1B, ever smokers: OR=29.5; p=0.004, p-value for interaction<0.05).



Average probabilities and 95% confidence intervals are depicted. Associations adjusted for age, gender, current and past smoking (Panel A only), rheumatoid factor and CCP2 seropositivity, DAS28, current use of methotrexate and prednisone, RA duration, and total Sharp-van der Heijde Score.

Conclusion: The prevalence of CT-ILD was markedly higher among RA patients with anti-PAD3/4 antibodies, even after accounting for relevant confounders, particularly among ever smokers. Further mechanistic studies are needed to determine whether there is a biologic interaction between smoking and pulmonary hyper-citrullination facilitated by anti-PAD3/4 antibodies that contributes to ILD pathogenesis.

Impact of Methotrexate Dose Reduction Upon Initiation of Adalimumab On Clinical and Ultrasonographic Parameters in Patients With Moderate to Severe Rheumatoid Arthritis. Gurjit S. Kaeley[1], Amy M. Evangelisto[2], Midori Jane Nishio[3], Shufang Liu[4] and Hartmut Kupper[5]. [1]University of Florida, Jacksonville, FL, [2]Arthritis, Rheumatic and Back Disease Associates, Voorhees, NJ, [3]Diablo Clinical Research, Walnut Creek, CA, [4]AbbVie Inc., North Chicago, IL, [5]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany.

Background/Purpose: Methotrexate (MTX) is the recommended first-line disease-modifying antirheumatic drug (DMARD) for the treatment of moderately to severely active rheumatoid arthritis (RA). Whether patients (pts) with inadequate response to MTX that begin combination therapy with adalimumab (ADA) can reduce MTX dose remains unclear. Clinical and ultrasonographic outcomes of MTX dose reduction when initiating ADA were examined.

Methods: MUSICA was a double-blind, randomized, parallel-arm study to examine the impact of MTX dose on disease outcomes and ultrasonographic signs in moderately to severely active RA pts who have failed prior synthetic DMARDs. The study enrolled 309 pts taking MTX ≥ 15 mg/week (wk) for ≥ 12 wks prior to enrollment. Patients blindly received either high (20 mg/wk) or low dose (7.5 mg/wk) MTX; all pts received open-label 40 mg ADA every other wk for 24 wks. Non-inferiority was assessed using the 95% confidence interval of the difference between high and low dose wk-24 outcomes. A 15% margin (0.56) of the high dose mean 24-wk 28-joint disease activity score (DAS28) was used as the primary endpoint. Ultrasound images acquired every 4 wks were independently read and scored blindly by 4 ultrasound-experienced rheumatologists. A 10-joint semi-quantitative scoring system incorporating OMERACT definitions for pathology (1) measured synovial hypertrophy, vascularity, and bony erosions.

Results: The study populations for both MTX dosages were well balanced for baseline demographics and disease characteristics and had overall age 54.8, 5.3 years RA disease duration, and a DAS28 of 5.8 (all means). Rapid improvement in clinical indices was seen in both groups after addition of ADA. After 24 wks of ADA combination therapy, pts receiving combination therapy with ADA displayed improvements consistent with other trials including low dose MTX. Differences in clinical and ultrasonographic outcomes comparing low vs high dose MTX were minimal. The primary endpoint, mean DAS28, did not meet non-inferiority criteria. Although outcomes favored maintaining 20 mg MTX, no statistically significant differences were detected for most clinical, functional, and ultrasound outcomes (**Table**). Statistically significant differences were only detected in wk-24 swollen joint count and physician's global assessment of disease activity. The number of adverse events (AEs), serious AEs, and infectious AEs were fewer in the low dose MTX arm.

Table. Week 24 Clinical, Functional, and Ultrasonographic Outcomes

Non-Inferiority Parameter	ADA + 7.5 mg MTX (N = 154)	ADA + 20 mg MTX (N = 155)	Difference (Low - High)
[a]DAS28(CRP)	4.11 (3.88, 4.34)	3.75 (3.52, 3.97)	0.37 (0.07, 0.66)
Clinical and Functional Outcomes*			***p* value**
ACR20, n/N (%)	86/151 (57.0)	95/154 (61.7)	0.395
ACR50, n/N (%)	45/151 (29.8)	58/154 (37.7)	0.145
ACR70, n/N (%)	20/151 (13.2)	31/154 (20.1)	0.114
HAQ-DI	0.98 ± 0.75	0.95 ± 0.78	0.476
HAQ-DI improvement ≥ 0.22, n/N (%)	96/151 (63.6)	101/154 (65.6)	0.707
TJC (0–68)	15.1 ± 16.0	13.5 ± 15.3	0.264
SJC (0–66)	9.6 ± 12.8	7.7 ± 10.5	0.028
PGA disease activity (100 mm VAS)	23.7 ± 21.3	19.0 ± 17.4	0.035
PtGA pain (100 mm VAS)	40.0 ± 27.9	36.4 ± 27.7	0.141
PtGA disease activity (100 mm VAS)	38.2 ± 27.5	33.8 ± 26.8	0.094
Ultrasound Outcomes			
Synovial hypertrophy	32.6 ± 7.2	32.9 ± 6.6	0.955
Synovial vascularity	4.43 ± 4.86	4.09 ± 4.53	0.779
Synovial vascularity improvement by 30%, n/N (%)	65/143 (45.5)	77/147 (52.4)	0.221
Synovial vascularity change from baseline	−1.52 ± 4.18	−1.46 ± 3.43	0.779
Bony erosions	1.36 ± 2.43	1.41 ± 2.01	0.598

[a]Primary endpoint, mean (95% CI).
*Mean ± SD unless noted otherwise. Means were calculated using last observation carried forward (LOCF).
ADA, adalimumab; MTX, methotrexate; DAS28, 28-joint disease activity score; CRP, C-reactive protein; ACR, American College of Rheumatology; HAQ-DI, disability index of the health assessment questionnaire; TJC, tender joint count; SJC, swollen joint count; PGA, physician's global assessment; VAS, visual analogue scale; PtGA, patient's global assessment.

Conclusion: Addition of ADA to MTX inadequate responders led to robust results consistent with prior studies. Compared to 20 mg MTX, lowering MTX weekly dose to 7.5 mg in combination with ADA resulted in small differences in clinical and ultrasonographic outcomes in RA pts. Statistically, non-inferiority was not met for mean DAS28. Based on the small differences in most outcomes, MTX dose reduction may be considered when initiating ADA therapy in MTX inadequate responders.

Very High Remission Rates Are Achieved By Methotrexate and Intraarticular Glucocorticoids Independent Of Induction Therapy With Adalimumab; Year 2 Clinical Results Of An Investigator-Initiated Randomised, Controlled Clinical Trial Of Early, Rheumatoid Arthritis (OPERA). Kim Hørslev-Petersen[1], Merete L. Hetland[2], Peter Junker[3], Jan Pødenphant[4], Torkell Ellingsen[5], Palle Ahlqvist[6], Hanne M. Lindegaard[7], Asta Linauskas[8], Annette Schlemmer[9], Mette Y. Dam[10], Ib Hansen[11], Tine Lottenburger[6], Anette Jørgensen[10], Sophine B. Krintel[12], Johnny Raun[1], Christian G. Ammitzbøll[10], Julia Johansen[12], Mikkel Østergaard[13] and Kristian Stengaard-Pedersen[10]. [1]University of Southern Denmark, Graasten, Denmark, [2]DANBIO, Center for Rheumatology and Spine Diseases, Glostrup Univ Hospital, Glostrup, Denmark, [3]University of Southern Denmark, Odense, Denmark, [4]Copenhagen University at Gentofte, Hellerup, Denmark, [5]Silkeborg Regional Hospital, Silkeborg, Denmark, [6]University of Southern Denmark, Vejle, Denmark, [7]Odense University Hospital, Odense, Denmark, [8]Vendsyssel Hospital, Hjørring, Denmark, [9]Aalborg University Hospital, Aalborg, Denmark, [10]Arhus University Hospital, Aarhus, Denmark, [11]Viborg Hospital, Viborg, Denmark, [12]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark, [13]Copenhagen University Hospital Glostrup, Copenhagen, Denmark.

Background/Purpose: In a double-blind placebo-controlled 2-year investigator-initiated trial of patients with early rheumatoid arthritis (RA), we investigated if additional adalimumab (ADA) for 1 year on top of an aggressive treat-to-target strategy with methotrexate (MTX) and intraarticular (i.a.) corticosteroid reduced disease activity. Previously published results *after 1 year* showed that >75% of patients in both groups achieved low disease activity, but remission rates and physical function were higher in the ADA group[1]. Here we present results from the 2nd year.

Methods: DMARD-naïve early RA patients (n=180) were randomized 1:1 to receive i.a. triamcinolone (40 mg/ml) in any swollen joint and MTX (20 mg/wk) for two years in combination with placebo-ADA (MTX+PLA) or MTX+ADA (40 mg eow) during the first year. Oral glucocorticoids were not allowed. ADA/PLA was withdrawn after 1 yr. During year 2, in both treatment arms, ADA (40 mg eow) was only (re)initiated in patients with recurrence of active disease (DAS28 CRP>3.2). Clinical response was assessed by DAS28(CRP), clinical disease activity index (CDAI), simplified disease activity index (SDAI) and ACR/EULAR remission criteria. Physical function was assessed by HAQ (health assessment questionnaire).

Results: Baseline characteristics were similar in the two groups: MTX+PLA/MTX+ADA: DAS28(CRP) 5.6(3.8–7.3)/5.5(3.8–7.8), p=0.53. After 2 years the median MTX dose and cumulated dose of i.a. triamcinolone were similar in the two groups (Table), and biologics were (re)initiated in 15%/17% of patients. During the 2nd year, disease activity (DAS28CRP, CDAI and SDAI) and HAQ scores decreased and ACR/EULAR remission rates increased in the MTX+PLA group. After 2 years, remission rates in MTX+PLA/MTX+ADA groups were: DAS28CRP remission: 69%/66%; CDAI remission: 55%/57%; SDAI remission: 54%/50%; ACR/EULAR(28 joints):44%/45% with no significant differences between MTX+PLA/MTX+ADA in any clinical outcome measure (p=0.36–1.00).

Table. Doses, disease activity, and remission rates at one and two years

	Year 1			Year 2		
Treatment	MTX+ 1st YR PLACEBO	MTX+ 1st YR ADA	P	MTX+ 1st YR PLACEBO	MTX+ 1st YR ADA	P
MTX dose mg/wk	20 (15–20)	20 (7.5–20)	0.17	20 (10–20)	20 (7.6–20)	0.33
I.a. triamcinolone (ml cumulated)	7 (2–18.8)	5.4 (1.8–17.4)	0.08	0 (0–7)	0 (0–7.7)	0.19
Triple DMARD	32 %	16 %	**0.018**	31 %	20 %	0.15
Biologics (open trial)	7 %	7 %	1.00	15 %	17 %	0.97
DAS28CRP	2.6 (1.7–4.7)	2.0 (1.7–5.2)	**0.009**	2.0 (1.7–4.5)	2.0 (1.7–4.4)	0.97
CDAI	3.9 (0–13.6)	1.9 (0–15.4)	**0.01**	1.9 (0.1–14.5)	2.2 (0–15.2)	0.75
SDAI	5.0 (0.8–20.2)	2.7 (0.7–30.4)	**0.006**	2.8 (0.7–19.0)	3.3 (0.7–17.7)	0.36
DAS28CRP<3.2	76%	80%	0.65	84%	83%	1.00
DAS28CRP<2.6	49%	74%	**0.001**	69%	66%	0.79
CDAI≤2.8	41 %	61 %	**0.01**	55 %	57 %	0.87
SDAI<3.3	36 %	57 %	**0.007**	54 %	50 %	0.66
ACR/EULAR Boolean (28)	30 %	48 %	**0.017**	44 %	45 %	1.00
ACR/EULAR Boolean (40)	29 %	49 %	**0.014**	44 %	42 %	0.91
HAQ	0.25 (0–1.44)	0.13 (0–1.5)	0.40	0.13 (0–1.63)	0.13 (0–1.5)	0.37

Values are medians (5%/95% percentiles) or percentage. We used Mann-Whitney or Pearson's chi-square tests. Analysis was by ITT with last observation carried forward. Completer analysis and ITT without imputations gave similar results.

Conclusion: An aggressive treat-to-target strategy of i.a. triamcinolone and methotrexate in early RA provided excellent disease control at 2 years' follow-up independent of 1 year induction therapy with adalimumab.

Methotrexate Dose Has Minimal Effects On Methotrexate-Related Toxicity In Patients With Early Rheumatoid Arthritis Treated In Combination With Adalimumab – Results Of Concerto Trial. Gerd R. Burmester[1], Alan J. Kivitz[2], Ronald F. van Vollenhoven[3], Stefan Florentinus[4], Piyalal M. Karunaratne[5], Hartmut Kupper[6], Maxime Dougados[7] and Roy M. Fleischmann[8]. [1]Charité - Universitätsmedizin Berlin, Berlin, Germany, [2]Altoona Center for Clinical Research, Duncansville, PA, [3]The Karolinska Institute, Stockholm, Sweden, [4]AbbVie, Rungis, France, [5]AbbVie Inc., North Chicago, IL, [6]AbbVie Deutschland GmBH & Co KG, Ludwigshafen, Germany, [7]René Descartes University, Paris, France, [8]University of Texas Southwestern Medical Center, Dallas, TX.

Background/Purpose: Adalimumab is usually used in combination with 15–20 mg methotrexate (MTX) weekly in early rheumatoid arthritis (RA). Lower doses of MTX in combination with biologics have not been evaluated in controlled clinical trials. The objective of this study was to evaluate the MTX dose-response of MTX-related toxicities in patients (pts) with early RA receiving ADA in combination with MTX.

Methods: CONCERTO was a 26-week (wk), phase 3, double-blind, parallel-arm study in MTX-naive pts with active RA <1 year in duration. Pts were randomized 1:1:1:1 to open-label ADA 40 mg every other wk + blinded weekly oral MTX doses of 2.5, 5, 10, or 20 mg. All pts took 5 mg folic acid weekly throughout the study. Pts in the 20 mg arm started with 10 mg MTX, with bi-weekly increases of 2.5 mg through wk 8. MTX-toxicity related adverse events (AEs) were defined according to MTX prescribing information and recorded as AEs at each visit through wk 26. Laboratory data were summarized through wk 26.

Results: Of the 395 randomized pts, 358 (91%) completed 26 wks. The safety population included 98, 100, 99, and 98 pts in the 2.5, 5, 10, and 20 mg arms, respectively. 9 pts (2.3%) discontinued study drug due to an AE that was not necessarily MTX-related. Of the total population, the percentage of pts with any AE was 62, 59, 67, and 69%, any serious AE was 5, 2, 3 and 7%, and any infection was 20, 17, 24, and 35% in the 2.5, 5, 10, and 20 mg arms, respectively. Two infections in the 5 mg arm were serious AEs, appendicitis and sepsis, but did not result in study discontinuation and were not associated with MTX. The overall incidence of MTX-related AEs was low (Table). Infection and abnormal hair loss appeared to have a MTX dose relationship. No differences in mean change from baseline in hematocrit, neutrophil count, platelet count, ALT, or AST values were observed at wk 26 among the 4 doses of MTX. The percentage of pts with ALT values >upper limit of normal (ULN) that were associated with MTX at wk 26 were 3, 1, 6, and 6% in the 2.5, 5, 10, and 20 mg arms, respectively. Regarding AST, 4, 0, 3, and 3% in the 2.5, 5, 10, and 20 mg arms, respectively, had AST values >ULN.

Table. Adverse Events Reported by Investigators to be Associated with MTX

	ADA+2.5 mg MTX (N=98) n (%)	ADA+5 mg MTX (N=100) n (%)	ADA+10 mg MTX (N=99) n (%)	ADA+20 mg MTX (N=98) n (%)	Total (N=395) n (%)
Infection	6 (6.1)	7 (7.0)	11 (11.1)	13 (13.3)	37 (9.4)
Nausea &/or vomiting	6 (6.1)	3 (3.0)	13 (13.1)	8 (8.2)	30 (7.6)
Stomach pain/ discomfort	5 (5.1)	4 (4.0)	7 (7.1)	7 (7.1)	23 (5.8)
Abnormal hair loss	1 (1.0)	5 (5.0)	5 (5.1)	8 (8.2)	19 (4.8)
Excessive fatigue &/ or malaise	4 (4.1)	1 (1.0)	3 (3.0)	2 (2.0)	10 (2.5)
Dizziness	4 (4.1)	0	4 (4.0)	1 (1.0)	9 (2.3)
Oral ulcers	0	1 (1.0)	5 (5.1)	2 (2.0)	8 (2.0)
Fever &/or chills	0	1 (1.0)	3 (3.0)	0	4 (1.0)

Conclusion: Overall, the combination of ADA plus varying doses of MTX was well tolerated, and MTX-related AEs were infrequent. The frequency of infections and abnormal hair loss appeared to have a MTX-dose relationship. Serious infections were very rare and had no relationship to MTX. No differences in mean change from baseline in blood cell counts or transaminases were observed at wk 26 among the 4 doses of MTX.

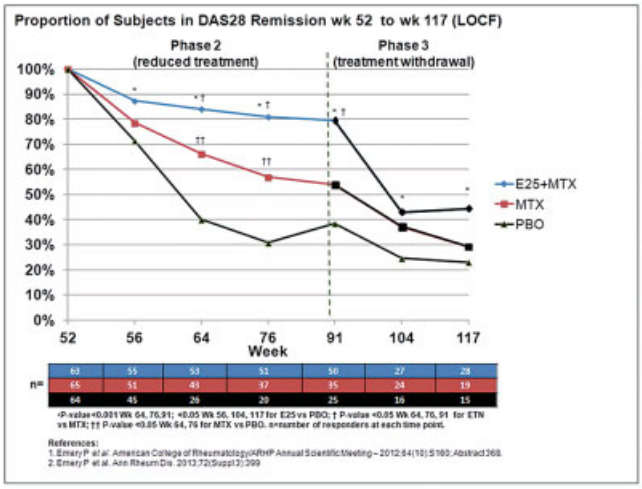
Assessing Maintenance Of Remission After Withdrawal Of Etanercept Plus Methotrexate, Methotrexate Alone, Or Placebo In Early Rheumatoid Arthritis Patients Who Achieved Remission With Etanercept and Methotrexate: The Prize Study. Paul Emery[1], Wolfgang Spieler[2], Maria Stopinska-Polaszewska[3], Nikolay I Korshunov[4], Jack Bukowski[5], Ronald Pedersen[5], Theresa Williams[6], Stefanie Gaylord[6] and Bonnie Vlahos[6]. [1]Institute Rheumatic and Musculoskeletal Medicine University of Leeds, Leeds, United Kingdom, [2]ZeFOR GmbH Zentrum für Forschung, Zerbst, Germany, [3]Family Physicians Specialists Clinic, Torun, Poland, [4]State Budgetary Healthcare Institution of Yaroslavl Region, Yaroslavl, Russia, [5]Pfizer Inc, Collegeville, PA, [6]Pfizer Inc., Collegeville, PA.

Background/Purpose: In the PRIZE study patients (pts) with early (mean 6 mos. since symptom onset) moderate-severe rheumatoid arthritis (RA), who achieved remission after open-label treatment with 50 mg etanercept (ETN) + 10–25 mg MTX (Phase 1)[1] were randomized to a double-blind 39-wk period of (25mg) ETN25+ MTX, MTX alone, or placebo (PBO, Phase 2)[2]; the study drugs were then withdrawn (randomized treatment remained blinded) and pts were monitored for an additional 26 weeks (Phase 3). Using patients who achieved remission in Phase 1, the objective of this analysis was to assess sustained remission and other clinical and safety outcomes in randomized pts (Phase 2) and subsequent withdrawal of drug treatments (Phase 3).

Methods: Pts with DAS28 remission (<2.6, n=193) began Phase 2 at wk 52; those maintaining DAS28 LDA by wk 91 (≤3.2, n=131) continued and had study drugs withdrawn (MTX tapered to week 95) through wk 117 (end of study). Remission and other standard clinical outcomes were assessed during Phase 2 and 3. LOCF was used for missing data. Fisher's exact test was used for significance.

Results: Between wks 52 and 91, the proportion of pts in the ETN25+MTX group who maintained DAS28 remission declined slower than those treated with MTX or PBO; at wk 117, significantly more pts in the ETN25+MTX group maintained remission relative to PBO following withdrawal of randomized treatment (Figure). Other outcomes had similar results. At the beginning of Phase 2, the proportions of pts in the ETN25+MTX group with DAS28 LDA, Boolean remission, ACR50/70 and normal HAQ (≤0.5) were 100%, 71%, 92%/83%, and 84%, respectively; MTX group: 100%, 72% 95%/87% and 86%, respectively; PBO group: 100%, 63%, 95%/82%, and 75%, respectively. At wk 91, the proportions declined to 89%, 68%, 78%/71%, and 78% (ETN25+MTX); 69%, 46%, 71%/62%, and 72% (MTX); 46%, 23%, 45%/37%, and 45% (PBO), respectively. After treatment withdrawal at wk 117, the proportions of pts who maintained these outcomes were 56%, 47%, 46%/41%, and 67% (ETN25+MTX), 43%, 25%, 38%/29%, and 59% (MTX), 37%, 16%, 35%/23%, and 40% (PBO), respectively. There were no unexpected safety findings.



Conclusion: Of the early RA pts with DAS28 remission at the beginning of Phase 2, those randomized to a reduced dose of ETN had a modest loss of efficacy in Phase 2, but randomization to PBO and withdrawal of ETN in Phase 3 both led to steep declines in all outcomes.

Survival Of The Second Biologic After The First Tumor Necrosis Factor Alpha Inhibitor's Failure In The Treatment Of Rheumatoid Arthritis: Prospective Observational Data From Biorx. Si Registry. ŽIga Rotar[1] and Matija Tomsic[2]. [1]University Medical Centre Ljubljana, 1000 Ljubljana, Slovenia, [2]University Medical Centre Ljubljana, Ljubljana, Slovenia.

Background/Purpose: Current recommendations for management of RA propose a tumor necrosis factor alpha inhibitor (TNFi) for patients failing to achieve the treatment target with synthetic DMARDs. If 1st TNFi fails, a different TNFi, abatacept, rituximab (RTX) or tocilizumab (TCZ) are equally recommended. It has been shown that non TNFi biologics are at least as effective as the TNFi in this setting. Since there is little is known about the survival of 2nd biologic agent, we decided to investigate the survival of the 2nd biologic after switching from the 1st TNFi.

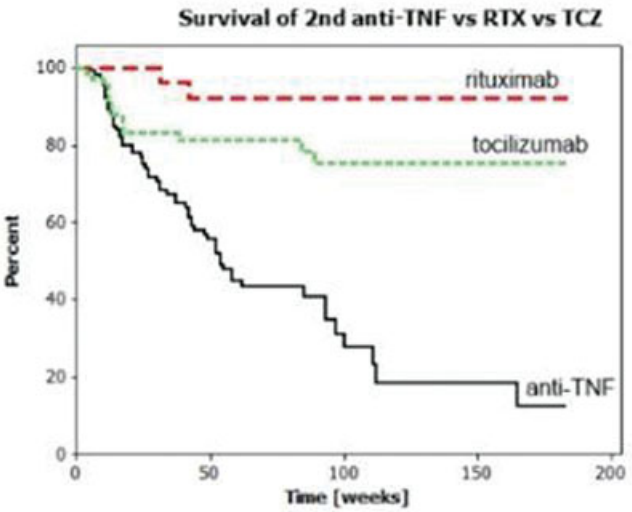

Figure 2.

Methods: Data was extracted from the mandatory nationwide registry of patients with rheumatoid arthritis treated with biologics on Dec 15th, 2012. Kaplan Meier survival analysis was performed. Statistical significance was determined using the Log-Rank and Wilcoxon tests.

Results: From the dataset collected between February 2007 and December 2012 we identified 688 RA patients who received TNFi as a first biologic. Flow of patients is depicted in Figure 1. Baseline patient characteristics are shown in Table 1. The 1st TNFi was stopped for inefficiency, adverse events, other reasons, and death in 73,4%, 16.7%, 8.7%, and 1.0%, respectively. Kaplan Meier survival curves for 2nd TNFi (as a group), RTX and TCZ are presented in Figure 2. 2nd TNFi failed due to insufficient efficacy in 90%, and adverse events in 8%.

Conclusion: After the 1st TNFi fails, a 2nd TNFi is more likely to fail earlier than RTX or TCZ (p=0.000). There is a trend of better survival of RTX vs TCZ, which did not reach statistical significance (p=0.057).

Results Of The Strass Trial Regarding Impact Of Progressive Spacing Of Tnf-Blocker Injections In Rheumatoid Arthritis Patients In Das28 Remission: Is There a Difference Between Drugs - Adalimumab and Etanercept - Or Their Mode Of Use - Monotherapy Or Combination?

Bruno Fautrel[1], Thao Pham[2], Jacques Morel[3], Toni Alfaiate[4], Emmanuelle Dernis[5], Philippe Gaudin[6], Olivier Brocq[7], Elisabeth Solau-Gervais[8], Jean-Marie Berthelot[9], Jean-Charles Balblanc[10], Xavier Mariette[11] and Florence Tubach[12]. [1]Paris 6 – Pierre et Marie Curie University; AP-HP, Rheumatology, Pitié-Salpêtrière Hospital, - GRC-UPMC 08 – EEMOIS, Paris, France, [2]Sainte Marguerite Hospital, Marseille, France, [3]Lapeyronie Hospital, Montpellier, France, [4]AP-HP, Paris, France, [5]Le Mans Hospital, Le Mans, France, [6]CHU Hôpital Sud, Grenoble Teaching Hospital, Echirolles, France, [7]Hospital of Princesse Grâce de Monaco, Monaco, France, [8]University Hospital of Poitiers, Poitiers, France, [9]Nantes University Hospital, Nantes, France, [10]Centre Hospitalier Général de Belfort, Belfort, France, [11]Bicêtre University Hospital, Le Kremlin Bicetre, France, [12]Universite Paris Diderot, Paris, France.

Background/Purpose: The STRASS trial was an 18-month randomized controlled trial, conducted in established RA patients in DAS28 remission with etanercept (ETA) or adalimumab (ADA), comparing the impact of a DAS28-driven step-down strategy based on TNF-blocker injection spacing (S arm) to a maintenance strategy (M arm). It demonstrated that, although relapses were more frequent with the spacing strategy arm, no substantial increase in disease activity or structural damage progression occurred throughout the 18-month follow-up. We aimed to assess in a subgroup analysis if the feasibility of TNF-blocker injection spacing differs by molecule –ADA or ETA – and/or its use as monotherapy (MONO) or in combination with synthetic DMARD (COMBO).

Methods: Inclusion criteria were: ETA or ADA > 1 year, DAS28 remission > 6 months, no progression of structural damage on X-rays. Patients were randomized and followed every 3 months for 18 months. In the S arm, the inter-injection interval was increased every 3 months up to complete interruption at 4th step. In these stratified analyses, disease activity was assessed by DAS28 repeated measures and analyzed in a mixed linear model (GLM). Relapse, defined by DAS28 >2.6 and ΔDAS28 >0.6, was in a Cox model and statistical comparison by Wald chi-square test.

Results: 137 patients were included, 64 and 73 in the S and M arm (mean/%: age 55 yrs, female 78%, RA duration 9.5 yrs, ACPA+ 78%, erosive 88%, DAS28 1.8, HAQ 0.5). Sixty-three patients were treated with ADA and 74 with etanercept; 33 received the TNF-blocker as MONO (ADA 11, ETA 22) and 104 in combination with either methotrexate or leflunomide (ADA 52, ETA 52). There were no significant differences in either trial arm in disease activity between the ADA- and the ETA-treated populations, with mean DAS28 of 2.7 ±1.2 and 2.3 ±1.2 respectively (p=0.55). The relapse incidence was higher in the ADA than in ETA group: 77.4% vs. 60.3% (p=0.03). The median time to relapse was 12 months in the S arm and 18 months in the M-arm for ETA, and 9 months in the S arm, 18 months in the M-arm for ADA. Comparisons between the use of TNF-blockers as MONO or COMBO showed no significant differences in disease activity: mean DAS28 of 2.7 ±1.3 and 2.4 ±1.1 respectively (p=0.88), nor in relapse rates: 69.7% vs. 67.6% (p=0.8). The median time to relapse was 12 months in the S arm and 18 months in the M-arm for MONO, and 9 months in the S arm, 18 months in the M-arm for COMBO.

Conclusion: The molecule and the way TNF-blockers are prescribed do not influence RA disease activity control. However, the risk of relapse appears higher with ADA compared to ETA in this subgroup analysis.

Evidence That Fat Metaplasia Is a Key Intermediary In The Development Of Sacroiliac Joint Ankylosis Following Repair Of Erosions In Patients With Spondyloarthritis. Walter P. Maksymowych[1], Stephanie Wichuk[1], Praveena Chiowchanwisawakit[2], Robert GW Lambert[1] and Susanne Juhl Pedersen[3]. [1]University of Alberta, Edmonton, AB, [2]Mahidol University, Bangkok, Thailand, [3]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark.

Background/Purpose: Fat metaplasia is detected as bright signal on T1W MRI and has been shown to develop after resolution of inflammation in spine and sacroiliac joints (SIJ). Tissue with bright signal on T1W MRI, termed backfill (BF), may also fill areas of excavated sacral and iliac bone along the joint space and is thought to reflect repair of erosion. Imaging studies in the spine have indicated that fat metaplasia predicts development of new bone. We hypothesized that ankylosis in the SIJ develops following repair of erosion and that fat metaplasia is a key intermediary step in this pathway.

Methods: We used the SPARCC SIJ Structural Score (SSS) method to assess fat metaplasia (FAT), erosion (ER), BF, and ankylosis (ANK). This score relies on the T1W sequence and assesses 5 consecutive coronal slices anteriorly through the cartilaginous portion of the joint from the transitional slice. Lesions are scored dichotomously (present/absent) in SIJ quadrants (fat, erosion) or halves (backfill, ankylosis). Scoring ranges are: FAT (0–40), ER (0–40), BF (0–20), ANK (0–20). Four readers assessed 45 pairs of MRI scans blinded to time point (baseline, 2 years) from 45 cases in a prospective cohort receiving either standard (n=22) or anti-TNF (n=23) therapies. In a second study, two readers assessed 147 pairs of scans blinded to time point (baseline, 2 years) from cases either on standard (n=69) or anti-TNF (n=78) therapies. Univariate analyses and multivariate linear regression focused on identifying significant MRI predictors of change in BF and ANK scores, adjusted for age, sex, symptom duration, treatment, CRP (baseline and 2-year change), SPARCC SIJ inflammation score (baseline and 2-year change), and baseline SSS scores for FAT, ER, BF, and ANK.

Results: Using mean SSS scores for 4 readers in the 45 cases, resolution of ER was significantly associated with the development of BF ($p = 0.0082$) and new ANK ($p=0.045$) at 2 years. Using mean scores of two readers in the 147 cases, resolution of ER was significantly associated with the development of BF ($p<0.0001$), FAT ($p<0.0001$) and new ANK ($p=0.0001$) at 2 years. New ANK was also significantly associated with development of FAT ($p=0.0005$). Associations were also significant in both treatment groups. A decrease in ER score was a significant predictor for development of new BF in the multivariate regression model (adjusted $R^2 = 0.44$, F ratio 14.6, $p<0.0001$) (change in SSS erosion: $\beta = -0.74$, $t = -4.1$, $p=0.0001$). 31 (21.1%) of patients developed new ANK and these had significantly more resolution of ER than patients without new ANK ($p=0.014$, Mann-Whitney). Significant independent predictors of new ANK in the multivariate model (adjusted $R^2 = 0.24$, F ratio = 10.0, $p <0.0001$) were baseline BF score, decreased ER score and development of new FAT (Table).

	β coefficient	SE	t	p value
Age	−0.022	0.010	−2.25	0.026
BL SSS Backfill score	0.073	0.027	2.75	0.0068
Change in SSS Erosion score	−0.14	0.045	−3.11	0.0023
Change in SSS Fat score	0.20	0.058	3.36	0.001

Conclusion: Ankylosis in the SIJ develops following repair of erosion and fat metaplasia is a key intermediary step in this pathway.

Proof Of Concept: Enthesitis and New Bone Formation In Spondyloarthritis Are Driven By Mechanical Strain and Stromal Cells. Peggy Jacques[1], Stijn Lambrecht[1], Eveline Verheugen[1], Elin Pauwels[2], Marleen Verhoye[3], Annemie Van der Linden[3], George Kollias[4], Rik J. Lories[5] and Dirk Elewaut[6]. [1]Laboratory for Molecular Immunology and Inflammation, Ghent University, Ghent, Belgium, [2]UGCT, Ghent University, Ghent, Belgium, [3]University of Antwerp, Antwerp, Belgium, [4]Biomedical Sciences Research Center 'Alexander Fleming', Vari, Greece, [5]Laboratory for Skeletal Development and Joint Disorders, KU Leuven, Leuven, Belgium, [6]Department of Rheumatology Ghent University Hospital, Ghent, Belgium.

Background/Purpose: Spondyloarthritides (SpA) are characterised by both peripheral and axial arthritis. Hallmarks of peripheral SpA are the development of enthesitis, most typically of the Achilles tendon and plantar fascia, and new bone formation. This study was undertaken to unravel the mechanisms leading towards enthesitis and new bone formation in preclinical models of SpA. $TNF^{\Delta ARE}$ mice are an established model for SpA, characterized by an enhanced TNF messenger RNA stability, which leads to the development of peripheral and axial arthritis (sacroiliitis, spondylitis), and Crohn′s like ileitis.

Methods: To study the development of enthesitis in relation to mechanical strain, hind limb unloading of $TNF^{\Delta ARE}$ mice was performed, followed by histological analysis. Activation of extracellular signal-regulated kinase (Erk1/2) and p38 pathways in response to mechanical strain was studied on Achilles tendon lysates. In addition, $TNF^{\Delta ARE}$ mice were treated with small molecular inhibitors of Erk1/2 and p38. Since new bone formation does not occur in $TNF^{\Delta ARE}$ mice, the collagen antibody-induced arthritis model, which is also characterized by enthesitis, was used to study this particular feature. Hind limb unloading was again performed, followed by histological analysis and micro-CT.

Results: We demonstrated that the first signs of inflammation in $TNF^{\Delta ARE}$ mice were found at the entheses. Importantly, enthesitis occurred equally in the presence or absence of mature T and B cells, underscoring the importance of stromal cells. Hind limb unloading in $TNF^{\Delta ARE}$ mice significantly suppressed inflammation at the synovio-entheseal complex of the Achilles tendon compared to weight bearing controls. Erk1/2 signalling played a crucial role in mechanotransduction associated inflammation. Furthermore, new bone formation was strongly promoted at entheseal sites by biomechanical stress and correlated with the degree of inflammation.

Conclusion: These findings provide a formal proof of the concept that mechanical strain drives both entheseal inflammation and new bone formation in SpA.

HLA-B27 Expression Prevents Tnfα-Induced Inhibition Of Bone Formation in Vitro In IFNγ/Tnfα-Treated Osteoblasts. Eva Yang, Grace Kwon, Robert A. Colbert and Gerlinde Layh-Schmitt. NIAMS NIH, Bethesda, MD.

Background/Purpose: HLA-B27 predisposes to ankylosing spondylitis (AS), an immune-mediated inflammatory disease associated with osteitis, bone loss, and dysregulated bone formation, most notably in the axial skeleton. Although the role of HLA-B27 is incompletely understood, it is thought to exert upstream pro-inflammatory effects. Recently however, it was shown that HLA-B27 promotes osteoclast development from monocytes in HLA-B27 transgenic rats. Given that MHC class I molecules can also be expressed in osteoblasts (OBs), we examined whether HLA-B27 alters the response of OBs to pro-inflammatory cytokines IFNγ and TNFα during differentiation and mineralization *in vitro*.

Methods: Wild type (WT), HLA-B7 (B7), and HLA-B27 (B27) transgenic rat calvarial OBs were harvested and differentiated in osteogenic medium for up to 3 weeks. Cultures were treated with rat IFNγ (100 ng/mL), TNFα (30 ng/mL) or both cytokines for up to 5 days of the 3-week culture period upon pre-calcified nodule formation, and collected for evaluation of gene (real-time PCR) and protein (immunoblotting) expression, and mineralization (alizarin red staining).

Results: IFNγ had no effect on mineralization while TNFα inhibited mineralization similarly for all 3 genotypes in a time- and dose-dependent

manner. TNFα also inhibited mineralization of IFNγ-treated WT and B7 OBs, similar to TNFα alone. In contrast, B27 OBs were refractory to the inhibitory effects of TNFα when cells were co-treated with IFNγ, exhibiting 3-fold higher mineralization than WT and B7 controls. HLA-B was synergistically upregulated at the mRNA and protein level by co-treatment with IFNγ and TNFα in both B7 and B27 OBs. Despite comparable upregulation of HLA-B27 and HLA-B7, only B27-expressing OBs exhibited activation of the unfolded protein response (UPR) as evidenced by induction of GRP78/BiP and CHOP, along with increased XBP1 mRNA splicing. B27-expressing OBs were responsive to TNFα as shown by RUNX2 degradation. However, RUNX2 degradation was incomplete in IFNγ/TNFα-treated B27-expressing OBs and RUNX2 binding to STAT1 was reduced compared to both WT and B7 controls.

Conclusion: This is the first demonstration to our knowledge that HLA-B27 expression can alter OB function as demonstrated in this transgenic animal model. Upregulation of HLA-B27 caused ER stress and activation of the UPR. In addition to its traditional role to maintain ER homeostasis, the UPR is also involved in development and differentiation and is activated during osteogenesis. Additionally, the ER chaperone BiP has been shown to affect mineralization processes, and IFNγ-activated STAT1 can inhibit mineralization through cytosolic sequestration of RUNX2. While the precise mechanism remains unclear, our studies strongly suggest that HLA-B27-induced UPR activation can affect OB function. The possibility that HLA-B27 expression and upregulation could interfere with TNFα-induced inhibition of bone formation might explain why patients with AS exhibit axial progression and develop ankylosis despite active inflammation.

Host Genetic Background Disrupts The Relationship Between Microbiota and Gut Mucosal Tolerance Leading To Spondyloarthritis and Ileitis After a Dectin-1 Trigger. Linda Rehaume[1], Stanislas Mondot[2], Daniel Aguirre de Cárcer[2], Jared Velasco[1], Helen Benham[1], Sumaira Hasnain[3], Jaclyn Bowman[1], Merja Ruutu[1], Philip Hansbro[4], Michael McGuckin[3], Mark Morrison[2] and Ranjeny Thomas[1]. [1]University of Queensland Diamantina Institute, Brisbane, Australia, [2]CSIRO Livestock Industries, Brisbane, Australia, [3]Mater Medical Research Institute, Brisbane, Australia, [4]Center for Asthma and Respiratory Disease and Hunter Medical Research Institute, Newcastle, Australia.

Background/Purpose: Chronic inflammatory diseases known as spondyloarthropathies (SpA) including ankylosing spondylitis, psoriatic arthritis, reactive arthritis, and arthritis associated with inflammatory bowel disease, collectively affect 3% of the population, and are strongly heritable. Consistent with shared clinical features and genetic associations, the pathology of each disease is associated with microorganisms, and flares in bowel symptoms correlate with arthritic and spondylitic activity. However, it is not clear how the microbiome influences disease expression in SpA and how this relates to host genetic background. We sought to understand this in BALB/c wild type and ZAP-70^{W163C} (SKG) point-mutant mice with reduced T cell receptor signaling.

Methods: SKG and BALB/c mice housed under specific pathogen-free (SPF) or germ-free (GF) conditions were injected intraperitoneally with microbial 1,3-D beta-glucan (curdlan). Arthritis, spondylitis and ileitis were assessed histologically. Microbiome composition in serial fecal samples of mice cohoused from weaning was analyzed by 454 pyrosequencing.

Results: By analysis 8 weeks after curdlan, pathological severity of arthritis, spondylitis and ileitis depended on both genetic background and microbiome. Under SPF conditions, SKG mice developed severe spondylitis, arthritis and ileitis whereas curdlan-treated BALB/c developed mild arthritis and spondylitis, but no ileitis. Under GF conditions, SKG mice had reduced spondyloarthritis incidence and no ileitis. Thus development of ileitis was most sensitive to genetic background and associated microbiome i.e. absent in GF SKG mice and SPF BALB/c mice, highest incidence and severity in SPF SKG and intermediate in GF SKG mice colonized with a limited bacterial consortium. Initiation of ileal IL-23 expression, ER stress, depletion of goblet cells and IL-17 response in draining lymph nodes depended on presence of the microbiome. By pyrosequencing, microbiome content in turn depended on the genetic background of the host and the microbial response to beta-glucan over time. Consistent with transmissible suppressive microbes in BALB/c feces, ileitis but not arthritis or spondylitis severity was reduced in SKG cohoused with BALB/c mice.

Conclusion: Our data are consistent with impaired microbial homeostasis in SKG hosts where T cells express ZAP70^{W163C}, and provide a molecular basis for understanding the relationship between immune genetic susceptibility and development of SpA in response to an inflammatory environmental trigger, through host genetic effects on the gut microbiome. Modification of the microbiome presents a novel prophylatic strategy to attenuate genetic risk of SpA.

Impaired Bacterial Clearance and An Exuberant Inflammatory Response Promote Chlamydia-Induced Reactive Arthritis In SKG Mice. Athan Baillet[1], Linda Rehaume[2], Helen Benham[2], Connor O'Meara[3], Charles Armitage[4], Marina Harvie[4], Geraldine Brizard[5], Jared Velasco[2], John V. Forrester[6], Mariapia Degli-Esposti[5], Kenneth Beagley[4] and Ranjeny Thomas[2]. [1]The University of Queensland, Brisbane, Australia, [2]University of Queensland Diamantina Institute, Brisbane, Australia, [3]Institute of Health & Biomedical Innovation, Biomedical Sciences, Faculty of Health, Queensland University of Technology, Brisbane, Australia, [4]Institute of Health & Biomedical Innovation, Brisbane, Australia, [5]Lions Eye Institute, Nedlands, Australia, [6]Lions Eye Institute, Nedlands, Bahrain.

Background/Purpose: The sterile inflammatory arthritis associated with spondylitis, uveitis and rash, known as reactive arthritis, commences weeks after certain gastrointestinal or genitourinary infections, including Salmonella and Chlamydia in genetically-susceptible patients. Several potential mechanisms are proposed, including auto-immunity by molecular mimicry and persistent inflammation in response to intra-cellular live *Chlamydia*. ZAP-70^{W163C} mutant BALB/c mice (known as SKG), which exhibit reduced T cell receptor signaling, an autoreactive CD4+ T cell repertoire, relative lymphopenia and increased regulatory T cells are susceptible to spondyloarthritis after bacterial beta-glucan. *Chlamydia muridarum (Cmu)* is an obligate intracellular pathogen normally controlled by macrophages. We studied whether *Cmu* genital infection triggered reactive arthritis in SKG mice to explore the relationship between host immunity, bacterial clearance and joint inflammation.

Methods: SKG and BALB/c mice were genitally infected with mouse-adapted *Cmu* ($5\times10^2-10^6$ IFUs). Conjunctivis, lid swelling/thickening and arthritis were assessed weekly for 12 weeks post infection (wpi). Eye, skin and joint sections were scored after sacrifice. Bacterial load was quantified in genital swabs. *Cmu* Major Outer Membrane Protein (MOMP) antigen-specific cytokine production was assessed in splenocytes 1 wpi; cytokines were measured in serum, skin and joint explants at 12 wpi. Regulatory T cells (Treg) were depleted from FoxP3-DTR BALB/c or SKG mice. *Cmu* genomic ompA DNA was quantified by PCR in spleens, iliac lymph nodes and joints. Non parametric tests assessed statistical significance.

Results: SKG but not BALB/c mice developed typical histological features of chronic reactive arthritis, with and remained autoantibody-negative, from 5 weeks after genital infection. *Cmu* load in genital tract was significantly increased in SKG relative to BALB/c mice in the first week after infection, associated with impaired *Cmu* MOMP-antigen-specific T cell interferon (IFN)-gamma and increased TNF response. Arthritis severity was correlated with prior *Cmu* load and live *Cmu* infection was required for reactive arthritis, as no disease occurred after bacterial inactivation with UV or antibiotics. While depletion of regulatory T (Treg) cells from *Cmu*-infected Foxp3.DTR SKG mice prompted rapid bacterial clearance, it also hastened onset of severe arthritis, conjunctivitis and dermatitis, accompanied by increased MOMP-specific IFN-gamma production. *Cmu* DNA was detected in myeloid cells derived from spleen and lymph nodes draining the genital tract of both strains, confirming their capacity to transport Chlamydial inclusions from the site of infection to other organs. The proportion of myeloid cells was 2-fold higher in SKG relative to BALB/c mice and this, together with the increased bacterial load, increases the likelihood of systemic delivery of *Cmu* DNA to peripheral sites.

Conclusion: *Cmu* induced reactive arthritis results from an exuberant inflammatory response to a deficient early control of infection and incomplete inflammatory suppression by Treg in the setting of host genetic T cell receptor-ZAP70 signalling deficiency.

Identification Of Genetic and Epigenetic Alterations In Spondyloarthritis. Tibor A. Rauch[1], Beata Tryniszewska[1], Andras Vida[1], Timea Ocsko[1], Sandor Szanto[2], Holly L. Rosenzweig[3], Matthew A. Brown[4], Gethin P Thomas[5], Katalin Mikecz[1] and Tibor T. Glant[1]. [1]Rush University Medical Center, Chicago, IL, [2]University of Debrecen, Debrecen, Hungary, [3]Oregon Health & Science University, Portland, OR, [4]University of Queensland Diamantina Institute, Brisbane, Australia, [5]University of Queensland Diamantina Institute, Woolloongabba, Australia.

Background/Purpose: Ankylosing spondylitis **(AS)** is the prototypic spondyloarthritis and affects approximately 0.2–0.5% of the human population. It is estimated that genetic risk factors contribute >90% of disease susceptibility, and the major genetic risk factor is HLA-B27. Approximately the other half of the genetic risk is composed by non-MHC traits. By generating interval-specific congenic (IVSC) strains utilizing the genetic combination of proteoglycan-induced SpA (PGISpA) in susceptible BALB/c mice and SpA-resistant DBA/2 mice (both carry the same MHC) we can identify non-MHC causative genes by excluding the effect of the MHC. These IVSC strains with overlapping chromosome (Chr) regions were used to narrow the (*Pgis2*) risk locus on mouse Chr2 (mChr2) to a small region syntenic with AS risk loci on human chromosomes 4 and 9.

Methods: PGISpA-resistant DBA/2 and –susceptible BALB/c strains were intercrossed, and then backcrossed with BALB/c mice until the entire *Pgis2* locus (mChr2) was from DBA/2 on a full BALB/c background. Congenic mice were tested for PGISpA, and then backcrossed to BALB/c strain. Recombination events were genotyped until partially overlapping DBA/2 intervals (n=12) completely covered the *Pgis2* locus. Heterozygous females and males with the same genomic intervals were intercrossed, homozygous offspring tested for PGISpA. Based on the overlapping Chr2 intervals, we narrowed a resistant (DBA/2 origin) to ~3.5 Mbp in size (mChr2:30.5–34.0 Mbp; syntenic with hChr9:129.−132.8 Mbp). All IVSC mice were tested with near infrared OsteoSenseTM 750 (Visen Medical) probe, spine histology, serum cytokines and cytokines in antigen-stimulated *in vitro* spleen cell cultures. The corresponding 3 Mbp genomic regions of PGISpA-resistant and –susceptible IVSC and parent strains (n=10) were sequenced by high-throughput methods and analyzed using the GeneSpring NGS program.

Results: We identified a total of 4,416 mutations within the 3.5 Mbp-long genomic region. The 3.5 Mbp region contains 70 protein-coding genes, 12 antisense transcripts (RNA) and 25 different forms (small nucloelar, miRNA) of non-coding RNAs. Mutations/indels were detected (93.38%) in three relatively small genomic regions affecting 3 (*Gpr107-Nsc1-Hmcn2*) genes and their intergenic regions, and two other genes (*St6galnac6* and *Lmx1b*). PGISpA was significantly reduced ($p<0.001$) in each IVSC strain carrying any of these three DBA/2 alleles. The *Gpr107-Nsc1-Hmcn2* triplet contained mutations affecting multiple transcription binding sites, the *Lmx1b* transcription factor has an in-frame 18-nucleotide deletion in exon 1, and the promoter region of the *St6galnac6* was hypermethylated in genomic regions of DBA/2 origin.

Conclusion: Although all three alleles affected PGISpA individually, it appears that an "epistatic triangle" exists among these alleles that protect against PGISpA. Overall, all mutations with predicted functional consequence are located in non-coding sequences underlining the critical role of epigenetic alterations in PGISpA (and perhaps in AS).

The Treg/Th17 Imbalance Of Patients With Systemic Lupus Erythematosus Were Mediated By Mir-663 Through Down-Regulating TGF-β1 Secretion Of Bone Marrow-Derived Mesenchymal Stem Cells. Lingyu Geng, Xia Li, Xuebing Feng and Lingyun Sun. Department of Rheumatology and Immunology, the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China.

Background/Purpose: Systemic lupus erythematosus (SLE) patients exist an imbalance between CD4+CD25+FoxP3+ T regulatory (Treg) and IL-17-producing cells (Th17). Correction of this Treg/Th17 imbalance may have therapeutic impact for SLE patients. Our previous study demonstrated that bone marrow derived mesenchymal stem cells (MSCs) from SLE patients are defective in immune modulation, which might be involved in Treg/Th17 imbalance, but the mechanisms are not clear yet. As a computer predicted target of miR-663, Transforming growth factor-beta1 (TGF-β1) is an important negative immune regulatory factors secreted by MSCs which could modulate SLE Treg/Th17 imbalance. The aim of this study is to investigate whether miR-663 could contribute to SLE Treg/Th17 imbalance though directly down-regulating TGF-β1 mRNA of SLE BMSCs, to further understand the pathogenesis of SLE.

Methods: BMSCs were isolated, cultured and expanded from iliac crest bone marrow of four healthy controls and five SLE patients. MicroRNA expressions of BMSCs from were determined by MicroRNA array analysis. Real-time PCR was used to further determine the miR-663 expression and TGF-β1 mRNA level in MSCs, secretion of TGF-β1 was detected by ELISA. As a computer predicted target of miR-663, TGF-β1 was determined using the luciferase reporter assay system. MSCs were transfected with miR-663a, pre-miR-663a, and anti-miR-663a, and then co-cultured with PBMCs from SLE patients for 3 days respectively with PHA pre-stimulated, flow cytometry was used to detect their effect on percentage of Treg and Th17 cells.

Results: Mir-663 was significantly up-regulated(2.52- fold higher, $P<0.05$) in MSCs from SLE patients(n=5) compared to normal controls(n=4) by microRNA array analysis. The expression of miR-663 was further determined by RT-PCR, and the synthesis of TGF-β1 mRNAs was significantly lower(3.88- fold lower, $P<0.05$) in MSCs from SLE patients. Transfection of SLE MSCs with pre-miR-663a caused significant upregulation of miR-663a expression(8.33- fold higher, n=3, $P<0.01$) and markedly lower synthesis of TGF-β1 mRNA(1.52-fold lower, n=3, $P<0.05$), while transfection with anti-miR-663a markedly decreased the miR-663a expression (3.01- fold lower, n=3, $P<0.05$). The mean value of Treg/Th17 was significantly decreased in PBMCs from SLE patients compared to normal controls (0.48 ± 0.12vs0.65 ± 0.09, n=8, $P<0.01$). Compared to SLE MSCs, MSCs from normal controls exhibited a better immune suppression effect through up-regulating Treg/Th17 of SLE patients (0.68 ± 0.15vs0.54 ± 0.14, n=3, $P<0.05$), and transfection of normal MSCs with pre-miR-663a caused significant downregulation of Treg/Th17 compared to miR-663-control group(0.38 ± 0.07vs0.68 ± 0.15, n=3, $P<0.01$), while transfection with anti-miR-663a led to an opposite effect (0.76 ± 0.08vs0.68 ± 0.15, n=3, $P<0.05$).

Conclusion: SLE patients exist an imbalance between Treg and Th17 cells, which might be associated with down-regulated TGF-β1 secretion of bone marrow-derived mesenchymal stem cells mediated by miR-663.

Transcription Factor RFX1 Regulates Th17 Differentiation and Its Role In The Pathogenesis Of Systemic Lupus Erythematosus. Ming Zhao, Gongping Liang, Qian Tang, Yang Yang, Yixin Tan and Qianjin Lu. Second Xiangya Hospital, Central South University, Changsha, China.

Background/Purpose: Recently, evidence is emerging that abnormal regulation of Th17 differentiation plays an important role in the pathogenesis of systemic lupus erythematosus (SLE). However, the molecular mechanisms are poorly understood. In our previous study, we found that transcription factor RFX1 expression was inhibited in SLE CD4+ T cells, which leads to overexpression of autoimmune-related genes CD11a and CD70. Here, we further investigate whether RFX1 regulates Th17 differentiation in SLE.

Methods: 40 SLE patients and 30 healthy controls were recruited. CD4+ T cells were isolated by magnetic beads. All patients fulfilled at least 4 of the SLE classification criteria of the American College of Rheumatology. RFX1 and cytokines expression levels were detected by real-time PCR, western blot and ELISA. CD4+ T cells were transfected with RFX1 expression plasmid (pSG-RFX1) or siRNA-RFX1 by nucleofector device in combination with the human T-cell nucleofector kit. Luciferase report gene assay and Chromatin Immunoprecipitation (ChIP) and Electrophoretic Mobility Shift Assay (EMSA) were used to confirm the target gene of RFX1. H3 acetylation levels and H3 lys9 (H3K9) tri-methylation levels in the promoter region of IL17A were measured by ChIP-qPCR.

Results: Compared with normal controls, RFX1 protein levels were decreased and IL17A mRNA levels were increased significantly in SLE CD4+ T cells. The IL-17A protein levels in serum of SLE patients were increased significantly. A negative correlation was observed between IL17A mRNA levels and RFX1 protein in SLE CD4+ T cells. Luciferase report gene assay, ChIP and EMSA showed that RFX1 can repress promoter activity of IL17A through binding the promoter of IL17A. Transfection of siRNA-RFX1 leads to up-regulated expression of IL17A through increasing H3 acetylation level and reducing H3K9 tri-methylation level in normal CD4+ T cells. In contrast, transfection of pSG-RFX1 inhibits expression of IL17A through reducing H3 acetylation level and increasing H3K9 tri-methylation level of IL17A promoter in SLE CD4+ T cells.

Conclusion: RFX1 is involved in repressing IL17A expression through regulating the epigenetic modifications in the promoter region of IL17A in CD4+T cells. Decreased RFX1 expression contributes to abnormal regulation of Th17 cells in SLE patients.

Abnormal Mitochondrial Electron Transport Chain Activity At Complex I Is Regulated By Nitric Oxide and N-Acetylcysteine In Lupus Lymphocytes. Edward Doherty[1] and Andras Perl[2]. [1]SUNY Upstate, Syracuse, NY, [2]SUNY Upstate Medical University, Syracuse, NY.

Background/Purpose: Systemic lupus erythematosus (SLE) peripheral blood lymphocytes (PBL) show mitochondrial dysfunction, characterized by elevated mitochondrial transmembrane potential ($\Delta\Psi_m$) and mass and low ATP, attributed to elevated production of nitric oxide (NO) and reduced glutathione (GSH). To understand the molecular bases of mitochondrial dysfunction we tested activity of the electron transport chain (ETC) complexes I and IV. As N-acetylcysteine (NAC) reversed GSH depletion and improved disease activity in SLE, its target of impact in mitochondria was also investigated.

Methods: PBL from 65 SLE subjects and 30 healthy controls, matched for patients' age within ten years, gender, and ethnicity were studied. Mitochondrial respiration was measured using a Clark-type O_2 electrode (Oxygraph, Hansatech, Norfok, UK) in 1) freshly isolated PBL, 2) PBL rested overnight, 3) PBL exposed to NO donors NOC-9 or NOC-18, 4) PBL exposed to NAC, 5) PBL exposed to β-mercaptoethanol (BME). S-nitrosylation was assessed with a biotin switch kit (Cayman, Ann Arbor, MI). $\Delta\Psi_m$, mass, NO, $ONOO^-$, Ca^{2+}, and H_2O_2 stress were assessed by flow cytometry (Meth. Mol. Biol. 900:61–89, 2012).

Results: SLE PBL have increased respiration upon T cell activation (SLE: 4.157nmol/ml/min ±0.186, control: 3.655nmol/ml/min ±0.167; p=0.012). Digitonin-permeabilized SLE PBL also show increased respiration without exogenous substrates (SLE: 2.492 nmol/ml/min ± 0.196, control: 2.137 nmol/ml/min ± 0.153; p = 0.027) and with substrates of ETC complex IV (SLE: 7.722 nmol/ml/min ± 0.419, control: 7.006 nmol/ml/min ± 0.505; p = 0.028). SLE PBL had elevated mitochondrial mass (+10% ± 3% p = 0.002). When normalized to mitochondrial mass, SLE PBL exhibit 33% reduced respiration through complex I (p=0.036) and 81% enhanced respiration through complex IV (p = 0.036). As expected, exposure to NOC-18 increased NO (+158% ± 51% p = 0.005) and mitochondrial mass in normal PBL (+162% ± 68% p = 0.016). NO exposure selectively increased O_2 consumption by SLE PBL through complex I relative to healthy controls (SLE: 1.405 nmol/ml/min ± 0.206; Controls: 1.277 nmol/ml/min ± 0.150; p = 0.026). In contrast, NAC decreased both $ONOO^-$ (−37% ±0.04 p=0.0001) and H_2O_2 levels without (−45% ± 5% p=0.0005) or with co-incubation with NOC-18 ($ONOO^-$: −38% ±7% p=0.002; H_2O_2: −71% ±2% p=0.000004). Compared to NOC-18 alone, co-incubation with NAC also decreased NO (−92% p=0.014), $ONOO^-$ (−38% p=0.006), mitochondrial mass (−87% p=0.017), and Ca^{2+} (−52% p=0.042). Direct addition of NAC into the Oxygraph chamber inhibited respiration by 53% through complex I (p=0.004) but not complex IV. In contrast, BME failed to affect respiration at complex I, but it reduced respiration by 80% at complex IV (p=0.031). NAC also blocked respiration through complex I by 56% in SLE PBL (p=0.0001). Upon NO exposure, S-nitrosylation is increased in freshly isolated lupus PBL relative to matched healthy control PBL (p=0.002).

Conclusion: The results of this data suggest that SLE PBL have defective ETC activity at complex I. NAC helps maintain a reducing environment, possibly by directly blocking respiration at complex I.

Spleen Tyrosine Kinase (Syk) Regulates Systemic Lupus Erythematosus T Cell Signaling. Alexandros P. Grammatikos[1], Debjani Ghosh[2] and Vasileios C. Kyttaris[3]. [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]The Brody School of Medicine, East Carolina University, Greenville, NC, [3]BIDMC, Harvard Medical School, Boston, MA.

Background/Purpose: Systemic Lupus Erythematosus (SLE) T cells display an aberrant response to CD3/ TCR stimulation. The CD3/TCR complex in SLE is characterized by the substitution of the CD3 associated kinase Zap70 by Syk. The objective of this study is to better understand the role of Syk in the dysregulated SLE T cell phenotype.

Methods: A two-step approach was followed: (i) to examine whether increased Syk expression creates an SLE-like phenotype Syk was overexpressed in healthy blood-donor T cells; and (ii) to examine whether aberrant gene expression changes in SLE T cells can be corrected by Syk downregulation, SYK was silenced using a SYK-specific siRNA. Cells were lysed following 72h of incubation and expression levels of 36 genes previously associated with SLE measured in real-time PCR. Protein was also collected and expression changes confirmed in flow cytometry and western blot. Expression was normalized towards CD3E and GPADH for PCR and β-actin for western blot.

Results: Forced expression of Syk in normal T cells reproduced many of the aberrant gene expression changes seen in SLE. Expression of cytokine IL-21, cell surface molecule CD44, and intracellular molecules PP2A and OAS2 were found to increase in cells overexpressing SYK (fold increase over control transfected ±SEM: IL-21, 5.7±1.5; CD44, 4.2±2.2; PP2A, 1.5±1; OAS2, 1.5±0.3). Silencing of Syk in SLE T cells normalized the expression of the above molecules (fold decrease over control transfected ±SEM: IL-21, −1.9±0.2; CD44, −2.8±0.4; PP2A, −2.7±1.9; OAS2, −1.1±0.8).

Findings were confirmed at the protein level using flow cytometry (mean positive cells ±SEM: (i) empty vector vs. SYK overexpressing, IL-21, 7.9±1 vs. 13±2.3, p=0.05; CD44v6, 10.7±1.2 vs. 16±2.1, p=0.05; (ii) control vs. SYK siRNA transfected, IL-21, 18.6±2.4 vs. 11.4±1.6, p=0.03; CD44v6, 11.7±0.7 vs.7.6±1.2, p=0.05) and western blot (mean relative expression ±SEM: (i) empty vector vs. SYK overexpressing, OAS2, 0.91±0.1 vs. 1.39±0.2, p=0.05; PP2A, 0.49±0.1 vs. 1.23±0.3, p=0.05; (ii) control vs. SYK siRNA transfected, OAS2, 1.39±0.3 vs. 1.06±0.2; PP2A, 1.14±0.3 vs. 0.69±0.1).

Conclusion: Our data show that overexpression of Syk in healthy T cells recapitulates at least part of the SLE T cell phenotype. Syk overexpressing T cells may provide more help to B cells through IL21 secretion, have enhanced migration to tissues through CD44 upregulation and produce pro-inflammatory rather than counter-inflammatory cytokines. Inhibiting Syk in SLE T cells leads to the opposite effect, further underscoring Syk's potential as a therapeutic target in SLE.

Molecular Pathogenesis and Genetics Of Tartrate-Resistant Acid Phosphatase Deficiency In Systemic Lupus Erythematosus. Jie An[1], Tracy A. Briggs[2], Audrey Dumax-vorzet[2], Alice Wiedeman[1], Laurence Chaperot[3], Joel Plumas[3], Yanick J. Crow[2] and Keith B. Elkon[1]. [1]University of Washington, Seattle, WA, [2]University of Manchester, Manchester, United Kingdom, [3]Immunobiology & Immunotherapy of Cancers, La Tronche, France.

Background/Purpose: Biallelic mutations in ACP5, encodng tartrate-resistant acid phosphatase (TRAP), result in the immuno-osseous disorder spondyloenchondrodysplasia (SPENCD), characterized by a variety of autoimmune phenotypes – most particularly systemic lupus erythematosus (SLE). Importantly, patients with SPENCD demonstrate an upregulation of type 1 interferon (IFN) stimulated genes (ISGs – an "interferon signatures") similar to that observed in SLE. Since very little is known about the function of TRAP in immune cells, the objectives of our study were: a) to determine the consequences of TRAP deficiency in human immune cells, B) to identify substrates of TRAP, and c) to determine whether ACP5 mutations occur in 'idiopathic' SLE.

Methods: Unbiased substrates of TRAP were queried using a yeast 2 hybrid (Y2H) screen in a human macrophage cDNA library, and interaction of a candidate substrate, osteopontin (OPN) with TRAP was determined by confocal microscopy and immunoprecipitation-western blot analysis (IP-western). TRAP overexpression / knockdown was performed by transfection with cDNA / lentivirus shRNA, respectively. Expression of ISGs was

determined by quantitative PCR (qPCR). Phosphatase activity was quantified by colorimetry, and dephosphorylation of substrates by Liquid Chromatogram-tandem Mass Spectrometer (LC-MS/MS). Sequencing of ACP5 coding exons was undertaken in patients with SLE.

Results: OPN is a substrate for TRAP in Macrophase and pDC. TRAP interacted and co-localized with OPN as determined by Y2H, confocal microscopy and by IP-western. Consistent with these data, recombinant human TRAP (rhTRAP) dephosphorylated recombinant human OPN (rhOPN) by the release of free phosphate in an in vitro assay. LC-MS/MS demonstrated rhTRAP dephosphorylated rhOPN at two serine residues in vitro. To relate the functional significance of TRAP deficiency to IFN-α production, we knocked down TRAP expression in pDC and observed that TRAP specific shRNA, but not scrambled shRNA, increased the expression of ISGs as well as IL-6 following TLR9 stimulation. This was associated with increased nuclear translocation of IRF7 and P50 in TRAP KD pDC cells compared to control cells. Sequencing of ACP5 in 865 SLE patients and 511 controls revealed an excess of heterozygous ACP5 possibly pathogenic missense variants in SLE patients (11 adults in the lupus cohort compared to 2 in controls). These variants were predicted as pathogenetic since they were: coding, non-synonymous, occurred at a frequency of less than 1/300 in controls, were in residues conserved in mammalian species and were predicted to destabilize protein on in silico testing. Transient transfection of several mutants and patient serum assays revealed a significant reduction in TRAP enzyme activity.

Conclusion: Our findings indicate that TRAP and OPN co-localize, and that OPN is a substrate for TRAP in immune cells. Significantly, TRAP deficiency in pDCs leads to increased IFN-α production, providing at least a partial explanation for why ACP5 mutations cause lupus in the context of SPENCD. Detection of ACP5 missense variants in lupus patients suggests that impaired function of TRAP may play a role increasing susceptibility to adult-onset idiopathic lupus.

2703

An Intronic *CR2* Polymorphism Associated With Systemic Lupus Erythematosus Alters CTCF Binding and *CR1* Expression. Jian Zhao[1], Brendan M. Giles[2], Rhonda L. Taylor[3], Gabriel A. Yette[2], Kara M. Lough[2], Lawrence J. Abraham[3], Hui Wu[1], Patrick M. Gaffney[4], Jennifer A. Kelly[4], Kenneth M. Kaufman[5], John B. Harley[6], Carl D. Langefeld[7], Elizabeth E. Brown[8], Jeffrey C. Edberg[9], Robert P. Kimberly[8], Daniela Ulgiati[3], Betty P. Tsao[1] and Susan A. Boackle[2]. [1]David Geffen School of Medicine University of California Los Angeles, Los Angeles, CA, [2]University of Colorado School of Medicine, Aurora, CO, [3]University of Western Australia, Perth, Western Australia, Australia, [4]Oklahoma Medical Research Foundation, Oklahoma City, OK, [5]Cincinnati Children's Hospital Medical Center and the University of Cincinnati, Cincinnati, OH, [6]US Department of Veterans Affairs Medical Center, Cincinnati, OH, [7]Wake Forest School of Medicine, Winston-Salem, NC, [8]University of Alabama at Birmingham, Birmingham, AL, [9]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by the production of antibodies to nuclear antigens, which form immune complexes that deposit in tissues and cause damage. Complement receptor 2 (CR2/CD21) is primarily expressed on B cells and follicular dendritic cells (FDC), and is required for normal humoral immune responses. Complement receptor 1 (CR1/CD35) is associated with CR2 on the B cell surface, and its cofactor activity is required for the conversion of iC3b to C3dg, the specific ligand for CR2. We previously identified *CR2* variants associated with decreased risk of SLE. To identify the causal variant(s) for the association, we conducted trans-ancestral fine-mapping of *CR2* and the surrounding genomic region.

Methods: Genotyped and imputed genetic variants located in a 57.6kb region spanning 5' of *CR2* to intron 1 of *CR1* were assessed for association with SLE in 15,750 unrelated case-control subjects from four ancestral groups using a logistic regression model adjusted for gender and global ancestry. Allele-specific functional effects of associated variants were determined using electrophoretic mobility shift assay (EMSA), chromatin immunoprecipitation (ChIP)-PCR, quantitative real-time PCR, and quantitative flow cytometry.

Results: The strongest association signal was detected at rs1876453, located in intron 1 of *CR2* ($P_{meta}=4.2\times10^{-4}$, OR 0.85), specifically when subjects with lupus were stratified based on the presence of dsDNA autoantibodies (case-control $P_{meta}=7.6\times10^{-7}$, OR 0.71; case-only $P_{meta}=1.9\times10^{-4}$, OR 0.75). Using EMSA, we demonstrated that the minor allele at rs1876453 altered the formation of several DNA-protein complexes, including one containing the highly conserved 11 zinc-finger protein CCCTC-binding factor (CTCF), which has pleiotropic effects on genomic organization, gene regulation, and alternative splicing. The allele-specific effects of rs1876453 on CTCF binding were confirmed by ChIP-PCR, with three-fold higher enrichment of the region surrounding this variant in the presence of the major allele ($p = 0.0178$). Although allele-specific effects of rs1876453 on B cell *CR2* mRNA or protein levels were not identified, levels of complement receptor 1 (*CR1/CD35)* mRNA and protein were significantly higher on the B cells of subjects harboring the minor allele ($p = 0.0248$ and $p = 0.0006$, respectively).

Conclusion: These data suggest that rs1876453 in *CR2* has long-range effects on gene regulation that decrease susceptibility to lupus. Since the minor allele at rs1876453 is preferentially associated with reduced risk of the highly specific dsDNA autoantibodies that are present in preclinical, active, and severe lupus, understanding its mechanisms will have important therapeutic implications.

Twist1 Regulates Transforming Growth Factor Beta Dependent Activation Of Fibroblasts In Fibrosis. Katrin Palumbo-Zerr[1], Andrea Liebl[1], Pawel Zerr[1], Michal Tomcik[2], Alfiya Distler[1], Christian Beyer[1], Oliver Distler[3], Georg Schett[4] and Joerg H. W. Distler[1]. [1]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [3]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [4]University of Erlangen-Nuremberg, Erlangen, Germany.

Background/Purpose: Twist1 is a member of the tissue-restricted class B of basic-helix-loop-helix (bHLH) transcription factors acting as master regulators on different tissues. Twist1 is controlled by spatial-temporal expression, dimer choice and cellular localization. Twist1 was shown to be a regulator of mesenchymal transition (EMT). Moreover, Twist1 regulates pathways such as Wnt/βcatenin signalling and responses to hypoxia. The aim of the present study was to investigate the role of Twist1 in TGFβ signaling and in fibroblast activation in systemic sclerosis (SSc).

Methods: Twist1 expression was quantified in SSc patients and different mouse models of fibrosis by qPCR, Western Blot and IF. Collagen synthesis was quantified by qPCR and SirCol in fibroblasts overexpressing or lacking Twist1. Interaction of Twist1, E12 and Id was shown by Co-IP. ChIP assays were performed to analyze Twist1transcriptional binding. The role of Twist1 ***in vivo*** was evaluated using inducible, conditional knockout mice with either ubiquitinous (Ubc CreER) or fibroblast-specific (col1a2 CreER) depletion of Twist1. Mice were either challenged with bleomycin or infected with constitutively active TGFβ receptor I adenovirus (TBRI^{CA}).

Results: Twist1 mRNA was elevated by 330 % in the skin of SSc patients ($p = 0.002$). Consistently, Twist1 was increased by 490 % ($p = 0.008$) and by 349 % ($p = 0.001$) in bleomycin-induced and TBRI^{CA} mouse models, respectively. Induction of Twist1 was mediated by TGFβ in a Smad3 dependent manner ***in vitro*** and ***in vivo,*** as demonstrated using the selective TGFβ receptor I inhibitor SD208 and Smad3/4 siRNA. Twist1 overexpression fostered the pro-fibrotic effects of TGFβ and enhanced fibroblast differentiation and release of collagen. In contrast, fibroblasts lacking Twist1 ameliorated TGFβ signalling. Chronic stimulation with TGFβ upregulated Twist1 and E12 in fibroblasts, but resulted in an even more pronounced induction of Id1 and Id3. Id proteins have great affinity for E12 and compete against class bHLH factor Twist1 for E12 binding. Co-IP revealed a time dependent shift of Twist1/E12 heterodimers to Id/E12 and Twist1/Twist1 complexes. In addition, binding of Twist1 homodimers to the col1a1 and col1a2 promoter was demonstrated using ChIP assay. Mice lacking Twist1 in

fibroblasts were less sensitive to bleomycin induced dermal fibrosis with diminished dermal thickening (−69,3 %, $p < 0.0001$), myofibroblast counts (−62,3 %, $p < 0.0001$) and hydroxyproline content (−58,1%, $p < 0.0001$). Mice with ubiquitous Twist1 knockout were protected to a similar degree, highlighting that fibroblasts are the key-effector cells for Twist1 signalling in experimental skin fibrosis. Twist1 deficiency also protected from $TBRI^{CA}$ induced dermal fibrosis.

Conclusion: We identified Twist1 as an important downstream mediator of TGFβ in SSc. TGFβ induces Twist1 expression and stimulates its promoter binding, which triggers myofibroblast differentiation and release of collagen. Knockdown of Twist1 ameliorates the pro-fibrotic effects of TGFβ and ameliorates experimental fibrosis in different murine models of SSc. Thus our study characterizes Twist1 as a key-regulator of fibroblast activation in SSc.

Inhibition Of Microrna-155 Ameliorated Experimental Fibrosis By Suppressing Wnt and Akt Pathways. Qingran Yan[1], Qiong Fu[1], Jie Chen[1], Xinfang Huang[1], Nan Shen[2] and Chunde Bao[1]. [1]Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China, [2]Shanghai Institute of Rheumatology, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.

Background/Purpose: MicroRNA-155 plays a critical role in various physiological and pathological processes including cell proliferation and migration, epithelial- mesenchymal transition, as well as inflammation. Previous research found that miR-155 could promote the development of murine pulmonary fibrosis. The aim of this study was to evaluate the role of miR-155 in a bleomycin induced mouse model of systemic sclerosis (SSc) and to investigate the potential mechanisms involved.

Methods: miR-155 knock-out (KO) C57BL/6 and background controlled mice were given bleomycin subcutaneously every other day for 21days to induce experimental fibrosis. Dermal thickness and collagen deposition were determined histologically by Sirius red dying. Tissue fibroblast number was measured through α-smooth muscle actin (α-SMA) staining by immunohistochemistry. For in vitro study, primary murine skin fibroblasts were cultured and stimulated with TGF-β. siRNA was applied to inhibit miR-155 expression. Real-time PCR was used to compare collagen synthesis and activation marker expressions in miR-155 knockdown fibroblasts with controls. Collagen release was analyzed by Sircol assay. Major TGF-β induced profibrotic pathways were analyzed by Western Blot. Targets of miR-155 were predicted by bio-informatics and were confirmed by using dual luciferase report assay and Western blot.

Results: The expression level of miR-155 was significantly elevated in mice injected with bleomycin, as well as in fibroblasts stimulated by TGF-β. Compared with control mice, miR-155 KO mice displayed significantly less fibrosis in both skins and lungs, as well as less number of activated fibroblasts *in situ*. Consistent with the *in viv*o findings, miR-155-knockdown primary fibroblasts showed significantly reduced collagen synthesis and lower activation markers (fibronectin and α-SMA) upon TGF-β stimulation. Analysis of major TGF-β downstream pathways including Smad2/3, JNK, ERK, Wnt and Akt revealed that the activation of Wnt and Akt pathway were notably suppressed in miR-155-knockdown fibroblasts. These two pathways were also attenuated in the skin of miR-155 KO mice injected with bleomycin. Further bio-informatics and literature research suggested that miR-155 could directly target casein kinase I (CK-1) and Src homology 2-containing inositol phosphatase-1 (SHIP-1), which are negative regulators of Wnt and Akt pathway, respectively. We found miR-155 inhibition would result in an increased level of these two proteins in primary fibroblast. Further studies using dual luciferase reporter assay confirmed the direct interaction between miR-155 and 3'-UTR of CK-1 and SHIP-1.

Conclusion: Inhibition of miR-155 could ameliorate experimental fibrosis in a bleomycin induced SSc mouse model. miR-155 modulates profibrotic Wnt and Akt pathway by directly targeting CK-1 and SHIP-1, respectively. miR-155 is a potential target for therapeutic intervention in SSc.

Fli1 Haploinsufficiency Exacerbates Dermal Fibrosis Via Activation Of Fibroblasts, Endothelial Cells and Macrophages In Bleomycin-Treated Mice. Takashi Taniguchi[1], Yoshihide Asano[1], Kaname Akamata[1], Shinji Noda[1], Takehiro Takahashi[1], Yohei Ichimura[1], Tetsuo Toyama[1], Maria Trojanowska[2] and Shinichi Sato[1]. [1]University of Tokyo Graduate School of Medicine, Tokyo, Japan, [2]Boston University, Boston, MA.

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disorder with clinical manifestations resulting from immune activation, vascular injuries and fibrosis development. Previous reports suggest that deficiency of the transcription factor Fli1 (Friend leukemia integration-1) has a pivotal role in the pathogenesis of SSc. Although Fli1 deficiency activates fibroblasts and endothelial cells toward an SSc phenotype *in vitro*, $Fli1^{+/-}$ mice show no clinical symptoms similar to SSc, suggesting that some additional factors are required to develop SSc in those mice. To address this issue, we generated bleomycin (BLM)-induced SSc murine model using $Fli1^{+/-}$mice and evaluated their phenotype by focusing on fibroblasts, endothelial cells, and immune cells.

Methods: Wild type and $Fli1^{+/-}$ mice were used in the BLM model of scleroderma. Degree of dermal thickness and fibrosis were determined by histological analyses. The quantity of the collagen-specific amino acid hydroxyproline was measured. Immunohistochemistry and real-time PCR were conducted to evaluate the degree of inflammation and the expression of cytokines, growth factors, chemokines, and cell adhesion molecules. The influence of Fli1 deficiency on the phenotypical changes in dermal fibroblasts, endothelial cells, and macrophages were also evaluated *in vitro* by real-time PCR and TGF-b bioassay.

Results: BLM induced dermal fibrosis to a much greater extent in $Fli1^{+/-}$ mice than in wild type mice. In addition, upon BLM treatment, $Fli1^{+/-}$ mice exhibited higher mRNA levels of CCN2 in the lesional skin than wild type mice, while mRNA levels of TGF-b were comparable. On the other hand, Fli1 haploinsufficiency greatly activated dermal fibroblasts in response to BLM treatment partly due to the elevated expression of integrin aVb3 and aVb5 in those cells, leading to the activation of latent TGF-b on their cell surface. Upon BLM treatment, the lesional skin of $Fli1^{+/-}$ mice showed higher expression of IL-4, IL-6, IL-10, IFN-g, TNF-a, iNOS, arginase1, Fizz1, and Ym1 than that of wild type mice. The numbers of myofibroblasts, macrophages, and mast cells and the ratio of $CD4^+/CD8^+$ T cells were increased in the lesional skin of BLM-treated $Fli1^{+/-}$ mice relative to that of BLM-treated wild type mice. Moreover, Fli1 haploinsufficiency promoted M2 macrophage infiltration in the lesional skin of BLM-treated mice and also promoted M2 differentiation of peritoneal macrophages by IL-4 or IL-13 stimulation *in vitro*. As for endothelial cells, Fli1 haploinsufficiency modulated the expression of cell adhesion molecules toward the induction of Th2 skewed inflammation by BLM treatment, as shown by the lower expression of E-selectin and P-selectin and the higher expression of ICAM-1 and GlyCAM-1 in the lesional skin of $Fli1^{+/-}$mice than in that of wild type mice.

Conclusion: With BLM treatment, $Fli1^{+/-}$ mice exhibited exacerbated dermal fibrosis due to the phenotypical changes of fibroblasts, endothelial cells, and immune cells toward an SSc phenotype to a much greater extent than wild type mice. Some additional factors induced by BLM treatment may be required for $Fli1^{+/-}$ mice to develop an SSc phenotype.

Downregulation Of KLF5 and Fli1 Cooperatively Contribute To Distinct Manifestations Of Systemic Sclerosis *In Vitro* and *In Vivo*. Shinji Noda[1], Yoshihide Asano[1], Katsuhito Fujiu[1], Ichiro Manabe[1], Ryozo Nagai[1], Kaname Akamata[1], Takashi Taniguchi[1], Takehiro Takahashi[1], Yohei Ichimura[1], Tetsuo Toyama[1], Daisuke Tsuruta[2], Maria Trojanowska[3] and Shinichi Sato[1]. Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disease characterized by initial vascular injuries and resultant fibrosis of skin and certain internal organs. Although the pathogenesis of SSc still remains unknown, our latest data have demonstrated that epigenetic suppression of transcription factor Fli1 is deeply involved in the constitutive activation of fibroblasts and endothelial cells in this disease. In murine

models, Fli1 haploinsufficiency results in increased expression of type I collagen at mRNA and protein levels in the back skin, but fibrosis does not occur at least partly because the expression of CTGF, which plays a critical role to establish and maintain tissue fibrosis, remains unchanged. Since our pilot studies have revealed that transcription factor KLF5 is a potent repressor of the CTGF gene and its expression is epigenetically suppressed in SSc dermal fibroblasts, we generated mice with heterozygous deletions of Fli1 and KLF5 and evaluated whether they recapitulated the clinical and histopathological features of SSc.

Methods: mRNA and protein levels of target molecules were determined by quantitative real-time PCR and by immunoblotting, immunohistochemistry and ELISA, respectively. Vascular structure in the back skin was visualized by FITC-dextran intravenously injected. Ultrastructue of collagen fibers was evaluated by electron microscopy. Auto-antibodies were detected by indirect immunofluorescence with Hep2 cells.

Results: $Klf5^{+/-}$;$Fli1^{+/-}$ mice (C57BL/6) were fertile, born in Mendelian ratio, and did not display any apparent early developmental abnormalities. Notably, these mice spontaneously recapitulated cardinal features of SSc, including peripheral vasculopathy, fibrosis of skin and lung, autoimmunity and inflammation. Dermal vascular abnormalities, including stenosis of arterioles with a moth-eaten pattern and bushy capillary tips, occurred around the age of 1 month prior to the development of dermal fibrosis with ultrastructural changes of collagen fibrils similar to those seen in SSc. Interstitial lung disease with B cell lymphoid aggregates and vascular changes characteristic of pulmonary arterial hypertension and pulmonary veno-occlusive disease appeared around the age of 2–4 months and progressed along with disease duration. Serum IL-6 levels and IL-6 mRNA levels in the skin and lung were elevated around the age of 2 months and splenic B cells secreted a greater amount of IL-6 in response to toll-like receptor 4 stimulation with LPS and/or T cell help in the form of an anti-CD40 antibody. Importantly, anti-nuclear antibodies were also detected.

Conclusion: These studies underscore the concept of epigenetic reprogramming underlying pathogenic changes in SSc and implicate the Fli1 and KLF5 pathways as central mediators of this disease.

The Hedgehog Transcription Factor Gli-2 Is a Novel Downstream Mediator Of The Pro-Fibrotic Effects Of Transforming Growth Factor-Beta. Barbora Sumova[1], Cinzia Cordazzo[2], Katrin Palumbo-Zerr[3], Clara Dees[4], Pawel Zerr[3], Oliver Distler[5], Georg Schett[4], Ladislav Senolt[6] and Joerg H. W. Distler[3]. [1]Department of Rheumatology of the First Faculty of Medicine, Institute of Rheumatology and Connective Tissue Research Laboratory, Prague, Czech Republic, [2]3Dipartimento Cardiotoracico e Vascolare, Laboratory of Respiratory Cell Biology, University of Pisa, Pisa, Italy, [3]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [4]University of Erlangen-Nuremberg, Erlangen, Germany, [5]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [6]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic.

Background/Purpose: Systemic sclerosis (SSc) is characterized by aberrant activation of fibroblasts with increased release of extracellular matrix components. TGFβ is a key-mediator of fibroblast activation in SSc. More recently, hedgehog signaling (Hh) has also been shown to induce tissue fibrosis in SSc. Gli-2 is activated by Hh signaling and induces the transcription of hedgehog target genes. Since the TGFβ and Hh signaling are both key drivers of fibroblast activation in SSc, the aim of this study was to investigate potential crosstalk between those two pathways in SSc.

Methods: The expression of Gli2 in the fibroblasts and tissue was analyzed by real- time PCR and IF staining. Collagen synthesis was quantified by real-time PCR and hydroxyproline assay. Selective knockdown strategies were used to evaluate the role of Gli2 in TGFβ signaling *in vitro* and *in vivo*. The interaction between Gli-2 and TGFβ signaling was analyzed using mice with inducible, fibroblast-specific knockout of Gli2 (Gli-2; Col1a2 CreER) and fibroblast-specific overexpression of a constitutively active TGFβ receptor I TBR (TBR; Col1a2 CreER). Cre mediated recombination was induced postnatally by injection of tamoxifen.

Results: The expression of Gli-2 was significantly increased in the skin of SSc patients compared to healthy controls. In particular, SSc fibroblasts expressed high levels of Gli-2. A prominent overexpression of Gli-2 in fibroblasts was also observed in mice overexpressing TBR. Consistently, stimulation with TGFβ increased the mRNA and the protein level of Gli2 in a time-dependent manner with maximal effects after 3 hours of stimulation (6-fold increase, $p<0.05$) and induced nuclear translocation of Gli2. Gli-2 knockout fibroblasts expressed lower levels of TGFβ targeted genes col1a2 (−47 %), CTGF (−30 %), Smad7 (−44 %), PAI-1 (−37 %) upon stimulation with TGFβ compared to control fibroblasts ($p<0.05$ each). The role of Gli-2 as a downstream mediator of TGFβ in fibroblasts was further analyzed *in vivo* using mice with fibroblast-specific depletion of Gli-2 and simultaneous overexpression of TBR. Fibroblast-specific overexpression of TBR in TBR; Col1a2 CreER mice induced progressive skin fibrosis. Fibroblast-specific, postnatal depletion of Gli-2 in Gli-2; Col1a2 CreER did not result in a basal skin phenotype. However, fibroblast-specific knockdown of Gli-2 protected from TBR induced fibrosis. Gli-2 × TBR; Col1a2 CreER mice treated with tamoxifen showed reduced dermal thickening (−30 %), decreased myofibroblast counts (−41 %) and lower hydroxyproline levels (−45 %) ($p<0.05$ each) compared to TBR; Col1a2 CreER mice.

Conclusion: We present here first evidence for a novel interaction of TGFβ and Hh signaling in fibrosis. TGFβ stimulates Hh signaling in a non-canonical manner by activation of the downstream transcription factor Gli-2. Fibroblast-specific knockdown of Gli-2 reduces the stimulatory effects of TGFβ on fibroblasts and ameliorates TBR-induced skin fibrosis, thereby demonstrating Gli-2 is as a novel downstream mediator of the pro-fibrotic effects of TGFβ.

Secreted Frizzled-Related Protein 4 Can Be Induced By Transforming Growth Factor-β, Is Regulated By Caveolin-1 and Can Induce Non-Canonical Wnt Signaling In Fibroblasts. Justin Gillespie[1], Giuseppina Abignano[1], Michael McDermott[1], Paul Emery[1] and Francesco Del Galdo[2]. [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom.

Background/Purpose: Systemic Sclerosis (SSc) is a heterogeneous disease characterized by autoimmune activation, fibroproliferative vasculopathy, and tissue fibrosis of skin and multiple internal organs. Several studies have indicated that both caevolin-1 (CAV-1) and WNT/β-catenin signaling play important roles in the pathogenesis of tissue fibrosis. Indeed, CAV-1 is downregulated by 40% in SSc skin compared to healthy controls and, intriguingly, tissue expression studies with SSc skin biopsies show both upregulation of canonical WNT ligands[1,2] and consistent upregulation of Frizzled-Related Protein 4 (SFRP4), a putative WNT antagonist, at both mRNA at protein level[3,4]. To evaluate the role CAV-1 and TGFβ on the expression of SFRP4, and the effects of SFRP4 upon WNT signaling in fibroblasts.

Methods: Immortalized primary healthy (HC) and SSc fibroblasts were cultured in 10% DMEM and starved in 0.5% DMEM for 24hrs prior to stimulation with recombinant TGFβ (10ng/ml), WNT-3a/5a (100ng/ml) and/or SFRP4 (100–500ng/ml). Gene expression was quantified by SYBRgreen RTPCR and by western blot. CAV-1 siRNA was transfected at 5μM. Canonical WNT signaling was assessed by TOPFlash luciferase reporter activity. ELISA was used to measure both the level of Phospho-c-JUN from whole cell lysates, and the level of SFRP4 from SSc patient sera.

Results: In SSc fibroblasts, the basal expression of SFRP4 was increased at protein level and also by 264% at mRNA level compared to HC [$p<0.001$]. TGFβ stimulation upregulated SFRP4 mRNA by 170% [$P<0.01$] at 48hrs and by 348% [$P<0.01$] at 72hrs. TGFβ also induced a time-dependent increase of both SFRP4 and α-SMA protein expression, while reducing CAV-1. The siRNA-mediated silencing of CAV-1 was sufficient to induce a time-dependent increase in SFRP4 protein expression. WNT-3a induced a 600% increase in TOPFlash activity, while co-treatment with SFRP4 suppressed this activation by 59%. In contrast, SFRP4 induced a 260% increase [$p<0.001$] in c-JUN phosphorylation, a non-canonical WNT target, at 10 min in both HC and SSc fibroblasts. This was similar to the activity of the non-canonical WNT-5a ligand. Interestingly, basal Phospho-c-JUN was

increased by 180% [P<0.005] in SSc compared to HC fibroblasts. Further, SFRP4 treatment increased *COL1A1* expression by 26% in HCs at 500ng/ml, while in SSc fibroblasts SFRP4 induced both *COL1A1* and *α-SMA* by 49–50% with 100–500ng/ml SFRP4, respectively. Additionally, SSc sera levels of SFRP4 inversely correlated with diffusion lung capacity of carbon monoxide % (r=−0.29, P=0.01) and positively with mRSS in patients with normal lung function (r=0.40, p=0.006).

Conclusion: The increased expression of SFRP4 observed in SSc skin biopsies may be a direct consequence of CAV-1 downregulation by TGFβ in tissue fibroblasts. Given the non-canonical WNT activity of SFRP4, a TGFβ primed microenvironment may be responsible for shaping the phenotype of both fibroblasts and neighboring cells, through aberrant WNT pathway activation. Additionally, circulating SFRP4 may have potential as a biomarker of fibrosis. Investigation of the mechanisms linking CAV-1 expression and SFRP4 function will improve our understanding of the pathogenic role that aberrant WNT activation plays in SSc.

Deficiency Of The Protein Kinase Ataxia Telangiectasia Mutated Accelerates T Cell Aging In Rheumatoid Arthritis. Zhen Yang[1], Hiroshi Fujii[2], Eric L. Matteson[3], Jorg J. Goronzy[1] and Cornelia M. Weyand[1]. [1]Stanford University School of Medicine, Stanford, CA, [2]Tohoku University, Sendai, Japan, [3]Mayo Clinic, Rochester, MN.

Background/Purpose: T lymphocytes hold a pinnacle position in the pathogenesis of rheumatoid arthritis (RA) and through their longevity contribute to disease chronicity. The protein kinase Ataxia telangiectasia mutated (ATM) is traditionally considered critical in DNA damage repair and cell cycle checkpoint regulation. Recent studies have extended ATM function from the nucleus to the cytoplasm where it acts as an oxidative stress sensor and regulates cellular metabolism and apoptosis, affecting cellular fate decisions and survival. CD4 T cells from RA patients express low levels of ATM protein and are inefficient in repairing damaged DNA. Whether ATM deficiency affects reactive oxygen species (ROS) sensing, metabolic competence, apoptotic sensitivity as well as T cell functional differentiation is unknown.

Methods: Naïve T cells ($CD4^+CD45RO^-$) were purified from the blood of RA patients (n=59) and age-matched controls (n=62). T cell proliferation, cell cycle progression and IL-2 production was compared 48 and 72 hours following TCR ligation. Naïve-to-Memory conversion was monitored by cytometric phenotyping. Resting and activated T cells were loaded with fluorogenic dyes (DCF and DHE) to quantify H_2O_2 and O^{2-}production. The G2/M cell cycle checkpoint was measured with anti-phospho-Histone H3. Expression of ATM, p-ATM (Ser1981), AMPKa1, and p-AMPKa1 (Thr172) were quantified by immunoblotting. ATM signaling was blocked through the inhibitor ku-55933 or siRNA-mediated knockdown.

Results: Compared to age-matched control T cells, RA T cells produced low levels of ATM transcripts, ATM monomers and ATM dimers. In search for upstream signals triggering ATM activity, control and RA T cells were compared for the intracellular levels of H_2O_2 and O^{2-}. Both ROS were diminished in RA T cells. Reduced ATM signaling in RA T cells resulted in delayed histone H2Ax phosphorylation. ATM-deficient RA T cells passed through the G2/M cell cycle checkpoint without proper arrest, accelerating their differentiation into IL-2-producing effector cells. The modified cell cycle behavior led to the rapid conversion of naïve into memory T cells, depleting the naïve T cell reserve in RA patients. Abnormalities in cell cycle progression and T cell differentiation were reproduced in healthy T cells by blocking ATM signaling with ku-55933 or by siRNA-mediated ATM knockdown. Further downstream effects of insufficient ATM signaling in RA T cells included decreased activation of AMPK, a kinase critically involved in energy sensing and metabolic regulation.

Conclusion: Deficiency of ATM redirects cell cycle behavior, metabolic fitness and functional differentiation of RA T cells. ATM-low RA T cells fail to adhere to cell cycle checkpoints, proliferate faster and differentiate prematurely. Also, ATM deficiency impairs triggering of the energy sensor AMPK, leaving the cell without sufficient energy supply. Consequences include the depletion of the naïve T cell reserve, accelerated T cell aging and excessive production of T cell effector cytokines. Overall, these abnormalities in T cell homeostasis and function bias the immune system toward chronic non-resolving inflammation.

Self-Specific Polyclonal CD4 T Cells Enter a $FR4^{hi}$ $CD73^{hi}$ Anergic State To Prevent Immunopathology and Serve As a Reservoir For The Differentiation Of Protective $Foxp3^+$ Tregs. Lokesh Kalekar and Daniel L. Mueller. University of Minnesota Medical School, Minneapolis, MN.

Background/Purpose: Clonal anergy has been proposed as a mechanism to allow for peripheral recognition of self antigens, without the consequence of immunopathology. Model systems have confirmed that CD4 T cells can become unresponsive to self antigen stimulation, but there is currently no evidence for the existence of anergic CD4 T cells in the normal polyclonal repertoire.

Methods: Gene arrays were used to identify mRNAs specifically overexpressed in anergic ovalbumin (OVA)-specific OT-II TCR-transgenic CD4 T cells after adoptive transfer into healthy OVA-transgenic mice. Overexpression of anergy molecules was confirmed by multiparameter flow cytometry in anergic glucose-6-phosphate isomerase (GPI)-specific KRN TCR-transgenic CD4 T cells after adoptive transfer to self antigen-expressing healthy mice. Antigen-experienced polyclonal CD4 T cells expressing these anergy molecules were characterized by flow cytometry, purified, and tested for their capacity to cause immunopathology in lymphopenic hosts. Finally, adoptive transfer recipients of anergic polyclonal CD4 T cells were tested for evidence of autoantibody production and weight loss versus the generation of protective $Foxp3^+$ Tregs.

Results: Using microarrays to compare mRNA expression in naive, effector, and anergic OT-II CD4 T cells, we discovered that genes for folate receptor 4 (*Folr4*; FR4) and ecto-5'-nucleotidase (*Nt5e*; CD73) were greatly over-expressed following the induction of clonal anergy. Examination of KRN CD4 T cells following their initial adoptive transfer to GPI-expressing hosts confirmed up-regulation of FR4 and CD73 during the induction of anergy, and a reversal of this anergic state following adoptive transfer of $FR4^{hi}$ $CD73^{hi}$ anergic KRN T cells to TCRa-deficient lymphopenic hosts. Making use of these FR4 and CD73 anergy markers, 2–3% of the peripheral mature polyclonal CD4 repertoire was discovered to be anergic. Foxp3 was not expressed; however, CD69, PD-1, CTLA4, CD5, and Nur77 up-regulation suggested continuous engagement by high affinity TCRs on these tolerant T cells. Consistent with *in vivo* anergy induction in response to self antigen recognition, antigen-experienced ($CD44^{hi}$) insulin/I-A^{g7} tetramer-binding polyclonal CD4 T cells in NOD mice demonstrated high expression of FR4 and CD73. Adoptive transfer of $FR4^{hi}$ $CD73^{hi}$ polyclonal CD4 T cells to syngeneic TCRa-deficient lymphopenic hosts led to reconstitution of the $Foxp3^+$ Treg compartment. Remarkably, elimination of newly differentiated Tregs in these anergic CD4 T cell recipients led to fatal wasting disease and the production of autoantibodies.

Conclusion: Peripheral self antigen recognition in normal hosts drives autoreactive CD4 T cells into an anergic state that is associated with the up-regulation of FR4 and CD73. Anergic T cells remain in the peripheral repertoire, both as a threat to health upon anergy reversal as well as a reservoir of precursors for protective $Foxp3^+$ Tregs. A greater understanding of the role of anergy induction and reversal in the development of rheumatic diseases will offer new insights into strategies designed to restore self tolerance.

Increased Soluble PD-1: A Link Between Generation Of Immunological Memory and Risk Of Disease Flare In Early RA. Stinne Greisen[1], Tue W. Kragstrup[1], Kristian Stengaard-Pedersen[2], Merete Lund Hetland[3], Kim Hørslev-Petersen[4], Malene Hvid[1] and Bent Deleuran[1]. [1]Aarhus University, Aarhus, Denmark, [2]Arhus University Hospital, Aarhus, Denmark, [3]The Danish Rheumatologic Database (DANBIO), Glostrup Hospital., Copenhagen, Denmark, [4]University of Southern Denmark, Graasten, Denmark.

Background/Purpose: Disturbances in the regulatory mechanisms of the immune system play a major role in rheumatoid arthritis (RA). Programmed Death 1 (PD-1) on lymphocytes negatively regulate T cell receptor (TCR)-

induced activation through interaction with two ligands (PD-L1 and PD-L2) on activated antigen-presenting cells, including fibroblasts. PD-1 exists in a soluble form (sPD-1), and is increased in chronic RA. Here, we investigate whether sPD-1 plays a role in the generation of immunological memory in early RA.

Methods: In a longitudinal set of steroid- and DMARD naïve RA patients (eRA) (n=76, <3 months of disease) we measured plasma levels of sPD-1 by ELISA (R&D systems) at baseline and after 3, 6 and 12 months of treatment with methotrexate (MTX) + placebo (PLA) or MTX + adalimumab (ADA). After 12 months of treatment, ADA/PLA was discontinued and patients were followed every third month for flare. sPD-1 was also measured in chronic RA (cRA) in plasma and synovial fluid (SF) (n=24, >8 years of disease). Data were expressed as median (IQR) and correlations were assessed by Spearman's rho. T cells were stimulated with anti-CD3/CD28 and co-cultured with RA fibroblast-like synoviocytes (FLS) for 3 days with addition of sPD-1 (20ng/ml), sPD-L1 (20ng/ml) or TNFα (10ng/ml). T cells were examined by flow cytometry for expression of PD-1, CD25, CD69 and proliferation, and FLS were examined for PD-L1 expression.

Results: The plasma levels of sPD-1 was increased in eRA (0.52 ng/ml (0.3–1.1 ng/ml)) compared with cRA (0.14 ng/ml (0.07 ng/ml −0.33 ng/ml), $p<0.001$) and decreased following treatment (0.26 ng/ml (0.2–0.6 ng/ml), $p<0.001$)). Treatment with ADA did not influence this decrease. Baseline sPD-1 correlated tightly with anti-CCP (r=0.42) and IgM-RF (r=0.60, both $p<0.001$). The correlation persisted at 3, 6 and 12 months. Patients with high baseline sPD-1 showed increased risk of disease flares ($p<0.05$). In cRA sPD-1 levels were increased in SF (0.31ng/ml, (0.14 ng/ml −0.73 ng/ml)) compared with plasma ($p<0.01$). T cell survival in FLS co-cultures was 76% when adding sPD-1 compared with 61% in controls. Stimulation with sPD-1 did not affect proliferation, CD25, CD69 or PD-1 expression by T cells. Co-culture with stimulated T cells increased PD-L1 expression on FLS from 2% to 45%. In co-cultures with TNFα, PD-L1 was expressed on nearly all FLS.

Conclusion: Plasma levels of sPD-1 were increased in eRA and decreased in response to treatment suggesting sPD-1 to be important for the initial phase of RA. The high concentrations found in SF points to a function of sPD-1 locally in the joint. The close association with IgM-RF and anti-CCP, the increased risk of flare with high sPD-1 in eRA plasma and the ability of sPD-1 to promote T cell survival in co-cultures with FLS support a role for sPD-1 in adaptive immunity and generation of immunological memory. Taken together, our findings suggest that sPD-1 is capable of blocking the PD-L1 binding-site on FLS, inhibiting the effects of the PD-1-induced TCR regulation and thereby increasing the risk of generating auto-reactive cells.

IL-21 Inhibited Follicular Regulatory T Cells To Promote Autoreactive Germinal Center Development In Autoimmune BXD2 Mice. Yanna Ding[1], Hui-Chen Hsu[2], Jun Li[1], PingAr Yang[1], Qi Wu[1], Allan J. Zajac[1] and John D. Mountz[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Birmingham VA Medical Center, Birmingham, AL.

Background/Purpose: Follicular T helper (Tfh) cells have been correlated with germinal center (GC) formation, autoantibody production and disease severity in human systemic lupus erythematosus (SLE). Follicular regulatory T cells (Tfr) are a regulatory CD4 T (Treg) subset that counteract Tfh cells and suppress GC B cell differentiation. We recently identified that interleukin 21 (IL-21) promotes Tfh differentiation in autoimmune BXD2 mice that develop spontaneous GCs. However, the role of IL-21 in regulating Tfr is unknown. The aim of this study is to determine the modulatory effects of IL-21 on Tfr/Tfh balance in BXD2 mice.

Methods: Real-time PCR analysis was used to determine the expression of Treg-related genes in sorted Tfr cells after *in vitro* cultured with IL-21 (50ng/ml) stimulation. Exogenous IL-21 was provided to BXD2-*Il21*$^{-/-}$ mice via adenovirus (Ad)-IL21 administration to investigate the effect of IL-21 on Tfr *in vivo*. Sorted Tfr cells from BXD2-*Il21*$^{-/-}$ mice were co-cultured with CD4 T cells and B cells *in vitro* as well as transferred into young BXD2 mice *in vivo* to determine the function of Tfr. FACS staining was used to determine the percent and phenotype of Tfh and Tfr. Confocal imaging analysis was used to visualize the distribution of Tfr cells and GCs. ELISA was used to determine serum levels of IL-21 and TGF-β1. ELISPOT was used to determine the generation of antibody producing B cells.

Results: GL-7^{+}Fas^{+} GC B cells and CXCR5^{+}ICOS^{+} Tfh cells were significantly reduced, but the frequency of FoxP3^{+}CXCR5^{+}ICOS^{+} Tfr cells was 2-fold higher in BXD2-*Il21*$^{-/-}$ mice than in wild-type BXD2 mice, although the frequencies of conventional Treg cells were equivalent. The Tfr cells in BXD2-*Il21*$^{-/-}$ mice expressed high level of other Treg markers including CTLA4, TGF-β1 and GITR. FoxP3^{+}Tfr cells were localized in spleen follicular areas of BXD2-*Il21*$^{-/-}$ mice. Transfer of Tfrs from BXD2-*Il21*$^{-/-}$ mice into BXD2 mice although decreased GC size and reduced IgM, it did not suppress IgG autoantibody producing B cells in the spleen. AdIL-21 administration to BXD2-*Il21*$^{-/-}$ mice increased GC B cells but decreased the serum TGF-β1, membrane TGF-β1 expression in Tfrs and the ratio of Tfr/Tfh in the spleen. *In vitro*, IL-21 decreased FoxP3^{+} and significantly reduced *Tgfb*, *Gitr* and *Il2* expression in Tfrs. IL-21 also counteracted Tfr-induced B cells death and inhibition of Tfhs.

Conclusion: The present study suggests that IL-21 positively promotes autoreactive GC reactions in BXD2 mice at least partially by decreasing Tfrs and compromising the suppressive function of Tfrs on B cells and Tfhs. The results further suggest that IL-21 can skew the balance between Tfr and Tfhs to favor Tfh differentiation. Thus, IL-21 blockage is necessary when developing a Tfr transferring therapeutic strategy to inhibit autoimmune GC response.

Commensal Intestinal Microbiota Drives Spontaneous Interleukin-1- and T Helper 17-Mediated Arthritis In Mice. Shahla Abdollahi-Roodsaz[1], Rebecca Rogier[2], Tom Ederveen[2], Harm Wopereis[3], Raish Oozeer[3], Marije I. Koenders[2] and Wim B. van den Berg[1]. [1]Rheumatology Research and Advanced Therapeutics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Rheumatology Research and Advanced Therapeutics, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, [3]Danone Research, Wageningen, Netherlands.

Background/Purpose: Altered composition of intestinal microbiota in recent-onset rheumatoid arthritis (RA) and possible efficacy of oral antibiotics suggest a role of intestinal microbiota in RA. This study aimed to investigate the involvement of commensal intestinal microbiota in T cell-dependent experimental arthritis.

Methods: IL-1 receptor antagonist deficient (IL-1Ra$^{-/-}$) mice spontaneously developing T cell-driven IL-17-dependent autoimmune arthritis were used. Intestinal and systemic T cell differentiation and arthritis development were studied in conventional and germ-free (GF) mice. Contribution of intestinal microbiota was investigated using oral broad-spectrum and selective antibiotic treatments via drinking water, combined with recolonization by specific microbiota. Multiplex 454 pyrosequencing of V5 and V6 hypervariable regions of fecal bacterial 16S rRNA was used to identify specific microbiota associated with arthritis.

Results: Compared to wild-type mice, small intestinal lamina propria of IL-1Ra$^{-/-}$ mice contained increased Th17 and to lower extent Th1 percentages, both of which significantly correlated with arthritis severity. Importantly, GF IL-1Ra$^{-/-}$ mice had a marked abrogation of arthritis along with reduced intestinal Th1 and in particular Th17. GF IL-1Ra$^{-/-}$ mice exhibited a notable decrease in IL-1β and IL-17 production by splenocytes upon CD3 and Toll-like receptor stimulations, suggesting abolishment of systemic Th17 response. Interferon γ was only detectable upon CD3 stimulation and was reduced as well.

Relevance of intestinal microbiota was underlined by significant long-term suppression of arthritis by one-week oral treatment with Metronidazole, Neomycin and Ampicillin (each 1g/l). Interestingly, recolonization of antibiotic-treated IL-1Ra$^{-/-}$ mice by segmented filamentous bacteria, previously reported as a prominent intestinal Th17 inducer, was sufficient to cause full-blown arthritis. Elimination of distinct intestinal microbiota subsets showed that arthritis is suppressed when Gram-negative, but not Gram-positive, bacteria are selectively eradicated, indicating members of intestinal Gram-negative commensals may drive arthritis.

High-throughput pyrosequencing revealed lower microbiota abundance (operational taxonomic units) and reduced species richness and diversity (Chao and Shannon indices, resp.) in arthritic IL-1Ra$^{-/-}$ compared to wild-type mice. The genus *Helicobacter*, belonging to Gram-negative bacteria, was found associated with arthritis severity (0.0% in wild-type versus 1.1 % in arthritic mice). The disease was further associated increased *Anaeroplama* and *Lactobacillus* accompanied by decreased *Bacteroidetes*. Valida-

tion of microbiota alterations and studies on T cell-modulatory and disease-inducing characteristics in GF mice are in progress.

Conclusion: The presence of commensal intestinal microbiota is critical for the development of autoimmune T cell-driven arthritis, probably via shaping the T cell differentiation by Gram-negative bacteria. Understanding the molecular and cellular mechanisms linking the intestinal T cell response with extra-intestinal disease may help identify novel therapeutic targets in RA.

Support For Psychological State May Be Effective to Attain Remission Of Boolean-Based Definition Of Patient Global Assessment In Patients With Rheumatoid Arthritis. Mie Fusama[1], Kumiko Yukioka[2], Takanori Kuroiwa[2], Chikako Yukioka[2], Miyako Inoue[2], Tae Nakanishi[2], Norikazu Murata[2], Noriko Takai[3], Kayoko Higashi[4], Taro Kuritani[4], Keiji Maeda[4], Yasushi Miura[1], Hajime Sano[5], Masao Yukioka[2] and Hideko Nakahara[4]. [1]Kobe University Graduate School of Health Sciences, Kobe, Japan, [2]Yukioka Hospital, Osaka, Japan, [3]Yukioka College of Health Science, Osaka, Japan, [4]NTT West Osaka Hospital, Osaka, Japan, [5]Hyogo College of Medicine, Nishinomiya-city, Japan.

Background/Purpose: The patients with rheumatoid arthritis (RA) often do not meet patient global assessment (PGA) remission criterion despite a good clinical disease state and, therefore, PGA is not solely influenced by RA disease activity. It has been reported that PGA is a limiting factor for reaching remission. We evaluated whether psychological state influences on Boolean-based definition of PGA remission for patients with RA.

Methods: The patients with RA (n=112) were recruited. Disease activity was evaluated with swollen joint counts (SJC) and tender joint counts (TJC) and evaluator's global assessment (EGA), PGA, and patient pain (Pain VAS) were assessed with visual analog scale. Depression and anxiety were examined utilizing the Hospital Anxiety and Depression Scale-Depression (HADS-D) and the State-Trait Anxiety Inventory (STAI), respectively. General health status was evaluated with Sort Form-36 (SF-36). Comparison analyses were performed between remission group (VAS=<1cm) and non-remission group (VAS>1cm) in PGA, EGA, and pain VAS. Data analyses were performed utilizing Wilcoxon rank-sum test and Spearman correlation analysis.

Results: There was no significant difference in age, duration and PSL dosage between PGA remission group (n=35) and non-remission group (n=77) or EGA remission group (n=38) and non-remission group (n=74). SJC and TJC of remission groups were significantly lower in PGA and EGA ($p<0.0001$, $p<0.0001$, respectively). Among TJC, SJC and pain VAS, PGA was most significantly related to pain VAS ($r=0.9232$, $p<0.0001$), while EGA was related to SJC ($r=0.7725$, $p<0.0001$). STAI (State) and HADS-D were significantly lower in pain VAS remission group ($p=0.0018$, $p=0.0005$, respectively). STAI (State) was significantly lower in PGA remission group ($p<0.05$), while no significant difference was found between two groups in EGA ($p=0.2463$). Similarly in HADS-D, the number of patients with depression was significantly fewer in PGA remission group ($p<0.05$), while no significant difference was found between two groups in EGA ($p=0.2522$). In SF-36, all of the eight components improved significantly in PGA remission group. There was no significant difference in mental health between two groups in EGA ($p=0.1602$). PGA is related to pain VAS, in contrast EGA is related to SJC. The patients with pain VAS remission are less depressive and less anxious. The patients with PGA remission have depression or anxiety less than those with PGA non-remission. Moreover, mental health of SF-36 was significantly better in PGA remission group. On the contrary, there is no significant difference in anxiety, depression and mental health of SF-36 between two groups in EGA.

Conclusion: Discrepancy between PGA and EGA, which is supposed to reflect disease activity of RA, may be partially explained by the difference in psychological state, and support for psychological state may be effective for improvement of PGA. At present, clinical, radiological and functional remissions have been proposed as goal of treatment of RA. As PGA remission is a limiting factor for Boolean remission and PGA relates to psychological state, psychological remission might be important to attain true remission.

Fatigue in Rheumatoid Arthritis Is Associated With Modifiable Lifestyle Factors. Patricia P. Katz[1], Vladimir Chernitskiy[2] and David I. Daikh[1]. [1]University of California, San Francisco, San Francisco, CA, [2]University of California San Francisco, San Francisco, CA.

Background/Purpose: Fatigue has been identified as a major concern for individuals with rheumatoid arthritis (RA) and has been endorsed as a core outcome measure. However, in order to develop adequate treatments for fatigue, its sources need to be identified.

Methods: During home visits (n=160), assessments were made of fatigue (Fatigue Severity Index; FSI), self-reported sleep quality (Pittsburg Sleep Quality Index; PSQI), depression (Patient Health Questionnaire-9; PHQ9), usual levels of physical activity (International Physical Activity Questionnaire; IPAQ), RA disease activity (RA Disease Activity Index; RADAI), muscle strength (by hand-held dynamometer), functional limitations (Short Physical Performance Battery; SPPB), body composition (body mass index and percent fat mass by bioelectrical impedance), and pulmonary function (by spirometry). Blood was drawn to measure inflammatory markers (C-reactive protein [CRP], tumor necrosis factor-a [TNF], and interleukin-6 [IL-6]), RA-specific markers, anemia, and thyroid function, and information was collected on demographics, medication use, and smoking. The FSI average fatigue level over the past 7 days, rated on a 0–10 (no-severe fatigue) scale, was used as the outcome measure. Analyses were first conducted to evaluate bivariate relationships with fatigue. Multivariate analyses, including all variables significantly associated with fatigue in the bivariate analyses, were then conducted to identify independent predictors of fatigue.

Results: Mean age (±SD) was 59 (±11), mean disease duration was 21 (±13) years, and 85% were female. Mean FSI rating was 3.8 (±2.0; range 0–10). Significant bivariate relationships with fatigue are shown in the Table. No significant associations were found for age, sex, ethnicity, disease duration, knee extension or grip strength, TNF, IL-6, pulmonary function, or prednisone or biologic use (not shown). In multivariate analyses, obesity, RADAI, depression, and smoking remained significantly and independently associated with fatigue.

Table. Factors associated with fatigue

	Bivariate b (p)	Multivariate* b (p)
BMI obesity	1.56 (<.0001)	1.54 (.006)
Disease activity (RADAI)	0.68 (<.0001)	0.30 (.005)
Depressive symptoms (PHQ)	0.25 (<.0001)	0.12 (.002)
Sleep quality (PSQI)	1.21 (<.0001)	0.36 (.07)
Hip flexor strength	−0.03 (.004)	−0.006 (.52)
CRP	0.22 (.008)	−0.009 (.89)
Physical activity ≥150 minutes/week in moderate/vigorous activity	−1.20 (.0005)	−0.23 (.41)
Ever smoke	1.16 (.0008)	0.69 (.009)

* Multivariate model included all variables significantly associated with fatigue in bivariate analyses

In additional analyses, performing ≥150 minutes/week of moderate/vigorous physical activity was associated with lower odds of obesity (OR=0.29 [95% CI 0.15, 0.55]), lower depression score ($p=.002$), and better sleep quality ($p=.04$), suggesting that that physical activity may have an indirect association with fatigue, mediated by these factors.

Conclusion: In this cross-sectional study, much of RA fatigue appeared to arise from factors that are secondary to the disease process itself (obesity, poor sleep quality, and depression), but are commonly present in RA. In addition, physical inactivity appeared to play a role, although its effects were indirect. Further research is warranted to determine the time-ordering of the relationships and if interventions that target modifiable lifestyle factors such as physical activity improve fatigue.

Exploring E-Health Ethics and Multi-Morbidity: A Qualitative Study Of Patient and Clinician Experiences Using Digital Media For Health Purposes. Anne F. Townsend[1], Paul Adam[2], Linda C. Li[3], Jenny Leese[4], Michael McDonald[1], Sheila Kerr[5], Gordon Whitehead[5] and Catherine L. Backman[4]. [1]University of British Columbia, Vancouver, BC, [2]Mary Pack Arthritis Centre, Vancouver, BC, [3]Arthritis Centre of Canada, Richmond, BC, [4]Arthritis Research Centre of Canada, Richmond, BC, [5]Consumer Advisory Board, Vancouver, BC.

Background/Purpose: E-Health can potentially transform and enhance health care delivery and empower patients. E-health includes a spectrum of digital health services and information communicated through the Internet and mobile technologies. As digital tools are embraced it is vital to examine emerging ethical issues. We apply a relational ethics lens to situations arising in e-health for patients with arthritis and their health care providers (HCP). Relational ethics emphasizes context, interdependence and relationships that facilitate or constrain meaningful self-direction. The prevalence of comorbidities in patients with arthritis amplifies the complexity of managing diseases concurrently for both patients and HCP. We explore their perspectives on the use of e-health technologies and how e-health use impacts the patient-physician relationship, and in so doing make ethical issues explicit.

Methods: This is Phase 1 of a 2-phase qualitative focus group (FG)/ interview study, informed by narrative and phenomenology to understand the 'lived experience' of e-health use. Eligible participants were: adults with multi-morbidity including arthritis and HCP with relevant caseloads, recruited via online ads, notices, and word of mouth. The FG guides were consistent across groups and organized around 4 areas: 1) E-health tools/devices; 2) descriptions of e-health experiences; 3) impact of e-health use on actions and decisions including patient-provider consultations; 4) a recap to check alignment and range of views. An iterative, constant comparative analysis began with independent open coding of transcribed data by at least 2 researchers; other team members discussed and clustered emerging codes; an ethical lens was then applied to clusters and key categories were identified and agreed upon by the wider team.

Results: 36 participants (18 patients, 18 HCPs) participated in 7 FG, 4 with patients and 3 with rehabilitation professionals and physicians (HCP). We interviewed 4 HCPs who were unable to attend a FG. Patients and HCP expressed similar views about e-health, though examples, emphasis and priorities varied. Predominant themes were: 1) Changing notions of trust (e.g. privacy was a concern but less so than expected; 2) Responsibilities (e.g. patients used e-health for tasks to prepare for consultations; 3) Partnerships (e.g. concordance); 4) Burden (e.g. searching for relevant information was time consuming and could be overwhelming.

Conclusion: There was evidence that fundamental aspects of patient-HCP relationships are shifting. It is critical to make the ethical issues in e-health explicit, as we track the transition towards empowered patients and receptive HCPs.

Urinary Angiostatin As Alternative To Biopsy In lupus Nephritis Patients Among Egyptian. Shereen Algergawy[1], Osama Alshaar[2] and Rania Zakaria[3]. [1]associate prof at benha university faculty of medicine rheumatology and rehabilitation department Egypt, cairo, Egypt, [2]benha university faculty of medicine, benha, Egypt, [3]benha university faculty of medicine, benha, Egypt.

Background/Purpose: Lupus nephritis (LN) is one of the most frequent manifestations of SLE and can be present in 60% of SLE patients. Kidney biopsy remains the basis of LN diagnosis. There is urgent need to identify biomarkers that alternative to renal pathology in lupus.

Aim: To study urinary angiostatin in SLE and investigate their possible role as indicative of renal involvement to be used as alternative to biopsy.

Methods: Angiostatin levels were measured in urine samples from 45 lupus patients and 14 healthy volunteers, renal biopsy was obtained from all patients

Results: SLE patients had elevated urinary angiostatin as compared to controls ($P < 0.001$). Levels of urinary angiostatin were higher in patients with an active LN (lupus nephritis) than those with inactive LN ($P < 0.001$). In patients with LN urinary angiostatin correlated with the renal score of the Systemic Lupus Erythematosus Disease Activity Index. Urinary angiostatin levels varied significantly and there is significant positive correlation ($P < 0.05$) levels with the activity and choronicty scores of the examined renal biopsies among the histopathological groups.

Conclusion: Urinary angiostatin is potentially useful markers of lupus activity. urinary angiostatin able to differentiate patients with active SLE from those with inactive disease.urinary levels are indicative of renal activity. Patients with Class IV lupus nephritis exhibited the highest levels of urinary angiostatin. Urinary angiostatin can be used as non invasive marker to detect renal involvement in lupus nephritis alternative to renal biopsy

Providing Comprehensive, Comparative Post-TJR Outcome Feedback To Surgeons For Quality Monitoring and Value Decisions. Patricia D. Franklin[1], Bruce Barton[1], Leslie R. Harrold[1], Wenjun Li[1], Regis O'Keefe[2], Jeroan Allison[1] and David Ayers[1]. [1]University of Massachusetts Medical School, Worcester, MA, [2]University of Rochester Medical Center, Rochester, NY.

Background/Purpose: With the CMS decision to publicly report hospital-specific post-operative total joint replacement (TJR) events and readmissions, surgeons and hospitals need comprehensive post-hospital data by which to manage and monitor outcomes. Currently, hospitals lack complete data on post-discharge events because patients seek care at multiple emergency rooms and hospitals. In addition, more than 40% of US TJR patients are under 65 years of age and are not captured in CMS data. To address this data void, we developed methods to capture comprehensive post-TJR medical and surgical events, as well as longitudinal patient-reported outcomes, and to report comparative data to participating surgeons and sites.

Methods: We established a national consortium of >120 diverse orthopedists representing all regions of the US with varied hospital and surgeon practices to ensure that data reflect typical US practice. We are enrolling >10,000 patients annually. Web-based and scannable paper data collection formats support efficient data gathering. Patients consent to participate and submit annual outcome assessments directly to us to assure complete reporting of hospital and emergency care. Post-TJR medical events are validated through chart review and CMS data (for those >65 years). Quarterly post-operative event rates and PROs are calculated for the national cohort, the individual surgeon, and site to deliver comparative feedback.

Results: A secure, HIPAA compliant MD website was established that presents summary and comparative descriptive statistics for primary TKR and THR for all of enrolled patients, specific to the site, and to the surgeon. A secure downloadable and printable report includes an Executive Summary of key outcome comparisons, as well as comprehensive tables of patient demographics, pre-operative medical and musculoskeletal comorbidities, post-operative events, and post-operative PROs enabling the providers to compare their outcomes to the other participating surgeons. Patient-level data are provided on request by the surgeon

Conclusion: In an era of public reporting of outcomes, surgeons and hospitals need a single comprehensive source of post-discharge medical events, readmissions, and PROs to manage and monitor all patient outcomes. We developed a secure web-site to return comparative data to providers. These data are used to demonstrate value in payer negotiations and to guide quality improvement efforts.

Exercise Therapy and Ultrasound Guided Glucocorticoid Injection In Patients With Painful Shoulder: A Randomised Controlled Trial. Karen Ellegaard[1], Robin Christensen[2], Sara Rosager Mortensen[1], Cecilie Bartholby[3], Søren Torp-Pedersen[4], Thomas Bandholm[5], Bente Danneskiold-Samsøe[4], Henning Bliddal[4] and Marius Henriksen[6]. [1]The Parker Institute, Copenhagen, Denmark, [2]Musculoskeletal Statistics Unit, The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, [3]The Parker Institute, Copenhangen, Denmark, [4]The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, Frederiksberg, Denmark, [5]Hvidovre Hospital, Copenhagen, Denmark, [6]The Parker Institute, Copenhagen University Hospital at Frederiksberg, Copenhagen F, Denmark.

Background/Purpose: SubAcromial Impingement (SAI) accounts for approximately 50% of all shoulder pain. The most commonly used treatments for SAI are glucocorticoid injection, exercise therapy or a combination of both. However the effect of exercise added to glucocorticoid injections is inadequately described in the peer reviewed literature. The aim of this study was to investigate the effectiveness of a standardized combination of exercise added to glucocorticoid injection compared to the glucocorticoid alone as the therapy for treatment of SAI.

Methods: Patients with unilateral SAI of minimum 4 weeks duration and thickened subacromial bursa (>2mm assessed by ultrasound) were included (NCT: 01506804). At baseline patients were randomized to two steroid injections into the painful shoulder separated by one week with subsequent 10 weeks exercise therapy of the involved shoulder (intervention group, IG), or two steroid injections into the painful shoulder separated by one week with subsequent 10 weeks exercise therapy of the un-involved shoulder (defined as sham-intervention, control group; CG). The patients were re-examined after the exercise program (at week 12) and again at week 26. Primary outcomes were change from baseline in shoulder pain at rest and during active shoulder abduction analyzed using intention-to-treat population with a non-responder imputation for missing data (i.e., baseline observation carried forward).

Results: 99 patients (58 females) with an average age of 49 years were randomised (49 IG/50 CG). In the IG, 17 participants were lost to follow-up; in the CG 18 were lost.

At the 12 week follow-up there were no statistically significant group difference in pain at rest (MD= 1.677 [95% CI −3.644 to 6.001], P=0.533); and during abduction (MD=2.230 [95% CI −6.462 to 10.921], P=0.612); both groups had decreased pain.. At the second follow up (26 weeks) the positive effect on pain at rest was maintained in the CG but decreased in the IG group; there was a trend towards a difference between groups (MD= 5.613 [95% −0.867 to 12.093], P=0.088). The beneficial effect on pain during active abduction was not different between groups at week 26 (MD= 2.234 [95% CI −6.754 to 11.224], P=0.623).

Conclusion: We found no beneficial effects of combined glucocorticoid injection and exercise therapy of the involved shoulder compared to injections combined with exercise of the uninvolved shoulder. In fact, the CG experienced a prolonged effect on pain at rest compared to the IG. This finding is in contradiction to other studies showing a positive effect of exercise in patients who have received glucocorticoid injection prior to exercise therapy.

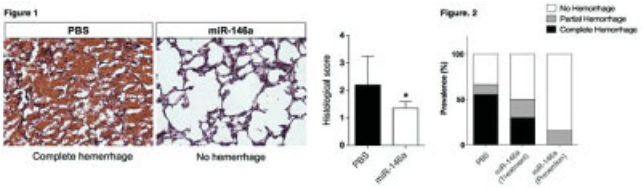
In Vivo Administration Of MiR-146a Protects C57BL/6 Mice From Pristane-Induced Pulmonary Hemorrhage Via Suppressing Type I Interferon Response. Dong Liang[1], Shiyu Zhou[2], Zheng Liu[3], Zhengyuan Shan[1], Philip Brohawn[3], Yihong Yao[3], John B. Harley[1] and Nan Shen[4]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Shanghai Institutes for Biological Sciences Chinese Academy of Sciences & Shanghai Jiao Tong University School of Medicine, Shanghai, China, [3]MedImmune, LLC, Gaithersburg, MD, [4]Shanghai Institute of Rheumatology, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.

Background/Purpose: miR-146a as an endogenous regulator plays a critical role in resolving acute inflammation. The risk-associated genetic variant in miR-146a promoter was linked to reduced expression of miR146a in the peripheral blood leukocytes of lupus patients. Our previous studies also showed that overexpression of miR-146a in PBMCs from patients with SLE suppressed coordinate activation of type I interferon (IFN) pathway. Pristane-induced lupus is a well established SLE murine model featuring abnormal activation of IFN pathway and unusual high penetrance of pulmonary capillaritis. This study explored a therapeutic potential of miR-146a in this induced murine model of lupus.

Methods: The C57BL/6 (B6) mice were intravenously injected with PBS or miR-146a via lateral tail veins. The peripheral bloods from 3, 7 and 14 days post Pristane injection were evaluated by real time PCR or gene expression profile analysis. For comparison, the B6 mice were categorized into 3 groups, receiving respectively 3 consecutive injections of PBS (control group, n=9) or miR-146a either 3 days before (prevention group, n =19) or 7 days after (treatment group, n=10) a single intraperiteneal injection of Pristane. The pulmonary hemorrhage was histologically investigated by HE staining 2 weeks post Pristane injection.

Results: The injections of miR-146a mimics (agomirs) resulted in a dramatic increase in the expression of peripheral blood miR-146a in both the prevention and treatment groups as compared to the control group receiving PBS. HE staining showed that miR-146a administration rendered mice resistant to Pristane-induced hemorrhagic pulmonary capillaritis (Fig. 1). While in the control group, 56% mice injected with Pristane developed complete pulmonary hemorrhage, the prevalence was reduced to 25% in the treatment group. Of note, the complete hemorrhage was completely blocked in prevention group (Fig. 2). Furthermore, qPCR revealed that miR-146a was significantly lower in mice with pulmonary hemorrhage compared with mice developing no hemorrhage ($p < 0.01$), and inversely correlated with expression of Mx1 ($p < 0.01$), an IFN-inducible gene. Gene expression profile analysis showed that miR-146a injection substantially suppressed the IFN response, accompanied by reduced production of multiple pro-inflammatory cytokines and chemokines.



Conclusion: Our study provides evidence that miR-146a plays a suppressive role in the Pristane-induced pulmonary hemorrhage in B6 mice. It also highlights a potential pathogenic role of type I IFN pathway activation in the development of pulmonary capillaritis in Pristane-induced murine lupus. These findings suggest that SLE patients with pulmonary hemorrhage may benefit from therapeutic intervention to induce miR-146a expression.

Role Of Interferon-Inducible RNA-Dependent Protein Kinase In The Pathogenesis Of Systemic Lupus Erythematosus. Aurélie De Groof[1], Benoît Van den Eynde[2], Frédéric A. Houssiau[1] and Bernard Lauwerys[1]. [1]Institut de Recherche Expérimentale et Clinique, Université Catholique de Louvain, Brussels, Belgium, [2]Institut de Duve, Université Catholique de Louvain, Brussels, Belgium.

Background/Purpose: PRKR (interferon-inducible RNA-dependent protein kinase) is an intracytoplasmic molecule that induces the production of interferon(IFN)-induced genes upon binding of double-stranded RNA viruses. PRKR is spontaneously over-expressed in PBMC from systemic lupus erythematosus (SLE) patients, and we previously demonstrated that in vitro exposure of SLE cells to 2-aminopurine (a pharmacological inhibitor of PRKR) results in a significant inhibition of IFN-induced genes and immunoglobulin production. In the present study, we wanted to further investigate the role of PRKR in the pathogenesis of SLE.

Methods: Intraperitoneal 2-aminopurine versus PBS injections were administered to $(NZB \times NZW)_{F1}$ mice three times a week for a period of 2 months. In addition, PRKR-KO mice were backcrossed in B6.Sle1.Sle2.Sle3 tricongenic SLE-prone mice, resulting in the generation of PRKR-KO versus

WT tricongenic animals. Exploratory studies on the role of PRKR in dendritic cell differentiation were performed using bone marrow cells from the original PRKR-KO mice versus Balb/c controls. The roles of 2-aminopurine and 6-mercaptopurine on IFN-induced gene expression were evaluated in TLR3-transfected HEK293 cells.

Results: While dsDNA antibody (Ab) titers and proteinuria significantly increase over time in PBS-treated $(NZB \times NZW)_{F1}$ mice, this is not the case in 2-aminopurine treated animals. 2-aminopurine therapy also results in a significant improvement of glomerulonephritis activity scores upon histological examination of the kidneys. Our first observations in PRKR-KO versus –WT SLE-prone mice indicate that dsDNA Ab titers display a significant increase from month 2 to month 10 in PRKR-WT B6.Sle1.Sle2.Sle3 mice, and this is not observed in their PRKR-KO littermates.

IL-4 and GM-CSF exposure of bone-marrow cells results in the generation of myeloid-derived dendritic cells (moDC). We observed that the percentage of bone-marrow-derived CD11c-positive cells was significantly decreased in PRKR-KO mice, compared to Balb/c age- and gender-matched animals. Similarly, CD86-positive CD11c cells were significantly less numerous in PRKR-KO compared to Balb/c animals.

Using 2-aminopurine and PRKR siRNA, we demonstrated that PRKR is involved in TLR3 signal transduction in TLR3-transfected HEK293 cells. Thus, poly I:C-induced expression of IFNβ and IFN-induced genes is abrogated in these cells upon PRKR blockade. Intriguingly, we found that exposure of these cells to 6 mercaptopurine resulted in the same inhibitory effects on IFNβ and IFN-induced gene expressio.

Conclusion: Our data indicate that PRKR, an intracytoplasmic danger-recognition molecule that has the ability to stimulate the expression of IFN-induced genes, is involved in the pathogenesis of SLE. The role of PRKR in the pathogenesis of the disease might be mediated by an increased differentiation and maturation of moDC, a hypothesis that we will verify in our PRKR-KO versus –WT SLE prone animals. Preliminary data indicate that the activity of PRKR is modulated by 6-mercaptopurine, the active metabolite of azathioprine.

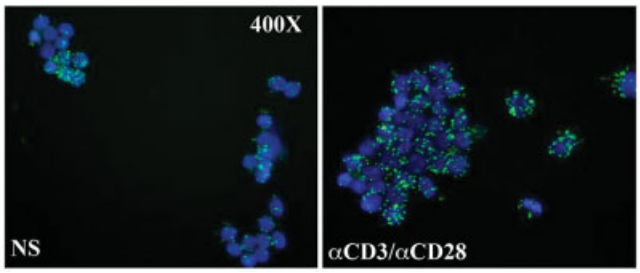
cAMP Responsive Element Modulator (CREM)α Governs CD8 Expression and Contributes to the Generation of $CD3^+CD4^-CD8^-$ T Cells in Lupus. Christian M. Hedrich[1], José C. Crispín[1], Thomas Rauen[1], Christina Ioannidis[1], Tomohiro Koga[2], Noe Rodriguez Rodriguez[1], Sokratis A. Apostolidis[2], Vasileios C. Kyttaris[1] and George C. Tsokos[1]. [1]BIDMC, Harvard Medical School, Boston, MA, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.

Background/Purpose: $CD3^+CD4^-CD8^-$ "double negative" T cells are expanded in the peripheral blood of patients with systemic lupus erythematosus (SLE) and lupus-prone mice. Double negative T cells infiltrate tissues, induce immunoglobulin production and secrete pro-inflammatory cytokines. Although double negative T cells have been claimed to derive from $CD8^+$ T cells through down-regulation of CD8 surface co-receptors, the molecular mechanisms orchestrating this process remain unclear. The transcription factor cAMP responsive element modulator (CREM)α, that is overexpressed in T cells from SLE patients, has been demonstrated to *trans*-regulate lupus-relevant genes and orchestrate epigenetic remodeling in mature T cells. Thus, CREMα is a promising candidate in the search for molecular mechanisms in T cell pathology in SLE.

Methods: Primary human and murine T lymphocytes were isolated to assess epigenetic differences of the *CD8* cluster in $CD8^+$, $CD4^+$, and double negative T cells using MeDIP and ChIP techniques. CD8 mRNA and protein expression was monitored in response to forced expression or knock-down of CREMα. CREMα-mediated effects on chromatin conformation were assessed using over-expression and knock-down techniques, followed by MeDIP or ChIP. Interactions between CREMα and epigenetic modifiers were established using Co-IPs and proximity ligation assays (PLA).

Results: We link CREMα with transcriptional silencing of *CD8A* and *CD8B* in T cells from SLE patients and lupus prone MRL/lpr mice. CREMα *trans*-represses *CD8* and mediates chromatin remodeling of the *CD8* cluster through the recruitment of DNA methyltransferase (DNMT)3a and histone methyltransferase G9a.



Conclusion: We conclude that CREMα is essential for the expansion of double negative T cells in SLE and propose that CREMα may be utilized as disease biomarker and therapeutic target.

An interaction between CREMα and G9a has been established applying proximity ligation assays. *Ex vivo* isolated $CD8^+$ T cells exhibit interactions between CREMα and G9a that are enhanced after TCR-stimulation (120h). Nuclei are stained with DAPI, green signals represent CREMα:G9a interactions.

Regulation Of Aberrant CD4 T Cell Activation By Suppressor Of Cytokine Signaling-1 (SOCS1) Mimetic Peptide, Has Relevance To Human Systemic Lupus Erythematosus. Tenisha Wilson, Cristina Armbruster, Simone Bedoya, Howard M. Johnson, Westley H. Reeves, Yi Li, Ying Yi Zheng, Laurence Morel and Joseph Larkin III. University of Florida, Gainesville, FL.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease, mediated by aberrantly activated CD4 T cells. Notably, suppressor of cytokine signaling-1 (SOCS1) regulates CD4 T cell activation. In addition, $SOCS1^{+/-}$ (SOCS1 deficient) mice develop lupus-like disease. Although murine studies implicate a relationship between decreased SOCS1 expression and increased lupus pathology, *the ability to translate these animal findings to human disease has not been established*. Therefore, the goals of this study were to (a) establish clinical relevance for SOCS1 deficiency in regard to *human* SLE and (b) establish the mechanism by which SOCS1 deficiency can lead to lupus development.

Methods: *Human:* qPCR was performed on PBMCs isolated from SLE patients (n=20) and healthy controls (HCs) (n=8) to assess SOCS1 expression, relative to GAPDH. SOCS1 expression was correlated with indicators of disease activity (monocyte CD64 MFI and C3 levels). *Mouse:* $SOCS1^{+/-}$ mice were studied prior to the onset of lupus disease. C57BL/6 mice served as wild-type (WT) controls. Naïve $CD4^+CD25^-$ T cells, isolated from spleen and LNs, were stimulated with anti-CD3 and anti-CD28 antibodies or only anti-CD3 antibody, with or without SOCS-1 KIR (mimetic peptide of SOCS1). Activation was assessed by flow cytometric analysis of CD25 and CD69. CFSE staining and ^3H Thymidine incorporation were employed to measure proliferation. Akt activation was measured by western blotting. For statistical comparisons between SLE patients and HCs and between $SOCS1^{+/-}$ and WT, the Mann-Whitney U test was performed. Spearman's correlation was used for correlation data.

Results: Similar to murine models of disease, SLE patients' PBMCs had reduced expression of SOCS1 in comparison to HCs. Additionally, SOCS1 expression was negatively correlated with monocyte CD64 expression and positively correlated with C3 levels. Mechanistic data revealed that stimulating $SOCS1^{+/-}$ naïve CD4 T cells with anti-CD3 antibody alone resulted in an elevated population of CD69 and CD25 expressing cells. In parallel with the elevated population of activated cells under this suboptimal T cell activation condition, these SOCS1 deficient cells also displayed enhanced ^3H thymidine incorporation and an increased $CFSE^{low}$ population - indicative of increased proliferation. The enhanced activation and proliferation was not due to an elevated population of memory T cells, but rather to a reduced requirement for Akt activation. Notably, SOCS1-KIR reduced the abnormal activation and proliferation.

Conclusion: SOCS1 deficiency is clinically relevant to human SLE. We also determined that SOCS1 deficient CD4 T cells do not require CD28-costimulation in order to undergo activation and proliferation. This has significant implications for lupus development, as SOCS1 deficient autoreactive T cells that have a reduced threshold for activation can activate

autoreactive B cells, which can perpetuate disease. Significantly, SOCS1-KIR has the capacity to restore the proper T cell activation threshold. Based on this data, we propose that SOCS1-KIR should begin to be explored as a potential candidate for the prevention/treatment of SLE.

A Polymorphism In The *Mif* Gene Is Associated With Cardiovascular Morbidity In Systemic Lupus Erythematosus – a Pilot Study. Eric F. Morand, Kathryn Connelly and Alberta Y. Hoi. Monash University, Melbourne, Australia.

Background/Purpose: Chronic inflammation is believed to be responsible for accelerated atherosclerotic cardiovascular disease (CVD) in patients with SLE. Macrophage migration inhibitory factor (MIF) is a pro-inflammatory molecule implicated in the etiology of both SLE and atherosclerosis via amplification of macrophage recruitment and activation. A single nucleotide polymorphism (SNP) in the *MIF* promoter regulates MIF expression and is associated with SLE risk, and an anti-MIF therapy is currently in Phase I trials in SLE. The association of *MIF* polymorphisms with CVD risk in SLE is unknown.

Methods: SLE patients (ACR criteria) attending a single centre were recruited fo a pilot study. Patients seen between 2007–2012 had disease activity (SLEDAI-2k) recorded at each visit, and organ damage (SLICC-SDI) recorded at baseline and annually. CVD was defined using the cardiovascular domains of the SLICC-SDI criteria. Genomic DNA was isolated from whole blood, amplified by PCR, and MIF-173*C genotype determined by restriction fragment length polymorphism.

Results: 153 SLE patients (80% female, median age 41y, disease duration 10y) were studied. The median (range) SDI and time-adjusted mean SLEDAI (AMS) were 1 (0–9) and 4 (0–22) respectively.

The distribution of MIF-173 genotypes observed was G/G(69%) G/C(28%) and C/C(3%), thus a MIF-173C SNP was present in 31%. Organ damage (SDI) in the overall population correlated with disease duration ($P<0.0001$) and disease activity (AMS; $P<0.0001$). The major finding was that CVD was increased among patients carrying a MIF −173*C allele. Among patients with SLE duration >10y, CVD was 13-fold more frequent among patients carrying a MIF -173*C allele (odds ratio 12.75 (95%CI 2.2–75.2), $p=0.0045$). A significant association was also detected when stroke was included (OR=6.13, 95% CI 1.4–26.9, $p=0.0204$), and when AMI and/or stroke were analysed independently (OR=6.06, 95% CI 1.2–31.0, $p=0.0375$). There was no significant difference in traditional risk factors in relation to MIF -173*C allele, and no association detected with renal or CNS disease, corticosteroid use, or the frequency of episodes of persistently active disease.

Conclusion: Although confirmation in larger cohorts is required, this pilot study suggests that carriage of the MIF-173C SNP is strongly associated with the risk of CVD in SLE. This suggests that anti-MIF therapy could alleviate SLE CVD risk in SLE.

Immunologic and Inflammatory Markers Of Impending Disease Flare In Systemic Lupus Erythematosus Patients Not Taking Immunosuppressive Medications In The Biomarkers Of Lupus Disease (BOLD) Study. Joel M. Guthridge[1], Mikhail G. Dozmorov[1], Melissa E. Munroe[1], Krista M. Bean[1], Sudhakar T. Sridharan[2], Joan T. Merrill[1] and Judith A. James[3]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Pfizer Inc, Collegeville, PA, [3]Oklahoma Medical Research Foundation and University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background/Purpose: Systemic lupus erythematosus (SLE) is a clinically heterogeneous disorder characterized by a waxing and waning clinical course. Predictors of clinical disease flare have been difficult to identify, leading to cumulative damage, therapeutic toxicities and difficulties designing clinical trials. The goal of this study is to identify immunologic associations and pathogenic mechanisms of disease flares in SLE patients no longer taking immunosuppressive medications.

Methods: As part of the Biomarkers of Lupus Disease (BOLD) study, 41 SLE patients with moderately severe, but not organ-threatening disease activity were enrolled, background immunosuppressants (IS) stopped, intramuscular steroids given until disease suppression and then serially followed until clinical disease flare. SLE patients met > 4 ACR SLE classification criteria and had SLEDAI > 6 or BILAG >/= 2 B or 1 A scores at baseline. Peripheral blood specimens were collected at baseline, time of disease suppression and serially until they developed a significant enough flare to require new treatment (and minimum >/= 1 new BILAG B or SLEDAI increase of >/= 4 points). In addition to autoantibody levels and extensive immunophenotyping, 52 soluble inflammatory mediators, including cytokines, chemokines, and soluble receptors, using either xMAP multiplex technology or sandwich ELISA (BLyS and APRIL), were measured. Gene expression profiling, with globin depletion, was performed on a subset of baseline samples from SLE patients.

Results: Forty of 41 SLE patients flared within 24 weeks, with 21 patients flaring within 60 days (early) and 13 flaring greater than 90 days (late) after stopping background IS. Patients who flared early were more likely to be of African-American descent, while Native American patients were more likely to flare late. Compared to late flaring patients, Caucasian SLE patients who flared early overexpressed 69 genes (including MMP9, CD11b (ITGAM), and MYH9) and showed decreased expression of 20 genes, including HLA-DRB5 and IFI6 at baseline. SLE patients who flared early also had higher baseline expression levels of CD11b on neutrophils ($p=0.003$) and monocytes ($p=0.03$) and higher CD86 expression on B cells ($p=0.03$) (all races combined). SLE patients who flared more than 90 days after stopping medications had higher baseline plasma levels of IL-1RA ($p=0.03$) and TNFRI ($p=0.04$), as well as higher levels of BLyS ($p=0.01$), IL-7 ($p=0.03$) and IFNg ($p=0.04$) at the flare visit.

Conclusion: SLE patients who will flare earlier after withdrawal of ineffective immunosuppressants and transient steroid treatment have increased levels of activated B cells and increased expression of CD11b at baseline, while SLE patients who flared later have evidence of regulatory pathway engagement through secretion of IL1RA.

Biology and Pathology of Bone and Joint II: Osteoclast Biology and Arthritis
Tuesday, October 29, 2013, 4:30 PM–6:00 PM

2728

The Small Ubiquitin Related Modifier-1 (SUMO-1) Regulates Osteoclast Differentiation *In Vitro* and *In Vivo*. Svetlana Frank[1], Daniel Umlauf[2], Olli A. Jänne[3] and Thomas Pap[4]. [1]University Hospital Münster, Muenster, Germany, [2]University Hospital Muenster, Muenster, Germany, [3]Univ Helsinki, Inst Biomed Physiol, Biomedicum, Helsinki, Finland, [4]University Hospital Münster, Münster, Germany.

Background/Purpose: Posttranslational modification of proteins by SUMO has been shown for a number of target molecules including transcription factors and is involved in a variety of cellular processes, including protein localization, transcriptional regulation, protein stability, cell survival and death. Previously, we have shown that the increased expression of SUMO-1 contributes to the inflammatory response in RA. Here, we investigated the role of SUMO-1 in osteoclastogenesis and studied the skeletal phenotype of *SUMO-1*$^{-/-}$ mice.

Methods: The skeletal phenotype of 8-week old *SUMO-1*$^{-/-}$ and wild type mice was investigated by μCT-analysis of trabecular bone in the lumbar spine and femora. L5 vertebral bodies from these mice mice were embedded into methylmetacrylate and analyzed using van Kossa and tartrate-resistant acid phosphatase (TRAP) staining. For *in vitro* experiments, bone marrow macrophages (BMMs) were isolated from *SUMO-1*$^{-/-}$ mice and wild-type controls. The cells were differntiated into osteoclasts in the presence of macrophage colony-stimulating factor and

receptor activator of nuclear factor k-B ligand (NF-kB). Osteoclast differentiation was characterized by staining for TRAP. Using PCR, the expression levels of DC-STAMP, Cathepsin K and Integrin β3 were analyzed. Proliferation and cell viability of BMMs was determined using CyQuant proliferation assay and MMT test. Osteoclast resorption capacity was analyzed using a calcium phosphate bone resorption assay.

Results: 8-weeks old *SUMO-1*$^{-/-}$ mice had a 20% higher trabecular bone volume fraction compared with wt mice. Moreover, trabecular thickness was higher and trabecular separation was lower in *SUMO-1*$^{-/-}$ mice. In addition, histological analyses revealed a significantly reduced number of osteoclasts in *SUMO-1*$^{-/-}$ mice *in vivo*. The loss of SUMO-1 was associated with impaired osteoclast differentiation and with impaired bone resorption capacity *in vitro*. In PCR analysis, we found a decreased expression of DC-STAMP, Cathepsin K and Integrin β3 in osteoclasts differentiated from *SUMO-1*$^{-/-}$ compared to wt mice. Proliferation and cell viability of BMMs were not affected by loss of SUMO-1. Using western blot analysis we found no differences in activation of MAPK p38 and p44/42 as well as in activation of NF-kB signaling in BMMs and osteoclasts in SUMO-1$^{-/-}$ and wt mice.

Conclusion: In our study, we found that *SUMO-1*$^{-/-}$ mice have high bone mass owing to a decrease in number and function of osteoclasts. These finding are most likely due to decreased expression of osteoclast markers contributing to osteoclast fusion and to osteoclast resorption capacity. These data suggest that SUMO-1 is involved predominantly in the regulation of bone mass by osteoclast formation and activity, and therefore may be an interesting target for treating diseases associated with bone loss.

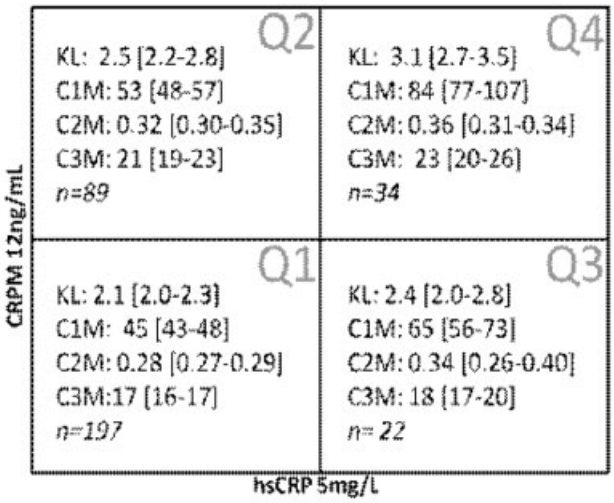
Identification Of Osteoarthritis Patients With Chronic Inflammation Driven Disease Progression. Anne Sofie Siebuhr[1], Kristian Kjaer Petersen[2], Lars Arendt-Nielsen[2], Line Egsgaard[2], Thomas Navndrup Eskehave[3], Ole Simonsen[4], Claus Christiansen[1], Hans Christian Hoeck[3], Morten Asser Karsdal[1] and Anne C. Bay-Jensen[1]. [1]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, [2]Center for Sensory-Motor Interaction, Aalborg, Denmark, [3]Center for Clinical and Basic Research and C4Pain, Aalborg, Denmark, [4]Frederikshavn Hospital, Frederikshavn, Denmark.

Background/Purpose: In osteoarthritis (OA) it is evident that a subset of patients experiences chronic tissue inflammation and may benefit from anti-inflammatory treatment. The systemic inflammation marker C-reactive protein (CRP) has shown limited use in predicting disease severity, progression or response to anti-inflammatory treatment. The aim of this study was to investigate whether OA patients can be segregated into groups dependent on the present or absence of systemic and/or chronic tissue inflammation and whether such groups have different levels of MMP driven tissue destruction.

Methods: A cross-sectional study of 342 patients: 281 patients had symptomatic knee OA and no planned total knee replacement (TKR) and 61 who underwent TKR. Serological biomarkers were measured by ELISA: high sensitive CRP (hsCRP), CRP degradation fragment (CRPM, chronic tissue inflammation), MMP-mediated degradation fragments of type I, II and III collagen; C1M (connective tissue), C2M (cartilage) and C3M (synovium). The associations between biomarkers and OA stage were investigated: Kellgren & Lawrence (KL) 0, Mild OA (n=12); KL1–2, Moderate OA (n=202); KL3–4, Severe OA (n=57); and KL3–4 with TKR (n=60). Cut-off values of CRPM and hsCRP were set as 12ng/mL and 5μg/mL (mean+2SD of controls). Patients were divided in quartiles (Q, fig) based on the cut-off values. Reference values of the biomarkers were recorded for healthy controls. Data are shown as mean [95%-CI].

Results: hsCRP was only elevated with TKR (5.9 [3.6–8.2] μg/mL) compared to controls. In contrast, the mean levels of the CRPM were twice as high in the OA groups (10–14ng/mL) compared to controls (5ng/mL). C1M and C2M were significantly elevated in the TRKs compared to Moderate ($p<0.001$) and Severe ($p<0.01$). There was no difference between patient and controls in C3M. Patients in Q4 (fig) had significantly higher KL compared to patients in Q1 ($p<0.0001$), Q2 ($P=0.017$) and Q3 ($p<0.0001$). C1M, C2M and C3M were lower in Q1 compared to all other quartiles. Comparing Q2 with Q3 showed that C1M was higher ($p=0.0005$) in Q3, but C3M was lower ($p=0.019$). Thus, the populations identified by systemic and chronic tissue inflammation have different structural integrity.



Conclusion: All OA patients had surprisingly high levels of chronic tissue inflammation. OA patients could be divided into quartiles or 2 separate groups: i) those who may benefit from anti-inflammatory treatment (Q3, Q4) and ii) those eligible for a more tissue centric treatment (Q1, Q2). Patients with high CRPM (Q2 and Q4) had higher levels of the tissue degradation markers C1M, C2M and C3M suggesting that they had elevated tissue turnover. In alignment, those OA patients undergoing TKR had even higher levels of tissue turnover markers, suggesting a distinct TKR serological phenotype. Clearly different types of OA with different levels and types of tissue destruction could be identified by CRPM, but not CRP.

Netrin1 Is a Critical Autocrine Factor For Osteoclast Differentiation. Aranzazu Mediero[1], Bhama Ramkhelawon[1], Kathryn Moore[1], P. Edward Purdue[2], Steven R. Goldring[2] and Bruce N. Cronstein[3]. [1]NYU School of Medicine, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Netrins have been extensively studied for their role in axonal guidance during neural development. In addition, netrins are chemopulsants for a variety of non-neuronal cell types via binding to their receptors Unc5b and DCC. Although thought to suppress inflammation in several settings, netrin1, acting via Unc5b, inhibits macrophage migration directed by chemokines CCL2 and CCL19 to promote macrophage retention in and exacerbation of atherosclerotic plaque. We asked whether Netrin1 was expressed during osteoclast (OC) differentiation and whether it plays a role in OC differentiation.

Methods: DEXAscan and MicroCT analysis were performed on Netrin1 deficient mice (radiation chimeras) and wildtype (WT, radiation chimeras) littermates. OC differentiation was studied as M-CSF/RANKL-stimulated differentiation of murine bone marrow precursors to TRAP+/multinucleated cells, in the presence/absence of recombinant Netrin1 and Unc5b antibody. Netrin1, Unc5b and DCC expression were studied by RT-PCR and Western Blot in primary bone marrow-derived osteoclasts. Netrin1 immunostaining was performed in human tissue obtained following primary prosthesis implantation or after prosthesis revision.

Results: During OC differentiation cell-associated Netrin1 and Unc5b (but not DCC) protein expression increased by 30±2% and 98±4% respectively ($p<0.001$,n=4) and Netrin1 secretion increased by 66±2% ($p<0.001$, n=4). Consistently, RANKL stimulates an increase in Netrin1 and Unc5b mRNA expression during OC differentiation (25±4 and 3±0.5 fold change respectively $p<0.001$, n=4). Moreover, in Netrin1-deficient marrow precursors OC differentiation was diminished by 65±2% as compared to control ($p<0.001$, n=6), an effect reversed by addition of recombinant netrin1 to cultures (121±5% increased, $p<0.5$, n=4). An antibody to the netrin1 receptor Unc5b reduces OC formation by 57±6% ($p<0.001$, n=6) whereas an antibody to DCC had no effect on OC formation (5±4% reduction, p=NS

vs. control, n=6). Finally, DEXAscan and MicroCT analysis demonstrated an increase in bone mineral density (BMD), total volume (TV), bone volume (BV) and TV/BV in both cortical and trabecular bone in Netrin1 deficient mice when compared to WT ($p<0.01$ for all, n=5). Netrin1 immunostaining in human tissue biopsies reflect enhanced expression in tissue from implant revision when compared to primary implants.

Conclusion: The chemorepulsant Netrin1 is required for osteoclast differentiation and stimulates OC differentiation by an autocrine mechanism. This finding suggests that Netrin1 may be a novel target to reduce OC-mediated bone resorption and to prevent joint prosthesis loosening.

An Acetyl-Histone Mimetic Blocks Proinflammatory Activation Of Rheumatoid Arthritis Fibroblast-Like Synoviocytes. P. A. Kabala[1], A.M. Grabiec[1], C. Angiolilli[1], Nicholas Smithers[2], Jason Witherington[2], Paul Peter Tak[3], Rabinder Prinjha[2] and Kris A. Reedquist[1]. [1]Department of Clinical Immunology and Rheumatology Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]GlaxoSmithKline, Stevenage, United Kingdom, [3]Academic Medical Center / University of Amsterdam, Department of Clinical Immunology and Rheumatology & GlaxoSmithKline, Amsterdam, Netherlands.

Background/Purpose: Genetic backgrounds and environmental factors do not completely explain the etiology of disease and predisposition to rheumatoid arthritis (RA), and increasing attention has turned to the potential contributions of heritable epigenetic mechanisms such as DNA methylation, post-translational modifications of histones, and expression of non-coding microRNAs. Fibroblast-like synoviocytes (FLS) isolated from affected joints of RA patients maintain an aggressive phenotype *in vitro*, indicating potential alteration of epigenetic regulatory processes, and changes in global and gene-specific promoter DNA methylation and histone modification are observed in RA FLS. I-BET compounds, acetyl histone mimetics which interfere with reading of acetylated histones by BET family bromodomain proteins BRD2–4, prevent LPS-induced inflammatory gene expression in murine bone marrow-derived macrophages *in vitro*, as well as *in vivo* models of endotoxic shock and bacterial sepsis. This study was undertaken to assess the potential of I-BET to influence the inflammatory activation of RA FLS.

Methods: RA fibroblast-like synoviocytes (FLS) were treated with IL-1β or TNF in the presence or absence of increasing concentrations of I-BET, and IL-6 and IL-8 production measured by ELISA. Cellular viability was assessed using MTT assay and cell death ELISA kits. Activation of intracellular signaling pathways was examined by immunoblotting. Total RNA was extracted and mRNA expression of genes regulated by IL-1β or TNF in RA FLS was analyzed using a low density quantitative PCR custom array.

Results: BRD2–4 mRNA expression was readily detected in RA FLS. I-BET reduced RA FLS (n=6) production of IL-6 protein in response to IL-1β (1 μM, 70% reduction, $P < 0.001$) and TNF (50%, $P < 0.001$). IL-8 production in response to IL-1β (>75% reduction, $P <$. 0.001) and TNF (>70%, $P < 0.001$) was also inhibited. Similar effects were observed on IL-6 and IL-8 mRNA expression. Inhibition of IL-6 and IL-8 production was maintained when I-BET treatment was delayed 1–4 hours post-stimulation. I-BET had no effect on cell viability or survival, and failed to modulate IL-1β or TNF–induced activation of MAPK or NF-κB signaling pathways. Low density qPCR array analysis of 26 genes induced by IL-1β in RA FLS (n=3) demonstrated that I-BET reduced induction of 17 genes by >50%, including TNF (>80% suppression), MMP-1 (>90%), MMP-3 (90%), SELE (>80%), VCAM-1 (>60%), CXCL-6 (>75%), CXCL-9 (>95%) and CXCL-11 (>90%).

Conclusion: Our results demonstrate that disrupting the recruitment of BET family proteins to acetylated histones efficiently blocks RA FLS production of inflammatory mediators, including cytokines, chemokines and MMPs, in response to IL-1β and TNF. This study provides initial evidence that the development of synthethic compounds targeting interactions between epigenetic modifications, such as histone acetylation, and the proteins which interpret these modifications may have therapeutic potential in the treatment of RA.

Inhibition Of Autophagy Prevents Ovariectomy Induced Bone Loss. Neng-Yu Lin[1], Joerg H. W. Distler[1], Alfiya Distler[1], Christian Beyer[1], Georg Schett[2] and Oliver Distler[3]. [1]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]University of Erlangen-Nuremberg, Erlangen, Germany, [3]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: Autophagy is an essential, homeostatic process by which cells digest unnecessary or damaged organelles. Atg7 is essentially required for formation of the autophagosome. The DMARD chloroquine (CQ) has been identified to arrest autophagy function by blocking the fusion between autophagosomes and lysosomes. Accumulating evidence demonstrates that autophagy is involved in the pathology of varies diseases including infections, cancer and neurodegeneration and recent reports also linked autophagy to osteoclastogenesis and rheumatoid arthritis.

Methods: Systemic bone loss was induced by ovariectomy (OVX). Autophagy was modulated by genetic as well as pharmacologic approaches. For genetic inhibition of autophagy, we crossbred $Atg7^{fl/fl}$ mice with LysM Cre^{+} mice to generate $Atg7^{fl/fl} \times$ LysM Cre^{+} mice with selective inactivation of autophagy function in the monocyte lineage. For pharmacological inhibition, eight-week-old mice underwent daily intraperitoneal injection of 20mg kg^{-1} CQ for a total of 50 days. We applied Microcomputed tomography to analyze bone density *in vivo*. TRAP staining and bone histomorphometry were used to confirm osteoclast number in tissue. To assess osteoclast formation and activity *in vitro*, $Atg7^{fl/fl} \times$ LysM Cre^{+} BMCs and CQ treated BMCs were cultured on bone slices and analysed by the TRAP staining and Toluidine blue staining (n=6, for each group). To assess the autophagy effect on osteoblast activity *in vitro*, primary osteoblasts were treated with Cre Adenovirus and CQ to analyse ALP staining and measure osteoblast markers by RT-PCR.

Results: To investigate the effect of CQ on OVX-induced systemic bone loss, we analyzed the bone density (bone volume/trabecular volume; Bv/Tv) and the trabecular number (Tb. N.) at the proximal tibias. Bv/Tv and Tb. N. were strongly reduced in sham-treated OVX mice. The decreases in Bv/Tv and in Tb. N. were reduced by 76 % and 60% in CQ treated OVX mice (n=6, $p<0.05$ for both). Inhibition of autophagy by selective knockdown of Atg7 in monocytic cells ($Atg7^{fl/fl} \times$ LysM Cre-mice) also prevented OVX-induced osteoporosis and prevented OVX-induced decreases in Bv/Tv and in Tb. N.. Histomorphometric analyses demonstrated decreased osteoclast counts in CQ-treated mice and $Atg7^{fl/fl} \times$ LysM Cre-mice, respectively, compared to controls. Consistent with these *in vivo* results, inhibition of autophagy, either by treatment with CQ or by knockdown of Atg7, also prevented osteoclast differentiation and osteoclast mediated bone resorption *in vitro*. In contrast to the effects on osteoclasts, inhibition of autophagy by genetic or pharmacologic approaches did not inhibit osteoblast activity.

Conclusion: We demonstrate that inhibition of autophagy by genetic or by pharmacological approaches significantly reduced OVX-induced osteoporosis in mice. These findings identify the autophagy machinery as a potential target for the treatment of osteoporoses. Considering the potent anti-osteoporotic effects and the availability of approved inhibitors such as CQ, these findings may have direct translational implications.

Spontaneous Osteoarthritis In Mice By Genetic Deletion Of *Nfatc1* and *Nfatc2*. Susan Y. Ritter[1], Matthew B. Greenblatt[1], Kelly Tsang[1], Dorothy Z. Hu[2], John Wright[1] and Antonios O. Aliprantis[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, MA.

Background/Purpose: Osteoarthritis (OA) was once viewed as a mechanical disease of "wear and tear", but recent advances suggest that OA results from active dysregulation of chondrocyte biology leading to catabo-

lism of the cartilage matrix. Little is understood regarding the transcription factors that regulate this catabolic program and ultimately the development of OA. Nuclear factor of activated T cells (NFATs) are a family of transcription factors with broad roles in vertebrate physiology including immune responses and tissue development. Since NFAT family members often display redundant functions and NFATc2-deficient mice were previously shown to develop OA at older ages, we tested the role of NFATc1 in OA.

Methods: Mice bearing two copies of a floxed allele of *Nfatc1* (*Nfatc1*$^{fl/fl}$) were crossed to *Col2-cre* mice to delete the gene in cartilage (*Nfatc1*^{col2} mice). *Nfatc1*^{col2} mice were analyzed in the destabilization of the medial meniscus (DMM) model of OA. The *Nfatc1*^{col2} strain was bred onto the NFATc2-deficient background to generate *Nfatc1*^{col2}*Nfatc2*$^{-/-}$ mice. These mice were analyzed by microCT, immunohistochemistry and quantitative real-time PCR (qPCR) of mRNA isolated from dissected cartilage tissue. mRNA purified from human cartilage tissue from joint replacement surgery was also interrogated for *NFATC1* and *NFATC2* expression by qPCR.

Results: *NFATc1*^{col2} mice were not more susceptible to OA in the DMM model than littermate controls, suggesting that in mice, NFATc1 deficiency is not sufficient to accelerate OA. In contrast, cartilage-specific ablation of *Nfatc1* in *Nfatc2*$^{-/-}$ mice led to a spontaneous, early onset, aggressive OA. The arthritis affects multiple joints including the knees, elbows and tarsal-metatarsal joints and is associated with subluxations. Histologically, joints from *Nfatc1*^{col2}*Nfatc2*$^{-/-}$ mice showed loss of proteoglycans, increases in collagen and aggrecan degradation products and eventual progression to cartilage effacement. MicroCT demonstrated increased osteophyte formation and changes to the subchondral bone in *Nfatc1*^{col2}*Nfatc2*$^{-/-}$ mice. Compared with littermate controls, cartilage dissected from the knee joints of *Nfatc1*^{col2}*Nfatc2*$^{-/-}$ mice showed increased expression of: *Mmp13, Adamts5, Col2a1 and Htra1*. Lastly, *NFATC1* expression is downregulated in paired lesional versus macroscopically normal cartilage samples from OA patients (1.63 vs. 2.72, $p=0.0065$ by paired t-test). No significant change was observed in *NFATC2* expression (2.44 vs. 2.06, $p=0.214$).

Conclusion: NFATs are suppressors of OA and regulating NFATs or their transcriptional targets in chondrocytes may lead to novel disease modifying OA therapies. The *Nfatc1*^{col2}*Nfatc2*$^{-/-}$ mice have a highly penetrant, early onset and severe OA phenotype, which could be an attractive platform for the preclinical development of treatments to alter the course of this disease.

Epigenetic Control Of a Gene Regulatory Network Associated With Experimental Autoimmune Arthritis and Rheumatoid Arthritis. Andras Vida[1], Janos Gal[2], Gyorgyi Soos[2], Attila Balog[3], Laszlo G. Puskas[4], Katalin Mikecz[1], Tibor T. Glant[1] and Tibor A. Rauch[1]. [1]Rush University Medical Center, Chicago, IL, [2]Bacs-Kiskun County Hospital, Kecskemet, Hungary, [3]Albert Szent-Gyorgyi University, Szeged, Hungary, [4]Biological Research Center, Szeged, Hungary.

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune inflammatory disorder that mainly affects the synovial joints, leading to destruction of articular cartilage and bone. There is accumulating evidence for the involvement of epigenetic events in the pathogenesis of RA. Recent genome-wide DNA methylation studies have reported disease-associated changes in DNA methylation profile. However, methylation status-dependent molecular mechanisms that can potentially drive or amplify inflammatory processes in arthritis have not been explored.

Methods: We separated lymphocytes from mice with proteoglycan-induced arthritis (PGIA), an autoimmune model of RA, and surveyed arthritis-induced DNA methylation events at genome-wide level using a Methylated CpG Island Recovery Assay (MIRA)-chip method. In addition, we isolated RNA from lymphocytes of arthritic mice and from peripheral blood mononuclear cells (PBMC) of RA patients, and monitored the DNA methylation-dependent changes in gene expression levels by quantitative RT-PCR. Disease-associated DNA-protein interactions were analyzed using electrophoretic mobility shift assays. A cell culture-based in vitro transient expression system was employed to investigate the functional consequence of the binding of specific transcription factors to gene promoters.

Results: Using the MIRA-chip method, we detected arthritis-associated epigenetic changes that preferentially occurred in B cells from mice with PGIA. Specifically, hypomethylation of the promoter of the gene encoding the "zinc finger and BTB domain containing 38" (ZBTB38) transcription factor resulted in a sharp upregulation of ZBTB38 expression in lymphocytes of arthritic mice relative to non-arthritic animals. Expression of the ZBTB38 gene was also elevated in PBMC of RA patients as compared to its expression in healthy subjects. Moreover, ZBTB38 could facilitate its own transcription, and stimulate the expression of a number of other genes including those encoding transcription factors, pro-inflammatory cytokines, as well as receptors for chemokines and Toll-like receptors. Intriguingly, many of the ZBTB38-targeted genes, identified in this study, have been implicated in RA pathogenesis.

Conclusion: ZBTB38 is involved in an intricate gene regulatory network that seems to control inflammatory processes in RA. Exploration of epigenetic mechanisms involved in the regulation of a major RA-associated inflammatory pathway may lead to identification of new genes as novel biomarkers and potential drug targets for RA.

Integrative Analysis Of Multiple Omics Technologies Reveals a Novel Therapeutic Target For Rheumatoid Arthritis (RA). David L. Boyle[1], John Whitaker[1], Beatrix Bartok[1], Wei Wang[2] and Gary S. Firestein[1]. [1]UCSD School of Medicine, La Jolla, CA, [2]UCSD, La Jolla, CA.

Background/Purpose: Identifying novel therapeutic targets for immune-mediated disease has become increasingly challenging. We used an unbiased method to integrate multiple "omics" methodologies and evaluate the overlap between RA-associated genes identified in genome-wide association studies (GWAS), genes that are differentially expressed or genes that are differentially methylated in RA fibroblast-like synoviocytes (FLS). This analysis narrowed the search to a limited number of genes and allowed us to focus on Engulfment and Cell Motility Protein-1 (*ELMO1*), a gene not previously considered as a therapeutic target. We show how this novel candidate gene plays a key role in the pathogenic behavior of RA FLS.

Methods: Data were from three types of genome-wide RA assays were integrated: (i) for sequence variation we used the NCBI GWAS database and extracted all gene that were mapped to SNPs that had been implicated in RA susceptibility (www.genome.gov/gwasstudies/); (ii) for gene expression we used public microarray datasets of RA, OA, and normal (NL) FLS (Gene Expression Omnibus Database); (iii) for DNA methylation we used a set of differentially methylated genes that we previously identified in RA, OA, and NL FLS (Genome Medicine 5:40 2013). For functional studies, passage 4 to 6 RA FLS were cultured in medium or PDGF and migration was measured using a scratch assay. Cell invasion was determined by measuring cell invasion into Matrigel-coated transwell plates. Rac1 activation was determined by measuring the Rac1-GTP bound form of Rac1 by Western blot. Gene knockdown was performed using the siRNA and Amaxa technology.

Results: The integrative analysis of the three unbiased genome-wide approaches identified 6 genes as different in RA compared to controls (OA and normal) in all datasets. Of the overlapping genes, we were particularly interested in the cytoplasmic engulfment protein, *ELMO1*, as it was differentially methylated in the promoter region, differentially expressed, and associated with RA due to an intron-6 polymorphism. This protein can bind to Rac1 in activated cells and potentially alter cell movement. We first confirmed that ELMO1 is expressed in RA FLS and synovium as determined by qPCR. siRNA knockdown was then performed, which decreased ELMO1 expression by >90% compared to control siRNA. ELMO1 deficiency decreased PDFG-induced FLS migration by 40% ($p<0.02$). In an invasion assay, ELMO1 siRNA markedly decreased invasion of PDGF stimulated RA FLS into Matrigel matrix compared with control siRNA. The mechanism ELMO1 function was determined by determining the effect of ELMO1 deficiency on Rac1 activation. These experiments showed that ELMO1 siRNA decreased peak PDGF-induced Rac1 activation by 80%.

Conclusion: Integrative analysis of multiple unbiased genome-wide datasets is a novel method to identify potential therapeutic targets. One previously unanticipated target, ELMO1, emerged as a candidate gene in RA. ELMO1 plays a critical role as a regulator of FLS migration and matrix invasion by activating Rac1. These data show how one can use integrative studies to identify and validate novel therapeutic targets.

High Density Microarray Analysis Identifies Novel Differentially Expressed Long Noncoding RNAs In Rheumatoid Arthritis Synovial Fibroblasts. Mojca Frank Bertoncelj[1], Michelle Trenkmann[1], Christoph Kolling[2], Beat A. Michel[3], Renate E. Gay[1] and Steffen Gay[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Schultess Clinic, Zurich, Switzerland, [3]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: Long noncoding RNAs (lncRNAs) have emerged as key regulators of gene expression. Recently, several new susceptibility loci were identified for rheumatoid arthritis (RA), mapping to noncoding genomic regions (Eyre et al., Nat Gen 2012). Furthermore, we showed that the lncRNA HOTAIR is epigenetically repressed in RA synovial fibroblasts (SF), enhancing their activated phenotype. The aim of the present study was to determine the global lncRNA expression in RASF and to identify differentially expressed (DE) lncRNAs in RASF with a potential role in the pathogenesis of RA.

Methods: Total RNA was isolated from cultured synovial fibroblasts (SF), passages 5–6, from 3 RA and 3 osteoarthritis (OA) age-matched female patients. Sample labeling and array hybridization were performed according to the Agilent One-Color Microarray-Based Gene Expression Analysis protocol. Fluorescently-labeled cRNA was hybridized to human LncRNA Array v3.0 (Arraystar) detecting 30,586 lncRNAs and 26,109 mRNAs. The arrays were scanned by the Agilent Scanner G2505C and analyzed by the Agilent Feature Extraction software. The Agilent GeneSpring GX v12.0 software was used for data processing. To identify DE transcripts the absolute fold change of normalized signal intensities between RASF and OASF was calculated (cut-off value 1.5, $p<0.05$). Gene ontology (GO) and pathway analysis were performed. Fourteen selected DE lncRNAs were confirmed by qPCR in a larger cohort of age- and gender-matched RASF and OASF (n=10 each) with normalization to GAPDH.

Results: The microarray analysis identified 225 DE RNA transcripts in RASF compared to OASF. Among these, 36 lncRNAs (x-fold range: 1.5–4.1) and 87 mRNAs (1.5–10.7) were significantly down-regulated, while 64 lncRNAs (1.51–3.5) and 38 mRNAs (1.5–3.3) were significantly upregulated in RASF. Among identified lncRNAs, small nucleolar RNA host gene 1 (SNHG1) (dCt±SD OASF: 6.92±0.29; RASF: 6.53±0.45, p=0.038) and RP11–39708.4 (dCt±SD OASF: 12.61±0.26; RASF: 12.07±0.69, p=0.042) were confirmed by PCR to be upregulated in RASF. Although their function is not known, it is of interest that RP11–39708.4 is a natural antisense transcript in the locus of fibroblast growth factor 14 and SNHG1 is a host gene for several small nucleolar RNAs, including SNORD22 and SNORD25–31. Among DE mRNAs, several transcripts linked to the pathogenesis of RA were found, such as interleukin 8, peroxisome proliferator-activated receptor (PPAR) gamma and sirtuin 1. Additionally, several novel DE mRNAs were identified, such as tumor protein p73, cell division cycle-associated protein 3 and chemokine-like receptor 1. DE mRNAs clustered to p53, Wnt and PPAR signaling and cell cycle-regulating pathways with significant enrichment of GO terms including cell adhesion molecules, cadherin and beta-catenin binding as well as mitosis and nuclear division.

Conclusion: In this study we identified novel DE lncRNAs in RASF, including SNHG1 and RP11–39708.4. This is the first study determining the global lncRNA profile in combination with differential expression of mRNAs in RASF, which will be a powerful tool to identify novel gene regulating pathways in RA.

In Vivo MiR-146a Administration Ameliorates Murine Lupus Nephritis. Dong Liang[1], Shiyu Zhou[2], Zheng Liu[3], Zhengyuan Shan[1], Philip Brohawn[3], Yihong Yao[3], Indu Raman[4], Quan-Zhen Li[4], John B. Harley[1] and Nan Shen[5]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Shanghai Institutes for Biological Sciences Chinese Academy of Sciences & Shanghai Jiao Tong University School of Medicine, Shanghai, China, [3]MedImmune, LLC, Gaithersburg, MD, [4]University of Texas Southwestern Medical Center, Dallas, TX, [5]Shanghai Institute of Rheumatology, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.

Background/Purpose: New Zealand black and white F1 (NZBW/F1) is a classic mouse model of systemic lupus erythematosus (SLE). Type I interferon (IFN) infusion accelerates lupus proteinuria and nephritis. miR-146a is a potent immune regulator to suppress inflammatory responses in T and dendritic cells. Potential involvement of this miRNA in lupus pathogenesis has been implicated in human SLE by both function and genetics. This study explored the novel functions and therapeutic potential of miR-146a in a mouse model of accelerated SLE.

Methods: At 15 weeks, NZBW/F1 mice were infused with IFNα delivered by subcutaneously implanted osmotic pumps. The miR-146a (n = 8) or PBS (n = 7) administration began one week before the IFNα infusion and lasted for 9 weeks. Age matched NZBW/F1 mice were used as negative controls (n=10). Urine samples were tested for proteinuria by dipstick. Blood sera were used for autoantibody profiling. Gene expression profile data were collected from peripheral blood RNAs of both miR-146a and PBS treated groups. At the end of 9-week intervention, the kidney tissues were harvested and renal damage was histologically investigated by HE and IgG1 staining.

Results: Administration of IFNα in NZBW/F1 mice resulted in an accelerated lupus. Proteinuria free survival rate differs between miR-146a treated and PBS-treated groups, with a significant delayed onset of proteinuria observed in the miR-146a-treated group ($p < 0.01$, Fig.1). IHC staining showed reduced IgG1 deposition in kidney tissues from mice treated with miR-146a, 9 weeks after miRNA treatment (Fig. 2). Gene expression profiling by microarray showed that miR-146a treatment decreased expression of immunoglobulin proteins (IgG1, IgG2b, IgM, and IgA). Consistent with these findings, autoantibody profiling of mouse sera showed that IFNα infusion triggered an induction of autoantibodies reactive with different glomerular or glomerular basement membrane antigens. However, the expression of some lupus relevant autoantibodies (anti-H3, anti-H4, anti-histone (total), anti-LC1, anti-MPO, anti-Ribophosphoprotein P1, anti-Sm-D1 and anti-U1-snRNP-BB') was significantly suppressed following miR-146a treatment.

Figure 1

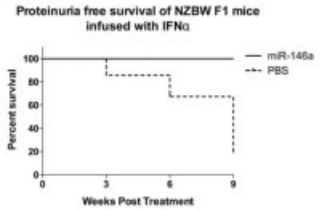

Figure 2

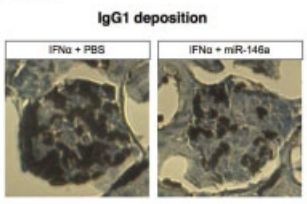

Conclusion: Overall, treatment with miR-146a attenuated lupus nephritis in the IFNα infused NZBW/F1 mice. The results are a proof of principal suggesting that interference with miR-146a may be a promising therapeutic strategy for treatment of lupus patients with renal involvement.

Microrna-Mediated Regulation Explains Allelic Risk Of *TLR7* Variant Predisposing To Systemic Lupus Erythematosis. Yun Deng[1], Jian Zhao[1], Jennifer M. Grossman[2] and Betty P. Tsao[1]. [1]David Geffen School of Medicine University of California Los Angeles, Los Angeles, CA, [2]UCLA David Geffen School of Medicine, Los Angeles, CA.

Background/Purpose: We identified a genome-wide significant association of the *TLR7* variant (rs3853839) with SLE susceptibility in multiple ancestries ($P_{meta} = 2.0\times10^{-19}$, OR =1.25), and the risk allele carriers exhibited elevated levels of *TLR7* mRNA and protein and more pronounced

type I interferon (IFN) signature in SLE PBMCs. At or near the location of this variant are targeted sequences for predicted multiple microRNA (miRNAs) binding sites that may affect transcript degradation, leading us to explore whether differential miRNA binding could explain allelic risk of *TLR7* for SLE.

Methods: Each of the six bioinformatically predicted miRNAs was co-transfected with the *TLR7* 3'UTR reporter construct carrying either the risk or non-risk allele of rs3853839 into HEK 293 cells to assess which miRNA inhibits luciferase activity. To test effects of miRNA(s) on regulation of endogenous *TLR7* expression and downstream IFN-α production, PBMCs from healthy donors were transfected with miRNAs or non-target control miRNAs for 24 hours, followed by stimulation with TLR7 agonist (CL097) for 24 hours to induce IFN-α production and measured in culture supernatants by ELISA. Cells were lysed for RNA extraction and mRNA levels of *TLR7* and IFN scores (*MX1*, *Ly6E*, *IFIT1* and *IFIT3*) were quantified by RT-PCR.

Results: Transfection of each of six miRNAs into HEK-293 cells showed that (1) only miR-3148 and miR-2278 could reduce luciferase activity driven by the *TLR7* 3'UTR construct containing either risk or non-risk allele of rs3853839; (2) allelic differences in reduction of luciferase activity were observed by overexpression of miR-3148 at increasing concentrations [reduction in non-risk allele vs. risk-allele construct: 13.2% vs. 4.8%, P =0.023 (6nM); 22.5% vs. 9.9%, P =0.0012 (12nM); 21.4% vs. 8.5%, P =0.0031 (48nM)], but only by overexpression of miR-2278 at the highest concentration [31.3% vs. 15.6%, P =0.039 (48nM)]. Expression levels of miR-3148, but not miR-2278, were inversely correlated with *TLR7* mRNA levels in PBMCs (R^2 = 0.255, P =0.001, and R^2 =0.086, P =0.08, respectively). Compared to the non-target control miRNA, preliminary results of overexpression of miR-3148 in PBMCs (n=15) led to 15% reduction in *TLR7* mRNA expression (P =0.003), resulting in a trend of decreased downstream production of IFN-α (P =0.07); whereas inhibition of miR-3148 led to 24% increase in *TLR7* mRNA expression (P =0.006) and a trend of increased production of IFN-α (P =0.09). Overexpression or inhibition of miR-3148 in PBMCs showed no significant difference in IFN scores.

Conclusion: Among the 6 tested miRNAs, miR-3148 and miR-2278 showed allelic difference in degradation of mRNA containing rs3853839, which results in increased expression of *TLR7* mRNA in risk-allele carriers. The inverse correlation between miR-3148 and *TLR7* mRNA levels and a trend of downregulation of IFN-α production in PBMCs *ex vivo* support miR-3148 regulates TLR7 expression and affects downstream IFN pathway. Our data suggests interactions between the genetic risk factor (rs3853839) and the epigenetic factor (miRNAs), implicating possibility of miRNA-based therapies to ameliorate SLE where excessive TLR7 activation exists.

Background/Purpose: The purpose of this study was to identify SSc risk *loci* shared with other autoimmune diseases on the Immunochip and to fine-map previously associated *loci*.

Methods: We genotyped 1,959 SSc cases and 3,582 controls of European ancestry from the United States and Spain using the Immunochip custom array containing 196,524 SNP variants within 186 known autoimmune risk *loci*. Ten SNPs were then chosen for replication in 4,017 SSc cases and 5,935 controls from 6 additional populations of European ancestry from the US, Canada, Europe and the UK for a combined population of 5,876 SSc cases and 9,517 controls.

Results: As noted in the Table below, we identified and validated 4 novel SSc risk *loci* including ***DNASE1L3*** at 3p14, ***SCHIP1 | IL12A*** at 3q25, ***ATG5*** at 6q21 and ***TREH/DDX6*** at 11q23. Remarkably, the association of the rs35677470 missense variant in the *DNASE1L3 locus* with the ACA+ subset of patients is the most significant non-HLA association with SSc revealed to date ($p = 2.70\times10^{-32}$ OR=2.00). In addition, we further refined the area of association for the *STAT4, IRF5/TNPO3 loci* and related an observed peak of association in the *PXK* gene to the novel *DNASE1L3 locus*.

Novel non-HLA loci associated with SSc and its subsets ($p < 5\times10^{-8}$) identified through Immunochip analysis.

Locus	SNP	Chr	Minor Allele	Comments	Phenotype	MAF Cases/CTRLs	*p*-value	OR
DNASE1L3	rs35677470	3p14	A	Missense Arg>Cys	All SSc	0.088/0.062	1.20×10^{-15}	1.43
					lcSSc	0.099/0.062	5.82×10^{-21}	1.6
					ACA+	**0.133/0.062**	$\mathbf{2.70\times10^{-32}}$	**1.99**
SCHIP1-I2A	rs77583790	3q25	A	Intergenic	All SSc	0.015/0.005	2.25×10^{-12}	2.54
					lcSSc	**0.016/0.005**	$\mathbf{3.60\times10^{-12}}$	**2.74**
					ACA+	0.016/0.005	2.24×10^{-8}	2.61
ATG5	rs9373839	6q25	G	Intronic	All SSc	0.241/0.185	2.16×10^{-8}	1.18
TREH/DDX6	rs7130875	11q23	G	Intergenic	All SSc	0.27/0.24	4.03×10^{-8}	1.17

Conclusion: The ***DNASE1L3*** association suggests that failure to clear apoptotic debris plays a role in SSc; that the ***IL12*** pathway is key to SSc susceptibility; that autophagy (***ATG5***), previously unreported in SSc, may be an important mechanism; and that ***DDX6***, which has been shown to regulate VEGF under hypoxic conditions may provide a clue to SSc vasculopathy.

High Efficacy Of Toll-Like Receptor 4 Targeting In Murine and Humanized Models Of Rheumatoid Arthritis In Comparison With IL-1 and TNF Inhibitors. Shahla Abdollahi-Roodsaz[1], Marije I. Koenders[2], Leo A. Joosten[3], Fons A. van de Loo[2] and Wim B. van den Berg[1]. [1]Rheumatology Research and Advanced Therapeutics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Rheumatology Research and Advanced Therapeutics, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, [3]Department of Medicine, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.

Background/Purpose: Increased expression of Toll-like Receptor (TLR) 4 and its endogenous agonists in rheumatoid joints suggest involvement in rheumatoid arthritis (RA). The aim of this study was to assess the therapeutic efficacy and downstream effects of TLR4 blockade in murine and humanized models compared with interleukin-1 (IL-1) and tumor necrosis factor (TNF) inhibitors.

Methods: Mice with established collagen-induced arthritis (CIA) systemically received TNF, IL-1 and TLR4 inhibitors (Enbrel, Anakinra and purified *B. quintana* LPS, resp., each 2 mg/kg/day) using osmotic minipumps. Severe combined immunodeficient (SCID) mice engrafted with active RA synovial tissue, and *ex vivo* synovial cultures served to translate the findings into RA.

Results: TLR4 blockade significantly suppressed clinical and histopathological manifestations of ongoing CIA to the same extent as IL-1 and TNF inhibitors. Targeting TLR4 substantially reduced serum IL-1β and IL-6, and was the only treatment capable of lowering serum TNFa. High-dose TLR4 inhibitor (8 mg/kg) was found significantly more

effective than high-dose Enbrel (10 mg/kg; $P < 0.05$ using Bonferroni's multiple comparison test). Importantly, TLR4 inhibition exceeded beneficial effects of TNF blocker by reducing serum IL-17 along with synovial gene expression of IL-23p19, IL-17 and the Th17-related transcription factor RORγt, while Th1 markers and type II collagen-directed T cell proliferation and antibody responses remained unaffected.

In intact RA synovial biopsies, TLR4 stimulation (100 ng/ml *E. coli* LPS) potently induced TNFα, IL-1β, IL-6 and IL-8 production *ex vivo*, indicating its functional relevance. When transplanted into SCID mice, one single i.p. injection of TLR4 agonist significantly increased IL-6 production by RA synovium *in vivo* and sustained the otherwise declining IL-8 levels for up to 7 days. Importantly, TLR4 activation clearly reversed the therapeutic efficacy of anti-TNF treatment in the humanized RA synovium-SCID model, suggesting involvement in anti-TNF non-responsiveness in subgroups of patients.

Therapeutic value of TLR4 targeting in RA was revealed by inhibition of TLR4 in the RA synovium-SCID model. Blocking endogenous TLR4 activation in this model resulted in substantial reduction of spontaneous IL-6 and IL-8 release and synovial inflammation, thereby equaling anti-TNF. In RA synovial explant cultures *ex vivo*, TLR4 blockade by either *B. quintana* LPS or the small molecule inhibitor TAK242 suppressed several inflammatory cytokines. High-density (phospho)protein microarray of synovial protein lysates showed 27% reduction in NFκBp65 phospho-Ser536, but not NFκBp105/p50, levels by TLR4 blockade. Interestingly, TLR4 inhibition suppressed synovial expression of multiple other key signaling molecules including TAK1 phospho-Thr187 and -Ser412 (26 and 23%, resp.), JAK1 phospho-Tyr1022 (22%), IRAK1 (22%), IRF3 (51%), Foxo3a (39%) and Btk (24%).

Conclusion: Data in murine and humanized models position TLR4 upstream to a number of inflammatory and pathogenic pathways. The findings including impact on IL-17 production and anti-TNF responsiveness collectively impel future research on TLR4 as a potential therapeutic target in RA.

Evidence That STAT3 controls NLRP3 inflammasome–dependent Release Of IL-1β and Pyronecrosis Through Regulation of mitochondrial activity. Jehad H. Edwan[1], Jae Jin Chae[2], Raphaela T. Goldbach-Mansky[3] and Robert A. Colbert[1]. [1]NIAMS NIH, Bethesda, MD, [2]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD.

Background/Purpose: Self-activating NLRP3 mutations are responsible for cryopyrin-associated periodic fever syndromes (CAPS), the most severe form of which is neonatal-onset multisystem inflammatory disease (NOMID). Spontaneous inflammatory responses initiated by NLRP3 mutations promote inflammasome-mediated IL-1beta processing and release, and can induce a rapid cell death in a process known as pyronecrosis that is dependent on cathepsin B activation. Emerging evidence suggests a role for mitochondria in activation of the inflammasome, and mitochondrial STAT3 has been implicated in regulating cellular respiration. The aim of this study was to determine whether STAT3 is involved in IL-1b release and pyronecrosis.

Methods: We used whole blood cells from NOMID and healthy donors, THP-1 cells with STAT3 expression knocked down, THP-1 cells with NLRP3 expression knocked down, and monocytes derived from NRLP3 deficient mice. Cells were stimulated with LPS in the presence of inhibitors of STAT3, followed by ATP. Cell supernatants were collected and incubated with IL-1beta-capturing beads. Cells were fixed and permeabilized. Then beads were added back to cells, and the mixture of cells with beads was stained with anti-IL-1beta, CD14, CD16, and CD83 antibodies and then evaluated by flow cytometry. LPS stimulated cells were also evaluated using immunofluorescent, electron microscopy and western blot analysis. In addition, cell metabolism pathways were analyzed using an XF extracellular flux analyzer.

Results: By flow analysis we found that a small population of monocytes, which undergoes pyronecrosis and is characterized by CD14hi/CD16low and intracellular CD83 expression, is responsible for the majority of IL-1beta production and release. Using confocal microscopy to visualize pyronecrosis, we provided and evidence that this process is NLRP3 dependent. Blockade of STAT3 function with inhibitors leads to complete inhibition of IL-1beta processing and release, as well as pyronecrosis in NOMID and ATP-stimulated healthy donor monocytes and in THP-1 cells. Similarly, STAT3 knockdown in THP-1 cells significantly inhibited IL-1beta release and pyronecrosis. Enhancement of the mitochondrial membrane potential in STAT3 knockdown cells bypasses the effect of STAT3 knockdown, and leads to increased IL-1beta processing and release, which was reversed with inhibitors of oxidative phosphorylation and glycolysis.

Conclusion: Taken together, these data suggest a previously unrecognized role for mitochondrial STAT3 in mediating NLRP3 effects on pyronecrosis and IL-1beta release, and provide a novel therapeutic target for NOMID and other NRLP3-mediated inflammatory diseases.

Blau Syndrome-Associated NOD2 Mutations Limit Production Of IL-6 and KC/IL-8 In Knock-In Mice and In Patients Suggesting a Loss Of Function Disease Mechanism. Jae Dugan[1], Eric Griffiths[1], Paige Snow[1], Holly L. Rosenzweig[1], Carlos D. Rose[2], Daniel Carr[1], James T. Rosenbaum[3] and Michael Davey[1]. [1]Dept. of Veterans Affairs Medical Center, Portland, OR, [2]Thomas Jefferson University/ AI duPont Hospital for Children, Wilmington, DE, [3]Oregon Health and Science University, Portland, OR.

Background/Purpose: Blau syndrome is an autosomal dominant disorder caused by mutations in nucleotide-binding oligomerization domain 2 (Nod2) and characterized by arthritis, dermatitis and uveitis. Nod2 binds muramyl dipeptide (MDP), a conserved structure from bacterial peptidoglycan, and activates NF-kB and MAPK signaling cascades. Prior *in vitro* studies using reporter assays indicated that Nod2 containing Blau mutations caused enhanced activation of NF-kB, suggesting a gain of function disease mechanism for Blau syndrome. However, studies with peripheral blood mononuclear cells (PBMCs) from patients with Blau syndrome stimulated with MDP show blunted cytokine responses. We tested the gain of function hypothesis *in vivo* by creating a knock-in mouse where a point mutation resulted in a change of arginine [R] to glutamine [Q] at position 314 (R314Q) of Nod2 (position 314 in mice corresponds to 334 in humans). Regulatory elements controlling Nod2 expression were not altered in this model.

Methods: Knock in mice were studied for systemic cytokine responses. Bone marrow derived macrophages (BMDM) from knock in mice were studied by western blot analysis for Nod2 expression and intracellular signaling, and by ELISA assays. Macrophages derived from patients with Blau syndrome were studied for cytokine responses to MDP and phosphorylation of p38 mitogen activated protein kinase (MAPK).

Results: R314Q heterozygous (+/m) and homozygous (m/m) mice did not spontaneously develop arthritis or dermatitis. BMDM from R314Q mice showed a reduction in full length (116 kD) Nod2 protein levels compared to wild type (WT) mice and they expressed an 80 kD protein that reacted with anti-Nod2 on western blotting. WT and mutant mice showed comparable amounts of Nod2 mRNA in BMDM and analysis of mRNA by PCR did not identify a splice variant. MDP treatment of BMDM showed reduced activation of NF-kB and p38 MAPK in +/m and m/m compared to WT mice that correlated with the copy number of mutated Nod2, with the greatest reduction in m/m mice. In response to *ip* MDP, reduced levels of IL-6 and KC were detected in the serum of +/m and m/m mice, also correlating with the copy number of the mutation. Macrophages derived from PBMCs of two patients with classic, familial Blau syndrome (a mother and son carrying an R334W mutation) showed negligible IL-6 and IL-8 production, and significantly reduced activation of p38 MAPK, in response to MDP compared to a healthy control.

Conclusion: These data indicate that R314Q-Nod2 mice as well as patients with Blau syndrome studied here have lost the ability to respond to MDP, a pathway that is dependent on Nod2. Rather than a gain of function as previously thought, the mutations cause a deficiency of Nod2-dependent responses to MDP and raise the possibility that Blau syndrome may fall within the spectrum of an immunodeficiency disease. This observation may provide insights into why granulomas form in Blau syndrome and it might have important implications for treatment.

Targeted Activation Of The Metabolic Super-Regulator AMP-Activated Protein Kinase (AMPK) Blunts Gouty Inflammation. Ru L. Bryan[1], Robert Terkeltaub[2] and Yun Wang[3]. [1]VA Medical Center/University of California San Diego, San Diego, CA, [2]VA Medical Ctr/University of California San Diego, San Diego, CA, [3]VA Medical Ctr, San Diego, CA.

Background/Purpose: Gout is associated with both multiple dietary triggers and metabolic co-morbidities, including obesity, metabolic syndrome, and diabates. AMP-activated protein kinase (AMPK) is a master regulator of energy homeostasis, and tissue AMPK activity is decreased by high fat diet and in diabetes, and is conversely increased by clarotic restraint, exercise, and several drugs in the clinic for arthritis (sodium salicylate, high dose aspirin, methotrexate) and by metformin. AMPK is a heterotrimeric complex compoased of an alpha catalytic subunit and two regulatory beta and gamma subunits. Phosphorylation at Thr-172 within the catalytic domain of the a subunit is critical for AMPK activity. Activation of AMPK exerts anti-inflamamtory effects partly by suppressing NF-kB activation. Thus, we assessed the function of AMPK in monsodium urate (MSU) crystal-induced inflammation *in vitro* and *in vivo*.

Methods: We added MSU crystals (0.2 mg/ml) for 18 h to bone marrow derived macrophages (BMDMs) from AMPKa1 knockout (KO) mice and C57BL/6 mice, and pre-treated with AMPK activators AICAR (1 mM) or highly AMPK selective A-769662 (0.25 mM). We analyzed conditioned media by ELISA for cytokines that drive gout arthritis, and cell lysates by Western blot for AMPK activity (phosphorylation of AMPKa). We also injected A-769662 (0.5 mM) one hour prior to injection of MSU crystals (3 mg) into mouse SQ air pouches *in vivo*, and collected samples 6 hrs later.

Results: MSU crystals decreased AMPK activity (phosphorylation of AMPKa Thr172) in BMDMs, and both AICAR and A-769662 inhibited IL-1b and CXCL1 induction by 75% ($p=0.0006$) and 88% ($p=0.0009$), respectively. Conversely, MSU crystal-induced production of IL-1b and CXCL1 was enhanced 1.5 to 2-fold in AMPKa1 knockout BMDMs. Colchicine at 10 nM concentration achieved by standard, low dose therapy for acute gout, up-regulated AMPK activity in BMDMs. Last, A-769662 attenuated inflammatory responses to MSU crystals *in vivo* by 72% reduction of number of infiltrating leukocytes ($p=0.04$) and decrease in IL-1b and CXCL1 in pouch fluid 60% ($p=0.003$) and 50% ($p=0.025$), respectively.

Conclusion: AMPKa1 deficiency enhances MSU crystal-induced macrophage IL-1b and CXCL1 release *in vitro*. Conversely, selective activation of AMPK by A-769662 markedly suppresses MSU crystal-induced inflammatory responses both *in vitro* and *in vivo*. We also established that nanomolar colchicine, in addition to certain other agents in the clinic for arthritis and diabetes, has the capacity to suppress gouty inflammation partly via AMPK activation. Our results indicate a novel, diet and drug targetable mechanism by which high fat diet, diabetes and the urate crystal by itself, are linked with heightened inflammatory potential of urate crystals in gout through decreased tissue activity of the metabolic super-regulator AMPK.

Caspase 8 Modulates The Polarisome To Prevent Lung Fibrosis In a Murine Ssc-Like Disease Model. Carla M. Cuda[1], Alexander Misharin[2], Gokhan Mutlu[2], Luisa Morales-Nebreda[2], GR Scott Budinger[2] and Harris R. Perlman[2]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University, Chicago, IL.

Background/Purpose: Pulmonary fibrosis has emerged as the leading cause of death in patients with Systemic Sclerosis (SSc). Currently available therapies are only marginally effective in treating this devastating complication and even patients who respond to therapy are left with significant respiratory morbidity. Caspase-8 is a cysteine-aspartic acid protease was originally identified as a key initiator of the apoptotic death receptor pathway and was later found to suppress necrotic programmed cell death (necroptosis) by inhibiting the receptor-interacting serine/threonine kinase 1/3 (RIPK1/3). We discovered a non-apoptotic role for caspase-8 in limiting the activation of macrophages and dendritic cells by toll-like receptor (TLR) agonists via a mechanism that involves RIPK. This novel function of caspase-8 is independent of its apoptotic function; unlike mice lacking Fas or overexpressing the general-baculoviral caspase inhibitor p35 in macrophages and DCs, the loss of caspase-8 does not result in changes in macrophage or DC numbers or affect their survival after bone marrow transplantation into lethally radiated mice.

Methods: Mice lacking caspase 8 specifically in DCs or macrophages were generated ($Cre^{CD11c}Casp8^{flox/flox}$ $Cre^{LysM}Casp8^{flox/flox}$) and examined using the bleomycin and adenoviral TGF-β models of lung fibrosis Flow cytometric analysis was used to characterize macrophage and DC. Luminex-based assays detected cytokine levels.

Results: We show that mice deficient in caspase-8 specifically in macrophages and DCs (have markedly less lung fibrosis than their littermate controls following intratracheal treatment with either bleomycin or an adenovirus encoding an active form of TGF-β. In wild-type animals, we found that the development of fibrosis was accompanied by a polarization of interstitial macrophages into an alternatively activated or M2 phenotype while interstitial macrophages from animals lacking caspase-8 remained polarized toward an M1 phenotype. M2 polarized macrophages have been associated with the release of profibrotic mediators involved in tissue fibrosis and M2 polarized macrophages are found in the lungs of patients with pulmonary fibrosis.

Conclusion: These data suggest a new paradigm for fibrosis in which caspase-8 functions as a key component of a "polarisome" regulating the polarization of macrophages toward an M1 or M2 phenotype. Inhibiting the function of this polarisome in macrophages from patients with scleroderma may prevent the development of lung fibrosis.

Reshaping Inflammatory Macrophage Development and Functions by a Monosaccharide Analogue In Rheumatoid Arthritis. Jun Li[1], Hui-Chen Hsu[2], PingAr Yang[1], Qi Wu[1], Bao Luo[1], Amber L Rowse[1], David M. Spalding[1], James A Mobley[1], S. Louis Bridges Jr.[1] and John D. Mountz[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Birmingham VA Medical Center, Birmingham, AL.

Background/Purpose: Inflammatory macrophages (MΦs) play key roles in pathogenesis of rheumatoid arthritis (RA). Fucosylation, comprising the transfer of a fucose (6-Deoxy-L-galactose) to proteins, is regulated by fucosyltransferases (FUTs) and involved in inflammation, oncogenesis, and cell differentiation. We have observed upregulated *FUTs* in synovial tissues from RA compared to osteoarthritis (OA) subjects. The purpose of the study is to determine: *(i)* the major cell types that produce *FUTs*; *(ii)* the roles of fucosylation; *(iii)* the efficacy of rebuilding the immune homeostasis by using a fucose analogue in RA.

Methods: Twenty eight RA and OA subjects were recruited and the study is approved by UAB IRB. Q-PCR was performed to determine the expression of *FUTs* in synovial tissues and FACS sorted cells from RA synovial fluids. Inflammatory MΦs were polarized by GM-CSF using monocytes from human PBMC, synovial fluid, and mouse bone marrow. Cells were treated with a fucose analog, 2-Deoxy-D-galactose (2-D-gal, inhibited the fucosylation mediated by FUT1/2) at different time points. Antigen presenting function was studied by using Eα-GFP peptide, DQ-Ova, and denatured bovine collagen II (CII)-FITC. Proteomics analysis was carried out by LCMS. Cytoskeleton images and video were collected using a Nikon spinning disk confocal microscope. Collagen-induced arthritis (CIA) was established in DBA/1J mice. 2-D-gal (200 mg/kg BW, every 2–3 days) was administered via I.P.. FACS and histopathology analyses were performed 6 weeks posterior primary CII immunization.

Results: There is a highly positive correlation between *TNFα* with *FUTs* 1, 2, 3, 4, 5, 6, 7, 9, 10, 11, 12 ($p=0.0001$ for all), but not *FUTs* 8 ($p=0.46$) and 13 ($p=0.47$) in human RA synovia. In sorted cells from RA synovial fluid, *FUTs* 1, 3, 5, 7, 9 were highly expressed in M1 inflammatory MΦ, but not in M2 MΦ, synovial fibroblasts, and T cells ($p<0.01$), whereas *FUTs* 8 and 13 were predominately expressed in synovial fibroblasts. This highly indicated that subsets of FUTs might associate with the inflammatory M1 MΦ characteristics. A fucose analog, 2-Deoxy-D-galactose (2-D-gal), precluded the differentiation of M1 MΦ. Phalloidin staining indicated 2-D-gal disrupted MΦ actin-based cytoskeleton. Furthermore, LCMS analysis revealed that plectin-10, an actin regulatory protein, is the major target of 2-D-gal in M1 MΦ. These data suggested a potential role of fucosylation in antigen processing. Indeed, 2-D-gal treatment of fully differentiated M1 MΦ for 2 days significantly reduced the uptake, processing and presentation of GFP-Eα (from I-Edα), DQ-OVA, and FITC-Collagen II (CII) antigens ($p<0.01$). Additionally, 2-D-gal skewed the M1 MΦ to M2 by increasing IL-10 secretion ($p<0.01$). *In vivo*, 2-D-gal treatment dramatically blocked bovine CII-induced arthritis (scores 9.5 ± 1.7 vs 0.5 ± 0.3, $p<0.01$) with reduced inflammatory MΦ in draining LN ($1.3\pm0.3\%$ vs $0.5\pm0.1\%$, $p<0.05$), decreased TNF-α (130 vs 39 pg/ml, $p<0.05$), and anti-CII in the serum.

Conclusion: Fucosylation, a hallmark of M1 MΦ, orientates MΦ polarization and function. 2-D-gal, a fucose analog restores the deranged M1 MΦ and leads to resolution of arthritis by inhibiting fucosylation of cytoskeleton molecules.

ACR Concurrent Abstract Session
Miscellaneous Rheumatic and Inflammatory Diseases I: Autoinflammatory Syndromes
Tuesday, October 29, 2013, 4:30 PM–6:00 PM

2746

A Novel Autoinflammatory Disorder Characterized By Ectodermal Dysplasia, Metaphyseal Chondrodysplasia, Growth Failure and Hyper-IgD In a Single Family. Edward J. Oberle and James W. Verbsky. Children's Hospital of Wisconsin, Milwaukee, WI.

Background/Purpose: Autoinflammatory disorders are characterized by chronic inflammation, and a variety of systemic complaints. Defects in the NF-kb essential modifier, or NEMO, are associated with an immune deficiency characterized by ectodermal dysplasia. We present a novel autoinflammatory disorder following an autosomal dominant pattern characterized by chronic inflammation, metaphyseal chondrodysplasia, ectodermal dysplasia with hypohidrosis, hyper-IgD and growth failure not associated with immune deficiency in a family.

Methods: Seven individuals from one family were identified. The proband, a male patient age 12 with known hypohydrosis, presented to our rheumatology clinic for chronic articular pain with bony hypertrophy of wrists, knees, and ankles. Standard labs were obtained including ESR, CRP, and CBC for all affected individuals. Plain radiographs and immunoglobulins were obtained from patient, father and sister. Films reviewed by two musculoskeletal radiologists. The proband underwent proximal tibial bone biopsy and marrow aspirate, as well as genetic testing for known autoinflammatory disorders.

Results: The proband, his father age 30, two brothers age 7 and 9, and his 2-year-old sister were all found to have ectodermal dysplasia, short stature and failure to thrive (Figure 1). The youngest affected was evaluated for fevers and elevated inflammatory markers from birth. The patient's father was admitted as a child for bone issues. All affected members exhibited chronically elevated ESR ranging between 64–118 mm/hr and elevated WBC. Radiographs of proband displayed symmetric lucent and sclerotic lesions of the metaphysis of distal radius/ulna, distal femora, and proximal and distal tibia/fibula (Figure 2). His father demonstrated widened metaphyses of distal ulna and tibia, but did not have lesions. Immunoglobulins were elevated in the patient and his father with IgD levels of 755 mg/L (<179 normal) and 600 mg/L, respectively. Bone biopsy of the proband was consistent with metaphyseal chondrodysplasia with marrow spaces consisting of loose fibrous stroma or cartilage, with scattered lymphocytes and plasmacytoid cells. Genetic testing was negative for mutations of CIAS1, LPIN2, MVK, IKBKG (NEMO), PSTP1P1, and TRAPS.

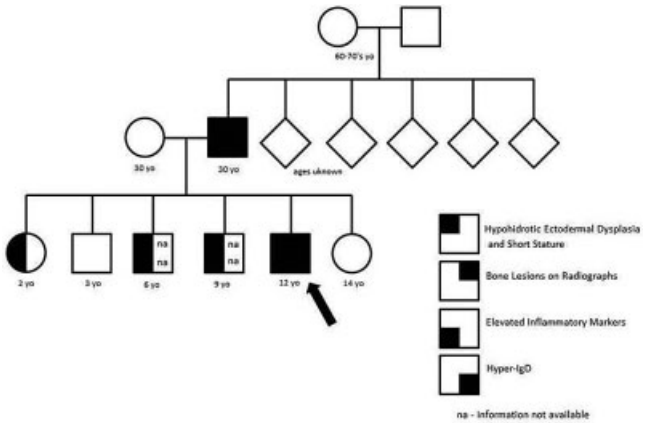

Figure 1. Pedigree.

Figure 2. Proband radiographs.

Conclusion: We propose a novel, autoinflammatory disorder resulting in osseous abnormalities, ectodermal dysplasia and Hyper IgD.

Disclosure: E. J. Oberle, None; **J. W. Verbsky**, None.

Canakinumab Treatment In Schnitzler's Syndrome: A Multi-Center Randomized Placebo-Controlled 4-Month Study. Karoline Krause, Karsten Weller, Martin Metz and Marcus Maurer. Dept. of Dermatology and Allergy, Allergie-Centrum-Charité, Charité – Universitätsmedizin Berlin, Germany, Berlin, Germany.

Background/Purpose: Schnitzler's syndrome (SchS) is an adult-onset autoinflammatory disease characterized by urticarial exanthema and monoclonal gammopathy in combination with episodes of fever, arthralgia, fatigue, and bone and muscle pain. Anti-IL-1 targeting therapies in small patient numbers including an open-label study with canakinumab (CAN) showed to be effective in reducing the clinical symptoms of SchS.

Methods: The current placebo-controlled study was designed to assess the effects of the selective anti-IL-1β humanized monoclonal antibody CAN on the clinical signs and symptoms of SchS in a larger patient cohort. A total of 20 patients with active disease enrolled in this multi-center trial. After a baseline period of up to 4 weeks, patients were randomized to receive a single CAN 150mg or placebo s.c. injection (day 0) and were evaluated for treatment response at day 7. This initial study period was followed by a 16-week open label phase with CAN injections upon confirmed relapse of clinical symptoms. Efficacy was determined by changes in the physician's global assessment (PGA; range 0–20), a combined symptom score which includes 5 key symptoms of SchS (urticarial rash, fever, fatigue, arthralgia and myalgia), measurement of the inflammation markers C-reactive protein (CRP) and serum amyloid A (SAA) as well as changes in quality of life assessment (SF-36).

Results: CAN was highly effective (P=0.001) in reducing median PGA total scores (14.0 to 2.0) within 7 days after first administration as compared to placebo treatment (15.0 to 13.0) in SchS patients. Also, significant (P<0.0001 – P<0.05) improvements were observed for each key symptom score. Median CRP reduced from 9.3mg/dL at baseline to 0.6mg/dL at day 7 in the CAN group vs increase from 3.0mg/dL to 5.0mg/dL for the placebo group. Similarly, median SAA levels reduced from 428mg/L to to 13mg/L for the CAN group vs increase from 160mg/L to 205mg/L for the placebo group. The median change from baseline between treatment groups for CRP (p=0.004) and SAA (p=0.002) was significant. Likewise, quality of life as measured by SF-36 significantly improved (P=0.001) for the CAN vs placebo groups at day 7. These improvements were maintained during the 16-week open label phase of the study. A total of 22 adverse events (AEs) were reported during the study including 3 serious AEs (2 hypertensive episodes in 1 patient and severe lumbago in another patient).

Conclusion: In this 4-month study, CAN s.c. injections significantly improved the clinical signs and symptoms of SchS, reduced inflammation

markers, and enhanced quality of life. CAN treatment may be considered a promising therapeutic option in these patients.

Safety Results From The Beta Confident Registry In Canakinumab-Treated Patients With Cryopyrin-Associated Periodic Syndrome. Hal Hoffman[1], Jasmin B. Kuemmerle-Deschner[2], Philip N. Hawkins[3], T. van der Poll[4], Ulrich A. Walker[5], Michael Nebesky[6], Ken Abrams[7] and Hugh Tilson[8]. [1]University of California at San Diego, San Diego, CA, [2]University Hospital Tuebingen, Tuebingen, Germany, [3]University College London Medical School, London, United Kingdom, [4]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [5]Universitäts-Poliklinik, Felix-Platter Spital, Basel, Switzerland, [6]Novartis Pharma AG, Basel, Switzerland, [7]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [8]The University of North Carolina, Gillings School of Global Public Health, Chapel Hill, NC.

Background/Purpose: Cryopyrin-associated periodic syndrome (CAPS) comprises an extremely rare auto-inflammatory disorders, including familial cold auto-inflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), and neonatal-onset multisystem inflammatory disease/chronic infantile neurological cutaneous and articular syndrome (NOMID/CINCA).[1] *NLRP3* gene mutation results in overproduction of IL-1β, leading to observed clinical symptoms of CAPS.[2] Canakinumab (CAN) is a selective anti-IL-1β monoclonal antibody, approved for the treatment of CAPS.[2,3] Here, we report the updated safety data for CAN in CAPS patients (pts) from the ongoing β-Confident Registry. The primary objective of the Registry is to monitor and further explore the overall safety of CAN, focusing primarily on serious infections, malignancies, hypersensitivity reactions, vertigo, and other selected adverse events in CAPS pts over a 5-year period (NCT01213641).

Methods: The Registry includes pts with CAPS and other auto-inflammatory disorders receiving CAN as part of regular medical care, after obtaining the written informed consent The study protocol does not mandate any visits or procedures, records all observed and reported adverse events (AEs) and serious adverse events (SAEs) or AEs potentially related to treatment with CAN. Cumulative safety data are reported, as incidence rate (number of events) per 100 patient-years (IR/100 pyr) from the date of first pt enrollment (November 19, 2009) until the data cut-off date (March 29, 2013). Additional safety data will be updated, as available, at the time of the conference presentation.

Results: A total of 245 pts were enrolled in the Registry at the current cut-off date, of which 229 patients reported a median duration of 50 weeks (range: 0.9 – 137.3) of prior treatment with CAN at the time of Registry enrollment. Of the total, 100 pts reported 238 AEs with an IR of 75.9/100 pyr. Infections with an IR of 20.7/100 pyr, were the most commonly observed AEs and included nasopharyringitis, rhinitis and urinary tract infections (UTI) among others. Eight pts reported 13 events of vertigo as AEs, resulting in an IR of 4.2/100 pyr, of which 8 were suspected to be CAN related. With regards to SAEs, 37 events were reported by 27 pts with an IR of 11.8 /100 pyr that included one fatal case of malignancy (metastatic rectal adenocarcinoma in a 76 yr MWS patient) and 12 events of serious infections. No case of hypersensitivity to CAN was reported. A total of 14 pts permanently discontinued CAN: 4 each due to pts preference and AEs, 3 due to lack of therapeutic effects, and 3 due to unspecified reasons.

Conclusion: No new or unexpected safety signals were reported to date in this ongoing Registry. Infections, as expected, were the most commonly occurring AEs and SAEs.

Amyloidosis and Its Related Factors In Patients With Familial Mediterranean Fever: A Nationwide Multicenter Study. Timucin Kasifoglu[1], Sule Yasar[1], Ismail Sari[2], Dilek Solmaz[2], Soner Senel[3], Hakan Emmungil[4], Levent Kilic[5], Sibel Yilmaz Oner[6], Fatih Yildiz[7], Sedat Yilmaz[8], Muhammet Cinar[8], Duygu Ersozlu Bakirli[9], Muge Aydin Tufan[7], Sema Yilmaz[10], Veli Yazisiz[11], Yavuz Pehlivan[12], Cemal Bes[13], Gozde Yildirim Cetin[14], Sukran Erten[15], Emel Gonullu[1], Tuncer Temel[1], Servet Akar[2], Kenan Aksu[4], Umut Kalyoncu[5], Haner Direskeneli[16], Eren Erken[7], Bunyamin Kisacik[12], Mehmet Sayarlioglu[17] and Cengiz Korkmaz[18]. Background/Purpose: Familial Mediterranean fever (FMF) is an autosomal recessive autoinflammatory disease that occurs worldwide and predominantly affects the populations arising from the Mediterranean origin. Secondary (AA) amyloidosis still remains the most devastating complication of FMF especially in untreated and noncompliant patients. However, pathogenesis and risk factors of amyloidosis still remains only partially understood in FMF. The primary aim of this study was to investigate the prevalence of amyloidosis and its related factors in a large number of FMF patients.

Methods: Fifteen centers from the different geographical regions of Turkey were included in the study. Detailed demographic and medical data based on structured questionnaire and medical records were collected. The diagnosis of amyloidosis was based on histological proof of congophilic fibrillar deposits in tissue biopsies.

Results: There were 2246 FMF patients. The male/female ratio was 0.87 (1049/1197). The mean ages of the patients were 33.6±0.25 years. Peritonitis was the most frequent clinical finding of the patients and it was present in 94.6% of the patients. The other clinical features were fever (91.9%), pleuritis (47.9%), arthritis (39.8%), erysipelas like erythema (ELE; 23.7%), myalgia (13%) and vasculitis (2.7%). Genetic testing was available in 1719 patients (76.5%). The most frequently observed genotype was homozygous M694V mutation which was present in 413 (24%) patients. Amyloidosis was present in 193 (8.6%) patients. Male sex, arthritis, M694V genotype, patients with end stage renal disease (ESRD), family history of amyloidosis and ESRD was significantly more prevalent in patients with amyloidosis compared with the amyloidosis negative subjects (Table 1). Patients with homozygous M694V mutations had significantly increased frequency of arthritis, ELE, amyloidosis, ESRD and family history of FMF and ESRD compared to the other genotypes.

Table 1. Comparison of patients with or without amyloidosis

	Amyloidosis (+) n=193	Amyloidosis (−) n=2053	*P*
Male sex	105, (54.4)	944, (46)	0.026
Peritonitis	170, (88.1)	1956, (95.3)	<0.001
Pleuritis	73, (37.8)	1002, (48.8)	<0.001
Arthritis	99, (51.3)	796, (38.8)	0.001
Patients with ESRD	101, (52.3)	10, (0.5)	<0.001
M694V homozygosity	90, (45.6)	323, (15.7)	<0.001
Delay in the diagnosis (years)	8	7	0.147
Family history of amyloidosis	54, (28)	428, (20.8)	0.027
Family history of ESRD	32, (16.6)	81, (3.9)	<0.001

Conclusion: In this nationwide study we revealed that 8.6% of our FMF patients had amyloidosis and homozygosity for M694V was the most common mutation in these patients. The latter finding confirms the association of homozygous M694V mutation with amyloidosis in Turkish FMF patients.

Long-Term Efficacy and Safety Of IL1 Receptor Antagonist In Schnitzler's Syndrome: A French Multicenter Study. Antoine Néel[1], Agathe Masseau[1], Sebastien Barbarot[1], Benoit Henry[2], Pierre-Jean Weiller[3], Olivier Decaux[4], Xavier Kyndt[5], Xavier Puechal[6], Arnaud Hot[7], Pierre Pottier[1], Amar Smail[8], David Launay[9], Jean-Marie Berthelot[1], Eric Hachulla[9], Leonardo Astudillo[10], Pierre-Yves Hatron[9], Laurent Sailler[10], Aurelien Lorleac'h[11], Achille Aouba[12], Bérangère Cador[4], Renato Fior[13], Robin Dhote[14], Fabrice Bonnet[15], Jean-Dominique de Korwin[16] and Mohamed Hamidou[1]. [1]Nantes University Hospital, Nantes, France, [2]Pitié-Salpêtrière University Hospital, Paris, France, [3]La Timone University Hospital, Marseille, France, [4]Rennes University Hospital, Rennes, France, [5]Hospital of Valenciennes,, Valenciennes, France, [6]Hôpital Cochin, Paris, France, [7]Edouard Herriot University Hospital, Lyon, France, [8]Amiens University Hospital, Amiens, France, [9]Claude Huriez University Hospital, Lille, France, [10]Toulouse University Hospital, Toulouse, France, [11]Lorient Hospital, Lorient, France, [12]Necker University Hospital, Paris, France, [13]Antoine Béclère University Hospital, Clamart, France, [14]Avicenne University Hospital, Bobigny, France, [15]Bordeaux University Hospital, Bordeaux, France, [16]Nancy University Hospital, Nancy, France.

Background/Purpose: Schnitzler's syndrome is a rare late onset autoinflammatory disease which associates a chronic/recurrent urticarial skin rash, a monoclonal gammopathy (mostly IgM kappa), and a variable combination of intermittent fever, osteoarticular pain, sclerotic bone lesions, lymphadenopathy and/or hepatosplenomegaly. This chronic disease can significantly alter patients' quality of life through intermittent fever, rash, pain and sometimes profound weight loss or anaemia. Patients can also develop a hematologic malignancy (mainly Waldenström's macroglobulinemia). In recent years several case reports have underscored the efficacy of Anakinra but long-term follow-up data are scare. Further, a few patients who did not respond to IL1 blockade have been reported recently.

Methods: Retrospective analysis of a French multicenter cohort of 40 patients with Schnitzler's syndrome.

Results: In this cohort mean age at disease onset was 61y (53–74). Mean diagnostic delay was 3 years. Disease manifestations included urticarial rash (100%), intermittent fever (81%), weight loss (62%), bone and/or articular pain (86%) and anaemia (Hb<10g/dL; 46%). All patients had systemic inflammation and 80% had bone lesions. Monoclonal gammopathy was IgM kappa in 85% of cases. Mean follow-up was 9 years (2–35). Twenty eight patients (70%) received Anakinra. Thirteen of those were corticodependant (mean dose: 15mg/d) when Anakinra was introduced. All 28 patients experienced a dramatic improvement of all clinico-biological signs of disease activity. Mean hemoglobin level rose from 11,2 to 13,4 g/dL ($p<0.001$). At last follow-up, all patients remained on anti-IL1 therapy. A single patient was switched to Canakinumab, due to injection site reactions to anakinra. Eighty percent of patients were in complete remission under anti-IL1 monotherapy, 11% were in complete remission under anakinra plus low dose corticosteroids and 4% were in partial remission under anakinra monotherapy. Mean follow-up under anakinra was 40 months (2–73). No loss of effectiveness was observed. In case of treatment interruption most patients experienced disease flare within 24–48 h. Alternate day injections were sufficient to maintain remission in only 4 cases. Three cases of uncomplicated neutropenia were recorded. Six patients developed severe infections including pneumonia in 5 cases, with local predisposing factor in 4 (severe COPD in 3, enteral feeding in 1). Anakinra had no obvious effect on the monoclonal component. No lymphoproliferative disease occured. When last seen, all 12 patients without anakinra had an active disease with variable impact on quality of life. Their mean corticosteroids dosage was 7mg/d.

Conclusion: Anakinra is dramatically effective in Schnitzler's syndrome. Treatment failure should lead to reconsider the diagnosis. Long-term follow-up reveals no loss of effectiveness and a favourable safety and tolerance profile. Alternate day injections are rarely sufficient to maintain remission. The effects regarding the risk of malignant transformation remain undertermined.

Recurrent Pericarditis In Children and Adolescents: Etiology, Presentation, Therapies, and Outcomes In a Multicenter Retrospective Cohort Of 100 Patients. Antonio Brucato[1], Massimo Imazio[2], Marco Gattorno[3], Antonella Insalaco[4], Chiara Di Blasi Lo Cuccio[1], Simona Marcora[5], Rolando Cimaz[6], Luca Cantarini[7], Luciana Breda[8], Manuela Marsili[8], Fabrizia Corona[9] and Alberto Martini[10]. [1]USC Internal Medicine, Ospedale Papa Giovanni XXIII, Bergamo, Italy, [2]Maria Vittoria Hospital, Torino, Italy, [3]G. Gaslini Institute, Genova, Italy, [4]Ospedale Pediatrico Bambino Gesù, Roma, Italy, [5]Ospedale Papa Giovanni XXIII, Bergamo, Italy, [6]A. Meyer Children's Hospital, Florence, Italy, [7]Policlinico Le Scotte, University of Siena, Siena, Italy, [8]University of Chieti G. D'Annunzio, Chieti, Italy, [9]Paediatric Department University of Milano, Milano, Italy, [10]Istituto G Gaslini, Pediatria II, Reumatologia, Genova, Italy.

Background/Purpose: Acute pericarditis is defined as at least 2 of the following criteria: typical chest pain (sharp and pleuritic, improved by sitting up and leaning forward), pericardial friction rub, suggestive EKG changes (widespread ST elevation or PR depression), new or worsening pericardial effusion. Pericarditis may recur in 15–30% of cases, and these children are frequently followed by pediatric Rheumatologists. In up to 68% of pediatric patients and in more than 80% of adult cases a specific etiology cannot be detected and pericarditis is considered idiopathic. Suggested explanations of recurrences include: insufficient dose and/or duration of non-steroidal anti-inflammatory drugs (NSAIDs), early corticosteroid treatment causing increased viral replication in pericardial tissue, too rapid tapering of corticosteroids, re-infection and exacerbation of the connective tissue disease.

Methods: Multicenter, retrospective cohort study including all consecutive cases of recurrent pericarditis of patients aged <18 years with at least 2 recurrences of pericarditis seen in referral centers in Italy. The study included 100 cases of recurrent pericarditis (median 13 years, range 1–17 years, 62 males).

Results: Pericarditis was idiopathic or viral in 87.0% of cases, post-pericardiotomy in 9.0% of cases; Familial Mediterranean Fever was diagnosed in 2.0% of cases, and a systemic inflammatory disease in 2.0% of cases. The majority of children had fever and CRP elevation at disease onset (96% fever, 98% CRP elevation), and pericardial effusion (57%), while pericardial rub (25%) and EKG changes (42%) were detected in a smaller percentage of patients. Corticosteroid-treated patients experienced more recurrences, side effects, and disease-related hospitalization (for all $p<0.05$). After a median follow up of 60 months (6–360 months), 470 recurrences were recorded (median 3, range 2–25). Duration of the active disease was unpredictable in the single patient and largely variable. Overall, 97% of cases had additional recurrences. ANA testing is ongoing. Additional adverse events during follow-up included: readmission in 74% of cases and cardiac tamponade in 13% of cases (in the first attacks). None of our patients diagnosed as having an idiopathic recurrent pericarditis developed a systemic autoimmune disease; 78% children were treated with NSAIDs, 62% with steroids and in 62% cases colchicine was added. Refractory cases (17%) were treated with immunosuppressant drugs (azathioprine, methotrexate, IVIG, Plaquenil), and 7 (7%) with Anakinra. Long term outcome was good, with no evolution in constrictive pericarditis, cardiomyopathy or systemic rheumatic diseases.

Conclusion: this is the largest ever published case-series of pediatric recurrent pericarditis. NSAIDs and colchicines remain the mainstay of the therapy while corticosteroids should be used with extreme caution, particularly in pediatric patients. In cortico-dependent cases anti-IL1 drugs proved to be very effective. The long term outcome is good.

Good, Moderate and Poor Outcome Trajectories Of Pain Severity In Early Symptomatic Knee Osteoarthritis; 5 Year Follow-Up Of *Check* study. Janet Wesseling[1], Alex N. Bastick[2], Sita M.A. Bierma-Zeinstra[2] and Johannes W.J. Bijlsma[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Erasmus MC - University Medical Center, Rotterdam, Netherlands.

Background/Purpose: Knee pain is often the first sign of knee OA (osteoarthritis) and it is known that its course can be very different between patients over time. This study identifies distinct groups of patients with different trajectories of pain in symptomatic knee OA, and describes lifestyle and coping characteristics for each trajectory of pain. Lifestyle factors might be important elements for prevention, since they are modifiable in nature. Yet de role of lifestyle factors in different pain trajectories in early OA is unclear.

Methods: Longitudinal data of five years follow-up of the CHECK (Cohort Hip and Cohort Knee) study was used. Participants had pain of knee, were aged 45–65 years, and had not yet consulted their physician for these symptoms or the consultation occurred within 6 months before inclusion. Pain severity was measured with numeric rating scale (0–10). Latent class growth analysis identified homogenous subgroups with distinct trajectories of pain. Multinomial regression analysis was used to examine different lifestyle and coping characteristics between the trajectories.

Results: Longitudinal data of 5 years follow-up of 705 participants with symptomatic knee OA was analyzed. Three pain trajectories were identified based on their outcome: good, moderate and poor outcome. Participants with good outcome trajectory (n=222) had over time a slight decrease in pain severity and ended up with a low pain severity. Participants with moderate outcome trajectory (n=294) had a stable course of moderate pain over time. The poor outcome trajectory participants (n=189) had an increase of pain severity over time and ended up with severe pain. Compared to the good outcome group, participants in the moderate and poor outcome group were characterized by higher BMI (both OR's 1.1; p=0.01), smoking (moderate outcome group OR=1.7, p=0.1; poor outcome group OR= 2.3, p=0.02) by using passive coping strategies worrying (moderate outcome group OR= 2.3, p=0.01; poor outcome group OR=3.7, p<0.001) and resting (moderate outcome group OR= 1.5, p=0.1; poor outcome group OR=2.4, p=0.002). The passive coping strategy 'retreating' reduced the chance of belonging to the poor outcome group (moderate outcome group OR= 0.6, p=0.05; poor outcome group OR=0.5, p=0.01). Baseline radiographic features of OA did not differ between the trajectories and did not have an association with the trajectories. However change from baseline to follow-up of radiological features (Kellgren & Lawrence grade and osteophyte area) differed between poor and good outcome.

Conclusion: This study identified 3 trajectories of pain: good, moderate and poor outcome. Unhealthy lifestyle characteristics (high BMI and smoking) and passive coping strategies (worrying and resting) characterized the poor outcome group. The pain evolution of the participants in the poor outcome trajectory corresponds with an increase in radiological damage (Kellgren & Lawrence grade and osteophyte size). Distinguishing different trajectories could have implications for the treatment. Treatment for each pain trajectory in early OA might be tailored to lifestyle and coping characteristics.

Relationship Of Pre-Radiographic MRI Lesions With Prevalent Frequent Knee Symptoms and Incident Persistent Knee Symptoms In Persons At Higher Risk For Knee Osteoarthritis. Leena Sharma[1], Joan S. Chmiel[1], Orit Almagor[2], Dorothy D. Dunlop[1], Marc C. Hochberg[3], Charles Eaton[4], C. Kent Kwoh[5], Rebecca D. Jackson[6], Joan M. Bathon[7], Ali Guermazi[8], Frank Roemer[9], Michel Crema[8], W. Jerry Mysiw[6] and Michael C. Nevitt[10]. [1]Northwestern University, Chicago, IL, [2]Northwestern University Medical School, Chicago, IL, [3]University of Maryland, Baltimore, MD, [4]Brown University, Providence, RI, [5]University of Pittsburgh, Pittsburgh, PA, [6]Ohio State University, Columbus, OH, [7]Columbia University, New York, NY, [8]Boston University, Boston, MA, [9]Klinikum Augsburg, Augsburg, Germany, [10]University of California, San Francisco, San Francisco, CA.

Background/Purpose: The clinical significance of pre-radiographic MRI lesions in persons at risk for knee OA is unclear. Understanding whether such lesions are inconsequential or early disease will aid prevention and disease-modifying strategy design. We hypothesized, in persons at risk but without radiographic OA, that cartilage damage, bone marrow lesions (BML), meniscal tear (MT), and meniscal extrusion (ME) are each associated with 1) prevalent frequent knee symptoms and 2) incident persistent knee symptoms.

Methods: The Osteoarthritis Initiative is a cohort study of men and women age 45–79 years with or at increased risk to develop knee OA. 850 participants were bilateral K/L 0 at 12 months. In their 12-month right knee (left if right inadequate) MR images, we assessed cartilage, BML, MT, and ME using a modified MOAKS system, blinding readers to hypotheses and all other data. At baseline, of the 850, 578 were without frequent knee symptoms (knee symptoms or medication use for knee symptoms most days of a month in the past 12 months). Incident persistent knee symptoms were defined as frequent knee symptoms at 2 consecutive annual OAI visits. Multiple logistic regression models evaluated associations between each lesion and 1) prevalent frequent symptoms and 2) incident persistent symptoms by 60 months, adjusting for age, gender, BMI, knee injury, and knee surgery.

Results: As shown in Table 1, cartilage damage, BML, and ME were each associated with prevalent frequent knee symptoms. As shown in Table 2, cartilage damage and BML (particularly patellofemoral), and MT were each associated with incident persistent symptoms.

Table 1. Pre-radiographic MRI Lesions and Risk of Prevalent Frequent Knee Symptoms

	Number of knees (1 knee per person)	Number of knees (row%) with frequent knee symptoms	OR (95% CI) Unadjusted	OR (95% CI) Adjusted for age, gender, BMI, previous knee injury, previous knee surgery

**Previous surgery also significant
n = 578 persons K/L 0 in both knees and without frequent knee symptoms at baseline [mean age 59.3 years (9.0), BMI 26.6 kg/m^2 (4.3), 324 (56.1%) women].

Conclusion: In persons at higher risk but without any evidence of radiographic knee OA, cartilage damage, BML, ME, and BMI were associated with prevalent frequent knee symptoms, and cartilage damage, BML,

MT, and BMI with the new development of persistent symptoms by 5 years. These findings suggest that these lesions, in persons at higher risk for knee OA, are clinically significant and may represent early disease.

Trajectory Of Cartilage Thickness Change During The Years Prior To Knee Replacement: Data From The Osteoarthritis Initiative. Felix Eckstein[1], Robert M. Boudreau[2], Zhijie Wang[3], Michael J. Hannon[3], Wolfgang Wirth[1], Sebastian Cotofana[1], Ali Guermazi[4], Frank Roemer[5], Michael C. Nevitt[6], Markus John[7], Christoph Ladel[8], David J. Hunter[9] and C. Kent Kwoh[2]. [1]Paracelsus Medical University, Salzburg, Austria, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh School of Medicine, Pittsburgh, PA, [4]Boston University, Boston, MA, [5]Klinikum Augsburg, Augsburg, Germany, [6]University of California, San Francisco, San Francisco, CA, [7]Novartis Pharma AG, Basel, Switzerland, [8]Merck KG, Darmstadt, Germany, [9]University of Sydney, Sydney, Australia.

Background/Purpose: Knee replacement (KR) represents a clinically important and cost-effective endpoint of knee osteoarthritis (OA). We have shown previously that, in a year prior to KR, medial cartilage loss (measured quantitatively with MRI) was greater in knees with KR than in controls, who displayed the same (baseline) radiographic disease stage. The best discrimination was observed in the central medial tibia (cMT). However, the trajectory of the more long-term cartilage thickness change prior to KR is unknown. The purpose of this study therefore was to examine rates of cartilage loss up to 4 years prior to KR.

Methods: We studied knees from the Osteoarthritis Initiative (OAI) who received a KR between 12–60 month follow-up (12M–60M). Each knee with KR was matched with one control who did not receive a KR through 60M by sex, baseline KLG (0–1, 2, 3, 4 strata), and age (±5y). Sagittal 3T DESSwe MR images were used for segmenting the weight-bearing femoro-tibial cartilages (Chondrometrics GmbH), with blinding to acquisition order. The visit directly prior to KR (T0) and those 12, 24, 36, and 48 months prior to T0 (i.e. T-1 through T-4) were analyzed as available. Cartilage thickness in cMT was selected as the primary and that in the total medial compartment (MFTC) as the secondary endpoint. Comparisons included paired t-tests between case/control pairs, and conditional logistic regression model, with and without adjustment for pain and BMI at the beginning of the respective observation interval.

Results: 220 knees of 190 OAI participants received a KR up to 60M (37@24M, 60@36M, 58@48M, and 65 @60M). Of these, 189 (58 baseline KLG 0–2, 69 KLG3, and 62 KLG4) had MRIs for at least one longitudinal interval, and a matched control (age 64±8.7; BMI 29±4.5; 85 male; 104 female). Analysis of slopes of annual change from all available time points revealed significantly greater rates of cMT cartilage loss in KRs than in controls (n=189: 94±137 vs. 55±104μm; p=0.0017; odds ratio [OR] = 1.36 [95% CI: 1.11;1.66] without, and 1.34 [1.09;1.66] with adjustment for pain and BMI). Between T-1 and T0, cMT cartilage loss was 2.9× that in controls (n=152: 114±209 vs. 39±159μm; p=0.0007, OR 1.42 [1.14;1.75] without, and 1.48 [1.18;1.86] with adjustment). The difference was less in previous time intervals (≤1.7x), but stronger for the T-2 to T0 period (n=127: 209±281 vs. 61±156μm [3.4x]; p<0.0001, OR=1.61 [1.29;2.01] without, and 1.64 [1.30;2.06] with adjustment). However, no significant difference was observed during T-4 to T-2 (n=60: 119±255 vs. 125±175μm; p=0.86, OR=0.97 [0.71;1.33] without, and 1.21 [0.81;1.81] with adjustment). Results for MFTC were similar to those for cMT.

Conclusion: The rate of medial cartilage loss was substantially greater in knees with KRs than in those without during a two-year period prior to T0 (i.e. within 2 years proximate of the timing of the KR), even after matching for baseline radiographic disease status. During earlier time intervals (i.e. 4 to 2 years prior to T0) the rates of medial cartilage loss were not different between KRs and controls. This trajectory of cartilage thickness change resembles that observed for change in symptoms prior to KR.

The Clinical Significance and Natural History Of Knee Bone Marrow Lesions Over 8 Years. Yi Chao Foong[1], Hussain Ijaz Khan[1], Dawn Aitken[1], Changhai Ding[1], Flavia Cicuttini[2] and Graeme Jones[1]. [1]Menzies Research Institute Tasmania, University of Tasmania, Hobart, 7000, Australia, [2]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3004, Australia.

Background/Purpose: There is increasing evidence to suggest that bone marrow lesions (BMLs) play a key role in the pathogenesis of OA. Whilst many studies have focused on short and medium term changes in BMLs, no study has explored BMLs over longer timeframes. The aim of this study was to describe the natural history of knee BMLs and their association with knee pain over eight years.

Methods: 199 subjects which consisted of 109 adult offspring of subjects who had a knee replacement and 90 controls who were initially matched by age and sex were studied. BMLs were measured at the two and ten year follow-ups using T2 weighted fat saturation MRI measuring the maximum area of the lesion at the medial and lateral tibial/femoral and patella sites. Knee pain was assessed by the Western Ontario and McMaster Universities Arthritis Index (WOMAC).

Multiple linear and logistic regression models were performed to investigate potential associations between BMLs and pain.

Results: At the two year follow-up, 64% of participants (n=128/199) had one or more BMLs, with a total of 231 BMLs present. Over eight years, of the 231 BMLs, 71% (164/231) increased in size, 8% (18/231) remained stable and 21% (49/231) decreased in size or resolved completely (Figure 1). Of those participants with no BMLs at baseline (71/199), 52% (37/71) developed one or more incident BMLs. In the whole sample, 31% of participants (62/199) developed a new BML at 1 site, 22% (44/199) at 2 sites, 9% (18/199) at 3 sites and 1% (2/199) at 4 sites or more. BML natural history did not vary between offspring and controls.

After adjusting for age, sex and BMI, the development of a new BML was associated with developing pain in those without pain at baseline (β=3.71, 95% CI 1.02–6.41). Those with a large BML at two years also had greater odds of having pain at ten years (OR=1.95, 95% CI 1.05–3.62). Eight year change in total BML size predicted an increase in total WOMAC pain in offspring but not controls (Table 1). The magnitude of the association in offspring was stronger in males as compared to females.

Table 1. Change in WOMAC pain score per change in BML size (linear regression)

	Univariable β (95% CI)	Multivariable* β (95% CI)	Females* β (95% CI)	Males* β (95% CI)
Total	0.46 (−0.17, 1.08)	0.47 (−0.16, 1.11)	0.14 (−0.58, 0.87)	**2.49 (0.86, 4.12)**
Controls	−0.09 (−0.71, 0.53)	−0.04 (−0.69, 0.60)	−0.14 (−0.93, 0.66)	1.56 (−1.10, 4.23)
Offspring	**2.68 (1.22, 4.13)**	**2.65 (1.20, 4.10)**	**2.22 (0.10, 4.34)**	**3.17 (1.04, 5.31)**

*Adjusted for age, sex, BMI.
βcoefficients are the change in pain score per unit change in BML size (cm^2).

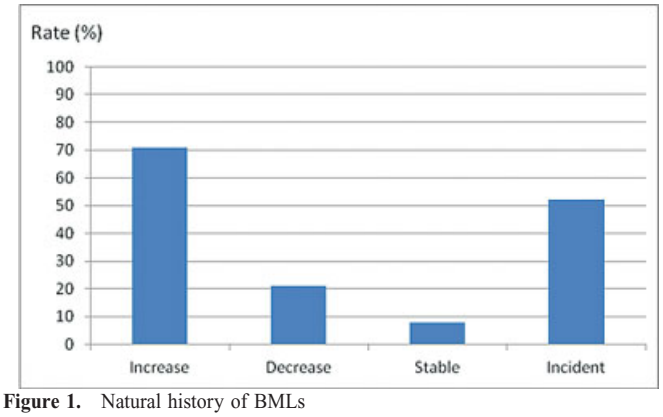

Figure 1. Natural history of BMLs

Conclusion: Over eight years, the proportion of BMLs increasing in size was more than triple those decreasing in size and stable BMLs were rare.

Incident BMLs were common, with slightly over half of our participants developing new BMLs, whilst one-fifth of BMLs resolved. Change in BML size was associated with pain only in those with a strong family history of OA, suggesting that knee pain associated with BMLs may have a genetic component.

Serum Periostin Is Associated With Prevalent Knee Osteoarthritis and Predicts Disease Progression In Women: The Ofely Study. Jean-Charles Rousseau[1], Elisabeth Sornay-Rendu[1], Cindy Bertholon[1], Patrick Garnero[2] and Roland Chapurlat[3]. [1]INSERM UMR 1033, Lyon, France, [2]INSERM, UMR 1033, Lyon and Cisbio Bioassays, Bagnols/Cèze, France, [3]INSERM UMR 1033 and Université de Lyon, Hôpital Edouard Herriot, Lyon, France.

Background/Purpose: Periostin (POSTN) is a secreted vitamin K-dependent (Gla-containing) protein produced by osteoblasts and chondrocytes. The aim of this study was to investigate the relationships between serum POSTN and both prevalent and incident knee osteoarthritis in women.

Methods: We investigated 753 women (mean age: 62.7 ± 11.2 yr) from the OFELY (Os des Femmes de Lyon) cohort, 19.3 % being premenopausal. Knee radiographs were performed and scored according to Kellgren & Lawrence at the ninth annual follow-up (baseline for this analysis) and 4 years later. Progression of knee OA was defined as an increase of the KL score ≥ 1 during the 4 years follow-up. Evaluation of the spine (X-rays), hip (self-reported) and hand OA (clinical exam) have been performed at the same visit. Serum POSTN was measured at baseline by ELISA (USCNK, China).

Results: Serum POSTN was significantly lower in the 110 women with a KL score ≥ 2 at baseline, compared to the 481 controls with a KL score < 2 (1118.9 ± 307 ng/ml vs 1182.3 ± 292 ng/ml, p = 0.018 after adjustment for age). During the 4 year follow-up, 181 women had a radiological progression in their knee OA. Baseline POSTN levels were significantly lower in progressors than in non progressors (1140 ± 296 vs 1182 ± 294 ng/ml, p = 0.039 after adjustment for age and for the presence of prevalent knee, spine, hip and hand OA**).** For each increase of one POSTN quartile, the risk of progression decreased by 0.82 (IC: 0.69–0.98, p = 0.034) after adjustment for age and for OA at the other anatomical sites.

Conclusion: We showed for the first time that serum POSTN is associated with prevalence and progression of knee OA in women. This biomarker may be of interest to study OA pathophysiology.

Metabolomics For The Identification Of Urinary Biomarkers In Knee Osteoarthritis Progression. Puja Saxena[1], Richard F. Loeser[2], Wimal Pathmasiri[3], Susan Sumner[3], Daniel Beavers[1], David J. Hunter[4] and Stephen P. Messier[5]. [1]Wake Forest University School of Medicine, Winston-Salem, NC, [2]Wake Forest School of Medicine, Winston-Salem, NC, [3]NIH Eastern Regional Comprehensive Metabolomics Resource Core, Research Triangle Park, NC, [4]University of Sydney, Sydney, Australia, [5]Wake Forest University, Winston-Salem, NC.

Background/Purpose: Obesity is an important risk factor for knee OA, not only due to effects of excess adipose tissue on joint loading, but also due to potential metabolic effects. It is not known if metabolic differences in people with OA might contribute to OA progression. The purpose of this study was to use a metabolomics approach to determine if a metabolic signature could distinguish overweight and obese adults with knee OA who exhibited radiographic progression during an 18 month exercise and/or weight loss intervention from those who did not progress.

Methods: Urine samples collected from 24 overweight or obese participants in the Intensive Diet and Exercise for Arthritis (IDEA) trial at baseline and at 18 months of follow-up were selected from two subgroups (n=12 each): a group that exhibited radiographic progression of knee OA and an age, race, sex, and BMI matched group who did not progress. Progression was defined as a decrease in medial joint space width of ≥ 0.7mm from baseline to 18 months (knees flexed at a 15° angle using a positioning device and the x-ray beam centered on the joint space). Non-progressors were defined as individuals who had a decrease in joint space width of ≤0.35mm.

Morning second void urine samples were collected at baseline and 18 months. After centrifuging and addition of internal standards, ^{1}H NMR spectra were acquired using a 950 MHz NMR spectrometer for each study sample and for a quality control sample prepared by pooling individual samples NMR data was processed by automated integration over the spectral window, and bins were normalized to the total intensity for each spectrum. Principal component analysis (PCA) and orthogonal partial least square discriminate analysis (OPLS-DA) were used to reduce the dimensionality and enable visualization of the separation of progressors and non-progressors. NMR bins that distinguished the study phenotypes were determined based on inspection of loadings plots and variable importance plots. Bins that distinguished the study groups were mapped to corresponding metabolites.

Results: The median age of this IDEA subgroup was 67 yrs. (range 60–78) and median BMI was 31.2 kg/m^2 (range 27.0–40.4). The mean minimum JSW change was −1.03 (SD=0.29, range −1.7 to −0.76) mm for progressors and 0.05 (SD=0.28 range −0.26 to +0.68)mm for non-progressors. After applying PCA, two outliers (non-progressors) with high levels of urine glucose were excluded. Using OPLS-DA, five urinary metabolites were determined that separated the progressors from non-progressors. At baseline, relatively higher levels of hippurate and glycolate and lower levels of lysine were identified in progressors. At 18 month follow-up, relatively higher levels of hippurate, glycolate, and sarcosine and lower levels of lysine and choline characterized the progressor group.

Conclusion: Metabolic differences were found for the first time to correlate with radiographic progression in overweight and obese adults with knee OA. These results merit further investigation in a larger sample set. Given that hippurate is a gut-flora derived metabolite, differences in the gut microbiome could be contributing to OA progression.

Quantifying The Risk Of Incident Type II Diabetes Following Oral Glucocorticoid Therapy In Patients With Rheumatoid Arthritis: Association With Dose and Duration Of Use. William G. Dixon[1], Mohammad Movahedi[1], Marie-Eve Beauchamp[2], David W. Ray[3] and Michal Abrahamowicz[2]. [1]The University of Manchester, Manchester, United Kingdom, [2]McGill University, Montreal, QC, [3]Institute of Human Development, The University of Manchester, Manchester, United Kingdom.

Background/Purpose: Glucocorticoid (GC) therapy is widely used in patients with rheumatoid arthritis (RA). Its association with incident type II diabetes mellitus (DM) is accepted, but the extent of the risk and its relationship with GC dose and treatment duration in RA are not known.

Methods: Adult patients with RA were identified from a large UK primary care research database using a validated algorithm during the study period 1992–2009. Patients with prevalent DM at the time of their first code for RA were excluded. GC exposure was identified from oral GC prescriptions and was analysed using multivariable time-dependent Cox models with conventional exposure measures (eg on/off treatment) and a novel weighted cumulative dose (WCD) model that accounted for

past doses and treatment duration and timing. Incident DM was defined as a READ code for type II DM, at least two oral anti-diabetic prescriptions or abnormal blood results (blood sugar, HbA1C or glucose tolerance test). Hazard ratios (HR) associated with different GC patterns were adjusted for gender, age, family history of DM, hypertension, prior cumulative dose of oral GC, current DMARDs and ever NSAID use.

Results: 22,535 adult RA patients were included. 70% were female with a median age of 60 years (IQR 49–71). Median follow-up time per patient was 5.4 years. 2,324 patients were diagnosed with type II DM during follow-up: incidence 13.7 events/1000 person years (pyrs) in unexposed patients versus 21.8 events/1000pyrs after GC exposure. Ignoring dose and duration, the conventional HR was 1.42 (1.30–1.56) in ever GC users compared with non-users. This equates to one additional case of DM per year for every 172 patients who received GCs at some time in the past. The WCD model showed risk increased with increased dose and duration of recent use, especially in the past 8 months. 5mg prednisolone equivalent (PEQ) for past 1, 3 and 6 months were associated with HRs of 1.14, 1.36 and 1.46, respectively, compared to non-use. Doses more than eight months ago added little to the current risk of DM, e.g. increasing the duration of 5mg PEQ exposure from the past 6 to 12 months increased the HR to only 1.49 compared to non-use. Risk increased significantly with dose: 30mg PEQ for 1, 3 or 6 months generated HRs of 2.2, 6.3 and 9.8, respectively, compared to non-use. 5mg or 30mg PEQ for 6 months equates to one additional case for every 140 or 7 patients treated, respectively.

Conclusion: Oral GC therapy is a clinically important and quantifiable risk factor for incident Type II DM in patients with RA, influenced by dose and duration of exposure within the last eight months.

Can RA Registries Provide Contextual Safety Data For Modern RCTs? Kaleb Michaud[1], Johan Askling[2], Hisashi Yamanaka[3], Deborah Symmons[4], Marie Holmqvist[2], Thomas Frisell[2], George Reed[5], Dimitrios A. Pappas[6], Eiichi Tanaka[3], Eisuke Inoue[3], Suzanne M.M. Verstappen[4], Christopher Garwood[4], Laura Horne[7], Kathy Lampl[7], Niklas Berglind[8], Stefan Franzen[8], Fredrik Nyberg[9], Trung Tran[10], Meilien Ho[11] and Jeffrey D. Greenberg[12]. [1]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE, [2]Karolinska Institutet, Stockholm, Sweden, [3]Tokyo Women's Medical University, Tokyo, Japan, [4]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [5]University of Massachusetts Medical School, Worcester, MA, [6]Columbia University, New York, NY, [7]AstraZeneca R&D Wilmington, Wilmington, DE, [8]AstraZeneca R&D Mölndal, Mölndal, Sweden, [9]AstraZeneca R&D, Mölndal, Sweden, [10]MedImmune LLC, Gaithersburg, MD, [11]AstraZeneca R&D Alderley Park, Macclesfield, United Kingdom, [12]NYU Hospital for Joint Diseases, New York, NY.

Background/Purpose: For ethical reasons, modern phase-III RCTs in rheumatoid arthritis (RA) have limited placebo exposure time, resulting in uncertainties when interpreting low frequency adverse events (AEs). We developed and implemented a novel method for providing contextual AE rates through coordinated analyses of 5 RA registries.

Methods: Participating observational registries included CORRONA (USA), CORRONA International (East Europe, India, Latin America), IORRA (Japan), NOAR (UK), and SRR (Sweden). By harmonizing AE definitions in a typical RA clinical trial program and corresponding available outcomes from the registries we defined specific outcomes in 4 areas: mortality, cardiovascular disease (CVD), infection, and malignancy. Each registry defined a primary cohort (all patients included from January 2000) for optimal sample size. To address comparability and potential bias several sub-cohorts were also defined for sensitivity analyses, based on disease activity, treatment, calendar time or duration of follow-up, and relevant RCT exclusions. Rates were standardized for the potential confounders age and sex, and in a sensitivity analysis also HAQ score to the distribution in a typical RA program.

Results: The primary cohorts included 57,251 RA patients (232,985 person-years [PY]) - mean (SD) baseline age 58.2 (13.8) years, 24.5% men, and RA duration 8.2 (11.7) years (Table 1). Some important demographic differences appeared; for example, smoking was most common in NOAR, and SRR had the highest proportion with early RA. Mean baseline HAQ and DAS28 were 0.88 (0.67) and 4.1 (1.5).

Specific outcome event rates were determined in each registry (Table 2). CVD rates varied the most with the lowest MI rate (0.09 per 100 PY) seen in IORRA and the highest (0.39) in SRR. Rates of hospitalized infections were quite consistent across registries. Sensitivity analysis returned higher mortality and MACE rates along with wider confidence intervals when standardized also for RCT HAQ levels. Additional sub-cohort analyses showed small and mostly consistent changes among registries.

Table 1. Baseline characteristics in 5 RA registries' primary cohorts.

Baseline characteristic	CORRONA	SRR	NOAR	CORRONA Int.	IORRA
Region	USA	West Europe		Other	
N	24,176	18,527	1,564	2,727	10,255
Age, >60 (%)	47.3	54.1	51.0	34.7	41.0
Gender, female (%)	76.0	70.3	69.9	84.7	82.2
Smoking, ever (%)	38.1	NA	66.9	26.5	37.7
RA duration, >5 yrs (%)	56.8	29.6	44.9	61.2	51.5
SJC, mean (SD)	4.3 (5.5)	6.3 (5.7)	5.8 (5.1)	2.9 (4.3)	2.8 (3.4)
TJC, mean (SD)	4.2 (5.8)	5.8 (5.8)	7.7 (8.3)	5.7 (6.7)	2.8 (3.8)
CRP, <10 mg/L (%)	72.4	47.3	37.8	64.9	62.8
DAS28, >3.2 (%)	58.3	75.9	75.0	67.4	70.5
HAQ, >1.1 (%)	35.0	39.2	54.5	49.3	30.3
RF^+ (%)	72.4	71.7	89.6	75.3	78.8
MTX from baseline (%)	64.6	71.5	33.8	68.9	74.7
Other nb-DMARDs from baseline (%)	30.1	22.4	24.2	52.8	76.2

Table 2. Standardized incidence rates (with 95% confidence intervals)* per 100 person-years of selected outcome events in 5 RA registries' primary cohorts.

Event	CORRONA	SRR	NOAR	CORRONA-INT	IORRA
All-cause mortality	0.42 (0.38, 0.46)	0.67 (0.63, 073)	0.80 (0.66, 0.98)	NA	0.74 (0.67, 0.81)
Major adverse cardiovascular events (MACE)	0.45 (0.40, 0.50)	0.77 (0.71, 0.83)	0.50 (0.39, 0.66)	0.36 (0.15, 0.81)	0.31 (0.26, 0.37)
Acute myocardial infarction (MI)	0.21 (0.18, 0.25)	0.39 (0.35, 0.43)	0.21 (0.14, 0.33)	NA	0.09 (0.07, 0.13)
Stroke	0.20 (0.17, 0.24)	0.31 (0.27, 0.35)	0.16 (0.10, 0.27)	NA	0.12 (0.09, 0.16)
Hospitalized congestive heart failure (CHF)	0.20 (0.11, 0.38)	0.16 (0.14, 0.19)	0.13 (0.07, 0.24)	0.42 (0.16, 0.92)	NA
Hospitalized infection	1.30 (1.18, 1.42)	1.62 (1.52, 1.72)	1.56 (1.30, 1.88)	1.51 (0.99, 2.24)	1.14 (1.05, 1.25)
Malignancies excluding non-melanoma skin cancer (NMSC)	0.64 (0.58, 0.71)	0.87 (0.80, 0.94)	0.77 (0.60, 0.99)	0.56 (0.27, 1.07)	0.65 (0.57, 0.75)
Solid malignancies	0.53 (0.47, 0.58)	0.86 (0.80, 0.94)	0.88 (0.70, 1.10)	0.37 (0.16, 0.81)	0.58 (0.49, 0.67)
Lymphomas	0.06 (0.04, 0.08)	0.06 (0.04, 0.08)	0.09 (0.03, 0.21)	NA	0.06 (0.04, 0.10)

* Standardized according to the age and sex distribution in a typical RA clinical trial program.
= Not Available. Too few events - incidence rates not calculated

Conclusion: While potential concern for bias may remain, we have successfully determined background safety rates that provide context for RCTs, through a coordinated approach between observational RA registries. This new approach may have utility to satisfy future regulatory requirements and support safety assessments.

Incidence and Severity Of Myocardial Infarction In Subjects Receiving Anti Tumour Necrosis Factor Drugs For Rheumatoid Arthritis: Results From Linking the British Society For Rheumatology Biologics Register For Rheumatoid Arthritis and Myocardial Ischaemia National Audit Project. Audrey SL Low[1], Kimme L. Hyrich[2], Mark Lunt[3], Louise K. Mercer[1], Christopher Gale[4], Kath Watson[1], British Society for Rheumatology Biologics Registers (BSRBR) Control Centre Consortium[1], William G. Dixon[5], Deborah P. Symmons[3] and On behalf of the BSRBR[6]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Sciences Centre, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [3]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [4]Department of Cardiology, York Teaching Hospital NHS Foundation Trust, York, United Kingdom, [5]The University of Manchester, Manchester, United Kingdom, [6]British Society for Rheumatology, London, United Kingdom.

Background/Purpose: Subjects with rheumatoid arthritis (RA) are at increased risk of myocardial infarction (MI) compared to subjects without RA, with the increased risk potentially driven by inflammation. Anti- tumour necrosis factor (TNFi) drugs may modulate the risk and severity of the MI. The aim of this analysis was to compare the risk and severity of MI in subjects treated with TNFi to non-biologic drugs (nbDMARDs) using linked data from BSRBR-RA (an ongoing prospective study of the safety of biologic therapy in RA) and the Myocardial Ischaemia National Audit Project (MINAP), a national database of hospitalisations with MI in England and Wales.

Methods: This analysis included subjects with RA starting TNFi (etanercept, infliximab, adalimumab) and a biologic-naïve comparator cohort receiving nbDMARDs recruited between 2001–2008; all followed via physician and patient questionnaires and flagged with the national death register. All subjects were also linked to MINAP using deterministic matching which provided both additional events and further event data regarding MI severity. Events from both datasets were verified using the American Heart Association/European Society of Cardiology criteria for MI with additional criteria of thrombolysis/angioplasty and MI listed as the underlying cause of death on death certificates, coded using International Classification of Diseases 10. When estimating incidence of MI, subjects were censored at first MI, death, 90 days following discontinuation of TNFi, last physician follow-up or 04/20/2010, whichever came first. The risk of MI was compared between subjects receiving nbDMARDs and TNFi using a Cox regression model, adjusted on deciles of propensity scores (PD) (Table). In a subset of MIs with additional event data from MINAP; MI phenotype and severity (using surrogates: cardiac arrest, peak creatine kinase (CK) levels and length of hospital stay) were compared between treatment groups using descriptive statistics.

Table.

	nbDMARD (n=3058)	TNFi (n=11200)	p-value
Years of follow-up per subject, median (IQR)	3.5 (1.8, 4.9)	5.3 (3.6, 6.4)	–
Person-years of exposure, pyrs	10337	55636	–
Number of verified MIs	58	194	–
Crude incidence rate of verified MIs from BSRBR & MINAP per 10,000 person-years (95% CI)	56 (43, 73)	35 (30, 40)	–
Risk of MI between nbDMARD and TNFi-treated subjects: Unadjusted HR (95%CI)	Referent	0.78 (0.58, 1.05)	–
Risk of MI between nbDMARD and TNFi-treated subjects: PD-adjusted HR (95% CI)	Referent	0.61 (0.41, 0.89)	–
Number of verified MIs with additional MINAP data	35	108	–
Phenotype of MI: n (%) of STEMI	16 (46)	53 (49)	0.32
Median peak CK, IU/L (IQR)	290 (172, 1598)	691 (150, 1293)	0.19
Cardiac arrest, n (%)	3 (8.6)	5 (4.7)	0.48
Median length of hospital stay, days (IQR)	6 (5, 9)	6 (4, 8)	0.46

Variables in PD: age, gender, disease duration, DAS28, HAQ score, steroid use, number of previous nbDMARDs, entry year to study, hypertension, diabetes, smoking, chronic lung disease, aspirin, statin, NSAID/COX2-inhibitor use, all at baseline.

Results: Using the linked data, a total of 252 verified first MIs were analysed: 58 in 3058 nbDMARD subjects and 194 in 11200 TNFi-treated subjects. The PD-adjusted hazard ratio (HR) of MI in TNFi referent to nbDMARD was 0.61 (95%CI 0.41, 0.89). The estimate was unchanged when all follow-up time following first dose of TNFi was included. There were 143 MIs (nbDMARD: 35, TNFi: 108) with additional MINAP data. No statistical differences were observed in MI severity when compared between nbDMARD and TNFi-treated subjects, although there was a trend towards higher peak CK levels recorded in TNFi-treated subjects (Table).

Conclusion: Subjects receiving TNFi drugs had a decreased risk of MI compared to subjects receiving nbDMARDs over the medium term which could relate to attributes of the drug itself or better overall disease control. The severity of MIs at presentation appears to be similar between both treatment groups.

Comparative Risks Of Herpes Zoster Among RA Patients Switching Biologics In The U.S. Medicare Program. Huifeng Yun[1], Fenglong Xie[1], Elizabeth S. Delzell[1], Lang Chen[1], Emily Levitan[1], James Lewis[2], Kenneth G. Saag[1], Timothy Beukelman[1], Kevin L. Winthrop[3], John Baddley[1] and Jeffrey R. Curtis[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Pennsylvania, Philadelphia, PA, [3]Oregon Health & Science University, Portland, OR.

Background/Purpose: Several newer biologics have been approved for treatment of rheumatoid arthritis (RA) in the United States. However, their comparative risks of herpes zoster infection are not well understood. The objective of the present study is to evaluate whether the risks of herpes zoster infections associated with various biologics differ among Medicare RA population.

Methods: Using Medicare data from 2006–2011 for patients with RA, we identified new users of abatacept, adalimumab, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab. New users were defined specific to each drug as no use of that therapy in the prior 12 month 'baseline' period. To increase homogeneity of patients characteristics to allow comparison with biologics typically not used as first line agents, patients were required to have used another biologic during baseline (i.e. they were 'switchers'). Eligible subjects must have been continuously enrolled in Medicare Parts A, B and D in baseline and throughout follow up and could not have had zoster medications during baseline. Follow up started from the drug initiation date and ended at the earliest date of: zoster infection, a 30 day gap in current exposure, death, loss of Medicare coverage or Dec 31, 2011. We identified herpes zoster infection using physician diagnosis code and use of antiviral medication within 7 days. Confounding was controlled through a person-specific infection risk score that was separately derived among biologic-naïve new users of anti-TNF and non-biologic DMARDs. We calculated the incidence rate of herpes zoster infection for each biologic and compared their herpes zoster infection risks during follow-up using Cox regression adjusting for infection risk score decile, disability status, glucocorticoids use during baseline, methotrexate use during baseline, most recent biologic during baseline and Medicaid eligibility.

Results: Of 25,274 biologic switchers, 11.3% used etanercept, 15.9% adalimumab, 6.1% certolizumab, 4.4% golimumab, 12.6% infliximab, 29.0% abatacept, 14.5% rituximab and 6.3% tocilizumab. Among 24,237 patients who had no history of herpes zoster infection, we identified 336 herpes zoster infections yielding similar crude incidence rates across different biologics. After adjustment for potential cofounders and compared to infliximab users, the adjusted hazard ratios of all types of biologics were not significantly different from infliximab users. Among 1,037 patients with a history of herpes zoster infection during baseline, we identified 14 recurrent herpes zoster infections

yielding an incidence rate for recurrence of 2.1 per 100 person years. We did not have enough data to look at drug-specific associations with recurrent infection.

Table. Events, absolute incidence rate and adjusted hazard rate of herpes zoster infection by different types of biologics

Biologic Exposures	Events	Crude incidence rate per 100 py	Adjusted Hazard Ratio* (95% CI)
Abatacept	118	1.81	0.88 (0.61–1.28)
Adalimumab	40	1.69	0.96 (0.62–1.49)
Certolizumab	14	2.03	1.14 (0.64–2.04)
Etanercept	34	1.86	1.01 (0.65–1.58)
Golimumab	<11	1.74	0.97 (0.49–1.94)
Rituximab	60	1.99	0.94 (0.63–1.41)
Tocilizumab	15	2.11	0.92 (0.50–1.69)
Infliximab	45	1.69	1.00 (Ref)

*Adjusted for age, gender, infection risk score decile, steroid use during baseline, recent biologic use during baseline, original reason for Medicare coverage and Medicaid eligibility.

Conclusion: Among patients with RA, the risk for herpes zoster was similar across biologics, include those with non-TNF mechanisms of action.

Rheumatoid and Psoriatic Arthritis Are Not Associated With Higher Risk Of Incident Diabetes Mellitus. Susan Mathew[1], Xiaoqin Tang[2], H. Lester Kirchner[3], Mary Chester M. Wasko[4] and Androniki Bili[1]. [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Center for Health Research, Danville, PA, [3]Geisinger Health System, Danville, PA, [4]Temple University School of Medicine, Pittsburgh, PA.

Background/Purpose: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are chronic inflammatory conditions that are associated with increased risk of insulin resistance and cardiovascular disease (CVD). However, the evidence for the association of these conditions with incident diabetes mellitus (DM) has been inconsistent. The purpose of this study was to evaluate this association in a cohort of patients with physician entered diagnosis and laboratory values.

Methods: We studied a retrospective cohort of patients with RA or PsA from 1/1/2001 to 12/31/2012 with age- (± 2.5 years) and gender-matched non-rheumatic controls (NRC) in a tertiary health center. Data were extracted from electronic health records. RA and PsA were defined using ICD-9 codes 714.0 and 696.0, respectively, entered twice by a rheumatologist; with a primary care physician within the health system were included. Patients with prevalent DM were excluded. Patients were followed over time for development of DM, defined by ICD-9 250, random blood glucose >200 mg/dl, HgA1c ≥6.5% or use of anti-diabetic medications; a more stringent DM diagnosis, with DM defined as HgA1c ≥6.5%, was also examined. A Poisson regression model was used to estimate the incidence rate (IR) of DM per 1000 person-years for the RA and PsA groups separately compared to the NRC. Cox proportional hazard regression (HR) models, accounting for the correlation induced by matching, were used to estimate the association on developing incident DM after adjusting for age, gender, race, body mass index (BMI), hypertension, hyperlipidemia, ESR, number of office visits, number of drug classes, glucocorticoid, immunosuppressive agent and statin use in the year prior to cohort entry. For the primary outcome, our study had 80% power to detect a 25% difference in the risk for incident diabetes between the RA/PsA and NRC groups.

Results: 1502 RA patients, 359 PsA patients and 7887 NRC were included. Overall, the mean age of the cohort was 55 years; 70% were female, and 98% were Caucasian. RA patients on average were older, more likely to be female, taking steroids and immunosuppressive drugs, and had higher ESR and lower median BMI than PsA patients. Statin use was not different across all groups. During observation, there were 1195 incident diabetes cases: 199 in the RA, 47 in the PSA and 859 in the NRC, with IR 23.2, 23.0 and 17.7 respectively, with an incidence rate ratio (IRR) of 1.32 (1.13–1.54) and 1.30 (0.97–1.75) for RA and PsA respectively compared to NRC. The adjusted HR (95% CI) for DM was 1.14 (0.94–1.38) and 1.28 (0.94–1.75) for RA and PsA respectively compared to NRC. Defining DM as HgA1c ≥ 6.5%, there were 708 incident cases: 122 in the RA, 25 in the PsA and 561 in the NRC, with IR 13.8, 11.8 and 11.2 respectively and IRR 1.05 (0.70–1.57) and 1.22 (1.01–1.49) for RA and PsA respectively compared to NRC. The HR (95% CI) was 1.06 (0.87–1.30) and 1.12 (0.82–1.52) for RA and PsA respectively compared to NRC.

Conclusion: In this cohort, RA and PsA were not associated with increased risk of incident DM, defined by both clinical and stricter laboratory criteria. Our results suggest that an excessive burden of DM does not account for the high risk of CVD in these patients.

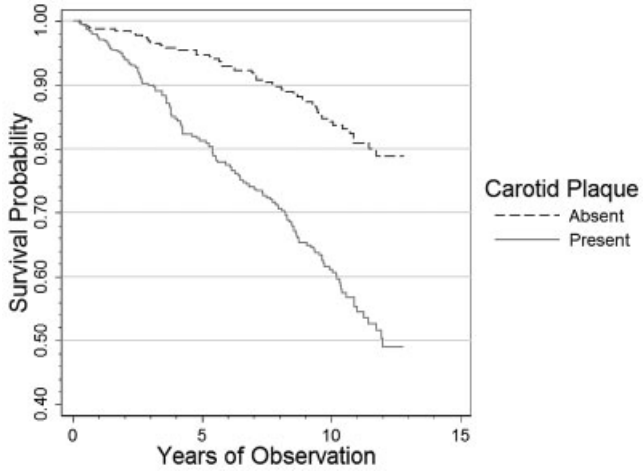
Carotid Atherosclerosis As a Predictor Of Mortality In Rheumatoid Arthritis. Inmaculada del Rincon[1], Roy W. Haas[1], Jose Felix Restrepo[1], Daniel F. Battafarano[2], Daniel H. O'Leary[3], Emily Molina[4] and Agustin Escalante[1]. [1]University of Texas Health Science Center, San Antonio, TX, [2]Brooke Army Medical Ctr, San Antonio, TX, [3]Tufts University-Boston Campus, Boston, MA, [4]University of Texas Health Science Center at San Antonio, San Antonio, TX.

Background/Purpose: Patients with rheumatoid arthritis (RA) have higher mortality than do persons of the same age and sex without RA. This is due in part to an increased risk of atherosclerosis and cardiovascular (CV) disease. The extent of atherosclerosis can be estimated non-invasively using high-resolution carotid ultrasound. In this study we examined the association of carotid atherosclerosis, as measured by carotid ultrasound, with mortality in a cohort of RA patients.

Methods: We recruited RA patients during a visit to their rheumatologist, and invited them to participate in a comprehensive clinical assessment that included a high-resolution carotid ultrasound. We also ascertained age, sex, RA duration, the CV risk factors and erythrocyte sedimentation rate (ESR), among other variables, using a predetermined protocol. After the assessment, we followed patients prospectively per protocol. We obtained a death certificate for all patients who died, from which we classified the causes of death using ICD9 codes. Deaths were classified as CV if the death certificate listed a CV condition, corresponding to ICD9 codes 390–459. We used standard time-to-event techniques to examine the association between the carotid ultrasound findings and all-cause and CV-mortality. Mortality rates are shown per 100 person-years. Rates and hazard ratios (HR) are shown with 95% confidence intervals.

Results: We recruited 1,328 RA patients, of whom 1,197 had a carotid ultrasound. We followed them prospectively over 6,500 person-years, during which 206 deaths occurred, for a mortality rate of 3.1 (2.7, 3.6). Death was attributed to a CV cause in 105 cases, for a CV mortality rate of 1.7 (1.4, 2.1). The presence of carotid plaque resulted in an increased all-cause mortality rate, 4.6 (3.9, 5.47), compared to 1.6 (1.2, 2.1) with absent plaque. The Figure shows a Kaplan Meier curve for all-cause mortality in patients with and without plaque ($P < 0.0001$, log rank test). Carotid plaque was also associated with an increased CV mortality rate, 2.7 (2.1, 3.4) vs. 0.8 (0.6, 1.2). The carotid intima-media thickness (IMT) was associated with increased all-cause mortality, with a HR of 2.28 per mm of IMT (2.00, 2.59), as well as CV mortality, with a HR of 2.26 per mm IMT (1.91, 2.68). The associations of both carotid plaque and the IMT with all-cause mortality were independent of age, sex, CV risk factors and the ESR. Their associations with CV mortality were independent of the all same variables, with the exception of the ESR.



Conclusion: Carotid atherosclerosis is significantly associated with mortality in RA, both all-cause and due to CV causes. The precise role of carotid ultrasound in mortality risk stratification and identification of candidates for intervention to reduce mortality in RA is an interesting area in need of study.

Rheumatoid Arthritis Treatment - Small Molecules, Biologics and Gene Therapy: Efficacy of Approved Biologics I

Tuesday, October 29, 2013, 4:30 PM–6:00 PM

2764

Combination of Intra-Articular Steroid Injection and Tocilizumab More Effective Than Tocilizumab in Rapid Radiographic Progression Patients With Rheumatoid Arthritis. A Randomized, Open Label, x Ray Reader Blinded Study. Kensuke Kume[1], Kanzo Amano[1], Susumu Yamada[1], Toshikatsu Kanazawa[2], Hiroshi Komori[2], Hiroyuki Ohta[3], Noriko Kuwaba[4] and Kazuhiko Hatta[5]. [1]Hiroshima Clinic, Hiroshima, Japan, [2]Hiroshima Clinic, Hiroshima, Japan, [3]Hiroshima Clinic, Hiroshima, Japan, [4]Sanki Clinical Link, Hiroshima, Japan, [5]Hatta Clinic, Kure, Japan.

Background/Purpose: Treatment of rheumatoid arthritis (RA) should aim at full remission. However, recent publications described rapid radiographic progression (RRP) existed despite initial biologics and methotrexate combination therapy in early RA. In RRP, initial biologics and methotrexate might be inadequate. We reported that infliximab plus intra-articular steroid injection is more effective than infliximab in RRP patients in RA. How about other biologics? To compare remission and radiographic non-progression in RRP patients treated with tocilizumab or with tocilizumab plus intra-articular steroid injection.

Methods: We designed a single-blind (X ray reader and assessment physician), randomized controlled trial. We screened 32 RRP (CRP> 35mg/L, RF +, and ACPA+) early (disease duration<6 months) RA patients for inclusion. 28 were randomly allocated tocilizumab group (T group) or tocilizumab plus intra-articular steroid injection group (T plus I group). All patients were taking methotrexate (from 12 to 22mg a week). For T plus I group, palpate examinations of both MP and PIP joints, wrists, elbows, shoulders, and knees were performed every 4 weeks. If swollen joints were existed, intra-articular steroid injections were intensified in each swollen joints by clinician's decision. **Co-** primary endpoints were proportion of patients showing clinical remission (SDAI <3.3) and radiographic non-progression (Δ modified total Sharp score ≤0.5) at 52 weeks. Analysis was by intention-to-treat with last observation carried forward to missing data.

Results: The characteristics of each group at baseline were not significantly different. Clinical remission at 52weeks was achieved by more patients in the T plus I group (42%) than in the T group (25%) ($p<0.05$). Radiographic non-progression at 52 weeks was achieved by more patients in the T plus I group (41%) than in the T group (18%) ($p<0.05$). Especially, swollen and tender joints counts at 52 weeks are significantly improved T plus I group(SJC: 3.6±1.3, TJC:4.2±2.1) than T group.(SJC: 8.5±4.2, TJC: 6.2±3.5)(p $p<0.05$). However C reactive protein at 52 is not significantly difference each group (T plus I group: 0.21±0.12 mg/L, T group: 0.26±0.22 mg/L) ($p=0.67$).

Conclusion: Results of this reveal that combination of intra-articular steroid injection and tocilizumab can achieve a high clinical and radiological remission rate in early RRP RA.

A Double-Blind Randomized Placebo-Controlled Trial Of Lovastatin in Patients with Rheumatoid Arthritis. Cynthia Aranow[1], John J. Cush[2], Marcy B. Bolster[3], Christopher C. Striebich[4], Maria Dall'Era[5], Meggan Mackay[1], Ewa Olech[6], Tracy M. Frech[7], J. Box[8], Richard M. Keating[9], Mary Chester M. Wasko[10], E. William St Clair[11], Alan Kivitz[12], Betty Diamond[1], Anne Davidson[1], Meagan Spychala[13], Ellen A. Goldmuntz[14] and Autoimmunity Centers of Excellence[15]. [1]Feinstein Institute for Medical Research, Manhasset, NY, [2]Baylor Research Institute and Baylor University Medical Center, Dallas, TX, [3]Medical University of South Carolina, Charleston, SC, [4]University of Colorado Denver, Aurora, CO, [5]University of California, San Francisco, San Francisco, CA, [6]Oklahoma Medical Research Foundation, Oklahoma City, OK, [7]University of Utah School of Medicine, SLC, UT, [8]Carolina Bone and Joint, Charlotte, NC, [9]The University of Chicago, Chicago, IL, [10]Temple University School of Medicine, Pittsburgh, PA, [11]Duke Unversity Medical Center, Durham, NC, [12]Altoona Center for Clinical Research, Duncansville, PA, [13]Rho, Inc., Chapel Hill, NC, [14]NIAID/NIH, Bethesda, MD, [15]National Institutes of Health, Bethesda, MD.

Background/Purpose: HMG-CoA reductase inhibitors (statins) are standard treatment for hyperlipidemia. In addition to lipid lowering abilities, statins exhibit multiple anti-inflammatory effects. The objectives of this study were to determine if treatment of patients with Rheumatoid Arthritis (RA) with lovastatin decreased CRP or reduced disease activity.

Methods: We conducted a randomized double blind placebo controlled 12 week trial. 64 patients with mildly active RA (defined as 2–8 tender joints and 1–6 swollen joints) and an elevated CRP (> 5mg/L) were randomized (1:1) to receive lovastatin 80mg or placebo. Patients could be on stable prednisone ≤ 10 mg, DMARDs and/or biologic therapy. The primary efficacy endpoint was the reduction in mean log CRP. Secondary endpoints included disease activity, RF and anti-CCP antibody titers. Safety was a co-primary endpoint; hepatic and muscle toxicities were of particular interest.

Results: Baseline features of the treatment groups were similar. The mean baseline CRP was 12.2 mg/L in the lovastatin arm and 12.6 mg/L in the placebo arm; mean baseline DAS-28 CRP was 3.5 and 3.6 in the lovastatin and placebo arms, respectively. No significant differences in mean log CRP reduction or % change in CRP from baseline between the two treatment arms were observed. No significant difference between the lovastatin and placebo arms was observed in a longitudinal model of the estimated mean log CRP. Disease activity assessed by DAS28 did not change from baseline in either lovastatin or placebo treated groups (−0.42 and −0.58, respectively, ns). At week 12, clinical responses were comparable in subjects receiving lovastatin or placebo: ACR 20 (29% vs.

40%) and Good/Moderate EULAR response (42% vs. 44%). Autoantibody titers were stable during the course of the study with no group differences. Although not statistically different, the frequency of subjects receiving biologic therapy was greater in the lovastatin treated group than placebo (59% vs. 38%). A post-hoc analysis of subjects not using biologic therapy (n=32) demonstrated a significantly greater proportion achieving ≥15% reduction in CRP from baseline in the lovastatin treated group (83%) compared to placebo (33%; p = 0.019). No analogous difference was observed in subjects receiving biologics (47% vs. 60%). The mean change from baseline CRP in subjects not using biologics was also numerically greater in subjects taking lovastatin (−4.75) than placebo (−2.00). Lovastatin was well tolerated with no serious safety concerns. Several subjects experienced transient reversible elevations of transaminases. Clinical myositis was not observed.

Conclusion: Statins were well tolerated in our patient population. This study showed no anti-inflammatory or clinical effects after 12 weeks of treatment with lovastatin. However, we observed a potential modest effect of lovastatin in subjects not using biologics, suggesting statins may be anti-inflammatory in selected patients.

Improvement In Insulin Resistance Greater With The Use Of Infliximab Following Intensive Treatment Of Early Rheumatoid Arthritis. Lesley-Anne Bissell[1], Elizabeth Hensor[2], Sarah L. Mackie[2], Agata Burska[2], Jackie L. Nam[2], Lukasz Kozera[2], Helen I. Keen[2], Edith Villeneuve[2], Heike Eberl[3], Helena Donica[4], Philip G. Conaghan[5], Jacqueline Andrews[2], Paul Emery[6] and Ann W. Morgan[2]. [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [2]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [3]Roche Molecular Diagnostics, Burgess Hill, United Kingdom, [4]Department of Biochemical Diagnostics, Medical University of Lublin, Lublin, Poland, [5]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [6]Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom.

Background/Purpose: Insulin resistance (IR), N-terminal pro-brain natriuretic peptide (NT-proBNP) and total cholesterol/high density lipoprotein cholesterol ratio (TC/HDL-C) profiles have been proposed as surrogate measures of CVD in RA, with some improving with suppression of disease activity. In early RA, few randomised controlled trials (RCTs) have compared the effects of DMARDs with TNFi on these biomarkers. A recent cohort study has linked TNFi to a reduced risk of diabetes. We aimed to determine whether TNFi had greater influence over DMARDs on homeostasis model assessment of IR (HOMA-IR), NT-proBNP and TC/HDL-C.

Methods: The Infliximab as Induction therapy for Early rheumatoid Arthritis (IDEA) multicentre double-blind RCT recruited 112 DMARD-naïve RA patients (pts) (1987 ACR criteria; 3–12 months duration). Pts were randomised 1:1 to IFX+MTX or MTX with single-dose 250mg IV methylprednisolone (MP) as induction therapy. Treatment was blinded to week 26 then guided using a treat to target (T2T) approach. 120mg IM MP was given in both groups at weeks 6, 14 and 22 if DAS>2.4 at that visit. A single centre conducted the CV sub-study. Fasting glucose, lipids, insulin and NT-proBNP were measured at baseline, week 26 (w26) and 78 (w78). Multiple imputation by chained equations, using predictive mean matching, created 20 datasets; linear regression analyses adjusted for baseline values. HOMA-IR (glucose*insulin/405) and NT-proBNP values were ln-transformed prior to analysis.

Results: CV biomarker data were available for 86 pts; 7 had known CVD and were excluded from the subsequent analysis. Of the 79 pts included (age 51.6 [range 19–75], 71% female, 57% RF+ve, 72% ACPA+ve), 38 received IFX and 41 MP. Baseline clinical characteristics were similar between the two groups, including CV risk factors. DAS44 remission rates did not differ between TNFi and DMARD groups at w26 (32% vs. 37%, p=0.956) and w78 (43% vs. 54%, p=0.593). In both groups the three surrogate CVD markers improved on average at w26 and w78 (see Table 1). TC/HDL-C or NT-proBNP did not differ, but the TNFi group showed greater improvement in HOMA-IR at w78. Adjusting for IA/IM steroid injection dose did not alter the result.

Table 1. Changes in surrogate measures of CVD over 78 weeks

	Baseline		Change at week 26			Change at week 78		
	MTX+IFX n=38	MTX+IV Steroid n=41	MTX+IFX	MTX+IV Steroid	Adjusted difference (95% CI), p-value	MTX+IFX	MTX+IV Steroid	Adjusted difference (95% CI), p-value
TC/HDL-C (mean (SD))	5.14 (1.60)	5.71 (2.26)	−0.67	−0.96	0.11 (−0.45, 0.66), p=0.709	−0.86	−1.01	−0.08 (−0.89, 0.73), p=0.838
HOMA-IR (geometric mean)*	2.17	2.54	FU/BL 0.68	FU/BL 0.69	IFX/IVS 0.87 (0.65, 1.16) p=0.333	FU/BL 0.51	FU/BL 0.87	IFX/IVS 0.51 (0.35, 0.76) p=0.001
NT-proBNP (geometric mean)*	82.47	62.92	FU/BL 0.80	FU/BL 0.82	IFX/IVS 1.06 (0.77, 1.46) p=0.708	FU/BL 0.85	FU/BL 0.88	IFX/IVS 1.06 (0.73, 1.52) p=0.768

*it was not possible to calculate SD in original units for log-transformed variables

Conclusion: Treatment of early RA was associated with improvement in TC/HDL-C, IR and NT-proBNP. To our knowledge this is the first double-blinded RCT to compare the change in HOMA-IR with TNFi versus non-TNFi in early DMARD-naive RA. We determined a greater long-term improvement in HOMA-IR in those treated with TNFi; on average at w78 HOMA-IR values were around half (0.51 times) as high as those treated with MTX/IV steroid. When implementing a T2T approach, there appears to be an advantage with the use of TNFi. Longer term follow up is underway to determine if these findings translate into reduced overt CVD.

Tocilizumab In Combination Therapy and Monotherapy Versus Methotrexate In Methotrexate-Naive Patients With Early Rheumatoid Arthritis: Clinical and Radiographic Outcomes From a Randomized, Placebo-Controlled Trial. Gerd R. Burmester[1], William Rigby[2], Ronald F. van Vollenhoven[3], Jonathan Kay[4], Andrea Rubbert-Roth[5], Ariella Kelman[6], Sophie Dimonaco[7] and Nina Mitchell[7]. [1]Charité - Universitätsmedizin Berlin, Berlin, Germany, [2]Dartmouth-Hitchcock Medical Center and Dartmouth Medical School, Lebanon, NH, [3]Karolinska Institute, Stockholm, Sweden, [4]UMass Memorial Medical Center and University of Massachusetts Medical School, Worcester, MA, [5]University of Cologne, Cologne, Germany, [6]Genentech, South San Francisco, CA, [7]Roche, Welwyn Garden City, United Kingdom.

Background/Purpose: Recent recommendations support intensive treatment of patients (pts) with early rheumatoid arthritis (RA) to achieve remission or low disease activity.[1–3] Tocilizumab (TCZ) was not previously studied exclusively in an early RA population. The purpose of this study was to assess the efficacy and safety of TCZ ± methotrexate (MTX) vs MTX in MTX-naive pts with early RA (defined as ≤2 y since diagnosis).

Methods: Pts were randomized 1:1:1:1 (double-dummy, double-blind) to receive TCZ 8 mg/kg (TCZ8) + MTX (primary intervention), TCZ8 monotherapy (TCZ8 MONO), TCZ 4 mg/kg (TCZ4) + MTX, or MTX for 104 wks. Pts received IV TCZ q4w, and MTX starting at 7.5 mg qw and escalating to 20 mg qw by wk 8. Inclusion criteria included RA duration ≤2 y, DAS28 >3.2, MTX-naive, elevated ESR or CRP, and presence of RF or anti-CCP antibodies or radiographic erosion(s). Primary endpoint was proportion of pts achieving DAS28 remission (DAS28 <2.6) at wk 24. Key secondary endpoints included mean changes from baseline (BL) to wk 52 in van der Heijde–modified Total Sharp Score (mTSS) and improvement in physical function (using HAQ-DI). A hierarchy of statistical testing was implemented to control the type 1 error rate for multiplicity. This trial is ongoing; 52-wk data are reported here.

Results: The intent-to-treat population consisted of 1157 pts. BL characteristics were similar in all treatment groups: mean RA duration, 0.4–0.5 y; mean DAS28, 6.6–6.7; mTSS, 5.66–7.72. Statistically significantly greater proportions of TCZ8 + MTX vs MTX pts achieved DAS28 remission and ACR20/50/70 responses at wks 24 and 52 ($p < 0.05$); statistically significant improvements in mean mTSS and HAQ-DI were also observed at wk 52 ($p < 0.05$; Table). TCZ8 MONO was also statistically significant for the primary endpoint of percentage of DAS28 remission responders in comparison to MTX at wk 24 ($p < 0.05$). Both TCZ8 MONO and TCZ4 + MTX exhibited numerically greater improvements vs MTX across key secondary endpoints and were more efficacious than MTX in preventing structural joint damage (Table). Adverse events (AEs) observed with TCZ were consistent with its known safety profile. Incidences of AEs and serious AEs were similar across groups, while serious infections were highest with combination therapy (Table). Overall, 9 deaths were observed across all groups; causes of death were variable.

Table. Primary and Selected Secondary Efficacy Endpoints (ITT Population) and Safety Data

	TCZ8+MTX n = 290	TCZ8 MONO n = 292	TCZ4+MTX n = 288	MTX n = 287

Deaths, n(%)	2 (0.7)	1 (0.3)	4 (1.4)	2 (0.7)

ITT, intent-to-treat; OR, odds ratio.
efficacy comparisons versus MTX (MTX + placebo). ***$p < 0.0001$; **$p < 0.001$: *$p < 0.05$.
†††$p < 0.0001$ and †$p < 0.05$; these comparisons occurred after break in the hierarchical testing sequence.
[a]Analyses were based on safety population to 52 weeks (TCZ8 + MTX, n = 290; TCZ8 MONO, n = 292; TCZ4 + MTX, n = 289; MTX, n = 282); multiple occurrences of the same AE in a patient were counted only once.
[b]$p < 0.05$; ACR/EULAR Boolean remission, ACR/EULAR index (SDAI) remission, and CDAI remission were performed as post hoc exploratory analyses; therefore, p values were not adjusted for multiplicity.

Conclusion: TCZ is effective as combination therapy and monotherapy in MTX-naive pts with early active RA. TCZ resulted in greater improvements from BL in signs, symptoms, and physical function and in inhibition of structural joint damage in all treatment groups vs MTX alone. Of the 3 TCZ treatment groups, efficacy outcomes for TCZ vs MTX were consistently greatest in the TCZ8 + MTX group. The overall safety of TCZ was consistent with its known profile.

Intravenous Golimumab Inhibits Radiographic Progression and Maintains Clinical Efficacy and Safety In Patients With Active Rheumatoid Arthritis Despite Methotrexate Therapy: 2-Year Results Of a Phase 3 Trial Of Intravenous Golimumab.

Michael E. Weinblatt[1], Clifton O. Bingham III[2], Alan M. Mendelsohn[3], Lilianne Kim[3], Kim Hung Lo[3], Lenore Noonan[3], Daniel Baker[3] and Rene Westhovens[4]. [1]Brigham and Women's Hospital, Boston, MA, [2]Johns Hopkins University, Baltimore, MD, [3]Janssen Research & Development, LLC., Spring House, PA, [4]University Hospital KU Leuven, Leuven, Belgium.

Background/Purpose: To evaluate long-term clinical/radiographic efficacy of IV GLM 2mg/kg+MTX in active RA despite MTX through wk112.

Methods: 592 pts with active RA (≥6/66 SJC, ≥6/68 TJC, CRP≥1.0mg/dL, RF and/or anti-CCP positive) despite ≥3 months of MTX (15–25mg/wk) participated in this multicenter, randomized, double-blind, placebo (PBO)-controlled study. Pts were randomized to IV GLM 2mg/kg or PBO at wks0&4 and q8wks; all pts continued stable MTX. PBO pts with <10% improvement in SJC+TJC at wk16 could early escape to IV GLM 2mg/kg (wks16&20, q8wks). All PBO pts received IV GLM 2mg/kg starting at wk24. Primary endpoint was wk14 ACR20. Radiographs of hands and feet at wks 0, 24(wk16, early escape), 52, and 100 were scored by 2 independent readers and adjudicator (as needed) using the vdH-S score. Reading Session 2 included wk0, wk52, and wk100 scoresIn general, analyses at wks 24, 52, and 100 were performed using ITT methodology, with imputation for missing data.

Results: 82% of pts (486/592) continued through wk112; 106 pts d/c, mostly due to AEs(44pts) and few due to lack of efficacy (12pts). At wk14, significantly ($p<0.001$) larger proportions of GLM+MTX vs PBO+MTX pts had ACR20/50/70, DAS28-CRP good/moderate responses, and greater improvements in HAQ. Clinical improvements were maintained through wk100 (final efficacy visit), when ACR20/50/70 responses among all GLM+MTX-treated pts were 68.1%, 43.8%, and 23.5%, resp; DAS28-CRP moderate/good response was 81.9%; and median improvement from wk0 in HAQ was 0.5; 67.1% of GLM+MTX pts had improvement in HAQ ≥0.25 from baseline. GLM+MTX-treated pts continued to have significantly less radiographic progression based on vdH-S total and subscores vs PBO+MTX at wk24, and PBO+MTXàGLM + MTX at wk52 and wk100. Pts randomized to PBO+MTX who began GLM at wk16/24 demonstrated marked slowing of radiographic progression from wk24–52 and from wk52–100. Through wk112 (final safety visit), the mean follow-up for all GLM-treated pts was 96wks. AEs and serious AEs occurred in 79% and 18%, resp, of GLM-treated pts (vs 49% and 2% at wk24). 3 cases of TB and 2 serious opportunistic infections (cryptococcal pneumonia, intervertebral discitis) were reported through wk112. 6pts (1.0%) died: 1 PBO+MTX and 5 (0.8%) GLM+MTX (pneumonia/MI, dehydration, abdominal TB, unknown × 2). Through wk112, the proportion of infusions with infusion reactions was 0.4% and the proportion of pts with infusion reactions was 3.9% (vs. 1.1% and 3.5%, respectively, at wk24).

RADIOGRAPHIC PROGRESSION (mean ± standard deviation)	Placebo → GLM 2 mg/kg + MTX (n=197)	GLM 2mg/kg + MTX (n=395)	All GLM 2 mg/kg + MTX (n=592)
Baseline Total vdH-S	50.26 ± 59.85	47.59 ± 54.63	–
Total vdH-S change from baseline at wk24	1.09 ± 3.19	0.03 ± 1.90 ***	–
Total vdH-S change from baseline at wk52	1.22 ± 3.98	0.13 ± 3.11**	0.49 ± 3.46
Total vdH-S change from baseline at wk100	2.10 ± 7.42	0.74 ± 6.32**	1.19± 6.73
Total vdH-S change from wk24-wk 52	0.12 ± 2.44	0.15 ± 1.83	0.14 ± 2.06
Total vdH-S change from wk52-wk100	0.80 ± 3.03	0.58 ± 3.07	0.64 ± 3.06

**, ***p-value vs. placebo + MTX <0.01, 0.001, respectively. Pts with missing total vdH-S score at wk52 excluded.

Conclusion: IV GLM+MTX significantly inhibited radiographic progression (vdH-S scores) at wks 24,52 and 100. Among PBO-treated pts who began GLM at wk16/24, marked slowing of radiographic progression, to rates similar to pts randomized to GLM, was observed from wk24–52 and from wk52–100. IV GLM+MTX also significantly improved and maintained RA signs/symptoms in pts with active RA despite ongoing MTX and continued to demonstrate an acceptable safety profile through wk112.

Clinical Remission After 52 Weeks Of Treatment Is a Predictor Of Adalimumab-Free Disease Control In Patients With Early Rheumatoid Arthritis: Hopeful 2 Study. Yoshiya Tanaka[1], Hisashi Yamanaka[2], Naoki Ishiguro[3], Nobuyuki Miyasaka[4], Katsuyoshi Kawana[5], Tadamichi Kubo[5], Aki Kuroki[5] and Tsutomu Takeuchi[6]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan, [3]Nagoya Univeristy Graduate School of Medicine, Nagoya, Japan, [4]Tokyo Medical and Dental University, Tokyo, Japan, [5]AbbVie GK, Tokyo, Japan, [6]Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Although it is possible to achieve remission or low disease activity (LDA) with the combination of methotrexate (MTX) and biologics for many patients with early rheumatoid arthritis (RA), it is uncertain whether disease is controlled following withdrawal of biologics. The purpose of this observational study was to assess the effect of withdrawal of adalimumab (ADA) on disease activity following treatment with MTX plus ADA, and to identify predictors of biologic-free disease control in patients with early RA.

Methods: Patients with early RA received blinded ADA 40 mg every other week (EOW) plus MTX 6–8 mg every week (EW) or MTX 6–8 mg EW alone for 26 weeks. Thereafter, all patients received open-label ADA 40 mg EOW plus MTX 6–8 mg EW for 26 weeks in the HOPEFUL 1 study. At week 52, patients could be enrolled in the 52-week observational, follow-up, HOPEFUL 2 study, during which time they received ADA plus MTX treatment (ADA-continued group), or MTX alone (ADA-withdrawal group) at the investigator's discretion. The primary outcomes of this study were disease activity score based on 28 joints count based on erythrocyte sedimentation rate (DAS28-ESR), Health Assessment Questionnaire-Disability Index (HAQ-DI), and modified total Sharp score (mTSS) at week 104. The factors correlated with the outcomes were also analyzed.

Results: Among 278 patients completing the 52-week HOPEFUL 1 study, 220 were enrolled in the HOPEFUL 2 study. At week 52, baseline characteristics including DAS28-ESR, HAQ-DI and mTSS were comparable between the ADA-continued (N=106) and ADA-withdrawal (N=114) groups. 70% and 50% from each group achieved low disease activity (LDA, DAS28-ESR<3.2) and clinical remission (DAS28-ESR<2.6), respectively. Table shows disease activity scores at week 104. Mean DAS28-ESR score at week 104 was significantly higher and the percentage of the patients who achieved LDA or clinical remission was significantly lower in the ADA-withdrawal group. There was no significant difference in HAQ-DI score and ΔmTSS in the two groups at week 104. In the ADA-withdrawal group, lower baseline CRP scores and lower DAS28-ESR scores at week 52 predicted LDA at week 104 in multivariate analysis. The cut-off point to sustain LDA through week 104 without using ADA was DAS28-ESR< 2.6 at week 52.

Table. Disease activity scores at week 104 in ADA-continued group and ADA-withdrawal group

	ADA-continued group	ADA-withdrawal group	P value
DAS28-ESR, Mean±SD	2.70±1.08	3.20±1.24	0.006
% of DAS28-ESR<3.2	72.5	55.8	0.021
% of DAS28-ESR<2.6	53.8	36.8	0.026
HAQ-DI, Mean±SD	0.20±0.29	0.26±0.39	0.609
ΔmTSS from week 52, Mean±SD	0.8±3.9	0.6±1.8	0.335

Conclusion: More patients who continued ADA therapy sustained LDA and clinical remission after 1 year. Nevertheless, half of ADA-withdrawal RA patients sustained LDA for 1 year. Achieving DAS28-ESR-remission after 52 weeks of treatment using ADA was the key determinant for biologic-free disease control in early RA patients.

Center for Autoimmune Diseases Research (CREA), Bogotá, Colombia, [17]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background/Purpose: Primary Sjögren's syndrome (pSS) is a common, heterogeneous exocrinopathy. Etiology involves complex environmental, genetic and genomic influences driving innate and adaptive autoimmune responses. This study sought to integrate genome-wide association study (GWAS) and classical HLA allele associations in SS, and to explore this genetically complex region for insight into disease mechanisms through bioinformatic approaches.

Methods: Genotype data was collected for 1638 pSS cases and 6754 controls on Illumina Omni1-Quad or ImmunoChip arrays. HLA classical allele imputation was performed using HiBag with a certainty threshold of >80% to define relationships with single nucleotide polymorphisms (SNPs). A set of 9122 pSS associated SNPs (P<5×10E-5) were tested for enrichment using GenomeRunner to determine if the set of SNPs co-localize with various functional genomic elements such as specific transcription factor binding sites. A subset of SS associated SNPs that were significantly enriched in genomic locations near functional elements related to the transcriptional regulator, RFX5, were tested by expression quantitative trait locus (eQTL) analysis using the MATRIXeQTL package in R using transcript levels measured by Illumina WG-6 arrays in 133 subjects.

Results: After adjusting for the most significant GWAS variant (rs115575857 in HLA Class II; P=1.65×10E-114), we found a second independent effect peaking at rs116232857 (P=1.33×10E-96). Imputation and regression analyses identified the previously reported ancestral haplotype including DQB1*0201 (P=1.38×10E-95), DQA1*0501 (P=8.50×10E-94), and DRB1*0301 (P=2.19×10E-84) and indicated rs115575857 was synonymous with this haplotype. The association at rs116232857 persisted and

accounted for DQB1*0501, but DQB1*0501 could not account for rs116232857, suggesting rs116232857 either tags multiple functional effects or, alternatively, DQB1*0501 is a false positive. Statistically significant co-localization (P=1.53×10E-14) was observed showing that 160 HLA region variants are located within or near (100 bp) ChIP-seq peaks for RFX5, a key transcriptional regulator of HLA Class I and II loci. Further analyses of RFX5 related variants identified multiple eQTLs (P-values between 8.31×10E-11 and 4.54×10E-33) in both the Class I and Class II HLA loci and include HLA-DRB6, HLA-C, HLA-DPB1, HLA-DQA1, and HLA-A. Risk alleles for these eQTLs reside on both pSS associated haplotypes.

Conclusion: We conclude that the ancestral haplotype of DQB1*0201, DQA1*0501, and DRB1*0301 corresponds to our top GWAS effect, rs115575857 and the second independent effect at rs116232857 is novel. RFX5 was identified as a novel potential functional candidate as the RFX5 binding elements were enriched for pSS associated variants affecting HLA Class I and II expression levels. This work suggests that complex functional elements in the HLA region involved in both transcriptional regulation and peptide binding impact SS.

Background/Purpose: NK cells are an important subset of cells involved in innate immunity. Their possible role has never been studies in pSS pathogeny. We aimed to assess the involvement of NCR3/NKp30, a NK-specific activating receptor regulating the cross-talk between NK and dendritic cells and type II IFN secretion, and its receptor named B7H6 in pSS pathogenesis.

Methods: First, a cohort of 584 pSS patients (ASSESS + KB cohort) and 451 controls of Caucasian ancestry, addressed by 48 AIMs, was used for exploratory genetic study. Nine single nucleotide polymorphisms (SNPs) within the 6p21.3 *NCR3* locus and 3 additional SNP proxies for *HLA-DR2,HLA-DR3* and *TNF-308* were genotyped. Two *NCR3* SNPs (rs11575837, rs2736191) and the SNP proxy for HLA-DR3 (rs2187668) were genotyped in the replication study that included 436 pSS Scandinavian patients and 441 healthy controls. Then, NKp30 mRNA levels were investigated in 102 pSS patients from the French ASSESS cohort according to their genotype. Second, we performed phenotypic characterization of NK cells in 38 pSS patients compared to 30 age-matched controls. The functional relevance of expression levels of NKp30 on NK cells was assessed by a cross-linking assay to analyze degranulation and IFN-γ secretion. Third, we assessed the presence of NK cells by immunohistochemistry (IHC) and transcriptional level of B7H6 within salivary glands. Last we investigated the NKp30-dependent cross-talk between NK cells and epithelial cells within salivary glands.

Results: Our case-control study of genetic polymorphisms of the NCR3/NKp30 gene demonstrated that the rare allele of the rs11575837 (G>A) residing in the promoter was protective for pSS and was associated with reduced gene transcription and function. We also demonstrated that circulating levels of NCR3/NKp30 were markedly increased among pSS patients compared with controls and correlated with higher NCR3/NKp30 IFN-γ secretion by NK cells. Excess accumulation of NK cells in minor salivary glands correlated with the severity of the exocrinopathy. B7-H6, the ligand of NKp30, was expressed by salivary epithelial cells and regulated by TNF-α triggering NKp30 mediated-effector functions.

Conclusion: These findings suggest that NK cells are involved in pSS pathogeny. Different levels of evidence (genetics, mRNA expression, function in blood, presence in the target organ as well as the ligand) demonstrate an NKp30-dependent inflammatory state in salivary glands. Blockade of the B7H6/NKp30 axis could be clinically relevant in pSS.

Identification Of a Sjögren's Syndrome-Associated Variant That Influences *OAS1* Isoform Switching. He Li[1], John A. Ice[2], Jennifer A. Kelly[2], Indra Adrianto[2], Stuart B. Glenn[2], Kimberly S. Hefner[3], Evan G. Vista[4], Donald U. Stone[1], Raj Gopalakrishnan[5], Glen D. Houston[1], David M. Lewis[1], Michael Rohrer[5], Pamela Hughes[5], John B. Harley[6], Courtney G. Montgomery[2], James Chodosh[7], James A. Lessard[8], Juan-Manuel Anaya[9], Barbara M. Segal[10], Nelson L. Rhodus[5], Lida Radfar[1], R. Hal Scofield[2], Christopher J. Lessard[1] and Kathy L. Sivils[2]. [1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Hefner Eye Care and Optical Center, Oklahoma City, OK, [4]University of Santo Tomas, Taguig City, Philippines, [5]University of Minnesota, Minneapolis, MN, [6]US Department of Veterans Affairs Medical Center, Cincinnati, OH, [7]Massachusetts Eye and Ear Infirmary, Harvard Medical School, Boston, MA, [8]Valley Bone and Joint Clinic, Grand Forks, ND, [9]School of Medicine and Health Sciences, Universidad del Rosario, Bogotá, Colombia, [10]Hennepin County Medical Center, Minneapolis, MN.

Background/Purpose: Sjögren's syndrome (SS) is a common, progressive autoimmune exocrinopathy characterized by symptoms of dry eyes and mouth present in 0.7–1% of the European population. Our previous gene expression profiling (GEP) study has demonstrated overexpression of transcripts induced by interferons (IFN) in SS patients. Here, we sought to identify and characterize underlying genetic contributions to dysregulation of IFN pathways in SS.

Methods: IFN signature genes of interest were selected from GEP studies performed in 180 SS cases and 73 controls using Illumina Human WG-6 v3.0 microarray data and evaluated for *cis*-expression quantitative trait loci (eQTL) in 222 subjects by integration with genome-wide association study (GWAS) data. Gene splicing patterns were evaluated using microarray data and supplemented with RNA-sequencing (RNA-seq) performed in 57 SS cases and 27 controls on the Illumina platform. Transcripts measured by RNA-seq were reconstructed using Cufflinks and the relative abundance of isoforms was compared across samples according to genotypes for loci of interest.

Results: GEP showed that *OAS1*, an IFN-inducible gene involved in inhibition of virus replication, was significantly overexpressed in SS patients. Multiple *cis*-eQTL were identified in *OAS1* with the most significant peaking at rs10774671, strengthening prior evidence of this variant for disease association ($P=6\times10^{-3}$) obtained in our large GWAS dataset consisting of 395 cases and 1975 controls. We further replicated this genetic association in an independent set of 648 cases and 2927 controls followed by meta-analysis using a weighted Z score ($P_{meta}=9\times10^{-6}$; OR=0.79). The rs10774671 A allele conferred risk, is a splice site variant located at the intersection between intron-5 and exon-6, and thus may switch the primary normal isoform, p46, to various alternatives. To characterize functional impact of this variant, we evaluated alternative splicing events using both microarray and RNA-seq data. Variation in splicing was detectable by a microarray probe that specifically recognizes a truncated form of *OAS1* (p42). Both microarray and RNA-seq showed that the risk allele A, which demolishes the splicing consensus sequence, was correlated with higher expression of p42 ($P_{micro}=2\times10^{-16}$ and $P_{seq}=1\times10^{-15}$). RNA-seq results also showed correlation of the A risk allele with higher proportions of p48 and p44 isoforms ($P=9\times10^{-8}$ and $P=4\times10^{-4}$, respectively), but a lower expression of the functionally normal isoform, p46 ($P=4\times10^{-30}$).

Conclusion: We identified *OAS1* as a novel candidate SS locus that confers risk through a functional eQTL at rs10774671. This splice site variant switches the primary p46 isoform to multiple alternatives with decreased OAS1 enzyme activity potentially contributing to reduced ability to inhibit viral replication. These results indicate the risk allele may cause vulnerability to viral infection that contributes to SS susceptibility.

Genome-Wide DNA Methylation Patterns In naïve CD4+ T Cells From Patients With Primary Sjögren's Syndrome. Nezam I. Altorok[1], Patrick S. Coit[1], Travis Hughes[1], Kristi A. Koelsch[2], R. Hal Scofield[3], Kathy L. Sivils[3], A. Darise Farris[4] and Amr H. Sawalha[1]. [1]University of Michigan, Ann Arbor, MI, [2]Oklahoma Medical Research Foundation, Okalahoma City, OK, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]Oklahoma Medical Research Foun, Oklahoma City, OK.

Background/Purpose: Primary Sjögren's syndrome (PSS) is a systemic autoimmune disease characterized by inflammation of the lacrimal and salivary glands and dryness of the eyes and mouth. There is evidence to suggest that PSS shares common pathogenic factors with other autoimmune diseases such as lupus, including common genetic susceptibility loci. Recent evidence strongly supports an epigenetic contribution to the pathogenesis of lupus, however, very little is known about the epigenetics of PSS.

Methods: We performed a genome-wide DNA methylation study in naïve CD4+ T cells in eleven PSS patients before receiving any treatment compared to age-, sex-, and ethnicity-matched healthy controls. Naïve CD4+ T cells were isolated from PBMCs by FACS or indirect labeling and magnetic bead separation. Cell purity was > 95%. DNA was isolated, and treated with sodium bisulfite. Cytosine methylation was quantified in more than 485,000 CpG sites that cover 99% of RefSeq genes, with an average of 17 CpG sites per gene region using the Illumina Infinium HumanMethylation450 BeadChip array. Differentially methylated CpG sites between PSS patients and controls with a fold difference ≥ 1.2 were identified. A false discovery rate (FDR) of 5% was applied to correct for multiple testing and differential methylation was considered statistically significant if the FDR corrected P value was ≤ 0.01.

Results: We identified 553 hypomethylated and 200 hypermethylated CpG sites in naïve CD4+ T cells from PSS patients compared to healthy matched controls, representing 311 hypomethylated and 115 hypermethylated gene regions. Hypomethylated genes in PSS include *LTA,* coding for Lymphotoxin α, which is involved in LTβ receptor signaling pathway, activation of follicular dendritic cells, and expression of interferon α. Other relevant genes such as *GSTM1, CD247*, *TNFSF25, PTPRC* and *PDCD1* were also hypomethylated. The interferon signature pathway was represented by hypomethylation of *STAT1*, *IFI44L*, and *IFITM1*. A group of genes encoding for members of the solute carrier proteins, which are membrane transport proteins that are important for maintenance of cell function were hypomethylated (*SLC11A1*, *SLC11A2*, *SLC22A23*, *SLC25A25*, *ALC25A3*, *SLC25A33*, *SLC6A20*), whereas, *SLC9A1*, which is important for the maintenance of PH homeostasis was hypermethylated in PSS patients compared to controls. In addition, the transcription factor *RUNX1* was hypermethylated in patients, suggesting an impact on the differentiation of hematopoietic stem cells, and possible connection to lymphoma predisposition. Gene ontology (GO) analysis of hypomethylated genes demonstrated enrichment of genes involved in lymphocyte activation (P= 1.10E-04), and immune response (P= 2.20E-03). GO terms for hypermethylated genes included antigen processing and presentation (P= 8.00E-06), and positive regulation of RNA metabolic process (P= 2.10E-02).

Conclusion: This is the first epigenome-wide DNA methylation study in PSS. Our data suggest wide-spread DNA methylation changes in naïve CD4+ T cells in PSS, and highlight several genes and pathways that may be involved in the pathogenesis of this disease and that will be the subject for our future investigation.

Distinct Role Of Plasmacytoid Dendritic Cells and Mast Cells In The Pathogenesis Of Sjögren's Syndrome. Jidong Zhao, Kunihiro Yamaoka, Satoshi Kubo, Shingo Nakayamada and Yoshiya Tanaka. University of Occupational and Environmental Health, Japan, Kitakyushu, Japan.

Background/Purpose: Sjögren's Syndrome (SS) is characterized by the destruction of the lacrimal and salivary grands due to autoreactive lymphocyte infiltration in the early phase and subsequent intralobular fibrosis and acinar atrophy at late phase of the disease. Involvement of plasmacytoid dendritic cells (pDCs) and mast cells (MCs) has been suggested, although their detailed role in pathology is poorly understood. The aim of this study was to investigate the role pDCs and MCs in the disease course of SS.

Methods: Lip biopsy specimen from 178 SS patients and 7 Sicca syndrome (Sicca) patients were analyzed. NanoZoomer Digital Pathology (NDP), a system to convert a histology slide into high-resolution digital slides and enables sequential pathological analysis of multiple sections and measurement of accurate specimen area was utilized for analysis. Density of pDCs and MCs (/mm^2) was measured with NDP and histological scoring was performed on lymphocytes infiltration, acinar atrophy and intralobular fibrosis. pDC, CXCL13 and CD68 were detected by immunohistochemistry and MCs were detected by toluidine blue staining. Histological stage was based on 'Greenspan grade'.

Results: Significant lymphocytes infiltration, acinar atrophy and intralobular fibrosis were observed in SS compared to Sicca patients with salivary gland destruction. Both, pDCs and MCs were significantly increased in SS compared to Sicca (12.6±10.2 vs 3.4±3.7, 43.7±21.8 vs 21.5±6.9). Positive correlation between density of pDCs with lymphocytes infiltration score (p□□0.02) and density of MCs with intralobular fibrosis score (p□□0.03) was observed in primary SS but not in secondary SS. Moreover, in the primary SS, density of CXCL13 positive infiltrating cells positively correlated with the degree of lymphocyte infiltration score and density of pDCs ($p<0.001$); by double immunostaining of anti-CXCL13 and anti-CD68, we found that most of CXCL13 positive infiltrating cells are from Macrophage(*57.8±22.1%*) and the localization of PDC and CXCL13 positive infiltrating cells are almost same around duct. On the other hand, no correlation was observed with secondary SS patients.

Conclusion: Our data suggests the specific role of pDCs in lymphocyte infiltration in primary SS. Correlation of CXCL13 expression, a chemoattractant for lymphocyte recruitement, with lymphocyte infiltration and density of pDCs further suggests the important role of pDCs. CXCL13 is induced by type 1 IFN, whereas pDCs are the major source of type 1 IFN. Therefore, it likely that type 1 IFN produced by pDCs in the early stage of the disease induces CXCL13 production of infiltrating cells, especially Macrophage, contributing to lymphocyte infiltration constructing germinal center. In addition, MCs seems to be involved in intralobular fibrosis which occurs in the mid to late stage of SS.

Adenosine A2b Receptor Agonist Bay60–6583 Restores Salivary Gland Function In a Mouse Model For Sjögren's Syndrome. Barbara Szczerba, Paulina Rybakowska, Paromita Dey, Harini Bagavant and Umesh Deshmukh. University of Virginia, Charlottesville, VA.

Background/Purpose: Primary Sjögren's syndrome (pSS) is a chronic autoimmune disorder mainly affecting the exocrine glands. However, it is now clear that both immune and non-immune mechanisms are responsible salivary gland dysfunction in this disorder. Thus, drugs capable of inducing immunosuppression as well as directly influencing salivary gland function would be highly desirable as therapeutics for SS. Adenosine is a major anti-inflammatory metabolite generated during tissue injury and it signals through four distinct G protein-coupled receptors, termed A1AR, A2aAR, A2bAR and A3AR. In addition it can have direct effects on different aspects of cellular metabolism. Thus, in this study we have tested the efficacy of adenosine A2b receptor agonist Bay60–6583 for restoration of salivary gland function in a mouse model for SS-like disorder.

Methods: The B6.Aec1Aec2 mouse model for SS-like disorder was used for this study. Gene expression of adenosine receptors on human and mouse submandibular gland cell lines, as well as mouse salivary glands was determined by real time PCR. ERK phosphorylation in cell lines treated with the drug and presence of serum autoantibodies were analyzed by western blotting. Mice with established glandular dysfunction were treated with the drug, 8 times, every third day by intraperitoneal route. Saliva production was measured following pilocarpine injection. Cytokine levels in sera were measured using Bioplex assay system. Formalin fixed salivary gland sections were stained with H and E and presence of inflammatory cell infiltrates quantified by Stereology.

Results: All adenosine receptors were expressed in the mouse salivary glands and in the mouse and human cell lines. Bay60–6583 readily induced ERK phosphorylation in the human and mouse cell lines. Mice treated with Bay60–6583 showed significant improvement in their saliva production than control (vehicle treated) mice. Salivary glands from drug treated mice showed significantly lower inflammatory cell infiltrates. Surprisingly, the inflammatory cytokine and autoantibody levels between the vehicle and drug treated mice were not different.

Conclusion: Our study has established for the first time the presence of functional adenosine receptors on salivary gland cells. The restoration of glandular function in drug treated mice demonstrates the potential of targeting adenosine receptors for therapeutic intervention in SS. Our study also demonstrates that in this mouse model, circulating inflammatory cytokine and autoantibody levels were dissociated from glandular dysfunction. This finding suggests that in some SS patients, biomarkers other than circulating cytokines and autoantibodies might be more relevant for following disease progression.

Spondylarthropathies and Psoriatic Arthritis: Clinical Aspects and Treatment: Clinical Features of Spondyloarthritis

Tuesday, October 29, 2013, 4:30 PM–6:00 PM

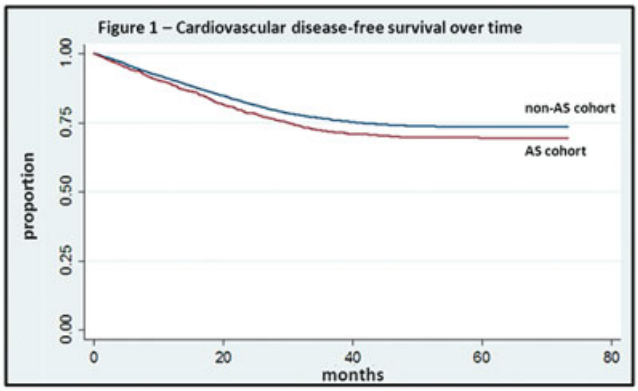
2776

Ankylosing Spondylitis Is Associated With An Increased Likelihood Of Cardiovascular Disease: A Nationwide Matched Cohort Study In Primary Care. Linda E. Dean[1], Gary J. Macfarlane[1], Alan G. MacDonald[2] and Gareth T. Jones[1]. [1]University of Aberdeen, Aberdeen, United Kingdom, [2]Aberdeen Royal Infirmary, Aberdeen, United Kingdom.

Background/Purpose: Cardiovascular disease (CVD) risk is well established in rheumatoid arthritis but less so in ankylosing spondylitis (AS). Due to a similar inflammatory profile, AS patients may be expected to be at increased risk of CVD, particularly ischemic heart disease, hyperlipidaemia and hypertension. Thus, the aim of this study was to determine whether there is an increased risk of CVD among persons with AS.

Methods: Design: matched cohort study. The Scottish Primary Care Clinical Informatics Unit collects demographic, diagnostic and clinical information from a nationally representative sample of general practices in Scotland, UK. As almost all UK residents are registered with a general practitioner and referrals to specialist services are made via this route, the database provides a source of nationwide health data. In April 2007, the database consisted of 3,256,108 patients, approximately 60% of the Scottish population. The 'exposed' cohort comprised all patients with a prior clinical diagnosis of AS (indicated by disease-specific codes). These patients were matched at a ratio of 4:1 to non-AS patients by age (+/− 1yr), gender and area-level deprivation. AS patients were followed up from date of diagnosis until either a CVD diagnosis or the end of follow-up period. Non-AS patients were assigned the same index date as their matched exposed patient and followed to the same end point. All those with a CVD diagnosis prior to the index date were excluded. Data was extracted on the following CVD outcomes: ischemic heart disease; congestive heart failure; cerebrovascular disease; cardiomyopathy; pericarditis; valvular disease; conduction disturbances; hyperlipidaemia; hypertension; atherosclerosis; and heart valve replacement. Differences in the occurrence of CVD between cohorts were examined using (a) Kaplan-Meier survival curves, and (b) Cox proportional hazards regression. Results were adjusted for smoking status and summarised as hazard ratios (HR).

Results: 1,964 AS patients, plus 7,856 matched non-AS patients, were identified (mean age 62yrs, 77% male). Median follow-up time was 16yrs (IQR 8–26). The risk of CVD, over time, is shown in Figure 1. Persons with AS were significantly more likely to receive a diagnosis of CVD than individuals without AS (HR 1.15; 95%CI 1.05–1.26) and, in particular, experienced a 20% increase in the risk of hypertension (1.20; 1.07–1.34). No significant individual associations were found with any of the other CVD diagnoses under investigation, including ischemic heart disease, heart failure or hyperlipidemia.



Conclusion: This large nationwide primary care cohort demonstrates an increased risk of CVD among AS patients which is evident from the time of diagnosis. Clinicians should be aware of the excess CVD risk in this patient group which may help inform their overall management, with the view to optimize long-term quality of life.

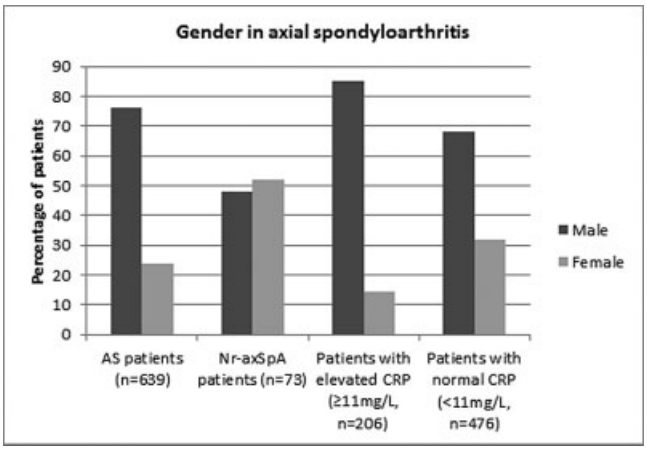
Ankylosing Spondylitis and Non-Radiographic Axial Spondyloarthritis: Part of a Common Spectrum Or Distinct Diseases? Analysis of a Longitudinal Prospective Cohort. Dinny Wallis[1], Nigil Haroon[1], Renise Ayearst[2], Adele Carty[1] and Robert D. Inman[1]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Historically ankylosing spondylitis (AS) has been defined by the modified New York classification criteria which require the presence of radiographic sacroiliitis. More recently the use of MRI has led to the identification of patients with features of axial spondyloarthritis (SpA) who do not fulfill the modified New York criteria (non-radiographic axial SpA, nr-axSpA). The natural history of axial SpA is not completely understood and current knowledge is drawn largely from European data. We aimed to compare the features of AS and nr-axSpA in a North American cohort.

Methods: Data were analyzed for all patients enrolled in a longitudinal spondyloarthritis cohort between January 2003 and December 2012 meeting modified New York criteria for AS or the ASAS classification criteria for nr-axSpA. Categorical variables were compared using Fisher's exact test with two-tailed p values. For continuous variables, a mean patient value was calculated based on all visits for that patient. Variables were compared using t-tests.

Results: 639 patients with AS and 73 patients with nr-axSpA were included. Of the nr-axSpA patients, 40 demonstrated inflammation on MRI, and 33 were classified according to ASAS clinical criteria for axial SpA (of whom 15 had MRI showing no inflammation and 18 did not have MRI). The proportion of male patients was higher in AS than in nr-axSpA (76.2% vs. 47.9%, $p<0.0001$). CRP and ESR levels were higher in AS than nr-axSpA (CRP 11.4 vs. 5.2, $p<0.0001$; ESR 13.7 vs. 9.9, $p=0.018$). Disease duration at last clinic visit was shorter in nr-axSpA than AS

(12.1y versus 17.7y, p=0.0002), providing some indirect support to the notion that nr-axSpA may represent a subset of axial SpA seen earlier in the course of the disease than AS. The proportions of patients receiving biologic therapy, non-steroidal anti-inflammatory drugs, disease modifying anti-rheumatic drugs and glucocorticoids were similar in AS and nr-axSpA. Further investigation of gender, inflammation and radiographic severity in the combined axial SpA cohort revealed that 31.9% of patients with a normal CRP were female, compared to only 14.6% of patients with an elevated CRP (p<0.0001). 96.6% patients with an elevated CRP had radiographic AS, compared to 86.8% of those with a normal CRP (p<0.0001). When data were analyzed for only the female patients, the difference in acute phase response between AS and nr-axSpA lost significance (CRP 9.4 versus 5.2, p=0.09; ESR 16.3 versus 11.5, p=0.07).



Conclusion: Analysis of this North American SpA cohort has identified some key differences between subsets of axial SpA, and highlights the influence of gender on inflammation and radiographic severity, thereby influencing the clinical classification of axial SpA patients.

Mortality In United States Veterans With The HLA-B27 Gene. Jessica Walsh[1], Brian C. Sauer[1], Daniel O. Clegg[1], Grant W. Cannon[2], Xi Zhou[1] and Chiachen Teng[1]. [1]George E. Wahlen Veteran Affairs Medical Center, Salt Lake City, UT, [2]Salt Lake City VA and University of Utah, Salt Lake City, UT.

Background/Purpose: HLA-B27 (B27) is carried by in 6–8% of Americans and is strongly associated with spondyloarthritis (SpA). SpA has been associated with premature mortality. However, increased mortality was not suspected in B27 positive (B27+) individuals without SpA, until recently published data from the 2009 National Health and Nutrition Examination Survey reported a lower prevalence of B27 in randomly selected people older than 50, compared to younger people (7.3% vs. 3.6%, OR 0.4, CI 0.3–0.8). The purpose of this study was to better define the relationship between the B27 gene and mortality, by comparing mortality in B27+ and B27- veterans with clinically available B27 test results.

Methods: The Corporate Data Warehouse was used to identify veterans with available B27 test results. Mortality differences between B27+ and B27- veterans were compared with Cox proportional hazard ratios. Logistic regression was used to evaluate the relationships between death and covariates including age at B27 testing, sex, race, and SpA diagnoses codes from rheumatology encounters.

Results: Among 17,209,732 veterans, 32,327 had both available vital status data and B27 test results (Figure 1). The mean age at testing was 50.5 for B27+ and 50.1 for B27- veterans. Male gender was recorded in 92.9% of B27+ veterans and 88.3% of B27- veterans (Table 1). The hazard ratio comparing mortality in B27+ and B27- veterans was 1.16 (CI 1.04 – 1.30), after adjustment for age at B27 testing, sex, race, and SpA codes (Table 2).

Figure 1. Study population

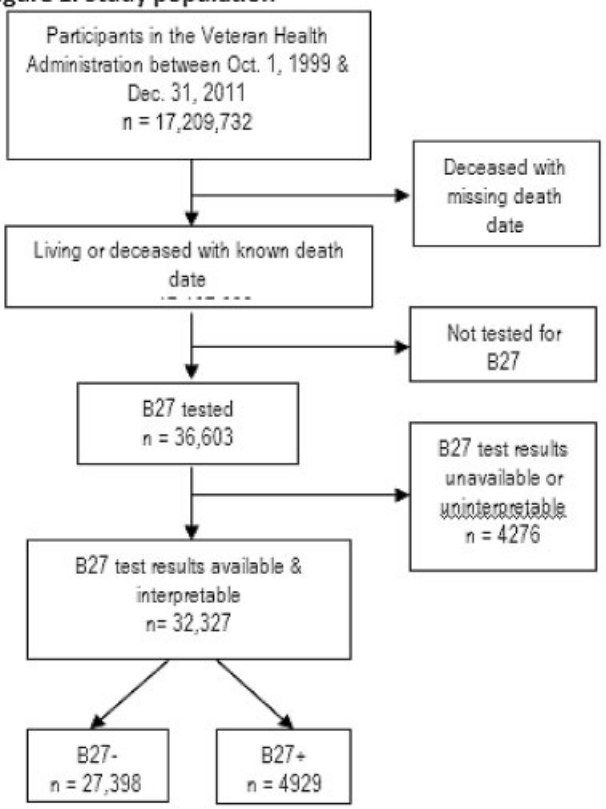

Table 1. Demographics, B27 testing, & spondylorthritis

	B27− n = 27,398 ± SD or (%)	B27 + n = 4929 ± SD or (%)
Age at B27 testing (mean)	50.1 ± 14.6	50.5 ± 14.3
Male gender	24,201 (88.3)	4578 (92.9)
Race		
White	19,321 (70.5)	3823 (77.6)
Black	5146 (18.8)	433 (8.8)
Other*	445 (1.6)	92 (1.9)
Unknown/declined to answer	2486 (9.1)	581 (11.8)
Years between B27 testing & study end or death (mean)	5.1 ± 3.3	5.3 ± 3.3
SpA ICD-9 code from a rheumatology encounter	2381 (8.7)	1717 (34.8)

*Other races included American Indian or Alaska Native, Asian, Native Hawaiian or Other Pacific Islander

Table 2. Mortality in B27− and B27+ veterans

	Person time (Years after B27 testing)	Deceased (%)	Adjusted HR* (95% CI)	P
B27−	140,120	1981 (7.2)	Ref.	
B27+	26,060	411 (8.3)	1.16 (1.04–1.30)	0.01

*Adjusted for age at B27 testing, sex, race, & presence of SpA diagnoses codes

Conclusion: Mortality was higher in B27+ veterans than B27- veterans, and the difference was not explained by age, sex, race, or SpA diagnoses codes. The mortality difference was likely conservative because the B27- group may have been disproportionately enriched with conditions mimicking SpA that are associated with increased mortality, such as chronic pain or rheumatoid arthritis. Additional research is required to estimate survival in unselected individuals from the general population and to identify specific disease processes that contribute to premature mortality. Recognizing these diseases may provide mechanistic insights into B27 functions and may lead to interventions that improve survival in B27+ individuals.

A Novel Evidence-Based Detection Of Undiagnosed Spondyloarthritis In Patients Presenting With Acute Anterior Uveitis: The DUET (Dublin Uveitis Evaluation Tool) Algorithm. Muhammad Haroon[1], Michael Anthony O'Rourke[2], Pathma Ramasamy[2], Conor Murphy[2] and Oliver FitzGerald[1]. [1]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]Royal Victoria Eye and Ear Hospital, Dublin, Ireland.

Background/Purpose: The prevalence of mostly undiagnosed underlying Spondyloarthropathy (SpA) is more than 60% among patients presenting with acute anterior uveitis (AAU). To date, there are no formal guidelines or referral pathways for AAU patients developed or endorsed by any international or national societies. The objectives of our study were: (1) to investigate the prevalence of undiagnosed SpA in patients presenting with idiopathic AAU; (2) to develop and validate an assessment algorithm for referral from Ophthalmologists of appropriate AAU patients to Rheumatology that will aid the early diagnosis of the SpA

Methods: All consecutive patients attending emergency department of local ophthalmology hospital with AAU, but who did not have a known diagnosis of SpA, were eligible to partake in this study. Patients with any other known cause of AAU were excluded.

DEVELOPMENT COHORT: The rheumatologic referral was made as per a test algorithm (Figure-1), and those who did not require a referral, remained part of the study as a control group; these patients also underwent detailed rheumatologic evaluation.

VALIDATION COHORT: To confirm the findings from the development cohort, we recruited a validation cohort with similar entry and exclusion criteria. Algorithm version-1 (revised form of test algorithm which is now named the DUET algorithm, figure-1) was used in this cohort to identify patients requiring rheumatologic referral.

Results: DEVELOPMENT COHORT: 104 consecutive patients from September 2011 through to June 2012 were recruited. However, 3 of these patients were lost to follow up prior to rheumatologic evaluation. After rheumatologic evaluation of the entire cohort (n=101), 41.6% (n=42) had undiagnosed SpA as per ASAS classification criteria. Our test algorithm was noted to have: sensitivity 100%, specificity 53.5%, PPV 61% and NPV 100%. Further regression analysis resulted in the development of the DUET algorithm which made the following improvements in the assessment of the development cohort: sensitivity 95%, specificity 98%, PPV 97.5%, NPV 96.6, positive LR 56.19, and negative LR 0.04.

VALIDATION COHORT: To obtain a 95% confidence interval of at least as narrow as ±10% or ±8% for all the statistics, a sample size of 44 or 69 participants, respectively, was deemed sufficient. Hence, consecutive 74 idiopathic AAU patients were recruited from November 2012 through to April 2013, but 2 of these patients were lost to follow-up. After rheumatologic evaluation of the cohort (n=72), 40% (n=29) were diagnosed with SpA, with the following performance of DUET algorithm - sensitivity 96%, specificity 97%, PPV 96.5, NPV 97.6, positive likelihood ratio 41.5 and negative likelihood ratio of 0.03

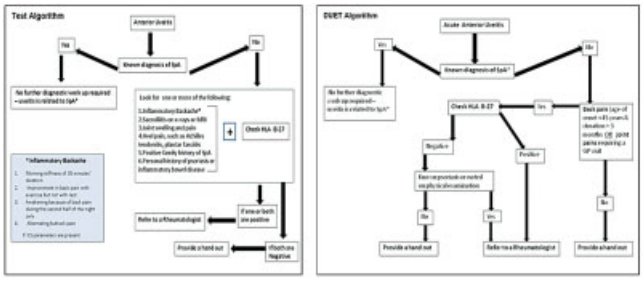

Figure 1.

Conclusion: Approximately 40% of patients presenting with idiopathic AAU have undiagnosed SpA. A simple to apply algorithm is described with excellent sensitivity and specificity.

Cumulative Exposure To Elevated Inflammatory Markers Is Associated With Increased Burden Of Atherosclerosis In Psoriatic Arthritis Patients: A Cohort Study. Lihi Eder[1], Arane Thavaneswaran[1], Vinod Chandran[1], Richard J. Cook[2] and Dafna D. Gladman[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Waterloo, Waterloo, ON.

Background/Purpose: Cardiovascular morbidity is increased in patients with psoriatic arthritis (PsA). Traditional cardiovascular risk factors do not fully explain this excessive risk. It is unclear whether the cumulative burden of inflammation in the skin and the joints contribute to the development of atherosclerotic plaques. We aimed to investigate whether higher burden of arthritis and psoriasis over time is associated with the development of atherosclerotic plaques among patients with PsA.

Methods: A retrospective cohort analysis was conducted in patients attending a large PsA clinic. Patients were assessed at 6–12 month intervals according to a standard protocol. Information about demographics, medical history, musculoskeletal and skin examination, patient-reported outcomes and laboratory tests was collected at each visit. The cumulative effect of inflammation was measured by a time-adjusted arithmetic mean (AM) of all available measurements from the first visit to the clinic. The following variables were considered as predictors: Psoriasis Activity and Severity Index (PASI), Erythrocyte Sedimentation Rate (ESR), total leukocyte counts (TLC), Tender and Swollen joint count (TJC, SJC), C - reactive protein (CRP), Psoriatic Arthritis Disease Activity Score (PASDAS) and Disease Activity for PsA (DAPSA). Ultrasound assessment of the carotid arteries was performed and Total Plaque Area (TPA) was measured. This measure represented the extent of atherosclerosis and was considered the outcome of interest. TPA was stratified into 4 categories: 1) TPA=0 (no plaques), 2) $0<TPA\leq0.1$ cm^2, 3) $0.1<TPA\leq0.4$ cm^2, 4) TPA>0.4 cm^2. The association between the various AM variables and TPA categories was assessed using logistic ordinal regression model adjusted age and gender.

Results: A total of 235 patients with PsA were analyzed. Their mean age was 55.4±11.4 years and the duration of psoriasis and PsA were 27±13.5 and 16.2±11.7 years, respectively. 56.6% of the participants were males. Patients in higher TPA categories were older at the time of assessment ($p<0.001$), were more likely to be smokers ($p=0.008$), hypertensive ($p=0.002$), diabetics ($p<0.001$) and were older at the onset of psoriasis ($p<0.001$) and PsA ($p<0.001$). In a multivariable regression model adjusted for age and sex AM-ESR was associated with higher TPA categories (category 3 vs. 1 Odds Ratio (OR) 1.04, 95% Confidence Interval (CI) 1, 1.08, p=0.04, category 4 vs. 1 OR 1.05, 95% CI 1.01, 1.1, p=0.02). The following variables were also associated with higher probability of having severe atherosclerosis (being in TPA category 4 vs. 1): AM-TLC (OR 1.45, 95% CI 1.09, 1.92, p=0.01) and AM-DAPSA (OR 1.08, 95% CI 1.02, 1.14, p=0.009). A trend for an association was observed between AM-PASDAS and being in the highest TPA category (OR 1.73, 95% CI 0.97, 3.09, p=0.06). No significant association was found between AM-PASI, AM-CRP, AM-TJC, AM-SJC and damaged joint count and TPA category in multivariate analysis.

Conclusion: An exposure to increased cumulative inflammation is associated with development of atherosclerotic plaques among patients with PsA.

The Disease Characteristics and Predictors Of Minimal Disease Activity On TNF Blockers- Results From A Longitudainal Observational Cohort. Amir Haddad[1], Arane Thavaneswaran[1], Ioana Ruiz Arruza[1], Vinod Chandran[1], Richard J. Cook[2] and Dafna Gladman[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Waterloo, Waterloo, ON.

Background/Purpose: A state of Minimal Disease Activity (MDA) has been defined and validated as a target for treatment in PsA. The purpose of the study is to identify disease characteristics and predictors of MDA in PsA patients treated with TNF blockers.

Methods: Patients fulfilled the CASPAR criteria and were followed regularly every 3–6 months and completed radiographic evaluation at 2-year intervals. TNFα blockers were prescribed when patients failed standard of care. Patients were considered in MDA when met at least 5/7 of the criteria defined by Coates et al[i].Sustained MDA was defined as MDA lasting for

≥ 12 months. Patients achieving MDA were compared to patients who did not achieve MDA. A proportional odds discrete time survival analysis model was applied adjusting for gender, age at visit, duration of PsA, presence of abnormal ESR and damaged joint count at each visit to identify predictors for MDA.

Results: Of the 306 patients treated with anti-TNF agents 23 were in MDA at baseline and 57 were prescribed anti-TNF agents prior to enrolment. 226 were in non-MDA state and constituted the study population. 145/226 patients achieved MDA after an average of 1.30 (1.68) years and for a mean duration of 3.46 (2.25) years. Patients who achieved MDA were more likely males (71.9% vs. 55.2%), younger at diagnosis (34.4 vs. 39.0 years), had a lower actively inflamed joint count (7.3 vs. 15.1), dactylitis (9.1% vs 13.9%), enthesitis (10.8% vs. 17.4% and tenosynovitis (9.2% vs. 21.7%), but more likely to have clinical damage (72.7% vs. 52.2%) and higher modified Steinbrocker score (25.5 vs. 11.5) as well as axial involvement (46.2% vs. 25%) at baseline compared to patients that didn't achieve MDA. Non-MDA patients had higher BMI (31.3 vs. 28.8), more were classified with functional class III/IV (33.3% vs. 10.1%) and had a lower SF-36 physical (28.1 vs. 43.9) and mental (41.9 vs. 49.9) component summary scores at baseline compared to the MDA group. HLA B*27 was found in 24.8% patients with MDA compared to 9.2% patients who didn't achieve MDA (P=0.007). The majority of patients in both groups were also treated with DMARDs and NSAIDs. No significant difference was found in disease duration, alcohol use, smoking, ESR, CRP or PASI score between the two groups. Patients who achieved MDA had less radiographic progression over time compared to patients without MDA. The survival analysis showed that after adjusting for characteristics at each visit male gender increased the odds of achieving MDA (OR=1.68 CI 1.11, 2.53, P=0.01), whereas an abnormal ESR lowered the odds of achieving MDA (OR=0.46 CI 0.27, 0.80, P=0.06). As for sustained MDA, only normal ESR was found to a predictor (OR 0.06 CI 0.03–0.15, P<0.0001).

Conclusion: 63% of the study group achieved MDA after an average duration of 1.3 years and those patients had less active disease at baseline but more damage with less radiographic progression over time. A normal ESR at each visit and male gender were predictors of MDA in patients treated with TNF blockers, the presence of HLA B*27 has a prognostic value also in identifying patients who achieve MDA.

Retreatment With Rituximab In The Rituximab In ANCA-Associated Vasculitis (RAVE) Trial. Eli Miloslavsky[1], Ulrich Specks[2], Peter A Merkel[3], Philip Seo[4], Robert F. Spiera[5], Carol A. Langford[6], Gary S. Hoffman[7], Cees G.M. Kallenberg[8], E. William St Clair[9], Nadia Tchao[10], Linna Ding[11], David Ikle[12], Brett Jepson[12], Paul Brunetta[13] and John H. Stone[14]. [1]Massachusetts General Hopsital, Boston, MA, [2]Mayo Clinic, Rochester, MN, [3]University of Pennsylvania and VA Medical Center, Philadelphia, PA, [4]Johns Hopkins Vasculitis Center, Baltimore, MD, [5]Hospital for Special Surgery, New York, NY, [6]Cleveland Clinic, Cleveland, OH, [7]Cleveland Clinic Foundation, Cleveland, OH, [8]University Medical Center Groningen, Groningen, Netherlands, [9]Duke Unversity Medical Center, Durham, NC, [10]Immune Tolerance Network, Bethesda, MD, [11]NIAID, Bethesda, MD, [12]Rho, Chapel Hill, NC, [13]Genentech, So San Francisco, CA, [14]Massachusetts General Hospital, Boston, MA.

Background/Purpose: Retrospective studies have demonstrated that repeat rituximab treatment may be effective in re-inducing remission in relapsing ANCA-associated vasculitis. We analyzed data from the Rituximab in ANCA-associated vasculitis (RAVE) trial in order to determine the safety and efficacy of a second course of rituximab for relapsing granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA).

Methods: Randomized controlled trial comparing rituximab (RTX, n=99) to cyclophosphamide (CYC) followed by azathioprine (AZA, n=98) for remission induction. Patients who suffered a severe disease flare (BVAS/WG > 3 or one major BVAS/WG item) between 6 and 18 months were eligible for open label RTX (OLR) (375mg/m^2 once weekly times four).

Results: 17 patients received two courses of RTX. Baseline characteristics are presented in the table.

Characteristics of patients treated with open label RTX

	N = 17
Originally assigned to RTX	16 (94%)
PR3-ANCA positive	14 (82%)
GPA	15 (88%)
Newly diagnosed disease	6 (35%)
Mean time to OLR (range, days)	367 (225–556)
BVAS/WG at OLR (range)	4.8 (3–11)
Mean prednisone dose at OLR (range, mg)	8.4 (0–40)
Detectable B-cells at flare	16 (94%)
Rising ANCA at flare	14 (82%)

After retreatment, patients were followed for an average of 301 days (range 35–427). Treatment with OLR led to remission (BVAS/WG=0) in 15 of 17 patients (88%) by an average of 55 days (range 1–181). One patient with diffuse alveolar hemorrhage did not improve and died 7 weeks after the initial flare. Another patient reached a BVAS/WG of 1 before suffering a limited flare at 12 months after OLR.

Six months after OLR, 15 patients (88%) were in remission (BVAS/WG = 0), 8 (47%) had achieved complete response (BVAS/WG = 0 and prednisone ≤ 10mg/day) and 6 patients (35%) were in complete remission (BVAS/WG = 0 and prednisone = 0). After 12 months, 13 patients (76%) had achieved complete responses and 8 (47%) had reached complete remission. There were 4 limited and no severe flares among the 17 patients (BVAS/WG 2.5) over one year of follow up after OLR.

There were a total of 3 severe (grade ≥ 3) adverse events after OLR, including one death (described above), metastatic colon cancer, and severe sinusitis.

Conclusion: This prospective study indicates that retreatment of GPA or MPA flares with rituximab is effective in re-inducing remission.

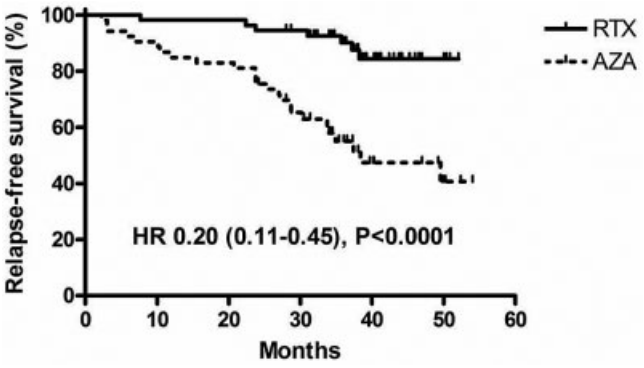
Rituximab Versus Azathioprine For Maintenance In Antineutrophil Cytoplasmic Antibodies-Associated Vasculitis: Follow Up At 39 Months. Benjamin Terrier[1], Christian Pagnoux[2], Alexandre Karras[3], Chahera Khouatra[4], Olivier Aumaître[5], Pascal Cohen[1], Francois Maurier[6], Olivier Decaux[7], Hélène Desmurs-Clavel[8], Pierre Gobert[9], Thomas Quemeneur[10], Claire Blanchard-Delaunay[11], Pascal Godmer[12], Xavier Puéchal[13], Luc Mouthon[14] and Loic Guillevin[15]. [1]Cochin University Hospital, Paris, France, [2]Division of Rheumatology, Mount Sinai Hospital, Toronto, ON, [3]Hôpital Européen Georges Pompidou, APHP, Paris, France, [4]CHU Lyon, Lyon, France, [5]Division of internal Medicine, Centre Hospitalier Universitaire, Hôpital Gabriel Montpied, Clermont–Ferrand, Clermont–Ferrand, France, [6]Division of internal Medicine, CHR Metz, Metz, Metz, France, [7]Rennes University Hospital, Rennes, France, [8]Hospices Civils de Lyon, Hôpital Louis Pradel, Lyon, France, [9]Centre Hospitalier d'Avignon, Avignon, France, [10]CHR de Valenciennes, Valenciennes, France, [11]Hôpital de Niort, Niort, France, [12]Department of Internal Medicine, Centre Hospitalier Bretagne Atlantique de Vannes, Vannes, France, [13]Hôpital Cochin, AP-HP, Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [14]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France, [15]Division of Internal Medicine, Hôpital Cochin, University Paris Descartes, Paris, France.

Background/Purpose: Rituximab was shown to be as effective as cyclophosphamide to induce remission in patients with ANCA-associated vasculitis (AAV). The prospective, randomized, controlled MAINRITSAN trial compared rituximab (RTX) to azathioprine (AZA) to maintain ANCA-associated vasculitis (AAV) remission. Once remission was obtained with a conventional regimen using corticosteroids and cyclophosphamide, patients were randomly assigned to receive a 500-mg RTX infusion on D1, D15, 5.5

months later, then every 6 months for a total of 5 infusions over 18 months, or AZA for 22 months at the initial dose of 2 mg/kg/d. The primary endpoint was the major relapse rate (EULAR/ACR criteria) at 28 months. This study demonstrated that 500 mg of rituximab (RTX) every 6 months was superior to azathioprine (AZA) to maintain ANCA-associated vasculitis (AAV) remission during the 28-month follow-up, with a similar profile of tolerance. This study describes the extended follow-up of patients included in the MAINRITSAN trial.

Methods: Extended follow-up was ascertained from the patients included in the trial. Data on relapse and survival were collected from physician records. All patients were analyzed according to the group to which they were randomized, except for 8 patients who were excluded from the extended follow-up because of severe violation to protocol.

Results: One hundred and nine patients were analyzed for the extension of follow-up. Median duration of follow-up was 38.6 months (IQR, 33.5–45.2 months). Seven out of 55 (12.7%) patients in the RTX arm and 26/54 (48.1%) patients in the AZA arm had at least one major relapse. Overall, the risk of major relapse remained significantly lower in the RTX arm compared to the AZA arm (hazard ratio 0.20, 95% CI 0.11 to 0.45, P<0.0001). During follow-up, 3 patients died in the AZA arm but none in the RTX arm. Causes of death were infection, cancer and mesenteric ischemia. Overall survival rate was better in the RTX arm compared to the AZA arm (P=0.07).



Conclusion: Despite relapses in the RTX arm after the end of the study period, RTX remains associated with a lower risk of relapse than AZA. RTX tends to be associated with a better overall survival compared to AZA.

Mononeuritis Multiplex Predicts The Need For Immunosuppressive Or Immunomodulatory Drugs For Eosinophilic Granulomatosis With Polyangiitis, Polyarteritis Nodosa and Microscopic Polyangiitis Patients Without Poor-Prognosis Factors. Maxime Samson[1], Xavier Puéchal[2], Hervé Devilliers[3], Camillo Ribi[4], Pascal Cohen[5], Boris Bienvenu[6], Christian Pagnoux[7], Luc Mouthon[2], Loic Guillevin[8] and French Vasculitis Study Group (FVSG)[2]. [1]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France; Internal Medicine and Clinical Immunology, Hôpital du Bocage, Dijon, France, Paris, France, [2]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France, [3]Internal medicine, Hôpital Général, Dijon, France, Dijon, France, [4]Immunology and Allergology, Internal Medicine, University Hospitals of Geneva, Geneva, Switzerland, Geneva, Switzerland, [5]Cochin University Hospital, Paris, France, [6]Division of Internal Medicine, Centre Hospitalier Régional Universitaire de Caen, Côte de Nacre, Caen, France, Caen, France, [7]Rheumatology, Mount Sinai Hospital, Toronto, Canada, Toronto, ON, [8]Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France.

Background/Purpose: Patients with eosinophilic granulomatosis with polyangiitis (EGPA), polyarteritis nodosa (PAN) or microscopic polyangiitis (MPA) without poor-prognosis factors, as defined by their 1996 Five-Factor Scores (FFS)=0, were included in 2 prospective CHUSPAN trials and initially received corticosteroids (CS) alone. Because some patients required add-on therapies (AT) during follow-up, baseline characteristics associated with their use were sought.

Methods: Patients' data were updated in 2012. Chapel Hill definitions classified EGPA, PAN and MPA. Analyzed AT were all cytotoxic agents, biologics (except omalizumab), intravenous immunoglobulins (IVIg) (>2 g/kg) and plasma exchange. Univariate and multivariate analyses were performed.

Results: The study included 193 patients (75 EGPA, 61 MPA and 57 PAN) initially treated with CS alone. Mean±SD overall follow-up was 97.6±39.6 months, with no difference among entities. During follow-up, 86/193 (24 PAN, 32 MPA and 30 EGPA) patients required AT (mean follow-up since CS onset: 23.3±34.1 months) because CS failed (37%), relapse (52%) or CS dependency (10%): 49 received IV cyclophosphamide (CYC), 13 oral CYC, 56 azathioprine, 15 methotrexate, 9 mycophenolate mofetil, 7 IVIg, 6 plasma exchange, 1 infliximab and 1 cyclosporine. The significant association of mononeuritis multiplex (MNM) with AT use (univariate analysis, Fig 1; P=0.008) was confirmed by multivariate analysis, with MM being the only factor independently associated with requiring AT (hazard ratio=1.81 [95% CI: 1.12–2.93]; P=0.02). AT prescription rates were comparable for the 3 entities. At last visit, 165/193 (85%) were alive, with 94 (57%) and 28 (17%), respectively, still taking CS and/or cytotoxic agent or biotherapy. Overall survival reached 90% at 7 years and was comparable for patients who had taken ≥1 AT vs those treated only with CS during follow-up (P=0.564). However, patients given ≥1 vs 0 AT had significantly higher Vasculitis Damage Indexes (VDI): 2.93±2.09 vs 1.96±1.40 (P<0.001), reflecting more frequent osteoporosis (33 vs 18%, P=0.013) or peripheral neuropathy (60 vs 38%, P=0.004).

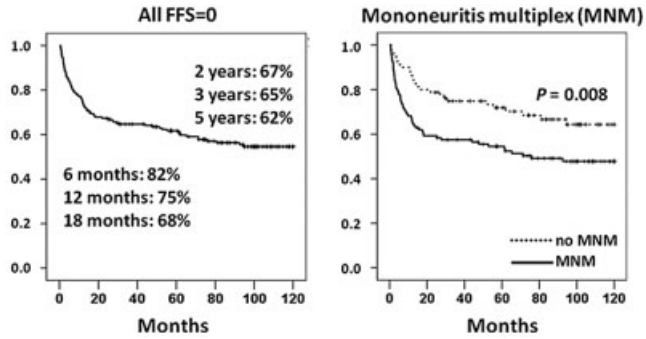

Figure 1. Probability of survival without prescription of new add-on therapies of 193 patients with EGPA, PAN or MPA without baseline poor-prognosis factors (FFS=0). P determined with log-rank test.

Conclusion: Despite the good and comparable overall survival of baseline-FFS=0 EGPA, PAN or MPA patients, 45% required AT, mostly those with MNM, and their VDI were significantly higher, indicating more sequelae than those of the other FFS=0 patients. Hence, this MNM subpopulation might be more likely to fail on CS alone, thereby supporting prospective evaluation of their initial cytotoxic agent use.

2785

Urinary Inflammatory Cells Strongly Reflect the Disease Activity and Renal Function in Antineutrophil Cytoplasmic Autoantibody-Associated Vasculitis. Yoko Wada[1], Minoru Sakatsume[1], Masaaki Nakano[2] and Ichiei Narita[1]. [1]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [2]School of Health Sciences, Faculty of Medicine, Niigata University, Niigata, Japan.

Background/Purpose: The antineutrophil cytoplasmic autoantibody (ANCA)- associated vasculitides (AAVs) include microscopic polyangiitis (MPA), granulomatosis with polyangitis (GPA; formerly Wegener's), and eosinophilic granulomatosis with polyangitis (EGPA). These small-vessel vasculitides are characterized by necrotizing inflammation of the vessel wall, particularly affecting small arteries, arterioles, and capillaries in systemic organs, and the kidney is one of the most frequently involved organs. We have already reported that T cells and macrophages appear in the urine of patients with glomerulonephritis, accompanied by active cellular infiltration

such as cellular crescent formation and diffuse interstitial cell infiltration, but not in the urine of patients with glomerulonephritis without the active inflammatory lesions. In this study, we examined the correlation between the numbers of urinary inflammatory cells and disease activity in AAVs, and assessed the utility of urinary immune cell analysis.

Methods: Thirty patients with AAVs (MPA; n=26, GPA; n=3, EGPA; n=1), who had been referred to Niigata University Hospital between 2004 and 2012, were recruited for this study. The patients were divided into two groups according to clinical renal function (renal involvement (RI) group, n=24); non-renal involvement (non-RI) group, n=6)). Flow-cytometric analysis of urinary inflammatory cells was performed for each subject. Numbers of urinary T cells or macrophages were determined by multiplying the number of viable cells in the gated mononuclear cell region in each sample by the percentage of urinary CD3-positive or CD14-positive cells in the population, respectively. The numbers of urinary CD3-positive cells and CD14-positive cells, laboratory data including the titers of serum ANCA, serum creatinine and C-reactive protein, and the Birmingham vasculitis activity score (BVAS), were examined in each subject, and compared between the RI and non-RI groups. We then examined the correlations between the numbers of CD3-positive or CD-14-positive cells and laboratory data and BVAS by Spearman's rank correlation coefficient in all subjects.

Results: The total numbers of urinary CD3-positive cells and CD14-positive cells were significantly elevated (>120/ml urine) in all patients in the RI group and 5 of 6 patients in the non-RI group. The number of urinary CD3-positive cells was positively correlated with the titer of serum ANCA (r=0.41, p=0.02) and BVAS (r=0.38, p=0.038), while the number of urinary CD14-positive cells was positively correlated with serum Cr (r=0.38, p=0.038) and negatively correlated with eGFR (r=−0.38, p=0.03).

Conclusion: These results indicate the usefulness of urinary immune cell analysis for assessment of both kidney function and disease activity in patients with AAVs.

Review Of The Expert Panel Methodology In The Diagnostic and Classification Criteria For Vasculitis Study: A Pilot Study. Cristina Ponte[1], Anthea Craven[2], Joanna Robson[2], Peter C. Grayson[3], Ravi Suppiah[4], Richard A. Watts[5], Peter A. Merkel[6] and Raashid A. Luqmani[2]. [1]Rheumatology and Metabolic Bone Diseases Department, Hospital de Santa Maria, CHLN and Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, [2]Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, Botnar Research Centre, University of Oxford, Oxford, United Kingdom, [3]Section of Rheumatology & the Clinical Epidemiology Unit, Boston University School of Medicine, Vasculitis Center, Boston, MA, [4]Auckland District Health Board, Auckland, New Zealand, [5]Rheumatology Department Ipswich Hospital and University of East Anglia, Ipswich, United Kingdom, [6]University of Pennsylvania, Philadelphia, PA.

Background/Purpose: The Diagnostic and Classification Criteria for Vasculitis (DCVAS) Study is a multinational observational study to develop diagnostic criteria and to update classification criteria for the primary systemic vasculitides.

By 2015 the database will include clinical, laboratory and radiology data from over 2000 patients with vasculitis and 1500 comparator patients who present with features similar to vasculitis. To avoid the inherent circularity of using the submitting physician diagnosis as the gold standard, a reference diagnosis for each patient will be established using a combination of expert panel opinion and data-driven methods (e.g. machine learning algorithms).

The aim of this analysis was to evaluate the methodology by which the expert panel will assess individual patient data to establish the reference diagnosis.

Methods: By November 2012, 1662 patients had been recruited; 391 had complete 6 month follow-up data. Forty cases were randomly extracted and developed into clinical vignettes (CVs). The CVs were assessed for diagnoses by 6 independent experts using an online platform. Ten patients were assessed by all experts and the other 30 were each assessed by 2 of the 6 experts, randomly chosen. The experts first chose between primary vasculitis, secondary vasculitis, or other illness; then the respective major class (small-, medium-, or large-vessel vasculitis, or no predominant size vasculitis); and then the subtype or the specific disease for each category. For each answer a level of certainty (unlikely, possible, probable, definitive, or unknown) was provided. The diagnoses of the expert panel and the submitting physician were compared.

Results: The 40 clinical vignettes represented 26 women and 14 men, with a mean age of 62.5 ± 20.3 years (range 20–86 years). Data from all 120 CV reviews were available for analysis. Treating clinicians submitted a diagnosis of primary vasculitis in 32 patients (17 small-vessel, 1 medium-vessel, 13 large-vessel and 1 with no predominant size); secondary vasculitis in 2, and other illness in 6. The expert panel agreed with the submitted diagnosis of primary vasculitis in 97% of the cases (definite 54%, probable 35% and possible 8%). However, only 78% of the submitted patients with primary vasculitis were classified as having the same sub-type of vasculitis when compared with the expert panel diagnosis (9% could not be sub-typed within the correct major class of vasculitis, 9% classified the cases with another sub-type of the same major class, 3% chose another major class or diagnosis and 2% selected the unknown option). There was an intraclass correlation coefficient of 0.82 (confidence interval 0.57–0.95) in the 10 CVs assessed by the 6 experts, indicating low variability between evaluators.

Conclusion: An expert panel agreed with the individual submitting physician regarding a diagnosis of some form of primary vasculitis in nearly all cases, but disagreement about the exact form of vasculitis occurred in 22% of cases. Physician-based opinion may be more reliable for defining general categories of vasculitis than for defining specific subtypes. This exercise highlights the potential for diagnostic bias when using physician-opinion to define the gold standard diagnosis.

Disclosure: C. Ponte, None; **A. Craven**, None; **J. Robson**, None; **P. C. Grayson**, None; **R. Suppiah**, None; **R. A. Watts**, None; **P. A. Merkel**, None; **R. A. Luqmani**, None.

2787

The Effect Of Smoking On The Clinical Expression Of ANCA-Associated Vasculitis. Neil Basu[1], Aladdin Mohammad[2], Richard A. Watts[3], Paul Gatenby[4], Luis F. Flores-Suarez[5] and Alfred Mahr[6]. [1]University of Aberdeen, Aberdeen, United Kingdom, [2]Skåne University Hospital, Lund, Sweden, [3]Rheumatology Department Ipswich Hospital and University of East Anglia, Ipswich, United Kingdom, [4]ANU Medical School, The Canberra Hospital, Canberra, Australia, [5]Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico, [6]Department of Internal Medicine, Hospital Saint-Louis, Paris, France.

Background/Purpose: It is well recognized that smoking has immunomodulatory effects in several chronic inflammatory disorders. For ANCA-associated vasculitis (AAV), which includes granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA), the influence of smoking on disease risk and expression is not well understood. A small retrospective study suggested a protective effect of smoking on ENT manifestations. We investigated the relationship between smoking and AAV characteristics within two large, prospectively collected cohorts.

Methods: The analyses used data from newly-diagnosed patients with AAV who were enrolled in 4 international randomized controlled trials of the Europe Vasculitis Society (EUVAS). Disease characteristics at diagnosis (age, sex, diagnosis, ANCA subtype, system involvement, BVAS, creatinine, CRP) were compared according to smoking status (current versus non-current; ever versus never). The analyses were repeated for the cumulative disease characteristics of consecutive patients with AAV from the Vasculitis Quality of Life (VASQoL) study, a multi-center cross-sectional study involving rheumatology and renal clinics across the United Kingdom. Univariate analyses used Chi^2 and Mann-Whitney tests for categorical and continuous variables, respectively; logistic regression was used for age-adjusted analyses.

Results: Of the 535 EUVAS patients, smoking data was available for 342 (GPA/MPA ratio: 186/156; males: 57%; median age: 60 years) among which 36 (11%) were current smokers and 158 (46%) ever smokers. Of the 360 VASQoL patients (GPA/MPA ratio: 265/95; males: 49%; median age: 64 years), all with complete smoking data, 26 (7%) were current smokers and 191 (53%) were ever smokers. Compared with non-current smokers, current smokers were significantly more likely to have vasculitis-related gastrointestinal (GI) manifestations in the EUVAS and in the VASQoL cohorts (17% vs. 6% [p=0.026] and 12% vs. 4% [p=0.044], respectively). In addition, VASQoL current smokers were significantly more likely to experience cutaneous (48% vs. 28%, p=0.035) and less likely to experience ENT (44% vs. 64%, p=0.046) manifestations. No other differences in AAV characteristics, including anti PR3/MPO status, were observed in the EUVAS and VASQoL cohorts although current smokers were younger than non-current smokers (p=0.047 and p=0.021, respectively). Age-adjustment did

not alter the interpretation of the identified associations of current smoking with disease characteristics. Both EUVAS and VASQoL ever-smokers were more likely to be males (both $p<0.0001$) and older (both $p=0.02$) but ever-smoking was not associated with clinical AAV characteristics in either cohort.

Conclusion: These analyses of 2 independent AAV cohorts indicate that current smoking is positively associated with GI involvement, a finding which is in keeping with the established association between smoking and risk for Crohn's disease. The VASQoL data also replicated a previous report supporting that smokers less often present with ENT manifestations. The lack of phenotype-modifying effects of ever-smoking could suggest an acute immune-modulatory effect of smoking in AAV.

Reliability and Responsivenss Of The Standardized Universal Pain Evaluations For Rheumatology Providers For Children and Youth (SUPER-KIDZ). Nadia Luca[1], Jennifer N. Stinson[1], Susanne M. Benseler[1], Brian M. Feldman[1], Dorcas Beaton[2] and Ahmed Bayoumi[3]. [1]Hospital for Sick Children, Toronto, ON, [2]Scientist, Institute for Work & Health, Toronto, ON, [3]Keenan Research Centre of the Li Ka Shing Knowledge Institute of St. Michael's Hospital, Toronto, ON.

Background/Purpose: Pain is the most common symptom in children and youth with juvenile idiopathic arthritis (JIA), however, currently there is no comprehensive validated pain measure for this population. The Standardized Universal Pain Evaluations for Rheumatology Providers for Children and Youth (SUPER-KIDZ) is a new multi-dimensional online pain tool, developed to fill this gap in clinical care. The objective of this study was to determine the test-retest reliability and responsiveness of the computerized 20-item version of the SUPER-KIDZ pain tool in children with JIA.

Methods: A single center prospective cohort study of JIA patients aged 8–18 years was performed. The SUPER-KIDZ questionnaire was administered to children expected to have stable pain for test-retest reliability analysis of each item using intra-class correlation coefficients (ICC) and weighted Cohen's kappa. Responsiveness of each SUPER-KIDZ item to change in pain was evaluated in patients undergoing intra-articular steroid injection(s) who are expected to have improvement in pain. Measures of responsiveness included standardized response mean (SRM), Wilcoxon signed rank test, linear mixed model regression, and receiver operating characteristic (ROC) curve analysis. Internal consistency of the three SUPER-KIDZ subscales (sensory, interference, emotional) was measured using ordinal reliability alpha and item-total correlation.

Results: Fifty-one children were included, of which 40 (78%) were female, and had a median of 3 active joints (1–5) and median physician global assessment of 2.5 cm (1.5–4) on 10 cm visual analog scale. Internal consistency was acceptable (ordinal $\alpha=0.73$–0.92) for the sensory, interference and emotional SUPER-KIDZ subscales. Good test-retest reliability (ICC or weighted kappa ≥ 0.80) was found for 15 SUPER-KIDZ items in at least one analysis. Reliability was strongest for the items on pain intensity, pain frequency, pain duration and physical function, and weakest for questions related to sleep, having fun, catastrophizing, and feeling angry. At 2 weeks post-injection, 16 items were responsive to change in pain (SRM=0.66–0.82, significant Wilcoxon signed rank and/or linear mixed model regression). ROC curve analysis of 9 items gave an area under the curve of ≥ 0.70, adequately distinguishing between improved and unimproved subjects. The questions less responsive to change in pain were those related to fatigue frequency and emotional function (feeling angry, cheerful, worried).

Conclusion: The majority of items of the new online SUPER-KIDZ tool have excellent test-retest reliability and responsiveness properties. The questions regarding fatigue and emotional function are less responsive to change after a joint injection procedure and could be tested after a cognitive intervention. If validity is demonstrated, this measure could be implemented as a standardized comprehensive pain tool for JIA patients, thereby fulfilling a longstanding gap in the care of patients with JIA.

Enhancing Uveitis Screening Compliance In Juvenile Idiopathic Arthritis Patients. Melissa S Oliver[1], Jennifer E. Weiss[2], Suzanne C. Li[2], Kathleen A. Haines[2], Ginger L. Janow[2], Esi Morgan DeWitt[3] and Yukiko Kimura[2]. [1]UMDNJ New Jersey Medical School, Newark, NJ, [2]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background/Purpose: Chronic uveitis is one of the more severe morbidities associated with juvenile idiopathic arthritis (JIA). Risk of developing uveitis, and the frequency of uveitis screening visits, differs between the different JIA subtypes. Through participation in the Pediatric Rheumatology Care & Outcomes Improvement Network (PR-COIN), a quality improvement collaborative, we developed a uveitis screening tool for patients to bring to their ophthalmologist to improve communication between providers. This tool includes education for the family on uveitis. Our objective was to determine if use of this tool improved adherence to uveitis screening recommendations and documentation of uveitis screening.

Methods: A retrospective chart review was conducted of 243 JIA patients without uveitis identified from our Childhood Arthritis & Rheumatology Research Alliance Registry and PR-COIN databases in the 13 months before and after beginning our participation in PR-COIN. Collected data included demographics, documentation of the uveitis assessment, and documentation of patient education. Effectiveness of implementation of the screening tool was assessed by comparing compliance with uveitis screening in the two time periods. Continuous variables were summarized as median (interquartile range). Categorical variables were summarized as frequency (percent). Paired binary outcomes of screening compliance were examined using McNemar's test.

Results: Data from 184 patients were included (table 1). Patients were excluded if they did not follow up during the study period or if charts were unavailable for review. Prior to our participation in PR-COIN, 132 (71.7%) patients reported compliance with screening but only 50 (27%) patients had documentation of their uveitis screening visits. Following introduction of our uveitis screening tool, documentation of screening increased significantly to 45.7% (table2). Of the 184 patients, 52 (28%) were non-compliant by self-report prior to participation in PR-COIN. Of those 52 patients, 32 (61.5%) increased their compliance following implementation of our uveitis screening tool.

Table 1. Demographics and characteristics of JIA patients (n = 184)

Age at diagnosis (years)	
Median (Interquartile range)	9.3 (4.5–13.2)
Range: minimum - maximum	0.3–17.9
Female n (%)	127 (69.0)
Duration of JIA disease (years)	
Median (Interquartile range)	4.4 (3.0–7.5)
Range: minimum - maximum	0.7–18.0
JIA sub-type n (%)	
Polyarticular rheumatoid factor (−)	65 (35.3)
Oligoarticular, persistent	39 (21.2)
Enthesitis related arthritis	20 (10.9)
Systemic arthritis	19 (10.3)
Psoriatic arthritis	17 (9.2)
Oligoarticular, extended	13 (7.1)
Polyarticular rheumatoid factor(+)	11 (6.0)
ANA Positive n (%)	
Yes	50 (27.2)

Table 2. Summary of patient and ophthalmologist compliance before and after implementation of our uveitis screening tool (n = 184)

	13 months prior to joining PR-COIN n(%)	13 months after joining PR-COIN n(%)	P-Value[a]
Patient self-report of compliance with uveitis screening schedule n (%)	132 (71.7)	143 (77.7)	0.1308
Ophthalmologist documentation of eye exam on chart	50 (27.2)	84 (45.7)	0.0001

a, P-value is based on the McNemar's test performed on repeated binary outcomes

Conclusion: Since joining PR-COIN and implementing a uveitis education and communication tool, there was improvement in patient compliance with uveitis screening. There was significant improvement in documentation

by ophthalmology of the patient's visit. Simple tools such as a uveitis screening form can facilitate communication with the ophthalmologist and better educate JIA patients on the importance of uveitis screening, thus improving their care.

The Research In Arthritis In Canadian Children Emphasizing Outcomes (ReACCh Out) Cohort: Are We Achieving Clinically Important Outcomes? Deborah M. Levy[1], Shirley ML Tse[1], Elizabeth Stringer[2], Jaime Guzman[3], Roberta A. Berard[4], Karen Watanabe Duffy[5], Dax Rumsey[1], Mercedes O. Chan[3], Rosie Scuccimarri[6], Adam M. Huber[2], Lori B. Tucker[7], Rae SM Yeung[1], Ciaran M. Duffy[5], Kiem Oen[8] and The ReACCh Out Investigators[1]. [1]The Hospital for Sick Children and University of Toronto, Toronto, ON, [2]IWK Health Centre and Dalhousie University, Halifax, NS, [3]BC Children's Hospital and University of British Columbia, Vancouver, BC, [4]Children's Hospital of Western Ontario, London, ON, [5]Children's Hospital of Eastern Ontario and University of Ottawa, Ottawa, ON, [6]Montreal Children's Hospital and McGill University, Montréal, QC, [7]University of British Columbia, Vancouver, BC, [8]Children's Hospital of Winnipeg and University of Manitoba, Winnipeg, MB.

Background/Purpose: Recent data suggests that achievement of inactive disease and early disease remission may result in improved outcomes for patients with juvenile idiopathic arthritis (JIA). Objectives of our study were to examine the probabilities of achieving i) active joint count (AJC)= 0; ii) inactive disease; and iii) disease remission for patients treated with contemporary treatments in a large prospective longitudinal inception cohort of patients with JIA.

Methods: ReACCh Out recruited consecutive patients diagnosed with JIA at 16 sites across Canada (Jan 2005 – Dec 2010), with prospective data collection every 6 months for the first 2 years, then yearly. Clinical information included the six ACR core outcome measures and medications. Inactive disease was defined as active joint count (AJC) =0, absence of systemic symptoms, enthesitis or uveitis and a physician global activity (PGA) of $<$ 1 cm on a 10 cm VAS. Remission was defined as $\geq$ 12 months with inactive disease with no anti-rheumatic or anti-uveitis medications. Descriptive statistics (median and interquartile range (IQR)) and Kaplan-Meier Survival analyses were examined; patients were censored at their last study visit or study end date.

Results: 1104 patients with newly diagnosed ($\leq$ 6 months) active JIA with $\geq$1 follow-up visit were analyzed. Patients were predominantly female (63%), age at diagnosis was 9.3 (3. 9, 13.0) years. Time from diagnosis to enrollment was 0.3 (0, 1.6) months. Follow-up to last visit or study end was 34.2 (21.5, 48) months. Patients were classified into ILAR subtypes at the 6 month visit: oligoarticular (416, 38%), polyarticular RF negative (235, 21%), polyarticular RF positive (46, 4%), psoriatic (64, 6%), enthesitis related arthritis (ERA) (157, 14%), systemic (sJIA)(76, 7%) and undifferentiated (110, 10%). Treatment received included intraarticular steroid injections in 46%, DMARDs in 55%, and biologics in 12%. Almost all patients (92%) achieved AJC=0 during the study period at a median of 7.0 mos (IQR 3.5, 13.3) from diagnosis. Patients with RF positive polyarthritis were last to reach AJC =0. Inactive disease was achieved by 81% of subjects at a median of 13.0 mos (IQR 7.7, 21.7) from diagnosis. Time to first episode of inactive disease was shortest in the oligoarthritis group, and longest in the RF positive polyarthritis group. Table 1 shows the time to achieve AJC =0 and inactive disease by JIA subtype. By survival analysis, the probability of disease remission by 4 years of disease was oligoarthritis (41%), polyarticular RF negative (8%), polyarticular RF positive (0%), psoriatic (47%), ERA (28%), sJIA (29%) and undifferentiated (30%).

Table 1. Disease duration (in months) to achieve outcomes

	AJC = 0		Inactive Disease	
	N	Median (IQR)	N	Median (IQR)
Oligoarthritis	412	5.9 (3.3, 10.0)	410	9.6 (6.8, 14.9)
Polyarticular RF negative	235	10.2 (5.0, 16.5)	232	14.9 (10.8, 27.3)
Polyarticular RF positive	46	10.0 (6.7, 20.2)	46	24.2 (13.5, 39.5)
Psoriatic	62	7.2 (4.7, 14.9)	63	12.6 (7.7, 18.1)
Enthesitis Related Arthritis	157	6.8 (3.0, 14.3)	153	16.0 (10.7, 24.5)
Systemic	75	3.6 (2.0, 11.3)	74	13.1 (6.7, 36.4)
Undifferentiated	110	6.4 (3.2, 15.9)	108	14.4 (9.4, 22.7)

Conclusion: Almost all patients achieve an AJC =0, and most attain inactive disease; however, the probability of remission remains low for the polyarticular subtypes.

Telephone Consultation Usage In a Pediatric Rheumatology Clinic: Considerations In Optimizing Nursing Resources. Julie Lemieux[1], Audrey Tran[2], Vincent Brienza[3] and Roman Jurencak[3]. [1]Children's Hospital of Eastern Ontario, Ottawa, ON, [2]University of Western Ontario, London, ON, [3]University of Ottawa, Ottawa, ON.

Background/Purpose: Telephone consultation is essential to the delivery of patient care in the ambulatory care clinics at the Children's Hospital of Eastern Ontario (CHEO). Our objective was to quantify and analyze all telephone calls received by the pediatric rheumatology nurses at CHEO.

Methods: As per CHEO policy and procedure, all telephone calls nurses receive are documented on standard forms. Calls documented by the nursing staff in the Division of Pediatric Rheumatology over a six-month period from Jan 1, 2012 until June 30, 2012 were retrospectively analyzed for selected characteristics. An incoming call addressing a new concern relating to a specific patient was considered to be the index call. Index calls and all subsequent documented communications generated by the index call were then examined. Calls that only confirmed appointments and calls confirming that a message was received were excluded from analysis.

Results: 321 index calls were received during the study period (0.6 calls per clinic hour), generating a total of 780 follow-up calls. The most frequent patient diagnosis was juvenile idiopathic arthritis (57%) and most patients were 12–18 years old (52%). 79% of calls were placed by the patient's mother, while only 1% of callers were the patient themselves. 44% of calls lasted 1–5 minutes, 29% lasted 5–10 minutes and 27% lasted more than 10 minutes. The most common reasons for call were concerns relating to rheumatologic condition and medications taken (50%). Large number of calls was related to administrative issues such as requests for appointment change, prescription refills, etc (34%). Pain management was discussed in 29% of all calls. Nurses managed independently 40% of calls; when other health care providers were consulted, the physician was approached in 91% of cases. Only 8% of index calls resulted in an advanced clinic appointment.

Conclusion: This study provides a descriptive analysis of calls nurses receive in a tertiary care pediatric rheumatology clinic. While nursing telephone consultation is beneficial in providing inter-disciplinary patient care and in minimizing clinic visits, the associated workload is significant and utilization of this service needs to be optimized, including re-distribution of administrative calls. Teenage patients rarely call themselves and their independence needs to be encouraged.

Pediatric Rheumatology Care and Outcomes Improvement Network Demonstrates Performance Improvement On Juvenile Idiopathic Arthritis Quality Measures. Julia G. Harris[1], Esi Morgan DeWitt[2], Ronald M. Laxer[3], Stacy P. Ardoin[4], Beth S. Gottlieb[5], Judyann C. Olson[1], Murray H. Passo[6], Jennifer E. Weiss[7], Daniel J. Lovell[8], Tzielan C. Lee[9], Sheetal S. Vora[10], Nancy Griffin[2], Jason A. Stock[2], Lynn M. Darbie[2] and Catherine A. Bingham[11]. [1]Children's Hospital of Wisconsin, Milwaukee, WI, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]University of Toronto, Toronto, ON, [4]Ohio State University College of Medicine, Columbus, OH, [5]Cohen Children's Medical Center of New York, New Hyde Park, NY, [6]Medical University of South Carolina, Charleston, SC, [7]Hackensack University Medical Center, Hackensack, NJ, [8]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [9]Stanford University School of Medicine, Stanford, CA, [10]University of North Carolina Chapel Hill, Chapel Hill, NC, [11]Penn State Hershey Children's Hospital, Hershey, PA.

Background/Purpose: Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) is a multi-site learning network designed to improve outcomes of juvenile idiopathic arthritis (JIA) care. Teams collect point of care data on measures of process of care and outcomes of care for the purposes of analysis to guide improvement activities. Eleven North American

pediatric rheumatology centers participate. This report illustrates our improvement in several JIA process quality measures (QMs).

Methods: Process of care QMs targeted for improvement include measurement of: arthritis-related pain, physician global assessment, joint count, health-related quality of life, physical function, as well as screening for uveitis, medication toxicity, and tuberculosis per guidelines. Outcome measures for JIA include clinical inactive disease, no or mild pain level, and optimal physical functioning. Network goals were determined for each process and outcome measure. Data are collected with IRB approval and informed consent, and the shared registry for data entry is the ACR's Rheumatology Clinical Registry. Site-specific and aggregate data are analyzed and displayed monthly via statistical process control charts allowing PR-COIN to track performance over time. Individual centers use established quality improvement methodology to reach and exceed pre-determined goals.

Results: Data from 3231 encounters for 905 JIA patients have been collected since April 2011. QMs with performance meeting or exceeding initial goals include: documentation of complete joint count every 180 days, measurement of arthritis-related pain at every visit, functional assessment every 180 days, and documentation of baseline toxicity labs. For PR-COIN network as a collective unit, QMs improved in five processes– measurement of functional ability, completion of ongoing medication toxicity labs, documentation of complete joint count, documentation of annual behavioral counseling, and measurement of health-related quality of life. All of these measures had a sustained shift above the baseline mean, demonstrating special cause. In addition, five sites have demonstrated individual improvement in at least one process QM.

Conclusion: PR-COIN sites are collectively and individually demonstrating significant improvements in JIA process of care QMs. Quality improvement efforts in PR-COIN are ongoing with the goal of improving the outcome for patients with JIA.

Towards Developing a Rheumatology-Specific Transition Of Care Program. Rina Mina[1], Janalee Taylor[2], Pamela A. Heydt[3], Terry M. Moore[4], Julie V. Ranz[2], Mary Beth Burns[2], Paula G. Melson[5], Abigail Nye[2], Jill Segerman[2], Yolanda Farhey[6], John Houk[6], Avis Ware[6], Jennifer L. Huggins[2] and Lisa Vaughn[2]. [1]Cincinnati Children's Hospital Medical Center/University of Cincinnati School of Medicine, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Childrens Hospital Medical Center, Cincinnati, OH, [4]Cincinnati Chiildren's Hospital Medical Center, Cincinnati, OH, [5]Children's Hosp Medical Center, Cincinnati, OH, [6]University of Cincinnati, Cincinnati, OH.

Background/Purpose: Because of their considerable medical challenges, adolescents and young adults with pediatric-onset rheumatic diseases are often reliant on the health care system, and any interruption in their care could have serious consequences. Their successful transition of care from pediatric to adult health care systems is crucial for maintaining their health and health-related quality of life. As such, an organized transition of care program is highly important for these patients.

Our objective was to determine components of a transition program from pediatric to adult rheumatology care using survey method.

Methods: A checklist oriented towards developmentally appropriate goals for transition of care was formulated after review of existing literature and other transition checklists in use for other diseases. An online survey to gather approval for the checklist and resolve transition of care related questions was sent to members of the pediatric rheumatology multidisciplinary staff at Cincinnati Children's Hospital Medical Center and to its adult rheumatology counterpart at the University of Cincinnati. The participants included attending pediatric and adult rheumatologists on staff, fellows-in-training, nursing staff, physical and occupational therapists, and social worker. All have direct patient contact.

Results: Response rate was 84% (27 of 32). The respondents unanimously accepted the self-management transition checklist in terms of content and format. The checklist contained transition goals that reflected developmental skills of the patients. All respondents want the checklist to be incorporated into the patient's electronic chart.

From the pediatric rheumatology side, there was no agreement as to (1) the frequency of transition readiness assessment, and (2) at what age should the preparation phase of transition should commence. In addition, majority agreed on the (1) usefulness of scheduled independent visits for adolescent patients to (67%) and (2) necessity of actual doctor visit with an adult rheumatologist prior to the transfer-of-care.

The adult rheumatology staff and fellows unanimously thought that patients should be able to communicate independently to care providers and be informed about their disease. Majority (60%) of the adult rheumatology providers felt that they need more information and education about caring for patients with pediatric onset rheumatic diseases.

Conclusion: Agreement was reached on several relevant aspects of a transition of care checklist and program for patients with pediatric onset rheumatic disease. Validation of this checklist is ongoing as are interventional support to meet gaps in the transition process.

Characterisation Of Antigens Driving *In Situ* Autoantibody Production In Human Lupus Tubulointerstitial Nephritis (TIN). Andrew Kinloch[1], Scott Henderson[1], Natalya Kaverina[1], Anthony Chang[1], D. James Haddon[2], Justin Jarrel[2], Carole Henry Dunand[1], Patrick C. Wilson[1], Paul Utz[2] and Marcus R. Clark[1]. [1]University of Chicago, Chicago, IL, [2]Stanford University School of Medicine, Stanford, CA.

Background/Purpose: We have demonstrated that the degree of tubulointerstitial nephritis (TIN) on diagnostic biopsy predicts progression to renal failure. TIN is associated with tertiary lymphoid structures, *in situ* B cell oligoclonal expansion and ongoing antigen-driven somatic hypermutation. These phenomena support the hypothesis that local antigen is driving in situ lymphocyte selection and activation. Therefore, we cloned and characterized the antigenic specificities of in situ selected antibodies in human TIN.

Methods: Human kidney biopsies with lupus TIN were stained for the proliferation marker ki-67 (6/8), or the post GC marker CD38 (1/8). Positive single cells were isolated by laser capture microscopy. An eighth sample was single cell sorted for $CD138^+$ plasmablasts. mRNA was purified and cDNA reverse transcribed. Matched IgG heavy and light chain variable regions were PCR amplified, cloned into human IgG1 heavy or light chain expression vectors and expressed as mAbs in HEK-293 cells. Antigen screening methods included clinical ELISAs, crithidia IIF (for DNA), human protein arrays (Invitrogen), confocal microscopy of HEp-2 cells. Antigens targeted in HEp-2 cells were sought by immunoprecipitation followed by mass spectrometry. Candidate antigen identity was confirmed by multi-color confocal microscopy, and purified antigen ELISAs and protein arrays. In situ expression pattern of target antigen was confirmed by immunofluorescence using kidney from lupus TIN and normal controls. Sera from lupus patients, with (n=40) and without nephritis (n=20), were tested for IgG reactivity with candidate antigens.

Results: 27 mAbs were generated. By HEp-2 analysis, 3/27 yielded nuclear speckled-patterns, 1/27 nucleolar-, 7/27 cytoskeletal-, 3/27 nuclear and cytoplasmic-, and 1/27 reacted with the golgi apparatus. None were DNA, Sm or RNP positive. Vimentin was confirmed as the dominant targeted antigen (40% of mAbs, from 7/8 patients), immunoprecipitated from HEp-2 cells, bound by TIN mAbs on arrays and ELISA, and yielding a co-staining pattern with an anti-vimentin antibody (V9, DAKO). Vimentin reactive TIN mAbs reacted strongly with both glomeruli and inflamed TI, but little with normal TI. Approximately 70% of serum samples reacted with vimentin by protein array and this tended to be more common in nephritis patients. Antigens targeted more strongly in nephritic serum included myosin and SSB (median % false discovery rate <.001).

Conclusion: Vimentin is an autoantigen upregulated during inflammation capable of driving in situ antibody production. These data support a model inwhich a positive feed-back loop of inflammation contributes to renal failure.

B Cell Derived Cytokines Induce Glomerular Injury in Mice. Alfred Kim[1], Shreeram Akilesh[2], Jeffrey Miner[3] and Andrey Shaw[3]. [1]Washington Univ School of Med, St. Louis, MO, [2]University of Washington, Seattle, WA, [3]Washington University School of Medicine, Saint Louis, MO.

Background/Purpose: Renal involvment remains the leading cause of mortality for SLE patients, and is associated with proteinuria and foot process effacement. In subsets of LN patients, B cell depletion therapies have been efficacious in lowering disease activity including glomerulopathy. The contributions of B cells to proteinuria and foot process effacement remain unknown. The development of a murine model of B-cell induced proteinuria and identification of pathogenic factors would enhance our understanding of immune-based glomerular diseases.

Methods: The B cell model antigen model hen egg lysozyme (HEL) was biotinylated, complexed to avidin and injected into mice. Naïve HEL-specific B cells were then adoptively transferred and proteinuria assessed. Kidneys were processed for immunofluorescence and scanning electron microscopy (SEM). Cultured podocyte membrane ruffling was assessed with DIC videomicroscopy. IL-4 expression in mice was achieved by hydrodynamically injecting murine IL-4 in the piggyBac vector system.

Results: HEL embedded within the glomerular basement membrane (GBM) following IV injection. Proteinuria occurred after the transfer of naive HEL-specific B cells and associated with focal foot process effacement. No antibody or complement deposition was observed in proteinuric glomeruli. Intravital two-photon microscopy demonstrated that HEL-specific B cells arrested trafficking within glomeruli only in the presence of glomerular-localized HEL. This demonstrated that B cells were capable of inducing glomerular injury and proteinuria.

These data suggested cytokines secreted by activated B cells may be responsible for podocyte injury. Since foot process effacement is the histologic correlate of actin cytoskeletal rearrangement, we hypothesized that cytokines mediate podocyte injury through alterations in the actin cytoskeleton. We found that IL-4 induced unstable actin cytoskeletal changes leading to membrane ruffling. In addition, IL-4 generated foot process retractions on ex vivo fragments of renal cortex. Hydrodynamic DNA injection of wild-type mice with plasmid encoding IL-4 lead to proteinuria, which was reversed by JAK1/3 inhibition.

Conclusion: We developed a novel model of B cell-induced proteinuria with focal foot process effacement. B cell derived cytokines such as IL-4 induced alterations in foot process morphology, leading to proteinuria. Transgenic IL-4 mice are associated with glomerulosclerosis independent of autoantibody production. We believe that IL-4 plays a direct role in podocyte injury through disruptions in the actin cytoskeleton. This has important implications in developing therapies to preserve podocyte function, limiting glomerular injury.

Effects Of BAFF Inhibition On B Cell Selection In Murine SLE. Alexis Boneparth[1], Ramalingam Bethunaickan[2], Weiqing Huang[2] and Anne Davidson[2]. [1]Feinstein Institute for medical Research, Manhasset, NY, [2]Feinstein Institute for Medical Research, Manhasset, NY.

Background/Purpose: BAFF inhibition is a new B cell targeted therapy approved for the treatment of moderately active SLE. Although BAFF regulates selection of naïve autoreactive B cells, belimumab only modest decreases autoantibody titers. To determine whether BAFF inhibition alters the quality of the autoantibody response by affecting selection of autoreactive B cells we generated NZW/BXSB.yaa (W/B) mice bearing the 3H9 site directed Ig heavy chain transgene. An extra copy of TLR7 conferred by the *Yaa* locus accelerates disease in the males. 3H9 associates with diverse light chains to generate anti-DNA and anti-cardiolipin specificity. We have previously shown that the autoreactive B cell response in 3H9.W/B mice uses predominantly Vk5-43 and Vk5-48 light chains that confer autoreactivity in their germline configuration and that such 3H9/Vk5-expressing B cells are rare in the naïve repertoire but are expanded in germinal centers (GCs). Male W/B mice have defects in tolerance both at the GC entry checkpoint and in negative selection of B cells that acquire autoreactivity as a consequence of somatic mutation. We now wish to know whether BAFF inhibition influences either of these two checkpoints.

Methods: To create a physiologic setting in which autoreactive B cells compete for survival with non-autoreactive B cells, we generated 50% 3H9/50% wt W/B bone marrow chimeras in which transferred 3H9. $TLR7^{+/+}$ or $TLR7^{+/-}$cells are GFP+ and can be easily identified. To determine when negative selection of 3H9+ cells occurs, we enumerated the % 3H9+/GFP+ cells in immature bone marrow, transitional, marginal zone (MZ), follicular (Fo), GC and plasma B cells using flow cytometry. To investigate the effect of TLR7 dose and BAFF inhibitors on selection of the autoreactive B cell repertoire, we performed single cell PCR and sequencing to determine the repertoire of light chains associating with the 3H9 heavy chain in Fo, GC, and plasma cells.

Results: When competition from wt B cells is provided, significant deletion of 3H9 B cells occurs at the immature and transitional stage in the bone marrow regardless of TLR7 status or BAFF inhibition. Relative enrichment of 3H9 B cells occurs in the GC $TLR7^{+/+}$ compared with $TLR7^{+/-}$ chimeras. BAFF-R-Ig treatment significantly decreases B cell percentage and total numbers but does not decrease the percentage of immature or mature 3H9 B cells or mediate deletion of anergic cells. Data from single cell sorts of GFP+ B cells indicates comparable naïve B cell repertoires but a decrease in selection of high affinity anti-chromatin Vk5-48/

Jk4 light chains among TLR7$^{+/-}$ and BAFF-R-Ig treated mice compared with TLR7$^{+/+}$ untreated controls.

Conclusion: Preliminary data indicates that when competition is provided, negative selection of naïve 3H9+ cells appears to be TLR7 and BAFF independent. In contrast, although autoreactive B cells still entered the germinal centers in mice treated with BAFF inhibition, modest changes were observed in germinal center selection. Future studies will explore the specific effects of BAFF inhibition on B cells that acquire autoreactivity in the GC as a consequence of somatic mutation.

B-Lymphocyte Stimulator and A Proliferation Inducing Ligand In Lupus Nephritis: Low Serum Levels Of BLyS Predict Treatment Response. Ioannis Parodis[1], Agneta Zickert[1], Elisabet Svenungsson[1], Vivianne Malmström[1] and Iva Gunnarsson[2]. [1]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: B-lymphocytes have a pivotal role in the pathogenesis of Systemic Lupus Erythematosus (SLE). B-Lymphocyte Stimulator (BLyS) has an important role in the activation, differentiation and maintenance of activated B-cells. A PRoliferation Inducing Ligand (APRIL) is involved in the induction and maintenance of B- and T-cell responses. The aim of our study was to assess serum levels of BLyS and APRIL in patients with lupus nephritis (LN) and investigate how these levels are affected by immunosuppression.

Methods: Sixty-four patients with biopsy-proven LN (52 proliferative nephritis, PN, and 12 membranous nephritis, MN) and 64 gender- and age-matched controls were included in our study (mean age 34 years). The patients were treated with corticosteroids combined with cyclophosphamide (CYC, n=45), mycophenolate mofetil (n=11), rituximab (n=7) or azathioprine (n=1) and underwent a second renal biopsy after completed induction therapy. Serum was collected before and after induction treatment (mean time 8 months) for the patients and at recruitment for the controls. The mean proteinuria at baseline was 2.2 g/d. BLyS and APRIL levels were estimated by ELISA (R&D Systems and eBioscience, respectively). The renal biopsies were assessed according to the ISN/RPS classification system, as well as Activity Index (AI) and Chronicity Index (CI). We defined clinical response (CR) as ≥50% reduction in proteinuria, normal or improved renal function (≥25% increase of GFR) and inactive urinary sediment. For complete response the proteinuria at follow-up should be <0.2 g/d and for partial response between 0.2 and 2 g/d. We defined histopathological response (HR) as ≥50% improvement in AI for partial response and additionally demanded a lack of signs for active inflammation (ISN/RPS class I, II, III C or IV C) in the follow-up biopsy for complete response.

Results: BLyS levels were significantly higher in patients with LN than in controls ($p<0.001$), but remained unchanged after induction treatment ($p=0.99$). APRIL levels were significantly higher in patients compared to controls at baseline ($p=0.005$), but not at follow-up (0.14). This is consistent with a significant reduction of APRIL levels at follow-up ($p<0.001$). This decrease was more prominent in patients who received CYC ($p=0.006$). APRIL levels decreased significantly in both responding and non-responding patients. In the patient group with PN, the decrease of APRIL in non-responding patients was not statistically significant ($p=0.13$). Interestingly, the ROC-curve for BLyS by treatment response revealed a potential predictive power. Further analysis showed that low baseline levels of BLyS had high positive predictive value for both CR and HR.

Conclusion: We observed an overall decrease in serum levels of APRIL after immunosuppression. No decrease was found in non-responding patients with PN, implying that APRIL could be of importance in this subgroup. BLyS levels remained unchanged after immunosuppressive treatment, suggesting that conventional treatments do not affect BLyS-producing cells. However, low baseline levels of BLyS were found to predict both CR and HR, suggesting that BLyS should be evaluated as a potential biomarker of response in LN.

Bone Marrow In Systemic Lupus Erythematosus Patients Contain a Highly Elevated Proportion Of Somatically Mutated, Activated Naive Cells Comprised Of Substantial Clonal Expansions. Jennifer Hom[1], Christopher Tipton[1], Christopher Fucile[2], Bridget Neary[1], Chungwen Wei[1], F. Eun-Hyung Lee[1], Alex Rosenberg[2] and Inaki Sanz[1]. [1]Emory University, Atlanta, GA, [2]University of Rochester, Rochester, NY.

Background/Purpose: Systemic lupus erythematosus (SLE) is a disease where autoreactive antibodies are produced as a result of abnormal B cell activation and broken self-tolerance. This activation is perhaps most prominently observed in elevated levels of circulating activated cells within the naïve compartment of SLE patients. The origin, diversity, and direct developmental consequences of this elevated activation are largely unclear though. In this study, we use a variety of multi-color flow cytometry panels to isolate and sort specific bone marrow (BM) and circulating B cell populations for immunoglobulin heavy chain (IGH) deep sequencing analysis. By developing a novel program to trace their inter-population relationships through mutational analysis, we aim to further characterize these cells and their contribution to the pathogenesis of SLE.

Methods: Peripheral blood and BM aspirates from healthy donors and volunteers with SLE were collected and sorted using several multi-color flow cytometry panels. The IGH gene was amplified from these cells using multiple sets of VH family-specific and isotype-specific primers. Deep sequencing was conducted using Illumina MiSeq technology, and results were analyzed using an internally developed analysis program that performs quality filtering, detailed mutational analysis, and identification and matching of clonal lineages.

Results: We found that a population of circulating mitotracker green (MTG) positive, CD23- activated naïve cells were highly elevated in flaring SLE patients, slightly elevated in non-flaring patients, and largely absent in healthy controls. This population was also identified in BM of SLE patients, and it was found to be highly elevated in all SLE samples. Deep sequencing analysis showed that unlike most other populations in the circulation and BM, this population was highly oligoclonal, with some clones accounting for greater than 5% of the total population. Sequences from these activated naïve cells were somatically mutated and typically found to be of lower VH mutation rates than memory and plasmablasts (PB), but higher than resting naïve cells. We found clonal relations between several circulating and BM B cell subsets and tracked the lineage maturation using mutation analysis. Surprisingly, the activated naïve fraction was highly related to PB and through mutational tree analysis, they were found to inhabit the more proximal portion of the same lineage branches as the more distal PB.

Conclusion: Our data suggest that in SLE, there is an expansion of activated MTG+, CD23- naive cells which may be an early implication of abnormal B cell activation as a result of damaged self-tolerance. We show that these cells are highly related to circulating and BM antibody-producing PB, which are typically also expanded in SLE.

Identification Of IL-10 Producing Plasma Cells In Human and Its Deficiency In Systemic Lupus Erythematosus Patients. Xiaoqian Wang[1], James Roger[2] and Ignacio Sanz[3]. [1]Emory University, Allergy, Immunology and Rheumatology, Atlanta, GA, [2]University of Rochester, Rochester, NY, [3]Emory University School of Medicine, Atlanta, GA.

Background/Purpose: Regulatory B cells are active participants in down-regulating inflammation and autoimmunity, through the production of IL-10. Despite intensive studies in mice, there is only a paucity of data concerning the regulation of IL-10 production in human. The purpose of this study is to understand IL-10 production by human B cells and to explore the development of regulatory B cells either in healthy individuals or in patients with SLE.

Methods: Healthy controls (HC) (n=15) and SLE patients (n=20) fulfilling the American College of Rheumatology revised classification criteria were included in this study. Total B cells were purified with MACS-negative selection and different B cell subsets were obtained by sorting. IL-10 producing B cells were identified with intracellular staining, Elispot, and dual color Flurospot assay. Elisa was used to determine the level of IL-10 in B cell cultures.

Results: In vitro and ex vivo analysis determined for the first time, that human plasma cells (PC: CD19+CD27++CD38++CD138+) and plasmablasts (PB: CD19+CD27++CD38^{++}CD138^{-}) are major sources of IL-10. This cytokine was secreted from PB and PC generated in vitro from cultured memory cells using Elispot assay and intracellular flow cytometry. Both assay identified 1–2% of IL-10 positive PB/PC. Similarly, ex vivo analysis of unstimulated B cell subsets sorted 7 days after flu vaccination of HC identified PB and PC as the only source of IL-10 and up to 1% of PC and PB are able to produce IL-10. In contrast, circulating PB and PC spontaneously expanded in the circulation of active SLE patients failed to produce IL-10 ex vivo. In vitro stimulation of purified B cell subsets with CpGDNA and IL-2 coupled with CFSE labeling identified the IgD(+)CD27(+) non-switched memory B-cell subpopulation as the main IL-10-producing precursor B cell in a division-linked fashion. Of interest, IL-10 production from stimulated B cells was significantly lower in SLE patient (380.1±60.94 pg/ml) than in HC (857.6±97.06 pg/ml) ($p<0.001$), in direct correlation with the reduction in non-switched memory cells typical of this disease. In contrast, SLE patients with normal distribution of B cell subsets had normal IL-10 secretion.

Conclusion: We provide the first description of spontaneous IL-10 production by human PB and PC in HC and its deficiency in SLE. These findings suggest that IL-10 could negatively regulate antibody secreting cells in an autocrine fashion that would be deficient in SLE thereby enhancing autoantibody production. Our data also identify non-switched memory B cells as an important source of potent regulatory B cells and indicate that the decrease of this population typically observed in SLE may be a major contributor to the deficiency of regulatory IL-10 in this autoimmune disease.

Dose-Response Effects Of Denosumab, a Novel Subcutaneous RANKL Inhibitor, On The Progression Of Bone Erosion In Japanese Patients With Rheumatoid Arthritis Treated With Methotrexate: Results Of Phase II DRIVE Study—A Twelve Month Placebo Controlled, Randomized, Double Blind Study. Tsutomu Takeuchi[1], Yoshiya Tanaka[2], Naoki Ishiguro[3], Hisashi Yamanaka[4], Toshiyuki Yoneda[5], Harry K. Genant[6] and Désirée van der Heijde[7]. [1]Keio University School of Medicine, Tokyo, Japan, [2]University of Occupational and Environmental Health, Kitakyushu, Japan, [3]Nagoya University Graduate School of Medicine, Nagoya, Japan, [4]Institute of Rheumatology Tokyo Women's Medical University, Tokyo, Japan, [5]Indiana University School of Medicine, Indianapolis, IN, [6]University of California, San Francisco, CCBR-Synarc, Newark, Tiburon, CA, [7]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Denosumab is a fully human monoclonal antibody (IgG_2 subclass) that binds specifically to RANKL. It inhibits osteoclast-induced bone resorption by preventing the binding of RANKL to RANK, thereby inhibiting progression of marginal bone erosion at the joints where inflammatory cytokines are highly expressed, stopping structural joint damage. In this study, we evaluated the dose-frequency of denosumab for safety and efficacy in Japanese patients with RA.

Methods: DRIVE Study (AMG162-D-J201) was a placebo-controlled, 4-arm randomized (1:1:1:1), double-blind, parallel-group study in patients receiving methotrexate treatment. Denosumab 60 mg (every 6 months (Q6M), 3 months (Q3M), or 2 months (Q2M)) or placebo was administered subcutaneously for 12 months. The primary endpoint was change in the bone erosion score assessed by the modified Sharp-van der Heijde method from baseline to 12 months. One-tailed Shirley-Williams's test were performed and differences were considered significant when $p<0.025$.

Results: Among 350 patients enrolled, 346 (placebo, n=88; Q6M, n=86; Q3M, n=85; Q2M, n=87) were treated with the study drugs (Table 1), and 35 (placebo n=6; Q6M, n=8; Q3M, n=13; Q2M, n=8) were discontinued.

Table 1. Baseline demographics and characteristics of Japanese patients with RA.

Characteristic	Placebo N = 88	Denosumab 60 mg Q6M N = 85	Denosumab 60 mg Q3M N = 82	Denosumab 60 mg Q2M N = 85
Female	76 (86.4)	65 (76.5)	59 (72.0)	66 (77.6)
Age (years)	57.0 ± 10.6	54.4 ± 10.6	52.0 ± 11.7	54.6 ± 10.5
Disease duration (years)	2.3 ± 1.3	2.2 ± 1.3	2.3 ± 1.3	2.3 ± 1.4
Rheumatoid factor positive	60 (68.2)	59 (69.4)	56 (68.3)	57 (67.1)
MTX dose (mg)	7.6 ± 1.8	8.0 ± 2.0	8.4 ± 2.2	8.3 ± 2.0
DAS28-CRP	3.5 ± 0.9	3.2 ± 0.9	3.3 ± 0.9	3.3 ± 0.8

Data presented are Mean ± SD or n (%).

Changes in the bone erosion score (deltaERO) at Month 12 were 0.99 ± 2.69 in placebo, 0.27 ± 0.98 in Q6M (Compared with placebo, p=0.0082), 0.14 ± 0.53 in Q3M (p=0.0036), and 0.09 ± 1.52 in Q2M ($p<0.0001$) (Figure 1). Percentages of patients without increase in ERO (≤0) at Month 12 were 62.5% in placebo, 78.8% in Q6M (p=0.0173), 80.5% in Q3M (p=0.0099), and 83.5% in Q2M (p=0.0019).

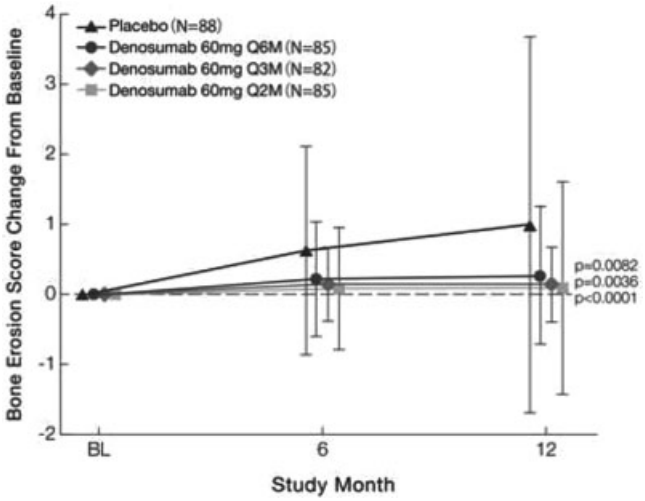

Figure 1. Mean (± SD) Bone Erosion Score Change From Baseline (Full Analysis Set)

No significant differences in the types and the overall incidence of adverse events (AEs) were observed among denosumab-treated groups and the placebo group. No hypocalcemia, osteonecrosis of the jaw, or atypical femoral fracture were observed.

Conclusion: Greater suppression of the bone erosion from baseline to 12 months and the less erosive progression were observed after denosumab treatment in all doses compared with placebo, with lower progression rates in groups with shorter dosing interval. Denosumab was well tolerated in Japanese patients with RA and shortening the dosage interval did not increase AE incidence.

Comparative Longitudinal Analysis Of Periarticular Bone Structure In Patients Treated With Methotrexate In Combination Of Either TNF Blockers Or Tocilizumab. Sebastian Kraus, Matthias Englbrecht, Juergen Rech, Roland Kocijan, Georg A. Schett and Stephanie Finzel. University of Erlangen-Nuremberg, Erlangen, Germany.

Background/Purpose: Inhibition of tumor necrosis factor alpha (TNFi) and interleukin-6 receptor (IL6Ri, tocilzumab) are among the most potent therapeutic strategies in patients with rheumatoid arthritis (RA) and have shown to retard structural bone damage. Comparative longitudinal studies on the impact of TNFi or IL-6i on periarticular bone damage in RA, however, have not been performed.

Methods: Observational study on 54 patients with RA receiving TNFi (N=25) or IL6Ri (N=29) in combinaton with methotrexate over one year. All patients received baseline and one-year follow-up examination of the 2nd–4th metacarpophalangeal and wrist joints for presence of erosions and osteophytes using high-resolution peripheral quantitative computed tomography (HR-pQCT). Erosions and osteophytes were quantified both numerically and metrically at baseline and one year follow-up. Demographic and disease specific characteristics such as age, gender, disease duration and -activity were recorded.

Results: Both cohorts were comparable for age, gender, disease duration and –activity, autoantibody status as well as baseline bone damage. At baseline 185 erosions (MCP:N=136; wrist:N=49) and 340 osteophytes (MCP:N=248; wrist:N=92) were detected in the 29 patients of the IL-6i group and 123 erosions (MCP:N=84; wrist;N=39) and 270 osteophytes (MCP: N=176; wrist: N=94) were detected in the 25 patients of the TNFi group. Erosion numbers significantly increased in the MCPs (+0.321mm^3, t(83)=−2.92, p=0.004) and tended to increase in the wrist joints: (+0.13mm^3, t(48)=−0.52, p=0.096) in the TNFi group, whereas they remained constant in IL-6i treated patients both in wrist and MCP joints. No significant volumetrical change of erosive changes of erosions was observed in either group. Osteophyte numbers (TNFi:+0.27mm, t(175)=−6.99, p<0.001; IL6i:+ 0.1mm, t(245)=−3.49, p=0.001) and size (TNFi: +0.19mm, t(174)=−7.01, p<0.0001; IL-6i:+0.08mm, t(247)=−3, p=0.003) in the MCP joints significantly increased in both groups. In the wrists, osteophytes increased both in size (+0.9mm, t(96)=2.49, p=0.015) and numbers (+0.19mm, t(93)=−3.14, p=0.002) in the TNFi group while remaining constant in size and increasing in numbers (+0.185mm, t(91)=−3, p=0.004) in the IL-6i group.

Conclusion: This study suggests that IL-6Ri allows an even better control of structural bone damage than TNFi in patients with erosive RA. Furthermore, the observation that HR-pQCT allows detecting structural progression in TNFi treated RA patients is important and indicated that high-level imaging technology allows very detailed analysis of changes of bone composition in RA patients, which could be valuable to improve the monitoring of strucrural effects of anti-rheumatic drugs.

A Treat-To-Target Strategy With Methotrexate and Intra-Articular Triamcinolone With Or Without Added Adalimumab Reduces Synovitis, Osteitis and Tenosynovitis and Halts Structural Damage Progression In Early Rheumatoid Arthritis: The Opera Magnetic Resonance Imaging Sub-Study. Mette Bjørndal Axelsen[1], Iris Eshed[2], Kim Hørslev-Petersen[3], Kristian Steengaard-Petersen[4], Merete L. Hetland[5], Jakob M. Møller[6], Peter Junker[7], Jan Pødenphant[8], Torkell Ellingsen[9], Palle Ahlquist[10], Hanne M. Lindegaard[11], Asta Linauskas[12], Annette Schlemmer[13], Mette Yde Dam[14], Ib Hansen[15], Hans Chr Horn[16], Christian G. Ammitzbøll[17], Anette Jørgensen[17], Sophine B. Krintel[18], Johnny Raun[19], Julia S. Johansen[20], Niels Steen Krogh[21] and Mikkel Østergaard[5]. [1]Copenhagen University, Copenhagen, Denmark, [2]Sheba Medical Center, Tel Hashomer, Israel, [3]South Jutland Hospital, Graasteen, Denmark, [4]Aarhus University Hospital, Aarhus, Denmark, [5]Copenhagen University Hospital Glostrup, Copenhagen, Denmark, [6]Copenhagen University Hospital at Herlev, Copenhagen, Denmark, [7]Odense University Hospital, Odense C, Denmark, [8]Copenhagen University at Gentofte, Hellerup, Denmark, [9]Diagnostic Centre Region Hospital Silkeborg Denmark, 8600 Silkeborg, Denmark, [10]Vejle Regional Hospital, Vejle, Denmark, [11]Odense University Hospital, Odense, Denmark, [12]Vendsyssel Hospital, Hjørring, Denmark, [13]Aalborg University Hospital, Aalborg, Denmark, [14]Silkeborg Regional Hospital, Silkeborg, Denmark, [15]Viborg Hospital, Viborg, Denmark, [16]Vejle Hospital, Vejle, Denmark, [17]Arhus University Hospital, Aarhus, Denmark, [18]Copenhagen University Hospital at Glostrup, Glostrup, Denmark, [19]University of Southern Denmark, Graasten, Denmark, [20]Herlev Hospital, Herlev, Denmark, [21]ZiteLab ApS, Copenhagen, Denmark.

Background/Purpose: The aim was to investigate if a treat-to-target strategy with methotrexate and intra-articular glucocorticoid suppressed synovitis and osteitis, and halted structural damage progression in early rheumatoid arthritis (ERA), and if added adalimumab provided an additional effect, as judged by magnetic resonance imaging (MRI).

Methods: In a double-blinded placebo-controlled investigator-initiated trial, 180 DMARD naïve ERA patients were randomized 1:1 to methotrexate, intra-articular glucocorticoid injections and placebo/adalimumab (1). Eighty-five patients (placebo/adalimumab: 43/42) had contrast-enhanced MRI of the right wrist and the 2nd–5thmetacarpohalangeal joints at months 0, 6 and 12. Synovitis, osteitis, tenosynovitis, bone erosion and joint space narrowing (JSN) were scored with validated methods (2–4).

Results: Synovitis, osteitis and tenosynovitis scores decreased highly significantly (p<0.0001) during the 12-months follow-up, with change scores of mean −3.7 (median −3.0[range −13;11]), −2.2 (−1 [−31;32]) and −3.3 (−1[−31; 32]), respectively. No overall change in MRI erosion and JSN scores were observed, with change scores of 0.1 (0 [-16;13]) and 0.2 (0 [-3;4]), respectively. See table for status scores. Clinical disease activity scores and patient-related measures decreased highly significantly during follow-up (table). Among MRI, clinical and biochemical outcome measures, the tenosynovitis score at month 6 was the only measure that differed significantly between the treatment groups; placebo group: 3.9 (2 [0;18])/the adalimumab group: 1.3 (0 [0;11]), Mann-Whitney: p<0.035. Furthermore, the osteitis score decreased significantly from month 0 to month 6 and 12 in the adalimumab group, but not in the placebo group, Wilcoxon; p≤0.002 and p≥0.062, respectively.

Table. MRI and clinical status values for patients in the placebo and the Adalimumab treatment groups at 0, 6 and 12 months, mean (median [range])

	0 months	6 months	12 months
Synovitis (0–21)			
Placebo group	8.2 (8 [0–19])	4.9 (4 [0–13])***	4.7 (4 [0–15])***
Adalimumab group	7.6 (7 [0–21])	5.0 (5 [0–13])**	4.8 (4 [0–15])*
BME (0–69)			
Placebo group	6.2 (1 [3–35])	**3.9 (0 [0–35])^{NS}**	**3.5 (0 [0–36])^{NS}**
Adalimumab group	4.3 (1 [0–34])	**1.4 (0 [0–11])****	**2.1 (0 [0–31])***
Tenosynovitis (0–30)			
Placebo group	7.3 (5 [0–26])	**3.9 (2 [0–18])***	**2.0 (0 [0–20])****
Adalimumab group	5.2 (3 [0–23])	**1.3 (0 [0–11])*****	**1.6 (0 [0–30])***
Erosions (0–30)			
Placebo group	12.5 (6 [0–64])	11.6 (5 [0–49])^{NS}	13.7 (6 [0–61])^{NS}
Adalimumab group	10.9 (8 [0–43])	9.9 (8 [0–30])^{NS}	10.3 (8 [0–30])^{NS}
JSN (0–84)			
Placebo group	(0 [0–8])	(0 [0–9])^{NS}	1.4 (0 [0–12])^{NS}
Adalimumab group	0.6 (0 [0–7])	0.6 (0 [0–7])^{NS}	0.9 (0 [0–7])^{NS}
DAS28			
Placebo group	5.3 (5.2 [3.5–8.1])	2.7 (2.5 [1.7–5.0])***	2.6 (2.3 [1.7–4.6])***
Adalimumab group	5.4 (5.4 [3.3–7.5])	2.6 (2.4 [1.7–6.0])***	2.4 (2.0 [1.7–4.7])***

Values are presented as mean (median [range]). The numbers in bold writing indicate differences between treatment groups. Between baseline and follow-up visit differences were tested using Mann-Whitney's test: .^{NS}: Not significant; *≤0.005; **≤0.001; ***<0.0001.

Conclusion: A treat-to-target strategy with methotrexate and intra-articular glucocorticoid in ERA patients effectively decreased synovitis, osteitis and tenosynovitis and halted structural damage progression judged by MRI. The addition of Adalimumab provided further suppression of osteitis and tenosynovitis.

Can Ultrasonographic Findings Predict Response To Tumor Necrosis Factor-α Inhibitor Treatment In Rheumatoid Arthritis? Nevsun Inanc[1], Gülsen Ozen[2] and Haner Direskeneli[1]. [1]Marmara University, School of Medicine, Istanbul, Turkey, [2]Marmara University School of Medicine, Istanbul, Turkey.

Background/Purpose: Tumor necrosis factor-α inhibitors (TNFi) are highly effective in patients with rheumatoid arthritis (RA), while not effective in all, with predictors of response being necessary. Although genetic, inflammatory and serologic biomarkers are under major investigation for this purpose, little is known about the predictive value of ultrasonographic parameters in RA. We aimed to investigate the ability of ultrasonographic parameters to predict which patients with RA will benefit from the treatment with TNFi in terms of EULAR response

Methods: Biologic naive RA patients starting treatment with TNFi were examined longitudinally by ultrasonography (US) (both Gray-Scale [GS] and Power Doppler [PD]) of 28 joints according to standard scans of EULAR guideline and clinically (tender/swollen joint counts, DAS28 and HAQ scores) at baseline and after 3 and 6 months. US examinations were performed by an experienced sonographer (NI) using a MyLab 70 US machine (Esaote, Italy) equipped with 6–18 and 4–13 MHz broad band multi-frequency linear transducer. US synovitis GS and PD signals were semiquantitatively graded from 0 to 3. Total PD and GS synovitis scores of all sites are recorded as sum scores of PD and GS, respectively. The clinical response was evaluated according to the EULAR response criteria at 3rd month. Potential ultrasonographic predictors of response were identified using multivariate binary logistic regression models.

Results: The study cohort consisted of 42 RA patients (F/M=33/9, mean age 49.0±10.7 years) with a mean disease duration of 9.1±7.5 years and mean baseline DAS28 score of 5.5±1.0. Rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (CCP) positivity were 76.2% and 64.3%, respectively. Baseline characteristics of TNFi responders (30/42) and non-responders (12/42) are shown in Table 1. Swollen joint count ($p= 0.05$), sum scores of baseline PD ($p= 0.048$), GS ($p= 0.048$) and PD+GS ($p= 0.046$) differed significantly between responders and non-responders. Baseline PD sum score was the only ultrasonographic parameter in the multivariate analysis predicting which patients achieve good/moderate EULAR response with TNFi at 3rd month ($p= 0.004$). The mean PD+GS, PD and GS sum scores decreased significantly from baseline to 3 months ($p<0.001$ for all parameters) whereas decrease between 3rd and 6th months was nonsignificant for all US parameters ($p=0.128$, $p=0.266$, $p= 0.105$, respectively).

Table 1. Baseline characteristics of TNFi responders and nonresponders

	Responders (n=30)	Non-responders (n=12)	p Value
Age (years)	48.8 ± 10.6	**49.6 ± 11.5**	0.81
Disease duration (years)	8.0 ± 7.2	**11.9 ± 7.8**	0.13
Treatment delay (months)	32.2 ± 51.0	**35.2 ± 38.2**	0.85
RF titer (IU/mL)	166.4 ± 233.9	**295.1 ± 586.8**	0.31
Anti-CCP titer (U/mL)	78.7 ± 147.0	**232.2 ± 457.5**	0.10
DAS28	5.5 ± 0.9	**5.5 ± 1.3**	0.99
Pain VAS (0-100 mm)	66.0 ± 21.7	**79.2 ± 16.7**	0.067
ESR (mm/h)	43.7 ± 20.7	**40.0 ± 22.5**	0.61
CRP (mg/L)	27.2 ± 34.1	**28.6 ± 28.4**	0.90
Tender joint count (0–28)	8.0 ± 6.8	**12.0 ± 9.5**	0.12
Swollen joint count (0–28)	5.7 ± 5.0	**9.8 ± 7.8**	0.05
HAQ score	1.1 ± 0.6	**1.3 ± 0.4**	0.22
Prednisolone dose, mg/day	5.7 ± 3.1	**5.8 ± 2.2**	0.93
Sum score of PD (0–84)	12.5 ± 9.8	**20.1 ± 13.2**	0.048
Sum score of GS (0–84)	16.1 ± 11.7	**25.7 ± 15.6**	0.048
Sum score of PD+GS (0–168)	29.0 ± 21.4	**45.6 ± 28.5**	0.046

The values were presented as mean±SD

Conclusion: Our data underline that baseline PD scores, despite similar clinical features, can predict which patients will respond to TNFi therapy. Ultrasonographic response to TNFi treatment can be achieved substantially in the first 3 months. Beyond 3rd month changes in US scores are mostly nonsignificant.

Radiological Outcome Of Joints With MRI Detected Subclinical Inflammation In Early Arthritis Patients. A. Krabben, W. Stomp, J. A. B. van Nies, T.W.J. Huizinga, D. van der Heijde, J.L Bloem, M. Reijnierse and A. H. M. van der Helm-van Mil. Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Extremity-MRI is becoming important in Rheumatoid Arthritis (RA) research as it is a sensitive tool to assess inflammation. Inflammation is measured by three features: bone marrow edema (inflammation of bone), synovitis and tenosynovitis. Part of the inflammatory lesions detected by MRI are subclinical, indicating that these were not observed by physical examination. The relevance of subclinical inflammation detected by MRI in a population of early arthritis patients for to the disease course is not known. In this study we investigated the relevance of subclinical inflammation on MRI in early arthritis patients for radiological joint damage.

Methods: 179 early arthritis patients (median symptom duration of 15 weeks) included in the Leiden Early Arthritis Clinic underwent a 68-tender and 66-swollen joint count (including MCP, wrist and MTP joints) and a 1.5T MRI of the MCP (2–4), wrist and MTP (1–5) joints at the most painful side at baseline. Synovitis and bone marrow edema were scored according to the RAMRIS method; tenosynovitis at the wrists and MCP joints was also determined. Scoring was performed by two readers and the average scores were studied. Radiographs of hands and feet were made at baseline and after one year of follow-up and scored according to the Sharp-van-der-Heijde scoring method (SHS).

Results: 1,790 small joints of 179 patients were studied. Of these joints 1,525 (85%) were not swollen at physical examination. Of all clinically non-swollen joints, any subclinical inflammation was present on MRI in 25%; 15% had bone marrow edema, 15% synovitis and 18% tenosynovitis. When evaluating these clinically non-swollen joints in relation to the radiographs at year-1, 7% of the joints had SHS ≥1 and 2% SHS progression ≥1.

The subclinical inflamed joints were evaluated with progression of radiological joint damage over the first year (SHS progression ≥1) as outcome. When comparing the non-swollen joints with and without any inflammation on MRI, 4% versus 1% had SHS progression ≥1, (RR 3.5 (1.3–9.6)). For bone marrow edema this was 6.5% versus 1% (RR 5.3 (2.0–14.0), for synovitis this was 5% versus 1% (RR 3.4 (1.2–9.3)) and for tenosynovitis this was 4% versus 1% (RR 3.0 (0.7–12.7)). Hence, although radiological progression was infrequent, it was significantly increased in joints with subclinical synovitis or bone marrow edema. For comparison we studied the outcome of the swollen joints. 8% of all swollen joints had SHS progression ≥1 over the first year, indicating that the frequency of progression in subclinical inflamed joints almost equaled the frequency of progression in clinically swollen joints.

Conclusion: Joints with subclinical inflammation detected by MRI have an increased risk of progression in structural damage in early arthritis. This points to the relevance of subclinical inflammation for the disease outcome in RA.

Synovial Explant Inflammatory Mediator Production Is Associated With Synovitis While Not With Bone Marrow Edema In Rheumatoid Arthritis: A Cross Sectional Study. Martin Andersen[1], Mikael Boesen[2], Karen Ellegaard[1], Robin Christensen[1], Kalle Söderström[3], Søren Torp-Pedersen[1], Bente Danneskiold-Samsøe[1], Else Marie Bartels[1], Nina Vendel[4], Niels H. Søe[5], Pieter Spee[3], Ulrik GW Mørch[6], Lars Karlsson[3] and Henning Bliddal[1]. [1]The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, Frederiksberg, Denmark, [2]Department of Radiology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, Frederiskberg, Denmark, [3]Translational Immunology, Biopharmaceutical Research Unit, Måløv, Novo Nordisk, Denmark, Måløv, Denmark, [4]Department of Anaesthesiology, Intensive Care and Operations, Gentofte University Hospital, Denmark, Hellerup, Denmark, [5]Department of Orthopedics, Section of Hand Surgery, Gentofte University Hospital, Denmark, Hellerup, Denmark, [6]Biomarkers, Søborg, Novo Nordisk, Denmark, Søborg, Denmark.

Background/Purpose: Synovitis and bone damage may represent two distinct but overlapping pathological processes in rheumatoid arthritis (RA).

Whereas the bulk of synovial cells contribute to general joint inflammation, the interplay between synovial cells, neighboring cartilage and bony tissue at the margins of the joint contribute to bone degradation(1). The aim of this study was investigate if the levels of inflammatory cytokines interleukine 6 (IL-6), interleukine 8 (IL-8), macrophage chemo-attractant protein 1 (MCP-1) and macrophage inflammatory protein 1 beta (MIP-1b), which all play key roles in RA pathology, correlate with disease intensity and/or can discriminate between key pathological processes in RA.

Methods: Fifty-seven synovial sites from the hand joints of twenty-five RA patients were evaluated by color Doppler ultrasound (CDUS, 52 synovial sites) and/or high field magnetic resonance imaging (MRI, 39 synovial sites) and subsequently synovectomized by a needle-arthroscopic procedure. Synovial tissue was cultured for 72h, and the concentration of Il-6, Il-8, MCP-1 and MIP-1b in the culture supernatants were measured by Multiplex immunoassays. Ultrasound Doppler was determined as the color fraction. MRI bone marrow edema, synovitis, and erosion score were estimated by the rheumatoid arthritis magnetic resonance score [RAMRIS]. The concentrations of inflammatory mediators were compared to imaging data from the individual sites using repeated samples from the same patients. Since data was clustered within patients, a mixed linear model was applied for the statistical analysis. Parsimony in the statistical model was achieved omitting covariates with ($P>0.1$) from the model.

Results: Ultrasound color fraction and the RAMRIS synovitis score were statistically associated with the release of MCP-1 ($P=0.004$ and $P=0.04$, respectively), IL-8 ($P=0.04$ and $P=0.04$, respectively), and MIP-1b ($P=0.01$ and $P=0.05$, respectively), but not with IL-6 ($P=0.29$ and $P=0.21$, respectively). IL-6 was the only supernatant mediator, which was associated to the RAMRIS erosion component ($P=0.002$). There were no statistically significant associations between mediator release and the RAMRIS bone marrow edema component: MCP-1($P=0.07$), IL-6 ($P=0.93$), IL-8 ($P=0.40$) and MIP-1b ($P=0.96$).

Conclusion: Levels of IL-8, MCP-1, MIP-1b were significantly associated with clinical assessment of synovitis, but not bone erosion, indicating that these molecules play key roles in general inflammation in the joint, and underlining their potential as biomarkers to measure levels of synovitis. In contrast, levels of IL-6 significantly associted with clinical assessment of bone erosion, indicating that this cytokine, which is known to have direct activating effects on osteoclasts, has potential as a biomarker for measuring bone destructive activity in RA patients.

Low Risk Of Hepatitis B Virus Surface Antigen Seroreversion In HBsAg Negative/Anti-Hbc Positive Carriers Undergoing Rituximab For Rheumatoid Arthritis. Valentina Varisco[1], Mauro Vigano'[2], Alberto Batticciotto[1], Pietro Lampertico[3], Antonio Marchesoni[4], Patrizia Gibertini[4], Raffaele Pellerito[5], Guido Rovera[5], Roberto Caporali[6], Monica Todoerti[6], Michele Covelli[7], Antonella Notarnicola[7] and Piercarlo Sarzi-Puttini[1]. [1]Rheumatology Unit, L. Sacco University Hospital, Milan, Italy, [2]San Giuseppe hospital, University of Milan, Milan, Italy, [3]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy, [4]Istituto Ortopedico Gaetano Pini, Milano, Italy, [5]Ospedale Mauriziano, Turin, Italy, [6]Rheumatology, IRCCS Policlinico San Matteo Foundation and University of Pavia, Pavia, Italy, [7]D.I.M.I.M.P, Rheumatology Unit—University of Bari, Bari, Italy.

Background/Purpose: B cell-targeted therapy using rituximab (RTX), anti-CD20 monoclonal antibody, is an effective treatment for Rheumatoid arthritis (RA). However, the safety of such therapy in hepatitis B surface antigen (HBsAg) negative/anti-hepatitis B core antigen (anti-HBc) positive recipients is unknown. The aim of this study is to evaluate the risk of HBsAg seroreversion in this kind of patients.

Methods: We retrospectively reviewed 306 patients of our multicentre database affected by RA and treated with RTX from August 2006 to December 2011 in 5 italian outpatient rheumatologic Clinics. Complete serological screening for HBV status before the first administration of RTX and adequate post-treatment follow-up were available in 35 HBsAg negative/anti-HBc positive patients who did not undergo antiviral prophylaxis with Lamivudine. All patients (75% female, median age 60 years, median disease duration 8 yrs, 100% serum HBV DNA negative by sensitive PCR assay, 87% anti-HBs positive) has been treated with one or more disease-modifying anti-rheumatic drugs (83% MTX, 26% CYS, 80% PDN, 8% LEF, 6% AZA) and were eligible for RTX therapy according to the international guidelines. RTX was administered for a median of 3 cycles (range: 1–8) and was ongoing in 76% of cases. Clinical and laboratory examinations, including serum HBsAg and serum HBV DNA were assessed every 6 months or in case of alanine aminotransferase (ALT) elevation and at the end of the follow-up period.

Results: During a median follow-up of 45 months (range: 12–80) 27% of patients had anti-HBs titer reduction (2 patient with a complete lost of anti-HBs levels). All patients remained viremic free except one (3%) who had an increase of serum HBV DNA (from undetectable to 24 and 44 IU/mL, 1 week apart) not associated to either HBsAg seroreversion or ALT increase. The mild virological breakthrough occurred 5 months after the first RTX administration and required Lamivudine treatment which successfully suppressed viral replication. Another patient (3%) had an ALT flare which was not related to HBV reactivation.

Conclusion: A retrospectively review of our multicentre experience suggest that in RA patients HBsAg negative/anti-HBc positive treated with RTX, Lamivudine prophylaxis should be avoid using an adequate monitoring of HBsAg or HBV DNA levels.

Management Of Vertebral Osteomyelitis: A Randomized Clinical Trial Comparing 6 Versus 12 Weeks Of Antibiotic Treatment. Louis Bernard[1], Aurélien Dinh[2], Idir Ghout[3], Valérie Zeller[4], Bertrand Issartel[5], Nadia Belmatoug[6], Michel Dupon[7] and Denis Mulleman[8]. [1]University hospital of Tours, Tours, France, [2]University hospital of Paris, Garches, France, [3]University Hospital of Paris, Boulogne, France, [4]La Croix Saint Simon Hospital, Paris, France, [5]Clinique du Tonkin, Lyon, France, [6]University hospital of Paris, Clichy, France, [7]University Hospital of Bordeaux, Bordeaux, France, [8]CHU Trousseau Tours, Tours, France.

Background/Purpose: As for most of bone and joint infection, optimal treatment duration for vertebral osteomyelitis (VO) is unknown. In an era of increasing bacterial resistance, we compare the effectiveness of 6 and 12 weeks antibiotic treatment.

Methods: We carried out anational, open blind, randomized controlled non-inferiority multicentre trial in 2 parallel groups comparing 6 versus 12 weeks of antibiotic treatment duration.

Adult patients with clinical and radiologic diagnosis of VO (MRI or CT) and a reliable microbiological identification (positive and significative blood culture or needle biopsy) were recruited since 2007 to 2011. At one year, after the end of antibiotic therapy, cure was define as the absence of clinical and biological signs related to VO without the need for additional or alternative antibiotic therapy.

Results: 359 patients were randomized, 175 in the group 12 weeks treatment group and 176 in the group 6 weeks; 240 (69%) were male with mean age 61 years old. Eight patients were secondarily excluded. Median

duration between first symptoms and diagnosis was 49 (1–80) days; 182 (52%) patients were febrile at diagnosis and 237 (68%) had positive blood culture. Infective endocarditis was present in 70 (20%) cases. Main bacteria involved were *Staphylococcus aureus* (n=143, 41%), Coagulase negative-*Staphylococci* (n=52, 15%) and *Streptococcus non enterococcus* (n=63, 18%).

At baseline, characteristics were similar in both group of treatment duration. During follow up, difference was non significative in both groups regarding median duration of parenteral antibiotictherapy, median length of hospitalization stay, most frequent antibiotics for oral treatment (rifadin and fluoroquinolon). Adverse events occurred in 100 cases of whom 26 deaths. In the intention to treat analysis, cure rates in the 6 weeks treatment group and in the 12 weeks treatment group were respectively 91% (159/171) and 91% (160/176)with a difference non significative between the two groups.

Conclusion: We have demonstrated in this large multicentre randomized clinical trial that 6 weeks of antibiotic treatment duration is as effective as 12 for VO.

Favorable Outcome Of Hepatitis E Virus Infection In Patients With Inflammatory Arthritides Treated With Immunosupressants. Hélène Bauer[1], Cécile Luxembourger[2], Sophie Fournier[2], Alain G. Cantagrel[3], Jean Marie Peron[2], Anne Marie Roque Afonso[4], Pascal Claudepierre[5], S. Fabre[6], Christophe Hudry[7], Guillaume Lefevre[8], Antoine Martin[9], Laurent Messer[10], Béatrice Pallot Prades[11], Christian Roux[12], Christelle Sordet[13], Claire Veissier[14], Daniel Wendling[15], Jacques-Eric Gottenberg[13] and Jean Sibilia[16]. [1]CHU de Hautepierre, Strasbourg, France, [2]CHU de Toulouse, Toulouse, France, [3]Centre Hospitalier Universitaire de Toulouse, Toulouse, France, [4]virologie hôpital Paul Brousse, Villejuif, France, [5]Henri Mondor Teaching Hospital, AP-HP, Créteil, France, [6]CHU MONTPELLIER, Montpellier, France, [7]Hopital Cochin, Paris, France, [8]Lille University Hospital, Internal Medicine Department, Lille, France, [9]Centre Hospitalier De St Brieuc, St Brieuc, France, [10]Hopitaux Civils de Colmar, Colmar, France, [11]CHU St Etienne, St Etienne, France, [12]CHU L' Archet University Nice, Nice, France, [13]Strasbourg University Hospital, Strasbourg, France, [14]CHU de Bordeaux, Bordeaux, France, [15]University Hospital, Besancon, France, [16]CHU Hautepierre, Strasbourg, France.

Background/Purpose: In inflammatory rheumatic diseases, the prevalence, clinical presentation and outcome of hepatitis E, an ubiquitous viral infection, remain unknown. We therefore addressed these issues in a large retrospective study. The main objective of this study was to investigate the severity of acute hepatitis E and the risk of chronic viral replication in patients suffering from inflammatory rheumatisms and treated with immunosuppressive drugs.

Methods: All French rheumatology and internal medicine practitioners registered on the Club Rhumatisme et Inflammation (nearly 2,000 physicians),were repeatedly sent newsletters asking to report observations of acute hepatitis E virus (HEV) infection in patients with inflammatory arthritides. They were subsequently sent a standardized and detailed questionnaire on baseline characteristics of the patients and the course of HEV infection.

Results: Nineteen observations of hepatitis E were collected. They occurred in patients with rheumatoid arthritis (n = 9), axial spondyloarthritis (n = 4), psoriatic arthritis (n = 3), juvenile idiopathic arthritis (n =1), Jaccoud arthropathy (n = 1) and undifferentiated arthritis (n = 1), treated with methotrexate (n = 13), anti-TNFα therapy (n = 6), rituximab (n = 4), abatacept (n = 3) or tocilizumab (n = 1). Eight patients were treated with corticosteroids with a median dose of 4.5 mg/d. Most of the patients had few symptoms, except asthenia. A woman, suffering from psoriatic arthritis treated with cyclosporine developed a bilateral Parsonage Turner syndrome, which was considered as an extrahepatic HEV-related manifestation. All of the patients had acute elevation of aspartate and alanine aminotransferase levels, and 7 patients also had moderate cholestasis. Two patients had an acute hepatic failure with decreased prothrombin time. The hepatitis E diagnosis either relied on positive PCR detection for HEV RNA (n = 13 patients), or on positive IgM result without PCR assessment (n = 2) or with negative PCR for HEV (n = 4). No other aetiology of the hepatitis could be found, except in 1 patient who had a HEV and HAV coinfection. Mean current follow-up is 13.4 months (standard deviation: 8.8 months). Treatment of HEV infection included the discontinuation of immunosuppressants in 18 out of 19 patients (adalimumab was maintained in 1 patient) and ribavirine in 5 patients. Liver enzymes normalized within 1 month in 7 patients, 3 months in 6 patients, and 4 months in 2 patients. Ten previously positive PCR tests were repeated and all became negative within 3 months after HEV infection.Among the 15 patients with a follow-up of at least 3 months, all are considered to be cured by their clinicians and an immunosuppressant (the same as before HEV infection in 14 patients, etanercept in 1 patient) could be reinitiated in all of them with no viral reactivation.

Conclusion: The diagnosis of acute hepatitis E should be considered in patients with inflammatory arthritides treated with immunosuppressants and elevated liver enzymes. The outcome of HEV infection is usually favourable, after transient discontinuation of immunosuppressants associated or not with ribavirin, with no reported evolution towards chronicity.

Prevalence and Clinical Presentation Of Lyme Arthritis In a Large Cohort Of Patients With Recent-Onset Arthritis. Jeska K. De Vries-Bouwstra, Nathalie D. van Burgel, Tom Vreeswijk, Aloys C. M. Kroes, Tom W. J. Huizinga and Annette H. M. van der Helm-van Mil. Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Lyme arthritis is a relatively uncommon form of arthritis that is relevant to identify because it requires specific therapy. The presents study aimed to describe 1. the seroprevalence of Lyme antibodies, 2. the prevalence of Lyme arthritis, and 3. the diagnostics accuracy of serologic testing for *Borreliae* among patients with recent-onset arthritis in The Netherlands.

Methods: The present study included all patients who presented to the Leiden Early Arthritis Clinic during the period of February 1993 to April 1997 (cohort 1) and the period July 2003 to June 2008 (cohort 2). In sera from cohort 1, antibodies against *Borreliae* were detected by the IgG and IgM flagellin-Enzyme Immune Assay (EIA). All available positive samples were retested with the IgG/IgM C6 EIA. In cohort 2, the C6 Lyme EIA Kit was used. All positive EIA results from both cohorts were confirmed by the *Borrelia* Europe LINE blot and a second EIA, the Liaison® *Borrelia burgdorferi* IgG (VlsE) and IgM (VlsE+OspC). The clinical records of the patients with positive or equivocal serology were thoroughly studied; Lyme disease was not diagnosed in case of a clear alternative diagnosis. The proportion of patients with Lyme arthritis was determined, as well as the diagnostic accuracy of *Borrelia* serology.

Results: Of 1180 patients with recent-onset arthritis, 53 patients had positive serology, indicating a seroprevalence of 4,5% (Figure 1 and 2). Eight cases of definite Lyme arthritis (0.7%) were identified These patients were characterized by younger age, and typically presented with monoarthritis or oligoarthritis including a knee. Retrospectively, possible Lyme arthritis was diagnosed in seven (0,6%) patients. In the remaining patients with positive or equivocal serology different clinical diagnoses were made (rheumatoid arthritis n= 14; spondylarthritis n= 11; systemic inflammatory disease n= 3; osteoarthritis n= 2; other n=8). Based on the low prevalence of Lyme arthritis, the positive predictive value of serology for Lyme disease was low (10–28%). By selecting patients with a higher prior chance of Lyme disease, eg in patients presenting with an oligo- or monoarthritis of large joints, the positive predictive value increased to 67%.

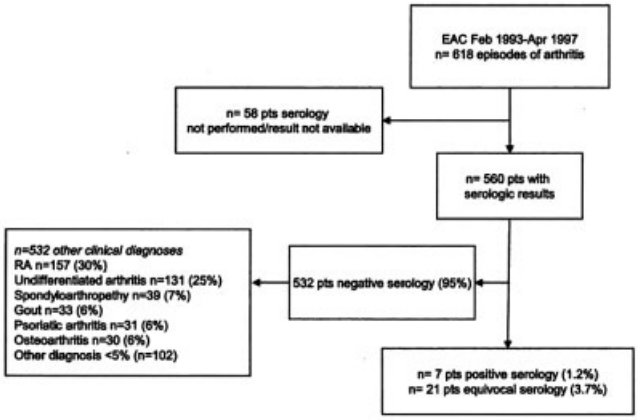

Figure 1: serologic results cohort 1; EAC= Early Arthritis Clinic; pts = patients

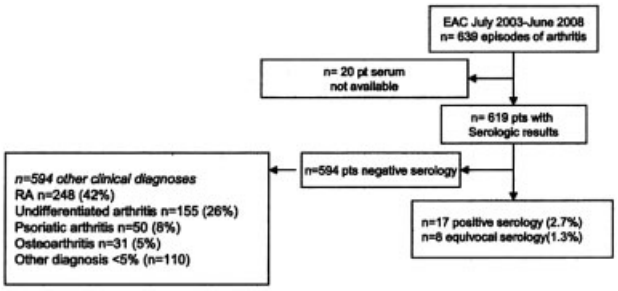

Figure 2: serologic results cohort 2; EAC= Early Arthritis Clinic; pts = patients

Conclusion: The prevalence of Lyme arthritis among patients with recent-onset arthritis in The Netherlands is low, 0.7%. Although sensitivity and specificity of Lyme serology are reported to be good, serologic testing for Lyme arthritis contributes poorly to clinical decision making in patient with recent-onset arthritis due to the low a priori chance on Lyme arthritis.

Follow-Up Testing Of Interferon-Gamma Release Assays For The Diagnosis Of Hidden Tuberculosis Infection In Patients Receiving Tumor Necrosis Factor Alpha Antagonists. Chan-Nam Son, Tae-Hwan Kim, Il-Hoon Sung, Jae-Bum Jun and Dae-Hyun Yoo. Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea.

Background/Purpose: Anti-tumor necrosis factor alpha (Anti-TNFα) therapy is often used in patients with rheumatic diseases who do not respond to conventional treatment. Risk of tuberculosis infection is high in patients receiving anti-TNFα treatments. Therefore, tuberculosis infection prophylaxes are recommended prior to anti-TNFα therapy if a tuberculin skin test or interferon-gamma release assay (IGRA) is positive. However, little data is available on the conversion of IGRAs in patients with rheumatic diseases who received anti-TNF treatment. We evaluated the utility of follow-up IGRAs for the diagnosis of latent tuberculosis infection and newly developing tuberculosis in patients receiving TNFα antagonists.

Methods: The study participants (n=117) were enrolled from September 2008 to August 2012, among ankylosing spondylitis (AS) and rheumatoid arthritis (RA) patients registered in tertiary care center. These patients had a negative IGRA screening before receiving anti-TNFα therapy and were evaluated by follow-up IGRA for detection of latent and newly developing tuberculosis until May 2013. We retrospectively examined data of the subjects according to age, gender, tuberculosis prophylaxis, IGRA conversion and TNFα blockers, including type and treatment duration. The QuantiFERON-TB Gold In-Tube test was used for the initial and follow-up screenings to detect tuberculosis infection.

Results: The median interval between initial and follow-up IGRAs in patients was 20.5 months, and the median age was 38.9 years. Of the 117 patients (92 AS and 25 RA), 105 patients (89.7%) showed consistently negative results, and IGRA conversion was found in 12 patients (10.3%). Among the 92 AS patients, IGRA conversion was found in 7 patients (7.6 %). Among the 25 RA patients, 5 patients with positive conversion (20%) were found. One RA patient developed extrapulmonary tuberculosis. IGRA conversion rate was higher in older patients ($\geq$ 40 years) (24.4%) than it was in younger patients ($<$ 40 years) (1.4%) ($p < 0.05$) (Table 1). AS patients were younger and used anti-TNFα inhibitors for extended time period. IGRA conversion rate was not significantly different between AS (7.6%) and RA (20%) ($p = 0.13$).

Table 1. Patients characteristics and interferon-gamma release assay (IGRA) conversion rate.

Characteristics	All (N=117)	Conversion (N=12)	Adjusted OR	95% CI	p-value
Diagnosis					
AS	92 (78.63)	7 (7.61)	0.42	(0.06–3.07)	0.394
RA	25 (21.37)	5 (20.00)	1.00		
Age, yrs, mean (SD)					
<40	72 (61.54)	1 (1.39)	1.00		
≥ 40	45 (38.46)	11 (24.44)	21.19	(2.12–211.57)	0.009*
Gender					
Male	76 (64.96)	6 (7.89)	1.00		
Female	41 (35.04)	6 (14.63)	0.34	(0.05–2.30)	0.271
TNFα antagonists					
Etanercept	43 (36.75)	7 (16.28)	1.00		
Adalimumab	37 (31.62)	1 (2.70)	0.19	(0.02–1.96)	0.164
Infliximab	37 (31.62)	4 (10.81)	0.53	(0.11–2.47)	0.418
Duration of TNFα inhibitor therapy					
< 2 yrs	74 (63.25)	5 (6.76)	1.00		
≥ 2 yrs	43 (36.75)	7 (16.28)	2.31	(0.46–11.70)	0.313
Tuberculosis prophylaxis					
No	102 (87.18)	8 (7.84)	1.00		
Yes	15 (12.82)	4 (26.67)	1.70	(0.25–11.54)	0.590

*$p < 0.05$

Conclusion: In patients with rheumatic diseases receiving TNFα blocker, IGRA conversions were observed. Patients with old age had higher IGRA conversion rate than patients with young age. These data suggest that follow-up IGRAs may identify false negative results of screening test and detect latent tuberculosis reactivation and new developing tuberculosis in patients receiving TNFα blockers in Korea. Larger-scaled studies may be needed for further evaluation about follow-up IGRAs.

Disease Characteristics and Treatment Patterns In US Veterans With Rheumatoid Arthritis and Concomitant Hepatitis C Infection. Ruchika Patel and Joshua Baker. University of Pennsylvania, Philadelphia, PA.

Background/Purpose: The prevalence of concurrent rheumatoid arthritis (RA) and hepatitis C (HCV) is estimated at 0.02%, affecting around 40,000 Americans. To our knowledge, no existing studies evaluated disease characteristics and treatment patterns in RA patients with and without HCV infection. Our aim was to evaluate disease characteristics, component and composite measures of disease activity, and treatment patterns in HCV-positive subjects with RA compared to HCV-negative subjects with RA in a large national registry

Methods: We utilized the Veterans Affairs Rheumatoid Arthritis Registry (VARA) to identify subjects with RA and concomitant HCV. Subjects who were identified by the physician to have comorbid HCV infection at the time of enrollment were considered HCV-positive. The registry includes baseline and longitudinal measures that are updated and entered into the VARA database by the treating physicians at routine clinical visits. Differences in disease characteristics, disease activity measures, and treatment patterns were assessed over the first 5 clinical visits. Chi^2 tests and T-tests or ranksum tests of significance were utilized for group comparisons. Linear and logistic regression analyses assessed group differences after adjustment for potential confounders (age, race and days from enrollment).

Results: Of 1870 registry participants, 53 were identified with concomitant HCV (2.8%). At enrollment, HCV-positive subjects were younger [60.7 $\pm$5.9 vs. 67.1 $\pm$11.1 ($p<0.0001$)], more likely to be African American (62% vs. 38%, $p=0.001$) and to smoke ($p=0.001$). Other disease characteristics (anti-citrullinated protein antibodies, erosions and disease duration) were similar between groups. At enrollment, HCV-positive subjects had greater DAS28 [4.7 $\pm$1.85 vs. 4.0 $\pm$1.61 ($p=0.05$)], tender ($p=0.001$) and swollen joint counts ($p=0.006$). By visit 2, there were no observed group differences in disease activity. During the five-visit period, HCV-positive patients had more frequent follow up [12.1 $\pm$ 5.3 vs. 17.4 $\pm$ 11.8 ($p=0.009$)]. No differences were observed in patient global score, global evaluator score,

Multidimensional Health Assessment Questionnaire (MD-HAQ), ESR, or CRP. At baseline, methotrexate use was less common among HCV-positive subjects (Table 1). By visit 2, subjects with HCV were more likely to use prednisone and, by visit 4, were more likely to use hydroxychloroquine. These differences in medications use persisted through the fifth visit (Table 1).

Table 1. Medication use among HCV-positive and HCV-negative subjects with Rheumatoid Arthritis at enrollment and over the initial 5-visits in VARA. Odds of use is adjusted for group differences in age, race, and days from enrollment for each visit.

Visit #	HCV− (%)	HCV+ (%)	Odds Ratio (95% CI)
Hydroxychloroquine			
1	28	34	1.26 (0.71–2.27)
2	28	36	1.23 (0.68–2.25)
3	26	42	1.59 (0.87–2.93)
4	25	43	1.91 (1.00–3.67)*
5	23	42	2.29 (1.12–4.68)*
Sulphasalazine			
1	12	21	1.68 (0.84–3.34)
2	13	21	1.43 (0.71–2.89)
3	13	23	1.58 (0.79–3.16)
4	12	19	1.16 (0.55–2.46)
5	11	21	1.69 (0.78–3.59)
Methotrexate			
1	45	21	0.32 (0.16–0.62)*
2	47	21	0.24 (0.12–0.47)*
3	43	19	0.20 (0.01–0.40)*
4	40	15	0.15 (0.07–0.34)*
5	36	15	0.16 (0.07–0.37)*
Prednisone			
1	37	40	1.14 (0.65–2.01)
2	38	55	1.85 (1.02–3.38)*
3	34	49	1.44 (0.78–2.66)
4	31	53	2.32 (1.16–4.67)*
5	28	48	2.41 (1.13–5.14)*
Anti-TNFs			
1	19	26	1.38 (0.73–2.60)
2	19	30	1.67 (0.89–3.13)
3	19	40	2.32 (1.25–4.29)*
4	17	30	1.71 (0.88–3.33)
5	17	26	1.46 (0.72–2.98)

* P value < 0.05

Conclusion: At enrollment, HCV-positive subjects were younger, more likely to be African American, smoke, had higher joint counts, and were less likely to be prescribed methotrexate. Our data suggest more frequent follow up and use of prednisone and hydroxychloroquine over time among subjects with RA and concomitant HCV, may result in comparable early disease control compared to RA subjects without HCV.

A Rheumatology Objective Structured Clinical Examination Using Challenging Patient Scenarios Shows Trainee Use Of Medical Jargon Correlates Inversely With Patient Perceptions Of Professionalism. Jessica Berman[1], Juliet Aizer[2], Anne R. Bass[2], Anne Davidson[3], Edward Dwyer[4], Theodore R. Fields[2], Jane Kang[4], Leslie Kerr[5], Svetlana Krasnokutsky-Samuels[6], Deana M. Lazaro[7], Stephen A. Paget[2], Julie S. Schwartzman-Morris[8] and Michael H. Pillinger[9]. [1]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [2]Hospital for Special Surgery Weill Cornell Medical College, New York, NY, [3]Feinstein Institute for Medical Research, Manhasset, NY, [4]Columbia School of Medicine, New York, NY, [5]Mount Sinai School of Medicine, New York, NY, [6]NYU School of Medicine, New York, NY, [7]Brooklyn VA, Brooklyn, NY, [8]Albert Einstein College of Medicine, Bronx, NY, [9]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: For 8 years, the New York City Rheumatology Objective Self Assessment Clinical Exam (NYC-ROSCE) has been used to assess trainee competencies such as patient care and communication. Most recently, we have refocused the NYC-ROSCE to assess professionalism, using a validated professionalism questionnaire. This year we asked which individual skills were most likely to correlate with overall achievement in the area of professionalism.

Methods: The 2012 NYC-ROSCE included 5 patient-centered stations focusing on rheumatic disease. For the first time, stations were designed to challenge fellows with patient psychosocial dilemmas, in order to assess specific aspects of the patient-doctor relationship including physician professionalism. Rheumatology trainees (n=28) and faculty MD-evaluators (n=32) from 6 NY rheumatology training programs participated. Professional actors (n=30) were trained to role-play patients. Quantitative assessments of the trainees were made at each station (9-point Likert scale) by patient- and MD-evaluators in the areas of: maintaining composure, partnering with the patient, being open and honest, professionalism, empathy and accountability. Qualitative free text comments were solicited after each station, regarding the strengths and weaknesses of each fellow's performance during the encounter. In addition, trainees rated their own performance after each encounter. Immediate oral feedback on professionalism was given to each trainee by both patient-actors and MD-evaluators.

Results: When assessing professionalism, MD-evaluators tended to rate trainees lower (6.74+/−0.58) than patient-actors (7.12+/−0.78), suggesting that physicians and patients may apply different criteria when assessing professionalism during observed encounters. Trainee self-evaluations for professionalism were in the range of the MD-evaluators rather than the patient-actors (6.70+/−1.16). MD-evaluators also tended to give lower ratings for accountability (6.32+/−0.82) than patient-actors (6.68+/−0.85) or the trainees themselves (6.53+/−1.04). In contrast, ratings of empathy were found to be closely in agreement for trainees (6.62+/−1.04), MD-evaluators (6.58+/−0.69) and patient-actors (6.55+/−1.05. MD-evaluators most often commented on the trainees' word choice and body language, ability to formulate a clear plan, ability to recognize and address patient's fears, and the need to actively partner with the patient. For all evaluators, excessive use of medical jargon was most often cited as the area that needed improvement. The use of jargon correlated inversely with the ratings of professionalism for MD-evaluators and patient-actors.

Conclusion: The introduction this year of new and challenging patient encounters allowed us to assess which patient-centered traits most contributed to perceptions of achievement in the area of professionalism. We found that our evaluators considered the ability to minimize medical jargon to be one of the most important markers of the competency of professionalism. This finding suggests that patients view communication as correlating most strongly with their doctor's professionalism.

2813

Expert Panel Consensus On Content Of a Rheumatology Objective Structured Clinical Examination. Lisa G. Criscione-Schreiber[1], Marcy B. Bolster[2], Beth L. Jonas[3], Richard Sloane[1], Jeffrey Hawley[4] and Kenneth S. O'Rourke[5]. [1]Duke University Health System, Durham, NC, [2]Massachussetts General Hospital, Boston, MA, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]Duke University School of Nursing, Durham, NC, [5]Wake Forest School of Medicine, Winston-Salem, NC.

Background/Purpose: Rheumatology objective structured clinical examinations (ROSCEs) are assessment tools to evaluate learner performance in simulated clinical experiences. ROSCEs allow standardization of learner assessment in competencies that are challenging to measure in other ways. While several regional groups in the United States conduct ROSCEs, none have been validated for use across programs. We aimed to establish agreement among subspecialty experts regarding the important benchmarks for rheumatology fellows to achieve in 11 theoretical ROSCE stations.

Methods: First, each author independently created a grid listing important attributes to assess in 11 possible ROSCE stations. The grids were combined (by LCS) into a 173-item checklist survey to assess the importance of each item for future use in ROSCEs. IRB exemption was granted to send the survey by email to 37 expert rheumatologists, defined as individuals who have helped create and administer regional ROSCEs. Participants in the expert

panel survey rated the importance of each item using a 5-point Likert scale (1=not important to 5=very important). Minimum and maximum scores, the mean, standard deviation, and lower 95% confidence level for the mean were calculated for each survey item. Consensus for high importance was predefined as a lower bound of the 95% CI ≥ 4.0.

Results: 11 individuals completed the expert panel survey. 123 of the 173 items (71%) met statistical cutoff for consensus to retain, distributed among the 11 proposed stations. Several items were rejected that had population means of ≥ 4.0 but did not meet the pre-determined definition for consensus. The percentage of retained items for individual stations ranged from 23.5 to 100% (Table). All items were retained for the core interpersonal and professionalism items included as part of general patient counseling and for x-ray interpretation tasks. Only 23% of items were retained for a station involving rehabilitation medicine, and 46% of items for a microscope use/synovial fluid analysis station.

Table. Item retention summary. Items were retained if statistical analysis revealed a lower bound of the 95% CI ≥ 4.0.

Station	Number of items assessed	Number of items retained	Agreement score range	Percentage of items retained
Phone call from primary care provider	18	10	1.98–5	55.5%
X-rays	19	19	4.19–5	100%
Non-formulary request letter to insurance company	16	12	3.03–5	75%
Osteoporosis/DXA interpretation	17	14	2.98–4.74	82.4%
Rehabilitation	17	4	2.51–4.6	23.5%
General counseling	13	13	4.08–5	100%
Counseling: anti-Ro+ woman pre-conception	13	11	3.13–5	84.6%
Counseling: new scleroderma	11	8	3.13–4.6	72.7%
Counseling: new biologic for RA	14	9	3.34–5	64.3%
Knee arthrocentesis	20	16	3.18–5	80%
Microscope synovial fluid	15	7	2.70–5	46.7%
Total	173	123	1.98–5	71.1%

Conclusion: In this single round expert panel survey, we established national consensus on 123 items to assess on 11 proposed ROSCE stations. This study represents the first use of such rigorous methods to establish checklist content agreement for an OSCE in any medical field. Next steps include 1) defining behavioral anchors (milestones) for performance on individual stations and 2) finalizing checklists and station manuals that can be shared among rheumatology programs nationally to improve the validity of regional OSCEs and initiate use in programs without regional collaborators. Use of these checklists by regional rheumatology groups will create the framework for collection of summary data and perhaps eventual creation of a high-stakes rheumatology OSCE.

2814

The Resident-Fellow Interaction: Limiting Barriers and Maximizing Learning. Eli Miloslavsky[1], Amy Sullivan[2], Jeremy Richards[2], Jakob I. McSparron[3], David Roberts[2] and Alberto Puig[4]. [1]Massachusetts General Hopsital, Boston, MA, [2]Beth Israel Deaconess Medical Center, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Massachusetts General Hospital, Boston, MA.

Background/Purpose: Subspecialty fellows may play an important role in Internal Medicine (IM) residents' education and career specialty choice (Horn 2008). This may be particularly important in rheumatology where a projected workforce shortage may require the expansion of the current training capacity (Deal 2007), and over 75% of fellows decide to pursue a career in rheumatology during residency (Kolasinski 2007). In this context, fellows may be underutilized as clinical teachers and role models, possibly due to the existence of barriers to an effective resident-fellow interaction (Miloslavsky 2010).

To our knowledge, the working relationship between IM subspecialty fellows and IM residents has not been examined. We conducted a study to determine the barriers and facilitating factors to the IM resident-fellow interaction on the wards.

Methods: We conducted 4 focus groups: IM residents at the Massachusetts General Hospital (MGH) and the Brigham and Women's Hospital (BWH), IM fellows at BWH/MGH, and IM fellows at MGH who received teaching awards. There were 32 participants from all residency classes and 7 IM subspecialties including rheumatology. Four investigators analyzed focus group transcripts via a theory driven immersion-crystallization process using activity theory (Engestrom 2011).

Results: Five themes of barriers were identified:

- Intrinsic: residents' and fellows' expectations of each other; absence of familiarity/personal relationship between residents and fellows; interest and availability (fellows - willingness to see the consult, residents - being available/interested in discussing the consult); knowledge (residents - patient history, fellows - subject matter).
- Logistical: resident work hours (e.g. frequent patient handoffs); primary team structure (e.g. team-based care model, de-regionalized teams).
- Attending-related: primary team attending (role in formulating the consult question, communication); consult attending (role modeling).
- Workload: resident and fellow patient census and the duration/complexity of the consult.
- Teaching: time available to teach and fellows' teaching skills.

Focus group participants cited increasing familiarity/personal relationships between residents and fellows as a critical variable in improving the interaction. Other means of overcoming barriers included limiting fellow pushback on residents' consult requests, standardizing fellows' and residents' expectations about the consult interaction, and improving fellows' teaching skills.

Positive and negative feedback loops appear to be important in the resident-fellow interaction, with positive interactions strengthening future ones and negative interactions creating additional barriers.

There was broad agreement between fellows from different subspecialties and residents with respect to both barrier and facilitating factors.

Conclusion: The resident-fellow interaction faces multiple barriers from both systems and personal domains, however many of these barriers may be modifiable. Future efforts should focus on implementing strategies to overcome these barriers. Such efforts may enhance IM residents' rheumatologic clinical skills and potentially influence their career choice.

Preliminary Entrustable Professional Activities in Muscloskeletal Ultrasound For Rheumatology Fellowship Training. Amy C. Cannella[1], Eugene Y. Kissin[2], Gurjit S. Kaeley[3], Jay B. Higgs[4], Kelly J. Caverzagie[5] and Karina D. Torralba[6]. [1]Omaha Veterans Affairs Hospital and University of Nebraska Medical Center, Omaha, NE, [2]Boston University, Boston, MA, [3]University of Florida, Jacksonville, FL, [4]San Antonio Military Medical Center, Fort Sam Houston, TX, [5]University of Nebraska Medical Center, Omaha, NE, [6]Loma Linda University, Loma Linda, CA.

Background/Purpose: As part of the Next Accreditation System (NAS), the Accreditation Council for Graduate Medical Education (ACGME) has mandated a change in the evaluation of postgraduate trainees by including the development of Entrustable Professional Activities (EPAs) for each specialty and subspecialty. EPAs are the routine professional activities which define a profession. They also provide a means of framing the 6 ACGME competencies in a way that allows them to be meaningful to learners and faculty. The American College of Rheumatology (ACR) is developing EPAs for Rheumatology training. Although not currently an ACGME requirement, many fellowship programs have incorporated Musculoskeletal Ultrasound (MSUS) in their curricula. We seek to define EPAs for MSUS in rheumatology as an initial step towards the development of standardized curriculum and assessment tools.

Methods: A group of educators utilized a modified nominal group technique (NGT) to develop EPAs for MSUS. A literature search was completed on MSUS education, certification, best practices and curriculum development to generate a list of potential EPAs specific for MSUS in rheumatology, framed within the ACGME competency and milestone vernacular.

Each item was rated for inclusion as an EPA using a Likert scale, where 1 represented the least agreement and 9 represented the most agreement. A median score of 7–9 was considered to have highest agreement, 4–6 was intermediate agreement, and <3 was rejected. An initial postal round was followed by a teleconference call, where each group member had the opportunity to discuss, defend or dispute the item. A second round was then completed to develop a final list of EPAs.

Results: 35 initial EPAs were developed for scoring in each round. In the postal round, 24 and 11 EPAs met criteria for highest and intermediate agreement, respectively. In the final round, 19 EPAs met criteria for highest agreement and included concepts such as indications, limitations and proper performance of MSUS. Eight EPAs met criteria for intermediate agreement, and included concepts such as communication with referring providers and patients regarding MSUS findings. The remaining 8 EPAs were rejected for reasons such as redundancy with predicted sub-specialty EPAs, and a lack of specificity for MSUS. As a result of conferencing, several EPAs were merged into single EPAs to enhance cohesiveness and included concepts such as combining patient positioning with other strategies to obtain optimal images, and approaches to self-reflection and self-directed learning. Out of the initial 35 items, a final list of 16 EPAs was developed for MSUS in Rheumatology.

Conclusion: A preliminary set of EPAs specific for the practice of MSUS in rheumatology was developed. These EPAs are the initial step in the development of assessment tools for determination of MSUS competency for a rheumatology fellow in training. Further studies will include validation of these EPAs by a larger group of educators and practitioners of MSUS.

2816

Pilot Phase Outcomes From The ACR/Carra Inter-Institutional Mentoring Program In Pediatric Rheumatology. Peter A. Nigrovic[1], Eyal Muscal[2], Lakshmi N. Moorthy[3], Sampath Prahalad[4], Marisa S. Klein-Gitelman[5], Meredith P. Riebschleger[6], B. Anne Eberhard[7] and Rayfel Schneider[8]. [1]Boston Children's Hospital, Boston, MA, [2]Baylor College of Medicine, Houston, TX, [3]Robert Wood Johnson Medical School-UMDNJ, New Brunswick, NJ, [4]Emory Children's Center, Atlanta, GA, [5]Children's Memorial Hospital, Chicago, IL, [6]University of Michigan Health System, Ann Arbor, MI, [7]Cohen Children's Hospital Medical Center, New Hyde Park, NY, [8]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati, OH.

Background/Purpose: In pediatric rheumatology, the small size of many academic programs translates into limited mentoring options for early career physicians. To address this "mentorship gap," the American College of Rheumatology (ACR) and the Childhood Arthritis and Rheumatology Research Alliance (CARRA) joined together to develop **AMIGO, the ACR/CARRA Mentoring Interest Group**, that now enrolls more than 80 pediatric rheumatology fellows and junior faculty in the US and Canada. We report program evaluation data from the AMIGO pilot project, launched in November 2011 with 20 mentor-mentee dyads.

Methods: Mentees and mentors participating in the AMIGO pilot phase were surveyed via online questionnaire 17 months after initial match to determine dynamics of contact and perceived benefit in domains relevant to professional success and work-life balance.

Results: Of 20 initial matches, 19 were still functioning while one had dissolved due to departure of the mentee from North America. Ninety-five percent of the participants reported at least two substantial interactions. Total mentoring time was estimated at under 60 minutes by approximately half of respondents, though 20% reported more than 3 hours of interaction. Thirty-one percent of participants rated the quality of the match as good and 51% as excellent (defined as 'excellent overlap of mentee needs and mentor experience'). All mentees considered the mentoring helpful in providing career guidance, with substantial benefit also in scholarship, and job satisfaction. Benefits reported by mentors included improvement of their mentoring skills and development of their academic portfolios. Both mentees and mentors reported improved connectedness to the wider pediatric rheumatology community. All participants favored continuation of the program (**Table 1**).

Table 1. Pilot survey data at 17 months after initiation of a mentoring program

	Mentees (n, %)	Mentors (n, %)	Overall (n, %)
Responses (%)	18/19 (95)	19/19 (100)	37/38 (97)
Benefit to mentee			
Career path/job search	18 (100)	13 (68)	31 (84)
Research/scholarship	12 (67)	10 (53)	22 (59)
Job satisfaction	13 (72)	12/17 (71)	25/35 (71)
Work-life balance	8 (44)	12/18 (67)	20/36 (56)
Benefit to mentors			
Mentoring skills	NA	12/18 (67)	NA
Professional portfolio	NA	8/17 (47)	NA
Enhanced connection to community	14/17 (82)	14 (75)	28/36 (78)
Should AMIGO be continued?	18 (100)	19 (100)	37 (100)

Conclusion: The success of the pilot AMIGO program indicates that a North American inter-institutional mentoring program in pediatric rheumatology is feasible. Participants identified benefits to both mentees and mentors in multiple domains, most prominently in career guidance, a core goal of the program. Although longer-term evaluation of the full AMIGO program is needed, the success of the pilot program suggests that AMIGO could serve as a model for mentoring more broadly within the ACR and potentially in other medical subspecialties.

2817

Objective Assessment Of Musculoskeletal Physical Examination Skills During Continuing Education Programs For Primary Care Providers Adds Significant Information Not Obtained Through Self-Assessment. Andrea M. Barker[1], Michael J. Battistone[1], J Peter Beck[1], Jorie Butler[2], Marissa Grotzke[1], Timothy A. Huhtala[1], Amy C. Cannella[3], David I. Daikh[4], Meika A Fang[5], Antonio A. Lazzari[6], Pedro Roldan[7], Joan Marie Von Feldt[8] and Grant W. Cannon[1]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]Salt Lake City VA, Salt Lake City, UT, [3]Omaha Veterans Affairs Hospital and University of Nebraska Medical Center, Omaha, NE, [4]University of California, San Francisco, San Francisco, CA, [5]VA Greater Los Angeles Healthcare System, Los Angeles, CA, [6]Boston VA Medical Center, Boston, MA, [7]Leesburg VA CBOC, Leesburg, FL, [8]Univ of Pennsylvania/Philadelphia VAMC, Philadelphia, PA.

Background/Purpose: Self-assessment is the most frequently used method in the evaluation of continuing medical education (CME) programs. This multi-institutional project was designed to examine convergent validity of learners' self-assessment competency ratings with their scores on a 2-station objective structured clinical examination (OSCE) during a musculoskeletal (MSK) CME program.

Methods: The VA Salt Lake City Health Care System developed a 3-day MSK Mini-Residency program in collaboration with six other VA facilities. This program for primary providers emphasizes physical examination and clinical management of common shoulder and knee disorders. Curriculum was introduced through focused didactics followed by small group hands-on practice sessions involving simulated patients. At the conclusion of the program, participants completed a self-reported competency assessment utilizing a 5-point Likert scale and an OSCE for both the shoulder and knee with a rater unaware of the self-reported competency. Self-assessment ratings were classified as low (<4.0), medium (4.0–4.5), and high (>4.5). OSCE ratings were classified with the same numerical boundaries based on a weighted scoring system for each component of the physical exam and then percentage of exam completed correctly (low <80%, medium 80%-90%, high >90%).

Results: A total of 107 and 109 participants completed all components of the shoulder and knee assessments, respectively. Over half the participants were rated high on both self-assessment and OSCE for the shoulder, though correlation was weak (Pearson coefficient = 0.28). For the knee, the OSCE ratings were more variable with approximately one-third of participants in each category while the majority of the participants assessed themselves as being highly competent. Correlation was again weak (Pearson coefficient = 0.05).

Table 1. Self-assessment ratings compared to OSCE ratings for shoulder.

SHOULDER		OSCE Rating			
	Low	Med	High		
Self-Assessment Rating	Low	0	1 (0.9%)	0	1 (0.9%)
	Med	5 (4.7%)	8 (7.5%)	10 (9.3%)	23 (21.5%)
	High	9 (8.4%)	18 (16.8%)	56 (52.3%)	83 (77.6%)
		14 (13.1%)	27 (25.2%)	66 (61.7%)	107

Table 2. Self-assessment ratings compared to OSCE ratings for knee.

KNEE		OSCE Rating			
	Low	Med	High		
Self-Assessment Rating	Low	0	0	1 (0.9%)	1 (0.9%)
	Med	13 (11.9%)	7 (6.4%)	8 (7.3%)	28 (25.7%)
	High	26 (23.9%)	28 (25.7%)	26 (23.9%)	80 (73.4%)
		39 (35.8%)	35 (32.1%)	35 (32.1%)	109

Conclusion: Following an intense MSK CME program, the majority of participants rated themselves as highly competent for the shoulder and knee. However, correlation of self-reported competency and OSCE rating was weak, particularly for the knee. Greater variability in the knee OSCE rating and correlation coefficient may be due to the exam maneuvers being more technically difficult to perform as they require more "hands-on" skills of the examiner. These data suggest that an OSCE should be included in evaluation of participants in CME programs to assess competency in the clinical skills being taught.

Administration Of a Multi-Epitope Citrullinated Peptide Attuneuates adjuvant Induced Arthritis In Rats Via Induction Of Immune Tolerance.
Howard Amital[1], Smadar Gertel[2] and Yehuda Shoenfeld[3]. [1]Sheba Medical Center,Tel-Hashomer, Tel-Aviv University, Tel-hashomer, Israel, [2]Sheba Medical Center, Tel-Hashomer, Israel, [3]Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Affiliated to Sackler Faculty of Medicine, Tel-Aviv University,Tel-Aviv, Tel-Aviv, Israel.

Background/Purpose: Antigen-induced peripheral tolerance is a potentially efficient and specific therapeutic approach to attenuate autoimmunity. Citrullinated peptides are major targets of disease-specific autoantibodies in Rheumatoid Arthritis (RA). Currently, citrullinated peptides serve primarily as biomarkers for the diagnosis of RA by measuring titers of anti-citrullinated protein antibodies.

In an attempt to develop a citrullinated peptides-based specific immunotherapy for RA, we previously showed the potential of two citrullinated peptides (citrullinated-filaggrin and citrullinated-β-fibrinogen) to up-regulate TGF-β mRNA expression and concomitant expansion of regulatory T cell population. In addition, our citrullinated peptides reduced the expression of inflammatory cytokines (INF-γ, TNF-α and IL-17), reduced the percentage of pathogenic IL-17$^+$ cells and increased the apoptosis rate of T cells following incubation with RA-derived peripheral blood mononuclear cells (PBMC).

In view of the multiplicity of citrullinated target autoantigens in RA we tailored a multi-epitope citrullinated peptide (Cit-ME) derived from major prevalent citrullinated autoantigens (citrullinated filaggrin, fibrinogen, vimentin and collagen type II). The later was tested for treatment of adjuvant induced arthritis (AIA) via immune tolerance induction by attenuating the disease manifestations.

Methods: Seven days following induction of AIA in Lewis female rats we administrated Cit-ME (300mg/rat) by 8 subcutaneous injections given on alternate days. Clinical scoring was performed once a week during the experiment. At the end of the experiment rats spleens were analyzed for apoptosis of CD4$^+$ T cells by flow cytomety.

Results: Treatment with Cit-ME ameliorated the clinical score of the diseased arthritic rats.

Rats treated with the Cit-ME had significantly less arthritic symptoms compared to untreated rats at day 21 (Figure 1). Amelioration of disease manifestations was associated with increased apoptosis rate of T cells.

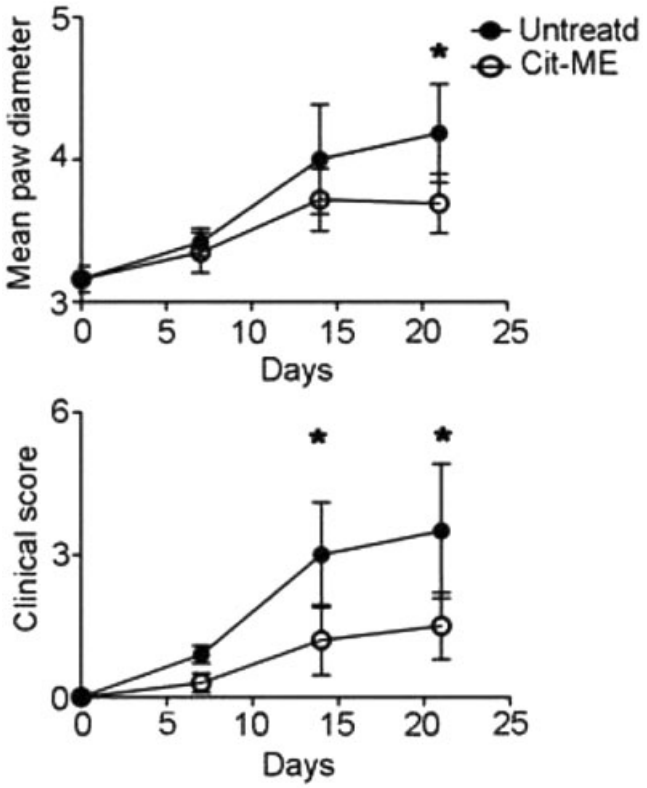

Figure 1. Treatment with Cit-ME suppressed Adjuvant induced arthritis (AIA) clinical score in Lewis rats

Conclusion: We demonstrated that citrullinated peptides induced immune tolerance in an experimental model of AIA.

Disease-Regulated Local Interleukin-10 Gene Therapy Diminishes Synovitis and Articular Cartilage Damage In Experimental Arthritis.
Eline A. Vermeij[1], Mathijs G.A. Broeren[1], Miranda B. Bennink[1], Onno J. Arntz[2], Inger Gjertsson[3], Wim B. van den Berg[1] and Fons A.J. van de Loo[1]. [1]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]Department of Rheumatology and Inflammation Research, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden, Gothenburg, Sweden.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic destructive autoimmune disease and in most patients the disease follows an intermittent course with periods of exacerbation and remission. Today's treatment is based on continuous immunosuppression, irrespective of the patient's inflammatory status. An attractive alternative treatment would provide a disease-regulated therapy that offers flexible drug delivery, high during flares and low during remission. To explore this concept we expressed the anti-inflammatory cytokine interleukin (IL)-10 gene under the control of an inflammation dependent promoter in a mouse model of RA, the streptococcal cell wall arthritis (SCW).

Methods: C57Bl6/N mice were injected intra-articularly in the knee joint with lentiviral vectors expressing a luciferase reporter or the therapeutic protein IL-10. The disease-regulated proximal promoters of S100a8, Cxcl1, Mmp13, Saa3, IL-1b, and TSG6 were selected from endogenous genes differentially regulated in the inflamed synovium of arthritic mice. The constitutive PGK promoter was used as a positive control. Arthritis was

induced by injection of 25μg SCW into the knee joint cavity 4 days after lentivirus injection. At 1, 4, and 7 days after arthritis induction, in-vivo bioluminescent imaging was performed or mice were sacrificed and knee joints were dissected for either histological analysis, or RNA isolation for qPCR analysis.

Results: The 6 disease-regulated promoters all showed a different activation profile during the course of the disease. Two promoters were selected for IL-10 overexpression in the SCW model; the Saa3 promoter which showed an immediate and high upregulation at day 1 after arthritis induction, and the MMP13 promoter which showed a delayed response and peaked at day 4. For both regulated promoters, overexpression of IL-10 showed significant less synovitis at day 4 after arthritis induction (decrease from 2.2±0.2 to 1.6±0.2) and significant less cartilage proteoglycan (PG) depletion at day 4 (decrease from 2.6±0.2 to 1.3±0.2) and day 7 (decrease from 2.2±0.3 to 0.7±0.3) after arthritis induction. At day 4, IL1-Ra and SOCS3 genes were upregulated by Saa3-IL10, whereas at day 7 both Saa3-IL10 and MMP13-IL10 caused an upregulation of IL1Ra and SOCS3 gene expression. IL-1Ra is known to counteract the detrimental effects of IL-1 on cartilage damage and SOCS3 can inhibit the JAK/STAT pathway and subsequent inflammation. Therefore, these IL-10 induced changes in gene expressions can explain the diminished synovitis and PG depletion. Probably because IL-10 is expressed in the synovial tissue at day 1 of SCW arthritis without any treatment, a major therapeutic difference between the MMP13 and SAA3 promoter was not evident in this study.

Conclusion: Local inflammation-dependent IL-10 gene therapy suppresses experimental arthritis and is a promising strategy in the development of novel treatments for RA.

2821

Evaluation Of Selective Manipulation Of The CD28 Co-Stimulation Pathway In The Rhesus Monkey Model Of Collagen-Induced Arthritis. Michel P.M. Vierboom[1], Elia Breedveld[1], Bert 't Hart[1], Flora Coulon[2] and Bernard Vanhove[3]. [1]Biomedical Primate Research Centre, Rijswijk, Netherlands, [2]Institut National de la Santé et de la Recherche Médicale, Nantes, France, [3]INSERM UMR-S 1064, Nantes, France.

Background/Purpose: T-cells are important in the pathogenesis of rheumatoid arthritis (RA). T-cell activation depends on at least two signals. Next to the first signal that is provided by the binding of the T-cell receptor (TCR) to a peptide bound by an MHC molecule it requires a second signal provided by one or more co-stimulatory pathways. If only the first signal is present without co-stimulation T cells become anergic. One of the most important pathways, which is of therapeutic interest is that between CD80/86 on antigen-presenting cells and CD28 on naïve T-cells. This interaction is necessary for T-cell activation. Intervention in this pathway has resulted in clinical success in the treatment of RA as demonstrated by treatment with the CD80/86 antagonist CTLA4-Ig (Abatacept). Here we present the beneficial result of treatment with a novel CD28 antagonist, which blocks CD28 instead of CD80/86, in a nonhuman primate model of inflammatory arthritis.

Methods: FR104, is a monovalent and pegylated humanized Fab' antibody fragment directed against CD28. FR104 functions as a CD28 antagonist that prevents the interaction between CD28-CD80/86 without inhibiting the interaction with CTLA-4 and PDL-1, thereby promoting immune regulation. FR104 is a primate specific antibody and safety and efficacy was tested in a collagen-induced arthritis (CIA) model in the rhesus monkey. The rhesus CIA model is an autoimmune-mediated model of polyarthritis with inflammation and erosion of joints that shares several important cellular and histopathological features with (RA). Treatment with either Vehicle (N=5) or FR104 (N=7) started at the day of induction and continued weekly until day 42 (7 administrations)

Results: Treatment with FR104 prevented the development of clinical arthritis leading to a significant disease free survival compared to placebo treated animals. This was supported by unchanged production of cartilage breakdown products and minimal histological changes. This was associated with a suppressed production of CRP and IL-6. Treatment with FR104 also resulted in a robust suppression of collagen type II-specific proliferation and antibody (IgM/IgG) production and prevented the development of joint swelling and the subsequent destruction of cartilage and bone.

Conclusion: FR104 was well tolerated after the multiple dosing in this nonhuman primate model of arthritis. Treatment resulted in a robust suppression of collagen specific immune responses and inhibited the development clinical arthritis. In addition it prevented the development of neutralizing antibodies, a phenomenon that is regularly observed in the model with treatments targeting inflammatory cytokines like IL-6. The current study demonstrated the strong potential of CD28 as a therapeutic target of antagonist antibodies in a range of inflammatory disorders, including RA.

IKKε Deficiency Prolongs Neutrophil Survival Paradoxically Prolonging Inflammation In The Absence Of a Type I Interferon Response. Maripat Corr[1], Christopher Chung[2], Seong-Kyu Kim[3], D. L Boyle[2] and G. S. Firestein[2]. [1]Univ of California-San Diego, La Jolla, CA, [2]UCSD School of Medicine, La Jolla, CA, [3]Catholic University of Daegu School of Medicine, Daegu, South Korea.

Background/Purpose: Deficiency of the IKK-related kinases IKKε synergizes with the anti-inflammatory effects of IFNβ in a murine model of arthritis, and this effect is mediated by IL-1Ra. To further explore the relationship between IFN signaling and IKKε, IKKε null mice were intercrossed with IL1Ra or type I interferon receptor deficient mice and evaluated in the passive K/BxN model of arthritis.

Methods: IKKε null, *Il1rn* (which encodes IL-1Ra) null, IL1Ra/IKKε null, IFNAR1 null, IFNAR1/IKKε null and wild type mice were injected with 150 ul of pooled K/BxN sera on day 0. Clinical response and histologic scores were assessed. Gene expression was measured by quantitative PCR. Mice were injected intraperitoneally with thioglycollate. The peritoneal lavage was evaluated for cell counts. The number and viability of neutrophils was determined by flow cytometry. Gene expression and protein production were tested by qPCR and western blot respectively.

Results: IKKε null mice had a modestly attenuated course of arthritis (area under the curve [AUC] for ankle diameter=5.1 vs. 5.9 for wild type controls, $P<0.05$). In contrast IFNAR1 null mice (AUC 6.3 vs. 5.9, $P<0.05$) and $Il1rn^{-/-}$ mice (AUC 11.4 vs. 5.9 $P<0.01$) had more severe serum transfer arthritis than wild type mice. The IL1Ra/IKKε null had arthritis similar (AUC 12.1) to the $Il1rn^{-/-}$ mice (AUC 11.4). Unexpectedly, IFNAR1/IKKε null mice (AUC 7.9, $P<0.05$) had even greater disease severity than the IFNAR1 null (AUC 6.3) mice. The ankle histology scores in each strain correlated well with the clinical course. Of interest, quantitative PCR of arthritis paws showed a significant increase in the neutrophil chemotactic protein GCP2 in the IFNAR1 (98+10) and IFNAR1/IKKε (81+11) null compared to the WT (19+1) mice ($p<0.05$). There was no difference in IL-6, IL-1β, IL-1a or IFNb in the IL1Ra/IKKε null or IFNAR1/IKKε null mice compared to the individual knockout controls. Concordant with higher GCP2 expression mice deficient in IFN signaling recruited higher numbers of neutrophils into the peritoneum after thioglycollate challenge: 4.6+1 (WT), 6.1+2 (IKKε), 15.8+4.8 (IFNAR1) and 13.5+2.8 (IFNAR1/IKKε) $\times 10^6$ neutrophils ($p<0.05$). The neutrophils recovered from the IFNAR1/IKKε mice, however, expressed higher mRNA and protein levels of the anti-apoptotic protein Mcl1 than those of the individual knockout controls, suggesting that the deficient neutrophils had defective apoptosis.

Conclusion: IKKε deficiency did not offset increased severity in IL-1Ra deficiency supporting a direct role of IL-1Ra in reducing arthritis. Surprisingly, IKKε deficiency increased disease severity in the IFNAR null mice, most likely due to increased neutrophil recruitment and prolonged survival.

2823

FLIP Deficiency In Dendritic Cells Promotes Spontaneous Inflammatory and Erosive Arthritis. Qi Quan Huang[1], Harris R. Perlman[1], Robert Birkett[2], Renee E. Koessler[1], Syamal K. Datta[3] and Richard M. Pope[4]. [1]Northwestern University, Chicago, IL, [2]Northwestern University Medical School, Chicago, IL, [3]Northwestern University FSM, Chicago, IL, [4]Northwestern Univ Med School, Chicago, IL.

Background/Purpose: FLIP is an anti-apoptotic protein induced by chronic inflammation. In this study a mouse line with FLIP deleted in CD11c+ dendritic cells (DCs), that spontaneously develops arthritis, was employed to define the potential role of tolerance induction and adaptive immune.

Methods: Mice with FLIP deficient in DC (*Flip* $^{f/f}$, *CD11c* $^{cre/+}$ or KO) were generated by crossing *Flip* $^{f/f}$ with *CD11c*^{cre} transgenic mice. Immune cells in lymphoid organs were analyzed by Flow-cytometry employing multi-fluorochrome-conjugated antibodies. Arthritis was evaluated by joint swelling and/or deformity. Pathology was analyzed by histologic HE staining. The levels of IgG and cytokines were determined by ELISA and serum rheumatoid factors (RF) by rabbit IgG-ELISA. *In vivo* antigen presentation was determined by T cell proliferation to OVA, monitored by CFSE labeled CD4+ T cells from OTII mice. All data are analyzed comparing with gender matched littermate controls.

Results: The KO mice spontaneously developed progressive, erosive arthritis, starting at 6 weeks of age and reaching ≥ 80% incidence at ≥ 4 months. For mice at ≥ 5 months, histological examination of knees, ankles, and paws demonstrated increased joint inflammation with neutrophils, macrophages and lymphocytes, bone erosion, pannus formation and cartilage destruction ($p < 0.05$-0.001). Further, increased TNFα, IL-1β, IL-6, IL-10, CXCL5, INF-g and RANKL, but reduced OPG, were present in ankle homogenates ($p < 0.001$). Old KO mice expressed increased circulating INF-γ, IgG1 and RF ($p < 0.05$-0.001). All 5 month KO mice developed lymphadenopathy with increased B cells and plasmablasts. Examination of 4 week old (young) KO mice, prior to the onset of arthritis, demonstrated reduction in the size and number of cells in the thymus. The subset of DCs expressing high CD11c and MHCII and were CD8+ were significantly reduced in the thymus, as well as the spleen, and lymph nodes (LN) young mice ($p < 0.05$-0.001). Further, single positive CD4+ or CD8+ T cells, the ratio of CD4:CD8 cells and CD4+/CD25+/Foxp3+ Treg cells were reduced ($p < 0.05$-0.001) in the thymus of young KO mice. CD3+,CD4+ and CD3+,CD8+ cells were reduced and B cells were increased in the LNs of young mice. In the LNs of old KO mice CD11c DC and CD3+,CD8+ cells normalized, while CD3+,CD4+ and B cells were increased. Finally, the young *Flip* $^{f/f}$, *CD11c* $^{cre/+}$ mice demonstrated reduced *in vivo* antigen presentation properties, identified by reduced CD4+ T proliferation in response to OVA.

Conclusion: These observations suggest that reduction of FLIP in DC results in reduced positive and negative selection, reduced Tregs and increased B cells, IFN-g, and autoantibodies. DCs expressing high levels of CD11c and MHCII are necessary for normal tolerance development and restraining the occurrence of inflammatory arthritis.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Clinical Aspects VI: Cardiovascular Disease in Rheumatoid Arthritis
Wednesday, October 30, 2013, 9:00 AM–10:30 AM

2824

Urinary Microalbumin Is Associated With Arterial Stiffness In Patients With Rheumatoid Arthritis. Karima Becetti[1], Annette Oeser[1], Joseph F. Solus[2], Paolo Raggi[3], C. Michael Stein[2] and Cecilia P. Chung[1]. [1]Vanderbilt University, Nashville, TN, [2]Vanderbilt Medical Center, Nashville, TN, [3]University of Alberta, Edmonton, AB.

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased risk for cardiovascular disease (CVD). Urinary microalbumin is a risk factor for CVD in the general population, but its association with CVD in RA is less well defined. Thus, we examined the association between urinary microalbumin and CVD, using coronary artery calcium (CAC) and augmentation index (AIX), measures of coronary atherosclerosis and vascular stiffness, respectively.

Methods: In a cross-sectional study, we evaluated 136 patients with RA and 79 controls with no diabetes or clinical history of CVD. MA was defined as urine albumin to creatinine ratio (UACR) > 30mg/g in a spot urine. Traditional CVD risk factors such as age, gender, smoking, family history of CVD, body mass index (BMI), hypertension, and lipids were recorded, and insulin resistance (defined using the homeostasis model assessment), metabolic syndrome and Framingham risk scores were calculated. Disease duration, DAS 28 score and inflammatory markers, including vascular cell adhesion molecule-1 (VCAM-1), interleukin-10 (IL-10), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), interleukin-6 (IL-6), tumor necrosis factor-a (TNF-a), and cystatin-C, were measured in RA. Subclinical atherosclerosis was assessed using electron beam computer tomography, and arterial stiffness using AIX. We compared traditional risk factors, UACR and measures of subclinical CVD between RA and controls using Wilcoxon rank sum and Fisher's exact test. The association between MA and CAC and AIX was adjusted for age, sex and race using linear or logistic multivariate analyses as appropriate.

Results: Patients with RA had a higher UACR [median (IQR): 7.6mg/g (4.0–15.5) than controls (5.6 (3.3–9.0), p=0.02). The presence of MA was significantly associated with HTN in RA (p=0.01). No significant association was observed with age, gender, smoking, HOMA-IR, or metabolic syndrome. In RA, but not controls, there was a significant association between AIX and log transformed UACR, β coefficient of 1.9 (95% CI 0.4–3.4), p=0.01. The association remained significant after adjusting for age, sex, and race. CAC was not significantly associated with UACR in RA or controls [Table]. UACR was significantly associated with higher levels of VCAM-1 (ρ=0.2, p=0.01) and lower levels of IL-10 (ρ=−0.2, p=0.02) in RA.

Table. Association between UACR and subclinical CVD in RA and controls:

		UACR			
		Unadjusted		Adjusted for age, sex, and race	
		b coef. (95% CI)	P value	b coef. (95% CI)	P value
AIX	RA	1.9 (0.4–3.4)	0.01	1.5 (0.1–2.8)	0.03
	Controls	−1.3 (−3.6–1.0)	0.26	−0.9 (−2.8–1.0)	0.34
		R (95% CI)	P value	OR (95% CI)	P value
CAC	RA	0.9 (0.7–1.2)	0.64	0.7 (0.5–1.1)	0.13
	Control	0.6 (0.4–1.1)	0.11	0.7 (0.4–1.3)	0.31

Conclusion: Urinary microalbumin is increased in patients with RA compared to controls and is associated with increased arterial stiffness as measured by AIX in RA, independent of other CVD risk factors. MA is not associated with CAC. In RA, urinary microalbumin is associated with higher levels of VCAM-1, which mediates the adhesion of inflammatory cells to vascular endothelium, and with lower levels of IL-10, an anti-inflammatory cytokine.

The Influence Of Early Menopause On Cardiovascular Risk In Women With Rheumatoid Arthritis. Emily Pfeifer, Cynthia S. Crowson, Shreyasee Amin, Sherine E. Gabriel and Eric L. Matteson. Mayo Clinic, Rochester, MN.

Background/Purpose: Lifetime exposure to female sex hormones may play a role in the development and severity of rheumatoid arthritis (RA). These same hormones have also been found to play a role in the development of cardiovascular disease (CVD) in women. Since RA is associated with an increased risk of CVD, the purpose of this study was to determine if early menopause, representing a surrogate for lower lifetime exposure to female sex hormones, affects the risk of developing CVD in women with RA.

Methods: A population-based inception cohort of 600 women with RA who first fulfilled 1987 ACR criteria for RA between 1955 and 2007 was assembled and followed until death, migration or 12/31/2008. Age at menarche, gravidity, parity, age at menopause, and duration, if any, of hormone replacement therapy (HRT), along with occurrence of CVD (including coronary artery disease, heart failure, cerebrovascular disease and peripheral vascular disease) was ascertained by review of medical records. Cox proportional hazard models were used to compare women within this cohort who underwent early menopause, defined as natural or artificial menopause at age ≤ 45 years, to those within the cohort who did not undergo early menopause.

Results: This study included 600 women with RA age ≥ 45 years at diagnosis, of whom 199 experienced early menopause (mean age ± SD: 64.3 ± 12.0 years; 67.x % rheumatoid factor (RF) positive) and 401 did not (mean age: 62.8 ± 11.4 years; 64.9% RF positive). The mean age at menopause in those who experienced early menopause was 40.9 ± 5.0 years,

while in those who did not the mean age at menopause was 50.7 ± 2.8 years. Among women without prior CVD, 73 with early menopause and 132 without early menopause developed CVD during a mean follow-up of 11.8 years. Women who underwent early menopause were at significantly higher risk for developing CVD when compared to women who did not experience early menopause (hazard ratio (HR): 1.41; 95% CI: 1.05–1.91, adjusted for age, calendar year of RA diagnosis and cardiovascular risk factors including smoking status, body mass index at RA diagnosis, diabetes mellitus and hypertension). This difference remained significant when age of menopause was defined as the end of HRT for women with artificial menopause who started HRT therapy at the time of artificial menopause (HR: 1.40; 95% CI: 1.03–1.88). CVD risk was increased in women with higher gravidity and parity (HR 1.06 per pregnancy increase; 95% CI 1.004–1.12 and HR 1.07 per 1 birth increase, 95% CI 1.01–1.14 respectively). There was a strong non-linear relationship between gravidity and parity and cardiovascular outcomes, whereby the increase risk of CVD was detected only at very high values (>7) of gravidity and parity. No associations were found between the development of CVD and cause of early menopause (natural vs. artificial), the use of HRT or the length of time on HRT.

Conclusion: The risk of CVD in women with RA was significantly higher in those who experience early menopause, and like other known risk factors should increase clinician concern for development of CVD in these patients. Further investigation is needed to determine the role that female sex hormones play in the development of CVD in women with RA.

Performance Of Five Current Risk Algorithms In Predicting Cardiovascular Events In Rheumatoid Arthritis Patients. Elke.E.A. Arts[1], Calin Popa[1], Alfons A. den Broeder[2], Anne G. Semb[3], Tracey Toms[4], George Kitas[4], Piet L.C.M. van Riel[1] and Jaap Fransen[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Sint Maartenskliniek, Nijmegen, Netherlands, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Dudley Group of Hospitals NHS Trust, Russells Hall Hospital, Dudley, United Kingdom.

Background/Purpose: Cardiovascular risk in rheumatoid arthritis (RA) is increased. The cardiovascular (CV) risk algorithms used in the general population may underestimate the risk of cardiovascular disease (CVD) in the RA population[1]. This study was undertaken to assess the predictive ability of 5 established CV risk models for the 10-year risk of fatal and non-fatal CVD in European patients with Rheumatoid Arthritis

Methods: Included were the Framingham risk score (FRS), the Systematic Coronary Risk Evaluation score (SCORE), the modified SCORE according to the EULAR recommendations for CV risk[2] (M-SCORE), the Reynolds risk score (RRS) and the QRisk II risk score. Prospectively collected data from the Nijmegen early RA inception cohort were used. Patients with CVD prior to enrollment were excluded. Discriminatory ability for CV risk prediction was estimated by the area under the receiver operating characteristic (ROC) curve. Calibration was assessed by comparing the observed versus expected number of events using Hosmer-Lemeshov tests and calibration plots. Sensitivity and specificity were calculated for the cut-off values of 10% and 20% predicted risk

Results: In total, n=1050 patients were included. During follow-up, 145 patients developed a CV event. The mean±SD age was 54±13.8 years, 66% were female and 74% were rheumatoid factor positive. Areas under the ROC curve were 0.75 (95% CI; 0.71–0.80), 0.75 (95% CI;0.71–0.80), 0.76 (95% CI; 0.73–0.80), 0.75 (95% CI; 0.71–0.79) and 0.77(95% CI; 0.73–0.80) for the SCORE, M-SCORE, FRS, Reynolds and QRisk II respectively, indicating moderate to good discrimination between patients with and without a CV event. All five models underestimated CV risk at low and middle observed risk levels, and overestimated CV risk at high observed risk levels (Fig. 1). For the 10% and 20% cut-off values used as indicators for CV preventive treatment, sensitivity ranged from 66–87% and 43–67% respectively and specificity ranged from 44–57% and 67–81% respectively. Depending on the model, 13% to 35% of observed CV events occurred in RA patients who were classified as low risk (<10%) for CVD.

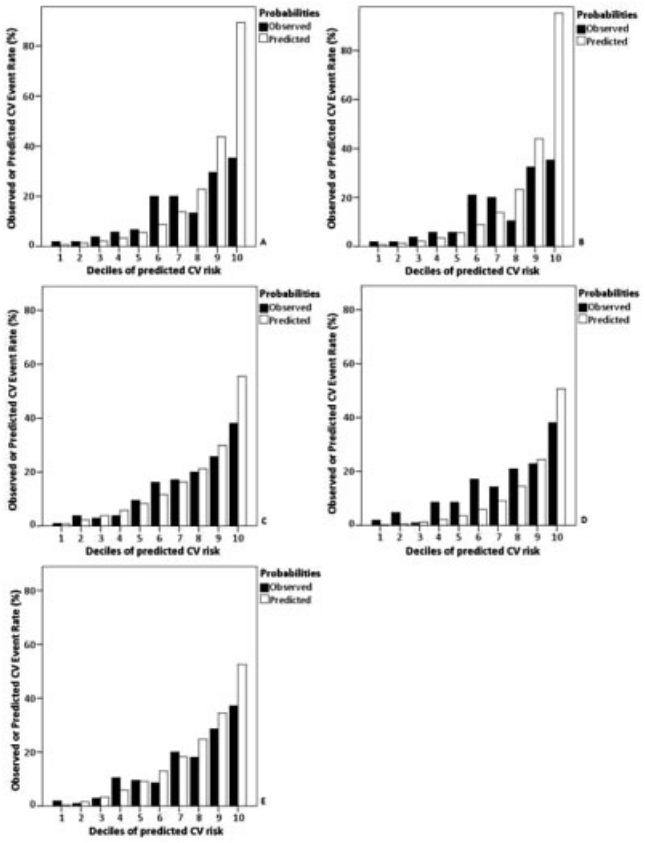

Figure 2. Observed (closed bars) versus predicted (open bars) CV event rate (%) in deciles of predicted risk, for the SCORE (A), M-SCORE (B), FRS (C), Reynolds (D) and QRisk II (E) risk algorithms.

Conclusion: Established risk models generally underestimate CV risk in RA patients. There is an unmet need for development of a RA-specific CV risk model.

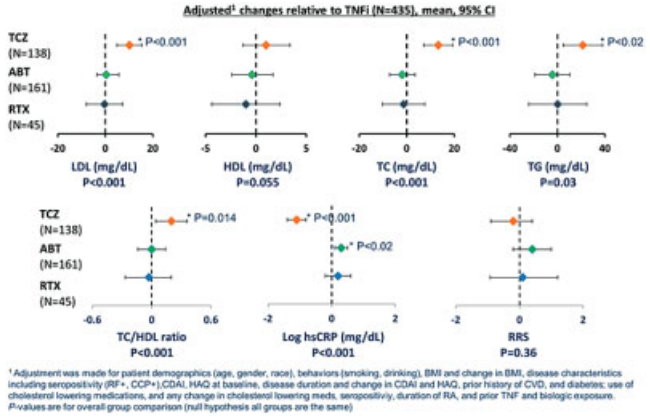
Effect Of Biologic Agents On Lipids and Cardiovascular Risk In Rheumatoid Arthritis Patients. Dimitrios A. Pappas[1], Ani John[2], Jeffrey R. Curtis[3], George W. Reed[4], Jeffrey D. Greenberg[5], Ashwini Shewade[2], Daniel H. Solomon[6], Joel M. Kremer[7] and Tanya Sommers[4]. [1]Columbia University, New York, NY, [2]Genentech Inc., South San Francisco, CA, [3]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL, [4]CORRONA, Inc., Southborough, MA, [5]New York Hospital for Joint Diseases, New York, NY, [6]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA, [7]Albany Medical College and The Center for Rheumatology, Albany, NY.

Background/Purpose: The risk for cardiovascular disease (CVD) is increased in patients (pts) with RA. The interplay between traditional CV risk factors and inflammatory burden may be responsible for this increased CVD risk. Therefore, CVD risk scores incorporating measures of inflammation such as the Reynolds risk score (RRS) may be more appropriate than the Framingham risk score or total cholesterol/HDL ratio to predict CVD risk in pts with rheumatoid arthritis (RA), though not yet validated for RA pts

(Ridker, 2007, 2008). This study investigated the effects of biologics on lipids, CRP and CVD risk using RRS.

Methods: Pts with moderate disease activity (CDAI >10) initiating a biologic DMARD participated in a comparative effectiveness prospective study (CERTAIN) nested within CORRONA. Characteristics, including LDL, HDL, total cholesterol (TC) (desirable < 200) and triglycerides (TG), high sensitivity C-reactive protein (hsCRP) and RRS in pts initiating a TNF-α inhibitor (TNFi) or non-TNFi (rituximab [RTX], abatacept [ABT] or tocilizumab [TCZ]), were measured at baseline and at 3 months. Linear, mixed effect regression models were fit to compare the effect of biologics on lipids, CRP and RRS outcomes after 3 months of therapy. In all models adjustment took place for the baseline levels of the outcome, biologically plausible covariates and other characteristics that were imbalanced among the four groups of medications.

Results: 779 initiations of a biologic were analyzed: 435 (55.8%) TNFi, 45 (5.8%) RTX, 161 (20.7%) ABA and 138 (17.7%) TCZ. Overall baseline characteristics: 75.9% women, 86.3% Caucasian, 65.5% seropositive. Mean ± SD age was 55.9 ± 13.3 years, RA disease duration 8.8 ± 9.5 years; CDAI 28.6 ± 12.7. 35.9% of pts were biologic naïve and 24.6% received anti-hyperlipidemic therapy. History of prior CVD was present in 8.0% of pts; 7.8% had diabetes mellitus and 41% were obese (BMI > 30). The adjusted effect of biologic agents on lipid levels, CRP and RRS after 3 months of treatment are summarized in Figure 1. ABT and RTX had a similar effect on lipid levels compared to TNFi after 3 months while TCZ increased TC, LDL and TG levels compared with TNFi after 3 months. Significantly different changes in CRP were observed across different biologics at 3 months. For CVD risk, as measured by RRS, ABT, RTX and TCZ had a similar effect compared with TNFi.



Conclusion: Our study showed that there was a differential effect on lipid levels and CRP when compared amongst biologics with different mechanisms of action. However, these changes did not translate to an increased CVD risk as measured by RRS. In order to better understand CV risk in RA, long term outcome studies are needed to evaluate the interplay among lipids, inflammation and other CVD risk factors.

The Performance Of The Original and An Updated Cardiovascular Risk Algorithm (SCORE) In Patients With Rheumatoid Arthritis. Elke.E.A. Arts[1], Calin Popa[1], Alfons A. den Broeder[2], Anne Grete Semb[3], Tracey Toms[4], George Kitas[4], Piet L.C.M. van Riel[1] and Jaap Fransen[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Sint Maartenskliniek, Nijmegen, Netherlands, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Dudley Group of Hospitals NHS Trust, Russells Hall Hospital, Dudley, United Kingdom.

Background/Purpose: Cardiovascular (CV) risk in rheumatoid arthritis (RA) is increased. The CV risk algorithms for the general population may underestimate the risk of cardiovascular disease (CVD) in RA patients[1]. The objective of this study was to test the performance of the original and updated SCORE risk algorithm for the prediction of the 10-year risk of CVD in RA patients.

Methods: Data from the Nijmegen early RA inception cohort (n=1017) were used. The systematic coronary risk evaluation algorithm (SCORE) recalibrated for the Dutch population was used as a basis for the new model. This algorithm was recalibrated in this cohort (SCORE recalibrated) by first adjusting the weights of only the risk factors that were included in the original SCORE (age, gender, smoking, systolic blood pressure and total cholesterol: HDL ratio) and in the following this step the original SCORE was updated (SCORE updated) by including other risk factors as assessed in univariate and multivariate Cox proportional hazard regression analysis (significant at p-value <0.2). Predictive performance was assessed by the area under the receiver operating characteristic (ROC) curve and by comparing the observed versus expected number of CV events using Hosmer-Lemeshov tests and calibration plots.

Results: During follow-up, 144 patients had a CV event. In addition to the risk factors of the original SCORE, the updated model included BMI, diabetes, hypertension and high disease activity (DAS28>5.1) at baseline. Areas under the ROC curve were 0.72 (95% CI; 0.68–0.77, 0.71 (0.67–0.75), 0.75 (0.71–0.79), for the original, the recalibrated and the updated SCORE respectively (figure 1A), indicating moderate to good discrimination. The agreement between the observed and the predicted CV events was poor for the original score which underestimated CV risk at low and middle observed risk levels, which was confirmed in the Hosmer and Lemeshow (H-L) test that indicated poor model fit (p< 0.001). The updated SCORE still showed some underestimation (figure 1B) in the low-middle risk groups (≤ 20% CV risk) and overestimation in the highest risk groups, but overall model fit and predictive accuracy improved (H-L test p=1.0).

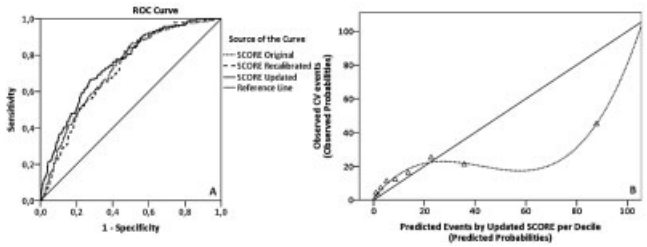

Figure 1. Panel A: ROC-curves for the different SCORE algorithms. Panel B: Calibration plot of the updated SCORE. Depicted are the observed events versus predicted events (observed versus predicted probabilities).

Conclusion: CV risk predictions according to the updated SCORE risk algorithm were more accurate compared to the original SCORE risk algorithm, particularly in the low and intermediate CV risk groups. The next step will be to externally validate these results in a different cohort.

Statin Adherence and Risk Of Mortality In Patients With Rheumatoid Arthritis: A Population-Based Study. Mary De Vera[1], Michal Abrahamowicz[2] and Diane Lacaille[3]. [1]Arthritis Research Centre of Canada, Richmond, BC, [2]McGill University, Montreal, QC, [3]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC.

Background/Purpose: Poor adherence with statin therapy is associated with increased mortality in the general population, but no corresponding data are available among patients with rheumatoid arthritis (RA). Since cardiovascular diseases (CVD) are the primary cause of excess mortality in RA, RA-specific data are highly relevant to RA clinical care. We evaluated the impact of statin adherence on risk of mortality in individuals with RA.

Methods: We conducted a cohort study of all incident statin users in a population-based cohort of RA identified from physician billing data, fol-

lowed from May 1996 to March 2010 using administrative health data. Each individual's observational time was divided into 90-day periods from the date of the first statin prescription until date of death or end of follow-up. For each period, we calculated the proportion days covered (PDC) of statin use and created three adherence categories: high adherence (PDC $\geq$ 0.80), poor adherence (0 < PDC < 0.80), and non-use (PDC = 0). Outcomes evaluated include deaths due to all causes and due to any CVD. We used Cox's proportional hazards analyses, modeling risk of death, with statin adherence as a time-dependent variable representing adherence in the current 90 day interval. We considered the following covariates: age, gender, comorbidities (e.g. acute myocardial infarction, cerebrovascular accidents, infections), use of diabetes, hypertension, and congestive heart failure medications, and use of medications known to influence cardiac risk (e.g. hormone replacement therapy), measured at baseline. Markers of RA severity and RA medication use that could influence mortality risk (DMARDs, glucocorticosteroids, methotrexate and rate of RA-related medical visits) were also included as time-dependent covariates. Covariates were included in the final model if they were significant predictors of death or if they had a confounding effect on the association between statin adherence and death.

Results: The cohort of RA patients with incident statin use included 6,525 individuals with 36,097 person-years of follow-up (60% females; mean age 67 years). We documented 1,193 deaths overall with 386 due to CVD. Adjusted HRs for statin adherence status in the current period and mortality risk are summarized (Table).

Statin Adherence Status	CVD Mortality aHR (95% CI)	All Cause Mortality aHR (95% CI)
High adherence (PDC≥0.80) *ref*	1.00	1.00
Poor adherence (0<PDC<0.80)	1.70 (1.27, 2.28)	1.69 (1.42, 1.99)
Non-use (PDC=0)	1.54 (1.21, 1.95)	1.83 (1.60, 2.08)

Conclusion: These population-based data indicate that RA patients who are poorly adherent with statins have a higher risk of death from CVD and from all causes. Findings emphasize the importance of discussing adherence with statin therapy during health care professional encounters with RA patients.

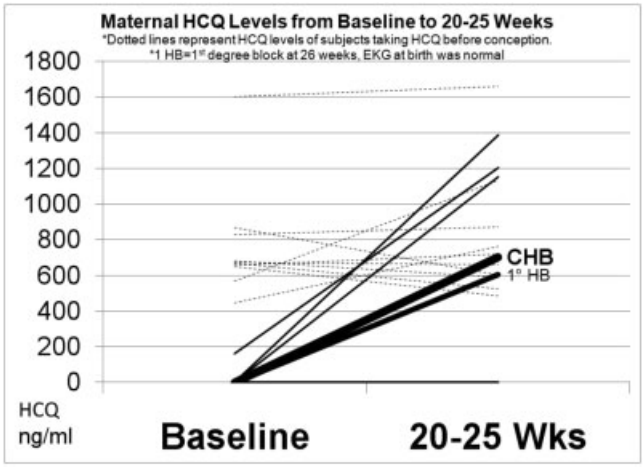
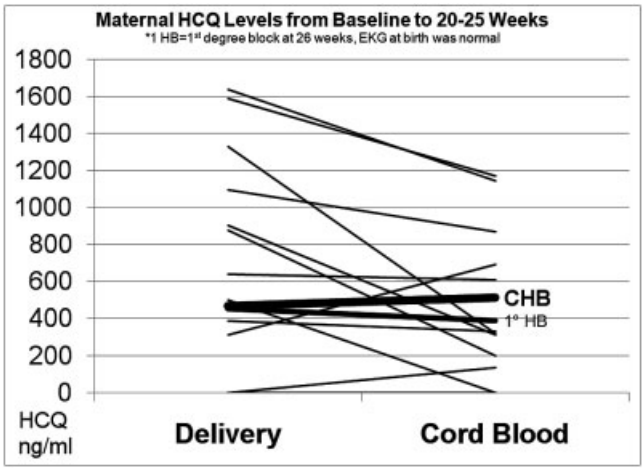
First Stage Of a Simon's Two-Stage Optimal Approach Supports Placental Transfer Of Hydroxychloroquine and a Reduced Recurrence Rate Of The Cardiac Manifestations Of Neonatal Lupus. Peter M. Izmirly[1], Nathalie Costedoat-Chalumeau[2], Amit Saxena[1], Amanda Zink[1], Zoey Smith[1], Deborah Friedman[3] and Jill P. Buyon[1]. [1]New York University School of Medicine, New York, NY, [2]Hopital Cochin, Paris, France, [3]New York Medical College, Valhalla, NY.

Background/Purpose: A previous case control study suggested that hydroxychloroquine (HCQ) might prevent the development of cardiac Neonatal Lupus (cardiac NL) in anti-SSA/Ro antibody (ab) exposed fetuses of SLE mothers. In a subsequent study the use of HCQ reduced the nearly 10 fold increased recurrence rate of cardiac NL in an international cohort of anti-SSA/Ro ab women. Based on these encouraging data, an open label prospective study was initiated to evaluate whether HCQ reduces the recurrence rate of cardiac NL

Methods: A Phase II trial using a Simon's two-stage optimal approach was employed to allow for early stopping due to absence of treatment efficacy. In this first stage of the study, 19 anti-SSA/Ro ab pregnant patients with a previous child with cardiac NL (1st degree block excluded) were enrolled and if 3 or more children with cardiac NL were born, the study would be terminated for inefficacy. The protocol called for initiation of HCQ by 10 weeks gestation. Serial echocardiograms (echos) to evaluate for the development of the primary (2nd or 3rd degree block) and secondary (1st degree block) outcomes were performed. Maternal and cord blood HCQ levels were evaluated to assess treatment adherence, pathobiology and efficacy.

Results: Eighteen pregnancies in 17 women have been completed. Seventeen babies (including a set of twins) had normal serial fetal echos and normal EKGs at birth. One pregnancy resulted in a primary outcome of 3rd degree block. In this pregnancy, the echo at 20 weeks revealed 2nd degree block which progressed 2 days later to 3rd degree. The neonate was not paced until 4.5 months of age. Another pregnancy resulted in a secondary outcome of a prolonged fetal PR interval > 150 msec at 26 weeks for which the mother was treated with 3 days of 4mg dexamethasone. The PR interval normalized and the EKG at birth was normal. In the one ongoing pregnancy, all echos through 37 weeks were normal (notable since the most vulnerable period for complete block is 18–24 weeks). Overall, the rate of recurrence of cardiac NL was 5.3%. Figure 1 reveals that therapeutic HCQ levels can be achieved by the mid second trimester in mothers who were not previously on HCQ prior to conception. Figure 2 substantiates cord blood levels of HCQ.





Conclusion: These prospective data affirm that HCQ may prevent the recurrence of cardiac NL. The feasibility of the strategy using the Simon's two-stage design was substantiated. Moreover, the study unequivocally demonstrates that measurable HCQ levels can be reached prior to the vulnerable period and are present in the cord blood, reflective of placental transfer.

Increased Risk Of Autism Spectrum Disorders In Children Born To Women With SLE: Preliminary Data From The OSLER Cohort. Evelyne Vinet[1], Susan Scott[2], Christian A. Pineau[1], Lawrence Joseph[3], Ann E. Clarke[1], Eric Fombonne[4], Robert W. Platt[3] and Sasha Bernatsky[1]. [1]McGill University Health Center, Montreal, QC, [2]McGill University Health Centre, Montreal, QC, [3]McGill University, Montreal, QC, [4]Oregon Health and Sciences University, Portland, OR.

Background/Purpose: Recent experimental data suggest in utero exposure to maternal antibodies and cytokines as important risk factors for autism spectrum disorders (ASD). Interestingly, women with SLE display autoantibodies (e.g. anti-N-methyl-D-aspartate receptor and antiphospholipid antibodies) and cytokines (e.g. interleukin-6), which, in animal models, alter fetal

brain development and induce behavioural anomalies in offspring. To date, no one has specifically assessed the risk of ASD in children of SLE mothers. Using the "Offspring of Systemic Lupus Erythematosus mothers Registry (OSLER)", we aimed to determine if children born to SLE mothers have an increased risk of ASD compared to children born to mothers without SLE.

Methods: OSLER is a large population-based cohort, which includes all women who had ≥1 hospitalization for delivery after SLE diagnosis, identified through Quebec's universal healthcare databases (1989–2009). OSLER also includes a randomly selected control group of women, matched at least 4:1 for age and year of delivery, who did not have a diagnosis of SLE prior to or at the time of delivery. We identified children born live to SLE mothers and their matched controls, and ascertained ASD based on ≥1 hospitalization or physician visit with a relevant diagnostic code, through to end of database follow-up.

We performed multivariate analyses to adjust for maternal demographics, sex and birth order of child, and obstetrical complications. In a subsample analysis of children with maternal public drug coverage throughout pregnancy, we further assessed relevant in utero medication exposures.

Results: 509 women with SLE had 719 children, while 5824 matched controls had 8493 children. Mean maternal age and follow-up were respectively 30.3 [standard deviation (SD) 5.0] and 9.1 (SD 5.8) years. Children born to women with SLE had more records of ASD diagnoses compared to controls [1.4% (95% CI 0.8, 2.5) vs 0.6% (95%CI 0.5, 0.8)]. Mean age at ASD diagnosis was slightly younger in offspring of SLE mothers (3.8 years, 95%CI 1.8, 5.8) as opposed to controls (5.7 years, 95%CI 4.9, 6.5).

In multivariate analyses (Table 1), children born to women with SLE had substantially increased risk of ASD versus controls (HR 2.31, 95%CI 1.03, 5.16). In the subsample of children with maternal drug coverage (n=1925), in utero medication exposures were rare in the 18 ASD cases: none were exposed to antimalarials, antidepressants, or immunosuppressants, while only one case born to a SLE mother and another born to a control mother were respectively exposed to corticosteroids and anticonvulsants.

Table 1. Multivariate analyses of the risk of autism spectrum disorders (ASD) in SLE mothers versus controls (n=9212)

[a] Matching for maternal age, calendar year, and accounting for birth order and sex; hazard ratio (HR); confidence interval (CI); systemic lupus erythematosus (SLE)

Conclusion: Compared to children from the general population, children born to women with SLE have a substantially increased risk of ASD. Our findings are supported by previous experimental data and should prompt further research on the potential role of SLE-related autoantibodies, such as N-methyl-D-aspartate receptor antibodies, in ASD.

The Effect Of Maternal Antimalarial Intake During Pregnancy On The Risk Of Neonatal Lupus. Julie Barsalou, Edgar Jaeggi and Earl D. Silverman. The Hospital for Sick Children, University of Toronto, Toronto, ON.

Background/Purpose: Neonatal Lupus (NLE) results from passive transfer of anti-Ro and/or anti-La antibodies to the fetus during gestation. It has been suggested that prenatal exposure to hydroxychloroquine (HCQ) reduces the risk of cardiac NLE through disruption of toll-like receptors signalling. The effect of HCQ on the risk of extra-cardiac NLE has not been specifically studied. The aim of this study was to assess if maternal intake of HCQ or chloroquine throughout pregnancy reduces the risk of NLE in the offspring. We hypothesized that these drugs would confer protection against NLE.

Methods: A case-control study was performed on a large single-center cohort of NLE and unaffected children, on whom prospective data has been collected since 1984. Inclusion criteria were: (1) first child born from a mother positive for anti-Ro and/or anti-La antibodies with a diagnosis of either cutaneous lupus, systemic lupus erythematosus, Sjogren's syndrome, dermatomyositis or rheumatoid arthritis and, (2) assessment of the child in the NLE clinic at least once in his first 6 months of life. Descriptive statistics and logistic regressions were performed.

Results: The study population consisted of 220 children, of whom 62 were exposed to HCQ or chloroquine throughout gestation (Table). NLE was diagnosed in 98 patients; 12 had cardiac NLE (11 congenital heart block and 1 cardiomyopathy). Neutropenia (n=41) was the most frequent extra-cardiac NLE feature followed by hepatitis (n=36), skin involvement (n=32), thrombocytopenia (n=4) and extraventricular obstructive hydrocephalus (n=4). One hundred and twelve children did not develop NLE. Ten children were classified as having no cardiac NLE involvement but could not be diagnosed as true unaffected children as one or more blood test components were missing. No statistically significant protective effect of HCQ or chloroquine exposure was found on the risk of NLE (OR 0.79; p=0.45). Similar results were found when extra-cardiac NLE cases were analyzed separately (OR 0.85; p=0.60). Only 1 of 62 children exposed to HCQ or chloroquine developed cardiac-NLE compared to 11 of 158 unexposed children (OR 0.22; p=0.19). On multivariable logistic regression, anti-La titer ≥100 U/mL was the only significant predictor of NLE (OR 2.23; p=0.03). The mother's age, diagnosis, intake of azathioprine, anti-Ro titers ≥50 U/mL and the child's gender did not significantly impact on the risk of NLE.

Table. Characteristics of mothers of NLE cases and unaffected children

	NLE (n=98)	Unaffected children (n=112)	p value
Mothers			
Age at birth of child	31.7 ± 4.8	32.2 ± 4.6	0.44
Diagnosis			0.13
SLE or cutaneous lupus	71 (72)	93 (83)	
Sjogren's syndrome	20 (21)	12 (11)	
Others	7 (7)	7 (6)	
Anti-Ro ≥50 U/mL*	62 (67)	63 (66)	0.96
Anti-La ≥100 U/mL§	26 (28)	14 (14)	0.01
On HCQ or chloroquine	26 (27)	35 (31)	0.45
On azathioprine	5 (5)	13 (12)	0.09
On prednisone	28 (29)	40 (36)	0.32
Older child with CHB	1 (1)	2 (2)	1.00

Mean±SD; n (%)
*n=93 NLE and 95 unaffected children; §n=94 NLE and 103 unaffected children

Conclusion: In the largest single-center case-control study of children born to anti-Ro and/or anti-La antibody positive women diagnosed with a connective tissue disease, HCQ or chloroquine exposure throughout gestation did not result in a significantly lower risk of NLE. High titers of anti-La antibodies in the mother were associated with an increased risk of NLE.

Increased Cardiac Septal Defects In Children Born To Women With Systemic Lupus Erythematosus: Results From The OSLER Study. Evelyne Vinet[1], Susan Scott[2], Christian A. Pineau[2], Ann E. Clarke[3], Robert W. Platt[3] and Sasha Bernatsky[1]. [1]McGill University Health Center, Montreal, QC, [2]McGill University Health Centre, Montreal, QC, [3]McGill University, Montreal, QC.

Background/Purpose: Cardiac septal defects, which include atrial septal defects (ASD) and ventricular septal defects (VSD), are the most frequent congenital heart anomalies in the general population. Uncontrolled small studies of children born to women with SLE suggest a potentially increased prevalence of structural heart defects, such as ASD and VSD. In a large population-based study, we aimed to determine if offspring born to mothers

with SLE have an increased risk of ASD and VSD compared to offspring born to mothers without SLE.

Methods: The "Offspring of SLE mothers Registry (OSLER)" includes all women who had ≥1 hospitalization for delivery after SLE diagnosis, identified through Quebec's universal healthcare databases (1989–2009). OSLER also includes a randomly selected control group of women, matched at least 4:1 for age and year of delivery, who did not have a diagnosis of SLE prior to or at the time of delivery. We identified children born live to SLE mothers and their matched controls, and ascertained ASD and VSD based on ≥1 hospitalization or physician visit with a relevant diagnostic code, within the first 12 months of life.

We performed multivariate analyses to adjust for maternal demographics, sex and birth order of child, and maternal co-morbidities. In a subsample analysis of children with maternal public drug coverage throughout pregnancy, we further adjusted for relevant maternal medications

Results: 509 women with SLE had 719 children, while 5824 matched controls had 8493 children. Compared to controls, children born to women with SLE experienced more ASD [2.9% (95%CI 1.9, 4.4) vs 0.8% (95%CI 0.6, 1.0) and VSD [1.7% (95%CI 1.0, 2.9) vs 0.7% (95%CI 0.5, 0.9)]. Among children with cardiac septal defects, those born to SLE mothers had more repair procedures compared to controls [9.7% (95%CI 3.4, 24.9) vs 4.4% (95%CI 1.9, 9.9)].

In multivariate analyses (n=9212), children born to women with SLE had a substantially increased risk of both ASD (OR 3.36, 95%CI 1.99, 5.70) and VSD (OR 2.48, 95%CI 1.20, 4.76) compared to controls. In addition, offspring of SLE mothers had a substantially increased risk of having a cardiac septal defect repair compared to controls (OR 4.90, 95%CI 1.11, 21.73).

When accounting for the possibility of detection bias by excluding children with ≥ 1 fetal echocardiography (n=331), adjusted effect estimates were similar to the primary multivariate analysis results for both ASD (OR 2.48, 95%CI 1.26, 4.87) and VSD (OR 2.09, 95%CI 0.96, 4.53). In the subsample analysis further controlling for relevant maternal medications (n=1925), though a trend remained for increased risk of ASD and VSD (combined) for offspring of SLE mothers versus controls, due to reduced sample size the 95% CI was wide and included the null value (both ASD and VSD combined; OR 1.83, 95%CI 0.59, 5.69).

Conclusion: Compared to children from the general population, children born to women with SLE have an increased risk of ASD and VSD, as well as an increased risk of having a cardiac septal defect repair. The effect of SLE on cardiac septal defects does not seem to be explained by detection bias and might be independent of medication exposures.

Background/Purpose: Congenital heart block (CHB) occurs in 1 to 2 % of pregnancies exposed to anti-SSA antibodies. Few data are available regarding the risk of the mothers of fetuses/children with CHB to develop an autoimmune disease.

Methods: The inclusion criteria in the French registry of neonatal lupus are the positivity of anti-SSA and/or anti-SSB antibodies and a manifestation of neonatal lupus. In this retrospective study, we analyzed the data of the mothers who had a foetus/child with CHB.

Results: 184 mothers of 205 fetuses/children with CHB were included: 99.5% (183) had anti-SSA antibodies and 69.6% (128) had anti-SSB antibodies.

At the time of their first diagnosis of CHB, 136 mothers (73.9%) were asymptomatic. The 48 mothers (26.1%) with an auto-immune disease had a systemic lupus erythematosus (SLE, n=20, associated with antiphospholipid syndrome with venous thrombosis in 2 cases), a sjogren syndrome (n=12), an undifferentiated connective tissue disease (UCTD, n=10), a rheumatoid arthritis (n=3), a idiopathic thrombocytopenic purpura (n=1), an auto-immune hepatitis (n=1) and a systemic scleroderma (n=1). Clinical manifestations of SLE mainly included cutaneous and articular manifestations and only 8 mothers had more severe manifestations (renal, neurological, pericarditis, hematological). Only one had received cyclophosphamide.

After a median follow up period of 8.8 years [1 day-36.5 years], 75 mothers (40.8%) remained asymptomatic. The 109 mothers (59.2%) with an autoimmune disease had a Sjogren syndrome (n=42), an SLE (n=37, including 2 associated with an antiphospholipid syndrome), an UCTD (n=20), a rheumatoid arthritis (n=3), an SLE associated with a Sjogren syndrome (n=2), a idiopathic thrombocytopenic purpura (n=2), an auto-immune hepatitis (n=1), a systemic scleroderma (n=1) and a primary obstetrical antiphospholipid syndrome (n=1).

Conclusion: At the time of the CHB diagnosis in their offspring, a third of the mothers had a diagnosis of autoimmune disease. During the follow up period, another third developed an autoimmune disease. The remaining third was still asymptomatic after a median follow up period of 8.8 years [1 day-36.5 years].

Safety Of Gardasil® Vaccine In Systemic Lupus Erythematosus. J. Patricia Dhar, Lynnette Essenmacher, Renee Dhar, Ardella Magee, Joel Ager, Malini Venkatram, Harpreet Sagar and Robert Sokol. Wayne State University, Detroit, MI.

Background/Purpose: Cervical neoplasia is increased in women with SLE presumably due to cervical infection with oncogenic Human Papillomavirus (HPV) types which persist in an immunosuppressed host. Vaccinating women with SLE against HPV is thus an important part of health prevention in this population. Gardasil® immunizes against the HPV types that cause the majority of cervical cancer (types 16 and 18) and genital warts (types 6 and 11), and has been shown to be protective against these HPV-related diseases.

Methods: For this ongoing trial, twenty women ages 18–50 years with a history of mild to moderate SLE and minimally active or inactive SLE disease received Gardasil® at the standard dosing schedule (0, 2 months, 6 months). This study was approved by the Human Investigation Committee at Wayne State University and the U.S. Food and Drug Administration. Patients were excluded if they had active disease (SELENA-SLEDAI >2), a history of severe disease, deep venous thrombosis, were on >400 mg/day of hydroxychloroquine, were on >15 mg/day of prednisone, or had active infections. To date, 20 patients have completed the second vaccine shot. Patients were monitored for adverse events (AE), SLE flare, and generation of thrombogenic antibodies and thrombosis.

Results: The women in the study were predominantly African-American (75%), mean age 39 years with mean age at diagnosis of SLE at 29.8 years. All patients met American College of Rheumatology (ACR) criteria for SLE; 25% had a history of smoking, 95% had 4 or more sexual partners, 35% had a history of sexually transmitted diseases, and only 21% used condoms on a regular basis. History of abnormal pap smears occurred in 40%, ranging from ASCUS (atypical glandular cells of undetermined significance) to CIN 3 (cervical intraepithelial neoplasia grade 3). Most of our patients had multiple comorbidities in addition to SLE. Vaccine site reactions (VSRs) occurred in 50%, 90% being mild, with the most common reaction being pain. This

compares favorably to data from the current prescribing label showing frequency of VSRs in normal women to be 83.9% for Gardasil® vs. 75.4% for controls. For the non-vaccine site adverse events (nvAE), 90% of our cohort experienced at least one nvAE; there were 105 nvAEs reported from 18 patients and 90% of these nvAEs were mild. There was one serious AE related to underlying osteoarthritis and cervical disc disease. The most common nvAEs reported were musculoskeletal (n=28) followed by cardiopulmonary (n=25), headache (n=21), and dermatologic (n=19). None of the nvAEs were related to vaccine or SLE. There was no flare of SLE, thrombosis, or generation of thrombogenic antibodies in any patient.

Conclusion: Preliminary data from our study shows that Gardasil® vaccine is safe to use in women with SLE. Vaccine site reactions are not increased in SLE patients. Other than vaccine site reactions, there were no related short term adverse events. Gardasil® vaccine administration did not result in any lupus flare or thrombosis. Women with SLE should be immunized with Gardasil® vaccine as part of their health prevention program, particularly since this population is at increased risk for HPV-related cervical dysplasia.

Development of a Health Index in Patients With Ankylosing Spondylitis (ASAS HI)—Final Result of a Global Initiative Based On the International Classification of Functioning, Disability and Health (ICF) Guided By Assessment of Spondyloarthritis International Society (ASAS). Uta Kiltz[1], Désiréé van der Heijde[2], Annelies Boonen[3], Alarcos Cieza[4], Gerold Stucki[5], Muhammad Asim Khan[6], Walter P. Maksymowych[7], Helena Marzo-Ortega[8], John D. Reveille[9], Simon Stebbings[10], Cristina Bostan[11] and Juergen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Maastricht University Medical Center, Maastricht, Netherlands, [4]University Southampton, Southampton, United Kingdom, [5]University of Lucerne, Lucerne, Switzerland, [6]Case Western Reserve University Hospital, Cleveland, OH, [7]University of Alberta, Edmonton, AB, [8]Leeds Musculoskeletal Biomedical Research Unit and University of Leeds, Leeds, United Kingdom, [9]Univ of Texas Health Science Center at Houston, Houston, TX, [10]University of Otago, Otago, New Zealand, [11]Paraplegic Research Unit, Nottwil, Switzerland.

Background/Purpose: The impact of ankylosing spondylitis (AS) on a patient's life can be considerable. Patients suffer from pain, stiffness and fatigue, are limited in their activities, and restricted in social participation. The International Classification of Functioning, Disability and Health (ICF) is a model to systematically classify and describe functioning, disability, and health in human beings. However no ICF-based patient-reported outcome measure has been developed. the objective is to develop a measure to assess health in patients with AS, the ASAS (Assessments of SpondyloArthritis international Society (ASAS)) Health Index, based on the Comprehensive ICF Core Set for AS.

Methods: Development has been performed in five phases.

Table 1. Phases of development for the ASAS Health Index

	Phase	Objectives	Methods
Ia	Preparatory	Development of a pool of items representing the categories of the Comprehensive ICF Core Set for AS	Linkage of various assessment tools for functioning and health to ICF categories
Ib	Patient meeting	Patient preference and weighting of the items per ICF category	Relative weight to each item, patients distributed 100 points per ICF category.
II	1st postal patient survey	Item reduction (within and across ICF categories)	Factor Analysis, Rasch Analysis, Spearman rank correlation coefficient
III	Expert consultation	Agreement on item reduction	Nominal Consensus Process
IV	2nd postal patient survey	Validation of the draft version and further item reduction	Testing psychometric properties Rasch Analysis
V	Consensus Meeting	Agreement on a final version	Nominal Consensus Process

Results: Phase 1: The item pool contained 251 items in 44 categories. Phase 2 was performed based on data collected along an international cross sectional study among 1915 AS patients (mean age 51.2±3.6, 53% male, BASDAI 5.5±2.4) in 4 continents. For 82 items of the *functioning* part a unidimensional scale, fit to the Rasch model and absence of Differential Item Function (DIF) could be confirmed. Phase 3: An expert committee selected 50 functioning items using predefined selection criteria. Phase 4: An international cross sectional study with 628 AS patients (mean age 48.5±14.2, 51.6% male, BASDAI 5.6±2.3) was conducted in 4 continents. Misfit was identified in 4 items and DIF in 15 items. More than 50% of the items showed a residual correlation between each other above a value of 0.2 in the initial round. Phase 5: Based on results of the analyses in step 4, the consensus members agreed on 17 final items. In the 17 items fit to the model, no residual correlation and absence of constant DIF could be confirmed with a Person-Separation Index of 0.82. The item location has been shown to be 0.00 ± 1.84 with a fit residual of 0.06 ± 1.24 and the person location has been shown to be 0.01 ± 1.80 with a fit residual of −0.30 ± 0.67. The chi-square probability was 0.73.

Conclusion: The ASAS HI measure contains 17 dichotomous items addressing categories of pain, emotional functions, sleep, sexual functions, mobility, self-care, community life and employment. In covering much of the ICF Core Set for AS, these items represent a whole range of abilities of patients with AS. The questionnaire will be translated and further tested for sensitivity to change. ASAS HI can be used in clinical trials and clinical practice as a new composite index that captures relevant information on the health status of the patients.

Higher Disease Activity Leads To More Damage In The Early Phases Of Ankylosing Spondylitis: 12-Year Data From The OASIS Cohort. Sofia Ramiro[1], A.M. van Tubergen[2], Désirée van der Heijde[3], Carmen Stolwijk[2], Maxime Dougados[4], Filip Van den Bosch[5] and Robert Landewé[6]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France, [5]Gent University Hospital, Gent, Belgium, [6]Academic Medical Center Amsterdam & Atrium Medical Center, Heerlen, Netherlands.

Background/Purpose: For years, it was unclear if inflammation and radiographic progression were related in ankylosing spondylitis (AS), but studies were only of short follow-up and not analysed optimally. We here present a true longitudinal analysis on the long-term relationship between disease activity and radiographic damage.

Methods: Patients from the Outcome in AS International Study (OASIS) were followed-up for 12 years, with biannual clinical and radiographic assessments. Two readers independently scored the x-rays according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) and scores were averaged. Disease activity measures include the BASDAI, ASDAS-CRP, CRP, ESR, patient's global assessment and spinal pain. The relationship between disease activity measures and radiographic damage was investigated using generalized estimating equations. Auto-regressive models with 2-year time-lags were used and analyses were adjusted for potential confounders. Different models were constructed: model 1 – with ASDAS as a continuous measure; model 2 – with ASDAS disease activity states; model 3 – with BASDAI continuous and CRP; model 4 – with BASDAI categories and CRP; model 5 – with patient global and CRP; model 6 – with spinal pain and CRP. Models were repeated replacing CRP by ESR. Model fit was compared using the quasi-likelihood information criterion (QIC). Interactions were tested for gender and disease duration.

Results: A total of 185 patients were included (70% males, mean (SD) age: 43(12) years, mean symptom duration: 20(12) years and 83% HLA-B27 positive). All disease activity measures, except ESR, were significantly longitudinally associated with radiographic progression (Table). Neither medication (NSAIDs, NSAID score or biologicals), nor the presence of extra-articular manifestations (uveitis, psoriasis or IBD) were confounding this relationship. The models with ASDAS had the best fit (i.e. lowest QIC): An increase in one ASDAS-unit led to an increase in 0.72 mSASSS-units and a 'very high disease activity state' (i.e. ASDAS>3.5) compared to inactive disease (i.e. ASDAS<1.3) represented an additional progression of 2.31

mSASSS-units per 2 years (Table). Results were consistent across all disease activity measures. The effect of ASDAS on mSASSS was higher in males vs females (β 0.98 vs −0.06) and in patients with shorter vs longer (<18 vs ≥18 years) disease duration (0.84 vs 0.16).

Table. Longitudinal relationship between disease activity measures and radiographic damage*

Variable	Univariable regression β (95% CI) (N = 174 - 185)	Multivariable regression 1 β (95% CI) (N = 183)	Multivariable regression 2 β (95% CI) (N = 183)	Multivariable regression 3 β (95% CI) (N = 184)	Multivariable regression 4 β (95% CI) (N = 184)	Multivariable regression 5 β (95% CI) (N = 184)	Multivariable regression 6 β (95% CI) (N = 184)

Patient's global assessment (0–10)	0.20 (0.08; 0.32)	§	§	§	§	0.17 (0.05; 0.29)	§
Pain (0–10)	0.25 (0.12; 0.38)	§	§	§	§	§	0.22 (0.00; 0.04)
QIC of the model		5349	5458	5665	5579	5664	5473

*All models are time-lagged (2 years) and auto-regressive
§ Not included in the model

Conclusion: In AS disease activity is unequivocally longitudinally associated with radiographic progression. ASDAS is the best measure to reflect this relationship. The effect of disease activity on radiographic damage is more pronounced in men and in the earlier phases of the disease. These findings may give support to use ASDAS as a treat-to-target.

Relationship Between Active Inflammatory Lesions In The Spine and Sacroiliac Joints and Development Of Fatty Lesions On Whole-Body MRI In Patients With Early Axial Spondyloarthritis—Long-Term Data Of The Esther Trial. In-Ho Song[1], Kay-Geert A. Hermann[2], Hildrun Haibel[3], Christian Althoff[4], Denis Poddubnyy[3], Joachim Listing[5], Anja Weiss[6], Ekkehard Lange[7], Bruce Freundlich[8], Martin Rudwaleit[9] and Joachim Sieper[10]. [1]Charité Universitätsmedizin Berlin, Campus Benjamin Franklin, Berlin, Germany, [2]Charité Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany, [3]Charité Universitätsmedizin Berlin, Berlin, Germany, [4]Charite Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany, [5]German Rheumatism Research Center, Berlin, Germany, [6]German Rheumatism Research Centre, Berlin, Germany, [7]Pfizer Pharma AG, Berlin, Germany, [8]University of Pennsylvania, Philadelphia, PA, [9]Endokrinologikum Berlin, Berlin, Germany, [10]Charité Universitätsmedizin Berlin, Campus Benjamin-Franklin, Berlin, Germany.

Background/Purpose: In patients with early axial spondyloarthritis (SpA) with evidence of active inflammation on magnetic resonance imaging (MRI) in the spine and/or sacroiliac (SI-)joints at baseline [1] we previously reported about the relationship between inflammation and the development of fatty lesions in the subchondral bone marrow [2]. We now assessed this relationship in the spine and SI-joints on MRI in these patients with 3 years of continuous treatment with etanercept (ETN).

Methods: Wb-MRIs of those 40 patients who reached the end of year 4 were scored for active inflammation (osteitis) and fatty lesions in the SI-joint quadrants and spine vertebral units (VUs). For this analysis we pooled the data of the patients who were continously treated with ETN for 3 consecutive years. Scoring was performed by two radiologists, blinded for treatment arm and MRI time point. Fatty lesions were scored for absence or presence according to our recently published score [2]. For this analysis, the presence or absence of osteitis and fatty lesions were only counted if both scorers agreed.

Results: New fatty lesions did not develop at all in sites (quadrants or VUs) where there was no osteitis at baseline.

New fatty lesions at year 2 (Y2) or Y3 primarily developed in SI-joint quadrants in which osteitis disappeared between baseline (BL) and Y2, this was the case in 28.6% quadrants (10 out of 35) (see Figure 1, section A2). In the spine only 1 VU developed a new fatty lesion in which osteitis disappeared between BL and Y2/Y3.

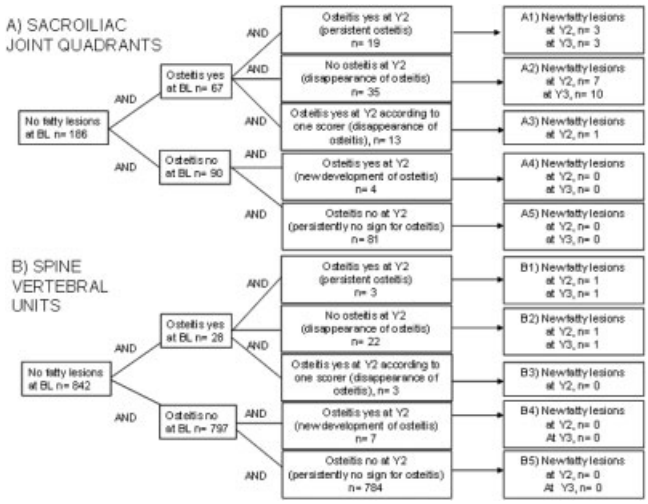

Figure 1. Development of new fatty lesions depending on the presence of inflammation on magnetic resonance imaging related to sacroiliac joint quadrants and spine vertebral units (VUs) with no fatty lesions at baseline (BL). Y= year; n= number of sites (SI-joint quadrants or spine vertebral units)

Persistent osteitis at Y2 or new development of osteitis (occurred rarely) was associated with a low rate of new development of fatty lesions, 16% (3/19) and 33% (1/3) for SI-joint and spine, respectively (A1, B1). New onset of osteitis at Y2 was not associated with new fatty lesions.

At baseline 74 SI-joint quadrants and 26 spine VUs showed fatty lesions. Until Y2 and Y3 only in 3 SI-joint quadrants and 0 VUs fatty lesions disappeared.

The mean spine fatty lesion scores were 1.1 (2.1) at BL, 1.4 (2.5) at Y2 and 1.3 (2.3) at Y3. The mean SI-joint fatty lesion scores were 4.6 (6.3), 5.2 (6.4) and 4.7 (6.3), respectively.

Conclusion: Our data indicate a strong relationship between presence of inflammation and new development of fatty lesions. Furthermore there was no increase of fatty lesions over continous treatment of axial SpA patients with etanercept over 3 years.. Whether this is predictive of stopping radiographic progression needs to be further investigated.

Effects Of Treatment On Spinal Fat Lesions As Assessed By MRI With The Fat Spondyloarthritis Spine Score. Susanne Juhl Pedersen[1], Zheng Zhao[2], Stephanie Wichuk[3], Robert GW Lambert[3] and Walter P. Maksymowych[3]. [1]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [2]Department of Rheumatology, University of Alberta and PLA General Hospital, Beijing, PR China, Beijing, China, [3]University of Alberta, Edmonton, AB.

Background/Purpose: Fat lesions develop after resolution of inflammation in the spine (1), and have also been shown to predict development of new syndesmophytes (2). Consequently, spinal fat lesions may constitute an

important measure of treatment efficacy and a surrogate for structural damage progression. The aim of this study was to investigate the effects of different treatments on development of fat lesions on spinal MRI.

Methods: A total of 135 patients with axial spondyloarthritis (SpA) had MRIs performed with a mean (SD) follow-up of 1.7 (0.8) years. Patients either received no anti-inflammatory treatment (n=12), or were treated with non-steroid anti-inflammatory drugs (NSAIDs) only (n=55), tumor-necrosis-factor-alpha (TNFα) inhibitor only (n=15) or NSAIDs and TNFα inhibitor in combination (n=53). Spinal fat lesions were assessed by the Fat Spondyloarthritis Spine Score (FASSS), where fat lesions are scored based on anatomical location and recorded dichotomously (present/absent) at each vertebral endplate (3). Scoring range per disco-vertebral unit (DVU) for the cervical spine is 0–8, and for the thoracic and lumbar spine: 0–24, resulting in a total score range of 0–456 for all 23 DVUs. Two rheumatologists evaluated pairs of scans blinded to clinical, biochemical or imaging data. Inter-class correlation coefficients were 0.96 (CI 95% 0.94–0.97) for baseline and 0.86 (0.80–0.90) for change scores.

Results: Patients treated only with NSAIDs had significantly shorter disease duration, lower CRP and structural damage on X-rays as assessed by mSASSS as compared to patients treated with TNFα inhibitor alone or in combination with NSAIDs (results not shown, Mann-Whitney test). Patients treated only with NSAIDs had lower FASSS at baseline (p=0.03) and had less change (p=0.01) as compared to patients treated only with TNFα inhibitors (Table 1). Furthermore, significantly more patients treated only with NSAIDs decreased or had no change in FASSS score during follow-up as compared to patients receiving no anti-inflammatory treatment (p=0.009) or TNFα inhibitor alone (p=0.03) (Table 1) (Chi2 test).

Table 1. FASSS baseline and change scores, and number and frequency of patients with decrease/no change or increase in FASSS scores stratified according to treatment.

	FASSS scores		Change in FASSS score	
Treatment group	**Baseline**	**Change**	**Decreased/ no change**	**Increased**
1: No anti-inflammatory treatment (n=12)	10.3 (0; 187)	2.0 (−1; 9.5)	2 (16.6)	10 (83.3)
2: NSAIDs only (n=55)	11.5 (0; 115)	0 (−9.5; 50)	32 (58.2)	23 (41.8)
3: TNFα inhibitor only (n=15)	18.5 (1; 118)	8.5 (−8; 51)	4 (26.7)	11 (73.3)
4: NSAIDs and TNFα inhibitor (n=53)	10.0 (0; 93)	1.5 (−35.5; 34)	21 (39.6)	32 (60.4)

Results are provided a median (range) or N (%).

Conclusion: Treatment with NSAIDs is associated with a lower propensity to develop fat lesions which could be associated with their effects on new bone formation.

Predictors Of Spinal Mobility Progression In A Multi-ethnic Cohort Of Patients With Ankylosing Spondylitis. Roozbeh Sharif[1], Trisha M. Parekh[1], Lianne S. Gensler[2], MinJae Lee[3], Mohammad Rahbar[4], Laura A. Diekman[4], Michael H. Weisman[5], Michael M. Ward[6], Shervin Assassi[3] and John D. Reveille[3]. [1]University of Texas Medical Branch, Galveston, TX, [2]University of California, San Francisco, San Francisco, CA, [3]University of Texas Health Science Center at Houston, Houston, TX, [4]The University of Texas Health Science Center at Houston, Houston, TX, [5]Cedars-Sinai Medical Center, Los Angeles, CA, [6]NIAMS/NIH, Bethesda, MD.

Background/Purpose: Clinicians utilize several different clinical measurements (metrology) in patients with Ankylosing Spondylitis (AS) to assess the spinal mobility. We aimed to examine the pattern of change in metrology over time and to evaluate the factors associated with these changes.

Methods: In a prospective study, we included participants from a multi-ethnic, multi-center cohort of AS patients meeting modified New York criteria. The primary outcomes were eight individual clinical measurements, recorded at baseline and follow up visits every 6 months: cervical rotation and flexion, occiput to wall distance, chest expansion, modified Schober, lateral lumbar spinal flexion, and hip internal/external rotation. The independent variables included demographic, health habits, medications, radiologic and the patient-perceived functional limitation index (Bath AS Functional and Disease Activity Indices [BASFI & BASDAI]). Mixed models that accounted for correlation of repeated measures longitudinally as well as interaction with time were conducted to examine whether the spinal mobility pattern is changed by each of independent variables among AS patients.

Results: Overall, 611 patients, including 177 female (29%) and 462 (75.7%) non-Hispanic white were followed up to 4 years. The univariable analyses are shown in table 1. Age, sex, disease duration, smoking habits, radiologic severity and patient perceived functional limitation and disease activity indices at baseline were associated with metrology over time. However, ethnicity and treatment with NSAID and anti-tumor necrosis factor (TNF)-α medications at baseline did not correlate with metrology over time among AS patients. Multivariable analysis indicated that after adjusting for age, sex, employment status, BASFI and BASRI at baseline, age>40 at enrollment associated with worse outcome among all measurements, except hip rotation. Gender, race, and educational status were not associated with the longitudinal changes in metrology. Smoking at baseline visit was associated with greater worsening of lateral flexion and cervical flexion and rotation. Moreover, being employed as well as lower BASDAI, BASFI, and BASRI score at baseline were associated with slower progression over time, across all eight metrology indices.

Conclusion: Demographics and disease severity indices at baseline were independent correlates of the worsening of clinical measurements among patients with AS. Further studies are encouraged to identify whether reversing the potentially modifiable factors such as smoking cessation can slow the rate of progression.

Inflammation and Structural Progression In The Sacroiliac Joints Of Patients With Axial Spa Treated With Adalimumab Or Placebo As Assessed By The Berlin and The Spondyloarthritis Research Consortium Of Canada MRI Methods. Susanne Juhl Pedersen[1], Denis Poddubnyy[2], Inge Juul Sørensen[3], Anne Gitte Loft[4], Jens Skjødt Hindrup[5], Gorm Thamsborg[6], Karsten Asmussen[7], Elka Kluger[8], Jesper Nørregaard[9], Torben Grube Christensen[10], Anne G. Jurik[11], J.M. Møller[12], Thomas Skjødt[13], Dorrit Mikkelsen[14] and Mikkel Østergaard[15]. [1]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [2]Charité Universitätsmedizin Berlin, Berlin, Germany, [3]Hvidovre Hospital, Copenhagen, Denmark, [4]Department of Rheumatology, Sygehus Lillebaelt, Vejle, Denmark, [5]Gentofte Hospital, Copenhagen, Denmark, [6]Glostrup Hospital, Copenhagen, Denmark, [7]Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, [8]King Christian 10th Rheumatism Hospital at Gråsten, Graasten, Denmark, [9]Hørsholm Hospital, Hørsholm, Denmark, [10]MD, Slagelse, Denmark, [11]Aarhus University Hospital, Aarhus, Denmark, [12]Copenhagen University Hospital in Herlev, Copenhagen, Denmark, [13]Vejle Hospital, Vejle, Denmark, [14]Aabenraa Hospital, Aabenraa, Denmark, [15]Copenhagen University Hospital Glostrup, Copenhagen, Denmark.

Background/Purpose: To investigate changes in inflammation and structural progression in the sacroiliac joints (SIJs) in patients with axial spondyloarthritis (SpA) during treatment with adalimumab and placebo in a randomized double-blind placebo-controlled trial, as assessed by two different MRI methods.

Methods: Fifty-one patients with axial SpA were treated with adalimumab 40 mg (n=26) or placebo (n=25) sc. e.o.w. for 12 weeks, followed by an open label extension phase of 36 weeks where all patients received adalimumab. MRIs of the SIJs were performed at weeks 0, 12, 24 and 48. Two rheumatologists evaluated the images in random order, blinded for clinical, biochemical and other imaging data with either the Berlin method (reader DP)(1) or the SPondyloArthritis Research Consortium of Canada (SPARCC) MRI Sacroiliac Joint Inflammation (2) and Structural Score (reader SJP)(2). By the Berlin method scoring ranges are: Inflammation (INF): 0–24, fat (FAT): 0–24, erosions (ER): 0–6, sclerosis (SCL): 0–2, and ankylosis (ANK): 0–2. In the SPARCC method scoring ranges are: inflammation (INF): 0–60, fat (FAT): 0–50, erosions (ER): 0–40, backfill (BF): 0–20, ankylosis (ANK): 0–20. The structural lesions are defined according to standardized and validated definitions (Morpho) (3).

Results: According to the Berlin method, INF decreased significantly in the adalimumab group from week 0 to 12 (Wilcoxon-Pratt; $p=0.01$), while the placebo group decreased from week 0 to 24 ($p<0.01$), i.e when patients had received 12 weeks of open-label adalimumab (Table 1). Berlin scores for FAT, ER, ANK and SCL did not change in any of the groups. According to the SPARCC method, INF decreased significantly in both treatment groups ($p<0.05$) from baseline to all time points. In patients treated with adalimumab, FAT increased from week 0 to 24 and 48 ($p<0.03$) and BF increased from week 0 to 12 ($p<0.02$). ANK increased from week 0 to 48 in both treatment groups ($p<0.03$), and ER decreased from week 0 to 24 and 48 ($p<0.02$) in the placebo group. At baseline, no differences between the treatment groups as assessed by the two scoring methods, besides that SPARCC ANK was higher in patients treated with adalimumab (Mann-Whitney; $p<0.05$) (Table 1). At week 12, INF was significantly lower in the adalimumab group than the placebo group, both by the Berlin ($p<0.003$) and the SPARCC ($p<0.002$) methods, and ER was lower when assessed by the SPARCC method ($p<0.01$).

Table 1. Berlin and SPARCC MRI scores for inflammation and structural lesions in the SIJs

	Berlin					
	Adalimumab			Placebo		
	0	12	24	0	12	24
INF	1 (0–14)	0 (0–6)*	1 (0–6)	2 (0–18)	2 (0–24)	1 (0–10)*
FAT	15 (1–24)	16 (1–24)	15.5 (1–24)	12 (2–24)	13 (2–14)	13 (3–24)
ER	3 (0–6)	3 (0–6)	2 (0–6)	4 (0–6)	4 (0–6)	4 (0–6)
SCL	0 (0–2)	0 (0–2)	0 (0–2)	2 (0–2)	2 (0–2)	2 (0–2)
ANK	0 (0–2)	0 (0–2)	0.5 (0–2)	0 (0–2)	0 (0–2)	0 (0–2)

	SPARCC					
	Adalimumab			Placebo		
	0	12	24	0	12	24
INF	0.5 (0–37)	0 (0–17)*	0 (0–18)*	5 (0–39)	4 (0–40)*	2 (0–26)**
FAT	15 (0–50)	17 (0–50)	17.5 (0–50)	9 (0–41)	9 (0–41)	10 (0–45)
ER	0 (0–8)	0 (0–4)	0 (0–13)	2 (0–20)	2 (0–20)	0 (0–8)**
BF	3.5 (0–20)	4.5 (0–20)*	4.5 (0–20)	4 (0–15)	6 (0–15)	7 (0–17)
ANK	3 (0–20)	3.5 (0–20)	4 (0–20)	0 (0–20)	0 (0–20)	0 (0–20)

Results are median (range). *$p<0.05$; **$p<0.01$; Wilcoxon-Pratt test.

Conclusion: After 12 weeks of therapy, SIJ inflammation was lower in adalimumab than placebo treated patients. The Berlin and SPARCC methods are both sensitive for changes in inflammation, while the SPARCC method may be more sensitive for changes in structural lesions.

Cochrane Systematic Review Of Self-Management Education Programs For People With Osteoarthritis. Féline P.B. Kroon[1], Lennart R.A. van der Burg[1], Rachelle Buchbinder[2], Richard H. Osborne[3] and Veronica Pitt[4]. [1]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [2]Monash Department of Clinical Epidemiology at Cabrini Hospital, Department of Epidemiology and Preventive Medicine, Monash University, Malvern, Victoria, Australia, [3]Deakin University, Melbourne, Australia, [4]National Trauma Research Institute, The Alfred Hospital, Monash University, Melbourne, Australia.

Background/Purpose: We performed a Cochrane systematic review to determine the effectiveness of self-management education programs (SMPs) for people with osteoarthritis (OA).

Methods: Published randomised controlled trials of SMPs delivered to people with OA were included up to 17 January 2013. We excluded studies of SMPs that did not have a reproducible structured format or that treated participants solely as passive recipients of care. Studies comparing different types of SMPs without a control group were excluded. We extracted data about SMP content using the domains of the Health Education Impact Questionnaire (heiQ) and considered contextual factors and participant characteristics relevant to health equity issues using PROGRESS-Plus and the Health Literacy Questionnaire. Main comparisons were SMPs versus attention control or usual care. Main outcomes were self-management skills, positive and active engagement in life, pain, global OA scores, function, quality of life and withdrawal rates.

Results: Twenty-nine trials (6753 participants) were included: SMP vs attention control (5 trials, N=937), usual care (17 trials, N=3738), information alone (4 trials, N=1251) or another intervention (7 trials, N=919). Most SMPs included elements of skill and technique acquisition (94%), health directed activity (85%) and self-monitoring and insight (79%). Most trials did not provide enough information to assess health equity issues; 8 included mainly Caucasian, educated females and only 4 provided any information on participants' health literacy. All studies were at high risk of performance and detection bias for self-reported outcomes.

Compared with attention control, there was low to moderate quality evidence that SMPs may not result in significant benefits at 12 months. Although there was a small difference in pain favouring SMPs (low quality evidence, 3 trials, N=575): SMD −0.26 (95% CI −0.44 to −0.09), this is unlikely to be of clinical importance, and there were no between-group differences for any of the other measured main outcomes, e.g. self-management skills (low quality evidence, 1 trial, N=344): MD 0.4 points (95% CI −0.39 to 1.19), withdrawal rates (moderate quality evidence, 5 trials, N=937): RR 1.11 (95% CI 0.78 to 1.57).

Compared with usual care, there was moderate quality evidence (11 trials, N=1706), of small but clinically unimportant benefits favouring SMPs up to 21 months. Differences favoured SMPs for self-management skills (absolute improvement 12.8% (2.4% to 23.2%), pain (SMD −0.19 (95% CI −0.28 to −0.1)), function (SMD −0.18 (95% CI −0.27 to −0.09)) and global osteoarthritis symptoms (SMD −0.28 (95% CI −0.39 to −0.17)) but there were no between-group differences in quality of life (SMD 0.02 (95% CI −0.09 to 0.13)) or positive and active engagement in life (SMD 0.01 (95% CI −0.2 to 0.21). There was low quality evidence (16 trials, N=3738) of similar withdrawal rates (RR 0.99 (95% CI 0.74 to 1.33)).

Conclusion: Although we found small statistically significant effects in a few outcomes favouring SMPs over attention control or usual care, these were of doubtful clinical importance. Our results challenge the current endorsement of SMPs in osteoarthritis treatment guidelines.

An Education Needs Assessment: Findings From Surveys Of Patients and Caregivers. Elizabeth M. Badley[1], Monique A. Gignac[2], Lynn Moore[3], Christina H. Chan[2], Xingshan Cao[4] and Julie Bowring[2]. [1]University of Toronto, Toronto, ON, [2]Toronto Western Research Institute, University Health Network, Toronto, ON, [3]The Arthritis Society, Toronto, ON, [4]Arthritis Community Research and Evaluation Unit, Toronto Western Research Institute, Toronto, ON.

Background/Purpose: Getting trustworthy information to patients with arthritis is a challenge facing health professionals and organizations concerned with arthritis. This study examined the perceptions of individuals with arthritis and family members of those with arthritis to learn about where they most frequently sought and received information about arthritis and their perceptions of the trustworthiness of arthritis information.

Methods: The Arthritis Society in Canada contracted a survey research organization to conduct parallel national surveys in June 2012 of adults living with arthritis and adults caring for individuals with arthritis. Respondents completed on-line or telephone interviews asking about their (or their relative's) arthritis; where and when they sought information about arthritis; their attitudes toward different sources of information; and any actions taken to manage arthritis.

Results: 1300 patients were surveyed (inflammatory arthritis (IA) = 399; osteoarthritis (OA) = 560, other arthritis = 341). Overall results did not differ by type of arthritis. The mean severity of arthritis (1–10 scale) was 5.4 and the major reported impact was being no longer able to do many of the things they used to enjoy (76%). The majority of participants had been given their arthritis diagnosis by a general practitioner and only a minority by a rheumatologist (17% of those with IA). Information provided at the time of diagnosis concerned mainly medical management: 17% reported getting no arthritis information. The most cited reason for looking for information was wanting to know more to help better manage arthritis symptoms. Topics included managing pain other than with medication (32%), medications for arthritis symptoms (30%), exercising safely (23%), and diet for good health (22%). Top changes made as a result of information were starting to exercise (22%), changes to diet (22%), and adjustments to lifestyle to deal with pain (21%). The two top sources of information were health care professionals and the internet. Only a minority of participants (30%) used The Arthritis Society online or print media. Health care professionals were viewed as a trustworthy source, but not easy to access, with the opposite view about the internet. The Arthritis Society online was viewed as trustworthy, easy to access and as providing current information. Only 13% of patients had attended a self-management or education programs. When asked about reasons for not attending, 30% expressed no interest and 27% did not answer. Overall, the findings from the 319 caregivers surveyed were similar to those of patients.

Conclusion: The findings reveal opportunities for arthritis organizations to help meet arthritis information needs. Major reasons for looking for information were related to how to live better with arthritis and a substantial proportion of individuals reported taking action as a result. Trustworthy information was not found to be easy to access. Providing this online is an opportunity for arthritis organizations. Many people sought advice from health professionals, especially family doctors who would also benefit from information to help patients better manage arthritis in their daily lives.

The assessment of education requirements for patients with rheumatoidarthritis, based on the Polish version of the Educational Needs Assessment Tool (Pol-ENAT). Matylda Sierakowska[1], Malgorzata Klepacka[1], Stanislaw Sierakowski[2], Justyna Sierakowska[3], Piotr Leszczynski[4], Maria Majdan[5], Marzena Olesinska[6], Wojciech Romanowski[7], Małgorzata Bykowska-Sochacka[8], Slawomir Jeka[9], Mwidimi Nondosi[10] and Elzbieta Krajewska-Kulak[1]. [1]Medical University of Bialystok, Bialystok, Poland, [2]Medical University in Bialystok, Bialystok, Poland, [3]University of Bialystok, Bialystok, Poland, [4]Medical University in Poznan and J. Strus, Poznan, Poland, [5]Medical University in Lublin, Lublin, Poland, [6]Institute of Rheumatology, Warsaw, Poland, [7]Poznań Centre of Rheumatology in Srem, Srem, Poland, [8]Dr. Jadwiga Titz-Kosko Regional Hospital for Rheumatic Diseases in Sopot, Sopot, Poland, [9]Clinic of Rheumatology and Connective Tissue Diseases University Hospital No 2 in Bydgoszcz Collegium Medicum UMK in Torun, Bydgoszcz, Poland, [10]University of Leeds, Leeds, United Kingdom.

Background/Purpose: Chronic rheumatic diseases lead to large deficits in physical, mental and social functioning. Only an early diagnosis, followed by the implementation of comprehensive and individualized therapeutic approach, enable to avoid the disease's negative consequences. The person with rheumatic disease needs advice and support in order to face the problems of everyday life, as well as suffering associated with the disease. Nurse/educator should attempt to raise the level of resourcefulness and independence of the patient, in order to help him or her in dealing with the consequences of disease.

PURPOSE: -to assess the learning needs of patients with RA.

-to determine the impact of socio-demographic variables on the level of knowledge about the disease.

-to assess the relationship between the deficit of knowledge about RA and the degree of pain, felt fatigue, morning stiffness of joints, the overall assessment of disease activity as well as the functional efficiency.

Methods: The study was conducted in seven rheumatologic centers in Poland, on 277 patients with RA. The inclusion criterion was to consider a classification of RA according to ARA in 1987, and the patient's age ≥ 18 years.

The method applied in the study was a diagnostic survey with a use of the questionnaire for evaluation of educational needs Pol-ENAT (0–4); HAQ disability index (0–3); analog scales (0–100) (overall disease activity of pain, fatigue, morning stiffness).

Results: Most of the respondents were women N = 214 (77%). Mean age was 13.01 ± 53.28 years, and disease duration 10.63 ± 13.71 years. More than one third of respondents had a high school education (38%, N = 105). The average value of the severity of disease activity (0–100 mm) was 54.16 ± 21.33, 54.93 ± 23.17 pain and fatigue, 52.97 ± 21.98. HAQ index - 1.40 ± 0.66, with an upward trend with duration of disease ($p \leq .05$).

The analysis of the questionnaire ENAT (0–4) demonstrated that the study group was in relatively high demand for education about the disease (2.5), self-care (2.4), and methods of coping with pain (2.3). The greatest interest in education was declared by respondents from the youngest group, with disease duration of 10 years ($p \leq .05$).

There was a positive correlation between the demand for knowledge about the movement and felt morning stiffness (Spearman $R=0.204$, $p \leq 0.05$) and disease activity ($R=0.127$, $p \leq 0.05$); self-care and the perceived morning stiffness ($R=0.1823$, $p \leq 0.05$); assistance /support and the perceived morning stiffness ($R=0.1194$, $p \leq .05$).

Conclusion: Respondents, especially from the youngest group and with an early RA, declare lack of knowledge about the disease as well as a desire to improve it.

- Patients want to know more about the disease, particularly on the subject of inflammatory process, methods of self-care and methods of coping with pain.
- The level of functionality is significantly reduced with the duration of disease, while the demand for knowledge about the course of disease and treatment, as well as dealing with pain and emotions decreases.
- The intensity of morning joints stiffness and the increased disease activity is combined with the greater demand for knowledge concerning the physical activity, self-care and the possibilities of help/support.

"Work It" Recruitment: Lessons Learned From An Arthritis Work Disability Prevention Randomized Trial. Rawan Alheresh[1], Saralynn H. Allaire[2], Michael P. Lavalley[3], Mary Vaughan[1], Rebecca Emmetts[1] and Julie J. Keysor[1]. [1]Boston University Sargent College, Boston, MA, [2]Boston Univ School of Medicine, Boston, MA, [3]Boston University, Boston, MA.

Background/Purpose: Participant recruitment is a critical component of randomized controlled trials, particularly large ones with long term outcomes like work disability. Recruitment needs to be cost-effective; but few guidelines are available to estimate recruitment costs. The objective of this study is to evaluate the recruitment methods to date of the "Work-It Study", a large randomized controlled trial examining the effects of a work barrier problem-solving intervention delivered by physical and occupational therapists on preventing work disability among persons with arthritis or rheumatic conditions.

Methods: Recruitment approaches included: 1) rheumatology and medical registries (displaying brochures in practices, mailing physician letters to patients, and mailing letters to persons in a medical registry), 2) social media (Facebook, LinkedIn, and Patientslikeme) and 3) community advertising (Craigslist, flyers, newspapers, direct marketing, and other (support groups, professional associations, and arthritis foundation events)). Recruitment costs were calculated by summing printing, mailing, and personnel costs. Percentages were calculated for screened eligible, enrolled, and yield (# enrolled/ #participants contacted), as available. Cost per enrolled participant in each recruitment approach was calculated. The different approaches were compared in terms of yield and cost-effectiveness. A 20-month recruitment time period was used for all approaches.

Results: 440 people were screened, with 74% eligible; 190 were enrolled to date (58% of screened eligible; 54% of targeted sample); average cost per subject enrolled was $115 (see Table 1 for details). Letters to patients and community approaches resulted in the highest numbers of enrolled participants. Social media generated zero participants enrolled. Yield for mailings ranged from 1–5%; the medical registry had the highest yield. Costs per-participant enrolled were lowest for medical registry, physician letters, flyers, and 'other' approaches; displaying brochures, newspapers, and direct marketing had the highest cost per-participant enrolled. Though cost-effective, physician letters and patient registries would require large numbers of persons to be contacted to meet the desired sample size of 350 (n=8750 and n=7000 respectively). With the exception of direct marketing, community advertising approaches can generate participants but longer time periods would be needed to recruit (e.g., approximately 4 years would be needed to recruit 350 participants).

Table 1. Yield and cost of rheumatology, medical database registry, and community advertising recruitment methods in the Work-It Study

	Rheumatology offices and medical databases			Community advertising					Total
	Brochure displayed in rheum practices	Letters sent to patients from rheum MDs	Medical registry	News papers	Flyers	Craigslist	Direct Market	Other	
Participants contacted	–	650	108	–	–	–	1975	–	–
Screened (% screened eligible)	20 (60%)	38 (74%)	12 (67%)	128 (70%)	43 (58%)	112 (75%)	41 (78%)	57 (75%)	440 (74%)
Enrolled (% from screened eligible)	9 (75%)	25 (89%)	6 (75%)	50 (56%)	13 (52%)	40 (48%)	20 (63%)	27 (63%)	190 (58%)
Yield	–	4%	5%	–	–	–	1%	–	–
Cost per enrolled	$300[a]	$71[b]	$17c	$185[d]	$91[e]	$53[f]	$177[g]	$28[h]	$115
Total costs	$2696[a]	$1780[b]	$100[c]	$9258[d]	$1181[e]	$2125[f]	$3533[g]	$762[h]	$21,435

[a]Payment to rheumatology practice, printing, brochures
[b]Payment to rheumatologists, printing, brochures, supplies, stamps
[c]Registry fees
[d]Advertising fees
[e]Staff time, printing
[f]Posting fees
[g]Direct marketing fees, printing, supplies, stamps
[h]Printing

Conclusion: Direct mailings to patients from rheumatology practices and medical registries are the most cost-effective approaches but may not be feasible given the low yield. Physician willingness to support these methods is essential. Community advertising is feasible but may take longer time periods if large sample sizes are needed.

Baseline Work Participation Of a Novel Intervention To Prevent Work Disability Among Persons With Arthritis: The "Work it" Study. Rawan Alheresh[1], Saralynn H. Allaire[2], Michael P. Lavalley[3], Mary Vaughan[1] and Julie J. Keysor[1]. [1]Boston University Sargent College, Boston, MA, [2]Boston Univ School of Medicine, Boston, MA, [3]Boston University, Boston, MA.

Background/Purpose: People with arthritis are at risk of work disability. Job accommodation and educational programs delivered before imminent work loss can minimize work disability, yet are not widely implemented. The Work It Study is a randomized controlled trial testing the efficacy of a work barrier problem solving program delivered by physical and occupational therapists to prevent work loss over a two year period among people with arthritis and rheumatological conditions (i.e. lupus, fibromyalgia and scleroderma) who are concerned about their ability to continue working due to their health. The purpose of this abstract is to describe the baseline work participation status of the subjects.

Methods: Eligibility criteria: age 23–65, self-report of physician diagnosed arthritis or rheumatic condition, report of "any concern about working now or in the near future due to your health", working at least 15 hours a week, plans to continue working, and work or live in Massachusetts. Subjects were recruited through community sources, rheumatology offices, and a medical registry. Work participation was measured at baseline. Self-reported data collected by telephone included i) work status/work hours, ii) number days off from work due to arthritis, iii) Work Limitation Questionnaire (WLQ), iv) WHO Health and Work Performance Questionnaire (HPQ), and v) Work Maintenance Self-Efficacy Questionnaire (WMSEQ). Other baseline data included visual analogue scales of pain, fatigue, stress, and job satisfaction, physical function (Health Assessment Questionnaire) and demographics (e.g., age, gender, ethnicity, education, and marital status), self-report diagnosis of arthritis or rheumatological condition.

Results: 428 people screened to date; 177 completed baseline data collection and were randomized. The mean age of the sample is 50 years old, 65% are white, and the majority are female. All participants were employed at baseline and worked 36.7 hours a week on average and had 3.4 days away from work due to arthritis in the past 3 months. The WLQ- output demand scale score showed respondents were limited on-the-job 48% of time in the past two weeks (SD=27.9; 0 least limited, 100 most limited). The HPQ presenteeism score was 1.04 (SD=0.34; 0.25 least productive, 2.0 most productive). The WMSEQ score was 2.85 (SD=0.70; 0 least confident, 3 most confident). Demographic and clinical variables are listed in Table 1.

Table 1. Descriptive statistics of the Work-It sample (n=177)

Variable	Mean or Percent
Age (in years)	49.9 (SD: 10.9)
Sex	
Female	77.8%
Male	22.2%
Race	
White	65.4%
Black	24.6%
American Indian/ Alaska Native	2.23%
Asian/other pacific Islander	2.79%
Mixed/Other	5.03%
Education	
Some high school	1.7%
High school	11.7%
Some college	25.0%
College	30.0%
Some graduate	5.0%
Graduate	26.7%
Marital Status- Married	35.0%
Self-Reported Arthritis or Rheumatic Condition	
Osteoarthritis	40.4%
Rheumatoid Arthritis	23.6%
Lupus	12.3%
Fibromyalgia	12.3%
Psoriatic Arthritis	3%
Other	8.4%
Pain VAS* (0 the least, 10 the most)	6.2 (SD: 2.16)
Fatigue VAS* (0 the least, 10 the most)	6.8 (SD: 1.98)
Stress VAS* (0 the least, 10 the most)	6.3 (SD: 2.55)
Job Satisfaction* VAS (0 the least, 10 the most)	6.5 (SD: 2.76)
HAQ** Score (0 the least, 3 the most)	0.82 (SD: 0.47)

* Visual Analogue Scale
**HAQ: Health Assessment Questionnaire, the higher score indicates greater disability

Conclusion: To date, the Work It sample seems to have presenteeism work limitations and high pain, fatigue, and stress. Thus, participants seem to be at risk of increasing work disability over the upcoming few years.

The Employment Experience Of People With Arthritis: Findings From An On-Line Survey. Monique A. Gignac[1], Elizabeth M. Badley[1], Lynn Moore[2], Julie Bowring[1] and Xingshan Cao[3]. [1]Toronto Western Research Institute, University Health Network, Toronto, ON, [2]The Arthritis Society, Toronto, ON, [3]Arthritis Community Research and Evaluation Unit, Toronto Western Research Institute, Toronto, ON.

Background/Purpose: Understanding the employment experience and needs of people with arthritis is growing in importance as baby boomers make up an increasing proportion of the workforce. This study examined the impact of arthritis on employment with an emphasis on 1) at-work productivity and absenteeism and 2) benefits, treatment, workplace practices and policies that might help sustain employment.

Methods: In September 2012 The Arthritis Society, Canada, commissioned a survey research organization with expertise in large panel designs to carry out an online, national survey of adult Canadians with arthritis. Questions asked about demographic factors, arthritis diagnosis, work status, and for those who were working, benefits, workplace policies and accommodations available, disclosure of health to employers, and the perceived impact of arthritis treatment at work.

Results: 1057 individuals were surveyed (mean age 57 years, 69% women, inflammatory arthritis (IA) = 414, osteoarthritis (OA) = 351, other = 292). 10.4% were on disability leave and 41.7% of respondents reported working in the past week (<54 years 62.2%, 55–64 years 38.0%, 65+ 16.4%) of whom 2/3 reported no productivity losses in the past week, and 80% had missed no time from work in the past month. Nevertheless, 66% of participants reported going to work even when they felt unwell because of their arthritis, 41% reported difficulty managing symptoms and their jobs, 41% said arthritis make it difficult to carry out work responsibilities or to travel to and from work (30%). Slightly more people with IA than OA reported difficulties, but there were few age differences. 83% of those currently employed had at least one workplace benefit, including health benefits or insurance (63%), flexible working hours (34%), or ability to work from home (30%). 46% had not told their supervisor about their arthritis—mainly because they felt their symptoms were under control or there was no point because nothing could be done to improve their situation. Among those who had disclosed, only 37% had discussed ways to better manage working with arthritis (17.4% of all workers). Among those employed 57% (more with OA than IA) reported that treatment (including prescription medication) did not have a positive impact on their work life. Overall 37% of respondents reported that challenges in accessing treatment (including physical and occupational therapy or massage therapy) had an impact on work—including having to leave the workforce, reduce work hours, or modify job responsibilities.

Conclusion: Although arthritis often did not affect productivity or work attendance, many experienced some difficulty managing both their arthritis and their jobs. There were few age differences and many similarities between IA and OA. Giving the aging workforce it is positive that older workers were not more likely to miss time from work or be less productive than younger workers, and a significant minority were employed after the age of 65. However the lack of disclosure and discussion of better ways to manage arthritis and work, and challenges in accessing therapy are concerning and point to the need for proactive initiatives to help sustain employment and to work well.

A Randomised Controlled Trial (RCT) of Telephone Delivered Cognitive Behaviour Therapy (tCBT) and Exercise In The Management Of Chronic Widespread Pain (CWP): Identifying Long-Term Outcome and Who Benefits From Which Treatment. Gary J. Macfarlane[1], Marcus Beasley[1], Philip Keeley[2], Karina Lovell[2], Philip Hannaford[1], Deborah PM Symmons[2], Steve Woby[3], Gordon J. Prescott[1] and The MUSICIAN study team[4]. [1]University of Aberdeen, Aberdeen, United Kingdom, [2]University of Manchester, Manchester, United Kingdom, [3]Pennine Acute Hospital NHS Trust, Manchester, United Kingdom, [4]Universities of Manchester and Aberdeen, Manchester and Aberdeen, United Kingdom.

Background/Purpose: CWP is challenging for rheumatologists to manage and results from long-term epidemiological studies demonstrate that improvement in symptoms is uncommon. Recent reviews have, however, suggested that non-pharmacological therapies such as behaviour therapy and exercise may be effective, at least in the short-term. The aim of the current study is to determine whether tCBT, exercise, or both treatments combined deliver long-term health benefits to patients with CWP in comparison to treatment as usual (TAU) and to characterise patients who benefit from each specific treatment.

Methods: A 2 × 2 factorial RCT. Patients with CWP were identified from a population screening survey of 45, 994 adults in the UK. Eligible individuals met the ACR definition of CWP and reported disability. They had consulted their family physician in the last year with pain, and with no cause identified which required specific treatment. Participants were randomly assigned to a) 8 sessions of tCBT over 6 weeks, and refresher sessions at 3 and 6 months, b) an individually tailored exercise programme with monthly review over 6 months at a local fitness centre c) a combination of these treatments, or d) TAU. Participants were followed up at the end of treatment and 3 and 24 months later. The primary outcome was self reported "change in health since entering the study" and a positive outcome was at least 6 ("I felt much better") on a scale from 0 ("I feel very much worse") to 7 ("I feel very much better"). Analysis was intention-to-treat with longitudinal logistic regression using generalised estimating equations (GEE). Results are presented as Odds ratios (OR) with 95% Confidence Intervals (CI). Additional models were run to assess the effect of baseline characteristics in predicting the response to the specific treatments received.

Results: A total of 442 persons (median age 57 years, 69% female) entered the study and 361 persons (82%) provided information at final follow-up. At 24 months post-treatment, the proportion of patients reporting a positive outcome was: tCBT 35.4%, Exercise 29.4%, combined treatment 31.2%, TAU 12.8%. Response, after adjustment for age, sex, baseline psychological distress, pain intensity and disability was significantly more likely for exercise (OR 2.5, 95% CI (1.2, 5.4), tCBT (3.6; 1.7–7.6) and the combination (2.9; 1.4,6.0) compared to TAU. Baseline characteristics associated with significantly greater response to tCBT (compared to those not receiving tCBT) were: high psychological distress, a passive coping style, high intensity and/or disabling pain and moderate levels of fatigue. Older persons responded significantly better to the exercise intervention, although this was evident at the end of treatment but not subsequently.

Conclusion: A six month programme of exercise or tCBT is associated with long-term improvements in the health of patients with CWP. The size of effect was similar with each treatment, and there was no advantage in subjects receiving both. However we identified specific characteristics associated with response to tCBT which can potentially allow future targeting of therapy.

Medication Adherence and Healthcare Costs Among Patients With Fibromyalgia: Combination Medication Versus Duloxetine, Pregabalin, and Milnacipran Initiators. Nicole Marlow, Kit Simpson, James Zoller and E. Baron Short. Medical University of South Carolina, Charleston, SC.

Background/Purpose: The combined use of prescription drugs (Rx) with complementary mechanisms of action has been described for treating fibromyalgia (FM). We examined medication adherence and healthcare costs for combination Rx (duloxetine/milnacipran with pregabalin) initiators vs. duloxetine, pregabalin, and milnacipran initiators among privately insured patients with FM.

Methods: Our retrospective cohort study used population-based claims data for the South Carolina Blue Cross Blue Shield State Health Plan (SHP). Patients with FM aged ≥18 years, with Rx initiation during 7/2007 – 6/2010, and SHP enrollment for 12-months pre- and post-index periods were included (combination Rx: N=491, pregabalin: N=1270, duloxetine: N=1460, milnacipran: N=167). Medication initiation was defined as no pill coverage for the Rx in the prior 90 days, and the index-date was defined as the Rx initiation date. Medication adherence measures included high adherence (medication possession ratio ≥80%) and total supply days; healthcare costs comprised direct medical expenditures. Propensity score stratification methods were used to control for selection bias due to differing demographic and clinical characteristics as well as Rx history during the 12-months pre-index. Multivariable regression models that incorporated adjustment for propensity score quintiles were used to compare post-index outcomes, including logistic regression models for high adherence, negative binomial regression models for total supply days, and generalized linear models with a log-link and gamma distributions for expenditures.

Results: Mean age at Rx initiation was 55 years, and 81% were women. Odds ratios for high adherence were significantly increased ($p<0.001$) among the combination Rx cohort vs. the duloxetine (1.89), milnacipran (3.99), and pregabalin (2.01) cohorts. Rate ratios for total supply days were significantly higher ($p<0.0001$) for combination Rx vs. duloxetine (1.14), milnacipran (1.34), and pregabalin (1.31). Expenditures for total healthcare and the initiated Rx were significantly higher ($p<0.05$) for combination Rx vs. duloxetine ($20488 vs. $16202; $2989 vs. $1315; respectively), milnacipran ($21401 vs. $17457; $2877 vs. $717), and pregabalin ($20530 vs. $17516; $2941 vs. $898). However, there were no significant differences observed for direct medical care expenditures (inpatient and/or outpatient services) for combination Rx vs. duloxetine ($11767 vs. $10531, respectively), milnacipran ($11869 vs. $10776), and pregabalin ($11429 vs. $11160), indicating costs neutrality.

Conclusion: Medication adherence was considerably better for combination Rx initiators. Furthermore, expenditure results showed that the use of polypharmacy for combination Rx did not produce a substantial burden to the healthcare system regarding services for direct medical care, indicating that it was safe and well tolerated by patients. Overall, our results suggest important benefits for patients with FM who use combination Rx as part of their multi-modal treatment regimen. Clinical practice guidelines for FM should continue to evolve with the availability of new therapies as well as emerging evidence from population-based naturalistic studies.

Once Daily Controlled-Release Pregabalin In Fibromyalgia Patients: A Phase 3 Double-Blind, Randomized Withdrawal, Placebo-Controlled Study. Lesley M. Arnold[1], Pierre Arsenault[2], Cynthia Huffman[3], Jeffrey L. Patrick[4], Michael Messig[4], Marci L. Chew[4], Luis Sanin[4], Lynne Pauer[4] and Andrew Clair[4]. [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]Université de Sherbrooke, Sherbrooke, QC, [3]Meridien Research, Tampa, FL, [4]Pfizer Inc, New York, NY.

Background/Purpose: Pregabalin (PGB) is currently approved for the treatment of fibromyalgia (FM) for twice daily dosing over a range of 300–450 mg/day. A pregabalin controlled-release (PGB CR) formulation was developed to enable once daily (QD) dosing.

Methods: The study involved 4 phases: baseline (BL; 1 week), single blind (SB; 6 weeks), double blind treatment (DB; 13 weeks), and a 1-week double blind taper. The SB starting dose was 165 mg/day and was escalated during the first 3 weeks, up to 495 mg/day based on efficacy and tolerability. Dosing was QD following an evening meal. Patients with ≥50% reduction in average daily pain score at the end of SB compared to BL were randomized (1:1) in the DB phase to continue PGB CR treatment at the optimized dose (330 to 495 mg/day) or to matching placebo (PBO). The primary endpoint (EP) of time to Loss of Therapeutic Response (LTR) was assessed during DB and defined as < 30% pain response relative to BL (SB) or discontinuation due to lack of efficacy or an adverse event (AE). Secondary endpoints included measures of pain relief, global assessment, functional status, tiredness, and sleep. A total of 290 SB patients were planned to provide the 74 LTR events needed to achieve 90% power to detect a difference in the primary EP. However, there was insufficient power, a priori, to detect differences in the secondary endpoints of this study.

Results: 441 patients, ≥18 years of age, meeting the American College of Rheumatology 1990 criteria for FM (Wolfe F, et al. *Arthritis Rheum*. 1990; 33(2):160–172) were enrolled. The majority were white (80%), female (89%) and an average age of 48 years. Of the 441 patients, 121 (27%) completed SB, had ≥50% pain response and were treated in DB. Seventy-five LTR events occurred. The median time from randomization to LTR (Kaplan-Meier analysis) was 58 days in the PGB CR group and 22 days in the PBO group ($p=0.021$). During the DB phase 34/63 (54.0%) PGB CR and 41/58 (70.7%) of PBO patients met LTR criteria. There was no statistically significant difference between DB treatments for the secondary endpoints with the exception of benefit from treatment; a domain of the Benefit, Satisfaction and Willingness to Continue scale: more patients reported "much benefit" in the PGB CR group ($p=0.0296$). While not significant, trends favoring PGB CR treatment were seen in the Fibromyalgia Impact Questionnaire Total Score, Patient Global Impression of Change, and the Sleep Quality domain of the Subjective Sleep Questionnaire. In PGB CR patients the most common AEs during SB were dizziness, somnolence, and headache; and during DB were dizziness, peripheral edema, and insomnia. The most common AEs in PBO patients were dizziness, somnolence, dry mouth, and peripheral edema. The majority of AEs were mild to moderate in severity. Five patients experienced serious adverse events (SAE) during SB and 1 event (glossitis) was considered related to PGB CR; 2 PGB CR patients experienced an SAE during DB. No deaths occurred.

Conclusion: PGB CR was effective in improving the time to and the number of LTR events in FM patients. PGB CR was well-tolerated in most patients and results were consistent with the known safety profile of PGB.

The Polysymptomatic Distress Scale As a Measure Of Disease and Practice Severity In Fibromyalgia. Frederick Wolfe[1], Don L. Goldenberg[2], Brian T. Walitt[3] and Winfried Häuser[4]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Newton-Wellesley Hosp, Newton, MA, [3]Washington Hospital Center, Washington, DC, [4]Klinikum Saarbrücken, Saarbrücken, Germany.

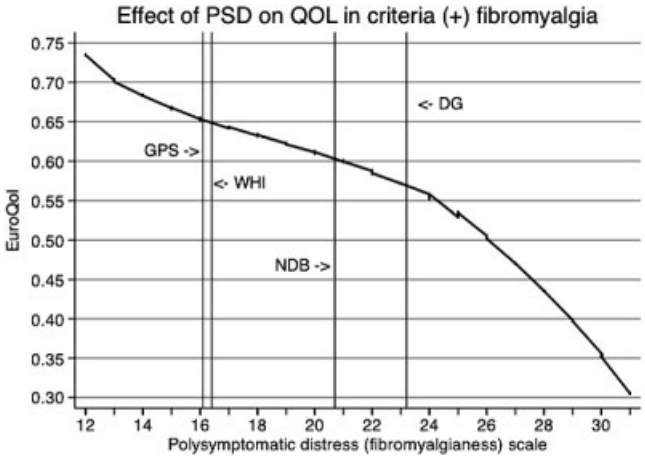
Background/Purpose: The 2010 American College of Rheumatology (ACR) fibromyalgia (FM) criteria created a scale for the measurement of severity of pain extent—the 0–19 Widespread Pain Index (WPI), and a symptom scale—the 0–12 Symptom Severity scale (SS). Subsequent research and clinic usage combined the scales by summing them into the polysymptomatic distress (PSD) or fibromyalgianess scale, a 0–31 overall measure of pain extent and symptom distress. We investigated the value of the PSD scale in capturing severity of illness, and also applied the PSD scale to determine relative severity of subjects with criteria (+) FM in different settings: epidemiological studies—844 persons in the Women's Health Initiative (WHI) and 52 in the German general population (GPS), and in clinical studies —1036 patients from the National Data Bank for Rheumatic Diseases (NDB) study of FM, and 64 from the tertiary referral practice of Dr. Don Goldenberg (DG). We hypothesized that DG's patients would have the most severe FM and persons in the GPS epidemiological study the least severe FM. We also investigated whether values of the PSD would have clinical relevance as measures of severity.

Methods: We measured the mean scores of PSD in ACR 2010 (survey) criteria (+) FM subjects. We calculated the SF-36 Physical and Mental Component Summary scores (PCS/MCS), the EuroQol quality of life score, the Health Assessment Questionnaire (HAQ) functional disability score, the

VAS pain scale, and the percentage of disabled patients, using data from the NDB at the 4 quartiles of the PSD.

Results: Severity of illness was related to PSD scores (Table 1) and Figure 1, and patients with higher mean PSD scores and in higher PSD quartiles demonstrated more severe illness. The quartile differences were large and clinically significant, and can also be seen clearly in the figure. By PSD, persons in the community (GPS and WPI) had the least severe illness, while illness was most severe in the tertiary referral practice (DG). From left to right, vertical lines in the figure represent PDS means for GPS, WHI, NDB and DG.

Quartile (Range)	PSD	SF-36 PCS	SF-36 MCS	EuroQol	HAQ	VAS Pain	Disabled (%)
Q1 (12–16)	14.5	32.5	41.5	0.66	1.05	5.5	25
Q2 (17–20)	18.4	31.2	39.8	0.61	1.18	5.9	30
Q3 (21–25)	23.2	29.3	40.0	0.59	1.29	6.5	36
Q4 (26–31)	28.0	27.5	34.5	0.43	1.59	7.4	43



Conclusion: There is a considerable range of severity that can be observed among FM patients, and the PSD appears to be an easy-to-use assessment tool. Thus, much of the difference between patients is hidden when we simply diagnose FM. Patients in clinical practice have greater severity of illness compared with community subjects. This information regarding differential severity in the community compared with practice, sheds light on the role of self-selection and self-referral, and allows placing clinical and epidemiological data into perspective.

Real-Life Assessment Of The Validity Of Patient Global Impression Of Change In Fibromyalgia. John S. Sampalis[1], Mary-Ann Fitzcharles[2], Peter A. Ste-Marie[2], Emmanouil Rampakakis[1] and Yoram Shir[2]. [1]McGill University, Montreal, QC, [2]McGill University Health Centre, Montreal, QC.

Background/Purpose: Assessing fibromyalgia (FM) is challenging due to the lack of hard outcomes and the need to rely on patient-reported symptoms. Completion of questionnaires by patients may be fraught with inaccuracy, and meaningful interpretation of results can only be performed with due consideration of the clinimetric properties and weaknesses of instruments. Global rating of change scales represent a practical method of measuring disease severity and treatment outcomes, and may be particularly useful in routine clinical practice. This analysis assessed the validity of Patient Global Impression of Change (PGIC) in patients treated in routine clinical care.

Methods: FM patients from a prospective cohort at a tertiary care multidisciplinary clinic with at least one follow-up (FUP) assessment were included. Disease severity at treatment initiation and FUP was measured with pain visual analog scale, patient global assessment (PGA), Fibromyalgia Impact Questionnaire (FIQ), Health Assessment Questionnaire (HAQ), McGill Pain Questionnaire (MPQ), and body map. PGIC was assessed at FUP. Between-group differences in disease severity improvement were assessed for statistical significance with one-way analysis of variance. Linear regression was used to assess the association between different measures. Parameter correlation was assessed with the Spearman's rank coefficient (rho).

Results: 167 patients (91% female) were included with a mean (SD) age of 48.8 (9.8) years, disease duration of 10.8 (10.2) years, and FUP duration of 30.0 (15.3) months. Patients rating their condition as much/moderately/little worse vs. same vs. little/moderately/much better since treatment began experienced significant ($P \leq 0.001$) differences in change in pain (1.03 vs. 0.31 vs. −1.31), PGA (0.67 vs. 0.90 vs. −1.18), body map (2.62 vs. 1.29 vs. −3.82), FIQ (6.52 vs. −0.32 vs. −10.73), and HAQ (0.20 vs. 0.06 vs. −0.19). However, no significant differences were observed between-groups in MPQ (−0.66 vs. −1.88 vs. −6.58; $P=0.086$). In correlation analysis, PGIC showed a statistically significant ($P<0.001$) weak positive correlation with improvement in MPQ (rho=0.250), pain (rho=0.387), PGA (rho=0.327), body map score (rho=0.287), and HAQ (rho=0.343) and moderate positive correlation with FIQ improvement (rho=0.423). Regression analysis showed that a significant ($P<0.01$) positive association exists between improvement in all disease severity measures and PGIC. Interestingly, upon adjusting for improvement in disease activity measures, FUP duration had a significant ($P<0.05$) impact on PGIC with patients followed for a longer period reporting a greater improvement in their condition compared to patients followed for shorter periods.

Conclusion: The results of this analysis suggest that, overall, a weak correlation exists between PGIC and improvement in standard FM outcome measures. Furthermore, FUP duration was identified as a significant confounder of patient perception of disease improvement which could be due to recall bias or survival bias. Altogether, these results have important implications for FM management and designing new instruments assessing outcomes in FM.

Restricting Back Pain and Subsequent Mobility Disability In Community-Living Older Persons. Una E. Makris[1], Liana Fraenkel[2], Ling Han[3], Linda Leo-Summers[3] and Thomas M. Gill[4]. [1]UT Southwestern Medical Center, VA Medical Center, Dallas, TX, [2]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT, [3]Department of Medicine, New Haven, CT, [4]Yale University, New Haven, CT.

Background/Purpose: Although back pain is common and costly, few longitudinal studies have evaluated the association between back pain, severe enough to restrict activity (hereafter referred to as restricting back pain), and the development of disability in mobility. Older persons who lose independent mobility have higher rates of morbidity and mortality, and experience a poorer quality of life. The objective of this study is to evaluate restricting back pain and subsequent mobility disability, both dynamic conditions that recur in older persons.

Methods: We evaluated the 709 participants (mean age 77.3 years, range 70–96, 63% women) of the Precipitating Events Project, a prospective study of community-living persons, aged 70+ years, all non-disabled at baseline, who completed monthly telephone assessments of restricting back pain and who were at risk for developing mobility disability for up to 159 months. Restricting back pain was defined as staying in bed for at least half a day and/or cutting down on one's usual activities due to back pain. Mobility disability was defined as needing help with or inability to complete any of the following three tasks in any given month: walking a 1/4 mile, climbing a flight of stairs, lifting or carrying 10 pounds. The event rate for mobility disability was estimated using a GEE Poisson model. A recurrent events Cox model was used to evaluate the associations between the occurrence of restricting back pain (yes/no) and subsequent (within one month) mobility disability. The model was adjusted for fixed-in-time (sex, education, ethnicity) and time-varying covariates (age, chronic conditions, BMI, depressive symptoms, cognitive impairment, hip weakness, and physical frailty defined by slow gait speed) that were updated every 18 months. In a secondary analysis, these models were re-run after excluding participants who had mobility disability at baseline. We ran a final set of analyses, focusing on the

relationship between restricting back pain and mobility disability that persisted for at least two months.

Results: The event rate for mobility disability was 7.26 per 100-person months (95% CI 6.89,7.64) with a median duration of 2 (interquartile range: 1–4) months. Overall, 213 (30%) of the 709 eligible participants reported one or more of the three disabilities at baseline and recovered at some point during the follow-up. The frequency of each of the three mobility disability items at baseline was 20.2% for walking a 1/4 mile, 6.6% for climbing stairs, and 19% for lifting/carrying 10 pounds. After adjusting for covariates, restricting back pain was strongly associated with subsequent mobility disability, with a hazard ratio (HR) (95% CI) of 3.23 (2.87,3.64) in the primary analytic sample, HR 3.71 (3.22,4.27) after omitting subjects with baseline mobility disability, and HR 3.64 (3.15,4.20) in the analyses evaluating longer duration of mobility disability.

Conclusion: In this longitudinal study, restricting back pain was independently associated with subsequent mobility disability among older persons. Interventions implemented to decrease or prevent restricting back pain may reduce the likelihood of mobility disability.

Association Of Back Pain With Functional Limitations In Patients With Knee and Hip Osteoarthritis. Adam P. Goode[1], Hayden B. Bosworth[2], Cynthia Coffman[2], Amy Jeffreys[2], Eugene Z. Oddone[2], William S. Yancy Jr.[2] and Kelli D. Allen[2]. [1]Duke University, Durham, NC, [2]Duke and Durham VA Medical Center, Durham, NC.

Background/Purpose: Back pain, most commonly occurring in the lower back, is a prevalent condition and common reason for both decreased function and quality of life. The influence of back pain on physical function among patients with osteoarthritis (OA) has received little attention. This study examined association of back pain with functional outcomes in patients with hip and / or knee OA.

Methods: Participants (n=300) were patients enrolled in a clinical trial of a combined patient and provider intervention for managing OA at the Durham Veterans Affairs Medical Center (mean age = 61.1 (SD 9.2), 90.7% male, 50.0% non-white – primarily African American). All measures were taken from baseline surveys and tests. Self-reported presence of back pain was measured with a single item from the Self-Administered Comorbidity Questionnaire. Functional outcomes included the Satisfaction with Physical Function Questionnaire (scores range −3 to +3, with higher scores indicating greater satisfaction), disease specific knee and/or hip function (Western Ontario and McMasters University Osteoarthritis Index physical function subscale; range 0–68), and the Short Physical Performance Battery (SPPB) consisting of walking, balance and chair stands tests, with scores ranging from 0 (worst performance) to 12 (best performance). Simple linear regression models examined the association of back pain with each functional measure (separately), and then multivariable models were fit, including all covariates. Covariates included participant age, race (white vs. non-white), gender, self-rated health (excellent, very good, or good vs. fair or poor) and number of joints with knee and/or hip OA (1–4).

Results: Back pain was present in 75.3% of patients. In bivariate analyses, back pain was associated with less Satisfaction with Physical Function (b= −0.64; 95% CI −1.06, −0.22; p<0.01), worse WOMAC function scores (b= 5.10; 95% CI = 1.70, 8.50; p=0.003), and worse SPPB scores (b= −0.73; 95% CI −1.31, −0.15; p=0.01). In the multivariable models, back pain remained significantly associated with Satisfaction with Physical Function scores (b= −0.49; 95% CI −0.89, −0.10; p=0.02) and WOMAC physical function scores (b= 4.1; 95% CI 0.90, 7.30; p=0.01), but not SPPB scores (b= −0.51; 95% CI −1.1, 0.04; p=0.07).

Conclusion: Among patients with hip and knee OA, back pain was highly prevalent. Back pain was associated with worse functional outcomes, specifically Satisfaction with Physical Function and WOMAC function scores. These results highlight that back pain is associated with lower extremity functional limitations above and beyond decreased function related to knee and/or hip OA. Because of its high prevalence and added impact on physical function, back pain is an important issue to identify and address among patients with OA.

Influence Of Mechanical Symptoms On Treatment Outcomes For Meniscal Tear In The Setting Of Osteoarthritis. Jeffrey N. Katz[1], John Wright[1], Lisa A. Mandl[2], Brian Cole[3], Laurel Donnell-Fink[1], Ali Guermazi[4], Morgan Jones[5], Bruce Levy[6], Scott Martin[1], Robert Marx[2], Anthony Miniaci[5], Kurt P. Spindler[7], Rick Wright[8] and Elena Losina[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Hospital for Special Surgery, New York, NY, [3]Rush University, Chicago, IL, [4]Boston University, Boston, MA, [5]Cleveland Clinic, Cleveland, OH, [6]Mayo Clinic, Rochester, MN, [7]Vanderbilt University, Nashville, TN, [8]Washington University, Saint Louis, MO.

Background/Purpose: Clinicians are challenged to identify those patients with knee pain, osteoarthritis (OA) and imaging evidence of a meniscal tear (MT) who are likely to benefit from arthroscopic partial meniscectomy (APM). Traditionally, clinicians have recommended that patients with "mechanical symptoms" (e.g. locking, clicking, catching) consider APM. The MeTeOR (MT in OA Research) Trial demonstrated similar symptomatic relief in persons treated with APM and those treated initially with physical therapy (PT), with referral for APM if PT did not relieve pain. We analyzed MeTeOR data to compare improvement in mechanical symptoms between subjects that received APM and those that received PT; and to examine whether frequency of baseline mechanical symptoms influenced pain relief at 6 month follow-up.

Methods: MeTeOR is a seven-center RCT of APM vs. standardized PT in subjects age 45+ with symptomatic MT and OA. The baseline survey asked about 5 mechanical symptoms (clicking, catching, popping, locking, giving way), each with 5 responses ("never" to "several times a day"). We summed these 5 items to create a mechanical symptom score. We used t-tests to compare patients who had surgery (at the outset or after crossing over) vs. those treated with PT with respect to changes in mechanical symptom score from baseline to 6 months. We compared baseline mechanical symptom scores with changes over 6 months in WOMAC Pain using correlations (presented as crude r-squared). We used multivariable linear regression with an interaction to assess whether the association between baseline mechanical symptom score and improvement in WOMAC Pain over 6 months differed between subjects treated with APM vs. those treated with PT.

Results: 351 subjects participated, 57% female, mean age 58.The baseline mean mechanical symptom score was 10.4 (SD 4.9) and mean WOMAC Pain 41.0 (SD 17.8, possible range 0–100 with 0=best). Subjects improved in WOMAC Pain over 6 months by a mean of 21.4 points (SD 18.7). Improvement over 6 months in mechanical symptom score was greater among subjects treated with APM (0.82 SD's) than among those treated with PT (0.42 SD's; p=0.01). However, improvement in mechanical symptom score explained just 8% of variability in improvement in WOMAC Pain. We did not find an association between baseline mechanical symptom score and improvement in WOMAC Pain (r-squared <0.02 for both APM- and PT-treated subjects.) Associations between individual symptom frequencies (e.g. locking, catching) and change in WOMAC pain and function scores were also negligible. The association of baseline mechanical symptom score and change in pain score did not differ between subjects receiving APM and those receiving PT (p for interaction=0.44).

Conclusion: While mechanical symptom scores improved more following APM than following PT, MeTeOR data did not support the clinical teaching that frequent mechanical symptoms at baseline predict greater pain relief following APM than following PT. Thus, clinicians should not rely upon the frequency of mechanical symptoms to predict pain relief following APM but can advise their patients that mechanical symptoms are more likely to resolve with surgery than without.

The Role Of FAM173b As a Newly Identified Regulator Of Chronic Pain. Hanneke Willemen[1], Annemiek Kavelaars[2], Rafael González Cano[3], Cobi Heijnen[2] and Niels Eijkelkamp[1]. [1]UMC Utrecht, Utrecht, Netherlands, [2]MD Anderson Cancer Center, Houston, TX, [3]University of Granada, Granada, Spain.

Background/Purpose: Chronic pain is a major debilitating problem in many inflammatory diseases including rheumatoid arthritis and osteoarthritis. Pain is an important problem during active disease but often continues during minimal disease activity or even after sustained remission. Chronic pain is often difficult to treat and new insights into the mechanisms underpinning the development of chronic pain are needed. Recently we have identified involvement of the 5p15.2 region that includes the coding region for CCT5 and FAM173b in chronic widespread pain (CWP). The minor allele frequency of two highly correlated SNPs (rs13361160 and rs2386592) annotated to the 5p15.2 region were associated with a 30% increased risk for CWP. 130 associated SNPs were identified that were in linkage disequilibrium with these two top SNPs and included one non-synonymous SNP (rs2438652) located in the coding region in the FAM173B gene. Here we examined the role of FAM173b in regulating chronic inflammatory pain.

Methods: FAM173b antisense oligonucleotides (asODN) were injected intrathecally to establish in vivo knockdown of FAM173b in sensory neurons. Transient inflammatory hyperalgesia was induced by intraplantar injection of a low dose of carrageenan in mice. Chronic inflammatory hyperalgesia was induced by intraplantar injection of Complete Freund Adjuvant (CFA). Development of hyperalgesia was assessed by using the Hargreaves' method to determine heat sensitivity, while Von Frey hairs were used to assess mechanical sensitivity.

Results: FAM173b is upregulated in the lumbar spinal cord and dorsal root ganglion after peripheral inflammation induced by intraplantar CFA. Knockdown of FAM173b by intrathecal injection of FAM173b antisense oligodeoxynucleotides reduced the intensity of transient carrageenan-induced inflammatory thermal and mechanical hyperalgesia. Importantly, FAM173b knockdown during established chronic CFA-induced hyperalgesia completely attenuated CFA-induced persistent thermal and mechanical hyperalgesia. Mechanistically, intrathecal FAM173b asODN treatment completely prevented CFA-induced increase in Iba1+ microglia/macrophages with an activated phenotype in the spinal cord and DRG. Moreover, FAM173b asODN treatment reduced spinal cord and DRG Iba1 mRNA expression. Intrathecal FAM173b asODN prevented CFA-induced upregulation of the pro-inflammatory cytokine TNF-a in the lumbar spinal cord and dorsal root ganglia. In contrast, FAM173b asODN did not affect CFA-induced increase in BDNF mRNA expression in the DRG.

Conclusion: We have identified an as yet unrecognized role for FAM173b in chronic inflammatory pain. We propose that FAM173b promotes spinal cord and DRG microglia/macrophages activation and subsequent pro-inflammatory cytokine production leading to persistent inflammatory pain.

Inhibition Of Chronic Pain By IL4–10 Synerkine Is Superior To IL-4 Or IL-10 Monotherapy: A Novel Strategy To Restrain Pain In Rheumatic Diseases. Niels Eijkelkamp[1], Sarita Hartgring[2], Cristine Steen-Louws[1], Hanneke Willemen[1], Qiu-Ling Mao-Ying[3], Cobi Heijnen[3], Erik Hack[1], Annemiek Kavelaars[3] and J.A.G. van Roon[2]. [1]UMC Utrecht, Utrecht, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands, [3]MD Anderson Cancer Center, Houston, TX.

Background/Purpose: Chronic pain is a major problem in many diseases, including RA and OA, arising from inflammation or structural damage. It is often associated with glial cell-mediated inflammatory responses in the spinal cord leading to enhanced pain perception (hyperalgesia), which is difficult to treat. Moreover, therapeutic options are limited. Despite the potential of IL4 and IL10 to inhibit inflammation and pain in experimental models, clinical studies were disappointing, likely due to poor bioavailability. We developed a novel option to inhibit multiple inflammatory responses by constructing an IL4/IL10 fusion protein (IL4–10 synerkine). This synerkine is a novel biologic that combines the distinct characteristics of IL4 and IL10, with an increased mass and anticipated improved bioavailability. Strong anti-inflammatory potential of the synerkine was demonstrated in human in vitro assays. Our objective was to investigate the capacity of IL4–10 synerkine to treat chronic pain induced by inflammation or nerve damage.

Methods: IL4–10 synerkine, injected intrathecally (it), was tested in 3 mouse models of chronic pain. First, chronic inflammatory hyperalgesia was induced by intraplantar injection of carrageenan. Secondly, we used mice with a cell-specific reduction of ~50% in GRK2 level in microglia/macrophages (LysM-GRK2+/− mice) that develop persistent inflammatory hyperalgesia after a single intraplantar injection of IL-1b, while WT mice develop a transient hyperalgesia. Thirdly, chronic neuropathic pain was induced by spared nerve injury (SNI). Hyperalgesia was assessed by Hargreaves test to determine heat withdrawal latencies and Von Frey hairs to determine mechanical thresholds. To demonstrate surplus value of the synerkine, IL-4 and IL-10 mono and combination therapies were tested.

Results: Intraplantar injection of carrageen induced profound persistent hyperalgesia in WT mice. A single it. injection of IL4–10 synerkine completely inhibited established carrageenan-induced persistent hyperalgesia (for 40, 100 and 200 ng all $p<0.001$) for at least 2 days. The highest dose of IL4–10 synerkine significantly inhibited hyperalgesia for 4 days ($p<0.05$). Injection of IL4, IL10, or a combination (100 ng) only modestly inhibited hyperalgesia (30–40%) for 1 day. It. administration of IL4–10 synerkine also dose-dependently inhibited IL-1β-induced persistent hyperalgesia in LYSM-GRK2+/− mice. Single injections of 100 ng and higher, completely prevented the development of IL-1β-induced hyperalgesia in LYSM-GRK2+/− mice ($p<0.001$). Moreover, it shortened the duration of transient IL-1β-induced hyperalgesia in WT mice. Interestingly, IL4–10 synerkine also inhibited mechanical hypersensitivity in the SNI neuropathic pain model, although for shorter time periods (6 hours).

Conclusion: IL4–10 synerkine, next to its strong anti-inflammatory properties, also robustly relieves hyperalgesia in models for inflammatory and neuropathic pain, superior to IL4 or IL10 mono or combination therapy. These data underscore the potential of IL4–10 synerkine to inhibit immunopathology and pain in inflammatory and degenerative rheumatic diseases.

Pain Pathway Activation In Dorsal Root Ganglia and Dorsal Horn In a Murine Surgical Model Of Osteoarthritis. Rachel E. Miller[1], Phuong Tran[1], Richard J. Miller[2] and Anne-Marie Malfait[1]. [1]Rush University Medical Center, Chicago, IL, [2]Northwestern University, Chicago, IL.

Background/Purpose: Using a surgical mouse model of osteoarthritis (OA), destabilization of the medial meniscus (DMM), we monitor pain and associated pathways over a period of 16 weeks post surgery. We observed longitudinal changes in pain-related behaviors as joint disease progresses, with concomitant molecular changes in the innervating DRG (Miller et al, 2012, PNAS). Specifically, mice develop progressive mechanical allodynia in the ipsilateral hindpaw over the first 4 weeks, while locomotive changes indicative of chronic pain appear 8 weeks after DMM. It has been hypothesized that activation of microglia in the dorsal horn (DH) – a dynamic process that contributes to pain through further neuronal activation - is dependent on signaling molecules (ie MCP-1 and fractalkine (CX3CL1)) that originate in DRG neurons and are transported to the DH, where they can act on microglia (Miller et al, 2009, Handb Exp Pharmacol). Our previous work has focused on MCP-1/CCR2 signaling in DRG neurons after DMM surgery. Here, we examined fractalkine expression in the DRG and activation of microglia and neurons in the DH following DMM surgery.

Methods: Animal procedures were approved by Rush University Medical Center. DMM or sham surgery was performed in the right knee of 10-week old male wild-type C57BL/6 mice. Pain-dependent behaviors were assessed at 0, 4, 8, and 16 weeks post surgery. Mechanical allodynia in the hind paw was assessed with von Frey fibers. Locomotion was assessed using a LABORAS platform, as described (Miller et al, 2012, PNAS). Eight weeks post DMM, L3-L5 DRG were harvested (these DRG contain neurons that innervate the knee joint) and cells were cultured for 4 days; supernatants were collected for CX3CL1 ELISA. For immunohistochemistry, mice were perfused transcardially with paraformaldehyde; L3-L5 DRG were dissected out or the spinal column was decalcified prior to spinal cord sectioning of the L3-L5 levels. Anti-Iba1 or anti-cFos was used to examine microglia or neuronal activation, respectively, in the dorsal horn.

Results: In order to investigate whether changes in the DRG and DH of the spinal cord correlated with observed changes in locomotion, we focused on the 8-week post surgery time point.

Eight weeks post DMM, cultured DRG cells produced elevated levels of CX3CL1 protein compared to age-matched naïve DRG ($p<0.05$). In addition, the DH in DMM mice showed markedly higher expression of Iba1 (marker of microglial activation) and of cFos (marker of neuronal activation) compared to age-matched naïve mice.

Conclusion: This is the first report of increased fractalkine release by DRG neurons in a model of osteoarthritis, which may contribute to cellular activation in the DH. Microglia and neuronal activation in the DH has been reported in murine mono-iodoacetate (MIA) arthritis (Ogbonna et al, 2013, Eur J Pain) and in non-disease-related animal models of nerve injury. Longitudinal assessments of these dorsal horn changes are currently underway. This will yield insight into how pain signaling spreads from the peripheral to the central nervous system in osteoarthritis.

Mir-26a, Mir-30b and HER2: New Players On Lupus Nephritis Pathogenesis. Patrícia Costa-Reis, Pierre Russo and Kathleen E. Sullivan. The Children's Hospital of Philadelphia, Philadelphia, PA.

Background/Purpose: microRNAS (miRNAs) are noncoding RNAs responsible for post-transcriptional gene silencing. These key regulatory molecules control the expression of multiple genes, so its dysregulation can contribute to sustained pathology. Our goal was to study the miRNA pattern of lupus nephritis (LN) in order to better understand its pathogenesis and to identify clinically relevant pathways.

Methods: RNA was extracted from paraffin embedded kidney samples of controls (n=6) and patients with LN (n=18) and post-streptococcal glomerulonephritis (n=2). Molecular digital detection of miRNAs was performed, analyzed on R, and confirmed by qRT-PCR. Gene expression of human kidney cells lines, submitted to knockdowns of the miRNAs of interest using lentivirus, was studied with GeneChip® 2.0 ST Arrays. Off-target lentivirus were used as controls. Immunohistochemistry, immunofluorescence and western-blots for HER2 were performed.

Results: There was a kidney LN specific miRNA signature, which, according to IPA® pathway analysis, mainly reflected cell proliferation and inflammation. miR-26a and miR-30b were found to be significantly decreased in LN ($p=0.002$; $p=0.008$, respectively). Furthermore, miR-26a levels inversely correlated with proteinuria ($p=0.005$), casts ($p=0.031$) and the presence of crescents ($p=0.030$), a sign of kidney cell proliferation. PPARCG1A, which is involved in type 1 interferon pathway, was found to be highly increased in mesangial cells submitted to miR-26a knock-down. Finally, HER2, a protein that regulates miR-26a and miR-30b levels in breast cancer cell lines, was found to be highly increased in the glomeruli and tubular compartments of LN patients. HER2 was found to be expressed in human podocytes, tubular and mesangial cell lines and its expression was increased by α-interferon ($p=0.002$).

Conclusion: The kidneys of LN patients have a specific miRNA pattern, characterized by a significant decrease of miR-26a and miR-30b. These miRNAs were previously found to be key regulators of cell proliferation in several malignancies and miR-26a was found to reduce cancer cell progression and cause tumor-specific apoptosis *in vivo*. Our data indicate that these miRNAs also regulate cell proliferation in LN. Interestingly, it was previously shown that trastuzumab, a monoclonal antibody against HER2, produces therapeutic actions by up-regulating miR-26a and miR-30b in breast cancer cell lines. Since we demonstrated that HER2 was highly increased in the kidneys of LN patients, blocking HER2 with trastuzumab may be a new promising pathway to decrease cell proliferation and damage in this disease. miR-26a, miR-30b and HER2 are, therefore, three new interesting players on LN pathogenesis.

Accounting For Parental Load and Identification Of Multiple Risk Variants For Anti-Ro Congenital Heart Block Through High-Density Genotyping Of Immune-Related Loci. Robert M. Clancy[1], Jill P. Buyon[1], Nathalie Costedoat-Chalumeau[2], Antonio Brucato[3], Kateri Levesque[2], Véronique Ramoni[4], Miranda C. Marion[5], Mary Comeau[5], Satria Sajuthi[6], Paula S. Ramos[7], Robert P. Kimberly[8], Timothy D. Howard[6] and Carl D. Langefeld[5]. [1]New York University School of Medicine, New York, NY, [2]Hopital Cochin, Paris, France, [3]USC Internal Medicine, Ospedali Riuniti, Bergamo, Italy, [4]Rheumatology University of Pavia, Pavia, Italy, [5]Wake Forest University Health Sciences, Winston-Salem, NC, [6]Wake Forest School of Medicine, Winston-Salem, NC, [7]Medical University of South Carolina, Charleston, SC, [8]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Anti-Ro associated congenital heart block (CHB) exhibits a 33% concordance rate in monozygotic twins, 17.5% recurrence of disease and a high sibling risk ratio (lamda s=3000). Given the strong maternal genetic influence on anti-Ro antibody production and the proposed pathogenesis of injury which implicates fetal innate immune responses, the Immunochip (SNP array for fine mapping 186 genomic regions previously connected to at least one of 12 autoimmune diseases) was selected to explore associations between immune-related variants and CHB. Pedigrees inclusive of affected and unaffected children and their parents were included in an attempt to untangle maternal from fetal contributions.

Methods: Caucasian CHB children (n=170) and nuclear family members (n=435) from three Registries (U.S., France, Italy) were genotyped. Sera from the mothers of all probands were confirmed to react with either 52kD SSA/Ro, 60kD SSA/Ro, or 48kD SSB/La. In 96%, 2nd or 3rd degree block was present; the remaining 4% had an isolated cardiomyopathy. Out-of-study controls (n=1087) were called together with CHB pedigree data. After standard QC, association analyses were computed using logistic regression for case-control and pedigree disequilibrium tests (PDT) for pedigree-based tests; the latter accounts for genetic maternal immune load. P-values were genomic control adjusted and genome-wide significance was assessed using the false discovery rate P-value (FDR-P<0.05). Primary inference is based on the FDR-P for the case-control analysis, conditional on the PDT/TDT P-value being <0.05.

Results: There were 18 SNPs inside and 25 SNPs outside the HLA region that met the dual criteria, case-control FDR-P<0.05 (i.e., genome-wide significance) and PDT/TDT P<0.05. The strongest association was inside the extended HLA region within an intronic region of *GABBR1* (rs29252: FDR-P=2×10E-10, OR=6.2) which encodes an inhibitory neurotransmitter receptor whose ligation resists ischemia/reperfusion-injury and fibrosis. Detailed imputation-based four digit HLA analyses are underway. Outside the HLA region the primary associations included rs3739706 [FDR-P=0.0009, OR=1.9] within *LPAR1* which encodes a lysophosphatidic acid G-protein-coupled receptor with a role in endothelial cell differentiation; rs62092154 [FDR-P=0.0026, OR=4.8] within *SLC14A2* (encodes a urea transporter, which in addition to being expressed in the kidney, is also expressed in the heart and increased in heart failure); rs8063008 [FDR-P=0.00598, OR=0.46] with an intergenic on 16q24 and numerous associations on 2p14 within FLJ16124 (e.g., rs7575614: FDR-P=0.02, OR=2.7), a region rich in regulatory elements. Interestingly, rs473024 showed evidence of association [FDR-P=0.01, OR=1.8] and is located within *MAGI2*, a gene identified in an imprinted gene expressed in human placenta.

Conclusion: Analysis with the Immunochip yielded numerous regions strongly associated with CHB, even after accounting for potential parental load. These associations corroborate the genetic influence on CHB and suggest a link between immune responses and exuberant fibrotic replacement of the atrioventricular node and in some cases a cardiomyopathy.

Autoantigen Microarray Analysis Of Sera From New-Onset Pediatric Systemic Lupus Erythematosus Patients: A Distinct Autoantibody Profile Associated With Class III/IV Lupus Nephritis. Imelda Balboni[1], David Haddon[2], Vivian Diep[2], Cindy Limb[2] and Paul Utz[2]. [1]Stanford University School of Medicine, Palo Alto, CA, [2]Stanford University School of Medicine, Stanford, CA.

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous systemic autoimmune disease characterized by the production of autoantibodies directed against highly-conserved nuclear antigens. 15–20% of SLE patients develop disease in childhood or adolescence, and pediatric (pSLE) patients often have more severe disease onset and organ system involvement. Autoantigen microarray technology allows the comprehensive analysis of autoantibodies directed against hundreds of antigens with minimal amounts of sera. The purpose of this study was to characterize the spectrum of autoantibody reactivity in a cohort of new-onset pSLE patients and to identify an autoantibody profile that could serve as a biomarker for class III/IV lupus nephritis.

Methods: New-onset pediatric rheumatology patients meeting the revised ACR diagnostic criteria for SLE were eligible for this study. The study was approved by the Stanford University Institutional Review Board and informed consent was obtained prior to participation in the study. Demographic and clinical data at disease onset were collected. Sera from 51 pSLE patients and 20 healthy age- and sex-matched controls were evaluated using an 1128-feature antigen microarray manufactured with approximately 135 antigens. Microarrays were probed with 1:200 dilutions of serum and a Cy5-conjugated goat-anti-human IgG secondary antibody, scanned with a GenePix 4000 scanner, and analyzed using GenePix 6.1 software to determine median fluorescence intensity minus background for each antigen. Significance Analysis of Microarrays (SAM) software was used to determine differences in autoantibody reactivity between pSLE patients and controls, and between pSLE patients with and without proliferative nephritis. Enzyme-linked immunosorbant assays (ELISAs) were performed to confirm autoantibody reactivity identified by microarray.

Results: SAM identified increased reactivity against 50 autoantigens in sera from new-onset pSLE patients compared to controls, with a false discovery rate of zero. In addition to reactivity against classically-described SLE autoantigens, reactivity against several basement membrane and extracellular matrix proteins was identified. Subgroup analysis comparing patients with class III or IV lupus nephritis to patients without significant nephritis demonstrated increased reactivity against several autoantigens including double-stranded DNA, C1q, histones, collagen and aggrecan in patients with proliferative nephritis. ELISAs confirmed a significant association between proliferative nephritis and reactivity against double-stranded DNA ($p=0.0037$), histones H2B ($p=0.047$) & H1 ($p=0.02$), C1q ($p=0.0005$), and type IV collagen ($p=0.0051$).

Conclusion: New-onset pSLE patients demonstrate a broad spectrum of autoantibodies directed against many autoantigens, including those not classically associated with SLE. Subgroup analysis of pSLE patients with and without nephritis revealed a distinct autoantibody profile that could serve as a biomarker for proliferative nephritis. We are currently developing a composite score, based on these autoantibodies and clinical data, to test on an additional cohort of pSLE patients.

Copy Number Variations Of Complement C4A and C4B Genes Are Genetic Risk Factor and Disease Modification Factor, Respectively, For Juvenile Dermatomyositis. Anjali Patwardhan[1], Katherine Lintner[1], Lisa G. Rider[2], Frederick W. Miller[2], Terrance O'Hanlon[2], Yee Ling Wu[1], Bi Zhou[1], Huanyu Wang[1], David Newsom[1], Peter White[1], Charles H. Spencer[3] and C. Yung Yu[1]. [1]The Research Institute at Nationwide Children's Hospital and The Ohio State University, Columbus, OH, [2]NIEHS, NIH, Bethesda, MD, [3]Nationwide Childrens Hospital, Columbus, OH.

Background/Purpose: Juvenile Dermatomyositis (JDM) is a systemic and inflammatory vasculopathy that affects mainly proximal muscles and skin in children. It is a rare but severe autoimmune disease featuring the presence of autoantibodies against the translational machinery for protein synthesis. Proteolytic products of antibody-mediated complement activation are often observed in affected tissues of JDM. The causal factors for JDM are unknown, but genetic variants of the HLA are strongly implicated, particularly in haplotypes with HLA-DR3. Recently, differential copy number variations (CNVs) for the HLA-associated complement C4A and C4B genes were demonstrated in healthy subjects and autoimmune disease patients. A deficiency of C4A is strongly associated with HLA-DR3 and systemic autoimmunity. Our objective is to investigate CNVs of total C4, C4A, and C4B on the pathogenesis of JDM.

Methods: The study population included 56 JDM patients (53 Whites, 3 Blacks) and 577 geographically matched healthy subjects, recruited upon informed consents according to IRB-approved protocols. The mean ($\pm$SD) age for JDM disease diagnosis was 7.91 ± 4.27 years old. Calcinosis, lipodystrophy, and skin ulceration were observed in 19.6%, 9.1% and 16.1% of patients, respectively. Genomic DNA, PAXGENE RNA, and EDTA-plasma were isolated from peripheral blood samples. Gene copy numbers (GCN) for total C4, C4A, and C4B were determined by genomic Southern blot and TaqMan-based, realtime qPCR. Global gene expression array were determined using PAXGENE RNA and Agilent SurePrint G3 8×60K microarrays. The expression of IFI44 was determined by SYBR-Green based qPCR using PAXGENE RNA and GADPH as standard.

Results: Among White subjects, the GCNs vary from 2 to 6 for total C4, 0 to 5 for C4A, and 0 to 4 for C4B. There were significant decreases in JDM (vs. controls) for GCNs of total C4 (cases: 3.42 ± 0.72, controls: 3.85 ± 0.69; $p=0.00007$, t-test) and C4A (cases: 1.74 ± 0.86, controls: 2.10 ± 0.76; $p=0.0009$, t-test). Remarkably, 43.4% of the JDM patients had a heterozygous or homozygous deficiency of C4A, compared to 18.5% in controls ($p=0.00008$, X^2analysis). The odds ratio (95% CI) for C4A deficiency in JDM was 3.37 (1.88– 6.04). Intra-group comparison of clinical presentations revealed that patients with calcinosis and lipodystrophy both had significantly higher GCN of C4B ($p=0.001$, Fisher's exact), reflecting a role of C4B in complement-mediated tissue injuries. Global gene expression studies using peripheral blood RNA (19 JDM, 8 controls) and Agilent microarrays revealed up-regulation of genes typical for interferon-α response signature and down-regulation for chemokine genes. SYBR-green labeled qPCR on transcripts for IFN-α response gene IFI44 showed a 4.7 and 2.6-fold increase in expression among patients with and without a C4A deficiency, respectively, vs. controls ($p=0.004$, t-test).

Conclusion: A deficiency of C4A is a common genetic risk factor for JDM with medium to high effect size. Peripheral blood RNA from JDM exhibited upregulation of IFN-α response gene IFI44, particularly among C4A deficient patients. Among established JDM patients, normal/high GCN of C4B was associated with disease complications, including calcinosis and lipodystrophy.

2864

Whole Exome Sequencing In Pediatric Patients With Early Onset Rare Immunodysregulatory Diseases That Present With Fever and Systemic Inflammation. Adriana Almeida de Jesus[1], Julie Niemela[2], Yin Liu[1], Steven Boyden[3], Ivona Aksentijevich[4], Daniel L. Kastner[4], Thomas A. Fleisher[2], Raphaela Goldbach-Mansky[1] and Zuoming Deng[1]. [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD, [2]Laboratory Medicine, NIH Clinical Center, Bethesda, MD, [3]National Human Genome Research Institute, NIH, Bethesda, MD, [4]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

Background/Purpose: WES (Whole Exome Sequencing) has increasingly become the tool of choice in translational research, providing molecular diagnoses in Mendelian diseases and identifying important genes in key biological pathways. Here we report using WES to investigate the molecular basis of a group of rare diseases presenting with autoinflammatory phenotypes that are characterized by perinatal onset of fever and systemic and organ specific inflammation.

Methods: Total blood DNA was extracted and whole exome sequencing was performed using human exome capture by Agilent V4 (51Mbp) exome enrichment kit, followed by next generation sequencing using Illumina HiSeq2000. We have developed a bioinformatics pipeline to process WES data and an integrated workflow to analyze variants in family trios or quartets. Using the pipeline, we were able to assess the quality of WES data and check discrepancies in sample gender and family relatedness.

Results: The number of coding variants per sample in our WES studies ranged from 19,000 to 25,000, correlating with exome coverage and sample ethnicity. The Transition to Transversion ratios (Ti/Tv) varied from 2.98 to

3.27 with a median of 3.15 after excluding a poorly performed batch. Other QC metrics such as heterozygous to homozygous ratio, synonymous to nonsynonymous ratio and indel percentage are all within expected ranges for WES. Concordance in two pairs of technical replicates was 97.25%. In total, 42 subjects were sequenced, including 14 patients and their parents (trios). Five probands were male (35.7%), 10 probands were Caucasian (56.3%), 3 were Hispanic and 1 had other ethnicity. All patients presented with immune dysregulatory clinical phenotypes including chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature (CANDLE) in 1 patient and neonatal onset multisystem inflammatory disease (NOMID) in 4 patients. The remained 9 probands presented with undifferentiated complex clinical phenotypes characterized by early-onset fever, skin rashes and organ-specific inflammatory involvement. On average, the novel variants (defined as not present in dbSNP137) count for about 2% of all variants in each sample. The variant annotation, analysis and filtering workflow has allowed us successfully identify *de novo* mutations in 5 trios. In 2 patients we identified disease-causing mutations in previously known genes, *PSMB8 and PSMA3* in 1 patient and NLRP3 in 1 patient, causing CANDLE and NOMID syndromes, respectively. In one patient we found a disease causing *de novo* mutation in a gene previously not associated with human disease with sufficient data to claim causality and in two patients we have found previously non-described variants that are suggestive of causing disease but functional studies are currently underway in the other families to confirm the pathogenicity of the mutations in these families. All mutations described were confirmed by Sanger sequencing.

Conclusion: Our results suggest that WES can be used as an effective tool in translational research of rare immunodysregulatory diseases.

2865

Gene Expression Profiles Of Fibroblast-Like Synoviocytes In Early Stage Of Oligoarticular Juvenile Idiopathic Arthritis Are Different In Extended Versus Persistent Course. AnneMarie C. Brescia[1], Megan M. Simonds[2], Suzanne M. McCahan[2], Paul T. Fawcett[2] and Carlos D. Rose[1]. [1]Thomas Jefferson University/ AI duPont Hospital for Children, Wilmington, DE, [2]Nemours/AI duPont Hospital for Children, Wilmington, DE.

Background/Purpose: Our goal is the identification of informative synovial biomarkers to predict persistent vs extended course in oligoarticular JIA patients.

Methods: Stored remnant synovial fluid samples obtained from patients undergoing medically indicated arthrocenteses were retrieved. Using our clinical database, JIA samples were separated into two groups: (1) oligoarticular JIA with persistent course (PR), (2) oligoarticular JIA with extended course (E). All samples were from steroid-naïve joints and all samples from E were obtained prior to extension. Primary cultures of fibroblast-like synoviocytes (FLS) were established for each subject. RNA from cultured passage 3–6 FLS were isolated, amplified and hybridized to Affymetrix Human GeneChips using the Affymetrix protocol. Expression values were determined with GC-RMA. Global gene expression of FLS from 5 PR and 9 E samples were obtained. Data was filtered for log2 expression >4 in all samples of either PR or E, then for absolute value of 1.5-fold change to reveal 3231 probesets. Of these, LIMMA revealed 39 probesets with statistically significant differential expression between PR vs E FLS ($p<0.05$), shown in heatmap (Figure 1).

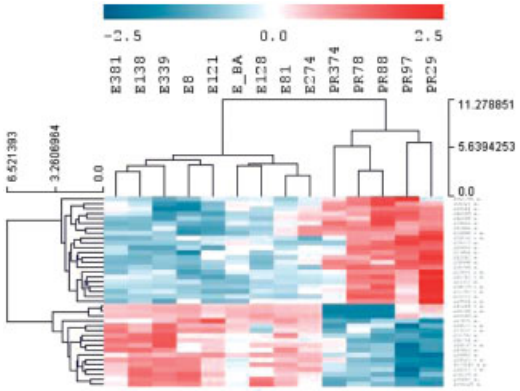

Figure 1

Results: Hierarchical clustering of the 39 probesets revealed samples from the different courses cluster together, with all the E to the left of the heatmap. Importantly, the E were all taken from the very first sample available, which preceded extension in all patients, highlighting that there are detectible differences in the gene expression of the FLS early in the course in the patients whose disease is destined to extend. These 39 probesets represent 32 unique genes. PR overexpressed 19 genes, including known biomarkers for other diseases, AURKA, CCNB1, PLAUR and the secreted protein IGFBP6, in addition to another secreted protein, COL5A1. E overexpressed 13 genes, including known biomarkers for other diseases, XIST and secreted protein GDF5, which is important in inflammatory and apoptotic pathways and activates macrophages within the TNFa pathway.

Conclusion: We were able to demonstrate differential gene expression in FLS from JIA patients who remained PR vs those who were destined to extend, demonstrating detectible difference early in disease which may be useful for prediction. The differentially expressed proteins, especially secreted proteins, provide a starting point for development of biomarkers to distinguish between PR and E JIA using aspirated synovial fluid.

Rheumatoid Arthritis - Clinical Aspects VII: Remission, Flare and Outcome Measures in Rheumatoid Arthritis
Wednesday, October 30, 2013, 11:00 AM–12:30 PM

2866

Determining The Absolute Change In The Clinical Disease Activity Index (CDAI) To Define a Minimally Important Difference. Jeffrey R. Curtis[1], Shuo Yang[1], Lang Chen[1], Janet E. Pope[2], Edward C. Keystone[3], Boulos Haraoui[4], Gilles Boire[5], J. Carter Thorne[6], Diane Tin[6], Carol A. Hitchon[7], Clifton O. Bingham III[8] and Vivian P. Bykerk[9]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]St Joseph Health Care, London, ON, [3]Mount Sinai Hospital/University of Toronto, Toronto, ON, [4]Centre Hospitalier de l'Université de Montréal, Montreal, QC, [5]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [6]Southlake Regional Health Centre, Newmarket, ON, [7]University of Manitoba, Winnipeg, MB, [8]Johns Hopkins University, Baltimore, MD, [9]Hospital for Special Surgery, New York, NY.

Background/Purpose: Simplified measures to quantify rheumatoid arthritis (RA) disease activity are increasing in use in clinical practice. However, the absolute minimally important difference (MID) in some of these measures, such as the clinical disease activity index (CDAI), has not been well defined in real-world settings, especially for early RA patients (ERA) with low or moderate disease activity. To determine the MID for improvement of the CDAI in a "real world" setting using an observational cohort of patients with ERA.

Methods: Data from the Canadian CATCH cohort of patients with ERA were used to identify pairs of rheumatology visits spaced 3 months apart occurring within 12 months of cohort entry. Patients with concomitant fibromyalgia (8% of cohort) were excluded. Absolute change in CDAI was examined between visit pairs and correlated with relevant changes corresponding to MIDs in patient self-reported improvement (better vs. same/worse), patient pain (>1 vs. <= 1, and >2 vs. <= 2) and HAQ (>0.22 vs. <= 22, and >0.30 vs. <= 0.30). The 10th and 90th percentile of the CDAI distributions for EULAR good response vs. non-response in DAS28 ESR (>1.2 vs. < 0.6 units improvement) were used to determine proposed CDAI cutpoints to define MID, overall and stratified by initial CDAI disease activity categories (low < 10; moderate 10<=-<=22; high > 22). Discrimination of these cutpoints was examined using area under receiver operator curves (AUROC). These CDAI cutpoints were used to describe the Sensitivity (Se), Specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) of the CDAI cutpoints for patient pain and HAQ.

Results: A total of 1191 unique CATCH patients (mean± SD age 53.5± 15.1 years; 72% women, median RA disease duration 5.8 ± 3.0 months and contributed 3262 visit pairs within 12 months of enrollment. Among those with available serologic results (91% of cohort for RF, 67% of cohort for anti-CCP), 70% were RF positive and 60% anti-CCP antibody positive.

Overall, there was excellent discrimination between DAS28 responders using a CDAI cutpoint of 5 units; the AUROC was 0.87. CDAI cutpoints for patients who started in low, moderate, or high disease were 2, 6, and 10,

respectively. The Se, Sp, PPV and NPVs shown in the Table showed acceptable performance characteristics using these proposed CDAI cutpoints.

Improvement in	CDAI Cutpoint and Starting Disease Activity	Sensitivity	Specificity	PPV	NPV
Patient self-reported improvement (better vs. same/worse)	5 (all data)	76	53	56	74
	2 (low)	84	58	42	90
	6 (moderate)	76	82	57	72
	11 (high)	82	73	88	63
Pain (>1 vs. <=1)	5 (all data)	45	85	55	80
	2 (low)	33	92	54	83
	6 (moderate)	46	75	52	70
	11 (high)	52	77	71	61
Pain (>2 vs. <=2)	5 (all data)	29	93	62	77
	2 (low disease)	15	96	54	80
	6 (moderate)	24	88	55	66
	11 (high)	40	85	73	58
HAQ (> 0.22 vs. <= 0.22)	5 (all data)	57	80	69	71
	2 (low disease)	28	87	40	79
	6 (moderate)	46	73	58	64
	11 (high)	70	64	77	55
HAQ (> 0.30 vs. <= 0.30)	5 (all data)	48	87	74	69
	2 (low disease)	17	93	44	78
	6 (moderate)	36	81	59	62
	11 (high)	63	72	80	53

Conclusion: These minimally important absolute differences in CDAI can be used to evaluate improvement and increase the usefulness of this clinical simplified disease activity measure in real-world settings.

Using Patient Reported Outcomes Measurement Information System Instruments To Identify Disease Flares In People With Rheumatoid Arthritis. Susan J. Bartlett[1], Ana-Maria Orbai[2], Trisha Duncan[2] and Clifton O. Bingham III[2]. [1]Johns Hopkins School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD.

Background/Purpose: Rheumatoid arthritis (RA) is associated with unpredictable episodes of disease worsening that may prompt consideration of treatment change. Core RA Flare domains have been ratified by OMERACT, but the optimal PRO instruments have not been determined. PROMIS offers population-normed measures to assess physical, emotional, and social health, including RA Flare domains. PROMIS use in RA is limited and has not been evaluated for flare detection

Methods: Data are from the baseline visit of the first 125 RA pts enrolled in an ongoing study integrating PROs into routine RA care. Pts were asked whether they were in a significant RA flare, flare duration and severity, and completed selected PROMIS CATs (pain, fatigue, physical function, and social roles/activities), along with MHAQ, pain, fatigue, pt global VAS, change from last visit and pt acceptable symptom state. MD global and joint counts were also recorded. Flare vs. no-flare groups were compared using t-tests and χ^2.

Results: Participants (N=126) were mostly female (79%) and white (86%) with a mean (SD) age of 56 (13) and RA duration of 12 (9) yr; 10% were diagnosed ≤ 2 yr. 20% reported a current flare with a mean severity of 6.0 (2.5)(0=none; 10=worst); 52% reported duration >14 d. Compared to others, flaring pts were more likely to rate RA worse than the prior visit (OR 7.6; 95% CI 2.9, 19.7) and current symptom state unacceptable (OR 5.6; 95% CI 2.2, 14.4). Flare was not associated with age, sex, race, RA duration, or education. Pts reporting flare had significantly higher PROMIS pain and fatigue scores, and lower physical function as well as participation in and satisfaction with social roles and activities (Table). Traditional PROs (pain, fatigue, pt global VAS, MHAQ) and clinical disease activity indicators (CDAI, MD Global, joint counts) were also significantly higher in the flare group.

	Flare (n=25)		No Flare (n=100)		
	Mean	SD	Mean	SD	p value
Pain					
100 mm VAS	53.6	25.8	25.0	26.5	.000
PROMIS Pain Intensity	50.7	7.0	43.0	7.8	.000
PROMIS Pain Interference	59.9	6.8	51.3	9.7	.000
Fatigue					
100 mm VAS	59.8	24.2	34.8	30.6	.000
PROMIS Fatigue	58.2	7.0	53.3	10.6	.032
Physical Function					
MHAQ	0.5	0.4	0.3	0.4	.014
PROMIS Physical Function†	37.9	6.2	44.2	9.0	.001
Social Roles and Activities†					
PROMIS Participation	46.4	7.6	50.7	9.3	.037
PROMIS Satisfaction	42.8	9.6	49.8	10.2	.002
Patient Global	47.0	24.4	24.1	25.7	.000
AM Stiffness 30 min	52%		31%		.049
Stiffness Intensity*	1.8	0.7	1.2	0.8	.001
Stiffness Interference**	1.8	0.9	1.2	1.1	.002
CDAI	14.8	10.5	6.8	7.0	.001
Swollen joints (28)	5.0	5.5	1.9	2.8	.000
Tender joints (28)	3.0	4.4	1.2	2.7	.017
MD Global	25.5	22.8	12.6	13.9	.013

†Higher scores reflect greater impairment. *0=none, 4=very severe; **0=never, 4=always

Conclusion: Patient reports of RA flares are associated with significantly higher PROMIS scores, legacy measures and clinical disease activity indicators, providing evidence of convergent validity of PROMIS instruments. Results suggest PROMIS measures can assess RA Flare domains and identify pts in flare, with shifts of 0.4–1 SD between groups. Prospective studies are ongoing to assess responsiveness of PROMIS for RA improvement and worsening. Beyond flare detection, selected PROMIS measures may aid in RA self-monitoring, and in the case of worsening, could signal the need for additional clinical assessment.

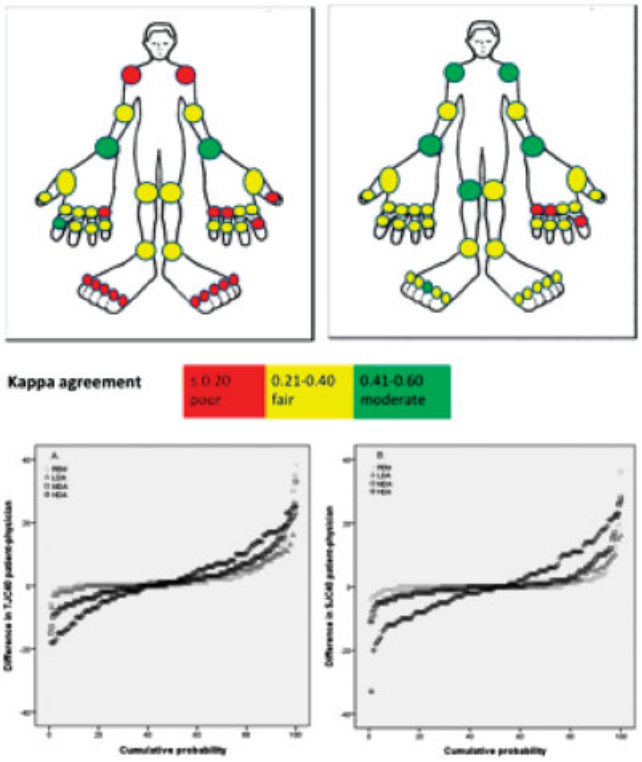
Reliability and Validity Of Patient-Reported Joint Counts and Determinants Of Disagreement With The Physician In Recent Onset Rheumatoid Arthritis. Karen Visser[1], Janet E. Pope[2], Ernest Choy[3], Clifton O. Bingham III[4], Susan J. Bartlett[5], Gilles Boire[6], Carol A. Hitchon[7], J. Carter Thorne[8], Boulos Haraoui[9], Diane Tin[8], Edward Keystone[10] and Vivian P. Bykerk[11]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]St Joseph Health Centre, London, ON, [3]Cardiff University, Cardiff, ENGLAND, United Kingdom, [4]Johns Hopkins University, Baltimore, MD, [5]Johns Hopkins School of Medicine, Baltimore, MD, [6]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [7]University of Manitoba, Winnipeg, MB, [8]Southlake Regional Health Centre, Newmarket, ON, [9]Institut de Rhumatologie de Montréal, Montreal, QC, [10]University of Toronto, Toronto, ON, [11]Hospital for Special Surgery, New York, NY.

Background/Purpose: Patient-reported joint counts (JCs) might improve the efficiency and consistency of disease monitoring, self-management and early recognition of changes in disease activity in rheumatoid arthritis (RA).

To assess the reliability and validity of patient-reported JCs as compared to physician JCs in recent onset RA and to identify determinants of disagreement.

Methods: Data from 795 recent-onset (< 1 year) RA patients from the Canadian early arthritis cohort (CATCH) were used. Patient-reported tender (T) and swollen (S) JCs were derived from a 40-joint homunculus and the 16-joint RA-disease-activity-index (RADAI) mannequin. Physician JCs were abstracted from the TJC68 and SJC66. Inter-rater reliability of patient TJCs and SJCs as compared with corresponding physician JCs was assessed, using intra-class correlation coefficient (ICC) two-way random effects model. Agreement on activity of joint areas was assessed by kappa. Pearson correlation coefficients were determined between the patient JCs counts separately and incorporated into the patient-disease-activity-score (pDAS) and routine-assessment-of-patient-index-data (RAPID4) with DAS28 and health assessment questionnaire (HAQ). Determinants of disagreement with the physician (over- or underestimation >=1 joint) were identified by multinomial logistic regression.

Results: The reliability of the patient TJC40 was moderate (ICC 0.61; 95%CI 0.51–0.69), with lower ICC for the 16 joint RADAI-derived TJC (ICC 0.51; 95%CI 0.21–0.68) and patient SJC40 (ICC 0.52; 95%CI 0.46–0.57). Positive agreement among joint regions ranged from 47%-82% (kappa 0.26–0.51) for tenderness and from 33%-60% (kappa 0.10–0.44) for swelling, being highest for tenderness in large joints (figure 1). Differences between patient and physician JCs were lowest in patients in DAS28 remission or low disease activity (figure 2). Determinants of disagreement on TJC were lower age, male gender, higher DAS28, disability and depressed mood. Disagreement on SJC was associated with male gender and higher DAS28. Correlations of DAS28 and HAQ with the PDAS (r 0.90; r 0.73, resp.) and RAPID4 (r 0.72; r 0.85, resp.) were higher than with the separate patient SJC40 (r 0.54; r 0.47, resp.) and TJC40 (r 0.57; r 0.54, resp.).



Conclusion: In recent onset RA, patient-reported JCs demonstrate moderate reliability and validity. Patient JCs can be incorporated in patient-reported outcomes in studies addressing remission induction and treatment withdrawal strategies to investigate their ability to detect changes in disease activity and discriminate flares.

Changes In Patient-Reported Joint Counts and Composite Indices Can Identify Flare Of Disease Activity In Recent Onset Rheumatoid Arthritis.

Karen Visser[1], Susan J. Bartlett[2], Clifton O. Bingham III[3], Ernest Choy[4], Daming Lin[5], Juan Xiong[6], Gilles Boire[7], Boulos Haraoui[8], Carol A. Hitchon[9], Edward Keystone[10], Janet E. Pope[11], J. Carter Thorne[12], Diane Tin[12] and Vivian P. Bykerk[13]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Johns Hopkins University, Baltimore, MD, [3]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [4]Cardiff University, Institute of Infection and Immunity, Cardiff, United Kingdom, [5]Mount Sinai Hospital, University of Toronto, Toronto, ON, [6]Mount Sinai Hospital, Toronto, ON, [7]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [8]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [9]University of Manitoba, Winnipeg, MB, [10]University of Toronto, Toronto, ON, [11]St Joseph Health Care, London, ON, [12]Southlake Regional Health Centre, Newmarket, ON, [13]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY.

Background/Purpose: Patient-reported joint counts (JCs) have been identified as core domains for assessment of flare in rheumatoid arthritis (RA) [1].

To assess the responsiveness and discriminative validity of patient-reported JCs, separately and incorporated in composite patient-reported outcomes (PROs), for worsening of disease activity in early RA (ERA).

Methods: Paired data from ERA patients in the Canadian early arthritis cohort (CATCH) who prospectively completed OMERACT preliminary flare questions twice over a 3-month interval between 12/2011 and 4/2013 were used. Patients reported tender (T) and swollen (S) JCs on a 40-joint homunculus and the 16-joint RA-disease-activity-index (RADAI) mannequin. Physicians assessed the TJC68, SJC66 and global assessment (MDGA). Flare was defined as: a worsening in DAS28 >1.2 (or > 0.6 if DAS28 >= 3.2) and patients answering: 'Are you having a flare at this time?' with no changing to yes. Median changes in patient JCs were compared between patients in a flare or not by Wilcoxon signed rank test. Discrimination of flare vs. non-flare for the patient JCs separately and incorporated into the patient-disease-activity-scores (pDAS1 and pDAS2) and routine-assessment-of-patient-index-data (RAPID4) was assessed via effect sizes (ES) and compared with ES of traditional parameters.

Results: Of 115 eligible patients, 90% fulfilled the ACR 2010 RA criteria, 79% were female, mean (SD) age was 55 (15) years and symptom duration 5 (3) months. At the initial assessment, 46%/15% of the patients were in DAS28 remission/low disease activity, with a median (IQR) patient SJC40 and TJC40 of 1 (0–3) and 3 (1–10), respectively. Mean physician SJC66 and TJC68 were 1.9 (SD 3.3) and 4.6 (SD 6.6). After 3 months, 16 (14%) patients reported a flare and 26 (23%) experienced a flare according to the DAS28 definition. DAS28 flare was associated with a significant increase in patient JCs and PROs, physician JCs, HAQ, MDGA and ESR (Table). The composite PROs, RADAI48, physician TJCs, ESR, MDGA and patient global best discriminated flare from non-flare (ES>1) (Figure). Flare according to the patient statement was associated with a significant increase in PDAS1, RAPID3 and 4, DAS28 and ESR and was discriminated best by the PDAS1, RAPID3 and 4, and physician SJC (ES>0.8).

Table. Median (interquartile range) change in patient joint counts, composite PROs and traditional parameters, for patients experiencing a flare or not according to two definitions.

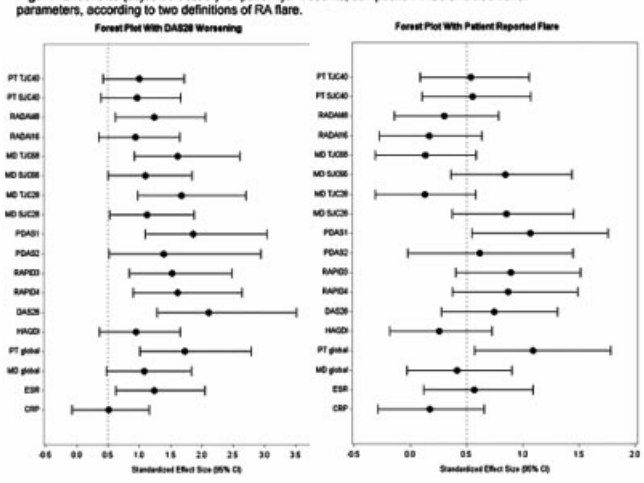
ESR	7 (3–10)	<0.001	−2 (−5–2)	0.037	4 (−2–6)	0.038	−2 (−5–2)	0.097
CRP	0.2 (0–3)	0.160	0 (−2–1)	0.279	0 (−2–2)	0.448	0 (−2–1)	0.454

Figure. Effect size (adjusted 95%CI) for patient joint counts, composite PROs and traditional parameters, according to two definitions of RA flare.



Conclusion: In ERA, a change in patient-reported JCs can identify worsening of disease activity and detect flares, with highest discriminative validity when used in composite indices. Patient derived composite indices incorporating patient JCs should be considered in developing a comprehensive definition of RA flare.

Higher Disease Activity and Serum Levels Of Angiogenic Factors In Patients With Rheumatoid Arthritis In Clinical Remission With Synovitis On Ultrasound. Julio Ramirez[1], Virginia Ruiz-Esquide[2], Isaac Pomés[1], Raquel Celis[1], Jaume Pomés[1], Sonia Cabrera[1], M. Victoria Hernández[2], Oscar M Epis[3], Jose L. Pablos[4], Raimon Sanmarti[5] and Juan D. Cañete[1]. [1]Hospital Clínic, Barcelona, Spain, [2]Hospital Clinic, Barcelona, Spain, [3]Ospedale Niguarda Cà Granda, Milano, Italy, [4]Instituto de Investigación Hospital 12 de Octubre, Madrid, Spain, [5]Hospital Clínic of Barcelona, Barcelona, Spain.

Background/Purpose: To identify and characterize subclinical synovitis in patients with rheumatoid arthritis in clinical remission using power Doppler ultrasound and serum levels of angiogenic factors.

Methods: We selected patients with rheumatoid arthritis in clinical remission (defined as DAS28-ESR<2.6) tested by two independent rheumatologists. Clinical, epidemiological, demographic and serological data were analyzed. Ultrasonography of knees and hands (wrists, metacarpophalangeal [MCP], proximal interphalangeal [PIP], flexor and extensor tendons of the hand) was performed by a radiologist with an ultrasound scanner (Acuson Antares, Siemens AG, Erlangen, Germany) with a linear probe of 10.5 MHz. Synovial hypertrophy and power Doppler signal were scored (grades 0–3). Synovial hypertrophy >2 plus power Doppler signal was classified as active synovitis.

Serum levels of angiogenic factors were determined by Quantibody® Human Array (RayBiotech, Inc, Norcross, GA, USA).

Results: Fifty-five patients were included of whom 25 (45.4%) met criteria for active synovitis. The most-affected joints were the wrist and second MCP. Patients with active synovitis on ultrasound had significantly higher DAS28-CRP (p=0.020) and only 12% were taking oral glucocorticoids (< 5 mg/day) compared with 40% of patients without active synovitis. No other clinical differences were found (Table 1). Patients with active synovitis had significantly-higher serum levels of angiogenic factors: angiopoietin-2 (p=0.038), VEGF-D (p=0.018), PIGF (p=0.043), SDF-1 (p=0.035), MMP-2 (p=0.027) and bFGF (p=0.007) (Table 1).

Table 1. Clinical, demographic and biological data of the 55 patients, stratified according the presence or not of active synovitis as defined by ultrasound*.

	All n=55	HS + Doppler (active synovitis) n=25	No HS+Doppler (no active synovitis) n=30	p-value

SDF-1 (pg/mL)	280 (115–1648)	750 (157–3420)	165 (80–1127)	0.035
MMP-2 (pg/mL)	2738 (1909–4109)	3762 (2101–5779)	2403.5 (1870–3448)	0.027
bFGF (pg/mL)	314 (267–521)	383 (285–762)	295 (260–327)	0.007

*Data are expressed as median (IQR) or as percentage. HS: synovial hypertrophy; RF: rheumatoid factor; ACPA: anti-citrullinated protein/peptide antibodies; DAS28: disease activity score; mHAQ: modified Health Status Questionnaire; ESR: erythrocyte sedimentation rate; DMARD: disease modifying anti-rheumatic drugs. ANG-2: angiopoietin-2; VEFG: vascular endothelial growth factor; PIGF: Placental Growth Factor. SDF: Stromal-cell derived factor-1; MMP-2: matrix metalloproteinase-2; bFGF: basic fibroblast growth factor.

Conclusion: Around half of patients with RA in clinical remission presented active synovitis on ultrasound. These patients have greater disease activity and higher serum levels of angiogenic factors. These findings are clinically and physiopathologically consistent and may help identify active synovitis in RA patients in clinical remission.

Background/Purpose: Defining flare in rheumatoid arthritis (RA) raises a complex issue related to the difference in perception or concept of flare between patients or health professionals. Altogether, defining a worsening in RA should clearly not depend on physicians' perspectives only. The Strategy of Treatment in Patients with Rheumatoid arthritis (STPR) group developed a self-administered questionnaire (FLARE) to detect a past or present RA flare to be used to identify patients whose appointment should be anticipated or treatment revised (Berthelot et al, ARD 2011). Purpose: To validate the measurement properties of the FLARE self-administered questionnaire.

Methods: the validation study was conducted in a prospective trial of RA patients with 3 main objectives to determine: 1) the truth of the tool.The internal validity was measured with a principal component factor analysis, the external validity evaluated by Spearman correlation coefficients with the DAS28, rheumatoid arthritis impact of disease [RAID], routine assessment of patient index data [RAPID], and HAQ scores. The measurement invariance was assessed with Rasch analysis; 2) the reliability by intra-class correlation coefficients (ICC) and Bland et Altmann);and 3) the feasibility of using this score in daily practice. To be included patients should be at least 8 years old, have RA according to ACR criteria 1987 and/or 2012, evolving for more than 6 months. RA treatments (DMARDs, symptomatic treatments including stéroids) should be stable for at least 2 months. Patients were examined at baseline and 3 months and questionnaires were filled in 2 days before and at M3 clinical visit.

Results: 207 patients were recruited from 13 centres: 78.7% women, 57.7 years old, 84.4% RF+, 78.7% ACPA+, DAS28 was 2.9, CRP was 5.7 mg/l and 81.2% had erosive disease. At baseline, mean FLARE score (SD) – arithmetic mean of the 13 subscales – were 2.1 (+/−2.1) and 2.4 (+/−2.3) in groups 2 and 3 respectively.

Flare score internal validity was fair, with scores left-skewed. A substantial floor effect (1.7%), but no ceiling effect (0.7%), were observed.

The principal component factor analysis evidenced 2 dimensions of the FLARE questionnaire , one dealing with physical items and the other with emotional items. Partial credit model analysis further confirmed that one item on steroid treatment was inadequate.

Flare scores were correlated with DAS28 (0.43; p<0.0001) and (0.40; p<0.0001), RAID (0.69; p<0.0001) and (0.69; p<0.0001), RAPID3 (0.70; p<0.0001) and (0.70; p<0.0001, HAQ (0.47; p<0.0001) and (0.39; p<0.0001) in physical and emotional dimension respectively.

FLARE questionnaire was reproducible in both physical (ICC=0.91 [95%CI 0.88–0.94[) and emotional (ICC=0.93 [95%CI 0.90–0.95]) dimensions.

Conclusion: FLARE self-administered questionnaire is highly reproducible. Internal validity is fair with a good correlation with other questionnaires assessing disease activity, functional status and quality of life. This self-administered questionnaire may represent a tool to detect flare between visits to the physician.

Long Noncoding RNA Nron Regulates The Cytoplasmic-Nuclear Shuttling and Activity Of NFAT5 In Rheumatoid Arthritis Synovial Fibroblast. Kunihiko Umekita[1], Michelle Trenkmann[1], Christoph Kolling[2], Beat A. Michel[3], Renate E. Gay[1], Steffen Gay[1] and Mojca Frank Bertoncelj[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Schultess Clinic, Zurich, Switzerland, [3]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: Long noncoding RNAs (lncRNAs) are critical regulators of gene expression and of major biological processes, such as cell migration, proliferation and invasion. The lncRNA NRON, Noncoding Repressor of Nuclear factor of activated T cells (NFAT), was recently shown to repress the cytoplasmic-nuclear translocation and function of NFAT1–4 transcription factors. It is unknown, however, whether NRON can regulate the function of NFAT5, which was reported to influence the migration and proliferation of rheumatoid arthritis synovial fibroblasts (RASF).

Here we investigated the expression and regulation of NRON in RASF and analyzed its role in regulating the function of NFAT5.

Methods: The expression of NFAT5 protein in RA (n=3) and osteoarthritis (OA) (n=3) synovial tissues was analyzed by immunohistochemistry. RASF were transfected with siRNA targeting NRON (n=4) or NFAT5 (n=4) using Lipofectamine 2000. Gene expression in SF was measured by quantitative real-time PCR with normalization to GAPDH or β2-microglobulin. Successful silencing of NFAT5 in SF was confirmed by Western blotting using α-tubulin for normalization. The secretion of IL-6 was measured by ELISA. Immunofluorescence microscopy was used to investigate the cytoplasmic- nuclear trafficking of NFAT5 in RASF transfected with siNRON or stimulated with TNFα (10ng/ml). The formation of stress fibers in SF after silencing of NRON was assessed by phalloidin staining. Migration of SF was analyzed by scratch assay.

Results: The expression of NFAT5 protein was increased in RA compared to OA synovial tissues. The constitutive levels of NFAT5 mRNA (mean dCt±SD: 5.1±0.5 vs 5.8±0.7, p= 0.01) and NRON (mean dCt±SD: 11.7±0.7 vs 13.0±0.5, p= 0.01) were significantly up regulated in RASF (n=15) compared with OASF (n=11). The expression of NRON significantly correlated with the levels of NFAT5 mRNA in RASF (R=0.71, p=0.003). Furthermore, silencing of NFAT5 in RASF resulted in a down regulation of NRON (x-fold±SD: 0.57±0.3, p=0.07, n=4), indicating that NFAT5 regulates the expression of NRON in RASF. Stimulation of RASF with TNFα (2h) also significantly decreased the expression of NRON (by 26.9±25%, p= 0.02, n=7). Importantly, down regulation of NRON in RASF after silencing or TNFα stimulation was accompanied by the translocation of NFAT5 protein from the cytoplasm to the nucleus and by up regulation of NFAT5 target genes, including IL-6 (x-fold±SD: 3.0±2.2, p=0.03, n=4) and MMP-13 (x-fold±SD: 4.7±2.0, p= 0.03) mRNAs. The levels of IL-6 protein also significantly increased by silencing of NRON compared to control (mean±S.D: 1676±479 vs 2433±504 pg/mL, p= 0.007, n=5). Furthermore, silencing of NFAT5 resulted in a significant down regulation of MMP-13 mRNA (x-fold±SD: 0.58±0.2, p=0.02, n=4). The formation of stress fibers (n=3) and the migratory abilities of RASF (n=4) were increased after silencing of NRON.

Conclusion: Our data indicate that the lncRNA NRON regulates gene expression profiles, stress fiber formation and migration of RASF in a NFAT5-dependent manner and can therefore significantly contribute to the pathogenic characteristics of activated synovial fibroblasts in RA.

The Ion Channel TRPV2 Is New Suppressor of Arthritis Severity and Joint Damage. Teresina Laragione[1], Max Brenner[1], Christine Beeton[2] and Percio Gulko[1]. [1]Hosftra North Shore-LIJ School of Medicine, Manhasset, NY, [2]Baylor College of Medicine, Houston, TX.

Background/Purpose: Rheumatoid arthritis (RA) is a common and chronic disease associated with increased risk of developing disability. Disease remission is still rarely achieved and better treatments are needed. The fibroblast-like synoviocyte (FLS) has a central role in the formation of synovial hyperplasia and in articular damage. The FLS *in vitro* invasive properties through Matrigel correlate with disease severity and joint damage in rodents and patients with RA, yet, little is known about the genes regulating RA severity, FLS invasion and joint damage. We have identified significantly increased levels of the non-selective cation channel Trpv2 (transient receptor potential vanilloid subfamily, type 2 channel) in highly invasive FLS obtained from arthritis-susceptible DA rats. In this study we characterize the role of this ion channel in arthritis.

Methods: Trpv2 was knocked-down using siRNA, or was stimulated with the specific agonist O-1821, and its role in FLS invasion determined in Matrigel invasion assays over 24 hours. For the *in vivo* studies, C57BL/6 mice received KRN serum intra-peritoneal to induce arthritis. After the onset of arthritis animals were assigned to receive either O-1821 or control vehicle BID.

Results: Knock-down of Trpv2 with siRNA unexpectedly significantly increased FLS invasion by nearly 4-fold suggesting that this gene is a suppressor of invasion. We next used the Trpv2-specific agonist O-1821 to treat FLS from DA rats and RA patients. O-1821 significantly reduced invasion by as much as 90% (p<0.01). O-1821 was then used to treat KRN serum-induced arthritis in C57BL/6 mice and it significantly reduced arthritis severity scores and preserved a nearly normal joint histology.

Conclusion: We have identified a new regulator of arthritis severity and joint damage *in vivo*, and show that at least part of Trpv2 activity involves suppression of the invasive properties of FLS both in rodents and patients with RA. These new discoveries should provide the basis for the development of new drugs targeting Trpv2 to better preserve joint architecture and improve outcome in RA.

Biological Roles of C5orf30 In Rheumatoid Arthritis Synovial Fibroblasts. Munitta Muthana[1], Holly Davies[1], Sachin Khetan[2], Gbadebo Adeleke Adeleke[2], Sarah Hawtree[1] and Anthony G. Wilson[1]. [1]University of Sheffield, Sheffield, United Kingdom, [2]Dr, Sheffield, United Kingdom.

Background/Purpose: A recent genome wide association study identified the variant rs26232 in the first intron of an uncharacterized gene *C5orf30* as a rheumatoid arthritis susceptibility variant. In addition, it has been associated with severity of radiological joint damage suggesting a role in tissue breakdown[1]. To date there is no function assigned for *C5orf30* and neither the gene or protein show homology to any known functional sequences. However, *C5orf30* is highly conserved in chimpanzee, dog, cow, mouse, chicken, and zebrafish (orthologs). The aim of this study is to determine the biological role of *C5orf30* in rheumatoid arthritis synovial fibroblast.

Methods: Immunohistochemistry on synovial samples was used to determine expression of *C5orf30* including co-localisation using antibodies to macrophages (CD68), fibroblasts (5B5), T (CD3) & B (CD19) cells. Real time PCR and western blotting were used to examine *C5orf30* transcript and protein levels in fibroblast-like synovial cells (FLS stimulated with TNF & hypoxia). To investigate gene function siRNA was used to knockdown either *C5orf30* or a non-targeting control (NTC) in synovial FLS *in vitro*.

Results: Confocal microscopy revealed *C5orf30* to be strongly expressed in both the nuclear and cytoplasmic compartment of synovial lining cells including macrophages and fibroblasts, but not T & B cells. *C5orf30* was undetectable in arthroscopy sections obtained from osteoarthritis or control synovium. *C5orf30* was expressed in FLS and was found to be up-regulated by hypoxia (8-fold) and down-regulated by TNF (0.5-fold). We found that $C5orf30^{KD}$ compared to the NTC increased the number of invading FLS using the Matrigel invasion assay ($p=0.01$) and increased FLS migration using a scratch assay ($p=0.02$) ($n=6$). Preliminary gene profiling studies suggest that multiple gene sets involved in cell proliferation, intracellular signal transduction, angiogenesis, and immune and inflammatory pathways were significantly modified following $C5orf30^{KD}$.

Conclusion: *C5orf30* knockdown increased FLS migration and invasion into matrigel suggesting *C5orf30* is negatively regulating cellular invasion. Together this identifies a potentially novel pathway mediating tissue damage in RA. We are currently performing proteomic and gene profiling (after *C5orf30* KD) studies in order to work out the biology of this important marker in the pathogenesis and severity of RA.

Metabolic Profiles of Synovial Fibroblasts. Sabrina Kapoor[1], Andrew Filer[2], Christopher D. Buckley[3], Karim Raza[1] and Stephen Young[1]. [1]University of Birmingham, Birmingham, United Kingdom, [2]Rheumatology Department, Birmingham, United Kingdom, [3]School of Immunity and Infection, MRC Center for Immune Regulation, Birmingham, United Kingdom.

Background/Purpose: Synovial fibroblasts play a key role in the persistence of inflammation and joint destruction in rheumatoid arthritis (RA). Cell function and proliferation are highly dependent on availability of nutrients and their metabolism. In the joint, fibroblasts have limited access to nutrients within a poorly vascularised hypoxic tissue and yet expansion of fibroblast numbers is a feature of the RA joint. This suggests fibroblasts may adapt their metabolism to this environment and this altered function may be involved in preventing the resolution of chronic inflammation.

We used NMR spectroscopy to assess differences in metabolite fingerprints in fibroblasts from patients with established RA, early arthritis and healthy controls, and determine how cytokine production by fibroblasts relates to their metabolic profile.

Methods: Fibroblasts were cultured from synovial biopsies from 6 newly presenting, disease-modifying drug naïve patients with established RA (>12 week symptom duration), 6 healthy controls (HC), and patients with arthritis of ≤12 weeks duration whose disease resolved ($n=6$) or evolved into RA ($n=6$) at follow-up. Cell metabolites were extracted for analysis using 1D ^{1}H-NMR spectroscopy and secreted IL6 measured by ELISA. NMR spectra were analysed using partial least squares discriminant analysis (PLSDA) and partial least squares regression (PLS-R) to correlate the metabolite profiles with 1) IL6 production by fibroblasts and 2) the level of CRP, at the time of synovial biopsy, in the serum of patients whose fibroblasts were being assessed.

Results: We were able to distinguish the metabolic profiles of fibroblasts from HC and early RA (sensitivity 67%, specificity 67%), HC and established RA (sensitivity 67%, specificity 50%) and resolving arthritis and early RA (sensitivity 67%, specificity 83%). The IL6 production of fibroblasts from patients with inflammatory arthritis was clearly distinct from that of healthy controls. There was a strong correlation between the metabolic profile of synovial fibroblasts and their IL6 production ($p<0.001$) with several metabolites (in particular citrate, carnosine, pyroglutamate, alanine and lactate) contributing. In patients with inflammatory arthritis the fibroblast metabolic profile correlated strongly ($p<0.001$) with patient serum CRP at the time of synovial biopsy, with several metabolites (in particular cholesterol, fatty acids, leucine, citrate and pyroglutamate) contributing.

Conclusion: There was a significant association between the metabolomic fingerprint of synovial fibroblasts and their IL 6 production, suggesting that IL6 production drives or is driven by significant changes in metabolism. There was also a significant association between CRP levels in the patients' serum and the metabolic profile of their synovial fibroblasts suggesting that fibroblasts retain their metabolic fingerprint during culture ex vivo and that this is strongly related to systemic measures of inflammation in patients with clinical synovitis.

Key Rheumatoid Arthritis-Associated Pathogenic Pathways Revealed By Integrative Analysis Of Rheumatoid Arthritis Omics Datasets. John Whitaker[1], Wei Wang[2] and Gary S. Firestein[1]. [1]UCSD School of Medicine, La Jolla, CA, [2]UCSD, La Jolla, CA.

Background/Purpose: Genome-wide analysis of RA has independently evaluated DNA sequence variation, differential RNA expression, and differential DNA methylation. Each approach alone implicates promising pathways and networks in the pathogenesis of disease. Prioritizing high value pathways from a large set of candidates can be difficult. To address this limitation, we performed an integrative analysis of genome wide association study (GWAS) as well as DNA methylation and RNA transcriptomics for cultured fibroblast-like synoviocytes (FLS). We then identified genes that found in at least two of these sets and evaluated whether they are enriched in the Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways.

Methods: Data were from three types of genome-wide RA assays: (i) for sequence variation we used the NCBI GWAS database and extracted all gene that mapped to SNPs that had been implicated in RA susceptibility (www.genome.gov/gwasstudies/); (ii) for gene expression we used public microarray datasets of RA, OA, and normal (NL) FLS lines (Gene Expression Omnibus Database (GSE 29746)); (iii) for DNA methylation we used a set of differentially methylated genes that we previously identified in 11 RA, 11 OA, and 6 NL FLS (Genome Medicine 5:40, 2013). We then overlapped the gene sets and identified those with two or three forms of evidence, termed the multi-evidence genes (MEGs). The significance of MEGs in KEGG human pathways was determined and resulting p-values represented the fraction of randomly selected background gene sets that were at least as enriched in genes found in the tested pathway as the DMG set. A q-value was calculated to correct for multiple comparisons and a threshold of 0.05 determined significance.

Results: 357 MEGs in RA FLS were identified for KEGG analysis. 14 out of 271 KEGG pathways were significantly enriched with MEGs. Perhaps most interesting, evaluation of MEGs identified a 3.88-fold enriched in the KEGG "rheumatoid arthritis" pathway (q = 1.4e-02) with 7 out 89 genes: ANGPT1, CSF2, CTLA4, HLA-DQA1, HLA-DQA2, HLA-DRA and HLA-DRB1. Involvement of this pathway strongly suggests that the MEGs are highly relevant to RA. At least four additional immunological pathways relevant to RA were also significantly enriched in the MEGs set. For example, the KEGG 'Cell adhesion molecules' pathway is 4.59-fold enriched (q = 2.00E-04) with 12 out of 129 genes in the MEGs set. The KEGG 'Cytokine-cytokine receptor interaction' pathway is 2.98-fold enriched (q =1.63e-03) with 15 out of 248 genes labeled in the MEGs set. The KEGG 'Antigen processing and presentation' pathway is 4.42-fold enriched (q =1.53e-02) with 6 out of 67 genes labeled as DMGs in the MEGs set. The KEGG 'Jak-STAT signaling pathway' pathway is 2.84-fold enriched (q =4.10e-02) with 8 out of 139 genes labeled in the MEGs set.

Conclusion: Pathway analysis demonstrates non-random identification of RA related genes through the integrative analysis of multiple genome-wide datasets. The identified genes and pathways, such as those involved with cytokines and Jak-STAT, are likely dysregulated in the disease and reflect the pathogenesis of disease. Therefore, genes identified in the pathways identified through integrative analysis could be novel targets for treatment of RA.

Background/Purpose: Human genetics has the potential to identify promising drug targets for complex traits such as rheumatoid arthritis (RA). Genes with a series of disease-associated functional alleles mimic the effect of pharmacological modulation, thereby allowing estimates of efficacy and toxicity before clinical trials in humans.

Methods: To search for genes with alleles that protect from RA susceptibility, we sequenced the protein-coding exons of 845 genes in 1,118 RA cases and 1,118 matched controls, and investigated excess of potentially damaging variants in controls compared to RA patients by gene-based association tests. We replicated findings at one gene, *TYK2*, by direct genotyping in two large datasets (9,372 RA cases and 18,868 controls). To investigate phenotypes that serve as proxies for potential adverse drug events, we performed a phenome-wide association study (PheWAS) with RA-associated *TYK2* variants and clinical data from electronic medical records (EMR).

Results: We demonstrate that multiple protein-coding variants in *tyrosine kinase 2* (*TYK2*), including variants reported to be loss-of function (LOF), independently protect from RA risk ($P=0.0018$ in sequencing, $P=1.6\times10^{-27}$ in replication genotyping). Using EMR clinical data from 3,102 individuals, we observe an enrichment of associations with *TYK2* LOF alleles for diagnoses related to infections.

Conclusion: Our findings identify a series of LOF alleles in *TYK2* that protect against RA and are associated with increased risk of clinical diagnoses that may be considered adverse drug events, suggesting that drugs that inhibit TYK2 may be an effective treatment in RA with predictable side effects.

The Importance Of Germinal Center-Like Structures In Primary Sjögren's Syndrome Salivary Glands Beyond Lymphoma Risk. Elke Theander[1], Thomas Mandl[2], Rolf Liedholm[3], Roland Jonsson[4], Malin V. Jonsson[4] and Gunnar Warfvinge[3]. [1]Lund University, Malmö, Sweden, [2]Skåne University Hospital Malmo, Lund University, Sweden, Malmö, Sweden, [3]Skåne University Hospital Malmö, Lund University, Malmö, Sweden, [4]University of Bergen, Bergen, Norway.

Background/Purpose: The association between germinal center (GC)-like structures and lymphoma in primary Sjögren's syndrome (pSS) has been demonstrated recently (1). Here we present a comprehensive analysis of associations between these GC-like structures in minor salivary glands and other disease characteristics.

Methods: One-hundred-and-sixty biopsies from pSS patients fulfilling the 2002 AECG criteria were evaluated by re-examining the original diagnostic minor salivary gland biopsies for the presence of ectopic lymphoid structures, defined as a densely packed dark zone and a less densely packed light zone in association with focal sialadenitis in otherwise normal glands. Demographic and disease characteristics were extracted from the Malmö pSS database. T-test and χ^2 statistics were applied as appropriate.

Results: Thirty-eight (23.8%) of 160 biopsies were GC-positive, with similar frequency in both genders. Age at diagnosis was slightly lower in GC-positive patients (48.3(12.9) vs 53.8(12.8) yrs respectively, ns. The frequency of anti-SSA/SSB antibodies was significantly higher in GC-positives (79% vs 61%, $p=0.045$), with a trend towards higher prevalence of RF. ANA frequency was similar. During follow-up systemic manifestations were reported cumulatively in 71% of GC-positive and 49% of GC-negative patients ($p=0.019$). The presence of additional autoimmune phenomena (presence of either autoimmune diseases such as thyroiditis, celiac disease, primary biliary cirrhosis, etc, or additional autoantibodies such as centromere, anti-DNA, anti-cardiolipin, anti-thyroid, etc, was overrepresented in GC-positives (50% vs 27%, $p=0.011$). As expected, GC-formation was associated with lymphoma development (12% vs <1%, $p=0.011$). There were no significant differences between GC-positive and GC-negative patients with regard to complement levels, IgG levels, or ESR.

Stimulated sialometry was significantly lower in patients with GC-like structures (2.40 (2.33) vs 3.39 (3.29) ml/5 min, $p=0.013$). Ultrasonography of major salivary glands demonstrated more often pSS typical hypoechoic lesions in those with GC-like structures (67% vs 35%, $p=0.012$). Other exocrine function tests such as unstimulated whole sialometry, Schirmer test and van Bijsterveld score resulted in trends towards more severe disease in GC-positives. No difference was demonstrated regarding subjective dryness.

Conclusion: Beyond being a strong predictor of lymphoma development, GC-like structures in minor salivary glands predict systemic disease manifestations and worse exocrine performance as well as higher grade of morphological destruction assessed by ultrasonography. The simultaneous presence of additional autoimmune phenomena may be a marker of general GC-formation not restricted to the salivary glands and thus characterize a separate pSS phenotype with potentially severe and complicated disease.

Prognostic Value Of Minor Salivary Gland Assessments In Primary Sjögren's Syndrome. Anna Risselada, A.A. Kruize, J.A.G. van Roon, F.P.J.G. Lafeber and J.W.J. Bijlsma. University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Salivary gland assessment is important for diagnosing primary Sjögren's syndrome (pSS), as the lymphocytic focus score (LFS) is part of pSS classification criteria. Quantitative immunohistology

(QIH) is another technique used for assessing pSS in which the percentage of immunoglobulin-specific plasma cells is measured, with IgA <70% and/or IgM >10% as positive criteria. Our objective was to investigate the prognostic value of minor salivary gland assessment (LFS and QIH) for disease severity of pSS.

Methods: Medical charts of all patients with pSS according to the 2002 classification criteria who attended our outpatient clinic for at least one year from 1998 to July 2011 were analyzed. In total, 174 patients had documented minor salivary gland histology and were included for this analysis. Histology results (LFS and percentages of IgA, IgM and IgG plasma cells) were compared with disease outcomes as non-Hodgkin lymphoma (NHL) and clinical scores: cumulative EULAR Sjögren's Syndrome disease activity index (ESSDAI) and the number of extraglandular manifestations (EGM) during disease course.

Results: Mean age at pSS diagnosis was 47 ± 14 years and median follow-up after biopsy was 105 months (range 10 – 408). LFS ≥1 were seen in 99%, <70% IgA-positive plasma cells in 90%, and >10% IgM-positive plasma cells in 71% of patients, respectively. The number of foci correlated to a decrease in the percentage of IgA-positive plasma cells (R=0.315, p=0.0001), but not to the percentage of IgM- or IgG-positive plasma cells.

NHL developed in 16 patients (9%). The mean LFS was significantly higher in patients with NHL (3.0 ± 0.9 versus 2.3 ± 1.1; p=0.021). The threshold of ≥3 foci had a positive predictive value of 16% for development of lymphoma, and a negative predictive value of 98% (OR 7.9; p=0,008). QIH results could not predict lymphoma development.

Only LFS ≥3 contributed significantly and independently to NHL development in a hierarchical multiple regression model, correcting for presence of anti-SSA/SSB antibodies (beta 0.244; p=0.017). Cumulative ESSDAI and EGM were significantly correlated to LFS, a decreased percentage of IgA-positive and an increased percentage of IgM-positive plasma cells (R range 0.166–0.284; p≤0.04), but not to the percentage of IgG-positive plasma cells.

Conclusion: Routinely performed minor salivary gland assessments have important prognostic value. The number of lymphocyte foci can be used to identify patients with increased lymphoma risk.

Acknowledgements: We would like to thank J.M. van Woerkom, R. Goldschmeding and the pathology department of the University Medical Center Utrecht for their work on the minor salivary gland assessments.

[1]Brest Occidentale university, Brest, France, [2]CHU de la Cavale Blanche, Brest, France, [3]Bicêtre University Hospital, Le Kremlin Bicetre, France, [4]Nantes University Hospital, Nantes, France, [5]Hôpital Sud, Rennes, France, [6]Internal Medicine, Lille CEDEX, France, [7]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France, [8]Cochin Hospital, Paris, France, [9]Strasbourg University Hospital, Strasbourg, France, [10]Internal Medicine, CHU Marseille, Marseille, France, [11]Amiens University Hospital, Amiens, France, [12]Bichat Hospital, Paris, France, [13]Lapeyronie Hospital, Montpellier, France, [14]Le Havre General Hospital, Le Havre, France, [15]CHU G.-Montpied, Clermont-Ferrand, France, [16]Brest Occidentale University, Brest, France, [17]Bicetre university hospital, LE Kremlin-Bicetre, France, [18]CHU Brest, Brest, France, [19]Université Brest Occidentale, Brest, France.

Background/Purpose: To calculate the sample sizes needed in future randomized controlled trials (RCTs) testing a therapeutic intervention in pSS, methodologists usually rely on data obtained from previous studies. To evaluate the reverse influence of each usual criteria on the number of patients needed to demonstrate the efficacy of rituximab in pSS, we have done a post hoc analysis on the multicenter, randomized, double-blind, placebo-controlled trial TEARS.

Methods: 122 Patients were assigned to receive either RTX infusions (1g) or placebo (P) at weeks 0 and 2. All patients fulfilled the new American-European Consensus Group criteria for pSS, had an active disease as assessed by mean values of the 2 highest visual analog scales (VAS) ≥50 evaluating dryness, pain, fatigue and global, and had either a recent and a biologically active pSS or at least one extra-glandular manifestation. Results concerning the primary end point (improvement of at least a 30 mm on 2 of 4 VAS) and secondary end points have shown a statistically improvement of the disease on global VAS score (continuous data) but not on the primary criteria and discrete variables, excepting VAS sicca). We also evaluated in a single centre (Brest, France) the echostructural changes (parotid and submandibular) using a semi-quantitative scoring (0 to 4). Here, we report the impact of various end points on the sample size calculated using EpiInfo. Analysis was made only when the proportion of patient improved in the RTX group was higher to the one obtained in the placebo group.

Results: The table shows the proportion of patients improved depending on the chosen cut-off of four VAS evaluating dryness, pain, fatigue and global disease or ultrasound and the number of patients needed to demonstrate a significant difference considering that the same proportions should be observed in a future study. At week 24, the more important clinical differences between the P group and the RTX group were observed with sicca VAS; the cut-off chosen between 20 or 30 mm gave quite similar results. ESSDAI improvement 'was observed in 9/54 (17%) in the P group vs 12/61 (20%) in the R group. Ultrasonographic changes seemed to be the most sensitive end point in terms of sample size needed to demonstrate an effect of RTX. Nevertheless, the US changes were not associated with the mean VAS improvement registered between W0 and W24 and the number of patient evaluated was low.

VAS improvement	≥10 mm P vs R; sample needed	≥20 mm P vs R; sample needed	≥30 mm P vs R; sample needed
Disease	18/53 (34%) vs 31/60 (52%) N: 258	13/53 (24%) vs 21/60 (35%) N: 574	12/53 (23%) vs 9/60 (15%)
Pain	21/54 (39%) vs 26/60 (43%) N: 4844	18/54 (33%) vs 15/60 (25%)	13/53 (24%) vs 8/60 (13%)
Fatigue	15/54 (28%) vs 29/60 (48%) N: 204	9/54 (17%) vs 17/60 (28%) N: 486	5/53 (9%) vs 11/60 (18%) N: 494
Sicca	15/53 (28%) vs 32/60 (53%) N: 136	11/53 (21%) vs 24/60 (40%) N: 204	6/53 (11%) vs 16/60 (27%) N: 212
Number of VAS improved ≥30 mm	**≥1**	**≥2**	**≥3**
	26/59 (44%) vs 30/63 (48%) N: 4972	16/59 (27%) vs 18/63 (29%) N: 16024	13/59 (22%) vs 12/63 (19%)
Improvement of the ultrasonographic grade	**≥1 grade**		
	1/14 (7%) vs 7/14 (50%) N: 42		

Conclusion: In future RCTs in pSS, ultrasound salivary gland changes could represent the most sensitive end point for pSS study, followed by sicca and fatigue. Nevertheless, ultrasound improvement was not associated with any clinical improvement. Change in a single VAS can be used but assesses only one domain of the patients's complaints. Change in ESSDAI could be the most logical end-point reflecting all the domains of activity of the disease but its change appeared low in the TEARS study.

Ultrasonographic Salivary Glands Response To Rituximab In Primary Sjögren Syndrome Patients In the Tolerance and Efficacy Of Rituximab In Primary Sjogren Syndrome Study Is Not Associated With The Anatomopathology Changes. Sandrine Jousse-Joulin[1], Valerie Devauchelle-Pensec[2], Divi Cornec[3], Simon Gestin[4], Luc Bressollette[3], Thierry Marhadour[5], Jacques-Olivier Pers[3], Emmanuel Nowak[4] and Alain Saraux[6]. [1]Brest university medical school, EA 2216, UBO and CHU de la Cavale Blanche,, Brest, France, [2]Brest Occidentale university, Brest, France, [3]Brest Occidentale University, Brest, France, [4]CHU Brest, Brest, France, [5]CHU de la Cavale Blanche, Brest, France, [6]CHU Brest et Université Bretagne Occidentale, Brest, France.

Background/Purpose: We conducted a multicenter, randomized, double-blind, placebo-controlled trial to evaluate the efficacy of Rituximab (RTX) in active pSS patients in France (TEARS study) and we evaluated, in a single centre (Brest, France), the echostructural and vascularisation changes in this population.

Methods: The TEARS study included pSS patients with scores above 50 mm on at least two of four visual analog scales (VASs) evaluating dryness, pain, fatigue, and global disease. They were randomly assigned (1:1) to RTX (1 g at weeks 0 and 2) or placebo (PBO). Patient had recent-onset (<10 years) biologically active pSS and/or systemic pSS. 28 pSS patients had ultrasonographic examination and a salivary gland biopsy before the first infusion (placebo or RTX) and at 24 weeks follow up. Both parotid and submandibular glands were assessed. The echostructure of each gland was scored using a semi quantitative scoring (0 to 4) (figure 1). We also evaluated the size of each glands and the vascularisation using the resistive index of the transverse facial artery of the parotid glands before and after stimulation with lemon juice. Concerning the echostructural scoring of each gland, we considered an improvement if the score of the glands was improved by one point or more and the comparison between the RTX and placebo group were obtained using the Fisher's exact test. Difference of size (mm) and resistive index before and after treatment (RTX or PBO) were evaluated using the non parametric Wilcoxon test.

Results: Parotid echostructural scoring was improved in 50% of pSS patients in the RTX group versus 7% in the placebo group (p=0.03). Table 1 shows the changes of grade before and after treatment in both RTX and PBO groups. The US submandibular scoring was also improved in 35% of pSS patients in the RTX group compared to 16% in the placebo but the difference was not statistically significant (p= 0.16). There were no changes concerning the size of each gland in RTX or placebo groups (figure 2). Regarding the modifications between week 0 and week 24 of lemon stimulation response, measured by resistive index variation before and after stimulation, the two groups were not different. 35 had a Chisholm score evaluation before and after treatment, 16 a focus score evaluation and 28 an ultrasound evaluation. At least one parotid gland had an improvement in 2/14 in the P group versus 7/14 in the R group. At least one submandibular gland had an improvement in 1/14 in the PBO group versus 7/14 in the R group (p: 0.03). Focus score was lower after treatment in 3/10 in both PBO and R groups. Similarly, 3/18 had an improvement of their Chisholm score in the P group versus 2/17 in the R group (NS). The concordance between both submandibular and parotid glands US score and focus score was low (kappa<0.1).

Conclusion: In our pSS population treated by RTX or PBO, ultrasound evaluation showed a more important improvement of the echostructure of the salivary glands in treated patients than in the placebo group. In contrast, RTX did not modify neither sizes of the salivary glands nor vascularisation inside the glands. Ultrasonographic improvement was not associated to anatomopathologic changes of the minor salivary gland labial biopsy.

B-Cell Depletion Modulates T-Helper Cell Balance In Patients With Primary Sjögren's Syndrome. WH Abdulahad[1], FGM Kroese[1], Gwenny Verstappen[2], MG Huitema[1], PM Meiners[1], A Vissink[1] and H Bootsma[1]. [1]University Medical Center Groningen, Groningen, Netherlands, [2]University of Groningen and University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: B-cell depletion therapy with a chimeric anti-human CD20 antibody (rituximab; RTX) is an effective treatment modality for patients with primary Sjögren's syndrome (pSS). However, the mechanisms through which RTX exerts its effects on pSS have not been fully elucidated. Alterations in T-helper (Th) cell homeostasis may contribute to the therapeutic effect of RTX as Th cell subset imbalances are involved in the emergence of autoimmune diseases. The current study assessed the influence of RTX on Th1/Th2/Th17 balance in peripheral blood of pSS patients.

Methods: Twenty-eight patients with pSS, diagnosed according to the American-European Consensus Group criteria, were treated on days 1 and 15 with RTX (1000 mg i.v.). The absolute numbers of circulating Th1/Th2/Th17 cell subsets were examined in fresh blood samples by 6-color flow cytometry at baseline and at 5, 16, 24 and 36 weeks after treatment. Expression patterns of chemokine receptors $CXCR3^+CRTh2^-CCR4^-CCR6^-$, $CXCR3^-CRTh2^+CCR4^+CCR6^-$ and $CXCR3^-CRTh2^-CCR4^+CCR6^+$ were used for distinction between Th1, Th2 and Th17, respectively. In addition, numbers of Th1/Th2/Th17 cells were analyzed based on their associated cytokines IFNg/IL-4/IL-17 upon *in vitro* stimulation of thawed PBMCs. Sixteen matched healthy individuals were studied in parallel as controls (HCs).

Results: At baseline, compared to HCs, pSS patients showed a significant decrease in numbers of circulating Th1-cells, and a significant increase in Th17-cells. In contrast, no differences were seen in numbers of Th2 cells between HCs and pSS patients. Following RTX treatment, numbers of circulating Th1 and Th2 subsets in pSS patients at 5, 16 and 24 weeks were comparable to their baseline values, whereas a significant decrease was observed in Th17 cells at week 5 post-treatment. Importantly, RTX treatment induced a significant decrease in number of IL-17 producing Th-cells at weeks 16 and 24 as compared to baseline, whereas IFNg and IL-4 producing Th-cells remained unchanged. Importantly, numbers of IL-17 producing Th-cells increased again and reached their baseline value by 36 weeks post RTX-treatment. This coincides with a reconstitution of B cells in peripheral blood of pSS patients.

Conclusion: B cell depletion therapy in pSS influences Th cell homeostasis affecting Th17 cells in particular. Recovery of Th17 cells coincides with B cell repopulation indicates that B cells modulate the pro-inflammatory Th17 responses. Reduction in Th17 responses post RTX-treatment may contribute to the observed clinical outcome of RTX in pSS patients.

Clinical Characteristics of Rheumatoid Arthritis Patients with Secondary Sjögren's Syndrome and Association with Joint Damage. Lindsay E. Brown[1], Michelle A. Frits[2], Christine K. Iannaccone[2], Michael E. Weinblatt[2], Nancy A. Shadick[2] and Katherine P. Liao[2]. [1]Massachusetts General Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Secondary Sjögren's syndrome (sSS) is a common extra-articular manifestation of rheumatoid arthritis (RA). However, the clinical characteristics of this subgroup of patients are not well characterized. In addition, whether sSS is associated with worse outcomes such as joint damage remains unclear. This study aims to characterize sSS patients in an RA cohort and determine whether there is an association between sSS and worse joint damage.

Methods: We conducted a cross-sectional study in an observational cohort of RA patients at a large academic center. We included all subjects with >=1 year of follow-up. Subjects with comorbid diseases, which can also result in sicca symptoms, e.g. sarcoidosis, viral hepatitis,HIV/AIDS, were excluded from the analysis. Subjects were considered to have sSS if they were reported as having sSS by their rheumatologist at recruitment into the cohort (baseline) and had the diagnosis confirmed by manual chart review. Fifty subjects without sSS were also reviewed to determine the negative predictive value (NPV) of having no sSS reported at baseline. The primary outcome was Sharp scores associated with bilateral hand radiographs at baseline. We conducted univariate analyses on potential clinical variables associated with sSS, e.g. age, gender, race, ACPA or RF positivity, DAS28-CRP, methotrexate and anti-TNF use at baseline. We constructed a linear regression model to determine the association of sSS status and baseline Sharp score, adjusted by age, gender, RA disease duration and variables significant from the univariate analyses.

Results: We studied 829 RA subjects, mean age was 57 years, 83% female, mean RA duration 13 years, 63% ACPA positive; fifty-seven subjects (7%) had sSS (the NPV of not having sSS if not reported at baseline was 100%). We observed a female predominance (98%) and a significantly higher

percentage of African-Americans subjects (10%) with sSS than the general RA cohort; subjects with sSS also had a significantly higher DAS28-CRP at baseline in the univariate analysis (**Table 1**). Having sSS at baseline was associated with higher Sharp scores (p=0.01), adjusted for age, gender, disease duration and variables significant from the univariate analyses (African American race, RF positive, baseline DAS28-CRP) (**Table 2**).

Table 1. Clinical characteristics of subjects with Secondary Sjögren's Syndrome (sSS) in the RA cohort (n=829).

Clinical characteristics	sSS, n=57 (6.9%)	No sSS, n=772 (93.1%)	p-value
Age, mean yrs (SD)	57.2 (10.5)	56.9 (13.7)	0.869
Female gender (%)	98.3	81.4	0.001
Disease duration, mean yrs (SD)	16.1 (10.8)	13.5 (12.4)	0.13
Race (%)			
Caucasian	84.2	93.7	0.004
African American	10.5	3.8	0.02
ACPA positive (%)	70.4	61.7	0.20
RF positive (%)	80.0	62.1	0.008
Baseline DAS28-CRP, mean (SD)	4.36 (1.7)	3.89 (1.6)	0.03
Baseline Sharp score, median (IQR)	48.0 (82.0)	17.0 (61.0)	0.002
Anti-TNF at baseline, %	45.6	35.8	0.14
MTX at baseline, %	57.9	46.3	0.10

Table 2. Association between sSS at baseline and joint damage (as measured by Sharp scores*).

Clinical variable	Beta coefficient (SE)	p-value
Age, yrs	0.02 (0.007)	0.18
Female gender	−0.13 (0.23)	0.62
Disease duration, yrs	0.04 (0.007)	<.0001
African-American race	−0.78 (0.32)	0.02
RF positivity	0.76 (0.19)	<.0001
Baseline DAS28-CRP	0.18 (0.05)	0.0003
Presence of sSS	**0.43 (0.17)**	**0.01**

*Sharp scores were non-normally distributed and were categorized into quintiles (Q1: <1, Q2: ≥1 and <10, Q3: ≥10 and <32.5, Q4: ≥32.5 and <81.5, Q5: ≥81.5 units)

Conclusion: In our RA cohort, sSS affected a significantly higher proportion of women and African Americans than the overall cohort. RA subjects with sSS had worse joint damage, suggesting that sSS may a marker of more aggressive disease.

Prevalence Of Structural Lesions Seen On MRI-Spine In Patients With (Possible) Axial Spondyloarthritis (axSpA) Included In The SPACE-Cohort. Manouk de Hooge[1], Rosaline van den Berg[1], Victoria Navarro-Compán[1], Monique Reijnierse[1], Floris van Gaalen[1], Karen Fagerli[2], Maureen C. Turina[3], Maikel van Oosterhout[4], Roberta Ramonda[5], Tom Huizinga[1] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [4]GHZ Hospital, Gouda, Netherlands, [5]University of Padova, Padova, Italy.

Background/Purpose: Little is known about the prevalence of structural lesions (erosions, syndesmophytes, fatty lesions) on MRI of the spine (MRI-spine) in patients with chronic back pain. Therefore the purpose of our study was to investigate the prevalence of structural lesions on MRI-spine in patients with chronic back pain.

Methods: Patients with back pain (≥3 months, ≤2 years, onset <45 years) recruited from 5 participating centres in Europe were included in the SPondyloArthritis Caught Early (SPACE)-cohort. Patients underwent MRI-spine scored independently by 3 blinded, well-calibrated readers for presence of erosions, fatty lesions and (bridging) syndesmophytes on T1-weighted images (STIR images viewed simultaneously). Fatty lesions suggestive of spondylitis were scored when visible on ≥2 consecutive slices. For erosions and syndesmophytes, suggestive of spondylitis, the presence on ≥1 slice was sufficient. Agreement of 2/3 readers was used. The prevalence of structural lesions was calculated based on several cut-offs.

Results: All patients with complete MRI-spine data were included for analysis (n=306). All patients were grouped according to the ASAS axSpA criteria; imaging arm (fulfilling the modified New York criteria (mNY+) and not fulfilling the modified New York criteria (mNY-)) and clinical arm, possible SpA (patients not fulfilling the ASAS axSpA criteria but with 1 SpA feature with a LR+ of ≥6 or 2 SpA features with a LR+ <6) and no-axSpA. Prevalence of fatty lesions was the highest of all structural lesions in the spine in all subgroups. With a cut-off of ≥3 fatty lesions, the 'false-positive' rate in the no-axSpA group was low (6.5%) with still a considerable prevalence in the imaging and radiographic axSpA groups. The prevalence of erosions and syndesmophytes was generally low (see the table).

	ASAS axSpA, n=126				
	Imaging-arm				
	mNY+ n=26	mNY− n=46	Clinical-arm, n=54	Possible axSpA, n=116	No-axSpA, n=64
Fatty lesions ≥1	9 (34.6%)	18 (39.1%)	8 (14.8%)	19 (16.4%)	8 (12.5%)
Fatty lesions ≥2	5 (19.2%)	14 (30.4%)	6 (11.1%)	12 (10.3%)	7 (10.9%)
Fatty lesions ≥3	4 (15.4%)	11 (23.9%)	3 (5.6%)	10 (8.6%)	3 (4.7%)
Fatty lesions ≥4	4 (15.4%)	9 (19.6%)	2 (3.7%)	5 (4.3%)	2 (3.1%)
Fatty lesions ≥5	4 (15.4%)	7 (15.4%)	2 (3.7%)	4 (3.4%)	2 (3.1%)
Fatty lesions ≥6	3 (11.5%)	5 (10.9%)	2 (3.7%)	3 (2.6%)	2 (3.1%)
Fatty lesions ≥7	3 (11.5%)	4 (8.7%)	2 (3.7%)	3 (2.6%)	2 (3.1%)
Erosions ≥1	5 (19.2%)	11 (23.9%)	9 (16.7%)	20 (17.2%)	10 (15.6%)
Erosions ≥2	2 (7.7%)	6 (13.0%)	5 (9.3%)	10 (8.6%)	7 (10.9%)
Erosions ≥3	1 (3.8%)	2 (4.3%)	2 (3.7%)	3 (2.6%)	4 (6.3%)
Erosions ≥4	0	1 (2.2%)	0	3 (2.6%)	0
Erosions ≥5	0	0	0	1 (0.9%)	0
Syndesmophyt ≥1	5 (9.3%)	10 (21.7%)	1 (3.8%)	17 (14.7%)	7 (10.9%)
Syndesmophyt ≥2	1 (1.9%)	2 (4.3%)	0	8 (6.9%)	3 (4.7%)
Syndesmophyt ≥3	1 (1.9%)	0	0	2 (1.7%)	2 (3.1%)

Conclusion: The prevalence of fatty lesions on MRI-spine is the highest of any structural lesions in all subgroups. Fatty lesions with a cut-off of '3 are primarily present in patients fulfilling the ASAS axSpA criteria, infrequent in possible axSpA patients and no-axSpA patients. Erosions and syndesmophytes in the spine are equally present in all groups. Fatty lesions are the only type of structural lesions that can potentially discriminate between patients with and without axSpA.

Erosions and Sclerosis, But Not Squaring, Predict The Development Of New Syndesmophytes: A 12-Year Longitudinal Analysis (OASIS). Sofia Ramiro[1], A.M. van Tubergen[2], Désirée van der Heijde[3], Carmen Stolwijk[2], Maxime Dougados[4], Filip Van den Bosch[5] and Robert Landewé[6]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France, [5]Gent University Hospital, Gent, Belgium, [6]Academic Medical Center Amsterdam & Atrium Medical Center, Heerlen, Netherlands.

Background/Purpose: Erosions, sclerosis and squaring are included in the modified Stoke Ankylosing Spondylitis (AS) Spine Score (mSASSS). However, their value in predicting the development of new syndesmophytes has not been established, and their value in the mSASSS has been argued. We aimed at analysing the effect of erosions, sclerosis and squaring on the development of new syndesmophytes over 12 years.

Methods: Biannual radiographs from patients with AS (mNY criteria) followed in OASIS (up to 12 years) were included. Two readers (R1 and R2) independently scored the x-rays according to the mSASSS and separately registered all the items with a score of 1 (erosions, sclerosis and squaring, or any combination) per vertebral corner (VC). The progression from erosions, sclerosis and squaring to new (bridging) syndesmophytes (either score of 2 or

3 in the mSASSS) in a 2-year period and over the 12 years was investigated by means of a multilevel (adjusted for time, reader and cervical/lumbar spinal region) auto-regressive and time-lagged longitudinal model, using generalized estimating equations. Interactions with reader and spinal region were investigated.

Results: 211 patients were included in this analysis (mean age 43 (SD 13) years old, 71% male, 85% HLA-B27 positive, 11.5 (SD 9.1) years since diagnosis and 20.5 (SD 11.6) years since symptom onset, 4.4 (SD 1.8) radiographs per patient). A total of 921 radiographs were included in this analysis, with a total of 20509 VCs (R1) and 20568 VCs (R2) evaluable. Of these, erosions were scored in 1% for R1 (2.5% R2), sclerosis in 0.3% for R1 (1.7% R2), squaring in 6.5% for R1 (5.1% R2) and syndesmophytes in 25% for R1 (27% R2). The presence of erosions, sclerosis and squaring together had, compared with a normal VC, a risk for the development of new syndesmophytes over a 2-year period of 2.0 (Table). There was a significant interaction with 'spinal region' (OR cervical spine: 3.1; OR lumbar spine: 1.3). There was no significant difference between the readers. Separately, the presence of erosions or the presence of sclerosis, but not the presence of squaring, gave an increased risk for new syndesmophytes, Squaring was predictive of the development of new syndesmophytes in the cervical spine only (Table).

Table. Longitudinal effect (GEE) of erosions, sclerosis and squaring on the development of new syndesmophytes over 12 years (adjusted for spinal region and reader)

		Multivariable GEE models with syndesmphytes as the outcome* OR (95% CI)	Same model, but with results stratified for spinal region or reader if significant interactions OR (95% CI)
	Factor: Erosion, sclerosis and/or squaring (score of 1 in mSASSS)	2.0 (1.7–2.3)	
Stratification	*- Cervical spine*		*3.1 (2.5–3.9)*
	- Lumbar spine		*1.3 (1.0–1.6)*
	- Reader 1		*No significant interaction*
	- Reader 2		
	Factor: Erosions	2.1 (1.6–2.8)	
Stratification	*- Cervical spine*		*No significant interaction*
	- Lumbar spine		
	- Reader 1		*No significant interaction*
	- Reader 2		
	Factor: Sclerosis	5.1 (3.9–6.8)	
Stratification	*- Cervical spine*		*No significant interaction*
	- Lumbar spine		
	- Reader 1		*15.3 (9.2–25.5)*
	- Reader 2		*3.9 (2.8–5.5)*
	Factor: Squaring	1.3 (1.0–1.6)	
Stratification	*- Cervical spine*		*8.5 (2.1–34.7)*
	- Lumbar spine		*1.1 (0.8–1.4)*
	- Reader 1		*1.6 (1.2–2.1)*
	- Reader 2		*1.0 (0.6–1.4)*

* Adjusted for spinal region and reader (each row reflects the OR for main predictor of the model, all different models).

Conclusion: Erosions and sclerosis occur rarely on X-rays, but if so, are predictive for the development of new syndesmophytes. Therefore, these lesions not only seem to precede the development of syndesmophytes, but are also correctly included in the mSASSS. The possibility of excluding squaring from the mSASSS in the lumbar spine may be considered.

2886

Prevalence Of Structural Lesions On MRI Of The Sacroiliac Joints In Patients With Early Axial Spondyloarthritis and Patients With Back Pain. Rosaline van den Berg[1], Manouk de Hooge[1], Victoria Navarro-Compán[1], Monique Reijnierse[1], Floris van Gaalen[1], Karen Fagerli[2], Maureen Turina[3], Maikel van Oosterhout[4], Roberta Ramonda[5], Tom Huizinga[1] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [4]GHZ Hospital, Gouda, Netherlands, [5]University of Padova, Padova, Italy.

Background/Purpose: Little is known about the prevalence of structural lesions on MRI in the SI joints (MRI-SI) in recent onset axial spondyloarthritis (axSpA) patients and patients with back pain of other origin. Therefore, we investigated the prevalence of structural lesions on MRI-SI in these patients.

Methods: Patients with back pain (≥3 months, ≤2 years, onset <45 years) from the 5 centers the SPondyloArthritis Caught Early (SPACE)-cohort were included. Patients underwent MRI-SI. Available MRIs-SI were scored by 3 well-calibrated readers independently for ankylosis, sclerosis, erosions, and fatty lesions (MRI T1-weighted images; STIR images viewed simultaneously). Erosions, sclerosis and fatty lesions were defined according to the MORPHO definition[1] (≥1 lesion on ≥2 consecutive slices or ≥2 lesion on 1 slice); ankylosis as 1 lesion on ≥1 slice. Lesions were considered present if 2/3 readers agreed. Prevalence based on several cut-offs of structural lesions was calculated. Patients were grouped according to the ASAS axSpA criteria[2][imaging-arm (mNY+, mNY-), clinical arm], no-SpA and possible SpA.

Results: Patients with MRI-SI data were included (n=299). If defined as ≥1, all structural lesions except ankylosis were frequent in all groups; in decreasing frequency in mNY+, MRI+mNY-, clinical arm, possible SpA and no-SpA (table). The higher the cut-offs, the better discrimination between the imaging-arm and no/possible SpA, with the clinical arm close to no/possible SpA. To define a proper cut-off for the presence of structural lesions in axSpA, the false-positive percentage in no-SpA patients should be low. We defined possible cut-offs based on the acceptance of ≤10% (italics) and ≤5% (bold) false-positives (table). E.g. if ≥4 structural lesions are present, false-positives are 6.0% and 5.2% respectively, with a frequency of 61.5% and 43.5% in the mNY+ and MRI+mNY- subgroups.

	AxSpA (ASAS), n=123

Any structural lesion, no sclerosis ≥5, n (%)	**16 (61.5)**	**19 (41.3)**	**4 (7.8)**	**4 (3.4)**	**1 (1.7)**

Italics represents ≤10% false-positives in the group of no SpA patients. **Bold** represents ≤5% false-positives in the group of no SpA patients

Conclusion: Prevalence of erosions, sclerosis and fatty lesions on MRI-SI is high in axSpA patients but also in no-SpA patients. Higher cut-offs than ≥1 lesion are needed to reduce false-positives; also with higher cut-offs structural lesions are frequent in early axSpA patients. These data suggest that with appropriate cut-offs, structural lesions might be helpful in defining sacroiliitis on MRI.

The Spondyloarthritis Research Consortium Of Canada MRI Sacroiliac Joint Structural Score: A Method For Reliable Detection Of Structural Progression. Walter P. Maksymowych[1], Stephanie Wichuk[1], Praveena Chiowchanwisawakit[2], Robert GW Lambert[1] and Susanne Juhl Pedersen[3]. [1]University of Alberta, Edmonton, AB, [2]Mahidol University, Bangkok, Thailand, [3]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark.

Background/Purpose: With increasing focus on effective treatment intervention in early spondyloarthritis, there is an unmet need for reliable assessment of structural progression in the sacroiliac joints (SIJ) but radiography is unreliable for detecting change and lacks responsiveness. There has been limited validation of MRI-based scores for structural lesions in the SIJ, primarily based on cross-sectional data and recording fat metaplasia, but it is unclear whether change in structural progression can be reliably detected and change in which specific MRI lesions is most consistently detected over time.

Methods: The SPARCC SIJ Structural Score (SSS) method for assessment of structural lesions on T1WSE MRI scans is based on: 1. Standardized and validated definitions (MORPHO) for fat metaplasia, erosion, backfill, and ankylosis, 2. Anatomical matching of all time points according to the transitional semi-coronal SIJ slice, defined as the first slice in the cartilaginous portion that has a visible portion of the ligamentous joint when viewed from anterior to posterior, 3. Dichotomous scoring (present/absent) of lesions in SIJ quadrants (fat, erosion) or halves (backfill, ankylosis) using a direct online data entry system based on schematics of the SIJ, 4. Assessment of 5 consecutive slices from the transitional slice anteriorly through the cartilaginous portion of the joint. Scoring ranges are: fat metaplasia (0–40), erosion (0–40), backfill (0–20), ankylosis (0–20). Four readers independently assessed 20 pairs of MRI scans from 20 cases (baseline, 2 years) blinded to time point (exercise 1). In exercise 2, 15 pairs of scans from exercise 1 were randomly scored with an additional 30 new pairs of scans from 30 cases (baseline, 2 years) to assess consistency of change in reliability data. This nested study design addresses the limitation for assessment of reliability posed by differences in progression rates between different study samples since changes in progression are typically small. Inter-observer reliability was assessed by intra-class correlation coefficient (ICC3,1).

Results: Mean (SD) for baseline scores were 3.4(4.0), 3.1(3.4), 3.7(4.3), and 5.3(7.9) for fat, erosion, backfill and ankylosis, respectively. Corresponding mean (SD) change scores were 0.2 (1.4), −1.3 (2.1), 0.5 (2.5), and 0.1(1.1). Consistently very good reliability was observed for detection of 2-year progression in ankylosis. Consistently good reliability was also evident for detection of change in backfill. Reliability was least consistent for detection of change in erosion.

Table. ICC [95% CI] values

		Fat metaplasia		Erosion		Backfill		Ankylosis	
	Readers	Status		Change		Status		Change	
Exercise 1 (n = 20)	All	0.72 [0.54–0.86]		0.68 [0.49–0.84]		0.60 [0.39–0.79]		0.59 [0.38–0.78]	
	N = 15*	0.71 [0.49–0.87]		0.59 [0.34–0.81]		0.67 [0.43–0.85]		0.61 [0.37–0.82]	
Exercise 2 (n = 45)	All	0.78 [0.69–0.86]	0.86 [0.74–0.93]	0.44 [0.29–0.60]	0.76 [0.34–0.76]	0.62 [0.49–0.75]	0.98 [0.96–0.99]	0.39 [0.24–0.56]	0.64 [0.65–0.90]
	N = 15*	0.80 [0.62–0.92]	0.90 [0.79–0.86]	0.42 [0.16–0.70]	0.72 [0.51–0.88]	0.53 [0.28–0.78]	0.98 [0.95–0.99]	0.32 [0.07–0.63]	0.84 [0.70–0.94]
			0.79 [0.53–0.77]		0.56 [0.41–0.69]		0.98 [0.97–0.99]		0.98 [0.51–0.76]
			0.76 [0.57–0.90]		0.58 [0.33–0.80]		0.97 [0.94–0.99]		0.84 [0.70–0.94]

* Cases read in both exercises

Conclusion: The SPARCC MRI SSS method is a reliable scoring method for detecting structural progression, especially ankylosis, even though progression is small.

Frequent Detection Of Inflammation and Fat Infiltration Suggestive Of Spondyloarthritis On MRI Of The Entire Spine In Healthy Subjects and Patients With Mechanical Back Pain. Ulrich Weber[1], Zheng Zhao[2], Veronika Zubler[1], Stanley Chan[3], Robert GW Lambert[3], Mikkel Ostergaard[4], Susanne Juhl Pedersen[5], Kaspar Rufibach[6] and Walter P. Maksymowych[3]. [1]Balgrist University Hospital, Zurich, Switzerland, [2]Department of Rheumatology, University of Alberta and PLA General Hospital, Beijing, PR China, Beijing, China, [3]University of Alberta, Edmonton, AB, [4]Copenhagen Center for Arthritis Research, Glostrup, Denmark, [5]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [6]rePROstat, Basel, Switzerland.

Background/Purpose: Mechanical back pain (MBP) patients and healthy subjects may show spinal MRI lesions suggestive for spondyloarthritis (SpA) such as corner inflammatory lesions (CIL) or corner fat lesions (CFL). There are few data about their frequency and whether they may result in a false positive classification of controls as having SpA. We aimed to assess the frequency of false positive classification as SpA in controls consisting of MBP patients and healthy volunteers, and to evaluate which MRI lesion type had the highest impact on misclassification.

Methods: The study sample comprised 2 independent cohorts A/B of 130 consecutive patients with back pain ≤50 years newly referred to 2 university clinics, and 20 healthy controls (HC). Patients were classified according to clinical examination and pelvic radiography as having non-radiographic SpA (nr-axSpA; n=50), ankylosing spondylitis (AS; n=33), or MBP (n=47). Age-matched healthy controls in cohort A were recruited according to the Nordic Questionnaire from hospital staff of the same clinic that also recruited the SpA patients. Spinal MRI scans were assessed by 4 blinded readers according to the Canada-Denmark MRI definitions for spinal lesions [1, 2]. Bone marrow edema (BME) and fat infiltration (FI) were reported in the central and lateral compartment of 23 discovertebral units. Readers recorded presence/absence of SpA and their level of confidence in this conclusion by global evaluation of the MRI scans (T1SE and STIR sequences) on a 0–10 scale (0 = definitely not SpA; 10 = definite SpA). The mean number (percentage) of controls misclassified as having SpA by ≥1 of 4 readers and the principal spinal lesions indicative of SpA were analysed descriptively

Results: 33.9%/28.0% of MBP patients in cohorts A/B, and 26.3% of healthy subjects in cohort A were misclassified as having SpA by global assessment of MRI of the entire spine. Both BME and FI in varying percentages were the most important MRI lesions leading to this misclassification. The mean number of CIL and CFL observed in controls was lower than in SpA patients.

Mean percentage of false positive controls, principal MRI lesions responsible for misclassification, and mean number for CIL and CFL on spinal MRI in cohort A/B.

	Cohort A (n=62)				Cohort B (n=88)		
Cohort Group	nr-axSpA	AS	MBP	HC	nr-axSpA	AS	MBP
Number of subjects	19	9	14	20	31	24	33
Classification as SpA (%) Confidence range 5–10	51.3	72.2	33.9	26.3	48.4	72.9	28.0
BME most important (%)	79.5	76.9	52.6	52.4	23.3	47.1	16.2
FI most important (%)	17.9	23.1	26.3	23.8	66.7	45.7	62.2
CIL (mean)	3.4	6.4	1.3	1.4	2.2	4.1	0.9
CFL (mean)	3.9	6.8	3.2	2.8	6.5	14.3	3.0
Classification as SpA (%) Confidence range 8-10	35.5	55.6	14.3	7.5	31.5	62.5	10.6

Conclusion: 26% to 34% of healthy controls and patients with MBP were misclassified as having SpA by evaluation of MRI of the spine alone. Misclassifications with high confidence ranged from 8% to 14%. Caution is warranted if a classification of SpA is based on MRI of the spine alone.

Bone Marrow Edema and Structural Lesions In The Sacroiliac Joint In a Large Cohort Of Patients With Axial Spondyloarthritis, Chronic Low Back Pain and Healthy Controls. L. van Hoeven[1], J.J. Luime[1], P.D.M. de Buck[2], J.M.W. Hazes[1] and A.E.A.M. Weel[3]. [1]Erasmus University Medical Center, Rotterdam, Netherlands, [2]MC Haaglanden, Den Haag, Netherlands, [3]Maasstad Hospital, Rotterdam, Netherlands.

Background/Purpose: MRI of the sacroiliac joint (SIJ) is included in the ASAS classification criteria for axial spondyloarthritis (axSpA) to identify patients at an earlier stage of the disease. However, the diagnostic utility is discussed since there are only few MRI data of patients with chronic low back pain and healthy populations. Therefore, we investigated the frequencies of bone marrow edema (BME) and structural lesions (SL) in a large cohort of axSpA patients, chronic low back pain (CLBP) patients and healthy controls (HC). Furthermore, to assess the added value of structural lesions for the sensitivity of a MRI of the SIJ (MRI-SIJ).

Methods: A cross-sectional study (CaFaSpA 2) was set up among primary care patients with CLBP aged 18–45 years (n=579) and healthy controls (n=79). The healthy controls were oversampled towards physical active controls and therefore included 25 runners. Also 4 women with pregnancy related pelvic pain were included. In all participants a MRI-SIJ was obtained. MRIs-SIJ were scored by one out of two experienced radiologist, blinded for clinical status. MRI evaluation followed ASAS recommendations for BME and SL, (ankylosis, sclerosis, erosions and fatty lesions).[1] The outcome was reported by descriptive statistics. To analyze the added value of SL as a MRI positive feature we tested the sensitivity and specificity.

Results: 95 out of 579 CLBP patients fulfilled the ASAS classification criteria for axSpA.[2] BME was observed in 71% of the axSpA patients, in 5% of the CLBP patients and in 14% of the HC. This resulted in a sensitivity of 71% and a specificity of 95%. No relationship between physical activity or pregnancy related back pain and BME frequency was observed.

The frequencies of structural lesions were 25%, 7%, and 8% for respectively, axSpA patients, CLBP patients and HCs. The sensitivity of the MRI, based only on the presence of BME, is 71%, with a 95% specificity. Adding the structural lesions as an MRI positive feature would increase the sensitivity to 84%, with a slight decrease in specificity, 88%.

Table 1. Patients characteristics and frequencies of BME and structural lesions (SL) on MRI-SIJ

	ASAS aSpA patients (n=95)			CLBP patients (n=484)	Healthy controls (n=79)
	Radiographic SpA (n=24)	Nonradiographic SpA (n=71)	Total (n=95)		
Male n (%)	6 (25)	36 (42)	36 (38)	202 (42)	33 (42)
Age yrs (sd)	38.6 (5.8)	36.8 (6.6)	37.3 (6.5)	35.8 (7.1)	36.9 (7.4)
CLBP duration yrs (sd)	9.3 (9.9)	9.6 (7.4)	9.5 (8.1)	9.2 (7.7)	NA
BME n (%) *	8 (33)	59 (83)	67 (71)	24 (5)	11 (14)
SL n (%) °	16 (67)	8 (11)	24 (25)	36 (7)	6 (8)
BME or SL n (%)	19 (79)	61 (86)	80 (84)	57 (12)	15 (19)

*BME lesion present on at least two consecutive slices or more than one signal on a single slice.
° Fat depositions, sclerosis, erosions or ankylosis.

Conclusion: Bone marrow edema on MRI will be seen in 5% to 14% of the chronic low back pain patients and healthy controls. Structural lesions will be seen in 7% to 8% of these populations. The added value of structural lesions in diagnosing axSpA is promising, since it increases the sensitivity and therefore facilitates the diagnostic utility of MRI-SIJ.

Novel Selective Inhibitors Of Nuclear Export (SINE) Decrease Type I Interferon Activation and Deplete Autoreactive Plasma Cells In The Kidney In Murine Lupus. Teresa Owen[1], Javier Rangel-Moreno[1], Boris Klebanov[2], Yosef Landesman[2], Michael Kauffman[2], Sharon Shacham[2] and Jennifer H. Anolik[1]. [1]University of Rochester Medical Center, Rochester, NY, [2]Karyopharm Therapeutics Inc., Natick, MA.

Background/Purpose: There is great interest in developing new treatment approaches for SLE, but the biologic therapies under investigation over the past several years have yielded disappointing results. SINE are orally available, well tolerated XPO1 (Exportin 1/CRM1) antagonists that are in human phase 1 clinical trials and show potent activity and tolerability in hematologic malignancies. We hypothesized that SINE would be efficacious in murine lupus through the combined targeting of interferon alpha production by plasmacytoid dendritic cells (pDCs) and autoantibody production by plasma cells (PCs).

Methods: Nephritic NZB/W F1 lupus-prone female mice, with elevated serum anti-dsDNA antibodies and established proteinuria, were treated with the SINE KPT-251 or vehicle control by oral gavage (n=9 per group). Proteinuria was monitored, and kidney histology assessed (0–4+ scale). Spleen, bone marrow (BM), and kidney were harvested, cells analyzed by flow cytometry, and antibody secreting cells (ASCs) enumerated by ELIspot. Serum samples and RNA were collected for Luminex assay and qPCR. Effects on pDC production of IFN were assessed using in-vitro cultures with BM cells stimulated with CpG 2216 10ng/ml for 5 hours.

Results: SINEs inhibit the production of IFN alpha by pDCs in a dose dependent fashion: pDC% positive for IFN no drug 10.5%, 3.125 uM 12.1%, 6.25 um 9%, 12.5 um 3.8%, and 25 uM 1.2%. IFN regulated chemokines in the serum of SINE treated lupus mice were decreased (MCP-1: 250+/−290 pg/ml vehicle vs. 54+/−26 pg/ml SINE, p=0.049), as was the PC survival factor IL6 (192+/−50 pg/ml vehicle vs. 11+/−23 pg/ml SINE, p=0.045). SINEs prevented nephritis progression with a statistically significant reduction in urine protein levels in the treated group ($p<0.05$ beginning at 5 weeks) and significantly reduced both IgG and anti-DNA ASCs in the spleen (81% reduction for anti-DNA, p=0.0048) and BM (63% reduction for anti-DNA, p=0.07). In the spleen, GC B cells (PNA+FAS+) and T follicular helper cells (CD4+CXCR5+ICOS+PD1+) were dramatically reduced (p =0.0016 and p=0.0051, respectively). Moreover, nephritis was improved histologically (GN score 3.3+/−1.2 vehicle vs. 1.0+/−0 SINE; lymphoid infiltrate score 1.3+/−0.6 vehicle vs. 0+/− SINE). There was also a dramatic reduction in autoreactive PCs in the kidney (98% reduction for anti-DNA, $p<0.0001$). We are presently examining the kidney tissue for IFN regulated genes and PC survival factors.

Conclusion: The combined reduction in IFN activation, GCs, and autoreactive plasma cells suggests that SINEs alter both the generation of PCs and the kidney PC niche with beneficial effects on nephritis. The mechanisms underlying these effects, including potential inhibition of NFkB signaling, are under investigation.

Loss Of Caspase 8 Exacerbates Dendritic Cell Activation In a MyD88- and RIPK1-Dependent Manner That Is Controlled By Inhibitory Molecules Transcribed By IRF3. Carla M. Cuda[1], Alexander V. Misharin[2], Rana Saber[2] and Harris R. Perlman[2]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University, Chicago, IL.

Background/Purpose: Previous studies implicate dendritic cells (DCs) in the initiation and persistence of systemic lupus erythematosus (SLE). While DCs from SLE patients exhibit elevated activation, the factors responsible remain unknown. To this end, we recently identified that caspase 8, an enzyme known to initiate apoptosis and/or suppress necroptosis (by inhibition of RIPK signaling) in a multitude of cells, is a novel DC-specific inhibitor of inflammatory processes independent of DC survival.

Methods: Mice lacking caspase 8 specifically in DCs were generated ($Cre^{CD11c}Casp8^{flox/flox}$). $Cre^{CD11c}Casp8^{flox/flox}$ mice were also crossed with $MyD88^{flox/flox}$, $IRF3^{-/-}$ or $IRF7^{-/-}$ mice to determine the role of these molecules in disease development. Flow cytometric analysis was used to characterize DC populations in mixed bone marrow chimeras and BrdU pulse assays. Bone marrow derived DCs were cultured with TLR agonists +/− necrostatin-1 (RIPK1 inhibitor), 1MT (indoleamine 2,3-dioxygenase (IDO) inhibitor), zIETD-FMK (caspase 8 enzymatic inhibitor). Luminex based assays detected cytokine and transcription factor DNA binding levels.

Results: $Cre^{CD11c}Casp8^{flox/flox}$ develop a SLE-like disease characterized by splenomegaly, lymphadenopathy, autoantibodies, glomerulonephritis, immune complex deposition in the kidney, proteinuria, an interferon signature, and early mortality. Loss of caspase 8 in DCs does not affect their survival, as there are equal numbers of $Cre^{CD11c}Casp8^{flox/flox}$ and WT DCs in mixed bone marrow chimeras, there is no change in DC turnover rate using BrdU pulse assays, and bone marrow derived DCs display similar levels of death independent of caspase 8 or RIPK1. However, caspase 8-deficient DCs are highly activated, leading to lymphocyte hyperactivation in a paracrine manner. Immune complexes containing self nucleic acids activate TLR7/9, which require the adaptor MyD88 for subsequent up-regulation of proinflammatory gene expression. The increased activation of $Cre^{CD11c}Casp8^{flox/flox}$ DCs is controlled by a MyD88-dependent mechanism, as DC-specific loss of MyD88 in $Cre^{CD11c}Casp8^{flox/flox}$ mice reduces disease, and caspase 8 defi-

cient DCs display a hyperresponsiveness to TLR7/9 ligation with increased DNA binding activity of IRF independent of caspase 8's enzymatic activity. Additionally, blocking RIPK1, but not IDO, signaling dampens TLR7/9 induced secretion of proinflammatory cytokines in caspase 8 deficient DCs. Despite caspase 8's known inhibitory role on IRF3 activity, deletion of IRF3, but not IRF7, in $Cre^{CD11c}Casp8^{flox/flox}$ mice exacerbates rather than ameliorates SLE-like disease, indicating that IRF3 transcribes inhibitory molecules that attempt to control the activation induced by the loss of caspase 8.

Conclusion: DC-specific loss of caspase 8 induces an SLE-like disease initiated by heightened DC activation via a MyD88- and RIPK1-dependent unknown mechanism. This constitutive activation is dampened by IRF3-specific transcription of unknown molecules possessing inhibitory functions, thereby uncovering novel roles for caspase 8 and IRF3 and highlighting potentially useful targets for autoimmune disease therapy.

Masp-1/3 Deficient MRL/Lpr Mice Lack The Alternative Complement Pathway Activation and Are Protected From Development Of Lupus-Like Glomerulonephritis. Takeshi Machida, Natsumi Sakamoto, Teizo Fujita, Minoru Takahashi and Hideharu Sekine. Fukushima Medical University School of Medicine, Fukushima, Japan.

Background/Purpose: Complement has both protective and pathogenic functions in lupus due to a balance between its role in the clearance of immune complexes (ICs) and apoptotic cells and its role in inflammation. The classical pathway is thought to contribute to IC and apoptotic cell clearance, whereas the alternative pathway is a key mediator of renal inflammation. Mannose-binding lectin (MBL)-associated serine proteases (MASPs)-1 and -3 are responsible for activation of the alternative pathway by activation of complement factor D which is required to cleave C3b-bound factor B to Bb (the C3 convertase (C3bBb)) during the alternative pathway activation. The aim of this study was to investigate the role of essential components of the alternative pathway, MASP-1/3, on lupus-like renal disease in MRL/*lpr* mice.

Methods: MASP-1/3 gene-knockout MRL/*lpr* mice were generated by backcrossing MASP-$1/3^{-/-}$C57BL/6 mice for seven generations to MRL/lpr mice, a mouse strain that spontaneously develops lupus-like disease. Alternative pathway activity in serum was measured by zymosan assay. Sera were analyzed every 2 weeks for total IgG, IgG anti-dsDNA autoantibodies, and C3 levels by ELISA. Urinary excretion of albumin was also determined. Kidneys were collected at 24 weeks for histologic evaluation.

Results: Sera from WT MRL/*lpr* mice showed significant C3 deposition on zymosan particles, whereas sera from MASP-$1/3^{-/-}$ MRL/*lpr* mice failed. Interestingly, compared to WT MRL/*lpr* mice, MASP-$1/3^{-/-}$ MRL/*lpr* mice had significantly increased levels of serum total IgG. However, there was no statistically significant difference of serum IgG anti-dsDNA antibody levels between the two groups. Serum C3 levels in WT MRL/*lpr* mice decreased as the mice aged. In contrast, serum C3 levels in MASP-$1/3^{-/-}$mice were maintained, and were significantly higher than those in the WT group at and after week 16. There was no significant difference in glomerular IgG deposition levels between WT and MASP-$1/3^{-/-}$ groups. Importantly, minimal or no glomerular C3 deposition was observed in MASP-$1/3^{-/-}$ MRL/lpr mice, while it was ready evident in WT MRL/*lpr* mice. Unlike WT MRL/*lpr* mice, none of MASP-$1/3^{-/-}$ MRL/*lpr* mice developed albuminuria (no more than 100 micro-g/day/mouse) until 24 weeks of age. Pathological analysis revealed minimal or no glomerular disease in MASP-$1/3^{-/-}$ MRL/*lpr* mice; however, there was no significant reduction in interstitial nephritis compared to WT MRL/*lpr* mice.

Conclusion: Unlike WT MRL/*lpr* mice, MASP-$1/3^{-/-}$ MRL/*lpr* mice lacked activity of the alternative pathway, and had maintained serum C3 levels, no albuminuria, and minimal or no glomerular C3 deposition and glomerular pathologic changes. Thus, inhibition of the alternative pathway protects against the development of glomerular disease in lupus-prone MRL/*lpr* mice. MASP-$1/3^{-/-}$ MRL/*lpr* mice, however, had no significant reduction in interstitial nephritis, suggesting that the pathological mechanism of interstitial kidney disease was distinct from that of glomerular disease in MRL/*lpr* mice.

Intestinal Microbiota Plays a Critical Role In The Production Of Antinuclear Antibodies In Lymphopenia-Induced Autoimmunity. Toshiki Eri[1], Kimito Kawahata[1], Mitsuru Imamura[1], Takeyuki Kanzaki[2], Lisa Akahira[1], Kazuya Michishita[1], Makoto Dohi[1], Takeshi Tokuhisa[3] and Kazuhiko Yamamoto[1]. [1]Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [2]Yamanashi Prefectural Central Hospital, Yamanashi, Japan, [3]Graduate School of Medicine, Chiba University, Chiba city, Chiba, Japan.

Background/Purpose: Production of antinuclear autoantibodies (ANAs) is one of the major characteristics of the systemic autoimmune diseases, such as systemic lupus erythematosus (SLE), but the mechanisms of their production are not known. Past studies showed athymic nude BALB/c mice developed spontaneous ANAs and lupus-like autoimmunity, and lymphopenic transfer model mice, in which $CD4^+CD25^-$ cells were transferred into nude mice, produced various autoantibodies including ANAs and anti-parietal cells antibodies, and organ specific autoimmune diseases. Here, using these mouse models, we investigated the mechanisms of the ANA production, in terms of the differentiation of transferred T cells into follicular helper T (T_{FH}) cells via lymphopenia-induced homeostatic proliferation (LIP). Moreover, by depleting intestinal microbiota by antibiotics administration, we elucidated the role of intestinal microbiota in this system.

Methods: $CD4^+$T cell subsets from wild-type BALB/c mice were adoptively injected into athymic BALB/c nude mice, with or without depleting recipient mice of their intestinal microbiota by orally administering broad-spectrum antibiotics in drinking water. Immunoprecipitation, immunofluorescent staining, and ELISA were performed to detect ANAs. Flowcytometry and immunostaining were performed to detect germinal center formation, and differentiation of transferred T cells.

Results: This lymphopenic mouse transfer model induced high titer IgG-type ANA production early and at high rates. Clinically important autoantibodies in SLE, such as anti- double strand-DNA, Sm, U1-RNP antibodies, were also detected by ELISA. Class switching and ANA production were enhanced when regulatory T cells-depleted $CD4^+$ T cells were transferred into. We identified IL-21-producing PD-1^+ T_{FH}cells which develop from conventional T cells during LIP and drive germinal center reactions with aberrant B cell responses. Depletion of intestinal microbiota resulted in significant reduction of both spontaneously occurring ANAs in nude mice and enhanced ANAs in lymphopenic transfer model. LIP and differentiation into TFH cells of transferred conventional T cells were also substantially impaired by microbiota depletion.

Conclusion: This study reveals that ANA production by nude mice is enhanced by LIP-T_{FH} cells. The novel insight that intestinal microbiota plays a critical role in both spontaneous and induced ANA production, would help to understand the immunopathogenesis of systemic autoimmune diseases. Moreover, the further investigation into the crosstalk between intestinal microbiota and the innate and adaptive immune systems may lead to a new therapeutic approach to systemic autoimmune diseases.

Triggering Receptor Expressed on Myeloid Cells 1 In Systemic Lupus Erythematosus. Laurie Davis[1], Yong Du[2], Tianfu Wu[2] and Chandra Mohan[3]. [1]UT Southwestern Medical Center, Dallas, TX, [2]University of Texas, Southwestern Medical Center at Dallas, Dallas, TX, [3]University of Texas Southwestern Medical Center, Dallas, TX.

Background/Purpose: In healthy individuals, TREM-1 proteins are cell surface receptors expressed by hematopoietic cells of the myeloid lineage. TREM-1 is a potent amplifier of proinflammatory responses. TREM-2 acts to downregulate inflammatory cytokines and is associated with suppressive macrophages. In prior studies increased soluble TREM-1 (sTREM-1) levels in serum accurately correlated with sepsis. TREM-1 hyper-expression has been observed in auto-inflammatory responses, such as rheumatoid arthritis and inflammatory bowel disease. In both sepsis and arthritis models, TREM-1 inhibitors prevent tissue destruction caused by inflammation. We posit that TREM-1 plays a significant role in regulating SLE renal disease and that TREM-1 is involved in the amplification of the inflammatory response.

Methods: We have explored TREM-1 expression and function in a murine anti-glomerular basement membrane antibody-induced nephritis (anti-GBM) model which shares a number of relevant pathogenic features with

lupus nephritis. Mice were pre-sensitized on day −5 (5 days before induction of anti-GBM) with rabbit IgG (250 μg/mouse) in adjuvant. On day 0, the mice received anti-GBM serum; 200μg of total IgG in a 300μl volume intravenously per mouse. After induction of anti-GBM disease, urine was collected from 129/SvJ and B6 mice at different timepoints and sTREM-1 was assessed by ELISA. Renal disease was measured by proteinuria and renal pathology. The impact of a TREM-1 inhibitory peptide (LP17) was assessed.

Results: In the anti-GBM model, 129/SvJ mice developed severe GN, whereas B6 mice did not. Renal macrophages from 129/SvJ mice expressed elevated TREM-1 compared to B6 mice. Anti-GBM disease induced elevated urine sTREM-1 levels in 129/SvJ versus control B6 mice. After induction of anti-GBM disease, urine was collected from 129/SvJ and B6 mice at different timepoints and sTREM-1 was assessed by ELISA. Elevated sTREM-1 levels were detected in the urine of 129/SvJ mice from day 7 through day 21. In the anti-GBM model, TREM-1 blockade with an inhibitory peptide ameliorated renal inflammation compared to control peptide. TREM-1 blockade inhibited proteinuria, as well as renal disease as measured by GN class, severity of tubulointerstitial disease, crescent formation, and inflammatory cell infiltrates. Elevated sTREM-1 levels were detected in serum of spontaneous murine lupus (SLN) models compared to controls and in SLN renal biopsies. Finally, elevated sTREM-1 levels were detected in serum of SLE patients with nephritis and TREM-1 was detected in renal biopsies from SLE patients but not controls.

Conclusion: These studies suggest that the TREM-1 hyper-expression in the nephritis prone 129/SvJ strain has critical pathogenic relevance, and that TREM-1 is amenable to therapeutic targeting for nephritis. These studies could have important implications in the understanding of pathogenic mechanisms driving SLE renal disease. More specific assays for nephritis, such as TREM-1 as a prognostic indicator of disease, might greatly enhance quality of therapeutic management for SLE nephritis.

Bacterial Amyloids Promote Type I Interferon Production and Accelerate Autoimmunity. Paul Gallo, Glenn Rapsinski, Cagla Tukel and Stefania Gallucci. Laboratory of Dendritic Cell Biology, Temple Autoimmunity Center, Temple University School of Medicine, Philadelphia, PA.

Background/Purpose: Infection is a major cause of morbidity and mortality in patients with systemic lupus erythematosus (SLE). This is largely due to the use of potent immunosuppressive therapy, but may also stem from inherent immune dysregulation. Curli is a bacterial amyloid that serves as a component of enteric bacterial biofilms including those of *Escherichia coli* and *Salmonella enterica* serovar Typhimurium. Patients are exposed to curli during urinary tract infections, gastrointestinal infections, and sepsis. Nucleic acids are also an integral part of curli biofilms as treatment with DNases leads to biofilm dissociation. Here we studied the immune response to nucleic acid-containing curli amyloids in the context of murine SLE.

Methods: Curli amyloid was isolated from *Salmonella* bacterial cultures. *In vitro* studies were performed using bone marrow-derived dendritic cells (BMDCs) from wild type and lupus-prone mice. BMDCs were activated with a dose titration of curli amyloid. Synthetic curli was used to study the role of nucleic acids in the immune response. *In vivo* studies were performed using lupus-prone NZBW-F1 mice. To simulate a chronic bacterial infection, eight 6-week-old mice were injected intraperitoneally (i.p.) with curli or PBS three times a week for 5 weeks and monitored for autoantibody production.

Results: We found that curli amyloids from bacterial cultures contain abundant nucleic acids and that exogenous DNA enhances amyloid fibrillization. BMDCs strongly respond to curli, producing large quantities of IL-12, IL-6, and IL-10. Curli also induces expression of IFN-β and IFN-simulated genes, with BMDCs from lupus-prone mice over-expressing these genes compared to wild type. Using both natural and synthetic curli, we found that curli and nucleic acids synergize to activate DCs. Lupus-prone NZBW-F1 mice injected i.p. with curli, compared to PBS, produce high quantities of anti-dsDNA and anti-chromatin autoantibodies within 2 weeks of the first injection.

Conclusion: The bacterial amyloid curli contains nucleic acids which are integral to the immune response to bacterial biofilms. Curli is a potent activator of dendritic cells and can rapidly accelerate autoimmunity in lupus-prone mice. This work suggests that nucleic acid-containing bacterial amyloids are an important environmental trigger for lupus and that curli injection may be useful as a novel method to accelerate murine lupus.

Damage In Systemic Lupus Erythematosus Is a Potentially Modifiable Outcome: Results From The Systemic Lupus International Collaborating Clinics (SLICC) Inception Cohort. Ian N. Bruce[1], Aidan O'Keefe[2], Li Su[3], Vernon Farewell[3], John G. Hanly[4], Susan Manzi[5], Murray B. Urowitz[6] and Systemic Lupus International Collaborating Clinics (SLICC)[7]. [1]Arthritis Research UK Epidemiology Unit and NIHR Manchester Musculoskeletal Biomedical Research Unit, The University of Manchester, Manchester, United Kingdom, [2]University of Cambridge, Cambridge, United Kingdom, [3]MRC Biostatistics Unit, Cambridge, United Kingdom, [4]Dalhousie University and Capital Health, Halifax, NS, [5]West Penn Allegheny Health System, Pittsburgh, PA, [6]University of Toronto, Toronto Western Hospital, Toronto, ON, [7]Toronto Western Hospital, Toronto, ON.

Background/Purpose: Irreversible damage is an important outcome in patients with SLE. We aimed to study damage accrual in early SLE. We examined the rate of accrual and factors that determine the development and progression of damage as well as the relationship between damage and survival.

Methods: The SLICC Inception Cohort Study includes patients from 31 centres in 11 countries in North America, Europe, and Asia. The cohort was recruited from 2000–2011 and enrolled within 15 months of their 4th 1987 ACR criteria. Damage was measured annually by the SLICC/ACR damage index (SDI). A multi-state model for transitions among damage states was used. Initial modelling was based on a proportional hazards analysis and assumed common explanatory variables effects across selected transition rates. We assessed the relative rates of transition using maximum likelihood estimation. The Kaplan-Meier method was used to estimate the probabilities relating to time until first worsening of SDI score. Cox regression analysis was performed with patient survival as the outcome against damage scores over time.

Results: We recruited 1722 patients. The mean (SD) age at cohort entry and number of visits was 35.0(13.4) years and 4.25(2.72) respectively. At baseline, 600 (34.8%) patients had at least one item of damage rising to 51.1% (178/348) by 6 years follow-up. 1502 patients, including 1337 (89%) females were analysed for SDI change over time. Patients with initial damage were more likely to increase their SDI at each follow-up visit [SDI 0 vs ≥1 ($p<0.01$)].

Multivariate models for transitions from no damage to damage and increase(s) in pre-existing damage were comparable; age, USA African race/ethnicity, SLEDAI score, steroid use and hypertension were all associated with increasing damage (Table 1). For transition from SDI 0 to >=1, male gender (Relative Transition Rates [95%CI]: 1.48 [1.06, 2.07]) and USA Caucasian race/ethnicity (1.68 [1.08, 2.46]) were associated new damage and Asian race/ethnicity with lower rates of new damage (0.60 [0.39, 0.93]). Increase in pre-existing damage was reduced in patients taking antimalarials (0.63 [0.44, 0.89]). Each point increase in SDI score was associated with an increased risk of death (HR [95%CI]: 1.46 [1.18, 1.81]).

Table 1. Analysis of factors significantly associated with accrual of damage in SLE patients either from no damage to damage (SLICC 0 to 1) or accrual in pre-existing damage (SLICC 1 to >1).

	Multivariate Relative Transition Rates (95% CI)	
Covariate	**SLICC 0→1**	**SLICC 1→1**
Gender (male)	**1.48 (1.06 ,2.07)**	**1.12 (0.86 ,1.46)**
Age diagnosis*	**1.30 (1.12 ,1.52)**	**1.00 (0.87 ,1.14)**
(Age diagnosis)^2	**1.12 (1.03 ,1.23)**	**1.07 (1.00 ,1.14)**
Caucasian USA	**1.63 (1.08 ,2.46)**	**1.26 (0.90 ,1.78)**
African USA	**1.58 (1.03 ,2.43)**	**2.40 (1.76 ,3.27)**
Asian	**0.60 (0.39 ,0.93)**	**0.95 (0.65 ,1.39)**
Steroid Use (Y/N)	**1.64 (1.21 ,2.21)**	**1.43 (1.12 ,1.84)**
Antimalarial Only	0.81 (0.53 ,1.22)	**0.63 (0.44 ,0.89)**
Immunosupp and AM	1.06 (0.69 ,1.62)	0.83 (0.60 ,1.16)
Hypertension (Y/N)	**1.71 (1.27 ,2.31)**	1.61 (1.28 ,2.03)
SLEDAI/3**	**1.17 (1.07 ,1.27)**	1.10 (1.03 ,1.16)

*Standardised age, **increase in rate for each SLEDAI increase of 3

Conclusion: Early damage in SLE is an important stratification factor that predicts future damage and mortality. We found a number of modifiable risk factors for damage (disease activity, hypertension, steroid use and a protective

effect of antimalarial use). An integrated intervention strategy to address these may improve long-term outcomes in SLE patients.

The Risk Of Deep Vein Thrombosis and Pulmonary Embolism In Systemic Lupus Erythematosus: A Population-Based Cohort Study. J. Antonio Avina-Zubieta[1], Eric C. Sayre[2], Diane Lacaille[1] and John M. Esdaile[1]. [1]Arthritis Research Centre of Canada, University of British Columbia, Richmond, BC, [2]Arthritis Research Centre of Canada, Richmond, BC.

Background/Purpose: Previous hospital-based studies have shown that patients with systemic lupus erythematosus (SLE) have an increased risk of cardiovascular disease, but limited population-based data are available on the risk of deep venous thrombosis (DVT) and pulmonary embolism (PE). We estimated the population-based risk of newly recorded DVT and PE among incident cases with SLE compared to controls from the general population using physician-billing and hospitalization databases that cover the entire population of the province of British Columbia, Canada (~ 5 million).

Patients and Methods: Our data include all visits to health professionals and all hospital admissions from Jan 1, 1990 to Dec 31, 2010 and all dispensed medications from Sept 1, 1995 to Dec 31, 2010 for all individuals. We conducted a retrospective matched cohort study among patients satisfying at least one of the following criteria: **a)** diagnosis of SLE in adults on at least two visits within a two-year period between Jan 1996 and Dec 2010 by a non-rheumatologist physician; **b)** diagnosis of SLE on at least one visit by a rheumatologist or from hospitalization. To increase specificity we excluded cases that were not confirmed by a rheumatologist if they were seen at a later point. Ten non-SLE controls matched by birth year, sex and calendar year of follow-up were selected from the general population for each case. Outcomes: incident PE, DVT, and PE or DVT events based on hospitalization records (for PE and DVT), outpatient visits (DVT) or death certificates (all outcomes). For non-fatal outcomes, we also required the use of anticoagulant medication within six-months of the event as part of all outcome definitions. We estimated relative risks (RRs) comparing SLE with age-, sex- and entry time-matched comparison cohorts, adjusting for potential cardiovascular risk factors.

Results: Among 5,031 incident SLE cases, 72, 72 and 121 developed a first time DVT, PE, and PE or DVT event, respectively (incidence rates = 3.4, 3.4 and 5.8 per 1,000 person years, respectively) (see table). Compared with the age, sex, and entry-time-matched controls, the RRs were 5.2 (95% CI; 3.8 – 6.9), 4.6 (95% CI; 3.5 – 6.2) and 4.8 (95% CI; 3.8 – 6.0) for DVT, PE, and DVT or PE, respectively. After adjusting for covariates the results remained similar (see table). The risk of developing DVT, PE or either event was highest within the first year following diagnosis of SLE, decreasing over time and persisting after 5 years.

Table. Risk of Incident PE, DVT or DVT or PE according to SLE Status

	SLE n = 5,031	Non-SLE n = 50,310
Incidence Rate Ratios of DVT		
DVT events, N	72	136
Incidence Rate/1000 Person-Years	3.4	0.7
Age-, sex-, and entry time-matched RRs (95% CI)	5.2 (3.8–6.9)	1.0
<1 year of disease duration	8.6 (4.9–15.1)	1.0
1–4.9 years of disease duration	4.7 (2.9–7.4)	1.0
5+ years of disease duration	3.4 (1.8–6.2)	1.0
Multivariable RR (95% CI)	3.9 (2.8–5.6)	1.0
Females	4.0 (2.7–5.9)	1.0
Males	4.0 (1.8–9.1)	1.0
Incidence Rate Ratios of PE		
PE events, N	72	150
Incidence Rate/1000 Person-Years	3.4	0.7
Age-, sex-, and entry time-matched RRs (95% CI)	4.6 (3.5–6.2)	1.0
<1 year of disease duration	14.9 (8.4–26.8)	1.0
1–4.9 years of disease duration	3.4 (2.1–5.4)	1.0
5+ years of disease duration	2.2 (1.1–4.2)	1.0
Multivariable RR	3.5 (2.5–4.8)	1.0
Females	3.4 (2.3–4.9)	1.0
Males	3.9 (1.6–9.4)	1.0
Incidence Rate Ratios of DVT or PE		
DVT and PE events, N	121	247
Incidence Rate/1000 Person-Years	5.8	1.2
Age-,sex-, and entry time-matched RRs (95% CI)	4.8 (3.8–6.0)	1.0
<1 year of disease duration	11.8 (7.8–17.8)	1.0
1–4.9 years of disease duration	3.9 (2.7–5.5)	1.0
5+ years of disease duration	2.3 (1.4–3.9)	1.0
Multivariable RR	3.6 (2.8–4.7)	1.0
Females	3.6 (2.7–4.8)	1.0
Males	3.6 (1.9–7.0)	1.0

Conclusion: This large population-based study indicates an increased risk of DVT and PE in patients with SLE. Our results support the need for increase monitoring for these complications in SLE patients, especially within the first year of disease onset.

Atherosclerosis In Systemic Lupus Erythematosus (SLE) and Controls, -An Analysis Of SLE Subgroups. Johanna Gustafsson[1], Kerstin Jensen-Urstad[1], Marie Herlitz-Lindberg[1], Sonia Möller[1], Susanne Pettersson[1], Iva Gunnarsson[1], Anders Larsson[2] and Elisabet Svenungsson[1]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Akademiska Hospital, Uppsala, Sweden.

Background/Purpose: Atherosclerosis is often assumed to be the main underlying cause of premature vascular events (VE) among patients with systemic lupus erythematosus (SLE) and accelerated atherosclerosis is frequently considered to be a general feature of SLE, though not confirmed in all studies. Since SLE is a very heterogeneous disease we studied the occurrence of atherosclerosis in unselected and in predefined subgroups of SLE patients. Individually matched population controls were used as comparators.

Methods: 281 SLE patients and 281 population controls, individually matched for age, sex, and region of living were included. All were investigated clinically including CVD risk factors and inflammatory biomarkers. The same investigator performed B-mode ultrasonography of carotid arteries. Mean intima media thickness (mIMT) and plaque occurrence (local IMT>1mm) were tabulated. Paired analyses were performed.

Results: In both groups: mean age was 48±14 years, 93% were females.

Patients had slightly thicker mIMT than controls (0.59±0.01 vs 0.57±0.01, p=0.003), but plaque occurrence did not differ, 20% and 16% respectively.

Manifest CVD (ischemic heart, cerebro- and peripheral vascular disease) was more common in patients (12 % vs. 1 %, p<0.0001).

Patients had lower high (HDL), low density lipoprotein (LDL) and albumine, but higher triglycerides (TG), apoB/A, C-reactive protein, homocysteine, cystatin C, creatinine, tumor necrosis factor receptor (TNFR) 1 and 2, and vascular cell adhesion molecule-1 (p<0.005 for all). Patients were more often on antihypertensive-, lipid-lowering, aspirin and warfarin treatments (p<0.05 for all).

Among SLE patients, after age adjustment: Manifest CVD was associated with plaques (p<0.0001), but not with mIMT (p=0.3).

mIMT was associated with smoking, sBP, HDL(negatively), LDL, TG, apoB/A, and glucose(p<0.05 for all).

Plaques were positively associated with smoking, sBP, TG, albumine, cystatin C, nephritis, TNFR 1 and 2, SLICC>1, and antihypertensive treatment, and negatively associated with leukopenia (p<0.05 for all).

Multivariable-adjusted models: In patients, age, sBP and apoB/A remained associated with mIMT (p<0.05 for all). Age, sBP and manifest CVD remained for plaques (p<0.05).

Stratified analyses: Analysis of SLE subgroups (nephritis(*112+112*), SSA/SSB(*131+131*) and anti phospholipid (aPL) (*75+75*)-positivity) compared to individually matched controls revealed that patients diagnosed with nephritis selectively had more plaques than their respective controls (p=0.008) and mIMT was was also thicker in the nephritis group (p=0.006). Thicker mIMT was also present in the SSA/SSB and aPL subgroups (p<0.05).

Conclusion: This is, to our knowledge, the largest study of atherosclerosis in SLE patients/matched population controls. Manifest CVD was more common among patients, but enhanced occurrence of atherosclerotic plaques was not a general feature of SLE as it was essentially confined to patients with a history of nephritis. mIMT was slightly thicker in patients, a more general SLE feature, but not associated with manifest CVD in this study. Our results imply that renal disease is an important driving factor behind accelerated atherosclerosis in SLE.

Outcome Of Incidental Silent Strokes In Systemic Lupus Erythematosus. Jamal Mikdashi University of Maryland School of Medicine, Baltimore, MD.

Background/Purpose: Silent strokes are brain infarcts that lack clinically overt stroke-like symptoms and fail to come to clinical attention. The prevalence of incidentally detected acute/subacute silent brain infarcts (SBIs) in systemic lupus erythematosus (SLE) is not known. Our aim is to determine the prevalence of SBIs in SLE and examine their outcome.

Methods: Consecutive subjects drawn from the Maryland Lupus Cohort, aged 18–50 years who underwent a cranial MRI between 2000 and 2010 were included. A total of 376 eligible patients were identified: 30 did not undergo diffusion-weighted MR imaging and 32 patients had inadequate follow-up, leaving a study population of 314 patients. Incidental silent stroke was ascertained when focal T2 hyperintense lesions ≥3 mm on diffusion-weighted imaging with corresponding apparent diffusion coefficient defects were identified. Demographic and clinical data for SLE patients with SBIs (n=86) were compared to SLE patients with no SBIs (n=228). The primary outcome was recurrent stroke and cognitive dysfuction determined at mean follow up of 24 months. A forward stepwise Cox regression model was used to determine factors associated with recurrent stroke or cognitive dysfunction in SBIs patients. Significant variables; age, ethnicity, smoking, alcohol intake, and cardiovascular risk factors were included in the model. SLE disease activity (SLEDAI), damage (SDI) and duration of SLE were adjusted for during analyses.

Results: 86 of 314 (27.4 %) subjects had SBIs with a mean age (SBIs=37.3 +/− 12.1 years, No SBIs=34.7 +/− 14.7 years), women (SBIs=80 %, No SBIs=80 %), African American (SBIs=70 %, No SBIs= 65 %), and mean duration of SLE (SBIs= 9.0 + 3.6, No SBIs= 6.9 + 2.8 years). Hypertension (SBIs= 80 %, No SBI= 65 %), migraine with aura (SBIs 10.4 %, No SBIs= *2.6 %),* and cardiovascular disease (SBIs= 11.6 %, No SBIs =1.7 %) were more frequent among patients with SBIs. There were no significant statistical differences among both groups with respect to baseline SLEDAI or SDI. SBIs were small and subcortical (basal ganglia 46.5%, cerebellum 23.4%, globus pallidus 7.0%, corpus callosum 4.7%).

Recurrent stroke occurred among SBIs patients (29%) and among those with no SBIs (6.5%), (p= 0.004). Independent predictors of recurrent stroke in SBIs patients included, anti-phospholipid syndrome [OR 12.0; 95% CI: 1.2–203.1].

A majority of the subjects with SBIs had significant cognitive impairment compared to no SBIs patients (60 % v 22%). SBIs patients had poorer memory and cognitive performance in all domains as compared to no SBI patients, including executive function, working memory, language, attention, and visuospatial abilities, but significantly in global cognition (48 % v 20 %) and information processing speed (42 % v 15 %). Independent predictors of cognitive dysfunction in SBIs patients included baseline presence of extensive white matter hyperintensity lesions in the periventricular and subcortical regions [OR: 10.1; 95 % CI: 1.1–98.4].

Conclusion: Silent strokes are prevalent in SLE, and are associated with recurrent strokes and cognitive dysfunction. Identifying novel risk factors that shed light on SBIs pathogenesis in SLE may offer potential therapeutic targets.

Predictors Of Damage Accrual Over a 2 Year Period In a Large Multi-Racial/Ethnic Lupus Cohort. Megan E. B. Clowse[1], Jennifer M. Grossman[2], Joan T. Merrill[3], Anca Askanase[4], Olga Dvorkina[5], Michael D. Lockshin[6] and Cynthia Aranow[7]. [1]Duke University Medical Center, Durham, NC, [2]UCLA David Geffen School of Medicine, Los Angeles, CA, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]New York University School of Medicine, New York, NY, [5]SUNY Downstate Medical Center, Brooklyn, NY, [6]Hospital for Special Surgery, New York, NY, [7]The Feinstein Institute, Manhasset, NY.

Background/Purpose: Clinical experience and some previous research suggest that patients with lupus who live in more socio-economically vulnerable conditions fair worse than other patients. We sought to identify factors associated with damage accrual using the Lupus Clinical Trials Consortium, Inc. (LCTC) Lupus Data Registry, a patient registry of SLE in 16 lupus centers in North America.

Methods: The LCTC Lupus Data Registry began enrollment in 2010. We compared lupus patients who had accumulated ≥2 points in the SLICC Damage Index (SDI) over 2 years to those who had not with respect to demographics, features of disease, and factors that may enhance socio-economic vulnerability. A Cox proportional hazards model was used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for the association between a ≥2 point change in SDI and factors that were statistically significant in a univariate analysis. A most parsimonious model was created using a backwards-selection process, keeping all variables in the multivariable model that had a p-value <0.10.

Results: 1,478 patients with documented SDI scores at both enrollment and follow-up contributed a total of 2,503 person-years of follow-up (mean 1.77 years). 91.4% were female, 37.4% were non-Hispanic Caucasian, 34.0% were non-Hispanic African-American, and 8.2% reported Hispanic ethnicity.

In univariate analysis, higher baseline damage, higher baseline lupus disease activity (SLEDAI), longer duration of SLE, and more ACR classification criteria were each associated with a ≥2point increase in SDI. Prior treatments with immunosuppressants or with high dose prednisone were also associated with damage accrual while hydroxychloroquine use at enrollment was protective against damage accrual.

Among socioeconomic characteristics, there was no association between rate of damage accrual and educational attainment, marriage status, and insurance status; however, a two-fold increase in the rate of damage accrual was observed for those not working compared to those who either were working or were students (RR 2.06, 95% CI 1.42–3.01). After adjusting for the other socioeconomic characteristics, this association remained (RR 2.34, 95% CI 1.53–3.56).

In the multivariable model, work was no longer significantly associated with the rate of damage accrual. Additional factors losing significance in the multivariable model included duration of SLE, number of ACR criteria, high dose prednisone, and prior immunosuppressant use. Baseline SDI (p<0.0001) and SLEDAI (p=0.0036) remained significantly associated with the rate of damage accrual.

Conclusion: Baseline SDI and SLE activity were associated with damage accrual. Socio-economic factors did not demonstrate independent associations, contrary to our perceived clinical experience. The cross-sectional relationship between work and damage may in fact be a result rather than a cause of severe illness and damage.

Standardized Incidence Ratios For Cancer After Renal Transplant In Systemic Lupus Erythematosus and Non-Systemic Lupus Erythematosus Recipients. Rosalind Ramsey-Goldman[1], Amarpali Brar[2], Moro Salifu[2], Ann E. Clarke[3], Rahul M. Jindal[4] and Sasha Bernatsky[3]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]SUNY Downstate, Brooklyn, NY, [3]McGill University, Montreal, QC, [4]Uniformed Services University and George Washington University, Washington, DC.

Background/Purpose: Differentiating between effects of drugs vs. disease activity on cancer risk in SLE is difficult. Because all renal transplant recipients are on similar immunomodulatory medications, we hypothesize that additional cancer risk due to SLE itself would manifest as a higher cancer risk in SLE vs. non-SLE transplant recipients.

Methods: A cohort of 143,652 renal transplant recipients contributing 585,420 patient-years of follow-up were identified between 2001–2009 from the United States Renal Data System, USRDS. Patients were stratified by primary cause of renal failure: SLE (n=4289 [3%], contributing 18,435 patient-years) and non-SLE (n=139,361 [97%], contributing 566,985 patient-years). ICD 9 cancer codes were identified from Medicare physician claims. All cancers and individual cancer types were expressed as incidence per 100,000 patient-years. The expected number of cancers was derived from SEER general population cancer data from 2000–2009, accounting for age and sex. Standardized incidence ratios, SIRs, were calculated by dividing the observed by the expected number of cancers and 95% confidence intervals were generated.

Results: We identified 10,160 cancers occurring 3 months post transplant in this cohort. Tables 1 and 2, indicate a 3–4 fold increased cancer risk over-all in renal transplant recipients, vs. the general population. SIRs were similar in SLE vs. non-SLE transplant recipients for many specific cancers, with increased risks (compared to the general population) for lip/oropharyngeal, Kaposi, renal, lymphoma, colorectal, breast, and decreased risk (compared to the general population) for prostate. The SIRs for neuroendocrine and melanoma were increased in SLE vs. non-SLE transplant recipients. In contrast, the SIR for lung was decreased in SLE vs. non-SLE transplant recipients.

Table 1. SIRs for Cancer in SLE Renal Transplant Recipients vs. General Population

Cancer	Observed Cases/100,000 person-years	Expected Cases/100,000 person-years	Standardized Incidence Ratio (SIR)	95% Confidence Interval (CI)
All Cancers	1622	466	3.5	2.1–5.7
Lip/Oropharyngeal	781	11	72.6	57.3–92.0
Kaposi	38	0.6	62.2	35.2–141.1
Neuroendocrine*	163	5	42.8	30.7–50.2
Renal	217	14	15.4	12.3–21.7
Lymphoma	293	22	13.1	9.0–14.6
Colorectal	222	49	4.5	3.2–6.1
Melanoma	27	20	2.1	1.6–2.8
Breast	255	127	2.0	1.1–3.1
Lung	43	65	0.7	0.6–1.0
Prostate	54	163	0.7	0.01–1.0

Table 2. SIRs for Cancer in Non-SLE Renal Transplant Recipients vs. General Population

Cancer	Observed Cases/100,000 person-years	Expected Cases/100,000 person-years	Standardized Incidence Ratio (SIR)	95% Confidence Interval (CI)
All Cancers	1739	469	4.0	2.4–5.7
Lip/Oropharyngeal	665	11	58.1	36.2–80.1
Kaposi	0.6	42	72.5	55.2–89.9
Neuroendocrine*	74	5	14.3	4.1–24.6
Renal	142	14	10.1	7.6–12.6
Lymphoma	194	22	9.0	7.4–10.5
Colorectal	150	50	2.8	2.2–3.4
Melanoma	22	20	1.0	0.7–1.25
Breast	280	127	2.1	1.3–2.8
Lung	90	64	1.4	1.0–1.7
Prostate	65	163	0.4	0.2–0.5

* Neuroendocrine tumors include carcinoid tumors, islet cell tumors, medullary thyroid carcinoma, Merkel cell, secondary neuroendocrine, pheochromocytoma

Conclusion: Cancer risk in transplant recipients is high and surveillance may need to be tailored to the indication for transplant. Different methods of cancer ascertainment using physician claims data vs. tumor registries and inclusion of different SLE patient populations, restriction to those with severe SLE renal disease vs. our multinational cohort, may explain higher SIRs for cancer seen in SLE renal transplant recipients than in our previous multinational SLE cohort study evaluating cancer risk.

Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics: Pathogenesis of Systemic Sclerosis
Wednesday, October 30, 2013, 11:00 AM–12:30 PM

2902

Key Roles For Interferon and Macrophage Activation In Progressive Lung Fibrosis Associated With Systemic Sclerosis. Romy Christmann[1], Giuseppina Stifano[1], Claudia Borges[2], Carlos Carvalho[3], Ronaldo Kairalla[3], Edwin R. Parra[3], Avrum Spira[1], Robert W. Simms[1], Percival Sampaio-Barros[3], Vera L. Capelozzi[3] and Robert Lafyatis[1]. [1]Boston University School of Medicine, Boston, MA, [2]CEUMA University, Sao Luis do Maranhao, Brazil, [3]University of Sao Paulo School of Medicine, Sao Paulo, Brazil.

Background/Purpose: Interstitial lung disease associate with Systemic Sclerosis(SSc-ILD) is one of the leading causes of mortality. We analyzed the gene expression of lung tissue in a prospective cohort of SSc-ILD compared to control lungs and to two prospective clinical parameters in order to understand molecular pathways implicated in progressive lung disease.

Methods: Lung tissue was obtained by open lung biopsy in 28 consecutive SSc-ILD patients and 4 controls. High-resolution computerized tomography(HRCT) and pulmonary function tests(PFTs) were performed on baseline and 2–3 years after treatment that was based on lung histologic classification. SSc lung RNA was available from 11 diffuse and 10 limited SSc patients. Microarray analysis was performed and the results correlated (Pearson's) with changes in HRCT score(FibMax) and PFTs values. Quantitative polymerase chain reaction(qPCR) and immunohistochemistry(IHC) were used to confirm differential levels of mRNA and protein levels. Interferon receptor alpha-1(IFNAR) deficient mice were submitted to a systemic bleomycin-lung fibrosis murine model. The study was approved by the Institutional Review Boards from both universities (Brazil and USA).

Results: Despite treatment, cyclophosphamide for non-specific interstitial pneumonia(NSIP) and intense anti-reflux treatment for centrilobular fibrosis-(CLF), most of SSc-ILD patients progressed based on delta FibMax($p<0.01$). Lung microarray data distinguished SSc-ILD from healthy controls. Macrophage markers, chemokines, collagen, TGF-beta- and interferon-regulated genes that were upregulated in SSc-NSIP were strongly correlated to the delta FibMax. IHC confirmed the collagen(Col1a1), interferon(OAS1 and IFI44), and macrophage(CCL18 and CD163) signatures and the positive correlation with delta FibMax was confirmed by qPCR in a larger group of SSc-NSIP patients: Col1a1 ($r^2=0.39$; $p<0.01$); IFI44 ($r^2=0.44$; $p<0.01$); OAS1 ($r^2=0.36$; $p<0.01$); CD163 ($r^2=0.24$; $p<0.03$), and CCL18 ($r^2=0.42$; $p<0,01$). Several genes were correlated with both the delta FibMax ($r>0.4$) and delta %FVC ($r<-0.1$), including interferon and macrophage markers; chemokines; and heat-shock proteins. IFNAR-deficient compared to wild-type mice exposed systemically to bleomycin developed a milder fibrotic score at day 21st. Several profibrotic genes, such as SPP1(osteopontin), LOX(protein-lysin oxidase), and PAI-1(serpine-1); macrophage markers (arginase-1 and chitinase-3) were blocked or partially blocked in IFNAR-deficient mice.

Conclusion: These results highlight the major pathogenic pathways relevant to progressive pulmonary fibrosis in SSc-ILD: macrophage activation, and upregulation of TGF-beta- and IFN-regulated genes. The importance of IFN was further supported here in a murine systemic lung-fibrotic model. These findings support the notion that blocking one or more of these pathways may be the best treatment approach for SSc-ILD.

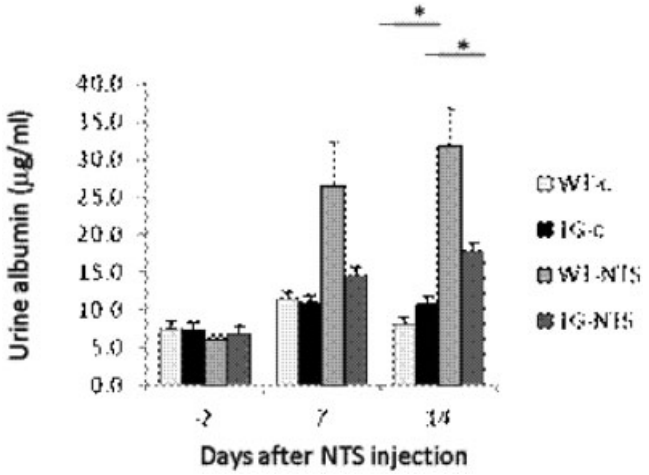
Perturbed Response To Experimental Renal Injury In a TGFβ Dependent Mouse Model Of Scleroderma. Emma Derrett-Smith, Mark Neal, David J. Abraham, Alan Salama, Mark A. Little and Christopher P. Denton. UCL Medical School, London, United Kingdom.

Background/Purpose: Scleroderma renal pathology is predominantly vascular and fibrotic without major inflammatory features. Accelerated hypertension and rapidly progressive renal dysfunction are hallmarks of scleroderma renal crisis. No current animal model of scleroderma (SSc) develops this complication. The TβRIIΔk-fib transgenic mouse model of SSc has a systemic vascular phenotype comprising hypertension and large vessel adventitial fibrosis without constitutive renal disease. However, the response to long-term further elevation of blood pressure or an inflammatory renal insult has not been studied. We have therefore explored the link between altered TGFb bioactivity, vasospasm and inflammatory stress on the systemic vascular endothelium using nitric oxide synthase inhibition and the nephrotoxic nephritis model using this strain.

Methods: Histological assessment of cardiac and renal architecture, immunostaining for microvessel density and inflammatory cells and assessment of microalbuminuria by ELISA were performed on adult male transgenic (TG) and littermate wildtype (WT) animals (n=6) treated with either the NO synthase inhibitor L-NAME for 20 weeks, or a single dose of nephrotoxic serum with pre-immunisation. Biochemical analysis of the TGFb signalling pathway was performed assessing RNA and protein using whole organ isolates, and by immunostaining of tissue sections. Results were compared to appropriate control groups.

Results: Increased cardiac mass, and an increase in cardiac collagen measured by qPCR and Sircol® assay in TG and WT treated groups demonstrated that L-NAME treatment successfully induced hypertensive stress in this strain. Whole kidney lysates from L-NAME treated TG animals showed upregulated expression of Col1a1 (TG untreated copy number 3937±315, TG treated 6319±48, $p<0.05$) and Pai-1 (TG untreated 410±57, TG treated 740±74, $p<0.05$), and glomerulosclerosis was present on sirius red staining in the TG treated group, suggesting that these animals exhibited an enhanced renal fibrotic response when compared to WT treated animals. No other structural vascular changes were identified. In contrast, by day 14, TG animals had developed significantly less proteinuria following treatment with nephrotoxic serum (NTS) when compared with WT littermates (figure 1). Examination of PAS stained samples showed increased severity and number of damaged glomeruli in WT treated mice compared with TG.



Conclusion: This mouse model of scleroderma demonstrates exaggerated fibrotic response to hypertensive injury and is relatively resistant to experimental glomerulonephritis. This is likely to be a consequence of increased tissue levels of TGFb. Both of these processes may underpin the unique vascular pathology seen in scleroderma renal crisis, this mouse strain provides a platform for further studies of renal injury in scleroderma.

Gadolinium-Based Compounds Induce NLRP3-Dependent IL-1β Production and Peritoneal Inflammation. Jonathan Kay[1], Lukas Bossaller[2], Christian Schmidt-Lauber[2], Hani H. Abujudeh[3], Gregory Vladimer[2], Eicke Latz[2], Katherine A. Fitzgerald[2], Ann Marshak-Rothstein[2] and Ellen M. Gravallese[2]. [1]UMass Memorial Medical Center and University of Massachusetts Medical School, Worcester, MA, [2]University of Massachusetts Medical School, Worcester, MA, [3]Massachusetts General Hospital and Harvard Medical School, Boston, MA.

Background/Purpose: Nephrogenic systemic fibrosis (NSF) is a progressive iatrogenic fibrosing disorder that develops in patients with chronic kidney disease following administration of gadolinium (Gd)-based contrast agents (GBCA) for imaging studies. In the setting of impaired renal clearance of GBCA, Gd deposits in various tissues and fibrosis develops. However, the precise mechanism by which Gd induces systemic fibrosis is incompletely understood. Because other profibrotic agents, such as silica and asbestos, activate the NOD-like receptor protein 3 (NLRP3) inflammasome and thereby initiate a cellular response associated with IL-1β release, we evaluated the effects of various Gd-containing compounds on inflammasome activation.

Methods: Bone marrow derived macrophages (BMDM) from wild type (WT), *NLRP3*$^{-/-}$ and *ASC*$^{-/-}$ mice were exposed to each of three Gd-containing compounds: $GdCl_3$ (free Gd salt), and Omniscan® and Gd-diethylenetriaminepentaacetic acid (Gd-DTPA) (chelated forms of Gd). IL-1β release into in culture media was quantified by ELISA and the extent of IL-1β processing was determined by ELISA and Western blot analysis. Inflammasome activation and regulation was determined in macrophages polarized to an M1 or M2 phenotype using ELISA, qRT-PCR and NanoString nCounter analysis. Finally, WT and *NLRP3*$^{-/-}$ mice were injected intraperitoneally (i.p.) with either 500 μM Gd-DTPA or phosphate buffered saline (PBS) and recruitment of inflammatory cells to the peritoneum was analyzed by FACS.

Results: All three Gd-containing compounds induced concentration-dependent IL-1β secretion. $GdCl_3$ was the most potent activator, leading to the release of detectable levels of IL-1β at a concentration of 2.5 μM. Gd-DTPA and Omniscan® also induced IL-1β production but at 200- and 4000-fold higher concentrations, respectively. For all three substances, Western blot analysis confirmed that pro-IL-1β was processed to mature IL-1β. None of the Gd-containing reagents induced IL-1β release by BMDM from *ASC*$^{-/-}$ or *NLRP3*$^{-/-}$ mice, in which inflammasome activation is impaired, demonstrating that IL-1β secretion is induced through engagement of the NLRP3 inflammasome. Furthermore, after priming with low doses of LPS, Gd-containing compounds activated IL-4-polarized (M2) macrophages more effectively than IFNγ-polarized (M1) macrophages, since the M1 macrophages preferentially expressed genes (CD40, SOCS1, STAT1, and STAT3) known to downregulate inflammasome signaling. Mice injected i.p. with Gd-DTPA exhibited both a relative and an absolute increase in the number of inflammatory monocytes and granulocytes recruited to the peritoneal cavity, as compared to PBS-injected mice. This effect was markedly reduced in *NLRP3*$^{-/-}$ mice, as compared to WT mice.

Conclusion: Both free Gd and GBCA activate the NLRP3 inflammasome in macrophages and induce IL-1β secretion *in vitro* and the recruitment of neutrophils and inflammatory monocytes *in vivo*. The preferential activation by Gd of M2 macrophages, which promote wound healing and fibrosis, is consistent with the predominantly fibrotic presentation of NSF and may be clinically relevant.

Demethylation of ITGAL (CD11a) regulatory sequences in CD4+T lymphocytes of Systemic Sclerosis. Yaoyao Wang[1], Ye Shu[2], Qing Wang[1], Ming Zhao[1], Gongping Liang[1], Qianjin Lu[1] and Rong Xiao[1]. [1]Second Xiangya Hospital, Central South University, Changsha, China, [2]Hunan Children's Hospital, Changsha, China.

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune connective tissue disease epitomized numerous cellular and humoral immunological abnormalities. The immune system undoubtedly plays a pivotal role in SSc pathogenesis. And a growing body of evidence indicates that alterations to epigenetic DNA methylation patterns contribute to many autoimmune diseases including SSc. CD11a, a subunit of the lymphocyte function-associated antigen 1alpha LFA-1 (CD11a/CD18)with costimulatory functions by adhesive interactions between T cells and other immune system cells including macrophages, dendritic cells and B cells plays a central role in inflammatory and immune responses. CD11a is overexpressed due to hypomethylation of its regulatory elements in CD4+ T cells from patients with several autoimmune diseases. However, it is unknown whether aberrant expression and methylation of CD11a occur in T cells from patients with SSc. We aimed to compare the CD11a expression level and the methylation status of the CD11a promoter and enhancer regions in CD4+ T cells from SSc patients, healthy controls (HC) and CD4+ T cells with DNA methylation inhibitors.

Methods: CD11a expression in CD4+T cells from patients with SSc and healthy control subjects was measured by flow cytometry and real-time reverse transcription polymerase chain reaction. Related DNA methylation modifier enzymes such as DNA methyltransferases (DNMTs), Methyl DNA binding domain proteins (MBDs) and Ten-eleven translocation protein-s(TETs) were measured by RT-PCR. Bisulfite sequencing was used to determine the methylation status of the CD11a promoter and flanking regions in CD4+ T cells from SSc and HC and in CD4+ T cells with DNA methylation inhibitors. Detection of CD4+T cell proliferation and autologous B cell IgG antibodies was performed using commercially available kits. Modified Rodnan total skin score(MRTSS) and Valentini Scleroderma Disease Activity Index (SDAI) for Systemic Scleroderma patients were performed.

Results: Elevated CD11a expression were observed in CD4+T cells from patients with SSc. Expression of TET1 was significantly increased but DNMT1, MBD3, and MBD4 were significantly down-regulated in SSc CD4+T cells relative to controls. Expression of DNMT1 mRNA was negatively correlated with transcript level of CD11a. The methylation levels of the DNA regulatory sequences of CD11a were reduced in patients with SSc compared with HC, and there was a significant inverse correlation

between the average methylation level and CD11a mRNA expression in patients with SSc. Treatment with a DNA methylation inhibitor decreased CD11a regulatory sequences methylation contribution to CD11a overexpression and increased B cell costimulation and subsequent immunoglobulin over-production. Further more, transcript level of CD11a was positively correlated with disease activity.

Conclusion: Demethylation of CD11a regulatory elements contributes to CD11a overexpression and results in T cell autoreactivity and B cell immunoglobulin overproduction in CD4+T cells from patients with SSc correlating with disease activity.

Peripheral Blood Mononuclear Cells Co-Cultured With Autologous Skin Fibroblasts Up-Regulate IL-17A and Play Anti-Fibrotic Effects In Systemic Sclerosis. Serena Vettori[1], Giuseppe Pasquale[2], Michele Iudici[1], Giovanna Cuomo[1], Giusi Barra[2], Barbara Russo[1], Raffaele De Palma[2] and Gabriele Valentini[1]. [1]Rheumatology Unit, Second University of Naples, Naples, Italy, [2]Immunology Unit, Second University of Naples, Naples, Italy.

Background/Purpose: IL-17A has been recently implicated in the pathogenesis of systemic sclerosis (SSc). Therefore, we explored its expression and effects in peripheral blood mononuclear cells (PBMCs) co-cultured with autologous skin fibroblasts.

Methods: PBMCs and autologous skin fibroblasts from 5 patients with early (disease duration < 3 years) diffuse (dc) SSc were co-cultured in presence of IL-2 20U/ml in a 1:10 ratio. Separate cultures of PBMCs with IL-2 20U/ml and unstimulated fibroblasts were used as controls. The expression of IL17A, IL1B, IL4, and TGFB1 mRNA was analyzed in co-cultured and control PBMCs after 10 days by real-time PCR. The expression of IL17RA, CCL2, CCL3, CXCL1, COL1A1, COL3A1, CTGF, TGFBR2, and SMAD3 mRNA was analyzed in co-cultured and control fibroblasts. Chemokine production was further investigated at the protein level in culture surnatants by multiplex suspension fluorescence-based immunoassay.

Results: Real-time PCR analysis showed an increased expression of IL17A in co-cultured PBMCs by 11.5 fold ($p < 0.01$). No significant difference was found in the expression of IL1B, IL4, and TGFB1 mRNA between co-cultured and control PBMCs. Consistently with IL17A up-regulation in co-cultured PBMCs, mRNA levels of IL17RA were increased by 4.3 fold in co-cultured fibroblasts ($p < 0.05$). In order to clarify whether this up-regulation ensued in the formation of a functional receptor, we analyzed the expression of CCL2, CCL3, and CXCL1 mRNA, which are IL-17A target genes, in co-cultured fibroblasts. Indeed, CCL2, CCL3, and CXCL1 were up-regulated by 11.9 fold, 773.26 fold, and 13 fold respectively ($p < 0.05$). This induction was confirmed at the protein level in surnatants from co-cultures (CCL-2 25014 pg/ml; CCL-3 2227 pg/ml; CXCL-1 605.8 pg/ml) compared to control PBMCs (CCL-2 2821 pg/ml; CCL-3 199.1 pg/ml; CXCL-1 2.4 pg/ml) and control fibroblasts (CCL-2 2894 pg/ml; CCL-3 21.56 pg/ml; CXCL-1 3.1 pg/ml) ($p < 0.05$). Lastly, we investigated the effects of co-cultured PBMCs on the expression of pro-fibrotic genes in fibroblasts. We found that COL1A1, COL3A1, and CTGF mRNA was down-regulated by 0.33 fold, 0.24 fold, and 0.31 fold respectively ($p < 0.05$). In addition, we also found a down-regulation by 0.78 fold of TGFBR2 and by 0.79 of SMAD3 mRNA, suggesting that co-cultured PBMCs may interfere with the TGF-beta pathway hyperactivity in SSc fibroblasts.

Conclusion: Here we show for the first time that PBMCs from early dcSSc patients co-cultured with autologous skin fibroblasts over-express IL17A and exert anti-fibrotic effects in vitro. The simultaneous up-regulation of IL17RA and IL-17A target genes in the co-cultured fibroblasts suggests that IL-17A pathway is active in early dcSSc fibroblasts. These findings are paralleled by the down-regulation of TGF-beta signalling components. We previously showed that in co-cultures performed with PBMCs and autologous skin fibroblasts from early dcSSc patients T cells are expanded and kill autologous fibroblasts. Taken together, our novel data support the hypothesis that immune system may be primarily aimed to control fibroblast activation in the early phases of the disease, potentially opening new therapeutic approaches in SSc.

D1398G Variant Of Hepatocyte Growth Factor Receptor—A Potential Biomarker Of Severe Interstitial Lung Disease In African American Scleroderma Patients. Ilia Atanelishvili, Tanjina Akter, Richard M. Silver and Galina S. Bogatkevich. Medical University of SC, Charleston, SC.

Background/Purpose: Interstitial lung disease (ILD) is a major complication and leading cause of mortality in scleroderma (SSc, systemic sclerosis). The morbidity and mortality rates in African American scleroderma patients are higher when compared with SSc patients of other races. We previously demonstrated that hepatocyte growth factor (HGF) is reduced in BALF and plasma from African American SSc-ILD patients compared with white SSc-ILD patients. Moreover, in African American SSc fibroblasts the anti-fibrotic effects of HGF are compromised due to a deficiency in phosphorylation of the HGF receptor (cellular mesenchymal-epithelial transition factor, c-MET). The present study was undertaken to identify potential inhibitory mutations in c-MET gene extracted from lung fibroblasts with impaired phosphorylation of the HGF receptor.

Methods: Lung tissue was collected postmortem from SSc patients who fulfilled the ACR criteria for SSc and had evidence of lung involvement. SSc-ILD was confirmed by histological examination of postmortem lung tissue. Lung fibroblasts were isolated using standard procedures. RNA samples from lung fibroblasts were prepared by QIAGEN RNeasy® kit; c-MET gene was extracted by QIAGEN OneStep RT-PCR Kit. The coding exons of c-MET were PCR amplified and sequenced on both strands on ABA Prism 377 Genetic Analyzer using taq dye terminator chemistry at our university's DNA Sequencing Core. The sequence data were analyzed by BLASTN 2.2.18 using CCDS 47689. D1398G c-Met mutant was created using the QuickChange Site-Directed Mutagenesis XL kit from Stratagene; c-Met wild type and D1398G adenoviruses were generated by AdEasy Vector System, Quantum Biotechnology. HGF receptor phosphorylation, connective tissue growth factor (CTGF) and collagen content were studied by immunoblotting.

Results: We have identified six variants of c-Met unique for lung fibroblasts with non-functional HGF receptor. All of them are located in the C-terminus of the c-Met gene. We found that 100% of cell lines with non-functional HGF receptor carry the D1398G variant of c-Met gene; approximately 20% of all tested SSc lung fibroblasts contain C1379W and V1380G variants of c-Met gene; approximately 10% of cells with reduced HGF receptor function contain H1366P, L1351W, or E1350D variants of c-Met gene. None of these mutations was found in the c-Met gene isolated from SSc lung fibroblasts containing functional c-Met receptor. Lung fibroblasts isolated from African American SSc-ILD patients with D1398G variant of c-Met gene and normal lung fibroblasts transfected with D1398G c-Met mutant were characterized by limited effects of HGF on CTGF and collagen and by reduced HGF receptor phosphorylation on tyrosine 1238, 1252, and 1253.

Conclusion: D1398G variant of c-Met gene results in defective HGF signaling in lung fibroblasts. The occurrence of D1398G in African American SSc-ILD patients may explain in part a pathophysiologic link between African American race and poor pulmonary outcomes in SSc patients.

The Roles Of Nurse Practitioners and Physician Assistants In Rheumatology Practices In The United States. Erika Brown[1], Asaf Bitton[1], Liana Fraenkel[2], Hsun Tsao[3], Jeffrey N. Katz[1] and Daniel H. Solomon[4]. [1]Brigham and Women's Hospital, Boston, MA, [2]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [4]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA.

Background/Purpose: A recent workforce study of rheumatology in the US suggests that during the next several decades the demand for rheumatology services will outstrip the supply of rheumatologists. Mid-level providers working in rheumatology, such as nurse practitioners (NPs) and physician

assistants (PAs), may be able to alleviate projected shortages, but national data on their current roles and responsibilities are sparse.

Methods: We administered a nation-wide survey to mid-level rheumatology providers during 2012 through the Association of Rheumatology Health Professionals and Society of Physician Assistants in Rheumatology. E-mails and mailed invitations with the survey were sent with one follow-up reminder. The survey contained questions regarding demographics, training, level of practice independence and responsibilities, disease modifying antirheumatic drug (DMARD) prescribing, use of objective RA outcome measures, and knowledge and use of Treat to Target strategies.

Results: The invitation was sent to 482 eligible mid-level providers via e-mail and 90 via US mail. We received a total of 174 (30%) responses, 47% from NPs and 51% from PAs (2% missing). The mean age was 46 (±11) years, and 83% were female. Nearly 75% had ≤10 years of experience, and 53% received formal training in rheumatology training. Sixty-three percent reported having their own panel of patients. Respondents reported seeing patients in the context of follow-up visits (98%), initial consults (74%), and urgent visits (89%). They described a variety of practice responsibilities, with the top five being: performing patient education (98%), adjusting medication dosages (97%), conducting physical exams (96%), treating patients (96%), and starting patients on medications (94%). Over 90% felt very or somewhat comfortable diagnosing RA and a similar percentage prescribed DMARDs (see Table). Forty-nine percent reported using DAS, CDAI, SDAI, and/or RAPID disease activity measures for RA and 56% reported that their practices used Treat to Target strategies.

Table. Survey Responses

	Total
Confidence diagnosing RA[1]	
Very confident	76.9%
Somewhat confident	21.3%
Not particularly confident	1.2%
Not at all confident	0.6%
Manages patient treatment[2]	
Yes	94.6%
No	5.4%
Knows of TTT[2]	
Yes	77.8%
No	22.2%
Practice uses TTT[3]	
Yes	75.4%
No	24.6%
Outcomes measures used[4]	
DAS	21.5%
CDAI	12.8%
SDAI	0.6%
HAQ	37.8%
RAPID	23.3%
Patient global	25.0%
Physician global	21.5%
Uses any outcomes measure	48.6%

Abbreviations: DAS = Disease Activity Score; CDAI = Clinical Disease Activity Index; SDAI = Simple Disease Activity Index; HAQ = Health Assessment Questionnaire; RAPID = Routine Assessment of Patient Index Data; TTT = Treat to Target Totals varied due to missing data: [1]N = 169; [2]N = 167; [3]N = 130; [4]N = 172

Conclusion: Most NPs and PAs responding reported substantial patient care responsibilities, working independently; many reported using disease activity measures and treat to target strategies. These data suggest the potential opportunity of expanding the use of NPs and PAs as practitioners in rheumatology to reduce the projected workforce shortages and meet current RA treatment recommendations.

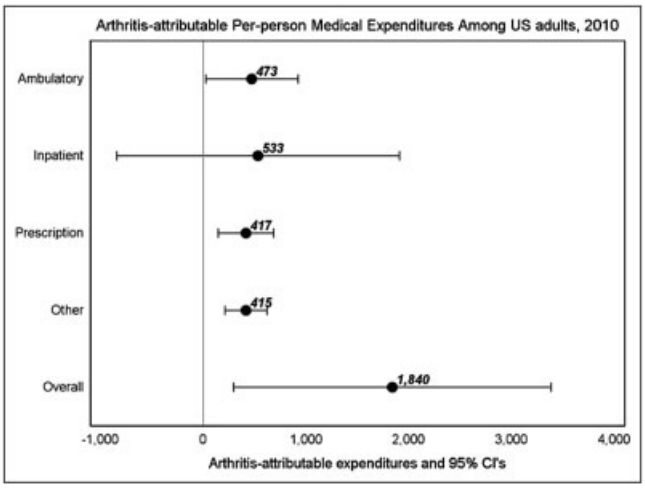
2010 Medical Care Expenditures Among US Adults With Arthritis. Miriam Cisternas[1], Louise Murphy[2], David Pasta[3], Edward H. Yelin[4] and Charles G. Helmick[5]. [1]MGC Data Services, Carlsbad, CA, [2]CDC, Atlanta, GA, [3]DMA Corporation, Palo Alto, CA, [4]UC San Francisco, San Francisco, CA, [5]Centers for Disease Control and Prevention, Atlanta, GA.

Background/Purpose: Using data from the 2010 Medical Expenditure Panel Survey (MEPS), we estimated total and arthritis-attributable medical care expenditures among US adults age 18 years and over with arthritis.

Methods: Arthritis was identified using an ICD-9-CM based definition of doctor-diagnosed arthritis. We estimated total and arthritis-attributable expenditures (the national sum and per–person mean) overall and for four categories: ambulatory care (office-based and hospital outpatient); inpatient care; prescriptions; and other (emergency room visits, home health care, vision aids, dental visits and medical devices). Arthritis-attributable expenditures were calculated using multi-stage regression models that adjusted for demographics (age, sex, race, Hispanic ethnicity, and education), health insurance coverage (any private, public only, or none), and nine costly comorbid conditions.

Results: In 2010, total medical care expenditures among adults with arthritis were $9,262 per person, (national sum = $566 billion), representing half of all expenditures among US adults in MEPS. Across categories, inpatient expenditures were highest ($2,972 per person), accounting for 32% of total medical expenditures among people with arthritis. National arthritis-attributable expenditures totaled $112.4 billion (mean per person = $1,840 [Figure]), and represented 10% of all national expenditures among US adults in MEPS, with inpatient expenditures comprising the largest portion of arthritis-attributable costs (29%). The national sum of arthritis-attributable expenditures were $33 billion for inpatient care, $29 billion for ambulatory care, $25 billion for prescriptions, and $25 billion for other services.



Figure

Conclusion: Analysis of US adults in 2010 showed that their arthritis-attributable medical care costs comprised 10% of all medical care expenditures nationally and total costs (including non-arthritis expenditures) for the arthritis population comprised half of all medical expenditures. This illustrates both the substantial economic impact of arthritis itself as well as the impact of comorbid conditions that occur in the 27% of the adult population living with arthritis. Population aging and increasing prevalence of obesity imply that these expenditures will increase in the future and suggest the need for intervention strategies such as weight management and increasing physical activity that prevent the adverse effects of arthritis including pain and disability.

Differences In Abatacept Use In Rheumatoid Arthritis Patients Across Europe: A Pan-European Database Analysis Of Abatacept In European RA Registries. David Neto[1], Axel Finckh[2], Florenzo Iannone[3], Estíbaliz Loza[4], Elisabeth Lie[5], Piet L.C. Van Riel[6], Merete L. Hetland[7], Karel Pavelka[8], Jacques-Eric Gottenberg[9], Xavier Mariette[10] and Carl Turesson[11]. [1]University of Geneva, Geneva, Switzerland, [2]Geneva University Hospital, Geneva, Switzerland, [3]D.I.M.I.M.P, Rheumatology Unit - University of Bari, Bari, Italy, [4]Spanish Society of Rheumatology, Madrid, Spain, [5]Diakonhjemmet Hospital, Oslo, Norway, [6]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [7]Copenhagen University Hospital Glostrup, Copenhagen, Denmark, [8]Department of Clinical and Experimental Rheumatology, Charles University, Prague, Czech Republic, [9]Strasbourg University Hospital, Strasbourg, France, [10]Bicêtre University Hospital, Le Kremlin Bicetre, France, [11]Skåne University Hospital, Malmö, Sweden.

Background/Purpose: Several European registries have pooled data of patients (pts) who received Abatacept (ABA) for rheumatoid arthritis (RA) to

acquire new knowledge about performance of ABA in clinical care in different settings.

The objective of this study was to analyze potential heterogeneity in pts initiating ABA across different European countries.

Methods: This is a cohort study of 8 longitudinal, observational, national RA registries from different European countries: ARTIS (Sweden), ATTRA (Czech Republic), BIOBADASER (Spain), DANBIO (Denmark), GISEA (Italy), NORDMARDS (Norway), ORA (France), SCQM (Switzerland), which have been described elsewhere. Inclusion criteria for this project were a diagnosis of RA and registered initiation of treatment with ABA. Key demographic variables, disease characteristics at ABA initiation, time on ABA treatment and reasons for discontinuation were collected from all registries and analyzed using descriptive statistics. Crude ABA drug retention was analyzed using Kaplan-Meier curves and log rank test.

Results: A total of 4041 pts were included, contributing 5980 pt-yrs of follow-up (median 1 year per patient; interquartile range [IQR]: 0.40–2.3). Pts in the different national registries had similar demographic characteristics (Table). More heterogeneity existed for RA disease characteristics: disability (by HAQ ranged from 0.9 (NORDMARDS) to 1.5 (ATTRA)) and disease activity (by DAS28 ranged from mean 4.2(SCQM) to mean 5.7(ATTRA)). The greatest difference across registries existed regarding treatment history prior to ABA initiation: the median number of prior inadequate responses (IR) on conventional DMARDs varied between a median of 1 ([IQR: 1–2], SCQM) and 4 ([IQR: 2–5 or 6], ATTRA, DANBIO); the number of prior IR on Biologics (*90%* anti-TNF agents) before first ABA initiation also varied between a median of 1 (SCQM) and 3 (DANBIO).

Registers (N)	NORDMARD (52)	SCQM (506)	ATTRA (215)	GISEA (375)	ORA (1032)	ARTIS (1019)	DANBIO (315)	BIOBADASER + Granada (487 + 40)

DAS28-ESR, (Mean ± SD)	5.4 ± 1.1	4.2 ± 1.0	5.7 ± 1.1	5.0 ± 1.3	5.3 ± 1.3	5.1 ± 1.4	4.9 ± 1.2	–
Smoker %	23.1	24.0	22.8	22.3	9.8	–	63.5	11.5
BMI (kg/m^2), (Mean ± SD)	24.0 ± 4.1	25.9 ± 5.1	25.5 ± 4.9	25.8 ± 5.0	–	24.8 ± 1.5	26.3 ± 5.6	–
CRP (mg/l), (Mean ± SD)	24.2 ± 34.2	13.9 ± 16.3	25.7 ± 29.3	3.9 ± 6.6	2.5 ± 3.3	19.6 ± 26.5	–	–
ESR (mm/h), (Mean ± SD)	36.4 ± 28.1	25.9 ± 20.3	38.3 ± 24.3	34.4 ± 23.4	35.6 ± 27.7	30.4 ± 23.0	–	–
N° past c. DMARDs, (Median [IQR])	3 [2–4]	1 [0–2]	4 [2–5]	2 [2–3]	3 [2–4]	1 [1–2]	4 [3–6]	–
N° past Biologics, (Median [IQR])	2 [2–3]	1 [0–2]	–	1 [1–2]	2 [1–3]	2 [1–3]	3[2–4]	2 [1–4]
ABA drug retention med (yrs), (Median [IQR])	0.9 [0.5–2]	0.9 [0.8–1.1]	3.1 [2.6–3.9]	< 4 [3.7–∞]	1.8 [1.5–2.0]	1.0 [0.9–1.0]	1.3 [1.0–1.7]	2.6 [2.4–2.8]

We found significant differences in drug survival for ABA ($p < 0.001$; log rank test). The median drug retention ranged from > 4 years in GISEA, to around 1 year in SCQM, NORDMARDs or ARTIS. When examining only drug discontinuation for ineffectiveness the same trends were found (not shown).

Conclusion: Patient characteristics at ABA initiation varied across European countries, probably reflecting differences in eligibility criteria and prescription patterns. There were also large differences in ABA drug retention, with a trend to shorter ABA maintenance in countries with relatively liberal access to biologics. National differences need to be accounted for when analyzing pooled data from several national registries.

The Challenge To Develop a Multidimensional Computerized Adaptive Test For Fatigue In Rheumatoid Arthritis. Stephanie Nikolaus[1], Christina Bode[1], Erik Taal[1], Cees A.W. Glas[1] and Mart A.F.J. van de Laar[2]. [1]University of Twente, Enschede, Netherlands, [2]Medisch Spectrum Twente & University of Twente, Enschede, Netherlands.

Background/Purpose: Computerized adaptive testing (CAT) provides the possibility to measure patient reported outcomes precisely at individual level. As items are selected based on the previous answer of a patient, the number of items needed to achieve the same level of precision as obtained in a traditional questionnaire can be up to 40% less. Multidimensional CAT has the further advantage that simultaneous measurement of multiple dimensions increases the efficiency of the adaptive item selection procedure. Aim of the study was the development of a multidimensional CAT for fatigue in rheumatoid arthritis (RA) whereby the perspectives of patients as well as modern psychometrics were included. Reporting on its construction is informative for health professionals since multidimensional CATs are still rare in health care and clear guidelines for their development are lacking.

Methods: For the construction of a CAT, an item pool has to be developed and calibrated according to item response theory (IRT). Our item pool was based on interviews with patients and existing fatigue questionnaires. It was examined for content validity by a Delphi study and examined with IRT and factor analysis to explore its statistical dimensionality structure and to fit a multidimensional IRT model. It contained 196 items and three dimensions of fatigue: severity, impact and variability of fatigue. Based on a functional script, and the item information gained by IRT analyses, software was constructed and provided as online application. Responses to the CAT were simulated for about 1000 virtual persons to determine start- and stopping rules. The first version of the CAT was tested for its usability by patients.

Results: Simulations showed that the standard error for each of the dimensions was acceptably low under the following conditions: test length of 20 items, at least two random start items per dimension and at least five items per dimension. A low standard error is desirable as it indicates high measurement precision. The first version of the CAT was checked for programming problems and a usability test was conducted with 15 patients with RA. They filled in the CAT while thinking aloud and were interviewed about their experience with the new instrument. Patients' comments were positive; they experienced the CAT as clear, short and innovative. Some patients noticed that several items of the dimension "severity" were formulated in a similar way. The first version of the CAT fatigue RA will be demonstrated in this presentation.

Conclusion: This study provided the first version of a multidimensional CAT for fatigue in RA. In this presentation, further important issues for the construction of a multidimensional CAT will be discussed since the thorough development of measurement instruments is essential for precise and reliable assessment of patient reported outcomes. Only then, an instrument will be able to provide benefits for further research, possible interventions and/or the enhancement of the communication between patients and health professionals. At the moment, a validation study is taking place to examine the psychometric properties of the multidimensional CAT in more detail.

Integrating Patient Electronic Health Records With An Electronic Data Capture System In a Biologics Registry For Inflammatory Arthritides. Inge C. Olsen, Espen A. Haavardsholm, Tore K. Kvien, Ellen Moholt and Elisabeth Lie. Diakonhjemmet Hospital, Oslo, Norway.

Background/Purpose: The NORwegian Disease Modifying Anti-Rheumatic Drugs (NOR-DMARD) registry has since 2000 been registering DMARD use and response in five different Norwegian rheumatology departments (ref). Almost 5,000 biologic treatment courses in 3,500 patients have been included so far, together contributing with 19,000 study visits. Clinical information was previously recorded on paper, but from May 2012 an electronic data capture (EDC) system has been implemented.

Methods: A commercial EDC system, Viedoc™, has been set up in order to capture study data using electronic case report forms (e-CRFs). All centers have implemented a structured electronic health record (EHR), GoTreatIt™, which facilitates the export of un-identified source data. The workflow of a new patient is as follows:

1. The patient is included into the EDC system with patient information such as patient initial, date of birth and biologic treatment, and a visit is initiated with some information not collected in the EHR.
2. The EDC system generates a unique patient number, which is then registered in the EHR. This key enables the transfer from one system to the other.
3. Study data are then registered in the EHR, both by the treating physician/nurse (e.g. DAS28, ASDAS) and the patient (e.g. MHAQ, RAID).

Once a month each center extracts data in an XML-format from the site's EHR system. The contents of the extracted data are pre-specified and in accordance with the study protocol and e-CRF. The trial data manager uses a SAS program to parse the XML-files to a flat file format readable in the EDC system. The SAS program also runs a validation check against patient numbers, dates of birth and visit dates. We then import the flat files into the EDC system using the system's import routine, merging by patient number. The system facilitates an audit trail, so any changes are registered. A patient's e-CRF with all collected data is then accessible for both site and trial data management.

Results: From May 2012 to June 2013, 1697 patients on biologic treatment have been successfully included into the EDC system. A Contract Research Organization (CRO) NOK handled the previous paper-CRF system at a price of 115 NOK (20 USD) per visit/CRF. The money saved from this contract has already made the shift into EDC profitable, taken the set-up and licensing costs of the EDC system into consideration. In addition to this, the paper CRF system required considerable manual resources at each participating center, including entering, copying and mailing of completed CRFs and administration of inclusion IDs.

Conclusion: We have developed a novel methodology where we gather patient′s health record information from five different centers into a central trial database. We avoid time-consuming handling of paper-CRFs and eliminate data entry errors since we import source data directly into the study database. Compared to a standard e-CRF solution we gain efficacy effects because we avoid redundant registration, i.e. both in the patient journal and in the e-CRF system.

The Validity Of Patient-Reported Short-Term Complications Following Total Hip and Knee Arthroplast. Leslie R. Harrold[1], David Ayers[1], Regis O'Keefe[2], Courtland Lewis[3], Vincent Pellegrini[4] and Patricia D. Franklin[1]. [1]University of Massachusetts Medical School, Worcester, MA, [2]University of Rochester Medical Center, Rochester, NY, [3]Hartford Hospital, Hartford, CT, [4]Medical University of South Carolina, Charleston, SC.

Background/Purpose: Given the absence of national longitudinal data on patients who undergo total joint arthroplasty (TJA) and the limitations of hospital databases to capture information on patients who seek post-TJA care elsewhere, there is growing interest in using patient self-report to identify complications following surgery. We examined the concordance between patients self-report of potential short-term complications with review of available medical records.

Methods: Patients undergoing primary hip or knee arthroplasty from 7/1/11 through 12/3/12 participating in a tertiary care center were identified. Patients completed a 6-month post-operative survey regarding evaluation at an emergency department, day surgery or hospitalization for possible medical or mechanical complications following primary TKA/THA. We reviewed available inpatient and outpatient medical records and examined the sensitivity, specificity, positive predictive values and negative predictive values for patient-self report and medical records.

Results: There were 328 patients who had 339 surgeries and completed the 6-month questionnaire. Patients reported 46 medical encounters (emergency department, day surgery or inpatient care): 15 were excluded as they were hospitalizations >90 days following surgery or unlikely to be related to TJA (e.g., tooth extraction) resulting in a 10% possible event rate; 12% of the events occurred at hospitals different from the surgical hospital. Review of medical records revealed 6 additional medical encounters that patients had not mentioned including 3 hospitalizations following surgery (2 for leg pain and 1 for cellulitis) and 3 emergency department visits where no complications from TJA were identified. Patient self-report of emergency department, day surgery and inpatient care for possible complications was both sensitive (91%) and specific (100%). The positive predictive value was 100% and negative predictive value 99%.

Conclusion: We examined the concordance between patients' self-report of possible complications following surgery with review of available medical records and found a sensitivity of 91% and positive predictive value of 100% suggesting this approach may be used to augment current hospital post-discharge surveillance procedures. Patients appropriately reported medical care signifying potential adverse events following TJA. Given the new public reporting requirements of all post-TJA discharge complications, patient reported post-operative events may augment current hospital-specific surveillance procedures.

Serum Proteins and Whole Blood Transcripts Suppressed By An Anti-Type I Interferon Receptor Monoclonal Antibody In Subjects With Systemic Sclerosis. Xiang Guo[1], Brandon W. Higgs[1], Christopher Kane[1], Chris, A. Morehouse[1], Zheng Liu[1], Liangwei Wang[1], Stephen Yoo[1], Yihong Yao[1], Lorin Roskos[2] and Wendy White[1]. [1]MedImmune, LLC, Gaithersburg, MD, [2]MedImmune, Gaithersburg, MD.

Background/Purpose: To identify serum markers that are modulated by an investigational human IgG1κ monoclonal antibody directed against subunit 1 of the type I interferon receptor (IFNAR1), MEDI-546, in systemic sclerosis (SSc) subjects.

Methods: An open-label single- and multiple-dose phase 1a clinical trial was conducted to evaluate the safety, tolerability, pharmacokinetics, immunogenicity, and pharmacodynamics (PD) of MEDI-546 in SSc patients (NCT00930683). Affymetrix whole genome arrays were used to measure transcript expression in whole blood before and after administration of MEDI-546, and a 5 gene type I IFN signature was used to assess the type I IFN activity and PD effects of MEDI-546 in SSc patients. Serum levels of 93 proteins were measured in 47 SSc patients and compared to 20 healthy controls to determine dysregulated analytes in SSc subjects using a Luminex-based immunoassay platform. Next, this same panel of analytes was used to determine the effects of MEDI-546 by comparing pre- and post-dose samples.

Results: Comparison of serum proteins between SSc subjects and healthy controls identified 35 dysregulated proteins, multiple of which were found to be associated with clinical/laboratory measurements, such as modified Rodnan Total Skin Score (mRTSS) and serum levels of collagen synthesis markers (PINP and PIIINP). Administration of MEDI-546 resulted in suppression of 8 proteins, among which 6 are type I IFN-inducible. Reduction of CXCL10 and soluble CD40L levels were significantly correlated with type I IFN gene signature suppression by MEDI-546. These two proteins are associated with T cell activation and movement, along with CXCL11 and IL2RA that also demonstrated significant down-regulation post-administration of MEDI-546. Furthermore, paired comparison of whole blood microarray data, pre- and post-MEDI-546 administration identified a list of differentially regulated transcripts enriched in regulatory functions by various IFN-related proteins, T cell receptor (TCR), nuclear factor of activated T cells (NFATC2), and CD40L. Thus, both proteomics and transcriptomic results suggest a suppressive effect of MEDI-546 in T cell activation and tissue infiltration. Using serum levels of CXCL10, CXCL11, soluble IL2R, and CD40L, we defined a protein index suppressible by type I IFN blockage. This index exhibited significant correlation with mRTSS and PIIINP levels at baseline, and down-regulation in the index was significantly associated with suppression of type I IFN gene signature post administration.

Conclusion: Our study demonstrated a robust overexpression of multiple serum proteins in SSc patients, particularly those with an elevated type I IFN gene signature score. Type I IFN blockade by MEDI-546 resulted in significant suppression of multiple type I IFN-associated proteins, particularly those related to T cell activation and

movement. A protein index suppressible by type I IFN blockage may serve as a responsive or predictive marker for type I IFN-targeted therapy in SSc subjects, which shall be examined in future clinical trials.

Effect Of Menopause On Skin Thickening In Systemic Sclerosis. Evelyne Vinet[1], Sasha Bernatsky[1], Christian A. Pineau[1], Marie Hudson[2], Murray Baron[2] and the Canadian Scleroderma Research Group[3]. [1]McGill University Health Center, Montreal, QC, [2]McGill University, Montreal, QC, [3]McGill University Health Centre, Montreal, QC.

Background/Purpose: Menopause, characterized by a low estrogenic state, is associated with skin thinning, due to decreased extracellular matrix protein deposition by fibroblasts. Although systemic sclerosis (SSc) most commonly occurs near the end of the reproductive period and predominantly affects women, no one has investigated the impact of menopause on skin involvement in women with SSc. Thus, we aimed to evaluate the effect of menopause on skin thickening, as measured by the modified Rodnan skin score (MRSS), in women with SSc

Methods: We identified women with either limited or diffuse SSc, aged ≥ 18 years, enrolled within the Canadian Scleroderma Research Group (CSRG) cohort, between 2004–2011. As part of the CSRG cohort, subjects undergo annual assessments with standardized questionnaires and physical examinations.

We performed multivariate regression analyses using generalized estimating equation (GEE) to determine the effect of menopause on the MRSS, adjusting for relevant covariates (Table 1).

Table 1. Multivariate analysis of covariates' effect on the modified Rodnan skin score

[a]Confidence interval. [b]disease modifying antirheumatic drugs

Results: We identified 1070 women with SSc, contributing a total of 3546 observations over the study period. Of these women, at baseline, 65% had limited disease and 35% diffuse disease. At cohort entry, mean age and mean disease duration were respectively 55.5 [standard deviation (SD) 11.7] and 11.2 (SD 9.6) years, and 72% of subjects had already reached menopause. Overall, at baseline, the mean MRSS was 9.6 (SD 9.1), and in pre- and postmenopausal women, it was respectively 12.0 (SD 10.5) and 8.7 (SD 8.4).

In multivariate analyses (Table 1), we observed a substantial effect of postmenopausal status on the mean MRSS in women with diffuse disease subtype [-2.62 units, 95% confidence interval (CI) −4.44, −0.80] and significant interaction between menopausal status and disease subtype (2.04 units, 95% CI 0.20, 3.88). The effect of postmenopausal status on the mean MRSS was smaller in women with limited SSc (−0.58, 95% CI −1.50, 0.34).

In a multivariate analysis restricted to women with early disease (i.e. baseline disease duration less than 5 years), we observed a larger effect of postmenopausal status on the mean MRSS (compared to premenopausal status) both in women with diffuse (−3.36 units, 95% CI −5.87, −0.85) and limited SSc (−1.45, 95% CI −3.21, 0.31), as opposed to the effect estimates observed in the overall sample.

Conclusion: Our results suggest that menopause has a substantial effect on skin thickening in diffuse SSc, with postmenopausal status being associated with a lower mean MRSS compared to premenopausal status. This effect might be more pronounced in early disease (i.e. baseline disease duration of less than 5 years). Our findings should prompt further research on the role of estrogen on skin disease progression in SSc.

Anti-Fibrillarin Antibodies Are Associated With More Severe Gastrointestinal Involvement and Poorer Survival. Shervin Assassi[1], Marie Hudson[2], Maureen D. Mayes[1], Jennifer Walker[3], Murray Baron[2], Wendy Stevens[4], Karen Patterson[5], Tiffany Graham[1], Solene Tatibouet[2], James Wick[6], Matt Stephenson[6] and Marvin J. Fritzler[6]. [1]University of Texas Health Science Center at Houston, Houston, TX, [2]McGill University, Montreal, QC, [3]Flinders Medical Centre, Adelaide, Australia, [4]St Vincent's Hospital, Melbourne, Australia, [5]Institute of Medical and Veterinary Science, North Adelaide, Australia, [6]University of Calgary, Calgary, AB.

Background/Purpose: Anti-fibrillarin (U3-RNP) antibodies (AFA) are a relatively specific biomarker for systemic sclerosis (SSc). Previous studies have indicated a higher prevalence of AFA among African American patients. The examination of demographic and clinical correlates of AFA has been hampered by its low prevalence. Our objective was to examine the clinical correlates of AFA in a large study population consisting of three well-characterized SSc cohorts from Canada, Australia, and the USA.

Methods: A total of 1596 SSc patients enrolled in the Canadian Scleroderma Research Group (CSRG), the Australian Scleroderma Interest Group (ASIG), and the Genetics versus Environment In Scleroderma Outcome Study (GENISOS) were included in this study. AFA were determined by a line immunoassay (EUROLINE, Euroimmun, Lübeck, Germany). In addition to demographic data, associations with clinical data including modified Rodnan Skin Score (mRSS), history of digital ulcers/pits, calcinosis, arthritis, telangiectasia, scleroderma renal crisis, gastrointestinal (GI), pulmonary manifestations and pulmonary function test parameters were examined. An association with the overall mortality was also examined by Cox regression analysis

Results: The mean (± SD) age at enrollment and disease duration were 55 (± 12.8) and 9.5 (± 9.2) in the overall study population. Diffuse cutaneous involvement was present in 606 patients (38.6%). The study population was multi-ethnic consisting of 1,106 white, 71 African descent, 90 Hispanic, 48 Asian, and 39 Native North-American, and 8 Australian Aboriginal patients. A total of 52 patients (3.3%) had AFA. These antibodies were more common among African descent (OR: 2.92, p= 0.033) and Native North-American patients (OR=4.4, p=0.008).

In the multivariate analysis after adjustment for age at enrollment and ethnicity, patients with AFA had more frequently bacterial overgrowth requiring antibiotics (OR=2.5, p=0.048). There were also trends for an association with diffuse cutaneous involvement (OR=1.78, p=0.057) gastroesophageal reflux disease (OR=2.56, p=0.074) and need for parenteral nutrition (OR=3, p=0.099).

In Cox regression analysis after adjustment for age at enrollment and ethnicity, patients with AFA had poorer survival (HR: 2.36, $p<0.001$). This relationship remained significant even after addition of disease type to the model (HR: 2.28, $p<0.001$).

AFA were not associated with vascular, renal, or pulmonary manifestations of disease.

Conclusion: This large international study confirmed the association of AFA with African decent ethnicity and GI involvement. The large, well-characterized study population allowed us to make the following novel observations: AFA are associated with Native North-American ethnicity, diffuse cutaneous involvement, and poorer survival. The more severe GI involvement might explain partially the observed poorer survival in this serological subtype of SSc patients.

Mortality, Recurrence, and Hospital Course of Patients With Systemic Sclerosis Related Acute Intestinal Pseudo-Obstruction. Chris T. Derk[1], Nora Sandorfi[2], Shivani Purohit[3] and Christopher Mecoli[1]. [1]University of Pennsylvania, Philadelphia, PA, [2]Thomas Jefferson Univ Med Coll, Philadelphia, PA, [3]Rheumatology Division, Department of Medicine, Thomas Jefferson University, Philadelphia, PA.

Background/Purpose: Acute intestinal pseudo-obstruction is a rare gastrointestinal manifestation of SSc with little data existing as to the demographics, clinical course, outcomes and mortality of this disease. With this study we attempt to describe the mortality, recurrence and hospital course of these patients.

Methods: We undertook a retrospective chart review of patients admitted at two University Medical Centers in the city of Philadelphia over an 11.5 year period (1/2001-6/2012). Medical records were searched using ICD codes for SSc in combination with ICD codes for intestinal obstruction and fecal impaction. The medical records were then reviewed for those patients who were identified as true cases of pseudo-obstruction and we collected information regarding demographic data, laboratory and radiological studies, hospital presentation and course, medical and surgical treatment, outcomes and mortality. Continuous variables were analyzed by student's unpaired two-tailed t test while categorical variables by Fisher's exact test.

Results: A total of 1,733 admissions of SSc patients to the two hospitals were identified during the time period in question. 103 admissions had ICD codes matching our search criteria and from them 64 admissions were identified as true acute intestinal pseudo-obstruction cases in 37 unique SSc patients. From these cases 73% had spontaneous resolution with conservative measures of IV hydration and bowel rest, 11% underwent surgical resection and 26% required permanent total parenteral nutrition (TPN). Hospital course was for a mean of 12+12.5 days and there was 10% mortality. In a subgroup analysis of patients who had recurrent episodes of pseudo-obstruction this was more commonly seen in women ($p=0.01$), associated with symptoms of nausea at presentation ($p=0.04$) and resulted more often to the use of prolonged TPN ($p<0.0001$). Mortality was higher in male patients ($p=0.014$) who had low hemoglobin ($p<0.00008$) and serum albumin ($p<0.001$). Patients who underwent surgery were more likely to die as compared to patients who did not ($p<0.005$). A prolonged hospital stay was more often related to the use of a nasogastric tube ($p<0.05$) and surgical resection ($p<0.05$).

Conclusion: Acute intestinal pseudo-obstruction is a rare cause of hospitalization of SSc patients (64/1733 (3.7%) admissions). This is the largest study attempting to characterize this subpopulation of SSc patients. Based on our results most patients have spontaneous resolution with conservative measures such as bowel rest and IV hydration. Women were more likely to have recurrences and these patients were more likely to suffer from nausea at their presentation, and progressed to need permanent TPN. Mortality was higher in males especially in those patients with a low hemoglobin and serum albumin at presentation. Patients who underwent a surgical resection had a higher mortality and a more prolonged hospital stay.

Survival After Lung Transplantation In Systemic Sclerosis. A Systematic Review. Irfan Y. Khan[1], Lianne G. Singer[2], Marc de Perrot[3], John T. Granton[4], Shaf Keshavjee[3], Cathy Chau[5], Amie T. Kron[6] and Sindhu R. Johnson[7]. [1]Pulmonary Hypertension Programme, University Health Network, University of Toronto, Toronto, ON, [2]Division of Respirology, University of Toronto; and Toronto Lung Transplant Program, University Health Network, Toronto, ON, [3]Toronto Lung Transplant Program, Division of Thoracic Surgery, University Health Network, University of Toronto, Toronto, ON, [4]Toronto Pulmonary Hypertension Programme, Toronto General Hospital and University of Toronto, Toronto, ON, [5]Toronto Scleroderma Research Program, Toronto Western Hospital, Mount Sinai Hospital, University of Toronto, Toronto, ON, [6]Toronto Scleroderma Research Program, Toronto Western Hospital, Mount Sinai Hospital, and University of Toronto, Toronto, ON, [7]Division of Rheumatology, Toronto Western Hospital, University Health Network Pulmonary Hypertension Programme, Toronto General Hospital, Mount Sinai Hospital and University of Toronto, Toronto, ON.

Background/Purpose: Lung transplantation is a life-saving option for systemic sclerosis (SSc)-associated pulmonary arterial hypertension (PAH) and interstitial lung disease (SSc-ILD) patients. Yet, there is risk of post-transplantation mortality. The objective of this study was to evaluate survival of SSc patients post-lung transplantation. We secondarily evaluated SSc lung transplant recipient characteristics, and compared post-lung transplantation survival of SSc patients to non-SSc patients (idiopathic PAH, and ILD).

Methods: A systematic review of MEDLINE, EMBASE, Cochrane Central Registry of Controlled Trials and CINAHL (all inception to 2012) was performed to identify studies evaluating post-lung transplant survival in SSc compared to non-SSc patients. Two reviewers independently abstracted study and survival data using a standardized form.

Results: 226 citations were screened to identify 7 observational studies reporting SSc patients who underwent single lung, double lung, or heart-lung transplantation. Mean age at transplantations ranged 46–53 years. SSc post-transplantation survival ranged 69%–91% at 30-days, 69%–85% at 6-months, 59%–93% at 1-year, 49%–80% at 2-years, and 46%–79% at 3-years. ILD post-transplant survival was 80% at 30-days, 80%–90% at 6-months, 59%–83% at 2-years, and 69% at 3-years. IPAH post transplant survival was 79% at 30-days, 79%–90% at 6-months, and 74%–90% at 1-year. The reporting of overlapping cohorts potentially including the same patients precluded meta-analysis. Causes of death in SSc patients, when reported, included graft failure (n=6), infection (n=8), cardiac events (n=3), hemorrhagic stroke (n=1), respiratory failure (n=3), malignancy (n=2), pulmonary hypertension (n=1), complications of bronchiolitis obliterans syndrome (BOS) (n=1), anesthetic complication (n=1), and scleroderma renal crisis (n=1). There were no reports of recurrence of SSc in the lung allograft.

Conclusion: SSc survival post-lung transplantation is very good, and improving with time. The short-term and intermediate-term survival post-lung transplantation are similar to IPAH and ILD patients requiring lung transplantation. Future researchers should delineate the access process for lung transplantation and report the occurrence of acute rejection, infection, bronchiolitis obliterans syndrome, renal dysfunction and dialysis, gastroparesis, and need for tube feeding.

The Clinical Utility Of Flow-Mediated Dilation In Systemic Sclerosis. Tracy M. Frech[1], Ashley Walker[2], Zachary Barrett-Okeefe[2], Russell Richardson[2], D. Walter Wray[2] and Anthony Donato[2]. [1]Salt Lake City VAMC, Salt Lake, UT, [2]University of Utah, Salt Lake, UT.

Background/Purpose: In systemic sclerosis (SSc, scleroderma) vasculopathy can result in the end-stage manifestation of a digital ulcer (DU). We hypothesized that bedside flow mediated dilatation (FMD) with ultrasound Doppler, which inexpensive, easy to use, and can directly measure endothelial function, could be used in SSc patients to identify features of patients at risk for DU.

Methods: 38 consecutive SSc patients were recruited from SSc Clinic and compared to 51 healthy controls (HC) which were age and body mass index (BMI) matched from the Veteran's Affair Medical Center Utah Vascular

Research Lab. Duplex ultrasonography was utilized to assess baseline vascular parameters forearm blood flow and brachial artery diameter. Afterward a blood pressure cuff was inflated to suprasystolic pressures (240 mmHg) distal to the ultrasound probe on the forearm and brief ischemia was induced for 5 minutes. Following cuff release measure of vascular reactivity (peak reactive hyperemia and hyperemia area under the curve [AUC]), brachial artery FMD (cm and % vasodilation) were obtained. A T-test was used to measure these continuous variables between SSc and HC, as well as SSc patients with DU and without DU.

Results: The SSc population's mean age was 54±3, with a BMI of 27±1, 33 were female, and 34 were white. Mean mRSS was 8; 31 with limited and 7 with diffuse cutaneous skin distribution. Mean duration of Raynaud's was 14.9 years and SSc (first non-Raynaud's symptom) was 11 years. Vasculopathy manifestations included 13 with DU, 6 with pulmonary arterial hypertension, and 1 with scleroderma renal crisis; 31 of these patients were on treatment with vasodilators. The age-matched HC group mean age was 51±2, with a BMI of 24±1 and included 42 females. None of the HC group had a history CVD, diabetes or respiratory disease and were not on prescription medication. None of the subjects in either group used tobacco.

Baseline vascular differences were seen in SSc patients displaying elevated forearm blood flow ($p=0.05$) and smaller brachial artery diameter ($p=0.002$) (Figure 1) versus age-matched healthy controls. Post-forearm occlusion, significant differences were seen in hyperemia ($p=0.00001$), shear stress ($p=0.002$), brachial artery FMD (cm, $p=0.001$ and %, $p=0.01$) compared to healthy controls (Figure 2). Within the SSc population brachial artery flow mediated dilation was significantly different between those with DU and without DU (cm, $p=0.05$ and %, $p=0.05$), whereas other parameters were similar ($p>0.31$).

Conclusion: Utilizing a non-invasive ultrasound technique developed for FMD we identified that SSc patients have significantly altered vascular structure and function which includes: smaller brachial artery diameter, blunted vascular reactivity, attenuated endothelial mediated dilation, despite an increased forearm flow at baseline. SSc patients with DU have a significantly attenuated endothelial mediated dilation, despite having an otherwise similar vascular structure and function profile to those SSc patients without DU. We believe that FMD has potential has clinical utility for identify SSc patients at risk for DU and monitoring response to endothelial-based therapeutics.

Arthritis & Rheumatism~~ism~~ology

Editor: Joan M. Bathon, MD
Columbia University Medical Center, New York

A&R is getting a new name!

Starting with Volume 66, Issue 1 (the January 2014 issue), *Arthritis & Rheumatism* will become *Arthritis & Rheumatology*.

Arthritis & Rheumatology (A&R) will be a continuation of *Arthritis & Rheumatism*, remaining an official journal of the American College of Rheumatology and continuing to publish cutting-edge articles related to clinical rheumatology as well as the mechanisms of the rheumatic diseases.
