Social Networks and Hip Replacement Outcomes In Rheumatoid Arthritis and Osteoarthritis. Danielle Ramsden-Stein, Wei-Ti Huang, Rebecca Zhu, Susan M. Goodman, Mark P. Figgie, Michael Alexiades and Lisa A. Mandl. Hospital for Special Surgery, New York, NY.

Background/Purpose: Social isolation is an independent risk factor for poor health outcomes. It is unknown if the degree of social isolation differs between RA and OA patients after total hip replacement (THR), or if social isolation is associated with poorer outcomes. This study evaluates the association between social isolation, measured by the Berkman-Syme Social Network Index, and post-operative pain and function in RA and OA patients who have undergone THR.

Methods: Primary and revision RA and OA THR patients enrolled in a large volume, single center arthroplasty registry from May 2007-February 2011 and were alive at follow-up were eligible to participate. RA cases were validated via chart review and were matched 3:1 to OA cases on age (+/− 5 years), sex, procedure type (primary or revision) and year of surgery, to control for both expected differences between patient populations and time since surgery. The Western Ontario and McMaster Universities Arthritis Index (WOMAC) and demographic information were collected pre-operatively and between 2 and 5 years post-operatively. In addition, the Berkman-Syme Social Network Index (BSSNI) was administered between 2 and 5 years post-operatively. The BSSNI was divided into four categories, with the most isolated category being the referent group.

Results: 132/223 (59.2%) RA and 392/561 OA (69.8%) responded. Demographics were similar in both groups (Table 1). RA and OA had similar proportions of very socially isolated patients. Overall, the most socially isolated patients had worse postoperative WOMAC pain (p-value=0.013) and WOMAC function (p-value= 0.0025). This relationship was statistically significant for OA patients, (WOMAC pain p-value=0.0029 and WOMAC function p-value= 0.048), and showed similar trends but was not statistically significant in RA patients. In a multivariate regression controlling for disease (OA vs. RA), education, race, and SF-36 Physical Component Score (PCS), being socially isolated was independently associated with poor (WOMAC < 60) post-op pain, (OR 2.9; 95% CI 1.07–7.25, p-value=0.04) but not poor post-op function, (OR 2.1; 95% CI 0.77–5.52; p-value=0.15). This model also showed that RA was statistically significantly associated with poor post-op function (OR 3.2, 95% CI 1.57–6.52, p-value=0.001), but not with poor post-op pain (OR 1.92; 95% CI 0.86–4.28, p-value=0.11).

Table 1.

	RA N = 132			OA N = 392		
	Very Socially isolated n = 11	Socially integrated N = 121	p-value	Very Socially isolated n = 34	Socially integrated N = 358	p-value
Age-years (SD)	66.1 (16.2)	62.8 (14.2)	0.47	59.3 (14.6)	62.8 (12.4)	0.12
Female (%)	9 (82%)	94 (78%)	0.79	25 (74%)	275 (77%)	0.67
White (%)	7 (64%)	96 (79%)	0.23	31 (91%)	329 (92%)	0.88
Education (%) (Some college or above)	6 (86%)	72 (81%)	0.75	30 (88%)	320 (90%)	0.76
BMI (SD)	24.2 (3.3)	26.5 (5.7)	0.34	29.6 (7.8)	26.7 (5.6)	0.11
PCS (SD)	25.6 (4.9)	29.1 (8.5)	0.28	30.7 (9.3)	33.5 (9.4)	0.12
Revision (%)	3 (27%)	22 (18%)	0.46	8 (24%)	77 (22%)	0.78
Pre-Operative WOMAC Pain (SD) Lower=worse pain	36.7 (17.5)	48.2 (21.3)	0.20	49.6 (22.8)	56.1 (20.3)	0.09
Post-Operative WOMAC Pain (SD) Lower=worse pain	80.0	86.32	0.34	86.9	92.8	**0.013**
Poor Post-Operative Pain (WOMAC <60) (%)	2 (20%)	17 (16%)	0.72	5 (15%)	17 (5%)	**0.016**
Pre-Operative WOMAC Function (SD) Lower=worse function	37.7 (8.5)	41.0 (20.4)	0.72	49.5 (19.8)	52.4 (20.3)	0.51
Post-Operative WOMAC Function (SD) Lower=worse function	69.7	78.49	0.24	81.64	90.16	**0.0021**
Poor Post-Operative Function (WOMAC <60) (%)	3 (30%)	26 (24%)	0.69	5 (15%)	18 (5%)	**0.02**

Conclusion: Being socially isolated is associated with an almost 3x increased odds of poor pain after THR, controlling for multiple potential confounders. Furthermore, social isolation appears to be more significant in OA, which comprises the vast majority of THR cases. Further prospective studies should be done to evaluate whether interventions to improve social networks can improve pain after THR.

Diabetes: A Risk Factor For Poor Function Outcome After Total Knee Arthroplasty. Jasvinder A. Singh[1] and David Lewallen[2]. [1]University of Alabama, Tuscaloosa, AL, [2]Mayo Clinic College of Medicine, Rochester, MN.

Background/Purpose: Previous studies have not provided any conclusive evidence whether patients with diabetes have worse patient-reported outcomes after joint replacement than patients without diabetes. Our objective was to assess the association of diabetes with postoperative limitation of activities of daily living (ADLs) after primary total knee arthroplasty (TKA).

Methods: We used the prospectively collected data from the Mayo Clinic Total Joint Registry to assess the association of diabetes and diabetes with complications with moderate-severe ADL limitation 2- and 5-years after primary TKA. Multivariable logistic regression with general estimating equations adjusted for preoperative ADL limitation, comorbidity and demographic and clinical covariates. Odds ratio (OR) and 95% confidence interval (CI) are presented.

Results: 7,139 primary TKAs at 2-years and 4,234 at 5-years constituted the cohorts. In multivariable-adjusted analyses, diabetes was associated with higher odds of moderate-severe limitation at 2- and 5-years, 1.71 (95% CI: 1.26, 2.32; P=0.001) and 1.66 (95% CI: 1.13, 2.46; P=0.01). Respective ORs for patients with diabetes with complications were 2.73 (95% CI: 1.47, 5.07; P=0.001) and 2.73 (95% CI: 1.21, 6.15; P=0.016). Sensitivity analyses that adjusted for anxiety and depression or anxiety, depression and ipsilateral hip involvement showed minimal attenuation of magnitude of the association.

Conclusion: In this large study of patients who underwent primary TKA, diabetes as well as its severity were independently associated with poorer functional outcome. Given the increasing rates of both diabetes as well as arthroplasty, more insight is needed into disease-related and treatment-related factors that underlie this higher risk of ADL limitation in diabetics. Poor functional outcomes may be preventable by modifying the control of diabetes and associated comorbidity in pre- and post-arthroplasty periods.

The Effect Of Statin Therapy On Venous Thromboembolism After Hip Or Knee Arthroplasty. Anne R. Bass[1], Yuo-Yu Lee[2], Stephen Lyman[2], Geoffrey H. Westrich[2] and Brian F. Gage[3]. [1]Hospital for Special Surgery Weill Cornell Medical College, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Washington University School of Medicine in St. Louis, St. Louis, MO.

Background/Purpose: Patients undergoing hip and knee arthroplasty are at high risk of venous thromboembolism (VTE). HMG Co-A reductases ("statins") can reduce the risk of post-operative cardiovascular complications in some populations undergoing cardiac or non-cardiac surgery, and may reduce the risk of venous thromboembolism (VTE) in healthy adults. We used the Hospital for Special Surgery Legacy Registry (HSS Registry) to determine whether statins protect against VTE after arthroplasty.

Methods: Of the 20,764 patients in the HSS Registry who underwent hip or knee arthroplasty between July 1, 2007 and December 31, 2011, 16183 returned 6-month questionnaires. VTE was identified using hospital discharge ICD-9 codes and self report on 6-month questionnaires. Self-reports of VTE were validated through a structured telephone interview. Among the patients who returned 6-month questionnaires, 230 patients (1.4%) experienced VTE postoperatively (76 pulmonary embolism (PE), 173 deep vein thrombosis (DVT), 19 both). We performed logistic regression to determine the risk of postoperative VTE in patients taking statins.

Results: Forty percent of patients in the HSS Registry were on statins. Compared to patients not on statins, patients on statins were older (68.9 vs 63 years), heavier (BMI 29.6 vs 28.3) and more commonly male (49.2% vs 38.5%). More patients on statins underwent knee (as opposed to hip) arthroplasty (52.4% vs 42.9%) and fewer underwent bilateral arthroplasty (6.5% vs 9.4%). Patients on statins had a longer length of stay (5.0 vs 4.9 days) and were more commonly discharged to a rehabilitation center (46.9% vs 37.9%). More patients on statins had coronary artery disease (22.5% vs 4.2%), congestive heart failure (1.5% vs 0.7%), and diabetes (15% vs 5.7%) while fewer had rheumatoid arthritis (2.75% vs 4.1%). More patients on statins received warfarin rather than aspirin as VTE prophylaxis (61.8% vs 50.6%). These differences were all significant, $p<0.001$. In logistic regression analysis statins were associated with a lower rate of PE (OR 0.6, 95% CI 0.4–0.98) but not DVT (OR 1.3, 95% CI 0.9–1.7) or total VTE (OR 0.97, 95% CI 0.7–1.3).

Conclusion: In this observational cohort, statins protected against PE but not total VTE following hip or knee arthroplasty. Given significant differences in the characteristics of patients on statins and those not on statins, a prospective randomized controlled trial is needed to determine whether statins protect these patients from VTE.

Pregnancy Does Not Adversely Affect Post-Operative Pain and Function In Women With Total Hip Arthroplasty. Lindsay Lally, Lisa A. Mandl, Rebecca Zhu, Wei-Ti Huang, Mark P. Figgie, Michael Alexiades and Susan M. Goodman. Hospital for Special Surgery, New York, NY.

Background/Purpose: Women of childbearing age undergo total hip arthroplasty (THA), yet little is known about effect of pregnancy on THA. We compared patients with a post-THA pregnancy to those with a pregnancy pre-THA or nulliparous.

Methods: Women ages 18–45 enrolled in an arthroplasty registry between 5/1/07 and 12/31/11 were identified. Information about the first pregnancy post-THA and the last pregnancy pre- THA was queried for demographics, WOMAC, and the HSS Expectations Score. 3 groups: nulliparous, pregnancy pre-THA, pregnancy post-THA.

Results: 325 eligible women identified; 171 (52.6%) responded, no significant differences between responders and non-responders. 79 women (46.2%) were never pregnant, 82 (47.4%) had pregnancy pre-THA and 10 (6.4%) had a completed pregnancy post-THA. Women with pregnancy pre-THA were older (40.7 years SD 4.3) than post-THA, (37.2 years SD 4.2) or nulliparous, (35.0 years SD 7.9) p -value<0.001. THA were performed for hip dysplasia (28.1%), osteoarthritis (26.3%), inflammatory arthritis (24.0%), osteonecrosis (15.2%), fracture (5.8%) and other (1.1%). There was no difference in race, education, BMI, or reason for THA. Time between delivery and THA: 85.3 months (SD 66.1) for pre-pregnancy THA; 25.6 months (SD 7.9) for post-THA pregnancy. There were no differences in birth weight, parity, weight gain, or pregnancy complications. There was no difference in delivery; vaginal (64% vs. 88% p-value=0.58), Cesarean (25% vs. 3% p-value=0.58). There were no significant differences in pre-operative or post-THA WOMAC, Expectations or satisfaction (p-value=0.61). There were no differences for groin, back or knee pain during pregnancy. 90% reported "great" or "more improvement than I ever dreamed" in quality of life after THA.

2119

Higher Mortality In Males Compared To Females Undergoing Total Knee Or Total Hip Arthroplasty: A Study Of National Time Trends, 2003–2010. Jasvinder A. Singh[1] and Rekha Ramachandaran[2]. [1]University of Alabama, Tuscaloosa, AL, [2]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: To assess the time-trends in gender differences in mortality after primary total knee and total hip arthroplasty (TKA and THA) by rural or urban residence.

Methods: We used the Nationwide Inpatient Sample (NIS) data from 1998 to 2010 to examine time-trends by gender in TKA and THA. Rates were calculated for the U.S. population.

Results: Mortality rates were higher in males compared to females through the study period. In 2003, mortality rates in rural females, rural males, urban females and urban males after primary TKA were: 115, 279, 140 and 230 per 100,000, respectively. Respective numbers for primary THA were: 326, 346, 360 and 168. In 2010, similar differences were seen by gender in both rural and urban dwelling females and males: (1) urban: 70, 92, 29 and 131; and (2) rural 145, 154, 94, 211, respectively. In all cohorts, a significant reduction in mortality was noted. The rate of reduction of mortality over time was most noticeable in rural-dwelling women among all groups.

Table 1. Mortality per 100,000 by gender in rural/urban residents

	Urban Residence			
	THA		TKA	
	Female	Male	Female	Male
2003	115.3	278.7	326.2	345.8
2004	104.7	199.0	251.6	238.3
2005	81.8	144.5	212.4	209.2
2006	76.1	153.6	171.6	213.5
2007	66.2	114.8	157.1	237.6
2008	82.3	123.2	173.1	173.0
2009	60.0	85.8	152.3	171.0
2010	69.5	92.1	144.8	154.2
	Rural residence			
	THA		TKA	
	Female	Male	Female	Male
2003	139.7	230.1	360.1	167.6
2004	119.8	144.3	462.2	307.7
2005	151.5	138.7	189.9	357.5
2006	79.3	161.1	199.7	239.1
2007	63.9	107.1	268.8	244.4
2008	51.4	115.1	273.4	259.7
2009	51.7	136.6	183.3	169.2
2010	28.8	131.4	94.4	211.3

Conclusion: The mortality rates following primary TKA and THA has decreased significantly over the last 7 years from 2003 to 2010. Mortality is higher in males compared to females, a difference that has not changed over time. More insights are need into understanding what factors contribute to lower mortality in females.

Total Knee Replacement Outcomes In Patients With Psoriatic Arthritis, Osteoarthritis With Cutaneous Psoriasis, and Osteoarthritis. Lisa A. Mandl, Rebecca Zhu, Wei-Ti Huang, Michael Alexiades, Mark P. Figgie and Susan M. Goodman. Hospital for Special Surgery, New York, NY.

Background/Purpose: Outcomes of total knee replacements (TKR) in psoriatic arthritis (PsA) are poorly studied. Previous studies are conflicting, often not separating inflammatory PsA from osteoarthritis (OA) with cutaneous psoriasis (PsC). This study evaluates TKR outcomes in PsA compared to both PsC+OA and OA alone.

Methods: This study utilized cases from a high volume single institution TKR registry enrolled between 5/2007 and 12/2011. Potential PsA cases were identified by ICD-9 code (696.0-.1) and matched 4:1 (on age (+/− 2.5 years), primary vs. revision and date of surgery) with OA TKR. TKR with other rheumatic diseases or fractures were excluded. Patient reported outcomes were collected at baseline and 2 years; non-responders received an additional questionnaire at 3–5 years. Differences between groups were compared using ANOVA, and multivariate logistic regressions were performed to identify independent predictors of poor post-operative pain and function, (WOMAC < 60).

Results: 253 potential PsA were identified; 76 PsA and 155 PsC+OA were validated by chart review. Post-op. self-report data were available in 76% PsA, 74% PsC+OA and 65% OA. 2% of self-reported outcomes were elicited 3–5 years post-op. PsA were younger than PsC+OA or OA, (p-value=0.009). PsA and PsC+OA had more co-morbidities and worse ASA class. More PsA and PsC+OA were previous smokers, more PsC+OA were current smokers. 71% of PsA were on biologics or non-biologic DMARDs compared to 5% of PsC+OA. There was no statistically significant difference in pre-or post-op WOMAC pain, WOMAC function or SF-12 physical component scores (PCS) scores between groups. Post-op. SF-12 mental component scores (MCS) scores were worse in PsA and PsC+OA (p-values=0.04). EQ-5D scores were worse both pre- and post-op. in PsA. Overall satisfaction with TKA was equally high for all groups, with > 70% being very satisfied (p-value=0.66). In a multivariate regression controlling for multiple potential cofounders, a diagnosis of PsA or PsC+OA did not statistically significantly increase the odds of either poor post-op. pain or function. Primary TKR had much lower odds of poor post-op pain or function, and worse pre-op. function was statistically significantly associated with poor post-op. function. No other variables were significant.

Table 1. Demographic Data

	PsA (N=76)	PsC+OA (N=155)	OA (N=547)*	P-Value

* 547/843 cases were available for analysis.

Table 2. Predictors of Having Poor Post-Operative Pain or Function (WOMAC <60) After THR*

	Poor Post-Operative Pain WOMAC (<60) Odds Ratio (95% CI)	Poor Post-Operative Function WOMAC (<60) Odds Ratio (95% CI)
PsC+OA vs. OA	0.64 (0.08, 5.24)	1.11 (0.23, 5.54)
PsA vs. OA	0.88 (0.18, 4.26)	0.37 (0.05, 3.07)
Primary vs. Revision	**0.32 (0.11, 0.99)**	**0.20 (0.07, 0.56)**
Pre-operative WOMAC Pain	0.997 (0.96, 1.03)	1.01 (0.98, 1.05)
Pre-operative WOMAC Function	0.98 (0.94, 1.01)	**0.96 (0.93, 0.998)**

*Multivariate regression controlling for gender, diagnosis, BMI, number of comorbidities, primary vs. revision surgery, smoker status, pre-operative WOMAC pain and function, pre-operative MCS.

Conclusion: Despite having worse pre-op. health status, patients with PsA and PsC+OA have equally good post-op. pain and function compared

with OA, and are equally satisfied. PsA have clinically significantly worse post-op. MCS. This information should be communicated to PsA and PsC+OA patients contemplating TKR.

2121

Total Hip Arthroplasty Outcomes In Patients With Psoriatic Arthritis, Osteoarthritis With Cutaneous Psoriasis, and Osteoarthritis. Lisa A. Mandl, Rebecca Zhu, Wei-Ti Huang, Michael Alexiades, Mark P. Figgie and Susan M. Goodman. Hospital for Special Surgery, New York, NY.

Background/Purpose: Outcomes of total hip replacements (THR) in psoriatic arthritis (PsA) are poorly studied. Previous studies are conflicting, often not separating inflammatory PsA from osteoarthritis (OA) with cutaneous psoriasis (PsC). This study evaluates THR outcomes in PsA compared to both PsC+OA and OA alone.

Methods: This study utilized cases from a high volume single institution THR registry enrolled between 5/2007 and 12/2011. Potential PsA cases were identified by ICD-9 code (696.0-.1) and matched 4:1 (on age, primary vs. revision and date of surgery) with OA THR. THR with other rheumatic disease or fractures were excluded. Patient reported outcomes were collected at baseline and 2 years; non-responders received an additional questionnaire at 3–5 years. Differences between groups were compared using ANOVA, and multivariate logistic regressions were performed to identify independent predictors of poor post-op pain and function, (WOMAC < 60). This study was IRB approved.

Results: 289 potential PsA were identified; 69 PsA and 167 PsC+OA were validated by chart review. Post-op self-report data were available in 64% PsA, 63% PsC+OA and 83% OA. 4% of self-reported outcomes were elicited 3–5 years post-op. There was no difference in race, age or education between groups. PsA and PsC+OA had more co-morbidities (0 Deyo co-morbidities: PsA 61% vs. PsC+OA 68% vs. OA 80%; p-value=0.004) and worse ASA class. More PsA and PsC+OA were current or previous smokers. 87% of PsA were on biologics or non-biologic DMARDs compared to 7% of PsC+OA. There was no statistically significant difference in pre-or post-op WOMAC pain or function or SF-12 PCS scores between groups. SF-12 MCS scores were higher in OA both pre-and post-operatively (p-values=0.003 and <0.001 respectively). EQ-5D scores were worse both pre-and post-operatively in PsA and PsC+OA (p-value=0.006 and p-value<0.001). Overall satisfaction with THA was equally high for all groups, with > 80% being very satisfied (p-value=0.82). In multivariate logistic regressions, (Table 2), a diagnosis of PsA or PsC+OA did not statistically significantly increase the odds of either poor post-op pain or function. Revision THR had much higher odds of poor post-op pain, and worse pre-op pain and function were statistically associated with poor post-op pain and function, respectively. Current smoking has >3x increased odds of poor post-op pain and function.

Table 1. Demographic Data

	PsA (N=69)	PsC+OA (N=167)	OA (N=771*)	P-Value
Male, n (%)	36 (52%)	92 (55%)	343 (45%)	**0.035**

Mechanical Back Pain Demonstrates Better Response To Celecoxib Than Acetaminophen Despite Lack Of MRI-Defined Inflammatory Changes In The Spine. Dinny Wallis[1], Finbar (Barry) D. O'Shea[2], David Salonen[3], Nigil Haroon[1], Ammepa Anton[4], Laura A. Passalent[1], Rebecca Morton[5], Christopher Hawke[1], Joan Blair[1] and Robert D. Inman[1]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]St James's Hospital, Dublin, Ireland, [3]University Health Network, Toronto, ON, [4]Toronto Western Research Institute, Toronto, ON, [5]University Health Network- Toronto Western Hospital, Toronto, ON.

Background/Purpose: Chronic back pain affects a significant proportion of the population. MRI-defined inflammatory lesions have been used to differentiate between axial spondyloarthritis and mechanical back pain, but the frequency of inflammatory lesions in mechanical back pain has not been ascertained. The efficacy of celecoxib in chronic, mechanical back pain and its effects on MRI inflammatory lesions have not been established.

Methods: A randomized, double-blind trial of celecoxib versus acetaminophen was conducted. Fifty two patients (52% male, mean age 40y)with back pain for at least 3 months, a total back pain score ≥4/10 and without clinical or radiographic evidence of axial spondyloarthritis were randomized to celecoxib (200mg twice daily, n=25) or acetaminophen (500mg twice daily, n=27) for four weeks. Total back pain, Oswestry Disability Index (ODI), nocturnal back pain, patient global assessment, morning stiffness, SF-36 mental component scale (MCS) and physical component scale (PCS), CRP, ESR and Spondyloarthritis Research Consortium of Canada (SPARCC) MRI index for inflammation of the sacroiliac joints (SIJ) and spine were measured at baseline and four weeks.

Results: A greater improvement was observed for celecoxib than for acetaminophen in total back pain (p=0.01), Oswestry Disability Index (p=0.003) and nocturnal back pain (p=0.01). A trend was observed for greater improvement in patient global assessment with celecoxib (p=0.07). The SPARCC MRI index was low at baseline and no change was seen over four weeks in either treatment group.

Table 1. Mean (SD) outcome measures from baseline to week 4

	Acetaminophen (n=27)				Celecoxib (n=25)				P value for change in acetaminophen group versus change in celecoxib group
	Baseline	Week 4	Mean of differences	P value	Baseline	Week 4	Mean of differences	P value	
Total back pain (0–10)	5.8 (2.1)	5.1 (2.4)	−0.7 (1.8)	0.04	6.5 (1.7)	4.2 (2.6)	−2.3 (2.6)	0.0001	0.01
ODI (0–100)	19.2 (9.1)	17.6 (10.0)	−1.6 (4.3)	0.08	20.3 (8.2)	13.1 (8.9)	−7.1 (7.8)	0.0002	0.003
Nocturnal back pain (0–10)	4.5 (2.5)	4.8 (2.8)	0.3 (2.8)	0.59	4.7 (2.3)	3.0 (2.7)	−1.7 (2.6)	0.003	0.01
Patient global (0–10)	4.6 (2.1)	4.1 (2.4)	−0.5 (1.7)	0.16	4.7 (2.8)	3.0 (2.6)	−1.7 (2.8)	0.0066	0.07
Morning stiffness (0–10)	5.0 (2.7)	4.4 (2.5)	−0.6 (1.8)	0.12	3.0 (2.8)	2.5 (2.6)	0-.6 (2.9)	0.34	-
SF-36 MCS	47.4 (9.6)	47.7 (10.2)	0.3 (6.3)	0.82	44.7 (11.6)	47.7 (12.1)	3.0 (12.2)	0.24	-
SF-36 PCS	39.0 (11.4)	41.9 (11.1)	2.8 (5.7)	0.02	39.5 (9.2)	44.1 (9.2)	4.6 (6.6)	0.0025	0.38
CRP (mg/L)	2.7 (4.4)	2.2 (4.1)	−0.5 (3.8)	0.51	2.1 (2.2)	2.1 (2.4)	0.0	>0.99	-
ESR (mm/h)	8.4 (9.5)	6.7 (7.4)	−1.7 (3.6)	0.02	5.0 (4.0)	5.3 (4.0)	0.3 (3.9)	0.71	-
MRI index SIJ (0–72)	1.6 (2.3)	1.6 (2.3)	0.1 (0.4)	0.48	0.9 (1.6)	0.9 (1.4)	−0.02 (1.06)	0.93	-
MRI index spine (0–108)	4.3 (4.8)	4.8 (5.3)	0.49 (1.44)	0.09	6.03 (4.60)	5.63	−0.41 (1.04)	0.06	-

Conclusion: To our knowledge, this is the first study to demonstrate the efficacy of celecoxib compared with acetaminophen in chronic mechanical back pain. MRI-defined inflammatory lesions were infrequent. This finding has implications for the specificity of MRI-defined inflammatory lesions in axial spondyloarthritis.

Assessment Of Gesture Behavior and Knowledge On Low Back Pain Among Nurses. Hisa Morimoto[1], Anamaria Jones[1] and Jamil Natour[2]. [1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo, São Paulo, Brazil.

Background/Purpose: Low back pain is a public health problem throughout the world. Particularly in the nursing profession, this condition is related to absenteeism and lawsuits. Emotional, physical and psychosocial forms of stress in the workplace are determinant factors of the onset and perpetuation of low back pain. The aim of the present study was to evaluate gesture behavior and knowledge on low back pain among nurses with and without low back pain and correlate these factors with pain, physical functioning and quality of life.

Methods: An observational, controlled, cross-sectional study was carried out involving 120 female nurses at the São Paulo Hospital (Brazil): 60 with low back pain and 60 without low back pain (control group). The two groups were matched for age. The following were the inclusion criteria for the group with back pain: actively exercising the nursing profession; age between 18 and 65 years; work performed in infirmary, emergency ward and/or intensive care unit; minimum daily workload of six hours; and self-report of low back pain on the majority of days in the previous three months with an intensity greater than 3 cm on a visual analogue scale (VAS ranging from 0 to 10 cm). The same inclusion criteria were employed for the control group, without low back pain. Individuals involved in litigation, those with a history of back surgery and pregnant women were excluded from the study. The measures used for the evaluation were the Gesture Behavior Test, Low Back Pain Knowledge Questionnaire, VAS for low back pain, Roland Morris Disability Questionnaire and the Medical Outcomes Study 36-item Short–Form Health Survey (SF-36) to assess quality of life.

Results: Mean age in both groups was 31 years. In the group with low back pain, the mean VAS score was 5.6 cm and the mean score on the Roland Morris questionnaire was 2.7. No statistically differences between groups were found regarding the scores of the Low Back Pain Knowledge Questionnaire or Gesture Behavior Test ($p=0.531$ and $p=0.292$, respectively). Statistically lower scores were found in the group with low back pain for the following SF-36 domains: physical functioning ($p<0.001$), physical role ($p=0.015$), pain ($p=0.001$), general health perceptions ($p=0.015$), vitality ($p<0.001$) and mental health ($p=0.001$).

Conclusion: No differences were found when comparing nurses with or without low back pain regarding gesture behavior or knowledge on low back pain. Nurses with low back pain showed a decrease in some domains of quality of life.

Disclosure: H. Morimoto, None; **A. Jones**, None; **J. Natour**, None.

Piriformis Muscle Syndrome: Diagnostic Criteria and Treatment Of a Monocentric Series Of 250 Cases. Fabrice Michel[1], Pierre Decavel[1], Laurent Tatu[1], Etienne Aleton[1], Guy Monnier[1], Bernard Parratte[1] and Eric Toussirot[2]. [1]University Hospital, Besançon, France, [2]CIC Biotherapy 506 and Rheumatology and EA 4266 Pathogens and Inflammation, Besançon, France.

Background/Purpose: Piriformis Muscle Syndrome (PMS) is caused by sciatic nerve compression in the infrapiriformis canal. However, its pathophysiology is poorly understood and this syndrome is difficult to diagnose. This study aimed to propose a clinical assessment score for facilitating PMS diagnosis and to develop a treatment strategy.

Methods: 250 patients versus 30 control patients with disco-radicular conflict, plus 30 healthy control subjects were enrolled in this study. A range of tests (Freiberg, FAIR [Flexion-Adduction-Internal Rotation], heel-contralateral knee manoeuvre and Beatty test) were used to produce a diagnostic score for PMS and an optimum treatment strategy was proposed (muscle relaxant medication, intense self-rehabilitation program, Onabotulinumtoxin A injection in the cases of non-response to rehabilitation and then surgery for the refractory cases).

Results: A 12-point clinical scoring system (Table) was devised and a diagnosis of PMS was considered 'probable' when it was ≥ 8. Sensitivity and specificity of the score were 96.4% and 100%, respectively, while the positive predictive value was 100% and negative predictive value was 86.9%. Combined medication and rehabilitation treatments had a cure rate of 51.2%. 122 patients (48.8%) were unresponsive to treatment and received Onabotulinumtoxin A. Visual Analogue Scale results were 'Very good/Good' in 77%, 'Average' in 7.4% and 'Poor' in 15.6%. 15 of 19 patients unresponsive to treatment underwent surgery with 'Very good/Good' results in 12 cases

Table. Proposal for a clinical scoring system for the diagnosis of Piriformis Muscle Syndrome. FAIR: Flexion-Adduction-Internal Rotation; HCLK: heel contralateral knee. Piriformis muscle syndrome: Probable if score greater than or equal to 8; Unlikely if score less than 8 and greater or equal to 6; Not considered if score less than 6.

criteria	point
Unilateral or bilateral buttock pain with fluctuating periods without pain throughout the course of the day	1
No lower back pain	1
Axial spinal palpation painless (L2 to S1)	1
Negative Lasegue's manoeuvre	1
Seated position (often for a prolonged period) triggering buttock pain and/or sciatic pain	1
Sciatic pain with fluctuating periods without pain throughout the course of the day	1
Buttock pain next to the projection of the piriformis muscle reproduced by Stretching manoeuvres (FAIR, Freiberg, HCLK)	1
Contraction resisted manoeuvres (Beatty)	1
Palpation	1
Sciatic pain (L5, S1 or truncal sciatic area) reproduced by the extension of clinical manoeuvres (several tens of seconds)	1
Stretching Resisted contraction	1
Absence of perineal irradiation	1
Total	12

Conclusion: the proposed evaluation score may facilitate PMS diagnosis and treatment standardisation. Rehabilitation has a major role associated in half of the cases with botulinum toxin injections.

2125

Comparison Of The Effectiveness Of Local Anesthetic and Corticosteroid Injections For The Treatment Of Piriformis Syndrome. Tugce Ozekli Misirlioglu, Kenan Akgun, Meryem Gul Erden and Tuba Erbilir. Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey.

Background/Purpose: Piriformis syndrome (PS), which is characterized by pain radiating to gluteal region and posterior leg, is accepted as one of the causes of sciatica. Although the importance of local piriformis muscle injections whenever PS is clinically suspected has been shown in many studies, there is not enough study considering the clinical efficacy of these injections. The objective of this study was to compare the effectiveness of ultrasound (US)-guided local anesthetic (LA) and corticosteroid (CS) injections for the treatment of PS.

Methods: Fifty-seven patients with a pre-diagnosis of PS after clinical evaluation were included in this prospective randomized double-blind study. After baseline assessments that were done by the first physiatrist, subjects who were blinded to group allocation, were randomized by the second physiatrist. US-guided injections of 4 cc of lidocaine 2% (LA group) and 4 cc of lidocaine 2%+1 cc of betametazone dipropionate (LA+CS group) with a 22-gauge 88 mm Spinocan were done by the third physiatrist with a Diasus dynamic imaging US equipped with a 5- to 10- MHz multifrequency transducer. The patients whose pain resolved 50% and more were included in the study. Seven patients whose injection tests were negative were excluded from the study. Each group contained 25 patients with a diagnosis of PS. The subjects were re-assessed by the first physiatrist with physical examination and Likert Analogue Scale (LAS) and Numeric Rating Scale (NRS) at the 1st week, the 1st and 3rd months after the injection.

Results: The difference between two groups was analyzed with Pillai's Trace, which is a multivariate analysis from general linear models. No statistically significant difference (p>0,05) was detected between the groups in NRS score values at resting (p=0.814), night (p=0.830) and in motion (p=0.145) and LAS values with long duration of sitting (p=0.547), standing (p=0.898) and lying (p=0.326) with evaluations at the baseline, 1st week, 1st and 3rd months after the injection. Each group was compared within itself by Friedman test, which is used for non-parametric repeated measures. A statistically highly significant (p<0,005) reduction of pain was evaluated through NRS scores at resting (p=0.001), in motion (p=0.001) and at night (p=0.001) and and LAS values with long duration of sitting (p=0.001), standing (p=0.001) and lying (p=0.001) in both of the groups.

Conclusion: LA injections for the PS were found to be clinically effective. However, addition of CS to LA did not give an additional benefit. This gives us the idea that PS has similar features with the other myofascial pain syndromes and responds well to trigger point injections.

Time Trends In Total Ankle Arthroplasty: A Study Of The U.S. National Inpatient Sample. Jasvinder A. Singh[1] and Rekha Ramachandaran[2]. [1]University of Alabama, Tuscaloosa, AL, [2]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: To assess the time-trends in utilization, clinical characteristics and outcomes of patients undergoing total ankle arthroplasty (TAA) in the U.S.

Methods: We used the Nationwide Inpatient Sample (NIS) data from 1998 to 2010 to examine time-trends in TAA. Rates were calculated for the U.S. population. We used the Cochran Armitage test for trend to test for trend across the years. We compared the first and the last period for trends using, ANOVA and chi-squared test as appropriately.

Results: TAA utilization rate increased from 0.12 per 100,000 in 1998 to 0.84 per 100,000 in 2010. The Cochran Armitage test for trend across years yielded a significant p-value of <0.0001. In females and males, the rate increased from 0.14 to 0.88 per 100,000 (p<0.0001 for time-trend) and from 0.11 to 0.81 per 100,000 (p<0.0001 for time-trend), respectively. Compared to the 1998–99, significantly fewer patients <50 years (37% fewer) and more patients ≥80 years (85% higher) in 2009–10 underwent TAA (p <0.0001). Compared to 1998–99, RA was less frequently the underlying diagnosis (55% reduction) and a greater proportion of patients had Deyo-Charlson index of 2 or more (33% more) in 2009–10. Comparing 1998–99 to 2009–10, we noted a slight decrease in the length of stay from 2.7 to 2.5 days (17% reduction), slight increase in the proportion of patients being discharged to inpatient facility from 12.9% to 14.1% (12% increase) and no change in mortality, 0.13% to 0.12% (9% decrease).

Conclusion: The utilization rate of TAA is rapidly increasing in the U.S. Underlying diagnosis and medical comorbidity has changed over time that can impact the type and frequency of complications after TAA. Further studies are needed to assess how the outcomes and complications of TAA have evolved over time.

Recurrences Of Hallux Valgus Deformity After Implant Surgery For Greater Toe In Rheumatoid Arthritis. Yuichi Mochida[1], Katsushi Ishii[1], Yuji Yamada[1], Naoto Mitsugi[1] and Tomoyuki Saito[2]. [1]Yokohama City University Medical Center, Yokohama, Japan, [2]Yokohama City University School of Medicine, Yokohama, Japan.

Background/Purpose: In advanced cases of rheumatoid arthritis (RA), Swanson implant have been widely usedfor hallux valgus deformity. Although the results for this surgery were acceptable, relatively high incidence of recurrence of hallux valgus deformity were reported. In this study, we analyzed the incidence of the recurrence of hallux valgus deformity after Swanson implant, then analyzed for the factors which affect the recurrence of the hallux valgus.

Methods: Post-operative radiological results of implant surgery for hallux in RA with the minimum follow-up of 12 months after surgery were analyzed in 54 cases, 87 joints (male 3cases, female 51cases). The mean age at the time of surgery was 67.7 ± 6.9 years (53~84). The mean duration after surgery was 40.8 ± 21.6 months (12~93). Post-operative hallux valgus angle (HVA) were analyzed at pre-, immediate after surgery, 6 months after surgery, and final follow-up. The changes of HVA between immediate after surgery and the final follow-up were calculated. The radiological results were evaluated using modified Granberry's grading. The toe lengths of hallux including soft tissue shadow after surgery were divided into three groups using the radiographical of each toe as follows; Type 1 (hallux length is 3 mm longer than 2nd toe length), Type 3 (hallux length is 3 mm shorter than 2nd toe length), and Type 2 (hallux length is within 3 mm of 2ndtoe length).

Results: The averaged HVA was significantly decreased after surgery, and maintained during follow-up period. There were no statistical correlation between the changes of HVA and follow-up period, pre-operative HVA, and HVA at immediate after surgery. For the toe lengths of hallux, 24 cases were Type 1, 20 cases were Type 2, and 11 cases were Type 3. Type 3 showed significantly less changes of HVA when compared to Type 1. Also, with the shortening of the length of hallux by toe lengths type, the HVA at the final follow-up was significantly decreased. There were no relationship between HVA and Granberry's grading.

Conclusion: Improvement of disease activity of RA, essentially due to introduction of methotrexate and biological agents, total number of RA surgery, especially for large joints has been decreasing. In contrast, the number of surgeries for small joints such as finger and toe arthroplasty are increasing. Based on this recent trend of changes of surgery, better clinical and radiological results for small joints will be needed to improve patients' quality of life. Our result clearly showed that the shorter the lengths of hallux, significantly less changes of HVA and HVA at the final follow-up, that may reflect better surgical results of hallux valgus deformity.

Longitudinal Relation Of Sensitization To Incident Knee Pain, Incident Symptomatic Knee Osteoarthritis and Increase In Pain Severity: The Multicenter Osteoarthritis Study. Tuhina Neogi[1], Michael C. Nevitt[2], Joachim Scholz[3], Lars Arendt-Nielsen[4], Clifford Woolf[5], Laurence A. Bradley[6], Emily Sisson[1] and Laura Frey-Law[7]. [1]Boston University School of Medicine, Boston, MA, [2]University of California, San Francisco, San Francisco, CA, [3]Columbia University, New York, NY, [4]Center for Sensory-Motor Interaction, Aalborg, Denmark, [5]Children's Hospital Boston, Boston, MA, [6]Univ of Alabama-Birmingham, Birmingham, AL, [7]University of Iowa, Iowa City, IA.

Background/Purpose: Peripheral and central sensitization is associated with knee pain severity in knee osteoarthritis (OA). Whether sensitization occurs prior to or only concurrently with development of OA pain is not known as no prior study has had longitudinal assessments. We examined the relation of 2 measurements of sensitization to the incidence of knee pain and of symptomatic knee OA, and change in pain severity over 2 years.

Methods: The Multicenter Osteoarthritis (MOST) Study is a NIH-funded longitudinal cohort of persons with or at risk of knee OA. Subjects had x-rays and pain questionnaires obtained at each study visit, and a standardized somatosensory evaluation of mechanical temporal summation and pressure pain thresholds (PPT) at the wrist and patella at 60 mo. Temporal summation was defined by increased pain during repeated mechanical stimulation (1 Hz × 30-sec) with a 60g monofilament. PPT was assessed with an algometer (1cm^2 tip, 0.5 Kg/sec) as the point at which the subject felt the pressure change to slight pain. The average of 3 PPT trials was categorized into sex-specific tertiles. Lower PPT indicates more sensitivity. Incident consistent frequent knee pain (CFKP, pain on most days of the past 30 days on both a telephone screen and clinic visit) at the 84-mo visit was determined from among knees that did not have CFKP at the 60-mo visit. Incident symptomatic knee OA (SxOA) at the 84-mo visit was defined as radiographic knee OA (ROA, KL grade ≥2) plus CFKP, assessed among knees free of pain at the 60-mo visit with or without ROA. We examined the relation of the somatosensory tests to incident CFKP and incident SxOA using logistic regression with GEE. We also assessed the relation of change in these

somatosensory measures among all knees with change in WOMAC pain between the 60- and 84-mo visits using linear regression. All analyses were adjusted for potential confounders (see Table for list).

Results: A total of 2308 subjects analyzed met eligibility criteria for these analyses (mean age 67.6, mean BMI 30.9, 61% female). Neither temporal summation nor PPT were associated with incident CFKP or incident SxOA. However, a decrease in PPT (sensitivity) over 2 years was associated with increased pain severity (Table).

Table. Temporal summation and PPT on Incident CFKP, Incident SxOA and Increase in WOMAC pain

		Temporal Summation			
		Wrist*		Patella*	
		Yes	No	Yes	No
Incident CFKP (N=1250)	N (% incidence)	480 (17.5%)	770 (16.6%)	995 (13.6%)	1570 (11.6%)

	Adj beta (95% CI)	Increase in WOMAC pain with incident temporal summation:			
		0.302 (−0.032, 0.636), p=0.06		0.261 (−0.084, 0.606), p=0.1	

		PPT Tertiles					
		Wrist			Patella		
		Low	Mid	High	Low	Mid	High
Incident CFKP (N=1234)	N (% incidence)	376 (19.4%)	434 (15.2%)	424 (16.5%)	729 (14.3%)	890 (11.0%)	924 (11.9%)
	Adj OR (95% CI)	1.17 (0.8–1.7)	0.90 (0.6–1.3)	1.0 (ref)	1.06 (0.8–1.5)	0.91 (0.7–1.2)	1.0 (ref)
	p for trend			0.4			0.6
Incident SxOA (N=1154)	N (% incidence)	357 (10.6%)	403 (11.2%)	396 (12.6%)	706 (8.5%)	875 (7.1)	901 (9.2%)
	Adj OR (95% CI)	0.79 (0.5–1.3)	0.91 (0.6–1.4)	1.0 (ref)	0.78 (0.5–1.1)	0.71 (0.5–1.0)	1.0 (ref)
	p for trend		0.6			0.2	
Increase in pain (WOMAC) (N=1895)	Adj beta (95% CI)	Increase in WOMAC pain for every unit increase in PPT:					
			0.104 (0.025, 0.184), p=0.01			0.173 (0.117, 0.230), p<0.0001	

*Wrist: person-based analyses; Patella: knee-based analyses
# These analyses examined the relation of incident temporal summation to change in WOMAC pain.
Adj=adjusted for potential confounders: age, sex, BMI, race, knee injury, KL, depressive symptoms, catastrophizing, widespread pain CFKP = consistent frequent knee pain; SxOA=symptomatic knee OA

Conclusion: While measures of sensitization are associated with knee OA pain presence and severity cross-sectionally, they were not related longitudinally to development of new pain symptoms over 2 years. However, decreases in PPT over 2 years were associated with increased pain severity. Enhanced pain sensitivity coinciding with new/increased knee pain may be mediated by sensitization or an imbalance between descending facilitation and inhibition. These results suggest that such changes may not necessarily precede development of knee pain, but may influence the experience of pain and its severity only once pain has been established.

2129

The Diagnostic Utility Of Anterior Knee Pain and Pain With Activities In Identifying Knees With MRI-Detected Structural Damage In The Patellofemoral Joint: The Multicenter Osteoarthritis Study.

Joshua J. Stefanik[1], Tuhina Neogi[2], Jingbo Niu[2], Neil A. Segal[3], Cora E. Lewis[4], Michael C. Nevitt[5], Frank Roemer[6], Ali Guermazi[1] and David T. Felson[2]. [1]Boston University, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]University of Iowa, Iowa City, IA, [4]University of Alabama, Birmingham, Birmingham, AL, [5]University of California, San Francisco, San Francisco, CA, [6]Klinikum Augsburg, Augsburg, Germany.

Background/Purpose: It is widely thought that patellofemoral joint (PFJ) pathology, a source of symptoms in knee osteoarthritis (OA), can be identified using patient history and pain location but this has not been evaluated in an OA population where tibiofemoral joint (TFJ) OA is also frequent. Treatment for PFJ and TFJ disease may differ making the identification of PFJ disease clinically important. Using MRI to identify knees with isolated PFJ disease, we sought to determine the diagnostic utility of anterior knee pain (AKP) and pain with specific activities to identify knees with isolated PFJ structural damage.

Methods: The Multicenter Osteoarthritis Study (MOST) is a NIH-funded prospective cohort study of older adults with or at risk of knee OA. We used data from the 60-month visit, the first visit at which a knee pain map was obtained, limiting our sample to knees with pain, aching, or stiffness in the past year. Subjects identified painful areas around their knee on the knee pain map, which was used to define AKP. Maximal WOMAC pain score was used to classify pain with stairs and walking on level ground (its absence might rule in PFJ pathology) to test their utility in identifying isolated PFJ damage. On MRIs from the same study visit, cartilage damage and bone marrow lesions (BMLs) were semi-quantitatively scored using the Whole Organ Magnetic Resonance Imaging Score. Knees with isolated PFJ damage (full-thickness cartilage loss or a BML in the PFJ and without either full-thickness cartilage loss or BML in the TFJ), isolated TFJ damage, and no structural damage were included (i.e., those with damage in both compartments were excluded). We determined the sensitivity (Sn), specificity (Sp), positive and negative predictive values (PPV and NPV) for AKP, pain with stairs, absence of pain with walking, and the combination of AKP and pain with stairs in identifying isolated PFJ damage. In sensitivity analyses we assessed pain with stair climbing vs. descending separately.

Results: 407 knees met our inclusion criteria (of 1185 knees with MRI read at 60 months). Of these, 193 (47%) had isolated PFJ damage, while 214 (53%) had either no damage (102; 25%) or isolated TFJ damage (112; 28%). AKP or activity pain showed only moderate or low Sn or Sp and correspondingly low PPV and NPV for identifying isolated PFJ (see table). Absence of moderate pain with walking had the greatest Sn (93%) but poor Sp. The combination of AKP and pain with stairs had the greatest Sp (82%) and but had low Sn (29%). We found similar results with other definitions of structural damage, WOMAC pain, and pain with stair climbing vs. descending.

Diagnostic utility of clinical symptoms commonly thought to indicate PFJ involvement with isolated PFJ structural damage (comparing knees with isolated PFJ damage to knees with either isolated TJF damage or no damage)

	Sensitivity	Specificity	PPV	NPV
Anterior knee pain	**60%**	**53%**	**53%**	**59%**
Pain with stairs (≥ minimal)	**74%**	**33%**	**50%**	**58%**
Pain with stairs (≥ moderate)	**40%**	**70%**	**54%**	**56%**
Absence of pain with walking (≤ minimal)	**58%**	**50%**	**48%**	**54%**
Absence of pain with walking (≤ moderate)	**93%**	**13%**	**49%**	**68%**
Anterior knee pain + pain with stairs (≥ minimal)	**49%**	**64%**	**56%**	**58%**
Anterior knee pain + pain with stairs (≥ moderate)	**29%**	**82%**	**60%**	**56%**

Conclusion: Location of and specific activity-related pain do not appear to highly discriminate underlying isolated PFJ pathology from isolated TFJ or lack of damage. Clinical exam parameters (e.g., localized tenderness on exam) may perform better in identifying isolated PFJ structural damage than patient-reported measures.

Factors Associated With Two-Year Pain Experience Outcome In Knee Osteoarthritis.

Jamie E. Rayahin[1], Joan S. Chmiel[2], Orit Almagor[3], Laura Belisle[2], Alison H. Chang[2], Kirsten Moisio[2], Karen W. Hayes[2], Yunhui Zhang[2] and Leena Sharma[2]. [1]University of Illinois, Chicago, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Northwestern University Medical School, Chicago, IL.

Background/Purpose: Few strategies to improve pain outcome in knee OA exist, in part because methods to evaluate this outcome are not established. ICOAP development included formulation of pain experience stages (Hawker 2008): 1) predictable pain, known trigger, only limiting

high impact activity; 2) mixed predictable/unpredictable pain, more constant, affecting some daily activities; 3) pain constant, superimposed unpredictable, major activity avoidance. We hypothesized that the probability of a good pain experience outcome is associated inversely with baseline depression and pain catastrophizing and directly with self-efficacy and social support.

Methods: Study participants (all with knee OA) reported pain stage (no pain, or stages 1, 2, or 3) at baseline and 2 years. 1-month test-retest reliability was excellent (weighted $\kappa = 0.85$; n = 28). Baseline assessments utilized the Geriatric Depression Scale, Pain Catastrophizing Scale, function Arthritis Self-Efficacy Scale, and MOS Social Support Survey. Good outcome was defined: baseline → 2-year reports of (no pain or stage 1) → (no pain or stage 1) or (stage 2 or 3) → (no pain or stage 1). Poor outcome was: (stage 2 or 3) → (stage 2 or 3) or (no pain or stage 1) → (stage 2 or 3). In multivariable logistic regression, pain outcome was the dependent variable, and all baseline variables with univariate $p \leq 0.20$ potential predictors.

Results: 212 persons [163 (77%) women, mean age 65 (10, SD), BMI 28.5 (5.7)] comprised the sample. 136 (64%) had a good pain outcome and 76 (36%) a poor outcome. Several baseline factors were associated with good pain outcome in univariate analyses (Table 1). In multivariable analysis, higher self-efficacy was associated with a significantly higher likelihood of good outcome; higher pain catastrophizing and BMI were associated with a lower likelihood of good outcome (Table 2).

Table 1. Baseline Characteristics of Good and Poor 2-Year Pain Experience Outcome Groups

Baseline Characteristics	Good Pain Experience Outcome* (n = 136 persons)	Poor Pain Experience Outcome* (n = 76 persons)	p value
Pain catastrophizing (higher score worse)	4.3 (4.7)	10.6 (8.5)	<0.0001
Self-efficacy (higher better)	27.1 (3.5)	22.8 (6.4)	<0.0001
Social support (higher better)	58.0 (16.4)	55.9 (15.2)	0.66
Age, years	65.7 (10.1)	62.7 (10.0)	0.91
Women, number (%)	107 (78.7%)	56 (73.7%)	0.50
BMI, kg/m^2	27.1 (4.6)	31.1 (6.6)	0.0004
Extensor strength, N-M (worse of R and L)	108.6(28.0)	97.6 (30.4)	0.40
K/L grade (worse of R and L)			0.0045
0–1	16 (11.8%)	7 (9.2%)	
2	77 (56.6%)	26 (34.2%)	
3	18 (13.2%)	16 (21.1%)	
4	25 (18.4%)	27 (35.5%)	
Depression (presence)**	2 (1.5%)	3 (3.9%)	0.35
Comorbidity***	0.8 (1.4)	1.5 (2.2)	<0.0001
Back pain, number (%)	93 (68.4%)	62 (81.6%)	0.052
Hip pain, number (%)	56 (41.2%)	33 (43.4%)	0.77
Physical activity (PASE)	152.8 (73.5)	157.8 (99.4)	0.0023
Medication use, number (%)	52 (38.2%)	43 (56.6%)	0.014

*Value shown is mean (SD) unless otherwise indicated
**p value for depressive symptoms as a continuous variable also exceeded 0.20
***Comorbidity questionnaire modification of Charlson Index (continuous)

Table 2. Multivariable Logistic Regression Model: Associations between Baseline Covariables and Baseline-to-2-Year Good Pain Experience Outcome (Dependent Variable)

Independent Variable	Adjusted Odds Ratio (95% CI)
Pain catastrophizing per 1 unit	***0.87 (0.82–0.93)***
Self-efficacy per 1 unit	***1.12 (1.03–1.22)***
BMI per 1 kg/m^2	***0.93 (0.86–0.995)***
K/L grade 2 (vs. 0–1, reference)	2.08 (0.59–7.33)
K/L grade 3 (vs. 0–1, reference)	0.33 (0.08–1.32)
K/L grade 4 (vs. 0–1, reference)	0.52 (0.14–1.97)
Comorbidity per 1 unit	0.86 (0.67–1.09)
Back pain (vs. no back pain, reference)	0.55 (0.23–1.36)
Physical activity (PASE) per 1 unit	0.997 (0.993–1.001)
Medication use (vs. no use, reference)	0.67 (0.32–1.38)

Findings are adjusted for all other variables in the table.

Conclusion: The odds of a good 2-year pain experience outcome in knee OA were lower in persons with greater pain catastrophizing and/or higher BMI, and higher in persons with greater self-efficacy. Specifically targeting these factors may help improve pain outcome in knee OA.

Osteoarthritis Pain: Variability and Clinical Correlations. Thomas J. Schnitzer, Renita Yeasted, Leijan Huang, Jennifer Duffecy, Mark Begale and A. Vania Apkarian. Northwestern University, Chicago, IL.

Background/Purpose: Although osteoarthritis (OA) is an intensely studied model of chronic pain, little is known about the temporal dynamics of OA pain intensity and how this correlates with physical function and other clinically meaningful outcomes. In this study, we collected pain ratings from individuals with knee OA at a granular level (several times per day) over 3 months to explore the temporal properties of OA pain and examine its association with other patient-reported outcomes.

Methods: Two OA populations were evaluated: one from a placebo arm of a large OA clinical trial and the other from a convenience sample of OA individuals. Participants had to be ≥40 years of age, meet the ACR definition for knee OA, have a minimum pain intensity of ≥4 on Numeric Rating Scale pain (0: no pain, 10: worst possible). All participants were asked to either report their pain on an electronic tablet twice daily (clinical trial) or on their cellphones (3 times per day) over 12–16 weeks and reported sleep performance and activity at 4 weekly clinic visits. To characterize the statistical properties of the time series of pain ratings, the means of the pain ratings in three blocks were calculated and compared by one way analysis of covariance. As well, fractal dimension, D, was calculated using rescaled range analysis to characterize the OA participants' pain fluctuations.

Results: 78 individuals were studied in the clinical trial and 35 individuals in the cell-phone collection study. Demographics of the two groups were both similar and typical of an OA population (data not shown). The distribution and mean fractal dimension, D, for the two populations were similar (Fig. 1), mean $D = 1.69 \pm 0.03$ for the clinical trial population (A) and mean $D = 1.65 \pm 0.04$ for the convenience sample (B). Data collected by cell phone demonstrated a close correlation between pain intensity and physical activity for the same day (Fig. 2) and a strong correlation between clinic sleep score rating and cell phone reported pain the preceding day ($r = 0.39$, $p < 0.001$).

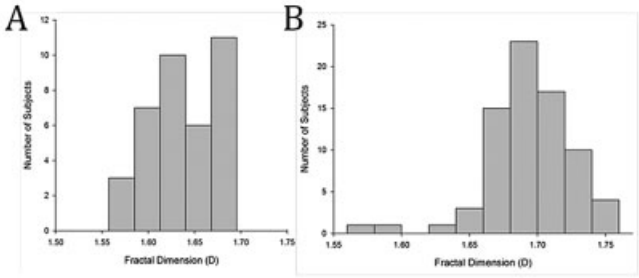

Figure 1.

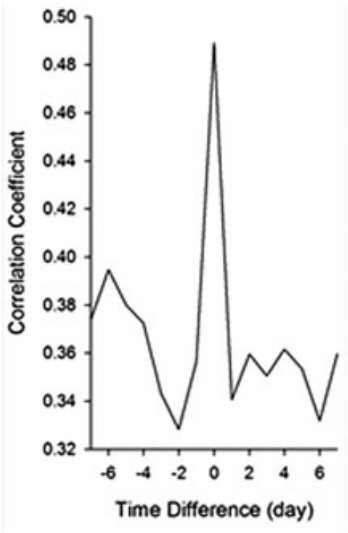

Figure 2.

Conclusion: This is the first study to characterize the temporal dynamics of OA pain. The finding of an anti-persistent time series in 2 separate populations provides strong confirmatory evidence of this pain pattern. These results are similar to those reported for chronic low back pain and in contrast

to purely neuropathic pain and acute pain. The anti-persistent pattern of pain is consistent with the concept of central pain processes activated to modulate peripheral pain input in OA. A strong temporal association between self-reported OA pain and physical function and sleep was also seen.

Short-Run Transitions In Pain States: Reflections Of Multiple Outcome Clinical Measures of Inadequate Pain Relief among Patients With Knee Osteoarthiritis. Stephanie Taylor[1], Christopher Black[2], Paul M. Peloso[3], Philip G. Conaghan[4], Leah Stokes[2], Mart A.F.J. van de Laar[5], François Rannou[6], Nigel K. Arden[7] and Panagiotis Mavros[2]. [1]Merck & Co., Inc., Whitehouse Station, NJ, [2]Merck, Whitehouse Station, NJ, [3]Merck Sharp & Dohme Corp., Rahway, NJ, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [5]University of Twente & Medisch Spectrum Twente, Enschede, Netherlands, [6]Physical Medicine and Rehabilitation Service, Paris-Descartes University, Cochin Hospital, Paris, France, [7]Oxford NIHR Musculoskeletal Biomedical Research Unit, University of Oxford, Oxford, United Kingdom.

Background/Purpose: Despite the importance of pain management in osteoarthritis (OA), there has been limited evidence confirming the adequacy of measuring pain relief in clinical practice setting. The objective of the Survey of Real World Therapies in Osteoarthritis (SORT) is to evaluate short run (30 days) changes in pain relief and its association with overall pain, physical functioning, stiffness and quality of life in patients with knee OA.

Methods: SORT, a 12-month prospective multinational study enrolled participants with knee OA receiving analgesics. Inadequate Pain Relief (IPR) was defined as a score of >4, indicating "moderate or greater pain", on BPI Question "What is your pain on average?". The Short-Form (SF)-12 and WOMAC were administered to measure quality of life, pain, stiffness, and physical function. Baseline and month one data were used to assess short run dynamics of knee OA management.

Results: 1254 participants were included: 67.3% women; mean age 68 years (SD=9.4); mean OA duration 5.9 years (SD=6.2). IPR was reported by 54% of the cohort. Overall, NSAIDs (64.1%) were used most often; followed by paracetamol (39.8%) and medications containing opioids (20.2%). IPR participants (vs. non-IPR) used more opioid containing medications (24.7% vs. 14.8%, p< 0.001). IPR participants (vs. non-IPR) differed QOL on: WOMAC Stiffness (115 vs. 67, p< 0.001), Pain (266 vs. 136, p< 0.001), Physical Function (892 vs. 459, p<0.001); SF-12 General Health (fair/poor 47% vs. 27%, p<0.001); Additionally, there were differences in IPR participants' report of response to treatment (fair, poor and no response 67% vs. 43%, p<0.001) as compared to non-IPR.

After 30 days, 28% of participants reported changes in pain relief, which was equally distributed (14% each) between the two baseline pain relief states. Participants whose pain relief state worsened experienced an average increase in pain measured by the BPI (27%) and WOMAC (9%). These participants also displayed worsened physical functioning (8%), greater knee stiffness (4%), as well as a decrease in health-related quality of life as measured by the physical component summary score (PCS) (2.1%) and mental component score (MCS) (2.7%).

In contrast, for those participants whose pain relief state improved, the BPI and WOMAC pain measurements improved 28% and 12%, respectively. Similarly, improvements were seen in physical functioning (8%), stiffness (11%) and both SF-12 components (1.8% each).

Conclusion: Short run changes in pain relief status were positively associated with significant changes in both the physical (PCS) and mental (MCS) components of SF-12, and the 3 domains of the WOMAC.

2133

Neuropathic Pain After Primary Total Hip and Knee Arthroplasty. Anne Lubbeke[1], Gabor J. Puskas[1], Domizio Suva[1], Sylvette Bas[1], Cem Gabay[1], Axel Finckh[2] and Pierre Hoffmeyer[1]. [1]Geneva University Hospitals, Geneva, Switzerland, [2]Geneva University Hospital, Geneva, Switzerland.

Background/Purpose: A sizeable number of patients continue to suffer from pain after total joint arthroplasty (TJA). The reason for this is not well established in many cases, and the presence of persistent postsurgical pain (PPSP) of neuropathic origin has been suggested. Possible mechanisms include intraoperative nerve injury, local inflammation, and central sensitization. Little is known about neuropathic pain after joint replacement, but its prevalence has been estimated at 5%.

Leptin could play a role in peripheral pain sensitization via its pro-inflammatory cytokine-like function. Moreover, animal models have suggested a possible influence of leptin in the development of neuropathic pain. In previous studies we found that high leptin concentrations were associated with greater pain preoperatively as well as 1 year postoperative.

Our objectives were to (1) assess the prevalence of neuropathic pain 2 years after TJA, (2) describe its influence on pain, function, general health and satisfaction after surgery, and (3) identify preoperatively assessed predictors (including leptin) of PPSP of neuropathic origin.

Methods: Prospective cohort study including patients with total hip and knee arthroplasty operated upon for primary OA in a large orthopaedic center between 1 and 12/2010. Prior to surgery baseline characteristics were recorded and leptin concentrations were sampled from blood (n= 175 TJAs) and assessed using an ELISA kit. At 2 years postoperative, the following outcomes of interest were assessed via questionnaire: (1) Presence of neuropathic pain measured with Neuropathic Pain Diagnostic Questionnaire (DN4); (2) Pain, function and general health measured with WOMAC, VAS pain, SF-12; and (3) Satisfaction.

Results: 275 TJAs were included, 161 THAs and 114 TKAs. Mean age was 72 (±9) years, mean BMI 28 kg/m^2, 62% were women.

Neuropathic pain at 2 years postoperative was reported by 5 THA (3.1%) and 11 TKA patients (9.6%). Presence of neuropathic pain was associated with significantly higher PPSP level, lower function, worse general health and low satisfaction (see Table). Eight of the 16 patients with neuropathic pain indicated they would not undergo the operation again.

Prior to surgery patients with neuropathic pain (vs. those without) had a significantly higher BMI (32 vs. 27 kg/m^2), higher ASA scores, more often OA of contra-lateral joints, greater pain (WOMAC pain 29 vs. 41), as well as significantly higher serum leptin concentrations (37 vs. 24 ng/ml, p=0.020). The latter association was seen in obese (55 vs. 44 ng/ml) and in non-obese patients (23 vs. 16 ng/ml).

Table. Patient-reported outcomes 2 years after TJA according to presence or absence of neuropathic pain

	Neuropathic pain yes (n=16)	Neuropathic pain no (n=259)	Risk difference (95% CI)
Very satisfied/satisfied (%)	8 (50.0)	223 (86.1)	36.1 (11.2; 61.0)
Would not undergo surgery again (%)	8 (50.0)	15 (5.8)	44.2 (19.5; 68.9)
Scores, mean, SD	27.0 (±4.7)		**Mean difference (95% CI)**
Pain (VAS)	5.5 (±1.6)	1.6 (±2.0)	3.9 (2.8; 4.9)
WOMAC pain	50.3 (±18.0)	83.6 (±18.7)	−33.3 (−42.7; −23.8)
WOMAC function	48.7 (±21.0)	74.6 (±20.9)	−25.9 (−36.5; −15.2)
SF-12 mcs	38.0 (±5.6)	48.0 (±10.3)	−10.0 (−15.2; −4.6)
SF-12 pcs	33.8 (±6.1)	42.5 (±9.4)	−8.7 (−13.6; −3.9)

Conclusion: Neuropathic pain is more frequent after knee than after hip arthroplasty. Its presence is associated with poor outcomes. Whether leptin is involved in the pathogenesis and /or a useful preoperative marker of neuropathic pain, merits further investigation.

Responsiveness and Predictive Ability Of The Knee Society Scale (KSS) Score. Jasvinder A. Singh[1], Cathy Schleck[2], W. Scott Harmsen[3] and David Lewallen[4]. [1]University of Alabama, Tuscaloosa, AL, [2]Mayo Clinic College of Medicine, Rochester, MN, [3]Mayo Clinic, Rochester, MN, [4]Mayo Clinic college of medicine, Rochester, MN.

Background/Purpose: The KSS questionnaire has previously been shown to have face, content and construct validity and test-retest reliability. Our objective was to assess the Responsiveness and Predictive Ability of the KSS.

Methods: We used data from the Mayo Clinic Total Joint Registry to assess the validity of KSS questionnaire, by including patients who underwent primary total knee arthroplasty (TKA) between 1993–2005 and responded to the baseline and 2-year post-primary TKA KSS questionnaire. KSS questionnaire generates three domain scores: KSS function score

(walking, stairs and use of knee supports), range of motion and KSS score (pain, range of motion and stability) scores. Convergent/divergent validity was examined with the association of select demographics (age, gender, number of joints involved) at baseline with KSS scores using linear regression and correlation analyses. Responsiveness was assessed with Minimally Clinically Important Difference (MCID) and Really Important Difference (RID) were calculated corresponding to "somewhat better now" and "much better now" patient responses, respectively to the question at 2-years-Compared to your condition before the surgery, how would you rate your knee now? For discriminant ability, we calculated effect size by taking the change in respective score from baseline to 2-years and dividing the result by the standard deviation at baseline. Predictive ability was assessed by association of improvement in KSS function (categorized as <=10, 11–40 and >40) and KSS scores at 2-years (minus preoperative scores; categorized as <= 35, 36–63, and 64–95) with revision surgery at time after 2-years.

Results: For primary TKA, there were 5,280 knees with both a baseline and a 2-year data. The sample consisted of 2,375 males (45%) and 2,905 females (55%). The mean age at surgery (SD) is 68 (10), median age was 70 (range, 17–93).

MCID and RID thresholds were as follows: KSS function score, 7.0 and 29.3; KSS score, 27.7 and 51.0; range of motion, 11.7 and 20.4. Respective effect sizes at 2-years were large, 1.37 for function score, 2.60 for knee score and 1.56 for range of motion; and consistent with effect sizes for other validated scales for arthroplasty.

Improvement in KSS-function score was associated significantly with the risk of revision after 2-years (Table 1); total KSS score showed a trend towards significant association (p=0.07)

Table 1. Predictive ability of KSS score for revision TKA

	Hazard ratio (95% CI)	p-value
Improvement in KSS-function (n=4270 with 179 events)		
<= 10 vs. 41–100	1.87 (1.23, 2.83)	0.003
11–40 vs.41–100	1.18 (0.78, 1.78)	0.43
Improvement in KSS (n=785 with 13 events*)		
<= 35 vs. 64–95	16.63 (2.07, 2150)	0.07
36–63 vs. 64–95	4.95 (0.56, 658)	0.31

*186 TKAs did not have data to calculate KSS scores

Conclusion: KSS and KSS-function scores are responsive in patients undergoing primary TKA. KSS scores can predict the risk of early revision after primary TKA. These findings imply that a regular monitoring of patient-reported outcomes of pain and function may allow signal detection for early TKA revision.

Musculoskeletal Pain Explains Differences In Function At Time Of Surgery In Black TKR and THR Patients. Anthony Porter[1], Wenjun Li[1], Leslie R. Harrold[1], Milagros Rosal[1], Philip Noble[2], David Ayers[1], Patricia D. Franklin[1] and Jeroan Allison[1]. [1]University of Massachusetts Medical School, Worcester, MA, [2]Baylor College of Medicine, Houston, TX.

Background/Purpose: The existence of racial disparities in total knee (TKR) and total hip (THR) replacement outcomes is well established but not well understood. The burden of musculoskeletal co-morbidities was investigated among black and white TKR and THR patients at the time of surgery to assess whether that explains disparities in a prospective cohort.

Methods: Descriptive analyses were performed on a cohort of 3,306 TKR and 2,439 THR patients. Data collected include sociodemographics (age, gender, race), body mass index (BMI), modified Charlson co-morbidity scores, operative joint pain severity using the Knee Injury/Hip Disability and Osteoarthritis Outcome Scores (KOOS/HOOS,), function based on the Short Form 36 (SF-36) Physical Component Score (PCS), emotional health using the SF-36 Mental Component Score (MCS), and musculoskeletal co-morbidity using the KOOS/HOOS (number of nonoperative hip and knee joints with moderate to severe pain; range 0–3) and Oswestry Disability Index (ODI). Factors associated with pre-operative pain and function were examined using multivariable stepwise linear regression models.

Results: At time of surgery, black TKR patients were significantly younger (62.0 vs. 66.9 years old), female (69.7% vs. 60.8%), heavier (34.6 vs. 31.3 BMI), exhibited higher prevalence of 2–5 medical co-morbidities (17.0% vs. 9.2%), poorer emotional health (47.4 vs. 52.1), poorer surgical knee pain (43.4 vs. 53.2), poorer function (31.3 vs. 33.1), and more pain in other weight-bearing joints than whites (p<0.02). In regression models, after adjusting for these independent variables, race did not explain the differences in surgical knee pain and function at time of surgery (−4.3–0.8 p>0.05), while moderate to severe pain in up to three lower extremity joints had a significant effect (−23.4–[−15.9], p<0.0001).

At time of surgery, black THR patients were significantly younger (59.9 vs. 64.7 years old), heavier (31.7 vs. 29.1 BMI), exhibited higher prevalence of 2–5 medical co-morbidities (14.1% vs. 6.9%), poorer emotional health (47.0 vs. 50.9), greater surgical hip pain (39.3 vs. 49.2), poorer function (30.0 vs. 31.6), and more pain in other weight-bearing joints than whites (p<0.04). In regression models, after adjusting for these independent variables, race did not explain the differences in surgical hip pain and function at time of surgery (−3.1–3.3, p>0.05), while moderate to severe pain in up to three lower extremity joints had a significant effect (−19.9−(−11.9), p<0.0001).

Conclusion: Black patients exhibit poorer function at the time of surgery compared to whites. This difference was influenced by a greater burden of musculoskeletal pain in the large weight-bering joints in the legs. Racial disparities have been well established in previous studies. In this sample, musculoskeletal co-morbid pain was found to explain much of the poorer pre-operative function seen in black patients.

2136

Does Functional Gain and Pain Relief After TKR and THR Differ By Patient Obese Status? Wenjun Li[1], Leslie R. Harrold[1], Jeroan Allison[1], Courtland Lewis[2], Thomas Bowen[3], Patricia D. Franklin[1] and David Ayers[1]. [1]University of Massachusetts Medical School, Worcester, MA, [2]Hartford Hospital, Hartford, CT, [3]Geisinger, Danville, PA.

Background/Purpose: Obesity is an important predictor of functional status and pain after total knee (TKR) and total hip (THR) replacement. However, variations in pre-post TKR and THR changes in function and pain by obesity status remain to be examined.

Methods: Pre- and 6 month post TKR data on physical function and pain were collected on 1,533 primary TKR and 1,118 primary THR patients between 5/2011 and 10/2012. Data included demographics, comorbidities, operative joint pain severity based on the Knee Injury/Hip Disability and Osteoarthritis Outcome Score (KOOS/HOOS), physical function (SF-36 PCS), mental health (SF-36 MCS), and musculoskeletal burden of illness. Pre-post changes in PCS and pain were analyzed using descriptive statistics and linear mixed models that accounted for the clustering of patients within clinic.

Results: Approximately 14% of TKR patients were under or normal weight (BMI<25), 33% overweight (BMI: 25.1–30), 29% obese (BMI: 30.1–35), 15% severely obese (BMI: 35.1–40) and 9% morbidly obese (BMI>40). Patients had average age of 67 years, included 61% women and 93% whites. Patients with greater level of obesity had lower PCS at baseline (p<0.001) and 6 month (p<0.001). However, pre-TKR to 6 month post-TKR change in PCS did not differ by level of obesity (p=0.554), and had an overall mean (SE) of 9.7 (0.23). Patients with greater levels of obesity had worse pain scores at baseline (p<0.001) but greater change in pain between pre-TKR and 6 months post-TKR (p=0.001). As a result, average pain scores at 6 months were similar across levels of obesity (p=0.150), and had an overall mean (SE) of 84.9 (0.40).

Approximately 27% THR patients were under/normal weight (BMI<25), 38% overweight (BMI: 25.1–30), 23% obese (BMI: 30.1–35), 9% severely obese (BMI: 35.1–40) and 4% morbidly obese (BMI>40). Patients had average age of 66 years, included 62% women and 95% whites. Greater level of obesity was associated with lower PCS at baseline (p<0.001) and 6 month (p<0.001). Mean change in pre-to-six month PCS was greater in patients with BMI <35 when compared to BMI>35 (14 vs. 11.5) Greater level of obesity was associated with a poorer baseline pain score (p<0.001) but larger change in post-op pain at (p=0.001). At 6 months, pain scores did not differ by level of obesity (p=0.068) with a mean score greater than 90.

Conclusion: At 6 months after TKR, severely obese patients (BMI>35) reported improvements in pain and function equal to or greater than patients with BMI<35. At 6 months after THR, all patients reported significant functional gains although patients with BMI>35 had lower mean functional gain than those with BMI<35. All patients reported excellent pain relief.

2137

Important Predictors Of Patient-Reported Outcomes After TKR and THR Are Not Included In Risk Models Based On Administrative Data. Patricia D. Franklin[1], Leslie R. Harrold[1], Wenjun Li[1], Jeroan Allison[1], David Ayers[1] and Courtland Lewis[2]. [1]University of Massachusetts Medical School, Worcester, MA, [2]Hartford Hospital, Hartford, CT.

Background/Purpose: Because total knee (TKR) and total hip (THR) replacement surgery is performed to relieve pain and improve physical function in patients with advanced arthritis, there is growing demand to use patient-reported outcomes (PROs) to assess TKR effectiveness. The UK and others now require PRO assessment after TKR. Thus, a clear understanding of pre-existing clinical factors that influence PROs after surgery is needed before comparing PROs across providers. We evaluated the roles of medical and musculoskeletal comorbidities in explaining variation in 6 month post-TKR and THR pain relief and functional gain.

Methods: A US cohort of 1,578 TKR and 1,166 THR patients reported sociodemographic (age, sex, race), BMI, modified Charlson comorbidity, arthritic disease severity (Hip Disability/Knee Injury and Osteoarthritis Outcome Scores (HOOS/KOOS)) in both knees and hips, lumbar disease using the Oswestry Disabiity Index (ODI), emotional health based on the Short Form 36 (SF-36) Mental Component Score (MCS), and physical function (SF-36 PCS). Predictors of change in pre-to-6 month post-TKR and post-THR pain and function were examined using linear mixed models adjusting for clustering within site.

Results: TKR patients had a mean age of 66 years, mean BMI of 31.5, and were 62% female and 6.8% black. Nine percent (9%) reported Charlson of 2–5, 15% with Charlson of 6, 7% moderate/severe pain in 2–3 knee/hip joints, and 26% moderate/severe lumbar pain. After adjusting for sociodemographic factors, significant predictors of poorer 6 month post-THR *pain* included poorer emotional health, higher Charlson comorbidities and any lumbar pain at time of THR. These factors also predicted poorer 6 month *function*.

THR patients had a mean age of 64 years, mean BMI of 29.2, and were 61% female and 4% black. Six percent (6%) reported Charlson of 2–5, 15% with Charlson of 6, 9% moderate/severe pain in 2–3 knee/hip joints, and 34% moderate/severe lumbar pain. After adjusting for sociodemographic factors, significant predictors of poorer 6 month post-THR *pain* included poorer emotional health, Charlson of 1, and severe lumbar pain at time of THR. These factors also predicted poorer 6 month *function*, as well as greater BMI and moderate/severe pain in non-operative knees/hips.

Conclusion: Before adopting PROs as a standard measure of TKR or THR effectiveness, a complete understanding of pre-existing clinical factors associated with poorer pain relief and functional gain is needed. These analyses suggest that greater musculoskeletal, as well as medical, comorbid conditions are associated post-operative patient-reported outcomes and should be included in risk-adjustment models.

2138

The Impact Of Arthritis Type On Post-TJR Functional Gain: Outcomes In RA Vs. OA Patients. Leslie R. Harrold[1], David Ayers[1], Brian Curtin[2], George Reed[1] and Patricia D. Franklin[1]. [1]University of Massachusetts Medical School, Worcester, MA, [2]Virginia Commonwealth University Medical Center, Richmond, VA.

Background/Purpose: Total joint arthroplasty (TJA) is commonly used in rheumatoid arthritis (RA) patients and yet there is little available information quantifying pain relief and functional gain following surgery and how that differs from the osteoarthritis (OA) population. Therefore we examined 6-month functional outcomes of TJR in a population-based observational cohort of RA and OA patients who underwent total hip (THR) or knee (TKR) replacement.

Methods: Patients undergoing primary TJR from 7/1/11 through 12/3/12 were identified from the FORCE-TJR national research consortium which enrolls patients from 111 surgeons across 27 states in the US. The registry gathers data on patient demographics, underlying type of arthritis, body mass index, non-arthritis comorbid conditions, arthritis in lower extremity large joints, back pain, operative joint pain severity based on the Knee Injury/Hip Disability and Osteoarthritis Outcome Score (KOOS/HOOS), function based on the Short Form 36 Physical Component Score (PCS), and mental health using the SF-36 Mental Component Score (MCS). Descriptive statistics were performed as well as linear regressions examining the influence of arthritis type on pain relief and functional gain.

Results: There were 136 RA and 1493 OA patients who underwent primary TKR, and 83 RA and 1139 OA patients who underwent primary THR. Among TKR patients, RA patients were more likely to be nonwhite (14% vs. 7%, $p=0.001$), unmarried (43% vs. 29%, $p<0.001$), have lower emotional health (47 vs. 53, $p<0.001$) with an annual income of ≤$45,000 (57% vs. 36%, $p<0.001$)) as well as greater operative joint pain (50 vs. 54, $p<0.01$) and impairment in functioning (32 vs 34, $p=0.02$). Similarly, RA THR patients were more likely to be nonwhite (14% vs. 6%, $p=0.005$), have lower emotional health (46 vs. 52, $p<0.001$) with an annual income of ≤$45,000 (54% vs. 34%, $p<0.001$) with worse operative joint pain (42 vs. 49, $p<0.001$) and functioning (28 vs 32, $p<0.001$). In unadjusted analyses, RA patients undergoing TKR as compared to OA patients had less functional gain 6 months post-surgery (7.0 vs. 9.8, $p<0.001$) but similar pain relief (31.9 vs. 31.1, $p=0.66$). With adjustment for sociodemographic and clinical factors as well as clustering by physician, RA patients had both less improvement in function (−2.5; 95% CI −4.2 to −0.7) and reduction in pain (−4.0; 95% CI −7.9 to 0.1). In contrast, RA patients who undergo THR have similar functional gain (12.6 vs. 14.0, $p=0.23$) and pain relief (45.9 vs. 41.9, $p=0.09$) as compared to OA patients in both unadjusted and adjusted analyses.

Conclusion: RA patients have less functional improvement and pain relief as compared to those with OA when undergoing TKR but similar when undergoing THR. More investigation is needed to assess whether there are modifiable factors that may be targeted for intervention to improve outcomes for RA patients undergoing TKR.

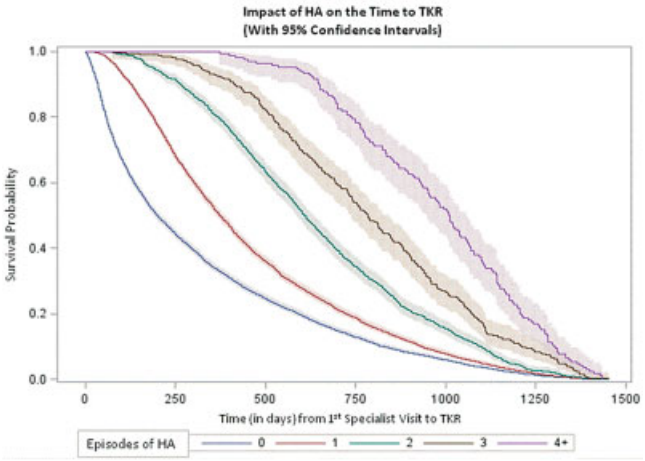
Do Hyaluronic Acid Injections Delay Total Knee Replacement Surgery? Thomas Abbott[1], Roy D. Altman[2], Robert Dimeff[3], Michael Fredericson[4], Vijay Vad[5], Peter Vitanzo Jr.[6], Sashi Yadalam[1], Ronald Levine[1], Brad Bisson[7] and Samir Bhattacharyya[7]. [1]Johnson & Johnson, New Brunswick, NJ, [2]UCLA, Los Angeles, CA, [3]UT Southwestern Medical Center, Dallas, TX, [4]Stanford University School of Medicine, Menlo Park, CA, [5]Weill Cornell Medical College, NY, NY, [6]Rothman Institute, Philadelphia, PA, [7]DePuy Synthes Mitek Sports Medicine, Raynham, MA.

Background/Purpose: More than 27 million adults in the US have knee osteoarthritis (OA), a painful and life-altering disease. Various non-pharmacologic and pharmacologic agents are recommended to alleviate pain, inflammation, and to improve function. When patients have inadequate response to these therapies, viscosupplementation with hyaluronic acid (HA) injections helps restore synovial fluid properties in the knee, leading to less pain and improved clinical outcomes. Total knee replacement (TKR) usually is reserved as the final treatment option. The present study examined the impact of the use of HA injections in delaying TKR in patients with knee OA.

Methods: A retrospective analysis of the Truven Marketscan databases was performed. All OA patients continuously enrolled during calendar year January, 2007 through December, 2011, that went on to TKR. Two cohorts were identified with this population: A cohort of patients receiving HA injections and the second cohort with no HA injections. Time-to-event analyses were performed in both cohorts, where the starting time was defined as the patients' 1st visit to an OA specialist (primarily orthopedic surgeons), and the ending point was TKR. The initial visit had to have occurred after January, 2008, providing a 12-month clean period. HA usage was grouped into episodes of treatment, where successive HA injections within 15 days were grouped into the same episode. An episode encompassed one course of a series of weekly injections or a single injection of HA, based on the standard

use of HA. A propensity scoring methodology was implemented to adjust for baseline characteristics of patients in HA and non-HA cohorts.

Results: The number of patients in the HA and non-HA cohorts were 7,000 and 19,627, respectively. Of the 7,000 HA patients, we successfully propensity score matched 6,891 with the non-HA cohort (98%) with caliper of 0.001. The majority of the patients were female (66%). The median times from the initial specialist visit to TKR were 199 and 443 days for non-HA cohort and HA cohort with one episode of HA treatment, respectively. There was a well defined "dose response curve", with each treatment episode increasing the median gap by on average 202 days. As an example, for HA cohort with 3 and 4 or more episodes of treatments, the median times to TKR were 784 (585 days delay) and 1,009 (810 days delay) days, respectively.



Conclusion: This observational, descriptive analysis of an administrative database provides evidence that HA injections delay patients' progression to TKR (up to approximately 2.2 years documented in the present study population). Although the analysis attempted to control for disease severity by propensity score matching, there could be remaining differences between the HA and non-HA populations not recorded in the database which could affect the interpretation of the results.

Effects Of Intra-Articular Hyaluronic Acid Injections On Gait Pattern In Patients With Knee Osteoarthritis. Bilal Uysal, Aysegul Ketenci, Sina Esmaeilzadeh and Dilsad Sindel. Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey.

Background/Purpose: The aim of this study was to determine the effects of intra-articular hyaluronic acid (HA) injections on gait pattern of both injected and un-injected knees with motion analysis in patients with knee osteoarthritis (OA).

Methods: In a prospective study 49 eligible patients who had knee OA according to the American College of Rheumatology criteria and had grade II-III knee OA in the X-ray examination according to Kellgren and Lawrence Grading Scale, were included in the study. The HA was injected into the affected joints in 62 knees, once a week for three weeks. Gait analysis was performed at baseline, end of treatment protocol and 6-month after treatment by the ELITE Motion Analysis System (BTS S.p.a., Milan, Italy) and two force plates. The motion analysis was assessed by the Davis protocol.

Results: The mean age of patients was 56.7 ± 6.3 (45–65) years; 45 (91.8%) were women. The ground reaction force was significantly decreased in the injected knees ($p<0.05$); however, there was no significant decrease ($p>0.05$) in the ground reaction force over six months. The extensor and flexor moments of the injected knees were significantly decreased ($p<0.05$) at the end of therapy and 6-month assessments compared with the un-injected knees ($p>0.05$). There were no significant changes in the walking velocity, stride time and stride length in both injected and un-injected knees over six months ($p>0.05$).

Conclusion: Our data suggest that intra-articular HA injections can reduce the ground reaction forces and flexion-extension moments, and consequently, lead to decrease in knee loading and improvement in the symptoms.

Interphalangeal Intra-Articular Injection With Triamcinolone Hexacetonide: Assessment Of effectiveness In Hand Osteoarthritis. Natalia de Oliva Spolidoro[1], Jamil Natour[2], Rita N.V. Furtado[3], Flavia S. Machado[3] and Hilda A. Oliveira[2]. [1]Universidade Federal de São Paulo - Unifesp, São Paulo, Brazil, [2]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [3]Universidade Federal de São Paulo, São Paulo, Brazil.

Background/Purpose: Despite being a very prevalent joint condition, there is a lack of studies on the effectiveness of the intra-articular injection (IAI) of corticosteroids in interphalangeal joints (IPs) with osteoarthritis (OA).

Methods: A randomized, controlled, double-blind trial was carried out involving 60 OA hands patients (proximal or distal IPs), allocated in two groups. The TH/LD group (n=30) received IAI in the most symptomatic IP with 0.1ml of 2% lidocaine and triamcinolone hexacetonide(TH) at a dose of 4mg(0.2ml) and 6mg(0.3ml) in the distal and proximal IPs, respectively. The LD group (n=30) received IAI with only 0.1ml of 2% lidocaine. The patients were evaluated by blinded raters at baseline (T0) and one, four, eight and twelve weeks (T1, T4, T8 and T12) after the procedure. Outcome measures: Visual Analogic Scale(VAS: 0 to 10cm) for pain in the IP at rest (VASr) and during movement (VASm), VAS for swelling (VASs), goniometry(°), grip strength(kgf), pinch strength(kgf) and hand function (COCHIN questionnaire and AUSCAN index). Ultrasound evaluation: Quantitative measure (in mm) of synovial hypertrophy in palmar and dorsal joint recesses of IP injected. The level of significance in the statistical analysis was set to 5% ($p<0.05$).

Results: Females accounted for 96.67%of the sample (58 patients). Mean age was 60.7 ± 8.2 years. Mean disease duration was 5.0 ± 3.6 years. Twenty-nine proximal (48.3%) and 31 distal (51.7%) IPs received IAI, with no significant differences between groups. Significant intra-group improvements ($p<0.05$) were found in both groups, with the exception of grip and pinch strength. Reductions in the VAS for pain at rest and during movement were found in both groups one week after IAI ($p=0.000$). A reduction in the VASs occurred from T4 to T12 in the TH/LD group ($p=0.000$), whereas a reduction in VASs only occurred at T8 in the LD group($p=0.008$).Both groups exhibited goniometric improvements only at T8($p=0.02$). Pulp-to-pulp and tripod pinch strength exhibited improvements beginning at T4($p=0.001$) and T8($p=0.000$), respectively. Hand function (COCHIN and AUSCAN) exhibited significant improvement beginning at T4($p=0.047$ and $p=0.000$, respectively), which was maintained through to the end of the study only with regard to the AUSCAN index ($p=0.001$).In the ultrasound evaluation, reductions in the quantitative measure of dorsal and palmar synovial hypertrophy occurred in both groups at T4($p=0.024$)and T8($p=0.005$), respectively. In the intergroup evaluation VASm ($p=0,014$) and VASs ($p=0,022$) showed better response in group TH/LD. There were no statistically significant differences intergroup for other variables. No substantial adverse effects were observed.

Conclusion: Proximal and distal IPs IAI with TH was effective in reducing swelling and joint movement pain in OA hands patients.

2142

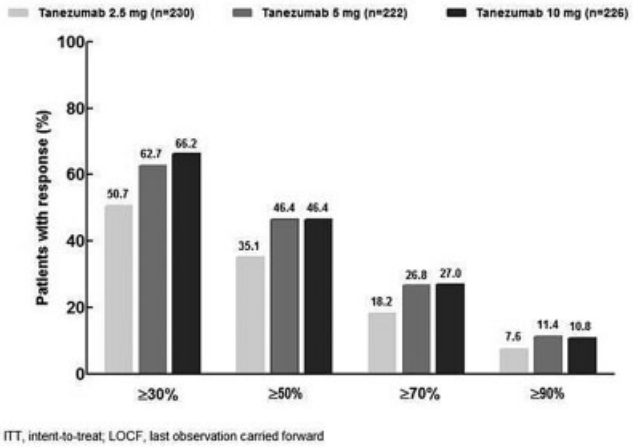
Long-Term Safety and Efficacy Of Subcutaneous Tanezumab In Patients With Knee Or Hip Osteoarthritis (NCT00994890). Leslie Tive[1], Eugene J. Dabezies[2], Robert J. Fountaine[3], Mark T. Brown[3], Michael D. Smith[3], Kenneth M. Verburg[3] and Christine R. West[4]. [1]Pfizer Inc, New York, NY, [2]Pensacola Research Consultants, Pensacola, FL, [3]Pfizer, Inc., Groton, CT, [4]Pfizer, Williamston, MI.

Background/Purpose: Tanezumab (TNZ), a monoclonal antibody that inhibits nerve growth factor, reduces hip or knee osteoarthritis (OA) pain. A non-controlled, randomized, double-blind study of TNZ 2.5, 5, and 10 mg administered by subcutaneous (SC) injection at 8-week intervals was conducted in patients with hip or knee OA.

Methods: Patients (N=678) with moderate to severe knee or hip OA were randomized in a 1:1:1 ratio and treated with TNZ 2.5 mg (n=230), 5 mg (n=222), or 10 mg (n=226) every 8 weeks. Efficacy analyses included change from baseline in Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain and Physical Function subscales, Patient's Global Assessment of OA (PGAO), and percentage of patients with ≥30%, ≥50%, ≥70%, and ≥90% improvement in WOMAC Pain. Safety assessments included adverse event (AE) documentation, physical and neurological examinations, and laboratory tests.

Results: The study discontinued prematurely due to a FDA partial clinical hold on TNZ non-cancer pain studies. Patients received 1 to 4 TNZ doses. Mean study treatment duration was 180, 191, and 187 days for TNZ 2.5, 5, and 10 mg treatment, respectively. TNZ 10 mg and TNZ 5 mg provided similar improvements from Baseline at Weeks 8 and 16 in WOMAC Pain, Physical Function, and PGAO; improvements were greater than with TNZ 2.5 mg. More patients had ≥30%, ≥50%, ≥70%, and ≥90% improvement in WOMAC Pain at Weeks 8 (Figure) and 16 with TNZ 10 and 5 mg than with TNZ 2.5 mg. Overall AE incidence was greatest with TNZ 10 mg (80.1%), followed by TNZ 5 mg (76.1%), and 2.5 mg (68.7%). The most frequently reported AEs were arthralgia, injection site reaction, and paresthesia. Osteonecrosis (ON) was reported as an AE in 4 patients (1.8%) treated with TNZ 10 mg, 4 patients (1.8%) in the TNZ 5 mg group, and 1 patient (0.4%) in the TNZ 2.5 mg group. Thirty-four patients had an all-cause total joint replacement. Of these, 22 (64.7%) events inclusive of the 9 cases of ON were subsequently adjudicated by a blinded external adjudication committee and none were adjudicated to primary ON. The percentage of patients with no new or worsened neurological examination abnormality at last assessment ranged from 82% to 88% across groups.

Figure. Reduction in WOMAC Pain Subscale for Week 8 (ITT, LOCF)



ITT, intent-to-treat; LOCF, last observation carried forward

Conclusion: Overall, SC TNZ provided improvements in Pain, Physical Function, and PGAO at all doses. TNZ 5 and 2.5 mg were better tolerated than TNZ 10 mg.

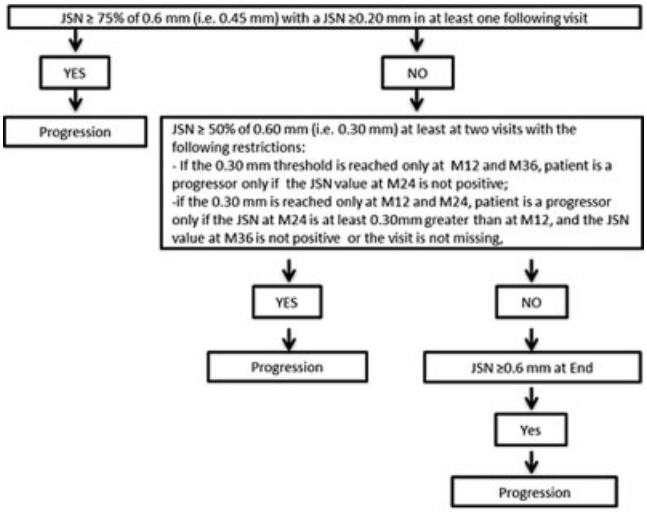
Strontium Ranelate Significantly Decreases Radiological Progression Using a New Definition For Radiological Progression In Patients With Primary Knee Osteoarthritis Treated With Strontium Ranelate. Olivier Bruyere[1], Roland Chapurlat[2], Cyrus Cooper[3] and Jean-Yves Reginster[1]. [1]University of Liège, Liège, Belgium, [2]INSERM UMR 1033 and University of Lyon, Hôpital Edouard Herriot, Lyon, France, [3]MRC Lifecourse Epidemiology Unit, Southampton, United Kingdom.

Background/Purpose: Strontium ranelate (SrRan) 2g/day has demonstrated a structure-modifying activity associated with symptoms improvement in patients with knee OA in a large, randomised, placebo-controlled, double-blind phase-III 3-year study. The objective of a planned analysis was to describe the efficacy of SrRan on radiological progression with a new definition of radiological progressing patients. This definition is based on an algorithm which aimed to ensure the robustness of the changes in JSW taking into account JSW change consistency over time. These radiological progressing patients have been demonstrated to be at higher risk of knee surgery[1].

Methods: 1683 patients with symptomatic primary knee OA (ACR criteria) were included and randomly assigned to SrRan 1g, 2g or placebo for 3 years. Percentage of radiological progressors between baseline and last observation were compared across groups in the intention to treat and per protocol populations using a chi-square test. A logistic model with adjustment on risk factors (age, BMI and Kellgren-Lawrence grade) was also carried out. Radiological progressors were defined as described below (exploratory method):



Results: The ITT set included 1371 (82% of the randomised set) patients. Age was 63±7 years, BMI was 30±5 kg/m^2, JSW was 3.5±0.8 mm. 61% were KL II. 69% were female. There were significantly fewer radiological progressors between baseline and last observation in the SrRan groups than in the placebo group: 23.8% ($p<0.001$), 25.3% ($p<0.001$) in the SrRan 1g and 2g groups respectively compared to the placebo group (41.7%%). The RRR (and NNT) compared to placebo were 42.9% (NNT=6) and 39.3% (NNT=7) in the 1g and 2g group, respectively. Results are confirmed on the per protocol population (N=865): 26.4% ($p<0.001$); 27.6% ($p<0.001$) in the SrRan 1g and 2g compared to 49.0% in the placebo group. After adjustment on confounding factors results are similar.

Conclusion: Strontium ranelate 1 and 2g/day significantly reduce the number of knee OA patients with a significant radiological progression suggesting a long-term beneficial effect on knee OA-related surgery.

Prevention Of Radiological Progression In Patients With Primary Knee Osteoarthritis With Strontium Ranelate. Jean-Yves Reginster[1], Roland Chapurlat[2], Francis Berenbaum[3], P. Nash[4], O. Zamani[5], Martine Cohen-Solal[6], Gerolamo Bianchi[7], Jaime Branco[8], F. Navarro[9] and Cyrus Cooper[10]. [1]University of Liège, Liège, Belgium, [2]INSERM UMR 1033 and University of Lyon, Hôpital Edouard Herriot, Lyon, France, [3]AP-HP, St Antoine Hospital, Paris, France, [4]University of Queensland, Brisbane, Australia, [5]Rheumazentrum Favoriten, Wien, Austria, [6]INSERM U606 Hôpital Lariboisière, Centre Viggo Petersen, Paris, France, [7]ASL3 Genovese, Genoa, Italy, [8]Centro Hospitalar de Lisboa Ocidental, Hospital Egas Moniz, Lisboa, Portugal, [9]University Hospital Virgen Macarena, Sevilla, Spain, [10]MRC Lifecourse Epidemiology Unit, Southampton, United Kingdom.

Background/Purpose: Strontium ranelate (SrRan) has demonstrated a structure-modifying activity with symptomatic improvement in patients with

knee osteoarthritis (OA). This analysis aimed to compare the proportion of patients in whom radiological OA progression was prevented between groups, considering different cut-offs of JSN.

Methods: SEKOIA study included patients with symptomatic primary knee OA (Kellgren and Lawrence [KL] grade 2 or 3, JSW:2.5–5 mm) randomly allocated to SrRan 1 or 2 g/day or placebo. Primary endpoint was JSW radiographic change over 3 years in the medial compartment. JSW was measured yearly with validated computer-assisted centralized reading method. Patients with no relevant radiological OA progression were defined as those with a JSW loss from baseline to End, lower than 0.1mm, 0.2 mm or 0.3 mm. Patients who withdrew from the study were counted as non-responder. Treatment groups were compared to placebo using a chi^2 test.

Results: ITT set included 1371 (82% of the randomized set) patients. Age was 63±7 years, BMI was 30±5 kg/m2, JSW was 3.5±0.8 mm. 61% were KL II. 69% were female. A significantly greater proportion of patients in SrRan1g and 2g groups had no radiological progression compared to placebo: 40.5% and 44.1% vs. 32.8% ($p=0.017$ and $p<0.01$) with the 0.3 mm threshold. It corresponds to a proportion of responders increased by 24% and 34% in the SrRan 1g and 2g groups compared to placebo, with a number of patients needed to be treated (NNT) of 13 and 9. Similar results were observed at additional JSN cut-offs:

	Strontium ranelate 1 g (N = 445)	Strontium ranelate 2 g (N = 454)	Placebo (N = 472)
Responders: JSN ≥ −0.1 mm			
Patients who responded, n (%)	130 (29.21)	136 (29.96)	101 (21.40)
p-value	**0.006**	**0.003**	
RRR	**36.0**	**40.0**	
NNT	13	12	
Responders: JSN ≥ −0.2 mm			
Patients who responded, n (%)	161 (36.18)	173 (38.11)	133 (28.18)
p-value	**0.009**	**0.001**	
RRR	**28.4**	**35.2**	
NNT	**13**	**10**	
Responders: JSN ≥ −0.3 mm			
Patients who responded, n (%)	180 (40.5)	200 (44.05)	155 (32.80)
p-value	**0.017**	**<0.001**	
RRR	**23.5**	**34.3**	
NNT	**13**	**9**	

Conclusion: Treatment with SrRan is associated with a significantly greater number of patients without OA radiological progression over 3 years.

Impact On Cartilage Volume Changes Over Time Of Conventional Treatment and Of Glucosamine and Chondroitin Sulfate In Knee Osteoarthritis Patients: Data From The Osteoarthritis Initiative Cohort. Johanne Martel-Pelletier[1], Camille Roubille[1], Jean-Pierre Raynauld[1], François Abram[2], Pierre Dodin[2], Marc Dorais[3], Philippe Delorme[1] and Jean-Pierre Pelletier[1]. [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [2]Imaging Research & Development, ArthroLab Inc., Montreal, QC, [3]StatSciences Inc., Notre-Dame de l'Île Perrot, QC.

Background/Purpose: To explore, using data from participants enrolled in the progression cohort of the Osteoarthritis Initiative (OAI), the effects of conventional knee osteoarthritis (OA) pharmacological treatment and those of the SySADOA glucosamine and chondroitin sulfate (Glu/CS) on disease structural changes.

Methods: Six hundred knee OA subjects were included in a 24-consecutive-month follow-up study with annual knee X-rays and magnetic resonance imaging (MRI) of the most symptomatic (greatest WOMAC pain) knee. Participants were further stratified based on whether or not they received OA conventional pharmacological treatment and/or Glu/CS. The main outcomes were the loss of joint space width (JSW) and the loss of cartilage volume measured by MRI using a newly developed fully-automated system.

Results: Three hundred participants reported taking (+) (n=300) or not (−) (n=300) OA treatment (analgesic/NSAIDs) for 24 months, with or without Glu/CS. The +analgesic/NSAIDs subjects showed higher WOMAC scores ($p<0.0001$) and smaller JSW ($p=0.013$), reflecting a more severe disease at baseline vs. the -analgesic/NSAIDs participants. In the -analgesic/NSAIDs group, a reduction in the cartilage volume loss at 24 months in the medial central plateau ($p=0.007$ univariate and $p=0.03$ multivariate analysis) was found in those taking Glu/CS. In the +analgesic/NSAIDs group, the subjects receiving Glu/CS demonstrated less cartilage volume loss in the plateau at 12 months ($p=0.05$) and in the central plateau at 24 months ($p=0.05$). In addition, in the +analgesic/NSAIDs group, participants taking Glu/CS and having a JSW at baseline greater than the median (less severe disease) had less cartilage volume loss at both 12 and 24 months in the lateral plateau ($p=0.02$ and 0.03, respectively). By contrast, in all groups, no significant reduction in JSW over time was found.

Conclusion: In both the +analgesic/NSAIDs and -analgesic/NSAIDs groups, participants who received Glu/CS had reduced cartilage volume loss over 24 months mainly on the plateau when assessed with qMRI, arguing for a targeted DMOAD effect of Glu/CS, which could not be identified by X-ray alone.

2146

Effects Of Chondroitin Sulfate On Brain Response To Painful Stimulation In Knee Osteoarthritis Patients: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial. Jordi Monfort[1], Jesús Pujol[1], O Contreras-Rodriguez[1], Jone Llorente-Onaindia[1], M López-Solà[1], Laura Blanco-Hinojo[1], J Deus[1], H Ortiz[1], Francisco Montañés[1], M Campillo[1], Pere Benito[1], Laura Sánchez[2], Marta Herrero[2] and Josep Vergés[3]. [1]Hospital del Mar, Barcelona, Spain, [2]Bioiberica, Barcelona, Spain, [3]Pre-Clinical and Clinical R&D Area, Pharmascience Division, BIOIBERICA S.A., Barcelona, Spain.

Background/Purpose: Knee osteoarthritis (OA) is a degenerative joint disease causing symptoms in 12% of people over the age of 65. A variety of treatments have been tested to alleviate knee OA symptoms, most being focused on reducing pain through analgesic or anti-inflammatory actions. Clinical studies have reported a beneficial effect of pharmaceutical-grade chondroitin sulfate (CS) on knee pain, and a parallel reduction in the rate of decline in joint space width. Nevertheless, not all clinical trials have been successful and reports exist suggesting that CS is not equally effective in all clinical situations (Clegg 2006). Inherent problems with efficacy assessment of pain medication are the lack of objective pain measurements and the large variability of subjective pain ratings. The aim of the present fMRI study was to objectively identify the effects of CS treatment on the brain response to pressure painful stimulation in patients with symptomatic knee osteoarthritis.

Methods: Phase IV, randomized, double-blind clinical trial in which patients received CS (pharmaceutical-grade manufactured by Bioibérica) 800 mg/day or placebo for a 4-month treatment course. Patients were assessed at baseline and after four-month of treatment. Two fMRI tests were conducted in each session by applying painful pressure on the knee medial interline (pain sensitive maneuver) and on the patella surface (cartilage selective targeting). The main outcome measurement was attenuation of the response evoked by knee painful stimulation in the pain-processing brain system.

Results: Twenty-two evaluable patients received CS and 27 placebo. No effects of CS were detected using the knee interline pressure test. Patients receiving CS showed a tendency to report reduced subjective pain after treatment during patella pressure test ($p=0.077$), but no significant group by session interaction was demonstrated. fMRI of patella pain, showed a larger activation reduction in the CS group than in placebo in a

posterior mesencephalon region including the periaqueductal gray (PAG). The entire PAG cluster (238 voxels) with significant interaction showed a pre>post-treatment difference at $p<0.05$ (peak difference at $x=-10$, $y=-34$, $z=-16$; $t=2.4$, $p=0.007$). In this paired analysis, the CS group showed significant activation reduction in the primary somatosensory cortex (including the cortical representation of the leg) and extending to the primary motor cortex and posterior supplementary motor area. Group by session interaction consistently revealed a tendency for this cortical change to be larger in the CS than in placebo (peak interaction $x=2$, $y=-6$, $z=72$; $t=2.96$, $p=0.002$ and 43 voxels -subthreshold- with $p<0.01$).

Conclusion: fMRI was sensitive to objectify CS effects on brain response to knee painful stimulation. The current work yields further support to the utility of fMRI to objectify treatment effects on OA pain. The positive treatment effect of CS on brain was identified on pain elicited by pressure on patellofemoral cartilage, where the cartilage component of pain is a relevant factor. This result is consistent with the known CS mechanisms of action and the results obtained in previous clinical trials.

Effect Of Fish Oil On Structural Progression In Knee Osteoarthritis: A Two Year Randomized, Double-Blind Clinical Trial Comparing High Dose With Low Dose. Catherine L. Hill[1], Graeme Jones[2], Susan Lester[3], Ruth Battersby[1], Tanya Fedorova[4], Kristen Hynes[5], Susanna Proudman[6], Leslie G. Cleland[6] and Lyn March[7]. [1]The Queen Elizabeth Hospital, Woodville, Australia, [2]Menzies Research Institute Tasmania, University of Tasmania, Hobart, 7000, Australia, [3]Queen Elizabeth Hospital, Woodville South, Australia, [4]University of Sydney, St Leonards, Australia, [5]University of Tasmania, Hobart, Australia, [6]Royal Adelaide Hospital, Adelaide, Australia, [7]University of Sydney Institute of Bone and Joint Research, Royal North Shore Hospital, St Leonards, Australia.

Background/Purpose: Fish oil is widely used for the symptomatic treatment of osteoarthritis. However, its effect on cartilage volume has not previously been investigated in an RCT. The objective of this study was to determine whether high dose fish oil is superior to low dose fish oil in retarding structural progression of symptomatic knee osteoarthritis.

Methods: Investigator initiated, government funded, randomized, double-blind, multicenter 24 month trial. Patients older than 40 years, with knee OA as defined by the ACR clinical criteria, suffering from regular knee pain were randomized 1:1 to (1) high dose fish oil liquid (EPA 18% and DHA 12%) 15mL/day or (2) low dose fish oil (blend of fish oil and sunola oil in a ratio of 1:9) 15mL/day. Each oil was also flavored with citrus to provide a comparable taste and ensure masking. Prior to randomization, a 4- week run in period with a similar oil was performed to exclude patients who were intolerant to liquid fish oil. Baseline knee radiographs were scored according to OARSI atlas. The co-primary end point was change in cartilage volume (medial tibial, lateral tibial, patellotibial) from baseline to 24 months. The co-primary endpoint of WOMAC pain score has previously been reported. Analysis of paired MRI data was performed, according to intention-to-treat and per-protocol analysis.

Results: Participants ($N=202$) were 49% female, mean age 60.9 yrs (SE 0.7), mean BMI 29.0 (SE 4.7). There was significantly greater and earlier dropout in the high dose group (34.6%, median 3 months), compared to the low dose group (19.8%, median 7.5 months). Participants from one site were excluded ($n=51$) due to technical MRI issue with baseline MRI data and a further 35 participants were excluded due to lack of paired MRI data. There was similar baseline characteristics in each group, except for gender (low dose group 38% female, high dose 58% female, $p=0.025$). The OARSI joint space narrowing and osteophyte scores were not different between groups. In intention to treat analysis ($n=116$), both groups demonstrated preservation or a slight increase in cartilage volume in each compartment over time with no significant difference seen between the two groups (Table 1). Similarly, per protocol analysis ($n=99$) demonstrated no decrease over time or difference between groups. There was no difference in results when males and females were analyzed separately.

Table 1.

		CHANGE FROM BASELINE (ITT)			Delta-Delta[1]		
MRI	Group	mean	sd	$p\text{-val}_{change}$	mean	sd	$p\text{-value}_{H\ vs\ L\ change}$
Lateral tibial	LowDose	0.015	0.027	0.58	0.000	0.038	1.00
	High Dose	0.015	0.026	0.57			
Medial tibial	LowDose	0.015	0.029	0.60	0.020	0.040	0.63
	High Dose	0.035	0.028	0.63			
Patellotibial	LowDose	0.027	0.040	0.50	0.030	0.055	0.59
	High Dose	0.003	0.039	0.94			

Conclusion: High dose fish oil supplementation for 2 years was not significantly different in its effect on cartilage volume in patients with symptomatic knee OA, when compared to low dose fish oil. The lack of a decrease in both groups is unexpected and may imply that both therapies have chondroprotective properties.

Disclosure: C. L. Hill, None; **G. Jones**, None; **S. Lester**, None; **R. Battersby**, None; **T. Fedorova**, None; **K. Hynes**, None; **S. Proudman**, None; **L. G. Cleland**, None; **L. March**, None.

2148

Use Of Low Dose Aspirin Is Associated With Reduced Medial Tibial Cartilage Loss In Symptomatic Osteoarthritis: DATA From A Cohort Study. Anita Wluka[1], Changhai Ding[2], Yuanyuan Wang[1], Graeme Jones[3], Andrew Teichtahl[1] and Flavia Cicuttini[4]. [1]Monash University, Melbourne, Australia, [2]Menzies Research Institute Tasmania, University of Tasmania, Hobart, 7000, Australia, [3]Menzies Research Institute, Tasmania, Australia, [4]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3004, Australia.

Background/Purpose: Inflammation and vascular disease have recently been shown to play a role in the pathogenesis of osteoarthritis (OA). Low dose aspirin is commonly used in the prevention of cardiovascular disease. Its effects have been attributed to a variety of actions, including anti-inflammatory effects and effects on platelet function (both anti-thrombotic and anti-inflammatory) and lipids. However whether it affects human joints has not been studied. The aim of this study was to examine whether the use of low dose aspirin affects change in knee cartilage volume over 2 years.

Methods: 117 people with symptomatic knee OA underwent magnetic resonance imasging of the knee at baseline and 2 years later. Medial and lateral tibial cartilage volumes were measured using validated methods. Annual absolute change and annual percentage change in cartilage volume were calculated. Information about regular low dose aspirin use was collected at baseline, 6, 12 and 24 months. Participants who reported taking regular low dose aspirin (< 150 mg per day) at more than 1 time point were defined as being aspirin users.

Results: Twenty six participants reported taking aspirin at more than one visit, with 91 not taking aspirin. At baseline, the only significant difference between the 2 groups was that those taking aspirin were older than those who did not ($p = 0.03$). In those taking aspirin, annual change in medial tibial cartilage volume and annual percentage change in cartilage volume was approximately half that seen in those not taking aspirin (−50 vs. −102 mm 3 and −2.5% vs. −5.5%, respectively, $P=0.04$ for both). These differences became more significant after adjusting for age, gender, body mass index, initial cartilage volume and severity of radiographic change in the medial compartment. The annual change in medial tibial cartilage volume was −40 mm 3 (95% confidence interval (CI) −83, 1.3) in aspirin users vs. −105 mm3 (95% CI −127, −82) in nonaspirin users ($P = 0.009$ for difference). The annual percentage change in medial tibial cartilage volume was −2.0% (95% CI −4.6, 0.53) in aspirin users vs. −5.6% (95% CI −6.9, −4.0) in non-aspirin users ($P=0.02$ for difference). There were no significant differences observed in change in lateral tibial cartilage volume.

Conclusion: This study showed that in people with knee OA, the use of low dose aspirin was associated with reduced medial tibial cartilage loss over 2 years. This requires confirmation in a randomised controlled trial. If this hypothesis were proven, aspirin may provide a cost effective disease modifying therapy for OA as it is a cheap medication that is already in common use and known to be well tolerated.

Safety Of Lower-Dose Diclofenac Submicron Particle Capsules Dosed Up To 12 Weeks In Patients With Osteoarthritis. Clarence Young[1] and Marc C. Hochberg[2]. [1]Iroko Pharmaceuticals, Philadelphia, PA, [2]University of Maryland, Baltimore, MD.

Background/Purpose: Osteoarthritis (OA) is the most common cause of disability in the US and is frequently managed with non-steroidal anti-inflammatory drugs (NSAIDs). NSAIDs, including diclofenac, are associated with dose-related gastrointestinal, cardiovascular, and renal adverse events (AEs). As a result, the US Food and Drug Administration issued a Public Health Advisory encouraging physicians to prescribe NSAIDs at "the lowest effective dose for the shortest duration consistent with individual patient treatment goals." The efficacy of new, submicron particle NSAIDs is under investigation. These drugs have enhanced absorption and may be efficacious at lower doses than commercially available NSAIDs. We report phase 3 safety data in patients with OA pain dosed up to 12 weeks with diclofenac submicron particle capsules.

Methods: This randomized, multicenter, double-blind, parallel-group study enrolled 305 patients 41 to 90 years of age with OA of the hip or knee, which was documented radiologically (Kellgren-Lawrence grade II–III). Enrolled patients were chronic NSAID and/or acetaminophen users with a WOMAC pain subscore ≥40 mm/100-mm at baseline and a documented OA pain "flare" (increase in WOMAC pain subscale ≥15 mm) following NSAID discontinuation. Patients received either diclofenac submicron particle capsules 35 mg TID or BID, or placebo. The primary endpoint was mean change from baseline in WOMAC pain subscore at week 12. Safety and tolerability were also assessed.

Results: Most patients were female (203/305, 66.6%) with an age (mean ± SD) of 61.6 ± 8.9 years. Diclofenac submicron particle capsules 35 mg TID provided significantly better pain relief than placebo (P = 0.0024) with numerical evidence of pain relief in the diclofenac submicron particle capsules 35 mg BID treatment group, although this did not achieve statistical significance (P = 0.0795). The most frequent AEs (>3% in any treatment group) were generally similar across treatment groups (**Table**). Serious AEs occurred in 3.0% (9/305) of patients and were generally comparable across treatment groups. No serious gastrointestinal bleeds or cardiovascular or renal AEs occurred in any treatment group. The most frequent AEs in patients who withdrew from the study (≥1% in any treatment group) included diarrhea (3/305, 1.0%), upper abdominal pain (3/305, 1.0%), and alanine aminotransferase elevation (3/305, 1.0%). There was no difference across treatment groups for withdrawals due to AEs.

Adverse Event	Diclofenac Submicron 35 mg TID (n = 98) n (%)	Diclofenac Submicron 35 mg BID (n = 104) n (%)	Placebo (n = 103) n (%)
Nausea	9 (9.2)	5 (4.8)	2 (1.9)
Diarrhea	7 (7.1)	5 (4.8)	3 (2.9)
Headache	6 (6.1)	2 (1.9)	3 (2.9)
Constipation	4 (4.1)	3 (2.9)	4 (3.9)
URI	3 (3.1)	3 (2.9)	6 (5.8)
Upper abdominal pain	3 (3.1)	3 (2.9)	1 (1.0)
Nasopharyngitis	1 (1.0)	5 (4.8)	5 (4.9)
Sinusitis	3 (3.1)	2 (1.9)	1 (1.0)
Serum creatinine elevation	3 (3.1)	1 (1.0)	0 (0.0)
Dyspepsia	3 (3.1)	1 (1.0)	1 (1.0)
ALT elevation	3 (3.1)	1 (1.0)	0 (0.0)
UTI	2 (2.0)	0 (0.0)	4 (3.9)

TID = three times daily; BID = twice daily; URI = upper respiratory tract infection ALT = alanine aminotransferase; UTI = urinary tract infection.

Conclusion: Investigational, lower-dose diclofenac submicron particle capsules were generally well-tolerated in a phase 3 study of patients with OA. No serious gastrointestinal bleeds or cardiovascular or renal AEs occurred over 12 weeks of treatment.

Comparative Effectiveness Of Pharmacological Interventions For Knee Osteoarthritis: A Network Meta-Analysis. Raveendhara R. Bannuru[1], Timothy E. McAlindon[1], John B. Wong[1], David Kent[1] and Christopher Schmid[2]. [1]Tufts Medical Center, Boston, MA, [2]Brown University, Providence, RI.

Background/Purpose: With the rapidly aging US population and obesity epidemic, the prevalence of knee osteoarthritis (OA) is increasing exponentially. Although a wide variety of symptomatic interventions are available, head to head comparisons are limited, and no study compares all of the treatment options against each other.

To date, we have relied on traditional meta-analysis, which only provides the relative merits of options compared directly in randomized controlled trials (RCTs) for a given condition. Network meta-analysis—an innovative approach for comparing multiple interventions in a single analysis- combines direct (head to head) and indirect (through a common comparator) evidence to increase power and precision for the effect estimates and also assigns probabilities of superiority. This approach can determine the relative comparative effectiveness of interventions that have never been compared directly in a single trial.

Methods: We searched Medline, EMBASE, Web of Science and Cochrane Database from inception to April 2013 with no language restrictions and actively sought unpublished data. We included RCTs conducted in adults with knee OA comparing two or more of the following most widely prescribed treatments: acetaminophen, non-selective NSAIDs (diclofenac, ibuprofen, naproxen), Cox-2 selective NSAIDs (celecoxib), intra-articular (IA) corticosteroids, IA hyaluronic acid, oral placebo and IA placebo. We calculated effect sizes for pain and function for each study at 12 weeks from baseline. We performed network meta-analysis using a Bayesian random effects model with non-informative priors.

Results: Of the 127 eligible RCTs, 124 reported pain and 72 reported function outcomes. These trials included 29,842 participants with an age range of 45–75 years (Figure 1). The proportion of women ranged from 28%–100%. For pain, all treatments were better than oral placebo and all were better significantly except for IA placebo (Figure 2). For function, oral treatments had effect sizes similar to pain, but IA treatments had a smaller effect size though comparable to oral treatments.

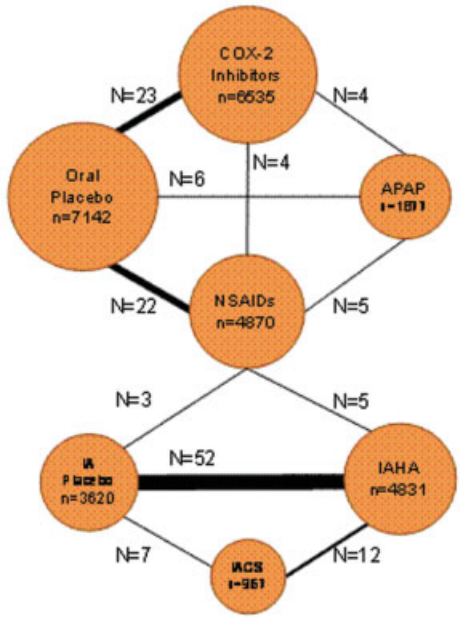

Figure 1. Network of Treatment Comparisons for Pain

Circle size reflects n of participants and the line width reflects N of direct comparisons. No connecting line between two circles indicates that there was no direct comparison between the two treatments. *APAP*=Acetaminophen; *IA*=Intra-articular; *IAHA*=Intra-articular hyaluronic acid; *IAGS*=Intra-articular Corticosteroids

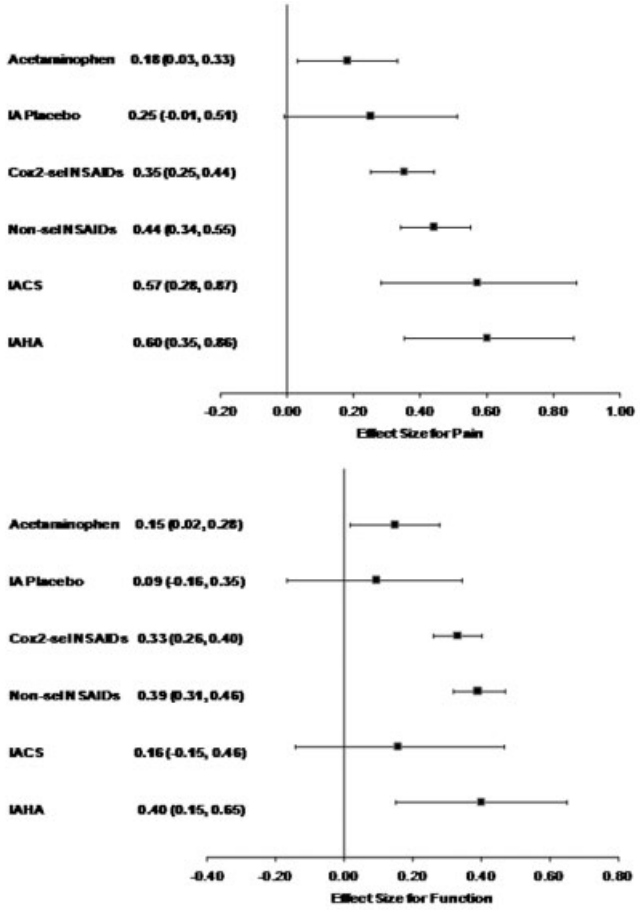

Figure 2. Treatment Effects Relative to Oral Placebo for Pain and Function

Positive effect size favors treatment over oral placebo; IA=Intra-articular; IAC=Intra-articular corticosteroids; IAHA=Intra-articular hyaluronic acid

Conclusion: For knee OA pain, IA treatments were more efficacious than oral treatments may be because of the integrated IA placebo effect. Both cox-2 selective and non-selective NSAIDs were substantially better than acetaminophen. This information along with the safety profile and relative cost would be helpful for clinicians in choosing care tailored to individual patient. This novel method may be of additional value for the treatment guideline groups, who would like to weigh multiple interventions against a common comparison.

Synergistic Effect of Combining BioniCare® in an Unloading Brace for Osteoarthritis of the Knee. Thomas Zizic[1], David S. Hungerford[2], Edmund J. MacLaughlin[3], Craig Mines[4], Shaili Deveshwar[5], Theresa Lawrence Ford[6], Cynthia Elliott[6], John R. Principe[7], Jack S. Tuber[8] and Joy Schechtman[9]. [1]The Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]The Johns Hopkins University School of Medicine, Cambridge, MD, [4]East Side OrthoCare, Snellville, GA, [5]Sports Medicine and Orthopedic Center, Greensboro, NC, [6]North Georgia Rheumatology, Lawrenceville, GA, [7]WellBeingMD, Palos Heights, IL, [8]The Johns Hopkins University, Baltimore, Maryland, Baltimore, MD, [9]SunValley Arthritis Center, Peoria, AZ.

Background/Purpose: The purpose of this study was to see if incorporating the BioniCare device into an unloading brace would produce more rapid improvement, greater compliance and therefore greater effectiveness

Methods: 289 patients who were treated with BioniCare alone served as historical controls and were compared with 225 patients treated with BioniCare combined with VQ's OActive unloading brace. A generalized linear model repeated measures analysis of change from baseline was performed, with sex, age, treatment (BioniCare in knee OActive unloading brace versus BioniCare alone), cumulative device use at each month of follow-up (1, 3, 6 and 12 months), and baseline score as predictors of the model.

Results: It was demonstrated that BioniCare combined with the OActive unloading brace was superior to BioniCare alone. Except for Sleep Pain, and Physicians Global Assessment which trended toward statistical significance, there was statistically significant superiority of BioniCare treatment combined with an unloading brace as compared to BioniCare alone. (Table I) With the exception of the one month evaluation of pain while sleeping at night, all seven outcome measures were superior with BioniCare combined in the OActive unloading brace as compared to BioniCare alone at 1,3,6 and 12 months of treatment. After three months of treatment both groups had a moderate effect size in all outcome parameters. As can be seen in the illustrative figures, the patient global assessment, patient pain on walking up and down stairs, and the physician global assessment had a large effect size (>1.0) at one year in the BioniCare combined with the unloading brace group. (Figures 1, 2) In the combined group, the effect size approached 1.0 with pain on walking on a flat surface (figure 2).

Efficacy End-point	Estimate Treatment Difference	Std Err	Chi-Square Test	p-value
48 hr. OA Pain	0.2060	0.0527	15.28	<.0001
MD Global Assessment	0.0927	0.0532	3.04	0.0814
OA Pain	0.1864	0.0516	13.07	0.0003
PT Global Assessment	0.2066	0.0543	14.48	0.0001
Sleep Pain	0.0295	0.0553	0.29	0.5933
Up/Down Stairs	0.2684	0.0582	21.29	<.0001
Walking Pain	0.2119	0.0536	15.65	<.0001

NOTE: Treatment effect as estimated from a generalized linear model of repeated measures

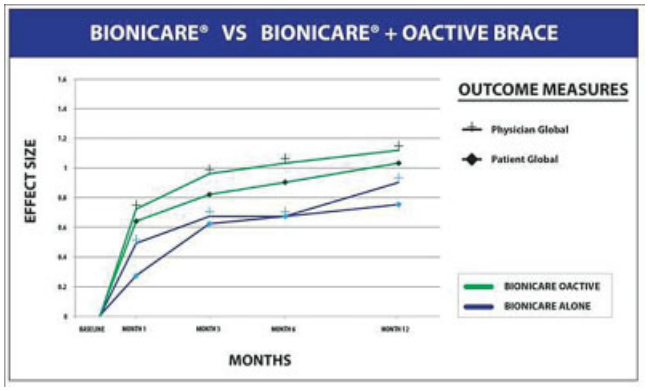

Fig. 1. Change From Baseline Time Physician and Patient Global

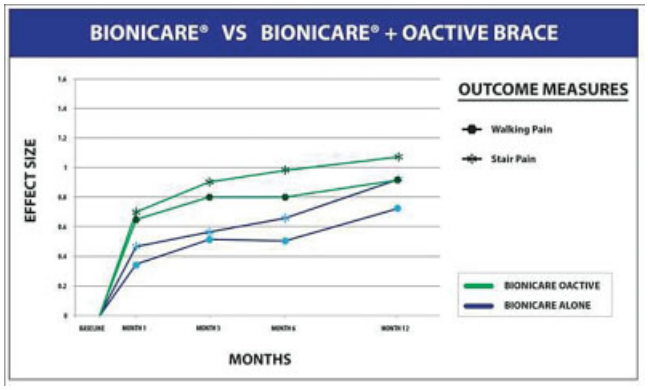

Fig. 2. Change From Baseline Time Walking Pain and Stair Pain

Conclusion: There is an additive benefit of combining an unloading brace with BioniCare device treatment and the advantage of this combination continued throughout the study and was apparent even after one year of treatment.

Predicting Benefit From Lateral Wedge Orthotics Using Radiographic Parameters In Medial Knee Osteoarthritis. Berna Goker[1], Roy H. Lidtke[2], Laura E. Thorp[2], Markus A. Wimmer[2] and Joel A. Block[2]. [1]Gazi University, Ankara, Turkey, [2]Rush University Medical Center, Chicago, IL.

Background/Purpose: Lateral wedge foot orthosis have been used therapeutically in patients with medial knee osteoarthritis (OA) with inconsistent results. The current theory suggests they reduce medial knee loading by shifting the ground reaction force vector, and thereby potentially modify progression of OA. Predicting a beneficial result from usage of lateral wedge orthotics is crucial since results to-date suggest that responses in large groups of subjects are heterogeneous. We aimed to investigate radiographic parameters in patients with medial knee OA that might prospectively distinguish those who benefit from lateral wedge from those who do not.

Methods: Participants (n=109) with radiographic (KL grades 2–3) and symptomatic (at least 30mm pain of 100 mm scale while walking) medial compartment knee OA were enrolled in a previously reported 36 month double blind study to clinically assess a 7 degree lateral wedge custom foot orthosis versus a neutral 0 degree posted control. In the current study, 35 patients in the lateral wedge arm who had complete data were included. Subjects underwent gait analyses. Post hoc analysis identified a group as 'unloaders' if knee adduction moments gradually decreased over time with the use of wedge. Image J software (US NIH, Bethesta, MD, http://rsbweb.nih.gov/ij/) was used to measure radiographic parameters that included: knee alignment angle, tibial shaft angle measured at three levels: from tibial plateau to the tibial plafond (long axis), from mid tibial level to plafon and from lower third of tibia to plafond (lower axis), as well as the narrowest joint space widths of the hip, knee and ankle joints. The difference between the varus angle of tibial long axis and tibial lower axis was calculated for each patient to estimate the varus angulation of the distal 1/3 of the tibial shaft. Correlations of radiographic parameters were analyzed in the entire group. Non-parametric tests were used for statistical analysis to compare groups. A p value of ≤ 0.05 was considered significant.

Results: Twenty patients were classified as 'unloaders' while 15 were noted to be unresponsive to the therapy. These responsive unloaders had larger distal tibial varus angle compared to those who did not have significant reduction in knee adduction moments with lateral wedge (median(IQR) 1.3(0.8) vs. 0.6(1.5) degrees, respectively, p=0.042). None of the other radiographic parameters studied differed between those who benefitted from lateral wedge and those who did not. Importantly, assessment of the difference between the tibial long axis and the lower one third tibial axis (lower angle minus long axis) revealed a significant correlation with the knee alignment angle (r=0.26, p=0.01).

Conclusion: The correlation between the knee alignment angle and the difference between tibial long axis and lower one third tibial axis suggests that as the knee presents with more varus, there is a varus bend in the lower tibia. Specifically, curvature of the lower tibia appears to be the primary varus deformity seen in the lower extremity with medial knee OA. These results suggest that distal tibial varus could be a radiographic parameter predicting a beneficial result from a lateral wedge orthotic in patients with medial knee OA.

2153

Arrest Of Progressive Loss Of Vibratory Perception In Knee Osteoarthritis: Effects Of a 48 Week Biomechanical Intervention. Najia Shakoor, Roy H. Lidtke, Louis F. Fogg, Laura E. Thorp, Markus A. Wimmer, Rachel A. Mikolaitis and Joel A. Block. Rush University Medical Center, Chicago, IL.

Background/Purpose: Somatosensory function has been shown to be altered in knee osteoarthritis (OA); for example, we previously observed that in knee OA there are generalized deficits of vibratory perception in the upper and the lower extremity compared to age-matched controls, though it remains unclear whether these deficits worsen during the course of OA. Biomechanical interventions that reduce dynamic loading during gait are promising strategies that may improve pain and retard disease progression, though their relationship to somatosensory function is unknown. Here, we present data from a double-blind randomized controlled study of a flexible shoe ("mobility" shoe), which has previously been shown to reduce medial compartment knee loading, on the progression of vibratory deficits in participants with knee OA.

Methods: Participants were enrolled in a randomized controlled study of a flexible-soled shoe ("mobility" shoe) vs an identical appearing "control" shoe with stiffer sole. This was a 6-month primary study and participants had the opportunity to continue for an additional 18 months. Here we evaluate the interim 48 week data. All participants had radiographic (KL grades ≥ 2) and symptomatic (at least 30/100 mm on VAS) medial compartment knee OA. In those with bilateral OA, the most symptomatic side was considered the "affected" side. Investigators and participants were blinded to shoe assignment. Vibratory perception threshold (VPT) was measured using a biothesiometer that provided vibratory stimulation at multiple predetermined anatomic sites, including an upper extremity site. VPT was recorded as the first sensation of vibration (volts).

Results: 50 participants were randomized, 22 to the active "mobility" shoe and 28 to the control group. 24 participants continued with the study extension, 11 in the "mobility" group (7 female, mean age 59±4 years) and 13 in the control group (10 female, mean age 52±9 years). Changes in VPT at the various sites are summarized in Table 1. VPT worsened significantly over 48 weeks at each site in the control group except the medial ankle, but there were no significant changes in the mobility group. Changes in VPT were not correlated with baseline age or with pain improvement.

	Mobility group				Control group			
	Baseline VPT (volts)	48 week VPT (volts)	Effect size	p value for difference	Baseline VPT (volts)	48 week VPT (volts)	Effect size	p value for difference
1st MTP	15.1±10.0	15.4±7.9	−0.03	0.91	11.2±5.7	13.4±6.1	−0.73	0.02
Medial ankle	18.6±8.2	18.1±5.0	0.07	0.81	15.7±6.9	17.0±6.9	−0.21	0.45
Lateral ankle	19.6±11.0	16.6±4.0	0.29	0.36	14.3±6.3	17±6.2	−0.59	0.05
Medial knee	18.1±8.8	17.5±5.7	0.07	0.81	15.4±7.3	19.0±10.1	−0.73	0.02
Lateral knee	17.2±6.0	18.5±6.5	−0.21	0.50	15.6±7.1	19.8±8.8	−0.60	0.05
Tibial tuberosity	15.8±5.3	17.3±6.6	−0.26	0.40	13.3±4.8	16.2±4.7	−0.65	0.03
Radial styloid	9.0±1.4	9.3±2.0	−0.14	0.64	7.1±2.3	8.2±1.8	−0.69	0.03

Conclusion: Lower extremity OA is known to be associated with altered somatosensory function, including vibratory perception deficits. Here we demonstrate that in knee OA, vibratory perception worsens significantly over time. In addition, alteration in footwear with sustained mechanical unloading during gait appears to arrest that progression of vibratory loss both in the affected lower extremity as well as in the upper extremity in such patients. The clinical significance and relationship of these findings to OA disease progression need better elucidation in future studies.

2154

Improvement In Clinical Symptoms After 48 Weeks Of Wearing Flexible Footwear In Osteoarthritis Of Knee: A Randomized Placebo-Controlled Study. Najia Shakoor, Roy H. Lidtke, Louis F. Fogg, Laura E. Thorp, Markus A. Wimmer, Rachel A. Mikolaitis and Joel A. Block. Rush University Medical Center, Chicago, IL.

Background/Purpose: Osteoarthritis (OA), the most common form of arthritis, is a major cause of pain and disability. Biomechanical interventions that reduce dynamic loading are a promising strategy to improve pain and retard disease progression, though prior studies in OA have not shown dramatic efficacy. In addition, the large placebo effect inherent in studies of OA pain make it difficult to prove clinical efficacy in short studies. Here, we present data from a double-blind randomized controlled study of a flexible shoe ("mobility" shoe), which has previously been shown to reduce medial compartment knee loading, on self-reported clinical outcomes over 48 weeks.

Methods: Participants were enrolled in a 6-month randomized controlled study of a flexible soled shoe (mobility shoe) vs identical appearing control shoe with stiffer sole. Participants had the opportunity to continue the study for an additional 18 months. Here, we evaluate the interim 48 week data. All participants had radiographic (KL grades ≥ 2) and symptomatic (at least 30/100 mm pain on VAS) medial compartment knee OA. Investigators and participants were blinded to shoe assignment. Baseline and follow up clinical symptoms were evaluated using WOMAC visual analog scales and modified KOOS questionnaires. Data were evaluated to determine "responders" according to modified OMERACT-OARSI responder criteria, with Chi-squared analysis to evaluate the difference in number of responders. Independent samples t-test was used to evaluate differences in percent improvement in WOMAC and KOOS subscales between the groups.

Results: 50 participants were enrolled in the randomized controlled trial, 22 to the active "mobility" shoe and 28 to the control group. 24 participants continued with the study extension, 11 in the "mobility" group (7 female, mean age 59±4 years) and 13 in the control group (10 female, mean age 52±9 years). Changes in pain and symptoms over 48 weeks are detailed in the Table. Overall, there were greater improvements in pain, function and quality of life measures in the active mobility group vs control group. Changes in pain were not correlated with age. In addition, using OMERACT-OARSI response criteria, the mobility group had significantly more responders (10 out of 11) than the control group (6 out of 13), (Chi squared= 5.37, df=1, p=0.023). Thus, participants who wore the flexible shoe were 1.98 times more likely to show clinical improvement than those in the control.

Table.

	Improvement in mobility group (%±SD)	Improvement in control group (%±SD)	p value for difference between groups
WOMAC pain	73±26	37±57	0.06
WOMAC function	70±40	40±70	0.22
WOMAC stiffness	73±30	41±44	0.05
KOOS symptoms	13±21	4±19	0.05
KOOS pain	39±56	6±35	0.10
KOOS quality of life	42±66	11±37	0.02
KOOS sports and recreation	67±200	29±33	0.55

Conclusion: These data demonstrate significant clinical improvements in the active group, assigned to flexible footwear, compared to a non-flexible footwear control group, including a higher percentage of OMERACT-OARSI responders and greater percent improvements in self-reported clinical outcomes measures in the active group. Notwithstanding the small numbers, these results suggest optimism for the long term efficacy of biomechanical interventions for knee OA.

Beneficial Effect Of Long-Term Use Of a Low-Cost Minimalist Footwear On Joint Load, Clinical, and Functional Aspects Of Elderly Women With Knee Osteoarthritis. Francis Trombini-Souza[1], Alessandra Matias[1], Mariane Yokota[1], Marco Butugan[1], Ivye Pereira[1], Claudia Goldenstein-Schainberg[2], Ricardo Fuller[3] and Isabel C.N. Sacco[1]. [1]School of Medicine, University of São Paulo, São Paulo, Brazil, [2]Reumatologia, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [3]University of Sao Paulo, São Paulo, Brazil.

Background/Purpose: Positive outcomes of minimalist shoes on reduction of overload in patients with knee osteoarthritis (OA) have been highlighted. We have recently shown beneficial effects of acute use of a low-cost minimalist flat, flexible and non-heeled footwear in aged women with knee OA. Based on the chronic aspect of the disease, we now aim to investigate the long-term effects of this same footwear on gait biomechanics, clinical, and functional features of elderly women affected by knee OA.

Methods: Twenty-eight elderly women with grade 2 or 3 Kellgren and Lawrence knee OA were randomized and allocated to either intervention group (IG, n=16) which wore this minimalist shoe (Moleca) for 6 months for at least 6 hours daily, or to control group (CG, n=12) which did not wear these nor similar shoes. Physical therapy treatment was not allowed throughout the study. A diary was used to record the amount of daily use of the footwear intervention and paracetamol intake; every 2 weeks, adherence to treatment was verified through phone calls. All patients were assessed at baseline, 3th and 6th month by a physician and a physiotherapist, both blinded to group allocation. Primary outcome was pain WOMAC score and secondary ones were global WOMAC; joint stiffness and disability WOMAC scores; amount of paracetamol rescue medication intake over 6 months; knee adduction moment (KAM) during gait; knee edema and joint effusion. Multiple imputation methods and intention-to-treat analysis were performed. Treatment-time interactions were detected by general linear models of analysis of variance for repeated measure. Statistical significance is based at $\alpha = 5\%$.

Results: Interaction effect was observed for WOMAC pain (p=.007), function (p=.035) and WOMAC total score (p=.012). The percentage changes are in table 1. IG experienced a reduction by 18% (p=.043) in first peak KAM, 39% (p=.025) in KAM during midstance phase, and 29% (p=.041) in KAM impulse compared with CG at the end of intervention. Paracetamol intake was lower IG vs. CG at 4th (p=.004), 5th (p=.006) and 6thmonths (p=.012). Clinical aspects as knee edema and effusion did not present any difference in both IG and GC at the end of intervention.

Table 1. Percentage of change in the 3rd and in the 6th month by both groups in the WOMAC scores.

Variable	Group	6thmonth	
WOMAC Pain (% reduction)	*Intervention*	47%	60%
	Control	32%	16% *(n. s.)*
WOMAC Function (% improvement)	*Intervention*	45%	51%
	Control	25%	14% *(n. s.)*
WOMAC Total (% improvement)	*Intervention*	46%	52%
	Control	24%	15% *(n. s.)*

Conclusion: Long-term use of this flat, flexible and non-heeled shoe proved to be beneficial in elderly women with knee OA and thus can be prescribed as a low-cost non-invasive treatment capable to decrease pain and knee overload, and to improve overall function.

Weight Change Has A Disease Modifying Effect On Knee Structure and Symptoms In Obese Individuals Without Diagnosed Knee Osteoarthritis. Andrew Teichtahl[1], Anita Wluka[1], Stephanie Tanamas[1], Yuanyuan Wang[1], Boyd Strauss[1], Joseph Proietto[2], John Dixon[3], Graeme Jones[4], Andrew Forbes[1] and Flavia Cicuttini[5]. [1]Monash University, Melbourne, Australia, [2]University of Melbourne, Melbourne, Australia, [3]Baker Institute, Melbourne, Australia, [4]Menzies Research Institute, Tasmania, Australia, [5]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3004, Australia.

Background/Purpose: Although the strongest modifiable risk factor for the development of knee osteoarthritis (OA) is obesity, there are a paucity of data examining the effects of weight change on knee joint structures and symptoms. This study examined the effect of weight change on change in knee cartilage volume and symptoms in an obese cohort.

Methods: 112 obese subjects (BMI ≥ 30 kg m^{-2}), unselected for any musculoskeletal disease, were recruited from various community sources to examine the effect of obesity on musculoskeletal health. Tibial cartilage volume, determined by magnetic resonance imaging, and knee symptoms, determined by the Western Ontario and McMaster Osteoarthritis Index (WOMAC), were collected at baseline and an average of 2.3 years later.

Results: Percentage weight change was associated with change in medial tibial cartilage volume (β −1.3mm^3, 95% CI −2.4 to −0.1 mm^3, p = 0.03) that was consistent throughout the spectrum of weight loss through to mild weight gain. Percentage weight change was not associated with change in the lateral tibial (p = 0.93) or patella (p = 0.32) cartilage volumes. Percentage weight change was associated with change in all WOMAC sub-scales (all p ≤ 0.01): pain (β −1.8mm, 95% CI −3.2 to −0.4mm), stiffness (β −1.6mm, 95% CI −2.5 to −0.7mm) and function (β −6.9mm, 95% CI −11.6 to −2.1mm).

Conclusion: The linearity of effect implies that weight loss reduces medial cartilage volume loss and improved knee symptoms, and weight gain increases medial cartilage volume loss and worsens knee symptoms. These results suggest that in obese people, even small amounts of weight change have a disease modifying effect on both knee joint structure and symptoms. While weight loss is an important primary management strategy in obese individuals, avoidance of further weight gain should also be a clinical goal.

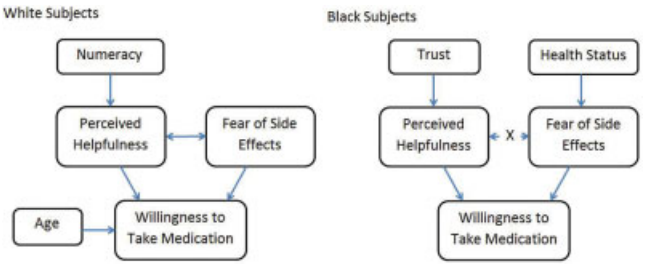
2157

Understanding Differences Between Black and White Patients' Reactions to New Treatment. Liana Fraenkel[1], Richard L. Street Jr.[2] and Ellen Peters[3]. [1]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT, [2]Texas A&M University, College Station, TX, [3]Ohio State University, Columbus, OH.

Background/Purpose: Numerous studies have found that Black patients are more risk averse than their White counterparts. In clinical practice, patients make judgments based on oral information provided to them by their physicians; yet most studies have examined patients' perceptions using written information. The objective of this study was to examine the factors underlying Black and White patients' treatment preference after hearing about a new medication described to them orally by a physician.

Methods: Subjects with a connective tissue disease, recruited from University-affiliated rheumatology practices, listened to a professionally-recorded standardized description of a medication. Prior to hearing the description, demographic and clinical characteristics (by self-report), trust in physicians and subjective numeracy (using validated scales) were ascertained. Helpfulness of the proposed treatment, fear about the side effects, and willingness to take the medication were measured using 7-point numeric rating scales. Kendall Tau b correlation coefficients between subjects' characteristics and their perceptions related to the medication are reported.

Results: We interviewed 284 subjects: 71 Black [mean (SD) age = 50.4 (13.5); 83% female] and 213 White [mean (SD) age 57.4 (14.7); 73% female]. Increased helpfulness and less fear of side effects were associated with increased willingness to take the medication among Black ($r = 0.60$, $p<0.0001$ and $r = -0.22$, $p=0.02$, respectively) and White subjects ($r = 0.49$, $p<.0001$ and $r = -0.36$, $p<.0001$, respectively). Older age was associated with decreased willingness to take the medication among White subjects only. Health status, trust and subjective numeracy did not have a direct effect on willingness to take the medication in either Black or White subjects. However, higher subjective numeracy was associated with increased perceived helpfulness in White subjects ($r = 0.125$, $p=0.005$), while greater trust was associated with increased perceived helpfulness ($r = 0.20$, $p=0.02$) in Black subjects. Poor health status was associated with greater fear ($r=0.247$, $p=0.01$) in Black subjects only. Helpfulness and fear were inversely correlated in White ($r = -0.126$, $p<.0001$), but not Black subjects ($r = 0.007$, $p=0.9$).



Conclusion: After hearing about a medication, Black subjects' treatment preferences were indirectly influenced by self-reported health status and trust and directly influenced by perceived helpfulness of the proposed treatment and fear of the side effects. In contrast, White subjects' treatment preferences were indirectly influenced by numeracy and directly influenced by age, perceived helpfulness and fear of the side effects. An inverse relationship between perceived helpfulness and fear (indicative of a confounding effect) was observed among White, but not Black subjects. The factors that influence how Black and White patients respond to information about medications differ.

2158

Do Numbers Make a Difference? Liana Fraenkel[1], Evan Wilhelms[2] and Valerie Reyna[2]. [1]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT, [2]Cornell University, Ithica, NY.

Background/Purpose: Patients frequently overweigh the risks associated with rare adverse events (AEs). This is particularly true for biologics associated with extremely rare AEs. As a result, significant efforts have been made to determine how best to present numerical information when describing the probabilities of rare AEs. What is unclear, however, is whether precise numeric estimates influence decision making or behavioral intentions.

Methods: We administered a survey to college students to examine the influence of probabilities and risk perceptions (worry, riskiness and gist evaluations) on subjects' stated likelihood of starting a medication. In this context, gist evaluations refer to the subjective meaning attached to the risk of the specified AE. We first described the impact of rheumatoid arthritis and subsequently asked subjects to imagine themselves as a patient with this disease in a clinical encounter during which a physician described a new treatment option to them. Route of administration, benefit, and cost were held constant. We varied current health state (able versus unable to maintain current level of activity and responsibilities), type of AE (pneumonia versus cancer) and probability of the AE (1 in 100, 1 in 1,000, 1 in 10,000 and 1 in 100,000). Each subject responded to a single, randomly-assigned scenario. Linear regression models were constructed to examine the association between current health state, type of AE, the probability of the AE and risk perceptions (worry, riskiness, and gist evaluations) with the likelihood of starting the medication (measured on a 5-point scale) after adjusting for age, gender, ethnicity, and numeracy (measured using the modified Lipkus-Peters numeracy scale). Levels of gist evaluations and ethnicity were treated as dummy variables.

Results: 415 subjects completed the survey. Their mean (SD) age was 19.8 (1.8). 72.5% were woman, and 55.7% were Caucasian, 5.5% were Black and 25.7% Asian. The mean (SD) numeracy score was 0.74 (0.20). Health state, type of AE, probability, worry, riskiness, and gist evaluations were associated with likelihood of taking the medication when evaluated separately. In the full model (containing all predictors and covariates), current health state and all three risk perceptions remained significantly associated with likelihood of taking the medication, while numeric probability was not (See Table).

Table. Predictors of willingness to take the medication

Parameter Estimates				
			Hypothesis Test	
Parameter	**B**	**Std. Error**	**Wald Chi-Square**	**Sig.**
(Intercept)	4.704	.7948	35.030	.000
Current Health State	.258	.0868	8.862	.003
Adverse Event	−.126	.0927	1.839	.175
Probability of Adverse Event	−.108	.1480	.531	.466
Gist = doesn't matter how small risk is	−.458	.1309	12.241	.000
Gist = even though risk is small, unacceptable	−.727	.1471	24.387	.000
Gist = risk is so small, nothing to worry about	.532	.1146	21.577	.000
Gist = risk is small, but reasonable	Reference			
Riskiness	−.178	.0608	8.591	.003
Worry	−.228	.0559	16.698	.000
Numeracy	−.494	.6697	.544	.461
Probability * Numeracy[1]	.209	.1919	1.183	.277
Gender	−.105	.0968	1.186	.276
Age	.009	.0239	.129	.720
Ethnicity = White Hispanic	−.150	.2059	.534	.465
Ethnicity = Other	−.315	.1702	3.431	.064
Ethnicity = Asian	−.215	.1019	4.456	.035
Ethnicity = Black	−.223	.1946	1.314	.252
Ethnicity = White non-Hispanic	Reference			

1: Interaction term between probability and numeracy.

Conclusion: Risk perceptions predict subjects' willingness to take medication, while probabilistic information does not. The results suggest that decision support must extend beyond presentation of probabilistic information in order to ensure informed choice.

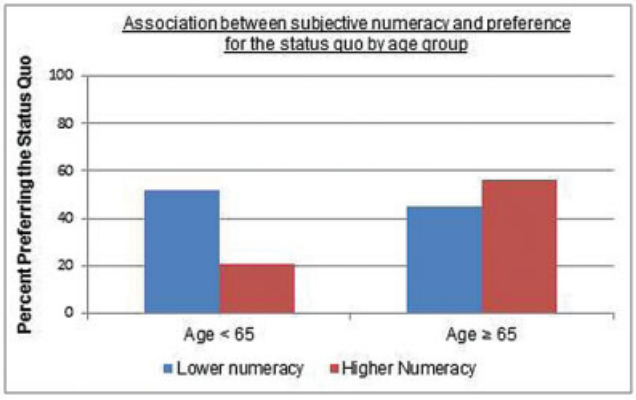
2159

Understanding the Preference to Stay With the Status Quo. Liana Fraenkel[1], Meaghan Cunningham[2] and Ellen Peters[3]. [1]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT, [2]Yale University School of Medicine, New Haven, CT, [3]Ohio State University, Columbus, OH.

Background/Purpose: Preference for the status quo is prevalent in patients with rheumatic disease and may be harmful in decisions for which there is strong evidence that a change in treatment is likely to improve outcomes, such as in active rheumatoid arthritis. The objective of this study was to 1) examine the influence of numeracy and emotion on patients' preference for the status quo, i.e., to remain with their current treatment, and 2) to determine whether age modifies these relationships.

Methods: Subjects with active rheumatoid arthritis, under the care of a rheumatologist and currently taking at least one DMARD, participated in an interview between 4/2/2009 and 10/26/2010. Numeracy was measured using the Subjective Numeracy Scale. Emotion was measured using the item: "If you were considering whether or not to start a new medication, how would you feel?" on a scale ranging from 1= "extremely worried" to 7= "extremely hopeful about what could happen." Treatment preference was measured using an Adaptive Conjoint Analysis survey. Associations between numeracy and emotion with preference for the status quo were measured using logistic regression. We also examined interactions between mean centered numeracy and emotion with mean centered age on preference for the status quo.

Results: Of 205 eligible subjects, 156 agreed to participate. The mean (SD) age was 59 (13), and the majority were female (85%), White (82%), and had some college education (70%). Overall, 39% preferred the status quo alternative. Preference for the status quo (vs preference to make a treatment change) was associated with lower subjective numeracy [median (IQR) = 32 (17) vs 38 (11), p= 0.001] and less hopefulness [median (IQR) = 5 (4) vs 7 (2), p= 0.003]. The association between both numeracy and emotion with preference for the status quo remained significant after controlling for variables found to be associated ($p \leq 0.05$) with preference for the status quo in bivariate analyses (age, race, employment, and current biologic use). However, the impact of emotion [Adjusted odds ratio (95% CI) = 0.75 (0.6–0.90), p=0.002], was much larger than that of numeracy [Adjusted odds ratio (95% CI) = 0.96 (0.92–0.99), p=0.028]. Higher numeracy was protective against status quo preferences in subjects less than 65 years of age but not in older subjects (see Figure). We found no interaction between age and emotion on preference.



Conclusion: The results highlight the strong influence of emotion (i.e. hopefulness) on patients' willingness to consider a change in treatment, and suggest that targeting numeracy alone may not improve the quality of decision making unless patient motivation is also considered.

The Journey to Diagnosis in As/Axial Spondyloarthritis - the Psychological Impact of Delay. Jane Martindale and Lynne Goodacre. Lancaster University, Lancaster, United Kingdom.

Background/Purpose: It is not uncommon for 8 to 11 years to pass between symptoms onset and definitive diagnosis of AS/axial SpA (Gran 1997, Feldtkeller, 2003). We are not yet fully conversant with all of the factors influencing this delay. The aim of this study was to conduct an in-depth exploration of the 'journey' to diagnosis of people with AS/SpA to gain insights into the experience, potential barriers and facilitators in this process.

Methods: Ethical approval was obtained for a qualitative phenomenological study embedded within a longitudinal cohort study of people newly diagnosed with AS/AxialSpA in the UK. 10 participants from 2 sites meeting the inclusion criteria, gave consent to be interviewed at diagnosis utilising an in-depth semi-structured approach. Interviews were recorded and transcribed verbatim. Thematic analysis comprised an iterative, interpretative process in which a systematic and rigorous approach was used to ensure that codes, code frameworks and themes were grounded within the data, to ensure credibility and trustworthiness.

Results: 7 males and 3 females consented to participate; age mean (SD) 40.2 (7.7) years (range: 26 – 49), with reported years of symptoms before diagnosis being 10.1 (7.3) years. Analysis identified 4 key themes: 'Trying to work out what was wrong' describes the worry that was associated with knowing that something was wrong and how this was complicated by the variability and the severity of the back pain participants were experiencing. 'Fighting for a diagnosis' encompasses an overall sense that participants felt that their back pain was being dismissed. Participants described having to be persistent and 'fighting' to be referred to a specialist, and a sense that they were not being believed. 'The impact of being given a diagnosis' describes the contradictory emotions of relief and empowerment associated with being believed, and the worries and uncertainty about the future. 'The impact of delayed diagnosis' describes the negative psychological price that people paid including desperation, distress, depression and feeling disheartened. For those in employment continuing to work had been challenging with the stigmatisation of a 'bad back'. Insights were provided also into the emotional price paid by family members during this journey to diagnosis.

Conclusion: These insights have identified that people endure a multiplicity of problems and psychological distress to achieve a diagnosis. Delay in diagnosis may be associated with lack of familiarity and knowledge of AS/axial SpA by the population and healthcare professionals, highlighting the importance of campaigns to bring this condition to the public domain. Clinicians need to consider the potential impact of the 'journey to diagnosis' on clinical management once a diagnosis has been made.

Biopsychosocial Typologies of Pain in a Cohort of Patients With Systemic Sclerosis. Erin L. Merz[1], Vanessa L. Malcarne[1], Shervin Assassi[2], Deepthi Nair[2], Tiffany Graham[2], Brayden Yellman[2], Rosa M. Estrada-Y-Martin[2] and Maureen D. Mayes[2]. [1]SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, CA, [2]University of Texas Health Science Center at Houston, Houston, TX.

Background/Purpose: Despite being a common problem in Systemic Sclerosis, the extant literature on pain has primarily focused on biomedical correlates, or bivariate relationships with a few psychological characteristics. There is a need to investigate the more heuristic biopsychosocial model, which incorporates the simultaneous contributions of medical, psychological, and social variables in understanding pain.

Methods: Patients with Systemic Sclerosis ($N = 333$) received clinical exams and completed self-report surveys at enrollment to the *Genetics versus ENvironment In Scleroderma Outcome Study*. Latent profile analysis was used to derive biopsychosocial profiles of patients using clinical indicators of disease severity (modified Rodnan skin score, percent predicted forced vital lung capacity), perceived physical health, health worry, mental health, and social support. The resultant profiles were examined in relation to pain and pain medication usage.

Results: A 3-profile solution provided the best fit to the data. Based on the biopsychosocial indicators, the profiles were characterized as *Managing* ($n = 217$), *Resilient* ($n = 86$), and *Distressed* ($n = 30$). Both the *Managing* and *Distressed* groups had relatively less severe skin thickening and percent predicted forced vital lung capacity, but the *Distressed* group reported much poorer perceived physical health, mental health, and social support. The *Resilient* group had a much more severe disease manifestation; however, *Resilient* patients mirrored the *Managing* group with relatively better psychosocial functioning. Between-group differences for pain emerged, with the *Distressed* group, whose disease was less severe than the *Resilient* group, reporting the highest pain and the greatest utilization of acetaminophen/nonsteroidal anti-inflammatory drugs, tramadol, and narcotic pain medication.

Conclusion: Clinicians should consider biopsychosocial characteristics as contributing factors to the experience of pain in patients with Systemic Sclerosis. Although disease severity is a risk factor for pain, psychological and social characteristics are also important in understanding disease-related pain. Patients with characteristics similar to those in the *Distressed* profile may be at an increased risk for pain and would likely benefit from a referral to a behavioral health or other ancillary service providers for an adjunct treatment for pain management, rather than relying solely on pharmacological therapies.

Physical, Psychological, and Social Impacts Of Restricting Back Pain: The Older Person's Perspective. Una E. Makris[1], Trisha V. Melhado[2], Simon C. Lee[2], Heidi A. Hamann[2], Lisa M. Walke[3], Thomas M. Gill[3] and Liana Fraenkel[4]. [1]UT Southwestern Medical Center, VA Medical Center, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, TX, [3]Yale University, New Haven, CT, [4]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT.

Background/Purpose: Although back pain is the most common type of pain reported by older adults, we have a limited understanding of its impact on the daily life of older persons. Qualitative research can capture the lived experience of back pain severe enough to result in restricted activity (hereafter referred to as restricting back pain), in older persons and help to identify patient-reported dimensions of this experience. In this qualitative study, we explored older persons' perspectives, experiences, and attitudes regarding how restricting back pain impacts various dimensions of daily life.

Methods: We recruited participants who reported restricting back pain during the previous 3 months from the Yale PEP Study, a longitudinal study of community-living persons. In-depth, semi-structured interviews were conducted in the participants' home by a single investigator (UM). The interviewer's guide explored the character and clinical course of restricting back pain as well as its impact on activities of daily life, including symptom management and quality of life, social relationships, coping strategies and other adaptive behaviors, including questions about other illnesses or conditions. Interviews were transcribed and independently coded by 4 reviewers using iterative thematic analysis (NVivo 9). Thematic codes were created to categorize the nuances of participants' restricting back pain experiences. To ensure inter-coder reliability, coding discrepancies were resolved through group discussion until consensus was reached. Recruitment stopped once no new codes emerged from the data, indicating theoretical saturation.

Results: We interviewed 23 participants (age range: 83–98, 57% women, 91% non-Hispanic white, 4% non-Hispanic black, and 4% Hispanic). All participants described the perceived consequences of restricting back pain on daily activities and quality of life. Specifically, analysis revealed that restricting back pain impacted participants' quality of life physically (including sleep), psychologically and socially. The participants described how restricting back pain resulted in social isolation that subsequently influenced psychological well-being. Salient quotes illustrating several of the prominent themes are listed below.

Quotes of restricting back pain impact by theme

Theme	Sample Quote
Physical impact	–It's very debilitating, both mentally and physically, because I'm not able to do what I want to do. My head says yes and my body says no.
Sleep impact	–Well, I really don't get a good rest at night. When I'm turning this way and that way because of the back pain.
Psychological/social impact	–I'm not as open as I used to be. I'm not, I don't get out there and talk with everybody. I'm usually, I stay in my house. I don't go out that much.
	–I guess it makes me depressed because I can't get outÉI don't see people and I'm a people person.
	–It's a writing group upstairs that I used to go and we wrote poetry and little stories. I used to love to participate in that and I won't even [go] up there by myselfÉI can't stand the pain of sitting in a groupÉif I take the pills or something to help, then I can't concentrate.

Conclusion: Thematic analysis revealed that restricting back pain in older persons has variable physical, psychological and social consequences. A better understanding of how older persons experience restricting back pain will enable clinicians and researchers to focus on the dimensions of the pain experience most relevant to this population and may help to identify novel measurable factors that can improve quality of care in older persons with back pain.

Predictors Of No Improvement In Subjective Health Perception In Newly Diagnosed Rheumatoid Athritis Patients With a Good DAS28 Response At 12 Months In The Dutch Rheumatoid Arthritis Monitoring Tight Control Cohort. Martijn Oude Voshaar[1], Erik Taal[1], Peter M. ten Klooster[1], Harald E. Vonkeman[2] and Mart A.F.J. van De Laar[3]. [1]University of Twente, Enschede, Netherlands, [2]Medisch Spectrum Twente, Enschede, Netherlands, [3]Medisch Spectrum Twente & University of Twente, Enschede, Netherlands.

Background/Purpose: Modern treatment strategies are highly successful in reducing disease activity in rheumatoid arthritis (RA). However, changes in clinical measures of disease activity may not always correspond with a patient's own opinions of improvement. Purpose of this study is to identify subjective predictors of self-reported health changes in patients with a good clinical response after one year of treatment in a tight control study.

Methods: Data from newly diagnosed patients of the Dutch Rheumatoid Arthritis Monitoring (DREAM) remission induction cohort who completed baseline and 12 months assessments was used for this study. Patients who achieved a good DAS28 response at 12 months were selected for analysis. Subjective change in health was assessed with the SF-36 health transition question (Compared to one year ago, how would you rate your health in general now?). Scores were dichotomized (improved vs not improved) for analysis. Binary logistic regression analysis was performed to identify predictors of patient reported health changes. Twelve month changes in DAS28 scores was added as predictor in the first step; changes in scores on SF-36 subscales were added in a second step. The general health scale of the SF-36 was excluded. Cohen's standardized effect size (e.s.) statistic (d) was calculated for 12 month change scores of significant predictors and compared between improvers and non-improvers.

Results: A good DAS28 response after 12 months of treatment was achieved by 162 (57%) out of 282 patients. Of these, 40 (24.7%) did not consider their health to have improved since starting treatment (non-improvers). Baseline SF-36 subscale scores did not significantly differ between improvers and non-improvers. Twelve month change scores in bodily pain (OR = 1.03, p = 0.04) and vitality (OR = 1.03, p = 0.04) were significant multivariate predictors of self-reported health improvement. About 19% of the variance in self-reported health changes was explained by the final model (Nagelkerke's R^2 = 0.19), whereas the model containing only DAS28 change scores explained about 6% of variance (Nagelkerke's R^2 = 0.06). Mean (SD) bodily pain scores improved from 38.9 (± 18.6) to 74.7 (±19.8) over 12 months for improvers (e.s.= 1.87) and from 41.8 (±19.8) to 62.9 (±19.6) for non-improvers (e.s.= 1.06). Mean (SD) vitality scores improved from 52.8 (±19.8) to 66.7 (±16.8) in improvers (e.s. = 0.71) and from 53.12 (±18.9) to 56.56 (±18.9) for non-improvers (e.s. = 0.17).

Conclusion: The majority of patients with a good DAS28 response after one year of tight control treatment also considered their health to have improved. However, a substantial minority did not consider their health to have improved, despite significant clinical improvements in disease activity. These results suggest that clinical improvements do not necessarily equate to improved subjective health. One possible explanation is that pain and fatigue are patient reported outcomes that may not be adequately represented in current clinical outcome measures in RA research.

2164

Rituximab In The Treatment Of Children With Systemic LUPUS Erythematosus: ONE Year Analysis Of 12 Patients. Ekaterina Alexeeva[1], Rina Denisova[1], Saniya Valieva[1], Tatyana Bzarova[1], Kseniya Isayeva[1], Tatyana Sleptsova[1], Elena Mitenko[1], Evgeniya Chistyakova[2], Anna Fetisova[1] and Elena Semikina[3]. [1]Scientific Center of Children's Health of RAMS, Moscow, Russia, [2]I.M.Sechenov First Moscow State Medical University, Moscow, Russia, [3]Scientific Center of Children's Health of RAMS, Moscw, Russia.

Background/Purpose: Treatment of childhood systemic lupus erythematosus (SLE) is an ongoing problem because of the severity of the disease in some patients and the side-effects of the currently available immunosuppressive agents. B-cell depletion might be useful and effective treatment for this disease according to researches in adults.

Purpose: To assess the clinical and basic serological consequences of rituximab treatment in patients with systemic lupus erythematosus who have failed conventional immunosuppression.

Methods: An open study of 12 patients with severe SLE followed for a minimum of 12 months is reported: 12 patients – 6 months, 11 patients – 12 months. Disease activity in these patients was assessed every 6 months using the SELENA SLEDAI, System Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) Damage Index and estimates of anti-double-stranded DNA antibodies and serum C3, C4 levels, number of CD20 B lymphocytes. During the follow-up period, significant side-effects were sought and the reduction in oral prednisolone was recorded too. Background therapy included cyclophosphamide, plasmapheresis, intravenous immunoglobulin, methylprednisolone pulse therapy, mycophenolate mofetil. Rituximab was given 375mg/m^2 weekly, [1]4. All patients were treated with prednisolone and immunosupressive agents.

Results: 11 patients were female and 1 male. At the initiation of rituximab treatment the mean age was 14.6 yr (range 10–17.5) and the mean disease duration was 3.6 yr (range 0.3–13.2). 5 had lupus nephritis. All parameters improved from in 6 and 12 months after rituximab treatment: the SELENA SLEDAI score from 16 (range 4–25) to 3 (range 0–14) (p=0.002) and 1 (range 0–4) (p<0.001), SLICC/ACR Damage Index from 3,5 (range 0–6) to 2 (range 0–4) (p=0.02) and 1 (range 0–4) (p<0.05), serum C4 from 0,13 (range 0,01–0,9) to 0,24 (range 0.06–1.25) (p=0.04) and 0,43 (range 0.09–0.66) (p<0.01) (normal range 0.14 – 0.47 g/l) and double-stranded DNA binding from 73,5 (range 0–250) to 8,9 (range 0–130) (p=0.04) and 1,9 (range 0–80) (p<0.01) (normal range 0 – 20 ME/ml). B-lymphocyte depletion was observed in all patients in the peripheral blood after 6 and 12months (p<0.01). The mean daily prednisolone dose fell from 0.8 mg/kg (range 0.4–1.5) to 0.5 mg/kg (range 0.2–0.8) and 0.2 (range 0.15–0.7) (p<0.01). Proteinuria was improved in 5 patients from 5.6 gr/day (range 0.3–15) to 1.7 gr/day (range 0.3–5.0) (p=0.06) and 0,2 gr/day (range 0.3–1.0). There were no flares follow up period. Serious Adverse events were registered: pneumonia (n=2), neutropenia (n=5), herpes Zoster infection (n=3), hypogammaglobulinemia (n=8).

Conclusion: In this open study of patients who had failed conventional immunosuppressive therapy, considerable utility in the use of B-cell depletion has been demonstrated. Our data provide strong support for the performance of a full doubleblind control trial.

Efficacy and Safety Of Biologic Agents In Patients With Poly-Articular Juvenile Idiopathic Arthritis: Network Meta-Analysis Of Randomized Controlled Withdrawal Trials. Gil Amarilyo[1], Simon Tarp[2], Ivan Foeldvari[3], Neta Cohen[1], Tracy D. Pope[4], Jennifer M.P. Woo[5], Robin Christensen[2] and Daniel E. Furst[4]. [1]Dana-Dwek Children's hospital, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Musculoskeletal Statistics Unit, The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, [3]Hamburger Zentrum für Kinder- und Jugendrheumatologie, Klinikum Eilbek, Hamburg, Germany, [4]David Geffen School of Medicine, University of California, Los Angeles, CA, [5]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA.

Background/Purpose: Although various biologic agents (BAs) are in use for polyarticular juvenile idiopathic arthritis (pJIA), a combined meta-analytic summary comparing the efficacy and safety among them in pJIA is lacking. An often applied trial design in pJIA, called withdrawal trials, consists of an open-label run-in phase where all patients receive active drug. After this phase, only those who respond to treatment enter the double-blind phase and are randomized to continue on drug or on placebo. Our objective was to compare the efficacy and safety of BAs in pJIA using all currently available randomized withdrawal trials (wRCTs) [1].

Methods: A systematic search of MEDLINE, EMBASE, CENTRAL and clinicaltrials.gov was performed. Eligible wRCTs included patients with pJIA where BAs, at any dose, were compared with another BA or placebo. Efficacy was evaluated with disease flare (as defined by the authors) and ACRPedi30, 50, and 70. Safety was evaluated by examining patients with adverse events (AEs) and serious AEs (SAEs). Two reviewers extracted data, and a third confirmed. A network meta-analysis was used to compare BAs, based on a mixed-effects logistic regression model (modeled in SAS) [2]. This approach combined statistical inference from both direct and indirect comparisons of the treatment effects between BAs. Results are reported as odds ratios with 95% confidence intervals (OR [95%CI]).

Results: Of 490 references identified, 23 were reviewed in detail and 5 wRCTs were included: abatacept, adalimumab, anakinra, etanercept and tocilizumab, one trial each, all vs. placebo. Nearly all placebo comparisons showed statistically significant efficacy ($P < 0.05$) for flare (Table 1) and for ACRPedi 30, 50 and 70; the anakinra trial did not report ACRpedi measures and etanercept was not different for ACRpedi70 (2.30 [0.73;7.29]; $P = 0.16$). There were no differences ($P > 0.05$) among BAs for efficacy. SAEs occurred very infrequently (0–8%) and an analysis was not possibly (Table 2). As noted in Table 2 there were no differences for AEs when compared to placebo or among BAs.

Table 1. Disease Flare, Biologic agents vs. other biologic agents or placebo

Biologic agent	Biologic agent/Placebo	OR Flare	Lower 95% CI	Upper 95% CI	*P*

Anakinra	Placebo*	0/25	0/25	1.008	0.368	2.760	0.987
Anakinra	Tocilizumab	0/25	3/82	1.014	0.322	3.193	0.982
Tocilizumab	Placebo*	3/82	3/81	0.995	0.532	1.859	0.986

Odds ratios (OR [95% CI]) and *P*-values for AEs. Note: etanercept SAE and AE data were not available. For SAE events in the placebo group is for the individual trial, for AE placebo refer to the combined placebo group in the analysis.

Conclusion: Overall BAs were effective and safe when compared placebo. There were no differences among BAs for either efficacy or safety. Based on these data, other considerations such as price and availability should be used to decide among BAs when treating pJIA patients as no personalized biomarkers etc. are available at present. Long term safety will be better examined in the biologic registries currently accruing data in JIA.

Infection Risk With Tumor Necrosis Factor Inhibitor Use In Polyarticular Juvenile Idiopathic Arthritis. Caroline Y Chang, Rika Meyer and Katherine AB Marzan. Children's Hospital Los Angeles, Los Angeles, CA.

Background/Purpose: Tumor Necrosis Factor inhibitors (TNFi) are extremely effective in treating Juvenile Idiopathic Arthritis (JIA). However, TNF-α is critical in immune function, raising concerns of increased infection(INF) rates in patients(pts) on TNFi. With current pediatric data primarily from drug registries and hospitalized patient data, it is unclear whether pediatric pts on TNFi have increased risk of INF, and if so, what types.

Methods: This is a retrospective cohort study of pts seen in our institution's pediatric rheumatology clinic with polyarticular JIA (pJIA) between 1/1/00 and 11/30/11. Demographic information (Table 1), diagnosis, medication history, and documented INFs (Table 2), classified as mild, moderate, and severe, were obtained from the medical record. Rates of INF were calculated and compared for pts on no immunosuppressants (IS), methotrexate(MTX), TNFi, and MTX plus TNFi (MTX+TNFi) (Table 3). Time periods on other IS or systemic corticosteroids were excluded. The data was evaluated in two ways: 1) each pt was analyzed under the therapy category that they were treated with for the longest length of time for that period of time, and 2) pts who had been on multiple categories of medications were analyzed with a paired t-test.

Results: 239 pts with pJIA were included in the study with a mean follow-up of 4.46 ± 2.91 years and a total of 531 INFs in 1067 patient years. Both analyses demonstrated that pts on MTX and MTX+TNFi had significantly higher INF rates than those on no IS ($p<.001$, $p<.0005$ and $p<.0005$, $p<.0005$), with INF rate ratios (IRR) of 3.2 (95%CI 2.1–4.8), and 5.5 (95% CI 3.7–8.2). Pts on MTX+TNFi also had significantly more INFs than those on TNFi ($p=.02$, $p=.001$, IRR 2.8 (95% CI 2.1–3.8)). Paired t-tests showed significantly higher INF rates in those on TNFi compared to no IS ($p<.001$, IRR 2.0 (95% CI 1.2–3.1)), and MTX+TNFi compared to MTX ($p=.004$, IRR 1.7(95% CI 1.4–2.1)). There was no significant difference between pts on MTX or TNFi.

Table 1. Demographic Information

	N = 239 (%)
Female Sex	195 (81)
Ethnicity	
Hispanic	146 (61)
Non-Hispanic	93 (39)
Age at disease onset, mean years (range)	9.6 (0.8–18)
Mean follow-up, years (SD)	4.46 (2.91)
Total patient years	1067
Number of Patients Exposed to:	
Systemic Corticosteroids	63
Other immunosuppressants	32

Table 2. Documented Infections

Mild	Moderate	Severe
Upper Respiratory Illnesses	Soft tissue Infections	Pneumonia
Pharyngitis	-Abscess/Cellulitis	EBV with hepatitis
Otitis Media	Pneumonia	Pyelonephritis
Urinary Tract Infection	Varicella Zoster	Systemic Coccidiomycosis
Gastroenteritis		
Nonspecific viral infections		
Mild skin infections		
-Impetigo, Paronychiae		
Superficial fungal infections		

Table 3. Infection Rates

Medication Category	Number of Patients N =234*	Mean infections/100 patient year(SD)
No Immunosuppression	34	12 (29)**
Methotrexate	58	54 (66)
Methotrexate + TNFi	85	61 (70)***
TNFi	37	30 (37)

* 5 excluded given same amount of time in multiple groups
** Significantly different compared to MTX and MTX + TNF $p = .001$, $p <.0005$
*** Significantly different compared to TNF alone $p = .022$

Conclusion: Pts with pJIA treated with MTX, MTX+TNFi, and TNFi have higher rates of INF than those on no IS, with increased rates of INF with each additional medication. However, TNFi do not put pts at a significantly higher risk of INF than MTX. Notably, there were predominantly mild INFs, with only 29 moderate and 5 severe INFs during the course of the study.

23-Valent Polysaccharide Pneumococcal Vaccine in Juvenile Idiopathic Arthritis Patients: Anti-Tumor Necrosis Factor Therapy Role in Short and Long-Term Immunogenicity. Nadia E. Aikawa[1], Ivan L.A. França[2], Ana C. M. Ribeiro[2], Adriana M. Sallum[2], Eloisa Bonfa[3] and Clovis A. Silva[2]. [1]Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [2]University of São Paulo, São Paulo, Brazil, [3]University of São Paulo, Sao Paulo, Brazil.

Background/Purpose: There is no study regarding short and long-term assessments of 23-valent polysaccharide pneumococcal vaccine (PPV23) in juvenile idiopathic arthritis (JIA) under biologic therapy. The objectives of this study were to assess the humoral response of the PPV23 in JIA patients pre- and post-anti-TNF therapy and controls without this treatment. The possible influence of demographic data, disease activity and treatment on immunogenicity and the potential deleterious effect of vaccine on disease itself were also evaluated.

Methods: 17 JIA patients immediately pre-anti-TNF (etanercept 0.8 mg/kg/week, Group 1) and 10 JIA patients on stable dose of methotrexate (median dose 0.8 mg/kg/week, Group 2) received one dose of pneumococcal vaccine. All patients were evaluated pre-vaccination, 2 months and 12 months post-vaccination for 7 pneumoccocal serotypes (4, 6b, 9v, 14, 18c, 19f, 23f). Serology for each serotype was performed by enzyme immunoassay. The immunogenicity endpoints included the seroprotection rate (SP) (percentage of subjects achieving antibodies titers ≥1.3 micrograms/mL), seroconversion rate (SP) (percentage of subjects with a minimum of 2-fold rise in post-vaccination antibodies titers) and the geometric mean concentration of antibodies (GMC). Adequate vaccine response was considered when SC occurred for at least 50% of vaccine serotypes. Patient and physician visual analogue scales (VAS), Childhood Health Assessment Questionnaire (CHAQ), number of active joints, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were evaluated before and after vaccination.

Results: Group 1 and Group 2 were comparable regarding current age (11.6 vs. 9.2 years, $p=0.15$), female gender (47 vs. 40%, $p=1.0$), age at diagnosis (7.6 vs. 7.1 years, $p=0.9$) and disease duration (3.7 vs. 2 years, $p=0.1$). The frequency of glucocorticoids and non-biologic drugs (methotrexate, leflunomide and cyclosporine) was similar in both groups ($p>0.05$). Patients in Group 1 had significantly higher number of active joints (4 vs. 0, $p=0.02$), limited joints (6 vs. 2, $p=0.01$) and ESR (31 vs. 15 mm/1sthour, $p=0.03$) compared to Group 2. Both groups were alike regarding pre-immunization SP and GMC ($p>0.05$). Two months and 12 months after vaccination, SP, SC and GMC for all pneumoccocal serotypes were similar in JIA patients with and without anti-TNF therapy ($p>0.05$). Moreover, the frequency of patients achieving adequate vaccine response at 2 months (53 vs. 30%, $p=0.424$) and 12 months (36 vs. 40%, $p=1.0$) were similar in both groups. There was a significant decrease in disease parameters, including morning stiffness duration ($p=0.001$), number of active joints ($p<0.001$), CRP ($p=0.045$), patient's, parent's and physician's VAS ($p<0.05$) and CHAQ ($p=0.01$) in Group 1. In Group 2, all parameters remained unchanged after immunization ($p>0.05$). Further comparison of patients with and without adequate response at two months revealed no influence of demographic, clinical and laboratorial JIA parameters ($p>0.05$). Serious adverse events were not observed.

Conclusion: Anti-TNF therapy has no deleterious effect on PPV23 short and long-term immunogenicity in JIA patients and this response does not seem to influence disease parameters.

Temporomandibular Joint Involvement and Quality Of Life In Juvenile Idiopathic Arthritis. Paula Frid[1], Ellen Nordal[2], Francesca Bovis[3], Denise Marafon[3], Donato De Angelis[3], Sheila Oliveira[3], Fabrizia Corona[3], Gabrieli Simonini[3], Joyce Davidson[3], Helen Foster[3], Rik Joos[3], Ivan Foeldvari[3], Michel Steenks[3], Pekka Lahdenne[3], Pavla Dolezalova[3], Elena Palmisani[3], Alberto Martini[3], Angela Pistorio[3] and Nicolino Ruperto[3]. [1]Public Dental Service Competence Centre of Northen Norway, Tromso, Norway, [2]University of Tromsø, Tromsø, Norway, [3]Istituto Giannina Gaslini, Pediatria II, Reumatologia, Paediatric Rheumatology International Trials Organisation (PRINTO) Coordinating Center, Genoa, Italy, Genoa, Italy.

Background/Purpose: Temporomandibular joint (TMJ) arthritis in childhood is seen in a substantial percentage of children with Juvenile idiopathic arthritis (JIA) and may lead to reduced mouth opening, pain and craniomandibular growth disturbances. The purpose of this study was to assess the prevalence of TMJ involvement in a JIA cohort and the association between TMJ involvement and other disease variables such as cervical spine and upper limb involvement, and the impact of TMJ involvement on daily life.

Methods: This descriptive study is based on data from a cross-sectional sample from 32 countries worldwide between 1998–2000, diagnosed with JIA, enrolled for validation of the Child Health Assessment Questionnaire (C-HAQ) and Child Health Questionnaire (CHQ), and also children enrolled in the PRINTO Methotrexate (MTX) trial. Disease activity and quality of life were assessed. Diagnosis of TMJ involvement was based on clinical assessment of the presence of swelling or limitation of motion (LOM) with pain and/or tenderness in at least one TMJ.

Results: Of the 3344 children included, 68.3% were female and 45.8% were diagnosed with persistent or extended oligoarthritis. The prevalence of TMJ involvement was 11.6%. TMJ involvement was strongly associated with polyarthritis (odds ratio (OR) 9.8 (confidence interval (CI) 6.1–15.8)), systemic (OR 7.4 (CI 4.5–12.3)) and extended oligoarthritis (OR 6.7 (CI 4.0 – 11.1)) > 2 joints with LOM in upper limb > 2 (OR 9.8 (CI 7.5 – 12.7)) and cervical involvement (OR 7.8 (CI 6.2–9.8)) in univariate analysis. Finally, a multivariate logistic regression model with the disease activity measures, polyarticular JIA course, active joints >5, MTX use, female gender, age at visit, higher CHAQ scores, erythrocyte sedimentation rate (ESR), positive rheumatoid factor (RF) and other variables was performed; we underline the role of the following predictors in the association with the TMJ involvement: cervical spine involvement (3.0 (CI 2.2–4.0)), eating difficulties (1.2 (CI 1.0–1.4)) and superior limb involvement (1.1 (CI 1.0–1.1)).

Conclusion: The prevalence of TMJ involvement was low in this large cohort compared with other studies probably due to a diagnosis based on clinical diagnostic criteria only. However, we found significant associations between TMJ involvement and cervical spine involvement, upper limb involvement, and eating difficulties. Further studies with both clinical and imaging diagnostic assessment of TMJ involvement in a longitudinal cohort study are warranted.

Short Term Efficacy Of Biologic Agents In Patients With Systemic Juvenile Idiopathic Arthritis: Network Meta-Analysis Of Randomized Trials. Simon Tarp[1], Gil Amarilyo[2], Ivan Foeldvari[3], Neta Cohen[2], Tracy D. Pope[4], Jennifer M.P. Woo[5], Robin Christensen[1] and Daniel E. Furst[4]. [1]Musculoskeletal Statistics Unit, The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, [2]Dana-Dwek Children's hospital, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [3]Hamburger Zentrum für Kinder- und Jugendrheumatologie, Klinikum Eilbek, Hamburg, Germany, [4]David Geffen School of Medicine, University of California, Los Angeles, CA, [5]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA.

Background/Purpose: Systemic juvenile idiopathic arthritis (SJIA) is a severe subtype of JIA, which includes systemic features such as fever, rash, elevated inflammatory markers along with poly-arthritis. It is frequently resistant to treatment. Until recently, patients were treated mainly with large doses of glucocorticoids. Breakthroughs in understanding the pathogenesis of SJIA have led to the evaluation of biologics, which block the pro-inflammatory cytokines interleukin (IL)-1 or IL-6 and their receptors.

Our objective was to compare the short-term efficacy of biologics in SJIA [1].

Methods: A systematic search in MEDLINE, EMBASE, CENTRAL and clinicaltrials.gov was performed. Eligible Randomized controlled trials (RCTs) included patients with SJIA where biologics, at any dose, were compared with another biologic or placebo. In SJIA a modified ACR pediatric (ACRPedi) response is often used with the required addition that systemic features need to be abrogated. Efficacy was evaluated with modified ACRPedi30, 50, and 70. Two reviewers extracted data and a third confirmed data. The network meta-analysis was based on a mixed-effects logistic regression model (modeled in SAS) [2] combining statistical inference from both direct and indirect comparisons of the treatment effects between biologics. Results were reported as odds ratios with 95% confidence intervals (OR [95%CI]).

Results: Of 490 references identified, 23 were reviewed in detail, and 4 RCTs were eligible for inclusion: anakinra, canakinumab, rilonacept and tocilizumab, one trial each all vs. placebo. Rilonacept was statistically significantly ($P < 0.05$) different from placebo for ACRPedi50, but not for ACRPedi30 or 70 ($P > 0.05$); anakinra, canakinumab and tocilizumab were statistically superior to placebo for ACRpedi 30,50 and 70, Figure 1. Comparing biologics, rilonacept treated patients were statistically less likely to respond than those treated with canakinumab or tocilizumab, Figure 2. All other biologics were comparable revealing no statistical signal ($P > 0.05$).

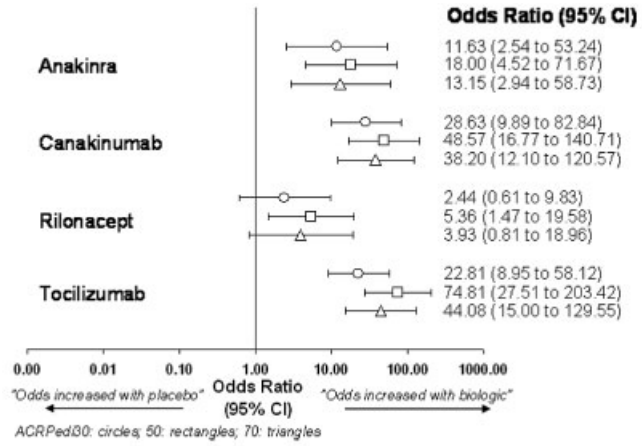

Figure 1. Biologic compared to placebo

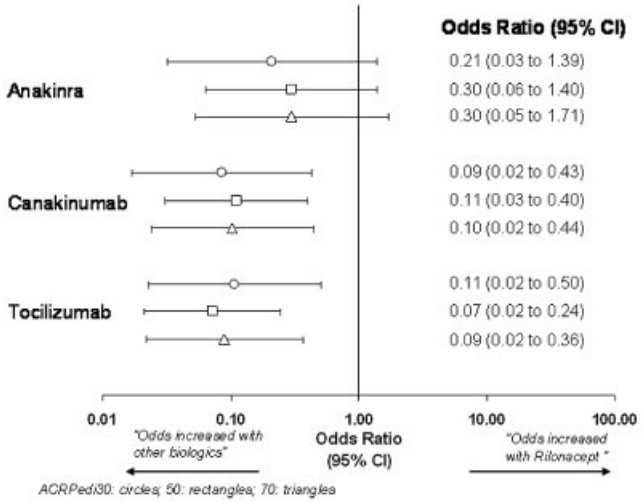

Figure 2. Rilonacept compared to other Biologic

Conclusion: This network meta-analysis of short term RCTs presents empirical evidence that canakinumab and tocilizumab were more effective than rilonacept. These results might be influenced by factors such as various study durations (tocilizumab 12 weeks; all other only 4 weeks), and variation in definitions of modified ACRPedi across trials.

2170

Efficacy and Safety Of Long-Term Rituximab Use In Patients With Systemic Juvenile Idiopathic Arthritis: The Results Of 5-Year Follow-Up In Real Clinical Practice. Ekaterina Alexeeva[1], Alexander Baranov[2], Saniya Valieva[2], Tatyana Bzarova[2], Rina Denisova[2], Kseniya Isayeva[2], Tatyana Sleptsova[2], Elena Mitenko[2], Evgeniya Chistyakova[1], Anna Fetisova[2], Elena Semikina[3] and Svetlana Akulova[2]. [1]I.M.Sechenov First Moscow State Medical University, Moscow, Russia, [2]Scientific Center of Children's Health of RAMS, Moscow, Russia, [3]Scientific Center of Children's Health of RAMS, Moscw, Russia.

Background/Purpose: To assess the efficacy and safety of rituximab (RT) treatment in long-term follow-up of children with systemic juvenile idiopathic arthritis (sJIA).

Methods: The results of the treatment of 60 children with sJIA (33 girls and 27 boys) aged from 1 year to 18 years (mean −8.7 y) were analyzed. Duration of disease at the time of RT prescription was 5.3 y on average. At the start of RT treatment, all children had arthritis and severe systemic manifestations. Previously 32 patients were treated with MT, 28 with MT+CsA, 56 with GK i/v, 32 with GK i/a, 36 with oral prednisolon, 19 with TNF blockers 5 with tocilizumab. ACR_{pedi} criteria and criteria of inactive disease and remission (Wallace) were used. The dose of RT was 375 mg/m^2 per infusion, weekly, 4 sequential weeks. One course of RT treatment was performed to 60 patients; two courses - to 36 patients, three courses – to 19 patients; 4 courses – to 5 patients, 5 courses – to 3 patients. The effect of therapy was assessed in 60 patients after 6 months, in 45 after 1 y, in 39 after 2 y, in 32 after 3 y; in 27 after 4 y; in 9 patients after 5 y.

Results: after 6 months of follow up remission of systemic manifestations was documented in 45 (75%) patients. Improvement by $ACR_{pedi30/50/70}$ was achieved by 65, 40 and 35% of patients, respectively; inactive disease by 15 (25%) patients. By month 12 (n=45) improvement by $ACR_{pedi30/50/70}$ was achieved by 80, 55, 45% of patients, respectively; inactive disease by 18 (30%) patients. After 2 (n=39), 3 (n=32), 4 (n=27) years of follow up improvement by $ACR_{pedi30/50/70/90}$ was observed in 90, 80, 75, 70%; 90, 85, 80 and 75% and 98, 95, 95 and 93% of patients, respectively; inactive disease and remission in 43, 33, 33% of patients. In all patients (n=9) who was followed up 5 years remission of disease was documented. Within all period of observation disease remission was documented in 26 (43%) patients, remission of systemic manifestations in 45 (75%) patients. Mean duration - 18 (6;32) and 25 (6; 41) months, respectively.

The second course of RT was made within 18 (6; 32) months in 36 patients after documentation of inactive disease, the third course - within 26 (6; 32) months, the forth course – within 38 (8; 42) months.

RT was discontinued in 39 (65%) patients within 18 (6;32) months due to primary inefficacy in 15 (25%) patients, partial efficacy 8 (13%) (active arthritis), flare of arthritis in 4 (7%) patients, flare of systemic manifestations in 7 (12%). Other patients turned 18 years old and were lost for follow-up.

Within all period of observation the following were reported: infusion reactions 0,8 AE/100 patient years; 0,7 infectious AE/100 patient year; 0,34 Infectious SAE/100 patient year (pneumonia pneumocystic carini); neutropenia 0,35 AE/100 patient year, decrease in serum concentrations Ig 0,25 AE/100 patient years.

Conclusion: RT may be effective in very severe course of sJIA resistant to immunosuppressive drugs, GK and other biologics. RT induced disease remission in 43% of patients and remission of systemic manifestations in 75% of patients. Infectious AEs and SAEs are controlled by antibiotics, non- infectious AEs by IVIG, and GM-CSF.

2171

Identification Of Best Cutoff Points and Clinical Signs Specific For Early Recognition Of Macrophage Activation Syndrome In Active Systemic Juvenile Idiopathic Arthritis. Mikhail Kostik, Margarita Dubko, Ludmila Snegireva, Vera Masalova, Tatyana Kornishina, Natalya Abramova, Irina Chikova, Natalya Glebova, Ekaterina Kuchinskaya, Eugenia Balbotkina, Olga Kalshnikova and Vyacheslav Chasnyk. Saint-Petersburg State Pediatric Medical University, Saint-Petersburg, Russia.

Background/Purpose: Macrophage activation syndrome (MAS) – is a severe life-threatening hematological condition, mostly complicated systemic juvenile idiopathic arthritis (SJIA). Early detection of MAS can lead to appropriate therapeutic interventions and change the outcomes. There are no strict criteria for early MAS detection in SJIA. Currently applied HLH criteria can determinate only advanced stage of MAS, which lead to delay diagnosis, late start of specific treatment and associated with poor outcomes. There are several sets of preliminary criteria of MAS in SJIA.

The aim of our study was to detect early clinical and laboratorial signs able to discriminate MAS from active SJIA without MAS.

Methods: our retrospective study was based on reviewing of medical charts of children who were admitted to our rheumatology department in 2005–2013 with SJIA and definite MAS (n=18) and active SJIA without MAS (n=40). We utilized the A.Ravelli criteria (2002, 2005, 2011) for detecting MAS. We evaluated demographic data, data related to SJIA and MAS. We used the main characteristic clinical and laboratorial markers of MAS only at the moment of MAS confirmation. We calculated cutoff points for MAS parameters (ROC-analysis), performed analysis of sensitivity and specificity and identified predictors.

Results: Several clinical signs were relevant to MAS in SJIA: oligoarthicular disease course (OR=5.6 [95%CI:1.6–19.4], p=0.005), splenomegaly (OR=67.6 [3.8–1205.9], p=0.000004), coagulopathy (OR=7.0 [1.9–26.1], p=0.006), lung (OR=11.3 [2.8–45.2], p=0.0001) and kidney involvement, realized in proteinuria<1.0g/24 h (OR=42.1 [2.2–801.2], p=0.0001). The involvement of wrist (OR=0.2 [0.1–0.8], p=0.03), MCP (OR=0.1 [0.0–0.9], p=0.02) and PIP joints (OR=0.1 [0.0–0.6], p=0.005) were protective against MAS development. The best cutoffs for laboratorial parameters, related to MAS are in table.

Parameter	Sensitivity	Specifisity	OR (95%CI)	AUC (95%CI)	p
Hb≤90 g/l	72.2	80.0	10.4 (2.9–37.8)	0.77 (0.64–0.87)	0.0001

Ferritin>400 μg/l	100.0	76.0	87.0 (4.5–1671.7)	0.92 (0.78–0.98)	0.000005
CRP>113 mg/l	52.9	89.5	9.6 (2.3–39.1)	0.59 (0.45–0.72)	0.001
ESR≤10 mm/h	61.1	92.5	19.4 (4.3–87.8)	0.78 (0.65–0.88)	0.0001
Na^+ ≤137 mmol/l	66.7	81.1	8.0 (2.1–31.0)	0.79 (0.65–0.0.89)	0.003
Active joints≤6	83.3	59.0	7.2 (1.8–29.0)	0.74 (0.61–0.85)	0.003

Conclusion: We detected clinical and laboratorial markers which can help to early recognition of MAS in children with active SJIA.

Single MVK Mutation and Recurrent Fevers. Karyl S. Barron[1], Amanda K. Ombrello[2], Donald P. Goldsmith[3], Ivona Aksentijevich[2], Anne Jones[2] and Daniel L. Kastner[2]. [1]National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD, [2]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, [3]St Christopher's Hospital for Children/ Drexel College of Medicine, Philadelphia, PA.

Background/Purpose: HyperIgD syndrome is an autoinflammatory disorder caused by mutations in the *MVK* gene. While mutations in most patients follow autosomal recessive inheritance, we have identified a cohort of patients with recurrent fevers and only 1 mutation in the *MVK* gene. The purpose of this study was to compare clinical features in those with 1 vs. 2 *MVK* mutations and to report therapeutic responses in all.

Methods: Patients were evaluated at the National Institutes of Health. Clinical and laboratory information were collected at each visit.

Results: 31 pts with mutations in *MVK* were evaluated: 22 had 2 mutations (21 with V377I and 1 other mutation; 1 with V203A/H380R), 9 had only 1 mutation after testing the whole gene (8 with V377I, 1 with I268V). The carrier frequency of V377I in our control Caucasian population is 0.3% (2/739).

Clinical or laboratory presentation at the time of a flare was compared between the 2 groups. There was no significant difference with regard to age of onset, duration of flares, frequency of flares, flares after immunization, GI symptoms, oral ulcers, sore throat, arthralgia, or adenopathy associated with flares. Rash was more common in pts with 2 mutations, 20/22 compared to 4/9 in those with one mutation ($p=.01$). Level of IgA was increased in those with 2 mutations (452 ± 230 mg/dl) compared to those with 1 mutation (230 ± 175) ($p=.01$), as well as level of IgD (95 ± 95, 2 mutations, vs. 8.3 ± 7.4, 1 mutation, $p=.01$).

Since there was no significant difference in clinical presentation, other than presence of rash and levels of IgA and IgD, pts were considered together to evaluate their therapeutic responses. Prednisone given at the time of a flare was helpful in 18/25, however one patient developed steroid psychosis. Colchicine was given to 8 pts and 7 showed no improvement or worsening. 15 pts tried montelukast: 4 reported some improvement, however 11 reported no improvement or worsening. Intermittent anakinra at the time of a flare was helpful in 14/19 pts, not helpful in 3 and too early to assess in 2 patients. One patient developed acute renal failure shortly after initiating intermittent anakinra therapy. Of the 9 pts receiving weekly etanercept, 4 showed some improvement and 5 showed no improvement of worsening (with one patient developing massive lymphadenopathy). 3 pts have required daily anakinra and shown a favorable response.

Conclusion: Aside from the presence of rash and higher IgA and IgD levels in those children with 2 *MVK* mutations, there are no significant clinical differences between those patients with 1 or 2 mutations. The relatively small number of children with 1 mutation may influence the analyses, but thus far there are no clear trends that allow identification or predictability of the disease course in children with either 1 or 2 mutations. Given the higher frequency of V377I heterozygotes in our patient cohort compared to the general population, our data suggest that under some circumstances this may be associated with recurrent fevers. Therapeutic options for children with MVK mutations include intermittent prednisone or anakinra, either given intermittently or daily; however, not all patients respond to therapy and there are associated adverse events in some patients.

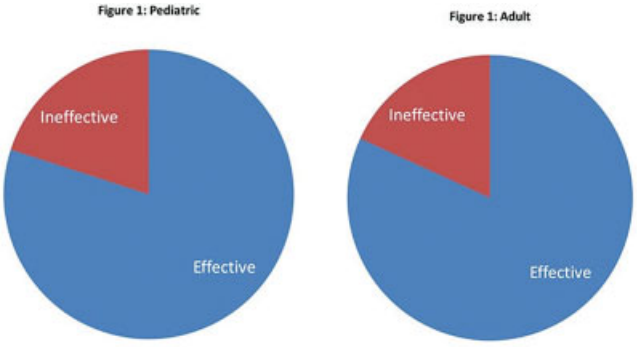
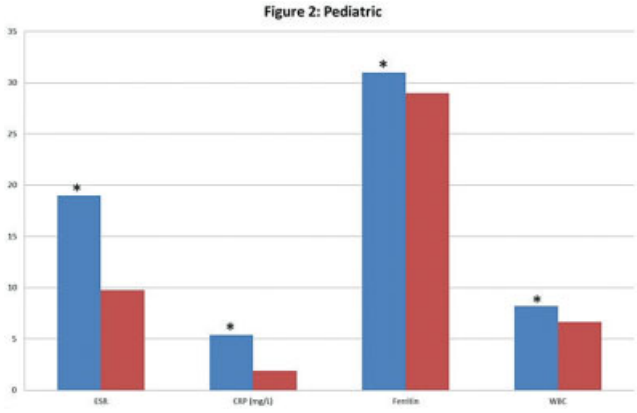
The Interleukin-1 Receptor Antagonist Anakinra Is Effective In The Treatment Of Undifferentiated Periodic Fever Syndromes. Daniella M. Schwartz[1], Runsheng Wang[2], Karyl S Barron[3], Daniel L. Kastner[4] and Amanda K. Ombrello[5]. [1]National Institutes of Health, National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, [2]NIH/NIAMS, Rheumatology fellowship and training branch, Bethesda, MD, [3]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, [4]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, [5]National Human Genome Research Institute, National Institute of Health, Bethesda, MD.

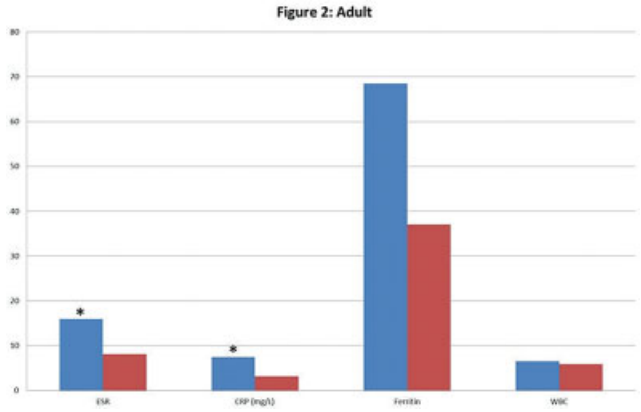
Background/Purpose: The autoinflammatory diseases are a group of disorders associated with dysregulation of the innate immune system. They are characterized by recurrent episodes of fever and systemic inflammation, typically presenting in early childhood. Since 1999, genetic causes have been discovered for several autoinflammatory diseases. Many patients with periodic fevers, however, are negative when tested for these mutations. Although the efficacy of interleukin-1 (IL-1) blockade in the known autoinflammatory diseases is established, this has not been systematically explored in the treatment of mutation-negative periodic fever syndromes. We describe our experience treating this heterogeneous group of children with the IL-1 receptor antagonist anakinra.

Methods: Records from patients enrolled in protocol 94-HG-0105 "Genetics and Pathophysiology of Familial Mediterranean Fever and Related Disorders" who were prescribed anakinra from 2009–2013 were reviewed. Patients were identified who had tested negative by commercially available methods for mutations known to cause autoinflammatory disease (MEFV, TNFRSF1A, NLRP3, and MVK). Results were confirmed by targeted sequencing. Medical records were reviewed for response to treatment based on patient-reported improvement in number or severity of flares. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), white blood cell (WBC) count, and ferritin values before and after treatment were obtained.

Results: Of 69 pediatric patients prescribed anakinra, 56 tested negative for mutations known to cause periodic fevers; longitudinal data were available in 35 children. 28 of 35 (80%) patients described a clinical response to anakinra (Figure 1). Decreases in erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), white blood cell (WBC) count, and ferritin were statistically significant. Adverse reactions were minimal and consisted solely of injection site reactions. Of note, similar results were seen in the adult population, with 18 of 22 (82%) of patients describing a clinical response to anakinra, and statistically significant reduction in ESR and CRP.







Conclusion: Anakinra is safe and effective in the treatment of undifferentiated periodic fever syndromes.

Urinalysis Monitoring In Children With Henoch-Schönlein Purpura: Is It Time To Revise? Hao Wang[1], Manasita Tanya[2], Justin Hung Tiong Tan[2], Sook Fun Hoh[2], Lena Das[2] and Thaschawee Arkachaisri[3]. [1]Duke-NUS Graduate Medical School, Singapore, Singapore, [2]KK Women's and Children's Hospital, Singapore, Singapore, [3]KK Women's and Children's Hospital and Duke-NUS Graduate Medical School, Singapore, Singapore.

Background/Purpose: Major complication of Henoch-Schönlein Purpura (HSP) is renal impairment. Recommended urinalysis (UA) monitoring over a period of 2 years has been a common practice in many pediatric rheumatology centers. Cost-effectiveness following this guideline is questionable. We explore the natural history of UA outcomes in our inception HSP cohort.

Methods: Patients with HSP with at least 6 mo follow-up and seen between 3/2009 and 6/2013, at our institute were recruited. A 2-year UA monitoring protocol was adopted (monthly for 6 mo, if normal then every 3 months for 18 mo). Minimal renal involvement was defined as isolated hematuria (urine RBC > 5/hpf) and/or proteinuria (urine protein > 1+), and renal impairment as presentation of nephritic, nephrotic symptoms, or renal failure. Recurrent HSP were excluded. Kaplan-Meier estimate and log-rank test were used to analyze the differences between groups for time to event. Logistic regression was used to assess relationships of cofactors.

Results: 56 patients (43% F) were analyzed. The ethnicity of our cohort reflected Singapore racial distribution. Majority of referrals (80%) were admitted. The median duration of follow up was 17.2 (10.6–24.2) mo. Over 1/2 of patients had subcutaneous edema and elevated serum IgA. 29 patients presented with abnormal UA at diagnosis (n=16, 55.2%, 5/16 developed renal impairment within 2 mo) or during follow up (n=13, 44.8%). Only one patient (7.7%) developed abnormal UA after 6 mo. UA was normalized in 24 patients during follow up, within a median time of 9.1 (95% CI: 3.5–14.6) mo. No association between demographic or clinical features and different renal outcomes was unveiled. Among patients with no renal impairment, an earlier subsidence of renal involvement ($p = 0.009$) was noted in patients with normal UA at diagnosis (n=13, median time: 2.9 mo, 95% CI: 1.5–4.4; 11 cases (84.6%) resolved by 12 mo), compared to children with abnormal UA at diagnosis (n=7, median time: 15.7 mo, 95% CI: 6.7–24.7). Non-renal indication of prednisolone use did not affect time to UA subsidence ($p = 0.32$).

Table 1. Patient characteristics, treatments and outcomes

DEMOGRAPHIC			
Age of Onset (years) (Median, IQR)	4.8 (3.8–6.5)		
Race	Chinese 43 (76.8%), Malay 8 (14.3%), Indian 1 (1.8%), Others 4 (7.1%)		
CLINICAL MANIFESTATIONS			
Previous infection	32 (57.1%)		
Rash	56 (100%)		
Subcutaneous edema	35 (62.5%)		
Abdominal pain	24 (42.9%)		
Arthritis	5 (8.9%)		
High IgA[a]	27 (64.1%)		
ESR (Median, IQR)[b] (Reference: 0–10 mm/50 min)	20.0 (10.0–32.0)		
CRP (Median, IQR)[c] (Reference: 0–9.9 mg/L)	8.6 (5.3–30.4)		
WBC (Median, IQR)[d] (Reference: 5.5–15.5×10^9/L)	11.9 (9.6–13.9)		
Platelets (Median, IQR) [d] (Reference: 150–450×10^9/L)	363.0 (303.8–459.8)		
TREATMENT			
Prednisolone	Renal impairment	N	5
		Duration (weeks) (median, IQR)	33.6 (23.5–51.8)
	Other indications	N	29
		Duration (weeks) (median, IQR)	8.0 (4.0–9.9)
Immunosuppressant		3 (5.4%)	
RENAL OUTCOME			
Normal UA at diagnosis	40 (71.4%)	Normal UA during follow up	27 (67.5%)
		Minimal renal involvement during follow up	13 (32.5%) **Abnormal UA** 29 (51.8%)
Minimal renal involvement at diagnosis	16 (28.6%)	Renal involvement resolved during follow up	7 (43.8%)
		Renal involvement persisted	4 (25.0%)
		Renal impairment during follow up	5 (31.3%)

a: Out of 41 patients with IgA tested, as per normal range for age.
b: Erythrocyte sedimentation rate, out of 39 patients with ESR tested.
c: C-reative protein, out of 35 patients with CRP tested.
d: White blood cells and platelets, out of 50 patients with CBC tested.

Conclusion: Several observations were demonstrated in our cohort: 1. One-third of normal UA at diagnosis developed abnormal UA and majority (92.3%) did so within the first 6 months. 2. Resolution of abnormal UA at diagnosis was slower than that of abnormal UA later. 3. As expected, the use of corticosteroids had no effect on time to UA resolution. With these findings, we propose a shorter duration of UA monitoring to 6 months in HSP patients with normal UA at diagnosis and follow up. A shorter duration of 12 months from onset of abnormal UA may be adequate for HSP patients with normal UA at diagnosis. Patients with abnormal UA at diagnosis may be followed up for a minimum of 24 months. This proposal is being evaluated and validated in our longitudinal cohort study with collaboration with other centers in the region.

Systematic Analysis and Pathologic Findings In Young Adults With Sudden Death Attributed To Kawasaki Disease In Childhood. Chisato Shimizu[1], Alka Sood[1], Hubert Lau[1], Steven Campman[2] and Jane C. Burns[1]. [1]UC San Diego, School of Medicine, La Jolla, CA, [2]San Diego County Medical Examiner Office, La Jolla, CA.

Background/Purpose: Coronary artery aneurysms (CAA) may remain silent after Kawasaki disease (KD) until adulthood when myocardial ischemia can lead to sudden death. CAA attributed to antecedent KD were present in 5% of young adults (<40 years (yrs)) evaluated for symptoms of myocardial ischemia by coronary angiography (Daniels et al. 2012). We postulated that there would be young adults with sudden, unexpected death due to CAA from KD who would have a state-mandated autopsy performed by the Medical Examiner (ME).

Methods: We systematically reviewed all autopsy cases < 35 yrs of age from 1997–2012 at the San Diego County ME Office with a cardiovascular cause of death. Cases were excluded if another medical condition was listed as a contributing factor to death including trauma, substance abuse, suicide, cancer, congenital heart disease, morbid obesity, diabetes, hypertension, or hyperlipidemia. We reviewed the ME records for demographic data, clinical history, and gross and histologic autopsy findings. For the two cases adjudicated as KD, the parents of the decedents were interviewed following written informed consent.

Results: There were 154 cases that met inclusion criteria and122 cases (80%) met exclusion criteria. Of the 32 cases reviewed, two (6.25%) had CAA described in the autopsy report. Case 1 was a 30-yr old Hispanic male with no significant medical history or cardiovascular risk factors who collapsed after a boxing work out. Cause of death was myocardial infarction due to thrombosis of the left anterior descending (LAD) aneurysm. Histologic findings included myocardial fibrosis a re-canalized aneurysm in right coronary artery (RCA) with multiple

lumens, and calcification of the LAD aneurysm wall with thinned media and organized and acute thrombus. Interview of the parents revealed a possible KD-compatible illness in childhood diagnosed as scarlet fever. Case 2 was a 22-yr old Korean male who collapsed during vigorous exercise. Sudden cardiac death was associated with chronic ischemic changes due to a partially occluded 15mm aneurysm at the bifurcation of the LMCA and LAD with diffuse calcification. There were two 6mm aneurysms of the RCA. There was patchy fibrosis throughout the myocardium. Interview of the mother revealed that this patient had been diagnosed with KD complicated by giant aneurysms at age 2.75 yrs. He had been maintained on aspirin therapy under the care of a cardiologist until he left home at age 20 yrs. Detailed immunohistochemical studies of these two cases are pending.

Conclusion: In an ME office serving a population of approximately 3 million people, 2/154 (1.3%) of cardiovascular deaths in persons <35 yrs could be attributed to CV complications of KD in childhood. Pathologic findings that support a diagnosis of antecedent KD include aneurysms with or without thrombosis, recanalization, or stenosis, luminal myofibroblastic proliferation, and CA wall calcification. Antecedent KD leading to myocardial ischemia or thrombosed aneurysms should be considered in the evaluation of all cases of sudden, unexpected death in young adults.

Relationships Between Physician and Patient Scored Clinical Outcome Measures In Pediatric Localized Scleroderma. Kaveh Ardalan, Christina Kelsey and Kathryn S. Torok. Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA.

Background/Purpose: Pediatric localized scleroderma (LS) is an autoimmune disease of the skin and underlying tissue leading to sclerosis and complications such as joint contractures. The impact of this disease on children and their parents has not been well described. Most published studies on LS outcomes have centered on physician based cutaneous assessment. Patient based outcomes are a critical component of research in disease management and clinical trials. The Childhood Dermatology Life Quality Index (CDLQI) is a quality of life (QOL) measure designed for pediatric skin conditions. The aim of this study is to explore the relationships between physician and patient scored measures of disease outcomes in pediatric localized scleroderma as compared to the CDLQI.

Methods: Patients included in this cohort were those with completed CDLQIs enrolled in the National Registry for Childhood Onset Scleroderma from 2007–2013. The following measures were extracted from the database for each patient; the modified Localized Scleroderma Skin Severity Index (mLoSSI), the Localized Scleroderma Damage Index (LoSDI), Physician Global Assessment of Activity, Damage and Severity (PGA-A, PGA-D, and PGA-S), CDLQI and patient and parent Global Assessment of Disease Impact (GA-Pt, GA-Par). Relationships between the physician and patient reported clinical measures were examined using Spearman's correlations ($p<0.05$).

Results: Sixty-eight subjects were identified. The majority were female (72%) and Caucasian (94%), and were representative of the major LS subtypes in pediatric onset disease. The median age of onset was 7.8 years old (IQR 4.4–10.3) and age at first clinic visit was 11.2 years old (IQR 8.1–14.7). Fifty-six patients had follow-up visits to include in the analyses. The relationships between the clinical outcomes and QOL measures at the initial and follow-up visits were similar. The median CDLQI decreased from 3 (IQR 1–7) at initial visit to 2 (IQR 1–4) at follow-up visits. The impact of disease on patient and parent decreased accordingly, with median GA-Pt 37.5 (IQR 8.8–64.3) at baseline and 9 (IQR 2–23.5) at follow-up, and median GA-Par 43 (IQR 9–67) at initial visit and 12 (5.0–33.8) at follow-up visit. CDLQI moderately and significantly correlated with the GA-par and GA-patient (rho = 0.584, 0.591, respectively). The GA-pt and GA-par were moderately and significantly related to each other (rho = 0.615). The clinician-scored outcome measures did not show a strong correlation to the CDLQI. At the initial visit, the LoSDI was weakly though significantly correlated (rho=0.256), and at the follow-up visits the PGA-A was weakly though significantly correlated (rho=0.284) to the CDLQI.

Conclusion: At this time, clinical outcomes in LS are based primarily on physician scored measures. However, the CDLQI did not correlate to the physician scored measures in this sample, but it did correlate to the patient's and parents' overall perception of disease impact. This study suggests that patient and parent global assessments are measuring the same underlying construct as the CDLQI but further study will be required to better clarify the nature of this construct and the reasons for the disconnect between the CDLQI and physician scored disease measures.

A Pilot Study Of Juvenile Localized Scleroderma (jLS) Consensus Treatment Plans. Suzanne C. Li[1], Kathryn S. Torok[2], Mara L. Becker[3], Fatma Dedeoglu[4], Robert C. Fuhlbrigge[5], Gloria C. Higgins[6], Sandy D. Hong[7], Maria F. Ibarra[3], Ronald M. Laxer[8], Thomas G. Mason II[9], Elena Pope[8], Marilynn G. Punaro[10], C. Egla Rabinovich[11], Katie G. Stewart[12], Christina Kelsey[13], Brian Feldman[14], Themba Nyrienda[15] and Knut M. Wittkowski[16]. [1]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [2]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [3]Children's Mercy Hospital, Kansas City, MO, [4]Boston Childrens Hosp, Boston, MA, [5]Childrens Hospital, Boston, MA, [6]Nationwide Childrens Hosp, Columbus, OH, [7]U of Iowa Children's Hosp, Iowa City, IA, [8]The Hospital for Sick Children, Toronto, ON, [9]Mayo Clinic Rochester, Rochester, MN, [10]University of Texas Southwestern Medical Center, Dallas, TX, [11]Duke Univ Med Ctr, Durham, NC, [12]Texas Scottish Rite Hospital, Dallas, TX, [13]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [14]Hospital for Sick Kids, Toronto, ON, [15]Hackensack University Medical Center, Hackensack, NJ, [16]Rockefeller University, New York, NY.

Background/Purpose: Purpose: To evaluate clinical assessment tools and standardized treatment regimens (consensus treatment plans, CTPs) developed for juvenile localized scleroderma (jLS)

jLS is a chronic, inflammatory and fibrosing disease often associated with severe morbidity in the growing child. Over 20% of the jLS subjects enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry have joint contractures and >10% have a limb length difference. A major issue with evaluating the relative efficacy of the many reported treatments has been the lack of agreed upon assessments and criteria for evaluating treatment response. Our CARRA subgroup recently developed jLS disease assessments, response criteria, and CTPs that reflect current treatment practices of CARRA members, and the performance characteristics of these tools and feasibility of conducting comparative effectiveness treatment studies will be evaluated in a pilot study.

Methods: We are conducting a prospective, multi-center (10 CARRA sites), 1 year observational study of a cohort of 50 jLS patients beginning treatment with one of three methotrexate (MTX)-based CTPs (MTX alone, MTX with oral corticosteroids [CS], or MTX with intravenous CS), with study data entered into the existing web-based CARRA Registry. The treating physician determines which CTP to use. Collected data includes scoring of clinical activity and damage parameters, scoring of joint/limb morbidity; medication log; adverse events; physician global assessments (PGA) for activity, damage, and response to treatment; and patient and parent quality of life measures. There is an optional patient sample collection substudy. A reliability workshop meeting was held at study onset to review and evaluate the reliability of scoring the clinical assessments with 14 study physicians scoring 13 jLS patient volunteers two times.

Results: There was moderate inter-rater reliability for clinical activity and damage scoring (Kendall's coefficient 0.628 and 0.508, respectively), and high intra-rater reliability (average Spearman's rho 0.783 for activity, 0.743 for damage). Some parameters appeared more problematic, with lower reliability scores found for the activity parameters of lesion warmth, violaceous color, and skin thickness of lesion edge, and for the damage parameters hypopigmentation, and dermal atrophy. Since study enrollment began in 12/2012, 18 subjects from 9 sites have been enrolled. Nearly all subjects have agreed to participate in the optional biosample collection

Conclusion: We have currently achieved 36% of our target enrollment of 50 jLS subjects into our pilot study. This study enables evaluation and refinement of clinical tools for assessing disease state and treatment response based upon patient data. This study will allow us to evaluate feasibility issues related to the developed CTPs and with conducting comparative effectiveness treatment studies. Because the biorepository being developed is linked to extensive clinical data in a prospective registry, these samples potentially will allow the identification of biomarkers associated with good versus poor outcome, as well as better understanding of disease pathogenesis.

Juvenile Onset Systemic Sclerosis: Clinical and Serological Features, and Mortality In Comparison With Adult Onset Disease. Juan G. Ovalles-Bonilla, Francisco Javier López-Longo, Indalecio Monteagudo, Esperanza Naredo, Carlos Gonzalez Fernandez, María Montoro Alvarez, Lina Martínez-Estupiñán, Juan C. Nieto, Julia Martínez-Barrio, Michelle Hinojosa, Natalia Bello, Belen Serrano, Carmen Mata and Luis Carreño. Hospital General Universitario Gregorio Marañón, Madrid, Spain.

Background/Purpose: Currently data regarding long-term outcome of juvenile systemic sclerosis (jSSc) is scarce. To describe the differences between patients with jSSc versus adult onset evaluated at a single medical center.

Methods: Patients with disease onset before the age of 17 years were included in the jSSc group, while subjects with SSc onset after age 18 formed the adult-onset cohort. The 2 groups were compared with respect to disease classification, clinical, serological data, and mortality.

Results: Seventeen jSSc cases seen between 1986 and 2011 were compared with 120 adult onset SSc cases. Mean age at onset in the jSSc group was 11.7±3.9 years, and the mean disease duration at the last follow-up was 19.3±7.8 years. The sex distribution was 7.5:1 (female:male). Among juvenile cases, 58.8% had diffuse SSc, while 41.2% had limited SSc. The clinical features seen in juvenile patients were: articular manifestations (arthralgia, arthritis, contractures and weakness) in the 100% of cases, Raynaud's phenomenon in 94%, digital ulcers and telangiectasia in 53%, interstitial lung disease in 11.8%. Antinuclear antibody was positive in 100%, and anti-U1RNP in 64.7%. A global mortality of 17.6% was seen. Articular manifestations, anti-DNA and anti-U1RNP were seen more frequently in the jSSc group. Adult onset SSc develop a higher frequency of sclerodactyly and interstitial lung disease.

Table 1. Clinical and serologic features, and mortality in comparison with adult onset disease

FEATURES (%)	Juvenile SSc n=17	Adult SSc n=120	p
Age at disease onset ± DE	11.7±3.9	46.5±14.4	<0.001
Disease duration ± DE	19.3±7.8	14.6±10.5	0.07
Diffuse SSc	10 (58.8)	52 (43.3)	0.23
Limited SSc	7 (41.2)	68 (56.7)	
sclerodactyly	5 (29.4)	68 (56.7)	0.03
Telangiectasia	9 (52.9)	74 (61.7)	0.49
Digital ulcers	9 (52.9)	80 (66.7)	0.27
Raynaud's phenomenon	16 (94.1)	111 (92.5)	0.81
Pulmonary Hypertension	2 (11.8)	9 (7.5)	0.54
Interstitial lung disease	2 (11.8)	49 (40.8)	0.02
Articular manifestations	17 (100)	71 (67.5)	0.005
Renal manifestations	3 (17.6)	17 (14.2)	0.70
Anti-centromere	3 (17.6)	36 (30)	0.29
Anti-Scl-70	2 (11.8)	30 (26.1)	0.19
ANA	17 (100)	109 (90.8)	0.19
Anti-DNA	5 (31.2)	11 (9.9)	0.016
Anti-U1RNP	11 (64.7)	13 (12.9)	<0.001
Mortality	3 (17.6)	31 (25.8)	0.46

jSSc: Juvenile Systemic Sclerosis, **SSc:** Systemic Sclerosis, **ANA:** antinuclear antibodies

Conclusion: Diffuse SSc, limited SSc, calcinosis, digital ulcers, pulmonary hypertension, anti-centromere, anti-Scl-70 and mortality shows a similar distribution between the 2 groups. Patients with jSSc presented a lower frequency of interstitial lung disease and sclerodactyly, but a higher expression of anti-DNA and anti-U1RNP.

2179

Consensus: What Agent To Use When First-Line Vasodilatadors Fail In Raynaud's Phenomenon Or Digital Ulcers Secondary To Juvenile Systemic Sclerosis? Marìa M. Katsicas[1], Mariana Gonzalez[2] and Ricardo A. G. Russo[3]. [1]Hospital de Pediatrìa Garrahan, Buenos Aires, Argentina, [2]Hospital de Pediatría Garrahan, Buenos Aires, Argentina, [3]Hospital de Pediatria Garrahan, Buenos Aires, Argentina.

Background/Purpose: Juvenile Systemic Sclerosis (JSS) is characterized by Raynaud's phenomenon (RP) and digital ulcers (DU).Conventional therapy includes calcium channel blockers (CCB). A growing number of vasodilators is available for treatment of refractory patients but there is no clear evidence of the best option. To aid clinical decision-making, an expert consensus was undertaken. Our objective was to identify the best therapeutic options and define the sequence of 2nd line vasodilators for RP and DU.

Methods: Steps in the process of consensus were: a) Identification of expert panel (EP) members, b) Identification of 2nd line vasodilators c) selection of outcome measures to define RP and DU improvement, d) systematic literature review; e) summary report of the latest scientific evidence f) expert consensus meeting; g) rating of the strength of evidence. RAND/UCLA appropriateness method was used for rating the medical decision: items were rated on a 9-point scale for each drug option. There were 2 scoring rounds: 1) anonymous and independent rating of the appropriateness of vasodilators based on scientific evidence and best clinical judgment. 2) Differences in scoring were discussed at a face-to-face meeting in a second rating round. Consensus was reached on appropriate / inappropriateness.

Results: The EP included 10 physicians from a tertiary center who are involved in the care of patients with JSS: 3 pediatric rheumatologists, 2 dermatologists, 1 pediatrician, 1 gastroenterologist, 1 nephrologist, 1 nutricionist, 1 pharmacologist, and a moderator. The EP identified 4 drugs for analysis: bosentan, iloprost, sildenafil, and trepostinil. Outcome measures were selected according to the literature references and EP judgment. RP improvement definition: ≥ 30% improvement according to the physician (in a visual analogue scale, VAS) and ≥ 30 % improvement in at least 2 patient-related domains (pain or function). Patient domains were: a) number of episodes, b) pain in a VAS, c) function (impaired activity of daily living, VAS), d) RP episodes average duration (in minutes). DU improvement definition: a favorable change in all physician- and patient-related domains: patient's domains: a) pain (VAS) b) function (VAS); physician′s domains: a) ulcer activity (VAS) b) horizontal and transverse DU diameter (in mm). Systematic literature review was performed independently by 5 EP members and guided by the moderator. All articles in English were eligible. Data bases included PuBmed and Cochrane. The search strategy included all relevant terms: bosentan, iloprost, sildenafil, trepostinil, RP, DU, combined in different sets of keywords. The summary report of the scientific evidence included 25 articles. Ranking of papers according to the strength of evidence showed: 1a (1 paper), 1b (7), 2b (2), 3b (2), 4(8), 5(5). After second scoring round consensus was reached: 1st appropriate indication Iloprost; 2nd bosentan, 3rd sildenafil; 4th trepostinil.

Conclusion: The EP reached a consensus on vasodilator drugs, providing direction for common dilemmas in the pharmacologic treatment of RP and DU in refractory patients.

Presentation, Diagnosis, and Treatment Of Chronic Recurrent Multifocal Osteomyelitis. Colin Anderson[1], Erin Wylie[2], Travis Heare[2], Jamie Stewart[2], Kelley Capocelli[2], Shelley Dell'Orfano[2] and Jennifer Soep[2]. [1]The University of Colorado, Aurora, CO, [2]Children's Hospital Colorado, Aurora, CO.

Background/Purpose: Chronic recurrent multifocal osteomyelitis (CRMO) is a rare, non-infectious inflammatory bone disorder in children. Knowledge about the disorder is limited secondary to its rare prevalence, often resulting in delayed diagnosis and unnecessary treatments. The purpose of this study is to report on one of the largest cohorts yet gathered for CRMO in order to provide more information about the presentation, diagnosis, and treatment.

Methods: Retrospective chart review was performed in 57 patients diagnosed with suspected CRMO (n = 32) or biopsy-confirmed (n = 25) at our institution over a 2-year period at a single tertiary referral center. Collected outcome measures included: gender, age at symptom onset, age at CRMO diagnosis, prior diagnosis, secondary diagnosis, antibiotic use, radiographic, laboratory and histology findings, treatment type and outcome, complications, duration of symptoms, and follow-up.

Results: The average age at symptom onset was 6.1 years (Range: 0.7–12.3 years). The average delay in diagnosis was 13.4 months (Range: 0.8–62.5 months). Incorrect initial diagnoses occurred in 56% of cases, resulting in 44% of patients unnecessarily treated with antibiotics prior to CRMO diagnosis. In 63% of cases, normal radiographs at presentation were observed. However, abnormal MRI findings were present in 100% of patients, with multifocal involvement in 75% of those studies. Average white blood cell count, erythrocyte sedimentation rate, and C-reactive protein at presentation were 11,600 /μL, 40.1 mm/hr, and 2.4 mg/dL, respectively. All biopsy

cultures were negative. Non-steroidal anti-inflammatory drugs (NSAIDs) provided complete symptomatic relief in 66% of patients, while 33% of patients required further treatment with methotrexate, steroids and/or TNF inhibitors.

Conclusion: Awareness of defining features of CRMO such as indolent onset of pain, multifocal involvement, presence of early MRI findings, inflammatory pathologic findings with sterile cultures, and marked clinical response to NSAIDs may assist with earlier diagnosis. Understanding of the clinical presentation of CRMO will assist healthcare providers in avoiding unnecessary treatments and lead to a quicker resolution of symptoms in patients diagnosed with this rare disease.

Methotrexate and Infliximab With Or Without Zoledronic Acid Improve Disease Activity and Prevent Damage Progression In Chronic Nonbacterial Osteomyelitis. Yongdong (Dan) Zhao[1], Nancy Chauvin[1], Diego Jaramillo[1] and Jon Burnham[2]. [1]Children's Hospital of Philadelphia, PHILADELPHIA, PA, [2]The Children's Hospital of Philadelphia and the Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Chronic nonbacterial osteomyelitis (CNO) is an inflammatory bone disease that causes pain, disability, and sometimes permanent skeletal damage. MRI allows for visualization of bone edema, soft tissue inflammation (STI), periosteal reaction (PR), and characteristics of bone damage, such as growth plate bony bar formation and vertebral collapse. However, no standard MRI-based outcomes have been validated in CNO. This retrospective study aimed to assess changes in CNO activity and damage after tumor necrosis factor alpha inhibitor (TNFi) and methotrexate therapy using a standard MRI scoring method.

Methods: Children 2–18 years of age with CNO were included if paired MRI scans were performed $\leq$ 2 months prior to and $\geq$ 2 months after TNFi initiation. Clinical and laboratory data before and after TNFi therapy were recorded. Unique inflammatory lesions, bone edema severity, STI severity, total lesion number with PR, total lesion number with hyperostosis, bony bar severity, vertebral compression severity, and the number of inflamed joints were recorded by a single radiologist (NC). The Wilcoxon matched pairs signed-ranks test was used to compare changes after TNFi.

Results: Nine CNO patients treated with TNFi met inclusion criteria. All received infliximab (IFX) and concomitant methotrexate (MTX). All nine (6 females) were Caucasian. Mean age was 12 $\pm$ 4 years. Seven patients previously received antibiotics, NSAIDs, prednisone, bisphosphonate, and/or MTX. The median duration between diagnosis and initiation of IFX was 6.8 months (range: 0.5–19.3). Baseline MRI was obtained 1.0 $\pm$ 0.7 months prior to IFX and the follow up MRI was obtained 6.7 $\pm$ 3.7 months later. Paired site-specific scans were obtained in 6, and whole body scans in 3 patients. The mean dose of IFX was 8.1 $\pm$ 1.9 mg/kg, every 4–8 weeks. Five of six patients received zoledronic acid for vertebral lesions. The numbers of patients with lesions at specific sites were: spine (5), pelvis (6), clavicle (2), long bone (4), and mandible (1). At the visit closest to the follow up MRI, significant reductions were seen in the median pain score (4 to 0, $p<0.01$), patient global assessment (3 to 0, $p<0.01$), physician global assessment (2 to 0, $p<0.01$), and Childhood Health Assessment Questionnaire (0.25 to 0, $p=0.02$). There were significant reductions in the erythrocyte sedimentation rate (15 to 5 mm/hour, $p=0.01$) and C reactive protein levels (0.8 to 0.5 mg/dL, $p=0.03$). Significant decreases in the median total inflammatory lesion number (5 to 2, $p=0.03$) and maximum bone edema score (2.2 to 1.3, $p=0.02$) were observed. Maximum STI score and inflamed joint count decreased, but not significantly. Periosteal reaction ($n=2$) and hyperostosis ($n=1$) resolved. Skeletal damage severity, including bony bar formation and vertebral compression, did not progress.

Conclusion: In this retrospective study, IFX and MTX with or without zoledronic acid for CNO resulted in significant clinical and radiographic improvement. Standard MRI assessment demonstrated reductions in active bone lesions and bone edema severity without worsening of spine or growth plate damage. Prospective studies are needed to assess the reliability and validity of standardized MRI protocols.

Spectrum Of Musculoskeletal Inpatient Diagnoses At The Largest Pediatric Center In East Africa In 2011. Angela Migowa[1], Ines Colmegna[2], Evelyne Ng'ang'a[3], John Wachira[4], Thomas Ngwiri[4], Carol A. Hitchon[5], Sasha Bernatsky[6] and Rosie Scuccimarri[7]. [1]Aga Khan University Hospital, Nairobi, Kenya, [2]McGill University Health Centre, Montreal, QC, [3]University of Nairobi, Nairobi, Kenya, [4]Gertrude's Children Hospital, Nairobi, Kenya, [5]University of Manitoba, Winnipeg, MB, [6]McGill University Health Center, Montreal, QC, [7]Montreal Children's Hospital and McGill University, Montréal, QC.

Background/Purpose: Pediatric rheumatic diseases are among the most common chronic illnesses of childhood and can cause considerable disease burden and disability. The frequency and outcomes of pediatric rheumatic conditions in East Africa are unknown. Defining the spectrum of inpatient diagnoses is critical to designing a context-specific educational program targeting African pediatricians and pediatric trainees to improve diagnosis and treatment of children with these conditions.

Methods: In order to assess the spectrum of diseases seen on the inpatient service from January to December 2011 at Gertrude's Children Hospital, the largest pediatric center in East-Africa, patients identified as having diseases of the musculoskeletal (MSK) system and connective tissues (CT) by ICD-10 diagnostic codes ('M-codes') at discharge were included. After IRB approval, the admission records of these patients were reviewed locally and the de-identified information sent to the McGill investigators. Diagnoses were validated by two independent rheumatologists using information gathered from the medical records as well as laboratory and microbiology investigations. True cases were defined as those with recorded clinical evidence corresponding to the standard definition of the 'M-code' assigned by the local physician. Frequencies of each 'M-code' identified were then calculated.

Results: The total number of admissions to Gertrude's Hospital during 2011 was 8,011. Among those, 35 patients were identified as having an 'M-code' diagnosis at discharge. When the records were reviewed, non-MSK conditions accounted for 20% (7 cases) of all 'M-code' admissions. Minor surgical procedures made up 14.3% (5 cases). When both of these were excluded, diseases of the MSK system and CT represented 0.28% of the total admissions in 2011. Validated diagnoses were classified as inflammatory arthropathies (39.1% or 9 cases), septic arthritis (30.4% or 7 cases); soft tissue and muscle infections (17.4% or 4 cases) and Kawasaki disease (KD) (13.1 % or 3 cases).

Conclusion: Following the exclusion of misclassified patients and the validation of true diagnoses, diseases of the MSK and CT represented 0.28% of the total admissions to the largest pediatric referral center during 2011. The spectrum of rheumatic conditions requiring admissions included inflammatory and infectious arthropathies, soft tissue and muscle infections, and KD. Surprisingly, there were no admissions for lupus and other systemic vasculitides beyond KD during the studied time interval. This may indicate under-diagnosis of these conditions, poor sensitivity of 'M-codes' to identify these diseases or a true low frequency of these diagnoses. Although using 'M-codes' to identify rheumatic conditions may have its limitations, this study was the first step at identifying the frequency of these conditions in this inpatient population.

Spectrum Of Outpatient Musculoskeletal Visits At The Largest Pediatric Center In East Africa In 2011. Laurel Broten[1], Angela Migowa[2], Rosie Scuccimarri[3], Evelyne Ng'ang'a[4], John Wachira[5], Thomas Ngwiri[5], Sasha Bernatsky[6], Carol A. Hitchon[7] and Ines Colmegna[8]. [1]McGill University, Montreal, QC, [2]Aga Khan University Hospital, Nairobi, Kenya, [3]Montreal Children's Hospital and McGill University, Montréal, QC, [4]University of Nairobi, Nairobi, Kenya, [5]Gertrude's Children Hospital, Nairobi, Kenya, [6]McGill University Health Center, Montreal, QC, [7]University of Manitoba, Winnipeg, MB, [8]McGill University Health Centre, Montreal, QC.

Background/Purpose: Pediatric rheumatic diseases are a major cause of morbidity, frequently leading to permanent disability, impaired functional status and quality of life, and significant direct and indirect costs to patients

and society. The prevalence and burden of pediatric rheumatic diseases in Sub-Saharan Africa are largely unknown. As a first step to design and promote policies to improve rheumatic patients' outcomes, we performed a cross-sectional study to evaluate the frequency and validity of the use of musculoskeletal ICD-10 diagnostic codes among outpatients at the largest pediatric center in East-Africa and its outreach clinics.

Methods: Using the Kranium database, the electronic medical record system containing all billing data for Gertrude's Children's Hospital System (GHS), we extracted all diagnoses classified under the ICD-10 codes for musculoskeletal (MSK) conditions (M00-M99) from pediatric outpatient visits recorded between January and December 2011. Frequencies were calculated for each disease category and subcategory within these ICD-10 categories. For cases coded in the category 'arthropathies' (M00-M25), the assigned ICD-10 diagnosis was verified against the patient's history, physical examination and investigations by two independent rheumatologists. True cases were defined as those with recorded clinical evidence corresponding to the ICD-10 code assigned by the local physician.

Results: Out of the 22 categories of all diseases in ICD-10, MSK conditions (M00-M99) were the 11th most commonly billed category at GHS, and more frequent than neoplasms and cardiovascular codes. The period prevalence of M-code diagnoses for outpatient consults at GH was 0.52% (1,197 total M-code consults / 232,273 total consults). The most frequent M-code categories assigned by local physicians corresponded to 'soft tissue disorders' (M60-M79) (57% of all M-code diagnoses) and 'arthropathies' (31%). Among the arthropathies an over-all diagnosis agreement of 36% was found between the M-code used and the verified clinical evidence recorded with 0% of agreement for the category of 'arthrosis' (M15-M19), 40% for the category of 'inflammatory arthropathies' (M05-M14) and 31% for 'other joint disorders' (M20-M25). Misclassification of patients with potential inflammatory and/or infectious diagnoses occurred in 50 out of 333 visits. After re-assigning diagnoses whose initial ICD-10 M code was found to be inaccurate, the most frequent MSK conditions seen were trauma (M12.5) (29%), inflammatory arthropathies (M05-M14) (20%) and pain in joint (M25.5) (15%).

Conclusion: Musculoskeletal conditions captured by M-codes are frequent among outpatient consults at the largest pediatric center in East-Africa. Trauma, inflammatory arthropathies and arthralgias all-together accounted for two-thirds of all MSK diagnoses. The lack of representation of systemic autoimmune diseases raises concern regarding their potential under-diagnosis or misclassification. Training local clinicians to recognize potential inflammatory conditions may help to improve the outcome of pediatric rheumatic disorders in Africa.

Application Of The Bonexpert Method For Bone Age and Bone Health Assessment In Patients With Juvenile Idiopathic Arthritis. Charlotte M. Nusman[1], Janneke Anink[2], Lisette W.A. van Suijlekom-Smit[2], Marion A.J. van Rossum[3], Mario Maas[1] and Rick R. van Rijn[1]. [1]Academic Medical Center, Amsterdam, Netherlands, [2]Erasmus MC Sophia Children's Hospital, Rotterdam, Netherlands, [3]Emma Children's Hospital / Academic Medical Center and Reade Institute, Amsterdam, Netherlands.

Background/Purpose: Both the maturation of bone and its mineral density are affected by chronic inflammation in juvenile idiopathic arthritis (JIA). Bone age is in most cases assessed by a pediatric radiologist using a bone age standard atlas, usually the 'Radiographic Atlas of Skeletal Development of the Hand and Wrist' by Greulich and Pyle. Dual-energy X-ray densitometry (DXA) is the most commonly used method to assess bone density. Recently however, the old method of radiogrammetry has regained attention with the development of BoneXpert, an automated method of assessing bone age (BA) and bone density expressed in the Bone Health Index (BHI), using conventional hand X-rays. The objective of this study was to apply BoneXpert, measuring BA and BHI, in JIA patients prior to starting etanercept.

Methods: Radiographs of both right and left hand were collected for 63 patients (2 systemic JIA, 20 polyarthritis RF negative, 7 polyarthritis RF positive, 15 extendend oligoarthritis, 1 enthesitis related arthritis, 4 psoriatic arthritis) included in the Dutch Arthritis and Biologics in Children Register at start of etanercept. Because BoneXpert is developed for the use in children and has a bone age range of 2.5–17 years for boys and 2–15 years for girls, patients were selected within these age ranges. BA (Greulich and Pyle) and BHI were reported as standard deviations (SDS) from the reference population. Reproducibility of BoneXpert was assessed in all patients by calculating the BA and BHI twice for the left hand radiograph. Intraclass correlation coefficient (ICC) was used to determine the agreement between the two repeated measurements. Differences between patients and the reference population were tested with a one sample t-test. Patients for whom BoneXpert was not able to calculate BA or BHI were analysed separately.

Results: For 52 patients (median age 10.0 IQR 6.5–11.3, 56% female), BoneXpert was able to calculate both BA and BHI. BA SDS (mean -0.47 ± 1.32) and BHI SDS (mean -0.70 ± 1.10) differed significantly ($P<0.01$) from the reference population. For 11 patients BoneXpert was not able to calculate either BA, BHI or both, most likely caused by a bone age close to the outer limits of BoneXpert. Reproducibility was excellent with an ICC ranging from 1.00 (for BA, BA SDS, BHI) to 0.84 (for BHI SDS).

Conclusion: BoneXpert is an easy to use and reproducible method for assessing BA and BHI in patients with JIA starting etanercept, provided that radiographs are of reasonable quality and patients' BA is well within the age ranges of the program. The population investigated had a delayed bone maturation and lower bone density than healthy children as indicated by BoneXpert.

Three Middle Finger Width Correlates With Maximum Mouth Opening and Is a New Reliable Parameter To Identify Joint Hypermobility In Schoolchildren. Francesca Sperotto[1], Gabriella La Falce[2], Fabio Vittadello[1], Lorenzo Favero[2] and Francesco Zulian[1]. [1]University of Padua, Padua, Italy, [2]Gnatology Unit, Department of Dentistry, Padua, Italy.

Background/Purpose: Maximum mouth opening (MMO) is a useful parameter to identify common temporomandibular joint (TMJ) disorders. Up to now, a few studies addressed the issue on MMO normal values in pediatric population, according to age and/or presence of generalized joint hypermobility (GJH), therefore it is not widely used in general medical practice.

Aim of the study was to evaluate the MMO in a cohort of healthy schoolchildren and to propose a new parameter, the *three middle finger width* (TMFW), the distance between 2nd and 4th fingers of the right hand at the level of the lowest nail bed, to evaluate the TMJ hypermobility in children. We also analyzed the relationship between GJH and TMJ hypermobility.

Methods: We conducted a cross sectional study in a cohort of healthy schoolchildren, aged 8–13 years. Information on family history of GJH and history of TMJ involvement were collected. Physical examination included height, weight, body surface area (BSA), body mass index (BMI) and musculoskeletal evaluation focused on the presence of GJH according to the Beighton criteria (BS≥4/9). TMJ evaluation included a complete gnathological visit, aimed to investigate the presence of TMJ disorders and to measure the MMO. The evaluation of TMFW was also performed and the Mouth Opening Ratio (MOR) was then calculated by the formula [(MMO-TMFW)/MMO]x100, adopting a 10% cut-off value to define the TMJ hypermobility.

Results: Two hundred and eighty-eight schoolchildren, 143 females and 145 males, entered the study. Mean MMO was 45.57 mm (± 5.12) for males and 44.87 mm (± 4.98) for females. Mean TMFW was 43.03 mm (± 4.09) for males and 41.71 mm (± 3.84) for females. Both MMO and TMFW significantly correlated with all growth parameters (height, weight, BMI and BSA). 89 subjects (30.9%) showed TMJ hypermobility (MOR>10%). In these subjects and in those with normal MOR, MMO correlated with TMFW ($r= 0.761$, $p<0.001$ and $r= 0.786$, $p<0.001$ respectively) although in the first group MMO showed an higher level distribution. The prevalence of subjects with GJH was significantly higher in the group with TMJ hypermobility than in the other (44.8% vs 21.5% $p<0.001$).

Conclusion: TMFW correlates with MMO in schoolchildren and may represent a simple and reliable method to evaluate TMJ abnormalities. MOR, as an index to identify TMJ hypermobility, correlates with the presence of GJH and could be reasonably included, as an adjunctive feature, to the Beighton Criteria.

Lower Extremity Strength Is Related To Diminished Quality Of Life In Obese Children. Sharon M. Bout-Tabaku[1], Matt Briggs[1], Tom Best[1], Colleen Spees[1], Ajit Chaudhari[1] and Laura Schmitt[2]. [1]The Ohio State University, Columbus, OH, [2]The Ohio State Universtiy, Columbus, OH.

Background/Purpose: Obese children have a higher prevalence of lower extremity (LE) pain, with associated diminished quality of life, greater knee malalignment, generate less knee extensor force, and are less physically active compared to healthy weight (HW) children, putting them at risk to be obese adults. In adults, obesity is one major risk factor in developing osteoarthritis (OA) that negatively affects quality of life. Obese children may have "adult" risk factors, which may confer a risk of developing OA. We explored the relationships between knee alignment, LE strength and quality of life in obese adolescents. We compared 1) knee alignment and lower extremity strength in OB and HW adolescents and 2) evaluated the relationship of BMI and LE strength, and LE strength and QOL.

Methods: Adolescents (ages 11–18) recruited from pediatric community and tertiary centers were enrolled into two age and sex matched groups based on obesity status. Body mass index (BMI= kg/m^2) was calculated to determine BMI Z-scores from CDC US 2002 data. QOL was assessed using the Pediatric Quality of Life™(PedsQL) physical function score. Frontal plane knee alignment was measured using umbilicus, knee and ankle landmarks. LE strength was measured bothisokinetically: quadricep peak torque (QPT) and hamstring peak torque (HSPT) and isometrically: hip abductor peak torque (AbdPT) and hip extensor peak torque (ExtPT). Peak torque was normalized to body weight and right side data were analyzed as all subjects were right leg dominant. Means and standard deviations described the data. Paired t-tests and Pearson's correlations coefficients evaluated group differences and associations among variables of interest.

Results: 12 males and 10 females were enrolled. They were divided into 2 groups: OB and HW based on mean BMI and BMI z-scores are reported in Table 1. Mean PedsQL physical function scores differ by group. (Table 1).

Mean right knee alignment did not differ between the OB and HW adolescents. (Table 1) The OB group had significantly lower QPT, HSPT, AbdPT, and ExtPT (Table 1).

BMI Z-scores were negatively correlated with LE strength (QPT $r = -0.443$, $p<0.05$, HSPT $r = -0.527$, $p< 0.05$, AbdPT $r = -0.394$, $p> 0.05$, ExtPT $r = -0.513$, $p< 0.05$). LE strength measures were positively correlated with physical function scores (QPT $r = 0.551$, $p< 0.05$, HSPT $r = 0.692$, $p< 0.001$, AbdPT $r = 0.538$, $p< 0.05$, ExtPT $r = 0.555$, $p< 0.05$).

Table 1. Clinical and serologic features, and mortality in comparison with adult onset disease

	Obese (n-11)	Non-obese (n=11)	p value
Age (years, sd)	13.9 ± 2.12	14.0 ± 2	p>0.05
BMI, (mean, sd)	29.56 ± 2.24	20.36 ± 2.94	p>0.001
BMI Z-score	1.96	0.19	p<0.001
PedsQL(mean, sd)	82.67 ± 10.59	91.76 ± 10.01	p<0.05
Right knee alignment (mean degrees, sd)	173.82 ± 6.23	170.82 ± 2.09	p>0.05
QPT (Nm/kg, sd)	1.44 ± 0.29	1.97 ± 0.32	p<0.001
HSPT (Nm/kg, sd)	0.77 ± 0.24	1.15 ± 0.22	p<0.001
AbdPT (Nm/kg, sd)	0.71 ± 0.38	1.08 ± 0.27	p<0.05
ExtPT (Nm/kg, sd)	0.94 ± 0.43	1.58 ± 0.44	p<0.05

Table 1. $p<0.05$ level of significance, sd= standard deviation

Conclusion: OB adolescents have diminished LE strength compared to HW counterparts. Higher BMI Z-scores correlated with lower LE strength while lower LE strength correlated with reduced physical function. LE strength may limit appropriate physical activity participation in obese adolescents further contributing to obesity and other risk factors that may lead to the development of knee OA. Future research need to explore why the muscles in obese children are not responding as expected to excess load by increasing muscular strength.

Inter-Rater Reliability Of Jumping Mechanography In Healthy Children and Adults. Johannes Roth[1], Ciaran M. Duffy[2], Tania Bennett[1], Marta Erlandson[3], Michele Gibbon[1], Heather Macdonald[4], Douglas Race[5], Leanne M. Ward[1] and Lori B. Tucker[5]. [1]University of Ottawa, Ottawa, ON, [2]Children's Hospital of Eastern Ontario and University of Ottawa, Ottawa, ON, [3]University of Toronto, Toronto, ON, [4]The University of British Columbia, Vancouver, BC, [5]University of British Columbia, Vancouver, BC.

Background/Purpose: Muscle function can be affected by many chronic disorders of childhood including Juvenile Idiopathic Arthritis (JIA). Whereas the term "muscle strength" is often used to describe muscle function, it does not provide an objective assessment. Instead, the various components of muscle function including muscle force and power need to be measured precisely. Portable ground reaction force plates have been used to assess dynamic muscle function in clinical settings and for clinical studies and this method is commonly referred to as jumping mechanography. While **intra**-rater reliability has been published, no data is available for **inter**-rater reliability which is particularly important for multi-centre and longer-term prospective studies. The aim of this study was to determine inter-rater reliability for muscle function assessments using Leonardo™ Jumping Mechanography.

Methods: As part of the trans-Canadian, prospective study "Linking Exercise, Activity and Pathophysiology in Juvenile Idiopathic Arthritis (The LEAP Study)", inter-rater reliability of the Single Two-Legged Jump (S2LJ) and the Multiple One-Legged Jump (M1LJ) on the Leonardo™Jumping Mechanography was assessed between three raters.

14 healthy subjects were recruited among them 6 adults (3 males, mean age [SD] of 33.2 years[12.42]) and 8 children (3 males, mean age [SD] of 9.0 years[2.27]).

Each participant performed a set of three different jump types, a S2LJ followed by right and left M1LH with each one of three operators. Three trials were completed per jump type and participants had 15 minutes of rest in between jumps.

For the S2LJ, maximum Power was the primary outcome. Efficiency, Maximum Velocity, Maximum Force, Maximum Force and Maximum Height were also captured. For the M1LH, right and left Maximum Force was the primary outcome.

All of these measures were recorded relative to body weight and as absolute measurements. Reliabilty was determined using the interclass correlation coefficient (ICC) and coefficients of variation (%CV).

Results: For the S2LJ, CV and ICC (95% CI) for maximum power were 3.82% and 0.997 (0.992–0.999) respectively for the whole group and 5.09 % and 0.987 (0.958–0.997) for the children only. All other parameters assessed in the S2LJ were in the same range with the maximum variation observed for maximum force with a CV of 5.80% and ICC of 0.997 (0.945–0.992) for all and 6.75% and 0.932 (0.800–0.984) for the children only.

For the M1LH, the CV for maximum force was up to 8.96% and ICC 0.865 (0.704–0.949) for all and 3.69% and 0.851 (0.592–0.965) for the children only. Maximum force relative to body weight showed a maximum CV of 4.04% and ICC of 0.813 (0.615–0.929) in the entire group and 4.24% and 0.752 (0.412–0.938) for the children only.

Conclusion: Leonardo™ Jumping Mechanography is a suitable test for objective assessment of muscle function for clinical use and multi-centre trials, with very good inter-rater reliability across multiple parameters of muscle function. We found that maximum force calculation in children may need to be adjusted for body weight to increase accuracy. This method is currently in use in the LEAP study across Canada.

Role of Interleukin-1 in Abnormal Monocyte Phenotype in Systemic Onset Juvenile Idiopathic Arthritis. Yujuan Zhang[1], Claudia Macaubas[1], Clarissa Klein[1], M. Virginia Pascual[2], Arielle Hay[3], Susan D. Thompson[4], Christy I. Sandborg[1], Norman T. Ilowite[3] and Elizabeth D. Mellins[1]. [1]Stanford University Med Ctr, Stanford, CA, [2]Baylor Institue for Immunology Research, Dallas, TX, [3]The Children's Hospital at Montefiore, Bronx, NY, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background/Purpose: Monocytes undergo phenotype changes when exposed to different microenvironments: the classic proinflammatory M1 phenotype, alternative regulatory M2 phenotype and M2-like phenotype,

are each regulated by specific transcriptional factors. Here, we investigate whether monocyte phenotypes change with interlukin-1 (IL-1) blockade in systemic onset juvenile idiopathic arthritis (sJIA). We took samples from RAPPORT (**RA**ndomized **P**lacebo **P**hase study **O**f **R**ilonacept in the **T**reatment of sJIA) to study the phenotype in monocytes by measuring level of transcriptional factors involved in monocyte polarization before and after treatment with Rilonacept, an IL-1 trap.

Methods: Subjects on the Rilonacept arm receive active drug from week 0 for a total of 24 weeks; subjects on Placebo arm receive placebo for 4 weeks then receive active drug Rilonacept for a total of 20 weeks. Blood samples are obtained at week 0, week 2, week 4, week 14 and week 24. RNA extracted from isolated monocytes is analyzed by real time PCR to measure M1 associated genes: Interferon Regulatory factor (IRF) family IRF5, Signal transducers and activators of transcription (STAT) family STAT1; M2 associated genes IRF4, STAT6, Kruppel-Like Factor 4 (KLF4) and peroxisome proliferator-activated receptor-γ (PPAR-γ). All transcript levels are normalized by the levels of 3 housekeeping genes.

Results: 30 RAPPORT samples from 15 subjects were tested. Samples from subjects treated with Rilonacept for 6 weeks or more ("Late RAPPORT") showed decreased expression of M2 genes except for PPAR-γ, compared to those treated for less than 6 weeks ("Early RAPPORT") (see Figure 1). KLF4 showed the most significant decrease in "Late RAPPORT"; in addition, KLF4 is persistently lower in those clinically improved by different measures, including PediACR30 (P=0.0006), joint count (P=0.0024), clinical lab values (P=0.02) or functional state (P=0.0015), but not by improvement in range of motion (ROM) (see Figure 2).

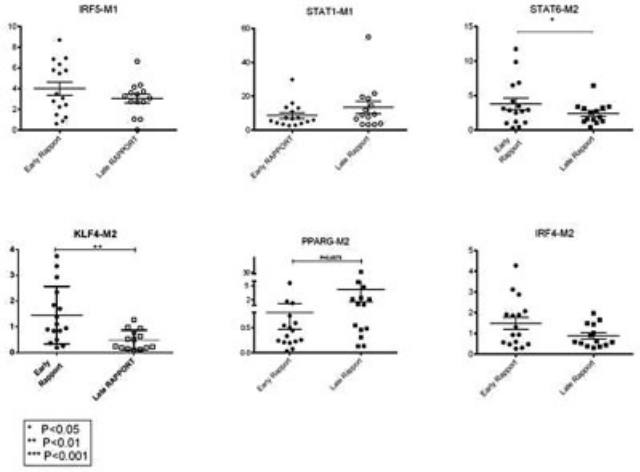

Figure 1.

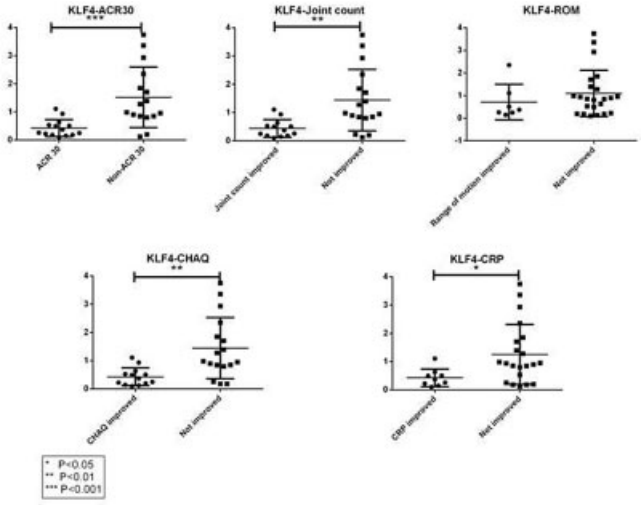

Figure 2.

Conclusion: Regulatory M2 genes (KLF4, IRF4 and STAT6) tend to decrease in sJIA monocytes after IL-1 blockade while M2-like gene PPAR-γ appears to increase. There is measurable impact of IL-1 blockade on monocyte phenotype at the transcription factor level.

TLR 4 Endogenous Ligand MRP8/14 Levels in Enthesitis Related Arthritis (ERA) and Its Association With Disease Activity and TLR 4 Expression. Amita Aggarwal, Mujeeb Rahman, Arpita Myles, Priyanka Gaur and Ramnath Misra. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background/Purpose: Enthesitis related arthritis (ERA) is an inflammatory disease of childhood that lacks autoreactive T and B cells. We have previously shown that surface expressed Toll Like receptors (TLRs) are over-expressed in ERA. Myeloid related proteins (MRP)8/14 are calcium binding proteins that act as an endogenous ligand of TLR-4. MRP8/14 levels are elevated in patients with systemic onset arthritis. Thus we studied its role in ERA.

Methods: The study enrolled patients with ERA (fulfilling ILAR criteria) less than 18 years of age. Plasma and synovial fluid levels of MRP8/14 were measured by ELISA and TLR-4 expression on peripheral blood and synovial fluid monocytes was measured by 2 color flow-cytometry. Control plasma samples were collected from 48 blood bank donors. Follow up samples were obtained from 26 patients after 3–4 months of first sample collection

Results: Among 69 patients 67 were males. Mean age was 15.2±2.7 years, disease duration was 5±3 years. Median plasma levels of MRP8/14 were higher in patients than controls (10862.31,4426.13 ng/ml; $p<0.0001$) was higher in those with active disease (11669.54, 4421.76 ng/ml, $p<0.0001$.

Patients with follow up were not different from other patients with respect to duration of disease and treatment received. Plasma MRP8/14 levels reduced on follow up after 3 months only in patients who responded to treatment (10862.31, 3784.41ng/ml, p=0.012). MRP8/14 levels negatively correlated with frequency of CD14+TLR4 positive cells (r=−0.372, p=0.02)

MRP8/14 levels were higher in synovial fluid as compared to plasma (15858.45, 10862.31ng/ml, p=0.024). SFMC showed significantly higher MFI than PBMC (1409.49 ± 890.60 vs. 946.11± 798.92, p=0.005) as well as higher percentage of CD14+TLR-4 positive cells (18.69 ± 4.51 vs. 5.96 ± 3.99, $p<0.0001$).

Conclusion: MRP814 levels are increased in plasma of ERA patients, are higher in those with active disease and levels decrease in patient who respond to treatment suggesting that it may be a good biomarker during follow up.

Clinical and Immunologic Description Of Pediatric Conditions With Interferon-Regulated Gene Signatures (Chronic Atypical Neutrophilic Dermatosis Lipodystrophy Elevated Tempature, Aicardi Goutieres Syndrome, Juvenile Dermatomyositis, Juvenile Systemic Lupus Erythematosus). Hanna Kim[1], Adriana Almeida de Jesus[2], Yin Liu[2], Yan Huang[1], Gina Montealegre[2], Dawn Chapelle[2], Nicole Plass[1], Wanxia Tsai[2], Massimo Gadina[3], Lisa G. Rider[4], Adeline Vanderver[5] and Raphaela Goldbach-Mansky[1]. [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD, [2]NIAMS / NIH, Bethesda, MD, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, [4]NIEHS, NIH, Bethesda, MD, [5]Children's National Medical Center, Washington, DC.

Background/Purpose: Increased interferon (IFN) regulated gene (IRG) expression has been reported in juvenile systemic lupus (JSLE)[1] and juvenile dermatomyositis (JDM)[2]. Recently, two monogenic conditions chronic atypical neutrophilic dermatosis lipodystrophy elevated temperature (CANDLE) syndrome[3] and Aicardi Goutieres syndrome (AGS)[4] have demonstrated IRG signatures. The goal of this study is to characterize their phenotypic and immunologic features versus neonatal-onset multiple inflammatory disease

(NOMID), IL-1 mediated disease control and healthy controls, and identify potential disease activity biomarkers.

Methods: History, physical, and laboratory evaluation performed on 9 CANDLE, 7 AGS, 4 JSLE, 5 JDM, and 5 NOMID disease control patients (prior to IL-1 blocking therapy). Cytokine profile done on serum (ratios of means versus 3 pediatric controls) and CSF (CSF:serum ratios compared to non-inflammatory neurologic diseases)[5] using Luminex (Austin, TX) assay. Gene expression analyzed with RNA-seq. Data analyzed with Partek 6.6 and Ingenuity Pathway Analysis.

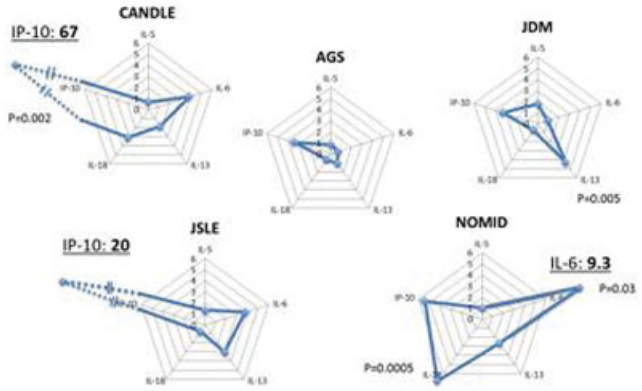
Results: A. Table of Clinical Characteristics

Systemic inflammatory markers were highest in NOMID and CANDLE patients. AGS, JDM and SLE patients were only mildly clinically active at time ofsampling. Systemic inflammatory markers were highest in NOMID and CANDLE patients. AGS, JDM and SLE patients were only mildly clinically active at time of sampling.

	With Type 1 Interferon-Regulated Gene Signature				IL-1 mediated
	CANDLE	AGS	JDM	JSLE	NOMID
rash	+++	++	+++	+++	+++
lipodystrophy	+++	−	+	−	−
myositis	++	−	+++	+	−
CNS	++ (L)	+++ (L)	−	++	+++ (N)
basal ganglia calcification	++	+++	−	−	−
autoantibodies	intermittent	intermittent	common	always	uncommon

+++: always or characteristic
++: sometimes or only with onset/flares
+: uncommon (L): lymphocytic
−: not described (N): neutrophilic

B. Serum/Plasma Cytokine Profiles



5 most distinguishing serum cytokines (Panel B, radar plots) show IP-10 was highly elevated in CANDLE and JSLE and IL-13 elevated in JDM. IP-10 and MCP-1 CSF/serum ratios were elevated for AGS. Gene expression identified upregulated IRGs for the 4 interferonpathies not present in the healthy controls or NOMID. There was a difference in disease-specific IFN signatures, with subsets uniquely upregulated and downregulated in each condition. IRGs were most upregulated in CANDLE, with greatest similarity to JSLE. AGS and JDM had other pathways higher-ranked than IFN pathways.

Conclusion: There are specific areas of phenotypic overlap such as basal ganglia calcifications (CANDLE, AGS), lipodystrophy (CANDLE, JDM), and myositis (CANDLE, JDM, less common JSLE). Disease-specific cytokine patterns included increased serum IP-10 (CANDLE, p=0.002), increased serum IL-13 (JDM, p=0.005), and increased CSF IP-10 and MCP-1 (AGS). These differences may indicate distinct and potentially organ-specific inflammatory pathways. Disease-specific differential gene expression patterns within the IFN response signature may reflect different pathogenesis, which may be due to differing triggers of IFN response.

Intestinal Microbiome In Polyarticular Juvenile Idiopathic Arthritis: A PILOT Study. Petra C.E. Hissink Muller[1], A.E. Budding[2], Cornelia F. Allaart[3], Danielle M.C. Brinkman[3], Taco W. Kuijpers[4], Michiel Westedt[3], J. Merlijn van den Berg[5], Lisette W.A. Van Suijlekom-Smit[6], Marion A.J. Van Rossum[7], Tim G.J. de Meij[2] and Rebecca Ten Cate[3]. [1]Reade Institute, Amsterdam, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Emma Children's Hospital/Academic Medical Center (AMC), Amsterdam, Netherlands, [5]Emma Children's Hospital / Academic Medical Center (AMC), Amsterdam, Netherlands, [6]Erasmus MC Sophia Children's Hospital, Rotterdam, Netherlands, [7]Emma Children's Hospital/Academic Medical Center and Reade Institute, Amsterdam, Netherlands.

Background/Purpose: The intestinal microbiome may play a role in the pathogenesis of Juvenile Idiopathic Arthritis (JIA). In IBD patients an overall decrease in microbial diversity of the intestinal microbiota has been observed. Studies comparing intestinal microbiome in children with JIA and healthy controls have not been conducted to date. Therefore we analyzed and compared the composition and diversity of the distal colon associated microbiome between children with Disease-Modyfying-Anti-Rheumatic-Drug (DMARD) naive JIA and healthy controls and tried to identify specific gut bacteria associated with polyarticular JIA before initiation of a DMARD.

Methods: Total microbiome profile in stools of 8 children with DMARD naive polyarticular JIA were analyzed by means of IS-pro, a 16S-23S interspacer (IS) region-based profiling method and compared to stools of 24 age-matched healthy controls.

Results: Faeces of 8 (6 girls, 2 boys) children with polyarticular JIA, all rheumatoid factor negative were investigated and compared to 24 healthy controls. Anti-Nuclear Antibodies were positive in 3 patients. Median age at evaluation was 11.1 years (7.3–13.1), median period from start complaints to diagnosis was 7.1 months (4.4–13.2). Median ACR pedi scores were: VAS physician 47mm(32–58), VAS patient well-being 32mm(27–52), ESR 8mm(2–9), active joint count 10(7–14), limited joint count 2 (0–4), CHAQ score 1.2 (0.4–1.7).

One intra-articular steroid injection was given to each of two patients respectively 1 and 4 months prior to stool collection. Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) were used by all patients at the time of evaluation. Median age of the healthy controls was 10.6 years (8.4–12.9).

Median Simpson reciprocal index within phylum of Firmicutes is significantly lower in children with JIA (6.0) compared to controls (8.0) ($p<0{,}012$). (figure 1). Diversity within the phyla Bacteriodetes and Proteobacteria did not differ between the 2 subgroups. By constructing a Pearson-correlation dendogram, no clustering was seen between the JIA group and the healthy controls on species-level (figure 2), a specific JIA associated microbiotal signature could not be identified.

Conclusion: Intestinal microbiome diversity within the phylum Firmicutes was significantly lower between children with DMARD naive polyarticular JIA and healthy controls. An overall decrease in microbial diversity of the intestinal microbiota has also been observed in IBD patients. Whether intestinal dysbiosis plays a role in the pathogenesis of JIA remains subject of further studies.

2192

Vitamin D Receptor Polymorphisms In A Cohort Of Italian Patients With Juvenile Idiopathic Arthritis. Fernanda Falcini[1], Francesca Marini[2], Donato Rigante[3], Federico Bertini[4], Gemma Lepri[5], Stefano Stagi[2], Marco Matucci Cerinic[5] and Maria Luisa Brandi[5]. [1]Department of Biomedicine, Division of Rheumatology AOUC, Excellence Centre for Research, Florence, Italy, [2]University of Florence, Firenze, Italy, [3]Università Cattolica Sacro Cuore, Rome, Italy, [4]Department of Internal Medicine, Rheumatology Section, University of Florence, Florence, Italy, [5]University of Florence, Florence, Italy.

Background/Purpose: A role for vitamin D has been hypothesized in generating disease activity for patients with juvenile idiopathic arthritis (JIA): specific polymorphisms of vitamin D receptor (*VDR*) gene have recently been associated with different biologic response to vitamin D itself.

To evaluate *VDR* polymorphisms in patients with JIA in comparison with unrelated healthy controls.

Methods: We recruited 81 Italian children, adolescents and young adults with JIA (mean age 20.21 + 7.11 SD, 67 female and 14 males, female/male ratio 4.79). After informed consent, during routine laboratory tests their genomic DNA was extracted from peripheral blood leukocytes, to analyze *VDR* polymorphisms by PCR-based sequencing (*CDX2* in the promoter region) and PCR-based enzymatic digestions (*FokI* in exon 2, *BsmI* and *ApaI* in intron 8, and *TaqI* in exon 9). An Italian population of 2221 unrelated individuals without JIA was used as healthy controls.

Results: The distribution of *FokI, BsmI, ApaI*, and *TaqI* polymorphisms did not show significant differences between children with JIA and controls. Regarding the *CDX2* polymorphism, we observed a statistical difference in the distribution of GG and GA genotypes, with the GG genotype more frequent in JIA subjects (Yates-corrected chi-square 6.64; Odds ratio=1.87; p=0.01) and the GA genotype in healthy controls (Yates-corrected chi-square 4.47; Odds ratio=0.58; p=0.035). Data about AA genotype were not significant due to their very low number (five) within the JIA population. G allele resulted to be more frequent in JIA subjects (Yates-corrected chi-square 5,64; Odds ratio=1.61; p=0.017).

Conclusion: Pathogenetic mechanisms influencing the predisposition to JIA are poorly elucidated. Our analysis of *CDX2* polymorphisms (located in the promoter region of the *VDR* gene) has revealed that both GG genotype and G allele are more represented in patients with JIA. We can speculate that the G allele decreases *VDR* transcriptional activity with respect to the A allele, as well as the presence of GG genotype could explain a reduction of *VDR* activity, with subsequent decreased response to vitamin D and potential immunity deregulation leading to JIA.

Altered Apoptosis Profile and Associated Soluble Factors In Patients With Juvenile-Onset Systemic Lupus Erythematosus. Bernadete Liphaus[1], Maria H. B. Kiss[1], Solange Carrasco[2] and Cláudia Goldenstein-Schainberg[3]. [1]Instituto da Criança, Hospital das Clínicas, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [2]University of Sao Paulo School of Medicine, São Paulo, Brazil, [3]Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: Apoptosis has been demonstrated to be involved in immune dysregulation and development of adult systemic lupus erythematosus (SLE) but less is known about its relevance in juvenile-onset SLE (JSLE). Therefore we aimed to assess a panel of apoptosis related proteins in patients with JSLE and their possible relationship with disease activity.

Methods: Forty-three JSLE patients (36F:7M, mean age=14.3 yrs, revised ACR criteria), 30 with active disease (SLEDAI score ^{3} 4), and 35 age and gender matched healthy controls were studied. After staining with specific moAbs, Fas and Bcl-2 expressions in peripheral B and T lymphocytes and monocytes were analyzed by flow cytometry. Soluble sera molecules (sFas, sFasL, sTRAIL and sBcl-2) were measured by commercial ELISA kits. Statistical analysis used Kruskal-Wallis test and Spearman's rank, with P value $<$ 0.05 considered significant.

Results: JSLE patients compared to controls had significant increased Fas expression on CD3+ (43.7±10.3 vs. 28.9±9.4%, p<0.01), CD4+ (20.3±6.7 vs. 16.2±6.2%, p<0.05) and CD8+ (21.5±9.6 vs. 12.3±5.8%, p<0.01) T cells, and on CD19+ B cells (2.1±1.4 vs. 1.4±0.7%, p<0.05), whereas, it was decreased on CD14+ monocytes (93.6±6.9 vs. 96.7±2.5%, p=0.01). Percentages of CD19+Fas+ cells were positively correlated with SLEDAI (r=0.38, p=0.02) and an inverse correlation was observed for percentages of CD14+Fas+ cells and SLEDAI (r= −0.55, p=0.01). Mean fluorescence intensity (MFI) of Bcl-2-positive cells from JSLE patients was significantly increased in CD3+ (28.8±8.4 vs. 22.9±4.2%, p<0.01), CD4+ (28.6±8.2 vs. 22.9±4.4%, p<0.01) and CD8+ (29.4±9.4 vs. 22.8±3.6%, p<0.01) T cells, and also in CD19+ B cells (25.5±9.6 vs. 21.5±3.6%, p=0.06). Bcl-2 expression in CD14+ monocytes was lower in JSLE compared to controls (25.2±18.2 vs. 34.5±16.6%, p=0.006). Direct correlation between percentages of CD19+Bcl-2+ cells and SLEDAI (r=0.47, p=0.04) was shown. JSLE patients had significantly increased sFas (188.1±69.2 vs. 133.2±80.6pg/ml, P<0.05) and sTRAIL (691.3±631.8 vs 346.6±251.1pg/ml, P<0.05), decreased sFasL (0.08±0.1 vs. 0.36±0.4ng/ml, P<0.05), and similar sBcl-2 (7.4±8.6 vs. 9.3±9.6mg/ml, P<0.05) levels compared to healthy controls. SLEDAI score directly correlated with sFas (r=0.52; p=0.001).

Conclusion: The present study demonstrated that dysregulation of apoptosis pathways and associated soluble factors underlie JSLE pathogenesis, particularly during active disease. A role for CD19+Bcl-2+ cells and/or sFas as a marker of disease acitivity in children deserves further investigation in prospective studies.

RNA-Sequencing In Peripheral Blood Mononuclear Cells Identifies Novel Differentially Expressed Coding and Non-Coding Transcripts In Juvenile Idiopathic Arthritis. Kaiyu Jiang[1], Xiaoyun Sun[2], Yanmin Chen[1], Yufeng Shen[2] and James N. Jarvis[1]. [1]The University at Buffalo, Buffalo, NY, [2]Columbia University, New York, NY.

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease of childhood. The aetiology of JIA remains largely unknown, but the interplay between genes and environment is likely to be important. Recent genetic studies in complex disease have shown that 80% of disease-associated SNPs map to non-protein coding DNA sequences that comprise 80% of the human genome. However, data from projects like NIH's ENCODE consortium suggest that much of the genome is transcriptionally active. We used RNA-sequencing (RNA-seq) to identify differentially expressed (DE) protein-coding and non- coding transcripts in 3 JIA patients with active disease (AD), 3 patients at clinical remission on medicine (CRM), and 3 healthy controls.

Methods: RNA samples were isolated from peripheral blood mononuclear cells and prepared for sequencing using the Illumina TruSeq RNA prep kit. Sequencing was performed using the Illumina HiSeq 2000. The pass filter reads were mapped to the genome (Enseml/GRch37) using Tophat (version 1.3.3). Probable transcripts were assembled using CUFFLINKS, and DE transcripts were determined using CUFFDIFF using an adjusted P-value of 0.01. Fold change (FC) calculations were obtained using the log2 (FPKM) ratio,

Results: The average number of reads per sample was 42.95 million, and average number of mapped to genome was 32.9 million. Of the protein-coding regions, there are 119 DE genes (83 down-regulated, 36 up-regulated) in fold change 1.2 or greater when AD compared to HC, 83 DE genes (62 down-regulated, 21 up-regulated) in the AD vs CRM comparison and 19 DE (11 up-regulated, 7 down-regulated) in CRM vs HC. DE genes in AD vs HC and AD vs CRM predictably included those associated with connective tissue disorders, immunological disease and inflammatory disease (e.g. CCR5, IL3RA, IL8 etc.). Among non-protein coding transcripts, we observed DE of two long non-coding RNA (lncRNA) at 10p12.1 (p=0.001, FC= −3.73 and −4.74) and one lncRNA at 5q33.3 (p=0.023, FC=3.99) when AD compared to HC. Biological functions of these LncRNAs are unclear.

Conclusion: In this RNA-seq study in JIA, we identified DE genes in different disease states in JIA. These data also confirmed our previous observations using microarray technology. Three DE lncRNAs were observed in JIA. Future studies in JIA are warranted to further elucidate the functional consequences of these novel lncRNA associations.

Expanding The Spectrum Of Recombination Activating Gene-1 Deficiency To Include Early Onset Autoimmunity. Lauren A. Henderson[1], Francesco Frugoni[1], Gregory Hopkins[1], Helen de Boer[1], Sung-Yun Pai[2], Yu Nee Lee[1], Jolan E. Walter[3], Melissa M. Hazen[1] and Luigi D Notarangelo[1]. [1]Boston Children's Hospital, Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Massachusetts General Hospital for Children, Boston, MA.

Background/Purpose: We sought to identify the etiology of early onset autoimmunity and T cell lymphopenia in two siblings through genetic and functional studies. Newborn screening identified a full term infant (Patient B) with undetectable T-cell receptor excision circles, raising a concern for severe combined immunodeficiency (SCID). A female sibling (Patient A) had died at 2 years of age secondary to complications from autoimmunity. At 6 months, Patient A had developed vasculitis leading to digital necrosis, myositis, autoimmune cytopenias, positive autoantibodies (ANA, anti-cardiolipin, thyroid peroxidase, and thryroglobulin), elevated inflammatory markers, and hypocomplementia. Both children were severely T cell lym-

phopenic with poor lymphocyte proliferation to mitogens, although natural killer cells, B lymphocytes, and immunoglobulin levels were preserved. Due to the sibling's ultimate fatality, Patient B received prophylactic antibiotics and IVIG; the child never developed autoimmunity and underwent a successful bone marrow transplant at 3 months of age.

Methods: Genomic analysis was done on DNA extracted from whole blood. Recombinase activity was explored using Abelson-immortalized murine *Rag1*$^{-/-}$ pro-B cells with an intrachromosomal inverted GFP cassette flanked by recombination signal sequences. The Abelson pro-B cells were transduced with vectors encoding either wild type or mutant *RAG1* alleles. Recombination-dependent expression of GFP served as an indicator of RAG1 activity. The Abelson system was also used to assess RAG1 protein expression through immunoblotting. Expression of TCRVβ families in CD3+ cells was detected using monoclonal antibodies conjugated to fluorochromes. The B cell repertoire was evaluated by pyrosequencing.

Results: Testing in Patient A for mutations classically associated with T$^-$B$^+$SCID was unrevealing. Patient B had compound heterozygous missense mutations in *RAG1* (c.2522 G>A, p.R841Q; c.2920 T>C, p.F974L). Analysis of frozen genomic DNA from Patient A confirmed identical *RAG1*mutations. The parents were carriers (paternal allele: p.R841Q; maternal allele: p.F974L). In the Abelson system, the R841 mutant lacked protein expression and recombinase activity while the F974L mutant demonstrated normal protein expression but reduced activity (56.5% of wild type). In Patient B, the T cell repertoire was oligoclonal with 8/24 TCRVβ families falling in normal range. The restricted T cell diversity corrected after transplant. By pyrosequencing, the usage of variable, diversity, and joining (V(D)J) segments was skewed in the B cells.

Conclusion: Lymphocyte receptor diversity is generated by the activity of RAG1 and 2, which create DNA breaks that allow recombination of V(D)J gene segments. The clinical presentation of RAG deficiency ranges from T$^-$B$^-$SCID to isolated CD4$^+$ lymphopenia with the variability partially explained by the residual activity of RAG1. We describe a novel presentation of hypomorphic RAG deficiency characterized by early onset autoimmunity in the presence of B cells, highlighting the importance of considering immunodeficiencies in children who present with immune dysregulation, as prompt treatment can be lifesaving.

Aberrant IgG Glycosylation Is Associated With Active Disease In Juvenile Idiopathic Arthritis Patients. Esperanza Cleland, Brooke Gilliam and Terry L. Moore. Saint Louis University, Saint Louis, MO.

Background/Purpose: Aberrant glycosylation of IgG is an abnormality of humoral immunity in patients with rheumatoid arthritis (RA) and juvenile idiopathic arthritis (JIA) that is not well understood. We examined the association between aberrant IgG glycosylation and clinical and laboratory parameters in JIA.

Methods: Sera from 100 JIA patients (32 IgM rheumatoid factor (RF)-negative polyarticular, 31 oligoarticular, 23 IgM RF-positive polyarticular, 11 systemic-onset, 3 psoriatic), 29 RA patients, and 27 healthy individuals were collected. Aberrant serum IgG glycan content was measured by ELISA in all sera samples. The positive cut-off point was OD>0.31 for aberrant IgG glycan levels. Anti-cyclic citrullinated peptide (anti-CCP) antibody and RF isotypes were also measured by ELISA. Patient records were evaluated for clinical and laboratory associations, including disease activity, erythrocyte sedimentation rate (ESR) and C-reactive proteins (CRP) levels.

Results: Forty-six (46%) JIA patients, 16 (55.2%) RA patients and 4 (14.8%) healthy individuals had elevated aberrant IgG glycan levels. Aberrant glycosylation of IgG was confirmed in JIA patients as compared with healthy individuals (OD=0.342 ± 0.213 versus OD=0.179 ± 0.110; p<0.001). Systemic-onset JIA patients demonstrated higher levels of aglycosylated IgG (OD=0.395 ±0.218) than other JIA subtypes and occurred more frequently in this subtype (54.5%). No significant difference in aberrant glycosylation of IgG was noted between JIA and RA patients (OD=0.319 ± 0.159; p=0.588). A significant correlation between aberrant IgG glycosylation and disease activity was noted in JIA patients (r=0.32, p=0.001), with aberrant IgG glycan levels significantly increased in patients with active disease (OD=0.35 ± 0.17) compared with asymptomatic patients (OD=0.23 ± 0.07) (p=0.024). This correlation was also present when looking at only the female JIA population (r=0.31, p=0.004), while no significant correlation was found in the male JIA population. Aglycosylated IgG correlated significantly with disease activity markers (ESR: r=0.47, p<0.001 and CRP: r=0.46, p<0.001) in JIA. Levels of ESR and CRP were significantly raised in JIA patients with increased aberrant IgG glycan levels (35±29 mm/hr and 2.2±2.4 mg/dl, respectively) compared to patients with normal levels (18±26 mm/hr and 0.91±1.45 mg/dl, respectively) (p<0.05). No association was found between anti-CCP antibody and RF isotypes and aberrant IgG glycosylation in JIA.

Conclusion: Aberrant IgG glycosylation was evident in all JIA subtypes included in this study, with the highest frequency and levels found in systemic-onset JIA patients. We have shown that IgG glycan aberrancy is strongly associated with disease activity in JIA patients. This correlation was also significant when only evaluating the female JIA patients, indicating a possible hormonal influence in IgG glycosylation regulation.

High Titer IgG Anti-Cyclic Citrullinated Peptide Antibodies Are Associated With Joint Destruction In Juvenile Idiopathic Arthritis Patients. Brooke Gilliam, Lance Feller and Terry L. Moore. Saint Louis University, Saint Louis, MO.

Background/Purpose: IgG anti-cyclic citrullinated peptide (anti-CCP) antibodies have been identified as an important indicator of destructive disease in juvenile idiopathic arthritis (JIA), as is the case in rheumatoid arthritis (RA). We evaluated sera from patients with three subtypes of JIA, in addition to RA patients and healthy individuals to investigate the significance of anti-CCP titers in relation to disease severity.

Methods: Sera from 90 JIA patients were collected, including 30 IgM RF-positive polyarthritis, 30 IgM RF-negative polyarthritis, and 30 oligoarthritis. Sera were collected from 30 patients with RA and 30 healthy individuals. All sera were measured for IgG anti-CCP antibodies and IgM RF by ELISA. IgG anti-CCP antibody serum levels more than three times the cut-off (>60 Units) were considered high titer (HT) antibody levels. Patient records were evaluated for clinical and laboratory associations, including joint damage.

Results: Fifteen IgM RF-positive polyarthritis patients had HT IgG anti-CCP antibodies, 5 had low titer (LT) anti-CCP antibodies, and 10 were considered negative. Two IgM RF-negative polyarthritis were positive for IgG anti-CCP antibodies, one with HT and one with LT. None of the oligoarthritis patients were positive for IgG anti-CCP antibodies, while 2 healthy children had LT IgG anti-CCP antibodies. Eighteen RA patients had HT IgG anti-CCP antibodies, one LT, and 11 were considered negative. IgM RF-positive polyarthritis patients demonstrated significantly elevated levels of IgG anti-CCP antibodies (85±80 Units) compared to IgM RF-negative polyarthritis (14±38 Units), oligoarthritis (5±5 Units), and healthy children (6±7 Units) (p<0.001). When IgM RF-positive polyarthritis levels were compared with levels in RA patients (102±85 Units), the difference was not significant (p=0.436). Nine of 16 (56.3%) JIA patients with HT IgG anti-CCP antibodies and 2/6 (33.3%) with LT IgG anti-CCP antibodies had joint damage. JIA patients with joint damage had significantly higher levels of IgG anti-CCP antibodies (83±84 Units) compared to those with no joint damage (23±49 Units) (p=0.008). Thirteen of 18 (72.2%) RA patients with HT, 1 LT, and 6/11 (54.5%) negative for IgG anti-CCP antibodies had joint damage. The difference in IgG anti-CCP antibody levels did not differ significantly in RA patients with or without joint damage (p=0.17). IgM RF levels were also significantly higher in JIA patients with joint damage (54±56 Units) compared to those with no joint damage (20±30 Units; p=0.026). Regression analysis showed that HT anti-CCP antibodies were the strongest independent determinant of joint damage in JIA (OR 8.13 [95% CI: 2.37–27.84], p=0.001).

Conclusion: IgM RF-positive polyarticular JIA and adult RA patients demonstrated similar mean levels of IgG anti-CCP antibodies, both greater than the HT cut-off of >60 Units. HT anti-CCP antibodies were strongly associated with joint damage in JIA. Measurement of IgG anti-CCP antibody serum levels was found to be useful in identifying JIA patients with destructive disease and would be useful in management of JIA, particularly patients with IgM RF-positive polyarthritis and overall in JIA patients exhibiting HTs.

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is a severe inflammatory disease of childhood characterized by periods of daily spiking fever, evanescent skin rash, arthritis, serositis, lymphoid hyperplasia, and in up to half of cases, macrophage activation syndrome. The causes of sJIA are unknown, and the rare nature and complex inheritance of sJIA have together stymied the investigation of sJIA genetics.

Methods: To identify genetic factors contributing to sJIA susceptibility, we generated single nucleotide polymorphism (SNP) genotypes in 988 children with sJIA and 514 healthy control subjects using a commercially available SNP array. These data were combined with SNP genotypes, *in silico,* from 7370 additional healthy control subjects. After dividing the dataset into 9 strata by country of origin, we excluded samples and markers that failed to meet strict quality standards. Haplotype phasing, SNP imputation, and association testing were performed independently in each stratum, and we then subjected the association results from > 1.6M SNPs to fixed- and random-effects meta-analyses. A second round of more intensive imputation employing a more densely genotyped set of reference haplotypes was performed in each region with $p_{min} < 1.0E-7$. Regions with association signals exceeding genomewide significance ($p < 1.7E-8$) were further evaluated with logistic regression and conditional analysis.

Results: Genome wide meta-analysis of sJIA identified associations between sJIA and two regions, the major histocompatibility complex (MHC) locus and an intergenic region on chromosome 1, each of which were subjected to a second round of SNP imputation. In both regions, meta-analysis of the second round of imputation data identified significant associations. Meta-analyses of the MHC locus identified two strong association signals, the first centered around *HLA-DRB1* ($p_{min} = 1.6E-10$, OR 1.5) and the second located between *BTNL2* and *HLA-DRA* ($p_{min} = 7.1E-15$, OR 2.2). Reciprocal univariate regression demonstrated that these two markers likely represent independent sources of sJIA risk. On chromosome 1, we identified an sJIA-associated cluster of 9 SNPs ($p_{min} = 5.4E-9$, OR 2.0) that was nearest to *LOC284661*, encoding a long, intergenic noncoding RNA. By cross referencing data from the ENCODE project with the 9 sJIA associated SNPs, we found evidence of transcriptional activity across the sJIA-associated region and in close proximity to many of the sJIA-associated SNPs. Furthermore, several of the sJIA-associated SNPs were located within known histone marks or transcription factor binding sites.

Conclusion: Our data implicate the class II MHC molecule, HLA-DR, in the pathogenesis of sJIA. The intergenic location of the most strongly associated variants raises the possibility that an alteration of HLA-DR regulation or expression may underlie its role in sJIA. Additionally, we have identified a novel genomic region on chromosome 1 as an sJIA susceptibility locus. Interestingly, the nearest gene encodes an uncharacterized long, intergenic noncoding RNA, a type of transcriptional regulator whose importance has only recently come to light.

Analysis Of The MHC Region In a Large Cohort Of Juvenile Idiopathic Arthritis Cases Identifies Independent Effects At HLA-DRB1. Anne Hinks[1], Joanna Cobb[1], Buhm Han[2], Miranda C. Marion[3], Marc Sudman[4], Paul Martin[1], John F. Bohnsack[5], Lucy R. Wedderburn[6], Johannes Peter Haas[7], Paul de Bakker[2], Carl D. Langefeld[3], Soumya Raychaudhuri[2], Sampath Prahalad[8], Susan D. Thompson[4] and Wendy Thomson[1]. [1]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Sciences Centre, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]Wake Forest University Health Sciences, Winston-Salem, NC, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]University of Utah, Salt Lake City, UT, [6]Arthritis Research UK Centre for Adolescent Rheumatology at University College London, Great Ormond Street Hospital and UCLH, University College London, London, United Kingdom, [7]German Centre for Rheumatology in Children and Young People, Garmisch-Partenkirchen, Germany, [8]Emory Children's Center, Atlanta, GA.

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common arthritic disease of childhood and is caused by a combination of genes and environment. In the last few years great advances have been made in dissecting the genetic basis of JIA with now 17 confirmed susceptibility loci identified. One of these loci, the MHC region, has been established for many years but the complexity and the broad linkage disequilibrium (LD) across the region has rendered fine-mapping associations challenging. Novel imputation strategies can now be utilized to impute HLA classical alleles and amino acids across the region. The aim of this work was to gain a greater understanding of the associations across the HLA region in the 2 most common subtypes of JIA, oligoarthritis and rheumatoid factor-negative polyarthritis.

Methods: Using the dense genotype data obtained from the analysis of the custom-designed Illumina ImmunoChip in 2816 JIA cases and 13056 controls, we imputed HLA classical alleles (2-digit and 4-digit resolution) and amino acids across the MHC region (Chr6:29–34Mb) using the SNP2HLA algorithm and a large reference panel of 5225 individuals from the T1DGC consortium. We performed logistic regression for all markers across the region and tested all amino acids in HLA-DRB1 performing an omnibus test of amino acid residues for each position. Conditional analysis to identify potential independent effects was performed.

Results: We observed high correlation (0.99) between imputed and classically typed actual allele frequencies for HLA-DRB1 2-digit and 4-digit alleles for a subset of JIA cases (n=394). The most significant association across the HLA region was for the phenylalanine residue at amino acid 67 of HLA-DRB1, OR=3.03, $p=1 \times 10^{-179}$. The omnibus test for all amino acids across HLA-DRB1 showed most significant association at HLA-DRB1 amino acid 13 and conditioning on all residues at amino acid 13 found significant association remaining at HLA-DRB1 amino acid 67, suggesting two independent effects in HLA-DRB1.

Conclusion: Analysis of the MHC region in the largest cohort of JIA cases and controls studied to date has found the strongest association with the HLA-DRB1 region. Two independent effects have been identified,

amino acid 67 and 13. Interestingly, amino acid 13 has previously been associated with adult rheumatoid arthritis (RA) whereas amino acid 67 has not. Further analysis to look for independent effects across the rest of the HLA region is now underway.

Fatty Acid Profiling In Juvenile Idiopathic Arthritis: The Balance Between Pro-Inflammatory and Pro-Resolving Prostanoids. Weng Tarng Cham[1], Enzo Ranieri[2], Janice Fletcher[2] and Christina A. Boros[3]. [1]Women's and Children's Hospital, North Adelaide, SA 5006, Australia, [2]SA Pathology, North Adelaide, SA 5006, Australia, [3]University of Adelaide/Women's and Children's Hospital, Adelaide, Australia.

Background/Purpose: The prostanoids are a family of biologically active lipids derived from the 20-carbon essential fatty acids (LCPUFA) and are involved in all aspects of the immune response. Omega −3 (ω3) fatty acids, Eicosapentaenoic acid (EPA) and Docosapentaenoic acid (DPA), Docosahexanoic acid (DHA) and Lipoxin A4 (LPA4) are anti-inflammatory, whilst the ω6-fatty acids Arachidonic acid (AA), 13-(S)hydroxy-octadecadienoic acid [13(S)HODE], 12(S)-hydroxyeicosatetraenoic acid(12(S)HETE), Thromboxane B2 (TXB2), Prostaglandin F2α (PGF2α) and 6-Keto-Prostaglandin F1α (6kPGF1α) are pro-inflammatory. Liquid Chromatography Tandem Mass Spectrometry (LC-MSMS) allows contemporaneous analyses of multiple prostanoids by stable isotope determination from 3mm dried whole blood spots. This method is novel in JIA and may find biomarkers which can help predict disease activity and treatment response with greater accuracy than current methods.

Methods: Samples of whole blood from 115 JIA patients and 6 healthy siblings (HC) were collected onto specially prepared filter papers and analysed using LC-MSMS.

Results: The JIA M:F ratio was 1:1.4, the average age at study entry (9.4 ± 5.0 y), average disease duration (56.1 ± 46.1 m). None of the participants was taking fish oil.

Cross-sectional analysis

- 13(S)HODE and DHA levels were significantly different between JIA patient groups (p=0.05 for both)
- In general, there were significantly lower levels of pro-inflammatory prostanoids in JIA than in HC, particularly in polyarthritis
- JADAS correlated positively with PGB2 in all JIA sub-groups (p=0.046).

Longitudinal analysis

- Within subject comparisons
  - o Levels of AA (p=0.03), Leukotriene B4 (LTB4, p=0.003) and TBX2 (p=0.02) were all significantly lower in patients with active vs inactive disease (JADAS ≥1 vs <1)
  - o LPA4 levels were higher in patients with active disease (p=0.004)
- Between subject comparisons
  - o 13-S-HODE was reduced in patients with active disease (p=0.004)
- Correlations between changes in prostanoid levels, irrespective of disease activity (within subjects), showed combined changes in pro-and anti-inflammatory prostanoids:
  - o Increases in EPA correlated positively with higher levels of 13(S)HODE, 12(S)HETE, LTB4, TBX2, 6κPGF1α, (p<0.05 for all) as well as with increased LPA4 (p<0.0001)
  - o Increases in LPA4 correlated positively with DPA, and 6κPGF1α and negatively with AA, 15(S) HETE and TBX2 (p<0.0001 for all)
  - o There were no correlations between changes in ESR or CRP and those in prostanoids.

Conclusion: In our cohort, we found that pro-inflammatory prostanoids were, in general, decreased in patients with active disease and in comparison to healthy controls. Increased EPA and LPA4 production were strongly associated with these changes. These are novel findings and likely reflect the degree to which pro-resolving prostanoids are produced to control the inflammatory response in JIA over time. Prostanoid levels appear more sensitive to change than traditional laboratory markers of inflammation. Future analyses will include more detailed investigation of the prostanoids involved in the active resolution of inflammation.

Exon and miRNA Arrays Reveal Complexity and Specificity Of The Juvenile Idiopathic Arthritis Neutrophil Transcriptome. Zihua Hu[1], Kaiyu Jiang[2], Mark B. Frank[3], Yanmin Chen[2] and James N. Jarvis[2]. [1]University at Buffalo, Buffalo, NY, [2]The University at Buffalo, Buffalo, NY, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: Data from the NIH Roadmap Epigenomics and ENCODE projects have revealed unexpected richness in mammalian transcriptomes. Large regions the genome that do not encode proteins have now been shown to be functional. These studies were performed to examine the JIA neutrophil transcriptome in detail.

Methods: We studied neutrophils in 35 children with newly-diagnosed, untreated polyarticular, RF-negative JIA using Affymetrix exon and miRNA arrays. Labeling, hybridization, and scanning were undertaken using standard procedures. Patients were compared with 43 healthy controls (HC) and 15 children with cystic fibrosis (CF), a control group added to distinguish transcriptional features specific to JIA and those generic to chronic inflammation in soft tissues. Both exon and miRNA expression data were processed using RMA software in the Affy package of Bioconductor and analyzed using t-tests to detect differentially expressed genes (DEGs) between JIA and HC as well as between CF and HC. Exon arrays were also processed using APT program for Exon-level analysis. Splicing analyses were performed using APT program MiDAS and in-house developed PERL scripts.

Results: We found significant differences in the transcriptomes of children with JIA compared with children with CF, which was evidenced by the number of DEGs from JIA and CF when compared to HC. Whereas the analyses detected 5965 DEGs from CF and 216 DEGs from JIA, 148 of them are common to both groups (p = 7.5E-28). Similar results were obtained from both exon-level and miRNA gene expression data analysis. While 159 and 73 differentially expressed miRNA genes were detected in CF and JIA, respectively, 27 of them are common to both groups (p <0.001). At the isoform level, we found 5617 isoforms from CF and 446 isoforms from JIA displaying differential exon splicing, 169 of them are common to both groups (p=1.56E-129). Functional analyses indicated that those 148 common DEGs were enriched for lysosome and proteasomal ubiquitin-dependent protein catabolic processes, while those DEGs unique to JIA (68) are involved in intracellular signaling cascades, hormone-mediated signaling, and cell motion. DEGs to unique to JIA were able to clearly separate JIA from healthy controls in a clustering analysis, and therefore these DEGs could serve as a gene expression signature for the disease. Functional associations from differential exon splicing analyses indicated that the common 169 isoforms were enriched in functions that included actin cytoskeleton organization, regulation of transcription, ceramide metabolic process, leukocyte activation, and cell activation during immune response. Those DEGs unique to JIA (277) were associated with functions that included as spliceosome regulation, B and T cell receptor signaling pathways, and apoptosis and MAPK signaling pathways.

Conclusion: These findings reveal the complexity and specificity of the JIA neutrophil transcriptome. Furthermore, they demonstrate the importance of filtering JIA transcriptome results with controls that include other chronic inflammatory conditions. Finally these results indicate that a set of DEGs unique to JIA can serve as gene expression signature for the disease.

TNF-α Is Associated With Cognitive Impairment In Childhood-Onset Systemic Lupus Erythematosus. Mariana Postal[1], Nailu A. Sinicato[1], Aline T. Lapa[1], Karina Peliçari[1], Bruna Bellini[1], Paula T Fernandes[1], Roberto Marini[1] and Simone Appenzeller[2]. [1]State University of Campinas, Campinas, Brazil, [2]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: Cognitive impairment is common in over 50% of SLE patients with active neurological and psychiatric disorders. Cytokine dysregulation and in flammation are mechanisms that may underlie cognitive

impairment. TNF-α leading to inflammatory brain disease may result in cognitive impairment in childhood-onset systemic lupus erythematosus (cSLE).

Objective: To determine if increased sera TNF-α levels are associated with cognitive impairment in cSLE.

Methods: We included 57 SLE patients (women 52; mean age 17.51±4.37; range 9–30) and 65 healthy (women 60; mean age 18.93±65.95; range 6–32) age and sex matched controls. Cognitive evaluation was performed in all participants using Wechsler Intelligence Scale for children (WISC-III) and Wechsler Intelligence Scale for adults (WAIS), according to age and validated in Portuguese. Mood disorders were determined through Becks Depression and Anxiety Inventory in all participants. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current drug exposures. Total dose of corticosteroids and other immunosuppressant medications used since the onset of disease were calculated by data obtained by careful review of the medical charts. Sera samples were obtained from all participants in the absence of infections. TNF-α levels were measured by enzyme-linked immunosorbent assay using commercial kits from R&D Systems. Mann-Whitney Test was used to compare TNF-α concentrations between groups. Multivariate analysis was performed including sex, age, SLE duration, disease activity, and cumulative damage, cognitive impairment and current drug exposures. A P value of <0.05 was considered statistically significant.

Results: Sera TNF-α levels were increased in cSLE (3.39±5.57pg/mL) when compared to healthy controls (1.54±0.92pg/mL) ($p=0.015$). Cognitive impairment was identified in 28 (49.12%) cSLE and in 6 (9.23%) healthy controls. Sera TNF-α levels were increased in cSLE patients (4.64±1.52pg/mL) with cognitive impairment compared to cSLE patients without cognitive impairment (1.52±0.75pg/mL) ($p=0.03$). No significant difference in TNF-α levels between cSLE patients without cognitive impairment and controls was observed ($p=0.76$). No association between TNF-α levels and other clinical, laboratory variable, SLEDAI and SDI scores was observed. In the multivariate analysis, sera TNF-α levels were independently associated with cognitive impairment (OR=3.84; 95%CI 2.39–5.71).

Conclusion: Sera TNF-α levels are elevated in cSLE patients with cognitive impairment. TNF-α were independently associated with cognitive impairment. Our findings support the neuromodulator role of TNF-α in brain activity.

DEK's Autoantigenicity In Juvenile Idiopathic Arthritis Resides In Its C-Terminal 25 Amino Acids. Barbara S. Adams, Miguel Rivas, Yuanfan Ye, Lili Zhao, Maureen Legendre and Nirit Mor-Vaknin. University of Michigan, Ann Arbor, MI.

Background/Purpose: The nuclear oncoprotein DEK is a known autoantigen associated with juvenile idiopathic arthritis (JIA) and other autoimmune diseases. DEK is actively secreted by human macrophages and is a chemoattractant for neutrophils and T cells. We have previously demonstrated that DEK and DEK autoantibodies are abundant in inflamed synovia of JIA patients. Posttranslational modification, especially acetylation, increases DEK's antigenicity substantially. In agreement with previous observations by Szer et al., our studies of the nature of DEK autoantibodies have shown that autoantibodies from JIA patients recognize the DEK C-terminal region. By screening 69 serum samples, including those from 38 patients with JIA, 20 patients with other inflammatory conditions, and 11 samples from healthy controls, we show that the C-terminal 25 amino acids (aa) alone is the most essential site for DEK antigenicity.

Methods: Sera were collected from patients being treated for JIA and other rheumatologic diseases in the Pediatric Rheumatology Division at the University of Michigan. Samples were analyzed by a specific ELISA developed in our laboratory for the detection of DEK antibodies. Recombinant DEK His-tagged proteins, including full length(1–375aa), and partial length (187–375aa and 1–350aa) proteins were made in a baculovirus system, and were used as the antigen for ELISA and immunoblotting. In addition, we inserted DEK's C-terminal 25aa domain into a GST vector to be expressed by E. coli with subsequent purification. ELISA results were calculated as area under the curve (AUC) by Simpson Rule.

Results: ELISA results showed significantly higher levels of DEK autoantibodies in sera of JIA patients compared to patients without JIA ($p=0.01$) or healthy controls ($p=0.001$). Immunoblot screening against full length DEK (1–375aa), the DEK C-terminus 25aa (position 350–375), and full-length DEK minus the last 25 amino acids (1–350aa) confirms that DEK's most immunogenic portion consists of the C-terminal 25aa. These results were also corroborated by expression of DEK's C-terminal 25aa alone.

Conclusion: We have previously demonstrated presence of DEK and DEK autoantibodies in joints of JIA patients, resulting in development of immune complexes that contribute to joint inflammation. In addition, DEK plays an active role in recruiting neutrophils to joints, as well as in formation of neutrophil extracellular traps (NETs). Our current data suggests that the C-terminal 25aa is the most immunogenic portion of DEK. This finding has significant importance with respect to future development of specific diagnostic tools for JIA, as well as for new strategies to eliminate DEK autoantibodies.

Early Treatment With Methotrexate Is Associated With Extensive Re-Ordering Of The Neutrophil Transcriptome In Juvenile Idiopathic Arthritis. Zihua Hu[1], Kaiyu Jiang[2], Mark B. Frank[3], Yanmin Chen[2] and James N. Jarvis[2]. [1]University at Buffalo, Buffalo, NY, [2]The University at Buffalo, Buffalo, NY, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: We have previously demonstrated a role for neutrophils in polyarticulartar juvenile idiopathic arthritis (JIA) disease pathogenesis. For example, JIA neutrophils show specific abnormalities in gene expression that do not correct when children reach remission. The studies here were intended to gain insights into mechanisms of therapeutic response in JIA by examining molecular events in neutrophils early in therapy

Methods: We examined 35 children with JIA who had active, untreated disease (ADU) and 26 children with active disease (ADM) who had been on therapy with methotrexate (MTX) for periods ranging from 2 weeks to 2 months. We also studied 15 healthy control children (HC) for comparison. We performed transcriptome analysis using Affymetrix exon and miRNA hybridization-based microarrays. Exon gene expression data were processed using RMA software in the Affy package of Bioconductor and analyzed using t-tests to detect differentially expressed genes (DEGs) between JIA and HC as well as between ADM individuals and healthy controls. Enrichment analyses to determine the associated functions for DEGs were performedd using by DAVID Functional Annotation Tools (http://david.abcc.ncifcrf.gov/).

Results: 216 genes were detected showing differential expression between JIA and HC. More than half of these genes (51%) are involved in regulating gene/exon splicing. Treatment with MTX was found to have substantial impact on JIA transcriptome, even while children still maintained active disease status. Of the 216 genes that were differentially expressed between HC and ADU, 112 of them (52%) reverted to normal expression levels. However, early treatment with MTX was associated with extensive re-ordering of the neutrophil transcriptome, as shown by the large number of DEGs. A total of 1271 DEGs were detected between ADM and HC, of which 1167 (92%) are unique to ADM when compared to ADU. These DEGs are associated with a broad range of functions, including more than 20 biological processes and 40 gene groups. Similar results were obtained from both isoform-level and miRNA expression data analysis. While 193 and 73 differentially expressed miRNAs were detected in ADM and ADU, respectively, 53 of them are common to both groups ($p = 1.3E-22$). At the isoform level, we found 2808 isoforms from ADM and 446 isoforms from ADU displaying differential exon splicing, 275 of them are common to both groups ($p < 6.5E-322$). Functional analysis indicated that the 446 isoforms were associated with pathways of spliceosome, apoptosis, endocytosis, B and T cell receptor signaling pathways. On the other hand, the 275 common isoforms display enrichment in the pathways of spliceosome and endocytosis.

Conclusion: Upon initiation of therapy with methotrexate, substantial re-ordering of the neutrophil transcriptome occurs. How these changes relate to eventual therapeutic response, and whether and how they relate to or lead to changes in adaptive immune function are ongoing areas of investigation in our research groups.

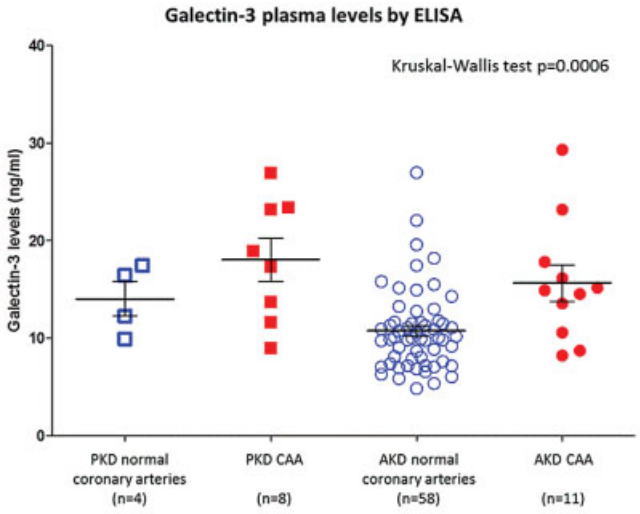
Galectin-3 and Transforming Growth Factor-β Signaling In The Pathogenesis Of Coronary Artery Aneurysms In Kawasaki Disease. Fujito Numano, Matthew Vejar, Chisato Shimizu, Susan Jimenez-Fernandez, Adriana H. Tremoulet, Jane C. Burns and Lori B. Daniels. UC San Diego, School of Medicine, La Jolla, CA.

Background/Purpose: Kawasaki disease (KD) is a self-limited acute vasculitis of young children, and coronary artery aneurysms (CAA) are the most significant complication. Despite appropriate treatment (intravenous immunoglobulin and aspirin), CAA will develop in 5–9% of cases. The etiology of the vascular inflammation is still unknown. We previously reported that the transforming growth factor-β (TGF-β) signaling pathway plays an important role in the development of CAA. Galectin-3 (Gal-3) is a novel cardiac fibrosis marker associated with cardiovascular events, and also regulates tissue inflammation and fibrogenesis, which is mediated through the TGF-β pathway. However, the association of Gal-3 with CAA in KD patients has not been previously reported.

Methods: We measured Gal-3 levels in the plasma of 69 young adults with a history of KD (AKD) and 12 acute (pre-treatment) pediatric KD patients (PKD) by enzyme-linked immunosorbent assay (ELISA). AKD subjects were classified as having CAA or normal coronary arteries (CA), based on coronary artery diameter measured by CT or standard coronary angiography. Classification of PKD subjects was based on coronary artery internal diameter measured by transthoracic echocardiography normalized for body surface area and expressed as standard deviation units for the mean (Z-scores). Z-max was defined as the largest Z-score of either the right or left anterior descending coronary artery during the first 8 weeks after disease onset. Data were analyzed by the Kruskal-Wallis test using Prism software, $p<0.05$ was considered to be statistically significant.

Results: AKD subjects with normal CA had significantly lower Gal-3 levels (median 10.0ng/ml, n=58) compared to PKD subjects with CAA (18.1ng/ml, n=8), PKD subjects with normal CA (14.4ng/ml, n=4), and AKD subjects with CAA (14.9ng/ml, n=11) (p=0.0006). Overall, there was a trend toward higher Gal-3 levels in PKD vs AKD subjects, and in subjects with CAA vs normal CA (Figure).



PKD: pediatric Kawasaki disease, AKD: young adults with a past history of KD, CAA: coronary artery aneurysms

Conclusion: Gal-3 levels in both PKD and AKD CAA subjects tended to be higher than in normal CA subjects. Gal-3 tethers the TGF-β receptor on the cell surface, and leads to increased TGF-β signaling resulting in endothelial/epithelial to mesenchymal transition (EMT). Increased TGF-β signaling and EMT are implicated in CAA formation based on KD autopsy studies. In addition, secreted Gal-3 binds to extracellular matrix proteins and acts as a cell adhesion molecule that promotes inflammation. Thus, Gal-3 may participate in the pathogenesis of CAA formation but whether higher Gal-3 levels are causal remains to be determined. Further investigation with larger numbers of PKD subjects is in progress.

2206

Detection Of State-Specific RNA Transcripts In Juvenile Idiopathic Arthritis Neutrophils Using RNA Sequencing. Kaiyu Jiang[1], Xiaoyun Sun[2], Yanmin Chen[1], Yufeng Shen[2] and James N. Jarvis[1]. [1]The University at Buffalo, Buffalo, NY, [2]Columbia University, New York, NY.

Background/Purpose: Once considered non-functional, the vast regions of the human genome that do not contain protein-coding genes are now known to contain important regulatory elements. These regulatory elements include both enhancer regions and regions encoding regulatory RNA transcripts such as long non-coding RNA (lncRNA). These studies were undertaken to examine in detail the transcriptome of neutrophils in children with polyarticular juvenile idiopathic arthritis (JIA).

Methods: We isolated RNA from neutrophils of children with 3 different phenotypes: children with active, untreated disease (AD, n=3), children on medication who fit criteria for remission by the Wallace criteria (CRM, n=3), and children with cystic fibrosis (CF, n=3), a control group designed to distinguish those transcriptome features specific to JIA and those common to other forms of chronic, soft tissue inflammation. RNA samples were prepared for sequencing using the Illumina TruSeq RNA prep kit. Sequencing was performed using the Illumina HiSeq 2000. The pass filter reads were mapped to the genome (NCBI/build 37.2) using TopHat (version 2.0.4). Probable transcripts were assembled using Cufflinks (version 2.0.2), and differential expressed transcripts were determined using DESeq. Fold change (FC) calculations were obtained using the log2(FPKM) ratio, where FPKM is the fragments per kilobase of exon model per million mapped fragments.

Results: For all phenotypes, we detected between 8,000–9,000 expressed genes, with children in CRM showing the highest number of expressed genes (n=8,668). Of these, 7,734 were common to all 3 phenotypes. Multiple isoforms of known genes were expressed in the 3 phenotypes, most of which were common to all 3. Of the protein-coding regions, there are 62 differentially expressed genes (29 down-regulated, 33 up-regulated) in fold change 1.2 or greater when AD compared to CRM, 64 DE genes (6 down-regulated, 58 up-regulated) in the AD vs CF comparison and 90 DE (40 down-regulated, 50 up-regulated,) in CRM vs CF. Principle component analysis (PCA) and hierarchical cluster analysis of DE genes showed clear separation between AD, CRM and CF. The functional enrichment analysis using DAVID for the DE genes shows they are associated with immune response (IFIH1, C4A, IFITM3, TNFSF15, APOBEC3G, OAS1, C4BPA, TRIM22, NOD2, FCGR2C, P2RY14, HLA-DRB5, ODZ1, CFD), innate immune response (IFIH1, NOD2, C4A, APOBEC3G, C4BPA, CFD), and inflammatory response (ORM1, TNFAIP6, C4A, IDO1, C4BPA, CFD, SPP1), etc. Finally, novel, previously uncharacterized transcripts were seen in each of the 3 phenotypes (n=5 for AD, n=11 for CRM, and n=9 for CF). These transcripts may represent previously-unknown lncRNA transcripts.

Conclusion: The sensitivity and dynamic range of RNAseq allow a much more detailed view of the neutrophil transcriptome. The finding of state-specific transcripts is expected to lead to new insights into JIA pathogenesis, response to therapy, and the development of diagnostic and prognostic biomarkers.

2207

Plasma Cytokine Concentrations Are Associated With Folate Perturbations and Methotrexate Polyglutamate Accumulation In The Peripheral Blood Of Juvenile Idiopathic Arthritis Patients Treated With Low-Dose Methotrexate. Ryan S. Funk, Leon van Haandel, Marcia Chan, Lanny J. Rosenwasser, Andrew Lasky, Maria F. Ibarra, Mark F. Hoeltzel, J.S. Leeder and Mara L. Becker. Children's Mercy Hospital, Kansas City, MO.

Background/Purpose: Methotrexate inhibits the production of inflammatory cytokines, but is also an antifolate. The activity of MTX is thought to depend on the formation of polyglutamate metabolites ($MTXGlu_n$) traditionally measured in erythrocytes (RBCs). Therefore, this study evaluates the relationship between cytokines, folate homeostasis and methotrexate polyglutamates in a cohort of JIA patients treated with low-dose MTX.

Methods: Blood samples from JIA patients between 3 and 17 years of age (n=32) were evaluated. Samples were collected prior to and 3 months after the initiation of MTX therapy. IL-1α, IL-1β, IL-1RA, IL-6, TNFα and NAMPT in the plasma were measured by immunoassay. Concentrations of MTX and its polyglutamate metabolites were measured in patient RBCs and a subset of patient PBMCs (n=10). Whole blood, plasma and RBC levels of

folic acid, tetrahydrofolate, 5-formyl tetrahydrofolate and 5-methyl tetrahydrofolate (5mTHF) were measured. MTX and folate analyses were conducted by previously established UPLC/MS/MS methods. Statistical analyses were conducted by simple linear regression and Wilcoxon signed rank tests using analyte measurements at each time point (0 and 3 month) and the change in analyte from 0–3 months.

Results: Consistent with folic acid supplementation and the inhibition of intracellular reduced folate formation by MTX, post-treatment concentrations [median (IQR)] of plasma folic acid increased [0.85 (0.6, 2.35) to 27 (0.83, 58.2) nM ($p<0.01$)] and RBC 5mTHF levels decreased [750.1 (513.7, 968.8) to 560.8 (376.3, 707.2) nM, ($p<0.001$)]. An increase in plasma folic acid from 0–3 months was associated with a reduction in IL-1α ($p<0.01$), IL-1β ($p<0.05$), IL-1RA ($p<0.01$) and IL-6 ($p<0.01$), and a reduction in RBC 5mTHF concentrations from 0–3 months was associated with a reduction in TNFα ($p<0.05$).

Reduced concentrations of RBC 5mTHF at 3 months were associated with an increase in short chain RBC $MTXGlu_{1-2}$ ($p<0.05$), and a reduction in long chain RBC MTX_{3-5} ($p<0.05$). Accumulation of RBC $MTXGlu_{3-5}$ was associated with increased IL-1β ($p<0.05$), IL-6 ($p=0.05$) and NAMPT ($p<0.01$) concentrations at 3 months. There were no changes in cytokine concentrations associated with short chain RBC $MTXGlu_{1-2}$ accumulation at 3 months.

In contrast, short chain PBMC $MTXGlu_1$ ($p<0.05$) and PMBC $MTXGlu_2$ ($p<0.05$) were inversely associated with 3 month IL-1α concentrations, and PBMC $MTXGlu_4$ ($p<0.01$) was inversely associated with 3 month TNFα concentrations.

Conclusion: The accumulation of folic acid and depletion of RBC 5mTHF following the initiation of low-dose MTX therapy are associated with reduced concentrations of several cytokines implicated in inflammatory arthritis. Furthermore, an accumulation of short-chain, but not long-chain, MTX polyglutamates in RBCs was observed to associate with the depletion of RBC 5mTHF at 3 months after therapy initiation. At this early time point after MTX initiation, long-chain RBC $MTXGlu_{3-5}$ were associated with *higher* concentrations of inflammatory cytokines, while short chain PBMC-$MTXGlu_{1+2}$ were associated with reduction of cytokines, suggesting perhaps PBMCs may be a more reliable cell type to investigate $MTXGlu_n$.

Psychological Condition Of JIA Patients Treated With Biologic Agents. - A Nation-Wide Survey In Japan. Yuki Osako[1], Yukiko Nonaka[2], Harumi Akaike[2], Tomohiro Kubota[2], Tsuyoshi Yamatou[2], Tomokazu Nagakura[3], Junko Yasumura[4], Hiroyuki Imanaka[2] and Syuji Takei[2]. [1]Kagoshima University, Kagoshima city, Japan, [2]Kagoshima University, Kagoshima, Japan, [3]House of Meguminoseibo, Usuki, Japan, [4]Hiroshima University, Hiroshima City, Japan.

Background/Purpose: Biologic agents, newly developed medications targeting for inflammatory cytokines such as TNF-alpha or IL-6, have been drastically improving the disease course of JIA who were resistant to conventional therapy. However, there are very few studies examined whether the biologic agents had also improved the quality of life (QOL) of patients. Focusing on their both physical and psychological condition, therefore, we examined QOL of JIA patients treated with biologic agents.

Methods: Nation-wide survey was conducted for 8–18 years old JIA patients treated with biologic agents. To the family members of the JIA patients, both PedsQL™ Generic Core Scales[1]) evaluating for QOL and questionnaires evaluating for medical condition were handed from medical doctors who had registered the patient for the Governmental Medical Support Program for Chronic Pediatric Diseases in Japan. Statistical analysis was performed by Spearman rank correlation coefficient or Kruskal-Wallis test by using SPSS ver.19.

Results: A total of 201 JIA patients (77 boys and 124 girls) were involved in the study. The biologic agent was initiated at mean 3 years from onset. Functional daily activities of JIA patients were classified from Class 1 to Class 4 according to the Steinbrocker's functional class health assessment questionnaire score[2]).

The incidence of patient who had no difficulty in daily activities (Class 1) increased from 25 % to 75 % after mean 3 years of biologic therapy. On the contrary, the incidence of patients with Class 3 difficulty in daily activities decreased from 34 % to 3 % during the treatment period.

PedsQL™ Generic Core Scalesindicate that total psychological health score statistically correlated with total physical health score in JIA patients treated with biologic agents ($P=0.559$, $p<0.001$) (Figure 1).

However, there were some JIA patients whose psychological health score were relatively low for their physical health score as seen in figure 1 (below −1SD correlation line).

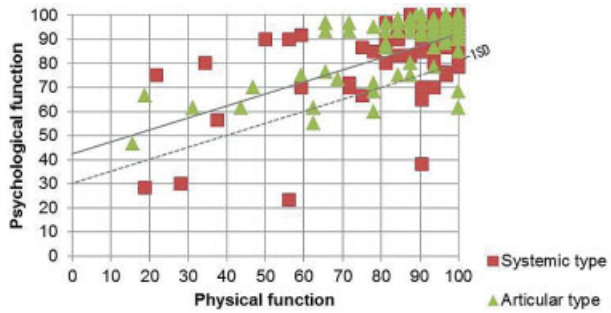

Figure 1 Correlation between physical and psychological health conditions

In such patients with relatively lower psychological health score, there were more patients who were systemic onset, treated with tocilizumab that forces to frequent refer to the hospital (every 2week), and, as the result, frequently absent from school.

Conclusion: In JIA patients treated with biologic agents, the psychological health condition improved in accordance with their physical health condition. However, we should aware that there are still patients who need psychological health support even if their physical function has improved, especially in systemic JIA patients treated with tocilizumab.

Transition From The Pediatric Rheumatologist To The Adult Rheumatologist: Outcomes Of 5 Years Of Experience Between Two Institutions. Elizabeth C. Ortiz[1], Agarwal Arunima[2], Sandra Mintz[3] and Bracha Shaham[4]. [1]University of Southern California, Los Angeles, CA, [2]Childrens Hospital Los Angeles, Los Angeles, CA, [3]Children's Hospital of LA, Los Angeles, CA, [4]Children's Hospital Los Angeles, Los Angeles, CA.

Background/Purpose: It is well documented that children with rheumatologic conditions are living into adulthood and require transition of care into the adult medical center. This process is frequently met with a number of barriers that require programs and processes to address the issues for successful transfer of care. Children's Hospital Los Angeles (CHLA) and the Los Angeles County+University of Southern California Medical Center (LAC+USC MC) decided to collaborate to meet this need. The objective of this study is to evaluate the transfer success rate and length of time from last pediatric appointment to the adult setting. In addition, whether the adherence rates prior to transition correlated with the attendnce rate in the adult setting and identify trends between diagnosis and compliance history while at CHLA.

Methods: Retrospective review of charts from patients scheduled to transfer care from 2008–2013 were reviewed. Patients identified were either without medical coverage or with state-funded Medi-Cal, as these patients require transfer of care to the LAC+USC MC. Demographic data, diagnosis, adherence to pediatric appointments and adherence to adult appointments were noted.

Results: 131 patients were to transfer care from CHLA to USC+LAC MC from fall 2008-spring 2013. There were 103 women, 28 men. Diagnosis included SLE (58), JIA (36), AS (10), MCTD (6), Dermatomyositis (4),

Scleroderma (4), Psoriatic arthritis (3), Vasculitis (5), FMF and Sjogrens (1 each) and other (3). Fifty-nine patients (45%) were never seen at LAC+USC MC, while 72 (55%) attended their provided appointment. The mean time from the last CHLA appointment to the first LAC+USC MC appointment was 179.7 days (range: −12 to 1614 days). Adherence with pediatric appointments within the last year of treatment was defined as good (no missed appointments), fair (1–2 missed appointments), or poor (3+ missed appointments). Thirty-two (41.6%) of the 77 patients with good adherence to pediatric appointments were not seen at LAC+USC MC, 26 (55.3%) of 47 patients with fair adherence, and 1 (14.3%) patient of 6 patients with poor adherence. Mean time from last CHLA appointment to first LAC+USC MC appointment for those with good, fair or poor adherence was 97.2 days, 289.5 days, 359.8 days, respectively. Seventeen (47.2%) of 36 patients with JIA did not transfer care to LAC+USC MC, 25 (43.1%) of 58 patients with SLE. The mean time from last CHLA appointment to first LAC+USC MC appointment for those with JIA and SLE were 206.2 days and 217.4 days, respectively.

Conclusion: There are many obstacles to a successful transition from the pediatric to the adult rheumatologist. This data shows, despite having an identified appointment, only 55% of patients successfully transferred care. In addition, of those who demonstrated poor appointment compliance at CHLA, most attended their LAC+USC MC. From our data, it is clear there is work to be done as only half of those requiring transfer of care to LAC+USC MC are seen and many of those after a substantial gap in their care. A large-scale, prospective study of patients during this time period could further elucidate the reasons for these observations and identify areas for improvment.

2210

Involvement In Leisure Activities Among Children and Youth With Juvenile Idiopathic Arthritis. Sabrina Cavallo[1], Annette Majnemer[2], Ciaran M. Duffy[3] and Debbie Ehrmann Feldman[1]. [1]Université de Montréal, Montreal, QC, [2]McGill university, Montreal, QC, [3]Children's Hospital of Eastern Ontario and University of Ottawa, Ottawa, ON.

Background/Purpose: Children with arthritis may be at greater risk for adopting a more sedentary lifestyle compared to their healthy peers in part due to disease related factors such as pain, joint stiffness and tenderness. The patterns of leisure participation and the identification of potential determinants of inactivity may guide the development of therapeutic strategies.

Objectives: To describe leisure activities in terms of diversity, intensity and enjoyment, as well as to identify potential socio-demographic and disease-related determinants.

Methods: Ninety three children and youth aged 8 to 18 years diagnosed with juvenile idiopathic arthritis (JIA) and their families participated in this cross-sectional study. Children and youth were administered the Children's Assessment of Participation and Enjoyment (CAPE), which measures involvement in leisure activities (recreation, physical, social, skill-based, self-improvement). The disease characteristics were abstracted from the child's medical file (JIA sub-type, active joint count, age of diagnosis), pain perception and functional status were obtained through self-report. Parents completed questionnaires on socio-demographic data.

Results: The most popular activities (>90%) were playing computer/video games, watching television, hanging out with friends and doing homework. Least popular activities were (<10%) martial arts, gymnastics and horseback riding. The level of enjoyment was highest for social activities (mean: 4.2 ±0.5). Involvement in informal leisure activities showed a significant negative association with functional limitations ($\beta = -0.266$; 95% CI= −0.589, −0.059; p=0.017).

Conclusion: Greater functional limitations may dissuade children and youth from participating in more active pursuits, which places them at greater risk for adopting sedentary lifestyles. The identification of determinants of leisure activities in children and youth with arthritis may allow healthcare professionals to assess children's health needs with more precision and promote a healthier lifestyle.

Hospital For Special Surgery's Charla De Lupus (Lupus Chat)® Teen/Young Adult/ Parent Group: Holistic Support For Lupus Patients and Their Families. Erica Sandoval[1], Lillian Mendez[2], Roberta Horton[3], Josephine Isgro[4] and Jillian A. Rose[3]. [1]Hospital For Special Surgery, New York, NY, [2]Hospital for Speical Surgery, New York, NY, [3]Hospital for Special Surgery, New York, NY, [4]Morgan Stanley Children's Hospital of New-York Presbyterian, Columbia University Medical Center, New York, NY.

Background/Purpose: Teens with chronic illnesses are faced with challenges to their identity, peer relationships, self-esteem, and developmental milestones, which can have a lasting impact on their psychosocial development; underscoring the need for a holistic approach when intervening with this population. Our lupus support and education group for teens/young adults and parents have been meeting monthly for 12 years at an urban medical center in collaboration with pediatric rheumatologists. Facilitated by social workers and bilingual/bicultural health educators, the group provides peer sharing, guest speakers, and recreational activities to improve and address the understanding and impact lupus has on families, medical adherence, self-image, and peer related concerns. We report on evaluations from our support group participants from 2011–2012, focused on the satisfaction and impact of our psychoeducational programs and special events.

Methods: There were 26 activities for teens/parents (16 programs, 10 special events). Derived from participants' expressed needs, programs focused on topics that directly affect teen health such as, "Lupus and Your Kidneys," "Taking Control of your Lupus", "Preparing for Transition," and "Depression and Lupus." Special events included plays, Thanksgiving Dinner, Holiday Party /Talent Show, Prom Night for Teens, and Spa Day for parents. After each program, a 9-item anonymous evaluation was self- administered(with mixed Likert scale and opened ended questions).

Results: 393 participants attended programs (254 teens, 139 parents); 247 completed evaluations. When asked overall satisfaction with the presentation 89% indicated they were "very much" satisfied; 82% both reported the presentations "very much" contributed to their understanding of lupus-related issues, and " very much" met their expectations; 60% reported that the presentation "very much" helped them to cope with their lupus.

In our annual satisfaction survey, when asked about the impact and satisfaction of special events, themes emphasized the importance of community and sense of family, i.e "this helps bring people closer." When asked for their favorite special event, respondents shared," Holiday Party because everyone meets and it's like a big holiday dinner," "Thanksgiving dinner because we were one big family." When asked what do you find most valuable, respondents shared, "it gives lupus patients a forum in which they can share their unique experiences"; "support in dealing with their chronic illness."

Conclusion: These programs address the many psychosocial, educational, and recreational needs of a culturally diverse lupus population. This model allows patients to gain practical knowledge about how to manage their illness while developing trusting relationships with practitioners in less formal settings, helping us learn how lupus impacts the family and how best to intervene to optimize outcomes.

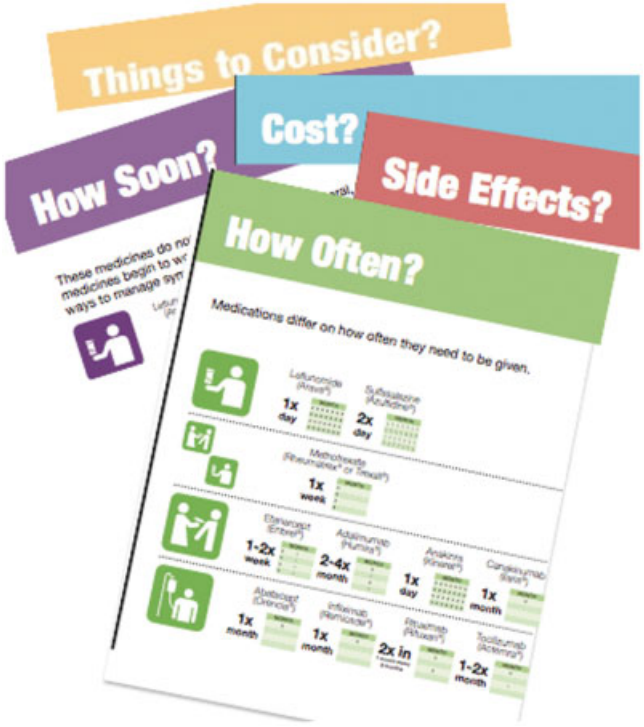
Development Of Tools To Facilitate Shared Decision Making About Medications For Juvenile Idiopathic Arthritis – A Project Of The Pediatric Rheumatology Care and Outcomes Improvement Network. Esi Morgan DeWitt[1], Ellen A. Lipstein[1], Katie Staun[2], Linda Scherer[1], Janalee Taylor[1], Carole M. Lannon[1] and William B. Brinkman[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]University of Cincinnati, Cincinnati, OH.

Background/Purpose: Medication options for juvenile idiopathic arthritis (JIA) are increasing. Medications differ on a variety of attributes, including mechanisms of action, dosing intervals, modes of administration, safety profiles, and cost. Some parents of children with JIA are left with questions and concerns about medications suggesting a need for improved clinician-parent communication. Decisions like this, with multiple reasonable options that differ in ways that matter to families, are conducive to "Shared Decision Making" (SDM). SDM is a process whereby clinicians share information about the options and patients/parents share information about their goals and preferences. Together, a treatment plan is developed that is the best fit for the individual patient and their family. We conducted a project to develop tools to facilitate SDM within the Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN). PR-

COIN is a learning network designed to improve outcomes of JIA care using quality improvement (QI) approaches.

Methods: Development of issue cards to facilitate SDM involved multiple steps including qualitative interviews with clinicians and care providers, direct observation of clinical encounters, and an iterative design process involving a graphic designer and a stakeholder panel of clinicians, allied health professionals and parents. We introduced the prototype issue cards for use in clinics using Plan-Do-Study-Act (PDSA) cycles. We elicited feedback to guide card revisions from PR-COIN members via weekly electronic surveys and discussions during monthly webinars and following direct observation of encounters using the cards.

Results: We identified the medication attributes deemed most important to discuss by our stakeholders, including "How Soon" will therapies take effect, "How Often" are they given, "Side Effects", "Cost", "How Long" will need to stay on the medication, and "Other Considerations." We used these attributes to organize the issue cards and symbols to convey key concepts (see Figure). Intended use of the cards involves clinicians showing the cards to patient and parent and asking which card they would like to discuss first. By selecting a card, the family reveals what is important to them. After 18 revisions, PR-COIN stakeholders at 6 sites found the issue cards to be acceptable for regular use.



Conclusion: PR-COIN issue cards are well accepted by clinicians and families within network sites. PDSA cycles continue as we seek to implement the issue cards in routine clinical care to facilitate SDM across the network. Our ultimate goal is to drive improvement in child JIA outcomes by reliably engaging patients/parents in SDM to select a medication that is a good fit.

Anti-IL-6 Receptor Antibody Normalizes Both DKK-1 and Sclerostin As Wnt Inhibitors In a Mouse Model Of Collagen-Induced Arthritis. Hiroto Yoshida[1], Mika Yagoto[1], Miho Suzuki[1], Keisuke Tanaka[1], Isao Matsumoto[2], Takayuki Sumida[2] and Yoshihiro Matsumoto[1]. [1]Chugai Pharmaceutical Co., Ltd., Gotemba, Japan, [2]University of Tsukuba, Tsukuba, Japan.

Background/Purpose: The Wnt pathway plays an important role in bone formation and regeneration. This pathway is regulated by several soluble inhibitors such as Dickkopf-1 (DKK-1) and sclerostin. However, it is not fully understood how development of arthritis affects DKK-1 and sclerostin production, or if levels of DKK-1 and sclerostin are improved by blockade of interleukin-6 (IL-6) or tumor necrosis factor-α (TNF-α). The purpose of this study was to examine DKK-1 and sclerostin production in inflammatory arthritis and how it is affected by blockade of IL-6 or TNF-α, using a mouse model of collagen-induced arthritis (CIA).

Methods: CIA in DBA/1J mice was triggered by intradermal injection of bovine type II collagen on Days 0 and 21. Mice were injected intraperitoneally with either anti-mouse IL-6 receptor antibody (MR16-1) on Days 0 and 21 or with TNF receptor-Fc (TNFR-Fc) 3 times per week from the first immunization. Serum was sampled on Days 14 (before swelling), 35 (peak of swelling), and 56 (after swelling subsides). Serum Wnt signalling inhibitors (DKK-1 and sclerostin) were measured by ELISA. Hind limb bones (periarticular bone) and the lumbar spine (systemic bone) were excised on Day 56. Bone volume (BV/TV) of the hind limb (cuboid bone) and the lumbar spine (trabecular bone of L6) was analysed by micro-computed tomography (μCT).

Results: In CIA mice, BV/TV of the hind limb and lumbar spine on Day 56 were significantly decreased to 72.6% ($p<0.0001$) and 62.1% ($p<0.0001$) of the respective values in non-immunized mice. MR16-1 and TNFR-Fc each significantly suppressed the development of arthritis ($p<0.001$ and $p<0.05$) and bone loss in the hind limb ($p<0.0001$ and $p<0.01$) compared with untreated CIA mice. On the other hand, bone loss in the lumbar spine was significantly suppressed by only MR16-1 ($p<0.0001$) and not by TNFR-Fc ($p=0.367$). On Days 14, 35, and 56, DKK-1 levels were significantly higher in CIA mice than in non-immunized mice ($p<0.0001$). Sclerostin levels were significantly lower on Days 14 and 35 in CIA mice than in non-immunized mice ($p<0.0001$). In MR16-1-treated CIA mice, DKK-1 was significantly lower than in untreated CIA mice on Days 35 and 56 ($p<0.0001$ and $p<0.01$), and sclerostin was significantly higher on Days 14 and 35 ($p<0.0001$). In TNFR-Fc-treated CIA mice, on the other hand, although DKK-1 on Day 35 was as significantly decreased as it was in MR16-1-treated mice ($p<0.0001$), sclerostin levels on Day 35 were similar to those of untreated CIA mice ($p=0.988$).

Conclusion: The high DKK-1 level in CIA mice was suppressed by blockade of not only TNF-α but also IL-6. This result indicates one mechanism through which blockade of TNF-α and IL-6 suppresses periarticular bone loss. However, DKK-1 might not affect systemic bone loss because TNFR-Fc treatment did not suppress bone loss in the lumbar spine. On the other hand, although sclerostin levels were significantly lower in CIA mice than in non-immunized mice, sclerostin levels were normalized only by blockade of IL-6. Our findings suggested that anti-IL-6 receptor antibody would have a beneficial effect on both periarticular and systemic bone loss by normalizing the Wnt pathway in inflammatory arthritis.

STAT3 Blockade Suppresses Autoimmune Arthritis In Mice Via The Reciprocal Regulation Of Treg and Th17 Cells. Jennifer Lee[1], Jae Ho Lee[1], Seung Min Jung[1], Young Sun Suh[1], Jung Hee Koh[1], Soo Young Lee[2], Dae Chul Jeong[1], Mi-La Cho[3], Seung-Ki Kwok[1], Ji Hyeon Ju[1], Kyung-Su Park[1] and Sung-Hwan Park[1]. [1]The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, South Korea, [2]The Catholic University of Korea, Incheon St. Mary's Hospital, Incheon, South Korea, [3]Catholic University of Korea, Seoul, South Korea.

Background/Purpose: IL-6-mediated STAT3 signaling which is essential to Th17 differentiation plays the central role in the pathogenesis of rheumatoid arthritis. To investigate the molecular mechanism underlying the anti-rheumatic effects and the T cell regulatory effects of STAT3 inhibition, we studied the effects of JAK2 inhibitor, AG490, on Th17/Treg balance and osteoclastogenesis.

Methods: AG490, inhibitor of Jak2, was administered via intraperitoneal injection in collagen-induced arthritis (CIA) model and the *in vivo* effects of AG490 were determined. The differential expressions of proinflammatory cytokines including IL-17, IL-1β and IL-6 were analyzed by immunohistochemistry. The levels of phosphorylated STAT3 and STAT5, the differentiation of Th17 and Treg after the treatment of AG490 in CIA model were analyzed by immunostaining. In vitro development of Th17 and Treg was analyzed by flowcytometry and real-time polymerase chain reaction.

Results: AG490 administration ameliorated the arthritic phenotype of CIA and increased the proportion of Foxp3-positive Treg cells. In contrast, the proportion of IL-17-producing T cells and the levels of inflammatory markers were reduced in AG490-treated group. The pSTAT3-positive CD4 T cells were reduced, whereas pSTAT5-positve CD4 T cells were elevated with treatment of

AG490. Further, AG490 markedly enhanced the expression of molecules associated with Treg development (ICOS, PD-1, ICAM-1 and CD103) as well as Foxp3. The development and the function of osteoclast were also suppressed with AG490 treatment.

Conclusion: Our results suggest that AG490 which specifically regulates JAK2/STAT3 pathway may be the promising treatment strategy for rheumatoid arthritis.

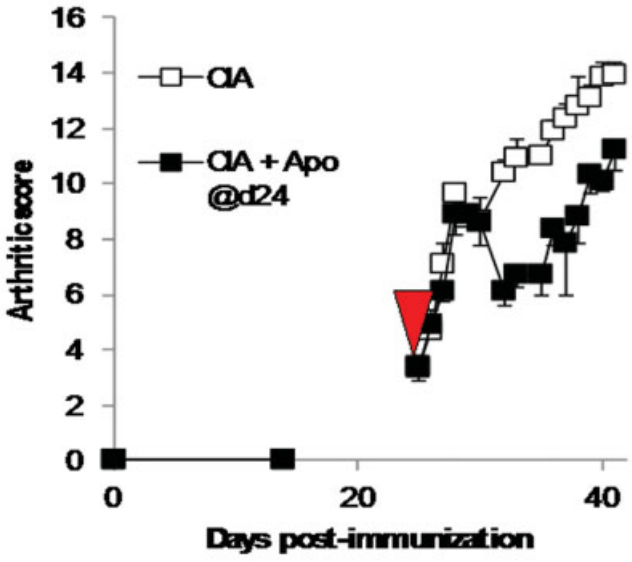
Apoptotic Cell-Based Therapy To Treat Collagen-Induced Experimental Arthritis. Rationale For The Use Of Apoptotic Cells In The Treatment Of Rheumatoid Arthritis. Sylvain Perruche[1], Amandine Clauzon[1], Francis Bonnefoy[1], Eric Toussirot[2] and Philippe Saas[3]. [1]EFS Bourgogne Franche Comté, Besançon, France, [2]CIC Biotherapy 506 and Rheumatology and EA 4266 Pathogens and Inflammation, Besançon, France, [3]INSERM UMR1098 / Plateforme de Biomonitoring, Besançon, France.

Background/Purpose: Most of the currently available biological agents used in the treatment of rheumatoid arthritis (RA) target a cellular or soluble factor involved in the physiopathology of the disease. Alternatively, cellular therapies are scarce in the therapeutic management of RA. Apoptotic cells display immunologic properties that have been used to resolve inflammation in various experimental models of autoimmune diseases (diabetes, demyelinating diseases) as well as in bone marrow transplantation to favour engraftment and prevent graft versus host disease. Apoptotic cell approach has been successfully assessed to prevent arthritis development in experimental rat model. Here we evaluated a cell-based therapeutic approach based on the immuno-modulatory properties of apoptotic cells to treat RA. In this study, we thus investigated the effects apoptotic cell injection to treat arthritis in a mouse model of collagen-induced arthritis (CIA).

Methods: CIA was induced in susceptible DBA/1 mice using type II bovine collagen immunization. Four to 8 days after arthritis development (d20 post-immunization) mice presenting arthritic symptoms were treated with apoptotic cells (5.10e6 cell/mouse). As control, methotrexate was used (MTX, 15 mg/kg, twice) alone or with apoptotic cells. Regulatory T cells (Treg) were assessed by FACS at time of sacrifice (day 40/45).

Results: Apoptotic cell injection demonstrated a significant decrease of arthritis score ($p>0.01$; 4 independent experiments), associated with an increased percentage of Treg in the spleen at time of sacrifice (Figure: Apoptotic cell injection in collagen induced arthritis attenuates arthritis score either after early or late injection. Data are obtained in DBA1 mice immunized with bovine type II collagen). In addition, MTX was sufficient to decrease arthritis as well and apoptotic cell injection did not influence MTX efficiency and *vice-et-versa*. Whereas MTX did not affect the percentage of Treg, MTX + apoptotic cell treatment induced a strong increase of Treg in the spleen and draining lymph nodes.



Conclusion: Apoptotic cell injection is an effective treatment to reduce arthritis severity and should be consider in clinic as an alternative method for the treatment of patients with RA. A phase I/II clinical trial using this therapeutic approach is currently planned by our group in patients with RA refractory to biological agents.

Tubastatin A, a Selective Histone Deacetylase-6 Inhibitor, Suppresses Synovial Inflammation and Joint Destruction In a Collagen Antibody-Induced Arthritis Mouse Model. Joong Kyong Ahn[1], Jaejoon Lee[2], Hyemin Jeong[3], Jiwon Hwang[3], Seulkee Lee[3], Ji Young Chai[4], Inyoung Kim[3], Eun Chung Hong[5], Eun-Kyung Bae[5], Hoon-Suk Cha[2] and Eun-Mi Koh[3]. [1]Kangbuk Samsung hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, South Korea, [3]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [4]Jesang Hospital, Seongnam-si Gyeonggi-do, South Korea, [5]Samsung Biomedical Research Institute, Seoul, South Korea.

Background/Purpose: Histone deacetylases (HDAC) play a key role in regulating gene expression by deacetylasing histones, and HDAC inhibitors induce various cellular effects, including apoptosis, cell cycle arrest and inhibition of angiogenesis. Tubastatin A is a potent and selective HDAC-6 inhibitor and its anti-rheumatic effect has not been determined. This study was undertaken to investigate the effect of Tubastatin A on synovial inflammation and joint destruction in collagen antibody-induced arthritis (CAIA) mouse model.

Methods: CAIA mice were given daily intraperitonial injections of various concentration of Tubastatin A (0, 10, 50, 100mg/kg, n=6 each). Clinical score, paw thickness, and body weight were measured for 14 days. On day 15, mice were sacrificed and the expression of TNF-α, IL-1, IL-6 from the serum was analyzed using ELISA. Hind foot was examined histologically and synovitis was scored by 2 independent pathologists. Micro CT of the joints was performed and joint destruction was quantified. Cell viability and the expression of inflammatory cytokines in human fibroblast-like synoviocytes (FLS) after incubation with various doses of Tubastatin A (0, 0.75, 1.5, 3μM) were measured using MTT assay and ELISA, respectively.

Results: In the Tubastatin A-treated group, clinical arthritis was attenuated and paw thickness was lower and this effect was statistically significant in the Tubastatin 100mg/kg group compared to control ($p<0.01$). All mice lost a small amount of weight but the difference was not statistically significant between groups. In the Tubastatin A 100mg/kg group, the histological severity of synovial inflammation as measured by synovial hypertrophy, density of resident cells, and inflammatory cell infiltrates was significantly lower compared with control ($p<0.01$, each). In addition, micro CT showed that joint destructions as measured by bone volume/tissue volume and bone surface area/bone volume were significantly less in the Tubastatin 100mg/kg group compared with control ($p<0.05$). Among pro-inflammatory cytokines, expression of IL-6 in the serum was significantly lower in the Tubastatin A 50mg/kg group compared with control ($p<0.05$). The expression of IL-6 from human FLS after incubation with Tubastatin A decreased in a dose-dependent manner without affecting the cell viability.

Conclusion: Our data demonstrated that Tubastatin A, a selective HDAC6 inhibitor, ameliorates synovial inflammation and protects against joint destruction in CAIA mice, and reduced expression of IL-6. Our data suggest that Tubastatin A warrant further investigation as a potential therapeutic agent in rheumatoid arthritis.

Experimental Arthritis Exacerbates Periodontal Disease But Periodontal Infection Does Not Exacerbated Experimental Arthritis. John Butcher[1], Jessica Oliver-Bell[1], Robert Benson[1], James Brewer[1], Paul Garside[1], Iain B. McInnes[1] and Shauna Culshaw[2]. [1]Institute of Infection, Immunity and Inflammation, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom, [2]Dental School, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom.

Background/Purpose: There is a proposed link between periodontal disease (PD) and rheumatoid arthritis (RA). A substantial, although not unanimous, body of epidemiological evidence indicates a bidirectional link, with patients with PD

more likely to suffer RA and vice versa. Several mechanisms have been proposed to explain the relationship between PD and RA, including i) periodontal bacterial generating autoantigens, ii) local periodontal inflammation generating autoantigens, ii) direct bacterial insult to the joint, iv) systemic inflammation associated with periodontitis exacerbating inflammation at distant sites, and v) shared risk factors. Previous studies, using experimental models of later stages of arthritis and joint destruction, suggest that periodontal infection may exacerbate arthritis and vice versa. We sought to investigate whether periodontal infection may impact on the initiation of arthritis and therefore used an experimental model of breach of immune tolerance, generation of autoantibodies and synovitis.

Methods: Mice were orally infected with *P. gingivalis* to initiate alveolar bone destruction, modeling human periodontal disease. Animals subsequently received Th1 polarized ovalbumin specific T cells by adoptive transfer, and were immunized, and then challenged in the footpad with ovalbumin. Paw swelling, joint histology, periodontal bone loss, responses of T cells from the draining lymph nodes, and serum antibody were assessed.

Results: Animals developed footpad swelling and histological evidence of synovitis. Circulating anti-CCP antibodies were significantly elevated in experimental arthritis compared with control animals (arthritis: 1189 ± 25.56 ELISA units (EU), control: 934.1 ± 99.39 EU; $p<0.05$), and a similar trend was observed for circulating anti-collagen antibodies, although this did not reach statistical significance (arthritis: 439.5 ± 124.2 EU, control: 224.0 ± 68.8 EU; $p=0.19$). Periodontal infection had no impact on any measures of this model of early arthritis. However, animals with periodontal infection and arthritis showed significantly more periodontal bone destruction (periodontal infection+arthritis: 0.44 ± 0.01 mm, periodontal infection: 0.40 ± 0.01 mm; $p<0.05$) compared with animals with periodontal infection alone.

Conclusion: These data suggest that periodontal infection may not be responsible for initiating the breach of tolerance associated with the initiation of arthritis. In this model system of breach of tolerance, oral infection made no impact on articular or autoantibody outcomes. Nonetheless, established periodontal inflammation may be detrimental to patients with RA and therefore further human and animal studies are required to unravel the mechanisms mediating the PD/RA relationship as understanding such a relationship offers potentially improved therapeutic strategies – for both PD and RA independently and in combination. *This project was supported by EUFP7 'Gums and Joints' Grant number 261460*

Gingival Stem Cells Suppress Osteoclast Formation and Bone Erosion In CIA Through CD39 Signal. Song Guo Zheng[1], Jian Gu[1], Maogeng Chen[1] and Yi Shen[2]. [1]University of Southern California Keck School of Medicine, Los Angeles, CA, [2]Shanghai East Hospital at Tongji University, Shanghai, China.

Background/Purpose: We recently have reported that human-derived gingival mesenchymal stem cells (GMSC) have strong capacity to suppress immune responses and T cell-mediated collagen-induced arthritis, however, the precise role and functions of GMSC in bone homeostasis are still unknown. This study was undertaken to determine the effects of GMSCs on osteoclastogenesis *in vitro* and on bone erosion *in vivo* in collagen-induced arthritis (CIA).

Methods: Human gingival tissues were gained from discard samples from suffers who underwent dental operation, GMSC were isolated from gingival tissues and cultured in α-MEM with 10% FBS. GMSC and mouse bone marrow derived-CD11b+ cells or human CD14+ cells were co-cultured with various ratios in the presence of 20ng/ml m-CSF and 30ng/ml RANKL. Fibroblast cells have been used for negative control. The osteoclast formation was determined by TRIP staining and numbers of osteoclast formation were calculated in microscope. In addition, GMSCs were adoptively transferred to mice with CIA to assess *in vivo* effects on disease development and bone erosion, the latter determined by CT scanning. To determine the molecular mechanisms, various inhibitors and antibodies have been added to cell cultures and administrated to CIA mice that had been infused with GMSC.

Results: We showed that GMSCs potently suppressed the genesis and proliferation of osteoclast cells from either mouse CD11b+ cells or human CD14+ cells. We also observed that that GMSC suppress osteoclast cell genesis via CD39 signal *in vitro*. Adoptive transfer of GMSCs reduced the severity of arthritis and bone erosion in CIA mice. Finally, we show that GMSCs are capable of preventing severity of CIA model via CD39 signals.

Conclusion: Use of GMSCs can treat rheumatoid arthritis and prevent bone erosion.

Active Immunization Against VEGF-Derived Oligopeptides Improves Joint Inflammation and Destruction In Collagen-Induced Arthritis. Emilie Duvallet[1], Laure Foulboeuf[1], Luca Semerano[2], Nadia Belmellat[1], Marc Lecouvey[3], Eric Assier[1], Sylviane Muller[4] and Marie-Christophe Boissier[2]. [1]EA4222, Li2P, University Paris 13, Sorbonne Paris Cité, Bobigny, France, [2]EA4222, Li2P, University Paris 13, Sorbonne Paris Cité and Rheumatology Department, Avicenne Hospital, Assistance Publique-Hôpitaux de Paris (AP-HP), Bobigny, 93009, France, Bobigny, France, [3]CSPBAT Paris 13 University, Bobigny, France, [4]CNRS, Strasbourg, France.

Background/Purpose: We have demonstrated in experimental models the efficacy of vaccination against cytokines, using a heterocomplex of keyhole limpet hemocyanin (KLH) and human TNF, called TNF kinoid (-K). VEGF plays a key role in the development of rheumatoid arthritis (RA), allowing hypertrophy of the pannus by neovascularisation, articular inflammation and destruction. Thus, VEGF is a potential target in RA.

We aimed at demonstrating an inhibitory effect of a sustained inhibition of VEGF by vaccines based on VEGF-derived peptides linked to KLH (Vpep-K) in collagen-induced-arthritis (CIA).

Methods: Anti-murine VEGF immunization was performed by injecting intra-muscularly Vpep1-K and Vpep2-K formulated in incomplete Freund adjuvant (IFA) in DBA/1 mice (at days −36, −22, −8, 7 and 37). Control groups received KLH or PBS on the same schedule. Arthritides were induced by two subcutaneous injections of bovine type II collagen, the first at day 0 in complete Freund adjuvant, the second at day 21 in IFA. Clinical scores of arthritis were evaluated twice per week. Histological scores of joint inflammation and destruction after Hematoxylin/Eosin staining were quantified at sacrifice. Anti-peptide, anti-VEGF and anti-KLH antibody (Ab) levels were assessed by ELISA.

Results: Vpep1-K group showed lower arthritic scores as compared to KLH and PBS groups ($p<0.05$). At histological analysis, inflammation and destruction scores of the paws were lower in Vpep1-K group versus KLH and PBS group ($p<0.005$). Vpep1-K and Vpep2-K groups induced anti-VEGF Ab production as assessed by ELISA at day −2 and sacrifice.

Conclusion: These data show that Vpep1-K induces anti-VEGF Abs and improves arthritis in a murine model of RA.

The Role Of CD11c+ Dendritic Cells In Inflammatory Arthritis. Antonia Puchner, Stephan Blüml, Victoria Saferding, Harald Leiss, Josef S. Smolen and Kurt Redlich. Medical University of Vienna, Vienna, Austria.

Background/Purpose: Dendritic cells (DCs) play an important role in bridging the innate and the adaptive immune response by serving as antigen presenting cells and are therefore implicated in the initiation of chronic autoimmune diseases, including rheumatoid arthritis.

Using the K/BxN serum transfer arthritis, a model of human rheumatoid arthritis, which depends only on the innate immune system, we investigated the innate role role of dendritic cells in inflammatory arthritis.

Methods: KBxN serum transfer arthritis was induced in CD11c-diphteria toxin receptor (DTR) transgenic mice, which express the human diphtheria-toxin receptor under the CD11c promoter. This allows for specific depletion of CD11c+ cells by administration of diphtheria toxin (DT). DT or PBS was given on day −1, 3, 6 and 9 and the severity of arthritis was determined clinically and histologically. In addition, serum transfer arthritis was induced in wild type animals, which also received DT.

Results: Efficient depletion of DCs from the spleen after injection of DT was confirmed by flow cytometry and histological analysis. Clinical scores of arthritis showed that CD11c-DTR transgenic mice had significantly reduced paw swelling and loss of grip strength compared to PBS treated animals. In contrast, wild type animals receiving DT showed identical clinical signs of arthritis as PBS treated animals, excluding unspecific effects of DT in mice. Histological analysis found that CD11c-DTR transgenic mice that had received DT displayed decreased synovial inflammation, local bone destruction and reduced the number of osteoclasts. In addition the number of CD115+ CD11b+ GR neg/low osteoclast precursors was significantly reduced in the peripheral blood of CD11c-DTR transgenic mice that had received DT, suggesting a role of CD11c+ cells for osteoclast precursor generation.

Conclusion: These data show that dendritic cells are involved in innate reactions leading to inflammatory arthritis and suggest that dendritic cells could be an important target for rheumatoid arthritis therapy.

The Histamine H_4 Receptor Drives Inflammation In Preclinical Models Of Arthritis. Paul J. Dunford, Jeffery Cowden, Fuqu Yu, Homayon Banie, Mandana Farahani, Ping Ling, Steven Nguyen, Jason Riley, Mai Zhang, Jian Zhu and Robin L. Thurmond. Janssen R&D, LLC, San Diego, CA.

Background/Purpose: The histamine H_4 receptor (H_4R) has been shown to drive inflammatory responses in models of asthma, colitis and dermatitis and in these models it appears to impact both innate and adaptive immune responses. In this study we utilized both H_4R-deficient mice and specific H_4R antagonists, to investigate the involvement of the H_4R in mouse arthritis models and in toll-like receptor (TLR) driven events in vitro and in vivo.

Methods: H_4R-deficient mice and wild-type mice administered the H_4R antagonist, JNJ 28307474, were studied in models of collagen antibody-induced arthritis (CAIA) and collagen-induced arthritis (CIA). The impact on Th17 cells was assessed by restimulation of inguinal lymphocytes in the disease or immunization models and upon in vitro stimulation of whole blood. The impact of H4R antagonists, JNJ 7777120 and 28307474, on innate immunity were also examined in LPS challenge of mice, and of in vitro mast cells and dendritic cells.

Results: Both H_4R-deficient mice and mice treated with the H_4R antagonist exhibited reduced arthritis disease severity in both CAIA and CIA models. This was evident from the reduction in disease score and in joint histology. In the CIA model treatment with the H_4R antagonist reduced the number of IL-17 positive cells in the lymph node and the total production of IL-17. Th17 cell development in vivo was reduced in H_4R-deficient mice or in mice treated with an H_4R antagonist. In human blood an H_4R antagonist reduced the production of IL-17 when cells were stimulated in vitro. Additionally, H4R antagonists were able to inhibit TNF production in response to LPS challenge in mice, and to decrease IL-6 and multiple cytokine and chemokine production from TLR stimulated mast cells and dendritic cells, respectively

Conclusion: These results implicate the H_4R in disease progression in arthritis, in innate driven, proarthritic inflammatory events and in the production of IL-17 from Th17 cells. This work supports future clinical exploration of H_4R antagonists for the treatment of rheumatoid arthritis and other autoimmune diseases.

Positive Allosteric Modulation Of The Adenosine A_{2a} Receptor Alters Inflammatory Cytokine Production and Alleviates Chronic Arthritis In Rats. Ajith A. Welihinda, Jordan A. Mechanic and Edward P. Amento. Molecular Medicine Research Institute, Sunnyvale, CA.

Background/Purpose: Rheumatoid arthritis is a chronic systemic autoimmune disease characterized by inflammation and joint destruction; a consequence of which is the high local concentration of adenosine. Adenosine, acting primarily through a member of the G-protein coupled receptor (GPCR) family of transmembrane receptors, the A_{2a} receptor ($A_{2a}R$), mediates anti-inflammatory and immunomodulatory activity. High affinity $A_{2a}R$ agonists have demonstrated therapeutic efficacy, however, their utility is hindered by lack of adenosine receptor subtype selectivity and inadvertent activation of the $A_{2a}R$ at non-disease sites. In light of the high concentrations of adenosine found at sites of chronic inflammation we explored the hypothesis that diminished receptor responsiveness to adenosine may play a role in disease expression. GPCR's are amenable to an agonist-independent mode of activity enhancement known as positive allosteric modulation (PAM). Positive allosteric modulators have no intrinsic agonist activity, yet enhance the activity of the receptor to its agonist. Using a positive allosteric modulator unique to the $A_{2a}R$, AEA061, we examined the effects of PAM of the $A_{2a}R$ on inflammatory cytokine production and chronic arthritis.

Methods: To assess the effect of PAM of the $A_{2a}R$ on cytokine production in vitro, mouse splenocytes were stimulated with LPS in the presence of AEA061. To determine whether PAM of the $A_{2a}R$ inhibits inflammation in vivo, control and $A_{2a}R$ deficient mice received vehicle or AEA061 i.v. 10 min prior to i.p. injection of LPS. The role of PAM of the $A_{2a}R$ on progression of chronic arthritis was evaluated in adjuvant-induced arthritis (AIA). Male Lewis rats were immunized by i.d. injection at the base of the tail with *M. tuberculosis* H37Ra in Freund's incomplete adjuvant. Paw volumes and clinical severity were assessed for 26 days. When the mean clinical score = 2, AEA061 was administered i.p. once daily. Splenocytes were cultured and cytokine in culture supernatants and in plasma were quantified using multiplex immunoassays.

Results: PAM of the $A_{2a}R$ inhibited LPS-stimulated production of TNF-α, MIP-1α, MIP-1β, MIP-2, IL-1α, RANTES and CXCL1 by mouse splenocytes in a dose-dependent manner in vitro ($p < 0.05$). AEA061 also reduced plasma TNF-α and MCP-1 levels while increasing IL-10 levels ($p < 0.05$) in control but not in $A_{2a}R$-deficient mice. In AIA rats, AEA061 reduced paw volumes ($p<0.01$) as well as reduced clinical scores ($p<0.01$). Splenocytes from AEA061-treated animals produced decreased IL-1 (45%) and increased IL-10 (341%) ex-vivo.

Conclusion: PAM of the $A_{2a}R$ to endogenous adenosine inhibits cytokine production in vitro and in vivo in models of acute inflammation and chronic arthritis. This is the first demonstration of the therapeutic utility of PAM of the $A_{2a}R$ and supports the notion that impaired receptor responsive to adenosine may contribute to the dysregulation of chronic inflammation. PAM of the $A_{2a}R$ presents a novel, unique and safe approach that focuses the therapeutic benefit at the site of disease, does not employ exogenous agonists and preserves the natural pattern of $A_{2a}R$ activation by endogenous adenosine while enhancing receptor responsiveness.

Monitoring Of Active Matrix Metalloproteinase-3 Using. Sung Jae Choi[1], Young Ho Seo[2], Young Ho Lee[1], Jong Dae Ji[1], Gwan Gyu Song[3], Aeju Lee[2] and Jae-Hoon Kim[3]. [1]Korea University Medical Center, Seoul, South Korea, [2]Korea University Medical center, Seoul, South Korea, [3]Korea Univ College of Med, Seoul, South Korea.

Background/Purpose: Active matrix metalloproteinase-3 (MMP-3) is a prognostic marker of rheumatoid arthritis (RA). Recently, we developed the MMP-3 probe which can specifically detect an active MMP-3.

Methods: The aim of this study was to investigate whether detecting and monitoring of active MMP-3 using the MMP-3 probe will be useful to predict therapeutic drug responses in collagen-induced arthritis (CIA) mice. During the period of drug treatments such as methotrexate (MTX) or infliximab (IFX), fluorescence signals in arthritic joint tissues and in serum of CIA mice were monitored using the MMP-3 probe to correlate with MMP-3 mRNA and protein levels. Also, micro-computed tomography (micro-CT), X-ray and histology were performed to confirm drug responses.

Results: Strong fluorescence signals observed in joint tissues and serum of CIA mice were significantly decreased when drugs were treated (Fig. 1.). The decrease of RA scores in drug-treated CIA mice leads to the fluorescence reductions, which is mainly due to down-regulation of MMP-3 mRNA or protein levels. The results that micro-CT, X-ray (Fig. 2.) and histology clearly showed the markedly decrease of bone and cartilage destruction were consistent with the fluorescence reduction by down-regulation of active MMP-3 in drug-treated CIA mice.

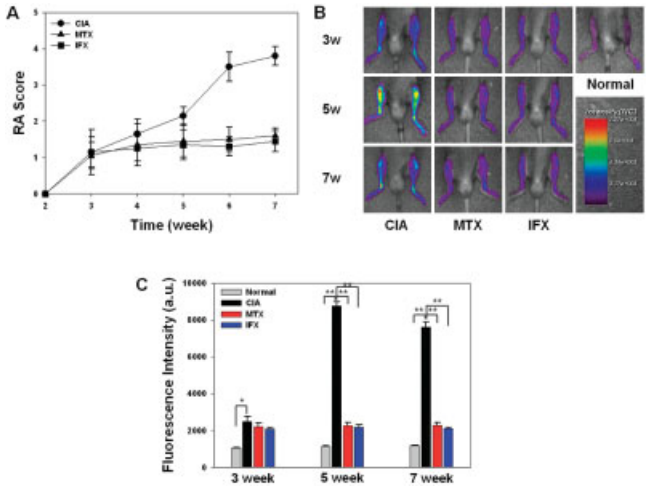

Figure 1. *In vivo* monitoring of RA activities and active MMP-3 levels using "smart probe" in arthritic joints of CIA mice with or without MTX or IFX treatment.

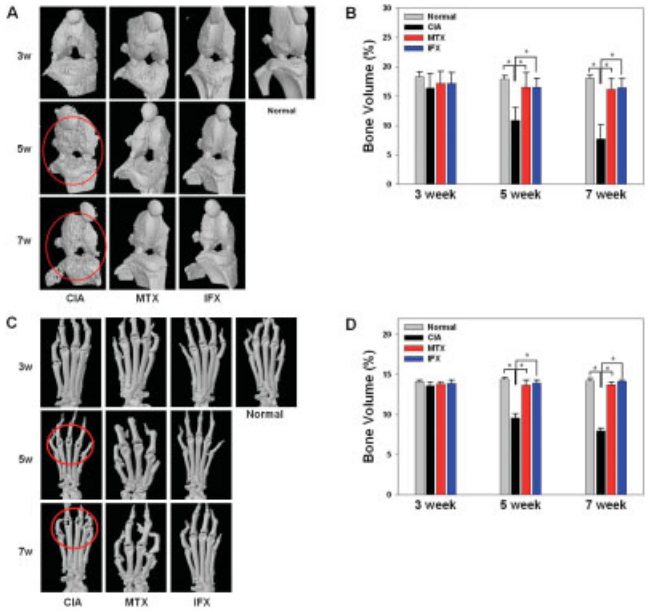

Figure 2. Three-dimensional reconstructions of micro-CT images and bone volume analysis using micro-CT in the knee joints and the paws of normal (n=5), CIA (n=5), and MTX (n=5) or IFX (n=5)-treated CIA mice at 3, 5, and 7 weeks after the first immunization.

Conclusion: We suggested that the MMP-3 probe could detect and monitor active MMP-3 of CIA mice serum in treatment course, and thereby predicting the drug response or resistance to RA therapies at an earlier stage. We hope that the MMP-3 probe will be a promising tool for drug discovery, development and drug responses in RA therapy.

Tumor Necrosis Factor Alpha Induces Anti-Citrullinated Protein Antibodies and Arthritis In Part Through Peptidyl Arginine Deiminase 4. Miriam A. Shelef[1], Jeremy Sokolove[2], Catriona Wagner[3], Eric Sackmann[4], Thomas Warner[4], David Beebe[4], William H. Robinson[5] and Anna Huttenlocher[1]. [1]Univ of Wisconsin Schl of Med, Madison, WI, [2]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [3]VA Palo Alto Heatlh Care System and Stanford University, Palo Alto, CA, [4]University of Wisconsin, Madison, WI, [5]Stanford University, Palo Alto, CA.

Background/Purpose: Rheumatoid arthritis is an autoimmune, destructive arthritis characterized by anti-citrullinated protein antibodies (ACPAs) and high levels of inflammatory cytokines like tumor necrosis factor alpha (TNFalpha). Citrullinated proteins may be a trigger for the development of rheumatoid arthritis since ACPA immune complexes can stimulate TNFalpha production, which promotes inflammation and arthritis. Inflammation appears to induce protein citrullination, but it is not known if TNFalpha can lead to citrullination with resultant ACPAs. We hypothesized that TNFalpha could augment ACPA production with a role for the citrullinating enzyme peptidyl arginine deiminase 4 (PAD4) as part of a feedback loop to accelerate arthritis development.

Methods: We measured ACPA levels by multiplex array in mice with chronic inflammatory arthritis due to overexpression of TNFalpha. We then crossed mice that overexpress TNFalpha with mice that lack PAD4. We compared ACPA levels by multiplex array, lymphocyte activation by flow cytometry, arthritis by clinical score, and systemic inflammation using microfluidics devices in TNF+PAD4+/+ versus TNF+PAD4−/− mice.

Results: Mice that overexpress TNFalpha have increased serum ACPAs, suggesting that high levels of TNFalpha, as is seen in human rheumatoid arthritis, can amplify ACPA production. Further, mice with TNFalpha induced arthritis that lack PAD4 have decreased ACPAs, reduced T cell activation, and less inflammation and arthritis, suggesting that PAD4 makes key contributions to TNFalpha driven, chronic inflammatory arthritis.

Conclusion: These data support a positive feedback loop in which ACPAs, TNFalpha, and PAD4 synergize to enhance inflammation and the development of rheumatoid arthritis.

COVA322: A Novel, Bispecific Tumor-Necrosis-Factor-Alpha/Interleukin-17A (TNF/IL-17A) Inhibitor With Excellent Pharmacokinetic Properties In Mice and Cynomolgus Monkeys. Mathias Locher, Dragan Grabulovski, Isabella Attinger-Toller, Susann Koenig-Friedrich, Ulrike von der Bey and Julian Bertschinger. Covagen AG, Schlieren, Switzerland.

Background/Purpose: The generation of bispecific antibody molecules with excellent biophysical and pharmacokinetic properties has been a challenging task in the past. We present here COVA322, a bispecific anti-TNF/IL-17A drug candidate moving towards the clinic that shows IgG-like pharmacokinetic properties.

Methods: Using phage display technology we have isolated Fynomers inhibiting human IL-17A. Fynomers are small binding proteins (7 kDa) derived from the human Fyn SH3 domain which can be engineered to bind to essentially any target of interest with high affinity and specificity. After genetic fusion of the anti-IL-17A Fynomer to a commercially validated anti-TNF antibody, the resulting bispecific molecule COVA322 was injected in mice and cynomolgus monkeys to determine its pharmacokinetic parameters. As controls, the commercially available antibodies adalimumab and golimumab were also injected into animals.

Results: The fusion of the anti-IL-17A Fynomer to the fully human anti-TNF antibody did not alter the favorable pharmacokinetic parameters of the parental anti-TNF antibody. COVA322 demonstrated comparable pharmacokinetic properties in mice and cynomolgus monkeys as adalimumab and golimumab. In addition, we could demonstrate that COVA322 stays fully functional and intact for at least ten days in cynomolgus monkeys, indicating that the Fynomer is not cleaved from the antibody.

Conclusion: These encouraging preclinical results indicate that COVA322 has highly promising pharmacokinetic properties. Through its unique mode-of-action of inhibiting simultaneously TNF and the IL-17A/A homodimer, COVA322 has game changing potential in the treatment of inflammatory diseases.

2226

Involvement Of Suppressor Of Cytokine Signaling In Anti-Arthritic Effect Induced By Anti-IL-6 Receptor Antibody. Miho Suzuki[1], Hiroto Yoshida[1], Keisuke Tanaka[1], Isao Matsumoto[2], Takayuki Sumida[2] and Yoshihiro Matsumoto[1]. [1]Chugai Pharmaceutical Co., Ltd., Gotemba, Japan, [2]University of Tsukuba, Tsukuba, Japan.

Background/Purpose: In the treatment of rheumatoid arthritis (RA), biologics such as IL-6 and TNF inhibitors have high therapeutic efficacy with extended duration of effect ["LITHE study" J Rheumatol. 2013; 40: 113–26, "ATTEST study" Ann Rheum Dis. 2008; 67: 1096–103]. Among RA patients treated with anti-IL-6 receptor antibody (anti-IL-6R), in particular, it is reported that 10% were able to suspend the biologic for an extended period without relapse/flare ["DREAM study" Mod Rheumatol. 2013 May 3. [Epub ahead of print] DOI:10.1007/s10165-013-0894-z]. Although not yet fully clarified, this is thought to be causally related to a sustained anti-inflammatory effect of anti-IL-6R. It was reported that levels of suppressor of cytokine signaling (SOCS)-1 and -3, well-known feedback inhibitors of the JAK/STAT pathway, are high in RA [Rheumatology (Oxford). 2007; 46: 1538–46] and should be considered when allowing a drug-holiday in RA. In this study, we investigated the efficacy of anti-IL-6R on SOCS-1 and -3 levels, using a mouse model of arthritis.

Methods: Glucose-6-phosphate isomerase (GPI)-induced arthritis was triggered in DBA/1J mice by intradermal injection of recombinant GPI. We used anti-IL-6R to inhibit IL-6. Anti-IL-6R was intraperitoneally administered once at a dose of 4 mg 5 days after immunization (Day 5). Clinical symptoms of arthritis were evaluated by observation and expressed as an arthritis score on a scale of 0–3 for each limb. Expression levels of IL-6, SOCS-1 and -3 mRNA in the hind limbs

of mice were measured by real-time PCR, and IL-6, SOCS-1 and -3 levels in blood were measured by ELISA on Days 0, 7, 14, 21, 28 and 35.

Results: The mouse model used here is a transient arthritis model: arthritis starts to develop from about Day 5 and reaches peak swelling on Day 14. Blood levels of IL-6 and SOCS-3 reached their peaks on Day 7. SOCS-1 level in blood reached the plateau level on Day 7. Expression levels of IL-6 and SOCS-3 mRNA in hind limbs reached their peaks on Day 14 in line with the arthritis score. Expression level of SOCS-1 mRNA in hind limbs reached the plateau level on Day 14. Anti-IL-6R significantly suppressed the arthritis score and SOCS-3 levels both in blood and hind limbs on Day 14. On the other hand, anti-IL-6R suppressed expression level of SOCS-1 mRNA in hind limbs on Day 14 but did not suppress SOCS-1 level in blood.

Conclusion: We demonstrated that, though each peak time was different, IL-6 and SOCS-3 changed similarly both in blood and the hind limbs, with the changes in hind limbs well associated with changes in the arthritis scores, and that anti-IL-6R inhibited both SOCS-1 and -3 in the hind limbs in line with arthritis scores and inhibited only SOCS-3 but not SOCS-1 in blood. These results suggest that a possible mechanism of the anti-arthritic effect of anti-IL-6R is a reduction in SOCS-3. However, if reduced arthritis scores were caused by an increase in SOCS-1 in blood, it would also be important to consider blood levels of SOCS-1 maintained by anti-IL-6R. Furtherconsideration is needed to explain why SOCS-1 levels in blood and hind limbs respond differently to anti-IL-6R. Therefore, further studies for investigating the effect of anti-IL-6R on SOCS-1 and -3 may help to make a drug-holiday in RA possible.

The Anti-Proliferative Function of RSK2 in Synovial Fibroblasts Protects Against TNF-á-Induced Joint Destruction in Inflammatory Arthritis. Anja Derer[1], Christina Boehm[1], Bettina Groetsch[1], Michael Stock[1], Kirsten Neubert[1], Sybille Boehm[1], Bettina Sehnert[1], Georg Schett[1], Axel J. Hueber[1] and Jean-Pierre David[2]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Background/Purpose: The pro-inflammatory cytokine Tumor Necrosis Factor alpha (TNF-α) directly activates the ribosomal S6 kinase RSK2 *in vitro*. We recently demonstrated the protective effect of RSK2 against TNF-induced bone loss. Interestingly, we found an increased activation of RSK2 in the inlfamed joints of arthritis patients as well as mice overexpressing the human TNF-α (*hTNF*tg). This prompted us to investigate the function of RSK2 in the development of TNF-α-induced inflammatory arthritis.

Methods: *hTNF*tg mice were crossed with RSK2-deficient ($Rsk2^{y/-}$) mice. Clinical scoring and histomorphometry of the joints were assessed. Levels of circulating pro-inflammatory cytokines as well as the cellularity of myeloid lineages in the spleen were compared. The expression of cytokines and mesenchymal markers in the joints was determined via QPCR. Bone marrow transfer of $Rsk2^{y/-}$ and wild-type littermates into *hTNF*tg mice was performed and clinical scoring as well as histomorphometry of the joints was assessed. Primary fibroblast-like synoviocytes (FLS) from *hTNF*tg and *hTNF*tg;$Rsk2^{y/}$ mice were isolated to analyze their expression of inflammatory cytokines and metalloproteinases as well as their proliferation and apoptosis *in vitro*.

Results: RSK2 deficiency in *hTNF*tg mice resulted in an early onset of clinical signs of arthritis as well as a drastic exacerbation of inflammation, increased cartilage destruction and increased local bone destruction. Increased levels of circulating pro-inflammatory cytokines and the increased proportion of all myeloid lineages in the spleen confirmed the enhanced inflammation in the *hTNF*tg mice lacking RSK2. Increased activation of synovial fibroblasts and macrophages in the joints of *hTNF*tg;$Rsk2^{y/-}$ mice was demonstrated by the locally increased expression of pro-inflammatory cytokines and matrix metalloproteinases (MMPs). Importantly, the phenotype could not be transmitted by the transfer of $Rsk2^{y/-}$ bone marrow into *hTNF*tg mice that demonstrated the essential role for RSK2 expression in mesenchymal cells driving the pathogenesis. In agreement, although no difference in the expression of pro-inflammatory cytokines or MMPs nor a change in apoptosis was detected in synovial fibroblasts isolated from *hTNF*tg;$Rsk2^{y/-}$, these cells displayed an increased proliferation rate.

Conclusion: The anti-proliferative function of RSK2 controls a cell autonomous negative feed-back against the activation of synovial fibroblasts by TNF-α, therefore limiting joint destruction in arthritis. Thus, activation of RSK2 is a potential target for the treatment of both local and systemic bone destruction in RA.

FMS-Like Tyrosine Kinase 3 Ligand -Dependent CD103+DC Are Crucial For The Initiation Of Collagen-Induced Arthritis. Maria Ines Ramos, Samuel Garcia, Saïda Aarrass, Boy Helder, Kris A. Reedquist, Paul-Peter Tak and Maria C. Lebre. Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.

Background/Purpose: Dendritic cells (DCs) are a heterogeneous cell population that plays an important role for the initiation of protective and pathogenic immunity. Flt3L is a growth factor that drives DC development from bone marrow (BM) progenitors and it is crucial for maintenance of DCsin the steady-state. The objective of this study was to address the role of Flt3L-dependent DCs in the initiation of collagen-induced arthritis (CIA).

Methods: CIA was induced in Flt3L−/− and WT C57/BL6 littermates. In vitro and in vivo uptake and migration was performed using BM-DCs and dermal DCs. Antigen presentation was studied in vivo by adoptive transfer of CFSE-labeled OT-I or OT-II T cells + OVA in Flt3L−/− and WT mice and in vitro by culturing BM-DCs with OT-I and OT-II cells. T cell proliferation was analyzed by CFSE dilution. To study BM-DC function qPCR array (Dendritic and Antigen Presenting Cell PCR Array- Qiagen) for 84 genes was performed. To test the potential of a Flt3 inhibitor (CEP701) in the prevention of CIA, an in vivo study was performed injecting CEP701 before the onset of disease in DBA-1 mice.

Results: We showed that Flt3L−/− mice are protected from CIA. In Flt3L−/− mice CD103+ DCs are almost absent. The amount of DCs carrying antigen reaching the LN in Flt3L−/− mice was reduced compared with WT. Uptake and migratory capacity was similar in Flt3L−/− BM-DCs compared to WT BM-DCs. Adoptive transfer of OT-I and OT-II T cells + OVA in Flt3L−/− mice resulted in a dramatic reduction of total cell proliferation and more importantly less divisions compared with WT animals. No intrinsic defects on DC function were observed by qPCR array. Mice treated with CEP701 before the onset of disease were protected from CIA and that correlated with the disappearance of $CD103^+$ migratory DCs. Synovial T cells were reduced and correlated with disease severity.

Conclusion: Antigen presentation in Flt3L−/− mice is impaired. As CD103+ DCs are absent in Flt3L−/− mice and are important in (cross)-presenting antigens our data reveals a crucial role for CD103+ DCs in the induction of CIA. As a consequence of CD103+ DC absence Flt3L−/− mice showed a reduction in T cell activation in particularly reduced CD8 T cell responses. Targeting this DC subset might be of interest in individuals at risk of developing autoimmune disorders.

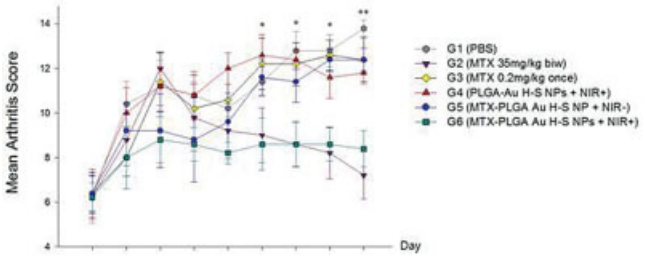
Alleviation Of Collagen-Induced Arthritis By Multifunctional Nanoparticle Containing Methotrexate. You-Jung Ha[1], Sun-Mi Lee[2], Ji-Hee Lim[1], Hyung-Joon Kim[2], Sang-Won Lee[1], Soo Kon Lee[1], Kyung-Hwa Yoo[2] and Yong-Beom Park[1]. [1]Yonsei University College of Medicine, Seoul, South Korea, [2]Yonsei University, Seoul, South Korea.

Background/Purpose: Methotrexate (MTX) is the most widely used disease-modifying anti-rheumatic drugs for the treatment of rheumatoid arthritis (RA). Despite of its efficacy, the continuous use of MTX is often accompanied by several adverse effects, especially in high-dosage MTX. We developed the multifunctional nanoparticle (MNP; Poly($_{DL}$-lactic-*co*-glycolic acid)-Au half-shell coated nanoparticles) containing 0.2mg/kg of MTX. Upon near-infrared (NIR) irradiation, these MNP can enhance the drug release and generate heat by Au half-shells. This study aimed to investigate the therapeutic efficacy of MNP containing MTX in a murine model of arthritis.

Methods: Collagen-induced arthritis (CIA) was induced in male DBA/1J mice by immunization with bovine type II collagen. Thirty CIA mice were divided into 6 groups (untreated, conventional MTX (35 mg/kg × 8 times intraperitoneal), MTX 0.2mg/kg once intravenous (IV), MTX-unloaded MNP

IV with NIR, MTX-loaded MNP IV, and MTX-loaded MNP IV with NIR). The clinical scores and hind paw thickness were evaluated. Histopathologic assessment of joint sections was performed. The serum levels of pro-inflammatory cytokines were measured by enzyme-linked immunosorbent assay.

Results: Treatment of MTX-loaded MNP with NIR significantly alleviated the severity of the arthritis, based on the reduced hind paw swelling and clinical scores, compared with untreated CIA mice. The treatment efficacy of MTX-loaded MNP with NIR group was comparable to that of conventional MTX-treated group. However, arthritis was not ameliorated in the mice treated with MTX 0.2mg/kg once or MTX-unloaded MNP with NIR. Treatment of MTX-loaded MNP without NIR showed partial treatment response only in an early treatment period. Histopathologic analyses and serum pro-inflammatory cytokines showed the similar pattern.



Conclusion: Treatment efficacy of MTX-loaded MNP with NIR was similar with conventional treatment in a much smaller dosage of MTX (about 1/1000 of MTX). Our results showed that this novel drug delivery system using MNP can be a new therapeutic tool for treatment of RA.

Specific Angiotensin Type II Receptor Stimulation Attenuates Collagen-Induced Arthritis Via Enhancement Of FoxP3 Regulatory T Cells. Bettina Sehnert[1], Veronica Valero-Esquitino[2], Georg Schett[3], Ulrika Muscha Steckelings[2] and Reinhard E. Voll[1]. [1]University Hospital Freiburg, Freiburg, Germany, [2]Medical Faculty Berlin, Berlin, Germany, [3]University of Erlangen-Nuremberg, Erlangen, Germany.

Background/Purpose: The renin-angiotensin system (RAS) is known to play an important role in inflammation, fibrosis, and end-organ damage. Moreover, AT2R signalling exerts anti-inflammatory and anti-apoptotic actions. Specific AT2R stimulation exhibits also neuroprotective characteristics. Compound 21 (C21) is the first non-peptide AT2 receptor agonist that stimulates selectively the AT2 receptor without affecting the AT1 receptor.

In the present study we examine the therapeutic potential of C21 in collagen-induced arthritis (CIA) and assess the role of Th1, Th17, and Treg subsets.

Methods: Collagen-induced arthritis was induced according standard protocols. Daily C21 treatment (0.1 mg/kg/i.p.) was started at day 20 after immunization. Etanercept was used as positive control. Disease activity was assessed by clinical scoring to a graded scale (0–4). At day 48 hind paws were removed for histological analysis. The stained sections (Hematoxylin/eosin, toluidine blue and tartrate-resistant acid phosphatase) were graded on a scale from 0–3. Serum cytokine profile (Th1) and splenic FoxP3+ regulatory T cells of arthritic mice were analysed by flow cytometry. *In vitro* differentiation of Th0, Th1, Th17, and Treg cells in the presence of C21 (1μM) was investigated using quantitative RT-PCR analysis of sorted naive T-cells isolated from spleen and lymph nodes of C57BL/6 mice.

Results: Systemic treatment with C21 attenuated the clinical severity of established CIA compared to the PBS group ($p<0.005$). The therapeutic efficacy of C21 was comparable to Etanercept which we used as a positive control. C21 administration reduced the cumulative incidence in CIA. Histological evaluation of C21 sections showed a well preserved articular cartilage and minor inflammatory infiltrates correlating with a reduction in disease severity. No significant difference between the groups was detectable on bone destruction. C21 did not suppress CIA by inhibition of anti-CII antibody production. Furthermore, the number of $CD4^+Foxp3^+$ cells was significantly increased after *in vivo* C21 treatment ($p<0.05$) compared to the PBS group. *In vitro* we detected decreased IFNγ mRNA expression in Th1, respectively a decrease in IL-17 mRNA expression in Th17 polarized T cells. Moreover, *in vitro* treatment of naïve T-cells with C21 significantly upregulated $FoxP3^+$Treg cells in the presence of polarizing factors.

Conclusion: C21-mediated AT2R-stimulation suppresses clinical severity, incidence and histological signs of established CIA. The regulation of IL-17-producing Th17 cells towards regulatory T cells (*Treg*) might explain the observed anti-inflammatory effect. Due to the absence of severe side-effects, C21 treatment presents an attractive concept in arthritis therapy.

The Actin-Crosslinking Protein Lasp-1 Regulates Synovial Fibroblast Migration and Cartilage Destruction In Arthritis. Denise Beckmann[1], Jan Hillen[1], Marianne Heitzmann[1], Catherine S. Chew[2], Stefan Butz[3], Dietmar Vestweber[3], Hermann Pavenstädt[1], Thomas Pap[4] and Adelheid Korb-Pap[1]. [1]University Hospital Muenster, Muenster, Germany, [2]Medical College of Georgia, Augusta, GA, [3]Max Planck Institute of Molecular Biomedicine, Muenster, Germany, [4]University Hospital Münster, Münster, Germany.

Background/Purpose: Lasp-1 localizes at focal adhesions along stress fibres and leading edges of migrating cells and regulates the metastatic dissemination of tumors. Although rheumatoid arthritis synovial fibroblasts (RASF) have been shown to contribute to the spreading of disease by leaving cartilage destruction sites, migrating via the bloodstream and re-initiating the destructive process at distant articular cartilage surfaces, the underlying mechanisms are not yet understood. Therefore, we investigated the role of Lasp-1 in SF migration and in a mouse model of RA.

Methods: We used Western blot analyses and immunofluorescence stainings of cells grown on different extracellular matrices (ECM) including fibronectin, laminin and in vitro reconstituted cartilage collagen fibrils to study the expression of Lasp-1 and its sub-cellular distribution in RASF as well as in SF isolated from the hind paws of wild type (wt) and human TNFalpha transgenic (hTNFtg) mice, an established animal model of human RA. To investigate the effects of a Lasp-1 deficiency on RA-like arthritis *in vivo*, we interbred Lasp-$1^{-/-}$ mice with hTNFtg mice. Wt, Lasp-$1^{-/-}$, hTNFtg and Lasp-$1^{-/-}$/hTNFtg mice were scored for clinical parameters such as paw swelling, grip strength and weight once weekly for 14 weeks. Hind paws of 14 weeks old mice of all genotypes were harvested, embedded into paraffin, and tissue sections were stained with toluidin-blue and analyzed using AxioVision software. The migration characteristics of SF derived from all genotypes were studied in a modified scratch assay as well as in live cell imaging studies.

Results: Western blot analyses showed a significantly increased expression of Lasp-1 in RASF and in hTNFtg SF compared to healthy and wt controls. Using immunofluorescence, Lasp-1 was localized to structures of cell adhesion and invasion especially when *in vitro* reconstituted cartilage collagen fibrils were used as ECM. Quantification of scratch assay data showed a significantly reduced migration of Lasp-$1^{-/-}$ SF compared to wt cells (-43.7%, $p<0.05$) and even more prominently of Lasp-$1^{-/-}$/hTNFtg SF compared to hTNFtg cells (-69.11%, $p<0.05$). Live cell imaging demonstrated striking differences both in the migration velocity and in migration edge formation of Lasp-$1^{-/-}$/hTNFtg SF compared to hTNFtg SF *in vitro*. Lasp-$1^{-/-}$/hTNFtg mice presented milder clinical symptoms compared to hTNFtg animals *in vivo*. Histopathologic analyses showed less cartilage damage in Lasp-$1^{-/-}$/hTNFtg compared to hTNFtg mice (5.2% vs. 33.6%, $p<0.05$) and attachment of synovial tissue to the cartilage (0.4 μm vs. 1.4μm, $p<0.05$) at an age of 14 weeks.

Conclusion: We conclude that Lasp-1 modulates SF migration and influences cartilage degradation and SF attachment to cartilage in hTNFtg mice. SF - when activated - migrate through the formation of invasive and adhesive membrane structures, where Lasp-1 is prominently localized. Thus, targeting Lasp-1 may be a promising strategy to reduce the invasive and migratory behaviour of RASF.

2232

Neutralization of Angiopoietin-2 Enhances the Efficacy of Anti-Tumor Necrosis Factor-Alpha Treatment in a Mouse Model of Rheumatoid Arthritis by Decreasing Cellular Infiltration into the Joint and Protecting Bone. Brian Naiman, Sean Turman, William Iverson, Ronald Herbst, Tomas Mustelin and Jane Connor. MedImmune, LLC, Gaithersburg, MD.

Background/Purpose: It has recently been established that >75% of patients on methotrexate and a biologic do not achieve complete remission based on the new definition set by ACR/EULAR in 2011. These findings aresupported by recent studies utilizing imaging technology such as PDUS or MRI that have detected "subclinical inflammation" in low disease activity patients that correlates with subsequent radiographic progression. Importantly, while anti-TNF-α therapies reduce neovascularization to some extent, the effect is incomplete. Our hypothesis is that inhibiting angiogenesis beyond that provided by anti-TNF-α therapy will provide tighter control of inflammation leading to greater impact on inhibiting disease progression. The key mediators of angiogenesis are members of the vascular endothelium growth factor (VEGF) and angiopoietin (Ang) families. Several investigators have reported increased expression of these mediators in the RA and PsA joint when compared to normal or osteoarthritis biopsies. Based on previous work demonstrating efficacy of anti-Ang2 therapy in models of RA, we chose to utilize a combination of anti-Ang2 along with anti-TNF-α to explore this hypothesis.

Methods: Arthritis was induced by immunization of DBA/1 mice with glucose-6-phosphate isomerase. Animals were treated with either 10 mg/kg anti-Ang2 antibody, 10 mg/kg anti-TNF-α antibody or a combination of the two beginning 7 days following immunization. Clinical scores were assessed daily. Animals were terminated 15 days following immunization and joints were evaluated for histological changes (H&E), CD31 staining for endothelial cells, F4/80 staining for macrophages and Cathepsin K for osteoclasts. In addition, selected joints were evaluated for bone cortical roughness around the joints using magnetic resonance imaging.

Results: Treatment with an anti-Ang2 antibody in addition to an anti-TNF-α antibody resulted in improved activity on clinical scores as well as protection from pathological changes in the joints compared to anti-TNF-α or anti-Ang2 treatment alone. Combination treatment provided a greater effect on inflammation/pannus formation and inflammatory cell infiltrates as well as on osteolysis and periosteal proliferation. CD31 staining revealed decreased vascularity in the synovium of combination treated mice with a concomitant decrease in macrophage and ostoeclast infiltration. MRI analysis of the bone surface of the joints revealed augmented protection from damage (cortical bone roughness) that is observed in this model as a result of the ongoing tenosynovitis.

Conclusion: These data suggest that the enhanced activity of combined anti-Ang2 and anti-TNF-α treatment is due to a greater effect in decreasing vascularity in the synovium which results in decreased infiltrating inflammatory cells, as well as osteoclasts, leading to decreased bone damage in the joint.

Porphyromonas Gingivalis **peptidylarginine Deiminase Exacerbates Collagen-Induced Arthritis In C57BL/6 mice.** Saba Alzabin[1], Anne-Marie Quirke[2], Elena B. Lugli[2], Muslima Choudhury[2], Peter J. Charles[2], Richard O. Williams[2] and Patrick Venables[2]. [1]Epistem Ltd., Manchester, United Kingdom, [2]Kennedy Institute of Rheumatology, Oxford, United Kingdom.

Background/Purpose: There is increasing molecular and epidemiological evidence linking *Porphyromonas gingivalis* to RA. *P. gingivalis* is unique amongst periodontal pathogens in possessing a citrullinating enzyme peptidylarginine deiminase (PPAD) with the potential to generate citrullinated antigens driving the autoimmune response in RA. To examine the effect of PPAD on collagen induced arthritis (CIA), we co-immunised C57BL/6 mice with PPAD and collagen and measured disease outcome by clinical scores, histology and antibody responses.

Methods: Male C57BL/6 animals (8–10 weeks, n=15/group) were immunised with 200ug type II collagen (cII) in CFA alone, or cII emulsified in 50ug PPAD or emulsified in 50ug of an enzymatically inactive PPAD mutant control (C531A) in CFA at the base of the tail. Mice were monitored daily for the first appearance of peripheral joint oedema. Clinical scores and paw swelling measurements were recorded daily and mice were culled after 10 days of disease onset. Their joints were fixed in 10% buffered formalin and decalcified with 10%EDTA for histological analysis, and serum was collected by terminal cardiac puncture for antibody titres. Antibodies to collagen, CCP2 and recombinant PPAD were measured by ELISA.

Results: Between days 5–10 post disease onset, PPAD immunised mice had a significantly increased clinical score of arthritis (mean = 6.83, p=0.0126) compared to cII alone immunised mice (mean= 3.40). There was a minor increase in the clinical scores when C351A immunised mice (mean=4.77) were compared to mice immunised with cII alone, but this did not reach statistical significance (p=0.290). This correlated with an increase in PPAD-specific antibodies ($p< 0.0001$) in PPAD immunised mice when compared to the mutant C531A or cII immunised mice. There was no increase in anti-collagen antibodies in the PPAD immunised mice and anti-CCP2 antibodies where negative in all 3 groups. Histological analysis showed that PPAD immunisation resulted in increased synovitis and joint erosion (p=0.021) when compared to cII controls.

Conclusion: PPAD immunisation exacerbated both clinical and histological parameters of CIA. There was no significant difference between the mice immunised with cII alone and the mice co-immunised with the enzymatically inactive mutant (C351A), supporting the hypothesis that enzymatic activity of PPAD is necessary to drive its arthritogenic effect. These data indicate a molecular mechanism that explains the link between periodontitis and RA and suggests potential therapeutic benefit by targeting PPAD.

Targeting Therapy Of Citrullinated Antigen-Specific B Cells Ameliorates Collagen-Induced Arthritis. Kazuya Michishita[1], Kimito Kawahata[1], Takeyuki Kanzaki[2], Lisa Akahira[1], Toshiki Eri[1] and Kazuhiko Yamamoto[1]. [1]Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [2]Yamanashi Prefectural Central Hospital, Yamanashi, Japan.

Background/Purpose: The clinical benefit of B-cell depletion therapy in rheumatoid arthritis(RA) is a well-known fact, but problems such as relapse of tuberculosis and reactivation of hepatitis B are reported. We thought that these problems were resolved by focusing on depletion of pathogenic antigen-specific B cells using a B cell epitope tetramer conjugated with immunotoxin. We treated collagen-induced arthritis (CIA) mice by the peptide-tetramer method.

Methods: Arthritis was induced by immunizing DBA/1J mice with Bovine Type II collagen. Toxin-conjugated peptide tetramers, which had the ability to deplete peptide-specific B cells, were intravenously administered to CIA mice. After first immunization (day0), tetramers were administrated in day10 and day20 and boost immunization was carried out in day 21. We used three kinds of peptides for preparing tetramers. One (CIA1), which has citrullinated arginine residue of C1 domain, is a major epitope of type II collagen. The second (CIAC) has non-citrullinated arginine residue of C1 domain. The third has the lysine residue-rich peptide (LKP) as a control. We conjugated immunotoxin to these peptide tetramers in order to deplete peptide-specific B cells. We chose saporin which was class I ribosome-inactivating proteins as a immunotoxin. Non-cytotoxic tetramer using CIA1, anti-CD20 antibody, the anti-CD79β antibody and PBS were also injected mice as a comparison. The incidence, arthritis score and antibodies to peptide were evaluated.

Results: In mice administered CIA1 tetramer, anti-CIA antibody completely dissapeared as compared with PBS group ($P = 0.01$) and the onset of arthritis was delayed. Because the antibody titers for U1 epitope of the type II collagen did not have the significant difference between CIA1 and PBS group, it was shown that we depleted the B cells which were an antigen-specific. In mice administered tetramers using CIAC or LKP, anti-CD20 antibody, antiCD79 antibody and non-cytotoxic tetramer using CIA1, the antibody titers for CIA1 have increased and the onset of the arthritis was delayed.

Conclusion: By the depletion of citrullinated antigen-specific B cells using a B cell-epitope tetramer, the onset of the arthritis was delayed. It was necessary for the tetramer to have the cytotoxicity and the citrullinated peptide in order to improve clinical and pathological score. Targeting of citrullinated antigen-specific B cells might be a new strategy of RA treatment.

Fas Signaling In Macrophages Promotes Chronicity In K/BxN Serum Transfer Induced Arthritis. Qi Quan Huang[1], Robert Birkett[2], Renee E. Koessler[1], Carla M. Cuda[3], J.-P. Jin[4], Harris R. Perlman[1] and Richard M. Pope[5]. [1]Northwestern University, Chicago, IL, [2]Northwestern University Medical School, Chicago, IL, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, [4]Wayne State University, Detroit, MI, [5]Northwestern Univ Med School, Chicago, IL.

Background/Purpose: A non-apoptotic role for Fas signaling has been implicated in the regulation of inflammation and innate immunity. These studies were performed to elucidate the role of Fas signaling on macrophages in the development of arthritis.

Methods: K/BxN serum transfer arthritis was induced in a mouse line with Fas conditionally deleted in the myeloid lineage ($Fas^{f/f}$, $LyzM^{cre}$). The arthritis was assessed clinically and histologically. IL-1b, CXCL5, IL-10, IL-6 and gp96 expression was determined by ELISA. Bone marrow derived macrophages were activated by IL-1b and gp96. Cells were analyzed for phenotype and apoptosis by flow cytometry.

Results: The onset of arthritis in $Fas^{f/f}$, $LyzM^{cre}$ mice was comparable to that observed in control mice, however, resolution was accelerated during the chronic phase. The attenuated arthritis was associated with reduced articular expression of the endogenous TLR2 ligand gp96 and the neutrophil chemokine CXCL5, and the enhanced expression of IL-10. Activation with IL-1b or gp96 induced increased IL-10 in Fas deficient, compared with control, macrophages. IL-10 suppressed IL-1b plus gp96 induced IL-6 and CXCL5. IL-1b-mediated activation of ERK, which regulates IL-10 expression, was increased in Fas-deficient macrophages.

Conclusion: Together, our observations suggest that impaired Fas signaling results in the enhanced expression of anti-inflammatory IL-10 and reduced gp96, which are associated with accelerated resolution of inflammation in the chronic phase of arthritis. These observations suggest that strategies to reduce endogenous TLR ligands and increase IL-10 may be beneficial in patients with RA.

Articular Inflammation Is Protected By Fat-1 During The Acute Phase Of Arthritis In Mice. Sang-Il Lee[1], Yun-Hong Cheon[1], Ji-Min Kim[2] and Won Seok Lee[3]. [1]Gyeongsang National University School of Medicine, Jinju, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Keimyung University School of Medicine, Daegu, South Korea, [3]Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea.

Background/Purpose: Omega-3 polyunsaturated fatty acids (n-3 PUFA) are well known to exert anti-inflammatory effects. The Fat-1 transgenic (Fat-1 TG) mice are capable of producing n-3 PUFA from the n-6 type and are emerging as a new tool for studying the role of n-3 PUFA without the interference of the potential confounding factors of diet. Therefore, this study was carried out to evaluate whether Fat-1 over-expression attenuate arthritis severity in passive K/BxN murine arthritis.

Methods: K/BxN serum transfer arthritis was induced in Fat-1 TG and age-matched wild type (WT) mice. Arthritis severity was assessed by clinical and histopathologic scoring. The levels of inflammatory cytokines in the joints and serum were measured by quantitative PCR and ELISA. The effect of Fat-1 on osteoclastogenesis was assessed using bone marrow monocytes (BMMs) and cytokine expression was assessed using fibroblast-like synoviocytes (FLS) from Fat-1 TG or WT mice.

Results: In the K/BxN serum transfer model, Fat-1 TG mice had significantly less severe arthritis than WT until day 6. The clinical scores were: 3.3 ± 0.5 in Fat-1 TG and 5.7 ± 0.3 in WT; $p < 0.01$) and the ankle diameter were: 2.17 ± 0.03 mm in Fat-1 TG and 2.35 ± 0.03 mm in WT; $p < 0.01$). The ankle joints from Fat-1 TG mice showed significantly decreased inflammation and bone erosion than WT (scores $= 0.75 \pm 0.2$ and 2.21 ± 0.4, for Fat-1 TG and WT, respectively; $p < 0.05$). These effects were paralleled by decreased levels of IL-1β, IL-6, MCP-1, and MMP-3. The BMMs of Fat-1 TG mice resulted in reduced osteoclastogenesis than WT. TNF-α stimulated FLS of Fat-1 TG mice displayed lower NF-kB activity than WT, resulting in decreased transcriptional activation of proinflammatory target genes.

Conclusion: These results suggest that Fat-1 plays a critical regulatory role in the NF-kB pathway and the expression of target genes and controls articular inflammation during the acute phase of K/BxN serum transfer-induced arthritis.

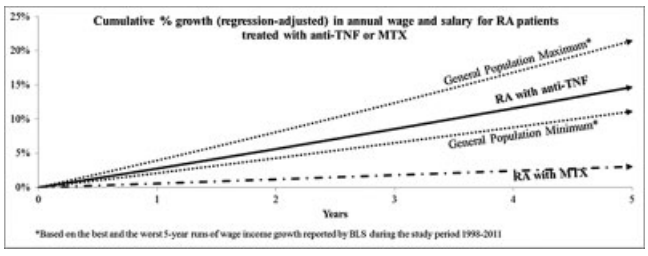
Assessment Of Wage and Salary Growth In Patients With Rheumatoid Arthritis (RA). Martin J. Bergman[1], Gourab De[2], Arijit Ganguli[3], James Signorovitch[4] and Yanjun Bao[5]. [1]Taylor Hospital, Ridley Park, PA, [2]Analysis Group, Inc., New York, NY, [3]AbbVie, Inc., North Chicago, IL, [4]Analysis Group, Inc., Boston, MA, [5]AbbVie Inc., North Chicago, IL.

Background/Purpose: RA negatively impacts patients' work outcomes. Treatment with tumor necrosis factor inhibitors (anti-TNFs) has been associated with improved work productivity and stability in RA. However, no studies have assessed the impact of anti-TNF treatment on changes in RA patients' income over time. Our study aims to compare growth of wage and salary income over time between employees with RA treated with anti-TNFs and those treated with methotrexate (MTX).

Methods: Adults with ≥ 1 RA diagnosis (ICD-9 CM: 714.0) were identified in a large-scale U.S. claims database (OptumInsight, 1998–2011). Patients were stratified into the following two groups: 1) those who filled ≥1 prescriptions for anti-TNFs, either with or without MTX (index date defined as the date of the first anti-TNF prescription) and (2) those who filled prescriptions for MTX monotherapy (index date randomly selected). During the 6-month baseline period preceding their index prescription, patients in both groups were required to have continuous health plan enrollment and to be free of anti-TNF prescriptions. The primary study outcome was annual wage or salary income (US dollars) observed from index year up to five years of follow-up (more than 90% of patients were lost to follow-up after five years). The effect of treatment on wage and salary income growth over time, starting from the same initial annual income, was assessed using a multivariable generalized linear model with adjustment for index year, age, region, gender, Charlson Comorbidity Index, health plan and total RA-related cost in the baseline period. Based on this regression model, income growth was compared to expected wage growth for the general population based on the best and worst 5-year runs of national wage data reported by Bureau of Labor Statistics during 1998–2011.

Results: The study included 1,866 patients in the MTX cohort and 1,848 patients in the anti-TNF cohort. At the index date, the MTX and anti-TNF cohorts had, respectively, average ages of 48.4 and 46.1 years, 64.8% and 62.0% females and average annual wage and salary income of $51,554 and $56,674. After adjusting for baseline characteristics, wage and salary incomes for patients in the anti-TNF cohort increased by 2.8% (CI: 1.9% – 3.6%) per year, significantly greater ($p<0.05$) than the 0.6% (CI: −0.2% – 1.4%) per year increase estimated for the MTX group. Based on this regression analysis, the average growth in wage and salary income for an RA patient treated with anti-TNF was consistent with that of the general population. In contrast, wage and salary growth for an RA patient treated with MTX was significantly lower than expected in the general population ($p<0.05$).



Conclusion: Compared to MTX monotherapy, anti-TNF treatment is associated with a greater rate of annual income growth among employees

with RA. In the anti-TNF group, income growth rate is comparable to the general employed population norm.

Comparison Of The Long-Term Outcome For Rheumatoid Arthritis Patients With persistent Moderate Disease Activity Or Disease Remission During The First Year After Diagnosis: Data From The Espoir Cohort. Bernard Combe[1], Isabelle Logeart[2], M. Belkacemi[3], S Dadoun[4], Jean-Pierre Daurès[5] and Maxime Dougados[6]. [1]Lapeyronie Hospital, Montpellier I university, Montpellier, France, [2]Pfizer, Paris, France, [3]CHRU Montpellier, Montpellier, France, [4]Paris-Pitié Salpêtrière University Hospital, Paris, France, [5]CHU, Nimes, France, [6]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France.

Background/Purpose: The Treat to Target and EULAR recommendations highlighted the need for achieving and maintaining remission in patients with early RA. We investigated if early RA patients with persistent moderate disease activity during the first year have in daily life a worst 3 to 5 year outcome than patients who achieved clinical remission.

Methods: The ESPOIR cohort included 813 patients with early arthritis in at least 2 joints of less than 6 months disease duration. They were treated according to standard of care. Within the 573 patients who had a 5 year follow-up, 93 % fulfilled the ACR/EULAR criteria for RA. This study compared patients who were in persistent moderate disease activity (DAS28>3.2 and ≤ 5.1) at both month 6 and month 12 visits (group.1) versus those who were in sustained DAS28 remission at both M6 and M12 visits (group.2). The primary outcome measure was radiographic progression ((modified Total Sharp Score (mTSS)) at month 36. Secondary endpoints were clinical remission (DAS28, SDAI, ACR/EULAR), HAQ-DI, number of missed workdays at month 36 and 60. Fisher exact test was used to compare categorical variables and Kruskal-Wallis test for quantitative variables. Logistic regression analysis was performed to determine confounding factors of outcome.

Results: Baseline characteristics were not significantly different between groups. Patients with persistent moderate disease activity during the first year, had greater radiographic progression, higher HAQ disability and number of missed workdays and lower rate of remission at 3 to 5 years than those who achieved early sustained remission (table).

3-year Outcome variable	Group 1 n=107	Group 2 n=155
mTSS	**16.1±14.9****	**11.2±11.8**
r mTSS from day 0	**10.8±6.5~**	**6.5±8.9**
rmTSS >5 (%)	**56.0°**	**39.2**
DAS28 remission (%)	**27.4***	**81.0**
SDAI remission (%)	**13.8***	**56.0**
ACR/EULAR remission (%)	**10.3***	**50.4**
HAQ-DI	**0.68±0.61***	**0.21±0.38**
Missed workdays (n)	**157.3±226.2***	**30.9±75.9**
5-year outcome variable	**Group 1 n=107**	**Group 2 n=155**
DAS28 remission (%)	**39.2***	**80.7**
SDAI remission (%)	**24.0***	**59.6**
HAQ-DI<0.5	**51.6***	**80.7**
Missed workdays (n)	**272.2±338.9~**	**45.2±90.2**

Data are mean±SD unless indicated; Group2 vs group 1: * p<0.0001; ** p=0.019; ~p=0.006; °p=0.021
By logistic regression, anti-CCP antibodies, baseline ESR, age and moderate disease activity during the first year were significant independent risk factors of 3-year radiographic progression Persistent moderate disease activity during the first year was the most significant risk factor for not achieving clinical remission and for worst disability at 3 and 5 years

Conclusion: Early RA patients with persistent moderate disease activity during the first year showed worst outcome than patients who achieved sustained clinical remission. Persistent moderate disease activity affects long-term structure, remission rate and functional and work disability. Such patients may benefit from an intensive therapeutic strategy.

Validation Of a Patient Reported Experience Measure In Patients With Rheumatoid Arthritis. Marwan Bukhari[1], Peter Jones[2], Ifeanyi Sargeant[3], Maureen Cox[4], Alison Elliott[5], Suzanne Bullock[6], Anne O'Brien[2] and Ailsa Bosworth[7]. [1]Royal Lancaster Infirmary, Lancaster, United Kingdom, [2]Keele University, Keele, United Kingdom, [3]IS medical communications, Stafford, United Kingdom, [4]Nuffield Orthopaedic centre, Oxford, United Kingdom, [5]Roche Pharmaceuticals, Welwyn Garden City, United Kingdom, [6]Lancaster University, Lancaster, United Kingdom, [7]National Rheumatoid Arthritis Society, Maidenhead, United Kingdom.

Background/Purpose: Improving patient experience is important in all diseases, but most important in patients with chronic rheumatic diseases like rheumatoid arthritis. To date there have been no specific patient reported experience measures (PREMs) in rheumatology. A multi-disciplinary group, commisioning for quality in rheumatoid arthritis (CQRA) was established to develop the first PREM in RA, this group was supported under the terms of a joint working agreement with Roche Products Ltd. Firstly, a series of focus groups was held with patients from the UK National Rheumatoid Arthritis Society to determine which elements of the patient experience was deemed most important and this was mapped against UK Department of Health Patient Experience Framework. This framework comprises 8 domains. A questionnaire was developed using the same 8 domains, but with questions developed specifically relating to RA and Rheumatology Services and these were piloted across ten UK sites. The final question asked respondents to evaluate their overall level of care. All questions were graded from very satisfied to very unsatisfied on a five point scale.

Aim: To determine the construct validity of the PREM questionnaire developed by the CQRA group.

Methods: Cronbachs alpha was used to check internal consistency within groups of scores in each domain if it contained more than one question and whether it was reasonable to combine scores within groups into a numerical scale. Additionally for each question the percentage agreement with the overall assessment on the five point scale was calculated, in case of multiple questions per domain, the responses are shown as a range.

Results: 524 patients were included in the analysis, median age was 65 years (IQR 55,80 years). 377 (72%) were female. Median disease duration was 8 years (IQR 3.5, 15 years). The Cronbach alpha co-efficients within the multi-question domains and their percentage agreement with the question on overall care are shown in table1 below.

Table 1. Result of Cronbach's alpha analysis and their agreement with overall care

Domain	Number of questions	Alpha within domain	%Agreement with overall care
Needs and preferences	5	0.90	64.5–67.2
Co-ordination of care	4	0.87	59.1–69.1
Information about care	4	0.75	22.5–66.4
Daily living	2	0.61	33.2–53.4
Emotional support	2	0.84	53.5–68.9
Family and friends	1	–	61.8
Access to care	1	-	70.4

Conclusion: The PREM has good construct validity and is a valid tool for measuring RA patient experience. Some domains have higher agreement with overall patient experience. This could provide a useful future tool for measuring patient experience. Modification of the tool to use in other rheumatic conditions is underway.

Correlative Analysis Of Swollen Joints Between Clinical Examination and Musculoskeletal Ultrasound For Rheumatoid Arthritis. Kenta Misaki[1], Takashi Nakazawa[2], Shunichi Fujita[1], Hirotaka Yamada[1] and Toshihiko Yokota[1]. [1]Kurashiki Central Hospital, Kurashiki, Japan, [2]Osaka Saiseikai Nakatsu Hospital, Osaka, Japan.

Background/Purpose: The disease activity score 28 (DAS28), clinical disease activity index (CDAI) and simplified disease activity index (SDAI) are all used in the clinical assessment of rheumatoid arthritis (RA). A consensus concerning the appropriate assessment method of swollen joints

has yet to be reached and standardized grading criteria are yet to be created. For our study we selected handy rheumatoid activity score, with 38 joints (HRAS38) *(Mod Rheumatol (2006) 16:381–388)* due to the recent attention it has gathered and performed a correlative analysis between HRAS38 assessment and musculoskeletal ultrasound by semi-quantitative grading assessment (MSKUS) for the purpose of evaluation.

Methods: One hundred and eighty patients who satisfied either the 1987 American College of Rheumatology (ACR) or 2010 ACR/European League Against Rheumatism (EULAR) rheumatoid arthritis (RA) criteria were enrolled in this study (mean age: 62.8±14.4 years, mean DAS28-C-reactive protein (CRP): 3.06±1.43, female: 123 cases, male: 57 cases, respectively). Ten joints of the left hand (metacarpophalangeal [MCP] 1–5 joints, metaphalangeal (MP) 1 and proximal interphalangeal [PIP] 2–5 joints) were validated both with HRAS38 and MSKUS semi-quantitative grading. The 38 joints included in the evaluation were 26 joints of DAS28 except for bilateral shoulder joints, as well as 10 metatarsophalangeal (MTP) joints and the bilateral ankle joints. Each joint was scored as follows: 0 = none; 1 = mild (not convincing by observation and confirmed by palpation); 2 = moderate (convincing by observation, but not tense); 3 = severe (tense).

The MSKUS estimation was divided into gray scale (GS) (grade 0–3) and power Doppler examination (PD) (grade 0–3). The agreement between HRAS38 and MSKUS (GS and PD) was calculated using Cohen's Kappa values. The Kappa tests for Inter-Observer variation were as follows (MCP2 = 0.77, MCP3 = 0.82, MCP4 = 0.89, PIP2 = 0.75, PIP3 = 0.87, PIP4 = 0.88, PIP5 = 0.82).

Results: The median Kappa Value for GS examination was 0.221 and for PD examination was 0.268, respectively. Fair agreement was observed for GS of the PIP 4 (Kappa =0.505) and PD of the MCP 3 (Kappa=0.420), respectively. For the total patients who scored 0 for HRAS38, indicating no swollen joints, positive GS (GS≥a1) was observed in 25.6 % of patients (387 joints/1494 joints) and PD (PD≥a1) was observed in 13.7 % of patients (205 joints/1494 joints).

Conclusion: According to our correlative analysis, agreement was fair between HRAS38 and MSKUS. Furthermore, analysis suggested that MSKUS is more significant in the assessment of RA, with swollen joints which were not revealed according to HRAS 38 being revealed as active synovitis by MSKUS. The authors recommend that MSKUS is used as the principal method of RA assessment.

Assessing Significant Flares In Rheumatoid Arthritis: Validity Of The Outcome Measures In Rheumatology Preliminary Flare Questions In The Canadian Early Arthritis Cohort. Susan J. Bartlett[1], Clifton O. Bingham III[1], Ernest Choy[2], Juan Xiong[3], Gilles Boire[4], Boulos Haraoui[5], Janet E. Pope[6], J. Carter Thorne[7], Carol A. Hitchon[8], Diane Tin[7], Edward C. Keystone[9] and Vivian P. Bykerk[9]. [1]Johns Hopkins University, Baltimore, MD, [2]Cardiff University, Institute of Infection and Immunity, Cardiff, United Kingdom, [3]Mount Sinai Hospital, University of Toronto, Toronto, ON, [4]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [5]Centre Hospitalier de l'Université de Montréal, Montreal, QC, [6]St Joseph Health Care, London, ON, [7]Southlake Regional Health Centre, Newmarket, ON, [8]University of Manitoba, Winnipeg, MB, [9]Mount Sinai Hospital/University of Toronto, Toronto, ON.

Background/Purpose: Rheumatoid arthritis (RA) flares are common, poorly defined, and understudied. A tool is needed to measure significant RA flares that may signal need for evaluation for treatment change. Qualitative and quantitative research by the OMERACT RA Flare Group with patients and providers has identified an RA Flare Core Domain Set, ratified by OM 2012 attendees. Next, we identified preliminary flare questions (PFQs) to assess core domains. Here, we report evidence of discriminant validity of PFQs between patients who report flaring and those not in flare and convergent validity among PFQs and validated RA measures in a cohort of patients with early RA (ERA).

Methods: 1190 patients in the Canadian early ArThritis CoHort (CATCH) completed PFQs at visits from 11–2011 through 5–2013. Both patients and MDs independently rated if patient was in flare. Patients completed PFQs for pain, physical function (PF), fatigue, stiffness, participation and coping over 1 week prior to visit using 11-point scales, as well as HAQ, SF12, RADAI, WPAI and Patient Global. Wilcoxon rank sum and χ^2 were used to compare groups. Correlations (Spearman, polychoric, polyserial) were calculated between PFQs and relevant HAQ, SF12, WPAI, RADAI items and other scales.

Results: Participants were mostly female (74%), white (81%), and 55% had > high school education. Mean (SD) age was 53 (15) years and RA duration 6 (3) months. 33% of patients and 38% of MDs classified patient as being in flare; agreement for being in flare was 62% and not in flare 73% (kappa =.33; 95% CI.28-.39). Scores were significantly higher across all domains in patients reporting flare (Table). Correlations were strongest between PFQ pain and other pain scales (r's=.84-.88). Moderate-strong correlations were evident among PFQ with other measures of PF (r's=.63-.75), fatigue (r's=.52-.85), stiffness (r=.66), participation (r's=.60-.77) and coping (r's=.30-.55).

Comparison of OMERACT PFQ domain scores in patients reporting and not reporting being in RA flare (N=1190).

	Not in Flare	Flare	Significance
Reported RA as worse* in past week	43%	17%	<.001
OM PFQs†			
Pain	2.5 + 2.5	6.0 + 2.6	<.0001
Physical Function	2.2 + 2.5	5.5 + 3.0	<.0001
Fatigue	2.7 + 2.8	5.3 + 3.1	<.0001
Stiffness	2.4 + 2.5	5.6 + 2.9	<.0001
Participation	2.0 + 2.5	5.1 + 3.1	<.0001
Coping	1.8 + 2.3	4.3 + 2.8	<.0001

†Higher scores reflect great impairment; *slightly worse, worse or much worse.

Conclusion: In ERA patients who report being in flare, PFQ scores were significantly higher across all domains. There was substantial agreement among single item PFQs and other validated RA measures. Results provide evidence of the validity of OMERACT PFQs to assess flares in RA patients. Additional psychometric evaluation is needed to establish the reliability, validity, and responsiveness of items and relevant thresholds across a range of RA populations and settings prior to widespread use.

Patient Versus Physician Joint Counts In Rheumatoid Arthritis Utilizing a Unique Self-Joint Examination Tool. Daisy Bang[1], Yomei Shaw[2], Christine L. Amity[3], Kelly A. Reckley[4], Ilinca D. Metes[1] and Marc C. Levesque[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, [3]Univ of Pittsburgh, Pittsburgh, PA, [4]University of Pittsburgh School of Medicine, Pittsburgh, PA.

Background/Purpose: The quantitative assessment of disease activity has been endorsed by the American College of Rheumatology (ACR) to improve rheumatoid arthritis (RA) outcomes. To facilitate more quantitative assessments of disease activity, we created a unique self-joint examination tool and compared patient and physician joint assessments in RA subjects using this tool.

Methods: Subjects were part of the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry. Subjects performed a self-joint count on a computer tablet utilizing line-drawings of human figures incorporating both audio and written instructions on assessment of 28 joints (bilateral shoulders, elbows, wrists, knees, and first through fifth PIP and MCP joints) for tenderness and swelling. Physicians performed independent joint counts at each visit and serum C-reactive protein (CRP) concentrations were measured. Comparisons between patient and physician individual and total swollen and tender joint counts and between patient and physician DAS28-CRP scores were made using t tests and Cohen's kappa statistic.

Results: There were 516 paired patient and physician joint counts for RA subjects completing the self-joint exam for the first time. CRP was measured in 364 patients. Patient vs. physician total swollen (mean ± SD, 5.94 ± 7.28 vs. 2.40 ± 3.96; p<0.0001) joint counts were significantly higher. Mean patient vs. physician DAS28-CRP scores were also significantly higher (mean ± SD, 3.49 ± 1.50 vs. 3.02 ± 1.25; p<0.0001). Cohen's kappa statistic of interrater reliability between patients and physicians for individual tender joint counts ranged from 0.10 to 0.39; for swollen joints it ranged from 0.12 to 0.36. Interrater reliability was greatest for the knees, wrists and the second and third MCP joints. DAS28-CRP scores calculated from the patient and physician joint counts were used to categorize patients into remission,

low, moderate or high disease activity. Cohen's kappa for patient versus physician categorization into remission/low disease activity or moderate/high disease activity based on DAS28-CRP scores was 0.60. In 291 cases (88%), the categorizations agreed. In 73 cases (18%), the categorizations differed. In 52 (13%) of the discrepant cases, the patient's joint count indicated moderate/high disease activity while the physician's did not; in 21 (5%) of the discrepant cases the reverse was noted.

Conclusion: On average, patients reported significantly higher tender and swollen joint counts with greater differences in tender joint counts between patients and physicians. The difference in joint counts resulted in significantly higher DAS28-CRP scores and higher DAS28-CRP disease activity categorization in some cases with discrepancies large enough to potentially alter treatment decisions. These findings suggest that despite the use of a self-joint count tool that incorporates training, mannequin-formats, and a computer tablet interface, patient and physician joint counts still differ. Analysis of the factors that characterize discordant patient-physician pairs will help to inform next steps.

How Well Do The Three Generic Patient Reported Outcomes Measurement Information System Fatigue Instruments Perform In Rheumatoid Arthritis? Susan J. Bartlett, Ana-Maria Orbai, Trisha Duncan and Clifton O. Bingham III. Johns Hopkins University, Baltimore, MD.

Background/Purpose: NIH Patient-Reported Outcomes Measurement Information System (PROMIS) has created highly precise and efficient instruments to measure patient-reported outcomes across health domains relevant to chronic medical conditions. PROMIS is available without charge, and many domains offer item banks for computer adaptive testing (CAT) through Assessment Center, a secure online management tool, in addition to paper-based short forms (SF) and single domain items that form the Global Health measure. **PROMIS Fatigue item bank** assesses both the experience of fatigue from mild tiredness to an overwhelming, debilitating, and sustained sense of exhaustion as well as impact on physical, mental and social activities. However, the feasibility, validity and psychometric performance of the three PROMIS measures has not been reported in persons with rheumatoid arthritis (RA) where fatigue is highly prevalent and disabling.

Methods: Data are from the baseline visit of the first 125 RA patients enrolled in an ongoing study integrating PROs into routine care at an academic RA clinic. Three PROMIS fatigue measures (CAT [average 5–8 items], 7-item SF and Global Health single item of fatigue) were administered in random order along with other legacy measures immediately before a routine clinic visit. Spearman correlations were used to evaluate convergent validity.

Results: Participants were mostly female (79%) and white (86%) with a mean (SD) age of 56 (13) and RA duration of 12 (9) yr; 10% were diagnosed ≤ 2 yr. In general, PROMIS fatigue measures correlated highly with VAS of fatigue, pain and patient global, moderately with mHAQ, morning stiffness, CDAI and MD global and weakly with joint counts (see Table). A dose response relationship across CDAI levels was evident in all measures.

	Fatigue VAS	PROMIS CAT	PROMIS Short Form	Fatigue Item*
Mean (SEM)	**39.9 (2.8)**	**54.3 (0.9)**	**53.6 (0.8)**	**2.6 (0.1)**
Median (IQR)	35.0 [61]	53.5 [15]	53.7 [13]	3 [1]
Range	0–97	26.3–76.0	29.4–71.1	1–5
Floor/Ceiling	11%/1%	2%/1%	1%/0%	12%/3.2%
Correlations†				
Fatigue VAS	–	.856	.787	.812
Pain VAS	.749	.677	.596	.591
Patient Global	.779	.707	.661	.604
MHAQ	.496	.497	.563	.497

Remission	12.7 (17.2)[a]	46.1 (8.5)[a]	47.4 (7.5)[a]	1.9 (0.7)[a]
Low	45.3 (29.0)[b]	55.6 (8.8)[b]	54.8 (9.2)[b]	2.7 (0.9)[b]
Moderate	57.5 (27.9)[c**]	59.5 (6.9)[c*]	58.0 (5.0)[b,c]	3.0 (0.7)[b,c]
High	64.3 (21.4)[c]	62.3 (9.4)[c]	58.8 (7.3)[c]	3.4 (0.9)[c]

*From Global Health SF. †Different superscripts reflect significantly different values ($p<.05$); **$p<.06$.

Conclusion: Our study contributes preliminary evidence of the feasibility of the 3 PROMIS fatigue instruments as part of routine RA visits and of construct validity with legacy measures and clinical indicators. All PROMIS fatigue measures correlated highly with the fatigue VAS; while the Fatigue CAT was most strongly associated with legacy measures and offers greater precision, the 7-item short form and single Fatigue item also performed adequately and are useful when paper-based or briefer versions are needed. PROMIS scores can be compared against population norms. Further evaluation of responsiveness and validity across diverse groups of patients and settings is warranted.

Diagnostic Accuracy Of Anti-Ccp Testing For Detecting Prevalent Rheumatoid Arthritis: Results From Screening a Population Based Cohort. Aase Haj Hensvold[1], Patrik KE Magnusson[2], Lena Israelsson[3], Monika Hansson[4], Vijay Joshua[3], Rikard Holmdahl[5], Per-Johan Jakobsson[3], Johan Askling[5], Vivianne Malmström[6], Lars Klareskog[3] and Anca I Catrina[3]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institut, Stockholm, Sweden, [2]Swedish Twin Registry Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [4]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [5]Karolinska Institutet, Stockholm, Sweden, [6]Rheumatology unit, Karolinska University Hospital, Karolinska Institutet, STockholm, Sweden, Stockholm, Sweden.

Background/Purpose: Anti-CCP testing is a part of the clinical routine investigations for rheumatoid arthritis (RA). Previous studies have relative few included controls per patients. We therefor aimed to screen a large population-based cohort and investigate the diagnostic accuracy of testing anti-CCP, in high concentration, and testing of other ACPAs, for detecting RA.

Methods: We used a subset of the Swedish twin registry, which includes 12 590 monozygotic and dizygotic twins born 1958 or earlier (median age 65, range 48–93). Cases of RA were identified by linkage to the Swedish National Patient Register and by this way we defined clinical RA as the reference standard when analyzing the diagnostic accuracy. Blood samples were analyzed for Anti-CCP2 using Immunscan CCPlus (Eurodiagnostica). Cut off set by the manufacture were used to define positive (≥cut off), and high positive (>3x cut off) CCP was defined in accordance to EULAR criteria for RA. All Anti-CCP positive samples were further investigated by ELISA for the presence of antibodies against autoantigen-derived citrullinated peptides (alpha-enolase: aa5–21; collagen type II: aa359–369; fibrinogen: aa563–583 and vimentin: aa60–75). Sensitivity and specificity as well as the positive (PPV) and negative (NPV) predictive values of Anti-CCP testing for detecting prevalent RA were estimated.

Results: 350 out of 12 590 tested individuals (2.8%) were positive for Anti-CCP. 1.5% (192/12590) had prevalent RA with in median 5 years from first occurring RA diagnosis in register to blood donation. Of these RA cases, 65% (124/192) were positive for Anti-CCP and a majority had high concentrations (93%). The rest of those positive for Anti-CCP were without RA diagnosis and fewer had high positive anti-CCP (39%).

The sensitivity and specificity for high positive Anti-CCP testing were 60% (95% CI: 53–67%) and 99% (95% CI: 99%), respectively. Both high positive Anti-CCP and Anti-CCP had a good predictive value for detecting RA (PPV 57%, 95% CI 50–64% for high positive Anti-CCP and 35%, 95% CI 30–40% for Anti-CCP) and a negative predictive values close to 100%.

Anti-CEP1 antibodies were the most common ACPA among Anti-CCP positive RA patients and Anti-CCP positive without RA. There was a correlation between anti-ccp concentration and occurrence other ACPAs (Spearman Correlation Coefficient $r= 0.75$ $p <0.0001$). In accordance we found 52% sensitivity for positive anti-CCP2 test and ≥1 other ACPA test positive and 99% specificity, PPV was 56% and the NPV was 99%

Conclusion: Anti-CCP testing has a good diagnostic accuracy for RA in a large population based cohort. Anti-CCP in high concentration is correlated with presence of other ACPAs in population based cohort. A follow up study to identify new incident cases of RA among tested individuals will allow more accurate estimates in the future.

Predictive Validity Of Low Disease Activity Using Patient Reported Measures On Long-Term Outcomes In Early Rheumatoid Arthritis-Results From Study Of New Onset Rheumatoid Arthritis and Ontario Best Practices Initiative. Pooneh Akhavan[1], Binu Jacob[2], Paul R. Fortin[3], George A. Tomlinson[4] and Claire Bombardier[5]. [1]Mount Sinai Hospital/ University of Toronto, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]University of Laval, Quebec, QC, [4]Toronto General Hospital, Toronto, ON, [5]University Health Network, Toronto, ON.

Background/Purpose: Patient reported outcome measures (PROM) are used in routine practice for assessment of disease activity. They have been shown to correlate well with other composite measures. Current guidelines suggest remission or low disease activity (LDA) as the target of therapy in rheumatoid arthritis (RA). Our objective was to assess the predictive validity of early LDA defined by PROMs on future joint damage and disability in patients with early RA.

Methods: We studied patients included in the Study of New Onset Rheumatoid Arthritis (SONORA), a multicenter early RA cohort and Ontario Best Practices Research Initiative (OBRI), a current clinical registry of RA patients followed in routine care. Patients with symptom duration ≤ 12 months at enrollment were included. In SONORA analysis, the main predictors were LDA (RADAI<2.2) at 4mo and 12 mo. Multivariate linear regression analysis was used for assessment of LDA predicting HAQ at 3 years and mutivariate logistic regression models were used for assessment of the impact of LDA on x-ray progression over 2 years adjusting for potential confounders. In OBRI analysis, the predictive validity of LDA at6 months (RADAI<2.2 and RAPID3<2) on HAQ at 2 years was estimated using multiple linear regression analysis..

Results: There were 984 early RA patients in SONORA. Baseline (BSL) mean(sd) HAQ was 1.0 (0.7) that improved to 0.7 (0.7) at 3 years. At 2 years, 116(17%) patients developed radiographic progression. At 4 mo 25% achieved LDA and it increased to 37% at 1 year. LDA at both 4mo and 1 year was a significant predictor of lower future HAQ (p<0.0001). LDA at 4 mo was associated with less radiographic progression (OR, 95% CI: 0.49, 0.25–0.95, p=0.03) in complete cases. Other significant factors associated with higher HAQ included higher BSL HAQ, older age and female sex and factors associated with future joint damage were BSL damage and positive RF and anti-CCP. There were 118 patients from the OBRI cohort who had at least 2-year follow-up with available outcome. At BSL 13(11%) were in LDA defined by RADAI that improved to 43(36%) at 6 mo. Mean (sd) HAQ 1.31 (0.8) at BSL improved to 0.78 (0.7) at 2 years. Based on RAPID3, 11% were determined to be in LDA at BSL which increased to 22 (22%) at 6 mo. LDA at 6 mo, defined by either PROM, was significantly associated with lower HAQ at 2 years (p=0.03 for RADAI, p=0.05 for RAPID3 criteria). Other significant factors associated with higher HAQ included older age, BSL HAQ and gender (female).

Conclusion: Achieving LDA as early as 4–6 months is associated with improved long-term outcomes in early RA. Disease status using PROMs seems to have significant predictive validity for future outcomes.

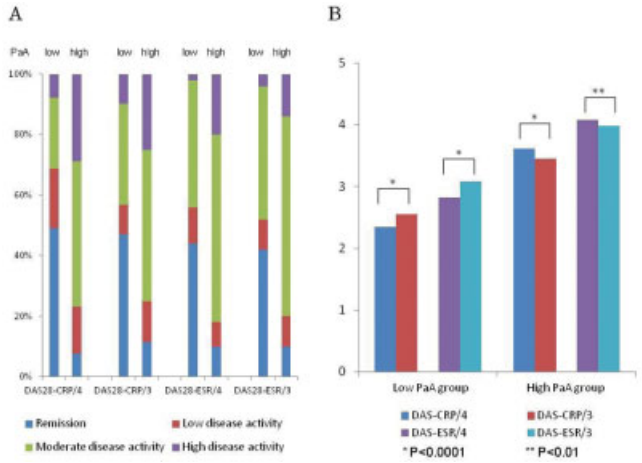
Patients' Assessment of the Disease Greatly Influences the Determination of Disease Activity and Remission in Rheumatoid Arthritis. Kenrin Shi[1], Kenji Miki[2], Masao Yukioka[2], Kosuke Ebina[1], Shoichi Kaneshiro[1] and Hideki Yoshikawa[1]. [1]Osaka University Graduate School of Medicine, Suita, Japan, [2]Yukioka Hospital, Osaka, Japan.

Background/Purpose: Recently defined remission criteria of rheumatoid arthritis (RA), Boolean criteria or Simplified Disease Activity Index (SDAI) <3.3, requires considerably low rating not only of physicians' assessment (PhA) but also of patients' assessment (PaA) of the disease. However, it is very often that remission cannot be achieved or maintained because PaA does not fulfill the requisite. Also, PhA and PaA often differ largely from each other, and it has been reported that patients tend to assess the state of disease mostly by pain.

Methods: One hundred and four patients with RA were studied. Tender joint counts (TJC), swelling joint counts (SJC), and PaA as well as PhA by 100mm of Visual Analogue Scale were clinically evaluated. After the patients were divided into two groups according to PaA, either lower or higher than the median value, the two groups were compared in terms of age, duration, functional status, history of joint surgeries, comorbidities, prescribed medications, and laboratory data such as C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and matrix metalloproteinase-3. Other clinical data as well as disease activity were also compared by SDAI and four types of Disease Activity Score 28 (DAS28) formula; either including CRP or ESR, with or without PaA. Moreover, the correlation between PaA and PhA was examined, and clinical and functional remission was evaluated by Boolean criteria and Modified Health Assessment Questionnaire <0.5, respectively.

Results: The average and median value of PaA was 23.9mm and 17.5mm, respectively. In high PaA group (>17.5mm), functional status was significantly poorer (Steinbrocker Class III and IV, 23% vs 7.7%) and comorbidities were significantly more (32.7% vs 13.5%), whereas age, duration, history of joint surgeries showed no differences. Prescription of non-steroidal anti-inflammatory drugs and corticosteroid was significantly more often in high PaA group (67.3% vs 36.5% and 63.5% vs 28.8%, respectively), but there was no difference in that of methotrexate and biologics. TJC, SJC and PhA were significantly more in high PaA group (5.0 vs 2.4, 3.1 vs 1.3 and 30.4mm vs 16.2mm, respectively), whereas all laboratory data studied exhibited no differences. PaA and PhA significantly correlated with each other (r=0.57). All indices of disease activity were significantly higher in high PaA group (DAS28, Figure-A), among which DAS28, either including CRP or ESR, was significantly higher in low PaA group whereas lower in high PaA group, when PaA was excluded from the formula (Figure-B). Both Boolean and functional remission rate were significantly low in high PaA group (0% vs 35.3% and 55.6% vs 80%, respectively), but 19.2% of the patients in high PaA group would have achieved Boolean remission only if PaA had fulfilled the requisite.



Conclusion: Since PaA greatly influences the determination of disease activity as well as remission, it is very important to properly control the pain in RA.

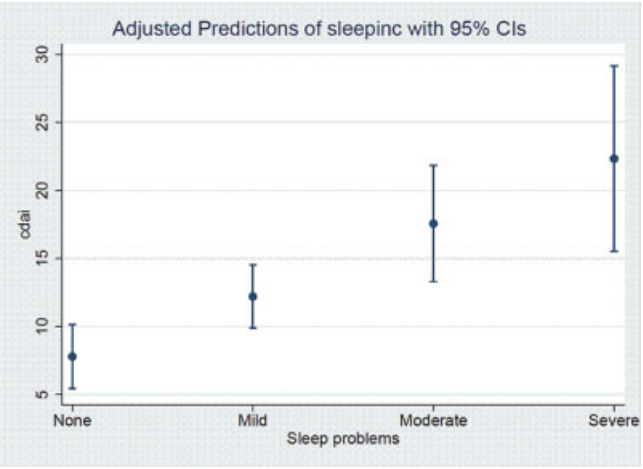
Response To a Sleep Query On The Multi-Dimensional Health Assessment Questionnaire (MDHAQ) Is Related To Levels Of Disease Activity. Martin J. Bergman[1], Sapna Sangani[2], Isabel Castrejón[3] and Theodore Pincus[3]. [1]Taylor Hospital, Ridley Park, PA, [2]Mercy Catholic Medical Center, Lansdowne, PA, [3]NYU Hospital for Joint Diseases and New York University School of Medicine, New York, NY.

Background/Purpose: Patients with rheumatoid arthritis (RA) often report fatigue, but a possible impact of disease on sleep and/or on disease activity are poorly characterized. We examined possible relationships between sleep and disease activity.

Methods: All patients with any diagnosis complete an MDHAQ at each visit to a single rheumatology practice. The MDHAQ includes sections regarding function, pain, patient global estimate, a patient self-reported joint

count, fatigue, exercise, AM stiffness and a brief psychological profile. The MDHAQ includes 3 "psychological profile" queries including "Over the past week, were you able to get a good night's sleep?" ("sleep"). The responses are 0–3 (without difficulty=0, with some difficulty=1, with much difficulty=2, unable to do=3). Each patient with RA also is assessed with an ESR and CRP, 28 tender and swollen joint counts, and a physician global estimate (0–10). From these values, multiple composite indices are calculated, including the DAS28(ESR), CDAI, SDAI and RAPID3. Patients are then characterized into disease activity categories ("remission", "low disease activity", "moderate disease activity", "high disease activity"), according to established criteria. Using a random visit for each patient, linear regression models were determined using the composite score value as the dependent variable, and "sleep" as the independent variable, to determine possible interactions between "sleep"score and disease activity scores. All statistical analyses were performed using Stata v12.

Results: 200 patients with RA had completed responses to "sleep". The median value for "sleep"=1 (with some difficulty). A patient with sleep=0 has a 95% chance of being in low CDAI, whereas a patient with sleep=1 has a 95% chance of not being in low CDAI. A "linear" worsening of CDAI was seen with each increment of "sleep" (fig.1). Similar findings were also seen in comparisons of sleep scores with DAS28, SDAI and RAPID3. (data not shown) Even if the patient global score is excluded from this calculation-("mdai"), a similar "linear" result is seen.



Conclusion: The response to a single question regarding having a good night sleep, explains variation in disease activity according to CDAI in patients with RA. Patients who report significant sleep disturbances are unlikely to be in a low disease state, whereas patients with no sleep disturbances are highly likely to be in a low disease state.

Disclosure: M. J. Bergman, None; **S. Sangani**, None; **I. Castrejón**, None; **T. Pincus**, None.

2248

Difference Between The Two Versions Of Disease Activity Score Based On C-Reactive Protein and Erythrocyte Sedimentation Rate. Pinar Cetin[1], Dilek Solmaz[1], Hacer Gulluoglu[2], Ismail Sari[1], Merih Birlik[3], Servet Akar[1], Fatos Onen[1] and Nurullah Akkoc[1]. [1]Dokuz Eylul University School of Medicine, Izmir, Turkey, [2]Dokuz Eylul University School of Medicine, Yzmir, Turkey, [3]Dokuz Eylul University School of Medicine, izmir, Turkey.

Background/Purpose: In some countries reimbursement criteria require a DAS28 score of >5.1 for initiating anti-TNF therapy in patients with rheumatoid arthritis. DAS28 score can be calculated based on C-reactive protein (CRP) levels (DAS28-CRP) or erythrocyte sedimentation rate (DAS28-ESR). The results of a recent mini-survey suggest that Turkish rheumatologists use DAS28-CRP more frequent. The aim of this study was to assess the agreement between the ESR and CRP based DAS28 scores in Turkish patients with RA.

Methods: 84 RA patients from one center with full data for both DAS28-ESR and DAS28-CRP were identified in our biological therapy database (TURKBIO). We compared their DAS28-CRP and DAS-ESR scores obtained from baseline and following visits. Mean DAS28-ESR and DAS28-CRP values were compared by Spearman correlation and linear regression analysis. Bland-Altman analysis and kappa statistics were used to assess the agreement between the two DAS definitions in the whole group as well as in different gender and age groups.

Results: Of the 84 patients 71 were females (85%) with a mean age (±SD) of 52.5 (± 14.2). Disease duration was 10.5 years (±6.2) RF and CCP positivity was 58 % and 63%. DAS28-CRP and DAS28-ESR scores were available for 364visits. Mean DAS28-CRP and DAS-ESR values were 3.3 (±1.4) and 4.0 (±1.4)showing a strong correlation with each other [(Spearman correlation coefficient: 0.947, $p<0.001$) and linear regression analysis ($R^2=0.909$, $p<0.001$)]. The agreement between the two DAS versions was good for both genders and all age groups with weighted kappa values ranging from 0.695 to 0.809 The number of visits with high disease activity based on DAS28-ESR was greater than that based on DAS28-CRP ($p=0.08$). 47 (49%) visits with moderate disease activity according to DAS28-CRP were classified as high according to DAS28-ESR (Table1). Bland-Altman plot analysis showed a mean difference (95% CI) of 0.69 (0.63 – 0.75) between the two methods (DAS28-ESR – DAS28-CRP), which was quite consistent in different gender and age categories (Table 2).

Table 1. Agreement between DAS28-ESR and DAS28-CRP on the classification of the patient visits into different categories of disease activity

		DAS 28 ESR			
		≤3.2	3.21–5.10	≥5.11	Total
DAS 28 CRP	≤3.2	128	64	0	192
	3.21–5.10	0	74	47	121
	≥5.11	0	2	49	51
	Total	128	140	96	364

Table 2. Summary of Bland-Altman plot data for comparison of DAS-ESR and DAS-CRP in different gender and age categories

Patients (# of patients, # of visits)	Mean difference (95% CI)	Lower Limit (95% CI)	Upper Limit (95% CI)
Females (n=71, n=308)	0.735 (0.688–0.783)	0.097 (0.179–0.015)	1.569 (1.487–1.651)
Males (n=13, n=56)	0.471 (0.357–0.589)	0.377 (0.576–0.177)	1.324 (1.124–1.524)
≤40 years old (n=17, n=65)	0.481 (0.377–0.588)	0.369 (0.533–0.184)	1.331 (1.147–1.516)
41–60 years old (n=42, n=182)	0.791 (0.667–0.795)	0.094 (0.200–0.011)	1.553 (1.447–1.659)
≥61 years old (n=25, n=117)	0.761 (0.683–0.840)	0.080 (0.215–0.054)	1.603 (1.468–1.738)
Overall (n= 84, n=364)	0.695 (0.650–0.740)	0.160 (0.237–0.083)	1.551 (1.473–1.628)

Conclusion: The results suggest that DAS28-CRP may underestimate disease activity in RA patients, as compared to DAS28-ESR for both genders and different age groups. A significant proportion of patients, who would not qualify for reimbursement of anti-TNF therapy according to DAS28-CRP would be classified as having high disease activity according to DAS28-ESR.

What Proportion Of Patients With Rheumatoid Arthritis Fail To Achieve Remission Based On The Patient Global? An Analysis From The Prospective, Observational Biologic Treatment Registry Across Canada. Andrew Chow[1], Philip Baer[2], William G. Bensen[3], Isabelle Fortin[4], Majed M. Khraishi[5], Dalton E. Sholter[6], May Shawi[7], Allen J. Lehman[7], Susan M. Otawa[7], Emmanouil Rampakakis[8] and John S. Sampalis[8]. [1]Credit Valley Rheumatology, Mississauga, ON, [2]Rheumatology, Scarborough, ON, [3]St. Joseph's Hospital and McMaster University, Hamilton, ON, [4]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [5]MD, Memorial University of Newfoundland, Nexus Clinical Research, St Johns, NF, [6]Rheumatology Associates, Edmonton, AB, [7]Janssen Canada Inc, Toronto, ON, [8]McGill University, Montreal, QC.

Background/Purpose: According to the latest ACR/EULAR guidelines, Boolean remission in RA is defined as achievement of patient global assessment (PtGA) ≤1, 28-swollen joint count (SJC) ≤1, 28-tender joint count (TJC) ≤1, and C-reactive protein (CRP) ≤1 mg/dL. Recently, PtGA has been criticized for not accurately assessing RA disease activity, as it may reflect aspects not directly related to RA disease activity such as fibromyalgia, low back pain, depression or other conditions. The aim of this analysis was to assess the proportion of patients failing to achieve remission based on PtGA in a real-world, routine clinical care setting in Canada.

Methods: Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with infliximab or golimumab as first biologics or after having been treated with a biologic for less than six months. In this analysis, data from RA patients who were treated with infliximab between January 2002 and June 2011 were used. Correlation of PtGA with other clinical outcome measures was assessed with general linear models.

Results: Eight hundred and thirty-eight RA patients who had 4,582 assessments were included in the analysis. Mean (SD) age was 55.6 (13.5) years and mean (SD) duration since diagnosis was 10.5 (19.8) years. A total of 2,015 instances of non-remission were identified, of which 620 (30.8%) were near-remission cases. Near-remission is defined as attainment of three of the four Boolean criteria (CRP, SJC, TJC and PtGA). Among these, PtGA was the most common reason of non-remission (54.0%), followed by 28-tender joint count (TJC28; 27.7%), C-reactive protein (CRP; 10.0%), and 28-swollen joint count (SJC28; 8.2%). General linear models using PtGA as the dependent variable showed a statistically significant ($P<0.001$) positive association with HAQ-DI (mean (95%CI) estimate = 2.57 (2.47, 2.67), TJC28 (0.21 (0.20, 0.22), SJC28 (0.24 (0.23, 0.26)), physician global assessment (0.67 (0.64, 0.70), and pain (0.940 (0.93, 0.95).

Conclusion: The results of this analysis have shown that PtGA is the most common limiting factor in achieving Boolean ACR/EULAR remission, accounting for as many as 54% of the near-remission cases. However, a positive association was observed between PtGA and clinical outcomes, functional activity, and pain. Further analyses are required to identify the determinants of patient global assessment.

What Is The Real World Relationship Between Patient-Reported Pain Or Patient Global Assessment and Disease Activity Indices In Rheumatoid Arthritis? An Analysis From The Prospective, Observational, Biologic Treatment Registry Across Canada.

Regan Arendse[1], Michael Starr[2], Proton Rahman[3], John T. Kelsall[4], Milton F. Baker[5], William Bensen[6], J. Carter Thorne[7], Philip Baer[8], Denis Choquette[9], Isabelle Fortin[10], Emmanouil Rampakakis[11], John S. Sampalis[11], Susan M. Otawa[12], May Shawi[12], Francois Nantel[12] and Allen J. Lehman[12]. [1]University of Saskatchewan, Saskatoon, SK, [2]Montreal General Hospital, Montreal, QC, [3]Memorial University, St. Johns, NF, [4]Mary Pack Arthritis Centre, Vancouver, Vancouver, BC, [5]University of Victoria, Victoria, BC, [6]St. Joseph's Hospital and McMaster University, Hamilton, ON, [7]Southlake Regional Health Centre, Newmarket, ON, [8]Rheumatology, Scarborough, ON, [9]Institut de Rhumatologie de Montréal, Montreal, QC, [10]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [11]JSS Medical Research, St-Laurent, QC, [12]Janssen Canada Inc, Toronto, ON.

Background/Purpose: Patient-reported outcomes such as pain and patient global assessment of disease activity (PtGA) have been critiqued for not accurately assessing rheumatoid arthritis (RA) disease activity as they may reflect aspects not directly related to RA disease activity (e.g. fibromyalgia, low back pain, depression, etc.) or related to non-RA conditions. The aim of this analysis is to describe the relationship between patient-reported pain and disease activity levels, as measured with DAS28-ESR, CDAI, and SDAI, in a real-world, routine clinical care setting. An additional aim is to assess the occurrence of non-remission driven solely by pain using PtGA as a proxy for pain.

Methods: Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, Canadian prospective registry of rheumatology patients initiating treatment with infliximab or golimumab. In this analysis, data from RA patients who were treated with infliximab between January 2002 and June 2011 were used. Correlation of pain (VAS mm) with DAS28-ESR, CDAI and SDAI in a continuous or binary (low disease activity: yes vs. no; remission: yes vs. no) scale was assessed with linear regression and logistic regression, respectively. For the assessment of non-remission due to PtGA, DAS28-ESR, CDAI, and SDAI remission rates were compared to "non-PtGA" remission rates, calculated by subtracting the relative contribution of PtGA to the index.

Results: Eight hundred thirty eight RA patients who had 4,582 assessments were included in the analysis. A significant ($P<0.001$) positive linear relationship was found between pain and DAS28-ESR (standardized coefficient (β) = 0.662), CDAI (β = 0.660), and SDAI (β = 0.659). Increased pain was associated with reduced odds of achieving remission or low disease activity as defined by DAS28-ESR, CDAI, and SDAI (Table 1). Correlation analysis showed that a strong positive linear correlation existed between pain and PtGA (r = 0.914), supporting the use of PtGA as a proxy for pain. Cross-tabulation of remission achievement with "non-PtGA" remission achievement revealed that omission of PtGA from the DAS28-ESR, CDAI, and SDAI indices would result in the re-classification of an additional 2.0%, 9.3%, and 9.6% of the cases as remission.

Table 1. Relationship Between Pain (VAS mm) and Low Disease Activity or Remission

Disease Activity	Threshold	OR	95% CI	P-Value
Low Disease Activity	DAS28-ESR	0.950	0.946, 0.954	<0.001
	CDAI	0.943	0.940, 0.947	<0.001
	SDAI	0.940	0.936, 0.944	<0.001
Remission	DAS28-ESR	0.946	0.941, 0.951	<0.001
	CDAI	0.890	0.880, 0.901	<0.001
	SDAI	0.892	0.881, 0.904	<0.001

Conclusion: The results of this analysis show that increased pain is associated with higher disease activity as measured by the DAS28-ESR, CDAI and SDAI, which may be due to the strong correlation of pain with PtGA. Omission of PtGA from these disease activity indices resulted in the classification of additional cases as remission cases to an extent that paralleled the strictness of the remission criteria (i.e., from the less "strict" DAS28-ESR index to the more "strict" SDAI). Therefore, the CDAI and SDAI might be more sensitive to pain not directly related to RA.

2251

Variability in the Classification of Remission Among Disease Activity Indices and Their Correlation: An Analysis From a Prospective, Observational Registry.

William G. Bensen[1], Algis V Jovaisas[2], J. Carter Thorne[3], Philip Baer[4], Majed M. Khraishi[5], Sanjay Dixit[6], Denis Choquette[7], Michael Starr[8], Isabelle Fortin[9], Dalton E. Sholter[10], Emmanouil Rampakakis[11], John S. Sampalis[11], Francois Nantel[12], Allen J. Lehman[12], May Shawi[12] and Susan M. Otawa[12]. [1]St. Joseph's Hospital and McMaster University, Hamilton, ON, [2]University of Ottawa, Ottawa, ON, [3]Southlake Regional Health Centre, Newmarket, ON, [4]Rheumatology, Scarborough, ON, [5]MD, Memorial University of Newfoundland, Nexus Clinical Research, St Johns, NF, [6]McMaster University, Burlington, ON, [7]Institut de Rhumatologie de Montréal, Montreal, QC, [8]Montreal General Hospital, Montreal, QC, [9]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [10]Rheumatology Associates, Edmonton, AB, [11]McGill University, Montreal, QC, [12]Janssen Canada Inc, Toronto, ON.

Background/Purpose: In recent years, disease remission in rheumatoid arthritis (RA) has been assessed using various disease activity indices such as the DAS28-CRP, SDAI, CDAI, ACR/EULAR-recommended Boolean definition and the Patient Activity Scale (PAS).

The aim of this analysis is to describe the agreement between these five indices in classifying remission as well as to assess their correlation in a routine clinical care setting.

Methods: BioTRAC is an ongoing, prospective Canadian registry of rheumatology patients initiating treatment with infliximab or golimumab. In this analysis, data from RA patients who were treated with infliximab between January 2002 and June 2011 and had available information in all indices were used. The definitions for remission were as follows: DAS28 <2.6; SDAI ≤ 3.3, CDAI ≤ 2.8; PAS ≤ 1.0. Factor analysis was used to assess the variability due to each of the indices while inter-item correlation was measured with the Pearson correlation coefficient.

Results: Seven hundred thirty four RA patients who had 3,035 complete assessments were included in the analysis. Non-remission was classified by all indices in 63.1% of the cases, while 36.9% achieved remission in one (13.1%), two (7.8%), three (1.9%), four (4.9%) and all five types (9.1%) of indices. Factor analysis showed that PAS accounted for 70.4% of the matrix variance, followed by DAS28-CRP (13.4%), SDAI (9.0%), CDAI (5.6%),

and Boolean remission (1.6%), suggesting that PAS may reflect different aspects than the clinical indices. PAS remission revealed the lowest correlation with remission classified by the remaining indices (Table 1) and removal of any index, except PAS, would result in a lower overall Cronbach's alpha.

Table 1. Inter-Item Correlation Matrix of Disease Activity Indices

	PAS	DAS28-CRP	SDAI	CDAI	Boolean
PAS	N/A	0.466	0.520	0.521	0.381
DAS28-CRP	0.466	N/A	0.653	0.626	0.661
SDAI	0.520	0.653	N/A	0.918	0.739
CDAI	0.521	0.626	0.918	N/A	0.718
Boolean	0.381	0.661	0.739	0.718	N/A

Conclusion: The results of this analysis show that variability exists in the classification of remission by various disease activity indices. This variability was found to be predominantly due to the Patient Activity Scale, a patient-driven composite tool, suggesting that the patient perception of disease activity may differ from that captured by clinical outcome measures.

Assessment Of Rheumatoid Arthritis Disease Activity By Patients and Physicians: Do Physicians Detect Improvement Before The Patient Does?

William G. Bensen[1], J. Carter Thorne[2], Philip Baer[3], Andrew Chow[4], Regan Arendse[5], Isabelle Fortin[6], Milton F. Baker[7], Boulos Haraoui[8], Algis Jovaisas[9], John S. Sampalis[10], Emmanouil Rampakakis[10], Allen J. Lehman[11], Francois Nantel[11], May Shawi[11] and Susan M. Otawa[11]. [1]St. Joseph's Hospital and McMaster University, Hamilton, ON, [2]Southlake Regional Health Centre, Newmarket, ON, [3]Rheumatology, Scarborough, ON, [4]Credit Valley Rheumatology, Mississauga, ON, [5]University of Saskatchewan, Saskatoon, SK, [6]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [7]University of Victoria, Victoria, BC, [8]Institut de Rhumatologie de Montréal, Montreal, QC, [9]University of Ottawa, Ottawa, ON, [10]McGill University, Montreal, QC, [11]Janssen Canada Inc, Toronto, ON.

Background/Purpose: Patient (PtGA) and physician (MDGA) global assessment of disease activity measure the same construct from two different perspectives. The objective of this study was to assess the agreement between these two measures over time as ascertained in Canadian routine clinical practice in patients with RA treated with infliximab or golimumab.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis (RA), ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab or golimumab as first biologics or after having been treated with a biologic for less than six months. In this analysis, people with RA treated with infliximab who were enrolled between 2002 and 2012 and had at least one follow-up assessment and up to 60 months of follow up were included. PtGA and MDGA were measured on a 10-point numerical rating scale (NRS) and 10 cm visual analog scale (VAS), respectively. The association between treatment duration and difference between MDGA and PtGA was assessed with linear regression. Internal consistency was assessed with the intra-class correlation coefficient (ICC) and Cronbach's alpha (CA).

Results: A total of 675 patients assessed over 4193 visits during a mean follow up time of 20 months were included in the analyses. The overall mean (SD) PtGA and MDGA was 3.73 (2.89) and 3.38 (2.67), respectively ($P<0.001$). At baseline the mean difference between the MDGA and PtGA was +0.41 ($P<0.001$). However, during all the follow up assessments, this was reversed, with PtGA being significantly higher (worse) when compared to MDGA. The mean difference changed by −0.012 per month ($P<0.001$) indicating progressively higher scores by patients over time compared to physicians. The overall ICC and CA were 0.767 and 0.770, respectively, indicating moderate agreement. Both ICC and CA decreased over time. The mean difference between MDGA and PtGA assessments was non-significantly higher for females (−0.37) when compared to males (−0.29) and significantly higher for patients with history of MTX use (−0.43 vs. −0.18; $P=0.002$). TJC, SJC, CDAI and SDAI had positive and significant ($P<0.001$) associations with increased difference between MDGA and PtGA. Slope analysis showed that MD assessments declined by −0.265/month and Pt assessments declined by −0.189/month ($P<0.001$).

Conclusion: The results of this Canadian longitudinal observational registry have shown that there is poor agreement between physician-based and patient-based assessments of disease activity. In addition, the rate of reduction in disease activity over time is considerably higher when rated by physicians when compared to patients. In this chronic condition, physicians should be aware of this increasing discordance between the patient and physician global when making treatment decisions and managing patient expectations over time.

2253

How Often Are Core Variables Reported To Calculate Common Disease Activity Scores Measured In Routine Care Of Rheumatoid Arthritis Patients?

Bindee Kuriya[1], Jessica Widdifield[2], Claire Bombardier[3], Xiuing Li[4], Binu Jacob[3], Pooneh Akhavan[5], J. Carter Thorne[6], Janet E. Pope[7], Edward C. Keystone[3], William G. Bensen[8] and Vandana Ahluwalia[9]. [1]Mount Sinai Hospital, University of Toronto, Toronto, ON, [2]Institute for Clinical Evaluative Sciences, Toronto, ON, [3]University of Toronto, Toronto, ON, [4]University of Toronto, University Health Network, Toronto, ON, [5]Mount Sinai Hospital/University of Toronto, Toronto, ON, [6]Southlake Regional Health Centre, Newmarket, ON, [7]St Joseph Health Care, London, ON, [8]St. Joseph's Hospital and McMaster University, Hamilton, ON, [9]William Osler Health Center, Mississauga, ON.

Background/Purpose: Treat-to-target (T2T) is a therapeutic strategy in rheumatoid arthritis (RA) that has been associated with improved outcomes. T2T relies on objective measurement of disease activity at regular intervals with escalation of treatment until remission or low disease activity is achieved. In clinical trials, variables needed to assess disease activity are routinely collected but the ability to do the same in clinical practice is uncertain. The objective of this study was to determine the frequency by which core variables needed to calculate common disease activity scores are collected in a cohort of RA patients followed in routine care.

Methods: All patients (N=2018) enrolled in the Ontario Best Practices Research Initiative since its inception in 2009 were included in this study. OBRI is a clinical registry of RA patients with both early and established disease and are treated according to the discretion of the rheumatologist. We determined the frequency by which components required to calculate common composite disease activity scores (DAS28, SDAI, CDAI) were collected and documented during the first 6 consecutive visits: physician global health assessment (MDGA), patient global health assessment (PtGA), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), tender joint count-28 (TJC) and swollen joint count-28 (SJC).

Results are reported as the % of measured variables, expressed as the number of measured components divided by the number of patients at each visit.

Results: At entry into the cohort, 77% of patients were female with mean (SD) age 57 (13) years, and the majority (85%) was Caucasian. Patients had moderate disease activity according to both mean (SD) DAS28 4.5 (1.5) and CDAI scores 21(14). Over time, the % measurement was consistent for most variables with the exception of ESR and CRP, which had a higher frequency of measurement at cohort entry (visit 1) than subsequent visits. Documentation of TJC and SJC assessment was universally high at each visit and ranged from 92–96%. Global health assessment reported by physicians (MDGA range 85–89%) and patients (PtGA range 88–90%) were similar. Missing data was greatest for values of CRP (missing range 29–40%) (Table).

Table. Frequency (%) of core component measurement in the OBRI cohort.

	Visit 1 (N=2081)	Visit 2 (N=1811)	Visit 3 (N=1530)	Visit 4 (N=1185)	Visit 5 (N=873)	Visit 6 (N=670)
MDGA	87	85	86	87	89	87
PtGA	89	88	88	89	90	90
ESR	85	76	76	77	77	77
CRP	71	60	66	69	67	68
TJC	94	92	92	93	93	94
SJC	96	95	95	95	96	96

Conclusion: Measurement of core variables required to assess RA disease activity are collected in a majority of RA patients followed in routine clinical practice. Objective measures such as TJC and SJC have near perfect collection. MDGA and PtGA are missing in ~15% of visits and measurement

of inflammatory markers are sub-optimal which may limit calculation of composite scores that drive T2T strategies and comparison of disease activity to other cohorts. Further work determining potential barriers to collection of these variables is needed.

2254

Complementary and Alternative Medicine in Rheumatoid Arthritis - Persistently High Use Over the Past Decade Despite Advent of Biologics.

Dana DiRenzo[1], Haiyan Sun[2], H. Lester Kirchner[2] and Eric D. Newman[3]. [1]University of Maryland Medical Center, Baltimore, MD, [2]Geisinger Health System, Danville, PA, [3]Geisinger Medical Center, Danville, PA.

Background/Purpose: Complementary and Alternative Medicine (CAM) is commonly used when traditional medicine cannot reliably alter the disease. Over the past decade, rheumatoid arthritis (RA) treatment has improved dramatically whereas osteoarthritis (OA) treatment has not. Accordingly, CAM use should be trending downward in RA relative to OA. Previous studies of CAM use by RA and OA patients have been limited by inaccurate diagnosis of arthritis and lack of long term trending. The purpose of this study was to evaluate the use of CAM in a well-defined population of RA and OA patients now and compared with a similar population 12 years previously.

Methods: 104 OA patients and 102 RA patients attending a Rheumatology clinic twice between May 1, 2011 and June 30, 2012 returned an 84 item questionnaire assessing their CAM use in the past 6 months. Inclusion criteria were met with ICD-9 codes; patients with other co-existing rheumatologic conditions were excluded. This survey was compared to survey results previously reported in 2000 assessing CAM use.

Results: In 2012, most participants were female (OA, 84%; RA, 74%). RA patients were younger and reported less pain than OA patients (57.9 vs. 70.1 years old, $p<0.001$; 3.5 vs. 4.9 on a 0–10 cm pain scale, $p<0.001$). Only 25% of OA and 20% of RA patients reported that their rheumatologist asked about CAM use. Likewise, only 30% of OA and 26% of RA patients reported that they told their rheumatologist about their CAM use.

In 2012, prayer was the most popular form of CAM for both OA and RA patients (63% and 61%) followed by glucosamine/chondroitin, green tea, fish oil, massage, and chiropracty (Figure 1). Additionally, glucosamine, chondroitin, fish oil, and water therapy were tried more commonly by OA patients than RA patients.

No significant decreases were found overtime in CAM use by RA patients compared with trends observed in OA patients for CAM use overall or by CAM category. Compared to 2000, RA patients in 2012 reported having tried several forms of CAM for specific treatment of their arthritis more often including cartilage, flaxseed, green tea, and melatonin ($p=0.049$, 0.049, 0.046, 0.014). Chiropracty, fish oil, and yoga were also tried more often by RA patients in 2012 ($p=0.078$, 0.007, 0.008).

Figure 1: Selected CAM Use	OA: 2012 survey (n=104)	RA: 2012 survey (n=102)	p value
Alternative Healing Systems	27.88%	22.55%	0.378
Chiropracty	**24.51%**	**20.00%**	0.441
Mind, Body & Spirit	65.38%	59.80%	0.408
Meditation	11.76%	14.29%	0.596
Prayer	**63.00%**	**61.22%**	0.797
Massage & Bodywork	27.88%	24.51%	0.582
Massage	**26.73%**	**24.00%**	0.656
Diets	43.27%	30.39%	0.056
Fish Oil	**36.54%**	**23.47%**	**0.043**
Herbs & Supplements	67.31%	57.84%	0.160
Chondroitin	**42.86%**	**15.84%**	**<0.001**
Glucosamine	**50.51%**	**21.78%**	**<0.001**
Green Tea	**33.00%**	**28.00%**	0.443
Miscellaneous	14.42%	21.57%	0.182
Copper Bracelets	7.84%	11.88%	0.334
Magnets	9.80%	11.00%	0.781
Moving Medicine	42.57%	18.18%	**<0.001**
Yoga	8.08%	10.20%	0.605
Water Exercise	36.00%	12.24%	**<0.001**

Conclusion: Despite pharmacologic advances for RA compared to OA over the past decade, there was not a decline in the use of CAM among RA patients. Prayer remains the most common CAM for both OA and RA patients in 2012. Increased use of certain individual therapies may reflect current cultural/market trends or possible immunologically active properties. A gap in communication between patient and physician about CAM use was identified, which is concerning due to the undetermined efficacies of the majority of CAM therapies. This may serve as an opportunity to change current practice and to improve shared medical decision making.

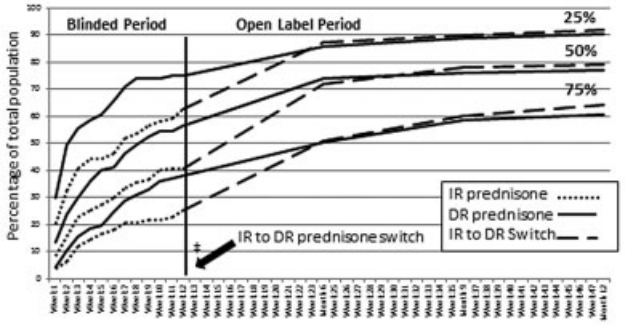
Threshold Analysis of Patient Reported Morning Stiffness Where Delayed-Release (DR) Prednisone Was Compared to, and Replaced, Immediate Release Prednisone in Rheumatoid Arthritis (RA) Patients Receiving Conventional Disease-Modifying Antirheumatic Drugs (DMARDs) Over 1 Year.

Frank Buttgereit[1], Jeffery Kent[2], Robert Holt[2], Amy Grahn[2], Patricia Rice[3], Rieke Alten[4] and Yusuf Yazici[5]. [1]Charité - Universitätsmedizin Berlin, Berlin, Germany, [2]Horizon Pharma, Inc, Deerfield, IL, [3]CliniRx Research, Naperville, IL, [4]University of Berlin, Berlin, Germany, [5]New York University, New York, NY.

Background/Purpose: RA patients typically present with pain and morning stiffness (MS) in addition to joint swelling and tenderness. Nocturnal inflammatory cytokines are assumed to be associated with MS. DR prednisone given at bedtime has previously shown significant absolute and relative reduction in MS and early morning cytokines compared to both conventional (IR) prednisone and placebo in well controlled studies.(1–3) Studies of categorical and comparative MS responses to DR and IR prednisone are lacking. In this new analysis of Phase 3 study data, we completed a time-to-event analysis of morning stiffness.

Methods: CAPRA-1, a 12-week, double-blind, controlled study, randomized patients to IR-prednisone taken in the morning or DR-prednisone taken once daily at bedtime (eg, 10pm) in addition to standard DMARD treatment.(1) In the following open label phase, patients previously receiving IR prednisone (N=110) were then switched to DR-prednisone and followed at 3, 6, and 9 months.(2) Patients previously on DR-prednisone (N=97) continued on therapy. Patients completed diary entries at least 7 days prior to each visit including waking time, stiffness (yes/no), time of resolution and intensity of pain (VAS) during the day. In a novel analysis, all diary entries +/− 4 weeks of each scheduled visit were analyzed over 1 year for threshold response (see Figure 1). Weekly data was available during the DB study. Chi-square tests for category treatment differences were completed at end of DB and months 6, 9, and 12. Kaplan-Meier estimates and p-values were computed using a Cox proportional model. The response categories were not mutually exclusive.

Figure 1. Percentage Threshold Improvement* in Morning Stiffness Before and After Switch



*Thresholds for improvement represent % of patients achieving 25, 50, and 75% improvement in morning stiffness ‡ $p \le 0.05$ for all categories favoring DR prednisone

Results: The DR prednisone arm had statistically significantly more responders in each of the 3 MS response categories at the end of the DB period as compared to IR prednisone ($p \le 0.05$). DR prednisone had higher percentages of responders in the 3 response categories at each 12 week evaluation. The separation started after 1 week of therapy. Of those who had responses in the DB study, it took longer for the IR prednisone group to reach

the same level of response. The IR prednisone group, when switched to DR prednisone, had comparable responses in all categories within 3 months and significantly shorter time to response when compared to patients already receiving DR prednisone ($p \leq 0.008$).

Conclusion: DR prednisone, as compared to IR prednisone, produces significantly higher MS response rates as defined by 25/50/75% improvement thresholds. The time to reach these thresholds is quicker with DR prednisone and patients switched to DR prednisone from IR prednisone quickly "catch up" and manifest comparable responses. Patients treated with DR prednisone maintained their response with no evidence of tachyphylaxis up to 1 year.

2256

Analysis of the Factors That Contribute to the Differences Between DAS28-ESR and DAS28-CRP. Toshihiro Matsui[1], Hirotaka Tsuno[1], Jinju Nishino[2], Yoshiaki Kuga[3], Atsushi Hashimoto[1] and Shigeto Tohma[4]. [1]National Hospital Organization Sagamihara Hospital, Kanagawa, Japan, [2]Nishino Clinic, Orthopedics and Rheumatology, Tokyo, Japan, [3]Wakaba Hospital, Saitama, Japan, [4]Sagamihara Hospital, National Hospital Organization, Sagamihara, Japan.

Background/Purpose: It is widely accepted that the remission rate of DAS28-CRP is larger than that of DAS28-ESR, SDAI, and CDAI in patients with rheumatoid arthritis. DAS28-CRP was introduced to be comparable to DAS28-ESR and the same cut-off values of disease activity category were generally used for both DAS28. However, it had been reported that DAS28-CRP underestimates the disease activity compared with DAS28-ESR (Matsui T, et al. Ann Rheum Dis 2007;66:1221) and that the differences between DAS28-ESR and DAS28-CRP (DAS28DIF) were affected by gender and disease duration (Castrejon I, et al. Clin Exp Rheumatol 2008;26:769). It is very important to know the factors which affect DAS28DIF for evaluating the data by DAS28-CRP.The purpose of this study is to analyze the factors which have an influence on DAS28DIF.

Methods: We analyzed the data from 5987 patients with rheumatoid arthritis (RA) registered in NinJa (National Database of Rheumatic Diseases by iR-net in Japan) 2011. The mean age was 63.1 ± 12.9 years old, disease duration was 12.1 ± 10.8 years, and 80.7% of the patients were female. The mean DAS28-ESR and DAS28-CRP was 3.24 ± 1.28 and 2.58 ± 1.10, respectively (mean DAS28DIF$=0.659$). Multivariate linear regression analyses were conducted. Variables that were significant at $p<0.01$ on the univariate analysis were entered into the multivariate model.

Results: A univatiate analysis showed that several variables (gender, age, disease duration, stage, class, mHAQ, ESR, CRP, PtPainVAS, PtGVAS, DrVAS, artificial joint, TJC28, SJC28) were associated with DAS28DIF with $p<0.01$. A multivariate linear regression analysis demonstrated that ESR (standard partial regression coefficient:0.633), female gender (0.194), age (0.119), mHAQ (-0.087), and BMI (-0.037) were associated with DAS28DIF (coefficient of determination:0.474). Category analysis also revealed that value of DAS28DIF was significantly higher with increasing ESR, age, disease duration, class, mHAQ, DAS28-ESR, DAS28-CRP, and with decreasing BMI (Jonckheere-Tepstra trend test, $p<0.001$). There was significant difference in DAS28DIF between male (0.41) and female (0.72) (Wilcoxon signed-rank test, $p<0.001$). Mean DAS28DIF was -0.002 in patients whose ESR was 11 mm/hr or less. Cut-off value for DAS28-CRP calculated by regression analysis between DAS28-ESR and DAS28-CRP was 2.1 for remission, 2.5 for low disease activity and 4.0 for high disease activity, respectively.

Conclusion: This study showed that DAS28DIF can be affected by many kinds of valuables. We should pay attention to the background of the patients when analyzing the data by using DAS28-CRP and evaluating the cut-off value of remission for DAS28-CRP based on that of DAS28-ESR.

Symptom Complexes At The Beginning Of Rheumatoid Arthritis: A Qualitative Exploration In At Risk Individuals and In New Patients Prior To Diagnosis. Rebecca J Stack[1], Lilian H.D. van Tuyl[2], Maurits Sloots[3], Lotte A. van de Stadt[3], Wijnanda Hoogland[3], Bertha Matt[3], Christian D Mallen[4], Rumandeep Tiwana[1], Karim Raza[1] and Dirkjan van Schaardenburg[3]. [1]University of Birmingham, Birmingham, United Kingdom, [2]VU University Medical Center, Amsterdam, Netherlands, [3]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [4]University of Keele, Keele, United Kingdom.

Background/Purpose: To achieve better prediction of the development of rheumatoid arthritis (RA) a EULAR study group recommended identification and assessment of symptoms in those with arthralgia and during the earliest phases of clinical arthritis as a research priority. The aim of this study was to explore early symptom experiences in individuals with arthralgia at risk of RA and in individuals with new onset RA.

Methods: Focus groups with fifteen arthralgia patients (positive anti-CCP) and in-depth interviews with eleven newly presenting RA patients (2010 criteria) were conducted. An active feedback procedure was used to share experiences of arthralgia patients with early RA patients and vice versa. When saturation was reached transcripts were analysed using thematic analysis and major themes were identified. The analyses were merged to explore similarities and differences in themes between groups.

Results: Themes common to arthralgia and early RA patients included: pain (described in the joints and also in muscles and tendons); tingling sensations; loss of strength and weakness; fatigue and sleeping difficulties; self-reported swelling, redness and warmth; joint stiffness and intermittent symptoms. However, some differences were noted. Arthralgia patients described pain that was often concentrated in their hands and feet as bothersome and annoying. Early RA patients described pain that had intensified to excruciating levels before diagnosis; in some cases pain was likened to a broken bone. Arthralgia patients reported short episodes of intermittent swelling which often involved feelings of pain and fatigue. RA patients recalled that changes in their experience of swelling marked a significant change in the course of their illness, with the nature and pattern of swelling (such as intensification, development of symmetry, translocation) changing shortly before being diagnosed. Such changes were reported to be triggers for patient consultation and physician referral. Fatigue and sleeping difficulties were a dominant problem for arthralgia patients, they noted intense and troubling pain at night. RA patients also reported that night pain was one of the first symptoms they recalled.

Conclusion: Understanding the features and patterns of symptoms characterising the earliest stages of RA is important if patients are to be identified and started on treatment early. Arthralgia and early RA patients shared symptoms which characterised the onset of disease, however, this detailed exploration of symptoms highlighted how the intensity (e.g. pain), and the pattern (e.g. changes in the pattern of swelling) differ between the two groups. Further research to develop measures of symptom patterns and clusters which occur in arthralgia patients and may signal the emergence of RA is required. This research should be followed by quantitative explorations of symptom clusters and their associated features.

Less Than 5% Of Ethnic Minority Rheumatoid Arthritis Patients Meet Inclusion Criteria For Randomized Controlled Clinical Trials. Gail S. Kerr[1], Yusuf Yazici[2], Christopher Swearingen[3], Chunqiao Luo[3], Yvonne R. S. Sherrer[4], Edward L. Treadwell[5], Angelia D. Mosley-Williams[6], Luis R. Espinoza[7], Rodolfo Perez Alamino[8], Sharon Dowell[9], Ignacio Garcia-Vallardes[10], Theresa Lawrence-Ford[11], Adrian Godoy[9], Akgun Ince[12] and Cindy Flower[13]. [1]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [2]New York University Hospital for Joint Diseases, New York, NY, [3]University of Arkansas for Medical Sciences, Little Rock, AR, [4]Centre Rheum Immunol Arthritis, Fort Lauderdale, FL, [5]East Carolina University, Greenville, NC, [6]John Dingell VAMC, Detroit, MI, [7]LSU Medical Center, New Orleans, LA, [8]Lousiana State University and LSU Medical Center, New Orleans, LA, [9]Howard University, Washington, DC, [10]Guadalajara, Gaudalajara, Mexico, [11]North Georgia Rheumatology Group, PC, Lawrenceville, GA, [12]Saint Louis University, St. Louis, MO, [13]University of the West Indies, Bridgetown, Barbados.

Background/Purpose: RCT are the gold standard for therapeutic efficacy, yet many studies indicate most patients seen in routine clinical care do

not meet inclusion criteria. Apart from cultural challenges to the enrollment of ethnic minorities in clinical studies, decreased access and care, and late presentation in disease course may preclude inclusion in RA RCT. However, eligibility of ethnic minorities for RA RCT, to the best of our knowledge, has not been reported. EMRAC is a prospective clinical registry that collects data reflective of routine clinical care. In this study, we evaluated the applicability of standard RCT inclusion criteria in a cohort of ethnic minority RA patients.

Methods: Enrollment data collected on EMRAC patients include socio-demographic parameters (age, gender, tobacco use), RA disease status variables (disease duration, serology [RF, ACPA], nodules, erosions, MD-HAQ, TJC, SJC, ESR, CRP, CDAI, DAS28, RAPID3), treatments (prednisone, DMARD, Biologic therapies) and comorbidities (HTN, DM, HLD). RA related disease measures were evaluated for the following standard, high disease activity, RCT inclusion criteria: swollen joints (28) >= 6, tender joints (28) >= 6, ESR >= 28, morning stiffness >= 45 min. We also evaluated the cohort for low disease activity, defined as swollen (28) <= 1, tender (28) <= 1, ESR <= 10, morning stiffness <= 15 min. Comparisons were made of each individual criteria, high (RCT eligible) versus low disease activity, and overall RCT eligibility by Race (Caucasian, African American) using Chi-square test.

Results: 242 EMRAC patients had complete datasets available for analysis: 81 (33%) were Caucasian and 161 (67%) were African American (AA). The mean age was 62.5 years and the mean disease duration was 13.2 years. Only 4% AA and 4% Caucasians met standard RCT inclusion criteria, despite only 4% AA and 7% of Caucasians meeting criteria for low disease activity. The most stringent criterion was swollen joint count, with only 17% of AA and 15% of Caucasians meeting criteria, followed by tender joint counts (24% of AA and 32% of Caucasians). 52% AA and 40% Caucasian patients, respectively, met ESR criteria, while 38% AA and 37% Caucasians met morning stiffness thresholds. Caucasians were more likely to have low disease activity ESR than AA (27% vs 11%, p=0.002), while AA had low disease activity tender (28) compared to Caucasians (58% vs 43%, p=0.032).

Conclusion: In addition to reported socio-economic and cultural hurdles that preclude enrollment of ethnic minorities in RCT, African Americans, like their Caucasian counterparts, also fail to meet eligibility for RCT despite active disease, despite half as many African Americans as Caucasians achieving low disease status. These data may suggest reconsideration of current entry criteria for RCT in all patients with RA.

Does a Ratingen Score Of ≥ 3 At Disease Onset Define RA In ACR/EULAR 2010 Criteria Negative Patients? Ruediger Mueller, Toni Kaegi, Sarah Haile and Johannes von Kempis. Kantonsspital St. Gallen, St. Gallen, Switzerland.

Background/Purpose: A EULAR task force has recently selected an evidence and consensus based definition of erosive disease defining rheumatoid arthritis (RA) in patients who do otherwise not fulfil the 2010 ACR/EULAR criteria for classification of the disease. Erosive disease was defined as a minimum of 3 erosions in particular joints.

Methods: For this observational cohort study within the RA cohort of the Swiss registry SCQM, we included patients suffering from early RA or undifferentiated arthritis (disease duration ≤1 year), as defined by the treating rheumatologist, who had not received any previous DMARDs. Baseline diagnosis of RA/UA was reassessed according to the 2010 ACR/EULAR criteria at baseline. 2010 ACR/EULAR criteria negative patients were separated into 2 groups depending on whether or not they had more than two erosions in the Ratingen score (Ratingen positive: >2; Ratingen negative <3). The primary outcome measures were the radiological progression. HAQ and DAS 28 were used as secondary outcome measures. The average observation period was 4 years.

Results: A total number of 592 patients was analysed. 240 were not classifiable as RA according to the new criteria at baseline. 133 patients were Ratingen positive and 50 patients were Ratingen negative, 57 patients were not classifiable. Treatment was initiated in all patients with DMARDs, mostly MTX. There were no significant differences in the therapeutic strategies between Ratingen positive and negative patients. No differences in DAS 28 and HAQ scores were found during follow up over 4 years. Average radiographic progression was higher among Ratingen positive as compared to Ratingen negative patients (6.6 erosions/year vs. 0.4, resp., p=0.0004).

Conclusion: The presence of more than 2 erosions in the Ratingen score selected RA patients not fulfilling the 2010 ACR/EULAR criteria who will suffer from a radiographic progressive disease. This indicates that the propose definition of erosive disease is, indeed, selecting patients, who will develop definite RA.

Smoking and Antibodies To Cyclic Citrullinated Peptides Predict Persistently High Levels Of Survivin In Early Rheumatoid Arthritis. Bjorn Svensson[1], Ingiäld Hafström[2], Malin Erlandsson[3], Kristina Forslind[4] and Maria Bokarewa[5]. [1]Lund University, Lund, Sweden, [2]Karolinska University Hospital, Stockholm, Sweden, [3]Göteborgs University, Göteborg, Sweden, [4]Section of Rheumatology, Department of Medicine, Helsingborg General Hospital, Helsingborg, Sweden, [5]University of Gothenburg, Gothenburg, Sweden.

Background/Purpose: High levels of the oncoprotein survivin may be detected in the majority of patients with early rheumatoid arthritis (RA). Survivin is a sensitive predictor of joint damage and persistent disease activity. Survivin-positive patients are often poor responders to anti-rheumatic and biological treatment. Present study investigates the reproducibility of survivin status in paired samples from RA patients.

Methods: Survivin levels were measured in 339 patients from the BARFOT cohort of early RA at baseline and after 24 months. The association of survivin status with joint damage (total Sharp-vd Heide score), disease activity (DAS28), functional disability (HAQ), and pain perception (VAS) was calculated in the groups positive and negative for survivin on both occasions, and for the positive-negative and negative-positive groups.

Results: In 268 patients (79%) the levels of survivin were similar at baseline and after 24 months, 15% converted from survivin-positive to being negative, and 5% from survivin-negative to being positive. A combination of smoking and aCCP antibodies predicted high levels of survivin on both test occasions (OR4.5 [95%CI: 7.54–2.74], p<0.001, PPV 0.67 and specificity 0.84). Survivin positivity on both test occasions was associated with the progression of joint damage, significantly higher DAS28 and lower rate of remission at 24 and 60 months compared to negative-negative patients. Survivin status was less associated with changes in HAQ and VAS.

Conclusion: Survivin status in RA patients may be predicted by smoking and aCCP and is highly reproducible at 24 months follow-up. Survivin is a relevant marker to use in predictive models and on which to base treatment decisions.

Motivations For Inadequate Persistence With Disease Modifying Anti-Rheumatic Drugs In Early Rheumatoid Arthritis: *The Patient's Perspective.* Virginia Pascual-Ramos and Irazú Contreras-Yáñez. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.

Background/Purpose: Knowledge of factors that contribute to non-persistence with disease modifying anti-rheumatic drugs (NP-DMARDs) is essential to improve rheumatoid arthritis (RA) outcomes. Aims of the study were to investigate patient's motivations and risk factors for NP-DMARDs in a cohort of early Mexican Mestizos patients with RA and traditional DMARDs.

Methods: Up to September 2012, data from 149 patients (93% of the entire cohort), who had at least 1 year of follow-up, and one DMARD indication, and 2 consecutive six-months-apart rheumatic evaluations that included assessment of compliance with treatment were reviewed. Compliance was evaluated according to a 22-items questionnaire locally designed that evaluates among others NP-DMARDs and patient's motivations of NP-DMARDs. Patients had partial health coverage and pay for their medication.

Descriptive statistics and logistic regression models were used. All statistical tests were 2-sided and evaluated at the 0.05 significance level. The

study was approved by the internal review board. Written informed consent was obtained.

Results: Up to cut-off, 715 questionnaires were applied to 149 patients, who had (mean ± SD) follow-up of 58.7 ± 27.9 months and were indicated (mean±SD) DMARDs/patient/follow-up of 2.4±0.7.

Patients were most frequently female (88.6%), middle-aged ([mean±SD] age of 38.5±12.8 years) with lower-middle/lower socio-economic status (87.9%) and (mean±SD) scholarship of 11±3.9 years.

Ninety-nine (66.4%) patients were NP-DMARDs and filled 330 questionnaires. Multivariate analysis showed that years of formal education (OR: 1.12, 95% CI: 1.1–1.24, p=0.03), perception of at least some difficulty to find arthritis medication (OR: 5.68, 95% CI: 2.48–13, p=0.000) and perception that arthritis medication is expensive (OR: 5.27, 95% CI: 2.1–13.84, p=0.001) at the first evaluation of patient′s compliance were all predictor of NP-DMARDs.

Among the 99 NP-DMARDs patients, 25 (25.3%) were recurrent-NP-DMARDs and accumulated more disease activity than their counterparts ([mean±SD cumulative DAS28] 3.7±2 vs. 2.9±1.7, p=0.04). Also, DAS28 remission was lower among recurrent-NP patients (8 vs. 45, p=0.002).

Combination of both reasons of NP-DMARDs ("Because it was not available at the drugstore" and "Because the medication is very expensive") when selected by the patient at the first evaluation of compliance was the only variable to predict recurrent NP-DMARD, OR: 4.8, 95%CI: 1.1–20.8, p=0.04.

Conclusion: Health systems should provide (first line) treatment for RA as a strategy to improve compliance with therapy and clinical outcomes, particularly in vulnerable populations.

Disclosure: V. Pascual-Ramos, None; **I. Contreras-Yáñez**, None.

Antibody To Malondialdehyde-Acetaldehyde Adducts (MAA) Is a Biomarker Of Inflammation and Is Correlated With The Disease Activity In Rheumatoid Arthritis. Kathleen Young[1], Dathe Benissan-Messan[2], Michael J. Duryee[2], Daniel Anderson[2], Liron Caplan[3], Lisa A. Davis[4], Harlan Sayles[2], Carlos D. Hunter[2], Lynell W. Klassen[5], James R. O'Dell[2], Ted R. Mikuls[6] and Geoffrey M Thiele[5]. [1]Univ of Nebraska Med Ctr, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE, [3]Denver Veterans Affairs Medical Center, Denver, CO, [4]Denver Health and Hospital Authority, Denver, CO, [5]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [6]Omaha VA and University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: Cardiovascular disease (CVD) is a major cause of morbidity and mortality in patients with rheumatoid arthritis (RA). While there are many markers used for evaluating the development and/or progression of CVD, the recent use of pro-inflammatory macromolecules (CRP, IL-6, TNF-α) has become increasingly helpful in the diagnosis and evaluation of CVD. Our laboratory has been evaluating antibody isotypes and concentrations to a unique malondialdehyde (MAA) adduct that appear to correlate with both systemic inflammation and cardiovascular events. We have hypothesized that inflammation directed against MAA could serve as a link between systemic inflammation and the excess CVD burden that both characterize RA. Thus, as a first step in addressing our overarching hypothesis, we sought to evaluate whether associations existed between anti-MAA antibodies and measures of RA disease activity and severity.

Methods: Serum samples from 704 RA patients from the Veterans Affairs RA (VARA) registry were evaluated for the presence and concentration of IgM, IgA and IgG antibodies to the MAA epitope using ELISA. Associations of these antibody concentrations with traditional markers of RA (RF, ESR, CRP, ACPA, DAS28, etc.) were performed using non-parametric Spearman Rank Correlation statistics. Additionally, antibody isotype concentrations to MAA were compared for patients with radiographic bone erosions to those without erosions using a two-sample t-test.

Results: Statistically significant correlations were observed between anti-MAA antibody concentrations and multiple RA measures (Table) including RF isotypes, ACPA, ESR, and CRP. Isotype variability was observed with measures including RF (by nephelometry) and swollen joint count, while no associations were observed between anti-MAA concentrations and tender joints, MD-HAQ, and DAS28. Finally, patients with radiographic erosions demonstrated higher concentrations of IgA anti-MAA compared to patients without erosions (p = 0.043), a difference that was not observed for IgG or IgM anti-MAA isotypes.

Table 1. Correlations of anti-MAA antibody concentration and measures of RA disease actvity/severity; top number in each cell represents the correlation coefficient while the bottom number represents the p-value.

	Isotypes of Anti-MAA Antibodies		
RA Measure	**IgG**	**IgA**	**IgM**
RF IgG	R = 0.2065	0.269	0.3634
	p <0.0001	**<0.0001**	**<0.0001**
RF IgA	0.1244	0.2951	0.4022
	0.0064	**<0.0001**	**<0.0001**
RF IgM	0.12	0.2516	0.4666
	0.0085	**<0.0001**	**<0.0001**
ESR	0.0961	0.1081	0.1424
	0.017	**0.0074**	**0.0004**
CRP	0.1415	0.1264	0.082
	0.0003	**0.0011**	**0.0344**
RF Nephelometry	0.0621	0.1943	0.4203
	0.1099	**<0.0001**	**<0.0001**
ACPA (anti-CCP)	0.1796	0.1393	0.1837
	<0.0001	**0.0003**	**<0.0001**
DAS28	0.0176	−0.0236	0.0498
	0.6801	0.5801	0.2416
Tender Joint Count	−0.0061	−0.0413	0.0387
	0.8751	0.2918	0.3244
Swollen Joint Count	0.1016	0.0178	0.0678
	0.0092	0.6499	0.0824
MD-HAQ	−0.0506	−0.0504	−0.0489
	0.2322	0.2341	0.2474

Conclusion: These results show there is a relationship between anti-MAA antibody levels and several traditional measures of disease activity and/or severity in RA. Although we have previously shown that both MAA and anti-MAA may play a role in CVD pathogenesis in patients without RA, further investigation will be needed to better elucidate whether MAA-related inflammation could serve as a mechanistic link between RA and CVD burden.

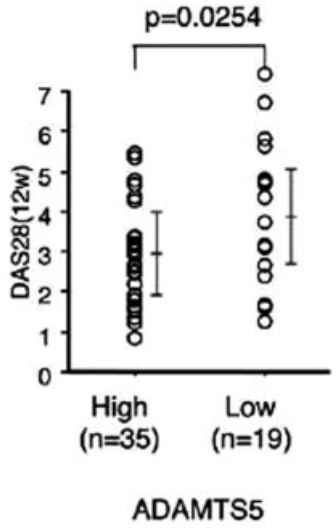
ADAMTS5 Is a Biomarker For The Efficacy Prediction Of Tocilizumab In Rheumatoid Arthritis. Kensei Tsuzaka, Masako Takao and Jiro Nishida. Ichikawa General Hospital, TDC, Ichikawa, Chiba, Japan.

Background/Purpose: We have previously (2009ACR, 2010ACR) reported that the efficacy of biologics, infliximab and adalimumab can be predictable using baseline blood a disintegrin and metalloproteinase with thrombospondin motifs 5 (ADAMTS5) mRNA level. In this study presented here, we investigated whether the efficacy of tocilizumab (TCZ) for the treatment of rheumatoid arthritis (RA) can be predicted by the baseline blood ADAMTS5 mRNA level because recently IL-6 has been reported to suppress ADAMTS5 expression.

Methods: Fifty-four randomly selected active RA patients were treated with TCZ. Peripheral blood samples were collected at baseline and ADAMTS5 mRNA was quantified using real-time PCR (BiologicMate®). Baseline IL-6 mRNA was also estimated using real-time PCR.

Results: Baseline ADAMTS5 mRNA levels (□L 10^{-4}) in the responder (2.85 ± 2.37 Index) was significantly (p=0.049) higher than that in the non-responder (1.56 ± 0.80 Index) at 12 wks' treatment with TCZ. Area under curve (AUC) of the ROC curve for predicting the clinical remission (DAS28<2.6) using the baseline ADAMTS5 mRNA at 12 wks was 0.75, and the cut-off value of ADAMTS5 mRNA was calculated as 1.70 Index. There observed no difference in the general patient backgrounds (average age, disease duration, dose of MTX, dose of steroid, baseline DAS28, etc) between the High-ADAMTS5 (^{3} 1.70 Index) group and the Low-ADAMTS5 group. However, DAS28 at 12 wks after treatment was significantly (p=0.0254) lower in the High-ADAMTS5 group (3.09 ± 1.29) than in the Low-ADAMTS5 group (3.88 ± 1.08) (Fig.1). The accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of

the baseline High-ADAMTS5 (^{3}1.7 Index) for predicting the clinical remission at 12 wks with TCZ was 75.0%, 94.1%, 48.7%, 45.7%, and 94.7%, respectively. Interestingly, we observed negative correlation between baseline IL-6 and ADAMTS5 mRNA expression.



Conclusion: The baseline ADAMTS5 mRNA level, which might be related to baseline IL-6, is a candidate biomarker for prediction of the response to TCZ in RA patients.

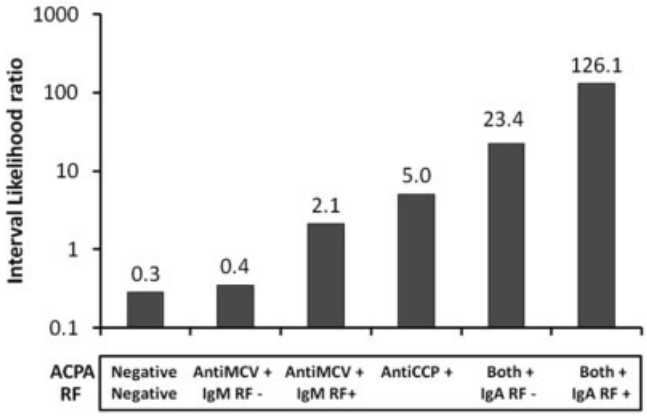
An Assay Panel Combining Anticitrullinated Peptide Autoantibodies and Rheumatoid Factor Isotypes Has High Yield In The Diagnosis Of Rheumatoid Arthritis. Nirupa J. Patel[1], Ignacio Garcia-Valladares[2], Derren Barken[3], Luis R. Espinoza[4], Heena Sheth[5] and Thierry Dervieux[3]. [1]LSU Health Sciences Ctr, New Orleans, LA, [2]Guadalajara, Guadalajara, Mexico, [3]Exagen Diagnostics, Vista, CA, [4]LSU Medical Center, New Orleans, LA, [5]University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: We sought to establish the diagnostic performances of rheumatoid factor isotypes (IgM and IgA) and anti-citrullinated peptide antibodies (ACPAs: anti-mutated citrullinated vimentin [anti-MCV] and anti-cyclic citrullinated peptide antibodies [antiCCP]) in a large population of patients with rheumatoid arthritis (RA) and other rheumatic diseases.

Methods: 1140 subjects were from the United States and informed consent was obtained from all patients. The group of 703 RA patients (78% females, age was 60.0±14 yrs) consisted of 452 patients diagnosed using the 1987 ACR criteria and 251 patients diagnosed using the 2010 ACR criteria. A total of 113 RA patients (16.1%) presented with disease duration lower than 2 years. Alternatively, the group of 387 patients with other diseases (83% females, age 44.6±15.0, mean±SD) consisted of 271 patients with Systemic lupus erythematosus and 116 patients with other autoimmune diseases. An additional 50 normal healthy volunteers were also enrolled. IgM RF, IgA RF, anti-CCP were measured using fluoroenzyme immunoassays (Phadia, Uppsala, Sweden) and anti-MCV was determined using enzyme linked immunosorbent assays (Orgentec, Mainz, Germany). Statistical analyses utilized area under receiver operating characteristic (ROC) curves, and calculations of diagnostic sensitivity, specificity, positive likelihood ratio (LR+) and interval LR. Cutoffs used for positivity were 5 U/ml for IgM RF, 20 U/ml for IgA RF, 10 U/ml for anti-CCP and 35 U/ml for anti-MCV.

Results: The area under the ROC curve was 0.857±0.022 for IgM RF, 0.724±0.031 for IgA RF, 0.828±0.025 for anti-CCP and 0.805±0.025 for anti-MCV. Sensitivity and specificity against other rheumatic diseases were 71% and 85% for IgM RF (positive LR=4.8), 41% and 90% for IgA RF (LR+=4.1), 70% and 96% for anti-CCP (LR+=18.0) and 62% and 92% for anti-MCV (LR=7.3). Specificity ranged from 94–100% against normal healthy individuals for all markers. A scoring system combining positivity for ACPA (anti-CCP and anti-MCV) and RF isotypes was calculated. Interval likelihood ratio increased from 0.3 among ACPA negative patients, to 126.1 among patients positive for both ACPAs and IgA RF (Figure). Interval LR differences when compared by disease duration and diagnostic criteria were not statistically significant.



Conclusion: An assay panel combining ACPAs (anti-CCP with anti-MCV) with RF isotopes can help in differentiating RA from other rheumatic diseases.

Switching From Immediate Release (IR) Prednisone To Delayed Release (DR) Prednisone Improves Patient Reported Outcomes In Rheumatoid Arthritis (RA) Patients On Conventional Disease-Modifying Antirheumatic Drugs (DMARDs). Rieke Alten[1], Robert Holt[2], Amy Grahn[2], Patricia Rice[3], Jeffery Kent[2], Frank Buttgereit[4] and Allan Gibofsky[5]. [1]University of Berlin, Berlin, Germany, [2]Horizon Pharma, Inc, Deerfield, IL, [3]CliniRx Research, Naperville, IL, [4]Charité - Universitätsmedizin Berlin, Berlin, Germany, [5]Hospital for Special Surgery, New York, NY.

Background/Purpose: A surge in nocturnal inflammatory cytokines causing morning stiffness (MS) is recognized as a therapeutic target in RA. MS has been underappreciated in impacting the quality of life (QOL) of RA patients. Along with renewed interest in glucocorticoids (GCs) as an option for targeting these circadian disease fluctuations, ACR is updating its practice guidelines. Optimal timing for glucocorticoid administration will be a new and important topic to address. DR prednisone administered at bedtime produces significant absolute and relative reduction in morning symptoms. Inflammatory cytokines are also reduced significantly. In this analysis of patients with RA, we evaluated the reduction of symptoms that impact QOL. This assessment examined 9 months of patient reported diary data from the CAPRA I trial who were switched from IR-prednisone to DR-prednisone after 3 months of previous therapy.

Methods: RA patients previously randomized to IR prednisone (N=110) were switched to DR-prednisone open label and evaluated at 3, 6, and 9 months to measure median absolute (paired t-test) and relative changes (Wilcoxon Rank Sum Test) in pain, patient's global, and MS as the primary outcome. Patients completed diary entries at least 7 days prior to each of the 3 month visits including waking time, stiffness (yes/no), time of resolution and intensity of pain (VAS) during the day. In an analysis not previously performed, all patient diary entries +/− 4 weeks of each visit were compared to Baseline at Switch in addition to other disease measures.

Results: There was a statistically significant and clinically meaningful reduction in morning stiffness during the first 3 months after the switch and the response was maintained over the entire study period of 9 months (Figure 1). Absolute reduction of MS was approximately 50 min from 143.5 min and there was a > 40% relative reduction in MS at each visit. IL-6 levels were reduced concomitantly by the same amount. The mean reduction in MS was over 60 minutes at each of the three visits (Figure 2).

Figure 1. Switching from IR prednisone to DR prednisone produces Sustained Morning Stiffness Reduction

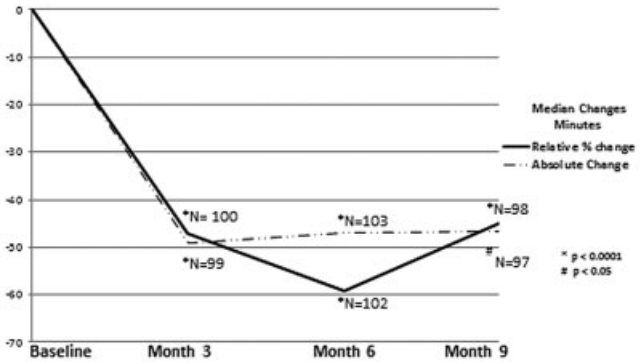

Figure 2. Observed Reduction in Morning Stiffness after switching to DR prednisone from IR Prednisone

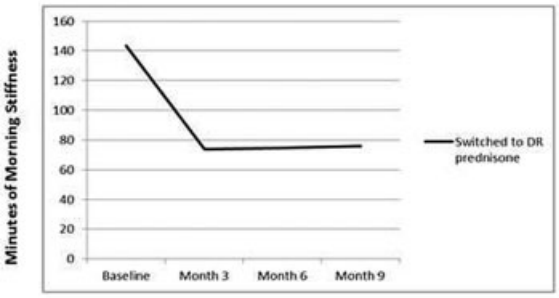

Conclusion: This analysis demonstrates that RA patients on stable DMARD therapy, who have not adequately responded to IR-prednisone with respect to morning stiffness, showed statistically significant and clinically meaningful improvement in this symptom when switched to DR prednisone which markedly impacts quality of life. This beneficial effect was maintained over the 9 month study duration.

Research On Factors Influenced For Bone Metabolic Markers In Rheumatoid Arthritis Patients From Prospective Cohort Study. Masahiro Tada, Tatsuya Koike, Tadashi Okano, Yuko Sugioka, Kenji Mamoto, Kentaro Inui and Hiroaki Nakamura. Osaka City University Graduate School of Medicine, Osaka, Japan.

Background/Purpose: Patients with rheumatoid arthritis (RA) develop osteoporosis more frequently than healthy individuals. Bone resorption and formation are respectively increased and inhibited in patients with RA, and steroids negatively affect bone metabolism in both patients with RA and healthy individuals. The effect of reducing the steroid dose on bone metabolic markers in patients with RA has remained unknown. We aimed to investigate the factors influenced for bone metabolic markers in RA patients using multivariate analysis technique.

Methods: We started the 10-year prospective cohort TOMORROW (TOtal Management Of Risk factors in Rheumatoid arthritis patients to lOWer morbidity and mortality clinical trial (registration number, UMIN000003876)) in 2010. We compared changes in urinary crosslinked N-telopeptide of type I collagen (NTx) and serum osteocalcin (OC), which are markers of bone resorption and formation, respectively, in a total of 404 age- and sex-matched RA patients and volunteers between 2010 and 2011 (delta NTx = NTx during 2011 – NTx during 2010; delta OC = OC during 2011 – OC during 2010). We also investigated the factors influenced for delta NTx and delta OC in RA patients using multivariate analysis technique.

Results: Baseline demographics were showed in Table 1. There were no significant differences in all parameters between groups. The delta NTx values were significantly lower in the patients than in the volunteers (-0.51 ± 29.4 vs. 7.41 ± 18.7 nmol; $p = 0.0013$), whereas the delta OC values were significantly higher in the patients (0.94 ± 2.47 vs. 0.37 ± 1.62; $p = 0.0065$). The change of prednisolone (PSL) dosage negatively correlated with delta OC ($\beta = -0.229$, $p = 0.001$), whereas change of disease activity score (DAS28), bisphosphonate therapy, and period of biologics therapy did not significantly correlate with delta OC (Table 2).

Table 1. Baseline demographics

	Volunteers (n = 202)	RA patients (n = 202)
Age, years	58.8 ± 12.8	59.3 ± 12.5
Height, cm	157.7 ± 7.8	155.5 ± 9.0
Weight, kg	56.3 ± 10.5	54.8 ± 10.4
BMI, kg/m^2	22.6 ± 3.2	22.6 ± 3.6

BMI: body mass index

Table 2. The factors influenced for delta OC in RA patients

	β value	P value
delta PSL dosage	**−0.229**	**0.001**
delta DAS28-ESR	−0.007	0.918
Bisphosphonate therapy	−0.033	0.673
Period of biologics therapy	0.018	0.802
Age	0.155	0.054
Sex (female)	0.013	0.855
Disease duration	0.037	0.601
Steinbrocker class	−0.059	0.456

PSL: prednisolone, DAS: disease activity score

Conclusion: A decrease in the dose of PSL respectively decreased and increased markers of bone resorption and formation among patients with RA. That is, bone metabolic makers were improved. However, disease activity, bisphosphonate therapy, and period of biologics therapy did not influence for bone metabolic makers. Thus, bone metabolic markers might degenerate even when disease activity is under good control. Decreasing the PSL dosage is important for bone metabolism in patients with RA.

The Diagnostic Accuracy Of Rheumatoid Factor Testing In Primary Care. Anne Miller[1], Alison L Nightingale[2], Cormac J Sammon[2], Tim Holt[3], Kamal R Mahtani[3], Neil McHugh[4], Corinne S de Vries[2] and Raashid A. Luqmani[1]. [1]Nuffield Orthopaedic Centre, Oxford, United Kingdom, [2]University of Bath, Bath, United Kingdom, [3]University of Oxford, Oxford, United Kingdom, [4]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom.

Background/Purpose: Studies of the diagnostic utility of rheumatoid factor (RF) testing for rheumatoid arthritis (RA) conducted in early arthritis clinics in secondary care have reported sensitivity and specificity of 69% and 85% respectively. However, few studies have been conducted in primary care where the pre-test probability of RA is low. We investigated the utility of RF in primary care using the Clinical Practice Research Datalink (CPRD), a large primary care electronic database representing 8.4% of the UK population.

Methods: The CPRD was searched for patients who had a first RF test between 1st January 2000 and 31stDecember 2008 and had at least 2 years of follow-up data or who died within 2 years of the test date. We excluded practice-years where there was evidence for preferential recording of positive RF tests. Patients diagnosed with RA within 2 years of their first test were identified using a validated algorithm; we then calculated the sensitivity, specificity and positive and negative likelihood ratios (LR+, LR-) for a diagnosis of RA. We calculated the relative risks (RRs) of positive compared

with negative RF results for patient characteristics and musculoskeletal symptoms recorded in the 6 months before the test using Poisson regression models.

Results: We found that 63,539 RF tests fulfilled the inclusion criteria; 92.3 % were negative and 68.4% were requested in females. There were 1753 incident cases of RA in patients undergoing RF testing giving an incidence rate of 1.4/100 /year (CI_{95} 1.3, 1.5) and 1013 RA cases (57.8%) had a positive RF test. The RR of RA diagnosis increased with RF titre from RR 5.0 (CI_{95} 4.0, 6.3) with titres of 1–9 IU/ml above the laboratory upper normal range (UNR) to RR 15.0 (CI_{95} 11.2, 20.0) at titres 40–50 IU/ml above UNR and RR 38.8 (CI_{95} 31.0, 48.4) at tires 500–999 IU/ml above UNR. The sensitivity and specificity of the RF test was 57.2% (CI_{95} 54.8%, 59.6%) and 93.8% (CI_{95} 93.6%, 94.0%) respectively. The LR+ was 9.3 (CI_{95} 8.8, 9.8) and the LR- was 0.5 (CI_{95} 0.4, 0.5). Patients were more likely to have a positive RF test when presenting with hand, shoulder or knee symptoms (RR 1.3 (CI_{95} 1.2, 1.4), 1.2 (CI_{95} 1.0, 1.3) and 1.1 (CI_{95} 1.0, 1.2) respectively), tenosynovitis (RR 1.5, CI_{95} 1.1, 2.0) or a history of connective tissue disease (RR 1.4, CI_{95} 1.2, 1.7). Those presenting with neck (RR 0.8, CI_{95} 0.7, 1.0) or back pain (RR 0.8, CI_{95} 0.7, 0.9) were less likely to have a positive RF test. Positive RF tests were associated with an increased risk of death in the 2 years following the test (RR 1.5 (CI_{95} 1.3, 1.7).

Conclusion: Whilst RF tests perform moderately well for identifying RA (LR+ 9.27), they do not perform well for ruling out disease if the result is negative (LR- 0.46). Forty two per cent of patients with an eventual diagnosis of RA had a negative initial RF test. We caution against the use of RF as screening tool to rule out RA in patients with symptoms consistent with RA and its indiscriminate use in patients with less specific musculoskeletal problems such as neck or back pain.

Patient-Reported Outcome Measures For Rheumatoid Arthritis: Minimal Important Differences Review. Helen Kitchen[1], Brian Bekker Hansen[2], Linda Abetz[1], Lise Højbjerre[2] and Martin Strandberg-Larsen[2]. [1]Adelphi Values Ltd, Cheshire, United Kingdom, [2]Novo Nordisk A/S, Søborg, Denmark.

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic autoimmune disease, affecting around 1.3 million people in the US. A patient-centred focus is increasingly advocated by healthcare authorities, making assessments of the impact of novel treatments on patient-reported outcomes (PRO) important. PRO data should be interpreted in context of whether it represents a clinically meaningful change. Minimal important difference/ minimal clinically important difference (MID/MCID) provide the benchmarks to define responders in clinical trials. The objective of the study was to review MIDs/MCIDs for PROs commonly applied in clinical trials in patients with RA.

Methods: Articles were identified in MEDLINE, EMBASE, and PsycINFO databases using pre-defined search terms related to RA, differential diagnosis, key PROs and MIDs/MCIDs. Reference lists of identified papers were manually searched. FDA/EMA regulatory guidance and reports, PRO user manuals, PRO Labels and PROQOLID were searched to identify information on MIDs/MCIDs. The following PROs in RA were included in the review: Health Assessment Questionnaire Disability Index (HAQ-DI), 0–100mm pain visual analogue scale (VAS), 0–100mm patient global assessment of disease activity (PtGA), Medical Outcomes Study Short-Form Health Survey (SF-36v2), EuroQol (EQ-5D-3L), Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-Fatigue), and Work Productivity and Activity Impairment Questionnaire: Rheumatoid Arthritis (WPAI:RA). MIDs/MCIDs were prioritised as follows: Available in: 1) RA, 2) related inflammatory conditions, 3) general population. If MIDs/MCIDs were sparse, the next approach was taken.

Results: The search identified 1019 abstracts; 32 abstracts met inclusion and exclusion criteria. From the reference list search, an additional 17 abstracts met the criteria, totalling 49 articles for in-depth review. MIDs/ MCIDs were identified for an RA population for the HAQ-DI (≥0.22 units), Pain (VAS) (−11.9 mm for minimal improvement), PtGA (−9.1mm for minimal improvement), SF-36v2 (change of 2.0 to 3.8 points for Physical Component Summary (PCS) score and 2.7 to 4.6 points for Mental Component Summary (MCS) score), EQ-5D-3L (0.06 to 0.20 [improvement]), FACIT-Fatigue (3.5 to 4.1 points). No MID/MCID information for the WPAI:RA was identified. Most articles focused on the MIDs/MCID's for change over time within a treatment group. MID's/MCID's used in clinical trials in RA were not always consistent with the literature: often applied responder definitions for HAQ-DI ranged from 0.22 to 0.3 units, was 10mm for Pain (VAS) and PtGA, was 3 to 4 points for FACIT-Fatigue, and was a change of 2.5 points for the PCS and MCS of the SF-36v2.

Conclusion: MID/MCID information is available for the core PRO measures in RA. However, some gaps in information remains for the newer PRO measures in RA. Further research to explore patients' perspectives of what constitutes important differences in symptoms, Health-Related Quality of Life, and functioning, and information on important differences between treatment groups, may be beneficial to extrapolate meaning from clinical trial data to the real-world experience of patients.

Patient Reported Pain: A Predictor Of Outcomes In Rheumatoid Arthritis From The Consortium Of Rheumatology Researchers Of North America Registry. Dimitrios A. Pappas[1], Chitra K. Karki[2], Chin Lee[3], George W. Reed[2], Ping He[4] and Sarah Al Sawah[3]. [1]Columbia University, New York, NY, [2]CORRONA, Inc., Southborough, MA, [3]Eli Lilly and Company, Indianapolis, IN, [4]UMASS Medical School, Worcester, MA.

Background/Purpose: Pain is a hallmark of rheumatoid arthritis (RA). The extent to which patient reported pain in RA is related to patterns of biologic treatment switching, change in physical function or work productivity has not been adequately explored. Understanding the impact of patient reported pain on these parameters has clinical relevance in the management of RA.

Objective: To investigate the impact of patient reported pain on biologic treatment switching, change in physical function and work productivity in patients with RA participating in the CORRONA registry.

Methods: The CORRONA registry is a network of rheumatology practices across the U.S. with patient and physician reported data on more than 30,000 patients with RA. To be included in the analysis, patients with RA had to initiate a biologic agent and remain on stable background RA therapy (no dose adjustments, discontinuations, additions or switching) for 6 months. Pain was assessed using a numeric rating scale from 0–10 with 10 defined as "pain as bad as it could be". Pain levels reported at the visit following 6 months of stable RA therapy served as the baseline visit for the analysis. Outcomes assessed during the 12 month follow up period or at the 12 month follow up visit included: 1) frequency of biologic treatment switching; 2) frequency of biologic treatment switching due to inefficacy; 3) change from baseline in physical function as measured by the modified health assessment questionnaire (mHAQ); and 4) days lost from work due to RA. Separate multivariate analyses were performed for each outcome. Covariates considered for adjustment were age, gender, race, education status, smoking status, insurance status, baseline clinical disease activity index (CDAI), disease duration, baseline mHAQ, and comorbidities. Covariates were included in the model if they were biologically plausible and significantly associated with the outcome of interest in bivariate evaluations.

Results: 1180 patients with RA met the eligibility criteria and had a 12 month follow up visit after baseline. The majority were females (77.9%) and Caucasian (84.7%) with a mean age of 57.4 (SD ±12.4) years, mean pain 3.1 (SD ±2.5); mean disease duration 11.5 (SD ±9.9) years, mean CDAI 11.45 (SD ±10.7), and mean mHAQ score 0.4 (SD ±0.5). More than half had a college or university education while a small percentage reported smoking (16.8%). The most common comorbidities reported were history of malignancies (16.5%), cardiovascular disease (7.7%), peptic ulcer (7.3%) and diabetes (7.2%).

The adjusted association between patient reported pain and outcomes of interest are shown in Table 1. Odds Ratios (OR), Relative Risk Ratios (RRR) and Coefficients refer to change in outcome associated with a one unit increase in patient reported pain.

Conclusion: Patient reported pain in RA patients is associated with biologic treatment switches, reduction in function, and days lost from work.

2270

US Guided Treat-To-Target Approach In Early RA: Implications For Uncoupling Of Disease Activity and Structural Damage. Yasser El Miedany[1], Maha El Gaafary[2], Sally Youssef[2] and Annie Nasr[2]. [1]Medway Hospital, Gillingham, United Kingdom, [2]Ain Shams University, Cairo, Egypt.

Background/Purpose: To assess the relationship between inflammation and joint destruction in RA patients who have not responded clinically to treatment using Musculoskeletal US as a sensitive tool to evaluate structural damage as well as residual synovial inflammation.

Methods: Changes from baseline to week 54 in clinical variables and measures of radiographic progression were compared between RA patients who received anti-TNF biologic therapy (Treat-to-Target approach), and those who received DMARDs therapy (standard protocol). Musculoskeletal US was used to assess for underlying radiographic progression and inflammatory status. Patients were divided into: in remission, low (LDA), moderate (MDA) and high (HDA) disease activity at 1-year of treatment according to DAS-28 score. Radiographic progression in both hands and feet was scored at base line and at 54 weeks using the modified total Sharp score (MSS). In addition, US examination of individual joints, both hands and feet, was carried out and scores for, number of erosions as well as synovial hypertrophy and PD using a validated semi-quantitative method (0–3) were recorded.

Results: At week 54, the progression of MSS, US-GS as well as US-PD scores in MDA and HDA cohorts were significantly lower in the biologic therapy than the DMARDs group: ($P < 0.01$). On comparing the MSS scores, the biologic therapy cohort who showed LDA (DAS-28: 2.6–3.1) exhibited no significant difference from the DMARDs cohort showing the same LDA status; whereas there was significant difference on comparing US-GS and US-PD scores ($P < 0.001$) between both groups of patients. On the other hand, the biologic therapy cohort showing DAS-28 score > 3.2 had significantly less number of erosions and joint space narrowing ($P < 0.001$) as well as US-GS and US-PD scores in comparison to the DMARDs therapy cohort.

In the DMARDs group, 1-year MSS progression in LDA, MDA and HDA was 0.40 ± 0.88, 1.04 ± 1.73, and 1.31 ± 3.02, respectively, whilst in the remission group, it was $0.1 + 0.64$. Analysis using US revealed: LDA: $0.86+0.65$, MDA: $2.15+1.82$, HAD: $2.73+1.94$ whilst in the remission group it was $0.12+0.57$. In contrast, in the biologic therapy cohort, MSS progression was 0.32 ± 0.26, 0.57 ± 0.42, and 0.63 ± 0.44, (for LDA, MDA and HDA respectively). Similar findings were found on comparing US scores for the inflamed joints: 0.31 ± 1.06, 0.93 ± 0.42, and 1.05 ± 0.37, (for LDA, MDA and HDA respectively) whereas in remission there was no significant difference between the 2 patients groups.

US-GS synovial score and/or US-PD score ≥ 2 increased the risk of structural progression: OR= (1.36–2.98) $p<0.001$.

Conclusion: The combination of biologic therapy and DMARDs retards damage independently of its effects on disease activity, contrasting DMARDs therapy. This indicates that beyond cytokine blockade, biologic therapy conveys profound anti-destructive effects and dissociates the link between disease activity and joint damage.

This study confirms the validity of the presence of US determined synovial thickness and PD signal for predicting subsequent structural deterioration and that US joint examinations may be relevant to optimally evaluate the risk of subsequent structural deterioration.

Dietary Sodium Increases The Risk For Rheumatoid Arthritis Among Smokers – Results From a Nested Case-Control Study. Björn Sundström[1], Ingegerd Johansson[2] and Solbritt Rantapää Dahlqvist[3]. [1]Umeå University, Umeå, Sweden, [2]Umeå Universitet, Umeå, Sweden, [3]Umeå University Hospital, Umeå, Sweden.

Background/Purpose: Recent studies using animal models and human cells *ex vivo* have indicated that sodium chloride may affect the immune system by the inducting of pathogenic Th17 cells mediated through a salt–sensing kinase (SGK1) leading to autoimmune disease. Since Th17 cells may play a role in the early stages of disease development in rheumatoid arthritis (RA), the dietary intake of sodium is of interest to analyse as a risk factor for the development of RA.

Methods: A nested case–control study was performed using the population based prospective data from the Västerbotten Intervention Programme collected between 1991 and 2011. The study included 386 individuals who later developed RA according to the 1987 ACR criteria. These 386 individuals (271 women, 115 men) had stated their dietary habits in a food frequency questionnaire (FFQ) as part of the community intervention programme before the onset of symptoms of RA (pre–symptomatic individuals). The pre-symptomatic individuals were compared using conditional logistic regression analyses with 1886 controls – matched for age, sex, time point of examination and version of the FFQ – drawn from the same database.

Results: Among current smokers with higher sodium consumption an increased odds ratio (OR) for developing RA was observed (OR) 2.26 (95% CI 1.06–4.81). Restriction of analyses to current smokers examined within the tertile closest to the onset of symptoms, the OR increased to 7.82 (95% CI 1.48–41.3). These associations were not found among non-smokers. Among current smokers with the lowest consumption of sodium, no significantly increased risk for developing RA could be identified. An interaction between high sodium intake and being current smoker was found.

Conclusion: Higher sodium consumption among smokers yielded an increased OR for development of RA. An interaction between smoking and sodium was found. These results provide new insights into the pathogenesis of RA. Furthermore, since sodium intake is related to the consumption of foods that are suggested to have an impact on health, *i.e.* meat, fruit, and vegetables, these results may have implications for studies of the effect of diet in RA, as well as in other diseases.

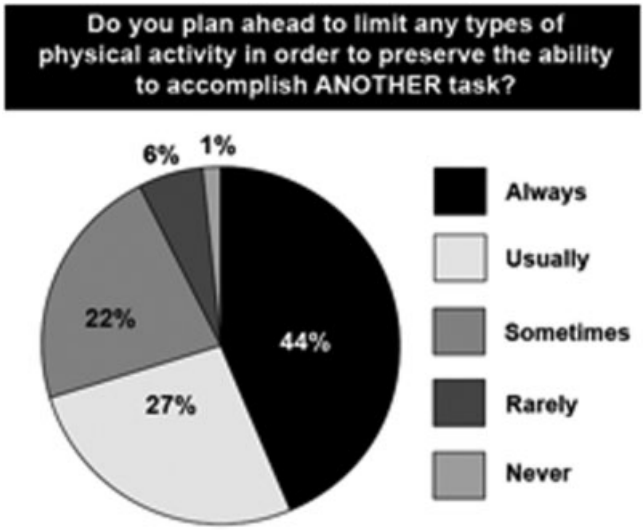
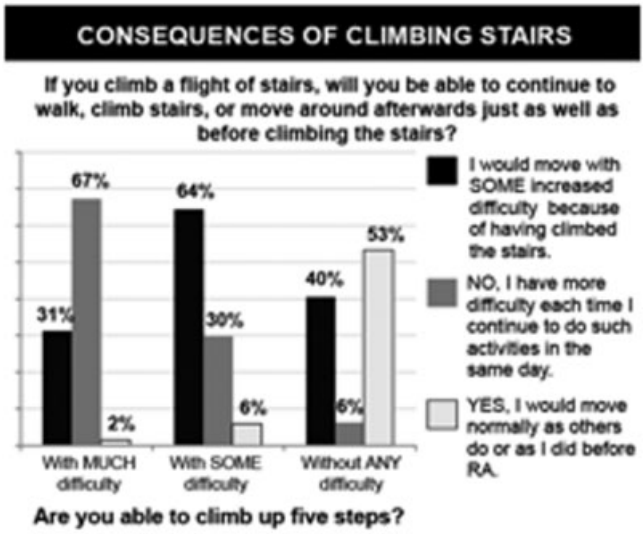
Patient Survey Regarding Utility Of The Health Assessment Questionnaire Reveals An Unrecognized Aspect Of Disease Activity In Rheumatoid Arthritis: Consequences Of Physical Activity. Kelly O'Neill Young[1], Dana M. Symons[1], Andrew T. Lumpe[2] and Cynthia S. Crowson[3]. [1]Rheumatoid Patient Foundation, Cocoa, FL, [2]Seattle Pacific University, Seattle, WA, [3]Mayo Clinic, Rochester, MN.

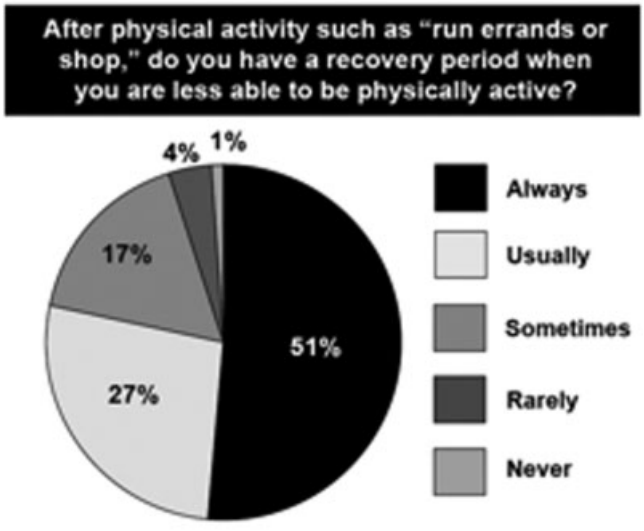
Background/Purpose: The Health Assessment Questionnaire (HAQ) has been used to assess disability in people with rheumatoid arthritis (RA) for over 30 years. However, the HAQ may not measure essential aspects of disease impact on ability to perform tasks because it does not consider real world context or consequences of performing particular tasks. The purpose of this study was to examine whether typical HAQ questions may miss fundamental information about functional status.

Methods: A web-based questionnaire was presented over 11 days in 2012 on a secure survey system preventing multiple entries. The questionnaire included 8 questions about consequences of performing certain physical tasks and whether a recovery period followed, and some questions directly from the HAQ. Analysis methods included reporting percentages, Pearson correlations and two-sample tests.

Results: The questionnaire was completed by 2,179 patients with self-reported RA (1997 women and 182 men; 72% seropositive) and a wide range of disease duration (< 2 years: 26%, 2–5 years: 29%, 5–10 years: 18% and >10 years: 26%). Of these, 71% reported often (44% "always" and 27% "usually") planning ahead to limit physical activities to preserve the ability to accomplish another task. Also 78% reported often (51% "always" and 27% "usually") having a recovery period when they are less able to be physically active after physical activity. The majority reported being unable to do chores such as vacuuming or yard work on the same day as running errands or shopping (24% "never", 33% "rarely", 28% "sometimes", 9% "usually" and 6% "always"). Comparing men and women, there were no significant differences in the responses to the consequence questions ($p=0.3$), but for the HAQ items men had significantly higher disease activity ($p<0.001$). Conversely, seropositive patients had higher levels of activity on the consequence questions than seronegative patients ($p=0.027$), but no differences in the HAQ items ($p=0.5$). The questions regarding consequences of physical activities for patients with RA were only moderately correlated with standard HAQ questions regarding shampooing and step climbing (correlation coefficients: 0.3–0.4; $p<0.01$), indicating these questions may be measuring similar but different aspects of RA disease activity than the HAQ.







Conclusion: Within the context of real-life, patients have lower functional capacity after performing tasks described in the HAQ, and may not be able to repeat such tasks with the same level of difficulty. Patients also modify tasks, which may not be detected by HAQ responses. Further investigation is needed to develop ways patient outcome measures can more accurately assess RA disease activity.

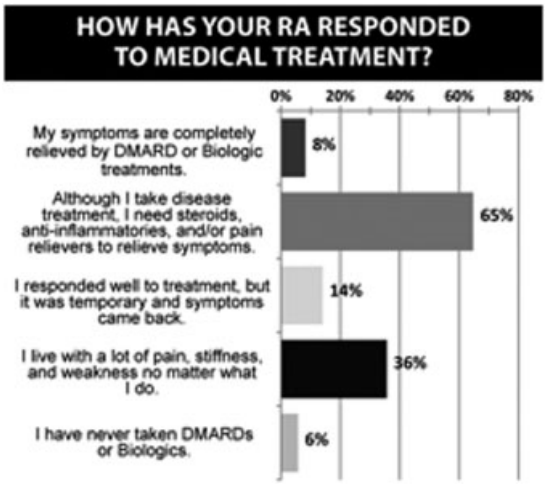
Patient Survey Challenges Conventional Notions Regarding Symptoms and Experiences Of People Living With Rheumatoid Arthritis.

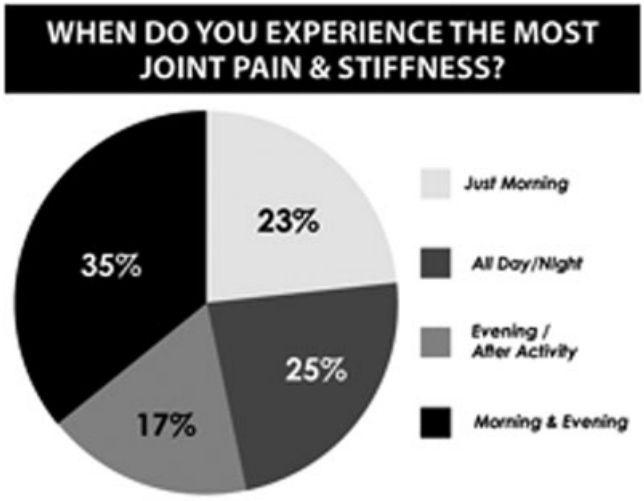
Kelly O'Neill Young[1], Cynthia S. Crowson[2] and Dana M. Symons[1]. [1]Rheumatoid Patient Foundation, Cocoa, FL, [2]Mayo Clinic, Rochester, MN.

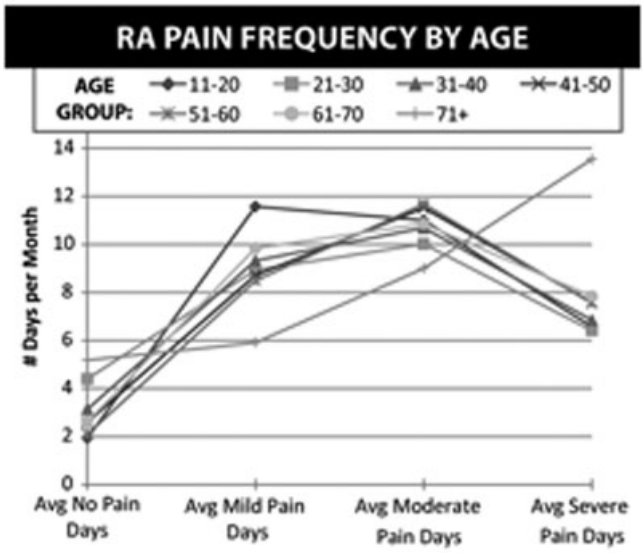
Background/Purpose: While rheumatoid arthritis (RA) has been studied for decades, many aspects of the disease are not well understood. Like systemic lupus erythematosus, RA manifests with a spectrum of symptoms that vary between patients and may not be accurately reflected in current literature. The goal of this study was to obtain greater understanding of the nature of RA as experienced by patients.

Methods: A 29-item web-based questionnaire was conducted in 2011 by a secure survey system preventing multiple entries. The questionnaire included questions about RA symptoms and treatments. Percentages and averages were used to summarize the data. 320 patients responded to an online poll with a follow-up question on morning stiffness.

Results: The questionnaire was completed by 1,465 self-reported RA patients (93% women and 7% men); 69% were seropositive (31% were seronegative or were unknown). Time since RA diagnosis varied with a mean of 6.6 years, 25% of respondents diagnosed within the past year, and 52% reported having RA symptoms for longer than a year prior to diagnosis. Low-grade fevers were common (80% reported experiencing sometimes) and most (99%) reported sometimes experiencing fatigue. On average, respondents experienced only 2 pain-free days per month with 68% having zero pain-free days in an average month. Pain levels were not affected by length of time since diagnosis and were similar across age groups, except for higher pain levels reported by those ≥ 71 years. Physical activity increased pain for 67%, and decreased pain for 18%. The top 3 factors cited as reducing pain were medications, rest and heat. Medications were reported to reduce pain by 80% of respondents, the majority stating that added medications (i.e., steroids, anti-inflammatories and/or pain relievers) were needed beyond disease treatments to address residual RA symptoms. Symptoms were completely controlled by treatments in only 8% of patients with 36% stating they continue to have a lot of symptoms "no matter what." While 23% of respondents reported they experience the most joint pain and stiffness in the morning, 25% have joint pain and stiffness all day and night; 52% experience some or most pain and stiffness in the evening or after activity. One-third said they always (12%) or usually (21%) have RA symptoms that their rheumatologists "do not believe or understand." 75% of respondents reported experiencing either joint damage without obvious swelling or having obvious joint swelling with no resulting damage, indicating the two are frequently unassociated.







Conclusion: The data in this survey indicate patient experiences and symptoms do not always reflect what is traditionally presented in the literature concerning RA pain, morning stiffness, the relationship between swelling and damage, and what worsens or improves symptoms. Additional research should seek a broader understanding of the disease experience of RA.

Assessment Of The Diagnostic Accuracy Of Different Strategies For Health Fair Case-Finding For Undiagnosed Inflammatory Arthritis. Kaylynn Aiona[1], Christopher C. Striebich[2], M. Kristen Demoruelle[3], Julia J. Rhiannon[3], Stuart M. Weisman[4], Marie L. Feser[4], Lezlie A. Derber[4], James H. Goddard[5], Stacey Brake[5], Jill Lysengen[6], Laura Rosseisen[6], John E. Hokanson[1], Anna E. Baron[1], Jill M. Norris[1], V. Michael Holers[3] and Kevin D. Deane[3]. [1]Colorado School of Public Health, Aurora, CO, [2]University of Colorado Denver, Aurora, CO, [3]University of Colorado School of Medicine, Aurora, CO, [4]University of Colorado School of Medicine, Division of Rheumatology, Aurora, CO, [5]9Health Fair, Denver, CO, [6]Arthritis Foundation, Great West Region, Denver Office, Denver, CO.

Background/Purpose: Early treatment of inflammatory arthritis (IA), and especially rheumatoid arthritis (RA), leads to improved outcomes, although diagnostic delays may impede timely treatment. We hypothesized that case finding in a community based health fair may improve the timing of diagnosis and treatment of IA. However, the diagnostic accuracy of this approach in a health fair where IA is likely rare is largely unknown. Therefore, we developed and tested the diagnostic accuracy of a case-finding strategy for IA in a Colorado-based health fair.

Methods: Volunteers were evaluated between 2009–2012 at 18 health fair sites using a self-reported joint symptom questionnaire and CCP3 (INOVA; ≥20 units positive) and RF (Roche RFII; >14 units positive) testing. IA was defined as synovitis identified by a trained clinician on examination of the wrists, elbows, and PIP and MCP joints performed at the same time as the questionnaire and blood testing.

Results: 3260 volunteers completed a questionnaire, joint examination and blood testing; 164 (5%) were identified with active, previously undiagnosed IA, of whom 33/164 (20%) were classified as RA by 2010 ACR/EULAR criteria. After modifications of an initial questionnaire to improve its ease of use and sensitivity for IA, the optimal prediction model for IA (multiple regression; bootstrap validated AUC of 0.73) included 4 items that each contributed similarly to the model: CCP positivity and self-reported: a) morning stiffness ≥1 hour, b) nodules, and c) joint pain, stiffness or swelling present the day of questionnaire completion. The maximal sensitivity (SENS) for IA was with ≥1 item positive (96%; corresponding specificity (SPEC) of 24%); ≥2 positive items resulted in the highest combination of SENS and SPEC (85% and 52%, respectively). In 2012 we piloted a questionnaire with a figure for subjects to identify symptom location, and symptoms in PIPs and MCPs were 93% SENS and 65% SPEC for IA, although there were too few cases of IA (N=15 out of 338 subjects) to evaluate adequately the diagnostic accuracy of additional factors. CCP and/or RF were positive in 279/3260 (9%) of subjects, and both autoantibodies (Abs) were independently significantly associated with IA ($p<0.01$ and 0.03, respectively). In evaluation of the diagnostic accuracy of Abs alone for IA, CCP and/or RF positivity was 11% SENS and 92% SPEC for IA, reflecting that most IA was seronegative. Additionally, CCP and RF levels >3 times normal were each highly specific for IA (CCP: SENS 5%, SPEC 99%; RF: SENS 5%, SPEC 99%).

Conclusion: Assessing self-reported symptoms and Abs in a health fair may identify previously undiagnosed IA/RA. As such, these items may be used initially independently of a clinician thus broadening the applicability of this approach to settings where trained joint examiners are absent. Further testing is necessary to validate these findings and to determine whether case-finding accuracy may be improved by ascertaining specific locations of joint symptoms. Additionally, determining final formal diagnoses, timing of treatment for IA, and post-health fair costs (including costs of evaluating false-positive results) will help determine the overall impact of this approach in arthritis care.

Responsiveness Of The Outcomes Measures In Rheumatology Clinical Trials Initiative's Preliminary Flare Questions To Detect Flares Within Patients In The Canadian Early Arthritis Cohort. Vivian P. Bykerk[1], Karen Visser[2], Ernest Choy[3], Clifton O. Bingham III[4], Daming Lin[1], Juan Xiong[1], Gilles Boire[5], Boulos Haraoui[6], Carol A. Hitchon[7], Janet E. Pope[8], J. Carter Thorne[9], Diane Tin[9], Edward C. Keystone[1], Susan J. Bartlett[10], - CATCH Investigators[11] and - OMERACT Flare Working Group[12]. [1]Mount Sinai Hospital, University of Toronto, Toronto, ON, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Cardiff University, Institute of Infection and Immunity, Cardiff, United Kingdom, [4]Johns Hopkins University, Baltimore, MD, [5]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [6]Institut de Rhumatologie de Montréal, Montreal, QC, [7]University of Manitoba, Winnipeg, MB, [8]St Joseph Health Care, London, ON, [9]Southlake Regional Health Centre, Newmarket, ON, [10]McGill University, Montreal, QC, [11]Canadian Collaboration, Toronto, ON, [12]International Collaboration, Baltimore, MD.

Background/Purpose: OMERACT (OM) recently developed preliminary flare questions (PFQs) that capture domains important to patients (pts) to identify a flare of RA[1]. Whether these change in pts who flare is unknown.

Objectives: To study responsiveness to change of the PFQs' 9 domains within early RA (ERA) pts who have a flare.

Methods: Paired data from CATCH (Canadian early arthritis cohort) pts who prospectively answered the PFQs twice in 3 months between 12/2011-5/2013 were used. The PFQs comprise 7 pt reported outcomes (PROs) assessing pt global, pain, physical function, stiffness, fatigue, coping, and participation as questions scored from 0–10 (best-worst) and pt reported tender and swollen joint counts (PtTJC40, PtSJC40). The median change (IQR) and effect size (ES) for each domain was compared in pts who flared based on a worsening of DAS28 of 1.2 (or 0.6 if DAS28> 3.2)[2] (DASdef) or by answering "Are you having a flare at this time?" with a flare defined as changing from no to yes (Fdef). Using the last pairs of 3-month interval PFQs, changes in PROs were analyzed by the Wilcoxon signed rank test. Responsiveness to change in each of the PFQs for flare vs. no-flare was assessed by non-parametric effect sizes (ES) calculated for both definitions.

Results: Of 115 eligible pts 79% were female, 85% Caucasian, 90% met ACR/EULAR 2010 criteria, 17% smoked, 24% had erosions, 69/73% were ACPA/RF+ve. Pts had a mean (SD) age of 55 (15) years, symptom duration 5.4 (3.0) months; Pts' initial DAS28 was 3.03 (1.34), HAQ-DI 0.52 (0.55); 46%/15% were in DAS28 remission/low disease activity. 23% reported a flare with a mean (SD) intensity of 6.3 (2.4) and duration ≥ 8 days in 59%. Median (IQR) increases in DAS28 using DASdef and Fdef was 1.8(1.–1.2) and 0.6(.4-.35). Changes in PtGlobal, pain, function, fatigue, stiffness, coping, PtTJC40 and PtSJC40 all changed significantly for flare vs. non-flare pts (Table). Responsiveness to change differed according to flare definitions (Figure).

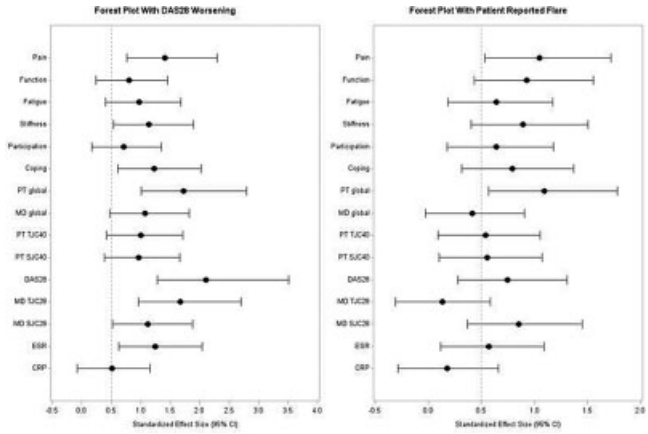

Figure. Effect Size (adjusted 95% CI) for each domain in the PFQs according to two definitions of RA flare.

Table. Responsiveness of OMERACT PFQ Domains and Physician/Lab based variables reported as median change (IQR) and effect size (p-value) in flare and non-flare groups using 2 flare definitions.

	DAS definition (increase of 1.2 or >.6 if 3.2)			Patient Flare definition (No to Yes)		
Variables	Flare* N = 16	Non-flare* N = 99	Effect Size** (p-value)***	Flare* N = 26	Non-flare* N = 89	Effect Size** (p-value)***
Pain	2 (2.5)	0 (2)	1.41 (<0.0001)	2 (2)	0 (2)	1.05 (<0.0001)
Function	1.5 (3.5)	0 (2)	0.8 (0.0043)	1.5 (3)	0 (1)	0.93 (0.0001)
Fatigue	1.5 (3.0)	0 (2)	0.97 (0.0006)	1 (3)	0 (2)	0.64 (0.0056)
Stiffness	3.0 (4.5)	0 (2)	1.14 (<0.0001)	1.5 (4)	0 (1)	0.89 (0.0002)
Participation	1.5 (4.5)	0 (1)	0.71 (0.0103)	0 (3)	0 (1)	0.64 (0.0057)
Coping	3.0 (3.0)	0 (1)	1.22 (<0.0001	1 (3)	0 (1)	0.79 (0.0008)
Pt global	3.0 (3.0)	0 (2)	1.72 (<0.0001)	1.5 (3)	0 (1)	1.09 (<0.0001)
PT TJC40	4.0 (12.0)	0 (5)	1 (0.0004)	1 (6)	0 (5)	0.54 (0.0179)
PT SJC40	2.0 (7.0)	0 (2)	0.96 (0.0007)	0 (4)	0 (2)	0.55 (0.0154)
Physician global	0.1 (2)	0 (1.5)	1.08 (0.0003)	0 (2)	0 (1.4)	0.41 (0.0677)
DAS28	1.5 (1)	−0.2 (1.3)	2.11 (<0.0001)	0.6 (1.6)	−0.2 (1.3)	0.75 (0.0014)
CRP	0.2 (3)	0 (2.9)	0.51 (0.0881)	0 (3.7)	0 (2.9)	0.18 (0.4544)
MD TJC28	3 (5.5)	0 (2)	1.67 (<0.0001)	0 (4)	0 (2)	0.13 (0.5563)
MD SJC28	0.5 (2)	0 (1)	1.12 (0.0001)	0 (1)	0 (1)	0.85 (0.0003)
ESR	6.5 (6.6)	−2 (7)	1.24 (<0.0001)	4 (8)	−2 (7)	0.57 (0.0129)

Responsiveness of PFQ Domains & Physician/Lab based variables (*Median change (IQR), **Effect Size (ES) (non-parametric), ***p-value using Wilcoxin Rank Sum Test. This analysis did not incorporate the self-management domain.

Conclusion: The OM PFQs are responsive to change with worsening of disease activity within ERA pts over time but the magnitude of change varies with flare definition. Studies are needed to understand the relative contributions of each domain to identify RA flares that necessitate treatment increases.

Does Socioeconomic Status Affect Outcomes In Early Rheumatoid Arthritis? Data From An Inception Cohort.

Grace Yang[1], Vivian P. Bykerk[2], J. Carter Thorne[3], Gilles Boire[4], Diane Tin[3], Carol A. Hitchon[5], Edward Keystone[6], Boulos Haraoui[7] and Janet E. Pope[8]. [1]Western University of Canada, London, ON, [2]Mount Sinai Hospital/University of Toronto, Toronto, ON, [3]Southlake Regional Health Centre, Newmarket, ON, [4]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [5]University of Manitoba, Winnipeg, MB, [6]University of Toronto, Toronto, ON, [7]Centre Hospitalier de l'Université de Montréal, Montreal, QC, [8]St Joseph Health Care, London, ON.

Background/Purpose: Assess the impact of socioeconomic status (SES) on outcomes in patients with early inflammatory arthritis using data from the Canadian Early Arthritis Cohort (CATCH) study.

Methods: 2023 patients were recruited into a prospective cohort study, and allocated to low- or high-SES groups based on education and income. Outcomes at baseline and 12 months analyzed against SES include the Disease Activity Score (DAS28), pain, patient global assessment scale, the Health Assessment Questionnaire Disability Index (HAQ), and the SF12-v2 Health Survey. Correlations and regression analyses were performed.

Results: Forty-four % had education of high school or less and 38% were in the lowest income group (<$50,000/year). The low-education group presented with higher DAS28 (p=0.045) at baseline; DAS28 and education were not correlated at 12 months. Low education was also associated with lower physical component score on SF12-v2 at baseline (p=0.018) and 12 months (p=0.024). Patients from the low-income group presented with higher HAQ (p=0.017), pain (p=0.035), patient global assessment (p=0.004), and Simplified Disease Activity Index (SDAI) (p=0.022). Comparing baseline low to high income groups was associated with an odds ratio (OR) for above-median: HAQ 1.220 (95% CI 1.013–1.470), patient global assessment 1.284 (95% CI 1.067–1.546), and SDAI 1.240 (95% CI 1.018–1.509). The predictive value of low income for HAQ remained at 12 months, OR 1.304 (95% CI 1.018–1.669) but the other variables were non-significant.

Conclusion: Low SES is associated at baseline with higher disease activity, poorer physical function, more pain, higher patient global assessment, and higher HAQ. Physical function and HAQ remain worse at one-year follow-up. This could be due to an effect of SES on health related behaviors or confounding (such as older patients having lower SES and more comorbidities).

Midcarpal Joint Effusion Is As Common As Radiocarpal Joint Effusion In Swollen Wrists Of Patients With Rheumatoid Arthritis.

Jae Ho Lee[1], Young Sun Suh[1], Jung Hee Koh[1], Seung Min Jung[1], Jennifer Lee[1], Ji Yeon Lee[2], Soo Young Lee[3], Seung-Ki Kwok[1], Ji Hyeon Ju[1], Kyung-Su Park[1], Dae Chul Jeong[1] and Sung Hwan Park[1]. [1]The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, South Korea, [2]The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, South Korea, [3]The Catholic University of Korea, Incheon St. Mary's Hospital, Incheon, South Korea.

Background/Purpose: Wrist joint is most commonly involved in rheumatoid arthritis (RA) and consists of multiple compartments; radiocarpal, midcarpal, and carpometacarpal joints. Intraarticular corticosteroid injection is usually done into radiocarpal joint for wrist joint swelling. However, it is hard to expect that drug injected into the radiocarpal joint spread to other compartments of wrist joint. To identify the distribution of joint effusions in swollen wrist joints of patients with RA and examine the effect of intraarticular corticosteroid injection into multiple compartments of wrist joints.

Methods: In RA patients with wrist joint swelling, we examined the distribution of joint effusion (radiocarpal, midcarpal, and carpometacarpal joints and extensor digitorum tendons) using musculoskeletal ultrasound.

Results: Twenty-seven patients presented with wrist joint swelling including 3 patients with both wrists involved and total of 30 wrist joints were examined. Twenty patients were female (74%), mean age was 55.8 ± 11.8 years, and mean disease duration was 62.5 ± 61.22 months. Twenty-four patients (88.9%) were seropositive and 9 patients (33.3%) had been treated with anti-TNF agents. Radio-carpal joint effusion was present in all 30 swollen wrist joints. Of note, effusion was found in midcarpal joints of 28 swollen wrists (93.3%). Among midcarpal joints, lunate-capitate joint was most commonly involved (n=28), followed by lunate-hamate joint (n=26), scaphoid-trapezoid joint (n=25), and triquetrum-hamate joint (n=25). In 15 wrists, effusion was also found in carpometacarpal joints (CMC); 4th CMC joint (n=10), 5th CMC joint (n=9), 3rd CMC joint (n=6), and 2nd CMC joint (n=2). Extensor digitorum tendons were involved in 3 wrists. We injected corticosteroid into both radiocarpal and midcarpal joints in 7 wrists and 6 of them (85.7%) showed marked improvement in pain and swelling at the next visit.

Conclusion: Midcarpal joint effusion is as common as radiocarpal joint effusion in swollen wrists of patients with RA. This suggests that, in patients with wrist joint swelling, not only radicarpal joint but also midcarpal joint should be considered for intraarticular corticosteroid injection.

Ordering Of Serologic Markers Of Rheumatoid Arthritis Among Primary Care and Subspecialty Providers: Under-Utilization Of Anti-Citrullinated Peptide Antibody Tests By Non-Rheumatologists. Emily H. Glynn[1], Mark H. Wener[1] and Michael Astion[2]. [1]University of Washington, Seattle, WA, [2]Seattle Children's Hospital, Seattle, WA.

Background/Purpose: Anti-citrullinated peptide antibodies (ACPA) are more specific and have a superior positive predictive value for diagnosis of rheumatoid arthritis (RA) compared to RF. The American College of Rheumatology revised the RA classification criteria to include ACPA in addition to RF in 2010 (Arthr Rheum. 2010; 62:2569–2581). This study's aim is to characterize utilization of RF and ACPA among primary care, non-rheumatology subspecialty, and rheumatology providers 2 years before and 2 years after the new criteria were published. The expectation is that the 2 tests will be ordered in a 1:1 ratio after the new criteria, whereas RF would be ordered more than ACPA before 2010.

Methods: The study was performed at an academic medical center in the western United States. All orders for RF and ACPA (ordered as anti-CCP) placed in 2008 and 2012 were retrieved and the medical records from outpatient encounters were reviewed. Orders meeting the following criteria were included: (1) RA was in the differential diagnosis, (2) patient endorsed musculoskeletal complaints, and/or (3) the provider noted tests were ordered for an "inflammatory," "rheumatologic," or "autoimmune" indication. Orders placed on patients with a previous history of RA or who were being evaluated only for extra-articular manifestations of RA or cryoglobulinemia were excluded. Included orders were sorted by provider type (primary care, non-rheumatology subspecialty, rheumatology), and the ratio of RF to anti-CCP orders for each type was calculated.

Results: Out of 765 RF & antiCCP orders reviewed, 463 orders (238 from 2008 and 225 from 2012) met the inclusion criteria. Of these, 297 (64%) were ordered by primary care providers, 80 (17%) by non-rheumatology subspecialty providers, and 86 (17%) by rheumatology providers. The RF/anti-CCP ratios by provider type comparing 2008 to 2012 were as follows: primary care providers 2.7 vs. 3.1, non-rheumatology subspecialty providers 12.5 vs. 3.5, and rheumatologists 0.85 vs. 0.96. Isolated RF orders represented the majority of orders placed by non-rheumatologists (primary care and subspecialty providers) comprising 72% and 70% of total orders placed in 2008 and 2012, respectively. Among rheumatologists, RF in isolation represented only 4% and 11% of orders, while the combination of RF and anti-CCP comprised 66% and 88% of orders placed in 2008 and 2012, respectively.

Conclusion: Our results indicate that 2 years after revision of the RA classification criteria, anti-CCP remains a vastly underutilized test among non-rheumatology providers considering the diagnosis of RA.

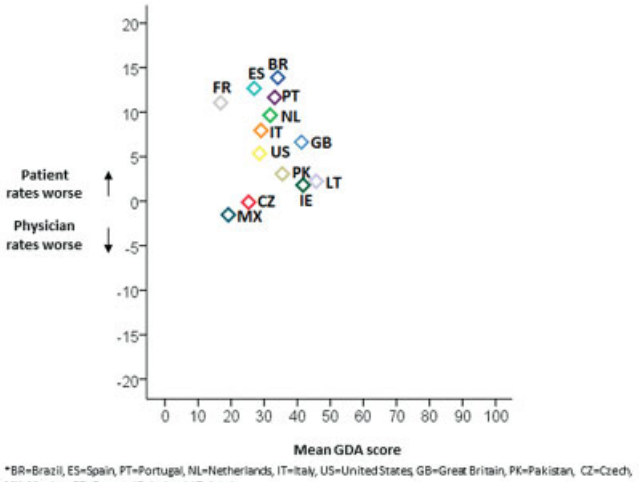
Assessment Of Global Disease Activity In Rheumatoid Arthritis By Patients and Physicians: Cultural Differences Among Countries In The Meteor Database. E. Gvozdenovic[1], R. Wolterbeek[1], C.F. Allaart[1], Claiton Brenol[2], Arvind Chopra[3], Maxime Dougados[4], Paul Emery[5], D. van der Heijde[1], T.W.J. Huizinga[1], Jonathan Kay[6], Emilio Martín Mola[7], Robert J. Moots[8], José A. P. Da Silva[9], Josef S. Smolen[10], Douglas J. Veale[11] and R. Landewe[12]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Universidade Federal do Rio Grande do Sul, Porto Alegre RS, Brazil, [3]Center for Rheumatic Diseases, Pune, India, [4]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France, [5]Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [6]UMass Memorial Medical Center and University of Massachusetts Medical School, Worcester, MA, [7]Rheumatology. La Paz Hospital. IdiPaz, Madrid, Spain, [8]University of Liverpool, Liverpool, United Kingdom, [9]Centro Hospitalar e Universitário de Coimbra – Hospitais da Universidade de Coimbra, E.P.E., Coimbra, Portugal, [10]Medical University of Vienna, Vienna, Austria, [11]St. Vincent's University Hospital, Dublin 4, Ireland, [12]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands.

Background/Purpose: Dissonant perceptions of disease activity between rheumatoid arthritis (RA) patients and their rheumatologists may influence treatment decisions. The discordance between patient's and physician's global disease activity assessment (PtGDA and PhGDA, respectively) may vary by country because of cultural differences. Our aim is to compare the differences between PtGDA and PhGDA among 13 countries in the METEOR database.

Methods: The Measurement of efficacy of Treatment in the Era of Rheumatology (METEOR) database, a worldwide online tool for disease monitoring in RA, was used to anonymously select 14,020 patients during the period between 2008 and 2012. PtGDA and PhGDA were scored independently on a 100 mm visual analogue scale (VAS) with 0 and 100 as extremes. Linear Mixed Models (LMM) were used to estimate the mean differences between PtGDA and PhGDA score in13 countries (Brazil, Czech Republic, Spain, France, United Kingdom, Ireland, Italy, Latvia, Mexico, Pakistan, Portugal, United States, and the Netherlands), adjusted for DAS. Generalized Estimated Equation (GEE) was used to model differences (>20mm) between PtGDA and PhGDA score as the outcome and countries as determinants, corrected for DAS.

Results: Mean difference between PtGDA and PhGDA score differs by country, varying from −2 mm (physician scores higher) in Mexico to 14 mm (patient scores higher) in Brazil (Figure 1), independent of DAS. GEE indicated that 'country' was a significant determinant of the difference between PtGDA and PhGDA score, independent of differences in DAS. With the Netherlands as a reference, PtGDA and PhGDA scores differ significantly within the same patient in almost all countries (Brazil, Czech Republic, Great Britain, Ireland, Italy, Latvia, Mexico, Pakistan, Portugal and United States).



*BR=Brazil, ES=Spain, PT=Portugal, NL=Netherlands, IT=Italy, US=United States, GB=Great Britain, PK=Pakistan, CZ=Czech, MX=Mexico, FR=France, IE=Ireland, LT=Latvia.

Conclusion: We find differences between patients' and physicians' assessment of global disease activity, the magnitude of which varies depending upon the country in which the patient and the physician both reside. Cultural influences must be taken into account when interpreting discordances between the patient's and the physician's assessment of global disease activity

in RA. Although the magnitude differs across countries, patients nearly always assess global disease activity to be worse than do their physicians.

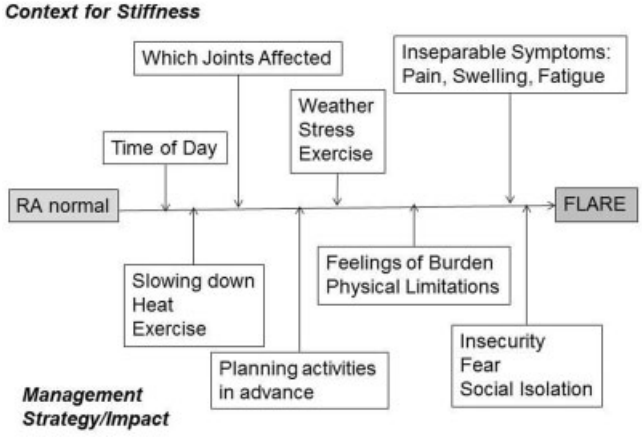
2280

Stiffness From The Perspective Of People Living With Rheumatoid Arthritis. Ana-Maria Orbai[1], Katherine Clegg-Smith[2], Susan J. Bartlett[3], Elaine De Leon[4], Michelle Jones[1] and Clifton O. Bingham III[1]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University School of Public Health, Baltimore, MD, [3]McGill University, Montreal, QC, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.

Background/Purpose: Stiffness was included in the 1961 and 1987 Rheumatoid Arthritis (RA) classification criteria and continues to be commonly queried in clinical care. Its relative contribution to disease activity levels is controversial possibly due to limited knowledge of how people with RA experience stiffness and its impact on daily life.

Methods: We held focus groups (FG) with people with RA recruited from an academic clinic and private practice setting to explore stiffness experiences. Inductive thematic analysis was conducted by a team of clinical and behavioral scientists to identify themes.

Results: FGs (N=20 people) were held 2 – 11/2012. Most (75%) were female, mean (SD) age 57 (13) yrs and RA duration 16 (8) yrs. Mean patient global scores were 44 (27), pain (100 mm VAS) 47 (30) and mHAQ 0.48 (0.55). Five themes were identified: 1. People with RA outlined a hierarchical and relational conceptualization of symptoms (stiffness, pain, swelling, fatigue) 2. Stiffness was associated with management strategies and symptom alleviation 3. Stiffness was described in temporal terms 4. Stiffness had individual meanings 5. Stiffness had impact on physical, emotional and social well-being. Stiffness, pain and swelling were difficult to distinguish between as they co-occurred or as pain increased. Strategies to alleviate or reduce stiffness were common (warmth, slow down, stretch, swim). Stiffness was primarily characterized by onset (morning, evening) and key exacerbating factors (weather, stress, exercise). Participants related their current level of stiffness to the usual for them since developing RA and independently introduced "RA normal" as their reference state. The spectrum of stiffness intensity spanned from "RA normal" to flare ("I went into total lock up"). Stiffness impacted physical, emotional, and social health and was poorly understood by people without RA in comparison to pain. Unexpected or overwhelming stiffness caused feelings of anxiety, fear and vulnerability.



Conclusion: Stiffness is an integral part of RA and may be more heterogeneous in presentation than previously recognized. People living with RA report stiffness can have a significant impact on daily life, often underappreciated by family and others. The current model of morning stiffness duration, used in clinical practice and clinical trials, poorly reflects the experiential descriptions of stiffness which encompass temporal patterns, location, intensity, and impact on life activities. Individuals' use of "RA normal" as the new reference point for change in disease states might affect how insightful our clinical questions are, when we probe disease activity and impact on health and health related quality of life. The diversity of stiffness experiences, adaptations, and life impact suggest that a more individualized assessment may be needed to effectively monitor stiffness and ultimately enhance clinical care.

An Analysis Of Highly Discordant Erythrocyte Sedimentation and C Reactive Protein Levels In Rheumatoid Arthritis. Micha Abeles[1], Manuel Gomez-Ramirez[2] and Aryeh M. Abeles[1]. [1]University of Connecticut Health Center, Farmington, CT, [2]Johns Hopkins University, Baltimore, MD.

Background/Purpose: Discordance between the erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) exists in a significant minority of rheumatoid arthritis (RA) patients. Interpretation of studies exploring the phenomenon is problematic for a number of reasons including: the dichotomization of continuous variables, failure to consider potential influence of none acute phase factors and common co-morbid conditions. To assess discordant values between the ESR and CRP we did a prospective case control study by establishing deciles of CRP and ESR values and evaluating the highest decile (i.e. the one having the most discrepant values).

Methods: Data on individual RA patients consecutively seen over a 6 month period were prospectively obtained. Serologic data included complete blood counts, albumin, liver and renal function, and serum protein electrophoresis. All co-morbid conditions and medications used were noted. Weight, sex, age, and length of time from diagnosis were recorded. The clinical disease activity index (CDAI) was used as a measure of disease activity. We established deciles and categorized participants into separate groups based on their ESR/CRP ratios (stratifying by ESR; age and gender were accounted for). The discordant group comprised participants with the top 10% elevated ESR and normal CRP values and vice versa. Each patient was matched to a non-discordant patient seen most closely to that visit and matched for age and sex (and when possible, weight). Data was consequently de-identified and evaluated. We computed between-subject (discordant vs. controls) univariate analyses of variance (ANOVA) on the above variables using age as a covariate.

Results: 251 individual RA patients were seen in the 6 month period. Of 26 patients meeting criteria 22 were in the high ESR normal CRP category. We elected not to include participants with high CRP normal ESR values because of low sample number (N = 4). Age, sex, ethnicity and weight were similar between groups, The most common co-morbid conditions included hypertension, gastric reflux disease and hyperlipidemia equally seen in each group. The only significant difference our data revealed was of hematocrit ($p < 0.01$), with the discordant group having significant lower mean values as compared to controls (36.30 vs. 40.15).The ANOVA failed to reveal an effect on CDAI ($p > 0.05$)

Conclusion: No previous study has looked at extreme discordance between CRP and ESR values in RA. We prospectively evaluated RA patients and compared those in the highest decile of discordance with matched controls (accounting for sex, weight, and ethnicity), analyzing multiple variables and found that aside from hematocrit values, there was no difference between groups.

Performance Of The 2010 ACR/EULAR Classification Criteria For Rheumatoid Arthritis In a Group Of Elderly Onset Patients. Pierluigi Macchioni[1], Giovanni Barausse[2], Luigi Boiardi[1], Giulia Pazzola[1], Roberto Bortolotti[2], Giovanna Restuccia[1], Maria Grazia Catanoso[1], Giuseppe Paolazzi[3] and Carlo Salvarani[4]. [1]Arcispedale S Maria Nuova, IRCCS, Reggio Emilia, Italy, [2]Ospedale di Trento, Trento, Italy, [3]Ospedale Santa Chiara, Trento, Italy, [4]Arcispedale S Maria Nuova-IRCCS, Reggio Emilia, Italy.

Background/Purpose: To evaluate the diagnostic ability of the 2010 ACR/EULAR classification criteria for Rheumatoid arthritis (RA) in a consecutive series of elderly onset (> 50y) RA (EORA) in comparison with a group of new onset polymyalgia rheumatica (PMR) patients.

Methods: All patients with early arthritis seen at our two centres are followed according to a standardized protocol which include clinical examination (including 66 joint count), determination of laboratory parameters, QOL questionnaire, X-ray examination of hands and feet. Consecutive patients seen in our rheumatological centres with recent onset arthritis and

followed for at least 12 months were included prospectively during a 5 year period. Patients entered the study if diagnosis of RA or PMR were confirmed at 12 month follow-up period according to rheumatologist opinion (PM, GB). Diagnostic performance of ACR/EULAR 2010 classification criteria were evaluated and compared in the two groups of patients

Results: 144 new EORA and 137 new onset PMR patients entered the study. Table 1 compare demographic, clinical and laboratory data between the two populations.

Table 1. Demographic, clinical and laboratory characteristics of the patients at first examination.

	EORA	PMR	p	Difference (95%CI)
Mean Age (y)	64.6+9.2	74.5+7.4	<0.001	9.4 (7.5–11.4)
Male/female	27/73	29/71	ns	
Mean Disease duration (Weeks)	13+12	13+19	ns	0.7 (−4.6–3.2)
ESR (mm/first hour)	41+26	60+24	<0.001	18 (12–24)
CRP (mg/dl)	2.5+3.2	5.1+4.3	<0.001	2.5 (1.6–3.4)
RF/ACPA +	49%	1%	<0.001	
Mean large joint involved	1.6+1.7	3.38+1	<0.001	1.7 (1.5–2)
Mean small Joint Involved	7.4+5.6	1+1	<0.001	6.5 (7.5–5.5)
Mean ACR/EULAR points	6.3+1.9	3.4+1	<0.001	3 (3.3–2.4)
ACR/EULAR positivity	66.2%	3.2%	<0.001	OR 48.9 (14–163)

Conclusion: In a group of new onset EORA patients ACR/EULAR 2010 RA classification criteria have 66.2% sensitivity. ACR/EULAR 2010 criteria have high specificity and could be used to exclude RA in a new onset PMR patients.

The Evolving Use Of Biologic Monotherapy In Rheumatoid Arthritis and Its Impact On Patient Outcomes. Laurent Chanroux, Katrina Johnson and Joan Casellas. The Research Partnership, London, United Kingdom.

Background/Purpose: The aim of our study is to understand whether the use of biologic monotherapy among rheumatoid arthritis (RA) patients is increasing and whether this has any impact on their potential outcomes when compared to combination therapy with traditional disease-modifying anti-rheumatic drugs (DMARDs).

Methods: We used data collected as part of an online treatment survey conducted among a panel of rheumatologists between May 2008 and December 2012 across the five largest EU countries (France, Germany, Italy, Spain and the UK). We selected a sub-sample of 43,193 patient records from this data set. Patient cases were selected if a patient was currently prescribed his or her first ever biologic. This limited any confounding effects due to patients' previous biologic experience. No other screening criteria or quotas were applied to the data to ensure a natural fall-out of monotherapy patients. Patient demographics and key indicators of current health and quality of life were analysed including: disease activity score (DAS), overall joint count, perceived disease severity at diagnosis and latest consultation (assessed by physician), ability to work and current co-morbidities.

Results: In Q4 2012, 24% of reported biologic patients were currently treated without the concomitant use of traditional DMARDs, a non-significant increase over the level observed in Q2 2008 (23%). The use of biologic monotherapy was most common for patients treated with tocilizumab (42%) and was most frequently seen among our Italian and UK patients (26%). Monotherapy patients were on average significantly older (> 60 years old) and were perceived to have milder disease at diagnosis when compared to patients simultaneously treated with biologics and DMARDs. In addition, monotherapy patients were significantly more likely to have inflammatory back pain, ankylosing spondylitis, congestive heart failure and wider cardiovascular disease, whereas fibromyalgia and dactylitis were more common in patients receiving combination therapy. There were no differences in patients' gender, time since diagnosis and ability to work or the number of DMARDs patients had tried prior to initiating their biologic. However, when adjusting for disease severity at diagnosis, we saw no difference in physicians' perceptions of the current disease severity of patients from both groups, although a significantly higher proportion of monotherapy patients had a DAS < 2.6 (51%) while a significantly greater proportion of combination therapy patients has a DAS > 5.1 (7%).

Conclusion: Our data show that the use of biologic monotherapy has remained steady over the last four years and has been concentrated primarily among tocilizumab patients. Biologic monotherapy appears to be reserved for older, potentially more fragile patients with milder disease whereas combination therapy may still be preferred for patients with more severe forms of RA. Moreover, use of biologic monotherapy does not seem to negatively impact on patient outcomes with a significantly higher proportion of these patients achieving disease remission.

How Well Do Generic Patient Reported Outcomes Measurement Information System Instruments Capture Health Status In Rheumatoid Arthritis? Susan J. Bartlett, Ana-Maria Orbai, Trisha Duncan and Clifton O. Bingham III. Johns Hopkins University, Baltimore, MD.

Background/Purpose: PROMIS offers precise, reliable generic measurement of physical, mental and social health across chronic conditions. However, little is known about the validity and performance of PROMIS instruments in rheumatoid arthritis (RA), where high levels of pain and fatigue and low physical function and mood are common.

Methods: Data are from the baseline visit of the first 125 RA patients enrolled in an ongoing study to evaluate systematically integrating patient reported outcomes (PROs) into arthritis care. Patients completed PROMIS computerized adaptive tests (CATs) assessing pain, fatigue, physical function, mood, sleep and social roles/activities using a tablet computer linked to Assessment Center in the waiting room immediately prior to the visit. Legacy measures (100 mm VAS for pain and fatigue, MHAQ) were also obtained as well as traditional clinical indicators of disease activity. PROMIS and legacy measures were compared using Spearman correlations and regression and across CDAI disease activity levels with ANOVA.

Results: Patients were mostly female (79%) and white (86%) with a mean (SD) age of 56 (13) and disease duration of 12 (9) yr; 10% were diagnosed <= 2 yr. PROMIS CATs included an average 63 (12) items requiring 12 (5–32) minutes to complete. PROMIS CATs for pain (intensity, impact), fatigue, physical function, anxiety, depression, anger, sleep (disturbance, impairment) and social roles/activities (participation, satisfaction) correlated highly with pain VAS (r's=.82-.83), fatigue VAS (r=.86) and mHAQ (r=-.74) (p's<.001). A dose-response relationship was evident in PROMIS measures across remission, low and moderate disease activity levels (except anger; see Table). Floor effects were common in legacy measures (16%, 11% and 43% for pain VAS, fatigue VAS and MHAQ, respectively) and were not common in PROMIS instruments.

Estimates of Impact and Mean Values across CDAI Disease Activity Levels on Legacy and PROMIS Measures in Rheumatoid Arthritis.

Variable	B	Effect Size (β/SE)	Remission N=33	Low N=50	Moderate N=23	High N=12
Pain 100 mm VAS	18.3	8.0	5.9 ± 7.8[a]	33.8 ± 25.2[b]	52.4 ± 28.2[c]	54.1 ± 26.0[c]
PROMIS Pain Intensity	4.6	6.6	38.0 ± 7.1[a]	46.0 ± 6.1[b]	48.1 ± 7.4[b,c]	51.7 ± 8.2[c]
PROMIS Pain Interference	5.6	7.0	45.9 ± 7.7[a]	55.4 ± 8.5[b]	58.2 ± 6.2[b,c]	62.1 ± 8.5[c]
Fatigue 100 mm VAS	18.4	7.1	12.7 ± 17.2[a]	45.3 ± 29.0[b,c]	57.5 ± 27.9[c*]	64.3 ± 21.7[c]
PROMIS Fatigue	5.7	6.7	46.1 ± 8.5[a]	55.6 ± 8.8[b]	59.5 ± 6.9[c*]	62.3 ± 9.4[c]
mHAQ	.19	5.1	0.1 ± 0.4[a]	0.3 ± 0.3[a]	0.5 ± 0.4[b]	0.7 ± 0.4[b]
PROMIS Physical Function[‡]	−5.6	−7.8	50.3 ± 8.7[a]	42.7 ± 7.1[b]	38.2 ± 5.7[c]	33.7 ± 5.6[d**]
PROMIS Anxiety	2.6	3.6	47.5 ± 7.6[a]	52.1 ± 8.9[b]	51.0 ± 8.0[a,b]	57.4 ± 8.3[c]
PROMIS Depression	3.0	3.5	46.4 ± 8.5[a]	49.8 ± 9.3[a]	50.9 ± 9.4[b*]	57.1 ± 8.6[c*]
PROMIS Anger	2.6	2.9	45.2 ± 7.9[a]	46.8 ± 9.7[a]	48.9 ± 10.9[a]	54.2 ± 8.8[b]
PROMIS Sleep Disturbance	3.2	3.6	46.6 + 9.1[a]	52.6 + 8.0[b]	54.3 + 10.2[b]	55.7 + 8.3[c]
PROMIS Sleep Impairment	3.8	4.2	46.3 + 9.3[a]	52.7 + 9.6[b]	53.7 + 9.1[b]	58.7 + 6.6[c]
PROMIS Social[†] - Participation	−4.7	−5.9	55.2 ± 9.5[a]	49.9 ± 8.2[b]	46.7 ± 6.1[b]	40.1 ± 6.4[c]
PROMIS Social[†] - Satisfaction	−5.5	−6.1	55.7 ± 9.6[a]	47.0 ± 9.6[b]	44.9 ± 6.6[b]	38.4 ± 7.1[c]

[†]Social Roles and Activities. Differing superscripts denote significantly different groups (p<.05). *p=.06; **p=.08

Conclusion: These data contribute preliminary evidence of convergent and known groups validity and demonstrate robust psychometric performance of PROMIS instruments to assess PROs in people receiving routine RA care. PROMIS CATs can be completed relatively quickly and appear to address some of the well-recognized limitations (non-linearity, floor effects) of existing legacy measures in RA.

Correlation Of Individual Health Assessment Questionnaire (HAQ) Questions With Outcome Measures In Rheumatoid Arthritis: Implications For Instrument Reduction. J. Carter Thorne[1], Majed M. Khraishi[2], Boulos Haraoui[3], Jude F. Rodrigues[4], Algis Jovaisas[5], Denis Choquette[3], Sanjay Dixit[6], Dalton E. Sholter[7], Philip Baer[8], Maqbool K. Sheriff[9], Emmanouil Rampakakis[10], John S. Sampalis[10], Francois Nantel[11], Allen J. Lehman[11], May Shawi[11] and Susan M. Otawa[11]. [1]Southlake Regional Health Centre, Newmarket, ON, [2]MD, Memorial University of Newfoundland, Nexus Clinical Research, St Johns, NF, [3]Institut de Rhumatologie de Montréal, Montreal, QC, [4]Rheumatology, Windsor, ON, [5]University of Ottawa, Ottawa, ON, [6]McMaster University, Burlington, ON, [7]Rheumatology Associates, Edmonton, AB, [8]Rheumatology, Scarborough, ON, [9]Nanaimo Regional General Hospital, Nanaimo, BC, [10]McGill University, Montreal, QC, [11]Janssen Canada Inc, Toronto, ON.

Background/Purpose: Despite the importance of the Health Assessment Questionnaire (HAQ) in assessing patient-reported functional status, it was originally developed primarily for research studies. As a result, HAQ has been critiqued for being time-consuming, not easily scored, and, thus, not contributing to decisions made in routine clinical care as well as for assessing general health and not specifically the clinical status of Rheumatoid Arthritis (RA).

The aim of this analysis is to describe the correlation of the individual HAQ questions with other outcome measures used in RA as well as to examine whether the instrument could be reduced to better reflect routine clinical practice.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with infliximab or golimumab as first biologics or after having been treated with a biologic for less than 6 months. In this analysis, data from RA patients who were treated with infliximab between January 2002 and June 2011 were used. Parameter correlation was described with the Pearson's correlation coefficient and the impact of each question on the use of aids/devices/help was assessed with logistic regression. Factor analysis was used to assess variability in HAQ score due to each of the individual questions.

Results: 877 RA patients who had 4,180 complete HAQ assessments were included in the analysis. Higher pain score, patient assessment of global disease activity (PtGA), 28-tender joint count (TJC-28) and, to a lesser extent, 28-swollen joint count (SJC-28) were associated with increased functional impairment. Correlation analysis showed that individual HAQ questions correlated at different extents with each outcome measure (SJC-28) (Table 1). Notably, Q5B showed the lowest correlation with patient outcome measures while the two questions related to "Rising" (Q2A, Q2B) showed the highest overall correlation.

Logistic regression showed that all individual questions were significantly associated with the use of aids/devices/help within their corresponding category with the exception of Q3B and Q8B. In factor analysis, "Dressing and Grooming" was found to account for 66.5% of the matrix variance (Q1A: 60.5%; Q1B: 6.0%) suggesting that the ability to dress/groom alone may be the main driver of the HAQ score.

Table 1. Correlation between individual HAQ Questions and Outcome Measures

HAQ Question	Pain	PtGA	TJC-28	SJC-28
Q1A: Dress alone	0.58	0.58	0.40	0.35
Q1B: Shampoo hair	0.48	0.48	0.36	0.29
Q2A: Stand up from chair	0.61	0.61	0.42	0.36
Q2B: Get in/out of bed	0.62	0.61	0.43	0.36
Q3A: Cut meat	0.50	0.50	0.37	0.31
Q3B: Lift a full cup/glass	0.49	0.48	0.35	0.33
Q3C: Open milk carton	0.52	0.53	0.40	0.35
Q4A: Walk outdoor on flat ground	0.56	0.55	0.36	0.31
Q4B: Climb up five steps	0.58	0.58	0.39	0.31
Q5A: Wash/dry body	0.55	0.54	0.40	0.33
Q5B: Take a tub bath	0.42	0.41	0.29	0.26
Q5C: Get on/off toilet	0.55	0.54	0.39	0.34
Q6A: Reach and get down object	0.53	0.52	0.38	0.32
Q6B: Pick clothing from floor	0.57	0.56	0.40	0.30
Q7A: Open car door	0.48	0.49	0.41	0.34
Q7B: Open jar	0.52	0.53	0.40	0.36
Q7C: Turn faucet on/off	0.47	0.48	0.40	0.35
Q8A: Run errands/shop	0.55	0.54	0.40	0.30
Q8B: Get in/out of car	0.60	0.59	0.43	0.36
Q8C: Do chores	0.52	0.51	0.37	0.29

* Weak: r < 0.30; Moderate: r = 0.30–0.39; Strong: 0.40–0.69; Very Strong: ≥0.70

Conclusion: Results of this analysis show that variability exists in the correlation of individual HAQ questions with patient-reported and clinical outcome measures. Pain and joint tenderness are significantly associated with the individual functions of the HAQ while the number of swollen joints appears to be of minor importance. Furthermore, the ability to dress/groom alone was the main driver of the variability in HAQ which may have implications from an occupational health perspective and in the design of self-report instruments assessing the (dis)ability to perform daily activities.

2286

Reliability and Smallest Detectable Difference Of The Patient Global Assessment, Pain and Fatigue In Rheumatoid Arthritis Patients. Paul Studenic[1], Josef S. Smolen[2] and Daniel Aletaha[1]. [1]Medical University Vienna, Vienna, Austria, [2]Medical University of Vienna, Vienna, Austria.

Background/Purpose: Patient reported outcomes (PRO) represent an important part of outcomes assessment in rheumatoid arthritis (RA) patients. The Patient Global Assessment (PGA) is an essential PRO; pain and fatigue can also be assessed by visual analogue scales. Since RA disease activity fluctuates, it is unclear how estimates of the smallest detectable difference (SDD) are influenced by the time elapsed between assessments, and if SDD differs in relation to disease activity. Thus we investigated if reliability estimates of PROs change when using different test-retest intervals, and if they can be better specified based on patients' disease activity.

Methods: Forty RA patients were asked to report their PGA, pain and fatigue daily over 28 days in this prospective observational study. We calculated variability of PROs comparing the initial measurement to ones performed 1–27 days thereafter. We calculated reliability using the intra-class correlation coefficient (ICC), which determines the amount of measurement variability attributable to true scores. The SDD was calculated as the standard deviation of the difference between two measurements multiplied by 1.95. We finally divided patients into tertiles by baseline simplified disease activity index (SDAI) and investigated the differences in SDD based on starting points.

Results: Data of forty patients (85% female, 60% rheumatoid factor positive, mean SDAI: 12.8±8.4, mean disease duration 11.3±8.3yrs) was used. Mean ICC between day 1 and each consecutive day was 0.63±0.13 for PGA, 0.56±0.14 for pain and 0.48±0.15 for fatigue. The mean SDDs of PGA, pain and fatigue were 26.5±5.7, 27.2±6.4 and 42.1±5.7mm, respectively (Figure). As expected, higher reliability (ICC) coincides with a smaller SDD, but no temporal trend was found for any PRO.

Ranges for the tertiles by baseline SDAI were 3.2–8.1 (mean=5.3), 8.3–16.8 (mean=12.5), and 17.4–37.7 (mean=23.9). For PGA, higher SDAI coincided with higher SDD ($p<0.001$), resulting in (mean, 95% confidence intervals) 18.2 (14.9–21.4), 27.14 (23.4–30.9), and 30.1 (26.1–34.1) mm, respectively. The same trend could be found for SDDs of pain ($p=0.002$): 22.5 (19.7–25.4), 28.1 (24.3–32.1), 29.9 (26.1–33.7). For SDDs of fatigue the trend was inverse, so that patients with higher SDAI had lower SDDs ($p<0.001$): 45.6 (39.5–51.7), 39.7 (34.8–44.5), 18.7 (16.6–20.8).

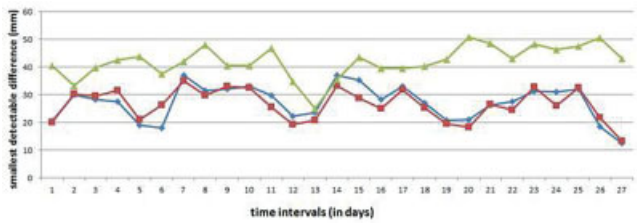

Figure. Smallest detectable differences (SDD) between day 1 and consecutive 27 days. Blue line: development of SDD for pain; the red line: for patient global assessment; the green line: for fatigue.

Conclusion: We demonstrated here, that reliability and SDDs of neither PGA, pain nor fatigue are dependent on the time between assessments. PGA showed the best reliability of all tested PROs. Cut-offs to identify true changes seem to be dependent on disease activity. Much lower SDDs of pain and PGA can be applied in patients with low disease activity.

What Is The Internal Consistency Of The Disease Activity Score (DAS)-28 In Rheumatoid Arthritis Patients Treated In a Real–World Setting? Andrew Chow[1], J. Carter Thorne[2], Regan Arendse[3], Dalton E. Sholter[4], Denis Choquette[5], Isabelle Fortin[6], Boulos Haraoui[5], Emmanouil Rampakakis[7], John S. Sampalis[7], Francois Nantel[8], Allen J. Lehman[8], May Shawi[8] and Susan M. Otawa[8]. [1]Credit Valley Rheumatology, Mississauga, ON, [2]Southlake Regional Health Centre, Newmarket, ON, [3]University of Saskatchewan, Saskatoon, SK, [4]Rheumatology Associates, Edmonton, AB, [5]Institut de Rhumatologie de Montréal, Montreal, QC, [6]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [7]McGill University, Montreal, QC, [8]Janssen Canada Inc, Toronto, ON.

Background/Purpose: The DAS-28 is used in clinical decision making and research as an outcome assessment for patients with RA. The tool measures clinical, patient centric and inflammatory components of disease activity. Simplification or improvement of the tool would be important in facilitating its use in real–world settings. The objective of this analysis was to assess the internal consistency of the DAS-28 components and contrast these upon replacing patient global assessment (PtGA) with HAQ-DI in RA patients treated with infliximab or golimumab in a Canadian real-world setting.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis (RA), ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab or golimumab as first biologics or after having been treated with a biologic for less than six months. Patients with RA treated with infliximab or golimumab who were enrolled between January 2002 and June 2012 and had a maximum of 60 months of follow-up were included in this analysis.

Results: A total of 510 patients evaluated over 3,817 visits were included in this analysis. Mean follow up was approximately 20 months. The overall correlation between TJC and SJC was high (r = 0.746), whereas the correlations of ESR with TJC (r = 0.187) and SJC (r = 0.212) were poor. The correlation between patient assessment of disease activity (PtGA) was poor with ESR (r = 0.190) and modest for TJC (r = 0.519) and SJC (r = 0.487). Internal consistency was low [Cronbach's alpha (CA) = 0.482) and Intra-Class Correlation Coefficient (ICC) = 0.205]. All item-item correlations, ICC and CA deteriorated with time over the 60-month follow up period. The correlations of TJC (r = 0.454) and SJC (r = 0.367) with HAQ-DI were lower when compared to those with PtGA while the correlation of ESR (r = 0.260) was higher with HAQ-DI. Replacement of PtGA with HAQ-DI would result in lower internal consistency (CA = 0.337) suggesting modest improvement in validity.

The slopes measuring rate of change over time for the DAS-28 items showed acceptable internal consistency (ICC = 0.638). Item-item correlations were low for the ESR-slope with PtGA-Slope (r = 0.262), TJC-Slope (r = 0.240) and SJC-Slope (r = 0.300); PtGA-slope had moderate correlation with SJC-Slope (r = 0.512) and TJC-Slope (r = 0.570). When compared to PtGA, HAQ-DI-Slope had comparable correlations with the slopes of the DAS-28 components.

Conclusion: There is poor cross sectional and longitudinal correlation between the DAS-28 components indicating that they are measuring related but discriminating concepts of disease activity. The exception being SJC and TJC and therefore exclusion of one of these measures may be considered. Replacement of PtGA with HAQ within the DAS-28 would not provide any significant statistical benefits however it could offer practical benefits (i.e. reduce measurement workload) without loss of the validity of DAS-28.

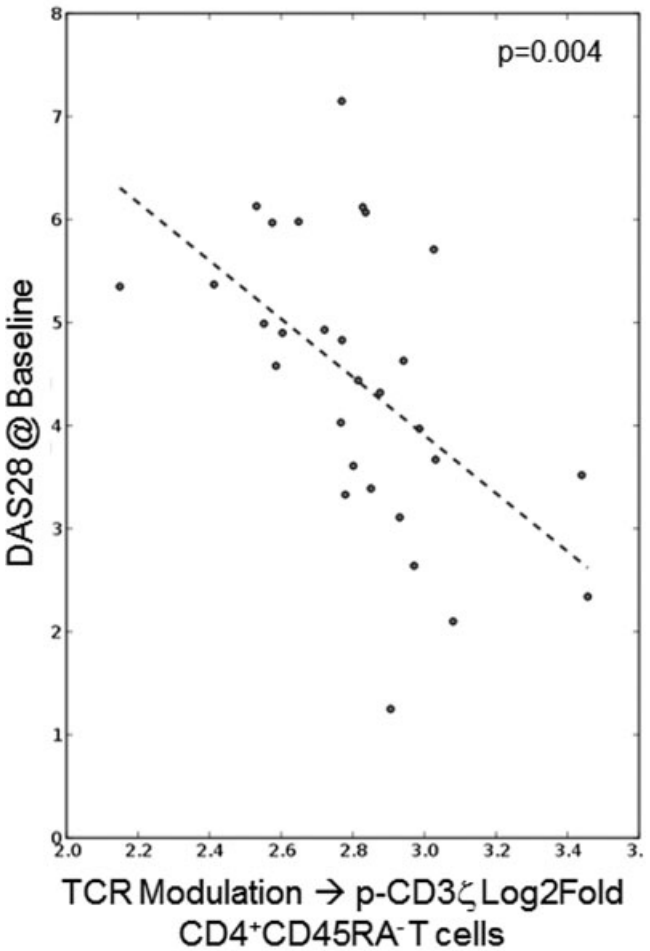
Novel Biomarkers From Peripheral Blood Mononuclear Cells Indicate Disease Activity In Rheumatoid Arthritis Patients. Jason Ptacek[1], Rachael Hawtin[1], Brent Louie[1], Erik Evensen[1], James Cordeiro[1], Barbara Mittleman[1], Michelle Atallah[1], Alessandra Cesano[1], Clifton O. Bingham III[2], Stacey Cofield[3], Jeffrey R. Curtis[4], Maria I. Danila[3], Richard A. Furie[5], Mark C. Genovese[6], Marc C. Levesque[7], Larry W. Moreland[7], Peter A. Nigrovic[8], James R. O'Dell[9], William H. Robinson[6], Nancy A. Shadick[8], E. William St Clair[10], Christopher C. Striebich[11], Geoffrey M Thiele[9], Peter K. Gregersen[5] and S. Louis Bridges Jr.[3]. [1]Nodality, Inc., South San Francisco, CA, [2]Johns Hopkins University, Baltimore, MD, [3]University of Alabama at Birmingham, Birmingham, AL, [4]University of Alabama at Birmingham, School of Public Health, Birmingham, AL, [5]The Feinstein Institute for Medical Research and North Shore-Long Island Jewish Health System, Lake Success, NY, [6]Stanford University, Palo Alto, CA, [7]University of Pittsburgh, Pittsburgh, PA, [8]Brigham and Women's Hospital/Harvard University, Cambridge, MA, [9]Omaha VA and the University of Nebraska Medical Center, Omaha, NE, [10]Duke Unversity Medical Center, Durham, NC, [11]University of Colorado Denver, Aurora, CO.

Background/Purpose: Biomarkers reflecting immune function and associating with disease activity can help stratify rheumatoid arthritis (RA) patients (pts) in practice and in clinical trials. Single cell network profiling (SCNP) is a multiparametric flow cytometry-based assay that measures induced changes in intracellular signaling proteins, providing a functional measure of pathway activity and immune networking in multiple cell subsets. In this study the association between disease activity as measured by DAS28 and signaling profiles in specific subsets of monocytes, B, and T cells from RA pts were assessed in an effort to identify biomarkers for immune monitoring.



Methods: SCNP of 42 nodes (combinations of modulator and intracellular readout) within 21 immune cell subsets was performed on PBMCs from 181 RA pts collected before initiating treatment with either metho-

trexate or a biologic agent for clinical indications and 10 age- and gender-matched healthy donors. RA pts were from the Treatment Efficacy and Toxicity in Rheumatoid Arthritis Database and Repository (TETRAD). Clinical data included DAS28 at enrollment (prior to starting the index drug). Statistical analyses, including Wilcoxon test and linear regression as appropriate, were performed using data from the 117 evaluable donors with no recent use of a biologic to identify signaling that associated with baseline disease activity, after controlling for age.

Results: This systems biology study identified several candidate signaling biomarkers associated with disease activity. As expected in donors with high disease activity (DAS28 $>$ 5.1), unmodulated cells had significantly elevated levels of p-S6, p-AKT, and p-p38 compared to donors with lower disease activity. Specific modulated signaling pathways responsive to IFNa (p-STAT5 in B cells, p=0.03) and T cell receptor modulation (p-LCK, p-ZAP70, p-PLCg2, and p-CD3z; e.g. p-CD3z in $CD4^+CD45RA^-$ T cells, p=0.004) showed signaling inversely correlated to the continuum of disease activity. The reduced signaling associated with higher disease activity potentially reflects disease processes including negative feedback from prior *in vivo* exposure or alterations in components necessary for signaling pathway integrity. Interestingly, signaling induced by TNFa (monocytes, p=0.0004) and IL-6 (central memory $CD4^-$ T cells, p=0.01) was higher in donors with high disease activity, which is consistent with these established treatment modalities.

Conclusion: Characterization of intracellular signaling within immune cells from RA patients provides insights into disease pathology and possible therapeutic targets. Functional pathway analysis of RA pts PBMCs has revealed potential predictive biomarkers that, once validated in future studies, may enable novel means for immune monitoring and therapeutic selection for the individual patient.

Correlation Of Anti-Citrullinated Protein and Anti-Carp Antibodies With Disease Duration and Activity In Rheumatoid Arthritis. Michael Mahler[1], Gabriella Lakos[1], Tyler Webb[1], Alvin Yee[1], Leendert A. Trouw[2] and Pier-Luigi Meroni[3]. [1]INOVA Diagnostics, San Diego, CA, [2]Leiden University Medical Center, Leiden, Netherlands, [3]University of Milan, Milano, Italy.

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF) are important serological markers in the diagnosis of rheumatoid arthritis (RA) and are part of the recent disease criteria. However, in early RA the sensitivities of ACPA and RF are low underlining the need for additional biomarkers. Additionally, there is a strong need for reliable markers for monitoring of disease activity and treatment response. Recently, antibodies directed against carbamylated antigens were identified. Those anti-CarP antibodies recognize antigens containing homocitrulline which is generated from lysine through chemical modification. This study analyzes the correlation of ACPA fine specificities and of anti-CarP antibodies with disease activity and disease duration.

Methods: A total of 80 RA patients were tested for anti-CCP2 (CCPlus® Immunoscan, Eurodiagnostica) and anti-CCP3 antibodies (QUANTA Lite CCP3, INOVA), for ACPA fine specificities (to three citrullinated peptides, ACPA 1 – 3) and for anti-CarP antibodies by ELISA using fetal calf serum as the antigen as previously described (Shi et al.). In addition RF (IgM) was determined. Disease activity was accessed using the disease activity score 28 (DAS28).

Results: ACPA, including anti-CCP2 (p=0.0050) and anti-CCP3 (p=0.0128) antibodies, as well as the ACPA fine specificities showed significant association with disease duration. In contrast, RF and anti-CarP antibodies did not show association with disease duration. Although no correlation between any of the autoantibodies and disease activity (DAS28) reached statistical significance, one ACPA peptide showed some degree of positive (p=0.0734) and anti-CarP antibodies negative correlation (p=0.0734). When those two biomarkers were combined in a score (ACPA peptide 1 divided by anti-CarP) a statistically relevant correlation was found (p=0.0264).

Assay/antibody	Correlation with disease duration	Correlation with DAS28
CCP2	**p=0.0050**	p=0.1058
CCP3	**p=0.0128**	p=0.2839
ACPA 1	**p=0.0051**	p=0.0734
ACPA 2	**p=0.0280**	p=0.1458
ACPA 3	p=0.0741	p=0.1814
RF	p=0.8178	p=0.1370
CarP	p=0.8700	p=0.0751
ACPA 1/CarP Score	**p=0.0128**	**p=0.0264**

Conclusion: We confirmed the presence of anti-CarP antibodies in RA using an independent cohort of RA patients from Italy. ACPA, but not RF IgM and anti-CarP antibodies are significantly correlated with disease duration. Combining one ACPA peptide with anti-CarP antibodies in an activity score showed association with DAS28. This score might represent a promising biomarker to measure disease activity, but further studies are needed to verify and validate those preliminary findings.

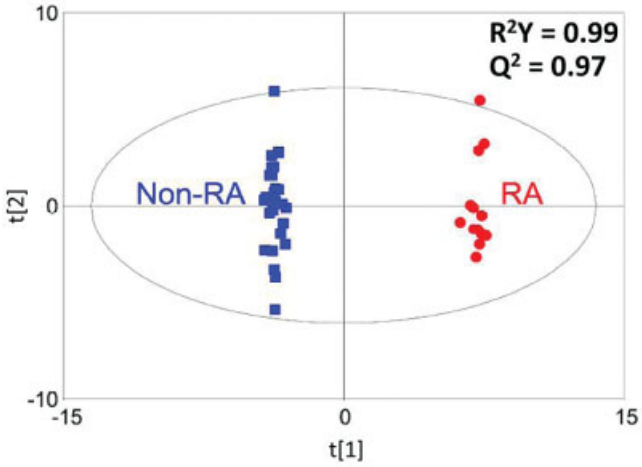
Global Metabolite Profiling Of Synovial Fluids From Different Forms Of Inflammatory Arthritis For The Identification Of Putative Biomarker In Rheumatoid Arthritis. Jiwon Hwang[1], Joong Kyong Ahn[2], Jaejoon Lee[3], Inyoung Kim[1], Seulkee Lee[1], Chan Hong Jeon[4], Eun-Mi Koh[1] and Hoon-Suk Cha[3]. [1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Kangbuk Samsung hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, South Korea, [4]Soonchunhyang University College of Medicine, Bucheon, South Korea.

Background/Purpose: Metabolomics is the study of unique chemical fingerprints of specific cellular processes. Metabolite profiling is recently applied in identifying biomarkers in medical research including rheumatologic diseases. The aim of this study is to assess the metabolite profiling of synovial fluid in patients with different forms of inflammatory arthritis and to identify putative biomarker for rheumatoid arthritis (RA) compared to the other inflammatory arthritis.

Methods: Synovial fluid samples were obtained from patients with RA (n = 13, mean age 44.2 ± 10.7 yr), ankylosing spondylitis (AS) (n = 7, mean age 35.4 ± 10.7 yr), Behcet's disease (BD) (n = 5, mean age 41.6 ± 12.5 yr) and gout (n = 13, mean age 45.9 ± 7.9 yr). To identify putative biomarkers for RA, the synovial fluid samples were divided into two groups; RA versus non-RA (NRA) which included AS, BD and gout. The metabolites of synovial fluid were analyzed using gas chromatography/time-of-flight mass spectrometry (GC/TOF MS). The multivariate statistical analyses by orthogonal partial least squares discriminant analysis (OPLS-DA) were conducted for the comparison between two groups. The potential biomarkers in RA patients were identified and evaluated by variable importance for projection (VIP) values, nonparametric Wilcoxon-Mann-Whitney test and one-way ANOVA test. Chemometric model validation was finally carried out using receiver operating characteristic (ROC) curve and area under the ROC curve (AUC).

Results: A total of 119 metabolites were identified from 38 samples. The metabolite profiling between RA and NRA were clearly discriminated by OPLS-DA (Figure 1). Candidates of biomarkers in RA were determined by VIP values extracted from OPLS-DA and 41 metabolites were selected by VIP scores of greater than 1.0, of which 29 metabolites were elevated in RA and 12 metabolites in NRA. After eliminating variables with no significant difference using Wilcoxon-Mann-Whitney test and one-way ANOVA test, 23 of 41 metabolites were selected as putative biomarkers for RA compared to NRA. Fifteen metabolites were higher level in RA (succinic acid, octadecanol, asparagines, terephtalic acid, salicylaldehyde, glutamine, citrulline, tyrosine, uracil, lysine, phenylalanine, ribitol, tryptophan, xylose and pyrophosphate) and 8 metabolites in NRA (isopalmitic acid, glycerol, myristic acid, palmitoleic acid, hydroxylamine, ethanolamine, alanine and serine). These metabolites were validated by AUC, all of which had AUC $>$ 0.8. ROC curve analysis for the power of discrimination of RA from NRA showed a sensitivity of 69.2% and a specificity of 84.0%.



Conclusion: Our study suggests that the synovial fluid metabolomic profiling can be a novel approach in differentiating RA from AS, BD and gout. A set of validated metabolites could be a putative biomarker in synovial fluid of RA patients.

2291

Only Rheumatoid Factor-Positive Subset Of Anti-Citrullinated Peptide/Protein Antibody-Negative Rheumatoid Arthritis Seroconverts To Anti-Citrullinated Peptide/Protein Antibody-Positive. Ryosuke Hiwa, Koichiro Ohmura, Shuichiro Nakabo, Chikashi Terao, Ran Nakashima, Yoshitaka Imura, Naoichiro Yukawa, Hajime Yoshifuji, Motomu Hashimoto, Moritoshi Furu, Hiromu Ito, Takao Fujii and Tsuneyo Mimori. Graduate School of Medicine, Kyoto University, Kyoto, Japan.

Background/Purpose: Sensitivity of anti-citrullinated peptide/protein antibody (ACPA) in early rheumatoid arthritis (RA) has been reported to be as low as 50%, whereas that in established RA is ~80%. The discrepancy of these figures has been explained by the seroconversion from ACPA-negative RA to ACPA-positive RA, but the seroconversion of ACPA seems to be rare in the previous reports. We investigated the precise proportion of seroconversion of ACPA retrospectively.

Methods: RA patients were recruited from January 2007 through November 2011 at Kyoto University Hospital and all the patients were Japanese. Titer of ACPA in sera or plasma was measured with the 2nd generation anti-CCP antibody ELISA kit. The ACPA-negative RA patients who were measured ACPA more than once with the interval of 3 months or longer were investigated for seroconversion of ACPA. The clinical characteristics of patients who turned into ACPA-positive were also assessed. Student's t-test and Fisher's exact probability test were used in statistical analysis.

Results: 216 (17.3%) out of 1,246 RA patients were negative for ACPA. In 149 cases of the ACPA-negative RA whose ACPA were measured more than once, only 8 patients (5.4%) turned into ACPA-positive during follow up. When we investigated the clinical characteristics of the 8 seroconverted cases (Table 1), we found all of them were positive for rheumatoid factor (RF) and showed bone erosions by X-ray. None of the ACPA-negative RF-negative RA turned into ACPA-positive. Since there were 56 ACPA-negative RF-positive RA, 14.3% of them seroconverted to ACPA-positive. The comparison of the basic clinical information of seroconverted and non-seroconverted RA patients were shown in Table 2.

Table 1. Clinical characteristics of each patient who turned into ACPA-positive

Pt No.	Age & Sex	Disease duration* (Y)	ACPA titer (U/ml) 1st	ACPA titer (U/ml) 2nd**	Interval of seroconversion (Y)	RF (IU/ml)	Stage	Treatment
1	76, W	0.2	3.3	20.4	0.8	104.9	II	MTX, SSZ
2	60, W	0.3	3.2	180.0	4	18.9	II	SSZ, PSL
3	39, M	1	3.0	10.8	0.4	420.8	II	MTX
4	36, W	4	2.6	8.4	3.3	79.2	II	LEF
5	64, W	6	3.2	8.3	2.4	942.0	IV	TCZ
6	63, W	18	3.7	6.1	0.7	55.5	IV	IFX, MTX
7	64, W	19	4.0	11.7	5	49.1	IV	TCZ, PSL
8	64, W	26	<0.6	14.2	5	23.0	IV	TCZ, SSZ, PSL

MTX; methotrexate, SSZ; sulfasalazine, PSL; prednisolone, LEF; leflunomide, TCZ; tocilizumab, IFX; infliximab
*Duration from disease onset to the first ACPA measured
**ACPA titer when ACPA was seroconverted.

Table 2. Basic cinical information of seroconverted RA and non-seroconverted RA

	ACPA(−)->(+)RA	ACPA(−)->(−)RA	P value
N	8	141	
Age	58.25 ± 13.66	65.64 ± 13.44	0.066
Women	7 (87.5%)	109 (77.3%)	0.44
RF positive	8 (100%)	48 (34.0%)	0.00029
RF titer (IU/ml)	211.68 ± 322.85	97.56 ± 244.26	0.88
Bone erosions	8 (100%)	72 (51.1%)	0.00058
ANA≥1:80	4 (50.0%)	40 (28.4%)	0.18
MTX administration	3 (37.5%)	78 (55.3%)	0.27
Biologic DMARDs	4 (50.0%)	23 (16.3%)	0.14
Onset to 1st ACPA (Y)	9.30 ± 10.15	5.24 ± 7.73	0.92
1st ACPA to 2nd ACPA (Y)	2.69 ± 1.92	2.27 ± 1.94	0.72

Conclusion: The proportion of seroconversion from ACPA-negative to ACPA-positive RA was as total 5.4%. This result is consistent with the previous report in an early arthritis cohort in Europe, in which only 0.8% was seroconverted from ACPA-negative to ACPA-positive. When we subdivided ACPA-negative RA into RF-negative and RF-positive, only RF-positive subset seroconverted to ACPA-positive. These results imply that ACPA-negative RF-negative RA and ACPA-negative RF-positive RA may be different subsets.

2292

Factors Affecting The Discrepancy Between Physician and Patient Global Assessment Of Disease Activity In Early and Established Rheumatoid Arthritis Patients- Results From The Ontario Best Practices Initiative. Pooneh Akhavan[1], Binu Jacob[2], Edward C. Keystone[3], Xiuying Li[4], J. Carter Thorne[5] and Claire Bombardier[2]. [1]Early Rheumatoid Arthritis Program, Mount Sinai Hospital and University of Toronto, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]University of Toronto/Mount Sinai Hospital, Toronto, ON, [4]University Health Network, Toronto, ON, [5]Southlake Regional Health Centre, Newmarket, ON.

Background/Purpose: Discrepancy between patient (PGA) and physician (MDGA) global assessments in Rheumatoid Arthritis (RA) can adversely affect therapeutic decisions. The pattern of PGA and MDGA, factors influencing each and the discrepancy between the two may be different in patients with established disease compare to patients with early disease. The objective of this study was to assess the pattern of PGA-MDGA discrepancy in early and established RA and to identify predictors of this discrepancy in the two patient populations.

Methods: Patients with RA were recruited from the Ontario Best Practice Initiative (OBRI), a clinical registry of RA patients followed in routine care. PGA and MDGA were scored from 0–100. PGA-MDGA discrepancy was calculated by subtracting MDGA from PGA at baseline. A clinically meaningful discrepancy was considered a difference of ≥30 (PGA-MDGA > 30: Positive (Pos) and PGA-MDGA < −30: Negative (Neg)). The rate of discrepancy was determined in patients with disease duration of less than or equal to 12 months (early RA) and disease duration of greater than 5 years (established RA) at baseline. Linear regression analysis was used to evaluate factors associated with MDGA, PGA and the PGA-MDGA discrepancy when adjusted for potential confounders including patient demographics, ESR, swollen joint count (SJC), tender joint count (TJC), pain, RF and anti-CCP and joint damage in both early and established disease.

Results: 439 early and 737 established RA patients were analyzed with the mean age of 57.0 and 59.0 years and DAS28 of 4.7 and 4.5 respectively. Mean PGA was 50.0 and 53.0 and MDGA was 48.0 and 43.0 in early and established groups respectively. A meaningful PGA-MDG discrepancy was found in182 (41%) early (101 positive and 81 negative) and 309 (42%) established (229 positive and 80 negative) RA. Regression analysis showed that there was a significant association between MDGA and pain, TJC, SJC and ESR at baseline in both groups and pain score was the only predictor of PGA. PGA-MDGA discrepancy was associated with pain ($p<.0001$), TJC ($p=0.0014$), SJC ($p=0.004$) and ESR ($p=0.01$) in early RA and was associated with pain ($p<.0001$), TJC ($p=0.002$), SJC($p<.0001$) and age ($p=0.05$) in patients with established disease (Table). In both groups higher pain score, SJC or TJC would increase the discrepancy. Higher pain score would increase the positive discrepancy (PGA>MDGA) whereas SJC, TJC and ESR (only in early RA) would increase the negative discrepancy (MDGA>PGA).

Table. Multivariate analysis assessing predictors of PGA- MDGA discrepancy in patient with early and established RA Predictors Early RA Established RA

	Early RA		Established RA	
Predictors	**β**	**p-value**	**β**	**p-value**
Age	0.07	0.51	0.17	0.05
Female	−2.83	0.38	−2.75	0.25
TJC	−0.90	0.001	−0.63	0.002
SJC	−1.00	0.004	−1.85	<0.0001
ESR	−0.15	0.01	−0.05	0.23
Pain score	6.68	<.0001	6.03	<.0001
RF positive	−0.10	0.29	−0.03	0.35
Anti-CCP positive	−0.03	0.33	−0.02	0.40
Joint damage	−2.26	0.33	−0.03	0.98
Education	0.89	0.68	2.21	0.17

Conclusion: PGA-MDGA discrepancy exists in a significant portion of RA patients irrespective of their disease duration. Pain score and active joints are the main clinical factors affecting this discrepancy in patients with either early or established disease.

2293

Anti-Citrullinated Peptide/Protein Antibody Specificities and Subclinical Synovitis In Palindromic Rheumatism: Towards a Better Understanding Of The Relationship With Rheumatoid Arthritis. Sonia Cabrera-Villalba[1], Julio Ramirez[1], Georgina Salvador[2], Virginia Ruiz-Esquide[1], M. Victoria Hernández[1], José Inciarte[1], Celia Saura[1], J. D. Cañete[1] and Raimon Sanmarti[1]. [1]Hospital Clinic, Barcelona, Spain, [2]Hospital Mutua de Terrassa. Barcelona, Barcelona, Spain.

Background/Purpose: Palindromic rheumatism (PR) may evolve to rheumatoid arthritis (RA), especially in anti-citrullinated peptide/protein antibody (ACPA) positive patients, although many do not evolve to RA after long-term follow-up. It is unclear whether ACPA-positive patients have more subclinical synovitis during the intercritical phase and whether this is a risk factor for progression to RA. There are no data on different ACPA specificities in PR compared with RA.

Objectives: To analyze differences in the presence of subclinical synovitis in PR patients according to ACPA status and determine whether fine specificities of citrullinated peptides differ between PR and RA.

Methods: Patients with pure PR (**Guerne et al* criteria) with no progression to chronic rheumatic disease at study entry were included. Clinical, demographic, serological and therapeutic variables were collected. Subclinical synovitis (grade≥ 2 synovial hyperplasia plus Doppler signal) in the intercritical period was analyzed by ultrasound of both hands. ACPA specificities were assayed by home-made ELISA tests using chimeric fibrin/filaggrin (CFFCP1), fibrin/vimentin (CFVCP), and vimentin/fibrin (CVFCP) citrullinated chimeric synthetic peptides in pure PR patients who were positive for commercial CCP2 tests: results were compared with controls with established RA (1987 ACR criteria).

Results: Fifty-seven patients (64.9% female, mean age 51.6±11.2 years and mean disease duration 11.9±10.5 years) with pure PR were included: 39 (68.4%) were ACPA+ (CCP2 test). No significant clinical differences were observed between ACPA+ and ACPA- patients except for a shorter duration of attacks and greater DMARD use (mainly hydroxychloroquine) in ACPA+ patients. RF was most-frequently found in ACPA positive patients. Subclinical synovitis by ultrasound was observed in 16 patients (28.1%), most-frequently in the metacarpal joints and wrists, without significant differences between ACPA+ and ACPA+ PR patients (30.8 vs. 22.2% p=0.51).

Citrullinated peptide specificities did not significantly differ between CCP2+ PR patients (n=39) and control patients (n=39) with established CCP2+ RA (66.7% female, mean disease duration 7.2±4.4 years), although there was a trend to a higher number of specificities and a higher titer of ACPAS in RA patients (Table 1).

Table 1. Frequency of citrullinated peptide specificities in CCP2-positive PR and RA patients.

	PR-CCP2 positive n=39	RA-CCP2 positive n=39	p value
CCP2 levels(IU/L)	467.72 ± 513.6	761.74 ± 595.7	0.09
CFFCP1 n (%)	29 (74.4%)	35 (89.7%)	0.24
CFVCP n (%)	24 (61.5%)	26 (66.7%)	0.6
CVFCP n (%)	29 (74.4%)	34 (87.2%)	0.43
CFFCP1 levels (ODU)	1.01 ± 0.97	1.25 ± 0.88	0.24
CFVCP levels (ODU)	0.59 ± 0.54	0.65 ± 0.60	0.25
CVFCP levels (ODU)	0.82 ± 0.80	0.89 ± 0.66	0.24
≥2 Specificities	28 (71.7%)	35 (89.7%)	0.2
3 Specificities	23 (59%)	25 (64.1%)	0.7

ODW: optic density units

Conclusion: ACPA are frequently found in patients with PR. Most PR patients do not have subclinical synovitis (by ultrasound), which is not associated with ACPA status, in the intercritical period. No significant differences in the different specificities of ACPAS were observed between PR and RA, suggesting that chronic PR might be considered an abortive form of RA

2294

The Role Of Patient Global Disease Activity Score In The Definition Of American College Of Rheumatology/European League Against Rheumatism Remission In Very Early Rheumatoid Arthritis From The Norwegian Very Early Arthritis Clinic. Maria Dahl Mjaavatten[1], Anne Julsrud Haugen[2], Halvor Nygaard[3], Olav Bjørneboe[4], Patrik Stolt[5], Cathrine Thunem[6] and Tore Kristian Kvien[7]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Østfold Hospital Trust, Fredrikstad, Norway, [3]Revmatismesykehuset Lillehammer, Lillehammer, Norway, [4]Martina Hansens Hospital, Gjettum, Norway, [5]Innlandet Hospital Trust, Brumunddal, Norway, [6]Betanien Hospital, Skien, Norway, [7]University of Oslo, Oslo, Norway.

Background/Purpose: In the ACR/EULAR criteria remission can be defined in two ways, either by fulfilment of 4 Boolean criteria or by a Simplified Disease Activity Index (SDAI) score ≤ 3.3. Failure to fulfill the patient global disease activity (PGA) score < 1 cm criterion in the Boolean version has been shown to be the major determinant of "near misses" of remission in established RA. It is not known if this factor is of the same importance when RA patients are identified and treated at a very early stage. The purpose of this study was to investigate the role of PGA in fulfilment of the ACR/EULAR remission criteria after 2 years in patients with RA in a very early arthritis clinic.

Methods: Patients with arthritis of <16 weeks' duration were included in an early arthritis cohort from 2004–2010 and followed for 2 years with a comprehensive data collection. Patients were treated according to current clinical practice and not with a structured treat-to-target approach. Patients with RA according to the 2010 classification criteria with 2 years follow-up time were included in the present analysis. Frequency of 2-year remission was calculated according to both versions of the criteria, as well as which criterion was not fulfilled in patients fulfilling 3/4 Boolean criteria.

Results: Of 1086 very early arthritis patients included, 185 (17.0 %) had RA according to the 2010 criteria at inclusion and had 2-year data on Boolean remission (mean (SD) age 52.5 (13.8) years, n (%) females 112 (60.5), median (25–75 percentile) duration of symptoms at inclusion 63 (40–83)). 171 of these patients had data on SDAI remission. After 2 years, 41/185 (22.2 %) were in Boolean remission, while 65/171 (38.0 %) were in SDAI remission. 63 patients (34.5 %) fulfilled 3 of the Boolean criteria (criterion not fulfilled: PGA n=52, CRP n=5, TJC n=3, SJC n=1, missing data n=2). If the PGA cut-off was raised to ≤2, the remission rate increased to 61/185 (33.0 %). A PGA cut-off of ≤ 3 gave a remission rate of 72/185 (38.9 %). Omitting the PGA criterion, the remission rate was 93/185 (50.3 %). Mean (range) PGA score in the 52 patients failing to fulfill the criteria due to elevated PGA was 3.5 (1.1–8.9). 44/52 (84.6 %) of patients with PGA > 1 had evaluator's global disease activity (EGA) ≤ 1; 25 of these 44 (56.8 %) were in SDAI remission. 13 patients who were not in ACR/EULAR Boolean remission fulfilled the PGA criterion.

Conclusion: In this very early arthritis clinic only 22% of early RA patients were in ACR/EULAR Boolean remission after 2 years of follow-up, while 38 % were in remission according to SDAI. Elevated PGA was the major reason for not being in remission in patients fulfilling 3/4 of the Boolean remission criteria, and in the majority of these patients EGA was ≤ 1. A PGA cut off of ≤ 3 resulted in a similiar remission rate (38.9 %) as with the index based (SDAI) remission definition.

Mortality In Early Rheumatoid Arthritis Comparing Lithuania and Finland. A 13-Year Follow Up. Tuulikki Sokka[1], Sigita Stropuviene[2], Hannu Kautiainen[3], Tuomas Rannio[4] and Jolanta Dadoniene[2]. [1]Jyvaskyla Central Hospital, Jyvaskyla, Finland, [2]Vilnius Univ, Vilnius, Lithuania, [3]Unit of Primary Health Care, Helsinki University Central Hospital, Helsinki, Finland, [4]Jyvaskyla Central Hospital, Jyväskylä, Finland.

Background/Purpose: Life span of patients with rheumatoid arthritis (RA) is reduced by 3–10 years compared to non-RA population. Only recent reports indicate improvements in survival outcomes in RA in a few countries. The QUEST-RA study indicated that RA continues to be an active and severe disease especially in countries with lower gross domestic product (ARD 2009;68:1666–7). Therefore, it is of interest to compare survival outcomes of patient with RA in different countries. Our objective was to study long-term survival of patients with early RA in Vilnius (VIL), Lithuania, and Jyväskylä (JYV), Finland, and predictors of vital status as well as comparison to the population.

Methods: A cohort of 191 patients with early RA (disease duration <4 years) was established in VIL in 1998 – 2003. A comparison cohort was drawn from the JYV RA database that includes all incident and prevalent patients with RA since 1982. To each VIL patient, a control subject was identified in JYV, matched for gender, year of birth, starting year of arthritis, and RF status (negative, positive). Vital status of the patients was acquired from the central statistics office in each country. Regression analyses for mortality included nation, baseline disease activity(DAS28_esr3), patient self-report of function(HAQ), early continuous use of DMARDs and systemic steroids(SS), presence of a life threatening disease(LTD), smoking, and a type of work (white vs blue collar) as a proxy of wealth. Patients were followed until December 2012 or death, which ever happened first. Standard Mortality Ratio (SMR) was calculated.

Results: A total of 186 patients and controls (age at diagnosis 52 years, 78%F, 85% RF+) were included in analyses. Over a median (IQR) follow-up of 13 (11, 15) years, 55 and 32 patients died in VIL and JYV, respectively, including 16(40%) and 11(28%) of men (p=0.24) and 39(27%) and 21(15%) of women (p=0.009) [HR=1.83 (95% CI: 1.18 to 2.83), p<0.001]. In multivariate analysis, age and country were the only independently significant variables for mortality. SMR (95%CI) was similar to that of the population in each country (VIL: 1.3, 1.0 to 1.7; JYV: 1.4, 1.0 to 1.9).

Conclusion: In this analysis of patients with early RA over a median of 13 years, higher mortality was seen in VIL compared to JYV patients but SMR was similar to the general population in each country indicating improved outcomes of RA in these countries.

Are SDAI50 and DAS28 Response Measures Comparable In Early Rheumatoid Arthritis Patients? Mohammed Omair[1], Edward C. Keystone[1], Juan Xiong[2], Gilles Boire[3], Janet E. Pope[4], J. Carter Thorne[5], Carol A. Hitchon[6], Boulos Haraoui[7], Diane Tin[5], Deborah Weber[2], Vivian P. Bykerk[1] and Pooneh Akhavan[1]. [1]Mount Sinai Hospital/University of Toronto, Toronto, ON, [2]Mount Sinai Hospital, Toronto, ON, [3]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [4]St Joseph Health Care, London, ON, [5]Southlake Regional Health Centre, Newmarket, ON, [6]University of Manitoba, Winnipeg, MB, [7]Institut de Rhumatologie de Montréal, Montreal, QC.

Background/Purpose: An essential element of treat to target strategy is adjusting therapy in the absence of achieving a target response by 12 wk. A ΔDAS28 of 1.2 and Simplified Disease Activity Index of 50% (SDAI50) are used as response measures (RM). Our objective was to assess the relationship between the 2 RM and to characterize patients failing to respond based on either RM.

Methods: Data from the Canadian early ArThritis CoHort (CATCH), an early arthritis cohort of patients with symptoms duration of ≤ 12 mo were used. Among patients with RA, we assessed biologic naive patients with available data to calculate DAS28 and SDAI at baseline (BSL) and 12 wk. We included patients on stable DMARD (no Δ in therapy) during the first 3 mo of f/u. Response to treatment was evaluated at 12 wk.

Correlation and agreement between 2 criteria was assessed by kappa statistics and Spearman correlation. BSL characteristics and median change from BSL were compared in patients with discordant RM. Probability plots of achieving each RM against BSL DAS28 score were evaluated.

Results: In total, 419 patients were included. Most were women (75%) with mean age of 52.6 years. Other BSL variables (mean): disease duration 5.7 months, tender joint count (TJC) 9.0, swollen joint count (SJC) 8.2, DAS28 5.2, SDAI 29.7 and CRP 14.4.

198 (47%) patients failed to achieve a DAS28Δ and 206 (49%) failed to achieve SDAI50. There was a significant agreement between DAS28 and SDAI50 RM (Kappa 0.66) with a Spearman Correlation of 0.66 (p<0001). Of patients failing SDAI50, 19.2% achieved a DAS28Δ, of patients failing a DAS28Δ, 16.6% patients achieved SDAI50. In patients with discordant RM, BSL disease activity measures were higher in DAS28 responders (Table). The probability of achieving the DAS28Δwas higher patients in higher disease activity and it was the opposite in the lower activity range (Figure). Median change of activity measures was higher in patient who achieved DAS28Δ (Table).

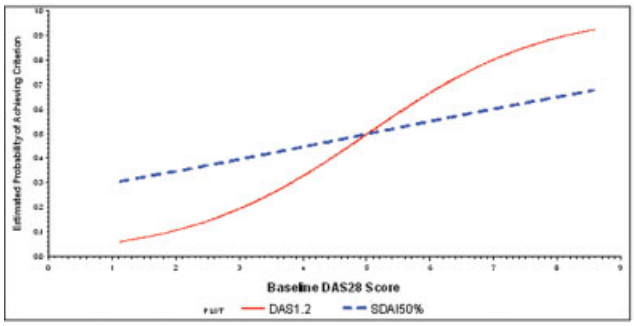

Figure. Plot of the predicted probability of achieving criterion DAS1.2 and SDAI50 against baseline DAS28 score.

Table. Comparing baseline characteristics and change in individual disease activity measures from baseline to 3 months in two patients with discordant RM

	Baseline characteristics			Median Δ in individual activity measures		
Baseline variables	SDAI50-No DAS1.2-Yes N=40	SDAI50-Yes DAS1.2-No N=32	p-value	SDAI50-No DAS1.2-Yes N=40	SDAI50-Yes DAS1.2-No N=32	p-value
Age (years)*	54.2 ± 13.4	52.7 ± 16.6	0.507	–	–	–
Female n (%)	29 (73)	27 (71)	0.266	–	–	–
SJC28*	10.3 ± 5.9	4.7 ± 5.26	<.0001	−3.0	−2.0	0.227
TJC28*	12.7 ± 7.0	4.5 ± 5.5	<.0001	−4.0	−2.0	0.012
PHGA*	59.5 ± 23.3	38.9 ± 26.6	0.002	−20.0	−30.0	0.083
HAQ *	1.2 ± 0.6	0.9 ± 0.7	0.061	−0.44	−0.44	1.000
PTGA*	72.6 ± 25.8	36.8 ±27.1	<.0001	−40.0	−10.0	0.005
Pain*	70.7 ± 23.6	45.0 ±29.5	<.0001	−40.0	−17.5	0.005
CRP*	23.9 ± 20.9	9.3 ±14.5	<.0001	−8.3	−0.3	<0.0001
DAS28*	6.1 ± 1.1	3.8 ± 1.0	<.0001	−1.7	−0.9	<0.0001
SDAI*	38.7 ± 14.8	17.6 ± 12.2	<.0001	−13.8	−10.7	0.158

* mean (sd)

Conclusion: SDAI50 and DAS28 RM are well correlated although in patients in high disease activity states the likelihood of achieving an SDAI50 is lower than achieving a DAS28Δ, while the reverse is true at lower disease activity states.

Evaluating Depression Questionnaires In German Rheumatoid Arthritis Patients – Preliminary Results From a Validation Study. Matthias Englbrecht[1], Rieke Alten[2], Martin Aringer[3], Christoph G. Baerwald[4], Harald Burkhardt[5], Nancy Eby[6], Gerhard Fliedner[7], Bettina Gauger[8], Ulf Henkemeier[9], Michael Hofmann[10], Stefan Kleinert[11], Christian Kneitz[12], Christoph Pohl[13], Georg Schett[1], Marc Schmalzing[11], Anne-Kathrin Tausche[14], Hans Peter Tony[15] and Joerg Wendler[16]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]University of Berlin, Berlin, Germany, [3]University Clinical Center Technical University of Dresden, Dresden, Germany, [4]University Hospital Leipzig, Leipzig, Germany, [5]CIRI /Div. of Rheumatology, Goethe-University, Frankfurt/Main, Germany, [6]AMS-Advanced Medical Services, Mannheim, Germany, [7]Praxis Osnabrück, Germany, Germany, Osnabrück, Germany, [8]Roche Pharma AG, Grenzach, Germany, [9]University Hospital Frankfurt, Frankfurt, Germany, [10]Chugai Pharma, Frankfurt, Germany, [11]University Hospital Würzburg, Würzburg, Germany, [12]Hospital Südstadt, Rostock, Germany, [13]Schlosspark Klinik, Berlin, Germany, [14]Universitätsklinikum Carl Gustav Carus an der Technischen Universität Dresden, Dresden, Germany, [15]University of Würzburg, Würzburg, Germany, [16]Schwerpunktpraxis Rheumatologie, Erlangen, Germany.

Background/Purpose: To date, only a few studies have discussed the prevalence of depression in RA patients in Germany and depression ques-

tionnaires have not been validated for use in RA patients in the German language. This was the aim of the first part of the Validation of Depression Questionnaires for Patients with Rheumatoid Arthritis (VADERA) study presented in this abstract.

To evaluate the construct validity, retest reliability and sensitivity to change of the following four tools measuring depressiveness: the WHO five well-being index (WHO-5), the patient health questionnaire (PHQ-9), the Beck Depression Inventory (BDI-II), and Montgomery-Åsberg Depression Rating Scale (MADRS).

Methods: A patients with no previous history of depressive disorders were asked to complete the WHO-5, PHQ-9 and BDI-II questionnaires and a subsequent structured interview (MADRS) at 2 time-points with a 10–14 week interval between assessments. Additional information on demography (e.g. age, sex, disease duration) and disease activity (e.g. CRP, ESR, disease activity score 28 [DAS28]) was collected.

In order to evaluate convergent and discriminant validity as subsets of construct validity, we calculated Pearson correlations of the PHQ-9, WHO-5, BDI-II, and MADRS at both time-points (= convergent) followed by Pearson correlation of the depression scores with age and DAS28 (= discriminant). Results from patients who had no psychotherapeutic intervention for depression and who had a change of < 0.6 in DAS28 between the first and second time-point were evaluated for the retest reliability of the instruments (i.e. a Pearson correlation). Sensitivity to change was evaluated among patients who had received psychotherapeutic intervention between the first and second time-point using the standardized response mean (SRM).

Results: 277 RA patients from 9 centers in Germany were evaluated in VADERA I. Baseline characteristics were: mean (±SD) age 60 (±13.0) years, 79% female, mean duration of disease 12.4 (± 9.4) years, 61% anti-citrullinated protein antibody positive and a mean DAS28 score 3.5 (± 1.6). 10.0% of the patients were undergoing anti-depressive therapy.

All Pearson correlations for convergent validity showed statistically significant correlations at both time-points. Corresponding coefficients ranged from r=0.63 (p<0.001) (PHQ-9 with BDI-II) to r= 0.79 (p<0.001) (BDI-II with MADRS) and from r= −0.36 (p<0.001) (WHO-5 with MADRS) to r=−0.54 (p<0.001) (WHO-5 with PHQ-9).

Correlations of discriminant validity ranged from r= −0.14 (p=0.05) (PHQ-9) to r= 0.17 (p=0.01) (WHO-5) for age and from r= −0.22 (p=0.002) (WHO-5) to r=0.43 (p<0.001) (MADRS) for disease activity.

All questionnaires showed good retest reliability which ranged from r= 0.68 (p<0.001) for the PHQ-9 to r= 0.85 (p<0.001) for the WHO-5.

The SRMs were rather small and ranging from −0.37 (n=12, BDI-II) to 0.13 (n=14, PHQ-9), suggesting the BDI-II to be most sensitive to changes in depression status.

Conclusion: Especially the PHQ-9, the BDI-II, and the MADRS may be assumed to be construct valid and retest reliable. SRMs were rather small and suggesting the BDI-II to be most sensitive.

Upper-Half Serum IgA (20+ TU/ml) and IgM (10+ IU/ml) Levels Significantly Predicted The Long-Term (mean 12 yrs) Onset Of Rheumatoid Arthritis When Combined, But Neither test Individually In Their Respective Full Ranges Of Values. Alfonse T. Masi[1], Azeem A. Rehman[1], Jean C. Aldag[1], Huaping Wang[1], Ned J. Goertzen[1] and Marius C. Teodorescu[2]. [1]University of Illinois College of Medicine at Peoria, Peoria, IL, [2]TheraTest Laboratories Inc, Lombard, IL.

Background/Purpose: Serum rheumatoid factor (RF) is a major predictor of the new onset of rheumatoid arthritis (RA). In very early arthritis patients, higher titers of both IgA and IgM RF isotypes predicted bone erosions at 2 years (A&R 2010; 62:1739–47). However, no data have been reported on efficacy of IgA or IgM RF isotypes to predict new onset of RA. This cohort study analyzed baseline IgA and IgM RF isotype levels as predictors of new onset of RA, and searched for factors associated with baseline levels of these biomarkers.

Methods: In 1974, baseline sera were obtained from a community-based cohort (n=21,061 adults) enrolled in the CLUE 1 follow up study. In 1994, baseline pre-RA cases were identified, who subsequently developed ACR-positive RA, 3 to 20 (median 12) years *after* entry. Four non-RA control (CN) cohort subjects were matched to each case on age, sex, and Caucasian race. The RF isotype assays were performed by ELISA concurrently and without identification, on stored (−70°C) baseline sera of 32 pre-RA and 119 CN subjects. Median (Md) levels were determined for IgA (20 TU/ml) and IgM (10 IU/ml) RF isotypes from total subject sample values, which were then stratified into 4 gradient subgroups (1 = both < Md, 4 = both ≥ Md). The subgroup with both RF isotypes lower than Md values (1) was used as baseline in odds ratio (OR, 95% CIs) prediction of RA for the other 3 subgroups (Table):

Mds: IgA = 20, IgM = 10	Means		Females (n)		Males (n)		Both Genders [n, ORs (95% CIs)]		
Isotype Subgroups	IgA	IgM	CN	pre-RA	CN	pre-RA	CN	pre-RA	ORs (95% CIs)
(1) IgA & IgM < Md	9.9	4.7	12	4	23	3	35	7	1.0
(2) Only IgA ≥ Md	32.1	5.5	14	2	13	2	27	4	0.74 (0.196–2.793)
(3) Only IgM ≥ Md	11.1	17.1	9	2	17	2	26	4	0.77 (0.204–2.906)
(4) Both RFs ≥ Md	50.4	25.5	16	7	15	10†	31	17†	2.74 (1.004–7.485)
Total Subgroups	21.5	10.8	51	15	68	17	119	32	(† = p < 0.010)

Results: Expected random frequencies were found for the CN in each of the 4 gradient categories, 31 (26%) of 119 in the highest subgroup, whereas pre-RA predominated in that subgroup, 17 (53%) of 32 (p = 0.005). In univariate analyses (Table), category 4 predicted RA onset in total subjects, OR 2.74 (1.004 – 7.485). In males, category 4 also predicted RA onset, 5.05 (1.642–15.520), but not in females, 1.91 (0.593–6.193). In a logistic regression (LR) model, the higher combined IgA/IgM RF category 4 was included as a dichotomous, independent factor (0 = no, 1 = yes), and predicted (p = 0.006) the dependent RA outcome, OR 3.16 (1.381 – 7.225). The model included other baseline variables: cohort entry age; sex; a 7-category cigarette smoking history score, and years from entry to RA onset. The smoking variable also independently predicted RA outcome, OR 1.28 (1.008 – 1.626). Unlike category 4, neither RF isotype alone in full-range values predicted RA in LR models. In other LR models, using the higher IgA/IgM RF category 4 as the dependent outcome variable, neither the cigarette gradient scores, nor individually-entered serum levels of acute phase proteins (CRP, ASAA, IL-1ra), inflammatory cytokines (IL-1B, IL-6, TNF-α), or selected receptors (sTNF-R1 and sIL-2Rα) were independent predictors.

Conclusion: The combination of upper-half IgA and IgM RF levels was a significant predictor of long-term development of RA in total subjects and males. Factors which influence the combined higher IgA/IgM RF isotype levels, as was found in pre-RA, deserve further study.

Disease Activity Scoring: Comparing Patient and Physician Global Assessment Of Disease Activity In Rhumatoid Arthritis Patients Starting a First Biologic Agent. Boulos Haraoui[1], Louis Bessette[2], Diane Sauvageau[1], Jean Pierre Pelletier[1], Jean-Pierre Raynauld[1], Edith Villeneuve[1], Louis Coupal[1] and Denis Choquette[1]. [1]Institut de Rhumatologie de Montréal, Montreal, QC, [2]Centre Hospitalier Universitaire de Québec, pavillon CHUL, Sainte-Foy, QC.

Background/Purpose: Visual analogue scales (VAS) are routinely used in daily clinical practice and are part of the different composite outcome measures such as the DAS, CDAI and SDAI. Studies often report weak to moderate positive correlations between physician and patient global assessment of disease activity. It is thought that they are driven by different considerations such as pain, fatigue and mental status for patients and more objective measures such as the swollen joint count and acute phase reactants for physicians. We hypothesized that while absolute values of patient and physician global disease activity do not always correlate, changes in these measures may offer a better correlation. To this end, we looked at global evaluation changes before and after introduction of a first biologic agent in patient with RA.

Methods: We included patients treated for at least 6 months with a first anti-TNF agent (adalimumab, etanercept or infliximab) starting in January 2005.The patient and physician global assessments of disease activity of RA patients were extracted from the RHUMADATA® clinical database and registry. Pearson correlations coefficients between pre, post and pre-post changes in patient and physician assessments were computed (SAS v 9.13) and compared.

Results: The global disease activity scores from 83 patient-physician pairs were available for this analysis. The pre-treatment assessments were

made within 0 and 176 days (mean 33 days) of biologic initiation while the post treatment assessments occurred between 182 and 799 days (mean 268 days). The patient and physician pre, post, and pre-minus-post global assessment means and standard deviations are presented below. The pre and post treatment Pearson correlations coefficients between patient and physician assessments are respectively $r^2=0.34$ ($p=0.001$) and $r^2=0.19$ ($p=0.08$). The correlation coefficient between patient and physician change in global assessment is 0.15 ($p=0.19$).

Physician and patient global disease activity assessment

	Physician Mean (StD)	Patient Mean (StD)	Difference (Patient-physician) Mean (StD)
Pre-treatment	5.27 (1.19)	5.58 (2.96)	0.31 (2.94)
Post-treatment	1.42 (1.78)	3.79 (2.81)	2.37 (3.02)
Difference (post-pre)	−3.85 (2.31)	−1.79 (2.95)	

Conclusion: While the pre treatment initiation global disease activity assessments showed moderate correlation, the change in these assessments exhibited a weak relationship. Both physicians and patients agree on disease activity improvement although their magnitudes differ. Reasons for this difference are being explored.

Rheumatologists Who Are Consistently Using An Objective Outcome Instrument Do Not "Treat To Target" In a Real World Setting. Gary Craig[1], Howard Kenney[2], Keith Knapp[2] and Sergio Schwartzman[3]. [1]Arthritis Northwest PLLC., Spokane, WA, [2]T3 JointMan LLC., Spokane, WA, [3]Hosp for Special Surgery, New York, NY.

Background/Purpose: The public database JointMan™ was launched January 2012 with a mission to provide a practical outcome tool to manage patients with RA in a clinical setting. This was not constructed as a research registry. The rheumatology community has been educated on the importance of measurement in patients with RA, but has not yet adopted the strict concept of treating to target; rather, in a real world setting rheumatologists may be measuring but not acting on their measurements.

In this observational study, the stated hypothesis is that rheumatologists who are consistently measuring are not yet treating to target and therefore not utilizing the obtained outcome measurements to attain a specific therapeutic goal.

Methods: JointMan™captures RA diagnostic criteria and selected disease features, formal joint counts, MDHAQ, DAS 28, CDAI, SDAI, RAPID3, CRP and ESR, medication use, toxicities and reason for discontinuation. This was a descriptive observational study.

Results: To date 16 national providers have entered patients. A total of 2465 unique RA patients and 6860 encounters were recorded between January 1, 2012 and December 31, 2012. Of the 2465 unique RA patients, 1862 patients had greater than one encounter reported. Only patients with greater than one encounter were evaluated. Demographic characteristics of this group revealed that 72 % were female, mean age was 62, 55 % were RF positive, 41 % were CCP positive, 34 % had documented erosions noted on radiographic studies.

CDAI and RAPID3 scores were available for 83.4% and 91.73% respectively. The mean initial CDAI score was 14.01 at the time of first encounter and a mean CDAI score of 12.05 was noted at the time of the last encounter for a 1.96 improvement (13.98% improvement). The mean initial RAPID3 score was 11.28 at the time of first and 10.94 was noted at the time of the last encounter for a 0.34 improvement (3.01% improvement). The mean number of encounters per patient where CDAI and RAPID3 were recorded was 4.71 and 4.38 respectively.

Conclusion: Utilizing a new database, JointMan™, constructed to easily enter patient data in a clinical setting, it was demonstrated that physicians in a real world setting consistently determine outcome measurements. However, although there is a definite mean improvement in chosen outcome measurements, a mean low disease state is not achieved for this group of patients.

The primary purpose of objective measurement is quality improvement. The optimal method to achieve this goal is to provide feedback through a real time data visualization tool. Having succeeded in educating physicians to actually obtain an outcome measurement consistently, there is now a need to more formally teach rheumatologist as to how to use the measurement to attain a desired disease state.

T Cell Proliferative Response To Type II Collagen In Patients With Rheumatoid Arthritis. Nida Saleem[1], Tahir Aziz Ahmed[2], Javaid Mahmood Malik[3], Mushtaq Ahmed[4] and Mukarram Bashir[5]. [1]Armed Forces Institute Of Pathology, RAWALPINDI, Pakistan, [2]Armed Forces Institute of Pathology, Rawalpindi, Pakistan, [3]Rahmat Noor Clinic and Arthritis Research Centre, Rawalpindi, Pakistan, [4]Military Hospital Rawalpindi, rawalpindi, Pakistan, [5]Armed Forces Institute Of Pathology, rawalpindi, Pakistan.

Background/Purpose: To compare the frequency of Collagen II reactive T cells in RA patients and healthy control and evaluating the relationship of Collagen II reactive T cells with disease activity in RA patients.

Materials and Methods: Patients with a clinical diagnosis of Rheumatoid arthritis on fulfilling 1987 ACR criteria were included in the study. Patients were compared with a group of age and gender matched healthy subjects. T cell proliferative response was assessed against Bovine Collagen II, PHA (positive control) and RPMI (negative control) by measuring incorporation of the 5-bromo-2- deoxyuridine (BrdU) into DNA of proliferating cells and expression of CD25 on proliferating cells and was subsequently detected with monoclonal antibodies (BrdU-moAb and CD25-moAb) as percentage of CD3+/BrdU+ and CD3+/CD25+ T-cells, respectively.

RA patients were classified into three groups of mild, moderate and severe disease activity as per Simplified disease activity index for RA. Four parameters, frequency of CD3+/BrdU+, frequency of CD3+/CD25+ T-cells, Mean Fluorescent Intensity (MFI) of BrdU-FITC and MFI of CD25-FITC were compared in mild, moderate and severe disease activity groups.

Results: Five male and twenty five female RA patients with an age range of 28–60 years (mean 42 years) and 25–58 years (mean 36 years) respectively were studied. Percentages of CD3+/CD25+ cells and CD3+/BrdU+ cells in T lymphocytes from RA patients induced by Collagen II were much higher (45.22% and 53.45%) than those observed for T lymphocytes in control group (33.51% and 45.22%). The difference was statistically significant ($p<0.05$).

Statistically significant differences were observed when frequency of CD3+/BrdU+ cells and CD3+/CD25+ cells along with MFI of BrdU-FITC and CD25-FITC was compared between the three disease activity groups, mild, moderate and severe in patients ($p<0.05$).

Conclusion: These observations suggest that Collagen II is an important auto antigen in joints of RA patients with Collagen II reactive T cells playing a critical role in pathogenesis of RA and Collagen II reactive T lymphocytes may be used as a specific prognostic laboratory marker for assessment of disease activity in RA.

Anti-Carbamylated Protein Antibody In Japanese Patients With Rheumatoid Arthritis. Shunichi Shiozawa[1], Leendert A. Trouw[2] and Kazuko Shiozawa[3]. [1]Kyushu University Beppu Hospital, Beppu, Japan, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Konan Kakogawa Hospital, Kakogawa, Japan.

Background/Purpose: Serology represents a powerful tool for the identification and sub-classification of patients with rheumatoid arthritis (RA). IgM-rheumatoid factor and anti-cyclic citrullinated peptide (CCP) antibodies are now part of the 2010 EULAR/ACR criteria for RA. Recently, anti-carbamylated protein (anti-CarP) antibodies have been described to be present over 40% of European patients with RA and to predict joint damage (Shi J et al. PNAS 108:17372, 2011). Here, we have characterized this antibody in Japanese patients with RA.

Methods: Sera of the patients fulfilling ACR diagnostic criteria who visited hospital within 2 yrs after disease onset between April 2003 and March 2006 were obtained. Anti-CarP fetal calf serum (CarP FCS) and anti-CarP fibrinogen (CarP Fib) were measured by using ELISA as before. Anti-CCP2 and anti-CCP3 were detected using commercial assays. Radiographic evaluation was done using van der Heijde-modified Sharp score (SHS), with a range of 0–306 (narrowing + erosion) and expressed as annual change from baseline. Statistical analyses were done using Student's t-test.

Results: Anti-CarP FCS and anti-CarP Fib antibodies were found in 82/ 258 (31.78%) and 87/ 258 (33.72%) of Japanese patients with RA. Anti-CCP2 and anti-CCP3 antibodies were found in 197/ 258 (76.36%) and 210/ 258 (81.40%) patients, respectively. Among anti-CCP2-positive patients, anti-CarP FCS and anti-CarP Fib were also positive in 78/ 197 (39.59%) and 87/ 197 (44.16%) patients, respectively. Likewise, among anti-CCP3-positive patients, they were positive in 82/ 202 (40.59%) and 87/ 202 (43.07%) of the patients, respectively. Several patients were negative for anti-CCP but positive for anti-CarP: 4/ 258 (1.55%) of the patients were anti-CCP2-negative but anti-CarPFCS-positive; 1/ 258 (0.39%) and 1/ 258 (0.39%) of the patients were anti-CCP3-negative but anti-CarP FCS-positive and anti-CarP Fib-positive, respectively. Radiographic progression as measured by using SHS in the patients positive for anti-CCP3 antibody alone was 10.02±11.48 (n=88), those positive for anti-CCP3 and for either anti-CarP FCS or anti-CarP Fib was 9.45±10.80 (n=61), and those positive for anti-CCP3 and both anti-CarP FCS and anti-CarP Fib antibodies was 36.55±9.25 (n=53); the values statistically significant as compared with 4.57±8.97 of those all negative for anti-CCP3 and anti-CarP antibodies (n=66) at p=0.001, 0.006 and 0.0007, respectively. Radiographic progression depended on the presence, but not the titer, of anti-CCP2, anti-CCP3, anti-CarP FCS and anti-CarP Fib antibodies at baseline.

Conclusion: Anti-CarP antibodies are present in a substantial fraction of Japanese patients with RA to the extent similar to previous findings in Europe.

Clinical Characteristics Of Rheumatoid Factor-Positive Or Negative Subsets Of Anti-Citrullinated Peptide/Protein Antibody-Negative Rheumatoid Arthritis. Ryosuke Hiwa, Koichiro Ohmura, Noriyuki Yamakawa, Moritoshi Furu, Chikashi Terao, Ran Nakashima, Yoshitaka Imura, Naoichiro Yukawa, Hajime Yoshifuji, Motomu Hashimoto, Hiromu Ito, Takao Fujii and Tsuneyo Mimori. Graduate School of Medicine, Kyoto University, Kyoto, Japan.

Background/Purpose: Although anti-citrullinated peptide/protein antibody (ACPA) is a specific autoantibody for rheumatoid arthritis (RA), ~20% of RA are ACPA negative. It has been reported that ACPA(−) RA is a distinct subset clinically and genetically; radiographic progression is more severe in ACPA(+) RA and HLA-DR shared epitope is not associated with ACPA(−) RA. Recently we further subdivided ACPA(−) RA into rheumatoid factor (RF) positive and negative subsets and showed that HLA usage is different between ACPA(−)RF(+) RA and ACPA(−)RF(−) RA. Here we investigated the clinical characteristics of each subset.

Methods: RA patients were registered in the KURAMA cohort from May 2011 through May 2013 at Kyoto University Hospital and all the patients were Japanese. Titer of ACPA in sera or plasma was measured with the 2nd generation anti-CCP antibody ELISA kit. RF were measured with latex agglutination turbidimetric immunoassay. A patient was considered to be RF-negative when all the available tests were negative for RF. Age, sex, distribution of affected joints, positivity of anti-nuclear antibody (ANA), disease activity and treatment were assessed. Van der Heijde modified Sharp score (mTSS) of hands & feet X-ray films were scored by two evaluators.

Results: 84 out of 451 RA patients were negative for ACPA. In the ACPA negative group, 43 were positive for RF and 41 were RF-negative. There were significantly more women in RF-positive subset compared to RF-negative (88.4% and 70.7%, respectively). Distribution of affected joints and positivity of ANA, disease activity (DAS28-ESR, SDAI) were similar among the two subsets. Administration of methotrexate, oral glucocorticoid and biologic DMARDs were also similar. The mean of mTSS divided by the disease duration (mTSS/Y) of RF-positive subset were greater than RF-negative subset although there was no statistically significant difference (9.81±1.00 and 8.88±9.62, respectively). The other results were shown in table 1.

Table 1. Clinical characteristics of ACPA(−)RF(+) RA and ACPA(−)RF(−) RA

	ACPA(−)RF(+)	ACPA(−)RF(−)	P value
N	43	41	
Age	62.67 ± 12.85	65.20 ± 13.80	0.19
Women	38 (88.4%)	29 (70.7%)	0.044
Disease duration (M)	152.98 ± 175.93	111.02 ± 146.39	0.88
ANA ≥ 1:80	17 (39.5%)	12 (29.3%)	0.32
DAS28-ESR	4.02 ± 1.44	3.50 ± 1.17	0.62
SDAI	12.83 ± 9.77	13.80 ± 10.15	0.34
MTX dose (mg/w)	6.09 ± 2.27	6.24 ± 2.91	0.43
PSL dose (mg/d)	4.56 ± 2.72	5.73 ± 3.39	0.15
Biologic DMARDs	2 (4.65%)	2 (4.88%)	0.67
mTSS/Y*	9.81 ± 1.00	8.88 ± 9.62	0.65

*mTSS were evaluated for 35 ACPA(−)RF(+) and 28 ACPA(−)RF(−) RA patients.

Conclusion: Although ACPA(−)RF(+) RA and ACPA(−)RF(−) RA are genetically distinct, there seems to be no substantial clinical differences between those two subsets.

Follow-Up Of Patients With Preclinical Rheumatoid Arthritis – Results Of a Telephone Survey. Pascal Klaus, Vivien Köhler, Hans Bastian, Tanja Braun, Eva Gremmelsbacher, Vera Höhne-Zimmer, Frank Buttgereit, Gerd R. Burmester and Jacqueline Detert. Charité - Universitätsmedizin Berlin, Berlin, Germany.

Background/Purpose: Preclinical rheumatoid arthritis (pre-RA) describes a subset of patients with arthralgia (but no synovitis) where either anti-citrullinated peptide antibodies (ACPA) and/or rheumatoid factor (RF) can be found, but without clinical synovitis, where there was no evidence of clinical RA, and no disease-modifying anti-rheumatic drug (DMARD) therapy was initiated. Recent data indicate that 35% of these patients develop arthritis after 12 months (van de Stadt et al, 2012). The objective of this investigation was to follow the course of disease in patients with pre-RA by means of a telephone survey, and evaluate how many patients develop clinical RA.

Methods: In a retrospective analysis, we identified patients with pre-RA who presented in the early arthritis clinic (EAC) of the Department for Rheumatology and Clinical Immunology of Charité – Universitätsmedizin Berlin between 2004 and 2011. All patient had given written consent to be contacted in the future. Approval from the local ethics committee was present. All patients were called who were in our EAC at least 12 months ago. The follow-up questionnaire included questions about tender and swollen joints, overall pain, current antirheumatic therapy, and whether a diagnosis of RA has been established. Descriptive statistical analysis was performed using SPSS.

Results: 47 patients (pts) with pre-RA out of 1,400 pts of our EAC (3.4%) were identified. 23 of these pts (49%) agreed to participate in the telephone survey. 14 (61%) pts were female. The mean age was 54 (standard deviation (SD) ± 15) years. Mean duration between first contact in EAC and follow-up was 6 (SD ± 2) years. RF >20 U/ml was present in 20 pts (87%) with a mean serum level of 86 ± 144 U/ml in RF positive pts, ACPA >20 U/ml ± were present in 7 pts (30%) with a mean serum level of 28 ± 68 U/ml. RF and ACPA were simultaneously present in 4 pts (17%).

When asked about the course of their symptoms including joint pain and joint swelling, 5 pts (22%) stated that they were now free of complaints, in 10 pts (44%) complaints were improved, in 5 (22%) they were unchanged, in 3 (13%) they had reappeared, and in none of the pts (0%) had complaints deteriorated.

3 pts (13%) developed clinical RA after a duration of 1, 3, and 6 years, respectively. These 3 pts are currently taking DMARD therapy (2 Methotrexate, 1 Leflunomide). 2 of these patients are RF positive (serum level 33 and 74 U/ml, respectively), 1 patient is ACPA positive (70 U/ml). None of the patients are double positive.

Conclusion: The overall risk of developing clinical RA in this cohort of pre-RA patients was low (13%). Serum levels of RF or ACPA were not predictive for the development of RA, and neither was double positive antibody status associated with a higher risk for RA. Large prospective cohorts are needed to confirm these findings.

Influence Of Disease Activity On The Physical Activity Of Rheumatoid Arthritis Patients. Vanesa Hernández-Hernández, Ivan Ferraz-Amaro, Esmeralda Delgado-Frías, Sagrario Bustabad-Reyes and Federico Diaz-Gonzalez. Hospital Universitario de Canarias, La Laguna, Spain.

Background/Purpose: It is generally assumed that rheumatoid arthritis (RA) patients tend to exercise less than what is currently recommended. However, there is little data on the level of daily PA in RA patients vs. to healthy controls, using objective procedures, such as accelerometry. Moreover, there remain two important unanswered questions concerning PA vis-à-vis RA: 1) Do patients who are sufficiently physically active suffer from less severe disease? and viceversa, 2) Does disease activity influence PA in RA patients?. With regard to the former, there is considerably more evidence in favor of prescribing PA for RA patients than there is against. However, there is currently no evidence that decisively answers the latter.

The purposes of this study were to compare PA in a group of RA patients versus healthy controls through both objective (triaxial accelerometry) and subjective (International Physical Activity Questionnaire- IPAQ) methods, and to explore the impact of disease levels on PA in these patients. We also sought to determine the potential role of PA assessment as a measure of RA disease activity.

Methods: A group of 50 RA patients and 50 age-and sex-matched healthy controls were included in this cross-sectional study. PA was assessed by accelerometry and with the IPAQ. We performed multiple regression analysis not only to compare PA between groups, but also to explore the relation between RA features, including disease activity and cardiovascular risk parameters, and PA. In a randomized group of 30 RA patients a test/re-test study was carried out in order to determine the correlation between variations in disease activity and PA.

Results: The number of minutes of moderate and vigorous activity/day, as evaluated by accelerometry and adjusted for sex, age, work activity was significantly lower in RA patients than in healthy controls (23±16 vs 33±27 min/day, p=0.02). In RA patients, accelerometry and IPAQ demonstrated concordance to a moderate degree (quadratic weighed Kappa index of 0.27 [0.06–0.48], p=0.02). HAQ negatively correlated with both IPAQ and accelerometry data (beta coef. −1623 (−2742– −503) MET/min/week, p=0.00; beta coef −43 (−81– −6.46) counts/min, p 0.02). DAS28-CRP was also inversely related with IPAQ. Framinghan score and metabolic syndrome were inversely associated with PA in RA patients. Interestingly, variations in PA, as measured by accelerometry, inversely correlated with RA disease activity (r:−0.42, p= 0.02), particularly in the patient group that exhibited changes in DAS28 consistent with an RA flare or improvement.

Conclusion: In RA patients, accelerometry is a reliable technique to evaluate PA. Not only showed that RA patients spend less time doing moderate and vigorous PA than healthy controls, but also PA, as assessed by accelerometry, was sensitive to any changes in disease activity.

2306

Comparative Study Of Patients With Peripheral Psoriatic Arthritis, Axial Psoriatic Arthritis and Axial Spondyloarthritis Without Psoriasis. Abhijeet Danve[1], Neha Garg[2] and Atul Deodhar[1]. [1]Oregon Health and Science University, Portland, OR, [2]Oregon Health and Sciences University, Portland, OR.

Background/Purpose: Axial involvement in Psoriatic Arthritis (PsA) is reported to be between 40 –70%. Both, axial and peripheral arthritis in patients with PsA can cause unique functional challenges and can reduce quality of life substantially. We aimed to compare the disease characteristics and quality of life (QoL) in three groups of patients: PsA with axial involvement (PsAax), PsA with only peripheral disease (PsApr), and axial spondyloarthritis patients without psoriasis (axSpA).

Methods: Patients with new diagnosis of PsAax seen at Oregon Health & Sciences University between 2007 and 2012 were identified by searching electronic medical records. Age and sex matched patients with PsApr and axSpA without psoriasis were identified. Demographic and clinical data was collected retrospectively. Disease activity and QoL was measured using validated measures such as RAPID 3 and BASDAI. Statistical significance was calculated using Mann-Whitney, Chi square and Fisher's exact tests as applicable.

Results: We found 28 patients with PsAax, who were compared with age and sex matched patients with PsApr (n=26) and axSpA without psoriasis (n=29) respectively. Disease duration, BMI, BASDAI and RAPID 3 scores were similar among three groups (see Table). Smokers were more prevalent in PsAPr than axSpA patients (p = 0.05). PsAax patients had more peripheral arthritis and uveitis compared to axSpA patients (p = 0.01 for both). Prevalence of depression was more in patients with psoriasis (PsAax and PsApr (about 40%) compared to axSpA (24%) but did not reach statistical significance. Prevalence of fibromyalgia, inflammatory bowel disease, mean ESR and CRP were similar in all three groups. More patients in axSpA group used NSAIDs compared to PsAax group (p = 0.05). DMARDs were used more often in patients with PsAax (p = 0.01) and PsApr (p = 0.01) than in axSpA. TNF blockers were used more often in PsAax than in axSpA group (p = 0.03).

	PsA with axial disease (PsAax) N =28 Mean (SD) or %	PsA peripheral (PsApr) N=26 Mean (SD) or %	Axial spondyloarthritis without psoriasis (axSpA) N=29 Mean (SD) or %
Age (years)	48 (14)	45 (14)	45 (13)
Females	57	62	55
Disease duration (years)	13 (13)	8 (9)	13 (13)
BMI (kg/m2)	29 (7)	31 (10)	30 (10)
Smoking	32	12*	34*
Peripheral arthritis	50∞	100	10∞
Uveitis	4∞	0*	31*∞
Depression	39	42	24
RAPID3	4 (2)	5 (2)	5 (2)
BASDAI	4 (1)	NA	5 (5)
NSAID use	17*	21	26*
DMARD use	68∞	85	17∞
Anti-TNF use	82*	77	55*

* $p < 0.05$
∞ $p = 0.01$
NA= Not applicable

Conclusion: In this comparative analysis of PsA patients with axial and peripheral disease and axSpA patients without psoriasis, PsAax patients had higher prevalence of peripheral arthritis compared to those with axSpA alone. Uveitis was less prevalent in PsAax and PsApr compared to axSpA patients. Depression was more prevalent in patients with psoriasis suggesting an important impact on QoL related to skin disease.

Disclosure: A. Danve, None; **N. Garg**, None; **A. Deodhar**, AbbVie, Merck-Sharp-Dohme, Pfizer and UCB, 5, AbbVie, Merck-Sharp-Dohme, Pfizer and UCB, 8, AbbVie, Amgen, Novartis, UCB, 2.

2307

Lifestyle Factors Were Seldom Discussed With Patients Visiting a Rheumatology Clinic. Ann B. I. Bremander and Stefan Bergman. Spenshult Research and Development Center, Halmstad, Sweden.

Background/Purpose: There is increasing evidence that lifestyle factors are of importance for outcome of rheumatic diseases, and lifestyle interventions should be a natural part of management.

The aim was to study if lifestyle factors (diet, physical activity, smoking and alcohol use) were discussed with patients on a regular visit to a specialized rheumatology clinic.

Methods: A questionnaire was distributed to 318 patients visiting an outpatient clinic, and 223 (70%) responded. The questionnaire assessed if lifestyle factors (diet, physical activity, smoking and alcohol use) were discussed at the visit. If not, it also assessed if the patients themselves felt that this discussion would have been desirable.

Results: The questionnaire was answered by 69 (31%) men and 154 (69%) women, and 69% were younger than 65 years. Diet was more frequently discussed with men (14.7% vs. 4.8%) although more women (11.6% vs 4.4%) would have desired it to be discussed. 83% of the patients did not consider that it was needed to discuss at all. Physical activity was discussed with 28% of the patients, without any significant difference between men and women. Only 8% of those not having this discussion thought that they needed it. Smoking was discussed with 15%, without any significant difference between men and women. Alcohol use was discussed

with more men than women (15.9% vs. 4.0%). Of those not having this discussion 3% of the women but none of the men thought that they needed it.

Conclusion: Although recommended as part of management, lifestyle factors are seldom discussed with the patients, and this discussion is not actively thought for by the patients. Lifestyle factors are more frequently discussed with men although women would have desired to have this discussion to a higher extent. There is a need for health care to actively take the initiative and discuss lifestyle as part of regular care.

2308

Rheumatoid Arthritis Flares: Inflammatory Or Avalanche? Caroline A. Flurey[1], Marianne Morris[1], Jon Pollock[1], Rodney A. Hughes[2], Pamela Richards[3] and Sarah Hewlett[1]. [1]University of the West of England, Bristol, United Kingdom, [2]St. Peters Hospital, Chertsey Surrey, United Kingdom, [3]University of Bristol, Bristol, United Kingdom.

Background/Purpose: Previous research has not addressed how RA patients' symptoms change daily. The aim of this study was to explore symptom patterns during daily life and flare.

Methods: RA patients completed self-reported NRS (0–10) of pain, fatigue, swollen joints, stiffness, anger, frustration, worry and flare status (yes/no) daily for 3 months either on paper or online. This was an exploratory study and therefore not powered for statistical significance. Data were analysed for descriptive statistics and visually analysed with the use of graphs to identify symptom patterns.

Results: 28 patients took part: 5 withdrew, 6 had missing data for >10/91 days. The 17 patients included in the analysis were 15 female, mean age: 62.9yrs, disease duration: 18.6yrs, HAQ: 1.86.

On plotting the symptoms onto graphs, 3 patients reported constant flare for 91 days (constant flare group), 6 patients self-reported ≥1 flare with periods of non-flare (intermittent flare group) and 8 patients did not report being in a flare (daily life group).

As expected, the group means of the individual symptoms were highest in the constant flare group and lowest in the daily life group. In the daily life group, patients' individual mean pain scores ranged from 0.2 to 5.8, whereas in the intermittent flare group patients' individual mean pain scores ranged from 2.5 to 7.0 and in the constant flare group patients' individual mean pain scores ranged from 2.4 to 9.3. Thus some individual patients reported lower mean pain in flare than other patients reported on non-flare days, this was also the case with the other self-reported measures (see Table 1).

Table 1. Mean symptom scores for the three different trajectories

		Pain	Fatigue	Stiffness	Swollen Joints	Frustration	Anger	Worry
Constant Flare Group	Group Mean (SD)	4.3 (2.7)	4.7 (2.7)	3.6 (2.6)	3.9 (2.6)	3.7 (2.9)	3.1 (3.3)	3.7 (3.1)
	Lowest Individual Patient Mean	2.4 (1.3)	4.4 (2.1)	2.3 (1.5	2.2 (1.4)	1.1 (1.3)	0.7 (0.9)	0.6 (0.9)
	Highest Individual Patient Mean	9.3 (0.8)	9.3 (0.7)	9.5 (0.8)	9.5 (0.7)	9.0 (0.7)	8.9 (0.7)	8.9 (0.7)
Intermittent Flare Group	Group Mean	4.8 (2.3)	4.9 (2.0)	4.0 (2.1)	4.4 (2.1)	4.1 (2.2)	3.1 (2.6)	4.3 (2.4)
	Lowest Individual Patient Mean	2.5 (1.2)	2.7 (1.2)	1.7 (0.7)	2.3 (0.8)	2.1 (0.7)	0.0 (0.1)	1.9 (0.8)
	Highest Individual Patient Mean	7.0 (0.6)	7.4 (1.0)	6.2 (1.1)	6.5 (0.9)	6.3 (1.2)	5.7 (1.3)	7.8 (1.2)
Daily Life Group	Group Mean	3.1 (2.3)	3.6 (2.6)	2.4 (1.5)	2.7 (1.9)	2.8 (2.9)	2.2 (3.3)	2.7 (3.1)
	Lowest Individual Patient Mean	0.2 (0.5)	0.4 (0.9)	0.3 (0.7)	0.5 (0.9)	0.0 (0.0)	0.0 (0.0)	0.0 (0.0)
	Highest Individual Patient Mean	5.8 (2.2)	7.6 (2.0)	4.8 (1.6)	6.5 (1.6)	8.7 (0.7)	9.2 (0.7)	9.4 (0.6)

Further 5/6 patients in the intermittent flare group rated their symptoms as more severe on non-flare days than on days in flare. Thus patients may be using different criteria other than symptoms to decide whether they are in a flare.

Whilst many patients report traditional 'Inflammatory Flare' of symptoms, other patients may be reporting flare based on experiencing overall loss of control in their lives and thus defining their overall disease activity as more severe (in flare) despite individual symptoms being less severe. The term 'Avalanche Flare' is proposed for this cascading effect of life.

Conclusion: Definitions of flare vary within and between patients and may not be defined by symptom severity alone. Clinicians need to be aware that patients use 'flare' to explain a range of experiences. Understanding the terminology is necessary to improve communication and inform treatment decisions.

2309

Quantifying The Gap Between General Population Guidelines and Expert Opinion For Cardiovascular Risk Management In Rheumatic Disease Patients. Katherine P. Liao[1], Jonathan Brown[1], Jonathan S. Coblyn[1], Paul Cohen[1], Jorge Plutzky[1] and Daniel H. Solomon[2]. [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA.

Background/Purpose: Cardiovascular (CV) risk is higher among rheumatic disease patients than the general population. However, CV risk management guidelines calibrated for the rheumatic disease population do not currently exist. At our academic medical center, we recently established an interdisciplinary Cardiovascular Rheumatology clinic aimed at optimizing CV care. The objective of this study was to characterize and quantify the change in management recommended for rheumatic disease patients after formal evaluation by cardiologists.

Methods: We studied patients referred to the CV Rheumatology clinic for cardiovascular risk assessment from January 2012 when the clinic began to April 2013. The clinic is held once a month in the rheumatology clinic with patients referred from the rheumatology practice, staffed by 3 board certified cardiologists. Patient demographic information was obtained from the medical record. CV risk factors and change in management was assessed by manual chart review of cardiologists' notes. The following were considered changes in management: (1) change in medication therapy (defined as starting, increasing dose, or switching CV related medications); or (2) further work-up to assess risk (e.g. further laboratory studies to stratify CV risk, stress testing or referral to a cardiac subspecialty). The Adult Treatment Panel III (ATP III) Guidelines were applied to the subset of subjects who were recommended to start or increase statin dose. The ATP III Guidelines specifies low density lipoprotein (LDL) goal levels for patients based on number of traditional CV risk factors and 10 year risk for heart disease according to the Framingham Risk Score.

Results: We studied 31 patients referred for CV risk assessment. The mean age was 57 yrs and 77% were female. The most common underlying rheumatic diseases in the CVR clinic were RA (38.7%) and SLE (25.8%). Hypertension (51.6%) was the most prevalent CV risk factor at presentation, followed by hyperlipidemia (45.2%). Of the patients seen, 83.9% were recommended a change in their current CV management. The most commonly recommended change or intervention was starting or increasing statin therapy (35.5%), change in anti-HTN therapy (16.1%) or stress testing (12.9%). Among the subjects recommended to start or intensify statin therapy, 63.6% would have been considered already at target LDL according to ATP III Guidelines.

Conclusion: We observed that the majority of rheumatic disease patients referred to the CV Rheumatology clinic had a change in CV risk management after evaluation by a cardiologist. Recommended LDL targets by cardiologists at our center were lower than ATP III guidelines, leading to intensification of statin therapy. These data suggest a need for CV risk management optimization in patients with rheumatic diseases.

Nurse Training; Confidence and Competence For Educating Patients Commencing *Methotrexate* Therapy. Sandra M. Robinson[1], Andrew Hassell[2], Sarah Ryan[3], Nicola Adams[4], Peta S. Heslop[1] and David Walker[5]. [1]North Tyneside General Hospital, North Shields, United Kingdom, [2]School of Medicine (Keele Campus), Keele, United Kingdom, [3]Keele University, Staffordshire, United Kingdom, [4]Northumbria University, Newcastle Upon Tyne, United Kingdom, [5]Freeman Hospital, Newcastle Upon Tyne, United Kingdom.

Background/Purpose: The education of patients is a central part of the nursing role in the UK. Nowhere is it more important than in relation to drugs such as methotrexate, where the effect is delayed and side effects are anticipated. Nurses had expressed variable confidence in educating patients starting *Methotrexate* and training for this varied from none, some training and observing other nurses to being observed. We were interested to explore this with a survey of nurses who educate patients starting *Methotrexate*. These are the results from the respondents.

Methods: A survey was designed using an online survey tool around questions about their role; training; confidence and we used multiple choice questions on clinical situations testing knowledge. A web link to the survey was sent to possible participants with encouragement to spread the link to colleagues.

Results: 44 nurses completed the online questionnaire. 70% were nurse specialists and 30% monitoring nurses. 62% had been counselling for more than 5 years.

Training: 17% had no training prior to starting this role. 66% described it as some training and 17% as a lot. For those who had training, 55% described it as very helpful and 45% as less than helpful. 61% expressed that they would have liked more training. Ranking training requirements, respondents rated knowledge highest followed by communication then consultation skills and finally experience.

Confidence: 60% of respondents described themselves as very confident in this role, with 23% confident and 15% somewhat confident. One person was not confident at all. 43% reported that their education of patients had changed a lot and 50% reported that this had changed somewhat while they had been performing the role. The time it took to become confident in the role was variable with 10% confident in 1–2months, 53% in 3–6 months and a further 20% by a year.

Competence: This was tested with MCQs on clinical situations. There was 90–100% accurate response to questions about vaccinations, antibiotics and liver function. Questions on pregnancy and alcohol, however, scored approximately 50% for complete accuracy. A question on Shingles was not well understood. A variety of written information was used in the education processs, this information was often used together. The Arthritis Research UK information sheet was used by 80% and judged to be very helpful.

Conclusion: The nurses included in this survey show a great variation in the training they had prior to starting this role with those nurses performing the role for the longest period of time having had the least training. The majority would like more training. Most respondents took 3–12 months to feel confident in this role. A training package aimed at satisfying these aspirations could shorten this period and result in better and more consistent education for patients. This should result in improved concordance and safety of treatment.

Impact Of Healing Architecture In a Rheumatology Outpatient Clinic. Gunhild Bukh[1], Erik Kehn Jensen[2], Anne Marie Munk Tommerup[3] and Ole Rintek Madsen[4]. [1]Copenhagen University Hospital Gentofte, Hellerup, Denmark, [2]Kehn & Warnøe, Copenhagen, Denmark, [3]Danish Architecture Centre, Copenhagen, Denmark, [4]Copenhagen University Hospital Gentofte, Copenhagen, Denmark.

Background/Purpose: Healing Architecture (HA) is a design concept primarily aimed at reducing factors of stress in the physical environment both for the patient and for the medical staff. HA works through modifications of the physical environment and the practical functionality of the room. HA has the long term goal of achieving measurable improvements on economy, ressources, productivity and user/staff satisfaction. The study objective was to examine whether the application of HA principles in an outpatient infusion room for treatment with biologic agents used in treatments of rheumatologic diseases would impact patient experience and ultimately improve patient satisfaction as well as work satisfaction of attending nurses.

Methods: A water wall making silent bobbles were installed in the infusion room in order to increase the stimulation of the senses and to improve relaxation. Artificial plants were introduced. Decorative art paintings substituted existing disease information related wall posters. The functionality of the room was improved by changing the layout of the seating and arrangement of infusion pumps. New ergonomic chairs were installed and for each chair a small table dedicated to the individual patient was provided. Furthermore, individual reading lamps were mounted for the allowing each patient to individually regulate the light. A high table was positioned in the center of the room with coffee, tea and water. In order to de-hospitalize the room all new furniture were similar in appearance and quality to what would be used at home. A questionnaire was designed to quantify the experience of the attending patients on 16 different parameters before and after application of HA modifications. The questionnaire, administered before and after the HA intervention recorded two sets of scores for each parameter: One set scored the perceived patient experience of each parameter. The other set scored the perceived importance of each parameter. A calculated combination of the two scores provided a composite score of the satisfaction with each parameter experienced (range 0–130). The change in the total composite patient satisfaction score before and after re-modeling of the treatment room was evaluated. In addition to this quantitative research, a total of four patients and nurses underwent a qualitative interview before and after the HA intervention.

Results: 43 patients completed a questionnaire before and after the HA intervention. Mean age was 54 $\pm$ 12 years, mean disease duration 13 $\pm$ 10 years, mean treatment duration 23 $\pm$ 8 months. The total score before and after the intervention was 56.6 $\pm$ 16.5 and 71.8 $\pm$ 19.2, respectively ($p<0.001$). Both nurses and patients reported highly positive attitudes regarding the HA modifications.

Conclusion: The study confirmed that the principles of HA significantly can increase patient satisfaction. The quantitative findings were supported by qualitative research, which demonstrated both increased patient satisfaction and increased satisfaction for the attending nurses.

Experiences Of Older People Living With Ankylosing Spondylitis. Jane Martindale, Elham Kashefi and Lynne Goodacre. Lancaster University, Lancaster, United Kingdom.

Background/Purpose: With an increasing demographic of ageing, more people may be living longer with a long-term health condition. There may be implications in terms of the knowledge, skills and expertise patients living with AS need to develop to manage their symptoms as they age. Our aim was to develop a greater understanding of the experience of ageing with AS and the needs of older people living with this condition.

Methods: Ethical approval was obtained for a qualitative study embedded within a longitudinal cohort study exploring the needs of people living with AS throughout the life course. Patients over 60 years were recruited from two Rheumatology outpatient clinics in the UK. Six focus groups were conducted to explore participants' experiences through peer group discussion. The groups were recorded and transcribed. Transcripts were coded and a thematic analysis was conducted using NVIVO 10.

Results: Four women and 28 men consented to participate; average age 68 years (range 60–83). Eight participants were on biologics. Six participants were still in employment. Analysis identified 5 key themes: 1. 'It doesn't go away" describes how AS remains active as people age with continuing functional and symptomatic challenges. Positive and negative aspects of the tendency to normalise symptoms were identified. 2. 'Wheels fall off after 60' describes participants' perceptions of their disease progression within the context of 'normal ageing'. Additionally, they describe how they no longer felt out of place in comparison to their peers. 3. 'Keep on pushing, keep on going' describes the challenges of maintaining motivation to remain active and the importance of a positive mental attitude. Monitoring, trust and support from health care professionals is seen as being an integral part of this theme. 4. 'Living a fulfilling life' describes how participants developed 'learnt expertise' and made active choices about how they managed their AS with its imposed restrictions. 5. 'Paying a price' describes the significant psychological, physical and financial consequences associated with living with AS on participants and their families.

Conclusion: As people living with AS make the transition into retirement, many aspire to live active lives whilst facing new challenges in relation to their lifestyles and priorities. However, ageing is often seen as a time of decline in physical and mental function. This coupled with a tendency to normalise symptoms highlights a continuing clinical need to monitor symptoms with an appreciation that the 'older person' faces some additional challenges. As well as monitoring, there is a need to offer tailored interventions to enable older people to remain active and to continue to lead the lives they choose within the context of an active and often debilitating condition.

Pain-Related Anxiety As a Barrier To Use Of Methotrexate In Rheumatoid Arthritis: Comparing Conventional Vial, Needles, and Syringe With An Investigational Auto-Injector In Healthy Volunteers. Victoria L. Ruffing[1] and Kaushik J. Dave[2]. [1]Johns Hopkins University, Baltimore, MD, [2]Antares Pharma Inc, Ewing, NJ.

Background/Purpose: Methotrexate (MTX) is the cornerstone of rheumatoid arthritis (RA) treatment. Limitations of systemic exposure of oral MTX can affect its efficacy. Subcutaneous (SC) MTX improves bioavailability, which may result in better efficacy, and tolerability. Self-administration of SC MTX via conventional vial, needle, syringe (VNS) is challenging for some patients due to functional limitations, injection-site adverse events (AEs), and especially anxiety associated with pain. Use of SC MTX is limited to <5% of patients in the U.S. An analysis of literature from 1982–2012 on patient perception and experiences with self-administered medication for multiple diseases (RA, diabetes, hepatitis, multiple sclerosis) also suggests that anxiety associated with pain when using conventional VNS is often a barrier to use. Improvements in the delivery of SC MTX may alleviate anxiety associated with pain. In this study, the prototype of an investigational, first-in-class auto-injector (AI) for MTX is evaluated.

Methods: This study compares administration-related pain and bleeding in healthy volunteers using conventional VNS and AI. 21 volunteers received 12 injections (6 with AI; 6 with VNS) of 1.0 mL saline administered by study personnel according to a randomized schedule. Pain was measured on a 20-point scale ranging from 0 (no pain) to 19 (extremely intense pain). Injection site bleeding was also assessed.

Results: Pain was rated as none or faint for 78.4% of 125 AI administrations and 59.7% for 129 injections with VNS (Fishers Exact Text, P=0.0017). In addition, no pain was reported for 56.0% of AI administrations vs. 34.9% with VNS (P=0.0010) (Table). No pain scores >10 were reported for either treatment. No bleeding was observed in 89.7% of AI administrations vs. 79.2% of those with VNS (P=0.0069).

Table. Pain scores

Pain Score	Auto-injector (n=125) %	VNS (n=129) %
0	56.0	34.9
1	22.4	24.8
2	6.4	6.2
3	5.6	17.0
4	3.2	6.2
5	2.4	3.9
6	0.8	1.5
7	2.4	2.3
8	0	2.3
9	0	0.8
10	0.8	0
>10	0	0

Conclusion: Pain-related patient anxiety often associated with SC administration of medications is a potential cause for underutilization of SC MTX in the treatment of RA. By decreasing pain associated with self-injection, an AI may address issues of needle phobia and improve rates of utilization of SC MTX in patients who may benefit from this method of delivery.

Reducing The Need For Total Knee Arthroplasty: The Experience Of a Multidisciplinary Osteoarthritis Clinic. Caroline Jones[1], Angelo Papachristos[1] and Laurence A. Rubin[2]. [1]St Michael's Hospital, Toronto, ON, [2]St. Michael Hospital, Toronto, ON.

Background/Purpose: St. Michael's Hospital (SMH) is a tertiary care facility located in Toronto, serving a diverse social, economic and cultural urban population. In 2008, a multidisciplinary osteoarthritis (MOA) clinic was established at SMH. The majority of referrals are received in the clinic from orthopaedic surgeons in patients contemplating knee replacement surgery. The team (Rheumatologist, Advanced Practitioner) designs and implements a comprehensive treatment plan.

Purpose: To complete a qualitative review of all of the patients who attended clinic and who subsequently went on to require a total knee arthroplasty.

Methods: A retrospective chart review was completed on all patients who attended the OA clinic between January 2011 and April 2012. During this time period there were 329 patients who attended clinic of which 24 went on to require a total knee arthroplasty (TKA). The charts of the patients who went on to a TKA were reviewed in detail and analyzed to determine if there are key criteria that determine who will subsequently elect to have a joint replacement. This project is designed as part of a continuous quality improvement initiative.

Results: In the 16 months that this data was obtained there was 329 patients who attended clinic of which 24 went on to require a total knee arthroplasty. All of the patients completed a WOMAC, an MDHAQ, x-rays as well as a complete physical exam. All of the patients had x-rays that demonstrated OA. The majority of patients had x-ray evidence of moderate to severe arthritis. Table showing the mean of results:

	General Cohort	Arthroplasty Group
WOMAC total, mean	41.3	49.8
MDHAQ pain	5.9	8
Global health	4.9	7
fatigue	4.8	5.4
ACR function	2	3

Discussion: The results from this project provide information with respect to actual clinical situations. A significant number of patients that attended the clinic had x-ray evidence of moderate to severe arthritis yet less than 10% went on to require an arthroplasty. There were some subtle differences between the two patient groups and it was the intent of this review to examine in more detail the criteria that patients feel is crucial in opting for surgical intervention.

Conclusion: The results show that the decision to proceed to surgery is multifactorial with pain and decreased function being the key criteria in patients' decision making process. Interestingly, patients who perceived their general health as negatively impacted were more likely to proceed with surgery.

Anti-Human TNF-Alpha Domain Antibody Construct, CEP-37247/ Placulumab, Is As Efficacious As Other Leading TNF-Alpha-Blockade Therapies in a Humanized Mouse Model of Rheumatoid Arthritis. Matthew M. Seavey[1], Linglong Zou[2], Adam Clarke[3], Anthony G. Doyle[3], Roberta Weiss[4], Aric Orbach[5], Brad McIntyre[6] and Merav Bassan[5]. [1]Teva Pharmaceuticals, Inc., West Chester, PA, [2]Teva Biopharmaceuticals, Rockville, MD, [3]Teva Pharmaceuticals, Inc., Sydney, Australia, [4]Teva Pharmaceuticals, Inc., Frazer, PA, [5]Teva Pharmaceuticals, Inc., Netanya, Israel, [6]Teva Pharmaceuticals, Inc., West Cheater, PA.

Background/Purpose: The cytokine tumor necrosis factor (TNF) alpha is a potent pro-inflammatory mediator involved in several autoimmune diseases including rheumatic arthritis and for over a decade has been a target of numerous biological therapies. CEP-37247 is a bivalent anti-TNF-alpha domain antibody (dAb) construct combining the antigen-recognition function of a dAb with the pharmacological advantages of human immunoglobulin-G Fc region. In order to assess

the therapeutic applicability of CEP-37247 in comparison to other marketed anti-TNF-alpha biologics, we performed head-to-head comparisons to approved reference agents in the well established human-TNF-alpha over expressing transgenic mouse model (Tg197) that develops spontaneous rheumatoid arthritis.

Methods: Symptomatic, arthritic animals were treated in a semi-therapeutic manner starting from week-3, at disease onset. Animals (N=8/group, male and female combined) were treated ip, twice weekly with either CEP-37247 at 30, 10, 3 or 0.3 mg/kg or reference agent Remicade at 10 or 3 mg/kg, Enbrel or Humira both at 10 mg/kg; untreated control included isotype Ab IgG_1at 10 mg/kg. Animals were monitored for changes in body weight and clinical disease score; end measurements included serum PK/PD and histopathology.

Results: CEP-37247 provided a dose dependent, and significant ($p<0.01$), effect on mean arthritic scores by week 10 of disease with 0.3 mg/kg providing an effect similar to isotype control. CEP-37247 at 30 mg/kg significantly reduced (85%, $p<0.001$) arthritic disease score of treated animals from onset until week 10 of age as compared to isotype control with no significant difference between dose matched groups of Remicade, Humira or Enbrel ($p>0.05$). Histopathology of blinded scored H+E stained sections revealed that the isotype control had extensive cartilage destruction, bone erosion and synovial infiltrates as expected from an untreated animal; CEP-37247 impact on joint pathology mirrored that of the disease score with 30, 10 and 3 mg/kg all providing significant reduction in damage and inflammation ($p<0.01$) below that of isotype control, however no difference in dose matched groups compared to reference agents. Serum CEP-37247 levels correlated with in vivo efficacy and ex vivo cytokine responses (e.g., reduction in IL-1-beta).

Conclusion: These data demonstrate the clear efficacy of a potent anti-human TNF-alpha domain antibody construct to suppress active disease in a humanized mouse model of rheumatoid arthritis as compared head-to-head against available anti-TNF-alpha therapies on the market. At half the size of a conventional Ab but with full functionality CEP-37247 may provide the benefits of lower cost of production, immunogenicity and improved tissue distribution.

Disclosure: M. M. Seavey, None; **L. Zou**, None; **A. Clarke**, None; **A. G. Doyle**, None; **R. Weiss**, None; **A. Orbach**, None; **B. McIntyre**, None; **M. Bassan**, None.

2317

Impact of PVA Coated Nanoparticles On Cellular Viability and Functionality of Immune Cells Obtained From Healthy Donors and Patients With Rheumatoid Arthritis Or Osteoarthritis. Cindy Strehl[1], Timo Gaber[1], Manuela Jakstadt[1], Martin Hahne[1], Saskia Schellmann[1], Barbara Szostak[1], Géraldine Coullerez[2], Heinrich Hofmann[2], Gerd-Rüdiger Burmester[3] and Frank Buttgereit[4]. [1]Charité University Medicine, Berlin, Germany, [2]École polytechnique fédérale de Lausanne, Lausanne, Switzerland, [3]Charite University Hospital, Berlin, Germany, [4]Charité - Universitätsmedizin Berlin, Berlin, Germany.

Background/Purpose: Nanotechnology has developed into a key technology of the 21st century. Over the recent years, the number of nanotechnical products has received an enormous boost. More and more efforts are currently being done to use this technology also in rheumatology for diagnostic and therapeutic purposes (see www.nanodiara.eu). Therefore, crucial questions concern the safety aspects. Thus, the focus of our work here was to identify putative effects of nanoparticles on human immune cell function. We analysed interactions between PVA coated super paramagnetic iron oxide nanoparticles (SPIONS) and human immune cells in the presence or absence of dexamethasone.

Methods: PBMCs were isolated from blood samples obtained from healthy donors, RA and OA patients, and CD4 positive T cells were separated via MACS-Sort. Cells were incubated in fully supplemented RPMI 1640 with/without dexamethasone treatment at the clinical relevant concentration 10^–8M. Functionalised amino-PVA-SPIONS were added at varying concentrations, and cells were incubated for 24h. Apoptosis was analysed by measuring the caspase-3/7-activity via luminescence. Caspase-3 and -7 are members of the cysteine aspartic acid-specific protease family, which play a key effector role in apoptosis in mammalian cells. Furthermore, CD4 positive T cells were incubated with/without PHA, with/without 10^–8M dexamethasone and/or with/without PVA-SPIONS at different concentrations. Functionality was determined via proliferation measurements of CFSE (carboxyfluorescein diacetatesuccinimidyl ester) labeled T cells after 72h under normoxic (5% CO_2 and 18% O_2) or hypoxic (5% CO_2 and <1% O_2) conditions by flow cytometry.

Results: Caspase measurements to investigate cellular toxicity of amino-PVA-SPIONS did not show any measurable effects on the survival of isolated CD4+ T cells (as already observed for whole blood assays) at concentrations less than 1000μg/ml. Interestingly, SPION-treatment with increasing concentrations in the presence of dexamethasone even resulted in a decrease of caspase activity indicating a diminished apoptosis of the CD4+ T cells in RA patients. Also in healthy donors a decrease of caspase activity with increasing SPION concentrations could be observed. Dexamethasone itself did not have any effects on caspase activity.

As expected, there was less proliferation under hypoxia than under normoxia; and treatment with dexamethasone decreased the percentage of divided cells for both RA patients and HD under normoxia and hypoxia. Focusing on the influence of dexamethasone on the T cell proliferation in the presence of PVA-SPIONS, we observed no difference in the impact of dexamethasone on proliferation.

Conclusion: PVA coated nanoparticles at concentrations up to 1000μg/ml do not interfere with effects of dexamethasone on proliferation and caspase-3/7-activity of human T cells. The impact of PVA-SPIONS on other human immune cells and on effects of glucocorticoids on these cells need to be further analyzed. This represents a critical need prior to the clinical use of nanoparticles in rheumatology.

Disease Activity in Moderate and Severe Rheumatoid Arthritis At Discontinuation in 10-Year Open-Label Extension Studies With Etanercept. Michael E. Weinblatt[1], Joan M. Bathon[2], Michele Hooper[3], Bojena Bitman[3], Yue Yang[4], David H. Collier[3], James Chung[5] and Mark C. Genovese[6]. [1]Brigham and Women's Hospital, Boston, MA, [2]Columbia University, New York, NY, [3]Amgen Inc., Thousand Oaks, CA, [4]Assent Consulting, South San Francisco, CA, [5]Amgen, Thousand Oaks, CA, [6]Stanford University, Palo Alto, CA.

Background/Purpose: Retention rates may be used as a surrogate of long-term effectiveness of drug therapy in open-label studies. Studies have reported that patients (pts) with moderate rheumatoid arthritis (RA) are more likely to achieve low disease activity or remission than pts with severe disease. We examined disease activity in pts who withdrew from long-term open-label extension (OLE) studies of etanercept (ETN) for reasons other than loss of efficacy (LOE) to see if they had lost drug response and whether response rates differed by baseline disease activity.

Methods: Data from pts with early RA (ERA) and long-standing RA (LRA) enrolled in OLE studies were analyzed. Using disease activity score with 28 joint count with CRP (DAS28-CRP) criteria, pts were categorized at baseline of the original study as having moderate (DAS28-CRP $\geq$3.2 and $\leq$5.1) or severe (DAS28-CRP >5.1) disease. In the original studies, ERA pts received methotrexate (MTX) or ETN monotherapy and LRA pts received ETN, MTX, ETN+MTX, or placebo. All pts received ETN in the OLE studies. For this analysis, DAS28-CRP was evaluated at the time of first efficacy measurement after patients initiated ETN (either parent study or OLE) as baseline and at study withdrawal. We compared DAS28-CRP in moderate and severe pts who had withdrawn for LOE or other reasons with pts who completed the OLE studies.

Results: Overall, 65.2% of ERA pts and 69.6% of LRA pts withdrew over the 10 years of the OLE studies. More pts withdrew for reasons other than LOE as listed by the investigator. Pts who withdrew for LOE showed no improvement in DAS28-CRP from baseline until last DAS28-CRP measurement (Table). Pts who withdrew for other reasons (eg, physician decision, protocol issues, patient refusal, others) had improved DAS28-CRP from baseline, but not as low as pts who completed the study. While DAS28-CRP scores in pts who withdrew for LOE were similar between moderate and severe pt groups, mean DAS28-CRP was lower in pts with moderate RA compared with pts with severe RA in both ERA and LRA pts at the time of withdrawal for reasons other than LOE and in the completer group.

Baseline and Last DAS28-CRP in Patients who Withdrew and Patients who Continued in Etanercept Clinical Trials by Withdrawal Category

	Moderate RA		Severe RA	
	n	Mean (SD)	n	Mean (SD)
ERA Patients				
MTX in original study, ETN in OLE				
Withdrew for LOE				
Baseline DAS28-CRP	4	4.81 (1.73)	7	4.48 (0.49)
Last DAS28-CRP	4	5.97 (0.98)	7	5.84 (1.14)
Withdrew for other reason (not AE)				
Baseline DAS28-CRP	13	3.50 (1.50)	47	4.39 (1.38)
Last DAS28-CRP	13	2.97 (0.91)	44	4.02 (1.64)
Continued to study closure				
Baseline DAS28-CRP	10	3.52 (1.72)	42	3.69 (1.37)
Last DAS28-CRP	10	2.55 (1.46)	42	2.73 (1.03)
ETN in original study, ETN in OLE				
Withdrew for LOE				
Baseline DAS28	6	4.63 (0.30)	29	6.37 (0.68)
Last DAS28	5	5.15 (1.70)	29	5.63 (1.52)
Withdrew for other reason (not AE)				
Baseline DAS28	34	4.50 (0.51)	118	6.45 (0.78)
Last DAS28	34	3.27 (1.43)	118	3.80 (1.50)
Continued to study closure				
Baseline DAS28-CRP	32	4.41 (0.46)	109	6.30 (0.74)
Last DAS28-CRP	31	2.50 (1.02)	108	2.79 (1.13)
LRA Patients				
Withdrew for LOE				
Baseline DAS28	8	4.61 (0.37)	69	6.66 (0.72)
Last DAS28	8	4.99 (1.30)	69	5.71 (1.27)
Withdrew for other reason (not AE)				
Baseline DAS28-CRP	35	4.59 (0.40)	143	6.55 (0.79)
Last DAS28-CRP	34	3.25 (1.35)	141	4.58 (1.44)
Continued to study closure				
Baseline DAS28-CRP	42	4.20 (0.98)	151	5.57 (1.51)
Last DAS28-CRP	41	2.51 (1.12)	149	2.77 (1.10)

ERA, early rheumatoid arthritis; LRA, long-standing rheumatoid arthritis; LOE, lack of efficacy; DAS28-CRP, Disease Activity Score using 28 joint count with CRP; AE, adverse events

Funded by Immunex, a wholly owned subsidiary of Amgen Inc. and by Wyeth.

Conclusion: ERA and LRA pts with moderate or severe disease who withdrew from ETN OLE studies for reasons other than LOE (the majority of pts) had a positive clinical response at the time of withdrawal so the overall withdrawal rate did not reflect lack of drug efficacy. Pts who withdraw from long-term studies for reasons other than LOE generally still demonstrate improvement over their baseline DAS28-CRP. Also, while ETN treatment is effective in ERA and LRA pts with moderate and severe disease, pts with moderate disease at baseline achieved lower DAS 28-scores than pts with severe disease.

2319

Comparative Safety Of Biological Agents Among Medicare Rheumatoid Arthritis Patients. Huifeng Yun[1], Fenglong Xie[1], Elizabeth S. Delzell[1], Lang Chen[1], Emily Levitan[1], James Lewis[2], Kenneth G. Saag[1], Timothy Beukelman[1], Kevin L. Winthrop[3], John Baddley[1], Paul M. Muntner[1] and Jeffrey R. Curtis[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Pennsylvania, Philadelphia, PA, [3]Oregon Health & Science University, Portland, OR.

Background/Purpose: Several new biologic disease-modifying antirheumatic drugs (DMARDs) have been approved for treatment of rheumatoid arthritis (RA) in United States. However, their comparative risks of serious infections are unclear. The objective of the current study is to determine if the risks of hospitalized infections associated with various biologics used for RA differs.

Methods: Using Medicare data from 2006–2011 for 100% of patients with RA, we identified new biologic users of etanercept, adalimumab, certolizumab, golimumab, infliximab, abatacept, rituximab and tocilizumab. New users were defined specific to each drug as no use of that therapy in the prior 12 month 'baseline' period. To increase homogeneity of patients for biologics typically not used as first line agents, patients were required to have used another biologic during baseline (i.e. they were 'switchers'). Eligible subjects were continuously enrolled in Medicare Parts A, B and D in baseline and throughout follow up. Follow up started from the drug initiation date and ended at the earliest date of: a hospitalized infection, 12 months after biologic initiation, a 30 day gap in current exposure, death, or loss of Medicare coverage. We identified hospitalized infection using inpatient physician diagnosis codes in primary or secondary position. Confounding was controlled through a person-specific infection risk score that was separately derived among biologic-naïve new users of anti-TNF and non-biologic DMARDs. We calculated the incidence rate of hospitalized infection for each biologic and compared their hospitalized infection risks during follow-up using Cox regression adjusting for infection risk score decile, disability status, glucocorticoids use during baseline, methotrexate use during baseline, most recent biologic during baseline and Medicaid eligibility.

Results: Of 29,776 new biologic switchers, 11.9% were exposed to etanercept, 15.0% adalimumab, 5.9% certolizumab, 4.3% golimumab, 12.3% infliximab, 29.0% abatacept, 14.9% rituximab and 6.4% tocilizumab. During follow-up, we identified 2,224 hospitalized infections yielding infection incidence rates from a low of 12.3 (abatacept) to a high of 17.4 (infliximab) per 100 person years across different biologics. After adjustment for potential cofounders, etanercept, infliximab and rituximab users had significantly higher hazard ratios of hospitalized infection compared to abatacept users. Adjusted HRs for all other drug-outcome comparisons were not significantly different from abatacept (table).

Table. Events, absolute incidence rate and adjusted hazard rate of hospitalized infection by different types of biologic exposures during follow-up

Biologic Exposures	Events	Incidence rate per 100 person years	Adjusted Hazard Ratio* (95% CI)
Abatacept	624	12.3	1.00 (Ref)
Adalimumab	278	13.8	1.10 (0.94 – 1.29)
Certolizumab	93	13.2	1.08 (0.86 – 1.35)
Etanercept	238	14.8	1.26 (1.08 – 1.48)
Golimumab	77	13.5	1.17 (0.91 – 1.49)
Infliximab	325	16.1	1.39 (1.19 – 1.61)
Rituximab	477	17.4	1.37 (1.20 – 1.55)
Tocilizumab	112	13.8	1.10 (0.89 – 1.36)

* Adjusted for infection risk score decile, steroid use during baseline, methotrexate use during baseline, recent biologic use during baseline, original reason for Medicare coverage and Medicaid eligibility.

Conclusion: Among RA patients with exposure to biologic therapies, etanercept, infliximab and rituximab were associated with a higher one year risk of serious infection compared to abatacept.

Ultrasonographic Monitoring Of Response To Infliximab In Patients With Rheumatoid Arthritis. Xiaomei Leng[1], Weiguo Xiao[2], Xiaochun Zhu[3], Zhonghui Xu[1], Wei Yu[1], Jing Lu[2], Jiakai Wang[2], Xiaoru Xia[3], Yongji Li[3], Yi Liu[4], Yi Zhao[4], Honghao Tang[4], Dongbao Zhao[5], Yeqing Shi[5], Huji Xu[6], Jun Bao[6], Lin Chen[6], Ling Lin[6], Ling Zhou[6], Guoqiang Chen[7], Weihong Zhang[7] and Yan Zhao[1]. [1]Peking Union Medical College Hospital, Beijing, China, [2]The First Hospital of China Medical University, Shenyang, China, [3]The First Hospital of Wenzhou Medical College, Wenzhou, China, [4]West China Hospital of Sichuan University, Chengdu, China, [5]Changhai Hospital of Shanghai, Shanghai, China, [6]Shanghai Changzheng Hospital, Shanghai, China, [7]The First People's Hospital of Foshan, Foshan, China.

Background/Purpose: To evaluate the efficacy of treatment with infliximab on joint inflammation and bone erosion in rheumatoid arthritis (RA) patients using ultrasonography.

Methods: 80 eligible subjects were enrolled from 7 sites. Subjects received infliximab 3 mg/kg IV infusion at 0, 2, 6 weeks, repeated every 8 weeks until 22 weeks. Endpoints included 7-joint and 12-joint ultrasound (US) synovitis scores at 22 weeks, and correlations between US scores and DAS28 (using CRP)/radiography (modified Sharp score (MSS)/van der Heijde scoring)/HAQ outcome. The 7 joints included those of the clinically dominant hand and foot: wrist, second and third metacarpophalangeal and proximal interphalangeal, and second and fifth metatarsophalangeal joints.

Results: The patients (81.25% women) had a mean age of 47.22Â± 14.27 years (meanÂ±SD). Baseline 7-joint and 12-joint synovitis scores were 22.35Â±11.67 and 42.09Â±29.64 in grayscale and power Doppler (GS+PD) US, 15.45Â±5.54 and 29.41Â±16.12 in GS US, and 6.90Â± 7.26 and 12.68Â±15.65 in PD US. At baseline, DAS28 was 5.73Â±1.05, MSS was 17.75Â±25.27, SDAI was 187.29Â±55.68, CDAI was 152.16Â±45.82, and HAQ score was 1.36Â±0.79. 64 patients (80.00%) completed all visits and 66 patients (82.50%) completed treatment for 22 weeks. After 22 weeks of therapy, 7-joint GS+PD US scores significantly decreased to 18.97Â±10.81 and the GS US and PD US scores significantly decreased to 11.98Â±6.42 (P<0.01) and 3.34Â±4.59 (P<0.01), respectively **(Figure)**. There were significant decreases in scores for 12-joint GS+PD US (28.47Â±20.93), GS US (22.65Â±15.19, P<0.01), PD US (5.82Â±8.17, P<0.01), DAS28 (3.20Â±1.31, P<0.01), SDAI (77.73Â±54.27), and CDAI (62.13Â±41.95). MSS increased (18.04Â±23.91, P>0.05) and HAQ score significantly decreased (0.56Â±0.61, P<0.01). There was a positive correlation between US scores and RA activity evaluation indexes, including DAS28, SDAI and CDAI (correlation coefficients 0.5535, 0.6364 and 0.5532) **(Table)**. 14 patients experienced an adverse event and 2 patients experienced a serious adverse event.

Figure. Ultrasonic total score contrast.

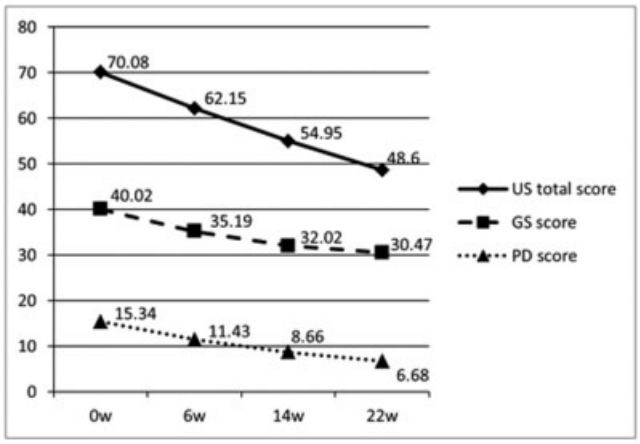

Table. Correlation between ultrasonic total score and DAS28.

Items	Correlation coefficient*	P-value
Baseline (0w)	0.3994	0.0005
6w	0.3975	0.0013
14W	0.4245	0.0007
22w	0.5535	0.0000

* Spearman rank correlation

Conclusion: In this study, treatment with TNF inhibitors relieved synovitis in patients with moderate to severe RA. US is a viable tool for examining patients with RA in daily practice because it significantly reflects therapeutic response. The 7-joint US synovitis score can be used for the evaluation of clinical efficacy in the clinic, instead of the 12-joint method. This trial showed that there is a positive correlation between US scores and DAS28. Large multicenter, prospective, randomized controlled studies are needed to confirm this preliminary observation.

Long-Term Safety and Efficacy Of Certolizumab Pegol In Combination With Methotrexate In The Treatment Of Rheumatoid Arthritis: 5-Year Results From a 24-Week Randomized Controlled Trial and Open-Label Extension Study.

Josef S. Smolen[1], Ronald van Vollenhoven[2], Arthur Kavanaugh[3], Vibeke Strand[4], Jiri Vencovsky[5], Michael H. Schiff[6], Robert Landewé[7], Boulos Haraoui[8], Susan Walker[9] and Désirée van der Heijde[10]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]The Karolinska Institute, Stockholm, Sweden, [3]University of California San Diego, San Diego, CA, [4]Stanford University, Palo Alto, CA, [5]Institute of Rheumatology, Department of Clinical and Experimental Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [6]University of Colorado, Denver, CO, [7]Academic Medical Center Amsterdam & Atrium Medical Center, Heerlen, Netherlands, [8]Centre Hospitalier de l'Université de Montréal, Montreal, QC, [9]UCB Pharma, Raleigh, NC, [10]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: In the RAPID2 randomized controlled trial (RCT; NCT00160602), certolizumab pegol (CZP) +MTX every 2 weeks (Q2W) improved signs and symptoms of rheumatoid arthritis (RA) over 24 weeks (wks). Previous results demonstrated long-term safety and efficacy of CZP+MTX over 3 yrs in RAPID2 open-label extension (OLE).[2] We present the final report on long-term safety and efficacy of CZP+MTX over 5 yrs.

Methods: Eligible patients (pts) from RAPID2 RCT were treated in OLE (NCT00160641) with CZP 400mg Q2W, reduced to 200mg Q2W after ≥6 months, +MTX. Combined safety data from RCT and OLE are reported for all pts treated with ≥1 dose of CZP (N=612). AEs and SAEs were assessed at each visit following first dose of CZP. DAS28(ESR), HAQ-DI and ACR20/50/70 are presented to Wk232 for CZP Completers (pts who completed RCT and enrolled onto OLE [N=342]) and CZP ITT population (all pts randomized to CZP in RCT [N=492]). Change from baseline in modified Total Sharp Score (mTSS) and % of pts with radiographic non-progression (mTSS change from RCT baseline ≤0.5) are reported to Wk128 for CZP Completers. Dose reduction efficacy data is presented for all Wk24 CZP Completers who received CZP 400mg Q2W +MTX for ≥6 months in OLE, following which the CZP dose was reduced to 200mg Q2W over 132 wks of CZP exposure. Modified non-responder imputation (mNRI) was used for ACR responses; LOCF for continuous efficacy measures; mTSS data imputed by linear extrapolation.

Results: Of 492 pts treated with CZP+MTX, 355 (72%) completed the RCT and 342 entered OLE, of which 215 remained after 232 wks from RCT baseline. Safety profile was consistent with previous reports. Most frequent AEs (preferred terms) are reported (Table). 19 pts (3.1%) died (IR=0.82) (including 5 malignancies, 4 cardiac disorders, 4 nervous system disorders, 4 injuries). No new safety signals were identified. Clinical improvements from RCT were maintained to Wk232 in CZP Completers and ITT Population, respectively: mean DAS28(ESR), 3.7 and 3.9; mean HAQ-DI, 0.96 and 1.06; ACR20/50/70, 68.4%/47.1%/25.1% and 65.9%/45.4%/24.2%. Radiographic progression in CZP-treated pts was minimal (mean mTSS change from RCT baseline to Wk24: 0.62, from RCT baseline to Wk128: 0.79; % of pts with radiographic non-progression at Wk24: 84.6%, Wk128: 73.2%). Clinical improvements were maintained in the dose reduction population (400mg to 200mg Q2W +MTX; N=288) from the first CZP 200mg treatment (DAS28[ESR]=3.5) through 132 wks of CZP 200mg Q2W (DAS28[ESR]=3.6).

Table. Summary of AEs and SAEs in the RAPID 2 RCT and OLE (Safety Population; N = 612)

Adverse Event	No. of Pts (%)	Total number of events	Event rate per 100 pt-years	Incidence rate per 100 pt-years
Total AEs	546 (89.2)	3789	162.7	100.5
Infections and Infestations [a]	420 (68.6)	1257	54.0	38.7
Malignancies	18 (2.9)	19	0.8	0.8
Most frequent adverse events by preferred term (ER > 4.0 per 100 pt-yrs)				
Upper respiratory tract	93 (15.2)	154	6.6	4.4
Nasopharyngitis	67 (10.9)	101	4.3	3.1
Urinary tract infections	65 (10.6)	94	4.0	3.0
AEs leading to withdrawal	119 (19.4)	157	–	5.2
AEs leading to death	19 (3.1)	25	–	0.8
Total SAEs	219 (35.8)	364	15.6	11.3
Serious infections/ infestations [a]	90 (14.7)	105	4.5	4.1

[a] MedDRA system organ class. AE: Adverse Event; ER: Event Rate; SAE: Serious Adverse Event.

Conclusion: In pts with active RA despite MTX, CZP+MTX maintained reduction in signs and symptoms of RA with a favorable long-term risk-benefit ratio.

Post–Hoc Analysis Showing Better Clinical Response With The Loading Dose Of Certolizumab Pegol In Japanese Patients With Active Rheumatoid Arthritis. Tsutomu Takeuchi[1], Kazuhiko Yamamoto[2], Hisashi Yamanaka[3], Naoki Ishiguro[4], Yoshiya Tanaka[5], Katsumi Eguchi[6], Akira Watanabe[7], Hideki Origasa[8], Mariko Kobayashi[9], Toshiharu Shoji[9], Nobuyuki Miyasaka[10] and Takao Koike[11]. [1]Department of Rheumatology, Keio University, Tokyo, Japan, [2]Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [3]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [4]Nagoya Univeristy Graduate School of Medicine, Nagoya, Japan, [5]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [6]Sasebo City General Hospital, Sasebo, Nagasaki, Japan, [7]Tohoku University, Sendai, Japan, [8]University of Toyama School of Medicine, Toyama, Toyama, Japan, [9]UCB Pharma, Tokyo, Japan, [10]Tokyo Medical and Dental University, Tokyo, Japan, [11]NTT Sapporo Medical Center, Sapporo, Japan.

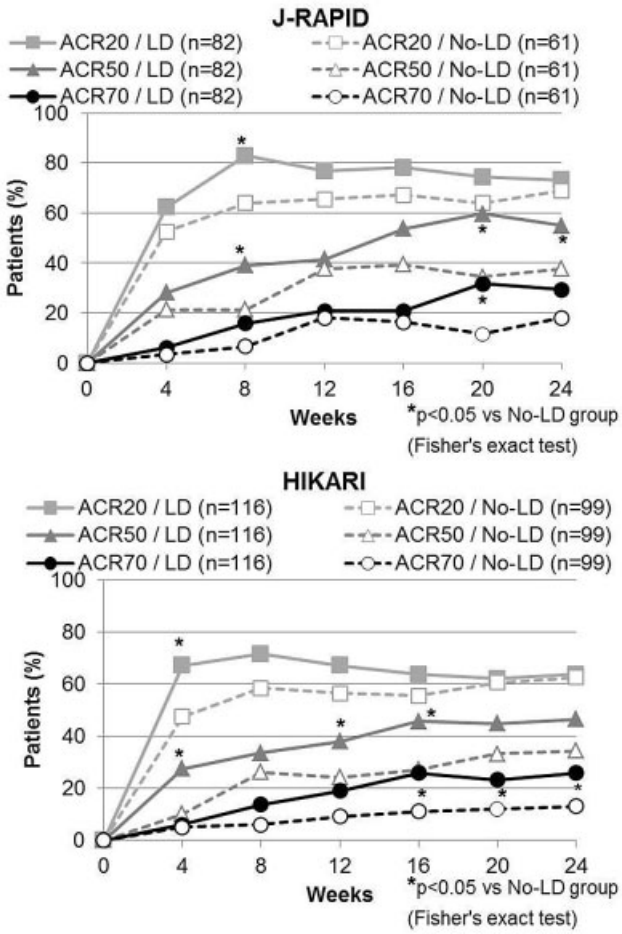
Background/Purpose: Certolizumab pegol (CZP) with MTX (J-RAPID; NCT00791999) and without MTX (HIKARI; NCT00791921) has demonstrated rapid and sustained improvements in disease activity in Japanese patients (pts) with active rheumatoid arthritis (RA) in placebo-controlled, double-blind (DB), randomized studies[1,2]. Based on these and previous studies, the recommended dose of CZP includes subcutaneous initial loading dose (LD) of 400mg at Weeks (wks) 0, 2 and 4 followed by 200mg every 2 wks (Q2W). Nevertheless, benefits of LD have never been directly demonstrated in a clinical study. We hereby report safety and efficacy of CZP, with and without LD, from two Japanese studies.

Methods: Data from J-RAPID and HIKARI were used for this analysis; pts eligible to enter open-label extension (OLE) studies at Wk16 or Wk24 received CZP 200mg Q2W or CZP 400mg Q4W without LD (label dose). In J-RAPID DB study, 316 pts were randomized to CZP 100, 200 or 400mg + MTX with initial LD or placebo + MTX Q2W for 24 wks. In HIKARI DB study, 230 pts were randomized to CZP 200mg with LD or placebo Q2W for 24 wks.

Safety and efficacy in pts who received CZP 200mg Q2W with LD during DB phases (LD group: n=82 J-RAPID; n=116 HIKARI) and pts who received CZP 200mg Q2W without LD during OLE phases after being assigned to placebo in DB phase (No-LD group: n=61 in J-RAPID; n=99 in HIKARI) were directly compared. Mean DAS28(ESR) in No-LD groups at OLE baseline were slightly lower than DB baseline (5.8 vs 6.5 J-RAPID; 6.2 vs 6.3 HIKARI). ACR response rates, DAS responses and development of anti-CZP antibodies (Abs) were assessed during 24 wks after initiating CZP. ACR responses were determined using non-responder imputation. Safety population consisted of 1) all pts who received CZP in DB (n=239), 2) LD group and 3) No-LD group. Adverse events were reported both within DB and OLE.

Results: No-LD group showed delayed initial kinetics of ACR20/50/70 responses and sustained lower response to Wk24 (ACR50/70) compared to LD group (Figure). Development of anti-CZP Abs was observed more frequently in No-LD group than LD group (J-RAPID: n=4 [6.6%] vs n=1 [1.2%]; HIKARI: n=27 [27.3%] vs n=18 [15.5%]). Similar safety profiles were reported between No-LD and LD groups during CZP administration period (incidence rates per 100 pt-years; any AEs: 299.2 vs 310.5 J-RAPID, 312.9 vs 308.6 HIKARI; any serious AEs: 17.9 vs 13.4 J-RAPID, 23.0 vs 21.5 HIKARI).

Figure: ACR20/50/70 response rates after CZP initiation



Conclusion: While comparison of DB and OLE data has limitations, administration of CZP loading dose over the first 24 wks is associated with more rapid onset of efficacy, development of lower Ab levels and sustained response compared with initiating CZP without loading dose. These results suggest administration of CZP loading dose improves clinical response in active RA pts with similar safety profile.

Comprehensive Disease Remission Achieved By Certolizumab Pegol Treatment, and Factors Associated With Certolizumab Pegol Comprehensive Disease Remission, In Rheumatoid Arthritis Patients With Predominantly High Disease Activity. Yoshiya Tanaka[1], Kazuhiko Yamamoto[2], Tsutomu Takeuchi[3], Hisashi Yamanaka[4], Naoki Ishiguro[5], Katsumi Eguchi[6], Akira Watanabe[7], Hideki Origasa[8], Tadao Okamoto[9], Yumiko Wada[9], Toshiharu Shoji[9], Nobuyuki Miyasaka[10] and Takao Koike[11]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]The University of Tokyo, Tokyo, Japan, [3]Keio University, Tokyo, Japan, [4]Tokyo Women's Medical University, Tokyo, Japan, [5]Nagoya University, Nagoya, Japan, [6]Sasebo City General Hospital, Sasebo, Japan, [7]Tohoku University, Sendai, Japan, [8]University of Toyama School of Medicine, Toyama, Toyama, Japan, [9]UCB Pharma, Tokyo, Japan, [10]Tokyo Medical and Dental University, Tokyo, Japan, [11]NTT Sapporo Medical Center, Sapporo, Japan.

Background/Purpose: The therapeutic goals of treating rheumatoid arthritis (RA) are clinical, structural and functional remissions.[1,2] Simultaneously achieving all three has been referred to as comprehensive disease remission (CDR). Certolizumab pegol (CZP) has demonstrated rapid and sustained improvement in disease activity and inhibition of structural damage in 2 double-blind (DB) trials, J-RAPID[3] (with MTX; NCT00791999) and HIKARI[4] (without MTX; NCT00791921), and in subsequent open-label extensions (OLE; NCT00851318 and NCT00850343, respectively) in Japanese patients (pts). This post-hoc analysis evaluated CDR achievement in RA pts with high baseline disease activity treated with CZP. Factors associated with CZP CDR at OLE Wk52 were also investigated.

Methods: CDR was defined as simultaneous achievement of DAS28 (ESR) ≤2.6 (DAS remission), HAQ-DI ≤0.5 (HAQ remission) and yearly change in (Δ) mTSS ≤0.5 (radiographic non-progression), while comprehensive disease control (CDC) was defined by substituting DAS28(ESR) <3.2 in CDR. CDC/CDR of CZP vs placebo (PBO), with and without MTX, were evaluated at Wk24 of DB trials on the full analysis set (FAS) population of CZP (200mg every 2 weeks [Q2W]; approved dose) and PBO groups in J-RAPID (CZP n=82, PBO n=77) and HIKARI (CZP n=116, PBO n=114). Additionally, CZP CDC/CDR were evaluated at OLE entry and Wk52 for DB CZP 200mg Q2W pts who entered OLE studies (J-RAPID n=74, HIKARI n=105; FAS). Factors associated with CZP CDC/CDR at OLE Wk52 were analyzed for all DB CZP pts, regardless of dose, who entered OLE (J-RAPID n=215, HIKARI n=105; FAS), using several Wk12 clinical response measures eg. DAS28(ESR) disease activity and HAQ.

Results: CDC and CDR at Wk24 of J-RAPID were 28.0% and 13.4% for CZP, and 5.2% and 0% fo PBO, respectively (Table). In HIKARI, 25.0% and 15.5% CZP pts achieved CDC and CDR at Wk24 vs 0% and 0% PBO pts, respectively. In HIKARI, CZP was shown to be similarly effective in attaining CDR as monotherapy (9/54, 16.7%) or with concomitant non-MTX DMARDs (9/62, 14.5%). CDC and CDR at OLE Wk52 were 37.8% and 24.3% in J-RAPID, and 28.6% and 21.9% in HIKARI, respectively (Table). Of pts with DAS remission at Wk12, 50% (14/28) and 50% (8/16) achieved CDR at OLE Wk52 in J-RAPID and HIKARI, respectively. Similarly, 35% (J-RAPID 43/124) and 31% (HIKARI 19/62) of pts with Wk12 HAQ remission achieved CDR at OLE Wk52.

Table Comprehensive Disease Remission (CDR) achieved by CZP With and Without MTX at Week 24 in DB and at Week 52 in OLE

	CZP vs PBO at DB 24 week [a]				at OLE entry and at OLE 52 week [b]

[a] The analysis was performed on the FAS, which included pts who were originally assigned to CZP 200mg Q2W group and PBO group in the DB phase of J-RAPID (CZP n = 82 and PBO n = 77)and HIKARI (CZP n = 116 and PBO n = 114), respectively.
[b] The analysis was performed on the FAS, which included pts who entered the OLE studies, and were originally assigned to CZP 200mg Q2W group in the DB phase (excluding pts who were in the placebo group during the DB phase) of J-RAPID (n = 74) and HIKARI (n = 105), respectively. During OLE, the pts were treated with CZP 200mg Q2W or CZP 400mg Q4W.
[c] Last observation carried forward.
[d] Yearly ΔmTSS from baseline: FAS-Linear extrapolation.
[e] CDC: DAS28(ESR)≤3.2, ΔmTSS≤0.5 and HAQ-DI≤0.5.
[f] For CDC and CDR, yearly ΔmTSS from baseline (Linear extrapolation, with NRI for patients with no data) was used.
[g] CDR: DAS28(ESR)<2.6, ΔmTSS≤0.5 and HAQ-DI≤0.5.

Conclusion: CZP treatment demonstrated high rates of CDC/CDR at Wk24 and OLE Wk52 in RA pts with high baseline disease activity. CZP treatment, regardless of concomitant MTX or as monotherapy, was effective in achieving CDC/CDR. Wk12 DAS or HAQ remission with CZP was associated with high achievement of CDR at OLE Wk52.

Persistence On Biologics Is Associated With Concomitant Methotrexate Use Among Rheumatoid Arthritis Patient. Jie Zhang[1], Fenglong Xie[1], Elizabeth S. Delzell[1], Huifeng Yun[1], James Lewis[2], Kevin Haynes[3], Lang Chen[1] and Jeffrey R. Curtis[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania., Philadelphia, PA.

Background/Purpose: Concomitant methotrexate (MTX) is associated with improved treatment efficacy in randomized controlled trials of biologic agents to treat rheumatoid arthritis (RA), yet many patients receive biologics without MTX. The present study compared persistence among RA patients who initiated a biologic alone vs. with MTX in routine clinical practice. We also examined if the association differed by type of biologic initiated.

Methods: We conducted a retrospective cohort study among RA patients using national Medicare administrative claims data from 2006 to 2010. Eligible patients were new users (no use of specific agent in 12 months prior) of etanercept, infliximab, adalimumab, or abatacept and were required to have ≥ 12 months continuous Medicare coverage before (baseline) and after treatment initiation. Exposure groups were biologic monotherapy (no MTX or any other non-biologic disease modifying anti-rheumatic drugs [NB-DMARDs]) versus biologic with MTX (with or without other NB-DMARD). The outcome was non-persistence with biologics, which included discontinuation or switching to a different biologic. Patients were censored if they changed from monotherapy to combination therapy or vice versa. We generated Kaplan-Meier curves to compare biologic non-persistence across different exposure groups. We also calculated the hazard ratio (HR) for biologic non-persistence comparing monotherapy to combination therapy overall and for each biologic agent separately adjusting for demographics, receipt of state subsidy, reason for Medicare enrollment, Charlson comorbidities, and any hospitalization during baseline.

Results: Of 22,073 eligible RA patients, 8,755 initiated biologic monotherapy and 13,318 initiated a biologic in combination with MTX. At treatment initiation, mean age (standard deviation) was 65.6 (12.6) and 82.0% were women. Patients who initiated a biologic without concomitant MTX were 1.7 (95% CI: 1.6–1.8) times more likely to be non-persistent. The magnitude of the association between concomitant MTX use and biologic non-persistence differed significantly by biologic agent ($p < .0001$); the strongest association was observed among infliximab users (HR: 2.1; 95% CI: 1.9–2.3) and the smallest among abatacept users (HR: 1.5; 95% CI: 1.3–1.6).

Kaplan-Meier figure presents detailed data.

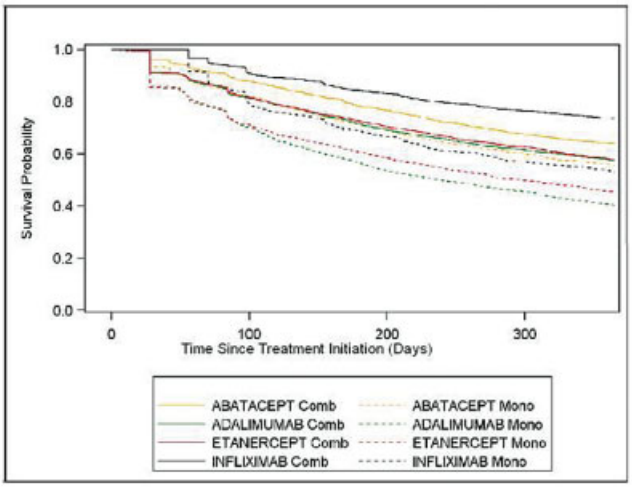

Figure. Kaplan-Meier curves of time to non-persistence by type of biologic therapy and use of concomitant methotrexate

Conclusion: Concomitant MTX was associated with better persistence on biologic therapy; the largest impact was observed among infliximab users.

Final 5-Year Safety and Efficacy Results Of a Phase 3, Randomized, Placebo-Controlled Trial Of Golimumab In Patients With Active Rheumatoid Arthritis Despite Previous Anti-Tumor Necrosis Factor Therapy. Josef S. Smolen[1], Jonathan Kay[2], Robert Landewé[3], Eric L. Matteson[4], Norman B. Gaylis[5], Jürgen Wollenhaupt[6], Frederick T. Murphy[7], Chenglong Han[8], Timothy A. Gathany[8], Stephen Xu[9], Yiying Zhou[9], Elizabeth C. Hsia[10] and Mittie K. Doyle[9]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]University of Massachusetts Medical School, Worcester, MA, [3]Academic Medical Center, University of Amsterdam and Atrium Medical Center, Heerlen, Netherlands, [4]Mayo Clinic, Rochester, MN, [5]Arthritis & Rheumatic Disease Specialties, Aventura, FL, [6]Schön Klinik Hamburg Eilbek, Hamburg, Germany, [7]Altoona Ctr for Clinical Research, Duncansville, PA, [8]Janssen Global Services, LLC., Malvern, PA, [9]Janssen Research & Development, LLC., Spring House, PA, [10]Janssen Research & Development, LLC./U of Penn, Spring House/Philadelphia, PA.

Background/Purpose: GO-AFTER was the first multicenter, randomized, placebo (PBO)-controlled trial of the safety/efficacy of an anti-TNFα agent, GLM, in pts with active RA despite prior anti-TNFα therapy.

Objective: Final safety and efficacy results through 5yrs are reported.

Methods: Pts were randomized (1:1:1) to PBO, GLM 50mg, or GLM 100mg q4w. At wk16, pts with inadequate treatment response entered double-blind early escape: PBO to GLM 50mg or GLM 50mg to 100mg. At wk24 (start of long-term extension), pts still receiving PBO switched to GLM 50mg, all other pts continued current treatment. After the last pt completed the wk24 visit, unblinding occurred, and a one-time GLM dose increase (50 to 100mg) or decrease (100 to 50mg) was permitted at investigator's discretion. The last GLM injection was at wk252. Observed efficacy results (ACR20/50/70, DAS28-CRP, CDAI) by randomized treatment group and cumulative safety data are reported through wks 256 and 268, respectively. Efficacy data from 1 site (16 pts) were excluded (protocol violations).

Results: 461 pts were randomized, and 459 received study agent; 183 pts continued treatment through wk252, and 276 pts withdrew (86 for AE, 107 for lack of efficacy, 9 lost to follow-up, 69 for other reasons, 5 deaths). 178 completed the safety follow-up through wk268. Efficacy results are shown in the table. Of pts with available data at wk256, 60.3% had an ACR20, 42.3% had an ACR50, 21.7% had an ACR70, 84.3% had DAS28-CRP EULAR response, 29.0% had DAS28-CRP <2.6, and 16.0% had CDAI$\leq$2.8. The most common AEs were upper respiratory tract infection(27.1%), sinusitis(17.1%), and nasopharyngitis(16.9%). Through wk268, 151/431 pts had an SAE, with similar rates among dose groups (50mg only, 50 and 100mg, 100mg only) Rates of serious infections, malignancies, and death were 13.9%, 4.6%, and 2.1%, respectively. 12.3% of pts had $\geq$1 injection-site reaction. Of 388 pts with available samples, 31 (8.0%) tested positive for antibodies to GLM.

Table. Efficacy results at wk256.

	PBO/GLM[a]	GLM 50mg[b]	GLM 100mg[c]	Total
ACR20	37/57 (64.9%)	39/65 (60.0%)	38/67 (56.7%)	114/189 (60.3%)
ACR50	24/57 (42.1%)	26/65 (40.0%)	30/67 (44.8%)	80/189 (42.3%)
ACR70	10/57 (17.5%)	16/65 (24.6%)	15/67 (22.4%)	41/189 (21.7%)
DAS28-CRP EULAR Response	50/55 (90.9%)	53/65 (81.5%)	53/65 (81.5%)	156/185 (84.3%)
DAS28-ESR EULAR Response	48/56 (85.7%)	47/65 (72.3%)	49/64 (76.6%)	144/185 (77.8%)
DAS28-CRP <2.6	18/55 (32.7%)	16/65 (24.6%)	20/66 (30.3%)	54/186 (29.0%)
DAS28-ESR <2.6	13/56 (23.2%)	14/65 (21.5%)	13/66 (19.7%)	40/187 (21.4%)
CDAI $\leq$2.8	7/56 (12.5%)	10/65 (15.4%)	13/67 (19.4%)	30/188 (16.0%)

[a]Pts randomized to PBO who switched to GLM 50mg at wk16 or 24; after wk24 pts could receive GLM50 or 100mg.
[b]After wk 24 pts could receive GLM50 or 100mg.
[c]After wk 24 pts could receive GLM100 or 50mg.

Conclusion: GLM efficacy was maintained through 5yrs among pts with refractory RA who continued treatment. The long-term safety of GLM is consistent with other anti-TNFα agents.

Head-To-Head Comparison Of Subcutaneous Abatacept Versus Adalimumab On Background Methotrexate In RA: Blinded Two Year Results From The Ample (Abatacept Versus Adalimumab Comparison in Biologic-Naive RA Subjectswith Background Methotrexate) study. Michael E. Weinblatt[1], Michael H Schiff[2], Robert Valente[3], Désirée M. van der Heijde[4], Gustavo Citera[5], Ayanbola Elegbe[6], Michael A Maldonado[6] and Roy M. Fleischmann[7]. [1]Brigham and Women's Hospital, Boston, MA, [2]University of Colorado, Denver, CO, [3]Arthritis Center of Nebraska, Lincoln, NE, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [6]Bristol-Myers Squibb, Princeton, NJ, [7]University of Texas Southwestern Medical Center, Dallas, TX.

Background/Purpose: AMPLE (**A**batacept Versus Adali**m**umab Com**p**arison in Bio**l**ogic-Naiv**e** RA Subjects with Background Methotrexate) is the first 2 year, active comparator study in RA patients utilizing biologic agents on a background of MTX. At Year 1, SC abatacept (ABA)

and adalimumab (ADA) demonstrated comparable efficacy, including radiographic outcomes, with similar safety.[1] Here we report 2 year study results including radiographic outcomes.

Methods: AMPLE is a phase IIIb randomized, investigator-blinded study of 2 years duration with a primary efficacy endpoint at Day 365. Biologic-naïve patients with active RA and an inadequate response to MTX were randomized 1:1 to receive 125 mg ABA weekly (without an IV load) or 40 mg ADA bi-weekly, with a stable dose of MTX.[1] Study conduct continued unchanged from Year 1, including investigator blinding; all clinical efficacy endpoints were captured through Day 729 including radiographs assessed using the van der Heijde modified Total Sharp score (mTSS). All efficacy analyses were done using the intent-to-treat population with non-responder imputation where appropriate. All radiographs were read through Day 729, including re-reading Year 1 images, by readers blinded to treatment allocation and sequence.

Results: Baseline characteristics of the 646 patients, equally randomized to each group, were similar as previously reported.[1] 79.2% (252 of 318) ABA patients and 74.7% (245 of 328) ADA patients completed Day 729. At Year 1, 64.8% ABA and 63.4% ADA patients were ACR20 responders. Consistent with Year 1, clinical efficacy measures and inhibition of radiographic progression were comparable between groups at Year 2 (Table). There were similar rates of AEs, SAEs (13.8% vs. 16.5%), and malignancies (2.2% vs. 2.1%). More autoimmune AEs occurred in the ABA arm (3.8% vs. 1.8%); none were SAEs. Fewer infections (3.8% vs 5.8%) and opportunistic infections (in 3 vs. 5 patients) occurred with ABA including 2 cases of tuberculosis in the ADA arm that led to discontinuation (DC). There were fewer DC due to AEs (3.8% vs. 9.5%), SAEs (1.6% vs. 4.9%), and serious infections (in 0/12 vs. 9/19 patients) in the ABA arm. Injection site reactions (ISR) occurred less frequently in the ABA arm (4.1% vs. 10.4%).

	ACR Responses ABA = 318 ADA = 328				DAS Responses				Radiographic score, mean ABA=257 ADA=260		
	ACR 20	ACR 50	ACR 70	ACR 90	Mean Change* ABA = 318 ADA = 327	<2.6 (%)** ABA = 251 ADA =244	HAQ (≥0.3 U) ABA = 318 ADA = 328	X ray non progression (SDC≤2.2; %) ABA = 257 ADA = 260	mTSS	Erosion	JSN
ABA	59.7	44.7	31.1	14.5	−2.35	50.6	54.1	84.8	0.89	0.41	0.48
ADA	60.1	46.6	29.3	8.2	−2.33	53.3	48.8	83.8	1.13	0.41	0.72

*LOCF **As-observed

Conclusion: Through 2 years of treatment, in this first active comparator study between biologic agents in RA patients with an inadequate response to MTX, this robust data set demonstrates that SC abatacept and adalimumab were equally efficacious in clinical, functional and radiographic outcomes. Overall, the frequency of AEs was similar in both groups but there were less discontinuations due to AEs, SAEs, serious infections, and fewer local ISR in patients treated with SC abatacept.

Dose Reduction Of Tocilizumab In Rheumatoid Arthritis Patients With Low Disease Activity Is Feasible. Noortje van Herwaarden[1], Susan Herfkens-Hol[1], Aatke van der Maas[1], Bart J.F. van Den Bemt[1], Ronald F. van Vollenhoven[2], Johannes W.J. Bijlsma[3] and Alfons A. den Broeder[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]Karolinska Institute, Stockholm, Sweden, [3]University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Tocilizumab, at a registered dose of 8mg/kg, has proven to be effective in the treatment of rheumatoid arthritis. Clinical trial data show that a large proportion of patients achieve low disease activity on a lower than registered starting dose.[1] A lower dose might reduce dose-dependent side effects and costs. We investigated the feasibility of dose reduction to 4 mg/kg in patients who reached low disease activity at a registered dose of 8 mg/kg.

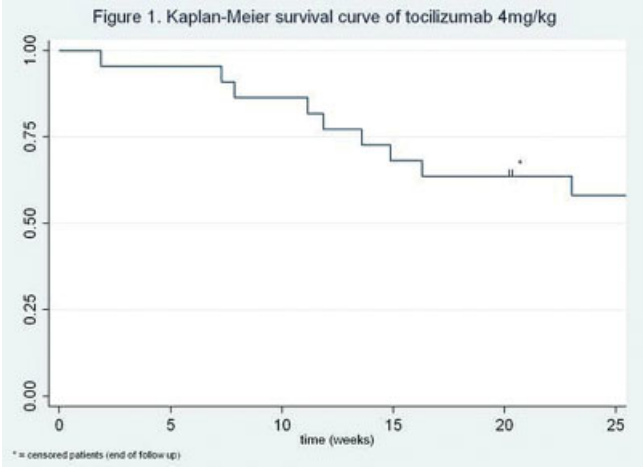
Methods: According to the local treatment protocol, rheumatoid arthritis patients start with tocilizumab 8mg/kg every 4 weeks. After about 6 months, the dose is reduced to 4 mg/kg if patients have low disease activity (DAS28<3.2 and/or judgement of rheumatologist). In case of loss of disease control (DAS28>3.2 and/or judgement rheumatologist), the dose could be increased again to 8mg/kg. In this retrospective study, baseline patient-, disease- and treatment characteristics were collected as well as data on disease activity before and 3 and 6 months after dose reduction and when applicable 3 and 6 months after dose escalation.

Results: In 22 patients tocilizumab dose was reduced because of low disease activity (table 1). After 3 and 6 months follow up, 77% (95% CI 54–91) and 55% (95% CI 32–76) of patients still had low disease activity, respectively (figure 1). Seven out of 9 flares after dose reduction (78%), occurred within the first 16 weeks. The mean DAS28 at time of dose reduction was 2.3 (SD 0.9). The DAS28 at 3 and 6 months was somewhat higher than baseline, 2.7 (SD 1.2) and 2.5 (SD 1.0) respectively. All patients who experienced worsening of disease activity after dose reduction regained low disease activity after dose escalation.

Table 1. Baseline characteristics (start tocilizumab 8 mg/kg)

	n = 22
Age, years (SD)	61 (12)
Woman, n (%)	20 (91)
Disease duration, years median [p25-p75]	10 [5–17]
Rheumatoid factor positive, n (%)	14 (64)
Anti-CCP positive, n (%)	14/19 (74)
Erosive disease, n (%)	13 (59)
DAS28 before start tocilizumab (SD)	4.9 (0.9)
Previous DMARDs, n median [p25-p75]	3 [2–5]
Previous biologicals n, median [p25-p75]	3 [2–5]
Concomitant DMARD, n (%)	9 (41)
Concomitant corticosteroid, n (%)	14 (64)

anti-CCP= anti-cyclic citrullinated peptide; DAS28 = 28 joints disease activity score; DMARD = disease-modifying antirheumatic drug



Conclusion: In this proof of principle study, dose reduction of tocilizumab to 4 mg/kg seems feasible in the majority of rheumatoid arthritis patients who had achieved low disease activity at a 8 mg/kg dose. Dose escalation after flare was effective in all patients.

Tofacitinib, An Oral Janus Kinase Inhibitor, In The Treatment Of Rheumatoid Arthritis: Open-Label, Long-Term Extension Safety and Efficacy Up To 5 Years. Jürgen Wollenhaupt[1], Joel Silverfield[2], Eun Bong Lee[3], Susan P. Wood[4], Ketti K. Terry[4], Hiroyuki Nakamura[5], Yukako Ohno[5], David Gruben[4], Birgitta Benda[6], Lisy Wang[4] and Richard Riese[4]. [1]Schoen-Klinik Hamburg-Eilbek Teaching Hospital of the University of Hamburg, Hamburg, Germany, [2]Healthpoint Medical Group, Tampa, FL, [3]Seoul National University, Seoul, South Korea, [4]Pfizer Inc, Groton, CT, [5]Pfizer Japan Inc, Tokyo, Japan, [6]Pfizer Inc, Collegeville, PA.

Background/Purpose: Tofacitinib is a novel, oral JAK inhibitor for the treatment of rheumatoid arthritis (RA). Here we report tofacitinib safety, tolerability, and durability of response up to 60 months (mo) in long-term extension (LTE) studies.

Methods: Data were pooled from two open-label studies (A3921024 [NCT00413699], A3921041 [NCT00661661]) of patients (pts) who previously participated in randomized Phase (P)2 or P3 tofacitinib studies. Treatment was initiated with tofacitinib 5 or 10 mg BID as monotherapy or with background disease-modifying antirheumatic drugs (DMARDs); data from both doses ± background DMARDs were pooled. Baseline was that of the P2 or P3 study for pts enrolling within 7 (A3921041) or 14 (A3921024) days of participation; if enrollment was >7 or >14 days after participation, baseline was the start of the LTE study. Primary endpoints were AEs and confirmed (2 sequential) laboratory safety data. Secondary endpoints included ACR responses, DAS28-4(ESR) (DAS28), and HAQ-DI. Safety data were included over 72 mo of observation and efficacy data up to Mo 60 (limited pt numbers [n=39] post-Mo 60).

Results: Overall, 4827 pts were treated for a total duration of 9196 pt-years (pt-y); mean (maximum) treatment duration was 687 (2187) days; 1246 pts (25.8%) discontinued (AEs: 616 [12.8%]; lack of efficacy: 110 [2.3%]; other: 520 [10.8%]). The most commonly reported AE classes were infections and infestations (55.8%), GI disorders (25.4%), and musculoskeletal/connective tissue disorders (27.8%). The most frequent investigator-reported AEs were nasopharyngitis (14.3%), upper respiratory tract infection (11.9%), and urinary tract infection (8.3%). Serious AEs (SAEs) were reported in 18.2% of pts with an incidence rate (IR) of 10.3 per 100 pt-y (95% CI 9.6, 11.0). Serious infection events (SIEs) were reported in 5.5% of pts with an IR of 2.9 per 100 pt-y (95% CI 2.6, 3.3). IRs for SAEs and SIEs did not increase between 48-[1]and 60-mo observations. All malignancies excluding NMSC were reported in 1.7% of pts with an IR of 0.9 per 100 pt-y (95% CI 0.7, 1.1).

Decreased hemoglobin (Hgb; ≥2 g/dL change from baseline, or Hgb <8 g/dL) was observed in 4.6% of pts. Raised aminotransferases (>3 × ULN) were observed in 2.0% (ALT) and 0.9% (AST) of pts. Moderate to severe neutropenia (absolute neutrophil count [ANC] 0.5–1.5 × 10^3/mm^3) was reported in 1.0% of pts; there were no cases of ANC <0.5 × 10^3/mm^3. Absolute lymphocyte counts <0.5 × 10^3/mm^3 were reported in <1.0% of pts. Increases >50% from baseline in creatinine were noted in 3.6% of pts. Mean values for laboratory safety measures were consistent with findings in P2 and P3 studies and stable over time.

Efficacy was maintained for tofacitinib ± background DMARDs between Mo 1 and Mo 60: ACR20, 60.2% and 77.9%; ACR50, 39.8% and 56.7%; ACR70, 22.7% and 40.4%, respectively. Mean DAS28 was 6.2 at baseline, 3.7 at Mo 1, and 3.6 at Mo 60. Mean HAQ-DI score was 1.4 at baseline, 0.8 at Mo 1, and 0.7 at Mo 60.

Safety and efficacy were similar for pts receiving tofacitinib as monotherapy or with background DMARDs.

Conclusion: Tofacitinib 5 or 10 mg BID in pts with RA showed a consistent safety profile and sustained efficacy over 5 years in LTE studies.

Improvements In Physical Function Correlate With Improvements In Health Related Quality Of Life: Reported Outcomes In Rheumatoid Arthritis Patients Treated With Tofacitinib: Results From 3 Randomized Phase 3 Trials. V. Strand[1], R. E. Alten[2], C. I. Nduaka[3], R. Riese[3], D. Gruben[3], S. H. Zwillich[3], J. Andrews[3] and G. Wallenstein[3]. [1]Stanford University, Palo Alto, CA, [2]Schlosspark-Klinik, University Medicine, Berlin, Germany, [3]Pfizer Inc, Groton, CT.

Background/Purpose: Tofacitinib is a novel, oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). RA affects all domains of health-related quality of life (HR-QoL), which patients report being more important to them than the joint counts and laboratory tests favored by many physicians.[1]

Objectives: To compare improvements in HR-QoL using the Medical Outcomes Survey Short Form-36 (SF-36) by Health Assessment Questionnaire-Disability Index (HAQ-DI) responders (based on improvement ≥0.3) and non-responders in the tofacitinib database at Month 3, by treatment.

Methods: Data are reported from 3 double-blind randomized controlled Phase 3 trials of tofacitinib: a) 6-month tofacitinib monotherapy in patients with an inadequate response (IR) to nonbiologic or biologic disease-modifying antirheumatic drugs (DMARDs) (ORAL Solo, NCT00814307); b) 12-month tofacitinib with methotrexate (MTX) combination in MTX-IR patients (ORAL Standard, NCT00853385); and c) 6-month tofacitinib with MTX combination in tumor necrosis factor inhibitors (TNFi)-IR patients (ORAL Step, NCT00960440). Patients were randomized to tofacitinib 5 mg or 10 mg BID, placebo or adalimumab (ADA; in ORAL Standard only).

Results: For each treatment group in ORAL Solo, regardless of HAQ-DI responder status, there were significant correlations between changes from baseline in HAQ-DI and SF-36 Physical Component Scores [PCS] at Month 3: tofacitinib 5 mg, r = −0.55 (N= 230; P<0.0001); 10 mg, r = −0.56 (N= 222; P<0.0001) placebo, r = −0.51 (N= 107; P<0.0001). HAQ-DI responders reported consistently greater improvements in all 8 domains of SF-36 compared with non-responders, all of which exceeded MCID (Table). This was similarly true when analyzed by treatment group, where HAQ-DI responders reported large improvements in BP and VT as well as PF, RP and GH domains (Table). Results from ORAL Standard and ORAL Step were similar.

Mean changes (SD) from baseline in domains and component summary scales of SF-36 by HAQ-DI responses (based on improvements ≥0.3) at Month 3 in ORAL Solo (monotherapy)

Relationship Between Lymphocyte Count and Risk Of Infection In Rheumatoid Arthritis Patients Treated With Tofacitinib. R. F. van Vollenhoven[1], R. Riese[2], S. Krishnaswami[2], T. Kawabata[2], C. Fosser[2], S. Rottinghaus[2], M. Lamba[2] and S. H. Zwillich[2]. [1]The Karolinska Institute, Stockholm, Sweden, [2]Pfizer Inc, Groton, CT.

Background/Purpose: Tofacitinib is a novel oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). Cytokines involved in lymphocyte development, function and homeostasis are known to signal through JAK. Here we characterize changes in absolute lymphocyte counts (ALC) following tofacitinib treatment and evaluate the relationship between ALC and rates of infection. These data were presented previously.[1]

Methods: ALC and adverse event data of treated (requiring antimicrobial therapy or surgical intervention; TIs), serious (SIs), and opportunistic infections (OIs) were analyzed from 5 randomized controlled Phase 3 (P3), and 2 open-label long-term extension (LTE) studies in patients (pts) with RA. Lymphopenia was defined by OMERACT criteria (ALC $\times 1000/mm^3$) as mild, ≥ 1.5 to <2; moderate to severe, <1.5 to ≥ 0.5; and potentially life threatening, <0.5. Confirmed lymphopenia was defined as lymphopenia in 2 consecutive measurements. Cox analysis was applied to evaluate the relationship between "time-varying" ALC and rates of infection. Threshold values of ALC were evaluated by calculating the percentage of correct decisions (POCD), based on the sum of pts falling below a specific threshold (e.g. 0.5 or 1.0) and experiencing an SI, and those with ALC above threshold and without an SI.

Results: Across treatment groups, at baseline 35–39% of pts in P3 (N = 3252) had ALC of <1.5. Pooled analysis of P3 data showed mean increases in ALC from baseline with tofacitinib at Month (Mo) 1 followed by a gradual decrease of approximately 10% from baseline after 12-mo of therapy. Further decreases in mean ALC were not seen in the LTE studies. Lymphopenia frequency in the P3 studies was similar between tofacitinib and placebo pts at Mo 3 and 6; all placebo pts were advanced to tofacitinib at Mo 6. Lymphocyte subset analyses from P2 dose-ranging studies (6 and 24 weeks [wks]) showed increases in B cell counts (~40%; 1–24 wks), decreases in NK cell counts (~40%; Wks 2–24) and a transient increase in T cell counts (Wks 1–2). Subset analyses from LTE studies (median exposure 22 mo) showed that NK cell counts were similar to baseline counts, B cell counts remained elevated and T cell counts decreased slightly ($<20\%$). For pts with ALC ≥ 0.5, there was no increase in the frequency of TI, SI or OI. Although confirmed lymphopenia of <0.5 was infrequent (5/2430 pts (0.2%) in P3; 10/3219 (0.3%) in the LTE), 11, 4, and 1 of these pts experienced a TI, SI, and OI, respectively. The SI in this group included 1 case each of pneumonia, cellulitis, tuberculosis (an OI), and pyelonephritis. Cox analysis using all available P2, P3 and LTE data showed a significant trend ($p<0.05$) for increased risk for infection (SI and OI) with decreased ALC. The POCD decreased from ~94% for an ALC threshold of 0.5 $\times 1000/mm^3$ to 66% for 1.0 $\times 1000/mm^3$.

Conclusion: Tofacitinib treatment in patients with moderate to severe RA is associated with modest mean decreases in ALC over 12-mo of therapy. Confirmed ALC $<0.5 \times 1000/mm^3$ occurred rarely and may be the optimum threshold for defining increased risk of SI. These data could inform appropriate risk mitigation strategies.

Efficacy and Safety Of Tofacitinib In Older and Younger Patients With Rheumatoid Arthritis. J. R. Curtis[1], H. Schulze-Koops[2], L Takiya[3], C. A. Mebus[4], K. Terry[4], R. Chew[4] and T. V. Jones[3]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Munich, Munich, Germany, [3]Pfizer Inc, Collegeville, PA, [4]Pfizer Inc, Groton, CT.

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). The clinical development program for tofacitinib in RA enrolled □500 patients (pts) aged ≥65 years (yrs). Rates of infection and other conditions seen in pts with RA typically increase with age. This analysis evaluated the efficacy and safety of tofacitinib in older (≥65 yrs) and younger pts (<65 yrs).

Methods: Efficacy was evaluated in a post-hoc, pooled analysis of four Phase (P) 2 and five P3 studies (ORAL Solo, ORAL Sync, ORAL Scan, ORAL Standard and ORAL Step). Efficacy results for rates of ACR20/50/70 and improvement from baseline in HAQ-DI ≥0.22 were reported as probability ratios (PRs; proportion of responders in tofacitinib group divided by placebo [PBO] at Month 3) with 95% confidence intervals. Pts randomized to PBO advanced to tofacitinib beginning at Month 3. Safety was evaluated in a post-hoc pooled analysis of five P3 studies (Month 0–12) and a pooled analysis of two ongoing long-term extension (LTE) studies. Incidence rates for safety endpoints were compared in older vs younger pts.

Results: A total of 3439 pts received tofacitinib 5 mg, tofacitinib 10 mg, or PBO, twice daily (BID), and 520 were aged ≥ 65 years. PRs for rates of ACR20/50/70 and HAQ-DI improvement in older pts treated with tofacitinib 5 mg BID (N=196) vs PBO (N=122) were 1.86 (1.42–2.42), 2.84 (1.72–4.70), 3.32 (1.49–7.42) and 1.23 (1.02–1.50) respectively, which were similar to, or slightly lower than, the PRs for other age groups (not shown). PRs for tofacitinib 10 mg BID vs PBO were numerically slightly higher for all outcomes. The rate of serious adverse events (SAEs) and discontinuations due to adverse events (AEs) was generally higher in older than in younger pts irrespective of treatment group. The rate of serious infection events (SIE) was greater by 6.2/100 pt yrs in older pts who received tofacitinib vs PBO; the corresponding rate difference in younger pts was 0.9/100 pt yrs (Table). Herpes zoster (HZ) rates were higher in tofacitinib pts vs PBO, and HZ rates for tofacitinib-treated pts were similar irrespective of age. MACE, or malignancies, did not occur in older pts receiving PBO in any of the P3 studies and were infrequent in both age groups of tofacitinib-treated pts (Table). Safety results for older and younger pts in LTE studies were generally consistent with P3 study results.

Table. Incidence rates for key safety endpoints by age group and treatment in five tofacitinib Phase 3 studies

Age group (yrs)	Younger pts (<65)			Older pts (≥65)

Opportunistic infections						
N	0	2	7	0	1	3
MACE						
N	2	2	2	0	2	4
All malignancies (excluding NMSC)						
N	0	3	7	0	2	1

BID, twice daily; CI, 95% confidence interval; MACE, major adverse cardiovascular events; N, number of cases; NMSC, non-melanoma skin cancer; PBO, placebo; pt, patient; yrs, years

Conclusion: Older pts (≥65 yrs) treated with tofacitinib were observed to be at increased risk of SIEs vs older pts treated with PBO, consistent with reports from multiple RA pt databases of biologic DMARDs (Listing et al 2013). Older pts generally were at increased risk of SAEs and discontinuations due to AEs vs younger pts (<65 yrs). The benefit-risk profile of tofacitinib must be taken into account when considering treatment of older pts with RA.

Assessment of Lipid Changes and Infection Risk In Diabetic and Nondiabetic Patients With Rheumatoid Arthritis Treated With Tofacitinib.

W. F. C. Rigby[1], L. Takiya[2], S. P. Wood[3], H. Fan[2] and T. V. Jones[2]. [1]Giesel School of Medicine at Dartmouth, Lebanon, NH, [2]Pfizer Inc, Collegeville, PA, [3]Pfizer Inc, Groton, CT.

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Studies have shown an increased prevalence of diabetes mellitus (DM) in patients (pts) with RA. Nearly 9% of pts enrolled into Phase 3 (P3) studies of tofacitinib in RA also had DM. Both RA and DM are associated with lipid changes and an increased risk of infection. This analysis evaluated selected safety endpoints in pts with and without DM receiving tofacitinib for RA.

Methods: Safety endpoints, including changes in fasting blood glucose (FBG), lipids and risk of all infections (regardless of severity), were evaluated in a post-hoc pooled analysis of five tofacitinib P3 studies in DMARD inadequate responders. Baseline (BL) clinical characteristics and lab data, and follow-up lipid data at Month (Mo) 3, were available for all studies. Follow-up FBG data were available for four studies of tofacitinib with background nonbiologic DMARDs. Categorical changes (defined by the American Diabetes Association [ADA]) in FBG vs BL were compared using shift analyses.

Results: Of 2430 pts who received tofacitinib, 8.7% (211) had DM: 8.9% (108/1216) 5 mg BID; 8.5% (103/1214) 10 mg BID. Additionally, 7.0% (48/681) of pts receiving placebo (PBO) had DM. At BL, 49.1% (tofacitinib 5 mg BID), 46.6% (tofacitinib 10 mg BID), and 50% (PBO) of pts with DM used glucocorticoids.

Mean BL FBG in pts with DM was 138 mg/dL, 129.8 mg/dL and 138.9 mg/dL in the tofacitinib 5 mg BID, 10 mg BID and PBO groups, respectively. Corresponding values at Mo 3 were 126.1 mg/dL, 124.0 mg/dL and 129.5 mg/dL. The shift analysis of FGB data from 82 tofacitinib 5 mg BID pts with DM showed 10 pts moved from lower to higher ADA category at BL at Mo 1 or 3, while 19 pts moved from higher to lower category (53 with no change, see Table). For tofacitinib 10 mg BID pts with DM, numbers moving to higher, lower, or no change in category were 19, 13, and 46, respectively. Corresponding numbers for PBO pts with DM were 9, 9, and 25 (not shown).

Increases in mean low density lipoprotein (LDL) and triglyceride (TG) levels were observed at Mo 3 in pts treated with tofacitinib, as reported previously, although the same pattern was seen in pts with and without DM. During 3 Mo of follow-up 23.1%, 21.4% and 25.0% of pts with DM in the tofacitinib 5 mg BID, 10 mg BID and PBO groups, respectively, had ≥1 infection. Corresponding proportions in pts without DM were 21.0%, 21.8% and 18.6%.

Table. Shift analysis of maximum fasting blood glucose levels from baseline to Month 1 or Month 3 in patients with rheumatoid arthritis and diabetes mellitus receiving tofacitinib 5 mg or 10 mg twice daily

		Maximum on-treatment FBG (mg/dL at Month 1 or Month 3)			
		<100 n (%)	100–125 n (%)	≥126 n (%)	Total n (%)
Tofacitinib 5 mg BID	**<100 n (%)**	15 (63)	5 (21)	4 (17)	24 (100)
	100–125 n (%)	7 (41)	9 (53)	1 (6)	17 (100)
Baseline FBG (mg/dL)	**≥126** n (%)	2 (5)	10 (24)	29 (71)	41 (100)
	Total n (%)	24 (29)	24 (29)	34 (41)	82 (100)

	Total n (%)	14 (17.9)	25 (32.1)	39 (50.0)	78 (100.0)

BID, twice daily; FBG, fasting blood glucose
Only patients with valid fasting blood glucose measurements at baseline and an on-treatment value at Month 1 or Month 3 are included

Conclusion: In the P3 studies evaluated, pts with RA and DM showed no increase in mean FBG levels after 3 Mo of tofacitinib therapy; the number of pts with DM whose FBG increased to ≥126 mg/dL was limited and similar to that observed in pts receiving PBO. Mean increases in LDL and TG were numerically similar in pts with and without DM. The proportion of tofacitinib-treated pts who experienced ≥1 infection, regardless of severity, was numerically similar between pts with and without DM.

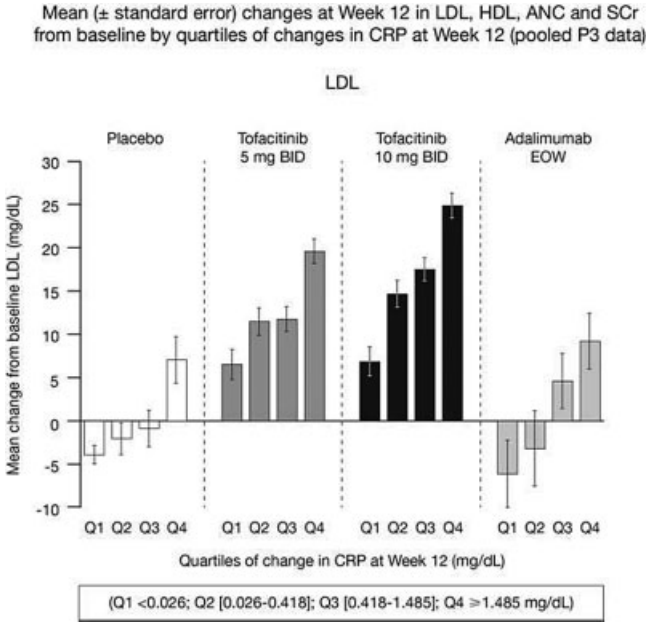
Association Of Mean Changes In Laboratory Safety Parameters With C-Reactive Protein At Baseline and Week 12 In Rheumatoid Arthritis Patients Treated With Tofacitinib.

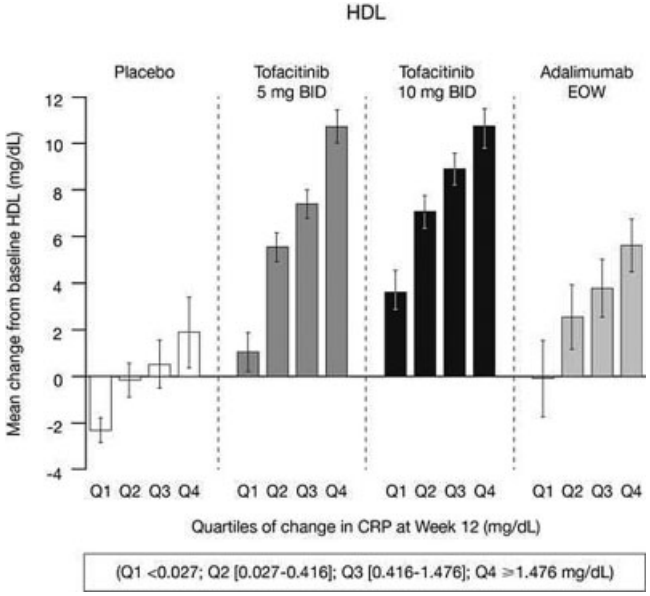
V. Strand[1], J. D. Isaacs[2], S. Menon[3], J. Beal[4], C. I. Nduaka[3], S. Krishnaswami[3], R. Riese[3] and M.G. Boy[3]. [1]Stanford University, Palo Alto, CA, [2]Newcastle University, Newcastle-upon-Tyne, United Kingdom, [3]Pfizer Inc, Groton, CT, [4]Pfizer Inc, Collegeville, PA.

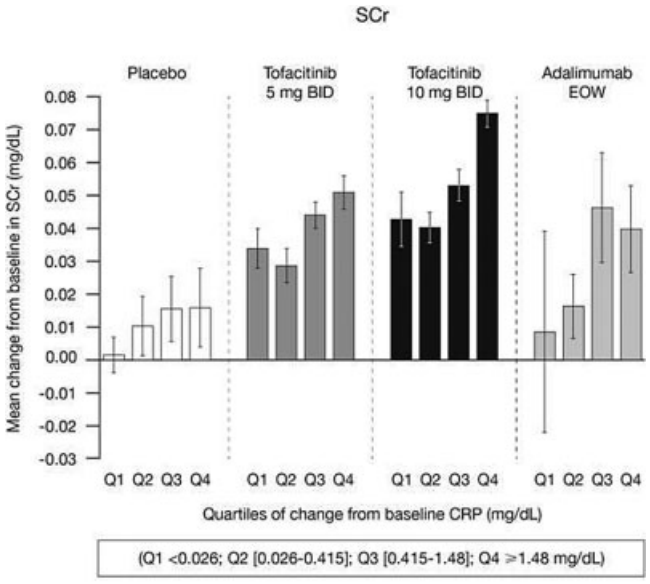
Background/Purpose: Tofacitinib is a novel, oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). Changes in laboratory parameters observed during tofacitinib treatment included mean increases in low (LDL) and high (HDL) density lipoproteins, serum creatinine (SCr) and mean decreases in neutrophils (ANC). Potential explanatory mechanisms were investigated.

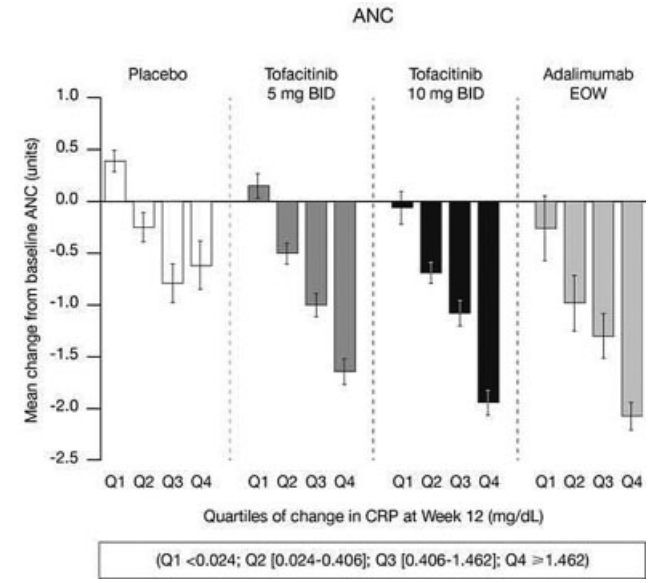
Methods: Baseline and Week 12 data from five Phase 3 (P3) traditional or biologic disease-modifying anti-rheumatic drug (DMARD)-inadequate responder (IR) trials were pooled for each treatment arm: placebo, tofacitinib 5 mg and 10 mg twice daily, and adalimumab 40 mg every other week. The defined laboratory parameters were explored with C-reactive protein (CRP) as a marker of inflammation. Mean changes at Week 12 were compared with quartile levels of CRP at baseline and quartiles of change in CRP at Week 12.

Results: Across the defined laboratory parameters, the smallest mean changes from baseline were observed in the quartile of patients with the smallest reductions in CRP (Figure, 1st quartile) and the greatest changes were observed with the greatest reductions in CRP (Figure, 4th quartile). A similar pattern of association was evident with baseline CRP, where the greatest mean changes in laboratory parameters occurred in patients with highest levels of baseline CRP. Numerical differences in the magnitude of changes across the treatment arms were observed, but no statistical comparisons were performed.









Conclusion: A consistent pattern of association between mean changes in each of the laboratory parameters and CRP was observed. The precise mechanism behind these laboratory changes is unknown. Based upon these analyses, the lowering of inflammation, as measured by CRP, may partly explain some of the observed mean changes in laboratory parameters during clinical studies.

ORAL SCAN: Effects Of The Oral JAK Inhibitor Tofacitinib In Combination With Methotrexate On Patient Reported Outcomes In a 24-Month Phase 3 Trial Of Active Rheumatoid Arthritis. V. Strand[1], D. van der Heijde[2], C. A. F. Zerbini[3], C. A. Connell[4], D. Gruben[4], R. Riese[4] and G. Wallenstein[4]. [1]Stanford University, Palo Alto, CA, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Centro Paulista de Investigação Clinica, Sao Paulo, Brazil, [4]Pfizer Inc, Groton, CT.

Background/Purpose: Tofacitinib is an oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). Efficacy, inhibition of structural damage, and safety of tofacitinib versus placebo (PBO) were reported previously from the tofacitinib Phase 3 ORAL Scan trial (NCT00847613) in patients with active RA with an inadequate response (IR) to methotrexate (MTX).[1,2] Here we report 24-month patient-reported outcomes (PRO) data from this study.

Methods: Patients on stable-dose MTX were randomized 4:4:1:1 to: tofacitinib 5 mg twice daily (BID), 10 mg BID, or PBO advanced to 5 or 10 mg BID. Patients receiving PBO advanced at Month 3 if non-responders (<20% reduction in swollen or tender joint counts) or at Month 6. Mean changes from baseline in PROs were secondary endpoints, including: Patient Global Assessment (PtGA) of disease activity (visual analog scale [VAS]); patient-reported pain (VAS); Health Assessment Questionnaire-Disability Index (HAQ-DI; mean change from baseline at Month 3 was a co-primary endpoint); and health-related quality of life (HR-QoL; Short Form-36 version 2, acute; SF-36). Analyses used a longitudinal linear mixed-effect model that included all post-baseline visits and accounted for repeated measures on patients, the randomized sequences and baseline values as covariates, on all patients who received ≥1 study drug dose and had both a baseline and ≥1 post-baseline value (full analysis set). Least squares mean changes from baseline at Month 24 are presented. No imputation was used for percentage of patients reporting improvements ≥minimum clinically important differences (MCIDs). Statistical significance at $p \leqq 0.05$, two-sided testing, no adjustment for multiple testing.

Results: 797 patients were randomized and treated; 535 (67.1%) completed 24-months treatment. Baseline characteristics were similar across groups. At Month 3, patients receiving tofacitinib reported statistically significant mean changes versus placebo in all PROs, exceeding MCID; NNTs ranged from 3.7–7.8 and 3.1–5.7 in 5 and 10 mg BID groups, respectively. At Month 24, tofacitinib treatment resulted in statistically significant improvements versus baseline in all PROs (Table), similar to those reported at Month 3. Mean changes across all PROs were numerically greater in patients receiving tofacitinib 10 mg BID, more of whom reported improvements ≥MCID (Table).

Table. PROs at Month 24; least squares mean changes (standard error) from baseline (FAS, longitudinal model) and rate of patients achieving ≥minimally clinically important difference (MCID; FAS, no imputation)

Epstein-Barr Virus In Peripheral Blood Of Rheumatoid Arthritis Patients Predicts Response To Rituximab Therapy. Heikki Valleala[1], Markku Korpela[2], Markku J. Kauppi[3] and Yrjo T. Konttinen[4]. [1]Helsinki University Central Hospital, Helsinki, Finland, [2]Tampere University Hospital, Tampere, Finland, [3]Department of Internal Medicine, Päijät-Häme Central Hospital, Lahti, Finland, [4]Helsinki Univ Central Hospital, Helsinki, Finland.

Background/Purpose: Autoreactive B-cells infected by Epstein-Barr virus (EBV) are suspected to be involved in the aetiology of various human chronic autoimmune diseases. The aim of this study was to determine whether EBV load in the peripheral blood of rheumatoid arthritis (RA) patients predicts response to B-cell depleting therapy with rituximab (RTX).

Methods: 35 RA patients who started treatment with RTX in a routine clinical setting were recruited to this observational study between February 2010 and August 2011. At baseline, disease activity was assessed using DAS28 (ESR) and whole blood (WB) samples were collected to be stored at −70°C. Treatment response was evaluated 3 – 7 months after RTX and if the patient had more than one visit the lowest DAS28 value was used for efficacy analysis. EBV viral load was assessed using quantitative PCR. Quantitative data are reported as median and range, and were compared using Mann-Whitney test. For qualitative data analysis Fisher's exact test was used.

Results: The median disease duration was 16.0 (3–38) years. The number of prior biologicals was 2 (0–4) and the median number of failed synthetic DMARDs was 6 (2–9). 34/35 (97.1%) of the patients were RF positive and 26/27 (96.3%) anti-CCP positive. EBV DNA was detected in 16/35 (45.7%) of the WB samples collected prior to RTX treatment. In the 16 EBV positive patients the median viral load was 3.15 (2.68 – 4.00) log copies/ml. Good/moderate EULAR response was observed in 16/16 of the EBV DNA positive *vs* 13/19 EBV DNA negative patients, $p = 0.022$. Significant response (DAS28 change >1.2) was observed in 14/16 of the EBV DNA positive *vs* 10/19 EBV DNA negative patients, $p = 0.035$. The decline in DAS28 after RTX was 2.10 (1.03 – 4. 78) in the EBV DNA positive *vs* 1.47 (−0.7 – 4.70) in the EBV DNA negative patients, $p = 0.13$.

Conclusion: Our results suggest that presence of EBV genome in WB predicts clinical response to B-cell depleting therapy with RTX. The results also putatively suggest that EBV may have an aetiopathogenic role in a subpopulation of RA patients. However, over 50 % of the EBV negative patients had a clinically significant response to RTX suggesting that, in addition to EBV, also other environmental triggers may be involved in the development of autoreactive B-cell clones.

Phase 2 Evaluation Of PF-04171327, a Dissociated Agonist Of The Glucocorticoid Receptor, For The Treatment Of Rheumatoid Arthritis In Patients With An Inadequate Response To Methotrexate. Thomas Stock[1], Dona Fleishaker[2], Xin Wang[2], Arnab Mukherjee[2] and Charles Mebus[2]. [1]Pfizer Inc., Collegeville, PA, [2]Pfizer Inc., Groton, CT.

Background/Purpose: PF-04171327, a pro drug of PF-00251802, is under investigation as a potential dissociated agonist of the glucocorticoid receptor (DAGR). PF-00251802 is a selective high-affinity partial agonist of the glucocorticoid receptor (GR). It manifests potent anti-inflammatory activity in preclinical in vivo models, at exposures that provide lower adverse effects on bone and glucose metabolism relative to prednisolone, a full GR agonist. If this dissociation is present clinically, PF-04171327 represents a therapeutic improvement relative to current glucocorticoids (GC). The purpose of this study was to evaluate efficacy and safety of PF-04171327, relative to placebo (PBO) and low-dose prednisone, in subjects with active rheumatoid arthritis (RA) and an inadequate response to methotrexate (MTX).

Methods: Adult subjects (>18 years) with active RA and receiving concomitant MTX were randomized to receive oral doses of either PF-04171327 10 mg (n=21) or 25 mg (n=22), prednisone 5 mg (n=21), or PBO (n=22) once daily for 2 weeks in a blinded fashion. Diagnosis of active RA was based on the ACR 1987 Revised Criteria (including at least 6 tender and 6 swollen joints plus elevated CRP of 0.7 mg/dL or higher). Subjects with prior use of GC within six weeks of baseline were excluded. The primary efficacy endpoint was the change from baseline on DAS28-4 (CRP) at Week 2. Secondary efficacy variables included: ACR20/50/70 response rates; individual components of ACR response; DAS28-3 (CRP) and DAS28-4 (CRP), and SF-36. Adverse events (AEs) and safety laboratory tests were recorded throughout. Blood samples were collected for pharmacokinetic and biomarker analyses.

Results: At Week 2, PF-04171327 10 mg and 25 mg showed a statistically significantly greater improvement in the mean change from baseline in DAS28 over PBO by −0.73 ($p=0.0141$) and −1.26 ($p<0.0001$), respectively. In addition, both doses of PF-04171327 demonstrated a greater reduction in DAS28 than prednisone 5 mg at Week 2. Prednisone did not show statistically significant differences in the mean change from baseline in DAS28 over PBO. The effects of PF-04171327 on secondary efficacy variables were generally consistent with those observed for the primary endpoint. Treatment-emergent all causality AEs were reported for 8 (38%), 3 (14%), 11 (19%), and 12 (55%) subjects in the PF-04171327 10 mg, 25 mg, prednisone 5 mg, and PBO groups, respectively. The majority of AEs were mild in severity, with headache the most frequently reported. Four subjects discontinued the study due to an AE (two subjects from the PF-04171327 10 mg group and 2 subjects from the PBO group). There were no SAEs during the study.

Conclusion: PF-04171327 10 mg and 25 mg demonstrated robust and rapid onset of efficacy relative to PBO and prednisone. Both doses were well tolerated. These results support ongoing evaluation of PF-04171327 as a treatment for RA.

Serious Adverse Events Associated With Using Biological Agents To Treat Rheumatic Diseases: Network Meta-Analysis From a National Guideline Panel. Simon Tarp[1], Ulrik Tarp[2], Lis S. Andersen[3], Tove Lorenzen[4], Hanne M. Lindegaard[5], Michael Stoltenberg[6], Hanne S. Jensen[7], Birgitte Brock[8], Camilla M. Mikkelsen[9], Dorte V. Jensen[10], Karsten Asmussen[7], Troels Herlin[11] and Robin Christensen[1]. [1]Musculoskeletal Statistics Unit, The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, [2]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark, [3]Department of Rheumatology, Copenhagen University Hospital, Gentofte, Denmark, [4]Department of Rheumatology, Region Hospital Silkeborg, Silkeborg, Denmark, [5]Odense University Hospital, Odense, Denmark, [6]Department of Rheumatology, Copenhagen University Hospital, Køge, Denmark, [7]Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, [8]Department of Clinical Biochemistry, Aarhus University Hospital, Aarhus, Denmark, [9]The Capital Region of Denmark Hospital Pharmacy, Medicine Information Centre, Copenhagen NV, Denmark, [10]The Danish Rheumatologic Database (DANBIO), Center of Rheumatology and Spine Diseases VRR, Copenhagen University Hospital, Glostrup, Denmark, [11]Aarhus University Hospital, Aarhus, Denmark.

Background/Purpose: Clinical guidelines are needed to help clinicians provide optimal medical treatment and advise patients about the potential hazards associated with certain drugs.

Our objective was to compare the number of serious adverse events (SAEs) for the biologics available for inflammatory arthritis (i.e., rheumatoid arthritis, psoriatic arthritis, and spondylarthritis), enabling a national consensus on safety associated with using these drugs.

Methods: A national guideline panel consisting of clinical experts and methodologists conducted systematic literature searches, identifying random-

ized controlled trials (RCTs) and inviting all pharmaceutical companies marketing the biologics in question. Eligible RCTs included patients with rheumatoid arthritis, psoriatic arthritis, or spondylarthritis, where approved biologics in standard dose were compared with another biologic or placebo. One reviewer extracted data on the number of patients with an SAE from included trials, and a second reviewer confirmed data, which also entailed inviting the respective pharmaceutical companies to verify extracted data regarding their own drug(s). The network meta-analysis was based on mixed-effects logistic regression (modeled in SAS) [1] combining statistical inference from both direct and indirect comparisons of the treatment effects of among the biologics.

Results were reported as odds ratios (OR [95%CI]). For sensitivity, we explored trial duration using weeks as a covariate in the model.

Results: From the 94 identified RCTs complying with our eligibility criteria, 7 did not report data on SAEs. Thus, the meta-analysis included 87 trials (27,333 patients) comprising 85 placebo and 90 biologic trial arms: abatacept (8), adalimumab (22), anakinra (2), certolizumab (8), etanercept (15), golimumab (8), infliximab (14), rituximab (5), and tocilizumab (8). The odds for SAEs were statistically higher ($P < 0.05$) for certolizumab and tocilizumab compared with the placebo (1.60 [1.19;2.16]; $P = 0.0022$ and 1.33 [1.03;1.70]; $P = 0.028$ respectively). Certolizumab was statistically more likely to result in SAEs compared with all of the following: golimumab (2.02[1.26;3.25]; $P = 0.0042$), etanercept (1.70[1.15;2.51]; $P = 0.0084$), rituximab (1.68[1.06;2.66]; $P = 0.027$), abatacept (1.53 [1.05;2.25]; $P = 0.028$), and adalimumab (1.44[1.02;2.02]; $P = 0.037$). Further, tocilizumab was statistically more likely to result in SAEs than golimumab (1.67[1.07; 2.62]; $P = 0.025$). All other comparisons showed no statistically significant differences ($P > 0.05$).

Conclusion: This network meta-analysis of RCTs provides empirical evidence that certolizumab and tocilizumab both present an increased likelihood of SAEs compared with placebo. Supported by a recent Cochrane review [2] the Danish guideline panel concluded that certolizumab was more likely to cause SAEs compared with several other biologics and thus made a weak recommendation against its use.

2338

Biologic Switching Rates Among Patients With Rheumatoid Arthritis.

L Rosenblatt[1], F Lobo[2], P Cockrum[2], L Wang[3], E Alemao[2], O Baser[4] and H Yuce[5]. [1]Bristol-Myers Squibb, Plainsboro, NJ, [2]Bristol-Myers Squibb, Princeton, NJ, [3]STATinMED Research, Dallas, TX, [4]STATinMED Research and University of Michigan, Ann Arbor, MI, [5]New York City College of Technology (CUNY), Brooklyn, NJ.

Background/Purpose: Treatment guidelines for the management of RA recommend sequential use of biologic therapies, and the majority of patients switch from one anti-TNF agent to another. Previous data from commercial claims databases have shown that patients on a second-line anti-TNF agent are more likely to switch biologic treatment than those on second-line abatacept, a biologic with a different mechanism of action.[1] We assessed treatment switching in a Medicare population of patients with RA, who had received a first- or second-line biologic DMARD (bDMARD; abatacept, adalimumab, etanercept, infliximab).

Methods: A retrospective, observational analysis using Medicare claims data (January 2006–December 2010) was conducted in patients with RA newly initiated on a bDMARD (first-line cohort). Further analysis in a subgroup compared first-line anti-TNF patients who switched to another anti-TNF (adalimumab, etanercept, infliximab) with first-line anti-TNF patients who switched to abatacept (second-line cohort). Patients in the first- and second-line cohorts were required to have a minimum of 6-month pre-index, and 12-month post-index, eligibility. Patients were defined as switchers if they had a claim for a new bDMARD within 200% days' supply of the last claim for index bDMARD during the post-index period. Switch rates in first- and second-line cohorts were determined. Patients who discontinued index bDMARD (and did not switch) in the post-index period were excluded from the analyses. Logistic regression determined the odds of switching for patients on abatacept compared with those on anti-TNFs, while controlling for covariates.

Results: Of the 18,148 first-line bDMARD patients with RA included in the analyses (81.5% anti-TNF and 18.5% abatacept), switch rates were 11.7% and 10.6% for those taking anti-TNFs and abatacept, respectively ($p=0.0174$). For the second-line analyses, 777 bDMARD patients were included (45.4% anti-TNF and 54.6% abatacept). Subsequent switch to a third bDMARD occurred in 12.7% of those who had previously switched to abatacept and 28.6% of those who had previously switched to an anti-TNF ($p<0.001$). Logistic regression demonstrated that, after adjusting for covariates, patients who switched to abatacept had significantly lower odds of switching again than anti-TNF switchers (odds ratio=0.33, 95% CI: 0.22, 0.51).

	Total, n (%)	Switchers, n (%)
First-line analysis (n=18,148)		
Anti-TNF	14,794 (81.5)	1728 (11.7)
Abatacept	3354 (18.5)	357 (10.6)
Second-line analysis (n = 777)		
Anti-TNF to anti-TNF	353 (45.4)	101 (28.6)
Anti-TNF to abatacept	424 (54.6)	54 (12.7)

Conclusion: In a Medicare population, patients with RA who switch between anti-TNFs have significantly higher rates of subsequent bDMARD switch compared with those who switch from an anti-TNF to abatacept. It is hypothesized that treatment pathways that include switching to a different class of bDMARD may reduce subsequent overall bDMARD switch rates and therefore reduce costs in the management of patients with RA.

Patient Evaluations Of Subcutaneous Golimumab Delivery By Autoinjector (SmartJect®) For Treatment Of Rheumatoid Arthritis.

H Schulze-Koops[1], R Giacomelli[2], W Samborski[3], S Rednic[4], M Herold[5], R Yao[6], M Govoni[7], N Vastesaeger[8] and HH Weng[6]. [1]University of Munich, Munich, Germany, [2]Università degli Studi dell'Aquila, L'Aquila, Italy, [3]Ortopedyczno-Rehabilitacyjny Szpital Kliniczny, Wielkopolskie, Poland, [4]University of Medicine & Pharmacy, Cluj-Napoca, Romania, [5]Medical University of Innsbruck, Innsbruck, Austria, [6]Merck Sharp & Dohme, Kenilworth, NJ, [7]Merck Sharp & Dohme, Rome, Italy, [8]Merck Sharp & Dohme, Brussels, Belgium.

Background/Purpose: Self-injection of subcutaneous (SC) golimumab (GLM) using an autoinjector device may be useful for patients with rheumatoid arthritis (RA), especially if they have functional impairment in the joints of the hand and fingers. An autoinjector designed to account for RA patient disability may improve patient satisfaction. The purpose of this study was to measure the acceptability, ease of use, and preferences for use of an autoinjector for SC GLM administration; effects of patient age and functional impairment were evaluated.

Methods: GO-MORE was an open-label, multinational, prospective study in biologic-naïve patients with active RA (DAS28-ESR ≥3.2). Patients self-injected 50-mg SC GLM once monthly for 6 months. At months 4 and 6, patients reported their use preferences and opinions of the autoinjector device on a questionnaire. Responses were analyzed descriptively. Effects of patient age and functional impairment on responses were evaluated.

Results: Overall, the vast majority of patients found the autoinjector to be easy to use, to cause mild or no discomfort, and to cause mild or no pain (table). At month 6, most of the efficacy-evaluable patients reported they preferred to self-inject in the thigh (75.2%; 1563/2077), followed by the abdomen (17.5%; 363/2077) and the upper arm (7.3%; 151/2077). More than 85% of patients indicated that they used their right hand for self-injection. More than 95% of patients were sure or very sure that when they used the

autoinjector, the treatment had been fully injected; and 92.1% were satisfied or very satisfied with the monthly autoinjection frequency. Responses did not differ by patient age group. Patients with minimal or no functional impairment (HAQ-DI ≤0.5) at baseline tended to have more favorable responses, including greater ease of injection and less pain with injection, than those with functional impairment. At month 6, the overall self-injection experience was considered extremely favorable by 53.7% and favorable by 39.5% of patients without impairment and extremely favorable by 42.5% and favorable by 49.1% of patients with impairment.

Table. Patient Assessments of Autoinjector Use for SC GLM Delivery at Month 6

Overall Impression	n (%)	Impressions of Pain	n (%)
Ease of autoinjector use	N=2089	Overall injection discomfort	N=2090
Extremely easy/easy	1744 (83.5)	None/mild	1983 (94.9)
Neither easy nor difficult	274 (13.1)	Moderate	96 (4.6)
Difficult/extremely difficult	71 (3.4)	Severe/prohibitive	11 (0.5)
Overall impression of self-injection	N=2094	Pain/stinging upon injection	N=2092
Extremely favorable/favorable	1922 (91.8)	None/mild	1977 (94.5)
Neither favorable nor unfavorable	151 (7.2)	Moderate	107 (5.1)
Unfavorable/extremely unfavorable	21 (1.0)	Severe/prohibitive	8 (0.4)

Conclusion: Most patients had very favorable evaluations of the autoinjector device for GLM, reporting it to be easy to use, with minimal pain or discomfort upon injection and satisfactory administration frequency.

Persistent Use Of Biologic Therapies At Lower Than Recommended Dosing Among Rheumatoid Arthritis Patients Enrolled In The US Medicare Program. Jie Zhang[1], Fenglong Xie[1], Elizabeth S. Delzell[1], Huifeng Yun[1], James Lewis[2], Kevin Haynes[3], Lang Chen[1], Kenneth G. Saag[1] and Jeffrey R. Curtis[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania., Philadelphia, PA.

Background/Purpose: Biologic therapy is associated with significant personal and societal costs. One possible strategy to reduce such cost is the use of reduced dose biologic whenever possible and the appropriateness of such an approach has been shown in a randomized clinical trial. The objective of the study is to examine the use of self-injectable biologics at reduced dose compared to the recommended dose in real world clinical practice.

Methods: We conducted a retrospective cohort study among patients with rheumatoid arthritis who were enrolled in the Medicare fee for service program with prescription drug coverage from 2006 to 2010. Eligible patients were required to have initiated either etanercept or adalimumab after a 12-month period with continuous coverage free of that agent. Follow-up started at treatment initiation and ended when a patient discontinued their biologic (> 90 day gap since end of days supply), switched to a different biologic, lost coverage, or died. For each patient, we calculated the number of days covered under each filled prescription assuming a constant rate of use (etanercept: 50 mg/week; adalimumab: 40 mg/2 weeks). We divided the follow-up time into 6-month intervals in which a patient remained under follow-up at the end of the interval; within each interval we calculated the proportion of days covered by the medications out of the total number of days. We defined reduced-dose biologic as having < 80% of the days covered and calculated the proportion of patients who continuously used reduced-dose biologic for 18 months, 24 months, and 30 months.

Results: We identified 3943 RA patients who were eligible to be included in this analysis, mean age 62 (standard deviation: 13); 83% were women; 2,541 initiated etanercept; and 2,389 initiated adalimumab. Among etanercept users, 11.4% of the patients received reduced-dose etanercept continuously for 18 months during their follow-up; 7.0% and 4.4% of the patient received reduced-dose etanercept continuously for at least 24 and 30 months, respectively. Among adalimumab users, the corresponding proportions were lower with 7.6%, 4.5%, and 1.9% of the persistent users received reduced-dose adalimumab for a continuous period of 18, 24, and 30 months. Data are also presented in the figure below.

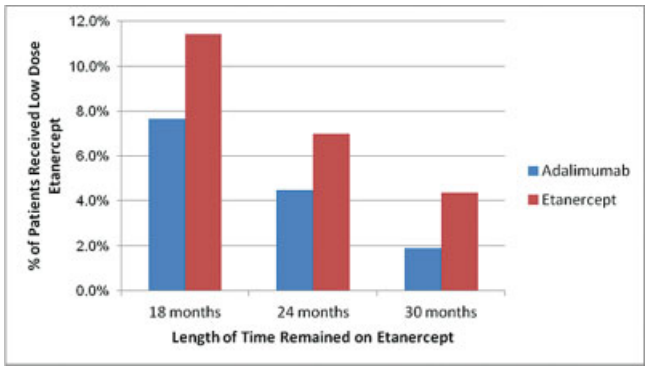

Figure. Proportion of RA Patients who Continuously Used Reduced Dose Injectable Etanercept or Adalimumab

Conclusion: In real-world clinical practice, up to 11% of RA patients received self-injectable biologics at a lower than the recommended dose for an extended period of time.

Efficacy Of Adalimumab Plus Methotrexate Therapy In Rheumatoid Arthritis Non-Responders Receiving Methotrexate Monotherapy Or Adalimumab Combination Therapy: Results From The Optima Trial. Josef S. Smolen[1], Ronald F. van Vollenhoven[2], Roy Fleischmann[3], Paul Emery[4], Stefan Florentinus[5], Suchitrita S. Rathmann[6], Anabela Cardoso[7], Hartmut Kupper[8] and Arthur Kavanaugh[9]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]The Karolinska Institute, Stockholm, Sweden, [3]University of Texas Southwestern Medical Center, Dallas, TX, [4]Leeds Teaching Hospital, Leeds, United Kingdom, [5]AbbVie, Rungis, France, [6]AbbVie Inc., North Chicago, IL, [7]AbbVie, Amadora, Portugal, [8]AbbVie Deutschland GmbH & Co KG, Ludwigshafen, Germany, [9]University of California, San Diego, La Jolla, CA.

Background/Purpose: EULAR recommendations advocate Methotrexate (MTX) as first line therapy. For patients (pts) who fail to attain remission or low disease activity (LDA) after 6 months of MTX treatment, TNF inhibitors should be added to the therapeutic regimen in pts with high risk of bad outcome. This *post hoc* analysis examined outcomes following open label (OL) adalimumab (ADA) +MTX in rheumatoid arthritis (RA) pts who did not achieve a stable LDA target at 22 and 26 weeks (wks) either from ADA+MTX or MTX monotherapy. Consequences of optimizing or not optimizing therapy were assessed.

Methods: OPTIMA was a 78 wk, randomized, double-blind, double-treatment period study designed to compare safety and efficacy of ADA+MTX with placebo (PBO) +MTX in early RA pts. Following ADA+MTX or PBO+MTX treatment for 26 wks (Period 1), non-responders (NR) were defined as pts failing to achieve a stable LDA target of DAS28(CRP) <3.2 at wks 22 and 26 and given OL ADA+MTX for an additional 52 wks, (Period 2) (OL ADA Carry On and Rescue ADA arms, respectively). Period 2 responders were defined as those achieving LDA at wk78 following OL ADA+MTX therapy. Logistic regression analysis was conducted with baseline and wk26 disease characteristics as variables.

Results: Compared with responders, Period 1 NR began the study with higher overall disease activity. Among these, 78/259 (30%) OL ADA Carry On and 157/348 (45%) Rescue ADA pts achieved DAS28(CRP) <3.2 following 26 wks of OL ADA+MTX therapy; 33/259 (13%) and 49/348 (14%) OL ADA Carry On and Rescue ADA pts, respectively, had DAS28(CRP) ≥3.2 at wk52 and achieved DAS28(CRP) <3.2 at wk78. Mean values of responders' clinical, radiographic, and functional outcomes

were much lower than those of NR and were similar to those seen for pts who achieved the treatment target within the first period. This indicates that starting with MTX followed by ADA in insufficient responders to MTX is an appropriate strategy; a small subset of pts responds more slowly to MTX/ADA combination from start (**Table**). ACR20/50/70 scores for the Rescue ADA arm from wk26 to wk78 were sizeable (51%, 34%, and 19%, respectively). OL ADA Carry On arm achieved ACR20/50/70 from wk26 baseline in 27%, 15%, and 8% of pts, respectively, at wk78. Age, patient and physician's global assessment of disease, and tender/swollen joint counts were all predictors of achieving DAS28(CRP) <3.2 at wk78.

Table. Period 2 Responder vs. Non-Responder Outcomes

	DAS28(CRP)				mTSS				HAQ-DI			
	Responders		Non-Responders		Responders		Non-Responders		Responders		Non-Responders	
	CO[a] n=106	RES[b] n=175	CO[a] n=121	RES[b] n=142	CO[a] n=106	RES[b] n=175	CO[a] n=120	RES[b] n=142	CO[a] n=106	RES[b] n=175	CO[a] n=121	RES[b] n=142
Baseline	6.13[c]	5.98[d]	6.32[e]	6.34[f]	10.16[c]	11.15	11.98	13.44	1.75[c]	1.59[g]	1.71	1.73
Week 26	3.73	4.13	4.41	4.88	10.34	12.75	12.27	14.14	0.82	0.94	1.10	1.20
Week 52	2.38	2.29	4.34	4.25	10.38	12.76	12.32	14.18	0.62	0.53	1.10	1.02
Week 78	2.71	2.28	4.02	3.81	10.66	12.65	12.41	14.51	0.60	0.50	1.08	1.01

[a]ADA Carry On arm; [b]Rescue ADA arm; [c]n=105; [d]n=169; [e]n=118; [f]n=141; [g]n=174; DAS28(CRP), 28-joint disease activity score with C-reactive protein; mTSS, modified total Sharp score; HAQ-DI, disability index of the health assessment questionnaire.

Conclusion: When advanced to OL ADA+MTX therapy, pts initially not achieving stable LDA target at wk26 following MTX monotherapy demonstrated improvements in clinical and functional outcomes at wk52 and wk78. In addition, structural progression was minimal. Some improvement was also seen among pts who did not yet attain stable LDA at wk26 on ADA+MTX but continued this treatment; however, it remains unknown whether pts who were not in LDA at wk78 might have benefited from earlier treatment adjustment in an attempt to further improve outcomes.

Long-Term Safety Of Rituximab: Pooled Analysis Of The Rheumatoid Arthritis Global Clinical Trial Program Over 11 Years. Ronald van Vollenhoven[1], Paul Emery[2], Clifton O. Bingham III[3], Edward Keystone[4], Roy M. Fleischmann[5], Daniel E. Furst[6], Eva W. Hessey[7], Abdul Mehbob[7] and Patricia B. Lehane[7]. [1]Karolinska Institute, Stockholm, Sweden, [2]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [3]Johns Hopkins University, Baltimore, MD, [4]University of Toronto, Toronto, ON, [5]University of Texas Southwestern Medical Center, Dallas, TX, [6]University of California, Los Angeles, Los Angeles, CA, [7]Roche Products Ltd., Welwyn Garden City, United Kingdom.

Background/Purpose: This analysis evaluated the long-term safety of rituximab (RTX) in rheumatoid arthritis (RA) patients in a global clinical trial program.

Methods: Pooled observed case analysis of safety data from patients with moderate to severe active RA treated with RTX+MTX. Patients were re-treated based on physician's determination of clinical need and evidence of active disease (defined as either SJC and TJC ≥8 or DAS28 ≥2.6). Subgroup analysis of patients with follow-up >5 years was undertaken. Pooled data from patients who received placebo during placebo-controlled study periods were also analyzed.

Results: As of Sep 2012, 3595 patients (All-Exposure population) had received up to 20 courses of RTX over the 11-year observation period (14 816 pt-yrs). Of these patients, 1246 had >5 years follow-up. The placebo population comprised 818 patients (1107 pt-yrs) with a mean follow-up of 1–1.5 years. In the All-Exposure population, infusion-related reaction (IRR) was the most frequent adverse event (AE); most were grade 1 or 2, were rarely serious (0.5%), and primarily occurred following the 1st infusion of the 1st course (799/3595 patients; 22%). Rates per 100 pt-yrs for AEs, serious AEs (SAEs), and infections were not increased when compared to placebo (Table). Overall serious infection rates in RTX-treated patients were comparable to those observed in the placebo population. Pneumonia was the most frequently reported serious infection (2% of RTX patients). There were no cases of hepatitis B reactivation. Serious opportunistic infections were rare (0.05/100 pt-yrs in RTX patients vs 0.09/100 pt-yrs in placebo). One confirmed case of PML in the RA clinical trial program has been reported, as previously described.[1] Following RTX treatment, low immunoglobulin (Ig) concentrations (particularly IgM, less often IgG) were observed. For both Ig classes, serious infection rates were similar before and during/after development of low Ig. No increased risk of malignancy over time or course was evident, and MI rates (0.39/100 pt-yrs) were consistent with rates in the general RA population (0.48–0.59/100 pt-yrs).[2]

Table 1. Summary of AE rates per 100 patient-years (95% CI)

	RTX All-Exposure (n=3595) 14 816 pt-yrs	RTX Long-Term (>5 yrs) (n=1246) 8970 pt-yrs	Pooled placebo (n=818) 1107 pt-yrs
AEs	239.11 (236.63–241.61)	219.36 (216.31–222.44)	315.43 (305.14–326.06)
SAEs	13.82 (13.24–14.43)	11.88 (11.19–12.62)	13.82 (11.79–16.19)
Infections	75.70 (74.31–77.11)	70.52 (68.81–72.28)	90.39 (84.96–96.17)
Serious infections	3.76 (3.46–4.09)	2.71 (2.39–3.07)	3.79 (2.80–5.13)

AEs, adverse events; CI, confidence interval; pt-yrs, patient-years; RTX, rituximab; SAEs, serious adverse events.

Conclusion: These long-term data from 3595 patients treated with RTX over 11 years (14 816 pt-yrs) of follow-up in clinical trials confirm that RTX remains well tolerated over time and multiple courses, with a consistent safety profile. No new safety signals were observed with increasing duration of exposure. Apart from IRRs and low Ig (where there was a lack of placebo comparator), the overall safety profile of RTX remains similar to that for the pooled placebo population and is consistent with published data for moderate to severe RA and with previous analyses of this patient cohort.[3]

Assessment Of Subclinical Atherosclerosis (Flow Mediated Dilatation and arterial stiffness) After 24 Weeks Of a Tocilizumab Therapy In 22 Patients With Rheumatoid Arthritis. Martin Soubrier[1], Thomas Frayssac[2], Bruno Pereira[3], Marion Couderc Sr.[4], Coline Daron[2], Jean Jacques Dubost[5], Sandrine Malochet-Guinamand[4], Anne Tournadre[4] and Sylvain Mathieu[4]. [1]CHU CLERMONT-FERRAND, Clermont-Ferrand, France, [2]CHU CLERMONT-FERRAND, Clermont-ferrand, France, [3]Clinical research department, Clermont-Ferrand, France, [4]Rheumatology CHU Gabriel Montpied, Clermont-Ferrand, France, [5]CHU G.-Montpied, Clermont-Ferrand, France.

Background/Purpose: Increased incidence of cardiovascular diseases and sub-clinical atherosclerosis have been observed in rheumatoid arthritis (RA). Inflammation and traditional risk factors could be involved in the pathogenesis. As Tocilizumab inhibits the IL6 pathway, it decreases inflammation and then could improved the cardiovascular risk. However, this positive effect could be counterbalanced by the induced dyslipidemia. Objectives: To investigate the effects of Tocilizumab treatment on flow mediated dilatation (FMD) and arterial stiffness (i.e augmentation index AIx and pulse wave velocity PWV), two markers of sub-clinical atherosclerosis in active RA.

Methods: Sub-clinical atherosclerosis was assessed in 22 RA patients at baseline and after 24 weeks of Tocilizumab therapy.

Results: 22 RA patients, including 18 women (81%) with a mean age of 58.2 ± 11.6 years were included. Of these 22 patients, 18 (81%) had positive rheumatoid factors, 16 (72%) had positive anti-CCP antibodies, 20 (90%) were erosive. 18 patients (81%) were refractory to TNF alpha inhibitors treatments, 2 (9%) to rituximab treatment, 4 (18%) to abatacept treatment. No changes in FMD (N = 9 patients) (6,63±4,68 at 6 month vs. 5,21±2,54 at baseline, p=0,59) or arterial stiffness (N = 22) (PWV: 7,95±3,59 vs. 7,96±2,98, p=0,93; AIX: 29,57±11,7 vs. 29,89±12,83, p=0,92) were detected after 6 months of treatment with Tocilizumab. DAS28 ESR and DAS28 CRP were significantly improved (2,67±1,1 vs. 5,03±0,84, p<0,001 and 3,11±0,95 vs. 4,78±0,66, p<0,001, respectively). Among the DAS28 parameters, a significant improvement in patient global score (41,33±25,88 vs. 64,18±15,29, p=0,003), and number of tender and swollen joints (respectively 4,54±6,42 vs. 7,63±5,63, p=0,01 and 2,5±2,61 vs. 6,63±4,47, p<0,001) was observed. After 6 months of Tocilizumab therapy, CRP (4,28±8,98 vs. 23,93±32,20 mg/l, p=0,015) and ESR (4,19±3,02 vs. 29,19±24,12 mm/h, p<0.001) significantly decreased. There was no change in systolic and diastolic blood pressure (SBP: 130.79±17.21 vs 131.32±22.96 mm Hg; p=0.87/DBP: 78.47±11.58 vs 74±12.29 mm Hg; p=0.16). Total cholesterol (2,26±0,45 vs. 1,97±0,48 g/l, p<0,001), LDL cholesterol (1,66±0,4 vs. 1,13±0,30 g/l, p=0,004), atherogenic index (3,62±1,18 vs. 3,07±1,11, p=0,026) and triglycerides (1,22±0,61 vs 1,04±0,48 g/l, p = 0,047) were significantly increased whereas no significant modification in HDL cholesterol (0,66±0,19 vs. 0,71±0,26 g/l, p=0,40) was detected. There was significant increase in hip circumference (99,43±13.14 vs. 96,68±13,99 cm; p=0,02).

Conclusion: Unlike Protogerou[1] and Kume[2], our results suggest that sub-clinical atherosclerosis observed in RA, was not improved after 6 months of Tocilizumab therapy. This lack of improvement might be due to the induced proatherogenic lipid profile. Further studies are needed.

Effect Of Tocilizumab On Treatment Patterns, Effectiveness and Safety With Laboratory Values For Patients With Rheumatoid Arthritis: Analyses From The Corrona-Certain Study.

Dimitrios A. Pappas[1], Ani John[2], Joel M. Kremer[3], Chitra Karki[4], Tanya Sommers[4], George W. Reed[4], Jeffrey R. Curtis[5], Ashwini Shewade[2] and Jeffrey D. Greenberg[6]. [1]Columbia University, New York, NY, [2]Genentech Inc., South San Francisco, CA, [3]Albany Medical College and The Center for Rheumatology, Albany, NY, [4]CORRONA, Inc., Southborough, MA, [5]University of Alabama-Birmingham, Birmingham, AL, [6]NYU Hospital for Joint Diseases, New York, NY.

Background/Purpose: Data from randomized clinical trials (RCTs) and their open-label extensions in patients (pts) with rheumatoid arthritis (RA) indicate that tocilizumab (TCZ) may be associated with treatment-related decreases in neutrophils and platelets and increases in lipids and liver enzymes1; however, analyses of treatment effects on laboratory parameters in real-world pt populations are limited. The objective of this study was to assess changes in laboratory measures with TCZ treatment over 6 months in pts with RA from the prospective CORRONA CERTAIN substudy.

Methods: Pts with at least moderate disease activity (CDAI >10) initiating TCZ were eligible for the ongoing biologic agent comparative effectiveness study (CERTAIN) nested within CORRONA. The decision to start TCZ was made by the physician prior to enrollment. Efficacy outcomes (CDAI and HAQ) and laboratory measures (CRP, hemoglobin, cell counts, lipids and liver enzymes) were assessed at baseline (BL) and every 3 months for a year. Cutoff values for laboratory normals were based on US Prescribing Information, where applicable.2 Data for pts who have completed a 6-month visit are presented.

Results: Of 1620 pts with RA enrolled in CERTAIN, 244 pts initiated TCZ therapy between November 2010, and February 2013. At the time of analysis, 65 pts had not yet completed 6 months of follow-up and 43 pts had exited the CERTAIN study prior to 6 months; available reasons for TCZ discontinuation include 8 safety (1 serious side effect), 11 efficacy and 4 other reasons. Of the 136 pts who completed a 6-month follow-up visit, 109 (80.1%) were female, 120 (88.2%) were Caucasian and 72/128 (56.3%) were seropositive at BL; the mean ± SD age and RA duration were 57.9 ± 12.9 years and 11.9 ± 9.4 years, respectively. A total of 41 (30.1%) pts received TCZ as monotherapy; of the pts initiating TCZ in combination with nonbiologic DMARDs, 72 (75.8%) received concurrent MTX. After 6 months of TCZ treatment, median (IQR) CDAI improved from 31.0 (23.0–41.7) to 15.0 (8.0–26.3). Median (IQR) HAQ improved from 1.25 (0.5–1.75) to 1.00 (0.5–1.63). Changes in laboratory values of interest over 6 months are shown in Table 1. The proportion of pts with anemia decreased from 19.5% at BL to 11.0% and 1.7% of pts developed neutropenia at 6 months. Median lipid values increased at 6 months and 15.5% and 17.9% of pts respectively had AST and ALT above the upper limit of normal at 6 months vs 2.7% and 6.5% at BL.

Table 1. Laboratory Measures for Patients Initiating TCZ Therapy Within CERTAIN at Baseline and After 6 Months Follow-up

Laboratory Measurements	Baseline	6-Month Follow-up
CRP, median (IQR), n=120	3.88 (1.64–12.50)	0.57 (0.23–1.42)
Hemoglobin (g/dL), median (IQR), n=118	13.1 (12.1–14.0)	13.4 (12.4–14.2)

[a]Anemia defined as <11.5 g/dL for females, <13.2 g/dL for males.
[b]Neutropenia defined as <1000 neutrophils/μL.
[c]Thrombocytopenia defined as <50,000 platelets/μL.
ALT, alanine aminotransferase; AST, aspartate aminotransferase; CDAI, clinical disease activity index; CRP, C-reactive protein; HAQ, health assessment questionnaire; HDL, high-density lipoprotein; LDL, low-density lipoprotein; TC, total cholesterol; TCZ, tocilizumab; TG, triglycerides; ULN, upper limit of normal; WBC, white blood cells.

Conclusion: TCZ improved clinical outcomes and was associated with alteration of specific laboratory parameters in pts with RA. The interim analyses of laboratory changes are similar with observations from RCTs for 6 months. Continued enrollments and longer follow-up in CERTAIN are needed to further assess clinical relevance of these laboratory changes.

Long-Term Targeted Safety Event Rates In RA Patients Following Initiation Of Rituximab: Interim Analysis From Sunstone Registry. Kenneth G. Saag[1], Kevin L. Winthrop[2], Kimberly Alexander[3], Steven Francom[3] and Daniel E. Furst[4]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Oregon Health & Science University, Portland, OR, [3]Genentech, Inc., South San Francisco, CA, [4]UCLA, Los Angeles, CA.

Background/Purpose: Rituximab (RTX) is used for the treatment of rheumatoid arthritis (RA) in patients (pts) with an inadequate response to anti-TNF therapy (TNF-IR). Long-term safety data on real world RTX use in RA are limited. The objective of this study is to describe the frequency of targeted safety events in an observational cohort of RA pts initiating RTX in the US.

Methods: SUNSTONE is a prospective observational cohort study designed to evaluate the safety of RTX in RA pts in the real-world setting. Pts are evaluated and treated according to their physician's standard practice and followed at standard of care visits every 6 mo. All pts were required to receive ≥1 RTX course but could subsequently receive other RA therapies including biologic DMARDs. Pts are assessed at baseline and at follow-up visits every ≤6 mo. Data collection focuses on targeted adverse events (AEs) (significant infections [infections that meet serious AE criteria or require IV antibiotics], cardiovascular [CV] thrombotic events, seizures, deaths, and pregnancies. Pts are followed for 5 y (regardless of time of RTX discontinuation or start of another biologic therapy), until death, withdrawal of consent or loss to follow-up. Interim analysis results (Apr 1, 2013) are presented (study completion expected 2014). Baseline demographic and disease characteristics, and safety events captured during follow-up are summarized. For calculating incidence rates (IR), patients were censored at the time of first event[1–3]. Crude IR per 100 pt-yrs (PY) are reported.

Results: Overall, 994 pts (3800 PY) received RTX (82% female; median age 58 y; median disease duration 9 y; 72% RF+). Mean follow-up was 3.8 y; mean number of RTX courses was 4; 72% received ≥2 courses. Significant infections were reported in 195 pts (20%), with a corresponding IR of 5.8 (95% CI: 5.0–6.7) per 100 PY. Respiratory (n=75), skin/soft tissue (n=32) and genitourinary infections (n=24) were the most common infections observed. IR per 100 PY (95% CI) of other safety events were: myocardial infarction 0.6 (0.4–0.9), stroke 0.5 (0.3–0.8), pulmonary embolism 0.3 (0.1–0.5), deep vein thrombosis 0.4 (0.2–0.7) and seizures 0.1 (0.1–0.3). Eight pregnancies were reported. No cases of progressive multifocal leukoencephalopathy or tuberculosis were reported. Overall, 62 deaths were reported (1.6/100 PY; 95% CI 1.3–2.1). CV disease (n = 14), malignancy (n = 12) and infection (n = 15) were the most common causes of death.

Conclusion: This interim analysis provides a preliminary summary of the frequency of targeted safety events from the SUNSTONE registry of RA pts who were TNF-IR and initiated RTX treatment. Although there are important limitations when comparing the results of the SUNSTONE registry with similarly designed observational studies, these results are consistent with registries of aTNF's and provide real-world data for rituximab.[1–3]

Effects Of Tofacitinib, An Oral Janus Kinase Inhibitor, On Work Limitations In Patients With Rheumatoid Arthritis. Vibeke Strand[1], Keith S. Kanik[2], Carol Connell[2], Bethanie Wilkinson[2], David Gruben[2] and Gene Wallenstein[2]. [1]Stanford University, Palo Alto, CA, [2]Pfizer Inc, Groton, CT.

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Participation, in particular work productivity, is increasingly recognized as an important outcome in RA. Here we describe workplace limitations in patients (pts) with RA treated with tofacitinib.

Methods: Data were reviewed from five, Phase 3, double-blind, randomized controlled trials of 6–24 months' duration in pts with 7–13 years' mean disease duration, having failed various disease-modifying antirheumatic drugs (DMARDs). Tofacitinib was dosed at 5 or 10 mg twice daily (BID) as either monotherapy (ORAL Solo, NCT00814307) or in combination with non-biologic DMARDs (mainly methotrexate) in pts with inadequate responses to ≥1 non-biologic or biologic DMARD, including tumor necrosis factor inhibitors (ORAL Scan, NCT00847613 [1-year data]; ORAL Sync, NCT00856544; ORAL Standard, NCT00853385; ORAL Step, NCT00960440). The 25-item Work Limitations Questionnaire (WLQ) was used to assess the impact of RA on job performance and productivity. Responses are combined into 4 scales ranging from 0 (no limitation) to 100 (limited all of the time): time management, physical, mental/interpersonal, and output demands.

Results: Proportions of pts working at the baseline visit were: 49% (302/611; ORAL Solo), 50% (394/792; ORAL Sync), 49% (387/797; ORAL Scan), 39% (278/717; ORAL Standard), 38% (153/399; ORAL Step). Least squares mean changes from baseline at Month 3 are presented in the Table.

		LSM change from baseline at Month 3				
Scale	Treatment	ORAL Solo	ORAL Sync	ORAL Scan	ORAL Standard	ORAL Step
Time Management Demands	Tofacitinib 5 mg BID	11.43	−11.31	−4.01	−9.83	−10.96*
	Tofacitinib 10 mg BID	11.55	−14.58	−9.43	−16.01**	−11.03*
	Placebo	5.67	−8.26	−5.64	−0.52	4.09
Physical Demands	Tofacitinib 5 mg BID	0.99	−5.60**	0.30	−0.10	−0.17
	Tofacitinib 10 mg BID	−3.75	−4.06*	−4.41	−5.84	−2.89
	Placebo	−2.47	6.17	−0.98	3.67	−9.42
Mental/Interpersonal Demands	Tofacitinib 5 mg BID	5.03	−9.29	−2.94	−3.37	−2.69
	Tofacitinib 10 mg BID	6.18	−9.67	−5.32	−7.99	−5.29*
	Placebo	4.52	−8.15	1.24	−0.48	7.11
Output Demands	Tofacitinib 5 mg BID	9.52	−9.71	−6.15	−8.29	−11.36**
	Tofacitinib 10 mg BID	9.80	−13.10	−11.40**	−13.49*	−8.15*
	Placebo	4.54	−8.89	−0.64	−3.82	6.25

*p<0.05; **p<0.01 versus placebo; no correction for multiple comparisons
P-values are for LSM change from baseline versus placebo. Negative values imply improvement
BID, twice daily; LSM, least squares mean

Conclusion: Across the five Phase 3 studies reviewed, pts receiving tofacitinib reported significant effects in at least one scale of the WLQ, but not across all scales. These pt populations had long disease duration having failed multiple DMARDs, including biologics, and only 38–50% of pts were working at the baseline visit. Taken together, these data indicate an overall positive effect of tofacitinib on work productivity in pts with RA.

Functional Single Nucleotide Polymorphisms In The Interferon-γ and The NLRP3 (Cryopyrin) Genes Associated With Anti-TNF Response In Danish Rheumatoid Arthritis Patients. Jacob Sode[1], Niels H. H. Heegaard[2], Henning Locht[3], Ulla Vogel[4], Steffen Bank[5], Merete Lund Hetland[6] and Vibeke Andersen[7]. [1]University of Southern Denmark, Odense, Denmark, [2]Statens Serum Institut, Copenhagen, Denmark, [3]Frederiksberg Hospital, Frederiksberg, Denmark, [4]National Research Centre for the Working Environment, Copenhagen, Denmark, [5]University of Aarhus, Aarhus, Denmark, [6]The Danish Rheumatologic Database (DANBIO), Glostrup Hospital., Copenhagen, Denmark, [7]OPEN (Odense Patient data Explorative Network), Odense, Denmark.

Background/Purpose: Most patients with rheumatoid arthritis (RA) benefit from tumor necrosis factor-a blocking treatment (anti-TNF). About 1/3, however, do not respond to this costly and potentially harmful treatment. The objective of this study was to determine whether polymorphisms of inflammatory pathway genes may predict the variation in response to anti-TNF treatment in RA patients.

Methods: Forty-one single nucleotide polymorphisms (SNPs), including 34 functional, in 28 genes involved in inflammatory pathways were assessed in 538 anti-TNF naive Danish RA patients. Prospectively collected clinical data including functional status (HAQ), patient global score, lifestyle factors (smoking), tender and swollen joint counts, treatments, rheumatoid factor status and CRP were obtained from the DANBIO registry. Multivariable logistic regression analyses were performed to test associations between genotypes and EULAR response at 3–6 months. ACR50 response and relative change in DAS28 were secondary outcomes. Subgroup analyses were stratified by smoking status, type of anti-TNF drug, and rheumatoid factor status.

Results: Statistically significant associations with EULAR response were found for two SNPs in the total cohort (*NLRP3* (rs4612666) and *INFG* (rs2430561), for seropositive RA patients (407) in *TNFRS1A* (rs4149570), and for seronegative RA patients (131) in *IL17A* (rs2275913), *TLR2* (rs1816702), *NFKB1* (rs28362491), *LY96* (rs11465996), *TGFB1* (rs1800469) and *IL10* (rs1800872) (Table 1). Significant associations with ACR50-response were present for six SNPs (*TLR4* (rs5030728), *IL1B* (rs1143623), *TLR4* (rs12377632), *IL17A* (rs2275913), *NFKB1* (rs28362491), *TLR2* (rs1816702)). Baseline HAQ-score (OR=0.72 (0.53–0.96), p=0.025) and CRP>10 mg/L (OR=1.91 (1.27–2.86), p=0.002) were significant clinical predictors of EULAR good/moderate response, whereas smoking status, type of anti-TNF drug and rheumatoid factor status were not.

Table 1. Genotypes in Danish patients with Rheumatoid Arthritis. Odds ratio (OR) for associations between gene variants and EULAR response to anti-TNF treatment.

Logistic regression, adjusted for gender, age, HAQ-, DMARD at baseline, CRP, presence of RF/ACPA under assumption of a dominant model.

Conclusion: Danish RA patients with genetically determined higher *NLRP3*– and *IFNG* (IFN-γ) expression were more likely to respond to anti-TNF treatment. Further, the data suggest a difference in pathophysiology between seropositive and seronegative RA patients and validate HAQ-score and CRP as clinical predictors of anti-TNF responses. These findings should be replicated in independent cohorts and augmented by assessing cytokine levels and activity of the relevant gene products.

Background/Purpose: To describe safety profile of IV GLM in RA from the Ph3 GLM IV program. AE rates of interest are indirectly compared to those observed in the GLM SC clinical program across rheumatologic indications.

Methods: 2 multicenter, randomized, double-blind, PBO-controlled studies were included in the integrated IV data safety analysis. GO-LIVE evaluated IV PBO or GLM 2mg/kg or 4mg/kg, ± MTX q12wks in pts with active RA despite MTX. GO-FURTHER is evaluating GLM 2mg/kg IV at wks 0, 4, and q8wks +MTX in active RA despite MTX. In the SC GLM program (GO-FORWARD, GO-BEFORE, GO-AFTER [RA], GO-REVEAL [PsA], GO-RAISE [AS]), PBO or GLM (50mg/100mg) was administered SC q4wks in Ph3 studies and q2 or 4 wks in Ph2 study. Approx. half of pts received MTX. Safety findings for the Ph3 GLM IV RA studies combined through the IV dosing period of GO-LIVE (median 60wks exposure) and through the August 15, 2012 cut-off for GO-FURTHER (median 92wks exposure) are reported; for the ongoing SC studies the data cut was through wk160. Comparison of targeted safety events between IV and SC GLM are reported. Pts who received ≥1administration were analyzed.

Results: 1210 pts were treated with IV GLM in the integrated Ph3 RA IV studies with median duration of follow-up of 72.7 wks. Overall AEs observed in the integrated Ph3 RA IV program are summarized(Table). Since follow-up was longer for the SC rheumatology program, more overall events were observed; however when corrected for events/100 pt yrs, no difference in AE rates or significant SAEs were observed between GLM IV and SC. Incidence of non-serious infusion reactions (median 30 minute infusions) remained low regardless of infusion length, and no serious infusion reactions, requiring study discontinuation, were reported. NMSC (incidence/100 pt-yrs of f/u: 0.49 [95%CI: 0.33,0.71] vs 0.14[95% CI: 0.03,0.42] for GLM SC vs GLM IV) and lymphoma rates were numerically higher in the GLM SC grp vs. the GLM IV grp.

Overall AE summary: Phase 3 GLM IV RA studies combined through 120 day safety update

	PBO	GLM
Pts treated/Avg duration of f/u (wks)	326/22.3	1210*/74.0
AE/Serious AE/ D/c due to AE	58.6% /4.0%/1.8%	82.2%/16.3%//7.2%
Overall infection/Serious infection	29.8%/0.9%	51.3%/5.8%
Infusion reactions	2.5%	4.5%

AEs of interest in pts receiving IV or SC GLM: Incidence per 100 pt-years of follow-up (95% CI)

	Integrated RA GLM IV studies[a] (n= 1213)*	Rheumatologic GLM SC studies[b](n=2363)
Total pt/yrs of follow-up	2103	5714
Deaths	0.62 (0.33, 1.06)	0.37 (0.23, 0.56)
Sepsis	0.38 (0.16, 0.75)	0.37 (0.23, 0.56)
Tuberculosis	0.29 (0.10, 0.62)	0.32 (0.19, 0.50)
Opportunistic Infections	0.33 (0.13, 0.69)	0.25 (0.13, 0.41)
Cellulitis	2.76 (2.09, 3.57)	2.24 (1.87, 2.66)
Postbaseline ALT ↑ (>1to<3xULN)	83.84 (79.97, 87.85)	85.82 (83.44, 88.26)
Lymphoma: Total pt yrs f/u	2103	5713
Observed # of pts with event/Incidence/ 100pt yrs (95% CI)	0/0.00 (0.00, 0.14)	7/0.12 (0.05, 0.25)
Other malignancies: Total pt yrs f/u	2101	5707
Observed # of pts with event/Incidence/ 100pt yrs(95% CI)	9/0.48 (0.23, 0.88)	32/0.56 (0.38, 0.79)
All malignancies: Total pt yrs of f/u	2101	5706
Observed # of pts with event/Expected #of pts with event/SIR (95% CI)	9/12.81/0.70 (0.32, 1.33)	39/33.04/1.18 (0.84, 1.61)

[a]Based on data cut off as of Aug 15, 2012; includes Phase 3 studies of IV GLM in RA pts: GO-LIVE(n=643), GO-FURTHER (n=592).[b]Includes C0524T02 (completed Ph2 PK study of SC GLM). Through Wk 160 for ongoing Phase 3 SC studies in rheumatologic indications: (RA: GO-FORWARD, GO-BEFORE, GO-AFTER, PsA: GO-REVEAL, AS: GO-RAISE); *3 PBO+MTX pts in GO-LIVE did not receive IV GLM during the double-blinded phase of the study, but received SC GLM during the LTE of the study.

Conclusion: Overall safety of IV GLM in RA pts observed through Aug 15, 2012 continue to demonstrate an acceptable safety profile. Rates for events of interest such as malignancies and serious infections in the IV studies are comparable with or lower than rates in the SC studies in RA pts, AS, and PsA.Follow-up through 2yrs will provide information regarding long-term safety of IV GLM.

Abatacept and Anti-Tumor Necrosis Factor Monoclonal Antibodies: Efficacy and Safety Comparisons. M Schiff[1], M Dougados[2], R Fleischmann[3], J Fay[4] and M Maldonado[4]. [1]University of Colorado, Denver, CO, [2]Hopital Cochin, Descartes University, Paris, France, [3]University of Texas Southwestern Medical Center, Dallas, TX, [4]Bristol-Myers Squibb, Princeton, NJ.

Background/Purpose: A paucity of clinical trial data exists comparing the efficacy and safety of biologic therapies for RA. This study evaluated remission rates and safety for patients (pts) treated with SC or IV abatacept compared with the anti-TNF monoclonal antibodies, adalimumab and infliximab, in a *post hoc*, cross-trial comparison.

Methods: In the head-to-head AMPLE study,[1] pts were randomized to SC abatacept (125 mg weekly) or SC adalimumab (40 mg biweekly), plus background MTX. In the double-blind, double-dummy, placebo- and active-controlled ATTEST study,[2] pts were randomized 3:3:2 to IV abatacept (~10 mg/kg every 4 weeks), infliximab (3 mg/kg every 8 weeks), or placebo, plus background MTX. Pts in both trials had active RA with inadequate response to MTX and were biologic naïve. Remission according to DAS28 (CRP) and SDAI was evaluated *post hoc* over 12 months of treatment for all randomized and treated pts with data available at the visit of interest. Safety was evaluated for all pts who received ≥1 dose of study drug.

Results: In AMPLE, 318 and 328 pts received SC abatacept and adalimumab, respectively; in ATTEST, 156 pts received IV abatacept and 165 received infliximab. Baseline DAS28 (CRP) scores (mean±SD) were 5.5±1.1 in AMPLE and 6.4±0.9 in ATTEST. Duration of RA was 1.9±1.4 and 1.7±1.4 years for SC abatacept and adalimumab in AMPLE, and 7.9±8.5 and 7.3±6.2 years for IV abatacept and infliximab in ATTEST. Remission rates over 12 months were similar for treatment groups in each trial (Table). Over 12 months, 11 (3.5%) vs 20 (6.1%) SC abatacept- vs adalimumab-treated pts, and 4 (2.6%) vs 12 (7.3%) IV abatacept- vs infliximab-treated pts discontinued due to adverse events (AEs); 32 (10.1%) vs 30 (9.1%) and 15 (9.6%) vs 30 (18.2%) experienced SAEs; 5 (1.6%) vs 4 (1.2%) and 1 (0.6%) vs 2 (1.2%) had malignancy; 10 (3.1%) vs 4 (1.2%) and 2 (1.3%) vs 1 (0.6%) experienced autoimmune events. Serious infections were reported in 7 (2.2%) vs 9 (2.7%) and 3 (1.9%) vs 14 (8.5%) pts treated with SC abatacept vs adalimumab in AMPLE and IV abatacept vs infliximab in ATTEST, respectively, with 0/7 vs 5/9 and 0/3 vs 4/14 serious infections leading to discontinuation, and opportunistic infections for 1 (0.3%) vs 1 (0.3%) and 0 vs 5 (3.0%).

		AMPLE		ATTEST	
	Month	SC abatacept	Adalimumab	IV abatacept	Infliximab
DAS28 remission	3	26.8	26.0	11.8	19.0
	6	30.6	38.1	20.0	25.2
	9	39.6	43.1	30.8	23.0
	12	43.3	41.9	29.9	21.4
SDAI remission	3	10.4	10.7	4.6	6.3
	6	13.2	16.6	9.0	10.6
	9	17.6	23.9	11.9	12.8
	12	23.3	24.8	13.1	11.4

Conclusion: Greater proportions of pts in the AMPLE trial achieved remission outcomes vs ATTEST; however, pts in AMPLE had shorter disease duration and lower disease activity at baseline. Over time both routes of abatacept administration provided similar remission rates to the anti-TNF therapies, regardless of disease duration. Safety outcomes were mostly balanced, with increased SAEs and serious infections for infliximab vs abatacept, and increased discontinuations due to AEs and serious infections in both anti-TNF groups vs abatacept. This analysis provides comparative insight into the efficacy and safety of these biologic agents.

Effects Of VX-509, An Investigational Oral Selective Janus Kinase 3 (JAK3) Inhibitor, On Patient-Reported Outcomes In a Phase 2A Study Of Patients With Active Rheumatoid Arthritis. Vibeke Strand[1], Ellison Suthoff[2], Roy M. Fleischmann[3], Montserrat Vera-Llonch[4], John Jiang[2], Yanqiong Zhang[2] and Nils Kinnman[5]. [1]Stanford University, Palo Alto, CA, [2]Vertex Pharmaceuticals Incorporated, Cambridge, MA, [3]Metroplex Clinical Research Center, University of Texas Southwestern Medical Center, Dallas, TX, [4]Vertex Pharamceuticals Incorporated, Cambridge, MA, [5]Vertex Pharmaceuticals Incorporated, Geneva, Switzerland.

Background/Purpose: VX-509 is an oral JAK3 inhibitor being evaluated as a treatment for RA. Safety and efficacy results from a phase 2a, 12-week, randomized placebo-controlled trial (RCT) in patients with active rheumatoid arthritis (RA) who had failed ≥ 1 DMARD have been reported previously. The objective was to assess impact of treatment with VX-509 on patient-reported outcomes (PRO) during the RCT.

Methods: Patients were randomized to treatment groups that received 1 of 4 doses of VX-509 (25, 50, 100, or 150 mg BID) or placebo BID as monotherapy for 12 weeks. PRO assessments included the Health Assessment Questionnaire-Disability Index (HAQ-DI), visual analog scale (VAS) assessments of patient's general health (subject general health; PtGH) and pain, and the Short Form 36 Health Survey (SF-36). Least squares (LS) mean changes from baseline (BL) were obtained for each group and significance testing versus placebo was conducted using a mixed-effects model for repeated measures analysis. The percentages of patients reporting clinically meaningful improvements (Minimal Clinically Important Differences; MCID) for each PRO are reported, using non-responder imputation for early terminations or incomplete data. In addition, the Cochran-Armitage test was conducted to assess trends in the MCID data across dose groups.

Results: 204 patients were randomized to treatment groups and received at least 1 dose of study drug. Patients receiving 50, 100, and 150 mg BID VX-509 reported significant (all $p<0.01$) and clinically meaningful improvements in PtGH, pain, HAQ-DI, and SF-36 Physical Component Score (PCS) at week 12 (Table).

	Placebo (N=41)	VX-509 25 mg BID (N=41)	VX-509 50 mg BID (N=41)	VX-509 100 mg BID (N=40)	VX-509 150 mg BID (N=41)

Tocilizumab In Patients With Rheumatoid Arthritis and Rates Of Malignancy: Results From Long-Term Extension Clinical Trials. Ronald F. van Vollenhoven[1], Andrea Rubbert-Roth[2], Anthony Sebba[3], Benjamin Porter-Brown[4], Lucy Rowell[4], Pavel Napalkov[5] and Devi Smart[4]. [1]Karolinska Institute, Stockholm, Sweden, [2]University of Cologne, Cologne, Germany, [3]University of South Florida, Tampa, FL, [4]Roche, Welwyn Garden City, United Kingdom, [5]Genentech, South San Francisco, CA.

Background/Purpose: Malignancy is a potential risk of immunomodulatory treatments and may be increased in patients (pts) with rheumatoid arthritis (RA). The risk of malignancy was analyzed over long-term treatment with tocilizumab (TCZ) in clinical trials in adults with RA.

Methods: Assessment of malignancies was performed in all pts who received ≥1 dose of intravenous TCZ in 1 of 5 phase 3 placebo-controlled studies (OPTION, TOWARD, RADIATE, AMBITION, LITHE), a clinical pharmacology study, or long-term extension studies. In addition, 6-month data were included from the phase 4 TCZ monotherapy study (ADACTA). Data were pooled and analyzed from initial TCZ exposure to May 2, 2012 (cutoff). The indirect method of standardization was used to calculate age- and sex-adjusted standardized incidence ratio (SIR=ratio of observed to expected malignancies). The Surveillance Epidemiology and End Results (SEER) program of the US National Cancer Institute was used to calculate expected cases based on malignancy rates in a general population.

Results: In total, 4171 pts were included. Mean (median [range]) duration was 3.9 y (5.1 [0.0–6.8]); total observation time was 16,204.8 pt-y (PY). In addition to routine study monitoring for potential malignancy, investigators were queried via targeted questionnaire to ascertain details such as tissue diagnosis and biopsy results. Events with confirmed malignancy and those in which malignancy was not confirmed but could not be excluded were considered malignant for this analysis. The malignancy rate described above, including nonmelanoma skin cancer (NMSC), was 1.26/100 PY (95% CI: 1.09, 1.44) and remained stable over time. SIR for all malignancies combined (excluding NMSCs, which are not collected by SEER) and for individual tumor types showed that, with the exception of lung and cervical cancer, the observed number of malignancies was not statistically different (95% CI for SIR include 1.00)[1] from that expected in the general population (Table). Meta-analysis of the incidence of malignancy in RA pts suggests that RA pts have a 63% increase in lung malignancy risk versus the general population.[2] The observed cases of cervical cancer occurred in South America and Eastern Europe, regions with disproportionately high burdens of cervical cancer and underserved by national cervical cancer screening programs.[3] As in other RA studies, the most frequent malignancy was NMSC: 42 basal cell carcinomas and 26 squamous cell carcinomas.

Table. Standardized Incidence Ratios for Malignancy (All TCZ Population)

Organ Class	Observed Cases*	Expected Cases	SIR (95% CI)
All sites	136†	117.36	1.16 (0.97, 1.37)
Lung and bronchus	29	13.24	2.19 (1.47, 3.15)§
Female breast	21	31.35	0.67 (0.41, 1.02)
Prostate	12	9.57	1.25 (0.65, 2.19)
Colon, excluding rectum	7	6.56	1.07 (0.43, 2.20)
Corpus uteri	6	7.14	0.84 (0.31, 1.83)
Cervix uteri	5	1.42	3.51 (1.13, 8.19)§
Non-Hodgkin lymphoma	5	4.27	1.17 (0.38, 2.74)
Stomach	4	1.36	2.94 (0.79, 7.53)
Ovary	4	2.83	1.41 (0.38, 3.62)
Urinary bladder	4	2.98	1.34 (0.36, 3.44)
Melanoma of the skin	4	5.29	0.76 (0.20, 1.94)
Oral cavity and pharynx	4‡	2.34	1.71 (0.46, 4.38)
Rectum	3	2.27	1.32 (0.27, 3.86)
Thyroid	4	4.84	0.83 (0.22, 2.12)
Esophagus	2	0.81	2.45 (0.28, 8.86)
Brain	2	1.18	1.70 (0.19, 6.13)
Leukemia	2	2.21	0.91 (0.10, 3.27)
Pancreas	3	2.66	1.13 (0.23, 3.29)
Kidney and renal pelvis	2	3.37	0.59 (0.07, 2.14)

*Excludes NMSCs (because they are not collected by SEER) and nonmalignant tumors.
†Includes 13 malignant cases (anal cancer, bone and joint, larynx, skin excluding basal and squamous, soft tissue including heart, other endocrine and thymus, and other) not listed in a site- specific category.
‡Includes 1 malignant case of nasopharynx, 2 malignant cases of tongue, and 1 case of pharyngeal cancer.
§Statistically significant (ie, SIR >1 and 95% CIs exclude 1.00).

Conclusion: The rate of all malignancies in RA pts receiving long-term TCZ treatment has remained stable over time. To date, there is no evidence of higher than expected malignancy risk in RA pts treated with TCZ versus the general population.

Evaluation and Management Of Laboratory Abnormalities During Tocilizumab Treatment Either As Monotherapy Or In Combination With Dmards In RA Patients: Findings From The ACT-STAR Study. Michael Weinblatt[1], Dennis Preston[2], Josh Friedman[2], Natasha Singh[2], Jenny Devenport[2] and Joel M. Kremer[3]. [1]Division of Rheumatology, Brigham & Women's Hospital, Boston, MA, [2]Genentech, Inc., South San Francisco, CA, [3]Albany Medical College and The Center for Rheumatology, Albany, NY.

Background/Purpose: Laboratory values from phase III clinical trials of tocilizumab (TCZ) in patients with RA were the basis of the recommendations for monitoring and managing the potential risks associated with laboratory abnormalities. In order to further evaluate and understand the extent and impact of lab abnormalities and their outcomes, additional analyses of the open-label phase IIIB ACT-STAR study, were undertaken.

Methods: ACT-STAR was a prospective, open-label phase IIIB study that evaluated safety, tolerability and efficacy of TCZ monotherapy (Mono) and TCZ + DMARDs in adults with moderate to severe, active RA who were inadequate responders or had safety/tolerability related issues with stable doses of their current DMARDs or biologic based regimens. All patients exposed to TCZ in ACT-STAR were included in this analysis. Scheduled labs were collected and analyzed centrally every 4 weeks during the core study

(24 wks + 8wks follow-up) and every 8 wks during the long term extension (eligible patients completing the core study could receive TCZ until ≥3 months after commercial availability). AEs were collected on an ongoing basis. Laboratory abnormalities of interest (LFTs, neutrophils, platelets) were assessed and subsequent AEs, study medication changes and outcomes were evaluated for possible associations.

Results: 883 patients received TCZ treatment in ACT-STAR (TCZ 8 mg/kg Mono, n=138; TCZ 4 mg/kg + DMARD with option to escalate to 8 mg/kg at or after week 8, n=364; TCZ 8 mg/kg + DMARD, n=381). Of the 142 (16.2%) patients with ALT > ULN (55 U/L) or 77 (8.8%) with AST > ULN (40 U/L) for ≥ 2 consecutive scheduled visits, > 50% normalized during the study and most completed the planned treatment and observation period. No cases of drug induced liver injury were reported for either group. Of the 26 (3%) patients with ANC ≤ 1000 cells/mm^3 at any point, 81% normalized during study and none experienced serious infections. Similarly, of the 24 (2.7%) patients with platelets ≤ 100,000 cells/mm^3 at any point, 75% normalized during study and no serious bleeding events were observed.

		Resolution		
Parameter	**Rate n/N (%)**	**Normalized n/N (%)**	**Did not normalize n/N (%)**	**Associations***
ALT†	142/876 (16.2)	73/142 (51)	69/142 (48.6)	No reports of drug-induced liver injury observed at any time point
Sustained‡ ALT> ULN (55 U/L)		· 43/73 normalized with medication changes after 2nd consecutive elevation	· 18/69 had no follow-up labs after 2nd consecutive abnormal lab finding (eg., at last visit)	
		· 30/73 normalized without medication changes after 2nd consecutive elevation	· 51/69 had labs after 2nd consecutive elevation [20 had no medication changes; 31 had medication changes]	
AST†	77/876 (8.8)	46/77 (60)	31/77 (40)	No reports of drug-induced liver injury observed at any time point
Sustained‡		· 28/46 normalized with medication changes after 2nd consecutive elevation	· 11/31 had no follow-up labs after 2nd consecutive abnormal lab finding (eg., at last visit)	
AST > ULN (40 U/L)		· 18/46 normalized without medication changes after 2nd consecutive elevation	· 20/31 had labs after 2nd consecutive elevation [10 had medication changes; 10 had no medication changes]	
Neutrophils	26/876 (3.0)	21/26 (81)	5/26 (19)	No serious infections observed at any time point
ANC ≤ 1000 cells/mm^3 on at least 1 occasion			· 5/5 had no follow-up labs after abnormal lab finding (eg., at last visit)	
Platelets	24/876 (2.7)	18/24 (75)	6/24 (25)	No serious bleeding events observed at any time point
≤ 100,000 cells/mm^3 on at least 1 occasion	2/876 (< 1)		· 6/6 had no follow-up labs after abnormal lab finding (eg., at last visit)	
Platelets < 50,000–25,000 cells/mm^3 on at least 1 occasion				

* Associations apply to all patients with the abnormality regardless of normalization status.
† LFT parameters were analyzed separately for events or resolution. However, 154 patients had either ALT or AST sustained elevations (12 AST only, 77 ALT only, 65 both).
‡ Sustained is defined as an abnormal value at ≥ 2 consecutive visits.

Conclusion: Management of patients with RA who receive tocilizumab requires periodic examinations and laboratory monitoring to assess potential risks. In ACT-STAR, no association between lab abnormalities and clinical consequences was observed. Results from this study support the current monitoring guidelines in place in the USPI for TCZ.

Evaluation Of An Irreversible Dual Target Inhibitor (AC0025) Of Bruton's Tryosine Kinase and Janus Kinase 3 As a Therapeutic Agent For Rheumatoid Arthritis. Xiao Xu, Long Mao, Biao Xi, Xiaoying Zhang, Che Fang, Jia Liu and Wanhong Xu. ACEA Biosciences Inc., San Diego, CA.

Background/Purpose: Bruton's Tryosine Kinase (BTK) and Janus Kinase 3 (JAK3) are intimately involved in the signaling pathways regulating B cell and T cell functions. Perturbing either pathway leads to immune disorders and diseases such as rheumatoid arthritis (RA). The purpose of the study is to develop a small molecule inhibitor targeting BTK and JAK3.

Methods: A novel small molecular inhibitor (AC0025) was rationally designed to selectively target BTK and JAK3 using computer-aided design. The inhibitory activity and selectivity were evaluated at enzymatic, molecular and cellular levels, and in rat CIA animal models. The pharmacological properties and safety were evaluated both in vitro AMEDT assays and in PK/PD/TOX animal models.

Results: AC0025 inhibited BTK and JAK3 enzyme activity with IC_{50} values of 0.9 nM for BTK and 0.1 nM for JAK3. AC0025 does not inhibit other JAK family members including JAK1 and JAK2 with the IC50 values of 10.5 μM and 2.16 μM, respectively. AC0025 covalently binds to Cys481 in BTK and Cys909 in JAK3 resulting in irreversible blockage of the ATP binding site of both kinases, and therefore silences BTK and JAK3 activities. The inhibitory potency and selectivity of AC0025 were further evaluated and confirmed in the cell lines either stably expressing BTK and JAK3, or activated by cytokines. In rat collagen-induced arthritis (CIA) model, AC0025 significantly reduced paw edema and the disease severity by oral administration. Pharmacologic properties of AC0025 as a therapeutic agent for RA were assessed using in vitro ADMET assays and PK/PD/Tox animal models.

Conclusion: AC0025 as a novel irreversible dual target inhibitor showed potent inhibitory activities against BTK and JAK3 and further studies to develop AC0025 as a therapeutic agent for RA are warranted.

Drug Survival Rates Of Anti-Tumor Necrosis Factor Therapies In Patients With Rheumatoid Arthritis and Ankylosing Spondylitis. Dong-Jin Park[1], Kyung-Eun Lee[1], Ji-Hyoun Kang[1], Jeong-Won Lee[1], Tae-Jong Kim[2], Yong-Wook Park[1] and Shin-Seok Lee[1]. [1]Chonnam National University Medical School, Gwangju, South Korea, [2]Chonnam National University Medical School and Hospital, Gwangju, South Korea.

Background/Purpose: We investigated the compliance of Korean patients using anti-tumor necrosis factor (TNF) agents to treat rheumatoid arthritis (RA) and anklyosing spondylitis (AS), and identified potential predictors associated with treatment discontinuation.

Methods: The study population comprised 114 RA and 310 AS patients treated with anti-TNF agents at a single tertiary center for at least 1 year from December 2002 to November 2011. Demographic, clinical, laboratory, and treatment-related data at the time of initiation of anti-TNF agents were collected, and the cause of discontinuation was also determined by reviewing patients' charts. Survival curves were plotted to compare the drug survival between three different anti-TNF agents; life-table analysis and multivariate Cox proportional hazard models were used to identify predictors of treatment discontinuation of anti-TNF therapy.

Results: Of the 114 RA patients, 64 (56.1%) discontinued their first anti-TNF agents with a mean duration of 18.1 months. In constrast, 65 of 310 patients (21.0%) with AS discontinued their first anti-TNF agents, with a mean duration of 84 months. Over a mean follow-up of 33.8 months (range, 10–77 months), the 1-year and 4-year drug survival rates were 44% and 37% in RA patients and 79% and 67% in AS patients, respectively. Although the survival rate did not differ among the three anti-TNF agents in the AS patients, the etanercept group had a lower discontinuation rate than the infliximab group in the RA patients. The most common cause of discontinuation of anti-TFF agents in RA patients was inefficacy, which was reported by 43 (67.2%) patients for all anti-TNF agents, whereas the reasons for discontinuation in AS patients were adverse events (39.7%), inefficacy (33.3%), intention of paitents (9.5%), economic status (11.1%), hospitalization (3.2%), and lost to follow-up (3.2%). In addition, RA patients who received corticosteroids in combination with anti-TNF agents were more likely to discontinue their anti-TNF therapies. The independent predictors of drug discontinuation in AS patients were male gender and complete ankylosis on radiographs of the sacroiliac joint.

Conclusion: We found that AS patients had a higher continuation rate of anti-TNF agent treatment compared to RA paitents and identified predictive variables for drug discontinuation in these paitents. Our results provide further evidence that real-life treatment outcomes of RA and AS patients may be different from those observed in randomized clinical trials.

Sarilumab, a Subcutaneously-Administered, Fully-Human Monoclonal Antibody Against The IL-6 Receptor Alpha: Using Acute Phase Reactants, Efficacy and Safety Parameters To Inform Phase 3 Dose Selection. Janet van Adelsberg[1], Steven P. Weinstein[2], Neil Graham[3], Tanya Momtahen[4], Chunpeng Fan[4] and Stefano Fiore[4]. [1]Regeneron Pharmaceutials, Inc., Tarrytown, NY, [2]Regeneron Pharmaceuticals Inc, Tarrytown, NY, [3]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [4]Sanofi, Bridgewater, NJ.

Background/Purpose: Sarilumab (SAR) is a fully human mAb directed against IL-6Rα. In phase 2 MOBILITY Part A (NCT01061736), SAR administered SC plus MTX (methotrexate 10–25 mg/wk) achieved primary endpoint of ACR20 at wk 12. Sensitivity analyses for several pharmacodynamic (PD) parameters, modification of disease activity scores, and safety parameters guided selection of 2 doses for Phase 3 studies. These post hoc analyses evaluated the relationship between SAR doses and change from baseline in serum levels of 3 acute phase reactants (APRs): C reactive protein [hs-CRP], serum amyloid A [SAA] and fibrinogen.

Methods: Pts were randomized to 6 groups: placebo (PBO), SAR 100, 150, 200 mg every other wk (q2w), and 100, 150 mg every wk (qw). Disease characteristics, including systemic inflammation (hs-CRP, SAA and fibrinogen) were collected at baseline and every 2 wks. ANCOVA models were used to analyze treatment effects on change from baseline at each visit to wk 12.

Results: Baseline characteristics were similar across all groups (n=306): mean age 52.2±12.3 yrs; 79% women; mean disease duration 7.8±8.1 yrs; RF+ 79.7%; mean hs-CRP 2.8±3.0 mg/dL. CRP results by dose group are shown (Figure). After the first dose, all SAR groups >100 mg q2w had robust and sustained suppression of hs-CRP, maintained throughout the dosing intervals. Similar responses were observed with SAA and fibrinogen and were accompanied by an increase of serum albumin levels. The 150 and 200 mg q2w doses had a response rate at wk 12 comparable to doses of 100 and 150 mg qw for PD parameters and clinical response measures, although the 150 mg q2w dose trended toward more favorable outcomes for some safety parameters. Comparisons of 150 and 200 mg q2w doses show that the 200 mg q2w had a greater and earlier suppression of APRs (at wk 2) but the difference was not significant over time. The most common TEAEs reported in all SAR groups were non-serious infections 12–26%, neutropenia 0–20%, and ALT increase 0–6%. Eight pts (none in the PBO and the 150 and 200 mg q2w groups) experienced at least 1 treatment emergent SAE; of these 6 led to permanent treatment discontinuation. There were no infection-related SAEs in pts with grade 3 or 4 neutropenia and total infection rates were similar to PBO. There was 1 death due to respiratory distress syndrome/cerebrovascular accident in 100 mg q2w group.

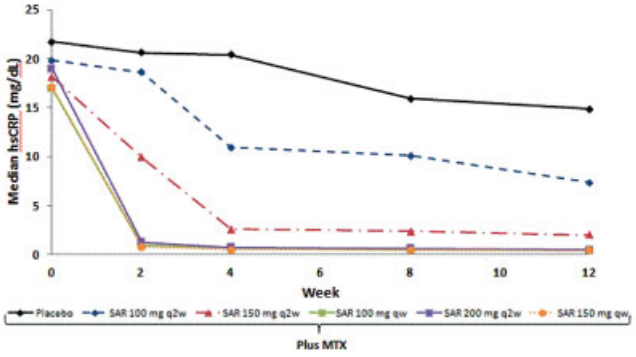

Figure. Change in hs-CRP concentration over time

Conclusion: SAR 150 and 200 mg q2w doses resulted in a significant suppression of APRs, evident at wk 2, maintained throughout the dosing intervals, and comparable to suppression achieved with qw dosing. These doses also demonstrated comparable ACR results to qw dosing. In consideration for a less frequent dosing, and potential for better safety profiles, the 150 and 200 mg q2w doses were selected for further Phase 3 studies.

Soluble Interleukin-2 Receptor Levels and The CD4/CD8 Ratio As Predictors Of The Efficacy Of Abatacept In Biologics-naïve Rheumatoid Arthritis Patients. Hajime Sano[1], Masahiro Sekiguchi[1], Masayasu Kitano[1], Naoto Azuma[1], Shinichiro Tsunoda[1], Kiyoshi Matsui[1] and Tsuyoshi Iwasaki[2]. [1]Hyogo College of Medicine, Nishinomiya-city, Japan, [2]Hyogo University of Health Sciences, Kobe, Japan.

Background/Purpose: Abatacept (ABT) is a recombinant fusion protein consisting of the extracellular domain of human CTLA-4, binding to CD80/86 on antigen presenting cells and thereby inhibits the interaction between these molecules and CD28 on T cells. ABT suppresses T cell activation and has been reported to have the therapeutic benefit for patients with rheumatoid arthritis (RA). However, there are limited data to compare the efficacy of ABT and biomarkers of T cell activation. Soluble IL-2 receptor (sIL-2R) is a marker of T-cell activation in diseases including RA and various cancers. The aim of this study was to investigate the relationship between the efficacy of ABT and biomarkers of T cell activation such as sIL-2R and CD4/CD8 ratio in biologics-naïve RA patients.

Methods: We analyzed 24 biologic-naïve RA patients treated with ABT from January 2010 to May 2012. (Patients received 10 mg/kg abatacept plus MTX during 24 weeks). To evaluate the efficacy of the treatment, we measured DAS28-CRP (DAS), CRP and MMP-3 levels at week 0, 4, 12 and 24 after treatment. We also examined serum levels of sIL-2R and peripheral blood CD4/CD8 ratio before and after treatment with ABT. sIL-2R and peripheral blood CD4+/CD8+ lymphocytes were analyzed using ELISA and flow cytometry.

Results: At week 0, 4 and 24 after ABT treatment, the mean DAS score and serum CRP/ MMP-3/sIL-2R levels were DAS (4.5→3.5→2.8), CRP (2.1→1.1→0.8 mg/dl), MMP-3 (219.1→169.7→114.1 ng/dl), and sIL-2R (441→259→232 U/ml), respectively. We observed statistically significant reduction of DAS scores and serum CRP/MMP-3/sIL-2R levels at week 4 after ABT treatment. The reduction of DAS scores was higher in patients who reduced more than 50% of sIL-2R than in patients who reduced less than 50% at week 4 after treatment (1.18 vs 0.61, p=0.023). At week 0 and 4 after ABT treatment, the mean CD4/CD8 ratio was not statistically different (2.00 vs 2.05). However, the reduction of DAS scores was higher in patients who reduced CD4/CD8 ratio after treatment than in patients who increased CD4/CD8 ratio (1.09 vs 0.60, p=0.014).

Conclusion: We observed the efficacy of ABT at week 4 after treatment of biologic-naïve RA patients. We also observed that the reduction of sIL-2R and CD4/CD8 ratio after treatment correlated with improvement of DAS scores. These results indicate that the decreased serum sIL-2R levels and peripheral blood lymphocyte CD4/CD8 ratio after treatment is a predictor of the efficacy of ABT in biologics-naïve RA patients.

Confounding By Indication Distorts The Relationship Between Steroid Use and Cardiovascular Disease In Rheumatoid Arthritis. Alper M. van Sijl, Maarten Boers, Alexandre E. Voskuyl and Mike T. Nurmohamed. VU University Medical Center, Amsterdam, Netherlands.

Background/Purpose: Glucocorticoids (GC) are among the most effective drugs in rheumatoid arthritis (RA), but concerns over long-term side effects have not been resolved. Recent studies indicate that cumulative exposure to GC is associated with an increased risk of cardiovascular (CV) disease, perhaps in part through worsening of the CV risk profile. However, GC also strongly decrease inflammation in RA, and inflammation also has an etiological role in the increased CV risk in this group. The net effect of GC use on CV risk in RA therefore remains unknown.

Methods: RA patients aged 50–75 years were followed for approximately 10 years to study the development of CV disease in the Cardiovascular Risk in RhEumatoid arthritis (CARRE) study. This study was the first to report that CV disease incidence in RA was equal to diabetes mellitus. For the current study, GC exposure was characterized by duration, last exposure by date, the mean dose of GC and cumulative exposure in grams. Data collection included traditional CV risk factors and RA-related parameters and disease activity. Cox proportional hazard analysed the association between GC exposure and incident CV disease, with adjustment for confounders.

Results: The study comprised 353 individuals of whom 59 (17%) were exposed to GC at the time of inclusion, with a median (interquartile range) the cumulative exposure was 8.7 (2.5–25.4) grams. After a total follow-up experience of 2361 years, 58 (17%) participants developed incident CV disease, yielding an incidence rate of 24.6/1.000 patient years. Incident cases were more frequently treated with GC at baseline than RA patients without CV disease (22 vs. 16%, p-value 0.089), were treated with GC for a longer period (4.1 vs. 1.9 years, p-value 0.090) and cumulatively used more GC (31.9 vs. 8.5 grams, p-value 0.046). These differences remained after adjustment for demographics and CV risk. However, additional adjustment for at baseline measured 28-joint disease activity score (DAS28) and disability (Health Assessment Questionnaire, HAQ) completely erased the associations of GC with incident CV disease. These observations appear robust and unaffected by power constraints, as the standard errors of the beta estimates remained essentially similar after adjustment.

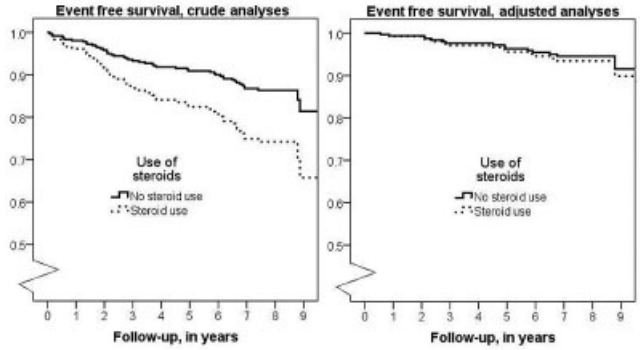

Figure. Kaplan-Meier survival curves

Conclusion: It appears that GC use in uncontrolled populations represents a marker of high RA disease activity; high disease activity itself represents an increased risk of CV disease. Thus the observed relationship of GC with CV disease in RA patients is strongly confounded by indication, as suggested by the adjusted analyses. In this setting, it is possible that the adverse CV effects of GC are balanced by positive effects working through inflammation control.

Sarilumab, a Subcutaneously Administered, Fully Human Monoclonal Antibody Inhibitor Of The IL-6 Receptor Alpha: 12 Week Infection Rates By Level Of Circulating Neutrophils In Rheumatoid Arthritis and Ankylosing Spondylitis. Kevin L. Winthrop[1], Tanya Momtahen[2], Stefano Fiore[2], Steven P. Weinstein[3], Janet van Adelsberg[4], Richard Wu[5] and Neil Graham[5]. [1]Oregon Health & Science University, Portland, OR, [2]Sanofi, Bridgewater, NJ, [3]Regeneron Pharmaceuticals Inc, Tarrytown, NY, [4]Regeneron Pharmaceutials, Inc., Tarrytown, NY, [5]Regeneron Pharmaceuticals, Inc., Tarrytown, NY.

Background/Purpose: Sarilumab is a human monoclonal antibody directed against the alpha subunit of the IL-6 receptor (IL-6Rα). IL-6 blockade is associated with a reduction in circulating neutrophil levels (CNL). It has been suggested that changes in CNL with IL-6 blockade may be due to margination of neutrophils or other mechanisms. The relationship between decrease in CNL and risk of infection is unclear.

Methods: To evaluate the risk of neutropenia and infection with sarilumab, we retrospectively assessed clinical trial data from two 12-week Phase 2b studies in patients with RA (MOBILITY Part A [NCT01061736]) and with AS (ALIGN [NCT NCT01061723]). In these studies, patients were randomized to 6 groups: placebo (PBO), sarilumab 100 mg, 150 mg, 200 mg every other week (q2w) and 100 mg, 150 mg weekly (qw). CNL were determined q2w and incidence of total, serious, viral, fungal and bacterial infections were recorded. Data were analyzed across the PBO and sarilumab groups, with a focus on the 150 mg and 200 mg q2w dose regimens that were subsequently chosen for study in phase 3.

Results: Three hundred six patients were enrolled in MOBILITY Part A (80% female; median age, 54 yrs [19:74]). 300 patients were enrolled in ALIGN (30% female; median age, 40 yrs [18:72]). One serious infection was reported in the 100 mg qw group of the ALIGN study. All other reported infections in both studies were non serious. Percent of patients with reported infections in the 6 dose groups above were 14, 12, 23, 26, 24, and 20% in MOBILITY and 18, 27, 22, 25, 18, and 29% in ALIGN. Infection rates in the Pbo groups and according to CNL in the pooled 150 mg (n = 103) and 200 mg (n = 100) q2w dose groups are presented in the Table. Infections in patients on sarilumab were most often observed among patients with normal CNL.

Number (%) of Patients With Infection From Baseline to Week 12 in MOBILITY Part A (RA) and ALIGN (AS): in Placebo Group; in Pooled Sarilumab 150mg q2w and 200mg q2w Dose Groups by Lowest Post-Baseline Circulating Neutrophil Level (CNL)

MOBILITY (150 mg q2w and 200 mg q2w	Normal CNL N=69	Grade 1 CNL (≥1500/mm^3 LLN) N=13	Grade 2 CNL (≥1000–1500/mm^3) N=12	Grade 3 & 4 CNL (<1000/mm^3) N=7	Pbo N=51
Any Infection	20 (29%)	2 (15%)	1 (8%)	1 (14%)	7 (14%)
Viral*	4 (6%)	0	0	0	0
Fungal*	1 (2%)	0	0	0	0
Bacterial*	1 (2%)	1 (8%)	0	1 (14%)	0
ALIGN (150 mg q2w and 200 mg q2w)	**Normal CNL N=55**	**Grade 1 CNL (≥1500/mm^3-LLN) N=16**	**Grade 2 CNL (≥1000–1500/mm^3) N=18**	**Grade 3 & 4 CNL (<1000/mm^3) N=11**	**Pbo N=50**
Any Infection	15 (27%)	2 (13%)	2 (11%)	2 (18%)	9 (18%)
Viral*	5 (9%)	0	0	1 (9%)	3 (6%)
Fungal*	0	1 (6%)	0	0	0
Bacterial*	0	0	0	0	1 (2%)

* Coded by etiology when provided à infections by etiology do not sum to total number of infections

Conclusion: In these 12 week studies, decreases in CNL did not appear to be associated with infection risk. This may be due to CNL margination or other mechanisms. These preliminary results warrant further exploration in the larger, longer phase 3 studies with sarilumab in patients with RA currently in progress.

Impact Of Etanercept-Methotrexate Treatment Withdrawal On Patient-Reported Outcomes In Patients With Early Rheumatoid Arthritis (PRIZE Trial). Piotr Wiland[1], B Combe[2], Oliver M. FitzGerald[3], Hasan Tahir[4], Stefanie Gaylord[5], Theresa Williams[5], Ronald Pedersen[6], Jack Bukowski[6], Bonnie Vlahos[5] and Sameer Kotak[7]. [1]Medical University of Wroclaw, Wroclaw, Poland, [2]Hôpital Lapeyronie, Montpellier, France, [3]St. Vincent's University Hospital, Dublin, Ireland, [4]Barts Health NHS Trust, London, United Kingdom, [5]Pfizer Inc., Collegeville, PA, [6]Pfizer Inc, Collegeville, PA, [7]Pfizer Inc., New York, NY.

Background/Purpose: Active rheumatoid arthritis (RA) is commonly associated with impairment of physical function and health-related quality of life (QoL), as well as work disability. The importance of patient-reported outcomes (PROs) in evaluating the impact of RA treatment on function, QoL, and the ability to work is well recognized. Patients with early (mean symptom duration, 6 months), moderate-to-severe RA who previously received induction therapy and achieved DAS28 remission with etanercept (ETN) 50 mg/methotrexate (MTX) in the 52-week, open-label Phase 1 of the PRIZE study received ETN 25 mg/MTX, MTX alone, or no treatment in the 39-week, randomized, double-blind Phase 2. The results of Phase 1/2 demonstrated a statistically significant and clinically meaningful favorable impact/sustained effect of biologic therapy on PROs.[1] Patients were subsequently included in a 26-week, observational, treatment-free Phase 3 if they had DAS28 ≤3.2 to assess the impact of complete therapy withdrawal.

Methods: Patients achieving response at end of Phase 2 (week 91: DAS28 ≤3.2) to treatment with ETN/MTX, MTX/placebo (PBO) injection, or PBO capsules/PBO injection continued to 26-week drug-free Phase 3. MTX was tapered to 0 by 5-mg weekly decrements. At week 117, the following PROs were assessed: the Health Assessment Questionnaire disability index (HAQ-DI); EuroQol-5 Dimensions utility score (EQ-5D); Short Form Health Survey Physical/Mental Component Summary (SF-36 PCS/MCS); Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-Fatigue); Work Productivity and Activity Impairment Questionnaire (WPAI: RA); and Work Instability Scale for Rheumatoid Arthritis (RA-WIS).

Results: After withdrawal of treatment in patients who responded to ETN/MTX and MTX/PBO therapy at week 91, worsening of most PROs was observed (Table 1). At week 117, the proportions of patients who achieved the following endpoints were not significantly different between the ETN/MTX and MTX/PBO groups after treatment withdrawal: normal HAQ-DI or

EQ-5D VAS; clinically relevant improvements in EQ-5D utility and SF-36 PCS; and low risk of work disability. Whereas worsening of most PROs plateaued among patients who were treatment free in both Phases 2 and 3, sharper declines were observed among patients withdrawn from ETN/MTX and MTX/PBO treatment in Phase 3.

Table 1. Effects of Biologic Treatment Withdrawal on PROs in PRIZE Phase 3 (LOCF)

		Patients, %			Pairwise Comparison *P* value§		
		ETN/MTX (n=63)	MTX/PBO (n=65)	PBO (n=65)	ETN/MTX vs MTX/PBO	ETN/MTX vs PBO/PBO	MTX/PBO vs PBO/PBO

Incidence Of Diabetes and Effect Of Etanercept and Adalimumab On HbA1c Over 1 Year: Data From a Randomised Trial In Patients With Rheumatoid Arthritis. Paola de Pablo[1], Fiona M. Maggs[2], David Carruthers[3], Abdul A. Faizal[4], Mark T. Pugh[5] and Paresh Jobanputra[6]. [1]University of Birmingham, College of Medical & Dental Sciences, Queen Elizabeth Hospital Birmingham, UK, Birmingham, United Kingdom, [2]Queen Elizabeth Hospital Birmingham, UK, Birmingham, United Kingdom, [3]Sandwell and West Birmingham Hospitals NHS Trust, UK, Birmingham, United Kingdom, [4]Heart of England NHS Foundation Trust, UK, Solihull, United Kingdom, [5]Saint Mary's Hospital, UK, Isle of Wight, United Kingdom, [6]Queen Elizabeth Hospital Birmingham, UK., Birmingham, United Kingdom.

Background/Purpose: Inflammation such as that which occurs in rheumatoid arthritis (RA) is associated with insulin resistance and risk of diabetes mellitus (DM). Some DMARDs including TNF inhibitors (TNFi) may improve insulin resistance and DM risk. However, it is unknown whether TNFi improve HbA1c in patients with RA with or without DM. Data on HbA1c was collected in a randomised trial comparing drug continuation rates for etanercept and adalimumab (BMJ Open 2012;2:e001395). We estimated the incidence of DM from this data and studied the impact of therapy on HbA1c.

Methods: Participants with active RA, who had previously failed to respond to 2 non-biologic DMARDs including methotrexate, were randomised to etanercept or adalimumab and followed 3-monthly over 1 year. Data collected included co-morbidities, clinical and laboratory parameters, and medications at each visit. The primary endpoint was newly recorded diabetes defined as HbA1c >48mmol/mol at any time point. Predictors of HbA1c and HbA1c change were determined with univariate and multivariate analyses.

Results: Of the 125 patients with active RA randomised to etanercept or adalimumab, 6 (4.8%) were known diabetics and 88% were RF/ACPA positive. Of the 119 without DM, 7 (5.9%) were diagnosed with DM (HbA1c >48mmol/mol) at baseline. 73 participants (73% female) completed 1 year of TNFi therapy: mean age 54 yrs (SD±12), mean BMI 27.8, mean HbA1c 38 mmol/mol. Of these, 4 (5%) patients had DM at baseline. A majority of patients were on methotrexate (67%) and 33% on prednisolone. Baseline characteristics were similar for patients' allocated to adalimumab (52%) or etanercept (48%), except more patients on etanercept were on prednisolone (49% vs. 18%; p=0.006); and more patients on adalimumab were on hydroxycloroquine (24% vs. 3%; p=0.01). After excluding those with known DM at baseline, among those completing one year of TNFi (n=69), 3 (4.4%) patients had an HbA1c >48 mmol/mol at baseline, 1 (1.5%) at 3 months, 1 (1.5%) at 6 months, and 2 (2.9%) at 12 months of follow-up. 2 (3%) cases had a HbA1c >48 mmol/mol at 2 follow-up visits. The incidence of DM was 29 new cases per 1000-person years (95% CI 3.51–105). Those on adalimumab tended to have higher levels of HbA1c than those on etanercept but the differences between groups at each time point were non-significant. However, there was a significant rise in HbA1c levels after 1 year of adalimumab therapy (37.27 mmol/mol and 38.80 mmol/mol; p=0.01). Etanercept therapy did not influence HbA1c levels over time.

Conclusion: Incidence of diabetes in patients entering a randomised trial of etanercept and adalimumab was considerably higher than other recent data. Treatment with a TNFi did not improve HbA1c levels with either agent in diabetics and non-diabetics. After excluding those with diabetes, those on adalimumab had higher mean HbA1c levels after 1 year of therapy.

Pharmacokinetic and Pharmacodynamic Characterization Of a Dissociated Agonist Of Glucocorticoid Receptor, Following Multiple Dose Administration In Healthy Japanese Adult Subjects. Brinda Tammara[1], Sou Miyoshi[2] and Judith Hey-Hadavi[3]. [1]Pfizer, Collegeville, PA, [2]Pfizer, Tokyo, Japan, [3]Pfizer, NewYork, NY.

Background/Purpose: PF-04171327 is a prodrug of PF-00251802, a dissociated agonist of the glucocorticoid receptor (DAGR) and being developed as treatment for Rheumatoid Arthritis. The objective of the study was to characterize the pharmacokinetics (PK) and pharmacodynamics (PD) of PF-00251802 following multiple doses of PF-04171327.

Methods: This was a randomized, placebo-controlled Phase 1 study of multiple doses of PF-04171327 in healthy adult Japanese subjects (N=8). PF-04171327 tablet (20 mg) or matching placebo once daily were administered in the morning for 12 days in a fasted state. The subjects were randomized in a 3:1 ratio to PF-04171327 or placebo, respectively. Blood samples for PK and PD analysis were collected at pre specified time points and analyzed using validated assay methods. Standard non-compartmental analyses methods were used to estimate PK parameters. PD effects were assessed using bone biomarkers (serum P1NP, serum CTX, osteocalcin, urine NTX), carbohydrate markers (fasting glucose, insulin, adiponectin) and HPA axis marker (plasma cortisol).

Results: The geometric mean summary of the plasma PK parameters of PF-00251802 and its metabolite PF-04015475 on Day 1 and Day 12 are shown in Table 1. The median percent change from baseline on Day 12 for the bone PD markers are shown in Table 2.

Table 1.

PK parameter (Units)		PF-00251802 N=6	PF-04015475 N=6
C_{max} (ng/mL)	Day 1	154	33.9
	Day 12	256	85
AUC_T (ng · h/mL)	Day 1	1430	610
	Day 12	3170	1520
$t_{1/2}$*(h)	Day 1	NA	NA
	Day 12	29	30

*Arithmetic mean, C_{max}: maximum observed concentration; AUC; area under the plasma concentration-time profile over the dosing interval; $t_{1/2}$, half-life

Table 2.

% Change from baseline	Placebo N=2	PF-04171327 N=6
P1NP	−19	−22
Osteocalcin	−11	−35
sCTX	6	11
uNTX	−4	31

P1NP: procollagen type 1 N-terminal propeptide.
sCTX: serum C-terminal telopeptide of type 1 collagen.
uNTX: urine N-telopeptide of type 1 collagen.

The mean observed accumulation ratios of exposure were 2.23 and 2.50 for PF-00251802 and PF-04015475, respectively. There was no change in the carbohydrate markers with treatment and complete suppression of cortisol levels was observed. There were no deaths, serious adverse events, severe AEs, subject discontinuations, in this multiple dose part of the study.

Conclusion: Following multiple dosing steady state concentrations of PF-00251802 were achieved by Day 9. There was a trend for greater suppression of bone formation markers osteocalcin and P1NP compared to placebo and increase in bone resorption marker urine-NTX, but not serum CTx. Overall, the treatments administered in this study were well tolerated with an acceptable safety profile.

Background/Purpose: The safety profile of a-TNF biologic drugs might have substantial regional differences due to geographic and socio economic factors and to epidemiology of infectious diseases. Registries are the best way to monitor drugs safety in the real world. In 2009, the Brazilian Society of Rheumatology started BiobadaBrasil, as part of a Latin America project (BiobadaAmerica) developed with the methodological support of the Spanish Society of Rheumatology and of the Biobadaser Study Group. Purpose:To report the incidence of adverse events (AE) in patients exposed to a-TNF drugs in Brazil.

Methods: Since January 2009 a growing number of centers from almost all Brazilian states (32 at 12/31/2012 when data were downloaded) included patients with active rheumatic diseases who started a biologic drug or a synthetic DMARD as a parallel control group. A constant three level monitory of data quality has been performed (online, by phone and in situ). The present study focuses on serious AE (SAE) and serious infectious AE (SIAE) (for SAE and SIAE definition: Protocolo 1.1 in https://biobadaser.ser.es/biobadamerica/Brasil/cgi-bin/upload/documentacion.aspx) in patients with Rheumatoid Arthritis (RA) and Spondyloarthritis (SpA = Ankylosing Spondylitis and Psoriatic Arthritis) exposed to a-TNFs. Time of exposure is considered from the beginning of therapy to the date of the last administration plus twice the half-life of the drug. Continuous variables were expressed as mean with standard deviation (SD). The AE incidence rate per 1000 patients per year of exposure and its 95% confidence level (95%CI) were calculated.

Results: 1372 subjects with RA (877) and SpA (495) exposed to a-TNF drugs were included in BiobadaBrasil, 3202 patient/yrs, mean age at baseline of 47 (SD12) yrs, mean disease duration of 9 (SD8) yrs, 65% females. Controls were 486 (RA 452, SpA 34), 1210 patient/yrs, mean age 50 (SD12) yrs, mean disease duration 6 (SD7), 82% females. The incidence rates of AE for 1000 patient/yrs [95%CI] in the a-TNF vs the control group were: SAE 58 [50,67] vs 19 [13,29] (ratio 3.04 [1.97,4.69] p=0.000), SIAE 26 [21,32] vs 4 [2,10] (ratio 6.2 [2.51,15.29] p=0.000). The incidence rates for the three more prescribed a-TNFs were: for SAE = ADAlimumab 50 [39,65], ETAnercept 58 [44,77], IFliXimab 64 [52,80] (ADA vs IFX p=0.35) and for SIAE = ADA 17 [11,26], ETA 30 [20,44], IFX 31 [23,43] (ADA vs IFX p=0.07). The first a-TNF was associated with a lower incidence of SAE and SIAE when compared with the subsequent but with no statistical significance. No significant difference of AE incidence rates has been found between RA and SpA patients.

Conclusion: In the BiobadaBrasil registry the incidence rate of SAE and SIAE in patients exposed to a-TNF drugs is similar to that reported by other registries. The comparison with the incidence rates of the internal control group showed a 3-fold risk for SAE and a 6-fold risk for SIAE.

Positivity Of Rheumatoid Factor and Anti-Cyclic Citrullinated Peptide Is Associated With The Response Rate Of Infliximab, But Not Tocilizumab, In Treatment Of Rheumatoid Arthritis. Masao Sato[1], Masao Takemura[1], Ryuki Shinohe[1], Yasuko Yamamoto[2] and Kuniaki Saito[2]. [1]Gifu University, Gifu, Japan, [2]Kyoto University, Kyoto, Japan.

Background/Purpose: Recent reports have shown that positivity for rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) can influence the efficacy of rheumatoid arthritis (RA) treatment. Additionally, RF^+ and $ACPA^+$ statuses were emphasized in the revised ACR–EULAR Classification Criteria for Rheumatoid Arthritis. This study examined whether RF^+ and $ACPA^+$ statuses in patients with RA impacted the clinical efficacy of anti-TNF-α or anti-IL-6 therapy.

Methods: We retrospectively evaluated 235 patients with RA who were observed through 52 weeks of follow-up after infliximab (IFX) or tocilizumab (TCZ) treatment at our hospital and related facilities (IFX, n = 142; TCZ, n = 93). Clinical efficacy was assessed based on a 28-joint disease activity score using erythrocyte sedimentation rate (DAS28-ESR) remission and achievement of Boolean-based remission criteria and its components ($\leq$1) at 52 weeks after initiating treatment.

Results: Before treatment, DAS28-ESR score in IFX and TCZ groups was 6.6 $\pm$ 1.5 and 6.5 $\pm$ 1.3, respectively. The proportion of RF^+ and $ACPA^+$ patients was 79.6% and 81.7% in the IFX group and 79.6%, and 87.1% in the TCZ group, respectively. The proportion of patients concomitantly treated with MTX was 100% in the IFX group and 55% in the TCZ group ($p < 0.0001$); the proportion of patients previously treated with biological products was 0% in the IFX group and 56% in the TCZ group ($p < 0.0001$). Among patients who achieved remission at 52 weeks in the IFX group, DAS28-ESR remission was seen in 36% and 59% RF^+ and RF^- patients ($p = 0.02$), respectively, and in 36% and 62% $ACPA^+$ and $ACPA^-$ patients, respectively ($p = 0.01$). TJC $\leq$1 was seen in 60% and 89% $ACPA^+$ and $ACPA^-$ patients, respectively ($p = 0.005$) and SJC $\leq$1 was seen in 60% and 85% $ACPA^+$ and $ACPA^-$ patients, respectively ($p = 0.01$). The proportion of patients who achieved remission was significantly lower in RF^+ and $ACPA^+$ patients. In the TCZ group, no efficacy index between RF^+ and RF^- patients or between $ACPA^+$ and $ACPA^-$ patients significantly correlated with remission. Correlations between pretreatment patient demographics and achievement of DAS28 remission at 52 weeks were evaluated. In the IFX group, patients who achieved no remission had higher CRP levels (3.0 vs. 1.9 mg/dL; $p = 0.0007$), higher disease activity by DAS28-ESR (6.8 vs. 6.2; $p = 0.01$), and a significantly higher RF^+ (86% vs. 71%; $p = 0.02$) and $ACPA^+$ rates (88% vs. 72%; $p = 0.01$) than those who achieved remission. However, similar differences were not observed in the TCZ group. A multivariate logistic regression analysis was performed to identify factors related to non-remission at 52 weeks after initiating treatment. DAS28-ESR (OR, 2.24; 95% CI, 1.52–3.47; $p = 0.0001$) and $ACPA^+$ (OR, 2.82; 95% CI, 1.19–6.97; $p = 0.04$) were identified as related factors in the IFX group; however, no factors were identified for the TCZ group.

Conclusion: RF^+ and $ACPA^+$ statuses are likely to be risk factors that affect the clinical efficacy of IFX treatment but not TCZ treatment.

Baseline Procalcitonin Levels Are Predictive Marker Of Remission In Biologic naïve Patients With Rheumatoid Arthritis Treated With Tocilizumab: Result From 24 Weeks Of Follow-Up. Soichiro Tsuji[1], Akiko Yura[2], Michihito Katayama[1], Satoru Teshigawara[1], Maiko Yoshimura[1], Eriko Tanaka[1], Yoshinori Harada[2], Yoshinori Katada[2], Masato Matsushita[1], Shiro Ohshima[3], Jun Hashimoto[1] and Yukihiko Saeki[3]. [1]Rheumatology, Osaka-Minami Medical Center, Kawachinagano City, Japan, [2]Allergology, Osaka-Minami Medical Center, Kawachinagano City, Japan, [3]Clinical Research, Osaka-Minami Medical Center, Kawachinagano City, Japan.

Background/Purpose: Procalcitonin (PCT) is a useful marker of infection. PCT-mRNA increases expression from peripheral blood mononuclear cells by stimulation of a pro inflammatory cytokine, IL-6 and TNF-α. Of the 216 Rheumatoid arthritis(RA) patients who started tocilizumab(TCZ) treatment until September 2012 at our center, about half of the patients did not attain remission after 24 weeks, and therefore, predictive marker will be useful for patient care. To purpose of this study is to investigate whether the levels of PCT, modified HAQ(mHAQ), MMP-3, RF, ESR, CRP, and ACPA at baseline(BL) of TCZ treatment can be used to predict remission at 24 weeks after the start of TCZ treatment (Week 24).

Methods: Biologic (Bio) naïve RA patients treated with TCZ for more than 24 weeks were enrolled in this study. PCT(n=30), mHAQ(n=71), MMP-3(n=98), RF(n=89), ESR(n=94), CRP(n=101) and ACPA(n=81) were identified at BL. The patients were divided into 2 groups, based on DAS28ESR remission (DAS28ESR<2.6) at Week 24. For each variable, there was a significant difference between the remission and non-remission group; ROC analysis was performed and cut-off values (COV) were analyzed. For each of these variables, 2 groups were formed by dividing the Bio naïve RA at the COV: the under COV (U) group and over COV (O) group, and the Week 24 remission rate in each group was found.

Results: The variables with significant difference between the remission and non-remission group were PCT(p=0.013), mHAQ(p<0.000), MMP-3(p=0.028), RF(p<0.000), ESR(p<0.000) and CRP(p<0.000). The COVs were 0.026ng/ml for PCT, 0.5 for mHAQ, 85mg/dl for MMP-3, 94U/ml for RF, 56mm/hr for ESR, and 1.09mg/dl for CRP. For each variable, the remission rate in the U group (PCT 91.7%, mHAQ 82.2%, MMP-3 68.8%, RF 72.3%, ESR 63.2% and CRP 65.2%) was significantly higher than in the O group. For PCT at BL, DAS28ESR was no different between the U group and O group and no correlation with DAS28ESR was observed. But the BL DAS28ESR was significantly lower in the U groups for other variables.

Conclusion: Baseline PCT level is a useful marker of predictive remission at week 24 in Bio naïve RA patients treated with TCZ. Moreover, unlike the other variables, it is not affected by the BL disease activity level.

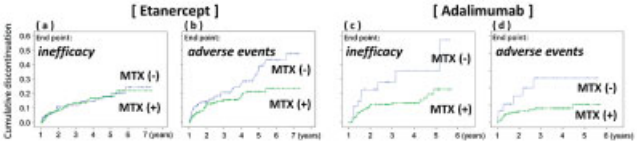
Concomitant Methotrexate Did Not Affect Discontinuation Rate Of Etanercept Due To Ineffectiveness: Six-Year Results From Japanese Multicenter Registry System. Nobunori Takahashi[1], Toshihisa Kojima[1], Atsushi Kaneko[2], Yuji Hirano[3] and Naoki Ishiguro[4]. [1]Nagoya University Hospital, Nagoya, Japan, [2]Nagoya Medical Center, Nagoya, Japan, [3]Toyohashi Municipal Hospital, Toyohashi, Japan, [4]Nagoya Univeristy Graduate School of Medicine, Nagoya, Japan.

Background/Purpose: In the last decade, treatment with tumor necrosis factor (TNF) inhibitors has significantly improved the outcome in patients with rheumatoid arthritis (RA). Recent studies have highlighted drug immunogenicity as a mechanism behind treatment failure. Concomitant immunosupressors, such as methotrexate (MTX), can reduce the production of anti-drug anitibodies (ADA) which might reduce drug efficacy and result in drug discontinuation. We investigated the effect of concomitant use of MTX on the long-term adherence of etanercept and adalimumab.

Methods: All eligible patients were registered in the Tsurumai Biologics Communication Registry (TBCR), an RA research consortium that consists of Nagoya University Hospital and 12 affiliated institutes. As of September 2011, 2,176 RA patients treated with biologics are registered in this registry. Seven hundred ninety four RA patients previously unexposed to biological DMARDs were treated with etanercept (n = 560) or adalimumab (n = 234). Drug discontinuation rates were calculated by Kaplan-Meier method using the end-point of inefficacy or adverse events. Statistical difference between two groups was tested by Log-rank test. Statistical significance was defined as p-value < 0.05.

Results: Among the etanercept group, the discontinuation rate due to inefficacy were quite similar between the patients with concomitant MTX (n = 385) and those without (n = 175) (16.8 vs 14.8% at 3 years and 22.2 vs 24.5% at 6 years, p = 0.936, Fig. a). Conversely among the adalimumab group, the patients with concomitant MTX demonstrated significantly lower discontinuation rate due to inefficacy (13.5 vs 36.2% at 3 years, p = 0.014, Fig. c). The patients without MTX demonstrated significantly higher discontinuation rate due to adverse events both in the etanercept (p = 0.011, Fig. b) and adalimumab group (p = 0.016, Fig. d). The reason for this difference would have included the patients' background complications for which they could not take MTX therapy. Unfortunately, such information was not available in the registry data.



Conclusion: It was quite interesting that the concomitant MTX usage did not improve the discontinuation rate due to inefficacy in the patients with etanercept therapy. Production of anti-drug antibodies (ADA) reduces the biological DMARDs effect that can be attenuated by concomitant methotrexate, which reduces ADA frequency. In the case of adalimumab, some previous reports demonstrated that the long-term clinical outcome is strongly dependent on the presence or absence of anti-adalimumab antibodies. On the other hand, some report showed that anti-etanercept antibody is hardly detected. Our current data clearly support these previous data that showed less immunogenicity of etanercept. Thus, we would conclude that the drug immunogenicity should be considered especially for the patients that cannot take concomitant MTX.

Economic Impact Of Adalimumab Treatment In Japanese Patients With Rheumatoid Arthritis: Analysis Of 24 Weeks Data From The Anouveau Study. Yoshiya Tanaka[1], Yasuhiko Shinmura[2], Ryo Nakajima[2], Takahiro Muramatsu[2], Shuichi Komatsu[2], Tadamichi Kubo[2], Aki Kuroki[2], Ataru Igarashi[3], Toshiro Tango[4] and Tsutomu Takeuchi[5]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]AbbVie GK, Tokyo, Japan, [3]The University of Tokyo, Tokyo, Japan, [4]Center for Medical Statistics, Tokyo, Japan, [5]Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Patients with rheumatoid arthritis (RA) incur higher costs owing to missed work days and short-time disability. Although methotrexate combined with adalimumab (ADA) provides comprehensive disease control in patients with RA, its impact in aspect of economic burden is less well understood. The purpose of this study is to assess the economic benefit of ADA treatment in Japanese patients with RA.

Methods: Data were taken from the first 24 weeks of a 48-week, multicenter, prospective, single-cohort study of self-reported work productivity and activity impairment in 512 Japanese patients with RA receiving ADA. Work-related outcomes were measured using the Work Productivity and Activity Impairment questionnaire for rheumatoid arthritis (WPAI/RA), including employment status (paid worker [PW] employed for ≥35hours/week, n=160, part time worker [PTW] employed for <35hours/week, n=80, or home worker [HW] non-employed, n=272), absenteeism (percentage of work time missed due to RA), presenteeism (percentage of impairment while working due to RA),

percentage of overall work impairment (OWI) due to RA, and percentage of activity impairment (AI) due to RA. The Health Assessment Questionnaire-Disability Index (HAQ-DI), EuroQol-5 Dimensions (EQ-5D), and disease activity score based on 28 joints count erythrocyte sedimentation rate (DAS28 ESR) were used to assess clinical response. Annually productivity loss was estimated using WPAI/RA scores and basic wages in Japanese workers 2012 by the Ministry of Health, Labor and Welfare.

Results: At week 24, disease activity measures were significantly improved. There were significant improvements in presenteeism of PWs and PTWs, in OWI of PWs, and in AI of all employment status. Changes in WPAI/RA domain scores correlated strongly with measures of clinical response. The saved productivity losses due to OWI and AI through week 24 were 7,400 USD for PWs, 1,300 USD for PTWs, and 4,700 USD for HWs. Improvements 2 in DAS28 ESR score, 0.5 in HAQ-DI score, and 0.2 in EQ-5D through one year were estimated to save 10,000 USD annually from productivity loss due to OWI in PWs (1 USD = 100 JPY in 2013).

Conclusion: ADA treatment reduced indirect cost due to work impairment in Japanese RA patients in different employment status.

Discontinuation Of Biological Therapy Due To Adverse Drug Reactions In Rheumatoid Arthritis Patients: 12 Years Follow-Up. Luis Rodriguez-Rodriguez, Leticia Leon, Zulema Rosales, Cristina Lajas, Lucía Arietti, Ana B. Rodríguez-Cambrón, Cristina Martínez-Prada, Jose María Leal, Pilar Macarrón, Gloria Candelas, Juan A. Jover and Lydia Abásolo. Hospital Clínico San Carlos, Madrid, Spain.

Background/Purpose: To describe in a cohort of rheumatoid arthritis (RA) patients followed up to 12 years, in standard clinical practice, the rate of biological agents (BAs) discontinuation due to adverse drug reactions (ADRs). Also, to analyze which factors influence the rate of severe ADRs (defined as those that required hospital admission or resulted in patient death), paying special attention on the comparison between BAs.

Methods: Observational retrospective longitudinal study, that included RA patients attending the rheumatology outpatient clinic of our center, whom started treatment with any BA [including etanercept (ETN), golimumab, certolizumab, infliximab (IFX), adalimumab (ADA), rituximab (RTX), abatacept (ABA), or tozilizumab], between January 1st, 2000, and January 1st, 2012. Clinical records were examined until withdrawal of the drug, loss of follow up, or December 18th, 2012. Survival techniques were used to estimate the incidence ratio (IR) of BA withdrawal due to ADRs, expressed per 100 patient-years with 95% confidence interval (95%CI). Cox bivariate and multivariate regression models (adjusted by age, gender and calendar time) were used to examine risk factors for BAs discontinuation due to severe.

Results: 405 patients were included, whom began 744 different courses of BA treatments, with a total follow up of 1,612 patient-years. 81% were women, with a mean [standard deviation (SD)] age at diagnosis of 52.5 (13) years and a mean (SD) elapsed time to the first BA of 5 (4.8) years. The most frequently used BAs were ADA (32%), ETN (25%), IFX (20.7%), and RTX (13.5%). There were 198 discontinuations due to ADRs, mostly due to infections (46%), mucocutaneous (14%), and infusion reactions (10%). 18% of the BAs therapies were discontinued during the first year due to ADRs, with a mean survival time of 5 years (95% CI 4.3–7.6). The IR was estimated in 12.8 (95%CI 10.7–14.1). 77 (39%) were severe ADRs, with an IR of 4.8 (95% CI 3.8–6.0). The most frequent types of severe ADRs were infections (51%) [IFX (55%), ADA (30%), RTX (7.5%) and ETN (2.5%)], cancer (13%) [IFX (30%), ADA (30%), and ETN (30%)], and congestive heart failure (9%) [IFX (58%), and RTX (42%)]. 50% were lower respiratory tract infections and 11% tuberculosis. 20% were lung and 20% were pancreatic cancers. 6 ADRs resulted in death [IFX (n=3), ADA (n=1), RTX (n=1), ABA (n=1)] with an IR of 0.4 (95% CI 0.2–0.8).

Both in the bivariate and multivariate regression analysis, age (HR: 1.04, 95%CI: 1.02–1.06), maximum rheumatoid factor (HR: 1.0001, 95%CI: 1.00006– 1.0002, p=0.002), and, compared with ETN, treatment with IFX or RTX (HR:5.7, 95%CI: 2.2–14.8, p=0.001; HR:3.3 95% CI: 1.2–9.8, p=0.02, respectively) were significantly associated to a higher risk of BAs discontinuation due to severe ADRs. Treatment with ADA did not achieve statistical signification (HR:2.4, 95%CI: 0.96–6.3, p=0.06).

Conclusion: This study describes the incidence of ADRs (50% related to infections) in RA patients taking BA in real life conditions. 39% resulted in hospital admissions and even in death, thus close monitoring is required in these patients. Within the BA more widely used in our setting, it seems that ETN generates less hospital admissions due to ADRs.

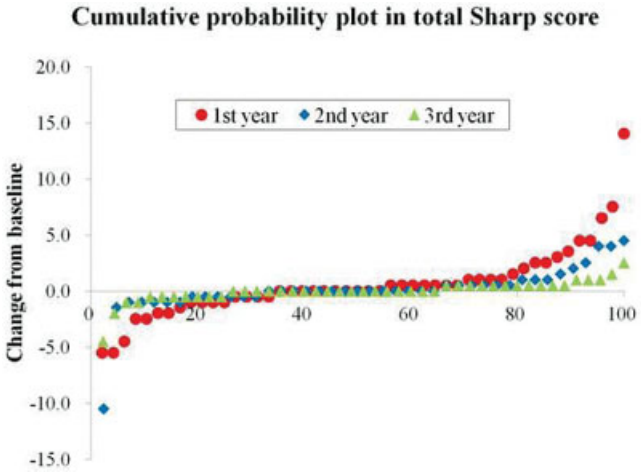
Tocilizumab Efficiently Halts Radiographic Progression In Patients With Rheumatoid Arthritis and Swollen Joint Counts Within a Year Predict Long-Term Radiographic Outcomes: Three Year Results From Michinoku Tocilizumab Study Group. Ryu Watanabe[1], Hiroshi Okuno[2], Tomonori Ishii[1], Yasuhiko Hirabayashi[3] and Hideo Harigae[1]. [1]Tohoku University, Sendai, Japan, [2]Tohoku University Graduate School of Medicine, Sendai, Japan, [3]Hikarigaoka Spellman Hospital, Sendai, Japan.

Background/Purpose: One of the important therapeutic goals in patients with rheumatoid arthritis (RA) is to halt radiographic progression. Tocilizumab (TCZ), an IL-6 receptor antibody, has been demonstrated that it efficiently improves clinical signs and inhibits structural damages in RA patients. However, it remains unknown what the predictive factor is for long-term radiographic outcomes in RA patients receiving TCZ. The objectives of this study are to assess the structural remission rate and to clarify the predictive factor for long-term radiographic outcomes in patients receiving TCZ under daily clinical practice.

Methods: Michinoku Tocilizumab Study Group comprised 34 institutions in the Northeast region of Japan. RA patients who received 8 mg/kg TCZ every 4 weeks were registered from June 2008 to December 2010 [1]. The clinical and radiographic outcomes were evaluated in 130 patients at 1 year, including 50 patients who received TCZ for 3 years.

Results: Baseline characteristics of patients who received TCZ for 1 year and 3 years, respectively, were as follows: mean age of 59.7/ 58.0 years, the mean disease duration of 10.8/ 10.9 years, the mean DAS28-ESR of 4.8/ 4.8, and 37.7/ 36.0% of patients were taking MTX. Mean change from baseline in van der Heijde-modified total Sharp score (mTSS) was 0.79 at 1 year, and the structural remission rate (ΔmTSS$\leq$0.5) was 69.2%. In the 50 patients who received TCZ for 3 years, the structural remission rate for 3 years (ΔmTSS$\leq$1.5) was 66%. Radiographic benefit gradually increased as the structural remission rate at the first, second, third year was 68.6%/78.6%/88.9%, respectively (Figure 1). At baseline, not tender joint counts (p=0.58), but swollen joint counts (SJC, p=0.04) predicted the structural remission at 3 years. Receiver Operating Characteristic (ROC) analysis showed that the cut-off value of SJC at baseline for structural remission at 3 years was 5. Even when SJC at baseline were above 5, SJC at 9 months (p=0.02) and at 12 months (p=0.004) were good predictors for structural remission at 3 years.



Conclusion: TCZ continuously inhibited radiographic progression in RA patients. SJC within a year could predict long-term radiographic outcomes irrespective of baseline disease activity in patients receiving TCZ.

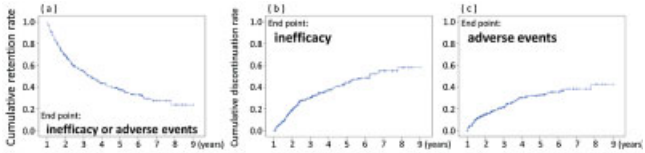
Long-Term Outcome Of Infliximab Therapy In Rheumatoid Arthritis Patients: Results From Japanese Multicenter Registry System. Nobunori Takahashi[1], Toshihisa Kojima[1], Atsushi Kaneko[2], Yuji Hirano[3] and Naoki Ishiguro[4]. [1]Nagoya University Hospital, Nagoya, Japan, [2]Nagoya Medical Center, Nagoya, Japan, [3]Toyohashi Municipal Hospital, Toyohashi, Japan, [4]Nagoya Univeristy Graduate School of Medicine, Nagoya, Japan.

Background/Purpose: After demonstration of effectiveness of anti-tumor necrosis factor (TNF) agents in patients with rheumatoid arthritis (RA), their use has become common practice in treating patients not responding to classical disease modifying anti-rheumatic drugs (DMARDs). In this paper, we studied the long-term clinical outcome of infliximab, which is first biological DMARD for RA in Japan, to demonstrate the 'the real-world' data using our registry system. To accumulate the data from daily clinical practice is quite important to improve the treatment strategy for RA.

Methods: All eligible patients were registered in the Tsurumai Biologics Communication Registry (TBCR), an RA research consortium that consists of Nagoya University Hospital and 12 affiliated institutes. As of September 2011, 2,176 RA patients treated with biologics are registered in this registry system. Four hundred forty seven RA patients previously unexposed to biological DMARDs were treated with infliximab (IFX). Drug retention rates were calculated by Kaplan-Meier method using endpoint of inefficacy or adverse events.

Results: As baseline characteristics, mean age was 56.6 years, disease duration was 14.9 years, proportion of patients with methotrexate was 99.6%, MTX dose was 7.2 mg/week, proportion of patients with prednisolone (PSL) was 76.1%, PSL dose was 5.2 mg, serum C-reactive protein was 3.8 mg/dL, and DAS28 was 5.7. IFX retention rate was 67.5% at 1 year, 31.0% at 5 years, and 22.5% at 8 years (Fig. a). IFX discontinuation rate due to inefficacy was 58.1% (Fig. b). Primary inefficacy was seen in 6.9% and secondary inefficacy was seen in 27.1% of patients. Discontinuation rate due to adverse events was 42.7% at 8 years (Fig. c). Most frequent adverse events resulted in IFX discontinuation was pulmonary complication (9.8%) including interstitial pneumonia (IP, 2.5%), bacterial pneumonia (4.3%), pulmonary tuberculosis (1.1%), pneumocystis pneumonia (0.7%), and organizing pneumonia (0.4%). The second most frequent was infusion reaction seen in 7.8%. The incidence of malignant neoplasm was seen in 1.8%.



Conclusion: We observed quite high discontinuation rate due to secondary inefficacy. This is probably dependent on the relatively low MTX dose, because of the Japanese regulation of public health insurance coverage. We are convinced of improved discontinuation rate if only with higher dose of concomitant MTX, which would reduce the production of anti-IFX antibodies resulting in secondary inefficacy and infusion reaction. It was the important data that the most frequent adverse events resulting in discontinuation was pulmonary complications. Putting all our results together, we would suggest that the most suitable patients for IFX treatment, expecting long-tern adherence, would be ones using sufficient dosage of concomitant MTX treatment and do not have baseline comorbidity of pulmonary diseases.

The Effectiveness Of Biological Agents Concomitant With Tacrolimus In Rheumatoid Arthritis. Kenya Terabe[1], Toshihisa Kojima[2], Nobunori Takahashi[2], Koji Funahashi[2], Atsushi Kaneko[3], Daihei Kida[3], Yuichiro Yabe[4], Yuji Hirano[5], Masatoshi Hayashi[6] and Naoki Ishiguro[1]. [1]Nagoya Univeristy Graduate School of Medicine, Nagoya, Japan, [2]Nagoya University Hospital, Nagoya, Japan, [3]Nagoya Medical Center, Nagoya, Japan, [4]Tokyo Kosei Nenkin Hospital, Tokyo, Japan, [5]Toyohashi Municipal Hospital, Toyohashi, Japan, [6]Nagano Red Cross Hospital, Nagano, Japan.

Background/Purpose: In Japan, oral tacrolimus (TAC) was approved for the treatment of RA in 2005 and the improvement of symptoms thorough the use concomitant with disease modifying antirheumatic drugs (DMARDs), including MTX has been reported. On the other hand, the efficacy and tolerance of biological agents therapy concomitant with TAC are unknown. The objective of this study was to investigate the efficacy and tolerance of biological agents concomitant with TAC in Japanese patients with RA using retention rate analysis.

Methods: Total patients (n=1541) who underwent 4 biological agents (etanercept: ETN, adalimumab: ADA, tocilizumab: TCZ, abatacept: ABT) treatment between 2003 and 2011 at Nagoya University Hospital and 12 other institutes (Tsurumai Biologics Communication Study Group) were enrolled. In each biologics analysis, patients were divided into three groups: (1) concomitant only MTX (MTX group) (2) concomitant only TAC (TAC group) (3) monotherary (mono group). In TAC or MTX group, these drugs were only ones which concomitant with biologics. Patients who underwent biologics combined with other DMARDs were excluded. Kaplan-Meier analysis was used to estimate retention rate in each biologics group. To estimate the tolerance of concomitant biologics with TAC, cumulative hazard function was performed in each biologics group.

Results: In total 1541 patients, 91 patients (5.9%) administered each biologics concomitant with TAC (ETN: n=38, 101.0 patient-years (PY) ADA: n=13, 12.8 PY TCZ: n=24, 40.8 PY ABT: n=17, 16.2 PY). Average dosages of TAC at starting were ETN: 2.1±0.9mg ABT: 2.4±0.9mg. With comparison of retention rate in each biologics concomitant with TAC, ADA was significantly lower rate than other 3 biologics (fig1). Each biologics agent's number was ETN (MTX: n=641, 1473.0 PY mono: n=194, 469.1PY), ADA (MTX: n=641, 1473.0 PY mono: n=34, 35.2PY), TCZ (MTX: n=181, 247.5 PY mono: n=85, 120.0PY), ABT (MTX: n=85, 89.6 PY mono: n=38, 35.1PY). In only ETN analysis, the retention rate of TAC group was higher than mono group (fig2). In ADA, that of MTX group was higher than TAC and mono group. There was no difference of comparison that of other 2 biologics analysis. Comparison of incidence of adverse event between TAC and mono group using cumulative hazard function in each biologics analysis, in only ETN analysis incident rate of mono group was higher than TAC group and there was no difference in other 3 biologics analysis.

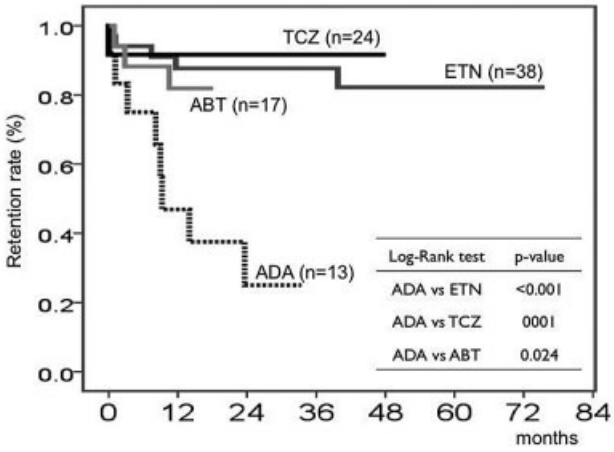

fig1: the retention rate of each biologics concomitant withTAC tretment (n=91)

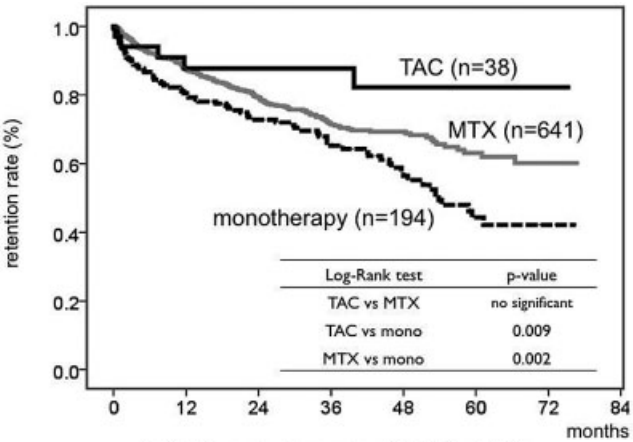

fig2: the retention rate of ETN (n=873)

Conclusion: We suspected that combination therapy ETN and TAC are subsequent options for treatment to RA patient, especially in whom MTX cannot be administration.

Is a Single Variable, The Swollen Joint Count, Valid As An Outcome Measure Separate From Being In An Index Measure? An Analysis From The Prospective, Biologic Treatment Registry Across Canada. J. Carter Thorne[1], Boulos Haraoui[2], William G. Bensen[3], Algis Jovaisas[4], Jude F. Rodrigues[5], Denis Choquette[2], Alice V. Klinkhoff[6], Emmanouil Rampakakis[7], John S. Sampalis[7], Francois Nantel[8], Allen J. Lehman[8], May Shawi[8] and Susan M. Otawa[8]. [1]Southlake Regional Health Centre, Newmarket, ON, [2]Institut de Rhumatologie de Montréal, Montreal, QC, [3]St. Joseph's Hospital and McMaster University, Hamilton, ON, [4]University of Ottawa, Ottawa, ON, [5]Rheumatology, Windsor, ON, [6]The Mary Pack Arthritis Ctr, Vancouver, BC, [7]McGill University, Montreal, QC, [8]Janssen Canada Inc, Toronto, ON.

Background/Purpose: The importance of joint counts as measures of synovitis is reflected in their prominence in all major clinical composite indices, the Disease Activity Score (DAS), the Clinical Disease Activity Index (CDAI) and the Simplified Disease Activity Index (SDAI). The twenty eight swollen joint count (SJC28) contributes numerically to approximately 16% of DAS28, 37% of CDAI and 33% of SDAI. The aim of this analysis was to examine whether SJC28 could be used as a stand-alone measure of disease remission.

Methods: Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with infliximab or golimumab as first biologics or after having been treated with a biologic for less than six months. In this analysis, data from RA patients treated with infliximab who were enrolled between January 2002 and June 2011 were used. Agreement between SJC28≤1 and remission or low disease activity as defined by the DAS28, CDAI, and SDAI criteria was assessed with the sensitivity, specificity, as well as the positive (PPV) and negative (NPV) predictive value.

Results: A total of 838 RA patients with mean (SD) age of 55.6 (13.5) years and mean (SD) duration since diagnosis of 10.5 (19.8) years were included in this analysis, providing information from 4,582 assessments. Using DAS28, CDAI, SDAI, and Boolean remission as reference standards, SJC28 sensitivity was 91.0%, 99.1%, 98.3%, and 100.0%, respectively. In addition, SJC28 correctly classified non-remission (NPV of 94.9%, 99.8%, 99.5%, and 100.0% for DAS28, CDAI, SDAI, and Boolean definition, respectively). However, specificity was only moderate (DAS28: 72.6%, CDAI: 64.0%, SDAI: 63.0%, Boolean: 61.8%), and SJC28 yielded a considerable proportion of false positives as indicated by the low PPV observed (DAS28: 58.9%, CDAI: 32.1%, SDAI: 33.0%, Boolean: 29.3%). When looking at low disease activity, SJC28≤1 showed lower sensitivity (DAS28: 83.2%, CDAI: 83.8%, SDAI: 85.0%) and NPV (DAS28: 85.8%, CDAI: 86.9%, SDAI: 87.5%) but higher specificity (DAS28: 83.2%, CDAI: 85.2%, SDAI: 84.2%) and PPV (DAS28: 80.1%, CDAI: 82.2%, SDAI: 81.1%).

Conclusion: The results of this analysis have shown that SJC28≤1 has high discriminatory power for low disease activity and moderate discriminatory power for remission as defined by the DAS28, CDAI and SDAI criteria. The more rigorous ACR/EULAR Boolean remission criteria were associated with increased sensitivity and NPV but decreased specificity and PPV.

Comparison Of Proposed Biosimilar PF-05280586 With Rituximab: Nonclinical and Phase I Clinical Assessments. Dolca Thomas[1], Jean-Claude P. Becker[1] and Chee-Keng Ng[2]. [1]Pfizer Inc., New York, NY, [2]Pfizer Inc., Andover, MA.

Background/Purpose: PF-05280586 is being developed as a potential biosimilar to rituximab, a monoclonal antibody (mAb) approved for the treatment of moderate-to-severe rheumatoid arthritis and lymphomas. The purpose is to present data demonstrating the structural and functional similarity of PF-05280586 to rituximab in nonclinical studies and pharmacokinetic (PK) and pharmacodynamic (PD) similarity in the first clinical study that has completed recruitment and dosing.

Methods: Nonclinical Studies: Structural similarity of PF-05280586 and rituximab-EU (MabThera®) was determined by side-by-side comparisons of peptide maps. In vitro functional similarity was determined with complement-dependent cytotoxicity (CDC) and antibody-dependent cell cytotoxicity (ADCC) assays using the Ramos B lymphoblastoid cell line as the target. Similarity of interaction with receptors was determined using SPR system.

Clinical Trial: A phase1/2 clinical trial (NCT 01526057) in patients with active rheumatoid arthritis (RA) is in progress to determine PK and PD similarity between PF-05280586 and the two marketed formulations of rituximab from the US (rituximab-US; Rituxan®) and the EU (rituximab-EU; MabThera®).

Results: Nonclinical Studies: The peptide map of PF-05280586 was similar to that of rituximab-EU indicating amino acid identity between the two mAbs. The dose-response curves of the 2 mAbs in the CDC and ADCC assays were essentially superimposable indicating similar in vitro function. Similarly, the binding to FcγRIIIa (158V) of PF-05280586 coincided with that of rituximab-EU, indicating similar mechanisms of actions of the two mAbs.

Clinical Trial: A total of 220 patients with active RA have been randomized into 3 arms and dosed. Monitoring for safety by an independent committee has shown no safety signals. The anticipated trial completion is Q42013.

Conclusion: PF-05280586 showed in vitro structural and functional similarity to rituximab-EU. PF-05280586 and rituximab appear to be well tolerated in nonclinical and clinical studies. These results support the development of PF-05280586 as a proposed biosimilar to rituximab.

UK Clinical Practice Use Of Biologics In Monotherapy For The Treatment Of Patients With Rheumatoid Arthritis. Andrew J. Ostor[1], G. Chelliah[2], Theodoros Dimitroulas[3], Margaret-Mary Gordon[4], Nicola Hewson[5], JA Mitchell[5], Senam Beckley-Kartey[6], Hok Pang[6] and Jose Saraiva-Ribeiro[6]. [1]Department of Rheumatology, Addenbrookes Hospital, Cambridge, United Kingdom, [2]Clinical Trials Unit, Wrightington Hospital, Wigan, United Kingdom, [3]Department of Rheumatology, Research and Development, Dudley Group NHS Foundation Trust, Russell's Hall Hospital, Dudley, United Kingdom, [4]Rheumatology Department, Gartnavel General Hospital, Glasgow, United Kingdom, [5]Syne Qua Non Ltd., Diss, United Kingdom, [6]Medical Department, Roche, Welwyn Garden City, United Kingdom.

Background/Purpose: NICE guidelines recommend that patients with severe active rheumatoid arthritis (RA) be treated with a biologic disease-modifying anti-rheumatic drug as monotherapy (bDMARD mono) if they respond inadequately to 2 traditional DMARDs and are intolerant to methotrexate (MTX). Registry and healthcare utilisation data have shown that around one-third of RA patients receive their biologic treatment as monotherapy. We intended to better understand the current management of RA patients with biologics in monotherapy, particularly why patients receive monotherapy and how effective this is in daily practice.

Methods: This UK wide chart review was conducted in 26 Rheumatology Hospitals between September 2012 and May 2013 and data from 309 RA patients, who had been prescribed a bDMARD mono, were collected retrospectively. We present data from an interim analysis of 150 patients.

Results: Mean age was 62.4 yrs. and mean duration of disease was 16.3 yrs. The majority of patients were female (109). 102 (74.4%) patients were Rheumatoid factor positive (n=137) and 34 (36.6%) anti-CCP positive (n=93). With regards to past RA treatment (prior to switch to monotherapy, n=61), the most frequently used bDMARDs mono (at any time prior to switch) were etanercept (ETN; 19.3%),adalimumab (ADA; 14%), certolizumab pegol (CZP, 7.3%), rituximab (RTX, 4.7%) and tocilizumab (TCZ, 2.7%). 55 (36.7%) patients had used two or more bDMARD mono. The most frequently used traditional DMARDs (n=146) were methotrexate (MTX; 92%), sulfasalazine (74.7%) and hydroxychloroquine (42.7%).With regards to current RA treatment (all patients receiving bDMARD mono), the most frequently used bDMARDs were ETN (42.7%), ADA (26%), TCZ (10.7%), RTX (9.3%) and CZP (8%). The main reason for prescribing bDMARD mono (n=150) was unknown (88%, assumed clinician decision). Others were patient preference (6.7%) and contra-indication (7.3%). Nearly a quarter of patients were on non-NICE approved monotherapy drug and only 10.7% were in DAS28 ESR remission.

Conclusion: Registry and healthcare utilisation data have shown that around one-third of RA patients receive their biologic treatment as monotherapy. The results of this audit draws attention to a patient population where treatment outcomes with bDMARD monotherapy are still not optimal (only 10.7% were in DAS28 ESR remission). 76.7% of the patients were treated with the above NICE approved TNF inhibitor. 55 (36.7%) patients had used two or more bDMARD monotherapies indicating that there are a significant number of patients where combination therapy with traditional DMARDs is not an option. As remission is the treatment goal and only 10.7% of patients were in remission there is an unmet medical need and therefore alternative treatment options should be explored to ensure better treatment outcomes for patients with this debilitating disease.

Pharmacodynamics Of a Novel Jak1 Selective Inhibitor In Rat Arthritis and Anemia Models and In Healthy Human Subjects. Jeffrey Voss[1], Candace Graff[2], Annette Schwartz[2], Deborah Hyland[2], Maria Argiriadi[2], Heidi Camp[3], Lori Dowding[2], Michael Friedman[2], Kristine Frank[3], Jonathon George[2], Eric Goedken[2], Gloria Lo Schiavo[2], Michael Morytko[2], Robert o'Brien[2], Robert Padley[3], Matthew Rosebraugh[3], Michael Rozema[3], Kent Stewart[3], Grier Wallace[2], Neil Wishart[2], Anwar Murtaza[4] and Lisa Olson[1]. [1]AbbVie Pharmaceuticals, Worcester, MA, [2]Abbvie Pharmaceuticals, worcester, MA, [3]abbvie pharmaceuticals, north chicago, IL, [4]Broad Institute, Cambridge, MA.

Background/Purpose: Anti-cytokine therapies have become the mainstay of treatment for rheumatoid arthritis (RA) disease symptoms and can arrest disease progression. Despite numerous treatment options there are still many RA patients who fail to experience substantial decreases in disease activity. Recently, Jak kinase blockade was shown clinically to be effective in managing disease and in some cases achieving remission. However, these first generation Jak inhibitors have failed to meet expectations due to dose-limiting tolerability and safety issues. ABT-494 is a second generation Jak kinase inhibitor with high selectivity for Jak1 thereby minimizing the potential for side effects related to Jak2 and Jak3 inhibition. Here we describe preclinical and early clinical data that suggest ABT-494 has potential to address some of the current unmet medical needs of RA patients.

Methods: ABT-494 was engineered for increased selectivity for Jak1 using structural predictions that indicated the potential for differential binding interactions outside the ATP-binding active site of Jak1 but not Jak2. The efficacy and selectivity of ABT-494 were tested in a battery of relevant cellular *and in vivo* pharmacology assays including bone marrow colony formation, adjuvant induced arthritis (AIA), erythropoietin induced reticulocyte deployment and NK/NKT cell suppression. The potency of ABT-494 in a variety of complementary pharmacodynamic assays was also assessed at multiple dosages in healthy human subjects administered orally for 14 days.

Results: ABT-494 demonstrates approximately 74 fold selectivity for Jak1 over Jak2 in cellular assays dependent on specific, relevant cytokines. ABT-494 is a potent inhibitor of inflammation and bone loss in rat AIA and, compared to Tofacitinib, spares relevant essential physiological processes such as erythropoietin signaling and peripheral NK cell counts at similarly efficacious doses in rats. When dosed orally for 14 days in healthy human subjects ABT-494 did not decrease reticulocyte or NK cell counts at predicted efficacious doses consistent with its pharmacodynamic properties in rats.

Conclusion: ABT-494 is a Jak1-selective inhibitor that demonstrates efficacy in rat arthritis models. Preliminary evidence suggests that pharmacodynamic properties of ABT-494 are consistent between those observed in rodent models and in healthy human subjects. Taken together, these encouraging observations support further testing of ABT-494 in RA patients in Phase II randomized placebo controlled trials and indicate it may have increased potential to address patient needs over existing agents.

The design, study, conduct and financial support for the clinical trial and research was provided by AbbVie. AbbVie participated in the interpretation of data, review and approval of this disclosure. AM was an employee of AbbVie at the time of data collection and analysis.

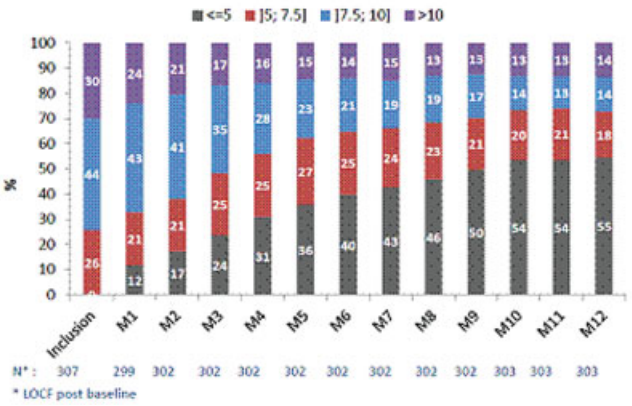
Tocilizumab Glucocorticoids Sparing Effect: The Spare-1 Study. Alain Saraux[1], Stephanie Rouanet[2], Rene-Marc Flipo[3], Jean-Cyril Poncet[4], Patrice Fardellone[5], Pascal Hilliquin[6], Isabelle Idier[7] and Alain G. Cantagrel[8]. [1]CHU Brest et Université Bretagne Occidentale, Brest, France, [2]Roche, Boulogne-Billancourt, France, [3]Hopital R Salengro CHRU Lille, Lille, France, [4]General Hospital Gap, Gap, France, [5]Hôpital Nord, C.H.U. d'Amiens, Amiens, France, [6]General Hospital Corbeil, Corbeil-Essonnes, France, [7]Chugai Pharma France, La Defense, France, [8]Purpan University Hospital Toulouse, Toulouse Cedex 9, France.

Background/Purpose: Although glucocorticoids (GCs) may be appropriate in rheumatoid arthritis (RA), there is general agreement that GCs sparing is desirable. The safety of GCs is duration and dose dependent and the risk has been demonstrated for a dose ≥ 5 mg/day. Tocilizumab (TCZ) is an effective biologic therapy in RA, even without concomitant methotrexate. The aim of this study is to describe the GCs sparing effect in patients treated with TCZ in real life clinical setting.

Methods: Multicenter, prospective, non-interventional 12-month study. Patients had active RA, were treated with more than 5 mg daily of prednisone for at least 3 months and initiated TCZ. No instructions were given regarding TCZ or GCs doses. Patient's characteristics were collected at baseline. After TCZ initiation, monthly disease activity components and RA treatments doses were collected. HAQ-DI and RAID were completed every 6 months. Primary endpoint: proportion of patients treated by 5mg/day or less of prednisone at M12 without intensification of synthetic DMARDs. Analysis: patients fulfilling inclusion/non-inclusion criteria and with at least one TCZ infusion. For primary endpoint, patients with missing GCs dose at M12 or with missing data on DMARDs intensification were considered as "non-responders". Last Observation Carried Forward (LOCF) method was used for missing cortisone dose value.

Results: 321 patients were selected and 307 analyzed. Baseline characteristics were: mean age 57±14 years, 249 females (78%), disease duration 10±9 years, RF or anti-CCP positive: 249 (82%); DAS 28-ESR: 5.1±1.3; CDAI: 27±12; SDAI: 29±13; HAQ: 1.6±0.7; RAID: 6.2±2.0; 216 (71%) previously treated by biologic DMARD. TCZ was initiated as monotherapy in 116 (38%) patients. At TCZ initiation, 92 (30%) patients received more than 10 mg of prednisone daily, 136 (44%) 7.5 to 10 mg, 79 (26%) 5 to 7.5 mg with a mean dose of 12±7 mg/day. At M12, 185 (66%) patients completed the study. 105 (34%) patients prematurely withdrew for: adverse event (AE) (n=38), TCZ discontinuation (n=47), lost-to-follow-up/move/refusal to continue the study (n=19). One 82-year old patient died after osteoporotic fracture. At M12, 124 patients (40%, 95%CI [35%; 46%]) received 5 mg or less of prednisone/day without DMARD intensification and 20% have stopped GCs. 33 % were in DAS28 remission and 42% had low disease activity. Mean DAS 28-ESR, CDAI and SDAI were 2.3±1.2, 9.3±8.4 and 9.7±8.5 respectively. At M12, 14% received prednisone daily dose>10 mg, 14% 7.5 to 10 mg, 18% 5 to 7.5 mg and 55% received 5 mg or less (Fig.1). No new safety signal was reported. 211 (67%) patients had at least one AE, 44 (14%) had at least one serious AE.

Fig.1.Evolution of prednisone daily dose (mg/day)



Conclusion: This study is the first large prospective study evaluating TCZ GCs sparing effect in RA in real life. 40% of patients were able to decrease their prednisone dose to 5 mg or below at 12 months without increasing disease activity.

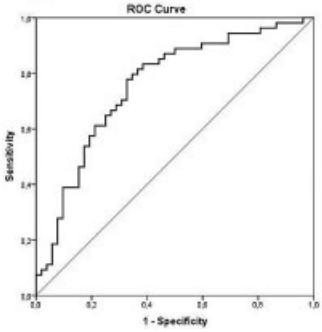
A Novel and Effective Prediction Model Of Response To Rituximab In Rheumatoid Arthritis. Alper M. van Sijl, Michel W.P. Tsang-A-Sjoe, Hennie G. Raterman, Michael T. Nurmohamed and Alexandre E. Voskuyl. VU University Medical Center, Amsterdam, Netherlands.

Background/Purpose: For patients with rheumatoid arthritis (RA) who are refractory to tumor necrosis factor (TNF)-inhibitors, it is still not clear which determinants are associated with response when switching to rituximab (RTX). Prior studies have shown anti-CCP positivity and a lower number of previously-failed TNF inhibitors to be associated with good-to-moderate response. We developed a prediction model for response to rituximab with widely available clinical and laboratory parameters.

Methods: RTX treated RA patients (n=115) were assessed prospectively for the following variables at baseline: demographic and disease characteristics, number of previous biologicals, co-morbidities, basic laboratory data, rheumatoid factor levels, anti-CCP levels and immunoglobulin levels (IgA, IgM and IgG). Clinical response was determined at 6 months after RTX initiation, using the European League Against Rheumatism (EULAR) response criteria for RA. Variables with $p < 0.10$ in univariate analyses were selected as candidate variables and entered into a forward and backward logistic regression analyses. A prediction model was constructed using backward logistic regression and an area under the curve (AUC) was calculated for the new prediction model.

Results: Mean disease activity score 28 (DAS28) was 5.34 at baseline and 4.44 at 6 months ($p<0.001$). A good-to-moderate response was achieved in 57 patients (49.6%). 101 patients (87.8%) used at least 1 biological prior to RTX treatment. RTX was re-administered in 70.9% of patients. The prediction model (see figure) consisted of age (in years), number of swollen joints, hydroxychloroquine use at baseline, steroid use at baseline and IgM level at baseline. The AUC (95% confidence interval) was 0.756 (0.663–0.850). When only using clinical variables (excluding IgM levels), the AUC was 0.714 (0.621–0.808).

A



B

	No response	Moderate response
Age, in years	58.6 ± 12.1	54.3 ± 13.8
Current use of HCQ, %	10	23
Current use of steroids, %	69	53
Swollen joint count, n	7 (4-11)	9 (5-14)
IgM level, gram/L	1.3 ± 0.8	1.8 ± 1.6

Results presented as mean ± standard deviation, median (interquartile range) or percentages, when appropriate

	Odds ratio (95%-Confidence Interval)
Age, in years	0.98 (0.95-1.00) *
Current use of HCQ, %	0.39 (0.14-1.11) *
Current use of steroids, %	2.00 (0.93-4.28) *
Swollen joint count, n	1.11 (1.03-1.20) *
IgM level, gram/L	1.44 (0.96-2.16) *

* p < 0.10 for associations between clinical determinants and EULAR response

Figure. Area Under the Receiver Operating Characteristic (AUROC) of a predictive model of EULAR response at 6 months after RTX treatment (A) and the clinical determinants comprising the model (B)

Conclusion: We developed a prediction model for response to rituximab with simple clinical and laboratory parameters. This model is easy to use and accurate in the prediction of response to treatment. Further validation of this model could make the implementation of this model cost-effective and patient friendly.

Biomarkers Associated With Rheumatoid Arthritis Disease Activity Including Joint Damage Correlate With Changes In Clinical Response In Subjects Treated With Mavrilimumab At Doses Above 10 Mg. Wendy White[1], Patricia Ryan[1], Xiang Guo[1], Dominic Sinibaldi[1], Gopi Ranganna[2], Alex Godwood[3], Didier Saurigny[3], David Close[3], Steve Eck[1], Dee Wilkins[4], Lorin Roskos[4], Matthew A. Sleeman[2], Wanying Li[5], Guy Cavet[5] and Nadine A. Defranoux[5]. [1]MedImmune, LLC, Gaithersburg, MD, [2]MedImmune, LLC, Cambridge, United Kingdom, [3]MedImmune, Ltd, Cambridge, United Kingdom, [4]MedImmune, Gaithersburg, MD, [5]Crescendo Bioscience Inc., South San Francisco, CA.

Background/Purpose: GM-CSF plays a central role in the pathogenesis of rheumatoid arthritis (RA) through effects on macrophages and neutrophils. Mavrilimumab (CAM-3001) is a human monoclonal antibody targeting the alpha subunit of GM-CSF receptor. Marvrilimumab was recently evaluated in RA subjects in a phase 2a study (EARTH). Results reported from the European (EU) cohort demonstrated that mavrilimumab may provide clinical benefit to patients with moderate to severe RA (Burmester GR, et al. ARD 2012). Here, we describe final data from EARTH comparing results in the EU

and Japanese (JA) cohorts. Biomarker (BM) assessments were also performed to elucidate mechanistic aspects of mavrilimumab.

Methods: Mavrilimumab (10, 30, 50 or 100 mg) or placebo was administered SC every other week to subjects with moderate/severe RA (DAS28 > 3.2) on stable methotrexate for 12 weeks followed by a 12 week drug free follow up period. A multi-biomarker disease activity (MBDA) score was calculated using the validated Vectra ®DA algorithm and used to track the effect of the drug on disease activity over time. An additional multi-BM-based algorithm (MBSD) was used to assess the impact of mavrilimumab on markers known to be associated with progressive joint damage. The relative ability of different mavrilimumab doses, over time, to saturate GM-CSF receptors in whole blood was examined by flow cytometry using receptor occupancy assay (ROA) in the EU cohorts.

Results: In the EARTH study, mavrilimumab demonstrated good clinical activity with generally similar responses in the EU and JA cohorts. In the overall population, the primary endpoint (DAS28-CRP reduction ≥1.2 at Week 12) was met. Improvements were seen as early as week 2 and persisted through the 12 week follow up especially in the 100 mg dose group. The MBDA score decreased significantly as early as day 8 ($p<0.05$) and remained suppressed during the entire treatment period in cohorts from both EU and JA. Additional samples from the 100 mg EU cohort showed that suppression of the MBDA was maintained for a minimum of 4 weeks after the last dose. Individual components of the MBDA score, as well as additional BMs in the EU cohort showed that CRP, SAA, IL-6, IL-2RA and MDC were significantly decreased on days 8, 15, 88 and 113 in the 100 mg cohort compared to placebo. Lesser or no changes were observed with the 10 mg cohort. There was an early and sustained dose-related inhibition of the joint damage composite index MBSD observed in the EU cohort. In the JA cohort a significant decrease was also observed when comparing treatment group to placebo group. The ROA results showed the 10 mg dose was sub-optimal in its ability to saturate GM-CSF receptor. This sub-optimal effect was reflected in the BM analysis and in the clinical efficacy endpoints.

Conclusion: Promising clinical safety and efficacy results of mavrilimumab support further clinical development at doses greater than 10 mg. Mechanistically, the drug suppressed both acute phase and inflammatory blood markers. Tracking of disease activity by MBDA showed a clear biomarker-based dose-response relationship. The association of MBSD decline with radiographic damage will be assessed in an on-going phase 2b study.

Safety Of Mavrilimumab In Cynomolgus Monkeys: Relevance Of Non-clinical Findings In Lung To Human Safety. Patricia C. Ryan[1], Matthew A. Sleeman[2], Marlon Rebelatto[1], Bing Wang[3], Hong Lu[3], Chi-Yuan Wu[3], Dee Wilkins[1], Susan Spitz[1], Gopi Ranganna[2], Alex Godwood[4], Alex Michaels[1], Didier Saurigny[4], Lorin Roskos[1], David Close[4], Heidi Towers[2], Kathleen McKeever[1] and Rakesh Dixit[1]. [1]MedImmune, Gaithersburg, MD, [2]MedImmune, LLC, Cambridge, United Kingdom, [3]MedImmune, Hayward, CA, [4]MedImmune, Ltd, Cambridge, United Kingdom.

Background/Purpose: GM-CSF plays a central role in the pathogenesis of rheumatoid arthritis (RA) through the activation, differentiation, and survival of macrophages and neutrophils. Mavrilimumab (CAM-3001) is a human monoclonal antibody targeting the alpha subunit of GM-CSF receptor which MedImmune is developing as a novel treatment for RA. Because GM-CSF plays a role in the regulation of pulmonary surfactant homeostasis (Trapnell and Whitsett, Ann Rev Physiology, 2002:775–802), lung toxicity is a potential concern for biologics such as mavrilimumab which inhibit GM-CSF receptor signaling. As a result, additional attention was given to the potential impact of lung toxicity during the development of mavrilimumab.

Methods: Nonclinical safety of mavrilimumab was evaluated in several repeat dose studies in cynomolgus monkeys. Comprehensive toxicity parameters were assessed in each study, and treatment duration ranged from 4 to 26 weeks. All animal studies were performed under approved protocols at AAALAC-accredited labs. In the recently completed Ph2a clinical study EARTH (Burmester et al., ARD 2012) intensive respiratory monitoring included chest X-rays, forced expiratory volume (FEV1), forced vital capacity (FVC), diffusing capacity of the lung for carbon monoxide (DLCO) and dyspnea scores. Serum biomarkers of lung damage, surfactant protein D (SP-D) and Krebs von den Lungen-6 (KL-6) were measured using commercially available immunoassays (BioVendor, LLC; Candler, NC).

Results: Mavrilimumab has an acceptable safety profile in monkeys with no changes in any parameters other than microscopic findings in lung. In several studies, minimal accumulation of foamy alveolar macrophages was observed. This finding was reversible following a dose-free recovery period and was considered non-adverse. At very high dose levels (≥30 mg/kg), in a 26-week repeat IV dose study, the presence of lung foreign material, cholesterol clefts, and granulomatous inflammation was also observed in a few animals and was considered adverse. These dose and time related changes in lung were consistent with mavrilimumab inhibitory effects on lung macrophage function arising from exaggerated pharmacology. Overall, a clean no-observed-adverse-effect-level (NOAEL) without any effects in lung was established and provided adequate clinical safety margins. In EARTH, mavrilimumab demonstrated good clinical activity with no clinically significant or persistent changes in the lung function tests performed. Likewise, the serum biomarkers of lung damage, SP-D and KL-6, showed no clinically significant changes following mavrilimumab treatment.

Conclusion: These results suggest that suppressing macrophage activity by targeting GM-CSF receptor alpha may be a novel approach with an acceptable safety profile for the treatment of RA.

In Rheumatoid Arthritis Patients With Stable Low Disease Activity On Methotrexate Plus Etanercept, Continuation Of Etanercept Is Superior Both Clinically and Radiographically To Discontinuation: Results From a Randomized, 3-Armed, Double-Blind Clinical Trial. Mikkel Østergaard[1], Marjatta Leirisalo-Repo[2], Till Uhlig[3], Marita Jansson[4], Esbjörn Larsson[4], Fiona Brock[5] and Ronald F. van Vollenhoven[6]. [1]Copenhagen University Hospital Glostrup, Copenhagen, Denmark, [2]Helsinki University Central Hospital, Helsinki, Finland, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Pfizer AB, Sollentuna, Sweden, [5]Quanticate, Hitchin, Hertfordshire, United Kingdom, [6]The Karolinska Institute, Stockholm, Sweden.

Background/Purpose: The randomized clinical trial "DOSERA" has shown that in patients receiving concomitant methotrexate (MTX) therapy, continuation of etanercept (ETN) at 50 mg wkly is clinically superior to placebo, as is continuation at 25 mg wkly. The aim of this post hoc analysis was to investigate differences in radiographic progression between these treatment groups.

Methods: RA patients on stable ETN 50 mg/wk plus MTX (stable dose 7.5–25 mg/wk) and documented low disease activity/remission (LDA/REM; DAS28 ≤3.2) for ≥11 mths based on retrospective data were included. Additional key inclusion criteria were: age ≥18 y, stable MTX, no prior non-anti-TNF therapy and no prior attempt to discontinue ETN due to stable disease. Patients were followed for 2 mths on ETN 50 mg/wk plus MTX to ensure stable LDA/REM, and stratified based on LDA/REM status, and randomly assigned 1:1:1 to ETN50 mg/wk (ETN50), ETN 25 mg/wk (ETN25), or placebo (PBO) while continuing MTX. Failure was defined as DAS28 >3.2 on ≥1 occasion or disease progression as determined by investigator or patient. In cases of failure, patients received open-label ETN 50 mg/wk. Radiographs of hands and feet were obtained at baseline and at 48 wks and scored double-blindly by two investigators using the van der Heijde modified Sharp method (SHS). Radiographic progression was assessed from week 0 to week 48 on an intent-to-treat basis and independent of whether patients entered open-label ETN50 mg/wk.

Results: Of 106 patients screened, 91 were enrolled, and 73 randomized. The groups were demographically and clinically well-balanced at baseline,

but a higher baseline SHS was seen in the ETN25 group. The average age (SD) was 57 (11) y and disease duration was 13.6 (8.8) y. After 48 wks the % of non-failures was 52% for ETN50, 44% for ETN25, and 13% for PBO ($p=0.007$ and 0.044 for the two doses vs. PBO, respectively). Sixty-four patients had radiographs at baseline and at 40–48 wk follow-up. SHS (mean±SD) at baseline was 51.0±53.4 and at follow-up was 51.2±53.4. The mean progression in all patients was 0.13 (median 0) and was numerically highest for PBO (0.43) and lower for ETN50 (–0.13), and ETN25 (0.10). The number of patients with progression (SHS change >0) was 9/20 (45%) for PBO, 6/24 (25%) for ETN25, and 2/20 (10%) for ETN50. Radiographic progression was limited to ≤2 points in all but one patient in the PBO group (SHS change 3). Adverse events were similar between the groups; no unexpected safety signals were noted.

Conclusion: For RA patients with stable LDA/REM on ETN 50 mg/wk + MTX, continued treatment with ETN at 50 mg/wk or 25 mg/wk provides a significantly higher likelihood of non-failure of treatment over 48 wks than PBO. More patients in the PBO group had radiographic progression than those in the ETN50 and ETN25 groups. These radiographic data plus the clinical findings suggest that discontinuing ETN after achieving a stable LDA/REM state may lead to clinical worsening and radiographic damage, and should therefore not be recommended. In addition, the results from the reduced ETN dosage used in this trial provide further evidence that an "induction-maintenance" strategy may be feasible even in some patients with established RA.

Is Isoniazid Treatment For LTBI Safe For RA Patients With TNF Inhibitor Therapy? Yoon-Kyoung Sung[1], Soo-Kyung Cho[2], Soyoung Won[2], Jeeseon Shim[2], Dam Kim[1], Ji-Young Choi[1], Chan-Nam Son[1], Chan-Bum Choi[1], Tae-Hwan Kim[1], Jae-Bum Jun[1], Dae-Hyun Yoo[1] and Sang-Cheol Bae[2]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea.

Background/Purpose: Isoniazid (INH) is increasingly used in RA patients with evidence of latent tuberculosis infection (LTBI) for whom TNF inhibitor therapy is planned. The potential for hepatotoxicity of INH has been concerned in RA patients treated with DMARDs including methotrexate (MTX). However, the safety and impact of INH for RA patients on persistency of TNF inhibitors has not been known. We aimed to study the safety of INH treatment for LTBI and its impact on the persistency of TNF inhibitors.

Methods: Data were extracted from medical records of RA patients who had treated with TNF inhibitor at our university hospital from December 2000 to November 2011 (REtrospective study for Safety and Efficacy of Anti-RA treatment with biologiCs, RESEARCh). Comprehensive chart reviews were undertaken on all patients, and the data for each patient consists of two components: demographic and clinical characteristics (age, sex, disease duration, disease activity, comorbidity and laboratory finding) and information related with TNF inhibitors (type of drug, history of DMARDs before starting TNF inhibitor, concomitant medication andtreatment period).

A total 312 patients aged 18 years old or older were enrolled in this study, and among them 96 patients (30.9%) experienced INH treatment for LTBI. The occurrences of LFT abnormality were evaluated in both patients with and without INH treatment. Then Kaplan-Meier curve and Cox proportional hazard analysis were used to evaluate its impact on persistency of TNF inhibitors

Results: There was no difference in demographic and clinical features in both groups except the frequency of MTX use (83.3% in INH treatment group and 72.2% in INH non-user group, $P=0.049$). The LFT abnormality was more commonly happened in patients treated with INH than those without INH treatment (20.8% vs. 8.8%, $P=0.005$). This increased risk for hepatotoxicity by INH treatment was persistent after adjusting covariates including MTX use in multivariate regression analysis (OR 3.18, 95% CI 1.48–6.84). However, the persistent rate of TNF inhibitors during 5 years using Kaplan-Meier curve was not different between two groups with and without INH treatment (49.4% vs. 54.6%, $p=0.79$ in log-rank test). INH treatment for LTBI was not associated with discontinuation of TNF inhibitors in Cox proportional hazard model (HR 1.02, 95%CI 0.66–1.58).

Conclusion: INH treatment for LTBI in RA patients who started TNF inhibitors is associated with the occurrence of LFT abnormality. However, it does not affect the persistency of TNF inhibitors.

The JAK1-Selective Inhibitor GLPG0634 Is Safe and Rapidly Reduces Disease Activity In Patients With Moderate To Severe Rheumatoid Arthritis; Results Of a 4-Week Dose Ranging Study. Chantal Tasset, Pille Harrison, Annegret Van der Aa, Luc Meuleners, Frédéric Vanhoutte and Gerben van 't Klooster. Galapagos NV, Mechelen, Belgium.

Background/Purpose: GLPG0634 is an oral, selective inhibitor of Janus kinase 1 (JAK1). JAKs signal for cytokines and growth factors, including those involved in rheumatoid arthritis (RA). Non-selective JAK inhibitors have demonstrated efficacy in patients with RA, but also dose-limiting toxicity. In a prior 4-week Proof-of-Concept (PoC) study, GLPG0634 showed promising efficacy and safety at a daily dose of 200 mg.

The objective of this study is to evaluate short-term safety and efficacy of a dose range of GLPG0634 administered as once-daily regimen in RA patients with insufficient response to methotrexate (MTX) alone.

Methods: 4-week, double-blind Phase IIA study, comparing GLPG0634 at 30, 75, 150 and 300 mg once-daily (QD) versus placebo in a total of 91 patients. Patients had active RA (mean DAS28 of 6.0) with insufficient response to MTX and naïve to biological therapies, and continued their stable background therapy of MTX.

Results: GLPG0634 treatment was generally well tolerated; most adverse events (AEs) were mild and no serious AEs were reported. No patient discontinued due to AEs. No anemia was observed but rather a dose related improvement in hemoglobin. There was a limited decrease in absolute neutrophil count, no neutropenia, and no impact on lymphocyte subsets. No consistent changes in LDL were observed. ALT/AST was stable with no elevations >1.5 times ULN.

After 4 weeks treatment	Once-daily GLPG0634				
	Placebo	30 mg	75 mg	150 mg	300 mg
CRP: mean change (mg/L)	−5.7	−13.3	−15.1	−20.5	−17.4
- CRP shift high to normal (% pts)	0	24	32	47	60
Mean change DAS28(CRP)	−1.2	−1.1	−1.7	−1.8	−2.3
- Low disease, <3.2 (% pts)*	18	12	32	13	45

* includes patients achieving remission (<2.6).

Within 4 weeks, GLPG0634 showed an encouraging dose trend in efficacy. There was a limited improvement with the 30 mg dose whereas good anti-inflammatory (CRP) response and change in disease activity (DAS28) was apparent for doses of 75 through 300 mg QD (table). The results achieved at 300 mg are similar to those with 200 mg QD in the prior PoC study (DAS28: −2.2, with 33% <3.2 at week 4). The improvement in RA disease parameters was similar for doses of 75 mg through 300 mg, with highest response rates (at 150 or 300mg) for TJC68: -15, SJC: -11, physician's global: -29, patient's global: -26, patient's pain: -30, and HAQ-DI: -0.7. A high response rate in the placebo group may be related to a lower disease activity at baseline. For the 150 mg group, having the highest level of disease, 4 weeks treatment was too short to obtain good patient-reported outcomes. For ACR scores, best results were obtained for the 300mg group (65% ACR20, 45% ACR50). In spite of the small study, statistically significant improvements were obtained for CRP, DAS28, HAQ-DI and ACR50 at the high dose.

Conclusion: These early clinical results demonstrate that selective JAK1 inhibition by GLPG0634 at daily doses of 75 to 300 mg QD is efficacious and generally well tolerated after 4 weeks in patients with RA. Safety and efficacy findings were consistent for two Phase IIA studies. A dose trend was found and current data suggest that a maximum level of efficacy is attained at 200 mg/day. Larger 24-week studies in RA patients are ongoing to evaluate optimal doses for efficacy and safety.

B Cell Analysis Is An Essential Tool To Anticipate Clinical Relapse In Rheumatoid Arthritis Patients Treated With Rituximab. Anne-Priscille Trouvin[1], Serge Jacquot[2], Sébastien Grigioni[1], Hélène Boulard[1], Ingrid Dutot[2], Olivier Vittecoq[3], Xavier Le Loët[3], Olivier Boyer[2] and Vincent Goëb[4]. [1]Rouen University Hospital, Rouen, France, [2]INSERM U905, University of Rouen, Rouen, France, [3]Rouen University Hospital & Inserm905, University of Rouen, Rouen, France, [4]Amiens University Hospital, Amiens, France.

Background/Purpose: Rituximab is a safe and effective treatment in rheumatoid arthritis (RA), however the current treatment regimen requires to wait for a clinical relapse before a new course of treatment. The interval between two courses of treatment varies from one patient to another and remains unknown prior to the treatment. Our aim was to evaluate the utility of following-up different B cells subtypes depletion as a tool to foresee RA clinical relapse. Our aim was to assess the usefulness of periodical B cell analysis to determine if it may predict clinical relapse of RA in patients treated with rituximab.

Methods: Prospective single-center observational study of 39 patients with RA treated with rituximab 1g twice 15 days apart. Patients were monitored clinically and biologically every 2 months until retreatment. Clinical assessment consisted of RA activity and report of adverse event, biological assessment consisted of inflammatory parameters, antibodies, gammaglobulins titres and B cell analysis. The clinician was blinded of the B cell analysis results.

Results: 39 patients were included from March 2010 to December 2011 with a follow-up until January 2013. 7 patients had two courses of treatment and a total of 46 cycles of rituximab were analysed. At baseline mean DAS 28 was 5,44; 33 patients were RF and/or ACPA positive. At 6 months, 44 patients (96%) had a good-to-moderate clinical response according to the EULAR criteria. The mean treatment duration was 13 months.

After the two infusions, total number of CD19+ cells decreased (0.155G/l vs 0.0002G/l, p=0.006) with a complete depletion for all patients in the memory (CD19+27+) and transitional subtypes (CD19+CD38++ CD24++) (p<0.0001). At relapse B cells were detected in all but 1 patient. Significant majority of patients relapsed within the 4 months that follows B cell CD19+ increase (p=0,04). Looking at B cell subtypes, significant majority of patients relapsed within the 4 months that follows increase in CD19+CD27+ (p=0,01) and increase in CD19+CD38++CD24++ (p=0,007).

Conclusion: Increase in peripheral B lymphocytes after initial depletion appeared to be predictive of a clinical relapse in the next four months, providing objective elements on a forthcoming clinical relapse.

A Useful Mathematical Model Able To Predict The Early Response To Tocilizumab In Rheumatoid Arthritis. Chiara Stagnaro, Claudia Ferrari, Rosaria Talarico, Camillo Giacomelli, Stefano Bombardieri and Laura Bazzichi. Rheumatology Unit, Pisa, Italy.

Background/Purpose: In the last few year the introduction of biological agents has radically changed the clinical outcome of patients with Rheumatoid Arthritis (RA). However, no single drug is able to control all patients with RA and it is known that each drug may be poorly effective in a sizable proportion of the treated patients. For these reasons the early identification of clinical responder patients may represent a crucial advantage for either clinical and socioeconomic reasons. Recently, mathematic algorithms, based on classical clinical parameters, have been proposed to predict the clinical response to anti TNF and DMARDs. In the present study we have applied the mathematic algorithm proposed to predict early response to anti TNF on our cohort of RA patients treated with tocilizumab (TCZ).

Methods: We collected the data of 61 RA patients (male: female= 52:9; mean age ± SD 50.0 ± 16.0; DAS28 at the onset:5.2±0.7; DAS28 at 1 year: 1.5±0.35) followed in our unit and treated with TCZ from Jan 2010 to Jan 2013, with a follow up of at least 12 months. The mathematic algorithm was based on the following parameters: Tender Joint, Swollen Joint, Illness activity VAS by Physician and patient, Pain VAS, ESR and CRP. It was applied to calculate the putative responders at one month of treatment and this value was compared with the DAS 28 at one month and at one year of therapy. The patients were classified as good responders if they had a delta DAS28> 1.2.

Results: The mathematical model allows to predict 90% of the final responders for all treated patients, with the occurrence of 3 false negative patients. Moreover, after 1 month of therapy a delta DAS 28>1.2 was recorded in 30% of patients, while at one it was found in 88% of cases.

Conclusion: these data suggest that the mathematical algorithm proposed to predict the clinical response to anti TNF, may be apply in the routine clinical practice also to RA patients treated with TCZ. Although we need further results from ongoing prospective clinical studies, it is desirable that this simple mathematical model will use to predict at one month the response in almost RA patients.

Variability In Patient Characteristics and Outcomes In Rheumatoid Arthritis Upon Infliximab Treatment Based On The Size Of Biologic Treatment Registry Site. J. Carter Thorne[1], William G. Bensen[2], Sanjay Dixit[3], Rafat Y. Faraawi[4], Dalton E. Sholter[5], Maqbool K. Sheriff[6], Philip Baer[7], Denis Choquette[8], Boulos Haraoui[8], Algis Jovaisas[9], Emmanouil Rampakakis[10], John S. Sampalis[10], May Shawi[11], Francois Nantel[11], Allen J. Lehman[11] and Susan M. Otawa[11]. [1]Southlake Regional Health Centre, Newmarket, ON, [2]St. Joseph's Hospital and McMaster University, Hamilton, ON, [3]McMaster University, Burlington, ON, [4]Rheumatologist, KW Musculoskeletal Research Inc., Kitchener, ON, [5]Rheumatology Associates, Edmonton, AB, [6]Nanaimo Regional General Hospital, Nanaimo, BC, [7]Rheumatology, Scarborough, ON, [8]Institut de Rhumatologie de Montréal, Montreal, QC, [9]University of Ottawa, Ottawa, ON, [10]McGill University, Montreal, QC, [11]Janssen Canada Inc, Toronto, ON.

Background/Purpose: Efficacy of TNFi agents in the management of rheumatoid arthritis (RA) has been demonstrated in numerous controlled clinical trials. Variations with respect to patient (pt) profile, extent of physician familiarization with TNFi agents, and pt management may affect real-world outcomes. The aim of this analysis is to compare the pt profile and outcomes of RA patients (pts) treated with infliximab under routine clinical practice in biologic treatment registry sites of different sizes.

Methods: BioTRAC is an ongoing, prospective registry of pts initiating treatment for RA with infliximab or golimumab as first biologics or treated with a biologic for <6 mons. Pts with RA treated with infliximab who were enrolled between 2002–2012 were included in the analysis (N=832). The number of pts enrolled in BioTRAC at each site was used as the measure for the size of the registry site, resulting in the classification of 3 sizes of registry sites - Group A: sites enrolling 1–15 pts; Group B: sites enrolling 16–35 pts; Group C: sites enrolling >35 pts. The total number of pts enrolled in each type of rheumatology practice site was; Group A: n=324, Group B: n=239, Group C: n=269.

Results: Mean (SD) age of the cohort was 55.8 (13.4) years with the majority of pts being female (76.0%) and rheumatoid factor (RF) positive (74.2%). No significant differences in demographic characteristics and RF status were observed between the three pt subgroups. Pts seen at larger sites had significantly shorter disease duration (Group A: 11.9 years, Group B: 10.9 years, Group C: 7.5 years; P<0.001) and had been treated with a smaller number of previous DMARDs (2.5, 2.5, 1.6, respectively; P<0.001). Furthermore, a trend towards lower disease activity at infliximab initiation was observed in larger sites as indicated by the decreased physician global assessment (7.0 vs. 6.4 vs. 6.2; P<0.001), DAS28-CRP (5.6 vs. 5.3 vs. 5.3; P=0.023), CDAI (38.1 vs. 34.5 vs. 35.0; P=0.019), and SDAI (40.9 vs. 36.3 vs. 36.9; P=0.009). Significant differences were also observed with respect to pt management with a significantly greater proportion of pts in the larger sites being treated with concomitant DMARD (87.3% vs. 89.5% vs. 95.2%; P=0.004) and lower proportion being treated with a corticosteroid (23.5% vs. 22.6% vs. 15.6%; P=0.044).

Upon adjusting for baseline disease activity, DAS28-CRP remission (P=0.013) and minimal clinically meaningful improvement in HAQ-DI (Δ≥0.25; P=0.025) over 24 mons of treatment was significantly greater among pts seen in larger sites. Achievement of CDAI and SDAI remission was numerically higher without reaching statistically significance.

Conclusion: Consistent with findings from a Canadian early RA registry[1], results of this real-world observational study demonstrate that significant variation in disease characteristics, pt management and outcomes exist within the BioTRAC registry based on the size of the site. A trend towards earlier

infliximab initiation and improved outcomes was observed with larger enrolment sites.

Anti-IL-6 Antibody Clazakizumab Is More Potent Than Tocilizumab In Blocking *In Vitro* and *Ex Vivo* IL-6-Induced Functions. Q Zhao, J Pang, D Shuster, C Hung, S Baglino, R Dodge, H Sun, W Trigona and L Salter-Cid. Bristol-Myers Squibb Research and Development, Princeton, NJ.

Background/Purpose: Interleukin-6 (IL-6), a pleiotropic cytokine, drives cell functions by binding to membrane-bound IL-6 receptor (IL-6R, classical signaling) or to soluble IL-6R (sIL-6R, trans-signaling) and is a key player in the pathogenesis of chronic inflammatory diseases including RA. Tocilizumab, an antibody targeting the IL-6 pathway via the IL-6R, is the only agent currently available for the treatment of RA and juvenile idiopathic arthritis. The objective of this study was to compare the potency of clazakizumab (BMS-945429), an antibody against the IL-6 cytokine that is in clinical development for several auto-immune conditions, with that of tocilizumab in blocking IL-6-induced cell functions.

Methods: Multiple *in vitro* assays for IL-6-induced functions (classical signaling) and IL-6/sIL-6R-mediated functions (trans-signaling) were used to compare the potential of clazakizumab and tocilizumab for inhibiting signaling, proliferation, activation, antibody production and secretion of acute phase protein (Table). Pharmacokinetic/pharmacodynamic (PK/PD) studies of clazakizumab and tocilizumab were also conducted using monkey and human IL-6R knock-in (hIL-6R KI) mouse models to examine pSTAT3 and serum amyloid A blockade, respectively.

Results: In multiple cell function assays, clazakizumab and tocilizumab inhibited both classical signaling and trans-signaling; clazakizumab was between 3 and 120 times more potent than tocilizumab (Table). Furthermore, PK/PD studies confirmed that clazakizumab is a potent blocker of *ex vivo* IL-6-induced pSTAT3 in cynomolgus monkey and of serum amyloid A protein induction in hIL-6R KI mice injected with human IL-6.

Cell function assay		Stimulus	Clazakizumab IC50, nM (SD)	Tocilizumab IC50,nM (SD)	Fold tocilizumab/ clazakizumab
Signaling	pSTAT3 in human whole blood	IL-6 (0.7 nM)	0.07 (0.04)	4.8 (0.08)	~66
Proliferation	TF-1 erythroleukemic cell line (classical)	IL-6 (0.1 nM)	0.007 (0.007)	0.23 (0.23)	~33
	PHA-activated blood T cell (classical)	IL-6 (0.1 nM)	0.005 (0.002)	0.6	120
Activation	Endothelial cell secretion of MCP-1 (trans)	IL-6 (1 nM)/sIL-6R (1 nM)	0.1 (0.05)	0.3 (0.2)	~3
	JURKAT T-cell line expression of JAK3 (trans)	IL-6 (1 nM)/sIL-6R (10 nM)	0.1 (0.05)	4.8 (0.2)	~44
Antibody production	SKW B-cell line secretion of IgM (classical)	IL-6 (0.1 nM)	0.007 (0.005)	0.3 (0.1)	~43
Secretion of acute phase protein	PLC/PRF/5 hepatocyte line secretion of CRP (classical)	IL-6 (0.1 nM)	0.008 (0.004)	0.7 (0.5)	~88

Conclusion: Both *in vitro* and *ex vivo*/*in vivo* studies have shown that clazakizumab is a potent blocker of IL-6-induced functions. Evidence collected thus far has demonstrated that clazakizumab is more potent than tocilizumab in blocking IL-6-induced functions.

Survival Of Biological Therapy In Rheumatoid Arthritis: 12 Years Follow-Up Cohort. Zulema Rosales, Cristina Vadillo, Leticia León, Rayma Peña, Margarita Blanco, Esperanza Pato, J.L. Fernández Rueda, Luis Rodriguez-Rodriguez, Benjamin Fernández-Gutiérrez, Lydia Abásolo and Juan A. Jover. Hospital Clínico San Carlos, Madrid, Spain.

Background/Purpose: After more than a decade of biological agents (BA) use for the treatment of rheumatoid arthritis (RA), it is necessary a thorough knowledge of their long-term use in real life conditions, with a special emphasis in the causes leading to treatment discontinuation, in order to improve and optimize the prescription and withdrawal of these medications. To evaluate the survival of BA and the causes of discontinuation in a cohort of patients diagnosed with RA.

Methods: We performed an observational retrospective longitudinal study from January 1st, 2000, until December 18th, 2012. We included subjects followed up in our outpatient clinic, diagnosed with RA, whom started treatment with a BA [etanercept (ETN), golimumab (GOLI), certolizumab (CTZ), infliximab (IFX), adalimumab (ADA), rituximab (RTX), abatacept (ABA), or tozilizumab (TZL)]. Our primary endpoint was BA discontinuation due to: a) adverse drug reaction (ADR) (including those that required hospital admission and those that resulted in patient death), b) inefficacy c) patient decision d) remission or improvement, e) other causes. Kaplan Meier curves were set to account for all drugs discontinuation. To estimate the incidence of BA suspension we used survival techniques, expressing the incidence rate (IR) per 100 patients-year with their respective 95% confidence interval (95% CI).

Results: 405 patients were included in the study, whom began 744 different courses of BA treatment, with a total follow up time of 1,612 patients-year. Of these, 81% were women with a mean age [standard deviation (SD)] at diagnosis of 52.5 (13) years and the mean time (SD) to the first BA of 5 (4.8) years. The drug most frequently used was ADA (32%), followed by ETN (25%), IFX (20.7%), RTX (13.5%), ABA (4.3%), CTZ (1.8%), TZL (1, 6%), and GOLI (1.1%). 61.3% of the BA were discontinued during the follow-up (456 suspensions in 248 patients): 45% due to inefficacy, 43.4% to ADR (including 17% of those that required hospital admission and 1.3% deaths) and 11.6% other (3.5% improvement, 5.4% patient decision and 2.7 due to other medical decision). In the first year of therapy 68% of the patients continued on BA, and the mean survival time was 2 years (95%CI 1.6–2.3). The IR of discontinuation, regardless the cause, was 28.3 per 100 patient-years (95% CI: 25–31). The IRs depending on the causes of withdrawal were 12.6 (95%CI 11.0–14.5; inefficacy); 12.3 (95%CI 10.7–14.1; all ADR); 4.8 (95%CI 3.8–6.0; severe ADR); 0.6 (95%CI 0.3–1.1; death); 0.9 (95%CI 0.6–1.6; improvement); and 1.5 (95%CI 0.9–2.2; patient decision).

Conclusion: The IR for BA suspension in RA patients was 28 per 100 patients-year, being the most common cause inefficiency, and ADR. This study contributes to increasing knowledge of the long-term survival of these drugs in real life.

2387

Change of serum Amyloid a predict The Effect Of Biological Treatment In Rheumatoid Arthritis Patient. Chisa Okura[1], Yukio Yonemoto[1], Koichi Okamura[1], Tetsuya Kaneko[2], Tsutomu Kobayashi[1] and Kenji Takagishi[1]. [1]Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan, [2]Inoue Hospital, Takasaki, Gunma, Japan.

Background/Purpose: The C-reactive protein (CRP) level and the erythrocyte sedimentation rate (ESR) are common markers of inflammation in patients with rheumatoid arthritis (RA). The serum amyloid A (SAA) level is also a sensitive inflammatory marker, and biologic medications, especially tocilizumab (TCZ), an inhibitor of IL-6, have been reported to decrease the SAA levels. However, thus far, few reports have compared the SAA level, disease activity, other inflammatory markers and future outcomes following treatment with biologics. The aim of this study was to assess the SAA level, the levels of other inflammatory markers and the disease activity in patients with RA who are receiving biologics.

Methods: The subjects included 32 RA patients who started to receive biologic treatment in or after July 2008 (17 patients received TNF inhibitors and 15 patients received TCZ). The swollen joint count, the tender joint count, the DAS28-ESR score and the levels of SAA, ESR, CRP and MMP-3 were assessed before treatment and at two, four and six months after treatment.

Results: No significant differences were found among the groups at baseline. At two, four and six months after treatment, the SAA, ESR and CRP levels in the TCZ group were significantly lower than those in the TNF inhibitor group. The DAS28-ESR scores obtained six months after treatment were significantly correlated with the SAA, ESR and CRP levels obtained two and four months after treatment in the TNF inhibitor group and with only the SAA levels obtained two and four months after treatment in the TCZ group.

Conclusion: We used the DAS28-ESR score as an endpoint in this study. It has been reported that comparatively high values may be obtained for both efficacy and remission rates, particularly in patients treated with TCZ, which directly inhibits inflammatory responses. Furthermore, there are also reports of relationships having been found between the DAS28-ESR and the CDAI and SDAI, thus indicating that DAS28 assessments are sufficiently useful. In our study, the DAS28-ESR scores obtained six months after treatment significantly correlated with only the SAA levels obtained after two and four months in the TCZ group. These results suggest that it may be possible to use the SAA level as a predictive factor of the therapeutic effects for not only TNF inhibitor therapy, but also for TCZ therapy.

Predictive Factors Of Relapse Or Persistent Stable Remission For Rheumatoid Arthritis (RA) Patients In Remission in a TNF Blocker-Spacing Strategy Trial (STRASS Trial). Thao Pham[1], Jacques Morel[2], Toni Alfaiate[3], Emmanuelle Dernis[4], Philippe Gaudin[5], Olivier Brocq[6], Elisabeth Solau-Gervais[7], Jean-Marie Berthelot[8], Jean-Charles Balblanc[9], Xavier Mariette[10], Florence Tubach[11] and Bruno Fautrel[12]. [1]Sainte Marguerite Hospital, Marseille, France, [2]Lapeyronie Hospital, Montpellier, France, [3]AP-HP, Paris, France, [4]Le Mans Hospital, Le Mans, France, [5]CHU Hôpital Sud, Grenoble Teaching Hospital, Echirolles, France, [6]Hospital of Princesse Grâce de Monaco, Monaco, France, [7]University Hospital of Poitiers, Poitiers, France, [8]Nantes University Hospital, Nantes, France, [9]Centre Hospitalier Général de Belfort, Belfort, France, [10]Bicêtre University Hospital, Le Kremlin Bicetre, France, [11]Universite Paris Diderot, Paris, France, [12]Paris 6 – Pierre et Marie Curie University; AP-HP, Rheumatology, Pitié-Salpêtrière Hospital, - GRC-UPMC 08 – EEMOIS, Paris, France.

Background/Purpose: The STRASS trial was a 18-month randomized controlled trial, conducted in established RA patients in DAS28 remission with etanercept (ETA) or adalimumab (ADA), comparing the impact of a DAS28-driven step-down strategy based on TNF-blocker injection spacing (S arm) to a maintenance strategy (M arm). We aimed to identify baseline characteristics predicting relapse (DAS28 $>$ 2.6 and ΔDAS28 $>$ 0.6) or persistent stable remission (DAS28 constantly $\leq$ 2.6) during the 18-month follow-up.

Methods: Inclusion criteria were: ETA or ADA $>$ 1 year, DAS28 remission $>$ 6 months, stable damage on X-rays. Patients were randomized and followed every 3 months for 18 months. In the S arm, the inter-injection interval was increased every 3 months up to complete interruption at 4th step. Relapse was defined by DAS28 $>$2.6 and ΔDAS28 $>$0.6 (Cox model). Predictive factors for relapse or persistent remission were identified by univariate then multivariate analysis using logistic regression. Optimal cut-off was determined with ROC curves analysis.

Results: 137 patients were included, 64 and 73 in the S and M arm (mean/%: age 55 yrs, female 78%, RA duration 9.5 yrs, ACPA+ 78%, erosive 88%, DAS28 1.8, ETA 54 %, ADA 46 %).

In the S arm, 46 (71.9%) patients were able to space out their injections, among which 17 (14.1%) completely stopped the TNF-blocker. Although mean DAS28 was not statistically different between the 2 strategy arms, RA relapse occurred in both arms more frequently in the S arm (81% vs. 56% in the M arm)[1] (see Table). By univariate analyses, predictors of relapse were HAQ score (p=0.05), treatment strategy arm (p=0.001), morning stiffness duration (p=0.04) and patient global assessment (PGA) (p=0.02). Baseline DAS score, Sharp score and smoking status were not associated with later relapse. Baseline factors predicting persistent remission were DAS28 score (p=0.003), HAQ score (p=0.01), treatment strategy arm (p=0.001), morning stiffness duration (p=0.008) and patient global assessment (PGA) (p=0.03). By multivariate analysis, predictors of relapse were spacing strategy – S arm – (OR=3.45; CI95%: 1.51–7.92, p=0.003) and HAQ score (OR=2.84; CI95%: 1.07–7.54, p=0.03). Predictors of persistent remission were strategy treatment arm (OR=0.30; CI95%: 0.13–0.70, p=0.005) and DAS28 score (OR=0.41; CI95%: 0.20–0.83, p=0,01). Receiver-operator characteristics of HAQ and DAS scores plotted as predictors of relapse and remission, respectively, resulted in no meaningful thresholds identified.

Table. Percentage of relapse according to assessment schedule and strategy treatment group.

N (%)	Visit (months)	Total (N=137)	M arm (N=73)	S arm (N=64)	Predictors OR (95% CI)
Time of 1st relapse	M0	0 (0.0%)	0 (0.0%)	0 (0.0%)	Spacing 3.45 (1.51, 7.92) HAQ 2.84 (1.07, 7.54)
	M3	25 (27.2%)	11 (27.5%)	14 (26.9%)	
	M6	19 (20.6%)	8 (20.0%)	11 (21.1%)	
	M9	10 (10.9%)	2 (5.0%)	8 (15.3%)	
	M12	15 (16.3%)	5 (12.5%)	10 (19.2%)	
	M15	8 (8.7%)	5 (12.5%)	3 (5.7%)	
	M18	15 (16.3%)	9 (22.5%)	6 (11.5%)	
Stable remission i.e., DAS28≤2.6	M0 thru M18	39 (28.5%)	28 (38.3%)	11 (17.2%)	Spacing 0.30 (0.13, 0.70) DAS28 0.41 (0.20, 0.83)

Conclusion: TNF-blocker injection spacing and HAQ/DAS28 were the main predictors of relapse/persistent stable remission in these established RA patients.

Tocilizumab Survives Introducing The Hemadialysis Longer Than Oral Medicine In AA Amyloidosis Patients With Rheumatoid Arthritis Of Renal Insufficiency. Osamu Saiki, Hiroshi Uda, Ayumi Matsumoto, Aya Mizumoto, Tamaki Harada and Toshirou Takama. Higashiosaka City General Hospital, Higashiosaka, Japan.

Background/Purpose: In AA amyloidosis patients with RA taking oral medicines such as methotrexate and prednisolone, it is generally accepted that the renal function deteriorates gradually and finally most of the patients will receive hemodialysis in five years, even the disease activity is in good control. However, the effect of biologics therapy on renal insufficiency is not clarified. The main focus of the present study is to compare the effect of tocilizumab and oral medicines on clinical course of the renal function of AA amyloidosis patients with severe renal insufficiency.

Methods: RA patients with amyloidosis who had high disease activity and renal dysfunction (creatinine clearance $<$ 20 ml/min/1.73m^2) were enrolled in the present study. The patients were treated with prednisolone and low dose of methotrexate (group 1) or tocilizumab monotherapy (group 2) and we followed up for more than three years prospectively. In those patients who had obtained DAS28 remission, we compared the clinical course of renal function and the disease activity between two groups.

Results: The mean creatinine levels of the group 1 patients and the group 2 patients were 2.2 and 2.4 mg/dl respectively at the entry. The mean CRP levels of the group 1 patients and the group 2 patients were 3.2 and 2.8 mg/dl respectively at the entry. After treated with either oral medicine or tocilizumab, the levels of CRP were decreased to normal levels in less than one year and DAS28 were improved significantly in both groups. The renal functions of group 1 patients were deteriorated rapidly and were introduced hemodialysis in 2.1 years. Typical clinical course was shown in figure 1A. However, the patients of group 2 did not progress renal insufficiency rapidly and were not introduced hemodialysis for more than three years. In a typical case, hemodialysis was not introduced for more than five years (figure 1B).

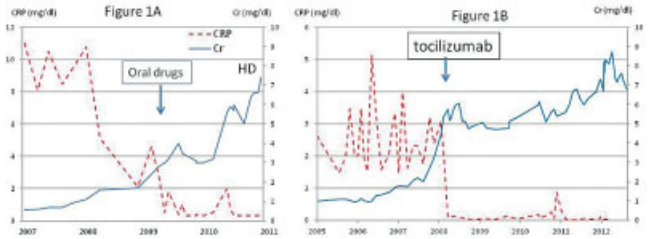

Figure 1. The typical clinical courses of CRP and Creatinine in amyloidosis patients treated with oral drugs (A) or tocilizumab (B).

Conclusion: Both oral medicines and tocilizumab monotherapy introduced clinical remission, however, tocilizumab but not oral medicines survives introducing the hemodialysis for more than three years in AA amyloidosis patients with renal insufficiency. This result shows the different effects on progression of renal insufficiency between tocilizumab and oral medicine, and suggests that we should select tocilizumab rather than oral medicine in these patients.

Low Dose Of Tocilizumab Can Be Effective In RA Patients Who Achieve Remission.. Cecilia Prieto- Candau[1], Virginia Moreira- Navarrete[2], Carmen Vargas-Lebrón[2], Juan M Prieto-Martinez[2], Dolores Ruiz-Montesinos[2], Javier Toyos-Saenz de Miera[2] and Federico Navarro-Sarabia[3]. [1]Hospital Virgen Macarena, SEVILLE, Spain, [2]Hospital Virgen Macarena, Seville, Spain, [3]Hospital Virgen Macarena, Serv. de Reumatología, Sevilla, Spain.

Background/Purpose: Tocilizumab (TCZ), an anti-IL-6-receptor antibody, is used for the treatment of moderate to severe rheumatoid arthritis (RA) in adults with inadequate response or intolerance to previous therapy with one or more disease modifying anti-rheumatic drugs (DMARDs) or anti-tumor necrosis factor (anti-TNF). The approved dose in EU is 8 mg/kg every four weeks. The reduction of these dose is recommended in selected cases for security reasons. There are studies that assess dose reduction with other biologic therapies in patients with clinical remission. However, no studies evaluate the effectiveness of reducing the dose, either for safety or low disease activity, in patients treated with TCZ. Our objective was to evaluate the effectiveness of reducing the dose of TCZ in a serie of patients with RA.

Methods: A retrospective longitudinal observational study that included RA patients receiving reduced doses of tocilizumab. The demographics and disease characteristics were recorded in all patients. The dose reduction was based clinical practice. For qualitative variables percentages were obtained and for quantitative variables means were calculated with confidence intervals. Comparison between disease activity before and after dose reduction was performed with a t- student test.

Results: A total of 67 RA patients treated with an initial dose of TCZ of 8 mg/kg were included in this study. A dose reduction was started in 25 of them - 22 patients reduced the dose due to clinical remission of the disease (DAS 28 < 2,6) and 3 aditional patients due to leukopenia. Initial dose reduction was 6 mg/kg of TCZ and afterwards in 8 patients the dose was reduced to 4mg/kg. All the patients with reductions due leukopenia received 4mg/kg. The mean follow-up before the dose reduction was 25 months (SD 22.4). At the end of the follow-up, 24 patients remained in dose reduction and 1patients had to discontinue because of severe leukopenia. The DAS28 mean at the begining of the dose reduction was 2.20 (SD 1.45) and at the end 1.59 (0.78) with a median follow-up of 14 months. There was no statistically significant difference regarding disease activity before and after dose reduction (p = 0.36).

Women n(%)	**26 (92,9)**
Age mean(SD)	**57,9 (12,1)**
RF positive n(%)	**25 (89.3)**
ACPA positive n(%)	**17 (60.7)**
RA duration mean(SD)	**13,7 (9.8)**
Erosive disease n(%)	**19 (67,9)**
Rheumatoid nodules n(%)	**4 (14,3)**
Previous treatment n(%)	**28 (100)**
Methotrexate	9 (32,1)
Leflunomide	7 (25,0)
Hidroxicloroquine	7 (25)
Anti TNF	
RA duration until Tocilizumab, mean (SD)	**6,5 (6,68)**

Conclusion: In RA patients treated with Tocilizumab who achieve clinical remission this condition can be mantained with a lower dose of the drug. The economic consequences may be relevant. Further studies are needed to verify these results.

2391

Pathogenic Pro-Inflammatory Cytokine Production Induced By Synovial Fluid From RA Patients Is Related To Levels Of Endogenous TLR4 Ligands and Is Blocked By a Novel Therapeutic Anti-Human TLR4 Monoclonal Antibody, NI-0101. Limin Shang[1], Greg Elson[1], Jeremy Sokolove[2], Prof Iain B. McInnes[3], James Reilly[3], Eric Hatterer[1], Marie Kosco-Vilbois[4], Walter Ferlin[4], Emmanuel Monnet[4] and Cristina de Min[4]. [1]NovImmune S.A., Plan-Les-Ouates, Geneva, Switzerland, [2]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [3]University of Glasgow, Glasgow, United Kingdom, [4]NovImmune S.A., Geneva, Switzerland.

Background/Purpose: Deregulation of Toll-Like Receptor 4 (TLR4) signaling is thought to play a role in the pathogenesis of certain autoimmune diseases. In rheumatoid arthritis (RA), increased expression of several endogenous TLR4 ligands has been reported in both blood and synovial fluids. We first confirmed that macrophages can be activated by immune complexes containing citrullinated fibrinogen (cFb-IC) via TLR4 and then demonstrated that this activation is inhibited by NI-0101, a new therapeutic anti-human TLR4 monoclonal antibody (mAb). The purpose of this study was 1) to investigate the ability of RA synovial fluids to induce cytokine production by fibroblasts and monocytes obtained from RA patients, 2) to analyze its relation with levels of endogenous TLR4 ligands and finally 3) to demonstrate the ability of NI-0101 to inhibit RA synovial fluids induced cytokine production.

Methods: cFb-IC were incubated with blood derived macrophages from healthy subjects and cytokine release determined by ELISA. The capacity of pooled and individual RA synovial fluids to stimulated cytokine production from RA blood-derived monocytes and RA joint-derived fibroblasts was analyzed by ELISA and multiplex analyses. The expression levels of S100A8/A9, High-mobility group protein B1 (HMGB1), tenascin C were measured by commercially available ELISA kits and anti-citrullinated protein antibodies (ACPA) were measured in RA synovial fluid samples by ELISA method developed for purpose. TLR4 antagonism was assessed using NI-0101.

Results: cFb-IC stimulated TNFα production in blood-derived macrophages was significantly inhibited by NI-0101 ($p<0.001$), confirming that the ability of cFb-IC to induce cytokine production is realized through TLR4-activation. Eleven out of fifteen individual RA synovial fluids stimulated IL-6 production from patient-derived synovial fibroblasts and 10 out of 14 from monocytes. NI-0101 significantly reduced the individual RA synovial fluids induced response (5/11 RA synovial fluids on fibroblasts and 10/10 RA synovial fluids on monocytes). Analysis of RA synovial fluids composition demonstrated variable patterns of ACPA, S100A8/A9, High-mobility group protein B1 (HMGB1), tenascin C and cFb-IC levels. These synovial fluids containing the highest combined level of ACPA, cFb-IC, HMBG1, S100A8/A9 were found to induce the more robust IL-6 response. Furthermore, the NI-0101 inhibitory response of IL-6 induction was also correlated with the combined presence of the afore mentioned TLR4 ligands.

Conclusion: The ability of RA synovial fluids to induce *ex vivo* inflammatory cytokine production is directly correlated to the levels of endogenous TLR4 ligands in RA synovial fluids (including S100A8/A9, HMGB1, ACPA and cFb-IC). NI-0101 effectively abrogates RA synovial fluids induced cytokine release in those samples with high levels of endogenous TLR4 ligands. These results indicate that TLR4 blockade by NI-0101, currently in late Phase I of clinical development, is a promising strategy in RA treatment and endogenous TLR4 ligand levels might be used as a biomarker to identify patients for anti-TLR4 therapy.

Impact Of CT-P13 and Originator Infliximab Treatment On Quality Of Life Derived From The Health Assessment Questionnaire (HAQ) and Short-Form 36 (SF-36) From a Randomized, Double-Blind Trial In Patients With Active RA. Dae-Hyun Yoo[1], Andriy Yagensky[2], Antoaneta Toncheva[3], Osca Ruiz Santacruz[4], Fidencio Cons Molina[5], Yunju Bae[6], Taek Kwon[6], SinHye Kim[6], Peter Lacouture[7], Teresa Kok[8] and Won Park[9]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Lutsk City Hospital, Lutsk, Ukraine, [3]National Multiprofile Transport Hospital, Sofia, Bulgaria, [4]Centro Integral de Reumatología e Inmunología - CIREI S.A.S, Bogotá, Colombia, [5]Centro de Investigacion en Artritis y Osteoporosis SC, Mexicali, Mexico, [6]Celltrion Inc., Incheon, South Korea, [7]Hospira Inc, Lake forest, IL, [8]Hospira Inc., Lake Forest, IL, [9]Inha University Hospital, Incheon, South Korea.

Background/Purpose: Quality of life and functionality are important outcome metrics in understanding the value of therapeutic interventions in RA. Biological products have become an established therapeutic modality in rheumatic conditions and the development of biosimilar products that offer therapeutic equivalence are in development. One such biologic treatment in clinical development currently approved in Korea is a biosimilar monoclonal antibody to infliximab which has been in clinical use for the treatment of RA.

Methods: As part of the development program for a biosimilar infliximab, in a phase 3, randomized, double-blind, active-controlled trial, 606 patients with RA were treated for up to 1 year with either biosimilar infliximab (CT-P13) or Originator infliximab (INX). Treatment was initiated with 3mg/kg doses infused IV over 2 hours at Week 0, Week 2, Week 6 and then every 8 weeks up to Week 54. The primary endpoint (ACR20) previously reported, achieved therapeutic equivalence. Key secondary endpoints were captured; one such endpoint evaluated quality of life based on the standard HAQ-disability index and SF-36. The HAQ assessment of physical function measures 20 items in eight categories on a scale from 0 (without any difficulty) to 3 (unable to do). SF-36 assesses eight subscales, a low score representing poor health status. Baseline measurement was determined at the initiation of treatment and on treatment at Week 14, Week 30 and Week 54.

Results: Adjusted HAQ and SF-36 outcomes in study patients with RA (mean ± standard deviation; per protocol population) are shown below in Table 1 and Table 2 respectively.

Table 1. Adjusted HAQ Outcomes

Baselines were similar between treatment groups. Scores between 1 and 2 generally represent moderate to severe disability reflected in this population. Early overall improvement as measured by a reduction in the HAQ scores was evident and similar in magnitude between biosimilar infliximab and originator infliximab by Week 14. Changes over time were similar between the two treatments. Effectiveness of CT-P13 and INX was sustained over the 1 year interval. The agents were generally well tolerated in RA patients in this study. In addition, there were clear correlations between HAQ and physical or mental component summary of SF-36 from Pearson's test.

Conclusion: Treatment with infliximab improved physical function as assessed by HAQ in patients with moderate to severe physical disability which was sustained over a one year interval. These data support the comparability with respect to improvement in physical function of CT-P13 and INX in patients with active RA.

ACR/ARHP Poster Session C
Rheumatoid Arthritis: Human Etiology and Pathogenesis II
Tuesday, October 29, 2013, 8:30 AM–4:00 PM

2393

Involvement Of Transitional T Follicular Like Helper Cells Bearing Triple Phenotypes Of Tfh/Th1/Th17 In The Pathogenesis Of Rheumatoid Arthritis. Shingo Nakayamada, Satoshi Kubo, Naoki Yunoue, Maiko Yoshikawa, Shunsuke Fukuyo, Kazuyoshi Saito and Yoshiya Tanaka. University of Occupational and Environmental Health, Japan, Kitakyushu, Japan.

Background/Purpose: T follicular helper (Tfh) cells are a new subset of T helper cells that regulate B cell function and promote autoantibody production. We previously reported that T helper cell differentiation exhibits Tfh-like transitional stage which is regulated by dynamic balance of transcription factors. However, the role of this subset in the pathogenesis of rheumatoid arthritis (RA) remains unclear. The purpose of this study was to assess the characteristic and pathological role of Tfh cells in patients with RA.

Methods: Peripheral blood mononuclear cell (PBMC) was obtained from patients with 49 RA and 35 other autoimmune diseases including systemic lupus erythematosus (SLE) and Sjogren's syndrome (SS), as well as from 10 healthy donors (HD). PBMCs were analyzed by 8 color staining multiparameter flow cytometry. The proportion of T cell subsets was determined by expression of chemokine receptors and the results were correlated with patient characteristics, including the titer of autoantibodies (RF, ACPA), CRP, ESR, MMP-3 and simplified disease activity index (SDAI).

Results: The number of effector memory T cells has increased in RA patients compared with HD. The proportion of $CD4^+CXCR3^+$ Th1 cells, $CD4^+CCR6^+$ Th17 cells, and $CD4^+CXCR5^+$ Tfh cells was not different among HD, RA, and other autoimmune diseases including SLE and SS. The frequency of activated Tfh cells was significantly correlated with the presence of ACPA in RA patients. The proportion of the $CD4^+CXCR3^+CXCR5^+$ (Th1/Tfh) cells and $CD4^+CCR6^+CXCR5^+$ (Th17/Tfh) cells was increased in patients with RA and SLE compared to HD. We found that the subpopulation of Tfh cells which express intermediate levels of CXCR5, CXCR3 and CCR6 all together has characteristically increased in patients with RA compared to both HD and other autoimmune diseases. Those cells also expressed surface activation markers such as CD38 and CD69. The frequency of those cells was closely correlated with CRP, ESR, MMP-3, and SDAI, whereas those of Th1 cells and Th17 cells showed no correlation.

Conclusion: The new population of T helper cells, which shares triple phenotypes of Th1/Th17/Tfh (transitional Tfh like: tTfh) cells, was identified. These findings have shown that the increased frequency of tTfh cells is correlated with disease activity of RA, indicating the possible involvement of tTfh cells in the disease progression of RA. Our findings also provided the concept that Tfh cells are most plastic and flexible T helper subsets in human and support the relevance of tTfh cells as a potential therapeutic target for RA.

2394

In Rheumatoid Arthritis, Smoking Is Not Primarily Associated With Anti-Citrullinated Protein Antibodies, But With The Presence Of Multiple Autoantibodies. Ammar Muhammad[1], Tineke van Wesemael[1], Yuta Kochi[2], Maria Mjaavatten[3], Kirsten Wevers-de-Boer[1], Cornelia F. Allaart[1], Leendert A. Trouw[1], Akari Suzuki[2], Kazuhiko Yamamoto[4], Annette H.M. van der Helm-van Mil[1], Tom W.J. Huizinga[1], René E.M. Toes[1] and Diane van der Woude[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]RIKEN, Yokohama, Japan, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Graduate School of Medicine, The University of Tokyo, Tokyo, Japan.

Background/Purpose: Smoking is associated with the presence of several autoantibodies in various autoimmune diseases. In rheumatoid arthritis (RA), smoking has been described to be specifically associated with the presence of anti-citrullinated protein antibodies (ACPA). We investigated whether smoking is specifically associated with ACPA-positive RA, or with autoantibody-positive RA in general.

Methods: A meta-analysis was performed using RA patients from 5 countries: Norway, Sweden, the United Kingdom, the Netherlands and Japan. Complete data on rheumatoid factor (RF)-, ACPA-status and tobacco exposure were available for 6320 RA patients. The odds ratios (ORs) and 95% confidence intervals (95% CIs) associated with the presence of RF, ACPA or both were calculated by logistic regression comparing ever smokers with never smokers, and using the RF-negative ACPA-negative RA patients as the reference category.

Results: There was no significant association between tobacco exposure and seropositive RA in patients who were positive for only one antibody, being either RF (OR 1.04, 0.76 – 1.42) or ACPA (OR 1.00, 0.82 – 1.22). However, smoking was significantly associated with double-positive (RF-positive and ACPA-positive) RA (OR 1.55, 1.20 – 2.00). When double-positive patients were compared to single-positive patients, the effect of the additional presence of RF or ACPA was comparable; OR for RF: 1.42 (1.20 – 1.67), OR for ACPA: 1.50 (1.26 – 1.79).

Conclusion: Smoking is not associated with ACPA-positive RA, but rather with the concurrent presence of RF and ACPA in RA patients. These data indicate that smoking predisposes to the development of multiple autoantibodies, and not exclusively to ACPA-positive RA.

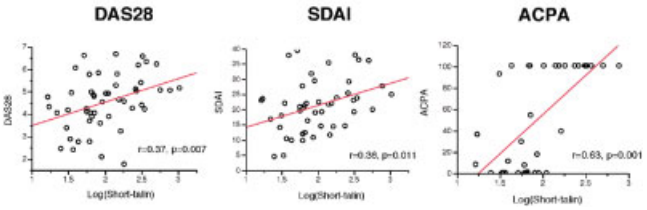
Plasma Short-Talin Is a New Rheumatoid Arthritis Monitoring Biomarker Independent Of The Inflammatory Markers. Kensei Tsuzaka, Masako Takao and Jiro Nishida. Ichikawa General Hospital, TDC, Ichikawa, Chiba, Japan.

Background/Purpose: Talin has been known as a cytoskeletal protein, which, by binding to integrin beta-subunit, enhances the inside-out signaling from intracellular to extracellular of integrins, cell adhesion, cell migration, and causes chronic inflammation and angiogenesis. Last 2012ACR meeting, we have reported that intracellular talin in RA patients is cleaved into short-talin and expressed predominantly in plasma. In 2011ACR meeting, we have demonstrated higher sensitivity and specificity of the plasma short-talin than those of anti-CCP antibody (ACPA). Although several RA biomarkers have been reported, some of them are not independent of the inflammatory markers like CRP and ESR due to the usage of the algorithm combined with them. In this paper, we investigated whether the plasma short-talin can be an RA biomarker independent of the inflammatory markers.

Methods: RA was diagnosed as the 2010 Rheumatoid Arthritis Classification Criteria. Plasma and sera were obtained simultaneously from 51 RA patients (Age, 60.9±14.4 y/o; DAS28, 4.54 ± 1.20). Sixteen (31.4 %) of these 51 patients were untreated, and 18 patients (35.3%) were treated with biologics DMARD at the time of collecting blood samples. Plasma short-talin was quantified using a sandwich ELISA with anti-short talin capture and detecting antibodies. Serum ACPA was measured using a commercial ELISA kit. RA activity at the time of collecting blood samples was estimated using DAS28, SDAI, and CDAI.

Results: The expression of the plasma short-talin was significantly correlated with DAS28 (r=0.37, p=0.0070), SDAI (r=0.36, p=0.011), CDAI (r=0.32, p=0.030), and ACPA (r=0.63, p=0.001) (Fig.1). However, plasma short-talin level was not correlated with ESR, CRP, and MMP-3.

Fig.1



Conclusion: The expression of the plasma short-talin could reveal the RA activity and can not only be an RA diagnostic marker, but also an RA monitoring biomarker independent of the inflammatory markers like ESR and CRP.

PI3Kdelta Regulates Invadosome Formation and Invasiveness Of Fibroblast-Like Synoviocyte In Rheumatoid Arthritis. Beatrix Bartok and G. S. Firestein. UCSD School of Medicine, La Jolla, CA.

Background/Purpose: Fibroblast-like synoviocytes (FLS) in the intimal lining are major effectors of cartilage damage in rheumatoid arthritis (RA). PI3Kdelta, a member of the Class IA phosphoinositide 3-kinases (PI3K), was recently identified as a regulator of aggressive behavior by RA FLS. Invasive migration requires dynamic interactions between the extracellular matrix (ECM), the actin cytoskeleton and the capacity for matrix degradation. The specialized ECM-degrading membrane protrusions like invadopodia in cancer cells or podosomes in macrophages are known to facilitate invasive migration. Therefore, we investigated the role of PI3Kdelta in formation of invadosomes and matrix degradation.

Methods: To visualize invadosomes, RA FLS were cultured in fluorescent labeled gelatin coated dishes for 16 h. Invadosomes were identified with anti-cortactin, anti-TKS5, anti-MT1-MMP and phalloidin staining and observed with confocal microscopy. To quantify the gelatin degradation, we measured the degradation area and normalized it to total cell surface area using Image J software. Co-localization analysis was performed for PI3Kdelta and Akt with cortactin, TKS5, MT1-MMP or F-actin. MMP expression was analyzed with qPCR following TNF stimulation for 24 h in the presence or absence PI3Kdelta inhibitors (INK007, CAL101) or a PI3Kdelta/gamma inhibitor (IPI145).

Results: The collective term invadosomes includes podosomes that form in monocytic cells and invadopodia that are associated with cancer cells. First, we examined whether RA synoviocytes spontaneously form extracellular matrix degrading invadosomes. 25–40% of the cells spontaneously formed invadosomes, which was increased by 2.5 fold in presence of TNF or IL-1 ($n=5$, $p<0.04$). Because TNF regulates expression and activity of PI3Kdelta in FLS, we next examined cellular distribution of p110delta using confocal microscopy. Immunofluorescence staining revealed colocalization of p110delta with invadopodia markers cortactin, TKS5 and MT1-MMP in TNF treated and control cells. To determine whether PI3Kdelta activity is required for invadosome formation and matrix degradation, cells were plated onto fluorescent gelatin coated dishes in the presence or absence of PI3Kdelta inhibitors INK007, CAL101, IPI145 (0.1–3 uM) or vehicle control. PI3Kdelta inhibition significantly decreased gelatin degradation in a concentration dependent manner, with 65±6% inhibition at 1 uM for INK007 ($p< 0.035$; similar results for other inhibitors). Furthermore, the percentage of cells with invadosomes was reduced by PI3Kdelta inhibition. Consistent with these findings, phosphorylation and accumulation of Akt, a downstream target of PI3Kdelta, was decreased by PI3Kdelta inhibition at the invadopodia-mediated gelatin degradation site. PI3Kdelta inhibition had no effect on MMP1, 2, 3 and MT1-MMP gene expression in TNF-treated RA FLS.

Conclusion: PI3Kdelta plays a critical role in invasive matrix degradation by RA FLS by regulating spontaneous and TNF-induced invadosome formation. These observations, together with previous findings that PI3Kdelta regulates FLS migration, growth and survival, suggest that PI3Kdelta inhibition could protect cartilage in RA.

To Which Extent May The Familial Risk Of Rheumatoid Arthritis Be Explained By Established Risk Factors? Xia Jiang[1], Thomas Frisell[1], Johan Askling[1], Lars Klareskog[2], Lars Alfredsson[1] and Henrik Källberg[1]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Rheumatoid arthritis (RA) is a complex inflammatory disease known to aggregate within families, implicating the crucial role of shared genetic and/or environmental factors in its etiology. Despite the many advances from genome-wide association studies, family history is an easily obtained aggregate of an individual's complete genetic risk, and is accepted to be important in clinical diagnosis. Our study is aimed to explore how much of the RA familial risk can be explained by established genetic and environmental risk factors; and to find out whether identified genetic markers enough to explain the burden of familial risk.

Methods: We used data from two Swedish population registers and the Epidemiological Investigation of Rheumatoid Arthritis (EIRA) project. First degree relatives (FDRs) of the index person (EIRA cases and controls) were identified through the Swedish Multi-Generation register. The index individual was considered 'exposed' to familial risk if any FDRs had a RA diagnosis from the Swedish Patient Register. Analysis was run divided by ACPA status in cases and by RF status in relatives. Established genetic risk factors (45 SNPs according to GWAS catalog and the shared epitope) were selected. Environmental risk factors (smoking, drinking, BMI, socio-economic status, silica exposure, fish consumption) were determined based on previous publications. Due to missingness for individual risk factors, the complete case analysis was followed by Multiple Imputation. All analysis was adjusted for age, gender and residential area.

Results: We found a stronger aggregation pattern in APCA/RF positive RA (OR=4.09) than ACPA/RF negative RA (OR=2.30); while the ORs for cross-phenotype familial risk was 3.18 in ACPA positive cases/RF negative relatives, and 1.62 in ACPA negative cases/RF positive relatives. Further, we found that established non-genetic risk factors do not visibly explain anything of the familial risk, while SE and the identified 45 SNPs only explain a small proportion for ACPA positive RA (ACPA+ cases/RF+ relatives: $OR_{Crude}=4.09$, $OR_{adjust\ for\ SE}=3.85$, $OR_{adjust\ for\ 45SNPs}=3.66$, $OR_{adjust\ for\ both}=3.55$; ACPA+ cases/RF- relatives: $OR_{Crude}=3.18$, $OR_{adjust\ for\ SE}=2.45$, $OR_{adjust\ for\ 45\ SNPs}=2.29$, $OR_{adjust\ for\ both}=2.07$) but not for ACPA negative RA.

Conclusion: We found that established genetic and environmental risk factor do not explain much of the familial aggregation of RA, suggesting that most heritability remain to be elucidated. It is likely that a large amount of additional loci with individually extremely small magnitude remain to be identified. In particular for ACPA negative RA, it seems that we have only found factors for a very minor (or no) part of the familial aggregation. This suggests a need for studies focusing specifically on ACPA negative RA, trying to find genetic risk factors or identify disease subtypes with a stronger familial risk.

Redox Mediated Angiogenesis In The Hypoxic Joint Of Inflammatory Arthritis. Monika Biniecka[1], Chin Teck Ng[1], Emese Balogh[1], Douglas J. Veale[2] and Ursula Fearon[2]. [1]Translation Research Group, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]St. Vincent's University Hospital, Dublin 4, Ireland.

Background/Purpose: To investigate whether *in vivo* synovial hypoxia and TNF blocking therapy determine expression of Nicotinamide Adenine Dinucleotide Phosphate Oxidase (Nox2) - a key source of Reactive Oxygen Species (ROS) in vasculature - and its relationship with macroscopic and microscopic markers of angiogenesis in inflammatory arthritis.

Methods: Fifty four patients with active inflammatory arthritis (RA n=33 and PsA n=21) were recruited prior to starting biological treatment and underwent arthroscopy, clinical assessment and synovial tissue oxygen (tpO_2) measurements. A subgroup of 16 patients pre/post-TNFi therapy was also recruited. Synovial tissue biopsies were obtained for immunohistochemical and *ex vivo* explant cultures. Paired peripheral blood samples were collected and peripheral blood mononuclear cells (PBMCs) were isolated for mRNA Nox2 analysis. Macroscopic synovitis/vascularity was measured by visual analogue scale. Synovial levels of Nox2, angiogenic markers (VEGF, Ang2, Factor VIII, NCAM and α-SMA), proinflammatory cytokine (TNF-α) and redox signaling factors (NF-κB) were quantified by immunohistology/immunofluorescence. Using RA synovial explant cultures *ex-vivo*, the effect of the Nox2 activators (4-HNE and TNF-α) and inhibitor (DPI) on IL-8 release was measured by ELISA.

Results: The median tpO_2 was 26.59 mmHg (range 3.2–63 mmHg), equivalent to an ambient oxygen tension 3.5% (range 0.42–8.28%). Nox2 was expressed both in lining layer (LL), sublining layer (SL) and vascular region (BV) of synovial tissue with a cytoplasmic pattern of staining. Microscopic Nox2 synovial levels and Nox2 mRNA expression in PBMC were increased in patients with tpO_2< 20mmHg compared to patients with tpO_2 >20mmHg (in LL, BV and PBMC $p<0.05$; in SL $p=0.07$). High synovial Nox2 expression correlated with greater macroscopic vascularity, synovitis, and angiogenic markers: VEGF, Ang2, Factor VIII, NCAM, and α-SMA (all $p<0.05$) and was co-localized with VEGF, Ang2, Factor VIII, TNF-α and NFκB. In biologic responders there was a significant reduction in cytoplasmic Nox2 positivity in synovial tissue ($p<0.05$), which was paralleled by a significant increase in tpO_2 levels ($p<0.05$) before and after starting TNFi. In contrast, in patients whose tpO_2levels remained the same or reduced after TNFi, no significant change in Nox2 expression was observed. 4-HNE and TNF-α significantly increased IL-8 spontaneous release from synovial tissue explants compared to unstimulated ($p<0.05$) and DPI inhibited TNF-α induced IL-8 secretion ($p<0.001$).

Conclusion: Synovial tissue hypoxia activates expression of Nox2 protein and Nox2-derived ROS may promote angiogenic processes in the inflamed joint. Following successful TNFi biologic therapy, a significant decrease in synovial Nox2 expression was coupled with higher *in vivo* tpO_2. These effects may in part be mediated through hypoxic activation of downstream redox sensitive signaling events.

Altered Histone Methylation Is Associated With IL-6 Dependent Matrix Metalloproteinases Gene Transcriptional Activation In Rheumatoid Arthritis Synovial Fibroblasts. Yasuto Araki[1], Takuma Tsuzuki Wada[1], Kojiro Sato[2], Kazuhiro Yokota[2], Fumihiko Miyoshi[2], Yu F. Asanuma[2], Yuji Akiyama[2] and Toshihide Mimura[1]. [1]Research Center for Genomic Medicine, Saitama Medical University, Saitama, Japan, [2]Saitama Medical University, Saitama, Japan.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease which causes progressive joint destruction. In spite of the modern medications including biologic reagents, it is still hard to cure RA completely. A line of evidence suggests that synovial fibroblasts (SFs) play an important role in the pathogenesis of RA. RASFs produce matrix-degrading enzymes and promote bone and cartilage destruction. Recent advances have revealed that epigenetic mechanisms including histone modifications are important regulators in gene transcription. We have hypothesized that aberrant epigenetic regulations might cause long-lasting synovitis in RA.

Methods: Human SFs were enzymatically isolated from knee articular synovial tissues removed at the time of joint replacement from patients with RA or osteoarthritis (OA) as a control. We compared matrix metalloproteinases (MMPs) gene expression by quantitative RT-PCR (qRT-PCR) and histone methylation in their promoters by chromatin immunoprecipitation (ChIP) assay in RASFs and OASFs. Interleukin-6 (IL-6) is an inflammatory cytokine and has been proved to be involved in the pathogenesis of RA. It was unknown whether IL-6 affected MMPs gene transcription, so we stimulated SFs with IL-6 and/or soluble IL-6 receptor α (sIL-6Rα) and examined the change in MMPs gene expression by qRT-PCR. IL-6 induces Signal Transducer and Activator of Transcription 3 (STAT3) activation. To elucidate the mechanisms of IL-6 dependent MMPs gene transcriptional activation in RASFs, we investigated cell surface expressions of IL-6 receptor (gp130 and IL-6Rα) by flow cytometry, phospho-STAT3 (p-STAT3) expression by immunoblotting, and STAT3 binding to the MMP1, 3, 9, and 13 promoters by ChIP assay.

Results: MMP1, 3, 9, and 13 mRNA levels were significantly higher in RASFs than in OASFs. Tri-methylation of histone 3 lysine 4 (H3K4me3) is associated with active gene transcription and tri-methylation of histone 3 lysine 27 (H3K27me3) with gene silencing. The amounts of H3K4me3 significantly increased whereas those of H3K27me3 substantially decreased in the MMP1, 3, 9, and 13 promoters in RASFs. These data showed that

histone methylation was correlated with MMP1, 3, 9, and 13 gene transcriptional activation in RASFs. Then, MMP1, 3, and 13 but not MMP9 mRNA levels significantly increased at 24 hr after stimulation with IL-6 (100 ng/ml) and sIL6Rα (100 ng/ml) in RASFs. Cell surface expressions of gp130 and IL-6Rα were comparable and STAT3 was similarly phosphorylated after stimulation with IL-6 and sIL-6Rα in RASFs and OASFs. STAT3 strongly associated with the MMP1, 3, and 13 promoters but not the MMP9 promoter in RASFs. Together, it was suggested that STAT3 binding to their promoters resulted in MMP1, 3, and 13 gene transcriptional activation after stimulation with IL-6 and sIL-6Rα in RASFs.

Conclusion: Characteristic histone methylation is associated with IL-6 dependent MMPs gene transcriptional activation and possibly arthritogenic properties of RASFs.

Targeted Exon Resequencing For Korean Rheumatoid Arthritis. So-Young Bang[1], Kwangwoo Kim[2], Young-Ji Na[2], Jaemoon Lee[3], Youngho Park[3], Sun Young Lee[4], Adnan Ahmad Ansari[4], Chan-Bum Choi[2], Yoon-Kyoung Sung[2], Tae-Hwan Kim[2], Jae-Bum Jun[2], Dae-Hyun Yoo[2], Junghee Jung[5], Hwanseok Rhee[6], Jong-Young Lee[7], Bok-Ghee Han[7], Sung-Min Ahn[4], Sungho Won[3], Hye-Soon Lee[1] and Sang-Cheol Bae[2]. [1]Hanyang University Guri Hospital, Guri, South Korea, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [3]Chung-Ang University, Seoul, South Korea, [4]Gachon University, Incheon, South Korea, [5]Bioinfomatics Center, Macrogen Inc, Seoul, South Korea, [6]Bioinfomatics Center, Macrogen Inc, Seoul, South Korea, [7]Korea National Institute of Health, Osong, South Korea.

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disorder with heritability estimated at 65% characterized by arthritis and autoantibodies formation against citrullinated peptides (ACPA). Although there have been many efforts to identify underlying genetic causes of RA by common variants from genome-wide association studies (GWAS), most of around 60 loci identified have modest effect sizes and explained fully little of missing heritability. To discover functional and causal rare variants, we targeted genes outside of MHC region by for which there was reasonable evidence for involvement in Korean RA.

Methods: We performed targeted exon resequencing for 402 candidate genes in non-HLA region for 1,997 Korean RA cases-controls with Agilent's SureSelect kit (target region = 1.36Mb) on the HiSeq2000 platform. The sequencing data was filtered by our quality control criteria. RA association was assessed by a logistic regression for common markers and by a gene-based analysis using both Score-Seq and SKAT-O for rare coding variants.

Results: A total of 10,590 high-quality single-nucleotide variants (SNVs) was found in 1,217 cases and 717 healthy controls after applying the quality criteria (minimal depth coverage = 20x). The majority of the variants had low or rare frequency (90.6%) and 7,208 SNV was not reported in public databases like the 1000 genome project data. There were no novel loci associated with RA susceptibility in a single-marker level but we identified a significant accumulation of rare nonsynonymous variants in *gene A* associated with RA (Score-Seq: $P = 3.5 \times 10^{-4}$, SKAT-O: $P = 7.0 \times 10^{-3}$).

Conclusion: The *gene A* involved in the differentiation and activation Th17 was associated with RA risk by gene-based approaches of rare coding variants.

Disease Activity (DAS-28CRP) In Rheumatoid Arthritis Correlates With Synovial Expression Of Tumor-Associated and IL-6-Dependent Genes. Bernard Lauwerys[1], Julie Ducreux[1], Adrien Nzeusseu Toukap[1], Valérie Badot[2], Frédéric A. Houssiau[1] and Patrick Durez[1]. [1]Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Brussels, Belgium, [2]Hôpital Erasme, Université Libre de Bruxelles, Brussels, Belgium.

Background/Purpose: The molecular mechanisms that regulate disease activity in rheumatoid arthritis (RA) are unknown. Using high-throughput transcriptomic data sets generated in knee synovial biopsies from patients with RA, we wanted to identify which probe sets display the highest levels of correlation with disease activity (DAS-28CRP values), and whether they cluster in specific molecular pathways.

Methods: We retrieved gene expression data obtained after hybridization of 65 synovial biopsy samples using GeneChip HGU133Plus2.0 microarrays. 21 of them originated from untreated RA patients. Paired samples were obtained in 12 of these patients, 3 months after initiation of tocilizumab therapy, and in another 8 patients, 3 months after initiation of methotrexate therapy. The last samples were obtained in methotrexate- and TNF blockade-resistant patients before (n=12) and 3 months (n=12) after administration of rituximab therapy. Correlation coefficients were calculated between normalized expression values of each probe set (n = 51,452) and DAS28-CRP among the samples.

Results: When the analyses were performed on all samples, we found that 1,304 probe sets display a >0.50 correlation coefficient with DAS-28CRP values. Strikingly, almost the totality of these probe sets are IL-6 dependent, since they are down-regulated in synovial tissue after administration of tocilizumab.

In a previous study, we found that tocilizumab, rituximab and methotrexate therapies preferentially target IL-6-dependent genes in the synovium. Therefore, correlation studies between gene expression and DAS-28CRP values, performed before and after administration of these treatments, presumably result in a bias favorable to these genes. We therefore performed our correlation study on 21 synovial biopsy samples from untreated patients with RA and active disease. In this case, we found that 393 probe sets display a > 0.50 correlation coefficient with DAS-28CRP values. 15% of them are significantly down-regulated by tocilizumab therapy in the synovium, however, the probe sets with the highest correlation coefficients (between 0.65 and 0.75: GADD45B, TACSTD2, PDE4D, . . .) are associated with chromatin remodeling, regulation of cell cycle and tumor progression in cancer tissues.

Conclusion: Our data indicate that two distinct sets of transcripts are associated with disease activity (expressed as DAS-28CRP values) in the RA synovium. Immunohistochemistry experiments are ongoing in order to identify which synovial cells express these IL-6-dependent- versus tumor progression-associated transcripts.

Association Between Life Events and Rheumatoid Arthritis, Results From The EIRA Case Control Study. Annmarie Wesley[1], Camilla Camilla Bengtsson[1], Marie Holmqvist[2], Töres Theorell[3], Saedis Saevarsdottir[4], Eva Skillgate[1], Lars Klareskog[4], Lars Alfredsson[1] and Sara Wedrén[4]. [1]Karolinska Insitutet, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]Public Health Sciences, Karolinska Insitutet, Stockholm, Sweden, [4]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: The association between life events and rheumatoid arthritis (RA) has previously been studied with contradicting results. No previous study have investigated the impact of life events on risk of developing RA in the two major subsets of RA defined by the presence or absence of anti-citrullinated protein antibodies (ACPA) (Klareskog, Catrina et al. 2009). We aimed to investigate the association between life events and the risk for RA with and without ACPAs.

Methods: We used a population based case-control study of individuals aged 18 to 70 years, living in geographically defined parts of Sweden between May 1996 and November 2009. We included incident cases (n=2774) diagnosed by rheumatologists according to the American College of Rheumatology 1987 criteria for RA and randomly selected controls (n=3911) matched to cases by age, sex, and area of residence. All answered a questionnaire, including questions about 15 life events. We calculated odds ratios (OR) and 95% confidence intervals (CI) from unconditional logistic regression models adjusted for matching variables and confounding factors.

Results: Having experienced a life event was weakly associated with ACPA positive as well as ACPA negative RA, OR 1.1, 95%CI 1.0–1.2, and 1.2 95%CI 1.0–1.4, respectively. The association with ACPA negative RA was stronger with increasing number of events (OR 1.4 95%CI 1.1–1.7 for having experienced 3 or more events vs. none). Several particular life events were associated with RA (e.g., "conflict at work", "change of residence", "change of workplace", and "increased responsibility at work"). The results were more consistent in women than in men.

Conclusion: Our study lends support to the concept that stress, here measured as life events, is associated with an increased risk of developing RA.

The Incidence Of Factor V Leiden A1691G, Methylene Tetrahydrofolate Reductase C677T, and Prothrombin G20210A Mutation In Patients With Rheumatoid Arthritis. Taskin Senturk[1], Zahit Bolaman[1], Sabri Batun[2], Irfan Yavasoglu[3] and Gurhan Kadikoylu[1]. [1]Professor, Aydin, Turkey, [2]Professor, Diyarbakır, Turkey, [3]Associated Professor, Aydin, Turkey.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, systemic and inflammatory disease. Thromboembolic phenomenas are more frequent in patients with RA than healthy individuals and several hemostatic factors increase in these patients with RA. The knowledge about FV Leiden A1691G, methylenetetrahydrofolate reductase (MTHFR) C677T, and prothrombin G20210A mutation in RA is very limited. We aimed to evaluate the incidence of factor V Leiden A1691G, MTHFR C677T, and prothrombin G20210 mutation in patients with RA.

Methods: Forty-seven patients with RA and 53 healthy individuals as control group are included to the study. The DNA of patients and control group were obtained from blood in tubes with EDTA by using pure polymerase chain kit. Then factor V Leiden A1691G, prothrombin G20210A, and MTHFR C677T mutation were investigated in DNA by using LightCycler-Factor V A1691G, prothrombin G20210A, and MTHFR C677T estimate kits. Yates chi-square and students t test for comparison of groups were used.

Results: The mean age of patients and control groups were 48.8 ±12.2 and 48.8 ± 7.9 years, respectively. There is no history or physical finding of venous thrombosis in patients and control group. The heterozygote FV Leiden A1691G point mutation was estimated in 9 patients with RA (6.3%) and 2 patients (3.7%) in control group ($p<0.001$). The homozygote FV Leiden and A1691G mutation were not determined among patients and control group. Heterozygote prothrombin G20210A mutation was estimated in 9 patients with RA (15%). There was no heterozygote prothrombin G20210A mutation in control group ($p<0.001$). Homozygote prothrombin G20210A mutation was not estimated among the patients and the control group. Heterozygote MTHFR C677T mutation was found in 40 patients (85%) with RA while in 13 patients (24%) of the control group ($p<0.001$). There was no homozygote MTHFR C677T mutation in patients with RA, while homozygote MTHFR C677T mutation was determinated in 2 patients of the control group ($p>0.05$).

Conclusion: The incidences of heterozygote prothrombin G20210A and MTHFR C677T are higher in patients with RA than healthy individuals. We do not know the importance of heterozygote prothrombin G20210A, and MTHFR C677T in patients with RA. It may be useful to follow up closely in respect of further thromboembolic events in RA patients with heterozygote prothrombin G20210A, and/or MTHFR C677T mutations.

CXCL13-Producing CD4 T-Cells In Rheumatoid Synovitis Are a Distinct Subset. Shio Kobayashi[1], Koichi Murata[1], Hideyuki Shibuya[1], Masahiro Ishikawa[1], Moritoshi Furu[2], Hiromu Ito[2], Shuichi Matsuda[1], Takeshi Watanabe[1] and Hiroyuki Yoshitomi[1]. [1]Kyoto University Graduate School of Medicine, Kyoto, Japan, [2]Graduate School of Medicine, Kyoto University, Kyoto, Japan.

Background/Purpose: Ectopic lymphoid structures are frequently formed in synovial tissues of patients with rheumatoid arthritis (RA). Several reports suggested that CD4 T-cells have a crucial role in pathogenesis of RA. Although Th1 and Th17 cells are key subsets in mouse arthritis models, roles of those subsets in RA patients are still controversial. In this study, we examined an involvement of other T-cell subsets in the pathogenesis of RA. Previous report showed CD4 T-cells in synovial tissues and synovial fluid of RA produced CXCL13 which was crucial for formation of germinal center. We examined whether these cells were related to known Th subset.

Methods: We analyzed CD4 T-cells of RA synovitis by flow cytometry and immunohistofluoresecence.

Results: CD4 T-cells of rheumatoid synovitis produced CXCL13 ex vivo without exogenous stimulation of TCR or cytokines and flow cytometric analyses showed that the CXCL13+ CD4 T-cells were a population independent of IFN-γ^+ Th1, IL-4^+ Th2, and IL-17^+ Th17 cells. Although human follicular helper T-cells, which express CXCR5 as a crucial marker, produce CXCL13, CXCR5 was not expressed in RA synovial CXCL13+ CD4 T-cells. CXCL13+ CD4 T-cells were limited in the local inflamed site but not in blood nor non-inflammatory joints. Moreover, we revealed that TCR stimulation and inflammatory cytokine were important for the maintenance of CXCL13 production and for the induction of CXCL13+ CD4 T-cells from blood CD4+T-cells of healthy volunteer.

Conclusion: Our results showed that CXCL13-producing CD4 T-cells were a newly identified Th subset and distinct from other known Th subsets. The CXCL13+ CD4 T-cells in RA are thought to recruit circulating Tfh cells and B-cells, which express CXCR5, to inflamed joint, to participate in the neogenesis of ectopic lymphoid organ, and to maintain inflammation.

Respiratory Diseases As Risk Factors For Rheumatoid Arthritis. Marie Holmqvist[1], Johan Askling[1], Lars Alfredsson[1], Camilla Bengtsson[1], Fredrik Nyberg[2] and Göran Tornling[3]. [1]Karolinska Institutet, Stockholm, Sweden, [2]AstraZeneca R&D, Mölndal, Sweden, [3]Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden.

Background/Purpose: The etiology of rheumatoid arthritis (RA) is only partly understood. In addition to smoking, other airway exposures, e.g. silica dust and traffic pollution, have been positively associated with RA. Inflammatory events in the lungs may thus be of pivotal importance in the pathogenesis of RA, in particular for anti-citrullinated protein antibody (ACPA) positive RA. The potential role for respiratory tract diseases (RTD) in RA pathogenesis has not been systematically explored. We aimed to explore the hypothesis that RTD may initiate the development of RA, with a specific focus on ACPA subtype.

Methods: Cases and controls included 1996–2009 in the population-based case-control study of incident RA, EIRA (2880 cases/4069 controls), were linked to the National Patient Register to detect hospitalizations and outpatient visits listing RTDs (exposures) that occurred prior to first symptom of RA (corresponding date in matched controls). The exposures were analysed overall (any RTD), and subdivided into chronic lower (CL), acute lower (AL), chronic upper (CU) and acute upper (AU) RTD. Asthma, chronic obstructive pulmonary disease (COPD), and interstitial lung disease (ILD) were also assessed separately. Using unconditional logistic regression models with RA as the dependent variable and RTDs as the independent variables, odds ratios (ORs) and 95% confidence intervals (CIs) were estimated. Models were adjusted for smoking (ever vs. never smoking). Subgroup analyses based on smoking history (never, former, non-regular, or current smoking) were performed.

Results: Overall (irrespective of ACPA status), subjects with a history of any RTD were at increased risk of developing RA (all ORs are found in the table). Individuals with a history of CU RTDs and asthma were at significantly increased risk. ACPA positive RA was not associated with a history of any RTD. However, there was a suggestive increased risk of ACPA positive RA following a history of interstitial lung disease. For ACPA negative RA, a history of a RTD conferred significantly increased risks. This was particularly true for chronic lower RTD and for asthma. When these associations were stratified by smoking status, the increased risk was most prominent in never or non-regular smokers (data not shown).

Table. Odds ratios (OR) and 95% confidence intervals (CI) assessing the relationship between respiratory tract diseases and rheumatoid arthritis. All models adjusted for smoking

	ACPA status	N exposed cases/controls	OR (95% CI)
Any respiratory tract disease	All	410/503	1.18 (1.02–1.36)
	Positive	251/503	1.08 (0.92–1.28)
	Negative	159/503	1.32 (1.09–1.61)
Chronic lower diseases	All	77/88	1.26 (0.92–1.71)
	Positive	43/88	1.03 (0.71–1.50)
	Negative	34/88	1.55 (1.03–2.32)
Acute lower diseases	All	99/128	1.07 (0.82–1.40)
	Positive	54/128	0.90 (0.65–1.25)
	Negative	45/128	1.40 (0.98–1.98)
Chronic upper diseases	All	190/217	1.27 (1.04–1.55)
	Positive	126/217	1.26 (1.00–1.59)
	Negative	64/217	1.23 (0.92–1.64)
Acute upper diseases	All	98/126	1.13 (0.86–1.48)
	Positive	56/126	0.98 (0.71–1.36)
	Negative	42/126	1.41 (0.98–2.02)
Asthma	All	54/57	1.46 (1.00–2.12)
	Positive	29/57	1.14 (0.72–1.80)
	Negative	25/57	1.85 (1.14–2.98)
Chronic obstructive pulmonary disease	All	11/21	0.63 (0.30–1.32)
	Positive	6/21	0.53 (0.21–1.32)
	Negative	5/21	0.86 (0.32–2.31)
Interstitial lung disease	All	5/4	1.74 (0.46–6.56)
	Positive	4/4	2.34 (0.57–9.61)
	Negative	1/4	0.92 (0.10–8.26)

Conclusion: In contrast to our hypothesis, RTD seems to be associated with ACPA negative, and not ACPA positive, RA.

The Relationship Between Anti-Citrullinated Protein Antibodies and Radiographic Damage In African-Americans With Rheumatoid Arthritis. Maria I. Danila[1], Richard J. Reynolds[2], Stella Aslibekyan[2], Ashutosh Tamhane[2], Laura B. Hughes[2], Jeremy Sokolove[3], William H. Robinson[4], Doyt L. Conn[5], Beth L. Jonas[6], Leigh F. Callahan[7], Larry W. Moreland[8], Richard D. Brasington[9], Edwin A. Smith[10], Ted R. Mikuls[11], Désirée van der Heijde[12] and S. Louis Bridges Jr.[2]. [1]Univ of Alabama-Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [4]Stanford University School of Medicine, Stanford, CA, [5]Emory Univ School of Medicine, Atlanta, GA, [6]University of North Carolina at Chapel Hill, Chapel Hill, NC, [7]University of North Carolina, Chapel Hill, NC, [8]University of Pittsburgh, Pittsburgh, PA, [9]Washington Univ School of Med, St. Louis, MO, [10]Med Univ of South Carolina, Charleston, SC, [11]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [12]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Joint erosions and joint space narrowing may lead to impaired functional status and disability in rheumatoid arthritis (RA). Autoantibodies to citrullinated proteins (ACPA) are present in RA sera, but the contribution of different specificities of ACPA to radiographic damage has not been studied. The objectives of this cross-sectional study were: to test the hypothesis that particular ACPA specificities are associated with radiographic damage in African-Americans with RA.

Methods: Using a custom Bio-Plex™ bead-based autoantibody assay platform, we measured serum (N = 730 RA patients) concentration of antibodies targeting putative RA associated hyper-citrullinated autoantigens [vimentin, fibrinogen, histone 2A (H2A), histone 2B (H2B), and apolipoprotein A1 (Apo A1)] and their constitutively citrullinated forms. Radiographic severity was defined as total Sharp/van der Heijde scores of hands/feet. Three negative binomial regression models of radiographic severity were fit: 1) conditional on sex, smoking, disease duration, BMI and ln(CCP), 2) Model 1 + each autoantibody, and 3) Model 2 without ln(CCP). A highly conservative Bonferroni corrected alpha level of 0.005 for testing the autoantibodies was used.

Results: Significant covariates from Model 1 included positive association of radiographic damage with disease duration and ln(CCP) (Table). In addition there was a weaker negative association of joint damage and body mass index (BMI). Results for model 2 demonstrated significant associations of antibodies against native H2A, while antibodies against vimentin and histone 2B were nearly significant. There were no statistically significant associations between total radiographic score and antibodies to the hyper-citrullinated proteins. Results from Model 3 demonstrated that the associations between joint damage and the antibodies against native and hyper-citrullinated proteins were slightly stronger if anti-CCP antibodies were not taken into account. The antibodies against native H2A, H2B, and vimentin remained statistically significantly associated with radiographic severity, but none of the antibodies against hyper-citrullinated proteins attained significance.

Table. Estimated parameters and negative binomial model fit statistics for the covariates and the natural logarithm of antibody concentrations given the covariates.

Model 1

Variable	Estimate	p
Intercept	1.3	**0.00073**
Sex(Male)	0.19	0.39
Smoking(Never)	0.25	0.09
Disease duration	0.095	**2.00E–16**
BMI	−0.019	0.043
ln(CCP)	0.14	**6.60E–07**

Model 2

Constitutive	Estimate	p	Citrullinated	Estimate	p
Fibrinogen	0.29	0.082	Fibrinogen	−0.028	0.65
Vimentin	0.27	0.0067	Vimentin	0.014	0.77
Histone 2B	0.32	0.0073	Histone 2B	−0.079	0.17
Apolipoprotein A1	0.34	0.11	Apolipoprotein A1	0.022	0.71
Histone 2A	0.49	**0.0018**	Histone 2A	−0.085	0.11

Model 3

Constitutive	Estimate	p	Citrullinated	Estimate	p
Fibrinogen	0.37	0.029	Fibrinogen	0.07	0.2111
Vimentin	0.31	**0.00256**	Vimentin	0.087	**0.033**
Histone 2B	0.4	**0.00057**	Histone 2B	0.064	0.14
Apolipoprotein A1	0.44	0.042	Apolipoprotein A1	0.098	0.064
Histone 2A	0.58	**0.00019**	Histone 2A	0.051	0.2

Conclusion: Autoantibodies against hyper- citrullinated proteins vimentin, fibrinogen, ApoA1, H2A and H2B were not associated with joint damage. However, for African-Americans with established RA, antibodies to constitutively citrullinated proteins are most strongly associated with radiographic damage.

Rheumatoid Arthritis-Related Autoantibodies In The Lung Evolve Over Time In Subjects At Elevated Risk For Future Rheumatoid Arthritis. M. Kristen Demoruelle[1], Patrick R. Wood[1], Michael H. Weisman[2], Mark C. Parish[1], Isabel F. Pedraza[2], Jill M. Norris[3], V. Michael Holers[1] and Kevin D. Deane[1]. [1]University of Colorado School of Medicine, Aurora, CO, [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]Colorado School of Public Health, Aurora, CO.

Background/Purpose: Recent data from our group have demonstrated that RA-related autoantibodies (Abs), including anti-CCP and RF, are detectable in sputum from subjects with early Classified RA (1987 criteria; <1 year from diagnosis) as well as those at elevated risk for future RA (Willis and Demoruelle 2013, in press). In this cross-sectional study, 71% of 49 subjects at elevated risk for future RA (At-Risk) had ≥1 RA-related Ab in sputa. By comparing the ratio of RA-related Ab to total immunoglobulin (Ig) levels in sputa and sera, a subset of these At-Risk subjects appeared to generate RA-related Abs in the lung. These findings support a hypothesis that the lung is a site of initial generation of RA-related autoimmunity; however, the stability and evolution of lung RA-related Abs in subjects at elevated risk for future RA is unknown.

Methods: From the 49 At-Risk subjects previously tested in cross-section, we studied 11 that had follow-up sputum testing (median 19 months from initial testing). These At-Risk subjects were from the Studies of the Etiology of RA (SERA) cohort and at elevated risk for future RA based on family history of RA, or seropositivity for RA-related Abs in absence of synovitis identified through community healthy screenings. All subjects had no history of RA and were without synovitis at the time of sputum testing based on 68-joint examination. Induced sputum was collected using nebulized 5% saline and a protocol designed to minimize salivary contamination. Sputa samples were homogenized with mechanical disruption, and tested for RA-related Abs using ELISAs: CCP2 (IgG, Axis-Shield), CCP3.1 (IgA/IgG, INOVA), and RF isotypes (IgM/A/G, INOVA). Sputum positivity for each RA-related Ab was determined based on previously established cut-off levels (2 standard deviations above the mean level in 21 healthy controls).

Results: In these 11 At-Risk subjects, the median number of RA-related Abs positive in sputa at initial testing was 1.0 (range 0–4). At follow-up, 6/11 (55%) had a net change in the number of positive sputa RA-related Abs. These changes included both gain (N=3) and loss (N=3) of ≥1 RA-related Ab. RF-IgA was the most likely Ab to become positive: 3 of 9 (33%) subjects initially sputa RF-IgA negative were RF-IgA positive in sputa at follow-up. CCP3.1 also detects IgA, and 4/11 (36%) subjects had a change in sputum CCP3.1 status (2 gained positivity, 2 lost positivity). Changes were not associated with smoking status. Additionally, in 4 subjects with Classified RA who had 2 sputa samples collected (median 8 months apart), 1 subject lost positivity for a single RA-related Ab (CCP2), and all other sputa RA-related Abs remained stable on repeat testing.

Conclusion: Sputum RA-related Abs are elevated and fluctuate over time in subjects at elevated risk for future RA. These results may represent evolving immune responses in the lung, and in particular mucosal IgA responses, that may be associated with generation and regulation of RA-related autoimmunity during the development of RA. Going forward, extended longitudinal study of these and additional subjects will be performed to evaluate the relationship between evolution in lung RA-related Abs and the development of serum RA-related Abs and/or incident clinically classifiable RA.

Secretory Leukocyte Protease Inhibitor Released By Rheumatoid Synovial Fibroblasts Exerts a Negative Control Of BAFF-Dependent B Cell Activation In Vitro and In Vivo In The Collagen-Induced and Chimeric RA/SCID Arthritis Models. Yvonne NW Kam[1], Andrew Filer[2], Christopher D. Buckley[3], Costantino Pitzalis[4] and Michele Bombardieri[4]. [1]Centre for Experimental Medicine and Rheumatology, QMUL, London, United Kingdom, [2]Rheumatology Department, Birmingham, United Kingdom, [3]University of Birmingham, Birmingham, United Kingdom, [4]William Harvey Research Institute, QMUL, London, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) is characterized by the formation of synovial niches of autoreactive B cells which are favored by the autocrine production of B cell survival factor BAFF by RA synovial fibroblasts (RASF). Secretory leukocyte protease inhibitor (SLPI) is a serine protease inhibitor which also acts as a potent immune-regulator. Here we investigated whether i) SLPI is expressed by RASF and is modulated by Toll-like receptors (TLR) ligands; ii) it can regulates BAFF expression by RASF and downstream B cell activation; iii) exerts immunoregulatory effects in vivo in the collagen induced arthritis (CIA) and the chimeric RA synovium/SCID models of arthritis.

Methods: mRNA and protein expression of SLPI in RASF and RADF (dermal) stimulated with TLR2/TLR3/TLR4 ligands was assessed by QT-PCR and ELISA. RASF were treated with/without recombinant SLPI to study: i) BAFF mRNA/protein expression; ii) AID expression and Ig class-switching in IgD+ B cells stimulated with BAFF/IL-4 or in co-culture with RASF. Furthermore, severity of arthritis, production of anti-CII antibodies, and joint histopathology were studied in CIA mice treated with rSLPI after arthritis onset. Finally, BAFF expression and antibody production were examined in rSLPI-treated RA/SCID mice.

Results: RASF expressed significantly higher baseline SLPI mRNA compared to RADF. Stimulation of RASF with TLR3-ligands led to a 15-fold induction of SLPI mRNA. SLPI protein was time-dependently released from TLR3-stimulated RASF, but not RADF. SLPI restrained the production of BAFF mRNA/protein in TLR3-treated RASF. Furthermore, SLPI down-modulated AID expression and IgA, IgG and IgM production in IgD+ B cells stimulated with BAFF/IL-4 or in co-culture with RASF. SLPI reduced BAFF expression and IgG/IgM production in RA/SCID mice while severity of arthritis, cartilage damage and anti-CII-IgG2a were significantly reduced in CIA mice by rSLPI administered after arthritis onset.

Conclusion: RASF release high levels of SLPI constitutively and upon TLR3 stimulation. SLPI directly modulates BAFF and B cell activation in vitro/in vivo and reduces joint inflammation and damage in animal models of arthritis, highlighting a novel endogenous anti-inflammatory pathway which could be exploited for therapeutic purposes in RA.

Association Of High Serum Interleukin-23 Levels With *Porphyromonas Gingivalis* Antibodies In Patients With Early Rheumatoid Arthritis. Sheila L. Arvikar[1], Klemen Strle[1], Deborah S. Collier[1], Mark C. Fisher[1], Toshihisa Kawai[2], Jose U. Scher[3] and Allen C. Steere[1]. [1]Massachusetts General Hospital, Boston, MA, [2]Forsyth Institute, Cambridge, MA, [3]NYU Hospital for Joint Diseases, New York, NY.

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased frequency of periodontal disease (PD) and antibodies to *P. gingivalis* (*Pg*), a major periodontal pathogen. Both Th1 and Th17 immune responses are thought to be important in RA, and a Th17 polarizing milieu has been demonstrated in periodontitis. Here we examined the association of *Pg* antibodies with specific cytokine and chemokine responses in early RA patients, prior to and during DMARD therapy.

Methods: Sera were obtained from 48 early RA patients, 36 from our cohort and 12 from NYU, who were enrolled prior to initiation of DMARDs, and from 24 healthy control subjects. Sera were tested for *Pg* IgG antibodies by ELISA using whole *Pg* sonicate (ATCC 33277). Protein levels of 20 cytokines and chemokines, including those associated with Th1 and Th17 immune responses, were quantified by Luminex in serum and, when available, in synovial fluid (SF).

Results: Prior to DMARD therapy, 23 of the 48 patients (48%) had positive IgG antibody responses to *Pg*. These patients more often had elevated anti-CCP antibodies than those who were *Pg*-negative (91% vs. 64%, P=0.06) and tended to have higher serum levels of most cytokines and chemokines tested. The differences between *Pg*-positive and *Pg*-negative patients were most striking for the Th17-associated cytokine, IL-23, the levels of which were at least 8-fold higher in serum than the other mediators. In the 7 patients in whom SF was available, IL-23 levels were 4-fold higher in serum than in SF, and serum levels of IL-23 were significantly higher in *Pg*-positive versus *Pg*-negative patients (P=0.04). In contrast, the levels of Th1-associated chemokines were more concentrated (>10X) in SF than in serum (CXCL9, P =0.1; CXCL10, P=0.02) of both *Pg*-positive and *Pg*-negative patients.

In *Pg*-positive patients, the levels of anti-CCP antibodies and most inflammatory mediators correlated directly with disease activity (DAS-28-CRP), whereas these correlations were not seen in *Pg*-negative patients (P≤0.05). Moreover, there was a trend towards a correlation between DAS-28 and the Th17-associated cytokines, IL-23 and IL-17α, in *Pg*-positive patients (P≤0.1), but not in *Pg*-negative patients (P≤0.8). During the 12 months of DMARD therapy, disease activity measures and inflammatory mediators declined, whereas the *Pg* antibody levels did not change significantly. Of the inflammatory mediators and biomarkers studied, *Pg* antibody levels were the strongest predictor of DAS-non-remission at 12 months (P=0.02) and a similar trend was observed for IL-23.

Conclusion: The levels of IL-23 were higher in serum than in SF of *Pg*-positive early RA patients, whereas Th1-associated mediators were concentrated in SF of both *Pg*-positive and *Pg*-negative patients. This suggests that in *Pg*-positive patients, IL-23 production may occur in extra-articular sites such as the oral mucosa. Moreover, *Pg* antibody positivity and high IL-23 levels were associated with a higher frequency of DAS-non-remission at 12 months. Thus, *Pg* infection is one factor that may contribute to Th17 immune responses and greater inflammation in a subset of early RA patients who may benefit from more aggressive initial therapy.

Effects Of Leptin and Adiponectin On Proliferation and Activation Were Are Significantly Increased In CD4$^+$ T Cells From Rheumatoid Arthritis Patients. Daniel Xibille-Friedmann[1], Carolina Bustos-Rivera Bahena[2], Marisol Sandoval-Rios[3] and Jose Luis Montiel-Hernandez[3]. [1]Hospital General de Cuernavaca, Cuernavaca, Mexico, [2]Facultad de Ciencias, Cuernavaca, Mexico, [3]Facultad de Farmacia, Cuernavaca, Mexico.

Background/Purpose: *In vitro* and *in vivo* studies suggest that leptin and adiponectin are involved in the development of inflammation in RA patients. Previous findings by our group have shown that levels of these adipokines are significantly higher in RA in comparison with healthy patients, and correlate with variations in DAS28 after two years of follow-up. We have observed that high levels of adiponectin at baseline predict a positive response to DMARD treatment after 6–12 months. However, the biological mechanism of leptin and adiponectin on T cell physiology is still poorly understood.

Objective: To compare the *in vitro* proliferative and activation effects of leptin and adiponectin on mononuclear (MN) and CD4$^+$ T cells from healthy donors and RA patients.

Methods: All RA patients included in the present study fulfilled the ACR 2010 criteria and were followed at the rheumatology clinic. Healthy donors samples were obtained from a local blood bank. Mononuclear cells were obtained by Ficoll Paque the same day the blood was obtained. CD4$^+$T cells were magnetically purified (Miltengy). *In vitro* assays were done employing recombinant human leptin and adiponectin (Peprotech). Proliferation was evaluated by MTT technique. Activation was evaluated by flow cytometry (CD25, CD69) and by ELISA (IL-1b, IL-2, IL-6, TNF-a). Th17 differentiation was evaluated by ELISA/cytometry (IL-17A) and western blot (RORγT). Descriptive statistics were employed to evaluate differences between groups and Spearman correlation was used to associate them with clinical parameters. A p-value <0.05 was considered as statistically significant.

Results: MN and CD4$^+$T cells from RA patients showed a significantly higher proliferative effect when exposed to leptin and adiponectin in comparison with healthy donors. According with these, leptin and adiponectin treatment were able to rescue MN cells from apoptosis induced by etoposide by an IL-2-related mechanism. Interestingly, the level of proliferation correlated with the DAS28 of patients. Similarly, cells from patients were more sensitive to leptin and adiponectin treatment when evaluating CD25$^+$/CD69$^+$ cell expression and IL-2, TNF-a secretion, in comparison to healthy donor cells. Comparatively, adiponectin treatment was significantly more effective in inducing the expression of CD25, CD69 and IL-6, whereas leptin was a better inductor of IL-2 and TNF-a on RA patient cells. Comparing this with the clinical activity of patients, we only observed a significant correlation between the DAS28 and IL-2 induction when exposed to leptin. On the other hand, CD4$^+$T cells from RA patients incubated for several days with leptin induced an increase of IL-6 and IL-17A in the cell culture supernatant and cell expression of RORgT, suggesting a direct mechanism by which high levels of leptin could favor inflammation during the progression of RA.

Conclusion: MN and CD4$^+$ T cells derived from RA patients were more sensitive to leptin/adiponectin treatment, in comparison to healthy donor cells with respect to their effects on proliferation, activation and Th17 differentiation. Additionally, clinical activity correlated with the proliferative effect and IL-2 secretion induced by treatment with leptin.

The Peripheral Blood T Cell Repertoire Before The Clinical Onset Of Rheumatoid Arthritis – a Study Of Incident Cases and Controls. Carl Turesson[1], Ulf Bergström[1], Edgars Grins[2], Olle Melander[1], Lennart Truedsson[2], Lennart Jacobsson[1] and Stefan Jovinge[2]. [1]Lund University, Malmö, Sweden, [2]Lund University, Lund, Sweden.

Background/Purpose: Previous studies indicate that circulating antibodies may be detected in individuals who later develop rheumatoid arthritis (RA) years before onset, and T cells have been implicated in the pathogenesis of RA. The purpose of this study was to investigate peripheral blood T cell phenotypes before the onset of RA.

Methods: Incident cases of RA were identified among participants (n=30447) in a community based health survey, which was linked to local and national registers, followed by a structured review of the medical records. One control, matched for age, sex and year of inclusion in the health survey, was selected for each validated case. Peripheral blood cells from a subset of participants in the health survey had been frozen according to a specified protocol and stored at −140° C. Phenotypes of peripheral blood T cells were determined by direct immunofluorescence staining and multicolor flow cytometry. Th1 cells were defined as CD4+ IFN-g+ cells, Th2 cells as CD4+ IL-4+ cells, Th17 cells as CD4+ IL-17+ cells, and regulatory T cells (Tregs) as CD25+ FoxP3+ cells. Anti-CCP2 antibodies (Euro-Diagnostica; reference interval <20 U/L) were measured in sera collected at the same time as the cell samples. Analyses were stratified by time from inclusion in the health survey to RA diagnosis and by anti-CCP2 status.

Results: Peripheral blood cell samples were available from 78 matched pairs of pre-RA cases and controls (mean age 57 years, 82 % women). The median time from inclusion in the health survey to RA diagnosis in the cases was 6 years [interquartile range (IQR) 3–8; range 1–13]. Twelve pre-RA cases (15 %) were anti-CCP2 positive. There were no major differences in lymphocyte counts or the proportions of CD3+, CD4+ or CD8+ cells among lymphocytes between cases and controls. Pre-RA cases and controls had similar proportions of Th1, Th2 and Th17 cells in the CD4+ population. The distribution of Tregs was skewed among pre-RA cases, with a reduced number of cases with high Treg counts compared to controls [median 0.50 % of CD3+ cells (IQR 0.22–1.03) vs. median 0.49 % (IQR 0.32–1.91)], although the difference did not reach significance (p=0.18). This trend was more pronounced in the subset of anti-CCP negative cases included 1–6 years before RA diagnosis and their controls [median 0.51 % (IQR 0.21–1.27) vs. 0.80 % (IQR 0.41–2.86); p=0.15]. Pre-RA cases had significantly lower proportions of CD4+ CD28null cells compared to controls [median 1.58 % of CD4+ cells (IQR 1.18–2.99) vs. 2.24 % (IQR 1.33–3.97); p=0.047]. Anti-CCP positive cases tended to have lower counts of Th1 cells [median 24.2 % of CD4+ cells (IQR 14.8–51.2) vs. 47.7 % (IQR 19.1–73.9); p=0.15] compared to controls.

Conclusion: In this study of a unique resource, we did not find any major abnormalities in the peripheral blood T cell repertoire before the clinical onset of RA. Given the limited sample, we can't exclude a downregulation of Tregs in anti-CCP negative pre-RA cases and a down-regulation of Th1 cells in anti-CCP positive cases. The lower levels of CD4+ CD28null cells in the pre-RA cases suggest that the demonstrated expansion of such cells in established RA is a consequence of chronic inflammation, rather than an inherent part of the immune phenotype of the disease.

Anti-CCP Antibodies and Increased Cartilage Turnover In Patients Developing Rheumatoid Arthritis. Carl Turesson[1], Christina Book[1], Ulf Bergström[1], Lennart Truedsson[2], Lennart Jacobsson[1] and Tore Saxne[2]. [1]Lund University, Malmö, Sweden, [2]Lund University, Lund, Sweden.

Background/Purpose: Autoantibodies may be detected years before the onset of rheumatoid arthritis (RA). We have previously shown that levels of Cartilage oligomeric matrix protein (COMP), a marker of cartilage turnover, are elevated in particular in individuals who are negative for anti-CCP antibodies before RA diagnosis. A similar pattern has been reported in early RA (Christensen J Rheumatol 2011; 38:1563–8). Our purpose was to investigate changes in COMP from the pre-clinical phase to early RA, and their relation to anti-CCP status.

Methods: Between 1991 and 1996, 30 447 subjects from a defined catchment area were included in a health survey. From this population, individuals who developed RA after inclusion were identified by linking the health survey database to a community based RA register and local and national patient administrative databases. In a structured review of the medical records, patients were classified according to the 1987 ACR criteria for RA. The identified sample of incident cases of RA was linked to an inception cohort of early RA patients (symptom duration <12 months) from the same area. Serum COMP at baseline and at inclusion as early RA was measured with a sandwich ELISA (AnaMar Medical) among those diagnosed with RA 1–5 years after inclusion in the health

survey. Based on previous studies, 12 U/L was used as a cut off for elevated COMP. Anti-CCP2 antibodies were determined by standard methods (Euro-Diagnostica).

Results: Among a total of 172 incident cases of RA, data on COMP were available from the pre-RA inclusion in the health survey (baseline) and from inclusion in the early RA cohort in 30 cases (22 females/8 males; mean age at RA diagnosis 62 years). The median duration of symptoms was 9 months [interquartile range (IQR) 6–11]. The median time from baseline to inclusion in the early RA cohort was 4.2 years (IQR 3.2–5.2). The proportion of anti-CCP positive individuals increased from 24 % at baseline to 63 % in early RA ($p<0.001$), and the proportion with elevated COMP levels increased from 20 % to 67 % ($p=0.006$). The median COMP levels were 10.1 U/L (IQR 8.0–11.9) at baseline and 12.7 U/L (IQR 11.2–14.2) in early RA ($p<0.001$). The increase in COMP tended to be less pronounced in the subset that was anti-CCP positive at baseline [median change 1.3 U/L (IQR – 1.0 to 3.8) vs 3.6 U/L (IQR 0.6 to 6.3) in anti-CCP negative pre-RA cases; $p=0.16$]. COMP levels increased among those who converted from anti-CCP negative to anti-CCP positive ($n=12$; median change 2.8 U/L) as well as among those who remained anti-CCP negative in early RA ($n=10$; median change 4.5 U/L). The proportion with elevated COMP levels in early RA was greater among those who were anti-CCP negative at baseline (77 % compared to 43 % in anti-CCP positive pre-RA cases; $p=0.16$), whereas there was no such difference by anti-CCP status in early RA (anti-CCP negative patients: 73 %; anti-CCP-positive patients: 63%; $p=0.70$).

Conclusion: The clinical onset of RA was associated with development of anti-CCP antibodies and increased COMP levels. The increase in COMP was greater among individuals lacking anti-CCP antibodies before the onset of RA. This suggests that RA-specific autoimmunity and increased cartilage turnover may represent distinct pathways in the pre-clinical phase of RA.

Expression and Function Of a YAP, a Novel Pathway In Fibroblast-Like Synoviocyte In Rheumatoid Arthritis. Beatrix Bartok, UCSD School of Medicine, La Jolla, CA.

Background/Purpose: Modulating molecular pathways that regulate pathogenic behavior fibroblast-like synoviocytes (FLS) could lead to new therapies for rheumatoid arthritis (RA). Targeting transcription factors are especially interesting, because they regulate the expression of multiple genes and therefore regulate diverse pathways that contribute to disease. The transcriptional coactivator YAP is emerging as a major regulator of proliferation. organ size and oncogenesis. Several downstream targets of YAP such as surviving and CTGF are implicated in different aspect of RA; however the YAP pathway itself has not been characterized yet in inflammatory synovitis. Therefore, we explored expression and function of YAP in RA synoviocytes.

Methods: For confocal microscopy cells were starved overnight, fixed and stained for YAP, DAPI, and with phalloidin for F-actin. For quantification, YAP signal was scored as nuclear/nuclear+cytoplasmic versus cytoplasmic only by analyzing 150–200 cells for each cell line. For qPCR analysis the relative abundance of mRNA was calculated by normalizing to GAPDH. For siRNA knockdown, YAP and control siRNA weretransfected using AMAXA technology. To quantify cell proliferation, 5 days following transfection cell were plated in 1% FBS containing media in the presence of absence of TNF (10 ng/ml) and cell number was assayed with MTT on day 0, 2, 4 and 6.

Results: Using Western blot analysis, YAP protein was abundant and levels were similar in RA and OA FLS ($n=4$). Next we assayed the subcellular localization of YAP in RA and OA FLS using confocal microscopy. 80% of the RA FLS had nuclear YAP compared with only 40% of OA cells ($n=4$, $p<0.035$). These observations suggested that YAP is constitutively active in RA FLS and is increased compared with OA. To confirm YAP transcriptional activity, qPCR was performed for YAP target genes survivin, CTGF and CCN1. mRNA levels for all three were significantly greater in RA compared with OA ($n=3$, $P<0.04$ for each). When RA FLS were stimulated with TNF, YAP was dephosphorylated (S473) and underwent nuclear translocation. This was followed by a 2.5 fold ($P<0.04$) increase in survivin and 1.5 fold ($P<0.03$) in CTGF mRNA levels ($n=3$). To determine critical role of YAP in TNF signaling, YAP was knocked down by siRNA and cells were stimulated with TNF. Proliferation increased 1.8 fold in control siRNA treated cells but not in YAP deficient cells ($n=3$, $P<0.03$).

Conclusion: This is the first study to demonstrate that YAP is expressed in FLS and that YAP activity is dysregulated in RA compared with OA FLS. Increased YAP activity might contribute to persistent activation and pathogenic behavior of RA FLS, especially TNF-regulated functions. Therefore, reprogramming RA FLS by modulating the YAP pathway represents a novel therapeutic approach for RA.

Elevated Serum Resistin Levels In Rheumatoid Arthritis With Periodontitis. Byoong Yong Choi[1], Jin-Hee Kim[2], Kyung Hwa Kim[2], Kyong Rok Kim[1], Sang Hyun Joo[3], Myeong Jae Yoon[4], Hye Jin Oh[5], Hye Won Kim[1], Sung Hae Chang[1], Eun Young Lee[1], Eun Bong Lee[1], Yong-Moo Lee[2] and Yeong Wook Song[1]. [1]Seoul National University College of Medicine, Seoul, South Korea, [2]Department of Periodontology, School of Dentistry, Seoul National University, Seoul, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University, Seoul, South Korea, [4]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, South Korea, [5]Seoul National University, Seoul, South Korea.

Background/Purpose: Epidemiological relationships between rheumatoid arthritis (RA) and periodontitis (PD) have been revealed recently. However, the pathologic link between RA and periodontitis has remained unclear. Resistin is adipokine which has been involved in insulin resistance in rodents but its pro-inflammatory properties are known to be superior to insulin resistance-inducing effects in human. Previous studies suggested that resistin may play a role in RA and periodontitis.

Methods: Serum resistin levels were determined by enzyme-linked immunosorbent assay (ELISA). Ninety RA patients and 45 healthy subjects (2:1 age and gender matched). Serum samples were analysed for C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), anti-cyclic citrullinated peptide (anti-CCP), IgM rheumatoid factor. The disease activity was determined using the Disease Activity Score in 28 joints (DAS28). We divided the subjects into high (DAS28 $\geq$ 3.2) and low (DAS28 $<$ 3.2) disease activity groups. Clinical measurement for PD such as plaque index (PI), gingival index (GI), probing pocket depth (PPD) and clinical attachment levels (CAL) were performed in total subjects.

Results: Serum resistin levels were significantly increased in active RA patients (DAS28 $\geq$ 3.2; n = 49, median 11.5 ng/mL) compared to inactive RA patients (DAS28 $<$ 3.2; n = 41, 7.3 ng/mL) or healthy control group ($p < 0.01$ and $p < 0.05$ respectively). In total RA patients, serum resistin levels were positively correlated with ESR ($r = 0.25$, $p < 0.05$), CRP ($r = 0.48$, $p < 0.01$) and DAS28 ($r = 0.26$, $p < 0.05$) as well as the severity of PD such as PI ($r = 0.36$, $p < 0.001$) and CAL ($r = 0.29$, $p < 0.01$). Active RA subgroup had more patients with clinically significant PD (n = 40/49, 81.6%) than inactive RA subgroup (n = 22/41, 53.7%; $p < 0.01$) and healthy controls (n = 14/45, 31.1%; $p < 0.001$). Serum resistin levels were also elevated in RA patients with anti-CCP antibody compared to those without (11.28 vs. 8.00 ng/mL, $p < 0.05$).

Conclusion: Serum resistin levels were elevated in active RA patients compared to inactive RA patients or healthy controls, and associated with the severity of PD and the presence of anti-CCP. The present study suggests that resistin may play a role of pathologic cross-link between RA and PD.

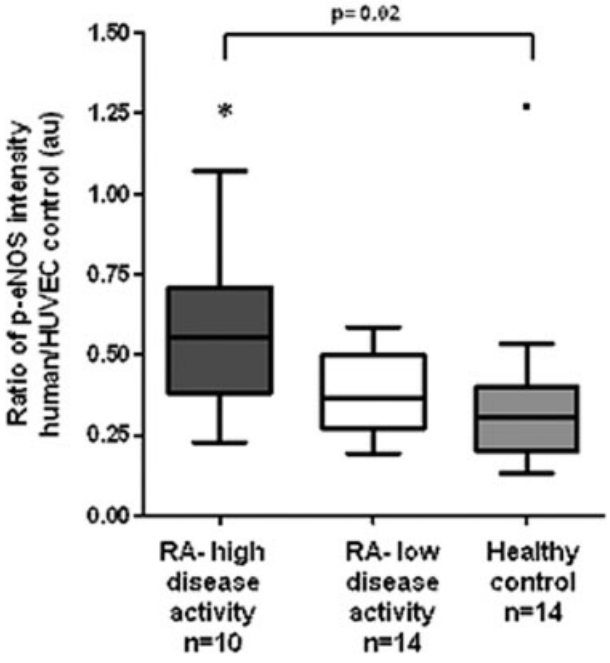
Phosphorylated Venous Endothelial Nitric Oxide Synthase Is Elevated In Rheumatoid Arthritis Subjects With High Disease Activity. Elizabeth Blair Solow, Wanpen Vongpatanasin and David R. Karp. UT Southwestern Medical Center, Dallas, TX.

Background/Purpose: Endothelial dysfunction is present in arthritis animal models and rheumatoid arthritis (RA), a population known to develop premature cardiovascular disease. Previous studies indicate inflammation modulates phosphorylation of endothelial nitric oxide synthase (eNOS) at the S1177 residue leading to endothelial impairment. The expression of eNOS in the RA vasculature has not been assessed. We investigated the hypothesis that subjects with high disease activity RA, defined by an abnormal C-reactive protein and disease activity score (DAS) >3.2, will have reduced levels of eNOS expression as compared to low disease activity RA patients and healthy controls.

Methods: We assessed endothelial function in 10 high disease activity RA, 14 low disease activity RA, and 14 healthy control (HC) subjects by brachial artery flow mediated dilation (FMD) and extracted venous endothelial cells by soft tipped J-wires from forearm catheters. RA subjects met the 1987 ACR diagnostic criteria and were either rheumatoid factor or anti-citrullinated peptide antibody positive. Expression of eNOS and phosphorylated eNOS (p-eNOS) was captured by digital immunofluorescence microscopy using human umbilical vein endothelial cell (HUVEC) controls.

Results: High disease activity RA subjects (mean age 44 years, 86% female) were significantly different from low disease activity (mean age 48 years, 91% female) for DAS (5.55±0.32 vs 2.36±0.16 au p=0.0001) and health assessment questionnaire (0.94±0.14 vs 0.34±0.10 au p=0.002). HC subjects (mean age of 43 years, 79% female) were found to have lower systolic blood pressure compared to high and low disease activity RA subjects (107±1.8 vs 119±3.6 vs 121±2.7 mmHg p=0.004). Body mass index was greater in high disease activity RA compared to low disease activity and HC (32±1.8 vs 26±1.5 vs 25±1.2 au respectively, p=0.008). Methotrexate and biologic medications were used with similar frequencies between RA subject groups (p=0.8 and p=0.7 respectively).

Despite higher levels of C-reactive protein in high disease activity RA (1.9±0.5 mg/dL vs 0.27±0.05, p=0.0001), we found the expression of p-eNOS to be significantly greater as compared to low disease activity RA and HC (0.58±0.08 vs 0.38±0.03 vs 0.36±0.08 au, respectively, p=0.02, see figure). eNOS expression was similar between high and low disease activity RA and HC (0.47±0.05 vs 0.54±0.06 vs 0.35±0.05 au, respectively, p=0.24). FMD percent change in dilation over baseline was similar between high and low disease activity RA and HC (8.5±1.12 vs 9.2±1.65 vs 9.3±1.10 au, respectively, p=0.99).



Conclusion: In conclusion, we show upregulation of p-eNOS expression in high disease activity RA subjects with elevated C-reactive protein. Further studies are required to better understand the molecular mechanisms of endothelial dysfunction in RA that lead to premature cardiovascular disease.

Discovery Of Novel Biomarkers In Rheumatoid Urine: Significance Of Urinary CD14. Yune-Jung Park[1], Hyun-Sook Kim[2], Seung-Ah Yoo[3], Susanna Choi[3], Dong-Ho Kim[4], Chul-Soo Cho[5] and Wan-Uk Kim[5]. [1]Division of Rheumatology, Department of Internal Medicine, The Catholic University of Korea, School of Medicine, Seoul, Korea, Suwon, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Soonchunhyang University of Korea, Seoul, Korea, Seoul, South Korea, [3]Research Institute of Immunobiology, The Catholic University of Korea, Seoul, South Korea, [4]Research Institute of Immunobiology, Catholic Research Institute of Medical Science, Seoul, Korea., Seoul, South Korea, [5]College of Medicine, The Catholic University of Korea, Seoul, South Korea.

Background/Purpose: Current serum measures for assessing rheumatoid arthritis (RA) are invasive and are not highly sensitive to changes in disease activity. Thus, there is a need for the discovery of additional non-invasive biomarkers for RA through an un-biased approach. Here, we postulated that urine may serve as a source of biomarkers that can reflect rheumatoid inflammation.

Methods: We found 134 novel, differentially expressed proteins (DEPs) between RA and osteoarthritis urine samples via proteomics analysis. Cellular processes enriched by DEPs were associated with cell adhesion, immune response, and proteolysis, suggesting that RA patients have inflammatory urine. After integrating the urinary DEPs with gene expression profiles in the joints and mononuclear cells, we identified 12 secretory DEPs that reflect joint pathology.

Results: Of the 12 candidates, we confirmed the increased expression of gelsolin, orosomucoid 1 and 2, and soluble CD14 (sCD14), in the RA urine via immunoassay. Moreover, urinary sCD14 had comparable diagnostic value to conventional serum biomarkers, even higher predictive power for RA activity when combined with serum C-reactive protein (CRP). Finally, we proposed a ratio of serum CRP to urinary sCD14 as a new measure for RA activity and determined a cutoff value (0.06) of the measure that minimizes false positive and negative errors.

Conclusion: This work defines the pro-inflammatory nature of rheumatoid urine, and suggests that urinary proteome profiles in RA offer new diagnostic dimensions beyond current serum parameters for disease activity.

This work was supported by grants from the Korea Healthcare technology R&D Project, the Ministry for Health, Welfare and Family Affairs (No. A092258), and the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology (R31–2008–000–10103–0, R33–2008–000–10064–0, 2009–0080087, NRF-M1AXA002–2011–0028392, and R31–2008–000–10105–0).

Antibodies To *Porphyromonas Gingivalis* Peptidylarginine Deiminase In Rheumatoid Arthritis Are Not Directed Against The Autocitrullinated Enzyme. Maximilian F. Konig[1], Alizay Paracha[2], Malini Moni[1], Clifton O. Bingham III[1] and Felipe Andrade[1]. [1]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [2]The University of Oklahoma, Norman, OK.

Background/Purpose: *Porphyromonas gingivalis* (*Pg*) has received considerable attention by investigators trying to explain the striking association of periodontal disease (PD) and rheumatoid arthritis (RA). Bacterial *Pg* peptidylarginine deiminase (PPAD) has provided an exciting model to mechanistically link bacterial-induced citrullination and loss of tolerance to citrullinated proteins observed in RA. The recent finding that autocitrullinated GST-His-tagged PPAD is preferentially

recognized by antibodies in RA has focused interest on PPAD as a bacterial target of anti-citrullinated protein antibody (ACPA) initiation. This observation would have significant implications on our understanding of RA pathogenesis.

Methods: PPAD was cloned from *Pg strain W83* (ATCC) into pET-28a(+). Mutant PPAD^{C351S} lacking the capacity to autocitrullinate was generated by site-directed mutagenesis. PPAD and PPAD^{C351S} containing only His-tags were purified by affinity chromatography. Patients with RA (n=77) and healthy controls (n=39) were assayed for IgG antibodies to autocitrullinated PPAD (citPPAD) and PPAD^{C351S} by ELISA. To minimize error, antibodies to both citPPAD and PPAD^{C351S} were assayed on the same plate. Arbitrary units were corrected for background from individual sera given by PBS-coated wells. Radiolabeled PPAD generated by in vitro transcription/translation was immunoprecipitated by RA sera. Antibodies to cyclic citrullinated peptides (CCP) were assayed by QUANTA Lite CCP3 IgG ELISA (INOVA). Correlation between anti-CCP3 units and anti-PPAD levels was analyzed using Spearman's correlation. Statistical analysis of PPAD ELISA groups was performed using the Wilcoxon and Mann-Whitney test, when appropriate.

Results: PPAD, but not PPAD^{C351S}, demonstrated prominent autocitrullination when expressed in *E. coli* BL21(DE3). Antibodies to citPPAD and PPAD^{C351S} did not differ significantly among patients with RA (p=0.89; Fig. 1A). Correlation of citPPAD and PPAD^{C351S} antibody levels was highly significant (r=0.99, p<0.0001; Fig. 1B). Anti- citPPAD and anti-PPAD^{C351S} levels were not significantly different in RA compared to controls (p=0.16). Anti-CCP3 antibodies were found in 74% of RA patients (57/77), and levels were not correlated with anti-citPPAD or anti-PPAD^{C351S} (r=0.04, p=ns; r=0.07, p=ns). Sera from RA patients with high titer anti-CCP3 did not immunoprecipitate radiolabeled PPAD.

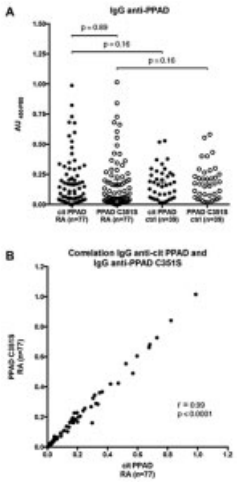

Fig. 1. Antibodies to citPPAD and PPAD^{C351S} in RA and healthy controls.

Conclusion: Anti-PPAD antibodies are present in RA, but demonstrate no preferential reactivity to autocitrullinated PPAD. Levels of anti-PPAD do not differ significantly between RA and controls. Anti-CCP antibodies do not correlate with anti-PPAD levels in RA, and do not cross-react with PPAD. Our findings suggest that PPAD autocitrullination is not the underlying mechanism linking *Pg*-associated PD and RA.

The Transmembrane Protein Tyrosine Phosphatase Kappa Promotes Aggressiveness Of Rheumatoid Arthritis Fibroblast-Like Synoviocytes. Stephanie M. Stanford[1], William B. Kiosses[2], Amanda M. Campbell[1], Michael F. Maestre[1], David L. Boyle[3], Gary S. Firestein[3] and Nunzio Bottini[1]. [1]La Jolla Institute for Allergy and Immunology, La Jolla, CA, [2]The Scripps Research Institute, La Jolla, CA, [3]UCSD School of Medicine, La Jolla, CA.

Background/Purpose: Fibroblast-like synoviocytes (FLS) in the synovial intimal lining are key mediators of inflammation and joint destruction in rheumatoid arthritis (RA). In RA these cells assume a tumor-like phenotype, aggressively invading the extracellular matrix and producing cartilage-degrading proteases and inflammatory cytokines. The behavior of synovial fibroblasts is controlled by multiple interconnected signal transduction pathways involving reversible protein phosphorylation. However, little is known about the role of protein tyrosine phosphatases (PTPs) in FLS function. The objective of this study was to identify PTPs involved in the aggressive phenotype of RA FLS.

Methods: Comparative screening was conducted of PTP expression in FLS from patients with RA or osteoarthritis (OA) by quantitative polymerase chain reaction (PCR). The functional effect on RA FLS of protein tyrosine phosphatase kappa (RPTPκ), a transmembrane PTP that was up-regulated in RA, was then analyzed by knockdown using cell-permeable antisense oligonucleotides (ASO). Transwell FLS invasion assays were performed with Matrigel-coated inserts, using fetal bovine serum or platelet-derived growth factor as chemoattractants. FLS adhesion and spreading was assessed by F-actin staining with phalloidin and visualized by immunofluorescence microscopy. Expression levels of matrix metalloproteinases (MMPs) were quantified by qPCR. Western blotting of cell lysates using phosphospecific antibodies was used to assess activation of signaling pathways. Cell survival was measured by flow cytometry following staining with propidium iodide and Annexin V.

Results: Expression of *PTPRK*, encoding the protein tyrosine phosphatase RPTPκ, was increased in RA (n=16) compared to OA (n=15) FLS (1.99±0.68 fold increase, p<0.05). RPTPκ, a proposed transforming growth factor β (TGFβ) dependent gene, belongs to a family of PTPs that mediate cell-cell adhesion through homophilic interaction between their extracellular domains. We found that *PTPRK* expression is induced by stimulation of RA FLS with 50 ng/ml TGFβ1 for 24 hours (1.91±0.45 fold increase, p<0.05). Subsequent studies focused on the functional role of RPTPκ in RA FLS. Knockdown of this PTP with ASO led to impaired cell invasion (67.8±16.5% decrease, p<0.05). Although cell adhesion to an extracellular matrix was unaffected, RPTPκ deficiency disrupted cell spreading (40.2±12.7% decrease, p<0.05). RPTPκ-deficient RA FLS displayed more than 2-fold decreased TNF (50 ng/ml) or TGFβ-mediated induction of *MMP1*, *MMP8*, *MMP10*, *MMP13* and *MMP14*, which correlated with reduced induction of JNK phosphorylation.

Conclusion: These findings indicate a novel role for RPTPκ as a key mediator of FLS function. RPTPκ promotes the invasiveness of RA FLS and, due to its higher expression in RA compared with OA FLS, could contribute to the unique "transformed" phenotype of rheumatoid cells. Therefore RPTPκ could be a novel therapeutic target for RA.

CDK6 Transcripts Expression Control By The Synoviocyte Proliferation Gene, SPACIA1. Rie Komatsu[1], Ryoji Fujii[1], Tomoo Sato[1], Yoshihisa Yamano[1], Kazuo Yudoh[1], Moroe Beppu[1], Kusuki Nishioka[2] and Toshihiro Nakajima[3]. [1]St. Marianna University School of Medicine, Kanagawa, Japan, [2]Tokyo Medical University, Tokyo, Japan, [3]Misato Marine Hospital, Kohchi, Japan.

Background/Purpose: SPACIA1 is a novel gene associated with abnormal synovial proliferation. We have already shown that SPACIA1 could be involved in the progression of synovitis *in vivo*. We previously reported that *SPACIA1* siRNA inhibited the proliferation of rheumatoid arthritis synovial fibroblasts (RASFs) and delayed the cell cycle at the G1 phase. These findings indicate that SPACIA1 is tightly linked to functional genes at the G1 phase; however, the molecular mechanism is still unclear. In particular, *CDK6* was found by transcriptome analysis to be downregulated in RASFs that were transfected with *SPACIA1* siRNA **(Fig. 1.)**. In the present study we investigated the mechanisms involved in the SPACIA1-related regulation of CDK6 gene expression *in vitro*.

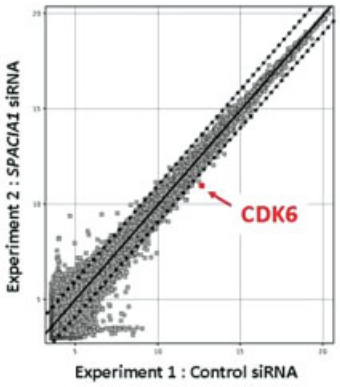

Fig. 1. Expression profiling reveals downregulation of *CDK6* by SPACIA1 siRNA in RASFs. Linear scatter plot of gene expression measured by transcriptome analysis.

Methods: RASFs were transfected with control siRNA or *SPACIA1* siRNA. Seventy-two hours after transfection, we examined the expression of several key regulators of G1 phase mRNA and protein production by qRT-PCR and Western blot analysis, respectively. To determine the processes responsible for SPACIA1 down-regulation of CDK6 expression, the basal luciferase activity of pGV-basic2 luciferase reporter-containing the *CDK6* 5'-upstream region was analyzed by luciferase assay in cells treated with control siRNA or *SPACIA1* siRNA. To determine whether the stability of *CDK6* mRNA is regulated by *SPACIA1*, we compared mRNA decay rates of *CDK6* transcripts analyzed by qRT-PCR at different time points following control/*SPACIA1* siRNA- and actinomycin D (Act-D)-treatment.

Results: Among the key regulators of the G1 phase, the only gene to be significantly reduced by *SPACIA1* siRNA was *CDK6,* which was reduced to half of its control expression. The basal luciferase activity of the reporter containing the Cdk6 5'-upstream region averaged 8 to 10-fold higher activity than the promoter-less pGV-basic2 luciferase vector. The *Cdk6* 5'-upstream region could function as a promoter, however, CDK6 promoter activity was not affected by *SPACIA1* knockdown. Knockdown of *SPACIA1* accelerated the degradation of *CDK6* mRNA in the presence of Act-D relative to control siRNA. After 60min of Act-D treatment, 40% of *CDK6* mRNA was reduced by *SPACIA1* siRNA, but, not control siRNA. This indicates that SPACIA1 is involved in regulation of *CDK6* mRNA decay.

Conclusion: We identified that SPACIA1 regulates the functional gene, *CDK6*, at the G1 phase, and found that the presence of SPACIA1 is due to alterations in *CDK6* mRNA turnover.

Pleiotropic Roles Of Fcγ Receptors Upregulated On Circulating Monocytes In Rheumatoid Arthritis Patients. Masako Tsukamoto, Katsuya Suzuki, Keiko Yoshimoto, Hideto Kameda and Tsutomu Takeuchi. Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: We have previously demonstrated that Fc gamma receptor (FcγR) IIIb(CD16b) polymorphisms were associated with infusion reaction in rheumatoid arthritis(RA) patients. While CD16b is mainly expressed on the surface of neutrophils, mast cells, role of FcγRs on monocytes in RA patients has not been fully elucidated. We hypothesized that FcγRs might play important roles in the interaction between immune complexes and monocytes. Aim of this study is to elucidate role of FcγRs expressed on monocytes and determine their clinical significance in RA patients.

Methods: Heparinized venous blood was obtained from 48 RA patients and 12 healthy controls (HC). Surface expression of CD16 (FcγR III), CD16b, CD32(FcγRII) and CD64(FcγRI) molecules on CD14+ cells were measured by flow cytometry FcγR.

Conclusion: We found CD16 and CD64 were aberrantly upregulated on CD14+ monocytes in RA patients. Clinically, CD16b upregulation together with its functional polymorphism may participate in adverse reaction such as infusion reaction, and CD64 and CD16a rather may relate to inflammation and autoantibody production in RA.

Association Between Physical Work Load and Rheumatoid Arthritis, Results From The EIRA Case Control Study. Annmarie Wesley[1], Henrik Källberg[2], Camilla Bengtsson[2], Eva Skillgate[1], Johan Rönnelid[3], Mohammed Mullazehi[3], Lars Klareskog[4], Lars Alfredsson[2], Saedis Saevarsdottir[4] and Sara Wedren[5]. [1]Karolinska Insitutet, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]Uppsala University, Uppsala, Sweden, [4]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [5]Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden.

Background/Purpose: The association between occupation and RA has previously been investigated where occupations associated with a physical work load (quarry workers, construction workers, assistant nurses, freight, and transport workers) have shown association with risk of developing RA. From a biological standpoint physical challenges to the joint and ensuing tissue injury may expose antigenic molecules that could trigger and /or perpetuate local activation of the immune system.

The aim of present study was to investigate the association between physical work load and the risk of developing rheumatoid arthritis (RA) with and without antibodies against cyclic citrullinated peptide (anti-CCP) and against native type II collagen (anti-CII).

Methods: A population based case-control study of individuals aged 18 to 70 years, living in geographically defined parts of Sweden between May 1996 and November 2009. We included incident cases (n=2268) diagnosed by rheumatologists according to the American College of Rheumatology 1987 criteria for RA and controls, matched to cases by age, sex, and area of residence (n=3176). All answered an extensive questionnaire, including questions about physical work load five years prior to study inclusion. In addition, we classified the individuals with regard to physical work load using Nordic Occupational Classification Code (NYK). We calculated odds ratios (OR) and 95% confidence intervals (CI) associated with physical work load by means of unconditional logistic regression models adjusted for matching factors, smoking, and education. Anti-CCP and anti-CII were measured by ELISA.

Results: Perceived physical work load was significantly associated with RA independent of anti-CCP-status OR 1.3 (95% CI 1.2–1.5) for anti-CCP positive RA and OR 1.5 (95% CI 1.3–1.8) for anti-CCP negative RA. The association was more pronounced in men. The occurrence of anti-CII showed no association to physical work load among RA patients.

Conclusion: Physical work load is associated with an increased risk to developing RA irrespective of anti-CCP status.

Anti-*P. Gingivalis* antibody Is Correlated With Severity Of Periodontitis But Not With Rheumatoid Arthritis Disease Activity In RA. Joo Youn Lee[1], In Ah Choi[2], Jin-Hee Kim[3], Kyung-Hwa Kim[4], Hye Jin Oh[5], Myeong Jae Yoon[6], Eun Young Lee[2], Eun Bong Lee[2], Yong-Moo Lee[3] and Young Wook Song[1]. [1]Department of Molecular Medicine and Biopharmaceutical Sciences, Seoul National University, Seoul, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University, Seoul, South Korea, [3]Department of Periodontology, School of Dentistry, Seoul National University, Seoul, South Korea, [4]Department of Periodontology and Dental Research Institute, School of Dentistry, Seoul National University, Seoul, South Korea, [5]Seoul National University, Seoul, South Korea, [6]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, South Korea.

Background/Purpose: Periodontitis (PD) has been suggested to be one of risk factors for rheumatoid arthritis (RA). *Porphyromonas gingivalis* (*P. ginvivalis, Pg*) is a gram-negative anaerobic bacterium that is recognized as a major pathogenic organism in periodontitis (PD). Anti-enolase 1 (ENO1) antibody is one of the autoantibodies in RA./This study examined the relationship between serum levels of anti-*Pg* and anti-ENO1 antibodies and PD severity and RA disease activity in patients with RA.

Methods: 248 Patients with RA and 85 age-, sex- matched non-RA controls were enrolled in this study. After rheumatologic and periodontal examination, serum levels of anti-*Pg* antibodies and anti-ENO1 antibodies were measured by enzyme-linked immunosorbent assay (ELISA).

Results: Patients with RA showed significantly higher levels of anti-*Pg* antibodies and, anti-ENO1 antibodies than controls ($P = 0.0082$, $P < 0.0001$). Anti-*Pg* antibodies were strongly correlated with anti-ENO1 antibodies in RA patients ($p<0.0001$). In active RA, there were significant correlations between anti-*Pg* antibodies with probing pocket depth (PPD), bleeding on probing (BOP) and clinical attachment level (CAL) ($P = 0.0015$, $P=0.006$, $P=0.0004$). However, there were no correlations of anti-*Pg* antibodies and periodontal parameters in controls and inactive RA. Anti-ENO1 titer did not correlate with periodontal parameters except bleeding on probing (BOP) in RA. Anti-*Pg* antibodies were not correlated with RA disease activity except ESR ($p= 0.0175$). However anti-ENO1 antibodies were significantly correlated with ESR, DAS28-ESR, anti-CCP titer ($P= 0.0008$, $P= 0.0092$, $P= 0.0129$).

Conclusion: Anti-*Pg* antibodies and anti-ENO1 antibodies were elevated in RA patients than controls. Anti- *Pg* antibodies were correlated with severity of PD and anti-ENO1 antibodies were correlated with RA disease activity in RA patients.

Mir-27b As Biomarker and Regulator Of IL-6R Pathway In Resistant Rheumatoid Arthritis Monocyte. Marina Frleta, Ashleigh-Ann Rainey, Derek S. Gilchrist, Lynn Crawford, Derek Baxter, Mariola Kurowska-Stolarska and Prof Iain B. McInnes. University of Glasgow, Glasgow, United Kingdom.

Background/Purpose: Whereas molecular mechanisms mediating treatment responses to biologic DMARDS in Rheumatoid Arthritis (RA) are emerging, those pathways that subserve treatment resistance are poorly explored. MicroRNAs (miRs) post-transcriptionally regulate different elements of given signal pathways, and as such capture a 'snapshot' of the cell state. We previously assembled a cross-sectional cohort of RA patients with distinct therapy response characteristics including rapid sustained response to conventional (c)DMARD, cDMARD failure and recurrent DMARD (conventional and biologic) resistance. We sought herein to identify dysregulated miR species in therapy resistant patients.

Methods: Peripheral blood (PB) CD14+ monocytes were isolated from three groups of RA patients meeting ACR 2010 criteria: good responders to cDMARD (n=20), failing cDMARDs (n=17) or resistant to biologic agents (n=30). Comparative samples from age-matched healthy volunteers (n=23) were obtained. Candidate miR profiling (based on cytokine receptor targeting miRs) was performed using real-time quantitative PCR. Potential miR-27a/b targets were identified using TargetScan with transcriptional pathway analysis data from PB RA CD14+ cells and functionally validated by Luciferase reporter assay. THP-1 cells were transfected with control or miRNA-27a/b antagomiR and membrane IL-6R expression evaluated by flow cytometry.

Results: We identified that miR-27b was significantly down-regulated in sorted CD14+ monocytes obtained from cDMARD failure and biologic treatment resistant, compared to cells from patients responding well to cDMARD and HV ($p<0.03$). Elevated levels of serum IL-6 were evident in both therapy resistant groups ($p<0.001$). TargetScan identified several potential miR-27 targets in the IL-6R signal pathway, including soluble and membrane bound variants of IL-6 receptor (IL-6R). Both IL-6R isoforms were confirmed as direct targets of miR-27a/b by luciferase reporter assay. Inhibition of endogenous miR-27a/b via antagomiR in THP-1 cells (myeloid line) significantly increased surface levels of Il-6R ($p=0.05$, n=4), demonstrating that miR-27a/b actively regulates membrane IL-6R expression.

Conclusion: Together our data uncover a previously unrecognized miR-27:IL-6R pathway interaction that operates particularly in monocytes of RA patients with active or treatment refractory disease. Our study thereby identifies a potential new biomarker and functional mechanism associated with disease chronicity.

Investigation Of The Role Of Histone Deacetylases In Rheumatoid Arthritis Synovial Fibroblasts. Sarah Hawtree, Munitta Muthana, Sarah Aynsley, J. Mark Wilkinson and Anthony G. Wilson. University of Sheffield, Sheffield, United Kingdom.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, autoimmune, inflammatory disease that affects synovial joints. A key characteristic of RA is hyperplasia of fibroblast-like synoviocytes (FLS). These FLS develop an aggressive phenotype that augments tissue destruction and it is not currently known how their phenotype is stably maintained, however epigenetic changes have been implicated. Histone deacetylases (HDACs) are key enzymes that contribute to the epigenetic signature through changes in the acetylation status of histones. Recent studies have reported conflicting evidence of HDAC activity in RA synovium and FLS; however promising results were obtained using HDAC inhibitors in murine arthritis models and human juvenile arthritis. Further investigations into the specific role of individual HDACs in RA are required and may allow discovery of more specific therapeutic targets. Our aim is to determine the role of HDACs in maintaining the autoaggressive phenotype of RA FLS.

Methods: Fresh synovial biopsies obtained from RA and osteoarthritis (OA) patients were used to isolate FLS following digestion with collagenase-1. Real time-qPCR (RT-qPCR) was used to assess the levels of HDAC1–11 in RA FLS compared to OA FLS. To determine the cellular localization of HDACs, sections from patient arthroscopies were co-stained with anti-HDACs and anti-fibroblast antibody. In addition, HDACs and a non-targeting control (NTC) were knocked down in FLS using siRNA transfection; this was confirmed by RT-qPCR and western blotting. Cell viability after knockdown was assessed by flow cytometry using annexin V/propidium iodide dual staining. Cell invasion and migration after knock down were assessed using a matrigel invasion assay and a scratch assay, respectively.

Results: The mRNA levels of HDACs 1–11 are higher in RA compared to OA, with HDAC1 levels showing the greatest difference (4.3-fold higher). A 65% knockdown of HDAC1 ($HDAC1^{KD}$) mRNA was achieved using siRNA compared to a NTC (n=3 patients) and this did not affect cell viability (n=6) (>95.5% viable $HDAC^{KD}$ cells vs. >95% viable NTC cells). Using the matrigel invasion assay we found that $HDAC1^{KD}$ reduced the number of FLS invading the Matrigel ($p=0.02$) compared to the NTC (n=6). Also $HDAC^{KD}$ reduced the number of FLS migrating ($p=0.01$) compared to the NTC (n=6).

Conclusion: HDAC1 expression is increased in RA FLS compared to OA FLS. Knocking down HDAC1 in RA FLS does not affect cell viability but does reduce their ability to invade and migrate, suggesting that HDAC1 may contribute to the invasiveness and migration potential of RA FLS. Further

work will determine the effects of HDAC1 knockdown in FLS on proliferation and the expressed genome.

Impaired TNFá Production By Dendritic Cells From Rheumatoid Arthritis Patients Upon Contact With Porphyromonas Gingivalis. Kim CM Santegoets, Mark H. Wenink, Wim B van den Berg and Timothy RDJ Radstake. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: The prevalence of periodontitis is increased in patients with rheumatoid arthritis (RA) and the severity of periodontitis can affect the level of arthritis. Porphyromonas gingivalis is one of the main bacteria causing periodontitis, it can citrullinate proteins and DNA from this bacterium is present in RA synovium. Our aim was to determine if there are differences in the innate immune response against P. gingivalis between healthy controls and RA patients.

Methods: We isolated monocytes from healthy controls, RA patients and psoriatic arthritis (PsA) patients and cultured them into monocyte-derived dendritic cells (DCs). DCs were stimulated with a set of bacteria possibly involved in RA (range of gram-negative and positive bacteria) including the periodontal bacteria P. gingivalis and Prevotella intermedia and single Toll-Like receptor (TLR) agonists (e.g. Pam3CSK4 and LPS). To determine which pathways could be involved in the different response between RA patients and healthy controls, P. gingivalis stimulation was performed in the presence of CXCR4 or CR3 blocking antibodies.

Results: TNFα production was significantly decreased by DCs from RA patients as compared to healthy controls upon stimulation with P. gingivalis, but not with any of the other bacteria tested. PsA patients were included as a diseased control group and did not differ from healthy controls, suggesting a RA specific deregulated response to P. gingivalis. The TNFα production upon P. gingivalis stimulation was similar in all medication groups and was not correlated with the presence of autoantibodies, disease activity or erosions. P gingivalis is mainly recognized via TLR2 and TLR4, of which the signaling pathways can be affected by simultaneous binding of the bacterium to CXCR4 or CR3. All these receptors were not differentially expressed between RA patients and healthy controls. Cytokine production upon specific TLR2 and TLR4 stimulation were not different between patients and controls and P. gingivalis stimulation was not affected by blocking of CXCR4. Blocking of CR3 however decreased the TNFα production by DCs from healthy controls to the level of the RA patients. The TNFα production in RA patients was not significantly decreased further by blocking of CR3, indicating that decreased signaling via CR3 is involved in the aberrant TNFα response towards P. gingialis by DCs from RA patients.

Conclusion: DCs from RA patients produce less pro-inflammatory cytokines upon P. gingivalis stimulation, which may be caused by defective CR3 signaling. The decreased cytokine response to P. gingivalis could facilitate its survival subsequently leading to a chronic systemic inflammatory status and the breakthrough of tolerance thereby facilitating RA onset.

Signaling Abnormalities In Neutrophil Granulocytes Of Rheumatoid Arthritis Patients Are Associated With Increased Extracellular Trap Formation and Provide a Basis For The Induction Of Anti-Citrullinated Peptide Antibodies. Chanchal Sur Chowdhury[1], Stavros Giaglis[1], Ulrich A. Walker[1], Andreas Buser[1], Paul Hasler[2] and Sinuhe Hahn[1]. [1]University Hospital Basel, Basel, Switzerland, [2]Kantonsspital Aarau, Aarau, Switzerland.

Background/Purpose: Rheumatoid arthritis (RA) is often associated with anti-citrullinated peptide antibodies (ACPAs) in the serum. While ACPAs have been associated with increased inflammation, joint destruction and reduced response to therapy, the mechanisms leading to the citrullination of arginine residues by peptidyl arginine deiminase (PAD) isozymes 2 and 4 on ACPA target antigens have remained unclear. PAD2 and PAD4 are present in polymorphonuclear granulocytes (PMNs), which represent the primary part of the leukocyteinfiltrate in the RA joint. Citrullination of histone by PAD4 is critical for neutrophil extracellular trap (NET) formation[1,2].

In the present study, we sought to investigate the signaling pathway leading to histone modification and NET extrusion in RA neutrophils.

Methods: Peripheral blood neutrophils from active RA patients and control subjects were isolated. Reactive oxygen species (ROS) production was evaluated by FACS utilizing a DCFH-DA assay. Spontaneous NET formation from RA and control neutrophils was observed by scanning electron (SEM) and SytoxGreen fluoresence microscopy. Combined immunostaining with anti-myeloperoxidase (MPO), anti-neutrophil elastase (NE), anti-PAD2, anti-PAD4, anti-citH3, anti-H1-core histones antibodies and staining with DAPI were applied for detailed characterization of the process. Protein translocation was confirmed by Western blotting.

Results: Peripheral blood PMNs from RA cases exhibited increased spontaneous NET formation *in vitro* assessed by fluorescence and SEM. This was associated with enhanced NE and MPO message and protein expression, elevated ROS production and translocation of PAD4 from the cytoplasm to the nucleus. Moreover, nuclear morphology and lobulation status indicated that RA PMN were in a significantly higher activation state from baseline. PAD4, together with PAD2, was found extruded and co-localized on NETs along with citrullinated histone (citH3) and DNA.

Conclusion: Altered signalling leading to NETosis and the extracellular presence of PAD4 and PAD2 could provide a mechanism for aberrant citrullination of relevant intra- and extracellular proteins and peptides. These findings suggest a novel explanation for *in vivo* autoantigen citrullination as a basis for ACPA induction, and implicate PMNs as key upstream factors in the pathogenesis of RA.

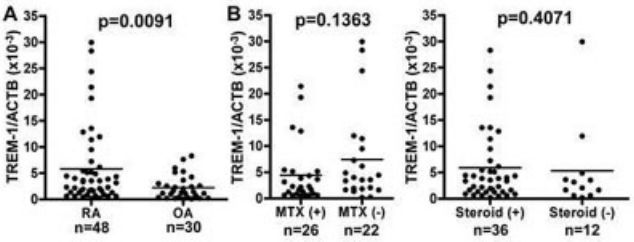
Enhanced Expression Of mRNA For Triggering Receptor Expressed On Myeloid Cells 1 In CD34+ Cells Of The Bone Marrow In Rheumatoid Arthritis. Tatsuo Nagai[1], Tetsuya Tomita[2], Hideki Yoshikawa[2] and Shunsei Hirohata[1]. [1]Kitasato University School of Medicine, Sagamihara, Japan, [2]Osaka University Graduate School of Medicine, Suita, Japan.

Background/Purpose: We previously showed that bone marrow (BM) CD34+ cells from rheumatoid arthritis (RA) patients have abnormal capacities to respond to tumor necrosis factor alpha and to differentiate into fibroblast-like cells producing MMP-1, resembling type B synoviocyte. In addition, we have recently demonstrated that the mRNA expression of nuclear factor kappa B1 (NFkB1) (p50), Krüppel-like factor 5 (KLF-5) and FK506-binding protein 5 (FKBP5) in BM CD34+ cells is significantly higher in RA patients than osteoarthritis (OA) patients. Triggering receptor expressed on myeloid cells 1 (TREM-1) is a recently identified cell surface receptor that is inducible mainly on monocytes and neutrophils, and plays an important role as amplifier of inflammatory response in acute and chronic inflammatory conditions. Recent studies have disclosed increased TREM-1 expression in rheumatoid synovial tissue, and have suggested that TREM-1 ligation contributes to the pathogenesis of RA. The current study therefore examined the mRNA expression of TREM-1 in BM CD34+ cells from RA patients.

Methods: BM samples were obtained from 48 patients with RA (6 males and 42 females: mean age 58.8 years) and 30 patients with OA (3 males and 27 females: mean age 71.1 years), who gave informed consent, during joint operations via aspiration from iliac crest. CD34+ cells were purified from the BM mononuclear cells by positive selection with magnetic beads. The expression of mRNA for TREM-1 was examined by quantitative reverse transcription PCR and is shown as the ratio of the copy numbers to those of beta-actin mRNA.

Results: The expression of mRNA for TREM-1 was significantly higher in RA BM CD34+ cells than OA BM CD34+ cells (Fig. A). The TREM-1 mRNA expression level was not correlated with serum C-reactive protein or with the administration of methotrexate or oral steroid (Fig. B). TREM-1 mRNA expression was significantly correlated with NFkB1 ($r=0.56$, $p<0.0001$), KLF-5 ($r=0.75$, $p<0.0001$) and FKBP5 ($r=0.62$, $p<0.0001$) mRNA expression in RA BM CD34+

cells.



Conclusion: These results indicate that the enhanced expression of TREM-1 mRNA in BM CD34+ cells plays a pivotal role in the pathogenesis of RA, and might be secondary to the enhanced mRNA expression of NFkB1, KLF-5 or FKBP5.

Disclosure: T. Nagai, None; **T. Tomita**, None; **H. Yoshikawa**, None; **S. Hirohata**, None.

Suppression Of Tumor Necrosis Factor Receptor Associated Factor (TRAF) 6 Attenuates The Proinflammatory Effect Of Rheumatoid Arthritis Fibroblast-Like Synoviocytes. Lang Jing Zhu, Jing Jing Zhou, Chan Juan Zou, Dong Hui Zheng, Xiu Ning Wei, Jian Da Ma, Ying Qian Mo and Lie Dai. Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by chronic inflammatory synovitis, leading to invasion of synovial tissue into the adjacent cartilage matrix with degradation of articular cartilage and bone. Fibroblast-like synoviocyte (FLS) in RA synovium plays a key role by producing cytokines that perpetuate inflammation and proteases that contribute to cartilage destruction. Tumor necrosis factor receptor-associated factor 6 (TRAF6) is essential for signaling downstream of IL-1R/TLR superfamily which plays critical roles in the activation and proinflammatory effect of RA-FLS. We have reported that elevated synovial TRAF6 expression in RA correlated significantly with histological synovitis severity and cell density of subintimal mononuclear inflammatory cells. Here we aimed to investigate the TRAF6 expression and its role in the proinflammatory effect of RA-FLS.

Methods: Synovium from inflamed knees of active RA patients, and osteoarthritis (OA) as "less inflamed" disease control was collected by closed needle biopsy, and double immunofluorescence staining of TRAF6 and CD55 were tested. FLS were isolated from active RA synovium or OA synovium by modified tissue culture method. TRAF6 expression in primary cultured RA-FLS or OA-FLS was detected by immunofluorescence staining. TRAF6 in RA-FLS was depleted by Lentiviral-TRAF6-RNAi. The mRNA expression of proinflammatory cytokines, including TNF-a, IL-1β, IL-6 and IL-8, as well as MMP 3 and MMP13, was evaluated by Real-time PCR.

Results:(1) Double immunofluorescence staining showed TRAF6 was obviously expressed in CD55+ cells as well as some other CD55- cells in intimal and subintimal area of RA synovium (Fig 1). (2) Immunofluorescence staining showed obviously higher expression of TRAF6 in RA-FLS than in OA-FLS (Fig 2). (3) Lentiviral-TRAF6-RNAi infection effectively suppressed the expression of TRAF6 in RA-FLS. Suppression of TRAF6 attenuates the mRNA expression of proinflammatory cytokines, including TNF-a, IL-1β, IL-6 and IL-8, as well as MMP3 and MMP13 in RA-FLS.

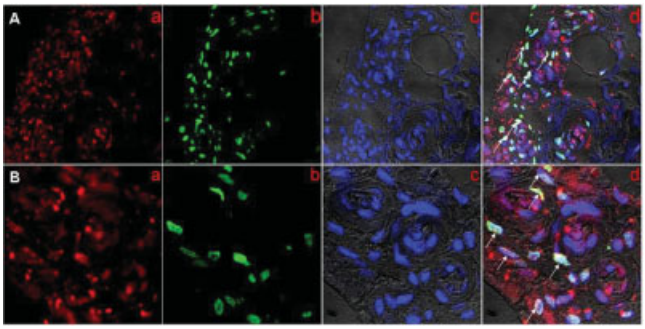

Fig 1. Representative confocal microscopic images showed TRAF6 and CD55 by indirect double immunofluorescence staining in RA synovium (A, original magnification *400; B, original magnification *1200. a, TRAF6 (red); b, CD55 (green); c, DAPI (blue); d, merged a, b with c. The white arrows point to intimal and subintimal CD55/TRAF6 double+ cells).

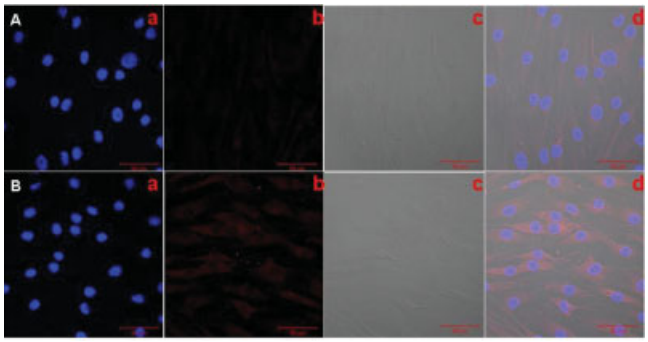

Fig 2. Immunofluorescence staining of TRAF6 in primary cultures of FLS from OA and RA patients. RA-FLS stained significantly positive with TRAF6 than OA-FLS (A: OA-FLS, B: RA-FLS; original magnification *400. a, DAPI (blue); b, TRAF6 (red); c, neutral light; d, merged a, b with c).

Conclusion: Elevated TRAF6 was involved in the pathogenesis of synovial inflammation and the proinflammatory effect of RA-FLS. TRAF6-blocking might provide novel target for the treatment of RA.

Enhanced Responsiveness To Stimulation and Increased Extrusion Of Extracellular Traps By Rheumatoid Arthritis Neutrophil Granulocytes and of Healthy Control Neutrophils to Serum and Synovial Fluid From Rheumatoid Arthritis Patients. Stavros Giaglis[1], Chanchal Sur Chowdhury[1], Ulrich A. Walker[1], Andreas Buser[1], Sinuhe Hahn[1] and Paul Hasler[2]. [1]University Hospital Basel, Basel, Switzerland, [2]Kantonsspital Aarau, Aarau, Switzerland.

Background/Purpose: Polymorphonuclear granulocytes (PMNs) are the most abundant immune cell population in the synovial fluid in the joints of patients with rheumatoid arthritis (RA) and appear to play a central role in the inflammatory process leading to destruction of the cartilage.

Upon certain types of activation, PMNs extrude their nuclear content in the form of nucleoprotein threads, known as extracellular traps (NETs), which have extensive pro-inflammatory and immune-stimulatory activities[2].

The focus of the present study was to investigate the responsiveness of RA neutrophils to PMA and of healthy control neutrophils to RA serum and joint fluid.

Methods: Peripheral blood neutrophils from RA patients and control subjects were isolated and cultured with and without the addition of PMA, an established chemical trigger of NET formation. Cl-amidine, a chemical PAD4 inhibitor, was applied for inhibition studies. Spontaneous NET formation was evaluated with simultaneous immunostaining for myeloperoxidase (MPO), neutrophil elastase (NE) and DAPI, immunofluorescence microscopy and morphometry. PMNs from healthy donors were incubated with sera and synovial fluid from RA patients. NET formation by RA and control neutrophils was assessed by combined immunostainings with anti-PAD4, anti-cit-H3 and anti-H1-core histone antibodies, and DAPI. Cell-free nucleosomes were measured by ELISA, and PAD4 protein translocation from the cytoplasm to the nucleus was confirmed by Western blotting.

Results: Freshly isolated neutrophils from patients with RA showed enhanced spontaneous NET release after 3 hours compared to the healthy controls. Intriguingly, the population of neutrophils with delobulated/diffused nuclear phenotype was also remarkably higher in RA from the outset. Moreover, neutrophils derived from RA patients exhibited even higher rates of NETosis and PAD4 nuclear translocation after chemical stimulation with PMA. The effect of PMA was practically abolished by pre-treatment with Cl-amidine, a chemical PAD4 inhibitor, which plays a key role in modifying histones and triggering NETosis. Treatment of control neutrophils with either RA serum or RA synovial fluid augmented the release of NETs significantly compared to cells treated with normal serum or synovial fluid from OA patients, respectively.

Conclusion: RA neutrophils show enhanced NET formation that is mediated by PAD4 and is driven by factors present in the serum and synovial fluid from RA patients. Further investigations will more clearly define the role of NET formation in the innate and adaptive immune responses in RA.

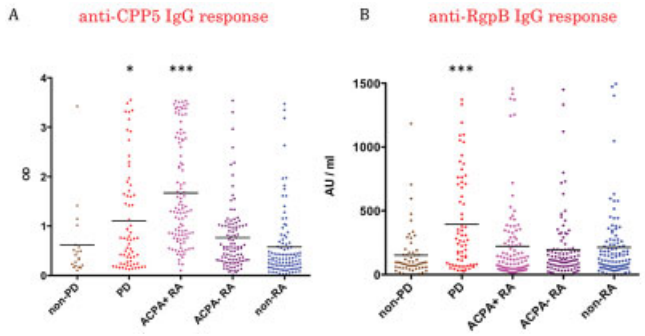
Antibodies To *Porphyromonas Gingivalis* as An Etiological Clue To The Development Of Anti-Citrullinated Protein Antibody Positive Rheumatoid Arthritis. Nastya Kharlamova[1], Natalia Sherina[1], Anne-Marie Quirke[2], Kaja Eriksson[3], Lena Israelsson[4], Jan Potempa[5], Patrick Venables[2], Tulay Yucel-Lindberg[3] and Karin Lundberg[6]. [1]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Kennedy Institute of Rheumatology, Oxford, United Kingdom, [3]Department of Dentistry, Karolinska Institutet, Stockholm, Sweden, [4]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [5]Jagiellonian University, Krakow, Poland, [6]Rheumatology unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Rheumatoid arthritis (RA) is characterized by the production of autoantibodies to citrullinated proteins (ACPA). Citrullinated proteins are generated by the actions of peptidyl arginine deminase (PAD) enzymes during inflammation. Since ACPA can be detected prior to joint symptoms develop, it has been suggested that citrullination and break of tolerance to citrullinated proteins may be triggered outside the joint, potentially at mucosal surfaces. We hypothesize that *Porphyromonas gingivalis*, a major cause of chronic periodontitis (PD) and the only known pathogen to express PAD (*P.*PAD), is etiologically involved in the development of ACPA+ RA. We (Quirke, Potempa and Venables) have recently shown that autocitrullinated *P.*PAD is targeted by antibodies in RA, while arginine gingipain (another *P. gingivalis*-specific protein) is not. We have now investigated these antibody responses in more detail, with an aim to develop a serological test for diagnosing PD and to elucidate the potential link between PD and RA.

Methods: In-house ELISA assays, based on five different citrullinated *P.*PAD peptides (CPP3, 5, 6, 8 and 10), one arginine-containing control peptide (RPP3) and recombinant arginine gingipain protein (RgpB) were used to examine IgG responses in serum from: 102 ACPA+ RA cases; 98 ACPA- RA cases; 100 non-RA controls; 66 patients with confirmed PD; and 60 non-PD controls (confirmed by dentist). Mann-Whitney U-test for independent groups was used to determine statistical differences.

Results: The anti-CPP3 IgG response associated only, strongly and significantly with ACPA+ RA, while no antibody response was recorded towards RPP3. Also anti-CPP6 and 8 IgG showed similar association with ACPA+ RA, while the anti-CPP5 response also associated with confirmed PD (fig 1A). No anti-CPP10 IgG response could be detected in any subgroup. The antibody response towards RgpB associated mainly and significantly with confirmed PD. Compared to non-PD controls, anti-RgpB IgG levels were also increased in ACPA+ RA, ACPA- RA and non-RA controls, although no statistical significance could be detected between the groups (fig 1B).



Conclusion: Based on these results, anti-RgpB IgG could potentially be used as a serological marker to identify PD-cases retrospectively. This would be of great help when investigating the etiological link between PD and RA, or PD and other inflammatory diseases, since validated information on periodontal status is often lacking, while serum cohorts are available. The antibody-response to citrullinated *P.*PAD in RA could be confirmed and evaluated in more detail. This antibody response was confined to ACPA+ RA and specific epitopes, where CPP5 was particularly interesting as antibodies associated with both ACPA+ RA and PD, supporting the hypothesis that PD/*P. gingivalis* may be causatively linked to the development of ACPA+ RA.

Association Of T Follicular Helper / Th17 T Cell and Memory B Cell Populations In Rheumatoid Arthritis With Disease Activity and Therapy With TNF Antagonists. Marc C. Levesque[1], Camilla Macedo[1], Lisa Boyette[1], Kevin Hadi[2], Erich R Wilkerson[1], Diana Metes[1], Larry W. Moreland[1] and Mandy J. McGeachy[2]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Univeristy of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Autoreactive memory B cells and T cells contribute to the pathogenesis of rheumatoid arthritis (RA) through production of antibodies and cytokines that activate monocytes and joint stromal cells. Memory B cells and T cells react to similar citrullinated joint proteins, and have been shown to decrease in response to therapy with TNF inhibitors. However, interactions between these cells have not been interrogated in the same RA patients in relation to disease activity and therapy response.

Methods: We obtained RA PBMC samples from the Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry. 26 subjects were selected based on disease activity (19 patients with active disease (Clinical Disease Activity Index (CDAI) > 2.8) and 7 patients in remission (CDAI ≤ 2.8)). Subjects were treated with methotrexate (MTX) ($n = 14$) or with a TNF inhibitor plus MTX ($n = 12$). Nine healthy subjects served as controls. We performed flow cytometry on PBMC to analyze monocyte and T and B cell subsets. Mann-Whitney tests were used for unpaired comparisons of T and B cell populations from RA subjects and healthy controls. Spearman's rho was determined for correlations of T and B cell populations with disease activity.

Results: The frequencies of peripheral blood classical, non-classical and intermediate monocytes were not different between RA subjects and healthy controls, and were not associated with disease activity or therapy. Of CD4+ T helper (Th) subsets, $CXCR5^{high}$ T follicular helper (TFh)-like cell subsets that co-expressed CCR6 ($CXCR5^{high}$ Th17) were increased in RA compared to healthy controls ($p = 0.0082$), and there was a trend towards increased frequencies of $CXCR5^{high}$ Th17 cells in patients with active disease compared to remission. In contrast, $CXCR3^{+}$TFh cells ($CXCR5^{high}$Th1) showed the opposite pattern, and were decreased in RA patients with active disease ($p < 0.0004$), but unchanged between those in remission and healthy controls. This resulted in significantly higher $CXCR5^{+}$Th17:$CXCR5^{+}$Th1 ratios in active RA patients compared to healthy controls ($p < 0.01$) or to patients in remission ($p < 0.05$). For these T cell populations, there was no association with treatment or between T helper subsets and memory B cell subsets. However, the proportion of isotype-switched memory B cells was positively correlated with disease activity in the MTX group (rho $= 0.54$, $p = 0.05$) but not TNF inhibitor plus MTX group (rho $= 0.37$, $p = 0.24$).

Conclusion: TFh/Th17 cells and memory B cells were both increased in RA while TFh/Th1 cells were decreased in active RA. Disease activity correlated with class-switched memory B cells in subjects treated with MTX but not with TNF antagonists. Although TNF inhibitors have been reported to decrease Th17 cell populations, our results suggest that disease activity rather than therapy may have a greater effect on frequencies of TFh/Th17 and TFh/Th1 cells.

Characterization Of Lung Inflammation and Identification Of Shared Citrullinated Targets In The Lungs and Joints Of Early RA. Vijay Joshua[1], Gudrun Reynisdottir[1], Jimmy Ytterberg[2], Marianne Engström[1], Anders Eklund[3], Magnus Skold[3], Per-Johan Jakobsson[1], Johan Rönnelid[4], Vivianne Malmström[5], Lars Klareskog[1], Johan Grunewald[3] and Anca I Catrina[1]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [2]Rheumatology Unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [3]Division of Respiratory Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [4]Uppsala University, Uppsala, Sweden, [5]Rheumatology unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden.

Background/Purpose: To investigate if lung changes are present in rheumatoid arthritis (RA) patients early in the disease process and to address the contribution of these changes to disease initiation.

Methods: 24 RA patients with patient-reported symptom duration less than 1 year and naive to DMARD treatment and 9 healthy individuals were subjected to bronchoscopy and mucosal large bronchial biopsies were retrieved. Histological analysis for identification of inducible bronchia associated lymphoid tissues (iBALT) and lymphocyte infiltration, as well as immunohistochemistry for PAD enzymes, CD3, HLA-DQ and HLA-DR were performed. Presence of citrullinated targets were detected by immunohistochemistry using biotinylated ACPA isolated from synovial fluid of RA patients. Mass spectrometry was used for identification of citrullinated epitopes in 6 of the lung biopsies and additional 8 synovial RA biopsies. An in house ELISA was set-up to measure reactivity against new identified citrullinated targets in the blood of RA patients in two distinct cohorts (in total 250 individuals).

Results: Bronchial lymphocyte infiltration and iBALT formation was observed in half of the ACPA+ RA patients but only 1 out of 6 ACPA- patients (17%) and 1 out of 9 healthy volunteers (10%). Higher expression of CD3, HLA-DQ, HLA-DR and citrullinated targets was observed in bronchial biopsies of ACPA+ as compare to ACPA- RA. BAL fluids were enriched in both IgG and IgA ACPA as compared to paired serum samples. Mass spectometry identified 5 proteins in the synovium (in total 8 sites) and 4 in the lungs (in total 6 sites) containing citrullinated residues. Two vimentin derived citrullinated peptides were present in a majority of both synovial and lung biopsies with slightly higher citrullinated/unmodified peptides ratios in the smokers as compared to non-smokers. An average of 15% of the RA patients tested by ELISA showed antibody reactivity against one of the new identified citrullinated target.

Conclusion: Signs of inflammation and local ACPA enrichment are present early in bronchial tissues of ACPA+ RA patients. Shared citrullinated targets in the lung and joints as well as systemic reactivity against these targets are present in RA patients. Our findings support the notion that early inflammatory events in the lungs may represent a critical initiating factor in the development of ACPA+ RA.

Evaluation Of The Two-Step Referral Strategy For Axial Spondyloarthritis In The Spondyloarthritis Caught Early Cohort. Ozair Abawi[1], Rosaline van den Berg[1], Désirée van der Heijde[1], Manouk de Hooge[1], Pauline Bakker[1], Monique Reijnierse[1], Tom Huizinga[1], Juergen Braun[2] and Floris van Gaalen[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Rheumazentrum Ruhrgebiet, Herne, Germany.

Background/Purpose: Currently, in primary care no satisfactory referral model exists for referral to the rheumatologist of patients with chronic back pain (CBP) with possible axial spondyloarthritis (axSpA). Recently, a non-invasive, inexpensive and easily applicable two-step referral strategy was developed, based on a computer-generated model.[1]The aim of our study was to validate this two-step referral strategy in the SPondyloArthritis Caught Early (SPACE)-cohort.

Methods: In the first step of the referral strategy, the presence of psoriasis, alternating buttock pain (ABP) and improvement of back pain by exercise (IBPE) were registered. If ≥2 of these anamnestic features are present, the patient is referred to a rheumatologist. In the second step, if ≤1 anamnestic feature is present, HLA-B27 testing is performed; if the result is positive, the patient is also referred. The required data was obtained from the SPACE-cohort, in which patients with CBP (≥3 months, ≤2 years, onset <45 years) were included (n=192). The model was tested in this cohort; the performance of the model was evaluated by calculating sensitivity, specificity and likelihood ratios (LR) using classification by ASAS axSpA criteria as external standard.[2] For the patients which were erroneously referred or erroneously not referred, post-test probabilities for axSpA were calculated based on LR products for the presence of SpA features[3], with a LR product of ≥78 which equals a probability of ≥80% defined as cut-off value for probable axSpA.

Results: A total of 74/192 patients had axSpA (ASAS), 61 of which would have been referred according to the strategy, yielding a sensitivity of 82.4%. The 13 false negatives are obligatory HLA-B27 negatives, have ≥1 SpA feature and sacroiliitis on imaging, 3/13 (23%) of which on X-ray. The referral strategy would have referred a total of 93/192 patients, yielding a specificity of 72.9%. Out of the false positive patients, 8/32 (25%) would have been referred erroneously due to HLA-B27 positivity in absence of ≥2 SpA features. Half of these 32 patients (n=16; 50%) had a combination of ABP and IPBE, which are features of inflammatory back pain, which itself is not specific for axSpA. Although none of these false positives fulfil the ASAS axSpA criteria, 6/32 (19%) had probable axSpA (probability ≥80%) (table).

Referred to rheumatologist by referral strategy	axSpA by ASAS criteria Yes	No		
Yes	61	32		
No	13	86		
Sensitivity: 82.4%	Specificity: 72.9%	LR+: 3.04	LR-: 0.24	

Number of anamnestic features present in false positive patients (n=32)	Post-test probability for axSpA 0–20% n (%)	20–50% n (%)	50–80% n (%)	≥80% (probable axSpA) n (%)
3: ABP, IBPE and psoriasis (n=2)	1 (3)	0 (0)	0 (0)	1 (3)
2: ABP and IBPE (n=16)	8 (25)	3 (9)	3 (9)	2 (6)
Psoriasis and IBPE (n=5)	2 (6)	2 (6)	0 (0)	1 (3)
ABP and psoriasis (n=1)	1 (3)	0 (0)	0 (0)	0 (0)
1*: ABP (n=2)	0 (0)	0 (0)	0 (0)	2 (6)
IBPE (n=3)	0 (0)	0 (0)	3 (9)	0 (0)
Psoriasis (n=0)	n/a	n/a	n/a	n/a
0* (n=3)	0 (0)	1 (3)	2 (6)	0 (0)

Number of anamnestic features present in false negative patients (n=13)	Post-test probability for axSpA 0–20% n (%)	20–50% n (%)	50–80% n (%)	≥80% (probable axSpA) n (%)
1: ABP (n=2)	0 (0)	1 (8)	0 (0)	1 (8)
IBPE (n=7)	3 (23)	2 (15)	0 (0)	2 (15)
Psoriasis (n=2)	0 (0)	1 (8)	1 (8)	0 (0)
0 (n=2)	0 (0)	0 (0)	0 (0)	2 (15)

Anamnestic features: ABP=alternating buttock pain; IBPE=improvement of back pain by exercise; psoriasis.
*: These patients are referred due to HLA-B27 positivity, not anamnestic features.

Conclusion: The two-step referral strategy performed well in the SPACE-cohort. These results show the potential of simple referral strategies for the early recognition of axSpA. However, all patients in this study had already been referred to the rheumatologist. Thus, the performance of this model in its target population (i.e. primary care) remains to be addressed in further studies.

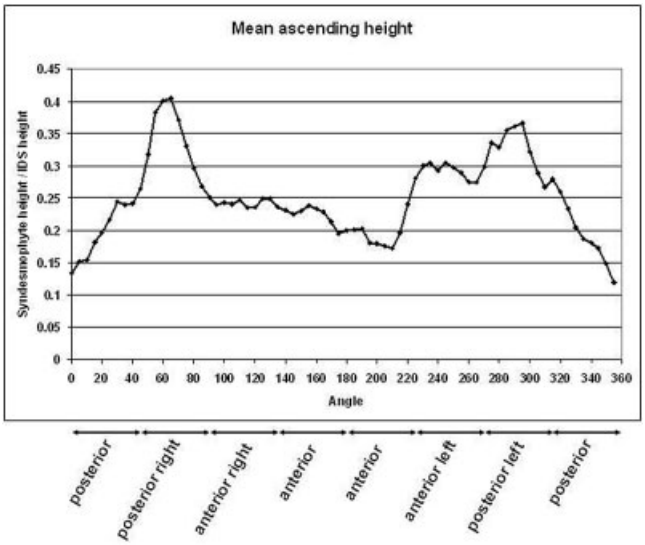
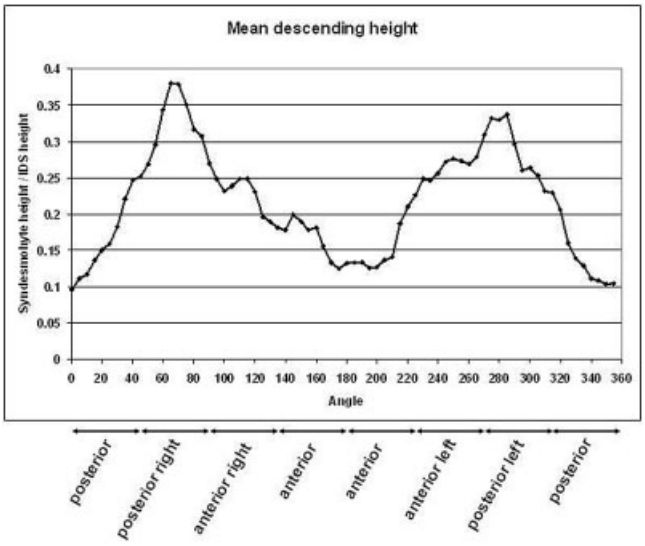
Syndesmophyte Distribution Along The Vertebral Rim In Ankylosing Spondylitis Is Non-Random. Sovira Tan[1], Abhijit Dasgupta[1], Jianhua Yao[2], John A. Flynn[3], Lawrence Yao[2] and Michael M. Ward[1]. [1]NIAMS/NIH, Bethesda, MD, [2]NIH Clinical Center, Bethesda, MD, [3]Johns Hopkins University, Baltimore, MD.

Background/Purpose: Syndesmophytes, the hallmark of structural damage in ankylosing spondylitis (AS), are typically visualized 2-dimensionally by radiographs. However, these projections only allow a limited view of syndesmophytes and their locations along the vertebral rim. With computed tomography (CT), a clear and complete view of syndesmophytes and their precise location is possible. The question immediately arises whether the distribution of syndesmophytes along the vertebral rim is random, as might be suspected if due to inflammation alone, or if they occur more commonly at particular locations. The radial distribution of syndesmophytes along the vertebral rim, if not random, could provide clues about the drivers of syndesmophyte development.

Methods: We scanned 38 patients (31 men and 7 women, mean age of 46.1 years) at the thoracolumbar junction (T10 to L4) using CT, providing 4 intervertebral disk spaces (IDS) per patient for analysis. Syndesmophytes were identified by a computer algorithm that detects them as bone projecting from the periphery of vertebral endplates. We divided the vertebral rim into angular sectors and measured syndesmophyte height every five degrees. We standardized syndesmophyte height by dividing by the height of the disk so that a value of 1 indicated bridging. We plotted radial heights for both ascending and descending syndesmophytes. Bridged syndesmophytes were counted as both ascending and descending. We used the permutation testing for correlated angular data devised by Follmann and Proschan to assess whether the distribution around the rim was uniform or not.

Results: Of 152 IDSs processed, 95 had syndesmophytes. For both ascending and descending syndesmophytes, the mean height distribution along the vertebral rim was non-random ($p<.0001$ for both). The mean radial height plots show that the most common location for syndesmophytes was posterolateral (Figure). The second most common location was anterior left. Ascending syndesmophytes were more frequent and taller than descending syndesmophytes. In a separate analysis, we sorted the 95 IDSs in rank order of increasing fusion. Isolated syndesmophytes and small (early) syndesmophytes were most common in the posterolateral left and posterolateral right locations, suggesting that syndesmophyte growth most often begins at these locations.





Conclusion: The distribution of syndesmophytes along the vertebral rim is strongly non-random, with posterolateral the most common location. The non-random distribution suggests that mechanical factors may be a driver of syndesmophyte growth.

2435

Prevalence Of Inflammatory Lesions MRI-Spine In Patients With Chronic Back Pain Of ≤2 Years Duration Included In The SPACE-Cohort. Manouk de Hooge[1], Rosaline van den Berg[1], Monique Reijnierse[1], Victoria Navarro-Compán[1], Floris van Gaalen[1], Karen Fagerli[2], Maureen C. Turina[3], Maikel van Oosterhout[4], Roberta Ramonda[5], Tom Huizinga[1] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [4]GHZ Hospital, Gouda, Netherlands, [5]University of Padova, Padova, Italy.

Background/Purpose: Inflammatory lesions of the spine are not included in the ASAS definition of a positive MRI for fulfilment of the ASAS axial spondyloarthritis (axSpA) criteria[1]. However, inflammatory lesions in the spine on MRI (MRI-spine) may occur in the absence of affected sacroiliac joints (SIJ). Therefore the aim of this study is to determine the prevalence of inflammatory lesions on MRI-spine and to investigate if axSpA patients with inflammatory lesions in the spine only exist.

Methods: The SPondyloArthritis Caught Early (SPACE)-cohort includes patients with chronic back pain (≥3 months, ≤2 years, onset <45 years) recruited from 5 participating centres in Europe. All patients underwent MRI of the SIJ (MRI-SI) and MRI-spine scored by 3 well-calibrated readers independently. MRI-SI were scored according to the ASAS definition[1] (the presence of ≥1 lesion on ≥2 consecutive slices or the presence of >1 lesion on a single slice). Inflammatory lesions on MRI-spine suggestive of spondylitis were scored when visible on ≥2 consecutive slices and according to the ASAS/OMERACT consensus definition[2] (the presence of ≥3 lesions on ≥2 consecutive slices). Lesions were considered present if 2/3 readers agreed.

Results: All patients with MRI-spine (n=306) were included to determine the prevalence of BME lesions in patients grouped according to the ASAS axSpA criteria (radiographic, non-radiographic (imaging & clinical arm), possible SpA (presence of ≥1 SpA features with a Likelihood Ratio (LR+) of ≥6 or ≥2 SpA features with a LR+ <6) and no-SpA (see table). In 292 patients MRI-SI and MRI-spine data were both available. There were 51 patients with a positive MRI-spine, of which 30 patients (58.8%) had a negative MRI-SI. Nine of these 30 patients fulfilled the ASAS axSpA criteria via the clinical-arm. Of the remaining 21 patients, 3 patients had no SpA features at all, 7 patients had 1 SpA feature, 8 patients had 2 SpA features, 1 patient had 3 SpA features and 2 patients had 4 SpA features. Only the sole patient with 4 SpA features had a probability (calculated from the LR+) ≥80%. When using the ASAS consensus definition of a positive MRI-spine in post-test probability calculations, another 6 patients would reach a probability ≥80% of having axSpA.

MRI-Spine	AxSpA (ASAS axSpA) n=126		Possible axSpA (≥1 SpA features with LR+ ≥6 or 2 with LR+ <6)		No-SpA n=64
	Imaging-arm n=72				
	mNY+ n=26	mNY− n=46	Clinical-arm, n=54	n=116	
BME lesion >1	12 (46.2%)	23 (50%)	17 (31.5%)	29 (25%)	17 (26.6%)
BME lesion >2	10 (38.5%)	16 (34.8%)	11 (20.4%)	21 (18.1%)	9 (14.1%)
BME lesion >3	8 (30.8%)	11 (23.9%)	3 (5.6%)	12 (10.3%)	4 (6.3%)
BME lesion >4	7 (26.9%)	7 (15.2%)	2 (3.7%)	5 (4.3%)	3 (4.7%)
BME lesion >5	6 (23.1%)	4 (8.7%)	1 (1.9%)	3 (2.6%)	2 (3.1%)
BME lesion >6	4 (15.4%)	3 (6.5%)	1 (1.9%)	2 (1.7%)	1 (1.6%)
BME lesion >7	4 (15.4%)	2 (4.3%)	1 (1.9%)	2 (1.7%)	0

Conclusion: A cut-off of ≥3 BME lesions discriminates well between patients with and without axSpA. A positive MRI-spine can be present in patients without inflammation on MRI-SI. MRI-spine might have (limited) additional value to MRI-SI in a group of patients with a certain level of suspicion of axSpA.

2436

Classification Of Axspa Based On Positive Imaging (Radiographs and/or MRI of the Sacroiliac Joints) By Local Rheumatologists Or Radiologists Versus Central Trained Readers In The DESIR-Cohort. Rosaline van den Berg[1], Grégory Lenczner[2], Fabrice Thévenin[3], Pascal Claudepierre[2], Antoine Feydy[3], Monique Reijnierse[1], Alain Saraux[4] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Henri Mondor Teaching Hospital, AP-HP, Créteil, France, [3]Paris Descartes University, Côchin Hospital, APHP, Paris, France, [4]Université Brest Occidentale, Brest, France.

Background/Purpose: Sacroiliitis on MRI and X-rays play an important role in the ASAS axial spondyloarthritis (axSpA) criteria[1]. Though, recognition of sacroiliitis on X-rays (X-SI) and MRI of the sacroiliac joints (MRI-SI) can be challenging, resulting in misinterpretations. Usually the reading in clinical trials is done by ≥1 trained readers. In cohorts it varies and in the DEvenir des Spondylarthropathies Indifferenciées Récentes (DESIR)-cohort, X-SI and MRI-SI at inclusion are read by a local radiologist/rheumatologist. The impact on classification of patients (pts) by local read (LocR) instead of centralized read (CentR) is unknown. We investigated the difference in classification of pts (ASAS axSpA) using LocR versus CentR as external standard.

Methods: In the DESIR-cohort, pts aged 18–50 with inflammatory back pain (IBP; ≥3 months, ≤3 years) were included (n=708). Local radiologists/rheumatologists read all baseline X-SI and MRI-SI; X-SI according to a method derived from the modified New York (mNY) criteria[2] (grade 2 and 3 pooled in one combined grade 'DESIR-2'). Sacroiliitis was defined by at least unilateral ≥DESIR-2. Sacroiliitis on MRI was defined as definite inflammatory lesions in ≥1 SI-joint. Next, 2 well-calibrated central readers independently read all X-SI (original mNY) and MRI-SI (ASAS[3]). An experienced radiologist was adjudicator in case the 2 readers disagreed. An image was marked positive if 2/3 readers agreed. Subsequently, LocR was compared to CentR and to the reads by the central readers separately; pts were classified (ASAS axSpA), using both LocR and CentR (external standard).

Results: Pts with onset IBP <45 and complete X-SI and MRI-SI (n=582) were included. LocR and CentR differed in 163/582 pts (28%; 91 X-SI; 59 MRI-SI; 13 both X-SI and MRI-SI). In 46/582 pts (7.9%), a different read resulted in a different classification; 18 no-SpA pts (3.1%) based on CentR were classified as axSpA using LocR (14 with positive X-SI); 28 axSpA pts (4.8%; 13 mNY+) based on CentR were classified as no-SpA using LocR (table). Among the patients classified as axSpA, additional discrepancies occurred if fulfilling the imaging arm was considered; 16 axSpA/582 pts (2.7%; 8 mNY+) fulfilled the imaging arm based on CentR but fulfilled the clinical arm based on LocR, and 29 axSpA pts (5.0%) fulfilled the clinical arm based on CentR but fulfilled the imaging arm based on LocR (table). Comparisons of LocR versus the separate readers show very similar results (table).

Patients in which the local and centralized read (2/3 readers) differed, n=163			Centralizedread(2/3readers)		
			axSpA (ASAS+)		No SpA (ASAS−)
			Imaging+	Imaging−	
Local reads	axSpA (ASAS+)	Imaging+	72	29	*18*
		Imaging−	16	–	–
	No SpA (ASAS−)		*28*	–	–
Patients in which the local read and central reader 1 differed, n=189			**Central reader 1**		
			axSpA (ASAS+)		No SpA (ASAS−)
			Imaging+	Imaging−	
Local reads	axSpA (ASAS+)	Imaging+	74	28	*18*
		Imaging−	26	–	–
	No SpA (ASAS−)		*43*	–	–
Patients in which the local read and central reader 2 differed, n=170			**Central reader 2**		
			axSpA (ASAS+)		No SpA (ASAS−)
			Imaging+	Imaging−	
Local reads	axSpA (ASAS+)	Imaging+	68	28	*23*
		Imaging−	26	–	–
	No SpA (ASAS−)		*30*	–	–

Only patients in which the local and centralized reads (either X-SI or MRI-SI, or both) differed are selected.
Imaging+ could be either a positive X-SI or a positive MRI-SI, or both positive.
Imaging- indicates that patients fulfil the clinical-arm only.
In the upper part the centralized read (2/3; CentR) is used as external standard to compare the local reads (LocR).
In the lower part the separate readers are used as external standard to compare the local reads (LocR).

Conclusion: Looking at the complete ASAS axSpA criteria, the classification changed in 7.9% of the pts when using LocR instead of CentR. However, when interested in whether pts fulfil the imaging arm or not, changes are seen in an additional 8.2% of the pts resulting in 15.6% of the pts classified differently.

2437

Prevalence Of Axial Spondyloarthritis In The United States Among Patients With Chronic Back Pain and Other Spondyloarthritis-Related Features. Atul Deodhar[1], Philip J. Mease[2], Jeffrey R. Curtis[3], Piyalal M. Karunaratne[4], Kailash Malhotra[4] and Aileen L. Pangan[4]. [1]Oregon Health & Science University, Portland, OR, [2]University of Washington and Swedish Medical Center, Seattle, WA, [3]University of Alabama at Birmingham, Birmingham, AL, [4]AbbVie Inc., North Chicago, IL.

Background/Purpose: The age-adjusted prevalence of spondyloarthritis (SpA) has been estimated to be 0.9–1.4% of the US population using the Amor and ESSG criteria. The objective of this study was to determine the prevalence of non-radiographic axial SpA (nr-axSpA) based on the Assessment of Spondyloarthritis International Society (ASAS) axial SpA criteria among undiagnosed patients (pts) with chronic back pain.

Methods: This is an ongoing, non-drug, multicenter study in the US. Pts previously undiagnosed with SpA, who have had chronic back pain for ≥3 months, with age at onset of <45 years, and at least 1 of the following: 1) positive HLA-B27, 2) current inflammatory back pain, or 3) imaging (MRI or x-ray) evidence of sacroiliitis were included. Pts were either new referrals from other physicians, self-referred, or existing pts in the rheumatologist's clinic. Medical history, physical exam findings, disease activity measures, and laboratory and imaging test results were collected. The rheumatologist was asked if a diagnosis of axial SpA could be made based on this information and the level of confidence with the diagnosis. Data collected were then analyzed independently to determine which patients are classified as nr-axSpA based on fulfillment of the ASAS criteria for axial SpA, but not modified New York (modNY) criteria for ankylosing spondylitis (AS).

Results: As of February 2013, 459 pts have been enrolled (31.6% new referrals, 6.5% self-referred, and 61.9% existing pts at the site). 210 (46%) pts fulfilled ASAS criteria, of whom 146 (32%) were classified as nr-axSpA (fulfilled ASAS but not modNY criteria), 59 (13%) classified as AS (fulfilled ASAS and modNY criteria), and 5 (1%) had missing data that did not allow for evaluation of fulfillment of the modNY criteria. Of those who fulfilled ASAS criteria and had available data, 74% were also given a diagnosis of axial SpA by the investigator (95% of those classified as AS and 64% of those classified as nr-axSpA). In addition, 20% of pts who did not fulfill ASAS criteria were given a diagnosis of axial SpA by the investigator, although the overall level of confidence in the diagnosis was lower for these pts. Demographics and disease characteristics for pts classified as nr-axSpA are presented in the Table.

Table. Baseline Demographics and Disease Characteristics of Patients Classified as nr-axSpA*

Characteristic	nr-axSpA N=146
Gender, n (%)	
Female	76 (52.1)
Age (years)	
Mean (SD)	40 (12.3)
Duration of chronic back pain (months)	
Mean (SD)	166 (145.7)[a]
Age at onset of chronic back pain (years)	
Mean (SD)	27 (9.3)[a]
Human leukocyte antigen-B27 (HLA-B27), n (%)	
Positive	110 (75.3)
Bath AS functional index (BASFI)	
Mean (SD)	4.4 (2.6)
Bath AS disease activity index (BASDAI)	
Mean (SD)	5.9 (2.1)
AS Disease Activity Score (ASDAS)	
Mean (SD)	2.3 (0.8)[b]
hs-CRP or CRP, category	
Elevated	48 (34.3)[b]
Missing	6

*fulfilled ASAS but not modNY criteria
[a]n=144. [b]n=140

Conclusion: Almost half of pts enrolled with chronic back pain and at least 1 SpA-related feature were classified as having axial SpA based on ASAS criteria. Two-thirds of these axial SpA pts had nr-axSpA, with an average of 14 years of symptoms, indicating a substantial delay in diagnosis. The majority of pts who fulfilled ASAS criteria were also diagnosed as having axial SpA by US rheumatologists, but a quarter of these patients were not.

Effectiveness Of Exercise Program in Ankylosing Spondylitis: Meta-Analysis Of Randomized Controlled Trials. Virginie Pécourneau[1], Arnaud L. Constantin[2] and Alain G. Cantagrel[3]. [1]CHU Toulouse, Toulouse, France, [2]Purpan University Hospital, Toulouse Cedex 9, France, [3]Hopital Purpan, Toulouse CEDEX 9, France.

Background/Purpose: Current recommendations for management of ankylosing spondylitis (AS) encompass appropriate medication and exercises as the cornerstones of treatment. The aim of our study is to assess the efficacy of exercise programs on disease activity and function in AS patients through a meta-analysis of randomized controlled trials.

Methods: A systematic literature search was performed on Medline and Cochrane databases up to February 2013. Randomized controlled trials examining the effectiveness of exercise programs for AS patients were included. Outcomes analyzed were evolution of BASDAI and BASFI after the completion of exercise programs. Modalities of exercise were compared and the use of biotherapy reported. Efficacy was assessed by weighted mean differences (WMDs) of exercise program versus control groups. Heterogeneity was assessed with Cochran's Q-test and I^2. Standardized mean differences (SMDs) were pooled through meta-analysis using the inverse variance model.

Results: After screening of 167 abstracts, a total of 23 trials were selected for detailed evaluation and 7 trials were finally included, assessing home based exercise programs (2/7), swimming (1/7), Pilates training (1/7) or supervised exercises (2/7), with a total of 275 AS patients. Two trials included patients with anti-TNF therapy. All trials except one showed a decrease of BASDAI and BASFI in exercise groups. The WMDs (95% CI) were −0.73 (−1.15, −0.30) (I^2=4%, p=0.0007) for BASDAI and −0.73 (−1.22, −0.23) (I^2= 2%, p=0.004) for BASFI in favor of exercise programs.

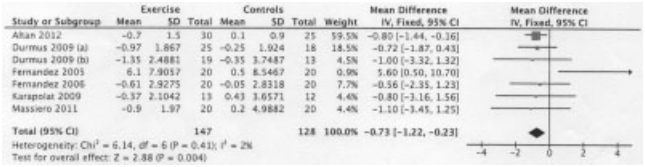

Fig. 1. Meta-analysis of randomized controlled trials assessing the impact of exercise program on BASDAI in AS patients.

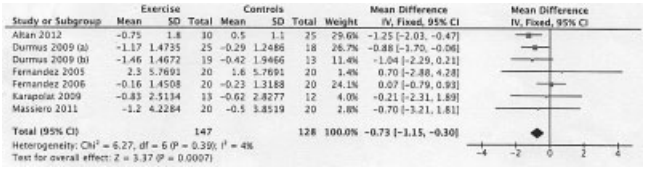

Fig. 2. Meta-analysis of randomized controlled trials assessing the impact of exercise program on BASFI in AS patients.

Conclusion: Even if the small numbers of patients and the quality of exercise programs constitute potential limitations of the randomized clinical trials included in this meta-analysis, its results support the potential of exercise programs to improve disease activity and function in AS.

Smoking Was Not Associated With Response To Adalimumab Therapy In Patients With Non-Radiographic Axial Spondyloarthritis. Joachim Sieper[1], Denis Poddubnyy[2], Aileen L. Pangan[3], Suchitrita S. Rathmann[3] and Jaclyn K. Anderson[4]. [1]Charité Universitätesmedizin, Berlin, Germany, [2]Charité Universitätsmedizin Berlin, Berlin, Germany, [3]AbbVie Inc., North Chicago, IL, [4]AbbVie, North Chicago, IL.

Background/Purpose: Cigarette smoking has been reported as a risk factor for early disease onset, higher disease activity, and poor function in patients (pts) with axial spondyloarthritis (SpA). Adalimumab (ADA), approved for treating ankylosing spondylitis (AS), was recently approved in the EU for the treatment of adults with severe axial spondyloarthritis without radiographic evidence of AS, but with objective signs of inflammation by elevated CRP and/or MRI who have had an inadequate response to, or are intolerant to non-steroidal anti-inflammatory drugs. The objective of this analysis was to examine the association of smoking with baseline pt characteristics, disease activity, and clinical outcome after treatment with adalimumab in pts with non-radiographic axial SpA (nr-axSpA).

Methods: ABILITY-1 is an ongoing phase 3, double blind (DB), randomized, controlled trial in pts with nr-axSpA fulfilling ASAS classification criteria for axial SpA but not modified New York criteria for AS who had an inadequate response, intolerance, or contraindication to NSAIDs. A 12-wk DB period of ADA 40 mg every other week (eow) or placebo was followed by an open-label (OL) extension phase in which pts could receive OL ADA 40 mg eow for up to an additional 144 wks. This post hoc analysis of data through wk 68 evaluated the differences in baseline characteristics and disease activity and response to treatment in current smokers vs. past smokers vs. nonsmokers in a subpopulation with positive MRI or elevated CRP (MRI+/CRP+) using a chi-square test or one-way analysis of variance (depending on categorical/continuous variables). Kaplan–Meier analysis was performed for time to first ASAS40 response using smoking status as strata.

Results: 142 pts were in the MRI+/CRP+ subpopulation; 63 (44%) were smokers [34 (24%) current smokers, 29 (20%) past smokers] and 79 (56%) were nonsmokers. Few differences were observed between current smokers, past smokers and nonsmokers at baseline (BL) and no differences were observed in age at SpA symptom onset or diagnosis. At BL more nonsmokers 43/79 (54%) than smokers [past smokers 13/29 (45%), current smokers 10/34 (29%)] had elevated CRP levels. Smoking status did not predict response to ADA therapy with no differences observed in ASAS20, ASAS40, ASAS PR, ASAS5/6, BASDADI50, ASDAS, BASFI, $BASMI_{lin}$, PGA, PtGA, HAQ-S or SF-36 PCS responses at wks 12 and 68. There was also no difference in the percentage of patients who had SPARCC scores of the SI joint or spine ≥2 at weeks 12 and 52 based on smoking status. Additionally, the time to reach ASAS40 response was not different between past smokers, current smokers and nonsmokers (figure).

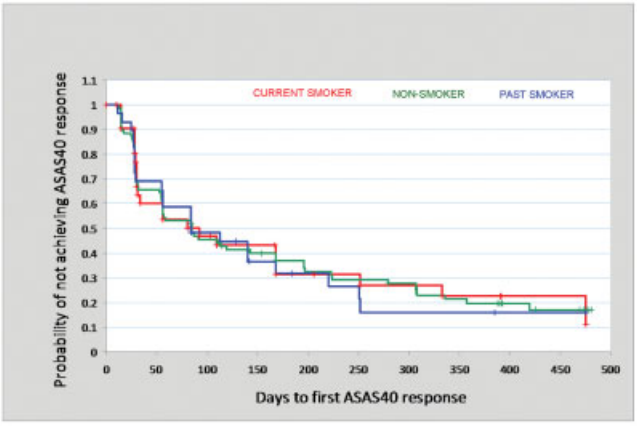

Figure.

Conclusion: In this MRI+/CRP+ nr-axSpA subpopulation of ABILITY-1, smoking status was not associated with age of symptom onset, disease activity, functional status, response to adalimumab therapy, or time to ASAS40 clinical response.

Is There a Role For Etoricoxib In Patients With Axial Ankylosing spondylitis Refractory To Traditional NSAID? Maria García Manrique[1], Pilar Font[2], Joan Calvet[3], María Cruz Fernandez[4], Carlos Montilla[5], Luis Linares[6], Elia Brito[7], Xavier Juanola[8], Juan Mulero[9], Rubén Queiro[10], Rosa M. Morla[11], Rosario Garcia-Vicuña[12], Alba Erra[13], Mireia Moreno[14], Marta Larrosa[15], Eduardo Collantes[16] and Jordi Gratacos[17]. [1]Hospital Parc Taulí, Sabadell, Spain, [2]IMIBIC-Reina Sofia Hospital, Cordoba, Spain, [3]Corporació Sanitària Parc Taulí, Sabadell, Spain, [4]Hospital General de Móstoles, Mostoles, Spain, [5]Hospital Universitario de Salamanca, Salamanca, Spain, [6]Hospital Universitario Virgen de la Arrixaca, Murcia, Spain, [7]Hospital Ramón y Cajal, Madrid, Spain, [8]Hospital Universitari de Bellvitge, Barcelona, Spain, [9]Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda (Madrid), Spain, [10]Rheumatology Department. Hospital Universitario Central de Asturias, Oviedo, Spain, [11]Hospital Sta Tecla, Tarragona, Spain, [12]Hospital Universitario de La Princesa, Madrid, Spain, [13]Hospital de Sant Rafael, Barcelona, Spain, [14]Hospital Universitari Parc Taulí, Sabadell, Spain, [15]Hospital Universitari Parc Tauli, Sabadell, Spain, [16]Hospital Reina Sofia, Cordoba, Spain, [17]Hospital Universitari Parc Taulí, Sabadell (Barcelona), Spain.

Background/Purpose: Anti-TNF treatment has demonstrated its effectiveness in axial ankylosing spondylitis (AS) patients with inadecuate response to traditional NSAIDs (tNSAIDs) therapy (>=2 tNSAIDs), but also aspects such as potential adverse events and cost must be considered. Etoricoxib(a selective COX-2 NSAID) has proved more efficacy than naproxen in these patients, and in an open label study up to 40% of patients refractory to tNSAIDs achieved a good clinical response with etoricoxib.

Objective: To evaluate the proportion of patients with axial AS with inadecuate response to tNSAIDs which achieve a good clinical response to etoricoxib after 4 weeks of treatment. To assess the proportion of these patients that mantain the good clinical response at 6 months follow-up. To analyze the effect of etoricoxib on the different clinical and biological parameters determined at 4 weeks and 6 months.

Methods: Open label, multicentric (12 centers) randomized, prospective (4 weeks with a 6-month open extension), non-controlled study, with inclusion period of approximately 2 years (mid 2010–2012). 57 axial AS patients with inadequate response to tNSAID following the consensus and guidelines previously published for the initiation of anti-TNF treatment were included. Patients who achieved a good clinical response at week 4 were followed in an open extension study for 6 moths. Variables analyzed at baseline, 2, 4 weeks and 6 months included: BASDAI, clinical symptoms such as back and nocturnal back pain, global patient and physician assessment of disease (VAS score), disability (BASFI), and biological parameters (CRP mg/dl). We also evaluated both the proportion of patients who achieved good clinical response defined as patients who did not fulfill anti-TNF therapy criteria after etoricoxib treatment, and ASASBIO response (50% in BASDAI and VAS physician global assessment improvements).

Results: 26/57 patients (46%, CI 34–58) achieved a good clinical response and 11/57 patients (19%, CI 8–31) achieved an ASASBIO response. 17/26 (65%) of patients included in the extension study maintaned the good clinical response and did not fulfill criteria of anti-TNF treatment at the end of 6 moths follow-up, representing 30% (CI 18–43) of the total of patients included. Moreover, 13/57 (23%,CI 11–36) achieved an ASASBIO response at 6-months follow-up. Only 17/57 (30%) showed a good clinical response at week 2. A discordant good clinical response between week 2 and 4 was observed in 9 patients, one of them losing response and the remaining 8 achieving response at week 4. All individual clinical variables analyzed improved significatively after 2 wks achieving around 30% of mean reduction after 4 wks of treatment ($p<0.001$ in all variables). The mean BASFI score significatively improved in the same range that clinical variables, however the improvement of CRP did not reach statistical significance (1.1 to 0.83 p=ns), although about 30% of patients with a good clinical response were showed with CPR normalization.

Conclusion: Etoricoxib treatment should be tried in axial AS patients before prescription of antiTNF treatment because around a third of patients achieved a good 6-months clinical response. Response at week 2 did not appear to predict response at week 4.

Do Postural Deformities In Patients With Ankylosing Spondylitis Cause Balance Problems? M. Ece Cinar, Yesim Akkoc, Hale Karapolat and Gokhan Keser. Ege University School of Medicine, Izmir, Turkey.

Background/Purpose: In this study, we assessed the impact of postural deformities caused by ankylosing spondylitis (AS) on balance.

Methods: 29 AS patients and 21 healthy controls were enrolled. Control group consisted of healthy hospital staff. Demographic data (age, sex, body mass index, treatment regimes, comorbidities, symptom and disease durations, smoking and alcohol use) were recorded. Physical examination, timed up-and-go test, 5 times sit-to-stand test, gait speed, functional reach test, 6 minute walk test, Romberg tests (eyes open and closed-feet together, tandem and on a soft surface), Dynamic Gait Index (DGI), Functional Gait Assessment (FGA), Berg Balance Scale (BBS) and for the AS group Bath Ankylosing Spondylitis Metrology Index (BASMI) were scored. Subjects were asked to fill out questionnaires for Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Back Depression Inventory (BDI), Activity Specific Balance Confidence Scale (ABC) and Dizziness Handicap Inventory (DHI).BASDAI, BASFI, and BASMI were only used in the AS group. The AS patients were then subgrouped according to their BASMI scores. Patients with scores ranging between 0–4 were assigned to subgroup AS1 while those with scores between 5–10 were assigned to subgroup AS2. These two subgroups were then compared with each other and with healthy controls.

Results: AS1 patients had higher Berg Balance Scores compared to AS2 patients($p<0.05$), while no significant difference was found between AS1 and AS2 groups in 5 times sit-to-stand test, timed up and go test, gait speed, Romberg tests, 6 min. walk test, functional reach test, DGI, FGA, BDI or ABC scales ($p>0.05$).

AS and control subjects were found to have significant differences in 5 times sit-to-stand test, tandem Romberg test with eyes closed, BDI, BBS and ABC scores ($p<0.05$).

The control and the AS2 group differed significantly in 5 times sit-to-stand test, timed up and go test, tandem romberg with eyes closed, 6 min. walk test, functional reach test, FGA, BBS, BDI, DHI and ABC scores ($p<0.05$), these differences were not observed in the AS1 group.

Conclusion: Our study results support the concept that ankylosing spondylitis patients have poorer static and dynamic balance compared to healthy subjects. Poor balance and resulting falls may increase disease morbidity and should be assessed in patients with AS.The chronic nature of the disease and slow progression of postural deformities may explain why poor balance is not a more common symptom of AS. Still, especially in patients with fracture risk factors such as osteoporosis and immobilisation, it is important to assess balance and take the necessary precautions.

[18F]-Fluoride PET/CT Assessment In Patients Responding To The ASAS Criteria For Spondyloarthritis Despite Negative Sacroiliac Joint MRI. Cecile Caoduro[1], Orland Angoue[1], Hatem Boulahdour[1] and Eric Toussirot[2]. [1]University Hospital, Besançon, France, [2]CIC Biotherapy 506 and Rheumatology and EA 4266 Pathogens and Inflammation, Besançon, France.

Background/Purpose: The ASAS group has defined criteria for the diagnosis of axial or peripheral spondyloarthritis (SpA). Sacroiliac joint MRI is included in these criteria and is a pivotal tool in daily practice to evaluate the patients with suspected early and non radiographic SpA. A substantial proportion of patient responds to the ASAS criteria (i.e. the clinical arm) despite negative MRI. Positron emission tomography/computed tomography (PET/CT) is a new imaging technique of potential interest in inflammatory rheumatic diseases. PET/CT has been rarely evaluated in patients with SpA and mainly used [18 F] fluorodeoxyglucose, a marker of inflammation. [18 F] fluoride is a specific bone tracer that may have potential in SpA imaging, a condition associated with spinal ossifications and sacroiliac ankylosis.

Objectives: to evaluate the clinical utility of [18 F] fluoride PET/CT in patients with negative sacroiliac joint MRI but fulfilling the ASAS criteria for SpA.

Methods: consecutive outpatients seen for inflammatory back pain and responding to the ASAS criteria for SpA were included. Patients were previously evaluated by sacroiliac joint MRI (STIR) which must be normal (no bone marrow edema). Whole body [18 F] PET/CT was performed using a SIEMENS Biograph device. Areas of interest (spine, entheseal structures and sacroiliac joints) were examined on whole body scan for the detection of increased uptake. Increased activity was defined as an activity greater than the activity of an adjacent normal bone. Patients with defined ankylosing spondylitis (AS) and positive sacroiliac joint MRI were used as positive controls.

Results: 10 patients were evaluated (8F, 2 M, mean age: 41.8, symptom duration: 3.2 years, HLA B27 positive 9/10; mean BASDAI: 5.6, mean ASDAS: 2.3). 9 responded to axial SpA ASAS criteria and I to peripheral SpA ASAS criteria. They all received or had received NSAIDs. No patients had DMARD or TNF inhibitors. All the patients had normal sacroiliac joint MRI. [18 F] fluoride PET/CT did not show increase activity for any patients. 5 patients with radiographic AS and positive MRI were also evaluated: for 4 patients, active lesions were detected with [18 F] fluoride PET/CT showing increased uptake in the sacroiliac joints, the spine and sternoclavicular joints.

Conclusion: [18 F] fluoride PET/CT does not seem useful in patients with inflammatory back pain, negative MRI and responding to the ASAS criteria. Thus, using this bone tracer, PET/CT does not give additional information relevant for the diagnosis of SpA. Conversely, this imaging technique using [18 F] fluoride may be able to detect active lesions in patients with defined disease and positive MRI. Measurement and quantification of maximal standard uptake value may be useful for improving the sensibility of this imaging modality in the diagnosis of SpA.

Prevalence Of Coronary Heart Disease In Spondyloarthopathies may Be Increased Due To Higher Prevalence Of Risk Factors As Well As The Disease Itself- A Retrospective Analysis At Single VA Medical Center. Trayton Mains[1] and Vikas Majithia[2]. [1]University of Mississippi Medical Center, Jackson, MS, [2]G.V. "Sonny" Montogomery VA Medical Center, Jackson, MS.

Background/Purpose: An increased prevalence of cardiovascular disease (CVD) and coronary heart disease (CHD) has been reported in patients with spondyloarthritides (SpA). This study investigated the prevalence of CVD risk factors, CVD including CHD and stroke in veterans with SpA (including PsA, Ankylosing Spondylitis (AS), and reactive arthritis (ReA) at the Jackson VAMC.

Methods: A retrospective chart review using ICD-9 codes for PsA, AS, and ReA was performed at Jackson, VAMC. Data including age, race, gender, medications, ESR, CRP, lipid panel, HbA1c, 25-OH Vitamin D level, hypertension (HTN), smoking, statin use, and CVD events were tabulated. Age, sex and race matched controls were selected from VA clinics with a 2:1 ratio. Comparisons of CHD, stroke, and CVD risk factors were made to a matched population from the American Heart Association data, as well as the CDC's 2003–2004 evaluation of chronic disease in Male veterans. Risk factors included smoking, dyslipidemia (DLD), HTN, and diabetes Mellitus (DM). Prevalence ration and odds ratio were calculated by standard method. Statistical significant (alpha <0.05) was calculated using Chi-square and Fisher's exact test.

Results: There were 81 patients, 79 were male and 2 female. With a mean age of patients with PsA, AS, and ReA being 61,8, 60.4, and 56, respectively. There was a significant increase in the prevalence of CHD and its risk factors in the SpA, PsA, and AS patients when compared with the AHA data, and General Male vets from the 2003–04-control population. When compared to the matched controls, prevalence was increased in the overall SpA, PsA and AS patients but did not achieve statistical significance suggesting increased an risk despite having slightly lower prevalence of risk factors. Also, in both SpA and matched controls population there was an increased prevalence of these risk factors, when compared to the AHA and national data. There was insufficient number of black patients in the cohort to assess effect of ethnicity.

Table 1. CHD comparison among spondyloarthropathies and 3 controls.

CHD	%	SpA	PsA	AS	ReA
%		26.9	29.3	30.4	14.2
AHA Controls	9.1	PR= 2.96 OR= 3.72 p-value= 0.002	PR= 3.21 OR= 4.18 p-value=0.003	PR= 3.34 OR= 4.42 p-value= 0.01	PR= 1.56
General Male Veterans	11.5	PR= 2.34 OR= 2.83 p-value=0.01	PR= 2.55 OR= 3.18 p-value= 0.04	PR= 2.64 OR= 3.36 p-value=0.05	PR= 1.23
Matched Controls	18.6	PR= 1.45 OR= 2.83 p-value - NS	PR= 1.57 OR= 3.18 p-value- NS	PR= 1.63 OR= 3.36 p-value- NS	PR= 0.76

Table 2. CHD Risk Factors

	AHA Controls (1) (%)	General Male Veterans (2) %	Matched Controls (3) %	SpA (%)	PsA (%)	AS (%)	ReA (%)
DM	7.6	13.6	29.5	24.7	22.7	26.1	28.6
PR				3.25	2.99	3.43	3.76
				1.81	1.67	1.92	2.1
				0.84	0.77	0.88	0.97
HTN	34.4	41.2	66	70.4	70.5	73.9	64.3
PR				2.05	2.05	2.15	1.87
				1.71	1.71	1.79	1.56
				1.07	1.07	1.12	0.97
DLD	45.2	44.6	69	60.5	69.8	56.5	42.5
PR				1.34	1.54	1.25	0.95
				1.36	1.57	1.27	0.96
				0.88	1.01	0.82	0.62
Smoking	23.1	22.8	63.1	62.7	62.5	56.5	75
PR				2.71	2.71	2.45	3.25
				1.5	1.54	0.87	1.83
				0.99	0.99	0.9	1.19
Family Hx			34.1	27.8	25	36.4	21.4
PR				0.87	0.73	1.07	0.63

Conclusion: Our results suggest that patients with SpA have an increased risk of developing CHD as well its risk factors. Our study is unique as increased risk and it quantification have not been previously reported in the U.S. veteran population. The increased CHD risk attributable to the increased prevalence of risk factors cannot be determined in this study but has been suggested to be over and above them.

The Contribution Of Disease Activity On Function and Quality Of Life In Patients With Ankylosing Spondylitis; Investigating Causality By Using Structural Equation Model. Servet Akar[1], Sabri Erdem[2], Kivanc Akat[1], Dilek Solmaz[1] and Ismail Sari[1]. [1]Dokuz Eylul University School of Medicine, Izmir, Turkey, [2]Dokuz Eylul University Faculty of Business, Izmir, Turkey.

Background/Purpose: It has been demonstrated that patient reported questionnaires including disease activity, functional impairment, anxiety and depression were correlated each other. However the causal relationships among activity, function and quality of life (QoL) in AS patients has never been evaluated before. Therefore we aimed to investigate the causal relationships among factor structures (A*ctivity*, *Function* and *QoL*) in AS patients by using Structural Equations Modeling (SEM) approach.

Methods: BASDAI, BASFI and Short Form 36 (SF 36) were used for the assessment of disease activity, function and QoL. All questionnaires simultaneously employed. BASDAI and BASFI were answered by both 10-cm VAS and numeric rating scale (NRS) format. Data analysis presented here was performed by VAS scores. Activity, Function and QoL were our latent variables (i.e. factor structures). A latent model was created that demonstrating the causality among these three factor structures by means of SEM approach in Lisrel 8.8 medium. Besides, Function was also tested for mediating role between Activity and QoL. Both model fit and parameter fit values were assessed against statistical significance of the proposed model.

Results: A total 114 consecutive patients with AS (87 [76%] male, mean age was 39.8 ± 10.9 years) according to the modified NY criteria were included in the study. Mean (±SD) BASDAI, BASFI, SF-36 physical component summary, and SF-36 mental health component summary score were 3.6 ± 2.6, 3.3 ± 3.0, 53.1 ± 25, and 59.2 ± 19.9 respectively. Significance of parameters of about relationships between factor structures, factor loadings of latent variables by observed variables, error terms of observed variables are all tested by t-test and results are found as significant ($p<0.05$). Proposed model is demonstrated in Figure 1. According to that model, *QoL* can be significantly ($|t|>1.96$ and $P<0.05$) explained by both *Activity* and *Function*. Additionally, *Function* plays a mediating role that reflects the indirect effect of Activity on *QoL*. Direct and indirect effects are shown in Equation Model (RMSEA=0.089, c^2/df =1.9, RMR=0.055, GFI=0.74, AGFI=0.69, NFI=0.95 and NNFI=0.97) and parameter fit (for all parameters $|t|>1.96$ and $P<0.05$) results satisfied allowable limits. NRS answering formats of BASDAI and BASFI were also produced similar results.

Conclusion: Our results show that proposed model is significant and both disease activity and function can explain the QoL in patients with AS. Function has also a mediating role as indirect effect of disease activity on QoL. This model can be utilized for the estimation of quality of life in AS patients in clinical practice or clinical trials.

Acute Phase Reactant As a Marker Of Anti-Drug Antibody Formation In Ankylosing Spondylitis. Seokchan Hong[1], Eun-Ju Lee[1], You Jae Kim[1], Bon San Koo[1], Wook Jang Seo[2], Kyung joo Ahn[3], Yong-Gil Kim[1], Chang-Keun Lee[1] and Bin Yoo[1]. [1]University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, [2]Seoul Veterans Hospital, Seoul, South Korea, [3]KEPCO medical center, Seoul, South Korea.

Background/Purpose: The development of antibodies to biologics is one of the main mechanisms of treatment failure in inflammatory arthritis, including rheumatoid arthritis (RA) and ankylosing spondylitis (AS). However, assessment of anti-drug antibodies (ADA) is not available in routine clinical practice. To address whether acute phase reactants (CRP and ESR) are useful to predict the ADA formation in AS, we analyzed the association between several disease parameters, including the levels of acute phase reactants and the presence of ADA.

Methods: In a cohort of 21 AS patients treated with TNF-blockers, ADA levels were measured in the serum using an enzyme-linked immunosorbent assay. All except one patient, serial samples were available before (baseline) and after 3 months of TNF-blockers therapy. We evaluated the levels of acute phase reactants and disease activity, as assessed by BASDAI, BASFI and patient global assessment at baseline and at 3 months after TNF-blocker treatment.

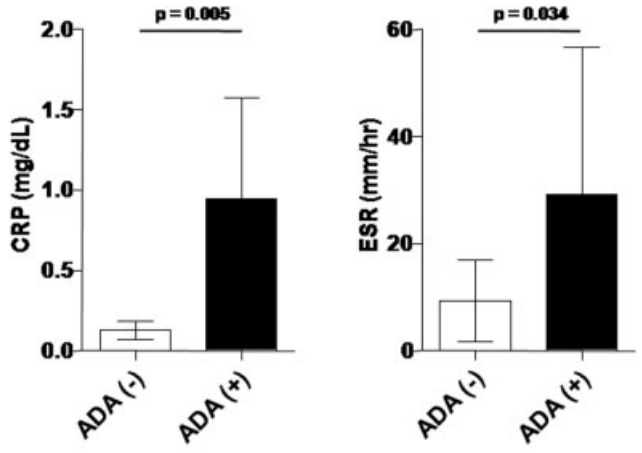

Figure 1. Differences in levels of acute phase reactants between patient with and without ADA at 3 months after TNF-blocker treatment.

Results: Among 21 patients (adalimumab n=16, infliximab n=5), ADA were detected in 5 (23.8%) patients (adalimumab n=2, infliximab n=3). At baseline, there was no significant difference in laboratory data and clinical activity scores between patients with and without ADA. After 3 months of TNF-blockers, ADA-positive patients had higher CRP levels in serum (0.9 +/− 0.6 ADA-positive vs. 0.1 +/− 0.1 ADA-negative, p=0.005). In addition, ESR levels in serum of patients with ADA were significantly higher than that of patients without ADA (29.2 +/− 27.5 ADA-positive vs. 9.4 +/− 7.6 ADA-negative, p=0.034) (Figure 1). However, we found no significant difference at 3 months in disease activity index according to the presence of ADA. The number of patients who received concomitant treatment with DMARDs or NSAIDs was not significantly different in both groups.

Conclusion: Patients who developed ADA had significant higher levels of acute phase reactants (CRP and ESR) in their serum after 3 months treatment with TNF-blockers. Acute phase reactant might be useful marker for early detection as well as for evaluation of drug immunogenicity in AS during TNF-blocker treatment.

Opiate Use In Patients With Ankylosing Spondylitis. John D. Reveille[1], Michael M. Ward[2], MinJae Lee[3], Mohammad Rahbar[3], Manouchehr Ardjomand-Hessabi[3], Laura A. Diekman[3], Matthew A. Brown[4], Lianne S. Gensler[5] and Michael H. Weisman[6]. [1]University of Texas Health Science Center at Houston, Houston, TX, [2]NIAMS/NIH, Bethesda, MD, [3]The University of Texas Health Science Center at Houston, Houston, TX, [4]University of Queensland Diamantina Institute, Brisbane, Australia, [5]University of California, San Francisco, San Francisco, CA, [6]Cedars-Sinai Medical Center, Los Angeles, CA.

Background/Purpose: Prescription opiates are commonly prescribed in patients with chronic pain, yet there is no evidence that these drugs ameliorate disease progression, and are associated with numerous side effects, including dependence and overdosage. The purpose of this study was to assess factors associated with narcotics usage in AS patients.

Methods: 611 AS patients, meeting the modified New York criteria followed up to 4 years and enrolled in a longitudinal outcome study were assessed. Demographic, clinical and self-reported outcomes were collected every 4–6 months. Usage of medications since last visit was collected every visit, including daily dosage, how many days in the prior month taken and how many months since the previous visit. Disease activity was defined by the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), functional outcomes by the Bath Ankylosing Spondylitis Functional Index (BASFI) and radiographic severity by the Bath Ankylosing Spondylitis Radiographic Index (BASRI) and the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). Depression was gauged by self-report, by the use of anti-depressant medications, and by Center for Epidemiologic Studies Depression Scale (CES-D) testing. Univariable mixed models were used to identify factors associated with narcotic usage accounting for correlation of repeated measures over time. Final longitudinal multivariable models were developed that identified independent factors associated with narcotic usage.

Results: The cohort was 71% male and 76% of patients were white, having a mean age 41.1 years (SD= 13.6). Mean disease duration was 17.6 years (SD=13.5). Opiate usage was reported in 87 (14.3%) of patients (9.36% taking continuously, 4.96% intermittently). Table 1 shows the univariable associations between narcotics usage and each independent variable from longitudinal model. Independent factors associated with narcotic usage in the multivariable analysis included subjective disease activity (measured by the BASDAI, OR=2.9, 95% CI=(1.8, 4.7), p<0.0001), functional impairment (measured by the BASFI, OR=1.9, 95% CI=(1.1, 3.15), p=0.023), depression (OR=2.3, 95% CI=(1.12 4.7), p=0.015) and the use of muscle relaxants (OR=5.3, 95% CI=(2.6, 10.7), p<0.0001). Complex interrelationships were encountered between depression, anti-depressives and other medications (anxiolytics and muscle relaxants).

Table 1. Univariable Association Between Narcotics Usage And Other Selected Variables

Variable	OR	95% CI	P
Male gender	0.647	(0.389, 1.075)	0.093
White	2.010	(1.113, 3.63)	0.021
Smoking (present or prior)	2.125	(1.324, 3.409)	0.0018
Age >40 years	1.853	(1.154, 2.974)	0.011
Patient employed	3.352	(1.999, 5.622)	<0.0001
Depression (self report)	5.907	(3.33, 10.478)	<0.0001
High blood pressure	2.186	(1.23, 3.885)	0.0077
Elevated ESR	1.285	(0.89, 1.855)	0.18
Patient Global Pain assessment	4.240	(2.866, 6.274)	<0.0001
Concomitant use of Prednisone	2.996	(1.345, 6.675)	0.0073
Concomitant use of TNFi Agents	1.526	(0.997, 2.336)	0.0514
Concomitant use of anti-depressants	2.601	(1.504, 4.498)	0.0006
Concomitant use of anxiolytics	8.042	(3.384, 19.114)	<0.0001
Concomitant use of muscle relaxants	8.458	(4.913, 14.562)	<0.0001
Radiographic severity (mSASSS)	1.236	(0.747, 2.043)	0.41
Depression (Elevated CES-D)	3.071	(2.078, 4.539)	<0.0001
Disease activity (BASDAI < 4)	5.460	(3.707, 8.043)	<0.0001
Impaired function (BASFI)	4.323	(2.857, 6.543)	<0.0001
Exercise 3 times or more per week	0.805	(0.569, 1.14)	0.22

Conclusion: AS patients using opiates have significantly greater subjective disease activity, report greater functional impairment, exhibit more depression and are more likely to take muscle relaxants than those that do not.

Disease Activity Is Associated With Development Of Inflammatory Bowel Disease In Ankylosing Spondylitis: 12-Year Results From OASIS. Ivette Essers[1], Sofia Ramiro[2], Carmen Stolwijk[3], Robert Landewé[4], Désirée van der Heijde[5], Filip van Den Bosch[6], Maxime Dougados[7] and Astrid Van Tubergen[3]. [1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Hospital Garcia de Orta, Almada, Portugal, [3]Maastricht University, Maastricht, Netherlands, [4]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [5]Leiden University Medical Center, Leiden, Netherlands, [6]Department of Rheumatology Ghent University Hospital, Ghent, Belgium, [7]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France.

Background/Purpose: Ankylosing spondylitis (AS) is associated with extra-articular manifestations (EAMs) such as acute anterior uveitis (AAU), inflammatory bowel disease (IBD), and psoriasis. Little is known about the characteristics of patients who develop any EAM. We aimed to identify characteristics associated with the development of EAMs in a prevalence cohort of patients with AS.

Methods: Twelve year follow-up data from patients included in the Outcome in AS International Study (OASIS) were used. Additionally, medical charts were checked for the presence of AAU, IBD or psoriasis, by two independent extractors. Baseline demographic, clinical and radiographic characteristics of patients with and without uveitis, IBD or psoriasis were compared. Logistic regression was performed to identify characteristics associated with the presence of any EAM. Furthermore, Cox regression and survival analyses were performed to identify characteristics associated with development of any EAM over time. Analysis were performed with baseline characteristics as well as with time-varying characteristics.

Results: 216 patients were included (mean age 43.6 years (SD 12.7), 154 (71%) men, mean symptom duration 20.5 years (SD 11.7), 174 (85%) HLA-B27 positive and mean follow-up period 8.3 years (SD 4.3)). At baseline, 59 (27%) patients had any EAM, of which 39 (18%) AAU, 15 (7%) IBD, and 9 (4%) psoriasis. Four patients (2%) had more than one EAM. At baseline, patients with AAU compared with patients without AAU were older (49.1 vs 42.4 years, p<0.01), had a longer symptom duration (25.9 vs 19.3 years, p<0.01), and more radiographic damage (modified Stoke AS Spinal Score 16.9 vs 10.6, p=0.03). Patients with psoriasis compared with patients without psoriasis were older (51.3 vs 43.3 years, p=0.05). There were no differences between patients with and without IBD. During follow-up 27 patients developed a new EAM; 19 AAU, 9 IBD, and 5 psoriasis with incidence rates of 0.9%, 0.4%, and 0.02% per year, respectively. The following time-varying characteristics were associated with the development of IBD in univariable analysis: AS Disease Activity Score (HR 2.81, 95%-CI 1.43–5.53), Bath Ankylosing Disease Activity Index (HR 1.47 95%-CI 1.09–1.98), C-reactive protein (HR 1.02, 95%-CI 1.00–1.05) Bath AS Functional index (HR 1.40, 95%-CI 1.09–1.80) and Bath AS Global Score (HR 1.46, 95%-CI 1.10–1.96). CRP was also weakly associated with the development of AAU (HR 1.02, 95%-CI 1.01–1.04) in time-varying analysis. No significant associations with development of psoriasis were found.

Conclusion: At baseline, a substantial number of patients already had an EAM in this prevalence cohort with relatively long symptom duration. Development of new EAMs was infrequently observed. In particular disease activity, but also physical function and patient global assessment, were associated with development of IBD. CRP was associated with the development of AAU. Characteristics associated with the development of psoriasis were not found.

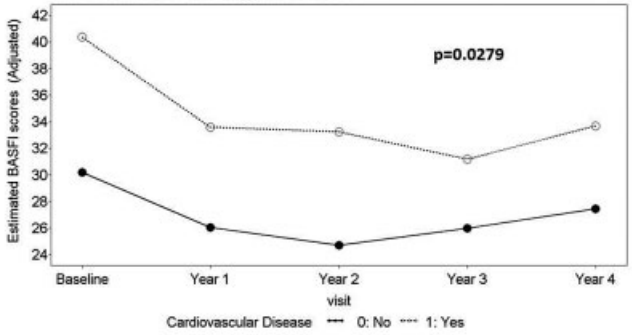
Cardiovascular Disease Is Associated With Worse Functional Outcomes In Ankylosing Spondylitis. Lianne S. Gensler[1], Michael M. Ward[2], MinJae Lee[3], Mohammad Rahbar[3], Matthew A. Brown[4], John D. Reveille[5] and Michael H. Weisman[6]. [1]University of California, San Francisco, San Francisco, CA, [2]NIAMS/NIH, Bethesda, MD, [3]The University of Texas Health Science Center at Houston, Houston, TX, [4]University of Queensland Diamantina Institute, Brisbane, Australia, [5]University of Texas Health Science Center at Houston, Houston, TX, [6]Cedars-Sinai Med Ctr, Los Angeles, CA.

Background/Purpose: Cardiovascular disease is an important comorbidity in inflammatory arthritis. There is evidence that AS patients have a significant burden of cardiovascular comorbidity. This appears to correlate well with disease activity. To date, there is very little evidence of how cardiovascular disease impacts function in AS. The purpose of this study was to assess the impact of cardiovascular disease, including hypertension, ischemic heart disease and valvular heart disease on long-term functional outcomes in AS.

Methods: This is a prospective cohort of 611 AS patients, meeting the modified New York criteria followed up to 4 years. We collected cardiovascular medical history (including hypertension, angina, coronary artery disease, myocardial infarction, stent or angioplasty, bypass surgery and valvular disease, including valve replacement) in addition to other comorbidities at baseline. We also collected clinical and self-reported outcomes every 6 months. Functional outcomes were assessed by the Bath Ankylosing Spondylitis Functional Index (BASFI). Tracer comorbidities (such as pulmonary disease) were included as controls. Using mixed models, we assessed univariable associations between independent variables and function that accounted for correlation of repeated measures over time. Potential confounding and effect modifications were addressed while developing a final longitudinal multivariable model.

Results: There were 611 patients included with a mean age of 41.1 ± 13.6 years. The cohort comprised 71% males and 76% of patients were white. The mean disease duration was 17.6 ± 13.5 years. The mean baseline modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) was 15.2 ± 21.1. At baseline, 24% of patients had any cardiovascular disease, including 4% with ischemic heart disease, 4% with valvular heart disease and 19% with hypertension. In the univariable analysis, composite cardiovascular disease ($p < 0.0001$), ischemic heart disease ($p = 0.011$) and hypertension ($p < 0.0001$), but not valvular heart disease were associated with BASFI longitudinally. Gastrointestinal disease was also significant ($p < 0.0001$), but pulmonary disease and diabetes were not associated with BASFI over time. The final model also adjusted for age, gender, prior joint surgery, smoking, erythrocyte sedimentation rate, education, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), mSASSS and depression (by the Center for Epidemiologic Studies Depression Scale [CES-D]). Figure 1 shows the adjusted means of BASFI by the cardiovascular disease status which was found to be statistically significant over time ($p = 0.0279$).

Figure 1. Longitudinal Association of Cardiovascular Disease with Function from the multivariable longitudinal model



p-value for Cardiovascular Disease group (yes vs. no)

Adjusted with potential confounders including: age, sex, race, past AS-related joint surgery, Smoked more than 100 cigarettes, ESR, disease activity (by BASDAI), disease damage (by baseline mSASSS), depression (by CES-D), gastrointestinal disease, pulmonary disease, diabetes.

Conclusion: AS patients with cardiovascular comorbidities have significantly worse function over time than those without cardiovascular disease.

Disclosure: L. S. Gensler, None; **M. M. Ward**, None; **M. Lee**, None; **M. Rahbar**, None; **M. A. Brown**, None; **J. D. Reveille**, None; **M. H. Weisman**, None.

2449

Patient-Reported Disease Activity and Outcome In Male Versus Female Patients Of The Groningen Leeuwarden Axial Spondyloarthritis (GLAS) Cohort. Suzanne Arends[1], Fiona Maas[2], Eveline van der Veer[2], Reinhard Bos[1], Monique Efde[1], Martha K. Leijsma[2], Hendrika Bootsma[2], Elisabeth Brouwer[2] and Anneke Spoorenberg[2]. [1]Medical Center Leeuwarden, Leeuwarden, Netherlands, [2]University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: Ankylosing Spondylitis (AS) occurs more often in males than in females. Most women tend to have milder disease and may therefore be underdiagnosed. Male AS patients are more likely to develop radiographic spinal damage. The aim of the present study was to investigate whether there are differences in patient-reported assessments of disease activity, physical function, and quality of life between male and female patients with axial spondyloarthritis (SpA).

Methods: All consecutive patients from the Groningen Leeuwarden Axial SpA (GLAS) cohort who visited the outpatient clinic between January 2011 and December 2012 were included in this cross-sectional analysis. All patients fulfilled the modified New York criteria for AS (>90%) or the ASAS criteria for axial SpA. Disease activity was assessed using Bath AS Disease Activity Index (BASDAI), AS Disease Activity Score (ASDAS; calculated from BASDAI questions 2, 3 and 6, patient global assessment of disease activity (GDA), and, C-reactive protein (CRP)), swollen joint index (range 0–44), and tender joint index (range 0–46). Physical function was assessed using Bath AS Functional Index (BASFI) and quality of life using AS Quality of Life (ASQoL) questionnaire.

Results: Of the 469 included patients, mean age was 45 years (SD±13), mean duration of symptoms was 17 years (range 0–61), 66% were male, and 80% were HLA-B27+. Males were significantly older, had longer disease duration, and were more frequently HLA-B27+ compared to females. Extra-articular manifestations, comorbidity, and current use of NSAID, DMARD, and anti-TNF were comparable between both groups.

Patient-reported measures of disease activity (BASDAI, patient GDA, and tender joints) and outcome (BASFI and ASQoL) were significantly higher in female compared to male patients. ASDAS, capturing both subjective and objective aspects of disease activity, was also significantly higher in females. This difference can be explained by patient-reported aspects of the ASDAS, since CRP levels were comparable between male and female patients (Table 1). Differences remained statistically significant after correcting for age, disease duration, and HLA-B27 status.

Table 1. Clinical assessments in male and female patients with axial SpA

	All patients (n = 469)	Males (n = 310)	Females (n = 159)	P-value
BASDAI	3.6 (0.0–9.6)	3.4 (0.0–9.4)	4.2 (0.2–9.6)	0.000
ASDAS(CRP)	2.3 (0.0–5.7)	2.2 (0.0–5.2)	2.5 (0.6–5.7)	0.004
Patient GDA	4 (0–10)	3 (0–10)	5 (0–10)	0.001
CRP (mg/L)	3 (0–94)	3 (0–94)	3 (0–82)	0.415
CRP ≥5	176 (38%)	115 (38%)	61 (39%)	0.731
Swollen joints	0 (0–9)	0 (0–9)	0 (0–2)	0.576
≥1 swollen joint	18 (4%)	13 (4%)	5 (3%)	0.575
Tender joints	0 (0–22)	0 (0–22)	0 (0–19)	0.018
≥1 tender joint	108 (23%)	61 (20%)	47 (30%)	0.020
BASFI	3.3 (0.0–9.9)	3.0 (0.0–9.7)	4.0 (0.0–9.9)	0.030
ASQoL	6 (0–18)	4 (0–18)	7 (0–18)	0.000

Values are presented as median (range) or number of patients (%).

Conclusion: This cross-sectional study shows that patient-reported measures of disease activity and outcome as well as ASDAS were significantly worse in female axial SpA patients. It is important to be aware of these differences when interpreting patient-reported measures in research and clinical practice. These findings underline the importance of research into more balanced and objective markers of disease activity and outcome including biomarkers in axial SpA.

Differences and Similarities Of Spondyloarthritis Classification Subgroups Defined By The Assessment Of Spondyloarthritis International Society (ASAS). Jacqueline E. Paramarta[1], Maud Van de Schoot[2], Maureen C. Turina[1], Carmen A. Ambarus[1], Johannes W.J. Bijlsma[2], Leen de Rycke[1] and Dominique L. Baeten[1]. [1]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands.

Background/Purpose: Since the Assessment of SpondyloArthritis international Society (ASAS) developed new classification criteria, spondyloarthritis (SpA) is no longer divided into different phenotypic subtypes such as ankylosing spondylitis and psoriatic arthritis, but into axial and peripheral SpA. This study aimed to compare the clinical characteristics and disease activity of the different SpA subpopulations according to the new ASAS criteria.

Methods: 389 patients presenting on two dedicated SpA outpatient clinics fulfilling the European Spondyloarthropathy Study Group (ESSG) criteria were included in a prospective observational cohort. Baseline characteristics were collected and patient's and physician's global assessment of disease activity, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS), 68 swollen and tender joint count, Schober, ESR and CRP were measured every 3 months. Data were analyzed with Mann Whitney U and chi square tests.

Results: 314 of the 389 SpA patients (81%) fulfilled the ASAS classification criteria. Patients fulfilling the ASAS criteria had a younger age at disease onset (median 34.1 vs 38.2), were more often male (61.8 vs 36.0%) and HLA-B27 positive (65.1 vs 2.9%), and had more often sacroiliitis on imaging (53.4 vs 1.4%) than those who did not fulfil the ASAS criteria. Strikingly, most disease activity parameters were similar between the two groups and the median BASDAI (4.6 vs 5.3) and TJC (0 vs 3) was even higher in the latter group.

Of the patients fulfilling the ASAS criteria, 230 (59% of the total population) fulfilled the axial and 84 (22%) the peripheral SpA criteria. ASAS peripheral SpA had an older age at disease onset (32.3 vs 38.2) and were less often HLA-B27 positive (76.2 vs 27.3%) than ASAS axial SpA. The parameters of global disease activity (patient's and physician's global assessment and ASDAS) were higher in axial than peripheral SpA, whereas CRP and ESR were similar.

As the ASAS criteria exclude patients with active axial symptoms from the peripheral SpA group but do not exclude patients with peripheral disease from the axial SpA group, we additionally subdivided patients who fulfilled the ASAS axial SpA criteria into pure axial and combined disease (back pain plus arthritis, enthesitis or dactylitis). The combined group was intermediate between pure axial SpA and peripheral SpA in terms of clinical characteristics such as disease symptoms and age at disease onset. Most importantly, the combined group had the highest disease activity compared to the other two groups (eg. ASDAS 3.0 vs 2.6 and 2.0, respectively).

Conclusion: The ASAS criteria fail to classify a subgroup of 20% of the patients fulfilling the ESSG criteria and having high disease activity. Within the patients fulfilling the ASAS axial SpA criteria, we discriminate two separate groups corresponding to exclusive axial disease versus combined axial and peripheral disease. These data support a classification into axial, combined, or peripheral disease rather than just axial versus peripheral disease. The combined group could enter the classification through either the axial or peripheral SpA criteria.

Work Instability Scores In Ankylosing Spondylitis and Non-Radiographic Axial Spondyloarthritis Are Equal and Higher Than In Psoriatic Arthritis. Sherry Rohekar[1], Robert D. Inman[2] and Dafna D. Gladman[3]. [1]St. Joseph's Hospital, London, ON, [2]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON, [3]University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Clinical subsets of spondyloarthitis (SpA), such as ankylosing spondylitis (AS) and psoriatic arthritis (PsA) may be associated with significant impact on work performance and attendance. Prior to becoming completely work disabled, patients will commonly experience a state of work instability (WI). Our purpose was to determine the characteristics of WI in a large population of patients with SpA.

Methods: Patients were recruited from two large, prospective longitudinal cohorts of AS and PsA. WI was evaluated using a validated questionnaire, the AS-WIS. Standard protocols were completed at the time of completion of the AS-WIS which included a detailed history, physical examination, physician-ascertained outcome measures and patient-reported outcomes.

Results: 718 respondents completed the questionnaire, 505 of which were employed at the time and included in the analysis. Mean age was 45.5 years (SD 11.8) and 69.3% were male. 60.4% had completed university. 63.3% were being treated with NSAIDs, 33.6% DMARDs and 54.1% TNF inhibitors. Mean swollen joint count was 0.08 (SD 0.40), tender joint count 0.85 (SD 2.76) and damaged joint count 3.47 (SD8.44). Mean AS-WIS score was 7.0 (SD 6.0), corresponding to low risk of work instability. AS-WIS scores were equally low in AS, non-radiographic axial SpA (nr-axSpA) and undifferentiated SpA (uSpA). AS-WIS scores in PsA were significantly lower than in AS, nr-axSpA and uSpA ($p<0.01$ for each). Higher AS-WIS were significantly associated with female gender, lower education level, higher tender joint count, current NSAID use, history of GI disease, history of CNS disease, and history of peripheral arthritis, enthesitis or dactylitis. TNF inhibitor use was not associated with higher WIS scores. Multinomial logistic regression showed that the groups at the highest risk of WI were those with GI history, peripheral arthritis, enthesitis and dactylitis history. All patient-reported outcome measures correlated highly with AS-WIS.

Conclusion: In axSpA, WI was low, and was comparable for AS, nr-axSpA and uSpA. PsA was found to have significantly lower WI than these subsets of ax-SpA, however, in this cohort, PsA was well controlled with low joint counts, which may have impacted the WIS scores. Female gender, history of GI, CNS or peripheral disease and NSAID use was associated with greater WI.

2452

Effects Of Smoking In Patients With Axial Spondyloarthritis - Ankylosing Spondylitis and Nonradiographic Axial Spondyloarthritis - Receiving Anti-TNF therapy. Ozlem Pehlivan, Yasemin Yalcinkaya, Nihat Huseyinsinoglu, Nilufer Alpay Kanitez, Burak Erer, Sevil Kamali, Murat Inanç, Orhan Aral, Ahmet Gul and Lale Ocal. Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey.

Background/Purpose: Ankylosing spondylitis (AS) is a systemic disease characterized by sacroiliitis and inflammatory back pain. The radiological findings of AS appear late causing delay in diagnosis, therefore axial spondyloarthritis (axSpA) which includes AS and nonradiographic axSpA (nr-axSpA) have been defined.

The objective of this study is to identify the potential impacts of smoking on disease activity markers, physical examination and laboratory findings in severe AS and nr-axSpA receiving anti-tnf therapy.

Methods: In this study, 211 patients treated with Anti-TNF diagnosed as axSpA based on ASAS criteria (of which 142 AS according to modified New York criteria and 69 as nr-axSpA) between 2000 and 2013 were included. Patients were evaluated retrospectively. Smoking intensity has been evaluated as per pack-year. Patients were separated into groups according to smoking habits and intensity. Acute phase reactants and functional indexes - erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Bath AS Metrology Index (BASMI), Bath AS Functional Index (BASFI), Bath AS Disease Activity Index (BASDAI) and AS Quality of Life (ASQoL)- were compared between groups. Physical examination including Schober's test (ST), chest expansion (CE), fingertip-to-floor distance (FFD), tragus wall distance (TWD), lateral lumbar flexion (LLF), cervical rotation (CR), occiput-to-wall distance (OWD), inter-malleolar distance (IMD), chin-sternum distance (CSD) was performed. Independent sample t, paired t test, one-way Anova were used to compare values.

Results: Based on comparison betweeen smokers (n:121) and non-smokers (n:90), physical mobility indicators ST (p:0.03), FFD ($p<0.001$) and LLF (p: 0.035) were found significantly more restricted in smokers and BASDAI (p: 0.011) values were significantly improved after anti-TNFα treatment in non-smokers. If smoking period is >20 years, LLF (p:0.004), CR (p:0.004), CE (p:0.005), OWD (p:0.021), TWD (p: 0.001), IMD (p: 0.015), BASFI (p: 0.019) and BASMI ($p< 0.001$) were significantly deteriorated. When effects of smoking were evaluated between AS (n:142) and nr-axSpA

(n: 69) groups, significant restriction of ST (p:0.04) and FFD ($p<0.001$) in AS group within smokers, restriction of FFD (p:0.02), CR(p:0.04), OWD (p:0.02), TWD (p:0.003), CSD (p: 0.02) and LLF (p:0.002) in AS group among smokers >10 years or more and significant restriction of ST (p: 0.04), FFD ($p<0.001$), LLF (p: 0.01) in AS group who had quit smoking compared to non-smokers were found. Among currently smoking patients (n:46) comparison between who smoke >20 pack-year (n:23) and who smoke <20 pack-year (n:46) showed significant deterioration of ST (p: 0.007), CR (p:0.01), CE (p:0.002), TWD (p:0.01), IMM (p: 0.007), BASFI (p: 0.004), BASDAI (p:0.005), BASMI (p: 0.005) and ASQoL (p:0.04) only in nr-axSpA group.

Conclusion: Our study showed that smoking and especially heavy smoking had negative effects on all stages of axSpA. In nr-axSpA, considered as early axSpA, to quit smoking would be more important for significant differences were seen in spinal mobility, functional situation, disease activity and quality of life in this group of patients.

Identification Of Determinants Of The Functional Outcome In Patients With Early Axial Spondyloarthritis: Results From The German Spondyloarthritis Inception Cohort. Denis Poddubnyy[1], Hildrun Haibel[1], Joachim Listing[2], Jürgen Braun[3], Martin Rudwaleit[4] and Joachim Sieper[1]. [1]Charité Universitätsmedizin Berlin, Berlin, Germany, [2]German Rheumatism Research Center, Berlin, Germany, [3]Rheumazentrum Ruhrgebiet, Herne, Germany, [4]Endokrinologikum Berlin, Berlin, Germany.

Background/Purpose: In cross-sectional studies it has been shown already that functional status in ankylosing spondylitis (AS), which represents probably the most important long-term outcome in this disease, is related to both the presence of structural damage in the spine and to disease activity. Nonetheless, studies investigating the clinical relevance of radiographic progression in the spine prospectively, especially early in the course of the disease, are lacking. The aim of the current study was to investigate the relationship between worsening of functional status, clinical disease parameters and radiographic spinal progression over two years in patients with axial spondyloarthritis (axSpA).

Methods: In total, 160 patients with early axSpA (91 with AS and symptom duration ≤10 years, and 69 with non-radiographic axSpA (nr-axSpA) and symptom duration ≤5 years) from the German Spondyloarthritis Inception Cohort (GESPIC) were included in the current analysis based on the availability of radiographic data and data on the functional status at baseline and after 2 years of follow-up. Spinal radiographs were scored according to the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) independently by two trained readers who were blinded for time point and all clinical data. Functional status was assessed by the Bath Ankylosing Spondylitis Functional Index (BASFI, 0–10 points), and clinical disease activity by the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI, 0–10 points).

Results: In total, 44 patients (27.5%) of the patients demonstrated worsening of the BASFI by at least one point after 2 years as compared to baseline, and 20 patients (12%) experiences BASFI worsening in 2 points and more, which was considered to be clinically relevant. BASFI worsening by ≥1 point was significantly associated only with higher BASDAI worsening over 2 years in comparison to those without functional worsening: 1.2 ± 1.4 vs -0.6 ± 1.6, $p<0.001$. BASFI worsening by ≥2 points was, however, associated not only with increased disease activity (as reflected by BASDAI), but also with a higher rate of radiographic spinal progression - table. Importantly, in the multivariate analysis both BASDAI increase and progression of structural damage in the spine remained statistically significantly associated with BASFI worsening. No other disease-related parameters were found to be significantly associated with BASFI worsening over two years.

Table Association of disease-related parameters with worsening of BASFI (≥2 units) over two years in patients with axial spondyloarthritis.

Parameter	BASFI worsening (n = 20)	No BASFI worsening (n = 140)	p	OR (95% CI) for the BASFI worsening
BASDAI change	1.5 ± 1.6	−0.3 ± 1.6	<0.001	-
mSASSS change	2.6 ± 5.6	0.5 ± 1.7	0.20	-
mSASSS worsening by ≥2 points	35.0%	13.6%		3.4 (1.2–9.7)
mSASSS worsening by ≥4 points	25.0%	5.7%	0.012	5.5 (1.6–19.0)
New syndesmophytes formation/progression	30%	10%	0.022	3.9 (1.3–11.6)
HLA-B27 (+)	70%	78%	0.41	0.7 (0.2–1.9)
Male sex	65%	51%	0.34	1.8 (0.7–4.7)
Smoking	55%	36%	0.14	2.1 (0.8–5.5)
Elevated (>20 mm/h) time-averaged ESR	45%	25%	0.11	2.5 (0.9–6.4)
Elevated (>6 mg/l) time-averaged CRP	55%	39%	0.22	2.0 (0.8–5.0)

Conclusion: In this prospective study we could demonstrate that only 2 factors were significantly associated with worse functional outcome over two years in patients with early axSpA: 1) increase of disease activity (BASDAI) and 2) progression of structural damage. It seems that even a relatively small progression of structural damage such as an mSASSS worsening by 2 units or formation of a new syndesmophyte might have an impact on the functional status, even early in the course of the disease.

High Prevalence Of Left Ventricular Diastolic Dysfunction In Patients With Ankylosing Spondylitis. Sjoerd C. Heslinga[1], Thelma C. Konings[1], Irene E. Van der Horst-Bruinsma[2] and Michael T. Nurmohamed[2]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands.

Background/Purpose: Patients with ankylosing spondylitis (AS) have an increased cardiovascular risk leading to decreased life expectancy. This is due to both accelerated atherosclerotic disease as well as cardiac morbidity such as valvular disease and congestive heart failure. In this study we investigated the prevalence of cardiac disease with echocardiography in patients with AS who were eligible for TNF-blocking therapy.

Methods: We performed a cross sectional study on consecutive patients with AS starting treatment with a TNF-blocker. Patients were screened for cardiac disease using standard transthoracic echocardiography that included two-dimensional, three-dimensional and M-mode echocardiography, spectral Doppler, color Doppler and tissue Doppler imaging. The ejection fraction (EF) was used to describe systolic function, with systolic dysfunction defined as EF<50%. For diastolic function a combination of echocardiographic measurements, namely peak early diastolic filling velocity (E), late diastolic filling velocity (A), E/A ratio, early diastolic mitral annular velocity (E'), deceleration time (DT) and isovolumetric relaxation time (IVRT) were used. Based on these parameters diastolic dysfunction is graded into three categories: mild (grade I), pseudonormal (grade II) and restrictive (grade III). Valvular abnormalities were evaluated according to the current echocardiographic guidelines. Disease activity was measured using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Blood pressure, serum glucose, total cholesterol, triglycerides, low density lipoprotein (LDL), high density lipoprotein (HDL), c-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were measured. Data was compared with data from literature using one-sample t-test.

Results: 17 AS patients were included with a mean age of 44 ± 11 years and a disease duration of 18 ± 10 years (Tabel1). In total, 5 out of 17 (29%) patients had diastolic dysfunction grade I, of which one was female. This was significantly higher compared to literature, in which the prevalence of diastolic dysfunction grade I is approximately 5% in an age and sex-matched control group ($p=0.046$). One patient had systolic dysfunction, with an EF of 49%, but had suffered from a myocardial infarction in the past. Two patients had mild aortic regurgitation and two other patients had mild mitral regurgitation (23.5%). Overall, 7 out of 17 (41.1%) patients had some form of cardiac dysfunction or disease.

Conclusion: Patients with AS have an increased prevalence of diastolic dysfunction compared with the general population. This may be attributable to the general inflammation process that results in a decreased relaxation ability of the left ventricle as well as compromised valve cups function. As diastolic heart failure is associated with increased mortality, diastolic dysfunction in AS patients might have an important role in the increased cardiovascular risk.

The Lipid Profile Improves In Patients With Ankylosing Spondylitis Responding To TNF Blocking Therapy. Sjoerd C. Heslinga[1], Irene E. Van der Horst-Bruinsma[1], Alper M. van Sijl[2] and Michael T Nurmohamed[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands.

Background/Purpose: Patients with ankylosing spondylitis (AS) have a decreased life expectancy due to an increased cardiovascular risk. Cardiovascular risk factors such as smoking, dyslipidemia, overweight, male gender and hypertension are implicated in atherogenesis. However, atherogenesis is also amplified by inflammation. Anti-inflammatory treatment with tumor-necrosis factor (TNF) inhibitors decreases the incidence of cardiovascular disease, which could be due to an improvement of cardiovascular risk factors, such as atheroprotective changes in the lipid profile. Therefore, the effect of treatment with TNF inhibitors on the lipid profile in patients with AS was investigated.

Methods: We evaluated all consecutive AS patients, who fulfilled New York 1984 criteria for AS, starting either with adalimumab or etanercept at our clinic Reade, Amsterdam. A total of 107 patients started adalimumab, and 183 patients started etanercept. Clinical data and blood samples were collected at baseline, at 24 and at 52 weeks of follow-up. A response to TNF blocking therapy was defined as a decrease in C-reactive protein (CRP) levels from >10 mg/L at baseline to <10 mg/L at 24 weeks, or a decrease in erythrocyte sedimentation rate (ESR) from >20 mm/h at baseline to < 20 mm/h at 24 weeks. Systolic and diastolic blood pressure, serum glucose, CRP, ESR, total cholesterol, triglycerides, low density lipoprotein (LDL), high density lipoprotein (HDL), apolipoprotein A (ApoA) and apolipoprotein B (ApoB) were measured. The students t-test was used to calculate changes.

Results: Patients with high disease activity (CRP >10 mg/L) had decreased lipid levels compared with patients with low disease activity. Seventy-four out of 206 (35,9%) patients showed a response to anti TNF therapy within 24 weeks. Total cholesterol levels increased significantly in responding patients (figure 1). In addition, triglycerides, HDL, LDL and ApoA levels also increased significantly. After one year of treatment this effect was still present. In non responding patients only HDL levels increased significantly after 24 weeks, but this effect disappeared after a year.

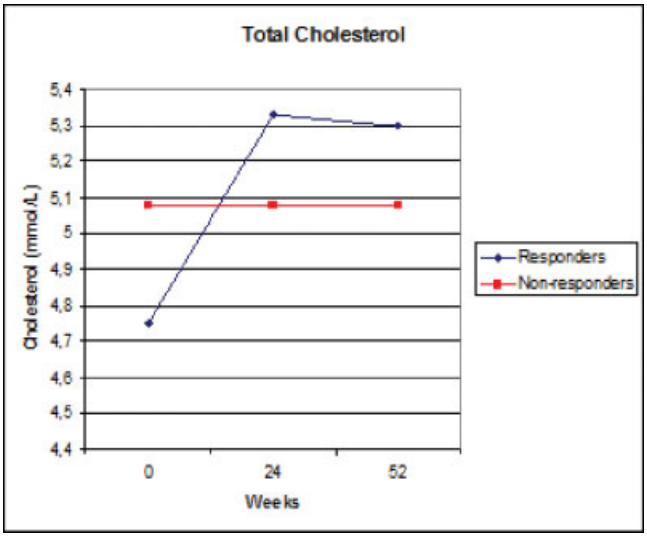

Figure 1. Changes in total cholesterol levels in responding and non-responding patients (n=292).

Conclusion: In AS patients with high disease activity lipid levels are depressed to a similar extent as observed in rheumatoid arthritis. Lipid levels normalized in responding AS patients. This effect was still present after one year of therapy. Anti-inflammatory therapy with TNF-blockers normalizes lipid levels and could potentially decrease the cardiovascular risk.

Prevalence Of Overweight and Obesity and The Relation To Disease Activity, Physical Function and Quality Of Life In Patients With Axial Spondyloarthritis. Fiona Maas[1], Anneke Spoorenberg[1], Eveline van der Veer[1], Reinhard Bos[2], Monique Efde[2], Hendrika Bootsma[1], Elisabeth Brouwer[1] and Suzanne Arends[1]. [1]University Medical Center Groningen, Groningen, Netherlands, [2]Medical Center Leeuwarden, Leeuwarden, Netherlands.

Background/Purpose: Obesity is a growing problem in Western society. It is associated with an increased risk for many disorders, impaired functional capacity, and impaired quality of life (QoL). The aim of the present study was to evaluate the prevalence of overweight and obesity and the relation with clinical assessments of disease activity, physical function, and QoL in patients with axial spondyloarthritis (SpA).

Methods: 465 consecutive patients from the Groningen Leeuwarden Axial SpA (GLAS) cohort who visited the outpatient clinic between January 2011 and December 2012 were included in this cross-sectional analysis. All patients fulfilled the modified New York criteria for ankylosing spondylitis (AS) (>90%) or the ASAS criteria for axial SpA. Body mass index (BMI) was calculated and patients were divided into groups according to the WHO criteria: low BMI (BMI <18.5 kg/m^2), normal BMI (BMI 18.5–25 kg/m^2), overweight (BMI 25–30 kg/m^2), and obesity (BMI >30 kg/m^2). Disease activity was assessed by Bath AS Disease Activity Index (BASDAI), AS Disease Activity Score (ASDAS), and C-reactive protein (CRP), physical function by Bath AS Functional Index (BASFI), and quality of life by ASQoL questionnaire.

Results: Mean age of the 465 patients was 45 years (SD±13), median symptom duration was 17 years (range 0–61), 65% were male, and median BMI was 26.0 kg/m^2 (range 17.0–45.4). In total, 8 (2%) patients had low BMI, 183 (39%) had normal BMI, 174 (37%) were overweight, and 100 (22%) were obese. Of the 100 obese patients, 19 had BMI between 35–40 kg/m^2 and 3 had BMI >40 kg/m^2. In comparison, the general Dutch population aged 30–70 years and matched for gender had an estimated prevalence of 1% low BMI, 44% normal BMI, 42% overweight, and 13% obesity.[1]

Obese axial SpA patients were significantly older, had longer disease duration, and more comorbidity than patients with normal BMI. Disease activity of obese patients was significantly higher and physical function and QoL were significantly worse compared to patients with normal BMI (Table 1). These differences remained statistically significant after correcting for age, disease duration, and comorbidity. No significant differences in clinical assessments were found between patients with overweight and normal BMI (Table 1).

Table 1. Disease activity, physical function, and QoL of axial SpA patients with overweight and obesity compared to those with normal BMI.

	Normal BMI [18.5–25] (n = 183)	Overweight BMI [25–30] (n = 174)	P-value*	Obesity BMI [>30] (n = 100)	P-value*
BASDAI (range 0–10)	3.4 (0–9.2)	3.5 (0–9.6)	0.235	4.4 (0.6–9.4)	0.029
ASDAS(CRP)	2.1 (0–5.2)	2.1 (0.3–5.1)	0.983	2.7 (0.5–5.7)	0.000
CRP (mg/L)	3.0 (0–73)	3.0 (0–94)	0.372	5.0 (0–82)	0.000
CRP ≥5 mg/L	62 (34)	56 (32)	0.795	53 (53)	0.001
BASFI (range 0–10)	2.9 (0–9.1)	2.7 (0–9.9)	0.635	5.1 (0.1–9.7)	0.000
ASQoL (range 0–18)	5.0 (0–17)	4.0 (0–18)	0.077	8.0 (0–18)	0.002

Values are presented as median (range) or number of patients (%). *P-values compared to patients with normal BMI.

Conclusion: In this large cohort of axial SpA patients with relatively longstanding disease, almost a quarter of the patients were obese. Cross-sectional analysis shows that the presence of obesity was associated with higher disease activity and worse physical function and QoL.

Ankylosing Spondylitis and a Diagnostic Dilemma: Coccydynia. Rabia Deniz[1], Gülsen Ozen[1], Sibel Yilmaz-Oner[1], Sibel Z. Aydin[2], Can Erzik[1], Osman Hakan Gunduz[1], Nevsun Inanc[3], Haner Direskeneli[1] and Pamir Atagunduz[1]. [1]Marmara University School of Medicine, Istanbul, Turkey, [2]Medeniyet University, Goztepe Training and Research Hospital, Istanbul, Turkey, [3]Marmara University, School of Medicine, Istanbul, Turkey.

Background/Purpose: Coccydynia is defined as pain in or around the tail bone area. The most common cause of coccydynia is either a trauma such as a fall directly on to the coccyx or repetitive minor trauma. The etiology remains obscure in up to 30% of patients as idiopathic. The literature on the contribution of rheumatic diseases to coccydynia is scarce. In this study, our aim was investigating the prevalence of coccydynia in Ankylosing spondylitis (AS) patients.

Methods: One hundered and seven consecutive patients with AS were evaluated for coccydynia were enrolled between January and November 2012 for a cross-sectional analysis. Seventy four consecutive patients followed for mechanical back pain as controls and the AS patients were interviewed for the presence of coccydynia. In AS patients, disease activity assessed by Bath AS disease activity index (BASDAI) and treatment with biologic agents. Collected data was evaluated on SPSS® version 11.5 and Microsoft Excel® Programmes.

Results: Prevalence of coccydynia in AS (38.3%) was significantly higher than the control group ($p<0.0001$) in both female and male AS patients (Female AS vs. control=40.9% vs. 18.4%, $p=0.015$ and male AS vs. control=36.5% vs. 8.0%, $p=0.005$). Both genders were affected equally in the AS group whereas coccydynia was slightly more frequent in female patients in the control group. In AS patients; when each individual domain of BASDAI was evaluated for the affect of coccydynia, the question about the neck, back or hip pain had significantly higher score (p:0.019) in patients with coccydynia. Overall BASDAI score was also higher in this subset of patients (p:0.020). Although not significant, the need for anti-tumour necrosis factor α (Anti-TNF α) therapy seemed also higher in patients with coccydynia, suggesting a higher disease severity (31.8 % vs. 22.2%, $p=0.20$).

Conclusion: Coccydynia is a previously neglected symptom of AS and it is almost three times more common in AS than in non-specific chronic low back pain. Our observation may implicate that inflammatory diseases have a role in the etiology of coccydynia, especially in those without a history of recent or past trauma and coccydynia may be a factor associated with the severity of AS as well.

Change Over Time In The Profile Of Ankylosing Spondylitis Patients Treated With Infliximab In Canadian Routine Care. Denis Choquette[1], Michael Starr[2], Majed M. Khraishi[3], William G. Bensen[4], Saeed A. Shaikh[5], Jude F. Rodrigues[6], Dalton E. Sholter[7], Maqbool K. Sheriff[8], Julie Vaillancourt[9], John S. Sampalis[10], Allen J. Lehman[11], Susan M. Otawa[11], Francois Nantel[11] and May Shawi[11]. [1]Institut de Rhumatologie de Montréal, Montreal, QC, [2]Montreal General Hospital, Montreal, QC, [3]MD, Memorial University of Newfoundland, Nexus Clinical Research, St Johns, NF, [4]St. Joseph's Hospital and McMaster University, Hamilton, ON, [5]McMaster University, St Catharines, ON, [6]Rheumatology, Windsor, ON, [7]Rheumatology Associates, Edmonton, AB, [8]Nanaimo Regional General Hospital, Nanaimo, BC, [9]JSS Medical Research, Montreal, QC, [10]JSS Medical Research, St-Laurent, QC, [11]Janssen Canada Inc, Toronto, ON.

Background/Purpose: Canadian provincial reimbursement policies in regards with infliximab coverage status have evolved in the last decade. The objective of this study was to describe and compare over time the demographics and disease parameters at infliximab treatment initiation and to assess the effectiveness of treatment at 6 and 12 months in Canadian AS patients.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis (RA), ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab or golimumab as first biologics or after having been treated with a biologic for less than six months. People with AS treated with infliximab who were enrolled between 2002 and 2013 were included in this analysis (N=303) and stratified to two groups (2005–2007: n=135; 2008–2013: n=168) based on the year of enrolment in the registry.

Results: Table 1 summarizes the patient characteristics at infliximab initiation by period of enrolment in BioTRAC. Patient demographics were comparable in the two cohorts with a mean (SD) age of 45.72 (11.74) years and the majority being males (62.4%). A significant change in the geographic distribution of patients enrolled in the BioTRAC registry was observed ($P=0.001$) and more patients with provincial coverage were enrolled in 2008–2013 compared to 2005–2007 ($P=0.012$). A trend towards earlier initiation of infliximab was observed in more recent years as indicated by the shorter disease duration (11.12 vs. 8.24 years; $P=0.013$) and the lower number of prior traditional DMARDs used (0.83 vs. 0.59; $P=0.078$). Furthermore, overall, patients recruited in 2008–2013 had lower disease activity compared to those enrolled in 2005–2007. ESR (29.96 vs. 19.91 mm/hr; $P<0.001$), physician global assessment (MDGA; 6.99 vs. 6.26; $P=0.001$) were significantly lower in the 2008–2013 cohort while a statistical trend was observed in morning stiffness (78.96 vs. 70.11 minutes; $P=0.064$) and ASDAS (3.90 vs. 3.70; $P=0.103$).

Treatment for 6 months resulted in a greater proportion of patients in the 2008–2013 cohort achieving inactive disease (ASDAS<1.3) without reaching statistical significance (20.7% vs. 34.9%; $P=0.140$).

Table 1. Demographics and Patient Characteristics at IFX Initiation by Enrolment Period

	Enrolment Period		
Parameter	2005–2007 (N = 135)	2008–2013 (N = 168)	P-Value
Age (years), mean (SD)	45.58 (11.61)	45.65 (11.89)	0.958
Male gender, n (%)	82 (60.7%)	107 (63.7%)	0.634
Disease duration (years), mean (SD)	11.12 (10.77)	8.24 (9.18)	0.013
Province			
Maritime	4 (3.0%)	9 (5.4%)	0.001
Quebec	53 (39.3%)	53 (31.5%)	
Ontario	50 (37.0%)	96 (57.1%)	
Manitoba	3 (2.2%)	0 (0.0%)	
Saskatchewan	2 (1.5%)	1 (0.6%)	
Alberta	3 (2.2%)	1 (0.6%)	
British-Colombia	20 (14.8%)	8 (4.8%)	
Coverage	n = 135	n = 160	
Provincial	38 (28.1%)	67 (41.9%)	0.012
Private	71 (52.6%)	70 (43.8%)	
Provincial and private	10 (7.4%)	16 (10.0%)	
Other	16 (11.9%)	7 (4.4%)	
Infliximab dose (mg/kg), mean (SD)	4.31 (1.02)	4.43 (1.19)	0.372
Previous use of DMARD, n (%)	56 (41.5%)	56 (33.3%)	0.144
Number of previous DMARDs, mean (SD)	0.83 (1.12)	0.59 (0.86)	0.078
Concomitant use of DMARDs, n (%)	37 (27.4%)	50 (29.8%)	0.653
Morning stiffness (minutes), mean (SD)	78.96 (38.86)	70.11 (42.42)	0.064
HAQ-DI, mean (SD)	1.26 (0.58)	1.19 (0.59)	0.318
ESR (mm/hr), mean (SD)	29.96 (23.07)	19.91 (18.09)	<0.001
CRP (mg/L), mean (SD)	20.43 (23.85)	16.68 (25.66)	0.243
MDGA (NRS: 0–10), mean (SD)	6.99 (1.56)	6.26 (2.05)	0.001
ASDAS, mean (SD)	3.90 (0.87)	3.70 (1.06)	0.103
ASDAS Disease Activity, n (%)	*n = 103*	*n = 130*	
Inactive (ASDAS <1.3)	0 (0.0%)	4 (3.1%)	0.160
Moderate (1.3 ≤ ASDAS <2.1)	1 (1.0%)	3 (2.3%)	
High (2.1 ≤ ASDAS ≤ 3.5)	34 (33.0%)	50 (38.5%)	
Very High (ASDAS >3.5)	68 (66.0%)	73 (56.2%)	
BASDAI, mean (SD)	6.54 (1.90)	6.37 (2.16)	0.490
BASFI, mean (SD)	6.30 (2.23)	6.09 (2.48)	0.447

Conclusion: The results of this analysis show that the profile of the AS patient population in the BioTRAC registry has changed over time towards lower disease activity and earlier initiation in the patient management process. These results may reflect differences in patient management over time or may be related to earlier access to care. Irrespective of enrolment period, 6-month treatment with infliximab was effective in reducing disease activity in Canadian AS patients.

Improvement In Physical Function, Health-Related Quality Of Life, and Work Productivity With Adalimumab Treatment In Non-Radiographic Axial Spondyloarthritis. Désirée M. van Der Heijde[1], Philip J. Mease[2], Aileen L. Pangan[3], Sumati A Rao[3], Naijun Chen[3] and Mary Cifaldi[3]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Swedish Medical Center and University of Washington School of Medicine, Seattle, WA, [3]AbbVie Inc., North Chicago, IL.

Background/Purpose: Adalimumab (ADA) was approved in the European Union for the treatment of severe non-radiographic axial spondyloarthritis (nr-axSpA) in patients with objective signs of inflammation (elevated C-reactive protein (CRP) or positive MRI) and inadequate response or intolerance to NSAIDs. We aimed to evaluate effects of long-term ADA treatment on patient-reported outcomes (PROs) and work productivity in nr-axSpA patients with elevated CRP or positive MRI.

Methods: ABILITY-1 is an ongoing Phase III, multicenter, randomized, controlled trial of ADA vs. placebo (PBO) in patients with nr-axSpA (fulfilling Assessment of Spondyloarthritis international Society axial SpA criteria but not modified New York criteria for ankylosing spondylitis). After the 12-week double-blind phase, all patients switched to open-label ADA (represented as ADA/ADA and PBO/ADA groups) for 144 weeks. This *post-hoc* analysis evaluated productivity and PROs until Week 52 among 142 patients with elevated CRP or MRI evidence of inflammation (spine or SI joints) at baseline. Physical function was assessed using the disability index of the Health Assessment Questionnaire for Spondyloarthropathies (HAQ-S) and health-related quality of life using the Short Form 36 Health Survey (SF-36) Physical Component Summary (PCS) score. Productivity was assessed using the Work Productivity and Activity Impairment Questionnaire (WPAI). Changes from baseline to Week 12 were compared between groups using ANCOVA with adjustment for baseline scores and with treatment as a factor.

Results: No significant differences between treatment groups were observed in baseline HAQ-S, SF-36 PCS, or WPAI domain scores. After 12 weeks of therapy in the double-blind period, the ADA group experienced significant improvements from baseline compared with PBO in mean HAQ-S (P=.007) and SF-36 PCS (P<.001) scores, and in 3 of 4 WPAI domain scores (P=.017, 0.041, 0.128, and 0.005, for absenteeism, presenteeism, overall work impairment, and activity impairment, respectively). By Week 52, PBO patients who switched to open-label ADA demonstrated improvements comparable to those in patients who received ADA during the double-blind period. Patients in both groups achieved SF-36 scores (43.2 and 44.3 for the PBO/ADA and ADA/ADA groups, respectively) approaching the US general population norm of 50 at Week 52.

Baseline Scores and Mean Change From Baseline Through Week 52 in HAQ-S, SF-36 PCS, and WPAI Domain Scores Among nr-axSpA Patients With Positive MRI or Elevated CRP Levels, Mean ± SD (n)[a]

Double-Blind Phase	HAQ-S[b]		SF-36 PCS[c]		WPAI Presenteeism[d]		WPAI Activity Impairment[d]	
	PBO	ADA	PBO	ADA	PBO	ADA	PBO	ADA
Baseline Score	1.02 ± 0.53 (n = 73)	1.01 ± 0.56 (n = 69)	33.2 ± 8.16 (n = 73)	33.3 ± 7.78 (n = 69)	44.2 ± 26.48 (n = 48)	38.5 ± 23.41 (n = 41)	55.7 ± 25.33 (n = 72)	56.4 ± 24.13 (n = 69)
Week 12	−0.13 ± 0.35 (n = 69)	−0.33 ± 0.52 (n = 68)	2.3 ± 6.81 (n = 72)	6.9 ± 9.32 (n = 69)	−7.6 ± 27.12 (n = 42)	−14.4 ± 26.93 (n = 39)	−4.6 ± 26.34 (n = 68)	−16.2 ± 24.02 (n = 69)
Open-Label Phase	**HAQ-S[b]**		**SF-36 PCS[c]**		**WPAI Presenteeism[d]**		**WPAI Activity Impairment[d]**	
	PBO/ADA	ADA/ADA	PBO/ADA	ADA/ADA	PBO/ADA	ADA/ADA	PBO/ADA	ADA/ADA
Week 36	−0.41 ± 0.46 (n = 64)	−0.45 ± 0.52 (n = 60)	8.4 ± 10.01 (n = 64)	9.9 ± 10.66 (n = 59)	−18.8 ± 30.76 (n = 41)	−19.7 ± 27.47 (n = 34)	−23.2 ± 30.52 (n = 63)	−22.2 ± 25.80 (n = 59)
Week 52	−0.45 ± 0.48 (n = 60)	−0.46 ± 0.46 (n = 56)	10.0 ± 9.91 (n = 61)	11.0 ± 9.93 (n = 55)	−23.1 ± 30.96 (n = 39)	−27.3 ± 24.34 (n = 30)	−26.1 ± 33.32 (n = 59)	−31.5 ± 24.45 (n = 55)

[a]n = number of subjects with nonmissing values for both baseline and the respective visit.
[b–d]MID = −0.26, 3.0, and −7.0%, respectively.

Conclusion: Among patients with elevated CRP or positive MRI, ADA therapy was associated with significant improvement in PROs and productivity compared with PBO during the double-blind phase of the ABILITY-1 trial. Patients who continued on ADA therapy and those who switched to ADA in the open-label period experienced comparable meaningful improvements in PROs and productivity through Week 52.

Spondyloarthritis Epidemiology and Burden Phase 2 [SPEED 2] Study: Disease Progression In Axial Spondyloarthropathy (SpA). Eric Ruderman[1], Vibeke Strand[2], Avani Joshi[3], Yanjun Bao[3], Keith Betts[4], Pooja Chopra[4], Michael B. McGuire[5] and Sumati A Rao[3]. [1]Northwestern University, Chicago, IL, [2]Stanford University, Palo Alto, CA, [3]AbbVie Inc., North Chicago, IL, [4]Analysis Group, Inc., Boston, MA, [5]Medical Data Analytics, Parsippany, NJ.

Background/Purpose: Limited information is available on progression of non-radiographic axial spondyloarthropathy (nr-axSpA) to ankylosing spondylitis (AS) in patients with SpA meeting the Assessment of Spondyloarthritis International Society (ASAS) criteria in the US. We assessed disease progression from nr-axSpA to AS and numbers of remissions and flares in this population in rheumatology practices.

Methods: SPEED-2 was a retrospective, multicenter, observational cohort study based on medical chart review. For inclusion, individuals met the following criteria (from 2000 to 2005): ≥18 years old; rheumatologists' diagnoses or suspected diagnoses of SpA (axial SpA, nr-axSpA, AS, or undifferentiated SpA); fulfilled ASAS criteria for axial SpA; with a minimum follow up of ≥7 years with ≥1 documented radiographic assessment of sacroiliac joints (SIJ). An index date was defined as the earliest date between 2000–2005 when subjects had SIJ radiographs after having retrospectively fulfilled ASAS criteria. Their disease course, from 7–12 years following the index date (follow-up period), was reviewed. Stratified analyses included patients with AS and nr-axSpA in an approximate 1:1 ratio. Rate of progression from nr-axSpA to AS over time was determined by Kaplan-Meier analysis according to SIJ radiographs. Number of rheumatologist-reported "remissions" (defined as symptom- and treatment-free periods) and "flares" (defined as periods with increased symptoms requiring treatment during follow-up) were summarized.

Results: Of 286 patients fulfilling ASAS criteria for axial SpA, 166 were classified as AS and 120 as nr-axSpA. Patients with AS or nr-axSpA were predominantly white, male, with a mean age of 45 and 43 years, respectively. Approximately 89% and 85%, respectively, had an original diagnosis of axial SpA, AS, or nr-axSpA. Of 120 patients with nr-axSpA, 51 had a repeat SIJ radiographs during follow-up: approximately 2% of these 51 patients progressed to AS in the first 2 years and 27.6% over a period of 11 years after the index date. The majority of patients with nr-axSpA did not have spontaneous (91%) or treatment-related (73%) remissions reported. During follow-up, 66% with nr-axSpA had ≥1 flare, with an average duration of 18 days, suggesting ongoing disease activity.

Patient Demographics and Disease Characteristics at Index Date and Outcomes During Follow-Up

Characteristic	AS N = 166	nr-axSpA N = 120
Age (years), mean ± SD	44.8 ± 10.18	43.4 ± 8.84
Male, n (%)	139 (83.7)	91 (75.8)
White, n (%)	128 (77.1)	100 (83.3)
Rheumatologists' Diagnoses at Index Date[a]		
Axial SpA, n (%)	38 (22.9)	25 (20.8)
Ankylosing spondylitis, n (%)	109 (65.7)	52 (43.3)
Non-radiographic axial SpA, n (%)	1 (0.6)	25 (20.8)
Undifferentiated SpA, n (%)	14 (8.4)	16 (13.3)
Inflammatory back pain, n (%)	12 (7.2)	5 (4.2)
Psoriatic arthritis, n (%)	3 (1.8)	3 (2.5)
Progression from nr-axSpA to AS[b]		
AS classification at 2 years, n (%)		1 (2.0)
AS classification at 11 years, n (%)		12 (27.6)
Remissions and Flares[c]		
Patients with ≥1 spontaneous remission, n (%)		11 (9.2)
Patients with ≥1 treatment-related remission, n (%)		33 (27.5)
Patients with ≥1 flare, n (%)		79 (65.8)
Average flare duration in days, mean ± SD		18.2 ± 26.05

[a]Rheumatologists' diagnoses or suspected diagnoses were determined from charts provided retrospectively. More than 1 clinical diagnosis was reported for some subjects.
[b]Patients fulfilling modified New York criteria for AS among 51 with follow-up radiographs.
[c]Reported by rheumatologists.

Conclusion: This observational cohort study demonstrated that few patients with nr-axSpA progressed to AS. Few spontaneous or treatment related remissions were reported among both nr-axSpA and AS patients, and

the majority experienced disease flares during the follow-up period, indicative of disease activity.

Quality Of Life, Physical Function and Symptoms In Non-Radiographic Axial Spondyloarthritis:The Patient Perspective. Philip J. Mease[1], Sumati A Rao[2], Avani D. Joshi[2], Sarah Clifford[3], Christina Vernon[3] and Mary A. Cifaldi[2]. [1]Swedish Medical Center and University of Washington School of Medicine, Seattle, WA, [2]AbbVie Inc., North Chicago, IL, [3]United BioSource Corporation, Bethesda, MD.

Background/Purpose: Pain, physical function impairment, and health-related quality of life (HRQoL) impact are substantial for patients with non-radiographic axial spondyloarthritis (nr-axSpA).[1] Understanding the most important aspects of nr-axSpA from the patient's perspective may offer insights regarding the relevance of the disease specific patient-reported outcome (PRO) instruments and lead to better disease assessment and management in this patient population. We explored the impact of nr-axSpA on patients' physical function and other HRQoL outcomes and assessed content validity for 3 commonly used PROs.

Methods: In this cross-sectional cognitive interview study, participants ≥18 years old with chronic back pain and physician-diagnosed nr-axSpA were interviewed at 4 US sites in the Midwest/West. Participants were asked open-ended questions regarding their nr-axSpA symptoms including frequency, severity, and effect on their lives. Participants then completed and were interviewed with the Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and Health Assessment Questionnaire–Spondyloarthropathies (HAQ-S).

Results: Among the 20 participants, mean age was 42.8 years, 45% were women, 85% were white, and mean duration of nr-axSpA was 3.5 years. The majority (90%) reported pain (**table**), which tended to increase in intensity during flares and as patients aged. Other symptoms—most notably stiffness, weakness, swollen joints, problems with the sacroiliac (SI) joints, and aches—were also mentioned. The most common physical functioning and HRQoL impacts were associated with sleeping, walking, athletic activity, bending, sitting for long periods, and household chores. Mean scores on the PRO measures were 4.7 (range of 0.52–8.85) for BASFI, 4.85 (range of 1.13–8.31) for BASDAI, and 1.09 (range of 0–2) for HAQ-S. The cognitive interviews suggested that HAQ-S covers key symptoms and effects of nr-axSpA and the majority of the participants found the items clear and relatable to their condition. The interviews also suggested overall relevance of the BASFI and BASDAI in nr-axSpA, but symptoms and difficulties such as swollen joints, SI joint problems, aches, and sexual/emotional aspects may not be addressed fully.

Table 1. Summary of Patient-Reported nr-axSpA Symptoms[a]

		n (%)
Typical SpA symptoms	Pain (hurt)	18 (90)
	Stiffness (body joints)	11 (55)
	Weakness	6 (30)
	Fatigue (drained)	3 (15)
Other symptoms[b]	Swelling in joints	8 (40)
	SI joint fusing	5 (25)
	Aches/achy/aching/sore	5 (25)
	Lack of flexibility (eg, in hands, knees)	3 (15)
	Tightness	2 (10)
	Hands go numb/numbness	2 (10)

[a]Symptoms reported in the patient's own language
[b]Anemia, fever, tender, wrist gets warm, hand turns purple, eyesight worsening, like a knot, stabbing, and burning each were reported by 1 patient.

Conclusion: This study highlights patients' perspectives of their nr-axSpA symptoms. Pain and other symptoms such as stiffness and joint problems often caused significant impairment in the participants' daily lives. The findings strongly support the relevance of the HAQ-S, BASFI, and BASDAI in the nr-axSpA population. Future studies could explore whether additional items or modification to wording and response options, as suggested by the participants, could enhance the measures or lead to the development of new measures.

Comparison Of Tumor Necrosis Factor Inhibitor Use For Ankylosing Spondylitis At University Rheumatology Clinics In Scotland and Oregon. Anusha Reddy[1], Abhijeet Danve[2], Kiana Vakil-Gilani[2], Jennifer H. Ku[2], Sanjay Ganhasan[1], Alison Black[1] and Atul Deodhar[2]. [1]Aberdeen Royal Infirmary, Aberdeen, United Kingdom, [2]Oregon Health and Science University, Portland, OR.

Background/Purpose: Use of tumor necrosis factor inhibitors (TNFi) for ankylosing spondylitis (AS) is directed by national guidelines in the UK. However in the US, in the absence of treatment recommendations, the use of TNFi is dictated by local practice patterns. We compared the use of TNFi in the treatment of AS at Aberdeen Royal Infirmary (ARI) in Scotland, and Oregon Health & Science University (OHSU) in Oregon.

Methods: This was a retrospective analysis of patients who were newly started on TNFi for treatment of AS between 2007 and 2012 at OHSU, and between 2004 and 2011 at ARI. Data on patient demographics, clinical characteristics and treatment were collected from electronic medical records. Descriptive analysis, Mann-Whitney U test and chi-square test (Fisher's exact test if N <5) was used to compare the two groups of patients.

Results: There were significant differences between the 2 groups regarding age, HLA B27 positivity, NSAID use, physical function and presence of depression, (see Table). Time to start TNFi after the symptom onset was median 10 (11.5) years at ARI compared to 6 (8) years at OHSU. The baseline BASDAI at the time of initiation of TNFi at ARI was 7 (2.2) compared to 6 (3.9) at OHSU (p=0.04). Adalimumab was the most frequently prescribed TNFi in both places (67% of ARI and 51% of OHSU patients). Percentage reduction in BASDAI in 1 year from baseline was significantly higher at ARI (64%) as compared to OHSU (17%). According to the NICE guidelines followed in the UK, AS patients are not allowed to switch the TNFi for inefficacy. In OHSU, 22% patients switched TNFi once and 12% switched TNFi more than once, for either allergic reaction or inefficacy. These patients had mean BASDAI score of 3.45 (2.6) and 3.97 (3) respectively after one year.

	OHSU (2007–2012) N = 41 N, median (iqr) Or N (%)	ARI 2004–2011 N=67 N, median (iqr) Or N (%)	P value
Age years	45 (12)	40.5 (17.5)	0.048*
Female	14 (34.2)	14 (21.9)	0.17
Symptom onset to time of starting TNFi in years	30, 6 (8)	20, 10 (11.5)	0.16
Positive HLA-B27	20 (64.5)	15 (100)	<0.01*
NSAID use	31 (75.6)	64 (100)	<0.01*
Baseline BASDAI	16, 6.0 (3.9)	61, 7.0 (2.2)	0.04*
Baseline RAPID 3	26, 5.2 (2.2)	N/A	N/A
Pain	26, 7 (2.5)	59, 7.4 (2.4)	0.97
Function	26, 2.7 (2.3)	60, 6.2 (3.3)	<0.01*
BASMI	N/A	58, 3.7 (3.2)	N/A
Uveitis	4 (9.8)	11 (17.2)	0.40
Psoriasis	5 (12.2)	5 (7.8)	0.51
Inflammatory bowel disease (IBD)	6 (14.6)	4 (6.4)	0.18
Depression	13 (32.5)%	4 (6.3)	<0.01*
Fibromyalgia	5 (12.2)	N/A	N/A
Ischemic heart disease	2 (4.9)%	1 (1.6)	0.32
% change in BASDAI at 1 year	17.6%	64.7%	<0.01

* statistical significanceN/A "not applicable"

Conclusion: Patients at ARI had higher baseline BASDAI and longer time to start TNFi after symptom onset as compared to OHSU. Higher prevalence of depression in OHSU patients may have affected the change in BASDAI, which is a subjective measure. OHSU patients who switched TNFi due to inadequate response had a good outcome suggesting that switching TNFi is a valid strategy, which is currently not available to patients in the UK.

Tomosynthesis As a New Diagnostic Tool For Evaluation Of Ankylosing Spondylitis With Modified Stoke Ankylosing Spondylitis Spinal Score: A Comparison With Plain Radiographs. Seunghun Lee[1], Tae-Hwan Kim[2], Jae-Bum Jun[2], Kyung-Bin Joo[3], Young Bin Joo[2] and Jina Park[4]. [1]Hanyang University College of Medicine, Seoul, South Korea, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [3]Hanynag University, Seoul, South Korea, [4]Hanyang University Hospital, Seoul, South Korea.

Background/Purpose: In assessment of ankylosing spondylitis (AS), accurate scoring of modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) is important to evaluate the treatment effects or follow-up results. Until now, lateral plain radiographs of cervical and lumbar spine were used for the assessment of mSASSS. We assessed the potential of tomosynthesis in evaluation of AS with mSASSS.

This study aimed to demonstrate the benefit of tomosynthesis in assessment of mSASSS, compared with plain radiographs.

Methods: The study group comprised 68 (55 men and 13 women; mean age, 32 years) patients with AS who underwent tomosynthesis and plain radiographs of cervical and lumbar spine on the same day. Two experienced radiologists (reader 1 and 2) independently assessed mSASSS with tomosynthesis and reader 1 assessed mSASSS with plain radiographs. Reader 1 also assessed the presence of facet narrowing or ankylosis on each level with tomosynthesis. Statistical agreements between tomosynthesis and plain radiographs in assessing total mSASSS score and scores on each spinal level were analyzed. And we analyzed the interobserver reliability between reader 1 and 2 in the interpretation of tomosynthesis.

Results: In scoring the anterior corner lesions, tomosynthesis and plain radiographs showed fair agreement in upper border of C3, upper border of C5 and upper border of L1 (kappa value of 0.324, 0.358 and 0.391, respectively). In lower border of C4, lower border of T12, lower border of L1 and upper border of L3, tomosynthesis and plain radiographs showed moderate agreement (kappa value of 0.584, 0.43, 0.573 and 0.541). 44 of 68 patients (64.7%) showed higher total mSASSS score on tomographic evaluation as compared with radiographic studies. The mean mSASSS with tomography and plain radiographs were 13 and 11.6, respectively. On tomosynthesis, cervical facet arthropathies were detected in 15 of 68 patients (22%) and lumbar facet arthropathies were detected in 23 of 68 patients (33.8%). Interobserver agreement between two readers in tomographic evaluation of total mSASSS score and scores on C-spine and L-spine levels showed excellent agreement (kappa values of 0.974, 0.924 and 0.969, respectively).

Conclusion: We suggest that tomosynthesis is an excellent method for evaluation of AS with mSASSS. Tomosynthesis is superior to plain films in detecting and assessing anterior corner lesions. And also, it is good method to evaluate facet joint involvement in AS patients.

Late-Onset Ankylosing Spondylitis Has Distinctive Presenting Symptoms and a Higher Inflammatory Burden. Yeon-Ah Lee[1], Sang-Hoon Lee[2], Ran Song[2], Hyung-In Yang[2] and Seung-Jae Hong[1]. [1]Kyung Hee University, Seoul, South Korea, [2]Hospital at GANGDONG, Kyung Hee University, Seoul, South Korea.

Background/Purpose: Most ankylosing spondylitis (AS) patients experience their first symptoms prior to age 45. However, symptoms of AS can develop after the age 45 and the initial manifestations may vary according to the different onset-age subsets. This study was performed to investigate whether there are characteristic clinical features and more inflammatory burdens in the late-onset AS patients compared to adult-onset AS.

Methods: We retrospectively studied the clinical and laboratory features of 499 AS patients. These patients was fulfilled the modified New York criteria for AS and were classified into 2 groups based on their age at symptom onset: adult-onset AS (>16 but < 45 years; AOAS); and late-onset AS (≥45 years; LOAS). The onset of disease was defined by the day of appearance of the first manifestation of AS. In both groups, the following data were compared:(1) epidemiological variables (sex, age at symptom onset, and duration of disease); (2) laboratory results (HLA-B27, ESR and CRP); (3) clinical manifestations, including signs and symptoms at diagnosis and during follow-up, involvement of the cervical spine, shoulder and hip, and extra-articular manifestations; (4) BASDAI and BASMI; (5) radiographic data (BASRI total and BASRI spine); (6) use of anti-TNF-α agent and time to start anti-TNF-α therapy.

Results: There were 29 patients (5.8%) with LOAS. LOAS group had more female patients (44.8% vs. 21.5%, p=0.004), shorter disease duration (6.2±4.9 vs.11.3±6.8 years, p<0.001) and less HLA-B27 positivity (69.0% vs. 82.6%, p=0.037) than AOAS group. As an initial manifestation, the patients with LOAS more often presented cervical pain (40.0% vs. 18.8%, p=0.005), shoulder pain (30.0% vs. 6.6%, p<0.001), lower extremity arthritis (56.7% vs. 36.5%, p=0.027), and the anterior chest wall pain (30.0 % vs. 6.6%, p<0.001) than AOAS. Clinical symptoms during follow-up and the radiological scores did not differ between the two groups. The most notable findings of the LOAS group were higher initial ESR (47.8±29.8 vs. 29.6±23.8 mm/hr, p< 0.001) and more frequent use of TNF-α inhibitors during the course of the disease (58.6% vs. 38.5%, p< 0.001). Among the all anti-TNF-α users, LOAS patients tended to show higher BASDAI score and higher ESR at the start of the therapy compared to AOAS.

Conclusion: Our results suggest that LOAS has distinctive presenting symptoms and a higher inflammatory burden. With increased clinical attention to LOAS as a cause of inflammatory arthritis in elderly patients, a timely initiation of disease-specific treatment can be provided.

Prevelance Of Inflammatory Back Pain and Axial Spondyloarthritis Among University Employees In Izmir, Turkey. Fatos Onen[1], Dilek Solmaz[1], Pinar Cetin[1], Ali Balci[2], Servet Akar[1] and Nurullah Akkoc[1]. [1]Dokuz Eylul University School of Medicine, Izmir, Turkey, [2]Dokuz Eylul University School of Medicine, izmir, Turkey.

Background/Purpose: The prevalence of axial spondyloarthritis (SpA) has not yet been investigated in a population based survey by using new ASAS classification criteria. The aim of this study was to determine the prevalence of axial SpA among university employees in Izmir, Turkey.

Methods: The study was conducted in the Health Sciences Campus with a population of 2894 medical and non-medical staff at Dokuz Eylul University in Izmir. A sample size of 395 subjects was calculated by assuming that the inflammatory back pain (IBP) prevalence of 5% in the general population (1) using OpenEpi (version 2.3 Atlanta, GA, USA), based on a confidence interval of ±2%. Six trained medical students using a standard questionnaire performed a face-to-face interview with participants. The subjects who were classified as having IBP based on ASAS Experts' criteria and other IBP criteria sets were invited to the Rheumatology out-patient clinic to participate in the study. They were evaluated for axial SpA by two rheumatologists using ASAS classification criteria. The patients with IBP were also evaluated to determine whether they met the modified New York (mNY) criteria for ankylosing spondylitis (AS) and both the ESSG and the Amor criteria for SpA.

Results: A total of 381 subjects (131 male, 250 female; mean age: 38.0 ± 9.4) were contacted with an acceptance rate of 96.5%. Twenty five subjects (6.5 %; CI 95% 4.0–9.0) with back pain lasting ≥ 3 months were classified as having IBP according to ASAS Experts' criteria. The prevalence of IBP according to Berlin and Calin criteria was found to be 7.0% (CI 95% 4.0–10.0) and 21.5% (CI 95% 17.0–25.0), respectively (Table).

Three subjects with IBP (0.78%) were classified as having axial SpA according to ASAS classification criteria. Two of these patients (0.52%) had radiographic sacroiliitis and they met the mNY criteria for AS. There were 8 patients (2.0%) who fulfilled both the Amor and ESSG criteria for whole group of SpA (Table). One of them had psoriasis.

Table. Prevalence of IBP and SpA according to various classification criteria in the university employees

	Total % (CI 95%)	Female % (CI 95%)	Male % (CI 95%)
IBP Criteria			
ASAS Experts'	6.5 (4.0–9.0)	8.0 (5.0–12.0)	3.0 (1.0–8.0)
Berlin	7.0 (4.0–10.0)	8.0 (5.0–12.0)	3.0 (1.0–8.0)
Calin	21.5 (17.0–25.0)	24.2 (19.0–29.0)	16.0 (11.0–24.0)
ASAS Criteria for Axial SpA	0.78 (0.16–2.30)	0.80 (0.097–2.89)	0.70 (0.02–4.25)
MNY Criteria for AS	0.52 (0.06–1.80)	0.40 (0.01–2.20)	0.70 (0.02–4.25)
Amor Criteria for SpA	2.00 (0.90–4.00)	2.40 (0.88–5.22)	1.40 (0.18–5.50)
ESSG Criteria for SpA	2.00 (0.90–4.00)	2.40 (0.88–5.22)	1.40 (0.18–5.50)

IBP: inflammatory back pain; SpA: spondyloarthritis; MNY: modified New York; ESSG: European Spondyloarthropathy Study Group

Conclusion: This is the first population-based survey of axial SpA using ASAS classification criteria. The prevalence estimates of IBP and SpA/axial SpA reported in this study are within the upper range of other studies in European countries and US.

Long Term Efficacy Over Five Years Of Adalimumab In Patients With Active Non - Radiographic Axial Spondyloarthritis. Hildrun Haibel[1], Xenofon Baraliakos[2], Joachim Listing[3], Juergen Braun[2] and Joachim Sieper[1]. [1]Charité Universitätsmedizin Berlin, Berlin, Germany, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]German Rheumatism Research Center, Berlin, Germany.

Background/Purpose: Adalimumab had demonstrated good efficacy in 46 patients with active non-radiographic axial SpA in a 12-weeks, placebo-controlled trial with a 40-weeks, open-label extension.[1,2]In 19 patients who flared after drug withdrawal therapy was restarted and patients were followed-up. The purpose of the study was to evaluate the long term efficacy over 5 years after re-treatment with adalimumab in patients whose disease flared after treatment was stopped at week 52.

Methods: Of 46 patients originally enrolled, all patients were stopped and 23 (52% male; mean age 32 years [range 24–45]; mean disease duration before treatment 4 years [range 1–10]; 74% HLA-B27+) had reached a major response defined as reaching an 40% improvement according to the ASsessments in SpondyloArthritis international Society (ASAS40). In case of a flare (defined as <ASAS40 response compared to baseline), adalimumab therapy (40 mg eow) was re-started and patients were treated continuously for up to 5 years (week R264). ASAS response criteria and Bath AS disease activity score were (BASDAI) were calculated using a completer analysis.

Results: 19 out of these 23 patients had to be retreated: 16/19 (84%) patients were still in the study at year 3 and 4. 12/19 (63%) patients completed year 5 of retreatment. After 3 years of adalimumab re-treatment, 13/16 (81%) again reached ASAS 40 and 11 of 16 (69%) achieved ASAS partial remission. After 4 years ASAS 40 was reached in 69% (11/ 16 patients) and after 5 years in 75% (9/ 12 patients). ASAS partial remission was reached in 56% (9/16) of patients after 4 years and in 58% (7/12) of patients at the end of year 5. The mean BASDAI for the completers at the different time points decreased from 5.1±1.8 at R-Baseline to 1.6±1.6 at year 3 ($p < 0.001$), to 2.2±2.1 at year 4 ($p = 0.001$) and 1.5±1.8 at year 5 ($p = 0.001$) of retreatment.

Conclusion: In this group of 19 patients with early axial SpA who had achieved a good response after 52 weeks of adalimumab therapy, and who had to be retrated because of a flare, the majority of patients who remained in the study had a good and sustained clinical response.

Response to Tumor Necrosis Factor inhibitors In Axial Spondyloarthritis: Does Sacroiliitis Make Any Difference? Julien Girodon[1], Vianney Jouhet[2] and Elisabeth Solau-Gervais[1]. [1]University Hospital of Poitiers, Poitiers, France, [2]University hospital Bordeaux, Bordeaux, France.

Background/Purpose: Axial spondyloarthritis (SpA) are characterized by sacroiliitis. The TNF inhibitors (TNFi) have been proven to be highly effective in ankylosing spondylitis. Recently, adalimumab demonstrate clinical efficacy in patients with axial SpA without radiographically defined sacroiliitis (SI). The objectives of the study are to compare patient's characteristics and response to treatment according to the presence of SI.

Methods: 162 records of patients with axial SpA treated with TNFi were analyzed. These patients were out and in patients followed in an university hospital in year 2009–2011. Patients have to fulfilled ASAS criteria and treated by at least one TNFi (infliximab, adalimumab, etanercept) to be included. Three groups of patients were designed: group 1: SpA with SI on X-Rays, group 2: SpA without SI on X-Rays and with SI on magnetic resonance analysis (MRI) and group 3: SpA without sacroiliitis on X-Rays and MRI. Statistical analysis used univariate, multivariate and survival analysis with GraphPad software.

Results: Characteristics of the patients and results of univariate analysis have been detailed in table 1:

	Group 1	Group 2	Group 3	1 versus 3	1 versus 2	2 versus 3
N	105	26	31			
Sex (M/F) (%)	64,7/35,3	38,46/61,54	38,7/61,3	0,01	0,014	0,98
Age	44,38 +/− 13,32	44,69 +/−9,18	40,93 +/− 11,97	0,22	0,7	0,17
HLA B27 (%)	83,8	65,38	87,1	0,65	0,035	0,052
Age at diagnostic	30,64 +/− 11,9	37,38 +/−8,1	33,03 +/− 9,9	0,136	0,001	0,088
Increased CRP (%)	77,1	50	51,6	0,006	0,006	0,9
CRP (mg/l)	31,27 +/− 32,07	13,92+/−13,77	20,38 +/− 31,88	0,013	0,007	0,96
TNFi n	1,33+/− 0,63	1,73+/−0,77	1,71+/−0,82	0,009	0,005	0,86

In multivariate analysis, factors associated statistically with the absence of radiological X-Rays sacroiliitis were (ORs; 95% confidence intervals): number of TNFi used (4,154; 1,41–12,1; p = 0,0032), age at diagnosis (0,89; 0,83–0,96; p = 0,0012) and increased of CRP (0,31; 0,14–0,69; p = 0,0045). At least the rate of the first TNFi maintenance was significantly (p=0.009) higher in the group 1 (68,5%) compared to group 2 (54.5%) and group 3 (34.6%).

Conclusion: Presence of sacroiliitis in axial SpA is associated with an earlier diagnosis and more frequent increased CRP as well as a greater maintenance rate of the first TNFi

The Prevalence Of Sjogren's Syndrome In Patients With Ankylosing Spondylitis. Ayse Balkarli[1], Adem Kucuk[2], Sahin Temel[3], Tayfun Gungor[4], Ramazan Ucar[5] and Veli Cobankara[6]. [1]Pamukkale University, Division of Rheumatology, Denizli, Turkey, [2]Necmettin Erbakan University, Division of Rheumatology, Konya, Turkey, [3]Department of Internal Medicine, Pamukkale University, Denizli, Turkey, [4]Department of Physical medicine and Rehabilitation, Necmettin Erbakan University, Konya, Turkey, [5]Konya Education and Research Hospital, Department ofInternal Medicine, Konya, Turkey, [6]Division of Rheumatology, Pamukkale University, Denizli, Turkey.

Background/Purpose: Sjögren's syndrome (SS) is a chronic autoimmune inflammatory disease that primarily affects exocrine glands with a prevalence of 1% to 4.8. SS mainly affects middle-aged women with a female-male ratio of 9:1. Ankylosing spondylitis (AS) is the prototype of spondyloarthropathy that is characterized by sacro-ileitis, inflammation, enthesitis and also involves peripheral joints, eye and aorta. The prevalence of AS is about 0.5% with a similar female-male ratio. We aimed to evaluate the SS prevalence in patients with AS.

Methods: 143 patients with the diagnosis of AS according to Modified New York Criteria were included in the study. Sicca questionnaire that includes sicca symptoms for SS was performed in all patients. Schirmer test was performed for xerophthalmia and unstimulated salivation test for xerostomia. Rheumatoid factor (RF), antinuclear antibody (ANA), anti-Ro and anti-La antibodies were measured as laboratory tests. Minor salivary gland biopsy was performed in patients with positive xerophthalmia and xerostomia tests and Sicca questionnaire. The presence of SS was assessed according to classification criteria of American-European Consensus Group.

Results: The mean age of patients was 39.6 years old and 73 of them were male. Fourteen (10%) of the patients were diagnosed as SS according to American-European Consensus Group classification criteria. Twenty-three of the patients were undergone minor salivary gland biopsy those fulfilled the three criteria. Fourteen biopsies of the patients were evaluated as pathologically. Three of them were reported as grade IV and 11 of them as grade III sialadenitis according to the criteria of Mason Chisholm. Seven of these 14 patients were male and there was no difference in terms of sex. Only one patient has a positive anti-Ro and anti-La antibodies. However, 13 of patients (except 1 patient) had ANA positivity (> 1/80). There was bilateral sacro-ileitis in MRI of all patients diagnosed as SS.

Table 1. General characteristics of the patients

	n(%)
Age (years)	39.6
Sex(F/M)	73/70
Duration of disease (years)	6.6±5.3
Drugs	89 (62.2%)
SLZ	13 (9.1%)
IFX ADA	19 (13.3%)
ETA	20 (14%)
Xerostomia	51 (35.7%)
Xerophthalmia	24 (16.8%)

Conclusion: In our study, we found a high prevalence of SS in patients with AS. ANA positivity was higher in co-existence of SS and AS and it may be a risk factor for SS.

Radiographic Sacroiliitis Progression In An Early Spondyloarthritis Cohort. Concepcion Castillo-Gallego[1], Eugenio de Miguel[1], Carmen Martin-Hervas[1], Diana Peiteado[2], Leticia Lojo[2] and Emilio Martin-Mola[1]. [1]Hospital Universitario La Paz, Madrid, Spain, [2]Hospital Universitario La Paz, Spain, Spain.

Background/Purpose: The improvement of treatment in axial Spondyloarthritis (axSpA) and the development of the ASAS classification criteria have facilitated the early diagnosis and management of this disease. It is important to know what are the more relevant predictors of radiographic progression in early SpA to take clinical decision.

The aim of this study was to assess predictive factors for radiographic sacroiliitis progression in a cohort of early axSpA.

Methods: Patients included in the study came from the early SpA unit at our hospital, as part of the ESPERANZA programme, a nationwide health management programme designed to provide excellence in care for early SpA. One of the inclusion criteria was symptom duration between 3 and 24 months. Every patient had a complete examination at baseline that included ESR, CRP, ASDAS-CRP, ASDAS-ESR, BASDAI, HLA-B27, radiographs of pelvis and Magnetic resonance (MRI) of sacroiliac joints (SIJ). MRI of SIJ were assessed according to ASAS definition for bone marrow oedema. Radiographs of pelvis at baseline and at follow up were done for every patient. These x-Rays were centrally digitized and the SIJ were scored according to the grading system of the modified New York criteria (mNYc). SPSS program version 17.0 was used for Statistical analysis. Paired-sample t test was used for comparison of radiographic sacroiliitis progression.

Results: Forty-one consecutive patients from the early axial Spondyloarhtritis cohort of the Esperanza program were analyzed, 39% of them were female. The average evolution time since onset of symptoms until baseline clinic visit was 10.9±7.1 months. All patients fulfilled ASAS criteria for axSpA and three of them had Ankylosing Spondytitis (AS) according to mNYc at baseline. The mean follow up time was 3.51 years (range: 2–5years; SD±1.03). Progression of sacroiliitis over follow up by at least one grade at one side was found in 61% (25/41). Among the 38 non radiographic axSpA patients at baseline, 5 of them (13.16%) progressed to AS according to mNYc. Statistically significant radiographic progression was observed in all the variables analyzed (see table 1).

Table 1.

	Baseline SIJ x-Ray score (mean±SD)	Follow up SIJ x-Ray score (mean±SD)	P	n
HLA-B27 positive	0.84 ± 0.91	1.48 ± 1.07	<0.001	23
HLA-B27 negative	0.25 ± 0.55	0.58 ± 0.73	<0.01	18
BASDAI<4	0.57 ± 0.96	1.18 ± 1.06	<0.001	14
BASDAI≥4	0.56 ± 0.75	1.04 ± 1.04	<0.001	26
CRP<5	0.47 ± 0.75	0.97 ± 0.90	<0.001	30
CRP≥5	0.82 ± 0.96	1.41 ± 1.30	<0.01	11
ESR<10	0.50 ± 0.78	1.03 ± 0.92	<0.001	29
ESR≥10	0.71 ± 0.91	1.21 ± 1.28	<0.01	12
ASDAS-CRP<2.1	0.35 ± 0.73	0.76 ± 0.85	<0.01	17
ASDAS-CRP≥2.1	0.72 ± 0.86	1.33 ± 1.12	<0.001	23
ASDAS-CRP<3.5	0.53 ± 0.82	1.00 ± 0.94	<0.001	31
ASDAS-CRP≥3.5	0.67 ± 0.84	1.39 ± 1.33	<0.01	8
ASDAS-ESR<2.1	0.34 ± 0.70	0.69 ± 0.82	<0.01	16
ASDAS-ESR≥2.1	0.71 ± 0.87	1.35 ± 1.10	<0.001	24
ASDAS-ESR<3.5	0.50 ± 0.78	0.95 ± 0.88	<0.001	31
ASDAS-ESR≥3.5	0.78 ± 0.94	1.55 ± 1.42	<0.01	9
MRI positive	1.11 ± 0.92	1.58 ± 0.99	<0.001	14
MRI negative	0.17 ± 0.38	0.67 ± 0.73	<0.001	20

Conclusion: Every patient of this early axSpA cohort had radiographic sacroiliitis progression independently of the outcome assessed. Patients HLA-B27 positive, with MRI positive, higher values of CRP or ESR and higher scores of BASDAI and ASDAS not only presented higher radiographic scores at baseline and but also more radiographic progression at follow up.

Combined Axial and Peripheral Involvement Is Associated With Miscegenation In A Large and Heterogeneous Brazilian Cohort Of 1505 Patients With Spondyloarthritis. Percival D Sampaio-Barros, Mittermayer Santiago, Adriana B. Bortoluzzo, Antonio Carlos Ximenes, José Antonio Braga da Silva, Manoel B Bértolo, Sandra Lúcia Ribeiro, Mauro Keisermann, Rita Menin, Thelma L. Skare, Sueli Carneiro, Valderilio F. Azevedo, Walber P. Vieira, Elisa Albuquerque, Washington A. Bianchi, Rubens Bonfiglioli, Cristiano Campanholo, Hellen M Carvalho, Izaias P. Costa, Angela Luzia B. P. Duarte, Charles Kohem, Nocy Leite, Sonia Lima, Eduardo S. Meirelles, Ivânio A. Pereira, Marcelo M. Pinheiro, Elizandra Polito, Gustavo G. Resende, Francisco AC Rocha, Maria de Fátima L. C. Sauma, Valéria Valim and Celio R. Gonçalves. Brazilian Registry of Spondyloarthritis, São Paulo, Brazil.

Background/Purpose: Spondyloarthritides (SpA) constitute a group of diseases that can present different patterns according to the genetic background. Brazilis a large country with a heterogeneous population, constituted by 48.7% of whites, 50.6% African-Brazilians (43.6% Mulatos, originated from the miscegenation of whites and blacks, and 7.0% blacks of pure origin), and 0.7% of Asian ancestry (predominantly Japanese) and Indians (National Census, 2010). This ethnic distribution varies a lot among the different geographic regions in the country. The objective of this study is to analyze disease patterns in a large cohort of patients with SpA, according to the five main geographic regions.

Methods: Brazilian multicentric cross-sectional study of 1505 SpA patients according to the European Spondyloarthropathy Study Group (ESSG), evaluated by a standardized protocol. There were 762 patients from the Southeast (68% whites and 20.1% African-Brazilians), 272 from the Midwest (49.4% whites and 43.7% African-Brazilians), 258 from the South (84% whites and 12% African-Brazilians), 126 from the North (66.7% whites, 16.7% African-Brazilians, and 16.6% mixed, including Indians), and 87 from the Northeast (32.1% whites and 56% African-Brazilians).

Results: Patients from the South region presented higher frequency of axial involvement ($p < 0.001$) and uveitis ($p = 0.001$), whereas patients from the more miscegenated regions (Northeast and North) presented higher frequencies of combined axial and peripheral involvement ($p < 0.001$), and higher mean values of erythrocyte sedimentation rate (ESR) ($p < 0.001$) and C-reactive protein (CRP) ($p < 0.001$). Patients from the Northeast region were characterized by a higher frequency of male patients ($p = 0.002$), hip involvement ($p < 0.001$) and work incapacity ($p = 0.001$), with higher scores of Maastricht Ankylosing Spondylitis Enthesitis Score (MASES; $p < 0.001$), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI; $p < 0.001$), Bath Ankylosing Spondylitis Functional Index (BASFI; $p < 0.001$), and Ankylosing Spondylitis Quality of Life (ASQoL; $p < 0.001$).

Conclusion: The present study provides evidence that miscegenation in the Northeast of Brazil may underlie the clinical presentation of SpA in this region with a distinct clinical pattern characterized by combined axial and peripheral involvement and a more aggressive disease.

2471

Prevalence Of Inflammatory Back Pain In Psoriatic Arthritis: The Prepare Study. Majed Khraishi[1], Dafna D. Gladman[2], Javier Coindreau[3], Lotus Mallbris[3], Annette Szumski[3], Eustratios Bananis[3] and Heather Jones[3]. [1]Nexus Clinical Research, St John's, NF, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, [3]Pfizer Inc., Collegeville, PA.

Background/Purpose: Up to 30% of patients with psoriasis (Ps) may develop psoriatic arthritis (PsA); ranging from mild and non-destructive disease to severe and erosive arthritis.[1] Spondylitis prevalence in PsA is approximately 25–30%. PREPARE, an international, multicenter, non-interventional study assessed PsA prevalence in patients presenting to dermatologists with Ps (285/949 had PsA, 117/285 = newly diagnosed; the Toronto Psoriatic Arthritis Screen [ToPAS] and Psoriasis and Arthritis Screening Questionnaire [PASQi] detected probable PsA in 42.9% and 45.1% of patients).[2] Since no formal assessment of inflammatory back pain (IBP) formed part of the PREPARE study, the focus of these post-hoc analyses was to determine if positive IBP correlated with PsA diagnosis as a useful screening tool.

Methods: Our analyses included patients with Ps who received either the PASQi or ToPAS screening questionnaires during their dermatologist's visit. Patients were subsequently evaluated by a rheumatologist to establish/exclude a clinical diagnosis of PsA. The prevalence of IBP was identified by the PASQi and ToPAS questionnaires: PASQi back pain was defined by patients who "ever had back troubles" with stiffness lasting >30 minutes and IBP total score>4; ToPAS had 1 question addressing back pain occurrence lasting >3 months that was not injury related (although this was not included in the scoring of ToPAS). *Cochran–Mantel–Haenszel* (CMH) tests were used to analyze differences in proportions of positive IBP between PsA vs non-PsA groups. Kappa coefficients determined the agreement between PsA diagnosis and positive IBP.

Results: Of the patients, 85/341 (24.9%) had positive PASQi defined IBP while 146/337 (43.3%) had positive ToPAS defined IBP. Patients with PsA detected by a rheumatologist/PASQi/ToPAS/a combination had higher IBP prevalence than Ps patients with no indication of PsA (32.6%-55.2% vs 17.6%-38.9%; Table). Of the patients with detected PsA or IBP, there was a higher extent of activity impairment in patients with IBP than those without IBP (PsA: 22.4% vs 15.75%, P=0.003; PASQi: 19.1% vs 16.2% P=0.3651 and ToPAS 23.5% vs 13.4% P=0.0003). Work productivity impairment was significantly higher in patients with PsA vs non-PsA (16.5% vs 10.9%, P=0.012) and positive vs negative IBP as detected by the ToPAS screen (19.1% vs 9.3%, P=0.003). All κ coefficients were <0.2 indicating slight agreement between IBP and PsA as defined by PASQi, ToPAS or a rheumatologist (Table).

IBP defined by:	PsA defined by:	PsA Proportion with IBP (%)	Non-PsA Proportion with IBP (%)	CMH P-value	Kappa coefficient
PASQi	PASQi	52/153 (34.0)	33/188 (17.6)	0.0005	0.171*
PASQi	Rheumatologist	30/92 (32.6)	50/225 (22.2)	0.0537	0.108
PASQi	PASQi and Rheumatologist†	26/62 (41.9)	27/144 (18.8)	–	–
ToPAS	ToPAS	76/141 (53.9)	70/196 (35.7)	0.0009	0.181**
ToPAS	Rheumatologist	53/96 (55.2)	86/221 (38.9)	0.0073	0.145***
ToPAS	ToPAS and Rheumatologist†	39/73 (53.4)	50/158 (31.7)	–	–

†PsA defined by both a questionnaire and by rheumatologist. PsA present if positive for both; PsA not present if negative for both.
*P<0.0001; **P<0.001; ***P<0.01

Conclusion: In this study, Ps patients with PsA had increased IBP incidence compared to those without PsA. Kappa coefficients indicate that IBP is not a good marker for PsA diagnosis in patients with Ps. However, the high incidence of IBP detected in Ps patients warrants further investigation.

Disease Burden Is Similar Between Non-Radiographic Axial Spondyloarthritis and Ankylosing Spondylitis and Independent Of Gender Influences. Salih Ozgocmen, Erkan Kilic, Gamze Kilic and Ozgur Akgul. Erciyes University, Faculty of Medicine, Kayseri, Turkey.

Disease Burden is Similar between Non-Radiographic Axial Spondyloarthritis and Ankylosing Spondylitis and Independent of Gender Influences

Background/Purpose: Axial spondyloarthritis (SpA) covers both ankylosing spondylitis (AS) with established radiographic changes and non-radiographic axial SpA (nr-axSpA) without definite radiographic sacroiliitis. Clinical characteristics and differences between women and men with nr-axSpA or AS have been documented; however comparison of patients with nr-axSpA and AS within the same genders may provide more data. Registry data revealed similar burden of disease, however baseline characteristics regarding gender distribution and HLA-B27 differ in nr-axSpA from AS. We compared nr-axSpA and AS within the same genders regarding the clinical characteristics in a cohort of patients with axial SpA.

Methods: A total of 170 consecutive patients diagnosed with axial SpA were studied and clinical and laboratory results were compared between male and female patients in subgroups of nr-axSpA and AS. Standard clinical assessment tools (VAS-pain, global assessment, BASDAI, BASFI, ASQoL and SF-36, ASDAS), laboratory data, existence of inflammation on the sacroiliac and lower-thoracic and lumbar spine MR (blindly assessed), SpA features and comorbidities were used in the analysis.

Results: Patients with AS (n=96) were predominantly male (79.2%) whereas patients with nr-axSpA (n=74) were predominantly female (55.4%) (p=0.0001). Women with nr-axSpA and AS did not differ in clinical variables except family history for SpA and spinal inflammation on MR (16.7% vs 68.8%, p=0.0001, respectively). Men with nr-axSpA and AS did not differ in clinical variables, except HLA B27, peripheral arthritis, younger age and spinal inflammation of MR (25.0% vs 52.1%, p=0.014, respectively).

Table 1. Comparison between groups for the measured parameters

	Women			Men		
	nr-axSpA (n=41)	AS (n=20)	p	nr-axSpA (n=33)	AS (n=76)	p
Age, y	34.7±9.6	38.3±7.1	0.142	29.7±7.6	37.5±8.7	0.0001
Age at symptom onset, y	29.5±7.8	28.1±8.2	0.454	24.1±7.7	26.9±7.4	0.07
VAS-pain	4.7±2.5	5.2±2.8	0.336	4.4±3.0	3.8±2.7	0.334
Physician's global	3.7±1.3	4.4±1.8	0.195	3.5±2.3	3.4±2.0	0.728
Patient's global	4.6±2.4	5.6±2.1	0.066	4.0±2.8	3.9±2.5	0.779
BASDAI	3.9±1.9	4.3±2.2	0.634	3.8±2.2	3.2±2.3	0.255
BASFI	2.2±1.9	3.5±2.8	0.122	1.8±1.9	2.6±2.3	0.085
SF-36 MCS	51.6±23.3	40.2±17.2	0.072	56.0±22.4	58.7±23.2	0.575
SF-36 PCS	49.9±22.1	42.1±19.9	0.213	54.7±21.6	55.5±23.2	0.869
ASQoL	7.7±4.7	10.1±6.0	0.118	5.7±4.9	6.6±5.4	0.399
ASDAS-CRP	2.7±0.9	2.9±0.9	0.509	2.5±0.9	2.7±1.0	0.452
HLA B27+ve, %	48.8	60.0	0.430	51.5	72.3	0.047
Smoking, %	29.3	15.0	0.224	54.5	44.7	0.346
Inflammation-SIJ MR, %	82.1	89.5	0.703	78.8	61.8	0.084
Uveitis, %	9.8	15.0	0.546	15.1	19.7	0.570
Psoriasis, %	2.4	10.0	0.248	9.1	3.9	0.261
Family history,%	12.2	35.0	0.035	18.8	26.7	0.382
Peripheral arthritis	24.4	15.0	0.400	28.1	11.8	0.038
Preceding infection, %	19.5	5.0	0.134	18.8	6.6	0.056

Conclusion: Results of our cohort confirm the earlier data showing that the burden of disease is similar between nr-axSpA and AS. Although disease burden seem to be independent of gender, men or women with nr-axSpA differ from AS in several clinical aspects including HLA B27, peripheral arthritis, positive family history for SpA and more prevalent inflammation on spinal MR.

Comparison Of The Two Subtypes Of Axial Spondyloarthritis Patients Fulfilling The Imaging Arm Based On Radiographic and MRI Findings. Dilek Solmaz, Servet Akar, Ismail Sari, Pinar Cetin, Fatos Onen and Nurullah Akkoc. Dokuz Eylul University School of Medicine, Izmir, Turkey.

Background/Purpose: New Axial Spondyloarthritis Classification Criteria include an imaging arm and a clinical arm. The imaging arm includes radiographic ax-SpA patients who have radiographic sacroilitis according to modified New York criteria and non-radiographic (nr) ax-SpA patients who have sacroiliitis only by MRI. Although there is no doubt that radiographic and non-radiographic axSpA have many overlapping features, it is now one of the hot topics of discussion whether they are different entities.

The aim of this study was to compare the demographics and clinical characteristics between the radiographic and nr-axSpA patients fulfilling the criteria of the imaging arm.

Methods: A local database has been used since December 2008 to register all patients fulfilling the imaging arm of AxSpA classification criteria.

Data related to demographics, clinical features, disease activity, functional status, treatment were recorded.

Results: 720 patients who met the study criteria were identified. Radiographic sacroiliitis according to modified New York criteria was present in 533 patients. The remaining 187 patients were classified as nr-axSpA based on MRI findings. Demographics and clinical characteristics are summarized in Table 1. Patients with nr-axSpA had an earlier onset of symptoms and were more often females. Prevalence of extraspinal manifestations was similar in both groups, except for anterior uveitis, which was more frequently reported by the patients with radiographic axSpA. C-reactive protein levels were significantly higher in patients with radiographic sacroiliitis as compared to those with nr-AxSpA. HLA-B27 prevalence was numerically greater among patients with radiographic axSpA, but was not statistically significant. Disease activity measured by BASDAI, but not by ASDAS, was higher in the nr-axSpA group; BASFI scores were similar in both groups. BASMI score was higher in radiographic ax-SpA patients. While anti-TNF therapy was used more frequently by patients with radiographic sacroiliitis, DMARD use was similar in both groups.

Table 1. Demographics and clinical characteristics of the radiographic and non-radiographic axSpA patients.

Demographic and clinical features	Radiographic sacroiliitis (n:533)	Non-radiographic sacroiliitis (n:187)	*P*
Age, mean ± SD	43 ± 12.0	42 ± 13.2	0.232
Male sex n,%	395, 74.1	72, 38.5	<0.001
Age at beginning of the symptoms, mean ± SD	25 ± 9.1	28 ± 10.3	0.010
Diagnostic delay, mean ± SD	8 ± 8.5	7 ± 8.0	0.023
Arthritis n,(%)	195, (36.6)	42, (22.5)	0.491
Hip replacement n,(%)	23, (4.3)	0	0.023
Anterior uveitis n,%	97, (18.2)	10, (5.3)	0.007
Psoriasis n,%	16, (3.0)	4, (2.1)	0.399
IBD n,%	16, (3.0)	2, (1.0)	0.082
HLA B27 positivity n1/n2 (%)	166/243 (68.3)	46.3 % (36/78)	0.146
CRP mg/dl, mean ± SD	19.0 ± 25.6	9.5 ±17.1	<0.001
BASDAI, mean ± SD	3.5 ± 2.2	4.3 ± 2.5	<0.001
ASDAS-CRP, mean ± SD	2.9 ±1.1	2.1 ±1.1	0.223
BASFI, mean ± SD	2.9 ±2.6	2.7 ±2.5	0.346
BASMI, mean ± SD	3.9 ±1.9	2.3 ±1.0	<0.001
SSZ, n, (%)	132, (24.2)	21, (11.2)	0.316
MTX, n, (%)	34, (6.3)	4, (2.1)	0.317
Anti TNF, n,(%)	103, (19.3)	8, (4.2)	<0.001

Conclusion: Although many demographic and clinical features are similar between the ax-SpA patients with and without radiographic sacroiliitis classified with the imaging arm, differences such as higher prevalence of females and numerically lower prevalence of HLA-B27 among patients with nr-axSpA are of interest.

Fat Mass and Resistin: Predictive Factors For Anti-TNF Therapy Response In Ankylosing Spondylitis Patients. Carla G.S. Saad, Andressa Silva Abreu, Ana Cristina Medeiros Ribeiro, Julio C. B. Moraes, Luiz A. Perandini, Thalita Dassouki, Rosa M. R. Pereira, Eloisa Bonfa and Ana Lucia S. Pinto. Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: The adipose tissue immune properties and pharmacokinetic consequences can contribute to the pathogenesis of inflammatory conditions. The hole of fat tissue in active Ankylosing Spondylitis (AS) patients and its influence on response to anti-TNF therapy has not been widely investigated. The purpose of this study was to evaluate the fat tissue in active AS patients and the influence on clinical response to TNF blockade therapy.

Methods: 37 patients with active AS referred to receive anti-TNF therapy with high/very high disease activity according to AS Disease Activity Score (ASDAS > 2.1) and have completed 6 months of treatment were included. At baseline patients were evaluated for weight, height, body mass index (BMI), waist circumference, body composition (DXA) including total fat and trunk fat. Factors related to adipocytokines and inflammation (leptin, resistin, adiponectin, TNFα and IL-6) were also evaluated at baseline. Disease parameters and inflammatory markers [erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)] were assessed at baseline and after 6 months of treatment. Responders to anti-TNF therapy were defined according to ASDAS improvement criteria with Δ ASDAS $\geq$ 2.0.

Results: Patients had a mean age of 37.0 ± 12.1 years, 75.7% were male with a mean of 9.0 ± 9.8 years of disease duration. At baseline patients had [mean (SD)]: weight 70.4(11.9)kg, BMI 26.1(4.3)kg/m2, waist circumference 89.0(10.4)cm, total fat 18.9(6.6)kg and trunk fat mass 19.5(6.7)kg. Regarding disease parameters, the mean ASDAS value was 3.2(0.9), BASFI 4.4(2.4) and BASMI 4.4(2.7). After 6 months of anti-TNF treatment 12 (32.4%) patients reached major improvement by ASDAS criteria. Comparing responders and non-responders groups we observed that the patients with good response had lower BMI ($p=0.01$), waist circumference ($p=0.005$), trunk fat mass (0.03) and higher resistin ($p=0.02$) serum levels and infflmmatory parameters [CRP ($p=0.02$) and ESR ($p=0.01$)]. Resistin serum levels at baseline correlated with CRP ($r=0.58$, $p<0.01$) and ESR ($r=0.37$, $p=0.02$).

Conclusion: This study provides evidence that fat mass and resistin serum levels may predict the anti-TNF response in AS patients. Further studies are necessary to elucidate the mechanism by which adipose tissue affects inflammatory condition in AS.

Relationship Between Extra-Articular Manifestations and Disease Activity In Patients Diagnosed With New-Onset Spondyloarthropathy In a Cohort In Spain. César Antonio Egües Dubuc[1], Maria Martin Martinez[2], Joaquin Belzunegui Otano[1], Miren Uriarte Ecenarro[1], Juan Mulero[3], Eugenio de Miguel[4], Santiago Muñoz[5], Pedro Zarco[6], Eduardo Collantes[7], Sabina Perez Vicente[2] and Milena Gobbo[2]. [1]Donostia University Hospital, San Sebastián, Spain, [2]Research Unit, Spanish Society of Rheumatology., Madrid, Spain, [3]Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda (Madrid), Spain, [4]Hospital Universitario La Paz, Madrid, Spain, [5]Hospital Infanta Sofia, Madrid, Spain, [6]Fundación Hospital Alcorcon, Alcorcon, Madrid, Spain, [7]Hospital Reina Sofia, Cordoba, Spain.

Background/Purpose: The Spondyloarthropathy (SpA) that affect in many aspects of life of the patients, either for their musculoskeletal or extra-articular manifestations (EAM). EAM vary in frequency and severity, the most common are: uveitis, inflammatory bowel disease and skin diseases. Some epidemiological studies have found increased incidence of EAM as a consequence of disease activity. This study aims to analyze the relationship between the EAM with disease activity in patients with new onset SpA.

Methods: This is a longitudinal study, for which the ESPERANZA Program database from Spanish Society of Rheumatology was analyzed. Database includes SpA patients with aged between 18 and 45 years, with duration of disease between 3 and 25 months, belonging to 25 health centers in Spain. The primary endpoint were all the EAM analyzed together and by themselves. The independent variables were: demographics; disease activity parameters as BASDAI, at least one painful and swollen joints, at least one enthesitis, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR); metrological parameter (BASMI), quality parameter (ASQoL) and functionality parameter (BASFI); HLA-B27, duration of disease at the diagnoses and the presence of sacroiliitis on magnetic resonance. The quantitative variables were described as mean and standard deviation (SD) if distributed symmetrically and if distributed asymmetrically by the median and interquartile ranges (IR), qualitative were described with percentages accompanied by absolute value. The Pearson or Spearman correlation, Student t test, analysis of variance and chi square test were used for bivariate analysis according to the variables to be analyzed. For multivariate analysis the variables analyzed were those that had $P<0.20$, or those that had clinical relevance for the study, we used multiple linear regression analysis or logistic regression model.

Results: 698 patients [426 men (61%)] with median age of 32.9 years (CI: 27.5–38.9) were studied. Table 1 shows the EAM studied. Table 2 shows the independent variables, which were analyzed with the EAM (table 3).

Table 1. Extra-articular manifestations in patients diagnosed with new-onset spondyloarthropathy (n=698).

	Patient without EAM	Patient with EAM
At least one EAM	406 (41.8%)	292 (58.2%)
Psoriasis	577 (82,7%)	121 (17.3%)
Urethritis	685 (98.1%)	13 (1.9%)
Uveitis/Iritis	656 (94%)	42 (6%)
Pustulosis	694 (99.4%)	4 (6%)
Acne	692 (99.1%)	6 (0.9%)
Inflammatory bowel disease	654 (93.7%)	44 (6.3%)
Nail psoriasis	670 (96%)	28 (4%)
Dactylitis	625 (89.5%)	73 (10.5%)
Enthesopathy	634 (90.8%)	64 (9.2%)

Table 2. Demographic, measurement parameters, markers of activity, presence of sacroiliitis on MRI, presence of HLA B27, according to the presence of extra-articular manifestations in patients diagnosed with new-onset spondyloarthropathy (n=698).

	Total Spa patients (n = 698)				Spa patients with at least one EAM (n=292)				Spa patients without EAM (n=406)

Periodontal Disease Is Not Associated With Ankylosing Spondylitis and TNF-Alpha Blockers Usage In Korea. Sung Hae Chang[1], Jung Tae Lee[1], Byoung Youg Choi[1], Hyon Joung Cho[1], Jong Jin Yoo[2], Hye Jin Oh[3], Eun Ha Kang[1], Yeong Wook Song[3], Hyo Jung Lee[1] and Yun Jong Lee[4]. [1]Seoul National University Bundang Hospital, Seongnam-si, South Korea, [2]Armed Forces Capital Hospital Seongnam Republic of Korea, Seongnam si, South Korea, [3]Seoul National University Hospital, Seoul, South Korea, [4]Seoul National University College of Medicine, Seoul, South Korea.

Background/Purpose: Periodontal disease (PD) is a chronic inflammatory disease, which has been reported to be associated with rheumatoid arthritis (RA). But, a few studies on an association between ankylosing spondylitis (AS) and PD showed inconsistent results. Thus, we performed a prospective and longitudinal study on the prevalence and course of PD and the effects of TNF-α blockers on PD in AS patients.

Methods: A total of 75 AS patients and 73 age- and gender-matched healthy controls (HC) were prospectively recruited. Full-mouth periodontal probing, 6 sites per tooth, was performed at the baseline and, if a subject had PD, 12 week after periodontal scaling. Periodontal status was assessed using the plaque index (PI), bleeding on probing (BOP), probing pocket depth (PPD), and clinical attachment loss (CAL). PD was defined using clinical case definitions proposed by the Centers for Disease Control and Prevention (CDC). AS disease activity, spinal mobility, and radiographic status were evaluated using the Bath ankylosing spondylitis disease activity score (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Metrology Index (BASMI), and the modified Stoke AS Spinal Score (mSASSS).

Results: The prevalence of PD was comparable between subjects with HC and AS (58.9% versus 68.0%, p = 0.250). There was no significant difference in PI, BOP, PPD and CAL between the two groups. In AS patients, male gender (p = 0.009) was significantly associated with PD at the baseline examination, whereas the other variables including current use of TNF-α blockers (17/51 versus 4/24, p = 0.288) was not. Periodontal status 12 weeks after periodontal scaling was not different between AS (n = 29) and HC (n = 14, p = 0.317). In addition, among AS patients with PD, current use of TNF-α blockers did not affect periodontal treatment outcomes.

Table 1. The prevalence and severity of periodontal disease in AS patients and healthy controls at the baseline.

Characteristics	AS	HC	P-value
Periodontal disease prevalence	51 (68.0%)	43 (58.9%)	0.314
Periodontal disease severity			0.607
Mild	0 (0.0%)	2 (2.7%)	
Moderate	44 (58.7%)	33 (44.6%)	
Severe	7 (9.3%)	10 (13.5%)	
Plaque index (%)	25.0 [13.4–41.7]*	23.2 [10.7–36.6]	0.521
Probing pocket depth (mm)	2.54 [2.30–2.77]	2.54 [2.38–2.77]	0.950
Bleeding on probing (%)	11.8 [7.14–22.6]	6.5 [6.35–17.6]	0.231
Clinical attachment loss (mm)	2.58 [2.38–2.86]	2.58 [2.39–2.92]	0.934

AS, ankylosing spondylitis; HC, healthy control; *, median [interquartile range]

Conclusion: Contrast to RA patients, the prevalence and severity of PD was not increased in AS patients. Furthermore, TNF-α blocker usage in AS patients was associated with neither the prevalence of PD nor the outcome of treatment in our interim analyses.

2477

Impact Of Stressful Life Events On Disease Activity In Spondyloarthritis: Results Of The Coenv-2 Prospective Cohort Study. Guanguan Luo[1], Pierre Yves Boelle[1], Clément Turbelin[1], Roula Said Nahal[2], Nadine Zeboulon[2], Maria-Antonietta D'Agostino[3], Solen Kerneis[1], Thomas Hanslik[3] and Maxime A. Breban[3]. [1]Faculté de Médecine Pierre et Marie Curie, Paris, France, [2]Ambroise Paré Hospital, Boulogne-Billancourt, France, [3]Ambroise Paré Hospital, and Versailles Saint Quentin en Yvelines University, Boulogne-Billancourt, France.

Background/Purpose: The relative contribution of environmental factors to triggering and/or progression of spondyloarthritis (SpA) remains poorly characterized. A link between disease activity and stressful life events and vaccination has been shown previously (J Rheumatol 2013,40:469). The

objective of this study was to specify the types of vaccine and life event related to disease activity.

Methods: Adult spondyloarthritis patients were enrolled in the dedicated cohort, CoEnv-2, which was prospectively followed for 2 years. Patients logged on to a secured website every month to complete an auto-questionnaire. They reported whether they had been exposed to stressful life events, vaccinations or other environmental factors through a detailed standardized questionnaire. Patients were asked to rate the impact of a potential exposure to life events occurring since the previous connection, on a visual numeric scale (VNS) from 0 (no impact) to 10 (worst impact). The main outcome variable was the difference of Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) measured on two consecutive connections. Months with occurring event(s) were compared to those without such event.

Results: Three hundred and one patients participated and returned 3,896 monthly questionnaires. Months when an abrupt and unexpected traumatic event (such as natural disaster, robbery, physical abuse. . .) occurred were associated with an increase in BASDAI of 0.58 [95%CI: 0.50;0.66], as compared to months without such occurrence ($p<0.001$). The events with the highest rating on the VNS had the largest impact (0.66 [0.40;0.92] for a VNS $\geq$5, and 0.96 [0.33;1.59] for a VNS $\geq$9). Among non-abrupt stressful life events, only work-related events were followed by an increased BASDAI (0.40 [0.13;0.67]). Seasonal influenza vaccination was associated with a more moderate increase in BASDAI (0.35 [0.06;0.34], $p<0.05$).

Conclusion: Among stressful life events, abrupt and unexpected traumatic events had a clear-cut measurable impact on disease activity in patients with SpA. The link between vaccination and disease activity appeared as limited to influenza immunisation. Ongoing analyses will allow us to determine the duration of such effects.

Clinical Characteristics Of Patients With Early Spondyloarthritis. Results From a Specialized Consultation In a Clinical Hospital. Juan Jose Aznar Sánchez, Eugenio Chamizo Carmona, Adela Gallego Flores, Raul Veroz Gonzalez and Tamara Libertad Rodriguez Araya. Hospital de Mérida, Mérida, Spain.

Background/Purpose: The classification criteria for spondyloarthritis (SpA) intend to identify patients with this disease from the initial stages. The nonspecific characteristics, symptoms, signs, and additional tests found in many patients at the onset of SpA, and the limitations of the classification criteria explain the delayed diagnosis. In Spain, the delay for the diagnosis is about 6 years[1]. Recently, the Assessment of SpA international Society (ASAS) has developed new criteria that try to reduce the time to diagnosis for axial SpA[2] and peripheral SpA[3]. In 2008 a SpA unit of recent onset was created in the General Hospital of Mérida (Spain) in order to establish an early diagnosis of this pathology. We describe the demographic and clinical characteristics of this population.

Methods: Between 2008 and 2013, we included patients aged from 18 to 45 years with symptoms for more than 3 months and less than 2 years including inflammatory back pain, asymmetric arthritis and/or mechanical low back pain (LBP) or arthralgias accompanied by at least one of the following: psoriasis, uveitis, inflammatory bowel disease, enthesitis, sacroiliitis imaging, positive HLAB27 or family history of SpA. Patients with previous diagnosis of SpA were excluded.

Results: The most common reason for consultation was LBP (76%). We studied 121 patients: 54 patients (45%) met ASAS criteria for SpA, 31 patients had axial SpA, and 23 patients had peripheral SpA. The gender distribution was similar in both groups. In axial SpA, 25.8% met NY criteria and most of these patients were men, the other 74,2% were non-radiological SpA with a female predominance. In the peripheral SpA, the most frequent was Psoriatic arthritis (PsA) (56.5%). The mean age at diagnosis was lower for axial SpA (30 years), undifferentiated SpA (uSpA 27.9 years) and AS (29 years) compared to peripheral SpA (35.7 years). HLA B27 was positive in 63% of patients with SpA and in 10.4% of no-SpA subjects. HLAB27 was more prevalent in axial SpA (84%), especially in AS (100%), compared to peripheral SpA (34%). It should be noted that 87.5% of the peripheral uSpA were positive HLAB27. The 39% of patients with SpA had family history, being more frequent in axial (55.5%) and peripheral (57%) uSpA and PsA (30%). Arthritis was present in 37% of SpA and 100% of PsA. Enthesitis was observed in 38% of SpA, in 50% of axial uSpA and 100% of the peripheral uSpA. There was one Dactylitis in a patient with peripheral uSpA and 5 cases of uveitis, all in axial SpA.

Conclusion: The creation of units of recent onset could help us to select patients fulfilling ASAS criteria. We achieved a diagnostic rate of 45% of patients referred. Axial SpA was more frequent (57.4%) and especially the non-radiological (74.2% of the axial). The most frequent peripheral SpA presentation was PsA (24%). Axial SpA, and especially axial uSpA, appears at a younger age than peripheral SpA. The gender distribution was similar for SpA, but non-radiographic axial SpA were more common in women. We found a family history of SpA more frequently in both axial and peripheral uSpA and a strong association between HLA B27 and AS (100%) and both axial and peripheral uSpA. In contrast, we found no association between HLA B27 and PsA or enteropathic arthritis.

Adalimumab Significantly Reduces Inflammation In Active Ankylosing Spondylitis: An Ultrasound Study. Zaiying Hu[1], Manlong Xu[2], Zetao Liao[1], Zhiming Lin[3] and Jieruo Gu[4]. [1]THIRD AFFILIATED HOSPITAL OF SUN YAT-SEN UNIVERSIT, Guangzhou, China, [2]THIRD AFFILIATED HOSPITAL OF SUN YAT-SEN UNIVERSIT, Guangzho, China, [3]third affiliated hospital of Sun Yat-sen Universtiy, Guangzhou, China, [4]Third Affiliated Hospital of Sun Yat-sen University, GuangZhou, China.

Background/Purpose: To evaluate the feasibility of using power Doppler ultrasound (PDUS) to detect inflammation in sacroiliac joints and entheses after adalimumab (a TNF-alpha antagonist) treatment in active ankylosing spondylitis (AS) patients.

Methods: This was a randomized, double-blind, placebo-controlled study. Active AS patients received 40 mg adalimumab ($n = 21$) or placebo ($n = 20$) every other week during an initial 12-week double-blind period, and all switched to adalimumab treatment for another 12 weeks. Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Function Index (BASFI), C-reactive protein (CRP), Ankylosing Spondylitis Disease Activity Scores (ASDAS) were measured and inflammation in sacroiliac joints and entheses were detected by PDUS at baseline, week 12 and week 24. The regions of enthesitis we detected including sternoclavicular joint, thoracic rib joints, lumbar spinous process, anterior superior iliac spine, posterior superior iliac spine, patellar tendon, and achilles tendon. The color flow signals of PDUS were scored on a 0–4 semi-quantitative scale.

Results: The total PDUS scores of active AS patients decreased significantly after 24 weeks treatment of adalimumab (4.95 ± 4.07 vs. 3.33 ± 3.12, $p=0.033$). And obvious improvements in clinical assessments (BASDAI, BASFI, CRP and ASDAS reduced, all $P < 0.05$) were also observed after 24 weeks of adalimumab. But the total PDUS scores of AS patients did not change statistically after 12 weeks treatment of adalimumab (4.67 ± 4.10 vs. 4.27 ± 3.20, $p=0.416$) or placebo (4.75 ± 3.63 vs. 4.35 ± 4.22, $p>0.05$). And the total PDUS score did not correlate with clinical assessments (all $p=0.494$).

Conclusion: Our study found that adalimumab was highly effective in reducing inflammation in active AS patients as detected by power Doppler ultrasound.

Predicting Progression Of Non-Radiographic Axial Spondyloarthritis. Nigil Haroon[1], Lianne S. Gensler[2], Dinny Wallis[3], Ammepa Anton[1], Grace Yoon[4] and Robert Inman[5]. [1]Toronto Western Research Institute, Toronto, ON, [2]University of California, San Francisco, San Francisco, CA, [3]Toronto Western Hospital, University of Toronto, Toronto, ON, [4]UCSF, San Franciscao, CA, [5]University of Toronto and Toronto Western Hospital, Toronto, ON.

Background/Purpose: A proportion of patients with non-radiographic axial spondyloarthritis (NR-AxSpA) progress to AS but the predictors of progression have not been well established. We studied the predictors of progression of NR-AxSpA.

Methods: Patients with NR-AxSpA who were followed in two major SpA centers were enrolled in this study. Patients are classified as NR-AxSpA if they do not satisfy the modified New York Criteria for AS but satisfied the ASAS criteria for axial SpA. All patients had two X-rays of the pelvis

separated by at least 1.5 years. All patients were followed with a standardized protocol and were assessed on an annual basis. Disease activity was assessed by Bath AS Disease Activity Index (BASDAI), ESR and CRP. Markers of inflammation were averaged over the period of follow-up to estimate the ongoing level of inflammation. HLA-B27 was done in all patients and MRI of the spine was done as clinically indicated. Smoking pack-year history was collected. Three readers, blinded to patient details scored the pelvis radiographs using the New York grading system for sacroiliitis. Progressors were defined as those who had significant increase in SI joint score (2 grades). Logistic regression analysis was done to identify predictors of progression.

Results: Fifty-one patients (51% females and 75% HLA-B27 positive) qualified for the study and were followed for a mean (± SD) duration of 3.6 ± 2.1 years. The mean disease duration was 9.5 ± 7.7 years. The baseline and time averaged BASDAI were 5.1 ± 2.0 and 4.8 ± 2.1 respectively. Iritis, inflammatory bowel disease (IBD) and Psoriasis were present in 29.4%, 7.8% and 13.7% respectively. Except for one patient, all others had inflammatory back pain (IBP). Only 14 patients were smokers with 2.1 ± 6.5 pack-years history. Only 6 patients had significant progression and 4 patients satisfied the Modified New York criteria at last follow-up. Except for one patient who progressed at 2.5 years, all others did so after 6 years of follow-up.

Progressors are compared to non-progressors in Table 1. All patients who progressed were HLA-B27 positive. Patients with iritis had a relative risk of progression of 4.8 (1.0, 23.5; p=0.053). Progressors had significantly higher baseline BASDAI (p=0.04, Median Test). Those who progressed had longer follow-up and after correction for this, logistic regression analysis showed significant association of progression with smoking pack years with an OR of 1.2 (1.03–1.4, p=0.02). In multivariate logistic regression analysis including all baseline parameters, the only significant variable associated with progression was the duration of follow up.

Table 1. Comparison of progressors with non-progressors

Variable	Progressors (N=6)	Non-progressors (N=45)	p
Median Age of Onset (IQR, years)	29 (18, 42)	28 (22, 36)	ns
HLA-B27 (%)	6 (100)	32 (71)	0.051
Female (%)	3 (50)	23 (51)	ns
Median Disease Duration (IQR, years)	14 (11, 17)	7 (2, 16)	ns
Baseline Median ESR (IQR, mm per hour)	8 (5, 12)	7 (3, 19)	ns
Baseline Median CRP (IQR mg/L)	3 (3, 4)	3 (3, 5)	ns
Average Median ESR (IQR, mm per hour)	5 (3, 8)	7 (3, 18)	ns
Average Median CRP (IQR mg/L)	3 (2, 4)	3 (2, 4)	ns
Baseline Median BASDAI (IQR)	6.2 (6, 7)	5 (3, 7)	0.04
Average Median BASDAI (IQR)	6 (5, 7)	5 (3, 7)	ns
Iritis (%)	4 (67)	11 (24)	0.054
IBD (%)	1 (17)	3 (7)	ns
Psoriasis (%)	2 (33)	5 (11)	ns
Peripheral Arthritis (%)	4 (67)	33 (73)	ns
Enthesitis (%)	4 (67)	30 (67)	ns
Dactylitis (%)	0	3 (7)	ns
IBP (%)	6 (100)	44 (98)	ns
Smoking (%)	3 (50)	11 (24)	ns
Smoking (Median, IQR Pack Years)	1 (0, 10)	0 (0, 0)	ns
Biologics (%)	2 (33)	25 (56)	ns
Biologics Median Duration (IQR, Yrs)	3 (0, 7)	3 (0, 4)	ns
Median Gap between X-rays (IQR, Yrs)	7 (4, 9)	3 (2, 4)	ns

Conclusion: Over a mean follow up of 3.6 years, 8% of patients with NR-AxSpA progressed to AS. Smoking appears to be a risk factor for significant progression of SI joint scores. HLA-B27, higher baseline BASDAI and iritis were more common in progressors.

External Validation Of The Spondyloarthritis Radiography Online Reference Module For Training Readers To Score The Modified Stoke Ankylosing Spondylitis Score. Praveena Chiowchanwisawakit[1], Susanne Juhl Pedersen[2] and Walter P. Maksymowych[3]. [1]Mahidol University, Bangkok, Thailand, [2]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [3]University of Alberta, Edmonton, AB.

Background/Purpose: The modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) is commonly used to assess disease severity and progression in patients with AS; however, the reliability of scoring change in mSASSS is still challenging. The SpondyloArthritis Radiography (SPAR) online training module is aimed at providing explicit instructions for scoring the mSASSS, reference cases in DICOM format, and raw expert reader scores aimed at training and calibration of readers for detecting change in mSASSS[1]. However, it has not been validated beyond the group of experts that originally developed the module.

Methods: The SPAR module is comprised of 4 parts: 1) slide review of mSASSS scoring methodology, 2) reference DICOM image set of 34 cases with pairs of radiographs with two year time frames and a schematic of the spine for direct online data entry, 3) raw data scores for reference DICOM image set from two expert readers and unblinding data, and 4) schematic of the spine illustrating the mSASSS scoring module for calibrated reviewers to conduct direct online data entry for test cases. The details are available at http://tools.carearthritis.com/spar/. In exercise 1, 2 inexperienced readers independently assessed the 34 pairs of cervical and lumbar spine radiographs of the SPAR reference case DICOM image set blinded to time point (baseline, 2 years). Exercise 2 was conducted after review of the SPAR module that included assessment of expert reader raw scores for the 34 case reference image set. Exercise 2 included 21 pairs of scans from exercise 1 that were randomly scored with an additional 34 new pairs of scans to assess consistency of reliability. This nested study design addresses the limitation for assessment of reliability posed by differences in progression rates between different study samples, which may significantly impact ICC scores when between-patient variability in progression is small. Inter-observer reliability of mSASSS for status and change scores was assessed by intra-class correlation coefficient (ICC). Inter-observer reliability of each type of lesion was assessed by kappa and percentage of agreement.

Results: There was consistent reliability of mSASSS for status score and the reliability of the change score was improved in exercise 2 after reviewing the online module (Table 1). Improved reliability in detecting specific lesions was also observed.

Table 1.

	Exercise 1		Exercise 2		
	All cases (n = 34)	Ex 1 Subset (n = 21)	All cases (n = 55)	Ex 1Subset (n = 21)	New cases (n = 34)
Status ICC (95% CI)	0.94 (0.88, 0.97)	0.97 (0.92, 0.99)	0.96 (0.92, 0.97)	0.97 (0.93, 0.99)	0.94 (0.89, 0.97)
Change ICC (95% CI)	0.38 (0.04, 0.63)	0.53 (0.13, 0.78)	0.67 (0.50, 0.80)	0.56 (0.19, 0.79)	0.71 (0.50, 0.85)

Table 2. *Cases scored in both exercises

		Squaring		Sclerosis		Syndesmophyte		Ankylosis	
	Cases	Kappa	Agreement	Kappa	Agreement	Kappa	Agreement	Kappa	Agreement
Exercise 1 (N = 34)	All	0.17	84.9%	0.12	94.1%	0.49	92.0%	0.76	94.6%
	N = 21*	0.09	78.7%	0.11	91.2%	0.51	90.3%	0.83	95.0%
Exercise 2 (n = 55)	All	0.65	90.9%	0.47	97.6%	0.59	90.7%	0.87	97.0%
	N = 21*	0.64	91.4%	0.61	97.6%	0.63	90.2%	0.86	96.2%

Conclusion: The reliable scoring of the mSASSS by inexperienced readers can be improved by using the SPAR online training module.

Which Contextual Factors Have An Important Influence On Work Outcome In Patients With Ankylosing Spondylitis. A Systematic Literature Review. Jose Dionisio Castillo-Ortiz[1], Carmen Stolwijk[2] and Annelies Boonen[1]. [1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Maastricht University, Maastricht, Netherlands.

Background/Purpose: It is increasingly recognized that contextual factors (either environmental or personal) play a role in the magnitude in which the disease influences work participation. However, no summary data exist on which factors might be relevant. Therefore, we reviewed the literature on contextual factors in relation to work outcomes in patients with Ankylosing Spondylitis (AS).

Methods: Medline, EMBASE, PsyINFO and Cinahl as well as references of selected articles were searched systematically up to June 2012. Articles were eligible if reporting original data on the influence of contextual factors (CF) on work disability, sick leave or presenteeism in patients with AS. Assessment of risk of bias and extraction of data were performed by two independent persons. CF were grouped in environmental and personal factors according to the framework proposed by OMERACT (1).. Analyses were

marked as 'high quality' if the CF was significantly contributing to work outcome in multivariable analyses, after adjustment for disease activity and physical function in a study that had a sufficient samples size for a multivariable analyses.

Results: Out of 1165 studies, 19 met the inclusion criteria of which one was added by hand search (seventeen cross-sectional and two longitudinal); 17 studies addressed employment/WD, three sick leave and 2 presenteeism. For work disability (n=11 studies), there was high quality evidence for the adverse influence of higher age (n= 4), (absence of) work accommodations (n=2), nature of work (n=1), (absence of) workplace support (n=1), (absence of) non-workplace support (n=1), avoidant coping (n=1) and being unmarried (n=1). Evidence was conflicting for gender and education. For sick leave and presenteeism there was no high level evidence for the role of any contextual variable.

Conclusion: Depending on the threshold used to decide whether evidence of the association between a CF and work-outcome can be considered as 'high quality', age, work accommodations, nature of work, workplace support and coping/ are candidate variables to be included as important contextual factors of work outcome in addition to disease related variables (function and disease activity). It should be noted all these studies reported cross-sectional associations.

Disclosure: J. D. Castillo-Ortiz, None; **C. Stolwijk**, None; **A. Boonen**, None.

Periarticular Bone Gain In Early Psoriatic Arthritis But Not In Rheumatoid Arthritis Following Anti-Rheumatic Treatment As Measured By Digital X-Ray Radiogrammetry. Agnes Szentpetery, Muhammad Haroon, Phil Gallagher, Eric J. Heffernan and Oliver FitzGerald. Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland.

Background/Purpose: Hand bone loss is an early feature in both RA and PsA, but there is less data available on periarticular bone gain, in particular in PsA following treatment. Digital X-ray radiogrammetry (DXR) is a sensitive method for quantifying changes in periarticular bone mineral density (DXR-BMD) in the early phase of the disease.

The aim of this study was (1) to investigate DXR-BMD changes in early PsA and RA prior to and 3, 12 months after introducing an anti-rheumatic drug; and (2) to explore associations between disease-related variables and DXR-BMD.

Methods: Recent-onset (<12 months), active, treatment naïve PsA and RA patients were selected. Hand BMD was measured by DXR based on digitized hand radiographs (Sectra, Sweden) at baseline, 3 and 12 months. Mean DXR-BMD (mg/cm^2) values of both hands and changes in DXR-BMD (mg/cm^2/month) were calculated and compared between the two groups at all time points. Changes in hand BMD were further analysed by dividing PsA and RA into 3 subgroups based on cut-offs for the categories normal, elevated BMD loss (>−0.25 mg/cm^2/month) and highly elevated BMD loss (>−2.5 mg/cm^2/month). DXR-BMD was correlated with clinical parameters including ESR, CRP, DAS28-CRP4v and HAQ.

Results: 64 patients (32 PsA, 32 RA) were included with median age 43 years. 95% of the patients were commenced on a DMARD therapy at baseline and 11.7 % (12.5% RA; 10.7% PsA) were also started on a TNF inhibitor. There were no patients taking anti-resorptive medications, 17.2% were on oral glucocorticoids (15.6% RA; 18.7% PsA) less than 10 mg per day. At 12 months 94.8% of the patients were on a DMARD and 34.5% on a TNF inhibitor (33.3% RA; 35.7% PsA).

Mean DXR-BMD decreased in both diseases at 3 months and was significantly lower in RA at 12 months (p=0.004) compared to baseline. In contrast mean DXR-BMD increased in PsA over 12 months (p=0.07) and was higher at both 3 and 12 months compared to RA.

DXR-BMD loss were significantly higher in RA compared to PsA from baseline to 12 months (p=0.0005) and also from 3 to 12 months (p=0.0006). There were no bone loss in 91.7% of patients with PsA, but only in 40.7% of patients with RA between baseline and 12 months. Among all patients with elevated BMD loss, change in DXR-BMD was less marked in the PsA group compared to RA from baseline to 3 (p=0.018) and from 3 to 12 months (p=0.014). Highly elevated bone loss was present only in the RA cohort (7.5%) at 12 months.

Disease activity scores were significantly lower in PsA than in RA at baseline and 3 months. ESR, CRP, DAS28-CRP4v improved significantly in both diseases during the study. Mean DXR-BMD correlated negatively with ESR at 12 months in RA (r = −0.39; p= 0.038), however no other significant correlations between other clinical parameters and DXR-BMD were found.

Conclusion: To our knowledge this is the first prospective study showing hand bone loss as early as 3 months as measured by DXR in both PsA and RA despite intervention of appropriate anti-rheumatic drug. After 1 year of treatment we observed cortical bone gain in PsA but further bone loss in RA supporting the hypothesis of different pathomechanisms being involved in hand bone remodelling in PsA.

2484

Immunogenicity Of TNFα Blockers In Patients With Psoriatic Arthritis. Michael Zisapel Zisapel[1], Noa Madar-Balakirsi[2], Hagit Padova[3], Irena Wigler[3], Daphna Paran[4], Uri Arad[3], Dan Caspi[5] and Ori Elkayam[3]. [1]Tel Aviv Medical Centet, Tel Aviv, Israel, [2]Tel Aviv Medical Center, Tel Aviv, Israel, [3]Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [4]Tel Aviv Sourasky Medical Ctr, Tel-Aviv university, Tel Aviv, Israel, [5]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel.

Background/Purpose: TNFα blockers have been shown to produce immunogenecity in patients with rheumatoid arthritis, spondyloarthrritis and inflammatory bowel diseases. Data on the induction of anti-drug antibodies against TNF alpha blockers in psoriatic arthritis is scarce. The purpose of this study was to assess the prevalence of anti-drug antibodies (ADA) against infliximab, adalimumab and etanercept in a cohort of patients with psoriatic arthritis (PsA).

Methods: Patients with PsA treated for at least 3 months with adalimumab (n=48), infliximab (n=24) and etanercept (n=21) participated in this study. Clinical activity was assessed using the DAS 28, physician and patient global assessment using a VAS of 100 mm, psoriasis assessement of severity score (PASI), BASDAI, ESR and CRP.

Results: ADA were detected in 26 (55%) patients on adalimumab, 5 (28%) on infliximab and none of the patients on etanercept. A significant correlation was found between the presence of ADA and drug levels of adalimumab and infliximab. A significant correlation was found between drug levels of adalimumab and global physician and patient assessment, and the PASI. In patients treated with infliximab, ADA was associated with higher DAS and PASI, Twenty-six % of the patients were concomitantly treated with methotrexate (MTX). A significant correlation between the use of MTX and the absence of ADA was demonstrated in patients treated with infliximab and adalimumab.

Conclusion: A substantial proportion of patients with PsA develop anti drug antibodies to adalimumab and infliximab. The use of MTX seems to lower immunogenecity. The presence of ADA correlated with drug levels and several parameters of disease activity.

High Incidence Of Disease Recurrence After Discontinuation Of Disease Modifying Anti-Rheumatic Drug Treatment In Patients With Psoriatic Arthritis In Remission. Elizabeth Araujo, Stephanie Finzel, Dominik A. Schreiber, Matthias Englbrecht, Axel J. Hueber, Francesca Faustini, Juergen Rech and Georg Schett. University of Erlangen-Nuremberg, Erlangen, Germany.

Background/Purpose: In the era of modern anti-rheumatic therapy, it is now possible to contemplate the idea of clinical remission in patients with psoriatic arthritis (PsA). It is however unknown whether patients in clinical remission can stop methotrexate (MTX) or tumor necrosis factor inhibitor (TNFi) treatment. The objective of this study was to investigate drug-free remission in patients with PsA and potential predictors for flare

Methods: Patients with PsA in remission (no musculoskeletal symptoms, no or minimal skin/nail disease) for at least 6 months were included. At baseline the following parameters were assessed: age, sex, BMI, disease duration, duration of remission, swollen joint count, tender joint count, VAS-pain, VAS-global, NAPSI, PASI, MASES, LDI, HAQ-DI, SF-36, FACIT-F, anti-rheumatic therapy (MTX, TNFi), ESR and CRP. In addition, ultrasound of 30 joints and 20 enthesis was performed. After discontinuation of therapy at day 1, patients were followed for 6 months for the occurrence of flares.

Results: 26 patients (methotrexate monotherapy: N =14, tumor necrosis factor inhibitors: N = 12) with a mean age of 55.2 years, absence of musculoskeletal symptoms and minimal skin disease (mean PASI: 0.21) were enrolled. Incidence of recurrence of disease was high (N=20, 76.9%,) and occurred rapidly (74.50 ± 51.72 days) after treatment discontinuation. Male PsA patients were significantly more likely to lose remission. Long disease duration, more severe skin involvement, and the presence of synovial hypertrophy by ultrasonographic examination at baseline decreased the likelihood for drug-free remission. Re-initiation of DMARDs promptly restored remission in all PsA patients with recurrence of disease.

Conclusion: This study shows that the chance to reach drug-free remission in PsA patients is low. Discontinuation of DMARD therapy cannot be recommended in patients with PsA.

Clinical Performance Of 4 Methods For Detecting Latent Tuberculosis Infection (LTbI) In Patients With Active Chronic Inflammatory Arthritis Taking TNFα Blockers. Carina M F Gomes[1], Maria Teresa Terreri[2], Maria Isabel Pinto[1], Karen Oseki[1], Fernanda Spina[1] and Marcelo M. Pinheiro[3]. [1]Universidade Federal de São Paulo, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo / UNIFESP, Sao Paulo, Brazil, [3]Brazilian Registry of Spondyloarthritis, São Paulo, Brazil.

Background/Purpose: About 5% of the Brazilian population has some chronic inflammatory arthropathy (CIA), including rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PA) and juvenile idiopathic arthritis (JIA), and 30 to 50% of them will need to use some TNFα inhibitor to control disease activity. However, several studies have shown greater rates of active mycobacterial infections after starting of these medications. According Brazilian database, the incidence of active cases of mycobacterial infection, especially tuberculosis, has increased in patients with CIA when compared to the adult (86.93/100.000 persons-year vs. 37.48/100.000 P-Y, respectively) and pediatric Brazilian population (22.53/100.000 P-Y vs. 15.91/100.000 P-Y, respectively). It is worthy emphasizing that all of them were negative for latent tuberculosis infection (LTbI) in the first medical evaluation. Purpose: To compare clinical performance of 4 methods for detecting LTbI in CIA patients taking TNFα blockers.

Methods: A total of 87 patients were included in this cross-sectional study, of whom 35 with RA, 35 with AS, 7 with PA and 10 JIA patients. Patients with active tuberculosis, hepatitis B or C and HIV infection were excluded. All participants answered a specific questionnaire, including details on epidemiologic data, medical history, and symptoms related to tuberculosis, as well as BCG vaccine history and socioeconomic status. Besides, they performed chest radiography and tuberculin skin test (PPD). In case of induration lower than 4 mm, the test was repeated in the contralateral forearm up to 3 weeks after the first reading (PPD-Booster). The interferon gamma specific release assays (IGRAs) were performed using Elispot (T-SPOT.*TB*) and Quantiferon (Quantiferon-TB GOLD).

Results: Fourteen new cases of LTBI were identified in CIA adult patients taking TNFα inhibitors (Table 1). All JIA children were negative for the 4 tests. Although the concordance between the 4 tests has been above 75%, the positivity was not associated with active tuberculosis.

Test for LTbI	Rheumatoid Arthritis (n=35)	Ankylosing Spondylitis (n=35)	Psoriatic Arthritis (n=7)
PPD before starting TNFα blockers	9 (25.7%)	8 (22.8%)	1 (14.2%)
PPD after starting TNFα blockers	13 (37.1%)	10 (28.5%)	3 (42.8%)
ELISPOT	12 (34.2%)	11 (31.4%)	3 (42.8%)
Quantiferon (QTF)	6 (17.1%)	7 (25.9%)	3 (42.8%)
PPD-Booster	2 (9%)	1 (4%)	0

Conclusion: Fourteen new cases of LTBI were identified in CIA adult patients taking TNFα inhibitors (Table 1). All JIA children were negative for the 4 tests. Although the concordance between the 4 tests has been above 75%, the positivity was not associated with active tuberculosis. Table 1. Clinical performance of 4 methods for detecting LTBI in patients taking TNFα blockers.

Role Of IL-33 In The Development Of Premature Atherosclerosis In Psoriatic Arthritis Patients. Priscilla Ching-han Wong[1], Qing Shang[2], Cheuk-Man Yu[2] and Lai Shan Tam[2]. [1]Prince of Wales hospital, New Territories, Hong Kong, [2]The Chinese University of Hong Kong, Hong Kong, Hong Kong.

Background/Purpose: Interleukin 33 (IL-33) is a newly identified member of the IL-1 cytokine family. It involves in T-cell mediated immune responses through the activation of the ST2 receptor that are widely expressed by the T helper 2 cells and mast cells. Many previous studies have demonstrated the role of IL-33 in chronic autoimmune diseases. Whether this may play a role in the pathogenesis of inflammation and accelerating atherosclerosis in psoriatic arthritis (PsA) has never been addressed.

Methods: A prospective study of 89 PsA patients followed up by the Prince of Wale hospital were recruited with comprehensive measurements of the traditional and novel CV risk factors, markers of clinical disease activity and severity, laboratory markers of inflammation, intima-media thickness (IMT) and augmentation index (AIx). Frozen plasma was retrieved for the measurement of IL-33. 66 patients came back for follow-up after 5 years and vascular assessments were repeated. SPSS was used for statistical analysis

Results: Among the 89 patients, 50.6% were male and 49.4% were female. The mean age was 46.1.9 ± 11.8 years old and the mean disease duration was 9.2 ± 7.1. IL-33 was measurable in only 54 out of 89 patients. Among these 54 patients, the mean of the IL-33 was 3.97 ± 17.79 pg/ml. IL-33 was associated with the mean IMT ($r=0.273$, $p=0.011$) and the maximum IMT ($r=0.239$, $p=0.026$), but it was not associated with AIx ($r=-0.016$, $p=0.891$). IL-33 was also not associated with the traditional and novel CV risk factors, the markers of clinical disease activities and severity, as well as the laboratory markers of inflammation.

Conclusion: IL-33 could be a novel pathway in accelerating the progression of premature atherosclerosis in PsA patients affecting both structural (IMT) and functional (AIx) modification of the blood vessels, independent of the CV risk factors.

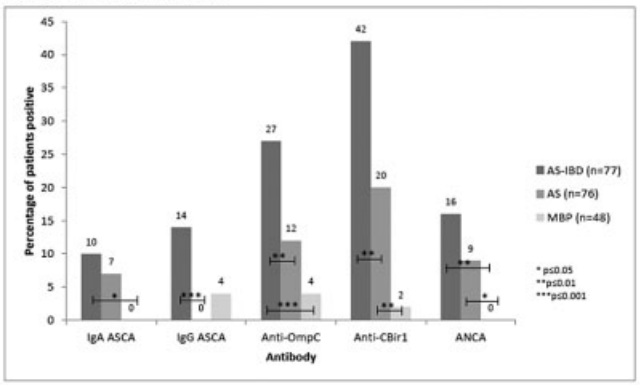
Elevated Serum Anti-Flagellin Antibodies Implicate Subclinical Bowel Inflammation in Ankylosing Spondylitis. Dinny Wallis[1], Arundip Asaduzzaman[1], Michael H. Weisman[2], Nigil Haroon[1], Ammepa Anton[3], Dermot P. B. McGovern[4], Stephan R. Targan[4] and Robert D. Inman[1]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Cedars-Sinai Med Ctr, Los Angeles, CA, [3]Toronto Western Research Institute, Toronto, ON, [4]Cedars-Sinai Medical Center, Los Angeles, CA.

Background/Purpose: Ankylosing spondylitis (AS) and inflammatory bowel disease (IBD) share genetic and clinical features. IBD is associated with the presence of antibodies to a variety of commensal microorganisms including anti-Sacchoaromyces cerevesiae antibodies (ASCA), antineutrophil cytoplasmic antibodies (ANCA), anti-I2 (associated with anti-Pseudomonas activity), anti-E. coli outer membrane porin C (anti-OmpC) and anti-flagellin antibodies (anti-CBir1). Subclinical intestinal inflammation may be present in up to 65% of patients with AS. This study evaluated the presence of antimicrobial antibodies in patients with AS alone, patients with AS and concomitant IBD (AS-IBD) and a control group of patients with mechanical back pain (MBP).

Methods: Patients with AS-IBD were identified from a longitudinal prospective AS cohort and matched by age and disease duration to patients with AS alone. Sera were tested by ELISA for ASCA IgG and IgA, anti-OmpC, anti-CBir1 and ANCA in 76 patients with AS alone, 77 patients with AS-IBD and 48 patients with MBP (who underwent clinical, laboratory and radiological investigation to exclude spondyloarthritis). Antibody positivity rates, median quantitative antibody levels and the proportion of patients with antibody levels in the 4th quartile of a normal distribution were compared between the three groups of patients.

Results: Antibody positivity rates are shown in Figure 1. Patients with AS alone demonstrated higher anti-CBir1 antibody positivity rates (19.7% versus 2.1%, p=0.005) and median antibody levels (15.0 [10.0–23.8] EU versus 10.0 [7.0–15.0] EU, p=0.0007) than MBP patients. AS-IBD patients demonstrated elevated responses when compared to AS alone for ASCA, anti-OmpC and anti-CBir1. Quartile analysis confirmed the findings. Acute phase reactants were significantly elevated in anti-CBir1 positive patients compared to anti-CBir1 negative patients: median (IQR) CRP 11.5 (5.3–20.5)mg/L versus 6.0 (3.0–15.5)mg/L (p=0.006); median (IQR) ESR 19.0 (8.5–32.0)mm/h versus 8.0 (3.0–18.0)mm/h (p<0.001). Among patients with AS alone, acute phase reactants remained significantly elevated in anti-CBir1 positive patients compared to anti-CBir1 negative patients (median (IQR) CRP 14.0 (7.0–19.0)mg/L versus 3.0 (3.0–15.0)mg/L, p=0.033); median ESR (IQR) 26.0 (10.0–33.0)mm/h versus 5.0 (3.0–20.0)mm/h). No significant difference was seen in acute phase reactants between anti-CBir 1 positive and negative patients within the AS-IBD group.

Figure 1 Positivity rates of antibodies



Conclusion: These data suggest that adaptive immune responses to microbial antigens occur in AS patients without clinical IBD and support the theory of mucosal dysregulation as a mechanism underlying the pathophysiology of AS.

Spondyloarthritis-Associated Polymorphisms Of ERAP1 Are Correlated With Gene Expression, Protein Level and Enzymatic Activity Of The Amino-Peptidase. Félicie Costantino[1], Alice Talpin[1], Irini Evnouchidou[2], Amir Kadi[1], Roula Said-Nahal[3], Ariane Leboime[3], Nelly Bonilla[1], Franck Letourneur[1], Tifenn Leturcq[1], Zeyna Ka[1], Peter van Endert[2], Henri-Jean Garchon[3], Gilles Chiocchia[3] and Maxime A. Breban[3]. [1]Institut Cochin - Université Paris Descartes - INSERM U1016 - CNRS (UMR 8104), Paris, France, [2]INSERM U1013 - Université Paris Descartes - Sorbonne Paris Cité, Paris, France, [3]Ambroise Paré Hospital (AP-HP), and Versailles Saint Quentin en Yvelines University, Boulogne-Billancourt, France.

Background/Purpose: Endoplasmic reticulum aminopeptidase 1 (ERAP1) exerts a central role in antigen presentation making it an attractive candidate gene for inflammatory diseases. Several polymorphisms in this gene have been associated with ankylosing spondylitis and then with the whole SpA group. A specific ERAP1 haplotype, rs17482078/rs10050860/rs30187-CCT, is strongly associated with increased risk of SpA, whereas the -TTC haplotype is associated with reduced risk. Because the linkage disequilibrium in the region is extensive, the causative polymorphism still remains to be determined. It has been suggested that rs30187, one of the polymorphisms of this haplotype may affect ERAP1 enzymatic activity. However, there is currently little data regarding the consequences of SpA-associated polymorphisms on gene expression level.

The aim of the present work was to determine whether SpA-associated ERAP1 polymorphisms might modify gene expression, protein level and enzymatic activity.

Methods: The discovery cohort included 9 HLA-B27+ SpA patients and 10 healthy controls. The replication cohort consisted of 13 SpA-discordant HLA-B27 positive sib-pairs and 18 additional independent controls (11 HLA-B27+ and 7 HLA-B27-). In both cohorts, we derived dendritic cells from monocytes (MD-DCs) and stimulated them or not with lipopolysaccharide (LPS). We also used Epstein-Barr virus (EBV) immortalized lymphoblastoid cell lines from HLA-B27+ individuals homozygous for risk, neutral or protective ERAP1 haplotype (7 patients, 1 control). In all the studied populations, we investigated the relation between ERAP1 haplotype and mRNA expression level (assessed by RT-PCR in the discovery cohort and in EBV cell lines and by microarray in the replication cohort) with a likelihood ratio test in Unphased software. Additionally, the relative protein expression of ERAP1 was measured in EBV cell lines by Western-blot and enzymatic activity was determined using a fluorogenic assay.

Results: In MD-DCs, there was a strong association between ERAP1 mRNA expression level and both rs30187 genotype and ERAP1 haplotype, at every time-point (table 1). This association was independent of the disease or HLA-B27 status. A similar trend was observed in EBV cell lines. Western-blot showed that ERAP1 protein level in cell lines harboring the risk haplotype was 2- and 1.5-fold higher than in those harboring the protective and the neutral ones, respectively. Moreover, ERAP1 enzymatic activity was higher in cell lines harboring increased risk haplotype, than in those harboring reduced risk haplotype.

Table 1. P-values of association tests between ERAP1 haplotype and mRNA expression

Stimulation time-point	Discovery	Replication	Pooled results
H0	0.04	4.56×10^{-5}	7.9×10^{-7}
H6	0.04	1.6×10^{-4}	1.2×10^{-6}
H24	0.09	9×10^{-4}	4.3×10^{-6}

Conclusion: Overall, these data provide strong evidence that SpA-associated ERAP1 polymorphisms affect the level of gene expression, protein production and aminopeptidase activity. How an increased production/activity of ERAP1 influences susceptibility to SpA remains to be determined.

Serum Levels Of Novel Noggin- and Sclerostin-Immune Complexes Are Elevated In Ankylosing Spondylitis. Florence W. Tsui[1], Hing Wo Tsui[2] and Robert D. Inman[3]. [1]Toronto Western Research Institute UHN and University of Toronto, Toronto, ON, [2]Toronto Western Research Institute UHN, Toronto, ON, [3]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON.

Background/Purpose: Unravelling the basis of joint inflammation and ankylosis represents a major challenge in ankylosing spondylitis (AS) research. As noggin (NOG) and sclerostin (SOST) have recently been associated with the disease process in mouse and human studies respectively, we explored the immune responses to these two molecules in AS.

Methods: Immune-complexes (ICs) comprised of IgG autoantibodies to NOG and SOST were detected by immunoprecipitation and Western blot analyses. Epitope-specific IgGs were measured using peptide-binding ELISAs. Serum samples were obtained from healthy controls and patients with AS, mechanical back pain (MBP) and inflammatory bowel disease (IBD) with or without concomitant AS.

Results: NOG- and SOST-IgG ICs were present in NOG-treated and untreated *ank/ank* (*progressive ankylosis*), but not in wild-type mice. Higher than normal levels of NOG- and SOST-IgG ICs are present in AS sera ($p<0.001$). We showed that a SOST peptide (SOST-S146, with homology to a bacterial glycotransferase peptide) binds to a NOG peptide (NOG-N54) which contains a N-glycosylation site. AS patients have higher levels of IgGs recognizing the NOG-N54 and SOST-S146 peptides compared to the levels in normal controls, IBD and MBP patients (1 way ANOVA: $p<0.0001$).

Conclusion: This is the first report showing IgG autoantibodies to NOG and SOST in normal individuals and higher levels of NOG- and/or SOST-IgG ICs likely contribute to neo-ossification in AS patients. These

novel findings implicate earlier diagnosis, better management of AS with comorbidities and new therapeutic approaches to modulate ankylosis in AS.

Functionally Distinct ERAP1 Haplotype Combinations Distinguish Individuals With Ankylosing Spondylitis. Edward James[1], Emma Reeves[1], Alexandra Colebatch[2], Tim Elliott[1] and Christopher J. Edwards[3]. [1]University of Southampton, Southampton, United Kingdom, [2]University Hospital Southampton, Southampton, United Kingdom, [3]NIHR Wellcome Trust Clinical Research Facility, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom.

Background/Purpose: The association of Ankylosing Spondylitis (AS) with HLA-B27 has been known for many years. Recent genetic linkage studies have identified polymorphisms within the aminopeptidase, *ERAP1*, associated with the disease. ERAP1 lies on the antigen processing pathway, generating peptide antigens for immune presentation by HLA. We examined the extent of polymorphism of *ERAP1* and the haplotype combinations present in affected and control individuals. In addition, we assessed the ability of the identified ERAP1 genotypes to trim peptides for presentation on MHC class I molecules.

Methods: Individual *ERAP1* haplotypes were cloned from patients with AS and control individuals recruited with informed consent and sequenced. ERAP1 trimming function was assessed by observing the ability of *Erap1* deficient cells, expressing the identified haplotype molecules, to trim and present peptide for stimulation of an antigen-specific T cell and also to reconstitute surface HLA-B27.

Results: We found that *ERAP1* from both AS cases (n=17) and controls (n=19) are highly polymorphic and comprise nine haplotypes that are predominantly made up of multiple SNPs. *ERAP1* haplotype combinations from AS cases were distinct from those found in controls. AS case ERAP1 haplotype combinations trimming capacity was significantly decreased as less than a third of the final epitope was generated from peptide precursors for presentation to T cells compared to controls. In addition, AS case ERAP1 combinations were unable to reconstitute HLA-B27 to normal levels recovering only 50% of that observed with control haplotype combinations.

Conclusion: These results demonstrate for the first time that ERAP1 from patients with AS is dysfunctional and provides strong evidence that ERAP1 variation predisposes to chronic inflammatory disease via its influence on the antigen processing pathway.

Interleukin-17 Serum Levels Are Associated With Markers Of Systemic Inflammation In Patients With Active Ankylosing Spondylitis. Denis Poddubnyy[1], Alain Vicari[2], Hildrun Haibel[1], Jürgen Braun[3], Martin Rudwaleit[4] and Joachim Sieper[1]. [1]Charité Universitätsmedizin Berlin, Berlin, Germany, [2]EMD Serono, Geneva, Switzerland, [3]Rheumazentrum Ruhrgebiet, Herne, Germany, [4]Endokrinologikum Berlin, Berlin, Germany.

Background/Purpose: There is accumulating evidence that the Th17-signaling axis, particularly interleukin-17 (IL-17), plays an important role in the pathogenesis of ankylosing spondylitis (AS). Furthermore, biologics targeting IL-17 have shown clinical efficacy inactive AS. The purpose of the current study was to investigate the association of IL-17A and IL-17F serum levels with clinical, laboratory and radiographic parameters in patients with AS.

Methods: 50 anti-TNF-naïve patients with AS, as defined by the modified New York criteria, with symptom duration of ≤10 years and clinically active disease (BASDAI ≥4), were selected from German Spondyloarthritis Inception Cohort (GESPIC) for this study. Available spinal radiographs (baseline and after 2 years, n=28) were scored according to the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS), by two independent blinded readers. Baseline serum levels of IL-17A and IL-17F were measured by the ultra-sensitive Erenna Immunoassay (Singulex, Almeda, CA).

Results: The mean (±SD) serum levels of IL-17A and IL-17F in the studied population were 0.87±1.48 pg/ml and 7.36±20.8 pg/ml, respectively. There was a significant correlation of serum cytokine levels with each other: Spearman's rho = 0.490, $p<0.001$. Serum level of IL-17A showed a significant correlation with the serum level of C-reactive protein: rho = 0.327, p = 0.020, while IL-17F correlated with erythrocyte sedimentation rate: rho = 0.331, p = 0.026. Also, there was a negative correlation of IL-17A with patients' age: −0.318, p = 0.025. Serum IL-17A level was significantly higher in HLA-B27 positive patients (n=39): 1.01±1.65 pg/ml vs. 0.36±0.24 pg/ml in negative ones, p = 0.021. Similar trend was observed also for IL-17F: 8.29±23.43 pg/ml vs. 4.08±3.80 pg/ml, respectively, p=0.29. A trend for a higher IL-17A serum level was found in patients with peripheral arthritis (n=7): 1.45±1.74 pg/ml vs. 0.79±1.44 pg/ml in patients without arthritis, p=0.37. No correlation between IL-17 serum levels and either symptom duration, sex, presence of enthesitis, levels of BASDAI and BASFI, smoking status, or presence and progression of structural damage in the spine was found.

Conclusion: IL-17 serum levels correlate with markers of systemic inflammation in patients with clinically active AS. IL-17A is significantly elevated in HLA-B27 positive patients.

Ankylosing Spondylitis Associated Endoplasmic Reticulum Aminopaptidase 1 Variants In Antigen Presentaing Cells Affect HLA-B27 Free Heavy Chain Expression and Binding To NK-Cell Receptors. Nigil Haroon and Zhenbo Zhang. Toronto Western Research Institute, Toronto, ON.

Background/Purpose: ERAP1 and HLA-B27 are strongly associated with ankylosing spondylitis (AS). Using well-controlled tissue culture systems, we studied the effects of AS-associated ERAP1 variants on HLA-B27 expression and interaction with KIR receptors

Methods: C1R cells stably expressing HLA-B27 were transfected with ERAP1shRNA to silence the endogenous ERAP1 expression ($C1R^{ERAP1sh}$). The stable cells were confirmed by flow cytometry with GFP and western blot for ERAP1. We then transfected either the common variant ERAP1 ($ERAP1^{WT}$) or one of the two AS-associated ERAP1 variants, K528R or Q730E into the $C1R^{ERAP1sh}$cells. Lentivirus expression vector alone was used as control and the ERAP1 variants were tracked with the HA-tag.

The stable cell lines were tested by flow cytometry for intact HLA-B27 (ME1 antibody), MHC-I free heavy chain (FHC) expression (HC-10), MARB4 staining and binding to KIR-3DL1 and KIR-3DL2-Fc. Anti-Mouse IgG-PE was used as secondary antibody.

Results: Following antibiotic selection, nearly all cells were GFP positive indicating successful stable ERAP1 shRNA expression. We achieved more than 80% suppression of ERAP1. After introduction of ERAP1 into $C1R^{ERAP1sh}$ cells, Western Blot with anti-HA antibodies showed similar expression of $ERAP1^{WT}$. K528R and Q730E variants respectively.

There was significant increase in surface FHC, intracellular FHC and MARB4 staining with ERAP1 shRNA and subsequent normalization of levels with introduction of $ERAP1^{WT}$. C1R cells with AS-associated ERAP1 variants failed to completely normalize these levels.

KIR3DL1 and KIR3DL2 binding to target cells were assessed using the Fc-chimeric molecules of these receptors. As expected, KIR-3DL1 and KIR-3DL2 binding was increased in $C1R^{ERAP1sh}$ cells and C1R cells with ERAP1 variants known to have less peptide trimming function compared to C1R-$ERAP1^{WT}$ Cells. The percentage of cells with KIR3DL1-Fc binding increased from 40.1% of cells to 64.9% with ERAP1 suppression. KIR-3DL1-Fc binding dropped to 55.9% with introduction of $ERAP1^{WT}$but was higher at 70.4% and 57.3% in C1R cells with K528R and Q730E ERAP1 variants respectively.

Conclusion: Cells with stable ERAP1 knock down had higher intracellular FHC, surface FHC expression and MARB4 staining as well as higher KIR-3DL1 and KIR-3DL2 receptor binding. These changes were corrected with the introduction of the common ERAP1 variant but not with AS-associated K528R or Q730E variants. Decreased ERAP1 activity could be protective because higher surface FHC can interact with inhibitory receptors on NK cells. On the other hand, higher intracellular FHC seen with decreased ERAP1 activity could be pathogenic by triggering the unfolded protein response. Thus the effect of ERAP1 variants on AS pathogenesis may vary depending on the relative balance of these effects.

Ankylosing Spondylitis Protective Endoplasmic Reticulum Aminopeptidase 1 Variants Lead To Decreased Natural Killer Cell Conjugation and Activation. Hasan Abdullah[1], Zhenbo Zhang[2], Robert Inman[3] and Nigil Haroon[4]. [1]University of Toronto, Toronto, ON, [2]Toronto Western Research Institute, Toronto, ON, [3]University of Toronto and Toronto Western Hospital, Toronto, ON, [4]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON.

Background/Purpose: Ankylosing Spondylitis (AS) is an inflammatory arthritis affecting the axial and peripheral joints. Human Leukocyte Antigen (HLA)-B27 and Endoplasmic Reticulum Aminopeptidase (ERAP) 1 genes are strongly associated with AS. An AS pathogenesis mechanism proposes that variant forms of HLA-B27 including B27 free heavy chains (FHC) can be recognized by Natural Killer (NK) cells through receptors like KIR3DL1and KIR3DL2, and could be pathogenic. ERAP1 variants K528R and Q730E with decreased function are protective in AS. Decreased function results in higher HLA-B27 (FHC) expression and can bind to the inhibitory receptors KIR3DL1 and KIR3DL2 altering NK cell activation.

Methods: C1R cells stably expressing HLA-B27 were transfected with ERAP1shRNA to silence the endogenous ERAP1 expression. These cells were transfected with either the common or one of the rare AS associated ERAP1 variants K528R/Q730E. The target cell line was co-cultured with both a KIR3DL1 expressing as well as a non-KIR3DL1 expressing YTS NK cell line for 9 hours. Supernatants were analyzed for 64 cytokines and chemokines using a bead based multiplex assay. Separately, co-cultured cells were stained for intracellular Macrophage Inflammatory Protein (MIP)-1α. NK cells and target cells were each labeled with separate surface staining fluorescent dyes before co-culture. Co-cultured cells were analyzed by flow cytometry at baseline and after 5 and 10 minutes of co-incubation, for NK cell-target cell conjugate formation. Activation of NK cells was also analyzed by flow cytometry after staining for the degranulation marker CD107a.

Results: Duplicate results of the multiplexing assay show MIP-1α is reduced when C1R-B2705 + wild type ERAP1, C1RB2705 + ERAP1 K528R, and C1RB2705 + ERAP1 Q730E cells were co-cultured with 3DL1 NK cells in comparison to YTS NK cells (60%, 45% and 40% reduction respectively). Conjugate formation with the passage of co-incubation time is also reduced in the variant co-cultures as a result of KIR3DL1 interaction (K528R: 27%, Q730E: 18% reduction). Intracellular staining for NK cell MIP-1α production in the above co-cultures revealed a corresponding inhibition of MIP-1α (K528R: 4.6%, Q730E: 28% reduction). YTS-3DL1 NK cell CD107a expression trends lower in the ERAP1 variants in comparison to wild type ERAP1.

Conclusion: Our results are a logical extension of our previous results that showed protective ERAP1 variants lead to increased surface HLA-B27 FHC in monocytes. Here we show that the protective ERAP1 variants, when expressed in C1R cells, result in decreased conjugate formation with KIR3DL1 expressing NK cells, in comparison to wild type ERAP1. A corresponding decrease in MIP-1α chemokine expression and NK cell activation was observed. Reduced function ERAP1 variants may be protective in AS because increased surface HLA-B27 FHC can interact with inhibitory NK cell receptors like KIR3DL1 and cause reduced conjugate formation and NK cell suppression.

HLA-B27 Influence On The Gut Microbiome. Robert D. Inman[1], Aifeng Lin[2], Phillip Sherman[3] and Lee Pinnell[3]. [1]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON, [2]Toronto Western Research Institute and University Health Network, Toronto, ON, [3]Hospital for Sick Children, Toronto, ON.

Background/Purpose: The interrelationship between the gut microbiome and spondyloarthritis (SpA) has been highlighted by recent findings of (i) Subclinical bowel inflammation in SpA (ii) Antimicrobial serology in AS which is comparable to inflammatory bowel disease (IBD) (iii) The association of HLA-B27 with chronicity in post-Salmonella reactive arthritis. This has raised the important unanswered question whether the HLA-B27 may influence disease susceptibility by an influencing the gut microbiome.

Methods: MHC-I transgenic mice were generated on a background of deleted endogenous MHC-I (DKO) and are designated by the transgenic allele: B27tg, B7tg, and A2tg, and compared with C57BL6 (WT). Mice were challenged with *Salmonella typhimurium* (5×10^7 organisms) by gavage and followed to establish differential host responses. Selected mice were euthanized at 24, 48 and 72 hr after infection. Colons were collected for H&E staining. Spleen, liver and mesenteric lymph nodes were dissected and cytokine gene expression determined by real-time PCR. At baseline and at selected time points, colonic contents were collected for analysis of the gut microbioata with primer sets specific for universal bacteria, g-proteobacteria, β-proteobacteria, bacteroidetes, firmicutes, and actinobacteria.

Results: Survival curves after oral Salmonella challenge indicated that the B27tg mouse demonstrated improved survival compared with B7tg and A2tg mice (Fig. 1) (**No figure available**). Review of colon pathology, however, revealed no significant differences in the degree of colonic inflammation. Cytokine profiling in mesenteric lymph nodes at 72hr post-challenge showed that B7tg mice expressed less IFN-g and IL-10 and B27 expressed less Foxp3 than respective tg controls. Analysis of the gut microbioal composition at baseline *prior to* infectious challenge revealed differences related to the MHC-I profile of the mouse: colonization by b-Proteobacteria was enhanced in the B27tg mouse compared with B7tg and A2tg as well as with the DKO and WT control mice (Fig. 2) (**No figure available**).

Conclusion: Class I MHC expression influences survival and host immune response to oral *S. typhimurium* challenge in an allele-specific manner. The endogenous gut microbial profile was distinctively different in B7tg mice, suggesting that the HLA-B27 status directly influences the composition of the gut microbiome. This raises the possibility that the clinical interface between SpA and IBD could be mediated by an interplay between host MHC and the gut microflora.

Evidence Of a Microbial Signature In The Intestinal Microbiome In Ankylosing Spondylitis. Mary-Ellen Costello[1], Francesco Ciccia[2], Brooke Gardiner[1], Mhairi Marshall[1], Dana Willner[3], Tony Kenna[1], Giovanni Triolo[2] and Matthew A. Brown[1]. [1]University of Queensland Diamantina Institute, Brisbane, Australia, [2]Rheumatology Unit, University of Palermo, Palermo, Italy, [3]Australian Centre for Ecogenomics, School of Chemistry and Molecular Biosciences, University of Queensland, Brisbane, Australia.

Background/Purpose: Ankylosing spondylitis (AS) occurs in genetically predisposed individuals exposed to an unknown but likely ubiquitous environmental trigger. In both AS and Crohn's disease (CD) interplay between host genetic factors and largely undefined environmental factors, most likely involving the gut microbiome, are thought to drive the disease. To date, no comprehensive characterization of intestinal microbiota in AS patients has been performed. Our objective was to characterize the intestinal microbiome of newly diagnosed TNF-antagonist naïve AS cases using next generation sequencing and to determine if the AS gut carries a distinct microbial signature. To explore the effect of host genotype on microbiome composition we also characterized the intestinal microbiome in stools of mice with knockouts of two major AS-susceptibility genes, *ERAP* and *IL23R*, in comparison with wild-type controls.

Methods: Terminal ileal (TI) biopsies from patients with AS, CD and healthy controls (HC) and mouse faecal samples were profiled using culture-independent high-throughput next generation sequencing of the 16S rRNA gene on an Illumina MiSeq.

Results: Our results show the TI microbial communities of AS patients differ significantly and are more diverse than the intestinal microbial communities from those with CD and HC. The AS microbial community is characterized by higher abundance of five families of bacteria, *Lachnospiraceae, Veillonellaceae, Prevotellaceae, Ruminococcusaceae* and *Porphyromonadaceae*. Increased abundances of the families *Lachnospiraceae* and *Prevotellaceae* have been strongly associated with colitis and CD. TI microbial composition was found to correlate with disease status ($P = < 0.001$) and greater differences were observed between disease groups than within disease groups. In mice, absence of either *ERAP* or *IL23R* alone was sufficient to significantly alter the microbiome. Absence of *ERAP* and *IL23R* caused an increase a member of the *Rikenellaceae* family bacteria, *Rikenella Alistipes spp.*, compared to wild type controls ($P = 0.001$). *Rikenella Alistipes spp.* is an indicator species found to be driving the AS TI microbiome signature ($P = 0.001$). In the *IL23R* $^{-/-}$ mice, there was an increase in the genus Parabacteroides ($P = 0.023$) (*Porphyromonadaceae* family). No clustering of mouse stool microbiome was noted in relationship to the cage mice were raised in, confirming that these differences are driven by the mouse genotype and not local environmental effects. In our AS cohort we also see an increase the same genus of bacteria.

Conclusion: AS case microbiomes are different from those of CD and HC, and knockout mouse studies show that AS-associated genes shape the intestinal microbiome. This is consistent with models for AS in which genetic effects lead to changes in the gut microbiome which in turn cause immunological effects which lead to AS.

ERAP2 Functional Knockout In Humans Does Not Alter ER Stress Or Evidence Of HLA-B27 Misfolding In Ankylosing Spondylitis. Philip Robinson[1], Yang Wang[2], Eugene Lau[2], Patricia Keith[2], Tony Kenna[2] and Matthew A. Brown[2]. [1]University of Queensland Diamantina Insititute, Brisbane, Australia, [2]University of Queensland Diamantina Institute, Brisbane, Australia.

Background/Purpose: SNPs in *ERAP2* are strongly associated with ankylosing spondylitis (AS). One associated SNP is rs2248374 which changes the strength of the exon 10 donor splice site, with the G allele resulting in a truncated protein which is degraded by nonsense-mediated decay, resulting in a complete absence of ERAP2. This allele has a frequency of approximately 0.5 in the European descendent population, therefore 25% of the population (those who are GG homozygous) are natural ERAP2 knockouts. We investigated the effect of this associated variant on HLA class I allele presentation, HLA class I heavy chain presentation, ER stress markers and pro-inflammatory cytokine gene transcription in AS.

Methods: AS patients and healthy controls with either AA or GG homozygous status for rs2248374 were recruited. Ficoll gradient separated PBMCs were analysed with flow cytometry. Anti-CD14-Pacific Blue, anti-CD19-ECD, anti-HLA-A, B, C-PECy7, anti-V alpha7.2-PE, anti-CD161-PerCy5.5, anti-HC10 and anti-HLA-B27 were used to analyse the PBMCs. Cells were analysed as monocytes, B cells and mucosal associated invariant T (MAIT) cells. Expression levels of endoplasmic reticulum (ER) stress markers (GRP78 and CHOP) and pro-inflammatory genes (TNF, IL-6, IL-17 and IL-22) were assessed by RT-PCR in unsorted PBMCs, normalised to RPL32 housekeeping gene-expression.

Results: 7 AS cases and 8 controls with GG genotype, and 8 AS cases and 8 controls with the AA genotype (all HLA-B27 positive) were analysed. rtPCR patient numbers were: B27+*ERAP2* AA = 8; B27+ *ERAP2* GG = 12; B27-*ERAP2* AA = 16; B27-*ERAP2* GG = 15. Comparing rs2248374 AA and GG genotype carriers, there were no significant differences in HLA Class I expression or free HLA Class I heavy chain levels either intracellularly or extracellularly, ER stress as measured by expression of markers GRP78 and CHOP, or pro-inflammatory gene expression. Also, no difference in ER stress markers or free HLA Class I heavy chain levels was noted between AS cases and healthy controls in any cell type studied.

Conclusion: The study demonstrates that there are not large differences in surface expression of class I antigens or heavy chains, ER stress or pro-inflammatory cytokine gene expression between the two genotypes in AS cases. This suggests that *ERAP2* loss of function variants which are protective against AS do not operate by effects on ER stress or HLA Class I misfolding. Further, the absence of a difference between cases and controls in measures of either free HLA Class I heavy chain levels or ER stress markers is not consistent with HLA-B27 operating to cause AS through either misfolding or ER stress induction, at least in the cell types studied.

Analysis Of Inflammatory Markers Within Facet Joints Of Patients Within Ankylosing Spondylitis. Uta Syrbe[1], Janine Bleil[2], Rene Maier[3], Heiner Appel[1] and Joachim Sieper[4]. [1]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [2]Charité, Berlin, Germany, [3]Charite, Berlin, Germany, [4]Charitè Campus Benjamin Franklin, Berlin, Germany.

Background/Purpose: Inflammation within sacroiliac joints and within the spine is a hallmark of ankylosing spondylitis (AS). Apart from nonsteroidal anti-rheumatic drug (NSAID) treatment, inhibition of TNF, but not of IL-6, has been proven successful in the treatment of signs and symptoms of AS. In addition to its direct inflammatory role, some cytokines might particularly affect bone metabolism. For instance, IL-23 can induce bone formation involving IL-22 as a secondary mediator.

To determine the potential involvement of several inflammatory mediators such as cytokines like IL-23, IL-22, IL-12, IL-6, IL-10 and prostaglandins in the inflammation-driven joint remodeling process in AS, we determined their expression within the cartilage, the subchondral bone and within entheses in zygapophyseal joints of patients with ankylosing spondylitis. Furthermore, we determined their expression within the subchondral bone marrow and within fibrous tissue, which we find in joints undergoing joint remodeling.

Methods: Expression of IL-6, IL-10, IL-12, IL-22, IL-23 as well as of PGE2 and its receptor EP2 were determined by immunohistochemistry in zygapophyseal joints of patients with ankylosing spondylitis (n=13 patients with AS), and in 9 patients with osteoarthritis (OA) and in zygapophysel joints of 10 autopsy controls (CO). AS patients joints were obtained from patients undergoing polysegmental correction surgery because of hyperkyphosis.

Results: The number of IL-6-expressing cells within the cartilage and bone marrow were reduced in AS joints compared to controls ($p<0.005$). The number of IL-10+ cells was reduced within cartilage and the entheses in AS joints ($p<0.005$ and $p<0.01$), but increased in osteocytes found within the subchondral bone plate ($p<0.01$). Numbers of IL-12+ cells were not significantly different between AS and the control groups. IL-22 was reduced within the cartilage and entheses in AS joints compared to autopsy controls ($p<0.001$ and $p<0.01$). Numbers of IL-23+ cells were reduced at enthesial sites of AS joints ($p<0.05$) compared to autopsy controls but not within cartilage or subchondral bone. Prostaglandin E2 expression and expression of the receptor EP2 was high within cartilage in general and particularly high within the fibrous tissue (i.e. about 90% of cells were positive within subchondral fibrous tissue of AS joints), which is not present in healthy joints obtained from autopsy controls.

Conclusion: In contrast to IL-23 and IL-17 (Appel et al. ARD, 2011, 2013), which are highly expressed within the subchondral bone marrow of AS joints we found no increase in IL-6 expression.

Within cartilage and/or entheses we rather find a reduction in IL-10, IL-22 and IL-23 expression which might reflect the disturbed homeostasis of the cartilage in the AS joints undergoing joint remodeling, i.e. intraarticular ankylosis. The high prostaglandin E2 expression and EP2 expression within the fibrous tissue might indicate that prostaglandins are involved in the putative pathological role of this tissue promoting joints remodeling. NSAIDs, which seem to retard radiographic spinal progression might block the pathogenic activity of this subchondral fibrous tissue.

Mast Cells Are a Major Source Of IL-17 In Synovium and Extra-Articular Tissues In Spondyloarthritis Related Diseases. T. Noordenbos[1], I. Gofita[1], M. Alsina[2], E.W.M. Vogels[3], A. A. te Velde[3], J. D. Cañete[4], D. Baeten[5] and N. Yeremenko[1]. [1]Department of Clinical Immunology and Rheumatology and Department of Experimental Immunology, Academic Medical Centre/University of Amsterdam, Amsterdam, Netherlands, [2]Department of Dermatology, Hospital Clinic de Barcelona, Barcelona, Spain, [3]Tytgat Institute for Liver and Intestinal Research, Academic Medical Centre/University of Amsterdam, the Netherlands, Amsterdam, Netherlands, [4]Hospital Clinic, Barcelona, Spain, [5]Department of Clinical Immunology and Rheumatology Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.

Background/Purpose: IL-17 plays a key role in the pathogenesis of spondyloarthritis (SpA) as demonstrated by a recent proof-of-concept trial with the anti-IL17A mAb secukinumab. The cellular source of IL-17A in SpA remains incompletely defined and may vary between different target tissues of the disease.

As we previously demonstrated strong colocalization of IL-17 and mast cells in SpA synovitis, we aimed here to prove that synovial mast cells are an important source of IL-17 in synovitis and to explore whether this was also the case in other target tissues such as psoriasis skin and IBD-affected gut mucosa.

Methods: Mast cells were isolated by *fluorescence-activated cell sorting (FACS)* of *FceR+/ c-Kit+ cells* from synovial tissue (n=5) and *tonsil (n=6)* as the most readily available source of human mast cells. IL-17 expression was assessed directly ex vivo by Western blot or after stimulation with *PMA* and *ionomycin by quantitative real-time PCR*

(qPCR). The frequency of IL-17-positive mast cells was analyzed in the *paraffin-embedded* biopsies from *lesional psoriatic (n=10)* or normal human *skin (n=10),* colon and ileum from *Crohn's disease (n=7), ulcerative colitis (n=6) and control (n=3) by immunofluorescence (IF).*

Results: Because previous studies described mast cells and neutrophils as sources of IL-17A in the synovial tissue were performed with *polyclonal goat anti-human IL-17A antibody,* the question arose whether these immunostainings really detect intracellular IL-17A and not a cross-reactive protein. Western blot analysis of freshly isolated mast cells using both mouse monoclonal and goat polyclonal anti-human IL-17A antibodies revealed expression of IL-17A protein in synovial and tonsil mast cells. In order to investigate if mast cells do not only contain but also produce IL-17A, we accessed IL-17A mRNA levels in directly ex vivo sorted mast cells and after stimulation with *PMA* and *ionomycin. IL-17A mRNA was undetectable in unstimulated mast cells, however* we were able to detect IL-17A mRNA in mast cells stimulated 12 h with *PMA* and *ionomycin. As these data confirmed that mast cells can express and produce IL-17A,* we next investigated whether mast cells were also a major source of IL-17A in other tissues which can be affected by SpA. Double immunofluorescent staining of *psoriatic lesions* identified that IL-17 in the skin is predominantly produced by mast cells (median 94%; interquartile range 86–100%). Analysis of intestine biopsies from IBD patients revealed that the major source of IL-17 is different between lamina propria and submucosal layers. Similar to synovium and skin, mast cells were found to express IL-17 within the submucosa (median 75%; interquartile range 60–90%). In contrast, IL-17 was expressed by CD15+ polymorphonuclear cells (median 80%; interquartile range 60–90%) rather than mast cells (median 23%; interquartile range 6–30%) in the lamina propria.

Conclusion: Our data confirmed expression of IL17 protein by synovial and tonsil mast cells. Our results indicate that mast cells are a major source of IL-17 not only in SpA synovitis but also in psoriasis skin and IBD gut.

Validation Of Gene Expression Biomarkers Of Psoriatic Arthritis. Fatima Abji[1], Remy Pollock[1], Fawnda Pellett[1], Kun Liang[2], Vinod Chandran[1] and Dafna Gladman[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Waterloo, Waterloo, ON.

Background/Purpose: Psoriatic arthritis (PsA) is a seronegative immune mediated arthritis that develops in about a third of patients with cutaneous psoriasis (PsC). The cellular pathways which distinguish the skin and joint manifestations in PsA are poorly understood. Through microarray and qPCR array studies, we have identified several genes which are dysregulated in PsA. The goal of this study was to validate the expression of these genes and associated signaling pathways in a large cohort of patients.

Methods: Total RNA was isolated from peripheral blood of PsA patients satisfying CASPAR criteria and PsC patients. All patients were Caucasian and were not receiving treatment with biological agents. Quantification of mRNA expression of 49 genes was completed using the Nanostring nCounter® system (NanoString Technologies). Fold change differences between PsA and PsC patients were determined from normalized results. Significance was determined by performing multivariate logistic regression analyses and controlling for clinical variables (FDR<0.05).

Results: Gene expression was computed in 48 PsA patients (mean age 46 years, 52% males, psoriasis duration 17 years, PASI 7.5, active joint count 6.3) and 48 PsC patients (mean age 46 years, 50% males, psoriasis duration 17 years, PASI 4.9). Twenty-nine genes were found to be significantly altered (FDR < 0.05) in PsA patients compared to PsC patients (Table 1), including several genes linking the innate immune system and chromatin modification. Downstream signaling molecules in the toll like receptor pathway, such as CXCL10, EZR, MyD88, and CD14, were upregulated in PsA. SMARCA4 is a component of the BAF complex linked to chromatin modification upon TLR4 activation which was also over-expressed in our PsA cohort. Out of these genes, 21 genes were upregulated and 8 genes were downregulated. No significant differences in clinical covariates for any gene were found. Cluster analysis revealed 19 PsA patients that grouped together.

Table 1. Significantly altered genes (FDR<0.05) in PsA patients compared to PsC

Gene	Description	Fold Change	OR (95% CI)	FDR
TLR7	Toll-like receptor 7	1.62	4.03 (1.82, 8.90)	0.0008
CXCL10 (IP10)	Chemokine (C-X-C motif) ligand 10	1.45	1.46 (0.95, 2.24)	0.0420
PARP1	Poly (ADP-ribose) polymerase 1	1.41	2.91 (1.44, 5.88)	0.0028
XRCC6	X-ray repair complementing defective repair in Chinese hamster cells 6	1.36	5.23 (2.37, 11.58)	0.0004
SMARCA4	SWI/SNF related, matrix associated, actin dependent regulator of chromatin, subfamily a, member 4	1.35	4.28 (2.03, 9.01)	0.0005
EZR	Ezrin	1.35	2.01 (1.07, 3.77)	0.0196
SYNCRIP	Synaptotagmin binding, cytoplasmic RNA interacting protein	1.34	4.10 (1.87, 9.03)	0.0007
EHMT2	Euchromatic histone-lysine N-methyltransferase 2	1.31	4.12 (1.95, 8.95)	0.0006
TICAM1 (TRIF)	Toll-like receptor adaptor molecule 1	1.31	3.36 (1.72, 6.53)	0.0006
SETD1A	SET domain containing 1A	1.31	2.28 (1.27, 4.09)	0.0049
RP11-94I2.2	NBPF11 neuroblastoma breakpoint family, member 11	1.30	2.33 (1.33, 4.10)	0.0028
IFNA1	Interferon, alpha 1	1.29	1.77 (1.02, 3.09)	0.0261
CD14	CD14 molecule	1.27	2.16 (1.21, 3.86)	0.0072
PRMT6	Protein arginine methyltransferase 6	1.24	2.13 (1.15, 3.96)	0.0120
TRAM1	Translocation associated membrane protein 1	1.22	3.23 (1.60, 6.51)	0.0011
PUM1	Pumilio homolog 1 Drosophila)	1.20	3.28 (1.66, 6.50)	0.0008
MSN	Moesin	1.16	2.02 (1.06, 3.85)	0.0201
IL15	Interleukin 15	1.16	1.81 (1.01, 3.26)	0.0278
SMYD3	SET and MYND domain containing 3	1.15	1.57 (0.96, 2.57)	0.0352
HAT1	Histone acetyltransferase 1	1.12	1.99 (1.08, 3.67)	0.0196
MyD88	Myeloid differentiation primary response 88	1.07	1.83 (0.95, 3.50)	0.0352
CXCL1	Chemokine (C-X-C motif) ligand 1 (melanoma growth stimulating activity, alpha)	0.61	0.27 (0.13, 0.54)	0.0006
LY96 (MD2)	Lymphocyte antigen 96	0.69	0.23 (0.11, 0.48)	0.0005
BCL2A1	BCL2-related protein A1	0.73	0.24 (0.11, 0.52)	0.0006
CD58	CD58 molecule	0.77	0.24 (0.12, 0.48)	0.0004
CLEC2B	C-type lectin domain family 2, member B	0.79	0.40 (0.22, 0.74)	0.0028
N2N	NOTCH2NL notch 2 N-terminal like	0.80	0.35 (0.19, 0.64)	0.0009
TLR2	Toll-like receptor 2	0.88	0.59 (0.33, 1.05)	0.0352
SETD2	SET domain containing 2	0.92	0.62 (0.38, 1.01)	0.0317

Conclusion: We validated genes involved in the regulation and activation of signaling pathways of the innate immune system that were dysregulated in PsA compared to PsC patients. Future studies will focus on understanding how expression of these genes is linked to clinical variables and progression of PsA, and distinguish whether these genes can serve as biomarkers of PsA susceptibility in patients with PsC.

Contributions Of Skin and Joint Manifestations To The Parent-Of-Origin Effect In Psoriatic Disease. Remy Pollock[1], Arane Thavaneswaran[1], Vinod Chandran[1], Art Petronis[2], Al Amin P. Rahman[3] and Dafna Gladman[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]Centre for Addiction and Mental Health, Toronto, ON, [3]Memorial University, St Johns, NE.

Background/Purpose: Excessive paternal transmission has been previously documented in psoriatic disease. Our objective is to delineate the differential contributions of skin and joint manifestations to this 'parent-of-origin' effect, and determine whether the effect is differentially associated with psoriasis or PsA.

Methods: Parental history of PsA and/or psoriasis without arthritis was ascertained by questionnaire or during clinical assessment of PsA and psoriasis patients from two large cohorts. Data was combined with previously-published data. Proportions of maternal and paternal transmissions were compared using a normal approximation to the binomial distribution. Parental and patient phenotypes were resolved where possible into psoriasis alone or PsA and compared by chi-square test and logistic regression. Patients with paternally and maternally-transmitted disease were compared with respect to demographic and clinical characteristics as well as carriage of risk alleles at *HLA-B*, -C, *-DR*, *-DQ*, and *MICA*, using Student's t-test or chi-square test.

Results: We found a preponderance of patients with affected fathers compared to affected mothers in the combined analysis (397 [56%] versus 313 [44%], p=0.002). There was a greater excess of paternal transmissions in

patients with a parental history of psoriasis (223 [58%] versus 162 [42%], p=0.002) compared to patients with a parental history of PsA (75 [54%] versus 65 [46%], p=0.45), but no difference in frequencies between these patients (p=0.37). Although the parent-of-origin effect also appeared to be stronger in PsA than in psoriasis patients, paternal history of psoriasis could not predict PsA. PsA patients with paternally-transmitted psoriasis had fewer damaged joints than patients with maternally-transmitted psoriasis (mean damaged joint count 6.3 compared to 12.9, p=0.04), and PsA patients with paternally-transmitted PsA had an earlier age of PsA diagnosis than patients with maternally-transmitted PsA (mean age 32.8 compared to 37.5 years, p=0.05). In one particular cohort, PsA patients with paternally-transmitted psoriasis had lower carriage rates of *HLA-B*38* (p=0.006), *HLA-C*06* (p=0.03), and *MICA-129*Met (p=0.01).

Conclusion: We have provided additional evidence of a parent-of-origin effect in psoriatic disease, which may be driven by paternal transmission of psoriasis without arthritis and may be characterized by an earlier-onset yet milder disease that is not associated with several known risk alleles in the MHC.

2503

IL-17+ CD8+ T Cells Are Enriched In The Joints Of Patients With Psoriatic Arthritis and Correlate With Markers Of Disease Activity and Joint Damage Progression. Bina Menon[1], Nicola J. Gullick[2], Hayley G. Evans[3], Gina J. Walter[3], Megha Rajasekhar[3], Toby Garrood[1], Leonie S. Taams[3] and Bruce W. Kirkham[1]. [1]Guy's and St. Thomas' Foundation Hospital NHS Trust, London, United Kingdom, [2]King's College Hospital Foundation NHS Trust, London, United Kingdom, [3]King's College London, London, United Kingdom.

Background/Purpose: Psoriatic arthritis (PsA) and rheumatoid arthritis (RA) have clear differences in clinical, radiological and genetic features, suggesting that the immunopathology of the conditions may also differ. IL-17/Th17 cells are thought to contribute to inflammatory arthritis as well as psoriasis. Given the strong association between MHC class I and PsA, we hypothesized that IL-17+ CD8+ T cells are enriched in PsA and correlate with disease activity and synovitis.

Methods: Mononuclear cells from synovial fluid (SF) and peripheral blood (PB) compartments from 21 patients with PsA, 14 patients with RA and 14 healthy controls (PB only) were isolated and stimulated for three hours in vitro with PMA and ionomycin in the presence of GolgiStop. CD3+ T cells were investigated for expression of IL-17A by flow cytometry. Clinical measures and Power Doppler Ultrasound (PDUS) of the affected joint were assessed at the time of joint aspiration. PsA subjects were assessed by a blinded observer for erosive changes in hand and feet radiographs.

Results: Both patients with PsA and RA had a significant increase in IL-17+ CD4+ T cells in the synovial fluid compared to their peripheral blood. Notably, we also found a significant increase in IL-17 expressing cells in the CD4- compartment in SF from patients with PsA (SF vs. PB, median (IQR)%, 1.10 (0.46–2.29) vs. 0.18 (0.09–0.32), p=0.0002)) whilst this population was virtually absent in SF from patients with RA (p=0.83). The IL-17+ CD4- cells consisted predominantly of CD8+ T cells. No significant differences were found between IL-17+ T cell frequencies from the blood in patients with PsA vs. HC. SF IL-17+ CD4-(CD8+) T cells correlated significantly (Spearman's r) with CRP (r= 0.57, p=0.005), ESR (r=0.62, p=0.002) as well as PDUS score of the affected joint (n=16, r=0.49, p=0.05), whilst SF IL-17+ CD4+ T cell frequency correlated only with ESR (r=0.42, p=0.05). Interestingly, patients with erosive disease (n=13) had elevated levels of IL-17+ CD3+CD4-(CD8+) cell frequencies in SF vs. non erosive subjects (n=8) (1.91 (1.03–4.94) vs. 0.32 (0.11–1.12), p<0.05, One-way ANOVA, post test: Dunn's). IL-17+ CD8+ T cells expressed low levels of perforin, granzyme B and CD107a in PB and SF (n=3) when compared to IFNγ+ CD8+ T cells, indicating that these cells may have a different effector function than cytotoxic CD8+ T cells.

Conclusion: This is the first report documenting elevated IL-17+ CD3+CD4-(CD8+) cell frequencies in the PsA SF compartment with strong correlates with clinical and imaging measures of disease activity. We propose that IL-17+ CD8+ T cells may be a hitherto unrecognised population in PsA that may contribute to the immunopathology of this disease.

Male Children With Higher SLE Disease Activity In An US Cohort. Lakshmi N. Moorthy[1], Elizabeth Roy[2], Margaret Peterson[3], Afton L. Hassett[4], Alexa B. Adams[3], Laura V. Barinstein[5], Elizabeth C. Chalom[6], Karen Onel[7], Linda Ray[8], Jorge Lopez-Benitez[9], Kathleen A. Haines[10], Philip Hashkes[11], Daniel J. Kingsbury[12], Victoria Cartwright[12], Nora G. Singer[13], Ingrid Tomanova-Soltys[14], Andreas Reiff[15], Sandy D. Hong[16] and Thomas J. A. Lehman[3]. [1]Robert Wood Johnson Medical School-UMDNJ, New Brunswick, NJ, [2]RWJMS-UMDNJ, New Brunswick, NJ, [3]Hospital for Special Surgery, New York, NY, [4]University of Michigan, Ann Arbor, MI, [5]Mount Sinai Med Ctr, New York, NY, [6]St. Barnabas Medical Center, Livingston, NJ, [7]PRCSG, Cincinnati, OH, [8]University of Mississippi Medical Center, Jackson, MS, [9]Pediatric Rheumatology Program Centro Medico La Costa, Asuncion, Paraguay, [10]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [11]Shaare Zedek Medical Center, Jerusalem, Israel, [12]Legacy Emanuel Children's Hospital, Portland, OR, [13]Director, Division of Rheumatology, MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH, [14]Winthrop University Hospital, Mineola, NY, [15]Children's Hospital Los Angeles, Los Angeles, CA, [16]U of Iowa Children's Hosp, Iowa City, IA.

Background/Purpose: Although systemic lupus erythematosus (SLE) is more common in females, males tend to have more severe disease. We compared age at SLE diagnosis, duration, activity, damage, and medication use in young males to that in young females in an expanded pediatric cohort from the US.

Methods: We examined age at SLE onset, and duration of pediatric SLE patients (≤18years) from a cross-sectional multicenter cohort. We determined use (current and past) of cyclophosphamide or rituximab, mycophenolate, and azathioprine. Physicians completed the SLE disease activity index (SLEDAI), Physicians Global Assessment of disease activity (PGA) and the Systemic Lupus International Collaborating Clinics/ACR damage index (SDI). We compared age at SLE diagnosis, duration, activity and damage in boys to that in girls. Depending on the data distribution, the independent samples t-tests (t) and/or Mann-Whitney U (MWU) tests were used to compare samples. We compared medication using the Chi-Square test.

Results: We identified 29 boys and 138 girls. Compared to girls, boys had a higher age of disease onset (p<0.01), lesser disease duration (p<0.01), and greater disease activity as assessed by SLEDAI and PGA (p<0.05) (Table 1). Differences in SDI and immunosuppressive medication use between the two groups were not statistically significant (Table 1).

Table 1. Comparison between young males and young females with SLE

Variables	Males (n=29 unless specified)	Females (n=138 unless specified)
Ethnicity (non-white, %)	23 (80%)	112 (81%)
Age at diagnosis in years (mean±SD)	13±3	11±4* (t)
Mean SLE duration in months (mean±SD)	18±20	40 ±41* (MWU)
PGA-none/mild SLE activity (n, %)	12 (45%)	86 (65%, n=133)
PGA-moderate-severe SLE activity (n, %)	17 (59%)	47 (33%, n=133)
PGA mean (mean±SD)	1.7±0.8	1.2±0.8* (n=133) (MWU)
SLEDAI mean (mean±SD)	7±6	5±6*(n=135) (MWU)
SDI mean (mean±SD)	0.9±1 (n=28)	0.8±1 (n=135)
Cyclophosphamide/ Rituximab (n, %)	10 (34%)	43 (31%)
Azathioprine (n, %)	5 (17%)	31 (22%)
Mycophenolate (n, %)	9 (31%)	44 (32%)

* p<0.05; Mann Whitney U test (MWU); Independent samples t test (t).

Conclusion: SLE activity was higher in boys compared to girls in our cohort. Boys had a later age at diagnosis and shorter disease duration when compared to the girls in our study. A higher index of suspicion is warranted to diagnose and detect worsening in young males with SLE, so that aggressive treatment can be instituted early.

Higher Disease Damage Among African Americans With Familial Versus Sporadic Systemic Lupus Erythematosus. April Barnado, Lee Wheless, Stephanie Slan, Gary S. Gilkeson and Diane L. Kamen. Medical University of South Carolina, Charleston, SC.

Background/Purpose: Studies in predominantly Caucasian cohorts have found no significant clinical or serologic differences in systemic lupus erythematosus (SLE) patients with a family history of SLE compared to those with no family history. Using a unique cohort of African Americans with SLE and a high prevalence of multipatient families, we examined whether having a family history of SLE would impact autoantibodies, age at SLE diagnosis, ACR criteria, and disease damage.

Methods: Utilizing data from a prospective longitudinal cohort of African Americans with SLE, familial SLE was defined as having a confirmed family history of SLE versus sporadic SLE defined as no known family history of SLE. SSA, SSB, ds-DNA, anticardiolipin, and lupus anticoagulant were all tested. A patient was considered to have a positive serology if the serology had ever been positive. Cumulative damage was measured using the Systemic Lupus International Collaborating Clinics/ American College of Rheumatology Damage Index (SDI). Chi-square testing was used for comparing categorical and Student's t-test used for comparing continuous variables. The association between familial vs. sporadic SLE and SDI was modeled using Poisson regression adjusting for covariates. Two-sided p-values < 0.05 were significant.

Results: 400 African American females had SLE, 55 of who were familial SLE cases. Mean age of familial cases was 47.1 +13.9 years vs. 43.3 + 14.7 for sporadic cases ($p = 0.08$). Mean age at diagnosis was 28.1 +11.5 years for familial vs. 31.0 + 13.0 for sporadic ($p = 0.13$). Mean disease duration was 18.7 + 9.1 years for familial vs. 12.3 + 7.1 for sporadic ($p < 0.01$). Familial SLE cases had similar rates of dsDNA, SSA, SSB, anticardiolipin, and lupus anticoagulant positivity compared to sporadic cases. Familial cases had similar rates of being on dialysis as sporadic cases (19.2% vs. 12.2%, $p = 0.17$). There were similar rates of fulfilling ACR renal criterion (58.0% familial vs. 52.8% sporadic). Familial cases were significantly more likely to fulfill ACR criterion of photosensitivity (65.3% vs. 49.3%, $p = 0.04$) but no significant differences in the other ACR criteria. Familial cases had significantly higher SDI scores (2.8 + 2.6 vs. 1.6 + 1.8, $p = 0.02$) compared to sporadic cases. After adjustment for age at diagnosis and disease duration, familial SLE was still associated with a significantly higher SDI ($p < 0.01$).

Conclusion: Consistent with predominantly Caucasian SLE cohorts, we found African American SLE familial and sporadic cases had similar serologic and clinical profiles. However, familial SLE cases had significantly higher SDI scores compared to sporadic cases, even after adjusting for age at diagnosis and disease duration. Further studies are underway to elucidate the causes of higher disease damage in familial versus sporadic SLE.

Systemic LUPUS Erythematosus Patients Presenting With Immune Thrombocytopenia and The Association Between Two Diseases. Omer Nuri Pamuk, Gulsum Emel Pamuk and Mehmet Sevki Uyanik. Trakya University Medical Faculty, Edirne, Turkey.

Background/Purpose: We evaluated the features of our systemic lupus erythematosus (SLE) patients who presented with immune thrombocytopenia (ITP) and compared them to other SLE patients. In addition, we searched for the frequency of autoantibody positivity in our ITP series and evaluated ITP patients who developed SLE during follow-up.

Methods: Patients who were diagnosed with SLE at our university's rheumatology department and those diagnosed with ITP at the hematology department were retrospectively evaluated. The clinical features, autoantibody profiles and outcome of the patients were recorded down. SLE was diagnosed according to revised ACR criteria. ITP was diagnosed according to American Society of Hematology (ASH) 2011 guidelines and a platelet count <100000/mm3 was a prerequisite. Antiplatelet antibodies were not routinely evaluated. SLE presenting with ITP was diagnosed when the clinical symptoms of SLE and autoantibody positivity did develop within the first year after the diagnosis of ITP.

Results: Twelve (6.7%) of the 280 SLE patients who were diagnosed within this time period presented with isolated ITP. The median time for the development of SLE in these patients was 3 years. Two SLE patients presented with thrombotic thrombocytopenic purpura (TTP) and one SLE patient had TTP during follow-up. When the features of 14 SLE patients who presented with ITP or TTP were compared to others, it was seen that the mean age (31.8 ± 11.1 vs. 38.6 ± 12.1, $p=0.043$) and anti-ds-DNA positivity (21.4% vs. 47.3%, $p=0.05$) were lower in this group; and these patients tended to have more active disease during pregnancy or had a higher probability of initially presenting with pregnancy (35.7% vs. 15.8%, $p=0.067$).Fortyone SLE patients (14.6%) had thrombocytopenia during any time of their disease. SLE patients with thrombocytopenia had more frequently initially active SLE (SLEDAI score >6) (70.7% vs 37.3%, $p<0.001$); fever (26.8% vs 14%, $p=0.038$); neurologic involvement (34.1% vs. 18.5%, $p=0.022$); renal involvement (45% vs 25%, $p=0.009$); low C3 level (61% vs 30.6%, $p<0.001$); also, the frequency of patients whose disease started with pregnancy or become aggravated with pregnancy were significantly higher (31.6% vs. 14.3%, $p=0.009$). There was no association between antiphospholipid antibodies (APS) and thrombocytopenia in SLE patients. Of 216 patients with ITP, ANA was positive in 18.5% (28/151), and anti-DNA was present in 1.6% (2/121). None of the patients had findings of SLE or other autoimmune rheumatic diseases. After 2, 5, and 6 years of follow-up, however, 3 female patients developed SLE. APS antibodies were positive in 29.3% (24/82) of ITP patients in which they were available. Nevertheless, except one, all were IgM antibody positivity at low titers. None of the cases with positive APS antibodies had history of thrombosis or abortion.

Conclusion: Some patients with ITP might develop SLE during follow-up. Onset of SLE with pregnancy, renal or neurologic involvement, and initially active disease are risk factors for the development of ITP in SLE patients.

What Is The Risk Of Having a Total Hip Or Knee Replacement for Patients With Lupus? Sandeep Mukherjee[1], David Culliford[2], Nigel K. Arden[3] and Christopher J. Edwards[1]. [1]NIHR Wellcome Trust Clinical Research Facility, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, [2]University of Southampton, Southampton, United Kingdom, [3]Oxford NIHR Musculoskeletal Biomedical Research Unit, University of Oxford, Oxford, United Kingdom.

Background/Purpose: Individuals with systemic lupus erythematosus (SLE) frequently have arthralgia, but joint damage leading to surgery is thought to be less common. In addition to inflammatory damage, other reasons like avascular necrosis (AVN), often associated with steroid use and antiphospholipid syndrome (APS), may increase the likelihood of large joint failure. Demonstrating the risk of joint replacement in lupus patients and factors contributing to this may allow preventative action.

Methods: We performed a retrospective matched case control study of all total hip replacements (THR) and total knee replacements (TKR) between 1991 and 2011 recorded in the General Practice Research Database (GPRD), a primary care database containing data on approximately 3.6 million patients from over 480 primary care practices. There were two controls for each case of primary THR or TKR, matched for age, sex and GP practice location (a proxy for socio-economic status). The odds of having THR or TKR for individuals with SLE were compared with those without lupus through Chi-squared analysis followed by conditional logistic regression taking account of the matching. Individuals with inflammatory arthritis due to any other cause were excluded and results adjusted for steroid use and APS.

Results: During the 20-year study period 63162 patients had a primary THR (123624 matched controls). Within this total sample size of 186786, 122 individuals with a previous diagnosis of SLE had a THR performed (see table). After excluding those who had an inflammatory arthritis other than lupus, there remained 181464 individuals without lupus and 60167 of them

underwent primary THR (see table). During the same period 54276 individuals had a primary TKR (106302 matched controls). Again out of this new total sample size of 160578, 124 individuals with a diagnosis of SLE had a TKR performed (see table). After exclusions for other inflammatory arthritis, there were 154850 individuals without lupus, 50658 of whom underwent primary TKR (see table). Overall, for individuals with a previous diagnosis of SLE, the unadjusted odds ratio (OR) of having a THR was 1.43 (95% confidence interval (CI): 1.13 to 1.81, p=0.0030) over those without lupus and that for having a TKR was 2.54 (95% CI: 1.94 to 3.33, p<0.0001). However, after adjustment the OR were 1.20 (95% CI: 0.94 to 1.52, p=0.1441) and 1.91 (95% CI: 1.44 to 2.53, p<0.0001) respectively.

	THR Without Lupus	THR With Lupus	TKR Without Lupus	TKR With Lupus
Number of individuals	60167	122	50658	124
Mean Age (years)	69.5	65.7	70.4	66.3
Male:Female	1:1.6	1:10	1:1.3	1:8
OR unadjusted		1.43 (p = 0.0030)		2.54 (p = <0.0001)
OR adjusted		1.20 (p = 0.1441)		1.91 (p = <0.0001)

Conclusion: Patients with lupus who have a THR or TKR tend to be younger than their peers without lupus. In addition, they appear to have a significantly increased risk of TKR but the increased risk of THR does not remain after adjustment for anti-phospholipid syndrome and steroid use.

Disclosure: S. Mukherjee, None; **D. Culliford**, None; **N. K. Arden**, None; **C. J. Edwards**, None.

2508

Clinical and Serological Discordance In The Systemic Lupus Erythematosus International Collaborating Clinics (SLICC) Cohort. Murray B. Urowitz[1], Dafna Gladman[1], Nicole Anderson[1] and Systemic Lupus Erythematosus International Collaborating Clinics SLICC[2]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]Toronto Western Hospital, Toronto, ON.

Background/Purpose: Anti-DNA antibodies and serum complement levels are considered important biomarkers for disease activity in SLE. Despite this many SLE patients present serologically active (positive antibody and or low complement) but clinically quiescent (SACQ). We aim to determine the frequency of SACQ in a multicentre, multinational cohort.

Methods: An inception cohort of SLE patients from 31 centres in 12 countries has been assembled according to a standardized protocol between 2000 and 2013 to study the risk factors for atherosclerosis. Patients enter the cohort within 15 months of SLE diagnosis (≥4 ACR criteria). Clinical and laboratory features of SLE and comorbidities are gathered in a standardized protocol at yearly intervals. SACQ was defined as at least two consecutive yearly visits with SLEDAI of 2 or 4 from serologic activity only (increased anti-double-stranded DNA and/or hypocomplementemia), during which patients could be taking antimalarials, but not steroids or immunosuppressives. We examined patients 1 year after the SACQ period and beyond. Flare was defined as any increase in clinical activity. Since patients were mandated to only be on antimalarials it is unlikely they had moderate to severe flares between yearly assessment visits. Serologically quiescent and clinically quiescent (SQCQ) was defined as SLEDAI-2K score of 0.

Results: 91 of 1837 (5%) patients met the criteria for SACQ. Of the 91 patients studied, 86.8% were female and the race/ethnicity distribution was 65.9% Caucasian, 9.9% Black, 13.2% Asian, 7.7% Hispanic and 3.3% other. The age at SLE diagnosis was 34.6 ± 11.9 years. Disease duration at last follow–up was 7.1± 3.0 years. Fifty-five patients did not retain SACQ status after the first year and 36 patients experienced a prolonged SACQ. Of the 55 patients that did not retain SACQ status, 25 (45.45%) flared, 14 (25.45%) became SQCQ and 16 (29.09%) were censored at the last visit. Of the 36 patients that went onto prolonged SACQ: 9 (25.00%) patients flared after 3 years of SACQ, 4 (11.11%) patients became SQCQ and 23 (63.89%) patients were censored at their last visit.

Conclusion: Sixty percent of the SACQ patients no longer retained SACQ status in the first year, while 40% experienced a prolonged SACQ period and 25% of those flared later. Therefore treatment decisions in these patients must be based on close clinical observation.

Disclosure: M. B. Urowitz, None; **D. Gladman**, None; **N. Anderson**, None; **S. L. E. I. C. C. SLICC**, None.

2509

Long Term Natural History Of Asymptomatic Avascular Necrosis In a Cohort Of Patients With Systemic Lupus Erythematosus Treated With Corticosteroids. Eileen J. Lydon[1] and H. Michael Belmont[2]. [1]NYUHJD, New York, NY, [2]NYU School of Medicine, New York, NY.

Background/Purpose: Avascular necrosis (AVN) is cellular death of bone components due to interruption of the blood supply resulting in area of ischemic necrosis but may or may not progress to collapse and painful arthritis. The incidence of AVN in SLE patients is high although the natural history (e.g. prevalence of progression) has not been well characterized. In 2002, we initiated the APLLE (Avascular Necrosis Prevention with Lipitor in Lupus Erythematosus), trial to assess the effectiveness of statin therapy to prevent the incidence of AVN in any of 12 sites per patient (femoral heads, medial and lateral femoral condyle, tibeal plateau, distal tibia or talar domes) ascertained by comparing baseline to follow up MRI's at four and nine months. We could not demonstrate that atorvastatin prevented AVN and the study was terminated in 2008. We now report on the course of AVN sites that were identified by MRI during the course of the study emphasizing the development of symptomatic (sx) AVN in patients previously asymptomatic.

Methods: APLLE trial participants were contacted starting 1/2013. A questionnaire was used to identify sx AVN and a chart review was conducted to collect pertinent information. Sx was defined as interfering with ADL [daily pain and loss of function]. If patient verbalized symptoms, they were invited for an office visit with the nurse practitioner to complete a focused history and physical.

Results: 23 of 42 APLLE participants available for follow-up at mean of 7.35 years; 19F, 4M; 9AA,9H,2C,3A; 18/23(78%) completed 9 month MRI with 5/18(28%) new AVN, 13 sites out of 216. During intervention trial; 11/23(48%) atorvastatin, 22/23(96%) hydroxychloroquine; During follow up study; 19/23(83%) hydroxychloroquine,3/23(13%) statin, 3/23(13%)bisphosphonate, 0/23 teriparatide.

AVN Site Results: Interventional & Follow up Studies

	N	# of Patients with AVN	# Total AVN Sites	# Symptomatic	# Asymptomatic
Interventional: Baseline MRI	42	15/42 (36%)	48/180 (27%)	2/48 (4%)	46/48 (96%)
Interventional: 9 month MRI	28	12/28 (43%)	47/144 (33%)	3/47 (6%)	44/47 (94%)
Follow-up Study	23	8/23 (35%)	33/96 (34%)	7/33 (21%)	26/33 (79%)

Follow-up study new sx AVN in 3 patients. 1st patient-2 sites sx delayed 2.5 years requiring bilateral THR, 2nd patient-2 sites sx delayed 8 years, 3rdpatient-3 sites, delayed.75, 1 and 4 years. No sx AVN in the 18 of 23 in follow-up study without AVN in interventional trial.

Conclusion: Although AVN is a frequent complication of steroid treatment in SLE, MRI studies are sensitive and can overestimate clinically relevant episodes which should be a source of reassurance to patients. Both at baseline of interventional trial (4%) and in follow-up study (21%) AVN infrequently sx. Results did not demonstrate protective role for statins or medications intended to preserve bone density. Symptomatic progression, often delayed over years (range.75 – 8 years), occurred in 7/33(21%) arguing against need for aggressive intervention in all patients (e.g. bisphosphonates, teriparatide, core decompression). Future studies will need to identify risk factors for progression to justify randomized controlled trials.

Disclosure: E. J. Lydon, None; **H. M. Belmont**, None.

The Epidemiology Of Systemic LUPUS Erythematosus and Clinical Features Of Patients At A Single Center In Northwestern Turkey. Omer Nuri Pamuk[1], Salim Dönmez[2], Gokce Busra Calayir[1] and Cigdem Mengus[1]. [1]Trakya University Medical Faculty, Edirne, Turkey, [2]Yüzüncü Yıl University Medical Faculty, Edirne, Turkey.

Background/Purpose: We evaluated the clinical features, treatment modalities, treatment responses and prognosis of patients diagnosed with systemic lupus erythematosus (SLE). We also estimated the prevalence and incidence of SLE in Thrace region of Turkey.

Methods: Twohundred-and-seventynine patients (260F, 19M, mean age: 38.7±11.6 years) diagnosed with SLE between 2003–2013 at our center were retrospectively evaluated. Clinical features, treatments and responses to various treatment modalities were recorded. In addition, the incidence and prevalence of SLE in our population were calculated. Our hospital has been the only tertiary referral center for rheumatological diseases for a mixed rural and urban population of 616000 people for >16 years (316000M, 300000F).

Our city, Edirne, is located in Thrace region in northwestern Turkey and makes borders with Greece and Bulgaria.

Results: The mean annual incidence of SLE was 4.5/100000 (8.7/100000 in females, 0.6/100000 in males). The overall prevalence of SLE was 45.3/100000 (86.7/100000 for females, 6.1/100000 for males). Malar rash was present in 37.9% of patients; photosensitivity, 72.4%; discoid rash, 15.6%; alopecia, 9.2%; raynaud phenomenon, 32.1%; pericarditis, 8%; pleural involvement, 16.1%; and livedo reticularis in 8.1%. The percentages for major organ involvement were as follows: neurologic involvement, 20.1%; renal involvement, 28.2%; autoimmune hemolytic anemia, 9.6%; and trombocytopenia, 14.7%. Results of positivity for autoimmune tests were ANA, 98.2%; anti-dsDNA, 46%; anti-Sm, 15.7%; anti-Ro, 31.3%; anti-nucleosome, 10.4%; anti-ribosomal P, 4.8%; RF, 15%; ANCA, 8.4%; and antiphospholipid antibody, 17.6%.

At a median follow-up of 49 months, 13 SLE patients (10F, 3M) died. The 5-year survival was 95%, and the 10-year survival was 92%. According to Kaplan-Meier survival analysis, being male (5-year survival 77% vs. 95%, p=0.015); having pleural involvement (5-year survival 95.4% vs. 87%, p=0.011); having renal involvement (5-year survival 88.4% vs. 98.5%, p=0.014); usage of cyclophosphamide (5-year survival 87.3% vs. 96.6%, p=0.004); and an initially high SLEDAI score (>6) (5-year survival 89% vs 97.8%, p=0.005) were poor prognostic factors.

Smoking (5-year survival 89% vs. 95.4%, p=0.07) and autoimmune hemolytic anemia (5-year survival 96.2%, 85%, p=0.058) tended to be associated with poor prognosis.

According to Cox regression analysis, pleural involvement (OR: 6.25, p=0.018), hemolytic anemia (OR: 4.1, p=0.05), renal involvement (OR: 4.8, p=0.045), and low C3 level at the time of initial diagnosis (OR: 5.1, p=0.038) were independent poor prognostic factors which influenced survival.

Conclusion: Our results revealed that the annual incidence and prevalence of SLE in northwestern Turkey were quite similar to western data. In our series, majority of patients were females. Survival was similar to data from western countries. Poor prognostic factors were renal involvement, pleural involvement, initially active disease and autoimmune hemolytic anemia.

Multicenter Validation Of The Lupus Activity Scoring Tool (LAST) As Compared To The Selena Sledai (SS) Modification. Majed M. Khraishi[1], Rana Aslanov[2], Sanjay Dixit[3], Krista Fudge[4], Vandana Ahluwalia[5] and Sarah Khraishi[6]. [1]MD, Memorial University of Newfoundland, Nexus Clinical Research, St Johns, NF, [2]MD, MSc, Memorial University of Newfoundland, St. John's, NF, [3]McMaster University, Burlington, ON, [4]Western Memorial Hospital, Corner Brook, NF, [5]Past President, Ontario Rheumatology Association, Brampton, ON, [6]Memorial University of Newfoundland, St. John's, NF.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic immune modulated disease with variable clinical manifestations. New advances in the management of SLE mandated closer monitoring of the disease activity and its response to treatment. Current disease activity indices (e.g. SELENA SLEDAI, BILAG & SLAM) have their own limitations.

In our centre, a new tool for the assessment of SLE activity: the Lupus Activity Scoring Tool (LAST) was developed and validated. This tool simplifies the approach to quantifying SLE activity while maintaining high sensivity. This study was designed to validate this tool in different clinical settings. Apple iPad and Windows web-based applications were developed for the LAST.

We aimed: To validate the LAST in multiple clinical settings using its correlation to the SELENA SLEDAI modification. To test the usability and the accuracy of an electronic application of the same tool.

Methods: This multicenter study was initiated in four Canadian clinics: two in Newfoundland and two in Ontario. The LAST included patient global assessment of disease activity (PGA), physician global assessment of disease activity (PHGA), C3, C4 and Anti-ds Anti-DNA titer abnormalities, and a formula incorporating the current immunomodulating medication used as an indication of SLE activity. Patients who met the SLE ACR 1997 criteria update were recruited and evaluated in the study centres using LAST. Some of the patients were prospectively followed and evaluated by the same tool at each visit. The SS was also calculated for each visit. Descriptive statistics and correlation bivariates were conducted. The LAST scores of the disease activity of patients with multiple assessments were compared to the SS scores.

Results: Thirty two patients (91% females) with 66 assessments from four study centers were included in this analysis. The mean (SD) age was 46.3 (14.7) years and the mean (SD) of disease duration was 13.6 (6.1) years. Scores from the LAST were obtained at each visit in addition to the SLEDAI scores. The mean (SD) SLEDAI score was 6.6 (3.9). The mean (SD) LAST (with C3, C4 and Anti-ds Anti-DNA) score was 34.9 (18.2). The SLEDAI scores were consistent and strongly correlated (r=0.791; p<0.001) with the LAST scores at the baseline and follow-up visits: SS scores 0–4 corresponded to the LAST scores of 0–30 while SS scores of 8 or higher corresponded to 50 and higher, respectively. The electronic applications of the LAST were easy to use and no errors were found with their results as compared to the manually obtained scores.

Conclusion: The Lupus Activity Scoring Tool (LAST) is a new disease activity index that correlates well with the SELENA SLEDAI modification. The use of simple clinical variables as a measure of SLE activity seems to be valid under different clinical settings with different assessors. The development of easy to use electronic apps will make the use of these activity tracking tools simpler and can possibly be utilized in non-specialist settings.

Smoking Is Associated With More Severe Skin Disease In Subjects With Moderate To Severe Systemic Lupus Erythematosus (SLE). Victoria P. Werth[1], Munther A. Khamashta[2], Gabor G. Illei[3], Stephen Yoo[3], Liangwei Wang[3] and Warren Greth[3]. [1]Philadelphia Veterans Affairs Medical Center, Philadelphia, PA, [2]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [3]MedImmune, LLC, Gaithersburg, MD.

Background/Purpose: The influence of smoking on the severity of cutaneous manifestations in adults with moderate to severe SLE was assessed in an ongoing international, multi-center, double-blind, randomized, placebo-controlled study.

Methods: Adult subjects with SLE (n=431; 94.7% female; median disease duration 6.3 years; 59% white; 37% Hispanic; median age 40; mean SLEDAI 2K 11.3) were assessed for mucocutaneous disease activity and smoking history at baseline. Subjects were classified as Current (within 1 year) (n=61) or Past (stopped >1 year)/Never Smokers (n=365). The 426 subjects who had Cutaneous Lupus Activity and Severity Index (CLASI), SLEDAI 2K, and smoking history available at baseline are included in this analysis.

Results: Based on SLEDAI 2K scoring at baseline 79.4%, 67.1%, and 45.2% had an inflammatory rash, alopecia, or mucosal ulcers, respectively, with no significant differences between smokers and non-smokers. Current smokers had significantly higher CLASI scores and were more likely to have moderate or severe rash (CLASI ≥10) (Table 1). There was no significant difference in CLASI scores between Past/Never smokers (7.1±6.6/7.0±6.3 P=0.890).

Table 1.

	Smoking History				
	Current	N	Never/Past	N	Significance
CLASI activity score (mean ± SD)	13.1±10.6	61	7.0±6.3	365	P<0.001†
CLASI damage (mean ± SD)	3.7±6.2	61	2.2±4.5	365	P=0.087†
CLASI <10 (%)	44.3%	27	75.3%	275	P<0.001‡
CLASI ≥10 (%)	55.3%	34	24.7%	90	
SLEDAI Rash present	83.6%	51	78.9%	288	NS‡
SLEDAI Alopecia present	73.8%	45	65.8%	240	NS‡
SLEDAI Mucosal ulcers present	44.3%	27	45.5%	166	NS‡

†2 sample t-test; ‡Chi-square test
CLASI: Cutaneous Lupus Activity and Severity Index; NS: not significant; SD: standard deviation; SLEDAI: Systemic Lupus Erythematosus Disease Activity Index

This observation was consistent across geography, races, ethnicities, and SLE medications at baseline (Table 2). There was no relationship between smoking and cutaneous damage.

Table 2.

Smoking	Never/Past Mean CLASI	SD	N	Current Mean CLASI	SD	N
Race/Ethnicity						
American-Indian	5.4	5.1	20	NA	NA	0
Asian	9.5	7.0	65	NA	NA	0
Black	6.5	3.7	27	8.4	6.9	5

Yes	7.0	6.4	312	13.5	10.8	51

CLASI: Cutaneous Lupus Activity and Severity Index; SD: standard deviation

Conclusion: Previous studies have shown that smoking is associated with an increased risk of cutaneous lupus. In agreement with a previous single center study, here we show in a large, multinational and multiethnic cohort that current smoker SLE subjects have higher CLASI activity scores than past or non-smokers. The CLASI seems more sensitive to detect these differences of inflammatory skin involvement in subjects with moderate to severe SLE than the SLEDAI 2K mucocutaneous descriptors (rash, alopecia, mucous ulcers). The lack of difference in the frequency of mucocutaneous manifestations based on SLEDAI 2K between current smokers and past/never smokers is in apparent contrast to published data but is a consequence of the study eligibility criteria enriching for patients with active mucocutaneous disease. The consistency of the relationship between smoking and higher CLASI activity but not chronicity scores in SLE subjects with skin involvement across geographies, races, ethnicities, and SLE medications suggest that smoking may actively worsen skin disease in SLE. As CLASI activity is similar in past smokers and never smokers, smoking cessation should be emphasized in the management of SLE with cutaneous involvement.

Anti-Mullerian Hormone In Patients With Systemic Lupus Erythematosus. Chiara Tani[1], Sabrina Vagnani[1], Linda Carli[2], Giovanni Gallo[2], Maria Rita Sessa[3], Chiara Baldini[2], Alessandra Della Rossa[2], Rosaria Talarico[2], Francesca Strigini[1], Marco Maccheroni[3], Stefano Bombardieri[1] and Marta Mosca[1]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Rheumatology Unit, Pisa, Italy, [3]S. Chiara Hospital, Pisa, Italy.

Background/Purpose: Systemic Lupus Erythematosus (SLE) frequently affects women in childbearing age; disease related factors and treatment can interfere with ovarian function. Anti-Mullerian-hormone (AMH) levels are considered a surrogate marker of the ovarian reserve in pre-menopausal women. In this study we aimed at evaluating AMH levels in SLE patients and at establishing possible correlations with disease variables, therapies and obstetrical history

Methods: AMH levels were assessed in pre-menopausal SLE patients with an enzymatically amplified two-site immunoassay (AMH Gen II ELISA; Beckman Coulter). According to the published literature in healthy subjects, values 1 to 8 ng/mL indicate normal, values $<$ 1ng/mL indicate reduced and $<$0.4 strongly reduced ovarian reserve. Demographic data, clinical variables, disease activity, ongoing therapies as well as cumulative glucocorticoids dosage (GC) and previous therapy with Cyclophsphamide (Cyc) at the time of AMH evaluation were collected from clinical charts. Obstetrical history and menopausal status at the end of follow up were also considered.

Results: Seventy-five SLE patients were examined (mean age and disease duration 32.9$\pm$7 and 9.4 $\pm$6 years respectively); 58 (77.3%) presented a history of renal involvement and 44 (58.6%) had received Cyc before AMH assay (mean cumulative dosage 7.31$\pm$6 g, intravenous in 33, oral in 8, both regimens in 3). The median time between the latest Cyc administration and AMH determination was 6.3 years ($\pm$5.5). At study entry, the mean GC dosage was 5.9 mg ($\pm$6.9) and the mean cumulative dosage was 14.9 ($\pm$11); 35 (46%) patients were receiving immunosuppressants. AMH values were within the normal ranges in 23 (30.6%) patients, reduced in 16 (21.3%) and strongly reduced in 36 (48%). AMH levels were inversely related to age ($p=0.0001$) and disease duration ($p=0.004$) and to previous therapy with Cyc ($p=0.03$). At the end of follow-up, 48 patients (64%) had at least one pregnancy and 4 (5%) were in menopause (2 premature ovarian failures). No relationships were observed between AMH levels and disease activity or cumulative GC. AMH levels were not correlated with the occurrence of pregnancy but were significantly associated with the number of pregnancies ($p=0.03$).

Conclusion: In our cohort, a high percentage of patients presented low or very low levels of AMH; as expected, a significant decrease with age progression have been observed and previous therapy with Cyc seem to be important contributors. The association of AMH levels and the number of subsequent pregnancies supports the significance of this testing to assess ovarian reserve in these patients.

The Brief Index of Lupus Damage, a Patient-Reported Measure of Lupus Damage, Is Sensitive to Change. Patricia P. Katz[1], Laura Trupin[2], Stephanie Rush[2] and Jinoos Yazdany[2]. [1]University of California San Francisco, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA.

Background/Purpose: Extending lupus research outside of the clinical setting remains a challenge, in part due to the complexity of measuring disease damage. Previously, we developed and validated a patient-reported measure of lupus damage (BILD) for research purposes. Here we report additional validation of the BILD, focusing on its ability to detect change.

Methods: Data were drawn from the UCSF Lupus Outcomes Study (LOS), in which participants are interviewed by phone annually. The BILD was administered in 2 waves, 5 years apart. Only participants who were interviewed in both years are included in the analysis (n=740). We calculated changes in BILD scores, and categorized increases in scores as 0, 1, 2, 3, or $>$3. (Only increases in scores are possible because, by definition, damage cannot be reversed.) We then examined changes in disease activity measured with the Systemic Lupus Activity Questionnaire (SLAQ), changes in the number of physician visits, and number of hospitalizations in the years between the two BILD administrations. These measures were chosen because the disease manifestations included in the BILD would likely give rise to increased symptoms or utilization at the time they occur. Increases in SLAQ and physician visits were defined by an increase of 0.5 standard deviation over baseline in at least one interview wave during the 5-year observation period, equivalent to an increase of 4 points on the SLAQ and 5 physician visits. For hospitalizations, we examined the occurrence of 2+ hospitalizations in at least one wave.

Results: BILD scores ranged from 0–13 with a median of 1 (IQR 0–3) in the first administration. At the second administration, scores ranged from 0–15 with a median of 2 (IQR 1–4). Changes in BILD ranged from 0–8 with a median of 1 (IQR 0–1). Of the 740 LOS participants, 369 had no increase in BILD score. Of the remaining participants, 210, 84, 41, and 36 had increases of 1, 2, 3, and $>$3 points, respectively (Table). Overall, 37% of LOS participants had an increase in SLAQ, 43% had an increase in physician visits, and 14% had 2+ hospitalizations in at least one interview wave. For SLAQ scores, the prevalence of an increase was highest among participants with changes in BILD $\geq$3. There was a greater prevalence of increased physician visits among participants with a change in BILD $>$0. Greater increases in BILD were associated with significantly greater likelihood of at least one year with 2+ hospitalizations.

Table. Increases in disease activity and physician visits and hospitalizations associated with increases in BILD scores

		Increase in BILD					
	Total (n=740)	0 (n=369)	1 (n=210)	2 (n=84)	3 (n=41)	>3 (n=36)	p*
SLAQ (at least 1 score > baseline by 0.5 SD)	37%	34%	40%	36%	39%	50%	.06
MD visits (at least 1 wave > baseline by 0.5 SD)	43%	36%	50%	44%	56%	47%	.0057
Hospitalizations (at least 1 wave with 2+)	14%	5%	19%	15%	29%	55%	<.0001

* p value from c^2 for trend

Conclusion: Change in BILD score corresponds with increases in disease activity and physician visits and with hospitalizations that are likely to reflect disease manifestations that could cause increases in disease damage. Previous cross-sectional examination of the BILD showed concurrent validity; this analysis provides evidence of the BILD's ability to detect change. While not intended to replace clinical evaluation of disease damage, the BILD does appear to be a useful tool for research.

Social Capital: A Novel Platform For Understanding Social Determinants Of Health In Systemic Lupus Erythematosus. Susan Kim[1], Carol Mancuso[2], Wei-Ti Huang[1] and Doruk Erkan[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, NY, NY.

Background/Purpose: Social capital is the degree of connectedness, and the extent and quality of social relations, networks, and interactions in a given population. The objective of this study was to assess the relationship between social capital and health-related psychosocial variables in SLE patients.

Methods: In a cross-sectional study, SLE patients completed: a) Adapted Social Capital Assessment Tool (A-SCAT), which measures cognitive and structural domains of social capital (range: 0–71) (higher scores reflect higher social capital); and b) health-related psychosocial variables including Medical Outcomes Study (MOS)-Social Support Survey (range: 0–100), Center for Epidemiologic Studies Depression Scale (CES-D) (range: 0–60), and Self Efficacy for Managing Chronic Disease 6-item Scale (range: 1–10) (higher scores reflect higher social support, depression, and self-efficacy, respectively). Pearson correlation and analysis of variance were used to evaluate for any associations and significant differences, respectively, between social capital scores and the psychosocial variables.

Results: We recruited 89 SLE patients who met ACR SLE criteria (female: 83; Caucasian: 28 (31%); African American: 32 (36%); Asian: 6 (7%); other: 23 (26%); and Hispanic: 53 (60%)). Mean age was 39 ± 15 y; mean disease duration 11.6 ± 8.2y, mean SLEDAI 3.5 ± 3.0, and mean SLICC 1.3 ± 1.8. Selected socioeconomic features were: Medicaid 47 (53%), ≥ high school degree 69 (78%), annual household income <$40,000 53 (60%), employed 25 (28%), unemployed 31 (35%), and disability 30 (34%). The mean A-SCAT score was 34 ±15; the mean CES-D score was 22 ± 13; the mean MOS-SSS was 66 ± 27; the mean self efficacy score was 5 ± 2, and 56 (63%) had a positive screen (CES-D≥ 16) for depression. Social capital was not associated with self-efficacy or affectionate and interaction social support, but was associated with informational and tangible social support. Cognitive social capital domain was negatively associated with the depression scale (Table 1). There were no significant differences in the SLEDAI and SLICC scores according to social capital, social support, and depression measures.

	Social Capital (A-SCAT)		
	Overall	Structural Domain	Cognitive Domain
MOS-Social Support Survey			
Informational Subscale	0.39‡	0.33‡	0.35‡
Tangible Subscale	0.26†	0.16	0.30‡
Affectionate Subscale	0.17	0.13	0.19
Positive Social Interaction Subscale	0.19	0.17	0.17
Overall	0.31‡	0.25†	0.31‡
CES-D	−0.20	−0.09	−0.27†
Self-Efficacy	0.17	0.16	0.13

Pearson Correlation Coefficient; †P<0.02; ‡P<0.005

Conclusion: This is the first study to use social capital as a novel platform in a lupus population defined by the commonality of a chronic illness, on which ideas of social connectedness can broaden our understanding of health disparities and chronic illness. Our results show that social capital has features that overlap with social support, specifically in the informational and tangible (provision of material aid or behavioral assistance) subscales, but is distinct from traditional health-related psychosocial measures.

Plasma Microparticles Are Associated With Venous Thrombosis In Systemic Lupus Erythematosus. Michelle Petri[1], Melissa Nastacio[1], Hong Fang[1], Thomas Kickler[1], Jayesh Jani[1] and Laurence S. Magder[2]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD.

Background/Purpose: Thrombosis in SLE is highly associated with antiphospholipid antibodies, yet the majority of those with antiphospholipid antibodies never have a thrombotic event. Plasma microparticles (PMP) have been identified as a risk factor for atherosclerosis. D-dimers are elevated in the setting of deep venous thrombosis. We investigated both as markers of thrombosis in SLE.

Methods: We measured plasma microparticles (by their capacity to generate thrombin) and D-dimer levels in 1044 SLE patients. The relationship between these biomarkers and history of, and future risk of, thrombosis was determined.

Results: The patients were 92% female, 37% African American, 54% Caucasian with mean age 48.1 ±13.1 years. Of the 1044 patients, 270 had at least one thrombotic event, including deep venous thrombosis (122), stroke (77), myocardial infarction (26), other venous (22), and other arterial thrombosis (13). Elevated levels of D-dimer were not associated with thrombosis. Thrombin generated microparticles were associated with history of a thrombotic event (Table 1). In subanalyses, we found that this association was only found with respect to venous (but not arterial) events (Table 2). There were 46 patients with a thrombotic event during prospective followup. The adjusted risk ratio for plasma microparticles (adjusted for presence of antiphospholipid antibodies) was 1,6,1.4,1.4 respectively for the 2nd 3rd and 4th quartiles.

Table 1. Life-time Rates of Thrombotic Events in SLE by Biomarker Levels

Group	# events	# of person-years at risk	Rate per 1000 person years	Risk Ratio (95% Confidence Interval)	P-value	Adjusted[1] Risk Ratio (95% Confidence Interval)	P-value

The Interferon-Alpha Signature In Patients With Serologically Active Clinically Quiescent Systemic Lupus Erythematosus. Amanda J. Steiman[1], Murray B. Urowitz[1], Dominique Ibanez[1], Carolina Landolt-Marticorena[2], Joan E. Wither[3] and Dafna D. Gladman[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON, [3]Toronto Western Research Institute, Toronto Western Hospital, University of Toronto, Toronto, ON.

Background/Purpose: Interferon-α (IFN-α) plays a prominent pro-inflammatory role in SLE. Studies suggest clinical/serologic discordance may illuminate systemic lupus erythematosus (SLE) pathophysiology, as peripheral IFN-α production is blunted in some autoantibody-producing, clinically quiescent SLE mice despite abundant IFN-α –producing plasmacytoid dendritic cells (pDCs). This goes against the current SLE paradigm which postulates that nucleic acid-containing immune complexes stimulate pDCs via Toll-like receptors to generate copious IFN-α, leading to upregulation of proinflammatory molecules and clinical disease. Thus serologically active clinically quiescent (SACQ) patients who, like these mice, exhibit persistent autoantibody production despite durable clinical quiescence, may provide unique insights. We investigated whether 5 IFN-associated genes and IFN-associated cyto/chemokines differed in SACQ patients compared to serologically and clinically active (SACA) and serologically and clinically quiescent (SQCQ) patients.

Methods: We defined SACQ and SQCQ as ≥2-year periods without clinical activity, with/without persistent serologic activity, respectively, by SLE Disease Activity Index 2000 (SLEDAI-2K), over which antimalarials were permissible but corticosteroids/immunosuppressives were not. SACA was defined as disease activity, by SLEDAI-2K, which compelled immunosuppression. Clinical and lab data were collected at each visit. Gene expression of *OAS1*, *IFT1*, *MX1*, *LY6E* and *ISG15* was measured by *q*RTPCR, and a composite IFN gene score was developed. Plasma cyto/chemokines were measured by 65-plex Luminex panel, with the 19 most relevant selected *a priori*for analysis. Non-parametric univariate and logistic regression analyses were conducted with Bonferroni correction applied.

Results: Twenty-two, 27 and 43 SACQ, SQCQ and SACA patients, respectively, were included in the analysis. There were no differences in gene expression, or in cyto/chemokine levels between SACQ and SQCQ. SACQ patients were older (43.7 ± 13.7 vs 28.7 ± 9.4, $p < 0.0001$) and had longer disease duration (18.5 ± 12.5 vs 7.4 ± 7.1 years, $p=0.0005$) at study start than did SACA patients. Anti-Ro (82% vs 46%, $p=0.007$) and anti-La (50% vs 13%, $p=0.002$), antibodies were significantly more prevalent in SACQ than in SACA patients. Anti-RNP antibodies were significantly more prevalent in SACA than in SACQ (74% vs 36%, $p=0.004$). The SACQ IFN gene score was significantly lower than that of SACA ($p=0.003$). Levels of GM-CSF, IL-6, IL-10, IP-10, MCP-1 and TNF-α were significantly lower in SACQ than SACA. Logistic regression analysis revealed that anti-La antibody positivity, and low levels of MCP-1 and *LY6E*were associated with SACQ status.

Conclusion: The SACQ interferon signature and cytokine/chemokine profile closely resemble those of patients who are in complete remission. Anti-La antibody positivity and low levels of MCP-1 and *LY6E* were associated with SACQ status in this small pilot study. The presence of this combination of factors may serve to reinforce the clinical impression of disease quiescence in SACQ patients.

2518

Only BAFF mRNA, Not BAFF Protein Level In Blood, Is Associated With SLE Activity Over One Year. Eric Zollars[1], Hong Fang[1], Jadwiga Bienkowska[2], Julie Czerkowicz[3], Ann Ranger[3], Norm Allaire[2], Alice Thai[3], Jeff Browning[4], Laurence S. Magder[5] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Biogen Idec Inc., Cambridge, MA, [3]Biogen Idec Inc, Cambridge, MA, [4]Boston University School of Medicine, Boston, MA, [5]University of Maryland, Baltimore, MD.

Background/Purpose: B-cell–activating factor (BAFF; also known as B lymphocyte stimulator or BLyS) is a prominent factor in the selection and survival of B cells. BAFF has been demonstrated to be elevated in the blood of systemic lupus erythematosus (SLE) patients and is implicated in the pathogenesis of the disease. We have shown that BAFF gene expression level (mRNA) in whole blood associates with same day disease activity and predicts future activity in SLE patients. The concentration of the BAFF protein in serum has also been used as a marker of disease activity. In this study, we investigated the utility of BAFF mRNA versus protein level as a predictor of future global disease activity in SLE patients.

Methods: 292 patients (59% Caucasian, 34% African-American, 92% female, mean age 46 ±12 years) were enrolled in a prospective observational study. At baseline, BAFF gene expression level was measured in peripheral blood RNA (PAXgene) using microarray (Affymetrix) and confirmed with quantitative PCR. Serum BAFF (protein) levels were measured using the Rules Based Medicine platform. The number of visits per patient over the following year ranged from 1–9. Six patients had 1 visit, 46 patients had 2–3 visits, 159 patients had 4 visits, and 81 patients had more than 4 visits. P-values were calculated using generalized estimating equations as implemented in SAS 9.2. P-values were then adjusted for ethnicity.

Results: Table 1 shows the association of BAFF mRNA with SLE global activity (physician global assessment, PGA; and SLEDAI) over the next year, as well as renal activity, serologies and ESR over the next year. Table 2 shows the association of BAFF protein with the same disease parameters.

Table 1. Association of baseline BAFF mRNA level with percentage of visits with disease activity over the subsequent year

Variable	Low BAFF (<10.7) N visits=387	Med BAFF (10.7–11.4) N visits=476	High BAFF (>11.4) N visits=347	Adjusted P-value for ethnicity
Physician global assessment >1	8%	21%	24%	0.0041
SLEDAI ≥2	36%	57%	71%	<0.0001
Urine Protein/Creatinine Ratio (≥0.5)	3%	13%	13%	0.0096
Anti-dsDNA ≥10	9%	21%	35%	<0.0001
C3 <79 mg/dL	4%	11%	21%	0.0004
C4 <12 mg/dL	4%	11%	19%	0.0005
ESR >20	35%	55%	63%	0.0005

Table 2. Association of baseline BAFF protein level with percentage of visits with disease activity over the subsequent year

Variable	Low (>950 pg/ml) N patients = 96 N visits = 405	Med (950–1400 pg/ml) N patients = 98 N visits = 404	High (>1400 pg/ml) N patients = 98 N visits = 401	P-value	Adjusted P-value for ethnicity
Physician global assessment >1	17%	15%	21%	0.49	0.53
SLEDAI ≥2	51%	52%	60%	0.30	0.073
Urine Protein/Creatinine Ratio (≥0.5)	9%	7%	12%	0.39	0.38
Anti-dsDNA ≥ 10	18%	14%	32%	0.0036	0.0031
C3 <79 mg/dL	7%	10%	18%	0.052	0.090
C4 <12 mg/dL	9%	7%	16%	0.090	0.14
ESR >20	45%	51%	55%	0.25	0.11

Conclusion: BAFF mRNA at the baseline visit was strongly associated with global disease activity, urine protein/creatinine ≥0.5, serologies, and ESR over the next year. In contrast, BAFF protein level in the blood at baseline only correlated with anti-dsDNA over the next year. This study supports the use of BAFF mRNA level in peripheral blood rather than protein as a predictive biomarker of disease activity in SLE patients.

A Systemic Lupus Erythematosus (SLE) Diagnostic Test Based On DNA Methylation Signatures From Peripheral Blood Mononuclear Cells. David W. Anderson, Robert Shoemaker, Kurt Krummel, Zachary Hornby and Jonathan E. Lim. IGNYTA, Inc., San Diego, CA.

Background/Purpose: The heterogeneous nature of SLE and a lack of reliable biomarkers make SLE a challenge to classify in patients. A differential diagnosis of SLE from other rheumatic and autoimmune diseases can be difficult due to lack of definitive tests with sufficient sensitivity and specificity. Genome-wide DNA methylation analysis of SLE patients' PBMCs was performed on *Illumina HumanMethyl450* BeadChips to assess whether SLE has a DNA methylation signature that outperforms current diagnostic tests.

Methods: PBMC Genomic DNA was isolated from 252 patients and evaluated with the Illumina *HumanMethylation450*chip. The 147 patient sample training set consisted of 15 SLE, 16 rheumatoid arthritis, (RA), 13 osteoarthritis (OA), 28 healthy control (HC), and 75 with undifferentiated arthritis (UA), but not SLE after one year of follow up. Differentially methylated loci (DML) were identified using a non-parametric statistical test

to rank CpG loci that were differentially methylated in SLE samples compared to non-SLE samples. An independent, blinded 105 patient PBMC sample test set: 17 SLE, 28 RA, 12 HC, 17 other rheumatic (ankylosing spondylitis, psoriatic arthritis, reactive arthritis, spondyloarthopathy), and 31 other autoimmune disease (Crohn's, Diabetes Type I, multiple sclerosis, psoriasis, ulcerative colitis) patients was used to confirm the model.

Results: Of 456,355 autosomal CpGs whose methylation frequencies were assessed, the top 25 DML were identified. These 25 DML were associated with 18 genes (10 kb upstream to 10 kb downstream of gene). 10 of these genes had previously been found to be differentially methylated or differentially expressed in published SLE studies. DML selection and model training were repeated on 258 CpGs associated with these 10 genes; a panel of the top 25-DML from the resultant list was selected. This 10 gene-based 25 DML panel was used to train a support vector machine model (radial basis function kernel, cost = 1). The model cut off for SLE/non-SLE classification was determined using leave one out cross validation on the training set. In a prospective study, our 25-DML SLE diagnostic model correctly classified 14 of 17 independent SLE samples (82% sensitivity) and 86 of 88 non-SLE samples (98% specificity), achieving overall accuracy of 95%. Disease severity and medication information did not explain the misclassification of 3 SLE samples. The 18 genes associated with the initial 25 DML were enriched in Ingenuity's pathways for 1) Interferon Signaling and 2) Activation of interferon regulatory factors by Cytosolic Pattern Recognition Receptors (Benjamini-Hochberg p-value < 0.01 for each). The Interferon Signaling pathway was also enriched in SLE patients for the selected 25 DML panel validated on the 105 prospective samples.

Conclusion: This study confirms that SLE can be distinguished with high accuracy from other rheumatic diseases using DNA methylation biomarkers from PBMCs. Expanded studies are warranted to improve the diagnosis of SLE based on DNA methylation signatures. Furthermore, these biomarkers could identify the underlying molecular pathways associated with SLE. This understanding might be used to select therapies for patients or to identify novel therapeutic targets.

A Freely Accessible Toolbox For Patient-Reported Outcomes: Development and Systematic Literature Review For Lupus Instruments. Isabel Castrejón[1], Loreto Carmona[2], Robin Christensen[3], Till Uhlig[4], Birgit Prodinger[5], Francis Guillemin[6], Marieke Scholte-Voshaar[7] and Laure Gossec[8]. [1]NYU Hospital for Joint Diseases and New York University School of Medicine, New York, NY, [2]Institute for Musculoskeletal Health, Madrid, Spain, [3]Musculoskeletal Statistics Unit, The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, [4]Diakonhjemmet Hospital, Oslo, Norway, [5]Swiss Paraplegic Group, Nottwil, Switzerland, Notwill, Switzerland, [6]CHU Nancy, Clinical Epidemiology and Evaluation, Université de Lorraine, Paris Descartes University, APEMAC, EA 4360, Nancy, France, [7]EULAR Standing Committee of People with Arthritis/Rheumatism in Europe, Zurich, Switzerland, [8]Pitié-Salpêtrière Hospital, Pierre et Marie Curie University, Paris, France.

Background/Purpose: Patient self-report has become prominent in the assessment of rheumatic and musculoskeletal diseases (RMD). In a workshop on priorities in PROs in 2009 it was proposed to generate a catalogue with the available instruments. The main objective of this project was to develop a structured design for this catalogue freely available online which would include a comprehensive database of validated instruments.

Methods: The first work package was aimed to develop the toolbox with the participation of 15 methodological collaborators to decide the toolbox′s aims and scope, and basic requirements. In a second work package, the aim was to feed the toolbox using systematic reviews of the literature by target disease with a common strategy to identify validation of PRO. The systematic literature review for systematic lupus erythematous (SLE) is described here as a methodological example. A search strategy was run in MEDLINE, EMBASE, and the Cochrane Library. Validation studies, cohort studies, reviews and meta-analyses were included. Selection criteria were: a) studies on adult patients with SLE defined by the ACR criteria, and b) validation studies of PRO. A reviewer screened title/abstracts and the relevant information was collected using a standardized data collection form based on the COSMIN checklist. The third work package was to provide educational support.

Results: Two hundred thirty six instruments have been identified of which 106 are generic and the remaining ones RMD specific. In particular for SLE, from 704 initial studies captured, we identified 18 articles meeting the predefined criteria. Studies addressed validation of 10 PRO, 1 to evaluate disease activity, 1 to evaluate lupus symptoms, 3 to evaluate quality of life, 2 to evaluate damage and 3 to evaluate patient's needs, health and family functioning. Internal consistency was studied in all, with Cronbach's α ranging from 0.71 to 0.96. Validity, examined by means of convergence with other instruments, was generally similar between tools. Responsiveness was tested in SLAQ, SLEQoL, with a standardized response mean (SRM) ranging from 0.12 to 0.44. Interpretability was only tested in SLE QoL, Lupus QoL and Lupus PRO with similar floor/ceiling effect (Table). Information about construct being measured, recommendations for use, translated versions and validation have been uploaded in the catalogue website. A list and definition for each validation aspect was included for educational support

Table. Summary of the results of the validity of the 10 SLE patient report outcomes

SLE PROs	Domain	# Items & Range	Measurement Properties				
			Reliability	Cronbach	Validity	Responsiveness	Interpretability
SLAQ (Systemic Lupus Activity Questionnaire)	Disease Activity	Items: 3 Range: 0–44		$\alpha = 0.87$	+++	**SRM:** 0.12	—
SSC (SLE Symptom Checklist questionnaire)	Lupus Symptoms	Items: 38 Range: 0–152		$\alpha = 0.89$	+++	++	—
SLEQOL (SLE-specific quality-of-life instrument)	Quality of Life	Items: 49 Range: 40–280		$\alpha = 0.95$	+++	**SRM:** 0.44 **Effect Size:** 0.33	**Floor:**14.9% **Ceiling:**<2.6%
LupusQoL (Lupus quality of life)	Quality of Life	Items: 34 Range: 0–100		$\alpha = 0.88$–0.96	+++	—	**Floor:**<10.8% **Ceiling:** 4–21%
SLENQ (SLE needs questionnaire)	Needs	Items: 97 Range: –		$\alpha = 0.77$	+++	—	—
LDIQ (Lupus Damage Index Questionnaire)	Damage	Items: 56 Range: 0–22		$\alpha = 0.72$	+++	—	+
L-QoL (Lupus quality of life)	Quality of Life	Items: 25 Range: 0–22		$\alpha = 0.92$	+++	—	—
BILD (Brief Index of Lupus Damage)	Damage	Items: 28 Range: 0–33		—	+++	—	—
LupusPRO (Lupus Patient-Reported Outcome)	Health outcome	Items: 44 Range: 0–100		$\alpha = 0.72$–0.94	+++	++	**Floor:**22.3% **Ceiling:**1.2%
SLE-FAMILY	Family functioning	Items: 6 Range: 1–7		$\alpha = 0.71$	+++	—	—

SRM: Standardized Response Mean

Conclusion: A freely accessible toolbox for PROs has been designed. This toolbox employs scientific measurement properties and provides PROs with advice on their application in a user-friendly manner. This toolbox is an on-going process led by rheumatologists, related professionals, and patients that should help to better understand and use PRO in RMD.

2521

Correlation Of Anti Single and Double Stranded DNA Antibodies and Disease Activity In Systemic Lupus Erythematosus. Cecilia Catoggio, Cecilia Reimundes and Carlos Edgardo Perandones. CEMIC, Buenos Aires, Argentina.

Background/Purpose: Anti DNA antibodies are considered a hallmark of systemic lupus erythematosus (SLE). Anti double stranded DNA antibody (dsDNA) is part of the SLE classification and activity criteria due to its high specificity. However its sensitivity is moderate. On the other hand, the role of single stranded DNA antibodies (ssDNA) has not been fully addressed. The objective of this study is to correlate the presence of anti ssDNA and dsDNA antibodies with SLE activity, measured by ECLAM (*European Consensus Lupus Activity Measurement).*

Methods: We reviewed the charts of our SLE patients who had both anti ssDNA and dsDNA antibodies measured simultaneously between 2001 and 2011. Anti dsDNA was determined by *Crithidia luciliae* immunofluorescence assay and anti ssDNA was determined by a home-made ELISA. In each serologic determination, disease activity was established by ECLAM according to chart information from the previous 30 days. Finally, determinations were classified in 4 serologic groups for analysis: Group 1 (negative ssDNA and dsDNA), Group 2 (positive ssDNA and negative dsDNA), Group 3 (positive ssDNA and dsDNA) and Group 4 (negative ssDNA and positive dsDNA).

Results: Ninety patients were evaluated (80 female), with a median age (range) of 39 (23–77) years. There were 328 simultaneous serologic determinations of anti ssDNA and dsDNA. According to the ECLAM, activity was

found in 269 (82%) determinations and inactivity was found in 59 (18%) determinations.

Considering the ECLAM as the gold standard for activity, we calculated sensitivity, specificity, positive and negative predictive value (PPV, NPV) and positive likelihood ratio (+LHR) for anti ssDNA and dsDNA, using dicotomic variables.

	Sensitivity % (95% CI)	Specificity % (95% CI)	PPV % (95% CI)	NPV % (95% CI)	+ LHR
Anti ssDNA	78 (73–82)	44 (39–49)	86 (83–90)	30 (25–35)	1.39
Anti dsDNA	28 (23–32)	92 (88–94)	94 (91–96)	22 (17–26)	3.29

When the serologic determinations were classified in groups, we calculated sensitivity, specificity, PPV, NPV and +LHR for anti ssDNA and dsDNA.

Serologic Groups	Sensitivity % (95% CI)	Specificity % (95% CI)	PPV % (95% CI)	NPV % (95% CI)	+ LHR
Group 1 (n: 83)	21 (17–27)	56 (42–69)	69 (57–78)	14 (10–18)	0.47
Group 2 (n: 165)	52 (45–58)	53 (39–65)	83 (76–88)	19 (14–26)	1.11
Group 3 (n: 77)	27 (22–33)	92 (80–97)	94 (85–98)	22 (17–28)	3.38
Group 4 (n: 3)	—	—	—	—	—

Finally, the seropositive determinations were correlated with the following variables:

	Group 2			Group 3		
Variables	RR	95 % IC	*p*	RR	95 % IC	*p*
<50 years	2.65	1.47–4.77	***0.001***	19.18	6.9–53.21	***0.0001***
Joints	1.31	0.46–3.74	0.607	3.79	1.17–12.27	***0.026***
Skin	0.93	0.27–3.12	0.902	1.79	0.49–6.45	0.370
Renal	4.17	1.11–15.73	***0.035***	6.35	1.62–24.95	***0.008***
Hematologic	0.74	0.41–1.34	0.323	1.03	0.48–2.22	0.939
Erythrosedimentation rate	1.43	0.72–2.85	0.304	1.66	0.71–3.87	0.238
Hypocomplementemia	4.13	2.05–8.31	***0.0001***	6.31	2.83–14.06	***0.0001***

RR: relative risk

Conclusion: Anti ssDNA antibody shows a higher sensitivity and lower specificity than anti dsDNA antibody for SLE activity. The presence of anti ssDNA with or without anti dsDNA, was associated with younger age, hypocomplementemia and renal involvement.

Disclosure: C. Catoggio, None; **C. Reimundes**, None; **C. E. Perandones**, None.

Novel Autoantibody Against CAF-1 Is a Biomarker For CNS Manifestation in patients With SLE. Kentaro Doe, Kazuhisa Nozawa, Kaori Hiruma, Yusuke Yamada, Yuko Matsuki, Soichiro Nakano, Michihiro Ogasawara and Yoshinari Takasaki. Juntendo University School of Medicine, Tokyo, Japan.

Background/Purpose: Proliferating cell nuclear antigen (PCNA) is known to be an autoantigen specifically recognized by antibodies in sera from patients with systemic lupus erythematosus (SLE). Although a prevalence of anti-PCNA antibody among the patients with SLE is relatively rare (less than 5%), we have demonstrated that patients with SLE often elicit autoimmune response against multiple proteins consisting of PCNA complex even though immune response against PCNA itself is absent. Therefore, the autoimmune response to the consisting proteins of PCNA complex is a unique mechanism of autoantibody production specifically recognized in SLE. Chromatine assembly factor-1(CAF-1) is an essential molecule for DNA replication belonging to the constitutive proteins of PCNA complex. Therefore, we conducted this study to confirm whether the autoimmune response to CAF-1 occurred in patients with SLE.

Methods: Immunoreactivity against CAF-1 among sera with SLE, normal healthy controls (NHCs), and other disease controls (PM/DM, SSc, SjS, MCTD, and RA) was evaluated by ELISA and immunoblotting. The gene expression of CAF-1, interferon regulating factor-1 (IRF-1), and pro-apoptotic molecules (Fas, BID, and TNFRS10B) were measured by quantitative RT-PCR in peripheral mononuclear cells (PBMCs) of SLE patient in comparison with those of NHCs. Serum level of interferon gamma inducing protein-10 (IP-10) was measured by ELISA.

Results: Increased autoimmune response to CAF-1 was significantly observed in SLE compared to the disease controls and NHCs. CNS involvement and disease onset of younger age were significantly recognized in the anti-CAF-1 antibody positive lupus patients in comparison with those of anti-CAF-1 antibody negative lupus patients. In addition, increased gene expression of CAF-1 and proapoptotic molecules on PBMCs was observed in SLE compared to those of NHCs. Moreover, increased gene expression of IRF-1 in PBMCs along with serum level of IP-10 was significantly observed in SLE.

Conclusion: In the present study, we identified anti-CAF-1 antibody as a novel autoantibody specifically recognized in patients with SLE. Measurement of anti-CAF-1 antibody is useful for the diagnosis of SLE and could be a new biomarker for CNS lupus. Moreover, our results indicated that increased apoptosis and aberrant regulation of IFN-g in peripheral mononuclear cells (PBMCs) played an important role for a mechanism for anti-CAF-1 antibody production in SLE.

Inflammatory Arthritis Activity During Pregnancy In Systemic Lupus Erythematosus. Sara K. Tedeschi, Bonnie L. Bermas and Karen H. Costenbader. Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background/Purpose: While overall SLE disease and lupus nephritis activity during pregnancy have been studied, the activity of inflammatory arthritis during SLE pregnancy has not been examined. Our goals were to evaluate the activity of inflammatory arthritis during pregnancy in SLE and its effects on pregnancy outcomes.

Methods: From our Registry of all patients seen in our Lupus Center with confirmed SLE by rheumatologist review for 1997 ACR Criteria for Classification, we identified women with >2 visits to our Center and ≥1 pregnancy between 1990–2013. From Registry and medical records, we collected data on: ages at SLE diagnosis and at pregnancy, history of inflammatory arthritis preceding and during pregnancy, SLE medications during pregnancy, and pregnancy outcomes. We analyzed the data using descriptive statistics and Fisher's exact tests.

Results: Of 1,127 women with SLE, 56% had a history of inflammatory arthritis and 134 had ≥1 pregnancy (184 pregnancies). Among women with pregnancies, mean age at SLE diagnosis was 23.1 (SD 6.8) years; 61% were White, 14% Hispanic and 13% Black. Mean age at conception was 30.8 (SD 5.3) years; average SLE duration prior to pregnancy was 7.1 (SD 5.8) years; 9% were diagnosed with SLE during pregnancy; 33% were primigravida. Of the women without a history of inflammatory arthritis (n=80), none experienced arthritis during pregnancy. Of the 104 pregnancies in women with a history of inflammatory arthritis, 16 had active arthritis in the 6 months prior to conception (**Table**). Five of these women received an immunosuppressant 6 months prior to conception and 13 had medication changes during pregnancy. In 4 of 16 pregnancies with active arthritis prior to pregnancy, arthritis flared during pregnancy (25%), whereas arthritis flared in 6 of 88 pregnancies with no active inflammatory arthritis within 6 months of pregnancy (7%, p 0.045). Overall, 83% of arthritis flares occurred in the 2nd trimester.

Of the 16 pregnancies in which the mother had recently active inflammatory arthritis, 62% were term deliveries, 19% were pre-term, and 19% 1st trimester abortions. Of the pregnancies with quiescent inflammatory arthritis 6 months prior to pregnancy, delivery outcomes were: 68% term, 17% preterm (p 0.73 vs. in those with arthritis), 10% 1st trimester abortions, and 5% 2nd or 3rd trimester fetal loss (p 0.71 vs. in those with arthritis).

Table. Arthritis Activity in 104 Pregnancies among Women with a History of SLE Arthritis, 1990–2013

				Medications 6 months prior to Pregnancy			
	Number of pregnancies	Age at pregnancy, mean (SD)	Arthritis during pregnancy, N (%)	Prednisone, N (%)	Immuno-suppressants*, N (%)	Hydroxy-chloroquine, N (%)	NSAID, N (%)
Arthritis active 6 months prior to pregnancy	16	29.8 (5.4)	4 (25)	8 (50)	5 (31)	10 (63)	7 (43)
History of arthritis, not active 6 months prior to pregnancy	88	30.9 (4.9)	6 (7)	31 (35)	11 (13)	44 (50)	12 (14)

* Immunosuppressants: azathioprine, mycophenylate mofetil, sulfasalazine, and rituximab. Not mutually exclusive categories.

Conclusion: Inflammatory arthritis activity during pregnancy was uncommon in this female SLE population. Among women with inflammatory arthritis symptoms 6 months prior to conception, a higher proportion had persistent or worsened symptoms during pregnancy than among women whose inflammatory arthritis was inactive 6 months prior to conception. Pregnancy outcomes were similar among those with and without active inflammatory arthritis prior to pregnancy.

Application of The 2012 Systemic Lupus International Collaborating Clinics Classification Criteria On a Regional Swedish Systemic Lupus Erythematosus Register. Anna Ighe[1], Örjan Dahlström[2], Thomas Skogh[1] and Christopher Sjöwall[1]. [1]Linköping University, Linköping, Sweden, [2]Linneaus Centre HEAD, Swedish Institute for Disability Research, Linköping, Sweden.

Background/Purpose: In addition to the 1982 American College of Rheumatology criteria (ACR-82) for scientific classification of systemic lupus erythematosus (SLE), many clinicians find the 'Fries criteria' (requiring an abnormal ANA titer *plus* at least two typical organ manifestations) helpful for diagnostic purposes. Last year, the Systemic Lupus International Collaborating Clinics group proposed a new set of validated classification criteria (SLICC-12), claimed to being more sensitive for SLE. The aim of the present study was to analyze the performance of SLICC-12 compared to Fries criteria and ACR-82 among well-characterized SLE cases and controls in a regional Swedish register.

Methods: The study population consisted of 231 SLE cases (93% Caucasians; 203 women, 28 men; mean age at diagnosis 38.8 years, range 3–85) confirmed by Fries criteria and/or ACR-82. 53 controls (46 women, 7 men; mean age 40.8 years; range 12–83 years) were enrolled on the basis of referral to a rheumatology specialist based on at least one criterion regarding 'immunologic disorder' according to ACR-82 and a clinical suspicion of SLE. Sensitivity and specificity figures for SLE were calculated. All confirmed SLE cases took part in a prospective follow-up programme at the Rheumatology clinic, Linköping University hospital. Informed consent was obtained from all subjects and the research protocol was approved by the Regional Ethics Committee in Linköping (M75-08). The controls were eventually diagnosed with the following conditions: SLE, rheumatoid arthritis, palindromic rheumatism, undifferentiated arthritis, pleuritis, undifferentiated connective tissue disease, primary antiphospholipid syndrome, scleroderma, polymyositis, fibromyalgia, primary Sjögren's syndrome, psoriatic arthritis, PAPA syndrome, renal infarction, mixed connective tissue disease, Muckle-Wells syndrome, arthralgia, multiple sclerosis and overlap syndrome.

Results: Of the confirmed SLE cases, 98% fulfilled Fries criteria, 81% ACR-82 and 91% SLICC-12. The combinations of Fries and/or SLICC-12 identified 99%, compared to 93% of all confirmed SLE cases identified by ACR-82 and/or SLICC-12. The sensitivity was high for Fries (97%) and SLICC-12 (91%), but lower for ACR-82 (79%), whereas the specificity was superior for ACR-82 (98%) compared to Fries (83%) and SLICC-12 (75%).

Conclusion: We confirm that the ACR-82 criteria set offers a very high diagnostic specificity, but fail to reveal >20% of the SLE cases as defined here. The SLICC-12 criteria provide important additional sensitivity, whereas the specificity was mediocre in this comparison. To increase sensitivity and specificity figures, we advice a combination of the ACR-82 and SLICC-12 criteria for future SLE studies.

An Assay Panel Combining Cell Bound Complement Activation Products With Autoantibodies To Extractable Nuclear Antigens and Mutated Citrullinated Vimentin Helps With The Differential Diagnosis Of Systemic Lupus Erythematosus. Chaim Putterman[1], Richard Furie[2], R. Ramsey-Goldman[3], Anca Askanase[4], Jill P. Buyon[4], Kenneth C. Kalunian[5], W. Winn Chatham[6], Elena M. Massarotti[7], Emily C. Somers[8], Irene Blanco[1], Puja Chitkara[9], Nicole Jordan[1], Kyriakos A. Kirou[10], Arthur Weinstein[11], Susan Manzi[12], Joseph M. Ahearn[12], Claudia Ibarra[13], Derren Barken[13] and Thierry Dervieux[13]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]North Shore-LIJ Health System, Lake Success, NY, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, [4]NYU School of Medicine, New York, NY, [5]UCSD School of Medicine, La Jolla, CA, [6]University of Alabama at Birmingham, Birmingham, AL, [7]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [8]University of Michigan, Ann Arbor, MI, [9]SDAMC, San Diego, CA, [10]Hospital for Special Surgery, New York, NY, [11]Washington Hospital Center, Washington, DC, [12]West Penn Allegheny Health System, Pittsburgh, PA, [13]Exagen Diagnostics, Vista, CA.

Background/Purpose: We previously established the value of cell-bound complement activation products (CBCAPS) in the diagnosis of systemic lupus erythematosus (SLE) (CAPITAL study). The purpose of this study was to enhance the performance of this diagnostic method for SLE patients compared with non-SLE rheumatic disease patients. For this, we combined CBCAPs together with autoantibodies to extractable nuclear antigens (ENA: anti-Smith [Sm], SS-B, Centromere, Scl-70, Jo-1), and mutated citrullinated vimentin (MCV).

Methods: The study population consisted of 678 subjects (291 SLE, 272 other diseases and 115 healthy) enrolled in CAPITAL (n=503) and follow-up studies (n=175). All SLE patients met the 1982 ACR SLE classification criteria and presented with active and non-active disease. The group of non-SLE patients consisted of subjects with rheumatoid arthritis, systemic sclerosis, primary Sjogren's, polymyositis/dermatomyositis and various other rheumatic diseases. ANA, autoantibodies to ENA and MCV were measured using solid phase immunoassays. C4d fragment deposited on erythrocytes (EC4d) and B-lymphocytes (BC4d) were determined using flow cytometry. The analysis involved two consecutive "tiers" of analyses. In tier 1 the diagnosis of SLE relied on anti-dsDNA positivity (base model) with the addition of positivity for anti-Sm and elevated CB-CAPS (EC4d>35 units or BC4d>200 units). Tier 2 was determined among subjects negative in tier1 and consisted of a weighted index score of ANA positivity (base model), with the addition of EC4d/BC4d levels and positivity for antibodies to ENA/MCV. Positivity for the index score (>0) was indicative of SLE, and the two-tier combination resulted in the overall performance characteristics. Statistical analyses utilized area under receiver operating characteristic (ROC) curves (SLE vs. non-SLE patients), and calculations of diagnostic sensitivity and specificity.

Results: Positivity for ANA was sensitive for SLE (89%); specificity for non SLE subjects was low (54%). Conversely, anti-dsDNA and anti-Sm were less sensitive (32% and 11%, respectively) but highly specific (96% and 100%, respectively). EC4d and BC4d levels were 2.6 and 3.2-fold higher in SLE than in non SLE subjects ($p<0.01$). The model combining anti-dsDNA with ANA positivity (base model) yielded poor performances (AUC=0.689) (Table). However, the stepwise addition of antibodies to ENA/MCV and CBCAPs in two-tier analysis improved the overall specificity (AUC=0.887; $p<0.01$ vs. base model; $p<0.01$ vs. base model with ENA/MCV). The overall performance of the best model consisted of 80% sensitivity for SLE, and 85% specificity in distinguishing SLE from other rheumatic diseases. Specificity against healthy individuals was 97%.

	Base Model	Base Model with ENA/MCV	Base Model with ENA/MCV, CBCAPS	Difference From base model
Tier1	dsDNA/ANA	dsDNA; Sm	dsDNA; Sm; CBCAPS	
Tier2	ANA	ANA; ENA/MCV	ANA; ENA/MCV; CBCAPS	
Specificity primary Sjogren's (n = 31)	12.9%	61.3%	67.7%	+54.8%
Specificity systemic sclerosis (n = 34)	35.3%	73.5%	88.2%	+52.9%
Specificity PM/DM (n = 27)	25.9%	40.7%	70.4%	+44.5%
Specificity rheumatoid arthritis (n = 162)	68.5%	87.0%	91.4%	+22.9%
Specificity Other diseases (n = 18)	66.7%	66.7%	72.2%	+5.5%
Total Specificity (non-SLE) (n = 272)	53.7%	76.5%	84.9%	+31.2%
Total Sensitivity (SLE) (n = 291)	88.7%	82.8%	80.1%	-8.6%
AUC (n = 593)	0.689	0.806	0.887	+0.198

Conclusion: An assay panel combining CBCAPS with ANA, anti-dsDNA, and autoantibodies to ENA and MCV is sensitive and specific for SLE.

An Autoantibody Profile for The Diagnosis Of Systemic Lupus Erythematosus Using the IMMUNARRAY iCHIP™. Chaim Putterman[1], Irene Blanco[1], Nicole Jordan[1], Yves Renaudineau[2], Vered Daniel Carmi[3], Rachel Sorek[3], Ornit Cohen-Gindi[3], Miriam Lerner[3], D. Scott Batty[3], Idan Tamir[3] and Irun R Cohen[4]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]Brest Occidentale University, Brest, France, [3]ImmunArray, Rehovot, Israel, [4]Weizmann Institute of Science, Rehovot, Israel.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, recurrent, and potentially fatal multisystem inflammatory disorder mainly affecting women. SLE patients produce antibodies to many different self-antigens, some of which play an important role in the pathogenesis of tissue injury in this disease. Accurate and timely diagnosis of SLE is important because early treatment can reduce morbidity and mortality, particularly from lupus nephritis. Nevertheless, currently used serological markers for SLE are lacking in specificity and/or sensitivity. The aim of this study was to develop

an improved diagnostic test by measuring and multiplexing specific autoantibody reactivities in SLE patients.

Methods: Autoantibody reactivity profiles in serum samples collected from 97 SLE patients within three years of the diagnosis were compared with those of 56 healthy controls. In addition, autoantibody profiles of SLE patients was compared with those of patients with progressive systemic sclerosis, primary Sjogren's syndrome, and primary anti-phospholipid antibody syndrome (APS). Autoantibody profiles were determined using the ImmunArray iCHIP™ - a proprietary protein microarray technology that allows the display of antigens representing a wide range of SLE-associated biochemical pathways on a single chip.

Results: Using this novel platform, SLE patients could be differentiated from healthy subjects and from patients with systemic sclerosis, Sjogren and APS by a relatively small subset of auto-antigens and Epstein Barr Virus (EBV) antigens. The autoantibody reactivity profile that allowed SLE diagnosis with high sensitivity and specificity displayed differential response to known SLE-specific antigens, such as single-stranded DNA and EBV, and to several novel ones. Validation of the autoantibody profile that differentiates SLE patients from healthy controls in additional patient samples showed good performance (75% sensitivity and 85% specificity).

Conclusion: We successfully developed a novel method of antibody profiling for SLE diagnosis, using a single multiplexed chip. The ImmunArray iCHIP™ was able to distinguish between lupus patients and healthy controls, as well as between lupus and other inflammatory rheumatic diseases.

2527

Association Of Nail Dystrophy With Capillaroscopic Abnormalities, Anti-Endothelial Cell Antibody, Endothelin-1, Activity and Chronicity In Systemic Lupus Erythematosus. Violeta Higuera[1], Luis M. Amezcua-Guerra[2], Felipe Massó[2], Mariana Patlan[1], Hugo Montoya[1], Araceli Paez[1] and Luis H. Silveira[3]. [1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico city, Mexico, [2]Instituto Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico, [3]Instituto Nacional Cardiología Ignacio Chávez, Mexico City, Mexico.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease of unknown etiology, characterized by a broad spectrum of clinical manifestations. There is a large variety of nail abnormalities described in SLE; these abnormalities were detected with a frequency of 25–31% in different series of patients with SLE. Although nail changes have been rarely considered a specific sign of the disease, they have been associated with an increased disease activity, higher incidence of Raynaud's phenomenon and oral ulcerations. It has been postulated that vascular damage plays a crucial role in the pathogenesis of SLE, so many studies have focused on the role of angiogenesis activity markers and endothelial damage. We suggest that the nail dystrophy (ND) could be a reflection of the damage to the microvasculature in patients with SLE.

Objectives: To evaluate the possible association between nail dystrophy (ND) and disease activity, damage index, capillaroscopic abnormalities, autoantibody profile, and endothelial cell activation markers in systemic lupus erythematosus (SLE).

Methods: Analytical and transversal study of SLE patients from a Rheumatology Clinic in a tertiary care hospital. The patients have been divided in two groups, one with, and the other without ND (control group). Clinical, demographic, activity, chronicity, serologic, nailfold capillaroscopy (NFC) characteristics, serum levels of anti-endothelial cell antibodies (AECA), and plasma levels of endothelin-1 (ET-1), were compared between groups. Activity was determined by the SLEDAI-2K and damage by the SLICC/ACR Damage Index. The AECA and ET-1 were determined by an enzyme-linked immunosorbent assay (ELISA).

The probability of differences in the variables frequency distributions was determined by χ^2 test, and the significance of the differences between the means was determined using Mann-Whitney test. *P*-values less than 0.05 were considered statistically significant. The unpaired t-test was used to assess differences between SLE subgroups.

Results: Sixty one patients were included; 50 (82%) were female. Thirty two (52.5%) patients showed ND and 29 did not (control group). The sex, mean age and disease duration were similar in both groups. A significant association of ND with an increased damage index was found ($p=0.04$). Cyclophosphamide was more used in the ND group ($p=0.03$). Onycholysis was the most frequently nail change, it was reported in 40% of the patients. NFC changes were detected in 43% of the ND patients and in 13% of the controls ($p=0.02$). The most frequent NFC finding in the ND group was elongated capillaries (40%). There was not an association of autoantibody profile, ET-1, and AECA with ND.

Conclusion: ND is associated with a greater index of chronicity and with capillaroscopic abnormalities. This might suggest that ND is caused by microvascular damage.

Pregnancy Outcome In 69 Pregnancies Of Multinational Population In Qatar With Systemic Lupus Erythematosus. Abdul Razzakh Poil[1], Mohammed Hammoudeh[1], Prem Chandra[2], Abdo Lutf[1] and Samar AL Emadi[3]. [1]Hamad General Hospital, Doha, Qatar, [2]Hamad Medical Corporation, Doha, Qatar, [3]ASSISTANT proffesor of clinical medicine weill cornell medical school Qatar, Doha, Qatar.

Background/Purpose: The aim of this study is to determine the frequencies of abnormal pregnancy outcomes in a cohort of patients in Qatar and to identify clinical and laboratory factors predicting adverse fetal and maternal outcomes with systemic lupus erythematosus (SLE) in multinational population in Qatar.

Methods: Data of 69 pregnancies of 36 SLE patients from January 2005 to July 2012 in Hamad General Hospital in Qatar were analyzed retrospectively. Associations between qualitative variables were assessed using Chi-square or Fisher exact tests. Quantitative variables means between the two groups were analyzed using unpaired t test. Lupus activity was assessed based on SLE Disease Activity Index (SLEDAI) criteria.

Results: Among 69 pregnancies (36 patients) 35 (50.7%) in Qatari and 34 (49.3%) were in non-Qatari national. Average numbers of pregnancies prior to and after onset of SLE were 3.73 ± 1.8 and 2.72 ± 1.5. Age at conception (years) and gestational age at delivery (weeks) were 34.5 ± 5.4 and 37.4 ± 2.8 respectively. Antiphospholipid (aPLs), Anti-Ro and Anti-La antibodies were present in 18 (26.1%), 23 (33.3%), 13 (18.8%) pregnancies respectively. There were 10 (14.5%) abortions, 5 (5.7%) stillbirths, 1 neonatal death and 54 (78.3%) live births including two twin gestations. Though, not statistically significant, baby weight at birth was found to be low (2.68 ± 0.64 vs. 2.87 ± 0.60, $p=0.360$) in active lupus patients compared to patients on remission. Pregnancy induced hypertension (PIH) (17.4% vs. 11.1%), intrauterine growth retardation (IUGR) (36.4% vs. 11.8%), preterm delivery (31.6 % vs. 11.8%), still birth (13% vs. 5.6%) and eclampsia (13% vs. 0%)were observed to be higher in active lupus patients compared to patients on remission. Compared with pregnancies without lupus nephritis ($n=44$), pregnancies with lupus nephritis ($n=7$) were associated with a higher risk of still birth (28.6% vs. 4.5%, $p=0.092$), higher rate of eclampsia (28.6% vs. 4.9%, $p=0.103$), IUGR (42.9% vs. 26.2%, $p=0.626$), and PIH (28.6% vs. 9.8%, $p=0.412$). The percentage of live births were higher in pregnancies without lupus nephritis compared to with lupus nephritis (42/44, 95.5% vs. 5/7, 71.4%, $p=0.092$), and live births were significantly higher in pregnancies without eclampsia compared to pregnancies with eclampsia (42/42, 100% vs. 2/7, 28.6%, $p<0.001$). Stillbirth and preterm delivery were found to be higher in pregnancies with proteinuria and presence of Anti-Ro antibody was significantly associated with IUGR (8/18, 44.4% vs. 6/37, 16.2%, $p=0.034$). One case of neonatal heart block was found in which Anti Ro/La antibody was positive. Low level of C3 was associated with higher rate of stillbirth, IUGR, preterm delivery, and PIH, however, the difference were not statistically significant ($p>0.05$).

Conclusion: SLE in pregnancies in Qatar population were associated with higher risk adverse pregnancy outcomes. Disease activity during pregnancy, proteinuria, lupus nephritis and eclampsia/preeclampsia were all negatively associated with pregnancy outcome such as IUGR, still births and preterm delivery. Anti-Ro/La antibodies and low level of C3 were also associated with adverse pregnancy outcomes.

Improved Outcomes In High Risk Lupus Pregnancies: Usefulness Of a Protocol Based Multidisciplinary Approach In Kerala, India. Vinod Ravindran[1], S Bhadran[2], P Shyjus[3], M Divakaran[4] and V Reshma[5]. [1]MES Medical College, Kerala, INDIA, Perinthalmanna, India, [2]Department of Obstetrics, National Hospital, Calicut, India, [3]Department of Obstetrics, MES Medical College, Perinthalmanna, India, [4]Department of Obstetrics, PVS Hospital, Calicut, India, [5]Department of Obstetrics, Indira Gandhi Hospital, Thalassery, India.

Background/Purpose: In patients with SLE who had previous adverse obstetric outcome(s) the risk of an adverse outcome in subsequent pregnancy rises. The primary objective of this study was to assess the impact of a protocol based multidisciplinary care on pregnancy outcome(s) in a prospective cohort of patients with SLE who had previous adverse obstetric outcome(s).

Methods: Between March 2010 and March 2013 all patients with SLE fulfilling the ACR classification criteria with previous at least one adverse obstetric outcome (maternal; preterm labour, pre ecalampsia or previous medical termination of pregnancy (MTP) in view of SLE flare, foetal; miscarriage, IUGR, preterm birth, low birth weight (LBW), intrauterine death or still birth) desirous of having more children were prospectively enrolled. All patients had in-depth preconception counselling and were prospectively followed throughout the pregnancy as per the protocol with multidisciplinary team input. Therapeutic changes were made as necessary at each visit.

Results: Twenty-one patients (age mean±SD years; 28±3) were enrolled. Previous poor obstetric outcomes were: miscarriage(s) in 8, MTP in 7, preterm labour with IUGR in 3, intrauterine death, still birth and pre ecalapmsia in 1 each. Five patients had secondary APS and 8 had both or either Ro/La positive. Three had lupus nephritis (LN); >6months ago in 2. There were 15 (75%) live births (3 LBW; instrumentation or caesarean section in 5). Three patients had miscarriages (one had ongoing LN). One decided against becoming pregnant after the initial counselling. Seven patients (35%) had lupus flare (4 mild, 2 moderate and 1 severe based on SLEDAI).

Conclusion: Majority of patients in our prospective cohort had acceptable pregnancy outcome. This highlights that for high risk lupus pregnancies a multidisciplinary input with protocol based care offers a superior chance of improved pregnancy outcome.

Sustained Improvements In Health-Related Quality Of Life In Patients With Systemic Lupus Erythematosus following Epratuzumab Treament: Results from a Phase IIb Trial and Its Open-Label Extension. Vibeke Strand[1], Joan T. Merrill[2], Enkeleida Nikai[3], Brian Kilgallen[4], Antoine Regnault[5] and Caroline Gordon[6]. [1]Stanford University, Palo Alto, CA, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]UCB Pharma, Brussels, Belgium, [4]UCB Pharma, Raleigh, NC, [5]Mapi HEOR & Strategic Market Access, Lyon, France, [6]University of Birmingham, Birmingham, United Kingdom.

Background/Purpose: Epratuzumab is a monoclonal antibody targeting CD22. Improvements in health-related quality of life (HRQoL) with epratuzumab in patients with systemic lupus erythematosus (SLE) have been reported in the ALLEVIATE trials from week 12 and sustained to 4 years.[1,2] In the EMBLEM™ study (dose-ranging phase IIb randomized controlled trial [RCT] in SLE), epratuzumab treatment resulted in clinically relevant improvements in SLE disease activity.[3] We report HRQoL data from EMBLEM™ and its open-label extension (OLE) (NCT00660881).

Methods: In EMBLEM™ patients with moderate-to-severely active SLE (≥1 BILAG 2004 A or ≥2 Bs) were randomized to 1 of 6 intravenous regimens over 12 weeks added to standard of care (SOC): placebo (PBO) or cumulative dose (cd) epratuzumab (200, 800, 2400 or 3600 mg in equal divided doses using 2 every other week [EOW] infusions or 2400 mg cd as 600 mg every week [QW]). Patients from any EMBLEM™ arm completing 12 weeks blinded treatment and those who discontinued due to lack of efficacy but completed ≥8 weeks were eligible to enter the OLE where all patients received 1200mg epratuzumab at weeks 0 and 2 of repeating 12-week cycles. Short Form-36 (SF-36) Version 2.0 was used to assess HRQoL. Data are reported to the end of EMBLEM™ and to weeks 48 and 108 of the OLE (week 108 is last time-point when ≥ 50% of patients reported SF-36 data). Mean changes and % pts reporting improvements ≥ minimum clinically important differences (MCID) (Increases from baseline ≥5.0-points in domain and ≥2.5-points in physical and mental component scores [PCS and MCS]) are presented. Observed case analyses are presented for the OLE.

Results: In EMBLEM™ mean SF-36 PCS, MCS and domain scores across epratuzumab and placebo groups (both receiving background SOC) generally increased over time from baseline through week 12, with greater increases in the PBO group. Longer treatment with epratuzumab during OLE resulted in clinically meaningful changes in HRQoL vs EMBLEM baseline (Table). At week 108 in the OLE 70.8% and 59.3% of patients reported improvements ≥ MCID in PCS and MCS scores.

Table. SF36 scores and MCID with epratuzumab in EMBLEM™ and EMBLEM™ OLE

	EMBLEM™ BL		EMBLEM™ OLE screening			Week 48 of the EMBLEM™ OLE			Week 108 of the EMBLEM™ OLE			
SF36 domain	N	Mean absolute Score	N	Mean absolute Score	Mean change from EMBLEM™ baseline	N	Mean absolute Score	Mean change from EMBLEM™ baseline	N	Mean absolute Score	Mean change from EMBLEM™ baseline	% pts with improvement ≥ MCID
Physical functioning	201	47.0	203	56.6	8.5	156	61.2	15.0	114	57.4	12.6	69.3
Role physical	201	37.9	203	51.1	13.3	156	53.5	15.1	113	54.7	16.5	73.5
Bodily pain	201	36.1	203	48.3	12.1	156	53.0	17.1	114	52.7	16.9	68.4
General health	201	32.6	203	41.3	8.7	156	46.5	13.6	114	47.8	16.2	82.5
Vitality	201	34.3	203	42.8	8.6	156	46.3	13.1	113	43.6	10.9	63.7
Social functioning	201	46.1	203	58.1	12.1	156	63.3	17.9	114	61.4	17.4	66.7
Role emotional	201	50.9	203	58.9	7.9	156	61.4	10.5	113	60.1	10.5	56.6
Mental health	201	50.8	203	57.8	7.1	156	61.5	11.6	113	60.5	11.4	66.4
PCS	201	34.2	203	38.7	4.5	156	40.1	6.4	113	40.5	6.4	70.8
MCS	201	36.1	203	40.0	3.9	156	41.6	6.0	113	40.9	5.7	59.3

Conclusion: In the 12 week EMBLEM™ study treatment period no differences in improvements in HRQoL were observed with epratuzumab, which may be attributed to short term treatment, small sample sizes and active background (SOC) therapy. Nonetheless, over a greater length of time sustained improvements were observed in the EMBLEM™ OLE, which are consistent with those in the ALLEVIATE RCTs.[1,2]

Elevated Combined Serum Free Light Chains Are Associated With Active Disease In Systemic Lupus Erythematosus. Lakhvir Kaur Assi[1], Larissa Lisnevskaia[2], Emma Ross[3], Richard G Hughes[1], Anisur Rahman[3] and David A. Isenberg[3]. [1]The Binding Site Group Ltd, Birmingham, United Kingdom, [2]Oshawa Clinic, Oshawa, ON, [3]University College London, London, United Kingdom.

Background/Purpose: Chronic and hyper-stimulated B cells are characteristics commonly found in patients with systemic lupus erythematosus (SLE). Due to the complexity and variability observed during the course of the disease there is a paucity of suitable biomarkers and those available do not always reflect disease activity. Polyclonal serum free light chains (FLC), a marker of immune status and renal function, have been reported to be elevated in SLE. The aim here was to compare FLC levels with both routine biomarkers and the British Isles Lupus Assessment Group Index (BILAG) for disease activity in a prospectively collected SLE cohort.

Methods: Combined FLC (FLCκ + FLCλ= cFLC; Combylite; The Binding Site Group Ltd), IgG, IgA, IgM and Cystatin C (The Binding Site Group Ltd) were measured in sera from 62 patients who met the revised ACR criteria for the classification of SLE. Results were compared to conventional biomarkers of SLE disease activity, including anti-dsDNA antibodies, C3, lymphocyte count and erythrocyte sedimentation rate (ESR). Serologically active disease was defined as patients with elevated anti-dsDNA antibody levels (>50 IU/ml) and reduced C3 (<0.9g/L). BILAG was used to assess disease activity; clinically active disease was defined as an A or B score in any organ system. Statistical analysis (Mann Whitney U test and Spearman correlations) was performed using SPSS v21.

Results: The median age was 43 years (range: 21–86); 90% were female and 50% were Caucasian. The median cFLC concentration was 31.86mg/L (IQR: 22.27–58.17; median concentration in a healthy population: 20mg/L). Moderate correlations were observed between cFLC vs: ESR (r: 0.5, $p<0.001$), cystatin C (r: 0.41, $p=0.002$), IgG (r: 0.6, $p<0.001$) and IgA (r: 0.6, $p<0.001$). A weak correlation was seen between cFLC and anti-dsDNA antibodies (r: 0.3, $p=0.02$), but there was no association with C3 (r: −0.2, $p=0.15$), lymphocyte count (r: −0.1, $p=0.36$) or IgM (r: 0.03, $p=0.82$). In patients with serologically active disease (N=19, 32%), median cFLC levels were significantly elevated: 58.1mg/L (34.67–80.9) vs 28.9mg/L (20.56–45.09), $p=0.02$. Using the BILAG score, cFLC levels were elevated in patients with clinically active (N=26, 42%) vs inactive disease (N=36, 58%): 39.6mg/L (IQR: 25.3–80.9) vs 29.7mg/L (IQR: 19.3–49.3), $p=0.05$. Anti-dsDNA antibody levels were also elevated: 258 IU/ml (16–644.5) vs 45 IU/ml (10–181), $p=0.04$; however, there was no significant difference in the levels of C3 ($p=0.32$), ESR ($p=0.65$), IgG ($p=0.31$), IgA ($p=0.27$), IgM ($p=0.68$), or cystatin C ($p=0.09$) between the two groups.

Conclusion: cFLC concentrations are likely to reflect B cell activity and therefore represent attractive markers in SLE. In this study, elevated levels correlated with disease activity supporting this hypothesis, however further work is required to evaluate the usefulness of this observation and to determine how cFLC may be used to monitor disease progression.

Changes In Quality Of Life In The First 5 Years Of Disease In The Systemic Lupus Erythematosus International Collaborating Clinics (SLICC) Cohort. Murray B. Urowitz[1], Dominique Ibanez[1], Nicole Anderson[1], Dafna D. Gladman[1] and Systemic Lupus SLICC[2]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]Toronto Western Hospital, Toronto, ON.

Background/Purpose: The Medical Outcome Survey Short Form 36 (SF-36) is one of the most widely used tools for measuring patient reported outcomes. In cross-sectional studies, there has been no correlation between QoL and disease activity or damage. The aim of this study is to assess QoL over time in the first 5 years of a multinational multicenter cohort.

Methods: An inception cohort of SLE patients from 31 centres in 12 countries has been assembled according to a standardized protocol between 2000 and 2013 to study the risk factors for atherosclerosis. Patients enter the cohort within 15 months of SLE diagnosis (≥4 ACR criteria). Clinical and laboratory features of SLE and comorbidities are gathered in a standardized protocol at yearly intervals. In addition patients complete the SF-36 at yearly intervals. Only patients who had 5 years of follow up and who had a minimum of 5 completed questionnaires were included in this analysis. The outcomes assessed include the 8 health domains of SF-36, in addition to physical component scores (PSC) and mental component scores (MCS) for each patient. In order to test for change in SF-36 domains over the 5 year period, GEE models were run separately for each of the 8 domains and the 2 composite scores. Each model adjusted for repeated measures by patients. Domains were also compared for gender, age, ethnicity and active disease (SLEDAI-2K ≥ 6) at enrolment.

Results: 485 patients (90.1% female) with 5 or more SF-36 evaluations were included. The disease duration at enrolment was 5.3 ± 4.1 months and the mean age at diagnosis was 35.8 ± 13.2 years. The race/ethnicity distribution was as follows: 57% Caucasian, 15% Black, 16% Asian, 8% Hispanic and 4% other. All 8 domains, in addition to MCS and PCS showed improvement that was statistically significant in the first 2 years of follow-up. No significant improvement was noted in any of the 8 domains or composite scores from years 3–5.

	SLE	APS	Whole group
IUFD	2	3	5
Perinatal death	0	1	1
Preterm delivery	17	12	29
IUGR	7	1	8
Pre-eclampsia	7	4	11
HELLP	0	2	2
Maternal thrombotic manifestations	2	3	5

Baseline domain scores range from 44.2–70.7 and PCS and MCS scores were 39.4 and 44.9. In year 2 domain scores range from 52.4–71.6 and PCS and MCS scores were 42.8 and 47.7.

Generally higher values of SF-36 scores are associated with male gender, younger age and Hispanic and Asian ethnicities. Levels of disease activity were not associated with SF-36.

Conclusion: Unlike late stage lupus where QoL is stable, in patients with early disease (within the first 2 years) all domains improve. Therefore SF-36 may be used as an outcome measure for improvement in the first two years of SLE.

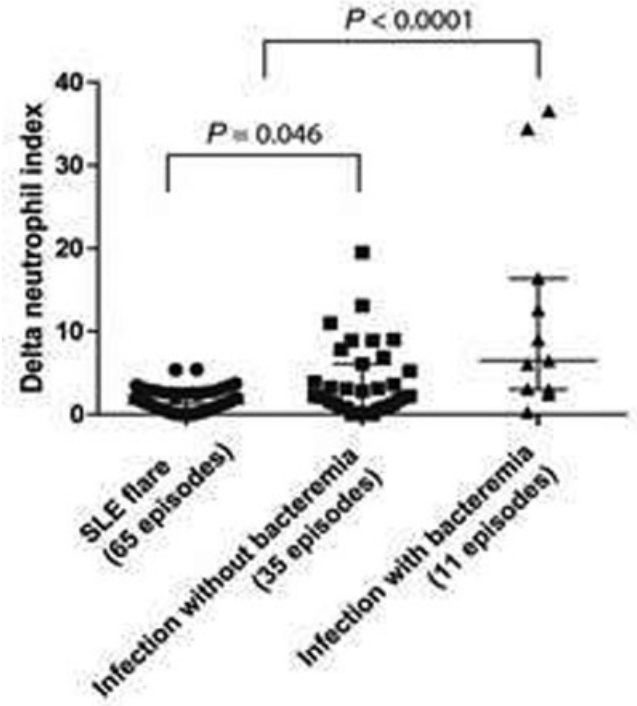
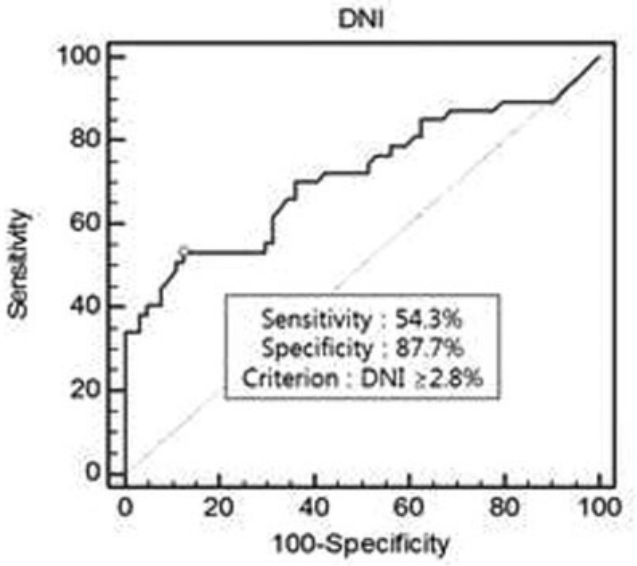
Delta Neutrophil Index As a Marker For Differential Diagnosis Between Flare and Infection In Febrile Systemic Lupus Erythematosus Patients. You-Jung Ha, Jung Yoon Pyo, Jin Su Park, Hee-Jin Park, Jason Jungsik Song, Yong-Beom Park, Soo-Kon Lee and Sang-Won Lee. Yonsei University College of Medicine, Seoul, South Korea.

Background/Purpose: The immature granulocyte count has been reported to be a marker of infection and sepsis. The difference in leukocyte subfractions (delta neutrophil index, DNI), automatically determined by the ADVIA 2120 electronic cell analyzer, reflect the fraction of circulating immature granulocytes in the blood. Because fever is a common symptom of systemic lupus erythematosus (SLE), it is difficult to discriminate between SLE flare and infection. In this study, we investigated the utility of DNI in discriminating infections from SLE flares in febrile SLE patients.

Methods: We included all consecutive SLE patients hospitalized due to febrile episodes at Severance Hospital, Yonsei University Health System, Seoul, South Korea, from January 2010 to February 2012. In total, 111 episodes in 92 febrile SLE patients were reviewed. All SLE patients were assigned to three groups: (1) patients with SLE flare, (2) patients with infection without bacteremia, and (3) patients with infection and bacteremia. DNI was determined using a specific blood cell analyzer.

Results: The infection group showed significantly higher white blood cell counts, neutrophil counts, C-reactive protein and procalcitonin than the SLE flare group. Complement (C)3 and C4 levels were decreased significantly in the SLE flare group. Patients in the SLE flare group had significantly lower DNI than those in both infection groups, with or without bacteremia. When we selected a DNI value of 2.8% as the cutoff for infection, SLE patients with DNI >= 2.8% were found to be at higher risk for infection than those with DNI < 2.8% (relative risk 8.48-fold). In a multivariate logistic regression analysis, only DNI >= 2.8% was a significant independent factor for the presence of infection (OR 18.9).





Conclusion: SLE patients with infection showed higher DNI than SLE flare group, and febrile SLE patients with DNI >= 2.8% are likely to have infection. Our findings suggest that DNI may be a useful marker to differentiate infections from SLE flares in febrile SLE patients.

Pregnancy Complications In Lupus: Retrospective Observational Analysis From a US Health Claims Database. Michelle. A. Petri[1], Paola Daly[2], Daphnee S. Pushparajah[3], David Friesen[4] and Lydia Makaroff[3]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Lupus Foundation of America, Washington DC, DC, [3]UCB Pharma, Brussels, Belgium, [4]UCB Pharma, Slough, United Kingdom.

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease most frequently affecting women of childbearing age. Women with SLE are known to be at increased risk of miscarriage and other complications during pregnancy. This study used a large health claims database to quantify the reported incidence of maternal and fetal complications in pregnant women with SLE compared to pregnant women without SLE.

Methods: A retrospective observational analysis of the MarketScan US administrative healthcare claims database from 2006 to 2012 was conducted. Records of all women aged 12–54 years were reviewed. SLE patients were defined by ICD-9 codes for 710.0 on at least 2 different days. Pregnancies were identified by including codes for live birth, miscarriage, and either first-or second trimester ultrasound. Pregnant women with SLE were matched 1:5 by index year and quarter, age, geography, data type, insurance plan type, and employee relationship with pregnant women without SLE. Conditional logistic regression was used to calculate p values. Statistical tests were not corrected for multiple comparisons. P values are presented in the table.

Results: 1721 pregnancies in women with SLE were matched with 8605 pregnancies in women without SLE. Demographics were similar; mean (± SD) age of 31.5 (± 5.6) in the SLE group and 31.4 in (± 5.6) in controls. 23 in every 100 SLE pregnancies resulted in a miscarriage before 22 weeks gestation vs. 19 in every 100 control pregnancies. There was an increased risk of threatened abortion/premature labour without delivery in pregnancies with SLE vs. those without (46.0% vs. 39.8%). Hypertension was reported in 28.4% of SLE pregnancies vs. 12.4% of controls. Preeclampsia occurred in 1 in every 10 SLE pregnancies vs. 1 in every 22 non SLE pregnancies. Preterm delivery occurred in 1 in every 9 SLE pregnancies vs. 1 in every 17 non SLE pregnancies, with stillbirths reported in 2.4% of SLE pregnancies vs. 1.3% of subjects without SLE. There was a 7.5% increase in the risk of fetal complications in pregnancies with SLE vs. those without. A code for known/suspected fetal abnormality affecting management of the mother occurred in 39.7% of SLE pregnancies vs. 28.0% of controls.

Table. Obstetric features, complications and outcomes between pregnant women with SLE vs. pregnant women without SLE

	SLE Pregnancies N = 1721 N (%)	Control Pregnancies N = 8605 N (%)	P value
Hypertension	489 (28.4%)	1066 (12.4%)	<0.0001
Preeclampsia	170 (9.9%)	386 (4.5%)	<0.001
Eclampsia	6 (0.3%)	9 (0.1%)	0.0321
Nephritis	288 (16.7%)	100 (1.2%)	<0.0001
Primary hypercoagulable state	132 (7.7%)	54 (0.6%)	<0.0001
Obstetric infections	23 (1.3%)	65 (0.8%)	0.0244
Miscarriage before 22 weeks gestation	398 (23.1%)	1634 (19.0%)	<0.0001
Threatened abortion/premature labor without delivery	791 (46.0%)	3429 (39.8%)	<0.0001
Pre-term delivery between 22 to 37 weeks gestation	197 (11.4%)	510 (5.9%)	<0.0001
Induction of labor	154 (8.9%)	657 (7.6%)	0.0683
Caesarean delivery	515 (29.9%)	2090 (24.3%)	<0.0001
Stillbirth	41 (2.4%)	114 (1.3%)	0.0019
Gestational diabetes	169 (9.8%)	1006 (11.7%)	0.0228
Fetal complications	1185 (68.9%)	5518 (64.1%)	0.0001
Known or suspected fetal abnormality affecting the management of the mother	684 (39.7%)	2413 (28.0%)	<0.0001

Conclusion: In this large database analysis of over 10,000 pregnant women, those with SLE had a higher risk for suspected fetal abnormalities affecting care of the mother, and a doubling of risk for hypertension, preeclampsia, pre-term delivery and stillbirths. However, increased risk for earlier adverse pregnancy events, including miscarriage prior to 22 weeks and threatened abortion, appeared modest. These data highlight the need for regular physician-patient interaction, counseling and high quality education for women with SLE who are pregnant or looking to conceive to ensure possible complications are recognized early and managed appropriately.

Rare Autoantibodies To Cellular Antigens In Systemic Lupus Erythematosous. Micaela Fredi[1], Ilaria Cavazzana[2], Marzia Quinzanini[2], Mara Taraborelli[1], Stefania Cartella[2], Angela Tincani[3] and Franco Franceschini[2]. [1]Rheumatology Chair, University of Brescia and Pavia, Brescia, Italy, [2]Rheumatology Unit, Spedali Civili, Brescia, Italy, [3]Rheumatology Unit, University of Brescia, Brescia, Italy.

Background/Purpose: a high number of antinuclear antibody specificities can be detected in Systemic Lupus Erythematosous (SLE). Some of them are related to a distinct clinical subset of disease, independently from their frequence. Aim of our study was investigate, in a cohort of SLE patients from a single Centre, the prevalence and the clinical relevance of autoantibodies to cellular antigens less frequently found in SLE.

Methods: antinuclear antibodies was detected by indirect immunofluorescence (IIF) on HEp-2 cells while counterimmunoelectrophoresis (CIE) was used to detect anti-ENA antibodies in 532 patients with SLE classified according to SLICC criteria[1]. Clinical and serological features about our cohort of SLE patients were collected from clinical charts. Categorical variables were analyzed with Chi-Squared test or Fisher's exact test. Multivarite analysis was conducted with a logistical regression model (Statview), $p<0.05$ was considered as significant.

Results: 311 (58.5%) of 532 sera were positive for anti-ENA antibodies. Anti-SSA/Ro was the most prevalent antibody found in 232 out of the 311 positive sera (74.5%), 50 of whom (16%) also contains anti-SSB/La. Anti-U1RNP were detected in 69 (22%) and anti-Sm in 45 (14.5%) patients. In a multivariate analysis anti-U1UNP and anti-SSA/Ro resulted to be associated with malar rash ($p= 0.010$ and $p=0.029$ respectively) while anti-U1RNP was also associated with leukopenia ($p=0.0065$). Other anti-ENA antibodies were found in 49 out of the 311 anti-ENA positive sera (15.8%). Anti-Ki/SL antibodies represented the most frequent between these rare antibodies and were detected in 31 sera, anti-Ku in 8 sera, anti-centromere in 4, isolated anti-SSB/La, PCNA and anti-Scl70 in 3 sera each and anti-Jo-1 in 2 sera. About half of these antibodies (26 out of 49; 53%) were detected as the single anti-ENA specificity in serum. Anti-Ki/SL was significantly associated with male gender ($p=0.0054$), being detected in 7 males and in 24 females; anti-Ku was significantly associated with African ethnicity (0.00031) being detected in 3 out of 11 patients of African origin. No sign of muscular or pulmonary involvement were found in the anti-Jo-1

positive patients while features of systemic sclerosis were detectable in 2 out of 3 anti-Scl70 and in one of the 4 anti-centromere positive patients.

Conclusion: our study shows that antibodies to cellular antigens more rarely found in SLE are detectable in more than 15% of patients with anti-ENA antibodies. The majority of them are found as a single anti-ENA specificity. Anti-Ki and anti-Ku appears to characterize a subset of disease with a prevalence of male and of patients from African origin respectively. Clinical features of scleroderma and/or myositis was found only in a minority of patients with antibodies to topoisomerase-1, Jo-1 or centromere. [1] Petri M, Orbai A-M, Alarcon G, et al. Lupus Impact Tracker Is Responsive To Changes In Physician Assessed Disease Status By Systemic Lupus Erythematosus Responder Index. Hervé Devilliers[1], Mark Kosinski[2], Cindy Garris[3] and Meenakshi Jolly[4]. [1]Internal medicine and systemic disease unit, Dijon University Hospital, Dijon, France, [2]QualityMetric Inc, Lincoln, RI, [3]GlaxoSmithKline R&D, Research Triangle Park, NC, [4]Rush University Medical Center, Chicago, IL.

Background/Purpose: Lupus Impact Tracker (LIT) is a 10-item patient reported outcome tool to measure the impact of Systemic Lupus Erythematosus (SLE) or its treatment on patients' daily lives. The transformed scores range from 0–100, where higher scores denote greater impact. The tool is responsive to self reported changes in SLE health status over time. Herein, we test the responsiveness of the LIT to changes in disease activity as judged by SLE responder index (SRI).

Methods: Adult SLE patients were prospectively recruited from 20 North American Rheumatology clinics for the LIT study- an observational, non-interventional prospective multi center study conducted across the US and Canada. Data (Demographics, LIT, BILAG, SELENA-SLEDAI) were obtained three months apart. Responders according to modified SRI were defined as (1) a decrease in SELENA-SLEDAI (4 points), (2) No new BILAG A and not more than 1 new B and (3) No increase in Physician Global Assessment (PGA). Latter definition was used as our PGA variable was categorical (0/1/2/3). Standardized response mean (SRM) and effect size (ES) for LIT was calculated among SRI responders and non-responders by taking the average difference divided by the standard deviation of the differences between the paired measurements, and baseline LIT, respectively. Difference in the LIT variation was compared among SRI responders and non responders using Kruskall Walis test.

Results: 325 patients participated (90% Female); 53% Whites, 33% Black and 17% Hispanic. Mean (SD) age and SELENA-SLEDAI at baseline were 42.3 (16.2) yrs and 4.3 (3.8), respectively. Mean (SD) LIT score at baseline was 39.4 (22.9). SRI data was available for 295 (40 R and 255 NR) at the 3 month timepoint. SRM and ES were −0.69 and −0.36 among SRI responders, −0.20 and −0.12 among non responders respectively. The mean LIT variation (SD) was −2.9 (14.4) and −7.9 (11.4) among non responder and responders, respectively (p=0.02). The mean difference in LIT variation between non-responders and responders was 5.0.

Conclusion: LIT was moderately responsive to changes in disease activity as assessed by SRI in patients with SLE in this study. The value of 5.0 seems to indicate a clinically important difference in LIT variation between two groups of patients

Inactive Systemic Lupus Erythematosus: Cytokines and Soluble Tumor Necrosis Factor Receptors Response To Moderate/Intense Exercise. Luiz A. Perandini[1], Diego Sales-de-Oliveira[1], Suzana B.V. Mello[2], Niels O Camara[3], Fernanda R. Lima[1], Eduardo F. Borba[2], Eloisa Bonfa[2], Ana Lucia Sá-Pinto[1], Hamilton Roschel[4] and Bruno Gualano[5]. [1]University of Sao Paulo, Rheumatology Division, Sao Paulo, Brazil, [2]University of Sao Paulo, Rheumatology Division, São Paulo, Brazil, [3]University of Sao Paulo, Sao Paulo, Brazil, [4]Universidade de São Paulo, Faculdade de Educação Física e Esporte, São Paulo, Brazil, [5]University of Sao Paulo, School of Physical Education and Sport, Sao Paulo, Brazil.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune rheumatic disease characterized by a chronic inflammation associated with worse cardiovascular outcome. Although a few studies have investigated the safety of physical exercise in this disease, none of them have assessed the underlying cytokine response, an important marker of inflammation. Therefore, the aim of this study was to evaluate the cytokines (INF-γ, IL-6, IL-10, TNF-α) and soluble TNF receptors (sTNFR1 and sTNFR2) response to either a moderate or an intense acute exercise session in inactive SLE patients.

Methods: Twelve patients with SLE [age: 35.3 ± 5.7 yrs; body mass index (BMI): 25.6±3.4 kg/m^2; SLEDAI: 1.4±1.0] and 10 healthy age- and BMI-matched controls (age: 30.6±5.2 yrs, P=0.12; BMI: 24.1±2.3 kg/m^2, P=1.00) performed 30min of moderate (~50% of VO_2max) and intense (~70% of VO_2max) exercises in a treadmill, on separate occasions. Serum cytokines (INF-γ, IL-10, IL-6, TNF-α) and sTNFRs were assessed at baseline, immediately after exercise, every 30 min during three hours of recovery, and 24h after the end of exercise. Serum cytokines and sTNFRs were evaluated by the multiplex technique.

Results: At baseline, SLE had higher levels of TNF-α (P=0.001) and sTNFR2 (P=0.001) when compared with controls, whereas all other cytokines and sTNFR1 levels were comparable between groups (P>0.05). After the moderate exercise session, INF-γ, IL-10, IL-6, TNF-α, sTNFR1 and sTNFR2 levels remained stable in SLE when compared with baseline in all time points (P>0.05). Likewise, both the sTNFR2 and cytokines levels remained unchanged in healthy controls (P>0.05), except for the sTNFR1 levels, which showed a decrease at the 90th (P=0.038), 120th (P=0.028), 150th (P=0.005) and 180th (P=0.037) minute of recovery, returning to baseline levels 24h after the moderate exercise (P=0.093). After the intense exercise, only the sTNFR1 was altered in SLE patients, showing a decrease at the 150th (P=0.041) and 180th (P=0.034) minute of recovery, returning to baseline levels at the 24h time point. The sTNFR2 and all other cytokines remained unchanged (P>0.05). In healthy controls, IL-10, TNF-α, sTNFR1 and sTNFR2 did not change in response to the intense exercise session. Conversely, INF-γ decreased (P=0.05) and IL-6 increased at the end of exercise (P=0.028), with no differences observed at the post-24h time point (P>0.05).

Conclusion: This study demonstrates that both moderate and intense acute exercise sessions results in mild and transient changes in cytokine levels in SLE, providing novel evidence that exercise does not trigger inflammation in this disease. This finding supports the safety and recommendation of physical exercise for these patients.

Impact Of Omega-3 Fatty Acids On Quality Of Life In Systemic Lupus Erythematosus. Cristina Arriens[1], Chandra Mohan[2] and David R. Karp[3]. [1]University of Texas Southwestern Medical Center at Dallas, Dallas, TX, [2]University of Texas Southwestern Medical Center, Dallas, TX, [3]UT Southwestern Medical Center, Dallas, TX.

Background/Purpose: A comprehensive metabolomic screen of sera from patients with Systemic Lupus Erythematosus (SLE) has shown that the concentrations of many substrates for energy generation, as well as physiological antioxidants, are reduced when compared to sera from healthy controls. It is possible that these metabolic alterations underlie one of the most common patient reported features of SLE - fatigue. The metabolomic studies also noted reduced omega-3 fatty acids (omega-3 FAs). Given that omega-3 FAs are powerful anti-oxidants, the reduction in these FAs may be causally related to the tremendous degree of oxidative stress and lipid peroxidation seen in lupus. Supplementation with omega-3 FAs in SLE has been shown to increase anti-oxidants and reduce reactive oxygen species to more closely resemble healthy controls. The effect of omega-3 FA supplementation on the serum metabolome and clinical measures of fatigue are the subject of a randomized clinical trial.

Methods: Fifty SLE patients were recruited, 25 supplemented with omega-3 FAs and 25 with olive oil placebo. At baseline and after 6 months of FA supplementation, Short Form-36 (SF-36), Fatigue Severity Scale (FSS), SLE Disease Activity Index (SLEDAI), and Physician Global Assessment (PGA) were completed; serum was also collected to perform metabo-

lomic analysis. Demographic information and baseline clinical laboratory data were collected from the electronic medical record.

Results: Eighteen subjects receiving FA and 14 placebo patients completed the study. The FA patients were: 14 female, 4 male, 10 black and 8 Hispanic patients aged 43 ± 8 years. The placebo patients were: 11 female, 3 male, 1 white, 6 black, and 7 Hispanic patients aged 35 ± 11 years. Each group had an average of 6 ACR criteria for SLE. The SF-36 total scores pre- and post-treatment were compared using a paired t test and noted a significant improvement in the omega-3 patients (32.60 vs.42.19, p=0.0076), and no significant change in placebo patients (60.58 vs. 64.76, p=0.235). The SF-36 Vitality/Fatigue also yielded significant improvement in the omega-3 group (29.44 vs. 39.17, p=0.023) and no significant change in the placebo group (52.50 vs. 52.86, p=0.92). PGA improved significantly in the omega-3 group (1.21 vs. 0.56, p=0.0018), and did not significantly change in the placebo group (0.94 vs. 0.92, p=0.95). No significant changes were noted for FSS or SLEDAI in either group. Metabolomic data are currently being analyzed.

Conclusion: In this placebo-controlled 6-month trial of omega-3 FA supplementation in SLE, improvement was noted in both the total SF-36 quality of life measure as well as the Vitality/Fatigue sub-score. There were also two assessments of disease activity, but only the PGA noted significant improvement in the omega-3 group. Serum from the subjects in this cohort is now under analysis for markers of oxidative stress and antioxidant response and will be correlated with patient-reported outcomes as well as disease activity.

The Reliability Of a Novel Automated System For ANA Immunofluorescence Analysis In Daily Clinical Practice. Mohammed Alsuwaidi[1], Margit Dollinger[1], Martin Fleck[2] and Boris P. Ehrenstein[1]. [1]Asklepios Clinic Bad Abbach, Bad Abbach, Germany, [2]University Medical Center of Regensburg, Regensburg, Germany.

Background/Purpose: Recently, automated interpretation (AI) systems for anti-nuclear antibody (ANA) analysis have been introduced based on assessment of indirect immunofluorescence (IIF) patterns. However, the reliability of these systems has not been assessed in routine clinical practice. Therefore, the diagnostic performance of a novel automated IIF reading system was compared with visual interpretation (VI) of IIF in daily clinical practice.

Methods: ANA-IIF tests of consecutive serum samples from patients with suspected connective tissue disease were carried out using HEp-2 cells according to routine clinical care. VI was performed first by two laboratory experts independently; discrepant results were resolved by collegial discussion with a third expert. Afterwards, AI of IIF findings were obtained using a visual analyzer (Zenit G-sight, Menarini, Germany) utilizing novel automated pattern recognition algorithms. VI and AI readings were stratified as negative (serum dilution of 1:80 with no fluorescence), ambiguous (dilution of 1:80 with slight fluorescence, but no defined pattern) and positive (dilution of ≥ 1:80 with definite IIF pattern). Agreement rates between ANA results by AI and VI were calculated. IIF patterns were categorized as either being homogeneous, fine granular, coarse granular, nucleolar, centromeric, or mitochondrial by AI and VI, respectively.

Results: Of the 340 samples investigated, VI yielded 205 (60%) negative, 42 (12%) ambiguous and 93 (27%) positive results, whereas 82 (24%) were determined negative, 176 (52%) ambiguous and 82 (24%) positive by AI. Of the 82 negative samples by AI, 78 (95%) were also negative, 3 (4%) were ambiguous and 1 (1%) was positive as judged by VI. Of the 176 ambiguous samples by AI, 125 (71%) were negative, 30 (17%) also ambiguous and 21 (12%) positive by VI. Of the 82 positive samples by AI, 2 (2%) were negative, 9 (11%) ambiguous and 71 (87%) also positive by VI. AI displayed a diagnostic accuracy of 179/340 samples (53%) with a kappa-coefficient of 0.35 compared to VI as the gold standard. Solely relying on AI with VI only performed for all ambiguous samples by AI would have missed 1 of 93 (1%) positive results by VI, and misclassified 2 of 205 (1%) negative results by VI as positive. Of the 93 positive samples by VI, AI identified 36 (39%) IIF patterns correctly (18 (95%) of 19 homogeneous, 1 (3%) of 3 fine granular, 13 (65%) of 20 coarse granular, 2 (18%) of 11 nucleolar, 1 (33%) of 3 centromeric, and 1 (100%) of 1 mitochondrial patterns).

Conclusion: Utilizing novel algorithms, AI of ANA-IIF displayed reliable detection of positive and negative results as confirmed by VI. However, there were a substantial number of ambiguous results as well as inconsistencies in the identification of the correct pattern by AI requiring additional VI analysis. In contrast to previous studies utilizing well defined biobank samples, the use of AI in daily clinical practice resulted only in a moderate reduction of the VI workload (82 of 340 samples: 24%), which was predominantly due to a large proportion of ambiguous AI-results.

Serum Mercury Level and Disease Activity Of Systemic Lupus Erythematosus (SLE): A Case-Control Study. Chi Chiu Mok[1], Becky Fong[1] and Chris Wong[2]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Baptist University Hong Kong, Hong Kong, Hong Kong.

Background/Purpose: Environmental contamination with mercury (Hg) is linked to autoimmune diseases. Exposure to low-dose non-organic mercury has been reported to exacerbate murine SLE. The aim of this study is to evaluate the serum Hg levels in patients with SLE and their associated risk factors

Methods: Consecutive patients who fulfilled >=4 ACR criteria for SLE were recruited. An equal number of age and sex matched healthy controls was also recruited. Blood was taken in the morning for the assay of Hg level (atomic absorption spectrophotometry by a DMA80 direct Hg analyzer, Milestone, Italy) and other markers of disease activity (anti-dsDNA, complement C3 and C4) (for SLE patients). Disease activity of SLE patients was assessed by the SELENA-SLE disease activity index (SLEDAI) and organ damage was assessed by the SLICC/SLE damage index (SDI). Bivariate correlation between Hg level and various clinical and serological markers was studied by Pearson's correlation test. A linear regression model was established to study the clinical risk factors associated with higher serum Hg levels in SLE patients.

Results: 246 SLE patients (93% women) were studied. All were ethnic Chinese. The mean age during venepuncture was 40.7±12.5 years and SLE duration was 7.7±7.0 years. The mean SELENA-SLEDAI and SDI score was 5.8±6.5 and 0.97±1.5, respectively. 85(35%) patients had clinically active SLE, defined as a SELENA-SLEDAI score of >=6. 107 (43%) patients had organ damage (SDI>=1). The mean serum total mercury level of the SLE patients studied was 1.34±0.69 ng/mL (NR <3.85), which was significantly higher than that of 246 age and gender matched healthy subjects (N=246) (0.72±0.34 ng/mL; p<0.001). Only 2 (0.8%) SLE patients had Hg level ^{3}3.85ng/mL. Patients with clinically active SLE had significantly higher mercury level than those with SLEDAI<6 (1.50±0.57 vs 1.26±0.74 ng/mL; p=0.006). In addition, the levels of mercury in patients with clinically and serologically inactive disease (SLEDAI =0) were significantly higher than those with controls (1.15±0.56 vs 0.72±0.34 ng/mL; p<0.001) adjusted for age and sex (by ANCOVA test). Bivariate correlation study revealed that younger age (r −0.24; p<0.001), female sex (r 0.19; p=0.003), shorter SLE duration (r −0.16; p=0.01), anti-dsDNA titer (r 0.22; 0.001), SLEDAI score (r 0.24;<0.001) and physicians' global assessment (PGA) of disease activity (r 0.17;p=0.007) were significantly associated with higher mercury level. SDI damage score (r −0.06; p=0.33), C3 (r −0.06; p=0.36), C4 (r −0.07; p=0.28), photosensitivity, serum creatinine and other clinical manifestations were not significantly associated with mercury levels. In a linear regression model, the SLEDAI score (beta 0.14; p=0.04) and female sex (beta 0.18; p=0.006) were independently and significantly associated with higher Hg level, after adjustment for age, SLE duration and serum creatinine level.

Conclusion: In this cross-sectional study, the total serum mercury level was significantly elevated in patients with both active and inactive SLE than matched controls. Mercury level correlated independently with clinical disease activity and the female sex in a multivariate model, suggesting mercury may be an environmental trigger for SLE.

Disease Activity Does Not Improve Significantly In One System and Worsen In Another System. Zahi Touma, Dafna Gladman and Murray B. Urowitz. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Systemic Lupus Erythematous Disease Activity Index-2000 (SLEDAI-2K) is a global index that describes disease activity overall in 9 systems. The use of multiple measures is time consuming and physicians favor one measure, as long as the results are

robust. We aimed to determine if SLEDAI-2K is valid in identifying patients who had a clinically important overall improvement with no worsening in other systems.

Methods: This is an analysis of prospectively collected data on all active lupus patients who attended the Lupus Clinic from 2000–2012. Patients were included if at baseline visit: 1) SLEDAI-2K ≥6, 2) at least 1 of the 6 SLEDAI-2K clinical organ systems was active and for the renal system the presence of proteinuria was mandatory and 3) start or increase in the dose of prednisone. All patients had at least one follow-up at 9–12 months.

Based on the change in the total SLEDAI-2K scores on follow up visits, patients were grouped as: 1) improved (SLEDAI-2K decreased by ≥4), 2) flared/worsened (SLEDAI-2K increased by ≥4) and 3) unchanged.

Focusing on patients who improve, each organ system was defined as 1) **New Organ:** organ system inactive at start but active at study end 2) **Same:** no change in activity between start and end 3) **Improved:** lower activity in organ system at the end and 4) **worse:** higher activity in organ system at study end.

Results: 158 patients were analyzed (table 1). SLEDAI-2K was 12.25±5.27 at baseline and 6.65±4.88 at follow-up visits.

Sex F	97 (89%)
Age at diagnosis (years)	26±11
Age at 1st visit in the study (years)	39±13
Disease Duration at 1st visit in the study (years)	12±9
Race	
Caucasian	67 (61%)
Black	13 (12%)
Asian	14 (13%)
Others	15 (14%)
Medications at 1st visit in the study: patients number (%)	
Steroid	109 (100%)
Anti-malarial	82 (75%)
Immunosuppressants	69 (63%)

Of the 158 patients studied 109 patients had improved on SLEDAI-2K scoring on follow-up visit, 38 stayed the same and 11 worsened.

109 patients improved with a mean SLEDAI-2K score at baseline visit of 13.1±5.7 and at follow-up visit of 4.8±4.4. In this group, no one had a new system at study end. Worsening was identified in 5 patients at study end and this resulted from abnormal laboratory results: 1) one patient developed pyuria at follow up visit in addition to existing proteinuria and hematuria that were persistent from study start and 2) 4 patients had worsening in the immunological system (either a new anti-DNA positivity or low complements). In all 5 patients, this laboratory worsening was not clinically significant and did not require a change in the management (table 2).

Table 2. Activity of SLEDAI-2K systems' descriptors in patients who improved at study end

Global disease activity	Improvement n = 109			
Organ systems	**New organ**	**Same**	**Improved**	**Worsened**
CNS	0	95	14	0
Vascular	0	92	17	0
MSK	0	65	44	0
Renal	0	61	47	1
Dermal	0	75	34	0
Serosal	0	105	4	0
Immunological	4	71	30	4
Constitutional	0	102	7	0
Hematologic	0	102	6	0

Conclusion: SLEDAI-2K is valid to identify improvement in disease activity overall and we have now shown that no clinically important worsening occurs simultaneously. Therefore, SLEDAI-2K can be used as a single measure in the assessment of disease activity.

Validation Of The Revised Selena Flare Index In Systemic Lupus Erythematosus. Michelle Petri[1], Joan T. Merrill[2], R. Maciuca[3], John C. Davis Jr.[3] and William P. Kennedy[3]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Genentech, Inc, South San Francisco, CA.

Background/Purpose: The SELENA flare index (SFI) has been used in clinical and clinical trial settings since 2005 (1), but has the limitation that it classifies only severe versus combined mild/moderate flares. Since mild flares are often clinically insignificant, and it is useful to distinguish flares by organ system, a revision of the SELENA flare index (2) was carried out to define severe, moderate and mild flares separately, in terms of clinical and/or treatment variables, and by organ system. This revised flare index (rSFI) is independent of SLEDAI and was compared to the original SFI in the Phase 2 (ROSE) trial of rontalizumab (anti-interferon alpha) in extrarenal lupus (3).

Methods: The ROSE study enrolled patients with moderate to severe active SLE disease (3). Study investigators were trained on the use of the rSFI and other instruments before the start of the trial. rSFI was administered at scheduled study visits in the ROSE trial along the original SELENA flare index (SFI) and BILAG index. The new BILAG 2004 flare definition was used (severe = new or worse A, moderate = ≥2 B new or worse, mild = ≥1B or ≥3C new or worse). The proportion of patients with flares from week 4 to 24 was tabulated. Inter-instrument agreement between the different flare classifications was evaluated with Cohen's kappa/weighted kappa coefficient (4).

Results: A total of 235 efficacy-evaluable patients were included in the analysis. The assignment of no flare/ mild-moderate flare/ severe flare was compared for the rSFI versus SFI. In general, there was substantial agreement between the rSFI and SFI (kappa 0.70, weighted kappa 0.73). The agreement between rSFI and SFI was better for the clinical part of the rSFI (kappa 0.69) than the treatment part of rSFI (kappa 0.35). The SFI showed fair agreement (kappa 0.30; weighted 0.39) and the rSFI showed moderate agreement (kappa 0.31; weighted 0.51) with the BILAG flare index. Many of the significant discrepancies between instruments (e.g., mild flare by rSFI, but severe by the BILAG flare index) were determined, after further review, to be correctable data reporting errors.

Conclusion: The revised SFI (rSFI) has substantial agreement with the previously validated SFI, and the clinical portion of the rSFI, tested independently, showed the best agreement. The rSFI has better agreement with the BILAG flare index than the original SFI. Some discrepancies were due to data entry errors that can be avoided with improved site training. One possibility to improve flare endpoints would be to combine moderate and severe flares, as those are most likely to be clinically important.

Patients' Perception Of Their Lupus Disease Activity, But Not Overall Health, Correlates With Physician Assessments. Anca Askanase[1], Samrawit Abraha[1], Ummara Shah[2], Aleks Merkovich[1] and Jill P. Buyon[3]. [1]New York University School of Medicine, New York, NY, [2]New York University School of Medicine, NYC, NY, [3]NYU School of Medicine, New York, NY.

Background/Purpose: The Physician Global Assessment represents the average assessment of a patient's disease activity based on physical examination and laboratory data while the Patient Global Assessment reflects the patient's perceived overall health and disease activity. The discordance between the physician and patient assessments has been previously observed. This current study investigates the influence of the specific question being asked in the questionnaire on the concordance between physician and patient assessments. This study will analyze the correlation between patient and physician assessments of disease activity in a longitudinal cohort.

Methods: Data was collected on a convenience sample of 43 patients with SLE enrolled in a subset of the NYU cohort. Each patient completed a questionnaire which included a Lupus Activity Patient Global Assessment (LA PtGA) on a visual analog scale (0–100) focusing on the patient's perceived SLE disease activity by asking the patient to indicate how active the patient thought her lupus was. Additionally, each patient

completed the Modified Health Assessment Questionnaire (MDHAQ), utilized in routine clinical care. This questionnaire contains a PtGA on a numerical rating scale (0–10) that specifically asks patients to evaluate how their illness and health conditions affect them. These two PtGAs values were compared to the physician global assessment (PGA) on a numerical rating scale (0–3) and SELENA-SLEDAI scores. Each patient had multiple visits included in the analysis. The level of correlation was determined by the Spearman rank order correlations.

Results: 43 patients seen on average of 2.3 visits were included in the study. The mean age was 42.1 years, 95% females, 34% were Caucasian, 24% Black, 30% Hispanic, 11% Asian, disease duration was 13.02 + 9.01 years, and 74% of patients had 3rdparty insurance. The mean SELENA-SLEDAI score (3.13±2.94), PGA (1.07±0.75), LA PtGA (25.68±24.66), and MDHAQ PtGA (3.04±2.80) reflect mild SLE activity. The correlation between PGA and SELENA-SLEDAI was 0.69 ($p<0.01$). The correlation between PGA and LA PtGA was 0.32 ($p<0.01$). In contrast, the correlation between the PGA and the MDHAQ PtGA was only 0.13 ($p=0.18$). The two PtGAs correlated well with each other with $r= 0.58$ ($p<0.01$).

Conclusion: As expected, the correlations between PGA and SLEDAI score as well as between LA PtGA and MDHAQ PtGA were high. The strength of association between LA PtGA and the physician measure were more modest. Given the absence of a statistically significant correlation between the MDHAQ PtGA and PGA, the data emphasizes the importance of the content of the questions being asked on patient instruments to ensure patients are evaluating lupus specific disease activity rather than overall health conditions. The latter may be misleading since it is less specifically focused on lupus per se. Understanding all the factors that influence patients' evaluation of their lupus disease activity is essential in creating an accurate SLE PtGA tool which can be used in clinical settings.

Serum Mediated Phagocytosis Of Necrotic Material By Polymorphonuclear Leukocytes May Be Used As a Tool To Predict Clinical Manifestations In Systemic Lupus Erythematosus. Michele Compagno, Birgitta Gullstrand, Andreas Jönsen, Lennart Truedsson, Gunnar Sturfelt and Anders A. Bengtsson. Lund University, Lund, Sweden.

Background/Purpose: Polymorphonuclear (PMNs) leukocytes with engulfed necrotic cell material (NCM), as formerly used in the LE-cell test, are frequently seen in SLE and associated to severe clinical manifestations.

The aim of this study was to investigate if phagocytosis of NCM could predict or was associated with specific clinical phenotypes and/or disease activity in patients affected by SLE.

Methods: Sixty-nine SLE-patients were followed longitudinally for a median time of 2.1 years. A total of 1074 serum samples were taken approximately every 60 days together with registration of an extensive set of clinical and laboratory variables. NCM was generated by heat treatment of mononuclear cells from healthy donors, and PMNs from healthy donors were isolated by density gradient centrifugation. Sera from SLE-patients were incubated with PMNs and NCM, and phagocytosis was assessed by flow cytometry. Association and prediction of relevant clinical phenotypes were evaluated with logistic regression and odds ratio (OR) and 95% confidence intervals (CI) were calculated.

Results: In serum samples from 46 of the 69 SLE patients, phagocytosis of NCM by PMNs was seen at least once and totally 417 times. Significant association between phagocytosis of NCM by PMNs was found with clinical phenotypes such as lupus nephritis (OR=1.7, CI=1.2–2.5), mucocutaneous involvement (OR=1.45, CI=1.1–1.9) and also with increased disease activity (SLEDAI score) (OR=1.41, CI=1.0–2.0). Arthritis, though, was inversely associated with phagocytosis of NCM (OR=0.51, CI= 0.3 –0.8). Furthermore, phagocytosis of NCM by PMNs could predict alopecia (OR=2.22, CI=1.3–3.7) while arthritis was inversely related (OR=0.38, CI=0.1–1.0).

Conclusion: In SLE, high capacity of serum mediated phagocytosis of NCM by PMNs is commonly seen. It is associated with disease activity and certain clinical phenotypes and was a predictor for alopecia and inversely related to arthritis. The assessment of phagocytosis of NCM by PMNs may be used as a complementary laboratory tool in management of SLE-patients.

Active Systemic Lupus Erythematosus: Cytokines and Soluble Tumor Necrosis Factor Receptors Response To Moderate/Intense Exercise. Luiz A. Perandini[1], Diego Sales-de-Oliveira[1], Suzana B.V. Mello[2], Niels O Camara[3], Fernanda R. Lima[1], Eduardo F. Borba[2], Eloisa Bonfa[2], Ana Lucia Sá-Pinto[1], Hamilton Roschel[4] and Bruno Gualano[5]. [1]University of Sao Paulo, Rheumatology Division, Sao Paulo, Brazil, [2]University of Sao Paulo, Rheumatology Division, São Paulo, Brazil, [3]University of Sao Paulo, Sao Paulo, Brazil, [4]Universidade de São Paulo, Faculdade de Educação Física e Esporte, São Paulo, Brazil, [5]University of Sao Paulo, School of Physical Education and Sport, Sao Paulo, Brazil.

Background/Purpose: Systemic lupus erythematosus (SLE) is a rheumatic autoimmune condition characterized by altered lipoprotein profile, physical dysfunction and increased risk of cardiovascular disease. Exercise is, therefore, a promising therapeutic strategy to counteract SLE disease outcomes. However, there are no studies evaluating exercise-induced inflammation in moderately active SLE patients, with some evidence of clinical safety in patients in remission. Therefore, the aim of the present study was to assess cytokines (INF-γ, IL-10, IL-6, TNF-α) and soluble TNF receptors (sTNFR) response to bouts of either moderate or intense exercises in patients with active SLE.

Methods: Eleven patients with active SLE (SLEDAI: 5.8±2.0) and 10 healthy controls with comparable age- and body mass index (BMI) performed 30 minutes of moderate and intense (~50% and ~70% of VO_2max, respectively) exercises in a treadmill. Serum cytokines (INF-γ, IL-10, IL-6, TNF-α) and sTNFR1 and sTNFR2 were assessed at baseline, immediately after the exercise, every 30 minutes of a 3-h recovery period and 24h after the end of exercise. Serum cytokines and sTNFRs were assessed by multiplex technique.

Results: SLE patients and controls had similar mean age (30.4 ± 4.5 vs. 30.6±5.2 yrs, $P=1.0$) and BMI (26.1±4.8 vs. 24.1±2.3 kg/m^2, $P=0.66$). At baseline, patients had a significant higher levels of IL-6 ($P=0.043$) and TNF-α ($P=0.020$) compared to controls. After moderate exercise, IL-6 decreased at the 60th (7.6±5.8 vs. 6.0±4.5 pg/mL; $P=0.035$) and 180th (7.6±5.8 vs. 5.2±3.9 pg/mL; $P=0.022$) minute of recovery compared to baseline whereas levels of IFN-γ, IL-10, TNF-α, sTNFR1, and sTNFR2 remained stable ($P>0.05$). Healthy controls showed solely a sTNFR1 decrease at 90th, 120th, 150th, 180th minute of exercise recovery ($P<0.05$) with no significant changes in the levels of IFN-γ, IL-10, TNF-α, IL-6, and sTNFR2 ($P>0.05$) when compared with baseline. In response to intense exercise, IL-6 at the end of exercise ($P=0.028$) and TNF-α at the 30th minute of recovery ($P=0.038$) increased transiently, followed by a decrease during late recovery [IL-6: 60th ($P=0.047$), 120th ($P=0.022$), and 180th ($P=0.028$) minute of recovery; TNF-α: 120th ($P=0.037$) minute of recovery]. IL-10 increased at the end of exercise ($P=0.034$) and at the 30th minute of recovery ($P=0.039$), whereas sTNFR1 decreased at the 180th minute of recovery ($P=0.05$) compared to baseline. IFN-γ and sTNFR2 did not change ($P>0.05$). Healthy controls showed no significant changes in IL-10, TNF-α, sTNFR1, and sTNFR2 after the intense exercise bout ($P>0.05$). INF-γ decreased at the end of the exercise ($P=0.05$), whereas IL-6 increased at the end of exercise ($P=0.028$) and at the 30th minute of recovery ($P=0.037$). Of note, cytokines and sTNFRs returned to baseline levels 24h after the end of the moderate and intense exercise bout ($P>0.05$) in active SLE and healthy controls.

Conclusion: In conclusion, the minor and transient change of cytokines and sTNFR with a complete recovery in 24h reinforces the safety of exercise in SLE patients with active disease. This finding opens a window of opportunity to develop interventions aimed to promote exercise in lupus patients in the course of treatment.

Anti-Nucleosome Antibodies As a Predictor Factor For Relapses In Clinically Quiescent Systemic Lupus Erythematosus: Results Of a Prospective Cohort Study. Dalia Sanchez-Mosco[1], Nadia Alejandra Gandarilla-Martinez[2], Nicte Selene Fajardo-Robledo[3], Valeria Diaz-Rizo[4], Soraya Amali Zavaleta-Muñiz[5], Miguel Huerta[6], Xochitl Trujillo[6], Arnulfo Nava[7], Ernesto German Cardona-Muñoz[8], Jose Francisco Muñoz-Valle[9], Jorge Ivan Gamez-Nava[10] and Laura Gonzalez-Lopez[2]. Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Jalisco, Mexico, [10]UMAE, Centro Médico Nacional de Occidente, IMSS; Doctorado en Farmacología, Universidad de Guadalajara, Jalisco, Mexico.

Background/Purpose: A significant number of studies have identified a correlation between anti-nucleosome antibodies (AN-ab) and disease activity in SLE; nevertheless, there is a lack of prospective cohort studies performed in clinically quiescent SLE directed to evaluate if these antibodies are associated with the increase in risk for relapses. The purpose of this study was to evaluate if serum anti-nucleosome antibodies (AN-ab) are predictor factor for the development of short-term relapses in patients with clinically quiescent systemic lupus erythematosus (SLE).

Methods: Patients with clinically quiescent SLE according to modified-SLEDAI (m-SLEDAI) and prednisone doses ≤15 mg/d were included. Baseline serum levels of (AN-ab), anti-DNA, C3 and C4 were determined. Patients were assessed at fixed times during 6 months by researchers blinded to serum levels of antibodies. A relapse was identified when the m-SLEDAI score increased to 3 or more points. Statistical analysis included Hazard risk (HR) and 95% confidence intervals (95%CI) for the development of relapses in presence of AN-ab. Survival curves were obtained for development of relapses in presence of different risk factors.

Results: Sixty-patients were followed. In patients with clinically quiescent SLE the frequency of AN-ab at the baseline was 15%. At six months 11/60 patients developed at least one relapse, 27% of the relapses achieved a m-SLEDAI store >8 points, involving mainly kidney or central nervous system. At 6-month was observed an increase in the development of relapses in patients with AN-ab at the baseline 4/9 (44%) compared with the relapses observed in SLE without these antibodies 7/51 (14%) HR=3.56 (IC95% 1.14–11.15, p=0.05). After the adjustment in the Cox regression analysis the presence of AN-ab and fewer time for inactive disease remained as predictors for relapses at short-term.

Conclusion: These results indicate that the identification of AN-ab is useful as marker to predict relapses in clinically quiescent patients in SLE, and this determination should be included in the clinical assessment of these patients in order to improve the tools for clinical decision-making.

Anti-Ribosomal P Antibody Has a Protective Role In The Development Of Chronic Kidney Disease In Patients With Lupus Nephritis. Kyung-Eun Lee[1], Dong-Jin Park[1], Tae-Jong Kim[2], Yong-Wook Park[1] and Shin-Seok Lee[2]. [1]Chonnam National University Medical School, Gwangju, South Korea, [2]Chonnam National University Medical School and Hospital, Gwangju, South Korea.

Background/Purpose: Anti-ribosomal P antibody (anti-P) in patients with systemic lupus erythematosus (SLE) is associated with neuropsychiatric manifestation. Of interest, recent studies have suggested that anti-P is a marker for renal flare and disease activity and is associated with renal histopathologic findings in patients with lupus nephritis (LN). However, the clinical relevance and prognostic value of anti-P in patients with LN are not well characterized. Therefore, we examined the association of the presence of anti-P with the identification of clinical, histopathologic, and prognostic values in Korean patients with biopsy-proven LN.

Methods: Seventy-nine patients with LN were included in this study based on the availability of kidney biopsy specimens. Sociodemographic, clinical, laboratory, and treatment-related data at the time of kidney biopsy and during follow-up were obtained by reviewing patients' charts. Renal biopsy specimens were reclassified according to the ISN-RPS classification by two renal pathologists blinded to the previous classification. Anti-P was measured by immunoblot assay at the time of renal biopsy. Kaplan-Meier analysis was performed to estimate the probability of progression to chronic kidney disease (CKD) according to the presence of anti-P.

Results: Twenty-eight (35.4%) of 79 patients were positive for anti-P. Patients with anti-P had an earlier age at LN onset (26.6 ± 10.1 versus 34.7 ± 12.1, P = 0.005), higher SLEDAI 2000 score (12.7 ± 4.2 versus 10.5 ± 4.8, P = 0.029), and higher *e*GFR level (129.0 ± 47.6 versus 102.2 ± 41.5, P = 0.005) at the time of renal biopsy than those without. The autoantibody profiles in patients with anti-P were not different from those without; however, anti-Sm antibodies were more common in patients with anti-P (71.4% versus 37.3%, P = 0.004). The renal histopathologic findings showed that patients with anti-P had less interstitial inflammation (67.9% versus 94.1%, P = 0.003) in the activity index and less glomerular sclerosis (21.4% versus 45.1%, P = 0.037), less tubular atrophy (42.9% versus 66.7%, P = 0.040), and less interstitial fibrosis (57.1% versus 78.4%, P = 0.046) in the chronicity index. In addition, anti-P positivity was significantly associated with lower chronicity scores (1.29 ± 1.24 versus 2.25 ± 1.63, P = 0.006). Although 13 of 51 (25.5%) patients without anti-P progressed to CKD after a median follow-up of 47 (6–108) months, only 1 of 28 (3.6%) patients with anti-P developed CKD (P = 0.015).

Conclusion: Our findings have shown that although anti-P is associated with an earlier age of onset and higher disease activity at the time of LN diagnosis, anti-P has a protective role in the development of CKD in patients with LN.

Assessment Of Worsening In Lupus Clinical Trials: Do The Endpoints Reflect Medical Judgement? Aikaterini Thanou[1], Eliza Chakravarty[1], Stan Kamp[2], Fredonna C. Carthen[1] and Joan T. Merrill[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma CIty, OK.

Background/Purpose: Discrimination between treatment and placebo is problematic in lupus trials. Recently, composite endpoints have evolved which define response by both improvement in baseline findings and lack of clinically significant deterioration in other features. The predominant endpoints, the SLE Responder Index (SRI) and BILAG-Based Composite Lupus Assessment (BICLA), do not preclude the designation of response if there is one new moderate organ score (BILAG B) vs baseline but do exclude **>/=2 new BILAG B scores**. The British Isles Lupus Assessment Group (BILAG) has reported a provisional definition of flares (1). Here a moderate flare is defined as **>/=2 B scores rated either new or worse.** We addressed this disparity in defining a moderate, clinically significant deterioration in a cohort study.

Methods: The BILAG 2004 index was prospectively scored at the time of 182 clinic encounters of 91 patients. Overall disease worsening was retrospectively judged by a clinician as either no worsening, mild, moderate, or severe flare.

		Physician-rated flares				
		No flare	Mild	Moderate	Severe	Total
BILAG 2004-defined flares (new or worse manifestations)	**No new/worse A or B**	**103**	**9**	**0**	**0**	**112**
	1 B	**1**	**20**	**16**	**2**	**39**
	>/= 2 B (wo A)	**0**	**2**	**11**	**3**	**16**
	2 B		2	9	2	
	>2 B			2	1	
	>/= 1 A	**2**	**0**	**5**	**8**	**15**
	No B	2		3	5	
	Plus 1B			2	1	
	Plus >/= 2 B				2	
	Total	**106**	**31**	**32**	**13**	**182**

		Physician-rated flares				
		No flare	Mild	Moderate	Severe	Total
BICLA and SRI-defined Worsening (only new scores counted)	**No new A or B**	**106**	**21**	**17**	**5**	**149**
	1 B	**0**	**9**	**10**	**1**	**20**
	>/= 2 B (wo A)	**0**	**1**	**3**	**4**	**8**
	2 B		1	2	3	
	>2 B			1	1	
	>/= 1 A	**0**	**0**	**2**	**3**	**5**
	No B			2	0	
	Plus 1B				1	
	Plus >/=2 B				2	
	Total	**106**	**31**	**32**	**13**	**182**

Results: Flares receiving one new BILAG B score or one new or worse B were usually considered mild by the clinician, confirming the approach by both constructs to discount increased disease at B level in only one organ as a moderate flare. Using the clinician's judgement as a standard to distinguish moderate flares, the sensitivity of the BILAG cutoff of >/= 2 B "new or worse" (detecting all flares that were as severe or more severe than the cutoff) was 60.0% as opposed to 26.7% for the SRI/BICLA definition of >/= 2 "new" B scores. Specificities were 97.1% and 99.3% respectively.

Conclusion: Whether worsening is defined by "new" or "new or worse" moderate disease, one BILAG B in isolation does not usually represent clinically significant deterioration by clinical judgement. Limiting the definition of moderate deterioration to 2 "new" B scores, which is now common practice in clinical trials for lupus, is a very insensitive measure for the degree of clinical deterioration considered moderate (or worse) by a physician. The concept of moderate flare defined by the BILAG group (>/= 2 "new or worse" B scores) might be a more helpful approach to define a threshold of moderate, clinically significant deterioration in composite endpoints for SLE trials.

Can Biomarkers Provide An Objective Standard Against Which To Assess Lupus Clinical Endpoint Measures? Aikaterini Thanou[1], Melissa E. Munroe[1], Stan Kamp[2], Joel M. Guthridge[1], Judith A. James[3] and Joan T. Merrill[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma CIty, OK, [3]Oklahoma Medical Research Foundation and University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background/Purpose: Despite the heterogeneity of SLE, specific pathways of immune dysregulation characterize significant subsets of patients. We examined cytokines reflecting IL6-TH17 pathology in lupus as an objective standard to test performance of clinical outcome measures.

Methods: 91 patients, all with active disease at baseline (SLEDAI >/= 6) participated in two visits at which BILAG and SLEDAI were prospectively scored. A clinician retrospectively assessed the second visit as overall worse, the same, or improved. Cytokines were measured by xmap multiplex bead-based assay.

Results: Using physician-rated improvement (PRI), 68 patients improved and 23 were same or worse at follow up. Cytokine changes were evaluated in patients who did or did not meet response criteria of PRI, SRI (SLE Responder Index) and BICLA (BILAG-based Composite Lupus Assessment). Of patients with detectable IL6 at baseline and/or follow up (IL6+) (n=51), those who improved by PRI, SRI or BICLA had a significant drop in IL6, not observed in patients who did not improve (Table 1). IL21 and IL23 decreased in those who improved by PRI, but did not track with SRI or BICLA. IL17 was only detected in 3 patients and could not be evaluated.

Table 1. P values of cytokine changes in patients with detectable cytokine levels at baseline and/or follow up

IL6 (n = 51)	PRI	SRI	BICLA	IL21 (n = 57)	PRI	SRI	BICLA	IL23 (n = 24)	PRI	SRI	BICLA
Endpoint met	n = 39 **p = 0.010**	n = 42 **p = 0.032**	n = 32 **p = 0.021**	Endpoint met	n = 45 **p = 0.008**	n = 43 **p = 0.042**	n = 41 p = 0.084	Endpoint met	n = 18 **p = 0.048**	n = 16 p = 0.252	n = 18 p = 0.08
Endpoint not met	n = 12 p = 0.569	n = 9 p = 0.82	n = 19 p = 0.141	Endpoint not met	n = 12 p = 0.266	n = 14 **p = 0.017**	n = 16 **p = 0.006**	Endpoint not met	n = 6 p = 0.625	n = 8 p = 0.195	n = 6 p = 0.313

IL21 and IL23 were detectable when IL6 was, both at baseline ($p<0.001$ and $p=0.002$ respectively) and at follow up ($p=0.032$ and $p=0.006$). In IL6+/IL21+ (double positive) patients (n=35), IL21 tracked well with IL6 ($p=0.0028$), driven by the patients who improved by PRI (n=26) ($p=0085$).

In IL6+ patients the PRI was tested as a standard to compare performance of SRI and BICLA (sensitivities 94.9% and 74.4%, specificities 58.3% and 75%). Using decrease in IL6 as an objective standard of improvement, sensitivities of SRI vs BICLA were 85.2% vs 66.7% and specificities were 35.9% vs 39.1%.

Conclusion: Decreases in IL6, IL21 and IL23 reflected improvements by SRI, BICLA and clinical judgement. IL21 and IL23 were detectable when IL6 was, consistent with expected relatedness in an IL6-TH17 pathway. The SRI was more sensitive than and as specific as the BICLA in detecting objective biologic change in this subset of IL6 producing patients. Low specificities underscore the multiple pathways of lupus pathology, but we speculate that a range of predictable cytokine changes in definable patient subsets could be formulated into objective standards for testing clinical outcome instruments.

Predictive Markers Of Preeclampsia During Pregnancy In Patients With Systemic Erithematosus LUPUS and / Or Antiphospholipid Syndrome. Esther Rodriguez-Almaraz[1], Elena Gonzalo-Gil[1], Ignacio Herráiz[2], Paula I Gómez-Arriaga[2], Paloma Vallejo[2], Elena A López-Jiménez[3], María Galindo Izquierdo[1] and Alberto Galindo Izquierdo[2]. [1]Department of Rheumatology. Hospital Universitario 12 de Octubre, Madrid, Spain, [2]Fetal Medicine Unit, Department of Obstetrics and Gynecology. Hospital Universitario 12 de Octubre., Madrid, Spain, [3]Department of Biochemistry. Hospital Universitario 12 de Octubre., Madrid, Spain.

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have an increased risk of preeclampsia (PE), which can be confused with lupus nephritis. Our objective was to evaluate the behaviour of mean pulsatility index in the uterine arteries (mPI-UtA), sFlt-1/PlGF ratio and endoglin levels in pregnant women with SLE and/or antiphospholipd syndrome (APS).

Methods: Pregnant women with SLE and/or APS attending our high-risk pregnancy unit were consecutively included. Clinical, analytical and sonographic evaluations were conducted at baseline, at different weeks (wk) of gestational age (10–13, 22, 28, 32), at delivery and postpartum. We collected demographic data, information regarding cardiovascular risk factors and toxic habits, the underlying disease, obstetrical history, last SLE flare, previous and current treatments, as well as usual blood tests including complement and a-dsDNA antibodies levels. Levels of sFlt-1, PlGF, and maternal serum endoglin were quantified by ELISA. PE and its severity were diagnosed according with the ISSSHP definition. Intrauterine growth restriction (IUGR) was defined as a small for gestational age newborn together with a Doppler PI in the umbilical artery above the 95th percentile.

Results: 34 consecutive patients were recruited, of whom 29 had SLE (4 with secondary APS), 3 had primary APS and 2 had antiphospholipid antibodies but without clinical criteria for APS. Five patients have not delivered at the time of writing and we missed 1 patient in the follow-up. Ten patients (36%) suffered an early pregnancy loss (<12 wks), being most frequent among patients with previous APS diagnosis ($p=0.03$),

high blood pressure ($p = 0.01$), arterial thrombosis related to APS ($p = 0.03$), and the presence of lupus anticoagulant ($p = 0.004$). In uneventful pregnancies the values of the studied markers were within normal limits for the gestational age throughout pregnancy. One SLE patient (5.6%) had mild PE after 32 wk together with IUGR. We observed a relationship between IUGR and higher SLEDAI both before and throughout pregnancy (baseline, $p = 0.01$; 10–13 wks, $p = 0.04$; 22 wk, $p = 0.02$; 28 wk, $p = 0.05$; 32 wk, $p = 0.01$). IUGR was also associated with higher mPI-UtA at 22 wk ($p = 0.05$). Endoglin levels (14.6 ng/ml vs <7.9, 26.9 vs <7.2, 49 vs <13.6, at 22 wk, 28 wk and 32 wk, respectively) and ratio curve sFlt1/PlGF (17 vs 14.8, 36.6 vs 16.9, 170.7 vs 86.4 at 22 wk, 28 wk and 32 wk, respectively) behaved abnormal in this case. Among remaining patients, 1 patient with SLE (5.6%) developed HBP before delivery, 1 SLE patient had premature rupture of membranes at term, and 3 SLE patients had a preterm delivery at 28, 32 and 36 wks, respectively. 12 patients (67%) had a mild exacerbation of SLE, and only 1 (8%) had moderate activity requiring high doses of corticosteroids and azathioprine.

Conclusion: Our preliminary results indicate that mPI-UtA, sFlt1/PlGF ratio and endoglin levels behave in patients with SLE and/or APS essentially as in the general population. Moreover, these markers may be useful to predict the onset of PE in women with SLE and to make the differential diagnosis between PE and an episode of lupus activity.

2551

Pharmacodynamics and Predictive Biomarkers In Patients Treated With Atacicept: Data From The APRIL-SLE Trial. David A. Isenberg[1], David Wofsy[2], Yong Li[3], Daiana Licu[4], Stephen D. Wax[3], Caroline Gordon[5] and Claudia Pena Rossi[4]. [1]University College London, London, United Kingdom, [2]University of California San Francisco and NIAID Autoimmunity Centers of Excellence, San Francisco, CA, [3]EMD Serono, Rockland, MA, [4]Merck Serono S.A., Geneva, Switzerland, [5]University of Birmingham, Birmingham, United Kingdom.

Background/Purpose: Atacicept is a fusion protein that inhibits B cell stimulating factors BLyS and APRIL. We examined the pharmacodynamic (PD) effects of atacicept in patients with SLE. We also investigated whether PD markers have the potential to function as predictors of flare and clinical response to atacicept.

Methods: APRIL-SLE was a double-blind, placebo-controlled study of subjects with active SLE that had become inactive during a 12-week course of tapered corticosteroids. Subjects were then randomized 1:1:1 to receive placebo or atacicept 75 or 150 mg twice weekly for 4 weeks, then weekly for 48 weeks. The primary outcome measure was the percent of subjects experiencing an SLE flare (BILAG A and/or B) during a 52-week treatment period. Patients also were followed during a 24-week follow-up period. PD analyses were conducted on the treatment completer population. Analyses of BLyS and APRIL levels as potential predictive biomarkers were performed on the potential completer population. Efficacy and safety results are reported separately.

Results: Atacicept induced substantial changes in PD and disease-related markers, including reductions in Ig levels, autoantibody levels, and both naïve and memory B cells, as well as increases in complement levels (Table). Except for memory B cells, which continued to decline, these effects lessened during the follow-up period but did not fully return to baseline over 24 weeks. The atacicept treatment effect (reduction in flares vs placebo) was observed in subjects with BLyS or APRIL levels ≥median, but not subjects with levels < median (except in the atacicept 150 mg arm). The difference was most pronounced in patients with both baseline BLyS and APRIL ≥median, with flare rates of 76, 53 and 23% in the placebo, 75 mg, and 150 mg groups, respectively. Atacicept-treated patients with the greatest absolute decrease in IgG experienced the fewest new flares (37.2% for patients in the bottom tertile [<–4 g/L] vs 61.5% for the upper tertile [≥–1.5 g/L]). This pattern was also observed for changes in IgM (47.5 vs 60.0%) and for naïve B cells (38.2 vs 57.1%). The incidence of infection was comparable regardless of BLyS or APRIL level at baseline, or the degree of decline in IgG or IgM levels.

Table. Median percent change from baseline; Treatment Completer population

	Placebo (n = 111)		Atacicept 75 mg (n = 112)		Atacicept 150 mg (n = 62)	
	Wk 52	24-wk FU	Wk 52	24-wk FU	Wk 52	24-wk FU
Total IgG	3.23	3.51	−30.40	−7.01	−37.62	−9.24
Total IgA	2.12	1.16	−52.61	−16.22	−57.89	−21.96
Total IgM	−1.44	−3.13	−65.74	−29.27	−68.75	−24.04
Naïve B cells*	−9.00	−5.63	−80.12	−66.67	−81.47	−66.67
Memory B cells*	−2.17	9.30	−12.50	−50.00	−28.21	−40.00
Plasma cells*	0.00	−34.85	−61.58	−55.00	−67.08	0.00
	Wk 52	**12-wk FU**	**Wk 52**	**12-wk FU**	**Wk 52**	**12-wk FU**
Anti-dsDNA (subjects +ve at screening)†	**13.89**	**41.42**	**−31.46**	**−20.85**	**−37.86**	**−11.78**
C3 (subj > normal at screening)‡	4.13	3.56	7.15	3.01	15.38	5.43
C4 (subj > normal at screening)§	−0.44	0.00	42.71	18.18	49.50	48.94

* Flow cytometry population: placebo, n = 37; atacicept 75 mg, n = 38; atacicept 150 mg, n = 25; †Anti-dsDNA > = 30 IU/ml; placebo, n = 71; atacicept 75 mg, n = 62; atacicept 150 mg, n = 43; ‡C3 <0.9 g/L; placebo, n = 33; atacicept 75 mg, n = 53; atacicept 150 mg, n = 28; §C4 <0.1 g/L; placebo, n = 28; atacicept 75 mg, n = 32; atacicept 150 mg, n = 17; Wk = week; FU = follow-up; IgG = immunoglobulin G; IgA = immunoglobulin A; IgM = immunoglobulin M.

Conclusion: Atacicept caused declines in IgG, IgA and IgM, as well as naïve and memory B cells. With the exception of memory B cells, these levels returned towards baseline after therapy. Atacicept also had favorable effects on anti-dsDNA and complement levels. The exploratory *post-hoc* analysis of potential predictive biomarkers identified a subgroup of patients with higher BLyS and APRIL levels at baseline who were more likely to benefit from treatment. In addition, patients with the largest decrease in Ig levels and/or naïve B cells demonstrated a greater clinical response. Further studies are required to clarify the associations between biomarkers and clinical response to atacicept.

Predictive Significance Of ANTI-Prothrombin Antibodies For Second and Third Trimester Obstetric Complications In Patients With Systemic LUPUS Erythematosus and ANTI-Phospholipid Syndrome. Marta Mosca[1], Chiara Tani[1], Martina Fabris[2], Francesca Strigini[3], Linda Carli[4], Sabrina Vagnani[1], Rosaria Talarico[4], Chiara Baldini[4], Alessandra Della Rossa[4], Elio Tonutti[5] and Stefano Bombardieri[1]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Institute of Clinical Pathology, Udine, Italy, [3]University of Pisa, Pisa, Italy, [4]Rheumatology Unit, Pisa, Italy, [5]Santa Maria Hospital, Udine, Italy.

Background/Purpose: Anti-prothrombin antibodies (aPT) either alone or in association with other anti-phospholipid antibodies have been associated with an increased risk of thrombosis as well as of adverse obstetric outcomes particularly, recurrent early miscarriages. To assess whether anti-prothrombin antibodies have a predictive significance for the occurrence of late obstetric complications and maternal events in patients with SLE and APS.

Methods: Sera from pregnant patients with SLE and APS collected during the first trimester of pregnancy were examined for the presence of anti-prothrombin antibodies (aPT), anticardiolipin antibodies (aCL), anti-B2GPI antibodies, Lupus anticoagulant (LA). Pregnancies were prospectively followed. The following obstetric complications were considered: preterm delivery, pre-eclampsia, eclampsia, intrauterine growth retardation, intrauterine fetal death. In addition the occurrence of maternal thrombotic complications was recorded.

Results: Seventy six pregnancies in 60 patients (18 APS and 52 SLE) with a duration >10 weeks were included in the analysis. Anti-phospholipid antibodies were positive in 26 patients (aCL 25, LA 17, aPT 16, anti- B2GPI 6). Pregnancy outcomes are reported in the table 1.

A significant correlation was observed between the presence of anti-prothrombin antibodies and the occurrence of obstetric complications ($p<0.05$). The positivity of anti-prothrombin antibodies in addition to either positive aCL, anti-B2GPI and/or LA increased the risk of developing late obstetric complications ($p< 0.001$). No correlations were observed between the presence of anti-prothrombin antibodies alone or multiple anti-phospholipid antibodies and the occurrence of maternal thrombotic events.

	SLE	APS	Whole group
IUFD	2	3	5
Perinatal death	0	1	1
Preterm delivery	17	12	29
IUGR	7	1	8
Pre-eclampsia	7	4	11
HELLP	0	2	2
Maternal thrombotic manifestations	2	3	5

Conclusion: The presence of aPT antibodies appears associated with an increased risk for late obstetric complications in SLE and APS and therefore their assessment is suggested in these patients at the beginning of pregnancy.

2553

The Clinical Value Of Testing For Aphl, a New ELISA Kit With a Unique Phospholipid Mixture In Patients With Systemic Lupus Erythematosus (SLE). Savino Sciascia[1], Giovanni Sanna[2], Veronica Murru[3], Munther A. Khamashta[3] and Maria Laura Bertolaccini[3]. [1]Centro di Immunopatologia e Documentazione su Malattie rare, Torino, Italy, [2]Louise Coote Lupus Unit, St. Thomas' Hospital, London, United Kingdom, [3]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom.

Background/Purpose: Antibodies directed to APhL (a mixture of phospholipids) have been reported to predict APS more reliably than aCL tests. We designed this study to evaluate the performance characteristics of the IgG and IgM APhL ELISA, in an attempt to establish the diagnostic utility of these new aPL antibody tests in a wide cohort of SLE patients.

Methods: This study included 158 patients (152 women, mean age 41.8±11.6 years, mean disease duration 11.7±7.8years), all fulfilling the 1982 criteria for SLE. All the patients were tested for the routinely used aPL, including LA, aCL and ab2GPI. Data were compared with that obtained by the APhL ELISA (Louisville APL Diagnostic, Inc, Louisville, KY, USA). The diagnostic accuracy for each test was assessed by ROC and their area under the curve (AUC) analysis.

Results: APhL were found in 77% of the patients. IgG and IgM APhL were more frequently found along with routine aPL than in isolation ($p=0.007$ and $p=0.04$, respectively). APhL were more frequently found in patients with definite APS than in those without ($p=0.001$). aPhL were not only more frequent in patients with thrombosis than in those without ($p=0.02$) but their titres were also significantly higher in thrombosis, when compared to those without ($p=0.02$). APhL showed an OR for thrombosis of 1.46 [95%CI1.08–3.19] (AUC 0.533). Twenty-seven patients (17.09%) were positive for isolated APhL. Of those 8 (29.6%) had a thrombotic event (6 arterial, 1 venous, 1 both). No associations were found between the presence of APhL and pregnancy loss. The presence of aPhL did not correlate with that of any of the other aPL tested. Multivariate analysis confirmed the associations with APS, particularly with thrombosis.

Conclusion: APhL are frequent in patients with SLE. Their presence is associated with thrombosis, making these antibodies a novel marker for APS. The finding of isolated APhL in thrombosis (particularly arterial) deserves further investigation.

In Vitro Fertilization In Systemic Lupus Erythematosus and Antiphospholipid Syndrome: A Series Of 82 Cycles. Pauline Orquevaux[1], Agathe Masseau[2], Véronique le Guern[3], Vanessa Gayet[3], Danièle Vauthier-Brouzes[4], Du Boutin[5], Bertrand Wechsler[6], Nathalie Morel[7], Jean Loup Pennaforte[1], Jean-Charles Piette[8] and Nathalie Costedoat-Chalumeau[9]. [1]CHU Reims, Reims, France, [2]Nantes University Hospital, Nantes, France, [3]Cochin Hospital, Paris, France, [4]Pitié Salpétrière Hospital, Paris, France, [5]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France, [6]Hôpital Pitié-Salpêtrière, AP-HP, UPMC Univ Paris 06 & French National Reference Center For Systemic Lupus and Antiphospholipid Syndrome, Paris, France, [7]COCHIN, Paris, France, [8]CHU Pitié-Salpêtrière, Paris, France, [9]Hopital Cochin, Paris, France.

Background/Purpose: Patients with systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) undergoing in vitro fertilization (IVF) are at increased risk of both hormone-associated flare and thrombosis. The literature is scarce with two series of IVF performed in 19 and 21 patients respectively [1; 2]. We report our experience with in vitro fertilization in 34 women with SLE and/or APS.

Methods: Retrospective study of women followed in four French centers (Pitié-Salpêtrière, Cochin, Nantes and Reims) who (1) had a diagnosis of SLE (ACR criteria) and/or APS (Sydney criteria), and (2) underwent at least one cycle of IVF between 2003 and 2012.

Results: The diagnosis of the 34 included women was: SLE alone (n=9, including one case diagnosed during the IVF), SLE associated with antiphospholipid antibodies (n=9), SLE associated with APS (n=5), and primary APS (n=11, including one case diagnosed during the IVF).

These women underwent 82 cycles of IVF. Underlying causes of infertility were of female origin (42%), male origin (33%), mixed (21%) or unexplained (4%). There was no premature ovarian insufficiency due to cyclophosphamide.

Median age at IVF was 34.7 years (range, 22–45). Median number of IVF cycles was 2.4 (1–7). 72 cycles (88%) of IVF were allowed and supervised by an internist. Women were treated with hydroxychloroquine (52%), steroids (61%), aspirin (79%) and/or low-molecular-weight heparin (67%). Ovulation induction protocols varied according to the centers.

Eight IVF cycles (10%) resulted in complications: SLE flare in 4 (three joint flares and one lupus enteritis) and thrombosis in 4. Interestingly, one SLE flare occurred in a patient with unknown SLE and 2 flares and 2 thromboses were explained by poor adherence to treatment. No ovarian hyperstimulation syndrome was observed.

24 pregnancies (29%) occurred, including four twin pregnancies, and lead to 22 live births (92% of pregnancies), 1 miscarriage and one medical termination for trisomy 13.

In addition, during the follow-up, eight spontaneous pregnancies occurred. Eventually, a total of 24 patients (70%) delivered at least one healthy child.

Conclusion: SLE flare and thrombosis were low (10%) and were often explained by poor adherence to treatment or absence of treatment. These preliminary results confirm that IVF can be successfully performed in SLE and/or APS women providing they have adequate treatment. The new protocols using GnRH antagonists may further decrease those risks.

Development and Validation Of a Questionnaire To Screen For The Presence Of Autoimmune Disease. Alan Boroway[1], Aileen M. Davis[2], Carolina Landolt-Marticorena[1] and Joan E. Wither[2]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Toronto Western Research Institute, Toronto Western Hospital, University of Toronto, Toronto, ON.

Background/Purpose: Healthy family members of patients with systemic autoimmune rheumatic diseases (SARDs) are at higher risk of developing autoimmune disease than the general population. It is postulated that serological changes precede the onset of clinical autoimmune disease in affected individuals. Our aim is to determine if these serological changes are present in the relatives of patients with SARD, and if so, whether they can be used to predict the development of autoimmune disease. This would permit introduction of treatment early in the disease course thereby preventing damage. We have previously obtained blood for serologic testing and performed a cellular analysis on the first-degree relatives of patients with systemic lupus erythematosus. At the time of blood draw, a questionnaire was administered seeking evidence of autoimmune disease. In total 893 medical histories were obtained via questionnaire, with 178 reporting an autoimmune disease. However, less than 50% were able to be confirmed as accurate (Cooper et al, J Rheumatol. 2008 35 (10): 2001–4). In this study, we developed a validated questionnaire that more accurately reflects the presence of autoimmune disease, that can be used for a follow-up of the first-degree relatives of patients with SARDs.

Methods: A questionnaire was developed in consultation with an expert for distribution to patients for validation. In contrast to our previous questionnaire it incorporates questions that have been developed to confirm the

presence of disease through questions regarding specific clinical manifestions of disease and/or treatment. After obtaining informed consent, the questionnaire was administered to patients with each autoimmune disease of interest, with those having other autoimmune diseases or osteoarthritis serving as controls. Accuracy at identifying the presence or absence of a particular autoimmune disease was confirmed against data from patients' medical records. False positive (FP) and false negative (FN) rates were compared for each autoimmune disease.

Results: 63 patients were consented and completed the questionnaire, including at least 5 patients with each autoimmune disease of interest. Results are shown below:

Comparison of Accuracy of Original Questionnaire (Cooper et al) and New Questionnaire

	Cooper et al Questionnaire FP Rate N *(%)*	Questionnaire FP Rate (Screening Question) N *(%)*	Questionnaire FP Rate (Confirmatory Questions) N *(%)*	Questionnaire FN Rate (Confirmatory Questions) N *(%)*
Systemic Lupus Erythematosus	9/24 *(32.5%)*	0/18 *(0%)*	—	—
Rheumatoid Arthritis	45/60 *(75%)*	6/12 *(50%)*	1/12 *(8.3%)*	—
Systemic Sclerosis	1/4 *(25%)*	0/13 *(0%)*	—	—
Polymyositis/Dermatomyositis	2/2 *(100%)*	6/10 *(60%)*	1/10 *(10%)*	—
Sjogren's Syndrome	3/9 *(33.3%)*	3/9 *(33.3%)*	1/9 *(11.1%)*	—
Antiphospholipid Syndrome	4/5 *(80%)*	2/5 *(40%)*	1/5 *(20%)*	—
Hemolytic Anemia	12/13 *(92.3%)*	2/7 *(28.6%)*	2/7 *(28.6%)*	4/56 *(7.1%)*
Multiple Sclerosis	2/4 *(50%)*	1/6 *(16.7%)*	1/6 *(16.7%)*	1/57 *(1.8%)*
Thyroid Disease	45/96 *(46.9%)*	5/12 *(41.7%)*	0/12 *(0%)*	—
Type 1 Diabetes	N/A	0/10 *(0%)*	—	—
Idiopathic Thrombocytopenic Purpura	N/A	3/7 *(43%)*	1/7 *(14.3%)*	1/56 *(1.8%)*

There were no FP results in the general screening questions of both SLE and Type 1 DM. In those SARDs that had FP responses to the original screening question, accuracy was was improved in many by the confirmatory questions. In general FN rates were low.

Conclusion: The new questionnaire improved overall accuracy over our original questionniare in screening for most autoimmune diseases and can be used to more accurately identify family members with these conditions.

Concordance Of Indirect Immunofluorescence and Multiplex Immunoassay For Measurement Of Antinuclear Antibodies. Caroline D'Souza[1], Donald L. Kimpel[1], Walter Oliveira[2] and Janet E. Lewis[1]. [1]University of Virginia School of Medicine, Charlottesville, VA, [2]University of Virginia, Department of Pathology, Medical Laboratories, Charlottesville, VA.

Background/Purpose: The indirect immunofluorescence assay (IIF) is the gold standard for ANA testing. However, many laboratories now use multiplex assay as an ANA screening test. Multiplex ANA assay tests for a limited number of autoantibodies (antibodies to dsDNA, chromatin, ribosomal P, SSA-52, SSA-60, SSB, Sm, SmRNP, RNP-A, RNP-68, Scl-70, Jo-1, centromere B) while IIF allows the detection of antibodies to a much larger number of autoantigens. There is a concern that reliance on multiplex analysis as a screening test might lead to cases where a positive ANA, and hence a diagnosis, is missed. Our study aims to evaluate the concordance between IIF and multiplex assay for ANA screening.

Methods: ANA is tested by IIF at UVA. Samples are considered positive at a titer of 1:80. Thirteen specific autoantibodies are tested by an automated multiplex platform. For this study, samples with at least one autoantibody positive on multiplex analysis were considered ANA + by multiplex. A total of 545 blood samples sent to the UVA lab between June and November 2012 to be tested for ANA and specific autoantibodies were analyzed.

Results: About 25.3% are ANA positive by IIF and 24.7% are ANA positive by multiplex. Only 13.8% of samples are positive by both methods (concordant). Kappa coefficient of agreement is 0.39 (fair). The most common antibody in all multiplex+ samples is that to RNP followed by SSA and dsDNA. In the subset of multiplex + samples that were IIF negative, RNP was the most common antibody (40%). The most common pattern overall was homogenous. When the threshold for a positive ANA by IIF was increased to 1:160, the number of total samples that were IIF positive is reduced as expected (20.4%). Kappa coefficient of agreement was improved only to a value of 0.428 (moderate). A large number (74%) of the low titer (1:80) IFA assays were also multiplex negative. The majority (84.7%) of strongly positive IIF samples (1:640 and above) were also multiplex positive. However, 9 of the 59 high titer IIF samples were multiplex negative.

		Multiplex	
I		**−**	**+**
I	**−**	**347 (63.6%)**	**60 (11%)**
F	**+**	**63 (11.5%)**	**75 (13.8%)**

Fig 1: Concordance chart for ANA tested by IIF and Multiplex with a positive cutoff for IIF at a titer of 1:80.

Conclusion: We found a high rate of ANA positivity by both IIF and multiplex. Most of the discordant samples were either low titer IIF or had autoantibodies that might be less specific like anti-RNP. The agreement between the two tests as measured by a kappa co-efficient was only fair at a cutoff of 1:80 and improved to moderate at 1:160. This suggests that there is at best moderate agreement between the two tests. Also, in some cases, multiplex did not identify samples with high titer ANAs. We conclude that there is still a role for IIF to be used for ANA screening in patients suspected to have an autoimmune disease.

Fluctuations In sVCAM-1 and Adiponectin Mirror Fluctuations In Disease Activity In Lupus, But Cannot Be Use To Accurately Predict Impending Changes In Disease State. Carolina landolt-Marticorena[1], Stephenie Prokopec[2], Stacey Morrison[3], Heather Reich[3], James Scholey[3], Dafna Gladman[4], Murray B. Urowitz[4], Paul Boutros[2], Paul R. Fortin[5] and Joan E. Wither[6]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Ontario Institute for Cancer Research, Toronto, ON, [3]The Toronto Western Hospital, Toronto, ON, [4]University of Toronto, Toronto Western Hospital, Toronto, ON, [5]University of Laval, Quebec, QC, [6]Toronto Western Research Institute, Toronto Western Hospital, University of Toronto, Toronto, ON.

Background/Purpose: Previous reports have identified a number of pro-inflammatory cyto/chemokines as candidate activity-specific SLE biomarkers. In our preliminary studies we found that out of a panel of 20 common cyto/chemokines examined, only MCP-1, IP-10, sVCAM and adiponectin were preferentially elevated in patients with active as compared to inactive disease. In this study, the relationship between fluctuations in disease activity and these four cyto/chemokines was examined to determine their utility in predicting fluctuations (exacerbation or improvement) in disease activity.

Methods: SLE patients (n = 55) satisfying 4 or more ACR criteria were recruited and followed over a 14-month period with a minimum of 3 clinical and biochemical assessments over that time. The plasma concentration of the 4 analytes was determined by Luminex assay. Disease activity was determined by the SLEDAI-2K (S-2K). A modified SLEDAI-2K (mS-2K) was calculated by subtracting the contribution of anti-dsDNA antibodies and complement (C3) from the global score. Variation between visits was examined with a change in S-2K of $\pm$ 4 between two consecutive visits deemed a clinically significant event. Event classification was compared with analyte levels using a one-way ANOVA followed by visualization. The ability of analyte levels to forecast disease activity was evaluated using a leave-one-out cross-validation analysis.

Results: Analysis of all available assessments showed a statistically significant positive correlation between adiponectin (Spearman's rho (r) = 0.25, $p < 1 \times 10^{-3}$), VCAM (r = 0.24, $p < 1 \times 10^{-3}$) and IP-10 (r = 0.21, $p = 2 \times 10^{-3}$) and global disease activity as defined by the mS-2K. These correlations were comparable to the performance of traditional biomarkers; anti-dsDNA antibodies (r = 0.22, $p < 1 \times 10^{-3}$) and complement (C3, r = −0.24, $p < 1 \times 10^{-3}$). The relationship between meaningful fluctuations in disease status between consecutive visits and biomarker levels was examined. Changes in disease state were exclusively reflected in changes in sVCAM-1 ($p = 0.04$) and adiponectin ($p = 0.05$). Both traditional biomarkers (anti-dsDNA antibodies and C3) and other tested cytokines (MCP-1, IP-10) did not reflect fluctuations in disease state. The ability of these biomarkers to predict a clinically meaningful change in disease status within 3 to 6 months of assessment was also assessed. In our analysis < 10% of events were accurately predicted.

Conclusion: These results suggest that despite their early promise, and evidence that some of the selected cyto/chemokines fluctuate with disease activity, none of the analytes examined could accurately forecast clinically significant changes in disease state.

Bone Morphogenic Protein Receptor 2 (BMPR2) Gene Mutations Are Associated To The Development Of Isolated Pulmonary Arterial Hypertension (PAH) In Systemic Sclerosis (SSc) Patients. Tatiana Sofia Rodriguez-Reyna[1], Jose Luis Hernandez-Oropeza[1], Tomas Rene Pulido-Zamudio[2], Felipe Massó[2], Jessica Gutierrez-Manjarrez[1], Alexandra Rueda de Leon-Aguirre[1], Julio Sandoval-Zarate[2] and Carlos Rodriguez-Osorio[1]. [1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico, [2]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico.

Background/Purpose: Isolated pulmonary arterial hypertension (PAH) secondary to Systemic Sclerosis (SSc) is a severe life-threatening complication. Several pathogenic pathways have been implicated in its development. Bone morphogenic protein receptor 2 (BMPR2) is a protein of the TGF-beta receptor superfamily; mutations in this gene seem to be implicated in the proliferation of pulmonary artery smooth muscle cells, a major component of pulmonary arteriolar remodeling in PAH, and they have been associated to the susceptibility to develop idiopathic and familial PAH; exon 5 has higher frequency of mutations according to previous analyses. The aim of this study was to evaluate if BMPR2 gene exon 5 mutations are associated to isolated PAH in Mexican Mestizo SSc patients.

Methods: DNA samples from 38 Mexican Mestizo SSc patients with isolated PAH (mean resting pulmonary artery pressure (PAP) >25 mmHg, pulmonary wedge pressure < 15 mmHg and pulmonary vascular resistance > 3 Wood units by right side catheterization; or systolic PAP >40 mmHg, tricuspid annular plane systolic excursion <20 mmHg and dilatation and hypertrophy of right ventricle by transthoracic echocardiogram; patients were also required to have no or minimal interstitial lung disease by computed tomography) and 38 Mexican Mestizo SSc patients without PAH, matched by SSc subtype, age (+/− 5 years), gender, time of evolution of the disease and SSc-associated autoantibody were analyzed. High resolution melting analysis (HRMA) of exon 5 of the BMPR2 gene was performed in previously amplified DNA (sense primer: 5′TCA TGC TAT TCT GCA TTC ATC.3′, antisense primer: 5′CAG GTC TAG TAT CAC AGT AGA.3′). Aberrant curves were considered as positive for mutation in the exon 5 of the BMPR2 gene. Severity of the organ involvement was evaluated using the Medsger severity scale. Statistical analysis was performed using SPSS v.19 and Epi-Info 7.0. Chi square was used to compare mutation frequencies between groups; Student's t test and Wilcoxon rank test were used to compare numeric variables. Values were considered significant when two-tailed p values were <0.05.

Results: Mean age was 50 years, mean time of SSc evolution was 12.25 years, 80% of patients were female, with no differences between PAH and non-PAH patients. Mean PAP was 57 mmHg in PAH-SSc patients and 25 mmHg in non-PAH-SSc patients ($p<0.001$); BMPR2 gene exon 5 mutations were detected in 7 (18%) of PAH-SSc patients and in 1 (3%) non-PAH-SSc patient ($p=0.001$, OR: 31, 95% CI 5.1–1263). From the 7 patients with PAH that had a mutation, 6 were female, 6 had limited cutaneous SSc, 6 had severe vascular involvement (digital ulcers and/or gangrene at any time of the evolution of the disease), 1 had anti-Topoisomerase I and 2 had anti-U1-RNP antibody. Prevalence of BMPR2 gene exon 5 mutation in our sample was 11%.

Conclusion: Prevalence of BMPR2 gene exon 5 mutations in PAH-SSc patients is higher than in non-PAH-SSc patients; prevalence of BMPR2 gene exon 5 mutations in this SSc sample is similar to the prevalence reported in some idiopathic PAH studies; our results suggest that BMPR2 gene exon 5 mutations increase the risk to develop PAH in Mexican Mestizo SSc patients.

Effect Of NOX4 Overexpression On The Levels Of Micro RNAs Relevant To Systemic Sclerosis Fibrotic Process. Sonsoles Piera-Velazquez, Alma Makul and Sergio A. Jimenez. Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center, Thomas Jefferson University, Philadelphia, PA.

Background/Purpose: Systemic sclerosis (SSc) is characterized by the excessive deposition of collagen and other connective tissue components in skin and multiple internal organs. Although transforming growth factor β (TGF-β) has been shown to play a crucial role in the development of tissue fibrosis in SSc, recently, other factors such as excessive oxidative stress have been implicated in the pathogenesis of the disease. Oxidative stress is caused by cellular overproduction of ROS (reactive oxidative species). NOX4 is one of seven NADPH isoforms which plays a crucial role in the generation of ROS. Numerous recent studies have described an important role of microRNAs (miRNA) in the pathogenesis of the fibrotic process in various fibrotic diseases including renal, pulmonary, and liver fibrosis as well as in SSc. The purpose of these studies was to induce overexpression of NOX4 in normal human dermal fibroblasts and to examine the effect of increased NOX4 levels on the expression of various miRNA that participate in the regulation of tissue fibrosis.

Methods: Two different cell lines of normal human dermal fibroblasts were isolated from skin biopsies, and were expanded in monolayer cultures to approximately 70% of confluence and then they were transiently transfected with either a NOX4 protein expression construct (pCI-NOX4) to induce in NOX4 expression or with the vector control pCI. The effects of NOX4 overexpression on global gene expression levels and on the expression of relevant miRNA were examined employing microarrays using Human gene 1.0 ST array Affymetrix gene chips.

Results: Induced NOX4 expression did not cause apparent morphological changes or cytotoxicity. Remarkable changes in the expression levels of numerous transcripts associated with the phenotypic activation of fibroblasts into myofibroblasts were observed. Also, NOX4 overexpression caused significant changes in the levels of several relevant miRNAs. It was of substantial interest that the predicted gene targets for these miRNA included highly relevant genes such as those encoding members of the TGF-β pathway, as well as genes encoding numerous ECM proteins, and several crucial regulatory/transcription factor genes including Fli1, Gli3, and Hif1A.

Conclusion: Induced NOX4 expression resulted in remarkable changes in the levels of expression of numerous transcripts associated with the phenotypic activation of myofibroblasts as well as changes in the levels of several miRNAs that exert important regulatory effects on various genes that participate in the fibrotic process. These observations provide strong support to the notion that targeting NOX4 expression may be a novel therapeutic approach for SSc and other systemic fibrotic disorders.

Analysis Of Global Gene Expression Of Pulmonary Endothelial Cells From Caveolin-1 Knock-Out Mice. Sonsoles Piera-Velazquez[1], Zhaodong Li[1], Sankar Addya[2], Peter J. Wermuth[1] and Sergio A. Jimenez[1]. [1]Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center, Thomas Jefferson University, Philadelphia, PA, [2]Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA.

Background/Purpose: Caveolin-1 (Cav-1) deficiency has recently been shown to participate in the pathogenesis of tissue fibrosis in Systemic Sclerosis (SSc). Although the mechanisms involved have not been fully elucidated, it has been shown that Cav-1 deficiency can induce the phenotypic conversion of quiescent fibroblasts into activated myofibroblasts, the effector cells responsible for the fibrotic process in SSc. It has also been shown that Cav-1 deficiency mediates the phenotypic conversion of endothelial cells (EC) into myofibroblasts through endothelial-mesenchymal transition (EndoMT). Furthermore, Cav-1 deficiency causes a synergistic stimulation of TGF-β-induced EndoMT. The objective of this study was to

examine the differences in global gene expression patterns of Cav-1 knockout (KO) and wild-type murine lung EC regarding genes participating in the EndoMT process.

Methods: Pulmonary EC were isolated from wild-type (WT) and cav-1 knockout (cav-1 KO) mice employing immunomagnetic methods with sequential anti-CD31 and anti-CD102 antibody selection followed by *in vitro*culture and treatment with TGF-β1. To assess the differences in gene expression we performed microarray analysis of RNA isolated from cultured early passage lung EC from wild-type and cav-1 KO mice, employing the Affymetrix mouse cDNA array. Pathway analysis was performed employing Ingenuity software.

Results: A large number of differentially expressed genes were identified in lung EC from cav-1 KO mouse in comparison to EC from wild-type controls, including several unexpected extracellular matrix proteins such as decorin (58-fold higher), dermatopontin (28-fold higher), and versican (17-fold higher), as well as fibroblast growth factor 7 (30-fold higher), and some metalloproteinases, such as, matrix metalloproteinase 3 which was increased 12-fold. Of interest was also the observation that podoplanin a small glycoprotein considered to be specifically expressed in EC of lymphatic origin and which is highly increased in a variety of malignant cells was elevated 17–20 fold in samples from the cav-1 KO mouse lung EC. Numerous genes involved in the EndoMT process were also found to be upregulated in the cav-1 KO mice lung EC compared with the wild-type (WT) controls. Cav-1 deficiency caused a synergistic stimulation of the TGF-β-induced gene expression patterns although some unique genes appeared to be induced by TGF-β treatment of the Cav-1 KO cells but not by treatment of the WT cells.

Conclusion: Cav-1 deficiency results in remarkable changes in the global gene expression patterns of murine lung EC and potentiates the stimulatory effects of TGB-β1 inducing the differential expression of numerous pro-fibrotic genes and of genes involved in EndoMT. These results provide novel information about the mechanisms responsible for the participation of Cav-1 in SSc pathogenesis and further suggest that modulation of Cav-1 expression or activity/function may be a novel therapeutic target for SSc.

Multiplex Cytokine Analysis Of Dermal Interstitial Blister Fluid In Systemic Sclerosis Defines Potential Pathogenic Pathways and Differentiates Clinical Subsets. Kristina E.N. Clark[1], Henry Lopez[2], Joanna Nikotorowicz-Buniak[1], Xu Shiwen[1], Korsa Khan[1], George Martin[3], David J. Abraham[1], Christopher P. Denton[1] and Richard J. Stratton[1]. [1]UCL Medical School, London, United Kingdom, [2]Murigenics, Vallejo, CA, [3]Aero Dap, Vallejo, CA.

Background/Purpose: Clinical diversity in systemic sclerosis (SSc) is likely to reflect multifaceted pathogenesis and the effect of key growth factors or cytokines operating within a disease-specific microenvironment. Dermal interstial fluid sampling offers the potential to examine local biological mechanisms and define protein expression within lesional tissue. We propose multiplex cytokine analysis could be a pragmatic method to define the inflammatory and immune activity in the lesions of SSc patients.

Methods: Interstitial fluid samples from forearm skin of patients (n=25; DcSSc =19, LcSSc=6) and comparable sites on healthy controls (HC) (n=10) were collected using the dermal suction blister method. These were profiled by Luminex array for inflammatory cytokines, chemokines, and growth factors. Permutation analysis (SAM in EXCEL) was used to compare cytokine levels in SSc and HC samples.

Results: Luminex array profiling of the dermal blister fluid showed increased inflammatory cytokines (mean IL-6 in SSc 77.2 pg/ml versus 17.8 pg/ml in HC p=0.009, mean IL-17 in SSc 0.61 pg/ml versus 0 pg/ml, p=0.03), and vascular growth factors (VEGF 21.7 pg/ml in SSc, 13.5 pg/ml in HC (p=NS) and PDGF-aa 16.4 pg/ml in SSc versus 0.97 pg/ ml in HC, p=0.049). Additionally MCP-3 (CCL7), IL-15, and IFN-g were all found to be significantly increased in SSc compared to HC ($p<0.05$) (Figure 1).

Subanalysis highlighted a correlation between IL-6 and skin score (r=0.44, p=0.024) in SSc, and MCP-3 with disease duration (r=0.54, p=0.005). There was also a significant correlation between IL-6 and IL-10 (r=0.59, p=0.002)

IFN-g, IL-17, PDGF-bb were largely undetectable in the blister fluid of HC, but were present in a subgroup of SSc patients. IL-17 was only detectable in DcSSc (5/19), and in 0/6 LcSSc and 0/10 HC, while IFN-g was present in the blister fluid of 1/10 HC, and 15/25 SSc. IFN-g levels were higher in the diffuse subset compared to those with limited disease (mean 1.76 pg/ml and 0.67pg/ml respectively). IL-6 showed a trend towards increased concentrations in DcSSc compared to LcSSc, but this was not statistically significant (mean 71.7 pg/ml in DcSSc, 32.3 pg/ml in LcSSc, p=0.07).

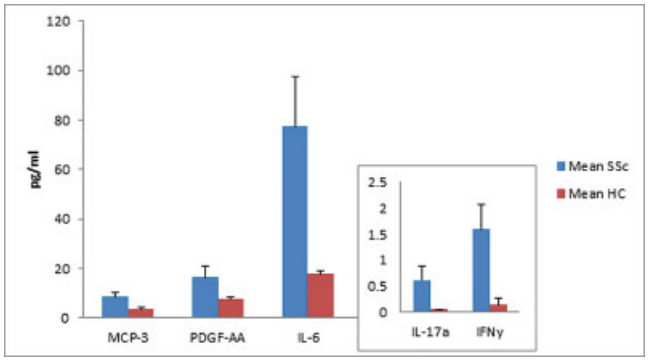

Figure 1. Graph to show mean concentration of MCP-3, PDGF-AA, IL-6, IL-17a and IFN-gamma in SSc patients and healthy controls.

Conclusion: Our results confirm the potential utility of dermal blister fluid to non-invasively define local biological processes in SSc, and identify profibrotic, angiogenic and T-cell derived factors expressed locally within the skin lesions. This technique of profiling patients using blister fluid has the potential to complement clinical and gene expression based classification to facilitate targeted therapy, as well as providing potential markers of disease activity or treatment effect.

Inhibition Of SOX9 Phosphorylation Abrogates The Increased Expression Of Profibrotic Genes In Systemic Sclerosis Dermal Fibroblasts. Sonsoles Piera-Velazquez, Alma Makul and Sergio A. Jimenez. Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center, Thomas Jefferson University, Philadelphia, PA.

Background/Purpose: SOX9, a high mobility group transcription factor is a master regulator of chondrogenesis and plays a crucial role in the regulation of chondrocyte gene expression. However, recent studies on hepatic fibrosis and segmental glomerulosclerosis have suggested that SOX9 may participate in tissue fibrosis. Furthermore, we previously demonstrated that human normal dermal fibroblasts contained high levels of SOX9 phosphorylated at serine residue 181 and that TGFβ1 stimulates Ser181 SOX9 phosphorylation mediated by RhoA kinase and to a lesser extent by PI3K. We explored here the role of Ser181 phosphoSOX9 in the fibrotic process of Systemic Sclerosis (SSc) employing cultured SSc dermal fibroblasts treated *in vitro*with specific inhibitors of the kinases that may be responsible for Ser181 SOX9 phosphorylation and examined the effect of these inhibitors on the increased expression of profibrotic genes and exaggerated production of extracellular matrix proteins characteristics of SSc fibroblasts.

Methods: Dermal fibroblasts obtained from normal skin and from clinically affected forearm skin from patients with diffuse SSc of recent onset were studied. Ser181 phosphoSOX9 levels were assessed by Western blot analysis of cell lysates of confluent dermal fibroblast cultures employing a phospho-specific antibody that recognizes a SOX9 epitope containing a phosphorylated Ser 181 residue. Gene expression analyses were performed employing real time PCR. Collagen production was assessed by Western blots of fibroblast culture media. The effects of kinase inhibitor treatment on Ser181 phosphoSOX9 were assessed in confluent cultures in the presence or absence of TGF-β1 (10ng/mL) for 24h. The potential kinases involved were identified employing Kinexus phosphoproteome databases. The intracellular kinases PIM1, PIM2 and PKCδ were identified as being responsible for Ser181 SOX9 phosphorylation. The role of these kinases was examined by inhibition with specific small molecule kinase inhibitors. For PKCδ inhibition studies two novel specific inhibitors developed by CompleGen (CG1037 and CG1056) were employed.

Results: Previous results showed that dermal fibroblasts from SSc patients displayed marked elevation of Ser181 phosphoSOX9 levels in comparison with normal fibroblasts. Here, we show that TGF-β caused potent stimulation of Ser181 SOX9 phosphorylation which was abrogated at nM concentrations by the two small molecule inhibitors targeting PKCδ as well as the PIM1 and PIM2 specific kinase inhibitors. The kinase inhibitors did not cause morphological changes or detectable cytotoxicity at the concentrations employed. The levels of type I collagen production were reduced in parallel with the changes in Ser181 phosphoSOX9 levels.

Conclusion: The results indicate that Ser181 phosphoSOX9 participates in the molecular mechanisms responsible for the exaggerated fibrotic process in SSc and demonstrate that PKCδ and PIM1/2 kinases are responsible for Ser181 SOX9 phosphorylation. Thus, the kinases involved in Ser181 SOX9 phosphorylation provide novel therapeutic targets for SSc and other fibrotic disorders.

Modulating Myofibroblast Transition Of Human Scleroderma Fibroblasts Through Inhibition Of Rho Guanine Nucleotidase-Regulated Gene Transcription. Andrew Haak[1], Pei-Suen Tsou[2], Dinesh Khanna[2], David A. Fox[2], Scott D. Larsen[3] and Richard R. Neubig[4]. [1]Department of Pharmacology, University of Michigan Medical Center, Ann Arbor, MI, [2]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI, [3]Vahlteich Medicinal Chemistry Core, College of Pharmacy, University of Michigan, Ann Arbor, MI, [4]Department of Pharmacology & Toxicology, Michigan State University, East Lansing, MI.

Background/Purpose: Systemic sclerosis (SSc) or scleroderma, like many fibrotic disorders, has no effective therapy. Deposition of collagen and excess extracellular matrix depends on the transition of dermal fibroblasts into myofibroblasts. Current drug development has focused on targeting the initial inflammatory stimuli and specific receptors involved in fibrosis. Recent evidence, however, indicates that a transcriptional program regulated by Rho GTPase is critical for myofibroblast transition. This could be a more effective convergent target for interrupting pathological fibrosis regardless of the initial inflammatory or fibrotic stimulus. We recently identified novel inhibitors of this transcription mechanism including CCG-203971 (Bell et al, Bioorg Med Chem Lett. 23:3826, 2013). Here we assess their effectiveness in human SSc dermal fibroblasts.

Methods: Primary human dermal fibroblasts were obtained from normal individuals and patients with diffuse SSc. Cells were passaged three times in DMEM containing 10% fetal bovine serum prior to studies which were carried out at passage 4 or 5. mRNA for connective tissue growth factor (CTGF), alpha-smooth muscle actin (ACTA2) and collagen type 1 alpha 1 (COL1α1) were quantified by qRT-PCR. The fraction of cells positive for the myofibroblast maker alpha-smooth muscle actin (α-SMA) was determined by immunocytochemistry. Inhibitors of Rho/MRTF/SRF-regulated gene expression (CCG-203971) and pirfenidone, the only approved antifibrotic therapy, were tested for their ability to suppress these markers of myofibroblast transition and fibrosis.

Results: SSc dermal fibroblasts express significantly more mRNA for CTGF (3.7-fold) and ACTA2 (4.6-fold) than do normal control fibroblasts. Similarly the percentage of cells staining positively for α-SMA was significantly greater for SSc (77$\pm$9%) than for normal (27$\pm$18%) dermal fibroblasts ($p<0.001$, $n=6$). CTGF, ACTA2, and COL1α1 mRNA in SSc fibroblasts were inhibited at 24 hours by CCG-203971 with an IC_{50} of $\sim$10 μM. Treatment of SSc fibroblasts for 72 hours with 10 μM CCG-203971 reduced the percentage of α-SMA positive cells to control levels (26$\pm$18%) while pirfenidone at 300 μM was only marginally effective (41$\pm$16%).

Conclusion: Targeting the Rho/MRTF/SRF transcriptional pathway strongly suppresses myofibroblast activation and fibrosis-related gene expression in human SSc dermal fibroblasts. This could represent a novel targeted approach to disrupt a key genetic switch involved in fibrosis mechanisms and may provide a broad spectrum approach to treatment for systemic sclerosis and other disorders of fibrosis.

Functional Activation Of The TRPV1 and TRPV2 Non-Selective Cation Channels Potentiates TGF-β1-Induced Endothelial-To-Mesenchymal Transition In Murine Pulmonary Endothelial Cells Suggest a Potential Role Of Trpv Channels In The Pathogenesis Of Systemic Sclerosis. Peter J. Wermuth and Sergio A. Jimenez. Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center, Thomas Jefferson University, Philadelphia, PA.

Background/Purpose: Transient receptor potential (Trp) cation channel, subfamily V (TRPV) members can impact a diverse range of vascular functions, including vascular tone, vascular permeability, mechanosensing, angiogenesis and endothelial cell (EC) proliferation, apoptosis, and death. Recently, it has been shown that endothelial-to-mesenchymal transition (EndoMT) may play a role in generating myofibroblasts responsible for the uncontrolled production of extracellular matrix in many fibrotic diseases, including Systemic Sclerosis (SSc). Thus the purpose of these studies was to investigate the effect of TRPV1 and TRPV2 inhibition on the EndoMT process.

Methods: Pulmonary EC were isolated from three C57BL/6J mice employing sequential immunomagnetic selection with anti-CD31 and anti-
CD102 antibodies followed by *in vitro* culture and treatment with TRPV1 and TRPV2 agonists or antagonists in the presence and absence of TGF-β1. EndoMT was assessed by α-smooth muscle actin (α-SMA) immunofluorescence and by Western blot analysis for α-SMA and type I collagen. Induction of type I, type III and type IV collagens, α-SMA, fibronectin, as well as various mesenchymal cell specific genes, including the transcription factor Twist1, and the transcriptional repressors Snail1 and Snail2 as well as expression of EC-specific genes (Pecam1 and VE-cadherin) was assessed by semi-quantitative RT-PCR in triplicate for two replicates per cell line.

Results: Exposure of lung ECs to either the TRPV1 antagonist capsazepine or the TRPV2 antagonist tranilast caused downregulation of expression of EC-specific genes and upregulation of mesenchymal-specific genes. These agents did not induce noticeable changes in cell morphology. Treatment of cells with either capsazepine or tranilast in combination with TGF-β1 showed synergisitic stimulation of TGF-β1 effects on gene expression. Capsazepine in combination with TGF-β1 produced a pronounced morphological change from EC to fibroblast morphology cells which was of greater magnitude than those induced by TGF-β1 alone. In contrast, neither the TRPV1 agonist capsaicin nor the TRPV2 agonist probenecid alone or in combination with TGF-β1 induced EndoMT in murine lung ECs. Capsaicin and probenecid, however, abrogated TGF-β1-induced EndoMT, and reversed TGF-β1-induced morphological changes in the lung EC.

Conclusion: Functional downregulation of TRPV1 and TRPV2 causes strong synergistic potentiation of TGF-β1-induced EndoMT and may play a pathogenetic role in pulmonary fibrosis and other fibrotic diseases, including SSc. The abrogation of TGF-β1-induced EndoMT by capsaicin and probenecid suggests that induction or activation of TRPV1 and TRPV2 activation could represent an important and novel strategy to prevent EndoMT-mediated generation of activated myofibroblasts in fibrotic diseases.

Synergistic Effects Of Endothelin-1 On Transforming Growth Factor-β1 (TGF-β1) Induced Endothelial-To-Mesenchymal Transition. A Novel Mechanism For The Fibrogenic Effects Of Endothelin. Peter J. Wermuth, Zhaodong Li and Sergio A. Jimenez. Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center, Thomas Jefferson University, Philadelphia, PA.

Background/Purpose: The process of endothelial-to-mesenchymal transition (EndoMT) may be a crucial pathway in the generation of activated myofibroblasts, cells that play a pivotal role in the development of tissue and organ fibrosis in fibrotic diseases such as Systemic Sclerosis

(SSc). It has been previously demonstrated that TGF-β1 induces EndoMT *in vitro* in murine lung endothelial cells (ECs). Since extensive previous studies demonstrated a potent profibrotic role for Endothelin-1 (ET-1), the role of ET-1 in the induction of EndoMT was investigated in cultured murine lung ECs.

Methods: Pulmonary EC were isolated from three C57Bl/6J mice employing trypsin/collagenase tissue digestion followed by sequential immunomagnetic selection with anti-CD31 and anti-CD102 antibodies. After *in vitro* culture, the purified EC were treated with ET-1 *in vitro* in the presence and absence of TGF-β1. EndoMT was assessed by immunofluorescence for α-smooth muscle actin (α-SMA) and by Western blot analysis for α-SMA and type I collagen. Induction of type I, type III and type IV collagens, α-SMA, fibronectin, as well as several mesenchymal specific genes, including the transcription factor Twist1 and the transcriptional repressors Snail1 and Snail2 was assessed by semi-quantitative RT-PCR triplicate assays for two replicates per cell line.

Results: Treatment of murine pulmonary ECs with TGF-β1 induced high levels of α-SMA expression in comparison to saline-treated control ECs. ET-1 alone did not affect α-SMA levels but produced a synergistic effect with TGF-β1 by potentiating TGF-β1-induced EndoMT as indicated by increased α-SMA production. A quantitative assessment of the number of α-SMA expressing EC in TGF-β1-treated cultures was 27% compared to 52% in cultures treated with both TGF-β1 and ET-1. These results were confirmed by Western blot analysis. Semi-quantitative RT-PCR analysis demonstrated that ET-1 synergistically potentiated TGF-β1-mediated increased expression levels of types I and III collagens, α-SMA, fibronectin, Twist1, Snail1 and Snail2. Expression of EC-specific VE-cadherin (Cdh5) was downregulated in TGF-β1-treated cultures compared to saline controls and ET-1 also synergistically potentiated this TGF-β1-mediated effect.

Conclusion: ET-1 plays an important role in regulating EndoMT by causing a synergistic potentiation of TGF-β1-induced EndoMT-mediated generation of activated myofibroblasts and of EndoMT-mediated increased expression of extracellular matrix components including Types I and III collagens. Furthermore, ET-1 also potentiated the TGF-β1-induced increase in expression of various genes involved in the phenotypic conversion of EC into myofibroblasts including Twist1, Snail1 and Snail2. Since ET-1 plays a crucial role in the pathogenesis of SSc-associated pulmonary arterial hypertension and may play a profibrotic role in skin and lung fibrosis, the results described here identify a novel mechanism supporting the concept that ET-1 plays a key pathogenetic role in SSc-associated pulmonary fibrosis.

Nilotinib Treatment Effect In The Skin As Measured By DNA Microarray In Patients With Diffuse Systemic Sclerosis. Jessica K. Gordon[1], Tammara A. Wood[2], Robert F. Spiera[1] and Michael L. Whitfield[3]. [1]Hospital for Special Surgery, New York, NY, [2]Dartmouth Medical School, Hanover, NH, [3]Geisel School of Medicine at Dartmouth, Hanover, NH.

Background/Purpose: Gene expression profiling by DNA microarray is used to identify potential biomarkers in Systemic Sclerosis (SSc). Discrete gene expression signatures have been observed to subset patients and correlate with clinical parameters. We tested the hypothesis that treatment modulates gene expression in SSc skin in the context of an open label study of nilotinib to treat early diffuse cutaneous (dc)SSc.

Methods: Ten adult patients with early progressive dcSSc of $<$3 yrs since the initial SSc symptom were treated with nilotinib 400 mg PO twice daily. Three mm punch biopsies of lesional forearm skin were performed at baseline and after 6 and 12 mos of treatment, and the Modified Rodnan Skin Score (MRSS) was recorded. Clinical improvement was defined as improvement in MRSS by 20% from baseline. Using this criterion, we classified 4 patients as improvers and 4 patients as non-improvers. RNA was extracted from the whole skin, converted to cRNA, and hybridized to Agilent 8$\times$60K whole human genome microarrays. Significance Analysis of Microarrays (SAM) was used to identify genes differentially expressed between pre- and post-treatment skin biopsies for both improvers and non-improvers separately and together. Patients before and after 6 and 12 months of treatment were assigned to intrinsic subsets using a gene expression classifier algorithm.

Results: Eight out of 10 patients from the nilotinib trial had at least baseline and 6 month biopsies that were included in the gene expression analysis. Patient characteristics (n=8) were: 75% female; median age 48.5 (IQR 41,53); median disease duration from the first non-Raynaud's symptom of SSc: 0.67 (IQR 0.42, 0.71); baseline Modified Rodnan Skin Score (MRSS): 27.5 (IQR 22, 32); 62.5% RNA Pol3 positive; 25% Scl70 positive. SAM identified 185 genes with significantly decreased expression post treatment in improvers. These genes were significantly enriched for inflammatory response, hematopoiesis and cell-cell adhesion. In contrast, we did not find significant changes in gene expression post-treatment in non-improvers. Analysis of patient intrinsic subsets showed that 3 out of 4 non-improvers showed stable or increasing inflammatory signatures. Improvers showed either rapid decrease in the inflammatory signature or absence of the inflammatory signature with concomitant stable or increasing fibroproliferative signatures.

Conclusion: We observed modulation of gene expression in skin as measured by DNA microarray in improvers but not in non-improvers during the course of the nilotinib trial. Patients that did not show improvement had an inflammatory signature that was stable or increasing, whereas patients that improved show decreasing inflammatory and increasing fibroproliferative gene signatures. Whether these changes in gene-expression signify biological effect of nilotinib or natural history of scleroderma will require an untreated control group to determine.

Cadherin-11 Regulates Pulmonary Fibrosis In Bleomycin-Induced Lung Injury. Mesias Pedroza, Anuh T. George and Sandeep K. Agarwal. Baylor College of Medicine, Houston, TX.

Background/Purpose: Pulmonary fibrosis (PF) is the leading cause of death in systemic sclerosis. Pathologically, PF is characterized by an aberrant wound healing repair mechanism leading to excessive fibroblast proliferation, myofibroblast differentiation, and extensive matrix deposition in the alveolar airways. Epithelial-to-mesenchymal transition (EMT) is the differentiation of fibroblast-like phenotype from epithelial cells that results in myofibroblast accumulation. Cadherin-11 (Cad11), a mesenchymal, homophillic adhesion molecule, has been reported to be expressed on hyperplastic alveolar epithelial cells (AEC), a populations of cells postulated to be undergoing EMT during the development of fibrosis. However it is not known if Cad11 is a regulator of EMT and if this contributes to the development of PF. We hypothesized that Cad11 contributes to the development of pulmonary fibrosis through the regulation of EMT.

Methods: Cad11 deficient mice and neutralizing Cad11 monoclonal antibodies were used to determine the role of Cad11 in the intraperitoneal (IP) bleomycin (BLM) model of pulmonary fibrosis that exhibits EMT. AEC cell lines (A549, MLE-12) and primary murine AEC induced to undergo EMT by TGF-beta were used to determine if Cad11 regulates EMT in vitro.

Results: Cad11 deficient mice had reduced fibrosis in the IP BLM model as assessed by improved arterial oxygen saturation, decreased collagen deposition, diminished alpha-smooth muscle actin (aSMA) accumulation, decreased TGF-b production and reduced b-catenin expression. These findings were confirmed using neutralizing antiCad11 monoclonal antibodies in wild type mice. *In vitro*studies demonstrated that activation of Cad11 using immobilized Cad11-Fc fusion protein increased Col1a expression by A549 and MLE-12 AEC. In contrast, siRNA knockdown of Cad11 expression in A549 and MLE-12 AEC decreased the expression of fibrotic genes such as Col1a, aSMA, and CTGF. In addition, primary AECs from Cad11 deficient mice had decreased capacity to undergo EMT induced by TGF-beta relative to primary AECs from wild type mice. Finally, Cad11 inhibition with soluble Cad11-Fc fusion protein reduced EMT markers in wild type AECs treated with TGF-beta.

Conclusion: These findings demonstrate that Cad11 is an important mediator of EMT in vitro and pulmonary fibrosis in vivo. Furthermore, these data suggest that Cad11 may be a therapeutic target in the treatment of pulmonary fibrosis.

Involvement Of Collagen-Binding Heat Shock Protein 47 In The Scleroderma-Associated Fibrosis. Haiyan Chu[1], Ting Wu[1], Wenyu Wu[2], Wenzhen Tu[3], Yanyun Ma[1], Qingmei Liu[1], Hejian Zou[4], Li Jin[1] and Jiu-Cun Wang[1]. [1]Ministry of Education Key Laboratory of Contemporary Anthropology, School of Life Sciences, Fudan University, Shanghai, China, [2]Division of Dermatology, Huashan Hospital, Fudan University, Shanghai, Shanghai, China, [3]Shanghai Traditional Chinese Medicine-Integrated Hospital, Shang hai, China, [4]Huashan Hospital, Shanghai, China.

Background/Purpose: Scleroderma or systemic sclerosis (SSc) is characterized by the fibrosis of skin and visceral organs, especially the uncontrolled fibrosis of multiple organs. Collagen is a major extracellular matrix (ECM) protein that deposited in the fibrotic organs. Heat shock protein 47 (HSP47) has been identified as a collagen-specific chaperon, and plays an important role in the development of fibrosis. Our previous study demonstrated that HSP47 was significantly up-regulated in the skin of dermal sclerosis mice induced by bleomycin. The aim of the present study is to investigate the role of HSP47 in the pathogenesis of scleroderma.

Methods: For *in vivo* studies, C57BL/6 female mice of 6–8 weeks (n = 5 for each treatment) were injected with bleomycin subcutaneously into the same site of the shaved upper back daily for 3 weeks. The mRNA and protein level of HSP47 in the lesion skins from the mouse model was assessed by real-time PCR and western blot. In clinical study, skin biopsies and fibroblasts, peripheral blood mononuclear cells (PBMC) and plasma of SSc patients were obtained to study the role of HSP47 during the pathogenesis of SSc. Immunohistochemical staining was performed to identify the localization of HSP47 in the skin of SSc patients, real-time PCR and western blot were conducted to respectively test the gene and protein expression levels of HSP47 in the skin fibroblasts, and ELISA was used to detect the protein level of HSP47 in the plasma of SSc patients. For *in vitro* study, silencing and over-expression of HSP47 in NIH/3T3 fibroblast cells were performed using HSP47 siRNA and HSP47 expression plasmid respectively to investigate the effect of HSP47 on collagen production.

Results: For *in vivo* study, HSP47 was significantly up-regulated in the skin lesion of the mice treated by bleomycin. Meanwhile, the expression of α-SMA increased in the skin lesion of the mice in response to bleomycin. In clinical study, the level of HSP47 increased in the fibroblasts cultured from SSc patients' skin, the number of HSP47 positive cells increased in the skin of SSc patients, and the localization of HSP47-positive cells were observed in accordance with the α-SMA-positive cells. Additionally, the protein level of HSP47 in the plasma and the mRNA level of HSP47 in the peripheral blood mononuclear cells were both elevated in the SSc samples. *In vitro*study found that over-expression of HSP47 in the fibroblasts increased the level of collagen, whereas knockdown of HSP47 gene decreased its expression.

Conclusion: The production of collagen is affected by HSP47, and HSP47 might be involved in the pathogenesis of scleroderma. Further investigations may be necessary to test this collagen chaperone as an important therapeutic approach.

Serum S100A4 Levels Correlate With Skin Fibrosis and Lung Involvement In Systemic Sclerosis. Michal Tomcik[1], Lucie Andres Cerezo[1], Simona Skacelova[1], Martin Komarc[2], Radim Becvar[1], Mariam Grigorian[3], Joerg HW Distler[4] and Ladislav Senolt[1]. [1]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Institute of Biophysics and Informatics of the First Faculty of Medicine, Charles University, Prague, Czech Republic, [3]Institute of Cancer Biology, Danish Cancer Society, Copenhagen, Denmark, [4]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany.

Background/Purpose: Our previous study demonstrated that S100A4 is overexpressed in scleroderma (SSc) skin, fibroblasts and preclinical models of SSc in a TGF-β dependent manner. Furthermore, we showed that S100A4 is a new regulator of canonical TGF-β signalling and its inhibition prevents the stimulatory effects of TGF-β on collagen synthesis. Similarly, deficit of S100A4 prevented dermal fibrosis induced by bleomycin or in Tsk-1 mice. The aim of this study was to evaluate S100A4 in the circulation of SSc patients and characterize its potential association with skin changes and SSc-related features.

Methods: A total of 33 patients (29 females; mean age 52.8; disease duration 4.2 years; dcSSc/lcSSc = 8/25) who met the ACR classification criteria for SSc and 20 healthy individuals matched by age and sex were included in this study. Serum S100A4 levels were measured using ELISA (CycLex Co., Ltd., Nagano, Japan). CRP, ANA and ENA complex were evaluated. SSc-related manifestations were obtained from the Czech Registry Database of SSc patients. Interstitial lung disease, pulmonary arterial hypertension, oesophageal dysmotility, cardiac and renal involvement, nailfold capillaroscopy and Raynaud's phenomenon were recorded. Skin changes were assessed using the modified Rodnan skin score and EUSTAR SSc activity score was determined. Data are presented as mean ± SEM.

Results: S100A4 serum levels were significantly increased in SSc patients compared with healthy controls (119.2 ± 23.4 vs. 43.9 ± 3.3 ng/ml, $p = 0.011$). Patients with diffuse cutaneous SSc had significantly higher levels of serum S100A4 compared with patients with limited cutaneous SSc or healthy controls (201.8 ± 53.1 vs. 92.7 ± 24.0 ng/ml, $p = 0.017$ and 201.8 ± 53.1 vs. 43.9 ± 3.3 ng/ml, $p = 0.001$, respectively). The levels of S100A4 positively correlated with the modified Rodnan skin score ($r = 0.556$, $p = 0.001$). In addition, S100A4 levels negatively correlated with forced vital capacity (FVC) and saturation of peripheral oxygen (SpO2) ($r = -0.362$, $p = 0.038$ and $r = -0.414$, $p = 0.029$, respectively). Of particular interest, S100A4 levels positively correlated with EUSTAR SSc activity score ($r = 0.750$, $p = 0.0001$). However, only relations between S100A4 and the modified Rodnan skin score, and S100A4 and EUSTAR SSc activity score were approved at corrected level of statistical significance after Bonferroni's correction ($p = 0.001 < 0.01$, $p = 0.0001 < 0.01$, respectively). The presence of autoantibodies (ANA, anti-centromere, anti-Scl70), a pathological capillaroscopic pattern (early, active, late), the administration of low dose glucocorticoids (or immunosuppressive treatment) and exhibition of the main individual clinical symptoms of SSc did not significantly affect levels of serum S100A4.

Conclusion: We demonstrate that S100A4 serum levels are significantly increased in SSc patients compared with healthy controls. Higher levels of S100A4 are associated with dcSSc subset, skin involvement, deteriorated parameters of lung involvement and higher disease activity. These data support our previous findings on the role of S100A4 as a regulator of TGF-β induced fibroblast activation and dermal fibrosis in SSc.

Tenofovir But Not Adefovir Prevents Liver and Skin Fibrosis In Two Models Of Adenosine-Mediated Injury. Jessica L. Feig[1], Doreen Tivon[1], Miguel perez Aso[2], Timothy Cardozo[1] and Bruce N. Cronstein[3]. [1]New York University School of Medicine, New York, NY, [2]NYU Univ Medical Center, New York, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY.

Background/Purpose: Acyclic nucleoside phosphonates are a key class of antivirals commonly used in the treatment of both DNA and retroviral infections. Adefovir and tenofovir are AMP analogues that resemble substrates of CD73. We have previously reported that adenosine, generated by the CD73-mediated dephosphorylation of AMP, acting at A_{2A}receptors, plays a critical role in development of both hepatic and dermal fibrosis in murine models of cirrhosis and scleroderma, respectively. A recent clinical trial demonstrated that tenofovir, but not other antiviral agents, reverses hepatic fibrosis/cirrhosis in patients with hepatitis B. We therefore proposed the hypothesis that tenofovir's antifibrotic effects are mediated by inhibition of adenosine production by CD73-mediated dephosphorylation of AMP.

Methods: In silico modeling and docking studies were performed using an ICM-Browser www.molsoft.com. CD73 enzyme activity was quantitated by malachite green. Alkaline Phosphatase activity (Abcam) was performed. Thioacetamide(TAA,100 mg/kg IP)-treated mice were treated with vehicle, Adefovir, or Tenofovir (75mg/kg, SubQ) [n=5–10 per group]. Bleomycin (0.25 U, SubQ)-treated mice were treated with vehicle, Adefovir, or Tenofovir (75mg/kg, IP) [n=5–10 per group]. Adenosine levels were determined by HPLC. Skin breaking strength was via tensiometer. H&E or picrosirus red-stained slides were imaged, and pixel quantification was performed with SigmaScan software. Scar index was determined as the ratio of red/green pixels representing compact/filamentous fibers; higher numbers indicate more fibrosis.

Results: In silico modeling data suggested that both adefovir and tenofovir bound to the enzymatic pocket of CD73. Tenofovir (Sequoia), but not adefovir (Sequoia), inhibited CD73 activity of 293T cells overexpressing CD73 (38+7.4%, at 10 uM) and of recombinant enzyme (72+1.0%, at 10uM). Yet, the inhibition of CD73 by Tenofovir (Gilead) was not pharmacologically relevant with an IC50>100uM. Alkaline phosphatase activity wasn't modulated by Adefovir or Tenofovir. Adefovir decreased adenosine levels in the skin of bleomycin-challenged mice though this trend was not significant. Tenofovir significantly decreased adenosine levels in the skin of bleomycin-challenged mice (273.95+8.41 vs. 432.58+24.34nM adenosine/12mm punch biopsy, n=8–10, [$p<0.05$]). Tenofovir (75mg/kg), but not Adefovir (75mg/kg), diminished hepatic fibrosis in thioacetamide-treated mice (fibrotic area/hepatic slide area 1.00+0.04% vs 4.45+0.37%) Tenofovir (75mg/kg), but not Adefovir (75mg/kg), diminished bleomycin-induced dermal fibrosis in bleomycin-treated mice (73.7+3.1% reduction of hydroxyproline content [$p<0.05$]; 33.5+3.8% reduction of dermal thickness [$p<0.06$] and reduction of breaking tension by 66.8+1.4% [$p<0.05$]). Picrosirius red staining showed dramatic altering of dermal collagen quality (scar index of 1.2+0.1 vs 22.2+0.7 [$p<0.001$], normal skin is 2.5) in Tenofovir-treated mice.

Conclusion: Tenofovir reduces fibrosis via inhibition of adenosine production. Tenofovir may have therapeutic potential in treating fibrosis in patients suffering from non-viral fibrosing diseases such as scleroderma.

Pigment Epithelium Derived Factor Secreted By Activated Fibroblasts Can Contribute To Impaired Angio and Vasculogenesis In Scleroderma. Vasiliki Liakouli[1], Georgia Mavria[2], Justin Gillespie[3], Margherita Scarcia[2], Paola Cipriani[1], Roberto Giacomelli[1], Paul Emery[4] and Francesco Del Galdo[4]. [1]Rheumatology Unit, University of Aquila, L'Aquila, IT, L'Aquila, Italy, [2]Signal Transduction and Angiogenesis group, Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, UK, Leeds, United Kingdom, [3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom.

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune disorder characterized by tissue fibrosis and vasculopathy. This latter comprises both neointima proliferation and defective angio and vasculogenesis. Although some of the clinical manifestations of the vasculopathy often precede the onset of fibrosis, there is scanty of data investigating the molecular mechanisms eventually linking the profibrotic activation of fibroblasts (FBs) and the poor angio/vasculogenesis in Scleroderma. Recently, a proteomic analysis of the secretome of SSc dermal FBs (SSc FBs), identified among other proteins a consistent increased secretion of Pigment Epithelium Derived Factor (PEDF) associated with the profibrotic phenotype (AJP, 2010). PEDF has been described as produced by retinal-pigmented epithelium and melanocytes, and is a major endogenous inhibitor of intraocular angiogenesis. Here we aimed to validate the increased expression of PEDF in SSc and test the hypothesis that PEDF might play an important role in establishing or perpetuating SSc vasculopathy.

Methods: PEDF expression was investigated in the involved skin and FBs of 4 SSc patients in the early phase of the diffuse form of the disease and 4 healthy controls (HC) by immunohistochemistry (IHC) and real time-PCR analysis. Functional effects of PEDF on angio/vasculogenesis were examined by Matrigel assays. Organotypic co-culture assays were performed seeding HUVECs or microvascular endothelial cells (MVECs), on monolayers of either primary healthy FBs (HC FBs) or SSc FBs or HC FBS silenced for Caveolin-1 (Cav-1). Endothelial cells were evidenced by IHC staining for CD31 in organotypic co-culture assays. Vascular tubule number, length and junctions were identified and analyzed by Angiosys software *(TCS* CellWorks).

Results: Both Healthy and Scleroderma skin biopsies showed high PEDF protein expression on melanocytes, as expected. Nevertheless, in SSc skin 52% (+/−5.9) of the FBs showed a strong expression of PEDF whereas only 13% (+/−0.68) of the FBs in HC skin were positive *(*$p<0.0006$). Double IHC studies indicated that FBs positive for PEDF showed a decreased expression of Cav-1 in both HC and SSc skin. *In vitro* studies confirmed that SSc FBs showed on average a 5-fold increased in PEDF expression compared to HC FBs ($p<0.05$). Functional studies confirmed that recombinant PEDF protein had a direct inhibitory effect on vasculogenesis, suppressing both tubule length and number. Consistently, organotypic co-culture assays indicated that SSc FBs or HC FBs silenced for Cav-1 inhibited tubulogenesis both on MVECs or HUVECs, respectively.

Conclusion: PEDF expression is increased in SSc biopsies and SSc FBs. PEDF expression is associated with decreased Cav-1 expression *in vivo* and it is induced by silencing Cav-1 *in vitro*. Functionally, PEDF can suppress vasculogenesis both in Matrigel and co-culture assays. This suggests that the decreased expression of Cav-1 observed in SSc FBs may contribute to the vasculopathy of Scleroderma. Further studies unraveling the mechanisms of the antiangiogenic effect of PEDF may shed light in understanding the molecular events linking the profibrotic phenotype and SSc vasculopathy.

An Atypical Cyclin-Dependent Kinase Mediates Fibrosis and Is a Novel Target In Scleroderma. Jun Wei[1], Roberta G. Marangoni[1], Wenxia Wang[1], Jingang Huang[2], Joerg H. W. Distler[2] and John Varga[3]. [1]Northwestern University, Chicago, IL, [2]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]Northwestern University Medical School, Chicago, IL.

Background/Purpose: Cyclin-dependent kinase 5 (CDK5), expressed primarily in the central nervous system, plays important roles in axonal guidance, dopaminergic signaling, neuronal migration, and pain sensing. Aberrant CDK5 function is implicated in neurodegenerative diseases including Alzheimer's disease. In contrast to other cyclin-dependent kinases, binding of the non-cyclin activator p35 is sufficient to induce CDK5 activity. Recent studies reveal novel extra-neuronal role for in inflammation and metabolism. The nuclear receptor PPAR-γ, a master regulator of adipogenesis and adipokine production, is impaired in scleroderma. Since PPAR-γ is a novel CDK5 substrate, we hypothesized that the CDK5/p35 pathway might be responsible for impaired PPAR-γ function in SSc and play a role in the development and persistence of fibrosis.

Methods: Expression of p35 was examined in skin biopsies from bleomycin-injected mice and explanted scleroderma fibroblasts. Regulation of p35/CDK5 expression and activity in vitro was examined in human and mouse skin fibroblasts, progenitor cells and mature adipocytes by real-time qPCR, Western analysis and in vitro kinase assays. Effects of CDK5/p35 loss-of-function and gain-of-function were evaluated in normal and scleroderma skin fibroblasts using monolayer cultured fibroblasts and ex vivo using human skin organ cultures. CDK5 inhibition was examined in vivo using mouse models of fibrosis induced by bleomycin or constitutively active Type I TGF-β receptor.

Results: Levels of p35 mRNA were markedly elevated in explanted scleroderma fibroblasts (n=6, $p<0.005$). p35 was also elevated in lesional skin from mice with bleomycin-induced scleroderma. Both p35 expression and CDK5 activity were strongly stimulated by TGF-β in human and mouse skin fibroblasts, mesenchymal progenitor cells and mature adipocytes. Ectopic p35 and CDK5 caused suppression of adiponectin expression and simultaneous stimulation of collagen synthesis in these cells, whereas RNAi-mediated knockdown of p35/CDK5 abrogated TGF-β-induced fibrotic gene expression. Pharmacological inhibitors of CDK5 not only prevented but even reversed TGF-β-induced fibrotic responses in monolayer cultures and in skin organ cultures, and ameliorated collagen overproduction in scleroderma fibroblasts. Moreover, CDK5 inhibitor prevented and reversed skin fibrosis in complementary inflammatory and TGF-β-driven mouse models of scleroderma.

Conclusion: The CDK5/p35 axis has a previously unrecognized important non-neuronal function in modulating fibrotic responses. Elevated p35 expression and CDK5 activity is an unexpected feature of scleroderma that might contribute to development of fibrosis. Pharmacological targeting CDK5/p35 might be novel treatment for fibrosis.

The Role Of STAT-3 In The Development Of Pulmonary and Dermal Fibrosis. Mesias Pedroza, Sarah To, Anuh T. George, David J. Tweardy and Sandeep K. Agarwal. Baylor College of Medicine, Houston, TX.

Background/Purpose: Fibrosis is the accumulation of excessive extracellular matrix in tissues, leading to tissue damage. In systemic sclerosis, the trigger is postulated to be an autoimmune response that leads to tissue injury, production of growth factors, pro-inflammatory and profibrotic cytokines, and accumulation of myofibroblasts. Two potential sources of myofibroblasts are the differentiation of local fibroblasts and the process of epithelial-to-mesenchymal transition (EMT). IL-6 is a proinflammatory and profibrotic cytokine that is increasingly recognized as an important mediator of fibrosis and may contribute to the accumulation of myofibroblasts. After engaging its receptor, IL-6 signals through the STAT-3. STAT-3 has been shown to be elevated in skin and pulmonary fibrosis. The extent to which STAT-3 is involved in the development of fibrosis and the mechanisms by which it leads to fibrosis are not known. We hypothesizes that STAT-3 signaling contributes to the development of tissue fibrosis in the lung and skin in part through the modulation of EMT.

Methods: Fibrotic tissue from systemic sclerosis patients, idiopathic pulmonary fibrosis patients, and mouse models of lung and skin fibrosis was processed for phosphor-STAT-3 staining by immunohistology. To determine if STAT-3 signaling contributes to the development of fibrosis, C-188-9, a novel small molecule STAT-3 inhibitor, was administered to C57/Bl-6 mice in both the intraperitoneal (IP) bleomycin mouse model of lung fibrosis and the subcutaneous (SC) bleomycin mouse model of skin fibrosis. To determine the role of STAT-3 in EMT and myofibroblast differentiation, C-188-9 was used in tissue culture experiments with alveolar epithelial cells (AEC; MLE-12 and primary AEC) and murine lung fibroblasts.

Results: Phospho-STAT-3 expression was increased in fibrotic tissue from systemic sclerosis patients, idiopathic pulmonary fibrosis patients, and mouse models of lung and skin fibrosis. STAT-3 inhibition by C-188-9 decreased fibrotic endpoints (collagen deposition by Sircol, expression of alpha-smooth muscle actin (SMA), and improved arterial oxygen saturation) in the IP bleomycin pulmonary fibrosis model. C-188-9 also decreased the development of dermal fibrosis in the SC bleomycin model as assessed by decreased dermal thickness, a reduction of alpha-SMA accumulation, and decreased collagen deposition. *In vitro* studies show that TGF-beta or IL-6 trans-signaling (IL-6/sIL-6R-alpha) were able to induce 1) EMT on primary AEC and MLE-12 cell line and 2) myofibroblast differentiation from fibroblasts. C-188-9 prevented TGF-beta and IL-6/sIL-6R-alpha induced EMT assessed by Col1a, alpha-SMA, Twist, and Snail mRNA levels and reduced myofibroblast differentiation as assessed by Col1a and alpha-SMA mRNA levels.

Conclusion: These findings demonstrate that STAT-3 contributes to the development of tissue fibrosis in the skin and the lung and plays a role in the development of myofibroblasts in vitro. Furthermore, these data suggest that STAT-3 may be a therapeutic target in the treatment of dermal and pulmonary fibrosis.

Early Use of Prostacyclin Therapy Improves Transplant-Free Survival in Patients With Systemic Sclerosis-Related Pulmonary Arterial Hypertension Plus Interstitial Lung Disease. Elizabeth Volkmann[1], Rajan Saggar[1], Bryant Torres[1], Lynne Yoder[1], Robert Elashoff[1], Rajeev Saggar[2], Harsh Agrawal[1], Nabeel Borazan[3], Sarah Thomas[1] and Daniel Furst[1]. [1]University of California, Los Angeles, Los Angeles, CA, [2]St. Joseph's Hospital and Medical Center, Phoenix, AZ, [3]Rheumatology UCLA, Los Angeles, CA.

Background/Purpose: The leading causes of death in systemic sclerosis (SSc) are pulmonary arterial hypertension (PAH) and interstitial lung disease (ILD). Use of PAH therapy in patients with both SSc-PAH and ILD is controversial and may not improve survival (1). This study investigates transplant-free survival in patients with SSc-PAH, both with and without ILD, treated aggressively with PAH therapies.

Methods: All SSc patients who had a right heart catheterization (RHC) diagnostic for PAH (mean pulmonary artery pressure (mPAP) greater than or equal to 25 mm Hg, pulmonary capillary wedge pressure (PCWP) less than or equal to 15 mm Hg, pulmonary vascular resistance (PVR) greater than or equal to 240 dynesxsecond/cm^5), between 2001–2012 were enrolled. ILD was defined as greater than 30% disease extent on high-resolution computed tomography (HRCT) or when disease extent 10–30%, forced vital capacity less than 70%. Kaplan-Meier and Cox proportional hazards models were used to analyze survival and identify prognostic variables.

Results: Of the 99 patients with SSc-PAH, 71 also had ILD. Patients with PAH+ILD were younger than patients with PAH alone (Mean 55 years vs. 60 years, respectively, p=0.07) and a smaller percentage were woman (70% vs. 93%, respectively, p=0.02). SSc type/disease duration, ethnicity, comorbidities, hemoglobin, creatinine, mPAP, PCWP, PVR, use of supplemental oxygen, and six-minute walk distance were similar between patients with PAH alone and PAH+ILD. Twenty-four percent of all patients started prostacyclin therapy within 6 months of the RHC, while 24% started prostacyclin therapy after 6 months of the RHC. The 1-, 2-, 3-year survival estimates were 72%, 59%, 50%, and 82%, 66%, 60%, for the PAH+ILD and PAH alone groups, respectively, p=0.5 (Figure 1). In the multivariate model, after controlling for potentially confounding variables, male gender (hazard ratio 0.6, p=0.008) and prostacyclin therapy initiation within 6 months of the RHC (hazard ratio 1.4, p=0.007) were the only factors significantly associated with transplant-free survival.

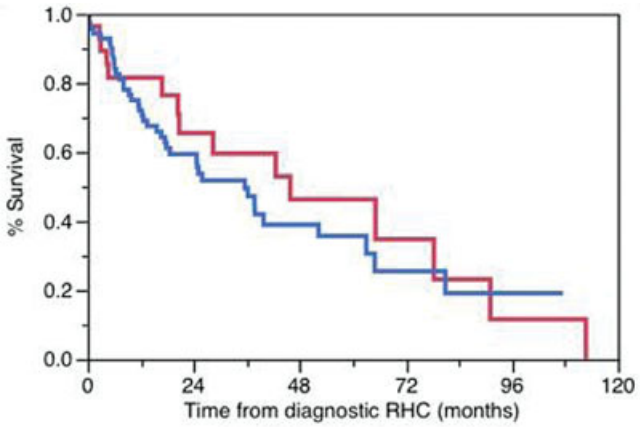

Figure 1. Kaplan-Meier survival curves demonstrating no significant difference in transplant-free survival for SSc-PAH patients with ILD (blue line) and without ILD (red line) (Log rank p-value 0.5).

Conclusion: Survival of SSc-PAH and ILD has improved compared with historical series (1); this may in part be due to aggressive use of prostacyclin therapy.

Utility Of Autoantibody Testing For Predicting Risk Of Pulmonary Arterial Hypertension: A Retrospective Analysis In Routine Autoantibody Laboratory. Masataka Kuwana[1], Yuichiro Shirai[1], Hidekata Yasuoka[1], Tsutomu Takeuchi[1] and Kenichi Masui[2]. [1]Keio University School of Medicine, Tokyo, Japan, [2]National Defense Medical College, Tokorozawa, Japan.

Background/Purpose: Pulmonary arterial hypertension (PAH) is an intractable complication of connective tissue disease (CTD). Current guidelines recommend early detection and intervention for improvement of

outcomes. To achieve this goal, it is imperative to identify subgroups with high risk for developing PAH. Patients with systemic sclerosis (SSc) are known to have the highest risk for PAH. Serum autoantibodies, such as anticentromere, anti-U1RNP, anti-U3 RNP, and anti-Th/To, were also associated with PAH in certain CTD subgroups. However, little information is available for utility of autoantibody profiles for predicting PAH risk in patients with CTD. Here, we examined a role of autoantibody testing in identifying patients with PAH risk using a large-scale database of a routine autoantibody laboratory.

Methods: This study enrolled 6,162 patients, whose sera were sent to our autoantibody laboratory between 1995 and 2008 because of clinical suspicion of CTD. They were selected from 9,872 consecutive patients based on observation period >3 years, and availability of full clinical information on medical charts. Indirect immunofluorescence, double immunodiffusion, and RNA immunoprecipitation assay were routinely conducted to identify autoantibodies to centromere, topoisomerase I, Sm, U1RNP, SSA, SSB, Th/To, U3RNP, SRP, aminoacyl tRNA synthetase, and ribosome.

Results: During 6.6 ± 5.6 years of follow-up, 71 patients (1.2%) were diagnosed as having PAH confirmed by right heart catheterization. Mixed connective tissue disease (MCTD), SSc, and systemic lupus erythematosus (SLE) were clinical diagnosis associated with PAH (unadjusted odds ratio [OR] 10.8, 8.4, and 2.0, respectively). PAH also occurred in a small population of patients with primary Sjögren's syndrome (n = 7; 0.8%), rheumatoid arthritis (n = 3; 0.2%), or dermatomyositis (n = 1; 0.3%). Autoantibodies associated with PAH included those to centromere, U1RNP, Sm, SSA, SSB, and Th/To (unadjusted OR 4.5–6.6). Female gender and Raynaud's phenomenon were also identified as PAH risk factors (unadjusted OR 8.0 and 10.5, respectively). Multivariate logistic regression analysis revealed that MCTD, SSc, and SLE were independent PAH risk, indicating that the overall PAH risk could be explained primarily by clinical diagnosis. Interestingly, anti-SSA antibody without diagnosis of MCTD, SSc, or SLE was another independent PAH risk, indicating limited utility of the autoantibody status. When we further developed a multivariate logistic regression model by combining the diagnosis and autoantibody profile, PAH risk can be explained by 6 independent variables, including SSc with anticentromere (OR 578, 95% confidence interval [CI] 119–10409), MCTD (OR 397, 95% CI 81–7174), SLE with anti-U1RNP (OR 150, 95% CI 29–2743), SSc without anticentromere (OR 103, 95% CI 18–1923), anti-SSA without diagnosis of MCTD, SSc, or SLE (OR 56, 95% CI 11–1028), and SLE without anti-U1RNP (OR 42, 95% CI 6.8–813).

Conclusion: A combination of clinical diagnosis and autoantibody profiles effectively stratifies PAH risk in patients suspected to have CTD, and may aid in selection of patients who benefit from active screening program for PAH detection.

Epoprostenol Rescue Therapy In Systemic Sclerosis-Associated Pulmonary Arterial Hypertension and Idiopathic Pulmonary Arterial Hypertension. Adrienne M. Roos[1], Christopher Pasarikovski[1], Amie T. Kron[1], John T. Granton[2], Peter Lee[3], John Thenganatt[4] and Sindhu R. Johnson[5]. [1]Toronto Scleroderma Research Program, Toronto Western Hospital, Mount Sinai Hospital, and University of Toronto, Toronto, ON, [2]Toronto Pulmonary Hypertension Programme, Toronto General Hospital and University of Toronto, Toronto, ON, [3]Mt. Sinai Hospital, Toronto, ON, [4]University Health Network Pulmonary Hypertension Programme, Toronto General Hospital, Divisions of Respirology and Critical Care Medicine, Toronto, ON, [5]Division of Rheumatology, Toronto Western Hospital, University Health Network Pulmonary Hypertension Programme, Toronto General Hospital, Mount Sinai Hospital and University of Toronto, Toronto, ON.

Background/Purpose: Epoprostenol has been demonstrated to improve hemodynamics, functional class, and six-minute walk distance (6MWD) in systemic sclerosis-associated pulmonary arterial hypertension (SSc-PAH) and idiopathic PAH (IPAH) patients. In contemporary practice, it is usually reserved for patients who have failed treatment with endothelin receptor antagonists and/or phosphodiesterase-5 inhibitors. The effect of epoprostenol rescue therapy on survival has not been evaluated. The objective of this study was to evaluate the role of intravenous epoprostenol as rescue therapy in the SSc-PAH and IPAH patients.

Methods: Patients attending the University Health Network Pulmonary Hypertension Program between 1998 and 2012 were included if they had a diagnosis of SSc-PAH and IPAH based on a mean pulmonary artery pressure (mPAP) of > 25 mmHg and a pulmonary capillary wedge pressure of <15 mmHg on cardiac catheterization, and had been treated with intravenous epoprostenol after treatment with endothelin receptor antagonists and/or phosphodiesterase-5 inhibitors for PAH. The primary outcome was survival. Survival was defined as the time from initiation of epoprostenol to death from any cause. Patients were censored as of May 1, 2012. Survival was evaluated using Kaplan Meier curves.

Results: 1140 patients were reviewed to identify 36 patients with SSc-PAH and 24 patients with IPAH treated with epoprostenol after failure with oral pulmonary hypertension specific therapies. 83% of SScPAH and 75% of IPAH patients were female. The mean (standard deviation) PAH duration prior to initiation of epoprostenol was 3.3 (5.7) years for SScPAH, and 2.1 (2.1) years for IPAH patients. Median 1-, 2-, 3-, 4-, 5-year survival for SSc patients was 85.7%, 60.7%, 53.6%, 46.1%, 42.3%; and for IPAH patients was 83.3%, 70.8%, 65.8%, 59.2%, 59.2%. There was no significant difference in survival between the SScPAH and IPAH patients treated with epoprostenol (p=0.13).

Conclusion: Our findings demonstrate desirable long-term survival and support the use of epoprostenol as rescue therapy for SSc-PAH and IPAH patients.

Sex Disparities In Survival Of Systemic Sclerosis-Associated Pulmonary Arterial Hypertension and Idiopathic Pulmonary Arterial Hypertension Patients. Christopher Pasarikovski[1], John T. Granton[2], Peter Lee[3], Adrienne M. Roos[1], Amie T. Kron[1], Cathy Chau[4] and Sindhu R. Johnson[5]. [1]Toronto Scleroderma Research Program, Toronto Western Hospital, Mount Sinai Hospital, and University of Toronto, Toronto, ON, [2]Toronto Pulmonary Hypertension Programme, Toronto General Hospital and University of Toronto, Toronto, ON, [3]Mt. Sinai Hospital, Toronto, ON, [4]Toronto Scleroderma Research Program, Toronto Western Hospital, Mount Sinai Hospital, University of Toronto, Toronto, ON, [5]Toronto Western Hospital, Toronto General Hospital, Mount Sinai Hospital, and University of Toronto, Toronto, ON.

Background/Purpose: Systemic sclerosis (SSc) associated pulmonary arterial hypertension (PAH) and idiopathic PAH (IPAH) are conditions with poor survival. There is evidence to suggest that sex affects survival. The primary objective of this study was to evaluate the effect of sex on survival in SSc-PAH and IPAH. We secondarily evaluated the effect of sex on disease onset, time to diagnosis, disease progression and treatment.

Methods: Patients were included if they attended the Toronto Scleroderma Program or the University Health Network Pulmonary Hypertension Program; had a diagnosis of SSc-PAH or IPAH defined as a mean pulmonary artery pressure >25mmHg and age > 16 years. Sex was defined as self-reported biological and physiological characteristics at birth (male, female). The primary outcome was the time from diagnosis to death from all causes. Secondary outcomes were sex differences in age of diagnosis, disease duration and SSc manifestations. Cox proportional hazards model were used to evaluate survival.

Results: 52 male and 267 female SScPAH; and 47 male and 107 female IPAH patients were identified. Male SSc patients had a shorter mean (standard deviation) time from SSc diagnosis to PAH diagnosis (5.6 (8.7)) versus (8.4 (9.6)), p=0.047), increased frequency of renal crisis (19% versus 9%, p= 0.04), interstitial lung disease (67% versus 49%, p=0.02), and digital ulcers (29% versus 19%, p<0.001). Male IPAH patients had a higher frequency of diabetes (30% versus 12%). Despite adjusting for these differences, male SScPAH patients have decreased 1-, 2-, 3-, and 5-year survival (82.6%, 70.6%, 60.8%, 48.2%) compared to females (84.4%, 73.4%, 64.2%, 52.8%). Similarly, male IPAH patients have decreased 1-, 2-, 3-, and 5-year survival (93.4%, 87.9%, 84.8%, 77.7%) compared to females (94.5%, 91.0%, 88.7%, 83.2%).

Conclusion: Sex disparities appear to exist in survival of SSc-PAH and IPAH patients. Further investigation is needed to evaluate this disparity, mechanisms for disparity, and the role of a targeted screening and treatment approach.

Pulmonary Hypertension In Systemic Sclerosis: Clinical Classification and Pulmonary Hypertension Subtypes. Monica Mohile[1], Mary Lucas[2], Virginia D. Steen[3], Thomas A. Medsger Jr.[2] and Robyn T. Domsic[2]. [1]University of Pittsburgh Medical Center, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Georgetown University Medical Center, Washington, DC.

Background/Purpose: Pumonary hypertension (PH) is a significant complication of systemic sclerosis (SSc), with prevalence reports of 10–25%. Predictors of PH remain somewhat elusive. Our objective was to assess the pattern of PH timing and subtype development in limited versus diffuse cutaneous SSc.

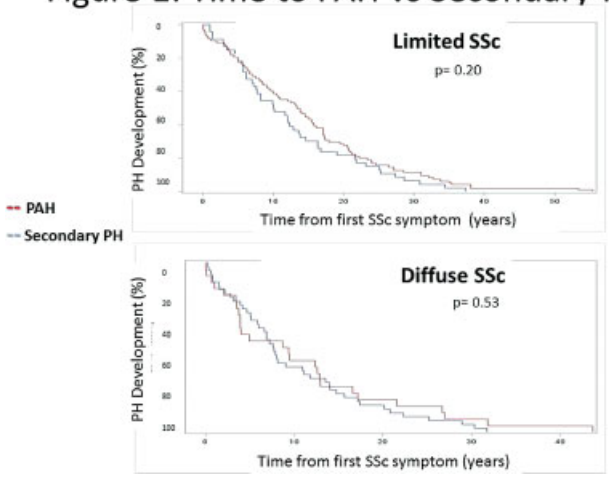
Methods: From our prospectively enrolled institutional scleroderma databank we performed a 10-year cross-sectional study of consecutive patients seen between January 1, 2000 and December 31, 2009. PH was defined as a mean pulmonary artery pressure (PAP) $>$ 25 mmHg on right heart catheterization (RHC) or transthoracic echocardiogram (TTE) with PAP $>$ 45 and PH diagnosed by a cardiologist. Descriptive statistics were used for baseline and PH characteristics, Kaplan Meier plots for time to development of PH and Cox proportional hazards for adjusted analysis.

Results: Of the 1,156 SSc patients included, 80% were female, the average age at first SSc symptom was 43.7 $\pm$ 14.2 years, and 44% had diffuse SSc. Two hundred thirteen (18%) had PH, of whom 122 (10% of total) had pulmonary arterial hypertension (PAH) and 90 (8% of total) had PH secondary to either ILD (PH-ILD) or cardiac involvement (PH-cardiac). 75% were confirmed by RHC; 25% did not have available RHC numbers in the hospital system but were confirmed as PH by cardiology evaluation. Prevalence of all PH was more common in limited (22%) vs diffuse SSc (14%; p=0.001). The profile of PH subtype was different, with 67% of limited SSc having PAH, compared to 37% in diffuse SSc ($p < 0.0001$). As shown in Table 1 approximately 5% of diffuse patients developed PAH with more secondary PH, whereas limited SSc patients developed predominantly PAH ($p =< 0.0001$). Patients with limited SSc developed all PH later in disease at a median 12.0 (IQR 5.7, 20.7), compared to 7.7 (3.5, 14.7) years since first SSc symptom in diffuse SSc (p=0.02), and this persisted after adjustment for age and gender (p=0.02). However there was no difference in the time to development of PAH compared to secondary PH in either diffuse or limited SSc (Figure 1).

Table 1. Prevalence of PH subtypes in limited and diffuse SSc

		Secondary PH		
	NoPH	PAH	PH-ILD	PH-cardiac
Limited cutaneous SSc	78%	15%	5%	2%
Diffuse cutaneous SSc	86%	5%	6%	3%

Figure 1: Time to PAH vs Secondary PH



Conclusion: These data suggest that although patients with limited SSc are more likely to develop PAH, the rate of PAH and secondary PH development is similar regardless of clinical subset. All SSc patients, including late diffuse SSc, should continue to be screened for all types of PH.

Recommendations For Screening and Detection Of Connective-Tissue Disease Associated Pulmonary Arterial Hypertension. Dinesh Khanna[1], Heather Gladue[2], John D. Fitzgerald[3], Richard N. Channick[4], Lorinda Chung[5], Oliver Distler[6], Daniel Furst[7], Eric Hachulla[8], Marc Humbert[9], David Langleben[10], Stephen C. Mathai[11], Rajeev Saggar[12], Scott H. Visovatti[13] and Vallerie McLaughlin[2]. [1]University of Michigan Medical Center, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]UCLA School Med Rehab #32–59, Los Angeles, CA, [4]Massachusetts General Hospital, Boston, MA, [5]Stanford Univ Medical Center, Palo Alto, CA, [6]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [7]University of California in Los Angeles, Los Angeles, CA, [8]Claude Huriez University Hospital, Lille, France, [9]Centre Chirurgical Marie-Lannelongue, Le Plessis-Robinson, France, [10]McGill University, Montreal, QC, [11]Johns Hopkins University, Baltimore, MD, [12]St. Joseph's Hospital and Medical Center, Phoenix, AZ, [13]The University of Michigan, Ann Arbor, MI.

Background/Purpose: Pulmonary arterial hypertension (PAH) affects up to 15% of patients with connective tissue diseases (CTD) and is one of the leading causes of mortality in systemic sclerosis (SSc) and mixed connective tissue disease (MCTD). Previous recommendationswere developed as part of larger efforts in PAH and did not provide detailed recommendations in CTD-PAH. To develop recommendations for screening and early detection of CTD-PAH using rigorous data-driven and consensus-building methodology.

Methods: We performed a systematic review for the screening and diagnosis of PAH in CTD by searching available databases. Using the RAND/UCLA methodology, we developed case scenarios followed by 2 stages of voting—first one was voted anonymously by 10 international experts on 1 (inappropriate) −9 (appropriate) scale and 2nd voting after face-to-face meeting.

Results: The key recommendations include:

1. All patients with SSc should be screened for PAH.
2. MCTD or other CTD's with scleroderma features (referred hereon as scleroderma-spectrum disorders) should be screened similar to patients with SSc.
3. Screening of asymptomatic patients is not recommended for MCTD or other CTD patients without features of scleroderma.
4. RHC is mandatory for diagnosis of PAH.
5. Acute vasodilator testing is not required as part of the evaluation of PAH in patients with SSc, SSc-spectrum disorders, or other CTDs.
6. Initial screening evaluation in patients with SSc and scleroderma-spectrum disorders include pulmonary function test (PFT) including diffusion capacity carbon monoxide (DLCO), Transthoracic echocardiogram (TTE), NT- Pro BNP, and DETECT algorithm if DLCO% $<$ 60% and $>$3 years disease duration.
7. In SSc and SSc-spectrum disorders, TTE and PFT should be performed on an annual basis or TTE, PFT, and NT-Pro BNP if new signs or symptoms develop.

Recommendations for RHC for SSc and scleroderma-spectrum disorders

Non-invasive test	Threshold for RHC	Signs or symptoms* required for RHC
TTE	TR velocity of 2.5–2.8 m/s	Yes
	TR velocity of $>$2.8 m/s	No
	Right atrial (RA major dimension $>$53 mm) or right ventricular enlargement (Mid cavity RV dimension $>$35 mm), irrespective of TR velocity	No
PFTs	FVC/DLCO ratio $>$1.6 &/or DLCO $<$60%**	Yes
	FVC/DLCO ratio $>$1.6 &/or DLCO $<$60% & NT-Pro BNP $>$2 times upper limit of normal**	No
Composite measure	Meets DETECT algorithm in patients with DLCO $>$60% & disease duration $>$ 3 years	No

* Symptoms: dyspnea on rest or exercise, fatigue, pre-syncope/syncope, chest pain, palpitations, dizziness, lightheadedness. Signs: Loud pulmonic sound, peripheral edema **TTE without overt systolic dysfunction, greater than grade I diastolic dysfunction or greater than mild mitral or aortic valve disease or evidence of PH.

Conclusion: We provide consensus-based and evidence-driven recommendations for screening and early detection of CTD-PAH. It is our hope that these recommendations will lead to early detection of CTD-PAH and ultimately improve patient outcomes.

Does Mycophenolate Mofetil (MMF) Have An Effect On Pulmonary Hemodynamics? Observations From The Pulmonary Hypertension Assessment and Recognition Of Outcomes In Scleroderma (PHAROS) Cohort. Lesley Ann Saketkoo[1], Matthew R. Lammi[1], Jessica K. Gordon[2], Paula Lauto[3] and Virginia D. Steen[4]. [1]LSU Scleroderma and Sarcoidosis Patient Care and Research Center, New Orleans, LA, [2]Hospital for Special Surgery, New York, NY, [3]LSU Health Sciences Center, New Orleans, LA, [4]Georgetown University Medical Center, Washington, DC.

Background/Purpose: Systemic sclerosis (SSc) related pulmonary hypertension (PH) carries a high mortality; with SSc pulmonary arterial hypertension (PAH) having a 4x higher mortality then idiopathic PAH. It is unknown whether immunosuppressant (IS) drugs, particularly mycophenoloate mofetil (MMF), have any effect on vascular remodeling in SSc PH since it has not been formally studied. This analysis looks at the possible effects of MMF in SSc patients who have developed PH.

Methods: PHAROS is a prospective registry designed to provide substantive data to recognize aspects of PH unique to SSc. Patients were stratified by history of MMF or No IS use (no MMF or other immunosuppressant drugs) at the time of the diagnosis of PH by right heart catheterization (RHC). Calculations are derived from non-parametric analyses using Mann-Whitney and Fisher's Exact as applicable followed by regression analyses.

Results: There were 39 SSc patients who had received MMF (mean duration 0.92 years) and 203 patients receiving No IS prior to diagnosis of PH. Patients treated with MMF when compared to the No IS group, were more likely to be younger, have diffuse SSc and have shorter disease duration. Patients treated with MMF had a significantly lower mean pulmonary artery pressure (mPAP) and pulmonary vascular resistance (PVR) with no difference in pulmonary capillary wedge pressure (PCWP) (Table 1). However, stratified analyses between diffuse and limited SSc patients on MMF revealed no significant differences in mPAP, PVR, PCWP nor in FVC, TLC, FEV/FVC nor DLCO (Table 2). In the group as a whole, MMF ($p=0.046$) and SSc subtype ($p=0.01$) were the only independent determinants of mPAP when adjusted for differences in age, FVC and disease duration.

Table 1. Comparison between SSc patients on No IS medications and MMF at time of first RHC. Continuous variables are reported as median, interquartile range; categorical values are proportional.

mPAP	29 (26,36)	29.0 (25.35)	0.7507
PVR	234 (140,466)	222 (166,340)	0.7495
PCWP	11.5 (9.8,16.5)	11.0 (9.15)	0.7621
FVC	75.9 (57.2,90.0)	61.7 (45.5,76.2)	0.1039
TLC	68,9 (54,7, 46,8)	60.3 (46.8,77.9)	0.1898
FEV/FVC	84.5 (79.0,88.5)	87.0 (81.8,93)	0.3181
DLCO	36.2 (31.4,40.2)	32.5(25.2,38.6)	0.2862
FVC:DLCO	2.04 (1.4,2.6)	1.73 (1.2,2.3)	0.5168
6MWD	417.1 (362,502)	388.8 (241,466)	0.3384

Conclusion: Patients treated with MMF compared to the No IS group had lower mPAP and PVR at time of the diagnosis of PH with no difference between groups in PCWP. Differences in mPAP between groups were not explained by differences in age, FVC, or disease duration. These data suggest that MMF could potentially play a role in pulmonary artery remodeling and modifying the severity of PH. These findings warrant prospective controlled investigations of MMF in SSc PH.

Can Changes In NT-Probnp Predict Early Response To Therapy and Prognosis In Systemic Sclerosis Associated Pre-Capillary Pulmonary Hypertension? Vincent Sobanski[1], Bernadette Lynch[2], Benjamin E. Schreiber[3], Clive Handler[2], Christopher P. Denton[4] and John G. Coghlan[5]. [1]Royal Free Hospital, London, United Kingdom, [2]The Royal Free Hospital, London, United Kingdom, [3]National Pulmonary Hypertension Service, London, United Kingdom, [4]Royal Free and University College Medical School, London, United Kingdom, [5]The Royal Free Hospital NHS Foundation Trust, London, United Kingdom.

Background/Purpose: Pulmonary hypertension (PH) is a severe complication of systemic sclerosis (SSc), affecting 5–12% of patients. Despite recent progress in treatment, prognosis remains poor. Early therapeutic management and goal-oriented approach can improve long-term prognosis. Response to therapy is usually assessed by functional and hemodynamic parameters between 3–6 months after initiation of treatment. This study aimed to compare the changes in NT-proBNP with functional and hemodynamic parameters between baseline and 3–6 months after initiation of therapy.

Methods: A retrospective study, undertaken in a National Pulmonary Hypertension Centre, identified patients diagnosed with SSc associated pre-capillary PH on right heart catheterisation (RHC) (mean pulmonary arterial pressure (mPAP) $\geq$ 25mmHg and pulmonary capillary wedge pressure (PCWP) $\leq$ 15mmHg) between 1998 and 2012 (n=600). Patients were included if they had a second RHC between 3 and 6 months after the initial RHC diagnosing PH and if NT-proBNP results were available within 30 days prior to each RHC. 53 patients were identified. 6 patients were excluded (glomerular filtration rate $<$ 30 mL/min/1.73m^2). Changes in variables (Δ) between baseline and 3–6 months were calculated in absolute value, percentage of variation and logarithm of each value. Pearson or Spearman methods were used to estimate correlation coefficient, where appropriate. Patients were divided into two groups: D="NT-proBNP decreasing" and I/S="NT-proBNP increasing or stable" according to the difference in NT-proBNP levels between baseline and repeat RHC. Survival analyses were performed using Kaplan-Meier method and log-rank test.

Results: 47 patients (42 female and 5 male) were included. 83% had limited cutaneous SSc and 53% were anti-centromere antibody positive. The mean age at diagnosis of PAH was 62.1 $\pm$ 11.5 years; the mean time between

both RHCs was 3.6 ± 1.0 months and the mean follow-up after first RHC was 28.0 ± 15.4 months. Six-minute walking distance (6MWD − p=0.002), mPAP (p=0.003), cardiac index (p=0.034) and pulmonary vascular resistances (PVR – p<0.0001) significantly improved in the group D. There was a trend in decreasing for PVR in the I/S group (p=0.094). In the total population, ΔNT-proBNP was negatively correlated with Δ6MWD in percentage (R= −0.305, p=0.050). ΔNT-proBNP in percentage tended to correlate with ΔmPAP in percentage (p=0.090) or log (p=0.073). No correlation was found between ΔNT-proBNP in percentage or in log with PVR, cardiac output, cardiac index, venous oxygen saturation, right arterial pressure and PCWP. Survival was significantly better in patients with decreasing NT-proBNP in all patients with pre-capillary PH (p=0.045) and in patients with PAH (p=0.002). There was no difference for PH-ILD patients (p=0.658).

Conclusion: Patients with decreasing NT-proBNP presented a significant improvement in hemodynamic parameters at 3–6 months. No strong correlation was found between ΔNT-proBNP and changes in functional or hemodynamic variables. However, early changes in NT-proBNP seem to be associated with prognosis – especially in PAH patients.

Treatment Of Pulmonary Hypertension In Scleroderma Patients With Restricitive Lung Disease. Observations From The Pulmonary Hypertension Assessment and Recognition Of Outcomes In Scleroderma Cohort. Virginia D. Steen[1] and Robyn T. Domsic[2]. [1]Georgetown University Medical Center, Washington, DC, [2]University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Trials of therapy in pulmonary hypertension (PH) have generally excluded patients with significant interstitial lung disease, but many patients with systemic sclerosis(SSc) and PH have some interstitial lung disease. There are concerns that PH drugs may cause ventilation-perfusion mismatch and worsen PH, and it remains unclear if PH drugs improve outcomes for these patients. PHAROS, Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma, is a prospective observational multi-center cohort study of SSc-PH. Our objective is to describe the real-world experience of SSc-PH patients with restrictive lung disease treated with a single PH medication.

Methods: We included patients with PH defined as a mean pulmonary artery pressure (mPAP) ≥25mmHg on catheterization who had a FVC <70% predicted at the time of the diagnosis. Patients were grouped into 3 groups, based on the treatment during the first year following the PH diagnosis: No drug treatment, treatment with an endothelin receptor blocker antagonist (ERA), or andphosphodiesterase inhibitor (PDE). For this initial look at the data, patients treated with combination therapy and/or prostacyclins (PCA) were excluded. The primary outcome examined was one-year survival, with secondary outcomes of hospitalization, change in functional class, 6 minute walk and patient questionnaires at one year.

Results: Of the 266 patients with PH in PHAROS, 98 had a FVC <70% and were included. There were 26 receiving no therapy (No Drug), 19 receiving ERA and 33 treated with PDE. We excluded 18 treated with combination and 2 treated with PCAs alone. There were no significant differences in the demographics or the cardiopulmonary parameters between the 3 groups. These patients had striking restrictive disease with a mean FVC between 50 and 55% predicted. Although over survival was not statistically different between the 3 groups, patients in the PDE group had fewer deaths and a better 1 and 2 year survival than the No Drug group. (p<0.05). There were more patients in the PDE group who had an improvement compared to the ND group and neither treatment group had an increase in hospitalizations after starting the drugs (Table 1).

	No Drug n = 26	ERA n = 19	PDE n = 33
Age–yr, mean	54.5	57.2	56.8
Disease Duration yr, mean	10.1	8.3	9.2
% Female sex	70	79	62
% White race	76	63	64
% Diffuse cutaneous	42	63	42
FVC% predicted	52.2	49.9	55.5
DLCO % predicted	33.6	25.9	42.0
RHC m PAP	31.85	33.3	36
PVR (Woods)	293	343	419
Response in 1st year	23%	37%	43%
Hospitalizations	2	1	2
Deaths in 1st year	7	3	1
Survival, 1, 2 year	69%, 61%	82%, 64%	96%, 76%

Conclusion: SSc patients with PH and restrictive lung disease are being treated with PH drugs. Our observations suggest that some patients may respond favorably, without evidence of worsening PH. We strongly encourage further study of PH drugs in SSc-ILD patients in a controlled setting.

Long-Term Treatment With Endothelin Receptor Antagonist Increases Peripheral Blood Perfusion In Systemic Sclerosis Patients. Maurizio Cutolo[1], Barbara Ruaro[1], Elena Bernero[1], Francesca Ravera[1], Giuseppe Zampogna[1], Elisa Alessandri[1], Vanessa Smith[2] and Alberto Sulli[1]. [1]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, [2]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium.

Background/Purpose: Systemic sclerosis (SSc) is characterized by progressive impairment of the microvascular system and decrease of peripheral blood perfusion (PBP) (1–3). The vasoactive peptide endothelin-1 (ET-1) seems to be implicated in these events (4). Laser Doppler flowmetry (LDF) is a technique to evaluate blood perfusion at peripheral sites, such as the central area of the fingertips (2). The aim of this study was to investigate long-term effects of ET-1 receptor antagonism on PBP evaluated by LDF technique in SSc patients.

Methods: Twenty-six SSc patients (mean age 62±12SD years, mean SSc duration 8±4 years) were enrolled during their programmed standard treatment protocols for digital ischaemia. At baseline (T0), 13 patients already receiving cyclic intravenous infusion of iloprost (average 80 mcg/day, for 5 continuous days, every three months), continued the treatment for further 3 years (ILO group: T1,T2,T3). The remaining 13 patients, although they continued the same cyclic intravenous iloprost treatment as the previous group, also received bosentan 125 mg twice a day for 3 years (ILO+BOS group: T1,T2,T3) since complaining digital ulcers. PBP was yearly evaluated in all SSc patients using LDF at both basal temperature and after heating of the LDF probe at 36°C to test microvascular dilation capacity. PBP was measured at the central area of the fingertips of the 2nd to 5thfinger bilaterally, scoring the average value as perfusion units (PU) (2). Non-parametric tests were used for the statistical analysis.

Results: A progressive and statistically significant increase of PBP was observed in the ILO+BOS group at basal temperature during the follow-up (median PU T0 51, T1 74, T2 70, T3 85, respectively, p=0.007); at 36°C, PBP significantly increased only during the first two years of follow-up (median PU T0 81, T1 104, T2 110, respectively, p=0.0003; T3 105). In contrast, not statistically significant PBP changes were observed in ILO group at both basal temperature (median PU T0 104, T1 78, T2 55, T3 44, p=0.70) and 36°C (median PU T0 126, T1 108, T2 109, T3 87, p=0.45). Gradient of PU between the evaluations at basal temperature and at 36°C was found progressively decreased during the followup in the ILO group, but not in the ILO+BOS group. Two SSc patients experienced new digital ulcers in the ILO+BOS group (15%), and four in the ILO group (31%). No serious side effects were observed. Transient increase of liver transaminases was managed by temporary discontinuation of bosentan treatment in two cases.

Conclusion: Long-term treatment with ET-1 receptor antagonist in combination with iloprost was found to significantly increase PBP in SSc patients, in contrast to the treatment with iloprost alone. This seems in agreement with the recent observation that long-term bosentan treatment reduces microvascular damage progression, as assessed by naifold capillaroscopy (5).

Screening and Diagnostic Modalities For Systemic Sclerosis-Associated Pulmonary Arterial Hypertension: A Systematic Review. Heather Gladue[1], Nezam I. Altorok[1], Whitney Townsend[1], Vallerie McLaughlin[1] and Dinesh Khanna[2]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: Pulmonary arterial hypertension (PAH) affects patients with connective tissue diseases (CTD), especially systemic sclerosis (SSc) and MCTD. Despite this, there continues to be delay in screening and diagnosis of these patients. We undertook a systematic review to summarize the best evidence for screening and diagnosis of PAH in CTD.

Methods: A systematic search was performed in Pubmed, EMBASE, Web of Science and Scopus databases up to June 2012 with an experienced librarian, related to PH and CTD. We only focused on WHO group I PAH and excluded manuscripts that did not rule out interstitial lung disease (WHO group III) or left heart disease (WHO group II), or if the diagnosis of pulmonary arterial hypertension (PAH) was not made by RHC.

Results: We started with 2805 titles, 838 abstracts, and included 21 manuscripts. Twelve studies assessed the tricuspid regurgitation velocity (VTR) or equivalent right ventricular systolic pressure (RVSP) using transthoracic echocardiogram (TTE) as a threshold for RHC in patients suspected as having PAH. 11 of these studies were in SSc, and one pertained to SLE. The screening threshold for RHC was VTR >2.73 to >3.16 m/s without symptoms or 2.5 to 3.0 m/s with symptoms and resulted in 20–67% of patients having RHC proven PAH (Table). In the SLE study, VTR >3.0 m/s on TTE led to RHC in 3 patients and none had PAH. Three studies looked at pulmonary function tests and various DLCO% predicted cut-offs. These studies suggest that a low DLCO% 45–70% is associated with a 5.6–7.4% development of PAH, and the decline in DLCO% is associated with an increase in the specificity (For 60% cut off, spec= 45%, and for 50% cut off, spec=90%]) for PAH. Five studies looked at NT-ProBNP and a cut-off >209pg/ml has a high sensitivity (90–100%) and a specificity ranging from 45–95%.

Single studies looked at EKG findings, cardiac MRI, Chest X-ray, CT, autoantibodies, laboratory values and physical exam findings.

Screening Modality	Number of Studies	Conclusion
TTE (TR velocity)	12 (11 SSc, 1SLE)	Studies had various inclusion criterion. VTR ranges to prompt RHC • 2.73–3.16 m/s without PAH-associated symptoms • 2.5–3.16 m/s with symptoms
NT-ProBNP	5 studies (2 cohort, 3 case control) All SSc	Various Cut offs >236pg/ml sensitivity (45–93%) specificity (83–100%)
PFT's	4 studies (3 cohort, 1 case control) All SSc	Decreased DLCO was associated with PAH.
Composite Measures	3 cohort studies All SSc	1. DLCO >70.3% and FVC/DLCO ≥1.82 and NT-ProBNP ≥ 209.8pg/ml −100% sensitive and 100% specific. 2. DLCO/VA<70% and NT-ProBNP >97th percentile for age 75% sensitive and 97% specific. 3. Cochin RPS score (RPS=0.0001107(age) +0.0207818 (100-FVC) +0.04905 (150-DLCO/alveolar volume). A cut off of 2.73 sensitivity of 89.5 and specificity of 74.1% for PAH

Conclusion: Our systematic review shows that most evidence exists for use of TTE, pulmonary function tests, and NT-ProBNP for screening and diagnosis of PAH in CTD. These data will be used to develop guidelines for screening and diagnosis of PAH in CTD.

Left Ventricular Dysfunction Reflected By Higher Serum Brain Natriuretic Peptide Accounts For Poorer Prognosis Of Pulmonary Arterial Hypertension Associated With Systemic Sclerosis. Sumiaki Tanaka[1], Yoshiyuki Arinuma[1], Tatsuhiko Wada[1], Tatsuo Nagai[1], Jun Okada[2] and Shunsei Hirohata[1]. [1]Kitasato University School of Medicine, Sagamihara, Japan, [2]Kitasato Junior Collage of health and Hygienic Sciences, Minami-Uonuma, Japan.

Background/Purpose: Recentry, development of potent effective newer drugs for pulmonary arterial hypertension (PAH) have resulted in improving survival of the patients. However, the prognosis of patients with PAH associated with SSc remains still poor compared with that of patients without SSc. To explore the characteristics relevant to the poor survival of patients with PAH associated with SSc, we analyzed serum levels of brain natriuretic peptide (BNP).

Methods: We analyzed 2786 measurements of serum levels of BNP (pg/ml) obtained from 83 patient with PAH associated with CTDs, including 41 patients with SSc, and 42 patients with CTDs other than SSc (16 patients with SLE, 20 patients with MCTD and 6 patients with other CTDs), who had been diagnosed as PAH based on right heart catheterization test and followed between April 2001 and March 2013 in our hospital. For statistical analysis, we converted serum levels of BNP into logarithmic values based on the distribution. Comparison of serum levels of BNP between PAH with SSc and that with non-SSc CTDs was carried out using mixed effects model in which we set presence or absence of SSc, WHO-functional class (WHO-FC) as fixed effects, and patient as a random effect. Comparison of hemodynamics between PAH with SSc and that with non-SSc CTDs was similarly carried out.

Results: Significant deviation of the distribution of serum levels of BNP was observed between SSc and non-SSc CTDs (Figure). Thus, median (IQR) of serum level of BNP in SSc and non-SSc CTDs were 104.6 (52.5, 214) pg/ml, and 48.9 (19.9, 149.4) pg/ml, respectively. Mixed effects model showed that serum levels of BNP of each WHO-FC in SSc were significantly higher than those in non-SSc CTDs (Table). On right heart catheterization examinations, pulmonary capillary wedge pressure in SSc was significantly higher than that in non-SSc CTDs (8 (5.6, 11.0) mmHg, 6.3(5, 8) [median (IQR)], respectively; p=0.04), although there were no significant differences in mean pulmonary artery pressure, cardiac output, or pulmonary vascular resistance between both group.

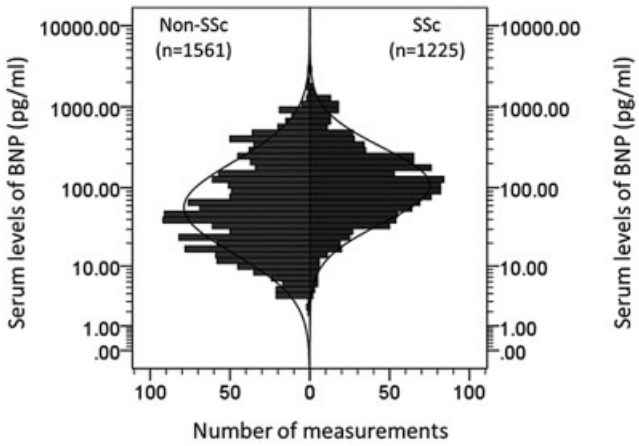

Table. Serum levels of BNP in PAH patients with CTDs

WHO-FC	serum levels of BNP(pg/ml)* PAH patients with non-SSc CTDs	PAH patients with SSc
I	35.0 (27.2–44.8)	54.0 (41.5–70)
II	67.1 (52.3–85.9)	103.5 (80.3–133.3)
III	108.3 (33.9–139.7)	167.1 (128.9–216.8)
IV	224.4 (170.0–297.9)	346.4 (261.6–458.6)

*Means (95% CI) were estimated with mixed effects models (fixed effect: SSc, WHO-FC(4), random effect; patient). SSc $p = 0.013$, WHO-FC: $p<0.0001$

Conclusion: Our results demonstrate that left ventricular dysfunction coexists with PAH associated with SSc, accounting for poor survival of PAH associated with SSc. Thus, special attention to this complication would be required in the management of patients with PAH associated with SSc using PAH-specific drugs.

Antinuclear Antibody Negative Systemic Sclerosis Patients Have Less Vasculopathic Disease Manifestations. Gloria Salazar[1], Shervin Assassi[1], Fredrick M. Wigley[2], Daniel E. Furst[3], Laura K. Hummers[2], Dinesh Khanna[4], John Varga[5], Elena Schiopu[6], Virginia D. Steen[7], Murray Baron[8], Marie Hudson[8], Janet E. Pope[9], Monique E. Hinchcliff[5], Marvin J. Fritzler[10], David B. Robinson[11], Robert W. Simms[12], Richard M. Silver[13], Tracy M. Frech[14], Barri J. Fessler[15], Jerry A. Molitor[16], Sara Zamanian[1], Niall Jones[17], John D. Reveille[1], Frank C. Arnett[1] and Maureen D. Mayes[1]. [1]University of Texas Health Science Center at Houston, Houston, TX, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]UCLA Medical School, Los Angeles, CA, [4]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI, [5]Northwestern University Medical School, Chicago, IL, [6]University of Michigan Medical School, Ann Arbor, MI, [7]Georgetown University Medical Center, Washington, DC, [8]McGill University, Montreal, QC, [9]St Joseph Health Care, London, ON, [10]University of Calgary, Calgary, AB, [11]University of Manitoba, Winnipeg, MB, [12]Boston University School of Medicine, Boston, MA, [13]Medical University of SC, Charleston, SC, [14]University of Utah School of Medicine, SLC, UT, [15]University of Alabama at Birmingham, Birmingham, AL, [16]Univ of MN MMC108, Minneapolis, MN, [17]Rheumatology Clinic at 124th Street Medical Clinic, Edmonton, AB.

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune disease characterized by fibrosis of skin and internal organs, as well as vasculopathy and immune dysregulation.

Autoantibody formation is one of the hallmarks of SSc. Autoantibodies in patients with SSc carry considerable value in diagnosis and in predicting various clinical outcomes; however their role in the pathogenesis of SSc is unclear.

While the great majority of patients with SSc have circulating antinuclear antibodies (ANA) (90–95%), a small percentage is ANA negative (5–10%). The detailed demographic and clinical characteristics of patients without ANA have not been clearly explored.

The objective of this study was to examine the demographic and clinical characteristics of systemic sclerosis (SSc) patients without antinuclear antibodies (ANA) compared to ANA positive patients.

Methods: SSc patients enrolled in the Scleroderma Family Registry and DNA Repository were included. Relevant demographic and clinical data were entered directly by participating sites or by chart review. Autoantibodies were determined at one site utilizing commercially available kits.

Results: This study included 3249 patients, of whom 208 (6.4%) were ANA negative. The proportion of male patients was higher in the ANA negative group (OR 1.65 $p=0.008$).

ANA negative patients experienced significantly less vasculopathic manifestations of SSc. The percent predicted diffusion capacity of carbon monoxide (DLco) was higher in ANA negative patients (p=0.03). Seven ANA negative patients had pulmonary arterial hypertension (PAH) per right heart catheterization (RHC) versus 213 ANA positive (OR= 0.23 $p<0.001$) indicating that PAH was significantly less common in the ANA negative group. They also had less often telangiectasias and digital ulcers/ pits ($p=0.01$ and $p<0.001$, respectively).

Although, diffuse cutaneous involvement was more common, the modified Rodnan Skin Score (mRSS) was lower in the ANA negative group (2.4 points lower, $p=0.018$). Furthermore, they experienced more malabsorption (p=0.003). There was no difference in the frequency of pulmonary fibrosis and scleroderma renal crisis. All-cause mortality was also not different between the two groups (p=0.28).

The above observations remained significant after adjusting for potential confounders (age, disease duration, gender, disease type) (Table 1).

Table 1. Multivariable analysis of clinical parameters in systemic sclerosis (SSc) patients who are ANA negative compared with ANA positive patients.

	OR/coef	95% CI	*p*
Telangiectasias	0.59	0.38, 0.91	0.01
Digital ulcers and pits	0.38	0.24, 0.59	<0.001
MPAP per RHC	−5.58	−10.85, −0.32	0.04
PAH per RHC	0.28	0.11, 0.70	0.006

Conclusion: ANA negative patients constitute a distinct subset of SSc characterized by fewer vasculopathic features of the disease, a higher proportion of men, more frequent lower gastrointestinal involvement as well as higher proportion of diffuse cutaneous disease but less severity of skin fibrosis overall.

2588

Pulmonary Hypertension In Patients With Anti-U1-RNP Antibodies. Vincent Sobanski[1], Bernadette Lynch[2], Benjamin E. Schreiber[3], Svetlana I. Nihtyanova[4], Jennifer Harvey[1], Clive Handler[2], Christopher P. Denton[4] and John G. Coghlan[5]. [1]Royal Free Hospital, London, United Kingdom, [2]The Royal Free Hospital, London, United Kingdom, [3]National Pulmonary Hypertension Service, London, United Kingdom, [4]Royal Free and University College Medical School, London, United Kingdom, [5]The Royal Free Hospital NHS Foundation Trust, London, United Kingdom.

Background/Purpose: Pulmonary hypertension (PH) is a leading cause of morbidity and mortality in patients with connective tissue diseases (CTD). Patients with anti-U1-RNP antibodies belong to a heterogeneous group, including systemic sclerosis (SSc), systemic lupus erythematosus (SLE) or mixed connective tissue disease (MCTD). This study aimed to (i) describe the prevalence, clinical and hemodynamic characteristics of PH in U1-RNP positive patients and (ii) analyse survival and compare prognosis between the different CTDs associated with these antibodies.

Methods: In this National Pulmonary Hypertension database, more than 2000 patients had a right heart catheterisation (RHC) performed between 1998 and 2012. One hundred and twelve patients were tested anti-U1-RNP positive. Twenty-two patients did not have PH (mean Pulmonary Arterial Pressure [mPAP] $<$ 25 mmHg). In the 90 patients with PH, 10 had post-capillary PH (pulmonary capillary wedge pressure [PCWP] $>$ 15 mmHg). Eighty had pre-capillary PH (PCWP $\leq$ 15 mmHg). Six patients were excluded because of incomplete RHC data. Thirty-seven had PH due to lung disease (PH-ILD) and 37 had pulmonary arterial hypertension (PAH). Anti-U1-RNP positive patients with PH were compared with unselected U1-RNP negative patients also having PH: 387 SSc and 21 SLE. For binary variables, comparison between 3 PH groups was performed using Monte-Carlo method with Fischer test for comparison one by one. ANOVA was used to compare continuous variables with a normal distribution. Kruskal-Wallis test was used for non-parametric comparisons. Kaplan-Meier method with log-rank test was used for survival analysis. All statistical analyses were performed using SPSS for Microsoft Windows®.

Results: The proportion of patients with SSc, SLE or MCTD was not significantly different between the 3 groups of PH. Anti-Sm antibodies were only seen in PH-ILD (p=0.038). Six-minute walking distance and WHO FC were significantly better in PAH vs. PH-ILD (p=0.003 and p=0.007 respectively). Mean PAP was similar in 3 groups. In U1-RNP negative patients, mPAP was significantly higher in SLE than in SSc patients (p=0.003). In PAH patients, SLE patients had higher mPAP than others groups (p=0.023). When comparing U1-RNP positive vs. negative in SSc or SLE patients, no difference was observed in hemodynamic values. Among PH-ILD patients, U1-RNP negative SSc had lower DLCO than U1-RNP positive (p=0.001). MCTD patients had lower CI (p=0.007) and higher PVR (p=0.05) than U1-RNP negative SSc patients. SLE and MCTD had a better survival than SSc (p=0.005 and p=0.037, respectively). PH-SSc patients carrying the U1-RNP antibody tended to have a better survival than U1-RNP negative (p=0.065). This trend was found in PAH patients (p=0.068) but not in PH-ILD patients (p=0.225).

Conclusion: These data confirm that patients with anti-U1-RNP antibodies are heterogeneous. To our knowledge, this is the largest cohort of patients with PH and MCTD. It provides hemodynamic data for all patients at PH diagnosis. In this group, patients with SSc have the worse

prognosis. Interestingly, survival of patients fulfilling MCTD classification criteria is intermediate between SSc and SLE.

Scleroderma Patients With Pulmonary Hypertension and Increased Pulmonary Capillary Wedge Pressure In The Pulmonary Hypertension Assessment and Recognition Of Outcomes In Scleroderma (PHAROS) Cohort. Matthew R. Lammi[1], Lesley Ann Saketkoo[2], Jessica K. Gordon[3], Paula Lauto[4] and Virginia D. Steen[5]. [1]Louisiana State University Health Sciences Center, Pulmonary and Critical Medicine, New Orleans, LA, [2]LSU HSC - New Orleans, Sections of Rheumatology and Pulmonary Medicine, New Orleans, LA, [3]Hospital for Special Surgery, New York, NY, [4]LSU Health Sciences Center, New Orleans, LA, [5]Georgetown University Medical Center, Washington, DC.

Background/Purpose: Systemic sclerosis (SSc) commonly leads to pulmonary hypertension (PH), which may be associated with left heart disease and an elevated pulmonary capillary wedge pressure (PCWP). Patients in this PH subgroup may have pulmonary artery pressures (PAP) in proportion to their elevated PCWP (pulmonary venous hypertension, "PVH") or higher than expected given their PCWP ("out-of-proportion PH"). It is not known what causes this difference in patients with SSc.

Methods: Baseline characteristics from 48 patients in the PHAROS registry (a prospective observational cohort of SSc patients at high risk for or with PH) who had a PCWP>15 on their inclusion right heart catheterization (RHC) were retrospectively analyzed. Using unpaired t-tests, characteristics of those who died before 2 years of follow-up (n=10) were compared to those who were alive at 2 years (n=20). Patients were divided into 2 groups based on their initial RHC diastolic pressure gradient (DPG=diastolic PAP minus PCWP): PVH (DPG ≤5mmHg) or out-of-proportion PH (DPG□5mmHg). Comparisons were made between groups using unpaired t-tests or Chi square. Kaplan-Meier analysis compared survival and time to first hospitalization between the 2 groups.

Results: At baseline, the mean PAP (mPAP) was 36.8±11.8 mmHg and the PCWP was 19.4±3.3mmHg. Univariate factors associated with death prior to 2 years are shown in the table. In multivariate analysis, the only independent factors associated with death prior to 2 years were lower 6MWD (p=0.01) and higher PCWP (p= 0.01). The out-of-proportion PH group (n=26) had higher baseline mPAP (42.7±13.0 vs. 29.7±3.7mmHg, p<0.0001), DPG (12.7±8.6 vs. 2.9±1.5mmHg, p<0.0001), and pulmonary vascular resistance (376±235 vs. 204±101 dynes/sec/cm^5, p=0.003) compared to the PVH group (n=22). Although there was no difference in baseline immunosuppression use overall, mycophenolate use was less common in the out-of-proportion PH group (8% vs. 37%, OR 0.15, p=0.027). There were no differences between the PVH and the out-of-proportion PH groups in age, sex, disease duration, pulmonary function, SSc subtype, or 6MWD (all p>0.05). There was no difference in 3-year survival between the 2 subgroups (PVH: 1-year=95%, 3-year=61%; out-of-proportion PH: 1-year=85%, 3-year=63%, p=0.73). There was a trend towards a shorter time to first hospitalization in the out-of-proportion PH group (p=0.13).

Table. Baseline characteristics in patients dying prior to 2 years of follow-up compared to those who survived for more than 2 years

Parameter	Death within 2 years	Survival > 2 years	p value
Age (years)	58.3 ± 15.5	54.1 ± 12.3	0.68
Sex (% female)	56%	85%	0.16
SSc disease duration (years)	8.9 ± 6.8	8.2 ± 8.4	0.83
Scleroderma type (%)			
Limited	40%	55%	0.71
Diffuse	50%	35%	
NYHA functional class			
I/II	30%	73%	p = 0.05
III/IV	70%	27%	
Immunosuppressant use at baseline (% yes)	20%	44%	0.40
6-minute walk distant (meters)	186 ± 96	366 ± 107	p = 0.002
Berg Dyspnea Score	5.7 ± 3.2	2.7 ± 2.0	p = 0.03
Mean pulmonary artery pressure (mmHg)	40.0 ± 9.8	32.7 ± 9.1	p = 0.05
Pulmonary capillary wedge pressure (mmHg)	22.9 ± 4.3	18.6 ± 2.4	p = 0.001

Conclusion: In patients with SSc-PH and a PCWP>15, lower 6MWD and higher PCWP were independently associated with an increased risk for death within 2 years. In SSc patients with a PCWP>15, those with out-of-proportion PH were less likely to be on mycophenolate (MMF) compared to those with pulmonary venous hypertension. The relationship between MMF and PH in SSc needs further investigation, as MMF's anti-fibrotic effects may theoretically decrease pulmonary artery remodeling in these patients.

Laser Speckle Contrast Analysis A New Method To Evaluate Blood Perfusion in Different Skin Areas Of Systemic Sclerosis Patients: Comparison With Laser Doppler Flowmetry. Alberto Sulli[1], Barbara Ruaro[1], Giorgia Ferrari[1], Elena Bernero[1], Carmen Pizzorni[1], Vanessa Smith[2] and Maurizio Cutolo[1]. [1]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, [2]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium.

Background/Purpose: In systemic sclerosis (SSc), blood perfusion (BP) may be evaluated by both laser speckle contrast analysis (LASCA) and laser Doppler flowmetry (LDF) techniques, as well as microangiopathy may be assessed by nailfold videocapillaroscopy (NVC) (1–3). This study aimed at investigating BP by LASCA in different skin areas of SSc patients, looking for any correlations with the extent of the nailfold microvascular damage. Correlations between LASCA and LDF analysis at fingertips were also checked.

Methods: Sixty-eight SSc patients and 68 sex and age matched healthy subjects were enrolled. The BP was assessed in the area of fingertips, periungual areas, dorsum and palm of both hands, as well as of face, forehead, tip of nose, zygomas and perioral region by LASCA, and scored as perfusion units (PU) (1). LDF was performed at the level of 2nd, 3rd, 4th, and 5th fingertip bilaterally (2), and average blood perfusion recorded as PU (2). NVC was performed in SSc patients and images classified and scored as previously reported (4–6). Non-parametric tests were used for the statistical analysis.

Results: Median BP was significantly lower in SSc patients when compared to healthy subjects at fingertips (86 vs 189 PU, respectively, p<0.0001), periungual areas (69 vs 140 PU, respectively, p<0.0001) and palms (77 vs 111 PU, respectively, p<0.0001). Conversely, both groups showed similar BP values at dorsum of hands and different areas of the face. The median BP gradient between fingertips and palm was lower in SSc patients than in healthy subjects (11 vs 67 PU, respectively, p<0.0001), as well as was the gradient between dorsum and periungual areas (25 vs 69 PU, respectively, p=0.0009). There was a statistically significant progressive decrease of BP in SSc patients with different NVC pattern of microangiopathy ("early", "active", or "late"), as well as a statistically significant negative correlation between microangiopathy evolution score (MES) and BP, at the level of fingertip areas (p<0.004), periungual areas (p<0.01) and palms (p<0.02), but not in the other areas. A positive correlation was detected between LASCA and LDF values at fingertip level, in all subjects (p<0.0001). LASCA, since evaluating large skin areas, is significantly less time consuming, is more accepted by patients and shows lower intra-operator variability than LDF (95% vs 88%).

Conclusion: This study shows that LASCA technique detects differences of BP at fingertips, periungual and palm areas between SSc patients and healthy subjects. Statistically significant correlations were observed between nailfold microangiopathy damage extent and BP at the level of fingertips, periungual and palm areas. LASCA positively correlates with LDF values at fingertips, but brings an higher reproducibility.

Scleroderma Renal Crisis and Pulmonary Arterial Hypertension Are Very Rare In The Same Patient. Bernadette Lynch[1], Vincent Sobanski[1], Clive Handler[1], Benjamin E. Schreiber[2], John G. Coghlan[3], Voon H. Ong[4], Aine Burns[1] and Christopher P. Denton[5]. [1]The Royal Free Hospital, London, United Kingdom, [2]National Pulmonary Hypertension Service, London, United Kingdom, [3]The Royal Free Hospital NHS Foundation Trust, London, United Kingdom, [4]The Royal Free and University College Medical School, London, United Kingdom, [5]Department of Rheumatology, London, United Kingdom.

Background/Purpose: Systemic Sclerosis (SSc) is associated with occlusive vasculopathy resulting in digital ischaemia, telangiectasia, scleroderma renal crisis (SRC) and pulmonary arterial hypertension (PAH). SRC and PAH have similar histological features with neointimal proliferation and medial hyperplasia and shared pathogenic mechanisms are plausible. Pulmonary hypertension (PH) after SRC is frequently observed but generally due to post capillary mechanisms with elevated post capillary wedge pressure (WHO Group II). We have explored the association of PAH (WHO Group I) with SRC based upon shared histopathological features and possible similarities in pathogenesis.

Methods: Of more than 2000 SSc patients attending our institution between 1990–2013, 150 patients had a confirmed diagnosis of SRC of which six (4%) patients had a diagnosis of PAH (mean pulmonary arterial pressure ≥25mmHg and pulmonary capillary wedge pressure <15mmHg) following right heart catherisation. Estimated glomerular filtration rate (eGFR) was calculated using the 4-variable Modified Diet in Renal Disease (MDRD) equation. Demographic, clinical and haemodynamic parameters are expressed as mean ± SD.

Results: Two patients had diffuse cutaneous SSc (dcSSc) and 4 patients had limited cutaneous SSc (lcSSc). 5/6 (83%) demonstrated an immunofluoresecence and ENA reactivity consistent with anti-RNA polymerase III reactivity, confirmed by specific ELISA. All patients with SRC and PAH were female. PAH was diagnosed after SRC in all patients (49 vs 44 years old). 4/6 (66.7%) patients required dialysis. 2/6 (33.3%) patients who did not require dialysis had an eGFR of 26 and 44mls/min/1.73m^2. 2 patients recovered renal function at 6 and 14 months after the diagnosis of SRC. The mean mPAP (mean pulmonary arterial pressure) was 42 ± 12mmHg with a mean pulmonary capillary wedge pressure (PCWP) 9.3 ± 2.6mmHg and a cardiac index of 5.2 ± 0.8 L/min. 5 patients were treated with Bosentan and 1 patient with intravenous Iloprost. 3/6 (50%) patients died with a mean survival from date of diagnosis of SRC of 112 ± 30 months and a mean survival from date of diagnosis of PAH of 47 ± 17 months.

Conclusion: The presence of SRC and PAH in the same patient is very rare and PAH occurred after SRC in all patients at a mean of 5 years later. Temporal separation of SRC and PAH suggests that these complications may occur independently, but the frequent association with ARA suggests common susceptibility factors may be relevant.

Clinical Significance Of Endothelial Vasodilator Function Evaluated By Endopat In Patients With Systemic Sclerosis. Naohiko Aozasa, Yoshihide Asano, Masaru Hatano, Ryosuke Saigusa, Kouta Takakuwa, Takehiro Takahashi, Tetsuo Toyama, Hayakazu Sumida, Atsushi Yao, Koichiro Kinugawa, Hisataka Maki, Toshiro Inaba, Hironori Muraoka, Shun Minatsuki, Issei Komuro and Shinichi Sato. University of Tokyo Graduate School of Medicine, Tokyo, Japan.

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disease characterized by initial vascular injuries and resultant fibrosis of skin and certain internal organs. Evidence has shown that vascular impairment in SSc may be a sign of endothelial dysfunction. The peripheral arterial tonometry (EndoPAT) is a device that is used to assess endothelial vasodilator function in a rapid and non-invasive fashion. Since its clinical significance has not been well established in SSc, we evaluated the association between the values of reactive hyperemia measured by EndoPAT and clinical features of SSc.

Methods: Thirty-three consecutive patients with SSc were studied, including 15 patients with limited cutaneous SSc (lcSSc) and 18 with diffuse cutaneous SSc (dcSSc). Clinical symptoms, such as swollen fingers, nailfold bleeding (NFB), pitting scars, digital ulcers, and Raynaud's phenomenon, were meticulously recorded. Reactive hyperemia peripheral arterial tonometry index (RHI) was measured using EndoPAT on all patients. Mean pulmonary artery pressure (mPAP) was measured by right heart catheterization. Correlations of RHI with various clinical symptoms, disease duration, laboratory data and disease subtypes were examined.

Results: RHI values were inversely correlated with mPAP ($r = -0.47$, $p < 0.01$), while positively correlated with %DLco ($r = 0.35$, $p < 0.05$). Furthermore, the values of RHI inversely correlated with disease duration in dcSSc patients ($r = -0.45$, $p < 0.05$), but not in lcSSc patients. Of note, RHI values were increased after one month of oral prednisolone in 4 patients with progressive skin sclerosis in whom skin stiffness was improved in response to the treatment.

Conclusion: Although mPAPs of all the patients enrolled in this study were less than 25 mmHg, the values of RHI were significantly and inversely correlated with mPAP, suggesting that the decreased RHI value reflects the reduction of the pulmonary vascular bed prior to the development of definite pulmonary arterial hypertension in SSc. Since skin sclerosis may affect the values of RHI, we have to be cautious to interpret the impact of prednisolone on endothelial function evaluated by EndoPAT in this disease.

The Prognosis Of Scleroderma Renal Crisis In RNA-Polymerase III Antibody (ARA) Positive Compared To ARA Negative Patients. Bernadette Lynch[1], Henry Penn[2], Jennifer Harvey[3], Aine Burns[1] and Christopher P. Denton[4]. [1]The Royal Free Hospital, London, United Kingdom, [2]Northwick Park Hospital, Harrow, United Kingdom, [3]Royal Free Hospital, London, United Kingdom, [4]UCL Medical School, London, United Kingdom.

Background/Purpose: Scleroderma renal crisis (SRC) usually presenting with accelerated hypertension and acute kidney injury (AKI) is one of the most severe complications of Systemic Sclerosis (SSc). The presence of RNA-polymerase III auto-antibodies (ARA) is recognized as a strong risk factor for SRC but studies have not explored long-term outcomes in ARA positive cases compared to ARA negative cases.

Methods: Of more than 2000 SSc patients attending our institution between 1990–2013, 150 patients had a confirmed SRC. 80% patients had diffuse cutaneous SSc (dcSSc) and 20% patients had limited cutaneous SSc (dcSSc). ARA was measured by commercial ELISA or radio-immunoprecipitation. Patients were divided into two groups: ARA positive or ARA negative. Demographic and clinical parameters were compared between groups using Student's t-test or Chi-squared analyses where appropriate.

Results: 61/150 (41%) patients were ARA positive and significantly more likely to have dcSSc (88.3% vs 73.8%, p=0.032) than lcSSc compared to ARA negative patients. There was no significant difference in age of onset of SRC (51.2 vs 51.9 years) or the number of females (73% vs 79%) between the two groups. 50.8% of ARA positive patients required dialysis compared to 29.2% of ARA negative patients (p=0.07). The mean time to recovery of renal function was significantly longer in ARA positive patients (14.25 vs 8.27 months, p=0.032). Significantly more ARA positive patients were able to discontinue dialysis compared to ARA negative patients (53.3% vs 25.5%, p=0.01). ARA positive patients had a significantly better survival outcome (figure 1).

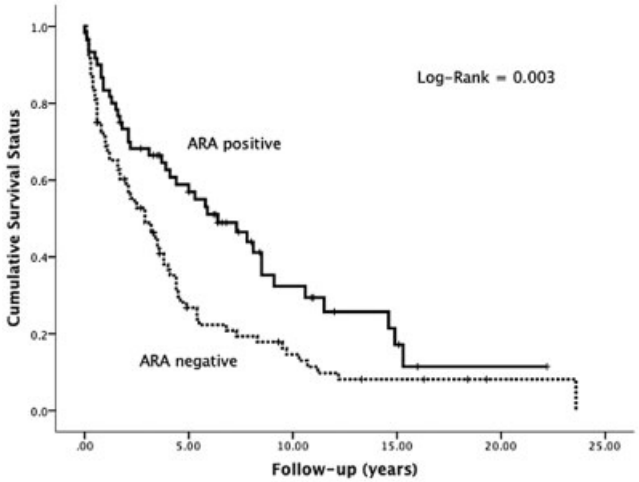

Figure 1. Kaplan Meier survival estimate showing the effect of ARA positive auto-antibodies in patients with SRC.

Conclusion: In SRC, although more ARA positive patients required dialysis they also had significantly greater capacity for long-term recovery and survival compared to ARA negative patients.

Stabilisation Of Microcirculation In Early Systemic Sclerosis Patients With Diffuse Skin Involvement Following Rituximab Treatment. Vanessa Smith[1], Carmen Pizzorni[2], Valeria Riccieri[3], Saskia Decuman[4], Yves P. Piette[1], Ellen Deschepper[5], Filip De Keyser[1] and Maurizio Cutolo[6]. [1]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium, [2]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, [3]Department of Internal Medicine and Medical Specialities, University Sapienza, Rome, Italy, [4]Department of Internal Medicine, Ghent University, Ghent, Belgium, [5]Biostatistics Unit, Department of Public Health, Ghent University, Ghent, Belgium, [6]University of Genova, Genova, Italy.

Background/Purpose: Microangiopathy in systemic sclerosis is progressive over time [1, 2]. This study assesses microangiopathic evolution by nailfold videocapillarocopic (NVC) analysis after two treatment course (month 0/6) with rituximab in early diffuse systemic sclerosis (dcSSc) patients.

Methods: Twelve months follow-up (open-label study) of six consecutive patients with early dcSSc. Patients received an infusion of two times 1000 mg rituximab at month 0 and 6, together with 100 mg methylprednisolone. All patients were on a stable dose methotrexate (10–25 mg/week) as background therapy since at least 12 weeks. Capillaroscopic assessment, clinical read outs (modified Rodnan skin score [mRSS], lung function and echocardiography) and disease activity score (DAS) were performed at 0, 3, 6 and 12 months.

Results: There was a clinical significant change in skin score with a mean (SD) mRSS of 24.8 (5.95) at baseline and 10.2 (1.17) at month 12 (Mixed Model Analyses [MMA] $p<0.001$) and a significant decrease in DAS, with a median of 3.8 at baseline (range: 2.0–7.0) and 0.5 at month 12 (range: 0.0–2.0) (MMA $p<0.001$). Indices of internal organ involvement remained stable. Semi-quantitatively scored NVC parameters remained stable showing no progression of the microvascular damage during the twelve months follow-up: mean score (SD) of capillary loss at baseline/12 months: 2.170 (0.408)/ 1.830 (0.408) (MMA $p=0.341$), mean score (SD) of giants at baseline/ 12 months: 0.670 (0.516)/ 1.17 (0.408) (MMA $p=0.093$), mean score of haemorrhages at baseline/12 months: 0.670 (0.516)/1.00 (0.000) (MMA $p=0.529$) and mean score of neoangiogenesis at baseline/12 months: 0.830 (0.408)/ 0.830 (0.753) (MMA $p=0.383$).

Conclusion: This is the first open pilot study to show that two immunosuppressive treatment courses with rituximab may not only have potential efficacy for skin and stabilisation of internal organ involvement but also additional stabilisation of microangiopathic parameters in early dcSSc.

Microvascular Abnormalities In Patients With Early Systemic Sclerosis: Less Severe Morphological Changes Compared To Patients With Definite Disease. Cintia Camargo, Juliana Sekiyama, Maria I. Arismendi and Cristiane Kayser. Universidade Federal de São Paulo, São Paulo, Brazil.

Background/Purpose: To analyze the morphological and functional abnormalities of the microcirculation through widefield nailfold capillaroscopy (NFC), videocapillaroscopy and cutaneous microvascular blood flow measurement before and after cold stimulus, associated with vascular injury markers in patients with early systemic sclerosis (SSc), compared to primary Raynaud's phenomenon (PRP), definite SSc, and healthy controls.

Methods: Eighty patients with definite SSc (American College of Rheumatology criteria), 46 patients with early SSc (2001 LeRoy's criteria), 40 PRP patients, and 45 controls were included. The morphological abnormalities were evaluated through widefield nailfold capillaroscopy (NFC) (10–25x magnification), and videocapillaroscopy (200x magnification). The following parameters were analyzed in eight digits of the hands (excluding the thumb) by widefield NFC and videocapillaroscopy: number of capillaries/mm, enlarged, giant and ramified capillaries, microhaemorrhages, and avascular score. A score based on a semiquantitative rating scale (score 0–3) was used for each videocapillaroscopy parameter. Patients with scleroderma pattern were distributed into three patterns: early, active and late. Fingertip blood flow (FBF) was measured using laser Doppler imaging (LDI) at baseline and during 30 minutes after cold stimulus. Serum endothelin-1 (ET-1), von Willebrand factor (vWF) and transforming growth factor beta-1 (TGF-β1) were measured by ELISA.

Results: Patients with early SSc showed significantly higher number of capillaries/mm, and lower enlarged, giant capillaries and avascular score compared to patients with definite SSc in widefield NFC and videocapillaroscopy ($p<0.001$). Besides the number/score of enlarged capillaries, microhaemorrhages and avascular score were higher in patients with early SSc compared to patients with PRP and controls in both methods ($p<0.001$). Ninety-six percent of patients with definite SSc, and 76% of early SSc patients presented the scleroderma pattern using videocapillaroscopy. The early pattern was most frequently found among early SSc patients (37% in early SSc vs 17% in definite SSc, $p<0.01$). The active pattern was found in 63% of early SSc and in 60% of definite SSc. Interestingly, the late pattern was not observed in patients with early SSc, but was observed in 23% of definite SSc patients. FBF values before and after cold stimulus were significantly higher in controls compared to PRP, early SSc and definite SSc ($p<0.001$), with no difference between early and definite SSc. Serum levels of ET-1, vWF activity and TGF-β1 were similar between early and definite SSc.

Conclusion: Early SSc patients showed functional changes and serum vascular markers levels similar to patients with established disease. Nonetheless, the morphological changes were less severe in early SSc, suggesting a progression of the peripheral microangiopathy along different phases of the disease. These findings may have important implications in the management of patients with early disease.

Association Between Nail Fold Capillaroscopy Abnormalities and Thermographic Assessment Of Peripheral Microvascular Dysfunction In An Unselected Cohort Of Patients Under Investigation For Symptoms Of Raynaud's Phenomenon. Bhavisha Vasta[1], Marina Scolnik[2], Darren Hart[1], Jacqueline A. Shipley[1], Sue Brown[1], Eleanor Korendowych[1], Neil J McHugh[3] and John D. Pauling[3]. [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]Rheumatology Section, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [3]Department of Pharmacy and Pharmacology, University of Bath, Bath, United Kingdom.

Background/Purpose: Nail fold capillaroscopy (NC) and infrared thermography (IRT) allow objective assessment of digital microvascular abnormalities in patients with Raynaud's phenomenon (RP) and have an important role in disease classification, particularly in systemic sclerosis (SSc). The relationship between NC appearances and assessment of digital microvascular function with IRT in an unselected population of patients with RP symptoms has not previously been explored.

Methods: A retrospective review of all patients investigated with both NC and IRT for symptoms of RP between August 2010 and November 2012 was undertaken. Thermographic assessment of the resting longitudinal thermal gradient of all fingers was undertaken by calculating the mean distal dorsal difference (DDD) at 23ºC (without prior knowledge of the clinical diagnosis or NC findings). NC images were reviewed (BV and MS) and categorized as normal, non-specific abnormalities and SSc-pattern abnormalities (Cutolo, Clin Exp Rheumatol. 2007). Indeterminate cases were reviewed by a 3rd assessor (JP) and consensus reached. A subsequent case note review was undertaken to categorize patients according to the following diagnoses; primary RP (no clinical features of connective tissue disease and ANA negative), SSc (sclerodactyly in conjunction with a SSc-specific autoantibody), fibromyalgia (FMS) (1990 criteria) and other diagnoses.

Results: One hundred and forty one patients were identified. NC appearances, IRT analysis and diagnoses are summarized in the accompany-

ing table. NC abnormalities were associated with a significantly lower median thermographic DDD indicating more severe peripheral microvascular function ($p=0.017$). There was no difference between thermographic findings of patients with non-specific and SSc-pattern NC abnormalities (possibly due to small patient numbers with SSc-pattern abnormalities). NC abnormalities were present in all patients with SSc and the majority (54.5%) had SSc-pattern changes. Patients with primary RP were significantly less likely to have NC abnormalities compared with SSc ($p<0.0001$). Non-specific NC abnormalities were identified in 15/46 (32.6) patients with primary RP but SSc-pattern abnormalities were not identified in any patients with primary RP. NC appearances were generally normal in FMS with only a small proportion of patients (3/18, 16.7%) exhibiting non-specific NC abnormalities.

	Normal NC appearance (n = 83)	Nonspecific NC changes (n = 48)	SSc-pattern NC changes (n = 10)
Median average DDD across all fingers, °C, median (IQR)	+0.15 (4.16)	−1.98 (4.21)	−2.09 (3.71)
p value vs. normal NC appearance (Mann Whitney U)		0.017	0.099
Proportion of patients with a mean DDD < −1, n (%)	35 (42.2)	25 (52.1)	7 (70)
Clinical diagnosis, n	31	15	0
Primary RP	0	5	6
SSc	15	3	0
FMS	37	25	4
Other rheumatic Diseases			

Conclusion: The presence of NC abnormalities is associated with thermographic evidence of more profound digital microvascular dysfunction in patients under investigation for symptoms of RP. The presence of NC abnormalities differs between primary RP and SSc. Despite a high reported prevalence of RP symptoms in FMS, the majority of patients have normal NC and thermographic findings.

Acupressure For The Treatment Of Raynaud's Phenomenon: A Pilot Randomized Controlled Trial. Heather Gladue[1], Richard E. Harris[1], Veronica Berrocal[1], Pei-Suen Tsou[2], Gautam Edhayan[3], Ray Ohara[3] and Dinesh Khanna[4]. [1]University of Michigan, Ann Arbor, MI, [2]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI, [3]University of Michigan Medical School, Ann Arbor, MI, [4]University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: Raynaud's phenomenon (RP) affects approximately 10% of the US population. The high cost, lack of efficacy, and side effects of conventional medical therapies necessitates the need for complementary or alternative options.

Objective: A pilot, randomized control trial (RCT) of acupressure vs. patient education for the treatment of RP.

Methods: A pilot single-center RCT of vasodilation acupressure, relaxation acupressure vs. RP education obtained from the Raynaud's Association (control). Patients with either primary (N = 15) or secondary (N = 8) RP were randomized from January through April by block randomization to the 3 groups for an 8 week period. Patients randomized to acupressure were instructed on how to self-perform at home by a single investigator and a DVD was provided with instructions. The primary endpoint was a decrease in the severity, frequency and duration of RP. All patients kept a daily Raynaud's diary, (recording the number and duration of attacks, pain, tingling and numbness on a 0–100 scale), and daily Raynaud's condition score. At baseline and 8 weeks, EndoPAT was performed to determine endothelial function, and serum was collected for biomarker analysis (VEGF, tPA, sE-Selectin, BFGF, VCAM-1, ICAM). Data analysis was conducted using the last observation carried forward and paired statistical analyses were used to assess difference.

Results: 23 patients were randomized and 9 discontinued prematurely (5 patients withdrew due to time restraints, 2 each for unrelated medical problems and lost to follow-up). Since there was no statistical difference between acupressure groups, they were combined and compared to the education group. 78% of patients were female, 96% were Caucasian, the mean age was 49.8 (SD=16) yrs; 5/16 patients in the acupressure group had secondary RP and 1/7 in the control group had secondary RP.. There was no statistical difference in the baseline characteristics between the acupressure groups vs. the control group. At the end of study, there were no statistical differences between the acupressure vs. education groups. However, there were trends in the patient reported severity of RP favoring acupressure groups (Table). In addition there were no significant differences in EndoPAT measurements or serum markers of vasculopathy. Sensitivity analysis using the completers showed similar results.

Table: Change from week 1 compared to week 8*

Variable	Group A+B	Control	P value
No of attacks	N: 12	N: 6	1.0
Mean (SD)	−6.3 (8.0)	−7.2 (12.8)	
Pain	N: 12	N: 6	0.12
Mean (SD)	−13.6 (30.1)	9.6 (27.6)	
Tingling	N: 12	N: 6	0.64
Mean (SD)	−5.3 (13.9)	−1.2 (7.5)	
Numbness	N: 12	N: 6	0.89
Mean (SD)	−10.5 (37.0)	1.1 (22.1)	
Average duration of attacks	N: 12	N: 6	0.08
Mean (SD)	−9.2 (18.7)	0.8 (11.2)	
RCS average for difficulty	N: 12	N: 5	0.72
Mean (SD)	−2.0 (2.4)	−0.6 (2.9)	
RCS average for pain	N: 12	N: 5	0.63
Mean (SD)	−1.4 (2.0)	−0.4 (3.0)	
Endopat	N: 14	N: 7	0.55
Mean (SD)	−0.1 (0.4)	−0.2 (0.8)	
Patient VAS	N: 16	N: 7	0.39
Mean (SD)	−1.6 (2.2)	−0.7 (2.0)	
MD VAS	N: 16	N: 7	1.0
Mean (SD)	−2.1 (2.0)	−1.9 (1.3)	

*Using LOCF.

Conclusion: Our pilot RCT showed that acupressure groups showed trends in improvement in symptoms associated with RP. However, there were no differences in the endothelial function and serum markers of vasculopathy. The parameters used to evaluate patients with RP have marked variability and supports the need for a composite measure to be developed for RP trials.

Timing and Outcome Of Transition From Primary To Secondary Raynaud's Phenomenon: A Capillaroscopic Based Study. Alberto Sulli[1], Giorgia Ferrari[1], Elena Bernero[1], Carmen Pizzorni[1], Vanessa Smith[2], Barbara Ruaro[1] and Maurizio Cutolo[1]. [1]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, [2]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium.

Background/Purpose: Raynaud's phenomenon (RP) is classified as primary (PRP) or secondary (SRP) depending on its association with an underlying disease (1,2). PRP can evolve to SRP during followup (1,3). This is a prospective study to investigate timing and outcome of transition from PRP to SRP in a large cohort of patients, as well as to assess the progression of the nailfold scleroderma-patterns of microangiopathy in patients with isolated RP.

Methods: 2,853 patients with RP were investigated. Patients achieving a diagnosis of PRP at first visit (normal nailfold videocapillaroscopy (NVC), normal or negative laboratory findings including autoantibodies, absence of other clinical findings and exclusion of an underlying disease) were followed to monitor the appearance of specific morphological alterations at NVC, autoantibodies positivity, or clinical symptoms for a mean period of 52±40SD months (1,3). Nailfold microangiopathy was detected by NVC, and capillary abnormalities were classified according to different patterns of microangiopathy (4–5).

Results: At first visit, 797 (28%) patients out of 2,853 showed a NVC scleroderma-pattern, and got the diagnosis of SRP. Among the remaining 2,056 patients showing a normal capillaroscopy at baseline, 1,677 patients were lost during follow-up or not prospectively evaluable, whereas 379 patients were followed for a mean time of 52±40SD months. Among these last, 180 patients (47%) were positive for ANA, and 199 (53%) were ANA

negative (PRP patients). During the follow-up, the NVC scleroderma-pattern was diagnosed in 62 patients out of 379 (16%). In particular, it was found in 48 (27%) of the ANA-positive patients (27 "early", 4 "active", 9 "late", 8 "like" NVC scleroderma-pattern at the end of the follow-up): these patients achieved the diagnosis of systemic sclerosis (46 patients), UCTD (1 patient) and Sjogren syndrome (1 patient). NVC was found positive also in 14 (7%) of the ANA-negative patients (transition to SRP) (13 "early", and 1 "like" NVC scleroderma-pattern at the end of the follow-up): these patients developed systemic sclerosis (9 patients) and UCTD (5 patients). The time of transition from normal/not specific capillary alterations to "early" scleroderma-pattern was 37±29 months. In particular, in ANA-positive patients NVC became positive within 43±36SD months, while in ANA-negative patients in 18±16 months. The 132 ANA-positive patients with a not defined NVC pattern developed respectively systemic sclerosis (7 patients), UCTD (104 patients), MCTD (8 patients), autoimmune thyroiditis (6 patients), Sjogren syndrome (4 patients), antiphospholipid syndrome (1 patients), LES (1 patients).

Conclusion: This large cohort study demonstrates that 7% of patients initially diagnosed as affected by PRP may transit to SRP in a mean time of 37±29 months. The transition from normal NVC pattern to scleroderma-pattern was more frequent in ANA-positive patients (27%).

Safety and Effectiveness Of Mycophenolate In Systemic Sclerosis: A Systemic Review. Mohammed Omair[1], Abdulaziz Alahmadi[2] and Sindhu R. Johnson[3]. [1]Mount Sinai Hospital/University of Toronto, Toronto, ON, [2]Toronto Scleroderma Research Program, Division of Rheumatology, Mount Sinai Hospital, Toronto Western Hospital, University Health Network, University of Toronto, Toronto, ON, [3]Toronto Western Hospital, Toronto General Hospital, Mount Sinai Hospital, and University of Toronto, Toronto, ON.

Background/Purpose: Mycophenolate reduces chronic allograft nephropathy and interstitial fibrosis by inhibiting TGF-β, which is an important molecule in the pathogenesis of systemic sclerosis (SSc). The main side effects observed are gastrointestinal disturbance, myelosuppression, and increased risk of infection. This maybe a limitation of its use in SSc patients since gastrointestinal involvement is very common. The objective of this study is to evaluate the safety, in particular gastrointestinal adverse events, of mycophenolate in SSc. Secondarily we evaluated the effectiveness of mycophenolate in SSc skin and lung disease.

Methods: A literature search of Medline, Embase, Cochrane Central Register of Controlled Trials, and CINAHL (inception - September 2012) was performed. Titles and abstracts were screened to identify studies that described the use of mycophenolate in SSc patients. Inclusion criteria included exposure to mycophenolate, and reporting of modified Rodnan skin score (MRSS), forced vital capacity (FVC), diffusing capacity of carbon monoxide (DLCO); or adverse events. The primary outcome was gastrointestinal events occurring after the initiation of mycophenolate. Secondary safety outcomes included myelosuppression, infection, malignancy, and death occurring after the initiation of mycophenolate.

Results: 616 citations were identified and 20 were included in the analysis. 477 patients have been exposed to mycophenolate. The mean disease duration ranged between 0.8–14.1 years. There were 89 non-lethal adverse events, of which 43 (48%) were gastrointestinal and 46 (52%) were non-gastrointestinal adverse events. The most commonly reported gastrointestinal events included diarrhea (n=18 (20%)), nausea (n=12 (13%)), and abdominal pain (n=3 (3%)). The most commonly reported non-gastrointestinal adverse events were infections (n=33 (37%), and 6 cytopenias (n=6, (7%)). The reported rate of discontinuation ranged between 8–40%. Seven observational studies report mycophenolate is effective improvement or stabilization in FVC, and 5 observational studies report stabilization or improvement in MRSS.

Conclusion: Observational studies report mycophenolate is effective in improving or stabilizing interstitial lung disease, and may be effective for skin involvement. However, gastrointestinal adverse events are common in SSc patients.

Shear Wave Elastography: A Novel Quantitative Approach For Evaluating Scleroderma Skin. Ingeborg Sacksen, Mark H. Wener, P. Scott Pollock and Manjiri K. Dighe. University of Washington, Seattle, WA.

Background/Purpose: Systemic sclerosis (SSc) is a multi-system disease with both visceral and cutaneous fibrosis. Dermal elasticity is reduced and stiffness increased due to excessive dermal and subcutaneous deposition of collagen leading to increased skin thickness as well as hardening and tightening of the skin. Shear wave elastography (SWE) is an emerging, operator-independent technique, which can obtain quantitative stiffness values. We describe a novel quantitative approach for evaluating the skin in scleroderma using shear wave elastography

Methods: We evaluated the skin of thirteen patients with diffuse systemic sclerosis and ten healthy controls using an Aixplorer shear wave ultrasound instrument (SupersonicImagine, Bothell, WA). Each patient underwent a SWE exam of the right arm at multiple sites (3rd finger, extensor forearm, upper arm), sternum, and face. The images consist of a spectrum of translucent colored bands superimposed on B-mode ultrasonographic images indicative of soft and highly elastic tissue to hard and minimally elastic tissue. The mean stiffness values of skin (measured in kPa units) were obtained at each site by averaging 3 measurements made per image obtained.

Results: The skin of seven men and five women with diffuse systemic sclerosis as well as 10 healthy controls was evaluated. The mean and 1SD SWE stiffness measures were (in kPa): finger –SSc 98.3 (SD-56) vs control – 32.1, (SD- 11.8); forearm – SSc 89.6 (SD- 58.9) vs control – 18.3 (SD-6.9), upper arm – SSc 34.5 (SD-19.2) vs control 17.7(SD8.6), face: SSc 19.3 (SD-17.7) vs control 8.4(SD-2.7), chest –SSc 23.6 (SD-17.1) vs control 10.9(SD-6.0). Maximum (out of range high) values of 300kPA were obtained for 1 patient at the finger and two patients at the forearm. Two-tailed t –tests were performed between the means of patients and controls at each site. Statistical significance ($p<0.01$) was achieved at the finger, forearm, all sites combined, and ($p<0.05$) at the upper arm. Statistical significance was not reached for the chest ($p=0.056$) and the face ($p=0.08$). Z scores (based on the mean and SD of each site in controls) were calculated for patient measurements at each individual site and combined sites compared to controls. Z scores at all sites were above the mean for controls (see figure 1).

	Control All Sites	Patients All Sites	Finger	Forearm	Upper arm	Chest	Face
Median	-0.07	3.44	6.49	7.94	0.92	0.57	1.93
mean+sd	1.00	12.48	12.77	20.64	4.47	5.08	11.82
Mean-sd	-1.00	-1.66	1.76	2.03	-0.43	-1.01	-3.06
Mean	0.00	5.41	7.27	11.34	2.02	2.04	4.38

Conclusion: Shear wave elastography is a valid and feasible quantitative method for assessing abnormal elasticity of the skin in scleroderma patients. It adds a new dimension to the assessment of skin involvement in SSc, and is an objective, non-invasive tool for potential use in clinical trials. Studies comparing its performance to stage of disease, skin thickness, and mRss are ongoing.

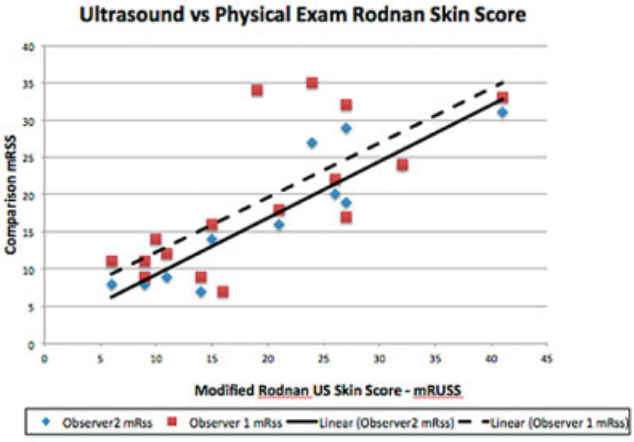
Modified Rodnan Ultrasound Skin Score: An Ultrasound Skin Scoring Approach In Systemic Sclerosis. Ingeborg Sacksen, P. Scott Pollock and Mark H. Wener. University of Washington, Seattle, WA.

Background/Purpose: Systemic sclerosis (SSc) is a multi-organ disease characterized by thickening, hardening and tightening of the skin. Skin

thickening is described by physical exam and measured semi-quantitatively as the modified Rodnan skin score (mRSS). Ultrasound (US) has been investigated to measure skin thickening, however, approaches to convert and relate US findings to mRSS's have not been adopted, in part because of the variability of normal skin thickness at different sites (as well as by age and gender). We present preliminary data reproducing a 17-point mRSS in scleroderma patients and controls by using mid frequency ultrasound (15mHz) and correlating it to physical exam findings. We propose development of an ultrasound adaptation of the mRSS: the Modified Rodnan Ultrasound Skin Score (mRUSS), which is easy to use, quantifiable, and allows ultrasound-based categorization of the skin in scleroderma patients.

Methods: We examined the skin of 16 patients (8 women) with diffuse cutaneous SSc and 10 healthy controls using a Sonosite M-Turbo 15mHz ultrasound machine operated by a single examiner. Each patient underwent a 17-point mRSS physical exam, and 12 patients had a second mRSS performed by an experienced rheumatologist. All patients then underwent a 17-point, comprehensive ultrasound skin exam at reproducible, predefined sites corresponding to the anatomic sites examined in the mRSS. The sites were: single sites on the face, chest wall, and abdomen, and bilateral 3rd finger, dorsum of the hand, extensor forearm, upper arm, thighs, lower legs, and the dorsal surface of the feet. Two dermal thickness measurements were taken from each image and averaged. The mean and standard deviation (SD) was calculated for controls at each site, and the z-score for each site calculated as [(skin thickness)-(mean control thickness at that site)]/(SD of control at that site)].

Results: Various cut-points were tested for translating the z-score to mRUSS's assigned to each anatomic site, and the best concordance between the overall mRSS and the overall mRUSS were obtained with the following criteria: z-score <1= mRUSS 0; z-score 1–3=mRUSS 1; z-score 3–5 =mRUSS 2; z-score >5 =mRUSS 3. Total mRUSS's were then correlated to the mRSS (physical exam). The correlation between observer 1 mRSS compared to US score (assuming this to be the gold standard) was.90 and.73 for observer 2 (less experienced provider) (see figure 1). The r-value comparing observer 1 to observer 2 was 0.97.



Conclusion: Use of mid frequency US (15-mhz) is a readily available, reproducible, objective method for evaluating skin thickness in scleroderma. The newly proposed mRUSS scoring system correlates well with the mRSS based on physical exam findings. These findings will require verification with more patients and by independent examiners, but they have promise for use of precise ultrasound measurements to generate a mRSS equivalent.

Disclosure: I. Sacksen, None; **P. S. Pollock**, None; **M. H. Wener**, None.

2602

Reduced Frequencies Of Circulating CD8 T Cells In Early Diffuse Cutaneous Systemic Sclerosis Is Associated With Worse Skin Scores. Marie Hudson[1], Maximilien Lora[2], Christopher Di Ioia[1], Solene Tatibouet[1], Sasha Bernatsky[3] and Ines Colmegna[4]. [1]McGill University, Montreal, QC, [2]McGill University Health Centre, Montréal, QC, [3]McGill University Health Center, Montreal, QC, [4]McGill University Health Centre, Montreal, QC.

Background/Purpose: Diffuse cutaneous systemic sclerosis (dcSSc) is associated with significant morbidity and mortality. Measurement of skin thickness (modified Rodnan skin score (mRss)) is a surrogate of dcSSc severity as an increase in this score is associated with involvement of internal organs and increased mortality. Recent studies have found that high levels of the profibrotic type-2 cytokine IL-13 are produced by peripheral blood effector CD8+ T cells from SSc patients and that IL-13-producing circulating CD8+ T cells express skin-homing receptors and induce a profibrotic phenotype in normal dermal fibroblasts. Although one study describes a reduction of the circulating CD8+ T cell subset in dcSSc, the clinical implications of this finding are unknown.

Methods: The frequencies of circulating CD4, CD8, CD20 and CD14 cells were determined by multi-parameter fluorescence-activated cell sorting (FACS) in peripheral blood mononuclear cells isolated from newly diagnosed, untreated dcSSc patients. Samples from patients with early onset, untreated seropositive rheumatoid arthritis were tested as controls. Clinical parameters recorded at the time of sample collection included: mRss, global assessment of activity, global assessment of severity, forced vital capacity and DLCO.

Results: Percentages and absolute counts of cell subsets isolated from dcSSc patients (n=10) with a mean age of 58±8.24 years and a mean disease duration of 2.7±1.8 years were compared with age matched early onset RA patients (n=10). The frequencies of the studied cell subpopulations was similar between RA and dcSSc except for the absolute number and percentage of the CD8+ fraction, which was lower among dcSSc (p=.007 and.03, respectively). Lower frequencies of CD8+ T cells were associated with higher mRss and higher global assessments of activity (p=.0037 and.0052, respectively). For an increase of 1 unit in the mRSS score (range 0–51) there was a decrease of 0.79 in absolute CD8+ T cells and for an increase of 1 unit in the global assessment of activity (range 0–10), there was a decrease of 0.75 in absolute CD8+ T cells.

Conclusion: Our findings suggest that early dcSSc have lower frequencies of peripheral blood circulating CD8+ T cells and that those are inversely associated with skin scores and disease activity. These findings are particularly relevant in light of recent evidence suggesting that skin homing – relocation IL-13-producing CD8+ T cells are directly involved in modulating dermal fibrosis in SSc, and emphasizes the need to prospectively assess the utility of reduced CD8+ T cell frequencies as a biomarker of dcSSc severity.

Are There Differences In Limited Systemic Sclerosis According To Extension Of Skin Involvement?. Marina Scolnik[1], Eliana Lancioni[2], Luis J. Catoggio[1], Mirtha Sabelli[2], Zaida Bedran[2], Carla Saucedo[2], Josefina Marin[2] and Enrique Soriano[1]. [1]Rheumatology Section, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.

Background/Purpose: There is consensus in classifying Systemic Sclerosis (SSc) according to extension of skin involvement as limited and diffuse, using the elbows and knees as "limits" to distinguish between them. Decades ago, Barnett classified SSc as Type 1(only sclerodactyly), Type 2 (acrosclerosis - distal but may reach up to elbows and/or knees plus face) and Type 3 (diffuse skin involvement). Patients with Type 2 had an intermediate degree of organ involvement compared to Type 1 (less) and Type 3 (more). This issue has not been recently addressed. We examined the characteristics of our patients with limited disease to see if we could find differences between Barnett Type 1 and Type 2 subsets.

Methods: electronic medical records of patients registered between years 2000–2011 with the problem: scleroderma, SSc or CREST and those with anti Scl-70, anticentromere or anti nucleolar antibodies in laboratory database were reviewed. Cases fulfilling ACR 1980 criteria were included and were classified as diffuse or limited according to LeRoy's criteria with limited being separated into sclerodactyly (only fingers) and acrosclerosis (fingers and up to elbows and/or knees) (Barnett's Types 1 and 2).

Results: 234 SSc patients (216 females) fulfilled criteria. Female/male ratio was 12:1; 24% had diffuse SSc and 76% limited (64% sclerodactyly and 12% acrosclerosis). Total follow up was 688 patients-years. Over half (55.1%) are still under our care and 17 died during this period. Ten year survival rate was 80% for limited and 70% for diffuse variants respectively (HR: 0.88 95% CI: 0.7–1.1). Table 1 shows clinical and serological profile of this cohort.

Anti Scl-70 was present in 16%, anticentromere in 53% and nucleolar ANA in 7% of overall patients. Within the limited group, several characteristics in the acrosclerosis (Type 2) group were more similar to the diffuse than the Type 1(sclerodactyly) patients. Duration of Raynaud was shorter, and they had significantly more anti Scl-70 and less anti centromere antibodies than those with Type 1. In particular, interstitial lung disease (ILD) was significantly more prevalent in Type 2 group, and similar to Type 3. Other characteristics did not reach statistical differences.

Table 1. Clinical and serological profile of this cohort

	Limited (n = 178)				
Type of systemic sclerosis	**Sclerodactyly (n = 149)**	**Acrosclerosis (n = 29)**	**p (sclero vs acro)**	**Diffuse (n = 56)**	**p (limited vs diffuse)**
Females, n (%)	142 (95.3)	25 (86.2)	0.06	49 (87.5)	0.13
Age at diagnosis, years mean (SD)	59.8 (15.2)	54.9 (16.2)	0.14	53 (18.3)	0.038
Duration of raynaud before diagnosis, years median (SD)	9.2 (3.4)	5.5 (1)	0.018	1.9 (0.8)	0.008
Anti Scl-70, %	6.4	39.3	<0.001	43.9	<0.001
Anticentromere, %	82.3	17.9	<0.001	4.8	<0.001
Nucleolar ANA, %	5.7	3.6	0.54	20.9	0.001
Other autoantibodies, %	26.1	23.5	0.54	25.9	0.76
GI involvement, %	65.9	81.3	0.22	64.3	0.45
Interstitial lung disease, %	17.1	50	<0.001	65.3	<0.001
Pulmonary hypertension with ILD,%	5.5	0	0.34	15.4	0.03
Pulmonary hypertension (without ILD), %	9.1	4.8	0.45	2.6	0.39
Echocardiographic abnormalities (other than PH), %	5.7	4.5	0.65	10	0.26
Digital ulcers, %	26.9	34.5	0.44	32.1	0.86
Renal Crisis, n	0	0		1	
Pregnancy after diagnosis, n	3	1		3	
Patient-year, years (SD)	462 (3.1)	81.2 (3.1)		144.8 (3.6)	
Currently followed, n (%)	88 (59.5)	15 (51.7)		26 (46.4)	
Died under our care, n	11	2		4	

Scl-70: anti-topoisomerase I; ANA: antinuclear antibodies; GI: gastrointestinal; ILD: interstitial lung disease; PH: pulmonary arterial hypertension

Conclusion: These results appear to confirm that extension of skin involvement within limited SSc may identify two different subsets with clinical and serologic characteristics. Indeed, Type 2 as defined by Barnett appears to have intermediate organ involvement, and serology may be more similar to the diffuse type.

Longitudinal Assessment Of Scleroderma Skin By Optical Coherence Tomography: Preliminary Validation Of Sensitivity To Change Over-Time. Giuseppina Abignano[1], Lesley-Anne Bissell[1], Jason Britton[2], Daniel Woods[3], Maya H. Buch[1], Dennis McGonagle[1], Paul Emery[1] and Francesco Del Galdo[1]. [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [2]Medical Physics Department, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [3]Michelson Diagnostics Ltd, Kent, United Kingdom.

Background/Purpose: Optical coherence tomography (OCT) has been shown to be a quantitative reliable tool to assess skin involvement in Systemic Sclerosis (SSc) (1). However the sensitivity to change over-time has not been evaluated. The present study aimed to compare skin assessment by OCT over-time in patients with SSc.

Methods: We performed 24 OCT scans of dorsal forearms on 12 sites of analysis from 7 SSc patients (6 with diffuse, 1 with limited subset according to Le Roy et al; mean disease duration at baseline= 8 ± 2.3 years) at 0 and 24 months. Clinical skin involvement was assessed using the modified Rodnan skin score (mRss). Minimum and Maximum Optical Density (Min and Max OD) of the mean-A scans were calculated employing Matlab software as previously described (1). Comparison of the local mRss and Min and Max OD at the 2 time-points was performed by two-tailed paired t-test employing GraphPrism software.

Results: Five sites of analysis with local mRss=0 did not change over 24 months. Accordingly, both Min and Max OD showed only an average −1.81% and −2.31% change, respectively ($p>0.05$) (1). On the contrary, in 5 sites of analysis mRss improved by 2 points (two sites with local score "2" improved to "0", three sites with local score of "3" improved to "1"). In these sites Min OD showed an increase of 29% (range=23–37%; $p=0.0005$) and Max OD of 29.8% (range=18–41%; $p=0.0027$). Furthermore, both Min and Max OD showed a trend forward a decrease (−3.54%, −5.41% respectively) at the 2 sites of analysis with worsening mRSS (one point increase) but the low sample size did not allow to perform a statistical evaluation.

Conclusion: Although preliminary for the low number of observations, this study provides the first evidence suggesting that OCT of the skin is sensitive to change over time and it changes consistently with mRss. Studies including a larger number of patients and sites of analysis with different grades of skin involvement and improvement/deterioriation of clinical score are needed to reach a definitive validation.

Quality Of Life and Psychosocial Aspects In Juvenile Localized Scleroderma. Roberta Culpo, Marco Ricca, Fabio Vittadello, Giuseppina Sequi, Francesco Zulian and Giorgia Martini. University of Padua, Padua, Italy.

Background/Purpose: Juvenile Localized Scleroderma (JLS) is a chronic, autoimmune disease, characterized by skin and subcutaneous tissues fibrosis, which can cause a poor quality of life and psychosocial and behavioural problems in affected children particularly when severe deformities such as face asymmetry, joint contractures, and growth disturbances of limbs develop. To date, quality of life and psychological aspects in JLS have been poorly investigated. Purpose: to evaluate quality of life and psychosocial aspects of patients with JLS as compared with healthy peers and identify specific disease characteristics possibly related to quality of life impairment and psychosocial problems.

Methods: Two types of questionnaires (Pediatric Quality of Life Inventory 4.0™ Generic Core Scales and Child Behaviour Check List (CBCL) 6–18/Youth Self Report (YSR) 11–18) were administered to 40 consecutive patients with JLS aged 6 to 18 years and their parents. Patients' demographic and clinical data were collected during medical examination and through the review of clinical records. Same questionnaires were administered to a control group of 44 healthy children and their parents.

Results: In PedsQL™ (children forms) no difference was found between JLS group and control group. In PedsQL™ (parents forms) children with JLS showed poorer quality of life as compared to control group (76.8 vs 84.8, $p=0.017$), especially in emotional area (64.5 vs 79, $p=0.004$). In CBCL/6–18 mean scores were lower in activity scale (35.2 vs 41.1, $p=0,006$) and higher in internalizing problems scale (58 vs 53.2, $p=0.026$) and depression scale (59.9 vs 55.9, $p=0.038$) in JLS group compared to control group. In YSR/11–18 mean scores were lower in social competence scale (44.2 vs 49.7, $p=0.007$) and in total competence scale (40.9 vs 42.4, $p=0.028$) and higher in internalizing problems scale (54.7 vs 50.9, $p=0.031$) in JLS group compared to healthy controls. Disease relapses, longer delay in correct diagnosis, onset of disease in adolescence and shorter disease duration significantly correlated with lower quality of life and psychosocial and behavioural problems.

Conclusion: Our study shows that quality of life is poorer in children with JLS compared to healthy peers. Emotional area and social activities are the most affected ambits and patients show also depressive and internalizing problems. Among patients with JLS, a greater need for psychological support is mainly related to disease relapses, longer diagnostic delay, shorter disease duration and onset in adolescence or pre-adolescence ages. Disease severity in terms of lesion extension or deformities and therapy related issues do not seem related to impairment in the investigated areas.

Evaluation Of The Construct Validity Of The Patient-Reported Outcomes Measurement Information System (PROMIS®) Gastrointestinal (GI) Symptoms Measures In Systemic Sclerosis (SSc). Dinesh Khanna[1], Puja Khanna[1], Brennan Spiegel[2], Lin Chang[3], Gil Y. Melmed[4], Roger Bolus[5] and Ron Hays[2]. [1]University of Michigan Medical Center, Ann Arbor, MI, [2]University of California, Los Angeles, Los Angeles, CA, [3]David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA, [4]Cedar-Sinai Medical Center, Los Angeles, CA, [5]Research Solutions Group, Encinitas, CA.

Background/Purpose: As part of the National Institutes of Health PROMIS¨ roadmap initiative, we developed GI Symptoms measures that assess 8 domains: Gastroesophageal reflux (13 items), disrupted swallowing (7 items), diarrhea (5 items), bowel incontinence/soilage (4 items), nausea and vomiting (4 items), constipation (9 items), belly pain (6 items), and gas/bloat/flatulence (12 items). All scales are calibrated using a two-parameter IRT graded response model and scored on a T-score metric with a mean of 50 and SD of 10 in the U.S. general population. This paper evaluates the construct validity of the GI measures in patients with SSc.

Methods: 165 patients with SSc were administered the PROMIS GI Symptoms measures and UCLA SCTC GIT 2.0 instrument. GIT 2.0 has 5 symptom scales: reflux, distention/ bloating, diarrhea, constipation, and fecal incontinence. Product-moment correlations of the PROMIS GI measures with the GIT 2.0 symptoms scales were used to evaluate construct validity. In a subset of patients (N=37), both instruments were administered at 2 time points. F-statistics was calculated from one-way ANOVAs to assess responsiveness to change

Results: Patients with SSc GI involvement had scale scores 0.2–0.7 SD worse than US population. Hypothesized correlations were larger than other scales and in the right direction (Table). F-statistics were greater for 6 of 8 PROMIS scales (range 0.45 for belly pain to 3.21 for reflux scale) vs. GIT 2.0 except for diarrhea scale (0.67 vs. 0.98 for GIT 2.0) and constipation scale (1.37 vs. 1.79 for GIT 2.0).

Table. Product-moment correlations between PROMIS GI Symptoms scales and UCLA SCTC GIT scales

	Reflux	Distention/ bloating	Diarrhea	Constipation	Fecal incontinence
Reflux	**0.77**	0.44	0.13	0.25	−0.03
Disrupted swallowing	**0.61**	0.39	0.16	0.21	0.13
Nausea and vomiting	**0.66**	0.44	0.20	0.22	0.18
Belly pain	0.45	0.49	0.23	0.34	0.04
Gas/bloat/flatulence	0.46	**0.73**	0.30	0.29	0.10
Diarrhea	0.25	0.25	**0.65**	0.02	0.54
Constipation	0.37	0.32	0.05	**0.76**	−0.01
Fecal incontinence	0.12	0.11	0.43	−0.18	**0.87**

GIT 2.0 Reflux scale asks about reflux, dysphagia to solid foods, and nausea/ vomiting.

Conclusion: PROMIS GI Symptoms scales are significantly correlated with the hypothesized GIT 2.0 scales and 6 of 8 scales showed greater responsiveness to change than the GIT 2.0.

Coeliac Disease In Scleroderma - Clinical Features, Frequency and Impact Of Screening In Scleroderma. Alfredo Guillén-Del Castillo[1], Vincent Sobanski[2], Jennifer Harvey[2], Christopher Denton[3] and Voon H. Ong[4]. [1]Hospital Universitari Vall d'Hebron, Barcelona, Spain, [2]Royal Free Hospital, London, United Kingdom, [3]Royal Free and University College Medical School, London, United Kingdom, [4]The Royal Free and University College Medical School, London, United Kingdom.

Background/Purpose: Recent studies suggest that coeliac disease (CD) affects 4–7% of Scleroderma (SSc) patients. This association however has not been well characterized in a large cohort of patients. We evaluate the key clinical features, nutritional complications, and clinical response after gluten free diet in SSc patients with CD (SSc-CD), compared with a group of SSc patients with gastrointestinal (GI) symptoms and negative coeliac antibodies.

Methods: This is a retrospective study of well-characterised cohort of 1920 SSc patients from 2008 to 2013 with data collected through clinical database and patient records including all SSc patients diagnosed with CD by duodenal biopsy (n=12), and 96 of 236 SSc patients with GI symptoms (chronic diarrhoea, bloating, constipation, discomfort, dysphagia, heartburn and faecal incontinence) and negative coeliac antibodies. 4 patients in the SSc-CD group had confirmed positive coeliac antibodies. Key demographic and clinical features including small bowel symptoms (chronic diarrhoea, bloating, constipation and discomfort) were examined.

Results: The prevalence of CD with positive coeliac antibodies in our SSc cohort with GI symptoms was 4/236 (1.69%). 92.6% were female, with median (interquartile range, IQR) of age at SSc onset of 45.0 (33.0 – 55.7) years, and 49.3 (41.0 – 55.7) years at CD diagnosis. 18.5% patients had diffuse subset and 66.7% of the patients were Caucasians. 33 (30.6%) had an overlap with another systemic autoimmune disease (17 had polymyositis-dermatomyositis, 8 rheumatoid arthritis, 5 Sjögren's syndrome, 3 others). A higher frequency of psoriasis was identified in 25% of SSc-CD patients compared with 2.1% (p=0.009) in negative-coeliac antibodies patients. SSc-CD patients had increased frequency of myopathy (33.3% vs 10.4%, p=0.04), and anti-Pm/Scl antibody (25.0% vs 3.1%, p=0.01). 88% of entire cohort had small bowel symptoms with no statistical differences between the two groups. Chronic diarrhoea was the most common symptom in 62.0% of patients. Upper endoscopy was performed in all SSc-CD patients and in 41.7% with negative-coeliac antibodies, with no statistical differences in frequency of esophagitis, gastritis, gastric antral vascular ectasia or macroscopic duodenitis. There were no differences in the prevalence of bacterial overgrowth or requirement for enteral/parenteral nutrition. Among all patients 44.4% had vitamin D deficiency, 40.7% iron deficiency and 7.4% osteoporosis. After gluten-free diet all SSc-CD patients had an improvement of small bowel symptoms. 50% of these patients achieved complete remission and the symptoms recurred in the remaining half with median (IQR) 5.0 (2.5 – 8.25) years. There was significant improvement in chronic diarrhoea (75% to 41.7%, p=0.04), abdominal distension or bloating (50% to 16.7%, p=0.04), and in weight loss (33.3% to 0%, p=0.04).

Conclusion: The clinical presentation of CD may be indistinguishable to SSc-GI disease and our study indicates that CD in this subgroup of SSc patients with GI involvement is no more common than the general population. The positive response to gluten-free diet suggests that screening for CD in selected SSc patients may be helpful.

Dutch Translation and Validation Of The University of California, Los Angeles scleroderma Clinical Trial Consortium Gastrointestinal Tract Instrument 2.0. Jessica Meijs, Daisy Pors, Theodora P.M. Vliet Vlieland, Tom W.J. Huizinga and Annemie J.M. Schuerwegh. Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Gastrointestinal tract (GIT) involvement occurs in approximately 90% of the patients with systemic sclerosis (SSc) and leads to a decrease in health-related quality of life. To identify and evaluate GIT involvement in patients with SSc, the University of California Scleroderma Clinical Trial Consortium Gastrointestinal Tract Instrument 2.0 (UCLA GIT 2.0) was developed. The UCLA GIT 2.0 consists of 34 items on 7-multi-item subscales. The total score averages 6 of 7 scales (excluding constipation) and ranges from 0 (no GIT problems) to 3 (most severe GIT problems) [1]. The aim of our study was to translate the UCLA GIT 2.0 from English into Dutch and validate the Dutch version.

Methods: First, the UCLA-GIT 2.0 questionnaire was translated according to international guidelines [2]. Secondly, the questionnaire was field-tested among 17 SSc patients. Then, in order to test internal consistency and validity, the final Dutch version was administered to SSc patients participating in a standardized, annual comprehensive medical assessment, compromising visits to health care professionals, laboratory and cardiopulmonary investigations, the SSc Health Assessment Questionnaire (SHAQ) and Short Form-36 (SF-36). The internal consistency was tested by computing Cronbach's alpha. For convergent and construct validity, Pearson correlations were computed between the Dutch UCLA-GIT and the SF-36 and SHAQ. ($r \leq 0.29$ is considered a small correlation, r 0.30 –0.49 a moderate, and $r \geq 0.50$ a strong correlation). To determine the reliability, the instrument was re-administered with an interval of two weeks to 27 of the patients, and the intraclass-correlation coefficient (ICC) was computed.

Results: Ninety-two patients were included. Patients were on average 53.8 (SD 15) years, mostly women (76%), Caucasian (82%) and 53% of the patients had limited cutaneous SSc. The median total UCLA GIT 2.0 score was 0.18 and a floor effect was seen (17% scored 0). Cronbach's alpha was ≥0.73 for all scales, except diarrhea (alpha=0.42). The total GIT score was weakly or moderately associated with the SF-36 mental component summary scale ($r=-0.247$, $p<0.05$), the SF-36 physical component summary scale ($r=-0.348$, $p<0.01$) and the SHAQ score ($r=0.287$, $p<0.01$). Correlations between the GIT subscale scores and the SF-36 subscale scores were strong with respect to the corresponding emotional wellbeing and social functioning scale ($r=-0.515$, $p<0.01$). The test-retest reliability was acceptable (ICC: 0.788).

Conclusion: The Dutch UCLA GIT 2.0 questionnaire showed good internal consistency, reliability and an acceptable construct validity according to comparisons with SF-36 and SHAQ. The Dutch translation will now be further validated with objective measures of GIT involvement.

A New Pathogenic Role Of BAFF As a Critical Mediator Of Skin and Lung Fibrosis In Experimental Bleomycin-Induced Pulmonary Fibrosis, Systemic Sclerosis and Idiopathic Pulmonary Fibrosis.

Antoine Francois[1], Pascal Schneider[2], Anne Davidson[3], Emmanuel Chatelus[4], Jérôme Avouac[5], Yannick Allanore[5], Bérengère Villeret[6], Aurélie Gombault[6], Paméla Gasse[7], Sylvain Marchand Adam[8], Bernhard Ryffel[9], Siamak Bahram[10], Philippe Georgel[11], Jean Sibilia[12], Isabelle Couillin[7] and Jacques-Eric Gottenberg[4]. [1]University of Strasbourg, Illkirch-Strasbourg, France, [2]University of Lausanne, Lausanne, Switzerland, [3]Feinstein Institute for Medical Research, Manhasset, NY, [4]Strasbourg University Hospital, Strasbourg, France, [5]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [6]University of Orleans and National Center for Scientific Research, Orléans, France, [7]University of Orleans and National Center for Scientific Research, Orleans, France, [8]National institute of the health and the medical research, Tours, France, [9]University and CNRS, 3b rue de la Ferollerie, Orleans, France, [10]Immunorhumatology Molécular, Strasbourg, France, [11]Laboratoire d'ImmunoGénétique Moléculaire Humaine, Strasbourg, France, [12]CHU Hautepierre, Strasbourg, France.

Background/Purpose: Interstitial pneumonitis and lung fibrosis are frequent systemic complications of inflammatory arthritides, including systemic sclerosis (SSc), rheumatoid arthritis, or primary Sjögren's syndrome. B lymphocytes are involved in the pathogenesis of such lung involvement. BAFF (B-cell activating factor of the TNF family) plays a crucial role in autoreactive B-cell activation and survival. We therefore investigated the pathogenic role of BAFF in fibrosis

Methods: Levels of BAFF were assessed using ELISA in serum of 150 patients with SSc and 80 healthy controls and in bronchoalveolar lavage of 12 patients with idiopathic pulmonary fibrosis (IPF) and 7 controls. Cocultures of B lymphocytes, stimulated or not with BAFF, and skin fibroblasts from patients with SSc and controls were performed. Lung fibrosis induced by bleomycin (BLM) was compared in BAFF−/− knock-out, BAFF-R-Ig treated mice and wild type (WT) mice. Lung BAFF expression was compared in BAFF IL-1R1−/−, IL-17A−/−, IL-17RA−/− mice after BLM challenge. Levels of IL-17 secreted by lung cells isolated from BLM-treated mice were analyzed after stimulation with anti-CD3 and BAFF

Results: Serum BAFF level was significantly increased in SSc patients compared to controls (median 1.5 vs. 0.5; $p< 0.0001$). Patients with SSc and increased BAFF levels had a significantly higher incidence of pulmonary fibrosis assessed by lung CT scan (63% vs. 37%; $p< 0.005$). A significant increase in BAFF bronchoalveoar levels was observed in patients with IPF, especially in those with clinical exacerbation, compared to controls. Coculture of B lymphocytes and skin fibroblasts induced collagen secretion, which was further enhanced after BAFF stimulation. In the BLM model of lung fibrosis, a marked increase of BAFF, mainly secreted by infiltrating neutrophils, was detected in the bronchoalveolar lavage and in lung extracts. Inhibition of BAFF using BAFF-R-Ig or gene depletion (BAFF−/− mice) resulted in a marked decrease of lung fibrosis, assessed by histology, and quantification of TGF-beta and collagen by qPCR and ELISA. Interestingly, levels of BAFF were significantly decreased in IL-1R1−/−, IL-17A−/− and IL-17 RA−/− mice, in which lung fibrosis was significantly reduced after BLM challenge, compared to WT mice. In vitro, recombinant BAFF induced a dramatic increase in IL-17 secretion by lung cells isolated after BLM challenge.

Conclusion: These results confirm the implication of B lymphocytes and sheds light to a new pathogenic role of BAFF in fibrosis according to consistent results in the bleomycin model, SSc and IPF. Taken together, these results suggest the following scenario: i) BAFF is induced by IL-1β and IL-17, which are potent pro-fibrogenic cytokines; ii)BAFF in turn induces IL-17 secretion by Th17 cells in an amplification loop. This study adds to the rationale of evaluating the therapeutic interest of BAFF inhibition in systemic sclerosis, inflammatory arthritis-related lung fibrosis and idiopathic pulmonary fibrosis.

Epidemiology Of Cancer In Systemic Sclerosis. Systematic Review and Meta-Analysis Of Cancer Incidence, Predictors and Mortality.

Tatiana Nevskaya[1], Shelly Chandran[2], Adrienne M. Roos[1], Christopher Pasarikovski[1], Amie T. Kron[1], Cathy Chau[3] and Sindhu R. Johnson[4]. [1]Toronto Scleroderma Research Program, Toronto Western Hospital, Mount Sinai Hospital, and University of Toronto, Toronto, ON, [2]Toronto Scleroderma Research Program, Toronto Western Hospital, University of Toronto, Toronto, ON, [3]Toronto Scleroderma Research Program, Toronto Western Hospital, Mount Sinai Hospital, University of Toronto, Toronto, ON, [4]Toronto Western Hospital, Toronto General Hospital, Mount Sinai Hospital, and University of Toronto, Toronto, ON.

Background/Purpose: To improve our understanding of the epidemiology of cancer in systemic sclerosis (SSc) by evaluating the incidence, prevalence, relative risk of overall and site-specific malignancies in comparison with the general population, and cancer-attributable mortality.

Methods: MEDLINE, CINAHL, EMBASE and Cochrane Library (inception-May 2012) were searched. Estimates were combined using a random effects model. Consistency was evaluated using the I^2statistic.

Results: 4,876 citations were searched to identify 59 articles. The average incidence of malignancy in SSc was 14 cases/1000 person-years; the prevalence ranged between 4%-22%. Cancer was the leading cause of non-SSc related deaths with a mean of 38%. Overall SIR for all-site malignancy risk was 1.85 (95% CI 1.52, 2.25; $I^2$76%).There was a greater risk of lung (SIR 4.69, 95% CI 2.84, 7.75; $I^2$93%) and haematological (SIR 2.58, CI 95% 1.75, 3.81; $I^2$0%) malignancies, including non-Hodgkin's lymphoma (SIR 2.55, 95% CI 1.40, 4.67; $I^2$0%). SSc patients were at a higher risk of leukemia (SIR 2.79, 95% CI 1.22, 6.37; I^2 0%), liver (SIR 4.75, 95%CI 3.09, 7.31; $I^2$0%), cervical (SIR 2.28, 95% CI 1.26, 4.09; $I^2$54%) and oropharyngeal (SIR 5.0, 95% CI 2.18, 11.47; $I^2$58%) cancers. Risk factors include a-RNAP I/III positivity, male sex, and late onset SSc. Smoking and longstanding interstitial lung disease (ILD) increase the risk of lung cancer; longstanding gastroesophageal reflux disease with Barrett's esophagus and a positive family history of breast cancer, respectively, increase the risk of esophageal adenocarcinoma and breast cancer.

Conclusion: SSc patients have a two-fold increase in malignancy, and greater risk of lung and haematological malignancies that contribute significantly to mortality. Vigilance should be considered in SSc patients with a-RNAP I/III antibodies, male sex, smokers, late disease onset, a positive family history of breast cancer, long duration of ILD, Barrett's esophagus.

NF-κB Pathway Is Depleted In Phagocytes From Behçet's Disease Patients Secondarily To Constitutive Phosphorylation Of The p65 Subunit. Sandro F. Perazzio[1], Paulo Vitor Soeiro Pereira[2], Alexandre W.S. Souza[3], Antonio Condino-Neto[2] and Luis Eduardo C. Andrade[1]. [1]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil, [2]ICB IV - Universidade de São Paulo, São Paulo, Brazil, [3]University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: Increased neutrophil activation has been previously shown in Behçet's disease (BD) patients and it is unclear whether neutrophil activation occurs constitutively or if it is secondary to a yet unknown stimulus or some serum or tissue soluble factor. NF-kB seems to modulate the immune response in BD and has been associated to apoptosis-related factors leading to apoptosis resistance in T cell subsets. The present study investigated the NF-kB pathway and its activation induced by TLR.

Methods: Neutrophils and peripheral blood mononuclear cells (PBMC) were obtained from patients with active BD (aBD; n=30), inactive BD (iBD; n=31), septic patients (SP; n=25), and healthy controls (HC; n=30). BD activity was established as Behçet's Disease Current Activity Form simplified (BDCAFs) score≥2. The functional analysis of the NF-kB pathway was performed by: 1) determining CD62L shedding after stimulation with specific ligands for TLR-2, -3, -4, -5, -7, and with *Streptococcus pneumoniae, Streptococcus sanguinis*, and *Candida albicans*; 2) the intracellular expression of phosphorylated NF-kB-p65 before and after stimulation with PMA, TLR-3, TLR-7, plasma from HC, aBD or iBD; 3) the intracellular expression of STAT3 before and after stimulation with PMA, IL-10, or plasma from HC or aBD.

Results: BD patients homogeneously presented very low CD62L shedding with all forms of stimulus, in contrast to the large dispersion observed in the other groups. The percent increase in CD62L shedding was more evident after activation by TLR3 in iBD (31±28%: p=0.022) and aBD (27±20%; p=0.029) than in SP (3.4±25%). In contrast, the activation by TLR7 was lower in iBD (27±23%; p=0.022) and aBD (32±27%; p=0.029) than in SP (74±39%). Neutrophils from aDB presented higher expression of phosphorylated NF-kB-p65 before stimuli (mean of intensity of fluorescence [MFI]=123.54±47.63 versus HC=69.43±39.29, p=0.050) and after PMA (MFI=194.10±97.18 versus HC=92.24±42.34, p=0.030) and TLR7 (MFI=135.76±45.92 versus HC=77.51±42.34, p=0.050). Monocytes from aDB also presented higher expression of phosphorylated NF-kB-p65 before stimuli (MFI=313.40±110.81 versus HC=135.98±87.61, p=0.018) and after PMA (MFI=372.80±145.01 versus HC=175.51±98.35, p=0.030) and TLR3 (MFI=320.40±117.39 versus HC=162.15±74.47, p=0.030). Phosphorylated NF-kB-p65 expression and CD62L shedding after human plasma and microbial stimuli, respectively, was equivalent for phagocytes from aBD, iBD, and HC. STAT3 expression in neutrophils and monocytes showed no difference among the aBD, iBD, and HC. There was no difference in medication use between aBD and iBD.

Conclusion: We originally showed that the NF-kB pathway of phagocytes is constitutively activated in BD patients and that there is additional increment after TLR stimuli. The low CD62L shedding of BD phagocytes may be due to exhaustion of the NF-kB pathway. These findings may underlie the characteristic hyperactivity of neutrophils in BD, represented by activation of the final pathway for several stimuli, like cytokines, chemoattractants and microorganisms, potentially involved in the pathophysiology of this disease.

Plasma Of Active Behçet's Disease Increases Oxidative Metabolism Profile Of Normal and Patients Phagocytes. Sandro F. Perazzio[1], Paulo Vitor Soeiro Pereira[2], Alexandre W.S. Souza[3], Antonio Condino-Neto[2] and Luis Eduardo C. Andrade[1]. [1]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil, [2]ICB IV - Universidade de São Paulo, São Paulo, Brazil, [3]University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: Behçet's disease (BD) exhibits several features suggestive of neutrophil hiperactivity. It is unclear whether neutrophil activation occurs constitutively or if it is secondary to yet unknown stimuli. Previous studies suggested a possible role for infectious agents and for unknown plasma factors in BD pathogenesis. The present study investigated the oxidative burst in phagocytes of patients with active BD (aBD) and inactive BD (iBD) in the presence of diverse stimuli.

Methods: Neutrophils and peripheral blood mononuclear cells (PBMC) were obtained from patients with aBD (n=30), iBD (n=31), septic patients (SP; n=25), and healthy controls (HC; n=30). BD activity was established as Behçet's Disease Current Activity Form Simplified (BDCAFs) score≥2. Oxidative burst was assessed by dihidrorhodamine (DHR) oxidation before and after stimulation with phorbol myristate acetate (PMA) or human plasma (from HC or aBD). H_2O_2 and O_2^- production was determined in neutrophils and PBMC by luminol/lucigenin luminescence intensity with or without stimulation with PMA, *Streptococcus pneumoniae, Streptococcus sanguinis*, *Candida albicans* or human plasma.

Results: There was no significant difference in medication use between aBD and iBD patients. Resting phagocytes from the four groups presented equivalent oxidative burst (DHR assay and H_2O_2/O_2^- production). However, aBD neutrophils produced more O_2^- when exposed to aBD plasma (median/range=96,297/19,202–298,941) compared to HC plasma (48,831/4,001–105,848; p=0.028) or non-stimulated (5,721/551–23,838; p<0.01). HC neutrophils also produced more O_2^- when stimulated by aBD plasma (93,452/12,242–226,932) versus HC plasma (36,225/8,432–79,461; p=0.028) versus non-stimulated (3,387/1,870–13,935, p<0.01). aBD neutrophils also produced more H_2O_2 when exposed to aBD plasma (404,045/24,825-1,408,347) compared to HC plasma (338,238/5,042–745,653; p=0.02) or non-stimulated (9,300/2,706–27,193; p<0.01). The same occurred with neutrophils from HC: aBD plasma (355,079/51,354–513,977); non-stimulated (15,092/4,959-47,814; p<0.01). PBMC from aBD produced more O_2^- when exposed to aBD plasma (39,208/9,656-315,306) compared to HC plasma (10,135/3,394-41,873; p=0.046) or non-stimulated (10,052/3,262-37,352; p=0.028). The same occurred with HC PBMC: 24,531/4,931–73,813; 3,661/1,697-28,992 (p=0.03); 1,994/928-5,532, respectively (p=0.02). Finally, H_2O_2 production in aBD PBMC was enhanced by aBD plasma (55,223/17,186–253,194) versus HC plasma (35,193/2,081–331,239; p=0.05) versus non-stimulated (18,690/2,340–78,728; p=0.046). The same was observed with HC PBMC: aBD plasma (10,357/4,024–75,036); HC plasma (2,502/975-7,810, p=0.028). H_2O_2 and O_2^- production after microbial stimuli was equivalent for phagocytes from aBD, iBD, and HC.

Conclusion: Phagocytes from BD patients were not constitutively activated and responded normally to microbial and PMA stimuli. Plasma from patients with active BD exerted a strong stimulus for H_2O_2 and O_2^- production. These findings warrant further studies in order to identify possible metabolic pathways involved in neutrophil activation in BD.

Serum Beta 2 Microglobulin and Its Association With Disease Activity in Patients With Behcet's Disease. Meltem Alkan Melikoglu[1] and Mehmet Melikoglu[2]. [1]Ataturk University Medical School, Rheumatology, Erzurum, Turkey, [2]Health Ministry Erzurum Regional Training and Research Hospital, Dermatology, Erzurum, Turkey.

Background/Purpose: β2-microglobulin (β2M) is a low-molecular weight protein, that is a constant component of human leukocyte antigen (HLA), which is secreted from all nucleated cells. Serum β2M levels increase in lymphoproliferative and autoimmune diseases related to the activities of B lymphocytes (1). The number of B cells secreting immunoglobulins increased in the active phase of Behçet's disease (2). The aim of this study was to evaluate a possible relation between B2M and Behcet's Disease (BD) clinical disease activity.

Methods: Seventy eight patients with BD were included in our study. Disease activity was evaluated with "BD Current Activity Form" (BDCAF) which offers an easy-to-complete, valid and reliable method of

assessing disease activity in BD. With this activity form, headache, mouth ulceration, genital ulceration, erythema, skin pustules, arthralgia, arthritis, new involvements in gastrointestinal system (GIS), eye, nervous system, major vessels and patient'-physician's assessments of the overall disease activity scores were analyzed. The levels of serum B2M of the patients were also measured. The independent samples t test and Pearson's correlation test were used to analyze the data.

Results: In the comparison of serum B2M levels of the patients with or without the components of BDCAF, no significant relation could be found between headache, mouth ulceration, genital ulceration, erythema nodosum, superficial thrombophlebitis, skin pustules, arthralgia, arthritis, new involvements in gastrointestinal system (GIS), nervous system, major vessels and patient'-physician's overall perception of disease activity. However, we found significantly higher levels of B2M in patients with uveitis than without eye involvement (p=0,032). Although each component of BDCAF did not show an association with B2M levels except from eye involvement, total BDCAF score was also found to be correlated with B2M levels (p□0,05).

Conclusion: Presence of a new developed eye involvement may be associated with higher levels B2M. Correlation between total disease activity score and B2M levels may contribute the overall disease activity perception in BD.

Ischemia-Modified Albumin: A Novel Marker of Vascular Involvement in Behcet's Disease? Erhan Capkin[1], Murat Karkucak[2], Mehmet Kola[3], Adem Karaca[2], süleyman Caner Karahan[4], Aysegul Sumer[4], Arzu Aydin Capkin[5], Ferhat Gokmen[2] and Refik Ali Sari[6]. [1]Rheumatolgy, Trabzon, Turkey, [2]Rheumatology, Trabzon, Turkey, [3]Oftalmology, Trabzon, Turkey, [4]BioChemistry, Trabzon, Turkey, [5]Dermatology, Trabzon, Turkey, [6]Immunology and Allergy, Trabzon, Turkey.

Background/Purpose: The etiology and pathogenesis of Behçet's disease (BD) are not yet well understood, but immunoregulatory abnormalities have been proposed as pathogenic mechanisms. Ischemia-modified albumin (IMA) is increased in diseases associated with oxidative stress, which plays an important role in the development of Behçet's disease. To investigate oxidative status and IMA levels in patients with Behçet's disease and their association with clinical and laboratory parameters

Methods: Thirty-five patients with Behçet's disease and 31 healthy controls matched for age and gender were enrolled. Patients' clinical and demographic characteristics were recorded. Serum IMA, malondialdehyde (MDA), total antioxidative status (TAS), total oxidative status (TOS) and oxidative stress index (OSI) levels were then evaluated.

Results: Serum IMA, MDA, TOS and OSI levels were significantly higher in patients with Behçet's disease than in the healthy control group. Serum TAS was significantly lower in patients with Behçet's disease than in the healthy controls. There was a statistically significant positive correlation between IMA levels and MDA, TOS, erythrocyte sedimentation rate and C-reactive protein levels. IMA levels were statistically significantly higher in patients with vascular involvement (p=0.016).

Conclusion: Our results demonstrate increased oxidative stress and decreased antioxidant capacity in patients with Behçet's disease. IMA levels were higher in patients with Behçet's disease than in healthy controls. IMA may be produced through an adaptive response to chronic hypoxia and oxidative stress, which may play a role in the systemic inflammation seen in Behçet's disease. IMA can be a useful guiding marker, particularly in patients with vascular involvement.

Clinical Features Of 127 Patients With Behcet's Disease In Japan. Keisuke Nishimura[1], Jun Saegusa[1], Sho Sendo[1], Yoshinori Kogata[1], Goichi Kageyama[1], Seiji Kawano[1], Shunichi Kumagai[2] and Akio Morinobu[1]. [1]Kobe University Graduate School of Medicine, Kobe, Japan, [2]Shinko hospital, Kobe, Japan.

Background/Purpose: Behcet's disease (BD) is characterized by recurrent oral aphthae and any of several systemic manifestations including genital ulcer, ocular disease, skin lesions, gastrointestinal involvement, neurologic disease, vascular disease, or arthritis. BD is more common along the ancient silk road, including Japan. We present the disease profile of Japanese BD patients at Kobe University Hospital.

Methods: We retrospectively investigated the clinical features of 127 patients (63 males and 64 females) who fulfilled the International Criteria for Behcet's Disease (ICBD) and were treated in our hospital from April 2008 to May 2013. We assessed sex, age of onset, symptoms, complications, type of HLA and medications.

Results: Median age at diagnosis was 37.6 ±12.7 years old. Oral ulcers were the most common manifestation (97.6%), followed by genital ulcer (52.0%), ocular involvements (52.0%), papulopustular lesion (45.7%), erythema nodosum (43.3%), gastrointestinal manifestations (22.0%), vascular involvements (11.0%), and neurogenic diseases (5.5%). Ocular involvements were found to be significantly more frequent in males (male 63.5%, female 40.6%, $P=0.01$). The frequency of gastrointestinal manifestations was significantly higher in patients with vascular involvements ($P=0.007$), while patients with gastrointestinal manifestations showed a lower association rate with ocular involvements ($P=0.001$). Of the 127 BD patients, 2 patients were associated with spondyloarthropathy, one patient with giant cell arteritis and one with systemic sclerosis. The relationship of HLA and disease manifestations was studied in 54 patients (32.7% with HLA-B51 and 23.1% with HLA-A26). Ocular manifestations were significantly higher in patients with B51 than those without B51 ($P=0.03$). Colchicine was most commonly used for the treatment of BD (49.6%). TNFα inhibitor, infliximab, was used for patients with refractory ocular manifestations (n=21) and gastrointestinal manifestations (n=8). Only 3 patients had to be discontinued because of ineffectiveness or adverse events. The cumulative proportion of patients continuing infliximab therapy at 1 and 2 years was 95.8% and 84.3%, respectively. Pneumonia was the only severe adverse event.

Conclusion: A higher incidence of gastrointestinal manifestations was observed in Japanese patients with BD in our hospital. The frequency of gastrointestinal manifestations was significantly higher in patients with vascular involvements. Of the 127 BD patients, 25 patients (19.7%) were treated with infliximab, and the long-term infliximab treatment persistence rate was high.

2618

Bipolar Disorders May Represent a Primary Feature Of Behçet's Disease. Rosaria Talarico[1], Laura Palagini[2], Elena Elefante[1], Claudia Ferrari[1], Chiara Stagnaro[1], Chiara Baldini[1], Chiari Tani[1], Marta Mosca[3] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Psychiatry Unit, Department of Neuroscience, Pisa, Italy, [3]Rheumatology Unit, University of Pisa, Pisa, Italy.

Background/Purpose: Frequency of psychiatric disorders in BD is a debated issue: while some experts attribute their presence to the chronicity of the illness, others think that they may be imputable to disease activity or to intrinsic features of the disease. The primary aims were to determine the frequency of psychiatric disorders in BD patients, both with neurological involvement or without; the secondary aims were: to investigate a possible association between disease activity/organ involvement and psychiatric profile of the BD patients and to compare the distribution of psychiatric disorders of patients with BD with those in patients with other chronic diseases.

Methods: One hundred and twenty BD patients with a diagnosis of BD according the ISG criteria were studied. Demographic profile of the cohort studied are summarized in Table 1. Psychiatric disorders evaluated were: bipolar disorder, obsessive-compulsive disorder, depression and sleep disorder. Age and sex matched disease controls of systemic lupus erythematosus (SLE) and chronic arterial hypertension were included. BD disease activity was evaluated by means of BD current activity form 2006 and clinician's overall perception of disease activity.

Results: Prevalence of psychiatric disorders are shown in Table 2. No correlations were found between the presence of psychiatric disorders and

disease activity; specifically either BD patients with an activity index ≤ 7 and ≥ 8 were equally characterized by a high prevalence of psychiatric disorders. Moreover, the occurrence of psychiatric disorders did not result correlating with a specific organ involvement. Comparing the frequency of bipolar disorder with the disease controls, the results have shown a significant difference in favor of bipolar disorder in BD ($p < 0.001$).

Table 1. Demographic profile.

	Neuro- BD	BD without neurological involvement
Number of patients	46	64
M/F	38/8	42/22
Mean age ± SD (min-max) (years)	43 ± 7 (15–68)	42 ± 8 (18–71)
Mean disease duration ± SD (min-max) (years)	9 ± 2 (3–28)	10 ± 2 (4–28)

Table 2. Prevalence of psychiatric disorders

psychiatric disorders	Neuro- BD n (%)	BD without neurological involvement n (%)
bipolar disorder	41 *(65)*	28 *(64)*
obsessive-compulsive disorder	29 *(46)*	20 *(43)*
depression	20 *(32)*	16 *(36)*
sleep disorder	5 *(11)*	10 *(16)*

Conclusion: Our results show a high frequency of psychiatric disorders in BD patients. This elevated prevalence both in BD patient with or without neurological involvement, independently from disease activity and significantly than in disease controls, strongly suggest that psychiatric disorders may represent a primary feature of BD.

2619

Suicidal Ideation Among Patients With Behcet's Syndrome. Didem Uzunaslan, Caner Saygin, Gulen Hatemi, Koray Tascilar, Hasan Yazici and Vedat Hamuryudan. Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey.

Background/Purpose: An increased frequency of depression has been reported in Behcet's syndrome (BS). While an increased suicidal ideation has been reported in other chronic rheumatologic conditions, this has not been studied in patients with BS. We aimed to evaluate the frequency of suicidal ideation among BS patients and to delineate the factors predicting an increase in suicidal ideation.

Methods: The frequency of suicidal ideation was evaluated with a standard questionnaire that was previously used (2), among BS patients with and without major organ involvement, and ankylosing spondylitis (AS) patients who attended our outpatient clinic for their routine visits and a group of healthy controls. We questioned whether the subjects 1) thought that life was not worth living, 2) thought about ending their lives within the previous year, 3) ever planned to end their lives and if yes, whether they had planned to end their lives before the onset of their disease. In addition, Beck depression inventory (BDI) and Behcet's disease quality of life (BDQoL) questionnaires were filled. Disease activity was assessed using the Behcet's disease current activity form (BDCAF) for BS patients and BASDAI and BASFI for AS patients.

Results: We surveyed 240 BS patients who had only mucocutaneous symptoms, 63 BS patients with active major organ involvement (30 eye, 31 vascular, 7 neurologic involvement), 50 patients with AS, and 106 healthy controls (Table). Number of subjects who answered affirmatively to the second and third questions were significantly higher among BS patients with active major organ involvement compared to the other groups ($p<0.001$ and $p=0.002$). Among BS patients with active major organ involvement, 9/27 with eye, ¼ with neurologic, 3/27 with vascular, and 3/5 with more than one type of major involvement had thought of ending their lives. 9/27 with eye, 2/4 with neurologic, 3/27 with vascular and 2/5 with more than one type of major involvement had planned to end their lives. BS patients with eye involvement had the highest frequency of answering positively to these 2 questions ($p<0.001$ for each). None of the drugs that were used seemed to be associated with suicidal ideation. For each of the questions regarding suicidal ideation, the BDCAF, BDQoL and BDI scores of BS patients were higher among those who answered positively. Regardless of suicidal ideation, the BDI scores of BS patients with active major organ involvement were higher than AS patients and healthy controls.

	BS major organ (n=63)	BS mucocutaneous (n=240)	AS (n=50)	Healthy controls (n=106)	p
M:F	36/27	83/157	14/36	77/29	< 0.001
Mean age ± SD	36 ± 12	38.2 ± 11	37.9 ± 10.3	36 ± 10.1	0.218
Thought about ending their lives	16/63 (25.4%)	21/240 (8.8%)	4/50 (8%)	7/ 106 (6.6%)	< 0.001
Ever planned to end their lives	16/63 (25.4%)	22/240 (9.2%)	4/50 (8%)	9/ 106 (8.5%)	0.002
Beck depression inventory scores	16.9 ± 11.4	10.9 ± 9	10.8 ± 10.1	9 ± 7.7	< 0.001

Conclusion: The frequency of suicidal ideation is increased among BS patients who have major organ involvement. This increase in suicidal ideation is correlated with higher disease activity and increased depression scores. Longitudinal studies are required for determining whether the frequency of suicidal ideation decreases with treatment and improvement in disease activity.

Development Of De Novo Major Involvement During The Follow-Up In Behçet's Disease. Claudia Ferrari[1], Rosaria Talarico[1], Chiara Stagnaro[1], Anna d'Ascanio[1], Chiara Tani[1], Chiara Baldini[1], Marta Mosca[2] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Rheumatology Unit, University of Pisa, Pisa, Italy.

Background/Purpose: Behçet's disease (BD) is globally characterized by a variable spectrum of disease profile: while prevalent mucocutaneous lesions and arthritis represent the only clinical features in patients with a benign disease subset, there are other patients who develop potentially sight or life-threatening manifestations, due to ocular, neurological or major vascular involvement. The primary aim of the study was to evaluate the incidence of the novo major involvement during the follow-up in a cohort of patients with BD; the secondary aim was to analyze the epidemiological profile and the long-term outcome of those patients who developed de novo major involvement.

Methods: One hundred and twenty patients were evaluated. The male/female ratio was 1.6:1, with a mean disease duration of 11±5 years. Their mean age was 42±9 years (min:18, max:77), while the mean age at disease onset was 25±4 years (min:10, max:58). The mean ± SD duration of follow-up at our centre was 8±2 (min:2, max:12) years. We have defined the development of de novo major involvement during the follow-up as the occurrence of severe ocular (anterior uveitis, posterior uveitis, retinal vasculitis), vascular (deep vein thrombosis, superficial vein thrombosis, arterial thrombosis, arterial aneurysm) or CNS (ischaemic pons-mesencephalon lesions and meningoencephalitis) involvement after a latency period from the diagnosis of at least 3 years

Results: At the time of diagnosis, the 52% of the cohort (n=62) presented a prevalent muco-cutaneous involvement. Among this sub group of patients, we observed that after at least 3 years from the diagnosis, 21 patients (34%) was characterized by the occurrence of de novo major involvement (i.e. ocular: 3; CNS: 9; vascular: 9). The demographic profile of this subgroup (male: 19, female: 2) was characterized by a mean age of 33±4 years (min 24-max 40) and a young age at disease onset. The long term outcome after a mean follow-up of 8 years has shown that the majority of these subjects presented during the disease course also relapsing attacks. Moreover, they were characterized by a bigger number of DMARDs (both traditional and anti TNF-alpha) compared to the other part of the cohort

Conclusion: As awaited, younger age and male sex represent predictive factors of poor long-term clinical outcome. We have found that ocular disease seems the organ involvement that more frequently has an onset before the first years of disease. Globally, he development of the novo major involvement during the course of BD represents an entity that may

confirm that a tight control is strongly recommended during the course of BD.

2621

Venous Claudication Is A Severe and Frequent Symptom In BEHCET'S Syndrome. SerdaL Ugurlu[1], Emire Seyahi[1], Veysel Oktay[2], Zerrin Yigit[2], Serdar Kucukoglu[2] and Hasan Yazici[1]. [1]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [2]Cardiology Institute, University of Istanbul, Istanbul, Turkey.

Background/Purpose: In a previous cross-sectional questionnaire survey, we had shown that intermittent claudication was significantly more common among BS patients when compared to healthy controls, and had proposed that this was a "venous claudication" (1) rather than due to atherosclerotic vascular disease since a. a history of myocardial infarction or angina pectoris were not increased in frequency in the same group of patients as compared to age and sex matched healthy controls; and b. this intermittent claudication was specifically more common among males with venous thrombosis. The so called venous claudication is thought to be an exercise induced pain resulting from venous outflow impairment (1). With this study we aimed to 1. To reassess the frequency of venous claudication by a questionnaire survey and 2. To further study this venous claudication prospectively by a formal treadmill exercise in BS patients with and without venous thrombosis along with healthy controls.

Methods: We studied 59 BS patients with lower extremity venous thrombosis (LEVT), 42 BS patients without venous disease and 55 healthy controls. All patients and controls were male. Patients and controls with peripheral arterial disease were excluded. Intermittent claudication was assessed initially by Rose questionnaire. After this, patients were asked to walk in the treadmill at a set speed of 3.5 km/h and 10% inclination for 10 minutes. Patients who first experienced persistent symptoms consistent with venous claudication but still able to walk and those who had to give up the treadmill were noted. Pre and post-exercise ankle brachial pressure indices (ABPIs) were also measured.

Results: The mean ages of the patients and controls were similar (Table). Pre and post-exercise ABPIs did not differ between patients and controls. There were significantly more patients who described claudication in the questionnaire among those with LEVT (31 %) compared to those with no venous disease (5 %) and healthy controls (0 %) ($P<0.001$) (Table). Similarly, the number of patients who experienced claudication but still continued to walk on the treadmill were significantly more among those with LEVT. Finally, only those with LEVT had to stop the treadmill challenge due to claudication. Pre and post exercise ABPI's were similar among BS patients with LEVT. There was no relation between the presence of vena cava, iliac or femoral vein involvement and the presence of claudication or limitation of walking capacity.

Table. Severity and frequency of claudication

	BS patients with venous thrombosis n = 59	BS patients without thrombosis n = 42	Healthy controls n = 55	p
Age, mean ± SD, years	37 ± 7	34 ± 7	36 ± 9	0.346
Claudication as assessed by questionnaire, n (%)	18 (31)	2 (5)	0	< 0.001
Leg pain during the treadmill exercise (the patient continues to walk) n (%)	10 (17)	3 (7)	1 (2)	0.016
Claudication necessating the termination of the treadmill exercise, n (%)	6 (10)	0	0	0.006

Conclusion: Venous claudication seems to be a severe and frequent symptom being present in up to 1/3 of BS patients with major vein involvement. It clearly limits the walking capacity in 10 % of these patients even when tested in a treadmill set at low pace.

Comparison Of Different Methods Of Skin Pathergy Test In Patients With Behçet's Syndrome. Aysegul Lacin, Cigdem Atan Uzun, Zafer Gunendi and Feride Gogus. Gazi University Faculty of Medicine, Ankara, Turkey.

Background/Purpose: Skin pathergy test (SPT) has a diagnostic value in Behçet's syndrome (BS). There are different descriptions of the test which may effect its positivity rate. We aimed to compare different methods of SPT in patients with Behçet's syndrome.

Methods: Patients with BS who fulfilled the International Study Group Criteria for Behçet's Disease and healthy volunteers were involved in the study. At 90% power (alpha= 0.5) for a 47% positivity rate for the oral method 20 patients and healthy volunteers were recruited (1). Pricks at five different sites were performed with a 20 gauge needle. i)subcutaneous ii) intradermal iii) intradermal with 0.1 cc of 0.09% saline solution iv) intravascular v) oral. The skin pathergy test was considered positive if there was a papule, pustule or oral aphtae (for the oral test) at the prick site after 48 hours. Sensitivity, specificity, positive and negative predictive values of SPT were calculated.

Results: All patients with Behçet's syndrome were positive for at least one SPT method where none of the healthy volunteers had a positive SPT. Among the five SPT methods subcutaneous and oral methods were most sensitive (70% and 60% respectively). All SPT methods showed 100% specificity and positive predictive value. Sensitivity and negative predictive values of SPTs are shown in Table 1.

Table 1. Sensitivity and negative predictive value of skin pathergy test methods

Skin Pathergy Methods	Sensitivity	Negative predictive value
Subcutaneous	%70	%77
Oral	%60	%71
Intradermal	%50	%67
Intradermal with saline	%50	%67
Intravascular	%20	%55

Conclusion: Subcutaneous method is the most sensitive test among SPTs. Oral method may be an alternative for subcutaneous SPT.

2623

A CT Evaluation Of Pulmonary and Cardiac Lesions In BEHÇET'S Syndrome Patients Without Pulmonary Symptoms. Emire Seyahi[1], Deniz Cebi Olgun[1], SerdaL Ugurlu[1], Idil Hanci[2], Reona Takahashi[1] and Hasan Yazici[1]. [1]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [2]Krankrenhaus Nordwest, Frankfurt am Main, Frankfurt, Germany.

Background/Purpose: In Behçet's syndrome (BS) patients with symptomatic pulmonary artery involvement (PAI) varying and multiple pulmonary parenchymal and cardiac lesions can be seen in thorax CT examinations (1). These lesions are pulmonary nodules of ≥ 1 cm (85 %), cavities (47 %), ground-glass opacities (45 %), mild pleural (45 %) and pericardial effusions (21 %), mediastinal lymphadenopathies (21 %) and intracardiac filling defects (28 %). Whether these pulmonary and cardiac abnormalities are exclusively observed in symptomatic BS with PAI or in vascular involvement without PAI have not been adequately studied. We now report the frequency of such lesions among BS patients with vascular disease but no PAI along with BS patients with no vascular disease at all.

Methods: Consecutive BS patients seen in the outpatient clinic between December 2011 and November 2012 were studied. Those with a disease duration of > 5 years were excluded. Contrasted thorax CT scans were obtained in BS patients with vascular disease along with BS patients with no vascular disease at all. Only patients with no prior history relevant with PAI or those with no pulmonary symptoms such as hemoptysis,

cough, chest pain and dyspnea were studied. CT scans were analyzed formally using a checklist by a radiologist who was blinded to the clinical diagnoses of the patients.

Results: We studied 49 (43 M/ 6 F) BS patients with vascular involvement and 35 (32 M/3 F) BS patients with no vascular involvement. Lower extremity deep or superficial vein thrombosis was present in all 49 patients with vascular involvement. The mean age (32 ± 7 years vs 33 ± 8 year, respectively) and disease duration (4 ± 3 years vs 3 ± 2 years, respectively) among patients with and without vascular involvement were similar. None of the patients had pulmonary artery aneurysms or thrombosis. Similarly, cavities, pleural or pericardial effusions, and intracardiac filling defects were not observed in any of the scans. The most common parenchymal lesions were nodules of < 1 cm, which were present in 61 % and 37 % patients with and without vascular involvement, respectively, (P = 0.029). Nodules of ≥ 1 cm were only present in 4 patients with vascular disease (8 %) and none of those with no vascular disease. Ground-glass opacities were present in 2 and 3 patients with and without vascular involvement, respectively. The frequency of pulmonary and cardiac lesions in the current study was much less when compared to that found in PAI.

Conclusion: Pulmonary parenchymal and cardiac lesions were rarely observed in BS patients with no pulmonary artery involvement. Although small pulmonary nodules (<1 cm) seemed to be more frequent among patients with vascular disease compared to those without, their significance remains to be further studied.

Evaluation of Asymptomatic Venous Disease By Venous Doppler Ultrasonography in Patients With Behcet's Disease. Fatma Alibaz-Oner, Emrah Karatay, Ihsan Nuri Akpinar, Tülin Ergun and Haner Direskeneli. Marmara University, School of Medicine, Istanbul, Turkey.

Background/Purpose: One of the major causes of mortality and morbidity in Behcet's disease (BD), especially in young males of Mediterranean origin, is vascular involvement. A limited data suggests also a high prevelance of venous insufficiency (VI) and some cases of asymptomatic thrombosis in BD. In this study, we aimed to investigate prospectively asymptomatic venous disease by venous doppler ultrasonography (US) in patients with BD without known vascular disease.

Methods: The study included 93 patients with BD (M/F: 45/48, age: 36.4±10 years), 97 patients with ankylosing spondylitis (AS)(M/F: 50/47, age: 37.5±9.5 years) and 43 healthy control subjects (M/F: 25/18, age: 34.7±4.5 years). Vessels of both upper and lower extremities were examined while the subjects were in supine position by venous doppler US. CEAP severity score was used to evaluate the severity of the venous insufficiency.

Results: Upper extremity veins were totally normal in all patients and controls. We also did not detect any "silent thrombosis" in study groups. Venous insufficiency findings in lower extremity were detected in 32.2% (n=30) in the BD group, 28.8% (n=28) in AS group and 9.3% (n=4) in the healthy control group. Both BD and AS patients had significantly higher VI rates than healthy controls (p=0.007 and 0.015). The rate of VI was similar between patients with BD and AS (p=0.64). Similarly, CEAP severity score in BD (0.34 (0–3)) was significantly higher than controls (0)(p=0.008), but similar to AS (0.18 (0–39)(p=0.18). No correlations were present between C-reactive protein elevations (>5 mg/L) and VI in patients with both BD (p=0.546) and AS (p=0.754).

Conclusion: A high prevelance of venous insufficiency was present in both BD and AS patients without asymptomatic thrombosis. Presence of VI also in AS, a disease without a major tendency to venous thrombosis, suggests that chronic inflammation might cause a mild insufficiency detected only by Power US in venous vessels. Long-term consequences of this finding requires further follow-up studies.

A Coruña, A Coruña, Spain, [39]Hospital Universitario Miguel Servet. Zaragoza, Zaragoza, Spain.

Background/Purpose: Several situations can be observed in patients undergoing biologic therapy in uveitis associated to Behçet's syndrome (BS): **a)** Patients are switched to another therapy because of insufficient response (IR), toxicity, or change in the route of administration, **b)** remission is achieved and discontinuation or reduction of dose is performed.

Our aim was to study these situations in a large series of BS patients receiving biologic therapy.

Methods: Multicenter study of 124 patients with uveitis refractory to conventional therapy who required at least one biologic agent. Standard dose of Infliximab (IFX), generally 5 mg/kg/i.v. was given at 0, 2, 6 and then every 4–8 weeks, Adalimumab (ADA) 40 mg/sc/every other week, golimumab (Goli) 50 mg/4 weeks, tocilizumab (TCZ) 8 mg/kg/i.v./4 weeks and rituximab (RTX) 1g/i.v./15 days (2 doses) every 6 months.

Results: The biological agent used as the first choice was either IFX in 77 patients or ADA in 47. All the IFX-treated patients received the standard dose at weeks 0, 2, 6 and then every 4–8 weeks. Initial IFX dosage was: a) IFX at 5 mg/k/i.v. (69 cases) with a maintenance dose every: 4 weeks (n=15 cases), 6 weeks (16), 7 weeks (1) or every 8 weeks (37). b) 3 mg/kg (7 cases) with a maintenance dose every: 4 weeks (1 case), 6 weeks (1) or every 8 weeks (5). c) IFX 4 mg/kg (1 case) with a maintenance dose every 4 weeks. *Shortening* infusion times for *IFX administration* as the maintenance treatment *was required* in 5 cases because of IR. Initial IFX therapy was changed to another single biologic agent in 32 cases; 30 to ADA (because of IR [16 cases], decision of changing from *i.v. to subcutaneous* route of *administration* [5 cases] or toxicity [9 cases]), 1 to RTX because of infusional reaction, and 1 to etanercept because of toxicity. Initial ADA therapy was changed to another single biologic agent in 5 cases; 2 to Goli (because of IR or toxicity in 1 case each) and 3 to IFX (2 cases because of IR and 1 because of toxicity). In 3 cases there was a double biologic switching, 1 case from ADA to IFX and to Goli, 1 case from IFX to ADA and to Goli and 1 case from ADA to IFX and to TCZ. Improvement was achieved in: a) 14 of the 16 patients switched from

IFX to ADA due to IR; b) 3 of the 3 patients switched from ADA to another biologic due to IR. Persistent clinical remission was achieved in 66 (53.2%) patients and, the dose was reduced or the agent was discontinued. IFX was decreased from 5 to 3 mg/k/i.v. in 4 patients and the maintenance dose interval was increased in 23 cases. ADA maintenance dose interval was increased for more than two weeks in 13 patients. The biologic agent was discontinued in 26 cases (21 with IFX and 5 with ADA) that had clinically persistent remission. After a mean follow-up of 13.1 ± 9.2 months after biologic agent discontinuation, 21 of these 26 patients remained in remission while 5 of the 26 experienced a flare that led to the resumption of the therapy with same agent achieving remission again in all of them.

Conclusion: Switching of biologic agents may be useful. Once clinical remission is achieved, dose reduction or in some cases discontinuation of the biologic agent may be obtained.

Infliximab For Sight-Threatening and Refractory Uveitis Of Behcet's Syndrome. Vedat Hamuryudan[1], Gulen Hatemi[2], Yilmaz Ozyazgan[2], Didar Ucar[2], Sebahattin Yurdakul[2], Emire Seyahi[2], Koray Tascilar[2], Serdal Ugurlu[2] and Hasan Yazici[1]. [1]Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey, [2]Behcet's Syndrome Research Center, Cerrahpasa Medical Faculty University of Istanbul, Istanbul, Turkey.

Background/Purpose: Uncontrolled studies suggest a beneficial effect of infliximab in the treatment of severe uveitis of BS. The majority of these studies had short observation periods.

Methods: The charts of 43 BS patients (33 men; age at the initiation of infliximab: 31±8.4 SD years) treated with infliximab (5 mg/kg) were reviewed retrospectively. All patients had severe, sight-threatening posterior uveitis of long-duration (82±50 SD months) refractory to previous treatments with multiple immunosuppressives (azathioprine=43, Cyclosporin A=42, Interferon alfa=38; duration of previous treatment: 62±43 SD months) and steroids. Efficacy was assessed by the change of visual acuity (LogMAR VA) and the decrease in the number of attacks under infliximab.

Results: The duration of infliximab treatment was 31±18 SD months (median 29 months). In 37 (86%) patients infliximab was combined with azathioprine (n= 26), azathioprine and cyclosporine A (n=10) or interferon alfa (n=1). Twenty-nine (67%) patients had no useful vision (LogMAR >1) in at least one eye at the time of initiation of infliximab. Five (17%) had gained useful vision of both eyes under infliximab. The mean VA (all patients) was maintained under infliximab (right eye: 0.83± 0.74 vs 0.84 ±0.79; left eye: 1.27±0.83 vs 1.13± 0.88). VA of the worse eye improved in 11 patients, remained stable in 24 and worsened in 8 patients under infliximab. Eleven patients (26%) had no attacks during previous treatment and were prescribed infliximab to protect the already compromised vision. The VA remained stable or improved in 10 patients and 9 patients remained attack free under infliximab. Thirty-two patients (74%) had attacks before infliximab. Eleven (34%) of them became attack free under infliximab. The number of uveitis attacks per year (all patients) under previous immunosuppressive treatment dropped from 1.9 ±3 to 0.3 ±0.6 in the right eye (p=0.0001) and from 2.5± 2.9 to 0.3 ±0.6 in the left eye (p=0.0001). There was also a significant decrease in the numbers of patients with hypopyon (11 and 3; x^2= 5.46, p=0.019), vascular infiltrations (23 and 12; x^2= 5.83, p=0.016), macular edema (8 and 1; x^2= 6.08, p=0.014), and retinal hemorrhages (7 and 0; x^2= 7.62, p=0.006) under infliximab. Infliximab treatment was terminated in 16 patients (adverse events =5, inefficacy =1, terminal eye disease = 4, unrelated reasons = 6). Fifteen of these patients received further treatment (biologics = 3, azathioprine =12) for 22±13 SD months and 12 of them remained attack free during this period. The adverse events causing discontinuation were pulmonary tuberculosis in 3 (at 17., 32., and 46. month of infliximab treatment, respectively), depression in 1, pneumonia in 1 patient.

Conclusion: Infliximab combined with immunosuppressives was useful in preserving visual acuity and in controlling the attacks of BS patients with refractory, sight-threatening uveitis at the long-term. Relapses were infrequent after discontinuation. Tuberculosis appears as a concern in prolonged treatment.

Prognostic Factors Of Visual Function In The Treatment With Infliximab For Uveitis Of Behçet's Disease. Akihiko Nakabayashi[1], Toru Hirano[1], Yoshihiro Hishitani[1], Keisuke Hagihara[1], Kei Nakai[2], Kouji Nishida[2] and Atsushi Kumanogoh[1]. [1]Osaka University Graduate School of Medicine, Suita, Japan, [2]Osaka University Graduate School of Medicine, Suita, Japan.

Background/Purpose: Infliximab, a chimeric monoclonal antibody against TNF-α, is expected to improve prognosis of visual function in patients with severe and refractory uveitis of Behçet's disease. However, prognostic factors remain to be determined.

Methods: Observational study in one institute was conducted in the cohort of patients with Behçet's disease treated with infliximab. Outcome was defined as failure to recover above 20/50 of visual acuity (VA) at 2 year after the first administration of infliximab. Associations between outcome and baseline characteristics were assessed by bivariable analysis and logistic regression analysis to adjust confounding factors. Significance of each factor was assessed by likelihood ratio test.

Results: Infliximab was initiated in 28 patients between February 2007 and May 2012. Nineteen patients continued to receive infliximab beyond 2 year and could be assessed. Among 38 eyes of 19 patients, 18 eyes could not achieve 20/50 of VA (Figure). Bivariable analysis between the outcome and baseline characteristics demonstrated p-value (p) = 0.53 for sex, p = 0.19 for disease duration, p = 0.43 for HLA-B51, p = 0.97 for C-reactive protein (CRP), p < 0.0001 for VA at the first administration, p = 0.088 for deviation of VA during 6 months before the first administration, p = 0.48 for concomitant use of corticosteroids and p= 0.042 for concomitant use of immunosuppressants such as cyclosporine or methotrexate. Adjusted analysis with confounding factors such as sex, age, disease duration, VA at the first administration and concomitant use of immunosuppressants by logistic regression analysis revealed disease duration (p=0.024) and visual acuity (p < 0.0001) as significant factors (Table). Receiver operating characteristic (ROC) analysis demonstrated 16.5 months of disease duration and 20/140 of visual acuity (Area under the curve: 0.95) for candidate cutoff values.

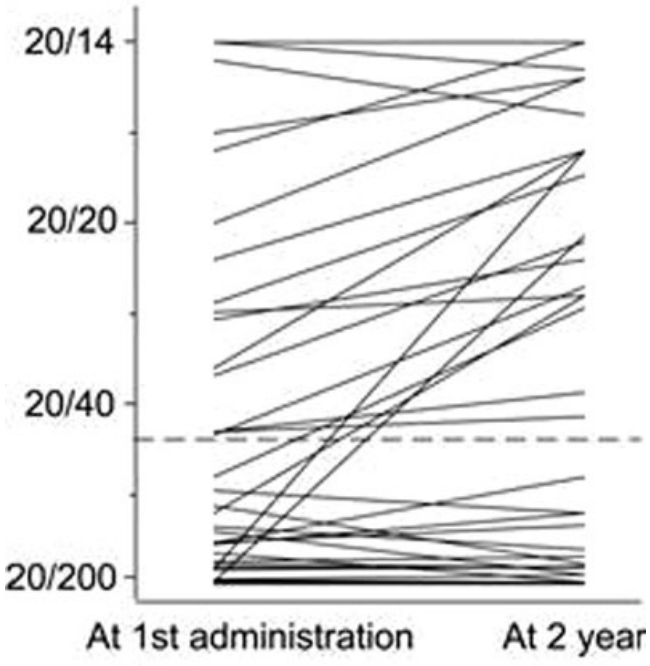

Figure. Change of visual acuity

Table. Contributable factors for visual acuity at 2 year

Factor	p-value
Sex	0.41
Age	0.42
Disease duration	0.024
Visual acuity	<0.0001
Immunosuppressants	0.64

*regression logistic analysis and likelihood ratio test

Conclusion: Disease duration and VA at the first administration of infliximab were the most contributable factors for the prognosis of visual function after 2 years. Cutoff values, 16.5 months of disease duration and 20/140 of VA suggest the importance of 'windows of opportunity' in treatment for uveitis of Behçet's disease.

Immunogenicity Of Infliximab Modulates Efficacy and Safety In Behcet's Disease Patients With Uveitis. Mitsuhiro Takeno, Kayo Terauchi, Yohei Kirino, Ryusuke Yoshimi, Nobuhisa Mizuki, Etsuko Shibuya and Yoshiaki Ishigatsubo. Yokohama City University Graduate School of Medicine, Yokohama, Japan.

Background/Purpose: Infliximab (IFX) suppresses ocular attacks in Behcet's disease (BD) with uveitis, resulting in favorable long-term visual prognosis. However, some patients had ocular attacks which accumulate one or two weeks before the next IFX infusion, suggesting that the efficacy of IFX depends on the concentration. This study investigates IFX through levels and antibody toward IFX (ATI) in BD patients receiving IFX and analyzes the relationship of the pharmacokinetics with clinical efficacy and safety.

Methods: We retrospectively examined clinical courses of 20 BD patients (female 7, male 22 age 41.9 + 14.4 yo) who met the Japanese revised Behcet's disease Diagnositic criteria (2003) and received IFX because of refractory uveitis to conventional therapies including cyclosporine A. In principle, immunosuppressants were discontinued before introduction of IFX therapy. In the original regimen, IFX (5mg/kg) was given at 0, 2, 6 week, and thereafter every 8 weeks, but the intervals were shortened to 5 weeks after major ocular attacks occurred. The blood samples were drawn prior to the next infusion. IFX concentrations and ATI in the sera were determined by ELSIA.

Results: Mean duration was 6.4 + 5.8 years from the disease onset to initiation of infliximab therapy. A. Duration of IFX was 7 to 80 months. The therapy was discontinued in 2 patients because of infusion reaction and/or insufficient efficacy. Frequencies of ocular attacks (/6 months) were 2.6 + 2.1 and 0.4 + 0.5 before and after therapy, indicating that IFX suppresses ocular attacks significantly. During the therapy, total 29 ocular attacks occurred at 6.87 + 1.12 weeks after the last infusion, 1.43 + 1.53 weeks before the next infusion. The infusion interval was shortened from 5 to 7 weeks in 8 patients who experienced major ocular attacks. Thereafter, frequency of ocular attacks was reduced from 0.84 to 0.37/6months, while that was 0.10 in patients who continued to receive the infusions every 8 weeks. The mean IFX through level was 5.0 + 6.1 μg/ml but it was undetectable (less than 0.1μg/ml) in 7 patients. Of the 7 patients, 3 had recent ocular attacks, 6 showed extraocular symptoms, 6 had infusion reaction, and 6 had ATI. Shortening the infusion interval was associated with increased through level, leading to another remission in a patient. Besides 6 patients, ATI was also positive in one patient who had infusion reaction but no ocular attacks. Three of 4 patients who required admission due to infusion reaction were positive for ATI.

Conclusion: The present study suggests that low IFX trough level is also associated with ocular attacks, extraocular manifestations, and ATI, which is partially responsible for serious infusion reaction. Therefore, shortening the infusion interval and concurrent usage of immunosuppressants appear reasonable strategies to circumvent the issues.

Is Complete Remission a Realistic Target With Current Therapeutic Options in Behçet's Disease? Fatma Alibaz-Oner[1], Gonca Mumcu[2], Zeynep Kubilay[1], Gülsen Ozen[3], Gülce Celik[1], Aslı Karadeniz[1], Meryem Can[1], Sibel Yılmaz Oner[1], Nevsun Inanc[4], Pamir Atagunduz[4], Tülin Ergun[1] and Haner Direskeneli[1]. [1]Marmara University, School of Medicine, Istanbul, Turkey, [2]Marmara University, Faculty of Health Sciences, Istanbul, Turkey, [3]Marmara University School of Medicine., Istanbul, Turkey, [4]Marmara University School of Medicine, Istanbul, Turkey.

Background/Purpose: The clinical course of Behcet's disease (BD) as a multi-systemic disorder with a remitting-relapsing nature is unsufficiently explored. As complete remission should be aimed in all inflammatory diseases, we investigated the frequency of complete remission in patients with BD in routine practice.

Methods: In this retrospective study, 258 patients with BD (F/M: 130/128, mean age: 41.1±11,5 years) classified according to ISG criteria were included. The demographic and clinical data for active organ manifestations and treatment protocols were evaluated, both for the current visit and in the last month. Patients having at least one of any disease manifestations were categorized as active.

Results: A total of 1757 visits of 258 patients were overviewed. Mean visit number was 6,8± 2,7 (range: 1–10) and mean follow-up duration was 45.8±36.5 months (2–165). One hundred twenty-five patients (48.4%) were of mucocutaneus type, whereas 133 patients (51.6%) had major organ involvement. When all visits combined, 19.8–43.9% of the patients were using immunosuppressives (IS), whereas 35.3–59.3% was under non-IS therapies such as colchicine or NSAIDs. There was also a group of noncompliant patients (6.4–45%) without any treatment in some visits. Patients were clinically active in 67.2% (n=1182) of the total visits (n=1757). Frequency of clinical activity increased to 75.6% (68.1– 90.3) when the month before the visit was also included. The major cause of the activity was aphthous ulcers (39.4–63.2%) with other mucocutaneous manifestations also commonly present (Genital ulcer: 3.5–27.1 %, erythema nodosum: 8.2–22.5%, papulopustular lesions: 18.2–33.7%, arthritis: 21.3–33.5%, uveitis: 0.5–8.5% and vascular involvement: 2.5–10.8%). No difference was observed between the frequency of activity of patients having ISs or non-IS therapies.

Conclusion: Although complete remission is the current, primary target in inflammatory rheumatological diseases such as rheumatoid arthritis or vasculitides, it is fairly difficult to achieve complete remission in BD with current therapeutic regimens. The reluctance of the clinicians to be aggressive for some BD manifestations with low morbidity, such as mucocutaneous lesions, might be influencing the continuous, low-disease activity state in BD patients.

2630

Low Medication Adherence Is Observed In Behcet's Disease. Gonca Mumcu[1], Ali Taze[1], Esra Kula[1], Semiha Yemez[1], Silay Eksi[1], Leyla Köksal[1], Fatma Alibaz-Oner[2], Sibel Yilmaz Oner[2], Pamir Atagündüz[2], Nevsun Inanc[2], Tülin Ergun[2] and Haner Direskeneli[2]. [1]Marmara University, Faculty of Health Sciences, Istanbul, Turkey, [2]Marmara University, School of Medicine, Istanbul, Turkey.

Background/Purpose: Symptom-control with reduction of mortality and morbidityare the main treatment goalsin Behcet's Disease (BD). However, similar to other chronic disorders, increased unnecessary visits, hospitalisation and medication costs are thought to originate from lack of adherence to medications of the treatment protocols in BD. Therefore, the aim of this study was to evaluate self-reported medication adherence in BD patients.

Methods: The study group was composed of 118BD patients(F/M:62/56, mean age:37.7±10.8 years) and disease control groups regarding 50

patients with Rheumatoid Arthritis (RA, F/M:37/13, mean age:39.9±10.4 years) and 58 patients with Familial Mediterranean Fever (FMF, F/M:39/19, mean age:34.4±11.9 years).

Medication adherence was evaluated by the Morisky scale that is a brief 4-item structured questionnaire. Each patient has a scale score ranging from "0" to "4" with low scores indicating better adherence. Trained interviewers (n=4) who were not involved in any disease assessment or treatmenthelped to individuals with visual impairment or illiterates in filling the questionnaire.

Results: The Moriskyscale score was similar in BD (2.05±0.99) and FMF (2.01±1.1) (p=0.99), whereas it was significantly lower in RA (1.54±1.05) than BD (p=0.021).In BD, no significant difference was present in the Morisky scale score according to gender (females:2.09±0.9vsmales: 2.0±1.02, p=0.60).The score of patients with major organ involvement (2.1±1.1) was also similar to mucocutaneous ones (1.9±0.9) (p=0.57) in males. In contrast, the score was lower in patients with major organ involvement (1.7±1.1) compared to patients with mucocutaneous involvement (2.29±0.8) in female BD patients (p=0.04). Moreover, a weak correlation was observed between the Morisky scale score and the number of medication (4.8±2.4, r:0.3 p=0.029).

Conclusion: Self-reported medication adherence was found to be low in BD patients. Medication adherence seems to be different according to gender in the frame of major organ involvement, suggesting that either the perception or consequences of disease-associated morbidity is associated to gender-related features in BD.

Fertility In Behçet's Syndrome: Structured Interview In A Multidisciplinary Center. Caner Saygin, Didem Uzunaslan, Gulen Hatemi, Koray Tascilar and Hasan Yazici. Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey.

Background/Purpose: Behçet's Syndrome (BS) follows an active course during the child-bearing years in both men and women. Whether fertility is decreased among the BS patients due to the condition itself or to the frequently used medications like cyclophosphamide (CYC), azathioprine or colchicine is not clear. We aimed to determine the infertility rate, and the effect of drugs and types of organ involvement on fertility in BS patients.

Methods: We included BS patients with and without major organ involvement, familial Mediterranean fever (FMF), ankylosing spondylitis (AS) patients and healthy controls recruited from hospital staff. In order to show a 20% increase in infertility in BS with 0.05 alpha and 80% power, we calculated that each group should contain at least 125 individuals. Among patients who visited the clinic for routine controls, individuals with an even waiting list number were selected. A structured interview was performed by two physicians and medical records were reviewed. Infertility was defined as the inability to conceive after one year of unprotected intercourse. We compared the differences in the proportion of individuals who had never conceived in their lifetime, who had a successful conception but became infertile after disease onset, and individuals who conceived late or with assisted reproductive technology (ART), between BS and control groups. Finally infertility was separately assessed in a group of 62 patients who had used CYC and was compared to that observed among patients with major organ involvement who were CYC naïve. Multivariate logistic regression analysis was used to determine the association of infertility with involved organs and the drugs which were used.

Results: The numbers of subjects who were not able to ever conceive, who were not able to conceive only after disease onset, and who were able to conceive late or only with ART were not increased among patients with BS (Table). There were more FMF patients who conceived late or only with ART. Average number of children, miscarriages, terminations and ectopic pregnancies were not significantly different in patients with BS. Univariate logistic regression showed an increased risk of infertility with CYC (OR 6.1, %95 CI 0.7–54.2), however this effect was not confirmed in multivariate analysis. This was attributed to a type II error caused by the low number of patients who had used CYC. Finally the infertility was higher among the separate group of 62 CYC users as compared to the patients with major organ disease who were CYC naive (7/20 vs 3/60 among those who atttempted to conceive, p=0.002).

	BS major organ (n=190)	BS mucocutaneous (n=135)	FMF (n=126)	AS (n=129)	Healthy (n=125)	p
Mean age at diagnosis	29.2±8.6	30.8±9.4	28.7±11.9*	31.4±10.5	NA	0.012*
Never conceived despite attempts	4/156 (%2.6)	0/108	3/91 (%3.3)	3/100 (%3)	3/103 (%2.9)	0.502
Failed to conceive after disease onset	7/88 (%8)	5/49 (%10.2)	6/80 (%7.5)	6/66 (%9.1)	NA	0.95
Conceived late or only with ART	10/156 (%6.4)	9/108 (%8.3)	15/91 (%16.5)	6/100 (%6)	4/103 (%3.9)	0.014

Conclusion: Infertility rate is not appreciably increased among BS patients as compared to FMF patients, AS patients and healthy controls. Major organ involvement does not seem to affect this. CYC is the only drug which seems to decrease fertility in BS.

Long Term Outcome Of Neuro-Behçet's Disease. Nicolas Noel[1], Remy Bernard[2], Bertrand Wechsler[1], Matthieu Resche-Rigon[2], Du Boutin[1], Jean-Charles Piette[1], Aurélie Drier[1], Didier Dormont[1], Patrice P. Cacoub Sr.[1] and David Saadoun[3]. [1]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France, [2]Hopital Saint-Louis, Paris, France, [3]Pitié-Salpêtrière Hospital, APHP, Paris, France.

Background/Purpose: Neurological involvement occurs in 5.3 to up to 59% of patients with Behçet's disease (BD). Although the clinical and imaging features of neuro-Behçet's disease (NBD) have been extensively described, few studies have reported on the long term outcome, treatment and prognosis of NBD by multivariate analyses. Moreover, no large study has focused on the impact of immunosuppressants on the outcome of NBD. In this study, we sought to report the long-term outcome of neurological involvement in patients with Behçet's disease (BD).

Methods: Retrospective analysis of 115 patients fulfilling the International Criteria for BD [57% male with median [Q1-Q3] age of 37 [30–46] years] with neuro-Behçet's disease (NBD) after exclusion of cerebral venous thrombosis. Factors associated with relapses of NBD, dependence and mortality were assessed by multivariate analysis. The event-free survival was calculated using Kaplan-Meier curves and a multivariate Cox proportional hazard ratio model was performed.

Results: Seventy eight (68%) patients presented with an acute onset of NBD and 37 (32%) with a progressive course. The HLA B51 allele was carried by 49% of patients. Overall, 46/115 (40%) patients had a severe initial disability status, represented by a Rankin score ≥ 3. The 5 and 7 years event-free survival rate were of 65% and 53%, respectively. In multivariate analysis, HLA-B51 positivity was independently associated with the risk of relapses of NBD (OR=4.2 [1.6–10.9]). After a median follow-up of 73 [59–102] months, 21 (25.2%) patients became dependent or died. Factors independently associated with poor outcome were a paresis at onset (OR=6.47 [1.73–24.23]) and a brainstem location of inflammatory lesions on MRI (OR=8.41 [1.03–68.43]). All the 115 patients were treated with glucocorticosteroids, including 53/115 (46.1%) with cyclophosphamide and 40/115 (34.8%) with azathioprine. A trend towards a longer event-free survival was observed in severe NBD patients (i.e. Rankin score ≥ 3 at onset) receiving intravenous cyclophosphamide compared with those treated with azathioprine (p =0.06).

Conclusion: NBD is a severe condition in which HLA-B51 carriers seems to have a worse prognosis.

Clinical Spectrum Of Cutaneous Vasculitis. Javier Loricera[1], Vanesa Calvo-Río[1], Francisco Ortiz-Sanjuan[1], Héctor Fernández-Llaca[1], Marcos A. González-López[1], Lino Álvarez[2], M. Carmen González-Vela[1], Domingo González-Lamuño[2], Cristina Mata[1], Javier Rueda-Gotor[3], Víctor M. Martínez-Taboada[4], Miguel Angel González-Gay[1] and Ricardo Blanco[3]. [1]Hospital Universitario Marqués de Valdecilla. IFIMAV. Santander. Spain, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla. IFIMAV. Santander, Santander, Spain, [3]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain, [4]Hospital Universitario Marqués de Valdecilla. IFIMAV., Santander, Spain.

Background/Purpose: Cutaneous vasculitis (CV) encompasses a large and heterogeneous set of syndromes characterized by inflammation of the skin vessels. The most common clinical manifestation is palpable purpura with leukocytoclastic vasculitis in biopsy. Our objective was to study clinical associations of a large series of patients with CV.

Methods: Study of 817 consecutive and unselected patients with CV of the same university hospital. The diagnosis required histological confirmation except in obvious cases like Henoch-Schönlein Purpura (HSP) in childhood. Primary vasculitic syndromes were classified according to the classification of Chapel Hill *(Jennette J et al. Arthritis Rheum 1994; 37:187)*.Secondary vasculitis were considered those due to malignancies, major infections and connective tissue diseases. The different clinical associations were studied according to different age groups, considering adults patients older than 20 years (Michel et al. J Rheumatol 1992; 19:721–8).

Results: Of 817 patients (457 men/360 women), 459 were adults (mean age±SD, 55.3±17.5 years) and 358 childrenyoung (mean age ± SD, 7.5 ± 4.2 years).Of the 358 children-young, 355 had primary VC: HSP (279 cases), cutaneous leukocytoclastic angiitis (CLA) (68) and urticarial vasculitis (8).Of the 459 adults, 369 had a primary CV: CLA (239), HSP(105), urticarial vasculitis (12) and mixed cryoglobulinemia (13 patients).The CV was a manifestation of a systemic necrotizing vasculitis in 13 adults; polyarteritis nodosa (3), microscopic polyangiitis (4), Wegener's disease (3) and Churg-Strauss syndrome (3).In addition, the CV was secondary to other processes in 77 adults: connective tissue diseases (34), severe infection (25), neoplasia (18).There were only three children-young patients, who had a secondary CV, a major infection (2 cases) and a connective tissue disease (1 case).Patients in which the CV was secondary to systemic necrotizing vasculitis, connective, serious infections or malignancies had clinical and laboratory data suggestive of this underlying disease.

Conclusion: CV in children in most cases (99.2%) is primary, usually HSP or CLA, and has a good prognosis. By contrast, in adults a 22.4% is due to malignancies, major infections, connective tissue diseases, systemic necrotizing vasculitis or cryoglobulinemic vasculitis. Therefore, clinical assotiations depends of age, being more serious in adults.

Henoch-Schönlein Purpura: Clinical Spectrum Of The Disease In 417 Patients From A Single Center. F. Ortiz-Sanjuán[1], Vanesa Calvo-Río[1], Javier Loricera[1], C Mata[1], L Martín Penagos[1], L Alvarez[1], M. Carmen González-Vela[1], D González-Lamuño[1], Javier Rueda-Gotor[2], Héctor Fernández-Llaca[1], Marcos A. González-López[1], Susana Armesto[1], M. Enriqueta Peiró[1], M. Arias[1], Miguel Angel Gonzalez-Gay[1] and Ricardo Blanco[2]. [1]Hospital Universitario Marqués de Valdecilla. IFIMAV. Santander. Spain, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain.

Background/Purpose: The severity of clinical features and the outcome in the different series of Henoch-Schönlein Purpura (HSP) shows great variability, probably due to selection-bias. Our aim was to establish the actual clinical spectrum of HSP in all age groups using an unselected and wide series of patients diagnosed at a single center.

Methods: Study of all consecutive patients classified as having HSP at a single center according to the criteria proposed by Michel et al (J Rheumatol 1992; 19: 721–8). HSP was pathologically confirmed in 110 cases by a skin biopsy showing the characteristic histological findings consistent with leukocytoclastic vasculitis. The remaining 307 patients without skin biopsy (mainly children) had typical non thrombocytopenic symmetric palpable purpura. In addition, all of them fulfilled the criteria proposed by Michel et al.

Results: We performed a retrospective review of 417 patients (240 men/177 women), with a median age at the time of disease diagnosis of 7.5 years (interquartile range-IQR: 5.3–20.1). Three-quarters of them (n=315) were children or young patients (age <20 years) and a quarter (n=102) were adults. The most frequent precipitating events were a previous infection (38%), usually an upper respiratory tract infection, and/or drug intake (18.5%) shortly before the onset of HSP. At disease onset the most common manifestations were skin lesions (55.9%), nephropathy (24%) gastrointestinal involvement (13.7%), joint symptoms (9.1%), and fever (6.2%). When the disease was fully established, the main clinical features were skin involvement (100%), mainly palpable purpura, gastrointestinal (64.5%), joint (63.1%), renal involvement (41.2%), fever (20.4%), constitutional syndrome (2.9%) and peripheral neuropathy (1.9%). The main gastrointestinal features were the typical colicky abdominal pain (64.5%), nausea and vomiting (14.4%), melena and or rectorrhagia (12.9%), and positive stool guaiac test (10.3%). Renal involvement (41.2%), usually behaving as a mild nephropathy; nephrotic syndrome (4.8%), nephritic syndrome (2.9%) and renal insufficiency (4.8%). The main laboratory data were leukocytosis (36.7%), anemia (8.9%) and increased of serum IgA levels (31.7%). The most frequent treatments used were corticosteroids (35%), nonsteroidal anti-inflammatory drugs (14%), and cytotoxic agents (5%). After a median follow-up of 12 (IQR: 2–38) months, complete recovery was observed in 346 patients (83.2%) and persistent, usually mild, nephropathy was observed in 32 cases (7.7%). Relapses were observed in 133 patients (31.9%).

Conclusion: Although HSP is a typical vasculitis affecting children and young people, it is not uncommon in adults. The prognosis is favorable in most cases depending mostly on renal involvement.

IgA Vasculitis In Adults – a Rare and Benign Disease? Alojzija Hocevar[1], Jaka Ostrovrsnik[1], Vesna Jurcic[2] and Matija Tomsic[3]. [1]University Medical Centre Ljubljana, Ljubljana, Slovenia, [2]University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia, [3]University Medical Centre Ljubljana, Ljubljana, Slovenia.

Background/Purpose: IgA vasculitis (IgAV) is the most common vasculitis in children, with a defined epidemiology (14 cases/ 10^5children), clinical picture and generally favourable prognosis. In adults IgAV is less well characterized. It is assumed to be rare, with a higher incidence of renal involvement but overall a benign disease. Our aim was to better define IgAV in our adult patient population.

Methods: A retrospective chart analysis of adult patients diagnosed with IgAV at our rheumatological department between June 2010 and June 2013. The demographics, clinical data, treatment and outcome were recorded.

Results: 205 new cases of vasculitis were identified (Table 1). In 71 (34.6%) IgAV was histologically confirmed, 42 males (59.2%), 29 females (40.8%), mean age 58.2 ± 21.5. Prior infection was detected in 26/71 (36.6%) cases. Leukemia and primary biliary cirrhosis was coincidently diagnosed in one and two patients respectively. In 11 cases a new drug was introduced before the IgAV episode (mostly antibiotics).

Skin involvement was seen in all patients (purpura 71/71 cases, skin necrosis 32/71 (45.1%), bullous lesions 7/71 (9.8%)) and there was an isolated manifestation in 15 cases (21.1%). Arthritis was present in 16/71 (22.5%) and gastrointestinal involvement in 29/71 (40.8%; severe with bleeding or ileus in 9/71 (12.6%). 43/71 (60.6%) had renal involvement. Lung, heart and testicular involvement was rare - one case of each. The most common combination of symptoms was skin, gastrointestinal and renal involvement (18/71 cases; 25.3%).

No treatment (13/71) or local glucocorticoids (6/71) were sufficient in the isolated purpura. 52 patients (73.2%) received systemic glucocorticoid, 10/71 (14.1%) needed additional immunosuppression (9 cyclophosphamide (CyC), 1 mycophenolate mofetil), four received IVIG and two patients plasmapheresis in addition to CyC. None needed dialysis.

Two patients died due to active vasculitis, lung and gastrointestinal manifestation respectively and one due to cytomegalovirus infection. Two patients died shortly thereafter due to heart failure and pneumonia respectively.

Table 1. Newly diagnosed vasculitis from June 2010 to June 2013

TYPE	number	%
Takayasu arteritis	1	0.5
GCA	77	37.6
Isolated aortitis	3	1.5
PAN	2	1.0
Localized PAN	3	1.5
AAV (GPA and MPA)	18	8.8
EGPA	3	1.5
Cryoglobulinemic vasculitis	12	5.9
IgA vasculitis	71	34.6
Anti-GBM disease	1	0.5
Behçet disease	5	2.4
Cogan syndrome	2	1.0
SVV secondary to infection	3	1.5
Undetermined SVV	2	1.0
PCNSV	1	0.5
Vasculitis secondary to RA	1	0.5
TOTAL	205	

GCA - giant cell arteritis; PAN - polyarteritis nodosa; AAV - ANCA associated vasculitis; GPA -granulomatosis with polyangiitis; MPA - microscopic polyangiitis; EGPA - eosinophilic granulomatosis with polyangiitis; SVV - small vessel vasculitis; PCNSV - primary central nervous system vasculitis; RA - rheumatoid arthritis

Conclusion: In our adult patient population IgAV is the second most common vasculitis. Adult IgAV patients frequently need systemic immunosuppression. The most common clinical manifestation is concomitant skin, gastrointestinal and renal involvement. Heart and lung involvement is rare.

IgA Vasculitis – The Second Most Common Systemic Vasculitis In Adults In Slovenia. Alojzija Hocevar[1], ŽIga Rotar[2], Jaka Ostrovrsnik[1], Vesna Jurcic[3], Jelka Lindic[1] and Matija Tomsic[4]. [1]University Medical Centre Ljubljana, Ljubljana, Slovenia, [2]University Medical Centre Ljubljana, 1000 Ljubljana, Slovenia, [3]University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia, [4]University Medical Centre Ljubljana, Ljubljana, Slovenia.

Background/Purpose: IgA vasculitis (IgAV) is assumed to be rare in adults. Reported annual incidence rates vary between 0.8 and 1.8 cases per 100,000 adults.[1] Our aim was to determine the incidence rate of histologically confirmed IgAV in our country.

Methods: A retrospective patient chart review of adult patients diagnosed with IgAV was performed at the departments of rheumatology, nephrology and dermatovenerology at an integrated secondary/tertiary university teaching hospital, which is the only hospital serving a region representing approximately a quarter of the national population. In order not to miss any cases managed by the few private dermatovenerology and nephrology outpatient clinics, the attached medical faculty's Institute of Pathology provided a list of all histologically proven cases of IaAV in the region. The annual incidence rate of histologically confirmed IgAV was calculated.

Results: From June 2010 to June 2013 48, 3, and 7 new cases of IgAV were identified at the departments of rheumatology, nephrology, and dermatovenerology, respectively in a well-defined region with a population of 517,445 white Caucasians aged 20 years or above. No additional cases were identified from records retrieved at the Institute of Pathology. The estimated annual incidence rate of IgAV is 3.7 (95% CI 2.2–5.7) per 100,000 adults. The largest proportion of cases were identified in the winter (31.0% cases) and the smallest in the spring (17.2% cases). Male to female ratio was 1.6.

Conclusion: The annual incidence rate of IgAV of 3.7 per 100,000 adults may be underestimated due to retrospective case ascertainment and inclusion of histologically confirmed cases only, yet IgAV none the less represents the second most common systemic vasculitis among adults in our population, second only to giant cell arteritis with an estimated annual incidence rate of 4.7 per100,000 adults, which is in striking discord with previous reports.[1]

Sacco, Milano, Italy, [39]Rheumatology Unit, University of Pisa, Pisa, Italy.

Background/Purpose: preliminary Classification Criteria for cryoglobulinemic vasculitis (CV) have been developed in 2011 by an European cooperative study, with an adequate methodology in a large number of real cases and controls (1). The aim of this study is to validate these classification criteria for CV.

Methods: Centres from Europe, United States, Japan and Egypt, were involved. A dedicated chart included: l) a validated questionnaire for CV (1); 2) the pattern of organ involvement (4 items: constitutional, articular, vascular and neurologic involvement); 3) laboratory tests (3 items: rheumatoid factor, complement C4 and serum monoclonal component), according to the preliminary criteria (1). New patients with CV (Group A) and controls (Group B), i.e., subjects with cryoglobulins but lacking CV based on the golden standard clinical judgment, were studied. A sample size of at least 140 patients for each group was estimated in order to obtain a sensitivity and a specificity of at least 90±5%, based on the previous results (1). Sensitivity and specificity were calculated by comparing Group A versus Group B. Finally, not for classification purposes, but to disclose whether the Criteria may be also clinically helpful in patients lacking serum cryoglobulins, but where CV is suspected (1), Group A was also compared with Group C, including patients with diseases mimicking CV, but without serum cryoglobulins.

Results: Six hundred forty-three patients were enrolled in 22 Centres (from Italy, Spain, France, Greece, Slovenia, Japan and Egypt). Major

organizative/local issues did not allow American experts to participate. Group A comprised 268 patients with CV, Group B 182 controls with serum cryoglobulins without CV, and Group C 193 controls without serum cryoglobulins. Notably, 20 patients showed type I cryoglobulinemia, 13 in Group A, and 7 in Group B. Group C included 108/193 (55.9%) systemic vasculitides, 100/108 (92.6%) were small vessel vasculitides. The classification criteria [positivity of at least 2/3 items among questionnaire (≥2/3 positive questions), clinical item (≥3/4 clinical manifestations), laboratory (≥2/3 tests)] showed 89.9% (95% CI 86.1–93.6) of sensitivity and 93.5% (95% CI 89.7–97.2) of specificity, replicating previous results (1). Sensitivity of 91.7% and specificity of 100% were observed in the subgroup of type I cryoglobulinemia. By the comparison of Group A vs. Group C, the Criteria showed a specificity 92.6% (88.8–96.5) and a sensitivity of 77.8% (72.6–83.0) when the laboratory item was positive (questionnaire + laboratory item; or clinical + laboratory item).

Conclusion: the International Classification Criteria for the CV have been validated in a new real cohort. High specificity and sensitivity were confirmed. Notably, in patients where CV is suspected on clinical grounds, but where cryoglobulins are negative by initial testing, or not yet available (patients who cannot be classified as CV, as positive serum cryoglobulinemia is a *conditio sine qua non* for classification) (1), the Criteria appear relevant to strengthen the suspicion for CV, and to optimize the follow-up.

Cryoglobulinemia Vasculitis With Or Without Associated Cryofibrinogenemia: A Different Phenotype? Martin Michaud[1], Guillaume Moulis[2], Jacques Pourrat[1], Benedicte Puissant[1], Antoine Blancher[1] and Laurent Sailler[3]. [1]Toulouse University Hospital, University of Toulouse, Toulouse, France, [2]Toulouse University Hospital, Clinical Pharmacology Department, University of Toulouse, UMR INSERM-UPS 1027, Toulouse, France, [3]Toulouse University Hospital, Toulouse, France.

Background/Purpose: Cryoglobulin (CryoGl) and cryofibrinogen (CryoFg) are cryoproteins, both responsible for well-described systemic vasculitis. Nevertheless, cryoglobulinemia may be associated with cryofibrinogenemia. Such mixed cryoprotein vasculitis (MCV) has not been properly described yet. This work aimed at determining whether the phenotype of MCV is different from CryoGl vasculitis.

Methods: Concomitant CryoGl and CryoFg dosages performed at our University Hospital from January 2011 to December 2012 were extracted and the corresponding medical files reviewed. We included all adult patients with systemic vasculitis associated with CryoGl with or without CryoFg. As in the CryoVas study, systemic vasculitis was defined by purpura or cutaneous ulcers, or other symptoms biopsy-proven associated with a detectable cryoprotein. Qualitative variables were compared with Fisher or chi^2 tests and quantitative variables with Student t-test or Wilcoxon-Mann-Withney test.

Results: Among 107 patients with cryoprotein positive dosage, 21 had MCV and 16 CryoGl vasculitis. Male:female sex ratio was respectively 1/2 and 5/3 ($p=0.8$). Mean age at diagnosis was respectively 58 ± 20 and 59 ± 16 years ($p=0.9$). Cutaneous manifestations (purpura, skin necrosis or ulceration and acrocyanosis) were similar in both groups as well as kidney (38 vs 31%) and peripheral nerve involvement (28 vs 32%). The frequency of rheumatic symptoms (arthralgia and/or myalgia) or of venous/arterial thrombotic events (43 vs 25%, $p=0.4$) was not different betweens both groups (51 vs 32%, $p=0.2$). Estimated glomerular filtration rate and cryoglobulin dosage were similar in both groups. As expected, α1 and α2globulin levels were higher in the MCV group ($p<0.05$). Decreased values of C3 and C4 were more frequent in the MCV group albeit not significantly (respectively, 29 vs 12% and 53 vs 35%). Regarding associated diseases, neoplasms tended to be 3 times more frequent in the MCV group (43 vs 12%, $p=0.07$) whereas the frequency of auto-immune disorders was similar in both groups (38% vs 50%, $p=0.5$). The use of systemic corticosteroids was more frequent in the MCV group (67 vs 31%, $p=0.03$), as well as exposure to immunosuppressives (47 vs 18%, $p=0.07$).

Conclusion: Cryofibrinogemnemia is associated with a more serious disease in cryoglobulinemic patients as they are associated with an increased use of corticosteroids and immunosuppressive drugs. Neoplasms should also be carefully searched in this group.

Long-Term Outcome of Monoclonal (type 1) Cryoglobulinemia. Antoine Néel[1], François Perrin[1], Olivier Decaux[2], Thomas Dejoie[1], Maxime Halliez[1], Béatrice Mahé[1], Thierry Lamy[2], Fadi Fakhouri[1], Patrick Jego[2], Christian Agard[1], Cécile Vigneau[2], Lucienne Guenet[2], Bernard Grosbois[2], Philippe Moreau[1] and Mohamed Hamidou[1]. [1]Nantes University Hospital, Nantes, France, [2]Rennes University Hospital, Rennes, France.

Background/Purpose: To investigate long-term outcome of symptomatic type 1 cryoglobulinemia and its determinants.

Methods: Retrospective analysis of a prospective cohort from 2 French university hospitals. Patients with type 1 cryoglobulinemia were identified using laboratory databases. Inclusion criterion was the presence of persistent symptoms of cryoglobulinemia.

Results: Among 227 screened patients, 36 were included. Skin or vasomotor symptoms were the most frequent features (75%). Nephropathy and neuropathy occurred in 30% and 47% of cases, respectively. The underlying B cell lymphoproliferative disorder (LPD) was a gammopathy of unknown significance (MGUS) in 13 (36%) and a hematologic malignancy (HM) in 23 (64%; Waldenstrom macroglobulinemia (WM) in 12, low grade non-Hodgkin lymphoma (NHL) in 6, multiple myeloma (MM) in 4, and chronic lymphocytic leukemia (CLL) in 1). Severe manifestations affected half the patients and were more frequent with IgG cryoglobulins (82 vs 30% ($p=0,006$)). At last follow-up, 64% of patients had suffered no hematologic manifestation. Potent chemotherapeutic regimens were mainly used in HM. For patients with MGUS, WM or NHL, fludarabine or rituximab-based regimens appeared to yield better therapeutic responses. Five-year actuarial survival rate was 82 %. Older age and hemoglobin level < 12g/dL at diagnosis correlated with a poorer survival ($p<0.05$, Log-rank test). Nephropathy, infections, Richter's transformation and second malignancies were important sources of morbi-mortality.

Conclusion: Despite its limitations, this series provide novel information regarding type 1 cryoglobulinemia. Further studies are needed to improve its management. To date, therapeutic strategy should be tailored according to patient's characteristics (age, comorbidities, underlying LPD), and therapeutic target.

VERY LONG-TERM Effects Of The "4 PLUS2 Infusion PROTOCOL" Of Rituximabalone In Patients With HCV-Associatedmixed Cryoglobulinemia With Diffusemembranoproliferative Glomerulonephritis, Severe Polyneuropathy and Necrotic Ulcersof Skin. Dario Roccatello[1], Savino Sciascia[1], Simone Baldovino[2] and Daniela Rossi[1]. [1]Centro di Immunopatologia e Documentazione su Malattie rare, Torino, Italy, [2]Centro di Ricerche di Immunologia Clinica ed Immunopatologia e Documentazione su Malattie Rare (CMID), Università di Torino, Torino, Italy.

Background/Purpose: Mixed cryoglobulinemia syndrome (MCs) is a systemic vasculitis characterized by multiple organ involvement due to the vascular deposition of IgMk/IgG cryoglobulins. B cells expansion usually triggered by HCV infection plays a central role in MCs.

Objectives: to evaluate the long term effects of B-cells depletion in MCs

Methods: Twenty seven patients, (mean age 60.2 [range 35–78] years, HCV infection in 96% of cases) with symptomatic type-II MCs with systemic manifestations, including renal involvement (diffuse membranoproliferative glomerulonephritis in 15 cases), peripheral neuropathy (26 cases) and large skin ulcers (9 case, in 7 necrotizing) were considered

eligible for Rituximab (RTX) therapy. RTX was administered at a dose of 375 mg/m2 on days 1, 8, 15 and 22. Two more doses were administered 1 and 2 months later. No other immunosuppressive drugs were added. Response was evaluated by assessing the changes in clinical signs, symptoms, laboratory parameters and electromyographic indices for a very long term follow-up (mean 54.3 months [12–96])

Results: Complete remission of pre-treatment active manifestations was observed in all the cases of skin purpuric lesions and non-healing vasculitic leg ulcers, and in 80% of cases of peripheral neuropathy. A significant improvement in the clinical neuropathy disability score was observed. Electromyography revealed that the amplitude of compound motor action potential had increased. Cryoglobulinemic glomerulonephritis, observed in 15 patients, significantly improved during the follow-up starting from the second month after RTX (serum creatinine from 2.2±1.9SD to 1.6±1.2SD mg/dl, p≤.05; 24-hour proteinuria from 2.3±2.1SD to 0.9±1.9SD g/24h, p≤.05). Significant improvement of serological hallmarks, such as cryocrit and low complement C4, were also detected (p≤.05). The safety of RTX was confirmed by the absence of side effects recorded during the mean 54-month follow-up. Re-induction was performed in 9 relapsed cases (after a mean of 31.1 months, range 12–54) with resolutive beneficial effects.

Conclusion: In this open prospective study, the "4 plus 2 infusion protocol" of RTX appeared to be very effective and safe in the treatment of patients with MCs-associated membranoproliferative nephritis, polyneuropathy and severe skin involvement

Earlier Admission To Specialized Care, Intensified Treatment and Improved Outcome In Patients With Autoimmune Connective Tissue Disorders and Vasculitides In Germany 2011 Compared To 1995. Dörte Huscher[1], Katinka Albrecht[2], Katja Thiele[2], Sascha Bischoff[2], Jutta G. Richter[3], Ina Kötter[4], Wolfgang Ochs[5] and Angela Zink[6]. [1]Charité University Hospital and German Rheumatism Research Centre, a Leibniz Institute, Berlin, Germany, [2]German Rheumatism Research Centre, Berlin, Germany, [3]Heinrich-Heine-University, Duesseldorf, Germany, [4]ZIRS, Centre for Interdisciplinary Rheumatology Stuttgart, Stuttgart, Germany, [5]Rheumatology Practice Bayreuth, Bayreuth, Germany, [6]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany.

Background/Purpose: Compared to rheumatoid arthritis and other arthritis-associated rheumatic diseases, autoimmune connective tissue disorders and vasculitides are still in the early stages of biological therapies. The study investigated whether health care and treatment with disease specific immunosuppressive drugs have changed in these indications. Furthermore, disease activity and outcomes of patients with autoimmune connective tissue diseases and vasculitides have been examined.

Methods: On average, a total of 3,900 patients with systemic lupus erythematodes (SLE), systemic sclerosis (SSc), primary Sjögren's syndrome (PSS), poly- and dermatomyositis (PM/DM), mixed connective tissue disease (MCTD), other connective tissue diseases (other CTD), polymyalgia rheumatica (PMR), primary systemic vasculitis, and other primary vasculitides (ICD10: I67.7, I77.6, L13.1, L95.0/8/9, M31.0/1/8/9, M35.2/6) were documented in the National Database of the German Collaborative Arthritis Centers in each of the years 1995 to 2011. Cross-sectional data of these years were analyzed to detect time trends.

Results: Between 1995 and 2011, the number of patients consulting a rheumatologist within six months after symptom onset increased from about 50% to 60%, especially patients with SLE and systemic sclerosis were seen earlier in specialized rheumatologic care. The overall percentage of patients receiving immunosuppressive drugs increased from 52.7% to 62.3%. High dose steroid use (>7.5 mg/d) decreased from 26.1% to 13.4%. In 2011, 3.5% of all patients received a biologic therapy, the most frequent use was seen in patients with other primary vasculitides (9.2%). Since 2005, the mean disease activity assessed by the physician (NRS 0–10) decreased from 3.0 to 2.2 and the percentage of patients with a high disease activity (7–10) from 7.6% to 1.8%. Overall, work participation (patients <65 years) remained stable (46.2% 1995, 49.4% 2011), but increased considerably in female patients with PSS, SSc and PMR (see Table 1).

	N		Mean age		Female		Immunosuppressive therapy		Mean disease activity (NRS 0–10)		Work participation (only patients <65 years)# female		male	
	1995	2011	1995	2011	1995	2011	1995	2011	1995	2011	1995	2011	1995	2011
SLE	1,432	946	43.1	46.3	89%	89%	69.6%	81.4%	3.0	2.2	45.6%	46.4%	55.3%	52.4%
SSc	317	317	55.7	57.5	86%	84%	42.9%	48.5%	3.8	3.1	36.5%	44.0%	–	–
PSS	320	200	53.1	57.9	93%	94%	43.7%	51.0%	3.2	2.5	44.2%	64.8%	–	–
DM/PM	143	94	50.7	54.9	76%	65%	65.9%	86.0%	3.1	2.4	43.2%	(41.7%)	–	–
MCTD/ overlap	329	165	47.4	50.0	89%	90%	68.8%	71.7%	3.4	2.4	47.0%	47.5%	–	–
other CTD	343	261	48.1	53.5	85%	86%	52.5%	54.5%	2.6	2.2	50.5%	63.0%	–	–
PMR	862	855	68.7	71.4	77%	67%	15.2%	28.6%	3.1	1.7	25.8%	40.0%	59.6%	60.0%
primary systemic vasculitis	292	435	50.6	60.3	52%	61%	72.0%	78.5%	3.1	2.3	31.1%	29.0%	63.0%	52.9%
other primary vasculitides	202	256	47.0	45.9	64%	45%	46.0%	57.6%	3.3	2.5	41.9%	(50.0%)	69.2%	(76.1%)

#For case numbers <50, percentages are given in brackets, for male patients with SSc, PSS, DM/PM, MCTD and other CTD case numbers were to low in both years for valid comparison.

Conclusion: Early rheumatologic care and immunosuppressive therapy have increased in patients with autoimmune connective tissue diseases and vasculitides during the past 15 years. Advancement in disease control and employment status in these rather infrequent chronic autoimmune diseases encourages to further improve disease outcomes and work participation.

Background/Purpose: Polyarteritis nodosa (PAN) is a systemic necrotizing vasculitis. Disease pathogenesis and possible genetic factors are poorly understood. We identified familial, mostly pediatric PAN, in twenty patients from six families, five of Georgian Jewish and one of German origin. Disease segregation was consistent with autosomal recessive inheritance.

Methods: Clinical data was collected from eight medical centers in Israel, Germany and Turkey. Exome sequencing was performed in six patients with familial PAN, four Georgian Jewish and two Germans. Targeted sequencing was done in another thirteen patients with familial PAN and in seventeen single cases: three of Gerogian Jewish and fourteen of Turkish origin. Mutations were assessed by impact on enzymatic activity in patient sera, analysis of protein structure, expression in mammalian cells, and biophysical analysis of purified protein.

Results: In most patients, disease onset was in early childhood and was most severe in those with onset in infancy. Skin manifestations almost universal: livedo reticularis, nodules, recalcitrant leg ulcers and acral necrosis. Raynaud's phenomenon, myalgia, arthralgia or arthritis were also common. Systemic involvement included gastrointestinal disease with significant weight loss and intestinal perforation, testicular pain, coronary and renal vasculitis with severe hypertension, peripheral neuropathy and brain strokes. Angiography demonstrated mesenteric, celiac, hepatic, or renal aneurysms, and infarcts in the renal cortex. There was a dramatically beneficial response to anti-TNF alpha blockade; life-saving in some cyclophosphamide refractory patients. All patients had recessive mutations in an immune-related gene, to be named at the meeting. Mutations in this gene have not been previously associated with any human phenotype. All Georgian Jewish cases were homozygous for this mutation, with variable phenotype; The German and the Turkish patients

were compound heterozygous for mutations in the same gene. In the endogamous Georgian Jewish population, the allele frequency was 0.05, reflecting high PAN prevalence. The other mutations were private or extremely rare. The missense mutations led to significantly reduced protein activity and secretion both in patient sera and in vitro. Protein activity was significantly reduced in patient sera.

Conclusion: Recessive loss-of-function mutations in an immune-related gene lead to PAN. Both population genetics and functional approaches were applied to demonstrate the causality of the founder allele. The mutations identified suggest blood vessels may be particularly vulnerable to impairment of the protein's catalytic, immune, and growth factor activities. A single-gene defect underlying a systemic vasculitis may provide new insights on disease pathogenesis and possibly help to develop new targeted therapy for PAN and other vasculitides.

Midkine Is a Novel Prognostic Factor In Patients With Vasculitis Syndrome. Yoshie Kusunoki[1], Yutaka Okano[1], Natsuko Kusunoki[2], Natsuki Fujio[2], Mai Kawazoe[2], Emiko Shindo[2], Kotaro Shikano[2], Makoto Kaburaki[2], Sei Muraoka[2], Kanako Kitahara[2], Kaichi Kaneko[2], Nahoko Tanaka[2], Tatsuhiro Yamamoto[2], Kenji Takagi[2], Tomoko Hasunuma[2], Hirahito Endo[2] and Shinichi Kawai[2]. [1]Kawasaki Municipal Kawasaki Hospital, Kanagawa, Japan, [2]School of Medicine, Faculty of Medicine, Toho University, Tokyo, Japan.

Background/Purpose: Midkine (MK) is a heparin-binding growth factor, promotes growth, survival, and migration of various cells. Recently several reports show that MK may also play an important role in chronic inflammatory disorders including, kidney diseases, hypoxia-induced angiogenesis and rheumatoid arthritis. To evaluate the role of MK in vasculitis syndrome, we measured the serum level of MK in patients with vasculitis and detected the expression of MK in vasculitis tissues.

Methods: Thirty-two patients with active vasculitis syndrome (17 microscopic polyangiitis; MPA, 3 granulomatosis with polyangiits; GPA, 3 eosinophilic granulomatosis with polyangitis; EGPA, 4 giant cell arteritis; GCA, 3 Takayasu arteritis; TA and 2 polyarteritis nodosa; PAN) before treatment, and 10 healthy subjects as control were included in this study. Serum level of MK was measured by enzyme-linked immunosorbent assay (ELISA). Expression of MK was detected by immunohistchemical methods in several biopsy tissues of patients with vasculitis syndrome.

Results: Serum levels of MK in patients with vasculitis syndrome were significantly higher than that of healthy control (Vasculitis syndrome, 2014 (mean)±1839 (S.D.) pg/ml; Control 284 ± 57 pg/ml, (P <0.01). Mean age of vasculitis patients was 65.6±17.4, and disease duration was 2.2±1.6 months. Mean disease activity of these patients expressed by vsculitis activity score (BVAS) was 16.5±9.1 and mean vasculitis damage index (VDI) of these patients was 1.8±1.3. Both of BVAS and VDI of patients with vasculitis syndrome were not correlated with serum MK levels. Serum levels of MK in these patients with were; MPA:3615±4080,GPA: 960±23, EGPA: 989±698, GCA: 1080±997,TA:495±272, and PAN:507±102pg/ml. Levels of serum MK in patients with poor prognosis were significantly higher than that of patients with good prognosis (dead: 4608.0±4406.1pg/ml, survival: 1891.9±2933.4pg/ml, Mann-Whitney U test p<0.05). Optimal cut off value of serum MK as indicator of prognosis was 1797 pg/ml in patients with vasculitis syndrome using receiver operating characteristic curve analysis (high MK group n=22, low MK group n=10). Life table analysis of these patients by Kaplan-Meier method revealed that survival rate of high MK group was significantly shorter than that of low MK group (log-rank test P <0.05). All dead patients were complicated with pulmonary involvements. MK was detected in renal tubular epithelial cells, mesangial cells, but not in inflammatory cells and vascular cells in renal tissues of vasculitis patients. MK also highly expressed in dermal epithelial cells of vasculitis skin biopsy specimens.

Conclusion: It is suggested that MK might play an important role in pathogenesis of vasculitis syndrome. Since increased serum MK level was associated with poor prognosis, it might also be a novel prognostic factor of vasculitis syndrome.

Phase IB/Iia Study On Intravenous Administration Of Expanded Allogeneic Adipose-Derived Mesenchymal Stem Cells In Refractory Rheumatoid Arthritis Patients. JM Alvaro-Gracia[1], Juan A. Jover[2], Rosario Garcia-Vicuña[1], Luis Carreño[3], Alberto Alonso[4], Sara Marsal[5], Francisco J. Blanco[6], Víctor M. Martínez-Taboada[7], Peter C. Taylor[8], Federico Díaz-González[9] and Lydia Dorrego[10]. [1]Hospital Universitario de La Princesa, Madrid, Spain, [2]Hospital Clínico San Carlos, Madrid, Spain, [3]Gregorio Marañón Hospital, Madrid, Spain, [4]Hospital de Cruces, Bilbao, Spain, [5]Vall d'Hebron Hospital Research Institute, Barcelona, Spain, [6]INIBIC-Hospital Universitario A Coruña. Rheumatology Division. Genomic Group, A Coruña, Spain, [7]Hospital Universitario Marqués de Valdecilla. IFIMAV., Santander, Spain, [8]University of Oxford, Oxford, United Kingdom, [9]University of La Laguna, Hospital Universitario de Canarias, La Laguna, Spain, [10]TiGenix, Tres Cantos, Spain.

Background/Purpose: Expanded adipose-derived stem cells (eASCs) are shown to have immune-modulatory effects both *in vitro* and in animal models of arthritis. eASCs are currently under investigation as potential treatments targeting auto-immune and inflammatory diseases such as Rheumatoid Arthritis (RA). The aim of the study was to determine the safety, feasibility and tolerance of intravenous (IV) administration of allogeneic eASCs in RA patients.

Methods: A 24-week, single blind dose-escalating study in RA patients under treatment with at least one non-biological DMARD and who previously failed treatment with at least two biologicals was conducted in 23 centers in Spain. Fifty-three patients with moderate to high disease activity (DAS28>3.2) were assigned to receive 1×10^6 eASCs/kg (cohort A: 20 patients), 2×10^6 eASCs/kg (cohort B: 20 patients), 4×10^6 eASCs/kg (cohort C: 6 patients) or placebo (Ringer's lactate solution: 7 patients). All patients received 3 IV eASC infusions at day 1, 8 and 15. Tolerability and treatment emergent adverse events such as Dose Limiting Toxicities (DLTs), serious adverse events (SAEs) and non-serious adverse events (AEs) were primary endpoints. ACR20/50/70, DAS 28, and SF-36 were secondary endpoints.

Results: Patient and disease characteristics were comparable for all three dose groups. Median disease duration was 13 years Repeated IV infusion of eASCs did not show any major safety signals and the dose-limiting safety signal was not identified Three serious adverse events were reported (lacunar infarction, peroneal palsy and fever of unknown origin) of which, lacunar infarction was possibly related and lead to discontinuation with patient recovery. Most frequent non-serious AEs (threshold: > 4%) in patients treated with eASCs, included pyrexia (19%), headache (13%), urinary tract infection (13%), upper respiratory tract infection (11%), nausea (11%), malaise, respiratory tract infection, vomiting and asthenia (6% each).

In secondary endpoints, a clear dose-response effect was not observed. Maximum clinical benefit in the ITT population was observed in cohort A. ACR20/50/70 responses were observed in 45/20/5% of patients in cohort A versus 28/14/5% of patients on placebo at month 1. At month 3, ACR responses were 25/15/5 and 0/0/0 in cohort A and placebo respectively. The DAS 28 good/moderate response was 10/35% in cohort A and 0/43% in the placebo group at month 1. These values were 20/20% and 0/0% at month 3 for cohort A and placebo respectively.

Conclusion: These early clinical results are the first to suggest that IV infusion of eASCs is well tolerated along 24 weeks and could be associated with clinical benefit in the treatment of refractory RA.

Pathological Roles Of The Anti-Oxidative Enzyme Peroxiredoxin 2 In Patients With Kawasaki Disease. Rie Karasawa[1], Toshiko Sato[1], Mayumi Tamaki[1], Mikiya Fujieda[2], Kazuhide Ohta[3] and Kazuo Yudoh[4]. [1]Institute of Medical Science, St. Marianna University School of Medicine, Kawasaki, Japan, [2]Department of Pediatrics, Kochi Medical School, Nankoku, Japan, [3]Department of Pediatrics, Kanazawa Medical Center, Kanazawa, Japan, [4]St. Marianna University School of Medicine, Kanagawa, Japan.

Background/Purpose: Anti-endothelial cell antibodies (AECA) are autoantibodies that are detected frequently in vasculitis caused by, for example, Kawasaki disease (KD)**.** However, AECA target molecules have been poorly identified, which hampers our understanding of the roles of AECA. We aimed to detect target proteins of AECA comprehensively by proteomics and investigate their clinical importance in patients with KD.

Methods: We separated proteins extracted from human umbilical vein endothelial cells (HUVECs) and HeLa cells by 2-dimensional electrophoresis and transferred them onto membranes. Antigens that were positive only in the HUVEC samples but not in the HeLa cell samples were detected by western blot, using serum samples from patients with vasculitis. Next, we identified the detected proteins by peptide mass finger-printing and characterized their antigenicity by preparing recombinant antigens and antibodies to them. Furthermore, we investigated the frequency, clinical significance, and pathological roles of AECA against individual identified target autoantigens.

Results: We identified 63 proteins, one of which was peroxiredoxin 2 (Prx2), an anti-oxidative enzyme. Using immunocytochemistry, antibodies against Prx2 were found to bind to the cell surface of live HUVECs. IgG antibodies to Prx2 were detected in 60% (18/30) of the patients with KD, but not in healthy controls. Furthermore, IgG antibodies to Prx2 were detected in all tested KD patients with coronary artery lesions. Stimulating endothelial cells (ECs) with anti-Prx2 antibodies resulted in increased H_2O_2levels in the cell lysates. The anti-Prx2 antibodies also increased various inflammatory cytokine secretions significantly; in particular, IL-6 in HUVECs and G-CSF in human coronary artery ECs. In addition, anti-Prx2 antibodies induced the increased expression of adhesion molecules, such as E-selectin and ICAM-1, on ECs. EC ELISA indicated that Prx2 proteins were released from ECs stimulated by inflammatory cytokines. By themselves, Prx2 proteins induced various inflammatory cytokine secretions, such as IL-6, IL-8, TNF-α and GM-CSF, from ECs, and the expression of adhesion molecules such as E-selectin and ICAM-1 on ECs. Interestingly, these effects of Prx2 proteins were enhanced significantly by the appearance of anti-Prx2 antibodies and were inhibited significantly by blocking Toll-like receptor 4 (TLR4) signaling with a TLR4-specific inhibitory peptide. Clinically, the duration of fever (>37.5°C) in KD patients was significantly longer in the anti-Prx2–positive group than in the anti-Prx2–negative group. There was no significant difference in inflammatory markers such as white blood cell counts and C-reactive protein between both groups.

Conclusion: IgG antibodies to Prx2 are expected to be useful markers for KD. Expression of endothelial adhesion molecules and inflammatory cytokine production are induced by the binding of anti-Prx2 antibodies to Prx2 proteins on ECs, and by the activation of TLR4 by extracellular Prx2 proteins, which could result in endothelial injury. Furthermore, anti-Prx2 antibodies may cause endothelial injury by inhibiting the anti-oxidative activity of intracellular Prx2 proteins.

Cost-Effectiveness Analysis Of Triple Therapy Versus Etanercept Plus Methotrexate In Early Aggressive Rheumatoid Arthritis: Analysis Based On The TEAR Trial. Hawre Jalal[1], Jeffrey R. Curtis[2], Stacey Cofield[2], Larry W. Moreland[3], James R. O'Dell[4] and Kaleb Michaud[5]. [1]University of Minnesota, Minneapolis, MN, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Pittsburgh, Pittsburgh, PA, [4]Omaha VA and the University of Nebraska Medical Center, Omaha, NE, [5]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: The long-term cost-effectiveness of triple therapy (methotrexate [MTX], sulfasalazine [SSZ], hydroxychloroquine [HCQ]) disease modifying anti-rheumatic drugs (DMARDs) compared to a combination of MTX and anti-TNF therapy in patients with early rheumatoid arthritis (RA) is unknown. In this study, we used patient-level data from the Treatment of Early Aggressive RA (TEAR) trial and the National Data Bank for Rheumatic Diseases (NDB) to evaluate the cost-effectiveness of immediate combination therapy (with biologic or non-biologic DMARDs) versus stepping up to combination therapy at 6 months if disease activity persists despite MTX monotherapy.

Methods: We developed a Markov simulation model to estimate quality-adjusted life years (QALYs) and costs associated with the treatment strategies examined in the TEAR trial. We evaluated four strategies: immediate triple (IT), immediate etanercept (IE), step-up triple (ST), and step-up etanercept (SE). The step-up strategies involved switching those with persistent disease activity (DAS28 >= 3.2) from MTX monotherapy to MTX plus either etanercept or triple therapy at 6 months. The simulation model extends the 2-year trial to the life-time horizon, using parameters taken from longitudinal NDB data for therapy discontinuation rates, HAQ transitions, and DAS28-HAQ-QALY mappings as well as the published literature for direct and indirect cost estimates. Annual discontinuation rates of triple therapy and etanercept from the NDB were estimated to be 22% and 10%, respectively. Those who discontinued were assumed to continue to receive methotrexate. Markov health states were defined by DAS28. DAS28 score transitions were obtained directly from individual patients in the trial. Death was modeled as an additional state with background mortality estimated from the 2007 US Life Tables. HAQ scores were used as a secondary variable to estimate QALYs, RA-specific mortality, and direct and indirect costs (e.g., due to productivity loss). We assumed a 3-month cycle length, and discounted both costs and effectiveness by 3% annually.

Results: The etanercept strategies (SE and IE) were more costly than the triple strategies (ST and IT) mainly due to treatment costs [Table]. The lifetime benefits from IT, ST and SE were numerically similar (within 0.06 QALYs). Although IE was more effective than IT, the incremental cost-effectiveness ratio (ICER) of IE relative to IT was $837,100/QALY. These results were robust to parametric sensitivity analyses.

Table. Cost-Effectiveness Analysis of TEAR Strategies

Treatment Strategies	Cost ($)	Effectiveness (QALY)	Incremental Cost ($)*	Incremental Effectiveness (QALY)*	ICER ($/QALY)
Immediate Triple (IT)	152,400	9.991			Reference Strategy
Step-up Triple (ST)	154,900	9.928	2500	−0.063	Excluded (dominated by IT, more effective)
Step-up Etanercept (SE)	269,500	9.929	117,100	−0.062	Excluded (dominated by IT, more effective)
Immediate Etanercept (IE)	338,100	10.213	185,700	0.222	837,100

* Compared to IT

Conclusion: We used patient-level data from the TEAR trial, and then projected their lifetime costs and benefits using the NDB. The benefits from all strategies were comparable, but biologics strategies were almost twice more expensive than triple strategies, producing ICERs greater than what most healthcare settings find acceptable.

Recombinant Monoclonal Antibodies Derived From Single CD19+ Synovial B Cells Of RA Patients With Tertiary Lymphoid Structures Display a Strong Immunoreactivity Towards Citrullinated Histones. Elisa Corsiero[1], Michele Bombardieri[1], Emanuela Carlotti[1], Hedda Wardemann[2], William H. Robinson[3] and Costantino Pitzalis[1]. [1]William Harvey Research Institute, QMUL, London, United Kingdom, [2]Max Planck Institute for Infection Biology, Berlin, Germany, [3]Stanford University School of Medicine, Stanford, CA.

Background/Purpose: Rheumatoid arthritis (RA) is characterised by breach of self-tolerance towards citrullinated proteins. Around 40% of patients display synovial tertiary lymphoid structures (TLS) with functional B cell follicles supporting a germinal-centre response and local autoantibody production (1). However, the nature of the main (auto)antigenic reactivity of synovial B cells is unknown. Here we characterized the autoreactive B cell response of lesional B cells isolated from TLS+ RA synovium.

Methods: Single CD19+ B cells were FACS sorted from synovial cell suspension of 4 TLS+ RA patients. RNA was used to amplify Ig VH and VL genes and PCR products were cloned and expressed as recombinant monoclonal antibodies displaying identical specificity of the original B cells (2). Recombinant antibodies were then tested 1) to determine the frequency of polyreactive clones and 2) to define their immunoreactivity towards native and citrullinated antigens using a synovial antigen microarray platform (3).

Results: We obtained 139 individual VH sequences of which 33% were IgM, 40% IgG, 27% IgA and 175 VL sequences and we generated a total of 66 complete (H+L chains) recombinant monoclonal antibodies. Analysis of the VH gene somatic mutation rate showed evidence of antigen selection and intra-synovial clonal diversification. No skewed distribution of the VH and VL gene usage was observed. Around 30% of synovial monoclonal antibodies were reactive towards citrullinated histones in the antigen microarray, in particular citH2A and citH2B. This reactivity was confirmed by citH2A and citH2B ELISA. Moreover, reactivity towards the citrullinated form of fibrinogen was observed.

Conclusion: Here we provided novel evidence that highly mutated, locally differentiated B cells within RA synovial germinal centre-like structures display a strong immunoreactive bias towards citrullinated histones. This suggests that citrullinated histones are the main antigens driving in situ B cell activation and differentiation sustaining the humoral autoimmune response within the RA joints.
