Physician Proclivity To Use Oral Glucocorticoids Among Rheumatoid Arthritis Patients. Huifeng Yun[1], Fenglong Xie[1], Elizabeth S. Delzell[1], Lang Chen[1], Emily Levitan[1], James Lewis[2], Kenneth G. Saag[1], Timothy Beukelman[1], Kevin L. Winthrop[3], John Baddley[1] and Jeffrey R. Curtis[4]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Pennsylvania, Philadelphia, PA, [3]Oregon Health & Science University, Portland, OR, [4]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL.

Background/Purpose: It is unclear if the elevated risks of adverse events in rheumatoid arthritis (RA) patients are due to use of biologics or DMARDs, glucocorticoids (GCs), or features associated with the disease itself. The selection of RA medications is potentially confounded due to disease severity (i.e. channeling). Physician proclivities to use specific medications have been shown in prior analyses to be partially independent of patient factors and may reduce confounding in observational analyses. Therefore, we evaluated variability in physicians' proclivity to use oral GCs among older RA patients.

Methods: Using 2009 Medicare data, we identified patients who had at least two RA diagnosis codes from rheumatologists. We classified patients as oral GC users if they had at least one prescription for >= 30 days' supply. Rheumatologists were identified in the data using NPI numbers.

We calculated proclivity to use GCs for each rheumatologist as a proportion, computed as the number of their RA patients who used GCs divided by total number of all their RA patients, and categorized each rheumatologist into one of 4 groups based on quartiles. For each rheumatologist, this proportion was plotted against the number of RA patients in their practice.

The analysis was repeated in the subgroup of patients who also used biologics in 2009. Physician variability in steroid use was examined based upon inter-quartile ranges of the proportion of their patients using GCs, as well as measures of central tendency (i.e. skewness and kurtosis). Weighted Kappa statistics evaluated whether assignment of physicians' steroid proclivity to quartiles was consistent between the main analysis and the subgroup analysis.

Results: We identified 313,108 RA patients (27,474 of whom used biologics) treated by 4,003 rheumatologists in 2009 Medicare data. Overall, 81,422 (26%) pts were oral GC users; 12,306 (44.8%) in the biologic subgroup used GCs.

The proportion of patients using oral GCs was plotted for each U.S. rheumatologist (Figure) and demonstrated substantial variability between physicians. After restricting to patients on biologics, there was greater

physician variability in use of GCS for their patients than in the main analysis (not shown). The weighted kappa statistic comparing physician's proclivity to use GCs using all their RA patients vs. proclivity to use GCs in the biologic-using subgroup was 0.32 (95% confidence limits: 0.30–0.35) indicating low to moderate agreement.

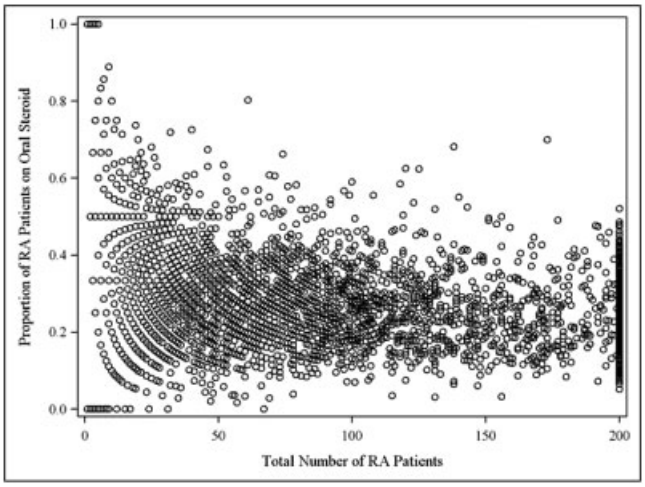

Figure. Proportion of rheumatologist's RA patients on glucocorticoids per practice in 2009

Conclusion: The frequency with which rheumatologists' prescribe oral GCs for RA patients was highly variable and was even greater for patients using biologics. Further work is ongoing to examine whether this approach might be effect to reduce unmeasured or residual confounding associated with glucocorticoid use.

Use Of Oral and Subcutaneous MTX In a Commercially Insured Rheumatoid Arthritis Population. Jeffrey R. Curtis[1], Fenglong Xie[1], Jie Zhang[1], Lang Chen[1], Huifeng Yun[1], Michael H. Schiff[2], Timothy Beukelman[1] and Seth Ginsberg[3]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Colorado, Denver, CO, [3]Creaky Joints, New York, NY.

Background/Purpose: Methotrexate (MTX) is the most commonly used medication in rheumatoid arthritis (RA), although use of oral and subcutaneous (SQ) preparations in real-world settings has not been well characterized.

Methods: Using national data from a large commercially insured population in the U.S. from 2005–2011, we identified RA patients (pts) on the basis of 2 RA diagnosis codes initiating oral MTX (no prior use ever, minimum of 6m clean period) who also had no prior use of hydroxychloroquine (HCQ), sulfasalazine (SSZ), leflunomide (LEF) or biologic use and had at least one year of follow-up available. Subsequent dose escalation of oral MTX or switch to SQ MTX, HCQ, SSZ, and LEF were characterized. Subsequent use and timing of addition of biologics was examined for those had at least one switch, adjusting for multiple potential confounders using Cox proportional hazards models with switch date as time zero.

Results: New oral MTX users (n=4,048) were 74.2% women, had mean +-SD age of 51.1+−11.9 years and contributed a median (IQR) follow-up of 2.4 (1.6, 3.6) years; 28.1% never changed dose of oral MTX and remained at their starting dose; common doses included 10.0 mg/week (24.9%) and 15.0mg/week (26.3%). Of all patients, only 48.2% used oral MTX at >= 20mg/week at any time. Overall, 73.8% stayed on oral MTX (with or without dose increase) and did not add or switch to HCQ, SSZ, LEF, or SQ MTX. The remainder switched or added HCQ (14.0%), SSZ (6.2%), LEF (9.5%) or switched to SQ MTX (2.9%). The median (IQR) dose of oral MTX prior to switch to SQ was 15.0 (15.0, 20.0) mg/week and occurred at a median (IQR) of 322 (146,527) days.

Overall, 35.3% of the cohort subsequently initiated a biologic, mostly (90.3%) anti-TNF therapy. Of these individuals, 46.0% never used MTX at a dose of >= 20mg; 21.9% never used MTX at a dose of >= 15mg. Among pts who used biologics after switch to SQ MTX, the median (IQR) interval of time between switching to SQ MTX and initiation of a biologic was 113 (65, 233) days. Among patients who increased dose or switched to SQ MTX or other nbDMARDs, (n=2,685) and after multivariable adjustment, there were no significant differences in subsequent biologic initiation between patients who switched to SQ MTX vs. added or switched to SSZ, LEF or HCQ.

Conclusion: Titration to higher doses of oral MTX and use of SQ MTX preparations among RA patients is uncommon, even for patients who subsequently used biologics. Further work to optimize MTX in RA is warranted.

Discontinuation Rates In Patients With RA Of Triple Disease Modifying Antirheumatic Therapy. Sofia Pedro[1], Frederick Wolfe[1], Hawre Jalal[2] and Kaleb Michaud[3]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]University of Minnesota, Minneapolis, MN, [3]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: Drug discontinuation rates are measures of effectiveness and are needed in health economic models. While a recent RCT demonstrated statistical equivalence of efficacy with etanercept [1], little is known regarding the real-world use and discontinuation rates of triple therapy, which includes methotrexate (MTX), sulfasalazine (SSZ) and hydroxychloroquine (HCQ).

Methods: We evaluated the treatment discontinuation rates of triple therapy in rheumatoid arthritis using a large observational cohort, the National Data Bank for Rheumatic diseases. We initially defined discontinuation as when all 3 DMARDs (MTX, SSZ & HCQ) were not taken (First). Since we cannot verify if triple therapy was purposely prescribed, our second discontinuation definition occurred when the patient was no longer on any combination of the 3 DMARDs or if they added a biologic (Second). In both cases missing data between periods on triple therapy were assumed to remain on treatment. Kaplan-Meier survivor functions were used to analyze discontinuation rates.

Results: From 10,156 patients on biologics and DMARDs, 388 (3.8%) initiated triple therapy at some point between 1998–2012. From these 304 (78.4%) discontinued triple therapy according to our first definition with 121 (39.8%) immediately switching to or adding another DMARD while 183 (60.2%) dropped one or two of the 3 drugs. A total of 216 (55.7%) discontinued according to our second definition. The discontinuation rate of triple therapy by our two definitions were 40.8% (First) and 23.5% (Second) per year (See Table). The median survival on triple therapy was 14 months (IQR 6–45 months), and doubled to 28 months (IQR: 10–112 months) when using the second definition. At 24 months, the discontinuation rates were: 39.1% (95% CI 33.9%–44.2%) and 53.4% (95% CI 48.2%–59.0%), for first and second definitions respectively. After triple therapy, patients tended to switch/add more DMARDs afterwards (59.3%) than biologics (41.2%).

[1] O'Dell JR et al. Therapies for Active Rheumatoid Arthritis after Methotrexate Failure. N Engl J Med. 2013

Table. Discontinuation rates and median survival for patients on triple therapy.

	Discontinuation Definitions	
	First-Strict	**Second-Relaxed**
Time at risk (patient years)	742.2	918.0
Discontinuation rate per year	0.408	0.235
Median survival (months)	14	28
Discontinuation rates (95% CI) after:		
1 year	0.501 (0.449, 0.551)	0.627 (0.621, 0.719)
2 years	0.391 (0.339, 0.442)	0.538 (0.482, 0.590)
3 years	0.291 (0.242, 0.343)	0.438 (0.381, 0.494)

Conclusion: This is the first study to provide discontinuation rates of triple therapy using community experience in the biologic era. Overall discontinuation rates were high and patients tended to switch between several combinations of MTX, SSZ, and HCQ. Future work is needed to identify rates of prescription and patient/physician preferences for triple therapy.

Adherence To Methotrexate Therapy Among Patients With Rheumatoid Arthritis In Denmark: A Registry Based Cohort Study. Henning Bliddal[1], Robin Christensen[1], Mikkel Østergaard[2], Tove Lorenzen[3], Michael Sejer Hansen[4], Peter Vestergaard[5] and Stine A Eriksen[5]. [1]The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark, Frederiksberg, Denmark, [2]Copenhagen University Hospital Glostrup, Copenhagen, Denmark, [3]Department of Rheumatology, Region Hospital Silkeborg, Silkeborg, Denmark, [4]Gildhøj Privathospital, Copenhagen, Denmark, [5]Aalborg University, Aalborg, Denmark.

Background/Purpose: Conflicting data have been presented on patient compliance with methotrexate (MTX) prescription. A Danish study found a mean period of 12.3% of the prescribed years in reality being non-covered by MTX[1], while recent data from Canada indicate that a rather large percentage of patients do not comply with the prescription of MTX[2]. The objective was to elucidate and quantify the use of MTX after a primary prescription for rheumatoid arthritis (RA).

Methods: The study was a register based cohort study including patients with a hospital diagnosis extracted from the National Hospital Discharge Register of RA (ICD10 codes M05.X, M06.X), diagnosed after January 1, 1998 and aged ≥18 years at the date of first diagnosis/contact. The register has a nationwide coverage, and an almost 100% capture of contacts[3]. Data was extracted of all patients registered as MTX users in the Pharmacies Register from 1996 onwards. Any drugs bought are registered with an ATC code, number and dosage of product, form of medication (tablets, injections etc.), and date of sale. Stability of MTX use was defined as regular MTX prescriptions of 100 tablets of 2.5 mg delivered from a pharmacy > 1 per year with cut-off of 6, 9, or 12 months respectively corresponding to an average weekly dose of minimum 10; 7.5; and 5 mg respectively.

These sources of information were linked through the Central Person Register Number which is a unique registration code given to every inhabitant–to some degree similar to the American social security number - that allows registration on an individual basis. The project was approved by the Danish National Data Protection Agency.

Results: The study population consisted of 5,368,354 inhabitants in Denmark, among whom 4,191,428 were ≥ 18 years during the study period. 39,286 had the diagnosis of ICD10: M05 or M06 after January 1st 1998 and n= 18,703 were found to have used a prescription of MTX, representing 47.6 per cent of all subjects diagnosed with RA at a hospital in the period 1998–2011. Of these subjects, 2,200 (12 %) only used a prescription on MTX once, Figure 1. The median adherence in days almost doubled from the estimated dose of 10 mg to 5 mg per week: 5 mg: 5433 days, 7.5 mg: 4002 days, 10 mg: 2768 days.

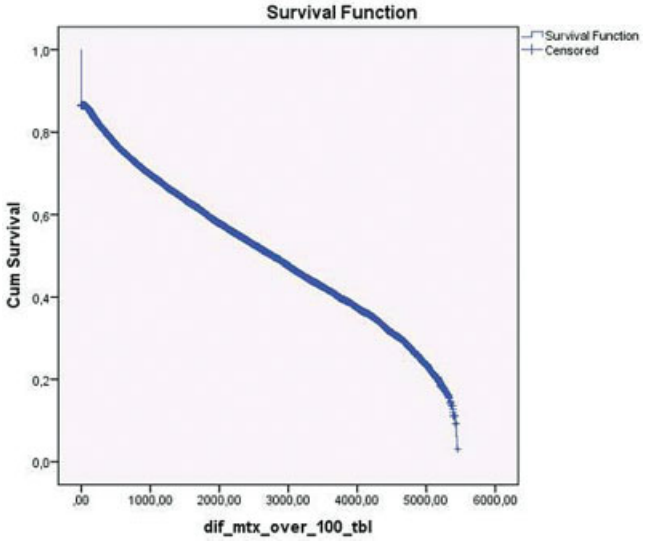

Figure 1. Kaplan-Meyer plot of the remaining subjects on MTX therapy the period 1998–2012. In this plot, the assumption was that the subject had a prescription of > 1 per year, i.e. a minimum average dose of ≥10 mg per week. The last part of the curve, i.e. > 5,000 days is dipping, presumably due to lack of sufficient follow-up time after the last prescription.

Conclusion: Adherence to MTX therapy was decreasing with increasing defined minimum doses 10; 7.5; and 5 mg weekly respectively. The median treatment time on these doses, however, was very long, e.g. 7.5 years on the 10 mg dose. Even so, the results indicate that patients taper their MTX over the years.

Regional Variations In Rheumatoid Arthritis Treatment and Health Outcomes Across The United States. Susan C. Bolge[1], Roxanne Meyer[2] and Kathy Annunziata[3]. [1]Janssen Scientific Affairs, LLC, Horsham, PA, [2]Janssen Scientific Affairs, LLC, Horsham, NY, [3]Kantar Health, Princeton, NJ.

Background/Purpose: Current ACR guidelines call for treatment of rheumatoid arthritis (RA) with non-biologic or biologic disease modifying anti-rheumatic drugs (DMARDs). The National Quality Forum has listed the prescribing of a DMARD as a specific measure of quality of care. This study seeks to evaluate regional variations in RA treatment and health outcomes.

Methods: Data were obtained from the 2012 U.S. National Health and Wellness Survey, a cross-sectional, self-administered, Internet-based survey of the general adult (aged 18+) population. Respondents reporting a diagnosis of RA (n=1088) were included in the analyses. Current treatments were obtained through a prompted list and categorized into a hierarchy: biologics; non-biologic DMARDs without biologics; other medication classes including steroids, opioids, and NSAIDS but without biologics or non-biologic DMARDs; untreated. Health outcomes included the SF-36v2, the Work Productivity and Activity Impairment (WPAI) questionnaire, and healthcare resource use in the previous six months.

Results: Variations in RA treatment are presented in the table. The Mountain region has the greatest use of biologic and non-biologic DMARDs (60%), as well as the greatest physical functioning (SF36v2 summary score 40.7), the least activity impairment (39%), and among the lowest proportion of ER (18%) and hospital use (11%). The East South Central region had the greatest proportion of patients who were untreated or undertreated with medications other than DMARDs (61%), while also having among the poorest mental and physical functioning (SF36v2 summary scores 43.3 and 38.0, respectively), the greatest activity impairment (52%), and the greatest proportion of ER (32%) and hospital use (22%).

Table. Current Treatment for RA within the U.S. Census Regions

	Biologics	Non-biologic DMARDs	Other Medication Classes	Untreated
New England (n=36)	28%	14%	39%	19%
Middle Atlantic (n=171)	33%	20%	25%	21%
East North Central (n=191)	25%	27%	29%	18%
West North Central (n=72)	21%	33%	28%	18%
South Atlantic (n=238)	28%	24%	29%	18%
East South Central (n=63)	11%	29%	37%	24%
West South Central (n=104)	38%	18%	25%	17%
Mountain (n=76)	34%	26%	17%	22%
Pacific (n=137)	39%	18%	25%	19%

Conclusion: These data suggest that there are regional variations in the care received by patients with RA in the U.S. as well as associated variations in patient outcomes. Initiatives to improve quality of care may benefit from a regional approach that considers these existing variations.

Concomitant Methotrexate Use and The Risk Of Drug Discontinuation For Adalimumab Compared With Etanercept In Anti-TNF-Naïve Rheumatoid Arthritis Patients: A Nationwide Population-Based Cohort Study. Hsin-Hua Chen[1], Der-Yuan Chen[2], Chao-Hsiung Tang[3], Ya-Wen Yang[4], Chi-Hui Fang[4] and Nicole Huang[1]. [1]National Yang-Ming University, Taipei, Taiwan, [2]Taichung Veterans General Hospital, Taichung, Taiwan, [3]Taipei Medical University, Taipei, Taiwan, [4]Pfizer Limited, Taipei, Taiwan.

Background/Purpose: To evaluate possible interaction effect by concomitant methotrexate (MTX) use on the risk of drug discontinuation for adalimumab (ADA) compared with etanercept (ETN) in anti-tumor necrosis factor (anti-TNF)-naïve patients with rheumatoid arthritis (RA).

Methods: This retrospective nationwide population-based cohort study identified 4592 anti-TNF-naïve RA patients (age at diagnosis ≥ 16 years) in whom ETN (n = 2,609) or ADA (n = 1,983) was initiated using administrative data. The outcome was the time to anti-TNF drug discontinuation. We defined drug discontinuation as non-persistence of prescription for more than 84 days. After adjusting for baseline characteristics and concomitant use of disease modifying anti-rheumatic drugs (DMARDs), the risk of drug discontinuation for ADA compared with that of ETN was quantified by calculating relative risk (RR) with 95% confidence intervals (CI) using Cox proportional hazard regression analysis for the follow-up time before and after one year. Subgroup analysis was conducted based on the average weekly dose of concomitant methotrexate use (i.e. not use, ≤10 mg, >10mg).

Results: During the first year of follow-up, 562 of 1,982 ADA users and 682 of 2,609 ETN users withdrew anti-TNF drugs after 1,507 and 2,094 person-years of follow-up respectively, and the incidence rates of drug withdrawal were 0.37 and 0.33 case per person-year. The crude and adjusted RRs of drug discontinuation for ADA compared with ETN were 1.16 (95% CI, 1.04–1.30) and 1.10 (95% CI, 0.98–1.23). The adjusted RR with 95% CIs for those with 0, ≤10mg/week and >10 mg/week concomitant MTX use were 0.83 (0.64–1.06), 0.91 (0.75–1.11) and 1.53 (1.28–1.82) respectively (p for interaction <0.001). If the follow-up time exceeded one year, 376 of 969 ADA users and 616 of 866 ETN users discontinued anti-TNF drugs after 1,012 and 1,846 person-years of follow-up respectively, and the incidence rates of drug discontinuation were 0.37 and 0.33 case per person-year. The crude and adjusted RRs of drug discontinuation for ADA compared with ETN were 1.07 (95% CI, 0.94–1.22) and 0.98 (95% CI, 0.86–1.12). The adjusted RRs with 95% CIs for those with 0, ≤10mg/week and >10 mg/week concomitant MTX use were 0.85 (0.68–1.06), 0.93 (0.77–1.15) and 1.42 (1.06–1.90) respectively (p for interaction 0.026).

Table 1. The adjusted relative risks with 95% confidence intervals of drug discontinuation for ADA compared with ETN

Follow-up time	No MTX use	≤10 mg/week	10 mg/week	P value for interaction
Within 1 year	0.83 (0.64–1.06)	0.91 (0.75–1.11)	1.53 (1.28–1.82)	<0.001
After 1 year	0.85 (0.68–1.06)	0.93 (0.77–1.15)	1.42 (1.06–1.90)	0.026

Note: Cox proportional hazard regression analyses per conducted after adjusting for the variables with p values less than 0.2 in univariate comparisons between adalimumab and etanercept, including sex, age at anti-TNF initiation, RA duration, Charlson comorbidity index (≤1, >2) within one year before anti-TNF use, the use of MTX (not use, ≤10 mg/week, >10 mg/week), leflunomide, salazopyrin, non-steroid anti-inflammatory drugs within one year before and after anti-TNF use, and average daily prednisolone equivalent (≤5 mg, >5 mg) within one year before anti-TNF use.

Conclusion: Among anti-TNF naïve RA patients, compared with ETN users, ADA users had a significantly higher risk of drug discontinuation if the concomitant MTX dose was more than 10 mg/week.

Perinatal and Early Life Risk Factors For Systemic Lupus Erythematosus In a National Cohort Of Women. Christine G. Parks, Aimee D'Aloisio and Dale Sandler. NIH/NIEHS, Research Triangle Park, NC.

Background/Purpose: Growing evidence supports the role of perinatal and early life exposures in risk for chronic adult diseases. We examined perinatal and early life environmental risk factors for SLE in a national cohort of women ages 35–74 at enrollment in 2003–2009.

Methods: Questionnaire data were collected on maternal and perinatal factors and characteristics of longest childhood residence. Prevalent SLE cases (N=124; median age 54, interquartile range, IQR 47–60; diagnosis age 43, IQR 33–50) were identified based on self-reported diagnosis after age 17, and confirmed by current or past use of disease modifying anti-rheumatic drugs (DMARDs) for SLE. Non-cases were women who did not report SLE or discoid lupus (N=50,465; median age 55 years, IQR 50–61). Odds Ratios (OR) and 95% Confidence Intervals (CI) were estimated by logistic regression, adjusting for age and race/ethnicity.

Results: Most cases were non-Hispanic whites (69% vs. 84% non-cases), but cases were more likely to be African-American (19% vs. 9%; OR=2.4; 95%CI 1.5, 3.8) or Hispanic (9% vs. 5%; OR=2.2; 95%CI 1.2, 4.1). Low birth weight (<2500 grams) was associated with risk of SLE (vs. 3000-<3500 grams; OR=2.2, 95%CI 1.2, 3.9), with a significant inverse linear dose-effect for increasing birth weight based on data for 84 cases and 36,477 non-cases. Premature birth (>4 weeks vs. full-term) was also associated with SLE (OR=3.0; 95%CI 1.4, 6.5), but only 47 cases and 15,996 non-cases reported gestational age. An association of SLE with young maternal age (<18 vs. 18–34 years) was not significant after adjusting for race/ethnicity (OR=1.7; 95%CI 0.71, 3.2), and no associations were seen for prenatal smoking exposure (maternal or household), having been breastfed, birth order, or sibling number. SLE was associated with having a mother who worked on a farm during pregnancy (OR=1.7; 95%CI 1.1, 2.7). Considering longest childhood residence, SLE cases were more likely to have lived on a farm (OR= 1.6; 95%CI 1.0, 2.6) and reported pesticides were regularly (at least monthly) applied in and around the home (OR=2.3; 95%CI 1.3, 4.1). SLE was not associated with residential well water or childhood socioeconomic status (household education, income, food insecurity).

Conclusion: Our observed association of premature birth with DMARD-treated SLE is consistent with other studies, but could not be separated from the effect of low birth weight. Findings on maternal farm work, childhood farm residence and household pesticide application require confirmation, but are supported by previous evidence on adult farming and pesticide exposures associated with systemic autoimmune diseases, including SLE.

Perinatal Risk Factors For Systemic Lupus: A Register-Based Case-Control Study. Elizabeth V. Arkema[1] and Julia F. Simard[2]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Stanford University School of Medicine, Stanford, CA.

Background/Purpose: One's own fetal environment has been linked to future heart disease, breast cancer, and rheumatoid arthritis. Prior work showed that among older women in the US, high birthweight and preterm birth were associated with an increased risk of SLE. Risk factors were self-reported in relatively crude categories, and data were limited on other factors of interest and unavailable for younger individuals or males. In systemic sclerosis and lupus, some have investigated links between birth order and future disease. Therefore we used population-based registers to study the association between perinatal factors and lupus in the Swedish population born 1973 onwards.

Methods: Cases were identified in the National Patient Register with at least two visits with an SLE-specific discharge diagnosis (using ICD codes) and at least one SLE-discharge from a specialty department. General population controls were matched (5:1) on birth year, sex, and residential county when the case was first identified. Using the Medical Birth Register, we obtained data on the case's mother's health and age during pregnancy and characteristics of labor and delivery. Restricting our study population to singleton births yielded 774 cases and 3337 controls. Birthweight was reported in grams and categorized according to standard definitions. Preterm birth was defined using gestational age in weeks and categorized. Parity was included as a continuous variable and an indicator for first born. Odds ratios and 95% CIs were estimated using conditional logistic regression models. Analyses were conducted for the entire population and separately for males and females. In sensitivity analysis, birthweight and preterm status were redefined using similar definitions to previous studies.

Results: High birthweight was not a risk factor for SLE in this younger population. Results were generally similar by sex. Preterm birth (<37 weeks) was not significantly associated with future risk of SLE overall, nor when very preterm was considered separately. Recategorizing these variables as they had been analyzed in the Nurses' Health Studies did not appreciably change the results, nor did adjustment for maternal age, smoking in early pregnancy, and maternal BMI. Being first born was associated with 20%

lower odds of SLE- this was driven by the association in females (OR=0.77, 95% CI=(0.64, 0.94)). Similarly parity was associated with SLE (OR=1.12, 95% CI=(1.02, 1.23)).

Conclusion: Lower parity and being born first were associated with reduced odds of SLE. Unlike previous work, high birthweight did not appear to be a risk factor, however this may be consistent with birth cohort trends when we examined previous published works.

Clinical Phenotypes and Disease Burden Of Discoid Lupus Erythematosus In a Sample Of Systemic Lupus Erythematosus Patients In The Southeastern United States. Leslie Anne Cassidy, Gaobin Bao, Charmayne M. Dunlop-Thomas, S. Sam Lim and Cristina Drenkard. Emory University, Atlanta, GA.

Background/Purpose: The rash of discoid lupus erythematosus (DLE) has been reported in 10–25% of patients with systemic lupus erythematosus (SLE). Prior reports suggest that DLE may be protective against severe disease in SLE; however, most studies have consisted of convenience samples of predominantly White patients. Although the incidence and prevalence of SLE is 3–4 times higher among individuals of African descent, and recent findings suggest that Blacks are more susceptible to DLE than Whites, no study has yet been conducted with a representative sample of Black SLE patients. We examined the association of DLE with clinical manifestations and disease outcomes in a predominantly Black community-based cohort of SLE patients in the Southeastern United States.

Methods: Data was collected from the Wave 1 (2011–12) annual survey of Georgians Organized Against Lupus (GOAL). GOAL is a large prospective cohort of validated SLE patients primarily derived from the Georgia Lupus Registry (GLR), a population-based registry of lupus patients in Atlanta, Georgia. GOAL includes patients of the full sociodemographic spectrum and collects self-reported data on health status, disease activity, and organ damage. SLE was defined by the presence of at least 4 American College of Rheumatology (ACR) criteria, or 3 ACR criteria and a diagnosis of SLE by a rheumatologist. DLE was assessed by chart review according to dermatologist or rheumatologist clinical evaluation with or without biopsy confirmation. We examined the association of DLE with clinical features and disease status, calculating the OR and 95% CI adjusted for demographic variables and disease duration.

Results: Among 767 SLE patients, 196 (26%) had DLE. DLE was present in 168/597 (28%) Blacks *versus* 25/156 (16%) Whites (p=0.008), and 18/45 (40%) males *versus* 178/722 (25%) females (p=0.02). Mean educational attainment (years) was 13.7 (SD 2.8) and 14.4 (SD 2.9) in patients with and without DLE, respectively (p=0.004), and mean disease duration (years) was 15.5 (SD 10.4) and 12.6 (SD 8.1) in these two respective groups (p=0.0001).

Association of DLE with Clinical Manifestations and Disease Outcomes

	Discoid Rash

Antinuclear Antibody	178 (90.8)	512 (89.7)	1.20 (0.66–2.18)
Renal Involvement*	63 (32.1)	220 (38.5)	**0.68 (0.46–0.99)**
Disease Outcomes			
Health Status Excellent/Very Good (ref)	24 (12.6)	85 (15.5)	-
Good	61 (32.1)	187 (34.1)	1.05 (0.60–1.85)
Fair/Poor	105 (55.3)	277 (50.5)	1.14 (0.67–1.96)
Disease Activity Score (SLAQ) Mild (0–10) (ref)	45 (23.7)	158 (28.7)	-
Moderate (11–16)	43 (22.6)	122 (22.2)	1.26 (0.76–2.07)
Severe (17+)	102 (53.7)	270 (49.1)	1.29 (0.85–1.97)
Organ Damage Score (BILD) No Damage (ref)	36 (18.9)	162 (29.5)	-
Mild (1–2)	75 (39.5)	206 (37.5)	1.38 (0.87–2.21)
Severe (3+)	79 (41.6)	182 (33.1)	1.41 (0.87–2.28)

Values are depicted as number (%) of individuals unless otherwise specified. ^Adjusted for gender, race, education, age at diagnosis, and disease duration. +With the exception of renal involvement, clinical manifestations are defined according to the ACR Criteria for the Classification of SLE. *Defined as positive proteinuria or red blood cell casts, lupus nephritis stated by rheumatologist or nephrologist (with or without renal biopsy), or end stage renal disease (ESRD) secondary to lupus nephritis.

Conclusion: DLE occurred in 26% of SLE patients, suggesting a stronger association of discoid rash with systemic manifestations than formerly believed. Males and Blacks were primarily affected. Consistent with prior studies, we found an association of DLE with non-specific cutaneous manifestations in SLE patients. Notably, DLE appears to be protective of renal and neurological involvement. Our findings may reflect more accurately the true epidemiology of DLE in high-risk SLE populations given the demographic makeup of this community-based cohort. Despite differences in clinical phenotypes, disease outcomes were similar in patients with and without DLE. Over 50% of patients reported poor health, organ damage, or severe disease activity, regardless of the presence of DLE. Our data suggest that environmental factors play a major role in outcomes of high-risk SLE patients.

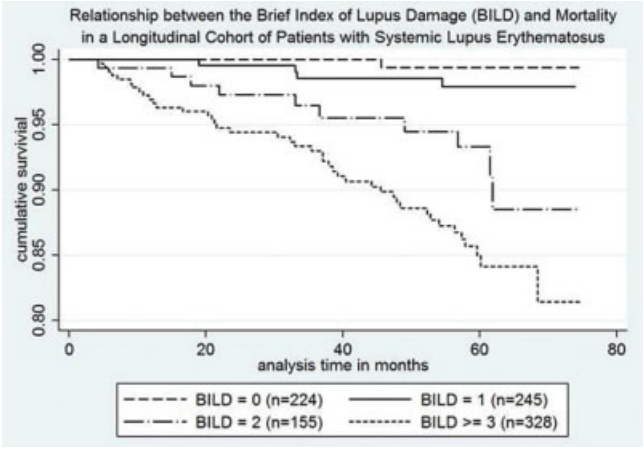
The Brief Index Of Lupus Damage As a Predictor Of Mortality In a Cohort Of Patients With Systemic Lupus Erythematosus. Stephanie Rush, Laura Trupin, Jinoos Yazdany and Patricia P. Katz. University of California, San Francisco, San Francisco, CA.

The Brief Index of Lupus Damage as a Predictor of Mortality in a Cohort of Patients with Systemic Lupus Erythematosus.

Background/Purpose: To examine whether a validated patient-reported measure of lupus damage, the Brief Index of Lupus Damage (BILD), is a predictor of mortality in a longitudinal cohort of patients with systemic lupus erythematosus (SLE).

Methods: Data were gathered from the UCSF Lupus Outcomes Study (LOS), an annual phone interview in which the BILD was administered beginning in 2007. We analyzed the initial BILD score for all participants. BILD scores were divided into 4 categories corresponding to 0, 1, 2, and ≥ 3 points (higher scores represent more damage). The number of deaths up to 75 months of follow-up was determined. Kaplan-Meier life table analysis was used to compare mortality rates by categories of the BILD. Using Cox proportional hazard models, multivariate analyses of possible predictors of mortality were performed. In addition to disease damage, predictors examined included a self-reported disease activity measure (Systemic Lupus Activity Questionnaire, SLAQ), non-white ethnicity, education beyond high school, gender, age, and disease duration.

Results: Among 952 subjects completing the BILD, the mean age was 49 years, 92% were female, 63% Caucasian, the mean disease duration was 16 years, and the median BILD score was 2 (range 0–13). During the follow-up period there were 57 deaths (6.0%). The mean follow-up time was 58 months (range 4–75). Kaplan-Meier analysis showed significantly higher mortality with increasing BILD scores (see figure). In Cox proportional hazards models adjusting for age, gender, disease duration, and SLAQ score, a BILD score of 2 (hazard ratio [HR]: 12.4; 95% confidence interval [CI]: 1.6–97.4), and a BILD score of ≥ 3 (HR: 21.4; 95% CI 2.9–159.2) were associated with higher risk of death over the follow-up period. Race, education, gender and SLE disease activity were not associated with increased mortality risk.



Conclusion: Independent of age, sex, race, disease duration and activity, a higher BILD score was a strong predictor of mortality in this cohort. Given the established relationship between SLE damage and mortality, the results

provide further validation of this patient-reported damage index and support its usefulness in clinical research.

1063

The Influence Of Socioeconomic and Race In Damage Score In Patients With Systemic Lupus Erythematosus. Roberto Teixeira[1], Eduardo F. Borba[2], Georges Christopoulos Sr.[3] and Emilia Sato[4]. [1]UNIVERSIDADE FEDERAL DE SÃO PAULO, SAO PAULO, Brazil, [2]Rheumatology Division; University of São Paulo, São Paulo, Brazil, [3]SANTA CASA DE MISERICORDIA DE MACEIO, MACEIO, Brazil, [4]Universidade Federal de São Paulo, São Paulo, Brazil.

Background/Purpose: The association between socioeconomic status and damage in Systemic lupus erythematosus patients is confounded by the influence of race in various previous studies. The objective of the study was to evaluate the association between socioeconomic status and Quality of life and damage in SLE patients.

Methods: SLE patients (ACR criteria), age ≥ 18 y.o. with at least 12 months of diagnosis were included. Socioeconomic status was evaluated by monthly income and years of formal education. The race was self-reported as white and nonwhite. The study was approved by Institutional Ethic Committee. Assessments were performed by questionnaire and review of medical charters; Mex-SLEDAI score; SF-36 and SLEQOL questionnaire. Statistical analysis: descriptive analysis, median, mean, t-student; Mann-Whitney, chi square, ROC curve to establish cut-off, Pearson and Spearman correlation test, univariate and multivariate regression test were used. $P<0.05$ was considered significant.

Results: 523 patients (96% female / 51.2% nonwhite) with mean age of 37,8±11,4 years were included. The mean years of study were 10.2±3.5. 63,7%; of patients did not work. The mean SLEDAI score was 1,82±2,83 and the per capita income was US$ 402.7± 610.95 and the family income was US$ 1,147.62 ± 1,713.40. Arthritis, photosensivity, hematological involvement and AAN positivity were the most frequent ACR criteria. Hypertension, fibromyalgia, and hypothyroidism were the most frequent comorbidities. Corticosteroids and antimalarials were most common treatment. The median prednisone dose was 15mg/day. Patients with income > US$ 402.7 used lower prednisone/day (P= 0,029 and more frequently antimalarial (P= 0,002). Persistent proteinuria and clearance < 50 ml/min were the most frequent damage. The mean SLICC/ACR ID was 1,4±1,52. Patients with SLICC > 0 had lower income (p= 0,039) and nonwhite patients had SLICC higher than white one (P= 0,005). The SLICC was correlated with disease duration (P < 0,001) and with patient age (P< 0,001), and negatively correlated with years of formal education (P = 0,001). Patients who were working had SLICC lower than those were not working (P <0,001). Univariate analysis showed that those with income < US$ 402.7 have 1,6 time more likely to have SLICC > 0 (P= 0,009); nonwhite patients have 1,6 times more likely to have SLICC > 0 (P= 0,009) and each additional year of study decreases by 91% the chance to have SLICC > 0. Multivariate analysis showed that race (P=0.044) and years of study were the best predictors of damage (P= 0,033). The lowest scores of the SF-36 were physical, emotional and mental domain. The SLICC correlated significantly with functional capacity; physical aspect; emotional aspect and physical domain. The SLICC score correlated significantly with SLEQOL total score, physical function, occupational activity and treatment.

Conclusion: Disease duration, age of the patients and mainly race and socioeconomic status are important factors that influence the onset of damage. The damage interferes with the quality of life, especially the physical domain of patients with SLE.

Trends In Hospitalizations Due To Organ Damage In Patients With Systemic Lupus Erythematosus In Canada, 2006–2010. Amyn Sayani, Neerav Monga, Marni Freeman and Jorge Alfonso Ross Terres. GlaxoSmithKline, Inc., Mississauga, ON.

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease that can affect multiple organs in the body, including the heart, kidney and lung, leading to increasing damage over time. Hospitalizations associated with organ damage in SLE patients across Canada have not been previously reported. The purpose of this study was to describe trends and provincial variations in hospitalizations due to organ damage in SLE patients in Canada between 2006–2010.

Methods: Aggregate hospitalization data for most common organ manifestations (kidney, lung, pericarditis, Libman-Sacks disease) associated with SLE was obtained from the Canadian Institute for Health Information's (CIHI) Discharge Abstract and Hospital Morbidity database, based on ICD–10 coding, for 2006–2010. Hospitalizations associated with organ damage were reported as a function of total hospitalizations due to SLE in Canada. Provincial data was grouped into geographical regions for ease of reporting. Length of stay (LOS) was categorized and reported by gender and province.

Results: Overall, total count of hospitalizations due to organ damage decreased over the study period (2006: 525; 2010: 416). Hospitalization due to kidney involvement was the most common reason for all SLE hospitalizations in Canada (2006: 48.2%; 2010: 41.7%), followed by lung involvement (2006: 9.1%; 2010: 6.8%), pericarditis (2006: 5.2%; 2010: 6.2%), Libman Sacks (2006: 0.6%; 2010: 0.5%), and other (2006: 36.9%; 2010: 44.8%). In all provinces, hospitalizations due to kidney involvement accounted for almost half of all SLE hospitalizations: BC reported the highest rates in 2006 (52.4%), but falling by 2010 (42.7%). A decreasing trend in SLE hospitalizations due to kidney involvement was seen in all provinces, except the Maritimes. Hospitalizations due to lung involvement showed the highest decrease in BC between 2006 (13.5%) and 2010 (4.9%): similar decreases were seen in other provinces and Canada-wide (2006: 9.1%; 2010: 6.8%). In contrast, hospitalizations due to lupus pericarditis increased over this time period, with the highest increase recorded in BC (2006: 2.4%; 2010: 8.4%). There was an increasing trend for patients with kidney involvement to stay longer in hospitals (12+ days; 2006: 33.2%; 2010: 35.6%), when compared to LOS due to any SLE-related hospitalizations (2006: 29%; 2010: 26.6%). Overall, more females than males were hospitalized for organ involvement, but males LOS was longer. Limitations to the study include the possibility of double counting events due to a lack of patient level data.

Conclusion: Kidney involvement accounted for almost half of all hospitalizations related to SLE in Canada, consistent with reported higher incidences of lupus nephritis (1–3). Overall, trends in hospitalizations tended to decrease over the time period, suggesting possibly better care of SLE patients. However, when patients did enter hospital, they tended to stay longer, which may suggest that with current medications, disease progression continues and may lead to greater downstream costs in the Canadian health care system.

1065

Acute Myocardial Infarction Variation Among U.S. Medicaid Recipients With Systemic Lupus Erythematosus By Race and Ethnicity, 2000–2006. Medha Barbhaiya[1], Candace H. Feldman[1], Jessica M. Franklin[2], Jun Liu[3], Joanne M. Foody[4], Michael A. Fischer[2], Daniel H. Solomon[1] and Karen H. Costenbader[1]. [1]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Division of Cardiovascular Medicine, Brigham and Women's Hospital, Boston, MA.

Background/Purpose: SLE patients have elevated rates of acute myocardial infarctions (MI), but the sociodemographic groups that are most affected have not been well studied. We examined acute MI rates among SLE patients in different sociodemographic groups enrolled in Medicaid, the program providing medical insurance to low income individuals in the U.S., from 2000 to 2006.

Methods: From Medicaid Analytic eXtract (MAX) data, containing all billing claims from 2000–2006 for Medicaid patients from 47 U.S. states and Washington, D.C., we identified patients aged 18–65 with prevalent SLE (>3 SLE International Classification of Disease, 9threvision, [ICD-9 codes] of 710.0, >30 days apart). Demographic data included age, sex, race/ethnicity, U.S. region of residence (Northeast, Midwest, South or West) and calendar year. Within MAX inpatient claims files, ICD-9 code were used to identify all inpatient diagnoses for acute MI (ICD-9 codes 410.XX). CVD event incidence rates per 1,000 person-years with 95% CIs for patients with SLE in each sociodemographic group were calculated. We also performed Cox regression models stratified by sex and race/ethnicity, and adjusting for age,

calendar year and U.S. region, to calculate hazards ratios for acute MIs in this population.

Results: We identified 43,351 patients with prevalent SLE. 40,417 (93%) were female. Racial and ethnic breakdown was: African American (35%), White (35%), Hispanic (14%), Asian (3%), and Native American (1%). The incidence rate for acute MI was 6.26 (95%CI 5.86, 6.69) per 1,000 person-years for the entire SLE population. Incidence rates were higher among males than females for all race/ethnicities (except for Native Americans for whom there were no events among males). (**Table**) Among women with SLE, Asians and Hispanics had the lowest incidence rates for acute MIs. Among males, incidence rates were also highest among White and African American patients, and lower in Asian and Hispanic SLE patients. Adjusted hazard ratios for acute MIs were significantly lower among Hispanic women compared to White women; however, they were not statistically lower among Asian women compared to White women. Although not statistically significant, lower hazard ratios for acute MIs were found in all non-White groups of men with SLE as well.

Table. Incidence Rates and Adjusted Hazards Ratios for Hospitalizations for Acute Myocardial Infarctions among Medicaid patients with SLE in the U.S. by Race and Ethnicity, 2000–2006

SLE Patients in Medicaid*	Total Individuals	N events	IR**	95% CI	Person-years	HR***	95% CI
			Females				
White	14,010	296	6.34	5.66–7.11	46,672	1.0 (ref.)	-
African American	14,195	277	5.93	5.27–6.67	46,702	1.05	0.89–1.24
Asian	1,095	****	**2.81**	**1.51–5.22**	3,558	0.68	0.36–1.28
Hispanic	5,887	63	**3.14**	**2.45–4.02**	20,045	**0.66**	**0.50–0.87**
Native American	519	11	6.65	3.68–12.01	1,654	1.21	0.66–2.22
Other/ Multiple	2,667	72	7.71	6.12–9.71	9,344	1.23	0.95–1.60
			Males				
White	1,007	44	15.89	11.82–21.35	2,769	1.0 (ref.)	-
African American	877	22	8.68	5.72–13.18	2,535	0.63	0.38–1.07
Asian	102	****	3.28	0.46–23.29	305	0.36	0.05–2.66
Hispanic	373	****	**3.78**	**1.42–10.07**	1,057	0.40	0.14–1.15
Native American	41	0	****	****	88	****	****
Other/ Multiple	176	****	11.12	5–24.75	540	0.81	0.34–1.93

*Race/ethnicity missing for 2043 females and 359 males
**IR: incidence rate, events per 1,000 patient-years
***HR: hazard ratio, adjusted for age, calendar year and region of the U.S.
****Cell size <11 suppressed per Centers for Medicare and Medicaid Services policies
Bold: confidence intervals are significant compared to White patients as reference group

Conclusion: We found marked sex and race/ethnicity-specific variation in acute MI incidence rates and adjusted hazards ratios among Medicaid patients with SLE. The rates were higher among Whites and African American individuals. Further research is necessary to understand whether there is variation in acute MI prevention, cardiac risk factors, presentation, diagnosis and management among SLE patients in different sociodemographic groups.

Depression Screening In Patients With Systemic Lupus Erythematosus From The Southeastern United States: Missing Opportunities For Early Diagnosis and Treatment. Cristina Drenkard, Charmayne M. Dunlop-Thomas, Gaobin Bao and S. Sam Lim. Emory University, Atlanta, GA.

Background/Purpose: Depression can be found in 20–60% of SLE patients and has substantial impact on quality of life, disease outcomes and health care costs. Although pathways are not fully unraveled, immune and disease-related factors have been found associated with depression in SLE. In the general population, racial minorities, women and people from lower socioeconomic status (SES) have increased risk. Thus, SLE patients of minority groups and SLE women carry additional factors to those directly associated with the disease. Depression screening, one of the preventive care services recommended by the United States Preventive Services Task Force (USPSTF) for adults receiving care in clinical practices, has shown to improve outcomes when it is combined with further treatment. However, no study has examined the provision of depression screening in adult SLE patients. We assessed depression screening and the contributing factors associated with being screening in a high-risk SLE cohort from the Southern US.

Methods: We used a cross-sectional design to examine Wave 2 data (2012–2013) from the Georgians Organized Against Lupus Cohort (GOAL). GOAL participants are validated SLE patients primarily derived from the Georgia Lupus Registry, a population-based lupus registry established in metropolitan Atlanta, GA, US. GOAL includes patients of the full sociodemographic spectrum and collects self-reported measures on health care utilization and health conditions. We assessed the proportion of SLE patients screened for depression in the past year using two screening questions recommended by the USPSTF. The prevalence of depression was assessed using the Hospital Anxiety and Depression Scale (HADS). We used Chi^2 tests and Student t-test to examine demographic and disease factors associated with being screened for depression.

Results: Among 519 respondents of the ongoing Wave 2 GOAL survey, 163 (31%) had depression and 113 (22%) had both depression and anxiety. Only 59% of patients indicated that they were screened for depression. Among 213 patients not screened, 18% reported symptoms compatible with depression.

Table 1. Factors Associated with Being Screened for Depression

Characteristic	Screened for Depression: Yes (n = 306)	Screened for Depression: No (n = 213)	P Value

Yes	106 (72.1)	41 (27.9)	
No	198 (54.4)	166 (45.6)	

Unless otherwise indicated, values are depicted as number of individuals (%) within each category MCS: mental component summary; PCS: physical component summary. MCS and PCS were assessed with SF-12.

Conclusion: We found important gaps in the quality of screening for depression among SLE patients. Over 40% were not screened and among them, 18% had depression. Thus, a substantial number of SLE patients missed the opportunity of early diagnosis and treatment. Patients from disadvantaged groups, such as Blacks, unemployed or of lower education, as well as those

with worse disease health status were more likely to be screened. However, even within those high-risk groups, at least 30% of cases were not screened. Depression screening was more frequent in patients who visited a cardiologist, the emergency department or were hospitalized in the past year. This study underscores the need for better performances in screening for depression services provided to SLE patients.

1067

Incidence and Prevalence Of Systemic Lupus Erythematosus: A 2010 Nation-Wide Population-Based Study Using French National Administrative Databases. Laurent Arnaud[1], Jean-Paul Fagot[2], Michel Païta[2], Alexis Mathian[3], Anne Fagot-Campagna[2] and Zahir Amoura[1]. [1]Hôpital Pitié-Salpêtrière, AP-HP, UPMC Univ Paris 06 & French National Reference Center For Systemic Lupus and Antiphospholipid Syndrome, Paris, France, [2]Caisse Nationale d'Assurance Maladie des Travailleurs Salariés, Paris, France, [3]Pitié-Salpêtrière Hospital, APHP, Paris, France.

Background/Purpose: To date, only a small number of studies have examined the epidemiology of systemic lupus erythematosus (SLE) on a nation-wide basis. These studies were restricted to specific age groups and/or non-representative insurance schemes. In our study, we used French national administrative databases to analyse the 2010 prevalence and incidence rates of SLE on a nation-wide basis.

Methods: The largest French health insurance scheme covers 88% of the population or 58,186,535 individuals. Patients with SLE were identified if they had full coverage for a chronic disease with a M32 code (ICD-10th) in the health insurance information system, or if they had a M32 code in the hospital discharge database in 2010.

Results: Overall, 27,390 individuals were identified as having SLE, 88% were female. The crude 2010 prevalence of SLE was 47.1/100,000, and the WHO age-standardized rate 40.8/100,000. The crude 2010 annual incidence of SLE was 3.32 cases per 100,000 with peaks in females aged 30–39yo (9.11/100,000) and in males aged 50–59yo (1.78/100,000). Major differences in regional age-standardized prevalence rates were observed, with the lowest rates in the North-West metropolitan areas and the highest in Caribbean overseas areas, ranging from 26 to 118/100,000.

Conclusion: This is the largest nation-wide study of SLE population to date, based on 58 million beneficiaries of the French health insurance system. Variations in regional rates may reflect ethnic differences. Rates may be underestimated as beneficiaries may not request full coverage and may not be hospitalised for SLE. The prevalence and incidence rates may however provide useful guidance to improve SLE care.

An In-Depth Analysis Of The Prevalence and Socio-Demographic Factors Associated With Lupus Nephritis In Major Industrialized Countries. Guiping Yang and Anne Tuomari. Teva Pharmaceuticals, Inc., Frazer, PA.

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease with incidence and prevalence well studied and documented worldwide. Lupus nephritis (LN) is a severe manifestation of SLE causing dramatic morbidity and mortality. We performed a study looking at large epidemiologic database and found that the information differed from what has been reported in clinical literature. Since healthcare cost distribution is often determined on the basis of large 3rdparty payer or government databases rather than data from academic clinical investigative studies, the social and demographic information from this study would have an important impact on how health resources are allocated.

Methods: The worldwide pattern of LN prevalence and socio-demographic influences were identified by combining the information from Kantar's Epi Database®, the National Health and Wellness Survey (NHWS) and available original research literatures. The association between the prevalence of LN and potential socio-economic factors was assessed for the United States and Europe (France, Germany, Italy, Spain and the United Kingdom) using a stratification-projection algorithm strategy commonly used for rare diseases. The LN diagnostic criteria in WHO served to define patients. All statistical tests on differences were conducted using Student's t-test or the Chi-square approach.

Results: The overall prevalence rate adjusted by gender and age equaled 40.9 per 100,000 patients in the US, but the averaged rate in Europe (15.7) was lower than half of the US ($p=0.03$), with specific numbers as 16.1 in France, 11.2 in Germany, 28 in Italy, 13 in Spain and 10.3 in the UK. In the US, patients ages 31–60 were at higher risk (58%) to develop LN. Female gender presented as a major risk factor (84%, $p=0.02$). Only 2% of the cases were pediatric patients (0–15 years old, $p=0.01$). Almost half of prevalent cases were black patients (46%), followed by Whites (27%) and Hispanics (20%). Geographically, the southern region was dominant in LN prevalence (42%) with the vast majority in urban areas (85%). Around 40% of LN patients were commercially insured through employers, followed by Medicare (34%) and Medicaid (13%), while self-insured subjects accounted for only 6%. Within Europe, the socio-demographic breakdown of LN by region and ethnicity was complex and country specific, but the patterns in gender and age distributions were similar to those in the US. LN patients were mainly insured by national public plans (60–86%).

Conclusion: The prevalence rates of LN in the US and Europe were very low. Female gender was a determinant factor contributing to higher LN prevalence. Adults were more likely to develop LN than children. Most patients were insured commercially in the US and by national health plans in Europe. Quantification and characterization of the LN population from epidemiologic database is key to informing treatment decisions, supporting new therapy development for this severely ill population as well as determining effecient health resource allocation.

1069

Racial Differences In Systemic Lupus Erythematosus Patients' Treatment Preferences: A Two-Site Study. Ernest R. Vina[1], Tammy O. Utset[2], Michael J. Hannon[3], Nicole Roberts[3], Christopher M. Masi[4] and C. Kent Kwoh[5]. [1]University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, [2]University of Chicago Department of Medicine, Chicago, IL, [3]University of Pittsburgh School of Medicine, Pittsburgh, PA, [4]NorthShore University Health System, Evanston, IL, [5]University of Pittsburgh, Pittsburgh, PA.

Background/Purpose: Racial disparities in systemic lupus erythematosus (SLE) exist, with African-American (AA) patients experiencing higher lupus damage scores and disease activity than white (WH) patients. Racial differences in SLE patients' treatment preferences may contribute to these differences and are only partly understood. The goals of the study are to determine whether there are racial differences in willingness to: 1) receive cyclophosphamide (CYC) when physician recommended or 2) participate in a research clinical trial (RCT) involving an experimental medication among SLE patients. We also seek to determine which demographic, clinical and psychosocial characteristics impact racial differences in either measure of treatment preference.

Methods: Data from 163 AA and 180 WH SLE patients recruited from two university clinics were evaluated. Structured interviews and chart reviews were conducted to determine socio-demographic characteristics, clinical factors, perceptions of medications and disease, and beliefs and attitudes towards providers and the healthcare system. Logistic regression models were performed to evaluate the impact of patient characteristics, including race, on preferences for treatment.

Results: AAs, compared to WHs, were less likely to have more than a high-school graduate degree ($p=0.004$), be employed ($p=0.024$), have higher income ($p<0.001$), have private insurance ($p<0.001$) and be married (<0.001). Among patients who had never received CYC (n=293), 62.9% AAs, compared to 87.6% WHs, were willing to receive the medication ($p<0.001$). This difference persisted (OR 0.37 [95% CI, 0.16–0.87]) after adjusting for socio-demographic variables, clinical characteristics, and perceptions about CYC and physicians. Income ($30,001–50,000 vs. <$10,000, OR 4.07 [95% CI, 1.15–14.33]; >$50,000 vs. <$10,000, OR 4.45 [95% CI, 1.24–15.97]) and higher perception of CYC effectiveness (OR 1.41 [95% CI, 1.25–1.59]) were other significant determinants of willingness to receive CYC in the adjusted model.

Among patients who had never participated in a RCT (n=326), 64.9% AAs, compared to 84.3% WHs were willing to do so ($p<0.001$). This difference persisted (OR 0.41 [95% CI, 0.20–0.83]) after adjusting for socio-demographics, clinical variables related to SLE and patients' perceptions of physicians. SLE damage index score (4 vs. 0, OR 0.23 [95% CI, 0.07–0.74]), current number of immunosuppressive medications (1 vs. 0, OR 3.65 [95% CI, 1.14–11.73]; ≥2 vs.

0, OR 5.45 [95% CI, 1.62–18.30]) and higher trust in physicians (OR 1.04 [95% CI, 1.00–1.08]) were also independently associated with willingness to participate in a RCT in the adjusted model.

Conclusion: Variations in lupus patients' treatment preferences are associated with income, medication history, perceived medication effectiveness and trust in physicians. Race remains an independent determinant of preferences after adjusting for these variables. While some factors related to racial differences in patient preferences are relatively fixed, other factors, including medication beliefs and trust in providers, are potentially modifiable and could be addressed to reduce outcome disparities.

Characteristics and Medication Use Patterns Among Belimumab Users In a Commercially Insured Population With Systemic Lupus Erythematosus. Xuehua Ke[1], Jeetvan Patel[2], Hong Kan[2], Debra F Eisenberg[1] and Alan Oglesby[2]. [1]HealthCore Inc, Wilmington, DE, [2]GlaxoSmithKline, Research Triangle Park, NC.

Background/Purpose: Belimumab is a B lymphocyte stimulator-specific inhibitor approved for treatment of systemic lupus erythematosus (SLE). The purpose of the study was to describe medication use patterns among belimumab users in a commercially insured population.

Methods: This is a retrospective cohort study of newly initiated belimumab users in the HealthCore Integrated Research Database during an intake period of 3/1/2011 through 9/30/2012. Newly initiated belimumab users were defined as those with ≥1 belimumab medical or pharmacy claim within the intake period and without belimumab use prior to index date (i.e., first belimumab claim date in the intake period). Patients were required to have ≥6 months pre- and post- index eligibility and ≥1 SLE diagnosis during the study period of 03/01/2010–09/30/2012. Demographics included age, gender, insurance type, and geographic region. SLE severity and comorbidities were reported in the 6 month pre-index period. Physician specialties associated with belimumab prescriptions in the post-index period were examined. First discontinuation of belimumab use (defined as a gap of >105 days between 2 administrations of belimumab) and concomitant medication use was assessed in the post-index period.

Results: 108 newly initiated belimumab users were identified with a mean age of 44 years, and 93.5% were female. Patients were more concentrated in west region (43.5%) and more were enrolled in preferred provider organization plans (60.2%). 18.5%, 66.7% and 14.8% of patients were categorized as mild, moderate and high SLE severity, respectively. The most prevalent pre-index SLE related comorbidities were cardiac disease (34.3%), hypertension (29.6%), and myositis (26.9%). During the post-index period, 32.4% and 12.0% of patients received belimumab prescriptions from rheumatologists and family/general practitioners/internal medicine physicians, respectively. 42.6% of patients discontinued belimumab use during the follow-up period. The mean [SD] length of belimumab therapy prior to the first discontinuation was 236 [154] days. Among patients who continuously used oral SLE medications prior to the index date, 58.1%, 32.1%, and 30.3% discontinued use of oral steroids, immunosuppressants and antimalarials, respectively within 1 month of belimumab initiation. Additionally, use of SLE medications was found to decrease from the first to sixth month of the post-index period: oral steroids (41.7% vs. 38.0%), immunosuppressants (38% vs. 36.1%) and antimalarials (52.8% vs. 48.2%).

Conclusion: This study described demographics and clinical profiles of newly-initiated belimumab users and utilization of SLE therapies in real-world US settings. Discontinuations of oral steroids, immunosuppressants and antimalarials were observed over 6 months after belimumab initiation. Impact of belimumab use on overall health resource utilization and cost needs further evaluation.

1071

Prevalence Of Systemic Lupus Erythematosus and Lupus Nephritis In The United States: Analysis Of Commercial and Public Insurance Billing Data. Kunal Gandhi[1], Evo Alemao[1], Hugh Kawabata[1] and Jan L. Hillson[2]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]Bristol-Myers Squibb, Seattle, WA.

Background/Purpose: Prevalence estimates of Systemic Lupus Erythematosus (SLE) in the U.S. vary, with numbers ranging from 161,000 (Helmick, 2008) to 1.5 million (Lupus Foundation of America). Renal involvement (Lupus Nephritis; LN), the most common serious manifestation of SLE is reported to develop in up to two-thirds of patients cared for in specialty centers. In the absence of population-based data, it is difficult to estimate the burden of SLE and LN in the US population.

Objective: To estimate the prevalence of SLE and LN among commercially insured and Medicare and Medicaid enrolled populations in the US.

Methods: Subjects with at least 12 months of continuous enrollment were selected from the following administrative databases: Truven MarketScan® Commercial Claims & Encounters Data (n=30,912,744), Truven MarketScan® Medicaid Multi-State data (n=3,979,342) and Centers for Medicare and Medicaid Services Medicare data (n=46,520,716). SLE cases were defined as minimum of 3 claims (ICD-9-CM 710.0) occurring within 2009. LN cases were defined using Chibnik, 2010 requiring at least 2 visits to the nephrologists or at least 2 LN diagnoses (ICD-9-CM codes 580–586, 791.0) within 12 months from SLE index date. Sensitivity analyses were conducted by varying the ascertainment criteria for SLE and LN. Overall and age, gender- specific SLE and LN prevalence rates per 100,000 were computed. An estimate of the total number of SLE and LN patients was projected by applying these prevalence rates to the 2009 U.S. population (~306 million).

Results: The overall prevalence of SLE was 81, 106 and 144 per 100,000 in the Commercial, Medicaid and Medicare databases respectively; leading to a projection of 313,436 SLE patients in US population. The prevalence of LN was 15, 31 and 40 per 100,000, in the three databases respectively; leading to a projection of 63,256 LN patients. The age-specific prevalence of SLE and LN were highest between ages of 18 and 64 years (112 and 22 per 100,000, respectively) compared to children (7 and 3 per 100, 000) and those over 65 (102 and 22 per 100,000). SLE and LN prevalence was greater in females (227 and 52 per 100,000, respectively) as compared to males (30 and 10 per 100,000), consistent with previous reports. Although only 15.1% of all US citizens were insured by Medicare as of 2009, 26.2% of all SLE patients were on Medicare; the majority of the latter (51.5%) were under 65, indicating the impact of disability in this disease.

Conclusion: Based on an analysis of billing records from 81 million subjects, the disease burden of SLE and LN in the US is estimated at 313,436 (100 per 100,000) and 63,256 (20 per 100,000) respectively. The estimate for SLE is consistent with the conservative published estimates, and reflects the stringent case definition applied. This proportion of SLE with LN (20%) is significantly lower that reported in cohort studies, suggesting that cohorts incorporate a more severe subset of the population identified by the present algorithms. Both SLE and LN were more frequent in the publically insured population, with highest rates among Medicaid subjects less than 65 years of age, consistent with the high risk of disability associated with this disease.

Gene-Environment Interaction Between HLA-DRB1 Shared Epitope and Occupational Textile Dust Exposure In The Risk Of ACPA-Positive Rheumatoid Arthritis In Female Patients: Evidence From The Malaysian Epidemiological Investigation Of Rheumatoid Arthritis Case-Control Study. Chun Lai Too[1], Nor Asiah Muhamad[1], Leonid Padyukov[2], Lars Alfredsson[3], Camilla Bengtsson[4], Lars Klareskog[2] and Shahnaz Murad[5]. [1]Institute for Medical Research, Jalan Pahang. Kuala Lumpur, Malaysia, Kuala Lumpur, Malaysia, [2]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [3]Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden, [4]Karolinska Institutet, Stockholm, Sweden, [5]Institute for Medical Research, Jalan Pahang, Kuala Lumpur, Malaysia.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease with interacting genetic and environmental factors contributing to its etiology. In this study, we investigated the association between textile dust exposure and the risk of developing RA in the Malaysian population.

Methods: The RA patients and controls were from the Malaysian Epidemiological Investigation of rheumatoid arthritis (MyEIRA) case-control study. The data from a total of 910 female patients with early RA and 910 age matched female population controls were analyzed. Information from interview-reported occupational exposure to textile dust defined as exposed / never exposed was examined for association between occupational textile dust exposure and the risk of developing anti-citrullinated protein antibodies (ACPA)-positive and negative RA. The odds ratio (OR) with 95% confidence interval (CI) was calculated. Interaction was evaluated by calculating attributable proportion (AP) due to interaction, with 95% CIs.

Results: Our data showed that occupational exposure to textile dust was significantly associated with an increased risk of developing RA among female patients compared to female controls (OR=3.16, 95% CI 1.71–5.83). Stratification analysis by ACPA status demonstrated significantly increased risk for developing both the ACPA-positive RA (OR=2.64, 95% CI 1.36–5.13) and ACPA-negative RA (OR=4.43, 95% CI 2.15–9.13) among female patients. We observed a strong association and interaction between occupational textile dust exposure and SE-positive for the risk of developing ACPA-positive RA in Malaysian female patients (OR=35.49, 95% CI 4.67–269.82; AP=0.85, 95% CI 0.53–1.16).

Conclusion: This is the first study demonstrating that the risk of developing ACPA-positive RA in female patients is associated with a strong gene-environment interaction between occupational textile dust exposure and HLA-DRB1 shared epitope in an ethnically diverse Malaysian population.

Longitudinal Decline In Steps/Day In Older Adults With Or At High Risk Of Knee OA. Daniel K. White[1], Roger Fielding[2], K. Douglas Gross[3], Michael C. Nevitt[4], Cora E. Lewis[5], James Torner[6] and Tuhina Neogi[1]. [1]Boston University School of Medicine, Boston, MA, [2]Tufts University, Boston, MA, [3]MGH Institute of Health Professions, Boston, MA, [4]University of California, San Francisco, San Francisco, CA, [5]University of Alabama, Birmingham, Birmingham, AL, [6]University of Iowa, Iowa City, Iowa City, IA.

Background/Purpose: Walking is the most common type of physical activity older adults employ for physical activity, which, when performed regularly, confers important health benefits. When people develop knee osteoarthritis (OA), it is thought that they are likely to decrease the amount of walking they engage in due to pain and functional limitations. Whether this occurs in reality is not known. The impact of psychological health (e.g., depressive symptoms) on declines in walking activity in such individuals is also not known. The purpose of this study was to examine change in objectively measured walking activity over a 2-year period, and evaluate its relation to radiographic knee OA (ROA), knee pain, and psychological health.

Methods: The Multicenter Osteoarthritis Study (MOST) is a NIH-funded longitudinal cohort of older adults who have or are at high risk of knee OA. Steps/day over 7 days were objectively measured with a StepWatch monitor at 2 study visits, two years apart. We calculated the absolute change in mean steps/day between visits. We also evaluated mean change by categories of baseline disease status, i.e., ROA, frequent knee pain, or symptomatic knee OA (ROA + knee pain), and baseline psychological health status, i.e., presence of depressive symptoms and catastrophizing, using linear regression, adjusting for age, sex, and body mass index (BMI).

Results: Of the 1,318 subjects with the necessary data obtained (Age 66.9 ± 7.7, 59% women, BMI 30.6 ± 5.9), absolute steps/day declined significantly, albeit only slightly, from a mean of 9,173 steps/day at baseline to 9,004 steps/day 2-years later (i.e., 168 fewer steps ± 2,268, p = 0.007). Those with depressive symptoms walked 927 ± 2,495 fewer steps/day 2-years later compared with 124 ± 2,959 fewer for people without depressive symptoms (p=0.007). People with symptomatic knee OA walked 421 ± 3,100 fewer steps/day, which was not statistically significantly different than people without either ROA or frequent knee pain, who walked 517 ± 3,694 fewer steps/day 2-years later. The other factors assessed were not statistically significantly associated with change in steps/day.

Conclusion: Declines in walking activity over a 2-year period were minimal overall, and appeared to be more likely related to psychological health in people with or at high risk of knee OA rather than having painful knee OA itself. Specifically, depressive symptoms were significantly associated with >900 fewer steps/day 2-years later, which is a clinically meaningful difference and beyond the 168 fewer steps/day due to aging. Given the multiple benefits of physical activity, maintaining or improving steps/day in people with knee OA is important. Our findings support the notion that addressing psychological- rather than disease- and pain-factors is promising to minimize declines in daily walking in people with or at high risk of knee OA.

1074

Obesity and Life-Space Mobility Among Older Mexican Americans With and Without Arthritis. Soham Al Snih[1], Rafael Samper-Ternent[2], Amit Kumar[1] and Kenneth J. Ottenbacher[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]Universidad Javeriana. Hospital San Ignacio, Bogota, Colombia.

Background/Purpose: To examine the relation between obesity and life-space Assessment (LSA) mobility at 2-year of follow-up among older Mexican Americans with and without arthritis.

Methods: Two-year prospective study of Mexican-American men and women aged >75 years and older residing in five southwestern states in the U.S. Data on socio-demographic variables, medical conditions, disability, body mass index (BMI), and the LSA were collected. The LSA is an instrument that assesses the range, independency, and frequency of movement in the past four weeks preceding the interview. The LSA composite scores ranged from 0 to 120, with higher scores representing greater mobility.

Results: Out of 624 subjects, 65.5 % reported arthritis. Mean score for the LSA instrument was 40.8 (SD=20.7) in subjects with arthritis and 45.5 (SD=20.0) in subjects without arthritis. Multiple regression analysis stratified by arthritis was conducted. The association between obesity (BMI ≥ 30 Kg/m^2) and the LSA mobility in subjects with arthritis was statistically significant (β= –6.49, SE=2.22, p=0.0036), after controlling for all covariates. The association between obesity (BMI ≥ 30 Kg/m^2) and the LSA mobility in subjects without arthritis was non-significant (β= −0.75, SE=3.20, p=0.8157), after controlling for all covariates.

Conclusion: The association between obesity and lower Life-Space mobility differed by arthritis status in older Mexican Americans. Among subjects with arthritis, obesity maintained a negative and independent association with Life-space mobility in models controlling for all factors that can influence mobility patterns. Conversely, obesity did not seem to affect life-space mobility in subjects without arthritis.

1075

Patient Characteristics Associated With Insomnia and Sleep Apnea In Knee and Hip OA. Kelli D. Allen, Hayden B. Bosworth, Cynthia Coffman, Amy Jeffreys, Eugene Z. Oddone, William S. Yancy Jr. and Christi Ulmer. Duke and Durham VA Medical Center, Durham, NC.

Background/Purpose: There is increasing recognition that sleep quality is a key outcome among patients with osteoarthritis (OA), but little is known about how clinical or demographic factors influence sleep quality in patients with OA. This study examined patient characteristics associated with insomnia and sleep apnea among patients with hip and knee OA.

Methods: Participants were 300 veterans enrolled in a clinical trial examining a patient and provider intervention for managing OA at the Durham Veterans Affairs Medical Center (mean age = 61, SD=9, 91% male, 50% non-white–primarily African American). All measures were obtained from a baseline interview. Self-reported sleep problems were assessed with the Insomnia Severity Index (ISI; range of 0–28, higher scores indicate more severe insomnia) and the Berlin Questionnaire (BQ; categorizes patients as "high risk" or "low risk" of having sleep apnea). We fit multivariable linear (ISI) and logistic (BQ) regression models to examine the associations of the following patient characteristics with insomnia and sleep apnea: age, gender, race (white vs. non-white), self-reported general health (excellent, very good, good vs. fair, poor), body mass index (BMI), diagnosis of post-traumatic stress disorder (PTSD), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale, depressive symptoms (Patient Health Questionnaire-8), and number of joints affected by arthritis.

Results: The mean ISI score was 11.4 (SD = 8.0); this value is slightly above the cut-point for detecting insomnia. 66% of participants were categorized as being at high risk for sleep apnea based on the BQ. In the

multivariable model of ISI scores, factors associated with more insomnia symptoms included younger age (b = −0.09, 95% Confidence Interval (CI) = −0.16, −0.02; p=0.01), PTSD diagnosis (b = 1.68, 95% CI = 0.26, 3.09; p=0.02), higher WOMAC pain score (b = 0.37, 95% CI = 0.18, 0.55; p<0.001), and more depressive symptoms (b = 0.85, 95% CI = 0.71, 0.98; p<0.001). The only variables associated with high risk for sleep apnea in the multivariable model were greater BMI (odds ratio = 1.13, 95% CI = 1.06–1.21; p<0.001)) and more depressive symptoms (odds ratio = 1.13, 95% CI = 1.06–1.20; p<0.001).

Conclusion: Sleep problems, particularly apnea symptoms, were very common in this sample of patients with hip and knee OA. Depressive symptoms were associated with symptoms of both insomnia and sleep apnea, but other patient characteristics associated with symptoms of insomnia vs. apnea were different. These results highlight the importance of screening for both insomnia and sleep apnea among patients with OA, particularly among those who may be at greater risk due to factors such as depression, PTSD, greater pain severity, and high BMI.

Disclosure: K. D. Allen, None; **H. B. Bosworth**, None; **C. Coffman**, None; **A. Jeffreys**, None; **E. Z. Oddone**, None; **W. S. Yancy Jr.**, None; **C. Ulmer**, None.

1076

Individuals With Knee Or Hip OA and Low SES Are Likely To Be Physically Active. Rebecca J. Cleveland[1], Kamil E. Barbour[2], Jordan B. Renner[1], Joanne M. Jordan[3] and Leigh F. Callahan[4]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Centers for Disease Control and Prevention, Atlanta, GA, [3]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC, [4]University of North Carolina, Chapel Hill, NC.

Background/Purpose: Osteoarthritis (OA) is a major cause of disability and pain in adults over the age of 45. It has been shown that physical activity (PA) can ease pain and improve quality of life for individuals with hip and knee OA, and may lessen disability. Despite these important health benefits of PA, many with OA do not exercise. Although socioeconomic factors (SES) have been associated in lower PA levels in population-based studies, they have not been meaningfully evaluated among individuals with lower body large joint OA.

Methods: We used cross-sectional data from the first follow-up and cohort replenishment of the Johnston County Osteoarthritis Project (1999–2004) which included 1,404 adults aged 45 and older with radiographic OA (rOA) of the knee and/or hip. rOA in a joint was defined as a Kellgren-Lawrence grade of ≥2. Symptomatic (sxOA) is a subset of those with rOA and symptoms in the same joint. The Minnesota Leisure Time Physical Activity questionnaire was used to collect PA information in the past year. Leisure time PA (LTPA) was assessed as a 4-level variable according to 2008 Physical Activity Guidelines for Americans based on min/wk of PA (0–9, 10-<150, ≥150-<300, ≥300 min/wk), and a dichotomous variable based on meeting Health and Human Services guidelines of ≥150 min/wk of moderate-vigorous PA. Individual SES measures were years of education (EDUC; <12 years, ≥12 years) and occupation type (managerial, non-managerial); community SES was measured using Census block group poverty rate (<12%, 12-<25%, ≥25%). All logistic regression models concurrently examined SES measures for associations with PA levels among those with rOA and sxOA separately, adjusting for age, gender, race, body mass index, occupational PA, and history of injury to matching joint, using the lowest LTPA category as the referent.

Results: Participants meeting recommended PA levels tended to be younger, male, white race, not obese, not have sxOA, with EDUC ≥12 yrs and in a managerial occupation. Among those with rOA, compared to those with EDUC ≥12 yrs, those with EDUC <12 yrs were less likely to participate in high LTPA levels (≥300 min/wk; adjusted odds ratio [aOR]=0.52; 95% confidence interval [CI]=0.34–0.79) and less likely to meet recommended LTPA levels (aOR=0.68; 95% CI=0.51–0.89). Similarly, among the subset of individuals with sxOA, those with EDUC <12 yrs were less likely to meet recommended LTPA levels (aOR=0.65; 95% CI=0.45–0.95). Further, individuals with sxOA living in high poverty block groups were less likely to engage in moderate (aOR=0.34; 95% CI=0.14–0.80), or high levels of LTPA (aOR=0.50; 95% CI=0.25–1.02). Occupation type was not associated with LTPA levels.

Conclusion: In both rOA and sxOA, those with lower SES were less likely to be active or to meet HHS recommendations for PA. Since individuals with lower SES are also more likely to have OA, targeting these groups about the benefits of PA is imperative.

Table 1. Odds ratio (OR)‡ and 95% confidence intervals (CI) for associations of SES variables with physical activity levels among those with knee and/or hip radiographic OA (rOA) and a subset of those with symptomatic* rOA

Less Time Spent In Sedentary Behavior Is Associated With Better Future Physical Function: Objective Data From The Osteoarthritis Initiative. Jungwha Lee[1], Jing Song[2], Rowland W. Chang[1], Linda S. Ehrlich-Jones[3], Pamela A. Semanik[2], Min-Woong Sohn[2] and Dorothy D. Dunlop[2]. [1]Northwestern University Medical School, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Rehabilitation Institute Chicago, Chicago, IL.

Background/Purpose: Public health physical activity interventions often focus on increasing exercise but give limited attention to reducing sedentary behavior. This study examined whether objectively measured time spent in sedentary behavior is related to subsequent physical function independent of time spent in moderate-to vigorous-intensity physical activity (MVPA) among adults with knee osteoarthritis (OA).

Methods: The Osteoarthritis Initiative cohort included 962 patients with radiographic knee OA, ages 49–83 years at baseline (48-month clinic visit) when physical activity was monitored. Physical function was assessed at baseline and 2 years using the 20-meter walk test (feet/second)) and chair stand rate (per minute). Average daily sedentary behavior and MVPA assessed by accelerometer monitoring was based on 4 or more valid monitoring days (i.e.,10 or more wear hours in a day) for each participant. The percentage of daily wear hours spent in sedentary behavior (minutes when activity counts< 100) was calculated. The relationship of baseline sedentary behavior percentage quartiles to subsequent (2-year) physical function was examined by multiple linear regression models adjusted for demographic factors (age, sex, race/ethnicity, and education), health factors (comorbidity, BMI, knee pain, knee OA severity, presence of knee symptoms) and average daily MVPA minutes.

Results: Adults with knee OA spent on average 66% of their daily time in sedentary behavior (range 28~89%).

For both chair stand rate and gait speed, the most sedentary people had the poorest physical function after 2 years. Compared to the most sedentary group (quartile 1), age-adjusted physical function average was significantly higher in less sedentary behavior groups (chair stand rate: 28.6, 32.1, 31.4, 32.7 stands/minute, P<0.0001; gait speed: 4.19, 4.48, 4.48 and 4.42 feet/second, P=0.0002). These trends persisted in multivariable analyses that controlled for demographic factors, health factors, and MVPA.

Conclusion: Being less sedentary is associated with better future physical function independent of time spent in physical activity. Maintaining physical function may be improved by pairing messages to limit sedentary activities with those promoting increasing levels of physical activity in adults with knee OA.

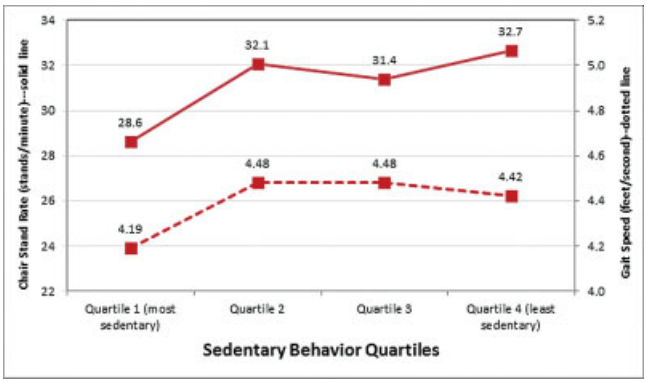

Figure. Average Chair Stand Rate (stands/minute) and Gait Speed (feet/second) at 2 Years, by Sedentary Behavior Quartiles at Baseline, adjusted for age (n=962).

1078

Trends In Prevalence Of Knee Pain Among US Adults, National Health Interview Survey 2002–2010. Jennifer M. Hootman[1], Charles G. Helmick[2] and Yvonne M. Golightly[3]. [1]Centers for Disease Control and Prevention, Kennesaw, GA, [2]Centers for Disease Control and Prevention, Atlanta, GA, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background/Purpose: Aging of the population as well as the obesity epidemic will play a significant roll in future cases of arthritis and other lower extremity orthopedic conditions. The purpose of this study is to examine trends in the prevalence of knee pain among adults age 18 and older, overall and by age and sex.

Methods: The National Health Interview Survey, conducted annually, targets the civilian, non-institutionalized population and gathers data on a variety of health topics. From 2002–2010 the adult sample size ranged from 21,781 to 31,428. Adults were asked if they had joint pain in the past 30 days not including the back or neck. For those responding "yes", respondents were then asked what joints were affected. Prevalence (%) and 95% confidence intervals (CI) of knee pain were calculated using statistical weights to account for the complex survey design. Prevalence was also stratified by age group (18–24, 25–44, 45–64, 65–74, 75+) and sex and graphed age to show trends over time. Percent increase was calculated using the formula: prevalence 2010–prevalence 2002/prevalence 2002*100. Statistical significance was determined by non-overlapping 95% CIs.

Results: The age adjusted prevalence of knee pain increased significantly from 16.5% (CI 15.6–17.4) in 2002 to 19.6% (CI 18.5–20.7) in 2010. In each year, knee pain prevalence was higher with increasing age and highest for the 75+ age group. (Figure) More than 1 in 4 adults aged 55–64 and 65–74 and 75+ reported having knee pain each year. Knee pain prevalence increased significantly over the 9 years in all age groups. The age groups with the largest percent increase were 25–44 (21.4%), 45–64 (27.7%), and 55–64 (25.2%). Women had higher prevalence of knee pain than men for all years, but prevalence increased more in men (23.0%) versus women (15.3%).

	2002	2003	2004	2005	2006	2007	2008	2009	2010
18-24	8.3	9.0	8.0	8.8	6.9	5.2	9.3	8.8	9.8
25-44	11.2	13.3	12.6	12.6	12.5	10.8	13.1	13.7	13.6
45-54	18.4	20.7	20.7	20.6	20.9	19.8	22.5	23.8	23.5
55-64	23.4	27.8	25.8	26.9	25.4	25.5	27.4	29.4	29.3
65-74	27.6	30.5	30.4	29.7	27.8	25.6	28.2	28.9	30.2
75+	29.7	32.1	32.9	30.8	29.4	27.7	27.7	31.9	30.9

Fig. 1. The effect of fatigue and pain on the physical activity of RA patients.

Conclusion: Knee pain prevalence is high and has increased over time for all age groups with adults aged 25–44 and 45–64 showing the largest increases. The findings suggest a large burden of knee pain among working age adults. Public health and worksite wellness efforts should consider implementing evidence based interventions aimed at reducing knee pain such as physical therapy, aerobic and muscle strengthening exercises, and weight loss. The data also support the need for increasing the number of primary care, rheumatology and orthopedic health professionals in the workforce to be best able to address the growing burden of knee pain in the population.

1079

Physical Activity and Rheumatoid Arthritis: State Of The Art. Jasper van Kuijk, Sanne van Dartel and Han Repping-Wuts. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: Growing body of research supports the benefit of physical activity in Rheumatoid Arthritis (RA) patients. Physical activity improves some of the most important RA patient outcomes: function, quality of life and pain, without any proven harmful effects on disease activity. However, little is known about physical activity levels among RA patients.

Objectives of this study were to determine how many RA patients meet the Dutch public health recommendation for physical activity, which is at least 30 minutes of moderate-intensity physical activities on at least 5 days a week, and to assess the main personal barriers of RA patients with regard to physical activity.

Methods: A questionnaire, consisted of three parts, was used to answer the objectives. The first part included several general questions describing the population. In this part also the fatigue and pain score of the patients was determined. The second part comprised the Short QUestionnaire to ASses Health-Enhancing Physical Activity (SQUASH) and the final part was the *'guideline for sport participation' (RSO).*The aim of the RSO questionnaire was to assess the main motivation to exercise and the advices by health care providers concerning physical activity. Completing the questionnaire took about 15–20 minutes on www.bewegen-en-reuma.nl. Four different ways of promoting the hyperlink of the questionnaire were used trying to obtain a population which is representing the total RA population. To analyze the answers SPSS was used. One-sample t-tests were performed to compare the RA population with the general Dutch population.

Results: 141 patients completed the questionnaire. The proportions of RA patients meeting the physical activity recommendation were similar to those of the general population (Table 1). Fatigue and pain did have an impact on the achieving of the recommendation for physical activity in RA patients (Fig. 1). 59,1% of the RA population did not receive any advice with regard to physical activity by professional health care providers and 35,5% of the patients is not informed at all about options for physical activity.

Table 1.

	Meeting recommendation for physical activity (%)			Minutes of activity/week
	RA population (n=141)	General population (n=2295)	*p*-value	RA population (n=141)

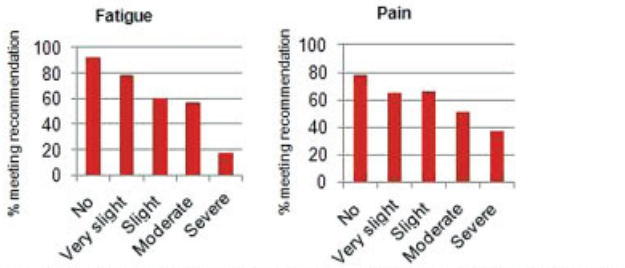

Fig. 1: The effect of fatigue and pain on the physical activity of RA patients

Conclusion: No significant differences were seen between the RA population and the general population in achieving the recommendation for physical activity. RA patients are being informed and advised insufficiently with regard to physical activity. More stimulation and motivation by health care providers is needed to overcome exercise barriers and therefore to help patients in becoming or staying physically active.

Incidence Of Coronary Heart Disease Associated With Arthritis: A Canadian Population-Based Cohort Study. Orit Schieir[1], S. Hogg-Johnson[2], Richard H Glazier[3] and Elizabeth M. Badley[4]. [1]University of Toronto, Toronto, ON, [2]Institute for Work and Health, and Dalla Lana School of Public Health, University of Toronto, Toronto, ON, [3]nstitute for Clinical Evaluative Sciences, Sunnybrook Health Sciences Centre, Toronto, ON, [4]Division of Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON.

Background/Purpose: Several individual types of arthritis have been associated with increased coronary heart disease (CHD) morbidity in clinical studies, but whether arthritis overall increases the risk of developing CHD is unknown. The objective of the present study was to estimate the extent to which arthritis is associated with the time-to-first occurrence of CHD in a Canadian population-based sample.

Methods: The present study was a secondary analysis of the longitudinal Canadian National Population Health Survey (NPHS), a nationally representative community sample followed every 2 years from 1994/95 through 2010/11. Standardized questionnaires were administered including information on chronic conditions, socio-demographic variables and lifestyle/health behaviours. Deaths were linked to the Canadian Vital Statistics Database. Arthritis was ascertained by self-reported physician diagnosis. CHD was ascertained by self-reported physician diagnosis or death due to ischaemic heart disease (ICD-10 codes I20-I25) or heart failure (ICD-10 codes I50.0-I50.9). Additional covariate information considered in the present analysis included: age, sex, education, body mass index (BMI), smoking, physical inactivity, activity limitation, self-reported physician-diagnosed diabetes and hypertension, and sum of non-cardiovascular comorbidities. Updated values of arthritis, age, education, smoking and comorbidity count were analyzed as time-varying covariates. Discrete-time survival analysis stratified by gender was used to estimate hazard rates for incident CHD associated with arthritis.

Results: The analytical cohort included 13, 369 Canadians age 18 years or older without prevalent CHD or a past history of CHD at baseline. After adjusting for all covariates, arthritis was associated with a 75% increased risk for incident CHD in women (HR: 1.75, 95% CI: 1.39, 2.20) but was not associated with a significant increased risk for CHD in men (HR: 0.95, 95% CI: 0.74–1.22). Women with arthritis who reported concomitant activity limitation had over a 2.5 times higher risk for incident CHD than those without arthritis or activity limitation (HR: 2.55, 95% CI: 1.91, 3.38), adjusted for all covariates. Older age, being a current smoker, baseline diabetes and hypertension, higher BMI and non-cardiovascular comorbidities were also independently associated with incident CHD.

Conclusion: These Canadian population-based estimates suggest that women with arthritis have a significant increased risk for developing CHD, and that women with related activity limitation indicative of more severe arthritis may represent a particularly high-risk population. These data support considering cardiovascular prevention strategies in women with arthritis.

The Effects of Coexisting Cervical Myofascial Pain Syndromes On Pain and Disability of the Computer Users With Cumulative Trauma Disorders. Hakan Genc[1], Ozgul Bozkurt Tuncer[2], Hatice Rana Erdem[3], Baris Nacir[1], Aynur Karagoz[1] and Burcu Duyur Cakit[1]. [1]Ministry of Health, Ankara Training and Research Hospital, Ankara, Turkey, [2]Ministry of Health, Yuksekova Public Hospital, Hakkari, Turkey, [3]Ahi Evran University, Kirsehir, Turkey.

Background/Purpose: Coexisting cervical myofascial pain syndromes (MPS) can have serious effects on pain and disability of computer users with cumulative trauma disorders (CTD). The aims of this study are to evaluate the existence of cervical MPS in computer users with CTD and to investigate the effects of coexisting cervical MPS on pain and disability of computer users.

Methods: 170 computer users were included in the study. Computer users were classified as complainant group (CDT+) who have complaints concerning to neck, back and upper extremity (group 1) and non-complainant group (CTD-) who have no complaint (group 2). 55 age, sex and body mass index matched non-computer user, healthy hospital stuff were recruited as the control group (group 3). All participants were asked to fill our questionnaire form including detailed risk factor query and physical examination. Pain assessment was made by visual analog scale. The existence of MPS was evaluated using specific diagnostic crtiteria. The existence of active trigger points on trapezius, levator scapula, multifidus, sternocleidomastoideus, rhomboideus and deltoideus muscles were evaluated and noted. In order to measure the general disability levels of the participants, Quick DASH Score (QDS) was used, besides to measure their disability levels during work, Quick DASH Work Score (QDWS) was used.

Results: The mean ages of the 114 participants with CTD (77 females and 37 males) was 31.3±6.3 years, of the 56 with non-CTD (33 females and 23 males) was 30.9±6.7 years and of the 55 controls (34 females and 21 males) was 31.7±5.8 years. Statistically significant differences weren't found between the groups with respect to sex, mean ages and body mass indexes. 114 (77%) of the computer users had CTD. The presence of cervical MPS in complainant group (n:87) was statistically significantly higher than non-complainant (n:8) and control (n:8) groups ($p<0.001$). When compared to non-complainant and control groups, QDS and QDWS were significantly higher in complainant group ($p<0.01$–$p<0.05$). In the presence of accompanying MAS, pain intensity, QDS and QDWS increased significantly ($p<0.01$–$p<0.05$).

Conclusion: The existence of cervical MPS is a serious factor in the increase of disability and pain levels of CTD patients. We believe that the evaluation of cervical MPS and treatment of the syndrome have a great importance in the treatment of CTD which can cause serious disability and workforce loss.

The Effects of Prolotherapy in Patients With Subacromial Impingement Syndrome. Eylem Akcan Hannan[1], Akyuz Gulseren Sr.[2] and Nertila Hysenaj[3]. [1]Marmara Univesrsity School of Medicine, Istanbul, Turkey, [2]Marmara University School of Medicine, Istanbul, Turkey, [3]Private Vital Hospital, Istanbul, Turkey.

Background/Purpose: Recent treatments for subacromial impingement syndrome (SIS) are palliative. Dextrose injection which is called prolotherapy has emerged as a treatment option for chronic situations such as tendinitis and bursitis. The aim of the study is to investigate the effects of dextrose injection in patients with chronic shoulder pain caused by subacromial impingement syndrome.

Methods: In this single-center, randomized placebo controlled, single blind, prospective study, 80 patients with chronic SIS who met the study criteria received two dextrose injections in the affected shoulder at two weeks intervals. The patients were randomly assigned into two therapy groups, either

dextrose or other control (lidocaine) groups. The injections were repeated two times with two weeks between injections. Clinical assessments included measurement of range of motion (ROM), pain assessment via Visual Analog Scale (VAS), shoulder functions and daily living activities through University of California (UCLA) shoulder rating scale, the Constant-Murley shoulder outcome score and The Quick Disabilities Arm, Shoulder and Hand (q-DASH) questionnaire were performed at the pre-injection visit, and at the 1-, 3- and 6- month follow-up visits. Magnetic resonance imaging (MRI) evaluation was conducted before the first injection and compared with MRI's taken again on the third month following the second injection.

Results: There were no adverse events reported. The study demonstrated significant improvements in VAS, UCLA, Constant and q-DASH scores in both injection groups. However, there was no significant difference between the two groups in terms of all these clinical scales. Shoulder flexion, abduction, internal and external rotations showed significant improvements in both groups in the first 3 months in accordance to other findings. Nevertheless, while the range of shoulder flexion did not improve in the control group during the last three months, this range of motion continued to improve significantly in treatment group over the same period.

Conclusion: Long-lasting improvements in ROM compared with the lidocaine injection demonstrated could potentially be used to inspire larger, blinded, and randomized clinical trials to determine the most efficient dextrose concentration, the optimal dosage interval, detailed findings on the MRIs and compare with other treatment techniques for the treatment of chronic SIS.

Something Ventured, Something Gained: Alternative Therapies For FMS and RA. Robert S. Katz[1], Hannah Bond[2], Jessica L. Polyak[2], Lauren Kwan[2], Alexandra Small[3] and Susan Shott[4]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL, [3]University of Illinois Medical School, Chicago, IL, [4]Rush University Medical Center, Chicago, IL.

Background/Purpose: Many patients with rheumatologic diseases resort to unproven alternative therapies. We compared FMS and RA patients with respect to the use and effectiveness of alternative therapies.

Methods: 211 office patients with FMS (150; 130 women and 20 men; mean age 51 + 12) or RA (61; 45 women and 16 men; mean age 55 + 15) completed a questionnaire about alternative therapies for treating FMS or RA. Patients rated therapies as 1 = not helpful, 2 = mildly helpful, 3 = moderately helpful, and 4 = very helpful. The chi-square test of association was done to compare FMS and RA patients with respect to percentages, and the two-sided Mann-Whitney test was done to compare them with respect to the ratings, using a 0.05 significance level.

Results: Significantly higher percentages of FMS patients reported having used meditation (44% vs. 26%, p = 0.025), massage (76% vs. 58%, p = 0.020), diet changes (75% vs. 56%, p = 0.018), exercise (92% vs. 79%, p = 0.013), and physical therapy (59% vs. 39%, p = 0.017) compared to RA patients. FMS patients were also more likely to report having tried herbal supplements (47% vs. 31%), biofeedback (21% vs. 9%), and chiropractic treatment (43% vs. 31%) (ns). For FMS patients, the most helpful therapies were yoga, exercise, massage, physical therapy, water therapy, and a gluten-free diet (median ratings = 3), followed by meditation, diet changes, herbal supplements, vitamins/minerals, acupuncture, biofeedback/cognitive behavioral therapy, chiropractic treatment, and tai chi (median ratings = 2), with hypnosis as least helpful (median rating = 1). For RA patients, the most helpful therapies were chiropractic treatment and water therapy (median ratings = 4 and 3.5), followed by yoga, meditation, exercise, massage, biofeedback/cognitive behavioral therapy, physical therapy, and tai chi (median ratings = 3), and diet changes, herbal supplements, vitamins/minerals, acupuncture, and a gluten-free diet (median ratings = 2), with hypnosis as least helpful (median rating = 1). The efficacy ratings were significantly different for FMS and RA patients only for chiropractic treatment efficacy, with lower ratings reported by FMS patients (median 2 vs. 4, p = 0.007).

Conclusion: FMS patients were more adventuresome than RA patients when it came to trying alternative therapies. Many of these therapies had high efficacy ratings for FMS and/or RA patients.

Age Distribution of Women With Idiopathic and Traumatic Fibromyalgia. Robert S. Katz[1] and Frank Leavitt[2]. [1]Rush Medical College, Chicago, IL, [2]Rush University Medical Center, Chicago, IL.

Background/Purpose: Fibromyalgia has both idiopathic and post traumatic forms. The idiopathic type is insidious in onset, becoming established without a known triggering event. The post-traumatic form is defined by the presence of a triggering event such as a significant illness, an injury or an accident. The purpose of this study is to examine the age distribution of the two forms of onset in order to determine if either form is age-linked.

Methods: Age of onset and the presence of a triggering event were investigated in 169 female patients who met ACR criteria for fibromyalgia. In response to the question "Did a specific event or condition trigger your symptoms of fibromyalgia", 97 (57.4%) recorded yes and formed the post-traumatic group. Forty two percent (42.6%) recorded no and formed the idiopathic group

Results: The mean age of post-traumatic FMS patients was 47.1±11.6 years and for idiopathic FMS patients was 49.7± 12.8 years. The mean age of symptom onset was 35.3 ±11.7 years in the post-traumatic group and 37.1±12.3 years in the idiopathic group. Differences between groups on the two variables were non-significant.

Table 1. illustrates that the age distribution in both forms of fibromyalgia is similar**.** The two forms of FMS occurred in people of all ages, and ranged from 8 to 65 in the post-traumatic group and 6 to 63 in the idiopathic group. The frequency of onset in both forms is highest between the ages of 30 and 49.

Distribution in age of Onset in Two Forms of Fibromyalgia

	Triggered	Idiopathic
Age 6 to 17	10 (10.3%0)	5 (6.9%)
Age 18 to 29	19 (19.6%)	15 (20.8%)
Age 30 to 39	30 (30.9%)	17 (23.6%)
Age 40 to 49	27 (27.8%)	24 (33.3%)
Age 50 to 65	11 (11.3%)	11 (15.3%)

Conclusion: It is curious that the mean age of onset in the group with post-traumatic FMS (35.3 y.o.) was similar to the mean age of onset in patients with idiopathic FMS (37.1 y.o.). Neither the idiopathic nor the post-traumatic form of FMS appears age dependent. Onset can be encountered both early and late in life with approximately 10% of each form occurring before the age of 18 and after the age of 50. FMS onset peaks in the 3rd, 4th and 5thdecades in women.

The similar pattern of onset is puzzling since one is presumably an internally generated process and the other occurs on an apparently chance basis, such as after car accidents. One theory is that the idiopathic form of fibromyalgia is also stress driven but on a more subtle basis. Like the post-traumatic form, it also occurs because cumulative stress builds, in an unnoticed manner, and exceeds a critical threshold dependent on life circumstances.

I Work Out: Exercise Appears To Increase FMS Pain. Robert S. Katz[1], Ben J. Small[2] and Susan Shott[3]. [1]Rush Medical College, Chicago, IL, [2]Rush University Medical School, Chicago, IL, [3]Rush University Medical Center, Chicago, IL.

Background/Purpose: A basic tenet of the treatment of FMS is that exercise decreases symptoms of the illness. We compared FMS and RA patients to assess their ability to exercise and the impact of exercise on their pain.

Methods: 211 office patients with FMS (150; 130 women and 20 men; mean age 51 + 12) or RA (61; 45 women and 16 men; mean age 55 + 15) completed a questionnaire about their ability to exercise, types of exercise, and effect of exercise on their pain (rated as 1 = much worse, 2 = moderately worse, 3 = somewhat worse, 4 = no change, 5 = somewhat better, 6 = moderately better, and 7 = much better). The chi-square test of association was done to compare FMS and RA patients with respect to percentages, and the two-sided Mann-Whitney test was done to compare them with respect to the ratings, using a 0.05 significance level.

Results: 71% of FMS patients and 67% of RA patients reported exercising (ns). FMS patients were less likely to report being able to exercise

(74% vs. 87%, ns). The exercise impact ratings were significantly worse for FMS patients compared to RA patients (median 3 vs. 4, p = 0.017). 60% of FMS patients reported that exercise made their pain somewhat, moderately, or much worse, compared to 35% of RA patients. 20% of FMS patients reported that exercise made their pain much worse, compared to only 6% of RA patients. Walking was by far the most common type of exercise, reported by 66% of FMS patients and 70% of RA patients. All other types of exercise were reported by 20% or fewer FMS or RA patients. High-impact exercise such as jogging was rarely reported by FMS or RA patients.

Conclusion: Almost two-thirds of FMS patients reported that exercise made their pain worse, compared to only about a third of RA patients. Exercise programs that can be tolerated by FMS and RA patients need to be designed with input from patients. Although exercise is generally recommended for FMS patients, current exercise programs appear likely to make their pain worse.

The Straight Neck in Fibromyalgia. Robert S. Katz[1] and Anthony Farkasch[2]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL.

Background/Purpose: In patients with fibromyalgia a straight neck is based on calculating the Cobb angle, a standard radiographic measurement, of lateral view radiographs of the cervical spine. Most fibromyalgia patients have lost the normal cervical lordosis. We re-evaluated cervical spine radiographs of fibromyalgia patients to determine what proportion of FMS subjects have straight necks.

Methods: The lordotic curve of cervical spine radiographs was measured by analyzing the Cobb angle in 138 consecutive patients in a rheumatology office practice. All patients met the ACR criteria for fibromyalgia and complained of moderate to severe neck pain. 23 additional patients with fibromyalgia followed in the same rheumatology practice had cervical radiographs reviewed visually by both a rheumatologist and an X-ray technician, but did not also have the Cobb angle measured (visual inspection group) The amount of visual curvature was noted by each as 1 (straight neck), 2 (slight lordotic curve) and 3 (normal lordotic curve).

Results: 98 of 138 (71%) fibromyalgia patients had a straight spine (Cobb angle less than 14 degrees). 24 of 138 (17%) fibromyalgia patients had a small lordotic curve of the lateral view of cervical spine radiographs (Cobb angle 14–18 degrees). 16 of 138 (12%) patients had a normal Cobb angle (more than 18 degrees) and a normal lordotic curve.

20 (87%) of 23 additional fibromyalgia patients (visual inspection group) had a straight cervical spine by visual inspection. They had lost the normal lordotic curve. 3 (13%) fibromyalgia patients had a slightly curved cervical spine. No fibromyalgia patient had a normal cervical lordosis by visual inspection of lateral views of radiographs of the cervical spine. The Cobb angle in 10 rheumatic disease controls was 22.5 degrees (and reported to be 26.8 degrees in healthy controls).

Conclusion: 88 % of fibromyalgia patients in this study had a straight neck based on measuring the Cobb angle, and 90 % had a straight neck (loss of the lordotic curve) by visualizing the lateral view of cervical spine radiographs. The cause of the straight cervical spine in fibromyalgia is unknown. Speculation of the pathophysiology includes chronic muscle contraction and tightness of other soft tissues.

A straight cervical spine in the absence of other radiological abnormalities might assist in the diagnosis of fibromyalgia, and it may be important in attempting to understand the pathophysiology of this disorder.

Abnormalities Of Central Processing Mechanisms In Fibromyalgia. Robert S. Katz[1] and Bhagwan T. Shahani[2]. [1]Rush Medical College, Chicago, IL, [2]University of Illinois College of Medicine, Chicago, IL.

Background/Purpose: Fibromyalgia may be associated with central pain processing abnormalities, including central sensitization. In this study, we describe three patients, two females (41 and 48 years old) and one male (49 years old) who had no evidence of peripheral neuropathy on detailed electrophysiological studies. Each individual patient described a different sensory perception to the same controlled stimulus, suggesting abnormalities of central processing mechanisms.

Methods: Detailed electrophysiological studies including motor sensory nerve conduction as well as late response studies were performed using a TECA EMG machine. Patients were asked to report the sensation they felt when electrical stimulation was delivered to peripheral nerves. The stimulus consisted of single electrical pulses of 0.1to 0.5 msec. duration. The stimulus intensity was adjusted to deliver a supramaximal stimulation.

Results: Motor and sensory nerve conduction as well as late response studies were within normal limits, suggesting that none of these patients had any evidence of peripheral neuropathy. Supramaximal electrical stimulation of peripheral nerves at the level of the ankles in the first patient produced a "burning" pain in the feet, which was so intense that she could not control crying during the study. In the second patient, a single electrical stimulus delivered to the peroneal and tibial nerves produced a ticklish feeling, which elicited uncontrollable laughter on the part of the patient. In the third patient, electrical studies of median and ulnar nerves produced a dull tapping sensation without any discomfort or dysesthesias.

Conclusion: Electrical stimulation of mixed peripheral nerves produced a distinctly different sensory response in each of these three patients with FMS. The stimulus parameter used for this study activated only myelinated fibers; small unmyelinated nerve fibers (C-fibers) were not stimulated. The different types of sensations, including burning and a ticklish sensation experienced by our patients, therefore must have resulted from activation of large and small diameter myelinated nerve fibers. Since the peripheral nervous system was intact in these patients, the perception of burning, tickling, and the dull tapping feeling must be related to abnormalities of central processing mechanisms.

Many of the clinical symptoms of FMS may be related to abnormalities of processing and/or modulating mechanisms in the central nervous system. Depending upon the central mechanism involved, the same stimulus may result in different sensory perceptions. The physiological mechanisms of excitatory postsynaptic potentials (EPSP), inhibitory postsynaptic potentials (FPSP), and presynaptic inhibition, as well as the levels of neurotransmitters and neuromodulation may play a part in producing specific clinical symptoms. Better understanding of these physiological mechanisms will result in better diagnoses and treatment of patients with FMS.

Fibromyalgia and Parental Medical Histories Of Depression and Alcoholism. Robert S. Katz[1], Ben J. Small[2], Sharon M. Ferbert[3] and Susan Shott[4]. [1]Rush Medical College, Chicago, IL, [2]Rush University Medical School, Chicago, IL, [3]Advocates for Funding Fibromyalgia Treatment, Education and Research(AFFTER), Libertyville, IL, [4]Rush University Medical Center, Chicago, IL.

Background/Purpose: We had found in a previous study suggestions of an increased prevalence of depression in the mothers and alcohol abuse in the fathers of fibromyalgia patients. We re-examined this finding in a group of fibromyalgia patients.

Methods: 115 FMS patients and 63 control patients with other rheumatic diseases answered a rheumatology office questionnaire that included questions about whether their mother or father had been diagnosed with or had symptoms of depression, alcoholism, or FMS. The chi-square test of association and Fisher's exact test were used to compare FMS and control patients with respect to percentages. The Mann-Whitney test was done to compare these groups with respect to age. A 0.05 significance level was used and all tests were two-sided.

Results: 81.7% of the FMS patients and 61.9% of the control patients were women (p = 0.004). The mean age was 48.1 ± 12.3 years for FMS patients and 50.7 13.6 for control patients (p = 0.092). 33.0% of FMS patients and 8.1% of control patients reported a depression diagnosis or symptoms in their mothers (p < 0.001). 26.3% of FMS patients reported a depression diagnosis or symptoms in their fathers, compared to 10.0% of control patients (p = 0.013). Although FMS patients were more likely than control patients to report an alcoholism diagnosis or symptoms in their mothers (9.6% vs. 4.8%. p = 0.38) and fathers (19.2% vs. 10.0%, p = 0.18), the differences were not statistically significant. FMS patients were significantly more likely than control patients to report a FMS diagnosis or symptoms in their mothers (26.4% vs. 3.2%. p < 0.001), but not in their fathers (6.2% vs. 0%, p = 0.083).

Conclusion: FMS patients were significantly more likely than control patients to report that their parents had a diagnosis or symptoms of depression, and significantly more likely to report that their mothers had the diagnosis or symptoms of FMS. No statistically significant differences were found with respect to paternal FMS or maternal or paternal alcoholism.

Synergistic Effects Of Transcranial Direct Current Stimulation and Trigger Point Injection For Treatment Of Myofascial Pain Syndrome: A Pilot Study With Randomized, Single-Blinded Trial. Shi-Uk Lee[1], Chang Han Lee[1] and Yoon-Hee Choi[2]. [1]Seoul National University Boramae Medical Center, Seoul, South Korea, [2]Seoul National University Bundang Hospital, Seoul, South Korea.

Background/Purpose: Chronic pain caused by myofascial pain syndrome (MPS) results in generalized and debilitating conditions. Trigger point injection (TPI) is the mainstay of MPS management to reduce acute and localized pain. Other adjunctive intervention to modulate the central pain pathway might be helpful if they are combined with TPI. Transcranial direct current stimulation (tDCS) which is a form of neurostimulation has been reported to be safe and effective in treating chronic pain by changing cortical excitability.

The purpose of this study was to determine whether there is synergistic effect of tDCS and TPI to reduce pain in patients with MPS.

Methods: Subjects: Patients (n=21, 8: M1, 7: DLPFC, 6: sham) with newly diagnosed MPS of shoulder girdle muscles.

Interventions: Patients were randomized into one of 3 groups (2 active and 1 sham stimulation groups) and received TPI. Immediately after TPI, tDCS (2mA, 20min for 5 consecutive days) was administered. For active stimulation groups, tDCS was applied over 2 different locations (primary motor cortex (M1) and dorsolateral prefrontal cortex (DLPFC)).

Outcome Measures: Visual Analogue Scale (VAS), Pain Threshold Test (PTT) and short form of the McGill Pain Questionnaire (SF-MPQ) was measured prior to and immediately after stimulation for 5 consecutive days.

Results: The mean VAS values were decreased in all three groups after 5 days. There was a significant change between before and after stimulation only in the DLPFC group. The significant change in the mean VAS value was shown from after the second stimulation session (p= 0.031) and those remained significant until the last stimulation session (p=0.027).

Conclusion: tDCS over DLPFC may have synergistic effects with TPI to reduce pain in patient with myofascial pain syndrome. tDCS over DLPFC can be used to reverse central pain pathway by modulating cortical plasticity.

Suprascapular Nerve Block For Shoulder Pain In The First Year After Stroke: A Randomised Controlled Trial. Zoe Adey-Wakeling[1], Maria Crotty[1] and E. Michael Shanahan[2]. [1]Flinders University, Adelaide, Australia, [2]Flinders University, Bedford Park, South Australia, Australia.

Background/Purpose: Shoulder pain is a significant complication of hemiplegic stroke in at least 25% of cases. The evidence base for the treatment of hemiplegic shoulder pain is poor. Suprascapular nerve block has been shown to be safe and effective in the treatment of shoulder pain associated with rheumatoid arthritis and degenerative shoulder conditions but its usefulness in a stroke population is unknown.

Methods: We undertook a randomised controlled trial assessing the effectiveness of suprascapular nerve block compared with placebo in a population of stroke patients with hemiplegic shoulder pain. The primary outcome was pain severity measured on a vertical visual analogue scale (VAS), and secondary outcomes are disability (Modified Rankin Scale, Croft Disability Index) and quality of life (EuroQol Health Questionnaire). All participants were assessed at baseline, and then at 1, 4 and 12 weeks post intervention. Both groups continued to receive routine physiotherapy and standard ward care.

Results: Patients who received a suprascapular nerve block (SSNB) consistently demonstrated superior and statistically significant pain reduction at all follow up time points. Mean VAS reduction in the SSNB group was at least 18mm greater when compared to the scores of those who received the placebo injection. The number needed to treat with suprascapular nerve block to reduce one stroke survivor's pain by 50% at four weeks is 4. No significant differences were noted between groups in regards to function or quality of life. No adverse events associated with the intervention were reported.

Conclusion: Suprascapular nerve block is a safe and effective treatment modality in patients with hemiplegic shoulder pain.

Altered Intrinsic Brain Connectivity In The Salience Network Of Fibromyalgia Patients At Rest. Seong-Ho Kim. Division of Rheumatology, Inje University College of Medicine, Haeundae Paik Hospital, Busan, South Korea.

Background/Purpose: Recent studies employing resting-state functional magnetic resonance imaging (fMRI) have demonstrated altered intrinsic brain connectivity in patients with fibromyalgia (FM); however, few studies have addressed the issue of the salience of pain in FM. In this study, we investigated the possible alteration in the salience processing of pain in patients with FM.

Methods: A total of 44 female subjects (20 FM patients and 24 healthy controls) underwent resting-state fMRI. Independent component analysis (ICA) was used for evaluation of resting-state salience network (SN) connectivity. Correlation analyses were performed for determination of correlation between changes in mood and intrinsic connectivity in brain regions within the MPN. The Beck depression inventory (BDI) and Beck anxiety inventory (BAI) were used for assessment of mood changes.

Results: Compared with healthy control subjects, the significant increase in functional connectivity of anterior insula within the SN was found in patients with FM. The increase in functional connectivity within the SN was not associated with symptoms of depression and anxiety.

Conclusion: Increased functional connectivity suggests spontaneous altered activity in the salience of pain in patients with FM implicating enhanced spontaneous salience to pain.

Low Dose Naltrexone In The Treatment Of Fibromyalgia. Samy Metyas[1], Karen Yeter[2], John Solyman[3] and D. Arkfeld[2]. [1]Assistant clinical professor Of Rheumatology at USC, covina, CA, [2]University of Southern California Keck School of Medicine, Los Angeles, CA, [3]Research Associate, Covina, CA.

Background/Purpose: Fibromyalgia is a chronic pain disorder characterized by diffuse musculoskeletal pain, fatigue, sleepdisturbance and cognitive impairment. A significant number of fibromyalgia patients do not respond adequately to the current drugs (pregabalin, milnacipran, duloxetine) approved for fibromyalgia treatment by the Food and Drug Administration (FDA). Thus, there is still a need for adjunctive therapies. Naltrexone is an opioid receptor antagonist used to treat alcohol and opioid dependence. It is hypothesized that low dose naltrexone causes transient blockade of opioid receptors centrally resulting in a rebound of endorphin function which may attenuate pain in fibromyalgia.

Objectives: The aim of this study was to determine the effect of low dose naltrexone on symptoms in fibromyalgia.

Methods: This was a prospective, open label study carried out at a single center. Twenty-five patients diagnosed with fibromyalgia (according to the American College of Rheumatology criteria) participated. Naltrexone was started at a doseof 3 mg at night time and could be titrated up to a maximum of 4.5 mg at night time. Patients were permitted to continue pregabalin, milnacipran, or duloxetine. The primary outcome measure was the Revised Fibromyalgia Impact Questionnaire (FIQR) at month 3. Adverse reactions were also recorded.

Results: Twenty-four females and 1 male were enrolled. Twenty-two patients completed the study. Seven (32%) patients were on naltrexone monotherapy throughout the study. There was a 19.5% overall improvement in FIQR at month 3 with naltrexone therapy. Eleven (50%) had an average of a 41% improvement in the FIQR. The patients reported decreases in anxiety, pain and sleeping habits from baseline. Two patients discontinued the drug because they felt it was ineffective and 1 patient discontinued because of diarrhea.

Conclusion: Treatment with low dose naltrexone may be an effective, highly tolerable and inexpensive treatment for fibromyalgia. Further controlled trials are needed.

SPA Therapy In The Treatment Of Chronic Shoulder PAIN Due To Rotator Cuff Tendinopathy: Rotatherm, A Large Randomized Multicentre Trial. Isabelle Chary-Valckenaere[1], Damien Loeuille[1], Nicolas Jay[1], François Kohler[1], Christian F Roques[2], Michel Boulange[1] and Gérard Gay[1]. [1]Nancy University Hospital, Nancy, France, [2]Université Paul Sabatier, Toulouse, France.

Background/Purpose: To determine whether spa therapy has a beneficial effect on pain and disability in the management of shoulder pain due to chronic rotator cuff lesions.

Methods: This multicentre randomized prospective clinical trial included patients with chronic shoulder pain due to rotator cuff tendinopathy who were attending French spa resorts as outpatients between March 2009 and April 2010. Subjects were randomized into two groups: spa therapy (18 days of standardized treatment) and control (spa therapy delayed for six months). All patients continued usual treatments during the 6-month follow-up period. The main endpoint was the mean change in the DASH score at six months. The effect size (ES) of spa therapy was calculated and the proportion of patients reaching minimal clinically important improvement (MCII) was compared between groups. Secondary endpoints were the mean change in SF-36 components, treatments use, and tolerance.

Results: 186 patients were included in the study (94 controls and 92 in the spa therapy group) and analyzed by intention to treat. At six months, the mean change in the DASH was statistically significantly greater among spa therapy patients than controls (−32.6% and −8.15%, respectively ($p<0.001$)) with an ES at 1.32 (95%CI: −1.68; −0.97). A significantly greater proportion of spa therapy patients reached MCII (59.3% versus 17.9%). Spa therapy was well tolerated, with a significant impact on SF-36 components but not on drug consumption.

Conclusion: Spa therapy provides a highly statistically significant beneficial effect on pain and function in patients with chronic shoulder pain after 6 months compared with usual treatment alone.

Hyperbaric Oxygen Ameliorates Fibromyalgia Symptoms and Functional Impairment–A Randomized Prospective Trial. Shai Efrati[1], Jacob N. Ablin[2], Yair Bechor[1], Shir Daphna-Tekoah[3], Gregory Fishlev[4], Yifat Faran[3], Jacob Bergan[1], Mony Friedman[1] and Dan Buskila[5]. [1]Asaf-Harofeh medical center, Beer Yaacov, Zerifin, Israel, [2]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [3]Ashkelon Academic College, Ashkelon, Israel, [4]Assaf Harofeh Medical Center, Beer Yaacov, Zerifin, Israel, [5]Ben-Gurion University, Beer-Sheva, Israel.

Background/Purpose: Fibromyalgia Syndrome (FMS), considered to represent a prototype of central nervous system sensitization, is a common condition characterized by chronic widespread pain and diffuse tenderness, along with symptoms of fatigue [1,2]. Hyperbaric oxygen (HBOT) has the capacity to induce neuroplasticity in different chronic brain pathologies [3]. The current study evaluated the utility of HBOT for influencing central sensitization as a therapeutic modality for FMS.

Methods: A prospective, randomized, controlled, two-group trial. The population included 60 female patients of ages 21–67years diagnosed with FMS for at least 2 years. Patients were randomized into two groups: a treated group and a cross group. The patients in the treated group were evaluated twice: at baseline and after HBOT. Patients in the cross group were evaluated three times: baseline, after control period of no treatment, and after HBOT. The following HBOT protocol was practiced: 40 sessions, 5 days/week, 90 minutes, 100% oxygen at 2ATA.

At each time point, level of pain was evaluated by physical examination including tender point count and dolorimetry, as well as extensive evaluation of parameters relating to quality of life, presence of widespread pain, fatigue, physical and social function, and symptoms related to anxiety, depression, and somatization.

Results: A significant reduction of all FMS symptoms such as pain (threshold and number of tender points) and fatigue was apparent following HBOT, sessions as well as significant improvement in distress symptoms. Moreover, the quality of life and functional capability of all patients were significantly improved following HBOT sessions. No improvement in any parameter was found during the control period of patients in the cross group.

Conclusion: The results indicate that HBOT can lead to significant improvement in all FMS symptoms as well as significant improvement in patients' quality of life.

Pooled Safety Data From Randomized, Controlled Trials Of Diclofenac Sodium Topical Gel 1% In Subjects With Acute Pain. Roy D. Altman[1], Helmut Pabst[2], Hans-Georg Predel[3], Bruno Giannetti[4], Ian Burnett[5], Morris Gold[6] and Evan F. Ekman[7]. [1]UCLA, Los Angeles, CA, [2]Independent Physician, Gilching, Germany, [3]German Sports University, Cologne, Germany, [4]CRM clinical trials GmbH, Rheinbach, Germany, [5]Novartis Consumer Health, Nyon, Switzerland, [6]Novartis Consumer Health, Parsippany, NJ, [7]Southern Orthopaedic Sports Medicine, Columbia, SC.

Background/Purpose: Diclofenac sodium topical gel (DSG) 1% is clinically proven to be effective and well-tolerated for treatment of osteoarthritis pain and could be appropriate to treat acute conditions, such as ankle sprains and soft tissue injuries. Current treatment options include oral non-steroidal anti-inflammatory drugs (NSAIDs), which may be associated with an increased risk of systemic side effects (eg, gastrointestinal), and topically applied rubefacients, which could be ineffective. Previous pharmacokinetic studies have demonstrated that topically applied diclofenac gel results in low systemic exposure. Three randomized, placebo-controlled phase III clinical trials were conducted to assess the efficacy and safety of DSG 1% in subjects with acute ankle sprain or soft tissue injury/contusion. Safety data from the 3 controlled trials were pooled and are presented in this analysis.

Methods: Two trials were conducted in ankle sprain and 1 trial in contusion. The 3 trials were similar in design and subject population except for the site of the acute injury. Treatment was 3 g DSG 1% or placebo to affected ankle q.i.d. for 7 days or 2 g DSG 1% or placebo to the contusion q.i.d. for 2–7 days, until resolution. AEs were reported either during subject visits or in subject diaries in each trial. The 3 AE databases were pooled for an overall safety analysis. Blood samples were collected for laboratory safety analyses before randomization and at end of study.

Results: Safety data were available for 615 subjects (mean age 30.9±12.0 years). A total of 7788 doses of DSG 1% (N=310) and 7670 doses of placebo (N=305) were applied over the 3 trials. There were no meaningful differences in the incidence of AEs between treatment groups. AEs occurred in 19 DSG 1% subjects (6.1%) and 16 placebo subjects (5.2%). Most were mild and self-resolving. Eight were considered treatment-related: 2 AEs in 1 DSG 1% subject (dry skin and erythema) and 6 AEs in 4 placebo subjects (application site pruritus, joint warmth, erythema, rash and pruritus [2]). There was 1 serious AE in the placebo group (distortion of wrist and rupture of scapholunate ligament), not considered to be treatment-related. Gastrointestinal, hepatic, and renal AEs were rare (≤2 events reported), while hematological and cardiac AEs were absent. Mean values for liver function test results, (alanine aminotransferase, aspartate aminotransferase, and total bilirubin) were within normal ranges at baseline and end of study and did not suggest any clinically significant systemic alterations during the course of the study. The overall safety profile of DSG 1% was similar to that of placebo.

Conclusion: DSG 1% applied 4 times daily for 7 days was found to be well-tolerated and no specific safety concerns were identified in these controlled clinical trials. Overall, the safety profile of DSG 1% demonstrates that it could be an appropriate treatment option for patients with acute painful conditions who have a need to minimize the systemic absorption of NSAIDS.

Is Vitamin D Deficiency a Risk Factor For The Development Of Statin Induced Myalgia, In Patients Treated With Statin? Ozlem Tasoglu[1], Yesim Kutsal[1], Irfan Tasoglu[2], Oya Ozdemir[1] and Yildiz Erdoganoglu[3]. [1]Hacettepe University Faculty of Medicine, Ankara, Turkey, [2]Türkiye Yuksek Ihtisas Training and Research Hospital, Ankara, Turkey, [3]Hacettepe University, Ankara, Turkey.

Background/Purpose: Vitamin D deficiency has become pandemic in the industrializing societies. Recently, the role of vitamin D deficiency in the development of statin myopathy has started to be discussed. The purpose of this study is to compare the serum vitamin D levels and objective muscle strength measures in males with or without myalgia who were under statin treatment.

Methods: Seventeen patients (mean age: 49,1± 7,9) with a diagnosis of statin induced myalgia and 23 patients (mean age: 50,6± 9,0) without myalgia were included in this study. The patients in the two groups were matched according to age, level of physical activity and sunlight exposure. After a detailed physical examination, serum 25-OH vitamin D levels were measured. The patients with myalgia were asked to complete a 10 cm Visual Analog Scale (VAS) and McGill-Melzack Pain Questionnaire. The measurement of grip strength were performed using Jamar type hydraulic hand dynamometer, and isometric/isokinetic measurements of the biceps and quadriceps muscles were performed using Biodex System 3 device.

Results: Statin dosages (mg) were: 19,1±16,7 (myalgia) and 17,0±7,7(without myalgia) (p value: 0,639) and durations (month) were: 32,9±28,4 (myalgia) and 40,4±39,4 (without myalgia (p value: 0,606).There was no significant difference in the mean values of vitamin D levels in both groups (myalgia: 34,8 ng/mL, without myalgia:31,9 ng/mL). In general, the patients with statin induced myalgia had an intermittant pain in the proximal parts of their extremities. They declared that the pain was induced by activity or exercise and reduced with rest. The mean VAS score was determined as 4.0 cm (min:1.3, max:8.4). No statistically significant correlations were found between the vitamin D levels and any of the pain parameters in the myalgia group (p>0,05). Furthermore, the measurement with the hand dynamometer and the isometric and isokinetic muscular strength analyses for both groups were found to be similar except for the biceps isokinetic 120° TT/VA.

Conclusion: The male patients with or without statin induced myalgia have similar serum vitamin D levels and muscle strength. Thus, it seems like vitamin D deficiency might not be a risk factor for the development of statin induced myalgia.

A Potential Use Of Neurotropin™, a Novel Neuro-Modulating Medication, For The Treatment Of Chronic Pain and Fibromyalgia. Kenji Miki[1], Ryota Hashimoto[2], Kenrin Shi[3] and Masao Yukioka[1]. [1]Yukioka Hospital, Osaka, Japan, [2]Osaka University Graduate School of Medicine, Suita, Japan, [3]Osaka University Hospital, Suita, Japan.

Background/Purpose: To date, no established treatment for chronic pain including fibromyalgia has been specified in Japan. Neurotropin, a non-protein extract isolated from the inflamed cutaneous tissue of vaccinia virus-inoculated rabbits, is often prescribed for mild to severe chronic musculoskeletal pain such as backache, lumbago and stiff neck in Japan. It is also prescribed for fibromyalgia, and its annual overall sales excesses 200 million USD solely in Japan. We conducted a study on efficacy of Neurotropin on chronic pain including fibromyalgia.

Methods: Among 175 patients with chronic pain, Neurotropin was prescribed for 113 patients in whom psychiatric disorders were absent or not contributing to the pain symptom. Of these, 84 patients met both 1990 classification criteria for fibromyalgia by American College of Rheumatology (ACR) and 2010 preliminary diagnostic criteria for fibromyalgia also proposed by ACR. The mean age of the patients was 51.5 year old (range, 13~81). All patients were assessed and diagnosed by experienced rheumatologists with necessary laboratory and imaging examinations, and any presence or absence of psychiatric disorders were also assessed by an experienced psychiatrist. Neurotropin was firstly introduced as monotherapy with the mean daily dosage of 15 Neurotropin unit. When the efficacy was insufficient after 1 month intake of Neurotropin, other neuro-modulating medications such as selective serotonin reuptake inhibitors (SSRI), serotonin-noradrenaline reuptake inhibitor (SNRI), tricyclic anti-depressants (TCA) and clonazepam were added. Intravenous tramadol was administered only when pain relief by above drugs were insufficient. The degree of pain was assessed by 10cm VAS scale (0, no pain; 10, the worst pain that the patient had ever experienced), and the efficacy was rated as "good", 50% or greater improvement in VAS scale at the final evaluation; "fair", 20%–50% improvement; and "poor", less than 20% improvement or worsening. Correlation between the dosage of Neurotropin and outcome was studied by Spearman's rank correlation test.

Results: After 1 month of Neurotropin intake, 23 patients expected to continue it as monotherapy but remaining 90 patients needed additional medications. Among 23 patients with monotherapy, the efficacy was "good" in 14 patients, "fair" in 6, and "poor" in 3. In the remaining 90 patients, the concomitant drugs were SSRI in 18 patients, SNRI in 4, TCA in 37 and clonazepam in 31. Then, only when these combined therapy of oral neuro-modulating drugs failed, intravenous tramadol was administered in 16 patients. Finally, the overall efficacy of Neurotropin was rated as "good" in 63 patients, "fair" in 39, and "poor" in 11, and its dosage and outcome demonstrated significant correlation either in total ($p=0.0416$), or in monotherapy ($p=0.0073$).

Conclusion: Neurotropin, a novel neuro-modulating drug which activates the descending inhibitory system from brain to peripheral nerve, was effective for the treatment of fibromyalgia and chronic pain.

1098

Safety and Efficacy Of Influenza Vaccination In Patients Suffering From Fibromyalgia. Jacob N. Ablin[1], Valerie Aloush[1], Ayelet Brill[2], Mark Berman[1], Merav Barzilai[1], Dan Caspi[1], Michal Mandelboim[3], David Levartovsky[4], Ari Polachek[5], Yonatan Wolman[1], Daphna Paran[6], Michael Barkagan[1] and Ori Elkayam[2]. [1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]Sheba Medical Center, Ramat Gan, Israel, [4]Tel Aviv Medical Ctr, Tel Aviv, Israel, [5]Tel Aviv Medical Center, Tel Aviv, Israel, [6]Tel Aviv Sourasky Medical Ctr, Tel-Aviv university, Tel Aviv, Israel.

Background/Purpose: Fibromyalgia syndrome (FMS) is considered to result from exposure of a genetically susceptible individual to various "triggers" including physical trauma, stress etc. Viral infections have also been linked to FMS etiology. A possible role of vaccination in FMS etiology has been raised. Gulf war syndrome, an entity with considerable clinical overlap with FMS, has been linked with exposure to multiple vaccinations. The possibility that vaccination–related adjuvants induce a multisystem disorder characterized by symptoms such as fatigue, cognitive impairment and arthralgia has also been raised. In view of this background, the aim of the current study was to evaluate the efficacy and safety of influenza vaccination in FMS patients.

Methods: Patients (19) were recruited at a specialized FMS clinic. After informed consent, patients underwent physical and dolorimetric examination and fulfillment of ACR 1990 FMS classification criteria was documented. Patients answered the Fibromyalgia Impact Questionnaire (FIQ) as well as the widespread pain index (WPI) and Symptoms severity scale (SSS) - components of the 2010 diagnostic criteria. 38 Healthy subjects were recruited as controls. All participants were vaccinated with inactivated split virion influenza vaccine, recommended by the WHO and serum was collected for antibody titer determination.

Six weeks after vaccination, patients were re-evaluated. Sera were tested by Haemagglutination (HI) against the three antigens included in the vaccine: A/California (H1N1), A/Perth (H3N2) and B/Brisbane. Humoral response was defined as either a fourfold or more rise in titer, or a rise from a non-protective baseline level of <1/40 to 1/40. Geometric mean titers of antibodies were calculated.

Results: No severe vaccination reactions were observed. As shown in the table, no significant change was observed between WPI, SSS and FIQ values before and after vaccination, indicating no worsening of FMS symptoms.

FMS patients (n=19)	Pre-Vaccination	Post-vaccination	P value
WPI (SD)	13.3 (4.7)	11 (5.4)	0.19
SSS (SD)	9.1 (1.6)	9.0 (2.7)	0.88
FIQ (SD)	67.3 (14.2)	65.9 (22.0)	0.82

Vaccine immunogenicity: Six weeks after vaccination, FMS patients displayed significant increases in geometric mean titers of HI antibody against H1N1 and B/Bri viruses: from 29.9 to 387.9 ($p=0.0011$), from 82.9 to 460.9 ($p=0.0007$) and from 28.8 to 96.0 ($p=0.08$) respectively. The rates of sero-protection (defined as antibody levels above 1/40) increased from 22.9% for H1N1 to 89.5% post vaccination. Significant increase in HI antibody titers were also demonstrated among healthy controls: H1N1 ($p=0.000435$), B/Bri ($p=0.000331$) and Perth ($p=0.004953$).

Conclusion: Influenza vaccination was both safe and effective in FMS patients. Neither severe adverse reactions nor significant worsening of FMS symptoms were recorded following vaccination and serological evidence of sero-conversion was observed, similar to healthy controls. In view of these results, FMS patients should be encouraged to undergo influenza vaccination according to standard WHO recommendations.

1099

IgG Autoantibodies Against p29ING4 In Early-Stage Type I Complex Regional Pain Syndrome (CRPS) and In Other Inflammatory Diseases Involving The Joints. Niklas T. Baerlecken[1], Torsten Witte[2], Reinhold E. Schmidt[1], Christina Lansche[1], Michael Bernateck[3] and Nils Pursche[3]. [1]Medical University Hannover, Hannover, Germany, [2]Medical University Hannover, Hanover, Germany, [3]Medical University of Hannover, Hannover, Germany.

Background/Purpose: Complex regional pain syndrome (CRPS, a.k.a. RSD) usually occurs after limb injury, especially fractures of the distal radius and elective hand surgery. Recent research has shown that some patients respond to treatment with immunglobulins supporting an autoimmune pathogenesis of CRPS. There are, however, no diagnostic markers of CRPS.

Methods: We screened both sera of patients with early-stage type I CRPS and spondyloarthritis (SpA), rheumatoid arthritis (RA), granulomatosis with polyangitis (GPA) for new autoantibodies by using a protein array. Protein-array Human Fetal Brain Cat. Lib. No. 888 was obtained from imagenes biolifesciences (Berlin, Germany,).

In order to study larger numbers of serum samples, we then established ELISA prototypes using the recombinant p29ING4 protein and the synthetic peptides with aminoacid sequence MAAGMYLEHYLDSIENLPFELQRN and DKHIRRLDTDLARFEADLKEK of p29ING4. For the evaluation of the autoantibodies, we used sera of 36 patients with early-stage type 1 CRPS before starting standard-treatment with glucocorticoids, and as controls of patients with SpA (n=50), RA (n=38), GPA (n=40), and blood donors (BD)(n=96).

Results:

	CRPS	SpA	RA	GPA	BD
recombinant p29ING4	39%	32%	21%	8%	2%
Aa1-23	28%	28%	45%	5%	2%
Aa94-114	42%	36%	8%	3%	2%
Combining all antigens	75%	62%	53%	8%	7%

Conclusion: IgG autoantibodies binding to p29ING4 are most frequently in early-stage type I CRPS compared to SpA, RA, GPA and BD supporting the autoimmune pathogenesis of CRPS.

Our findings could help both in the differential diagnosis of different kinds of arthritis and might be an interesting diagnostic marker of CRPS.

Relationship Between Body Mass Index, Fat Mass and Muscle Mass Withmusculoskeletal Pain In Community Residents. Young-Il Seo[1], Hyun Ah Kim[2], Nam H. Cho[3] and Jong Jin Yoo[4]. [1]Hallym university sacred heart hospital, Kyunggi, South Korea, [2]Hallym University Sacred Heart Hospital, Kyunggi, South Korea, [3]Ajou University School of medicine, Suwon, South Korea, [4]Armed Forces Capital Hospital Seongnam Republic of Korea, Seongnam si, South Korea.

Background/Purpose: The association between parameters related to obesity like fat mass, fat/muscle mass ratio and metabolic syndrome and musculoskeletal pain has scarcily been assessed. The objective of the present study was to evaluate the relationship between fat mass, muscle mass, fat/muscle mass ratio and metabolic syndrome and musculoskeletal pain including widespread pain in community residents.

Methods: In the Korean Health and Genome Study, 1530 participants completed pain questionnaire and underwent dual x-ray absorptiometry calculating body composition. Widespread pain was defined as pain above the waist, below the waist, on both sides of the body and in the axial region. Three other categories of pain in these analyses were pain in two or more regions that did not meet the criteria for widespread pain, pain in one region, and no pain. Metabolically obese normal weight (MONW) was defined as the presence of more than 3 features of metabolic syndrome and normal BMI. Tests for a linear trend across categories of pain constellations were performed using Mantel-Haenszel chi-square tests for categorical variables and the F-statistics from linear regression models for continuous variables.

Results: BMI, fat mass, muscle mass and fat mass/muscle mass ratio were significantly correlated with pain categories, however, the correlation was only significant among women. The presence of widespread pain was significantly associated with BMI, fat mass and fat/muscle mass ratio after multivariate analysis, however, the association was significant only among women. The prevalence of MONW was 16.4% (12.7% in men, 19.4% in women). Compared to non-obese subjects without metabolic syndrome features, widespread pain was more common in subjects with MONW subjects.

Conclusion: Fat mass, fat/muscle mass ratio and metabolic syndrome as well as BMI was significantly correlated with musculoskeletal pain.

Neuromuscular Taping On Patients With Fibromyalgia May Be a Useful Tool To Relief Muscular Pain. Camillo Giacomelli, Antonino Santagati, Arianna Consensi, Alessandra Rossi, Stefano Bombardieri and Laura Bazzichi. Rheumatology Unit, Pisa, Italy.

Background/Purpose: Fibromyalgia (FMS) is an illness characterized by an anomalous perception of the painful stimuli that are supposed to be attributable to a combination of interactions among neurotransmitters, nociceptive routes, individual psychological characteristics, hormones and the nervous system. Moreover the FM patients frequently showed a muscular stiffness. The use of an elastic tape, neuro muscular Tape, in medicine practice has recently gained popularity and may help improve postural control deficits and pain relief in several conditions. The purpose of this study was to examine the immediate effects of neuro muscular Taping on pain and functionality in FM patients.

Methods: We enroll 40 FM patients, all female, mean age 49.80 $\pm$ 13.79 yrs. A specialist in neuro muscular tape applications, applied the tape on superior fibers of the trapezius, and after 1 hour we evaluate by a goniometer the inclination and rotation of the neck and by a VAS scale, the pain related to the neck. We excluded the patients with a clinical condition that could interfere with measurement, such as cervical hernia or traumatic neck condition.

Results: We found a significative reduction in neck pain after the tape application ($p<0.001$). Moreover we observe that degree rotation (left and right) and lateral inclination in FM patients had increase after the tape application. In table 1 we summarize the significant results of the application of the tape. Any correlation between age and clinical parameters were found. In any case we observed a local reaction.

Table 1. clinical data of FM patients

	Before tape application	After tape application	p value
VAS pain	7.050 ± 1.825	3.850±1.494	<0.0001
Right rotation (Degree)	43,28 ± 12,43	57,38 ± 10,23	<0.001
Left rotation (Degree)	44,83 ± 11,44	57,80 ± 9,608	<0.001
Right inclination (Degree)	14,10 ± 5.55	19,80 ± 5.94	<0.001
Left inclination (Degree)	13,38 ± 5.66	19,95 ± 6.013	<0.001

Conclusion: The neuromuscular taping is a non-invasive technique that require a specific skills to obtain satisfactory results. Moreover the application of Neuro muscular taping is generally well tolerated by the patients, and the local reaction is very rare. This is a preliminary work that underline the beneficial effects of neuro muscular tape application in FM patients. The improvement of local pain could be associated to a reduction of muscular stiffness, which leads to an increase of motility. The limit of the study was the absence of the control group, for example a placebo group. We actually conducted a study with a prolonged observation and with a control group.

The Correlation Among Macromastia, Spinal Pain, Thoracic Kyphosis and Fall Risk. Ulku Akarirmak[1], Hidayet Sari[1], Murat Uludag[1], Sibel Ozbayrak[1], Hasan Battal[1], Hasan Huseyin Gokpinar[1] and Sukru Aras[2]. [1]Istanbul University Cerrahpasa Medical School, Istanbul, Turkey, [2]Private Capa Hospital, Istanbul, Turkey.

Background/Purpose: Large breasts are commonly associated with musculoskeletal symptoms such as neck, shoulder, and back pain, as well as stiff neck, painful brasserie strap grooving, and intertrigo in the inframammary folds. We aimed to show if there is any correlation among size of breasts, spinal pain, thoracic kyphosis (Cobb) angle and fall risk in a group of women with macromastia.

Methods: Seventy women diagnosed with macromastia included to the study. The complaints, physical examination findings and radiographyc thoracic kyphosis angle were recorded. The "Tetrax Interactive Posturography and Balance System" (Tetrax System, Ramat Gan, Israel) was used for assessment of fall risk.

Results: The mean age of patients was 43.6 ± 11.8 (21–66), and body mass index (BMI) was 30.9 ± 5.1. All patients had painful brasserie strap grooving, and persistent intertrigo in the inframammary folds. The rate of back, neck, shoulder and low back pain were 91.4%, 52.8%, 44.5%, 27.2%, respectively. Duration of musculoskeletal pain was 8.4 ± 5.7 years (1–23). The mean thoracic kyphosis (Cobb) angle was 40.6 ± 12.1 (range, 17–64). In the present study, it was found a very strong correlation between the breast size and BMI (r:0.780, p=0.0001). There was also a moderate correlation between breast size and posturographyc falling index (r:0.300, p=0.048).

Conclusion: Macromastia might be also associated with increased thoracic kyphosis and fall risk as well as musculoskeletal symptoms such as neck, back and shoulder pain.

Brain Derived Neurotrophic Factor Is Elevated In Patients With Rheumatoid Arthritis and Secondary Fibromyalgia. Able Lawrence, Venkatesh Pai, Rajni Srivastava, Vikas Agarwal, Ramnath Misra and Amita Aggarwal. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Background/Purpose: Secondary Fibromyalgia is seen in 15% of patients with rheumatoid arthritis (RA). Neurotrophins are elevated in patients with active arthritis and BDNF is elevated in primary Fibromyalgia. We did a cross sectional and longitudinal study to evaluate the association of FMS and tender points with RA disease activity, depression and neurotrophins in patients with RA.

Methods: Female patients of RA with and without Fibromyalgia (ACR 1990 criteria) were recruited. RA disease activity was assessed by DAS28-3v, depression by BPHQ and health related quality of life by WHO HRQoL Bref. Plasma neurotrophins NGF, BDNF, NT3 and NT4 were tested by ELISA. Longitudinal analysis was done using linear mixed model analysis using a fixed effects model adjusting for covariates.

Results: We recruited 40 female patients with RA and secondary FMS and 43 with RA and no FMS. Mean age was 42.2 yrs (20– 66), duration of RA 5.9 yrs (0.6– 22) and mean age of onset was 36.4 yrs (16–59). Of these 38 patients had two or more visits and 14 had 3 visits. At baseline, patients with FMS had more depression by BPHQ (12.8 vs 8) and tender points (14.8 vs 3.4) compared to those without FMS while HAQ, DAS28, age and ESR were similar.

FMS status, DAS28-3v, swollen joints, and HAQ-DI were independent predictors of fibromyalgia tender points with standardized regression coefficients of 0.75 (p<0.001), 0.13 (p<0.05), 0.16 (p<0.005) and 0.14 (p<0.05) respectively. Quality of life was significantly decreased in physical, psychological, social and environmental domains in patients with fibromyalgia even after controlling for disease activity, HAQ-DI and depression with mean differences of 5.71 (p<0.001), 6.06 (p<0.001), 9.19 (p<0.001) and 2.99 (p<0.001) respectively.

At baseline patients with RA and FMS had higher mean BDNF (49.8 +/− 18.2 ng/ml) compared those without FMS (41.5 +/− 17.5; p<0.05). On multivariate analysis, the estimated means were 54.5 ng/ml (SE 2.1) and 43.5 ng/ml(SE 2.3) respectively with p<0.001 and. NGF, NT3 and NT4 were detectable in 3, 14 and 4 patients at baseline.

Conclusion: Rheumatoid arthritis disease activity and disability influences the severity of fibromyalgia. BDNF is elevated in secondary FMS associated with RA. Elevated BDNF may be contributing to FMS in RA patients.

1104

Quality Of Life and Burden Of Ehlers-Danlos Syndrome (EDS) Type III. Marion Geoffroy[1], Christelle Guillaume[1], Amélie Servettaz[1], Violaine Laurant-Noel[1], Christine Serratrice Sr.[2], Jacques Serratrice[3], Boris Bienvenu[4] and Roland Jaussaud[1]. [1]Hôpital Robert Debré. CHU de Reims, Reims, France, [2]Foundation Hopital Saint Joseph, Marseille, France, [3]Hôpital de la Timone, Marseille, France, [4]Division of Internal Medicine, Centre Hospitalier Régional Universitaire de Caen, Côte de Nacre, Caen, France, Caen, France.

Background/Purpose: The Ehlers-Danlos syndrome (EDS) is a clinically and genetically heterogeneous group of inherited connective tissue disorders. Hypermobility type EDS is the most common type of EDS, although commonly misdiagnosed variant of EDS. It is also the most difficult type to diagnose due to the lack of specific diagnostic laboratory tests. This type is characterized by marked joint instability, mild cutaneous involvement, chronic pain, fatigue, gastrointestinal, pelvic, neurologic and cognitive dysfunctions. The burden of delayed diagnosis and misdiagnosis, the severity of symptoms may contribute to explain.

Methods: A questionnaire study was performed among 43 Hypermobility type EDS patients followed beetwen January and June 2013 in our center. Diagnosis was established on both the Villefranche and Brighton criteria. The following dimensions were assessed: fatigue (Fatigue severity scale, FFS), pain (visual analog scale VAS), anxiety (Hamilton score), depression (Beck depression inventory, BDI-II). Quality of life (QoL) was assessed through the French version of Short Form 36 (SF36).

Results: Thirty five females (81%) and 8 males (19%) were included during the study period (January to June 2013). All patients had an hypermobility assessed by a Beighton score > 5. The mean age of EDS patients was 41 years. The mean age at onset was 18 years. 84% had a fatigue score ≥ 6 (FFS) and 17% reached the maximal score of 7. Of the patients included, 43 (100%) reported having pain. The mean VAS score was 67 mm. Pain was most frequently localized in neck, shoulder, hips, and forearms, and legs. 90 % of patients reported myalgia in trunk, arms and legs. Headhache, abdominal, thoracic and pelvic pains were also frequently reported (> 50%). All the patients reported anxiety. 92 % suffered from major anxiety. Depression affected 54% of patients and a quarter presented a severe depression as depicted by the BDI-II (score ≥ 27). A marked deterioration of QoL was observed in all SF36 domains.

Conclusion: Hypermobile EDS patients are characterized by fatigue, musculoskeletal pain, anxiety and depression. All of these symptoms are major determinant of disability, which significantly influences the

quality of life. Treatment of pain and fatigue should be a prominent aspect of clinical management of EDS in association with rehabilitation therapies.

1105

New and Not Improved? The Efficacy Of FMS Medications. Robert S. Katz[1], Hannah Bond[2], Lauren Kwan[2], Jessica L. Polyak[2] and Susan Shott[3]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL, [3]Rush University Medical Center, Chicago, IL.

Background/Purpose: A wide variety of medications are used to treat FMS, with an equally wide variety of opinions about their efficacy. We asked FMS patients which medications they had tried for treating their disease, and how effective these medications were.

Methods: 150 office patients with FMS (130 women and 20 men; mean age 51 + 12) completed a questionnaire about the FMS medications they had taken and the effectiveness of these medications (rated as 1 = not helpful, 2 = mildly helpful, 3 = moderately helpful, and 4 = very helpful). The two-sided Friedman test was used to compare pairs of medications with respect to the ratings given by patients who had tried both medications, using a 0.05 significance level.

Results: The following medications were tried by at least 40% of patients: NSAIDs (93%), prednisone (72%), Flexeril (64%), amitriptyline (64%), Norco/Vicodin (56%), Tramadol (50%), Lyrica (47%), Cymbalta (45%), and Ritalin (44%). The two least frequently tried medications were Vyvanse (9%) and nortriptyline (12%). Based on the percentage of patients who rated the medication as moderately or very helpful, the most helpful medications were Norco/Vicodin (75%), prednisone (70%), Ritalin (65%), Tizanidine (58%), NSAIDs (56%), phentermine (56%), amitriptyline (52%), Tramadol (50%), and Nuvigil/Provgil (50%). The least helpful medications were Savella (12%) and Lunesta (19%). Norco/Vicodin was significantly more helpful than Lyrica (median 4 vs. 1, $p < 0.001$), Cymbalta (median 4 vs. 1, $p < 0.001$), Flexeril (median 4 vs. 2, $p < 0.001$), Tramadol (median 4 vs. 2, $p < 0.001$), prednisone (median 4 vs. 3, $p = 0.004$), NSAIDS (median 3.5 vs. 2, $p = 0.001$), and amitriptyline (median 4 vs. 3, $p = 0.041$). Prednisone was significantly more helpful than Cymbalta (median 3 vs. 1, $p < 0.001$), Lyrica (median 3 vs. 1, $p = 0.019$), Flexeril (median 3 vs. 2, $p = 0.028$), and Tramadol (median 3 vs. 2, $p = 0.009$). Tramadol was significantly more helpful than Cymbalta (median 2 vs. 1, $p = 0.018$). Ritalin was significantly more helpful than Lyrica (median 3 vs. 1, $p = 0.008$), Cymbalta (median 3 vs. 1, $p = 0.003$), NSAIDs (median 3 vs. 2, $p = 0.028$), and Flexeril (median 3 vs. 2, $p = 0.034$). NSAIDs were significantly more helpful than Cymbalta (median 2 vs. 1, $p = 0.001$) and Lyrica (median 2 vs. 1, $p = 0.020$). Amitriptyline was significantly more helpful than Cymbalta (median 2 vs. 1, $p = 0.005$) and Lyrica (median 2 vs. 1, $p = 0.033$).

Conclusion: Older medications were significantly more helpful for treating FMS than some newer medications. However, a wide variety of FMS medications may still be needed because different patients often respond to different medications.

1106

Effectiveness Of Interdisciplinary Program For Fibromyalgia. Dianne Whiting, Debbi Huskey, Emily Rosario and Samy Metyas. Casa Colina Centers for Rehabilitation, Pomona, CA.

Background/Purpose: Fibromyalgia (FM) affects 5 million Americans, and the prevalence is estimated to be 2– 6 percent in the general population. The symptoms associated with FM significantly affect patients' quality of life and can lead to extensive use of health care services. Fibromyalgia is a chronic, widespread pain condition accompanied by fatigue, tenderness, decrements in physical functioning, sleep disturbance, and disruptions in psychological and cognitive functioning (for example, memory problems, diminished mental clarity ("fibro fog"), mood disturbances, and lack of well-being). In this study we investigated the effectiveness of an interdisciplinary program for FM on overall pain and disability resulting from this syndrome.

Methods: The Fibromyalgia Management Program at Casa Colina Hospital is an eight-week outpatient program based on a wellness model designed to educate patients with FM in the self-management of health. Participants meet 3 times weekly and treatment includes pool therapy, education, relaxation, exercise, Yoga, and Tai Chi along with psychology and home management techniques. All patients enrolled in the outpatient FM program were asked to complete several outcomes at admission and discharge from the program, including the Revised Fibromyalgia Impact Questionnaire (FIQR), Tampa scale, and general questions about fatigue and pain. Questions were asked to compare the original onset of symptoms with the initial date of diagnosis.

Results: The study population consisted of 28 patients who completed the FM program. The mean age was 51 years with a range from 25 to 67 years. Using the FIQR, we found a significant reduction in the impact of fibromyalgia symptoms between admission and discharge. When patients were separated into two groups based on their initial FIQR scores we found that those with more severe involvement had more significant changes throughout the program when compared with patients with less involvement. The Tampa scale was used to assess fear of movement. While there was no overall significant change in movement-related fear avoidance patients did report a significant change in how they viewed the *impact* of pain throughout their body.

Conclusion: Taken together our findings support the efficacy of an interdisciplinary approach including exercise, education, cognitive behavioral therapy, and home management skills to improve outcomes in patients with FM. Specifically, we found the most significant changes in symptoms and impact of FM, resulting in improved daily life. Results from this study suggest the importance of establishing multidisciplinary treatment centers to deliver comprehensive primary care to people with Fibromyalgia.

A Randomized Trial Of a Physical Self-Management Program For Fibromyalgia Syndrome. Aline Ranzolin[1], Suélem S. Barros[2], Vanessa M. Fernandes[3], Eduardo A. S. Pimentel[3], Claudia Diniz L. Marques[1] and Angela Luzia B. Pinto Duarte[1]. [1]Hospital das Clínicas - Universidade Federal de Pernambuco, Recife, Brazil, [2]Programa de Pós-Graduação em Ciências da Saúde da Universidade Federal de Pernambuco, Recife, Brazil, [3]Centro Universitário Maurício de Nassau, Recife, Brazil.

Background/Purpose: Fibromyalgia syndrome (FMS) is a painful disorder that interferes directly in the functional capacity and quality of life. Treatment advocates interventions in the physical, pharmacological, cognitive-behavioral and educational aspects. Scientific evidences show that physical exercises minimize pain, fatigue and muscle tension, improving levels of stress, anxiety and depression in individuals with FMS, when performed on a regular basis. Educational policies for self-management of symptoms are increasingly encouraged as complementary treatment, due to the chronicity of the clinical picture. This study was made to evaluate the effectiveness of a physical self-management program for FMS patients.

Methods: We conducted a single-blind, randomized trial of a physical self-management program for FMS patients compared with a control group. The physical self-management program consisted of sessions lasted 90 minutes each and took place once a week for 10 weeks, aiming to wellness and postural education and active stretching exercises, that were orientated to been done at home. The control group was only monitored through medical appointments, without any physical intervention. No drug changes were allowed during the study period. It was selected 45 FMS patients that were on stable treatment in the last month before the selection. It was excluded patients that were on physical therapy, in use of auxiliary resources gait and those who have autoimmune rheumatic diseases associated or relevant uncontrolled comorbidities. They were evaluated through the Fibromyalgia Impact Questionnaire (FIQ), the Pain Visual Analogue Scale (VAS pain) and the Sit and Reach Test (SRT). The number of analgesic tablets ingested was accounted during the study through diaries. The data were been compared through Student t test, Mann-Whitney test and Wilcoxon test and results are presented as significant differences with 95% confidence intervals.

Results: There was a loss of 11% of the sample (4 in experimental group and 1 in controls) and the study ended with 40 participants. The experimental group (n=19) had clinically important improvements in the levels of flexibility, VAS pain, FIQ total score and in the FIQ's issues Feel Good, VAS fatigue and VAS stiffness (table). The VAS depression in the control group (n=21) worsened significantly. The experimental group consumed less

analgesic tablets during the study period (p=0.046). There was no difference regarding non-refreshing sleep and anxiety.

Variables Experimental	Evaluation	Group Control	Group P Value	
Flexibility (cm)	Initial	18.25 ± 10.93	23.23 ± 7.24	p = 0.041†
	Final	25.74 ± 8.36	21.23 ± 7.49	
	P Value	**p = 0.001***	**p = 0.067***	
VAS pain	Initial	8.46 ± 1.11	7.70 ± 1.90	p = 0.067†
	Final	5.77 ± 2.65	7.27 ± 2.20	
	P Value	**p = 0.004 ‡**	**p = 0.347***	
Feel good	Initial	8.73 ± 1.78	8.44 ± 2.21	p = 0.743†
	Final	4.74 ± 2.66	8.10 ± 2.91	
	P Value	**p < 0.001***	**p = 0.782‡**	
VAS fatigue	Initial	9.11 ± 0.94	8.48 ± 2.46	p = 0.907†
	Final	7.68 ± 2.11	9.00 ± 1.92	
	P Value	**p = 0.006‡**	**p = 0.264***	
VAS stiffness	Initial	8.26 ± 2.33	7.71 ± 1.95	p = 0.245†
	Final	7.00 ± 2.49	7.95 ± 2.04	
	P Value	**p = 0.037***	**p = 0.554***	
VAS depression	Initial	8.74 ± 1.48	7.19 ± 3.46	p = 0.162†
	Final	7.53 ± 2.91	8.71 ± 2.03	
	P Value	**p = 0.083‡**	**p = 0.004‡**	
FIQ total score	Initial	79.17 ± 11.47	73.07 ± 16.22	p = 0.182*
	Final	64.46 ± 15.66	77.16 ± 12.70	
	P Value	**p = 0.001***	**p = 0.101***	

Conclusion: The physical self-management program significantly improved pain, fatigue, stiffness, total FIQ and flexibility in patients with FMS and could be an important complementary therapy, mainly, in a context of public medical assistance.

Methylphenidate Improves Concentration, Energy and Mood In Fibromyalgia. Robert S. Katz[1], Hannah Bond[2] and Frank Leavitt[3]. [1]Rush Medical College, Chicago, IL, [2]Rheumatology Associates, Chicago, IL, [3]Rush University Medical Center, Chicago, IL.

Background/Purpose: Central nervous system stimulants such as methylphenidate appear to have short term benefits for naming speed and cognitive functioning in fibromyalgia (FMS). Methylphenidate quickly allows patients with FMS to operate at a more normal pace in naming words and broadly improves cognitive functioning. The present study addresses the question of whether the benefits of methylphenidate extend to concentration, energy and feelings of well-being that are often found with treatment of ADHD.

Methods: Interference from pain on energy, mood and concentration was measured on a 10 point visual analogue scale, with endpoint of one indicating that pain does not interfere, and 10 indicating that pain completely interferes. The four measures were administered to 48 patients with FMS, before receiving methylphenidate and post methylphenidate. The FMS patients were female, met the new ACR criteria for FMS. Methylphenidate dosage was clinically determined and ranged from 10 to 60 mg. The median methylphenidate usage at retesting was 30 days.

Results: The mean age of the FMS sample was 48.3±12.3 years. Table 1 shows test performance at the pretest and posttest sessions. A repeated measures ANOVA showed significant reduction in pain interference on energy ($p<0.01$), concentration ($p<0.001$) and mood ($p<0.05$). The largest change occurred with concentration.

Conclusion: Methylphenidate, a primary treatment for attention deficit hyperactivity disorder (ADHD), was helpful in alleviating some of the problems patients with fibromyalgia have with concentration, energy and mood. The parallel treatment results underscore the possibility of a link between ADHD and fibromyalgia. In a previous investigation of linkage, adult symptoms of ADHD and FMS were found to co-occur more frequently than might be expected by chance. However, as a group, FMS patients satisfying criteria for ADHD in adulthood were not abnormally inattentive or disinhibited in childhood. The likelihood that ADHD in FMS has its onset in childhood is minimal. Energy, concentration and mood can be improved in fibromyalgia by the administration of methylphenidate.

Which Baseline Characteristics Influence The Response To Milnacipran In Patient With Fibromyalgia? Olivier Vitton[1], Olivier Vitton[1], Pierre Bunouf[2], Lilia Abtroun[3] and Frederic Bonfils[1]. [1]Pierre Fabre, Castres, France, [2]Pierre Fabre, Toulouse, France, [3]Ariana Pharma, Paris, France.

Background/Purpose: Milnacipran (MLN) has demonstrated its benefit in treating patients with fibromyalgia. Fibromyalgia is a persistent pain condition that aggregates numerous symptoms (pain, fatigue, sleep disturbance, quality of life impairment...). The aim of this study is to find patient baseline characteristics in fibromyalgia clinical trials that influence MLN treatment effect.

Methods: Two methods were used to address this problem: the first is knowledge-oriented and consisted of post-hoc analyses describing the relationships between the clinical outcome and baseline factors. The second is a data mining analysis which takes into consideration relationships between the outcome and the candidate influencing factors. Analysis was performed using KEM (Knowledge Management and Extraction) algorithm. Data were analyzed from phase 3 placebo-controlled clinical trials. In total, 75 variables including total scores, sub-scores and items of baseline scales and demography were selected as candidate influencing factors. Continuous variables were categorized into 3 categories defined according to the 33.3% and 66.6% percentage limits of values in the whole sample. Outcomes were the response on the composite criterion, improvement in both pain, and PGIC and on the two components separately. Treatment effect was measured using odds-ratio.

Results: More than 2500 patients were investigated from three clinical phase III clinical trials (FMS-031, MD-02 and GE-302). Different variables corresponding to potential patient profiles led to a significant increase in odds-ratio measuring the treatment effect versus placebo. For the 100mg/d dosage, 8 variables were identified which increase the odds-ratio beyond 2. The most three relevant variables are "unable to work due to FMS" OR=2.63 [2.15,3.19], "MFI-General Fatigue" OR=2.22 [1.81,2.72], and "FIQ-Physical functioning" OR=2.21 [1.80,2.70]. For the 200mg/d dosage, 18 such variables were identified. The most three relevant are "FIQ-Stiffness" OR=3.45 [2.78,4.30], "VAS-Pain(CRF)" OR=3.12 [2.50,3.90], and "FMS Duration" OR=2.99 [2.39,3.74].

For all the identified variables, the odds-ratio increase is coherent across the composite responder criterion and the two components Pain and PGIC. The identification of "fibromyalgia duration" as influencing factor in the exploratory KEM analysis was confirmed in a post-hoc analysis that compared the response rates in three subgroups: short, medium and long fibromyalgia duration. This analysis evidenced higher response rates and a higher odds-ratio in the "medium fibromyalgia duration" group. Furthermore, the "high fibromyalgia duration" group seemed to benefit more from the 200mg/d dosage.

Conclusion: KEM analysis allowed the identification of baseline characteristics associated with higher odd-ratios suggesting a greater treatment effect. Thus patient profiling can be very useful for clinicians to individualize drug therapy and advice. The coherence across the primary endpoint and its two components confirmed the robustness of the primary endpoint in the milnacipran fibromyalgia development program.

Onychopathy: When Ultrasound Can Help The Dermatologist. Andrea Delle Sedie[1], Valentina Dini[2], Linda Carli[3], Sabrina Barbanera[2], Lucrezia Riente[1], Stefano Bombardieri[1] and Marco Romanelli[2]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Dermatology Unit, University of Pisa, Pisa, Italy, [3]GenOMeC PhD, University of Siena, Siena, Italy.

Background/Purpose: Nail disease represents a very important symptom in subjects with psoriasis and psoriatic arthritis (PsA). From a dermatologic perspective, onychopathy is a predictor for the development of arthritis while, for rheumatologist, it is associated with distal interphalangeal joint arthritis. Besides, it is included in the CASPAR classification criteria for PsA. Psoriatic onychopathy has recently become a new hot topic for ultrasound (US) in

rheumatology and a few authors have illustrated the most important findings. Nowadays, one of the main problems for dermatologists is the differential diagnosis between psoriatic onychopathy and onychomycosis or, in general, infective disease of the nail.

The aim of the study is to find possible differences in the US findings between onychopathy due to psoriasis and mycosis.

Methods: A group of patients referring to the Dermatology unit of our hospital, presenting onychopathy, was examined by US (Logiq9, General Electrics, USA), using a multi-frequency linear probe operating at 15 MHz. The nail to be assessed was decided by the dermatologist who also requested cultural examination when onychomycosis was suspected. The US examination, made by a rheumatologist who is well experienced in US and unaware of the diagnosis of the patient, was performed according to what was shown by Gutierrez *et al* (1). We also used the group of patients without an established diagnosis as self-controls, scanning at least one other nail apparently without any visible onychopathy. The final diagnosis was given by the dermatologist based on the results of the clinical examination and the laboratory test.

Results: 15 patients were studied (10 with an established diagnosis of psoriasis and 5 with a final diagnosis of mycosis). The results of the US examination are reported in Table I.

Table 1.

	US findings			
Diagnosis (N of nails)	**Conserved 3 lines appearance (yes/no)**	**Nail thickness (mm)**	**Nail matrix thickness (mm)**	**Power Doppler score (yes/no; mean value 0–3)**
Psoriasis (N=20)	11/9	0.56 ± 0.13	2.11 ± 0.20	15/5 (0.95)
Mycosis (N=8)	8/0	0.82 ± 0.19	3.65 ± 1.39	4/8 (0.625)
Controls (N=8)	8/0	0.65 ± 0.26	2.42 ± 1.36	1/5 (0.20)

Conclusion: As shown in the table, none of the patients with mycosis presented a change in the trilaminare pattern of the nail, which was thickened with respect to both the psoriasis and the "healthy" nail group. Both the mycosis and psoriasis group showed an increase of power Doppler signal with respect to the "healthy" control group. The striking difference between US findings in patients with psoriasis and mycosis could suggest that US examination of the nail might be an easy and rapid way to differentiate between nail involvement in psoriasis and mycosis.

Utility Of An Ultrasound Enthesitis Score As a Complementary Diagnostic Tool To Detect Psoriatic Arthritis In Patients With Psoriasis. Tomas Cazenave, Christian A. Waimann, Gustavo Citera and Marcos G. Rosemffet. Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina.

Background/Purpose: To evaluate the prevalence of subclinical enthesopathy in psoriasis (Ps) patients compared with psoriatic arthritis (PsA) and healthy controls (HC), and to assess the utility of an ultrasound enthesitis score as a complementary diagnostic tool to detect PsA in patients with Ps.

Methods: We designed a cross-sectional study including patients with diagnosis of Ps (dermatologist criteria), PsA (CASPAR criteria) and HC. Each subject underwent clinical and ultrasonographic evaluation. Ultrasound evaluation was performed by two rheumatologists who were blind to clinical examination. Ten enthesal sites were evaluated: bilateral quadriceps tendon, proximal and distal patellar ligament, Achilles tendon and plantar aponeurosis. Ultrasonographic enthesopathy (UE) was defined as the presence of at least one of the following characteristics: thickening, erosion, enthesophytes and/or bursitis. The Glasgow Ultrasound Enthesitis Scoring System (GUESS) was calculated, with ranged from 0 to 36, being 36 the highest involvement. The performance of the score to discriminate between PsA and Ps was evaluated using ROC's curve. An alternative model was tested, evaluating the addition of Power Doppler (PD) assessment to the GUESS. Differences among groups were compared using Pearson's chi-squared test and Kruskal Wallis. Post hoc analysis was adjusted by Bonferroni method. P value of 0.05 was considered statistically significant.

Results: We included 51 subjects: PsA=16, Ps=15 and HC=20. Mean age was 42±13 years and 39% were female. Mean cutaneous and joint disease duration were 17±13 and 5±7 years, respectively. Half of PsA patients presented clinical enthesopathy compared with none in the other groups. A total of 510 enthesal sites were evaluated (PsA=160, Ps=150, HC=200). UE was present in 291 (57%) sites versus only 13 (3%) using clinical examination. Ps patients showed UE in 98 (65%) enthesal sites. Tendon's thickening was present in 25%, enthesophytes 43%, Bursitis 5%, Erosion 9% and Power Doppler 7%. All patients with Ps showed at least one enthesal site affected on ultrasound evaluation. None of these sites were positive on clinical examination. When comparing with PsA and HC, Ps patients showed significantly less thickning and enthesophytes than PsA, and a significantly higher frequency of enthesophytes, erosions and PD than HC. Mean GUESS score were different across the groups: PsA= 13±4, Ps=8±4, HC=3±2 ($p<0.01$). The area under the curve (AUC) for the diagnosis of PsA was 0.79 (95%CI= 0.63 to 0.95). A cutoff point >=8 showed a sensitivity and specificity of 94% and 60%, respectively [Likelihood ratio (LR) + 2.34; LR-0.1]. The addition of PD did not have a significant impact on the discriminant ability of the score (AUC 0.78, 95%CI= 0.62 to 0.95).

Conclusion: All patients with psoriasis showed subclinical enthesopathy on ultrasonographic evaluation. The GUESS showed a high sensitivity and moderate specificity to discriminate between patients with PsA and Ps. This score may be useful as a complementary diagnostic test for early detection of joint and enthesal involvement in patients with psoriasis.

1112

Examining Phenotypes Of Patients With Psoriasis In The Prepare Study For Similarities Between Diagnosed Psoriatic Arthritis and Those With Signs Of Subclinical Psoriatic Arthritis Detected By Imaging. Philip J. Mease[1], Javier Coindreau[2], Lotus Mallbris[2], Annette Szumski[2] and Heather Jones[2]. [1]Swedish Medical Center and University of Washington, Seattle, WA, [2]Pfizer Inc., Collegeville, PA.

Background/Purpose: Progression of psoriatic arthritis (PsA) has traditionally been evaluated using clinical assessments. However, a strong relationship between clinical and radiological outcomes has been shown, as radiological changes often precede clinical damage detection. Our post-hoc analysis examines the characteristics of plaque psoriasis (Ps) patients without diagnosed PsA, but with imaging evidence of damage (possible early signs of PsA). The objective was to determine whether these patients have a phenotype more similar to patients diagnosed with PsA than to patients confirmed non-PsA who exhibit no evidence of damage.

Methods: In the PREPARE study, all subjects were initially seen by a dermatologist and assessed for Ps. Subjects determined to have Ps, regardless of severity, were randomized to receive one of three PsA screening questionnaires. Following questionnaire completion, patients were evaluated by rheumatologists to establish or exclude a clinical diagnosis of PsA based on the subject's medical history and physical examination. Designated site imaging assessments (magnetic resonance imaging [MRI] and ultrasound) were performed in a subset of subjects to confirm the absence or presence of abnormalities. Continuous parameters were analyzed using one-way ANOVA while categorical parameters were analyzed using chi-square tests.

Results: In these analyses, 285 patients were diagnosed with PsA and 115 were determined not to have PsA (non-PsA) by clinical assessment. Baseline demographic and disease characteristics of non-PsA patients ± imaging abnormalities were similar to one another and tended to be different to those of PsA patients. At baseline, PsA patients were significantly older, with a higher proportion of whites, higher DAS28 and had more swollen/tender joints, higher ESR, worse HAQ, longer Ps duration and worse EQ-5D than non-PsA patients either ± imaging abnormalities (Table). For most radiological measures the proportions of patients with abnormalities were similar between PsA and non-PsA groups, with the exception of dactylitis (Table). Of the imaged patients, PsA patients have a significantly greater likelihood of dactylitis than non-PsA patients (44.3% vs 9.2%; OR=7.81; P<0.0001), while the association was more muted (90.9% vs 79.1%;OR=2.65; P=0.0301) when combining all imaging abnormalities in the 'any abnormality' group.

Baseline Demographics and Disease Characteristics

Characteristic	Non-PsA + imaging result for "any abnormality" n=91	Non-PsA – imaging result for "any abnormality" n=24	PsA n=285	*P*-value†
Age, years	47.5	46.6	51.5	0.014
Race, white (%)	87.9	91.7	97.2	0.007
Duration Ps, years	16.5	17.1	21.7	0.011
DAS28	2.1	2.1	3.3	<0.001
Swollen joint count	0.03	0.08	2.7	<0.001
Tender joint count	1.5	1.2	5.0	<0.001
Erythrocyte sedimentation rate (ESR)	10.1	11.8	15.5	0.009
Health assessment questionnaire disability index (HAQ)	0.3	0.3	0.7	<0.001
EuroQol-5 dimensions utility score (EQ5D)	0.8	0.8	0.7	0.003

Radiological measure	Patients with imaging abnormalities PsA (%)	Non-PsA (%)
Any abnormality¶	90.9	79.1*
Enthesitis (Ultrasound)	70.1	61.1
Abnormality of foot joint (Ultrasound)	5.3	2.7
Abnormality of hand joint (Ultrasound)	5.3	0.9
Abnormality of sacroiliac joint (MRI)	61.3	54.0
Abnormality of spine (MRI)	50.7	45.0
Dactylitis‡ (Ultrasound)	44.3	9.2**

*P<0.05, **P<0.0001 vs patients with PsA, †Overall P-value indicates whether at least one of the three groups are statistically different.
‡*The number of subjects with ultrasound imaging of dactylitis (n=126) was smaller than other imaging studies (n=172–188) because at 2 sites dactylitis imaging was performed only in those with a suspected problem. This may have introduced some bias in the ultrasound evaluation and analyses of dactylitis.*
¶Combines the data of patients with any of the abnormalities listed in the table.

Conclusion: A higher proportion of patients diagnosed with PsA had subclinical imaging abnormalities than non-PsA patients. Radiological detection of 'any abnormality' confirmed a significant difference in the extent of joint abnormalities in diagnosed PsA patients to those with imaging detected subclinical joint damage. The baseline results indicate a phenotypic difference between PsA patients and non-PsA patients, but a lack of distinction between non-PsA patients with and without imaging detected abnormalities.

Scintigraphic Detection Of TNFα With a Radiolabeled Anti-TNFα In Patients With Active Peripheral Spondyloarthritis and Rheumatoid Arthritis. Philippe Carron[1], Bieke Lambert[2], Filip De Vos[3], Gust Verbruggen[1], Dirk Elewaut[1] and Filip van Den Bosch[1]. [1]Department of Rheumatology Ghent University Hospital, Ghent, Belgium, [2]Department of Nuclear Medicine Ghent University Hospital, Ghent, Belgium, [3]Department of Radiopharmacy Ghent University, Ghent, Belgium.

Background/Purpose: Spondyloarthritis (SpA) and rheumatoid arthritis (RA) are the most common chronic inflammatory joint diseases, with a combined prevalence close to 2%. The pathogenetic role of proinflammatory cytokines such as tumor necrosis factor alpha (TNFα) is now beyond question, with immunohistological studies showing the cytokine and its receptors to be present in inflamed synovial tissue. Nevertheless, there is a large variability in the level of TNFα expression, which may have clinical consequences, since it has been recognized that a subset of patients do not respond to TNFα antagonism. Accurate information on TNFα expression in the joints might be helpful to optimise and/or monitor the effect of TNFα blockade. Scintigraphy with 99mTc-radiolabelled anti-TNFα monoclonal antibodies may offer an exciting possibility for identifying TNF driven disease and predict anti TNF responders in SpA and RA patients in a non-invasive way.

Objectives: To evaluate the concordance between uptake of Tc99m-labeled certolizumab pegol and peripheral arthritis/dactylitis as assessed by clinical examination and ultrasound (greyscale (GS), power Doppler (PD)) in patients with active RA and peripheral SpA (pSpA).

Methods: Certolizumab pegol was conjugated with succinimylhydrazinicotinamide (S-HYNIC) and subsequently radiolabeled with Tc99m: patients were injected with 740 MBq, and whole body images and static images of hands and feet were acquired immediately following administration, after 4–6 hours and 24 hours post injection. Prior to the immunoscintigraphy, patients underwent a full rheumatological examination (68-joint count, dactylitis assessment), as well as a targeted ultrasound assessment. Ultrasound and immunoscintigraphic findings were scored semiquantitatively (0: normal, 1: mild, 2: moderate, 3: severe).

Results: Six patients were included (RA n=3, pSpA n=3). In most of the clinically involved joints of hands and feet a marked tracer uptake was visualized within minutes following injection, with the evaluation 4–6 hours post-injection, yielding the best discriminatory results. In peripheral SpA patients with dactylitis a typical scintigraphic pattern was observed with tracer uptake in both the joints and the accompanying flexor tendon. Concordance results per patient are shown in table 1. Overall, a concordance of approx. 90% was found for ultrasound and swollen joint count.

Table 1.

Patient		Concordance scintigraphy vs ultrasound PD	Concordance scintigraphy vs ultrasound GS	Concordance scintigraphy vs tender joints	Concordance scintigraphy vs swollen joints
1	p SpA	91,3%	91,3%	89,1%	91,7%
2	p SpA	100%	100%	98,4%	98,8%
3	p SpA	91,5%	91,5%	87,5%	86,6%
4	RA	80,8%	80,8%	32,3%	78,3%
5	RA	89,3%	89,3%	78,1%	85,5%
6	RA	100%	80,8%	95,2%	98,4%
Overall		92,1%	88,9%	80,1%	89,9%

Conclusion: In patients with active RA or pSpA, a high concordance rate was observed between Tc99m-labeled certolizumab pegol uptake and clinically or ultrasound detected peripheral arthritis or dactylitis (the latter with a distinct scintigraphic pattern). This technique might provide a possibility to perform 'evidence-based biological therapy' by assessing in inflamed joints/tendons the local expression of a target cytokine with a radiolabeled antibody, before using the same cold antibody therapeutically.

Entheses Ultrasound In Patients With Ankyosing Spondylitis: A Controlled Study With Healthy Subjects. Suellen Narimatsu, Andre Rosenfeld, Germana. B. Q. Estrela, Jorge E. P. Proglhof, Rita N.V. Furtado and Jamil Natour. Universidade Federal de São Paulo, São Paulo, Brazil.

Background/Purpose: Inflammation of the entheses (enthesitis) is a characteristic finding of ankylosing spondylitis (AS). Despite the growing interest in rheumatology for musculoskeletal ultrasound (US), there are not many studies evaluating the entheses in AS through the US.

The purpose of the study are: to compare US findings of entheses between AS patients and healthy subjects; to correlate US findings with clinical, functional and inflammatory aspects in patients with AS.

Methods: We conducted a cross sectional study of 50 patients with AS and 30 healthy volunteer subjects matched for age and gender. Were evaluated by US the following entheses: brachial triceps, femoris quadriceps, proximal patellar tendon, distal patellar tendon, calcaneal tendon, and plantar fascia. The clinical evaluation of patients included visual analogue scale (VAS) for pain, swollen and global health scale, calculation of BASDAI, BASFI, BASMI, HAQ-S, ASDAS-VHS and clinical enthesitis index SPARCC (Spondyloarthritis Research Consortium of Canada Enthesitis Index). The US was performed at right and left entheses of by a radiologist expert in musculoskeletal "blind" to clinical findings and based on MASEI index (Madrid Sonographic Enthesis Index) and the analysis of its sub items (bursistis, calcification, erosion, power doppler, thicknening of tendon, structural change). For evaluation was used the Esaote MyLab60 machine equipped with a linear transducer with a frequency of 6–18 MHz.

Results: Were evaluated by US 960 entheses of total sample of 63 men (78,75%) and 17 women (21,25%). The patients had mean age of 43,44 (+ 9,91) years and healthy subjects 38,7 (+8,52) years. The mean disease duration was 11,11 (+ 6,77) years. The comparison of average MASEI total score between patient and control groups (16,32 + 11,11/ 10,70 + 5,27) was not statistically different (p = 0,519). There was a statistical difference between groups for the detection of erosion (17 patients/0 healthy; p= 0,00) and power Doppler (PD) in calcaneal entheses (6 patients/0 healthy; p= 0,053) and for erosion (7/0; p=0,037) and thickening of the plantar fascia (38/9 p = 0,002); with an odds ratio of 3,47 (p = 0,03) of belonging to AS group, according to logistic regression. There was no difference between groups for ultrasound evaluation of other entheses. Correlation of entheses US findings and clinical, functional, inflammatory aspects was weak. However, the PD of the calcaneal entheses was correlated with VAS pain (0,344 p= 0,00) and VAS swollen (0,486 p = 0,00). The VAS pain and VAS for swollen of the calcaneal entheses correlated statistically (0,653 p = 0,00).

Conclusion: At ultrasound, the entheses of the feet were the only parameters able to differentiate AS patients from healthy subjects. This difference was mainly due to bone erosion in both the calcaneal entheses, as in plantar fascia. The PD on the calcaneal entheses was the only parameter on US that correlates with clinical variables.

Prevalence Of Structural and Inflammatory Sacroiliitis, Assessed Using Computed Tomography and MR Imaging, In Inflammatory Bowel Disease: A Retrospective Study In 78 Patients. Sophie Leclerc-Jacob[1], Guillaume Lux[1], Anne Christine Rat[1], Valérie Laurent[1], Alain Blum[1], Isabelle Chary-Valckenaere[1], Laurent Peyrin-Biroulet[1] and Damien Loeuille[2]. [1]Nancy Teaching Hospital, Nancy, France, [2]CHU Brabois, Vandoeuvre les Nancy, France.

Background/Purpose: The primary objective was to assess the prevalence of structural and inflammatory sacroiliitis on computed tomography (CT) and MRI in inflammatory bowel disease (IBD). The secondary aim was to elucidate clinico-biological factors associated with the presence of sacroiliitis in patients with IBD.

Methods: This study involved 78 patients suffering from IBD who were followed in a gastroenterology department between 2004 and 2011: 61 of them with Crohn's disease (CD) (78.2%) and 17 with ulcerative colitis (UC) (21.8%). Clinico-biological, endoscopic and imaging (CT and MRI) data were collected during patient follow-up. Structural sacroiliitis was assessed from CT exams performed according to the modified New-York criteria for structural assessement. Inflammatory sacroiliitis was assessed on axial and coronal fat suppressed injected T1-weighted sequences according to ASAS (Assessment of SpondyloArthritis international Society) criteria. Both imaging modalities were scored blindly by two independent readers (a rheumatologist and a radiologist) and the diagnosis of sacroiliitis (structural and inflammatory) was established by consensus.

Results: The prevalence of structural sacroiliitis was 14.1% (n=11) and that of inflammatory sacroiliitis 15.4% (n=12). On MRI, unilateral sacroiliitis was depicted in five cases and bilateral sacroiliitis in seven. The prevalence of sacroiliitis according to both imaging modalities was 28.2% (n=22). Sacroiliac joints (SIJ) were considered normal in 71.8% (n=56). Disease duration of IBD was significantly associated with the presence of structural sacroiliitis (p=0.01) on CT and inflammatory sacroiliitis (p=0.02) on MRI. Others factors such as gender, age, type of IBD, localization of IBD, surgery history, biological inflammation, bowel disease activity and treatment were not associated with sacroiliitis.

Conclusion: Structural or inflammatory sacroiliitis was revealed by CT or MRI in 28.2% of patients suffering from IBD. These imaging methods have a complementary role in establishing a diagnosis of sacroiliitis and contributing to an earlier diagnosis of axial spondylarthritis.

1116

A Prospective Evaluation Of The Diagnostic Value Of Conventional Radiography, Ultrasound and MRI In Comparison To Clinical Examination For The Assessment Of Heel and Knee Enthesitis In Patients With Peripheral Spondyloarthritis and Controls. Xenofon Baraliakos[1], Uta Kiltz[2], Frank Heldmann[1], Heiner Appel[3], Friedrich Dybowski[4], Manfred Igelmann[5], Ludwig H. Kalthoff[6], Claudia Klink[7], Dietmar MJ Krause[8], Ertan Saracbasi[1], Elmar Schmitz-Bortz[9] and Jügen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Ruhr-University Bochum, Herne, Germany, [3]Rheumatology and Nephrology Practice, Hamm, Germany, [4]Rheumatology Practice, Herne, Germany, [5]Private Rheumatology office, Bochum, Germany, [6]Private rheumatology office, Herne, Germany, [7]Private rheumatology office, Gladbeck, Germany, [8]Internistische und rheumatologische Gemeinschaftspraxis, Gladbeck, Germany, [9]Rheumatism Practice in Hattingen, Hattingen, Germany.

Background/Purpose: Spondyloarthritides (SpA) are characterized by inflammatory and structural changes in the axial skeleton and in peripheral joints and entheses. Imaging has an essential role in the new classification criteria for axial SpA (axSpA) but not for peripheral manifestations (pSpA). This is largely due to limited knowledge about the value of imaging to detect peripheral arthritis and enthesitis in SpA and whether it differentiates SpA from other conditions (non-SpA). We evaluated the significance of imaging procedures and their influence on treatment decision in patients with peripheral involvement of the lower limbs in pSpA vs. non-SpA.

Methods: Consecutive patients with pSpA (n=30) and non-SpA (n=30), aged <45 years presenting with a painful heel or knee were examined by a rheumatologist, blinded for the patient's diagnosis, who decided on the further treatment based on the actual clinical findings. Thereafter, several imaging procedures were performed: conventional radiographs, power-doppler ultrasound (PDUS) and magnetic resonance imaging (MRI) of the painful sites. In total 105 entheses, 71 heels and 34 knees were assessed and evaluated. Finally the treatment decisions were re-evaluated.

Results: The groups were similar in mean age (37.2±6.8 years), CRP (0.6±0.9mg/dl), NRS-pain (6.1±2.1) but symptom duration (SpA: 17.2±27.5 vs. non-SpA: 4.4±4.3 months) and HLA-B27 (67% in axSpA vs. 13% in non-SpA) differed (both n<0.005). At presentation <66% of patients were taking NSAIDs, <35% DMARDs and <20% biologics. A total of 71 heels and 34 knees were examined in both groups. There were no differences in the distribution of lesions between patients with pSpA and non-SpA. Pathologic findings were discovered most frequently using MRI of the heel (85.3% of patients), while x-rays were regarded pathologic in only 16.7% of patients (p<0.05). Bone erosions in the Achilles' insertion as assessed by PDUS occurred more frequently in pSpA than in non-SpA: 48.6 vs. 23.5% (p=0.002) and the patellar tendon at the tibial tuberosity as assessed by MRI was thicker in pSpA: 38±8mm vs. 34±5mm in non-SpA (p=0.011), while inflammatory findings were seen in similar frequencies. Based on the clinical evaluation only, a change in treatment was suggested in 47% and 57% of patients with axSpA and non-SpA, respectively. Imaging (only US and MRI) contributed to

Conclusion: In symptomatic patients with knee or heel involvement, heel erosions (assessed by PDUS) and patellar tendon thickness (assessed by MRI) helped to differentiate pSpA from non-SpA patients but active enthesitis did not. Imaging of inflammation but also of chronic changes at peripheral sites contributed in addition to the clinical findings to make treatment decisions in a limited number of patients with pSpA but not with non-SpA.

Integrated ^{18}f-Fluoride Positron Emission Tomography and Magnetic Resonance Imaging Of The Spine – a Pilot Study and Comparison Of Signals In Patients With Axial Spondyloarthritis. Xenofon Baraliakos[1], Dr. Christian Buchbender[2], Ben Ostendorf[3], Verena Hartung, MD[4], Thorsten Poeppel, MD[4] and Juergen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Univ. Duesseldorf, Düsseldorf, Germany, [3]Heinrich-Heine-University, Duesseldorf, Germany, [4]University Duisburg-Essen, Duisburg, Germany.

Background/Purpose: Positron emission tomography (PET) is a high sensitive nuclear imaging technique that depicts functional processes within

the body. PET scanners detect annihilation radiation from radioactive decay of a positron-emitting radionuclide labeled to a biologically active molecule (tracer) and introduced into the body. User-defined cross-sectional images of the tracer distribution can then be reconstructed from the acquired 3D data set. ^{18}F-fluoride (^{18}F) can be used for PET as a bone-seeking agent reflecting bone perfusion and remodeling. The concentration of the tracer then represents the metabolic activity and regional bone remodeling. Recently, an integrated PET/MR device was introduced with the ability to provide simultaneously acquired images that combine morphological and metabolic information. Based on our long experience with MRIs of patients with axial spondyloarthritis (axSpA) we inaugurated a pilot study with simultaneous PET/MR in order to examine whether the addition of the PET technique may provide different and additional information in comparison to MRI alone.

Methods: Eleven axSpA patients, median age 39 years, disease duration range 0.5–10 years, mean BASDAI 5.3, most of them fulfilling the NY criteria for AS, were examined by PET/3-Tesla MRI 40 minutes after injection of a mean dose of 157 MBq of ^{18}F using a integrated whole-body PET/MR scanner (Siemens Biograph mMR®). 3T-MRIs were scored blinded to patient′s clinical characteristics by two readers (1 rheumatologist and 1 radiologist/nuclear medicine specialist) using the Berlin MRI score and also by recording inflammatory lesions on a vertebral edge (VE) level. In a second step PET/MRIs were read blindly by the same readers also based on the VE involvement of individual vertebral bodies.

Results: Acquisition of whole-spine integrated ^{18}F PET/MRI scans was successful in all patients. The resulting mean effective radiation dose per patient was 3.76 mSv. Co-registration of PET/MRI fusion images was highly accurate and allowed a precise comparison of MRI and PET findings. The mean Berlin MRI score was 6.8 (range 0 – 31). In the direct comparison of the MRI and PET signal the two readers saw consistent signals in almost 90% of the sites studied. However, there were some areas where signals differed, for example within existing syndesmophytes where the PET signal was increased but conventional MRIs showed no signal of active inflammation, or the area of sternum and lateral or posterior spinal elements such as facet joints and spinous process.

Conclusion: The new technique of integrated PET/MRI provides largely similar imaging signals as conventional MRI. However, we did observe differences between the two modalities - especially in areas with less inflammatory activity where bone metabolism seemed to be active or in areas with blurred resolution on conventional MRI. More studies are needed to answer the question whether the differences between these techniques are pathogenically relevant, whether they can be reliably reproduced and quantified, and, of course, whether they are sensitive to change. Especially the possibility that PET detects osteoblastic activity in areas where no inflammatory signal is detected with MRI seems to be of interest.

1118

Assessment Of Structural Damage In Patients With Ankylosing Spondylitis Using 18F-Fluoride Positron Emission Tomography-Magnetic Resonance Imaging. GeunTae Kim[1], Seung-Geun Lee[2], Seong-Ho Kim[3], Joung-Wook Lee[4] and Seung-Hoon Baek[5]. [1]Kosin University College of Medicine, Busan, South Korea, [2]Divsion of Rheumatology, Department of Internal Medicine, Pusan National University School of Medicine, Pusan National University Hospital, Busan, South Korea, [3]Division of Rheumatology, Inje University College of Medicine, Haeundae Paik Hospital, Busan, South Korea, [4]Divsion of Rheumatology, Department of Internal Medicine, Busan St. Mary's Medical Center, Busan, South Korea, [5]Divsion of Rheumatology, Department of Internal Medicine, Ilsin Christian Hospital, Busan, South Korea.

Background/Purpose: 18F-fluoride uptake represents active osteoblastic bone synthesis. We explored structural damage of patients with ankylosing spondylitis (AS) using 18F-fluoride positron emission tomography (PET)-magnetic resonance imaging (MRI).

Methods: Whole spine of 6 male AS patients was examined with 18F-fluoride PET-MRI and conventional radiography. All participants were biologics naïve patients and fulfilled modified New York criteria. All images were assessed by two independent observers blinded for clinical data who recorded the presence or absence of increased 18F-fluoride uptake lesion in PET, acute (type A) and advanced (type B) corner inflammatory lesion (CIL) in MRI and syndesmophyte in conventional radiography at the anterior vertebral corners (Figure 1). Increased 18F-fluoride uptake was defined as an uptake which is greater than the uptake in the adjacent normal vertebral body. The association of increased 18F-fluoride uptake lesion with CIL and syndesmophyte was investigated by generalized linear latent mixed models analysis (GLLMM) to adjust within-patient dependence for total numbers of vertebral corners.

Results: There were 49 type A CIL (17.8%), 7 type B CIL (2.5%) and 38 increased 18F-fluoride uptake lesion (13.8%) out of 276 vertebral corners (C2 lower to SI upper) and 30 syndesmophyte (20.8%) out of 144 vertebral corners (C2 lower to T1 upper and T12 lower to SI upper). Increased 18F-fluoride uptake lesion was significantly associated with type A CIL (OR=6.9, 95% CI=3.1–15.2, p<0.001), type B CIL (OR=10.7, 95% CI=2.1–55.1, p=0.005) and syndesmpophyte (OR=55.6, 95% CI=7.3–422.3, p<0.001).

Conclusion: Our findings suggest that increased bone synthetic activity assessed by 18F-fluoride tracer uptake in the spine of AS patients can be associated with both inflammation and pre-existing new bone formation.

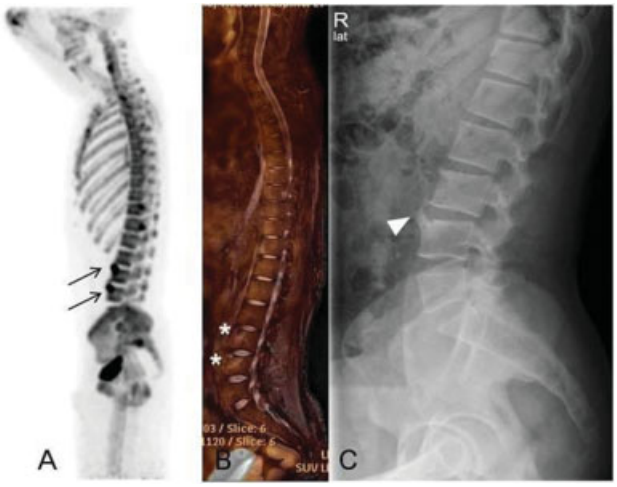

Figure 1. Forty-two-year-old male patient with ankylosing spondylitis. Increased 18F-fluoride uptake in positron emission tomography (arrows in A) and type B corner inflammatory lesion in short tau inversion recovery magnetic resonance image (asterisks in B) at L3 and 4 upper and corresponding syndesmophyte at L4 upper (arrowhead in C).

Quantification Of Inflammatory Disease Of Spine In Ankylosing Spondylitis Using Volumetric Magnetic Resonance Imaging Analysis. Ejaz Pathan[1], Adrian Lim[2], Andy Graham[3], Keshthra Satchithananda[2], Dobrina Hull[4], Sonya Abraham[5], Anshul Rastogi[6], Andrew Keat[7], Mark Hinton[8], Olga Kubassova[9], Peter C. Taylor[10] and J.V. Hajnal[11]. [1]Kennedy Institute of Rheumatology, London W6 8RF, United Kingdom, [2]Imperial College Healthcare NHS Trust, London, United Kingdom, [3]Image Analysis, London, United Kingdom, [4]The Kennedy Institute of Rheumatology, London, United Kingdom, [5]Charing Cross Hospital, Imperial college NHS trust London UK, London W6 8RF, United Kingdom, [6]Barts and the London NHS Trust, London, United Kingdom, [7]Northwick Park Hospital, Harrow, United Kingdom, [8]Image Analysis Ltd, London, United Kingdom, [9]Image Analysis Ltd., Leeds, United Kingdom, [10]University of Oxford, Oxford, United Kingdom, [11]King's College London, London, United Kingdom.

Background/Purpose: To develop methodology for quantification of spinal inflammation in AS using a volumetric MRI-based technique and to explore relationships between these findings and clinical measures of disease activity.

Methods: MRI scans were undertaken using the same scanning protocol on a 3T Philips Achieva system in 11 AS patients prior to and 12 weeks after commencing anti-TNF therapy. Scans were anonymized for patient identity and time points. They were initially scored using the Berlin method by 2 musculoskeletal radiologists (AL and KS) concurrently. Images were subsequently assessed using Dynamika software to perform volumetric analysis by 2 independent scorers (scorer 1-EP and scorer 2- AL). Areas in mm^2, volumes in mm^3 and intensity of corresponding lesions drawn by both scorers were also compared using

Bland-Altman plots. The product of volume in mm^3 and mean intensity was calculated. The volume in mm^3 of lesions was compared to total Berlin scores as well as BASDAI scores using Spearman Rank correlation. Percentage change in volume, intensity and the product of volume and intensity was also compared to percentage change in BASDAI scores.

Results: Bland-Altman plots showed good inter-observer variability for corresponding areas in mm^2, volume in mm^3 and mean intensity of lesions but compared most favourably for maximum intensity.

Correlations were observed between total volume scores and total Berlin scores, more so at baseline ($r=0.7$, $p = 0.01$ for scorer 1, $r=0.63$, $p=0.04$ for scorer 2) than at follow-up ($r=0.4$, p value $= 0.14$). No correlation was seen between volumes and BASDAI scores. However, good correlations were seen between percentage change in BASDAI and percentage change in volume in mm^3 ($r=0.8$, $p=0.002$ for scorer 1 and $r=0.6$, $p=0.04$ for scorer 2) as well as the product of volume and intensity ($r=0.7$ for both scorers, $p=0.02$ for scorer 1 and $p=0.03$ for scorer 2). A poor correlation was seen between percentage change in Berlin scores and percentage change in BASDAI ($r=0.2$, $p=0.56$).

Conclusion: Volumetric analysis of active bone oedema lesions compares well to semi-quantitative scoring using the Berlin method. Unlike semi-quantitative scoring, volumetric analysis also shows a good correlation to change in BASDAI.

1120

Concordance Between 'a Positive MRI Of The Sacroiliac joints' Based On The Local Reading Versus a Centralised Reading: Experience From The DESIR-Cohort. Rosaline van den Berg[1], Fabrice Thévenin[2], Antoine Feydy[2], Pascal Claudepierre[3], Monique Reijnierse[1], Alain Saraux[4] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Paris Descartes University, Côchin Hospital, APHP, Paris, France, [3]Henri Mondor Teaching Hospital, AP-HP, Créteil, France, [4]Université Brest Occidentale, Brest, France.

Background/Purpose: Reading of MRIs of the sacroiliac joints (MRI-SI) in clinical trials is usually performed by ≥1 trained readers while in daily practice this is done by local radiologists/rheumatologists. However, this varies in cohorts and in the DEvenir des Spondylarthropathies Indifferenciées Récentes (DESIR)-cohort, MRIs-SI at inclusion were first read by the local radiologist/rheumatologist, then by central readers. The impact of reading by multiple readers in various centres as in daily practice, instead of a centralized reading, is unknown. We compared the local reading (LocR) to centralized reading (CentR) regarding the presence or absence of inflammation on MRI-SI.

Methods: The 25 participating centers included patients aged 18–50 with inflammatory back pain (IBP; ≥3 months, ≤3 years) in the DESIR-cohort (n=708). Available baseline MRIs-SI were read by local radiologists/rheumatologists with access to clinical and laboratory data, on the presence of inflammatory lesions in both SI-joints. A grade 0 corresponds to 'normal', a grade 1 to 'doubtful', and a grade 2 to 'definite inflammatory lesions'. For this analysis, a positive MRI was defined as at least one SI-joint marked grade 2. Next, 2 well-calibrated central readers independently read all MRIs-SI according to the ASAS definition[1], blinded for clinical and laboratory data. In case the readers disagreed, an experienced radiologist served as adjudicator. An MRI-SI was marked positive if 2/3 readers agreed. Agreement between the 2 central readers, between LocR and CentR and between LocR and the central readers separately was calculated (Kappa; % agreement).

Results: In this analysis patients with complete MRI-SI data (n=663) were included. Inter reader agreement between the 2 central readers is acceptable (Kappa 0.73), and the percentage agreement (87.5%) is good (table). The adjudicator scored 84/663 (12.7%) MRIs-SI because of disagreement between the 2 central readers. Comparison between CentR (2/3) and LocR shows the same levels of agreement (kappa 0.70, % agreement 86.6%; table). In 38/663 patients (5.7%), the MRI-SI was positive by LocR but negative by CentR; in 51 patients (7.7%) it was the other way around. There was no difference in agreement between LocR and CentR if MRIs-SI were scored by local rheumatologists or by local radiologists (data not shown). Comparisons of LocR versus the separate readers show very similar results (table).

		Central reader 2	
Central reader 1			
	MRI-SI+ (ASAS)	**MRI-SI+ (ASAS)**	**MRI-SI− (ASAS)**
	MRI-SI+ (ASAS)	200	56
	MRI-SI− (ASAS)	28	380
	Kappa (95% CI)/Agreement (%)	0.73 (0.67–0.78)	87.5
		Centralized reading (2/3)	
Local reading		**MRI-SI+ (ASAS)**	**MRI-SI− (ASAS)**
	MRI-SI+	185	38
	MRI-SI −	51	389
	Kappa (95% CI)/Agreement (%)	0.70 (0.65–0.76)	86.6
		Central reader 1	
Local reading		**MRI-SI+ (ASAS)**	**MRI-SI− (ASAS)**
	MRI-SI+	180	43
	MRI-SI −	76	364
	Kappa (95% CI)/Agreement (%)	0.61 (0.55–0.67)	82.1
		Central reader 2	
Local reading		**MRI-SI+ (ASAS)**	**MRI-SI− (ASAS)**
	MRI-SI+	177	46
	MRI-SI −	51	389
	Kappa (95% CI)/Agreement (%)	0.67 (0.62–0.73)	85.4

Conclusion: Both inter reader agreement between the 2 central readers and agreement between the local and centralized readings is acceptable to good. This indicates that local rheumatologists/radiologists perform as good as trained readers in identifying inflammation on MRI-SI in patients with recent onset IBP, thereby suggesting that MRI-SI is a reliable assessment in diagnosing and classifying the majority of patients with spondyloarthritis.

Volatility Of The Site and Type Of Lesions In The Spine In Patients With Recent Onset Spondyloarthritis and Possible Spondyloarthritis Over a 3-Month Period. Rosaline van den Berg[1], Manouk de Hooge[1], Victoria Navarro-Compán[1], Monique Reijnierse[1], Floris van Gaalen[1], Karen Fagerli[2], Robert Landewé[3], Maikel van Oosterhout[4], Roberta Ramonda[5], Tom Huizinga[1] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [4]GHZ Hospital, Gouda, Netherlands, [5]University of Padova, Padova, Italy.

Background/Purpose: Inflammatory lesions on MRI of the sacroiliac joints show volatility over a short period of 3 months in patients with recent onset axial spondyloarthritis (axSpA)[1]. We investigated whether the site and/or type of lesions in the spine change over a 3-month period in patients with recent onset axSpA and possible axSpA.

Methods: 158 patients with back pain (≥3 months, ≤2 years, onset <45 years) included in the SPondyloArthritis Caught Early (SPACE)-cohort from the 5 participating centers underwent MRI of the spine (MRI-spine) at baseline and after 3 months. MRIs-spine were scored by 2 readers independently, blinded for the time sequence. Presence of corner inflammatory lesions (CIL; type A and B) and fatty lesions (FL) were scored[2,3]. Scores of both time points were compared on the vertebral unit level (VU; 23 per patient) for inflammatory lesions and on the quadrant level (4 per VU) for all lesions. Quadrants were summed (14536 in total) to study (changes in) the number, site and type of lesions. All possible changes were studied for each reader separately.

Results: On the VU level, reader 1 scored no CIL at both time points in 98/158 patients (62.0%). In 16.5% of the patients the number of inflamed VUs increased over 3 months (mean 1.7 SD 1.3; range 1–4); in 21.5% the number decreased (mean −2.1 SD 1.6; range −7 to −1). The upper 9 VUs were almost never affected. On the quadrant level, no CIL and FL were scored at both time points in 68/158 (43.7%) patients. In 18 patients, lesions (in 9 patients CIL; in 6 patients FL; in 3 patients both CIL and FL) did not change over time (mean 1.9 SD 1.7; range 1–8). In 72/158 patients (45.6%) site and type of lesions changed over time; in 18/72 purely occurrence of lesions (any type) was seen (mean 1.7 SD 0.8; range 1–3) and in 19/72 purely resolving of lesions (any type) was seen (mean −2.2 SD 1.8; range −8 to −1). Within the remaining 35/72 patients, various types of changes were seen (e.g. occurrence of CIL in a quadrant and disappearance of FL in another quadrant etc; mean number of changed quadrants 6.7 SD 5.1; range 1–22) as well as lesions that remained stable. Remarkably, more FL occurred in

quadrants without previous CIL (46 FL; in 23 patients) than in quadrants with previous CIL (14 FL; in 7 patients), and 118 FL (whether or not surrounded by CIL) resolved over time (in 48 patients) (table). The results of reader 2 are very similar to reader 1 (table).

			3 months				
	Reader 1/reader 2	No lesions	CIL type A	CIL type B	FL	CIL type A & FL	CIL type B & FL
Baseline	No lesions	14013/14024	57/46	4/4	46/54	1/2	0/2
	CIL type A	4/1	48/43	3/3	12/14	2/2	5/1
	CIL type B	12/5	4/5	3/3	2/2	0/1	1/1
	FL	53/58	5/3	2/1	157/167	4/5	0/1
	CIL type A & FL	64/50	2/2	1/0	7/10	2/9	0/0
	CIL type B & FL	1/2	1/0	2/0	8/5	3/4	7/6

FL; fatty lesion. CIL; corner inflammatory lesion

Conclusion: Almost half of the patients (45.6%) showed changes in site and/or type of lesions in the spine over a 3-month period only. Noteworthy, FL occurred more frequently de novo than in quadrants with previous CIL. Furthermore, FL can resolve over time, also when surrouneded by inflammation. The value of FLs in the spine need to be re-evaluated.

How Reliable Is The Scoring Of Msasss In Clinical Practice In Centers Participating In DESIR? Comparison With The Gold Standard Central Reading. Pascal Claudepierre[1], Manouk de Hooge[2], Antoine Feydy[3], Monique Reijnierse[2], Alain Saraux[4], Maxime Dougados[5] and Désirée van der Heijde[2]. [1]Henri Mondor Teaching Hospital, AP-HP, Créteil, France, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Paris Descartes University, Côchin Hospital, APHP, Paris, France, [4]CHU de la Cavale Blanche, Brest Cedex, France, [5]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France.

Background/Purpose: Spinal X-rays are considered as gold standard for assessing structural damage in the spine in AS, and a scoring system, the modified Stoke Ankylosing Spondylitis *Spinal* Score (mSASSS) is the preferred assessment method. In clinical studies and therapeutic trials, the mSASSS scoring process is usually done by ≥1 trained readers. In daily practice, the ability of rheumatologists and radiologists to adequately use the mSASSS without a specific training is unknown. In addition, it is not known what the impact would be in studies when using the score of multiple readers in various centres as in daily practice, instead of using a centralized scoring with a few trained readers. Therefore we want to compare the results of the mSASSS of the local reading of baseline spinal X-Rays to the centralized reading as the gold standard.

Methods: Patients aged 18–50 with recent chronic back pain (≥3 months, ≤3 years) from 25 participating centers in France were included in the DESIR (Devenir des Spondylarthropathies Indifferenciées Récentes) -cohort (n=708). All available baseline X-rays of cervical and lumbar spine were scored by the local radiologist/rheumatologist who might have access to clinical data, according to the mSASSS scoring method. In addition, 2 well-calibrated centralized readers independently scored the same X-rays, blinded for any other data. In case the centralized readers disagreed, an experienced radiologist served as adjudicator. Agreement between the 2 centralized readers, and between the local and centralized scores was calculated (Kappa; percentage agreement). To calculate the agreement between readers a cut-off of <1 for mSASSS was used. When comparing centralized readers with local readers the mSASSS of the centralized readers was combined.

Results: Patients with complete X- ray data (n=664) were included in these analyses. The large majority of patients had a normal mSASSS both scored by the central and local readers. The agreement between the 2 centralized readers was 89.3% with a kappa of 0.50 (see table). Comparing the local readings with the centralized scores there was an agreement in 72.2% of the cases with a kappa of 0.19. The local readers scored an mSASSS ≥1 in 169 cases, while this was in 119 cases if scored by central readers.

		Reader 2	
Reader 1		mSASSS≥1	mSASSS<1
	mSASSS ≥1	45	29
	mSASSS <1	42	548
	Kappa = 0.50/Agreement = 89.3%		
		Centralized score (2/3)	
Local score		mSASSS≥1	mSASSS<1
	mSASSS ≥1	52	117
	mSASSS <1	67	427
	Kappa = 0.19/Agreement = 72.2%		

Conclusion: The agreement between two trained central readers is better than between central and local readers. Local readers overestimate damage in the spine in comparison to the gold standard of central reading.

1123

Comparison Of The Performance Of The BASRI and Msasss In Patients With Early Inflammatory Back Pain From The DESIR Cohort. Manouk de Hooge[1], Pascal Claudepierre[2], Antoine Feydy[3], Monique Reijnierse[1], Alain Saraux[4], Maxime Dougados[5] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Henri Mondor Teaching Hospital, AP-HP, Créteil, France, [3]Paris Descartes University, Côchin Hospital, APHP, Paris, France, [4]CHU de la Cavale Blanche, Brest Cedex, France, [5]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France.

Background/Purpose: For assessing structural damage in AS on spinal X-rays the Bath Ankylosing Spondylitis Radiology Index (BASRI) and modified Stoke Ankylosing Spondylitis *Spinal* Score (mSASSS) scoring systems can be used. No comparison of the results of those 2 scores is available at an early stage of the disease. The purpose of this study is to present the prevalence of abnormalities based on the BASRI and mSASSS in patients with recent inflammatory back pain (IBP) and to compare these 2 scores.

Methods: Patients aged 18–50 with recent IBP (≥3 months, ≤3 years) from 25 participating centres in France were included in the DESIR (Devenir des Spondylarthropathies Indifferenciées Récentes)-cohort (n=708). All available baseline spinal X-rays (cervical and lumbar) were scored by 2 well-calibrated central readers independently, blinded for clinical data. When readers disagreed, an experienced radiologist served as adjudicator. BASRI and mSASSS were calculated from the mean of the scores of the 2 readers (and adjudicator if applicable).

Patients were classified according to the ASAS axial SpondyloArthritis (ASAS axSpA) criteria into patients fulfilling the imaging arm, either fulfilling or not fulfilling the modified New York (mNY) criteria, fulfilling the clinical arm and not fulfilling (no-axSpA patients) the criteria.

Results: Patients with complete X-ray data (n=637) were included in these analyses. Overall, 87.8% of the patients had no definite abnormalities assessed by mSASSS <2, and 88.5% by BASRI <2 (see table); those values were 88.5% and 89.0% within the ASAS axSpA patient group, respectively. A BASRI of ≥2 was scored more frequently in the imaging arm compared to the clinical arm of the ASAS criteria and the no-axSpA patient group (table). When comparing mSASSS and BASRI readings, using a cut-off of ≥2 (definite abnormalities) for both scoring methods, we found a very high percentage of agreement in all the different patient groups: range 95.4% to 98.2%.

Only in few patients syndesmophytes were found, and these were present in all patients groups (see table). More syndesmophytes were present in the cervical spine than in the lumbar spine. The number of syndesmophytes in the cervical vs the lumbar spine was 6 vs 3 in the no-axSpA group, 6 vs 1 in the clinical arm, 5 vs 1 in the imaging mNY-group, and 8 vs 1 in the imaging mNY+ group.

	ASAS axSpA, n=453			
	Imaging arm			
	mNY+ n=135	mNY− n=119	Clinical arm n=199	No-SpA, n=184
mSASSS <2	123 (91.9%)	100 (84.0%)	178 (89.4%)	158 (85.9%)
mSASSS ≥2 & <5	4 (3.0%)	8 (6.7%)	9 (4.5%)	7 (3.8%)
mSASSS ≥5 & <10	3 (2.2%)	2 (1.7%)	1 (0.5%)	0
mSASSS ≥10 & ≤15	1 (0.7%)	0	2 (1.0%)	3 (1.6%)
Total BASRI <2	117 (86.7%)	104 (87.4%)	182 (91.5%)	161 (87.5%)
Total BASRI = 2	10 (7.4%)	4 (3.4%)	7 (3.5%)	5 (2.7%)
Total BASRI = 3	2 (1.5%)	2 (1.7%)	0	1 (0.5%)
Total BASRI = 4	2 (1.5%)	0	1 (0.5%)	0
Total BASRI = 5	0	0	0	1 (0.5%)
No syndesmophytes	125 (92.6%)	105 (88.2%)	182 (91.5%)	161 (87.5%)
≥1 & <5 syndesmophytes	6 (4.4%)	3 (2.5%)	8 (4.0%)	5 (2.7%)
≥5 & <10 syndesmophytes	0	2 (1.7%)	0	2 (1.1%)
Missings	4 (3.0%)	9 (7.6%)	9 (4.5%)	16 (8.7%)

Conclusion: The agreement between mSASSS and BASRI ≥2 is very high in all patient groups. Abnormalities typical for AS such as syndesmophytes are generally infrequent in this early cohort, but if observed, syndesmophytes are more frequent in the cervical spine compared to the lumbar spine. An mSASSS and BASRI of ≥2 is more often seen in patients fulfilling the ASAS classification criteria compared to no-SpA patients.

Lumbar Degenerative Changes In The Spondyloartritis Caught Early Cohort. F. de Bruin[1], S. ter Horst[1], Karen Fagerli[2], R. Landewe[3], M. van Oosterhout[4], J.L Bloem[5], D. van der Heijde[5] and M. Reijnierse[5]. [1]LUMC, Leiden, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [4]Groene Hartziekenhuis, Gouda, Netherlands, [5]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: The early diagnosis of axial spondyloarthritis (axSpA) is difficult, however new classification criteria are available, the ASAS axSpA criteria. The SPondyloArthritis Caught Early (SPACE) cohort, back pain ≥ 3 months, ≤ 2 years, onset < 45 years, was set up to diagnose SpA early. In addition to SpA associated features on MRI and conventional radiographs, degenerative changes of the spine might be clinically important. Therefore we describe the prevalence of lumbar degenerative changes in axSpA patients (ASAS+) and no-axSpA patients (ASAS-).

Methods: In 276 patients (pts) 1.5T T1 and STIR MRI and in 257 pts lateral radiography images of the lumbar spine and antero-posterior radiographs of the pelvis were available. Two readers scored for: disc degeneration (5 point scale of Pfirrmann), High intensity zone, bulging (extrusion and protrusion), herniation (central and lateral), Modic changes (3 point scale) and Schmorl's nodes on MRI and loss of disc height, facet joint osteoarthrose (FJOA), osteophytes, sclerosis, Schmorl's nodes, and sacralization on radiography. Kappa was calculated for inter rater agreement. Chi-square test was used to test for differences between pts groups.

Results: Table 1 lists the number of patients from the whole cohort with none, one or multiple lesions.

	0	Number of lesions 1	≥2
Pfirrmann*	143 (51,8%)	64 (23,2%)	69 (25%)
HIZ	86 (31,2%)	89 (32,2%)	101 (36,6%)
Extrusion	218 (79,0%)	46 (16,7%)	12 (4,3%)
Protrusion	170 (61,6%)	70 (25,4%)	37 (13,4%)
Stenosis central	274 (99,3%)	2 (0,7%)	0 ()
Stenosis lateral	262 (94,9%)	14 (5,1%)	0 ()
Modic	237 (85,9%)	35 (12,7%)	4 (1,4%)
Schmorl	111 (40,2%)	34 (12,3%)	131 (47,5%)
Loss of Disc Height	200 (66,9%)	53 (17,7%)	46 (15,4%)
FJOA	277 (92,6%)	21 (7,0%)	1 (0,3%)
Osteophytes	227 (75,9%)	49 (16,4%)	15 (5,0%)
Schmorl node	275 (92,0%)	13 (4,3%)	9 (3,0%)
Sclerosis	257 (86,0%)	34 (11,4%)	6 (2,0%)
LSTV	213 (71,2%)	86 (28,8%)	NA

On MRI, 133 pts (48%) had lower signal intensity of at least one (lumbar) intervertebral disc with or without loss of height (Pfirrmann class 3). No difference between ASAS+ (47/112, 42%) and ASAS- (86/163, 53%) pts was found (P=.078). Modic changes were seen in 39 pts (14%) and was statistically significant more present in ASAS- pts (29 vs 10, P=.038).

On X-ray, loss of disc height was found in 59 pts (23%), in 40 ASAS- pts and in 19 ASAS+ pts (P=.047). Osteophytes were present in 48 pts (19%, 13 ASAS+ and 35 ASAS-) and statistically significant more in ASAS- pts (P=.028).

Conclusion: Pts have a high prevalence of degenerative changes. Nearly half of all pts have dehydrated intervertebral discs, a smaller proportion has loss of height on both MRI and conventional images. ASAS- pts have a higher prevalence of Modic changes, loss of disc height and osteophytes than ASAS+ pts. Prevalence of Modic changes was higher than reported in literature. The high prevalence of degenerative changes in ASAS- pts might be an explanation for the back pain, although clinical correlation is required.

Fatigue In Ankylosing Spondylitis Is Associated With The Brain Networks Of Sensory Salience and Attention. Robert Inman[1], Q. Wu[2] and Karen Davis[2]. [1]University of Toronto and Toronto Western Hospital, Toronto, ON, [2]Toronto Western Research Institute, Toronto, ON.

Background/Purpose: Fatigue is one of the cardinal features of ankylosing spondylitis (AS) and contributes substantially to the disability associated with this disease. The mechanisms underlying fatigue in AS remain poorly understood, and this has hampered the development of targeted, effective treatment for this disabling feature of AS. Thus, the current study investigated brain networks underlying fatigue.

Methods: Twenty patients with back pain secondary to AS (15M/5F; age 34.8 +/− 11.9 yr) and 20 age/sex-matched controls consented to the approved study. Patients underwent clinical assessments for AS including the Fatigue Severity Scale, Affect Intensity Measure and the McGill Pain Questionnaire. 3T MRI was performed to assess brain gray matter (GM) and white matter (WM) connectivity.

Results: The AS patients had significant fatigue that correlated with measures of their emotional strength as well as spinal mobility. Individual fatigue scores were negatively correlated with the amount of GM in areas of the dorsal and ventral attention networks, the somatosensory cortices, and caudate nucleus, but were positively correlated with GM within the executive control network and putamen (Table 1). Moreover, WM tracts connecting these brain structures (e.g., inferior fronto-occipital fasciculi, superior/inferior longitudinal fasciculi, and corticothalamic tracts) exhibited low fractional anisotropy (indicative of decreased WM tract integrity) in AS patients with high fatigue scores.

Table 1.

Opportunistic Computed Tomography Screening For Determining Osteoporosis In Patients With Ankylosing Spondylitis and Spine Fractures. Amanda Cagan[1], Osa Emohare[1], Robert Morgan[1], David Polly[2] and Elie Gertner[3]. [1]Regions Hospital, Saint Paul, MN, [2]University of Minnesota, Minneapolis, MN, [3]Regions Hospital and University of Minnesota Medical School, St. Paul, MN.

Background/Purpose: In advanced disease Ankylosing Spondylitis (AS) is frequently associated with a reduction in bone mineral density (BMD) which contributes to pain and predisposes to fractures. Quantifying this reduction in BMD is complicated because overgrowth of bone and loss of trabecular bone occur at the same time. Traditional methods, such as dual-energy X-ray absorptiometry (DXA), may not generate accurate estimates of BMD in AS patients. It has recently been shown that osteoporosis, osteopenia, and normal BMD can be differentiated by evaluating the L1 vertebra on abdominal Computed tomography (CT) scans. The aim of the present study was to evaluate the use of opportunistic CT screening in the diagnosis of osteporosis in patients with severe AS who had sustained vertebral fractures.

Methods: A retrospective study of patients with severe AS and bridging syndesmophytes who presented to our Level 1 trauma center with acute fractures of the spine (both high impact and low impact) and had an evaluable CT scan of the abdomen. Using a picture archiving and communication system (PACS), a region of interest (ROI) was generated to fit to the body of L1 (excluding the cortex) and a mean value for Hounsfield Units (HU) was computed. The values derived were compared against threshold values which differentiate between osteoporosis and osteopenia. For specificity of 90%, a threshold of 110 was set; for balanced sensitivity and specificity, a threshold of ≤135 HU was set, and for 90% sensitivity a threshold of ≤160 HU was set.

Results: A total of 17 AS patients fit the above criteria. Using an L1 CT-attenuation threshold of ≤135 HU balanced for sensitivity and specificity, 14/17 (82%) patients were found to have osteoporosis. Using an L1 CT-attenuation threshold of ≤160 HU to increase sensitivity, 15/17 patients (88%) were found to be osteoporotic. Even using the L1 CT-attenuation threshold of ≤110 HU to increase specificity 14/17 (82%) had osteoporosis.

Conclusion: A high proportion of AS patients who sustain fractures have osteoporosis as shown by using opportunistic CT screening. This overcomes some of the difficulties that have been encountered with the use of DXA in this unique group of patients. This simple and accessible diagnostic method saves on excess cost and exposure to radiation. It may also inform the surgeon in structuring surgical approach.

Semiquantitative MRI Features Of Knee Osteoarthritis Show Compartment-Specific Relationships With Quantitative Cartilage Thickness Loss: The Multicenter Osteoarthritis Study. Ali Guermazi[1], Felix Eckstein[2], Daichi Hayashi[3], Frank Roemer[3], Wolfgang Wirth[2], Tianzhong Yang[3], Jingbo Niu[3], Leena Sharma[4], Michael C. Nevitt[5], Cora E. Lewis[6], James Torner[7] and David T. Felson[3]. [1]Boston University, Boston, MA, [2]Paracelsus Medical University, Salzburg, Austria, [3]Boston University School of Medicine, Boston, MA, [4]Northwestern University, Chicago, IL, [5]University of California, San Francisco, San Francisco, CA, [6]University of Alabama, Birmingham, Birmingham, AL, [7]University of Iowa, Iowa City, Iowa City, IA.

Background/Purpose: Structural progression of knee OA has been associated with several radiographic and MRI-measured pathological features of OA, including malalignment, meniscal pathology and bone marrow changes but studies examining these risk factors generally examine one of them and not their constellation although these features coexist. To date no study has been done to assess if baseline MRI-based scores of various knee OA features predict progression of knee OA as determined by quantitative cartilage thickness measurement. We aimed to determine which semiquantitative MRI-based OA features were most predictive of subsequent cartilage thickness loss measured with quantitative MRI.

Methods: From the Multicenter OA Study subcohort, participants (one knee per person) who volunteered for a longitudinal substudy in which MRI measurement of cartilage thickness and volume were done were selected: These subjects also had conventional MRI's allowing Whole Organ MRI Score (WORMS) based scoring of cartilage lesions, bone marrow lesions (BML), meniscal pathology, effusion synovitis, and Hoffa synovitis at both time points. Progression in the medial or lateral femorotibial compartment (MFTC/LFTC) was defined as cartilage thickness loss exceeding the change observed in OAI control cohort knees (mean ± 2xSD, MFTC/LFTC: −162μm/−145μm). All MRI predictors were dichotomized into "present" (score≥2 for cartilage, ≥0 for others) or "absent". Differences in baseline scores of ipsi-compartmental predictor variables were compared between progressor and non-progressor knees by multivariable logistic regression, adjusting for age, sex, body mass index, and anatomical alignment axis (degrees). We combined MFTC and LFTC to calculate ajusted odds ratio (aOR) and 95% CI of ipsi-compartmental cartilage thickness loss across compartments, using Generalized Estimating Equations. Also, ORs and 95%CIs were calculated for MFTC and LFTC cartilage thickness loss, separately.

Results: 196 participants were included and their mean age was 59.8±6.3 years, mean BMI 29.5±4.6 kg/m^2, and 62% were women. 46 knees had radiographic knee OA at baseline. In the MFTC/LFTC, there were 35/29 progressors and 161/167 non-progressors. For analysis combining MFTC and LFTC, predictors of cartilage thickness loss were baseline cartilage lesions (aOR 2.6 [1.4–5.0]), BML (aOR 1.9 [1.1–3.3]), meniscal damage (aOR 4.5 [2.4–8.4]) and meniscal extrusion (aOR 3.3 [1.9–5.8]), all in the ipsilateral compartment, but not effusion synovitis or Hoffa synovitis. In MFTC-only analysis, MFTC progressors had higher aOR for having baseline medial meniscal damage (aOR 2.4, [95%CI 1.1–5.6]), medial meniscal extrusion (aOR 2.6 [1.1–5.8]), but not cartilage lesions, BML, effusion synovitis and Hoffa synovitis. In the LFTC-only analysis, baseline lateral cartilage lesions (aOR 3.4 [1.3–9.3]), lateral meniscal damage (aOR 13.9 [3.3–9.0]) and lateral meniscal extrusion (aOR5.0 [1.4–18.0]) predicted LFTC progression.

Conclusion: Amongst MRI features, the presence of cartilage lesions, BML, meniscal damage and extrusion in the ipsilateral FTC predict quantitatively assessed cartilage thickness loss over 30-months, but not effusion synovitis or Hoffa synovitis.

1128

Validation Of a Rapid, Quantitative Method Of Magnetic Resonance Imaging-Detected Osteoarthritis-Related Bone Marrow Lesions In The Patellofemoral Joint. Charles Ratzlaff[1] and Jeffrey W. Duryea[2]. [1]Harvard Medical School/Brigham and Women's Hospital, Boston, MA, [2]Brigham & Women, Boston, MA.

Background/Purpose: We recently developed an efficient semi-automated measure of tibial and femoral BML volume and validated it against the Whole-Organ Magnetic Resonance Imaging Score (WORMS). Since patella-femoral (PFJ) osteoarthritis (OA) is increasingly being recognized as a cause of knee pain in OA, we have extended the method to the PFJ. The purpose of this study was to compare PFJ BML volumes with WORMS, and test the hypothesis that PFJ BML volume is associated with stair-climbing pain (but not walking or standing pain).

Methods: 115 subjects from the baseline data of the Osteoarthritis Initiative (OAI) Progression Cohort whose knees were WORMS-scored by OAI central imaging were included. Sagittal turbo spin echo fat saturated (TSE FS) (0.357 × 0.357 × 3.0 mm, TR 3200ms, TE 30ms) IW MRI were obtained on a 3T Siemens Trio MR system. A reader used software to segment subchondral BMLs in the patella and anterior femur (trochlea). The software applies a grayscale thresholding algorithm to the raw image and reader judgment is used to select, usually with 1 or 2 mouse clicks, the clinically appropriate region(s) of BML. Reliability on a random sample of 20 subjects was: ICC 0.96, and 0.97 for intra-and inter-reader respectively.

Primary outcome: segmented volume of BMLs (mm^3) in the patella and trochlear femoral compartment.

WORMS score: Comparison of PFJ BML volume was made with OAI public-release WORMS scoring for the patella and trochlea. WORMS reports BML in 4 categories based on size of BML relative to the total sub-region (0-no BML, 1–<25%, 2–25–50%, 3–>50%). Spearman's correlation and Kruskall-Wallis tests were used to assess association between the two methods.

Pain. We used the WOMAC pain sub-scale and defined the primary outcome of knee pain dichotomously as moderate to severe pain (scores 2–4) on any of the 3 weight-bearing (WB) WOMAC pain questions (pain on walking, climbing stairs, standing), acquired at the same baseline OAI visit as the MRI scans. Kruskall-Wallis test were used to assess the associations.

Results: The sample was 84% white, 52% male and were 90% K-L grade 2 and 3. Median BML volumes were progressively larger by WORMS category for patella (figure), trochlea and PFJ (all $p<0.001$) and strongly correlated (Spearman's r = 0.89, 0.74 and 0.81 respectively, all $p=0.000$). We found significant positive associations between stair-climbing pain and PFJ BML volume but not for other WOMAC WB pain items.

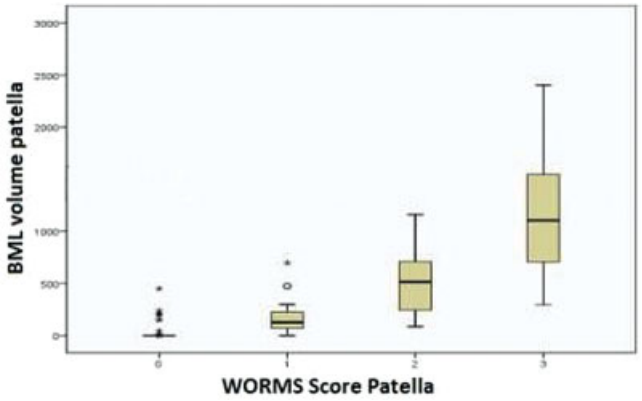

Figure. Box and whisker plots showing mean, median, lower and upper quartiles, and outliers of BML volume by WORMS scores, for patella.

BML Volume		No Stair pain (n = 58)	Stair Pain (n = 57)	p-value[1]
PFJ BML (mm3)	median	44	338	0.01
Trochlear BML (mm^3)	median	0	22	0.04
Patellar BML (mm^3)	median	0	192	0.01

Conclusion: This study reports good criterion and clinical validation of an efficient method for measuring BML in the PFJ, providing a a potentially useful tool for trials in the PFJ.

Development and Validation Of a Rapid Knee Cartilage Quantification Method. Ming Zhang[1], Jeffrey B. Driban[1], Lori Lyn Price[1], Daniel Harper[1], Grace H. Lo[2], Eric Miller[3], Robert J. Ward[1] and Timothy E. McAlindon[1]. [1]Tufts Medical Center, Boston, MA, [2]Michael E. DeBakey VA Medical Center, Baylor College of Medicine, Houston, TX, [3]Tufts University, Medford, MA.

Background/Purpose: Cartilage morphometry on magnetic resonance images (MRIs) may become an acceptable outcome measure for clinical trials among patients with knee osteoarthritis (OA). However, obtaining accurate and reproducible cartilage data is burdensome. To conduct large clinical trials it will be vital to use an efficient, sensitive and reproducible method to assess cartilage morphometry. The purpose of this study was to develop and validate a rapid semi-automated method to detect cartilage loss in the medial tibiofemoral compartment.

Methods: The rapid knee cartilage quantification method was developed using 263 manually-segmented knee MRIs. We designed a pair of two dimensional, rectangular, universal coordinate systems to represent the articular surface of the distal medial femur and proximal medial tibia. Next, we projected segmented cartilage onto coordinate system and evenly selected 9 informative locations across the region most frequently denuded (Figure 1). The primary outcome is a cartilage damage index (CDI), which summates the products of cartilage thickness, cartilage length and voxel size from each informative location. To validate CDI we selected 102 subjects from Osteoarthritis Initiative with a diverse range of Kellgren-Lawrence (KL) grades (0 to 4). 3D Double-echo steady-state sagittal images were obtained on four 3-Tesla systems (0.37 mm × 0.37 mm, 0.7 mm slice thickness). One reader used customized software to measure the CDI in the medial femur and tibia from the baseline and 24-month visit. Another reader evaluated 20 subjects to establish the inter-tester reliability test.

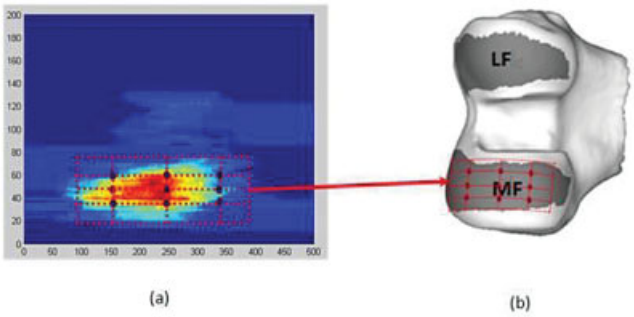

Figure 1. (a) Femur denuded projection and 9 informative locations on the coordinate system. (b) Corresponding denuded peak on the cartilage map. Note: MF = Medial Femur; LF = Lateral Femur.

Results: The average measurement time was 14 minutes per pair of knees. The intra-tester reliability (intraclass correlation coefficient ICC [3,1 model] 0.95 to 0.99) and inter-tester reliability (ICC [2,1 model] 0.85 to 0.94) were good. Knees with greater medial joint space narrowing (JSN) had lower mean CDI (i.e. greater loss, Table 1). Knees with radiographic progression (JSN grade change) had 4.5 to 22 times greater CDI loss than knees with no progression ($p < 0.0001$), Table 2.

Table 1. Cartilage damage index stratified by joint space narrowing (JSN) grade

Cartilage Measure	JSN=0 (n=43) mean	JSN=1 (n=25) mean	JSN=2 (n=26) mean	JSN=3 (n=3) mean	p-value
		Cross-sectional			
Femur CDI (Baseline)	747.95	664.55	521.57	308.95	<0.01
Tibia CDI (Baseline)	389.56	368.12	292.77	149.53	<0.01
Tibiofemoral CDI (Baseline)	1137.50	1032.70	814.34	458.48	<0.01
		Longitudinal			
Femur CDI (Change)	−2.95	−19.33	−47.15	−99.30	<0.01
Tibia CDI (Change)	−9.31	−26.25	−45.00	−43.86	<0.01
Tibiofemoral CDI (Change)	−12.26	−45.58	−92.15	−143.2	<0.01

Notes: change = follow-up minus baseline; SD = standard deviation.

Table 2. Change in cartilage damage index among knees with and without structural progression defined by change in radiographic JSN grade

Cartilage Measure	JSN change	N	Mean	SD	SRM	p-value
Femur CDI (Change)	No change	74	−3.38	47.98	−0.07	<0.0001
	Change	25	−66.17	56.76	−1.17	
Tibia CDI (Change)	No change	74	−12.85	23.38	−0.55	<0.0001
	Change	25	−55.55	39.82	−1.40	
Tibiofemoral CDI (Change)	No change	74	−16.23	56.68	−0.29	<0.0001
	Change	25	−121.70	77.17	−1.58	

Notes: JSN change, the follow-up has different JSN score with baseline; N = number of knees (the numbers were excluded JSN=3 which is the highest grade); SD = standard deviation; SRM = standard response mean.

Conclusion: This novel knee cartilage damage quantification method is rapid, reliable, and has good construct validity in the medial tibiofemoral compartment. It has utility for deployment in large epidemiological studies.

Change In Knee Osteophyte Volume By Semi-Automated Method In Knee Osteoarthritis Over Four Years Using 3T DESS 3D MRI. Michael Hakky[1], Charles Ratzlaff[2], Ali Guermazi[3], Mohamed Jarraya[4] and Jeffrey W. Duryea[5]. [1]Lahey Clinic, Burlington, MA, [2]Harvard Medical School/Brigham and Women's Hospital, Boston, MA, [3]Boston University, Boston, MA, [4]Boston University School of Medicine, Boston, MA, [5]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: The development and growth of osteophytes are considered a radiographic surrogate for osteoarthritis (OA) at the knee. Methods to determine osteophyte burden are largely semi-quantitative and subjective. Quantifying osteophyte volume could potentially provide an improved measure of change for OA trials and observational research. We have developed a software method for semi-automated osteophyte segmen-

tation on MRI. Our objective was to validate the responsiveness of this method to osteophyte volume change over four years in subjects with established knee OA according to Kellgren and Lawrence (KL) grade. We assume that OA is a progressive process, thus osteophyte burden should increase over time.

Methods: Ninety subjects (51 KL 2 and 39 KL 3) were selected from the Osteoarthritis Initiative (OAI) Progression Cohort. Double echo steady state 3D sagittal images were obtained on a 3T Siemens Trio MR system. Measurements were performed on coronal reformatted series. A reader used the software method to segment marginal osteophytes of the knee at baseline and 48-month follow up. Readings were performed paired but blinded to order of visit. The reader identified the first and last slice of the central weight bearing region and an edge detection algorithm demarcated the bone edges. The reader marked the expected normal bone contour at the base of the osteophytes (Figure 1a). The software calculated the area of the osteophyte (Figure 1b) on each slice and generated volume measurements.

The primary outcome was change in osteophyte volume (ΔV) from baseline to follow-up. Statistics used were the average change in osteophyte volume from baseline to 48 months (ΔV), the standard deviation (SD) of ΔV, the standardized response mean (SRM) ΔV/SD of ΔV, and the percentage of subjects with net increase in osteophyte burden.

Results: The average change in osteophyte volume (ΔV) was 1240 mm^3, the SD = 1557 mm^3, and the SRM was 0.80. A net increase in osteophyte volume from baseline to 48 months was observed for 83% (75/90, 40 KL 2 and 35 KL 3) of the subjects. The average reading time was approximately 10 minutes per knee.

Table 1. Responsiveness to change over 48 months

	Net Increase	Mean ΔV	SD ΔV	SRM
KL 2 + KL 3 (90)	75/90 (83%)	1240 mm^3	1557 mm^3	0.80
KL 2 (51)	40/51 (78%)	1004 mm^3	1477 mm^3	0.68
KL 3 (39)	35/39 (90%)	1549 mm^3	1624 mm^3	0.95

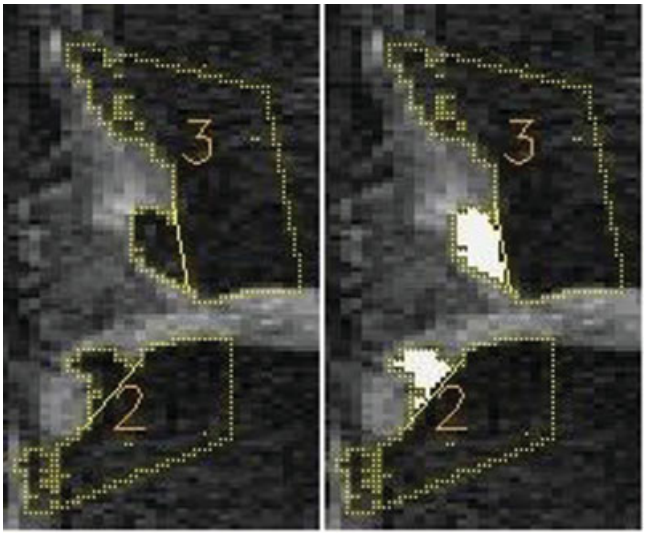

Figure 1a and b

Conclusion: The results confirm that quantitative measure of osteophyte volume can be performed efficiently and is responsive to change over time. This method has the potential be a powerful tool for monitoring longitudinal osteophyte change, and could assess a large study cohort rapidly while potentially reducing study costs and allow for evaluation of large scale trials such as the OAI.

Peri-Articular Fractal Signature Analysis and Bone Mineral Density Measure Different Aspects Of Bone: Cross-Sectional Data From The Osteoarthritis Initiative. Jeffrey B. Driban[1], Felix Liu[2], Alina O'Brien[1], Lori Lyn Price[1], Grace H. Lo[3], Michael C. Nevitt[4], Charles Eaton[5], Timothy E. McAlindon[1] and John A. Lynch[6]. [1]Tufts Medical Center, Boston, MA, [2]University of California at San Francisco, San Francisco, CA, [3]Michael E. DeBakey VA Medical Center, Baylor College of Medicine, Houston, TX, [4]University of California, San Francisco, San Francisco, CA, [5]Brown University, Providence, RI, [6]University of California-San Francisco, San Francisco, CA.

Background/Purpose: Peri-articular fractal signature analysis (FSA) and bone mineral density (paBMD) are potentially cost-effective prognostic imaging markers for osteoarthritis (OA) progression. While we know that paBMD relates to trabecular morphology, it remains unclear whether FSA, which assesses the texture of bone on radiographs, measures a similar construct of bone structure as paBMD. Understanding this association is paramount for determining if these two measurements are redundant. Therefore, we evaluated the association between FSA, paBMD, and trabecular morphology.

Methods: The sample comprised 450 participants in the Osteoarthritis Initiative (OAI) progression cohort who had weight-bearing radiographs, magnetic resonance imaging (MRI), and knee dual-energy x-ray absorptiometry (DXA) at the 48-month OAI visit. The right knee was assessed unless MRI was contraindicated. Three separate readers measured the medial proximal tibia to generate 1) paBMD on DXA, 2) fractal dimensions with FSA on digital radiographs, and 3) MRI-based apparent trabecular morphology: bone volume fraction (aBV/TV), trabecular number (aTb.Tn), spacing (aTb.Sp), and thickness (aTb.Th). Fractal dimension data in the horizontal "tension" and vertical "compression" directions were reduced into 3 piece-wise, centered linear regression from 0 to 3mm radii. We assessed univariate associations with Spearman correlations and conducted 5 robust regression models to determine the association between FSA-based data (compression and tension together; predictors) and the five other bone measures (paBMD and trabecular morphology) as outcomes. These models were adjusted for OAI clinical site.

Results: The 450 participants were 47% female, 72% radiographic knee OA in the study knee (Kellgren-Lawrence > 2), and on average 66 (SD=9) years of age with a mean body mass index of 29.6 (SD=4.7) kg/m^2. Table 1 shows that FSA-based data were not associated with paBMD. The significant associations between FSA-based data and trabecular morphology indicated that lower tension and compression gradients may be related to greater aBV/TV, aTb.Th, aTb.Tn, but lower Tb.Sp (Table 1). In the multivariate analyses we found that FSA-based compression offsets had a small relationship with paBMD (R^2 = 0.03). Furthermore, we found that lower FSA-based compression gradients were associated with greater aBV/TV (p=0.04) and aTb.Th (p=0.01) but lower aTb.Sp (p=0.01; R^2 = 0.04–0.05). Lower FSA-based tension gradients were associated with greater aTb.Th (p= 0.02) but lower aTb.Sp (p=0.04).

Cross-sectional Relationships Between Peri-articular FSA-Based Data and Other Apparent Bone Measures (n = 450 knees)

FSA-Based Data	Bone Mineral Density	Bone Volume Fraction	Trabecular Thickness	Trabecular Number	Trabecular Spacing
	r (95% CI)	r (95% CI)	r (95% CI)	r (95% CI)	r (95% CI)

Tension gradient[1]	0.02 (−0.07, 0.11)	−0.01 (−0.10, 0.09)	−0.09 (−0.18, 0.01)*	0.01 (−0.08, 0.10)	−0.01 (−0.11, 0.08)
Tension offset[2]	0.02 (−0.07, 0.11)	0.03 (−0.06, 0.12)	−0.06 (−0.16, 0.03)	0.04 (−0.05, 0.13)	−0.05 (−0.14, 0.05)

Note: FSA = Fractal Signature Analysis, r = Spearman rho, 95% CI = 95% confidence interval.
1 = gradients are defined as the x-coefficient in the 3 piece-wise, centered linear regressions from 0 to 3mm radii
2 = offsets are defined as the constants in the 3 piece-wise, centered linear regressions from 0 to 3mm radii
* = correlations that were significant in multivariate analyses with all of the FSA-based data included as predictors.

Conclusion: We found that lower peri-articular FSA values were not associated with paBMD but had some small associations with trabecular morphology that is typical of greater OA severity (greater aBV/TV, aTb.Th,

and aTb.N and lower aTb.Sp). This suggests that these are not redundant measures and both imaging markers warrant further evaluation.

Sensitivity To Change Of Radiographic Fixed-Location and Magnetic Resonance Imaging-Based Cartilage Thickness Measures In The Lateral Compartment Of Knees With Radiographic Osteoarthritis – Data From The Osteoarthritis Initiative. Wolfgang Wirth[1], Jeffrey W. Duryea[2], Michael C. Nevitt[3], Robert J. Buck[4], David Hunter[5] and Felix Eckstein[1]. [1]Paracelsus Medical University, Salzburg, Austria, [2]Brigham and Women's Hospital, Boston, MA, [3]University of California, San Francisco, San Francisco, CA, [4]StatAnswers Consulting, Minneapolis, MN, [5]Royal North Shore Hospital, St. Leonards, Australia.

Background/Purpose: Radiographic joint space width (JSW) is frequently employed to indirectly assess structural progression in the medial femorotibial compartment, but it is unclear whether assessment of the lateral compartment provides accurate results. In contrast, magnetic resonance imaging (MRI) directly delineates articular cartilage and has been employed for quantitative analyses of cartilage thickness status and progression in both the medial and the lateral compartment. In the current study, we compared the sensitivity to change between recently proposed radiographic fixed-location measures in the lateral femorotibial compartment (obtained from fixed-flexion radiography [FFR]) - vs. MRI-based cartilage thickness measures, in knees with and without lateral JSN.

Methods: One- and two-year change was assessed in one knee of 290 OAI participants with radiographic OA (210 female, age 61.8±9.1 y, BMI 29.5±4.9 kg/m^2) based on FFR and DESS (n=161) or FLASH (n=129) MRI. Of the 290 knees, 147 had definite osteophytes only and 57/78/8 had grade 1/2/3 lateral JSN. Fixed-location JSW was measured semi-automatically at 9 locations in the lateral femorotibial compartment (LFTC) between 70% (JSW(X=0.7)) and 90% (JSW(X=0.9)) of the femoral width (medial to lateral). Cartilage thickness was measured by manual segmentation in the entire LFTC and in combined external (eLFTC), central (cLFTC), and internal (iLFTC) lateral subregions. The standardized response mean (SRM=mean change/standard deviation of change) was calculated as measure of the sensitivity to change. The most sensitive MRI and FFR measures were selected for comparing the sensitivity between MRI and FFR.

Potential sample sizes for a two-arm study with an estimated treatment effect of 50 % (i.e. reduction in structural progression) was calculated using G*Power based on sensitivity results of the current study. The calculation was based on the assumption of parametric t-tests, a false positive rate of 0.05, a false negative rate of 0.2, and 15% drop-out.

Results: The greatest overall sensitivity to change in both knees without JSN and knees with lateral JSN was observed in cLFTC for MRI and in JSW(X=0.8) for FFR. In knees without JSN, the one-year SRM was relatively low in both MRI (−0.16) and FFR (−0.11). This results in required sample sizes of n=6,165 (MRI) and 11,264 (FFR). Over two years, a greater SRM was observed for both MRI (−0.30) and FFR (−0.20), reducing the required sample size to 1,626 (MRI) and 3,502 (FFR).

In knees with lateral JSN, the one-year SRM observed for MRI (−0.73) was twice that for FFR (−0.37), suggesting sample sizes of 286 (MRI) and 1048 (FFR). Over two years, the SRM for MRI was −0.86 and that for FFR was −0.64, resulting in required sample sizes of 204/364 knees, respectively.

Conclusion: The study shows that fixed location measures of lateral JSW can be used to follow structural progression in the lateral femorotibial compartment in knees with lateral JSN. However, the sensitivity to change tended to be greater for MRI than for FFR, particularly over 1 year. Treatment studies with reasonable sample sizes appear feasible when following knees with lateral JSN using MRI over one, or using FFR over two years.

Sensitivity To Change Of a New Method Of Computer Measurement Of Hip Joint Space Width: Performance Of Location-Specific Measures Obtained At a 48 Month Interval. Charles Ratzlaff[1] and Jeffrey W. Duryea[2]. [1]Harvard Medical School/Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Responsive measures of radiographic joint space width (JSW) in hip osteoarthritis (OA) are a major requirement for the evaluation of treatment interventions. The primary purpose of this study was to validate a semi-automated quantitative software tool for hip JSW by measuring responsiveness at 3 different fixed locations.

Methods: We used data from the Osteoarthritis Initiative (OAI), a longitudinal cohort study of knee OA. All OAI participants had standing AP radiographs at baseline and 48 month visits using a standardized protocol.

We used a nested case-control design, and had two case definitions. First, subjects who had a total hip replacement (THR) sometime after the 48 month visit (at 60 and 72 months) and available AP pelvic films at 0 and 48 months (n=27) were selected and matched (1:1) on sex and age (2 years) to subjects without a THR and no hip pain during the study period.

Second, a larger sample of cases was selected that included all subjects who had a THR at any point after baseline and had AP pelvis films at 0 and 48 months (n=72). The *contralateral* (CL) hip from the THR was designated the case hip, and subjects were matched (1:1) as above.

Measurements of superior hip JSW were made at 3 fixed locations (10°, 30° and 50° medial to a line from the femoral head centre to the outer edge of the acetabular roof – lateral line in Figure 1) and were facilitated by software that delineated the femoral head and found the acetabular margin along each of the 3 lines. A reader used software to correct margins if needed.

Statistical analysis. Sensitivity to change was estimated by the standardized response mean for change from baseline to 48 months. Paired t-tests were used to test statistical significance between cases and controls.

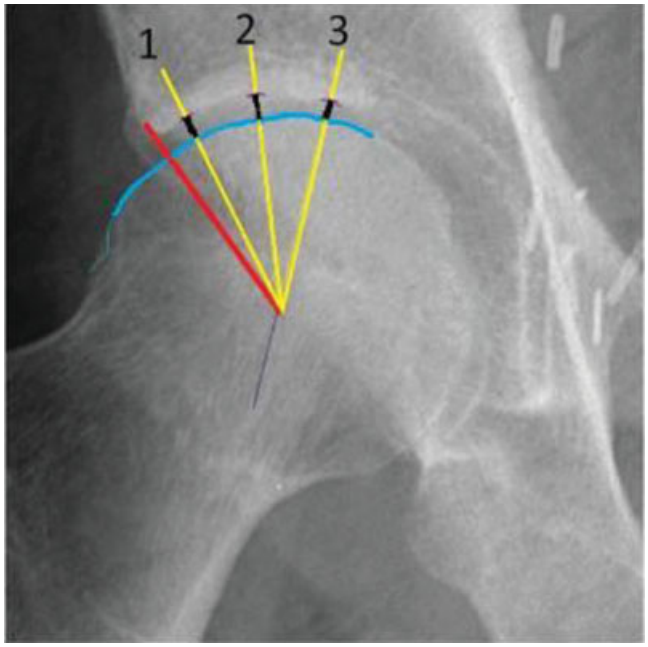

Figure 1. Example of hip JSW measurement.

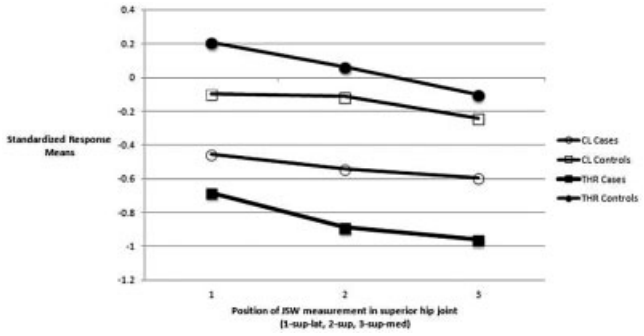
Results: The overall sample was 47% male, 91% Caucasian had a mean age of 64.2 and BMI of 27.9. The results are given in Table 1 and Figure 2. Significant differences were observed between cases and controls in both case-control groups. The superior medial location (position 3) was the most responsive.

	Standardized Response Mean (baseline to 48 months)		
	Location 1 Sup-lateral (10°)	Location 2 Superior (30°)	Location 3 Sup-medial (50°)
THR Cases (n = 27)	−0.68	−0.89	−0.96
Controls (n = 27)	0.21	0.06	−0.10
p-value	0.001	0.001	0.001
Contralateral Cases (n = 72)	−0.46	−0.54	−0.59
Controls (n = 72)	−0.10	−0.11	−0.24
p-value	.002	.003	0.002



Conclusion: Location 3 (sup-med) was the most responsive in all 4 groups and warrants further study. Location specific measures of JSW are potentially an improved method to assess hip OA.

More Evidence For Breaking The 'law Of valgus': Imaging Evidence For Higher Prevalence and Volume Of Bone Marrow Lesions In The Medial Patellofemoral Joint. Charles Ratzlaff[1] and Jeffrey W. Duryea[2]. [1]Harvard Medical School/Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: We recently developed an efficient semi-automated measure of tibial and femoral BML volume and validated it against the Whole-Organ Magnetic Resonance Imaging Score (WORMS). Since patella-femoral (PFJ) osteoarthritis (OA) is increasingly being recognized as a cause of knee pain in OA, we have extended the method to the PFJ. The purpose of this study was to compare PFJ BML volumes with WORMS, and test the hypothesis that PFJ BML volume is associated with stair-climbing pain (but not walking or standing pain).

Methods: 115 subjects from the baseline data of the Osteoarthritis Initiative (OAI) Progression Cohort whose knees were WORMS-scored by OAI central imaging were included. Sagittal turbo spin echo fat saturated (TSE FS) (0.357 × 0.357 × 3.0 mm, TR 3200ms, TE 30ms) IW MRI were obtained on a 3T Siemens Trio MR system. A reader used software to segment subchondral BMLs in the patella and anterior femur (trochlea). The software applies a grayscale thresholding algorithm to the raw image and reader judgment is used to select, usually with 1 or 2 mouse clicks, the clinically appropriate region(s) of BML. Reliability on a random sample of 20 subjects was: ICC 0.96, and 0.97 for intra-and inter-reader respectively.

Primary outcome: segmented volume of BMLs (mm^3) in the patella and trochlear femoral compartment.

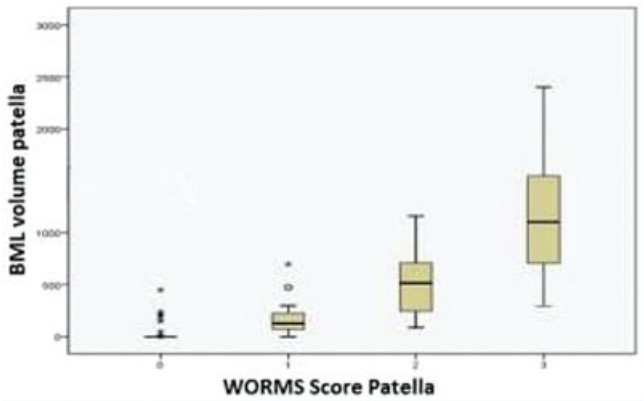

Figure. Box and whisker plots showing mean, median, lower and upper quartiles, and outliers of BML volume by WORMS scores, for patella.

BML Volume		No Stair pain (n = 58)	Stair Pain (n = 57)	p-value[1]
PFJ BML (mm^3)	median	44	338	0.01
Trochlear BML (mm^3)	median	0	22	0.04
Patellar BML (mm^3)	median	0	192	0.01

WORMS score: Comparison of PFJ BML volume was made with OAI public-release WORMS scoring for the patella and trochlea. WORMS reports BML in 4 categories based on size of BML relative to the total sub-region (0-no BML, 1-<25%, 2–25–50%, 3->50%). Spearman's correlation and Kruskall-Wallis tests were used to assess association between the two methods.

Pain. We used the WOMAC pain sub-scale and defined the primary outcome of knee pain dichotomously as moderate to severe pain (scores 2–4) on any of the 3 weight-bearing (WB) WOMAC pain questions (pain on walking, climbing stairs, standing), acquired at the same baseline OAI visit as the MRI scans. Kruskall-Wallis test were used to assess the associations.

Results: The sample was 84% white, 52% male and were 90% K-L grade 2 and 3. Median BML volumes were progressively larger by WORMS category for patella (figure), trochlea and PFJ (all $p<0.001$) and strongly correlated (Spearman's $r = 0.89$, 0.74 and 0.81 respectively, all $p=0.000$). We found significant positive associations between stair-climbing pain and PFJ BML volume but not for other WOMAC WB pain items.

Conclusion: This study reports good criterion and clinical validation of an efficient method for measuring BML in the PFJ, providing a potentially useful tool for PFJ trials.

Synovial Fluid Vascular Endothelial Growth Factor Could Predict Progression Of Osteoarthritis According To Radiological and Ultrasonographic Findings. Sang-Heon Lee, Hae-Rim Kim and Ho-Youn Kim. Konkuk University Medical Center, Seoul, South Korea.

Background/Purpose: Vascular endothelial growth factor (VEGF) may have important contribution in the pathogenesis of knee osteoarthritis. MMP-13 is expressed by chondrocytes and synovial cells, and is thought to play a critical role in cartilage destruction. It is not certain whether VEGF correlate with the radiographic severity of knee osteoarthritis(OA). The aim of this study was to determine VEGF and MMP13 as new potential biomarkers in patients with knee OA, and their relevance for radiographic severity and ultrasonographic finding.

Methods: The study was conducted with 34 consecutive patients with clinical and radiographic evidence of knee OA with joint effusion detected clinically. The questionnaire included the duration of knee pain, 100 mm visual analog scale (VAS), and Western Ontario McMaster Universities (WOMAC) Osteoarthritis Index. All patients were examined by plain radiography on the same day as ultrasonography and arthrocetesis of knee joint were performed simultaneously. Knee radiographs were analyzed by Kellgren-Lawrence (KL) grading system. Plasma and synovial fluid (SF) VEGF and MMP 13 levels were determined by ELISA.

Results: Thirty four patients with knee OA included two men and 26 women, with a mean age of 65.5 ± 7.9 years and mean disease duration of 38.2 ± 48.9 months. Mean pain VAS was 56.8 ± 23.9 mm and total WOMAC score was 89.9 ± 42.9. Fourteen patients were categorized as grade 2 (KL 2), 16 as grade 3 (KL 3), and 4 as grade 4 (KL 4). The median value of SF VEGF were higher in KL grade 4 than those of KL grade 2 (845.0±82.3 pg/ml vs 624.6±37 pg/ml, $p=0.025$). By Spearman analysis, SF VEGF levels positively correlated with KL scores ($r=0.444$, $p=0.009$). No significant difference in SF and plasma levels of MMP-13 as well as plasma levels of VEGF were found among OA subjects with radiographic severity. We further analyzed the correlations between laboratory and ultrasonographic finding adjusted by age and BMI. The SF VEGF correlated positively with the length of the medial osteophytes ($r=0.502$, $P=0.012$), lateral osteophytes ($r=0.528$, $P=0.008$) and joint capsule distension ($r=0.423$, $p=0.048$). The SF MMP-13 did not show any correlation with ultrasonographic finding.

Conclusion: SF VEGF levels significantly increased in advanced OA according to KL scores and correlated well with ultrasonographic findings such as length of medial and lateral osteophytes and joint capsule distension.

MR T1ρ and T2 Of Meniscus After Acute Anterior Cruciate Ligament Injuries. Elijah Abramson, Michael Hoppe, Toran MacLeod, Lorenzo Nardo, Julien Rivoire, Richard Souza, Thomas M Link, C. Benjamin Ma and Xiaojuan Li. University of California, San Francisco, San Francisco, CA.

Background/Purpose: Acute anterior cruciate ligament (ACL) injuries are high-risk factors for post-traumatic osteoarthritis. Cartilage changes in

such cases have been widely studied; however, there are fewer reports on MR quantitative evaluation of meniscus after acute ACL injuries. The goal of this study was to evaluate changes in meniscal T1ρ and T2 quantification in patients with acute ACL injuries and correlate those changes to MR clinical grading and patient-reported outcomes.

Methods: 18 control patients and 30 patients with acute ACL injuries (19 females; age = 29.9 ± 7.2 years) were studied using a 3T GE MR scanner. Injured patients were scanned post-injury and prior to ACL reconstruction (58 ± 48 days). Patients filled out the Knee Injury and Osteoarthritis Outcome Score (KOOS), a validated self-assessed questionnaire with five categories: pain, other symptoms, function in sport and recreation, function in daily living (ADL), and knee-related quality of life (QOL), on the same day of MR scan. Imaging protocol included sagittal T2-weighted 3D fast spin-echo images (CUBE) and sagittal 3D T1ρ and T2 quantification sequences. Modified whole-organ magnetic resonance imaging scores (WORMS) were determined using CUBE images. Menisci were segmented semi-automatically using CUBE images into four sub-compartments: anterior horn of the lateral/medial meniscus (AHLAT/AHMED) and the posterior horn of the lateral/medial meniscus (PHLAT/PHMED). These regions of interest (ROI) were overlaid onto T1ρ and T2 maps. Mean T1ρ and T2 values were calculated for each ROI. Paired T-tests were performed when comparing injured knees to contralateral (contra) knees; unpaired T-tests were performed when comparing injured knees to the control group; Spearman correlation coefficients were calculated between meniscal T1ρ/T2 and KOOS.

Results: Mean T2 values were significantly higher in ACL-injured knees than control group knees in the AHLAT, PHLAT, and AHMED ($P < 0.05$), but were not significant ($P = 0.06$) in the PHMED. T2 values were significantly higher in the AHLAT of ACL-injured knees than the contra knees ($P < 0.01$) but did not reach statistical significance in the PHLAT, AHMED, or PHMED ($P = 0.08$, $P = 0.11$, $P = 0.09$). ACL-injured patients with meniscal tears in the PHLAT (meniscus WORMS > 1) had significantly elevated T1ρ and T2 values ($P < 0.03$) compared to those without meniscal tears in the PHLAT. There was a significant negative correlation between KOOS and T2 ($P < 0.05$) in the PHLAT for pain, symptoms, and ADL ($\rho = -0.38, -0.48, -0.46$).

Conclusion: Quantitative MR imaging can be used to detect damage and early degeneration in meniscal matrices. This study found that acute ACL injuries led to elevated T2 values in the meniscus. We observed a significant association of meniscal degeneration to elevated T1ρ and T2 measurements in patients with acute ACL injuries in the PHLAT. There were more significantly elevated T1ρ and T2 in comparing the injured knees to control group than to contra knees. We also observed that T1ρ and T2 increased with severity of meniscal tears in acute ACL injuries. The correlation between T2 (especially in PHLAT) and KOOS suggested a relationship between meniscal damage and patient outcomes after acute injuries.

Evaluating Indeterminate Quantiferon-TB Gold In-Tube Results in Patients With Chronic Inflammatory Diseases On Immunosuppressive Therapy. Cassandra Calabrese[1], Robert A. Overman[1], Stacie Dusetzina[2] and Rula Hajj-Ali[3]. [1]Cleveland Clinic, Cleveland, OH, [2]Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Raleigh-Durham, NC, [3]Cleveland Clinic Foundation, Cleveland, OH.

Background/Purpose: The Quantiferon test (QFT) is used to for screen for tuberculosis in patients with autoinflammatory conditions (IC) prior to the use of immunosuppressant medications. Indeterminate results limit the utility of QFT and strategies are need to reduce their impact on the diagnostic progress. The aim of this study was 1) To analyze the rate of indeterminate QFT in patients with IC as compared to both the general hospital population and a healthy reference (HR) group, and 2) To analyze factors contributing to an indeterminate test result.

Methods: Adults (≥18 years) with a QFT result within the Cleveland Clinic Health System electronic medical record between 2007–2012 were included. Patients were categorized as having IC if any of the following conditions were present in the year preceding their first QFT: rheumatoid arthritis, psoriatic arthritis, systemic vasculitis, inflammatory bowel disease, inflammatory spondylarthropathy, or systemic lupus erythematous. Subjects who did not have an IC receiving their QFT at a corporate health screening center were considered the HR group of hospital employees, with all others receiving the QFT considered the general hospital population. Prevalent use of glucocorticoids (GC), biologics, or disease modifying anti-rheumatic drugs (DMARDs) or cessation within 5 days of QFT was used to evaluate the effect of these drug classes on indeterminate tests in the IC group. Binomial regression was used to estimate the risk of having an indeterminate test result, adjusting for age, gender, co-morbidities (Human immunodeficiency virus, chronic kidney disease, diabetes mellitus, chronic obstructive pulmonary disease, and asthma), and health services use in the prior year.

Results: Of the 55,132 included patients, 5.2% had inflammatory conditions and 46.6 % were employees. The mean age of patients in our sample was 40.2 years and 68.5% were female. Indeterminate tests were present in 5.3% of the IC group, 1.9% of the general hospital population, and 1.5% of the HR group. Patients with IC were 3.6 times as likely as the HR group to have indeterminate test results (adjusted risk ratio (aRR): 3.60, 95%CI: 3.00, 4.30). There was no significant difference between the general hospital population and the HR group. In adjusted models restricted to patients with IC, GC use significantly increased the likelihood of an indeterminate test (aRR:1.43, 95%CI: 1.02, 1.99) while DMARD use decreased this likelihood (aRR: 0.67, 95%CI: 0.46, 0.97) when compared to patients without medication use.

Conclusion: Patients with autoinflammatory conditions were more likely to have indeterminate QFT results as compared with a reference group of hospital employees. Among patients with IC, only prior use of GC was associated with an increase in the likelihood of having an indeterminate test result.

Tuberculin Skin Test and Booster Phenomenon In a Rheumatoid Arthritis Population. Differences Between Early and Established Disease. Lorena Perez-Barbosa[1], David Vega-Morales[2], Janett Carmen Luzmilla Riega-Torres[1], Octavio Ilizaliturri-Guerra[1] and Mario Alberto Garza-Elizondo[1]. [1]Early Arthritis Clinic, Rheumatology Service, Hospital Universitario, Monterrey, Mexico, [2]Rheumatology Service, Hospital Universitario, Monterrey, Mexico.

Background/Purpose: Tuberculosis (TB) remains a major global health problem. Chronic inflammation in Rheumatoid Arthritis (RA) and the use of immunosuppressive drugs, increase the risk of reactivation of latent TB (LTB). Although other tests are available, tuberculin skin test (TST) is widely used method which detects LTB. There are reports that the TST response is decreased in RA. TST sensitivity may be increased by a second test done 1–4 weeks after the first, referred as the "booster" phenomenon.

The purpose of our study was to evaluate the TST and booster reactivity in patients with RA divided by the time evolution.

Methods: A cross-sectional analytical study was conducted. Patients who fulfilled the RA ACR/EULAR 2010 classification were included. Five Units of PPD CT-68 were administered with the Mantoux technique. Indurations equal to or greater than 5 mm were considered positive. Patients with negative reactions were scheduled within 15 days for a booster application. We reviewed clinical records and settled a database for analysis using SPSS v. 20.

Results: We analyzed 143 patients, 126 (88.1%) were females, with a mean age of 46.9 (SD 12.8); 60 (42%) had current use of corticosteroids, with a mean dose of 7.07 mg/day (SD 3.3). One hundred patients (69.9%) had a current use of DMARDxs. The mean DAS28 was 4.5 (SD 1.9). In first TST application there were 39 patients (27.3%) with a positive test (PT). Of the negative patients, 84 (81 %) had the booster application, 9 (10.7 %) of them had a PT. On table 1 is the bivariate analysis between early RA (<52 weeks) and established RA, on table 2 for the first TST positivity ad on table 3 for the booster positivity. At the end we have a LTB prevalence of 33.6%. There was an increased prevalence on the early RA group (OR 1.3 CI 95% (1.007–1.7) $p = 0.04$).

Pyogenic Arthritis: Clinical and Epidemiological Features Of 101 Cases At a University Hospital. Anne Riveros-Frutos, Lourdes Mateo, Melania Martínez-Morillo, Beatriz Tejera, Samantha Rodriguez-Muguruza, Juana Sanint, Susana Holgado, Jerónima Cañellas, Xavier Tena, Alejandro Olivé and Montserrat Gímenez. Hospital Universitario Germans Trias i Pujol, Badalona, Spain.

Background/Purpose: To describe the clinical characteristics, treatment and outcome of patients diagnosed with pyogenic septic arthritis.

Methods: Design: retrospective (1984–2012). Location: University hospital. Referial area: 800,000 inhabitants. The medical records of patients with pyogenic arthritis were reviewed. Inclusion criteria: isolation of bacteria in joint fluid or blood. Patients with soft tissue infection, prosthetic, fungal and mycobacterial septic arthritis were excluded.

Results: One hundred one patients were selected: 66 males and 35 females. Mean age: 54.5 ± 21.2 years. The following risk factors were identified: alcoholism (24), cirrhosis (12), diabetes mellitus (18), chronic renal failure (17), neutropenia (6), immunosuppression (10), HIV (10), AIDS (5), parenteral drug addiction (12), cancer (6), RA (4) and microcrystalline arthritis (17). Seventeen patients had undergone joint manipulation prior to the onset of the infection: 9 arthrocentesis with corticosteroids injection, 6 arthrocentesis and 2 arthroscopies. The pattern of join involvement was monoarticular in 72 patients (71.3%): knee 38 (36.8%), and shoulder and ankle 8 (8%) respectively. Polyarticular involvement was found in 29 patients (28.7%). Fifty nine patients 58.4% had fever. Cellulitis was observed in 17 cases (17%). The mean time between onset of symptoms and diagnosis was 7.9 ± 8.2 days. Mean hospital stay was 30.4 ± 28 days. Blood cultures were positive in 40 cases (39.7%) and in 85% of them the same microorganism was isolated in joint fluid. Septic arthritis was caused by gram positive in 79%, gram negative 19% and 2% were polymicrobial. The most common were: S. aureus methicillin sensitive (45), S. aureus methicillin resistant (MRSA in 5 cases since 2008), S. agalactiae (6), S. pyogenes (3), S. pneumoniae (9), E. Coli (9), P. aeuriginosa (3), Enterobacter cloacae (2) and Salmonella (2). Acute phase reactants were increased: ESR: 89.5 ± 29.6 mm/1sth and C-reactive protein 162 ± 122 mg/dl. The mean leukocyte count of joint fluid was 65,602 ± 62477/mm3. Synovial glucose was decreased in 50% of patients. Mean duration of intravenous antibiotic therapy: 3 weeks. Thirty-four patients (33.6%) required surgical treatment. Three patients required a second arthrotomy. Complications were: septic shock (20), pneumonia (6), reflex sympathetic dystrophy (2), osteonecrosis (2), endocarditis (3), respiratory distress (1). Most of the cases evolved favorably. Fifteen cases resulted in death (15%): 8 cases had monoarticular involvement and 7, polyarticular involvement. The causative organisms were: S. Aureus (10 cases), MRSA (3 cases), Pneumococcal (1 case) and polymicrobial (1 case of S. aureus more E. Coli).

Conclusion: S. aureus is the most common pathogen isolated. Furthermore MARSA is an emerging microorganism. Hematogenous spread and polyarticular involvement are poor prognostic factors. Prolonged antibiotic therapy and surgical debridement are essential for proper healing.

Study Of The Antibody Titer By Influenza Vaccination In Rheumatoid Arthritis Patients Treated With Biologics In JAPAN. Hisato Ishikawa[1], Daihei Kida[2], Yosuke Hattori[2], Atsushi Kaneko[2] and Tomotaro Sato[2]. [1]Nagoya Medical Center, nagano, Japan, [2]Nagoya Medical Center, Nagoya, Japan.

Background/Purpose: Vaccination for influenza virus is recommended for patients with rheumatoid arthritis (RA) with underlying such as disease elderly people over the age of 65, respiratory disease, cardiovascular disease. Especially, it is believed that in general, should be vaccinated actively in patients with biologic agents. Biologic agents might suppress the immune response to influenza vaccines, but, the report is limited to the number of papers. The aim is the study to compare antibody titers changeafter influenza vaccination for rheumatoid arthritis.

Methods: 182 patients with RA of our hospital received inactive trivalent influenza vaccination. All RA patients who have been treat with methotrexate (MTX; contorol; n=48), abatacept (ABT; n=37, include the MTX combination of 18 cases), tocilizumab (TCZ; n=80, include the MTX combination of 22 cases), golimumab (GLM; n=17, include the MTX combination of 13 cases). We used commercially available inactivated trivalent influenza vaccine. Patients received a single dose of vaccine (0.5 ml). Vaccines (A/H1N1, A/H3N2, B/B-1 strains) which was used this time was a vaccine for 2012–2013 in Japan. Measuring the antibody titer prior to vaccination, again, by measuring titer one month after, examined seroprotection rates and seroconversion rate. Serum antibody titers were measured hemagglutination inhibitory assay (HI).

subcutaneously from October 2012 until January 2013. For RA patients receiving biologics, the vaccination was done on the same day as biologics infusion. Seroprotection was defined as antibody titres of ≥40. Seroconversion was defined as post vaccination antibody titres of ≥40 in patients whose pre vaccination titres were <10. Seroresponse was defined as seroconversion or 4 fold increases in antibody titres of in patients whose pre-vaccination titres were ≥10.

Results: In seroprotection rate of the type B, compared to the control, group of biologic agents was higher. But, there were no difference in the seroconversion rate in all types between control and biologics. Seroprotection rate, TCZ was higher than control in type B. In type H3N2, ABT and GLM were lower than control. Seroconversion rates, ABT tended to be lower in all types and TCZ tended to be higher in all. In type H3N2, ABT was lower than control. TCZ was higher than control in type B. This tendency is more pronounced in the Biologics group used in combination with MTX, which was the lowest antibody levels in the ABT + MTX group.

Conclusion: Treatment with anti tumour necrosis factor α (anti-TNFα) agents may impair antibody response to influenza vaccination in patients with RA and other rheumatic diseases, but the response is enough to warrant influenza vaccination for such patients. Mori et al, reported that TCZ does not hamper antibody response to influenza vaccine in RA patients and Influenza vaccination is considered effective in protecting RA patients receiving TCZ therapy with or without MTX. The results of our TCZ group did not affect the change of antibody titers as well. In ARRIVE test, Influenza vaccine seroconversion rate who patients treated with ABT, was similar to normal people. However, in our study, no significant difference, but the results were lower than the control reviews.

Response To H. Pylori Treatment and Autoantibody In Chronic Thrombocytopenia. Mitsuyo Kinjo[1] and Kensuke Nakanishi[2]. [1]Okinawa Chubu Hospital, Uruma City Okinawa, Japan, [2]Okinawa Chubu Hospital, Uruma, Japan.

Background/Purpose: Helicobacter pylori (H. pylori) infection has been linked to pathogenesis of autoimmune disease including chronic idiopathic thrombocytopenic purpura (ITP). Prior studies showed platelet counts have improved after eradication of H. pylori in some patients with ITP. To clarify the role of H. pylori in chronic thrombocytopenia and its response to treatment in association with autoantibody status.

Methods: Medical records from 2002–2012 were reviewed at Okinawa Chubu Hospital to locate patients > 18 years old with chronic ITP (platelet < 100,000/mm^{3}for > 12 months). After exclusion of acute ITP and secondary chronic thrombocytopenia, 49 patients were included. We recorded antinuclear antibody (ANA), antiphospholipid antibody (APLA) and H. pylori status. Treatment for H. pylori infection was administered to patients with positive H. pylori detected by breath test. Platelet count was monitored at least for one year after eradication of H. pylori.

Results: Median age was 44 years (range, 18–86); 39/49 subjects were female (80%). ANA or APLA was positive but H. pylori was negative in 25/49 (50%); H. pylori infection was present in 15/49 (31%), and both H. pylori and autoantibody were positive in 10/49 (20%). All patients with H. pylori infection were treated with antibiotics. Eradication failed to improve platelet counts in 10/10 cases with positive ANA or APLA. Among patients with H. pylori without autoantibodies, 3/5 responded with increased platelet counts and 2/5 did not. The overall rate of positive autoantibody in non-responders was therefore 10/12 (83%), and zero in responders.

Conclusion: Among patients with chronic ITP and H. pylori infection, refractory thrombocytopenia after eradication may identify a subset of patients with positive autoantibody. Immunological response to H. pylori may be associated with poor response rate to antibiotic treatment in patients with concomitant ITP and H. pylori infection.

Distinct Pathways Of Ly6C^{hi} Monocyte Development Identified By a Novel Dual-Reporter Murine Myeloid Progenitor Cell Line. Pui Lee[1], David Sykes[2], Sarah Ameri[3], Demetrios Kalaitzidis[2], Peter A. Nigrovic[1] and Astrid Cardona[4]. [1]Boston Children's Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]University of Texas - San Antonio, San Antonio, MA.

Background/Purpose: Monocytes are essential to innate immunity but also propagate the inflammatory response in autoimmune arthritis and crystal arthropathies. Development of inflammatory monocytes (Ly6C^{hi} CCR2$^+$) and residential monocytes (Ly6C^{lo} CX$_3$CR1$^+$) from murine bone marrow precursor cells is an enigmatic process that involves numerous transcription factors with influence by growth factors and cytokines. Elucidation of these critical pro-inflammatory pathways is limited by the paucity of precursor cells and the need for extensive ex-vivo manipulation and cell sorting.

Methods: To develop an informative myeloid cell line, we infected bone marrow from CCR2$^{RFP/+}$ CX$_3$CR1$^{GFP/+}$ dual-reporter mice with a murine stem cell virus encoding Hoxb8 under the control of estrogen receptor. These cells remain immortalized at the myeloid precursor stage until induced by estrogen withdrawal to initiate synchronous myeloid differentiation. To identify pathways important to monocyte development, small molecule inhibitors, cytokines and growth factors were added to cell culture at specific timepoints, and key findings were confirmed in live mice.

Results: Upon cessation of Hoxb8 expression after estrogen withdrawal, our novel dual-reporter cell line spontaneously differentiated into Ly6C^{hi} CCR2$^+$ inflammatory monocytes, followed by maturation to Ly6C^{lo} CX$_3$CR1$^+$ residential monocytes. Using this cell line as a screening tool, we identified an essential role of phosphoinositide-3 kinase (PI3K) and mechanistic target of rapamycin (mTOR) in spontaneous monocyte development through a small molecule library screen. These findings were confirmed *in vivo* as mice with conditional deletion of mTOR complex 1, but not mice lacking mTOR complex 2, failed to develop Ly6C^{hi} monocytes. While macrophage colony-stimulating factor (M-CSF) was not required for spontaneous production of monocytes, the addition of exogenous M-CSF induced Ly6C^{hi} monocyte development via a PI3K/mTOR-independent pathway.

Conclusion: We describe a novel dual-reporter myeloid progenitor cell line that recapitulates the monocyte development continuum. Studies using these cells enabled identification of a previously unrecognized role of mTORC1 in normal development of inflammatory monocytes, as well as a potential "rescue" pathway of mTORC1-independent differentiation. Our work highlights the utility of this technology in studying myeloid differentiation and provides evidence for the existence of two distinct pathways of monocyte production that may be differentially employed in physiologic and inflammatory conditions.

Increased Frequency Of Pratroling Monocytes In Experimental Arthritis and Rheumatoid Arthritis Patients In Response To IL6-R Blockade. Julie Quentin[1], Jessy Presumey[2], Florence Apparailly[2], Yves-Marie Pers[3], Pascale Louis Plence[4] and Christian Jorgensen[3]. [1]Inserm U844, Montpellier, France, [2]Inserm, Montpellier, France, [3]Inserm U844, CHU saint-Eloi, Université Montpellier 1, CHU Lapeyronie, Montpellier, France, [4]INSERM U844 Montpellier, Montpellier, France.

Background/Purpose: Monocytes represent a heterogeneous circulating population of immune cells that play important roles in the inflammatory response. Two main functional subsets of human monocytes have been identified, as well as their counterparts in mouse. Increasing numbers of reports suggest that each of them exert specific roles in homeostasis and inflammation in vivo, and their involvement in pathological inflammatory responses is growing. The aim of our study was to investigate the effect of the anti-IL6R antibody therapy, in the mouse CIA model and in Rheumatoid arthritis patients, on the frequencies of monocyte sub-populations.

Methods: The CIA has been induced by immunization of DBA1 mice with bovine type II collagen. The anti-IL6R antibody (MR16-1) treatment was initiated on day 22 post-immunization using i.p. injections of 0.5mg/mouse twice a week. Blood samples were collected weekly from day 23 and the different monocyte subsets were analyzed by flow cytometry.

15 RA patients were recruited and Tocilizumab was given with approval of the French Drug Agency, in a dose of 8 mg/Kg as a 60-minute intravenous infusion every 4 weeks. For immune monitoring, blood samples from RA patients were collected just before the 1st and 4th tocilizumab infusions (8 mg/Kg).

Results: Clinical monitoring of CIA showed a stabilization of disease features from day 29 until euthanasia (D44) demonstrating that the anti-IL-6R Ab treatment was able to slowdown CIA progression and decrease disease severity when injected after the boost. We monitored the percentage of monocyte subsets and evidenced fluctuations during clinical course of the disease. The percentage of circulating inflammatory $Ly6C^{high}$ monocytes was transiently reduced on day 37 in the treated group as compared with controls, while the percentage of the non-inflammatory $Ly6C^{low}$ monocytes was significantly increased from day 30.

In parallel, we have monitored monocytes cell populations in the blood of RA patients before and during treatment with Tociluzumab and found (1) fluctuations of monocyte subsets following Tociluzumab therapy and (2) significant difference in frequencies in the various subsets before treatment between responders and non-responders and (3) a correlation between clinical benefit and increased frequency of the non-classical $CD14^{dim}CD16^{+}$ monocytes.

Conclusion: Similar to the increased frequency of the non-classical $CD14^{dim}CD16^{+}$ monocytes that we observed in the blood from RA patients under Tocilizumab therapy, an increased percentage of their mouse counterpart $Ly6C^{low}$ monocytes was observed following treatment of CIA mice with MR16-1 Ab. These data suggest new cellular mechanisms insight into clinical benefit associated with anti-IL6R-based therapy and suggest that frequency of the $CD14^{dim}CD16^{+}$ monocytes can predict clinical response to treatment.

Wnt Signaling Pathway Regulates Multi-Unconventional Differentiation and Function Of Human Dendritic Cells. Jia Wang[1], Yi Liu[2] and Yi Zhao[2]. [1]Sichuan Provincial People's Hospital, Chengdu, China, [2]West China Hospital of Sichuan University, Chengdu, China.

Background/Purpose: Dendritic cells (DCs) play a central role in regulating immune responses and govern T cell priming and polarization, mediating immunity and tolerance. Recent progress uncovered the Wnt signaling pathway is crucial for the immune balance and focuses on DCs as a direct target for their immunoregulatory role. In this study, we investigated the effect of the canonical and non-canonical Wnt signaling pathways regulate the differentiation and function of human DCs.

Methods: Human peripheral blood CD14+ monocytes were cultured for 6 days with GM-CSF/IL-4 and then treated with LPS, Wnt3a, Wnt5a, GSK-3β inhibitor (SB216763) or silencing β-catenin for 24 h. Immunophenotypic characterizations of DCs were analyzed by flow cytometry. The supernatants were collected and cytokines (IL-17, IL-23, IL-10, TNF-α, IFN-γ) were assessed. Human peripheral blood and active rheumatoid arthritis patients' synovial fluid CD3+ monocytes were isolated for mixed lymphocyte reaction. Proteins were extracted and incubated with antibodies against the total or phosphorylated forms of β-catenin, GSK-3β.

Results: Our results showed that regulating the canonical and non-canonical Wnt signaling altered the maturation status and function of already differentiated DCs. The differentiation of DCs resulted in inhibiting activity of GSK-3β and stabilizing its substrate, β-catenin. GSK-3β inhibitor induced a full maturation phenotype of DCs that expressed mostly CD14. These DCs produced low levels of IL-17, IL-23 but high level of IL-10. Consequently, these DCs have a reduced capacity to stimulate Th17 differentiation and increased Th2 and Treg differentiation. The addition of Wnt3a or Wnt5a both increased CD1a+DCs but reduced CD83, CD80, CD86, CD40 and HLA-DR expression. Wnt3a-DCs produce scant amounts of cytokines and have a reduced capacity to stimulate all T cell subsets differentiation. Wnt5a-DCs produced low level of IL-17, TNF-A while increased IL-23, IL-10 secretion and have an increased capacity to stimulate Th2 and Treg differentiation. β-catenin silencing reduced CD83 expression on LPS-induced DCs maturation and IL-10 secretion, without significant effect on capacity of DCs to stimulate T cells differentiation.

Conclusion: Wnt signaling pathway regulates multi-unconventional differentiation and function of human DCs. GSK-3β inhibitor could induce terminal differentiation DCs into unconventional phenotypic maturation of DCs with tolerogenic features. Silencing of β-catenin partly impair LPS induced maturation of DCs. Exogenous Wnt3a inhibited maturation and function of DCs while Wnt5a inhibited maturation of DCs with regulatory features.

1145

Regulation Of Plasmacytoid Dendritic Cells By Prostaglandin E2. Alice E. Wiedeman and Keith B. Elkon. University of Washington, Seattle, WA.

Background/Purpose: Plasmacytoid dendritic cells (pDCs) constitute a rare blood cell subset exquisitely attuned for production of large quantities of interferon-alpha (IFN-α), and these cells have been implicated in several autoimmune diseases. There is therefore much interest in understanding how IFN-α is regulated in pDCs. Prostaglandin E2 (PGE2) is known to have an inhibitory effect on pDCs via receptors EP2 and EP4, but the mechanism(s) underlying this inhibition is not known. The goal of this study was to elucidate the molecular pathways involved in the inhibition of IFN-α by PGE2.

Methods: Human peripheral blood mononuclear cells (PBMCs), isolated "untouched" primary pDCs, or a pDC line were cultured in the presence of lupus immune complexes (ICs) or agonists of TLR7 (Loxoribine) or TLR9 (CpG-A, ODN 2216) with or without PGE2 (1, 10, and 100 ng/mL), dibutyryl-cAMP (100 μM), or Rapamycin (10 ng/mL). At 1h, cells were harvested and fixed to slides, then stained with DAPI and fluorescently-labeled antibody against IRF7, and analyzed by confocal or fluorescence microscopy. At 20h, IFN-α, IL-6, and TNF in the supernatants were quantified by ELISA, and cells were analyzed by flow cytometry using fluorescently-labeled antibodies to identify pDCs (CD123+BDCA2+), and quantify cell death (Annexin V, propidium iodide).

Results: Lupus IC and TLR7 or 9 agonists induced IFN-α by PBMC which could be inhibited by PGE2 in a dose-dependent manner, whereas production of IL-6 and TNF were unaffected. This was also true for isolated pDC stimulated by CpG-A, and this was not due to pDC death. By confocal microscopy of primary pDCs, IRF7 translocation was increased by TLR9 agonist stimulation and significantly reduced by addition of PGE2 but not carrier control (DMSO). By fluorescence microscopy of primary pDC or the pDC line, the TLR9 agonist increased the IRF7 signal and the intensity of staining was reduced by PGE2. Because PGE2 action on pDC is believed to be via the receptors EP2 and EP4, which drive an increase in cAMP and activation of PKA in other cell types, we addressed whether dibutyryl-cAMP, a cell-permeable cAMP analog, could mimic the effects of PGE2. Indeed, dibutyryl-cAMP reduced the production of IFN-α by 56.7 ± 9.8 % ($p < 0.04$). Lastly, to determine if mTOR played a role in IFN-α regulation, we treated PBMCs with a suppressor of mTOR, Rapamyin, and found that it, too, could robustly inhibit IFN-α production (76.8 ± 5.2 %, $p < 0.004$) but not IL-6 or TNF, without inducing pDC death.

Conclusion: PGE2 is able to inhibit pDC production of IFN-α in response to both lupus IC and TLR agonist stimulation without affecting other pro-inflammatory cytokines or inducing pDC death. We show for the first time that PGE2 can inhibit pDC IRF7 protein expression and nuclear translocation. Consistent with a role for PGE2 receptors EP2 and EP4 in this inhibition, a cAMP analog could also inhibit IFN-α. Lastly, mTOR plays a significant role in IFN-α production, as treatment with its suppressor, Rapamycin, significantly inhibits IFN-α but not other pro-inflammatory cytokines IL-6 and TNF. These results are consistent with a role of PGE2 in inhibition of the mTOR pathway in pDCs, and may represent a novel target for immune modulation in type 1 IFN-associated diseases.

Human Dendritic Cells Produce Thymic Stromal Lymphopoietin In Response To Pattern Recognition Receptor Ligation and This Secretion Is Augmented By Endoplasmic Reticulum Stress. Matthew J Elder[1], Anthony YKC Ng[1], Steven J Webster[1], Michael J Bacon[1], JS Hill Gaston[2] and Jane C Goodall[1]. [1]University of Cambridge, Cambridge, United Kingdom, [2]University of Cambridge/Clin Med, Cambridge, United Kingdom.

Background/Purpose: Thymic stromal lymphopoietin (TSLP) is a cytokine that has an important role in inducing Th2 cell differentiation and has also been implicated as a pathogenic factor in the development of inflammatory arthritis. We have previously shown that human monocyte-derived dendritic cells (DC) secrete significant quantities of TSLP. The precise stimuli which induce TSLP secretion in DC and possible autocrine effects of TSLP production are poorly understood. Endoplasmic reticulum (ER) stress is an important signalling pathway which enables cells to adapt to increased protein synthesis. PRR and ER stress pathways are both engaged in DC following uptake of bacterial pathogens and we have previously shown that both signals synergise to enhance TSLP secretion. Our aim was to identify the key signals that induce and modulate TSLP induction.

Methods: DC were differentiated from peripheral blood monocytes, purified using positive magnetic selection, by stimulation with IL-4 and GM-CSF. Flow cytometry analysis of MoDC phenotype showed them to be $CD1c^{+}$ $CD11b^{Hi}$ $CD11c^{Hi}$ $CD14^{Lo}$ $CD86^{Lo}$ and $HLA\text{-}DR^{Hi}$. Transcriptional analysis was assayed by qRT-PCR following RNA extraction and quantified relative to HPRT; cytokine secretion was assessed by ELISA of cell supernatants.

Results: Heat killed Gram-negative bacteria including *S. typhi*, *P. aeruginosa* and *E. coli* stimulated TSLP secretion. To further examine the PRR requirements for TSLP expression we utilised the pattern recognition receptor (PRR) agonists, Peptidoglycan (TLR2 and NOD2) ultra pure LPS (TLR4) and particulate forms of β-1,3 glucan (dectin 1). These agonists stimulated TSLP mRNA transcription and protein secretion by DC, with the most potent effects induced by β-1,3 glucan (475pg/ml $+/-200$ SEM).

As expected, TSLP secretion induced by β-1,3 glucan was dependent on the dectin 1 adaptor molecule Syk. NF-κB and p38/MAPK were also shown to be essential signalling molecules for this response. Addition of IL-1 receptor antagonist substantially blocked TSLP secretion. Although TNFα was previously shown to enhance TSLP by synovial fibroblasts, neutralisation of TNFα did not reduce TSLP secretion by DC. Dectin 1 stimulation alone was sufficient to activate ER stress, as demonstrated by eIF2α phosphorylation and XBP-1 splicing. Inhibitors for the ER stress signalling molecules IRE-1α and PERK reduced TSLP secretion, suggesting that ER stress signals contribute significantly to induction of TSLP.

Conclusion: TLR2, TLR4 and Dectin 1, are important PRRs in the induction of TSLP secretion by human DC. In addition to fungal derived β-1,3 glucans, we show that bacteria can also induce significant quantities of TSLP. TSLP secretion by DC is induced following a complex integration of signals from PRRs, ER stress pathways and cytokine receptors. Since DC have previously been shown to respond to TSLP made by epithelial cells; possible autocrine effects of TSLP on DC, and their influence on T cell differentiation, warrant further exploration. Autocrine effects of TSLP would be especially relevant in primary and secondary lymphoid tissues where epithelial cells are not present, rather than in the periphery.

Autologous Tolerogenic Dendritic Cells In Rheumatoid and Inflammatory Arthritis. Gillian Bell[1], Amy Anderson[1], Julie Diboll[1], Rachel Harry[1], Elaine McColl[1], Anne Dickinson[1], Catharien Hilkens[1] and John Isaacs[2]. [1]Newcastle University, Newcastle upon Tyne, United Kingdom, [2]National Institute for Health Research, Newcastle Biomedical Research Centre, Newcastle Hospitals Foundation Trust and Newcastle University, Newcastle Upon Tyne, United Kingdom.

Background/Purpose: Rheumatoid arthritis is a chronic autoimmune disease which results from a breakdown of immune tolerance. Current therapies include traditional DMARDs, anti-TNF, B cell depleting therapies and co-stimulation blockade. Despite their efficacious role in reducing disease activity, these therapies non-specifically suppress the immune system, with resulting risks from infection and malignancy. This has led to the development of more specific immune-modulatory therapies in order to specifically switch off the pathological immune response, inducing immune tolerance in an auto-antigen specific manner. Tolerogenic dendritic cells (tolDC) are one such autologous cellular therapy with such potential, with significantly efficacious results in animal models. We are performing a phase I study of intra-articular tolDC in inflammatory arthritis patients. Our primary and secondary objectives are to assess safety, tolerability and feasibility of treatment; exploratory objectives seek preliminary evidence of a potential therapeutic effect.

Methods: An ascending dose, randomised, controlled, un-blinded phase I study is currently underway. Three dosing cohorts are planned of 1 million, 3 million and 10 million tolDC administered arthroscopically into an inflamed knee joint following saline washout; controls will receive saline washout only. Each cohort comprises 4 patients (3 active, 1 placebo). The primary endpoint of the study is the proportion of patients experiencing adverse and serious adverse events following treatment.

Results: To date 8 subjects with inflammatory arthritis have been treated, 5 with tolDC (3 at 1 million and 2 at 3 million tolDC) and 2 controls. Manufacture of tolDC failed in a further patient. TolDC have not induced acute flares of local synovitis (defined as within 5 days of administration). Two delayed knee flares occurred between 11 and 14 days from treatment (one in a subject receiving 1 million tolDC and 1 receiving 3 million tolDC). Two patients experienced a systemic flare of their arthritis 14 days after treatment (1 in subject receiving one million tolDC and 1 in a subject receiving 3 million tolDC). There have been no knee or systemic arthritis flares in control patients. To date patient acceptability has been high but there has been no evidence of a beneficial effect of tolDC administration. There have been two infections: one wound infection at an arthroscopy port and one pneumonia.

Conclusion: In this ascending dose phase I study of intra-articular tolDC we have not seen evidence of acute toxicity. To date we have also not witnessed a beneficial effect and local inflammation has recurred following intervention. Two systemic flares were judged unrelated to therapy. Our results to date suggest that intra-articular tolDC do not induce an acute flare of inflammatory arthritis and is acceptable to patients.

Phenotypic and Molecular Profile Of Innate Lymphoid Cells In Chronic Synovial Inflammation. Hulda S. Hreggvidsdottir[1], Maureen C. Turina[1], Troy Noordenbos[1], Marius Munneke[1], Charlotte Peters[1], Jochem Bernink[1], Jenny Mjosberg[2], Dominique L. Baeten[1] and Hergen Spits[1]. [1]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Innate lymphoid cells (ILCs) represent a novel family of effector and regulatory cells in innate immunity and tissue remodelling. The family comprises several phenotypically and functionally distinct subsets that respond rapidly upon stimulation by producing various T helper cell cytokines such as IL-22, IL-17, IFNγ, TNF, IL-13 and IL-5, of which many are shown to be important in arthritis pathogenesis. The IL-17 and IL-22 producing ILCs are of major interest as they are implicated in chronic gut inflammation. Based on the broad clinical overlap between inflammatory bowel disease and spondyloarthritis (SpA) and the clinical importance of IL-17 in SpA we hypothesize that IL-17 and IL-22 producing ILCs contribute to inflammation and remodelling in SpA synovitis. As these cells have never been described in the joint we aimed at characterising ILC in chronic inflammatory arthritis.

Methods: ILCs (lineage negative, $CD45^{+}CD127^{+}$) were analysed and sorted by flow cytometry from synovial tissue and fluid from rheumatoid arthritis (RA) and SpA patients as well as in blood from SpA patients and healthy donors. mRNA expression of sorted and expanded cells was analysed by qPCR.

Results: ILCs were identified in blood as well as in synovial tissue and fluid from both RA and SpA patients. The frequency of ILCs was higher in the inflamed joint (0,5–3,3% of the lymphocyte population) than in the peripheral blood compartment (0,1%). In the inflamed joint, the ILC3 ($CRTH2^{-}NKp44^{+}ckit^{+}$) and ILC1 ($CRTH2^{-}NKp44^{-}ckit^{-}$) populations, shown to express IL-22 and IFNγ respectively in other tissues, were present in all samples whereas the Th2 cytokine expressing ILC2s

(CRTH2$^+$) were found in low frequencies. Frequencies of ILC subpopulations varied considerably between patients and no differences could be detected between RA and SpA patients. qPCR analysis of expanded cells from the synovium revealed that ILC1s expressed *TBX21* whereas ILC3s expressed *RORC*. Accordingly, stimulated ILC3s expressed transcripts for both IL-23R and IL-22 but not IL-17. A trend towards higher frequency of total ILC and ILC3s was found in the blood of SpA patients compared to controls.

Conclusion: ILC1s and ILC3s are present in the chronically inflamed joint, are enriched compared to peripheral blood and express the key transcription factors associated with specific cytokine profiles. These data indicate that ILCs could contribute to local cytokine-driven immune alterations in SpA and RA.

Differential Regulation Of IL-10 and Dusp1 Production By Kinases In The p38 MAPK Pathway. Deepa Hammaker, Katharyn Topolewski and G. S. Firestein. UCSD School of Medicine, La Jolla, CA.

Background/Purpose: MAPK kinases MKK3 and MKK6 regulate p38 function in inflammatory diseases like rheumatoid arthritis (RA). Targeting MKK3 or MKK6 might be superior to traditional p38 blockade because MKK-deficiency maintains p38-mediated anti-inflammatory responses. Production of IL-10 and the de-activating phosphatase Dusp1 is higher in activated MKK-deficient bone marrow-derived macrophages (BMDM) compared with p38 inhibition, especially for MKK6−/− cells. The concept that MKK6 might be the optimal target in the p38 pathway was confirmed by the observation that MKK6−/− mice have lower disease severity in collagen-induced arthritis than wild type (WT) or MKK3−/− mice (Arthritis Rheum 2012;64:2887). In this study, we explored the mechanism of protection by evaluating differential regulation of IL-10 and Dusp1 expression in MKK3−/−, MKK6−/− and p38 inhibitor-treated BMDMs.

Methods: Bone marrow isolated from WT, MKK3−/− and MKK6−/− mice was differentiated into BMDMs in vitro (n=3/group). The cells were then treated with LPS (100ng/ml) for various times. Gene expression was determined by qPCR in LPS-stimulated BMDM (4h). mRNA half life was measured in LPS-treated BMDM incubated with actinomycin D ± SB203580 (p38 inhibitor) by qPCR. De novo mRNA synthesis was quantified in BMDM treated with ethynyl-uridine ± LPS for 1h. The RNA was biotinylated using Click-iT Nascent RNA capture kit (Invitrogen). Nascent RNA was isolated with streptavidin-magnetic beads. Reverse transcription was performed using SuperScript VILO cDNA synthesis kit (Invitrogen) and IL-10 expression was measured by qPCR and presented as fold of medium-treated cells.

Results: We first determined the effect of MKK-deficiency or p38 inhibitor on the de novo synthesis of IL-10 mRNA in response to LPS. Pre-treatment of WT BMDM with p38 inhibitor significantly reduced IL-10 transcription in WT cells by 75±8% compared with control (n=3 mice/group, $p<0.0001$). Compared with WT, IL-10 induction in MKK3−/− was decreased by 60±7% ($p<0.0001$), whereas inhibition in MKK6−/− cells was minimal (16±3%, $p>0.05$). We also evaluated levels of Dusp1, a p38 phosphatase that is regulated transcriptionally by p38 and de-activates other MAPKs. Dusp1 expression was significantly reduced by 38±6% ($p=0.002$) in p38 inhibitor-treated and 46±5% ($p=0.004$) in MKK3−/− BMDM but not in MKK6−/− cells. We then measured the effect of MKK-deficiency and a p38 inhibitor on mRNA decay of IL-10. WT BMDM treated with p38 inhibitor showed a significantly higher IL-10 mRNA decay rate (t1/2 = 30 min, n=3, $p<0.005$) compared with WT control (t1/2 = 54 min). Surprisingly, IL-10 decay rates were similar in WT, MKK3−/− and MKK6−/− groups (t1/2 MKK3−/− = 45 min, MKK6−/− = 41 min), indicating that unlike p38 inhibition, MKK-deficiency does not alter IL-10 mRNA stability.

Conclusion: Suppressed expression of IL-10 and Dusp1 by MKK3-deficiency or p38 inhibition occurs primarily at the transcriptional level, but gene transcription is maintained in MKK6−/− cells. Preservation of Dusp1 expression in MKK6 deficiency permits de-activation of other MAPKs and terminates the inflammatory cascade. Together these data suggest that MKK6 is a potential therapeutic target in RA.

Snapin Is Required For Functional Autophagy and Is Critical For Monocyte To Macrophage Differentiation. Bo Shi[1], Qiquan Huang[1], Robert Birkett[1], Renee E. Koessler[2], Andrea Dorfleutner[1], Christian Stehlik[1] and Richard M. Pope[3]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Northwestern Univ Med School, Chicago, IL.

Background/Purpose: Our recent data indicate that Snapin, a SNAP associated protein, is significantly increased in macrophages (MΦs) in rheumatoid arthritis (RA) synovial tissue and its expression level was correlates with inflammation. Reduction of Snapin hindered the maturation of autophagosome and phagosome, resulted in autophagosome accumulation and delayed bacterial clearance in MΦs. In this study, we further explored the mechanisms by which Snapin is involved in autophagy in MΦs as well as its role on monocyte to MΦ differentiation.

Methods: The reduction of Snapin in primary human MΦs was performed using siRNA, while in J774A mouse MΦ cell line was implemented by infection with a lentiviral vector expressing Snapin shRNA. Snapin, Lamp1 and LC3B protein levels were determined by Western blot analysis. Cell fractions enriched in lysosomes were isolated using density gradient centrifugation. Autophagosomes were purified by anti-LC3B antibody and Dyna magnetic beads. Autophagy in MΦs was detected by electron microscopy as well as by LC3B punctae determined by immunofluorescence microscopy. Human peripheral blood monocytes isolated by counter-flow elutriation were differentiated in 20% FBS plus CSF-1. Non-specific (NS), Snapin, or Beclin 1 siRNA was transfected into monocytes at Day0 and Day3 by lipofectamine. Monocyte to MΦ differentiation was measured by morphology and by the levels of differentiation markers CD163 and CD71 by flow cytometry.

Results: The forced reduction of Snapin in primary human MΦs and the murine J774A MΦ cell line resulted in increased late autophagosome vacuoles that contain partially digested organelles and other cellular material. Large sized LC3 punctae were also dramatically increased in these MΦs detected by immunofluorescence. These changes were similar to those observed by inhibition of lysosomal maturation with chloroquine but not the induction of autophagy by starvation or rapamycin. The results suggest that the reduction of Snapin blocked autophagy efflux. Snapin was abundant in lysosome-enriched cell organelles in MΦs. Snapin also co-isolated with LC3B and Lamp1 in autophagosomes which were isolated by anti-LC3B antibody from the lysosome-enriched fraction. By co-IP, Lamp1 was co-purified with Snapin employing MΦ cell lysates. These data suggest that Snapin directly interacted with Lamp1 and is necessary for the maturation of autophagosomes.

The control monocytes transfected with NS siRNA differentiated normally after 5 days into MΦs determined phenotypically and by the strong expression of both CD163 and CD71. However, monocytes transfected with Snapin or Beclin1 siRNA appeared as small round cells that loosely attached to plastic and the expression of both CD163 and CD71 was greatly reduced. These results indicate that arresting autophagy, by the reduction of Beclin1, or Snapin, suppressed monocyte to MΦ differentiation.

Conclusion: Snapin is required for the fusion of lysosomes with autophagosomes and the maturation of autophagosomes which is critical for monocyte to MΦ differentiation. These observations suggest that Snapin contributes to the pathogenesis of RA and may be a therapeutic target.

Ligation Of TLR5 Promotes Myeloid Cell Infiltration and Differentiation Into Mature Osteoclasts In RA Patients and Experimental Arthritis. Seung-jae Kim[1], Zhenlong Chen[1], Nathan D. Chamberlain[1], Michael V. Volin[2], Suncica Volkov[1], William Swedler[1], Shiva Arami[1], Anjali Mehta[1], Nadera J. Sweiss[1] and Shiva Shahrara[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]Chicago College of Osteopathic Medicine Midwestern University, Downers Grove, IL.

Background/Purpose: The aim of this study was to examine the importance of TLR5 ligation in the pathogenesis of rheumatoid arthritis (RA) and experimental arthritis.

Methods: The role of TLR5 ligation was determined on RA myeloid cell chemotaxis and osteoclast formation *in vitro*. Studies were conducted to investigate the mechanism by which TLR5 ligation promotes osteoclast

maturation in RA peripheral blood mononuclear cells (PBMC)s. Next, significance of myeloid and T cells were examined in osteoclastogenesis facilitated by TLR5 ligation. Finally, experiments were performed in collagen induced arthritis (CIA) as well as in TLR5 induced arthritis to assess the impact of joint TLR5 ligation on myeloid cell migration and osteoclast differentiation.

Results: We demonstrate that the TLR5 agonist, flagellin, is strongly chemoattractant for monocytes and can further facilitate differentiation of myeloid cells into mature osteoclasts. Consistently, RA synovial fluid induced myeloid cell infiltration and osteoclast differentiation is markedly suppressed by myeloid TLR5 blockade. We show that flagellin ligation of TLR5 promotes RA osteoclast differentiation through induction of receptor activator of nuclear factor kappa-B (RANK) on myeloid cells (by 8 fold) and its corresponding ligand, RANKL, from T cells (by 2 fold). We found that ligation of TLR5 could drive precursor myeloid cells to form fully mature osteoclasts in the absence of T cells when monocytes were cultured in the presence of suboptimal doses of M-CSF and RANKL. These results suggest that monocytes are the effector cells in TLR5 mediated osteoclastogenesis and that flagellin can facilitate osteoclast formation by increasing RANK expression and by allowing the cells to be more responsive to RANKL binding, hence lower levels of RANKL is required for this process. We next asked whether homing and differentiation of myeloid cells to mature osteoclasts are altered in acute and/or chronic arthritis driven by TLR5 ligation. We document that when CIA mice were therapeutically treated with TLR5 agonist, joint swelling was markedly greater in mice that received flagellin treatment compared to the PBS control. We also show that the F480 staining, number of TRAP+ cells and the concentration of bone erosion markers calcitonin receptor, Cathepsin K and RANKL (8–34 folds) were lower in the control ankles compared to the flagellin treated CIA joints. Since CIA ankle swelling and bone erosion were exacerbated by flagellin post onset treatment we next asked whether local injection of flagellin alone could drive joint inflammation and osteoclastogenesis. We demonstrate that ectopic TLR5 ligation elevates ankle circumference from day 0 to 2, subsequently joint inflammation plateaus until day 8, however swelling remains consistently higher than the PBS group. Corroborating with the CIA data, i.a. injection with flagellin resulted in 10 fold greater mature osteoclasts compared to the control group.

Conclusion: These novel results demonstrate for the first time that in RA as well as in acute and chronic experimental arthritis models, flagellin ligation to joint TLR5 contributes to myeloid cell infiltration and osteoclast maturation.

Rheumatoid Arthritis Synovial Fibroblasts Lack Tolerization Of Inflammatory Cytokines and Matrix Degrading Enzymes After Repeated LPS Stimulation. Kerstin Klein[1], Renate E. Gay[1], Christoph Kolling[2], Adrian Ciurea[3], Beat A. Michel[4], Lih-Ling Lin[5], Steffen Gay[1] and Caroline Ospelt[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Schultess Clinic, Zurich, Switzerland, [3]University Hospital of Zurich, Zurich, Switzerland, [4]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [5]Pfizer, Cambridge, MA.

Background/Purpose: In macrophages, repeated stimulation of Toll-like receptor (TLR) 4 leads to adaptation of signaling pathways and epigenetic modifications resulting in a tolerant state of the cell and protecting inflamed tissues from inflammation-induced damage. We hypothesized that a lack of tolerization in rheumatoid arthritis synovial fibroblasts (RASF) significantly contributes to sustained inflammation and inflammation-induced damage seen in RA.

The objective was to investigate tolerizable and non-tolerizable effects in RASF compared to macrophages.

Methods: RASF and *in vitro* differentiated peripheral blood derived macrophages from healthy donors and RA patients were treated with LPS (100 ng/ml). 24h after the initial stimulation, cells were re-stimulated with LPS (10 ng/ml) for another 24h. Supernatants were collected from the second treatment period for ELISA and cells were harvested for isolation of RNA or protein extracts after a total treatment period of 48h. The expression of different genes, including cytokines and chemokines (IL6, CCL5, IL33, CXCL10), matrix metalloproteinases (MMP1, MMP3, MMP13), receptors (TLR2, TLR3, TLR4, MDA5, RIG1) as well as signaling molecules, activators and inhibitors of the TLR pathway (SHIP1, SOCS1, TNFAIP3, OAS1) was analyzed by quantitative Real-time PCR, Western blotting and ELISA. Nuclear factor-κB (NF-κB) and activator protein-1 (AP-1) promoter activities in RASF were evaluated by Dual-Luciferase reporter assays after repeated stimulation with LPS (100 ng/ml, 10 ng/ml).

Results: As expected, the expression of IL6 decreased in double-stimulated (886 $\pm$ 596 pg/ml) compared to single-stimulated (2368 $\pm$ 315 pg/ml; $p<0.01$) macrophages from healthy donors (n=4) and RA patients (n=6, $p=0.06$). On the other hand, RASF (n=10) maintained their production of IL6 after repeated TLR4 stimulation and secreted 13237 $\pm$ 5764 pg/ml IL6 after a single LPS stimulation and 12421 $\pm$ 7178 pg/ml IL6 after double stimulation. A lack of tolerizable effects after LPS stimulation of RASF was also found for MMP1, MMP3, MMP13, CCL5, IL33, TLR3 and TNFAIP3. Interestingly, the known interferon-responsive genes OAS1, RIG1, MDA5 and CXCL10 were tolerizable not only in macrophages but also in RASF. RASF (n=5) secreted 531 $\pm$ 385 pg/ml CXCL10 after a single LPS stimulation and 111 $\pm$ 97 pg/ml CXCL10 after double stimulation ($p<0.05$). TLR4 mRNA was not changed in macrophages or in RASF by LPS double stimulation suggesting that a change of TLR4 expression itself was not responsible for tolerization. Reporter gene activities for NF-κB and AP-1 were similar in single and double stimulated RASF, excluding changes in signaling molecules as the underlying mechanism for tolerizable/non-tolerizable effects.

Conclusion: Based on the fact that neither TLR4 expression nor signalling pathways are altered by repeated LPS stimulation, epigenetic modifications on target gene promoters are likely to contribute to differences in tolerization between RASF and macrophages. Since many pro-inflammatory cytokines and MMPs are non-tolerizable genes in RASF, we conclude that the lack of tolerization in these cells keeps them aggressive in persistent inflammation.

Poly(I:C)-Induced Cell Death Of Synovial Fibroblasts via an Unknown dsRNA Receptor. Jörg Hamann[1], Paul P. Tak[2] and Olga N. Karpus[1]. [1]Academic Medical Center, Amsterdam, Netherlands, [2]GlaxoSmithKline U.K. and Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands.

Background/Purpose: Rheumatoid arthritis (RA) is characterized by hyperplasia of the synovial tissue due to local proliferation of stromal and recruitment of inflammatory immune cells. Accumulation of synovial fibroblasts likely is due to an imbalance between cell proliferation, survival and death. Both cytosolic dsRNA receptors, MDA5 and RIG-I, can initiate pro-apoptotic signalling in a variety of cell types. In animal models of cancer and multiple sclerosis, treatment with dsRNA ligands causes apoptosis of effector cells and ameliorates disease. We showed that fibroblast-like synoviocytes (FLS) from RA synovial tissue are equipped with functional cytosolic dsRNA receptors. We have studied the consequences of stimulation with dsRNA on the survival of FLS.

Methods: FLS from arthritis patients were stimulated with poly(I:C) or 3pRNA complexed with fugene (FG) for intracellular uptake. Stimulation was confirmed by RT-PCR of dsRNA response genes (MDA5, RIG-I and CXCL10). Cell death of FLS after triggering of dsRNA sensors was detected by flow-cytometric analysis using annexin V/PI staining. Changes in protein expression of anti- and pro-apoptotic genes were analyzed by Western blot. Knockdown of MDA5, RIG-I and their adaptor proteins was performed using SMART pool siRNAs.

Results: dsRNA response genes, including MDA5, RIG-I and CXCL10 were similarly induced after 16 h stimulation of RA FLS with either 3pRNA or poly(I:C), complexed with FG. However, 3pRNA + FG treatment of FLS caused about 15% of cell death after 48 h, whereas poly(I:C) + FG treatment induced up to 75% cell death. Surprisingly, we did not find differences in the expression of pro- and anti-apoptotic proteins between cells stimulated with 3pRNA + FG or poly(I:C) + FG. siRNA knockdown of MDA5, a known receptor for poly(I:C), did not effect poly(I:C) + FG stimulation on dsRNA response genes, whereas knockdown of RIG-I, a known receptor for 3pRNA, completely abrogated the response to 3pRNA + FG. Knockdown of downstream adaptor proteins IPS, STING and TRIF did not have any effect on dsRNA response genes after poly(I:C) + FG stimulation.

Conclusion: Stimulation of RA FLS with artificial dsRNA poly(I:C), but not 3pRNA induced apoptosis of FLS. We confirmed that 3pRNA is recognized by the dsRNA sensor RIG-I. In contrast, intracellular recognition of poly(I:C) in FLS does not involve MDA5 and the adapter proteins IPS, STING and TRIF, suggesting the existence of a different recognition mechanism.

Suppression Of Immune Responses and Joint Inflammation By Myeloid-Derived Suppressor Cells In a T Cell-Dependent Mouse Model Of Rheumatoid Arthritis. Katalin Mikecz[1], Julia Kurko[1], Timea Ocsko[1], Andras Vida[1], Beata Tryniszewska[1], Tibor A. Rauch[1], Joel A. Block[1], Robert S. Katz[2], Anjali Nair[1], Carla R. Scanzello[1] and Tibor T. Glant[1]. [1]Rush University Medical Center, Chicago, IL, [2]Rush Medical College, Chicago, IL.

Background/Purpose: Myeloid-derived suppressor cells (MDSCs) are a heterogeneous population of innate immune cells with immunosuppressive properties. We previously identified MDSCs in the synovial fluid (SF) of mice with proteoglycan-induced arthritis (PGIA), a T cell-dependent model of rheumatoid arthritis (RA). Although SF MDSCs potently inhibited antigen-specific T cell proliferation in vitro, they were not available in quantities necessary for testing their in vivo suppressive activity in PGIA. Using bone marrow (BM)-derived MDSCs, expanded in culture in the presence of growth factors, we sought to determine whether these cells could exert suppression on antigen-specific responses and arthritis severity upon their transfer to syngeneic mice with PGIA. An important additional goal of this study was to identify MDSCs in the SF of human patients with RA.

Methods: As reported previously, MDSCs with strong suppressor activity were successfully expanded from murine BM in vitro in the presence of GM-CSF, G-CSF, and IL-6. We used the adoptive transfer model of PGIA, in which spleen cells from arthritic wild type donors were injected with antigen (PG) into syngeneic SCID recipients. After the clinical signs of arthritis began to develop, the SCID mice were divided into groups with similar average disease scores. The control groups received a second injection of arthritic spleen cells and PG, while the experimental groups received the same plus MDSCs. Disease severity was monitored by visual scoring. Three weeks later, spleen cells from the SCID recipients were tested for antigen (PG)-specific proliferation, and sera were assayed for anti-PG antibody titers. Human SF and blood were obtained from consenting RA patients undergoing therapeutic joint aspiration. The phenotype of SF cells was determined by flow cytometry with antibodies to human MDSC-specific markers. The ability of RA SF MDSCs to suppress T cell proliferation was tested by culturing autologous blood mononuclear cells in the presence or absence of SF cells. T cell proliferation was induced via anti-CD3/CD28 antibodies or with Mitomycin C-treated allogeneic lymphocytes.

Results: Arthritis severity in SCID mice injected with BM MDSCs were significantly lower (mean score 3.5) than in control mice injected with spleen cells only (mean score 8.25) (n=10 mice/treatment). PG-specific T-cell responses and serum IgG1 type antibodies were also significantly reduced in the BM MDSC recipient groups. Regarding the human system, both granulocytic and monocytic MDSC-like cells were identified in SF samples (n=9) from RA patients. RA SF MDSCs suppressed the proliferation of autologous blood T cells ex vivo, although the inhibitory effects were not as strong as those in the murine system. Depletion of T cells from the RA SF cell population further improved the MDSC-mediated suppression of blood T cell proliferation.

Conclusion: Murine BM-derived MDSCs effectively suppress arthritis upon injection into SCID mice developing adoptively transferred PGIA. Cells with MDSC-like phenotype and immunosuppressive activity are also present in the SF of RA patients. Our results suggest that MDSCs could represent a novel therapeutic tool in RA.

Peptidylarginine Deiminase Inhibition Prevents Neutrophil Extracellular Trap Formation, Modulates Innate Immune Responses, and Reduces Vascular Damage In Mice. Jason S. Knight[1], Wei Luo[2], Alexander A. O'Dell[1], Wenpu Zhao[1], Venkataraman Subramanian[3], Chiao Guo[2], Robert C. Grenn[1], Paul Ryan Thompson[3], Daniel T. Eitzman[2] and Mariana J. Kaplan[1]. [1]University of Michigan Rheumatology, Ann Arbor, MI, [2]University of Michigan Cardiology, Ann Arbor, MI, [3]The Scripps Research Institute, Jupiter, FL.

Background/Purpose: Neutrophil extracellular trap (NET) formation promotes vascular damage, while stimulating interferon alpha (IFN-α) production in diseased arteries. Patients with rheumatoid arthritis and systemic lupus erythematosus have evidence of exaggerated NET formation, and suffer from a propensity toward accelerated atherosclerosis. Peptidylarginine deiminase (PAD) inhibition is a strategy that can decrease *in vivo* NET formation. We tested whether PAD inhibition can inhibit innate immune responses and reduce vascular damage in murine models of atherosclerosis.

Methods: $Apoe^{-/-}$ mice were treated for 10 weeks with daily injections of Cl-amidine, a PAD inhibitor. Innate immune responses including NET release and IFN-α production were characterized, as was anti-NET autoantibody formation. Degree of atherosclerosis and time to carotid artery thrombosis were also determined.

Results: In $Apoe^{-/-}$ mice, we found evidence of accelerated NET formation, enhanced IFN-α production in diseased arteries, and autoantibody formation to components of NETs. Further, PAD inhibition blocked NET formation, reduced atherosclerotic lesion area, and delayed time to carotid artery thrombosis in a photochemical injury model. Decreases in atherosclerosis burden were accompanied by reduced recruitment of netting neutrophils and macrophages to arteries, as well as by reduced arterial IFN-α expression.

Conclusion: A pharmacologic intervention that blocks NET formation can reduce atherosclerosis burden in murine systems. These results support a role for aberrant NET formation in the pathogenesis of atherosclerosis through modulation of innate immune responses, with implications for the accelerated atherosclerosis of rheumatoid arthritis and systemic lupus erythematosus.

Decreased NK-Cell Numbers and Upregulation Of Markers Of Systemic Inflammation In Autoantibody –Positive Arthralgia Patients and Early Rheumatoid Arthritis Patients But Not In Autoantibody-Negative Rheumatoid Arthritis Patients. Paulina Chalan, Johan Bijzet, Kornelis S.M. van der Geest, Bart-Jan Kroesen, Annemieke M.H. Boots and Elisabeth Brouwer. University Medical Center Groningen, Groningen, Netherlands.

Background/Purpose: Identification of seropositive individuals at risk for arthritis development would open opportunities for early clinical intervention. In a recent study on seropositive arthalgia patients (SAP), 35% of the patients were found to develop RA within 12 months (van de Stadt et al, *Ann Rheum Dis* 2012). Not only autoantibodies precede clinically apparent synovitis but also serological immune features are modulated prior to the development of clinical synovitis (Rantapää-Dahlquist et al, *Ann Rheum Dis* 2007). So far, little is known on modulation of leukocyte subsets before arthritis development. Therefore, in a cross sectional study, we investigated and compared the numbers of circulating leukocyte subsets and levels of cytokines, cytokine receptors, chemokines in SAP, new-onset RA and in long-standing RA patients.

Methods: Whole blood samples obtained from 32 patients with arthralgia who were ACPA and/or RF-positive (termed seropositive arthralgia patients [SAP]), 50 early RA (39 were ACPA+ and/or RF+, 11 were ACPA- and RF-), 11 long-standing RA patients (all were ACPA+ and/or RF+) and 33 healthy controls (HC) were used to quantify the absolute numbers of leukocyte populations. Serum samples from 20 HC, 30 SAP, 21 early ACPA/RF+, 11 early ACPA/RF- RA and 8 long-standing RA patients were used to quantify systemic levels of cytokines, cytokine receptors and chemokines using Human Cytokine 25-plex Panel.

Results: Seropositive arthralgia patients showed a decrease of both the absolute number and the frequency of NK-cells compared to HC (p=0.006 and p=0.004, respectively). A similar decrease of NK-cell absolute number and frequency was observed for ACPA/RF+ early RA patients (p=0.004 and p=0.018, respectively) but not for ACPA/RF- early RA patients. The majority of systemic cytokines/cytokine receptors (IL-1β, IL-1RA, IL-2R, TNF-α, IFN-α, IL-4, IL-17, IL-2, IL-15, GM-CSF) and chemokines (MIP-

1β, IL-8, Rantes, Eotaxin, MCP-1, MIP-1α, MIG) were found to be elevated both in SAP and in early ACPA/RF+ RA compared to HC, while the levels found in ACPA/RF- RA patients were similar to HC.

Conclusion: Seropositive arthralgia patients, showed decreased numbers of circulating NK-cells and upregulation of various mediators of systemic inflammation. The same was found in ACPA/RF-positive early RA but not in ACPA/RF- negative early RA. Immune alterations found in SAP and early RA seem to be related to the presence of ACPA and or RF. In addition, marked differences in leukocytes and inflammatory markers between autoantibody- positive and –negative early RA patients suggest clear differences in disease pathogenesis between these groups.

Exercise Suppresses Systemic Inflammation Via Inhibition Of NF-κB Activation In Monocytes. Alisa Blazek[1], Derrick Knapik[1], Lai-Chu Wu[2], Nicholas A. Young[2], Wael N. Jarjour[2] and Sudha Agarwal[2]. [1]The Ohio State University, Columbus, OH, [2]The Ohio State University Wexner Medical Center, Columbus, OH.

Background/Purpose: Inflammation is integral to joint damage and bone erosion in rheumatoid arthritis. We reported previously that physiologic levels of exercise are anti-inflammatory and suppress local inflammation of joints *in vivo*. Here, we demonstrate that the physiological levels of exercise are potent systemic biological response modifiers that block monocyte/macrophage activation.

Methods: Mice carrying a transgene containing a modified firefly luciferase cDNA whose expression is under the control of NF-κB responsive elements were used to study the regulation of NF-κB activation by exercise (treadmill walking at 8M/min). LPS (1 μg/gm body weight) was injected in the paw to trigger inflammation. The mice were treated as follows: (i) no treatment (ii) exercise alone, (iii) LPS alone, (iv) pre-exercised (Pre-Ex) for 7 days prior to LPS injection, or (v) exercised post LPS injection (Post-Ex). Activation of NF-κB was assessed following LPS injection by digitizing bioluminescent activity. Multiplex ELISA was used to assess the induction of cytokines in the serum. Human macrophages were enriched from healthy peripheral blood and subjected to Interferon-γ and LPS stimulation +/− dynamic strain (2% at 0.5 Hz) for various time intervals to assess NF-κB activation.

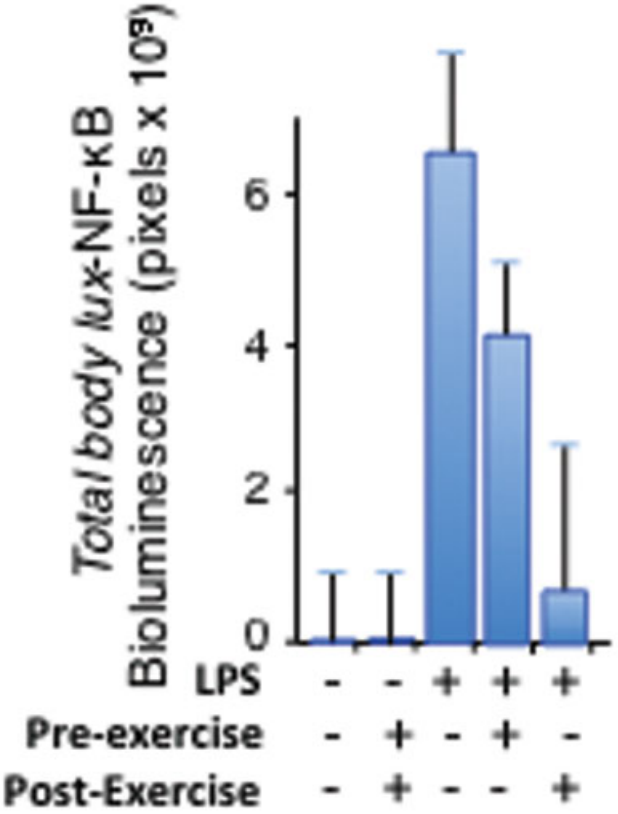

Fig. 1. Suppression of LPS induced NF-κB activation by LPS by Exercise in *NFκB-RE-luc* mice.

Results: Exercise alone did not induce significant NF-κB activation; whereas LPS injection in the right ankle provoked a robust systemic and local inflammatory response that was most severe within 2 h post-injection. Both Pre-Ex and Post-Ex mice showed a significant inhibition of LPS-induced NF-κB activation (Fig 1). As expected, the NF-κB activation was primarily in lymphatic tissue and at the site of LPS injection. Strikingly, exercise effectively suppressed LPS-induced NF-κB activation in all lymphatic tissues examined and at the site of injection. We next examined the tenacity of the effects of exercise and demonstrated that the anti-inflammatory response is transient, lasting only 24 h post-exercise. Assessment of the consequences of NF-κB inactivation by exercise (Both Pre-Ex and Post-Ex) revealed the suppression of multiple pro-inflammatory cytokines: IL-1β, TNF-α, IL-6, IL-17, IL-12 and IL-8. However, the effects of exercise were more dramatic (<90%) in Post-Ex than Pre-Ex mice. Using primary human macrophages, dynamic strain significantly suppressed NF-κB activation.

Conclusion: These findings suggest that exercise suppresses both local and systemic inflammation by inhibiting NF-κB activation in monocytes/macrophages. Importantly, these effects are transient, which supports the need for a regular exercise routine in order to achieve clinical efficacy. Our results (i) demonstrate that the signals generated by exercise are true biological response modifiers and (ii) provide the molecular basis for the actions of exercise in suppressing the inflammation observed in rheumatic diseases.

Oxidative Stress As a Disease Marker and Therapeutic Target In Patients With Tumor Necrosis Factor Receptor Associated Periodic Fever Syndrome. Cornelia Cudrici[1], Ariel Bourla[1], Martin Pelletier[1], Leah Billingham[1], Amanda K. Ombrello[2], Michael Murphy[3], Daniel L. Kastner[4] and Richard M. Siegel[5]. [1]Immunoregulation Section, Autoimmunity Branch, Bethesda, MD, [2]National Human Genome Research Institute, National Institute of Health, Bethesda, MD, [3]Medical research council mitochondria biology unit Cambridge, UK, Cambridge, United Kingdom, [4]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, [5]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD.

Background/Purpose: TRAPS (Tumor necrosis factors receptor associated periodic fever syndrome) is an autosomal dominant autoinflammatory disease associated with missense mutations in *TNFRSF1A* (tumor necrosis factor receptor superfamily, member 1A) gene. Our laboratory has recently demonstrated a role for mitochondrial reactive oxygen species (ROS) in triggering the hyper-responsiveness characteristic of cells from TRAPS patients. When the level of ROS generation exceeds the anti-oxidant defense capacity of the cell, oxidative damage to macromolecules including DNA ensues. We have investigated the metabolic sources of mitochondrial ROS production and levels of oxidative stress in cells from TRAPS patients, and will test the ability of MitoQ, a mitochondrial-targeted anti-oxidant to ameliorate symptoms in TRAPS patients.

Methods: Peripheral blood mononuclear cells (PBMC) from TRAPS patients and mouse embryonic fibroblasts (MEFs) from mice engineered to express TNFR1 mutations were analyzed for mitochondrial ROS production and quantification of oxidative DNA damage via the DNA adduct 8-oxo-guanine (by using flow cytometric method for detection of mitochondrial superoxide and 8-oxo-guanine). Blockers of fatty acid and glucose metabolism were used to investigate the fuels which favor ROS production and excess cytokine production in fibroblasts and myeloid cells from TRAPS patients and TNFR1 mutant mice.

Results: We previously showed that the increased inflammation in TRAPS is dependent on mitochondrial ROS rather than NADPH oxidases. Elevated levels of mitochondrial ROS were seen in cells from TRAPS patients and in mice with engineered TRAPS gene mutations. Monocytes from TRAPS patients but not from healthy donors showed significantly higher spontaneous mitochondrial ROS production. Blockade of fatty acid vs. glucose metabolism showed that fatty acid metabolism favors excess mitochondrial respiratory capacity, ROS production, and heightened expression of inflammatory cytokines after LPS treatment. Inhibition of mitochondrial ROS can reduce normal cytokine production and reverse hyperinflammatory responses in TRAPS.PBMC from TRAPS patients and MEFs from mice harboring TRAPS associated TNFR1mutation have increased levels of oxidized DNA compared controls. Inhibition of mitochondrial ROS by Mito Q can reduce normal cytokine production and reverse hyperinflammatory

responses in PBMC from TRAPS patients and MEFs from mouse with similar mutations.

Conclusion: Our data suggest that mitochondrial ROS production and 8-oxo-guanine are increased in TRAPS patients and in mice engineered to express TNFR1 mutations compared with non-inflammatory controls. Pharmacological blockade of mitochondrial ROS by mitoQ reduces inflammatory cytokine production in vitro in TRAPS patients and mice with similar TNFR1 mutations. These findings suggest that mitochondrial ROS may be a novel therapeutic target for TRAPS patients. A phase 2 clinical therapeutic trial using Mito Q for TRAPS is planned.

Microrna-155 As a Proinflammatory Regulator via SHIP-1 Down-Regulation In Acute Gouty Arthritis. Hye Mi Jin[1], Young-Nan Cho[1], Seung-Jung Kee[1], Dong-Jin Park[2], Yong-Wook Park[2], Shin-Seok Lee[2] and Tae-Jong Kim[1]. [1]Chonnam National University Medical School and Hospital, Gwangju, South Korea, [2]Chonnam National University Medical School, Gwangju, South Korea.

Background/Purpose: Gout is characterised by episodes of intense joint inflammation in response to intra-articular monosodium urate monohydrate (MSU) crystals. miR-155 is crucial for the proinflammatory activation of human myeloid cells and antigen-driven inflammatory arthritis. Since, the functional role of miR-155 in gouty arthritis has not been defined. The aim of this study was to examine the role of miR-155 in pathogenesis of acute gouty arthritis.

Methods: Samples from 14 patients with gouty arthritis and 10 healthy controls (HCs) were obtained. Peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) were cultured *in vitro* with MSU crystals, and gene expression (human miR-155 and Src homology 2-containing inositol phosphatase, SHIP-1) were assessed by real-time PCR. THP-1 cells and human monocyte-drived macropharges were stimulated by MSU crystals and/or miR-155 transfection. Whole-cell lysates were subjected to Western blot analysis. Human TNF-α and IL-1β in cell culture supernatants were measured by Luminex. Immunohistochemistry was performed on formalin-fixed gout tissues with anti–SHIP-1 Ab. Gout peritonitis mice (Male C57BL/6J) model used to analyze expressions of miR-155, SHIP-1, and inflammatory cytokines.

Results: The samples from gouty arthritis proved to be highly enriched in miR-155, with levels of expression being higher than those found in PBMC from HC. Mir-155 was found to be strongly induced by stimulation of MSU crystals after 24 hours and their expressions gradually decreased. Stimulating with MSU crystals, the level of SHIP-1 was found to be gradually decreased in according to overexpression of mir-155. miR-155 promoted MSU-induced proinflammatory cytokine production such as TNF-α and IL-1β. Consistent with *in vitro* observations, miR-155 expression was also elevated in gout mice model. The production of inflammatory cytokines was markedly increased in MSU crystal induced peritonitis mice.

Conclusion: Our study confirmed that overexpression of miR-155 in SFMC led to down-regulation of SHIP-1 and an increase in the production of proinflammatory cytokines.

The Role Of Microrna 155 In Innate Immunity and Arthritis. Antonia Puchner, Victoria Saferding, Eliana Goncalves-Alves, Josef S. Smolen, Kurt Redlich and Stephan Blueml. Medical University of Vienna, Vienna, Austria.

Background/Purpose: MicroRNA 155 (miR155) has been demonstrated to be essential for the development of collagen induced arthritis by controlling the generation of autoreactive T and B cells. However, the contribution of miR155 in innate immune cells is not known.

Methods: We analyzed activation and cytokine production of macrophages and dendritic cells (DCs) *in vitro* and *in vivo*. We analyzed T-cells stimulatory capacity of DCs. We crossed miR155 deficient mice into hTNFtg mice and analyzed arthritis development clinically as well as histologically.

Results: MiR155 deficiency did not alter the expression of costimulatory molecules or MHCII expression after stimulation of macrophages and DCs *in vitro* and *in vivo*. We also Facs-sorted DCs after stimulation with LPS in vivo and determined the production of proinflammatory cytokines such as IL-23, IL-6 as well as TNF. We did not detect differences between wt and miR155$^{-/-}$ mice. In addition, the T cell stimulatory capacity of wt and miR155$^{-/-}$ was identical. When we analyzed hTNFtg/miR155$^{-/-}$ mice compared to wt mice, we did not detect differences in the clinical signs and symptoms of arthritis. Histologically, we even found slightly increased synovial inflammation in hTNFtg/miR155$^{-/-}$ mice compared to wt mice.

Conclusion: In contrast to the pivotal role of miR155 in autoimmunity requiring the adaptive immune system, the role of miR155 in innate immunity seems to be limited. This is emphasized by the fact that miR155 hardly influences the course of TNF-driven arthritis, which is mainly dependent on components of the innate immune system.

The Receptor For Advanced Glycation End Products (RAGE) As a Modulator Of Inflammatory Responses and Its Contribution To Gender-Specific Effects During Arthritis. Timo Wirth[1], Christoph Kessel[1], Philipp Becker[1], Toni Weinhage[2], Nadine Nippe[2] and Dirk Foell[1]. [1]University of Muenster, Muenster, Germany, [2]University of Muenster, Münster, Germany.

Background/Purpose: The receptor for advanced glycation end products (RAGE) is a multi-ligand receptor expressed on various cells which interacts with a diverse class of ligands, e.g. 'danger signals' such as neutrophil-derived S100A12. RAGE has been implicated in the pathogenicity of various inflammatory diseases including inflammatory arthritis. However, the exact role of RAGE has not been sufficiently defined. Our recent data on S100A12-induced activation of monocytes points to a modulatory rather than pro-inflammatory function of human RAGE. To assess the role of RAGE in a more systematic way, we generated RAGE−/− mice and analyzed immune cell functions *in vitro*, followed by murine models of *staphylococcus aureus* infection (host defense), chemically induced colitis (mucosal immunity), lethal inflammatory liver injury (septic shock) and collagen induced arthritis (autoimmunity) comparing RAGE−/− and C57BL/6 wildtype (wt) mice.

Methods: Reactive oxygen species (ROS) production, phagocytosis and cytokine production of bone marrow derived monocytes were measured using flow cytometry. *Staphylococcus aureus* (*S. aureus)*infection was induced by footpad injection. Acute and chronic colitis were induced chemically by dextran sodium sulfate (DSS) solution. For the inflammatory liver injury model, mice were challenged with D-galactosamine (D-Gal) along with lipopolysaccharide (LPS). Arthritis was induced by injection of heterologous type II collagen (CII).

Results: We observed no differences of cellular immune function (ROS and cytokine production, phagocytosis) in RAGE−/− compared to wt monocytes. Male, but not female RAGE−/− mice showed more footpad swelling and bacterial dissemination in the *S. aureus* infection model. In the DSS colitis model we observed no significant differences between the two strains, whereas RAGE−/− mice were significantly protected from lethal D-Gal/LPS induced liver injury. RAGE−/− and wt mice develop arthritis at similar clinical scores and incidence with no significant differences in type II collagen autoantibody levels. However, in female animals there is a strong tendency towards aggravated disease, less remission and higher disease penetrance.

Conclusion: Overall, the contribution of RAGE seems to largely depend on the disease model and cell type studied. While no overall differences with respect to immune cell activities were observed, a striking gender-specific effect of RAGE seems to be involved in some conditions, especially in arthritis. The exact role of RAGE and its soluble form (sRAGE) during the development of arthritis and the influence of gender-specific factors is under further investigation.

Both Endosomal and Surface Toll-Like Receptors Can Act As Biomarkers In Lupus. Maria Perez-Ferro, Cristina Serrano, Fredeswinda I. Romero, María J Martínez-Becerra, Jorge E Rojas, María Sanchez-Blazquez, Raquel Largo, Juan A Martínez-López, Gabriel Herrero-Beaumont and Olga Sanchez-Pernaute. Jiménez Díaz Foundation University Hospital, Madrid, Spain.

Background/Purpose: Toll-like receptors (TLR) are a major class of pathogen detectors in the cell that can trigger the innate defense and lead to activation of immunocompetent cells. Endosomal TLR have been recently associated to the pathogenesis of SLE and to the production of autoantibodies. In this study we have explored associations between TLR and disease phenotypes, which could help us understand pathogenesis and find biomarkers in specific subgroups of patients.

Methods: Thirty four patients diagnosed with lupus and 12 matched healthy controls were recruited. Patients had stable treatment during the last 4 weeks prior to recruitment. Cumulative features, and serologic markers were registered. Selena-SLEDAI and BILAG scales were employed to measure disease activity. The distribution of peripheral blood mononuclear cells (PBMC) subpopulations and their expression of TLR2, TLR4, TLR3, TLR7, and TLR9 were analyzed in patients and controls with flow cytometry. Statistics were carried out with Spearman's correlation and Mann Whitney tests for independent samples, setting significance at 95%. The relationship between dual variables was assessed with contingency tables and Fisher's exact test, setting significance at 99%.

Results: The appearance of TLR3, TLR7, and TLR9 in lymphoplasmocytoid (CD19lp) cells was higher in SLE than in healthy controls. The presence of TLR3 in CD19 cells (n = 9) was associated to active disease (p 0.006), hypocomplementemia (p 0.002), and SLEDAI and BILAG scores (p 0.018, p 0.012). SLEDAI scores were also higher in patients with TLR9 expression in CD19 cells (n= 14, p 0.044). The percentage of CD19lp cells expressing TLR3, and TLR9 increased with SLEDAI scores (rho 0.401, p 0.021; and rho 0.403, p 0.02, respectively), but not with other activity measures.

Subgroups of patients with TLR2 expression in CD3+ cells (n = 5) or in CD19+ cells (n = 6) displayed higher activity as reflected by SLEDAI (p 0.05, p 0.015) and BILAG (p 0.005, p 0.004) scores. Patients with TLR4 in CD3+ cells (n = 5) or in CD19+ cells (n = 6), showed higher SLEDAI scores (p 0.05, p 0.045), while presence of TLR4 in CD19+ and in monocytes (n = 5) were associated to higher BILAG scores (p 0.004, p 0.005). Serological markers of activity were also found more frequently in patients showing expression of TLR2 or TLR4 in PBMC. Furthermore, the appearance of TLR2 or TLR4 in CD19+ cells, CD3+ cells or monocytes was associated with renal disease and with major organ involvement. Interestingly, patients with positive past history for bacterial or viral infections more often showed TLR2 and TLR4 in CD3 and CD19+ cells, and TLR4 in monocytes (CI 99%).

Conclusion: Endosomal TLR were found significantly enhanced in patients with lupus compared to controls, and TLR3 and TLR9 expression by CDlp cells could be used as a biomarker of disease activity. However, the induction of TLR2 and TLR4 in different PBMC subsets identified a subgroup of patients with high activity, whom frequently displayed major organ involvement. Our data suggest that there could be a subgroup of patients with lupus, in whom exposure to germs could sensitize immunocompetent cells, and facilitate their activation during flares.

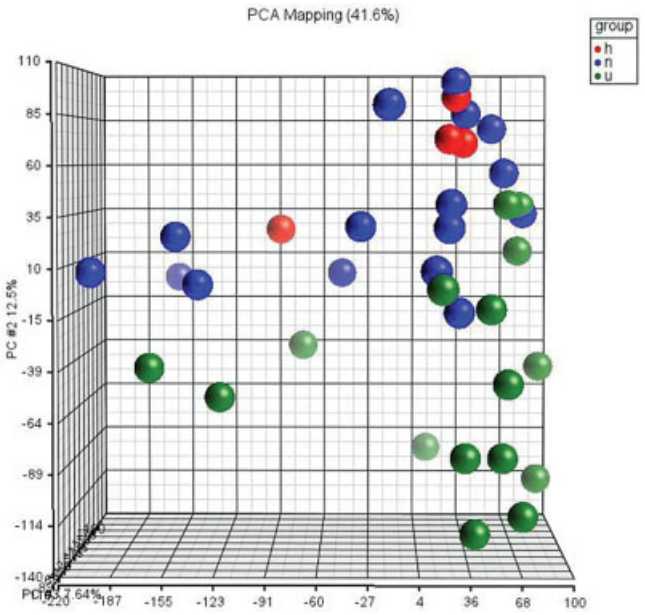
Systems Approach To The Study Of the Microbiome and Inflammatory Pathways In Oral Ulcer Tissue From Patients With Active Behçet's Syndrome (BS). Cailin Sibley[1], Gulen Hatemi[2], Yusuf Yazici[3], Yin Liu[4], Steve Brooks[1], Hasan Yazici[5] and Raphaela Goldbach-Mansky[6]. [1]NIH/NIAMS, Bethesda, MD, [2]Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [3]NYU Hospital for Joint Diseases and New York University School of Medicine, New York, NY, [4]NIAMS/NIH, Bethesda, MD, [5]Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey, [6]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD.

Background/Purpose: Behcet's syndrome (BS) exhibits features of both innate and acquired immunity. Oral ulceration is the cardinal lesion which usually precedes other manifestations. Despite the presence of clues from clinical and basic research suggesting the role of an infectious trigger in pathogenesis, a specific microorganism has not been identified. 16S rRNA sequencing provides an advantage over conventional techniques as it is quantitative and not reliant on tissue culture. This study aims to assess the microbiome in oral ulcer tissue in Turkish BS patients compared to non-lesional and healthy control mucosal tissue in parallel with pathogen recognition and pro-inflammatory cytokine pathways.

Methods: 5mm punch biopsies were obtained from ulcerated oral tissue and the contralateral unaffected side in 16 BS patients and 5 ethnically matched controls. Each sample was divided in half with16S rRNA sequencing of bacterial genomes performed in one half and mRNA-Seq performed in the other half. RNA-Seq data was probed by gene set enrichment analysis (GSEA) for the following pathways important in pathogen recognition: NOD-like receptor (NLR), Toll-like receptor (TLR), IL-1 receptor and IL-10 pathways.

Results: Bacterial sequence taxonomic representation of 16S rRNA sequencing data by Jaccard indices did not segregate 6 ulcerated, 6 unaffected and 4 normal control tissue samples on the basis of taxonomic membership. In contrast, a principal component analysis of RNA-Seq data showed the 16 ulcerated samples to cluster together with the 16 unaffected and 4 control samples clustering separately (See Figure. Green – ulcer, blue – unaffected, red – control). Of the 34,799 reads, 4595 transcripts were 2 fold or greater up-regulated in ulcerated compared to unaffected BS samples with 971 down-regulated greater than 2 fold. GSEA of NLR, TLR, IL-1 receptor and IL-10 pathways all showed enrichment in ulcerated compared to unaffected samples with normalized enrichment scores of 1.45, 1.48, 1.39 and 1.36 and nominal p-values of 0.02, 0.02, 0.11 and 0.05, respectively. These pathways did not differ between unaffected and control samples.



Conclusion: Taken together, these results show that while bacterial patterns did not differ in BS oral ulcers compared to unaffected mucosa or controls, pathways of pathogen recognition were enriched in ulcerated BS tissue. These pathways were not enriched in unaffected mucosa compared to controls. This may be due to non-bacterial triggers or may indicate an abnormal tissue response to normal flora supporting the previous contention that several microorganisms may be using a common pathway to trigger a series of events. Understanding these mechanisms is an area of active investigation.

Anti-Inflammatory Property Of HDL In NOD1 Ligand Induced Kawasaki Arteritis In Mice. Hajime Kono, Tamiko Yanagida, Kurumi Asako, Toshihiro Nanki, Hirotoshi Kikuchi, Akiko Okamoto, Akiko Onda and Maki Takayama. Teikyo University School of Medicine, Tokyo, Japan.

Background/Purpose: Atherosclerosis is a chronic metabolic disease of inflammatory processes. Immune cells including monocytes are recruited to the subintimal lesion of the vascular wall and store lipids to transform themselves to the foam cells. The lipid profiles in the serum are shown to be risk factors for developing atherosclerosis, such as high LDL (low density lipoprotein) or low HDL (high density lipoprotein) concentration. In addition to deliver cholesterol from vascular wall to liver, HDL is supposed to exert antiinflammatory properties which are not well characterized. We recently indentified that HDL exert an antiinflammatory property which is not ascribed to it's capacity to lower the cholesterol level of the peripheral tissue.

Objectives: To investigate the antiinflammatory function of reconstituted HDL (rHDL) in the Kawasaki arteritis murine model in vivo.

Methods: Coronary arteritis mimicking Kawasaki disease was induced by administrating 20 microgram of lipopolysaccharide followed by weekly injection of 500 microgram of the nucleotide-binding oligomerization domain 1 (NOD1) ligand FK-565 for 4 times. 2 mg of rHDL or control PBS was injected 4 times along with FK-565 administration. After a week after the last injection of FK-565 or control PBS, the severity of coronary arteritis was quantified by measuring the inflammation area surrounding the coronary arteries. The cytokine levels were determined by multiplex.

Results: The rHDL treatment reduced the inflammatory area of coronary arteries compared with the control PBS treated groups, showing statistically significance ($P=0.008$ with Student t-test, 0.29 ± 0.24 mm^2 (PBS control group) and 0.13 ± 0.07 mm^2 (rHDL group)). Serum level of IL12p40 was decreased inn mice treated with rHDL.

Conclusion: The data indicate that rHDL exert an antiinflammatory activity in the NOD1 ligand induced Kawasaki arteritis model in vivo.

A Possible Mechanism Of NLRP3 Inflammasome Hypersensitivity In Cryopyrin-Associated Periodic Syndrome. Sayaka Ito, Chie Tagami, Yukichi Hara and Tetsuo Kubota. Tokyo Medical and Dental University, Tokyo, Japan.

Background/Purpose: NLRP3 in monocytes and other cell types plays a role in innate immunity as one of the intracellular pathogen recognition receptors, and its mutation is responsible for cryopyrin-associated periodic syndromes (CAPS). Once activated, NLRP3 forms a protein complex called the inflammasome with procaspase-1 and an adaptor protein ASC, leading to activation of caspase-1 and production of mature proinflammatory cytokine IL-1β. Some investigators have proposed a model of NLRP3-inflammasome containing CARD8, another adaptor protein, but the role of CARD8 in the NLRP3-inflammasome system remains obscure. In a previous ACR meeting, we presented some data suggesting that CARD8 normally plays a role as a negative regulator of NLRP3-inflammasome. In the assay system using HEK293 cells transiently transfected with genes for inflammasome components, CARD8 interacted with wild-type NLRP3 resulting in suppression of IL-1β secretion. In contrast, CARD8 did not interact with CAPS-associated mutant NLRP3. Current study aimed to extend the previous study to obtain more convincing data using also cells endogenously expressing components of NLRP3 inflammasome and CARD8.

Methods: HEK293 cells were transiently transfected with ASC, CARD8, procaspase-1, proIL-1β, and NLRP3. The interaction of CARD8 and NLRP3 was studied by immunoprecipitation using lysates of peripheral blood mononuclear cells (PBMCs). Human monocyte-derived macrophages (HMDMs) were obtained by culture of monocytes from peripheral blood cells with GM-CSF for 7 days. Control or specific siRNA against CARD8 was transfected to HMDMs and the knockdown efficacy was evaluated by quantitative RT-PCR. After priming with LPS, HMDMs were stimulated by ATP, and secreted IL-1β was measured by ELISA.

Results: When HEK293 cells were transfected with every inflammasome components, large amounts of IL-1β were secreted spontaneously, which was partially but significantly reduced by coexpression of CARD8. On the other hand, CARD8 did not suppress IL-1β secretion from the cells transfected with CAPS-associated mutant NLRP3 (R260W, D303N, H312P, or N477K). In immunoprecipitation experiments using resting PBMCs from healthy subjects, NLRP3 was precipitated with CARD8, but not with ASC. When PBMCs were primed with LPS followed by ATP stimulation, however, NLRP3 was precipitated with ASC instead of CARD8. By stimulating HMDMs with LPS and ATP, HMDMs secreted IL-1β, and it was further increased by CARD8 knockdown.

Conclusion: These results support our hypothesis that CARD8 normally associates with NLRP3 to prevent unnecessary activation of the inflammasome by subtle stimuli. Taken together with previous data which showed CARD8 was unable to bind to NLRP3 with CAPS-related mutation, one of the mechanisms of hypersensitivity of the NLRP3 inflammasome in CAPS patients might be the escape from CARD8 restriction.

Innate Immune Cell Production Of Interleukin-12 Drives CpG-Induced Macrophage Activation Syndrome. Lehn K. Weaver and Edward M. Behrens. Children's Hospital of Philadelphia, Philadelphia, PA.

Background/Purpose: Hemophagocytic syndromes are caused by an uncontrolled systemic inflammatory response resulting in cytopenias, multisystem organ failure, and rapid death, often despite aggressive therapy. Macrophage activation syndrome (MAS) is one of the hemophagocytic syndromes known to complicate severe inflammatory diseases, and can be seen in patients with systemic rheumatologic conditions. Previous work describes a novel murine model utilizing repeated injection of CpG, a Toll-like Receptor 9 (TLR9) agonist, into wild-type mice to stimulate MAS. This model recapitulates the inflammatory, "cytokine storm" milieu and clinical features of MAS. TLR9, Interleukin (IL)-12 and interferon gamma are necessary for the development of MAS in this model. However, the initial cellular responses contributing to CpG-induced MAS remain elusive.

Methods: Wild-type (WT) and TLR9$^{-/-}$ bone marrow chimeras, transgenic clec4-DTR mice, and IL-12 reporter mice were treated with or without CpG, and parameters of MAS were measured. WT and TLR9$^{-/-}$ mixed *in vitro* splenocyte cultures were treated with or without CpG, and IL-12 production was measured from supernatants by ELISA and intracellular IL-12 was assessed by flow cytometry.

Results: We show that TLR9 expression within the hematopoietic compartment is necessary and sufficient for CpG-induced systemic inflammation. In contrast, TLR9 expression in radioresistant cells is not sufficient to drive CpG-mediated MAS. Surprisingly, depletion of individual innate immune cell populations does not alter the course of CpG-induced systemic inflammation including the depletion of plasmacytoid dendritic cells, cells known for their potent proinflammatory response to CpG. Using IL-12 reporter mice, IL-12 production upon CpG stimulation is shown to be redundant, as multiple innate immune cell populations produce IL-12 in this model. Finally, in contrast to *in vivo* infection models, mixed *in vitro* cultures of TLR9-deficient and TLR9-sufficient cells demonstrate that IL-12 production is intrinsic to cells capable of sensing CpG.

Conclusion: These data demonstrate that multiple innate immune cells contribute to CpG-induced immunopathology by producing IL-12. This redundancy in IL-12 production explains the inability to cure disease by targeting depletion of a single innate immune cell population. Futhermore, the ability of a cell to produce IL-12 is dependent on its ability to sense CpG through TLR9 expression. Thus, our data identify the most proximal cellular events leading to CpG-induced immunopathology providing novel insights into disease mechanisms and robust targets for the development of future therapeutic interventions in MAS.

A Novel Pro-Inflammatory Signaling Pathway Regulated By Follistatin-Like Protein 1. Yury Chaly[1], Anthony Marinov[2], Yu Fu[2], Brian Campfield[2], John Kellum[3], Bruce Hostager[1], Daniel Bushnell[2], Yudong Wang[2], Jerry Vockley[2] and Raphael Hirsch[1]. [1]University of Iowa Carver College of Medicine, Iowa City, IA, [2]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [3]University of Pittsburgh School of Medicine, Pittsburgh, PA.

Background/Purpose: Follistatin-like protein 1 (FSTL1) is a secreted glycoprotein produced mainly by cells of the mesenchymal lineage. The function of FSTL1 is still unclear, but it appears to play roles in the regulation of cell proliferation, differentiation, and organ development. We have

previously shown that FSTL1 is an important mediator in the pathogenesis of arthritis and other systemic autoimmune diseases, and that FSTL1 expression is induced in vitro by Toll-like receptor 4 signaling. The aim of the current study was to determine the molecular mechanism by which FSTL1 promotes inflammation.

Methods: The level of FSTL1 in the sera of patients with sepsis was measured by ELISA. To further test the contribution of FSTL1 to inflammatory response in vivo, we utilized a model of endotoxin shock in FSTL1 null mice recently generated in our laboratory. Serum IL-1β levels were determined by ELISA. FSTL1 binding to monocytes/macrophages and its intracellular trafficking were assessed by confocal microscopy. The expression of inflammasome components was evaluated by quantitative RT-PCR and Western blotting. To test whether FSTL1 plays a role in cellular energy production, we performed gene expression microarray analysis on ST2 stromal cells in which FSTL1 expression was knocked down using lentiviral short hairpin RNA. Enzymatic assays and in situ gel staining were used to measure the activity of mitochondrial electron transport chain complexes. ATP determination in cell lysates was performed using a colorimetric assay.

Results: We found that the sera of septic patients contained elevated levels of FSTL1 compared to healthy controls. In a mouse model of sepsis, animals deficient in FSTL-1 exhibited a significantly lower IL-1β response than did control mice. Our results indicate that FSTL1 may function to augment cellular responses to infectious organisms or various other noxious stimuli. We found that FSTL1 was able to gain access to the intracellular space of cells that do not normally express FSTL1, such as monocytes/macrophages, either via increased plasma membrane permeability or via an unidentified cell surface receptor. We found intracellular FSTL1 associated with mitochondria, where it enhanced ATP production. FSTL1 also increased NLRP3 and pro-caspase-1 expression. Together, these promote activation of the NLRP3 inflammasome and secretion of IL-1β, one of the key regulators of inflammation.

Conclusion: Here, we demonstrate that FSTL1 has the ability to enhance the responses of monocytes/macrophages to inflammatory signals. The results reveal a novel mechanism by which FSTL1 acts in inflammation. Our work suggests that the neutralization of FSTL1 activity may be useful in the treatment of various inflammatory conditions.

Expression and Function Of Human Mfg-E8 In The Clearance Of Apoptotic Cells and Suppression Of Inflammation. Lucrezia Colonna, Jie An, Xizhang Sun, Nalini Agrawal, Alice Wiedeman and Keith B. Elkon. University of Washington, Seattle, WA.

Background/Purpose: Effective clearance of apoptotic cells (AC) is necessary for the maintenance of tolerance to self. MFG-E8 is one of ~20 different opsonins reported to promote AC clearance in mice. Deficiency of MFG-E8 on certain strain backgrounds promotes a lupus-like disease in mice. However, very little is known about the expression and function of MFG-E8 in humans, and its potential role in systemic lupus erythematosus (SLE). The goals of this study were to examine the expression and function of MFG-E8 in human phagocytes and its potential role in SLE.

Methods: Macrophages and dendritic cells (DC) were derived from monocytes by culture with M-CSF or GM-CSF and IL-4 respectively. MFG-E8 expression and secretion were quantified by flow cytometry (FACS) and ELISA respectively. Phagocytosis of AC was quantified by microscopy (phagocytic index) and by FACS using CFSE-labeled AC. Phagocytes were stimulated by LPS (1 ng/ml) or zymosan (50ug/ml) and cytokines quantified by ELISA.

Results: MFG-E8 expression and function was very different in human macrophages and DCs. Unlike murine thioglycollate-elicited macrophages, human macrophages did not express or secrete MFG-E8. However, when MFG-E8 was added to AC, increased cell clearance was observed in a dose responsive manner. Furthermore, specific addition of MFG-E8 to AC resulted in suppression of TNF and IL-1b in response to LPS and zymosan. In striking contrast, human DCs expressed high levels of intracellular and cell surface MFG-E8 but exogenous MFG-E8 addition to AC did not enhance DC-mediated AC uptake. Remarkably, at higher doses MFG-E8 actually exerted an inhibitory effect on AC clearance by DC.

Conclusion: These results suggest that MFG-E8 plays an important role in clearance of AC by macrophages in humans. In addition, coating of AC by MFG-E8 alone enhances the known anti-inflammatory effects of AC by further dampening the production of pro-inflammatory cytokines such as TNF and IL-1b. Surprisingly, human DC did not seem to be functionally impacted by MFG-E8 coated AC despite or, perhaps, because MFG-E8 was expressed at high concentrations on the surface of these cells. We propose that MFG-E8 plays a central role in AC clearance and dampening inflammatory responses in human macrophages. It should therefore be considered as a therapeutic to enhance AC clearance and suppress inflammation in lupus and, possibly, other autoimmune disorders.

Treatment Of Psoriasis Patients With IMO-3100 Shows Improvement In Gene Expression Patterns Of Meta-Analysis Derived-3 Transcriptome and IL-17 Pathway. Mayte Suarez-Farinas[1], Jennifer Belasco[1], Tim Sullivan[2], Robert Arbeit[2] and James G. Krueger[1]. [1]The Rockefeller University, New York, NY, [2]Idera Pharmaceuticals, Inc., Cambridge, MA.

Background/Purpose: IMO-3100, an antagonist of TLRs 7 and 9, has shown significant improvement in Psoriasis Area and Severity Index (PASI) scores in a randomized, double-blind, placebo-controlled Phase 2 trial in patients with moderate-to-severe plaque psoriasis. In the Phase 2 clinical trial, 44 patients were randomized to receive 4 once-weekly injections (Days 1, 8, 15, and 22) of IMO-3100 at 0.16 or 0.32 mg/kg or placebo; 40 patients were clinically evaluable, and clinical data were presented at IID 2013. To evaluate immunological changes following treatment with IMO-3100, biopsy samples were obtained on Days 1 (lesional and normal skin) and 29 (lesional skin). Biopsy samples from six patients in the 0.16-mg/kg group with positive clinical responses and six placebo patients also were used for gene expression analysis by DNA microarray.

Methods: Meta-analysis derived (MAD)-3 transcriptome represents a gene-expression profile associated with psoriasis (PLoS ONE 7(9): e44274). The overall effect of IMO-3100 vs. placebo treatment on the psoriasis transcriptome was compared by gene set enrichment analysis (GSEA).

Results: Principal component analysis of the microarray data showed clear distinction between lesional and normal skin within the twelve patients. Analysis showed that IMO-3100-treated patients had significant improvement in MAD-3 gene profile compared to placebo-treated patients. Placebo treatment did not significantly modulate gene expression, whereas genes up-regulated in the psoriasis transcriptome were significantly ($p<10^{-16}$) improved by IMO-3100 treatment. GSEA identified strong improvements in genes regulated in keratinocytes by IL-17 and the combination of IL-17 and TNF. In addition to the DNA microarray analysis, gene expression targets were analyzed by qPCR, which showed IL-17 was downregulated in IMO-3100 treated patients with PASI improvements.

Conclusion: In summary, treatment of patients with psoriasis with IMO-3100 leads to down regulation of the IL-17 pathway, which is central to the pathogenesis of psoriasis.

Molecular Characterisation Of The Killer Cell Immunoglobulin-Like Receptor 3DL2 Binding To Aberrant HLA-B27 Heavy Chains In Spondyloarthritis. H. Hatano, J. Shaw, K McHugh, P. Bowness and S. Kollnberger. University of Oxford, Oxford, United Kingdom.

Background/Purpose: KIR3DL2 is a Killer cell Immunoglobulin-like Receptor which binds to HLA class I including HLA-B27 (B27) β2m-free heavy chains (FHC) and HLA-A3/A11. KIR3DL2 is comprised of 3 immunoglobulin-like domains (D0, D1 and D2) which together determine binding to HLA-class I.

We have shown that KIR3DL2 expression is enriched on a subset of CD4 T cells known as Th17 cells which produce proinflammatory mediators including IL-17 in spondyloarthritis (SpA). Indeed, we have also shown that inhibiting KIR3DL2 binding to HLA-B27 inhibits T cell production of IL-17 *in vitro*. We hypothesise that HLA-class I binding to KIR3DL2 promotes Th17 differentiation and that targeting this interaction could be therapeutically beneficial in disease. A detailed characterization of the KIR3DL2-B27 binding face could assist the development more specific molecular inhibitors of this interaction.

Methods: We developed KIR3DL2-expressing cell lines, HLA-class I tetramers and KIR3DL2Fc fusion proteins to study KIR3DL2 ligand interactions. We also developed KIR3DL2CD3ϵ expressing Jurkat T reporter cells which produce IL-2 when stimulated with HLA- class I ligands.

Results: KIR3DL2 binds more strongly to HLA-B27 free heavy chains than other HLA-class I ligands. This interaction is inhibited by B27 FHC-reactive antibodies and KIR3DL2 antibodies. The recent crystal structure of KIR3DL1 suggests that the D0 domain contacts a region that is conserved between many different HLA class I. Our results show that antibodies against the D0 domain of KIR3DL2 inhibit binding to B27.

We also studied the effect of targeted mutagenesis of potential contact amino acids in the D0 domain of KIR3DL2 shared with the D0 domain of KIR3DL1 on binding of B27 and other HLA class I. Since KIR3DL1 binds more weakly to B27 FHC than KIR3DL2, we studied the effect of mutating amino acids in KIR3DL2 close to these contact residues to the corresponding residues in KIR3DL1 on binding of B27 and other ligands.

Mutagenesis of key contact residues in the D0 domain of KIR3DL2 abolished or enhanced binding to B27 while not affecting binding to other ligands.

Conclusion: We have shown that B27 FHC binding to the immune receptor KIR3DL2 promotes the survival of IL-23 receptor expressing CD4 T cells and innate lymphocyte cell subsets. Stronger binding of B27 FHC to KIR3DL2 could promote the survival of CD4 T cells and innate lymphocytes in SpA, accounting for our observations of increased proportions of these cells in patients. A detailed characterization of the KIR3DL2-B27 binding face will assist the development of more specific molecular inhibitors of this interaction with the potential for development as novel therapeutics.

A Clinically Significant Interaction Between Furosemide and Allopurinol: Potential Implications for Clinical Practice. Lisa K. Stamp[1], Claudia Knake[2] and Andrew Bahn[2]. [1]University of Otago, Christchurch, Christchurch, New Zealand, [2]University of Otago, Dunedin, New Zealand.

Background/Purpose: The xanthine oxidase (XO) inhibitor allopurinol is the most commonly used urate lowering therapy in gout. Allopurinol is metabolized to oxypurinol, which is responsible for most of the XO inhibition. Co-morbidities, such as hypertension, are common in gout patients and result in concomitant therapy with diuretics such as furosemide, which is known to inhibit renal urate clearance. It has been reported that patients receiving furosemide and allopurinol have higher serum urate (SU) and oxypurinol concentrations compared to patients' not receiving furosemide. The aim of this study was to identify the molecular basis for this observation.

Methods: The effect of oxypurinol and furosemide (alone and in combination) on XO activity was determined using a cell-free *in vitro* assay. HepG2 cells were incubated for 24 hours with oxypurinol (250μM), furosemide (1mM), probenecid (250μM) or a combination of oxypurinol/furosemide or probenecid/furosemide. XO protein expression was determined by Western blot analysis. *In silico* analysis revealed that miR-448 could act as a potential regulator of XO expression by binding to the 3'UTR of the XO gene. miR-448 expression was examined in the presence of oxypurinol, furosemide, probenecid or a combination by qPCR.

Results: Oxypurinol inhibited XO activity, an effect that was maintained in the presence of furosemide within the examined physiologically-relevant activity range of 1–7 mU/mL. There was a significant reduction in XO gene expression in HepG2 cells after incubation with oxypurinol. This reduction in XO gene expression was blocked by the addition of furosemide (Fig 1). Probenecid also led to a reduction in XO gene expression, but this effect was not reversed by the addition of furosemide. miR-448 showed a mirrored expression pattern to XO gene expression in the presence of oxypurinol, furosemide, probenecid or a combination. However, these results did not reach statistical significance.

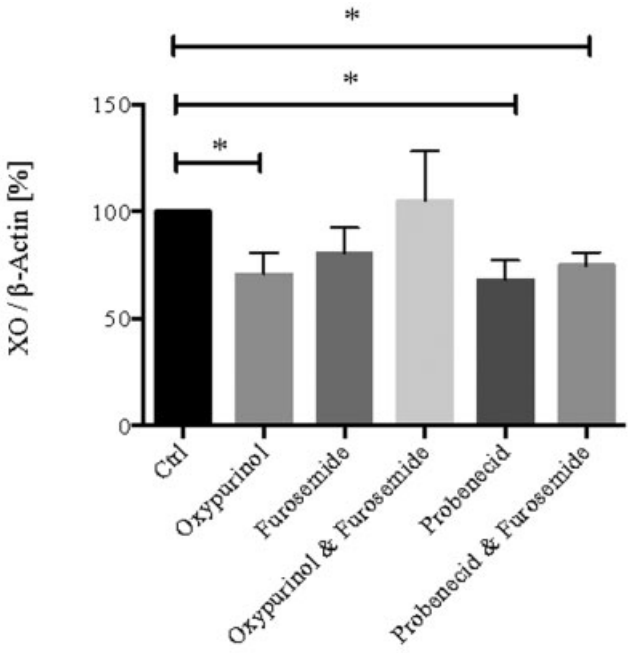

Figure 1. XO expression in HepG2 cells treated with oxypurinol (250μM), furosemide (1mM), probenecid (250μM) or a combination compared to non-treated cells (Ctrl). *$p<0.05$.

Conclusion: Oxypurinol may have effects on urate production by down-regulation of XO gene expression as well as by inhibiting XO function. Furosemide in combination with oxypurinol appears to have effects on XO expression, which may contribute to the observed increase in SU in addition to its effects on renal urate clearance. miR-448 may be a drug dependent regulator of XO expression. These effects on XO gene expression may contribute to the relative inefficiency of allopurinol in urate lowering in patients receiving furosemide. The lack of effect of probenecid, in combination with furosemide, on XO expression suggests it may be a better therapeutic option in patients receiving furosemide. Further clinical studies in patients with gout receiving different urate lowering therapies with and without furosemide are required.

Disclosure: L. K. Stamp, None; **C. Knake**, None; **A. Bahn**, None.

Impact Of Bariatric Surgery On Serum Urate Targets in People With Morbid Obesity and Diabetes: A Prospective Longitudinal Study. Nicola Dalbeth[1], Peggy Chen[2], Marie White[3], Gregory Gamble[1], Caran Barratt-Boyes[2], Peter J. Gow[4] and Brandon Orr-Walker[2]. [1]University of Auckland, Auckland, New Zealand, [2]Counties Manukau District Health Board, Auckland, New Zealand, [3]CCRep, Auckland, New Zealand, [4]Middlemore Hospital, Auckland, New Zealand.

Background/Purpose: Weight loss leads to reduced serum urate (SU) in people with obesity. However, the clinical relevance of such reductions in SU are unknown. This study examined the impact of non-surgical weight loss and bariatric surgery on SU targets in people with morbid obesity and diabetes.

Methods: This was a single-centre, prospective study of 60 people with type 2 diabetes and morbid obesity (body mass index $\geq$ 35kg/m^2). Following six months of non-surgical weight loss, all participants had laparoscopic sleeve gastrectomy, with a further one year of follow-up. SU concentrations were measured at each visit throughout the study.

Results: Participants experienced mean (SD) weight loss of 5.5 (4.1) kg prior to surgery and 34.3 (11.1) kg following surgery. SU did not change following non-surgical weight loss (mean (SD) SU 6.4 (1.5) mg/dL at baseline and 6.4 (1.7) mg/dL at follow-up), but increased to 7.4 (2.5) mg/dL in the immediate post-operative period and reduced to 5.0 (1.3) mg/dL one year after surgery ($p<0.05$ for both compared to baseline) (Figure). Baseline SU, cessation of diuretics, female sex, and

change in creatinine independently predicted change in SU at the final visit. In participants without gout, SU above saturation levels (>6.8 mg/dL) were present in 19/48 (40%) at baseline and 1/48 (2%) one year after surgery ($p<0.0001$). In participants with gout, SU above therapeutic target levels (>6.0 mg/dL) were present in 10/12 (83%) at baseline and 4/12 (33%) one year after surgery ($p=0.031$). At the final study visit, 8/12 (67%) participants with gout were on no urate-lowering therapy. SU concentrations were above therapeutic target in 8/8 of these participants at baseline and 3/8 at follow-up ($p=0.004$).

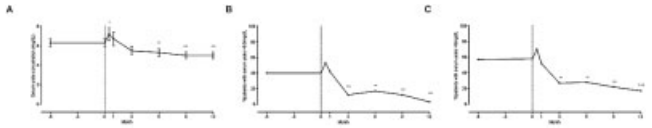

Figure. Changes in SU concentrations in the entire study group (n=60). A. Mean (95% CI) SU concentrations. B. Percentage of participants with SU above saturation levels (>6.8mg/dL). C. Percentage of participants with SU above therapeutic treatment target levels (>6mg/dL). *P<0.05, **P<0.01, ***P<0.001 compared with baseline (−6 months) values. Dashed line refers to day of surgery.

Conclusion: Clinically relevant reductions in SU occur following bariatric surgery in people with morbid obesity and diabetes. The reduction of serum urate concentrations to sub-saturation concentrations indicates that the risk of developing gout can be substantially reduced in most people following bariatric surgery. Furthermore, for those with gout, bariatric surgery allows achievement of therapeutic target serum urate concentrations and may enable cessation of urate-lowering therapy.

***ABCG2* May Influence Risk Of Gout Through Extra-Renal Metabolic Pathways: Analysis Of The Effects Of The Q141K Variant On Serum Urate Responses To a Fructose Load.** Nicola Dalbeth[1], Meaghan House[1], Gregory Gamble[1], Bregina Pool[1], Anne Horne[1], Lauren Purvis[1], Angela Stewart[1], Marilyn E. Merriman[2], Murray Cadzow[2], Amanda Phipps-Green[2] and Tony R. Merriman[2]. [1]University of Auckland, Auckland, New Zealand, [2]University of Otago, Dunedin, New Zealand.

Background/Purpose: Genetic variation in *ABCG2* is a major risk factor for hyperuricemia and gout. This gene encodes a high-capacity urate transporter expressed in the intestine, liver and renal tubule. Intake of fructose-containing beverages is also associated with development of hyperuricaemia and gout. A recent report has shown that variation in the other major genetic risk factor for gout, *SLC2A9*, influences serum urate (SU) and fractional excretion of uric acid (FEUA) responses to a fructose load. The aim of this study was to test the hypothesis that the *ABCG2* gout risk allele 141K also promotes the hyperuricemic response to fructose loading.

Methods: Healthy volunteers (n=74) provided serum and urine samples immediately before and 30, 60, 120 and 180 minutes after ingesting a 64g fructose solution. Data were analyzed based on the presence or absence of the *ABCG2* 141K gout risk allele using a mixed models approach to repeated measures.

Results: The 141K risk allele was present in 23 participants (31%). Overall, SU concentrations during the fructose load were similar in those with and without the 141K allele ($P_{SNP}=0.15$). However, the presence of the 141K risk allele was associated with a smaller increase in SU following fructose intake ($P_{SNP}<0.0001$) (Figure 1A). Those with the 141K allele also had a smaller increase in serum glucose following the fructose load ($P_{SNP}=0.002$) (Figure 1B). Higher FEUA at baseline and throughout the fructose load was observed in those with the 141K risk allele ($P_{SNP}<0.0001$). However, the change in FEUA in response to fructose was not different in those with and without the 141K risk allele ($P_{SNP}=0.39$).

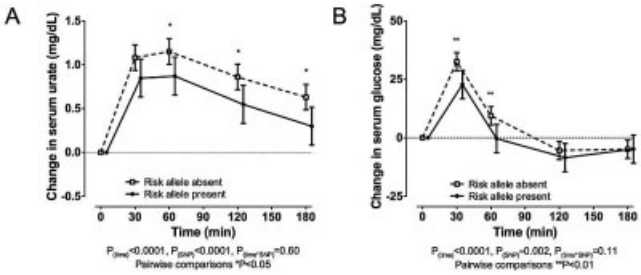

Figure 1. A. Change in SU. B. Change in serum glucose. Data are presented as mean (95% CI). Dashed line represents 141K (risk) allele absent, solid line represents 141K (risk) allele present.

Conclusion: In contrast to the predicted responses for a hyperuricemia/gout risk allele, the *ABCG2* 141K allele is associated with smaller increases in SU following a fructose load. The FEUA data provide further evidence that the *ABCG2* 141K allele does not increase hyperuricemia/gout risk through direct effects on renal tubular uric acid transport. Rather, the results suggest that *ABCG2* variants may act through extra-renal metabolic pathways, which, in turn, influence SU levels and gout risk.

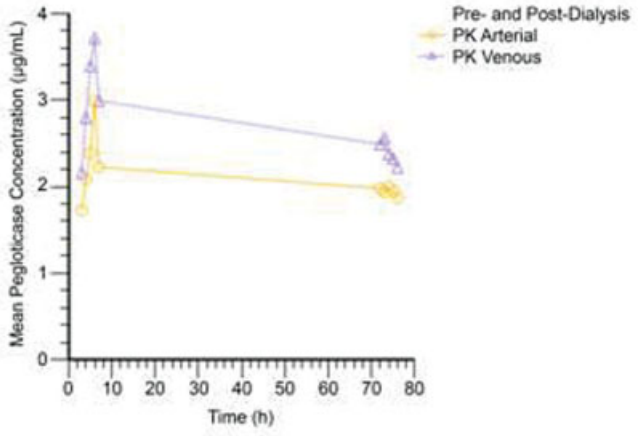
Pharmacokinetics and Pharmacodynamics Of Pegloticase In Patients With End-Stage Renal Failure Receiving Hemodialysis. Anthony J. Bleyer[1], David E. Wright[2] and Alan Glicklich[3]. [1]Wake Forest University School of Medicine, Winston-Salem, NC, [2]Savient Pharmaceuticals, Inc., San Diego, CA, [3]Savient Pharmaceuticals, Inc., Bridgewater, NJ.

Background/Purpose: Among the estimated 8.3 million adults in the US with gout, approximately 40% have coexistent chronic kidney disease (CKD).[1,2] Further, the presence of gout in CKD appears to confer an increased risk for progression to end-stage renal disease (ESRD).[3] Thus, patients often proceed to dialysis with chronic gout, and some suffer from severe tophaceous gout. There has been little detailed study of the use of urate-lowering medications in the hemodialysis (HD) population. Pegloticase, a recombinant uricase conjugated to PEG, acts by converting urate to a soluble product (allantoin) that is readily excreted. Pegloticase is reserved for patients with chronic gout who are refractory to current oral urate-lowering treatments and does not require dose adjustment based on renal function. Here we present results from a Phase 1 pharmacokinetic (PK)/pharmacodynamic study of single-dose pegloticase in patients undergoing HD.

Methods: A single intravenous dose of pegloticase (8 mg) was administered over a 2-hour period to male or female (age 18–75 years) HD patients without gout (N=12), 3 hours prior to the Day 1 dialysis session; a second dialysis session was monitored on Day 4. Patients received prophylactic antihistamine and corticosteroid prior to pegloticase infusion. Blood samples were drawn predialysis and hourly over 4 hours postdialysis during the Day 1 and Day 4 sessions. The limit of detection for pegloticase was 0.6 μg/mL; all samples below this value were set to zero. Safety assessments included standard vital signs, laboratory testing, and adverse event (AE) determinations.

Results: Following a single dose of pegloticase started approximately 3 hours prior to HD, the mean C_{max} was 3.27 μg/mL (arterial) and 4.00 μg/mL (venous). Pegloticase AUC_{3-7h} was 9.86 h · μg/mL (arterial) and 12.91 h · μg/mL (venous) at the Day 1 dialysis and for the Day 4 dialysis AUC_{72-76h} was 7.93 h · μg/mL (arterial) and 9.70 h · μg/mL (venous). Mean arterial and venous pegloticase concentrations during the Day 1 and Day 4 dialysis sessions are shown in the figure. Baseline mean serum uric acid in this non-gout population was 5.98 mg/dL; by 3 hours postinfusion, serum uric acid was undetectable and remained so over the 72-hour sampling period. One patient reported an AE of headache that was possibly related to study drug.



Conclusion: In a small cohort of patients with ESRD and no evidence of gout, pegloticase concentration was not affected by a first HD session and displayed stable decline during a second HD session. Serum uric acid levels in this cohort fell to nondetectable levels 3 hours postinfusion confirming that patients with ESRD can achieve urate-lowering with pegloticase. Data presented here support the use of pegloticase in patients with chronic gout undergoing HD.

1177

Efficacy and Safety Of Canakinumab Pre-Filled Syringe Versus Triamcinolone Acetonide In Acute Gouty Arthritis Patients. Prashanth Sunkureddi[1], Edith Toth[2], Jacques P. Brown[3], Rüdiger Möricke[4], Jan Michael Nebesky[5], Gerhard Krammer[5], Aiyang Tao[6], Markus John[5] and Alan Kivitz[7]. [1]Clear Lake Rheumatology, Nassau Bay, TX, [2]Flór Francis Hospital Rheumatology Department, Kistarcsa, Hungary, [3]CHU de Québec Research Centre and Laval University, Quebec City, QC, [4]Institut für Präventive Medizin & Klinische Forschung GbR, Magdeburg, Germany, [5]Novartis Pharma AG, Basel, Switzerland, [6]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [7]Altoona Center for Clinical Research, Duncansville, PA.

Background/Purpose: Canakinumab (CAN), a selective, fully human, monoclonal anti-IL-1β antibody has demonstrated long-term benefits in gouty arthritis (GA) patients (pts) by targeting the inflammatory pathway through IL-1β inhibition[1]. Efficacy and safety of CAN (sc), formulated as a lyophilized (LYO) powder requiring reconstitution with water, vs triamcinolone acetonide (TA) in pts with acute GA was demonstrated in phase III trials[1]. Here, we report the efficacy and safety of CAN-PFS (pre-filled syringe) vs TA in acute GA pts.

Methods: In a 12-week, multicenter, double-blind, active controlled study, pts (≥18-'85 yrs) meeting the ACR 1977 preliminary criteria for acute GA and contraindicated, intolerant or refractory to NSAIDs and/or colchicine, with ≥3 attacks in the previous year, were randomized 1:1:1 to receive a single dose of CAN- PFS 150 mg sc or CAN- LYO 150 mg sc or TA 40 mg im and re-dosed "on demand" upon each new attack. The primary objective was to confirm superiority of CAN-PFS vs TA in reducing pain intensity in the most affected joint, measured on the 0–100 mm VAS scale, at 72h post-dose. Secondary objectives included evaluation of CAN-PFS vs TA and CAN-LYO vs PFS for the following: time to first new attack; percentage of pts with at least 1 new attack; and safety over 12 weeks.

Results: A total of 397 pts were randomized (CAN-PFS [n=133], CAN-LYO [n=132], TA [n=132]), of which 87.9% completed the study. CAN-PFS provided a statistically significant reduction in pain intensity at 72h post dose vs TA (estimated difference, −14.9mm; 95% CI: −20.6, −9.2, p<0.0001). The least square mean pain scores at 72h post-dose were comparable for both CAN formulations (PFS, 17.1mm; LYO, 19.7mm), and both were lower than that for TA (32.0mm). The percentage of pts with at least 1 new attack was lower with CAN-PFS (9.2%) vs TA (40.3%) (OR, 0.15 [95% CI: 0.07, 0.30], p<0.0001) and comparable for both CAN formulations (CAN-LYO, 9.3%) over the 12-week period. CAN-PFS treatment significantly delayed (p<0.0001) time to first new attack vs TA and both CAN formulations had similar results for this outcome. Adverse events (AEs) were observed in 43.6 % of pts in both the CAN-PFS and TA groups, and 42.9% pts in the CAN-LYO group. Serious AEs were reported in 17 pts (CAN-PFS, n=6; CAN-LYO, n=6; TA, n=5), with infections (CAN-PFS, n=2; CAN-LYO, n=3; TA, n=0) being the most common SAEs. Two patients discontinued the study: one due to non-fatal SAE in the CAN-LYO group and the other due to AE in the TA group.

Conclusion: CAN-PFS was superior to TA in relieving pain and reducing risk of new attacks, and had a safety profile similar to CAN-LYO. The safety profile was also consistent with that observed in previous CAN-LYO studies[1, 2]. Efficacy and safety of the two CAN formulations were comparable.

Effect Of Febuxostat On Serum Urate Levels In Gout Subjects With Hyperuricemia and Moderate-To-Severe Renal Impairment: A Randomized Controlled Trial. Kenneth G. Saag[1], Michael A. Becker[2], Andrew Whelton[3], Patricia A. MacDonald[4], Yun Zhou[5] and Lhanoo Gunawardhana[5]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Chicago, Chicago, IL, [3]The Johns Hopkins University and Universal Clinical Research Center, Inc., Baltimore, MD, [4]Takeda Pharmaceuticals USA, Inc., Deerfield, IL, [5]Takeda Global Research & Development Center, Inc., Deerfield, IL.

Background/Purpose: Up to 20% of patients with hyperuricemia (serum urate [sUA] >6.8 mg/dL) and gout have moderate-to-severe renal impairment. Higher sUA (>8.5 mg/dL) may increase the risk for progressive decline in renal function. The objective of this prospective 12-m pilot study was to evaluate the effect of treatment with febuxostat (FEB) vs placebo (PLB) on urate-lowering, renal function, and general safety in gout subjects with moderate-to-severe renal impairment.

Methods: In this multicenter, double-blind, phase 2 study, subjects were randomized 1:1:1 to receive 12 m of daily treatment with either FEB 30 mg BID, FEB 40/80 mg QD (titrated from 40 to 80 mg to achieve sUA <6.0 mg/dL) or PLB. Eligible subjects fulfilled ARA criteria for gout (subjects with tophi were excluded), had sUA >7.0 mg/dL, and had an estimated glomerular filtration rate (eGFR; by MDRD) ≥15 to ≤50 mL/min (severe, eGFR ≥15 to <30 mL/min; moderate, ≥30 to ≤50 mL/min) on d −21. Endpoints at m 12 included the proportion of subjects with sUA <6.0 mg/dL (Cochran-Mantel-Haenszel test) and change from baseline (CFB) in sUA and eGFR (by ANCOVA analysis). Adverse events (AEs) were recorded throughout the study.

Results: Among 96 subjects enrolled, 80% were male with a mean sUA (SD) of 10.5 (1.70) mg/dL; 95 subjects qualified for primary efficacy analysis. At m 1 visit, 20 subjects were titrated from FEB 40 mg to 80 mg QD based on d 14 sUA. At baseline, 28%, 31%, and 53% of subjects in the FEB 30 mg BID, FEB 40/80 mg QD, and PLB groups, respectively, had severe renal impairment. The proportion of subjects with sUA <6.0 mg/dL at m 12 was significantly greater in both FEB groups compared to PLB: 69%, 45%, and 0% for FEB 30 mg BID, FEB 40/80 mg QD, and PLB, respectively (p<0.001). The CFB in sUA at m 6 and m 12 was significantly greater in both FEB groups vs PLB (**Table**). Mean (SE) baseline eGFR was 34.14 (1.46), 34.08 (1.48), and 29.31 (1.46) mL/min/1.73 m^2. Mean eGFR CFB (SE) at m 12 for FEB 30 mg BID and 40/80 mg QD (0.33 [1.17] and −0.86 [1.19] mL/min/1.73 m^2, respectively) was not significantly different from PLB (−2.05 [1.20] mL/min/1.73 m^2; p>0.1). Overall, ≥1 AE was reported by 78%, 88%, and 78% of subjects in the FEB 30mg BID, FEB 40/80 mg QD, and PLB groups, respectively. The majority of AEs were mild to moderate in intensity and not considered to be related to study treatment. Elevated serum creatinine (increase from baseline ≥0.3 mg/dL) was seen in 13/32, 16/32, and 17/32 subjects in the FEB 30mg BID, FEB 40/80 mg QD, and PLB groups, respectively.

Table. CFB in serum urate

	FEB 30 mg (N=32)	FEB 40/80 mg (N=31)	PLB (N=32)
		LS mean (SE)	
Baseline	10.36 (0.31)	10.35 (0.31)	10.72 (0.31)
CFB at m 6	−5.08 (0.30)*	−4.29 (0.31)*	0.07 (0.30)
CFB at m 12	−4.97 (0.32)*	−4.17 (0.32)*	−0.15 (0.32)

LS = least squares; SE = standard error; FEB = febuxostat; PLB = placebo; CFB = change from baseline; *p <0.001 vs PLB

Conclusion: In subjects with moderate-to-severe renal impairment, FEB urate-lowering was efficacious, with no emergent serious safety issues at 12 m. The sUA was significantly reduced in subjects receiving either regimen of FEB compared to PLB. CFB in renal function did not differ significantly between groups. Limitations include small sample size and a baseline imbalance in the distribution of subjects with severe vs moderate renal impairment across the treatment groups.

Colchicine Use and The Risk Of Myocardial Infarction Among Gout Patients: Interim Results From a VA Retrospective Cohort Study. Daria B. Crittenden[1], Jessica N. Kimmel[1], Virginia C. Pike[1], Daniel Diaz[1], Avni Shah[1], Cilian J. White[1], Michael DeBerardine[1], Grace Kim[1], Binita Shah[2], Christopher J. Swearingen[3], Jeffrey D. Greenberg[4], Steven P. Sedlis[2], Craig T. Tenner[5], Bruce N. Cronstein[1] and Michael H. Pillinger[1]. [1]NYU School of Medicine, Division of Rheumatology, New York, NY, [2]NYU School of Medicine, Division of Cardiology, New York, NY, [3]Pediatric Biostatistics, University of Arkansas for Medical Sciences, Little Rock, AR, [4]NYU Hospital for Joint Diseases, New York, NY, [5]NYU School of Medicine, Department of Internal Medicine, New York, NY.

Background/Purpose: Gout patients are at increased cardiovascular (CV) risk. Since atherosclerosis is an inflammatory process, anti-inflammatory strategies to reduce CV risk are currently being investigated. The anti-inflammatory colchicine is commonly used in gout, and inhibits cell types implicated in atherosclerosis. Our preliminary data suggest that colchicine may reduce myocardial infarction (MI) among gout patients (Crittenden et al, J Rheum 2012). To further assess colchicine's possible effect on MI risk, we initiated a retrospective cohort study in a Veterans Affairs population and here present an interim analysis.

Methods: We identified all active NY Harbor VA patients with an ICD-9 code for gout or hyperuricemia from 2000-09. Charts were manually screened to confirm gout diagnosis (ACR criteria) and pharmacy records were used to identify subjects on daily colchicine for ≥ 30 days (colchicine group). Subjects receiving no colchicine formed the control group. We excluded patients who did not meet gout criteria, or who received PRN colchicine only. We defined colchicine lapse as any period of non-colchicine use ≥ 2 weeks after medication cessation (to account for colchicine elimination time). Primary outcome was MI (adjudicated by universal criteria) during the study period.

Results: 7819 subjects had requisite ICD-9 codes. 4486 charts have been reviewed to date; 844 patients met ACR gout criteria and 644 were enrolled. 410 subjects (64%) used colchicine (1184 person-years of active use and 682 person-years of lapse); 234 (36%) used no colchicine (1041 person-years of follow-up). Colchicine and control groups did not differ in baseline characteristics including gender (99.3 vs 97.4% male, p=0.08); age (66 vs 67 years, p=0.3); BMI (30.5 vs 30.2, p=0.7); uric acid level (8.4 vs 8.0 mg/dL, p=0.1); hypertension (80 vs 81%, p=0.9); diabetes (30 vs 30% p=1.0); hyperlipidemia (51 vs 43%, p=0.06); coronary artery disease (24 vs 26%, p= 0.6); and medication use including allopurinol (22 vs 20%, p=0.1); aspirin (30 vs 32%, p=0.7); statins (41 vs 39%, p=0.5); ACE-inhibitors (48 vs 42%, p=0.1); and beta-blockers (41 vs 34%, p=0.1). Colchicine users experienced 11 total MIs—8 occurring during lapse time (2%) and 3 during active use (0.7%). Control patients had 7 MIs (3%; active colchicine vs control p=0.04). The shortest time from last colchicine use to MI was 2 months (mean 4 months). We also compared rates of MI per person-year exposure to colchicine (0.003), control (0.007), lapse (0.012), and pooled control+lapse (0.009) periods, and observed significant differences between colchicine active use vs lapse (p=0.02), and vs lapse+control (p=0.04). Active colchicine use vs control was not statistically different (p=0.16), but is expected to reach significance if the current rates persist through the remaining data collection.

Conclusion: In this interim analysis, gout patients actively taking colchicine had a significantly reduced incidence of MI vs never-users, and significantly reduced person-year incidence rates vs lapse patients and vs a pooled group of patients not on colchicine. These data suggest that colchicine protects against MI, though probably only during active use. Evaluation of the remaining 3333 patients is ongoing.

Rising Burden Of Gout and Poor Management Of The Disease In The United Kingdom: A Nationwide Population Study. Chang-Fu Kuo[1], Michael Doherty[2], Matthew J. Grainge[2] and Weiya Zhang[2]. [1]Chang Gung Memorial Hospital, Taipei, Taiwan, [2]University of Nottingham, Nottingham, United Kingdom.

Background/Purpose: To describe the trends of epidemiology of gout and patterns of urate-lowering treatment in the UK general population from 1997–2012.

Methods: We used the Clinical Practice Research Data-link (CPRD) to estimate the prevalence and incidence of gout and the proportion of gout patients being treated by urate-lowering therapy for each calendar year from 1997 to 2012. To determine trends of prevalence, incidence and management of gout, we used direct standardisation considering the distribution of age, sex and length of data contribution with the population structure in year 2012 as reference. Good adherence for urate-lowering treatment (ULT) was classifed as a proportion of days covers (PDC) of 80% or higher.

Results: Of 4,604,203 eligible individuals in 2012, 115,608 prevalent cases of gout were identified, giving a prevalence of 2.51% (95% CI, 2.50%–2.52%). Men had a significantly higher prevalence (4.00%; 95% CI, 3.97%–4.03%) than women (1.05%; 95% CI, 1.04%–1.06%). There were a total of 4,484,830 person-years of follow-up in this year during which 8401 incident cases of gout were identified (overall incidence 1.87 [95% CI, 1.83–1.91] per 1000 person-years). Men had a higher incidence (2.74 [95% CI, 2.67–2.81] per 1000 person-year) than women (1.05 [95% CI, 1.00–1.09) per 1000 person year). Prevalence and incidence both were significantly higher in 2012 than in 1997, with a 66.7% increase in prevalence and 25.7% increase in incidence. Among prevalent gout patients in 2012, only 44% were under medical attention (with at least one consultation with a gout diagnosis or a prescription for ULT, 31% were prescribed with ULT of which only 47% adhered to treatment. The percentage of patients under medical attention and treated by ULT remained poor from 1997 to 2012 (annual change −0.3% [95%CI −0.5%–−0.2%] and 0.1% [95%CI −0.1%–−0.3%]), while the adherence increased slightly from 10.7% to 14.6%.

Conclusion: Both prevalence and incidence of gout increased significantly in the UK in the period between 1997 and 2012. Only one-third of gout patients were given ULT and the adherence was poor. The pattern of gout management has not changed despite the rising burden of disease.

The Effect Of Uric Acid Lowering Therapy In Preventing Comorbidity and Acute Attack Of Gout; A Retrospective Study. Kowoon Joo[1], Won Park[1], Seong-Ryul Kwon[1], Mie-Jin Lim[1], Kyong-Hee Jung[1], Hoyeon Joo[1] and Sung-Soo Kim[2]. [1]Inha University Hospital, Incheon, South Korea, [2]Ulsan Univ College of Medicine and Gangneung Asan Hospital, Gangneung, South Korea.

Background/Purpose: We evaluated the effect of uric acid lowering therapy (ULT) in reducing the new development of comorbidities and the frequency of acute attacks in gout patients.

Methods: We retrospectively examined data of 200 patients who were diagnosed to have gout according to the American College of Rheumatology (ACR) criteria. The patients with at least 3 years of follow up during the period from January 1996 to December 2012 were divided into 2 groups; those whose mean serum uric acid level (sUA) < 6mg/dL (2012 ACR uric acid treatment target) and mean sUA °Ã 6mg/dL. Comorbidities of gout such as hypertension (HTN), type II diabetes mellitus (DM), chronic kidney disease (CKD), cardiovascular disease (CVD) and kidney stone were compared in each group at baseline and at last follow-up visit. Frequency of acute gout attacks were compared between the groups. Mann-Whitney U test and chi-square test was used to compare the variables between the 2 groups. McNemar's test was used to evaluate the treatment effects in comorbidities of gout in each group. A value of $p < 0.05$ was considered significant.

Results: Fifty-three patients were allocated to the adequately treated group (mean sUA < 6mg/dL) and 147 patients were allocated to the inadequately treated group (mean sUA °Ã 6mg/dL). Only 1 patient in the adequately treated group was woman. Patients in the adequately treated group was older (54 ± 13 years vs. 44 ± 12 years, $p<0.001$) with lower BMI (24.5 ± 4.5kg/m©÷ vs. 25.9 ± 4.5kg/m©÷, $p=0.003$) and kept higher medication possession rate (MPR) (94 ±10% vs. 61 ± 27 %, $p<0.001$) compared to the inadequately treated group. There was no difference in the duration of gout, ULT duration, tophi, family history of gout, smoking, alcohol, hypercholesterolemia between the groups. During the mean follow up period of 8 years, the yearly rate of acute attack (0.25 ± 0.39 vs. 0.47 ± 0.53, $p<0.001$) was lower in the adequately treated group compared to the inadequately treated group. New development of HTN, DM, CVD and kidney stone was lower in the adequately treated group compared to the inadequately treated group (Table 1). The frequency of CKD tended to decrease in the adequately treated group from 21 patients at baseline to 19 patients at last follow up visit.

Table 1. Comorbidities of gout according to uric acid level.

		sUA < 6mg/dL n = 53		sUA ≥ 6mg/dL n = 147	
		n(%)	p value	n(%)	p value
Hypertension	Baseline	31 (58)		33 (22)	
	Last visit	36 (68)	p = 0.063	71 (48)	p < 0.001
Diabetes mellitus	Baseline	4 (8)		9 (6)	
	Last visit	8 (15)	p = 0.125	27 (18)	p < 0.001
Chronic kidney disease[a]	Baseline	21 (40)		26 (18)	
	Last visit	19 (36)	p = 0.727	27 (18)	p = 1.000
Cardiovascular disease	Baseline	12 (23)		8 (5)	
	Last visit	15 (28)	p = 0.250	17 (12)	p = 0.004
Kidney stone	Baseline	4 (8)		5 (3)	
	Last visit	6 (11)	p = 0.500	16 (11)	p = 0.001

[a] Calculated by MDRD (modification of diet in renal disease).
CKD defined as GFR less than 60 mL/min per 1.73m^2.

Conclusion: Tight control of uric acid decreased the development of acute gout attacks and comorbidities of gout such as HTN, DM, CVD and urinary stone despite the same CVD risk factors. The renal function can be recovered by intensive ULT therapy.

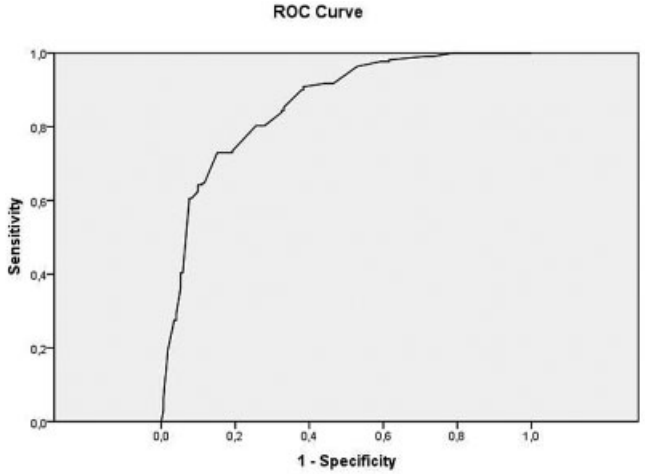
The Performance Of a Diagnostic Rule For Acute Gouty Arthritis Without Joint Fluid Analysis: a Validation Study. Laura Kienhorst[1], Hein Janssens[2], Jaap Fransen[2] and Matthijs Janssen[1]. [1]Rijnstate Hospital, Arnhem, Netherlands, [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: The gold standard to diagnose gout is the identification of monosodium urate (MSU) crystals in joint fluid. In primary care gout is mostly diagnosed clinically without joint fluid analysis. However, this clinical diagnosis of gout has a positive and negative predictive value of 0.64 and 0.87, respectively.[1] To improve the clinical diagnosis of gout a diagnostic rule has been developed in a primary care population.[1] The aim of this study is to validate this diagnostic rule in a secondary care population.

Methods: In this validation study adult patients who were referred to the rheumatology department from 1 January 2011 until 8 May 2013 with signs and symptoms of monoarthritis at their first visit and who conceivably could have gout were included. The affected joint was aspirated and joint fluid analysis was performed for the presence of MSU crystals. The seven variables of the diagnostic rule (male sex, previous patient-reported arthritis attack, onset within one day, joint redness, first metatarsophalangeal joint involvement, hypertension or one or more cardiovascular diseases, and serum uric acid >0.35 mmol/L) were collected and scored without knowledge of the joint fluid analysis result. The performance of the diagnostic rule was compared to the presence of MSU crystals.

Results: 390 patients were included in this study. In 218 (56%) patients MSU crystals were found. As confirmed by the presence of MSU crystals, the prevalences of gout at the cut-off scores ≤4, >4 to <8, and ≥8 points were 6% (4 of 69), 46% (76 of 163), and 88% (138 of 157), respectively. The area under the receiver operator characteristic curve for the diagnostic rule was 0.85 (figure 1). The Hosmer-Lemeshow goodness-of-fit test showed that the difference between the expected and the observed probability was non-significant ($p=0.64$), indicating well agreement.



Conclusion: The diagnostic rule to diagnose gout without joint fluid analysis, which was developed in a primary care population, has a good performance in a secondary care population.

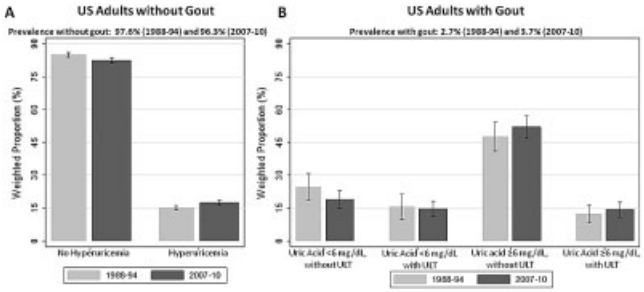
The Treatment Of Gout In Relation To The 2012 Uric Acid Target Guidelines In The US Population. Stephen Juraschek, Lara Kovell, Edgar Miller III and Allan C. Gelber. Johns Hopkins University, Baltimore, MD.

Background/Purpose: Gout is a debilitating form of arthritis mediated by elevated serum uric acid (SUA) levels. Pharmacologic interventions to prevent recurrent gout are largely focused on urate-lowering therapy (ULT). In 2012, the American College of Rheumatology (ACR) released gout

management guidelines encouraging providers to target a SUA <6 mg/dL. The proportion of US adults with gout undergoing ULT, in relation to this SUA target, is unknown. Further, while gout risk factors are well-characterized, demographic and clinical factors associated with a SUA above target have not been determined.

Methods: We examined the National Health and Examination Survey (NHANES), in the 1988–1994 and 2007–2010 survey periods. Participants <20 years or those missing data for SUA, ULT use, or gout status were excluded. Gout status was based on self-report of a physician (or health professional) diagnosis. According to the recent ACR gout treatment guidelines, a SUA above target in participants with gout was defined as a SUA ≥6.0 mg/dL in both men and women. Demographic and clinical factors associated with a SUA above target among NHANES participants with gout, were analyzed using adjusted and weighted Poisson regression.

Results: There were 15,505 NHANES participants in 1988–1994 and 10,977 in 2007–2010, among whom 443 and 514 had gout, respectively. The prevalence of gout rose from 2.7% in 1988–1994 to 3.7% in 2007–2010. In 2007–2010, the mean age was 48 years; 52% were female, 69% were white, 10% were black, and 8% were Mexican American. Notably, 66% of US adults with gout in 2007–2010 had a UA ≥6 mg/dl (**Figure**); among this hyperuricemic subgroup, 79% were not using ULT. In both time periods, higher BMI (prevalence ratio: 1.02 per 1 kg/m^2; 95% CI: 1.00, 1.03; P = 0.02) and ULT (prevalence ratio: 0.56; 95% CI: 0.45, 0.70; P <0.001) were associated with a SUA above target (**Table**). Male sex, reduced glomerular filtration rate (eGFR), low HDL cholesterol, and diuretic use were significantly associated with a SUA above target in a least one time period.



Demographic and clinical factors associated with a uric acid level above target (≥6 mg/dL) among US adults with gout.

	1988–94 (N with gout = 443)		2007–10 (N with gout = 514)	
	Prevalence Ratio (95% CI)*	*P*	Prevalence Ratio (95% CI)*	*P*
Age, per 10 yrs	1.01 (0.91, 1.11)	0.92	0.99 (0.90, 1.10)	0.91

Mexican American	1.11 (0.78, 1.59)	0.56	0.90 (0.74, 1.11)	0.31
Body mass index per 1 kg/m^2	1.02 (1.01, 1.03)	<0.001	1.02 (1.00, 1.03)	0.02
eGFR < 60 mL/min per 1.73m^2	1.43 (1.13, 1.81)	<0.001	1.17 (1.00, 1.37)	0.06
Low HDL cholesterol	0.97 (0.77, 1.21)	0.77	1.25 (1.03, 1.51)	0.03
Urate-lowering therapy†	0.55 (0.40, 0.76)	<0.001	0.56 (0.45, 0.70)	<0.001
Diuretic medications	1.32 (1.05, 1.64)	0.02	1.20 (0.97, 1.47)	0.09

*All models were adjusted for age, sex (vs. female), race/ethnicity (vs. non-Hispanic white), body mass index, eGFR < 60 mL/min per 1.73m^2 (vs. eGFR ≥ 60 mL/min per 1.73m^2), low high density lipoprotein cholesterol (vs. elevated high density lipoprotein cholesterol), elevated total cholesterol (vs. low total cholesterol), hypertension (vs. no hypertension), diabetes (vs. no diabetes), no urate lowering therapy (vs. urate lowering therapy), diuretic use (vs. no diuretic medication use), and alcohol use (vs. never drank alcohol). Clinical factors that were not significant in either survey period (i.e.total cholesterol, hypertension, diabetes, and alcohol use)were not shown.
†Allopurinol, probenecid, sulfinpyrazone, or combination colchicine-probenecid

Conclusion: The majority of US adults with gout had a SUA above the ACR target level and were not taking ULT. This study establishes a meaningful baseline to assess the effectiveness of ACR treatment guidelines for lowering UA in coming years.

High Mobility Group Box 1 Plays a Role In Gouty Arthritis. Kiwon Moon[1], Jinhyun Kim[2] and Yun Jong Lee[3]. [1]Kangwon National University Hospital, Chuncheon city, Kangwon province, South Korea, [2]Chungnam National University School of Medicine, Daejeon, South Korea, [3]Seoul National University Bundang Hospital, Seongnam-si, South Korea.

Background/Purpose: High mobility group box 1 (HMGB1) is a crucial cytokine that mediated the response to infection, injury and inflammation. It is recently discovered that HMGB1 plays a role in the pathogenesis of inflammatory arthritis, such as rheumatoid arthritis. However, the role of HMGB1 in gouty arthritis has not yet determined. The purpose of the study was to investigate the role HMGB1 in gouty arthritis.

Methods: HMGB1 concentrations of the synovial fluid (SF) of gouty arthritis and osteoarthritis (OA) were measured by ELISA. Immunohistochemistry was performed in synovial tissue of gouty arthritis and OA. Double immunofluorescence staining was also performed using anti-CD55, anti-CD68, and anti-HMGB1 antibody. In vitro THP-1 cell was stimulated by monosodium urate (MSU) crystal and lipopolysaccharide (LPS). HMGB1 and IL-1β concentrations were measured by ELISA. THP-1 cell and synovial fibroblast were stimulated by IL-1β alone or in complex with HMGB1. IL-1β, IL-6, TNF-α levels were measured by ELISA, and cyclooxygenase-2 (COX-2) expression was assessed by Western blot.

Results: HMGB1 concentration was significantly higher in SF of gouty arthritis than that of OA (73.1±57.1 vs 14.8±7.3, p < 0.01). Immunohistochemistry revealed that HMGB1 was localized in the nucleus of synoviocyte in OA. However, in gouty arthritis, HMGB1 was found in the cytoplasm of synoviocyte as well as nucleus. Double immunofluorescence staining showed that HMGB1 was found in mainly synovial fibroblast in gouty arthritis. MSU crystal and LPS induced HMGB1 and IL-1β production in THP-1 cell. However, IL-1β, IL-6, TNF-α levels and COX-2 expression were not stimulated by IL-1β alone or IL-1β/HMGB1 complex in THP-1 cell. IL-1β alone enhance COX-2 expression, but IL-1β/HMGB1 complex decreased COX-2 expression in synovial fibroblast.

Conclusion: HMGB1 was highly expressed in SF and synovial tissue in gouty arthritis. MSU crystal and LPS induced HMGB-1 and IL-1β production in macrophage. Extracellular HMGB1 decreased IL-1β induced COX-2 expression in synovial fibroblast. These findings suggest that HMGB1 might plays as an anti-inflammatory mediator in gouty arthritis.

More Than One-Third Of Patients Reach Serum Urate Target and Continue To Report Multiple Flares. Dinesh Khanna[1], Puja Khanna[2], Chris Storgard[3], Scott Baumgartner[4] and Robert Morlock[3]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Medical Center, Ann Arbor, MI, [3]Ardea Bioscience, San Diego, CA, [4]Ardea Biosciences, San Diego, CA.

Background/Purpose: Gout is a common inflammatory arthritis, and its worldwide prevalence is increasing. EULAR and ACR guidelines recommend a target serum urate (sUA) ≤6 mg/dL. We describe US and EU physician, patient, and treatment characteristics in patients treated with xanthine oxidase inhibitor (XOI) therapy who achieve sUA ≤6 mg/dL yet have 2 or more physician-confirmed gout flares per year.

Methods: A large survey of more than 500 physicians across the US and EU was conducted. Data was confirmed through in-depth chart audits, which assessed diagnosis, comorbid conditions, disease severity, and laboratory results of the last 5 patients with gout that they treated. Disease severity was measured using a physician global assessment (mild, moderate, or severe), flare counts, joint damage, and presence of tophi. Type and dose of XOI, length of current treatment, compliance, physician type, and patient sociodemographic factors were identified. Comorbidities were captured using chart review and analyzed as present or absent. Descriptive and multivariate statistics described patients having 2 or more

flares per year (excluding treatment initiation flares) in patients achieving sUA ≤6 mg/dL.

Table 1. Demographics: Patients With Most Recent sUA Level ≤6 mg/dL

	≥2 Flares (n=122)	≤1 Flare (n=233)	Total (n=355)
Sex (male)	87%	79%	81%
Age (years)	60.22	58.93	59.37
Number of flares (last 12 months)*	3.11	0.43	1.35
Most recent sUA level (mg/dL)	5.20	5.16	5.18
12-month average sUA level (mg/dL)*	6.34	5.84	6.01
Tophi*	31%	19%	23%
Treated with allopurinol	72%	74%	74%
Treated with febuxostat	28%	26%	27%
Months on current urate-lowering therapy	36.78	37.19	37.05
Rheumatologist management	65%	69%	67%

*p<0.05.

Results: In total, 251 rheumatologists and 250 primary care physicians were interviewed. Of 2505 patients with gout, 82% were male and the average age was 58 (SD=12) years; 1826 (73%) patients were treated with a XOI. Of these, 811 (44%) had at least one assessment of sUA ≤6 mg/dL and 305 (38%) reported 2 or more flares in the last 12 months (Table). A backward stepwise multivariate model predicting patients classified as controlled (sUA ≤6 mg/dL) and continuing to flare (2 or more flares in the last year) found physician-reported and chart-documented coexisting comorbidities, including chronic kidney disease (OR 2.8; p<0.01), alcoholism (OR 3.6; p<0.01), and diabetes mellitus (OR 1.9; p<0.05). There was no difference by XOI or physician type. Results were similar for patients with single or multiple sUA assessments ≤6 mg/dL during the study period.

Conclusion: Less than 50% of patients treated with a XOI alone achieved sUA target. Of the patients achieving a sUA level of ≤6 mg/dL, more than one-third reported 2 or more flares in a 12-month period despite being treated with the same ULT for more than 3 years. Frequent flares and greater tophaceous burden requires treatment to an even lower urate target than 6.0 mg/dL.

Use Of High-Dose Allopurinol To Reach Serum Uric Acid Targets In Patients With Gout Across Multiple Countries. Jasvinder A. Singh[1], Chris Storgard[2], Scott Baumgartner[3] and Robert Morlock[2]. [1]University of Alabama, Tuscaloosa, AL, [2]Ardea Bioscience, San Diego, CA, [3]Ardea Biosciences, San Diego, CA.

Background/Purpose: Allopurinol is the most commonly used urate-lowering therapy (ULT) in the world. Although allopurinol is FDA approved for up to 800 mg/d and EMEA authorized for up to 900 mg/d, the majority of patients with gout receive ≤300 mg/d. We describe physician, patient, and treatment characteristics in patients with gout treated with allopurinol.

Methods: Data from a quantitative survey of physicians in the United States (US), France, Germany, Italy, Spain, and the United Kingdom (UK) were assessed and results confirmed through in-depth chart audits. Initial and current allopurinol doses, presence of comorbid conditions, use of anti-inflammatory prophylaxis for flare prevention, serum uric acid (sUA), physician subspecialty, and patient factors were evaluated. Data on number of patients achieving target sUA <6 mg/dL were also collected.

Results are presented as proportions or means and standard deviations (SD). Descriptive statistics and multivariable-adjusted logistic regression analyses were used to describe patients with sUA <6 mg/dL.

Results: In total, 251 rheumatologists and 250 primary care physicians were interviewed. Of 2505 patients, 1437 (57%) were treated with allopurinol.

Table 1 presents patient characteristics, treatment, and percent with sUA <6 mg/dL.

Table 1. Patients Treated with Allopurinol: Unadjusted Characteristics by Country

	France (n=146)	Germany (n=180)	Italy (n=167)	Spain (n=186)	UK (n=137)	US (n=621)
Age, years (mean±SD)	63±9.7	60±11.5	62±11.2	58±10.7	56±13.4	57±12.2
Male (n, %)	112 (77)	148 (82)	139 (83)	167 (90)	118 (86)	515 (83)
Comorbidities (n, %)						
-Hypertension	53 (36)	106 (59)	75 (45)	91 (49)	52 (38)	348 (56)
-Cardiovascular disease	26 (18)	45 (25)	42 (25)	24 (13)	30 (22)	112 (18)
-Kidney disease	12 (08)	23 (13)	23 (14)	13 (7)	34 (25)	81 (13)
-Diabetes	25 (17)	40 (22)	42 (25)	4 (13)	19 (14)	143 (23)
Allopurinol dosing (n, %)						
<300 mg/d	74 (51)	54 (30)	47 (28)	67 (36)	29 (21)	139 (22)
300 mg/d	64 (44)	117 (65)	104 (62)	108 (58)	62 (45)	361 (58)
>300 to <600 mg/d	5 (3.4)	5 (2.8)	9 (5.4)	5 (2.7)	27 (20)	86 (14)
≥600 mg/d	3 (2.1)	4 (2.2)	8 (4.8)	7 (3.8)	19 (14)	35 (5.6)
Average allopurinol dose (mean±SD)	239±97.2	261 ± 96.9	279 ± 119.0	249 ± 116.8	347 ± 168.5	303 ± 129.3
Months on allopurinol (mean±SD)	48±56.8	35 ± 42.4	39 ± 46.3	59 ± 67.9	42 ± 53.2	43 ± 53.7
% sUA ≤6 mg/dL (n, %)	57 (39)	61 (34)	62 (37)	48 (26)	92 (67)	261 (42)

Across all countries, the majority of patients were treated with ≤300 mg/d of allopurinol; ≤6.5% in France, Germany, and Spain were given >300 mg/d, whereas 10% in Italy, 19.6% in the US, and 34% in the UK achieved a dose >300 mg/d (p<0.01). Over 12 months, the number of patients achieving target sUA <6.0 mg/dL differed across the 6 countries (Spain < Germany < Italy <France <US < UK, Table 1); yet, there was no difference in achieving target sUA <6.0 mg/dL by allopurinol dose. A multivariable-adjusted model predicting use of high-dose allopurinol found patients with tophi (OR 3.53; p<0.01), coexisting alcoholism (OR 1.66; p=0.06), COPD (OR 2.01; p<0.05), and patients using smoking-cessation treatments (OR 3.53; p=0.02), and from the UK (OR 3.86; p<0.01) were more likely to be using ≥600 mg/d of allopurinol. However, only physician subspecialty [general practitioners vs rheumatologists (OR 0.56; p<0.01)], UK vs other countries (OR 3.51; p<0.01), time on therapy (OR 1.39; p=0.04), and chart-documented coexisting alcoholism (OR 0.67; p<0.05), hyperlipidemia (OR 0.74; p<0.05), hypertension (OR 1.4; p<0.05), and kidney stones (OR 0.49; p<0.05) were found to be associated with achieving sUA <6 mg/dL. After adjusting for confounding factors (age, sex, time on ULT, dose, comorbid conditions, physician type), allopurinol dose was not associated with achieving sUA <6 mg/dL.

Conclusion: Allopurinol is the most widely used ULT. Although it is approved for up to 800 mg/d in the US and 900 mg/d in the EU, the majority of patients are treated with ≤300 mg/d. On average, <50% of patients achieve sUA <6 mg/dL at any allopurinol dose.

A Large-Scale, Multicenter, Prospective, Open-Label, 6-Month Study To Evaluate The Safety Of Allopurinol Monotherapy In Patients With Gout. Michael A. Becker[1], David Fitz-Patrick[2], Chris Storgard[3], Matt Cravets[4] and Scott Baumgartner[5]. [1]University of Chicago, Chicago, IL, [2]East-West Medical Research Institute, Honolulu, HI, [3]Ardea Bioscience, San Diego, CA, [4]Ardea Biosciences, Inc., San Diego, CA, [5]Ardea Biosciences, San Diego, CA.

Background/Purpose: Documentation of the safety profile of allopurinol at doses ≥300 mg/day is important for its ongoing use as first-line monotherapy or in combination with newer agents. Current data are limited. This study examined the safety profile of allopurinol titrated as described below (ClinicalTrials.gov Identifier: NCT01391325).

Methods: Patients meeting ARA criteria for the Classification of Acute Arthritis of Primary Gout and at least 2 gout flares in the preceding year were enrolled; caregivers were encouraged but not required to titrate allopurinol doses to achieve serum urate levels (sUA) of <6.0 mg/dL. Patients receiving pretrial urate-lowering therapy other than allopurinol underwent a 7-day washout period before initiating (or re-initiating) allopurinol therapy. Regular safety assessments were made; AEs were monitored throughout the study.

Results: Of 1735 patients enrolled, 1732 received at least 1 dose of allopurinol and constituted the safety population (93% male; 75% white; mean age, 51 years; mean BMI, 34.4 kg/m^2). Baseline characteristics and comorbidity rates were similar across dosage ranges, but a higher

percentage (29.2%) of those receiving <300 mg as maximal dose had moderately impaired renal function (CrCL <60 mL/min) than those who received 300 mg (13.8%) or >300 mg (9.7%). Patients who received >300-mg maximal daily dose had more severe disease at baseline (longer gout duration, tophi, more gout flares in prior year). Maximum daily dose was <300 mg in 250 patients (14.4%), 300 mg in 1132 patients (65.4%), and >300 mg in 350 patients (20.2%). In the safety population, only 744 patients (43%) achieved sUA levels <6.0 mg/dL at their last dose.

Table. Summary of Treatment-Emergent AEs (TEAEs, Safety Population)

Category	Maximum Allopurinol Daily Dose (mg) <300 (N=250) n (%)	300 (N=1132) n (%)	<300 (N=350) n (%)	Total (N=1732) n (%)
Any TEAE	124 (49.6)	623 (55.0)	208 (59.4)	955 (55.1)

Serious TEAE	8 (3.2)	35 (3.1)	9 (2.6)	52 (3.0)
TEAE with outcome of death	1 (0.4)	2 (0.2)	0	3 (0.2)
TEAE leading to allopurinol withdrawal or study discontinuation	27 (10.8)	41 (3.6)	6 (1.7)	74 (4.3)
TEAE leading to prophylaxis switch or withdrawal	27 (10.8)	56 (4.9)	11 (3.1)	94 (5.4)

No clinically meaningful changes in laboratory values, including liver function tests, occurred. Rash incidence was low overall (1.5%), and allopurinol hypersensitivity syndrome was not encountered. The discontinuation rate in patients with a maximal dose of <300 mg was 49.6% vs 19.4% in those who received >300 mg.

Conclusion: This study revealed no new safety signals with medically appropriate allopurinol doses (approximately 300 mg/day). Data inspection showed few differences in TEAEs possibly related to allopurinol. Fewer than 50% of patients achieved the target sUA of <6 mg/dL at 6 months.

An Assessment Of The Response Of Chronic, Occult, Synovial-Based Inflammation Of Gout To Serum Urate Lowering Therapy. John D. Carter[1], Michelle Patelli[1], Scott Anderson[1], Neelish Prakash[1], Robyn Aydelott[1], Ernesto Rodriguez[1], Helen E. Bateman[2], Ashley G. Sterrett[3], Joanne Valeriano-Marcet[1] and Louis R. Ricca[4]. [1]University of South Florida, Tampa, FL, [2]James A Haley VA Hospital USF, Tampa, FL, [3]JAHVA, Tampa, FL, [4]University of South Florida College of Medicine, St Petersburg, FL.

Background/Purpose: We recently demonstrated that synovitis is present in the vast majority of patients with inter-critical gout and that the severity of this synovitis did not correlate with serum urate levels[1]. The aim of this sub-study was to determine if aggressive serum urate lowering therapy can improve this chronic occult synovitis.

Methods: All patients in this sub-study had inter-critical gout and received a 3Tesla MRI with and without gadolinium of their index joint (i.e. the joint most often involved with acute attacks of gout) at their screening visit. Each subject also had a serum urate level, CRP, and creatinine obtained on the same day. If the subject had a serum urate level of ≥ 7.0mg/dL and evidence of synovial pannus (synovitis) on their MRI, they were eligible for enrollment. All subjects were treated with febuxostat with a target serum urate level of ≤ 6.0mg/dL; each subject also received colchicine prophylaxis until month 6 (corticosteroids were not permitted). At month 9, the MRI of the index joint was repeated and the severity/degree of synovial pannus (graded on a scale of 1–6 [1 best; 6 worst]) was compared to baseline. The MRI's were read by two musculoskeletal radiologists in an independent and blinded fashion. The primary endpoint was to determine if there was significant improvement in the severity of synovial pannus from baseline to month 9.

Results: 25/32 subjects enrolled in this sub-study completed the entire protocol. 20 (80%) of the participants were males (17 Caucasian, 3 African-American, 2 Hispanic, 3 other) with an average age and disease duration of 57.2 years (range 40–70) and 10.1 years (range 1–31), respectively. 20/25 (80%) index joints were the first metatarsalphalangeal joint; the average number of attacks in the index joint was 8.3 (+/− 7.1 SD) with an average of 20.6 (+/− 27.1 SD) total attacks in any joint. The average serum urate level and synovial pannus score at screening was 9.3 mg/dL (+/− 1.3 SD) and 3.66 (+/− 1.2 SD), respectively. After 9 months of treatment with febuxostat, the average serum urate level decreased significantly to 5.36 mg/dL (+/− 1.4 SD; $p<0.0001$), but there was no significant change in the severity/degree of synovial pannus with the average score being 3.42 (+/− 1.3 SD; $p=0.34$). The inter-reader agreement between the two radiologists for all of the MRIs was good (kappa=0.63). There was also no significant change in the CRP or eGFR from screening to month 9.

Conclusion: Nine months of serum urate lowering therapy significantly decreases serum urate levels but has no effect on the chronic, occult, synovial-based inflammation of gout.

Allopurinol Dose Titration and Efficacy: A Large-Scale, 6-Month, Multicenter, Prospective Study. Scott Baumgartner[1], Hyon Choi[2], Nicola Dalbeth[3], David Fitz-Patrick[4], Matt Cravets[5] and Chris Storgard[6]. [1]Ardea Biosciences, San Diego, CA, [2]Boston University School of Medicine, Boston, MA, [3]Auckland District Health Board, Auckland, New Zealand, [4]East-West Medical Research Institute, Honolulu, HI, [5]Ardea Biosciences, Inc., San Diego, CA, [6]Ardea Bioscience, San Diego, CA.

Background/Purpose: Allopurinol is the first-line urate-lowering therapy (ULT) for most people with gout, but target serum uric acid (sUA) levels of <6.0 mg/dL (recommended by current ACR guidelines) are often not achieved with doses up to 300 mg/day. Data on allopurinol dose titration and its efficacy are limited. The aim of this international, multicenter, prospective study was to evaluate the efficacy of allopurinol dose titration in a real-world setting (ClinicalTrials.gov Identifier: NCT01391325).

Methods: Adult patients meeting ARA criteria for the Classification of Acute Arthritis of Primary Gout and at least 2 gout flares in the preceding year were enrolled in this 6-month study. Patients who had received ULT other than allopurinol before the trial underwent a 7-day washout period before initiating or re-initiating allopurinol therapy, which was prescribed according to approved product labels and/or institutional standards of care. The study protocol encouraged upward titration of the allopurinol dose to an optimal, medically appropriate dose as determined by the investigator. The main efficacy endpoint was the proportion of patients with a sUA level of <6.0 mg/dL at the end of the study.

Results: Dosing and sUA Levels

Table 1. Final Allopurinol Dose by Baseline Dose

Baseline Dose (mg/day)	Final Allopurinol Dose (mg/day) ≤100	<100–200	<200–300	>300–400	>400–500	<500–600	>600
≤100 (n=591)	**40 (6.8)**	90 (15.2)	361 (61.1)	76 (12.9)	11 (1.9)	12 (2.0)	1 (0.2)
>100–200 (n=395)	5 (1.3)	**129 (32.7)**	209 (52.9)	31 (7.8)	14 (3.5)	5 (1.3)	2 (0.5)
>200–300 (n=662)	1 (0.2)	8 (1.2)	**557 (84.1)**	55 (8.3)	19 (2.9)	14 (2.1)	8 (1.2)
>300–400 (n=62)	0 (0.0)	0 (0.0)	2 (3.2)	**34 (54.8)**	17 (27.4)	7 (11.3)	2 (3.2)
>400–500 (n=11)	0 (0.0)	0 (0.0)	0 (0.0)	1 (9.1)	**8 (72.7)**	0 (0.0)	2 (18.2)
>500–600 (n=8)	0 (0.0)	0 (0.0)	2 (25.0)	0 (0.0)	0 (0.0)	**5 (62.5)**	1 (12.5)
>600 (n=3)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	**3 (100)**

Shading: percentage of patients in same dose category at last visit as at baseline. Those above the diagonal were at a higher dose level and those below the diagonal were at a lower dose level.

Table 2. Levels of sUA by Final Daily Allopurinol Dose

sUA Response Categories (mg/dL)	Final Allopurinol Dose (mg/day) ≤100 (n=46)	>100–200 (n=227)	>200–300 (n=1131)	>300–400 (n=197)	>400–500 (n=69)	>500–600 (n=43)	>600 (n=19)	Total (N=1732)
>6.0	6 (13.0)	77 (33.9)	485 (42.9)	111 (56.3)	40 (58.0)	19 (44.2)	6 (31.6)	744 (43.0)
>5.0	1 (2.2)	23 (10.1)	152 (13.4)	44 (22.3)	16 (23.2)	11 (25.6)	3 (15.8)	250 (14.4)
>4.0	0 (0.0)	2 (0.9)	27 (2.4)	8 (4.1)	3 (4.3)	6 (14.0)	1 (5.3)	47 (2.7)
>3.0	0 (0.0)	0 (0.0)	2 (0.2)	0 (0.0)	1 (1.4)	0 (0.0)	0 (0.0)	3 (0.2)

As shown, 54.1% (937 patients) finished on a higher dose than at baseline, but only 15.8% of patients exceeded 300 mg/day (Table 1). Another 44.8% finished at the same dose as baseline. At the time of the last dose, only 43.0% of all patients had achieved target sUA levels <6.0 mg/dL (Table 2). Even at

doses above 300 mg/day, approximately 46% did not reach target sUA levels of <6.0 mg/dL.

Conclusion: In this large, multinational, prospective observational study of gout, optimal allopurinol dose escalation occurred infrequently. Fewer than 50% of patients overall achieved target sUA level <6.0 mg/dL and the majority of those with a baseline dose ≥300 mg/day did not increase their dose. These data, consistent with published literature, likely reflect real-world circumstances in which a significant proportion of patients fail to reach sUA targets with allopurinol therapy as currently used.

The Synergistic Effects Of Metabolic Syndrome Indicators and Hyperuricemia In Contributing To Cardiac Event Risk: A Cross-Sectional Examination Of The Nhanes III Data. Daniel A. Albert[1] and Sayyad Kyazimzade[2]. [1]The Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, NH, [2]The Dartmouth Institute for Health Policy & Clinical Practice, Lebanon, NH, Lebanon, NH.

Background/Purpose: The focus of this project is to assess the contribution of hyperuricemia and gout to the risk for cardiovascular events. In a preliminary analysis we examined known characteristics of the metabolic syndrome in vascular events. Of the five metabolic syndrome indicators, hypertension, hyperglycemia, dyslipidemia, obesity and elevated triglycerides, each has been shown to increase the risk for experiencing cardiac events (heart attack or stroke). There has yet to be an investigation, however, assessing whether or not these indicators are additive or synergistic in their contribution to the risk for experiencing a cardiac event and their relationship to hyperuricemia and gout.

Methods: Using the NHANES III data set (1988–1994), we conducted a cross-sectional analysis to assess whether or not the five facets of the metabolic syndrome are additive or synergistic in contributing to the risk for experiencing a cardiac event (defined as either a heart attack or stroke). To do so, we used interaction terms in a multiple logistic regression model, controlling for age, sex, race/ethnicity, education, smoking status, exercise, gout diagnosis and serum uric acid levels. Synergy was assessed based on statistical significance of interaction term odds ratios (ORs).

Results: Among all of the interaction terms, only the interaction between all five metabolic syndrome facets was statistically significant (OR = 240.06, 95% CI: 1.73; 33,304.89, p = 0.030), indicative of a synergistic effect. All other ORs had p-values ≥ 0.060. It is important to note that both ORs for the interaction terms of four of the five indicators had p-values of 0.060 and 0.067, while all other ORs were > 0.1. In this dataset hyperuricemia and gout did contribute additional risk (Hyperuricemia OR 1.11), p-value:0.036, 95%, CI: 1.01, 2.22. Gout OR 2.20 (p-value:0.001, 95% CI: 1.39, 3.49).

Conclusion: Of the five metabolic syndrome indicators, contribution to the risk of experiencing a cardiac event is predominantly additive. Only once a patient acquires four or five of the indicators, does a synergistic relationship begin to become evident in contributing to the odds of experiencing a cardiac event. Hyperuricemia and gout contribute additional risk. Further investigation will examine the interaction between hyperuricemia, gout, and the other components of the metabolic syndrome.

Low-Dose Anakinra Is Effective For The Prophylaxis Of Acute Episodes Of Inflammation In Severe Tophaceous Gout. Fernando Perez-Ruiz[1], Ana M. Herrero-Beites[2], Monike de Miguel[3] and Joana Atxotegi[1]. [1]BioCruces Health Institute, Baracaldo, Spain, [2]Hospital de Gorliz, Gorliz, Spain, [3]Hospital Universitario Cruces, Baracaldo, Spain.

Background/Purpose: anakinra has been used off-label for the treatment of severe episodes of acute inflammation (EAIs) in gout. Only a retrospective series of 3 patients has reported the use of ankinra as prophylaxis when used in an intermittent schedule. Therefore studies are needed to explore whether a low-dose prescription of anakinra would be effective in patients with severe difficult to treat gout and a formal contraindication of other current treatments for the prophylaxis of AEIs when starting urate-lowering therapy (ULT).

Methods: an agreement between the Rheumatology and Pharmacy Divisions was approved to treat with anakinra patients with severe or recurrent EAIs and a formal contraindication for current treatments for prophylaxis (colchicine and NSAIDs) and requiring repeated doses of parenteral corticosteroids not acceptable from the clinical point of view. As a pilot study, patients with crystal-proved gout were included in a cohort for follow-up from Jul 2011 to Jan 2013. All patients were scheduled for a 6-month period of treatment: anakinra 100 mg sc once a week with additional 100 mg doses on demand during the first 3 months and only on demand 100 mg sc doses from month 3 to 6. In addition to full clinical evaluation, serum urate, hsC-reactive protein, estimated glomerular filtration (CKD_EPI), complete blood cell counts, and liver function tests were tested once a month for the first three months, and at 6-month follow-up. AEIs were evaluated using the EULAR/ACR preliminary criteria for self-referred AEIs in gout and expressed as EAIS/patient-year exposure.

Results: 11 patients with chronic tophaceous (either subcutaneous or ultrasonographic/MRI), polyarticular (> 3 joints involved), crystal-proven gout were been included in the protocol. Ten were 10 men, mean age was 60±14 years (median 61, IQ range 48–69), time from the onset of gout 8±5 years (8, 5–15), subcutaneous tophi in 9/11, chronic heart failure 4/11, CKD 3–5 in 8/11, serious AEs to NSAIDs in 9/11. Diabetes or steroid-induced hyperglycemia in 8/11. Febuxostat 80 to 120 mg/day was prescribed to 6 patients, allopurinol 50 up to 300 mg/day to 6 patients (average dose 5.2 mg/ml FG-day). One patient was on hemodialysis and one showed normal serum urate and no need for urate-lowering agents.

Results are shown in Table. In the 0–3 period, 4/11 required additional doses, and 6/11 while on demand dosing from month 3–6. A patient had an episode of heart failure (4th in the year) but was maintained on treatment, doing well 16 months after treatment. No intercurrent infection was observed in any patient. No local reaction complaint was retrieved with a weekly schedule.

*P< 0.01 vs baseline	Baseline (median, IQ range)	1st mo (100 mg qw+100 mg on demand)	2nd mo (100 mg qw+100 mg on demand)	3rd mo (100 mg qw+100 mg on demand)	6th mo (100 mg on demand)
SuA (mg/dl)	10.2 ± 2.1 (9.5, 9.1–10.3)	5.6 ± 1.4 (5.6, 5.0–6.9)*	4.6 ± 0.7 (4.6, 4.2–5.2)*	4.6 ± 1.3* (4.8, 3.6–4.9)	5.0 ± 1.1* (5.4, 4.8–5.7)
hsCRP (mg/dl)	2.05 ± 2.98 (2.4, 1.7–21.9)	1.4 ± 1.3 (0.8, 0.3–2.7)*	1.22 ± 1.52 (0.2, 0.2–2.3)*	0.39 ± 0.88* (0.1, 0.1–0.2)	0.56 ± 1.07 (0.1, 0.10–0.45)
CCR (ml/min)	67 ± 30 (62, 43–89)	65 ± 32 (63, 38–86)	69 ± 41 (67, 42–88)	78 ± 35 (78, 43–111)	74 ± 32 (65, 46–111)
EIA (per patient/ year)	13 ± 9 (10, 6–24)	-	-	2.6 ± 5.3 (0, 0–4)*	2.0 ± 2.1 (2, 0–4)*

Conclusion: this pilot study is, to our knowledge, the first to prospectively explore in pre-established doses the efficacy of low-dose anakinra for the prophylaxis of AEIs in patients with severe comorbidities and difficult to treat tophaceous gout. These encouraging results deserve further studies.

Disclosure: F. Perez-Ruiz, Menarini International, 5, SOBI, 5, AstraZeneca, 5, Menarini, 8; **A. M. Herrero-Beites**, None; **M. de Miguel**, None; **J. Atxotegi**, None.

Pharmacovigilance Update On Pegloticase For Treatment Refractory Gout: United States Clinical Experience Demonstrates The Value Of Serum Uric Acid Monitoring As a Biomarker Of Risk and Efficacy. Robert T. Keenan[1], Raymond L. Malamet[2], Tina L. Howson[2] and Kenneth M. Bahrt[2]. [1]Duke University, Durham, NC, [2]Savient Pharmaceuticals, Inc., Bridgewater, NJ.

Background/Purpose: Pegloticase was approved in the US in late 2010 for patients with chronic gout refractory to xanthine oxidase inhibitors (XOIs). The clinical development program for pegloticase used a primary endpoint based on uric acid (UA) response <6 mg/dL and 42% of treated patients were classified as "responders" (vs 0% with placebo; $P<0.001$).[1,2] Post hoc analyses revealed that UA nonresponse was associated with high titer antibodies against pegloticase resulting in increased drug clearance and risk for infusion reactions (IRs). Pegloticase treatment recommendations thus included that UA be monitored preinfusion and discontinuation considered if serum UA was >6 mg/dL (particularly with 2 consecutive levels >6 mg/dL). Postapproval safety data has provided valuable insights into UA monitoring, concomitant medication use, and risk mitigation. Here we present pharmacovigilance data with a focus on infusion-related reactions and educational efforts to prevent the use of concomitant XOIs. Concomitant XOI use can mask the loss of UA response to pegloticase and confound the use of UA as a biomarker of efficacy and IR risk. Guidance cautioning against the use of pegloticase and XOIs was distributed via a Dear Healthcare Provider (DHCP) letter and a label update.

Methods: For safety surveillance, IRs were defined as adverse events (AEs) that occurred during or within 2 hours following the end of study drug infusion and could not be reasonably attributed to another cause. The

incidence of IRs was drawn from voluntary AE reporting via MedWatch from September 2010 to March 2013 (to be updated through September 2013). All cases of IRs were evaluated for concomitant XOI use. An estimate of the total number of infusions given was based on the number of vials sold.

Results: During the postapproval period of 2.5 years, there were an estimated 12,736 vials sold and the sponsor received 91 spontaneous reports of patients with IRs (70 reports of IRs and 21 reports of possible anaphylaxis). When compared with IR rates from the clinical trials, postapproval data represents a significant reduction in IR risk of 72%. Among the 91 IRs, 78 events occurred during the infusion and 4 occurred in the 2 hours postinfusion (9 did not provide timing). The incidence of concomitant XOI use with pegloticase among patients with IRs was reduced ($P=0.0028$) after the DHCP letter and label change (table).

Concomitant Urate-Lowering Status for IRs Reported Before and After DHCP Letter	Number of IR Reports
Prior to letter (Total IR reports=31)	
Patients with IR and concomitant urate-lowering	12
Patients with IR and no concomitant urate-lowering	13
Patients with IR and unknown conmed status	6
After the letter (Total IR reports=60)	
Patients with IR and concomitant urate-lowering	5
Patients with IR and no concomitant urate-lowering	37
Patients with IR and unknown conmed status	18
Total	91

Conclusion: Given known limitations of estimating based on unsolicited AE reporting during pharmacovigilance, increasing utilization of pegloticase has been associated with a decline in the number of IRs. Educational efforts have led to significant reductions in the proportion of IRs with concomitant XOI use. Continued educational efforts regarding the need for UA monitoring with pegloticase and avoidance of concomitant XOI use should further reduce IR risk.

1193

Target Tophus Size and Complete Response Rates In Patients Treated With Open-Label Pegloticase For Chronic Gout Refractory To Conventional Therapy. Robert T. Keenan[1], Nicola Dalbeth[2] and Herbert S. B. Baraf[3]. [1]Duke University, Durham, NC, [2]University of Auckland, Auckland, New Zealand, [3]Arthritis & Rheumatism Associates, PC, Wheaton, MD.

Background/Purpose: Pegloticase, a methoxy PEG-conjugated mammalian recombinant uricase, has been approved in the US and EU for the treatment of chronic gout refractory to xanthine oxidase inhibitors. The pegloticase development program included 2 replicate randomized placebo-controlled trials (RCTs) followed by an open-label extension (OLE) study for a maximum therapy duration of up to 3 years.[1,2] The pegloticase trials were unique in enrolling a majority of patients with baseline tophi (155/212 or 73%) and in the use of detailed digital quantitative assessment of each tophus. Here we present data on long-term treatment with pegloticase and tophus response rates as a function of tophus size.

Methods: Patients enrolled in the RCTs (n=212) were ≥18 years of age with baseline serum uric acid (UA) ≥8 mg/dL and at least 1 of the following: ≥3 self-reported gout flares in the past 18 months, ≥1 tophi, or gouty arthropathy; and contraindication to allopurinol or failure to normalize UA after ≥3 months of treatment at the maximum medically appropriate dose. Target subcutaneous tophi identified at baseline were photographed and assessed at multiple study time points using computer-assisted quantitative digital image analysis in patients receiving pegloticase (8 mg; q2wks or q4wks) or placebo in the RCTs, and pegloticase in the OLE. Complete response was defined as complete resolution of the target tophus. Tophus size was assessed at the baseline visit of the RCTs and categorized as small (<250 mm^2), medium (250–750 mm^2), or large (>750 mm^2).

Results: This tophus size analysis focused on patients receiving the approved twice-monthly pegloticase dose who entered the OLE study. These included patients treated with either q2wk pegloticase (both UA responders and nonresponders; see table for definition) or placebo in the RCTs who received q2wk pegloticase at OLE study entry. The table presents the number of tophi undergoing complete resolution for each of these subgroups by tophus size. Among patients who showed response to therapy, the majority of small and medium tophi resolved within 6–9 months of therapy. For larger tophi, 12 to 18 months of therapy resulted in complete response in over 60% of tophi.

Percentage of Target Tophi With Complete Response Over Time Based on Size Pegloticase q2wks UA Responders* in the RCTs

Study Visit	Small <250 mm^2	Medium 250–750 mm^2	Large >750 mm^2
RCT 25 weeks Total n**=37	42% (11/26)	30% (7/23)	8% (1/12)
OLE 13 weeks Total n=35	76% (19/25)	55% (12/22)	8% (1/12)
OLE 25 weeks Total n=34	84% (21/25)	67% (14/21)	18% (2/11)
OLE 53 weeks Total n=32	86% (19/22)	65% (13/20)	18% (2/11)
OLE 77 weeks Total n=32	79% (19/24)	90% (18/20)	64% (7/11)
Progressing tophi at 53 weeks Total n=32	0/22	0/20	0/11
Pegloticase q2wks UA Nonresponders* in the RCTs			
RCT 25 weeks Total n=30	6% (1/17)	16% (3/19)	6% (1/18)
OLE 13 weeks Total n=30	27% (4/15)	32% (6/19)	0/15

Progressing tophi at 53 weeks Total n=21	0/10	6% (1/16)	23% (3/13)
Placebo → q2wks at OLE Entry			
RCT 25 weeks Total n=37	6% (1/17)	7% (2/31)	0/20
OLE 13 weeks Total n=30	44% (7/16)	26% (6/23)	0/16
OLE 25 weeks Total n=25	85% (11/13)	50% (11/22)	33% (4/12)
OLE 53 weeks Total n=21	100% (12/12)	82% (14/17)	90% (9/10)
OLE 77 weeks Total n=21	92% (11/12)	94% (16/17)	70% (7/10)
Progressing tophi at 53 weeks Total n=21	0/12	0/17	0/10

*Responders were patients who met the primary endpoint of UA reduction defined as UA <6 mg/dL for 80% of time during RCT study months 3 and 6.
**Total n is all patients in the subgroup irrespective of tophus response.

Conclusion: Many small and medium subcutaneous tophi resolved within the first 6 months of pegloticase therapy. These data show that substantial incremental benefit in tophus response for unresolved small to medium tophi can be gained with 9–12 months of therapy in UA responders. Longer periods of treatment (up to 18 months) with pegloticase were shown to resolve large tophi.

Enhanced IL-1β and IL-6 Production In Gout Patients Upon Stimulation With Mono Sodium Urate Crystals and Synergizing Agents Compared To Healthy Volunteers. Tania O. Crisan[1], Maartje Cleophas[1], Mihai G. Netea[1], Tim L. Jansen[1] and Leo A. Joosten[2]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Department of Medicine, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.

Background/Purpose: Gout is an autoinflammatory disease characterized by the deposition of monosodium urate (MSU) crystals in the joints of hyperuricaemic patients and subsequent attacks of severe gouty arthritis. It is known for centuries that the MSU crystals are the necessary causative agent of gout but, in addition, it is now proven that MSU requires synergizing stimuli to induce high cytokine responses, relevant for the clinical picture of gout. Here we investigate the inflammatory response in gout patients and healthy controls upon stimulation with MSU crystals in combination with other ligands. We also investigate the effects of elevated uric acid concentrations on the pro-inflammatory cytokine production in human immune cells.

Methods: Peripheral blood mononuclear cells (PBMCs) were harvested from patients diagnosed with crystal-proven gout and from age matched healthy volunteers. Cells were stimulated for 24 hours with Pam3Cys or palmitic acid (C16) in the presence or absence of MSU crystals. In separate experiments, the cells were first treated with uric acid or left untreated for 24h

and then subjected to stimulation with Pam3Cys or LPS for another 24h. Production of IL-1beta, IL-6 was assessed using specific sandwich ELISA kits. mRNA levels were measured using quantitative real time PCR. Differences were assessed using the Mann-Whitney test and a p-value$<$0.05 was considered statistically significant.

Results: MSU crystals stimulation alone did not induce detectable levels of IL-1β or IL-6 neither in patients nor in controls, however, a significant synergy between MSU and Pam3Cys or C16 was observed. Of high importance, significantly higher levels of IL-1β and IL-6 were observed in patients compared to controls. Subsequently, when cells were pretreated with uric acid, an enhanced cytokine production was observed in cells stimulated with Pam3Cys or LPS in the presence or absence of MSU, however, uric acid alone did not induce this effect. This enhanced cytokine production correlated with higher mRNA levels observed in uric acid pre-treated cells.

Conclusion: Enhanced cytokine production was observed in cells originating from gout patients compared to controls when stimulated with MSU crystals and synergizing stimuli. Similar trends could be identified when the cells were pre-treated with high uric acid levels in vitro and then subjected to MSU crystals stimulation. These results indicate that high uric acid levels could have an effect on immune cells and facilitate higher responses upon encounter of inflammatory stimuli and this could be a mechanism for the enhanced pro-inflammatory response observed in gout patients.

Sex Differences In Gout Evaluation and Management. Leslie R. Harrold[1], Carol Etzel[2], Allan Gibofsky[3], Joel M. Kremer[4], Michael H. Pillinger[5], Kenneth G. Saag[6], Naomi Schlesinger[7], Robert Terkeltaub[8], Vanessa Cox[2] and Jeffrey D. Greenberg[9]. [1]University of Massachusetts Medical School, Worcester, MA, [2]CORRONA, Inc, Southborough, MA, [3]Hospital for Special Surgery, New York, NY, [4]Center for Rheumatology, Albany Medical College, Albany, NY, [5]NYU School of Medicine, Division of Rheumatology, New York, NY, [6]University of Alabama at Birmingham, Birmingham, AL, [7]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [8]VA Medical Ctr/University of California San Diego, San Diego, CA, [9]New York Hospital for Joint Diseases, New York, NY.

Background/Purpose: Little is known regarding the evaluation, characteristics and management of women with gout. To characterize potential gender differences, we therefore compared clinical manifestations and treatment of women versus men in a nationwide sample of men and women with gout cared for by rheumatologists.

Methods: Rheumatologists participating in the Consortium of Rheumatology Researchers of North America (CORRONA) registry agreed to enroll their gout patients regardless of gender, disease severity, disease activity or medication use. All patients enrolled between 11/1/12 and 5/1/13 were included in the current study. Data was gathered at the time of enrollment from patients and their rheumatologists including demographics, gout evaluation, clinical characteristics, comorbid conditions, current treatments, and physical exam findings. Logistic regression models were created to examine the influence of sex on use of a urate-lowering drug (ULD) adjusting for patient age and duration of gout and accounting for clustering by practice site.

Results: Fifty-four rheumatologists enrolled 109 women and 414 men with gout. Women were older (71 vs. 62 years, p$<$0.001) and more commonly had a comorbid illness including hypertension (76% vs. 59%, p=0.001), diabetes (32% vs. 17%, p=0.001) and renal disease (29% vs. 14%, p$<$0.001). Women had a shorter duration of gout (6 vs. 11 years, p$<$0.001) and were less likely to have a crystal proven diagnosis (19% vs. 34%, p=0.003). While women had similar clinical features in terms of acute gout presentation (e.g., podagra, oligoarthritis, etc), and gouty arthritis (tophi, joint deformity), they were more likely to have contraindications to treatment with nonsteroidal anti-inflammatory drugs (NSAIDs) (32% vs. 21%, p=0.02) or colchicine (14% vs. 6%, p=0.01). Among those patients with 2 or more attacks per year or those with tophi, women (n=63) were less likely to be on a urate-lowering drug (ULD) as compared to men (n=233) (78% vs. 89%, p=0.02) in both unadjusted and adjusted (OR 0.42, 95% CI 0.19–0.92) analyses.

Conclusion: Compared to men, women with gout were older and less likely to have received a definitive diagnosis of gout by crystal identification. Women were more likely to have contraindications to NSAIDs and colchicine, and less likely to be receiving ULDs. Our data suggest the presence of health care disparities between women and men with gout, and that gout in women may have unique features and challenges. Further investigation is needed to ensure optimal care in women with gout.

Chronic Renal Injury Does Not Prevent Achievement Of Target Serum Uric Acid In Tophaceous Gout. Mireille Aujero[1], J. Steuart Richards[2], Carl A. Nunziato[3], David D. Maron[4] and Gail S. Kerr[5]. [1]Washington DC VA Medical Center and Georgetown University, Washington, DC, [2]Washington DC VA and Georgetown University, Washington, DC, [3]Howard University Hospital, Washington, DC, [4]Washington DC VA Medical Center, Washington, DC, [5]Washington DC VAMC, Georgetown and Howard University, Washington, DC.

Background/Purpose: ACR 2012 management guidelines for tophaceous gout (TG) recommend urate lowering therapies (ULT) to achieve a target serum uric acid (SUA) of $<$ 6.0 mg/dl, but in some patients, a SUA of $\leq$ 5.0 mg/dl may be appropriate. Despite new ULT, allopurinol remains the most commonly used drug. Yet, achievement of target SUA in clinical practice is subpar, with comorbidities frequently limiting optimum ULT use. We evaluated a cohort with TG and significant comorbidities to determine the applicability of recent ACR guidelines, that is, achievement of target SUA of less than 6 mg/dl and 5 mg/dl, respectively.

Methods: VA administrative data over a 3-year period was used to identify patients with gout (ICD 9 codes: 274.xx) who had at least two related outpatient visits, and BMI $>$ 28 Kg/m^2. Medical records from primary care and rheumatology clinics were filtered electronically for the prefix 'toph' and then searched manually for presence of 'tophaceous gout' or 'tophus' to identify TG subset. Demographic data, including age, race, BMI, comorbidities [hypertension (HTN), chronic renal injury (CRI) and diabetes mellitus (DM)], SUA, serum creatinine and creatinine clearance (CrCl) were extracted from Veterans Affairs Decision Support System (DSS) database. Natural Language Processing was used to extract gout behavioral modification counseling (BMC). Colchicine and allopurinol use was recorded for each patient; for allopurinol, dose and dates of therapy were obtained for patients with TG. Data were analyzed for number and percent of patients achieving target SUA $<$6 mg/dl and $\leq$ 5 mg/dl.

Results: Clinical characteristics of the 1576 eligible patients are shown in (Table). One hundred and twenty (73.2%) patients with TG were on allopurinol. SUA was evaluated at least once in 119 (99.2%) patients. Seventy-eight patients (65%) achieved target SUA $<$ 6 mg/dl at least once during follow up and 44 (36.7%) achieved SUA levels $\leq$ 5 mg/dl. Forty-two patients had CrCl $<$ 60 ml/min; 24 (57.1%) and 15 (35.7%) achieved SUA $<$ 6 mg/dl and $\leq$ 5 mg/dl, respectively. Patients with a CrCl $\geq$ 60 ml/min had mean allopurinol dose of 257.7 mg/day [54/78 (47.4%) SUA $<$ 6 mg/dl], significantly greater than patients with CrCl $<$ 30 ml/min who received a mean of 69.0 mg/day [3/6 (50%) SUA $<$ 6 mg/dl]. However, both groups had similar mean SUA levels [6.52 $\pm$ 2.1 vs. 6.03 $\pm$ 1.06 (p $<$ 0.948)], respectively. Mean allopurinol dose for patients with SUA $<$ 6 mg/dl and $\geq$ 6 mg/dl was 255.1 ($\pm$ 124.5) and 157.7 ($\pm$ 109.4) (p $<$ 0.001), respectively. There were no differences in demographics, severity of CRI, frequency of comorbidities, BMC or number of rheumatology visits between patients achieving SUA $<$ 6 mg/dl and those who remained above target values.

Table.

Characteristic	Total Population N = 1576	Tophaceous Gout N = 164	Non tophaceous gout N = 1412	P value
Age (mean and SD)	66.59 ± 11.9	65.8 ± 13.4	66.7 ± 11.8	0.36
African American (n)	502 (31.9%)	64 (39.0%)	439 (31.1%)	0.04
Caucasian (n)	83 (5.3%)	7 (4.3%)	76 (5.4%)	0.55
BMI (mean and SD)	30.75 ± 5.7	30.2 ± 5.5	30.8 ± 5.8	0.21
Cr Cl < 60	490 (31.1%)	60 (36.6%)	428 (30.3%)	0.10
Cr Cl <30 (n)	78 (4.9%)	11 (6.7%)	67 (4.7%)	0.27
Cr Cl ≥ 30 and <60 (n)	412 (26.1%)	49 (29.9%)	363 (25.7%)	0.68
Cr Cl ≥60 (n)	1086 (68.9%)	104 (63.4%)	982 (69.5%)	<0.0001
HTN	1459 (92.6%)	158 (96.3%)	1303 (92.3%)	0.06
Hyperlipidemia	820 (52.0%)	87 (53.0%)	736 (52.1%)	0.82
CVD	955 (60.6%)	106 (64.6%)	851 (60.3%)	0.27
DM	736 (46.7%)	79 (48.2%)	658 (46.6%)	0.70
Colchicine use EVER	1095 (69.5%)	152 (92.7%)	943 (66.8%)	<0.0001
Allopurinol use EVER	968 (61.4%)	141 (86.0%)	826 (58.5%)	<0.0001
Rheum visits > 1	1576 (100%)	164 (100%)	1412 (100%)	1.00
Avg # of Rheum visits 2008–2010	3.40 ± 2.7	6.14 ± 4.2	3.08 ± 2.3	0.0001
BMC	60 (3.8%)	16 (9.8%)	44 (3.1%)	<0.0001

Conclusion: Despite frequent associated comorbidities the majority of TG patients can achieve target SUA levels. In CRI, BMC and allopurinol pharmacokinetics may have significant roles in achieving SUA target.

Gout Medications and The Risk For Incident Coronary Heart Disease and Stroke: The Framingham Heart Study. Weiqi Wang[1], Vidula Bhole[2] and Eswar Krishnan[3]. [1]stanford university, palo alto, CA, [2]EpiSolutions Consultancy Services, Thane, India, [3]Stanford University, Palo Alto, CA.

Background/Purpose: Recent studies suggest a protective association between both urate lowering medications and colchicine and the risk for coronary heart disease. The goal of the present study was to confirm this.

Methods: We analyzed data from the Framingham heart study (FHS) spanning 20 years from 1980 to 2000, over 10 study visits (17 to 26) for gout patients only. The definition of Coronar Hert Disease (CHD) included myocardial infarction, coronary insufficiency, angina pectoris and related death. The definition of stroke included thrombotic and hemorrhagic stroke as well as transient ischemic attacks. Gout was defined by any one of: self-report, physician diagnosis, gout medication use, and radiographic changes. Hypertension was defined as systolic blood pressure >= 140 mm Hg or diastolic blood pressure >= 90 mm Hg or usage of anti-hypertensive medications. Diabetes status, BMI and total cholesterol were obtained from FHS official documents. Two types of gout medications (uric acid lowering medications and colchicine) were combined as both have been associated with beneficial cardiovascular effects in prior studies. Data were analyzed using Cox proportional hazard regression models where the dependent variable was the time to incident event and independent variables (gout medication, sex, age, BMI, hypertension, diabetes, total cholesterol) were treated as time-varying. Missing values were addressed by multiple imputations.

Results: There were 414 participants with gout included in this study, among whom 235 used gout medication before the cardiovascular event. At the baseline the proportion of men was 63.77%. Overall there were 229 incident cases of CHD and 117 incident cases for stroke during the follow up. The incidence rate per thousand person-years of CHD in the gout medication group was 24.74 and in the other group was 27.93; the incidence rates of stroke were 16.78 and 16.93, respectively. The unadjusted and age adjusted hazard ratio for gout medications were 0.88 (95% confidence interval 0.51–1.53) and 0.88 (0.51–1.53) for CHD; 0.87 (0.48–1.56) and 0.87 (0.49–1.57) for stroke. In multivariable Cox models, gout medication was associated with a hazard ratio of 0.80 (0.45–1.41) for CHD and 0.85 (0.47–1.53) for stroke. When the regressions were repeated for stroke and CHD combined, the multivariable hazard ratio was 0.81 (0.49–1.33).

Conclusion: Gout medication is associated with a beneficial effect for both incident CHD and stroke in most of our analyses. However the magnitude of the observed statistical association was small and the threshold of statistical significance was not crossed, suggesting that the real-world impact of these drugs may be negligible.

Allopurinol Dose Above Creatinine Clearance Based Dose Is Safe and Effective in Gout - Compliance, Efficacy and Safety At 2 and 3 Years. Nicole Coman-Wright[1], Peter T. Chapman[2], John L. O'Donnell[3] and Lisa K. Stamp[1]. [1]University of Otago, Christchurch, Christchurch, New Zealand, [2]Christchurch Hospital, Christchurch, New Zealand, [3]Canterbury Health Laboratories, Christchurch, New Zealand.

Background/Purpose: Gout is a common form of inflammatory arthritis caused by the crystallisation of uric acid. Sustained reduction of SU below 6mg/dl is critical for successful management of gout. Allopurinol is the most commonly used urate lowering therapy. The creatinine clearance (CrCL) based allopurinol dosing recommendations were based on a proposed relationship between allopurinol dose and allopurinol hypersensitivity syndrome. We have previously reported that target SU can be achieved at year one by titrating allopurinol dose above the CRCL based dose. The aim of this study was to determine if allopurinol was continued and if the reduction in SU was sustained during the subsequent two years.

Methods: Patients with gout receiving the CrCL based dose of allopurinol with SU >6mg/dl were recruited. The dose of allopurinol was increased until target SU (< 6mg/dl) was achieved. Patients were seen monthly for 12 months and then annually for a further 2 years. Between the annual visits, the patient's general practitioner (GP) was advised to monitor SU three monthly to ensure target SU was maintained.

Where patients were lost to follow-up after year 1 available data was collected until the 3 year time point from public and private laboratory databases and hospital records.

Results: Forty five patients were enrolled in the dose escalation study. The mean age was 59.5 years (range 27–83), 93.3% were male, and 80% were of European ancestry. Thirty-five patients completed year 1, 29 patients year 2, and 26 patients year 3. Four patients were lost to follow up, 2 experienced rashes resulting in allopurinol discontinuation, 2 were deemed too unwell to continue and 1 patient died from liver cancer. All patients who completed year 1 and 2 and 25/26 patients at year 3 were receiving allopurinol. The mean dose of allopurinol was 355.71 mg/d (150–600mg/d) at year 1, 353.5 mg/d (150–600mg/d) at year 2 and 358 mg/d (200–600mg/d) at year 3. 31/35 (88.8%) patients that completed year 1 achieved the target SU, mean 5.4mg/dl (3.9–11.3mg/dl). 24/29 (82.8%) patients that completed year 2 achieved target SU, mean 4.9mg/dl (3.2 – 7.2mg/dl). 23/26 (88.5%) patients that completed year 3 achieved target SU, mean 5.4mg/dl (3.9–10.8mg/dl). During year 2, 7/35 (20%) patients had ≥ 4 biochemistry tests including SU. At year 3, 4/35 (11.4%) patients had ≥ 4 biochemistry tests including SU. The majority of patients had been able to discontinue regular NSAIDs, colchicine or prednisone by year 3.

Conclusion: In those patients who remain compliant with allopurinol therapy, target SU can be maintained out to three years. Clinicians need to be mindful that rashes can occur even after receiving allopurinol for a prolonged period. There is poor monitoring of SU in the community. Further study is required on how frequently SU should be monitored once target is achieved and attacks have resolved.

1199

The Performance Of a Novel Scoring System In The Differential Diagnosis Between Acute Gout and Septic Arthritis. Jung-Soo Song[1], Kwang-Hoon Lee[2], Sang Tae Choi[1], Eun-Jin Kang[3] and You-Jung Ha[4]. [1]Chung-Ang University College of Medicine, Seoul, South Korea, [2]Dongguk University Ilsan Hospital, Goyang, South Korea, [3]Busan Medical Center, Busan, South Korea, [4]Yonsei University College of Medicine, Seoul, South Korea.

Background/Purpose: Recently, a novel scoring system was developed for the diagnosis of gout without joint fluid analysis (1). The performance of this scoring system in the differential diagnosis between acute gout and septic arthritis has not been validated yet. This study aimed to evaluate the diagnostic performance of this scoring system in the differential diagnosis between acute gout and septic arthritis in patients with acute monoarthritis.

Methods: The medical records of 33 patients with acute gout and 27 with septic arthritis who presented as acute monoarthritis and were diagnosed at Chung-Ang University Hospital in Seoul, South Korea and Dongguk University Hospital in Goyang, South Korea from 2007 to 2012 were reviewed. Patients with podagra were excluded. All gout patients were MSU positive and all septic arthritis patients had positive results of bacterial culture. The

diagnostic scoring system (1) gives different scores to several clinical criteria as follows: 2 to male sex, 2 to previous patient reported arthritis attack, 0.5 to onset within one day, 1 to joint redness, 2.5 to 1st MTP involvement, 1.5 to hypertension or at least one cardiovascular disease and 3.5 to serum uric acid greater than 5.88 mg/dL. The probability of gout is high when the sum of the score is ≥ 8, intermediate when between 4 and 8 and low when ≤ 4. Patients were classified to one of each probability groups according to the scores they got.

Results: Both patient groups were similar in age (55.6 ± 21.0 vs. 58.4 ± 20.2 years). However, patients with acute gouty arthritis were more likely to be male (90.9% vs. 59.2%), had shorter duration of onset (1.54 ± 1.22 vs. 2.92 ± 2.0 days, $p = 0.004$), lower levels of ESR (38.3 vs. 73.7 mm/hr, $p < 0.001$), CRP (7.8 ± 7.0 vs.13.6 ± 9.9 mg/dL, $p = 0.010$), WBC count (9,813 ± 2,122 vs. 12,502 ± 5,060/m^3, $p = 0.021$) and synovial fluid WBC count (37,295 ± 26,998 vs. 63,210 ± 41,211/m^3, $p = 0.014$) and had higher levels of serum uric acid compared to those with septic arthritis (7.88 ± 1.8 vs. 5.13 ± 1.7 mg/dL, $p < 0.001$). The sum of scores in patients with acute gout was significantly higher than those of patients with septic arthritis (7.8 ± 1.59 vs. 3.4 ± 2.3, $p < 0.001$). In 33 patients with acute gout, the numbers of patients classified to each of the 3 probability groups were 22, 11 and 0 (high, intermediate and low probability, respectively). However, in 27 septic arthritis patients, only 2 and 6 patients were relevant to high and intermediate probability groups and 19 were classified as a low probability group. The proportion of patients with high probability was significantly higher in patients with acute gout compared to those with septic arthritis (66.6% vs. 7.4%, $p < 0.001$).

Conclusion: This novel scoring system showed a good performance in distinguishing between acute gout and septic arthritis. It may be helpful to the primary care physicians.

Proportion Of Patients Achieving Serum Urate Target In a Longitudinal Veterans Administration (VA) Gout Registry: Crystal Registry. Puja Khanna[1], Andreas M. Reimold[2], Gail S. Kerr[3], J. Steuart Richards[4], Elizabeth Chang[5], Jasvinder A. Singh[6], H. Ralph Schumacher[7], Tanima Bannerjee[8] and Dinesh Khanna[9]. [1]Ann Arbor VA, Ann Arbor, MI, [2]Dallas VA and University of Texas Southwestern, Dallas, TX, [3]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [4]Washington DC VAMC and Georgetown University, Washington, DC, [5]Phoenix VAHCS, Phoenix, AZ, [6]University of Alabama, Tuscaloosa, AL, [7]Department of Medicine, University of Pennsylvania and VA Medical Center, Philadelphia, PA, [8]University of Michigan, Ann Arbor, MI, [9]Division of Rheumatology, University of Michigan Medical Center, Ann Arbor, MI.

Background/Purpose: Gout is the most common inflammatory arthritis managed by healthcare providers at the VA Healthcare System. CRYSTAL registry is a longitudinal observational study at six VA centers across US to help understand and improve quality of care of gout. The current objective is to present data from first follow-up in patients who achieved disease control as defined by a target serum urate (sUA) of < 6 mg/dL per recommendations of the 2012 American College of Rheumatology (ACR) guidelines.

Methods: Patients who met the ACR and/or New York criteria are enrolled. At each visit, gout medications (acute and chronic) and comorbidities are reviewed. Subjects complete standardized gout-related questions on flares, interval hospitalizations, HAQ-DI, pain and severity of disease (VAS, 0–10), patient global assessment (0–10 VAS), and alcohol use. Joint exam is performed to assess disease activity and acute phase reactants, sUA, estimated glomerular filtration rate (eGFR), and complete blood counts are monitored as routine care. Data are presented as mean ± standard deviation (SD) or percentage (%). P-values of <0.05 were considered statistically significant.

Results: Of 355 enrolled in the registry, 205 (57%) had at least 1 FU visit, with average FU for 2nd visit was 8 months (range 17 days-46 months). Patients were predominantly male (96%), mean (SD) age was 67.2 (10.5) years, 34% were Caucasian and 63% were African American, and 58% had crystal proven gout. Significant improvement was seen at FU for sUA (−0.94 mg/dl, p<0.0001), patient severity scores (−1.2, p=0.002), physician severity score (−1.2, p=0.01), and HAQ-DI (−0.12, p=0.04). However, there was no significant change in number of flares between 2 visits (p=0.84). Of patients who had sUA > 6 mg/dL at baseline (N=129), 96 (74.4%) achieved the target sUA < 6 mg/dL.

Conclusion: Of gout patients who started with a sUA above 6 mg/dL at enrollment, 74% achieved sUA target of 6 mg/dL at a mean follow-up of 8 months. Further analysis will determine the predictors of sUA target in this cohort. These analyses provide a benchmark to improve quality of care for the Veterans and highlight the need for continued monitoring.

A Progress Report On An Emerging Disease: NOD2-Associated Autoinflammatory Disease. Qingping Yao. Cleveland Clinic, Cleveland, OH.

Background/Purpose: We recently reported a new disease designated as NOD2-associated autoinflammatory disease (NAID). The aim of this study was to update the progress on defining the disease.

Methods: A single tertiary medical center study and report of cases of NAID were comprehensively analyzed and summarized. The phenotypes, genotypes, and therapy of NAID were characterized based upon the author's own experience and publications with the disease.

Results: NAID does not appear very rare, and may account for approximately 1% of our Rheumatology outpatients of Cleveland Clinic. White adults of both men and women are equally affected, and NAID is largely sporadic and occasionally familial. This disease may have fever, weight loss and fatigue, and is characterized by periodic occurrence, dermatitis, inflammatory polyarthritis, distal lower extremity swelling, gastrointestinal (GI), and sicca-like symptoms. Acute phase reactants can be elevated, autoantibodies are absent, and NOD2 gene mutations (variants), mostly IVS8+158, R702W, and occasionally R703C are associated with the disease. NAID is distinct from Blau's syndrome.

Table 1. Differentiating features between NAID and Blau's syndrome

	NAID	Blau's syndrome
Age at onset	Adult	< 5 years
Fever	Several days	Rare
Serositis	Can be present	Absent
Joints	Polyarthritis, pedal swelling	Polyarthritis, granulomatous, Camptodactyly
Skin	Spongiotic dermatitis, primarily erythematous patches/plaques	Granulomatous dermatitis, mostly papulonodular and subcutaneous plaques
GI symptoms	Present 50%	Absent
Uveitis	Absent	Present
Inheritance	Mostly sporadic	Dominant
Gene mutations	NOD2: between LRR and NBD	NOD2: NBD
Therapy	GC, Sulfasalazine	NSAID, GC, Infliximab

NAID, NOD2 associated autoinflammatory disease; GI, gastrointestinal; LRR, leucin-rich repeat; NBD, nucleotide binding domain; NSAID, nonsteroidal antiinflammatory drug; GC, glucocorticoids

The pathogenesis of NAID is unclear currently; the interaction between NOD2 gene mutations and environment may play a role. Therapy for NAID should be individualized, depending on clinical manifestations. Glucocorticoids of small dose are used to successfully treat skin disease and to temporarily relieve polyarthritic symptoms. Sulfasalazine is helpful in joint, skin and GI symptoms in some cases. Biologics need to be defined. Most patients run an intermittent benign course.

Conclusion: NAID represents a polygenic autoinflammatory disorder, and it often poses diagnostic challenges, leading to superfluous workups. This report should alert physicians to the novel entity.

Two Family Kindreds With Blau's Syndrome Associated With Unusual NOD2 Mutations. Qingping Yao. Cleveland Clinic, Cleveland, OH.

Background/Purpose: The aim of this study was to report families of Blau's syndrome with unusual NOD2 gene variants.

Methods: Two proband patients were seen, and their clinical phenotypes and genotypes were analyzed. Pedigree charts of both families were made.

Results: Proband A, a white 57-year-old woman, noticed painless flexion contractures of her 3rd, 4th and 5th proximal interphalangeal joints (PIPs) of both hands at age 6. She developed inflammatory polyarthritis and intermittent facial erythematous plaques/patches since age 30. As a result of cough and dyspnea, chest radiograph and computerized tomography showed multiple lung nodules without hilar adenopathy noted, and subsequent mediastinal lymph node biopsy revealed noncaseating granuloma. These symptoms markedly improved with prednisone 40 mg daily with taper. She had dry eyes on cyclosporine drops without uveitis. There were right parotid gland enlargement consistent with peiomorphic adenoma and left scanty granuloma composed of lymphocytes and mixed with debris and rare collections of histocytes. There was low grade fever. Her erythrocyte sedimentation rate (ESR), antinuclear antibodies, and blood CD4, CD8, and NK cell counts were all normal. Her blood vascular endothelial growth factor and TNFa levels were normal. A positive family history included flexion contractures of the 4th and 5thPIPs (Photographs and Pedigree chart). On examination, there was camptodactyly of the PIPs 3, 4 and 5 of both hands. Genetic testing revealed the presence of the NOD2 variant IVS8+158 in the patient, daughter and son.

Proband B, a white 50-year-old woman, developed inflammatory polyarthritis during the previous 5 months. She also had aching skin and subcutaneous nodules over her elbows, wrists and knees. She complained of mild dry eyes and mouth without parotid gland enlargement or fever; ophthalmic examination showed no evidence of uveitis. A positive family history involved flexion contractures of the 5thPIPs in several members (Pedigree chart). On examination, there were minimally tender and mobile subcutaneous nodules of 0.5 to 1.5 cm over the joints (Photograph). Her ESR and serologic testing were normal. A skin nodule biopsy showed non-necrotizing granuloma. Genetic testing revealed the presence of the NOD2 mutation R703C. These nodules resolved after 2 months of treatment with sulfasalazine.

Conclusion: Both families have autosomal dominant phenotypes of Blau's syndrome. Proband A has familial NOD2 IVS8+158, and proband B is linked to the NOD2 R703C. This study indicates that Blau's syndrome is also associated with the NOD2 variants away from the commonly reported nucleotide binding region and may present as an adult-onset disease.

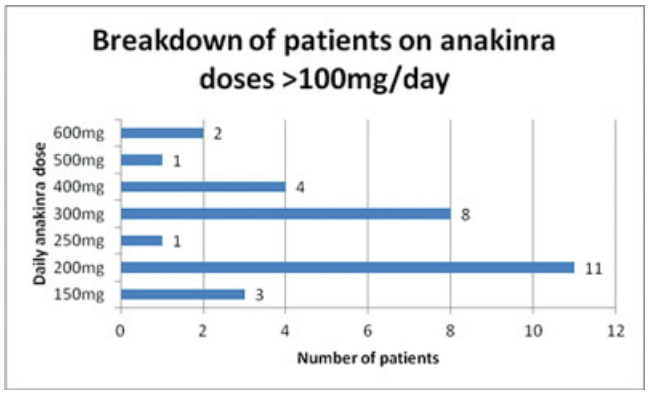
An Escalating Dose Of Anakinra In Patients With Autoinflammatory Disease Is a Safe and Reasonable Therapeutic Option. Amanda K. Ombrello[1], Karyl S Barron[2], Patrycja M. Hoffmann[3], Anne Jones[3], Deborah Stone[3] and Daniel L. Kastner[3]. [1]National Human Genome Research Institute, National Institute of Health, Bethesda, MD, [2]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, [3]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

Background/Purpose: The autoinflammatory diseases are diseases in which there is seemingly unprovoked stimulation of the innate immune system. The enhanced release of cytokines in these diseases (TNF-α, IL-1, IL-6), enable biologic medications targeting these cytokines to be good treatment options. The IL-1 antagonist, anakinra, has been approved for use in rheumatoid arthritis and neonatal onset multisystem inflammatory disease (NOMID) but is also frequently used in other autoinflammatory diseases such as the tumor necrosis factor associated periodic syndrome (TRAPS), familial Mediterranean fever (FMF), familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS) and pyogenic arthritis, pyoderma gangrenosum and acne (PAPA) syndrome. In addition, anakinra is often used in patients with undiagnosed autoinflammatory syndromes. Although commonly effective at the approved daily dose of 100mg, there are a number of patients who continue to have frequent disease flares and documented inflammation. We have found that aggressive titration of anakinra can help to better control disease and that higher doses have not been found to have increased adverse events.

Methods: A retrospective chart review of adult patients seen in the National Institutes of Health Autoinflammatory Disease clinic was completed. Patients on daily anakinra were assessed for what dose of anakinra provided adequate disease control. Number and types of adverse events were noted.

Results: 56 patients were identified who were taking at least 100mg daily of anakinra. 26 patients were on 100mg daily. The daily dose of the remaining 30 patients is detailed in Figure 1. Comparing patients on 100mg daily with those on higher doses, local site reactions were the most common adverse event in both groups (NS). Regarding more serious adverse events, in the 100mg group there was 1 patient who developed viral meningitis and one who developed a facial abscess. In patients on greater than 100mg daily, one patient with a chronic PICC line developed Serratia bacteremia and one patient with PAPA syndrome developed a C. difficile infection after treatment with clindamycin for presumed skin infection. Inflammation was able to be suppressed in 24/26 patients (92%) and 3/3 patients who underwent organ transplantation secondary to AA amyloidosis (2 kidney and 1 liver) had viable transplants at 7, 9, and 16 years post-transplant on 300, 600, and 200mg anakinra respectively.



Conclusion: In autoinflammatory disease patients who have inadequate disease suppression on anakinra 100mg daily, an upward titration of anakinra is relatively safe and well-tolerated. Close physician supervision is needed to try and minimize adverse events. Local site reactions are the most commonly reported adverse event and the majority of patients have resolution of these reactions within one month of initiating therapy.

Model-Based Pharmacokinetics Of Canakinumab and Pharmacodynamics Of IL-1Beta Binding In Cryopyrin Associated Periodic Syndromes, a Step Towards Personalized Medicine. Aurélie Gautier[1], Phil Lowe[1], Andrej Skerjanec[1], Phil McKernan[1], Wenping Wang[2] and Olivier Luttringer[1]. [1]Novartis Pharma AG, Basel, Switzerland, [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ.

Background/Purpose: Cryopyrin-associated periodic syndrome (CAPS), comprises of extremely rare, inherited auto-inflammatory diseases, including the mildest form familial cold auto-inflammatory syndrome (FCAS), the more severe Muckle-Wells syndrome (MWS), and the most severe form chronic infantile neurologic cutaneous and articular syndrome/neonatal onset multisystem inflammatory disease (NOMID).[1] Canakinumab (CAN), a high-affinity fully human monoclonal antibody of the IgG1/k isotype, is designed to bind and functionally neutralize the bioactivity of interleukin 1β (IL-1β); recognized as one of the principal pro-inflammatory cytokines in CAPS.[2] The objectives of the study were: 1) to describe the pharmacokinetics (PK) of CAN and pharmacodynamics (PD) of binding IL-1β in CAPS patients; 2) to determine if PK, PD are different in 2- and 3-year-old children compared with older children and adults; and 3) to explore the impact of CAPS phenotype on the PK of CAN and PD of binding to IL-1β.

Methods: A mathematical PK-binding model was developed to describe the kinetics of CAN and binding dynamics of IL-1β patients with CAPS, other auto-inflammatory diseases and healthy volunteers. The subgroup of 7 CAPS patients who were 2 and 3 years of age at baseline was also compared with the overall CAPS population.

Results: The 7 CAPS patients did not show any difference in terms of PK. However, they showed a higher IL-1β turnover including IL-1β clearance and production. IL-1β levels were linked with age and with the severity of the CAPS phenotype. In these youngest patients, MWS and especially NOMID patients had higher concentrations of the inert CAN/IL-1β complexes after administration of CAN, indicating more cytokine in the body to be captured.

Conclusions: Correlation with clinical responses suggested that these increased levels of IL-1β may explain why younger and especially NOMID phenotype patients require escalation to higher CAN doses.[3]

1205

Effectiveness Of Canakinumab In a Cryopyrin-Associated Periodic Syndrome Cohort. A Single Center Experience. Virginia Moreira-Navarrete[1], Francisco Javier Toyos Saenz de Miera[2], Carmen Vargas Lebrón[3] and F. Navarro Sarabia[4]. [1]University Hospital Virgen Macarena, Sevilla, Spain, [2]Hospital Virgen de la Macarena, Sevilla, Spain, [3]Hospital Virgen Macarena, SEVILLA, Spain, [4]Hospital Universitario Virgen Macarena, Sevilla, Spain.

Background/Purpose: Cryopyrin-associated periodic syndrome (CAPS) comprises a group of rare, but severe, autoinflammatory diseases, characterized by urticaria, periodic fever, central nervous system inflammation, arthropathy, and increased risk of amyloidosis. In a recent trial the use of subcutaneous doses of 150 mg of canakinumab every 8 weeks was associated with complete control of clinical manifestations and laboratory parameters in patients with CAPS. The aim of this study was to verify efficacy and safety of the drug in clinical practice.

Methods: Retrospective longitudinal observational study, which included all patients diagnosed with CAPS in a tertiary hospital. Demographic and disease characteristics of all patients were collected. The decision to treat was performed by their rheumatologists. Clinical and laboratory variables at last follow-up were compared with those registered at Canakinumab treatment baseline. Percentages were obtained for qualitative variables and means with standard deviation (SD) for quantitative variables. Comparison between disease activity before and after therapy was performed with a t-student test.

Results: 10 genetically proved CAPS patients were included. 9 of them presented with the typical MWS phenotype and one of them patients with an overlapping MWS/FCAS phenotype. Seven of the patients belonged to the same family. All 10 patients were heterozygous carriers of different mutations in the NLRP3 gene: p.Thr-348-Met in exon 3, D303N in all family affected members, a deletion of bp (A) in exon 3, a mutation not described before, and finally, pR260W. Because disease activity, 50% of the patients were treated with a subcutaneous dose of 150 mg every 8 weeks of Canakinumab. Clinical and laboratory parameters of those patients are shown in Table 1. Both clinical and laboratory parameters responded quickly to that therapy. The mean decrease in CRP levels was 83.2 mg/L (SD 64.1) (p 0.04) in the levels of ESR of 40.8 mm/h (SD 24.9) (p 0,02). The mean increase in hemoglobin levels was 2.5 points (SD 2.62) (p 0.1) and the mean decrease in the platelet count was 161250 (SD 158838) (p 0.135). One of the patients is in a reduced dose schedule, receiving canakinumab every 10 weeks. No patients presented with any adverse events during follow up.

Table 1. Clinical and laboratory parameters of patient on Canakinumab Therapy.

Cases	Sex	Age	Previous Therapies	Mutation	Clinical Manifestations
1	Male	50	Colchicine Glucocorticoids Methotrexate	D303N	Arthritis Urthicaria Deafness Fever Conjunctivitis Meningitis
2	Male	35	Colchicine Glucocorticoids Methotrexate Infliximab	D303N	Arthritis Urthicaria Deafness Fever Conjunctivitis
3	Male	30	Colchicine Glucocorticoids Methotrexate	D303N	Urthicaria Deafness Fever Conjunctivitis Amiloydosis
4	Male	48	Colchicine Glucocorticoids Methotrexate Cyclosporine Etanercept	p.Thr-348-Met	Arthritis Urthicaria Deafness Fever Conjunctivitis
5	Male	53	Colchicine Glucocorticoids	pR260W	Arthritis Urthicaria Deafness Fever Conjunctivitis

Conclusion: The use of canakinumab in daily practice is associated with persistent satisfactory control of disease activity. Here 10 patients with different mutations are presented, including a not previously reported mutation.

Canakinumab Treatment Regimens In CAPS Patients. Ferdinand Hofer[1], Theresa Endres[1], Birgit Kortus-Goetze[2], Norbert Blank[3], Elisabeth Weissbarth-Riedel[4], Catharina Schuetz[5], Tilmann Kallinich[6], Karoline Krause[7], Christoph Rietschel[8], Gerd Horneff[9] and Jasmin B. Kuemmerle-Deschner[1]. [1]University Hospital Tuebingen, Tuebingen, Germany, [2]Klinikum der Philipps-Universität Marburg, Marburg, Germany, [3]University of Heidelberg, Heidelberg, Germany, [4]Universitätsklinikum Eppendorf, Hamburg, Germany, [5]Klinik für Kinder und Jugendmedizin, Universitätsklinikum Ulm, Ulm, Germany, [6]Charite, University Hospital Berlin, Berlin, Germany, [7]Dept. of Dermatology and Allergy, Allergie-Centrum-Charité, Charité – Universitätsmedizin Berlin, Germany, Berlin, Germany, [8]Clementine-Kinderhospital, Frankfurt, Germany, [9]Asklepios Klinik Sankt Augustin, Sankt Augustin, Germany.

Background/Purpose: Canakinumab is a recombinant monoclonal fully human antibody against Interleukin-1β and approved for the treatment of CAPS in many countries including Europe and the US. Current dose recommendations are 150mg (body weight >40kg) respectively 2mg/kg body weight (15 to 40kg) every 8 weeks but yield insufficient response in some individuals, especially in children and patients with severe phenotypes1.

In this study we analyzed the response to daily practice (in contrast to trial condition) canakinumab treatment regimens in CAPS patients with focus on age, mutation and clinical presentation and the necessity and effect of dose adjustment.

Methods: An observational national multicenter study was conducted. CAPS patients were included if they received at least two doses of canakinumab. Data included information regarding demographics, treatment, clinical disease activity and inflammatory markers (including SAA, CRP, ESR, IL-6). Response to treatment was assessed using CAPS-disease activity scores, CRP and/or SAA levels.

Results: A cohort of 68 patients with CAPS was analyzed. Median age was 25.4 years (range 22 months to 73 years). When treatment was initiated, 27 patients had been younger than 18 years. The most frequent mutations were R260W, A439V, E311K, V198M, Q703K and most patients showed MWS or FCAS/MWS phenotype (3 patients with NOMID, 4 with MWS/NOMID).

The median treatment duration was 855 days (range: 28–1973 days). In 39 patients (57%) full response was sustained until the next scheduled drug application (34% (23 patients) partial remission). With standard treatment 21 patients (31%) achieved full response. In 30 patients (44%) canakinumab dose and/or application interval was increased above the standard regimen (2/3 NOMID, 3/4 MWS/NOMID).

Neither laboratory parameters nor clinical disease activity at the beginning of treatment were able to predict the necessity to adjust treatment regimen. Two serious adverse events were reported (severe infection, osteonecrosis), mild and moderate adverse events were mostly upper respiratory tract infections but almost no injection site reactions.

Conclusion: Most CAPS patients achieve full remission with canakinumab. However, almost 50% of patients, particularly children, require

dose adjustment. Full remission by dose increase was achieved without an increased rate of adverse events. Individual adjustment of therapy should be performed as needed as predictive parameters are lacking.

1207

Efficacy Of Tocilizumab In Patients With AA Amyloidosis Secondary To Familial Mediterranean Fever: A Single Centre Experience. Sedat Yilmaz, Muhammet Cinar, Ismail Simsek, Hakan Erdem and Salih Pay. Gulhane School of Medicine, Ankara, Turkey.

Background/Purpose: The most frequent underlying diseases responsible for AA amyloidosis worldwide are rheumatoid arthritis, juvenile idiopathic arthritis and ankylosing spondylitis, while familial Mediterranean fever (FMF) is responsible for almost 60% of the cases in Turkey and in countries where the FMF is prevalent. Tocilizumab (TCZ), an IL-6 antagonist, seems to be a promising agent in AA amyloidosis associated with rheumatic disorders, while there is no data regarding its use in amyloidosis due to FMF. We herein describe the short-term results of TCZ treatment in 7 patients with amyloidosis secondary to FMF.

Methods: We described a series of adult FMF patients complicated with amyloidosis and treated with TCZ (8 mg/kg once monthly) in one reference center. Diagnosis of AA amyloidosis was confirmed in the renal biopsy specimens in all patients with Congo red and immunohistochemical staining.

Results: The longest duration on the treatment with TCZ was 16 months in one patient, while 3 months in 3 patients with the shortest follow-up. At the beginning of TCZ treatment all patients had proteinuria, which was severe (>10 g/day) in 2. Following treatment with TCZ, proteinuria was normalized in one (Case with the longest duration of treatment), and considerably decreased in 5. The ameliorative effect of TCZ on proteinuria seemed to begin as early as 3 months. The renal function was normal in all but 3 patients at the beginning, and remained stable throughout the follow-up (Table 1).

Table 1. Demographic, clinical and laboratory features of study patients

Cases	Age	Diagnosis	Treatment cycles	Initial proteinuria (mg/24 hours)	Final proteinuria (mg/24 hours)	Initial creatine (mg/dl)	Final creatine (mg/dl)
1	32	FMF	16	6810	84	0,82	0.64
2	20	FMF	6	10485	3234	0,62	0,9
3	75	FMF	7	4368	901	3,21	3,05
4	45	FMF	3	1800	2300	1,32	1,44
5	38	FMF	3	5648	4935	1,62	1,79
6	33	FMF	7	11960	7714	0,67	0,68
7	23	FMF	3	29260	13801	4,06	3,63

Conclusion: To our knowledge this is the first report showing the efficacy of TCZ on renal amyloidosis secondary to FMF. While previous reports confirm the efficacy of TCZ in amyloidosis secondary to other rheumatic diseases, our findings suggest that this effect can be extended to other diseases.

Disclosure: S. Yilmaz, None; **M. Cinar**, None; **I. Simsek**, None; **H. Erdem**, None; **S. Pay**, None.

1208

Canakinumab In Patients With FMF. Serdal Ugurlu, Emire Seyahi, Gulen Hatemi, Ayse Hacioglu and Huri Ozdogan. Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey.

Background/Purpose: In a recent pilot study, it was reported that Canakinumab reduced the frequency of attacks in 9 patients with Familial Mediterranean Fever (FMF) resistant to colchicine with no apparent side effects (1). Here, we present our experience with Canakinumab in FMF patients with insufficient response to colchicine.

Methods: The charts of the patients with FMF who were on Canakinumab were evaluated retrospectively and the patients who had received 3 or more injections were asked to come to the clinic to assess the response and safety

Results: There were 19 patients with FMF (13 F/6 M) who were receiving canakinumab for various indications. Here we report 12 (8 F/4 M) who had at least 3 injections. Three patients had concomitant diseases such as psoriasis, ankylosing spondylitis and polyarteritis nodosa. The indications for canakinumab (150mg) were colchicine resistancy in 9 patients (>1 attack/month), amyloidosis in 2 and injection site reaction due to anakinra in one. The mean age of the patients was 31.25±14.51 years, while the disease duration was 22.0 ± 8.65 years. The mean colchicine dose was 2.37 ± 0.43 mg/day. The median injection number with canakinumab was 5 (range 3–10). Although injections were planned to be monthly, patients received the drug with irregular intervals due to shortage of the drug. The duration of canakinumab use was 7 ± 3.28 months. Ten of the patients had no attacks after canakinumab, while in two patients attack frequency was reduced more than 50%. In two patients with amyloidosis, proteinuria was stable in one and increased from 1.7g/d to 4.7g/d in the other. Eight of the patients who were complaining of severe myalgia, improved significantly after treatment. According to patient global assessment eleven patients reported significant improvement while only one, reported no change.

Canakinumab was tolerated well in general. None of the patients had injection site reactions. Although, the patient with psoriasis reported a flare in psoriatic plaques, the treatment was not interrupted and psoriasis was controlled eventually by local applications.

Conclusion: Canakinumab is effective in decreasing the frequency of attacks in colchicine-resistant FMF patients. In spite of the small number of patients, and short duration of follow-up, the side effect profile seems favorable. There is need for larger trials to further evaluate its long-term efficacy on amyloidosis.

1209

Starting Time Of Inflammatory Attacks In Patients With Familial Mediterranean Fever. Feyza Berktas, Nilufer Alpay Kanitez, Bahtiyar Toz, Oguz Kaan Bakkaloglu, Burak Erer and Ahmet Gul. Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey.

Background/Purpose: Familial Mediterranean fever (FMF), the most common form of the hereditary autoinflammatory diseases, is characterized by recurrent self-limiting attacks of fever and/or serositis accompanied with acute phase response. Recurrence of attacks does not show a clear periodicity, and its timing is usually unpredictable. Little is known about the factors triggering or precipitating the attacks, and some patients describe physical or emotional exertion, menstrual cycle and dietary changes as possible triggers of the attacks. In other hereditary autoinflammatory disorders, a diurnal variation for the attack was observed with a tendency to experience attacks during evening or night. Recent data suggest that expression of some genes may show a circadian rhythm and affect the immune system, especially innate immune response. In this study, we aim to collect data retrospectively from FMF patients about the starting time of their attacks.

Methods: As a pilot study, we did a questionnaire based survey in 199 consecutive adult FMF patients. All patients fulfilled the Tel-Hashomer criteria for the diagnosis of FMF, and experienced attack(s) during the last year. All patients were interviewed directly or by telephone contacts to answer the questionnaire items about their attacks. The list of questions included usual start time of attacks during the day, their attack frequency, severity and possible triggers (such as sleeplessness, hunger, tiredness, stress, diet, medications, other diseases, menstruation and cold exposure) of the attacks during the past year.

Results: All patients (n=199) agreed to participate in the study and provided answers to the questions. Their mean age was 35.7 and sixty-two (61%) were female. The most commonly reported attack triggering factors were emotional stress (61%), tiredness (57%), menstruation (42% of female patients), followed by dietary changes (18%), cold exposure (5%), sleeplessness (18%) and hunger (3%). Only 9 patients (4%) had an occupation with night shifts. In all group, 63% of the patients provided a definite answer to the question about starting time of attacks. The majority reported that of their attacks started in the evening (41.3%), and less frequently in the morning (28.6%), at night (17.4%) and in the afternoon (12.7%). There was no correlation between the start time of the attacks and triggering factors or night shifts.

Conclusion: This questionnaire-based retrospective survey suggests that starting time of FMF attacks have a tendency for evening. This information may provide some clues about circadian changes affecting the FMF-related inflammation and the threshold for attack development, after its confirmation with prospective data collection.

Epicardial Adipose Tissue and Atherosclerosis In Patients With Familial Mediterranean Fever. Adem Kucuk[1], Yalcin Solak[2], Hakan Akilli[3], Oguzhan Yildirim[3], Ibrahim Guler[4], Ramazan Ucar[5], Alpay Aribas[3], Orhan Ozbek[6], Mehmet Kayrak[3] and Recep Tunc[7]. [1]Necmettin Erbakan University, Division of Rheumatology, Konya, Turkey, [2]Karaman State Hospital, Division of Nephrology, Karaman, Turkey, [3]Necmettin Erbakan University, Division of Cardiology, Konya, Turkey, [4]Konya Research and Education Hospital, Division of Radiology, Konya, Turkey, [5]Konya Education and Research Hospital, Department ofInternal Medicine, Konya, Turkey, [6]Necmettin Erbakan University, Division of Radiology, Konya, Turkey, [7]Selçuk University, Konya, Turkey.

Background/Purpose: Familial Mediterranean Fever (FMF) is a chronic autosomal recessive hereditary disease characterized by episodic attacks of fever and inflammation of serosal and synovial membranes. Premature development of atherosclerosis has been observed in patients with chronic inflammatory diseases such as systemic lupus erythematosis and rheumatoid arthritis. The relation between epicardial adipose tissue (EAT) volume and increased inflammatory cytokines, diastolic dysfunction, myocardial ischemia and adverse clinical outcomes has been shown. We aimed to evaluate EAT as a novel marker of atherosclerosis and its relation between carotis intima media thickness (CIMT) and inflammatory markers in patients with FMF.

Methods: Seventy-nine FMF patients who had been diagnosed according to Tel-Hashomer criteria in Rheumatology outpatient clinic of a university hospital were included in the study between May 2012 and December 2012. Twenty-six age and sex matched healthy individuals were recruited as the control group. CIMT and EAT were measured and the relation between inflammatory markers were evaluated.

Results: The EAT was thicker in patients with FMF than the control group (EAT 0.47 ± 0.13 vs 0.36 ± 0.10cm, p=0.001). CIMT was also greater in patients with FMF than the control group (0.78 ± 0.2 vs 0.68 ± 0.13 mm, p=0.24). In correlation analysis, EAT was correlated with CIMT (r=0.17, p=0.1), CRP (r=0.31, p=0.005), BMI (r=0.14, p=0.16), total cholesterol (r=0.170, p=0.086), LDL (r=0.212, p=0.035) and age (r=0.188, p=0.054). CIMT was correlated with CRP (r=0.211, p=0.05), serum creatinine (r=0.224, p=0.022), total cholesterol (r=0.231, p=0.019), LDL (r=0.219, p=0.03), triglyceride (r=0.214, p=0.03), age (r=0.453, p<0.001), serum glucose (r=0.267, p=0.022) and BMI (r=0.241, p=0.013).

In multivariate linear regression model, total cholesterol level (β: 0.399, t:2.716), CRP (β: 0.150, t: 2.139) and BMI (β: 0.431, t: 2.581) were found to be independent predictors of EAT.

Table 1. Baseline characteristic of FMF patients and control subjects

	FMF Patients	Control Subjects	P value
Age (year)	38.4 ± 10	41.5 ± 9.5	0.18
BMI (kg/m^2)	26.8 ± 4.9	28.1 ± 4.2	0.20
EAT (mm)	0.47 ± 0.13	0.36 ± 0.1	**0.001**
CIMT (mm)	0.78 ± 0.2	0.68 ± 0.13	**0.02**
CRP (mg/dL)	5.5 ± 2.7	2.8 ± 1.3	**<0.001**
ESR (mm/h)	12.5 ± 1.4	5.2 ± 0.8	**0.008**
WBC (u/L)	7.5 ± 1.8	6.8 ± 1.2	0.1
Hgb (g/dL)	13.3 ± 2	14.6 ± 1.3	**0.002**
Creatinine (mg/dL)	0.7 ± 0.2	0.8 ± 0.1	0.29
ALT (u/L)	28 ± 17	25 ± 12	0.53
LDL (mg/dL)	111 ± 34	112 ± 28	0.87

Conclusion: Both EAT and CIMT were significantly greater in FMF patients than control subjects. In patients with FMF, EAT may be a novel marker of increased cardiovascular risk.

1211

Adult Autoinflammatory Phenotypes Associated With Heterozygous MEFV Mutations: A Continuum of Familial Mediterranean Fever? Qingping Yao. Cleveland Clinic, Cleveland, OH.

Background/Purpose: Familial Mediterranean fever (FMF) is traditionally regarded as an autosomal recessive disease characterized by periodic fever, serositis, erysipelas-like erythema and good response to colchicine. The aim of this study was to analyze a cohort of adult patients with autoinflammatory phenotypes and heterozygous MEFV mutations.

Methods: A group of 8 patients were cared for by the author between 2011 and 2012, and retrospectively studied for their clinical phenotypes. Genetic testing for MEFV mutations was performed (GeneDx, MD).

Results: Eight patients consisted of 5 women, 3 men, 7 whites and 1 Arab. The mean age at disease onset was 30.5 years with only 1 patient with early-onset. All but the early-onset patient denied any family history of periodic fever syndrome. Of the 8 patients, there were 7 patients with arthritis, 6 intermittent fever, 4 abdominal pain, 3 chest pain, and 3 non erysipelas-like rash. None of the patients had proteinuria. All patients carried a single copy of heterozygous MEFV mutations, including V726A (2), K695R (2), M694V (1), E148Q (1), new mutations R329H (1) and G136V (1) (Table 1). In a study of 18 FMF early-onset patients with a single MEFV mutation, most patients reportedly presented with fever and abdominal pain with prompt response to colchicine therapy. In the current adult cohort, most patients had fever and inflammatory arthritis with poor response to colchicine. Instead, 3 of the 8 patients required treatment with prednisone in 2 cases and etanercept in 1 (R329H).

Conclusion: This study supports the presence of the clinical entity associated with a single heterozygous MEFV mutation. The adult-onset entity may be distinct from classic FMF and early-onset form. Future study to differentiate between the adult- and early-onset forms will be needed.

Disclosure: Q. Yao, None;

1212

Are Different Disease Subtypes With Distinct Clinical Expression Present In Familial Mediterranean Fever: Results Of a Cluster Analysis. Servet Akar[1], Timucin Kasifoglu[2], Dilek Solmaz[1], Sule Yasar Bilge[2], Ismail Sari[1] and Mehmet Tunca[1]. [1]Dokuz Eylul University School of Medicine, Izmir, Turkey, [2]Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey.

Background/Purpose: Familial Mediterranean fever (FMF) is an auto-inflammatory disorder characterized by self limited attacks of fever and serositis. The disease expression may be different in different ethnic groups and patients with certain MEFV mutations may be prone to have more severe disease and a greater probability of developing amyloidosis. Recently we showed that amyloidosis is the only predictor of mortality in Turkish FMF patients, however clinical subtypes with different clinical and genetic characteristics have been never identified previously. The aim of this study was to evaluate whether there are clinical subgroups, which may have different prognosis, among FMF patients.

Methods: The cumulative clinical features of a large group of FMF patients (1168 patients, 575 female [49.2%] and mean age was 35.3 ± 12.4 years) were studied. To analyse our data and identify groups of FMF patients with similar clinical characteristics, a two-step cluster analysis using log-likelihood distance measures was performed. For clustering the FMF patients, we evaluated the following variables: gender, current age, age at symptom onset, age at diagnosis, the presence of major clinical features (fever, peritonitis, pleuritis, arthritis, erysipelas like erythema [ELE], febrile myalgia, amyloidosis), variables related with therapy (the dosage of colchicine, compliance with therapy, and the presence of attacks despite colchicine), the family history for FMF and for renal failure and the presence of M694V allele.

Results: Three distinct groups of FMF patients were identified. Cluster 1 was characterized by high prevalence of arthritis, pleuritis, ELE, and febrile myalgia. The dosage of colchicine and the frequency of amyloidosis were lower in cluster 1. Patients in cluster 2 had earlier age at symptom onset and diagnosis. Other characteristics of cluster 2 were high frequency of arthritis, amyloidosis, M694V allele and family history for FMF. This group of patients was using highest dose of colchicine. The cluster 3 was characterized by the lowest frequency of M694V allele, ELE, arthritis, protracted febrile myalgia. The colchicine resistance was

also lower in cluster 3. The mean age and age at diagnosis was the highest in cluster 3.

Table 1. Clinical and demographical findings according to the cluster analysis

	Cluster 1		Cluster 2		Cluster 3	
Current age, years (mean ± SD)	29.5 ± 11.2	↓	31.3 ± 10.2	↓	36.5 ± 12.6	↑
Age at symptom onset, years(mean ± SD)	17.9 ± 10.9	↑	10.7 ± 5.7	↓	17.5 ± 9.7	↑
Age at diagnosis, years (mean ± SD)	25.8 ± 11.7	↔	21.5 ± 9.5	↓	28.3 ± 11.7	↑
Colchicine dosage, mg (mean ± SD)	1.1 ± 0.4	↓	1.5 ± 0.4	↑	1.3 ± 0.4	↔
Peritonitis (%)	99	↔	91	↓	98	↑
Pleuritis (%)	95	↑	57	↔	60	↔
Arthritis (%)	100	↑	98	↑	13	↓
ELE (%)	99	↑	39	↔	9	↓
Protracted febrile myalgia (%)	100	↑	16	↓	3	↓
Amiloidosis	2	↓	15	↑	7	↔
To have attacks despite colchicine (%)	80	↑	60	↑	34	↓
Family history for FMF (%)	39	↓	62	↑	48	↔
Family history for renal failure (%)	5	↓	16	↔	14	↔
The frequency of M694V allele (%)	76	↔	87	↑	52	↓

Conclusion: Patients with FMF could be clustered into distinct patterns of clinical and genetic manifestations and these patterns may have different prognostic significance.

Low-Penetrance NLRP3-Variants. Theresa Endres[1], Ferdinand Hofer[1], Raphaela T. Goldbach-Mansky[2], Hal M. Hoffman[3], Norbert Blank[4], Karoline Krause[5], Christoph Rietschel[6], Gerd Horneff[7], Peter Lohse[8] and Jasmin B. Kuemmerle-Deschner[1]. [1]University Hospital Tuebingen, Tuebingen, Germany, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD, [3]University of California at San Diego, La Jolla, CA, [4]University of Heidelberg, Heidelberg, Germany, [5]Dept. of Dermatology and Allergy, Allergie-Centrum-Charité, Charité – Universitätsmedizin Berlin, Germany, Berlin, Germany, [6]Clementine-Kinderhospital, Frankfurt, Germany, [7]Asklepios Klinik Sankt Augustin, Sankt Augustin, Germany, [8]Institut für Laboratoriumsmedizin und Humangenetik, Singen, Germany.

Background/Purpose: Cryopyrin-associated periodic syndrome (CAPS) presents as rare, autosomal dominant disease spectrum, due to mutations in the *NLRP3*-gene which lead to excessive interleukin-1 (IL-1) release.

In patients with low-penetrance NLRP3 variants, the clinical presentation varies widely. So far, a correlation with a specific phenotype could not be demonstrated.

The aim of this study was to analyze the association of the V198M, R488K, and Q703K substitutions with a specific phenotype, laboratory markers, and the response to IL-1 inhibitors anakinra, canakinumab and rilonacept.

Methods: This multi-center observational study included 45 patients (26 children and 19 adults) (study group). At baseline examination, all patients displayed some symptoms suggestive of CAPS. Genetic analysis detected one of the following NLRP3 variants: Q703K (n=19), R488K (n=6), and V198M (n=20).

Clinical presentation was recorded and inflammation markers were analyzed. Data from follow-up visits were also evaluated to assess response to IL-1 inhibitors. Results were compared to a (control) group of CAPS patients (n=28) in which disease-causing mutations had been confirmed (A439V, E311K, T348M).

Results: At baseline examination, study patients reported signs of systemic inflammation such as fever (76%), headache (73%), musculoskeletal symptoms (84%) and fatigue (78%). Other CAPS-specific features were rash (80%), conjunctivitis (44%) and sensorineural hearing loss (29%).

Compared to the control group, a history of eye impairment, hearing loss and renal involvement was significantly less frequent in the study group. However study group patients presented significantly more often with gastrointestinal symptoms such as abdominal pain (56% versus 25%, p=0.01) and gastroesophageal reflux (22% versus 0%, p=0.01). Also, a wide spectrum of concomitant diseases such as thyroid disorders (7) and neurological and psychiatric diseases were reported (epilepsy (3), Asperger syndrome (2)).

Inflammation markers were only slightly increased: ESR was elevated in 26% (9/35) and C-reactive protein (CRP) in 34% (14/41). Serum amyloid A (SAA) was raised in 36% (8/22) of the patients. Nine out of ten patients (90%) had elevated TNF-α-levels at baseline examination.

Data from follow-up visits during the first year of treatment was available from 20 patients, treated with IL1 – inhibitors. Clinical disease activity was reduced in all cases; 10 patients (50%) achieved full remission and 10 patients showed partial response to the treatment with mild disease activity and/or persistently elevated inflammation markers.

Conclusion: Heterozygous carriers of the NLRP3 variants V198M, R488K, and Q703K display distinct clinical characteristics compared to CAPS patients with confirmed disease causing mutations, including a high incidence of gastrointestinal symptoms, only slightly elevated inflammatory parameters, and a potentially inferior response to IL-1 inhibition. Also susceptibility for concomitant diseases is observed.

Resistant Or Recurrent Acute Pericarditis: A New Therapeutic Opportunity? Claire Massardier[1], Claire Dauphin[2], Romain Eschalier[2], Jean-René Lusson[2] and Martin Soubrier[3]. [1]CHU CLERMONT-FERRAND, Clermont-ferrand, Colombia, [2]CHU CLERMONT-FERRAND, Clermont-ferrand, France, [3]CHU CLERMONT-FERRAND, Clermont-Ferrand, France.

Background/Purpose: The treatment of recurrent pericarditis relies on aspirin and/or non-steroidal anti-inflammatory drugs, as well as colchicine. Corticosteroid therapy, which is offered in resistant forms, puts patients at risk of recurrence. Anakinra has shown itself to be effective in idiopathic recurrent pericarditis in childhood[1, 2].

Methods: To report case studies of two patients who responded well to anakinra.

Results: Case 1: A 60-year old obese female with insulin-dependent diabetes and hypertension who had acute pericarditis with very high inflammatory markers (CRP 337) that recurred when her treatment with aspirin was tapered.

Investigations for aetiology were unremarkable. The patient presented clinical signs of constrictive pericarditis. The ultrasound scan showed circumferential pericardial effusion with compression of the right chambers. It was assessed as 1 liter on the chest CT scan.

After four days of the standard treatment with aspirin and colchicine, which was unsuccessful, treatment with anakinra was initiated, chosen over corticosteroids due to the patient's diabetes. The patient quickly showed a favourable response. At two months, the patient is asymptomatic and no longer has pericardial effusion or signs of inflammation.

Case 2: A 52-year old female with a 7-month history of persistent recurrent pericarditis in spite of receiving a long-term standard treatment of aspirin, followed by naproxen, then IV ketoprofen, all combined with colchicine.

The clinical examination found an intermittent pericardial friction rub, echocardiography and CT found moderate pericardial effusion without compression, and inflammatory marker tests were negative (CRP<2.9 mg/l, ESR 2 mm).

Initiation of anakinra led to rapid clinical improvement, which persisted at two months, with gradual reduction of the pericardial effusion.

Conclusion: Anakinra could be a treatment for recurrent pericarditis or pericarditis with very high inflammatory markers that does not respond to the standard treatment and for which corticosteroid therapy is being considered.

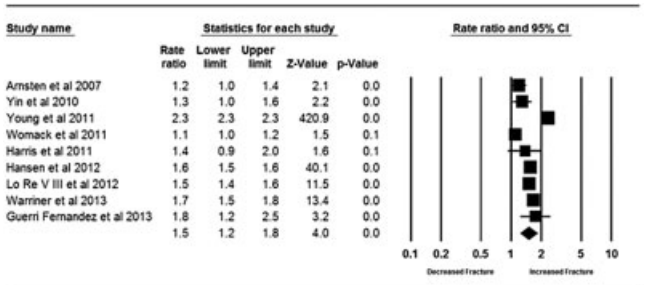
Human Immunodeficiency Virus Infection and Fracture Risk-a Meta-analysis. Sian Yik Lim, Ana Marcella Rivas and Kenneth Nugent. Texas Tech University Health Sciences Center, Lubbock, TX.

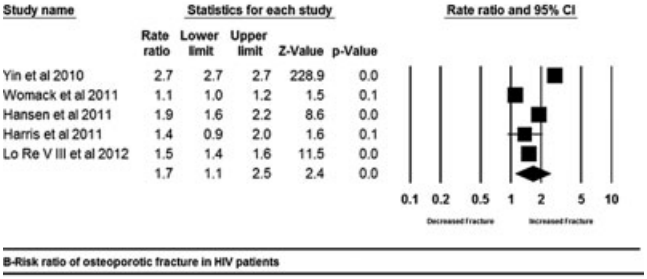
Background/Purpose: Human Immunodeficiency Virus (HIV) infection is associated with development of osteoporosis and decreased bone mineral density. However, studies have been inconclusive in whether this translates to increased fracture incidence. In our study, a meta-analysis of observational studies was performed to examine fracture rate ratio in HIV patients.

Methods: 2 independent researchers systematically searched Pub Med and Embase from earliest available online year of indexing up to March 2013 using Medical Subject Headings terms and key words pertaining to two major themes-HIV and fractures. Abstracts from the Conference on Retroviruses and Opportunistic Infections, the International Acquired Immunodeficiency Syndrome (AIDS) Society Conference on HIV Pathogenesis and Treatment, and the International AIDS Conference were also manually searched. All controlled observational studies that compared fracture incidence in HIV patients with a control group (consisting of uninfected individuals or the general population) were included. Pooled rate ratio was calculated using generic inverse variance weighting and a random effects model.

Results: Of 2050 identified publications, 9 publications (6 prospective cohort studies and 3 retrospective cohort studies) were eligible for analysis. The analysis included 169544 HIV patients with 2101 incident fractures. The pooled rate ratio for any fracture was 1.5 (95% CI 1.2–1.8), and 1.7 (95% CI 1.1–2.5) for osteoporotic fractures. For site specific fractures, the pooled rate ratio for hip, spine, and wrist/forearm fracture were 2.5 (95% CI 1.3–5.0), 1.5 (95% CI 0.8–3.0), 1.3 (95% CI 0.7–2.4). There was significant heterogeneity present among studies for main analyses and subgroup analyses. Subgroup analyses did not show significant differences regarding gender, study design, whether BMI was adjusted, and duration of follow-up. For fractures and osteoporotic fractures, both funnel plots were symmetrical and the Orwin's Fail-Safe N was 737 and 492 respectively.



A-Risk ratio of fracture in HIV patients



B-Risk ratio of osteoporotic fracture in HIV patients

Conclusion: In our meta-analysis of observational studies, HIV infection was associated with increased incidence of fracture, osteoporotic fracture, and hip fracture as compared to uninfected individuals or the general population. Because there was significant heterogeneity present in pooled estimates, and residual confounding cannot be excluded, the results have to be interpreted with caution. However, clinicians need to be aware that HIV patients may be at increased risk for fractures. Therefore, appropriate evaluation and treatment is required, especially in HIV patients with other risk factors for osteoporosis. As the HIV population ages, it is important to evaluate the timing of screening and the individual contributions of HIV, antiretroviral therapy, and traditional risk factors in the development of osteoporosis and fractures in HIV patients.

Risk Factors Associated With Fracture Occurrence Appear to Differ Between Distal Radius, Clinical Vertebral, and Hip Fractures in Japanese Patients With Rheumatoid Arthritis: A Prospective Observational Cohort Study. Kensuke Ochi[1], Takefumi Furuya[1], Yuki Go[1], Eisuke Inoue[2], Katsunori Ikari[1], Atsuo Taniguchi[1], Hisashi Yamanaka[1] and Shigeki Momohara[1]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: Patients with rheumatoid arthritis (RA) are at high risk of developing fractures. Previously, utilizing data from our Institute of Rheumatology Rheumatoid Arthritis (IORRA) cohort study, we reported clinical risk factors for clinical vertebral and any nonvertebral fractures in women [1] and men [2] and hip fractures [3] in Japanese patients with RA. However, we did not evaluate the risk factors for distal radius fractures alone, because in our previous studies, the number of distal radius fracture patients was small. In this study, we evaluated the association between potential risk factors and the occurrence of distal radius fractures and compared the risk factors for clinical vertebral, any nonvertebral, and hip fractures in Japanese patients with RA [1–3].

Methods: IORRA is a prospective observational cohort study of Japanese patients with RA at the Institute of Rheumatology, Tokyo Women's Medical University that was established in 2000. A total of 9,987 patients (82.0% female; mean age, 55.7 years) with RA were enrolled in a prospective, observational study from 2000 to 2011. Self-reported distal radius fractures were verified using patient medical records. Cox proportional hazards models were used to analyze independent contributions of various risk factors to distal radius fracture occurrence.

Results: During a mean follow-up period of 5.7 years, 139 patients reported 153 distal radius fractures. Among these patients, 85 distal radius fractures in 85 patients (6 men, 79 women) were verified by medical records. The multivariate Cox regression analyses estimated that the hazard ratios of sustaining a distal radius fracture increased by 15.27 for female gender [95% confidence interval (CI), 1.96–119.02], 1.60 for every 10 years of increased age (95% CI, 1.15–2.22), 1.11 for body mass index (BMI) (kg/m^2, 95% CI, 1.01–1.22), and 1.09 for daily prednisolone dose (mg, 95% CI, 1.01–1.18). Unlike risk factors for clinical vertebral, any nonvertebral, and hip fractures evaluated using data from this same cohort [1–3], no significant association was observed between the occurrence of distal radius fractures and Japanese health assessment questionnaire (J-HAQ) disability score (Table). A high BMI was a risk factor for distal radius fractures, whereas a low BMI was a risk factor for hip fractures [3] (Table).

Table. Risk factors for fractures in Japanese patients with RA

Risk factors \ Fractures	Clinical vertebral	Any nonvertebral	Hip	Distal radius
Advanced age	Yes [1]	Yes [1, 2]	Yes [3]	Yes
Female gender	ND	ND	NS [3]	Yes
J-HAQ disability score	Yes [1,2]	Yes [1]	Yes [3]	NS
Body mass index (BMI)	NS [1,2]	NS [1,2]	Low BMI [3]	High BMI
Daily prednisolone dose	Yes [2]	NS [2]	NS [3]	Yes
History of orthopedic surgery for RA	Yes (any) [1]	Yes (TKR) [2]	Yes (TKR) [3]	ND

ND, not determined; NS, not significant; TKR, total knee replacement

References:
1) Furuya T, et al. J Rheumatol 34: 303–310, 2007; 2) Furuya T, et al. J Bone Miner Metab 26: 499–505, 2008; 3) Furuya T et al. Osteoporos Int 24: 1257–1265, 2013

Conclusion: Female gender, advanced age, high BMI, and high daily prednisolone dose appear to be associated with the occurrence of distal radius fractures in Japanese patients with RA. Risk factors appear to be different between distal radius, clinical vertebral, any nonvertebral, and hip fractures in Japanese patients with RA.

Determination Of Vitamin D Level Prior To The Initiation Of Bisphosphonate Therapy. Chris T. Derk, Ruchika Patel, Rennie L. Rhee, Yiu Tak Leung, R. Michelle Koolaee, Shiv Sehra and Ashwini Komarla. University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Vitamin D deficiency is under-recognized and in 18–35% of patients who do not respond to bisphosphonates, concurrent use of vitamin D 1000 units daily increases bone mineral density (BMD) at the lumbar spine and femoral neck, and reduces hip and non-vertebral fractures. Recent work has shown that patients with a serum vitamin D level at 30ng/ml or above are more likely to achieve improved BMD when treated with bisphosphonates. We undertook this study to identify how many of our patients have an adequate vitamin D level prior to starting and during bisphosphonate therapy.

Methods: We identified consecutive patients at our University based rheumatology clinic as well as our Veterans Affairs (VA) rheumatology clinic who were at the time on bisphosphonate therapy and conducted a retrospective chart review. Information on age, gender, reason for bisphosphonate use, type of bisphosphonate, vitamin D levels, date levels were checked, and date of bisphosphonate prescription were obtained. Vitamin D deficiency was defined at levels <30ng/ml. A two-tailed Fisher Exact Test was used for statistical analysis of categorical variables and students t-test for continuous variables.

Results: Sixty-eight patients on bisphosphonate therapy were identified from the two clinic sites out of which 24 were from the University clinic and 44 from the VA clinic. The VA patients were more likely to be men [91% vs. 21% (p=0.0001)] and older [68.5 + 10.8 vs. 58.8 + 11.4 (p=0.0008)]. Reasons for bisphosphonate therapy included chronic steroid use (N=30), osteoporosis (N=21), osteopenia and chronic steroids (N=5), osteoporosis and chronic steroids (N=4), Paget's disease (N=3) and hypogonadism (N=1). Patients were either on zolendronate (N=13), alendronate (N=53) or risedronate (N=2). Vitamin D deficiency was identified in 47% of patients (mean vitamin D level = 22.2 ng/ml + 12.4). Vitamin D level was not checked in 29% of patients prior to initiation of bisphosphonate therapy, and when subsequently tested 21% of them were deficient. While there was no statistical significance of vitamin D deficiency between the two clinics, vitamin D level was checked more frequently prior to bisphosphonate therapy at the VA as compared to the University clinic [83.3% vs 43.5% (p =0.002)].

Conclusion: We have shown that during bisphosphonate therapy 47% of our patients can be vitamin D deficient. Vitamin D was not checked prior to initiation of bisphosphonate therapy in 29% of our patients, this being more commonly the case at our University based clinic as compared to the VA based clinic, and from these patients who were subsequently tested 21% of them were deficient. This may help explain a lack of response to bisphosphonates in many of our patients, and deserves consideration.

Incidence Of and Risk Factors For Clinical Fractures In Patients With Systemic Lupus Erythematosus and Matched Controls: A Population-Based Study In The United Kingdom. Irene Bultink[1], Nicholas Harvey[2], Arief Lalmohamed[3], Cyrus Cooper[4], Willem Lems[1], Tjeerd Van Staa[5] and Frank de Vries[6]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]MRC Lifecourse Epidemiology Unit, Southampton, United Kingdom, [3]University Medical Center Utrecht, Utrecht, Netherlands, [4]University of Oxford; Southampton General Hospital, Southampton, United Kingdom, [5]Utrecht University, Utrecht, Netherlands, [6]Care and Public Health Research Institute, Maastricht, Netherlands.

Background/Purpose: Systemic lupus erythematosus (SLE) has been associated with an increased risk of low bone mineral density and fractures. However, data on absolute fracture risk and risk factors associated with clinical fractures are very scarce. The purpose of the present study was to estimate incidence rates of clinical fractures in patients with SLE and relative risks compared with matched controls, and to evaluate risk factors associated with fractures in SLE.

Methods: We conducted a population-based cohort study using the Clinical Practice Research Datalink (from 1987 to 2012). Each SLE patient (n=4343) was matched with up to 6 controls (n=21780) by age and sex. Fracture type was stratified according to WHO definitions into osteoporotic fracture (clinical spine, hip, forearm, or humerus) and non-osteoporotic fracture. Cox proportional hazards models were used to calculate relative rates (RR) of fracture, and time interaction terms to evaluate fracture timing patterns. Incidence rates of fractures in SLE patients, stratified by age, gender, type of fracture, disease duration, and therapy variables, were compared with fracture rates in controls.

Results: Mean age was 46.7 years. Follow-up duration was 6.4 years in SLE patients and 6.6 years in matched controls. Overall, SLE patients had an increased risk of any fracture compared to controls, after adjustment for confounders (adj RR 1.22; 95% confidence interval (CI) 1.05–1.42), and the risk further increased with a longer disease duration. Glucocorticoid (GC) use in the previous six months raised the risk of any fracture (adj RR 1.27; 95% CI 1.02–1.58), but was not further increased with higher cumulative GC exposure. A similar pattern was found for osteoporotic fracture, but did not reach statistical significance (adj RR 1.23; 95% CI 0.91–1.67). Use of antimalarials was not associated with an altered fracture risk. Cerebrovascular events, seizures, and (as expected) previous osteoporotic fractures were identified as significant predictors for any and osteoporotic fractures (Table 1).

Table 1. Risk of fracture within SLE patients (n=4343), stratified according to organ damage. (reference = no risk factor)

	Any fracture		Osteoporotic fracture	
	Events	Adj RR (95% CI)*	Events	Adj RR (95% CI)*
Cognitive impairment	5	1.67 (0.68–4.08)	4	2.25 (0.82–<6.16)
Seizures	34	**2.01 (1.41–2.86)**	22	**2.81 (1.80–4.40)**
Cerebrovascular event	55	**1.49 (1.12–2.00)**	35	**1.77 (1.22–2.57)**
Renal disease	54	1.30 (0.96–1.75)	32	1.35 (0.91–2.00)
Previous osteoporotic fracture	172	**4.26 (3.49–5.18)**	95	**3.85 (2.92–5.07)**
Diabetes	21	1.39 (0.89–2.17)	11	1.33 (0.72–2.45)
Malignancy	50	1.23 (0.91–1.68)	28	1.22 (0.81–1.84)

* Adjusted for: previous fracture, use of glucocorticoids, antimalarials, calcium/vitamin D supplements, benzodiazepines, and proton pump inhibitors in the previous 6 months.

Conclusion: SLE patients in the United Kingdom have an increased risk of clinical fractures compared to age- and sex-matched controls. GC use in the previous six months and longer disease duration are important factors associated with the increased fracture risk in SLE. In addition, special attention should be paid to lupus patients with neuropsychiatric organ damage or a history of osteoporotic fractures since these subgroups of patients are at high risk of the occurrence of (subsequent) fractures.

Phase 3 Fracture Trial Of Odanacatib For Osteoporosis – Baseline Characteristics and Study Design. Socrates Papapoulos[1], Henry G. Bone[2], David W. Dempster[3], John Eisman[4], Susan Greenspan[5], Michael McClung[6], Toshitaka Nakamura[7], Joseph Shih[8], Albert Leung[9], Arthur Santora[9], N. Verbruggen[10] and Antonio Lombardi[11]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Michigan Bone and Mineral Clinic, Detroit, MI, [3]Helen Hayes Hospital, West Haverstraw, NY, [4]The Garvan Institute of Medical Research, Sydney, Australia, [5]University of Pittsburgh, Pittsburgh, PA, [6]Oregon Osteoporosis Center, Portland, OR, [7]University of Occupational & Environmental Health, Kitakyushu, Japan, [8]Robert Wood Johnson Medical School, Piscataway, NJ, [9]Merck Sharp & Dohme Corp., Whitehouse Station, NJ, [10]MSD Belgium, Brussels, Belgium, [11]Merck Sharp and Dohme Corp, Whitehouse Station, NJ.

Background/Purpose: Odanacatib is a selective and reversible inhibitor of cathepsin K; a collagenase secreted by osteoclasts, and is currently being evaluated for the treatment of osteoporosis. In a Phase 2 study of postmenopausal women with low BMD, oral odanacatib 50 mg once-weekly increased

BMD progressively over 5 years by 11.9% at the lumbar spine and 9.8% at the femoral neck.

Methods: A randomized, double-blind, Phase 3 trial designed to examine osteoporotic fracture reduction and safety enrolled 16,227 postmenopausal osteoporotic women to receive odanacatib 50 mg or placebo once weekly (without regard to food). All participants also received vitamin D3 5600 IU weekly, and calcium supplements as needed. This event-driven trial was designed to be completed after 237 hip fractures had accrued, but allowed for early termination based on the results of 2 pre-planned interim analyses. The trial has three primary endpoints: morphometric vertebral fracture, non-vertebral fracture, and hip fracture. Controls are employed for elevation of the false-positive error rate due to multiple primary endpoints. Clinical fractures are adjudicated centrally via clinical history, radiology reports, and/or x-rays. Secondary endpoints include clinical vertebral fractures, BMD, height, bone turnover markers, and safety and tolerability. Collection of extensive baseline clinical information, pharmacogenomic data, archived serum and urine samples for all participants and trans-iliac bone biopsies from some participants will provide additional information.

Results: Postmenopausal women with (n=7,470) or without a prior radiographic vertebral fracture (n=8,757) were enrolled at 383 centers worldwide. At baseline they had a mean age of 73 years, were 57% Caucasian, and had mean BMD T-scores at lumbar spine −2.7, total hip −2.4, femoral neck −2.7, and trochanter −2.3.

Conclusion: This trial was designed to provide information on the efficacy and safety of once-weekly odanacatib 50 mg in reducing the risk of osteoporotic fractures in postmenopausal women with osteoporosis. A pre-planned interim analysis demonstrated anti-fracture efficacy and a favorable benefit/risk profile. Some safety findings were identified that will be followed in the pre-planned extension of the study. The trial is being extended as a placebo-controlled study with the same design for a minimum total period of observation of 5 years for each participant, in order to collect additional safety and efficacy data.

Rheumatoid Arthritis Characteristics and Fracture Risk: A Population-Based Study. Shreyasee Amin, Sherine E. Gabriel, Sara J. Achenbach, Elizabeth J. Atkinson, Terry M. Therneau and L. Joseph Melton III. Mayo Clinic, Rochester, MN.

Background/Purpose: Women and men with rheumatoid arthritis [RA] are at increased risk for a fragility fracture [fx]. To help better target those in need of fx prevention, we sought to determine which RA characteristics were associated with this increased risk for fragility fxs and specifically examined the effect of chronic glucocorticoid [GC] use.

Methods: We studied a population-based inception cohort (age ≥18 yrs), who fulfilled 1987 ACR criteria for RA between 1955–2007, and were followed until death or last available follow-up. RA characteristics (presence of rheumatoid factor [RF+], erosions, nodules, and other extra-articular manifestations), major joint surgeries, oral GC use, and all incident fxs after RA diagnosis were identified through a review of complete (inpatient and outpatient) community medical records. We studied fragility fxs, which excluded pathologic fxs and fxs resulting from severe trauma (e.g. motor vehicle accident). Chronic GC use was defined as >3 months at any dose. Using age-and sex-adjusted Andersen-Gill models, we examined the impact of RA characteristics on the subsequent risk for fxs. Most risk factors were modeled as time-dependent covariates. We performed similar analyses stratified by sex and then chronic GC use.

Results: In 1171 RA subjects, (822 women [66% RF+] and 349 men [69% RF+]; mean [± SD] age at RA diagnosis: 56 ± 16 years and 58 ± 14 years, respectively), followed for 15,195 person-years, there were 828 fragility fxs in 328 women and 253 fragility fxs in 112 men since their RA diagnosis. Over follow-up, about 1/3 of women and men each had nodules; a similar proportion developed erosions; ~12% each had other extra-articular manifestations; and 29% underwent major joint surgery. There were 424 (52%) women and 209 (60%) men who were chronic GC users; the remainder either never used GC for RA (70%) or had only limited GC exposure. We found that RF+, erosions, nodules, extra-articular manifestations, major joint surgeries and chronic GC use were all associated with an increased risk for fragility fxs (see Table). Extra-articular manifestations and major joint surgeries were associated with an increased risk for fxs regardless of GC exposure (data not shown). However, the other RA characteristics tended to be associated with increased fx risk only in chronic CG users, but not in those with no/limited GC use (data not shown).

	Hazard Ratio (95% CI) Predicting Fragility Fxs		
RA Characteristic	**All†**	**Women‡**	**Men‡**
RF+	1.4 (1.1–1.7)	1.3 (0.99–1.7)	1.8 (1.2–2.9)
Nodules*	1.6 (1.2–1.9)	1.5 (1.2–2.0)	1.7 (1.1–2.7)
Erosions*	1.4 (1.1–1.8)	1.4 (1.0–1.8)	1.3 (0.8–2.1)
Extra-articular*	1.6 (1.2–2.1)	1.4 (0.99–2.0)	2.2 (1.3–3.8)
Major joint surgery*	1.7 (1.3–2.1)	1.7 (1.3–2.2)	1.5 (0.9–2.5)
GC use >3 months*	1.9 (1.6–2.4)	2.0 (1.6–2.5)	1.7 (1.1–2.5)

† Models adjusted for age and sex; ‡Models adjusted for age
** RA characteristics modeled as time-dependent covariates*

Conclusion: RA characteristics that are often associated with greater disease severity are also associated with increased fx risk. However, only extra-articular manifestations and major joint surgeries were associated with increased fx risk regardless of chronic GC use. Although further work is required to understand their interaction on fx risk, some RA characteristics may simply be indicators of chronic GC use; on the other hand, others may either better represent greater disease activity or reflect greater frailty and/or fall risk.

The Effects Of Hyperthyroidism On Bone Mineral Density At Different Sites—An Observational Case-Control Study. Christopher Varley[1], Alexander Oldroyd[1] and Marwan Bukhari[2]. [1]Lancaster University, Lancaster, United Kingdom, [2]Royal Lancaster Infirmary, Lancaster, United Kingdom.

Background/Purpose: Hyperthyroidism has been described as a risk factor for poor bone health.[1, 2] The FRAX™ tool has been used to identify the ten year risk of fracture by utilising hip bone mineral density (BMD) only. If hyperthyroidism is predominantly associated with bone loss in the lumbar spine, the fracture risk in these patients may have been underestimated. No previous study has examined the differential amount of bone loss in hyperthyroidism. This study will determine the extent and site of bone loss in patients with primary hyperthyroidism compared to controls, looking at lumbar spine and femoral neck BMD.

Methods: Using a nested case-control approach, a cohort of patients referred between 2004 and 2011 for a dual-energy x-ray absorptiometry scan with hyperthyroidism as their main risk factor was identified. These were then age and gender matched with controls referred in the same time period with no indication for scanning. Sites of bone loss were ascertained by comparing the BMD in two areas (L1-L4 vertebrae and the left femoral neck) between cases and controls, using students T-test. A logistic model was then fitted to determine the odds of having a significantly reduced BMD with a diagnosis of hyperthyroidism. The fit of the model was tested using receiver operating characteristic (ROC) curves.

Results: 232 patients with current hyperthyroidism were identified, comprising 184 females (79.7%), with a mean age of 62 (SD 10.7). 232 controls were age and sex matched. Simple comparisons between cases and controls were identified using the students t-test; mean difference between L1-L4 BMD was 0.085 g/cm^2 (95% CI 0.051– 0.119) and femoral neck BMD difference was 0.057 g/cm^2(95% CI 0.031– 0.083); both had a p-value ≤0.001. The odds of having a significantly reduced BMD was found to be greater in the femoral neck, with an odds ratio of 19.4 for femoral neck BMD (95% CI 4.8–79.0) compared with 12.2 for L1-L4 BMD (95% CI 4.3–34.8). When the area under the ROC curve was calculated for both L1-L4 and femoral neck BMD, the result was a similar sensitivity and specificity, with an area under the ROC curve of 0.63 for L1-L4 BMD, and an area of 0.62 for the femoral neck.

Conclusion: Both hip BMD and lumbar spine BMD are significantly reduced in thyrotoxic patients- while BMD loss was found to be greater in the

femoral neck than in the lumbar spine, this was only marginally more. Further analysis looking at whether this risk factor has more implications on fracture risk than those used in the FRAX™ tool is needed.

Analysis Of Corelation Of Bone Mineral Density Of Spine With Other Sites In Ankylosing Spondylitis As Compared To Rheumatoid Arthritis and Control Populations. Janie Bruce[1] and Vikas Majithia[2]. [1]University of Mississippi School of Medicine, Jackson, MS, [2]G.V. "Sonny" Montogomery VA Medical Center, Jackson, MS.

Background/Purpose: Bone mineral density (BMD) at the 3 central sites usually correlates with each other but the effect of disease states on this correlation is not known. Ankylosing spondylitis (AS) with spinal involvement may increase BMD at spine but not at hip. Alternatively, RA or osteoporosis may not have any effect the on it. These aspects have not been well quantified and this study aims to assess the correlation amongst patients with the three disorders.

Methods: Retrospective chart review of patients who had been seen in rheumatology clinics at VA medical center with diagnosis of AS, RA or OP and had a DEXA scan done was performed. Data including age, race, gender, BMI, BMD with T-scores was tabulated. Patients with BMD at all 3 sites-lumbar spine, hip and arm were included in analysis. Correlation amongst the amongst the T-scores at three sites was calculated using pearson coefficient.

Results: A total of 350, patient charts were reviewed. After excluding patients with missing data, 241 were included in analysis. There were 16 patients with AS (Mean age = 63 years, Average BMI= 28.81, all males), 117 patients with RA (Mean age = 63.92 years, Average BMI= 28.38, 104 males and 13 females), and 98 patients with osteoporosis (Mean age = 70.42 years, Average BMI= 25.17, 93 males and 5 females). The correlation between the total hip and femoral neck was strong in all three groups. We found moderate correlation among the t-scores between spine – total hip and forearm – total hip t-scores in both AS and RA. The correlation was poor at these 2 sites in patients with osteoporosis. The spine BMD was found to be lower than other sites in 1/16 (6.25%) of AS and 5/117 (4.3%) of RA patients as compared to 16/98 (16.4%) of patients with OP, where it was also likely to influence treatment decision. Also additional forearm testing did not yield a better result in all 3 groups. These results are summarized in the table 1.

Table 1. Correlation among BMD at 3 sites (Hip, Lumbar spine and forearm) in patients with AS, RA and OP.

Diagnosis	Site	r	r^2	p-value
Ankylosing Spondylitis (n=16)	Lumbar spine- total hip	0.5552	0.3083	0.02
	Total hip- femoral neck	0.93	0.865	<0.0001
	Forearm- total hip	0.5995	0.3594	0.01
Rheumatoid Arthritis (n=117)	Lumbar spine- total hip	0.643	0.4134	<0.0001
	Total hip- femoral neck	0.9453	0.8936	<0.0001
	Forearm- total hip	0.618	0.3819	<0.0001
Osteoporosis (n=98)	Lumbar spine- total hip	0.3429	0.1176	0.0005
	Total hip- femoral neck	0.8248	0.6802	<0.0001
	Forearm- total hip	0.3412	0.1164	0.0005

Conclusion: The results show that there was correlation among the three sites of BMD in the whole cohort and no significant difference was found among the three disorders. Having AS where spine is frequently involved did not seem to impact the correlation coefficient when compared to RA and OP patients. This suggests that spinal involvement in AS may not have any significant impact on the BMD at LS spine in majority of patients. The correlation was lowest among the patients with osteoporosis who were older than the other 2 groups and osteophyte formation may have influenced the BMD at spine. Interestingly the BMD at spine was most useful in this group impacting the treatment decisions more than other 2. The results suggest that evaluation of BMD at both spine and hip is important regardless of the underlying disorder including AS and should be done collectively. On the other hand, forearm BMD evaluation was not useful in majority.

Disclosure: J. Bruce, None; **V. Majithia**, None.

Monitoring Osteoporosis Therapy: Can FRAX Help To Assess Success Or Failure In Achieving Treatment Goals? Yasser El Miedany[1], Ahmed Elyassaki[2], Sally Youssef[2], Annie Nasr[2], Mohammed Hegazi[3] and Ihab Ahmed[4]. [1]Medway Hospital, Gillingham, United Kingdom, [2]Ain Shams University, Cairo, Egypt, [3]Al Adan Hospital, Kuwait, Kuwait, [4]Cairo University, Cairo, Egypt.

Background/Purpose: 1. To determine whether FRAX can be used for monitoring patients receiving osteoporosis therapy and its clinical implications 2. Study the correlation between the post-treatment FRAX and the incidence of fractures.

Methods: A total of 1026 women (age ≥ 50 years) diagnosed to have osteoporosis who had baseline risk factors assessment and BMD testing were screened. All the patients were treated according to guidelines. 579 women who were adherent to the prescribed osteoporosis therapy, had FRAX probabilities calculated which were included in this study. All the patients had a follow-up DXA scan at 2 and 5-years of osteoporosis therapy. At both times, re-assessment of the risk factors was carried out and FRAX probabilities were calculated. A subgroup of patients who did not achieve an improvement in their neck of the femur BMD or who sustained a fracture in the first 2-years, had their osteoporosis therapy changed. BMD assessment and FRAX calculation were carried out 3-years after starting the new osteoporosis therapy. The patient subgroup who responded well to therapy and did not sustain a new low trauma fracture in the first 2 years, continued their therapy and had another reassessment in 3-years.

Results: During mean 5.3 years of observation, 16.9% individuals sustained incident major osteoporotic fractures, of which 48% were hip fractures. There were also 4.3 % deaths and 2.7% changed their address. 26% were excluded for non-adherence to therapy. A total of 579 women were included in this work. Femoral neck BMD strongly predicted major osteoporotic fractures and hip fractures, and this was unaffected by medication use ($P<0.05$). Assessment for major osteoporotic fractures and hip fractures showed significant negative correlation with BMD at the neck of the femur at 2-years of therapy ($R= -0.218$ and -0.445 respectively), as well as at 5-years ($R= -0.212$ and -0.220 respectively). At both 2 years and 5 years of therapy, there was significant correlation between 10-year fracture probability (both major osteoporosis and hip fractures) and the fracture incidence ($P< 0.001$). When major fracture probability was assessed with BMD, there was a significant ($P< 0.05$) difference between the responders and non-responders to osteoporosis therapy.

Conclusion: This work suggests that the FRAX tool can be used to predict fracture probability in women currently or previously treated for osteoporosis. Osteoporosis therapy does not invalidate fracture predictions and FRAX may still have value for guiding the need for continued treatment or treatment withdrawal. There are many differences between subjects in clinical trials and patients being treated in clinical practice. Thus, although defining a clinical practice patient as a "nonresponder" or "suboptimal responder" to treatment is problematic, a pragmatic approach would be to consider evaluation for contributing factors and possible changes in therapy in patients who have a statistically significant decrease in BMD, or have a fracture. Further monitoring of osteoporosis therapy, is necessary and helps the treating clinician to identify early the non-responders to therapy.

Prednisone Has No Effect On Odanacatib Pharmacokinetics In Healthy Subjects. Gene Marcantonio[1], Chengcheng Liu[1], Stefan Zajic[2], Chantal Mahon[1], David Hreniuk[1], Anish Mehta[3], Kate Mostoller[1], Denise Morris[4], Hongwei Xue[4] and S. Aubrey Stoch[1]. [1]Merck Sharp & Dohme Corp., Whitehouse Station, NJ, [2]Merck Sharp & Dohme Corp, Whitehouse Station, NJ, [3]Merck Sharp & Dohme Corp., Whitehouse Station, NJ, [4]Covance, Madison, WI.

Background/Purpose: We evaluated the effect of prednisone, a glucocorticoid believed to induce the CYP P450 enzyme, on the pharmacokinetics of odanacatib, a novel Cathepsin K inhibitor that is in development for the treatment of osteoporosis.

Methods: This was an open-label, 2-period crossover study in healthy male subjects. In Period 1, midazolam 2 mg was administered on Day −1 followed by a single oral dose of odanacatib 50 mg on Day 1. There were at least 14 days from the last pharmacokinetic sampling on Day 15 of Period 1

to the Day 1 dosing in Period 2. In Period 2, subjects were administered a single oral dose of prednisone 10 mg qd on Days 1 through 28. On Day 14 of Period 2, subjects were co-administered prednisone 10 mg and odanacatib 50 mg. On days 1 and 28 of Period 2, subjects were co-administered prednisone 10 mg and midazolam 2 mg. On Days 42 and 56 of Period 2, subjects were administered a single oral dose of midazolam 2 mg. The plasma pharmacokinetic parameters ($AUC_{0-\infty}$, C_{max}, T_{max}, and apparent terminal $t_{½}$) were assessed based on blood samples that were collected at predose and various time points through 336 hours following odanacatib administration on Day 1/Period 1, as well as predose on Day 1, predose on Day 14, and various time points through 336 hours following odanacatib administration on Day 14/Period 2. Safety and tolerability were assessed by physical examination, evaluation of vital signs and electrocardiogram (ECG) measurements, and monitoring adverse experiences (AE) throughout the study.

Results: There were 15 subjects enrolled. Mean age was 31 years and a mean BMI was 25.8. The odanacatib $AUC_{0-\infty}$ GMR (90% CI) [odanacatib + prednisone/odanacatib alone] was 1.06 (0.96, 1.17). The estimated C_{max} GMR (90% CI) was 0.96 (0.84, 1.10). The median T_{max} value remained 4 hours for odanacatib alone and with co-administration of prednisone and the harmonic mean (jack-knife standard deviation) for apparent terminal $t_{½}$ was 74.6 (17.9) for odanacatib alone and 66.8 (25.1) for odanacatib + prednisone. There were no serious AEs or AEs leading to discontinuation.

Conclusion: Prednisone had no effect on odanacatib pharmacokinetics when co-administered with odanacatib.

1225

FRAX 10-Year Fracture Risk In Women With a Fracture Of The Distal Forearm: Agreement Between Assessments With and Without Bone Mineral Density and Influence Of Measurement Side In Individual Patients. Emilie Egsmose[1], Mette Birkvig[2], Thora Buhl[2] and Ole Rintek Madsen[2]. [1]Copenhagen University Hospital Hvidovre, Copenhagen, Denmark, [2]Copenhagen University Hospital Gentofte, Copenhagen, Denmark.

Background/Purpose: The FRAX® tool has been developed by WHO to evaluate fracture (Fx) risk of patients. It is based on individual patient models that integrate the risks associated with clinical risk factors as well as bone mineral density (BMD) at the femoral neck (FN). The output is a 10-year probability of hip Fx and of a major osteoporotic Fx (clinical spine, forearm, hip or shoulder Fx). The tool allows calculation of Fx risk with and without (±) BMD. Assessment of Fx risk in the individual patient without BMD may be an advantage in the busy emergency room dealing with patients with distal forearm Fxs. Differences between Fx risk assessed ±BMD has previously been evaluated on group level, but not on the individual patient level. There is no recommendation on which side to measure BMD. The purpose was to examine the agreement between the FRAX 10-year Fx risk calculated ±BMD in patients with a recent Fx of the distal forearm. Furthermore, to examine the influence of measurement side for Fx risk assessment.

Methods: BMD of the left and right FN and of the spine was measured in 140 Danish women with a recent Fx of the distal forearm using a Lunar DXA-scanner. Only patients eligible for bilateral hip measurements were included. None of the patients were or had been on antiresorptives or anabolic treatment. Information of clinical risk factors were collected by questionnairing the patients. Using the FRAX tool for Denmark, the 10-year risk of a major Fx and of a hip Fx was calculated ±BMD with BMD from both measurement sides. Student's t-test was used for comparison of paired Fx risk assessments. The Bland-Altman method was used to examine agreement between the risk assessments. Differences between pairs of risk assessments were calculated. Agreement on the group level was expressed as the bias (mean value of individual differences) and on the individual level as the 95 % limits of agreement (LoA).

Results: Mean age, height and weight were 66±8 (range 51–85) years, 163±14 cm and 68±13 kg. Mean BMD and T-score of the left FN were 0.81±0.15 g/cm2 and −1.6±0.9 and of the spine 1.0±0.2 g/cm2 and −1.3±1.4. Fourteen (10%) patients had a parent with hip Fx, 28 (20%) were smokers, 4 (2.8%) had 3 or more alcohol units per day, 15 (11%) had conditions strongly associated with osteoporosis (predominantly early menopause), 1 (0.7%) had RA and 2 (1.4%) were on steroids. The 10-year risk of hip Fx and of a major Fx based on left hip BMD was 6.9±7.7% and 22.7±10.2%, respectively. The bias of hip Fx risk assessed without BMD was 4.2 (LoA −10.8; 19.2)% ($p < 0.0001$) and of a major Fx 5.3 (LoA −11.7; 22.3)% ($p < 0.0001$). The bias of the risk of a hip and of a major Fx assessed with the highest vs. the lowest BMD-value was −1.7 (LoA −6.1; 2.7)% ($p < 0.0001$) and −2.4 (LoA −7.4; 2.6)% ($p < 0.0001$), respectively.

Conclusion: The FRAX 10-year Fx risk calculated without BMD was averagely increased by 4–5% compared to assessment with BMD. In the individual patient, differences between risk assessments ±BMD approached 22%. Thus, Fx risk assessment without BMD should be used with caution when counselling individual patients with forearm fractures. The side of BMD measurement may also influence the risk assessment significantly, especially in individual patients.

Adherence With Current Osteoporosis Treatment Guidelines Among Rheumatologists Caring For Patients With Rheumatoid Arthritis Using Items From The Fracture Risk Assessment Tool Score. Jennifer Watt[1], Andrew E. Thompson[2], Nicole G. H. Le Riche[3] and Janet E. Pope[4]. [1]University of Western Ontario, London, ON, [2]St. Josephs Health Ctr, London, ON, [3]St. Joseph's Hospital, London, ON, [4]Schulich School of Medicine and Dentistry, Western University, London, ON.

Background/Purpose: To assess whether the Fracture Risk Assessment Tool (FRAX) score in patients with RA correlates with likelihood of osteoporosis (OP) prescription including drug treatment, calcium and vitamin D.

Methods: Charts of serial RA outpatients (age>40 with a calculable BMI) were reviewed to determine the 10-year risk of major osteoporotic fracture with the FRAX. Use of calcium, vitamin D, OP treatment, and a patient's BMD results were recorded. Odds ratios (OR) were calculated to determine if a higher FRAX score increased the likelihood of OP prescribing.

Results: 10-year risk of fracture was high in 92 (12.5%), moderate in 216 (29.3%), and low in 429 (58.2%). No patients had a FRAX score calculated in their records. Compared to those at low risk, patients identified as high risk were more likely to receive OP treatment (OR 16.31, 95% CI 9.45–28.13, $p<0.0001$); calcium (OR 3.89, 95% CI 2.43–6.25, $p<0.0001$); vitamin D (OR 3.46, 95% CI 2.12–5.64, $p<0.0001$); and have a BMD performed (OR 10.22, 95% CI 5.50–18.96, $p<0.0001$). Among 137 patients currently taking prednisone, 44.5% were prescribed a bisphosphonate. BMD tests were performed in 415 (56.3%), but only 228 were recorded on the specialists' charts.

Conclusion: Higher risk patients are more likely to have a BMD and receive treatment, as indicated by the clear dose response seen along the 10-year fracture risk from low to medium to high-risk groups. Although rheumatologists didn't calculate the FRAX score, they recognize important clinical risk factors included in the FRAX tool.

Trabecular BONE Score In Rheumatoid Arthritis and Ankylosing Spondylitis and Changes During LONG TERM Treatment With TNFA Blocking Agents. Eric Toussirot[1], Laurent Mourot[2], Daniel Wendling[3], Gilles Dumoulin[4] and CIC BT[5]. [1]CIC Biotherapy 506 and Rheumatology and EA 4266 Pathogens and Inflammation, Besançon, France, [2]University of Franche Comté, Besançon, France, [3]University Hospital, Besancon, France, [4]Department of Endocrine and Metabolic Biochemistry, Besançon, France, [5]University Hospital, Besançon, France.

Background/Purpose: Inflammatory rheumatic diseases such as rheumatoid arthritis (RA) and ankylosing spondylitis (AS) are associated with osteoporosis. Bone mass in RA and AS has been well evaluated by measuring areal bone mineral density (BMD) with DXA. Trabecular bone score (TBS) is a new method evaluating bone microarchitecture by assessing pixel gray-level variations in DXA images from lumbar spine.

Objectives: In a case-control study, TBS was evaluated in patients with RA or AS and healthy controls (HC) and the results were compared to lumbar spine (LS) BMD measurements. Changes in LS and hip BMD and TBS score after initiating and during long term anti-TNFa treatment were also examined in a prospective study.

Methods: In the case control study, 30 patients with RA (ACR criteria, 19 F; 12 post menopausal women; age [mean ± SD]: 56.9 ± 9.7 yrs; disease duration: 11.7 ± 8.8 yrs; 26 under low dosage corticosteroids [CTC]) and 30 patients with AS (modified NY criteria, 27 M, age 43.8 ± 13.4 yrs; disease duration: 13.0 ± 11.1 yrs; no CTC) were evaluated and compared to 50 HC (29 F, 12 post menopausal women, age: 46.6 ± 11.1 yrs). L2-L4 BMD and hip BMD were measured using DXA (Lunar GE iDXA). TBS was calculated from L2-L4 BMD images (TBS insight®, Med-Imaps).

- In the prospective study, a group of 20 patients requiring TNFa blocking agent (6 F; 12 AS, [age: 40.7 ± 16.1 yrs] and 8 RA [age 60.5 ± 9.7 yrs]; disease duration: 9.6 ± 9.8 yrs; 9 under low dose CTC) were followed for 2 years. LS BMD, hip BMD and TBS score were measured at baseline and after 6, 12 and 24 months of treatment.

Results: Case control study: RA patients had lower BMD and T score at the hip ($p < 0.005$) compared to HC. Hip T score in patients with AS was also decreased ($p = 0.02$). LS BMD did not differ between patients and HC. TBS was lower in RA and AS compared to HC: 1.242 ± 0.16 and 1.282 ± 0.13 *vs* 1.365 ± 0.14, respectively ($p= 0.005$).

- Prospective study: under anti-TNFa, LS and hip BMD at M24 increased (+ 6.3% and + 2.4% respectively), with significant changes at the spine ($p< 0.001$). In the whole group, TBS score slightly increased from baseline to M12 (1,304 ± 0.13 to 1.32 ± 0.09) without significance, then returning to initial values at M24 (1.309 ± 0.09). However, in patients with RA, TBS score decreased (baseline to M24: 1.362 ± 0.048 to 1.308 ± 0.07) ($p = 0.032$) while in patients with AS, TBS progressively increased (1.257 ± 0.15 vs 1.309 ± 0.11; NS).

Conclusion: TBS score is decreased in inflammatory rheumatic diseases, especially in RA, suggesting alterations of bone micro architecture. Long term anti TNFa treatment is associated with a positive effect on (LS) bone mass but no major changes in TBS score. Surprisingly and on the contrary of AS, TBS score decreased in RA treated by TNFa blocking agents, suggesting different influences and responses of the bone to this drug's class.

A Before and After Comparison Of The Effects Of Monitoring On a Quality Indicator For glucocorticoid–induced Osteoporosis In a Japanese Hospital. Yasuhiro Suyama, Mitsumasa Kishimoto, Chisun Min, Yoichiro Haji, Yuri Ohara, Ryo Rokutanda, Hisanori Shimizu, Ken-ichi Yamaguchi, Yukio Matsui and Masato Okada. St. Luke's International Hospital, Tokyo, Japan.

Background/Purpose: Glucocorticoid-induced osteoporosis (GIOP) is one of the most devastating side effects of glucocorticoid use, leading to a substantially increased risk of fracture and disability. Prevention is considered to be more critical than treatment, especially in patients with known risk factors. In rheumatology, the use of quality indicators (QI) has been receiving increasing attention; the American College of Rheumatology published recommendations in 2010 for the prevention and treatment of GIOP, recommending that patients on as low as 7.5 mg daily of prednisolone or equivalent for more than 3 months be treated with anti-osteoporosis medications. However, few studies have reported on QI implementation and interventions to improve its adherence in the clinical setting. Herein, we assess the efficacy of implementation of a QI initiative to prevent GIOP.

Methods: We reviewed records of all patients prescribed prednisolone as low as 7.5 mg daily or equivalent for more than 3 months in our institution. To evaluate adherence to population-specific preventive care for GIOP, we divided patients into 3 groups based on gender and age:, men recommended to take a vitamin D analogue (Group A); women <50 years old recommended to take a vitamin D analogue (Group B); and women ≥50 years old recommended to take a bisphosphonate with vitamin D analogue (Group C). Clinical data from 2010 to 2012 were collected to compare the proportion of patients receiving appropriate therapy in each group before and after initiation of QI monitoring, implemented in 2011. Furthermore, prescription rates of preventive therapy were assessed by department in subanalysis.

Results: We identified 1800 eligible patients (586 in Group A, 540 in Group B, and 674 in Group C) in 2010; 2125 patients (760 in Group A, 643 in Group B and 722 in Group C) in 2011; and 2446 patients (851 in Group A, 851 in Group B and 744 in Group C) in 2012. Analysis revealed significant increases of targeted anti-osteoporosis treatment per QI standards after implementation of QI monitoring. Pooled rates of compliance with recommendations improved from 46.8% in 2010 to 52.7% in 2011 and 55.21% in 2012 ($p<0.001$). Appropriate preventive therapy increased for Group A from 43.34% in 2010 to 57.50% in 2011 and 58.87% in 2012; Group B increased from 63.9% in 2010 to 66.7% in 2011 and 68.2% in 2012; and Group C increased from 36.2% in 2010 to 35.0% in 2011 and 39.5% in 2012. Subanalysis by department demonstrated QI adherance to GIOP guidelines in 2012 as follows: nephrology (81.7%), rheumatology (69.9%), gastroenterology (66.3%), dermatology (60.8%), pulmonology (54.5%), otorhinolaryngology (52.6%), endocrinology (51.5%), orthopedic surgery (41.8%), ophthalmology (31.1%), hematology (29.5%), and neurology (10.4%).

Conclusion: Implementation of a QI for GIOP significantly improves adherence to 2010 ACR GIOP guidelines for appropriate population-specific, preventive therapy. Our results also indicate that, despite institution-wide announcements of QI goals, a substantial information gap may exist between the various clinical subspecialties involved in GIOP patient care.

Analysis Of Fracture Risk Assessment Score (FRAX) Correlation With Bone Mineral Density (BMD) In Males and Post-Menopausal Females. Vikas Majithia[1] and Khush Aujla[2]. [1]University of Mississippi Medical Center, Jackson, MS, [2]University of Mississippi School of Medicine, Jackson, MS.

Background/Purpose: Fracture Risk Assessment Tool (FRAX) is a useful clinical tool for assessment of fracture risk and a major development in evaluation of osteoporosis. Its external validity is not established. This study was done to assess how well FRAX correlates with BMD in postmenopausal females and males of White and African-American ethnicity and calculate its test characteristics in a cohort of patients undergoing BMD.

Methods: Retrospective chart review of 1026 postmenopausal women and 2 men who underwent DEXA scan performed at UMC from 2005–2009. Data regarding demographics, BMD, FRAX and other relevant variables were abstracted, tabulated and analyzed using Statistical software. standard stratification was used. Scatter plot, were calculated.

Results: In males, FRAX demonstrates a low agreement with the BMD with Kappa=0.496, Low Sensitivity and Negative Predictive Value (NPV). Agreement was low/poor (K=0.167) in African-Americans (AA). In postmenopausal females, FRAX demonstrates a moderate agreement with the BMD with Kappa=0.647, adequate Sensitivity and NPV. It had good agreement (K= 0.847) in whites and low/poor agreement (K=0.313) in African-Americans.

It had adequate/good test characteristics in whites but poor sensitivity and NPV in AA males and females. and 2 these results in detail. These highlight the lack of correlation with a gold standard bone mass measurement and raise doubts on the validity of using FRAX in males as well as in AA PM females.

Table 1. CSP.

	Normal Bone Density (T-score >−1)	Low Bone Density (T-score <−1)	Osteoporosis (T-score <−2.5)	p-value
MALES N=237	N=62	N= 114	N=61	
Mean Age (years)	**60.06**	**62.97**	**59.42**	**p-NS**
Whites	**63.48**	**65.79**	**63.53**	
African-Americans	**50.94**	**60.59**	**54.70**	
Mean BMI (Kg/m^2)	**31.53***	**27.28***	**26.03***	***p< 0.001**
Whites	**30.93**	**26.97**	**26.12**	
African-Americans	**33.15**	**27.12**	**25.92**	
FEMALES N=1026	N=229	N=552	N=245	
Mean Age (years)	**64.43**	**63.32**	**62.84**	**p-NS**
Whites	**64.23**	**63.09**	**62.63**	
African-Americans	**64.64**	**63.55**	**63.06**	
Mean BMI (Kg/m^2)	**34.69***	**28.79***	**27.39***	***p< 0.001**
Whites	**32.01**	**26.95**	**25.44**	
African-Americans	**37.37**	**30.63**	**29.34**	

Table 2. A/TC.

	Overall	Whites	African-Americans
MALES (N= 112)			
Sensitivity	54.55	78.13	21.74
Specificity	94.74	93.18	100
Positive Predictive Value (PPV)	90.91	89.29	100
Negative Predictive Value (NPV)	68.35	85.42	41.94
Agreement (Kappa)	0.496 (CI=0.335–0.658)	0.725 (CI=0.567–0.884)	0.167 (CI=0–0.439)
PM-FEMALES (N= 469)			
Sensitivity	67.75	89.61	30.76
Specificity	97.37	95.40	100
Positive Predictive Value (PPV)	96.50	95.80	100
Negative Predictive Value (NPV)	73.84	88.80	41.94
Agreement (Kappa)	0.647 (CI=0.576–0.713)	0.8467 (CI=0.785–0.908)	0.313 (CI=0.175–0.451)

Conclusion: Use of FRAX to analyze fracture risk in US males and AA postmenopausal females may not lead to valid results. FRAX analysis did not have good agreement with BMD in these populations in this analysis. The lack of agreement was significantly worse in African-Americans as compared to Whites. These results suggest the need to do further population studies in larger cohorts of these subset populations to assess its external validity.

The Quality Of Life and Resource Use Related To Hip Fractures Based On Data From The International Costs and Utilities Related To Osteoporotic Fractures Study. Moa Ivergård[1], Viktor Wintzell[1], László B Tankó[2], Victoria Barghout[2], Axel Svedbom[1], Vidmantas Alekna[3], Maria Luisa Bianchi[4], Patricia Clark[5], Manuel Díaz Curiel[6], Hans Peter Dimai[7], Mikk Jürisson[8], Olga Lesnyak[9], Eugene McCloskey[10], Kerrie M Sanders[11], Thierry Thomas[12], Fredrik Borgström[13] and John A Kanis[14]. [1]OptumInsight, Stockholm, Sweden, [2]Novartis Pharma AG, Basel, Switzerland, [3]Vilnius University, Faculty of Medicine, Vilnius, Lithuania, [4]Bone Metabolism Unit, Istituto Auxologico Italiano IRCCS, Milan, Italy, [5]Clinical Epidemiology Unit, Hospital Infantil Federico Gómez and Faculty of Medicine UNAM, Mexico City, Mexico, [6]Catedra de Enfermedades Metabolicas Óseas, Universidad Autonoma, Madrid, Spain, [7]Department of Internal Medicine, Division of Endocrinology and Metabolism, Medical University of Graz, Graz, Austria, [8]Faculty of Medicine, Tartu University, Tartu, Estonia, [9]Ural State Medical Academy, Yekaterinburg, Russia, [10]Academic Unit of Bone Metabolism, Metabolic Bone Centre, University of Sheffield, Sheffield, United Kingdom, [11]Department of Medicine, NorthWest Academic Centre, The University of Melbourne, Melbourne, Australia, [12]INSERM U1059, CHU-St-Etienne, Saint Etienne, France, [13]LIME/MMC, Karolinska Institutet, Stockholm, Sweden, [14]WHO Collaborating Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom.

Background/Purpose: The International Costs and Utilities Related to Osteoporotic fractures Study (ICUROS) is an ongoing 18 months prospective observational study with the objective of estimating resource use and health related quality of life (HRQoL) related to osteoporotic fractures. This study aims to describe the resource utilization for hip fractures pooled from 10 countries (Australia, Austria, Estonia, France, Italy, Lithuania, Mexico, Russia, Spain and the UK).

Methods: We studied 2,407 patients with low-energy hip fracture sustained from 2007 to 2012. For the purpose of the present study patients had to be <50 years, live in their own home prior to the fracture, and have had the first study interview within 2 weeks after fracture. Data were collected through patient interviews and review of medical records in four phases (at baseline, Month 4, 12, and 18). Key data included patient reported HRQoL (EQ-5D), and resource utilization due to the fracture. HRQoL before fracture was collected immediately after fracture. Patients with complete data at each follow-up were included in the analyses. The EQ-5D is a HRQoL instrument consisting five dimensions (mobility, self-care, usual activities, pain/discomfort and anxiety/depression) with 243 possible response combinations. These health states can be translated into health utilities on a unison scale using UK population based preference values (range −0.59 to 1; 1 for full health, 0 for dead, below 0 for health states worse than dead) [1].

Results: There were 1795, 1435, 1256 patients available for analysis at the 4, 12 and 18 months follow-up, respectively. The mean age (±SD) at fracture was 77±10 years and 79% were women. Emergency or traumatology departments were the first point of contact with the healthcare system for 89% of patients. 96% of patients were hospitalized and the mean hospital length of stay due to the fracture (±SD) was 17.2±20.4 days. During the first four months after fracture, the mean number of physician, nurse and physiotherapy visits related to the fracture were estimated at 2.8±3.1, 2.4±9.6, and 8.2±13 respectively. During the same time period, 65% of patients used analgesics, 41% calcium/vitamin D, and 27% pharmacological interventions for osteoporosis. The mean utility was 0.75±0.28 before fracture, −0.13±0.37 after fracture, 0.48±0.39 at Month 4, 0.58±0.37 at Month 12, and 0.66±0.36 at Month 18 following the fracture.

Conclusion: Hip fractures were associated with severe immediate loss in HRQoL. The mean health utility was estimated at −0.13 directly after fracture, which is worse than death on the 0 (death) to 1 (full health) scale. Whereas patients gradually recovered, the mean health utility estimate of 0.66 at 18 months after fracture (compared to 0.75 prior to fracture) show that, on average, hip fractures result in substantial and persistent long-term loss in HRQoL. In addition, the mean hospital length of stay of 17.2 days suggests that hip fractures are associated with substantial costs to society.

Osteoporosis In Rheumatoid Arthritis – Still a Threat In The Biologic Era? Glenn Haugeberg[1], Torhild Garen[2], Hege Sommerseth[3], Anne Prøven[3] and Knut Helgetveit[3]. [1]Hospital of Southern Norway Trust, Kristiansand, Norway, [2]Oslo University Hospital Rikshospitalet, Oslo, Norway, [3]Martina Hansens Hospital, Bærum, Norway.

Background/Purpose: Osteoporosis is a well-known extra articular manifestation in rheumatoid arthritis (RA). In RA biologic disease modifying anti rheumatic drugs (DMARDs) has been shown to be superior to synthetic DMARDs to reduce bone destruction including generalized bone loss. Our aim was primarily to study short- and long term changes in bone mineral density (BMD) at hip and lumbar spine in patients with early RA followed in the biologic treatment era.

Methods: RA patients with early disease diagnosed at an out-patient clinic between 1999 and 2001 were consecutively enrolled in the study. Demographic, disease and treatment data were collected at standard visits. Dual energy X-ray absorptiometry at hip and spine L1–4 was performed at baseline and after 2, 5 and 10 years.

Results: At baseline mean age (SD) in the 92 RA patients was 50.9 (13.3) years, symptom duration 12.4 (6.7) months, 62.0% were women, 66.3% were RF positive and 65.9%% were CCP positive. In the first 2 years ever use of biologic DMARDs was 18.5%, synthetic DMARDs 91.3% and prednisolone 62.0% whereas the figures for the subsequent 8 years were 62.6%, 51.4% and 89.2%, respectively. Baseline, mean values for 0–2 years and 2–10 years follow up was for ESR mm/hr 30 (21), 21 (12) and 13 (7), for CRP mg/dl 29 (34), 19 (15) and 8 (7), for DAS28 5.2, 4.2 and 2.9 and for MHAQ 0.68 (0.51), 0.42 (0.30) and 0.27 (0.27).

The annual rate of BMD loss in the first 2 years and in the subsequent 8 years was at femoral neck −1.00% vs. −0.56%, at total hip −0.96% vs. −0.41% and at spine L1–4 −0.42% vs. 0.00%. The corresponding figures at femoral neck, total hip and spine L1–4 were in men −0.89% vs. −0.29%, −1.01% vs. −0.07% and −0.20% vs. 0.76%, in pre-menopausal women −0.93% vs. −0.39%, −1.20% vs. −0.11% and −0.42% vs. −0.06% and in post-menopausal women −0.75% vs. −0.91%, −0.74% vs. −0.85% and −0.49% vs. −0.61%.

Conclusion: Our study adds evidence that aggressive anti-inflammatory treatment in particular with biologics reduces the rate of bone loss in RA down to a level reported in the general population.

Strontium Ranelate Uncouples Bone Resorption From Bone Formation In Osteoporotic Patients With Or Without Clinical Risk Factors. Olivier Bruyere[1], Julien Collette[2] and Jean-Yves Reginster[1]. [1]University of Liège, Liège, Belgium, [2]Labo RIA, CHU Sart Tilman, Liege, Belgium.

Background/Purpose: Strontium ranelate has proven efficacy against vertebral and nonvertebral fractures in postmenopausal osteoporosis. We explored whether the effect of strontium ranelate on bone turnover markers is influenced by the presence of well-established risk factors for fracture (i.e. age, prevalent fractures, parental history of osteoporosis, low body mass index, and addiction to smoking).

Methods: Analysis of pooled data from two three-year randomized controlled trials (i.e. the Spinal Osteoporosis Therapeutic Intervention (SOTI) and Treatment Of Peripheral Osteoporosis (TROPOS) studies). Bone-specific alkaline phosphatase (BALP, immunoradiometric assay Tandem®-R Ostase® kit, Beckman Coulter, USA), C-terminal propeptide of type I procollagen (PICP, RIA, Orion Diagnostic) and serum C-terminal telopeptides (S-CTX, ELISA using the Serum CrossLaps® ELISA kit, Nordic Bioscience Diagnostics, Denmark) were assessed at baseline, after 3, 6, 12 24 and 36 months. Comparisons of percentage changes from baseline in strontium ranelate and placebo groups were performed with use of the Mann–Whitney test. Results were analysed on an intention-to-treat (ITT) basis.

Results: 5082 patients were included in this study (2536 receiving strontium ranelate 2 g/day and 2546 receiving a placebo). In the strontium ranelate group, the bone resorption marker S-CTX decreased compared to the placebo group at every time point (all $p<0.05$) independently of age (below or over 80 years), familial history of osteoporosis (yes/no), body mass index (below or over 25kg/m^2), or prevalent vertebral fracture (absence, 1, 2 or more). During the 2 first year of treatment, S-CTX is also decreased independently of addiction to smoking (yes/no). After 3 years of treatment the differences of S-CTX change between the placebo and the strontium ranelate groups varied between 4 and 15%, depending on the risk factor considered. In patients with family history of osteoporosis, after 3 years of follow-up, the between-group difference in S-CTX was 8.9%. In the same way, an increase in the bone formation markers PICP and BALP in women taking strontium ranelate compared to placebo was observed after 3 months and sustained during the 3 years independently of the presence of fracture risk factor in the study population (all $p<0.05$).

Conclusion: During a 3-year treatment, strontium ranelate decreases bone resorption and stimulates bone formation in postmenopausal women independently of baseline osteoporosis risk factors. This effect is independent of the disease severity as demonstrated by a significant decrease in bone resorption markers and an increase in bone forming markers in patients with, no, 1 or 2 and more prevalent fracture.

Effects Of Biological Therapy In Bone Metabolism In Patients With Chronic Inflammatory Arthropathies. Maria Victoria Hernández, Andrea Cuervo, Pilar Peris, Ana Monegal, Raimon Sanmarti, Juan D. Cañete and Nuria Guañabens. Hospital Clínic de Barcelona. IDIBAPS. University of Barcelona, Barcelona, Spain.

Background/Purpose: The efficacy of biological agents in the treatment of chronic inflammatory arthropathies is well known, however, the effect of this therapy in bone metabolism has been scarcely evaluated. Therefore, the aims of this study were to analyze the effects of biological therapy on bone mineral density (BMD), bone turnover and the incidence of fractures in patients with chronic inflammatory arthropathies

Methods: Prospective 2-year study including patients diagnosed with chronic inflammatory arthopathies initiating or switching biological therapy in a hospital day-care unit of a Rheumatology Department. Demographic data including diagnosis and duration of the disease, current biological agent and concomitant treatment (DMARD, glucocorticoids (GC)) were evaluated in all patients as were the following determinations at baseline and at 12 and 24 months: erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), calcium, phosphate, 25-hydroxyvitamin D, parathyroid hormone (PTH), bone turnover markers of formation (P1NP and bone ALP) and resorption (urinary NTX and serum CTX), bone densitometry (DXA) and spinal x-rays. Patients with chronic renal failure and/or known metabolic bone disease were excluded.

Results: Fifty-seven patients were included (84.2% female); mean age 50 ± 13.4 years; mean disease duration 14 ± 9.4 years. The diagnoses were: rheumatoid arthritis 73.7%, psoriatic arthritis 3.5%, ankylosing spondylitis 3.5%, undifferentiated spondyloarthropathy 3.5% and overlap syndrome 8.8%. 40.4% were biologic-naive patients and 59.6% switchers: 80.7% were receiving a non-anti tumour necrosis factor (TNF) agent and 19.3% a TNF antagonist; 77% received concomitant treatment with DMARDs. The number and dose of GC therapy significantly changed at two years from baseline. Thus, the number of patients on GC decreased from 73.7% to 56.1% ($p=0.018$) and the percentage of patients with a daily dose $>$ 5 mg of prednisone from 48.8% to 32.2% ($p=0.001$). Also, a significant decrease in acute serum reactants (ESR, $p=0.002$; CRP, $p=0.005$) as well as in NTX ($p=0.005$) and PTH ($p=0.03$) values was found at 24 months with a trend to an increase in lumbar BMD compared to baseline (1.105 ± 0.101 vs 1.065 ± 0.175 g/cm^2, $p=0.06$); with no changes in total hip BMD (0.828 ± 0.126 vs 0.888 ± 0.146 g/cm^2, $p=0.11$). No fragility fractures were observed in the follow-up period.

Conclusion: Patients with chronic inflammatory arthopathies receiving biological therapy show a decrease in bone resorption markers and a preservation of lumbar BMD at 2 years, a finding which may be related with the reduction in glucocorticoid dose during therapy and the outcome of the inflammatory process.

1235

Predictors Of Fracture In Patients With Osteopenia: Data From An Observational Cohort. Kathryn Mitchell, Peter Diggle and Marwan Bukhari. Faculty of Health and Medicine, Lancaster, United Kingdom.

Background/Purpose: The risk factors for osteoporotic fragility fractures are well documented in the literature and although they are associated with a diagnosis of established osteoporosis (T score < -2.5) it is known that the majority of fragility fractures occur in osteopenic individuals (T score between -1.0 and -2.5)[1]. It is not known whether traditional risk factors for osteoporosis convey additional fracture risk in an osteopenic population. Objectives:To identify and examine the predictors of fracture in patients with diagnosed osteopenia.

Methods: Using a nested case control approach, patients referred for a first dual energy X-ray absorptiometry (DXA) scan at a district scanner in the North West of England between 2004 and 2012 were identified and their data included in the analysis if they were found to be osteopenic at the lumbar spine and/or femoral neck. Data collected included: age at scan, gender and indication information (including history of fracture). Univariate logistic regression was used to estimate the odds of fracture in this group using traditional risk factors and subsequently multivariate logistic models were fitted to predict any fracture for using the hip and spine bone mineral density (BMD).

Results: A total of 5021 patients were diagnosed with osteopenia at the femoral neck, of whom 80.5% were female and mean age at scan was 65.1 years (standard deviation 11.8 years). 1709 of these had a history of fracture. At the lumbar spine, 3737 patients were found to be osteopenic, of whom 83.6% were female and the mean age was 64.0 years (standard deviation 12.4 years). 1300 of these had a history of fracture.

Odds ratios for risk of fracture with the presence of a classical fracture risk factor are listed in table 1. Table 2 contains the coefficients of the multivariate logistic models for fracture risk. Standardised residuals suggest good fit for both multivariatelogistic models as they lie between 2 and -2.

Table 1. Odds ratios for fracture.

	Femoral Neck	Lumbar Spine
Age (per year)	1.03 (1.02, 1.03)	1.04 (1.03, 1.04)
BMI (per unit)	1.03 (1.02, 1.05)	1.03 (1.02, 1.05)
T-score at site (per unit)	0.59 (0.51, 0.67)	0.78 (0.66, 0.91)
Female	1.18 (1.02, 1.37)	1.16 (0.96, 1.39)
Maternal Hip Fracture	1.66 (1.09, 2.55)	2.54 (1.54, 4.21)
Smoking	1.09 (0.96, 1.23)	1.15 (0.99, 1.32)
Alcohol Excess	1.37 (1.09, 1.72)	1.32 (1.01, 1.72)
Corticosteroid Therapy	0.55 (0.47, 0.64)	0.63 (0.53, 0.75)
Rheumatoid Arthritis	0.49 (0.35, 0.68)	0.56 (0.38, 0.82)
Inflammatory Bowel Disease	0.38 (0.23, 0.63)	0.42 (0.25, 0.72)
Coeliac Disease	0.33 (0.21, 0.52)	0.43 (0.27, 0.69)
Hyperthyroidism	0.89 (0.34, 2.36)	1.46 (0.54, 3.93)
Hyperparathyroidism	0.51 (0.29, 0.91)	0.52 (0.27, 1.03)

Table 2. Results of multivariate logistic modelling for both sites: the femoral neck and lumbar spine. Variables that did not significantly add to the model show NS.

Coefficients	Femoral Neck: Estimate	p-value	Lumbar Spine: Estimate	p-value
Age (per year)	0.02	<0.001	0.04	<0.001
BMI (per unit)	0.03	<0.001	0.03	<0.001
T-score at site (per unit)	−0.45	<0.001	−0.18	<0.05
Female	NS		NS	
Maternal Hip Fracture	0.57	<0.05	1.01	<0.001
Smoking	NS		0.17	<0.05
Alcohol Excess	0.43	<0.001	0.37	<0.01
Corticosteroid Therapy	−0.57	<0.001	−0.45	<0.001
Rheumatoid Arthritis	−0.63	<0.001	−0.49	<0.05
Inflammatory Bowel Disease	NS		NS	
Coeliac Disease	−0.90	<0.001	−0.57	<0.05
Hyperthyroidism	NS		NS	
Hyperparathyroidism	−0.92	<0.01	−0.83	<0.05

Conclusion: Increasing age, reducing T-score, maternal hip fracture and excessive alcohol consumption predict fracture in osteopenic individuals irrespective of site. Other classical risk factors are unreliable predictors of fracture in this cohort, some even showing protective effects. Differences exist between predictors of fracture at the two sites. Possible unmeasured confounders could predict fractures in this cohort. Further research is needed.

Outcomes and Costs Of Sacral Insufficiency Fractures. Shahryar Hadavi[1], Sanam Kia[1], Christian Dejaco[1], Bhaskar Dasgupta[1] and Frances Borg[2]. [1]Southend University Hospital, Westcliff-on-Sea, United Kingdom, [2]Southend University Hospital, Westcliff-on-sea, United Kingdom.

Background/Purpose: Sacral insufficiency fracture (SIF) is a poorly recognised cause of lower back pain in the elderly with significant potential morbidity. Diagnosis is often slow as the typical clinical picture is poorly recognised. SIFs are seldom seen on plain radiographs, and routine lumbar MRI rarely includes the sacrum. However they can be reliably identified on isotope bone scan.

Existing studies are small (cohorts up to 25 patients) and primarily highlight radiological findings rather than clinical outcomes. We report a cohort of 124 patients with SIF, describing patient outcomes and associated health care costs.

Objectives: 1 To describe patient outcomes following SIF.

2 To determine delays in diagnosis and length of hospital stay.

3 To estimate the financial healthcare costs of SIF.

Methods: Patients were identified retrospectively from isotope bone scans performed at Southend hospital from 2000–2012. Case notes were reviewed for clinical features, time to diagnosis, length of hospital stay, IV bisphosphonate use and mobility and functional status pre- and post-fracture. Mortality was calculated using Kaplan Meier analysis.

Results: 135 patients were identified, of which case notes for 124 patients were reviewed.

Clinical: 83.9% were female. The mean age was 79 years (range 44–96). 51.6% were inpatients at the time of diagnosis. 54.8% presented with back pain, 17.7% groin pain, 17.7% thigh pain and 20.7% buttock pain. 39.2% had preceding minor trauma. 58.9% had a previous fracture, most commonly vertebral and pubic ramus. 23/34 (67.6%) had known osteoporosis. Median time to diagnosis was 13 days (longest 345 days). The median inpatient stay was 22 days (longest 76 days).

Radiology: In 58.1%, bilateral SIF were seen on bone scan. SIF was suspected in only 37.9% of patients prior to scan. 30.6% of bone scans showed co-existing pubic rami fractures. Of 110 patients with pelvic radiographs, only 2 had sacral fractures visible on plain films.

Outcomes: Although 62.1% were fully independent and 30.6% at home with care prior to fracture, functional status fell in 32.5% and 15.8% of these patients respectively following fracture. Prior to fracture 45.3% were independently mobile and 33.3% used a stick. Similarly mobility fell in 32.1% and 41% respectively. The mean survival was 76.2 months, compared to a UK life expectancy of 118 months at 80 years of age.

Based on UK national average figures, the estimated cost per stay for inpatient bed alone is £8159 (US$12587), and the average increase in weekly cost of long-term care post SIF is £115 ($177). A single dose of intravenous bisphosphonate post-fracture was associated with a better outcome, with functional status preserved in 45/49 (91.8%) treated patients, compared to 39/65 (60%) of those untreated. The cost of a single 60mg dose of pamidronate is £55 ($84.9).

Conclusion: Our data suggest that SIF is associated with delayed diagnosis, long hospital stays, poor functional outcomes and decreased life expectancy, with large financial costs per patient. The morbidity, mortality and economic burden may be comparable to hip fracture. Intravenous bisphosphonate use post-fracture may help preserve function.

Denosumab Leads To Significantly Greater Increases In Bone Mineral Density Than Ibandronate and Risedronate In Postmenopausal Women At High Risk For Fracture Who Were Previously Treated With An Oral Bisphosphonate. Jacques P. Brown[1], Michael A. Bolognese[2], Pei-Ran Ho[3], Jesse Hall[3], Christian Roux[4], Henry G. Bone[5], Sydney Bonnick[6], Joop van den Bergh[7], Irene Ferreira[8], Prayashi Ghelani[9], Paula Dakin[3], Rachel B. Wagman[3] and Chris Recknor[10]. [1]CHU de Québec Research Centre and Laval University, Quebec City, QC, [2]Bethesda Health Research Center, Bethesda, MD, [3]Amgen Inc., Thousand Oaks, CA, [4]Paris Descartes University, Paris, France, [5]Michigan Bone and Mineral Clinic, Detroit, MI, [6]Clinical Research Center of North Texas, Denton, TX, [7]VieCuri Medical Centre and Maastricht University, Venlo, Netherlands, [8]Amgen Inc., Cambridge, United Kingdom, [9]Ovatech Solutions, London, United Kingdom, [10]United Osteoporosis Centers, Gainesville, GA.

Background/Purpose: Low bone mineral density (BMD) is an important and modifiable risk factor for fracture in postmenopausal women with osteoporosis. Denosumab (DMAb), which has a unique mechanism of action, has demonstrated a stronger relationship between BMD increases and antifracture efficacy (new or worsening vertebral and nonvertebral fracture) than bisphosphonate (BP) therapies. There is a clinical need to treat subjects who remain at higher risk for fracture despite current BP therapy. In 2 open-label studies, DMAb significantly increased BMD and decreased bone turnover markers vs a monthly oral BP, specifically ibandronate (IBN; 150 mg, single dose once monthly) or risedronate (RIS; 75 mg on 2 consecutive days once monthly), in subjects previously treated with, though suboptimally adherent to, a BP. Here we evaluate the effects of DMAb vs a monthly oral BP (IBN and RIS) to increase BMD in a subset of subjects at higher risk for fracture.

Methods: Both studies were multicenter, randomized, open-label, parallel-group designs in which postmenopausal women ≥ 55 years were randomized 1:1 to DMAb 60 mg subcutaneously every 6 months or a BP 150 mg orally every month for 12 months. In this combined post-hoc analysis, higher-risk subjects were identified by meeting ≥ 1 risk criteria (advanced age, low BMD, prior osteoporotic fracture, high baseline sCTX-1; Table) and the BMD percentage change from baseline in total hip, femoral neck, and lumbar spine at month 12 was calculated.

Results: Subjects from these 2 studies (852 DMAb; 851 BP) had a mean (SD) age of 67 (7.4) years, and mean (SD) T-score at the total hip, femoral neck, and lumbar spine of −1.7 (0.8), −2.0 (0.7), and −2.4 (1.0), respectively. For subjects at higher risk for fracture, DMAb significantly increased BMD at 12 months compared with a BP (IBN and RIS) at the total hip (2.2% vs 0.8%, respectively), femoral neck (1.8% vs 0.3%), and lumbar spine (3.8% vs 1.4%) ($p < 0.0001$ for all; Figure). These results are consistent with the overall study population (treatment-by-risk subgroup interaction $p > 0.05$). In general, AEs and SAEs were similar between DMAb and the comparator BP group.

Table. Identification of Subjects at Higher Risk for Fracture.

	BP N = 851	DMAb N = 852	All N = 1703
Higher-risk subjects, n (%)	469 (55.1)	475 (55.8)	944 (55.4)
1. Age ≥ 75 years	150 (17.6)	160 (18.8)	310 (18.2)
2. Baseline BMD T-score ≤ −2.5 at total hip or femoral neck	250 (29.4)	245 (28.8)	495 (29.1)
3. Baseline BMD T-score ≤ −1.0 at total hip or femoral neck and with prior osteoporotic fracture	256 (30.1)	265 (31.1)	521 (30.6)
4. Baseline sCTX-1 > 0.9 ng/mL and BMD T-score ≤ −2.0 at total hip or femoral neck	17 (2.0)	10 (1.2)	27 (1.6)
Subjects remaining at risk*	319 (37.5)	319 (37.4)	638 (37.5)
Subjects with unknown risk status due to missing data	63 (7.4)	58 (6.8)	121 (7.1)

N = number of subjects randomized. *Subjects who did not meet any of the higher-risk criteria. BP = ibandronate and risedronate. DMAb = denosumab.

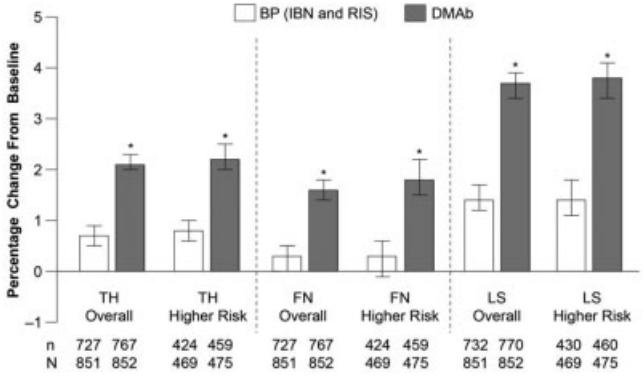

Figure. BMD Percentage Change From Baseline at Month 12.

Conclusion: For subjects previously or suboptimally treated with a BP who remain at higher risk for fracture, transitioning to DMAb led to significantly greater increases in BMD at month 12 compared with cycling to another BP. These results in higher-risk subjects are consistent with those obtained in the overall population and support DMAb as an alternative therapeutic option for women at higher risk for fracture.

Persistence At 12 Months With Denosumab (Prolia®) In Postmenopausal Women With Osteoporosis: Interim Results From a Prospective Observational Study. Stuart L. Silverman[1], Ethel Siris[2], David L. Kendler[3], Dea Belazi[4], Jacques P. Brown[5], Deborah T. Gold[6], E. Michael Lewiecki[7], Alexandra Papaioannou[8], Christine Simonelli[9], Irene Ferreira[10], Paula Dakin[11], Suresh Siddhanti[11], Bradley Stolshek[11] and Christopher Recknor[12]. [1]Cedars-Sinai Medical Center, UCLA Center of Excellence, Beverly Hills, CA, [2]Columbia University, New York, NY, [3]University of British Columbia, Vancouver, BC, [4]AlchemiPharma LLC, Wayne, PA, [5]CHU de Québec Research Centre and Laval University, Quebec City, QC, [6]Duke University Medical Center, Durham, NC, [7]University of New Mexico School of Medicine, Albuquerque, NM, [8]McMaster University, Hamilton, ON, [9]Health East Osteoporosis Care, Woodbury, MN, [10]Amgen Inc., Cambridge, United Kingdom, [11]Amgen Inc., Thousand Oaks, CA, [12]United Osteoporosis Centers, Gainesville, GA.

Background/Purpose: Persistence with osteoporosis therapy is important for optimal reduction of fracture risk. Persistence with denosumab was >90% in a randomized clinical trial in women with low bone mineral density (BMD), but persistence in the community setting is undetermined. We are conducting a prospective observational study to evaluate persistence with denosumab in routine clinical practice in the United States (US) and Canada (CAN).

Methods: In this ongoing multicenter, single-arm study, women were enrolled within 4 weeks after the first injection of subcutaneous denosumab recommended for administration every 6 months for the treatment of osteoporosis per the local product label. Clinical sites include primary care and specialty practices. No clinical procedures, assessments, or changes to routine management of patients are required. Participants are followed for 24 months after study entry. We report results of a 12-month interim analysis. Study endpoints include persistence with denosumab at 12 months (defined as receipt of at least 2 injections no more than 6 months + 8 weeks apart); patient and physician attributes predicting persistence; and occurrence of serious adverse events (SAEs). Persistence rates are based on total patient enrollment.

Results: Enrollment was completed in April 2012 (N=935; US n=632; CAN n=303). Of 80 participating physicians (US n=54; CAN n=26), 41% in the US and 19% in CAN are rheumatologists. In the US, 76% of patients were ≥65 years of age at baseline, vs 62% in CAN. The mean (SD) Wolfe comorbidity index was 2.4 (2.0) in the US and 1.9 (1.6) in CAN. More than half of patients (53%) had osteoarthritis, 9% had rheumatoid arthritis, and 9% had other rheumatologic disorders. During the 5 years before enrollment, 92% of patients in both the US and CAN had taken a prescription osteoporosis therapy, and 59% (US 57%; CAN 62%) had used osteoporosis therapy >5 years before enrollment. Patients in the US took a mean (SD) of 8.4 (5.0) prescription medications, vs 5.7 (4.3) in CAN.

At 12 months, 82% of patients were persistent with denosumab (US, 79%; CAN 88%; Table). Several baseline factors in the US and one in CAN showed a statistically significant association with persistence (Table). Of the 118 patients (13%) who had discontinued the study at 12 months, 55 (6%) withdrew consent, 9 (1%) were lost to follow-up, 8 (1%) died, and 46 (5%) cited other reasons. SAEs were reported in 66 patients (7%); no SAEs of osteonecrosis of the jaw (ONJ), atypical femoral fracture, fracture healing complications, hypocalcemia, eczema, or hypersensitivity were reported. AEs of fracture were reported by 21 patients (2%).

Persistence at 12 Months With Denosumab

	Total N = 935	US N = 632	Canada N = 303
Persistence with denosumab (2 injections), percentage of patients	81.9%	79.3%	87.5%

Baseline factors that show statistically significant association with persistence by country

Country	Covariate	Category	Persistence	P-value
USA	Use of osteoporosis medications	Yes	83.3%	0.0040
	> 5 years before enrollment	No	73.9%	
	Lumbar spine BMD T-score	> −2.5	82.7%	0.0472
		≤ −2.5	75.9%	
	Region	Midwest	87.0%	0.143
		Northeast	83.3%	
		West	80.0%	
		South	72.2%	
	Physician gender	Female	85.2%	0.0362
		Male	77.3%	
	Marital status	Married	83.8%	0.0197
		Never married	76.9%	
		Divorced	74.5%	
Canada	Prior hip fracture	No	88.9%	0.0028
		Yes	60.0%	

Univariate analysis. The P value represents the statistical significance of the covariate when added to the univariate logistic model, with persistence as the response variable.

Conclusion: In this study of routine clinical practice, more than 80% of patients for whom denosumab was prescribed persisted on therapy at 12 months. Denosumab appears to be well tolerated; no new safety risks have been identified to date.

The Effects Of Hyperparathyroidism On Body Mass Index and Bone Mineral Density- An Observational Case-Control Study. Chris Varley[1], Alexander Oldroyd[2] and Marwan Bukhari[3]. [1]Lancaster University, Llandudno, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom, [3]Royal Lancaster Infirmary, Lancaster, United Kingdom.

Background/Purpose: Hyperparathyroidism is associated with reduced bone mineral density (BMD) and increased fracture risk. A previous study from this group has shown that bone loss in hyperparathyroidism occurs at both the lumbar spine and femoral neck.[1] The condition is also associated

with weight gain, and increased body mass index (BMI).[2] A low BMI is a risk factor for BMD loss and osteoporosis, meaning that the higher BMI of hyperparathyroid patients may play a protective role against the increased BMD loss. This study aims to determine the relationship between BMD and BMI in hyperparathyroidism.

Methods: Using a nested case-control approach, a cohort of patients referred between 2004 and 2011 for a dual-energy x-ray absorptiometry scan with hyperparathyroidism as their main risk factor was identified. These were then age and gender matched with controls referred in the same time period with no indication for scanning. The odds of having osteoporosis were compared between cases and controls using a univariate logistic model. Simple differences in BMI were ascertained using students t-test, and sites of bone loss were ascertained by comparing BMD at two sites (L1-L4 vertebrae and the left femoral neck) between cases and controls. A multivariate logistic model was fitted to determine the interaction between BMI and bone loss in patients with hyperparathyroidism.

Results: 281 patients with hyperparathyroidism were identified, with 281 age and sex matched controls. There were 233 females (83%) in each group. Both groups had a mean age of 67.4 (SD 12.2). The odd of having osteoporosis in the hyperparathyroid group was 5.08 (95% CI 3.37–7.67). BMI was found to be significantly increased in the hyperparathyroid cohort (27.9 kg/m2 v 26.2 kg/m20, mean difference of 1.612 kg/m^2 (95% CI 0.782–2.442, p≤0.001). BMD was shown to also be significantly reduced in both the lumbar spine and the femoral neck, with maximal loss in the femur; mean BMD difference was 0.0345 g/cm^2 in L1-L4 (95% CI 0.0003–0.0686, p≤0.05), and 0.0357 g/cm^2 in the femoral neck(95% CI 0.0115–0.0598, p≤0.01). In the multivariate logistic model, a significant difference in BMD only persisted in the femoral neck, with an odds ratio of 6.86 (95% CI 1.37–34.3, p≤0.05) for a lower BMD compared to an odds of 1.89 (95%CI 0.60,5.73) in the lumbar spine.

Conclusion: Hyperparathyroidism is shown to be associated with both a high BMI and an increased osteoporosis risk, with significantly reduced BMD at the femoral neck, but not the lumbar spine when adjusted for BMI. A reduced BMD in the presence of an increased BMI may be due to certain unique circumstances found in hyperparathyroidism, such as the presence of extra PTH-secreting cells in adipose tissue, or the sequestration of vitamin D in adipose tissue, which may lead to further PTH secretion and BMD loss.

Study On The Relationship Between The Preoperative Stay and Morbimortality In Patients With Hip Fracture. Irene Martin, Maria Aparicio, Laura López-Vives, Montserrat Jordana, Antoni Coscujuela, Abelardo Montero and Carmen gomez-Vaquero. Hospital Universitari de Bellvitge, Barcelona, Spain.

Background/Purpose: Introduction: The preoperative stay (PS) in patients with hip fracture has been classically associated with the resultant morbimortality of the process. As a consequence, current clinical guidelines recommend that surgery be performed within 24 or 48 hours of the fracture event. Latest communications question these assumptions. Objectives: To analyze the factors present at the time of admission of patients with hip fracture that determine the length of PS. Analyze the relationship of the length of PS with the resultant morbimortality.

Methods: From March 1, 2009 to December 31, 2011, all patients admitted with fragility hip fracture in a university hospital were visited in a prospectively and formalized way. We collected socio-demographic, clinical and analytical data concerning the patient's status before the fracture and the complications arising during admission and follow-up at 3 months and a year. For this study, we analyzed the relationship between the length of PS, the variables present at admission [age, sex, body mass index (BMI), type of fracture, serum haemoglobin, creatinine, and calcidiol, weekday of admission, Charlson comorbidity index (CI), Pfeiffer test (PT), Barthel index (BI)], the type of surgery and the outcome variables [total stay and postoperative stay, one year mortality and worsening of the parameters of functional and cognitive status]. The variables were entered in a database and analyzed with SPSS Windows version 15.0.

Results: We included 631 patients (70% women) with a mean age of 83 ± 8 years. On admission, the mean BMI was 25.6 ± 4.5 kg/m2. The mean IC was 1.8 ± 2.0 and IB, 75 ± 29 points. The PT was normal in 54% of patients and showed mild, moderate or severe impairment in 17%, 15% and 14%, respectively. The most prevalent types of fractures were the subcapital (48%) and the intertrochanteric (39%) fractures. Regarding laboratory parameters, mean serum haemoglobin was 11.6 ± 1.9 g/dL, creatinine, 100.9 ± 77.4 mmol/L and calcidiol, 31.6 ± 22.8 nM/L. Osteosynthesis was the most commonly used surgical procedure (60%), prosthetic replacement was performed in 38% of the patients. The mean PS was 4.25 days, postoperative stay 13.4 days and total stay 17.4 days. One hundred and sixty-five patients (26%) died during the year after the fracture. None of the variables present at the time of admission or the type of surgery were related to the length of PS. A longer PS was correlated with significant higher postoperative and total stays. The length of PS was not associated with an increase in the mortality rate or with an impairment of the parameters of functional and cognitive status.

Conclusion: In this prospective series of patients with fragility hip fracture, the length of the preoperative stay is not related to the resultant morbimortality. We could not identify any factor that determines preoperative stay length. A longer preoperative stay is associated with higher postoperative and total hospital stays.

A Low Serum 25(OH) Vitamin D Level As a Risk Factor For Incidence and Severity Of Vertebral Fracture In Glucocorticoid-Induced Osteoporosis In Japan. Mari Ushikubo[1], Harumi Kuda[1], Sayaka Kubo[1], Keisuke Izumi[2], Kumiko Akiya[1] and Hisaji Oshima[1]. [1]National Tokyo Medical Center, Tokyo, Japan, [2]Keio University School of Medicine, Tokyo, Japan.

Background/Purpose: Although levels of serum 25(OH) vitamin D (25(OH)D) have been discussed for preventing osteoporotic fractures in primary osteoporosis, an importance of the levels has not been well documented in glucocorticoid-induced osteoporosis (GIO). Also, regional differences of serum 25(OH)D levels for bone health have not been established. This study was conducted to demonstrate roles of serum 25(OH) levels for osteoporotic vertebral fractures in GIO in Japan.

Methods: A 2-year cohort study recruiting 97 patients (81 women) with collagen vascular diseases taking glucocorticoids other than rheumatoid arthritis was conducted in Tokyo, Japan. Vertebral fractures were defined from X-ray films with the semi-quantitated method (SQ, Genant 1993). Means of age, disease duration, and prednisolone dosages of subjects were 60 +/− 15 (SD), 14 +/− 12 (y), and 8.0 +/− 5.9 (mg/day), respectively. Prevalent vertebral fractures were seen in 40 patients.

Results: 1) Incident vertebral fractures were observed in 42% of the patients, and 9 patients showed more than 2 grades of the progress of fractures (DSQ≥2). 2) A mean of serum 25(OH)D levels were 18.8 +/− 6.9 pg/ml (5.9 – 36.0). Fifty five patients showed less than 20 pg/ml. 3) Patients with incident vertebral fractures showed significantly lower (p<0.04) levels of serum 25(OH)D when compared to patients with no fractures (16.9 vs 20.0 pg/ml). 4) After adjusting with known risk factors of GIO (age, predonisolone dosage, BMD, prevalent fracture, and treatments) using logistic regression analysis, a lower serum 25(OH)D level was a significant (p<0.03) risk factor (OR 1.6/5pg) for incident fractures. Patients with less than 20 pg/ml of serum 25(OH)D showed a significant higher rate (p<0.03, OR 1.2) of incident fractures than patients with more than 20. 5) A low level of serum 25(OH)D was also revealed as an independent risk factor (p<0.03, OR 3.1/5pg) for severer incident fractures (DSQ≥2).

Conclusion: It was suggested that a serum 25(OH)D level was an important factor for bone fragility in GIO in Japan.

A Prospective Randomized Open Label Trial To Evaluate The Effect Of Food On Vitamin D Absorption. Lucas Grisanti[1], Zeenat Ali[2], Joseph M. Grisanti[3], James Hatem[3], Mary Brennan[3], Michael Grisanti[3], Mary Margaret O'Neil[3], Linda Burns[3] and Kostas Botsoglou[4]. [1]College of Wooster, Wooster, OH, [2]Mercy Hospital of Buffalo, Buffalo, NY, [3]Buffalo Rheumatology, Orchard Park, NY, [4]Sisters Hospital, Buffalo, NY.

Background/Purpose: Vitamin D deficiency is commonplace throughout the world and is associated with a number of health related consequences. Being a fat-soluble vitamin, speculation has emerged regarding enhanced

vitamin D absorption when administered with food. Theorizing that bile salts and digestive lipases enhance vitamin D absorption, we conducted this randomized controlled clinical trial. The objective of this study was to determine if administering vitamin D with the largest meal of the day enhanced vitamin D absorption when compared to a similar group where replacement vitamin D was given following an overnight fast.

Methods: Subjects 18 years of age or greater with a low 25(OH) vitamin D level between 10 and 30 ng/mL were considered for enrollment. A total of 326 subjects were randomly assigned to a vitamin D replacement regimen that was administered either with the largest meal of the day or following an overnight fast. Four separate vitamin D replacement regimens were studied: 50,000 IU vitamin D2 once weekly, 4,000 IU vitamin D3 daily, 2,000 IU vitamin D3 daily, and 1,000 IU vitamin D daily. Results were assessed by improvement in repeat serum 25(OH) vitamin D levels obtained following 12 weeks of replacement therapy. Completers were defined as subjects who were at least 80% compliant with study medication and had a follow-up vitamin D level drawn at study completion. A total of 249 subjects completed the study.

Results: Of the 249 individuals completing the study, 118 took vitamin D with their largest meal while 131 fasted. The mean improvement in 25(OH) vitamin D levels for the "with food" group was 57% (mean baseline: 23.0, mean ending value: 36.1) with a mean raw difference of 13.2 (95% CI 11.2–15.2). Subjects in the fasting group demonstrated a mean improvement in 25(OH) vitamin D levels of 51% (mean baseline: 22.7, mean ending value: 34.2) with a mean difference of 11.5 (95% CI 9.4–13.6). While improvement in 25(OH) vitamin D levels in the entire cohort was 15% greater when administered with food, this improvement was not statistically significant ($p=0.26$) when compared to repletion following overnight fasting. Subset analysis of the four dosing regimens did demonstrate a statistically significant greater improvement in serum 25(OH) vitamin D levels when replacement was administered with food for the 4,000 IU dosing regimen ($p=0.001$). In this group the mean change when administered with food was 13.7 (CI 10.3–17.2) while the mean change when fasting was 6.9 (CI 4.6–9.1). Statistical differences were not achieved in the other three dosing regimens.

Conclusion: Administering vitamin D replacement with the largest daily meal resulted in a 15% greater improvement in serum 25(OH) vitamin D levels when compared to repletion following an overnight fast. This difference was not statistically significant. Subset analysis of various dosing regimens identified a statistically significant greater improvement when 4,000 IU of daily vitamin D was administered with the largest meal of the day. We conclude that administering vitamin D with the largest meal of the day may enhance vitamin D absorption, compared to taking it with a morning fast. The difference was modest and not statistically significant.

Osteoporosis Medication Adherence: Reasons For Stopping and Not Starting. Amy H. Warriner[1], Ryan C. Outman[1], Allison Wyman[2], Fred H. Hooven[3], Jonathan D. Adachi[4], Roland Chapurlat[5], Juliet E. Compston[6], Cyrus Cooper[7], Jeffrey R. Curtis[8], Adolfo Díez-Pérez[9], Robert Lindsay[10], Lyn March[11], Jeri W. Nieves[10] and Kenneth G. Saag[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Center for Outcomes Research, UMass Medical School, Worcester, MA, [3]University of Massachusetts, Worcester, MA, [4]McMaster University, Hamilton, ON, [5]INSERM UMR 1033 and Université de Lyon, Hôpital Edouard Herriot, Lyon, France, [6]University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom, [7]MRC Lifecourse Epidemiology Unit, Southampton, United Kingdom, [8]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL, [9]Hospital del Mar-IMIM, Universitat Autònoma de Barcelona, Barcelona; and RETICEF, ISCIII Madrid; Spain, Barcelona, Spain, [10]Helen Hayes, West Haverstraw, NY, [11]University of Sydney Institute of Bone and Joint Research, Royal North Shore Hospital, St Leonards, Australia.

Background/Purpose: Medication adherence with prescription osteoporosis medications is poor, with approximately half remaining adherent in the first year of treatment. Moreover, approximately one-third who are prescribed an osteoporosis medication do not fill the new prescription. Reasons for the poor initiation and persistence are multiple. The effect of the recent reports of potential long-term side effects of osteoporosis medications is unknown.

Methods: The Global Longitudinal Study of Osteoporosis in Women (GLOW) is an observational cohort through which survey data are collected annually from women aged ≥55 years old at baseline. The women were initially recruited from 17 regional sites in 10 different countries.

Results: Of 34,971 women that completed surveys in the fifth year, 3,735 were classified as osteoporosis prescription medication "stoppers" as they had been on an osteoporosis medication but stopped it in the past 2 years; whereas 175 were osteoporosis medication "non-starters" and never initiated an osteoporosis medication despite receiving a prescription from their physician. The majority (52%) of stoppers report they were instructed by their doctor to stop their medication. A large proportion also listed concerns of long-term risks associated with the medication(s) (36%) and a specific concern about effects on teeth or jaw (19%) as reasons for stopping (Table 1). For the non-starters, the majority (55%) listed possible side effects as their reason for not initiating an osteoporosis prescription medication, despite the recommendation from their physician (Table 2).

Table 1. Reasons for stopping osteoporosis medications

Reasons for Stopping	n (%)
Instructed by doctor	1947 (52)
Possible long-term risks	1327 (36)
Side effects	753 (20)
Bone density not improving	752 (20)
Taking a drug holiday, on it long enough	721 (19)
Concern about effects on teeth or jaw	693 (19)
Bone density improving	398 (11)
Efficacy (it wasn't helping)	335 (9)
Too many other medications	247 (7)
Too expensive	182 (5)
Difficult to take as directed	174 (5)
Not covered by insurance	140 (4)

Table 2. Reasons for NOT starting osteoporosis medications

Reasons for NOT taking	n (%)
Possible side effects	97 (55)
Too many other medications	31 (18)
Efficacy (would not work)	23 (13)
Too difficult to take	18 (10)
Too expensive	16 (9)
Other	72 (41)

Conclusion: Osteoporosis medication adherence is known to be poor. Our findings reflect women's concerns over possible long-term effects of these medications as a major contributor to not taking or starting these medications. However, most women that were taking medications in the past have stopped taking their osteoporosis medication per the instruction of their physician. These findings highlight increasing concerns of patients and their physicians about the safety of osteoporosis medications.

Low Bone Mineral Density In African-American Males May Be More Prevalent Than Previously Reported and Exhibits Association With Low BMI But Not Older Age - Results Of a Retrospective Cohort Analysis. Khush Aujla[1] and Vikas Majithia[2]. [1]University of Mississippi School of Medicine, Jackson, MS, [2]University of Mississippi Medical Center, Jackson, MS.

Background/Purpose: Osteoporosis (OP) in Males is prevalent and frequently under-recognized. There are a number of known demographic factors such as age, race and BMI as well as secondary causes of low bone mineral density (BMD) i.e. osteopenia and OP. The effect of these on the prevalence of low BMD has not been well quantified. This study aims to describe the prevalence of the demographic factors and SC in men with low BMD and also assess their impact on the prevalence.

Methods: Retrospective chart review of men who underwent DEXA scan performed at UMC from 2005– 2012 was done. Data regarding BMD, demographics i.e. age, race, height, weight, BMI, secondary medical causes, medications, social factors such as smoking and alcohol use was abstracted, tabulated and analyzed using STATA software. Statistical significance was assessed using T-test and Odds ratio as appropriate.

Results: A total of 585 charts were analyzed. There were 410 whites (W), 175 African-Americans (AA). 148 patients had normal BMD. Low bone density was prevalent and seen in 437 patients (74.7%). Amongst these 143 (24.4%) had T-score < -2.5 (osteoporosis) and 294 (50.25%) had T-score > -2.5 and < -1.0 (osteopenia) BMD. The prevalence results are presented in the table with significant differences highlighted.

	NORMAL BONE DENSITY	OSTEOPOROSIS (T-Score < -2.5)	
DEMOGRAPHICS			
AGE (mean)	57.59 years	59.34 years	p-NS
AA	55.33	56.04	p-NS
Whites	62.80	62.64	p-NS
BMI (mean)	31.74	26.07*	*p<0.001
AA	33.18	26.63*	*p<0.001
Whites	30.30	25.51*	*p<0.001
SECONDARY MEDICAL DISORDERS (%)			
ANY Disorder	69.69 %	80.32 %	p=0.11
Thyroid Disorders	13.63 %	16.39 %	p-NS
Hyperparathyroidism	4.54 %	3.27 %	p-NS
Diabetes	28.78 %	16.39 %	p-NS
Asthma/COPD	6.75 %	16.1 %	*p<0.05
Rheumatoid Arthritis	10.6 %	16.66 %	p-NS

SOCIAL FACTORS			
Smoking	15.15 %	36.06 %*	*p=0.01
Alcohol Use	0	1.63 %	–

In this cohort of patients undergoing DEXA scan, osteoporosis was seen more commonly in 53/175 AA males (30.28%) versus 90/410 white males (21.95%). These AA males were younger than whites (Mean age 56.04) as compared to whites (Mean age 62.64). There were a number of factors present with low BMD. Amongst these, low BMI seemed to be the major contributor to low bone mass in these males. Surprisingly, the patients with low BMD had no difference in the age as compared to those with normal BMD. BMI was similar in both AA and white patients. Other factors such as overall medication use, smoking and respiratory disorders were found to be significantly more prevalent than others but no racial difference was found in the prevalence of the secondary disorders.

Conclusion: The results suggest that racial differences exist in the epidemiology of male osteoporosis and these need to be assessed further. In this cohort osteoporosis was seen in a higher % of AA males as compared to white males and at a younger age but no racial differences were found in the prevalence of known risk factors. Also found was that Low BMI, smoking and overall medication use may be better associated with low BMD and potentially better predictors than older age and secondary medical disorders. Limitations of this study include its retrospective design and small sample size. Nonetheless these results highlight that the racial differences in prevalence and effect of underlying factors needs to be better quantified in population studies, so that males at risk of OP may be better identified and screened earlier. This may have significant implications on decision to consider screening for OP in males.

The Differential Effect Of Smoking On Bone Mineral Density At The Lumbar Spine and Neck Of Femur In Each Gender: An Observational Study. William Hedges[1], Alexander Oldroyd[2] and Marwan Bukhari[3]. [1]Royal Lancaster Infirmary, University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom, [3]Royal Lancaster Infirmary, Lancaster, United Kingdom.

Background/Purpose: Current smoking is a known risk factor for loss of bone mineral density (BMD), and is part of the FRAX ™ 10-year fracture risk stratification tool developed by the World Health Organisation (1).

Reduction in BMD due to smoking seems to be more in men than women, but far less data exists looking at the effects of smoking on BMD in males. The site of maximal bone loss has not been clearly identified, varying between the hip and lumbar spine in different studies in a recent review of three meta-analyses (2). There could also be a potentially confounder in abdominal aortic calcification due to atherosclerosis falsely increasing the lumbar spine BMD (3). This study aimed to establish the anatomical area of maximal BMD reduction due to smoking and to examine the differential impact in each gender.

Methods: Data was analysed from male and female patients having dual-energy X-ray absorptiometry (DEXA) assessment between 2004 and 2011. Patients were categorised as never-smoked, current smokers, and previous smokers. Student's t-test was performed to identify whether differences existed between smokers and non-smokers by gender. Logistic models, adjusting for age and body mass index (BMI) were then fitted examining the odds of a low bone density in both sites by gender. Finally the odds of being diagnosed as having osteoporosis (OP) (T score <-.25 at either spine or hip) was ascertained using logistic regression.

Results: 25,904 patients were included in the study, of which 3,136 were ex-smokers and 2,224 were current smokers. This included 3901 males (15%). Mean age at scan in the whole cohort was 62.6 years (SD12.6). Current smokers were more likely to be male 398/1826 vs 3503/20169 (17.9% vs 14.8% P <0.001). Using Student's t-test, the BMD in women was not significantly different in the lumber spine (1.06g/cm2 vs 1.05 g/cm2 p=NS) but was significantly reduced in the hip (0.84 vs 0.85 P =0.004). In men, despite the lower numbers both spine and hip BMD were significantly lower (1.08 vs 1.13 p <0.001 and 0.88 vs 0.90 p=0.02). In females, after adjustment for age at scan and BMI the odds of a low BMD in the lumbar spine were higher than the odds in the femoral neck when adjusted for age and BMI (0.54 95%CI 0.41, 0.73 vs 0.38 95%CI 0.24, 0.60 respectively) indicating more loss in the femoral neck. In men the effect was also greater in the femoral neck (OR 0.45 95%CI 0.25, 0.81 in the lumbar spine vs 0.25 95%CI 0.10 0.66 in the femoral neck). The odds of OP in female smokers was 2.13 (95%CI 1.93,2.35) and in male smokers it was 3.17 (95%CI 2.56,3.92).

Conclusion: Smoking causes significant BMD loss at both the spine and the hip but the effect appears to be more pronounced in male smokers. Abdominal aortic calcification appears to have a minor impact on assessing BMD in the lumbar spine.

Efficacy Of a 6-Month Treatment With Strontium Ranelate 2g/Day In The Improvement Of Long Bone Fractures With Delayed-Union Or Non-Union. Jean-Marc Feron[1], Vaclav Vyskocil[2], Carlina Albanese[3], Luis Augusto Tavares Russo[4] and Jean-Denis Laredo[5]. [1]Hôpital Saint Antoine, GHU Est, AP-HP, Paris, France, [2]3. interní klinika, Všeobecná fakultní nemocnice, U Nemocnice 1, Praha2, Czech Republic, [3]Università degli studi, ROMA, Italy, [4]CCBR Brasil, Rua Mena Barreto, 33 Botofogo, 22271, Rio de Janeiro, Brazil, [5]Hopital Lariboisière, 2, rue Ambroise Paré, 75475, Paris, France.

Background/Purpose: To assess the efficacy of strontium ranelate 2g/day in the improvement of healing of peripheral fractures with delayed union or aseptic non-union.

Methods: International, phase III, open label study with a treatment duration of 6 months. Primary endpoint was the radiological status of the fracture (progress to union, union, failure to union) at 6 months (central X-ray reading), among assessable patients according to intent-to-treat principle. Other efficacy criteria included pain assessment using a Visual Analog Scale (VAS), Lower limb questionnaire, QuickDASH questionnaire (upper limb and clavicle) and quality of life (EQ-5D questionnaire).

Results: 48 patients were included (28 men and 20 women) and 44 completed the study. 4 patients withdrew the study, 3 due to non-medical reasons and 1 due to protocol deviation. Mean age at inclusion was 49.4±18.5 years. 53.7% were osteoporotic. The qualifying fracture was localised for 34 patients in the lower limb, and for 14 patients in the upper limb/clavicle. The status of the fracture at baseline was non-union* in 60.4% and delayed

union** in 39.6%. The mean duration of the qualifying fracture was 22.8+27.5 months.

40 patients were included in the intend-to-treat (ITT) population. In this population, 72.5% of the fractures had improved, with 32.5% of progress to union and 40% of union over 6 months. 18 of the 26 fractures reported as non-union fractures at baseline and 11 of the 14 fractures assessed as delayed union fractures at baseline improved to union or progress to union over 6 months.

48.7% of the patients reported a decrease of more than 50% of their pain, with a mean change in the VAS from baseline (36.9 ± 24.7 mm) to last post-baseline value over M0-M6 of −18.6 ± 3.6 mm ($p \leq 0.0001$).

There was also a positive trend in the changes in the algo-functional behaviour of the affected limb and in the patient's global quality of life as assessed with the EQ-5D questionnaire. No unexpected adverse events were reported.

Conclusion: This open label study suggests that a 6-month treatment with strontium ranelate (2g/day) improves healing of aseptic delayed or non-united fractures of the limbs or of the clavicle.

*Non-union defined as non-union for at least 6 months and no sign of radiological healing or bone reaction since at least 3 months.

**Delayed union defined as an absence of radiological full union after 6 months according to investigator's opinion.

1247

Association Between Bisphosphonate Switching Behavior and Cost Outcomes In Postmenopausal United States Veterans. Joanne Lafleur[1], Scott L. DuVall[2], Jeffrey R. Curtis[3], Robert A Adler[4], Tina Willson[5], Irene Agodoa[6], Bradley Stolshek[7] and Richard E. Nelson[8]. [1]University of Utah College of Pharmacy, Salt Lake City, UT, [2]VA Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Hunter Holmes McGuire VA Medical Center, Richmond, VA, [5]University of Utah, Salt Lake City, UT, [6]Amgen Inc, Thousand Oaks, CA, [7]Amgen, Inc., Thousand Oaks, CA, [8]Salt Lake City VA and University of Utah, Salt Lake City, UT.

Background/Purpose: Many bisphosphonate-treated patients discontinue therapy within the first year. Some later restart the same or a different bisphosphonate. The implications of this on total healthcare costs are unclear. In a national cohort of postmenopausal veterans, we examined the relationship between bisphosphonate switch behaviors and total healthcare costs, defined as a sum of inpatient, outpatient, and pharmacy costs from the Department of Veterans Affairs (VA) Decision Support System dataset.

Methods: We identified bisphosphonate-treated female veterans ages ≥50 in the VA healthcare system in 2003-11 who lacked an alternative indication for bisphosphonate treatment. We classified patients as "high risk" if they had a prior fracture at the hip, wrist, spine, or proximal humerus; a baseline femoral neck bone mineral density (BMD) T-score ≤-2.5; or age ≥75 and lumbar spine, total hip, or 1/3 radius BMD T-score ≤-2.5. We used generalized estimating equation regression models with a gamma distribution to estimate the percentage difference in quarterly cost associated with bisphosphonate switch behaviors, classified quarterly as non-switching, switching, discontinuing (defined as a 90-day gap from the end of the prior supply), or restarting the initial bisphosphonate after a prior discontinuation or switch. Models were stratified on risk level and adjusted for demographic characteristics, comorbid conditions, other drug exposures in the prior year, and costs in the prior year; separate models were run for high- and non-high-risk patients to assess any differences due to disease severity.

Results: 36,280 patients met all eligibility criteria, including 5,567 high-risk and 30,713 non-high-risk patients. The mean (SD) age of the cohort was 65.7 (12.5). Race was known in 87.1%; of those 85.7% were Caucasian and 10.2% were Black. Over an average follow-up time of 4.3 years, 6.9% switched, 83.8% discontinued, and 38.3% reinitiated at least once. Compared to patients who continued with their initial bisphosphonate (N=5,691), patients with change behaviors had significantly higher total healthcare costs: switchers, discontinuers, and reinitiators had 15.1%, 5.0%, and 17.2% higher costs, respectively (all p values <0.001). Findings were similar in the high- and non-high-risk strata.

Conclusion: VA patients who switched or discontinued had significantly higher quarterly total healthcare costs compared to those who continued on their initial treatment, even if they later reinitiated their original bisphosphonate. While it is not certain if higher costs are directly attributable to the switch behavior, efforts to reduce bisphosphonate change behaviors may decrease healthcare costs in this population.

Prevalence Of Vitamin D Inadequacy In European Postmenopausal Women Aged Over 80 Years. Olivier Bruyere[1], Justine Slomian[1], Charlotte Beaudart[1], Fanny Buckinx[1], Etienne Cavalier[2], Sophie Gillain[2], Jean Petermans[2] and Jean-Yves Reginster[1]. [1]University of Liège, Liège, Belgium, [2]CHU de Liege, Liege, Belgium.

Background/Purpose: Inadequate vitamin D level is associated with secondary hyperparathyroidism and increased bone turnover and bone loss, which in turn increases fracture risk. The objective of this study is to assess the prevalence of inadequate serum vitamin D levels in postmenopausal European women aged over 80 years. There are no clear international agreements on what constitutes a level of vitamin D inadequacy, but recent publications suggest that the circulating level of vitamin D should be over 75 nmol/L or at least between 50 and 75 nmol/L.

Methods: Assessment of 25-hydroxyvitamin D [25(OH)D] was performed in 8532 European postmenopausal women with osteoporosis or osteopenia of which 1984 were aged over 80 years. European countries included France, Belgium, Denmark, Italy, Poland, Hungary, United Kingdom, Spain and Germany. Two cut-offs of 25(OH)D inadequacy were fixed: < 75 nmol/L and < 50 nmol/L.

Results: Mean (SD) age of the patients was 83.4 (2.9) years, body mass index was 25.0 (4.0) kg/m^2. Level of 25(OH)D was 53.3 (26.7) nmol/L. There was a highly significant difference of 25(OH)D level across European countries ($p < 0.0001$) with the lowest level of 25(OH)D found in France [47.7 (26.4) nmol/L]. In these women aged over 80 years, the prevalence of 25(OH)D inadequacy was 88.6% and 53.4% when considering cut-offs of 75 and 50 nmol/L, respectively. In the 397 (20.0%) patients taking supplemental vitamin D with or without supplemental calcium, the mean serum 25-OH-D level was significantly higher than in the other patients (65.2 (29.2) nmol/L vs. 50.3 (25.2) nmol/L; $P < 0.001$).

Conclusion: This study indicates a high prevalence of vitamin D [25(OH)D] inadequacy in old European women. The prevalence could be even higher in some particular countries. A greater awareness of the importance of vitamin D inadequacy is needed to address this public health problem.

Contrasting Pathophysiology and Behavioural Responses Associated With Osteoarthritis and An Inflammatory Arthropathy. Sanaa Zaki[1], Margaret M. Smith[1], Susan Smith[1], Mark Connor[2] and Christopher B. Little[1]. [1]University of Sydney, St Leonards, Australia, [2]Macquarie University, North Ryde, Australia.

Background/Purpose: Osteoarthritis (OA) affects more than 15% of the population, and is the major cause of disability in people over 60. There are no therapies that halt OA progression, and available symptom-modifying treatments have limited efficacy. Knowledge of OA pain-pathways is lacking, because most pre-clinical OA-pain studies use models that do not mimic human OA pathophysiology. To determine whether there are OA-pain-specific molecular mechanisms, we directly compared post-traumatic (pt)OA and inflammatory-arthritis (IA) pain pathways and how these change with time and pathology.

Methods: Forty-two male 10 wk C57BL6 mice had unilateral ptOA or sham surgery, IA or sham-IA induced. At day 0, 3, 7, 14, 28, 56, 84 and 112 mice were tested for mechanical allodynia, hind-limb weight-bearing and stride length. At each time knee joints were histologically scored for synovitis, cartilage erosion, subchondral bone (SCB) vascular invasion and sclerosis. Expression of μ-opioid-receptor (MOR), inflammatory neuropeptides (Tac1, CGRP), neuropathic marker (ATF3), and nociceptors (TRPV1, TRPV2, TRPV4, TRPA1) were quantified in ipsi- and contra-lateral lumbar dorsal-root-ganglia (DRG).

Results: IA had significantly greater synovitis and SCB vascular invasion and this corresponded to greater and persistent decrease in hind limb weight bearing, at day 3, 7, 14 and 28, and early phase (day 3–14) mechanical allodynia. In contrast, ptOA was characterized by greater SCB sclerosis and cartilage erosion at day 3, 7, 14 and 28, and osteophyte formation; with reduced stride length and late phase (day 112) mechanical allodynia, the predominant pain outcomes. Changes in DRG gene expression were similar 1–2 weeks after arthritis induction, with minor temporal differences between ptOA and IA. Increased TRPA1, CGRP and MOR were unique to late stage ptOA.

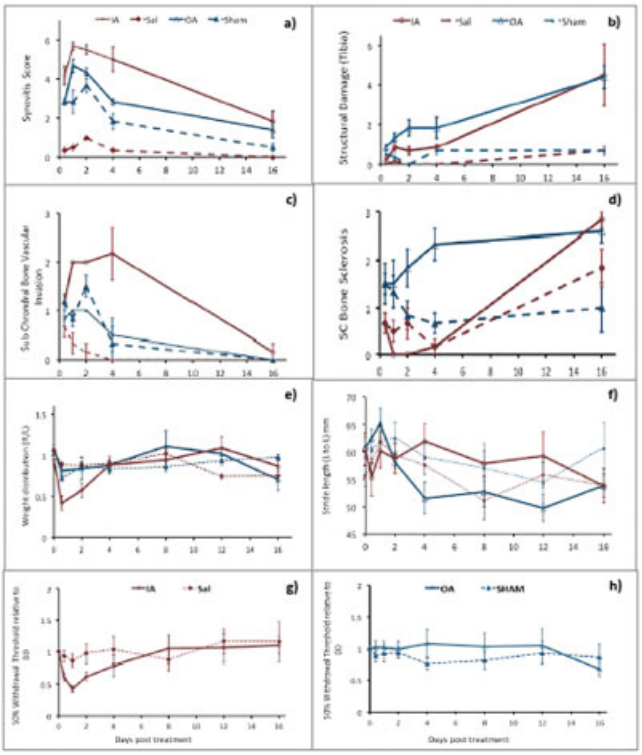

Figure 1. Temporal changes (a) synovitis, (b) Tibial structural damage—AC erosion, (c) SCB vascular invasion, and (d) SCB sclerosis in mice following unilateral ptOA or sham surgery, IA or sham-IA (SaI). Hindlimb weight distribution (R/L) (e); hindlimb stride length (L toL) (f), and mechanical allodynia [ipsilateral (g) & contralateral (h)] as measured at D3, D7, D14, D28, D56, D84 & D112 after arthritis induction. Values expressed are mean +/− S.E.

Conclusion: Our findings suggest there are temporal and model-related differences in the type of pain observed, and its mechanisms. This supports a link between particular tissue pathologies and pain, and suggests OA-specific pain mechanisms that may be therapeutic targets.

Serological Markers Of Structural Integrity and Inflammation Is Associated With Pain In Osteoarthritis. Anne Sofie Siebuhr[1], Lars Arendt-Nielsen[2], Thomas Navndrup Eskehave[3], Morten Asser Karsdal[1], Kristian Kjaer Petersen[2], Ole Simonsen[4] and Anne C. Bay-Jensen[1]. [1]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark, [2]Center for Sensory-Motor Interaction, Aalborg, Denmark, [3]Center for Clinical and Basic Research and C4Pain, Aalborg, Denmark, [4]Frederikshavn Hospital, Frederikshavn, Denmark.

Background/Purpose: Pain is associated with diagnosed osteoarthritis (OA), but little clinically association is found between joint integrity and the pain the individual patient experience. Peripheral and central pain mechanisms are suggested to play roles in OA-pain. Patients experiencing pain for longer periods can become sensitized; hence lesser stimulus is need for the patient to feel pain in the affected site and other remote places of the body (spreading sensitization). Biochemical markers mirroring the pathological processes in OA may aid in the linking of pain mechanisms and tissue integrity. This study investigate the link between the mechanistic, experimental pain biomarkers and serological biochemical markers of inflammation (CRPM), connective tissue turnover (C1M) and synovium (C3M) to investigate underlying causes of knee OA-pain.

Methods: A cross-sectional study of 281 participants recruited from Northern Denmark, age 42–80, with varying degrees of symptomatic knee OA (rated on a 0–100 visual analog scale, max pain for the last 24hours). Serological markers were measured in fasting serum samples: high sensitive C-reactive protein (hsCRP) and matrix metalloproteinase-mediated degradation of CRP (CRPM) and type I (C1M; connective tissue) and III collagen (C3M: synovium). Patients were divided into groups depending on sensitization; 1) sensitized, 2) moderate and 3) non-sensitized. Pressure pain thresholds (PPT) and conditioning pain modulation (CPM) were assessed from the knee, arm and leg. One-way analysis of variance with a Bonferroni post-hoc-test was used. Results are shown as mean (SD).

Results: Compared with un-sensitized patients C1M and hsCRP were higher in patients with localized knee sensitization ($p=0.047$ and $p=0.001$, respectively) and C3M and hsCRP were higher in patients with spreading sensitization ($p=0.018$ and $p=0.001$, respectively). CRPM was higher in patients with developed centralized sensitization ($p=0.006$). Interestingly, the percentage of males was higher in the non-sensitized groups and the percentage of female was higher in the sensitized groups.

	C1M	C3M	hsCRP	CRPM
PPT (knee)				
Sensitized *(N=52)*	56 (20)	19 (5.7)	2.9 (2.3)	11 (3.5)
Moderate *(N=190)*	50 (16)	19 (5.5)	2.3 (2.0)	11 (3.1)
Non-sensitized *(N=40)*	47 (14)	18 (4.3)	1.7 (1.4)	9.7 (2.7)
PPT (arm/leg)				
Sensitized *(N = 45)*	56 (18)	21 (5.7)	3.3 (2.6)	11 3.4)
Moderate *(N = 192)*	50 (16)	19 (4.9)	2.2 (1.9)	10 (3.0)
Non-sensitized *(N = 42)*	48 (14)	18 (5.1)	1.6 (1.3)	10 (3.9)
CPM (knee)				
Sensitized *(N=42)*	58 (20)	21 (6.1)	3.3 (3.6)	12 (4.2)
Moderate *(N=191)*	50 (16)	19 (4.7)	2.2 (2.0)	11 (3.0)
Non-sensitized *(N=47)*	49 (19)	19 (5.2)	2.2 (1.9)	10 (3.2)

Table 1: Values are depicted of mean (SD). PPT: Pressure pain threshold. CPM: Conditioning pain modulation. C1M, C2M, C3M and CRPM are in nmol/L and hsCRP is in mg/L. Lines between values represents statistical significance.

Conclusion: Associations between pain sensitization and serological markers of structural integrity (C1M, C3M) and inflammation (hsCRP and CRPM,) were found. These results indicate that pain in OA is highly related to inflammation and structural integrity.

Collagen Antibodies Induce Pain-Like Behavior In Mice Without Signs Of Inflammation. Gustaf Wigerblad, Katalin Sandor, Kutty Selva Nandakumar, Rikard Holmdahl and Camilla Svensson. Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Collagen Antibody Induced Arthritis (CAIA) is a mouse model of rheumatoid arthritis (RA). It is induced by injection of a cocktail of monoclonal antibodies (mAb) against collagen type II (CII) and a LPS boosting of the immune response day 5, which produces inflammation and swelling of the joints. Interestingly, in our studies aimed at characterizing pain-like behavior in the CAIA model we found that the mice displayed clear signs of nociception (pain) prior to injection of LPS and prior to the onset of inflammation. Thus, the purpose of this study was to characterize the pre-RA phase from a pain perspective and to investigate if a low-grade inflammation drives CII antibody-induced nociception.

Methods: Male B10.RIII mice were injected i.v. with either a mix of the four CII mAbs M2139, UL1, CIIC1 and CIIC2 (1 mg each, total 4 mg/mouse) or 4 mg of the respective single CII mAb and monitored for 5 days. Mice

injected with M2139 (0.5–4 mg/mouse) were followed for 21 days. LPS was not injected to any of the mice. Joint inflammation and development of arthritis were examined by visual scoring of the paws (0–60), histological examination of the ankles and assessment of mRNA levels of RA and pain-associated genes in ankle joint extracts using quantitative PCR. Pain-like behavior was assessed by measuring evoked mechanical hypersensitivity using von Frey filaments and ongoing pain by the Comprehensive Lab Animal Monitoring System.

Results: No visual signs of inflammation were observed in any of the mice days 1–4 and day 5, 3 of 14 mice showed arthritis scores <10. Histologically no signs of cell infiltration, bone erosion or cartilage destruction were observed day 5, except for the mice with arthritis scores, which had minor cell infiltration and bone erosion in the ankle joints. In contrast, all mice injected with CII mAbs, but not control mAbs, displayed a significant reduction in mechanical thresholds day 2, which remained low throughout the study and a significant decrease in ambulation, rearing and total movement during the night between day 2–3. Even though the different CII mAbs have different pathogenicity, they induced similar decreases in mechanical thresholds. To further investigate the nociceptive properties of the J1 epitope-specific M2139 CII mAb, the dose-response relationship was investigated over 21 days. Even at doses (0.5 and 1 mg) that did not induce arthritis at any time point, significant mechanical pain hypersensitivity was observed from day 5 to 21. While IL-1b, TNF, COX2, and MMP2/9/13 mRNA levels were significantly increased in joint extracts from mice with CAIA-induced joint inflammation day 15, none of these mRNAs were elevated in the CAIA mice on day 5, compared to controls.

Conclusion: As no correlation between pathogenicity of the different CII mAbs, arthritis scores, histological changes or gene expression of inflammatory factors and nociception was found, our data indicate that pre-RA pain-like behavior induced by CII antibodies are not driven by a low-grade inflammation. Thus, the current work suggests that certain RA-associated antibodies have the capacity to evoke pain through mechanisms that are uncoupled from the inflammatory process.

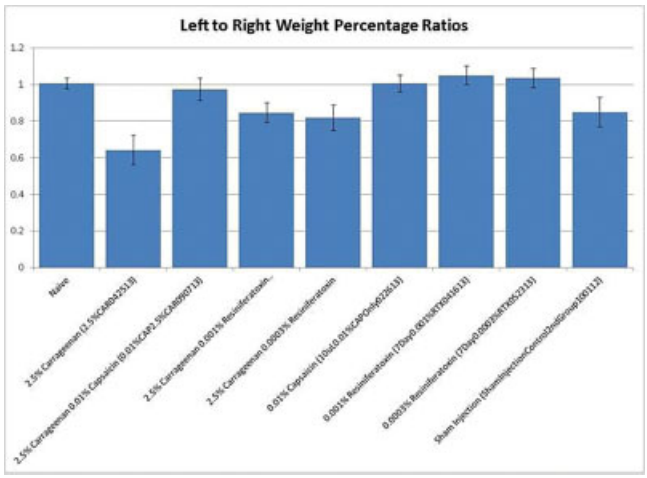
The Effect of Pretreatment With Resiniferatoxin On Dynamic Weight Bearing Measures and Evoked Pain Responses in An Acute Arthritis Murine Model. Mishal Abdullah[1], Christopher W. Dorman[2], Sandra Frizelle[2], Sonia C. Funkenbusch[2], Maren L. Mahowald[3] and Hollis E. Krug[4]. [1]University of Minnesota Medical School, Minneapolis, MN, [2]Minneapolis VA Health Care System, Minneapolis, MN, [3]University of Minnesota Medical School and Minneapolis VA Health Care System, Minneapolis, MN, [4]VA Health Care System, Minneapolis, MN.

Background/Purpose: We have previously shown that activation of vanilloid receptors by intra-articular (IA) Capsaicin (CAP) injection normalizes Evoked Pain Scores (EPS) and Dynamic Weight Bearing (DWB) measures in carrageenan-induced acute inflammatory arthritis. Resiniferatoxin (RTX) is an ultrapotent CAP analogue that has a similar mechanism of action, and may have a greater efficacy on carrageenan-induced arthritis when administered intra-articularly. We hypothesized that mice with acute arthritis would have measurable changes in DWB and EPS due to joint pain, and that these changes could be prevented by pre-treating with IA RTX.

Methods: C57Bl6 mice were used for all experiments. Acute inflammatory arthritis was produced by IA injection of 10μl of 2.5% carrageenan into the left knee 3 hours prior to pain behavior testing. Two groups of mice were injected with different doses of IA RTX (10μl of 0.001% and 10μl of 0.0003%) 7 days prior to induction of arthritis. Similarly, another group of mice was injected with 10μl of 0.01% IA CAP 7 days prior to induction of arthritis. DWB was measured with a Dynamic Weight Bearing apparatus (Bioseb, Vitrolles, France). Evoked pain behavior was measured by tallying fights + vocalizations/1 min with repeated firm palpation of the knee.

Results: Arthritis pain can be clearly and reproducibly indicated by increased EPS and reduced DWB measures in the affected limb of arthritic mice. Naïve mice demonstrated low EPS scores (1.01) and equal left to right DWB ratios for weight (1.01) and time (1.00). Induction of acute arthritis by IA Carrageenan resulted in a significantly increased EPS (6.25) and a significant decrease in left to right DWB ratios for weight (0.64) and time (0.89) when compared with controls. Pretreatment with IA CAP 7 days prior to IA Carrageenan resulted in significant improvement in EPS (3.25) and near normalization of left to right DWB ratios for weight (0.975) and time (1.00). Pretreatment with the high dose and the low dose IA RTX 7 days prior to IA Carrageenan lead to significantly improved EPS (1.5 & 1.5, respectively) and left to right DWB ratios for weight (0.85 & 0.82, respectively) and time (0.99 & 0.96, respectively) when compared with the acute arthritis model. IA administration of CAP alone and RTX alone did not have a significant impact on EPS or DWB ratios after 7 days.



Conclusion: Pain can be quantitated in murine arthritis models using DWB and EPS. IA Carrageenan administration resulted in a significant increase in EPS and a significant decrease in DWB measures in the affected limb. IA RTX pretreatment in these mice clearly improved pain measures as assessed by EPS and DWB measures and these results were comparable to those previously reported for IA CAP. The potential advantages RTX may have over CAP include a possibly lower therapeutic dose and longer duration of effect. These factors represent important directions for future studies.

Studies On The Relationship Between Intraplantar Carrageenan-Induced Bradykin B1 Receptor Messenger Ribonucleic Acid Expression and Oedema and Hyperalgesia In Rats: Effects Of Dexamethasone and a B1 Receptor Antagonist, BI-113823. Guy Kennett[1], Jessica Arlott[1], Phil Butler[2], Mike Comer[1], Andrew Clarkson[2], Alex Coulthard[1], Sean Lightowler[1], Rachel Upcott-Gill[2], Rebecca Upton[1], Louise Wray[2], Philipp Wabnitz[3], Sven Kühnert[3] and Simon Cruwys[3]. [1]Saretius Ltd, Reading, United Kingdom, [2]Cyprotex Ltd, Macclesfield, United Kingdom, [3]Grunenthal GmbH, Aachen, Germany.

Background/Purpose: Kinins are a group of peptides formed in plasma and tissues in response to infection, tissue trauma or inflammation (inflamm) whose actions are mediated by activation of B1 and B2 receptors (B1R and B2R). B1R are normally sparsely expressed, but can be induced by inflammatory stimuli. The current study explored the time dependence of oedema and B1 messenger ribonucleic acid (mRNA) expression in different tissues following intraplantar (ipl) carrageenan (carra) injection as well as the action of dexamethasone (dex). In a separate study, the importance of B1 mRNA induction to carra-induced oedema and hyperalgesia were explored using a novel selective bradykin B1 receptor antagonist, BI-113823.

Methods: Male rats were dosed orally with water (n=110) or dex (1 mg per kg, n=20). 1 h later at T=0, rats were given ipl injections of carra (100 μL × 1% in saline, n=60) or saline (n=70). Of the dex treated rats, half received carra. Paw volumes were measured 0, 1, 2, 4, 8 and 24 h after ipl injections. Corresponding liver, lung and paw pad samples were also collected at each timepoint (10 carra and 10 saline rats per time point) and frozen. All dex treated rats were culled after the 2 h time point.

Tissues and blood were lysed and tissues homogenised on ice. Total RNA was extracted using a MagMAX™-96 Total or Blood RNA isolation procedure and quality (260:280 ratios) and quantity assessed by spectrophotometer. Reverse transcription was performed using a high capacity RNA-to-copy deoxyribonucleic acid (cDNA) kit and 96 well Thermal Quantitative polymerase chain reaction (PCR) analysis was performed on the resultant cDNA, using TaqMan® gene expression assay kit for the target gene B1R and endogenous control (β-actin). Samples were then analysed using a real time PCR machine.

In thermal hyperalgesia and oedema studies, rats were habituated to the test room on day 1. On day 2, basal paw volumes were measured prior to compound administration. At T=-0.75 h vehicle or dex (1 mg/kg po) or B113823 (30 or 100 mg/kg po) were administered. Carra (100 μL × 1%) or saline was then injected into the right paw at T=0. Paw volume was measured at T=0, 3, 4, 6 and 24 h post-carra injection while thermal sensitivity of left and right paws was assessed at T=0, 1 and 3 h using an incident light beam.

Results: Ipl injection of carra elicited paw oedema persisting over 24h. Ipl injection of carra also induced B1R mRNA expression in paw pads which peaked between 2 and 4 hour after ipl injection but remained significant 24h later. Both oedema and B1R mRNA expression were attenuated by pretreatment with dex (1 mg per kg) when assessed 1 and or 2 h post carra. B1R mRNA in lung tissue was not increased by carra, although lowered by dex treatment. No B1R mRNA was found in either liver or blood samples. Dex also reduced thermal hyperalgesia, but BI-113823 had no effect on either oedema or thermal hyperalgesia.

Conclusion: The onset of ipl carra-induced hindpaw pad B1 mRNA induction parallels that of oedema development and both are attenuated by dex. However, the selective B1R antagonist, B113823 had no effect on oedema or thermal hyperalgesia challenging the hypothesis that the B1R might have a key role in the onset and maintenance of carra-induced inflamm and pain.

Prevalence Of Antinuclear Antibodies In Schoolchildren Across Puberty and Possible Relationship With Musculoskeletal Pain. A Longitudinal Study. Francesca Sperotto[1], Sara Brachi[2], Mara Seguso[1], Fabio Vittadello[1] and Francesco Zulian[1]. [1]University of Padua, Padua, Italy, [2]University of Ferrara, Ferrara, Italy.

Background/Purpose: Antinuclear antibodies (ANA) are frequently found in children with connective tissue diseases but can also be found in healthy individuals even in absence of autoimmune conditions, with a prevalence ranging from 13.3% (titer >1:80) to 5.0% (titer >1:160). Puberty is a period of important changes of the immune system, because of sexual and adenohypophyseal hormones modulation which may affect the onset of many autoimmune and connective tissue diseases. To date, a few studies have evaluated the role of ANA in healthy subjects but no one has explored their meaning and frequency across the puberty switch.

Aim of our study was to evaluate prevalence and persistence of ANA in subjects with no evident autoimmune disease followed for 3 years, and their possible relationship with chronic non-inflammatory musculoskeletal pain (MSP).

Methods: Each subject underwent a general and rheumatologic examination focusing on presence of chronic non-inflammatory MSP and including the evaluation of the pubertal stage. Chronic MSP was defined as continuous or recurrent pain lasting more than 3 months and heavily interfering with daily activities, according to the International Association for the Study of Pain. Subjects with past of present sign of any neurological, skeletal, metabolic or autoimmune conditions were excluded. Family history for autoimmune diseases in first degree relatives was also investigated. Finally, each subject underwent laboratory tests to determine the presence of ANA, ENA and anti-dsDNA, following the international guidelines. Subjects with ANA positivity (titer >1:80) and/or MSP have been re-evaluated with the same methods 3 years later.

Results: 261 subjects, aged 8–13 years, entered the study. 32 (12.3%) resulted ANA+, equally distributed as far as gender and pubertal status. None of the ANA+ subjects resulted positive at ENA or anti-dsDNA testing. A positive family history for autoimmune conditions was reported in 6.5% of the subjects.

Three years later, in the group of patients followed for MSP (no. 67) ANA-positivity significantly increased from 13.4% to 44.8% ($p<0.001$) showing a trend to involve more pre-pubertal subjects than the pubertal ones and more females than males. Particularly, ANA positivity involved more pubertal females than pubertal males (50.0% vs 28.0%). In the ANA-positive cohort (no. 28) 92.9% of subjects confirmed the ANA-positivity 3 years later and showed a significant increase of the autoantibody titer (p 0.002). The prevalence of positive family history did not significantly change during the study period. None of the ANA+ subjects resulted positive at ENA or anti-dsDNA testing. Overall, no significant association between ANA-positivity and chronic non-inflammatory MSP was found.

Conclusion: Prevalence and titer of ANA increase across puberty, especially in females, but have no relationship with MSP. This phenomenon could be explained by the complex hormonal changes of the puberty switch period. Further long-term prospective studies are needed to clarify the potential role of ANA as marker of autoimmune-rheumatic conditions, particularly in this period.

Ovarian Dysfunction In Adult Childhood-Onset Systemic Lupus Erythematosus Patients: A Possible Role Of Methotrexate? Daniel B. Araujo[1], Lucas Yamakami[2], Eloisa Bonfá[3], Vilma S. T. Viana[3], Sandra G. Pasoto[2], Rosa M. Pereira[3], Paulo C. Serafin[2], Eduardo F. Borba[4] and Clovis A. Silva[5]. [1]Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [4]Rheumatology Division; University of São Paulo, São Paulo, Brazil, [5]University of São Paulo, São Paulo, Brazil.

Background/Purpose: Reduction of ovarian reserve has been observed in childhood-onset SLE (c-SLE) and adult SLE populations, and most of them were limited to follicle stimulating hormone (FSH) levels and few recent reports included antral follicle count (AFC) and/or anti-Müllerian hormone (AMH) levels. In addition, the contribution of diminished follicle ovarian pool using anti-corpus luteum antibodies (anti-CoL) was not available in pediatric lupus population. There are, however, no data regarding the impact of isolated methotrexate exposure and anti-CoL in ovarian reserve of adult c-SLE patients.

Methods: Fifty-seven adult c-SLE female patients and 21 healthy controls were evaluated for anti-CoL by immunoblot. Complete ovarian function was assessed on the early follicular phase of the menstrual cycle or randomly for those with sustained amenorrhea, blinded to the other parameters of ovarian function. Ovarian reserve was assessed by: FSH, luteinizing hormone (LH), estradiol, AMH and AFC in patients without hormonal contraception for at least 12 consecutive months. Demographic data, menstrual abnormalities, disease activity, damage and treatment were also studied.

Results: The median of current age was similar in adult c-SLE patients and controls (27.7. vs. 27.7 years, $p=0.414$). The median of AMH levels (1.1 vs. 1.5ng/mL, $p=0.037$) and AFC (6 vs. 16, $p<0.001$) were significantly reduced in SLE patients *versus* controls without any significant menstrual abnormalities. Anti-CoL was solely observed in SLE patients (16% vs. 0%, $p=0.103$) and not associated with demographic data, ovarian reserve parameters, disease activity/damage and treatment. Further evaluation of patients treated with cyclophosphamide revealed a higher median of FSH levels compared to SLE patients not treated with cyclophosphamide and with controls (8.8 vs. 5.7 vs. 5.6IU/L, $p=0.032$) and a lower median AMH levels (0.4 vs. 1.5 vs. 1.5ng/mL, $p=0.004$) and AFC (4.0 vs. 6.5 vs. 16IU/L, $p=0.001$). Nineteen patients were treated with methotrexate without cyclophosphamide use, and a negative correlation was observed between cumulative methotrexate dose and AMH levels ($r= -0.507$, $p=0.027$).

Conclusion: The present study demonstrated for the first time that high cumulative methotrexate dose is a possible relevant cause of subclinical ovarian dysfunction in adult c-SLE patients and confirms the deleterious effect of cyclophosphamide. These data reinforce the need of gonadal protection during immunosuppressive treatment and fertility counseling.

Depression, Anxiety and Suicidal Thoughts In a Cohort Of Pediatric Lupus and Mixed Connective Tissue Disease Patients. Andrea Knight[1], Pamela F. Weiss[2], Knashawn Morales[3] and Ron Keren[1]. [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]The Children's Hospital of Philadelphia, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Emerging data reveals that depression and anxiety disorders are highly prevalent in adult patients with systemic lupus erythematosus (SLE). These disorders are associated with increased healthcare utilization and poor outcomes. The prevalence of depression and anxiety disorders and their effect on children with lupus is unclear. We therefore aimed to characterize depression and anxiety in a cohort of children with SLE and the lupus-like syndrome of mixed connective tissue disease (MCTD).

Methods: The study is a cross-sectional analysis of pediatric-onset SLE and MCTD patients followed by CHOP rheumatology and nephrology. Subjects were consecutively recruited and consented at outpatient clinic visits. The presence of depression and anxiety disorders was measured by Patient Health Questionnaire 9 (PHQ-9) and the Screen for Child Anxiety Related Disorders (SCARED), using iPads and REDCap database technology. Scores of >=5 on the PHQ-9 and >=25 on the SCARED identified depression and anxiety symptoms, respectively, and educational handouts with psychiatric referral were given for subjects with positive screens. In addition, positive screens for suicide risk on the PHQ-9 were administered a suicide prevention protocol. Demographic characteristics as well as mental health history, disease duration, manifestations, medications, and activity were also measured.

Results: Forty-five patients were recruited, of which 38 had SLE and 7 had MCTD. The mean age of the study cohort was 15.6 years (SD 3.1) and 87% were female. The median PHQ-9 score was 4 (IQR 1,12) and depressive symptoms were identified in 9 patients (20%). Suicidal thoughts in the past 2 weeks were identified in 7 patients (16%), however, none required emergent psychiatric intervention. The mean SCARED score was 17.4 (SD 10.9) and anxiety symptoms were identified in 10 patients (22%).

Conclusion: Depression and anxiety symptoms, as well as recent suicidal thoughts were prevalent in the study cohort of children with pediatric lupus and MCTD, at frequencies higher than those reported in the general pediatric and adolescent population. Further investigation is needed to characterize the effects of these symptoms on clinical outcomes, quality of life and healthcare utilization.

Feasibility and Clinical Implications Of The Pediatric Automated Neuropsychological Assessment Metrics for Screening Of Childhood-Onset Neuropsychiatric Systemic Lupus Erythematosus. Patricia Vega-Fernandez[1], Natasha M. Ruth[2], Deborah M. Levy[3], Frank Zelko[4], Eyal Muscal[5], Marisa S. Klein-Gitelman[4], HaiMei Liu[6], Adam Huber[7], Jiha Lee[8], Jessica Hummel[8], Lori B. Tucker[9], Tresa Roebuck-Spencer[10] and Hermine Brunner[11]. [1]Cincinanti Children's Hospital Medical Center, Cincinnati, OH, [2]Medical University of South Carolina, Charleston, SC, [3]The Hospital for Sick Children, University of Toronto, Toronto, ON, [4]Children's Memorial Hospital, Chicago, IL, [5]Baylor College of Medicine, Houston, TX, [6]Children's Hospital of Fundan University, Shanghai, China, [7]IWK Health Centre, Halifax, NS, [8]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [9]University of British Columbia, Vancouver, BC, [10]University of Oklahoma, Norman, OK, [11]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati, OH.

Background/Purpose: Neuropsychiatric disease is common in childhood-onset Systemic Lupus Erythematosus (cSLE). Signs of cNPSLE can be subtle and difficult to ascertain in daily clinical practice. Formal neuropsychological testing can be used to assess cognitive ability in SLE but can be expensive, time-consuming, and not always readily available. Automated neurocognitive computerized tests, such as the Pediatric Automated Neuropsychological Assessment Metrics (PedANAM), are convenient, require less training to administer, and cost-effective. PedANAM has shown to have good reproducibility and criterion and concurrent validity in cSLE. The *purpose* of this study is to determine 1) if the PedANAM is feasible for monitoring cognitive status in daily clinical care and 2) its relationship with disease activity indicators.

Methods: 10 subsets of the PedANAM were administered to cSLE patients (pts) recruited from 7 centers. Demographic and clinically relevant information was collected. Mean reaction time for correct responses (MNc, in msec) and accuracy (AC, % of correct responses) were measured for each subtest.

Results: Preliminary analysis of 113 of 200 expected pts was performed (mean age 15 years; White 29%, Black 32%, Asian 20%, Hispanic 14%). Most pts were in high school, 10 repeated a grade, and 19 received special services. Very low AC (<60%) scores were seen in 48 pts on at least one subtest. Only 7 pts showed low AC on 3 or more subtests. Potential reasons for the low AC scores observed were reversed key responses (1 pt) and very fast response time combined with low accuracy. The latter can be explained by either lack of effort or poor understanding of the task. Pts had the greatest difficulty (e.g. low AC) on subtests evaluating delayed and working memory (continuous performance (CPT), code substitution delayed (CDD), and matching to sample (M2S). Hispanic pts had the lowest AC especially on CPT (p=.014), M2S (p=.019), and subtest assessing associative learning (code substitution CDS, p=.019), suggesting greater illness burden. Pts with a history of a greater number of cNPSLE symptoms performed more slowly and less accurately, especially on the spatial processing (SPD) MNc and CPT AC (p's<.05). Pts with active disease measured by the SLEDAI (scores >4) were consistently slower and less accurate on all the subtests with significant differences on CDS, SPD, and simple reaction time (Fig 1). Presence of a SLEDAI-DNA binding was the only SLEDAI parameter significantly associated with PedANAM performance, especially with SPD (p=.041).

Conclusion: The PedANAM appears to be a feasible tool for the assessment of cognitive status in cSLE. Elevated disease activity scores were significantly associated with decreased PedANAM performance. The meaning of atypical low AC scores and cSLE activity needs to be investigated.

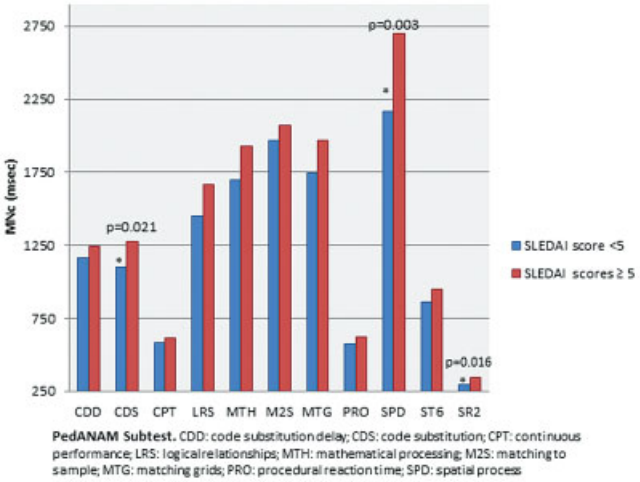

Figure 1. MNc per Subtest vs SLEDAI scores.

Cognitive Functions In Childhood-Onset Systemic Lupus Erythematosus. Bruna Bellini[1], Cleonice de Souza[1], Mariana Postal[1], Nailu A. Sinicato[1], Paula T Fernandes[1], Roberto Marini[1] and Simone Appenzeller[2]. [1]State University of Campinas, Campinas, Brazil, [2]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: To determine differences in cognitive functions in childhood-onset systemic lupus erythematosus (cSLE).

Methods: We performed a cross-sectional study including patients with age of onset of disease ≤ 18 years and controls matched for gender, age and education level. Cognitive evaluation was performed in all participants using Wechsler Intelligence Scale for children (WISC-III) and Wechsler Intelligence Scale for adults (WAIS), according to age. The subjects were divided in two groups: WISC (≤16 years and 9 months) and WAIS (>16 years and 10 months) according to the age at evaluation. Anxiety and depression were assessed by the Beck scales in all subjects. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease

Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current drug exposures. Total dose of corticosteroids and other immunosuppressant medications used since the onset of disease were calculated by data obtained by careful review of the medical charts.

Results: In the WISC group we included 35 cSLE (mean age=13.43 ± 2.10 years, range 8–17 years; mean age of disease onset of 11.23 ± 3.21; mean disease duration=2.80 ± 2.63 years) and 38 controls (mean age=12.32±2.83). In the WAIS group a total of 29 cSLE (mean age=20.34 ± 3.42 years, range 18–29; mean age of disease onset of 13.76 ± 4.08; mean disease duration=6.59 ± 4.72 years) and 35 controls (mean age 21.03±2.86) were included. cSLE patients in the WISC group had lower scores in speed processing (z-score= −0.33±1vs 0.29±1.27; $p<0.05$) and mental flexibility (zscore= −0.12±0.7vs −0.60±0.51; $p<0.05$) when compared to controls. Age at disease onset correlated with cognitive flexibility (r=0,352; p=0,038), anxiety with visuographic memory (r=0.43; p=0,016) and depression with visual perception (τ=-0,261; p=0,044). Lower scores in visual recognition and naming was observed in patients with positive anticardiolipin (p=0.022) and anti-Sm (p=0.046) antibodies. Positive lupus anticoagulant (LA) was associated with lower scores in verbal fluency (p=0.019) and motor dexterity (p=0,046).

cSLE patients in the WAIS group had significant lower scores in semantic memory (z-score −0.22±0,.80 vs 0.46±0.94), speed processing (z-score −0.02±0.78 vs 0,41±0,93) and motor dexterity (z-score=0.40±0,82 vs 0,66±0,91) when compared to controls. Lower scores of visual recognition and naming (p=0.015) and sustained attention (p=0.02) were observed in WAIS cSLE patients with anxiety. Lower temporal reasoning scores were observed in cSLE patients with positive lupus anticoagulant (p=0,013). No association of current and cummulative corticosteroid dose and other medication, disease activity, damage scores and cognitive performance in either group was observed.

Conclusion: According to age, different aspects of cognition are affected in cSLE. Overall, cSLE patients had lower scores in speed processing than controls. Mood disorders, antiphospholipid antibodies, and anti-Sm antibodies influence cognitive function in cSLE patients.

Cognitive Dysfunction In Childhood Systemic Lupus Erythematosus: Comparison Of Different Classification Criteria. Bruna Bellini[1], Cleonice de Souza[1], Mariana Postal[1], Nailu A. Sinicato[1], Roberto Marini[1], Paula T Fernandes[1] and Simone Appenzeller[2]. [1]State University of Campinas, Campinas, Brazil, [2]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: Cognitive deficits are frequently observed in systemic lupus erythematosus (SLE), in both adult and childhood (cSLE) onset. However there are several different cutoff levels to define cognitive impairment in cSLE. Objective: To determine the frequency of cognitive impairment in cSLE according to different classification criteria and to identify the relationship with clinical, immunological and treatment features of the disease.

Methods: We performed a cross-sectional study including patients with age of disease onset ≤ 18 years and controls matched for gender, age and education. We performed a battery of tests, selected from the American College of Rheumatology battery. Fifteen subtests were used to evaluate 13 cognitive functions. Cognitive dysfunction were categorized by 3 different classification criteria with different cutoff scores: criteria 1 (dysfunction=score ≤-2 SD below the standardized mean in 1 cognitive function, or scores between −1 and −2 SD below the mean in 2 or more functions); criteria 2 (dysfunction = score ≤-2 SD below the normative mean in 1 or more cognitive functions and cognitive decline = scores between −1.5 and −1.9 SD below published norms in 1 or more functions); criteria 3 (dysfunction = score ≤-1.5 SD below the normative mean). Anxiety and depression were assessed by the Beck scales. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current drug exposures. Total dose of corticosteroids and other immunosuppressant medications used since the onset of disease were calculated by data obtained by careful review of the medical charts. Statistical analysis was performed using SPSS and significance level was 5% ($p<0.05$).

Results: 64 cSLE patients (92.2% women; mean age 16.56±4.43 years; range 8–29) and 71 controls (78.9% women; mean age 16.37±5.21 years; range 8–29) were included. Active disease (SLEDAI ≥3) was identified in 28 (43.8%) cSLE patients. Following criteria 1 definition, 33 (51.6%) cSLE patients and 26 (36.6%) controls had cognitive dysfunction (p=0.08). Following criteria 2 definition 22 (34.4%) cSLE and 14 (19.7%) controls had cognitive dysfunction and 7 (10.9%) cSLE and 2 (2.8%) controls had cognitive decline (p=0.013). Applying criteria 3, 14 (21.9%) cSLE and 13 (18.3%) controls had cognitive dysfunction (p=0.61). There was no relation between cognitive impairment following any criteria and education, age of disease onset, disease duration, cumulative damage, presence of antiphospholipid, ds-DNA, Ro and Sm antibodies, chloroquine, corticosteroids and other immunosuppressive therapy.

Conclusion: Cognitive impairment is frequently observed in cSLE and in healthy age and sex matched controls. However, changes in criteria for defining cognitive dysfunction led to significant changes in frequency rates. Criteria 2 had the best discrimination between cSLE and controls in our cohort. Further studies should determine the ideal cutoff in cSLE.

Serum S100β Is Associated With Neuropsychiatric Manifestations In Childhood-Onset Systemic Lupus Erythematosus. Aline T. Lapa[1], Mariana Postal[1], Nailu A. Sinicato[1], Bruna Bellini[1], Paula T Fernandes[1], Roberto Marini[1] and Simone Appenzeller[2]. [1]State University of Campinas, Campinas, Brazil, [2]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil.

Background/Purpose: Involvement of the central nervous system (CNS) in systemic lupus erythematosus (SLE) is an important source of morbidity and mortality. S100β has been considered a potential biomarker that could indicate damage or dysfunction of the CNS in adult SLE patients. However there are no studies in childhood-onset SLE patients (cSLE). Objective: To investigate serum S100β protein levels in cSLE and to elucidate their association with disease activity and NP manifestations.

Methods: We included 72 SLE patients (women=67; mean age 18.21± 4.75; range 9–37) and 53 healthy (women =45; mean age 19.72±6.10; range 6–31) age and sex matched controls. Neuropsychiatric manifestations were analyzed according to the American College of Rheumatology criteria. Cognitive evaluation was performed in all participants using Wechsler Intelligence Scale for children (WISC-III) and Wechsler Intelligence Scale for adults (WAIS), according to age and validated in Portuguese. Scores lower than 2 standard deviations were considered abnormal. Mood disorders were determined through Becks Depression and Anxiety Inventory. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current drug exposures. Total dose of corticosteroids and other immunosuppressant medications used since the onset of disease were calculated by data obtained by careful review of the medical charts. Sera samples were obtained from all participants in the absence of infections at the day of clinical evaluation. S100β protein levels were measured by enzyme-linked immunosorbent assay using commercial kits from BioVendor, Inc (Czech Republic) and compared by non-parametric tests. Multivariate analysis was performed including S100β protein levels, total corticosteroid dose, disease duration, antiphospholipid antibodies, anxiety and depression.

Results: The mean S100β protein levels was significantly higher in cSLE patients [143.98 pg/mL (SD± 99.34)] when compared to controls [56.63 pg/mL (SD±44.07); $p<0.001$)]. NP manifestations were observed in 53 (73.6%) cSLE. S100β protein levels was significantly higher in NPcSLE patients (N=53; mean=161.98; SD=106.8) when compared to non-NPcSLE patients (N=19; mean=95.11; SD=52.1; $p<0.001$). Among individual NP manifestations, serum concentrations of S100β protein were significantly higher in cSLE patients with cognitive impairment (N=28; mean=186.76; SD=1022.61) when compared to cSLE patients without cognitive impairment (N=44; mean=115.37; SD=85.0; $p<0.001$). No difference of S100β levels were observed in cSLE patients with other NP manifestations, disease activity or damage. In the multivariate analysis cognitive impairment was independently associated with serum S100β levels (OR=2.69; 95%CI=1.25–5.78).

Conclusion: Serum S100β levels are significantly increased in cSLE patients with NP involvement, especially cognitive impairment, independently of otherdisease feature. S100β protein may be considered a potential biomarker for cognitive impairment in cSLE.

The Usefulness Of Traditional Neurocognitive Testing and N-Methyl-D-Aspartate Receptor Antibodies In Pediatric Lupus Patients. Natasha M. Ruth[1], Mary C. Kral[2], Tamara K. Nowling[3], Stephanie Slan[1], Murray H. Passo[1] and Gary S. Gilkeson[1]. [1]Medical University of South Carolina, Charleston, SC, [2]MUSC, Charleston, SC, [3]Medical University of South Carolina and Ralph H. Johnson VA Medical Center, Charleston, SC.

Background/Purpose: In order to identify lupus patients at risk for CNS disease, and specifically, cognitive dysfunction, the ACR recommended a standard battery of tests for use in individuals with SLE. This led to the use of formal neurocognitive testing as the gold standard when measuring cognitive function in SLE. Almost all studies when measuring neurocognitive function in SLE use a standardized battery of traditional psychometric tests. These tests have been used to assess which areas of cognition are most affected in patients with SLE and also to help assess the validity of other tools that are thought to be useful in measuring cognitive function in SLE. Anti-NMDA receptor antibodies are anti-double stranded DNA antibodies that cross-react with the NMDA receptors NR2a and NR2b. The activation of the NMDA receptor is critical in learning and memory and is expressed on neurons throughout the hippocampus and cortex. To measure the prevalence of anti-NMDA receptor antibodies in pediatric patients with SLE and JIA and to assess the association between elevated anti-NMDA receptor antibodies and neurocognitive dysfunction in these populations.

Methods: Patients diagnosed with SLE prior to age of 18 were recruited. Each underwent formal neurocognitive testing. The test battery included a comprehensive assessment of cognitive domains. The patients also underwent NMDA receptor-NR-2 subunit antibody testing by ELISA.

Results: 21 pediatric lupus and 9 JIA patients were enrolled in the study. Independent samples t-tests comparing group means on the cognitive data revealed statistically significant group differences for full scale IQ ($t=-3.173$, $p<.01$), auditory working memory ($t=-2.180$, $p<.05$), single word reading skills ($t=-3.001$, $p<.01$), math calculation skills ($t=-2.805$, $p<.01$). There were trends toward significance in verbal memory ($t=-1.997$, $p=.056$), inattention [omission errors on the CPT-II] ($t=2.025$, p-.053) and reading fluency ($t=-1.968$, $p=.059$). In all cases above, the JIA group outperformed the cSLE group. There was not a significant group difference for the NMDA receptor antibody levels. There was a significant correlation between the NMDA receptor antibody level and the CPT-II reaction time ($r=.542$, $p<.01$) ie. the higher the antibody value, the slower the reaction time for all participants (including JIA patients and SLE patients).

Conclusion: Patients with SLE appear to have multiple areas of cognition that are affected as determined by traditional neurocognitive testing. NMDA receptor antibodies do not appear to correlate well with the formal testing except in the area of reaction time. Although promising in mouse models, this antibody may not prove to be a good biomarker for assessing cognition in pediatric patients with SLE.

Comparison Of Remission Rates For Pediatric Membranous Plus Proliferative Lupus Nephritis Versus Isolated Proliferative Lupus Nephritis: An Analysis Of The Childhood Arthritis and Rheumatism Research Alliance Registry. Alexis Boneparth[1], Norman T. Ilowite[1] and The CARRA Registry Investigators[2]. [1]The Children's Hospital at Montefiore, Bronx, NY, [2]Duke Clinical Research Institute, Durham, NC.

Background/Purpose: Lupus nephritis (LN) affects many patients with pediatric systemic lupus erythematosus (pSLE) and is a significant cause of disease morbidity. Inability to achieve remission of LN is associated with worse outcomes. Data from studies of adult patients with combined proliferative plus membranous LN (P/MLN) suggests that this combined subtype may be more refractory to current treatment strategies than isolated proliferative LN (PLN). The possibility that P/MLN may represent a more difficult to treat subtype in the pediatric population has not yet been examined. We aim to assess whether remission occurs less frequently in pediatric P/MLN, compared to pediatric PLN.

Methods: CARRA Registry data was obtained for 320 subjects with pSLE (age at onset <18 years) and LN; LN was diagnosed by renal biopsy and categorized according to ISN/RPS classification criteria. Remission of proteinuria was defined as protein/creatinine ratio < 0.5. Remission of hematuria was defined as < 6 RBC/hpf on urinalysis. These cutoffs were determined by the available clinical data from the CARRA registry. Remission was assessed at the most recent CARRA registry visit gathered ≥ 6 months after diagnostic kidney biopsy. Medication exposure data, non-renal disease characteristics, and demographic data were also assessed. Comparison of these data between subjects with P/MLN and subjects with PLN was conducted.

Results: A total 184 subjects had PLN (class III or class IV) and a total of 38 subjects had M/PLN (class III+V or class IV+V). No significant difference in proportion of subjects with remission in either proteinuria or hematuria was found between groups with and without membranous disease. (See Table). Estimated GFR less than 90 ml/min/1.73m^2, indicating renal insufficiency, was found in 6.1 and 16.1% of subjects with PLN and P/MLN respectively, approaching statistical significance ($p=0.07$). Exposure rates to mycophenolate, cyclophosphamide, and rituximab were similar between groups. Patients in PLN and M/PLN groups were similar with respect to SLEDAI scores at last study visit, age of SLE onset, gender distribution, and ANA positivity. Subjects with class IV+V were significantly older at first renal biopsy compared to subjects with class IV (mean age 14.83 vs. 12.71, $p=0.005$), although this trend was not significant for comparison of subjects with class III vs. class III+V.

Table. Percentage of patients with persistent hematuria/proteinuria

Class	IV	IV + V	p	III	III + V	p	III or IV (no V)	III or IV (+V)	p
N (hem)	93	16		62	12		155	28	
hematuria	16 (17.2%)	1 (6.3%)	0.458	13 (21.0%)	2 (16.7%)	1	29 (18.7%)	3 (10.7%)	0.421
N (prot)	90	16		62	12		152	28	
proteinuria	21 (23.3%)	2 (12.5%)	0.513	14 (22.6%)	4 (33.3%)	0.47	35 (23.0%)	6 (21.4%)	1

hematuria = >5rbc/hpf
proteinuria = (pr/cr >0.5).

Conclusion: CARRA registry subjects with P/MLN and PLN have similar rates of remission for hematuria and proteinuria assessed at the last CARRA registry visit. There was a trend for the P/MLN group to have more renal insufficiency. This study was limited by its cross-sectional, retrospective design, and future longitudinal prospective studies will be useful in further assessing the relationship between renal histology findings and response of pediatric LN to treatment.

Disclosure: A. Boneparth, None; **N. T. Ilowite**, None; **T. CARRA Registry Investigators**, None.

Childhood-Onset Systemic Lupus Erythematosus In Ontario: Long Term Outcomes In a Population-Based Cohort With Universal Health Care Coverage. Deborah M. Levy[1], Nadia Gunraj[2], Janet E. Pope[3], J. Carter Thorne[4], Wesley Fidler[5], Peter B. Dent[6], Johannes Roth[7], Roberta A. Berard[8], Murray Berall[9], Astrid Guttmann[10] and Earl D. Silverman[11]. [1]The Hospital for Sick Children and University of Toronto, Toronto, ON, [2]Institute for Clinical Evaluative Sciences, Toronto, ON, [3]St. Joseph's Health Care, University of Western Ontario, London, ON, [4]Southlake Regional Health Centre, Newmarket, ON, [5]St. Joseph's Hospital, Thunder Bay, ON, [6]McMaster University, Hamilton, ON, [7]University of Ottawa, Ottawa, ON, [8]Children's Hospital of Western Ontario, London, ON, [9]Humber River Regional Hospital, Toronto, ON, [10]Institute for Clinical Evaluative Sciences, The Hospital for Sick Children and University of Toronto, Toronto, ON, [11]The Hospital for Sick Children, University of Toronto, Toronto, ON.

Background/Purpose: Little is known about the long-term morbidity and mortality of childhood-onset SLE (cSLE) after transition to adult care; however, linking clinical data to administrative databases enables study of previously unknown outcomes. Our objectives were to: i) describe differences in cSLE phenotype over time; ii) determine the mortality rate; and iii) describe health care utilization trends.

Methods: A retrospective chart review of all cSLE patients (<18 years at diagnosis) diagnosed between Jan 1, 1984 and Dec 31, 2011 and followed for ≥ 1 year was conducted after contacting all pediatric and adult rheuma-

tologists and nephrologists practicing in Ontario. Clinical data and Ontario Health Insurance Plan (OHIP) numbers were securely transferred to the Institute for Clinical Evaluative Sciences (ICES). OHIP numbers were transformed into an encrypted ICES key number (IKN) used to link the cohort to multiple administrative datasets to determine the outcomes of interest. Patients were stratified by era of diagnosis (1984–1989; 1990–2001; 2002 – 2011) because of available data on income and utilization, and to examine trends as immunosuppressive treatments changed over time. Means ± standard deviations are given unless noted.

Results: IKN linkage was successful for 620 cSLE patients in this inception cohort. The cohort was predominantly female (81%) with follow-up of 10.7 (± 7.3) years, representing 6629 person-years of disease. Age at diagnosis was 12.8 ± 3.2, which was similar across eras. Based on postal codes, patients were evenly distributed among the income quintiles; 18% were in the lowest and 13% in the highest quintile. For the whole cohort, self-reported ethnicity was White 42%, Asian 24%, Black 15%, South Asian 13%, Aboriginal 1.3% and Other 4%; however there is a larger percentage of non-white patients in the most recent era (61%), likely reflecting immigration patterns. See Table for differences in distribution of clinical features over time. There were 23 deaths for a crude mortality rate 3.7%, and standardized mortality rate of 2.8%. Six deaths (26%) occurred in the first year following cSLE diagnosis, and 14 (61%) after transfer to adult care. Physician office visits were frequent within the first year after diagnosis, with 23% requiring ≥ 20 visits, and 46% with 10 – 19 physician visits. Moreover, in the first year 43% of patients had at least one emergency room visit, 38% were hospitalized at least once, and 12% required ≥ 3 hospitalizations.

Table. Clinical Features by Era of Diagnosis (*cell size <6 suppressed)

		Era of Diagnosis			
	cSLE Cohort (N=620)	1984–1989 (N=52)	1990–2001 (N=194)	2002–2011 (N=374)	p-value
Disease Duration (y)	10.7 ± 7.3	25.7 ± 3.4	16.0 ± 3.9	5.8 ± 2.7	
Malar Rash (N, %)	485 (78)	44 (85)	155 (80)	286 (77)	0.32
Discoid Rash		<6*	12 (6)	11 (3)	0.18
Oral/Nasal Ulcers	240 (39)	24 (46)	87 (45)	129 (35)	0.03
Photosensitivity	232 (37)	26 (50)	85 (44)	121 (32)	0.004
Coombs+ Anemia	178 (29)	22 (42)	55 (28)	101 (27)	<0.001
Leukopenia	118 (19)	10 (19)	29 (15)	79 (21)	0.20
Lymphopenia	341 (55)	34 (65)	108 (56)	199 (53)	0.25
Thrombocytopenia	186 (30)	13 (25)	70 (36)	103 (28)	0.08
Arthritis	449 (72)	41 (79)	137 (70)	271 (73)	0.50
Pleuritis	96 (16)	9 (17)	39 (20)	48 (13)	0.07
Pericarditis	85 (14)	17 (33)	37 (19)	31 (8)	<0.001
Nephritis (by biopsy)	273 (44)	36 (69)	107 (55)	130 (35)	<0.001
Psychosis		<6*	13 (7)	41 (11)	0.23
Seizures		<6*	9 (5)	12 (3)	0.27
ANA	608 (98)	51 (98)	191 (99)	366 (98)	0.89
dsDNA	441 (71)	44 (85)	166 (86)	231 (62)	<0.001
ENA (Sm, Ro, La, RNP)	426 (69)	38 (73)	146 (75)	242 (65)	0.03
Antiphospholipid Abs	263 (43)	9 (17)	102 (53)	152 (41)	<0.001
Thromboembolism		<6*	16 (8)	13 (4)	0.04

Conclusion: The prevalences of autoantibodies and certain clinical manifestations such as lupus nephritis are declining in more recently diagnosed cSLE patients. These differences may reflect changes in cSLE over time, earlier diagnosis or a shifting ethnicity distribution in Ontario. For cSLE, the mortality rate is highest in the first year following diagnosis, and overall health care utilization is high.

Evaluation Of Quality Indicators and Disease Damage In Childhood-Onset Systemic Lupus Erythematosus Patients. Julia G. Harris[1], Kristyn I. Maletta[2], Evelyn M. Kuhn[2] and Judyann C. Olson[3]. [1]Children's Hospital of Wisconsin, Milwaukee, WI, [2]National Outcomes Center, Children's Hospital of Wisconsin, Milwaukee, WI, [3]Medical College of Wisconsin, Milwaukee, WI.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that can affect virtually every organ system and may lead to significant morbidities. A recent publication identified quality indicators specific to childhood-onset SLE (cSLE) based on scientific evidence and expert opinion. Our study measured compliance with certain quality indicators and assessed organ-specific dysfunction in our cSLE population using a validated damage index, which will help define a baseline for which to optimize management and focus treatment to control the underlying disease and prevent adverse effects of therapy.

Methods: A retrospective chart review was performed on patients diagnosed with SLE prior to age 18 who were followed for at least one year between January 1999 and August 2012. The Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index was calculated to assess for chronic damage.

Results: Analysis was performed on 75 patients with mean disease duration of 4.55 years. Eighty-four percent of patients were female, 38.7% were black, 14.7% were Hispanic, and mean age of diagnosis was 13.2 years. The proportion of patients for whom care met the proposed quality indicators include: hydroxychloroquine use 94.6%, discussion of cardiovascular risk factors 17.3%, bone mineral density testing 26.7%, Vitamin D recommendation 81.3%, ophthalmologic examination 49.0%, influenza vaccination 70.3%, pneumococcal vaccination 25.3%, and meningococcal vaccination 47.2%. Disease damage was present in 41.3% of patients with average overall damage index score of 0.81. The most common entities leading to a damage score were cataracts, avascular necrosis, and diabetes. There was an association of disease damage at last follow-up with minority race ($p = 0.008$) and with presence of vitamin D recommendation ($p = 0.005$). On the contrary, there was no statistical significance relating disease damage to lupus nephritis, age at diagnosis, body mass index, hydroxychloroquine use, or discussion of cardiovascular risk factors.

Conclusion: Baseline application of proposed quality indicators in our cSLE population is varied ranging from 17.3% to 94.6%. This data is important to standardize care and target certain domains of disease management for improvement such as education and vaccination. The three most common areas of damage in our study may be related to corticosteroid use. This knowledge of organ-specific damage is important to help identify at-risk patients to optimize care and focus quality improvement efforts.

Initial Benchmarking Of The Quality Of Medical Care Of Children and Adolescents With Lupus. Ahmad I. Zaal[1], Julia G. Harris[2], Clovis A. Silva[3], Marco F. Sliva[3], Jiha Lee[1], Alexandria J. Greenler[1], Simone Appenzeller[4], Maraisa Centeville[4], HaiMei Liu[5], Joshua D. Pendl[1], Jennifer L. Huggins[1], Jessica M. Sage[1] and Hermine Brunner[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Children's Hospital of Wisconsin, Milwaukee, WI, [3]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [4]Faculty of Medical Science, State University of Campinas Unicamp, São Paulo, Brazil, [5]Children's Hospital of Fundan University, Shanghai, China.

Background/Purpose: Recently, 26 quality indicators (QI) for childhood-onset systemic lupus erythematous (cSLE) have been developed based on international consensus and scientific evidence. QI are defined as minimum standards of medical care in support of optimal disease outcomes. The current level at which these QI are followed has not well documented. Hence, the objective of this study was to assess the current quality of medical care received by patients with cSLE at tertiary pediatric rheumatology centers.

Methods: Cross-sectional data pertaining to the QI were acquired via chart review and analyzed collectively in 229 cSLE patients followed at four tertiary pediatric rheumatology centers – two in United States and two in Brazil.

Results: Adherence to the QI differed by QI domain, ranging from 62 to 100%. The QI domain with the highest adherence was appropriate 'Laboratory testing at the time of diagnosis and with cSLE screening', while the recommended kidney biopsies for newly diagnosed lupus nephritis were not regularly done (Table 1). Education on medication safety and treatment with antimalarials was generally performed. Conversely, educational efforts on cardiovascular risk factors were not consistently recorded in the medical record, despite the perception of the providers that education had occurred. Likewise, transition planning was not systematically done in over 1/3 of the cSLE patients, and 18% of the patients did not have all of the recommended vaccinations. Adherence to the QI was similar across centers, supporting that the set of current QI are suitable for international use.

Table 1. Adherence to QI by Domain

Quality Indicators by Domain	Results
Lab testing at diagnosis & screening	99%
General prevention	
Vaccination against influenza & encapsulated organisms	82%
Education about sun avoidance	76%
Transition plan for adolescents	67%
Lupus nephritis (LN) and hypertension management	
Renal biopsy for newly diagnosed LN	63%
Treat proliferative nephritis with corticosteroids and immunosuppressive agent within 1 month of diagnosis	73%
Obtain kidney biopsy if patient without LN and develops proteinuria (>500 mg/day) or worsening GFR/urinary sediment	95%
Clinical assessment every 3 months if known LN	94%
Prescribe angiotensin-converting enzyme inhibitor or angiotensin receptor blockers if LN and ongoing proteinuria	90%
Consider co-management with nephrologist	63%
Medication management	
Discuss risks versus benefits of new medications	95%
Prescribe antimalarial therapy	93%
Attempt to taper unacceptably high dose of chronic steroids	71%
Laboratory surveillance for medication safety	94%
Bone Health	
Bone mineral density testing if received chronic steroids	71%
Repeat bone mineral density testing if baseline testing outside normal limits (Z score ≤ -2)	80%
Recommend calcium and vitamin D after 3 months of steroid therapy	81%
Ophthalmological surveillance	
Annual eye screening if treated with corticosteroids	74%
Annual eye screening if treated with antimalarial therapy	71%
Education on cardiovascular risk factors	
Education regarding cardiovascular risk factors with parent and patient age 13 years and older	69%
Education on lifestyle modifications	72%

Conclusion: Based on this initial benchmarking effort, the medical care of patient with cSLE at tertiary pediatric rheumatology centers is very good, although there is room for improvement. Systematic planning and documentation of patient education on lifestyle modifications seems warranted and is expected to improve the self-management skills of cSLE patients. Furthermore, increased focus on adequate vaccination of cSLE patients appears to be needed.

Impact Of Disease Duration On Vascular Surrogates Of Early Atherosclerosis In Childhood-Onset Systemic Lupus Erythematosus. Julie Barsalou, Timothy J. Bradley, Cameron Slorach, Lawrence W.K. Ng, Deborah M. Levy and Earl D. Silverman. The Hospital for Sick Children, University of Toronto, Toronto, ON.

Background/Purpose: Cardiovascular disease is a leading cause of morbidity and mortality in adults with systemic lupus erythematosus. Exposure to atherogenic risk factors in childhood-onset SLE (cSLE) likely leads to accelerated atherosclerosis. The aim of the study was to determine the effect of disease duration on vascular surrogates of early atherosclerosis in cSLE. We hypothesized that longer disease duration would negatively impact vascular measurements.

Methods: A cross-sectional analysis of a prospective longitudinal cSLE cohort was performed. All subjects fulfilled $\geq$ 4/11 American College of Rheumatology classification criteria for SLE. Disease activity (adjusted mean SLEDAI), disease damage (SLICC/ACR DI) and medications were recorded. Homocysteine, fasting lipid and inflammatory profiles were performed. Carotid intima-media thickness (CIMT), flow-mediated dilation (FMD) and pulse wave velocity (PWV) were measured using standardized protocols. Data from the last set of vascular studies were used. Vascular data of cSLE patients were compared to those of 138 healthy controls.

Results: One hundred and forty-nine cSLE patients participated in the study (Table). Mean disease duration at the most recent study visit was 3.5±2.6 years. Seventy-three percent of cSLE subjects had inactive disease with a SLEDAI score $\leq$2. CIMT and FMD were not worse in cSLE patients when compared to controls. PWV was slightly higher in cSLE patients. We observed a negative correlation between disease duration and FMD ($r=-0.18$, $p=0.03$) but not with CIMT or PWV. In multivariable linear regression analysis, longer disease duration was significantly associated with worse FMD ($p=0.02$). Gender, a history of lupus nephritis, inflammatory markers, the adjusted mean SLEDAI and the cumulative glucocorticoid dose did not significantly impact on vascular data.

Table. Characteristics of cSLE patients and controls.

	cSLE (n=149)	Controls (n=138)	p value
Male:female ratio	25:124	69:69	<0.001
Age at vascular test (yrs)	16.3 ± 2.4	14.4 ± 2.3	<0.001
BMI, percentile	66 ± 27	55 ± 29	0.001
SBP, percentile	52 ± 29	45 ± 27	0.04
DBP, percentile	42 ± 25	30 ± 21	<0.001
Disease duration (yrs)	3.5 ± 2.6		
Lupus nephritis, n (%)	54 (36)		
Neuropsychiatric lupus, n (%)	43 (29)		
Adjusted mean SLEDAI	3 ± 2		
SLICC/ACR DI	0		
Ever on glucocorticoid, n (%)	139 (93)		
Cumulative prednisone dose (mg/kg)	303 ± 260		
Cholesterol-total (mmol/L)	4.03 ± 1.00		
LDL-cholesterol (mmol/L)	2.13 ± 0.78		
HDL-cholesterol (mmol/L)	1.39 ± 0.41		
Triglyceride (mmol/L)	1.11 ± 0.56		
Vascular measurements*:			
CIMT (mm)	0.410 ± 0.056	0.437 ± 0.047	<0.001
FMD (% change)	9.1 ± 4.2	7.5 ± 3.1	0.003
PWV (m/s)	5.3 ± 0.9	5.1 ± 0.9	0.04

Numbers are presented as mean±SD unless otherwise specified.
*CIMT (n=148), FMD (n=142), PWV (n=146)

Conclusion: In this large single-center cSLE cohort, longer disease duration was associated with worse FMD, suggesting progressive endothelial dysfunction over time. CIMT and PWV were independent of disease duration.

Long-Term Follow-Up Of a Pediatric Lupus Cohort: Transition Of Care and Health Related Outcomes. Susanna Felsenstein, Anusha Ramanathan, Beatriz Gonzalez and Andreas Reiff. Children's Hospital Los Angeles, Los Angeles, CA.

Background/Purpose: Transition from pediatric to adult care is a difficult process with the potential for negative impact on medical, psychological and social outcomes. In this study we assessed the social and health related outcomes of a cohort of pSLE patients transitioned to adult care.

Methods: We conducted a cross-sectional observational survey based on a telephone questionnaire of young adults with pSLE diagnosed and treated at Children's Hospital Los Angeles between 1992 and 2007. All patients met ACR criteria for SLE at diagnosis and had originally participated in a SLE genetic study prior to their transition. Outcome measures were self-reported survey responses related to transition of care, medication knowledge and adherence, employment status and disease related damage.

Results: After an average follow-up period of 5 years since transition (SD 3.7 years) 51 of the original 150 pSLE patients could be contacted of whom 41 consented to participate in the study. 2 were deceased. Median age at the time of interview was 24 years (range 18–34 years), median disease duration was 11.2 years (range 6–21 years), The patients were primarily female (90%) and Hispanic (71%). A significantly lower need for hospitalizations was seen in those patients who had been referred to the adult physician by their pediatric rheumatologist (8/18; 44%), compared to those who had no assistance in the referral process (15/19; 56%), ($p=0.04$). 38/41(93%) reported that they saw a physician regularly, 35/41 (85%) a rheumatologist. 20/41 (49%) had had an appointment with a physician within the last month, 16/41 (39%) within the last 6 months. Three patients (2 with active disease) had no regular interaction with a medical professional at all. 22/41(54%) of patients experienced difficulties with the transition process; 13/41 (31.7%) due to loss of insurance and 10/41 (24%) reported difficulties due to emotional readjustment. Patients reported taking on average 4 medications and 78% reported full compliance. Compliance did not increase with age or extent of end-organ involvement. 16/41 (39%) of patients were unemployed, and 9/16 (56%) of those reported this to be lupus-related ($p=0.01$). At the time of the interview 37/41 (90%) of patients reported symptoms with involvement of 3 or more organ systems in two thirds. Most symptoms were mild and managed as an outpatient and 34/41 (83%) felt their lupus was under good control. 9/24 (37.5%) with renal involvement at disease onset had undergone or were awaiting renal transplant and (36%) reported either new or ongoing neuropsychiatric symptoms which were associated with unemployment (10/15 vs 6/26; $p=0.009$).

Conclusion: The majority of our patients successfully transitioned from pediatric to adult rheumatologic care. However frequent challenges during transition were loss of insurance and emotional attachments to the former pediatric provider. This highlights the importance of a structured transition process by pediatric rheumatologists to their adult colleagues including preparation for the emotional readjustment and guidance for financial and insurance matters. Morbidity remains high in pSLE through adulthood, with renal and CNS manifestations as the leading cause for disease related unemployment.

The Development Of a Mobile Application For Adolescents and Young Adults With Lupus. Natasha M. Ruth[1], Deborah M. Levy[2], Andrea Regina[3], Christy Taberner[4], Edith M. Williams[5] and Miriam Kaufman[3]. [1]Medical University of South Carolina, Charleston, SC, [2]The Hospital for Sick Children, University of Toronto, Toronto, ON, [3]The Hospital for Sick Children, Toronto, ON, [4]Mohawk College, Toronto, ON, [5]University of South Carolina, Columbia, SC.

Background/Purpose: Young adults with lupus need reliable disease-specific knowledge that includes information about lupus, the effect of lupus and lupus medication on their lives, and education about how their life choices affect their health. In order to attain autonomy and adequately manage their condition, young adults with lupus must learn effective self-management and communications skills, and build a strong, supportive social network to assist their efforts. The emergence of smartphones, devices that merge the functionalities of traditional mobile phones with computer capabilities, has created new opportunities for innovation by increasing point of care delivery of healthcare interventions. The purpose of this study was to develop a lupus application for smartphones to improve the quality of life (QOL) and ease the difficult transition to adult care for adolescents and young adults with lupus.

Methods: A team of researchers came together in Toronto, Canada in December of 2012 for a consensus conference that resulted in the development of *The Lup*. The team included two pediatric rheumatologists, one from the Medical University of South Carolina, United States and one from SickKids, Toronto, Canada. These two medical centers were chosen based on the diverse ethnic background in these regions. Information technology experts consisting of two software development students and a full-time project leader through a partnership with iDeaWORKS (Mohawk College), adolescent medicine specialists, and adolescents and young adults with lupus were also included in the consensus conference.

Results: The weekend resulted in a dynamic plan for the conceptualization, development, and implementation of *The Lup*. The app is designed to run on the iOS (Apple) operating system for iPhone, iPod Touch, and iPad with plans to eventually include Android and Windows platforms in order to reach patients that prefer these platforms. *The Lup* was conceptualized as a patient-centered tool to better understand and manage lupus. The app is equipped with tools to record demographic data and personal health information (if desired), provide medications reminders, facilitate social networking through the Lupus Foundation of America (LFA) Facebook page and Twitter feed, and provide information about lupus medications. In addition, the app includes a dynamic symptoms report/tracker and mood tracker, and will allow communication of this collected data with the health-care team. The app also includes a lupus support group locator, and multi-media peer-modeling examples using pre-existing LFA YouTube channel videos. Teens (ie users) with lupus have vetted the graphics and appearance of the app, as well as potential functionalities throughout the active development and programming process.

Conclusion: The app will be completed in August 2013. The next steps of this innovative and exciting project will evaluate the feasibility and determine preliminary estimates of effectiveness of the mobile app to improve the QOL among adolescents and young adults with lupus. *The Lup* shows promise as the first mobile app designed specifically for adolescents with lupus.

Risk Factors For The Development Of Avascular Necrosis In Pediatric Systemic Lupus Erythematosus Patients. Reut Gurion[1], Howard Yang[2], Hong Li[3], Stephanie Frenkian[2], Kathleen A. Haines[2], Jennifer E. Weiss[2], Yukiko Kimura[2], Andrew S. Zeft[4], Angela B. Robinson[1], Suzanne C. Li[2] and for The CARRA Registry Investigators[5]. [1]Rainbow Babies and Children's Hospital/Case Medical Center, Cleveland, OH, [2]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [3]Case Western Reserve University, Cleveland, OH, [4]The Cleveland Clinic, Cleveland, OH, [5]Duke Clinical Research Institute, Durham, NC.

Background/Purpose: Avascular necrosis (AVN) is a serious morbidity of pediatric systemic lupus erythematosus (pSLE) associated with disability, impaired quality of life, and increased cost of care. Both SLE and corticosteroid (CS) treatment have been associated with AVN but understanding of pathogenesis remains limited, and few pSLE studies have been conducted.

Methods: We conducted retrospective reviews of two pSLE cohorts, a single center site (HUMC) and from the CARRA Registry. Data from the HUMC cohort (pSLE patients seen at HUMC between 2006–2009) included disease course and manifestations, morbidity, CS treatment details, and laboratory test results at selected times. Data on HUMC pSLE AVN patients was collected from initial clinic visit until diagnosis of AVN, and on HUMC non-AVN patients from initial visit through 2009. The CARRA Registry is a prospective registry of patients with pediatric rheumatic diseases in the US that includes demographic data, disease duration and manifestations, morbidity, and some laboratory studies. Only limited disease treatment data is available from this registry. We analyzed data on the CARRA pSLE patients from 5/2010-5/2013. For the HUMC data, non-parametric two-tailed p values were calculated. For the CARRA data, t-test and Chi-square tests were performed.

Results: There were 62 pSLE subjects in HUMC cohort, of whom 7 (11.3%) had AVN. Sufficient data were available for 38 of the non-AVN subjects to use as case controls. HUMC AVN patients had an older age at onset of SLE and CS treatment, and a higher mean daily CS dose than non-AVN. The median initial and highest daily CS dose were higher for HUMC AVN than non-AVN patients, but these did not achieve statistical significance (Table). There were 849 pSLE subjects in the CARRA Registry, and AVN was reported in 38 (4.5%). Factors associated with AVN are shown in Table.

Table. Univariable analysis for both cohorts

Variable	AVN*	No AVN*	P-value
HUMC Registry	**n = 7**	**n = 38**	
Female	7 [100]	30 [78]	<0.01
Black race	2 [29]	8 [21]	NS
Age at SLE onset, yrs	16.0 (13–16)	12.5 (4–18)	<0.01
Age at onset of CS therapy, yrs	16.0 (13–17)	13.0 (4–18)	<0.01
Time to AVN, or until stopped data collection for non-AVN pSLE, mos	40.8 (8.7–109.6)	55.3 (7.5–131.6)	NS
Longest consecutive CS duration, mos	17.0 (8.7–28.5)	34.0 (0.9–88.3)	NS
Initial CS dose, mg/day	60.0 (20–80)	40.0 (5–150)	NS
Highest daily dose of CS, mg/day	80.0 (60–125)	60.0 (5–250)	NS
Mean daily CS dose, mg/day	32.8 (22.4–47.1)	19.1 (2.8–72.8)	<0.01
Highest daily dose by body weight, mg/kg/day	1.3 (0.84–1.99)	1.1 (0.10–4.23)	NS
Mean daily dose by body weight, mg/kg/day	0.48 (0.35–0.78)	0.37 (0.05–1.08)	0.05
Cumulative total dose, mg	19,373 (7,655–56,687)	18,245 (350–154,160)	NS
Number of methylprednisolone pulses	2 (0–6)	0 (0–19)	NS

* Median (range), n [%]

Grants: The CARRA Registry is supported by grants from NIAMS, Friends of CARRA, and the Arthritis Foundation. The CARRA Registry is supported by NIH grant RC2AR058934.

Conclusion: AVN is an uncommon but potentially devastating complication. In both cohorts, older age at SLE onset was associated with occurrence of AVN. In the CARRA Registry, longer disease duration, Black race, and presence of Smith antibodies were also associated. In the HUMC cohort, a higher mean daily CS dose was associated with AVN, while total cumulative dose, duration of treatment, and highest dose were not. Prospective studies are needed to better assess these potential risk factors and work towards improving our understanding of AVN pathogenesis.

1271

Longitudinal Disease Trajectory Of Juvenile Dermatomyositis. Lily Siok Hoon Lim[1], Eleanor Pullenayegum[2], Dafna Gladman[3], Earl D. Silverman[4] and Brian M. Feldman[5]. [1]University of Toronto, Toronto, ON, [2]The Hospital for Sick Children, Toronto, ON, [3]University of Toronto, Toronto Western Hospital, Toronto, ON, [4]The Hospital for Sick Children, University of Toronto, Toronto, ON, [5]Hospital for Sick Children, Toronto, ON.

Background/Purpose: 1) To determine the longitudinal disease activity trajectory of an inception cohort of Juvenile Dermatomyositis (JDM) patients, 2) To identify predictor(s) for longitudinal disease activity trajectory of JDM.

Methods: A single-center, inception cohort of juvenile dermatomyositis (JDM) patients (age of diagnosis <18 years old), recruited within 1 year of their initial presentation was studied. The patients were accrued from January 1991 to December 2010, in a JDM subspecialty clinic. Patients were evaluated at every clinic visit for disease activity with the modified Disease Activity Score (mDAS). Each individual's mDAS trajectory was plotted and compared to the whole cohort using a trellis plot. Baseline disease features– swallowing difficulty, skin ulcer, calcinosis, duration of symptoms before evaluation, age and gender– were evaluated as predictors of the longitudinal trajectory of JDM. Time-varying treatment status was also tested. Longitudinal trajectory modeling was performed with mixed random effects modeling (random slopes).

Results: Ninety-five JDM patients (33 males, 35%) were studied. The median age of onset was 7.8 ($25^{th}-75^{th}$ percentile (P): 4.9– 12.1) years. The median mDAS score at presentation was 7 ($25^{th}-75^{th}$ P: 6–9), the median skin subscale score was 3($25^{th}-75^{th}$ P:2–4), the median musculoskeletal subscale was 4 ($25^{th}-75^{th}$ P: 3–6). The median duration of follow-up was 4.6 ($25^{th}-75^{th}$ P: 2.4– 6.9) years. All patients in the cohort were treated with a standardized protocol comprising prednisone alone (before 2000) or methotrexate (MTX) and prednisone (after 2000). The disease trajectory of mDAS in this inception cohort followed a rapid reduction of activity within the first 2 years with a minor flare in disease activity beyond 2 years. Swallowing difficulty was associated with higher mDAS at diagnosis. Treatment with MTX 3 months before and baseline swallowing difficulty predicted faster improvement in mDAS trajectory.

Conclusion: Disease activity trajectory of JDM showed a general rapid reduction of mDAS followed by a small flare of disease activity beyond 2 years. Although difficulty with swallowing at presentation was associated with higher mDAS at diagnosis, it did not predict a slower rate of response of mDAS to treatment.

1272

Whole-Body Versus Thigh Magnetic Resonance Imaging In The Assessment Of Juvenile Dermatomyositis. Clara Malattia[1], Annalisa Madeo[2], Marta Dellepiane[1], Diliana Beleva[1], Stefania Viola[3], Alessandro Consolaro[4], Nicolino Ruperto[4] and Alberto Martini[5]. [1]Pediatria 2, Genoa, Italy, [2]Istituto G Gaslini, Pediatria II, Reumatologia, Genova, Italy, [3]Pediatria 2, Genova, Italy, [4]Istituto Giannina Gaslini, Genova, Italy, [5]Istituto Giannina Gaslini, Pediatria II, Reumatologia, Paediatric Rheumatology International Trials Organisation (PRINTO) Coordinating Center, Genoa, Italy, Genoa, Italy.

Background/Purpose: MRI is a promising tool to assess disease activity in juvenile dermatomyositis (JDM). So far all MRI JDM studies focused on the thigh musculature. Whole-body(WB)-MRI screens the entire body with the advantage to evaluate larger areas of muscles and subcutaneous tissue. Aim of the study was to compare WB-MRI and thigh-MRI (T-MRI) in the assessment of disease activity and in predicting treatment efficacy in JDM.

Methods: WB-MRI were obtained from 43 JDM patients and 43 controls. Muscle abnormalities were scored by 2 independent readers in 36 muscular groups while perifascicular and subcutaneous inflammation were assessed on 8 sites (arm, forearm, thigh and lower leg). Two different readers separately scored both thighs for muscles, subcutaneous and perifascicular oedema. WB- and T-MRI scores were compared in terms of reliability, construct validity and predictive value.

Results: WB-MRI revealed myofascial and subcutaneous inflammation of areas other than the thigh in 8 (18.6%) and 10 (23.2%) patients. Concordance between WB- and T-MRI myofascial and subcutaneous scores was moderate (rs=0.59 and rs=0.69 respectively) while the concordance for muscle inflammation was excellent (rs=0.97). Inter-reader agreement was excellent for both T- and WB-MRI scores (ICC:0.96 and 0.98). Both scores showed excellent correlations with Manual Muscle Test (rs=−0.82 for T-MRI; rs=−0.84 for WB-MRI) and Childhood Myositis Assessment Scale (rs=−0.83 for T-MRI;CMAS rs=−0.81 for WB-MRI). WB- and T-MRI muscle scores were significantly higher in JDM active patients when compared with control group (pB<0.0001 for both the scores) and inactive patients (T-MRI pB=0.0022, WB-MRI pB=0.0037). Responsiveness to change was higher for WB-MRI score (SRM=1.65) compared to that of T-MRI score (SRM=1.04). The ability of WB and T-MRI to predict treatment efficacy was tested only in patients with disease duration ' 2 months (N=21) who started treatment with prednisone alone (N=4) or in combination with methotrexate (N=15) or cyclosporine (N=2). Eleven patients (52.4%) met the PRINTO criteria for improvement at 3-months follow-up. WB-MRI muscular score (median value: 61.2) and T-MRI score (7.2) were higher in non-responders compared to responders (34.5; p=0.001 and 5; p=0.01, respectively). WB-MRI muscle score > 57 was predictive of a poor response to treatment, as evaluated by ROC curve analysis (AUC:0,9). Non-responders showed higher WB myofascial MRI score (1.5) compared to responders (0; p=0.04); no significant difference in myofascial T-MRI score and in subcutaneous involvement were found between responders and non-

responders. Seven out of 8 patients (87.5%) with diffuse homogeneous pattern of inflammation at WB-MRI were non responders; *viceversa* 10 out of 13 patients with the typical patchy distribution of muscle inflammation were responders (p=0.02).

Conclusion: WB-MRI provides a complete assessment of total inflammatory burden and was more accurate than T-MRI in identifying myofascial and subcutaneous inflammation and in predicting treatment efficacy.

Granulomatosis With Polyangiitis In Children Is More Severe Than In Adults. A Long-Term, Single Center, Follow Up Study. Francesco Zulian[1], Grazia Minardo[1], Valeria Carraro[2], Franco Schiavon[2] and Giorgia Martini[1]. [1]University of Padua, Padua, Italy, [2]Rheumatology Clinic, University of Padova, Padova, Italy.

Background/Purpose: Granulomatosis with polyangiitis (GPA) is a rare disease in childhood. Treatment strategies and clinical approach are still mostly derived from adult GPA studies. The present study was aimed to compare onset, disease course, therapeutic approach and clinical outcome of two cohorts of children and adults affected by GPA.

Methods: The study included children and adult patients selected on the basis of complete data set and follow up of at least one year, followed at a pediatric and adult rheumatology center, over a period of 20 years (1993–2012). GPA was diagnosed according to the ACR and EULAR/PRES criteria. Clinical features, instrumental findings, laboratory parameters and therapeutic regimens of both cohorts were analyzed at diagnosis, six months later (T6) and at the last follow-up visit. Disease activity was assessed by the Birmingham Vasculitis Activity Score (BVAS) modified for GPA.

Results: Ten children with mean age at disease onset of 10.3 years (range 3–15) entered the study, 7/10 were female. Mean follow-up time was 8.4 years (range 2.5–18). Of the 23 adults 65.3% were female, mean age at onset 53 years (range 37–71) and mean follow-up 2.2 years (range 1.9–3.5). At disease onset, BVAS, clinical features and laboratory parameters of the two cohorts were not significantly different. BVAS decreased more slowly in children (p 0.002). As for internal organs involvement, renal disease was significantly higher at T6 and persisted over time in children (p 0.003). Similarly, pulmonary involvement remained elevated at T6 in children while rapidly decreased over 50% in adults (p 0.01). At the last F/U visit, eye involvement was present in 44% of children while no adult showed signs of ocular disease (p 0.004). As for the treatment strategies, immunosuppressive drugs were more widely used in children at diagnosis (p 0.06) and biological agents were used at an earlier disease stage than adults. Despite the longer follow up, all children were still on treatment at the last follow-up visit while 17% of adults were off therapy.

Conclusion: Adults and children with GPA had similar disease activity at onset. However, childhood GPA had a more severe-course due to persistent renal, pulmonary and eye involvement. Lower disease activity was obtained with a more aggressive treatment approach although no pediatric patients reached a drug-free remission.

Maternal Vitamin D, Fetal C-Reactive Protein and Brain Natriuretic Peptide Associate With The Development and Morbidity Of Cardiac Neonatal Lupus. Amit Saxena[1], Peter M. Izmirly[1], Joanne H. Reed[1], Sara Sahl[1], Deborah Friedman[2], Robert M. Clancy[1] and Jill P. Buyon[1]. [1]New York University School of Medicine, New York, NY, [2]New York Medical College, Valhalla, NY.

Background/Purpose: Women with anti-Ro antibodies face the risk of having a child with cardiac Neonatal Lupus (NL), characterized by congenital heart block and/or cardiomyopathy. Biomarkers in maternal and/or fetal blood may provide insight into pathogenesis, treatment, and risk of disease. Vitamin D has anti-fibrotic properties, and in a Swedish cohort, low maternal levels were postulated to contribute to an increase in cardiac NL cases since gestational susceptibility weeks 18–24 occurred more commonly during the winter. C-reactive protein (CRP) is known to be activated by macrophages, which have been shown to infiltrate the AV node in cardiac NL autopsy cases. Brain Natriuretic Peptide (BNP) is a predictor of cardiac disease in adults and associates with both ventricular dysfunction and cumulative damage index in Systemic Lupus Erythematosus. Troponin I is associated with myocardial damage and is elevated in autoimmune myocarditis.

Methods: Maternal and cord blood samples were obtained from the Research Registry for Neonatal Lupus. Samples were analyzed using standard laboratory assays for Vitamin D, CRP, BNP and Troponin I. Levels were then evaluated for associations with cardiac NL development, fetal echocardiographic evidence of endocardial fibroelastosis (EFE), dilated cardiomyopathy (DCM), and hydrops, as well as child's need for a pacemaker, and maternal use of fluorinated steroids (FS) at the time of blood draw.

Results: Maternal samples closest to gestational week 20 were analyzed for Vitamin D in 36 cardiac NL and 35 unaffected pregnancies. Mean vitamin D levels from affected cases were lower than unaffected pregnancies (40.8 ng/mL ± 28 vs. 53.8 ± 36, $p=0.075$). This trend became significant in comparing 9 cases with fetal EFE vs. 58 without (26.1 ng/mL ± 6.4 vs. 52.0 ± 32.3, $p=0.010$). Maternal CRP in 49 cardiac NL and 51 unaffected cases closest to week 20 did not associate with disease. Cord blood was analyzed for CRP and Troponin I in 38 affected and 52 unaffected children, and BNP in 30 affected and 42 unaffected children. Mean cord blood CRP was significantly higher in cardiac NL cases compared to unaffected children (12.9 ± 68.1 mg/L vs. 0.59 ± 1.8, $p<0.001$). In 28 affected and 32 unaffected cases where both cord blood and maternal blood from the time of delivery were available, cardiac NL was associated with higher CRP in cord blood (16.5 mg/L ± 79.3 vs. 0.39 ± 0.70, $p<0.001$), while maternal blood did not have a significant association (47.2 mg/L ± 43.8 vs. 37.2 ± 38.4, $p=0.265$). Mean cord blood BNP was higher in cardiac NL cases compared to unaffected children (237.2 ng/mL ± 412 vs. 127.9 ± 292, $p=0.04$). Troponin I in cord blood did not associate with disease. No blood tests associated with DCM, hydrops, pacemaker or FS use.

Conclusion: Maternal vitamin D levels may play a role in the development of cardiac NL. Perhaps lower values, albeit in the normal range, confer reduced "protection" from fibrosis. Increased cord blood CRP in cardiac NL cases independent of maternal levels suggests an ongoing fetal inflammatory response at the time of birth. This supports close postnatal follow up to identify worsening of disease.

Prenatal Exposure To Fluorinated Steroids Does Not Affect Long Term Morbidity In Cardiac Neonatal Lupus. Amit Saxena[1], Peter M. Izmirly[1], Sara Sahl[1], Deborah Friedman[2] and Jill P. Buyon[1]. [1]New York University School of Medicine, New York, NY, [2]New York Medical College, Valhalla, NY.

Background/Purpose: Cardiac Neonatal Lupus (NL), characterized by inflammation and fibrosis of the conduction system, endocardium, and myocardium in anti-Ro exposed fetuses, results in significant morbidity and mortality. There is considerable debate regarding the efficacy of maternal fluorinated steroids (FS) in cardiac NL. While permanent reversal of complete block has not been reported, less advanced blocks have regressed and 6 month mortality appears decreased if fetal disease was associated with a more global cardiomyopathy. Long term information regarding the cardiac health of affected children is limited. Accordingly, substantive data on prenatal exposure to FS and outcomes are critical to decision making.

Methods: 161 individuals with cardiac NL or their mothers enrolled in the Research Registry for Neonatal Lupus responded to a questionnaire regarding current treatment with cardiac medications (beta blockers, ACE inhibitors, and/or digoxin) and overall cardiac status. Data were analyzed to determine whether fetal echocardiographic evidence of endocardial fibroelastosis (EFE), dilated cardiomyopathy (DCM) or hydrops, and the use and cumulative dosage (dexamethasone equivalent) of FS during pregnancy associated with long term morbidity.

Results: Cardiac meds were required in 3/14 (21.4%) affected children ages 0–2, 3/25 (12%) ages >2–5, 2/35 (5.7%) ages >5–10, 2/20 (10%) ages >10–15, 4/31 (12.9%) ages >15–20, and 8/36 (22.2%) >20 years. Digoxin was used by 6 individuals, ACE inhibitors by 18, Beta Blockers by 13, and

systemic hypertension was diagnosed in 3. The age ranges 0–2 and >20 years were significantly associated with taking cardiac meds ($p=0.048$). Thirty four (21.1%) had ever been told by a doctor that they had congestive heart failure, and 68 (42.2%) were told of an enlarged heart. Those with a history of an enlarged heart were significantly older at the time of the questionnaire (15.2 ± 9.75 years vs. 10.8 ± 8.03, $p=0.011$). Fetal echo evidence of EFE, DCM, or hydrops vs. 3rd degree block alone was associated with the future requirement for cardiac meds ($p=0.039$). Eighty two (50.9%) were exposed to FS in utero, with cumulative dose ranging from 12 – 693 mg of dexamethasone. Exposure to FS and cumulative dose did not associate with a decreased future need of cardiac meds, development of CHF, or an enlarged heart. The absence of an association between in utero exposure to steroids and overall cardiac well being was observed for both those children with isolated 3rd degree block and those with fetal echo documentation of EFE, DCM, or hydrops.

Conclusion: Medical therapy for cardiac NL is more frequently required shortly after birth, perhaps in order to treat the continuing primary insult which developed in utero. Increased use of cardiac meds in those over 20 and the reporting of an enlarged heart in older individuals suggests the possibility of decreased heart function as children age, perhaps due to worsening disease or the effects of long term pacing. FS exposure in utero did not associate with overall better cardiac outcomes. In those with isolated 3rd degree block, there is no long term benefit to in utero treatment with fluorinated steroids.

Immunologic Monitoring and Infectious Complications In Pediatric Rheumatology Patients Treated With Rituximab. Alysha Taxter[1], Kathleen E. Sullivan[1] and Jon Burnham[2]. [1]The Children's Hospital of Philadelphia, Philadelphia, PA, [2]The Children's Hospital of Philadelphia and the Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA.

Background/Purpose: Rituximab is an anti-CD20 monoclonal antibody increasingly used in immunologic and malignant conditions to deplete B cells. Suppression of humoral immunity after rituximab exposure may last for months or years and may increase the risk of bacterial and viral infections. The aims of this study were to characterize changes in immunoglobulin G (IgG) concentrations after rituximab exposure and determine the relation between low IgG concentrations and serious infections requiring hospitalization in children with rheumatic diseases.

Methods: This retrospective cohort study included patients in the Division of Rheumatology at our institution receiving at least one dose of rituximab therapy from 2002–2012 at our institution. Medication exposure, IgG levels, and infections requiring hospitalizations were recorded.

Results: We identified 101 patients (74% female) who received 174 rituximab courses. The median age was 15.2 years (range: 2.5–19.7 years) at initiation of rituximab therapy. More than one rituximab course was given in 41 patients with a maximum of 8 courses. The most common indications for rituximab were systemic lupus erythematosus and related conditions (n=60), inflammatory myopathies (n=17), and granulomatosis with polyangiitis (n=9). Of the 53 with baseline IgG measurements not receiving concurrent IVIG, IgG decreased by a median of 252 mg/dL ($p<0.001$) over a median of 0.63 years. IgG continued to be lower than baseline by a median of 190 mg/dL ($p<0.001$) at the last documented follow up, which was after a median of 1.5 years. Of the 51 with baseline IgG greater than 600 mg/dL, new-onset hypogammaglobulinemia was noted in five (range 307–560 mg/dL). Two patients had baseline and post-exposure IgG levels less than 600 mg/dL. In the 247.2 person years of follow up, there was a total of 31 hospitalizations for infection in 18 patients (12.5 infections per 100 person-years; 95% CI 8.1 to 16.9). The median time to first infection was 1.1 years (range: 0.1–4.2). Exposure to cyclophosphamide or more than one course of rituximab was not associated with a greater infection risk. However, IgG levels less than 400 mg/dL were associated with greater odds of infection (OR 5.7, 95% CI 1.1–28.8). Two of three patients who died of infectious complications had IgG levels less than 400 mg/dL.

Conclusion: IgG levels decreased after exposure to rituximab, but significantly low IgG levels at follow up were uncommon, particularly if levels were normal at baseline. However, infections requiring hospitalization were common in this study population. Infection rates at our institution were similar to published infection rates in clinical trials. Significant hypogammaglobulinemia was associated with a greater risk of infection and was present in two of the three children who died of infectious complications. Future research is required to define predictors of infection in rituximab recipients and strategies to reduce infection risk are urgently needed.

A Pilot Study Of Young Adults With Juvenile Dermatomyositis With Decreased Nailfold Capillary End Row Loops: Brachial Artery Reactivity and Oxidized Lipids. Lauren M. Pachman[1], Maureen A. McMahon[2], Tamar Polonsky[3], Gabrielle A. Morgan[1], Maria Amoruso[1] and Chiang-Ching Huang[4]. [1]Ann & Robert H. Lurie Children's Hospital of Chicago Research Center, Chicago, IL, [2]UCLA David Geffen School of Medicine, Los Angeles, CA, [3]University of Chicago Medicine, Chicago, IL, [4]Department of Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL.

Background/Purpose: Our center previously reported increased carotid intima media thickness, and lower high-density lipoprotein (HDL) levels in young or middle-age adults with a history of JDM, who were not taking medication for JDM symptoms compared to normal controls. Whether even younger adults with JDM have evidence of subclinical cardiovascular disease (CVD) is not known.

Objective: To determine whether an inception cohort of young adults with JDM have lower brachial artery reactivity (BAR) or HDL antioxidant function compared to normal controls.

Methods: After obtaining informed consent, we enrolled an inception cohort of 20 white adults, 14 F, mean age at study 21.8± 4.2 years, and mean age at JDM onset 7.6 ± 3.7 years, mean duration of untreated disease (DUD) at diagnosis 5.4 ± 4.8 months, and mean total duration of disease 14.2 ±3.9 years. JDM adults had a mean Total disease activity score (DAS) 1.9 ± 2.5, but were not taking medications for JDM symptoms. They were matched by age, race, sex and BMI with 20 healthy volunteers (mean age 23.8 ± 4.2 years). Both groups were tested for: BAR, nailfold capillary end row loop number (ERL), height and weight. To determine the antioxidant function of HDL, we measured change in fluorescence intensity caused by oxidation of dichlorfluorescein-diacetate by oxidized low density lipoprotein ±HDL. Fluorescence in the absence of HDL was normalized to 1.0. Values greater than 1.0 after the addition of HDL indicated pro-inflammatory HDL (mean HDL function in healthy controls ranges from 0.44 to 0.66).

BAR reflects endothelial function. Normal endothelial cells release nitric oxide in response to sheer stress, causing vasodilation. For BAR measurement individuals presented fasting, and lay supine in a temperature-controlled room for 10 minutes before imaging. Brachial artery diameter was measured with an 8L5 linear array transducer, 1 cm distal to the antecubital fossa. To create sheer stress, a BP cuff was inflated 50 mm Hg above the baseline BP for 4.5 min. Brachial artery diameter was then re-measured 60 seconds after cuff deflation. BAR was defined as [(post-deflation – baseline diameter)/baseline diameter] ×100%.

Results: The ERL numbers were significantly different in the JDM group, 6.35 ± 1.29 vs the controls, 7.4±0.58, p=0.003. The TNF-α −308A allele was increased in the JDM group 40% vs 15% in controls (p=0.15). Of note, the group with JDM were shorter in stature than their controls, for both JDM women, 159.7 ±8.8 cm vs 165.6 ±5.4 cm, p=0.048, and for JDM men, 172.7±3.6cm compared to controls, 181.5 ±4.6cm, p=0.0046. BAR in adults with JDM was 3.35±3.06%, and 5.22±3.07%- in normal controls (p=0.068). After adjusting for height and sex, BAR in adults with JDM was significantly decreased by 2.78 unit when compared with controls (p=0.018). There was no significant association of BAR values with the following: ERL, DUD, or DAS. The oxidized lipids did not differ between the JDM and controls.

Conclusion: The decrease in height in JDM may be a consequence of previous corticosteroid administration. The data show a marginal association of BAR in JDM, p=0.068 and a significant association with decreased BAR, p=0.018 after adjustment for height. Larger studies in young adults with JDM are needed to validate our finding.

The Arthritis Severity and Joint Damage Locus Cia25/Pia42 Is a New Genetic Regulator of the Invasive Properties of Synovial Fibroblasts. Max Brenner, Teresina Laragione and Percio Gulko. Hosftra North Shore-LIJ School of Medicine, Manhasset, NY.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic and commonly disabling disease with a prevalence of 1% world-wide. Disease remission is rarely achieved with current treatments and little is known about the genes that control disease severity and joint damage. We have identified the arthritis severity and joint damage regulatory quantitative trait locus, *Cia25/Pia42* on rat chromosome 12, in an intercross between MHC-identical arthritis-susceptible DA and arthritis-resistant ACI rats. *Cia25/Pia42* regulates collagen-induced arthritis (CIA) and pristane-induced arthritis (PIA), two established models of RA. *Cia25/Pia42* regulates the synovial expression of IL-6, IL-1β, MMP-3 and other key mediators of arthritis pathogenesis. In this study we aimed at reducing the chromosomal interval containing the gene accounting for *Cia25/Pia42*, and to study its effect in fibroblast-like synoviocytes (FLS).

Methods: We used genotype-guided breeding to generate twelve different DA.ACI(Cia25/Pia42) subcongenic strains. These new strains were studied in the homozygous state in PIA, and their FLS studied in an *in vitro* invasion assay through Matrigel known to correlate with histologic and radiographic damage.

Results: Based on the analyses of the arthritis severity and protection in the twelve new subcongenics we were able to reduce the gene-containing interval from 23Mb to 1.7Mb. The new and reduced interval contains 34 genes. FLS from congenics had an 80% reduction in invasion, compared with DA ($p=0.02$).

Conclusion: We have significantly reduced the *Cia25/Pia42* interval towards positional cloning, and identified evidence suggesting that at least part of its effect is mediated via FLS function and invasion. The discovery of the *Cia25-Pia42* gene has the potential to generate a new target for therapy in arthritis, and a new prognostic biomarker for RA.

1279

Anti-IL-6 Receptor Antibody Is Effective In Arthritis Regardless Of Obesity In Mouse Model. Miho Suzuki, Hiroto Yoshida and Yoshihiro Matsumoto. Chugai Pharmaceutical Co., Ltd., Gotemba, Japan.

Background/Purpose: Compared with non-obese patients, obese patients with rheumatoid arthritis (RA) reportedly experience worsening of symptoms [Arthritis Care Res (Hoboken). 2013; 65: 78–87] and do not respond as well to TNF inhibitors [Arthritis Rheum. 2011; 63: 359–64, Arthritis Care Res (Hoboken). 2013; 65: 94–100]. However, the efficacy of IL-6 inhibition in the treatment of RA under conditions of obesity has not yet been fully examined. In this study, we investigated the response to IL-6 inhibition in an obese mouse model of collagen-induced arthritis (CIA).

Methods: 1) To prepare a model of obesity, mice were fed a high-fat diet for 5 weeks. The level of mRNA expression of macrophage marker F4/80 in hind limbs of non-collagen-immunized obese and non-obese mice was measured by real-time PCR. CIA was then induced according to a previously described method [Arthritis Rheum. 1998;41:2117–21]. We treated CIA mice with anti-IL-6 receptor antibody (anti-IL-6R) and TNF inhibitor TNFR-Fc. Clinical symptoms of arthritis were evaluated by observation and expressed as an arthritis score on a scale of 0–4 for each limb. The level of cyclooxygenase (COX)-2 mRNA expression as a parameter of inflammation was measured by real-time PCR in hind limbs of mice at the peak of arthritis. 2) The mouse macrophage cell line RAW264.7 and synovial cells from non-obese CIA mice were cultured with IL-6 or TNF-α for 24 h. After culture, to evaluate the inflammatory response, expression level of COX-2 mRNA was determined by real-time PCR.

Results: 1) We confirmed that obesity was induced by the 5-week high-fat diet (relative body weight: 125%). At this time the expression of F4/80 mRNA was higher in obese mice than in non-obese mice. Moreover, arthritis scores were relatively higher (but not significantly) in obese mice than in non-obese mice at the peak of arthritis (Day 33). Anti-IL-6R significantly inhibited the arthritis scores on Day 33 in both obese (87% inhibition) and non-obese mice (62% inhibition). On the other hand, TNFR-Fc significantly inhibited the arthritis scores on Day 33 in non-obese mice (64% inhibition) but not obese mice (54% inhibition). The expression level of COX-2 mRNA correlated well with arthritis score and was higher in obese mice than in non-obese mice on day 33. 2) Expression of COX-2 mRNA was dramatically increased by IL-6 in RAW cells and by TNF-α in synovial cells.

Conclusion: We demonstrated that there is the potential for inflammation to be increased by obesity and that the anti-arthritis effect of TNFR-Fc was reduced in obese mice, as has been shown in clinical reports. We also demonstrated that anti-IL-6R was effective in this mouse model regardless of whether the mice were obese. One reason might be that obesity promotes macrophage infiltration, and IL-6 is prominently involved in the inflammatory response of macrophages in mice. It goes without saying that it is essential for every patient to reduce excess weight not only because of its risk of exacerbating inflammation but also because of its association with risk of developing other diseases such as cardiovascular disease and diabetes. However, anti-IL-6R has the potential to be useful in the treatment of all RA patients, even those who are obese.

The Role of Sphingosine-1-Phosphate Receptor 3 Signaling in Murine Collagen-Induced Arthiritis. Hidetake Nagahara[1], Masataka Kohno[1], Ken Murakami[1], Aihiro Yamamoto[1], Takahiro Seno[1], Wataru Fujii[1], Kazuki Fujioka[1], Yuji Kukida[1], Ryo Oda[2], Hiroyoshi Fujiwara[2] and Yutaka Kawahito[1]. [1]Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan, [2]Graduate School of Medical Science, Kyoto Prefectural University of Medicine, kyoto, Japan.

Background/Purpose: Sphingolipids represent a major class of lipids that are ubiquitously expressed in eukaryotic cell membranes. Through the interaction with a family of five G-protein-coupled receptors (S1P1–5), sphingosine-1-phosphate (S1P) triggers diverse cellular responses, including cytoskeletal changes, proliferation, and migration. The importance of S1P in inflammation has been extensively demonstrated. Some reports have shown that elevated S1P level and S1P1, 3 expression are detected in RA synovium, and S1P signaling via S1P1 promotes synoviocyte proliferation. It is suggested that S1P is an important inflammatory mediator in the pathogenesis of arthiritis, but the role of S1P3 in the pathogenesis of arthiritis are poorly understood. Thus, we examine the role of S1P3 receptor signaling in the development of collagen-induced arthritis (CIA) in murine.

Methods: Wild-type(WT) and S1P3-deficient($S1P3^{-/-}$) mice backcrossed more than 9 generations to DBA/1J mice were immunized with bovine type II collagen (CII), and the severity of arthritis was assessed over time. The severity was assessed using an established semiquantitative scoring system of 0–4: 0=normal, 1=mild, 2=moderate, 3=severe and 4=most severe. The cumulative score for all four paws of each mouse (the maximum score is 16) was used as the arthritis score to represent overall disease severity and progression in an animal. Mice were sacrificed on the 42nd day and their paws were fixed in 4% buffered formaldehyde. Paraffin sections of paws stained with hematoxylin and eosin (H&E) were systematically scanned in a microscope and histopathological changes were scored based on cell infiltration, cartilage destruction and bone erosion parameters.

Results: $S1P3^{-/-}$ mice showed signiflcantly lower arthritis severity score compared with WT mice ($P < 0.05$). Histopathological evaluation of paws obtained on day 42 showed marked reductions in synovial inflammation, cartilage destruction and bone erosion parameters in $S1P3^{-/-}$mice compared with WT mice ($P < 0.05$).

Conclusion: These results indicate that S1P3 receptor signaling plays an important role in the development of murine collagen-induced arthritis model. This pathway could be a therapeutic target for rheumatoid arthritis, although further investigations are required to elucidate the mechanism via S1P3 receptor signaling.

Inadequate Glucocorticoid Secretion in Experimental Arthritis in Rats Is Closely Linked to Impaired Mitochondria and Reduced Lipid Breakdown in the Adrenal Cortex. Christine Wolff[1], Katharina Krinner[1], Josef Schröder[2] and Rainer H. Straub[3]. [1]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, Department of Internal Medicine I, University Hospital, Regensburg, Germany, [2]Department of Phatology, University Hospital, Regensburg, Germany, [3]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, University Hospital of Regensburg, Regensburg, Germany.

Background/Purpose: In rheumatoid arthritis a functional deterioration of the HPA-axis in form of inadequately low secretion of glucocorticoids in relation to severity of inflammation can be detected. The reasons for this phenomenon are not known. The purpose of this study was to find possible reasons responsible for adrenal insufficiency during arthritis.

Methods: DA rats were immunized with type II collagen in incomplete Freund adjuvant to induce arthritis. Plasma corticosterone was evaluated by RIA and plasma ACTH by ELISA. Adrenal cholesterol was quantitatively studied by Sudan-III staining and scavenger receptor class BI (SR-BI, the HDL receptor) by immunohistochemistry. Fluorescent NBD-cholesterol uptake kinetics were analysed by flow cytometry. Ultrastructural morphology of adrenocortical mitochondria and lipid droplets was studied by electron microscopy.

Results: Initially increased corticosterone and ACTH levels were reduced to baseline levels in the later phase of the disease. Serum levels of corticosterone relative to IL-1β were markedly lower in arthritic than control animals (inadequacy). Cholesterol storage in adrenocortical cells and expression of SR-BI did not differ between immunized and control rats. However, number of impaired mitochondria largely increased during the course of arthritis (maximum on day 55), and this was paralleled by reduced numbers of activated cholesterol droplets (inhomogenous droplets relevant for generation of glucocorticoids). In addition, number of normal mitochondria positively correlated with serum corticosterone levels.

Conclusion: This first study on adrenal reasons for inadequate glucocorticoid secretion in arthritis demonstrated impaired mitochondria and altered cholesterol breakdown paralleled by low corticosterone levels in relation to ongoing inflammation.

Effect of RC-3095, An Antagonist of Gastrin-Releasin Peptide Receptor, Regulating Synovial Fibroblasts in Experimental Arthritis. Patricia Oliveira[1], Lidiane Filippin[2], Mirian Farinon[2], Vanessa Clarimundo[2], Gilberto Schwartsmann[2] and Ricardo M. Xavier[3]. [1]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil, [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [3]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil.

Background/Purpose: The gastrin-releasing peptide (GRP) is the mammalian homologue of the bombesin (BN), and its receptor signaling is involved in several functions, including inflammatory response. Both the GRP and its receptor have been found in synovial membrane and fluid of rheumatoid arthritis patients [2]. RC-3095 is an antagonist of the GRP receptor. The objective is evaluate the role of gatrin-releasing peptide and the RC-3095, a specific antagonist of the gastrin-releasing peptide receptor, in synovial fibroblast proliferation and invasion.

Methods: Mouse DBA/1J fibroblast-like synoviocyte (FLS) were isolated from the tarsus of the hind paws of collagen-induced arthritis. FLS immunocitochemistry was performed to evaluate the presence of GRP-receptor (GRPR). FLS (2×10^4/96-wells) viability in 24 h treated with RC-3095 (concentration from 0.05 to 10 mM). FLS proliferation stimulated with Lipopolysaccharide (LPS) (1 and 10 μg/mL) or GRP (0.1, 1 and 10 mM) was performed using the MTT assay in 24 h. The invasion of FLS was assayed in a transwell system using Matrigel-coated inserts from BD (Franklin Lakes, NJ, USA) and treated with GRP (10 mM), RC-3095 (1 mM) and GRP+RC-3095 (GRP 10 mM and after 30 min RC-3095 1 mM) (n= 4 per group). Differences between experimental groups were compared by ANOVA one-way test.

Results: The immunocitochemistry confirmed the presence of GRPR on FLS. RC-3095 concentrations used were not toxic on FLS, maintaining cellular viability. The dose of 1 μM was defined for other experiments because this was the highest dose with lower cell mortality ($p<0.05$). The GRP 10 mM increased the fibroblast proliferation in 18%, while LPS 10 mM increased 15% compared to FLS unstipulated ($p<0.05$). Treatment of highly invasive DBA/1J FLS with RC-3095 (1934 ± 941 cells) significantly decreased the number of cells invading Matrigel over 24 h period in 35.3% ($p=0.003$) compared to GRP (5371 ± 418.1 cells) and non-different to FLS treated with GRP+RC-3095 (3054 ± 794.5 cells).

Conclusion: RC-3095 was able to decrease synovial fibroblasts invasion stimulated by GRP. GRP increased FLS proliferation and invasion and could be involved in the development of experimental arthritis through FLS. These findings suggest that interference with the neuropeptide GRP pathway is a potential new strategy for the treatment of arthritis.

Power Doppler Ultrasound Phenotyping of Expanding Versus Collapsed Popliteal Lymph Nodes in Murine Inflammatory Arthritis. Echoe M. Bouta[1], Yawen Ju[2], Homaira Rahimi[1], Ronald Wood[2], Lianping Xing[1] and Edward M. Schwarz[1]. [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY.

Background/Purpose: Rheumatoid arthritis is a chronic inflammatory disease manifested by episodic flares in affected joints that are challenging to predict and treat. Longitudinal contrast enhanced-MRI (CE-MRI) of inflammatory arthritis in tumor necrosis factor-transgenic (TNF-Tg) mice has demonstrated that popliteal lymph nodes (PLN) increase in volume and contrast enhancement during the pre-arthritic "expanding" phase, and then suddenly "collapse" during knee flare. Given the potential of this biomarker of arthritic flare, we aimed to develop a cost-effective means of phenotyping PLN using ultrasound (US) imaging.

Methods: Power Doppler (PD) US was performed on TNF-Tg mice whose PLN were previously phenotyped as expanding or collapsed using CE-MRI. B-mode (Figure 1A) and PD (Figure 1B) 3D scans were used to generate 3D volume estimates (Figure 1C) to calculate the PD volume normalized to the PLN volume, or the normalized power Doppler volume (NPDV). To verify this methodology for vessels near the PLN, a mouse underwent Microfil perfusion and micro-CT to confirm the US structures were blood vessels near the PLN (Figure 1D).

Results: PD-US demonstrates that expanding PLN have a significantly higher NPDV versus collapsed PLN (0.553 ± 0.007 vs. 0.008 ± 0.003 mm^3; $p<0.05$). Moreover, we define the upper (>0.030 mm^3) and lower (<0.016 mm^3) quartile NPDVs in this cohort of mice, which serve as conservative thresholds to phenotype PLN as expanding and collapsed, respectively. To observe agreement between PD-US and CE-MRI, PLN were phenotyped as collapsed by PD-US and then underwent CE-MRI. Of the 12 PLN in the study, there was disagreement in 4 cases. However, these 4 cases presented with marked synovitis in the adjacent knee, a hallmark of arthritic flare, which occurs after PLN collapse. Therefore, we find that PD-US correctly phenotyped all of the PLN in this cohort.

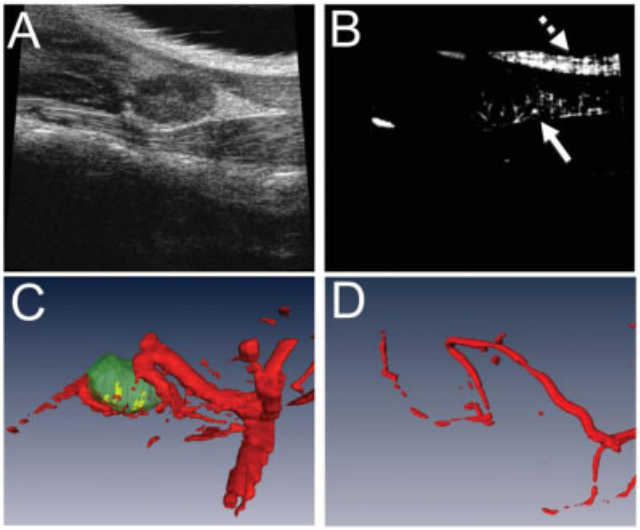

Figure 1. Quantification of NPDV using PD-US and validation with vascular micro-CT. PD-US was performed to generate the 2D images obtained using B mode (A) and PD (B) scans of the PLN. Note the artifact in the PD due to the surface of the skin (dashed arrow in B) versus the true PD signal (solid arrow in B). The PLN (green structure in C) was used to apply a mask to the total blood volume (red structures in C) to give the total PD volume within the PLN (yellow structure in C). To confirm this methodology, the mouse underwent Microfil perfusion and the micro-CT is shown (D). Note the similarities in vessel structure with decreased vessel diameter due to live *in vivo* imaging vs. perfusion.

Conclusion: We find PD-US to be more accurate for phenotyping PLN than CE-MRI. PD-US permits the PLN in the middle quartiles to be subsequently phenotyped with longitudinal scans and studied accordingly. This is a major advantage over CE-MRI phenotyping, which is too costly to utilize for this purpose. PD-US is both a safe and feasible approach and can be used to phenotype PLN as expanding versus collapsed for prospective studies.

Nuclear Receptor 4A2 Is Differentially Expressed In Animal Models Of RA During Inflammation and Resolution. Jordan Everett[1], Fiona E. McCann[2], Andrew C. Palfreeman[2], Anita T. Shaw[3], Ellen M. Gravallese[4] and Kimberlee S. Mix[1]. [1]Loyola University New Orleans, New Orleans, LA, [2]The Kennedy Institute of Rheumatology, University of Oxford, London, United Kingdom, [3]UMass Memorial Medical Center and University of Massachusetts Medical School, Worcester, MA, [4]UMass Memorial Medical Center, Worcester, MA.

Background/Purpose: Nuclear receptor 4A2 (NR4A2/nuclear receptor related 1/Nurr1) is a constitutively active transcription factor with diverse roles in normal physiology and disease processes. NR4A2 and related receptor NR4A3 are immediate-early genes potently induced by inflammatory cytokines, growth factors, and prostaglandins in inflamed joints, suggesting that these factors may mediate chronic inflammation. NR4A2 regulates transcription of MMPs and pro-inflammatory cytokines in synoviocytes and chondrocytes, and thus may serve as a novel therapeutic target for modulating inflammatory pathways in arthritis. However, the impact of NR4A expression on the onset and progression of arthritis has not been examined. In the current study, we documented receptor expression in three different murine models of rheumatoid arthritis and correlated NR4A levels with joint inflammation and resolution.

Methods: Antigen-induced arthritis (AIA), collagen-induced arthritis (CIA), K/BxN serum transfer arthritis (STA) were studied. NR4A2 protein was detected by immunohistochemistry in knee and ankle joints from the AIA and STA models, respectively. Joint images were processed with CellSens software, and NR4A2 positivity was determined for multiple regions of the synovium and cartilage. NR4A2 and NR4A3 mRNA levels were also quantified by RT-qPCR in inflamed paws from mice with CIA. Clinical scores were recorded over the course of disease, and were correlated with protein and mRNA expression levels of the NR4A receptors.

Results: In the AIA model, NR4A2 protein levels peaked during the inflammatory phase (day 8) and declined to baseline during resolution (day 12), mirroring changes in knee swelling and histological signs of inflammation. Approximately 45% of synoviocytes and 70% of chondrocytes expressed NR4A2 protein at day 8, and receptor expression was identified in both the cytoplasm and nuclei of these cells. However, in the CIA model, NR4A2 mRNA expression remained low throughout the induction and inflammatory phases, but it was induced 2.5-fold during the resolution phase (day 10 post-onset, $p<0.05$,). In contrast, NR4A3 levels peaked during the inflammatory phase of CIA (day 5 post-onset, 2.5-fold, $p<0.05$) and correlated strongly with clinical scores (Pearson's $r = 0.98$). Interestingly, NR4A2 protein was not detected at any stage in the STA model, despite robust inflammation and evidence of joint degradation.

Conclusion: This study provides evidence for the differential regulation of NR4A receptors in response to distinct pathogenic mechanisms in models of RA. NR4A2 expression coincides with inflammation in AIA and resolution in CIA, a dichotomy that may be due to differences in the effector cytokines driving these models. Furthermore, the temporal expression patterns of NR4A3 and NR4A2 suggest that these receptors may have distinct transcriptional roles during disease progression.

Choline Kinase: A Novel Target For Rheumatoid Arthritis. Monica Guma[1], Elsa Sanchez-Lopez[1], Alessia Lodi[2], Stefano Tiziani[2], Juan Carlos Lacal[3], Michael Karin[1] and Gary S. Firestein[1]. [1]UCSD School of Medicine, La Jolla, CA, [2]University of Texas at Austin, Austin, TX, [3]University Hospital Fundacion Jimenez Diaz, Madrid, Spain.

Background/Purpose: Choline kinase (ChoKa) is an essential enzyme for phosphatidylcholine biosynthesis and is required for cell proliferation. The enzyme has also been implicated in cancer disease progression, metastasis, and invasiveness. The unique tumor-like behavior of rheumatoid arthritis (RA) fibroblast-like synoviocytes (FLS) led us evaluate whether this pathway could play a role in inflammation and joint damage due to synovitis. Therefore, we examined the role of ChoKa in RA FLS and in murine arthritis and performed a targeted metabolomics assessment of this pathway.

Methods: ChoKa expression was evaluated by immunohistochemistry (IHC) and Western blot (WB). The metabolic profile of the choline kinase was determined by ^{1}H-MRS. FLS function using the ChoKa inhibitor MN58b (IC50=~5 nM) in medium and PDGF stimulated cells was evaluated by measuring 1) migration into a cleared area in cultured FLS monolayers; 2) proliferation using an MTT assay; and 3) protein expression by WB. Cell survival was determined in H2O2 treated cells by light microscopy. For arthritis experiments, mice were injected with K/BxN sera on day 0. MN58b (3mg/kg) was injected daily i.p. beginning on day 0 or day 4 after serum administration. Clinical arthritis scores were serially assessed. Joints were evaluated for inflammation and joint damage using histology and a semiquantitative scoring system.

Results: ChoKa mRNA and protein were highly expressed in RA synovial tissue and in cultured FLS. Its expression in FLS was increased 2–3-fold after TNF and PDGF stimulation, respectively with peak expression within 48 hours. Metabolomic studies of choline-containing compounds in cultured FLS extracts showed increased levels of phosphocholine in RA FLS compared to control FLS, confirming activation of this pathway. ChoKa regulated key FLS functions that might contribute to cartilage destruction in RA. For example, ChoKa inhibition with MN58b (5 uM) reduced proliferation by $79\pm3.2\%$ and migration by $54\pm15\%$ ($p<0.05$). ChoKa inhibition also markedly increased H2O2-induced apoptosis in FLS. Akt phosphorylation in response to PDGF as determined by WB was blocked by ChoKa inhibition. Finally, ChoKa inhibition signficantly decreased arthritis in pre-treatment protocols (day 0) as well as in established disease (day 4). For example, day 8 scores were 12 ± 1.6 and 7 ± 2.6 ($P<0.05$) for vehicle and MN58b-treated mice, respectively, when initiated on day 0; and were 6.6 ± 0.9 and 1.6 ± 2.5 ($P<0.05$) for PBS and MN58b-treated mice when initiated on day 4. Joint histology scores for vehicle and MN58b-treated mice for inflammation were 3.2 ± 0.5 and 1.25 ± 1 ($p<0.05$), bone erosion scores were 2.7 ± 0.5 and 0.25 ± 0.5 ($p<0.05$), and cartilage damage scores were 1.5 ± 1 and 1.6 ± 0.5 ($p<0.05$) respectively.

Conclusion: Careful dissection of the metabolic profile in RA FLS indicate that choline metabolism is abnormal and is similar to transformed cells. Blocking this pathway with a selective ChoKa inhibitor suppressed inflammatory arthritis in mice as well as the aggressive behavior of cultured RA FLS, including cell migration and resistance to apoptosis. These data suggest that ChoKA inhibition could be an effective strategy for arthritis.

Anti-Inflammatory Effects Of Tyrosine-Hydroxylase(TH)-Positive Catecholamine Producing Cells In Chronic Arthritis. Zsuzsa Jenei-Lanzl[1], Silvia Capellino[2], Frieder Kees[3] and Rainer H. Straub[4]. [1]Laboratory of Experimental Rheumatology and Neuroendocrine Immunology, Regensburg, Germany, [2]2Department of Pediatrics, Division of Endocrinology, Johns Hopkins University School of Medicine, Baltimore, Maryland 21287, USA, Baltimore, MD, [3]University of Regensburg, Regensburg, Germany, [4]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, University Hospital of Regensburg, Regensburg, Germany.

Background/Purpose: In previous studies we have shown that inflammatory processes in experimental arthritis are strongly affected by the sympathetic nervous system (SNS): In the early acute phase SNS acts proinflammatory, whereas in the late chronic phase anti-inflammatory. At the beginning of the chronic phase, the loss of sympathetic nerve fibers in synovial tissue was reported, which is paralleled by appearance of tyrosine-hydroxylase-positive (TH+) catecholamine-producing cells. Recently, TH+ cells of rheumatoid arthritis (RA) and osteoarthritis (OA) patients have been shown to exhibit anti-inflammatory properties in vitro.

In addition, it is known that the microenvironment of inflamed joints is hypoxic and that hypoxia induces tyrosine hydroxylase (TH) *in vivo*. However, further important cofactors and inducers of this catecholamine-producing enzyme have never been studied and the role of TH+ cells in vivo is not yet known.

Methods: Synovial cells of rheumatoid arthritis (RA) and osteoarthritis (OA) patients were isolated and cultivated under normoxia or hypoxia with/without stimulating enzyme cofactors of TH and inhibitors of TH. Expression of TH, TH activity, and release of cytokines and catecholamines was analyzed. The effect of TH+-cells was tested by adoptive transfer into DBA/1 mice with collagen type II - induced arthritis (CIA). TH+-cells were generated from mesenchymal stem cells (MSC) by a defined dopaminergic factors.

Results: Hypoxia increased TH protein expression, TH enzyme activity, catecholamine synthesis, and decreased release of TNF in OA/RA synovial cells compared to normoxic conditions. This inhibitory effect on TNF was reversed by TH inhibition with alpha-methyl-para-tyrosine (αMPT). Incubation with specific TH cofactors tetrahydrobiopterin (BH_4) and iron (Fe^{2+}) increased hypoxia-induced inhibition of TNF, which was also reversed by αMPT. The success of TH+ cell generation from murine MSCs was confirmed by detetction of neuronal/dopaminergic markers. Adoptive transfer of TH+ cells reduced CIA score in mice significantly, and 6 hydroxydopamine, which depletes TH+ cells, was able to reverse this effect (Fig.1).

Conclusion: In summary, this study presents that TH-dependent catecholamine synthesis exhibits anti-inflammatory effects in human RA synovial cells in vitro, which can be augmented under hypoxic conditions. In addition, the anti-inflammatory effect of TH+ cells on experimental arthritis in mice has been presented. Using generated TH+ cells might open new avenues for cellular arthritis therapy.

Pre-Clinical Proof-Of-Concept Of ALX-0761, a Nanobody® Neutralizing Both IL-17A and F In a Cynomolgus Monkey Collagen Induced Arthritis Model. Katrien Vanheusden[1], Laurent Detalle[1], Alex Hemeryck[1], Alain Vicari[2], Roland Grenningloh[3], Sofie Poelmans[1], Heidi Wouters[1] and Thomas Stöhr[1]. [1]Ablynx NV, Gent, Belgium, [2]Calypso Biotech, Geneva, Switzerland, [3]Merck-Serono, Darmstadt, Germany.

Background/Purpose: Interleukin (IL)-17 and Th17 cells are implicated in many auto-immune diseases, such as rheumatoid arthritis (RA), psoriasis and multiple sclerosis. Although IL-17(A) is the most characterized IL-17 family member, IL-17F may play a non-redundant role in Th17 driven diseases as it is secreted by other cell types. Therefore, a trivalent half-life extended Nanobody® ALX-0761 (MSB0010841) has been developed that neutralizes both IL-17A and IL-17F. A collagen induced arthritis model in cynomolgus monkey was used to demonstrate proof-of-concept.

Methods: Cynomolgus monkeys were immunized twice intra-dermally with bovine collagen type II to induce an arthritic disease mimicking human RA. Prophylactic ALX-0761 treatment was compared to vehicle: ALX-0761 was administered weekly for eight consecutive weeks and dosed subcutaneously at 2.8mg/kg or 10mg/kg. A tocilizumab treatment group (IV administration, 10mg/kg) was included as positive control. The preventive effect of ALX-0761 on arthritis development was evaluated by the measurement of arthritis score (AS) of the joints, general condition score, X-ray examination scores of the affected joints, C-reactive protein (CRP) concentrations and body weight. In addition, total target levels (both IL-17A and IL-17F), pharmacodynamic biomarkers, immunogenicity and drug exposure were analyzed.

Results: Immunisation with collagen type II established an arthritis-like disease in all animals. This was observed by worsening of the arthritis and general condition score and X-ray scores A and B, indicative of an increase in joint space narrowing and architectural joint destruction respectively. In addition, body weight loss and prevalence of high-CRP animals was most pronounced in the vehicle group. The levels of IL-17A and IL-17F increased during the establishment of the disease in the vehicle group, supporting a role for these cytokines in the onset and/or maintenance of the disease.

Treatment with ALX-0761 attenuated the disease symptoms when compared to the vehicle group. For the arthritis score as well as for the X-ray score B, ALX-0761 reached statistical significance. Clinical improvement was also observed based on the general condition score, X-ray score A, CRP levels and body weight, although no statistical significance was reached. Serum levels of the inflammatory cytokines IL-6, TNF-α, IL-15 and the cartilage degradation marker MMP-3 decreased in ALX-0761-treated animals, at day 28 or day 56, when compared to vehicle albeit not statistically significant. Serum IL-17A and IL-17F levels increased markedly upon first ALX-0761 administration and reached a plateau after two to three injections.

Conclusion: This model, responsive to the anti-rheumatic effect of tocilizumab proved to be at least partially dependent on IL-17 as evidenced by increased IL-17A and IL-17F levels in the vehicle group. We emphasize that ALX-0761 significantly improved the clinical endpoints, X-ray score B and the arthritis score and that promising biomarkers (IL-6, IL-15, MMP-3, TNFa) were identified to aid further clinical development.

1288

Development Of Antibodies Specific For Carbamylated Protein Precedes Disease Onset In Mice With Collagen-Induced Arthritis. Leendert A. Trouw[1], Bisheng Liu[1], Jing Shi[1], Diahann T.S.L. Jansen[1], Martin Hegen[2], Tom W.J. Huizinga[1], Jeroen N. Stoop[1] and René E. M. Toes[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Pfizer, Cambridge, MA.

Background/Purpose: Antibodies against citrullinated proteins are a characteristic of rheumatoid arthritis (RA). Recently, we demonstrated that autoantibodies recognizing homocitrulline containing proteins are present in sera of RA patients and predict joint damage (1). Because homocitrulline is post-translationally formed by a process called carbamylation, we named these novel auto-antibodies anti-Carbamylated Protein antibodies (anti-CarP antibodies). As no information is present on the molecular mechanisms underlying the break of tolerance and hence the induction of anti-CarP-responses, therefore we analyzed their appearance in the mouse collagen-induced arthritis (CIA) model.

Methods: CIA was induced in mice by immunization with type II collagen (CII) in complete Freund's adjuvant (CFA). Arthritis severity was monitored by clinical scoring and anti-CarP levels were determined by ELISA. The specificity of the ELISA was validated using inhibition and immunoblotting assays.

Results: Anti-CarP antibodies were not detected in naïve, non-immunized mice. However they were readily detectable in mice injected with CII and CFA demonstrating arthritic scores. The ELISA results of the specificity of the antibodies for carbamylated proteins were confirmed by inhibition assays and immunoblotting. No correlation between anti-CarP antibody levels and disease severity was observed. Injection of CFA could also cause the development of anti-Carp antibodies, indicating that arthritis is not required for the emergence of anti-CarP antibodies. However, in mice with arthritic disease, the anti-CarP response was stronger and developed more rapidly. The onset of clinical symptoms of CIA was preceded by an increase of anti-CarP IgG2a levels in the serum.

Conclusion: Anti-CarP antibodies can be detected before disease onset in mice with CIA, but are not required for disease induction. Our data indicate that induction of inflammation by e.g. CFA can lead to a break of B-cell tolerance to carbamylated proteins and the emergence of anti-CarP-antibodies.

IL-6 Is Required For Th1- and Th17-Mediated Arthritis. Alison Finnegan, Yanxia Cao and Susan Olalekan. Rush University Medical Center, Chicago, IL.

Background/Purpose: We have reported that the route of immunization in proteoglycan-induced arthritis (PGIA) determines the T helper phenotype responsible for arthritis. Intraperitoneal (i.p.) immunization induces a Th1 IFN-γ dependent arthritis whereas subcutaneous (s.c.) immunization induces a Th17 IL-17 dependent arthritis. IL-6 has been implicated in the control of leukocyte recruitment, differentiation, activation, and survival. In addition, IL-6 is involved in the differentiation of Th17 cells and in the inhibition of IFN-γ expression. In this study we examined the role of IL-6 in Th1-dependent PGIA and Th17- dependent PGIA.

Methods: Female BALB/c wild type (WT) and IL-6$^{-/-}$ littermate mice (>3 months of age) were immunized i.p. or s.c. with the G1 domain of human PG in adjuvant 3 times at 3 week intervals. Paws were examined every third day for arthritis and scored based on the intensity of erythema and swelling on a scale of 1–4. For short term in vivo T cell priming, mice were immunized and cells harvested on day 9. T cells from T cell receptor (TCR) Tg mice were transferred in WT and IL-6$^{-/-}$mice and immunized with PG in adjuvant. TCR cells were recovered 5 days later. ELISA was used to measure cytokines. Intracellular cytokines were measured by flow cytometry.

Results: In IL-6$^{-/-}$ mice, the onset and severity of arthritis was significantly reduced in both i.p. and s.c immunized mice in comparison to WT. The reduction in arthritis was associated with a reduction in IL-17 in both i.p. and s.c. immunized mice but only with reduction in IFN-γ in s.c. immunized mice. To determine the role of IL-6 in early T cell cytokine production after i.p. versus s.c immunization, we assessed IFN-γ and IL-17 in CD4+ T cells on day 9 after immunization or in TCR transfer into IL-6$^{-/-}$ mice. Despite a reduction in IFN-γ levels after arthritis induction, IFN-γ was significantly increased in s.c immunized IL-6$^{-/-}$mice in comparison to i.p. immunized mice or WT mice. IL-17 was reduced after either i.p. or s.c. immunization.

Conclusion: IL-6 is required for IL-17- and IFN-γ-dependent arthritis induced by s.c. and i.p. immunization respectively. Interestingly, despite the fact that IL-6 is known to inhibit IFN-γ, arthritis was suppressed in the IFN-γ-dependent arthritis induced by i.p. immunization. These results suggest that IL-6 effects on arthritis may be boarder than T helper cytokine responses.

Pro-Inflammatory and Anti-Inflammatory Roles Of Interferon Regulatory Factor 5 In The Development Of Collagen-Induced Arthritis. Yoshifumi Tada, Syuichi Koarada, Rie Suematsu, Satoko Tashiro, Natsumi Nagao and Akihide Ohta. Saga University, Saga, Japan.

Background/Purpose: Interferon regulatory factor 5 (IRF5) is a transcription factor that mediates signals activated by engagement of Toll-like receptors (TLRs). IRF5 polymorphisms are associated with the risk of systemic autoimmune diseases, including systemic lupus erythematosus and rheumatoid arthritis. Although it has been shown that IRF5 has crucial roles in the development of lupus in murine models, its role in arthritis has yet to be fully investigated. Therefore, the role of IRF5 in the development of murine collagen-induced arthritis (CIA) was examined.

Methods: CIA was induced in IRF5-deficient, IRF5-heterozygous, and wild-type DBA/1 mice by injecting type II collagen (CII) emulsified with CFA followed by CII with IFA 21 days later. The incidence and severity of arthritis were then evaluated, and cytokine production by spleen cells in response to CII and serum anti-CII antibody levels were determined. Wild-type mice were treated with IRF5-specific siRNA during the progression phase of CIA. For non-specific suppression, siRNA was mixed with atelocollagen and injected intravenously. For antigen-presenting cell (APC)-specific suppression, siRNA was mixed with schizophyllan, a beta-glucan that binds to dectin-1, and injected intraperitoneally.

Results: IRF5-deficient mice developed a similar degree of arthritis as wild-type mice. However, IRF5-heterozygous mice showed reduced incidence and severity of arthritis compared with wild-type or IRF5-deficient mice. The final incidence was 79%, 56%, and 75%, and the mean arthritis index was 4.8, 1.8, and 4.2, in IRF5+/+, IRF5+/−, and IRF5−/− mice, respectively. These data suggest that IRF5 has the dual effects of suppression and promotion in the development of CIA. IRF5-deficient mice showed decreased levels of anti-CII antibody, but spleen cells from IRF5-deficient mice produced higher amounts of IL-17 in response to CII. Administration of siRNA by a non-specific delivery system during the course of CIA attenuated the arthritis in wild-type mice. In contrast, treatment with siRNA by an APC-specific delivery system significantly exacerbated the CIA.

Conclusion: IRF5 has roles in anti-CII antibody production and Th17 induction, and it shows both pro- and anti-inflammatory effects in the development of CIA. IRF5 in APCs has a regulatory role in the development of CIA.

COVA322: Overcoming Limitations Of Current Biologics In Rheumatoid Arthritis By a Novel, Bispecific Tumor-Necrosis-Factor-Alpha/Interleukin-17A (TNF/IL-17A) Inhibitor Moving Towards The Clinic. Dragan Grabulovski, Michela Silacci, Nadja Baenziger-Tobler, Wibke Lembke, Wenjuan Zha, Richard Woods, Isabella Attinger-Toller, Roger Santimaria, Susann Koenig-Friedrich, Ulrike von der Bey, Mathias Locher and Julian Bertschinger. Covagen AG, Schlieren, Switzerland.

Background/Purpose: Biologic treatment options such as TNF inhibitors have revolutionized the treatment of inflammatory diseases, such as rheumatoid arthritis (RA), psoriasis and psoriatic arthritis. However, there is still a significant unmet medical need in these diseases. In RA for example, only about half of all patients achieve an ACR50 score and many become refractory to anti-TNF treatment after a few years. Recent data suggest that full and long-lasting responses to TNF inhibitors are limited because of the activation of the pro-inflammatory T_H17/IL-17 pathway in patients. Therefore, an attractive avenue to achieve superior efficacy levels in inflammatory diseases represents dual TNF/IL-17A inhibition. In Collagen-Induced-Arthritis (CIA) animal models it was recently demonstrated that dual TNF/IL-17A inhibition resulted in significant superior activity as compared to the treatment of mice with the monospecific anti-TNF and anti-IL-17A inhibitors. We present here COVA322, a bispecific anti-TNF/IL-17A drug candidate moving towards the clinic.

Methods: Using phage display technology we have isolated Fynomers inhibiting human IL-17A. Fynomers are small binding proteins (7 kDa) derived from the human Fyn SH3 domain which can be engineered to bind to essentially any target of interest with high affinity and specificity. After genetic fusion of the anti-IL-17A Fynomer to a commercially validated anti-TNF antibody the resulting bispecific molecule COVA322 was characterized in-depth for its biophysical and *in vitro*/*in vivo* inhibition properties.

Results: COVA322 inhibited TNF and IL-17A with picomolar inhibition potencies as shown in a variety of different cell assays. Moreover, we could show that COVA322 bound and inhibited simultaneously TNF and IL-17A, as determined by simultaneous binding studies and inhibition cell assays. Importantly, COVA322 was able to inhibit both TNF and IL-17A in an acute inflammation model in mice. In addition, the fusion of the anti-IL-17A Fynomer to the fully human anti-TNF antibody did not alter the favorable biophysical properties of the antibody: First, COVA322 could be purified with very high yields (3.5 g/l in a 10 liter fermentor) from a stable CHO cell line, using standard methods as typically applied for the purification of conventional monoclonal antibodies. Second, COVA322 was monomeric and showed no signs of aggregation even after months of storage at 4 °C in PBS as determined by size exclusion chromatography.

Conclusion: These encouraging results indicate that COVA322 has highly promising biophysical properties. Through its unique mode-of-action of inhibiting simultaneously TNF and the IL-17A/A homodimer, COVA322 has game changing potential in the treatment of inflammatory diseases.

The Spatial Energy Expenditure Configuration and Possible Applications In An Experimental Model Of Arthritis. Susanne Klatt[1] and Rainer H. Straub[2]. [1]Laboratory of Exp. Rheumatology and Neuroendocrine Immunology, University Hospital Regensburg, Regensburg, 93055, Germany, [2]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, University Hospital of Regensburg, Regensburg, Germany.

Background/Purpose: An autoimmune response with differentiation and proliferation of immune cells and the subsequent tissue-directed inflammatory process in the symptomatic phase of the disease are very energy-demanding. As recent calculations demonstrate, the activated immune system needs approximately 20% of the basal metabolic rate.

Thus, energy regulation and cellular bioenergetics are of outstanding importance to serve a stimulated immune system. During inflammation, particularly during the chronic process of inflammation in long standing inflammatory diseases like rheumatoid arthritis, a reallocation of energy-rich fuels to the activated immune system is necessary in order to nourish the inflammatory process. Energy consumption and, thus, ATP generation can be measured by studying the consumption of oxygen.

The energy expenditure in different organs at different time points has never been investigated during immunization. We want to find out if, and how the energy expenditure in different organs changes during the course of experimental arthritis.

Methods: A new technique termed "spatial energy expenditure configuration (SEEC)" was developed to demonstrate bodily areas of high energy demand. SEEC is based on removal of tissue during the course of arthritis, and subsequent determination of oxygen consumption. For that purpose, small weighed pieces of the respective organ with a size of 4 mm are placed in 24-well multidishes with integrated oxygen sensors, which allows for non-invasive detection of oxygen consumption *in vitro*. SEEC was established in healthy control animals, arthritic animals and animals that underwent prior sympathectomy. The model of type II collagen arthritis in DBA/1 mice is used in order to develop an arthritic-specific SEEC. We determined the oxygen consumption in spleen, thymus, draining lymph nodes, liver, kidney, brain and knee joints during the course of experimental arthritis for 70 days. The values are given in μmol O_2/l/h and refer to 4 mm sized pieces as percentage of mouse weight.

Results: In draining lymph nodes of arthritic DBA/1J mice we observed a marked increase in oxygen consumption during the course of arthritis (200 %). Sympathectomy prior to immunization increases energy consumption in draining lymph nodes, which is most probably a sign of retention of leucocytes in the lymph node. C57BL/6 mice deficient for the important adipose triglyceride lipase revealed an increased oxygen consumption in the liver. This might be due to a lack of lipolysis activity, and therfore increased gluconeogenetic activity in the liver for the generation of energy rich fuels in form of glucose. ATGL-deficient arthritic animals also showed higher energy demand in lymph nodes, adrenals and gut.

Conclusion: The SEEC technique enables us to identify locations of high energy demand that are involved in the initiation and continuation of the autoimmune process in an animal model of arthritis. We identified the draining lymph nodes as target organ of the sympathetic nervous system, which will be further investigated. The technique will be applied to other chronic inflammatory disease models in order to detect further participating organs.

Serum Matrix Metalloproteinase 13 As a Translational Marker For Efficacy Of Anti-Arthritic Treatments In Rat Collagen Induced Arthritis and Mouse Model Of Lipopolysaccharide-Induced Bone Resorption. Ines Glojnaric, Snjezana Cuzic, Boska Hrvacic, Vanesa Ivetic Tkalcevic, Miroslava Dominis Kramaric and Vesna Erakovic Haber. Fidelta Ltd., Zagreb, Croatia.

Background/Purpose: Matrix metalloproteinase 13 (MMP-13) is expressed by chondrocytes and synovial cells in human osteoarthritis and rheumatoid arthritis (RA) (Takaishi et al., 2008). Serum MMP-13 is increased in stages III and IV in RA and treatment with methotrexate (MTX) reduced serum concentrations of MMP-13 in RA patients (Takemura et al., 2005; Fiedorczyk et al., 2006). The aim of the study was to evaluate translational potential of serum MMP-13 as a biomarker for treatment efficacy. Therefore, we investigated effects of different anti-arthritic treatments on serum MMP-13 concentrations in correlation with severity of bone destruction in rat collagen induced arthritis (CIA). Serum MMP-13 was also used as a systemic marker of bone destruction in a mouse LPS-induced bone resorption model.

Methods: CIA was induced in male Dark Agouti rats by immunization with bovine type II collagen (days 0 and 7) and the animals were treated intraperitoneally with etanercept (10 mg/kg, 3 times per week) or orally with MTX (0.1 mg/kg once daily) starting from day 17 to day 31. Histological evaluation was performed on hind paws by scoring bone and cartilage lesion, cell infiltrate and pannus severity (scoring system ranged from 1 to 4 for all parameters). In the LPS induced bone resorption model, mice were subcutaneously injected by a single dose of 20 mg/kg LPS (*E.coli*) and treated subcutaneously with MTX (5, 0.5 and 0.05 mg/kg once daily) for 4 days. Serum MMP-13 concentration was determined in both models by ELISA (USCNK Life Science Inc., China). Serum MMP-13 concentrations were correlated with histological data on individual level.

Results: Treatment with both etanercept and MTX significantly reduced the mean serum MMP-13 concentration in rat CIA (63% and 33%, respectively). On the level of individual values, serum MMP-13 concentration correlated with individual total histological scores with $R^2=0.74$ for MTX and $R^2= 0.67$ for etanercept. The correlation with individual bone and cartilage lesion scores showed to be even better for etanercept ($R^2=0.72$ and $R^2=0.68$, respectively) while for MTX the correlations were comparable with the one obtained for individual total histological scores ($R^2=0.71$ for both). In LPS induced bone resorption model, treatment with MTX dose dependently reduced the mean serum MMP-13 concentrations: a 100% reduction at 5 mg/kg, 84% at 0.5 mg/kg and no inhibition at 0.05 mg/kg.

Conclusion: Our data showed that serum MMP-13 concentration measurement is an useful tool to assess effects of anti-arthritic therapy since it correlates with severity of bone and cartilage destruction. Furthermore, serum MMP-13 concentrations can be effectively used as marker of compound potency in a short, simple model of LPS-induced bone resorption in mice to predict efficacy of treatment in CIA. Since MMP-13 was shown to be a marker of disease activity in humans, these results strongly support its usefulness as a translational marker.

Anti-Inflammatory Effect Of Resveratrol As a Dietary Supplement In An Antigen-Induced Arthritis Rat Model. Romina R. Riveiro-Naveira[1], Jesus Loureiro[1], Alberto Centeno-Cortés[2], Eduardo López-Peláez[2], Carlos Vaamonde-García[1], M. Noa Valcárcel-Ares[1], Francisco J. Blanco[3] and Maria J. López-Armada[1]. [1]Aging and Inflammation Research Lab, INIBIC-CHU A Coruña, A Coruña, Spain, [2]Experimental Surgery Unit, CHU A Coruña, A Coruña, Spain, [3]Osteoarticular and Aging Research Laboratory, Proteomics Unit-Associated Node to ProteoRed-ISCIII, INIBIC-CHUAC, A Coruña, Spain.

Background/Purpose: Inflammatory cells like macrophages, lymphocytes and neutrophils in hyperplasic synovial tissue have been identified as key players in the onset and development of rheumatoid arthritis (RA). Resveratrol (RSV) is a natural antioxidant with potent immunomodulatory and anti-inflammatory properties. The aim of this study was to investigate the preventive effect of dietary resveratrol and its ability to suppress inflammatory arthritis progression in an acute antigen-induced arthritis (AIA) rat model.

Methods: Six-week-old female Lewis rats were randomized into four study groups: healthy group (n=19), AIA group (n=24), RSV group (n=26) and diclofenac (DCF) group (n=17). RSV (2 mg/day) was administered daily by oral gavage as a dietary supplement beginning one month before AIA induction until sacrifice day, 48h after intraarticular injection. DCF (1,2 mg/day) was orally administered three days before AIA induction until sacrifice day. Joint swelling was assessed by measuring the mediolateral diameter of both right and left knee joints with a digital calliper. Severity of inflammation was evaluated using a blind damage scoring system (H&E). To characterize inflammatory cell infiltration and chemokine levels, CD68, CD3 and MCP-1 expression were evaluated by immunohistochemistry.

Results: On day 2 after intraarticular injection, RSV animals exhibited significant reduced knee swelling, similar to DCF group, in comparison to AIA animals (mediolateral diameter mean: RSV 7,775 mm ± 0,169, n=26; DCF 7,776 mm ± 0,253, n=17 vs. AIA 8,281 ± 0,127, n=24; $p<0,05$). Accordingly, histopatological evaluation demonstrated a reduction in synovial hyperplasia and cell infiltration in both RSV and DCF groups compared with AIA animals. CD68 and CD3 infiltrate was significantly attenuated in RSV rats synovium (0,843 ± 0,369, n=5 and 1,290 ± 0,198, n=19, respectively) compared with AIA group (CD68 3,741 ± 1,428, n=5 and CD3 2,868 ± 0,5707, n=18, $p<0,05$), similar to DCF group (CD68 1,656 ± 0,522, n=13 and CD3 1,753 ± 0,359, n=15). MCP1 levels in the synovium were significantly attenuated in RSV and DCF groups compared with AIA animals (3,167 ±

0,2649 and 2,453 ± 0,628, respectively vs. AIA 4,400 ± 0,4922, $p<0,05$).

Conclusion: The results of this study suggest that a dietary supplement with the natural antioxidant resveratrol can effectively control inflammation and could exert a protective effect against RA establishment and progression.

Mechanisms For Fostamatinib-Induced Blood Pressure Elevation. Matthew Skinner[1], Karen Philp[1], David Lengel[2], Lucy Coverley[1], Eva Lamm Bergstroem[3], Philip Glaves[1], Helen Musgrove[1], Helen Prior[1], Martin Braddock[1], Russell Huby[1], Jon O Curwen[1], Paul Duffy[1] and Alex Harmer[1]. [1]AstraZeneca R&D Alderley Park, Macclesfield, United Kingdom, [2]AstraZeneca R&D Waltham, Waltham, MA, [3]AstraZeneca R&D Mölndal, Mölndal, Sweden.

Background/Purpose: Fostamatinib is a kinase inhibitor with activity at spleen tyrosine kinase. In clinical studies in patients with rheumatoid arthritis, fostamatinib treatment was associated with an increase in arterial blood pressure (BP). Some tyrosine kinase inhibitors are known to cause BP elevation, potentially by inhibiting vascular endothelial growth factor receptor 2 (VEGFR2). Therefore, we investigated whether there was a mechanistic link between fostamatinib-induced BP elevation and inhibition of VEGF signaling.

Methods: BP was measured in conscious rats using combined automated blood sampling and radio telemetry following oral dosing with fostamatinib. The effects of intravenous dosing of R406 (the active metabolite of fostamatinib) on BP, femoral vascular conductance and responses to acetylcholine (ACh), reactive hyperemia and VEGF were assessed in rats anesthetized with isofluorane (0.5 to 5%). The effects of R406 on contractile parameters were determined using rat isolated aorta and human resistance vessels in vitro. The effects of R406 on VEGF-stimulated nitric oxide production were determined using human microvascular endothelial cells in vitro. VEGFR2 phosphorylation was determined in mouse lung, ex vivo, following oral dosing with fostamatinib.

Results: In conscious rats, fostamatinib caused a dose-dependent increase in BP. The time course of the BP effect correlated closely with changes in R406 plasma concentration, consistent with a direct pharmacologic relationship. In anesthetized rats, infusion of R406 increased BP and decreased femoral arterial conductance. Endothelial function was not reduced, as infusion of R406 did not inhibit hyperemia- or ACh-induced vasodilatation in rats. R406 had no effect on the contraction of intact isolated vessels, suggesting the decreased arterial conductance was an indirect effect. R406 inhibited VEGF-stimulated nitric oxide production from human endothelial cells in vitro, and treatment with R406 inhibited VEGFR2 phosphorylation in vivo. R406 also inhibited VEGF-induced hypotension in anesthetized rats (see Figure).

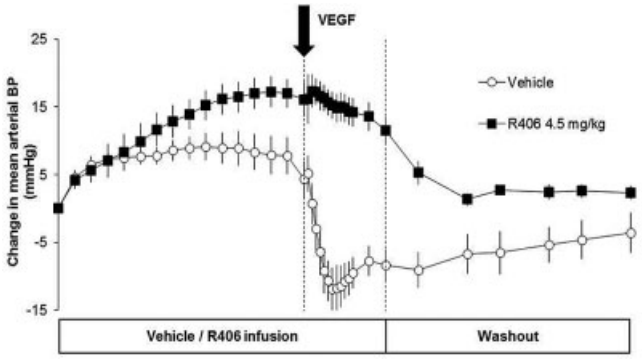

Figure. Effect of R406 on VEGF-induced vascular responses in anesthetized rats. The effects of intravenous infusion of vehicle or 4.5 mg/kg R406 on mean arterial Bp when given in conjunction with VEGF. Vehicle or R406 were administered for 20 minutes as an i.v. infusion. At 15 minutes into the infusion a bolus 55 μg/kg dose of VEGF was administered. Parameters were monitored for a further 15 minutes after the 20 minute infusion period. Data are shown as mean ± s.e.m. change from baseline, n=6 per group. Data were statistically compared via ANCOVA. The first vertical line represents the VEGF application at 15 minutes, and the second line represents the end of the R406 infusion at 20 minutes, and the start of the washout.

Conclusion: These data suggest that increased vascular resistance, potentially secondary to reduced VEGF-induced nitric oxide release from the endothelium, may contribute to BP increases observed with fostamatinib. This is consistent with the means by which other drugs that inhibit VEGF signaling elevate BP, although the contribution of other mechanisms cannot be excluded.

Deletion Of RBP-J In a Murine Model Of Inflammatory Arthritis Reveals Pro-Inflammatory Cytokine Expression and Immunophenotypic Differences. Soumya D. Chakravarty, Karmen Au, Lionel B. Ivashkiv and Xiaoyu Hu. Hospital for Special Surgery, New York, NY.

Background/Purpose: RBP-J, a DNA-binding protein, serves as the central transcriptional regulator of the Notch signaling pathway. Prior *in vitro* work has demonstrated that RBP-J plays a critical role in macrophage activation, polarization, and modulating pro-inflammatory cytokine expression under LPS stimulation. Others have demonstrated that TNFα can induce myeloid derived suppressor cell (MDSC; suppressors of T cell function) activity via iNOS and arginase expression, both of which are strongly dependent on RBP-J and thus implicating its role in mediating potential downstream effects of MDSCs in inflammatory arthritis. Here, we evaluated the *in vivo* effects of RBP-J's conditional deletion using the Mx1Cre system, as well as in the myeloid cell compartment only, on pro-inflammatory cytokine expression, lymphoid tissue immunocyte composition, and MDSC populations, using a K/BxN serum transfer model of inflammatory arthritis.

Methods: RBP-J$^{flox/flox}$ Mx1Cre and LysM-Cre knock-out mice with controls (n=4–5 mice per group) were used. After treatment with K/BxN serum, the clinical course of arthritis was followed by measuring total joint thickness up to 14 days, at which point the mice were sacrificed. Total joint RNA from each mouse was obtained for gene expression analyses by real-time PCR. Splenic tissue was pooled collectively from each group of mice for immunophenotyping through flow cytometry. The same was done for superficial inguinal and draining popliteal lymph node (LN) tissue, as well as bone marrow. Statistical analysis was done using the unpaired student's t-test with $p < 0.05$ considered significant.

Results: Mx1Cre deletion, but not myeloid-specific deletion, of RBP-J resulted in significantly heightened K/BxN serum-induced arthritis (up to 14 days post-induction) versus controls. Gene expression profiling of total joint tissue from RBP-J Mx1Cre deleted mice showed trends toward increased IL-12p40 expression, decreased IL-1β expression, with expression levels of IL-6, TNFα, Notch target genes, as well as bone turnover markers, being comparable. In contrast, myeloid-specific RBP-J deleted mice showed decreases in IL-12p40/IFNγ gene expression with variable expression of IL-6, TNFα, and Notch target genes. Post-arthritis induction, Mx1Cre deletion of RBP-J resulted in higher proportions of CD11b$^+$ and Ly6G$^+$ cells in splenic tissue. MDSC populations identified using various combinations of CD11b/Ly6G/Ly6C/CD115 markers in lymphoid tissue and bone marrow demonstrated a downward shift in proportions with RBP-J deletion and TNFα expression.

Conclusion: Deletion of RBP-J using the Mx1Cre system, but not myeloid-specific deletion, leads to heightened K/BxN serum-induced inflammatory arthritis. Along with selective modulation of pro-inflammatory cytokine gene expression *in vivo*, coupled with differences in myeloid cell composition and trafficking observed, including that of the MDSC population, this suggests that the stromal versus hematopoietic compartments expressing RBP-J may be contributing to these observations. Further functional studies to better characterize these conclusions are currently underway.

Human IL-1alpha Conditional Transgenic Mice Mimic Autoinflammatory Syndromes In Human. Hiroya Kanagawa[1], Yasuo Niki[2], Yoshiaki Toyama[3] and Takeshi Miyamoto[4]. [1]Department of Orthopaedic Surgery, Keio University, Shinjuku-ku, Tokyo, Japan, [2]Department of Orthopaedic Surgery, Keio University, Tokyo, Japan, [3]Department of Orthopaedic Surgery, Keio University School of Medicine, Shinjuku, Japan, [4]Department of Orthopaedic Surgery, Keio University, Shinjuku-ku, Tokyo, Japan.

Background/Purpose: Recently, IL-1 is implicated in the pathogenesis of autoinflammatory syndrome, which characterized by rash, fever, systemic polyarthritis and neurological comorbidity. Recently, IL-1 becomes noticed now as a therapeutic target of adult onset still's disease and macrophage activation syndrome. To date, animal model of adult onset "IL-1 disease" has not been reported. Herein, we newly established IL-1alpha transgenic mice with conditional regulation of IL-1alpha overexpression, which mimicked adult onset IL-1 disease in humans. The purpose of the present study is to clarify the pathology of adult onset IL-1 disease through these mice.

Methods: Human IL-1alpha (hIL1alpha) conditional transgenic (cTg) mice were generated as loxP-neomysin resistant gene (Neo)-polyA-loxP-hIL1alpha sequence under an beta-actin promotor in a C57BL/6 background. In non-inducing condition, Neo was expressed without hIL1alpha-expression, whereas in inducing condition in the presence of Cre, Neo-polyA sequence was popped out, and hIL1alpha overexpression was induced. We crossed inducible MxCreTg mice with hIL1alphacTg to yield MxCre/hIL1alphacTg. PolyIpolyC (pI-pC) was administered to 8 week-old cTg mice to activate Mx promotor. The mice were sacrificed two weeks after pI-pC administration, and the severity of arthritis was evaluated using arthritis score, followed by a histological examination.

Results: Two weeks after pI-pC administration, hIL1alphacTg mice developed large joint arthritis in upper and lower limbs, and its incidence was 100%. Histopathologically, loss of cartilage, bony erosion, and the formation of pannus-like tissues were observed in all cTg mice. The level of transgene-derived hIL1alpha in blood was significantly elevated. The number of white blood cells and platelets were significantly elevated, in contrast, red blood cell count and hemoglobin level were decreased. The levels of IL-6, TNF, and leukemia inhibitory factor (LIF) was significantly elevated. The bone mineral density of the femur was significantly reduced. Flowcytometric analysis revealed that the proportion of Mac1+Gr1+ was significantly elevated in joint fluid and bone marrow.

Conclusion: We generated a mouse model of autoinflammatory syndrome in which systemic inflammatory arthritis was intentionally induced under a control of pI-pC administration. The incidence of large joint arthritis was 100% even in a relatively arthritis-resistant C57BL/6 background. These mice are recognized as a useful tool for better understanding of adult onset IL-1 disease.

Statin Alleviates Rheumatoid Arthritis Progression Through Diminishing Inflammation Or Oxidative Stress-Induced Cyr61 Synthesis. Kuo Liang Hou and Sze Kwan Lin. School of Dentistry, College of Medicine National Taiwan University, Taipei, Taiwan.

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease stimulated by inflammatory mediators and oxygen species within joint space cause joint deformity and destruction. Excess amounts of Cysteine-rich protein 61 (Cyr61) will stimulate dysregulated angiogenesis, macrophage chemotaxis and cell apoptosis. Epidemiological study also suggested the connection between Cyr61 and RA development, although the pathogenesis remained unclear. In patients with autoimmune disease, genetic polymorphism was noted in their forkhead transcription factor (FoxO), a molecule responsible for DNA repair and longevity. Furthermore, a positive correlation between the degree of genetic deformity and disease severity was demonstrated. Sirtuin (SIRT) −1 is an essential co-factor of FoxO activity: interaction between SIRT1 and FoxO can resist the ROS-induced apoptosis. Concerning the connection between FoxO and RA, only a few studies have addressed the modulation of FoxO on the apoptosis of fibroblast-like synoviocyte, macrophages and T cells in RA. However, great controversy about the role of FoxO on their fate still existed. Taken together, it may be possible that FoxO may involve in RA development via its inflammation-modulating effect. Statin can attenuate inflammation, in addition to its well-known cholesterol-lowering effect. Mechanisms underlying the modulation of statin on RA progression are still unclear, since most of the investigations on the effects of statin on RA were epidemiological studies. The aims of the study were to examine the role of SIRT1/FoxO3a in Cyr61 expression in rheumatoid arthritis synovial fibroblasts (RASFs) and the influence of simvastatin on this pathway. In a model of collagen-induced arthritis (CIA), the relation between disease progression and FoxO3a/Cyr61 signaling in synovial fibroblasts (SFs) was assessed

Methods: Cyr61 and SIRT1 expressions, localization of FoxO3a in the nucleus/cytoplasm and phosphorylation/acetylation of FoxO3a were examined by immuneprecipitation and Western blotting. Promoter activity of *Cyr61* gene was evaluated by luciferase assay with or without forced expression of FoxO3a and SIRT1 by lentiviral transduction. FoxO3a/*Cyr61* promoter interaction was examined by chromatin immunoprecipitation. In CIA rats, expressions of Cyr61 and phospho-FoxO3a in SFs were examined by immunohistochemistry.

Results: In RASFs, simvastatin suppressed Cyr61 and CCL20 secretion. Simvastatin maintained Foxo3a binding to *Cyr61*promoter. SIRT1 decreased Cyr61 expression and deacetylated FoxO3a whereas simvastatin upregulated SIRT1 and SIRT1/FoxO3a binding in RASFs. In rats with CIA, simvastatin alleviated arthritis and suppressed Cyr61 expression and FoxO3a phosphorylation in SFs.

Conclusion: Cyr61 is important in RA pathogenesis and SIRT1/FoxO3a signaling is crucial to Cyr61 induction in RASFs. Simvastatin is beneficial to inflammatory arthritis by upregulating SIRT1/FoxO3a signaling in SFs. Continued study of the pathways linking sirtuins, FoxO proteins and inflammatory responses of RASFs may provide new insights into the pathophysiology of RA.

PTEN Controls Osteoclastogenesis and Inflammatory Bone Destruction In a TNF-Driven Model Of Arthritis. Stephan Blueml[1], Gernot Schabbauer[2], Antonia Puchner[1], Victoria Saferding[1], Emine Sahin[2], Julia Brunner[2], Tobias Lohmeyer[2], Josef S. Smolen[1] and Kurt Redlich[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University Vienna, Vienna, Austria.

Background/Purpose: Local bone destruction in inflammatory arthritides in humans such as rheumatoid arthritis is a serious health burden and the major cause of disability and severely reduced quality of life in these diseases. Damage to the bony structures is exclusively mediated by a special cell type, the osteoclast (OC). Therefore, it is important to understand factors and pathways regulating the generation of OCs under inflammatory conditions. In this study, we analyzed the impact of the PI3-Kinase/PTEN axis on OC generation and bone biology in an animal model of inflammatory bone loss.

Methods: We induced osteoclastogenesis in wt and PTEN deficient bone marrow cells and measured the generation of OCs, their resorptive capacity and induction of OC differentiation markers *in vitro*. Moreover, we analyzed mice with a monocyte/macrophage-specific deletion of PTEN (myeloid specific $PTEN^{-/-}$) by bone histomorphometry and crossed these mice into hTNFtg animals.

Results: We show that myeloid specific $PTEN^{-/-}$ mice display increased osteoclastogenesis *in vitro* and *in vivo* compared to wt mice. Loss of PTEN did not affect the generation or survival of osteoclast precursor cells. However, PTEN deficiency greatly enhanced RANKL-induced expression of the master transcription factor of osteoclastogenesis, NFATc1, resulting in markedly increased terminal differentiation of osteoclasts *in vitro*. Under non-inflammatory conditions, enhanced

osteoclastogenesis did not result in systemic bone loss *in vivo*. However, when we crossed myeloid specific PTEN$^{-/-}$ into hTNFtg mice we found significantly decreased grip strength scores in myeloid specific PTEN$^{-/-}$/hTNFtg mice compared to wt hTNFtg mice. Joint swelling scores, however, were not different between both groups. In line, myeloid specific PTEN$^{-/-}$/hTNFtg mice displayed enhanced local bone destruction as well as OC formation in the inflamed joints, whereas the extent of synovial inflammation was not different between the groups. Analysis of the synovial membranes of wt and myeloid specific PTEN$^{-/-}$ animals revealed similar relative compositions of the cellular infiltrate including neutrophil granulocytes as well as macrophages which can serve as OC precursors. This suggests that increased capacity for osteoclastogenic differentiation rather than enhanced recruitment of precursor cells is responsible for the enhanced local generation of OCs.

Conclusion: Taken together, these data demonstrate that sustained PI3-Kinase activity in myeloid cells specifically elevated the osteoclastogenic potential of these cells, leading to enhanced inflammatory local bone destruction. Therefore, targeting the PI3-Kinase pathway therapeutically may be especially useful for the prevention of structural joint damage.

The Role Of Celastrol On Osteoclastogenesis and Bone Erosion In Collagen-Induced Arthritis. Ke Gan[1], Wenfeng Tan[2], Miaojia Zhang[2], Xiaoke Feng[3] and Lingxiao Xu[2]. [1]Nanjing University of Chinese Medicine, nanjing, China, [2]the First Affiliated Hospital of Nanjing Medical University, Nanjing, CHINA., Nanjing, China, [3]the First Affiliated Hospital of Nanjing Medical University, China, Nanjing, China.

Background/Purpose: Celastrus and its extract have been proven effective for treatment Rheumatoid arthritis (RA). Celastrol is one of bioactive component of Celastrus with a potent anti-inflammatory effect in RA therapy. However, the direct role of Celastrol on osteoclast remain unknown.

Objectives: To examine the effects of Celastrol on osteoclastogenesis in vitro and bone erosion in collagen-induced arthritis(CIA).

Methods: The roles of Celastrol on osteoclastogenesis in RAW264.7 was evaluated by tartrate-resistant acid phosphatase (TRAP) staining, Real-Time PCR and Western-blot Activity of bone resorption was tested by pit formation assay in the presence or absence of Celastrol. CIA mice were by intraperitoneal injections (IP). The effects of Celastrol bone erosion was analyzed using ELISA, Real-Time PCR, histological analysis and Micro-CT.

Results: Celastrol inhibited RANKL-induced formation of TRAP+ multinucleated cells and bone-resorbing activity in a dose-dependent manner. The osteoclast formation was completely blocked with 0.3 μM of Celastrol. Celastrol reduced the RANKL-induced expression of NFATc1, c-Jun and c-Fos and phosphorylation of NF-κB and MAPK signals in RAW264.7. In CIA mice, administration of Celastrol markedly supressed the arthritis score and reduced bone damage in the joints as demonstrated by histology and bone Micro-CT. Osteoclastic markers in the serum and joint tissues were significantly downregulated by Celastrol.

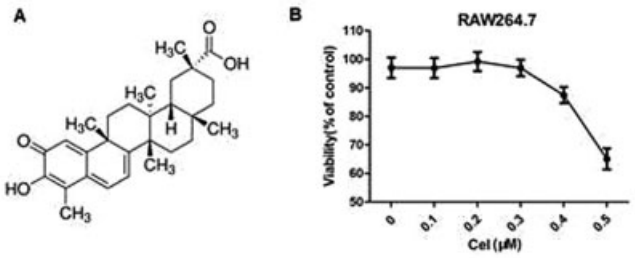

Figure 1. Cytotoxicity of Celastrol for RAW264.7 cells.

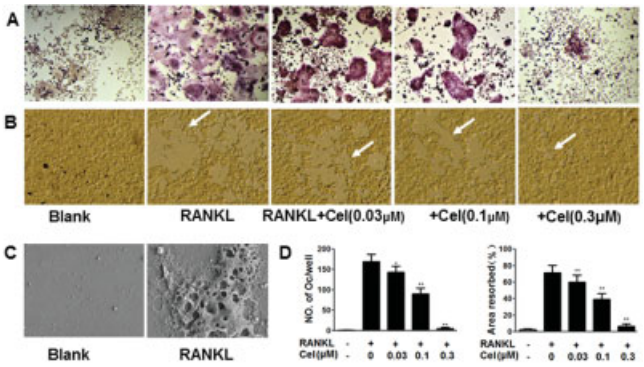

Figure 2. Effect of Celastrol for RANKL-induced osteoclast differentiation and bone resorption of RAW264.7

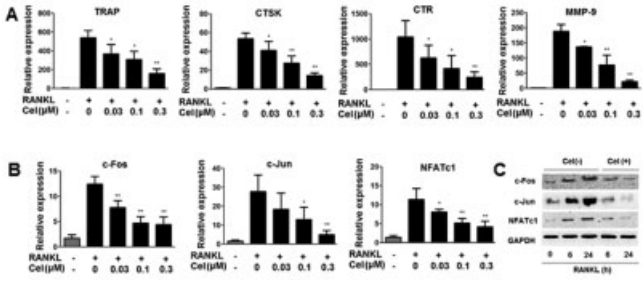

Figure 3. Effect of Celastrol on osteoclastogenic mRNA expression.

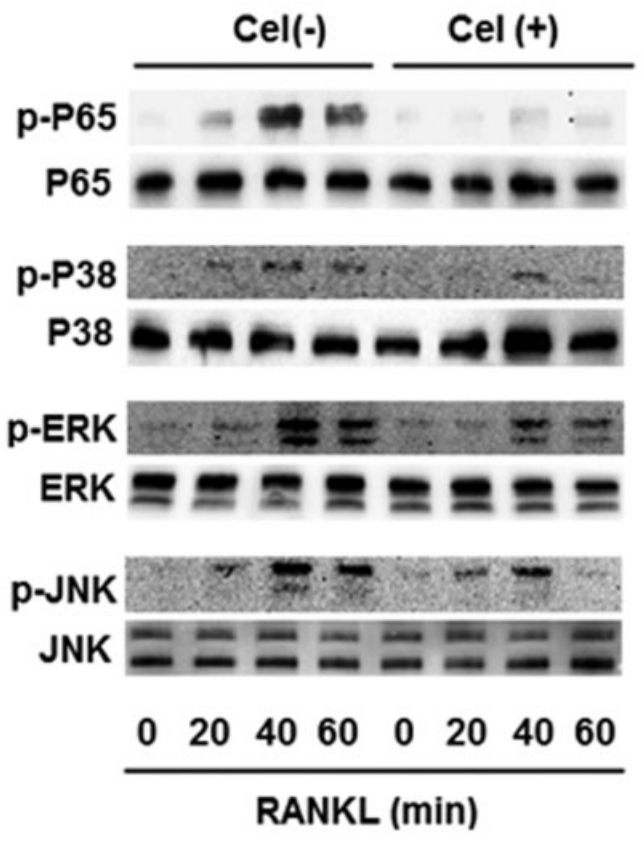

Figure 4. Effects of Celastrol on the activation of MAPKs and NF-κB p-65 in RAW264.7 cells.

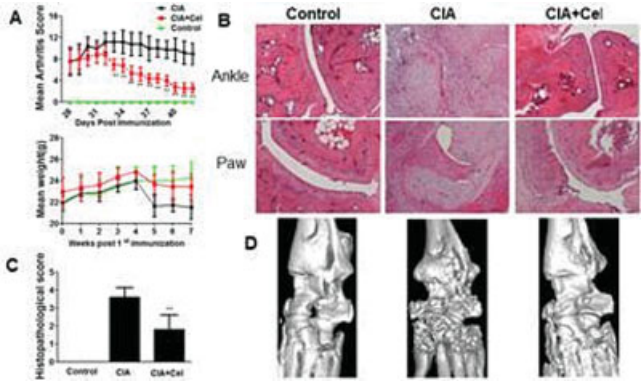

Figure 5. Effects of Celastrol on clinical evaluation and bone erosion in CIA mice.

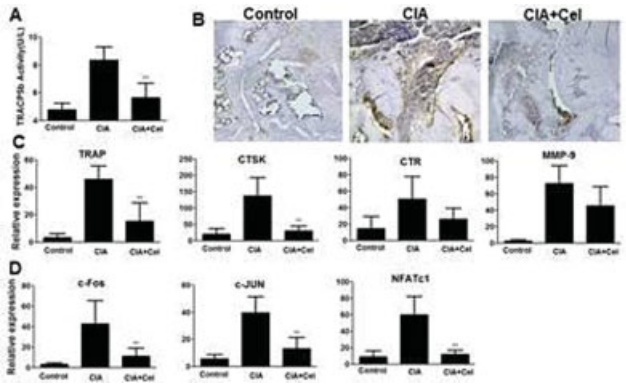

Figure 6. Effect of Celastrol on ostoclastogenic mRNA expression in CIA mice.

Conclusion: These findings suggests that Celastrol is a potent inhibitor of RANKL-induced bone resorption and has a potential therapeutic benefit in treating bone loss of rheumatoid arthritis or other bone diseases.

The Tumor Necrosis Factor Stimulated Gene-6 Promoter Reporter Can Monitor The Disease Activity In Rheumatoid Arthritis. Mathijs G.A. Broeren[1], Eline A. Vermeij[1], Onno J. Arntz[2], Miranda B. Bennink[1], Emma Sterken[1], Calin Popa[2], Tim L. Jansen[2], Wim B. van den Berg[1] and Fons A.J. Van de Loo[1]. [1]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background/Purpose: An important step in the optimal personalized treatment of rheumatoid arthritis (RA) patients, is the accurate assessment of disease activity, disease progression and therapy response. The quantification of biomarkers has been proposed to monitor these processes, but no single biomarker has proven to be sufficiently reliable for this purpose. Instead of measuring the quantity of a biomarker, we focus on the biomarker promoter activity to take into account the complex interplay between stimulating and inhibiting factors.

The TNF stimulated gene 6 (TSG-6) encodes a 35-kDa secretory glycoprotein that is induced in fibroblasts, chondrocytes, synovial cells and mononuclear cells by proinflammatory cytokines. Large amounts of TSG-6 protein were found in synovial fluid of patients with RA. In this study, we set out to use the TSG-6 promoter to develop a promoter-reporter construct to monitor disease activity in RA.

Methods: Arthritis was induced in DBA1/J mice by immunization with bovine collagen-type II (CIA), or by intra-articular injection of 5 μg Streptococcal Cell Wall (SCW). Microarray experiments were performed on 15 CIA samples, 20 human end-point RA synovium samples and 6 control synovium samples. The TSG-6 promoter (−499 to +63) was cloned in a lentiviral vector (LV) encoding firefly luciferase. Murine 3T3 cells were cultured and stimulated with 1% mouse serum or 10% human serum for 6 hours. Luciferase activity was measured using BrightGlo reagent.

Results: TSG-6 was upregulated in arthritic CIA joints and expression correlated with disease severity. It was also upregulated ~6-fold in 20 human end-point RA synovium samples, compared to 6 non-arthritic synovium samples ($P=0.01$).

Subsequently, we studied the disease-inducibility of the TSG-6 promoter by developing a lentiviral construct in which the isolated TSG-6 promoter controls the expression of a luciferase reporter transgene (TSG6-luc). We infected mice with the TSG6-luc promoter reporter and induced SCW arthritis. The expression peaked at day 7 (19-fold compared to naive mice), indicating the disease-responsiveness at full blown synovitis.

Next, we transduced murine 3T3 cells with the LV TSG6-luc construct and incubated the cells with serum from mice with increasing severity of collagen induced arthritis. The response of the promoter correlated significantly with the macroscopically assessed disease severity (R^2 0.47, $P<0.0001$) and with their circulating levels of the neutrophil chemokine KC (R^2 0.31, $P=0.002$), the functional homologue of human IL-8. In addition, serum from human RA patients showed a significantly higher activation of the TSG6-luc construct, compared to serum from healthy patients ($P=0.001$).

An important characteristic of a successful reporter is a reduced signal after successful treatment. We tested this by comparing the response to serum from diseased arthritic mice to serum from mice that were successfully treated with Enbrel. Serum from Enbrel treated mice showed a significantly lower activation of the TSG-6 promoter, compared to serum from untreated mice.

Conclusion: The TSG-6 promoter reporter might be a valuable tool to monitor disease progression in RA patients.

Application of Cytostatic Agent Kinesin Eg5 Inhibitor Litronesib (KF89617) On Rat Adjuvant-Induced Arthritis and Mouse Type II Collagen-Induced Arthritis. Ichiro Miki[1] and Masako Uchii[2]. [1]Kyowa Hakko Kirin, Co., Ltd., Shizuoka, Japan, [2]Kyowa Hakko Kirin Co., Ltd., Shizuoka, Japan.

Background/Purpose: Kinesins are family of motor proteins that are involved in mitosis and intracellular transport of vesicles and organelles. The mitotic kinesin, Eg5, acts during mitosis and centrosome separation. Selective inhibitors of Eg5 would be expected to be growth inhibition of inflammatory cells and synovial cells undergoing cell division. Litronesib (KF89617, LY2523355) is a newly synthesized compound at Kyowa Hakko Kirin. Litronesib is an ATP-noncompetitive, allosteric, reversible inhibitor of Eg5 that has no observed effect on microtubule formation. Litronesib has been investigated in clinical trials for the treatment of multiple cancers by Eli Lilly and Company. Remission of rheumatoid arthritis with a mitotic inhibitor taxol in patient with breast carcinoma was reported. In this study, we investigate the anti-rheumatoid activities of Litronesib on animal models of rheumatoid arthritis.

Methods: The effect of Litronesib was tested on rat adjuvant-induced arthritis (AIA) and mouse collagen-induced arthritis (CIA). KF89617 (Litronesib) or KF88373 (L-aspartate of the racemic mixture of KF89617 and its enantiomer) was synthesized in our laboratories. Mycobacterium butyricum was intradermally injected into the right hind footpad of Lewis rats (8 weeks, female), and AIA was induced. KF88373 was intravenously administered twice a week at 2 mg/kg from the day of the immunization with the adjuvant. Type 2 collagen (CII) with Freund's complete adjuvant was intradermally injected at the base of the tail of DBA/1J mice (7 weeks, male), and CIA was induced. KF88373 at 4 mg/kg was subcutaneously administered twice a week from the day of the 2nd immunization with CII. KF89617 or KF88373 were orally administered twice a week from the day of the 2nd immunization with CII.

Results: In rat AIA, KF88373 at 2 mg/kg i.v. twice/week markedly inhibited the swelling of adjuvant-non-treated foot at 78.9% ($p<0.01$) on Day 21. The inhibitory activity of KF88373 was similar to that of MTX (0.1 mg/kg p.o. 5 times/week) on rat AIA. Inhibition of swelling of adjuvant-injected foot was 21.4% ($p<0.05$) which was less effective than that of of adjuvant-non-treated foot. Body weight loss by the induction of AIA was also improved by the treatment of KF88373 but was not by the treatment of MTX. In mouse CIA, KF88373 at 4 mg/kg s.c. twice/week markedly inhibited the arthritis score at 97.7% ($p<0.001$) on Day 35. Body weight loss by the induction of CIA was also improved by the treatment of KF88373. Effect of orally administered KF89617 was tested on CIA. KF89617 or KF88373 at 4 mg/kg p.o. twice/week, potently inhibited the arthritis score at 90.8% ($p<0.001$) or 87.1% ($p<0.01$) on Day 35, respectively. Intraperitoneal administration of Taxol (1 mg/kg i.p. twice/week) inhibited CIA score at 61.0% ($p<0.01$) which was weaker than that of KF89617. Taxol did not improve body weight loss.

Conclusion: KF89617 (Litronesib) is a newly synthesized mitotic kinesin Eg5 inihbitor. KF89617 and KF88373 markedly reduced joint inflammation on both rat AIA and mouse CIA. KF89617 and KF88373 showed pharmacological activities on various administration rute such as p.o., i.v. and s.c. The treatment of KF89617 is expected to provide a novel treatment of rheumatoid arthritis.

Background/Purpose: The CORRONA International (C.Intl) rheumatoid arthritis (RA) registry is the first multinational RA registry uniformly collecting baseline and longitudinal data. We explored variations in RA disease (dx) activity and drug utilization across regions participating in this new international registry, with the well-established CORRONA US (C.USA) RA registry.

Methods: The C.Intl registry, launched in September 2011, is a multi-center, observational registry. Adult RA patients (pts) have been enrolled from 83 rheumatology practices in 10 countries in 3 regions [Latin America (LA): Mexico, Brazil, Argentina; Eastern Europe (EEu): Poland, Czech Republic, Hungary, Romania, Russia, Ukraine; Asia (AS): India]. The only exclusion criteria are functional class IV and age >85 years old. The C.USA registry was launched in 2001 and enrolls pts from 111 rheumatology practices across the US. There are no exclusion criteria.

Both registries collect data in a similar manner on demographics, lifestyle characteristics, anthropometry, medication exposures, adverse events and comorbidities from rheumatologists and RA pts at regular clinical encounters.

We present baseline descriptive data across the regions participating in C.Intl, including variations in: RA drug utilization, dx activity and functionality. We explored differences stratified by new (≤3 years duration) versus established (3+ years) dx. We compared cross-sectional baseline C.Intl data by region with cross-sectional data from the most recent visit of pts enrolled in C.USA excluding those with functional class IV and >85 years of age. No formal statistical testing was conducted.

Results: As of March 4 2013, 5696 pts had been enrolled in C.Intl and 20,291 RA pts with a functional class <IV and age ≤85 were actively followed in C.USA.

Mean (Standard Deviation (SD)) age was highest in the US and lowest in Asia [LA 54.2 years (12.9), EEu 57.1 (12.2), AS 47.6 (11.9), US 60.3 (12.6)]. The majority of patients were women (LA: 86.7%, EEu: 83.4%, AS: 85.5%, US: 76.6%). Mean (SD) disease duration was indicative of overall established dx [LA 9.9 years (8.7), EU 9.1 (8.6), AS 6.3 (5.8), US 12 (10.1)]. The majority of pts were seropositive (LA 83.5%, EU 76.4%, AS 65.4%, US 76%).

Overall and when stratified by disease duration, dx activity was higher, but functionality, biologic drug utilization and narcotic pain medication use were lower in C.Intl regions compared to C.USA (Table 1).

Table 1*. Disease activity and therapy in RA patients with new (<=3 years) and established (>3 years) disease from international regions and from the US.

	CORRONA International-regions			
	Latin America	Eastern Europe	Asia	CORRONA US
Patients with duration ≤ 3 years

Narcotic Pain Medication n(%)	38 (2.6%)	18 (1%)	7 (1%)	3368 (22.5%)
NSAIDs n(%)	884 (59.9%)	787 (44.8%)	295 (42.7%)	7818 (48.3%)

*All data are from baseline visits for CORRONA International, and cross-sectional data from the most recent visit of pts enrolled in CORRONA US.
CDAI: Clinical Disease Activity Index; mHAQ: modified Health Assessment Questionnaire; DMARDs: Disease Modifying Anti-Rheumatic Drugs; NSAIDs: Non-Steroidal Anti-Inflammatory Drugs.

Conclusion: There are important regional differences in disease activity, functionality, and management of RA, which may be influenced

by variations in demographic and genetic backgrounds of pts populations, prescribing patterns of local physicians and regional differences in standard of care. The ongoing recruitment and follow-up of more patients in C.Intl will enable prospective studies of therapeutic variations and disease outcomes in different regions.

Anti-Carbamylated Antibody Positivity Is Associated With More Severe Radiological Progression In Patients With Recent Onset ACPA Negative Rheumatoid Arthritis: Results From The Norfolk Arthritis Register (NOAR). Jenny H. Humphreys[1], Suzanne M. Verstappen[1], Kimme L. Hyrich[2], Tarnya Marshall[3], Anne Barton[1], René E.M. Toes[4], Leendert A. Trouw[4] and Deborah P. Symmons[5]. [1]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Sciences Centre, Institute of Inflammation and Repair, The University of Manchester, Manchester, United Kingdom, [3]Norfolk and Norwich University Hospitals Trust, Norwich, United Kingdom, [4]Leiden University Medical Center, Leiden, Netherlands, [5]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Science Centre, Manchester, United Kingdom.

Background/Purpose: Autoantibodies against carbamylated proteins (anti-CarP) have been associated with more severe radiological damage in patients with rheumatoid arthritis (RA), including in a small subgroup seronegative for anti-citrullinated protein antibodies (ACPA) (1). The aims of this study were to i) validate these findings in a cohort of ACPA negative patients with early RA and ii) investigate the relationship between anti-CarP antibodies and markers of disease activity and disability cross-sectionally and over time.

Methods: The Norfolk Arthritis Register (NOAR) recruits adults with recent onset inflammatory polyarthritis (IP) (≥2 swollen joints for ≥4 weeks) from primary and secondary care in Norfolk, UK. At baseline, 5 and 10 years patients underwent a 51-tender and swollen joint count, gave a blood sample and completed a Health Assessment Questionnaire (HAQ). The 2010 ACR/EULAR classification criteria for RA were applied at baseline. X-rays of the hands and feet were performed at 5 years in all patients and at 10 years in those who were erosive at year 5. X-rays were read by two assessors using the Larsen method. ACPA and CRP measurements were performed in Manchester and anti-CarP antibodies were measured in the baseline sample in Leiden (IgG ELISA). Linear regression models tested for associations between anti-CarP antibodies and HAQ, joint counts, CRP at each assessment and Larsen score at 5 and 10 years, in ACPA negative patients with IP and those with ACPA negative RA. Multivariate models were adjusted for age, gender and disease duration.

Results: 292 patients were included in the analysis; 205 (72%) female; median age at symptom onset (IQR) 47 (36–56) years. Median symptom duration at baseline (IQR) was 26 (12–53) weeks. 87 (30%) patients were positive for anti-CarP antibodies and 161 (57%) patients satisfied the 2010 RA criteria. Anti-CarP positivity was not associated cross-sectionally with HAQ or joint counts at baseline, but there was a trend to association with CRP (table 1). X-rays were available on 240 patients at 5 years, 72 patients at 10 years. Anti-CarP positivity was associated with raised CRP at 5 years, but there was no association with Larsen score. At 10 years there was a significant association between anti-CarP antibodies and Larsen score in IP (adjusted β-coefficient 16.2, 95% CI 2.73–29.7), and RA subgroup (adjusted β-coefficient 21.2, 95% CI 3.00, 39.54).

Table 1. Association between baseline anti-CarP antibody status and outcomes at baseline, 5 and 10 years

Outcome	IP Multivariate β coefficient (95% CI)	RA Multivariate β coefficient (95% CI)
Baseline:	*n=292*†	*n=161*§
HAQ (per0.25 units)	0.06 (−0.12, 0.23)	−0.03 (−0.27, 0.21)
Tender/swollen joint count	−0.72 (−3.32, 1.88)	−2.68 (−5.75, 0.39)
CRP (mg/l)	6.76 (−0.55, 14.07)	7.55 (−2.68, 17.80)
5 year:	*n=240*	*n=129*
HAQ (per0.25 units)	0.02 (−0.17, 0.21)	−0.19 (−0.46, 0.07)
Tender/swollen joint count	−0.60 (−3.02, 1.82)	−2.37 (−5.91, 1.17)
CRP(mg/l)	*3.95 (0.89, 7.01)	*4.66 (0.96, 8.35)
Larsen score	0.52 (−2.84, 3.89)	2.61 (−2.55, 7.79)
10 year:	*n=72*	*n=36*
HAQ (per0.25 units)	0.03 (−0.19, 0.24)	−0.19 (−0.50, 0.12)
Tender/swollen joint count	−0.82 (−3.18,1.54)	−1.67 (−5.14, 1.80)
CRP(mg/l)	0.35 (−2.26, 2.95)	0.78 (−1.74, 3.30)
Larsen score	*16.22 (2.73, 29.7)	*21.2 (3.00, 39.54)

*p<0.05, † 87 anti-CarPA positive, §40 anti-CarP antibody positive

Conclusion: In a cohort of patients with ACPA negative IP and ACPA negative early RA, anti-CarP antibodies were associated with higher CRP at baseline and 5 years, and more severe radiographic disease at 10 years follow up in patients who were erosive at 5 years. Only a small proportion of patients had x-rays at 10 years, thus this association may be liable to selection bias. Nevertheless, anti-CarP antibodies may identify an important group of ACPA negative patients with poor long-term prognosis.

Clinical Joint Involvement Is Decisive For Radiographic Progression. Miriam Gärtner[1], Farideh Alasti[1], Gabriela Supp[1], Josef S. Smolen[2] and Daniel Aletaha[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria.

Background/Purpose: Today's therapeutic targets in rheumatoid arthritis (RA) are remission or low disease activity, but it was shown that joint damage may continue to progress despite these favourable clinical states.[1;2] While progression of joint damage is related to joint swelling,[3] radiographic damage may progress even without evidence of clinical synovitis, at least in early RA.[4]

It was the aim of this study, to evaluate the frequency of radiographic progression in clinically persistently inactive joints of patients with established RA.

Methods: We included 134 RA patients (mean disease duration: 7.12±9.5yrs.) who showed a radiographic progression (increase>1) in any of the joints assessed by the Sharp van der Heijde (SvdH) score over an observational period of 3–5 years. To conform with the records of clinical joint assessment, we only considered radiographic progression in any of the 22 hand/finger joints (10 proximal interphalangeal joints, 10 metacarpophalangeal joints, 2 wrists), but excluded the feet (not assessed by the 28 joint count). Clinical data on individual joints (swelling and tenderness) from each clinical visit performed between one year prior to the baseline x-ray until the time of the x-ray endpoint were collected from the patient charts. We evaluated associations of clinical joint activity (swelling and tenderness) and radiographic progression on the individual joint level.

Results: The mean±SD time between x-rays was 3.5±0.4yrs and the mean number of clinical visits per patient was 16.2±4.6. A total of 195 (6.6%) of the 2948 evaluated joints showed progression in erosions and 343 (12.7%) worsened in joint space narrowing (JSN). Of all joints with progression in erosions, 64 (32.8%) were never swollen during the observation period (in 40 patients) and only 18 (9.2%) never showed any activity also by tenderness.

In the total patient population, progression was higher in joints with clinical swelling (during the observation period) compared to joints without

swelling (1.76±1.06 vs 1.28±0.68; p=0.01). We found a significantly higher baseline SvdH Score in patients with radiographic progression in clinically inactive joints vs. active joints (68.2±78.8 vs 42.5±51.2; p=0.022). The overall sensitivity for progression of damage of any joint activity during the observation period was 73.1% for erosion, and 73.5% for JSN. Only 25.6% of the patients showing radiographic progression in clinically inactive joints were treated with a biological during the majority (>50%) of the observation period.

Conclusion: Only 9% of joints with radiographic progression in patients with established RA show continued absences of clinical activity by both swelling and tenderness, and their degree of progression is low. Thus, structural progression without evidence of clinical activity is a negligible event on joint level. Risk factors of this are high baseline radiographic scores and absence of biological treatment, but the strongest risk factor for progression remains to be clinical joint involvement.

Do Sustained Clinical Remission and Sustained Low Disease Activity Equally Predict Functional Status In Early Rheumatoid Arthritis?

Bindee Kuriya[1], Juan Xiong[1], Gilles Boire[2], Boulos Haraoui[3], Carol A. Hitchon[4], Janet E. Pope[5], J. Carter Thorne[6], Diane Tin[6], Edward C. Keystone[1], Cheryl Barnabe[7], Pooneh Akhavan[8] and Vivian P. Bykerk[9]. [1]Mount Sinai Hospital, University of Toronto, Toronto, ON, [2]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [3]Institut de Rhumatologie de Montréal, Montreal, QC, [4]University of Manitoba, Winnipeg, MB, [5]St Joseph Health Centre, London, ON, [6]Southlake Regional Health Centre, Newmarket, ON, [7]University of Calgary, Calgary, AB, [8]Early Rheumatoid Arthritis Program, Mount Sinai Hospital and University of Toronto, Toronto, ON, [9]Hospital for Special Surgery, New York, NY.

Background/Purpose: Sustained clinical remission (REM) is the therapeutic goal in rheumatoid arthritis (RA) but low disease activity (LDA) may be acceptable. Little is known whether sustained LDA is "as good" as sustained REM for reducing disability in early rheumatoid arthritis (ERA). Our objectives were to: (1) compare the prevalence of sustained REM and sustained LDA in ERA patients and describe any differences in core variables among the groups and; (2) determine if sustained REM and LDA are independently associated with function, measured by the health assessment questionnaire disability index (HAQ-DI).

Methods: ERA patients with at least 2 years of follow-up in the Canadian early ArThritis CoHort (CATCH) (N=833) were included in the analysis. REM/LDA was classified according to the clinical disease activity index (CDAI; ≤2.8 vs. 2.9–10) and simplified disease activity index (SDAI; ≤3.3 vs. 3.4–11). REM and LDA was defined as sustained if present for ≥ 2 consecutive visits or ≥ 6 months during the first 18 months. Linear regression models were performed with HAQ-DI score at 2 years as the outcome, and each REM or LDA definition as the independent variable, adjusted for baseline confounders.

Results: Only 77 (9%) patients achieved sustained REM by each the CDAI and SDAI definitions over the first 18 months. 426 (51%) were in sustained CDAI LDA and 333 (40%) were in sustained SDAI LDA. At baseline, there were no significant differences in demographic, clinical, laboratory or early treatment variables between patients in REM vs. LDA by either index. At follow-up, mean HAQ-DI scores for those in sustained REM ranged from 0.10 to 0.13 compared to baseline HAQ-DI (range 0.87–1.0) and scores were 0.39–0.40 at follow-up for those in sustained LDA compared to their baseline values ranging from 0.97–0.98. Overall, HAQ-DI scores were significantly lower at year 2 for those achieving sustained REM compared to sustained LDA (table). Joint counts, pain, fatigue and global health assessment were also significantly lower in the REM groups (table). Multivariable regression analyses showed that sustained CDAI REM and sustained SDAI REM were both independently associated with lower HAQ-DI than sustained LDA (p<0.001).

Table. HAQ-DI scores and differences in core variables among patients achieving sustained REM vs. LDA according to CDAI and SDAI cut-offs at year 2.

	CDAI			SDAI		
	Sustained REM	Sustained LDA	*p*	Sustained REM	Sustained LDA	*p*
TJC-28, mean ± SD	0.46 ± 1.21	1.34 ± 2.81	0.002	0.58 ± 1.84	1.42 ± 2.88	0.001
SJC-28, mean ± SD	0.58 ± 1.70	0.88 ± 2.00	0.009	0.42 ± 1.27	0.92 ± 1.97	0.002
CRP, mean ± SD mg/L	5.29 ± 8.71	5.37 ± 8.55	0.87	5.37 ± 9.08	5.34 ± 8.79	0.58
ESR, mean ± SD mm/hr	14.3 ± 12.0	15.1 ± 14.8	0.988	12.9 ± 11.7	14.9 ± 14.5	0.27
Pt-GA, mean ± SD cm (0–10 cm)	0.68 ± 1.33	2.42 ± 2.53	<0.001	0.89 ± 1.57	2.30 ± 2.45	<0.001
MD-GA, mean ± SD cm (0–10 cm)	0.36 ± 0.93	0.78 ± 1.30	<0.001	0.43 ± 1.08	0.77 ± 1.29	0.01
VAS pain, mean ± SD cm (0–10 cm)	8.60 ± 15.9	23.4 ± 24.5	<0.001	10.7 ± 18.3	22.0 ± 23.0	<0.001
VAS fatigue, mean ± SD cm (0–10 cm)	12.9 ± 21.4	26.4 ± 26.6	<0.001	15.3 ± 22.7	24.9 ± 25.1	<0.001
HAQ-DI, mean ± SD	0.10 ± 0.20	0.40 ± 0.55	<0.001	0.13 ± 0.26	0.39 ± 0.53	<0.001

Conclusion: HAQ-DI scores at year 2 are significantly lower among patients who achieve sustained REM vs. sustained LDA. This difference is greater than the minimal clinically important difference for HAQ of 0.22, suggesting there are clinically important differences in long term function based on best achieved sustained disease activity state. Further study is needed to understand what influences achieving sustained REM as opposed to sustained LDA in early RA.

Synovial Subset–Derived Baseline Serum Biomarkers Segregate Rheumatoid Arthritis Patients Into Subgroups With Distinct Serum Protein and Clinical Characteristics.

A. Francesca Setiadi, Nicholas Lewin-Koh, Sarah Kummerfeld, David F. Choy, Cécile T.J. Holweg, Sally Fischer, An Song and Michael J. Townsend. Genentech, South San Francisco, CA.

Background/Purpose: Rheumatoid arthritis (RA) is a heterogeneous disease. Predictive biomarkers have the potential to enhance treatment effectiveness by enabling identification of likely responders to a specific therapy.[1,2] Our previous analysis of RA synovium showed the existence of 3 large subsets characterized by gene expression signatures suggestive of lymphoid, myeloid, or fibroid biology.[3] In the present study, we demonstrated the ability of serum proteins produced by genes selected from those signatures to recapitulate the segregation of patients into these subsets.

Methods: Several protein biomarker candidates were selected based on differential gene expression in 1 RA synovial subset versus the others and on detectability in serum. Quantitative immunoassay methods were used to measure these proteins in baseline serum from 3 biologic-naive RA cohorts: Cohort 1 (cross-sectional natural history cohort, n = 197), SERENE[4] (n = 412), and TOWARD[5] (n = 526). Levels of serum proteins were also compared between Cohort 1 patients and healthy controls (n = 30). Serum protein data were used to cluster patients and proteins. Patients were clustered into a specified number of groups using Partitioning Around Medoids (PAM), whereas proteins were clustered hierarchically. Each clinical characteristic of patients in each biomarker group was compared to the respective characteristic in all other groups within the same cohort using the Wilcoxon rank-sum test of each pair.

Results: Analysis of baseline serum biomarker levels in Cohort 1 showed that MMP1, MMP3, MMP9, TIMP3, TIMP4, CXCL13, IL8, CCL2, CCL13, CXCL10, and sICAM1 were elevated compared to those in healthy controls ($p < 0.0001$). These analytes had a wide dynamic range in all RA cohorts analyzed. The patient populations within each RA cohort segregated reproducibly into 3 groups, named by the characteristics of the serum proteins in each group: Protease, Chemokine, and Low Inflammatory. The 2 inflammatory groups (Protease and Chemokine) were dominated by serum biomarkers related to lymphoid and myeloid biology, respectively (Table 1). The third group generally displayed lower levels of inflammatory proteins, CRP, and ESR and was less often rheumatoid factor positive. This group likely corresponded to the synovial fibroid subset. The clinical characteristics of each biomarker group are summarized in Table 2.

Table 1. Three Major RA Synovial Subsets and the Corresponding Serum Biomarkers

Synovial Subsets	Serum Protein Characteristics	Serum Biomarkers
Lymphoid	Inflammatory - protease	MMP1, MMP3, MMP9, TIMP3, TIMP4, CXCL13
Myeloid	Inflammatory-chemokine	IL8, CCL2, CCL13, CXCL10, sICAM1
Fibroid	Low inflammatory	Low CRP, ESR, and inflammatory biomarkers

Table 2. Clinical Characteristics of Patients in Each Biomarker Group in All Cohorts Analyzed

	Cohort 1 n = 197			SERENE n = 412			TOWARD n = 526		
Groups	Protease/ Lymphoid	Chemokine/ Myeloid	Low inflammatory	Protease/ Lymphoid	Chemokine/ Myeloid	Low inflammatory	Protease/ Lymphoid	Chemokine/ Myeloid	Low inflammatory
Population	26	39	35	34	34	32	47	35	18
CRP, mg/dL	0.8	1.7	0.4	3.1	1.2	0.7*	0.9	3.1	0.9
ESR, mm/h	39	29	21*	47	42	33*	37	52	34
SJC (66)	4	7	2*	18	18	15.5*	16	18	16

RF status (+), %	86	84	69	85	79	70	82	76	60
Disease duration, years	7	7	5	4.8	5.3	3.4	7.8	6.9	5.8
HAQ	1.25	1.38	1.06	1.72	1.65	1.46*	1.34	1.61	1.42

Data shown as medians.
* $p < 0.05$ in low inflammatory group versus all other groups within the same cohort by Wilcoxon rank-sum test of each pair.

Conclusion: We have identified serum biomarkers that segregate groups of patients associated with lymphoid and myeloid subtype–derived biomarkers in 3 large RA cohorts. These subpopulations of RA patients with distinct pathobiology can possibly demonstrate differential clinical response to treatments that target different inflammatory mediators. In addition, a low-inflammatory group was observed in all cohorts analyzed. This group is less likely to respond well to current biologic anti-inflammatory therapy.

Low Accuracy Of Radiograph Reports In Identifying Patients With Rheumatoid Arthritis In The Veterans Affairs Rheumatoid Arthritis Registry. Maria P. Martes[1], Alan R. Erickson[2], Ted R. Mikuls[3] and Grant W. Cannon[4]. [1]Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, [2]Omaha VA and University of Nebraska Medical Center, LaVista, NE, [3]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [4]Salt Lake City VA and University of Utah, Salt Lake City, UT.

Background/Purpose: The accurate interpretation of hand radiographs is critical in the diagnosis and management of rheumatoid arthritis (RA) patients. This project determined first, if the reading request and/or clinical history provided to the radiologist (RAD) improved the accuracy of the reported findings and second if the overall interpretation of the radiographs in the Veterans Affairs (VA) computerized patient record system (CPRS) was consistent with that of an expert reader (ER).

Methods: Bilateral hand and wrist radiographs of 302 RA patients enrolled in the Veterans Affairs Rheumatoid Arthritis (VARA) registry, a multi-center observational cohort, were assessed by an ER for the presence and/or absence of erosions (ERO) and/or joint space narrowing (JSN). RAD reports on these patients were evaluated by a blinded chart abstractor (CA) to determine if the CPRS report contained a clinical history for RA and if there was a specific request for the evaluation for ERO and/or JSN. The CA also specifically noted if a RAD reported the diagnosis of RA and/or an alternative diagnosis such as osteoarthritis (OA), mentioned ERO and/or JSN.

Results: The patients' mean age was 64±11 years, 88% were male, RA disease duration was 13±11 years, and the majority was sero-positive for rheumatoid factor (84%) and anti-CCP (80%). As noted below, 157 were reported to have abnormal findings by both CPRS RAD and ER and 38 patients were reported normal by both CPRS RAD and ER. Ten patients were reported as abnormal by CPRS RAD but were reported normal by ER and 97 were reported abnormal by ER but normal by CPRS RAD (35% overall discordance). Of the 302 reports, 27 (8.9%) were given an alternative diagnosis by the CPRS RAD, the most common being OA and Calcium pyrophosphate deposition disease (CPPD). The sensitivity, specificity, positive and negative predictive values were determined comparing the RAD to the ER as gold standard.

		Expert Reader Abnormal	Normal	TOTAL
CPRS Report	Abnormal	157	10	167
	Normal	97	38	135
TOTAL		254	48	302
Sensitivity				61.8%
Specificity				79.2%
Positive predictive value				94.0%
Negative predictive value				28.1%

A notation of 'RA' and/or a specific request for an evaluation of ERO and/or JSN in the X-ray request did not improve the accuracy of the diagnosis and/or reporting of ERO and JSN. The only factors associated with higher likelihood of CPRS RAD reporting RA was joint swelling count ($p<0.01$) and C-reactive protein level ($p<0.05$).

Conclusion: The accuracy of RAD to identify patients with RA in comparison to the ER is not enhanced in reports that provided the RAD with a clinical history and specific directions to assess for ERO and JSN. While a positive RA diagnosis by the RAD in CPRS has a high potential to be correct, the absence of this diagnosis does not possess sufficient accuracy to exclude the diagnosis of RA.

Prognosis Of Seronegative Patients In a Large Prospective Cohort Of Patients With Early Inflammatory Arthritis. Lillian J. Barra[1], Janet E. Pope[1], Boulos Haraoui[2], Carol A. Hitchon[3], J. Carter Thorne[4], Edward C. Keystone[5], Diane Tin[4], Gilles Boire[6] and Vivian P. Bykerk[7]. [1]Schulich School of Medicine and Dentistry, Western University, London, ON, [2]Centre Hospitalier de l'Université de Montréal, Montreal, QC, [3]University of Manitoba, Winnipeg, MB, [4]Southlake Regional Health Centre, Newmarket, ON, [5]Mount Sinai Hospital, University of Toronto, Toronto, ON, [6]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [7]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY.

Background/Purpose: Rheumatoid Factor (RF) and anti-Cyclic Citrullinated Peptide (anti-CCP) are believed to be associated with more severe clinical outcomes; however, studies in Early Inflammatory Arthritis (EIA) have yielded conflicting results. The objective of this study is to determine the prognosis of baseline anti-CCP and RF-negative patients at 12 months follow-up in the Canadian Early Rheumatoid Arthritis cohort (CATCH).

Methods: Data were collected on patients enrolled in CATCH, a multicentre, observational, prospective inception cohort of patients with Early Inflammatory Arthritis (EIA). Treatment was based on physician discretion. IgM RF was measured and depending on the site, two different anti-CCP2 IgG (CCP) kits were used (Euroimmune™ and Inova™). Disease activity was determined using the Disease Activity Score-28 (DAS28) and remission was defined as a DAS28<2.6. Presence of erosions was determined using plain radiographs of the hands and feet. Follow-up was 12 months. Multiple logistic regression was used to account for confounders.

Results: 216/841 (26%) of patients were negative for both RF and anti-CCP2. These patients were older (57 years old) and more likely male (31%) compared to seropositive patients (51 years old and 23% male), $p<0.001$. Seronegative patients were less likely to meet 1987 ACR and 2010 ACR/EULAR criteria for RA, however, at baseline they had higher swollen joint counts (SJC) (9 vs 6), more erosive disease (32% vs. 23%) and higher DAS28 scores (5.00 vs. 4.75), $p<0.05$. Seronegative patients had shorter duration of symptoms (166 days vs. 192, $p=0.007$). The initiation of DMARDs, biologics and steroids was similar between the two groups. At 12 months follow-up, seronegative patients had greater reductions compared to seropositive patients in SJC (7 vs.4) and similar DAS28 scores (2.97 vs. 2.83); $p=0.0017$ and $p=0.3$, respectively. Accounting for confounders, seronega-

tive patients were as likely to achieve DAS28 remission as seropositive patients (OR 1.18; 95%CI: 0.70–1.99), however, they were less likely to have erosive disease at follow-up (OR 0.43; 95%CI: 0.19–0.95, p<0.04).

Evaluation Of The Japanese Patients With Rheumatoid Arthritis (RA) Of Rapid Radiographic Progression (RRP) Treated With Synthetic Disease Modifying Anti-Rheumatic Drugs (DMARDs) In Daily Practice: A Large-Scale Prospective Longitudinal Cohort Study (an interim report of Apple Survey). Akitomo Okada[1], Atsushi Kawakami[2], Takaaki Fukuda[3], Toshihiko Hidaka[4], Tomonori Ishii[5], Yukitaka Ueki[6], Takao Kodera[7], Munetoshi Nakashima[8], Yuichi Takahashi[9], Seiyo Honda[10], Yoshiro Horai[2], Tomohiro Koga[2], Mami Tamai[11], Kiyoshi Aoyagi[2], Ryu Watanabe[5], Hiroshi Okuno[12] and Katsumi Eguchi[13]. [1]Japanese Red Cross Nagasaki Genbaku Hospital, Nagasaki, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Kurume University Medical Center, Kurume, Japan, [4]Zenjinkai Shimin-No-Mori-Hospital, Miyazaki, Japan, [5]Tohoku University, Sendai, Japan, [6]Sasebo Chuo Hospital, Sasebo, Japan, [7]Tohoku Kosei Nenkin Hospital, Sendai, Japan, [8]Japanese Red Cross Nagasaki Genbaku Hospital, Nagasahi, Japan, [9]Yu Family Clinic, Sendai, Japan, [10]Kurume University School of Medicene, Kurume, Japan, [11]Center for Health & Community Medicine, Nagasaki University, Nagasaki, Japan, [12]Tohoku University Hospital, Sendai, Japan, [13]Sasebo City General Hospital, Sasebo, Nagasaki, Japan.

Background/Purpose: Disease modifying anti-rheumatic drugs (DMARDs) are known to inhibit radiographic progression in patients with rheumatoid arthritis (RA). However, there has been few epidemiological report of longitudinal radiographic progression in RA patients captured in daily practice. In 26 related-centers of the Nagasaki University and Tohoku University in Japan, we are conducting a large-scale prospective study (Apple Survey) to investigate extent of radiographic progression. We have tried to assess the extent of rapid radiographic progression (RRP) in DMARDs-treated RA patients.

Methods: Nine hundred forty-two patients with RA, treated not by biologic DMARDs but by synthetic DMARDs at entry, were registered between May 09 and March 12 in this study. We have selected 742 RA patients having DAS28-ESR at entry >3.2 or apparent radiographic bone erosion and followed at least 1 year. Regarding to the RA patients treated by synthetic DMARDs without biologic DMARDs for 1 year, two hundred sixty-one patients had evaluable data at present. Patients gave their informed consent to be subjected to the protocol that was approved by the Institutional Review Board of Nagasaki University, Tohoku University and related centers. DAS28-ESR was assessed every 3 months. Radiographs of the hands and feet were taken every 6 months. The images were scored by trained readers through modified total Sharp score (mTSS). RRP was defined as yearly progression of mTSS >3.0. We have examined what variables are associated with the development of RRP at 1 year.

Results: RRP was found in 31 out of 261 patients (11.9%). Eleven variables including gender, age, disease duration at baseline, DAS28-ESR at baseline, time-integrated DAS28-ESR during 1 year, CRP at baseline (mg/dl), presence of autoantibodies (RF or ACPA), the use of MTX or non-MTX DMARDs, the use of prednisolone, HAQ at baseline, mTSS at baseline were evaluated to explore the development of RRP at 1 year. Logistic regression analysis has found that short disease duration ($p = 0.013$, 2 year decrease), high time-integrated DAS28-ESR ($p = 0.027$, 10 increase) and high mTSS at baseline ($p = 0.010$, 5 increase) are independent variables to predict the development of RRP. There was the trend of non-MTX DMARDs use ($p = 0.071$) toward RRP at 1 year.

Conclusion: Considering the development of RRP, mTSS at baseline is high and the progression of joint destruction may occur at the early-stage of RA in case of treatment without MTX. Since not high DAS28-ESR at baseline but high time-integrated DAS28-ESR is also an independent predictor toward RRP, tight disease control by treat-to-target strategy is needed in daily clinical practice.

Aiming Simple Disease Activity Score Remission At One Year Leads To Better 3-Year Radiographic and Functional Outcomes Than aiming low Disease activity in Early Rheumatoid Arthritis Patients Treated In Routine Practice. Data From Espoir Cohort. Adeline Ruyssen-Witrand[1], Gregory Guernec[2], Delphine Nigon[3], Gabriel Tobon[4], Bénédicte Jamard[5], Anne-Christine Rat[6], Olivier Vittecoq[7], Alain G. Cantagrel[8] and Arnaud L. Constantin[1]. [1]Purpan University Hospital, Toulouse, France, [2]Inserm, Toulouse, France, [3]Purpan University Hospital, Toulouse Cedex 9, France, [4]Unit of immunology, Brest, France, [5]Toulouse University Hospital, Toulouse, France, [6]Université de Lorraine, Nancy, F-54000, France; Inserm, CIC-EC CIE6, Nancy, F-54000, France; CHU de Nancy, Clinical Epidemiology and Evaluation Department, Nancy, F-54000, France; CHU de Nancy, Rheumatology department, Nancy, France, [7]Rouen University Hospital & Inserm905, University of Rouen, Rouen Cedex, France, [8]Centre Hospitalier Universitaire de Toulouse, Toulouse, France.

Background/Purpose: The ultimate goal of Disease Modifying Anti-Rheumatic Drugs (DMARDs) treatment in early rheumatoid arthritis (RA) is to achieve remission in order to prevent structural damage and long term disability according to EULAR's recommendations. However, remission status is not always obtained and low disease activity (LDA) might be an alternative goal. Recently, an ACR/EULAR initiative recommended the use of Simple Disease Activity Score (SDAI) as a remission criterion. The aim is to assess whether obtaining SDAI remission status or LDA status at one year has a differential impact on Sharp van der Heijde Total Score (mTSS) and Health Assessment Questionnaire Disability Index (HAQ-DI) score at 3 years in early RA patients treated in routine practice.

Methods: *Patients:* 813 DMARD and corticosteroids-naïve patients with early arthritis were included in the ESPOIR cohort and were prospectively followed. Among them, 625 fulfilled the 2010 ACR/EULAR criteria for RA at baseline and had a SDAI score at one year. 496 of them had available radiographs at 3 years and 535 had available HAQ-DI score at 3 years. *Data analyzed:* Remission was defined by a SDAI $\leq$ 3.3; LDA by a 3.3 < SDAI score $\leq$ 11. Radiographs were centrally read by one rheumatologist and scored using the Sharp van der Heijde scoring method at the inclusion and 3 years. *Analysis:* comparison of mTSS and HAQ-DI scores at 3 years between patients in SDAI remission or LDA at one year using a t-test. A multivariate analysis using a linear mixed model was performed to assess the independent effect of patient SDAI status at one year on mTSS and HAQ-DI at 3 years, including age, gender, disease duration, clinical center, erosions at baseline, ACPA presence, smoking habits, DMARDs use, the delay of DMARD start, biologic agents use and glucocorticoid use as covariables. The comparison

between remission and LDA in terms of mTSS and HAQ-DI score at 3 years was obtained from the multivariate model with contrasts method.

Results: Of the 625 patients included in the study (age median=49 years [IQR:40–58], women: n=391 (79%), disease duration median=5 months [IQR:3–8] n=121 (19%) were in remission after one year and n=223 (36%) were in LDA. The mTSS mean score at 3 years was about 9.6 (SD: 9.2) in patients in remission at one year compared to 15.8 (SD:16.1) in patients with LDA (t-test: p=0.0005). The HAQ-DI mean score at 3 years was about 0.23 (SD: 0.42) in patients in remission at one year compared to 0.43 (SD:0.52) in patients with LDA (t-test: p=0.0005). After multivariate analysis, the remission status obtained after one year was independently associated with lower 3-year mTSS compared to LDA status (mean difference=−0;265, SD=0.094, p=0.005). After multivariate analysis, the remission status obtained after one year was not independently associated with HAQ-DI score at 3 years compared to LDA status (mean difference=−0;54, SD=0.59, p=0.4).

Conclusion: This study shows that aiming SDAI remission at one year leads to better radiographic and functional outcomes at 3 years compared to LDA in early RA patients treated in routine practice.

A Multi-Biomarker Disease Activity Score Correlates With Radiographic Progression In Early Rheumatoid Arthritis: Results From a Randomized Trial. Karen Hambardzumyan[1], Rebecca Bolce[2], Scott E. Cruickshank[3], Eric H. Sasso[2], David Chernoff[2], Kristina Forslind[4], Saedis Saevarsdottir[1], Ingemar F. Petersson[5], Pierre Geborek[5], Sofia Ernestam[6] and Ronald F van Vollenhoven[1]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Crescendo Bioscience Inc., South San Francisco, CA, [3]Scott E. Cruickshank and Associates, Inc., Santa Barbara, CA, [4]Section of Rheumatology, Department of Medicine, Helsingborg General Hospital, Helsingborg, Sweden, [5]Lund University, Lund, Sweden, [6]Karolinska University Hospital, Huddinge, Sweden.

Background/Purpose: In early rheumatoid arthritis (eRA), predictors of radiographic damage would be useful for optimal targeting of therapy. It has been suggested that combining various biomarkers may improve this prediction. The multi-biomarker disease activity (MBDA, Vectra DA) score has been validated as a measurement of rheumatoid arthritis (RA) disease activity. The MBDA score ranges from 1–100 and is based on 12 serum biomarkers: VCAM-1, EGF, VEGF-A, IL-6, TNF-RI, MMP-1, MMP-3, YKL-40, leptin, resistin, SAA and CRP. In the SWEFOT study, 487 patients with eRA (symptom duration < 1 year) were started on methotrexate (MTX); at 3 months, responders (DAS28 < 3.2) continued MTX monotherapy and were followed in regular care, whereas non-responders were randomized to receive either triple DMARD therapy or the addition of infliximab.

The objective of this study was to assess the value of the baseline MBDA score as a predictor of radiographic progression over one year in eRA.

Methods: Analyses were performed for 235 patients from SWEFOT with baseline (BL), month 3 (n=220) and week 52 (n=235) assessments of DAS28, DAS28-CRP, CRP, MBDA score, and radiographs at BL and 1 year (using the Van der Heijde modified Sharp score [SHS]). Month 3 responders and non-responders were analyzed together. Associations between disease activity indices and radiographic progression at one year were evaluated using Wald's chi-square test. Spearman's correlation coefficients (r) were determined for the BL disease index scores versus radiographic progression (ΔSHS >5) over 1 year.

Results: For the 235 patients, mean BL values were: CRP = 3.5 mg/dl, DAS28-ESR = 5.7, and MBDA = 60. More than half of patients with low CRP (≤ 1 mg/dL) or moderate DAS28 at BL had a high BL MBDA score (>44). Baseline SHS was 4.7 (median 2.0); mean ΔSHS from BL to 1 year was 3.1 ± 6.0 (median 1.0). Baseline MBDA score correlated with ΔSHS from BL to 1 year: r = 0.271 (p<0.001); correlations of DAS28, DAS28-CRP, and CRP with ΔSHS were weaker: r = 0.063, 0.014, and 0.178, respectively (p=NS, p=NS, p=0.006). In bivariate analyses adjusting for DAS28 or CRP, MBDA had a significant additive value to prediction of radiographic progression at one year (p < 0.01). Of the 43 patients with ΔSHS > 5, 98% had a high BL MBDA score, 77% a high DAS28 (>5.1) and 49% a high CRP (>3mg/dL). Of patients with a high MBDA score at BL, 21% had SHS progression >5, versus 3% and 0% for moderate and low MBDA, respectively (p<0.04). In patients with a high MBDA score at 3 months or 1 year, 24/96 (25%) and 13/40 (33%) progressed (ΔSHS > 5) from BL to 1 year, respectively.

Conclusion: In eRA patients who were treated initially with MTX and then according to a step-up protocol, the MBDA score at baseline correlated significantly and independently from CRP or DAS28, with radiographic progression during the first year. A high MBDA score at baseline was associated with a higher risk of radiographic progression, even in patients who had a low CRP or moderate DAS28 at baseline. Conversely, for patients with low or moderate MBDA at baseline the risk of radiographic progression was small. In untreated eRA, MBDA may help identify patients at low versus high risk of radiographic progression and thereby support rational treatment choices.

Tobacco Exposure Is Associated With Radiographic Damage In Hispanic and African American Rheumatoid Arthritis Patients. Rodolfo Perez Alamino[1], Luis R. Espinoza[2], Gail S. Kerr[3], Christopher Swearingen[4], Chunqiao Luo[4], Yusuf Yazici[5], Yvonne R. S. Sherrer[6], Edward L. Treadwell[7], Angelia D. Mosley-Williams[8], Sharon Dowell[9], Ignacio Garcia-Valladares[10], Theresa Lawrence-Ford[11], Adrian Godoy[9], Akgun Ince[12] and Cindy Flower[13]. [1]Lousiana State University and LSU Medical Center, New Orleans, LA, [2]LSU Medical Center, New Orleans, LA, [3]Washington DC VAMC and Georgetown University and Howard University Hospital, Washington, DC, [4]University of Arkansas for Medical Sciences, Little Rock, AR, [5]New York University Hospital for Joint Diseases, New York, NY, [6]Centre Rheum Immunol Arthritis, Fort Lauderdale, FL, [7]East Carolina University, Greenville, NC, [8]John Dingell VAMC, Detroit, MI, [9]Howard University, Washington, DC, [10]Guadalajara, Guadalajara, Mexico, [11]North Georgia Rheumatology Group, PC, Lawrenceville, GA, [12]Saint Louis University, St. Louis, MO, [13]University of the West Indies, Bridgetown, Barbados.

Background/Purpose: Although the etiology of rheumatoid arthritis (RA) is unknown, there are reported interactions of genetic and environmental factors. Tobacco exposure is a well-documented risk factor, both in Caucasian and African American (AA) RA cohorts for disease susceptibility and severity. Yet there are no data addressing the association of tobacco use with RA-phenotypic expression, particularly within multi-ethnic cohort, specifically Hispanic patients. We examined the association of tobacco exposure and RA phenotype in a diverse ethnic RA cohort.

Methods: Patients enrolled in EMRAC, with baseline demographics data (age, gender, tobacco use), RA disease status (severity [RF, ACPA, nodules, erosions], activity [TJC, SJC, ESR, CRP, CDAI, DAS28, RAPID3], and extra-articular manifestations) were available for analysis. Smoking status was categorized as current, former, or never use. Comparisons of RA-features with smoking status between ethnic groups were analyzed using Cochran-Mantel-Haenzel test. Any association between tobacco exposure and clinical disease activity measures and outcomes were estimated using logistic regression adjusting for race (Caucasian vs. Non-Caucasian), age and disease duration.

Results: Of 861 EMRAC patients available for analysis, the mean age was 56.3 (sd 13.5) years, and disease duration 10.2 (sd 10.1) years. 405 (47%) were Caucasians, 287 (33%) AA and 169 (20%) Hispanics. Erosions were reported in 10%, predominantly in AA (25%). Only 20% reported tobacco use (ever), and exposure was not associated with disease activity [high CDAI score: non-smokers (49%) vs. former (53%) and current smokers (62%) (p=0.253); high DAS 28 score: non-smokers (61%) vs. former (62%) and current smokers (78%) (p=0.205); high RAPID3: non-smokers (74%) vs. former (75%) and current smokers (75%) (p=0.713)] or frequency of extra-articular disease in the cohort.

Smoking ever (former or current) was associated with erosive disease, adjusting for ethnic groups (p=0.002). Smoking ever had a 144% increase in odds of having erosions compared to never smoking (OR=2.44, p=0.003), and non-Caucasians had 638% increase in odds for erosions compared to Caucasians (OR=7.38, p<0.001) in a multiple logistic regression adjusting for disease duration, age and disease activity (Table).

Table: Multiple Logistic Regression Model (Dependent Variable: Erosion)

Variables	OR (95% CI)	p
Smoking (Reference=Never)	2.44 (1.34–4.39)	0.003
Race (Reference=White)	7.38 (3.44–18.04)	<0.001
Disease duration (years)	1.05 (1.03–1.08)	<0.001
Age (years)	1.01 (1.00–1.04)	0.142
RAPID3	0.97 (0.93–1.01)	0.100

Conclusion: In a diverse ethnic RA cohort, cigarette smoking and non-Caucasian ethnicity were independently associated with higher risk of erosive disease. While further studies are developed to better understand the relationship of tobacco exposure and RA, more aggressive anti-smoking efforts and counseling, as well as more aggresive RA therapy, appears warranted in ethnic minorities with the disease.

Synovial Ectopic Lymphoneogenesis Predicts Clinical Response To Certolizumab Pegol In Patients With Rheumatoid Arthritis. Maria Di Cicco[1], Stephen Kelly[1], Frances Humby[1], Nora Ng[1], Sabrina Dadoun[2], Rebecca Hands[1], Vidalba Rocher[1], Alessandra Nerviani[1], Michele Bombardieri[3] and Costantino Pitzalis[3]. [1]Centre for Experimental Medicine and Rheumatology, Queen Mary University of London, London, United Kingdom, [2]APHP, Pitié-Salpêtrière University Hospital, Paris, France, [3]William Harvey Research Institute, QMUL, London, United Kingdom.

Background/Purpose: Predicting response to anti-TNF alpha inhibitors (TNFi) in rheumatoid arthritis (RA) patients is challenging. Therefore there is a high need for identification of biomarkers of clinical outcome to guide therapeutical decisions. A number of studies have suggested that the differential response to TNFi may partly be explained by modulation of synovial ectopic lymphocytic aggregates (ELN) within the synovial tissue.

Certolizumab pegol is a pegylated fully humanized TNFi and at present data regarding in vivo effects on pathobiological responses within the synovial membrane of patients with RA are limited. In particular whether specific synovial pathotypes predict response to treatment is unknown.

The main aim of this study is to investigate whether the presence of synovial ELN at baseline predicts clinical response to treatment with certolizumab pegol in RA patients.

Methods: A cohort of biologic-naïve RA patients who qualified for treatment with TNFi according to NICE guidance (National Institute for Health and Clinical Excellence, http://guidance.nice.org.uk/TA186) were recruited to the study at Barts and the London Hospital. Patients underwent ultrasound guided synovial biopsy of an active joint prior to commencing therapy with certolizumab pegol. Following 3 months of therapy, response to treatment was assessed according to EULAR response criteria and a repeat ultrasound guided synovial biopsy of the same joint obtained for 20 patients.

Paraffin embedding sequentially cut sections of synovial tissue underwent routine H&E staining and immunohistochemical staining for CD20 to detect B cells. Sections were graded as either a diffuse or aggregate infiltrate as previously described [Manzo, Eur J Immunol 2005]. The study received local ethics approval.

Results: 25 patients were recruited, 72% female, median age 54 years old (IQR: 45 –59), with a median disease duration of 4 years (IQR: 2 – 8.5). Median DAS28 was 6.2 (IQR: 5.7 – 6.8), 10 pts (40%) had an erosive disease and 17 (68%) were seropositive for RF or CCP, with 16 (64%) CCP positive. ELN was found in 11 patients (44%). 18 patients (72%) responded to the drug according to EULAR response criteria (32% were good responders and 40% moderate responders). The clinical response was maintained at 48 weeks. All patients with lymphocytic aggregates had a good or moderate response, while patients with negative ELN were equally either responders (50%) or non responders (50%) [p=0,01]. 9 of the 11 patients who resulted ELN positive at baseline had a second biopsy, and 4 (44%) reversed into a ELN negative status. Univariate analysis showed that ELN was the only independent predictor of good or moderate clinical response [$p<0.05$].

Conclusion: To the authors' knowledge, this is the first time that clinical response to certolizumab pegol has been evaluated in association with synovial ELN.

Our work shows that the presence of ELN is an independent predictor of clinical response to certolizumab pegol treatment, in line with previous data observed for other TNFi [Klaasen, Arthritis & Rheum 2009], suggesting that histopathology could be considered in the future as a potential key tool to guide therapeutic decisions for RA patients.

14-3-3η and Its Auto-Antibodies Predict Response To Anti-TNF Therapy. Walter P. Maksymowych[1] and Anthony Marotta[2]. [1]University of Alberta, Edmonton, AB, [2]Augurex Life Sciences Corp, North Vancouver, BC.

Background/Purpose: Serum 14-3-3η is an RA diagnostic marker and higher levels are associated with joint damage and more severe disease. Mechanistically, 14-3-3η upregulates factors involved in joint damage and inflammation, including TNFα. 14-3-3η's extracellular expression in RA elicits a robust, early auto-antibody response to the native protein, which may confer a protective effect. We investigated the relationship between the 14-3-3η protein as well as its auto-antibodies and response to anti-TNF therapy, in established RA.

Methods: Serum 14-3-3η protein and its auto-antibodies were measured at baseline in 99 RA patients who were refractory to either a standard DMARD or a first TNF-blocker. 14-3-3η protein was measured by ELISA and the auto-antibody levels by Meso-Scale-Discovery electrochemiluminescent platform. The changes in clinical response variables (within 15 weeks of treatment initiation) were determined and median group differences between patients who were 14-3-3η protein positive ($>$ 0.19 ng/ml) and negative or 14-3-3η auto-antibody positive ($>$ 380 U/ml) and negative were tested using the Mann-Whitney U-Test. Regression analyses were used to test whether the 14-3-3η markers were independent predictors of a good EULAR response (DAS28 $<$ 3.2, ΔDAS $>$ 1.2) or DAS remission (DAS-ESR$<$2.6) and contingency analyses for frequency distribution of biomarker positivity and response were conducted. Spearman correlations were performed to evaluate the relationship between the expression of the 14-3-3η protein and its auto-antibodies.

Results: At baseline, 88 of 99 (89%) patients were positive for 14-3-3η and 11 of 99 (11%) were positive for the 14-3-3η auto-ab. Median (IQR) and mean (SD) 14-3-3η serum levels were 2.1 (0.7 – 15.7) ng/ml and 6.6 (8.1) ng/ml with median and mean auto-ab titres being 216 (172 – 311) U/ml and 248 (103) U/ml. At 15 weeks, median ESR (29 vs. 17, $p < 0.02$) and CRP (7.3 vs. 2.9, $p < 0.03$) were significantly higher in 14-3-3η +ve patients. 14-3-3η auto-ab +ve patients achieved a significantly lower DAS (4.2 vs 4.7, $p < 0.03$), a greater change in DAS (2.3 vs 1.7, $p < 0.03$), a lower ESR (29 vs. 15, $p=0.05$), and a lower CRP (6.8 vs. 2.9, $p=0.05$) than 14-3-3η auto-ab -ve patients. Contingency analysis revealed that 14-3-3η negativity was predictive of achieving a good EULAR response with an LR of 5.0, $p<0.03$, OR=4.8 (1.3 – 18.1) and RR=3.1 (95%CI, 1.4–7.0). 14-3-3η auto-ab positivity marked a higher likelihood of achieving both a good EULAR response [LR = 5.0, $p < 0.03$, OR=0.2 (95%CI, 0.1–0.8), RR=3.1 (1.4–7.0)] and DAS remission [LR = 4.0, $p < 0.05$, OR=0.2 (0.1 – 0.9), RR=3.2 (1.4–8.5)]. The multivariate logistic regression returned both 14-3-3η and its auto-antibodies as significant independent predictors of a good EULAR response ($p<0.02$). The low Spearman correlation ($r = -0.13$, $p = 0.2$) between serum 14-3-3η and its auto-antibodies, supports their combined utility to inform therapy response.

Conclusion: RA patients who are negative for 14-3-3η and positive for its auto-antibodies are more likely to achieve a Good EULAR response and DAS remission with anti-TNF therapy.

MMP3 As a Predictor Identifying a Subgroup Of Rheumatoid Patients Who Are Successfully Treated With Methotrexate (MTX) Alone But Still Subject To Radiographic Progression. Shunichi Shiozawa[1], Yasushi Tanaka[2], Ryosuke Yoshihara[2], Miki Murata[2], Takashi Yamane[2], Chihiro Tanaka[2], Noriaki Yo[2] and Kazuko Shiozawa[2]. [1]Kyushu University Beppu Hospital, Beppu, Japan, [2]Kohnan Kakogawa Hospital, Kakogawa, Japan.

Background/Purpose: To discover the prognostic factor identifying a subgroup with clinical relevant radiographic progression (CRRP) and rapid radiographic progressoion (RRP) among rheumatoid patients successfully treated clinically with methotrexate (MTX) alone but still need additional biologics to halt radiographic progression, we compared the baseline data on initiation of MTX therapy and subsequent radiographic progression of patients.

Methods: Clinical, structural and functional outcomes of rheumatoid patients fulfilling the ACR diagnostic criteria who were successfully treated with MTX-alone (n=151) were evaluated using DAS28-4ESR, modified total Sharp score (mTSS) and modified health assessment of questionnaire (mHAQ), MMP-3, anti-CCP2 antibody and others for 3 yrs prospectively. To identify the predictor of CRRP (ΔTSS>3) or RRP (ΔTSS>5), baseline data were assessed in relation to radiographic progression using univariate logistic regression and Fisher's test procedures.

Results: The patients (mean: age 57.7 yrs, disease duration 4.6 yrs) were with high disease activity (mean:DAS28-4ESR 5.5, CRP 2.4mg/dL) and joint destruction (mean: ΔTSS 8.3) on initiation of MTX therapy. Clinical disease activity was significantly improved yearly from baseline to 3yrs: DAS28-4ESR from 5.5±1.2 to 3.7±1.4, %DAS28 remission from 2% to 19%, mHAQ from 0.53±0.46 to 0.18±0.31, and %mHAQ remission from 16% to 60%. After 1 yr of MTX therapy, 64/151 (42.4%) of patients were under structural remission, 45/151 (29.8%) under CRRP, and 26/151 (17.2%) under RRP: the values remained similar 48.6%, 21.5% and 12.1%, respectively at 3 yrs. When the patients who attained structural remission were compared with those classified into CRRP or RRP, baseline CRP and MMP-3 values were significantly different ($p<0.01$). According to logistic regression analysis, MMP-3 levels at baseline showed most significant association with CRRP and RRP especially after 1 yr of treatment. The cut-off value of MMP-3 was calculated to be 103.7 ng/ml by using a logistic regression receiver operating characteristics (ROC) analysis. The result showed that the patients containing MMP-3 below 103.7 ng/ml were classified not to CRRP and RRP with the sensitivity of 80.0% and 90.0%, respectively; Fisher's exact test 0.0021 and 0.0011, respectively.

Conclusion: We identified basal MMP-3 level as a predictor identifying a subgroup with CRRP and RRP among the patients who appeared successfully treated with MTX-alone but still require additional treatment with biologics to halt radiographic progression.

1317

Methotrexate Optimization (ie introduction during the first 3 months and with dose escalation at 6 months at least at 20mg/w or 0.3mg/kg/w) Is Associated With Better Clinical Outcomes In Daily Practice: Results From The Espoir Cohort. Cécile Gaujoux-Viala[1], Simon Paternotte[2], Bernard Combe[3], Maxime Dougados[4] and Bruno Fautrel[5]. [1]EA 2415, Montpellier I University, Nîmes University Hospital, Rheumatology Department, Nîmes, France, [2]Paris- Descartes University, Cochin hospital, Paris, France, [3]Lapeyronie Hospital, Montpellier I university, Montpellier, France, [4]Paris-Descartes University, APHP, Cochin Hospital, Paris, France, [5]Paris 6 – Pierre et Marie Curie University; AP-HP, Rheumatology, Pitié-Salpêtrière Hospital, - GRC-UPMC 08 – EEMOIS, Paris, France.

Background/Purpose: Methotrexate (MTX) is recommended as the first DMARD in rheumatoid arthritis (RA) at a weekly dose of 20–25mg in combination with folic acid supplementation. Despite its widespread use and more than two decades of experience, considerable variations exist among rheumatologists in prescribing MTX.

Objective: To describe symptomatic and structural impact of the MTX optimization in early arthritis (EA) in daily clinical practice over 2 years.

Methods:

- *Patients:* from the French cohort of EA ESPOIR (at least 2 swollen joints for less than 6 months and suspicion of RA), fulfilling the new ACR-EULAR criteria for RA at baseline, and treated by MTX as first DMARD.

- *Treatment group:* optimized MTX was defined by at least 3 months of MTX during the first 6 months and dose of initiation at least 10 mg/week with escalation at 6 months at least at 20 mg/w or 0.3mg/kg/w if DAS28>2.6.

- *Outcomes:* remissions (Boolean, SDAI and DAS28), functional stability (HAQ≤0.5 and deltaHAQ≤0.25), absence of radiographic progression (delta Sharp score <1) and absence of fast radiographic progression (delta Sharp score <1).

- *Analyses:* evaluation of the symptomatic and structural efficacy has been performed by generalized linear regression after adjustement on propensity score (by modelling the optimization of MTX by disease specific- and demographic variables obtained at baseline, using logistic regression analysis) in the group of patients receiving optimized MTX versus the ones receiving MTX without optimization.

Results: Within the first year of follow-up of 600 RA patients, 352 received MTX as first DMARD. The mean dose of MTX was 13.1 +/− 3.9 mg/week. In all, 76.1% of patients received at least 3 months of MTX during the first 6 months and 25.3% were treated initially at least by 10 mg/week with escalation at 6 months at least at 20 mg/w or 0.3mg/kg/w if DAS28>2.6; only 22.1% fulfilled the 2 criteria. MTX optimization was initiated in younger patients (45.2 years ± 12.6 vs 49.3 ± 11.3, p=0.009) with higher CRP (29.3±32.0 vs 24.4±36.7, p=0.006). After adjustment, optimized MTX was found to be more efficient in terms of remission and function than control (table).

Outcome	Optimized MTX N = 76 N (%) at m12	Non optimized MTX N=268 N (%)	Adjusted OR m0-m12 [95%CI]	Adjusted OR m12-m24 [95%CI]
Boolean remission	20 (27.4%)	25 (10.0%)	2.56 [1.22–5.37]	1.85 [0.98–3.52]
SDAI remission	23 (31.5%)	27 (10.8%)	2.35 [1.16–4.75]	2.30 [1.22–4.32]
DAS28 remission	40 (55.6%)	74 (29.6%)	2.81 [1.53–5.18]	2.72 [1.46–5.07]
Functional stability	54 (74.0%)	134 (52.6%)	3.01 [1.49–6.08]	1.93 [0.97–3.85]
Absence of radiographic progression	23 (34.9%)	81 (35.2%)	1.06 [0.56–2.01]	0.54 [0.26–1.10]
Absence of fast radiographic progression	23 (34.9%)	81 (35.2%)	0.76 [0.37–1.54]	0.44 [0.19–1.03]

* Ajusted on: SJC, CRP, ACPA or RF, Sharp score, Center, Age, Smoking, HAQ, ACR1987 criteria.

Conclusion: Optimized MTX is more efficacious on remission and function than MTX without optimization in EA in daily practice but without impact on radiographic progression over 2 years.

Prevalence and Impact Of Soft Tissue Manifestations In Early Inflammatory Arthritis: Results From The Canadian Early Arthritis Cohort. Mihaela Popescu[1], Edith Villeneuve[2], Boulos Haraoui[3], Gilles Boire[4], Carol A. Hitchon[5], Edward C. Keystone[6], Janet E. Pope[7], J. Carter Thorne[8], Diane Tin[8] and Vivian P. Bykerk[6]. [1]University of Montreal, Montreal, QC, [2]Institut de Rhumatologie de Montréal, Montreal, QC, [3]Centre Hospitalier de l'Université de Montréal, Montreal, QC, [4]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [5]University of Manitoba, Winnipeg, MB, [6]Mount Sinai Hospital/University of Toronto, Toronto, ON, [7]St Joseph Health Care, London, ON, [8]Southlake Regional Health Centre, Newmarket, ON.

Background/Purpose: It is increasingly recognized that soft tissue inflammation in patients with inflammatory arthritis is frequent and might be of clinical importance. However, when therapeutic adjustments are made, the extent of soft tissue involvement is often not taken into consideration, because it is not measured objectively in disease activity indices. Our study objective was to determine the frequency of soft tissue inflammation such as tenosynovitis, enthesitis, and bursitis in a Canadian cohort of patients presenting with early inflammatory arthritis and to investigate the impact of these manifestations on disease activity, functional ability, quality of life, and self-reported outcome measures.

Methods: Soft tissue prevalence and impact was assessed at baseline in a nationwide cohort of 1509 Canadian adults who were enrolled in the Canadian Early Arthritis Cohort (CATCH) between 2007 and 2012. Disease activity, patient reported outcomes (pain and fatigue), Health Assessment Questionnaire (HAQ), and Short Form quality of life (SF-12) were collected. Soft tissue involvement was assessed by clinical examination.

Results: Our analysis included 1509 patients with a mean age of 54 years old, of whom 73% were women and the mean disease duration until diagnosis was 5.7 months. We found 290 periarticular soft tissue involvement in 222 (14.74%) patients. Periarticular involvement was found in more than one

anatomic site in only 59 (26.6) of the 222 patients and in >3 sites, in only 2 (0.9%) patients. The majority of lesions were localized to hands and wrists (56.6%) followed by feet and ankles (16.9%), elbows (11.0%), shoulders (10.4%), hips (3.4%) and knees (1.7%). There was no difference in disease activity score (DAS28), pain, fatigue, function (HAQ), or SF-12 between patients with or without soft tissue disease (Table 1).

Table 1. Comparison of patients with and without soft tissue involvement at baseline*

	Patients with soft tissue involvement (n=222)	Patients without soft tissue involvement (n=1287)	p
Pain VAS (0–100) (n=1454)	60.04 (26.83)	56.14 (28.33)	NS
Fatigue VAS (0–100) (n=1479)	52.84 (30.28)	56.3 (29.42)	NS
DAS28 (0–9.4) (n=1387)	5.04 (1.44)	5.19 (1.38)	NS
CDAI (0–76) (n=1449)	27.05 (14.04)	28.02 (1.38)	NS
SDAI (0–86) (n=1333)	28.31 (14.69)	29.55 (14.76)	NS
HAQ (0–3) (n=1484)	1.03 (0.71)	1.09 (0.69)	NS
SF-12 (physical score) (0–5) (n=1346)	3.66 (1.06)	3.55 (9.57)	NS
SF-12 (mental score) (0–5) (n=1346)	4.54 (1.58)	4.58 (1.18)	NS

* Values are presented as means and SD.

Conclusion: The clinical prevalence of soft tissue manifestations in this early inflammatory arthritis cohort was low. The presence of soft tissue involvement was not associated with differences in disease activity indices, patient self-reported symptoms, HAQ, or SF-12. In conclusion, despite the presence of periarticular soft tissue inflammation, current disease activity indices may be sufficient to guide treatment adjustments in this cohort of early inflammatory arthritis.

Diagnostic Value Of Anti-Citrullinated Proteins Antibodies In Rheumatoid Arthritis. Claudia L. Giraldo[1], Rafael Chaparro del Moral[2], Mercedes Ciancio[3], Oscar L. Rillo[3], Emilia Saint Martin[4], Emilce Schneeberger[5], Gustavo Citera[5], Federico Zazzetti[6], Amalia Schiel[7] and Juan C. Barreira[7]. [1]Hospital General de Agudos, Buenos Aires, Argentina, [2]Hospital General de Agudos Dr. E. Tornu, Buenos Aires, Argentina, [3]Hospital General de Agudos "Dr. E. Tornú", Buenos Aires, Argentina, [4]Instituto de Rehabilitacion Psicofisica, Buenos Aires, Argentina, [5]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [6]Buenos Aires Hospital Britanico, Buenos Aires, Argentina, [7]Buenos Aires British Hospital, Buenos Aires, Argentina.

Background/Purpose: Citrulline and vimentin are some of the proteins used as antigens for anti-citrullinated proteins antibodies (ACPAs) detection for the diagnosis of rheumatoid arthritis (RA). In our country, anti-mutated citrullinated vimentin (anti-MCV) kit is 50% cheaper than the anti-cyclic citrullinated peptide (anti-CCP3) kit. The aim of our study was to evaluate the diagnostic value of anti-MCV compared to anti-CCP3 and rheumatoid factor (RF) and to explore the relationship between them and disease activity.

Methods: Consecutive patients ≥ 18 years with RA (ACR 1987 and ACR/EULAR 2010 criteria) were included. The control group consisted of 73 subjects with undifferentiated arthritis, SLE, Psoriatic Arthritis, Sjögren's Syndrome and Erosive Osteoarthritis (non RA arthritis). Anti-MCV and anti-CCP3 were determined by ELISA and RF by immunoturbidimetry. The cutoff value for the three methods was ≥ 20 IU/ml. Sensitivity (S), Specificity (E), Positive and Negative Predictive Values (PPV, NPV) and Likelihood Ratio (LR) of the RF, anti-CCP3 and anti-MCV were assessed using a two way table (Table). Binary logistic regression analyses were performed, using high disease activity (DAS28>5.1) as dependent variable. According to the RF, anti-CCP3 and anti-MCV concentrations, three groups of patients were obtained: low concentrations (under 25 percentile); intermediate concentrations (between 25 and 75 percentile) and high concentrations (above 75 percentile).The values of DAS28 for these three groups were compared by ANOVA and post-hoc tests.

Results: 234 patients were evaluated (161 RA and 73 controls). In the RA group, 85% were female, the mean age was 53 (18–91) years, the median symptoms duration was 120 months (IQR 39–180) and 31(19%) were early RA patients (<2 years). Mean DAS28 was 3.6 (±1.5); and the median HAQ 0.75 (IQR 0.25–1.25). The median of RF was 104 IU/ml (IQR 35–225); anti-CCP3 180 IU/ml (IQR 95–210) and anti-MCV 300 IU (IQR 55–1000). Higher values of DAS28 were observed in the group of patients with RF > 225 IU/ml (mean DAS28 4.3 p = 0.006) and also in patients with anti-MCV > 1000 IU (DAS28 4.2 p=0.01). There were no differences for anti-CCP3. In early RA patients, a multivariate analysis (adjusted by symptom duration) showed that anti-MCV levels were associated with high disease activity. The OR estimated for the association between high disease activity and anti-MCV ≥ 1000 IU in early RA patients was 11.8 (CI 95%1.049–132.9). There was not significant association between RF, anti- MCV nor anti-CCP3 and DAS28 > 5.1 in established RA patients.

	S	E	PPV	NPV	LR
Anti-MCV	**93.4**	**83.6**	**93**	**85**	**5.69**
Anti-CCP3	**83.7**	**84.9**	**93**	**69**	**5.54**
RF	**84.9**	**84.9**	**93**	**71**	**5.62**

Conclusion: In our study, anti-MCV compared to anti-CCP3 and RF had a higher sensitivity with equal specificity. We found increased RA activity in patients with higher titers of RF and anti-MCV.

1320

Categorization Of Rheumatoid Arthritis Subjects By Rheumatoid Factor and Anti-Cyclic Citrullinated Autoantibody Status Identifies Rheumatoid Arthritis Subjects With Different Characteristics. Swati Modi[1], Mariely Nieves-Plaza[1], Donald M. Jones[1], Erich R Wilkerson[1], Christine L. Amity[2], Kelly A. Reckley[3], Ilinca D. Metes[1], Jason Lyons[1], Heather Eng[4], Stephen R. Wisniewski[4] and Marc C. Levesque[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Univ of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh School of Medicine, Pittsburgh, PA, [4]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA.

Background/Purpose: Rheumatoid factor (RF) and anti-citrullinated cyclic peptide (CCP) antibodies have been used to diagnose rheumatoid arthritis (RA) patients, although there is substantial heterogeneity among RA patients regarding the presence of these biomarkers. Previously, we found that RA patients grouped on the basis of RF and CCP status into 4 groups: RF+CCP+, RF+CCP-, RF-CCP+, RF-CCP- had different clinical characteristics including a higher percentage of female subjects and less use of biologics in the RF+CCP- group. Our aim was to determine whether these subgroups of RA patients had features suggestive of other overlapping connective tissue diseases.

Methods: Patients from the Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry who met the 1987 and/or 2010 ACR criteria for a diagnosis of RA were categorized based on clinical cut-offs for RF and CCP into 4 groups: RF+CCP+, RF+CCP-, RF-CCP+, RF-CCP-. We determined the association of these four RF and CCP groups with autoantibodies and inflammatory markers measured by ELISA (IL-6) or in a clinical laboratory (ANA, anti-SSA/SSB, anti-dsDNA, C3, C4, gammaglobulin and CRP). Categorical and continuous variables were analyzed using chi-square and Kruskal-Wallis tests, respectively.

Results: IL-6 levels were significantly associated with disease activity (DAS28-CRP) but only in the RF+/CCP+ and RF-/CCP- groups, while CRP levels were significantly associated with disease activity in all groups. ANA positivity was significantly different across groups (p = 0.008) (Table 1). The percentage of ANA positive subjects was highest in the RF+CCP+ group (71%) and lowest among the RF-/CCP- group (48%). There were no significant differences for the remaining laboratory characteristics, although RF+/CCP- subjects were more likely to have a low C4 level and a positive anti-SSA and/or -SSB and anti-dsDNA.

Table 1. Serological analysis

Serological Tests	RF−/CCP− (n=110)	RF+/CCP− (n=61)	RF−/CCP+ (n=33)	RF+/CCP+ (n=260)	p value
ANA (n=379)	44/92 (48%)	34/54 (63%)	18/28 (64%)	145/205 (71%)	0.008
dsDNA (n=32)	2/11 (18%)	2/5 (40%)	0/1 (0%)	3/15 (20%)	0.722
SSA (n=120)	3/22 (14%)	3/19 (16%)	0/4 (0%)	10/75 (13%)	0.942
SSB (n=113)	0/21 (0%)	2/16 (13%)	0/4 (0%)	2/72 (3%)	0.280
Low C3 (n=99)	0/30 (0%)	0/15 (0%)	0/5 (0%)	5/49 (10%)	0.963
Low C4 (n=98)	4/30 (13%)	3/15 (20%)	0/5 (0%)	5/48 (10%)	0.155
Hyper-gammaglobulinemia (n=127)	3/32 (9%)	5/18 (28%)	0/8 (0%)	21/69 (30%)	0.111

Conclusion: RF+CCP- subjects were typically ANA positive and more likely than other RF/CCP groups to be female, have low C4 levels and to have a positive anti-SSA and/or -SSB suggesting that some of these subjects may have RA and/or Sjogren's syndrome. The lower percentage of subjects in the CCP negative groups treated with biologic therapies may be due to lower levels of disease activity as seen in the RF-CCP- group and/or may be due to the presence of subjects with diseases poorly responsive to biologic therapies such as Sjogren's syndrome in the RF+/CCP- group. In summary, we believe that categorization of RA subjects by RF and CCP status may identify RA subjects with different syndromes, differential responses to therapy and different outcomes.

Vasoactive Intestinal Peptide Serum Levels As a Marker Of Prognosis In Rheumatoid Arthritis. Rosario Garcia-Vicuña[1], Ana M. Ortiz[1], Iria Valino-Seoane[2], Amalia Lamana[1], Javier Leceta[2], Yasmina Juarranz[2], Isidoro González-Alvaro[3], Rosa P Gomariz[2] and Carmen Martinez-Mora[4]. [1]Hospital Universitario de La Princesa. IIS Princesa, Madrid, Spain, [2]School of Biology. Universidad Complutense de Madrid, Madrid, Spain, [3]Hospital Universitario de La Princesa, IIS Princesa, Madrid, Spain, [4]School of Medicine. Universidad Complutense de Madrid, Madrid, Spain.

Background/Purpose: The current shift to earlier treatment of Rheumatoid Arthritis (RA) has a major unmet need in the availability of biomarkers to identify patients requiring more intensive treatment, even in undifferentiated disease stages. Vasoactive intestinal peptide (VIP) has demonstrated physiological anti-inflammatory and immunoregulatory roles both in murine arthritis models and in "in vitro" studies with human synoviocytes and lymphocytes by decreasing the expression of proinflammatory molecules and favouring Th2 responses. In addition, low levels of VIP expression in the synovial fluid of severe forms of osteoarthritis has been described.

The aim of this work is to analyze the potential value of studying VIP serum levels (VIPs) as a prognostic biomarker in RA by longitudinal assessment of its levels in patients with early arthritis (EA).

Methods: We studied 91 patients from our prospective EA registry, in which we collect by protocol sociodemographic, clinical, laboratory, and therapeutic information. 73% were female, with age at disease onset 54 years [45–66] (median [p25-p75]), duration of disease at entry 5.4 [3.2–8.4] months and follow-up 2 to 5 years. 76% of patients met 1987 ACR classification criteria for RA after two years of follow up. VIPs were measured by ELISA (Phoenix Pharmaceutical, Karlshure, Germany) in the patients sera collected from 353 visits (3.8 visits per patient), and in 100 healthy controls. Low VIPs were considered if below the 25th percentile of the normal population. We created the variable treatment intensity (IT) as the sum of the number of days on treatment with each disease modifying anti-rheumatic drugs, including biologics. To determine the effect of independent variables on VIPs, we performed a longitudinal multivariate analysis, nested by patient and visit, through the command xtgee of Stata 12 for Windows (StataCorp LP, College Station, TX, USA).

Results: We could not detect significant differences in the VIPs between patients and controls either at their first visit (409 pg/ml [359–469] versus 403 [371–441] respectively, p = 0.915) or over the two year follow-up. Nevertheless, substantial heterogeneity in these levels was observed. Multivariate analysis aimed to deepen this VIPs heterogeneity showed differences by gender (being female beta coefficient [coef. Beta]: 0.25 ± 0.09, P = 0.007) and age of disease onset (coef. beta per year 0.003 ± 0.007, P = 0.006). In terms of disease-related variables, VIPs were lower in subjects with greater disease activity measured by DAS28 (coef. beta: −0.043 ± 0.019, P = 0.026). In addition, patients with lower VIPs at the first visit had higher disease activity at the end of follow-up (3.47 [2.83–4.37] versus 3.03 [2.16–3.77], p = 0.14) and received more intense treatment according to the variable IT (1352 [1092–1754] vs 1119 [870–1473], p = 0.22).

Conclusion: Our data suggest that VIPs may be a prognostic biomarker in RA since baseline levels are lower in patients who show a worse clinical course and increased requirements for treatment in the first two years of disease monitoring.

Osteoprotegerin and TNF-Related Apoptosis Inducing Ligand Are Respectively Predictive Factors Of Remission and Erosion In Early Rheumatoid Arthritis Patients Included In The French Cohort Espoir. Rachel Audo[1], Laura Papon[1], Claire I. Daien[2], Cédric Lukas[2], Bernard Combe[2], Olivier Vittecoq[3], Michael Hahne[1] and Jacques Morel[2]. [1]IGMM, CNRS UMR5535, Montpellier, Montpellier, France, [2]Lapeyronie Hospital, Montpellier, France, [3]Rouen University Hospital & Inserm905, University of Rouen, Rouen Cedex, France.

Background/Purpose: TNF-Related Apoptosis Inducing Ligand (TRAIL) is a member of the TNF familly. Its soluble receptor Osteoprotegerin (OPG) also inhibits Receptor activator of nuclear factor kappa-B ligand (RANKL). We previously reported that, in a cohort of early arthritis (< 2 years), a high TRAIL/OPG ratio at baseline was associated with remission (DAS28<2.6) at 6 months, suggesting that the TRAIL/OPG ratio could be a predictive factor for remission in early arthritis.

Methods: The aim of this study was to confirm these results in the larger French cohort ESPOIR including patients with early arthritis (<6 months). Patients were assessed for clinical and biological parameters and Sharp's score at baseline (M0), 12 (M12) and 24 (M24) months. TRAIL and OPG concentrations in serum were measured at M0. We correlated these values with inflammation, disease activity and radiographic progression. We also aimed to compare TRAIL and OPG between patients with arthritis responding to ACR/EULAR 2010 criteria (RA) and those with undifferentiated arthritis (UA). Values of TRAIL and OPG were log transformed to be normalized. Correlations were performed using Pearson tests. For mean comparisons, adjustment with baseline CRP, DAS28, rheumatoid factor, BMI, steroids doses, age and sexe was performed using ANCOVA. Logistic regression was used to determine predictive value for remission (DAS28 ≤2.6) and radiographic progression (DSharp score>0).

Results: TRAIL, OPG and TRAIL/OPG at M0 were not different between patients RA (n = 641) and UA patients (n = 53). Among RA patients, OPG at M0 was significantly correlated with DAS28 (r=0.14; p=0.001), ESR (r=0.14; p=0.001) and CRP (r=0.11; p=0.007). TRAIL/OPG ratio was inversely correlated with DAS28 (r=−0.13; p=0.002), ESR (r=−0.14; p=0.002) and CRP (r=−0.15; p<0.001). TRAIL was only inversely correlated with CRP (r=−0.10; p=0.02). Patients in remission at M12 had a significantly lower concentration of M0 OPG (921±418 (n=204) vs 1014±383 pg/ml (n=342), respectively, p=0.0018). Patients in remission at M12 also tend to have a higher baseline TRAIL/OPG ratio (1.38±1.01 vs 1.17±0.59 pg/ml, p=0.051), but after adjustment, only a low M0 OPG remained significantly associated with remission at M12 (p=0.007). Logistic regression confirmed the predictive value of OPG (OR: 0.21, CI: 0.07–0.067, p=0.008). Patients with progression of Sharp score erosion at M24 have significant higher M0 TRAIL (1128±615, n=334 vs 1010±490 pg/ml, p=0.013). After adjustment, TRAIL is still significantly associated with progression of Sharp score erosion (p=0.003) and logistic regression confirmed that TRAIL is a protective factor for structural damage (OD: 0.22, CI: 0.81–0.609, p=0.003).

Conclusion: Concentrations of TRAIL and OPG could not help in distinguish UA and RA. OPG was correlated with ESR, CRP and DAS28 and TRAIL inversely correlated with CRP. In a larger cohort, this study did not confirm the predictive value of the ratio TRAIL/OPG. However, a low M0 OPG was associated with EULAR remission at M12 and is predictive of remission. A low TRAIL at baseline is associated with Sharp erosion increased at M24 and is also predictive of progression of Sharp's score erosion.

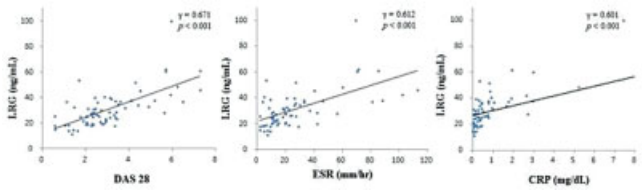
1323

Plasma Leucine-Rich Alpha-2 Glycoprotein Is a Useful Disease Activity Biomarker In Rheumatoid Arthritis. Jung-Soo Song[1], You-Jung Ha[2], Eun-Jin Kang[3], Kwang-Hoon Lee[4], Sang-Won Lee[2], Yong-Beom Park[2], Soo-Kon Lee[2] and Sang Tae Choi[1]. [1]Chung-Ang University College of Medicine, Seoul, South Korea, [2]Yonsei University College of Medicine, Seoul, South Korea, [3]Busan Medical Center, Busan, South Korea, [4]Dongguk University Ilsan Hospital, Goyang, South Korea.

Background/Purpose: Leucine-rich α2-glycoprotein (LRG) is a plasma protein which contains leucine-rich repeats (LRRs). Though physiological functions of LRG have not been clarified yet, it has been reported that LRG could be a marker of granulocytic differentiation and its expression was up-regulated during neutrophil differentiation. LRG could show a significant increase in some inflammatory conditions, such as ulcerative colitis, in where serum LRG concentrations were well correlated with disease activity, and the expressions of LRG were increased in inflamed colonic tissues. However, the association between plasma LRG level and disease activity in RA patients remains obscure. This study aimed to investigate whether the plasma LRG level is elevated in patients with RA and its correlation with disease activity and other parameters.

Methods: Our study included 69 patients with RA and 48 age- and sex-matched healthy controls. Plasma samples were obtained from patients with RA during active and inactive disease status and from controls. We assessed the clinical characteristics and laboratory parameters including erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and disease activity score 28 (DAS28). Plasma concentrations of tumor necrosis factor-α (TNF-α) and LRG were determined by enzyme-linked immunosorbent assay (ELISA).

Results: Plasma LRG concentrations were significantly elevated in RA patients compared with healthy control (30.8 $\pm$ 14.4 ng/mL vs 22.2 $\pm$ 6.1 ng/mL, $p < 0.001$). In patients with RA, plasma LRG levels were found to be correlated with DAS28, ESR, and CRP ($\gamma = 0.671$, $p < 0.001$; $\gamma = 0.612$, $p < 0.001$; and $\gamma = 0.601$, $p < 0.001$, respectively), but not with plasma TNF-α levels. Plasma LRG levels in patients with an active disease status (DAS28 >= 2.6) were significantly higher than in patients with a remission status (DAS28 < 2.6) (36.45 $\pm$ 14.36 ng/mL vs 24.63 $\pm$ 8.81 ng/mL, $p <$ 0.001).



Conclusion: Patients with RA had higher plasma LRG levels than healthy subjects, and plasma LRG concentrations were well correlated with disease activity measures. Our findings suggest that plasma LRG could play a role in the inflammatory process independently of the TNF- α, and that it may be a novel biomarker for reflecting inflammatory activity in RA patients.

Evaluation Of The Usefulness Of Interferon-Gamma Release Assays and Tuberculin Skin Test For Detection Of Latent Mycobacterium Tuberculosis Infection In Korean Rheumatic Patients With Biologic Agents. Jae-Hoon Kim[1], Soyoung Won[2], Chan-Bum Choi[3], Yoon-Kyoung Sung[3], Gwan Gyu Song[1] and Sang-Cheol Bae[3]. [1]Korea Univ College of Med, Seoul, South Korea, [2]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [3]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea.

Background/Purpose: The screening for and treatment of latent tuberculosis infection (LTBI) before starting biologic agents is crucial to prevent reactivation and resultant serious infection. Several national guidelines recommended to test tuberculin skin test (TST) initially and Interferon-γ Release Assay (IGRA) if TST result is indeterminate. In Korea with an intermediate tuberculosis(TB) burden, national guideline recommends use of both IGRA and TST for detection of LTBI before starting biologic therapies, and chemopreventive TB treatments are recommend in case of positive IGRA or TST results. Our study was conducted to estimate the concordance between QuantiFERON-TB Gold in tube Test (QFT-GIT) as an IGRA and TST, and to evaluate the difference in the occurrence of active TB in patients who are candidates of biologic agents who receive both QFT-GIT and TST compared with those who receive either TST or QFT-GIT alone for detection of LTBI.

Methods: A total of 959 patients who received both QFT-GIT and TST from Jan. 2004 to Dec. 2012 at Hanyang University Hospital for Rheumatic Diseases were recruited for the concordance between the 2 tests. The concordance between the 2 tests was estimated by Cohen's kappa (κ). A total of 842 patients who performed QFT-GIT or TST and used biologics from Jan. 2007 to Dec. 2012 were recruited for the usefulness of LTBI screening test. The screening test of LTBI, TB prophylaxis, TB occurrence, and clinical characteristics were examined. Among 842 patients, 260 patients received only TST, 149 patients received only QFT-GIT, and 436 patients received both QFT-GIT and TST. The occurrence of TB according to the screening method of LTBI was identified. The incidence rates of active TB were calculated as number of events per 100,000 person-years exposure.

Results: The concordance between QFT-GIT and TST was low in the whole group ($\kappa = 0.312$). A total of 5 patients developed TB after initiation of biologics according to the screening guideline of LTBI. Among them, extra-pulmonary TB occurred in 3 patients. Some patients did not comply with LTBI prophylactic strategy. TB occurred in 2 patients according to LTBI prophylactic strategy (Table). TB incidence in the group that received both QFT-GIT and TST was 151.05/100,000 person-years and that in the group that received only TST was 169.78/100,000 person-years among the patients who complied with LTBI prophylactic strategy.

Table. The incidence of TB according to LTBI prophylactic strategy

LTBI Screening	Number	LTBI Result	TB prophylaxis		Number	Occurrence of TB	Incidence rate(/100,000 person-years)
Only TST	260	Positive	120	Yes	100	233	0	0
		Negative	140	No	133		1	169.78
Only QFT-GIT	144	Positive	27	Yes	25	125	0	0
		Negative	117	No	100		0	0
TST & QFT-GIT	421	Positive/Positive	52	Yes	50	393	0	0
		Positive/Negative	67	Yes	57		0	0
		Negative/Positive	26	Yes	21		0	0
		Negative/Negative	271	No	265		1	151.05

Conclusion: The concordance between QFT-GIT and TST was low. TB did not occur in patients who received TB prophylaxis after positive results by either only TST strategy or QFT-GIT & TST strategy. TB incidence in patients who performed both QFT-GIT and TST and prophylaxis seems to be lower than that in those who performed only TST and prophylaxis. However, it was difficult to calculate the significant of this difference or superiority because the observation period was short.

A Novel Index to Identify Interstitial Lung Disease in Rheumatoid Arthritis Patients. José Félix Restrepo[1], Inmaculada del Rincón[1], Roy W Haas[1], Daniel F Battafarano[2], Agustín Escalante[1]. [1]University of Texas Health Science Center at San Antonio; [2]San Antonio Military Medical Center, San Antonio, Texas.

Background/Purpose: Interstitial lung disease (ILD) is associated with significant morbidity and mortality in rheumatoid arthritis (RA). Diagnosis requires imaging studies or invasive procedures that are costly and may entail risk. Because of this, diagnostic procedures are only performed on patients who display symptoms or sign of the disease. A strategy to identify patients at high risk would help target those who would benefit from a diagnostic intervention. The objective of the present study is to develop an index for the identification of RA patients at high risk of ILD.

Patients and Methods: We studied patients with RA recruited from rheumatology practices. We assessed each patient for the following variables: Age, sex, joint tenderness and swelling, rales on auscultation, subcutaneous nodules, disease severity, use of methotrexate and current prednisone use, smoking status, rheumatoid factor, antibodies against cyclic citrullinated peptide (anti- CCP), and ESR. ILD was diagnosed using chest X-ray, CT scan, and/or lung biopsy. We divided the study sample into two equivalent groups using a random procedure. We used the first group as the development sample. We performed a stepwise logistic regression model using the above

variables as predictors. Using the results of the model we developed an index, which we then tested in the second group, or validation sample.

Results: The sample included 779 patients, of whom 69 had ILD, 147 had other pulmonary diseases and 563 had no lung diseases. We conducted the current analysis on 542 patients (52 with ILD, 490 without ILD) who had all the variables for the index. The variables and score in the index were as follow: male sex=2; ESR (mm/hr.) ≤ 30=0, 31–60=1,61–100=2,>100=3; anti- CCP ≤20=0, 21–60=1, 61–150=2, >150=3; rales present=2. The Index is the sum of the score for each variable. The maximum value is 10. The performance of the index in identifying patients with ILD in the development and validation sample is shown in Table.

Table. Performance of Index in 542 Patients with Rheumatoid Arthritis

Sample	Development		Validation	
Interstitial Lung Disease	**Absent**	**Present**	**Absent**	**Present**
Index ≤ 5, n (%)	212 (97)	7 (3)	224 (95)	13 (5)
Index > 5, n (%)	25 (53)	22 (47)	29 (74)	10 (26)
ROC Area		0.83		0.66

Conclusion: This novel index may be used to identify RA patients at increased risk of ILD. Patients with a score higher than 5 may benefit from additional diagnostic testing to detect ILD, while those with 5 or less are unlikely to have ILD.

Disclosure: Nothing to disclose.

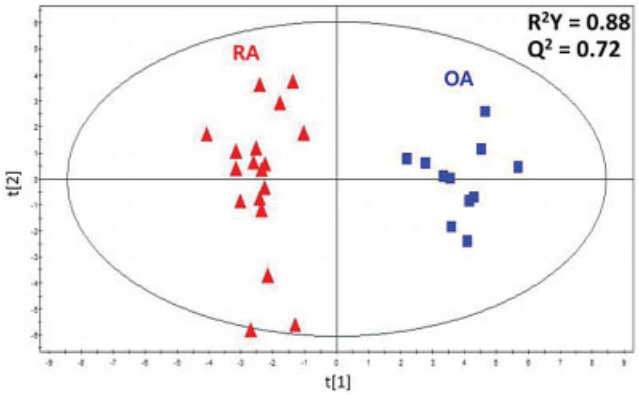
Discriminative Metabolite Profiling Of Synovial Fluid In Rheumatoid Arthritis Compared To Osteoarthritis. Jiwon Hwang[1], Joong Kyong Ahn[2], Jaejoon Lee[3], Inyoung Kim[1], Seulkee Lee[1], Chan Hong Jeon[4], Eun-Mi Koh[1] and Hoon-Suk Cha[3]. [1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Kangbuk Samsung hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, South Korea, [4]Soonchunhyang University College of Medicine, Bucheon, South Korea.

Background/Purpose: Metabolomics is the study of unique chemical imprints that represent specific cellular processes in a cell, tissue, organ or organism. Synovial fluid in pathologic conditions reflects the diseased process and its distinctive metabolite profiles could facilitate the diagnostic ability and the understanding of disease state. The aim of this study is to investigate the metabolites of synovial fluid in patients with rheumatoid arthritis (RA) and osteoarthritis (OA) and to identify characteristic metabolites to differentiate two diseases.

Methods: Synovial fluid samples were obtained from patients with RA (n = 18, 17 females, mean age 50.3 ± 13.9 yr, disease duration 7.9 ± 6.8 yr) and OA (n = 11, 10 females, mean age 60.9 ± 8.4 yr, disease duration 2.8 ± 4.7 yr). The extracted metabolites from synovial fluid were analyzed by gas chromatography/time-of-flight mass spectrometry (GC/TOF MS). The identified metabolites from synovial fluid extracts of RA and OA were then subjected to multivariate statistical analysis by orthogonal partial least squares discriminant analysis (OPLS-DA): R^2 indicates the fitting ability of total variation and Q^2 designates the validity of discrimination. Both have range from 0 to 1, where the higher R^2 or Q^2 connotes a model with the higher predictive and discriminative value. Values of variable importance for projection (VIP) greater than 1 from OPLS-DA were used to identify potential biomarkers and the significance was defined by Welch's test with level of $p < 0.01$.

Results: Sixty-three metabolites were identified; 20 amino acids, 14 fatty acids, 10 sugars, 7 organic acids, 5 amines and 7 others. The OPLS-DA demonstrated a distinctive metabolite profile of synovial fluid between RA and OA (Figure 1), with the variation value (R^2) of 0.88 and the predictive capability value (Q^2) of 0.72. Twenty four metabolites were obtained by VIP values of greater than 1 and 17 of them were selected as specific biomarkers by Welch's t-test. Of 17 metabolites, 6 were up-regulated in RA (maltose, lignoceric acid, uracil, mannitol, pyrophosphate and phosphoric acid) and 11 in OA (lysine, tyrosine, valine, glyceric acid, alanine, asparagines, hydroxylamine, tryptophan, glycerol, glutamine and citrulline).



Conclusion: Our results demonstrated that metabolite profiling of synovial fluid clearly separates RA from OA. This study suggests that metabolomics could be a useful diagnostic tool by identifying discriminative biomarkers.

Autoantibodies To Citrullinated Proteins Associate With Bone Destruction Marker and Are Modulated By First Anti Rheumatic Treatment In Early Rheumatoid Arthritis. Aase Haj Hensvold[1], Vijay Joshua[2], Saedis Saevarsdottir[2], Michaela Larkin[2], Lena Israelsson[2], Ferhan Qureshi[3], Per-Johan Jakobsson[2], Nadine A. Defranoux[4], Lars Klareskog[2], Vivianne Malmström[5] and Anca I Catrina[2]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institut, Stockholm, Sweden, [2]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [3]Crescendo Bioscience, Inc., South San Francisco, CA, [4]Crescendo Bioscience Inc., South San Francisco, CA, [5]Rheumatology unit, Karolinska University Hospital, Karolinska Institutet, STockholm, Sweden, Stockholm, Sweden.

Background/Purpose: Antibodies against citrullinated proteins (especially anti citrullinated-vimentin antibodies) and high levels of RANKL have been linked to altered bone metabolism in early RA. We aimed to investigate ACPA fine specificities in relation to serum RANKL and disease activity in early-untreated RA.

Methods: 186 patients with newly diagnosed RA (patient reported symptom duration less than 1 year), naïve to disease anti modifying drug (DMARD) were started on methotrexate (MTX) monotherapy. Treatment response at 3 months was defined by EULAR response criteria. Disease activity using DAS28-ESR score, anti CCP2 antibodies (anti-CCP2 kit, Euro-Diagnostica, Malmö, Sweden), specific antibodies (Abs) against citrullinated (cit) alpha-enolase (CEP-1) aa5–21, cit vimentin aa60–75 and cit fibrinogen aa563–583 peptides (ELISA) were measured in serum samples at baseline and after 3 months. To avoid RF interference with RANKL ELISA (Biovendor Human sRANKL, Brno, Czech Republic) results, only RF negative samples (baseline and 3 month samples) were analyzed. Mann-Whitney and Wilcoxon sign tests were used to analyze differences between independent and paired variables respectively with a $p < 0.05$ being considered statistical significant.

Results: Anti-CCP2 Abs were detected in 68% (126 out of 186) of the patient sera. 54% (101 of 186) of the patients tested positive for any ACPA specificities at baseline and 46% (85 of 186) tested negative. Positive anti-CCP2 Abs titers significantly decreased from a median of 747 AU/ml (interquartile range, IRQ 2171–278) at baseline to a median of 576 (IRQ 1914–197). A significant titer decrease was similar observed for all tested ACPA specificities. Interestingly 38 % (38 out of 101) of the patients positive for any ACPA specificities at baseline become negative for at least one specific ACPA at 3 months. In contrast only 6% (5 out of 85) of the patients negative for ACPA specificities at baseline become positive at 3 months. No correlation between ACPA titers and disease activity were observed at any time point.

RANKL concentration was significant higher ($p<0.001$) in anti-CCP2+ RF- patients (n=15; median 19 ng/ml, IQR 26–12) as compared to anti-CCP2-RF- patients (n=45; median 9 ng/ml, IQR 13–5). Similar RANKL concentration was significant higher in any-ACPA specificity+ RF- patients

(n=13; median 20 ng/ml, IQR 26–15) as compared to any-ACPA specificity-RF- patients (n=47, median 9, IQR 13–6). Same differences were still detectable at 3 months but overall RANKL concentrations decreased (from a median of 11ng/ml, IQR 16–6 to a median of 9, IQR 13–6, $p<0.05$). RANKL was correlated with age ($r= -0.33$ $p= 0.01$ $n=60$).

Neither ACPA positivity, nor RANKL at baseline were discriminatory for EULAR treatment response.

Conclusion: Presence of ACPA in early-untreated RA patients is associated with increased levels of RANKL, but not disease activity and is modulated by first anti rheumatic treatment. Validation of our results in larger number of patients and investigation of potential direct effects of MTX on B cells are needed.

Physician Global Assessment At Three Months Is Strongly Predictive Of Remission At 12 Months In Early Rheumatoid Arthritis. Results From The Canadian Early Arthritis Cohort. Tommy Choy[1], Vivian P. Bykerk[2], Gilles Boire[3], Boulos Haraoui[4], Carol A. Hitchon[5], J. Carter Thorne[6], Edward C. Keystone[7] and Janet E. Pope[8]. [1]University of Western Ontario, London, ON, [2]Hospital for Special Surgery, New York, NY, [3]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [4]Institut de Rhumatologie de Montréal, Montreal, QC, [5]University of Manitoba, Winnipeg, MB, [6]Southlake Regional Health Centre, Newmarket, ON, [7]Mount Sinai Hospital, University of Toronto, Toronto, ON, [8]Schulich School of Medicine and Dentistry, Western University, London, ON.

Background/Purpose: To determine predictors of 1-year remission in early rheumatoid arthritis (ERA) using baseline and 3 months data.

Methods: The Canadian Early Arthritis Cohort (CATCH) patients were included if baseline, 3 and 12 months data were available. Regression analyses for four different definitions of remission at 12 months were done to determine baseline and 3 months predictors of remission. Four remission definitions were evaluated: (1) Simplified Disease Activity Index (SDAI) score ≤ 3.3; (2) Clinical Disease Activity Index (CDAI) score ≤ 2.8; (3) 28 Joint Disease Activity Score (DAS28) score < 2.6; (4) Boolean based ACR/EULAR clinical trial definition requiring a tender joint count (TJC) ≤ 1, swollen joint count (SJC) ≤ 1, patient global assessment of disease (PTGA) ≤ 1 on a 0–10 cm scale, and C-reactive protein (CRP) ≤ 1 mg/dl using 28/28 TJC/SJC.

Results: 562 had complete data at 12 months; mean age 53.4 years, disease duration 6.2, 73% were female. The factors at baseline associated with all four remission outcomes at 12 months were age, gender, income, education, TJC, patient global assessment (PTGA), HAQ and pain. Baseline ESR was associated with DAS28 remission only. At 3 months, all four remission definitions were associated with: TJC, SJC, physician global assessment (MDGA), PTGA, HAQ, pain, ESR and CRP in univariate analyses. In the regression model, variables associated with SDAI remission were MDGA (OR 0.77, $p<0.001$), pain (OR 0.85, $p=0.004$), age (OR 0.98, $p=0.006$) and HAQ (OR 0.49, $p=0.011$); CDAI remission was associated with MDGA (OR 0.77, $p<0.001$), pain (OR 0.85, $p=0.003$), Age (OR 0.98, $p=0.015$) and CRP (OR 0.80, $p=0.031$). DAS28 remission was predicted by ESR (OR 0.95, $p<0.001$), MDGA (OR 0.76, $p<0.001$), age (OR 0.98, $p=0.001$), HAQ (OR 0.57, $p=0.006$) and male (OR 2.01, $p=0.005$), whereas Boolean remission was associated with pain (OR 0.79, $p=0.009$), age (OR 0.98, $p=0.016$), PTGA (OR 0.83, $p=0.025$), and MDGA (OR 0.86, $p=0.038$).

Conclusion: Younger age was associated with more remission. A low MDGA at 3 months was consistently associated with 1-year remission in ERA.

Prednisone Use Associated With Worse Outcomes In Rheumatoid Arthritis Pregnancies. Prateek Chaudhary and M. E. B. Clowse. Duke University Medical Center, Durham, NC.

Background/Purpose: Prior reports suggest that disease activity in rheumatoid arthritis (RA) improves in the setting of pregnancy. However, prior studies report half of patients having moderate-severe disease activity throughout pregnancy; these are levels of activity unacceptable in our current RA treatment paradigm. The use of TNF-inhibitors remains controversial in pregnancy with many clinicians more comfortable with prednisone. The purpose of this study was to prospectively evaluate RA disease activity and medication use as predictors of pregnancy outcomes.

Methods: RA pregnancies were followed prospectively in a single clinic. An assessment of each patient was performed at all pregnancy and postpartum visits, and included demographic data and measures of disease activity, such as the physician global assessment (PGA) and 28 joint DAS-CRP. A DAS-CRP <2.6 was considered remission. Medication use was determined in collaboration between the physician and patient. Outcome measures included the presence of a miscarriage, preterm birth or preeclampsia. Non-parametric testing was used for the analysis.

Results: The 31 pregnancies in this cohort had a mean age of delivery of 32.5 years; 23 (74.2%) of mothers were Caucasian. Nine (29%) were exposed to TNF-inhibitors, while 15 (48.4%) were exposed to prednisone. 2 pregnancies (6.5%) ended in early miscarriages, neither with prednisone or TNF-inhibitor exposure and both with low RA activity. Of the 29 live births, preterm delivery occurred in 5 (17.2%) and preeclampsia in 3 (10.9%). Remission was achieved in 54% of women in the 1st trimester, 77% in the 2nd trimester, 67% in the 3rd trimester, and 61% postpartum. There was a strong correlation between DAS-CRP and PGA ($R=0.86$). Higher disease activity in the 1st trimester was associated with an increased risk of preterm birth (DAS-CRP = 5.58 preterm vs. 2.20 term, $p=0.028$; PGA= 30.0 preterm vs. 75.2 term, $p=0.019$). All pregnancies fell into one of three 1st trimester medication groups (table). Hydroxycholoroquine and sulfasalazine were evenly distributed in each group and did not appear to impact pregnancy outcomes. The patients with neither TNF-inhibitor nor prednisone exposure had a mean 1st trimester DAS-CRP of 1.63, while patients exposed to prednisone or TNF-inhibitor had a mean DAS-CRP of 3.92 or 3.19, respectively. Over half of patients (54.2%) exposed to prednisone had preterm birth and/or preeclampsia compared to 14.3% of those with TNF-inhibitor exposure.

Table. Medication group and pregnancy outcome

Medication	Mean 1st Trimester DAS-CRP	Preterm Birth	Preeclampsia	Either preterm birth or preeclampsia
No Prednisone or TNF-Inhibitor	1.63	0%	0%	0%
Prednisone	3.92	36.4%	27.3%	54.5%
TNF-Inhibitor	3.19	14.3%	0%	14.3%
p-value	0.150	0.086	0.099	0.0078

Conclusion: In the 1st trimester, high RA activity and prednisone use are both associated with an increased risk of preterm birth and/or preeclampsia. While both the prednisone and TNF-inhibitor groups had similar disease activity in the 1st trimester, prednisone use was significantly associated with a higher risk of adverse outcome. This study suggests that TNF-inhibitors may be preferable to prednisone in RA pregnancies.

Mathematical Model To Predict The Early Responders In a Monocentric Cohort Of Patients With Rheumatoid Arthritis Treated By Anti TNF-Alpha. Camillo Giacomelli, Claudia Ferrari, Chiara Stagnaro, Rosaria Talarico, Arianna Consensi, Francesca Sernissi, Laura Bazzichi and Stefano Bombardieri. Rheumatology Unit, Pisa, Italy.

Background/Purpose: In the last few year the introduction of biological agents has radically changed the clinical outcome of patients with Rheumatoid Arthritis (RA). However, no single drug is able to control all patients with RA and it is known that each drug may be poorly effective in a sizable proportion of the treated patients. For these reasons the early identification of clinical responder patients would be a crucial advantage for both a clinical and

socioeconomic point of view. Recently, mathematic algorithms, based on classical clinical parameters, have been proposed to predict the clinical response to Anti TNF and DMARDs. In the present study we have applied the mathematic algorithm proposed to predict early response to anti TNF on our cohort of patients treated with antiTNF agents.

Methods: We collected the data of 96 patients followed in our unit and treated with antiTNF (Adalimumab, Etanercept, Infliximab, Golimumab and Certolizumab Pegol) from Jan 2010 to Jan 2013, with a follow up of at least 12 months. The mathematic algorithm, utilizing the following parameters: Tender Joint, Swollen Joint, Illness activity VAS by Physician and patient, Pain VAS, ESR and CRP; was applied to calculate the putative responders after one month of treatment and this value was compared with the DAS 28 at one month and after one year (yr). The patients were classified as good responders if they had a delta DAS28>1.2. In table 1 we summarized the main epidemiological and clinical data of patients under investigation.

Results: The clinical response at 1 yr was very significant for all kind of treatment. After 1 month of therapy a delta DAS 28>2.6 was recorded in 50% of all treated patients, while at one yr a delta DAS28>1.2 was found in percentage variable between 86% and 91.6% (table 1). In contrast, the mathematical model allows to predict 100% of the final responders for patients treated by Infliximab, Golimumab and Certolizumab Pegol, 93% for patients treated with Adalimumab and 90% with Etanercept, 5 false negative were registered for Etanercept and 3 false negative for Adalimumab.

Table 1.

	Certolizumab Pegol	Adalimumab	Infliximab	Etanercept	Golimumab
Number of patients	12	25	13	42	4
Age	52.63 ± 15.58	54.76 ± 15.57	58.00 ± 10.30	59.73 ± 15.32	51.21 ± 13.60
Sex	10 ♀ 2 ♂	21 ♀ 4 ♂	10 ♀ 3 ♂	35 ♀ 7 ♂	2 ♀ 2 ♂
$DAS28_{\text{at baseline}}$	5.77 ± 0.90	5.60 ± 0.89	6.46 ± 1.13	6.24 ± 0.78	5.27 ± 0.61
DAS28 at final visit	1.99 ± 0.43	2.80 ± 1.23	2.75 ± 0.74	3.14 ± 0.96	3.93 ± 0.84
% of Response Delta DAS28>1.2	91.6	86.0	91.9	88.1	89.4

Conclusion: These data indicate that in a routine clinical practice the application of a simple mathematical model is capable, at one month, to predict a good response in the majority of patients. Prospective studies are underway.

Metaflammation, PEDF and Chemerin: Potential Systemic Factors Which Link Obesity To Response To Therapy In Early Rheumatoid Arthritis. Elisa Gremese, Barbara Tolusso, Anna Laura Fedele, Maria Rita Gigante, Angela Carbonella, Silvia Canestri, Clara Di Mario and Gianfranco Ferraccioli. Division of Rheumatology, Institute of Rheumatology and Affine Sciences, Catholic University of the Sacred Heart, Rome, Italy.

Background/Purpose: Obesity *per se* is a systemic, low-grade inflammatory state and the adipose tissue is an endocrine organ that releases bioactive substances, including pro-inflammatory cytokines, like TNFα and IL6, and specific adipokines. There are only few data about early RA (ERA), suggesting that obesity associates with disease outcomes. In this work we aimed to evaluate whether the body weight, and its metabolic (PEDF) and meta-inflammatory parameters (Chemerin), could be associated with the outcomes in terms of disease remission and treatment in ERA patients (symptoms duration <12 months).

Methods: 346 ERA patients, treated according to a treat-to-target strategy, were enrolled. At each visit the ACR/EULAR core data set was registered. Baseline BMI was collected and baseline PEDF and Chemerin plasma levels were evaluated by ELISA's methods. Adipose tissue PEDF gene expression was evaluated in overweight and obese subjects (24 ERA and 6 healthy controls). Logistic regression models were applied to determine the influence of independent variables reaching a *p*value<0.25 at the univariate analysis, on the dependent variables "DAS remission at 12th month and anti-TNF therapy at 12th month".

Results: Of the 346 ERA patients (76.3% female, age 54.6±14.0 years, 32.9% very ERA, 70.2% seropositive, baseline DAS 3.6±1.1), 168 (48.6%) were normal weight, 135 (39%) overweight and 43 (12.4%) obese. BMI values correlated with baseline PEDF (r=0.33, p<0.001) and chemerin (r=0.31, p<0.001) plasma levels. Moreover, BMI values correlated with age (r=0.23, p<0.001), baseline inflammatory markers (ESR: r=0.14, p=0.009, CRP: r=0.19, p<0.001), DAS (r=0.18, p=0.001) and HAQ (r=0.17, p=0.001). PEDF relative gene expression was 1.55 times higher in ERA patients compared to healthy subjects. Overweight and obese patients reached a lower remission rate at 6 and 12 month follow-up visits (DAS remission at 6th month: 52.1% in normal, 41.2% in overweight, 28.1% in obese, p=0.03; sustained DAS remission at 12th month: 51.0% in normal, 28.8% in overweight, 34.4% in obese, p=0.004). Moreover, an higher percentage of obese and overweight ERA patients were under anti-TNF treatment after 12 months of follow-up (27.3% of obese, 30.2% of overweight, 11.4% of normal weight, p=0.003). At the multivariate analysis, the independent baseline variables associated with the risk of "not obtaining DAS remission at 12th month follow-up" were duration of symptoms >3 months (OR: 2.3 (1.0–5.3)), baseline CRP≥5.0 mg/l (OR: 2.4 (1.1–5.6)) and baseline chemerin plasma levels>99.5ng/ml (OR: 2.4 (1.1–5.6)). The independent variables associated with the probability of being in anti-TNF therapy at 12th month follow-up were age <55 years (OR: 2.70 (1.41–5.34)), baseline DAS≥3.7 (OR: 2.27 (1.19–4.34) and BMI≥25 (OR: 2.36 (1.21–4.59)).

Conclusion: In ERA patients, not only obesity, but also overweightness, are associated with worst outcomes, like higher disease activity, lower remission rates, and greater use of anti-TNF therapy. PEDF and chemerin seem to be biomarkers of metaflammation.

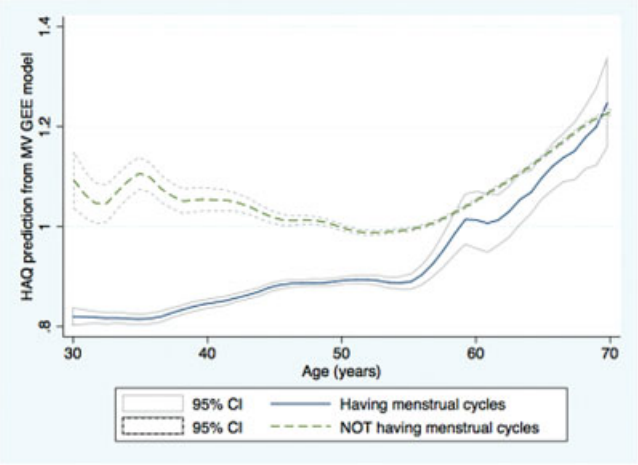
1333

The Impact Of Menopause In Rheumatoid Arthritis Activity. Sofia Pedro[1], Eliza Chakravarty[2], Megan E. B. Clowse[3], Rebecca Schumacher[1] and Kaleb Michaud[1]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Duke University Medical Center, Durham, NC.

Background/Purpose: Factors such as menopause, hormonal replacement therapy (HRT), oral contraceptives (OC), pregnancy, and breast-feeding have been associated with the risk of developing Rheumatoid Arthritis (RA) in women. However, the effect of these factors on RA disease progression has had little investigation.

Methods: Using a large US observational cohort, the National Data Bank for Rheumatic Diseases, we investigated the impact of menopause on RA functional outcomes as measured by the Heath Assessment Questionnaire (HAQ) and HAQ annual progression rates. We excluded all women who went through menopause before RA onset. Menopausal status (1=menstruating, 0=reached menopause) was further analyzed by comparing 3 groups of women based on their menopausal status while under observation in the study: premenopausal, post-menopausal, & transitioned through menopause. Possible confounders controlled for included age, educational level, household income, use of anti-TNF agents, HRT, and OC. We used univariate and multivariate (MV) generalized estimating equations (GEE) methods with the sandwich estimator. To account for a possible non-linear relationship between age and HAQ, we used a cubic spline with 3 knots at age 40, 56, 72, and an interaction term. Best models were selected using the QIC_u criterion

Results: A total of 7,632 women were eligible between 1998 and 2012 with an average of 2.9 years in the study. Of these, 2,102 were premenopausal (28%), 618 underwent menopause (8%), and 4,912 were entirely postmenopausal (64%). Within each respective group, the mean (SD) ages were 40 (8.2), 51 (SD 6.1), and 61 (9.9) years. Our results showed that women who were still having menstrual cycles tended to have a better HAQ score by −0.33 (−0.52, −0.14) than women who stopped having menstrual cycles; these results were robust even after full adjustment for other significant factors, −0.32 (−0.51, −0.14) (see Figure). The use of OC ever in reproductive life seemed also protective for disability as well as having had a pregnancy. On the other hand, HRT did not seem to be associated with disability. HRT and pregnancy did not qualify by our criterion for the final multivariate model. Using the menopause status with the 3 groups in the full model, in comparison with pre-menopausal women, HAQ of post-menopausal women were increased by 0.51 (0.16, 0.85), and not differ for who underwent menopause, 0.038 (−0.26, 0.33). The HAQ rate of progression was −0.001 per year (−0.248, 0.117) when comparing women who reached menopause with those who didn't.



Conclusion: In this large observation study, our results suggest that higher levels of estrogen may be associated with reduced functional limitations. However, HAQ progression continued similarly post-menopause as it did pre-menopause.

1334

Predicted Versus Observed Radiographic Progression In a Rheumatoid Arthritis Randomized Trial. Adrian Levitsky[1], Kristina Forslind[2] and Ronald F. van Vollenhoven[1]. [1]Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), the Karolinska Institute, Stockholm, Sweden, [2]Department of Clinical Sciences, Section of Rheumatology, Skåne University Hospital, Lund, Sweden.

Background/Purpose: Radiographic progression is a key outcome in early RA. We previously developed a radiographic progression prediction method based on the patient's report of symptom duration and the radiological damage at first examination[1]. We previously included data on predicted radiological progression for a subset of patients in the SWEFOT trial. Here, we applied the analysis of predicting radiological progression (prediction of progression in early RA, or POPERA) to the full data set from this randomized trial with the aim to compare predicted versus observed radiological progression in early RA patients treated with MTX or combination therapies.

Methods: In the SWEFOT trial[2, 3], 487 patients with early RA were given MTX, and non-responders after 3–4 months (DAS28>3.2) were randomized to MTX+SSZ+HCQ ("Triple therapy") vs. MTX+infliximab ("anti-TNF"). The others continued on MTX ("MTX-responders"). Hand and foot X-rays (baseline, 1, and 2 years) were analyzed with the Sharp-van der Heijde Score (SHS). Predicted progression at 1 and 2 years was calculated as the baseline SHS divided by symptom duration in months multiplied by 12 or 24, respectively. The analysis involved intention-to-treat (ITT) patients, and, in order to allow inclusion of patients with SHS 0 at baseline in the mathematical model, all SHS values in the entire data set were increased by 1. Comparisons between observed progressions were done by non-parametric, Mann-Whitney U testing.

Results: In all three groups of patients, observed radiographic progression was reduced from predicted by 50–96%. In patients who had failed both MTX monotherapy and subsequent triple therapy, the reduction of radiographic progression was numerically the least at 12 months (40.7%). After 12 months, there were no significant between-group differences. After 24 months, progression was reduced more in the anti-TNF arm than in both the MTX and triple therapy arms.

Table I. Mean Observed Radiographic Reduction from Predicted

	MTX responders	Triple therapy ITT	Anti-TNF ITT	Triple therapy completers	Anti-TNF completers
Percent reduction at 12 months	73.9 (±5.5)	50.1 (±10.1)	72.3 (±5.6)	56.7 (±14.2)	76.5 (±4.8)
Percent reduction at 24 months	87.8* (±2.8)	87.2† (±3.1)	89.8†* (±3.1)	91.0 (±3.4)	96.0 (±1.8)

* Anti-TNF (ITT) vs. MTX: p=0.013.
† Anti-TNF (ITT) vs. Triple therapy: p=0.021.

[1]Wick et al. Ann Rheum Dis 64:134–137, 2005.
[2]Van Vollenhoven et al. Lancet 374:459–466, 009.
[3]Van Vollenhoven et al. Lancet 379:1712–1720, 2012.

Conclusion: The progression observed in patients who failed their first 2 antirheumatic therapies was 59.3% of predicted at 12 months. The overall results demonstrated significant reductions from predicted radiological progression in patient groups who were successfully treated with MTX and in those who were included in either group of the randomization. Over 24 months, anti-TNF therapy was superior to triple therapy. The POPERA method may provide valuable information on the relative radiographic efficacy of treatments for early RA.

Sarcopenia Is Associated With Joint Damage In Rheumatoid Arthritis patients a Cross Sectional Study In a Peruvian Population. Erika Noriega[1], Rocio V. Gamboa-Cardenas[1], Manuel F. Ugarte-Gil[1], Mariela Medina-Chinchon[1], Francisco Zevallos-Miranda[1], J. Mariano Cucho-Venegas[1], Risto A. Perich-Campos[2], Jose L. Alfaro-Lozano[1], Zoila Rodriguez-Bellido[2] and Cesar A. Pastor-Asurza[2]. [1]Hospital Almenara, Lima, Peru, [2]Universidad Nacional Mayor de San Marcos, Lima, Peru.

Background/Purpose: Sarcopenia is a low-level, smoldering inflammatory state driven by cytokines and oxidative stress. In rheumatoid arthritis (RA) the relationship between sarcopenia and severity of disease as reflected by joint damage (JD) has not been established. The aim of this study was to determine the association between sarcopenia and joint damage in patients with RA.

Methods: We conducted a single center cross-sectional study. All subjects were older than 18 years at diagnosis and met the ACR criteria. We excluded patients with prosthetic or metallic elements, infections, trauma/recent surgery, cancer, hospitalized, neurological sequelae from stroke, pregnant or weight> 140 kg. Appendicular skeletal muscle mass (ASM) was measured using dual X-ray absorptiometry (DXA), sarcopenia was define as ASM/m^2 less than 5.45 kg/m^2, we assessed physical performance using the Short Physical Performance Battery (SPPB) and muscle strength of the knee and elbow flexion/extension using a digital dynamometer. A blinded investigator to sarcopenia status determined JD score according to Sharp van der Heidje method. An univariated linear regression model to determine association between sarcopenia and joint damage was applied after that, a multiple regression model, ajusted to age, disease duration, diagnosis delay, DAS28CRP, Fn-HAQ and current doses of prednisone, was performed to determine persistence of the association. Data was analyzed using SPSS v20.0.

Results: Ninety three women were evaluated, mean (SD) age was 51.56 (10.21) years, disease duration was 14.12 (8.86), and diagnostic delay was 1.73 (2.28) years, 83% were rheumatoid factor positive. Fn-HAQ score was 3.15 (1.50) and DAS28-CRP: 3.52 (1.06). The average value of ASM was 13.48 (2.63) kg/m^2. Twenty seven (29%) patients were found to be sarcopenic. Patients with sarcopenia had lower muscle strength and performance. In the multivariate linear regression model sarcopenia was independently associated with JD (β: 0.261, p: 0.031).

Conclusion: Sarcopenia was associated with JD in our female patients with RA independently of other well known risk factors for damage. Sarcopenia contributes to physical frailty, an state that distinct from functional disability, contributes indeed to adverse patient outcomes.

The Safety and Feasibility Of a Treat-To-Target Strategy Aimed At Achieving a Simplified Disease Activity Index Of ¡Ü3.3 While Administering Entecavir In Rheumatoid Arthritis Complicated By Hepatitis B Virus. Yukitomo Urata[1], Yoshihide Nakamura[2] and Ken-ichi Furukawa[2]. [1]Seihoku Central Hospital, United Municipalities of Tsugaru, Gosyogawara, Japan, [2]Hirosaki University Graduate School of Medicine, Hirosaki, Japan.

Background/Purpose: To elucidate the safety and feasibility of a treat-to-target (T2T) strategy aimed at achieving a simplified disease activity index (SDAI) of ≤3.3 while administering entecavir (ETV) in patients with rheumatoid arthritis (RA) complicated by hepatitis B virus (HBV).

Methods: Written informed consent was obtained from patients with rheumatoid arthritis who satisfied with SDAI>3.3, alanine aminotransferase (ALT) ≤30 and unidentified HBV –DNA under medicating with ETV for HBV. The time of enrolment was set as the baseline (BL) and the time of observation two years later was set as the endpoint (EP). SDAI was measured at once every three months, and in accordance with the modified strategy of T-4 study (1), treatment was intensified with a target SDAI of ≤3.3. HBV-DNA was measured on a monthly basis from BL. SDAI, health assessment questionnaire disability index (HAQDI), and modified total Sharp score (mTSS) were measured one and two year after the enrolment. Primary, secondary and outcome measures consisted of the proportions of patients showing rate of absence of HBV-DNA reactivation (HBV-DNA>2.1 log copies/mL), clinical remission (SDAI≤3.3), normal liver function (ALT≤30), lack of radiological progression (DmTSS≤0.5), normal physical function (HAQDI=0), or comprehensive disease remission defined as the combination of clinical remission, lack of radiological progression, and normal physical function.

Results: Subjects comprised 14 patients (mean age, 61.0 ± 8.9 years; mean disease duration, 7.8 ± 7.8 years; mean SDAI, 8.7 ± 5.4; mean HAQDI, 0.2 ± 0.3; mean ALT, 21 ± 6), 8 of whom were women (57%). Among these subjects, five were carriers and 9 experienced reactivation of a resolved HBV. Treatment after the enrolment consisted of 31% of patients taking an antirheumatic drug (bucillamine, n=4;; leflunomide, n=1), 43% taking glucocorticoids (GCs) with a mean GCs dose (prednisolone equivalent of 3.4mg/day (maximum dose; 9mg/day), 57% taking methotrexate (MTX) with a mean MTX dose of 7.1 mg/week, 50% taking folic acid, and 50% taking biological drugs (etanercept, n=4; abatacept, n=2; tocilizumab, n=1). At 2 years, the rate of absence of HBV-DNA reactivation, SDAI≤3.3, ALT≤30, DmTSS≤0.5, HAQDI=0, and comprehensive disease remission were follows, 100%, 50%, 93%, 43%, 64% and 21%. ALT, SDAI, ΔmTSS and HAQDI at EP was 19 ± 7, 4.3±4.5, 0.8±2.2 and 0.2±0.3, respectively. No significant differences were observed between BL and EP for value of ALT, SDAI or HAQDI. No patient had ALT value in excess of 100 IU/L during the observation period. All of the 7patients who had HAQDI=0 at BL also had HAQDI=0 at EP.

Conclusion: T2T aimed at achieving SDAI≤3.3 is also possible safety in patients with RA complicated by HBV by performing ETV administration and appropriate HBV-DNA monitoring.

Nearly Pain Free Self-Administration Of Methotrexate Using An Investigational Auto-Injector: Results Of a Phase-2 Clinical Trial In Rheumatoid Arthritis Patients With Mild-To-Severe Functional Limitations. Alan J. Kivitz[1], David McLain[2], John Hill[3], Bruce Freundlich[4], Jonathan Jaffe[5] and Kaushik J. Dave[5]. [1]Altoona Center for Clinical Research, Duncansville, PA, [2]Rheumatology, McLain Medical Associates, PC, Birmingham, AL, [3]Avail Clinical Research, DeLand, FL, [4]University of Pennsylvania, Philadelphia, PA, [5]Antares Pharma Inc, Ewing, NJ.

Background/Purpose: Methotrexate (MTX) is the cornerstone of rheumatoid arthritis (RA) treatment. Limitations of systemic exposure of oral MTX can affect its efficacy. Subcutaneous (SC) MTX improves bioavailability, which may result in better efficacy, and tolerability. Self-administration of SC MTX via conventional vial and syringe is challenging for some patients due to injection-associated anxiety, functional limitations, injection-site adverse events (AEs), and especially pain. An investigational auto-injector that delivers SC MTX was tested with the intention of addressing these patient concerns.

Methods: 101 RA patients were enrolled in this phase 2, multi-center, open-label, single-dose, single-arm, in-clinic study to evaluate the actual human use of SC MTX administered via a developmental MTX auto-injector (MTXAI). MTX dose (10, 15, 20, 25 mg) was determined by investigators based on patient MTX regimen and disease status (controlled or uncontrolled) at time of enrollment.

Results: 99 patients were evaluable. (79.2% female, mean age 60.9 yrs. [SD± 10.1], mean disease duration 13.3 yrs. [SD± 11.0], 84.2% ACR Class II or III, 89.1% Functional Class II or III). All patients had been taking MTX for ≥3 months prior to study enrollment; 20% had used SC MTX. Safety was assessed by recording AEs and evaluating administration sites before and at 0.25, 1, 6, and 24 hours after self-administration. Administration site pain (measured on a 100-mm VAS) is summarized in the table. Mean administration site pain was 3.6 mm/100 mm [SD± 9.1] on Day 1 with a median 1.0 mm/100 mm (0–72) and a mean of 1.4 mm [SD± 3.2] with a median of 0.0 mm (0– 21) on Day 2. 93/99 pts. (94%) reported VAS scores of ≤10 on Day 1; 86/99 pts. (87%) reported scores of ≤5 on Day 1. Of 404 post-administration evaluations, 92.3% found no erythema. The remainder indicated "very slight, barely perceptible" erythema. Three patients had AEs (sick sinus syndrome, exostosis, and headache) not considered related to the study drug by the investigators. 100% of patients, including those with moderate-to-severe functional limitations in dexterity, successfully used the auto-injector.

Table. Administration site pain and erythema (Scale 0–100mm)

Administration site pain	MTX 10 mg (N=20)	MTX 15 mg (N=30)	MTX 20 mg (N=31)	MTX 25 mg (N=20)	Overall (N=101)
Day 1 (mean ± SD, median [range])	1.0 ± 1.0 1.0 (0–3)	7.6 ± 15.6 2.0 (0–72)	2.2 ± 2.9 1.0 (0–10)	2.4 ± 2.6 2.0 (0–9)	3.6 ± 9.1 1.0 (0–72)
Day 2 (mean ± SD, median [range])	1.7 ± 4.5 0.0 (0–20)	2.0 ± 4.1 0.0 (0–21)	1.0 ± 1.6 0.0 (0–7)	1.0 ± 1.2 0.5 (0–4)	1.4 ± 3.2 0.0 (0–21)

SD = standard deviation.

Conclusion: The MTXAI was well tolerated with almost no administration site pain and minimal erythema. Limitations in functional status did not affect ability to self-administer. Improving the delivery of SC MTX with this developmental, first-in-class auto-injector may increase patient tolerance of self-injection thereby improving adherence in patients with RA.

Time To Institution Of Disease Modifying Anti-Rheumatic Drugs In Australian Patients With Early Rheumatoid Arthritis. Sharon Van Doornum[1], Joanne Tropea[2], Mark Tacey[1] and Danny Liew[1]. [1]The University of Melbourne, Melbourne, Australia, [2]Royal Melbourne Hospital, Melbourne, Australia.

Background/Purpose: Early introduction of disease-modifying anti-rheumatic drugs (DMARDs) has been shown to reduce joint destruction and long-term disability in rheumatoid arthritis (RA). Substantial and irreversible harm can occur as little as 12 weeks after onset of symptoms. Recent international studies have examined time to institution of DMARD in early RA, with median delays of between 13 and 36 weeks. The aim of the present study was to examine the time to DMARD therapy in Australian patients with early RA.

Methods: The study included patients referred to a metropolitan tertiary hospital and to 14 community-based rheumatologists in Australia. The hospital-based patients were identified retrospectively via hospital records and included patients with early RA who were first seen between January 2008 and October 2012. Medical charts were reviewed and, if necessary, the local doctor contacted for additional information. The community-based patients were recruited via the treating rheumatologists and data were collected prospectively by the rheumatologists over the period February 2012 to April 2013. Data recorded included dates of symptom onset, initial local doctor consultation, referral to rheumatologist, rheumatologist review and commencement of DMARD. Serologic status and first DMARD commenced were also noted.

Results: One hundred and thirty five patients (66% female, mean±SD age 55±16 years) were identified and contributed data. RhF and/or ACPA was positive in 66% (n=89) of patients. The median time from symptom onset to initiation of DMARD therapy was 163 days (inter-quartile range (IQR) 88–323). The median time from referral to first rheumatology appointment was 33 days (IQR 9–55) and from first rheumatology appointment to DMARD commencement was 0 days (range 0–22). The major component of the delay comprised the time from symptom onset to referral to the rheumatologist, for which the median duration was 98 days (range 51–239). Stratified analysis did not reveal any substantial differences in delays between hospital-based and community-based patients. However, among hospital-based patients, ACPA positive status resulted in more rapid commencement of DMARD therapy (median 35 vs 93 days from time of referral, p=0.014). The first DMARD commenced was methotrexate monotherapy in 61% (n=82) of patients and methotrexate combination therapy in 5% (n=7) of patients.

Conclusion: As noted in other countries, there are considerable delays in the commencement of DMARD therapy for Australian patients with early RA. A substantial component of the delay is prior to the referral of the patient by the local doctor for rheumatologist review.

Efficacy and Safety Of Biologics Agents For Patients With Rheumatoid Arthritis and Hepatitis B Carrier. Masahiro Tada, Tatsuya Koike, Akihiro Tamori, Tadashi Okano, Yuko Sugioka, Kenji Mamoto, Kentaro Inui and Hiroaki Nakamura. Osaka City University Graduate School of Medicine, Osaka, Japan.

Background/Purpose: Biologics suppress hepatitis B virus (HBV) replication and play an important role in eradicating HBV by stimulating HBV-specific cytotoxic T-cell responses. We found that HBV reactivates or flares after biologics therapy in patients with chronic hepatitis B infection and in those with inactive hepatitis B surface antigen (HBs-Ag). The guideline, prevention of immunosuppressive-induced reactivation of HBV infection, recommend nucleoside analogs for treating patients with rheumatoid arthritis (RA) who are positive for HBs-Ag. We aimed to determine the efficacy and safety of biological therapy in patients with RA carrying hepatitis B by evaluating clinical characteristics and changes in serological and biological markers of HBV flare.

Methods: Six patients with RA who screened positive for HBs-Ag were prescribed with entecavir (ETV) under the direction of a hepatologist when HBV-DNA levels decreased to < 2.1 log copies/mL. The patients were also treated with infliximab (n = 1), etanercept (n = 2), adalimumab (n = 2) and tocilizumab (n = 1) (Table). We evaluated the disease activity score of RA (DAS28-ESR), HBV markers and genotype before starting treatment as well as changes in the amount of HBV-DNA, HBs-Ag and alanine aminotransferase (ALT).

Results: The average age, duration of RA and DAS28-ESR at baseline was 54.7 years, 10.9 years and 5.51, respectively. The minimum HBs-Ag value is 12.2 and three patients had values over >2000 before starting ETV therapy. The pre-treatment values of HBV-DNA and ALT were 4.28 log copies/mL and 20.2 U/L, respectively. Flare of HBV was not confirmed during 2.1 years the patients were treated with these agents. Hepatitis B viral DNA was undetectable in all cases at final follow-up (Table). The DAS28-ESR was 3.14 at final follow-up and disease RA activity remained low (Figure).

Table. Changes in the amount of HBs-Ag, HBV-DNA, and ALT

	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5	Patient 6
Age, years	56	33	58	63	64	54
HBs-Ag at baseline, mIU/mL	233.9	2000<	2000<	2000<	12.2	332
HBs-Ag at final F/U, mIU/mL	259.2	2000<	2000<	2000<	17.3	215.1
HBV DNA at baseline, log/mL	4.8	3.6	7.6	4.9	2.3	2.5
HBV DNA at final F/U, log/mL	undetectable	undetectable	undetectable	undetectable	undetectable	undetectable
ALT at baseline, U/L	13	12	58	13	8	17
ALT at final F/U, U/L	10	14	15	15	10	15
Biologics	ETN	IFX	ADA	TCZ	ETN	ADA

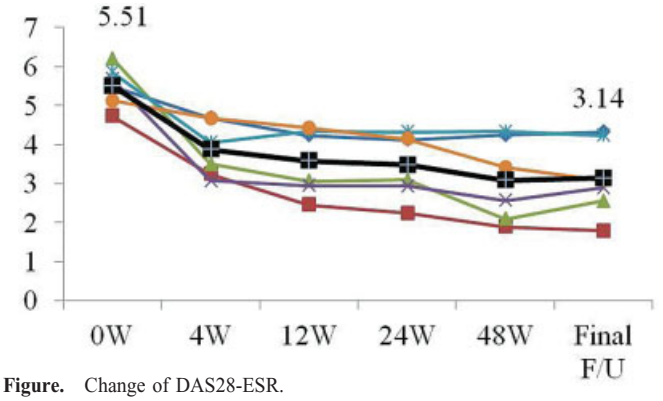

Figure. Change of DAS28-ESR.

Conclusion: Antiviral prophylaxis protected against HBV reactivation in patients with RA, indicating that biologics are relatively safe for treating such patients. Biologics could serve as a useful treatment for hepatitis B carriers who are simultaneously prescribed with nucleoside analogs under the control of a hepatologist.

Functional Disability and Quality Of Life Are More Likely Improved In Patients With Rheumatoid Arthritis Who Achieved The New ACR/EULAR Remission Criteria Compared To DAS28 Remission In Daily Practice. Yoko Shimizu[1], Ayako Nakajima[1], Eisuke Inoue[2], Eiichi Tanaka[2], Akiko Kobayashi[1], Yohei Seto[1], Shigeki Momohara[1], Atsuo Taniguchi[1] and Hisashi Yamanaka[2]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: The new ACR/EULAR remission criteria were proposed to predict favorable outcome in patients with rheumatoid arthritis (RA).

To evaluate the functional disability and quality of life (QOL) in patients with RA who achieved the ACR/EULAR remission criteria compared to that in patients who achieved 28-joints disease activity score (DAS28) remission in 1 year in a large daily practical observational cohort, IORRA.

Methods: Patients who had moderate or high disease activity according to simplified disease activity score (SDAI) in April 2010 survey were extracted. Functional disability and QOL was assessed by the validated Japanese version of Health Assessment Questionnaire (J-HAQ) score and the European QOL-5 dimension (EQ-5D) acore, respectively. The disease activity after 1 year in each patient was assessed by SDAI and DAS28. The mean changes of progression of J-HAQ and EQ-5D scores in 1 year in each patient were calculated for the patients achieving remission criteria defined by SDAI or DAS28, respectively. The factors associated with achieving SDAI remission were evaluated by multiple regression analysis.

Results: Among a total of 5,587 patients participated in the IORRA cohort in April 2010, 1,307 (23.4%) patients had high or moderate disease activity assessed by SDAI. In these patients, 85.7 % were female, and median age was 62.2 years and RA duration was 13 years. After 1 year, 11.7% and 16.9% patients achieved SDAI remission and DAS28 remission, respectively. The progression of J-HAQ score in 1 year was −0.30 + 0.49 in patients who achieved SDAI remission and −0.05 + 0.35 in patients who didn't ($p<0.001$), whereas −0.26 + 0.47 in patients who achieved DAS28 remission and −0.05 + 0.35 in patients who didn't ($p<0.001$). The odds ratio (OR) for non-progression of functional disability by achieving SDAI remission was 2.79 (95% confidence interval (CI), 1.70–4.59), whereas that by achieving DAS28 remission was 1.96 (95% CI, 1.34–2.86). The progression of QOL score in 1 year was 0.165 + 0.162 in patients who achieved SDAI remission and 0.028 + 0.123 in who didn't ($p<0.001$), whereas 0.129 + 0.169 in patients who achieved DAS28 remission and 0.028 + 0.121 in patients who didn't ($p<0.001$). The OR for non-deterioration of QOL by achieving SDAI remission was 2.90 (95% CI 1.62–5.23), whereas that by achieving DAS28 remission was 2.11 (95% CI 1.35–3.29). The factors associated with achieving SDAI remission in 1 year were disease duration (OR 0.96, 95%CI 0.93–0.98), baseline physical function (OR 0.52, 95%CI 0.39–0.70) and biologics initiation within 6 months (OR 3.70, 95%CI 2.05–6.54).

Conclusion: Achieving SDAI remission has more impact on both better physical function and improved QOL than achieving DAS28 remission.

Significantly Less Glucocorticoids and Better Patient-Reported Outcomes In Women With Early Inflammatory Arthritis Using Oral Contraceptives Compared To Never Users. Gisela Westhoff[1], Rainer H. Straub[2], Frank Buttgereit[3], Johanna Callhoff[4] and Angela Zink[5]. [1]German Rheumatism Research Center Berlin, Berlin, Germany, [2]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, University Hospital of Regensburg, Regensburg, Germany, [3]Charité - Universitätsmedizin Berlin, Berlin, Germany, [4]German Rheumatism Research Center, Berlin, Germany, [5]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany.

Background/Purpose: Data on the effects of oral contraceptives (OC) on the course of inflammatory arthritis (IA) are controversial. However, a recent analysis of data from the Norfolk Arthritis Register (NOAR) showed that the use of OC is associated with beneficial functional outcomes. We aimed at investigating the associations between OC use, need of therapies, and outcomes in women with early IA within the first year of care.

Methods: A total of 324 women with early IA (symptoms <6 months, 18 – 60 years, never having used hormone replacement therapy), were followed with respect to disease activity (CRP, ESR, S/TJC28, morning stiffness), use of DMARDs and glucocorticoids (GC) and patient-reported outcomes (PROs) according to the Rheumatoid Arthritis Impact of Disease Score (RAID 0–10), the PROFAD (0–10), the PHQ9 Depression Scale (0–27), and the Functional Scale FFbH (0–100). Use of OC was reported as never, past, or current. Outcomes by use of OC were adjusted for age, body mass index, number of natural children, and years of education using generalized linear models.

Results: At baseline, mean age was 46 ±10 years and symptoms lasted for 13 ±7 weeks. Of these women, 68% fulfilled the 2010 criteria for rheumatoid arthritis (RA), 82% were clinically diagnosed with RA at 12 months and 89% took DMARDs at that point in time. 24% had never used OC, 57% had used them in the past, and 19% used them currently. Current users were younger (36 vs. 50 yrs) and less frequently mothers than past and never users (58 vs. 80%). Independent of the time point (t0, 3, 6, 12 months), current use of OC, compared to past and never use, was not associated with biomedical measures, duration of morning stiffness or DMARD use (not shown). However, current and past OC use was associated with steadily decreasing GC use (54 and 57% at 12 months), while never users remained unaltered at 74% (P 0.016). Finally, current and past OC use was associated with significantly better outcomes in almost all considered patient-reported dimensions, such as pain, fatigue, well-being and function (Table). The effect of OC on PROs was, notably, almost the same in past and current users, although half of the past users were older than 50 years and might not have used OC for several years.

PROs at 12 months by use of oral contraceptives (means)

OC use	n	Pain*	Overall fatigue	Problems getting started	Problems to focus	Problems daily chores	Physical well being	Mental well being	Depression (PHQ90-27)	Physical function (0–100)
never	88	3.9	4.4	4.1	3.5	3.6	4.4	4.5	6.7	78.7

* Means adjusted for age, BMI, number of children and education; #P never vs. current use.

Conclusion: Our findings confirm that women with past or current OC use have better functional outcomes without having less signs of inflammation. The specific spectrum of obviously ameliorated conditions indicates that estrogens seem to have neuro- and psycho-protective effects on many symptoms that compromise well-being in IA. It may be suggested that OC act directly at CNS cytokines rather than influencing the course of peripheral inflammation. Long-lasting programming of CNS function may explain positive effects of OC. The use of hormones should be routinely reported in studies observing IA.

Prognosis In Espoir Rheumatoid Arthritis Cohort At 24 Months According To Remission Status At 12 Months: No Differences In Radiographic Scores According To Prior Remission Status, But Significant Differences In HAQ Scores, Highest For Boolean and RAPID3RJ1 Criteria. Isabel Castrejón[1], Maxime Dougados[2], Bernard Combe[3], Francis Guillemin[4], Bruno Fautrel[5] and Theodore Pincus[1]. [1]NYU Hospital for Joint Diseases and New York University School of Medicine, New York, NY, [2]Cochin Hospital, Paris, France, [3]CHU Lapeyronie, Montpellier, France, [4]Hopitaux de Brabois, Nancy, France, [5]APHP, Pitié-Salpêtrière University Hospital, Paris, France.

Background/Purpose: Different criteria for remission in rheumatoid arthritis (RA) have been developed from a Core Data Set of 7 measures for the DAS28, SDAI, CDAI and RAPID3 (with only patient self-report measures). An ACR/EULAR committee proposed two criteria: "Boolean," with TJC28, SJC28, CRP, PATGL all '1; and SDAI ≤3.3 *[Arthritis Rheum 2011;63:573]*. A recent report indicated that remission criteria based on RAPID3 ≤3 with ≤1 swollen joint (RAPID3RJ1) gave results similar to Boolean and SDAI criteria, but without a formal joint count to be more feasible for usual care *[J Rheumatol 2013;40:386]*. This new study analyzed 6 remission criteria to predict a good outcome for physical function and radiographic damage one year later in the ESPOIR cohort of French early arthritis patients.

Methods: ESPOIR includes patients with early arthritis who received routine care. Remission was assessed 12 months after baseline by 6 criteria: ACR/EULAR Boolean criteria; SDAI (≤3.3); CDAI (≤2.8); DAS28 (≤2.6); RAPID3 (≤3) and RAPID3RJ1 (RAPID3 ≤3 and ≤1 swollen joint). Analyses were conducted to determine status 12 months later (at 24 months) to recognize whether a patient who met each remission criteria 12 months earlier was likely or not to have a good functional outcome [stable or lower HAQ scores, and absolute score of ≤0.5 at both 12 and 24 months after baseline] or good radiographic outcome [no change in the modified Sharp/van der Heijde score from 12 to 24 months]. The proportions of good outcomes in patients who had been classified 12 months earlier as in or not in remission were compared by chi square tests and likelihood ratios.

Table. Prognosis for good HAQ physical function and radiographic outcomes at 24 months, based on 12-month remission evaluation in 656 RA patients

	Prevalence of good HAQ outcome at 24 mo			
Remission criteria	In remission at 12 mo	Not in remission at 12 mo	P (chi square)	Positive likelihood ratio
Boolean	83.1% (103/124)	50.2% (267/532)	<0.001	3.8
SDAI ≤3.3	78.6% (121/154)	49.6% (249/502)	<0.001	2.8
CDAI ≤2.8	79.1% (121/153)	49.5% (249/503)	<0.001	2.9
DAS28 ≤2.6	69.8% (190/272)	46.9% (180/384)	<0.001	1.8
RAPID3 ≤3	80.2% (170/212)	45.0% (200/444)	<0.001	3.1
RAPID3 ≤3 + SJC≤1	83.7% (134/160)	47.6% (236/496)	<0.001	4.0
	Prevalence of good radiographic outcome at 24 mo			
Remission criteria	In remission at 12 mo	Not in remission at 12 mo	P (chi square)	Positive likelihood ratio
Boolean	67.3% (74/110)	68.7% (338/492)	0.771	0.95
SDAI ≤3.3	70.4% (95/135)	67.9% (317/467)	0.583	1.09
CDAI ≤2.8	71.1% (96/135)	67.7% (316/467)	0.448	1.14
DAS28 ≤2.6	68.4% (169/247)	68.4% (243/355)	<0.994	1.00
RAPID3 ≤3	68.9% (129/187)	68.2% (283/415)	0.847	1.03
RAPID3 ≤3 + SJC≤1	69% (96/139)	68.2% (316/463)	0.856	1.03

Results: 656 patients had available data to evaluate remission; 76% were women; mean age 48 years; median baseline disease duration 5 months; 40% ACPA-positive and 44% rheumatoid factor-positive. Patients who were in remission at 12 months according to each of 6 criteria were significantly more likely to have a good functional status outcome 12 months later (24 months after baseline), ranging from 70–84%,versus 45–50% of patients not in remission. Positive likelihood ratios for having a good functional outcome were 3.8 and 4.0 for Boolean and RAPID3RJ1; 2.8–3.1 for RAPID3, CDAI and SDAI; and 1.8 for DAS28 criteria. Patients who were in remission at 12 months according to each of the 6 criteria had a similar 67–71% likelihood to have a good radiographic outcome 12 months later (24 months after baseline), similar to patients who were not in remission (Table). Similar analyses performed in subsets of patients who were RF+ and/or had baseline damage, yielded similar results.

Conclusion: A good functional outcome at 24-month follow-up was 1.8–4.0 times more likely in patients who were in remission versus not in remission 12 months after baseline; the highest likelihood ratios were seen for the Boolean and RAPID3RJ1 criteria. Radiographic outcomes at 24 months were similar, regardless of remission status 12 months earlier.

Are There Differences Between Young and Older Onset Early Rheumatoid Arthritis and Does This Impact Outcomes? An Analysis From The Canadian Early Arthritis Cohort. Michael Arnold[1], Vivian P. Bykerk[2], Gilles Boire[3], Boulos Haraoui[4], Carol A. Hitchon[5], J. Carter Thorne[6], Edward Keystone[7] and Janet E. Pope[8]. [1]University College Dublin, Ireland, Dublin, Ireland, [2]Hospital for Special Surgery, New York, NY, [3]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [4]Institut de Rhumatologie de Montréal, Montreal, QC, [5]University of Manitoba, Winnipeg, MB, [6]Southlake Regional Health Centre, Newmarket, ON, [7]University of Toronto, Toronto, ON, [8]Schulich School of Medicine and Dentistry, Western University, London, ON.

Background/Purpose: To determine the impact of age on disease and remission in early rheumatoid arthritis (ERA).

Methods: Data from the Canadian Early Arthritis Cohort (CATCH) were examined at baseline, 6 and 12 months. Patients were divided into three

groups based on age. ANOVA and regression models were performed to determine the impact of age on DAS28 and remission at 12 months.

Results: 1809 patients were assessed at baseline, 442 (24.4%) 'young' (<42 years), 899 (49.7%) 'middle-aged' (^{3} 42, <64 years) and 468 (25.9%) 'old' (^{3}64 years); 72.9% were female, 63.8% met 2010 ACR/EULAR Classification Criteria for RA, symptom duration at first visit was 186.0 days, DAS28 4.9, HAQ 1.0; 25.3% had baseline erosions. A significant correlation existed between older age and less percent females, less positive RF and CCP, less meeting RA criteria, shorter symptom duration, more erosions at first visit, higher DAS28 and HAQ at baseline and 12 months, and less DAS28 remission at 12 months (all $P<0.003$). Age group did not affect the change in DAS28 and HAQ from 0–12 months. Comorbidities increased with age; more DMARDs including methotrexate and steroids and less biologics were used in older age. Age and female had a lesser chance of remission in regression model.

Conclusion: In ERA, older onset RA patients start and end their first year worse in terms of DAS28 and HAQ, with less meeting RA criteria, less remission, more DMARDs and steroids but less biologic use; however there were no differences between age groups in change in DAS28.

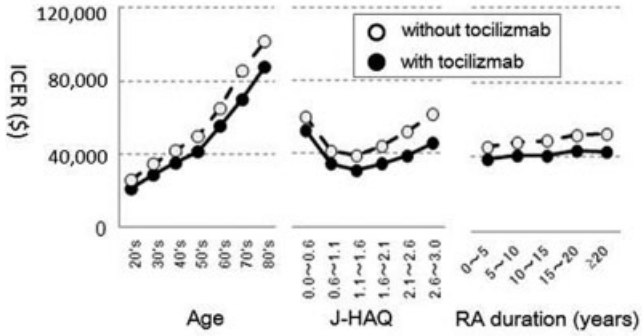
Optimal Rheumatoid Arthritis Patient Selection For Biological Treatment From Pharmacoeconomic Perspectives Based On The Institute Of Rheumatology, Rheumatoid Arthritis (IORRA) Cohort. Eiichi Tanaka[1], Eisuke Inoue[1], Yoko Shimizu[2], Akiko Kobayashi[2], Naoki Sugimoto[2], Daisuke Hoshi[2], Kumi Shidara[2], Eri Sato[2], Yohei Seto[2], Ayako Nakajima[2], Shigeki Momohara[2], Atsuo Taniguchi[2] and Hisashi Yamanaka[1]. [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: With the recent introduction of biological DMARDs, the economic burden of rheumatoid arthritis (RA) treatment has increased. Previous studies evaluated the cost-effectiveness of biologics, although those studies were usually conducted based on controlled clinical trials, which do not precisely reflect daily practice. From an economic point of view, it is desirable to treat patients with biologics when the cost-effectiveness is maximized, especially in daily practice. We conducted a pharmacoeconomic study to investigate the optimal timing of biologics administration to RA patients using the RA cohort database of the Institute of Rheumatology, Rheumatoid Arthritis (IORRA).

Methods: We conducted a state-transition model-based probabilistic simulation from the societal perspective. Model parameters were determined using clinical data for 421 patients from the IORRA who had failed at least one DMARD and had started either one of four biologics (adalimumab, etanercept, infliximab, and tocilizumab) or methotrexate (MTX) between April 2008 and April 2011. Patients who had not used biologics were matched using propensity scores. A hypothetical population of 10,000 patients treated with sequences of three biologics after MTX and then best supportive care (BSC) were compared to those starting MTX after BSC. The incremental cost-effective ratios (ICERs) of the biologics groups against the MTX group were estimated using base-case analysis and probabilistic sensitivity analysis. Scenario sensitivity analyses were also done for different backgrounds of the initial population classified by age, disease duration, and disability based on scores of the Japanese version of HAQ (J-HAQ). Because tocilizumab differed from TNF-blockers in mechanism and had a large decrease in price in Japan in 2012, sequences of three of four biologics and three except for tocilizumab were also considered for biologics groups.

Results: The ICERs of treatment sequences with biologics and with or without tocilizumab were $38,180 and $48,855, respectively. By probabilistic sensitivity analysis, these sequences had respective probabilities of 89.5% and 80.9% of falling below an assumed threshold of $54,000 as the societal willingness-to-pay in Japan. Scenario sensitivity analyses showed that the most influential factors on the ICER were age and J-HAQ scores. Starting biologics at a younger age had better cost-effectiveness, whereas disease duration had no effect. J-HAQ scores followed "J-curves" and the ICER was best for patients with J-HAQ scores of 1.1 to 1.6 (Figure).



Conclusion: Our results demonstrate that biological DMARDs are cost-effective for RA patients based on data from an observational cohort representing daily practice in Japan. From pharmacoeconomic perspectives, the best population for biologics use is younger RA patients with J-HAQ baseline scores between 1.1 and 1.6 and using tocilizumab as the biological DMARD.

Retinal Vascular Calibre – a Novel Biomarker Of Inflammation and Treatment Response In Rheumatoid Arthritis. John HY Moi[1], Lauren AB Hodgson[2], Ian P Wicks[3], Tien Yin Wong[1] and Sharon Van Doornum[1]. [1]The University of Melbourne, Melbourne, Australia, [2]Centre for Eye Research Australia, Melbourne, Australia, [3]Walter & Eliza Hall Institute of Medical Research, Parkville, Australia.

Background/Purpose: Retinal vascular calibre measurement is a non-invasive tool for assessing systemic and vascular health. Widened retinal venular calibre (RVC) is associated with systemic inflammation, increased cardiovascular (CV) risk and has previously been associated with rheumatoid arthritis (RA), particularly high disease activity[1]. To date there have been no longitudinal studies assessing the effect of suppressing systemic inflammation on RVC in RA. The aims of this study were to investigate the stability of serial retinal vascular calibre measurements (RVC and retinal arteriolar calibre (RAC)) in well controlled RA and the effect of reducing systemic inflammation in RA patients requiring treatment escalation.

Methods: Two groups of patients with RA were recruited and studied concurrently. Group A included patients with moderate or high disease activity (DAS28-CRP>3.2) who required treatment escalation as standard of care. Group B had stable low disease activity (DAS28-CRP≤3.2) not requiring any alteration of medical therapy and were the control for Group A. Both groups underwent retinal photography at baseline and at weeks 6 and 24 (to assess the early and later response respectively) in Group A and at week 12 in Group B. Images were analysed by purpose designed software and a trained assessor blinded to subject identity and timing of retinal photography. Simple linear regression and paired t-tests were used to compare serial retinal vascular calibre measurements in Groups A and B respectively, with a p value <0.05 considered significant.

Results: Group A included 24 patients (71% female) with a mean (SD) age of 50.9 (18) years and a mean (SD) disease duration of 5.8 (6.4) years. Between baseline and week 6, disease activity improved signifi-

cantly (DAS28-CRP mean reduction of −2.0 (95% CI −2.5 to −1.5). This was accompanied by a significant reduction in RVC (mean difference (MD) −7.6μm; 95% CI −13.4 to −1.7μm, p=0.01), whereas RAC remained unaltered (MD −2.29μm; 95% CI −5.7 to 1.1μm, p=0.18). Week 24 data collection from Group A is ongoing. Group B included 26 patients (81% female) with a mean (SD) age of 54 (9) years and a mean (SD) disease duration of 14.5 (10.8) years. Disease activity and therapy remained unchanged between baseline and week 12 (DAS28-CRP MD −0.1, 95% CI −0.36 to 0.15, p=0.39). There was no significant change in RVC (MD 1.37μm; 95% CI −2.82 to 5.57μm, p=0.5) or RAC (MD 0.39μm; 95% CI −3.04 to 3.82μm, p=0.82) in Group B over this period.

Conclusion: This is the first study to demonstrate that suppressing inflammatory disease activity in RA reduces RVC widening as early as 6-weeks after treatment escalation. In contrast, RVC measurements were unchanged in RA with stable, low-level systemic inflammation during short-term follow-up. Taken together, these findings suggest that retinal vascular calibre measurement may be a biomarker of RA disease activity as well as CV risk and that immunosuppressive treatment may also have potential vascular benefits in RA.

Drug Free Holiday In Patients With Rheumatoid Arthritis (RA): patients' Opinion. I.M. Markusse, G. Akdemir, T.W.J. Huizinga and C.F. Allaart. Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: Clinical trials have shown that in many patients tapering and/or stopping antirheumatic medication is a realistic option. We interviewed patients to investigate their opinions, expectations and emotions with regard to tapering and discontinuing antirheumatic drugs.

Methods: 20 patients randomly identified at the rheumatology outpatient clinic were asked 12 questions through structured interviewing by two investigators (10 patients each). Interviews were sound recorded, typed out in full and screened by three assessors independently for content items. After 20 interviews, data saturation was reached.

Results: Mean (SD) age was 64.6 (15.2) years and median (minimum; maximum) disease duration was 15.0 (0.1; 40.0) years. 13 patients were female. Disease Activity Score (DAS) was ≤ 2.4 in 13 patients, even <1.6 in 8 patients, and >2.4 in 7 patients. 17 patients used antirheumatic medication at the moment of interviewing.

Six patients were of the opinion that discontinuing is a possibility for both other patients and themselves, one patient thought only tapering could be possible and five did not see this possibility. Two patients thought it could be possible for other patients, but not for themselves.

Patients' replies conveyed hope (being free from symptoms), happiness and relief (being free from drugs), fear (for a disease flare) and faith (in the decision of the rheumatologist) as feelings about tapering/discontinuing their medication. Conditions mentioned before a drug holiday might be tried were longstanding low disease activity, first tapering before stopping, intensive monitoring. Severe side effects were also a motive to stop medication.

Ten patients expected increased disease activity after stopping medication, four expected that low disease activity would be maintained, and four patients thought both could happen. Most patients expect that disease activity will decrease again after restarting medication, but they also expect that this will take (too much) time.

Conclusion: Although most patients are unaware of the option to taper and discontinue antirheumatic medication, patients express positive emotions about this option. However, they also have concerns that disease activity will flare and they expect that improvement upon restarting medication will take time. Patients' expectations and feelings should be addressed before a drug holiday is attempted.

A Multi-Biomarker Disease Activity Score For Rheumatoid Arthritis Predicts Radiographic Damage In The BeSt Study. I.M. Markusse[1], L. Dirven[1], M. van den Broek[1], K.H. Han[2], M.F. van Lieshout[3], N. Riyazi[4], R.J. Bolce[5], E.H. Sasso[5], P.J.S.M. Kerstens[6], W.F. Lems[7], T.W.J. Huizinga[1] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Maasstad Hospital, Rotterdam, Netherlands, [3]Spaarne Hospital, Hoofddorp, Netherlands, [4]Haga Hospital, The Hague, Netherlands, [5]Crescendo Bioscience Inc., South San Francisco, CA, [6]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [7]VU University Medical Center, Amsterdam, Netherlands.

Background/Purpose: To determine whether a multi-biomarker disease activity (MBDA) score could predict radiographic damage progression in patients with rheumatoid arthritis (RA).

Methods: The BeSt study enrolled 508 patients. Of these, 84 patients had MBDA scores at baseline and radiographs of hands and feet at baseline and 1 year later and 81 patients had MBDA scores at 1 year and radiographs at 1 year and at 2 years. Radiographs were scored by two independent blinded readers using the Sharp van der Heijde Score (SHS).

MBDA scores were calculated using a validated algorithm (Vectra® DA algorithm score) integrating the levels of 12 biomarkers, (VCAM-1, EGF, VEGF-A, IL-6, TNF-RI, MMP-1, MMP-3, YKL-40, leptin, resistin, SAA, CRP) for assessing disease activity in patients with RA. The generated MBDA score ranges between 1 and 100, and can be categorized in low (≤ 29), moderate (>29 – 44) and high (>44) disease activity levels.

Receiver Operating Curves (ROC) were used to calculate an area under the curve (AUC) with outcome any radiographic damage progression (increase ≤ 0.5 points SHS) yes or no. Poisson regression with increase in SHS as continuous outcome was used to calculate a relative risk (RR). In all analyses MBDA scores are compared to disease activity scores (DAS) in predicting radiographic damage in the following 12 months.

Results: Baseline characteristics of patients in this analysis were similar to the entire BeSt cohort. Mean age was 53 and 75% were female. Mean Disease Activity Score (DAS) was 4.30, 62% were rheumatoid factor positive and 56% anti-citrullinated protein antibodies (ACPA) positive.

At baseline, DAS had an AUC of 0.373 (95% CI 0.248 – 0.498) and MBDA had an AUC of 0.606 (95% CI 0.482 – 0.729) on radiographic progression in the subsequent year. At one year, the AUC for DAS was 0.527 (95% 0.392 – 0.729) compared to an AUC of 0.686 (95% CI 0.564 – 0.809) for MBDA.

Poisson regression showed a RR of 1.039 for MBDA at baseline to develop radiographic progression, adjusted for DAS and ACPA, indicating a 1.47 times higher risk of radiologic progression with each 10 points MBDA increase. At 1 year, the RR of MBDA, also adjusted for DAS and ACPA, is 1.037, indicating a 1.44 times higher risk with each 10 points MBDA increase. A high baseline MBDA shows a RR of 3.7 for radiologic progression in the next year compared to low and moderate (≤ 44) baseline MBDA levels combined. At 1 year, high MBDA showed a RR of 4.6 compared to low MBDA. Moderate MBDA compared to low MBDA at 1 year does not show a significantly greater risk of radiologic progression at 2 years (Table 1).

Table 1. Poisson regression analysis with MBDA categories and progression in the subsequent 12 month period

	Risk for SHS progression, baseline to 1 year		
Baseline (N=84)	RR	95% CI	P value
MBDA ≤ 44	ref	ref	ref
MBDA > 44	3.74	1.45–9.66	0.006
At 1 year (N=81)	Risk for SHS progression, year 1 to year 2		
MBDA ≤ 29	ref	ref	ref
MBDA > 29–44	1.44	0.45–4.55	0.537
MBDA > 44	4.62	1.34–15.95	0.015

Conclusion: Adjusted for DAS and ACPA, baseline MBDA scores predicted radiographic damage progression at 1 year as well as MBDA at 1 year predicted radiographic progression at year 2 during disease course. Therefore, MBDA may be of value in future treatment strategies in RA patients.

Initial Combination Therapy In Early Rheumatoid Arthritis: Which Patients Benefit? I.M. Markusse[1], K.H. Han[2], A.J. Peeters[3], H.K Ronday[4], P.J.S.M. Kerstens[5], T.W.J. Huizinga[1], W.F. Lems[6] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Maasstad Hospital, Rotterdam, Netherlands, [3]Reinier de Graaf Gasthuis, Delft, Netherlands, [4]Haga Hospital, The Hague, Netherlands, [5]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [6]VU University Medical Center, Amsterdam, Netherlands.

Background/Purpose: Initial combination therapy has proven to be effective in early rheumatoid arthritis (RA) patients. To determine which patients benefit from initial combination therapy.

Methods: In the BeSt study, 508 patients were randomized to 4 treatment strategies: 1 Sequential monotherapy 2 Step-up therapy 3 Initial combination with a tapered high dose prednisone 4 Initial combination with infliximab. For this subanalysis, groups 1 & 2 (methotrexate monotherapy) were compared to groups 3 & 4 (initial combination therapy).

Clinical assessments were performed every 3 months and radiographs of hands and feet yearly. Radiographs were assessed by 2 independent blinded readers using the Sharp van der Heijde Score (SHS).

High risk was defined as ≥ 3 of 4 features present at baseline: Swollen Joint Count ≥ 10, erosions ≥ 4, Disease Activity Score (DAS) ≥ 3.7, both rheumatoid factor and anti-citrullinated peptide autoantibodies positive.

Chi square and T-tests were used to test differences between the groups and regression analysis was performed to calculate odds ratios (OR) and risk ratios (RR).

Results: Baseline characteristics were similar among the groups. 417 of 508 patients could be categorized into high or non-high risk with available data, of which 192 were identified as having high risk for progression. At 3 months, high risk patients who started with combination therapy significantly more often than those who started with monotherapy fulfilled ACR 20 (33 vs 20%), 50 (22 vs 7%) and 70 (11 vs 2%) response criteria, and achieved more DAS-remission (DAS < 1.6) (8 vs 3%) and more functional improvement (median 0.750 vs 0.375 decrease in HAQ). At 1 year, differences in DAS-remission and ACR 20 response criteria were sustained. Also, high risk patients who started combination therapy showed significant less RRP (≥ 5 points increase in SHS) than who started with monotherapy (5 vs 14%).

Also non-high risk patients who started with combination therapy at 3 months significantly more often than who started with monotherapy met the ACR 20 (40 vs 19%), 50 (27 vs 6%) and 70 (9 vs 1%) response criteria, achieved more DAS-remission (10 vs 3%) and more functional improvement (median 0.625 vs 0.375 improvement in HAQ). At 1 year, differences remained for ACR 20 and 50 response and functional improvement. There was less RRP in non-high risk patients, without a significant difference between initial monotherapy and initial combination therapy patients (2 vs 5%). ORs and RRs are shown in table 1.

Table 1. Regression analyses: initial monotherapy was set as reference

	High risk		Non-high risk	
Logistic regression	**OR**	**95% CI**	**OR**	**95% CI**
DAS remission				
at 3 months	3.67	1.28 to 10.56	2.96	1.21 to 7.22
at 1 year	2.06	1.07 to 3.95	0.99	0.57 to 1.73
ACR20 response				
at 3 months	3.94	2.09 to 7.43	3.11	1.73 to 5.63
at 1 year	3.08	1.16 to 8.20	2.24	1.12 to 4.48
ACR50 response				
at 3 months	6.29	3.00 to 13.20	6.25	3.08 to 12.70
at 1 year	1.84	0.98 to 3.46	1.99	1.12 to 3.56
ACR70 response				
at 3 months	7.08	2.31 to 21.68	6.39	1.84 to 22.23
at 1 year	1.81	0.967 to 3.38	1.33	0.74 to 2.38
Poisson regression	**RR**	**95% CI**	**RR**	**95% CI**
RRP at 1 year	0.351	0.20 to 0.62	0.62	0.32 to 1.21
Linear regression	Beta	95% CI	Beta	95% CI
ΔHAQ				
at 3 months	−0.42	−0.61 to −0.24	−0.33	−0.51 to −0.15
at 1 year	−0.16	−0.36 to 0.04	−0.21	−0.40 to −0.01

Conclusion: High risk as well as non-high risk patients benefit from initial combination therapy. To avoid RRP, high risk patients benefit the most from combination therapy. However, taking into account the clinical outcome measurements, non-high risk patients also do benefit by achieving earlier ACR response, DAS-remission and functional improvement when starting treatment with a combination therapy.

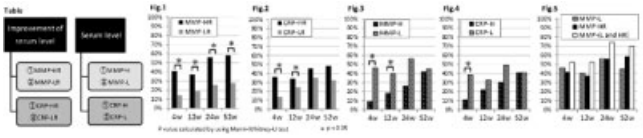
High Rate Of Improvement In Serum Matrix Metalloproteinase-3 Levels At 4 Weeks Predict Remission At 52 Weeks In RA Patients With Adalimumab Therapy. Yosuke Hattori[1], Atsushi Kaneko[1], Daihei Kida[1], Hisato Ishikawa[2], Toshihisa Kojima[3] and Naoki Ishiguro[4]. [1]Nagoya Medical Center, Nagoya, Japan, [2]Nagoya Medical Center, nagano, Japan, [3]Nagoya University Hospital, Nagoya, Japan, [4]Nagoya University Graduate School of Medicine, Nagoya, Japan.

Background/Purpose: Serum MMP-3 is a specific inflammatory marker of the synovium in patients with rheumatoid arthritis (RA). Our aim in this study is to investigate whether serum MMP-3 is the predictor for remission in treatment for RA patients with biologics.

Methods: All RA patients (n=175) who underwent adalimumab (ADA) treatment in TBC (Tsurumai Biologics Communication) registry were enrolled in this study. We analyzed 107 patients in continuation with ADA therapy for 52 weeks. We divided into 2 groups based on the improvement of serum level of MMP-3 and CRP: high rate of improvement (MMP-HR group) and low rate of improvement (MMP-LR group) in serum MMP-3 levels at 4 weeks, and: high rate of improvement (CRP-HR group) and low rate of improvement (CRP-LR group) in serum CRP levels at 4 weeks. We also divided into 2 groups based on the serum level of MMP-3 and CRP: high value (MMP-H group) and low value (MMP-LR group) in serum MMP-3 levels at 4 weeks, and: high value (CRP-H group) and low value (CRP-L group) in serum CRP levels at 4 weeks (Table). We evaluated the rate of remission at 4, 12, 24, and 52 weeks in HR group and LR group.

Results: In patients continuing at 52 weeks, the rate of remission at 4, 12, 24 and 52 weeks in MMP-HR group is 41%, 37%, 56%, and 58%, and MMP-LR group is 14%, 19%, 26%, and 28% respectively. The rate of remission at 4, 12, 24 and 52 weeks in MMP-HR group is significantly higher than in MMP-LR group (Fig.1). However, the rate of remission at 24 and 52 weeks had no significance in CRP-HR group and CRP-LR group (Fig.2).The rate of remission at 4, 12, 24, and 52 weeks in MMP-H group is 9%, 18%, 26%, and 42%, and MMP-L group is 46%, 40%, 56%, and 45%. The rate of remission at 4 and 12 weeks in MMP-H group is significantly higher than in MMP-L group (Fig.3). However, the rate of remission at 4 weeks in CRP-H group is significantly higher than in CRP-L group (Fig.4). Moreover, the rate of remission at 24 and 52 weeks in MMP-(L and HR) group is very high (Fig.5). In patients continuing at 52 weeks, the best cut-off rate of improvement in MMP-3 at 4 weeks for determining remission at 52 weeks was 40% determined by ROC analysis (sensitivity: 60%, specificity: 80%, accuracy: 66%).



Conclusion: We considered that high rate of improvement in serum MMP-3 at 4 weeks can be useful for predicting the remission at 52 weeks in RA patients with ADA therapy.

Factors Influencing Selection Of Biologic Therapy and Comparative Effectiveness In Patient Reported Outcomes Among Patients With Rheumatoid Arthritis. Iris Navarro-Millan[1], Lang Chen[1], Leslie R. Harrold[2], Lisa Herrinton[3], Liyan Liu[3] and Jeffrey R. Curtis[4]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Massachusetts Medical School, Worcester, MA, [3]Kaiser Permanente, Oakland, CA, [4]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL.

Background/Purpose: Treatment of rheumatoid arthritis (RA) with biologics is increasingly common. A better understanding of factors that influence the selection of RA therapies and comparative effectiveness between therapies is warranted. The objectives of this study were to describe physicians' and patients' preferences in selecting specific biologics and comparing clinical response using patient reported outcomes (PROs) among RA patients started on different anti-TNF therapies.

Methods: Eligible patients for this analysis were enrollees in Kaiser Permanente Northern California. RA patients with at least 2 Kaiser visits who started a new anti-TNF therapy from 10/2010 – 8/2011 were initially eligible for participation in a longitudinal telephone survey at baseline (initiation of anti-Tumor Necrosis Factor therapy) and 6 months later. Patients' preferences in selecting their biologics were collected at baseline. PROs for effectiveness were collected both at baseline and 6 month surveys. Ordinary least squares regression evaluated the change at 6 months across PROs comparing etanercept (ETA) vs. adalimumab (ADA) initiators and controlled for multiple potential confounders.

Results: There were 384 eligible RA patients available to be contacted; 267 initially responded and 242 initiated etanercept or adalimumab and 187 completed both the baseline and 6 month follow-up telephone surveys. Mean age was 54.4 (SD ± 12.1) and 73.4% were females. A total of 56% of patients self-reported that they were involved in the selection of their specific biologic. The majority of patients (57%) preferred an injectable biologic, 22% preferred an infused biologic, and 21% had no preference. Preferences for injection biologics were mainly motivated by convenience (92%); those preferring infusion therapy were motivated by dislike or lack of self-efficacy for self-injection (15.7%). After 6 months of treatment with anti-TNF biologics, 44% of the patients reported a level of burning and stinging with injection of ≤ 4 in a scale of 0–10 with the last biologic dose, 30% experienced a level > 5 and 26% reported no burning and stinging. RAPID 3, MDHAQ and physical function via the SF12 were significantly better at 6 months without significant difference between ETA or ADA initiators (Table).

	Etanercept (N = 118)	Adalimumab (N = 69)
	All initiators	All initiators
RAPID3		
Baseline (mean, SD)	16.6 (5.7)	15.9 (5.9)
Mean difference at 6 months	−6.6 (7.1)	−3.6 (5.5)
Adjusted mean difference at 6m*	Referent	2.2 (−0.31, 4.71)*
MDHAQ		
Baseline (mean, SD)	3.6 (2.0)	3.6 (2.0)
Mean difference at 6 months	−1.3 (1.8)	−0.8 (1.6)
Adjusted mean difference at 6m*	Referent	0.5 (−0.11, 1.13)**
SF12_PCS		
Baseline (mean, SD)	30.5 (10.2)	31.2 (10.6)
Mean difference at 6 months	6.0 (12.6)	1.8 (9.5)
Adjusted mean difference at 6m*	referent	−2.2 (−6.96, 2.65)**
SF12_ MCS		
Baseline (mean, SD)	44.3 (12.8)	46.1 (13.1)
Mean difference at 6 months	5.9 (13.3)	4.8 (12.4)
Adjusted mean difference at 6m*	referent	0.05 (−4.54, 4.64)**

RAPID3 = Routine assessment of patient index data 3; MDHAQ = Multidimensional health assessment questionnaire; SF12_mcs/pcs = Short form-12 item survey mental composite scale/physical composite scale; SD = standard deviation. *Controlling for age, gender, RA duration and baseline PRO. **Data shown as Beta coefficients and 95% confidence interval.

Conclusion: Convenience, fears of self-injection and self-efficacy for self-injection were important aspects to patients when selecting an individual therapy. There were clinically small and non-significant differences in effectiveness at 6 months of etanercept versus adalimumab across several PROs.

A Comparison Of The Clinical Effectiveness Of Treatment Strategies For Active RA Patients: Using a Prospective Biologic Registry (BIOPSY) and an RA Specific Cohort (KORONA). Yoon-Kyoung Sung[1], Soo-Kyung Cho[1], Chan-Bum Choi[1], Soyoung Won[2], So-Young Bang[3], Hoon-Suk Cha[4], Jung-Yoon Choe[5], Won Tae Chung[6], Seung-Jae Hong[7], Jae-Bum Jun[1], Hyoun Ah Kim[8], Jinseok Kim[9], Seong-Kyu Kim[5], Tae-Hwan Kim[1], Hye-Soon Lee[3], Jaejoon Lee[4], Jisoo Lee[10], Shin-Seok Lee[11], Sung Won Lee[6], Yeon-Ah Lee[7], Seong-Su Nah[12], Chang-Hee Suh[8], Dae-Hyun Yoo[1], Bo Young Yoon[13] and Sang-Cheol Bae[1]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [3]Hanyang University Guri Hospital, Guri, South Korea, [4]Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, South Korea, [5]Catholic University of Daegu School of Medicine, Daegu, South Korea, [6]Dong-A University Hospital, Busan, South Korea, [7]Kyung Hee University, Seoul, South Korea, [8]Ajou University Hospital, Suwon, South Korea, [9]Jeju National University Hospital, Jeju, Korea, South Korea, [10]Ewha Womans University Mokdong Hospital, Seoul, South Korea, [11]Chonnam National University Medical School and Hospital, Gwangju, South Korea, [12]Soonchunhyang University Cheonan Hospital, Cheonan, South Korea, [13]Inje University Ilsan Paik Hospital, Goyang, South Korea.

Background/Purpose: The results from RCTs may not be generalizable to clinical practice because of their inclusion and exclusion criteria. Instead, observational cohorts and registries might provide complement information for each treatment strategies in the real world. This study aimed to compare the clinical effectiveness of treatment strategies for active RA patients refractory to non-biologic DMARDs using independent biologic registry and disease specific cohort for Korean RA patients.

Methods: One year follow-up data on drug uses and clinical outcomes were compared between Korean biologics registry (BIOlogics Pharmacoepidemiologic StudY, BIOPSY) and established RA cohort (KORONA). Since all the BIOPSY patients had moderate to high disease activity (DAS28>3.2) and have started TNF inhibitors, we selected patients from KORONA with inclusion criteria at baseline: 1) DAS 28>3.2, 2) changing DMARDs within 3 months, and 3) non-biologic DMARD user. A total of 528 subjects (208 from BIOPSY and 320 from KORONA) were included in this study. Propensity score matching was used to equalize patient characteristics between TNF inhibitor user and non-biologic DMARD user groups. The one year remission rates with DAS 28 and HAQ scores were compared between two treatment strategies for active RA patients: starting TNF inhibitors vs. changing non-biologic DMARDs.

Results: Of the 208 TNF inhibitor users and 320 non-biologic DMARDs users identified from each registry and cohort, 184 patients (92 in BIOPSY and 92 in KORONA) were included in this analysis after the propensity score matching. Their baseline characteristics were comparable with age (46.5 vs. 46.6, P=0.97), female (89.1% vs. 91.3%, p=0.81), RF positivity (83.7% vs. 84.8%, p=1.0), disease duration (6.0 years vs. 5.2 years, p=0.39), DAS 28 (5.58 vs. 5.60, p=0.63) and HAQ scores (1.20 vs. 1.20, P=0.97). Remission rates after 1 year follow up with sustaining baseline treatment were 16.3% in TNF inhibitor users and 13.0% in non-biologic DMARDs users (P=0.68). For the patients with continuing initial treatment for 1 year, TNF inhibitor users had lower HAQ score than non-biologic DMARDs users (0.59 vs. 0.77, P<0.01).

Conclusion: We compared clinical effectiveness of TNF inhibitors and non-biologic DMARDs in active RA patients using independent biologics registry and RA cohort. Although the use of TNF inhibitors did not increase the one year remission rate compared to the use of non-biologic DMARDs, it decreased the one year functional disability in active RA patients.

What Factors Lead To Achieve and Sustain Remission In Rheumatoid Arthritis Patients With Moderate To High Disease Activity? Soo-Kyung Cho[1], Yoon-Kyoung Sung[1], Jeeseon Shim[2], Chan-Bum Choi[1], Jung-Yoon Choe[3], Won Tae Chung[4], Seung-Jae Hong[5], Jae-Bum Jun[1], Tae-Hwan Kim[1], Tae-Jong Kim[6], Eun-Mi Koh[7], Jisoo Lee[8], Shin-Seok Lee[6], Sung Won Lee[4], Dae-Hyun Yoo[1] and Sang-Cheol Bae[1]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [3]Catholic University of Daegu School of Medicine, Daegu, South Korea, [4]Dong-A University Hospital, Busan, South Korea, [5]Kyung Hee University, Seoul, South Korea, [6]Chonnam National University Medical School and Hospital, Gwangju, South Korea, [7]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [8]Ewha Womans University Mokdong Hospital, Seoul, South Korea.

Background/Purpose: Clinical remission has now become the treatment goal in rheumatoid arthritis (RA), but it is not common in clinical practice. This study aimed to evaluate predictors for achieving remission and it's sustaining in RA patients.

Methods: A total of 709 RA patients with moderate or high disease activity at enrollment and who have data of two years annual follow-up were included in this analysis from the KORean Observational study Network for Arthritis (KORONA). Clinical remission of RA was defined as a DAS28 score less than 2.6. The prevalence of clinical remission at first follow-up visit was estimated and its predictors were identified using multivariate logistic regression analysis. Using the second follow-up data, we further divided patients who had achieved remission into two groups: sustained remission or not. We also performed multivariate logistic regression analysis to identify predictors for sustained remission.

Results: Among the patients in moderate or high disease activity (n=709), only 102 patients (14.4%) achieved remission at their first follow-up visit. Patients with remission had lower functional disability (HAQ score 0.68±0.56 vs. 0.91±0.67, P<0.01) and lower disease activity (DAS28 4.13±0.73 vs. 4.59±0.95, P<0.01) at baseline than patients who could not achieve remission. In multivariate analysis, early RA (disease duration of less than 2 years, OR 2.03, 95%CI 1.14–3.59) and moderate disease activity compared to high disease activity at baseline (OR 2.37, 95%CI 1.25–4.50) were identified as predictors for remission (See table).

Among the patients who are in remission at first visit (n=102), 45 patients (42.1%) stayed in remission while the other 57 patients (57.9%) experienced flare of their disease activity at their second follow-up. Early RA (disease duration <2 years) and moderate disease activity compared to high disease activity at baseline showed increased OR for sustained remission in multivariate logistic model, but there was no statistical significance (OR 2.61, 95%CI 0.84–8.08, OR 3.96, 95%CI 0.82–19.08, respectively).

Table. Predictors for achieving remission and sustained remission in RA patients with moderate to high disease activity

Baseline characteristic	Predictors for achieving remission univariate	Predictors for achieving remission multivariate	Predictors for sustained remission univariate	Predictors for sustained remission multivariate
Age (years)				
<40	Ref	Ref	Ref	Ref
40–49	0.62 (0.28–1.35)	0.67 (0.30–1.48)	0.96 (0.23–4.10)	1.05 (0.20–5.63)
50–59	0.85 (0.44–1.67)	1.04 (0.51–2.10)	0.58 (0.17–1.99)	0.45 (0.11–1.95)
≥60	0.70 (0.35–1.39)	0.88 (0.41–1.90)	0.38 (0.10–1.35)	0.29 (0.06–1.50)
Female	0.66 (0.36–1.21)	0.82 (0.42–1.58)	0.47 (0.15–1.44)	0.46 (0.11–1.86)
Income level				
~$9,999	Ref	Ref	Ref	Ref
$10,000~29,999	0.93 (0.55–1.56)	0.87 (0.49–1.53)	2.29 (0.84–6.23)	3.78 (0.97–14.77)
$30,000~	1.30 (0.78–2.17)	1.16 (0.64–2.12)	1.45 (0.55–3.87)	1.29 (0.33–5.05)
Disease duration				
<2 years	**1.92 (1.12–3.30)**	**2.03 (1.14–3.59)**	2.40 (0.89–6.48)	2.61 (0.84–8.08)
2≤ and <5 years	1.43 (0.83–2.45)	1.27 (0.73–2.21)	1.84 (0.67–5.03)	2.20 (0.70–6.86)
≥5 years	Ref	Ref	Ref	Ref
HAQ ≥1	**1.90 (1.21–2.98)**	1.48 (0.90–2.46)	0.65 (0.28–1.51)	0.34 (0.11–1.02)
DAS 28				
moderate	**2.77 (1.51–5.09)**	**2.37 (1.25–4.50)**	1.31 (0.40–4.31)	3.96 (0.82–19.08)
high	Ref	Ref	Ref	Ref
Biologics use	1.41 (0.71–2.81)	1.72 (0.80–3.67)	0.44 (0.11–1.76)	0.27 (0.05–1.38)
Methotrexate use	1.22 (0.66–2.28)	1.26 (0.65–2.42)	–	–
Steroid use	1.03 (0.61–1.73)	1.08 (0.62–1.86)	–	–

Conclusion: Short disease duration less than 2 years and lower disease activity are the predictors for achieving remission in RA patients with moderate to high disease activity. These factors might be associated with sustained remission.

Remission After Twelve Month Of Treatment In The Prague Early Rheumatoid Arhritis Cohort. Herman F. Mann[1], Olga Ruzickova[1], Olga Sleglova[2], Marketa Fojtikova[3], Dana Tegzova[4], Sarka Forejtova[1] and Ladislav Senolt[4]. [1]Institute of Rheumatology, Prague, Prague, Czech Republic, [2]Institute of Rheumatology and 1st faculty of medicine, Charles University, Prague, Czech Republic, [3]Institute and Clinic of Rheumatology, Charles University, Prague 2, Czech Republic, [4]Institute of Rheumatology, Prague, Czech Republic.

Background/Purpose: Recent data have demonstrated that early treatment with disease modifying anti-rheumatic drugs (DMARDs) improves outcome in patients with Rheumatoid arthritis (RA). Early arthritis clinic (EAC) is a useful tool which allows high risk patients to bypass long waiting times for a rheumatology evaluation and thus start treatment early. We have used the data from Prague Early Rheumatoid Arthritis Clinic (PERAC)to evaluate first year treatment outcomes of patients with early RA.

Methods: Patients with symptom duration ≤6 months were reffered by their primary care physicians in accordance with published recommendations. Only patients with rheumatoid arthritis fulfilling the 2010 ACR/EULAR classification criteria or undifferentiated inflammatory arthritis which, at the time of presentation, did not fulfill classification criteria of another disease entity were included in the ERA cohort. There was no pre-specified treatment protocol in place and non-biological DMARDs were started based on the discretion of treating physician. Clinical and laboratory data were collected at pre-specified time points.

Results: 427 patients were evaluated in the PERAC between 2008 and 2012. 131 of these were included in the ERA cohort. 119 patients (91%) fulfilled RA classification criteria at baseline. 30% of newly diagnosed RA patients had normal CRP (≤0.5 mg/dl). Most patients were started on methotrexate in accordance with current guidelines. 81% of patients were initially treated by oral glucocorticoids. Data at 12 months were available for 89 patients. Mean age in this subgroup was 51 years, 67% were women, 56% were ACPA and 55% rheumatoid factor positive. Mean DAS28 score had decreased from 5.50 at baseline to 3.05 after 12 months of treatment. 40 patients (45%) were in remission based on SDAI ≤ 3.3 and 42 patients (47%) fulfilled the ACR/EULAR proposed Boolean-based definition of remission. 12 patients (13%) had to change their initial DMARD during first 12 months of treatment and only 5 patients started on methotrexate (5%) had to discontinue the drug due to side-effects during the first 12 months of treatment. 50% (4 out of 8) patients not fulfilling RA classification criteria at baseline were classified as having RA at month 12. 2 patients (2%) initially fulfilling RA classification criteria were diagnosed with another disease (paraneoplastic arthritis and systemic lupus erythematodes) at month 12.

Conclusion: Our data confirm that early RA patients have a very good clinical response to initial DMARD choice. Side effects of methotrexate leading to treatment discontinuation were rare. 2010 ACR/EULAR RA classification and provisional remission criteria are applicable in clinical practice. Appropriate refferral of patients at risk by their primary care physicians remains a problem.

Successful Self-Administration Of Methotrexate In Rheumatoid Arthritis Patients Using a Prefilled Autoinjector Pen. Jaime Pachon[1], Alan Kivitz[2], Kay-Uwe Heuer[3] and Uwe Pichlmeier[3]. [1]Miami Research Associates, South Miami, FL, [2]Altoona Center for Clinical Research, Duncansville, PA, [3]medac GmbH, Wedel, Germany.

Background/Purpose: Methotrexate (MTX) is the most commonly used and recommended DMARD for the treatment of RA. SC administered MTX is well absorbed and appears to overcome the problems associated with oral administration, including variable absorption and saturation of the absorption mechanism with increasing doses.

The purpose of this study was to assess the usability, label comprehension, robustness, safety, and bioavailability of SC self-administration (SA) of the prefilled MTX pen containing 0.3 mL of MTX 50 mg/mL solution (medac

GmbH, Germany) in a typical population of RA patients requiring MTX treatment.

Methods: The study population consisted of 104 patients aged 16 years or older, including newly diagnosed and MTX naïve and those switching from an oral route of administration, or those already receiving an off-label SC route of administration.

The actual use study was performed at 5 sites over a 2-week period.

Visit 1 (V1) consisted of training on the use of the device followed by an actual self-injection. Training and SA were carefully documented by a 10-item questionnaire.

Visit 2 (V2) (8–10 days after V1) consisted of a written examination for assessing patient's retention of information and a panel of the following 4 scenario test case observations, including an actual self-injection: 1) Holding the needle in place for approximately 5 seconds, 2) Checking the window of pen to confirm MTX delivery, 3) Performing the skin pinch in preparation for self-administration, and 4) Proper disposal of pen following self-administration.

Ease of performance of each scenario was also judged by the patients. A subjective measures questionnaire was used to record patients' impressions, difficulties, and general comments on the device.

Bioavailability was assessed in 25 patients. Stratified by body weight categories, patients were randomly assigned to either inject MTX in the abdomen or in the upper thigh.

Results:

- After training at V1, 12 patients had questions about the MTX pen, 4 patients required assistance to perform the self-injection
- At V2, 98.1% of patients scored 80% or better on their written examination
- The successful completion rates of scenarios 1 through 4 were 96.2%, 100%, 98.1%, and 100%, respectively
- For the respective test scenarios, 91.3%, 98.1%, 99%, and 100% of patients did not require any assistance
- The mean rating of easy performance for each test case scenario was 9.8 or higher on a 1 to 10 scale with 1 being very difficult and 10 being very easy
- The subjective measures questionnaire indicated that patients felt the MTX pen was easy to use and their overall impression was favorable
- After use, all the MTX pens were intact and had reliably delivered 0.3 mL MTX
- PK analysis revealed that excessive body weight (>100 kg) significantly decreased both AUC and C_{max} of MTX when administered SC to the abdomen
- No adverse device effects, unanticipated adverse device effects, deaths, serious adverse events, or adverse events leading to study drug discontinuation were reported

Conclusion: The MTX pen was consistently and reliably used by the intended population with a high degree of effectiveness, patient satisfaction, and safety.

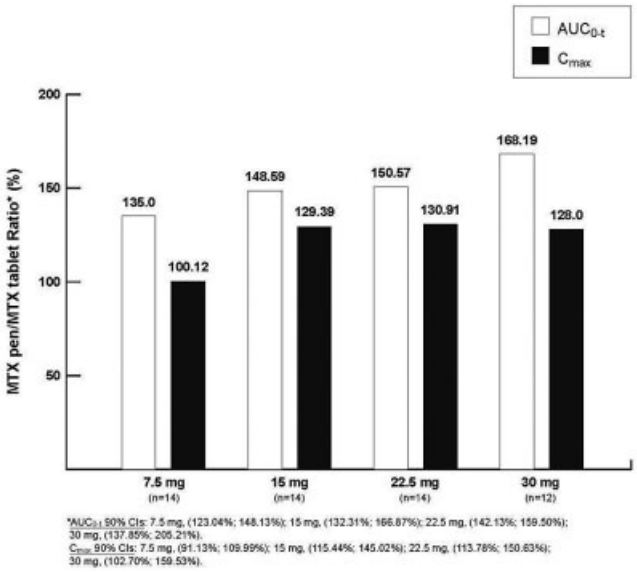
Subcutaneous Administration Of Methotrexate With a Prefilled Autoinjector Pen Results In a Higher Relative Bioavailability Compared To Oral Administration Of Methotrexate. Uwe Pichlmeier and Kay-Uwe Heuer. medac GmbH, Wedel, Germany.

Background/Purpose: Methotrexate (MTX) is commonly used in the treatment of RA, psoriasis, and psoriatic arthritis. Subcutaneously administered MTX is well absorbed and appears to overcome the problems associated with oral administration, including variable absorption and saturation of the absorption mechanism with increasing doses.

The purpose of this study was to investigate the relative bioavailability of MTX administered by subcutaneous (SC) injection with a prefilled MTX autoinjector pen (MTX pen) as compared to oral administration.

Methods: A single center, open label, randomized, 2-period, 2-sequence, single dose crossover study in 4 dose groups (7.5 mg, 15 mg, 22.5 mg, and 30 mg) with healthy subjects aged 18 to 55 years. A subject participated in only 1 of the 4 dose groups and received a single dose of the test product (MTX pen) and the reference product (methotrexate tablets, USP (Dava)). Pharmacokinetic blood samples were collected predose and at 0.25, 0.5, 0.75, 1, 1.5, 2, 2.5, 3, 4, 6, 8, 10, 12, 16, 24, and 48 h postdose.

Results: Bioavailability of MTX administered SC with the MTX pen compared with MTX tablets.



Dose	MTX pen AUC_{0-t} (h·ng/mL)	MTX tablet AUC_{0-t} (h·ng/mL)	MTX pen C_{max} (ng/mL)	MTX tablet C_{max} (ng/mL)
7.5 mg	782.73	579.79	185.99	185.77
15 mg	1594.84	1073.32	392.00	302.96
22.5 mg	2272.55	1509.34	512.71	391.64
30 mg	2824.72	1679.47	576.26	450.20

The safety results were in line with the current knowledge about the safety profile of MTX. No serious adverse events were reported after SC administration of MTX. A total of 80 adverse events were reported by 35 of the 62 subjects, of which 63 were mild and 17 were moderate events. None of these were serious. Differences in the safety profile were related to the route of administration, i.e., more GI disorders were observed after oral administration (15% vs. 28%) whereas injection site reactions were observed after administration with the MTX pen. Overall, single administrations with the MTX pen were locally well tolerated. No redness or swelling occurred, and only 2 subjects had a mild hematoma. Mild pain or burning sensation at the injection site was reported by 5 of the 59 subjects.

- AUC_{0-t} was higher after MTX pen compared to oral administration for all dose groups
- MTX pen administration resulted in a higher C_{max} compared to oral administration for all dose groups, with the exception of the lowest dose
- AUC_{0-t} ratios increased with ascending doses whereas C_{max} ratios did not increase with ascending doses

Conclusion: Administration of MTX with the MTX pen resulted in a higher relative bioavailability compared to oral administration of MTX after single doses of 7.5, 15, 22.5, and 30 mg.

Disease Activity Of Rheumatoid Arthritis Is Influenced By Seasonal Change, As Analyzed Based On a Nationwide Japanese Cohort Database. Tetsuji Sawada[1], Hiroaki Mori[2], Kota Shimada[3], Haeru Hayashi[1], Koichiro Tahara[1], Jinju Nishino[4] and Shigeto Tohma[5]. [1]Tokyo Medical University, Tokyo, Japan, [2]Tokyo Meidical University, Tokyo, Japan, [3]Tokyo Metropolitan Tama Medical Center, Tokyo, Japan, [4]Nishino Clinic, Orthopedics and Rheumatology, Tokyo, Japan, [5]Sagamihara Hospital, National Hospital Organization, Sagamihara, Japan.

Background/Purpose: Previous studies have suggested that environmental factors, such as weather, humidity and seasonal change, may affect rheumatoid arthritis (RA). In the present study, we aimed to determine whether there is seasonal variation in disease activity of RA, as assessed by subjective and objective components, using a nationwide Japanese cohort

database, NinJa (National Database of Rheumatic Diseases by iR-net in Japan) in 2009, 2010 and 2011.

Methods: We analyzed data from RA patients, who were registered in NinJa and evaluated at any point during the indicated year, to evaluate seasonal effects on disease activity of RA, including tender joint count (TJC), swollen joint count (SJC), ESR, C-reactive protein (CRP), patient's assessment of pain on a visual analogue scale (pain VAS), patient's global assessment of disease activity (patient's global VAS), physician's global assessment of disease activity (physician's global VAS), DAS28, Modified Health Assessment Questionnaire (MHAQ).

Results: Univariable analysis using NinJa 2011 database revealed that pain VAS and patient's global VAS, which were subjective components of RA disease activity, as well as SJC, inflammatory markers (ESR and CRP), DAS28, mHAQ and physician's global VAS were lowest during the fall months with statistical significance, although TJC was lowest in the summer months. Furthermore, it was reproducibly demonstrated that pain VAS, patient's global VAS, DAS28 and physician's global VAS were lowest during the fall months when analyzing using Ninja 2009 and 2010 database.

Conclusion: We have clearly demonstrated that RA disease activity, as assessed both subjectively and objectively, was lowest in fall. Seasonal changes can thus affect RA, which should be taken into account when examining RA patients to better understand their symptoms.

	Spring	Summer	Fall	Winter
Number of patients	1905	628	1210	4398
TJC	2.63	1.65	2.01	2.97
SJC	2.34	2.42	1.54	1.77
ESR	29.9	27.3	26.1	32.0
CRP	0.68	0.64	0.57	0.70
pain VAS	2.71	2.84	2.25	2.76
mHAQ	0.50	0.47	0.45	0.49
patient's global VAS	2.77	3.01	2.39	2.82
DAS28	2.64	2.53	2.40	2.66
physician's global VAS	1.76	2.01	1.48	1.86

Coping Style Is An Independent Predictor For Disease Activity At Three Months In Early Arthritis Patients Initiating Therapy With Disease Modifying Anti-Rheumatic Drugs. T. Martijn Kuijper[1], Hong Xiong[1], A.E.A.M. Weel[2], A.H. Gerards[3], Jendé van Zeben[4], P.H.P. de Jong[5], Ilja Tchetverikov[6], P.B.J. de Sonnaville[7], M.V. Krugten[8], B.A. Grillet[9], Jolanda J. Luime[1] and Johanna M.W. Hazes[1]. [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Maasstad Hospital, Rotterdam, Netherlands, [3]Vlietland Hospital, Schiedam, Netherlands, [4]Sint Franciscus Gasthuis, Rotterdam, Netherlands, [5]Erasmus University Medical Center, Rotterdam, Netherlands, [6]Albert Schweitzer Ziekenhuis, Dordrecht, Netherlands, [7]Admiraal de Ruyter Ziekenhuis, Goes, Netherlands, [8]Admiraal de Ruyter Hospital, Vlissingen, Netherlands, [9]Zorgsaam Hospital, Terneuzen, Netherlands.

Background/Purpose: To explore the effect of psychosocial factors on the Disease Activity Score (DAS) and its components in early arthritis patients three months after initiating treatment with DMARDs.

Methods: Data were used from patients with recent-onset arthritis participating in a single-blinded clinical trial (Treatment in the Rotterdam Early Arthritis CoHort (tREACH))(1,2) in which three induction therapy strategies were compared: (A) combination therapy (methotrexate (MTX) + sulfasalazine + hydroxychloroquine) with glucocorticoids (GCs) intramuscularly; (B) combination therapy with an oral GC tapering scheme and (C) MTX with oral GCs similar to B.

Data were collected on demographics, clinical and psychological characteristics, including questionnaire data on coping, fatigue, depression, social support, locus of control and physical activity. The effect of baseline psychological characteristics on the DAS three months after initiation of therapy were evaluated using a multivariate linear regression model corrected for treatment arm, baseline DAS, age, sex, Rheumatoid Factor and ACPA. Separate analyses were performed for the DAS components: SJC (Swollen Joint Count), Ritchie Articular Index (RAI), ESR and patient self-report of general health (Visual Analogue Scale).

Results: 281 patients (91 men, 190 women; mean baseline DAS 3.4, median baseline HAQ 0.75) were included in the analysis. We found that passive coping with pain and higher anxiety scores at baseline were associated with higher levels of disease activity (DAS) at three months. Taking the individual components of the disease activity score at three months as an outcome, passive coping with pain was associated with higher levels of ESR, while anxiety was related to higher tender joint scores (RAI) and patient self-report of general health.

Conclusion: Our results suggest that psychological factors, especially anxiety and coping style, are associated with disease activity in early arthritis patients three months after initiation of DMARD therapy. This was not explained by baseline levels of disease activity or initial type of DMARD treatment.

No Differences In Patient-Reported Outcomes By Methotrexate Dose Among Early Rheumatoid Arthritis Patients Treated Concomitantly With Adalimumab: Results From The Concerto Trial. Roy M Fleischmann[1], Alan Kivitz[2], Ronald F van Vollenhoven[3], James W. Shaw[4], Stefan Florentinus[5], Piyalal M. Karunaratne[4], Hartmut Kupper[6], Maxime Dougados[7] and Gerd R Burmester[8]. [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Altoona Center for Clinical Research, Duncansville, PA, [3]Karolinska Institutet, Stockholm, Sweden, [4]AbbVie Inc., North Chicago, IL, [5]AbbVie, Rungis, France, [6]AbbVie Deutschland GmBH & Co KG, Ludwigshafen, Germany, [7]René Descartes University, Paris, France, [8]Charité-Universitätsmedizin Berlin, Free University and Humboldt University of Berlin, Berlin, Germany.

Background/Purpose: Methotrexate (MTX) in combination with the tumor necrosis factor inhibitor adalimumab (ADA) is an effective therapy for treating rheumatoid arthritis (RA), but the minimum dose of MTX in combination with ADA that can achieve an acceptable clinical response is not known.

Objectives: To evaluate different MTX doses in combination with ADA in achieving clinically meaningful improvement in patient-reported outcomes (PROs) in patients with early RA.

Methods: CONCERTO was a 26-week, phase 3, double-blind, parallel-arm study in MTX-naïve patients with active RA <1 year in duration. Patients were randomized 1:1:1:1 to open-label ADA 40 mg every other week plus blinded weekly oral MTX in a dose of 2.5, 5, 10, or 20 mg. Patients in the 20 mg arm started with 10 mg MTX with bi-weekly escalation of 2.5 mg through wk 8. PROs measured at weeks 8 and 26 included the following: Health Assessment Questionnaire Disability Index (HAQ-DI); patient global

assessment of disease activity (PGA); 36-item Short-Form Health Survey, Version 2 (SF-36v2), Physical Component Summary (PCS) and Mental Component Summary (MCS); Medical Outcomes Study Sleep Scale (MOS SS); Compliance Questionnaire Rheumatology (CQR); and Treatment Satisfaction Questionnaire for Medication (TSQM). Differences in mean changes in PROs among the 4 treatment groups were analyzed using mixed models. No adjustments for multiplicity were applied.

Results: Of the 395 patients included in the intent-to-treat population, 358 (91%) completed 26 weeks of treatment; 15, 7, 6, and 9% of pts receiving 2.5, 5, 10, or 20 mg MTX, respectively, discontinued treatment prior to completion. Clinically and statistically significant improvements from week 0 in most PROs occurred in all 4 dose groups by 8 weeks, were maintained through 26 weeks, and were similar regardless of MTX dose with no statistically significant difference between the dose groups with respect to the HAQ-DI, PCS, and MCS.

Image/graph:

Table. PRO means at wk 0 and mean changes at wks 8 and 26

	MTX Dosing Regimen											
	2.5 mg (N = 98)			5 mg (N = 99)			10 mg (N = 100)			20 mg (N = 98)		
PRO	Wk 0	ΔWk 8	ΔWk 26	Wk 0	ΔWk 8	ΔWk 26	Wk 0	ΔWk 8	ΔWk 26	Wk 0	ΔWk 8	ΔWk 26
HAQ-DI	1.5	−0.61[c]	−0.73[c]	1.6	−0.61[c]	−0.76[c]	1.6	−0.66[c]	−0.78[c]	1.6	−0.65[c]	−0.85[c]
PGA	70.5	−30.5[c]	−38.8[c]	71.7	−32.0[c]	−36.7[c]	67.6	−30.5[c]	−38.6[c]	65.5	−30.3[c]	−40.7[c]
PCS	31.2	9.1[c]	8.8[c]	31.4	7.5[c]	9.0[c]	31.1	8.4[c]	10.4[c]	31	9.5[c]	12.2[c]
MCS	37.1	7.6[c]	8.6[c]	39.4	6.6[c]	6.7[c]	39	6.1[c]	7.0[c]	39.7	6.5[c]	7.8[c]
MOS SS	48.2	−11.7[c]	−12.3[c]	48.7	−13.6[c]	−12.6[c]	48.7	−11.1[c]	−13.4[c]	50.5	−12.3[c]	−11.7[c]
CQR	80.6	1.6	1.3	80.3	1.7	−1.1	79.3	3.1[b]	2.5	80.2	2	2.1
TSQM	54.2	21.7[c]	18.9[b]	56.5	14.2[b]	11.9[a]	53	22.5[c]	22.0[c]	52.8	24.4[c]	26.2[c]

Number of randomized pts are presented. The HAQ-DI, PGA, and MOS SS were scaled such that higher values indicated worse outcomes. All other PROs were scaled such that higher values were better. Global tests of differences in mean changes among the 4 treatment groups at wks 8 and 26 were insignificant, $P > 0.05$. [a]$P < 0.05$, [b]< 0.01, [c]$P < 0.001$, mean change from Wk 0 different from 0. Wk 26 n = 83, 93, 93, and 89 for MTX doses 2.5, 5, 10, and 20 mg, respectively.

Conclusion: Patients treated with ADA in combination with MTX 2.5, 5, 10 or 20 mg per week experience similar improvements in PROs by week 8 that are maintained through 26 wks. The differences associated with MTX dose are not statistically significant and, in general, not clinically meaningful.

Does Rheumatoid Arthritis Disease Activity Correlate With Weather Conditions? Eimear Savage[1], David McCormick[1], Stephen McDonald[1], Michael Stevenson[2], Owen Moore[3] and Andrew Cairns[4]. [1]Belfast Hospitals Trust, Musgrave Park Hospital, Belfast BT9 7JB, Northern Ireland, [2]Queens University, Belfast. School of Medicine, Dentistry and Biomedical Sciences., Belfast BT12 6BJ, Northern Ireland, [3]St. Vincent's Hospital, Melbourne, Australia, [4]Belfast Hospitals Trust, Musgrave Park Hospital, Belfast, United Kingdom.

Background/Purpose: Rheumatoid Arthritis is a common inflammatory joint condition affecting up to 1% of the Northern Ireland population. Patients often report increasing joint pain with changing weather conditions. Previous studies examining the impact of weather on pain severity have yielded contradictory results (1,2). The relationship between disease activity scores in Rheumatoid Arthritis patients and weather variance has not previously been examined.

Methods: Patients attending the Biologics Therapy Unit at the Department of Rheumatology, Musgrave Park Hospital, Belfast; with a diagnosis of Rheumatoid Arthritis and receiving injectable anti-TNF therapy (Etanercept or Adalimumab) for a period of greater than 6 months were invited to participate. A retrospective analysis of a total of 133 patients was performed. Data collected at 5 time points included tender joint count, swollen joint count, patient visual analogue score, Erythrocyte Sedimentation Rate (ESR), C-reactive protein (CRP), and DAS-28 (Disease Activity Score). This was correlated with maximum/minimum temperature, hours of sunshine, rainfall, relative humidity, pressure and wind-speed from a local weather station on the day of attendance. A linear regression analysis was used to determine relationship between weather components, disease activity and pain.

Results: The weather-based components were extracted after a global factor analysis using data from all time-points had revealed three weather components from the seven quantitative variables (maximum temperature, minimum temperature, hours of sunshine, mm rainfall, relative humidity, wind-speed and pressure). These seven variables were converted to z-scores. Three components indicated by the factor analysis were as follows: temperature component, sunny/dry component, wet/windy component. All components were calculated from z-scores.

Using DAS-28 as an outcome variable, when tested against weather components, it was evident that increased hours of sunshine and low humidity resulted in a lower das-28 score (p 0.001). Sunny and dry conditions ((hours of sunshine – relative humidity)/2) resulted in a DAS-28 reduction of 0.143 (95% CI −0.230, −0.057) p=0.001. Temperature component (max temperature + min temperature)/2) resulted in a DAS-28 reduction of 0.048 (95% CI −0.129, 0.032), p = 0.23. Wet and windy conditions (rainfall + wind-speed – pressure)/3) led to a das-28 increase (0.013 (95%CI −0.098, 0.123) p=0.82.

Conclusion: This study demonstrates statistically significant lower DAS-28 scores in sunny and dry conditions. A non-significant trend to higher DAS-28 scores in times of low temperature, and dull, wet and windy weather was also noted.

Evaluation Of Biomarkers Involved In Periondontal Disease Including *Porphyromonas Gingivalis* Antibodies To Predict Response To Infliximab In Rheumatoid Arthritis Patients. Mélanie Rinaudo-Gaujous[1], Pierre Miossec[2], Vincent Blasco-Baque[3], Philippe Gaudin[4], Christian Genin[1], Thierry Thomas[5], Stéphane Paul[1] and Hubert Marotte[6]. [1]Laboratory of Immunology and immunomonitoring, CIC CIE3 Inserm Vaccinology, GIMAP EA3064, Hôpital Nord, Saint-Etienne, France, [2]Immunogenomics and inflammation research unit, Lyon, France, [3]Institute of Cardiovascular and Metabolic Diseases, CHU Rangueil, Toulouse, France, [4]CHU Hôpital Sud, Grenoble Teaching Hospital, Echirolles, France, [5]INSERM U1059 and University Hospital, Saint-Etienne, France, [6]LBTO INSERM U1059 University Jean Monnet, Saint-Etienne, France.

Background/Purpose: This study evaluates biological markers of rheumatoid arthritis (RA) severity including matrix metalloproteinase 3 (MMP-3) and *Porphyromonas gingivalis (P. gingivalis)* serology during infliximab therapy and highlights predictive factors for infliximab response.

Methods: We enrolled 79 RA patients requiring infliximab therapy in this study. DAS28, anti-citrullinated protein antibodies *(*ACPA), rheumatoid factor (RF) Iga and IgM, anti-*P. gingivalis* antibodies, anti-*Prevotella intermedia* (*P. intermedia*) antibodies, and MMP-3 were monitored before and 6 months after the beginning of infliximab therapy. ACPA, RF, MMP-3 anti-*P. intermedia* antibodies, and anti-*P. gingivalis* antibodies (LPS specific and whole extract) antibodies were determined by ELISA.

Results: At baseline, ACPA titers are associated with anti-*P. gingivalis* LPS specific antibodies titers ($P<0.01$) and anti-*P. gingivalis* whole extract antibodies titers ($P<0.01$), but no association has been found between IgM RF and anti-*P. gingivalis* antibody. Conversely, anti-*P. intermedia* antibodies are not correlated with ACPA titers, but with IgM RF levels. Anti-*P. gingivalis* antibodies were not significantly correlated with clinical, biological, or destruction parameters of RA disease. At 6 months of infliximab therapy, MMP-3 levels decrease ($P<0.0001$), whereas *P. gingivalis* and anti-*P. intermedia* antibodies levels increase ($P<0.01$). DAS28 and inflammation markers (CRP and ESR) also decrease significantly during infliximab

therapy (P<0.05), as ACPA levels (P<0.001). Presence of anti-*P. gingivalis* antibodies at baseline did not influence the treatment outcome. Only high MMP-3 levels at baseline and a decreased of ACPA at 6 months were associated with infliximab efficacy (P<0.01).

Conclusion: Anti-*P. gingivalis* is associated with ACPA at baseline suggesting a role of periodontal infection in RA pathogenesis. Unlike anti-*P. gingivalis* antibodies, MMP-3 level can be a useful marker of the infliximab efficacy in RA patients as well as the evolution of ACPA during treatment.

Stringent Therapies Improve Clinical, Radiographic and Magnetic Resonance Imaging Outcome In Early-Stage Rheumatoid Arthritis Patients From Japanese Population: Longitudinal Study From Nagasaki Early Arthritis Cohort. Mami Tamai[1], Yoshikazu Nakashima[2], Junko Kita[2], Ayuko Takatani[2], Ayako Nishino[2], Takahisa Suzuki[2], Yoshiro Horai[2], Akitomo Okada[3], Shin-ya Kawashiri[2], Naoki Iwamoto[2], Kunihiro Ichinose[2], Kazuhiko Arima[2], Hideki Nakamura[2], Tomoki Origuchi[2], Masataka Uetani[2], Katsumi Eguchi[4] and Atsushi Kawakami[2]. [1]Center for Health & Community Medicine, Nagasaki University, Nagasaki, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Japanese Red Cross Nagasaki Genbaku Hospital, Nagasaki, Japan, [4]Sasebo City General Hospital, Sasebo, Nagasaki, Japan.

Background/Purpose: Prognosis of the patients with rheumatoid arthritis (RA) nowadays is supposed to become better by treat-to-target (T2T) strategy. Osteitis determined by magnetic resonance imaging (MRI) is known as a predictor toward radiographic progression. We have tried to examine in the present study whether the change of therapeutic strategy affect the clinical, radiographic and MRI outcome of early-stage RA patients of Japanese population.

Methods: All of early-stage RA patients in the present study were recruited from Nagasaki University Early Arthritis Cohort in which the subjects received Gd-enhanced MRI of both wrist and finger joints. We have divided the periods of the Cohort into two parts. The first half includes the RA patients DMARDs treatment initiated from 2003 to 2007 (Group I: traditional therapy phase) whereas the second half includes those DMARDs treatment initiated from 2008 to 2011 (Group II: T2T phase). All of patients gave their informed consent to be subjected to the protocol that was approved by the Institutional Review Board of Nagasaki University. The good outcomes at 1 year after initiation of therapy were set as SDAI remission for clinical outcome, no radiographic progression by Genant modified Sharp score for radiographic outcome and improvement of RAMRIS osteitis score over 67% decrease or no appearance of RAMRIS osteitis for MRI outcome, respectively. We have tried to examine whether therapeutic strategies affect the outcome at 1 year in early-stage RA patients.

Results: Ninety-two patients were included. Median disease duration at entry was 3 months and there were no significant differences of patients' background between the 2 treatment groups. In T2T phase, the frequencies of MTX initiation, introduction of MTX within 1 year and the use of biologics within 1 year were significantly high as compared with traditional therapy phase. Regarding to the efficacy, the rate of SDAI remission, radiographic no progression and good outcome of MRI were significantly high at 1 year in T2T phase as compared with traditional therapy phase. Multivariate logistic regression analyses have identified; SDAI remission at 1 year is associated with T2T phase and no radiographic progression. No radiographic progression at 1 year is associated with SDAI remission and good outcome of MRI. Good outcome of MRI is associated with T2T phase and no radiographic progression. Good clinical, radiographic and MRI outcome associated each other.

Conclusion: Present data suggest that stringent therapies in early-stage RA patients improve clinical, radiographic and MRI outcome, indicating an importance of T2T in daily clinical practice.

Isymind Significantly Reduces MTX-Induced Nausea In a Pilot Trial. Eva Ostermeier[1], Hans Ulrich Koetter[2], Hans-Peter Tony[3] and Ruth Pfister[2]. [1]University of Würzburg, Würzburg, Germany, [2]iSyMind Institut, Giessen, Germany, [3]University Hospital Würzburg, Würzburg, Germany.

Background/Purpose: MTX is the standard DMARD for treating rheumatoid arthritis and the most important partner for biological DMARDs. However MTX often induces heavy nausea accompanied by disgust and phobic fear concerning drug application leading to premature discontinuation of treatment. Therefore we analyzed the effectiveness of *Neurointrinsic Mind Modulation and Synchronization* (iSyMind), a neuropsychological method to reduce or eliminate the reported MTX side-effects in a clinical pilot study.

Methods: 4 patients with strong side-effects were screened using Visual Analog Scale (VAS; 0–100) for Intensity of Problem (IoP), Ability to Cope (AtC), Wish to Discontinue (WtD), Disgust (D), Anxiety (A). Each Patient was treated in a one-session group treatment with iSyMind 2×30 min in combination with psychoeducation concerning the development of disgust and phobia. All parameters were examined pre and post treatment and after 7, 28 and 90 days.

Results: After iSyMind treatment patients were able to receive MTX s.c. or p.o. with a highly improved tolerance. In 3 patients all 6 parameters (VAS) showed clinically significant reduction between day 1 and day 90: IoP from 91 to 24, AtC from 80 to 13, WtD from 59 to 12, D 87 from to 26, A 88 from to 26. The treatment satisfaction index via Visual Analoge Scale (0= not at all satisfied, 100 = very satisfied) at day 90 was .81. The positive effect was ongoing in 3 of 4 patients till day 90 while one patient showed a fast relapse probably because of underlying moderate depression. Due to large standard deviation, inflicted by 1 patient, the statistical significances scored between $p < .002$ and $p < .09$.

Conclusion: This pilot trial suggests that iSyMind significantly reduces MTX induced nausea, disgust and phobic fear with a response rate of about 75% enabling continuation of medication. The results indicate that the studied MTX related side-effects concerning drug application are primarily neuropsychological results of an intrinsic learning process which can be resolved. Further studies are necessary for statistical validation.

Active Tuberculosis Risk With Tumor Necrosis Factor Inhibitors After Treating Latent Tuberculosis -a 7-Year Retrospective Observational Study. Minkyung Kwon, Mindong Sung, Yong-Jin Kwon, Young Goo Song, Sang-Won Lee, Min-Chan Park, Yong-Beom Park, Soo-Kon Lee and Jason Jungsik Song. Yonsei University College of Medicine, Seoul, South Korea.

Background/Purpose: Active tuberculosis (TB) risk increases during anti-tumor necrosis factor (TNF) therapy and latent TB infection (LTBI) screening is recommended in potential TNF inhibitor users. It is unclear whether anti-TNF therapy elevates active TB risk even after LTBI treatment. We sought to evaluate the risk of active TB development in LTBI-positive TNF inhibitor users following the current treatment guidelines for LTBI in South Korea, TB prevalent area.

Methods: We retrospectively studied 949 TNF inhibitor users with immune-mediated inflammatory diseases at Yonsei University Health System from 2005–2012. Long-term TNF inhibitor users who followed current national guidelines for LTBI were enrolled for analysis. We compared the incidence rate of active TB among LTBI-positive TNF inhibitor users (n=256) and LTBI-negative TNF inhibitor users (n=521) using Poisson regression.

Results: There were 256 LTBI-positive and 521 LTBI-negative TNF inhibitor users. Six LTBI-positive and five LTBI-negative TNF inhibitor users developed active TB during the 7.8-year study duration. To adjust for different TNF inhibitor exposure durations among patients, we calculated patient-years (PY) exposure rates. Active TB incidence rate was 1107 per 100,000 PY in LTBI-positive TNF inhibitor users and 490 per 100,000 PY in LTBI-negative TNF inhibitor users. Active TB risk was not elevated in LTBI-positive versus LTBI-negative TNF inhibitor users (sex- and age-adjusted incidence rate ratio, 2.2; 95% CI 0.6–7.7). The median onset of active TB in LTBI-positive TNF inhibitor users was 8.6 months (range 3.9–22.4 months) and 14.6 months in LTBI-negative TNF inhibitor users (range 9.6–18.1 months) Among the 11 TNF inhibitor users who developed

active TB, 50% of LTBI-positive TNF inhibitor users (three patients) developed active TB within 9 months while they were on isoniazid, whereas no LTBI-negative TNF inhibitor users developed active TB in the same period.

Conclusion: Risk of developing active TB in LTBI-positive TNF inhibitor users is not significantly higher than in LTBI-negative TNF inhibitor users, after receiving LTBI treatment.

Detection of Latent Tuberculosis Infection in Rheumatologic Diseases Before Anti-TNFα Therapy: Tuberculin Skin Test Versus IFN-γ Assay. Suleyman Ozbek[1], Ismail Hanta[2], Sedat Kuleci[2], Gulsah Seydaoglu[2] and Ezgi Ozyilmaz[2]. [1]Cukurova University Faculty of Medicine, Adana, Turkey, [2]Cukurova University, Adana, Turkey.

Background/Purpose: We aimed to evaluate tuberculin skin test (TST) and interferon-gamma (IFN-γ) test results for latent tuberculosis infection (LTBI) in patients with rheumatologic diseases prior to anti-TNFα therapy.

Methods: Ninety patients were evaluated in the study at the Departments of Chest Diseases and Rheumatology for anti-TNFα therapy for their rheumatologic diseases. Tuberculin skin test was performed (Mantoux method) and peripheral blood samples were collected for IFN-γ assay (QuantiFeron TB-Gold In Tube) before the anti-TNFα therapy.

Results: Of 90 patients, TST positivity was detected in 56 (62.2%) patients, while IFN-γ positivity was detected in 34 (37.8%) patients. Among 56 TST positive patients, IFN-γ positivity was detected in 24 (42.9%) patients, and among 34 TST negative patients, IFN-γ positivity was detected in 10 (29.4%) patients. There was no significant agreement between TST and IFN-γ assay results (Kappa = 0.12, P = 0.2). Forty-three (47.8%) patients were using immunosuppressive drugs owing to their rheumatologic diseases. In this group, TST and IFN-γ positivity is significantly lower than in those who did not receive immunosuppressive treatment ($P < 0.05$).

Conclusion: We conclude that the IFN-γ assay may not be preferred to TST as a diagnostic test in patients with rheumatologic diseases prior to anti-TNFα treatment.

Incidence Of Hepatitis B Virus Reactivation In Patients With Rheumatoid Arthritis During Treatment With Biologics. Jun Nakamura[1], Takao Nagashima[1], Katsuya Nagatani[1], Taku Yoshio[2], Masahiro Iwamoto[3] and Seiji Minota[4]. [1]Jichi Medical University, Tochigi, Japan, [2]Jichi Medical University, School of Medicine, Shimotsuke-shi, Tochigi-ken, Japan, [3]Jichi Medical University, Shimotsuke, Tochigi, Japan, [4]The Safety Evaluation Committee of Actemra® for JIA, Tokyo, Japan.

Background/Purpose: Reactivation of hepatitis B virus (HBV) is very problematic in patients who are receiving biologics. Optimal precaution and management for those patients are still controversial. The aim of this study is to clarify the incidence of HBV reactivation in rheumatoid arthritis (RA) patients on biologics and to find out whether there is difference in reactivation rates among different biologics.

Methods: Retrospective observational study. HBV reactivation was defined as conversion from quantitative negativity to qualitative positivity of HBV-DNA in sera. All the patients with RA who were treated with biologics from July 2010 to December 2012 were tested for HBsAg, anti-HBs and anti-HBc. If the patients were positive for HBsAg, or negative for HBsAg but positive for anti-HBs and/or anti-HBc, ALT and AST were also retrieved from patients' records. HBsAg, anti-HBs and anti-HBc were examined using chemiluminescent immunoassay, and the levels of HBV-DNA were measured by real-time PCR (lowest detection limit was 2.1 log copies/ml). The ethics committee of our hospital approved this study.

Results: Among 247 patients received biologics, none was found positive for HBsAg. 57 patients (23.0%) were negative for HBsAg but positive for anti-HBs and/or anti-HBc. These patients were considered to have resolved HBV infection. Infliximab, etanarcept, adalimumab, tocilizumab and abatacept were used in 27, 25, 17, 18 and one, respectively; some of the patients received multiple biologics. HBV-DNA became positive in 4 patients (7.0%): 1 while on etanercept, 1 while on infliximab, and 2 while on tocilizumab. However, the levels of HBV-DNA were below the quantitative detection limits in these 4 patients. In one patient on tocilizumab, HBV-DNA levels fluctuated between positive and negative ranges for 4 months; first HBV-DNA positivity was found at 2 months after tocilizumab-use. In another case on tocilizumab, HBV-DNA was first found at 2 months after tocilizumab-use, persisted for 3 months, and disappeared thereafter. In one patient on infliximab, HBV-DNA became positive only once at 22 months after infliximab-use. In one patient on etanercept, HBV-DNA was found only once at 17 months after etanercept-use. Liver function tests were within normal ranges in all examinations from all the patients. All the patients continued treatment with the biologics and HBV-DNA became negative eventually without anti-viral treatment.

Conclusion: HBV reactivation was observed in 7.0% of RA patients with resolved HBV infection during treatment with biologics. However, HBV-DNA levels were below the quantitative detection limits and liver function tests were normal throughout. There were no differences among biologics in regards to the incidence of HBV reactivation. Anti-TNFs and anti-IL-6 receptor antibody may be used safely in RA patients with a history of HBV infection.

Abdominal Adiposity and Body Composition In Rheumatoid Arthritis: Relation With Disease Characteristics In A Case-Control Study. Ivan Ferraz-Amaro[1], Esmeralda Delgado-Frías[1], Vanesa Hernandez-Hernandez[2], Jose Ramon Muñiz[3], Antonieta Gonzalez-Diaz[4], Angeles Gomez Rodriguez-Bethencourt[4] and Federico Diaz-Gonzalez[5]. [1]Hospital Universitario de Canarias, La Laguna, Spain, [2]Rheumatology Service, Santa Cruz de Tenerife, Spain, [3]Resonancia Magnetica IMETISA, Santa Cruz de Tenerife, Spain, [4]Servicio de Medicina Nuclear, Santa Cruz de Tenerife, Spain, [5]University of La Laguna, Hospital Universitario de Canarias, La Laguna, Spain.

Background/Purpose: To determine the relationship between measures of body composition (total body composition derived from dual energy X-ray absorptiometry and abdominal adiposity through magnetic resonance imaging) with comorbidities in rheumatoid arthritis (RA) like disease activity, radiological damage and endothelial dysfunction.

Methods: 216 subjects, 111 RA patients and 105 age and sex-matched healthy controls were included in this case-control study. Anthropometric and demographic characteristics, cardiovascular risk measurement through SCORE index, C-reactive protein (CRP), Disease Activity Score (DAS28), Health Assessment Questionnaire (HAQ), and radiological damage through Sharp index were determined. Quantification of visceral and parietal abdominal fat area was assessed using magnetic resonance imaging. Total body composition, total and regional lean mass, and fat mass and fat free mass indexes were measured by dual energy X-ray absorptiometry (DEXA). The presence of sarcopenia or overfat phenotype was established. Endothelial dysfunction was assessed through brachial artery flow-mediated dilatation sonography. Multivariate analysis was performed to define the relation of this body composition with disease characteristics.

Results: *1) Body composition.* Percentage of lean and fat mass did not differ between patients and controls. Appendicular to total lean mass (0.42 ± 0.02 vs. 0.40 ± 0.03, $p=0.00$) and appendicular to trunk lean mass (0.82 ± 0.08 vs. 0.78 ± 0.08, $p=0.00$) were significantly lower in RA patients. Parietal abdominal tissue was lower in male RA patients (19089 ± 1234 vs. 1345 ± 3930 cm^2, $p=0.02$), this difference were not reached in female patients. Presence of sarcopenia tended to be higher in RA patients (13 versus 7%, $p=0.17$) when compared to controls. Although differences in overfat were not reached between controls and patients, 44% of RA patients had a body mass index higher than 30 kg/m^2 (32% in controls, $p=0.09$) and 96% of RA patients were considered to be overfat through DEXA criteria (96% in controls). *2) Radiological damage.* Patients with a lean mass index lower that the hypothetical percentile 25 expressed higher Sharp index when compared to patients in percentile 75 or superior (22 ± 28 vs. 9.4 ± 9, $p=0.02$) and after adjusting for disease activity. Overfat phenotypes did not show associations with radiological damage. 3) *Disease activity.* Sarcopenic patients had higher CRP (3.8 [1.8–29.7] vs 2.8 [1.3–7.2] mmg/dL, $p= 0.04$) and a trend to higher

HAQ score (1.2 [0.38–1.75] vs 0.75 [0.30–1.38], p=0.18). 4) Endothelial dysfunction. Patients with 2 standard deviation of lean mass below normality expressed lower flow-mediated when compared to controls (1.9 [0–8] vs 5.4 [0–9], p=0.14).

Conclusion: Overfat and sarcopenia are present in RA patients and are related to several disease characteristics.

Performance Of a Two-Step Latent Tuberculosis Screening Algorithm In Patients With Rheumatoid Arthritis, Psoriatic Arthritis Or Ankylosing Spondylitis Prior To Treatment With Tumor Necrosis Alpha Inhibitors: Prospective Observational Data From The Biorx.Si Registry. ŽIga Rotar[1] and Matija Tomsic[2]. [1]University Medical Centre Ljubljana, 1000 Ljubljana, Slovenia, [2]University Medical Centre Ljubjana, Ljubljana, Slovenia.

Background/Purpose: Reactivation of latent tuberculosis infection (LTBI) is of concern in patients treated with TNFi. Conversely, TB chemoprophylaxis (CP) is time consuming, delays the initiation of treatment, adds to the overall cost of treatment, and carries risk of adverse events in its own right. Since 2002 our national guidelines require following a two-step screening algorithm prior to the initiation of the first TNFi. The first step includes tuberculin skin test (TST), and a chest X-ray (CXR). If TST < 5 mm, and the radiologist finds no changes consistent with TB on CXR TNFi is prescribed. If any test is abnormal, the patient is evaluated by a pulmonologist who usually orders QuantiFERON TB Gold IT (QF) and decides whether TB CP (rifampicin/isoniazid 600/300 mg qd for 3 months) is required prior to TNFi treatment.

In February 2012 we showed that in a setting with low background annual TB incidence rate (IR; e.g. 8.4 per 10^5) following of this algorithm resulted in TB IR of 0.11 (95% CI 0.01–0.38), and 0.16 (95% CI 0.02–0.58) per 100 person years (PY) overall, and in rheumatoid arthritis (RA) patients, respectively. The costly QF and CP were required in 13.9%, and 5.2% of patients, respectively. Our aim was to revaluate the performance of this algorithm.

Methods: We cross-linked the data from the mandatory national registry of patients with rheumatic diseases treated with biologics and national TB registry to identify cases of TB in patients who were ever treated with TNFi.

Results: 1203 patients were treated with at least one TNFi for 3146.5 PY (Table 1). Flow of patients through the screening algorithm and case patient characteristics are depicted in Figure 1. QF was performed in 214/1174 (18.2%). 88/1203 (7%) patients received CP. Four cases of TB were identified; hence the incidence rates were 0.13 (95%CI 0.03–3.2), and 0.22 (95% CI 0.06–0.57) per 100 PY overall, and in RA patients, respectively. Cases of TB were only observed among RA patients. The TB IR for certolizumab vs. other TNFi prescribed for RA was 2.1 (95% CI 2.56–7.40) vs. 0.12 (95% CI 0.01–0.43) per 100 PY (p=0.016 Fisher's exact test). The first two received appropriate CP (adherence was good, isolated M. tuberculosis strains were susceptible to CP) prior to TNFi; screening was concluded after 1st, and 2nd step for the third and fourth patient, respectively. Interestingly, the third case was screened for TB again before switching to rituximab. At repeated screening two months prior to TB diagnosis the TST was 10 mm, CXR− and QF−.

Table 1.

	Rheumatoid arthritis	Ankylosing spondylitis	Psoriatic arthritis
N (%)	701 (58.3)	331 (27.5)	171 (14.2)
% female	82	34	41
Age at screening (SD)	54.9 (11.6)	45.8 (11.6)	49 (11.2)
% Glucocorticoids at screening	47.0	/	/
% ever glucocorticoids	66.2	/	/
TNFi exposure years	1792.5	950.6	403.4
% Adalimumab (ADA)	44.4	36.9	44.4
% Certolizumab (CZP)	5.3	0.0	0.3
% Etanercept (ETA)	37.4	31.1	27.2
% Golimumab (GOL)	2.3	7.1	10.9
% Infliximab (IFX)	10.7	24.9	17.2

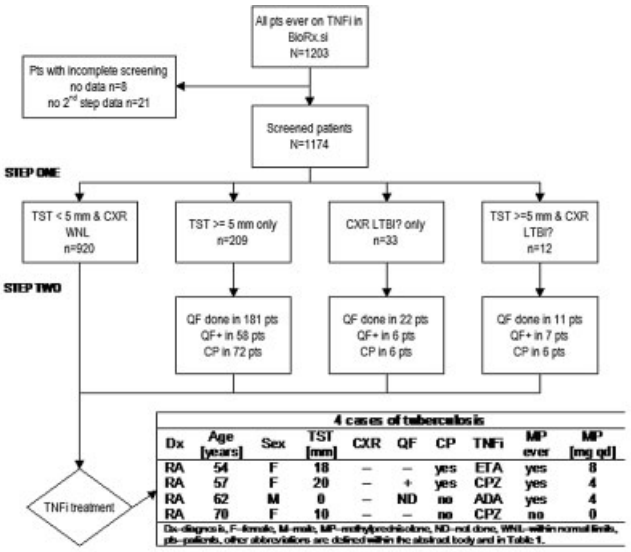

Figure 1.

Conclusion: At follow-up our two-step algorithm is still performing well. Further vigilance is warranted, especially in RA patients and those treated with CPZ.

The Effect Of Vitamin D On Early Rheumatoid Arthritis: A Retrospective Cohort Analysis. Faye A H Cooles[1], Arthur G Pratt[1], Wan-Fai Ng[1], Terry J Aspray[2] and John D Isaacs[3]. [1]Newcastle University, Newcastle upon Tyne, United Kingdom, [2]The Freeman Hospital, Newcastle upon Tyne, United Kingdom, [3]National Institute for Health Research, Newcastle Biomedical Research Centre, Newcastle Hospitals Foundation Trust and Newcastle University, Newcastle Upon Tyne, United Kingdom.

Background/Purpose: There is increasing evidence that vitamin D has immunoregulatory properties in autoimmunity. In established rheumatoid arthritis (RA) there appears to be an inverse association between serum vitamin D levels and disease activity scores (DAS-28) (Rossini et al., Arthritis Res Ther, 2010; 12(6);R216) although others suggest this may be skewed by the global health visual analogue scale (GH-VAS) (Higgins et al., Clin Rheumatol, 2013 Jun; 32(6): 863–7). Given the confounding problems in established RA, such as medications or lifestyle, we wished to investigate the role of vitamin D in early RA.

Methods: We retrospectively analysed an inception cohort of patients presenting to an Early Arthritis Clinic at the Freeman Hospital, Newcastle-upon-Tyne between October 2007 - March 2009. Serum 25 hydroxy vitamin D levels (25OHD measured using the DaiSorin Liaison automated immunoassay), DAS-28, CRP, ESR, TJC (tender joint count), SJC (swollen joint count), GH-VAS and autoantibody status were measured at baseline. Diagnoses were confirmed at 1 year follow-up. Statistical analyses involved linear regression, binary logistic regression and Mann-Whitney U tests and were all performed using SPSS (statistics 19) with significance when p<0.01. Where applicable all analyses were corrected for age and sex.

Results: Of a total cohort of 453 patients, complete data was available for 344 (76%; 2:1 females:males, mean age 49 [range 16–97], median symptom duration 16 weeks [range 1–230]). No significant association was seen between serum 25OHD and GH-VAS, SJC, TJC, ESR, CRP, auto-antibodies or disease outcome in this cohort (corrected for age and sex). Amongst the 73 (21%) patients diagnosed with RA (2:1 females:males, mean age 49 [range 18–88]), associations between serum 25OHD and DAS-28, GH-VAS, SJC, TJC, ESR, CRP and autoantibody status were again not seen (corrected for age and sex). However, in those diagnosed with osteoarthritis, OA, (n=58; 3:1 females:males, mean age 55 [range 47–78]), we identified a significant inverse association between GH-VAS and serum 25OHD (p=0.006), although the other measured parameters (as above) were again non-significant (corrected for age and sex). Notably symptom duration was significantly higher in the OA group than in the RA group (median 24 versus 12 weeks; p<0.0005).

Conclusion: This is the first study to our knowledge to look at the effects of serum 25OHD in early RA. Contrary to published work in established RA, our data suggest that serum 25OHD does not impact on disease activity parameters (including GH-VAS) in early disease. We do however demonstrate a significant inverse association between GH-VAS and serum 25OHD in OA patients. The significantly prolonged symptom duration observed in this group may have permitted an association to develop between perceived health and vitamin D status, for example driven by reduced mobility/sunlight exposure. Similar factors may confound apparent associations between RA and vitamin D status in established disease. Larger scale studies are needed to validate our preliminary findings in early arthritis.

1369

Evaluation Of *Porphyromona Gingivalis* Serology In Rheumatoid Arthritis and Non-Rheumatoid Inflammatory Disease. Mélanie Rinaudo-Gaujous[1], Adeline Moreau[1], Vincent Blasco-Baque[2], Xavier Roblin[3], Christian Genin[1], Thierry Thomas[4], Stéphane Paul[1] and Hubert Marotte[5]. [1]Laboratory of Immunology and immunomonitoring, CIC CIE3 Inserm Vaccinology, GIMAP EA3064, Hôpital Nord, Saint-Etienne, France, [2]Institute of Cardiovascular and Metabolic Diseases, CHU Rangueil, Toulouse, France, [3]Department of gastroenterology, Hôpital Nord, Saint-Etienne, France, [4]INSERM U1059 and University Hospital, Saint-Etienne, France, [5]INSERM U1059 and University Hospital, Hôpital Nord, Saint-Etienne, France.

Background/Purpose: Periodontal disease (PD) is associated mainly with rheumatoid arthritis (RA), but recent data suggest an association with ankylosing spondylitis (AS). Role of *Porphyromonas gingivalis* (*P. gingivalis*) in RA disease is growing fast since it is the only bacteria able to citrullinate peptides and may induce autoimmune response through development of ACPA. However, few studies have reported its presence in others inflammatory diseases. The aim of this study was to evaluate immunization against two oral pathogens: *P. gingivalis* and *Prevotella intermedia* (*P. intermedia*) in patients with RA, AS, inflammatory bowel disease (IBD), and healthy subjects.

Methods: Seventy-nine RA patients, 56 AS patients, and 39 IBD patients requiring infliximab therapy enrolled in these study as well as 30 healthy controls. Anti-*P. intermedia* antibodies and anti-*P. gingivalis* LPS specific and whole extract antibodies were determined by specific ELISA. Specificity of these antibodies was evaluated by the measure of antibodies against the *Escherichia Coli (E. coli)* commensal bacterium of the intestinal tract.

Results: Anti-*P. gingivalis* antibody titers directed against LPS and/or whole extract were correlated together ($P<0.0001$) as well as antibody titers against the two oral bacteria (*P. gingivalis* and *P. intermedia*) ($P<0.0001$). By using LPS from *E. coli*, no cross reaction was observed between these two species.

Anti-*P. gingivalis* antibodies titers were higher in RA and AS patients than in healthy subjects ($P < 0.0001$) or in IBD patients ($P < 0.0001$). Moreover, there was a tendency for higher titers in RA patients than in SA patients (Fig 1A). Same results were found with anti-*P. intermedia* antibody titers which were higher in RA and AS patients than in healthy controls ($P < 0.0001$) or IBD patients ($P < 0.0001$) (Fig 1B).

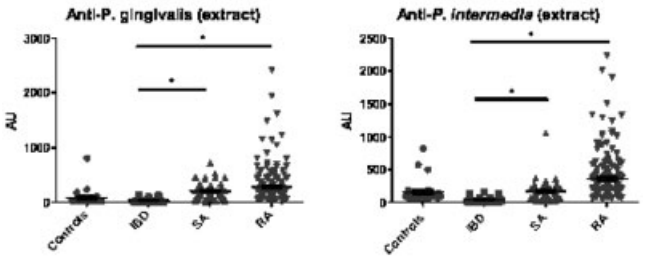

Fig 1. Evaluation of anti-*P. gingivalis* (A) and anti-*P. intermedia* (B) antibodies in RA, AS, and IBD patients and in healthy controls.

*$P < 0.0001$

Conclusion: Immunity against *P. gingivalis* and *P. intermedia* oral bacteria seems to have an important role in RA, but also in AS compared to other inflammatory disease as IBD.

Prednisone Is a Risk Factor For Pneumocystis Jirovecii Pneumonia In Patients With Rheumatic Diseases: A Case-Control Study With 36 Cases. Wieneke van den Hombergh[1], Annelies van Ede[2], J. Fransen[3], Femke BG lamers-Karnebeek[3], Saskia Kuipers[2] and Matthijs Janssen[4]. [1]UMC st. Radboud, Nijmegen, Netherlands, [2]UMC st Radboud, Nijmegen, Netherlands, [3]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [4]Rijnstate Hospital, Arnhem, Netherlands.

Background/Purpose: Pneumocystis jirovecii is a fungal pathogen that causes pneumonia in immunocompromized hosts. Prednisone is frequently suggested as a risk factor for developing pneumocystis pneumonia (PCP) in patients with rheumatic diseases. If prednisone use is a risk factor indeed, targeted preventive measures can be taken. The aim of this study was to analyze whether prednisone is a risk factor for developing PCP in patients with rheumatic diseases.

Methods: In this case-control study all cases with a rheumatic disease who developed PCP from 2005 to 2012 in one of two clinics were included. Clinical and laboratory results were compared with controls with rheumatic disease without PCP in the same period, matched for disease duration. At least four controls were included for every PCP patient. Confounders were selected using existing literature, including concomitant medication, comorbidity and laboratory results. Logistic regression was used for analysis.

Results: Thirty-six patients with a variety of rheumatic diseases were diagnosed with PCP in the 8-year study period and 167 controls were matched to these cases. Forty-two percent of the patients with PCP required admission to the intensive care unit (ICU), and 28% died in the course of PCP. In the 6 months before PCP onset, 75% of the patients with PCP used prednisone, which was 25% for controls in the corresponding period, with an OR (95%CI) of 20 (5–85) while corrected for confounders (model 3 in the table). Especially also receiving i.v. corticosteroids (25% vs. 0,6% in the PCP group and control group, $p < 0,05$) was a risk for developing PCP, with an OR (95%CI) of 60(2–1627).

Table 1. Logistic regression models

Characteristic	OR (95% CI)	P-value
Model 1		
Use of prednisone	**23,84 (6,98–81,46)**	**0,000**
Model 2		
Use of prednisone	**26,52 (7,32–96,10)**	**0,000**
Age	1,04 (1,01–1,08)	0,024
Sex	1,05 (0,43–2,55)	0,923
Use of methotrexate	2,90 (1,19–7,03)	0,019
Model 3		
Use of prednisone	**20,18 (4,82–84,53)**	**0,000**
Age	1,04 (0,99–1,08)	0,105
Sex	0,55 (0,18–1,68)	0,295
Use of methotrexate	8,67 (2,36–31,86)	0,001
Diabetes mellitus	2,98 (0,60–14,92)	0,184
Pre-existing lung disease	3,52 (1,06–11,76)	0,041
Pneumonia	9,92 (1,78–55,45)	0,009
Leukopenia	13,96 (2,15–90,59)	0,006

OR odds ratio; use of prednisone: during 6 months prior to PCP; 95% CI: 95% confidence interval.

Conclusion: Pneumocystis jirovecii pneumonia remains a challenging infection with often severe consequences. Confirmative arguments for prednisone as a strong independent risk factor for development of PCP were found. Prophylaxis with trimethoprim-sulfamethoxazole might be considered in patients using corticosteroids, and particularly during 2 to 6 months in patients receiving high dose corticosteroids (orally or intravenously).

Tuberculosis Infection In Patients With Tumor Necrosis Factor–α Antagonists In South Korea; retrospective Analysis Using By National Health Insurance Review and Assessment Service. Jong Wook Beom[1], Eun-Jung Park[2], Jinseok Kim[2], Se Chang Park[3] and Gi Hyeon Seo[4]. [1]Medicine, Jeju National University Hospital, Jeju, South Korea, [2]Jeju National University Hospital, Jeju, South Korea, [3]Seoul National University, Seoul, South Korea, [4]Health Insurance Review and Assessment Service, Seoul, South Korea.

Background/Purpose: Tumor necrosis factor-α (TNF-α) antagonists bring new hope for treating rheumatoid arthritis (RA) over the past decade. However, the subsequent increased risk of developing tuberculosis (TB) is one of the major drawbacks in patients with TNF-α antagonists.

The aim of this study was to evaluate the overall incidence rate of TB in RA patients treated with TNF-α antagonists and compare of incidence rate according to type and duration of TNF-α antagonists, and history of treatment for latent TB infection (LTBI) in South Korea, TB-endemic area.

Methods: All RA patients treated with TNF-α antagonists registered with the National Health Insurance Review and Assessment Service (HIRA) in South Korea between January 2006 and December 2011 were included and retrospectively analyzed. The incidence of LTBI by screening test and of TB after starting TNF-α antagonists were reviewed.

Results: Total 5,853 RA patients with TNF-α antagonists were observed. Of these, 1133 (19.4 %) patients were treated with LTBI before starting TNF-α antagonists. One hundred-thirty two (2.6 %) patients developed TB during follow-up period, and the incidence rate of TB was 583.7 per 100,000 person years (PY). The incidence rate of TB in patient with infliximab revealed 1408.1 per 100,000 PY which is the highest rate, followed by adalimumab of 1211.4 per 100,000 PY and etanercept of 618.4 per 100,000 PY. Forty-five (1648.8 per 100,000 PY), 24 (1038.2 per 100,000 PY), and 63 (647.5 per 100,000 PY) cases of TB were observed during first 6 months, 7–12 months, and 13 months or more after starting TNF-α antagonists, respectively. Among the patients who developed TB, 13 (9.8 %) patients had completed treatment of LTBI. The incidence rate of TB demonstrated 477.6 per 100,000 PY and 987.7 per 100,000 PY in patients with and without history of treatment of LTBI, respectively.

Conclusion: The risk of TB infection increased in RA patients treated with infliximab, and during first 6 months with TNF-α antagonists. Relatively lower risk of TB infection were observed in patients treated with etanercept, and during 13 months and more after starting TNF-α antagonists compare to the rest of the RA patients. RA patients with TNF-α antagonists need watchful observation for TB infection, even in patients who had completed treatment of LTBI.

Do We Really Identify Latent Tuberculosis? Comparison Of The Performance Of Tuberculin Skin Test and Interferon Gamma Release Assay Before Biologics: A Systematic Review and Meta-Analysis. Marie Locci[1], Françoise Barchechath-Flaisler[1], Jean-Louis Leroux[1] and Cécile Gaujoux-Viala[2]. [1]Nîmes University Hospital, Rheumatology Department, Nîmes, France, [2]EA 2415, Montpellier I University, Nîmes University Hospital, Rheumatology Department, Nîmes, France.

Background/Purpose: Current guidelines mandate screening for latent tuberculosis infection prior to commencing anti-tumor necrosis factor therapy. However, many patients are already taking immunosuppressive therapy, which can affect current diagnostic tests. Due to the recent introduction of the interferon-gamma release assays (IGRA), we sought out to assess their ability to detect latent tuberculosis infections in patients before biotherapy and the impact of immunosuppressive therapy on these new tests.

Methods: MEDLINE, EMBASE and COCHRANE were searched (up to April 2013) to identify studies evaluating the performance of interferon-gamma release assays (QuantiFERON QTF, T-SPOT.TB) compared to the performance of Tuberculin Skin Test (TST) in individuals candidates for anti TNF treatment, with inflammatory bowel disease or rheumatic disease.

Results: On 533 studies, 45 studies (n= 9226 patients) were included for analysis. The agreement between IDR/IGRA was poor. Kappas between QTF and TST were calculated in 18 studies, ranging from 0.03 to 0.52: poor in 15 studies (<0.4) and moderate in 3 studies (0.4–0.6). Kappas between T-SPOT and TST were calculated in 7 studies, ranging from 0.13 to 0.40: poor in 6 studies and moderate in 1 study. Moreover, the agreement between the two IGRA was moderate. Kappas ranged from 0.28 to 0.71 in 8 studies: poor in 1 study, moderate in 5 studies and good in only 2 studies.

Immunosuppressive therapy did not significantly influence positive QTF results (pooled OR 0.86, 95% CI 0.56 – 1.33) and positive T-SPOT results (pooled OR 0.74, 95% CI 0.46 – 1.21).

Conclusion: The screening of latent tuberculosis raises concerns, especially due to the lack of agreement between IGRA. The impact of immunosuppressive therapy on IGRA was not significant.

Rheumatoid Arthritis - Human Etiology and Pathogenesis

Monday, October 28, 2013, 8:30 AM–4:00 PM

1373

Connective Tissue Growth Factor Promotes Angiogenesis Through Increased Notch-1 Signaling in Rheumatoid Arthritis. Kazuhisa Nozawa[1], Maki Fujishiro[2], Ayako Yamaguchi[1], Mikiko Kawasaki[2], Kazuhisa Iwabuchi[2], Mitsuaki Yanagida[2], Keigo Ikeda[3], Shinji Morimoto[4], Yoshinari Takasaki[5] and Iwao Sekigawa[3]. [1]Juntendo University School of Medicine, Tokyo, Japan, [2]Juntendo University Graduate School of Medicine, Chiba, Japan, [3]Juntendo University Urayasu Hospital, Tomioka, Urayasu, Chiba, Japan, [4]Juntendo University Urayasu Hospital, Tokyo, Japan, [5]Division of Rheumatology, Department of Internal Medicine, Juntendo University, Tokyo, Japan.

Background/Purpose: Increased angiogenesis has been associated with various inflammatory disease states including rheumatoid arthritis (RA), and it has been considered as one of main factors for pathogenesis of RA. Angiogenic mediators excessively released by various types of cells within the synovium possibly activate vascular endothelial cells (ECs) in RA subsequently resulting in pannus formation. A series of our previous studies has demonstrated that connective tissue growth factor (CTGF) was massively produced on synovial fibroblasts in RA. In addition, we have also demonstrated that excessive CTGF contributed to aberrant activation of osteoclasts in RA, suggesting that CTGF is an important factor for pathogenesis of RA. To extend our research project regarding CTGF function on RA pathogenesis, this study was conducted to clarify whether CTGF relates to aberrant angiogenesis of RA.

Methods: Various effects of CTGF on angiogenesis were evaluated using human umbilical vein endothelial cells (HUVECs). The efficacy of CTGF on vascularization, proliferation, and migration were evaluated by tube formation assay, BrdU assay, and boyden chamber assay respectively. Regulation of CTGF production by proinflammatory cytokines (IL-6 and TNF-a) on HUVECs was evaluated by quantitative RT-PCR and *immunoblotting.* Notch-1 activation induced by CTGF on HUVECs was evaluated by immunobolttting and IIF.

Results: CTGF had positive effects for vascularization, proliferation, and migration on HUVECs. IL-6 upregulated CTGF expression even though TNF-a oppositely downregulated CTGF expression on HUVECs. Interestingly, we found that CTGF related to not only Notch-1 production but also activation of Notch-1.

Conclusion: Our data indicated that CTGF is massively produced on not only fibroblasts but also vascular endothelial cells in synovial tissue of RA due to aberrant regulation of proinflamatory cytokines. Excessive CTGF production possibly causes aberrant angiogenesis and osteoclasts activation in synovial tissue in RA. In addition, we newly found that CTGF related to production and activation of Notch-1which has been recently postulated as important factor of angiogenesis in RA. The present study clearly demonstrated that CTGF significantly related to angiogenesis through direct or indirect mechanisms, suggesting that CTGF plays an important role for disease progression of RA. CTGF may become a new target molecule for treatment of RA.

NR1D1 Is a New Suppressor of Rheumatoid Arthritis Fibroblast-Like Synoviocyte Invasion. Teresina Laragione and Percio Gulko. Hosftra North Shore-LIJ School of Medicine, Manhasset, NY.

Background/Purpose: Rheumatoid arthritis (RA) is a common and chronic autoimmune disease. Arthritis severity and joint damage predict clinical outcome and the risk for disability in RA. Yet, little is known about disease severity and joint damage regulatory genes. We have previously identified a new nuclear receptor (NR) expression signature in synovial tissues that correlates with arthritis protection and development of mild and non-erosive disease. NR1D1 (Rev-erba) was the NR with the most significant difference in expression in synovial tissues, with an 8.75-fold increase in the protected rats, suggesting that increased levels and activity of NRs have a suppressive effect on disease severity and joint damage. We hypothesized that NR1D1 mediates arthritis protection at least in part via inhibition of the invasiveness of fibroblast-like synoviocytes (FLS) derived from RA patients and arthritic rats, an *in vitro* phenotype known to correlate with histologic and radiographic joint damage.

Methods: FLS were obtained from DA rats and patients with RA and used after the third passage (>95% FLS purity). Cells were treated with the NR1D1 agonist GSK4112 and studied in an *in vitro* invasion assay through Matrigel over 24 hours. qPCR was used to quantify the expression of MMPs. Confocal and immunofluorescence microscopy were used to characterize cell and actin cytoskeleton morphologic changes.

Results: Treatment of FLS from arthritic DA rats and from RA patients with the NR1D1 agonist GSK4112 reduced their invasiveness by 70% and 60%, respectively ($p<0.002$), compared with vehicle. GSK4112 treatment reduced numbers of thick actin filaments, numbers of elongated cells, and the polarized formation of lamellipodia, all actin cytoskeleton and FLS morphologic changes required for invasion. GSK4112 did not significantly affect the IL-1β-induced expression of MMP-1, MMP-2 and MMP-3 in FLS.

Conclusion: We have identified an association between increased synovial expression of NR1D1 and arthritis protection, and a new role for this gene in the regulation of FLS invasion. NR1D1 interferes actin cytoskeletal changes required for cell motility and invasion and could become a useful target for therapies aimed at preserving joint architecture and function.

Synergistic Enhancement Of Aggregated IgG-Induced Tumor Necrosis Factor α In Human Synovial Mast Cells By Interleukin 33. Hyunho Lee[1], Jun-ichi Kashiwakura[2], Masahiko Yanagisawa[1], Yuki Okamura[1], Takao Ishii[1], Masayuki Seki[1], Shu Saito[1], Yasuaki Tokuhashi[1], Chisei Ra[1] and Yoshimichi Okayama[1]. [1]Nihon University School of Medicine, Tokyo, Japan, [2]RIKEN Center for Integrateive Medical Sciences, Kanagawa, Japan.

Background/Purpose: Recent studies suggest that human synovial mast cells (MCs) are involved in the pathogenesis of rheumatoid arthritis (RA). Circulating IgG isotype autoantibodies and synovial immune complexes are detected in RA patients. Therefore a plausible pathway for the activation of synovial MCs is through IgG receptors. However, it has not been well known whether IgG receptors are expressed on human synovial MCs. The purpose of this study was to investigate which IgG receptor(s) on synovial MCs are responsible for MC activation in response to immune complexes (IC), and to evaluate the effect of IL-33, which is believed to play an important role in RA, on IC-induced synovial MC activation.

Methods: We obtained synovial tissue specimens from RA patients and osteoarthritis (OA) patients after total knee replacement surgery. Synovial MCs were enzymatically dispersed. Cultured synovium-derived MCs were generated by culturing synovial cells with stem cell factor, and receptor expression was analyzed using fluorescence-activated cell sorting and immunohistochemical techniques. Mediators released from MCs were measured using enzyme immunoassays or enzymelinked immunosorbent assays.

Results: Primary synovial MCs and cultured synovium-derived MCs obtained from both RA patients and OA patients expressed Fcϵ receptor I (FcϵRI), FcγRI, FcγRII and ST2 but not FcγRIII. Cultured synovium-derived MCs induced degranulation and the production of prostaglandin D_2 and tumor necrosis factor α (TNF-α) through FcγRI. The activation through FcγRII caused histamine release from cultured MCs but not from primary MCs. Neutralizing anti-FcγRI monoclonal antibody and anti-FcγRII monoclonal antibody significantly inhibited histamine release induced by aggregated IgG. Aggregated IgG induced TNF-α production ($\sim$330 pg/ml/1×10^6 MCs) from cultured synovium-derived MCs. Although IL-33 did not enhance aggregated IgG-triggered histamine release, IL-33 (30 ng/mL) synergistically enhanced aggregated IgG-induced TNF-α production ($\sim$5.2 fold) in cultured synovium-derived MCs.

Conclusion: With Regard to the FcR expression profile, synovial MCs from RA patients and from OA patients were similar. FcγRI was responsible for producing abundant TNF-α from synovial MCs in response to aggregated IgG. Immune complexes may activate synovial MCs through FcγRI and FcγRII. In addition, IL-33 may exacerbate IC-mediated inflammation associated with RA by abundantly producing TNF-α from synovial MCs.

1376

Low Vitamin D Level Is Not Associated With Increased Incidence Of Rheumatoid Arthritis. Jonida Cote[1], Androniki Bili[1], H. Lester Kirchner[2] and Xiaoqin Tang[3]. [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Health System, Danville, PA, [3]Geisinger Center for Health Research, Danville, PA.

Background/Purpose: Vitamin D is thought to be an immunomodulator able to suppress autoimmunity in rheumatoid arthritis (RA). Some reports describe an association between low vitamin D and RA, but they had significant limitations. The objective of this study was to evaluate the association of vitamin D level with incident RA in a well characterized patient population using electronic health records (EHR).

Methods: Case-control study with data extracted from EHR in a tertiary health system, from 2001 to 2012. RA was defined as ICD-9 code 714.0 twice by a rheumatologist. Only patients with a primary care physician in the system were included. Incident RA patients (cases) were identified at one point in time and followed retrospectively with regard to vitamin D levels prior to the development of RA. Cases were matched for age and gender with 5 controls from the general non-RA population. An index date was created such that for cases it was the date of the RA diagnosis and for the controls it was the date of the RA diagnoses of the matched case. The most recent value of vitamin D to the index date was used in the analysis. Vitamin D levels were treated both as continuous and categorical; we used <30 IU as the primary cutoff, but also used <20 IU to investigate the RA association with severe vitamin D deficiency. This association was presented as the odds ratio (OR) from a conditional logistic regression model adjusting for obesity and smoking status. The study had a power of 82% to detect an OR of 1.5 between cases and controls.

Results: 270 patients with incident RA and 1341 matched controls were included in the analysis with median age 62.4 years, BMI 28.8 kg/m^{2}and vitamin D level 31 IU. There were no significant differences in median BMI and vitamin D levels between cases and controls. Smoking was significantly more prevalent in the cases than the controls. Of the RA patients, 141 (52.2%) were rheumatoid factor (RF) positive, 97 (35.9%) were RF negative, and 32 (11.9%) had unavailable RF status. The OR for the association between RA and vitamin D overall and stratified by gender is shown in Table 1. Subgroup analysis according to RF positivity is shown in Table 2.

Table 1. Association between low vitamin D level and Rheumatoid arthritis according to gender*

	All		Female		Male	
Vitamin D level	**OR (95% CI)**	**p-value**	**OR (95% CI)**	**p-value**	**OR (95% CI)**	**p-value**
Vitamin D (continuous)	0.996 (0.987, 1.005)	0.3652	0.996 (0.985, 1.006)	0.4014	0.997 (0.976, 1.018)	0.7693
Vitamin D <30 IU vs.≥ 30 IU	0.980 (0.745, 1.288)	0.8825	0.924 (0.682, 1.254)	0.6134	1.233 (0.649, 2.343)	0.5231
Vitamin D <20 IU vs. ≥ 20 IU	1.121 (0.801, 1.570)	0.5048	1.192 (0.825, 1.724)	0.3493	0.860 (0.362, 2.045)	0.7336

* adjusted for smoking, BMI (kg/m^2).

Table 2. Association between low vitamin D and Rheumatoid Arthritis according to Rheumatoid Factor positivity*

	RF-positive vs. controls		RF-negative vs. controls	
Vitamin D level	**OR (95% CI)**	**p-value**	**OR (95% CI)**	**p-value**
Vitamin D (continuous)	0.991 (0.978, 1.005)	0.1945	0.997 (0.981, 1.013)	0.6974
Vitamin D <30 IU vs. ≥30 IU	1.062 (0.723, 1.561)	0.7594	0.810 (0.503, 1.304)	0.3854
Vitamin D <20 IU vs. ≥20 IU	1.244 (0.790, 1.961)	0.3464	0.789 (0.415, 1.502)	0.4710

* adjusted for smoking, BMI (kg/m^2); RF=rheumatoid factor.

Conclusion: Low vitamin D level was not associated with increased odds for incident RA in this patient population. Our study was powered at 80% to detect a minimum of 50% increase in the odds of low vitamin D levels.

Decoy Receptor 3 Regulates the Expression of Tryptophan Hydroxylase TPH1 in Rheumatoid Synovial Fibroblasts. Toshihisa Maeda[1], Yasushi Miura[2], Koji Fukuda[1], Shinya Hayashi[1] and Masahiro Kurosaka[1]. [1]Kobe University Graduate School of Medicine, Kobe, Japan, [2]Kobe University, Kobe, Japan.

Background/Purpose: Tryptophan hydroxylase (TPH) which catalyzes the hydroxylation of L-tryptophan is the rate-limiting enzyme involved in the synthesis of serotonin. TPH has two isoforms; TPH1 expresses in peripheral and central nerve system (CNS) tissues expressing serotonin, such as skin, intestine, and pineal gland, while TPH2 expresses exclusively and dominantly in CNS. Recently several studies suggested that serotonergic systems play an important role in modulating inflammatory pain and bone remodeling. We previously reported that decoy receptor 3 (DcR3), a member of TNF receptor superfamily, overexpressed in rheumatoid synovial fibroblasts (RA-FLS) stimulated with TNFα inhibits Fas-induced apoptosis. We recently reported that DcR3 induced VLA-4 expression in THP-1 macrophages to inhibit cycloheximide-induced apoptosis, and that DcR3 inhibited cell proliferation induced by TNFα or IL-1β via TL1A expressed on RA-FLS. We also reported that the concentration of DcR3 in sera and joint fluids of patients with RA was significantly higher than those with osteoarthritis (OA).

Further, by using comprehensive genetic analysis using microarrays, we newly identified TPH1 as one of the genes of which expression in RA-FLS was suppressed by DcR3.

Therefore, in this study, we investigated the expression of TPH1 in RA and OA-FLS stimulated with DcR3 and inflammatory cytokines to elucidate the involvement of TPH1 and DcR3 in the pathogenesis of RA.

Methods: *Real-time polymerase chain reaction (real-time PCR).* Primary cultured RA or OA-FLS were incubated with 1.0 μg/ml recombinant human DcR3-Fc protein or 1.0 μg/ml control IgG1 for 12 hours, or 1.0 ng/ml recombinant human TNFα or 1.0 ng/ml IL-1β for 24 hours, then the relative expression levels of TPH1 mRNA were quantified by real-time PCR.

Immunohistochemistry. Serotonin expressed in rheumatoid synovial tissues was detected by immunohistochemistry.

Results: TPH1 mRNA was expressed in both RA and OA-FLS. TPH1 mRNA expression was decreased significantly by DcR3 in RA-FLS, but not in OA-FLS. Meanwhile, TPH1 mRNA expression was significantly decreased by TNFα or IL-1β both in RA and OA-FLS. Immunohistochemistry confirmed that serotonin was present in multi-layered synovial lining cells.

Conclusion: In this study, we first revealed that TPH1 in RA-FLS was suppressed by DcR3 in a disease-specific fashion. Therefore, TPH1 in RA-FLS regulated by DcR3 may affect serotonin expression to be involved in the pathogenesis of RA, such as modulating inflammatory pain and bone remodeling. Both DcR3 and TPH1 could be a possible therapeutic target of RA.

1378

Associations Of Periodontitis (PD) With Established Seropositive Rheumatoid Arthritis are Independent of Smoking and Other Risk Factors. Ted R. Mikuls[1], Jeffrey Payne[2], Fang Yu[3], Geoffrey M. Thiele[3], Richard J. Reynolds[4], Grant W. Cannon[5], Jeffrey Markt[6], David McGowan[7], Gail S. Kerr[8], Robert Redman[9], Andreas M. Reimold[10], Garth Griffiths[10], Mark Beatty[2], Shawneen Gonzalez[2], Debra Bergman[6], Bartlett C. Hamilton III[11], Alan R. Erickson[12] and James R. O'Dell[6]. [1]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [2]University of Nebraska Medical Center, Lincoln, NE, [3]Univ of Nebraska Med Ctr, Omaha, NE, [4]University of Alabama at Birmingham, Birmingham, AL, [5]Salt Lake City VA and University of Utah, Salt Lake City, UT, [6]University of Nebraska Medical Center, Omaha, NE, [7]George E. Wahlen VA Medical Center, Salt Lake City, UT, [8]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [9]Washington DC VA, Georgetown and Howard University, Washington, DC, [10]Dallas VA and University of Texas Southwestern, Dallas, TX, [11]University of Nebraska Medical Center and Omaha VA Medical Center, Omaha, NE, [12]Omaha VA and University of Nebraska Medical Center, LaVista, NE.

Background/Purpose: Periodontitis (PD) has been proposed as a risk factor in RA. Reports have suggested that this association may be due to confounding from smoking, sicca syndrome, impaired oral hygiene, and HLA-DRB1 alleles (increased in rare forms of PD). Recent speculation has focused on the role of P. gingivalis (Pg), an oral pathogen with the unique capacity of citrullinating protein. We sought to examine the degree to which shared risk factors might explain or confound the relationship of PD with established RA.

Methods: RA cases (N=287) and osteoarthritis controls (N=330) underwent a standardized exam with PD defined using the criteria of Machtei et al (J Periodontol, 1990). The percentage of sites with supragingival plaque served as a measure of oral hygiene. HLA-DRB1 SE containing alleles were imputed using SNPs from the extended MHC. Anti-Pg antibody to outer membrane antigen (OMA) was measured using ELISA. Subgingival plaque was assessed for the presence of Pg using PCR. Anti-cyclic citrullinated protein (aCCP) antibody and RF were measured by ELISA and nephelometry, respectively. Associations of PD with RA (and aCCP positive RA) were examined using multivariable regression.

Results: Cases and controls were similar in all demographics assessed. PD was more common in RA (35%, p = 0.022) and aCCP positive RA (n=240; 37%; p = 0.006) vs. controls (26%). There were no RA-control differences in anti-Pg or the frequency of Pg positivity by PCR. Anti-Pg antibody showed weak but statistically significant associations with both aCCP (r=0.14, p=0.022) and RF (r=0.19, p=0.001). PD was associated with increased RA disease severity based on swollen joint count (p=0.004), DAS-28-CRP (p=0.045), total Sharp score (p=0.015), aCCP (p=0.011), and RF (p<0.001) levels. Associations of PD with established aCCP positive RA were independent of all covariates examined (with similar, albeit non-significant ORs observed in never smokers). In models not shown, associations were also independent of anti-Pg and Pg PCR status.

Table. Multivariable associations of PD with RA (Odds Ratios and 95% CIs)

	Full Cohort		Analysis Limited to Never Smokers	
	All RA	**aCCP pos. RA**	**All RA**	**aCCP pos. RA**
Periodontitis	1.36 (0.89, 20.6) P = 0.153	1.59 (1.01, 2.49) P = 0.043	1.37 (0.65, 29.1) P = 0.409	1.87 (0.82, 4.25) P = 0.157
HLA-DRB1 SE pos.	3.95 (2.68, 5.83) P < 0.001	5.32 (3.44, 8.22) P < 0.001	4.71 (2.55, 8.71) P < 0.001	7.01 (3.43, 14.32) P < 0.001
Ever smoking	1.93 (1.31, 2.83) P = 0.001	1.97 (1.29, 2.99) P = 0.002	—	—

*Full models not shown; covariates included age, gender, race, BMI, diabetes, marital status, oral dryness, oral hygiene, and education; MVmodels limited to participants reporting either Caucasian or African American race/ethnicity.

Conclusion: The relationship of PD with established aCCP positive RA does not appear to be driven by the prevalence of shared risk factors such as smoking or HLA-DRB1 SE nor does this relationship appear to be dependent on evidence of Pg infection. Defining the precise role that Pg plays in early disease evolution and mechanisms linking PD with more severe RA remain important knowledge gaps for future research.

Differential Effects Of TNF Inhibitors, Anti-IL-6 Receptor Antibody and CTLA4-Ig On Human Monocytes. Toshihiro Tono[1], Yoshiyuki Arinuma[2], Tatsuo Nagai[2], Sumiaki Tanaka[2] and Shunsei Hirohata[2]. [1]Kitasato University school of medicine, sagamihara, Japan, [2]Kitasato University School of Medicine, Sagamihara, Japan.

Background/Purpose: Biological agents inhibiting proinflammatory cytokines, especially IL-6 and TNFa, have brought a great impact in the treatment of rheumatoid arthritis (RA). In addition, CTLA4-Ig has been shown to have beneficial effects in the treatment of RA. Although several studies have disclosed the in vitro effects of biological agents on the immune competent cells, the precise mechanisms of action in RA remain unclear. On the other hand, abnormalities in monocytes have been shown to play an important role in the pathogenesis of RA. The current study was undertaken to explore the effects of etanercept, infliximab, tocilizumab and abatacept on human monocytes.

Methods: Monocytes, which were highly purified from peripheral blood from healthy donors using magnetic beads, were cultured in the presence of staphylococcal enterotoxin B (SEB) with pharmacologically attainable concentrations of various biological agents, control IgG (control for etanercept, infliximab, tocilizumab) or IgG Fc (control for abatacept). The induction of apoptosis of monocytes was evaluated by staining with annexin V and propidium iodide, followed by analysis on flow cytometry. The expression of CD80, CD86 and HLA-DR were also measured on flow cytometry. The concentrations of IL-6 and TNFα in the culture supernatants were measured using ELISA.

Results: All of etanercept, infliximab, abatacept and tocilizumab promoted apoptosis of SEB-stimulated monocytes. The induction of apoptosis of monocytes by these biological agents were reversed by addition of normal human IgG, but not by IgG F(ab)'$_2$ fragments (Figure). Of note, etanercept as well as infliximab significantly suppressed the expression of CD80, CD86 and HLA-DR on SEB-stimulated monocytes. By contrast, tocilizumab and abatacept suppressed only the expression of CD80, but neither CD86 nor HLA-DR. Finally, etanercept, infliximab, abatacept but not tocilizumab, suppressed the production of IL-6 and TNFα of SEB-stimulated monocytes.

Conclusion: These results demonstrate that all the biological agents, including TNF inhibitors, anti-IL-6 receptor antibody and CTLA4-Ig, have direct action on human monocytes, leading to the induction of apoptosis thereof, which involves interaction with Fc receptor on monocytes. Moreover, the data also indicate that these biological compounds display differential influences on various functions of monocytes, including the expression of costimulation molecules, HLA-DR and proinflammatory cytokines, depending on their interactions with different molecules on monocytes.

Histone Modifications In The Interluekin-6 Gene Promoter Region Of Rheumatoid Arthritis Synovial Fibroblasts. Takuma Tsuzuki Wada[1], Yasuto Araki[2], Kazuhiro Yokota[1], Fumihiko Miyoshi[1], Kojiro Sato[1] and Toshihide Mimura[2]. [1]Saitama Medical University, Saitama, Japan, [2]Research Center for Genomic Medicine, Saitama Medical University, Saitama, Japan.

Background/Purpose: Rheumatoid arthritis (RA) is a disease of unknown origin, which develops continuous inflammation and progressive joint destruction resulting from an autoimmune response mainly occurred in the joints. Although genetic factors in RA have been reported, another factors might be important for RA because of low concordance rate of monozygotic twins. Additionally, it is well known that environmental factors, for example smoking and infections, are involved in the pathogenesis of RA. Recently, epigenetic abnormalities in acquired chronic disorders including RA have been reported. DNA methylations, microRNAs, and histone modifications are major epigenetic abnormalities. DNA methylations and microRNAs in RA have been well characterized, however, evidences of histone modifications in RA are limited. Histone modifications are associated with gene transcriptions. In promoter regions of target genes, high-level histone acetylation and histone H3 lysine 4 trimethylation (H3K4me3) exist. One of the major pathological conditions in RA may be overproduction of interleukin (IL)-6 from RA synovial fibroblasts (SFs) stimulated by tumor necrosis factor (TNF)-alpha derived from activated macrophages. The purpose of this study is to clarify the relation of histone modifications in the IL-6 gene promoter region and IL-6 gene transcription in RASFs.

Methods: Synovial fibroblasts from the patients with RA and osteoarthritis (OA) as a control were harvested on the occasion of total knee arthroplasty in our hospital and were used for passages 4 through 8. Histone modifications (histone H3 acetylation (H3ac), H3K4me3) in the IL-6 gene promoter region were compared between RASFs and OASFs by chromatin immunoprecipitation (ChIP) assay. IL-6 mRNA and protein levels after stimulation with 10 ng/ml of TNF-alpha were detected using reverse transcription-polymerase chain reaction and enzyme-linked immunosorbent assay. Furthermore, we investigated how a treatment of histone acetyltransferase inhibitor (HATi) before stimulation with TNF-alpha had an influence on H3ac in the IL-6 gene promoter region and IL-6 mRNA in RASFs.

Results: IL-6 mRNA of RASFs were significantly increased compared with OASFs. In ChIP assay, both H3ac and H3K4me3 in the IL-6 gene promoter region of RASFs were significantly higher than those of OASFs. IL-6 mRNA and protein levels of RASFs were significantly increased more than those of OASFs after stimulation with TNF-alpha. Taken together, it is suggested that high levels of H3ac and H3K4me3 in the IL-6 gene promoter region of RASFs lead to be accessible for transcription factors to bind the region. In order to obtain more confirmed evidence of H3ac in the IL-6 gene promoter region in RASFs, we examined H3ac in the IL-6 gene promoter region and IL-6 mRNA of RASFs treated by HATi, curcumin. Both H3ac in the IL-6 promoter region and IL-6 mRNA of RASFs treated by curcumin were significantly reduced compared with those of untreated RASFs.

Conclusion: Histone modifications, especially high levels of H3ac and H3K4me3 in the IL-6 gene promoter region of RASFs, could be involved in a part of the pathogenesis in RA.

The *ZC3HC1* rs11556924 Polymorphism Is Associated With Increased Carotid Intima-Media Thickness In Patients With Rheumatoid Arthritis. Raquel lopez Mejias[1], Fernanda Genre[2], Mercedes García-Bermúdez[3], Alfonso Corrales[4], Carlos González-Juanatey[5], J. Llorca[6], Encarnación Amigo[7], Jose A. Miranda-Filloy[8], Javier Rueda-Gotor[1], Ricardo Blanco[1], Santos Castañeda[9], Javier Martin[10] and Miguel A. Gonzalez-Gay[2]. [1]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IFIMAV, Santander, Spain., Santander, Spain, [2]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IFIMAV, Santander, Spain, [3]Instituto de Parasitologia y Biomedicina López-Neyra, IPBLN-CSIC, Granada, Spain, [4]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain, [5]Cardiology Division, Hospital Lucus Augusti, Lugo, Spain, [6]Department of Epidemiology and Computational Biology, School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), Santander, Spain, [7]Division of Rheumatology, Hospital Lucus Augusti, Lugo, Spain, [8]Hospital Xeral-Calde, Lugo, Spain, [9]Hospital Universitario de La Princesa, IIS Princesa, Madrid, Spain, [10]Instituto de Parasitologia y Biomedicina Lopez-Neyra (IPBLN-CSIC), Granada, Spain.

Background/Purpose: Rheumatoid arthritis (RA) is a complex polygenic disease associated with chronic inflammation, accelerated atherosclerosis and increased cardiovascular (CV) mortality. A recent meta-analysis has described the *ZC3HC1* rs11556924 polymorphism as one of the most important signals associated with coronary artery disease (CAD) in non-rheumatic Caucasian individuals. In the present study we evaluated the potential association of this gene polymorphism with subclinical atherosclerosis assessed by the evaluation of carotid intima-media thickness (cIMT) in RA patients.

Methods: For this purpose 502 RA patients from Northern Spain were recruited in this study. The *ZC3HC1* rs11556924 polymorphism was genotyped with TaqMan single-nucleotide polymorphism (SNP) genotyping assays (C__31283062_10) in a 7900 HT real-time polymerase chain reaction (PCR) system. cIMT was also assessed in these patients by carotid ultrasonography (US) technology.

Results: RA patients carrying the TT genotype had significantly higher cIMT values than those homozygous for the CC genotype (mean $\pm$ standard deviation (SD): 0.76 $\pm$ 0.18 mm and mean $\pm$ SD: 0.71 $\pm$ 0.16 mm respectively; p=0.02). Moreover, RA patients carrying the mutant allele T exhibited significantly higher cIMT values than those carrying the wild allele C (mean $\pm$ SD: 0.74 $\pm$ 0.17 mm and mean $\pm$ SD: 0.71 $\pm$ 0.17 mm

respectively; p=0.02) even after adjusting the results for sex, age at the time of US study, follow-up time and traditional CV risk factors (p=0.019) evidencing that the effect conferred by *ZC3HC1* rs11556924 polymorphism is independent of the traditional CV risk factors.

Conclusion: Our results indicate that *ZC3HC1* rs11556924 polymorphism is associated with subclinical atherosclerosis in RA.

Background/Purpose: Rheumatoid arthritis (RA) is a complex polygenic inflammatory disease associated with accelerated atherosclerosis and high risk of cardiovascular (CV) disease. A recent meta-analysis has described the rs964184 polymorphism as one of the most important signals associated with coronary artery disease, increased LDL-cholesterol and decreased HDL-cholesterol levels in non-rheumatic Caucasian individuals. In the present study we assessed the potential association of this gene polymorphism with CV disease in RA.

Methods: 2160 Spanish patients with RA were genotyped for the rs964184 polymorphism. Three hundred and eighty-four (17.7%) of them had experienced CV events. The rs964184 polymorphism was genotyped with TaqMan single-nucleotide polymorphism (SNP) genotyping assays (C___8907629_10) in a 7900 HT real-time polymerase chain reaction (PCR) system.

Results: Sex (men), age at RA diagnosis and most traditional CV risk factors (diabetes mellitus, dyslipidemia and smoking habit) were associated with increased risk of CV events ($p<0.05$ in all the cases). Interestingly, when RA patients were stratified according to the presence or absence of CV disease after adjusting for sex, age at RA diagnosis, and traditional CV risk factors, we observed that RA patients carrying the rs964184 GG genotype had significantly higher risk of CV events than those with CC genotype (HR = 2.91, 95% CI: 1.36 – 6.26, p = 0.006).

Conclusion: Our results indicate that rs964184 polymorphism is associated with CV disease in RA.

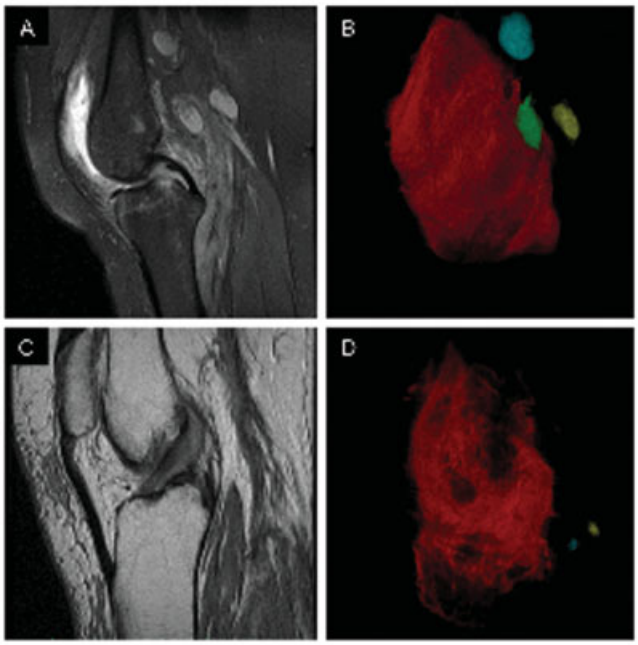
Validation Of Popliteal Lymph Node Phenotype and Bin Expansion As Biomarkers Of Rheumatoid Arthritis Knee Flare. Homaira Rahimi[1], Ronald Wood[2], Igor Kuzin[1], Wakenda Tyler[1], Gregory Dieudonne[1], Stephen Kates[2], Christopher T. Ritchlin[1] and Edward M. Schwarz[1]. [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY.

Background/Purpose: Factors precipitating joint flare in rheumatoid arthritis (RA) patients are poorly understood. Contrast enhanced (CE) MRI studies in murine models have identified popliteal lymph node (PLN) phenotypes that correlate with arthritic flare in the adjacent knee defined by a sudden increase in synovial volume and focal erosions. Prior to flare, the PLN expands in size and CE due to increased lymph volume and accumulation of $CD23^{+}CD21^{hi}CD1d^{hi}$ B cells (Bin). Arthritic flare following PLN collapse is characterized by decreased CE and translocation of Bin to the paracortical sinuses with loss of efferent lymphatic drainage. To validate lymphatic biomarkers in RA, we performed pilot studies to demonstrate the feasibility of detecting expanding and collapsed PLN via CE-MRI. We analyzed PLN from RA patients undergoing total knee replacement or amputation for ischemic limbs in patients without RA.

Methods: RA patients experiencing knee flare had a 3T CE-MRI prior to initiation of biologic therapy. PLN and synovial volumes were measured with Amira. PLN from RA patients and amputees were harvested, cells were stained and examined by flow cytometry.

Results: MRI and 3D volume rendering of a representative flaring knee from early vs. long-standing RA (Fig. 1) show evidence of expanding PLN (n=3; 3.57, 1.23, 2.2 cm^3) adjacent to highly vascular synovitis (203.40 cm^3). In contrast, knee flare in long-standing RA (>30yrs) presents with collapsed PLN (n=2; 0.24, 0.16 cm^3) adjacent to pannus (159.88 cm^3) that contains both bright (vascular) and dark (necrotic) regions on MRI. Flow cytometry confirmed large numbers of Bin-like cells ($CD23^{hi}CD21^{hi}$) in RA vs. non-RA PLN. Clinical endpoints measured by disease activity score (25% improvement) and C-reactive protein levels (40% decrease) preliminarily show a correlation between effective therapy and CE-MRI changes.



Conclusion: We present evidence that similar to murine inflammatory arthritis, knee flare in RA is modulated by altered dynamics of draining lymph nodes and lymphatic vessels. We found that the flare in early arthritis is characterized by extensive joint inflammation that appears to exceed the capacity of expanded lymphatics. In contrast, knee flare in long-standing arthritis is associated with loss of lymphatic drainage, which in mice, is caused by loss of the lymphatic pulse and clogging of efferent lymphatics by Bin cells. Additional studies are warranted to demonstrate the reliability of these findings of knee flare in early vs. chronic RA. Figure 1. Representative images of MRI and corresponding 3D rendering from RA patients with knee flare shows inflamed synovium with bright PLN in the T2 fat-suppressed MRI

(A) and uniform inflammatory tissue and large PLN (B) in early RA. In contrast, note the marked focal erosions in the proton density weighted MRI (C) and patchy synovium with collapsed PLN (D) in long-standing RA.

Estimation Of The Effect Of Denosumab On Bone Loss From The Results Of The 12-Month Phase II Study In Patients With Rheumatoid Arthritis (RA) On Background Methotrexate (MTX). Yoshiya Tanaka[1], Tsutomu Takeuchi[2], Naoki Ishiguro[3], Hisashi Yamanaka[4], Toshiyuki Yoneda[5], Harry K. Genant[6] and Désiréé van der Heijde[7]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Keio University, Tokyo, Japan, [3]Nagoya Univeristy Graduate School of Medicine, Nagoya, Japan, [4]Tokyo Women's Medical University, Tokyo, Japan, [5]Indiana University School of Medicine, Indianapolis, IN, [6]University of California, San Francisco, CCBR-Synarc, Newark, Tiburon, CA, [7]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: RANKL is an essential factor for osteoclast differentiation and activation. Denosumab, a fully human monoclonal IgG_2 antibody, is a potent inhibitor of RANKL and osteoclastgenesis. In this study, the pathological effect of denosumab was investigated with efficacy on bone turnover and structural damage in Japanese patients with RA receiving MTX.

Methods: The 12-month, multicenter, randomized, double-blind, placebo-controlled, phase II study included 4 treatment groups; denosumab 60 mg every 6 mos (Q6M), 3 mos (Q3M), or 2 mos (Q2M) or placebo. Daily supplements of vitamin D (≥400 IU) and calcium (≥600 mg) were taken concomitantly in all groups. Bone mineral density (BMD) of the lumbar spine (L1 to L4) and total hip (including the femoral neck) were measured by dual energy X-ray absorptiometry at 0, 6 and 12 mos. Serum CTX-I and P1NP, and urinary CTX-II were collected at 0, 1, 2, 3, 4, 6 and 12 mos. Bisphosphonates treatment was prohibited throughout the study.

Results: Of the 350 pts enrolled, 346 pts received treatment and 35 pts were discontinued; placebo n=6; Q6M, n=8; Q3M, n=13; and Q2M, n=8. Demographic and clinical characteristics were comparable between groups (Table 1).

Table 1. Demographic and clinical characteristics of enrolled pts

		Denosumab 60mg			
	Placebo (N = 88)	Q6M (N = 85)	Q3M (N = 82)	Q2M (N = 85)	All (N = 340)
Female, n (%)	76 (86.4)	65 (76.5)	59 (72.0)	66 (77.6)	266 (78.2)
Age, mean (SD), years	57.0 (10.6)	54.4 (10.6)	52.0 (11.7)	54.6 (10.5)	54.5 (10.9)
Disease duration, mean (SD), years	2.3 (1.3)	2.2 (1.3)	2.3 (1.3)	2.3 (1.4)	2.3 (1.3)
Osteoporosis, n (%)	23 (26.1)	12 (14.1)	10 (12.2)	12 (14.1)	57 (16.8)
Glucocorticoid use, n (%)	37 (42.0)	36 (42.4)	37 (45.1)	37 (43.5)	147 (43.2)

Significant increases of BMD in lumbar spine and total hip at month 12 were demonstrated in the RA pts treated with denosumab, including the pts with concomitant glucocorticoid use (Table 2).

Table 2. Difference between denosumab and placebo in percent change from baseline in lumbar spine (L1–L4) and total hip BMD at month 12

	Denosumab 60mg		
Percent change difference from placebo	Q6M (N = 78)	Q3M (N = 72)	Q2M (N = 79)
Lumbar spine (L1–L4)			
Least squares means (SE)[a]	4.62 (0.47)	5.35 (0.48)	6.30 (0.47)
95% confidence interval[a]	3.70, 5.53	4.41, 6.29	5.38, 7.23
P-value[a]	<0.0001	<0.0001	<0.0001
Total hip			
Least squares means (SE)[a]	3.32 (0.38)	3.28 (0.38)	3.51 (0.38)
95% confidence interval[a]	2.58, 4.06	2.53, 4.04	2.77, 4.26
P-value[a]	<0.0001	<0.0001	<0.0001

a: Based on repeated measures model adjusting for treatment, visit, baseline BMD, randomized strata (4 strata from the combination of baseline glucocorticoid use and baseline rheumatoid factor) and treatment-by-visit interaction.

Markers of bone resorption and bone formation, CTX-I and P1NP, respectively, were decreased by denosumab treatment. These results correspond with significant increases in BMD and suppression of progression of RA in patients treated with denosumab for 12 mos. Denosumab treatment rapidly reduced CTX-II with sustained levels in a dose dependent manner (Figure 1).

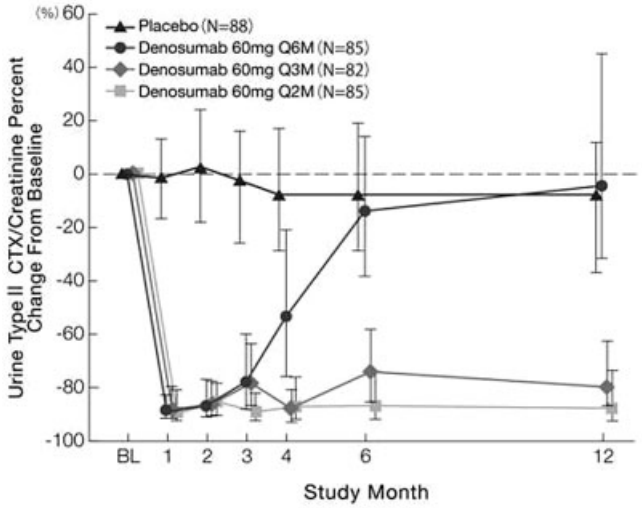

Figure 1. Percent change from baseline for CTX-II/creatinine

Conclusion: Significant increases in BMD were observed after 12-mo denosumab treatment in comparison to placebo in patients with RA regardless of glucocorticoid use. Denosumab inhibits the activation and survival of osteoclasts, which leads to the reduced bone turnover and reduction of bone resorption. Furthermore, suppression was evident in marker of cartilage metabolism, CTX-II, suggesting an effect of denosumab on cartilage turnover.

1385

A Study Of Natural Killer Cell Subfractions In Abatacept Therapy For Rheumatoid Arthritis. Masao Sato[1], Masao Takemura[1], Ryuki Shinohe[1], Yasuko Yamamoto[2] and Kuniaki Saito[2]. [1]Gifu University, Gifu, Japan, [2]Kyoto University, Kyoto, Japan.

Background/Purpose: Inflammatory cytokines and cell-mediated immunity function of mainly lymphocytes are complicatedly involved in disease onset of rheumatoid arthritis (RA). Recently, together with biologicals such as tumor necrosis factor-alpha (TNF-α) inhibitor and interleukin-6 (IL-6) inhibitor, which block the signal transduction into cells via cytokine, T-cell costimulatory modulator (Abatacept, ABT), which uses mechanism of cytotoxic T-Lymphocyte Antigen 4 (CTLA4) as cell auxiliary signal molecule that frequently develops on the membrane with activated T lymphocytes, has been used to treat RA. In this study, we examined the impact of treatment with ABT on a subfraction of natural killer (NK) cells (CD57) in peripheral blood.

Methods: The subjects were 32 RA patients treated with ABT (6 men and 26 women; aged 39 to 81 years, mean 62). The duration of disease was 10.0 ± 7.9 years (1 to 30 years). Eight, 14, and 10 patients had stage II, III, and IV RA, respectively. Of these, 16 biological-naïve patients and 16 patients who had received other biologicals were included. Blood samples were collected before each administration at 0 week (before treatment), and at 4, 12, 24, and 52 weeks. The changes in CD8+/CD57, CD8+/CD11b+, and CD4+/CD25+, which were demonstrated by double-staining with fluorescein isothiocyanate and phycoerythrin, were assessed by flow cytometry.

Results: Lymphocyte subset (%) according to the stage at the induction of ABT was as follows (mean ± SE). For CD8+/CD11b+, 13.2 ± 1.8, 15.7 ± 2.2, and 22.0 ± 3.1 in patients with stage II, III, and IV, respectively. For CD8+/CD57+, 12.9 ± 1.9, 18.0 ± 3.1, and 19.5 ± 3.9 in patients with stage II, III, and IV, respectively; higher values were observed in patients with advanced stage, although there was no statistically significant difference among the stages. For CD8+/CD57+, 26.9 ± 2.9, 25.4 ± 2.5, and 26.3 ± 3.1 in the patients with stage II, III, and IV, respectively; there was no substantial difference among the stages. The change between the value before treatment with ABT and that at the 52nd week was as follows: for CD8+/CD11b+, 16.7 ± 1.6 and 12.1 ± 1.1, $p < 0.02$; for CD8+/CD57+, 16.9 ± 1.9 and 10.2 ± 1.1, $p < 0.004$; both values were significantly decreased after 52 weeks. For CD4+/CD25+, 26.4 ± 1.6 and 28.1 ± 1.6; although the value increased at 52 week, there was no significant difference. However, CD4+/CD25+high cells were decreased gradually until the 52nd week in the biological-naïve patients, but were increased from the 12th week after administration in patients receiving ABT switched from other biologicals.

Conclusion: In this study, CD8+/CD57 and CD8+/CD11b+ before treatment tended to be higher as the stage of RA advanced. This tendency was maintained after 52 weeks. The values were decreased for 52 weeks in each patient. The proportion of D8+/CD57 and CD8+/CD11b may reflect the therapeutic effect of ABT. It is not known whether the changes in CD4+/CD25+high cells observed in the patients receiving ABT switched from other biologicals indicated cell activation or showed the dynamics of auto-regulatory cells such as regulatory T cells.

Intracellular Concentration Of Methotrexate Is Influenced By Polymorphisms Of Gamma-Glutamyl Hydrolase Gene In Japanese Patients With Rheumatoid Arthritis. Tatsuhiro Yamamoto, Mai Kawazoe, Emiko Shindo, Natsuki Fujio, Kotaro Shikano, Kanako Kitahara, Sei Muraoka, Makoto Kaburaki, Nahoko Tanaka, Kaichi Kaneko, Natsuko Kusunoki, Yoshie Kusunoki, Kenji Takagi, Tomoko Hasunuma, Hirahito Endo and Shinichi Kawai. School of Medicine, Faculty of Medicine, Toho University, Tokyo, Japan.

Background/Purpose: Methotrexate (MTX) is an anchor drug for treatment of rheumatoid arthritis (RA). Appropriate effective and/or tolerable doses of weekly pulse MTX therapy vary widely among RA patients, especially in different countries. MTX is intracellularly converted to polyglutamate compounds (MTX-PGs) being active forms by several transporters and enzymes. Although genetic polymorphisms of enzymes such as dihydrofolate reductase and methylenetetrahydrofolate reductase have been studied in patients with malignant lymphoma, relationships between the genetic conditions of these enzymes and intracellular MTX-PGs or also clinical responses in RA patients were not cleared yet. We then investigated genetic polymorphisms of solute carrier family 19 member 1 (SLC19A1), a transporter protein of MTX into cells, and gamma-glutamyl hydrolase (GGH), an enzyme that has the capacity to cleave gamma-glutamyl bonds from MTX-PGs.

Methods: Two hundred and seventy-three RA patients (Mean±SD; 58.3±9.8 y.o.) undergoing stable oral doses of weekly pulse MTX (8.9±2.6 mg/week) for at least more than 3 months were inclued in this study. MTX-PGs concentration in red blood cells (RBCs) was measured by TDX analyzer (Abbott, IL) after extraction and purification from RBCs. The polymerase chain reaction-restriction fragment length polymorphism assay was applied to determine the genotypes of *SLC19A1* and *GGH*.

Results: Mean concentration of MTX-PGs in RBCs of 273 patients was 108±12 nmol/L. Mean concentration in the patient group receiving different doses of MTX was increased in a dose-dependent manner, however, individual MTX-PGs concentration was widely distributed among patients. MTX-PGs concentration was then devided by weekly MTX dose to exclude the influence of doses. The adjusted MTX-PGs values revealed a tendency of constant levels among the different dose groups. Results of minor allele frequencies of *SLC19A1* and *GGH* in our Japanese RA patients were shown in the Table. Adjusted MTX-PGs (11.70±6.70 nmol/L/mg) in patients with at least either one of 3 *GGH* variants (−401C>T, −354G>T, or 16T>C) was significantly ($p<0.03$) increased, when compared to that (9.88±6.24 nmol/L/mg) in patients with wild types of these genes. Adjusted MTX-PGs in patients with other *SLC19A1* and/or *GGH* gene variants was not changed from that in patients with wild types of these genes.

Table 1. Minor allele frequencies of *SLC19A1* and *GGH* genes in our Japanese RA patients

SNPs		No. of rs	Minor Allele Frequency
SLC19A1	80G > A	rs1051266	0.698/0.302
GGH	−401C > T	rs3758149	0.799/0.201
	−354G > T	rs719235	0.892/0.108
	16T > C	rs1800909	0.850/0.150
	452C > T	rs11545078	0.952/0.048
	14269G > A	rs12681874	0.638/0.362

Conclusion: GGH may play an important role in regulation of the intracelluler MTX-PGs. Since intracellular MTX-PGs level is known as a surrogate marker of the efficacies and/or adverse responses of MTX, measurement of the *GGH* polymorphisms may predict clinical responses to MTX therapy.

Reversing Vascular Dysfunction In Rheumatoid Arthritis: Peroxisome Proliferator-Activated Receptor Gamma Agonist Therapy Improves Augmentation Index But Not Endothelial Function. Michelle J. Ormseth, Aihua Bian, Annette M. Oeser, Andrew Cunningham, Ayumi Shintani, S. Bobo Tanner and C. Michael Stein. Vanderbilt Medical Center, Nashville, TN.

Background/Purpose: Rheumatoid arthritis (RA) is associated with insulin resistance and increased cardiovascular (CV) risk. Impaired vascular function, including arterial stiffness and endothelial dysfunction, is associated with insulin resistance and is an important CV risk factor. Pioglitazone, a thiazolidinedione PPAR-γ agonist insulin sensitizing drug, decreased CV risk in diabetes, but little is known about its CV effects in RA. We examined the hypothesis that treatment with pioglitazone would improve vascular function in RA patients.

Methods: We performed a 20-week, single center, randomized, double-blind, placebo-controlled, cross-over study. Patients with RA (n=34) and moderate disease activity on stable disease modifying anti-rheumatic drug therapy were randomized to drug sequence, receiving either pioglitazone 45mg daily or matching placebo for 8 weeks separated by a 4-week washout period and the alternative treatment for 8 weeks. We measured change in augmentation index, aortic pulse wave velocity, reactive hyperemia index, and blood pressure. High sensitivity C-reactive protein (CRP), and the homeostatic model assessment of insulin resistance (HOMA) were also measured. Intention-to-treat analysis and linear mixed-effects models were used to determine the treatment effect of pioglitazone.

Results: Pioglitazone reduced augmentation index by −4.7% units (95% CI, −7.9, −1.5% units) P=0.004 and diastolic blood pressure by −3.0 mmHg (−5.7, −0.2 mmHg) P=0.03, but did not significantly change aortic pulse wave velocity (P=0.33), reactive hyperemia index (P=0.46) or systolic blood pressure (P=0.45). The improvement in augmentation index and diastolic blood pressure were not mediated by pioglitazone's effect on insulin resistance (HOMA) or inflammation (CRP).

Conclusion: Pioglitazone improves some indices of vascular function, including augmentation index and diastolic blood pressure in patients with RA.

Multiplex Cytokine Analyses In Patients With Rheumatoid Arthritis Require Use Of Agents Blocking Heterophilic Antibody Activity. Peter Olsson[1], Elke Theander[1], Ulf Bergström[1], Stefan Jovinge[2], Lennart Jacobsson[1] and Carl Turesson[1]. [1]Lund University, Malmö, Sweden, [2]Lund University, Lund, Sweden.

Background/Purpose: Rheumatoid factor (RF) and other circulating heterophilic antibodies have been shown to interfere with antibody-based immunoassays, in particular with multiplex protein detection platforms. Previous studies have suggested that available blocking agents reduce such erroneous signal amplifications. The purpose of the present study was to develop a protocol for multiplex cytokine analyses using standardized blocking procedures in patients with rheumatoid arthritis (RA), and to test this protocol in samples derived from patients with active RA who were started on adalimumab therapy.

Methods: Analyses of cytokines in peripheral blood samples was performed using a custom made 12-plex kit (Bioplex®, Bio-Rad). Samples were obtained from patients with known high levels of serum RF, as well as from healthy controls. Based on the literature (Todd et al. Arthritis Rheum 2011; 63: 894–903), various concentrations of Heteroblock®, an agent that is known to block heterophilic binding activity, were added. In controls, including sera from healthy controls spiked with a cytokine mix (Bio-Rad), the results were stable regardless of the concentration of Heteroblock®. The optimal blocking concentration was determined based on analyses of patients with high levels of RF.

Furthermore, we investigated cytokine levels in 14 patients with active RA [11 females; mean age 63.7 years; median RA duration 9.0 years; 78 % RF positive; mean DAS28: 5.6], who were started on treatment with adalimumab 40 mg subcutaneously every two weeks. In the present pilot study, data on interleukin (IL)-6, IL-7 and IL-8 are reported.

Results: In patients with RA and high RF levels, there was a major effect on the measured signal from adding the blocking agent, with some differences across analytes and across individuals. In analyses using multiple concentrations of Heteroblock®, a higher optimal concentration than previously described was found and used in subsequent investigations.

In the 14 patients treated with adalimumab, the median impact of blocking on the estimated cytokine concentration was 39 % of the unblocked value for IL-6, 13 % for IL-7 and 9 % for IL-8. In analyses of baseline samples from patients in the adalimumab study with no blocking agent added, there was no significant correlation between IL-6 and CRP ($r=0.19$; $p=0.51$). By contrast, in baseline samples exposed to optimal concentration of the blocking agent, there was a significant correlation between IL-6 and CRP ($r=0.65$; $p=0.01$). The decrease in IL-6 from baseline to three months after adalimumab initiation correlated with the decreases in ESR ($r=0.89$; $p=0.02$) and CRP ($r=0.77$; $p=0.07$), with a similar trend for DAS28 ($r=0.32$; NS). IL-7 and IL-8 did not correlate with disease severity parameters.

Conclusion: These results support the concept that agents blocking heterophilic antibody activity should be used and systematically evaluated in immunoassays involving multiplex protein detection platforms. In analyses using optimized concentrations of the blocking agent, IL-6 levels correlated with baseline markers of inflammation, and changes of IL-6 correlated with clinically important measures of reduced inflammation in patients treated with adalimumab.

Serum 14-3-3η Precedes and Independently Predicts The Development Of RA. Dirkjan van Schaardenburg[1], Reetinder Dhaliwal[1], Walter P. Maksymowych[2] and Anthony Marotta[3]. [1]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [2]University of Alberta, Edmonton, AB, [3]Augurex Life Sciences Corp, North Vancouver, BC.

Background/Purpose: We have previously reported on a risk prediction rule for the development of rheumatoid arthritis (RA) in 374 seropositive (RF and/or ACPA) arthralgia patients, incorporating such variables as a first degree relative with RA, alcohol consumption and ACPA status. Serum 14-3-3η is a new marker that complements ACPA/RF in the diagnosis of RA. In this study, we investigated whether 14-3-3η is present in the serum of subjects prior to the onset of RA and whether its expression is useful as a predictor of RA development.

Methods: Serum 14-3-3η protein levels at study entry were measured in 40 seropositive arthralgia subjects, selected on the basis of twenty (20) subjects developing RA within 4 years from study entry, and the other half not. 14-3-3η positivity was defined as >0.19 ng/ml. Twenty-eight (28) of the 40 subjects were ACPA positive, 26 were RF positive, and 16 were positive for both markers. Contingency and logistic regression analyses were performed to determine if 14-3-3η positivity was independently associated with RA development and whether titres of ACPA, 14-3-3η and RF could strengthen its prediction.

Results: Eleven (11) of the 40 subjects were seropositive for the 14-3-3η protein, 9 (82%) of which developed RA, and of the 29 who were 14-3-3η negative, 18 (62%) did not develop RA. Similar to our findings in the larger cohort, ACPA positivity was associated with the development of RA with a Likelihood Ratio (LR) of 17.3, $p < 0.01$ while RF positivity was not. Contingency analysis revealed that 14-3-3η positivity was an independent predictor of RA development delivering an LR of 6.5, $p = 0.01$, an Odds Ratio (OR) of 7.4 $p < 0.01$ (95%CI, 1.3 – 40.6) and a Relative Risk (RR) of 2.2 (95%CI, 1.3 – 3.7). Consistent with previously published findings, median ACPA levels were significantly higher in 14-3-3η positive versus 14-3-3η negative subjects [312 IU/ml (IQR, 155 – 1403) versus 113 IU/ml (IQR, 1 – 735), $p = 0.05$]. RF titres did not differ significantly between these two groups. The predictive value of 14-3-3η positivity was strengthened through the addition of actual 14-3-3η titres yielding an OR of 17.1, $p < 0.009$ (95%CI, 1.9 – 660.2). Since ACPA titres were also significantly different between 14-3-3η positive and negative subjects, adding the actual ACPA titres to the model further strengthened the predictive power of 14-3-3η positivity delivering an OR of 21.5, $p < 0.008$ (95%CI, 2.0 – 981.2).

Conclusion: 14-3-3η expression precedes the onset of RA and its presence is strongly associated with the development of RA. The predictive power of positive 14-3-3η status was further strengthened by the addition of 14-3-3η and ACPA titres to the model. A larger study is underway to investigate 14-3-3η as a diagnostic biomarker to screen seropositive arthralgia patients for the risk of developing RA.

Chaperonin Protein 14-3-3n (eta) In Rheumatoid Arthritis and Arthritogenic Viral Infections. Stanley J. Naides, Olga S Zhukov, Rania W Abolhosn and Joanna M Popov. Quest Diagnostics Nichols Institute, San Juan Capistrano, CA.

Background/Purpose: The 14-3-3 proteins are ubiquitously-expressed intracellular chaperonins. Expression of the η (eta) isoform is restricted to synovial and CNS tissues. Extracellular 14-3-3η induces proinflammatory MAPK and NFkB cascades in THP-1 cells *in vitro*. Extracellular 14-3-3η has been proposed as a novel biomarker for joint damage in rheumatoid arthritis (RA) and psoriatic arthritis, with serum elevation occurring in early RA. 14-3-3η positivity may add diagnostic sensitivity to laboratory RA markers such as rheumatoid factor (RF) and citrullinated cyclic peptide antibody (CCP). However, 14-3-3η expression in arthritogenic viral infection has not been studied. The aim of this study was to determine the frequency of elevated 14-3-3η in patients with RA and in those with HCV, acute EBV, or acute B19 infections.

Methods: We developed a quantitative 14-3-3η sandwich ELISA and verified the reference range using 134 serum specimens from healthy donors (67 males, 67 females; ages 18–65). 14-3-3η was measured in de-identified residual clinical specimens originally submitted for routine RA or infectious disease diagnostic testing.

Results: The 14-3-3η 95th-percentile reference range was defined as <0.2 ng/mL and the reportable range was <0.2 to >20.0 ng/mL. Six healthy subjects (4%) had elevated 14-3-3η levels; 2 of them were weakly RF positive. RF+/CCP+ subjects had the highest frequency of elevated 14-3-3η (56%) and the highest 14-3-3η median level (Table). Frequency of elevated 14-3-3η was lower in the RF+/CCP- and virus-infected groups. None of the RF-/CCP+ subjects had elevated 14-3-3η, but the number of subjects was small (n=10). The frequency of elevated 14-3-3η in the RF-/CCP- group was 5%. Of 23 subjects with elevated 14-3-3η in the HCV group, 1 was RF+/CCP+, 13 RF+/CCP-, and 9 RF-/CCP-. Of 6 subjects with elevated 14-3-3η in the EBV group, 1 was RF+/CCP+, 2 RF+/CCP-, and 3 RF-/CCP+. All 5 subjects with elevated 14-3-3η in the B19 group were RF-/CCP-.

Subject Group	n	Number with Elevated 14-3-3η (%)	Median Abnormal 14-3-3η Value (Interquartile Range) (ng/mL)
Healthy	134	6 (4%)	1.19 (0.66–4.61)
RF+/CCP+	43	24 (56%)	4.37 (0.66–8.24)
RF+/CCP-	131	20 (15%)	0.73 (0.39–1.15)
RF-/CCP+	10	0 (0%)	NA
RF-/CCP-	305	14 (5%)	0.54 (0.33–0.73)
HCV (RIBA)+	162	23 (14%)	0.46 (0.29–1.21)
EBV VCA IgM+	101	17 (17%)	0.44 (0.33–1.54)
B19 IgM+	34	5 (15%)	0.26 (0.20–0.72)

Conclusion: 14-3-3η elevation was most frequent among patients with RF+/CCP+ results (consistent with an RA diagnosis). The data suggest that RA and some HCV, EBV, and parvovirus B19 infections may share pathogenetic mechanisms characterized by synovial release of 14-3-3η. Of note, the median abnormal 14-3-3η level was higher in the RF+/CCP+ group than in the virus-infected groups. This suggest less synovitis in viral arthritis than in RA, consistent with clinical observations.

Transporters As Drug Gateway Into The Cell For Specific Targeting Of Tyrosine Kinase Signaling Pathway In Rheumatoid Arthritis. Saliha Harrach[1], Christian Schmidt-Lauber[1], Bayram Edemir[2], Eberhard Schlatter[1], Thomas Pap[1], Giuliano Ciarimboli[1] and Jessica Bertrand[1]. [1]University Hospital Münster, Münster, Germany, [2]University Hospital Münster, Muenster, Germany.

Background/Purpose: Tyrosine kinase inhibitors (TKI) are effective in treating malignant disorders and were suggested to also have an impact on non-malignant diseases such as rheumatoid arthritis (RA). To exert their effect hydrophilic TKI are actively accumulated in target cells by membrane transporters, a process which is known to govern drug efficiency. This study aims to evaluate the importance of this process for TKI delivery in inflammatory diseases and its pathology induced regulation at the example of the treatment of RA with the SRC kinase inhibitor Saracatinib (AZD0530). Since Saracatinib is an organic cation and fibroblasts are major players in RA-development, we focused on its interaction with transporters for organic cations (OCTs) in human RA synovial fibroblasts (hRASF).

Methods: Saracatinib transport was investigated in OCT-transfected HEK293 cells and hRASF by HPLC detection of Saracatinib accumulation. The anti-proliferative effect of Saracatinib on PDGF stimulated hRASF was quantified by cell counting. Saracatinib transport under disease-relevant conditions like an altered pH milieu, following stimulation with TNF-α and in the presence of specific transporter inhibitors was quantified by HPLC. Gene expression analysis for OCTs with and without TNF-α was performed using quantitative RT-PCR.

Results: Saracatinib demonstrated concentration dependent inhibition of hRASF cell proliferation at sub-micromolar levels. In transfection experiments, hOCTN1 (organic cation transporter, novel, type 1) showed the highest apparent affinity (IC50 = 72 nM) for Saracatinib among the OCTs. Experiments quantifying the Saracatinib uptake in the presence of specific inhibitors identified hOCTN1 as mediator of the uptake in hRASF. This uptake was significantly reduced by an acidic extracellular pH as present in the inflamed joints of patients with rheumatoid arthritis. The stimulation with TNF-α enhanced Saracatinib uptake in hRASF by increasing hOCTN1-mRNA expression.

Conclusion: The uptake of Saracatinib in hRASF via hOCTN1 is regulated by the pH and RA associated pro-inflammatory cytokines. pH alterations and cytokine levels (TNF-α) as present in RA enhance the effective Saracatinib concentration in hRASF. Our results suggest that investigating transporter mediated drug processing is important for developing intracellularly acting drugs used in inflammatory diseases (supported by IMF of the Medical Faculty Münster, BE121009).

The Expression Of Proto-Oncogene Survivin Splicing Variant 2B In Synovial Tissues and Blood From Patients With Rheumatoid Arthritis. Sho Mokuda[1], Tatsuhiko Miyazaki[2], Junya Masumoto[2], Masamoto Kanno[3] and Kiyoshi Takasugi[4]. [1]Center for Rheumatic Diseases, Dohgo Spa Hospital, Matsuyama, Japan, [2]Ehime University Graduate School of Medicine, Toon, Japan, [3]Graduate School of Biomedical Sciences, Hiroshima University, Hirosima, Japan, [4]Dohgo Spa Hospital, Matsuyama, Japan.

Background/Purpose: It has been reported that serum survivin level was an independent risk factor for predicting joint destruction in early rheumatoid arthritis (RA). The proto-oncogene *BIRC5* generates alternative splicing variants, including wild-type (WT) survivin, survivin 2B, survivin delta-Ex3, survivin 3B and survivin 2-alpha. We herein examined which variants of survivin were expressed in the synovial tissues and blood samples of patients with RA and osteoarthritis (OA).

Methods: We observed the expression of survivin splicing variants in synovial tissues by the real-time PCR and immunohistochemistry (IHC) analyses, and serum survivin 2B was measured with enzyme-linked immunosorbent assay (ELISA). Moreover, to determine the effects of survivin splicing variants in fibroblasts, cell viability and chemosensitivity of an anti-metabolite were evaluated by overexpression experiments in a fibroblast model with the MTS and LDH assays.

Results: We found that three types of splicing variant (WT survivin, survivin 2B and survivin delta-Ex3) were expressed in RA and OA synovial tissues by RT-PCR, and the WT survivin and survivin 2B mRNA expression levels in RA synovial tissues were higher than those in OA patients by real-time PCR (6 RA cases vs. 6 OA cases) ($p=0.010$ and 0.016, respectively). On the other hand, there was no significant difference in the survivin delta-Ex3 expression levels between the RA and OA synovial tissues ($p=0.150$) (Figure 1). In the IHC analyses, survivin delta-Ex3 was expressed in both RA and OA synovial tissues, while survivin 2B was strongly expressed in RA tissues and hardly expressed in OA tissues. In addition, the serum survivin 2B levels of RA patients were higher than those of OA patients and healthy controls (40 RA cases vs. 16 OA + controls cases) (mean 17.9 μg/ml vs. 6.1 μg/ml, $p=0.019$). Furthermore, double staining by IHC revealed that survivin and CD55 merged, so survivin was mainly expressed in synovial fibroblasts. Transfection experiments revealed that survivin delta-Ex3-overexpressing fibroblasts were fast-growing and their sensitivity to anti-metabolites was elevated compared with that of fibroblasts transfected with a vector plasmid. On the other hand, survivin 2B-overexpressing fibroblasts were fast-growing, but their sensitivity to anti-metabolites was not elevated compared with that of fibroblasts transfected with a vector plasmid.

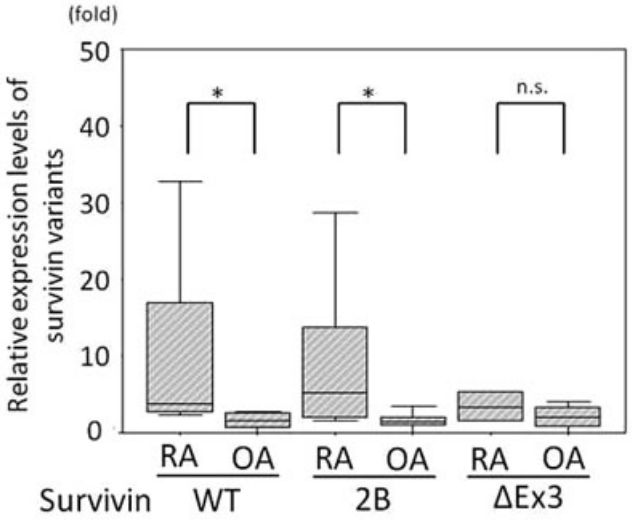

Figure 1. Relative expression levels of survivin splicing variants in synovial tissues from RA and OA. Results were presented relative to expression of the housekeeping gene Hprt. * Mann-whitney U test, $p<0.05$.

Conclusion: The expression of survivin 2B in synovial tissue and serum samples was a specific biomarker of RA. In addition, survivin

2B-expressing fibroblasts were associated with proliferation and resistance to an anti-metabolite. Therefore, survivin 2B is a RA-specific molecule and might contribute to the rheumatoid synovial hyperplasia.

1393

Survivin But Not Fms-Like Tyrosine Kinase Ligand Is Up-Regulated Before Onset Of Rheumatoid Arthritis. Mikael Brink[1], Maria Bokarewa[2], Malin Erlandsson[2] and Solbritt Rantapää Dahlqvist[3]. [1]Umeå University, Umea, Sweden, [2]Göteborgs University, Göteborg, Sweden, [3]Umeå University Hospital, Umeå, Sweden.

Background/Purpose: Presence of antibodies against citrullinated peptides (anti-CCP2) and increased levels of cytokines and chemokines precedes the development of rheumatoid arthritis (RA) by several years. Recently, the proteins survivin and Fms-like tyrosine kinase 3 ligand (Flt3L) have been associated with RA and RA associated joint damage. The objective with this study was to investigate the potential of survivin and Flt3L as predictors of RA and their relationships to cytokines and anti-CCP antibodies in blood samples from individuals before onset of symptoms of RA.

Methods: This study includes 47 individuals sampled before onset of symptoms of RA (median 2.5 years (IQR 1.1–5.6) and 155 population controls matched for sex and age, all donors to the Medical Biobank of Northern Sweden. 36 of the pre-symptomatic individuals were also sampled at the time of RA diagnose (ACR criteria 1987). Levels of survivin and Flt3L were measured using sandwich ELISAs (both, R&D Systems, Minneapolis, MN). Anti-CCP antibodies was analyzed using ELISA (Euro-Diagnostica AB, Malmö, Sweden) and 29 cytokines, and chemokines (IL-1β, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-12, IL-13, IL-15, IL-17, eotaxin, IL-1Ra, bFGF, G-CSF, GM-CSF, IFNγ, IP-10, MCP-1, MIP-1α, MIP-1β, PDGFBB, TNFα, VEGF, Mig, MIF and IL-2Rα by multiplex detection (Bio-Rad, Hercules, CA). The cut-off levels were for survivin 450 pg/mL, and for Flt3L 130 pg/mL.

Results: The levels of survivin were increased in the pre-symptomatic individuals compared with the controls ($p=0.003$) whilst the levels of Flt3-ligand ($p=0.21$) were similar. The frequency of survivin in the pre-symptomatic individuals was increased compared with controls (36.2 vs. 14.2% $p=0.001$). The odds ratio (OR) for predicting disease development in individuals with survivin levels above cut-off was 3.4 (95%CI 1.6–7.2). The frequencies of survivin and Flt3L were increased in RA patients compared with controls (both, $p<0.0001$. OR12.1 [95%CI, 5.3–27.6] and OR11.0 [3.9–30.9], respectively). Anti-CCP positive pre-diseased individuals and RA-patients had significantly higher concentrations of survivin compared with those being negative. After correction for the number of comparisons, IL-1β, GM-CSF in pre-symptomatic individuals was correlated with survivin and IL-1α, IL-10, eotaxin and TNF-α was correlated with Flt3L, while IL-2, IL-9 and IL12 was correlated with both survivin and Flt3L in the pre-symptomatic individuals.

Conclusion: The proto-oncogene survivin was increased in individuals before onset of symptoms of RA and it was related to cytokines suggesting its role in the events preceding development of the disease.

1394

Self Reported Dental Symptoms Do Not Predict Periodontal Status In Patients With Rheumatoid Arthritis. Gurpal Buttar, Anastasia Zelekis-Cholakis, Robert Schroth, Hani S. El-Gabalawy, Christine A. Peschken and Carol A. Hitchon. University of Manitoba, Winnipeg, MB.

Background/Purpose: Periodontal disease (PD) and inflammatory arthritis (IA) share features of inflammation and bone loss and are linked in epidemiologic studies. Severe PD may be one environmental trigger for the development of seropositive rheumatoid arthritis. We evaluated the prevalence of periodontal disease in patients with inflammatory arthritis and determined the validity of self-reported dental symptoms and hygiene habits for periodontal disease.

Methods: Sixty one patients with IA (mean age 50.3 ($\pm$11.1) years; rheumatoid arthritis n=47 or undifferentiated arthritis n= 14) answered questions about their periodontal symptoms (bleeding gums, metallic taste, halitosis, xerostomia, loose teeth, pain with food impaction) and dental habits (frequency of brushing, flossing and dental visits), functional status (modified health assessment questionnaire mHAQ), co-morbid medical conditions, and smoking history. All were examined by a periodontist using the periodontal screening and recording index (PSR) a validated screening tool which records the presence of bleeding on probing, calculus, and defective restorative margins at six points per tooth in six segments of the mouth. The highest score in each sextant was recorded. Patients were classified as periodontically healthy, gingivitis, mild, moderate or severe periodontitis based on the PSR. Associations between dental exam findings, arthritis severity and symptoms, arthritis serology (CCP2, RF) and dental symptoms and habits and the validity of the self-reported dental questionnaire were tested. Percentages or means(SD) are reported.

Results: No patients were periodontically healthy; 23 gingivitis, 14 mild periodontitis, 16 moderate periodontitis and 3 severe periodontitis, 5 edentulous. The mean PSR score was 2 (0.5). Patients were seropositive (RF 67%, CCP2 67%) with moderate disease activity (DAS28CRP(3var) 2.69($\pm$1.05) and function (mHAQ 0.4($\pm$0.41) despite 95% taking DMARDs, 49% combination DMARDs and 36% biologics. There was no correlation between the PSR score and disease activity (DAS28CRP(3var), functional status (mHAQ), arthritis duration or age at the time of the dental exam. There were no robust associations between PSR and RF, CCP2, or diabetes, a known risk for PD. Increased total pack years of smoking was moderately associated with worse periodontal health ($p=0.05$). The majority (28/42) rated their overall oral health as very good or good. The sensitivity for self-reported responses of "sometimes" "often" or "always" for moderate or severe PD based on the PSR was greatest for reporting bleeding gums (72%), metallic taste (89%) loose teeth (95%) and pain on food impaction (84%). However, the sensitivity of these questions for moderate or severe PD was poor (32%, 5%, 21% and11% respectively).

Conclusion: Periodontal disease is common in patients with inflammatory arthritis but does not correlate with severity or activity of arthritis. Self-reported dental symptoms have reasonable specificity but poor sensitivity for detecting significant periodontal disease thus a formal periodontal examination should be part of arthritis care. Periodontal disease may play a more important role in the pathogenesis of imminent or very early arthritis.

CXCL13 Is Elevated In Early and In Established Seropositive Rheumatoid Arthritis and Correlates With Rheumatoid Factor Levels. Jonathan D. Jones[1], B. JoNell Hamilton[1], Greg Challener[1], Artur Fernandes[2], Pierre Cossette[2], Patrick Liang[2], Ariel Masetto[2], HA Menard[3], Nathalie Carrier[2], Gilles Boire[2] and William Rigby[1]. [1]Geisel School of Medicine at Dartmouth, Lebanon, NH, [2]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [3]McGill University, Montréal, QC.

Background/Purpose: CXCL13 is a B cell chemokine whose expression has been reported to be elevated in serum and synovium from patients with rheumatoid arthritis (RA). Synovial production of CXCL13 has been associated with lymphoid aggregates and germinal center formation. We analyzed the relationship of serum CXCL13 levels to several clinical and serologic parameters, using both established and early RA cohorts.

Methods: Patients with established RA were recruited from the rheumatology clinic at Dartmouth-Hitchcock Medical Center. Serum CXCL13, Rheumatoid Factor (RF) levels, anti-citrullinated peptide antibody (ACPA) and total IgG were measured by ELISA. Seropositivity (positive for RF, ACPA, or both) and highly sensitive C-Reactive Protein (hsCRP) were determined by the clinical lab. HLA-DR status was obtained previously in RA patients from this cohort. A confirmatory analysis was performed using seropositive and seronegative samples from early RA patients from the Canadian Early Undifferentiated PolyArthritis (EUPA) Cohort. Statistical analysis was performed using STATA software, with t-test and linear regression utilized to evaluate relationships between variables.

Results: In the cross-sectional Dartmouth Cohort (n=193), log-transformed CXCL13 levels strongly correlated with seropositivity (Figure 1A, $p=0.0002$). Among the seropositive patients, several interesting patterns emerged. Linear regression of log-transformed CXCL13 plotted against RF levels was highly significant ($p<0.0001$). Tertile analysis demonstrated the strong association of high CXCL13 levels with RF titers (Figure 1B, $p<0.0001$). A weaker relationship was seen between CXCL13 levels and ACPA titers ($p=0.02$). A relationship between CXCL13 and total IgG was also observed ($p=0.0009$), but not with age, gender, shared epitope or hsCRP. Analysis of the Canadian EUPA Cohort (n=339) confirmed the strong

relationship between CXCL13 and seropositivity ($p<0.0001$), as well as serum RF titer ($p<0.0001$). No relationship with ACPA or serum IgG levels was seen in this cohort. Moreover, no relationship was seen with age, gender, shared epitope status, DAS28-CRP or the presence of erosions. In contrast to DAS28-CRP, there was a weak association between CXCL13 levels and hsCRP ($p=0.05$).

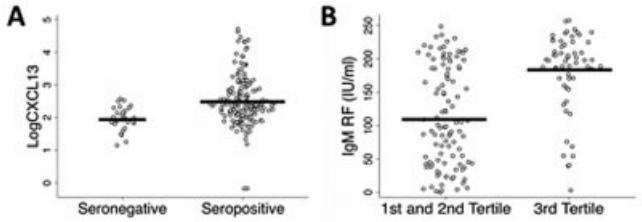

Figure 1. Serum CXCL13 levels correlate with seropositivity and rheumatoid factor (RF) status. **A,** Seropositive patients exhibit marked elevation of serum CXCL13 (n=193, $p=0.0002$) in an established RA cohort. **B,** Tertile analysis of CXCL13 in seropositive patients reveals that IgM RF has a strong relationship with the highest CXCL13 tertile ($p<0.0001$). Identical patterns were seen in the Canadian EUPA Cohort.

Conclusion: Using both established and early RA cohorts, marked elevations of serum CXCL13 levels resided nearly completely within the seropositive population. Within this seropositive RA subset, CXCL13 elevations exhibited a surprisingly strong relationship with RF. The association of CXCL13 levels with either clinical (age, gender, DAS28-CRP, erosions) or serologic (ACPA, IgG) parameters was either much weaker or absent. These results suggest that serum CXCL13 levels not only identify differences in the pathophysiology of seronegative RA, but also may define a subset of seropositive RA patients.

Survivin–positivity Increases Risk For RA and Has a Strong Additive Effect On The Shared Epitope Alleles and Antibodies To Citrullinated Peptides In Patients Of The Malaysian Epidemiological Investigation Of Rheumatoid Arthritis (MyEIRA) Study Group. Chun Lai Too[1], Shahnaz Murad[2], Malin Erlandsson[3], Heselynn Hussein[4], Wahinuddin Sulaiman[5], Jasbir Singh Dhaliwal[1] and Maria Bokarewa[6]. [1]Institute for Medical Research, Allergy and Immunology Research Center, Jalan Pahang, Kuala Lumpur, Malaysia, [2]Institute for Medical Research, Jalan Pahang, Kuala Lumpur, Malaysia, [3]Göteborgs University, Göteborg, Sweden, [4]Putrajaya Hospital, Putrajaya, Malaysia, [5]Tengku Bainun Hospital, Ipoh, Perak, Malaysia, [6]University of Gothenburg, Gothenburg, Sweden.

Background/Purpose: The human leukocyte antigen (HLA)-DRB1 with alleles that contain common amino acid motif QKRAA termed shared epitope (SE) confer the major locus of genetic susceptibility to rheumatoid arthritis (RA). Molecular basis of tolerance loss marked by autoantibody production remains to be resolved. The aim of this study was to analyse an association between survivin, oncoprotein recently reported to be associated with early bone damage and poor therapy response, HLA-DRB1 SE alleles and antibodies to citrullinated peptides (ACPA) in Malaysian patients.

Methods: 1233 RA patients and 1566 age, sex and ethnically matched healthy controls of the Malaysian Epidemiological Investigation of rheumatoid arthritis (MyEIRA) study group were included in the study. The levels of survivin, ACPA and rheumatoid factor were measured by specific and standardized ELISAs. HLA-DRB1 genotyping was performed by the PCR-SSO method. Among the HLA-DRB1 alleles, DRB1*01, DRB1*0401, DRB1*0404, DRB1*0405, DRB1*0408, DRB1*0410, and DRB1*10 were defined as SE alleles. The odds ratio (OR[95%CI]) and relative risk (RR) of developing ACPA-positive and ACPA-negative RA was calculated for survivin and the presence of any SE allele. Potential interaction between survivin and HLA-DRB1 SE alleles was also calculated.

Results: The prevalence of survivin-positivity among RA patients was 50.7%, compared to 5.4% in healthy controls ($p=2.66E-164$) with a significantly higher prevalence in the Indian ethnic population compared to the Malay and Chinese ($p<0.0001$). Survivin-positivity was associated with an increased risk of developing ACPA-positive RA (OR 33.5[25.8–43.6]) and ACPA-negative RA (OR 5.3[3.9–7.2]), both $p<0.0001$. The survivin-positivity was associated with SE-alleles in 23.6% of RA patients and the majority of patients combining survivin and SE (91%) were also ACPA–positive. The combination of survivin-positivity and SE increased the risk of ACPA-positive RA 19 folds.

Conclusion: The survivin-positivity increases risk of the development of ACPA-positive and ACPA-negative RA. Combination of survivin-positivity, SE and APCA has a strong additive effect for the risk of RA in the population from Malaysia.

1397

Changes In MMP In Fibroblast-Like Synoviocytes Following Adipogenesis. Satoshi Yamasaki, Kazuhiko Kumagai, Kouji Endo, Takaki Nojima and Eiji Sugiyama. Hiroshima University Hospital, Hiroshima, Japan.

Background/Purpose: Fibroblast-like synovial cells (FLS) play important roles in the disease progression of RA. FLS produce cytokines and chemokines that contribute to chronic inflammation of RA-affected joints. They also secrete matrix metalloproteinases (MMPs) that cause degradation of joint tissues, including bone and cartilages, which leads to severe structural destruction of inflamed joints. We previously reported that the production of IL-6, a cytokine that contributes to the progression of RA, by FLS is reduced by adipogenesis induction. Therefore, we predict that induction of FLS adipogenesis could be a new therapeutic strategy to treat RA. Our objective in this study was to examine whether MMPs production in FLS could be altered by adipogenesis induction.

Methods: FLS were isolated from the synovial tissues by enzymatic digestion. MSC were purchased from Lonza (Walkersville, USA). Adipogenesis of FLS was carried out by using the MSC adipogenic differentiation medium BulletKit (Lonza), according to the manufacturer's instructions. The mRNA expression levels of MMPs and tissue inhibitors of metalloproteinases (TIMPs) were evaluated by DNA array (SurePrint G3 Human GE 8×60K Microarray, Agilent Technologies) by using two-colour detection mode. Production of MMP and TIMP proteins in FLS culture supernatant was evaluated by Human MMP Antibody Array (RayBiotech, Inc., Norcross, USA) and confirmed by ELISA (MMP1, MMP2, and MMP3 purchased from Abcam).

Results: After adipogenesis induction, transcripts unique to adipocytes (e.g., lipoprotein lipase 4, fatty acid-binding protein 5, fatty acid-binding protein 4, aquaporin 7, perilipin 2, adiponectin, and peroxisome proliferator-activated receptor γ) were clearly induced in FLS, which confirms that adipogenesis was properly induced. Expressions of MMP-1, -2, and -11 transcripts were decreased in FLS following adipogenesis. Conversely, expression of MMP-3 and -25 transcripts was increased by FLS adipogenesis. Consistent with these results, antibody array studies demonstrated that MMP-1 protein production was reduced in FLS culture medium following adipogenesis, whereas MMP-3 protein production increased. Supernatant concentrations of MMP-1 and -2 from FLS obtained from 4 different RA patients were reduced after adipogenesis. The mRNA and protein expression of TIMP-4, a MMP-2 inhibitor, were induced by FLS adipogenesis.

Conclusion: Our data demonstrate that MMP-1 and -2 production was inhibited in FLS by adipogenesis induction. If the FLS in pannus were to differentiate into adipocytes with reduced IL-6 and MMPs, the adipocytes would be a more physiological component that would produce fewer pathogenic molecules in the joint. Specifically, the strategy of inducing adipogenesis in FLS may restore both the levels of the harmless cytokine and protease production as well as fat-rich tissue deposition in the affected joint as seen in a normal joint. Further studies are required to include "adipogenesis-induction therapy" in the treatment of RA.

Comparison Of Atherogenicity Of Plasma From Patients With Rheumatoid Arthritis and Psoriatic Arthritis. Beenish Hafiz, Iryna Voloshyna, Michael J. Littlefield, Steven E. Carsons, Elise Belilos, Kristina Belostocki, Lois A. Bonetti, Gary C. Rosenblum and Allison B. Reiss. Winthrop University Hospital, Mineola, NY.

Background/Purpose: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are immune mediated inflammatory disorders linked to increased risk of cardiovascular disease (CVD), mostly due to accelerated atherosclerosis. An imbalance between cholesterol inflow and outflow leads to lipid overload

and is one mechanism for initiation of atherosclerosis. This study examines the effect of RA and PsA plasma compared to healthy control (HC) plasma on expression of genes responsible for cellular cholesterol efflux and influx by exposing naïve THP-1 human macrophages to RA, PsA and HC plasma. In addition, cytokine levels were measured in RA, PsA and HC.

Methods: THP-1 differentiated macrophages (10^6 cells/ml, phorbol dibutyrate, 100nM, 48h), were incubated (37°C, 5% $C0_2$, 18h) in RPMI 1640 media in the presence of 10% plasma from the following subjects: 1) 22 RA, 2) 21 HC age and sex-matched to the RA group, 3) 8 PsA, 4) 8 HC age matched to the PsA group. The study was performed under a Winthrop University Hospital IRB-approved protocol. Cytokine levels were evaluated by ELISA. Cholesterol transport protein mRNA was quantified by real-time RT-PCR using specific primers for each gene.

Results: 10% RA plasma increased macrophage expression of cholesterol influx genes (scavenger receptors CD36 and LOX-1). CD36 mRNA increased by 134.45±38.56% ($P<0.001$) and LOX-1 by 68.9±12.45% ($P<0.001$) above cells exposed to HC plasma (set at 100%). SR-A1 expression did not different in RA vs. HC. Expression of cholesterol efflux genes (ATP binding cassette transporter (ABC)A1, ABCG1 and 27-hydroxylase) was suppressed in macrophages treated with RA plasma vs. HC plasma. Mean ABCA1 mRNA expression decreased to 55.29±10.23% ($P<0.001$) compared to cells treated with HC plasma. ABCG1 mRNA fell to 73.65±9.67% ($P<0.05$) upon exposure to RA plasma vs. HC plasma. 27-Hydroxylase mRNA in THP-1 macrophages in the presence of RA plasma was diminished to 26.5±8.56% ($P<0.01$). In contrast, 10 % PsA plasma did not alter message level of the cholesterol influx or efflux proteins compared to HC (Figure). Pro-inflammatory cytokines were significantly higher in RA plasma compared to HC plasma: IL-6 (4.66±0.44 pg/ml vs. 1.71±0.045 pg/ml, $P<0.01$), TNF-α (4.34±0.40 ng/ml vs. 1.30±0.22 ng/ml, $P<0.001$) and IFN-γ (171.2±125.5 pg/ml vs. 9.54±0.7 pg/ml, $P<0.001$), respectively. In contrast, PsA plasma did not show significant elevations in IFN-γ, TNF-α or IL-6.

Conclusion: RA plasma but not PsA plasma induced a pro-atherogenic profile of genes responsible for cholesterol infux and efflux. This may be due to the significantly greater elevation of inflammatory cytokines, notably IFN-γ (which is known to alter cellular cholesterol flux in a pro-atherogenic manner) demonstrated in the RA plasma samples. A lack of significant effect on cholesterol transport gene expression by PsA plasma is consistent with less CVD risk in PsA compared to RA.

1399

Citrullinated Proteoglycan (Aggrecan) Present In Human Cartilage Is Recognized By Serum Antibodies From Rheumatoid Arthritis Patients. Timea Ocsko[1], Beata Tryniszewska[1], Andras Vida[1], Janos Gal[2], Gyorgyi Soos[2], Zoltan Szekanecz[3], Tibor A. Rauch[1], Joshua Jacobs[1], Tibor T. Glant[1] and Katalin Mikecz[1]. [1]Rush University Medical Center, Chicago, IL, [2]Bacs-Kiskun County Hospital, Kecskemet, Hungary, [3]University of Debrecen Medical and Health Sciences Center, Debrecen, Hungary.

Background/Purpose: Citrullination is a post-translational protein modification, where arginine (Arg) is converted to citrulline (Cit) by peptidyl arginine deiminases (PADI). The presence of anti-citrullinated protein antibodies (ACPA) in serum is highly specific for rheumatoid arthritis (RA). Some of these ACPA may recognize citrullinated cartilage components such as type II collagen (CII) or the proteoglycan (PG) aggrecan in the RA joints afflicted with inflammation. The major goals of this study were (1) to determine whether a citrullinated form of cartilage PG is present in normal or diseased human cartilage, and (2) to identify citrullinated PG (CitPG)-specific serum antibodies (Abs) in $ACPA^+$ RA patients.

Methods: PG from cartilage of normal human joints was extracted with 4M GuHCl and purified by CsCl gradient ultracentrifugation. Crude extracts were also prepared from osteoarthritic (OA) and RA cartilage specimens obtained from joint replacement surgery. Serum ACPA concentrations in RA patients were measured using anti-MCV (Orgentec) and anti-CCP3 (Inova) kits. RA serum samples with high ACPA titers were reacted with both purified PG and crude cartilage extracts in dot blots and Western blots. The PG specificity of reactions was verified using monoclonal Ab G18 to the G1 domain of human PG. Recombinant G1 domain of PG and purified human CII, both citrullinated in vitro with PADI4, were used for the measurement of CitPG- and CitCII-specific serum Abs, respectively, by ELISA. CitPG was visualized in frozen sections of human cartilage specimens by immunohistochemistry.

Results: While there was a strong correlation between anti-MCV and anti-CCP3 titers, the correlation was weaker between anti-CitPG and anti-CCP3 Ab levels in the 68 $ACPA^+$ RA serum samples tested. ELISA assays, using CitPG and CitCII as a capture antigens, showed that 66% of the $ACPA^+$ sera reacted with CitPG, 46% with CitCII, and 41% with both CitPG and CitCII. When we compared sera from healthy subjects and OA patients with the 'calibrator' serum standards supplied with the anti-CCP3 kits, only the anti-$CCP3^+$ calibrator sera gave a positive reaction with CitPG. Comparison of matched cartilage and serum samples from OA patients demonstrated the presence of CitPG in ~60% of OA cartilage extracts, while CCP3- or CitPG-specific Abs could not be detected in any of their serum samples. On the other hand, all cartilage specimens from RA patients contained CitPG, and 92% of the serum samples from the same RA donors were positive for both anti-CCP3 and anti-CitPG Abs. Western blot of fragmented cartilage PG showed that the G1 domain contained an abundance of citrullinated epitopes. In cartilage tissue sections, CitPG was predominantly localized intracellularly and in the pericellular matrix of chondrocytes.

Conclusion: PG (especially the Arg-rich G1 domain) in both normal and diseased cartilage is subjected to citrullination in vivo, likely by PADI in chondrocytes. While a significant proportion of normal, OA, and RA cartilage specimens contains CitPG, only sera from RA patients seem to recognize it. There is a significant overlap between anti-CitPG Abs and other ACPA, including anti-CCP3, anti-MCV, and anti-CitCII Abs in RA.

Dipeptidyl Peptidase IV (DPP-IV, CD26) Levels In Patients With Rheumatoid Arthritis Treated With Biologic Therapies and Correlation With The Activity Of The Disease. José M. Pego-Reigosa[1], Oscar Cordero[2], Tania López-González[2], Coral Mouriño-Rodríguez[3], Bruno Aspe[4], Juan Viñuela-Roldán[5], Rubén Varela-Calviño[6], Cristina Calviño[6], Marina Rodríguez-López[4], Iñigo Hernández-Rodríguez[4] and Víctor del Campo-Pérez[4]. [1]Instituto de Investigación Biomédica de Vigo (IBIV), Vigo, Spain, [2]Universidade de Santiago de Compostela, Santiago de Compostela, Spain, [3]Meixoeiro Hospital, Vigo, Spain, [4]University Hospital Complex of Vigo, Vigo, Spain, [5]University Hospital Complex of Santiago, Santiago de Compostela, Spain, [6]Faculty of Pharmacy, University of Santiago de Compostela, Santiago de Compostela, Spain.

Background/Purpose: Dipeptidyl peptidase IV (DPP-IV, CD26), a protease cleaving N-terminal X-Pro dipeptides from selected proteins including chemokines is expressed both as a soluble form and on the surface of various immune and non-immune cells. In rheumatoid arthritis (RA), low DPP-IV/sCD26 activity has been shown in serum and synovial fluid, with restoration of normal levels of activity in patients treated with anti-TNF-alfa therapy. The objective of our study was to study DPP-IV/sCD26 in RA patients and its correlation with disease activity and the different therapies received.

Methods: Patients diagnosed with RA according the 1987 ACR classification criteria for RA were included. The degree of RA activity was evaluated by using DAS 28, acute-phase reactants and hemoglobin levels. Data about all the medications and their doses were collected.

Expression levels of CD26 on white blood cells were evaluated by flow cytometry analysis and the serum levels of the enzyme DPP-IV by ELISA. All laboratory tests were performed blindly. An institutional review board approved this study. All patients gave written informed consent.

To evaluate the correlation among clinical and serological variables, bivariate analysis was performed (SPSS 16.0).

Results: Sixty-eight patients were recruited: 75% woman, median age (IR): 57.1 years (18.6), median disease duration (IR): 9.8 years (14.0). Regarding the RA activity variables, median DAS28, ESR, CRP and Hemoglobin (IR) were: 3.4 (1.7), 30.5 (31), 4.1 (10) and 13.3 (2.2), respectively.

There were not significant differences in the percentages of CD26 expressing T helper subsets in RA patients treated vs. non-treated with biologics. However, we found a statistically significant raise in the levels of cell surface CD26 expression (mean of fluorescence intensity, MFI) in the T helper effector/memory CD45RO+ CD26+ or CD26high subset in patients on biologic therapy compared with those without biologic therapy ($p = 0.03$).

Overall, the levels of cell surface CD26 expression measured by MFI in the T helper effector/memory CD45RO+ CD26+ correlated significantly

with the activity of the disease measured by DAS28 score (Pearson's CC: 0.4, p = 0.001).

Conclusion: Higher levels of plasma membrane CD26 (measured by MIF) may be related with the decreased circulating sCD26 levels in RA, and these levels correlates with the disease activity. Patients on biologic therapies showed increased levels of plasma membrane CD26 in a similar way to the restoration of circulating levels of CD26 associated with anti-TNF-alfa therapy described in the literature. These changes may be also related with the number of Th17 cells, which express high levels of CD26, this hypothesis being under study. Thus, different therapies may influence distinctly the CD26-mediated regulation of the chemotactic SDF-1/CXCR4 axis of inflammation.

Reduced Oral Glucose Tolerance Is Associated With a Lower Risk Of Rheumatoid Arthritis. Carl Turesson, Ulf Bergström, Mitra Pikwer, Jan-Åke Nilsson and Lennart Jacobsson. Lund University, Malmö, Sweden.

Background/Purpose: Studies have demonstrated a negative association between high body mass index (BMI) and development of rheumatoid arthritis (RA) in men, and a neutral or positive association in women. This may reflect effects of body fat distribution and related metabolic pathways on the risk of RA. The purpose of the present study was to investigate the impact of oral glucose tolerance on the risk of future development of RA.

Methods: Between 1974 and 1992, subjects (n=33346; 22444 men and 10902 women) from a defined catchment area were included in a Preventive Medicine Program (PMP). Information on life style factors was obtained using a self-administered questionnaire. A standard oral glucose tolerance test (OGTT) was performed after an overnight fast. From this population, we identified individuals who developed RA after inclusion by linking the PMP register to the local community based RA register and to local and national patient administrative databases. In a structured review of the medical records, patients were classified according to the 1987 American College of Rheumatology criteria for RA. Four controls for each validated case, matched for sex, year of birth and year of screening, who were alive and free of RA when the index person was diagnosed with RA, were selected from the PMP register. The impact of the 2-hour OGTT glucose level on the risk of RA was examined in conditional logistic regression models.

Results: Two hundred and ninety patients [151 men and 139 women; median time from inclusion to RA diagnosis 12 years (interquartile range 8–18, range 1–28); mean age at diagnosis 60 years] were diagnosed with RA and fulfilled the ACR criteria after inclusion in the PMP. An OGTT was performed in 177 cases (104 men, 73 women) and 708 controls (413 men, 295 women). Fasting glucose levels were similar in cases and controls (mean 4.91 vs 4.90 mmol/l). Cases with a diagnosis of RA during the follow-up had lower 2-hour OGTT glucose levels at baseline compared to controls [mean 5.58; standard deviation (SD) 1.76 vs. 6.03 (SD 1.77) mmol/l; OR 0.72 per SD; 95 % confidence interval (CI) 0.58–0.89)]. Impaired glucose tolerance (2-hour OGTT glucose level ≥ 7.8 mmol/l) was less frequent in pre-RA cases compared to controls (9.0 % vs. 15.1 %; p=0.04). The association between lower 2-hour OGTT glucose levels and subsequent development of RA remained significant in separate multivariate analyses adjusted for smoking (p=0.01) or socio-economic status (p=0.04). In analyses stratified by sex, the estimated impact of 2-hour OGTT glucose was similar in men (OR 0.71 per SD; 95 % CI 0.54–0.92) and women (OR 0.73 per SD; 95 % CI 0.51–1.05). Two-hour OGTT glucose levels were correlated with BMI in men (r=0.22; p<0.001) and, to a lesser extent, in women (r=0.13; p=0.02). In analysis adjusted for BMI, a lower 2-hour glucose level remained a significant predictor for RA in men (OR 0.75 per SD; 95 % CI 0.50–0.98).

Conclusion: A reduced oral glucose tolerance was associated with a lower risk of RA. Taken together with the known impact of fat distribution on glucose tolerance, and previous observations of sex-specific effects of BMI on the risk of RA, this suggests that mechanisms related to abdominal or visceral fat may protect against RA.

Regulatory B10 CELLS ARE Decreased In Patients With Rheumatoid Arthritis and Inversely Correlated With Disease Activity. Claire I. Daien[1], Sarah Gailhac[2], Thibault Mura[3], Bernard Combe[1], Michael Hahne[4] and Jacques Morel[1]. [1]Lapeyronie Hospital, Montpellier, France, [2]CNRS, Montpellier, France, [3]Hopital Gui De Chauliac, Montpellier, France, [4]IGMM, CNRS UMR5535, Montpellier, Montpellier, France.

Background/Purpose: Regulatory IL-10 producing B cells (B10) have been shown to prevent and cure collagen-induced arthritis in mice. In human, very little is known about B10 cells in rheumatoid arthritis (RA). Several B cell subsets such as CD24hiCD38hi, CD24hiCD27+ and CD5+ B cells were suggested to be precursors of B10 cells. In the present study, we aimed to analyze these B cell subsets and B10 cells in RA patients and healthy controls. We also compared the ability of these different B cell subsets to produce IL-10.

Methods: B10 cells were generated from PBMCs stimulated for 24 hours with CpG and 4 hours with PMA and ionomycine. Intra-cellular B cell IL-10 was assessed by cytometry. Thirty-one controls + 99 RA patients were included for B cell subsets and 21 controls + 66 RA patients for B10 cell assessment. To study the ability of the different B cell subsets to produce IL-10, we sorted them using cytometry before activation.

Results: After multiple adjustments, CD24hiCD38hi, CD24hiCD27+ and CD5+ B cell levels were found to be similar in patients with RA and in controls. CD24hiCD27+ levels were higher in patient with active disease than in patient with DAS28≤3.2 whereas other subsets were not different between the two groups. Levels of B10 cells were lower in patients with RA, especially in RA with disease duration under 5 years than controls. B10 cells inversely correlated with DAS28. It was more pronounced in RA≤5 years where B10 cells also inversely correlated with CRP levels. Moreover, B10 cells inversely correlated with rheumatoid factor and anti-citrullinated peptide antibody levels. CD24hiCD27+ B cells were found to be the main producers of IL-10 when taking into account their percentage in peripheral blood. However, all B cell subsets were able to produce more or less IL-10 after stimulation.

Conclusion: B cell ability to produce IL-10 was altered in RA and this impairment influenced disease activity, biological inflammation and autoantibody levels, especially in patients with RA≤5 years. This strongly suggests a role of B10 cells in RA initiation.

Protein Tyrosine Phosphatase Non-Receptor Type 2 (PTPN2) Is Expressed In a TNF-Dependent Manner In RA Synovial Tissues. Borbala Aradi[1], Masaru Kato[1], Mária Filková[2], Stephanie Kasper[3], Kerstin Klein[1], Michael Bader[1], Michael Scharl[3], Beat A Michel[4], Renate E Gay[1], Edit I Buzas[5], Steffen Gay[1] and Astrid Jüngel[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Institute of Rheumatology and Department of Rheumatology of the First Faculty of Medicine, Charles University in Prague, Czech Republic, Prague, Czech Republic, [3]Division of Gastroenterology and Hepatology, University Hospital Zürich and Zürich Center for Integrative Human Physiology, Zurich, Switzerland, [4]Rheumatology, University Hospital Zurich, Switzerland, Zurich, Switzerland, [5]Department of Genetics, Cell- and Immunobiology, Budapest, Hungary.

Background/Purpose: Protein Tyrosine Phosphatase Non-receptor Type 2 (PTPN2) is a protein phosphatase that has been associated with the development of autoimmune diseases in GWA studies. Here we analyse its contribution to inflammation in RA before and after anti-TNFα therapy.

Methods: Immunohistochemistry was used to detect PTPN2 in synovial tissues from patients with osteoarthritis (OA) and RA with and without

anti-TNF treatment. The mRNA expression of PTPN2 was measured in synovial tissues using real-time PCR. RASF and OASF were stimulated with TNFα for short (10 ng/ml, 24 h) or long term (10 ng/ml, in 7 days), TNFα and IL1-β (1 ng/ml, 24 h), LPS (100 μg/ml, 24 h), and hypoxia (1%, 24 h). The levels of PTPN2 transcripts and protein were measured with real-time PCR or Western blotting. PTPN2 was silenced with three silencing RNAs. Commercially available ELISA was used to measure IL-6 and IL-8 production. TRAIL (20 ng/ml, 24h) was used to induce apoptosis. Apoptotic cells were detected by flow cytometry, using AnnexinV staining. Thapsigargin-induced (5μM, 24 h) autophagy was measured by Western blot using antibodies against LC3B-I and LC3B-II.

Results: Levels of PTPN2 expression were higher in the lining and sublining layers of RA compared to OA synovial tissues (OA n=11, RA n=30, 1.75-fold, $p<0.001$). This was also confirmed with real-time PCR on mRNA level (2.0 fold, RA tissue n=4, OA tissue n=5). Most interestingly, in synovial tissues from patients who were treated with anti-TNFα, 30% less PTPN2 staining could be detected by immunohistochemistry than in patients without anti-TNFα treatment (n=8, $p<0.05$). In synovial fibroblasts, the constitutive expression of PTPN2 was higher in RASF compared to OASF on mRNA (1.6 fold, $p<0.01$, n=10–16) and on the protein level (2.0 fold, $p<0.05$, n=3–7). The transcript levels of PTPN2 could be upregulated after stimulation with TNFα (3.1 fold, $p<0.05$, n=4), TNFα and IL-1β (2.3 fold, n=5), LPS (1.9 fold, n=5) and hypoxia (1.3 fold, n=3). The upregulation after stimulation with TNFα could also be confirmed on the protein level (1.7 fold, $p<0.05$, n=7). Moreover, PTPN2 protein expression was further increased after long term stimulation with TNFα (2.4 fold, n=3). Next, the function of PTPN2 was studied in synovial fibroblasts. Using siRNAs, PTPN2 was silenced by 80%. PTPN2 silenced cells produced more IL-6 (2.1 fold, n=4) than scrambled control cells, whereas levels of IL-8 did not change. TRAIL-induced apoptosis was increased by 37 % (n=5) and TG induced autophagy was decreased by 20% (n=5) after PTPN2 silencing.

Conclusion: We show here for the first time that PTPN2 is expressed in a TNF-dependent manner in RA synovial tissues. PTPN2 counter regulates the expression of the inflammatory cytokine IL-6 and regulates apoptosis and autophagy in RASF.

Effects Of Smoking On Joint Physiology In Men and Mice. Caroline Ospelt[1], Giovanni Camici[2], Anna Engler[1], Christoph Kolling[3], Renate E. Gay[1], Beat A. Michel[4] and Steffen Gay[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Institute of Physiology, University of Zurich, Zurich, Switzerland, [3]Schultess Clinic, Zurich, Switzerland, [4]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: Smoking is a major risk factor for the development of anti-citrullinated protein antibodies positive rheumatoid arthritis (RA) in individuals who carry shared epitope alleles. The molecular mechanisms that confer this risk are however not clarified up to now. Even more it is not clear whether smoking can affect joint physiology directly or via indirect immune mechanisms that cross-react with joint structures. We analyzed synovial tissues of human smokers and of mice exposed to cigarette smoke as well as in vitro stimulated RA synovial fibroblasts (SF) to find effects of smoking on joint physiology.

Methods: Synovial tissues were obtained from smoking (n=5) and non smoking (n=6) RA patients undergoing joint replacement surgery and from mice exposed to cigarette smoke (n=6) or room air (n=8) or) in a whole body exposure chamber for 3 weeks. RASFs were incubated with 5% cigarette smoke extract (CSE) (n=7). Changes in gene expression were detected using whole genome microarrays and verified with Real-time PCR and immunoblotting.

Results: Gene expression analysis and functional classification showed that CSE treatment in vitro leads to a broad activation of the chaperone and heat shock protein system. This finding could be confirmed *in vivo*, where we found a significant increase in the expression of the HSP40 family members, DnaJB4 (1.8 fold) and DnaJC6 (2.2 fold) in synovial tissues of human smokers as well as in mice exposed to cigarette smoke (DnaJB4 2.2 fold, DnaJC6 2.7 fold). Furthermore, in human synovial tissues, but not in mice, smokers had 3.5 fold higher levels of Hsp70 and 3.2 fold higher levels of HspB8 similar to what was seen in *in vitro* stimulations.

The list of CSE altered genes also contained a ligand of the activating immune receptor NKG2D. This ligand, MICB, together with other ligands of this receptor namely MICA, ULBP2 and ULBP3 was significantly increased after CSE *in vitro*. MICA (2.6 fold) and MICB (2.1 fold) were also significantly higher in synovial tissues of smokers compared to non-smokers. In addition the mouse homologue of these ligands, H60 was 2.9 fold higher expressed in joints of smoke exposed mice.

Conclusion: Our results clearly show that systemic effects of cigarette smoke include changes in joints. Since synovial fluid is passively filtrated from the blood, it is feasible to assume that cigarette smoke components in the blood can reach the synovial fluid and influence local tissue physiology. Therefore smoking can increase the risk to develop RA by locally changing gene expression in the synovium.

Expression Of High Mobility Group Protein B1 and Its Receptors In Heart Of Patients With Coronary Artery Disease With and Without Inflammatory Rheumatic Disease: A Biopsy Study. Mei Zong[1], Ivana Hollan[2], Huiyuan Xiao[3], Cecilia Grundtman[4], Eva Lindroos[5], Helena E. Harris[6], Knut MIkkelsen[7], Stein E. Rynning[7], Sven M. Almdahl[8] and Ingrid E. Lundberg[1]. [1]Rheumatology Unit, Department of Medicine, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [2]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway, [3]University of Oxford, Oxford, United Kingdom, [4]Innsbruck Medical University, Innsbruck, Austria, [5]Rheumatology Unit, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden., Stockholm, Sweden, [6]Karolinska University Hospital, Solna, Karolinska Institutet, Stockholm, Sweden, [7]Feiring Heart Clinic, Feiring, Norway, [8]University Hospital of North Norway, Tromsø, Norway.

Background/Purpose: Patients with inflammatory rheumatic diseases (IRD) have increased risk of morbidity and mortality in coronary artery disease (CAD) compared to the general population. High mobility group protein B1 (HMGB1) is an alarmin that can drive the pathogenesis of IRD when it is released from nuclei. Recently it was also shown that HMGB1 can mediate myocardial dysfunction in rat. In this study, we aimed to investigate whether and how HMGB1 and its signal-mediated receptors are expressed in heart muscle tissues of humans with CAD with or without IRD.

Methods: We examined myocardial specimens from the right atria (1.5×2.0mm) taken during coronary artery bypass grafting from 18 patients with CAD included in Feiring Heart Biopsy Study between 2001 and 2004. Among them, 10 patients had an IRD (IRD group) and 8 patients were without IRD (control group). The IRD group comprised of 5 patients with rheumatoid arthritis, 2 with polymyalgia rheumatica, 1 with psoriasis arthritis, 1 with temporal arteritis and 1 patient with ankylosing spondylitis. The heart samples were snap-frozen and stored at −80°C until they were cryostat-sectioned and stained by immunohistochemistry using the antibodies specific for HMGB1 and its three most well-known receptors: Toll-like receptor (TLR) 2, TLR4 and receptor for advanced glycation end products (RAGE). The cytosol HMGB1 staining was described as weak (+) and strong (++) which was scored without knowing the identity of the patients.

Results: In the control group, HMGB1 was localized to the nuclei of cardiomyocytes in 7 out of 8 patients, while in one patient it was also detected in the cytoplasm weakly (+). In contrast, in the IRD group, HMGB1 was strongly expressed in the cytosol of the cardiomyocytes in 6 out of 10 patients (++), and weakly expressed in cytosol in the remaining 4 patients (+). For the receptors, RAGE and TLR4 displayed a general expression in the cardiomyocytes mainly localized to the cytosol, while TLR2 was detectable in the cytosol of occasional cardiomyocytes.

Conclusion: HMGB1 and its receptors are expressed in the cardiomyocytes of patients with CAD. However, the HMGB1-signalling pathways may get a "better" chance to be activated in the patients with IRD as HMGB1 was detected with a more pronounced extranuclear staining pattern compared to the non-IRD patients. Therefore, targeting HMGB1 therapy in the future may protect the patients with IRD from developing severe cardiovascular diseases.

The Scaffold Protein p62 Is Involved In NF-κB Signaling, Caspase-3 Dependent and -Independent Cell Death and Autophagy In Rheumatoid Arthritis Synovial Fibroblasts. Masaru Kato[1], Caroline Ospelt[1], Christoph Kolling[2], Beat A. Michel[3], Renate E. Gay[4], Steffen Gay[4] and Kerstin Klein[1]. [1]University Hospital Zurich, Zurich, Switzerland, [2]Schultess Clinic, Zurich, Switzerland, [3]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [4]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland.

Background/Purpose: Sequestosome 1 (p62/SQSTM1) is a multifunctional ubiquitin-binding protein implicated in selective autophagy, cell signaling pathways and regulation of cell death. Recently, we described a functional role of p62 in the formation of poly-ubiquitinated protein aggregates and non-apoptotic cell death associated with autophagy in rheumatoid arthritis synovial fibroblasts (RASF). Here we investigated the role of p62 in the activation of apoptosis and nuclear factor-κB (NF-κB) activity in RASF.

Methods: The expression of p62 in synovial tissues from RA and osteoarthritis (OA) patients was verified by immunohistochemistry using antibodies against p62. RASF were incubated with and without TNF-α (10 ng/ml), IL-1β (1 ng/ml) and IL-6 (50 ng/ml) in presence or absence of soluble IL-6 receptor (30 ng/ml) for 24 hours and p62 expression was evaluated by quantitative Real-time PCR and immunoblotting. RASF were transfected with siRNA targeting p62 and knockdown was verified by immunoblotting. To induce cell death, RASF were treated with TRAIL (100 ng/ml) in presence or absence of a pan-caspase inhibitor (20 μM Z-VAD) for 24 hours. Apoptosis was evaluated by flow cytometry using annexin V/propidium iodide staining and a caspase-3 activity assay (NucView 488, Biotium). RASF were transfected with reporter-gene vectors containing NF-κB response elements and control vectors (GAPDH). NF-κB activity was measured by Dual-Luciferase reporter assays.

Results: The expression of p62 was restricted to the lining layer of synovial tissues and was increased in synovial tissues from RA patients (n=30) compared to OA patients (n= 9, p=0.01). Interestingly, the expression of p62 in RA patients treated with anti-TNF agents (n=14) was similar to the p62 expression observed in OA patients and was decreased compared to patients treated with non-biologics (n=9, p = 0.006) or patients treated with tocilizumab (n=4, p=0.008) or abatacept (n=3, p=0.02). Consistently, p62 mRNA (n=4, p=0.02) and protein (n=5, p=0.002) were induced in RASF by TNF-α, but not by IL-1β or by IL-6 stimulation even in the presence of soluble IL-6 receptor. p62 knockdown in RASF promoted TRAIL-induced cell death (n=6, p=0.02) that was accompanied by caspase-3 activation and was inhibited by a pan-caspase inhibitor. Furthermore, p62 knockdown strongly suppressed basal NF-κB activity (68.0 ± 10.6% reduction, n = 3, p = 0.008) in RASF.

Conclusion: Our data indicate that the scaffold protein p62 is involved in the regulation of multiple pathways in RASF, including NF-κB signaling, as well as the induction of caspase-3 dependent and -independent cell death and autophagy. p62 is positively regulated by TNF-α and plays a protective role against apoptosis in RA.

High Serum Cholesterol Predicts Rheumatoid Arthritis In Women. Carl Turesson, Ulf Bergström, Mitra Pikwer, Jan-Åke Nilsson and Lennart Jacobsson. Lund University, Malmö, Sweden.

Background/Purpose: Patients with active rheumatoid arthritis (RA) tend to have low cholesterol levels due to effects of inflammation on lipid metabolism. However, several prospective studies have indicated that a high serum cholesterol may be associated with increased risk of of RA. Metabolic pathways in the development of RA may be affected by hormonal factors, and have a different impact in men and women. The purpose of this study was to examine sex-specific effects of total serum cholesterol on the future risk of RA.

Methods: Between 1974 and 1992, subjects (n=33346; 22444 men and 10902 women) from a defined catchment area were included in a Preventive Medicine Program (PMP). Information on life style factors was obtained using a self-administered questionnaire. Blood samples were taken in the morning, after an overnight fast. Serum cholesterol was immediately assessed by an enzymatic method routinely used by the local hospital laboratory. From this population, we identified individuals who developed RA after inclusion by linking the PMP register to the local community based RA register and to local and national patient administrative databases. In a structured review of the medical records, patients were classified according to the 1987 American College of Rheumatology criteria for RA. Four controls for each validated case, matched for sex, year of birth and year of screening, who were alive and free of RA when the index person was diagnosed with RA, were selected from the PMP register. The impact of serum cholesterol on the risk of RA was examined in conditional logistic regression models, stratified by sex.

Results: Two hundred and ninety patients [151 men and 139 women; median time from inclusion to RA diagnosis 12 years (interquartile range 8–18, range 1–28); mean age at diagnosis 60 years] were diagnosed with RA and fulfilled the ACR criteria after inclusion in the PMP. There was no difference in cholesterol levels between men who subsequently developed RA and controls (mean 5.66 vs. 5.64 mmol/l). By contrast, women with a diagnosis of RA during the follow-up had higher cholesterol levels at baseline compared to controls [mean 6.04; standard deviation (SD) 1.16 vs. 5.71 (SD 1.11) mmol/l; OR 1.54 per SD; 95 % confidence interval (CI) 1.22–1.94)]. A higher cholesterol was predictive of RF positive RA (OR 1.45 per SD; 95 % CI 1.08–1.94) as well as RF negative RA (1.85 per SD; 95 % CI 1.22–2.80) in women. The association between higher cholesterol and subsequent development of RA in women remained significant in separate multivariate analyses adjusted for smoking (p=0.001) or early menopause (at age <46 vs. ≥ 46 years) (p=0.01). The association with future RA was statistically significant among those included 1–12 years before RA diagnosis (OR 1.36 per SD; 95 % CI 1.02–1.80) as well as among those included 13–28 years before RA diagnosis (OR 1.94 per SD; 95 % CI 1.30–2.87).

Conclusion: A higher serum cholesterol was associated with increased risk of RA in women, but not in men. This suggests that sex-specific exposures modify the impact of lipids on the risk of RA. The strong association with higher cholesterol among women surveyed long before RA diagnosis implicates early metabolic pathways in the etiology of RA.

High Body Mass Index Is Associated With a Reduced Long Term Risk Of Rheumatoid Arthritis In Men. Carl Turesson, Ulf Bergström, Mitra Pikwer, Jan-Åke Nilsson and Lennart Jacobsson. Lund University, Malmö, Sweden.

Background/Purpose: There are diverging results on the relation between body mass index (BMI) and risk of rheumatoid arthritis (RA). From a previous nested case-control study, based on a population based health survey performed in 1974–1992, we reported a reduced risk of RA in men with high BMI, whereas BMI did not affect RA development in women. The purpose of the present study was to investigate the impact of BMI on the risk of RA in a later population based survey performed in the same area.

Methods: Between 1991 and 1996, 30447 subjects (12121 men; 18326 women) were included. Height and weight were measured, and alcohol exposure was assessed using a diary, completed during 7 consecutive days, and classified as low/moderate/high intake. From this population, we identified individuals who developed RA after inclusion by linkage to 4 different RA registers. In a structured review of the medical records, patients were classified according to the 1987 American College of Rheumatology criteria for RA. Four controls for each validated case, matched for sex, year of birth and year of screening, who were alive and free of RA when the index person was diagnosed with RA, were selected from the health survey database. The impact of BMI on the risk of RA was examined in conditional logistic regression models, stratified by sex. Models including alcohol use were restricted to individuals classified as adequate reporters of total energy intake based on previous studies, and adjusted for total energy intake.

Results: A total of 172 patients (36 men/136 women, mean age at RA diagnosis 63 years) were diagnosed with RA after inclusion in the health survey. The median time from inclusion to RA diagnosis was 5 years (range 1–13). Seventy-nine cases (24 men/55 women) had been included in the previous survey. There was no difference in BMI between women who subsequently developed RA and controls [mean 25.9; standard deviation (SD) 4.9 vs. 25.6 (SD 4.4) kg/m^2; odds ratio (OR) for RA development 1.09 per SD; 95 % confidence interval (CI) 0.88–1.35]. By contrast, men with a diagnosis of RA during the follow-up had a lower BMI at baseline compared to controls [mean 24.6 (SD 3.1) vs. 26.5 (SD 3.5) kg/m^2; OR 0.47 per SD (95

% CI 0.29–0.76)]. The negative association between BMI and RA development in men remained significant in separate models adjusted for smoking (p=0.007) and level of formal education (p=0.034), and adjustment for alcohol intake did not lead to major change in the estimated effect of BMI (OR 0.57; 95 % CI 0.30–1.09). Similar adjustments had no significant impact in women. For pre-RA cases who participated in both surveys, the mean time between BMI measurements was 12.4 years in men and 8.7 years in women. Among these subjects, there was on average a slight decrease in BMI in men (mean change −0.06 kg/m^2 per year; 95 % CI −0.27 to 0.15) and a slight increase in women (mean change 0.14 kg/m^2 per year; 95 % CI −0.25 to 0.53).

Conclusion: BMI was negatively associated with future RA development in men. This pattern did not appear to be explained by differences in smoking, education or alcohol use. There were no major changes in BMI over time in cases who later developed RA. Hormonal factors related to adipose tissue may reduce the long term risk of RA in men.

Long-Term Impact of Delaying Combination Therapy With Adalimumab Plus Methotrexate By 2 Years in Patients With Early Rheumatoid Arthritis: Final 10-Year Results of the Premier Trial. Edward C. Keystone[1], Ferdinand C. Breedveld[2], Désiréé van der Heijde[2], Robert Landewe[3], Stefan Florentinus[4], Udayasankar Arulmani[5], Shufang Liu[5], Hartmut Kupper[6] and Arthur Kavanaugh[7]. [1]University of Toronto, Toronto, ON, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Academic Medical Center, Amsterdam, Netherlands, [4]AbbVie, Rungis, France, [5]AbbVie Inc., North Chicago, IL, [6]AbbVie Deutschland GmbH & Co KG, Ludwigshafen, Germany, [7]University of California San Diego, San Diego, CA.

Background/Purpose: The PREMIER trial demonstrated the superiority of initial adalimumab (ADA)+MTX vs the individual monotherapies in MTX-naïve patients (pts) with early, aggressive rheumatoid arthritis (RA). The purpose of this study was to assess long-term outcomes in pts treated with ADA, with or without MTX, for up to 10 years (yrs).

Methods: Pts completing the 2yr blinded study were eligible to receive open-label (OL) ADA for up to an additional 8 yrs; MTX could be added at the investigator's discretion. This *post hoc* analysis evaluated data as observed (ie, no imputation for missing data); results are summarized overall and by initial treatment arm. DAS28(CRP) and HAQ-DI were used to assess clinical and functional outcomes, respectively. Radiographic progression (change from baseline in mTSS) was assessed in 10yr completers with radiographic data available at baseline and yr 10. Adverse events (E) of interest were summarized for pts receiving ≥1 ADA dose and presented as E/100-pt yrs (PY).

Results: Of the 799 pts randomized, 497 (62%) entered the OL extension; 250 (31%) maintained OL ADA±MTX through yr 10. MTX co-therapy was (re)initiated in 261 pts (53%) during the OL extension. Overall, pts completing 10 yrs of therapy continued to demonstrate effective disease control (mean DAS28=2.4; mean HAQ-DI=0.6; mean ΔmTSS=7.8). Although the addition of OL ADA±MTX to the initial MTX and ADA arms at yr 2 led to increases in the proportions achieving DAS28(CRP) <2.6 and HAQ-DI <0.5 over time, differences between initial treatment arms persisted through yr 10 (**Table**). Further, ΔmTSS remained significantly lower over time in the initial ADA+MTX arm compared with the 2 monotherapy arms (ΔmTSS = 4.0, 11.0, and 8.8 at yr 10 for the initial ADA+MTX, MTX, and ADA arms, respectively; both P <0.05), despite OL ADA±MTX slowing progression comparably in each of the arms (both P>0.05). No new safety signals arose following 3708 PY of ADA exposure (N=697 pts): serious infections = 2.6 E/100-PY; TB =0.2 E/100-PY; malignancy (other than NMSC) SIR (95% CI) =0.89 (0.62, 1.26). There were 23 deaths during this 10yr study, resulting in an SMR (95% CI) of 0.72 (0.49, 1.02).

Parameter	ADA+MTX → OL ADA±MTX	MTX → OL ADA±MTX	ADA→ OL ADA±MTX
DAS28(CRP) <2.6, n/N (%)			
Yr 2[a]	131/198 (66)	64/167 (38)	69/160 (43)
Yr 10	59/78 (76)	41/73 (56)	50/81 (62)
HAQ-DI <0.5, n/N (%)			
Yr 2[a]	130/199 (65)	88/167 (53)	74/160 (46)
Yr 10	54/85 (64)	42/77 (55)	45/85 (53)
ΔmTSS ≤0.5, n/N (%)			
Yr 2[a]	61/85 (72)	33/77 (43)	39/84 (46)
Yr 10	31/86 (36)	24/77 (31)	22/85 (26)
DAS28(CRP) <2.6 + HAQ-DI <0.5 + ΔmTSS ≤0.5[b], n/N (%)			
Yr 2[a]	29/85 (34)	10/77 (13)	12/84 (14)
Yr 10	17/86 (20)	5/77 (7)	6/85 (7)

[a]End of double-blind period.
[b]NRI was used to replace missing DAS28(CRP) or HAQ-DI values.

Conclusion: ADA±MTX maintained effective disease control for up to 10 yrs in pts with early, aggressive RA. Of the pts who continued in the study, those who initiated ADA+MTX combination therapy retained better outcomes through 10 yrs than pts who began treatment with MTX or ADA monotherapy.

Tocilizumab Improves Left Ventricular Mass and Cardiac Output in Patients With Rheumatoid Arthritis. A Cohort Study. Kensuke Kume[1], Kanzo Amano[1], Susumu Yamada[1], Toshikatsu Kanazawa[2], Hiroshi Komori[2], Hiroyuki Ohta[3], Kuniki Amano[4] and Noriko Kuwaba[5]. [1]Hiroshima Clinic, Hiroshima, Japan, [2]Hiroshima Clinic, Hiroshima, Japan, [3]Hiroshima Clinic, Hiroshima, Japan, [4]Sky Clinic, Hiroshima, Japan, [5]Sanki Clinical Link, Hiroshima, Japan.

Background/Purpose: Rheumatologists need to develop primary prevention strategies for cardiovascular disease (CVD) in rheumatoid arthritis (RA) patients. We reported tocilizumab (TCZ) improved arterial stiffness as well as etanercept and adalimumab. RA is associated with an increased **left**ventricular mass index (LVMI), a strong marker of cardiovascular mortality. There is no evidence that TCZ effects on left ventricular (LV) morphology and function. To study the effect of TCZ plus methotrexate (MTX) on LV morphology and function in MTX resistant active RA patients, in a cohort study design.

Methods: RA patients were eligible if they had active disease despite treatment with MTX. All patients have no steroids, and no previous history of CVD. Consecutive 34 patients with moderate to severe active RA patients (DAS28>3.2) despite MTX were received TCZ plus MTX. LV morphology and function was assessed with cardio-MRI at baseline and 24 weeks follow-up. Cardiovascular risk factors and clinical data were collected at regular visits.

Results: 31 patients completed 24 weeks. Left ventricular mass index (LVMI) was attenuated significantly by TCZ (week 0-week24, −19.8±6.9 g/m^2; p=0.0002). Cardiac output (CO) was attenuated significantly by TCZ (week 0-week24,-0.99 ± 1.4l/min). DAS28 and CRP improved significantly by TCZ (week 0-week24; DAS28: −2.35±0.85; CRP: 24.3±7.2 mg/l) (p<0.05). Surprisingly, the change of disease activity (DAS 28 and CRP) is no correlation with the change of LVMI or CO in this study. Observationally, 6 cases significantly improved right ventricular mass as well as left ventricular mass (20 % improved right ventricular mass index from baseline).

Conclusion: TCZ improved LVMI and CO in active RA despite MTX. TCZ improves LVMI and CO independently of its effects on disease activity. TCZ might be improved right ventricular mass. Interleukin (IL) 6 might be an important role of LV hypertrophy. TCZ, anti- Interleukin (IL) 6 receptor antibody, may prevent cardiovascular morbidity and mortality in RA.

The Peroxisome Proliferator Activated Receptor-gamma pioglitazone Decreases Cardiovascular Risk and Disease Activity In Patients With Rheumatoid arthritis. Wendy Marder[1], Shokoufeh Khalatbari[2], James D. Myles[3], Rita Hench[1], Susan Lustig[1], Srilakshmi Yalavarthi[4], Aishwarya Parameswaran[1], Robert Brook[2] and Mariana J. Kaplan[4]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan at Ann Arbor, Ann Arbor, MI, [3]Michigan Institute for Clinical and Health Research, University of Michigan, Ann Arbor, MI, [4]University of Michigan Rheumatology, Ann Arbor, MI.

Background/Purpose: Rheumatoid arthritis (RA) is associated with heightened mortality due to atherosclerotic cardiovascular disease (CVD). Inflammatory pathways in RA negatively affect vascular physiology and promote metabolic disturbances that contribute to CVD. We hypothesized that the peroxisome proliferator activated receptor-γ (PPAR-γ) pioglitazone could promote potent vasculoprotective and anti-inflammatory effects in RA, thereby decreasing CV risk and RA disease activity.

Methods: 143 non-diabetic adult RA patients (76.2% female, age 55.2 $\pm$ 12.1 (mean +SD) on stable RA standard of care treatment were enrolled in a randomized, double- blind placebo controlled crossover trial of 45 mg daily pioglitazone versus placebo, with a 3 month duration/arm with a 2 month-washout period. Brachial artery flow mediated dilatation (FMD), nitroglycerin mediated dilatation (NMD), pulse wave velocity of the aorta (PWV), microvascular endothelial function (reactive hyperemia index [RHI]) and circulating biomarkers of inflammation, insulin resistance and atherosclerosis risk were quantified. RA disease activity was assessed with the 28 Joint-Disease Activity Scale-C-reactive protein (DAS28-CRP) and the SF-36 quality of life questionnaire.

Results: When added to standard of care RA treatment, pioglitazone significantly decreased pulse wave velocity (i.e., aortic stiffness) ($p=0.01$), while FMD and RHI remained unchanged when compared to treatment with placebo. Further, pioglitazone significantly reduced RA disease activity ($p=0.02$) and CRP levels ($p=0.001$), while improving lipid profiles. The drug was well tolerated.

Conclusion: Addition of pioglitazone to RA standard of care significantly improves aortic elasticity and decreases inflammation and disease activity with minimal safety issues.

Use Of a Biologic Marker For An Integrated Pharmacodynamic and Clinical Analysis To Inform Further Clinical Development, Including Dose Selection For The Phase 2b Trial - *Treat 2b* - Of Tregalizumab In Rheumatoid Arthritis. Eva Dokoupilova[1], Slawomir Jeka[2], Jiri Vencovsky[3], Janusz Badurski[4], Klaas Prins[5], Vibeke Strand[6], Edward C. Keystone[7], Ronald F van Vollenhoven[8], Jurgen Wollenhaupt[9], Andrea Wartenberg-Demand[10], Gabriele Niemann[10], Ahmed Abufarag[10], Silke Aigner[10], Sibylle Kaiser[10], Faiza Rharbaoui[10], Niklas Czeloth[10], Ralf Wolter[10], Benjamin Dälken[10] and Thorsten Holzkämper[10]. [1]Medical Plus s.r.o, Uherske Hradiste, Czech Republic, [2]Clinic of Rheumatology and Connective Tissue Diseases University Hospital No 2 in Bydgoszcz Collegium Medicum UMK in Torun, Bydgoszcz, Poland, [3]Institute of Rheumatology, Department of Clinical and Experimental Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [4]Center of Osteoporosis and Osteo-articular Diseases, Bialystock, Poland, [5]qPharmetra, Nijmegen, Netherlands, [6]Stanford University, Portola Valley, CA, [7]Mount Sinai Hospital, University of Toronto, Toronto, ON, [8]Karolinska Institutet, Stockholm, Sweden, [9]Schoen-Klinik Hamburg-Eilbek Teaching Hospital of the University of Hamburg, Hamburg, Germany, [10]Biotest AG, Dreieich, Germany.

Background/Purpose: In patients with rheumatoid arthritis (RA) reduced numbers and functional impairment of regulatory T cells (Tregs) have been observed. Tregalizumab is a humanized, agonistic monoclonal antibody which binds to a unique epitope of CD4, and induces Treg-specific activation and suppresses CD4 and CD8 effector cell proliferation and activity *in vitro*. Phase 2a randomized controlled RA trials of monotherapy (Study 962) and in combination with methotrexate (MTX) (Study 971) indicated efficacy in RA patients at SC doses of $\geq$25 mg with most pronounced effects on tender and swollen joint counts.

A biomarker was developed to monitor biologic response in humans. An integrated pharmacokinetic-pharmacodynamic (PK-PD) model was utilized to better characterize the optimal doses of tregalizumab for further investigation.

Methods: In the Phase 2b trial 979, MTX inadequate responders (MTX-IR) were randomized to tregalizumab 25, 50, 75 mg, or placebo SC weekly (in combination with stable MTX) for 12 weeks with 12 weeks' follow-up. The primary endpoint was ACR20 response at week 13 (1 week post treatment); SDAI, CDAI, PK-PD, and safety were also evaluated.

The integrated model utilized biomarker and clinical data from all completed RCTs and healthy volunteer studies of tregalizumab, together with interim data from the ongoing Study 979. This model was able to describe the relationship between SC tregalizumab doses and biologic responses. The model was then used to predict the dose-response relationship and to inform dose selection for the planned Phase 2b trial TREAT 2b (Study 986).

Results: The interim clinical analysis of Study 979 in 112 patients indicated efficacy vs. placebo (ACR20/50/70 responses at Week 13). The most pronounced effects were seen for tender and swollen joint counts. In Study 979 tregalizumab was well tolerated with no major safety findings, no CD4 cell depletion was observed.

PK-PD modeling demonstrated a significant correlation between dose, biomarker data, and clinical efficacy. Moreover, the model showed that maximal biologic response had not yet been attained with weekly doses up to 75 mg, predicting greater biologic response and better clinical efficacy with higher doses exceeding 75 mg, approaching a plateau at 200 mg weekly.

Conclusion: Interim efficacy and safety data from the Phase 2b Study 979, combined with data from previous RCTs, indicated the feasibility and tolerability of this therapeutic approach. The integrated PK-PD model confirmed the rationale for testing higher doses of tregalizumab up to 200 mg SC weekly in combination with MTX. Therefore, in the Phase 2b multicenter RCT (TREAT 2b – Study 986) 304 MTX-IR patients will receive tregalizumab 25 mg, 100 mg, 200 mg, or placebo SC weekly for 24 weeks, followed by an extension phase of 24 weeks. The available data support further development of tregalizumab.

Long-Term Safety and Efficacy Of Certolizumab Pegol In Combination With Methotrexate In The Treatment Of Rheumatoid Arthritis: 5-Year Results From a 52-Week Randomized Controlled Trial and Open-Label Extension Study. Edward Keystone[1], Robert Landewé[2], Ronald van Vollenhoven[3], Bernard Combe[4], Vibeke Strand[5], Philip J. Mease[6], Laura Shaughnessy[7], Brenda VanLunen[7] and Désirée van der Heijde[8]. [1]University of Toronto, Toronto, ON, [2]Academic Medical Center Amsterdam & Atrium Medical Center, Heerlen, Netherlands, [3]The Karolinska Institute, Stockholm, Sweden, [4]Montpellier University Hospital, Montpellier, France, [5]Stanford University, Palo Alto, CA, [6]Swedish Medical Center and University of Washington School of Medicine, Seattle, WA, [7]UCB Pharma, Raleigh, NC, [8]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: In the RAPID1 randomized controlled trial (RCT; NCT00152386),[1] certolizumab pegol (CZP) every 2 weeks (Q2W) plus MTX over 52 weeks (wks) provided rapid improvements in signs and symptoms and inhibition of radiographic damage in patients (pts) with active rheumatoid

arthritis (RA). In this publication we examine the safety and efficacy of CZP plus MTX over 5 yrs in RA.

Methods: Eligible pts were treated in the open-label extension (OLE) to RAPID1 (NCT00175877) with CZP 400mg Q2W, reduced to 200mg Q2W after ≥6 months, plus MTX.[2] Primary objective of the OLE was to monitor safety; secondary objective was to assess efficacy. Combined safety data from RCT and OLE are presented to Wk334 (6.4 yrs) for all pts receiving ≥1 dose of CZP in RCT or OLE (Safety population, N=958). ACR20/50/70, DAS28(ESR) and HAQ-DI are reported to Wk256 (4.9 yrs) for CZP pts who completed the 52-wk RCT (CZP Completers, N=508) and for all pts randomized to CZP 400mg or 200mg in RCT (ITT population, N=783). Change from baseline in modified Total Sharp Score (mTSS) and % of pts with radiographic non-progression (defined as a change in mTSS from RCT baseline of ≤0.5) are reported to Wk148 (2.8 yrs) for CZP Completers. Missing categorical data were imputed by modified non-responder imputation, continuous data by last observation carried forward, and radiographic data by linear extrapolation. Kaplan-Meier analysis was used to estimate pt retention.

Results: Overall event rate per 100 pt-yrs (ER) of AEs was 290.4 and SAEs was 20.3 (serious infections=5.9; total exposure [including 84-day safety follow-up period]: 3,732 pt-yrs). The most common AEs (MedDRA preferred terms) were urinary tract infection (ER=7.9), nasopharyngitis (ER=7.3) and upper respiratory tract infection (ER=7.3). 177 pts (18.5%) experienced an AE leading to withdrawal (incidence rate per 100 pt-yrs [IR]=4.8). 21 (2.2%) experienced an AE leading to death (IR=0.6) (including 5 malignancies, 5 cardiac disorders, 3 infections). ACR20/50/70 response rates for CZP Completers and ITT population were maintained to Wk256 (74.4%/57.3%/39.6% and 59.0%/43.7%/28.8%, respectively), as were DAS28(ESR) remission rates (25.2% and 20.3%), improvements in DAS28(ESR) (mean values: 3.43 and 3.83; mean change from baseline: −3.49 and −3.08) and HAQ-DI (mean values: 0.90 and 1.00; mean change from baseline: −0.77 and −0.66). The rate of radiographic progression in CZP-treated pts was not observed to change over time (mean change in mTSS from RCT baseline to Wk52: 0.27, from RCT baseline to Wk148: 0.77; proportion of pts achieving radiographic non-progression at Wk52: 76.5%, Wk148: 68.9%).

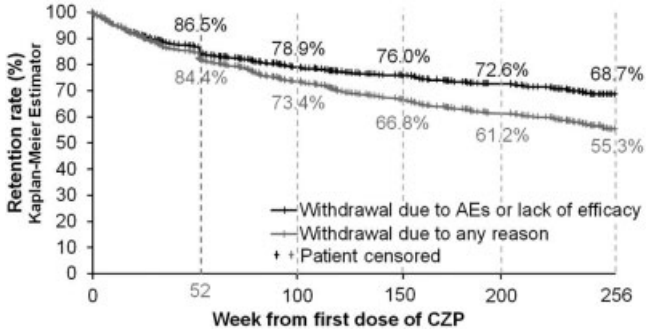

Figure. Kaplan-Meier estimators of pt retention to Wk256 (ITT Population).

Conclusion: CZP plus MTX provided a favorable risk-benefit profile over 5 yrs of treatment in pts with active RA. No new safety signals were identified.

Final 5-Year Safety and Efficacy Results Of a Phase 3, Randomized Placebo-Controlled Trial Of Golimumab In Patients With Active Rheumatoid Arthritis Despite Prior Treatment With Methotrexate.

Edward Keystone[1], Mark C. Genovese[2], Stephen Hall[3], Pedro Miranda[4], Sang-Cheol Bae[5], Chenglong Han[6], Timothy A. Gathany[6], Yiying Zhou[7], Stephen Xu[7] and Elizabeth C. Hsia[8]. [1]University of Toronto/Mount Sinai Hospital, Toronto, ON, [2]Stanford University, Palo Alto, CA, [3]Cabrini Medical Centre, Melbourne, Australia, [4]Universidad de Chile and Centro de Estudios Reumatologicos, Santiago de Chile, Chile, [5]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [6]Janssen Global Services, LLC., Malvern, PA, [7]Janssen Research & Development, LLC., Spring House, PA, [8]Janssen Research & Development, LLC./U of Penn, Spring House/Philadelphia, PA.

Background/Purpose: The safety and efficacy of subcutaneous golimumab (GLM)+/−MTX has been evaluated through 2yrs in a phase 3 trial (GO-FORWARD) of pts with active rheumatoid arthritis (RA) despite MTX therapy. Final safety and efficacy results through 5yrs are reported.

Methods: Pts in GO-FORWARD were randomized to placebo (PBO)+MTX, GLM 100mg+PBO, GLM 50mg+MTX, or GLM 100mg +MTX q4w. PBO+MTX pts crossed over to GLM+MTX at wks 16 (blinded early escape) or 24 (crossover). Pts continued treatment at wk52 (start of long-term extension). After the last pt completed wk52 and unblinding occurred, MTX and corticosteroid use could be adjusted, and a one-time GLM dose increase (50 à100mg) or decrease (100 à50mg) was permitted based on investigator judgment. The last GLM injection was at wk252. Observed efficacy results (ACR20/50/70, DAS28-CRP, HAQ-DI, radiographic) by randomized treatment group and cumulative safety data are reported through wks 256 and 268, respectively.

Results: A total of 444 pts were randomized; 313 pts continued treatment through wk252, and 131 pts withdrew (64 for AE, 25 for lack of efficacy, 1 protocol violation, 6 lost to follow-up, 32 for other reasons, 3 deaths). 301 completed the safety follow-up through wk268. Efficacy results are presented in the table. At wk256, 76.0% of all pts had an ACR20, 89.5% had a DAS28-CRP EULAR response, and 68.5% had improvement in HAQ-DI ≥0.25. Changes from baseline in mean total vdH-S scores were small; 54% of pts randomized to GLM+MTX had no radiographic progression (DvdH-S ≤0). The most common AEs were upper respiratory tract infection (32.9%), nasopharyngitis (17.1%), and bronchitis (17.1%); 9.2% of pts had an injection-site reaction. Through wk268, 172/434 pts (39.6%) had an SAE; 14.1% of pts discontinued study agent due to AEs. The rates of serious infections, malignancies, and death were 11.5%, 6.2%, and 1.8%, respectively. Of 429 pts with available samples, 33 (7.7%) were positive for antibodies to GLM.

Table. Efficacy results at wk256

Efficacy at wk256	PBO+MTX[a]	GLM100mg+ PBO[b]	GLM 50mg +MTX[b]	GLM 100mg +MTX[b]	Total
ACR20	69/91 (75.8%)	71/93 (76.3%)	57/74 (77.0%)	44/59 (74.6%)	241/317 (76.0%)
ACR50	43/91 (47.3%)	48/93 (51.6%)	40/74 (54.1%)	28/59 (47.5%)	159/317 (50.2%)
ACR70	21/91 (23.1%)	27/93 (29.0%)	28/74 (37.8%)	15/59 (25.4%)	91/317 (28.7%)
DAS28-CRP EULAR Response	81/90 (90.0%)	83/92 (90.2%)	65/73 (89.0%)	52/59 (88.1%)	281/314 (89.5%)
DAS28-CRP Remission (<2.6)	38/90 (42.2%)	41/92 (44.6%)	35/73 (47.9%)	27/59 (45.8%)	141/314 (44.9%)
SDAI ≤3.3	25/90 (27.8%)	21/92 (22.8%)	20/73 (27.4%)	17/60 (28.3%)	83/315 (26.3%)
DAS28-CRP ≤3.2	56/90 (62.2%)	59/92 (64.1%)	46/73 (63.0%)	38/60 (63.3%)	199/315 (63.2%)
HAQ-DI improvement ≥0.25	61/91 (67.0%)	59/93 (63.4%)	55/74 (74.3%)	42/59 (71.2%)	217/317 (68.5%)
Radiographic results at wk256.					
Estimated annual progression rate at baseline[c]	5.3 ± 7.8	5.6 ± 8.9	4.7 ± 6.9	5.4 ± 13.7	5.3 ± 9.3
Mean ± SD annual rate of progression through 5yrs[d]	0.7 ± 2.0	1.0 ± 2.3	0.3 ± 1.2	0.7 ± 2.2	0.7 ± 2.0
Mean ± SD change in vdH-S score	3.2 ± 9.2	4.6 ± 10.9	1.7 ± 6.1	3.3 ± 10.2	3.3 ± 9.4
Change in vdH-S score ≤0	52/95 (54.7%)	43/99 (43.4%)	47/79 (59.5%)	30/65 (46.2%)	172/338 (50.9%)

[a]Pts switched to GLM at wk16 or 24. [b]After wk52 pts could receive GLM50 mg or 100mg, and MTX could be added/adjusted. [c] vdH-S score divided by the disease duration per pt. [d]Change in vdH-S score divided by GLM treatment duration per pt.

Conclusion: The retention rate was high (70.5%), and improvements in signs/symptoms of RA and in physical function with GLM+MTX therapy were maintained long-term. Radiographic progression appeared controlled with small changes in mean vdH-S scores observed through 5yrs. The long-term safety of GLM is consistent with other anti-TNFα agents.

Safety and Effectiveness Of Abatacept In 3985 Japanese Patients With Rheumatoid Arthritis; Japan All-Cases Post-Marketing Surveillance.

Takao Koike[1], Masayoshi Harigai[2], Naoki Ishiguro[3], Shigeko Inokuma[4], Junnosuke Ryu[5], Syuji Takei[6], Tsutomu Takeuchi[7], Y. Tanaka[8], Masahiko Watanabe[9] and Hisashi Yamanaka[10]. [1]NTT Sapporo Medical Center, Sapporo, Japan, [2]Tokyo Medical and Dental University, Tokyo, Japan, [3]Nagoya Univeristy Graduate School of Medicine, Nagoya, Japan, [4]Japanese Red Cross Medical Center, Tokyo, Japan, [5]Nihon University School of Medicine, Tokyo, Japan, [6]Kagoshima University, Kagoshima, Japan, [7]Keio University School of Medicine, Tokyo, Japan, [8]University of Occupational and Environmental Health, Kitakyushu, Japan, [9]Bristol-Myers K.K, Tokyo, Japan, [10]Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: A large-scale post-marketing surveillance (PMS) has been implemented to evaluate the safety and effectiveness on the use of intravenous abatacept (ABT) in Japanese patients with rheumatoid arthritis (RA) as per approval condition.

Methods: This observational study has registered all of the patients intended to be treated with ABT in Japan after its start of marketing in September 2010. Patients were prospectively monitored for adverse events (AEs) for 24 weeks. Disease Activity Score 28-CRP (DAS28-CRP) was calculated at baseline, Weeks 4, 12 and 24 of treatment.

Results: Of 4256 patients treated with ABT between September 2010 and June 2011, the safety and effectiveness were analyzed in 3985 and 3094 patients, respectively. Most of the patients from the safety population had established RA. Their mean age was 61.3 years and mean RA duration was 10.3 years. About 70% of patients had received biologic drug(s) prior to ABT. Methotrexate (MTX) and corticosteroid were used concomitantly in 67.0% and 63.3% of patients, respectively. Adverse drug reactions (ADRs) and serious ADRs occurred in 15.4% and 2.5% of patients, respectively. ADRs in ≥0.5% of patients included upper respiratory tract inflammation (1.2%), herpes zoster (1.0%), bronchitis (0.9%), stomatitis (0.9%), nasopharyngitis (0.9%), abnormal hepatic function tests (0.8%), pyrexia (0.6%), and rash (0.6%). Infections occurred in 5.9%; pneumonia in 28 patients (0.7%), *Pneumocystis jirovecii* pneumonia in 4 patients (0.1%), tuberculosis in 1 patient (0.03%) and atypical mycobacterial infection in 2 patients (0.05%). Serious infections were reported in 1.0% of patients. ABT was tolerated even in patients who had prior biologics use, there was no statistical difference of the incidence of ADRs or serious ADRs between biologic-naïve and -experienced patients. The incidence of ADRs was numerically lower, although not statistically, in patients using MTX than in patients not using MTX. Multivariate logistic regression analyses showed that age >65 years, body weight <40 kg, hepatic comorbidities, history/presence of respiratory disorders, history of allergies, prior use of tocilizumab, and concomitant use of prednisolone >5 mg/day were risk factors for infections. DAS28-CRP decreased from 4.47 at baseline to 3.25 at Week 24, with significant reductions from baseline as early as Week 4 ($P < 0.001$). The decrease in DAS28-CRP was significantly greater in the biologic-naïve group than in the biologic-experienced group ($P < 0.001$). The mean change in DAS28-CRP from baseline to Week 24 in patients not using MTX (–1.10) was almost same as in patients using MTX (–1.27), although with a statistical difference ($P = 0.003$). In the biologic-naïve group, the reduction in DAS28-CRP at Week 24 was not statistically different between patients using MTX and not using MTX.

Conclusion: This large-scale PMS program showed that ABT was well tolerated with no new safety concerns and significantly reduced signs and symptoms of Japanese patients with RA treated in real-world settings.

Safety and Efficacy Of Subcutaneous Golimumab In Chinese Patients With Active Rheumatoid Arthritis Despite MTX Therapy: Results From a Randomized, Placebo-Controlled, Phase 3 Trial.

Zhanguo Li[1], Fengchun Zhang[2], Jonathan Kay[3], Kaiyin Fei[4], Chenglong Han[5], Yanli Zhuang[4], Zhong Wu[4] and Elizabeth C. Hsia[6]. [1]Peking University People's Hospital, Beijing, China, [2]Peking Union Medical College Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China, [3]University of Massachusetts Medical School, Worcester, MA, [4]Janssen Research & Development, LLC., Spring House, PA, [5]Janssen Global Services, LLC., Malvern, PA, [6]Janssen Research & Development, LLC./U of Penn, Spring House/Philadelphia, PA.

Background/Purpose: Assess safety and efficacy of GLM+MTX over 1yr in a multicenter, randomized, placebo (PBO)-controlled study of Chinese pts with active RA despite MTX therapy.

Methods: 264 pts were randomized (1:1) to subcutaneous PBO+MTX (Group1) or GLM 50mg+MTX (Group2) q4wks. All pts received stable doses of oral MTX (7.5–20mg/wk). Group1 pts with inadequate treatment response entered blinded early escape to GLM 50mg+MTX at wk16. All remaining Group1 pts switched to GLM 50mg+MTX at wk24. Blinding to randomization assignment was maintained through wk 56. The last GLM injection was at wk48; the last efficacy assessment was wk52. The primary endpoint was ACR20 at wk14. Efficacy assessments included DAS28-CRP, HAQ-DI, SF-36 PCS and MCS, and FACIT-Fatigue scores. Adverse events (AEs) were monitored through wk56.

Results: Baseline demographics and disease characteristics were generally similar between the groups; median age was 49 yrs and 81.1% of pts were female. 23 (8.7%) pts discontinued treatment through wk56. Efficacy results are shown in the table. At wk14, 15.9% of Group1 pts and 40.9% of Group2 pts had ACR20 response ($p<0.001$). At wk24, Group2 pts had significantly greater improvements in DAS28-CRP, SF-36 PCS and MCS scores, and FACIT-fatigue score. A greater proportion of Group2 pts had HAQ-DI improvement ≥0.25 vs. Group1. The responses to GLM+MTX therapy were maintained through wk52 in Group2; after switching to GLM, Group1 pts also achieved rapid improvement. Through wk16, 23.5% of Group1 pts and 26.7% of Group2 pts reported AEs (infections were the most common); 0.8% and 1.5% reported serious AEs. Through wk56, 130/259 (50.2%) of GLM+MTX-treated pts had an AE, and 11/259 (4.2%) had an SAE. 3 serious infections (pneumonia, lung infection, respiratory tract infection) and 1 death (acute myocardial infarction) occurred in GLM+MTX-treated pts. No malignancies or opportunistic infections were reported. Only 1 pt had an injection site reaction (mild pain).Of the 251 GLM+MTX-treated pts with available samples, 6 (2.4%) were positive for antibodies to GLM through wk52.

Table. Efficacy results through week 52

	PBO+MTX/GLM 50 mg+MTX (n = 132)	GLM 50 mg +MTX (n = 132)
Wk24		
ACR20	21 (15.9%)	56 (42.4%)**
DAS28-CRP, Mean±SD change from baseline	−0.2 ± 1.5	−1.2 ± 1.3**
HAQ-DI improvement ≥ 0.25	39 (29.5%)	65 (49.2%)*
SF-36 PCS, Mean±SD change from baseline	−0.88 ± 6.92	4.30 ± 7.05**
SF-36 MCS, Mean±SD change from baseline	−2.68 ± 12.07	2.23 ± 10.59**
FACIT-F, Mean±SD change from baseline[a]	−2.2 ± 11.2	3.4 ± 9.4**
Wk52		
ACR20	75 (56.8%)	92 (69.7%)
DAS28-CRP, Mean±SD change from baseline	−2.0 ± 1.4	−2.2 ± 1.4
HAQ-DI improvement ≥ 0.25	65 (49.2%)	87 (65.9%)
SF-36 PCS, Mean±SD change from baseline	3.6 ± 7.1	6.8 ± 8.9
SF-36 MCS, Mean±SD change from baseline	0.2 ± 9.8	3.9 ± 11.0

* $p = 0.001$, ** $p < 0.001$
[a] No assessments past wk24.

Conclusion: Among Chinese pts with RA, GLM+MTX-treated pts had significantly greater improvements in RA signs/symptoms vs. PBO+MTX-treated pts through wk24, and responses were maintained through wk52. GLM+MTX was well tolerated and no unexpected safety events occurred through wk56. In Chinese pts, GLM+MTX demonstrated efficacy and acceptable safety similar to that in a global population in the GO-FORWARD trial.

Lack Of Correlation Between Golimumab Exposure and Selected Safety Events Following Intravenous Or Subcutaneous Administration In An Integrated Analysis Of Phase 3 Data Of Patients With Rheumatoid Arthritis, Psoriatic Arthritis, Or Ankylosing Spondylitis.

Jocelyn H. Leu[1], Anna Beutler[1], Alan M. Mendelsohn[1], Sam Liao[2], Hugh M. Davis[1], Honghui Zhou[1] and Zhenhua Xu[1]. [1]Janssen Research & Development, LLC., Spring House, PA, [2]PharMax Research, Inc., Newport Beach, CA.

Background/Purpose: For anti-TNFα agents, infections and malignancies are key safety concerns. It is unknown whether safety events are driven by peak (C_{max}), trough (C_{min}), average (C_{avg}) concentrations or by total systemic exposure (AUC). This PK/safety analysis was performed by pooling data from Phase 3 IV/SC golimumab (GLM) studies to investigate if there is any relationship between PK exposure and the occurrence of infections, serious infections, SAEs and malignancies after treatment with IV or SC GLM in pts with RA, PsA, or AS.

Methods: Seven Phase 3 GLM rheumatology studies (2 IV/5 SC) were included to leverage data from a large number of pts over a wide range of dosing regimens. Dosing regimens ranged from 2 mg/kg q8w to 4 mg/kg every q12w (IV studies) and 50 mg q4w to 100 mg q4w (SC studies) and included GLM as monotherapy and in combination with MTX/other nonbiologic DMARDs. Established population PK models of SC & IV GLM were used to generate empirical Bayesian estimates of steady-state GLM PK exposure metrics (C_{max}, C_{avg}, C_{min} and Cumulative AUC) for individual pts using actual dosing records. Infections, serious infections and SAEs were evaluated through ~1yr after initial GLM exposure. Malignancies were evaluated through the latest data cut for the IV program (Aug 15, 2012) and through wk 160 in the SC studies to leverage as much data available as possible due to lower incidence of malignancies compared to infections and SAEs. A total of 2486 pts were included in the PK/safety dataset. For infections, serious infections and SAEs, 2 analyses were performed: (1) a quartile analysis where the proportion of pts with these events were assessed by 4 PK quartile subgroups and (2) the distribution of PK exposure vs. number of occurrences. For malignancies, the distribution of PK exposure vs. the occurrence of malignancies was plotted.

Results: From the quartile analyses of the pooled SC & IV data, as systemic exposures to GLM increased there was no trend of increasing infections, serious infections or SAEs regardless of the distribution of the number of safety events for all PK exposure metrics. When comparing SC to IV data for serious infections, there was also no trend of increasing serious infections with higher exposures. From the distribution plots of the combined IV & SC data, it was observed that for C_{avg}, C_{max}, and AUC, the ranges of exposures across categories of having 0, 1, or >1 infections were similar, while for SAEs and serious infections, higher rates of infections trended to occur in pts having lower exposures. A trend toward the observation of higher systemic exposure to GLM correlating with more safety events was not observed, contrary to what might be expected. From the distribution plots for malignancies, no difference was observed in the PK exposure for pts who had no malignancies vs. pts who had malignancies.

Conclusion: No correlation of the occurrence of infections, serious infections, and SAEs with GLM C_{max}, C_{avg}, C_{min} and Cumulative AUC was observed over 1yr of treatment with SC or IV GLM. There was also no correlation of PK GLM exposure with malignancy occurrences up to 3yrs of treatment. The data suggest that the GLM IV and SC dosing regimens evaluated in these studies have similar safety profiles.

Effects Of Smoking Status On Response To Treatment With Tofacitinib In Patients With Rheumatoid Arthritis.

J. M. Kremer[1], J. D. Greenberg[2], C. Turesson[3], D. Gruben[4], C. A. Mebus[4], E. Bananis[5] and T. Robinson[5]. [1]Albany Medical College and The Center for Rheumatology, Albany, NY, [2]NYU Hospital for Joint Diseases, New York, NY, [3]Lund University, Malmö, Sweden, [4]Pfizer Inc, Groton, CT, [5]Pfizer Inc, Collegeville, PA.

Background/Purpose: Cigarette smoking is a known risk factor for developing rheumatoid arthritis (RA).[1] Several recent observational studies suggest that cigarette smoking may be associated with a poor response to treatment with methotrexate (MTX) and TNF inhibitors (TNFi).[2,3] Tofacitinib is a novel, oral Janus kinase inhibitor for the treatment of RA. Analyses investigated the effects of smoking on the response to tofacitinib treatment in patients (pts) with RA enrolled in the Phase (P) 3 program.

Methods: Data from five P3 studies of tofacitinib as monotherapy (ORAL Solo, NCT00814307) or in combination with MTX or other nonbiologic disease-modifying anti-rheumatic drugs (DMARDs) (ORAL Scan, NCT00847613 [1 year data]; ORAL Sync, NCT00856544; ORAL Standard, NCT00853385; ORAL Step, NCT00960440) in DMARD-inadequate responder pts were pooled and analyzed by smoking status at baseline (BL) for pts treated with tofacitinib 5 mg twice daily (BID), 10 mg BID and placebo (PBO). ORAL Standard included an adalimumab (40 mg Q2W; ADA) arm; data from the small subgroup of this population are presented for completeness.

Results: Of the 3315 pts included in the analysis, 1143 (34.5%) reported to be smoking or an ex-smoker ("ever" smokers) at BL. There were greater proportions of males (non-smokers 8.8%, ever smokers 30.7%) and white pts (non-smokers 52.9%, ever smokers 80.2%) among ever smokers; other BL demographics and disease characteristics were similar for non-smokers and ever smokers (age, BMI, RF status, anti-CCP status, DAS28-4(ESR) and HAQ-DI). A history of ever smoking at BL was associated with a higher probability of previous treatment failures with TNFi (non-smokers 19.0%, ever smokers 31.0%) for tofacitinib and PBO arms; a smaller proportion of ADA pts had previous exposure to TNFi regardless of smoking history (<10%). Significant and similar treatment differences for tofacitinib vs PBO for efficacy parameters at Month 3 were seen regardless of smoking status at BL (Table; significance declared as $p \leq 0.05$, 2-sided testing, no adjustment for multiple comparisons). Correlations calculated between smoking duration as of BL and Month 3 continuous efficacy measures (e.g. change from BL in Patient Global Assessment) indicated that smoking duration was generally uncorrelated with efficacy. No consistent differences across efficacy measures were observed between pts that never smoked, were ex-smokers or currently smoked at BL.

Table. Efficacy parameters at Month 3

	Non-smokers (N = 2041)				Ever smokers* (N = 1070)			
	PBO	Adalimumab 40 mg Q2W	Tofacitinib 5 mg BID	Tofacitinib 10 mg BID	PBO	Adalimumab 40 mg Q2W	Tofacitinib 5 mg BID	Tofacitinib 10 mg BID

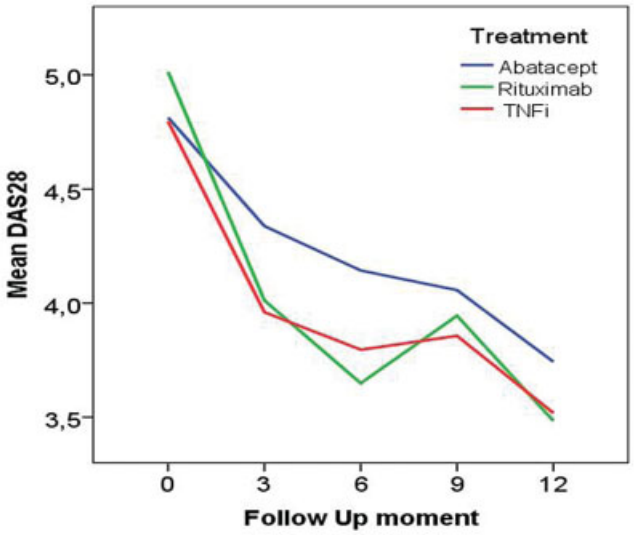
Mode Of Action Change Not Necessary After Failing The First Tumor-necrosisfactor Inhibitor: Preliminary Results Of a Randomized Controlled Trial. Sofie H.M. Manders[1], Wietske Kievit[1], Herman L.M. Brus[2], Hein J. Bernelot Moens[3], Andre Hartkamp[4], Reinhard Bos[5], Elisabeth Brouwer[6], Henk Visser[7], Harald E. Vonkeman[8], Rene Westhovens[9], Mart A.F.J. van de Laar[8] and Piet LCM Van Riel[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]TweeSteden Ziekenhuis, Tilburg, Netherlands, [3]Ziekenhuisgroep Twente, Almelo, Netherlands, [4]Jeroen Bosch Hospital, 's-Hertogenbosch, Netherlands, [5]Medical Center Leeuwarden, Leeuwarden, Netherlands, [6]University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [7]Rijnstate, Arnhem, Netherlands, [8]Medisch Spectrum Twente & University of Twente, Enschede, Netherlands, [9]University Hospital KU Leuven, Leuven, Belgium.

Background/Purpose: The best treatment option after a patient has failed a first TNFi is still unknown. Therefore the objective of this randomized open label study is to compare the effectiveness of abatacept, rituximab or another TNFi after failing a first TNFi, with the DAS28 as outcome measure, in patients with Rheumatoid Arthritis.

Methods: The inclusion criteria for this pragmatic randomized trial within the DREAM cohort were: failing a first TNFi, a DAS28 > 3.2, not treated before with abatacept or rituximab and no contraindications. Patients were randomized to abatacept, rituximab or TNFi treatment. The DAS28 was compared between the three groups with ANOVA, 6 and 12 month after randomization.

Results: 143 patients were randomized into one of the treatments (mean age 56.5 yrs, 76.5% female, median disease duration 5.85 yrs, 63.6% rheumatoid factor positive, mean DAS28 of 4.9). The mean DAS28 (+95% Confidence Interval) after 6 and 12 months respectively was 4.1 (3.7–4.6) and 3.7 (3.2–4.2) for abatacept, 3.6 (3.2–4.1) and 3.5 (3.0–3.9) for rituximab and 3.8 (3.3–4.3) and 3.5 (2.9–4.1) for TNFi, see figure. These were not statistically significant. Remission (DAS28<2.6) was attained in 10.7% and 12.0% in the abatacept group, 24.3% and 27.3% in the rituximab group and 12.9% and 24.1% in the TNFi group at 6 and 12 month respectively.



Conclusion: The data do not reveal a significant difference in effectiveness, measured with the DAS28, between the three different biological. Therefore other reasons than DAS28 status at 6 and 12 months might play a more important role in the choice of a second biological like long term stability of response, side effects, costs or patients preferences for route of administration of treatments.

Induction Therapy With Adalimumab On Top Of An Aggressive Treat-To-Target Strategy With Methotrexate and Intraarticular Corticosteroid Reduces Radiographic Erosive Progression In Early Rheumatoid Arthritis, Even After Withdrawal Of Adalimumab. Results Of a 2-Year Trial (OPERA). Kim Hørslev-Petersen[1], Lykke Midtbøll Ørnbjerg[2], Merete L. Hetland[3], Peter Junker[4], Jan Pødenphant[5], Torkell Ellingsen[6], Palle Ahlqvist[7], Hanne M. Lindegaard[8], Asta Linauskas[9], Annette Schlemmer[10], Mette Y. Dam[11], Ib Hansen[12], Tine Lottenburger[7], Anette Jørgensen[11], Sophine B. Krintel[2], Johnny Raun[1], Christian G. Ammitzbøll[11], Julia Johansen[2], Mikkel Østergaard[13] and Kristian Stengaard-Pedersen[11]. [1]University of Southern Denmark, Graasten, Denmark, [2]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark, [3]DANBIO, Center for Rheumatology and Spine Diseases, Glostrup Univ Hospital, Glostrup, Denmark, [4]University of Southern Denmark, Odense, Denmark, [5]Copenhagen University at Gentofte, Hellerup, Denmark, [6]Silkeborg Regional Hospital, Silkeborg, Denmark, [7]University of Southern Denmark, Vejle, Denmark, [8]Odense University Hospital, Odense, Denmark, [9]Vendsyssel Hospital, Hjørring, Denmark, [10]Aalborg University Hospital, Aalborg, Denmark, [11]Arhus University Hospital, Aarhus, Denmark, [12]Viborg Hospital, Viborg, Denmark, [13]Copenhagen University Hospital Glostrup, Copenhagen, Denmark.

Background/Purpose: In a randomized double-blind, placebo-controlled 2-year investigator-initiated trial of patients with early rheumatoid arthritis[1] (RA) we aimed to investigate if additional adalimumab (ADA) for 1 year on top of an aggressive treat-to-target strategy with methotrexate (MTX) and intraarticular (i.a.) corticosteroid reduces structural damage progression assessed by conventional radiography.

Methods: DMARD naïve early RA patients (n=180) were randomized 1:1 to receive i.a. triamcinolone (40 mg/ml) in any swollen joint and MTX (20 mg/wk) for two years in combination with placebo-ADA (MTX+PLA) or MTX+ADA (40 mg eow) during the first year. Oral glucocorticoid was not allowed. After 1 year, PLA/ADA was withdrawn. During year 2, in both treatment arms, ADA (40 mg eow) was only (re)initiated in patients with recurrence of active disease (DAS28CRP>3.2). Radiographic changes in hands, wrists and feet (Joint Space Narrowing (JSN), Erosion (ES) and Total Sharp Score (TSS)) were evaluated at baseline, 1 and 2 years.

Results: Baseline characteristics were similar in the MTX+PLA and MTX+ADA groups: DAS28CRP 5.6 vs. 5.5, p=0.53. After 2 years the

median MTX dose in the MTX+PLA/MTX+ADA group was 20/20 mg/wk, p=0.33, and the cumulated i.a. triamcinolone dose 8/6 ml, p=0.15. During the 2nd year biologics were initiated in 15%/17%, p=0.97. The 1- and 2-year remission rates (DAS28CRP<2.6) in the MTX+PLA/MTX+ADA group were 49%/74% (p=0.0001) and 69%/66% (p=0.79), respectively. ADA reduced erosive progression (ΔES) throughout the study (table). The percentage of patients with erosive disease increased in the MTX+PLA/MTX+ADA group with 12%/2% during year 1 and remained unchanged during year 2. The annual erosive progression (ΔES) and the percentage of patients who progressed were lower in the MTX+ADA group in year 1 (p=0.02/p=0.04) and also in year 2, after ADA withdrawal (p=0.005/p=0.04). After 2 years total ES was borderline lower in the MTX+ADA group (p=0.06). ΔTSS was lower in the ADA+MTX group than in the PLA+MTX group in year 1 (mean 0.27 vs. 1.64, p<0.009) but not in year 2 (0.78 vs. 0.99, p=0.46).

Erosion (ES), Joint Space Narrowing (JSN) and Total Sharp (TSS) scores at baseline, year 1 and 2; and Δ scores 0–1, 1–2 and 0–2 years. Values are median [5%; 95% percentiles]/mean(SD) or percentage. P values are based on Mann-Whitney or Pearson's chi-square tests. Analysis was by intention-to-treat. ITT with last observation carried forward and completer analyses gave similar results (not shown).

Conclusion: Despite very limited radiographic progression following an aggressive treat-to-target therapeutic strategy applying methotrexate and i.a. glucocorticoid injections into swollen joints during 2 years, radiographic erosive progression was significantly reduced by adding induction therapy with adalimumab during the 1st year. The effect of adalimumab persisted even after its withdrawal.

Treatment Responses and Their Predictors Of Abatacept In Biologic naïve Patients With Rheumatoid Arthritis; Data Form Abroad Study.

Yutaka Kawahito[1], Takao Fujii[2], Akira Yokota[3], Hideo Hashimoto[4], Kiyoshi Matsui[5], Kenji Miki[6], Masayasu Kitano[5], Naoki Shinmyo[7], Aihiro Yamamoto[1], Koichiro Ohmura[2], Takanori Kuroiwa[8], Toshihiko Hidaka[9], Ichiro Yoshii[10], Hideko Nakahara[11], Takashi Fujimoto[12], Kosaku Murakami[13], Satoshi Morita[14], Masahiro Sekiguchi[5], Norihiro Nishimoto[15], Tsuneyo Mimori[2] and Hajime Sano[5]. [1]Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan, [2]Graduate School of Medicine, Kyoto University, Kyoto, Japan, [3]Yokota Clinic for Rheumatology, Osaka, Japan, [4]Rinku Hashimoto Rheumatology Orthopaedics, Osaka, Japan, [5]Hyogo College of Medicine, Nishinomiya-city, Japan, [6]Amagasaki Central Hospital, Amagasaki, Japan, [7]Kashiba Asahigaoka Hospital, Kashiba, Japan, [8]Yukioka Hospital, Osaka, Japan, [9]Zenjinkai Shimin-No-Mori-Hospital, Miyazaki, Japan, [10]Yoshii Hospital, Shimanto, Japan, [11]NTT West Osaka Hospital, Osaka, Japan, [12]Nara Medical University, Kashihara, Japan, [13]Osaka Red Cross Hospital, Osaka, Japan, [14]Yokohama City University, Kanagawa, Japan, [15]Osaka Rheumatology Clinic, Osaka, Japan.

Background/Purpose: The identification of predictors of good response to biologic therapy is needed in the perspective of personalized medicine. To determine the predicting factors of efficacy of abatacept (ABT) in biologic naïve rheumatoid arthritis (RA) patients, we conducted the ABROAD study (Abatacept Research Outcomes as a first-line biological Agent in the real worlD) in collaboration with 46 institutions in Japan.

Methods: Patients received 500mg of ABT for patients weighted less than 60kg or 750mg for patients with more than 60kg with or without methotrexate (MTX) for 24 weeks. We measured SDAI, DAS28-CRP (DAS), CRP levels at week 0, 4, and 24 after treatment. To evaluate the response to abatacept, we used validated response definitions (50/70/85% improvement) for the simplified disease activity indices (SDAI), which are correlated with ACR (20/50/70 improvement) response and influenced with radiographic progression and function (Aletaha D, et al. Ann Rheum Dis. 71:1190-6, 2012). Predictors of good SDAI response were identified by using univariate followed by multivariate logistic regression analysis.

Results: We examined 179 RA patients with moderate and high disease activity (SDAI >11, female = 85.5 %, mean age = 62.4 years old, mean disease duration =7.9 years, mean dosage of MTX: 7.5 ± 2.6mg/week). SDAI remission (<3.3) at 24 week was achieved in 13% of our patients. SDAI 50%, 70%, and 85% improvement rate at week 24 were 71%, 39%, 16%, respectively. In univariate analyses, very high-positive ACPA (equal or more than 22 times of the ULN, ≧99 U/mL) at baseline was significantly associated with SDAI 50% improvement at week 24 (OR = 3.390, 95% CI = 1,434-8.0, p = 0.005). Short disease duration (< 1 year) was significantly associated with SDAI 85% improvement (OR = 3.191, 95% CI = 1.262–8.072, p = 0.014). In multivariate analyses, very high-positive ACPA, short disease duration (<1 year), 70% improvement of CRP at week 4 were significantly associated with SDAI response.

ACPA titer at baseline influences on SDAI response.

1. Patients with short disease duration (<1 year)

	SDAI 50% improvement (24wk)	SDAI 70% improvement (24wk)	SDAI 85% improvement (24wk)
ACPA< 4.5	25.0%	0.0%	0.0%
ACPA< 99	50.0%	12.5%	12.5%
ACPA ≧ 99	85.7%	71.4%	50.0%

2. Patients with CRP 70 % improvement (at week 4)

	SDAI 50% improvement (24wk)	SDAI 70% improvement (24wk)	SDAI 85% improvement (24wk)
ACPA < 4.5	44.4%	33.3%	0.0%
ACPA < 99	58.6%	37.9%	13.8%
ACPA ≧ 99	95.0%	65.0%	30.0%

Conclusion: In this large biologic naïve observational cohort of RA patients treated with ABT, we suggest that very high-positive ACPA at baseline, short disease duration and CRP improvement at week 4, may be predictors for good response to ABT.

Efficacy and Safety Of a Novel Disease-Modifying Antirheumatic Drug, Iguratimod, As Add-On Therapy For Patients With Rheumatoid Arthritis.

Daisuke Kobayashi[1], Satoshi Ito[2], Akira Murasawa[1], Ichiei Narita[3] and Kiyoshi Nakazono[1]. [1]Niigata Rheumatic Center, Shibata, Japan, [2]Niigata Rheumatic Center, Niigata, Japan, [3]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.

Background/Purpose: Iguratimod is a newly-developed disease-modifying antirheumatic drug (DMARD) that was approved in Japan in September 2012. It has been reported to suppress tumor necrosis factor-alpha-induced production of interleukin (IL)-6, IL-8, and monocyte chemoattractant protein 1 via inhibition of nuclear factor kappa B activation in cultured human synovial cells and human acute monocytic leukemia cells. It can also reduce

immunoglobulin production by acting directly on human B lymphocytes. A double-blind, placebo-controlled study of iguratimod in Japanese patients with rheumatoid arthritis (RA) revealed that it achieved a 20% improvement based on the American College of Rheumatology criteria (ACR20), being almost equivalent to the effect of salazosulfapyridine. In the present study, we examined the efficacy and safety of iguratimod as add-on therapy for patients with RA who had shown inadequate responses to previous therapy.

Methods: Patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria who had been unresponsive to previous therapy, and who had been prescribed iguratimod as add-on therapy at Niigata Rheumatic Center between September 2012 and Feburary 2013 were enrolled. Details of the patients' background factors, clinical parameters and laboratory findings, including C-reactive protein (CRP) level, erythrocyte sedimentation rate (ESR), matrix metalloprotease-3 (MMP-3), rheumatoid factor (RF), Disease Activity Score for 28-joint counts based on the erythrocyte sedimentation rate (DAS28-4[ESR]), Disease Activity Score for 28-joint counts based on the C-reactive protein (DAS28-4[CRP]), clinical disease activity index (CDAI) and simplified disease activity index (SDAI) were obtained from their medical records retrospectively. The efficacy of iguratimod was evaluated at week 12.

Results: Twenty-six patients (5 males, 21 females) participated in this study. They had a mean age of 65.6 ±12.4 years and a mean disease duration of 7.5±8.3 years. Patients were treated with corticosteroids and/or DMARDs as monotherapy or in combination (corticosteroids 20 cases, salazosulfapyridine 18 cases, methotrexate 10 cases, bucillamine 5 cases, tacrolimus 5 cases, tocilizumab 1 case), together with iguratimod. Clinical parameters of disease activity at the baseline had improved 12 weeks later as follows: ESR, 29.9±25.9 mm/h to 25.8±21.5 mm/h (p = 0.33); CRP, 2.44±3.46 mg/dL to 1.27±1.64 mg/dL (p = 0.11); MMP-3, 257.7±160.0 ng/mL to 207.5±128.0 ng/mL (p = 0.17); RF, 141.3±168.7 U/mL to 97.6±121.0 IU/mL (p = 0.011); DAS28-4[ESR], 4.36 ± 3.46 to 3.75 ± 1.00 (p=0.053); DAS28-4[CRP], 3.96±1.28 to 3.27±0.94 (p= 0.02); SDAI, 18.9±13.6 to 13.3±6.2 (p= 0.062); CDAI, 17.0±10.6 to 12.0±5.5 (p= 0.042). Among these 26 patients, 5 discontinued taking iguratimod because of nausea in 2, skin rash in 1, brain hemorrhage in 1, and pulmonary hemorrhage in 1 who was receiving warfarin.

Conclusion: Iguratimod is effective as add-on therapy in RA patients who have shown inadequate responses to previous therapy, although caution is necessary regarding hemorrhagic tendency in patients receiving warfarin, which was cautioned by Ministry of Health, Labour and Welfare of Japan.

The Influence Of Body Mass Index On The Efficacy Of Tumor Necrosis Factor Blocking Therapy For Rheumatoid Arthritis. Ingrid M. Visman[1], Inge A.M. van den Oever[1], Charlotte L. M. Krieckaert[1], Gertjan Wolbink[1] and Michael T. Nurmohamed[2]. [1]Jan van Breemen Research Institute Reade, Amsterdam, Netherlands, [2]VU University Medical Center & Jan van Breemen Research Institute, Amsterdam, Netherlands.

Background/Purpose: The impact of Body mass Index (BMI) on efficacy of TNF blocking therapy is an important question, as adipose tissue appears to have an immunomodulating effect (Tilg et al 2006), and may adversely impact treatment response in patients receiving TNF blocking therapy (Gremese et al 2013). The aim of this study is to ascertain the impact of BMI on the efficacy of TNF blocking therapy with either adalimumab or etanercept for the treatment of RA.

Methods: At the outpatient clinic in Amsterdam, the Netherlands, 853 consecutive RA patients were included who started with TNF blocking therapy adalimumab (411) or etanercept (442), and of whom baseline BMI and follow-up data for at least 16 weeks was available. Adalimumab was dosed at 40 mg fortnightly and etanercept at 50 mg weekly for all patients, regardless of body weight.

Results: The average BMI was 26.0 (SD: 5.2, range 14–50). The baseline DAS was high at 4.9 (SD: 1.3). Mean age was 54 years (SD: 13) and 682 (80%) were female. Median disease duration was 7 years (IQR: 3–16). Median follow-up was 2.1 years (IQR 0.7–4.4 years), 2337 patient years total. Nearly half (407, 48%) of patients were of healthy weight according to the WHO criteria (BMI 18.5–25), 257 (30%) of the patients were overweight, and another 168 (20%) were obese (BMI of 25–30, and >30 respectively). Few patients (21, 2%) were underweight (BMI<18.5). Overall, the patients with healthy weight responded best to TNF blocking therapy, followed by the overweight and the underweight groups. The group who performed worst was the obese group (see Figure 1). After one year the overweight group had a significantly higher DAS (28 joints) than the normal weight group (3.0 (1.3) vs. 2.6 (1.2), p= 0.005), and the obese group did significantly worse than either (3.4 (1.4), p=0.000 (vs. normal) and 0.026 (vs. overweight)). The DAS at one year of the underweight group did not differ significantly from any other weight group. When comparing the individual components of the DAS for obese vs. normal weight RA patients, both tender joint score and BSE were elevated at baseline and 52 weeks, and patient global assessment was only significantly higher at 52 weeks for the obese group. Swollen joint score was not significantly different at baseline or 52 weeks.

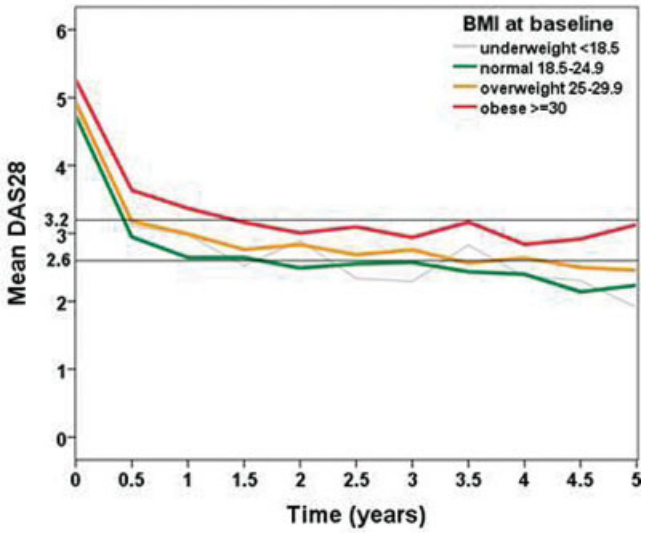

Figure 1. Mean DAS over time.

Conclusion: Our findings support the hypothesis that adipose tissue has an impact on treatment outcome of TNF-blockers in RA. This is important as it may have implications for other immune-mediated inflammatory conditions treated with TNF blocking therapy.

In addition, as adalimumab and etanercept are given in a standard dose, regardless of body weight, it may be that for obese patients a better response could be achieved with an increased dose. This could be an important avenue for further study, and eventually leading to better treatment outcomes of obese RA patients.

1424

Persistence On Single Disease Modifying Anti-Rheumatic Drug Therapy In US Veterans With Rheumatoid Arthritis Is Extremely Rare. Jonathan Kruger[1], Ted R. Mikuls[2] and Grant W. Cannon[1]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]Omaha VA and University of Nebraska Medical Center, Omaha, NE.

Background/Purpose: A limited number of rheumatoid arthritis (RA) patients are managed with a single disease-modifying anti-rheumatic drug (DMARD). Previous studies have suggested that DMARD naïve patients could potentially have a sustained clinical response to single DMARD therapy. However, little information has been available regarding the persistence of single agent therapy. This investigation determined the prevalence and clinical characteristics of US veterans with RA treated with a single DMARD in comparison to patients receiving multiple DMARDs alone or in combination.

Methods: Using the multi-centered observational Veterans Affairs Rheumatoid Arthritis (VARA) registry and VA pharmacy databases, US veterans receiving DMARDs and with ≥3 years of RA were identified. Patients were classified as persistent single DMARD (PS-DMARD), current single DMARDs (CS-DMARD), or combination/complex DMARD (ComCX-DMARD) groups. PS-DMARD patients were persistently treated with a single DMARD since diagnosis. CS-DMARD had received only a single DMARD for the past 12 months of observation but previously received one or more prior DMARDs as either mono-therapy or in combination. ComCX-DMARD patients received more than one DMARD within the prior

12 months of observation. The clinical characteristics, laboratory values and clinical outcomes in these three groups were compared.

Results: There were 966 VARA with ≥ 3 years RA disease duration who had received DMARDs with55 (6%) PS-DMARD, 280 (29%) CS-DMARD and 631 (65%) ComCx-DMARD. The most commonly used DMARD in the PS-DMARD group was methotrexate (75%). However, while methotrexate was still the most dominant agent in the CS-DMARD group, the use of other agents increased, especially anti-TNF agents. PS-DMARD patients were older at onset, more likely to be seronegative, had fewer nodules and had less radiologic evidence for RA. There was not a clear difference in disease duration, smoking status, and genotype in comparison of the three groups.

	PS-DMARD N=55	CS-DMARD N=280	ComCX-DMARD N=631	p-value
Age at diagnosis	57±16	52±14	51±14	0.01
Age at VARA enrollment	68±11	66±11	63±11	0.01
Disease duration (years)	15±13	18±12	17±11	0.06
Gender (male)	52 (95%)	257 (92%)	572 (91%)	0.25
Smoking status				
Never	15 (27%)	62 (22%)	137 (22%)	0.36
Former	28 (51%)	154 (55%)	315 (50%)	
Current	12 (22%)	64 (23%)	179 (28%)	
Education level (years)	13±2.5	13±2.6	13±2.7	0.85
Rheumatoid Factor (pos)	35(64%)	212 (76%)	516 (82%)	0.01
Anti-CCP (pos)	32 (58%)	209 (75%)	489 (77%)	0.01
Rheumatoid nodules (pos)	17 (31%)	151 (54%)	342 (54%)	0.01
Radiographic changes of RA	34 (62%)	206 (74%)	448 (71%)	0.18
Shared Epitope				
2 copies	12 (22%)	58 (21%)	141 (23%)	0.86
1 copy	25 (46%)	142 (53%)	303 (49%)	
Negative	17 (31%)	70 (26%)	171 (28%)	
Most recent DAS28 Score	2.8±1.1	3.4±1.4	3.7±1.5	0.01
Current DMARD Rx				
MTX	41(75%)	93 (33%)	Complex DMARDs–not applicable	
Hydroxychloroquine	7 (13%)	53 (19%)		
Sulfasalazine	3 (5%)	24 (9%)		
Leflunomide	1 (2%)	31 (11%)		
Anti-TNF	3 (2%)	55 (20%)		
Other DMARDs	0	14 (5) (1%)		

Conclusion: Persistent single DMARD therapy was very rare after three years of therapy (approximately 6%) and current single DMARD therapy uncommon (approximately 28%) in this cross-sectional analysis of US veterans. Persistent single DMARD therapy was associated with older age at RA diagnosis and VARA enrollment, lower rates of sero-positive status, fewer rheumatoid nodules, and lower DAS28 scores at the most recent VARA evaluation. While CS-DMARD and ComCX-DMARD patients were very similar in presentation, no clear association was seen in smoking, gender, radiographic changes or in genotypes between all groups. These data suggest that most RA patients will require multiple DMARDs and/or a combination of concurrent DMARDs for management of their disease while persistent single DMARD therapy is very rare.

1425

Discontinuation Of Tumor Necrosis Factor Inhibitors In Rheumatoid Arthritis Patients In Low Disease Activity: Persistent Benefits. Arthur Kavanaugh[1], Susan J. Lee[2], Daniel H. Solomon[3], Jeffrey D. Greenberg[4], Joel M. Kremer[5], Lilian Soto[6], Carol J. Etzel[7] and George W. Reed[8]. [1]University of California, San Diego, La Jolla, CA, [2]University of California San Diego, La Jolla, CA, [3]Harvard Medical School, Brigham and Women's Hospital, Division of Rheumatology, Division of Pharmacoepidemiology, Boston, MA, [4]NYU Hospital for Joint Diseases, New York, NY, [5]Center for Rheumatology, Albany Medical College, Albany, NY, [6]University of California San Diego, San Diego, CA, [7]CORRONA, Inc., Houston, TX, [8]CORRONA, Inc., Worcester, MA.

Background/Purpose: A key question is whether biologic agents can be stopped but clinical benefit maintained for rheumatoid arthritis (RA) patients (pts) in remission or low disease activity (LDA). Potential benefits include lower costs, reduced safety concerns, and conforming with pt preference. To date, this has been addressed in a few clinical trials, using heterogeneous methods (1). We sought to determine the time course for persistent clinical benefit among RA pts in LDA (CDAI ≤ 10) who discontinued their first TNF Inhibitor (TNFi).

Methods: We assessed RA pts from the CORRONA registry. End of Benefit (EOB) was defined as: a) having CDAI>10 at any followup b) initiation of another biologic or DMARD, or c) adding or increasing prednisone. Pts with no EOB event were censored at their last recorded CORRONA visit. Kaplan-Meier method was used to estimate median time to EOB and proportion remaining 'with benefit' at 6 month intervals from 6 to 36 months after drug discontinuation. Cox proportional hazard models were assessed to identify factors related to EOB. Factors that were significant at the 20% level in univariable modeling were evaluated in a multivariable models, adjusting for age, gender, race, smoking, and BMI.

Results: Among 35,656 RA pts, we identified 717 who had: a) discontinued their 1st TNFi while in CORRONA, b) did not add another biologic or DMARD, c) were in LDA at the time TNFi discontinuation, and d) had ≥ 1 followup visit: 301 of these pts had initiated their first TNFi while in CORRONA. At discontinuation, pts had median RA duration of 8 yrs, mean CDAI of 4.3 ± 0.11. 41.8% used TNFi as monotherapy. 601/717 (83.8%) patients had an EOB event and 116 (16.8%) were censored. Kaplan-Meier estimates for the proportion of patients remaining with benefit (percentage, 95%CI) were: 6 mos - 98.7 (97.6–99.3), 12 mos - 73.4 (70.0–76.5), 18 mos - 55.6 (52.8–59.2), 24 mos 42.2 (38.6–46.0), 36 mos 27.6 (24.2–31.0)(Figure). Time course was similar among the 301 pts initiating their 1st TNFi within CORRONA.

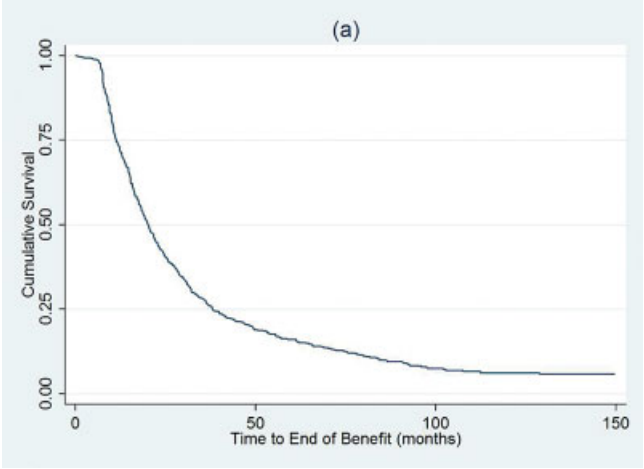

Fig 1. Kaplan-Meier Curve for Time to End of Benefit (in months)

Factors predictive of EOB in univariate analysis included higher CDAI, pt pain score, and HAQ at discontinuation, as well as smoking, higher BMI, and positive RF/ACPA. In multivariate analysis, the 1st 3 factors remained significant with a HR for EOB with CDAI of 1.28 (1.08–1.5 95%CI). Among pts initiating their 1st TNFi within CORRONA, slower responders (time to LDA while on TNF>4 months) did worse than faster responders (HR 1.54 [1.17–2.04 CI]). Of note, RA disease duration did not affect time to EOB.

Conclusion: These data show that discontinuation of a first course of TNFi may be associated with persistent benefit, and that patient characteristics at TNFi discontinuation may help predict persistent benefit.

Inhibition Of Spermidine/Spermine N1-Acetyltransferase Activity – a New Therapeutical Concept In Rheumatoid Arthritis. Emmanuel Karouzakis[1], Astrid Jungel[1], Beat A. Michel[2], Renate E. Gay[1], Steffen Gay[1] and Michel Neidhart[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland.

Background/Purpose: Spermine/spermidine N1-acetyltransferase (SSAT1) and polyamine modulating factor 1 (PMF1) are increased in rheumatoid arthritis synovial fibroblasts (RASF). Since PMF1 regulates the expression of SSAT1, we hypothesized that changes in PMF1 promoter DNA

methylation favor the expression of SSAT1 that causes an excessive consumption of S-adenosylmethionine (SAM) in RASF. The second objective was to decrease the activity of SSAT1 and to evaluate the effect of this treatment - alone or in combination with a supplement of SAM on DNA methylation and behavior of RASF.

Methods: Synovial fibroblasts were isolated from patients with RA or osteoarthritis (OA). Promoter methylation of PMF1 was determined by pyrosequencing. The fibroblasts were treated for 2 weeks with 40 mM diminazene aceturate (DA), an inhibitor of SSAT1. DNA 5-methylcytosine content, SSAT1, adenosylmethionine decarboxylase (AMD), PMF1, DNA methyltransferase 1 (DNMT-1), CXCL12, integrin b1 and CD44 were measured by flow cytometry. Cell adhesion to fibronectin was tested. Levels of matrix metalloproteinases (MMP-1 and -3) were measured in cell culture supernatant. The SCID-mouse model of RA allowed monitoring the invasiveness of RASF.

Results: Compared with OASF (n = 6), RASF (n= 12) expressed more SSAT1, AMD and PMF1: 240+57%, 169+38% and 196+20%. However, PMF1 promoter methylation was unchanged. DA, like siRNA against SSAT1, decreased the expression of AMD in RASF (by 33±5%; $p<0.001$). DA increased the DNA 5-methylcytosine content (by 150±12%; $p<0.05$), increased the expression of DNMT-1 (303±70%; $p<0.001$), decreased the expression of activation markers (CXCL12: 42±7%; Integrin β1: 29±2%, $p<0.001$) and MMP1 (9±2%, $p<0.05$) and altered the adhesion of RASF to fibronectin (Control: 100±17, DA: 72±13%; $p<0.001$). DA was more efficient in RASF with higher levels of SSAT1. The combination of DA plus SAM increased most efficiently DNMT-1 (523±110%; $p<0.001$), than DA or SAM alone. In addition, it further decreased CXCL12 and integrin b1 expression, as well as MMP-1 levels (by 48±5%, 58±5% and 24±6%; $p<0.001$), but not of MMP-3. Most interestingly, the combination DA and SAM reduced the invasiveness of RASF in the SCID mouse model of RA by 70%.

Conclusion: The use of DA alone or in combination with SAM/L-methionine might introduce a new therapeutic concept in RA.

Discovery and Characterization Of ABT-122, An Anti-TNF/IL-17 DVD-Ig™ Molecule As a Potential Therapeutic Candidate For Rheumatoid Arthritis. Chung-Ming Hsieh[1], Carolyn Cuff[1], Edit Tarcsa[2] and Margaret Hugunin[2]. [1]AbbVie Pharmaceuticals, Worcester, MA, [2]AbbVie Bioresearch Center, Worcester, MA.

Background/Purpose: Rheumatoid arthritis (RA) is a serious autoimmune disease that significantly impacts patients' quality of life. Several approved biologic drugs targeting tumor necrosis factor (TNF) and other immune targets are efficacious treatments for RA, and newer drug candidates, including antibodies to interleukin-17 (IL-17), are at various stages of clinical development. Previous and current studies have demonstrated that in a preclinical mouse model of arthritis treatment with antibodies to TNF and IL-17 is significantly more efficacious than treatment with either antibody alone. We therefore generated a novel bispecific dual variable domain immunoglobulin (DVD-Ig™) molecule to both TNF and IL-17 as a potential drug candidate for RA.

Methods: An *in vitro* PROfusion™ mRNA display technology was used to screen for fully human antibodies against human IL-17. The identified IL-17 antibodies were further engineered to improve affinity. We inserted the variable domain of several affinity-matured IL-17 antibodies between an available anti-TNF variable domain and the human IgG1/κ constant region to obtain a panel of novel DVD-Ig" molecules. These DVD-Ig™ molecules differ from each other in the anti-IL-17 variable domains and the peptide linkers (lengths and sequences) connecting the two variable domains. We characterized the DVD-Ig™ activities by ELISA, surface plasmon resonance, and cell-based potency assays. To demonstrate the activities of these DVD-Ig™ molecules *in vivo*, we studied the pharmacokinetic profiles of the top three candidates in rat. The *in vivo* pharmacologic activity was assessed in mouse models by inhibition of recombinant human TNF-*D*gal-induced lethality and recombinant human IL-17-induced KC production.

Results: Fully human antibodies with sub-nM affinity to human IL-17 were selected from human antibody libraries. Their affinities were enhanced by molecular engineering to low pM range. The affinity-matured IL-17 antibodies were combined with an antibody to TNF into a panel of DVD-Ig™ molecules, and screened for optimal activities in antigen binding and neutralization assays. Three drug candidates with strong affinities and potencies (K_D and IC_{50} in the low pM range) were selected for further characterization. In rat pharmacokinetic studies these DVD-Ig™ molecules had 9 to 13 day circulating half-lives upon intravenous injection. In acute mouse models *in vivo*, these DVD-Ig™ molecules also demonstrated potent inhibition of human TNF and IL-17 activity. The DVD-Ig™ molecule with the best affinity and potency, as well as the longest half-life in rat was designated ABT-122 for further development.

Conclusion: ABT-122 is a novel DVD-Ig™ molecule that is engineered to have high affinity and neutralizing potency to both human TNF and IL-17 cytokines. Based on the combined efficacy in a preclinical mouse arthritis model, the demonstrated efficacy of TNF-targeted therapy in RA patients, and encouraging response to IL-17 antibodies in RA clinical trials, we will be evaluating the efficacy and safety profile of the anti-TNF/IL-17 DVD-Ig™ molecule in human RA clinical trials.

The Safety and Efficacy Of Tocilizumab Subcutaneous In Combination With Traditional Dmards In Patients With Moderate To Severe Rheumatoid Arthritis Up To 48 Weeks (BREVACTA). Alan Kivitz[1], Ewa Olech[2], Michael A. Borofsky[3], Beatriz M. Zazueta[4], Federico Navarro-Sarabia[5], Sebastião C. Radominski[6], Joan T. Merrill[7], Chris Wells[8], Sunethra Wimalasundera[8], Wendy Douglass[8] and Janet E. Pope[9]. [1]Altoona Center for Clinical Research, Duncansville, PA, [2]University of Nevada School of Medicine, Las Vegas, NV, [3]Clinical Research Center of Reading, Reading, PA, [4]Centro de Investigacion en Enfermedades Reumaticas, Mexicali, Mexico, [5]Hospital Virgen Macarena, Serv. de Reumatología, Sevilla, Spain, [6]Universidade Federal do Paraná, Curitiba, Brazil, [7]Oklahoma Medical Research Foundation, Oklahoma City, OK, [8]Roche, Welwyn Garden City, United Kingdom, [9]St Joseph Health Centre, London, ON.

Background/Purpose: The BREVACTA study assessed the efficacy and safety of subcutaneous tocilizumab (TCZ-SC) in pts with moderate to severe RA who had an inadequate response to ≥ 1 DMARD (21% had failed an antiTNF). The primary objective of the study was to assess efficacy and safety up to week 24; as reported previously, superiority over placebo was demonstrated, with a safety profile comparable to intravenous TCZ (TCZ IV). Here we report the longer-term efficacy and safety data for TCZ SC administration to Week 48.

Methods: This phase 3, randomized, multicenter, parallel-arm study included a 24 week double-blind, PBO controlled period followed by open label treatment for 72 weeks and 8 weeks of safety follow up. Pts were randomized 2:1 to receive TCZ SC 162 mg every 2 weeks (q2w) or PBO SC q2w via a pre-filled syringe (PFS), in combination with stable doses of pre-study DMARD(s). Escape therapy with TCZ SC qw (PFS) was available from week 12. At week 24, pts remaining on q2w therapy in both arms were re-randomized 1:1 to receive open-label TCZ SC q2w via PFS or Autoinjector Pen. The data presented here focuses on pts who received TCZ SC from baseline to week 48, regardless of injection device used. Efficacy was assessed to week 48. Safety was assessed to 29 October 2012 (when all pts had reached ≥ week 48) using AE reports and laboratory data.

Results: 437 pts were randomized at baseline to receive TCZ SC q2w, with 334 (76%) re-randomized at week 24 to continue to receive TCZ SC q2w in the open-label phase. Efficacy was maintained to week 48, with the proportion of pts with ACR20/50/70 responses, in clinical remission (DAS28 < 2.6) and with a clinically meaningful improvement in physical function (change from baseline in HAQ-DI ≥ 0.3) remaining stable or improving from week 24 to 48 (table). Mean reduction in radiographic progression of structural joint damage (measured as change in modified Total Sharp Score, mTSS) was also maintained from week 24 to 48. The rates of AEs and SAEs, including serious infections, remained stable or decreased between weeks 24 and 48. The most common AEs were infections, particularly respiratory ones. No anaphylaxis or medically confirmed serious hypersensitivity occured. The most common injection site reactions were erythema, pain and pruritis. Ten pts developed antiTCZ antibodies postbaseline, but did not experience loss of efficacy or clinically significant or serious hypersensitivity. A total of 21 pts withdrew from TCZ SC due to AEs, most commonly due to infections or elevated liver enzymes. Six pts died up to the week 48 cut-off.

Withdrawals due to AEs, n	9	21
Deaths, n	3	6

[a] Escape therapy with weekly open-label TCZ SC 162 mg was offered from week 12 to 48 to pts with less than 20% improvement from baseline in both their tender and swollen joint count, and from week 48 onwards to pts with less than 70% improvement in both their tender and swollen joint count. Escape pts were not rerandomized to PFS or AI at week 24, and remained on TCZ SC qw using the PFS for the remainder of the study. The number of pts who received escape therapy includes pts who subsequently withdrew from escape therapy.
[b] Number of pts who completed the TCZ SC q2w regimen to week 24 and week 48, excluding pts who withdrew or received escape therapy with TCZ SC qw.
[c] Mean change in mTSS at week 24 was 0.62 ± 2.692 for TCZ SC vs 1.23 ± 2.816 for placebo (P = 0.0149), and at week 48 was 0.64 ± 3.266 for TCZ SC vs. 1.48 ± 3.804 for pts who switched from placebo to TCZ SC at week 24.
[d] 29 Oct 2012 was the clinical cut-off for week 48.At this time point, the majority of pts had received TCZ SC for longer than 48 weeks.
[e] Events that occurred during or within 24 hours of an injection (excluding ISRs) that were not deemed unrelated to treatment and led to withdrawal.
[f] AEs occurring at the site of a SC injection as recorded by the investigator.

Conclusion: TCZ SC demonstrated long term efficacy, including sustained ACR response rates and reduced progression of joint damage over 48 weeks. There was no change in the AE profile for TCZ SC compared with earlier evaluations. TCZ SC is an effective treatment in RA, and will offer an alternative route of administration and the possibility of self-administration for pts.

Adiponectin Levels Are Increased After Tocilizumab Therapy Among Adults With Rheumatoid Arthritis: Results From The Measure Study.

Hoda Mirjafari[1], Micki Klearman[2], Jianmei Wang[3], Naveed Sattar[4] and Jon T. Giles[5]. [1]Arthritis Research UK Epidemiology Unit, Institute of Inflammation and Repair, Manchester Academic Health Science Centre; The University of Manchester; and Roche;, Manchester, United Kingdom, [2]Roche, South San Francisco, CA, [3]Roche, Welwyn Garden City, United Kingdom, [4]University of Glasgow, Glasgow, United Kingdom, [5]Columbia University, College of Physicians & Surgeons, New York, NY.

Background/Purpose: Cardiovascular disease (CVD) is the leading cause of death in patients (pts) with rheumatoid arthritis (RA). Adiponectin has been shown to have anti-inflammatory and atheroprotective effects on the vasculature, with higher levels associated with improved insulin sensitivity, lower triglyceride levels, and less atherosclerosis. The effect of tocilizumab (TCZ) on adiponectin level has not been studied. The purpose of this study was to explore the change in adiponectin level associated with treatment with TCZ and response to treatment.

Methods: Pts from the MEASURE study (moderate to severe RA with inadequate response to methotrexate [MTX]) who received randomized treatment with either TCZ 8 mg/kg or placebo (PBO) plus MTX were examined if they had fasting adiponectin samples at baseline and week 24. Demographics, RA disease parameters, CVD risk factors, and laboratory assessments of fasting lipids and leptin were assessed at baseline and after 24 weeks of treatment. Within-group change was examined using paired *t*-tests. All association analyses were conducted using linear regression, adjusted for age and sex.

Results: Baseline and week 24 adiponectin samples were available for 108/132 pts, with equal allocation to TCZ + MTX and PBO + MTX. Median (IQR) age was 56 (49–63) years, and median (IQR) body mass index (BMI) was 29 (26–33) kg/m^2. Median (IQR) baseline fasting adiponectin level was 11.2 (7.5–17.7) mg/mL. Baseline characteristics did not significantly differ according to treatment allocation. At baseline, older and female pts were more likely to have higher adiponectin levels, whereas those with higher BMI and/or diabetes were more likely to have lower adiponectin levels. Baseline inflammatory disease activity (DAS28 and C-reactive protein) was not significantly associated with baseline adiponectin. Pts treated with TCZ + MTX had a significant increase in adiponectin by an average of +10% (Table). There was no change in adiponectin among the PBO + MTX group (mean change [95% CI]: 0.25 [–0.54, 1.28]). There was no significant change in leptin or BMI in the TCZ + MTX group. No baseline variables showed significant association with change in adiponectin; however, among pts treated with TCZ + MTX, higher increase in adiponectin level was associated with greater increase in total cholesterol level (β=1.00; p<0.05) and larger improvement in disease activity (β for association for DAS28ESR=–0.67; p<0.05). Increasing adiponectin levels paralleled increases in both LDL and HDL levels and increases in proatherogenic (ApoB) and anti-atherogenic (ApoA-1) apolipoproteins (Table).

Table. Baseline, Week 24, and Change From Baseline in Variables for Patients Treated With TCZ (n = 54)

Variable	Baseline Value Median (IQR)	Week 24 Value Median (IQR)	Mean Change (95% CI)
Adiponectin, μg/mL	11.8 (8.3, 17.4)	13 (7.3, 17.8)	0.85 (0.01, 1.93)*
BMI, kg/m^2	29.3 (25.5, 32.8)	28.9 (26.2, 33.2)	0.25 (–0.1, 0.47)
Leptin, ng/mL	23.5 (11.3, 39.6)	28.8 (14.4, 44.7)	1.6 (–2.7, 4.5)
Total cholesterol, mmol/L	5 (4.19, 5.87)	5.7 (4.78, 6.34)	0.67 (0.45, 0.89)*
LDL-P, mg/dL	1108 (924, 1372)	1343 (1020, 1568)	119 (77, 227)*
HDL-P, mg/dL	30.8 (26.6, 33.7)	34.5 (30.4, 39.5)	4.6 (3.2, 5.8)*
ApoB, mg/dL	0.94 (0.78, 1.15)	1.07 (0.91, 1.36)	0.16 (0.11, 0.22)*
ApoA-1, mg/dL	1.23 (1.06, 1.47)	1.46 (1.18, 1.59)	0.18 (0.09, 0.2)*
DAS28	6.74 (5.9, 7.28)	3.15 (1.93, 4.46)	–3.2 (–3.8, –2.8)*

*Paired *t*-test showed statistically significant change.

Conclusion: Adiponectin is increased with TCZ treatment in RA pts, with higher increases observed in pts with greater degrees of RA disease activity suppression. Future studies should confirm whether TCZ increases adiponectin level and, if so, whether adiponectin change predicts CVD risk change with TCZ.

Safety and Efficacy Of Subcutaneous Tocilizumab Monotherapy In a Long-Term Extension Study In Japanese Rheumatoid Arthritis Patients.

Atsushi Ogata. Osaka University Graduate School of Medicine, Suita, Japan.

Background/Purpose: Tocilizumab (TCZ) blocks interleukin-6-receptor signaling and is an effective rheumatoid arthritis (RA) therapy. The MUSASHI[1] and SUMMACTA[2] studies showed the efficacy and safety of TCZ 162 mg subcutaneous injection (TCZ-SC) to be comparable to those of TCZ 8 mg/kg intravenous infusion (TCZ-IV). Here we assess the long-term

(108-wk) safety and efficacy of TCZ-SC monotherapy in Japanese RA patients (pts).

Methods: This long-term, open-label study followed a 24-wk double-blind, non-inferiority study (MUSASHI study). Pts completing the MUSASHI study were administered 162 mg TCZ-SC every 2nd wk for 84 wks without concomitant DMARDs. Depending on disease activity of individual pts, adjustment of administration interval within a 1- to 3-wk range was allowed after Wk 36.

Results: 346 pts received TCZ for a total exposure of 639.0 pt-yrs. At last observation (Wk 108), 278 pts remained. Most withdrawals were due to AEs (10.3%, 36/346) and insufficient therapeutic response (4.9%, 17/346). AEs occurred at 498.3 events/100 pt-yrs (E/100PY); most common were infections and infestations (138.3 E/100PY). SAEs occurred at 16.9 E/100PY; most common were infections and infestations (5.3 E/100PY). There was 1 death from gastric cancer and disseminated intravascular coagulation. Incidence of malignancy was 0.8 E/100PY. There were no serious anaphylactic events during the TCZ-SC dosing period. The incidence rate of injection site reaction was 13.2% (44/333) in patients who were administered TCZ-SC. The severity of all injection site reactions was mild and tolerable.

ACR20, 50, and 70 response rates increased slightly with continuous TCZ-SC treatment. At Wk 24, ACR20, 50, and 70 response rates were 84.8% (274/323), 65.9% (213/323), and 39.9% (129/323); and at Wk 108, they were 92.5% (258/279), 80.6% (225/279), and 61.6% (172/279). DAS28 and CDAI remission rates at Wk 48 were 64.7% (202/312) and 27.6% (86/312); at Wk 108 they were 79.6% (222/279) and 47.7% (133/279). TCZ administration interval was shortened in 24 pts due to insufficient response; in those pts, DAS28(SD) improved from 4.63(1.56) at before shortening to 2.39(1.14) at 12 wks after shortening. Administration interval was extended in 26 pts due to sufficient response; in 61.5% of those pts, disease activity remained low during the study period with the interval extended.

Table. Events per 100 pt-yrs in TCZ-SC and TCZ-IV[3]

	TCZ-SC pooled *N*=346	TCZ-IV pooled[3] *N*=601
Total exposure (pt-years)	639.0	2188
AEs (E/100PY)	498.3	465.1
Infections and infestations	138.3	129.2
Investigations	86.4	100.9
SAEs (E/100PY)	16.9	23.1
Serious infections	5.3	6.2
Malignancies	0.8	0.8
Deaths	0.2	0.2

Conclusion: The incidence rates of SAEs, serious infections, malignancies, and deaths with TCZ-SC were comparable to those of TCZ-IV pooled data[3] in Japanese RA pts, suggesting that the long-term safety profile of TCZ-SC is not different from established TCZ-IV. Efficacy remained stable with long-term exposure to TCZ-SC. TCZ-SC is a tolerable and useful treatment option for RA.

Algorithms Using Genome-Wide SNP Analysis For Prediction Of Efficacy and Adverse Events Of Abatacept Using Two Population Samples From Multiple Medical Cohorts. Tsukasa Matsubara[1], Satoru Koyano[2], Keiko Funahashi[2], Takako Miura[1], Kosuke Okuda[1], Takeshi Nakamura[1], Mitsuyoshi Iwahashi[3], Tomomi Tsuru[4], Shoichi Uchimura[5], Shigeru Honjo[6], Akira Sagawa[7], Takeo Sakurai[8], Hiroaki Matsuno[9], Tomomaro Izumihara[10], Eisuke Shono[11], Kou Katayama[12], Toyomitsu Tsuchida[13] and Motohiro Oribe[14]. [1]Matsubara Mayflower Hospital, Kato, Japan, [2]Research Institute of Joint Diseases, Kobe, Japan, [3]Higashi-Hiroshima Memorial Hospital, Higashi-hiroshima, Japan, [4]PS Clinic, Fukuoka, Japan, [5]Kanzaki Municipal General Hospital, Kanzaki, Japan, [6]Honjo Rheumatism Clinic, Takaoka, Japan, [7]Sagawa Akira Rheumatology Clinic, Sapporo, Japan, [8]Inoue Hospital, Takasaki, Japan, [9]Matsuno Clinic for Rheumatic Diseases, Toyama, Japan, [10]Izumihara Rheumatic and Medical Clinic, Kagoshima, Japan, [11]Shono Rheumatology Clinic, Fukuoka, Japan, [12]Katayama Orthopedic Rheumatology Clinic, Asahikawa, Japan, [13]Tsuchida Clinic, Chiba, Japan, [14]Oribe Rheumatism and Internal Medicine Clinic, Oita, Japan.

Background/Purpose: Abatacept (ABT), a CTLA4-Ig fusion protein agent targeted to T-cells, is a relatively new biological agent for RA treatment in Japan. However, there is no method for prediction of responders, non-responders, or adverse events which can occur during treatment. We established SNP algorithms for prediction of responsiveness, remission and adverse events in ABT-treated patients by using multiple medical cohorts.

Methods: The first population sample included 46 RA patients treated with ABT and the second, 52 patients; a total of 98 patients from 13 hospitals in different regions of Japan. Efficacy was assessed by DAS28 (CRP) at 48 weeks after the initiation of treatment. Any adverse events that may have been related to ABT administration and observed at 48 weeks of this long-term administration and during phase II were considered to be side effects. Genome-wide SNP genotyping was performed by Illumina HumanHap 300K chip technology. Case-controlled analyses between 302,814 SNPs and responsiveness, remission or occurrence of adverse events were examined by Fisher's exact test. We selected 10 SNPs associated with ABT-responsiveness, remission, and adverse events which were common in both analyses of the first and second populations ($p < 0.05$). We scored the relationship between each SNP and responsiveness, the estimated total score of 10 SNPs (estimated scoring in each SNP was as follows: homo allele in the majority in responders: +1 point, hetero allele: 0 points, and homo allele in the majority of non-responders: -1 point), and then examined relationships between responders and non-responders, remission and non-remission, and occurrence of adverse events, plus or minus, and the total score.

Results: Accuracy ((true positive+true negative)/total), specificity (true negative/(false positive+true negative)), and sensitivity (true positive/(true positive+false negative)) of the algorithm for responsiveness of abatacept ranged from 87–92%. For remission, accuracy, specificity and sensitivity of the algorithm ranged from 81–87%. For adverse events, accuracy, specificity and sensitivity of the algorithm ranged from 83–96%. It is therefore suggested that the SNP algorithms can predict responders and adverse events prior to the initiation of treatment with abatacept.

Conclusion: These highly accurate algorithms using SNP analysis may be useful in the prediction of responsiveness and adverse events before treatment with abatacept, and in this way can contribute to future tailor-made treatment with biologic agents.

The Rate Of Serious Infections Remains Stable In Patients With Multiple Retreatments In Real life: Data From The "Auto Immunity and Rituximab" (AIR) Registry. Jacques-Eric Gottenberg[1], Philippe Ravaud[2], Patrice Cacoub Sr.[3], Thomas Bardin[4], Alain G. Cantagrel[5], Bernard Combe[6], Maxime Dougados[7], Rene-Marc Flipo[8], Bertrand Godeau[9], Loic Guillevin[10], Xavier Le Loet[11], Eric Hachulla[12], Thierry Schaeverbeke[13], Jean Sibilia[14], Isabelle Pane[15], Gabriel Baron[16] and Xavier Mariette[17]. [1]Strasbourg University Hospital, Strasbourg, France, [2]Hopital Hotel Dieu, Paris Descartes University, Paris, France, [3]CHU Pitié-Salpêtrière, Paris, France, [4]Hôpital Lariboisière, Paris, France, [5]Purpan University Hospital, Toulouse Cedex 9, France, [6]Lapeyronie Hospital, Montpellier, France, [7]Paris-Descartes University, APHP, Cochin Hospital, Paris, France, [8]Hopital R Salengro CHRU, Lille, France, [9]University of Paris, AP-HP, Hôpital Mondor Créteil, Creteil, France, [10]Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, [11]CHU of ROUEN, Rouen, France, [12]Claude Huriez University Hospital, Lille, France, [13]Groupe Hospitalier Pellegrin, Bordeaux, France, [14]CHU Hautepierre, Strasbourg, France, [15]Hotel Dieu University Hospital Paris, Paris, France, [16]Groupe Hospitalier Bichat-Claude Bernard, Paris, France, [17]Bicêtre University Hospital, Paris, France.

Background/Purpose: Serious infections in patients with rheumatoid arthritis (RA) treated with rituximab (RTX) are slightly more frequent in common practice than in clinical trials. Morevover, retreatment with multiple cycles might result in hypogammaglobulinemia, which is associated with an increased risk of serious infections. We therefore addressed this issue in the "Auto Immunity and Rituximab" (AIR) registry.

Methods: The AIR registry is an independent multicenter prospective 7-year registry promoted by the French Society of Rheumatology. Serious adverse events are validated by copy charts by the coordinators of the registry. Serious infections are defined as infections which required hospitalization,

intravenous antibiotics or resulted in death. All serious infections occurring in the 12 months following a RTX infusion are considered to occur on RTX therapy.

Results: 1985 patients with RA have been included. Baseline characteristics of the patients are the following: mean age: 58 years, women: 79%, disease duration: 19 years, RF-positivity: 79.5%, anti-CCP positivity: 72,6%, number of previous synthetic DMARDs: 3, 22% of patients without prior anti-TNF, 13% of patients with history of cancer, 34.7% of patients with previous serious or recurrent infections, 65.8% of patients treated with a concomitant synthetic DMARD, 77.2% with corticosteroids (mean dose: 12 mg/d), DAS28 at initiation of RTX: 5.6. 1977 patients have already had at least 1 follow-up visit, with a mean follow-up of 3 years (5865 patient/years).

- Retreatment with RTX: 70.6% of patients with RA were retreated (at least 2 cycles of RTX): ≥2 cycles: 1405 patients; ≥3 cycles: 1043 patients; ≥4 cycles: 763 patients; ≥5 cycles: 532 patients; ≥6 cycles: 330 patients).

- Safety: 95 deaths, 81 cancers, and 281 serious infections occurred. 961 patients (48.4%) discontinued RTX (initiation of a new biological, death, or no infusion in the 18 months preceding last follow-up visit) including 557 patients for inefficacy, 100 for adverse events (including 91 for a serious infection, 32.4% of the patients with serious infections), and 294 patients for other reasons. 96 serious infections occurred after the 1st cycle (4.8% of patients), 69 after the 2d cycle (4.9%), 38 after the 3d (3.6%), 32 after the 4th (4.2%), 20 after the 5th (3.8%), 8 after the 6th (2.4%), respectively, resulting in RTX discontinuation in 36 (37.5% of the serious infections occurring after 1stcycle), 28 (40.5%), 11 (28.9%), 10 (31.2%), 3 (15.0%), 2 (25.0%), after cycle 1 to 6, respectively.

Conclusion: In common practice, the proportion of patients with serious infections remains stable over cycles of RTX despite the increasing risk of hypogammaglobulinemia. It could be partly related to the depletion of the more susceptible patients with time. However, approximately two thirds of patients who experienced a serious infection did not discontinue RTX. Analysis of the contribution of the improvement of disease activity and decrease of corticosteroid dosage to this stable risk of serious infections, is currently ongoing.

Lack Of Early Clinical Response To Treatment With Baricitinib Predicts Low Probability Of Achieving Long Term DAS28-ESR Low Disease Activity Or Remission In Patients With Rheumatoid Arthritis. Edward Keystone[1], Mark C. Genovese[2], Peter Taylor[3], Baojin Zhu[4], Scott D. Beattie[4], Stephanie de Bono[4], Terence Rooney[4], Douglas E. Schlichting[4] and William Macias[4]. [1]University of Toronto, Toronto, ON, [2]Stanford University Medical Center, Palo Alto, CA, [3]University of Oxford, Oxford, United Kingdom, [4]Eli Lilly and Company, Indianapolis, IN.

Background/Purpose: Baricitinib, an oral inhibitor of JAK1 and JAK2 activity, was investigated as treatment for patients with moderately to severely active RA despite use of conventional disease modifying anti-rheumatic drugs (Phase 2b Study JADA; NCT01185353). Compared to placebo, baricitinib (4 mg or 8 mg once daily (QD)) improved signs, symptoms, and physical function through 12 weeks of treatment with statistically significant effects observed as early as Week 2 of the study. Beneficial responses to baricitinib were maintained or improved through Week 24[1]. The objective of this post-hoc analysis was to determine whether early clinical response to baricitinib at Week 4 for the combined 4 and 8-mg dose groups predicted low disease activity (LDA) or remission at Week 12 and 24.

Methods: In Study JADA, 301 patients were randomized 2:1:1:1:1 to receive placebo or 1, 2, 4, or 8 mg baricitinib QD for 12 weeks, respectively, with the 2, 4, and 8-mg doses continued for an additional 12 weeks. Early clinical response was assessed by a variety of measures including DAS28-ESR (DAS-ESR). Week 12 and 24 outcomes were also assessed by a variety of measures including DAS-ESR LDA (DAS-ESR ≤3.2) or remission (DAS-ESR < 2.6). The association between improvements in clinical response at Week 4 for the combined 4/8-mg dose group (n=97) and Week 12 and 24 outcomes was evaluated based on observed data.

Results: Compared to placebo, baricitinib treatment was associated with rapid decrease in DAS-ESR observed as early as Week 2 ($p<0.001$ for both 4 and 8-mg dose groups). DAS-ESR LDA and remission rates were similar at Week 12 and Week 24 (35.1% and 35.2% for LDA; 21.6% and 24.2% for remission, respectively) for the combined 4/8-mg dose group. In 16.5% of patients, the decrease in DAS-ESR was <0.6 at Week 4. Among these patients, only 6.3% and 7.1% achieved DAS-ESR LDA at Week 12 and 24, respectively. No patients achieved remission at either time point. Among the 83.5% of patients whose DAS-ESR improved by ≥0.6 at Week 4, 40.7% and 40.3% achieved DAS-ESR LDA and 25.9% and 28.6% achieved DAS-ESR remission at Weeks 12 and 24, respectively (Table). Larger decreases in DAS-ESR at Week 4 were associated with a higher percentage of patients achieving LDA or remission at Weeks 12 and 24.

Low Disease Activity and Remission After 12 and 24 Weeks of 4 or 8 mg Baricitinib Treatment

Change in DAS-ESR from Baseline to Week 4	LDA (DAS28-ESR ≤ 3.2)		Remission (DAS28-ESR < 2.6)	
	Week 12	Week 24	Week 12	Week 24
	% (Number) of Patients Achieving Clinical Outcome of Interest			
<0.6	6.3% (1/16)	7.1% (1/14)	0% (0/16)	0% (0/14)
<0.8	8.7% (2/23)	14.3% (3/21)	0% (0/23)	4.8% (1/21)
<1.0	9.4% (3/32)	16.7% (5/30)	0% (0/32)	6.7% (2/30)
<1.2	8.3% (3/36)	17.6% (6/34)	0% (0/36)	5.9% (2/34)
	% (Number) of Patients Achieving Clinical Outcome of Interest			
≥0.6	40.7% (33/81)	40.3% (31/77)	25.9% (21/81)	28.6% (22/77)
≥0.8	43.2% (32/74)	41.4% (29/70)	28.4% (21/74)	30.0% (21/70)
≥1.0	47.7% (31/65)	44.3% (27/61)	32.3% (21/65)	32.8% (20/61)
≥1.2	50.8% (31/61)	45.6% (26/57)	34.4% (21/61)	35.1% (20/57)

Conclusion: Baricitinib treatment was associated with a rapid decrease in DAS-ESR with stable DAS-ESR LDA and remission rates observed as early as Week 12 with persistence of benefit through Week 24. A <0.6 decrease in DAS-ESR after 4 weeks of baricitinib treatment was associated with a very low percentage of patients achieving LDA or remission at either Week 12 or Week 24. Larger decreases in DAS-ESR at Week 4 were associated with improved clinical responses. If replicated in Phase 3 studies, a lack of early response to baricitinib may be useful in tailoring therapy to individual patients.

Assessing Janus Kinase inhibitor's Place In Therapy In Established Rheumatoid Arthritis Patients – From a Simplified Indirect Comparison Versus Tumor Necrosis Factor Inhibitors To a Bayesian Probability Of Response – The Value Of Transparency. Michael P. Ingham[1], Paul Song[2], Shannon Cartier[3], Karin Lawson-Remer[2] and Erin Murray[2]. [1]Janssen Scientific Affairs, LLC, Horsham, PA, [2]Doctor Evidence LLC, Santa Monica, CA, [3]Optum, Eden Prairie, MN.

Background/Purpose: Bayesian style network meta-analyses and mixed treatment comparisons help address potential bias from effect modifying trial covariates within indirect comparisons and are theoretically easier to incorporate into decision making, but are not commonly used today by providers when making treatment decisions. Health care reform is paving the way for potentially easier access to tools like this, however quick interpretation still requires as simple an indirect comparison as is reliable, with a preference for greater transparency. From provider perspective, compare tumor necrosis factor inhibitors (TNFi) to Janus kinase inhibitor tofacitinib (TOFA) in

established RA patients when used with non-biologic disease modifiers (DMARDs).

Methods: A systematic review focused on randomized controlled trials (RCTs) with unsatisfactory response to prior DMARD, placebo comparator, active treatment with add-on DMARD, lowest labeled dose and 24-week ACR20 endpoint. Outcomes were extracted double-blind and analysed using a payer validated simulation tool. Indirect comparisons followed ISPOR taskforce on good research practices. ACR20 response was also analyzed within a Bayesian framework, estimating the percentage of time TNF inhibitors had a greater response than tofacitinib. Results presented as relative risks (RR) with confidence intervals where appropriate. Probabilities did not include statistical analyses. Each trial result versus placebo was graphically presented, for transparency, and rank ordered based on relative risk (RR) versus placebo.

Results: Eight TNFi and three TOFA RCTs were identified that reported ACR20 results at 24 weeks. Trials differed primarily in placebo response and intent-to-treat (ITT) reporting methodology. Based on published ITT evidence, it was not possible to extract ACR50 and ACR70 scores for all TOFA trials. For ACR20, six of eight TNFi trials had RR values larger than combined TOFA 5mg results. The indirect RR (and confidence interval) of TNFi versus TOFA for ACR20 was 1.48 (1.02 to 2.14). I^2heterogeneity values were zero for TOFA trial data, and were $>$ 85% for TNFi trials. The probability the risk difference (RD) $>$ 0 from the Bayesian analysis was 85.4% and 80.6% when unadjusted and adjusted for baseline risk respectively. RR $>$ 1.0 and RD$>$0 favor TNFi. DAS Remission and HAQ-DI results were not significantly different TNFi versus TOFA. Results may be sensitive to trials included and time point selected.

Conclusion: Visual inspection of original trial results and the multiple traditional meta-analyses helped identify how and why TNFi compares favorably to TOFA on the most common trial primary outcome (ACR20). Simple indirect comparisons demonstrate analyses of relative treatment effects available to providers, based on published evidence and with access to simulation tools. Supplementing with easily interpretable and adjustable probability of response versus placebo analysis, allows for a more transparent discussion on place in therapy of new treatments. Based on this analysis, time point and outcome, TNFi are likely to be more effective than TOFA more often, when considering biologics used concomitantly with DMARDs.

Effectiveness Of TNF-á Inhibitor Therapy Does Not Differ Between Elderly and Younger Patients With Rheumatoid Arthritis: Results From The Corrona Registry.

Aviva C. Hopkins[1], Melisa Martinez-Marti[1], George W. Reed[2], Ping He[3], Jeffrey D. Greenberg[4], Carlos J. Lozada[1], Ozlem Pala[1], Joel M. Kremer[5] and Dimitrios A. Pappas[6]. [1]University of Miami Miller School of Medicine, Miami, FL, [2]CORRONA, Inc., Southborough, MA, [3]UMASS Medical School, Worcester, MA, [4]New York Hospital for Joint Disease, New York, NY, [5]Albany Medical College and The Center for Rheumatology, Albany, NY, [6]Columbia University, New York, NY.

Background/Purpose: Biologics have revolutionized the therapy and prognosis of patients (pts) with Rheumatoid Arthritis (RA). Studies evaluating whether the effectiveness of TNF-α inhibitor (TNFi) therapy varies by age group are lacking. The present analysis compares the effectiveness of TNFi treatment between older and younger pts with RA.

Methods: Data were obtained from the Consortium of Rheumatology Researchers of North America (CORRONA) registry. We identified RA pts having at least moderate disease activity (CDAI $\geq$10) who initiated their first TNFi and had a follow up visit 6 months (4–9 months) later. We subsequently compared the odds of achieving low disease activity (LDA), as measured by CDAI, in older ($\geq$65 years old) vs younger (18–64 years old) pts. Non-response was imputed for pts who discontinued the TNFi and switched to another biologic prior to the 6 month follow up visit. The actual 6 months disease activity was used if TNFi was stopped without switching to a different biologic.

Multivariate models (MV) compared the odds of achieving LDA between older and younger pts. Propensity scores (PS) were used to evaluate the probability of pts to belong in the elderly group and were used to fit MV models in two ways: a) After excluding pts in the non overlapping regions of the PS distribution, we adjusted for variables still not balanced after trimming. b) Using the PS to 1:1 match older to younger TNFi initiators we adjusted only for disease duration.

Results: 1415 biologic naïve TNFi initiations were identified: 377 of them were $\geq$ 65 years old and 1038 pts were $<$ 65 years old. Baseline characteristics in older versus (vs) younger group: 72.4% vs 77.1% women, 88.3% vs 81.7% Caucasian, 74.2% vs 70.2% seropositive. Mean $\pm$ SD age was 72.4$\pm$6.1 vs 50.8$\pm$9.6 years, RA disease duration 10.9$\pm$10.8 vs 6.1$\pm$7.6 years; CDAI: 25.7$\pm$ 10.8 vs 26.3$\pm$12.8 in older vs younger pts respectively. 82.2% of older pts received the TNFi in combination with non-biologic DMARDs vs 85.4% in the younger group. 72 (19.10%) older pts discontinued the TNFi during the follow up period and 10 of them (2.65%) switched to different biologic vs 180 (17.34%) and 50 pts (4.82%) respectively in the younger group.

After trimming pts in non-overlapping regions of PS, 365 pts remained in the older and 1021 in the younger group. After PS 1:1 matching, 326 pts remained in each group. Table 1 shows the results of unadjusted and adjusted comparisons in the odds of achieving LDA in older and younger pts.

Table 1.

Treatment	Odds Ratios	[95% CI]	p-value
	Unadjusted Results		
Younger patients (N=1038)	1 (referent)		
Older patients (N=377)	0.98	0.76–1.26	0.874
	Adjusted Results after trimming of patients on non-overlapping Propensity Score* distributions**		
Younger patients (N=1021)	1 (referent)		
Older patients (N=365)	0.89	0.67–1.17	0.387
	Adjusted Results after Propensity Score* 1:1 matching***		
Younger patients (N=326)	1 (referent)		
Older patients (N=326)	0.91	0.65–1.27	0.575

* Propensity score variables: gender, functional class, subcutaneous nodules, baseline CDAI, baseline mHAQ score, BMI, smoking status, history of cardiovascular disease, and history of malignancy.
** Adjusted for: gender, functional class, subcutaneous nodules, baseline mHAQ, baseline CDAI, BMI, history of cardiovascular disease, history of malignancy, and smoking status.
*** Adjusted for: duration of Rheumatoid Arthritis.

Conclusion: The effectiveness of TNFi therapy does not differ between older and younger pts with RA based on the current analysis. This suggests that treatment decisions for those with RA should not be based on age considerations alone.

Early Changes In a Multi-Biomarker Disease Activity Score After Starting Adalimumab Treatment Predict Change In MRI Inflammation At 6 Months.

Simon Krabbe[1], R.J. Bolce[2], Cecilie Heegaard Brahe[1], Uffe Møller Døhn[1], Scott Cruickshank[3], Bo J. Ejbjerg[4], Merete L. Hetland[1], E.H. Sasso[2], D. Chernoff[5], Michael Sejer Hansen[6], Lene Surland Knudsen[7], Annette Hansen[8], Ole Rintek Madsen[8], Maria Hasselquist[9], Jakob M. Møller[9] and Mikkel Østergaard[1]. [1]Copenhagen University Hospital Glostrup, Copenhagen, Denmark, [2]Crescendo Bioscience Inc., South San Francisco, CA, [3]Scott Cruickshank and Associates, Inc., Santa Barbara, CA, [4]Slagelse Sygehus, Slagelse, Denmark, [5]Crescendo Bioscience, Inc., South San Francisco, CA, [6]Gildhøj Privathospital, Copenhagen, Denmark, [7]Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark, [8]Copenhagen University Hospital Gentofte, Copenhagen, Denmark, [9]Copenhagen University Hospital Herlev, Copenhagen, Denmark.

Background/Purpose: A multi-biomarker disease activity (MBDA) score has been validated as a measure of disease activity in rheumatoid arthritis. This study aimed to see if baseline MBDA score and early treatment-induced changes in MDBA score predict magnetic resonance imaging (MRI) inflammation and joint damage at week 26 and 52 in patients initiating anti-TNF therapy in an investigator-initiated trial (HURRAH trial, NCT00696059).

Methods: Fifty-two RA patients with active disease despite conventional DMARD therapy were included. All started adalimumab 40 mg s.c. eow at baseline and continued on methotrexate. MRI of the wrist and MCP joints of one hand was obtained at baseline, week 26 and 52, and OMERACT RAMRIS scores were assigned. Blood tests were drawn at baseline, week 2, 6, 12, 26, 39 and 52 for measurement of 12 serum biomarkers (VCAM-1, EGF, VEGF-A, IL-6, TNF-RI, MMP-1, MMP-3, YKL-40, leptin, resistin, SAA, CRP) used to generate a Vectra® DA algorithm score. Associations between MBDA score, DAS28-CRP and changes in MRI inflammation and joint damage at week 26 and 52 were tested using Spearman's rank correlations. We did not control for multiple testing in this post-hoc analysis.

Results: Of the 52 patients, 67% were women, 79% IgM rheumatoid factor positive. At baseline, age was median 61 years (range 19–86), disease duration 7 years (0–36), DAS28-CRP 4.9 (2.9–7.4), HAQ 1.125 (0–2.125), MRI synovitis score 15 (3–21), MRI bone marrow oedema score 7 (0–42), MRI erosion score 16 (3–155), MBDA score 63 (15–89).

At week 26 MBDA score was statistically significantly correlated with MRI synovitis (rho = 0.42, p=0.016), but not with MRI bone marrow edema (rho = 0.32, p=0.06). At baseline and week 52 no statistically significant correlations between MBDA score and MRI inflammation were found.

MBDA score at week 2 and 6 and percent change in MBDA score at week 6 predicted changes in MRI synovitis score at week 26. In similar analyses at week 52, no statistically significant associations were found. A borderline significant (p = 0.07) correlation was observed between percent change in MBDA score at week 6 and change in MRI erosion score at week 26.

In all 15 patients with clinical remission (DAS28-CRP<2.6), subclinical inflammation could be detected at 6 months by MRI (all had synovitis, 9 had bone marrow edema). Of these 15 patients only 2 (13%) were grouped as in MBDA remission (≤25), 7 (44%) in MBDA moderate disease activity (30–44) and 6 (40%) in MBDA high disease activity (>44). 4 patients had MRI erosive progression above the smallest detectable difference (change in score ≥3) at week 52, none of these were in clinical or MBDA remission at week 26.

	Change in MRI synovits score from baselineto week 26			Change in MRI bone marrow edema score from baselineto week 26			Change in MRI erosion score from baselineto week 26		
	N	rho	P-value	N	rho	P-value	N	rho	P-value
Baseline MBDA	36	0.28	0.10	36	0.06	0.73	38	0.08	0.62
MDBA at week 6	34	0.49	0.033	34	0.10	0.58	36	0.28	0.10
Change in MBDA score at week 6	34	0.30	0.09	34	0.15	0.41	36	0.23	0.17
Percent change in MBDA score at week 6	34	0.44	0.009	34	0.15	0.41	36	0.31	0.06
Baseline DAS28-CRP	36	0.37	0.025	36	0.17	0.31	38	−0.00	0.99
DAS28-CRP at week 6	33	0.15	0.40	34	0.32	0.06	35	0.02	0.91
Change in DAS28-CRP score at week 6	33	−0.10	0.59	34	0.19	0.28	35	0.09	0.61
Percent change in DAS28-CRP score at week 6	33	−0.06	0.73	34	0.28	0.10	35	0.11	0.54

Conclusion: MDBA score at week 2 and 6 and percent change in MBDA score at week 6 was predictive of MRI synovitis at week 26, but not at week 52. This study encourages further investigation of MBDA as en early marker of treatment response and risk of erosive progression in patients with RA.

[1]Leiden University Medical Center, Leiden, Netherlands, [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [3]Hospital Universitario La Paz, Madrid, Spain, [4]University of Erlangen-Nuremberg, Erlangen, Germany, [5]Sheba Medical Center, Tel-Hashomer, Tel-Aviv University, Tel-hashomer, Israel, [6]Faculdade de Medicina, Universidade Federal do Rio Grande do Sul - Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil, [7]University of Southern California School of Medicine, Santa Monica, CA, [8]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [9]Cochin Hospital, Paris, France.

Background/Purpose: 24- and 52- week data from ACT-RAY comparing an add-on strategy (tocilizumab [TCZ] + methotrexate [MTX]) with a switch strategy (TCZ + placebo [PBO]) in MTX-IR pts have been previously reported, demonstrating relevant clinical and radiographic benefit without clinically meaningful between-arm differences for most endpoints. During year 2, the study included a step-down strategy with the goal of achieving drug free remission (discontinuation of study drugs with DAS28 <2.6). The objective here is to further assess the efficacy and safety of TCZ-based treatment strategies and to determine the ability to discontinue study drugs in year 2 after sustained clinical remission (DAS28 <2.6 at 2 consecutive visits 12 weeks apart).

Methods: ACT-RAY is a phase 3b trial. Pts on stable doses of MTX were randomized to either add TCZ 8 mg/kg IV every 4 weeks (q4w; add-on) or switch to TCZ 8 mg/kg IV with oral PBO (switch). Utilizing a treat to target (T2T) approach, OL DMARDs other than MTX were added from week 24 usually if DAS28 was >3.2, while maintaining MTX/PBO blinding. In year 2, if sustained clinical remission was achieved, first TCZ and then OL DMARDs and MTX/PBO were discontinued. In case of flare, the last effective treatment or TCZ with blinded MTX/PBO was restarted.

Results: Pt baseline (BL) data were similar between treatment arms (mean disease duration 8.2 y, BL DAS28 6.4) except for higher Genant-Sharp Scores (GSS) in the switch group (41.2 vs 36.9 for add-on pts). 76% of 556 randomized pts (277 add-on and 276 switch) completed year 2. Reasons for withdrawal included lack of efficacy (1.8% add-on, 4.7% switch) and adverse events (AEs; 9.7% add-on, 11.2% switch, including 3 and 6 deaths, respectively). Of pts entering into year 2,~50% discontinued TCZ after achieving sustained remission, and 86% of these pts experienced flare before the end of year 2 (flares can still occur in year 3). For pts who restarted TCZ and had a DAS28 assessment (n = 164), mean DAS28 at flare was 4.46. The effects of restarting TCZ were rapid with mean DAS28 dropping to 2.99, 2.18 and 2.02 within 4, 12 and 20 weeks, respectively. See table for additional results. Despite many pts stopping TCZ for some period, radiographic progression was minimal in both arms (table). Safety was consistent with previous findings. SAEs and serious infections per 100 PY were 11.9 and 4.2, respectively, for the add-on and 14.6 and 3.8, respectively, for the switch arm. In pts with normal BL values, ALT elevations >3× ULN were observed in 13.5% of add-on and 4.9% of switch pts.

Table. Week 104 Efficacy Results

Clinical Parameter	Add-on N = 277[1]	Switch N = 276[1]	*P*value
TCZ discontinuation after achieving sustained remission[2], %	53%	47%	0.13
Pts achieving study drug-free remission[2,3], %	5.1%	1.8%	0.037
Flares[2,4], %	85%	87%	0.075
Median time to flare (days)[5]/Mean DAS28-ESR at flare	113/4.4	79/4.4	0.075/0.22
Mean DAS28-ESR 12 weeks after TCZ restart/% with DAS28-ESR<2.6[6]	2.22/76%	2.13/74%	–
DAS28-ESR, mean change ± SEM from baseline[7,8]	−3.5±0.14	−3.6±0.14	0.43
GSS, mean change ± SEM from baseline[8]	0.35±0.35	0.95±0.32	0.036
Pts without radiographic progression[9], %	94%	91%	0.14

[1]Ns for ITT population only. See additional footnotes for analysis-specific ns. [2] Kaplan-Meier estimates (for TCZ discontinuation and drug-free remission based on the 85% of ITT pts eligible for step-down phase). Further flares and drug-free remissions may still occur. [3] First TCZ, then OL DMARDs and then MTX/PBO were stopped if remission was maintained. Does not consider steroids. [4] Definition of flare was at the investigator's discretion. [5] *P* value from a Log-Rank test. [6] N = 73 (add-on) and 68 (switch). [7] N = 218 (add-on) and 192 (switch). [8] Estimates and *P* values adjusted for region, baseline DAS28 (DAS28 change)/baseline GSS (GSS change). Baseline GSS scores from reading campaign 2. [9] No progression defined as change from baseline GSS ≤2.1 (smallest detectable change for reading campaign 2); N = 214 (add-on) and 202 (switch): pts with a Week 104 reading; *P* value from a Cochran-Mantel-Haenszel test stratified by baseline GSS quartile and DAS28 ≤ or >5.5.

Conclusion: Previous clinical improvements were largely maintained in year 2 of ACT-RAY. Year 2 results suggest that T2T strategies can be successfully utilized in MTX-IR pts (whether or not currently on MTX) to achieve sustained remission. However, stopping TCZ in this established RA pt population was associated with a high flare risk. Pts who restarted TCZ achieved improvements in DAS28.

Comparative Effectiveness Of Rituximab Vs. Subsequent Anti-Tumor Necrosis Factor In Patients With Rheumatoid Arthritis With Prior Exposure To TNFi. Leslie R. Harrold[1], George W. Reed[2], Robert P. Magner[1], Ashwini Shewade[3], Ani John[3], Jeffrey D. Greenberg[4] and Joel M. Kremer[5]. [1]University of Massachusetts Medical School, Worcester, MA, [2]CORRONA, Inc., Southborough, MA, [3]Genentech Inc., South San Francisco, CA, [4]NYU Hospital for Joint Diseases, New York, NY, [5]Albany Medical College and The Center for Rheumatology, Albany, NY.

Background/Purpose: In patients (pts) who have failed 1 or more TNF-α inhibitors (TNFi), there is little data to guide clinical decision making in terms of changing mechanism of action or prescribing another TNFi. The objective of this study was to examine the comparative effectiveness of rituximab (RTX) versus a subsequent TNFi in RA pts with prior TNFi exposure using data from the Consortium of Rheumatology Researchers of North America (CORRONA), a multi-center observational registry within the United States.

Methods: Using CORRONA data spanning from 10/8/2001 through 10/31/2012, we identified RTX-naïve RA pts with prior TNFi use who were initiating RTX or a subsequent TNFi, had a 1-year follow-up visit and had Clinical Disease Activity Index (CDAI) measurements at baseline and 1-year follow-up. A propensity score (PS) for TNFi vs. RTX was estimated using baseline clinical characteristics. The PS distributions were trimmed to exclude pts who fell outside the region of common support ($n = 2$). Effectiveness outcomes at 1 year included achievement of low disease activity (LDA, CDAI $\leq$ 10), achievement of modified ACR (mACR) 20/50/70 and decrease in mHAQ of 0.25. Nonresponse was imputed for pts who switched biologics. A sensitivity analysis using stratified matching by 1 vs. $\geq$ 2 prior TNFi and matching by PS was performed. Multivariable regression models adjusted for baseline parameters with a standardized difference > 0.1, baseline CDAI, steroid use, number of prior TNFi (1 vs. $\geq$ 2), and concomitant MTX use.

Results: 265 RTX pts and 737 TNFi pts met the inclusion criteria for the analysis. At baseline, both groups were mostly female (79–81%) with a mean age of 56–58 years, mean CDAI of 25.2–27.3 and mean mHAQ of 0.64–0.78. RTX pts had longer duration of disease (15 vs 11 years), greater prior use of $\geq$ 2 TNFi's (63% vs 27%) and greater prior use of non-TNF biologics (41% vs 13%) compared with TNFi pts. Results of comparative effectiveness analyses are presented in Table 1. In the PS-trimmed population, RTX treatment was estimated to be associated with a 35–66% increased likelihood of response compared with TNFi treatment, however this was only significant for mACR20, mACR50 and mHAQ. In the TNFi-stratified matched and PS-matched population, RTX treatment was associated with a significantly increased likelihood of achieving LDA compared with TNFi treatment (OR 1.54 [95% CI: 1.01 to 2.35]). During the 1-year follow-up, 16.2% of RTX pts and 29.4% of TNFi pts switched biologics.

Table 1. Effectiveness Outcomes by Treatment Regimen and Adjusted Odds Ratios (OR)

	RTX responders	TNFi responders	Adjusted OR (95% CI)[a]
LDA (CDAI $\leq$ 10), %	34.3	33.7	1.35 (0.95, 1.91)
mACR20, %	36.6	28.7	1.66 (1.17, 2.36)
mACR50, %	21.1	17.4	1.53 (1.01, 2.30)
mACR70, %	10.2	8.8	1.59 (0.92, 2.76)
mHAQ, %	33.2	24.2	1.46 (1.01, 2.12)

[a]Adjusted for demographics, RA characteristics, baseline disease activity, comorbidity and medication use (past and current).

Conclusion: In a population of RA pts with prior exposure to TNFi, RTX initiators had longer duration of active disease and had more prior biologic use compared with TNFi initiators. Across measures of disease activity and function, there was an estimated 35–66% increased likelihood of response in pts treated with RTX compared with those treated with TNFi. Fewer RTX pts than TNFi pts were switched to another biologic over the 1-year follow-up period.

Safety, Pharmacokinetics, and Pharmacodynamics Of SAN-300, a Novel Monoclonal Antibody Against Very Late Antigen-1: Results Of a Phase 1 Study In Healthy Volunteers and Patients With Active Rheumatoid Arthritis. Charles Inderjeeth[1], Andrew Redfern[1], Michael Huang[2], Yun Hardiman[2], Theresa Grant[2], Lawrence C. Fritz[2], David Fuller[3], David Haughey[4] and Mark C. Totoritis[2]. [1]Linear Clinical Research Ltd, Perth, Australia, [2]Santarus, Inc., San Diego, CA, [3]INC Research, Inc., New South Wales, Australia, [4]ICON Development Solutions, Whitesboro, NY.

Background/Purpose: Very late antigen-1 (VLA-1; $\alpha 1\beta 1$ integrin), a cell adhesion molecule expressed on activated lymphocytes and monocytes/macrophages, binds extracellular matrix molecules and facilitates migration, proliferation, and retention of these cells at sites of inflammation. Inhibition of VLA-1 by antibody blockade or genetic ablation is associated with decreased disease severity in animal models of acute and chronic inflammation, including models of rheumatoid arthritis (RA). This Phase 1, escalating single-dose study evaluated safety, pharmacokinetics, pharmacodynamics, and preliminary efficacy of intravenous (IV) and subcutaneous (SC) administration of SAN-300, an anti-VLA-1 antibody, in healthy subjects and patients with active RA.

Methods: In a randomized, placebo-controlled design, 66 healthy subjects received single IV or SC SAN-300 administrations (0.03–2.0 mg/kg IV; 2.0–6.0 mg/kg SC; N=45) or placebo (N=21). Two patients with active RA received SAN-300 2.0 mg/kg IV (N=1) or placebo (N=1). Serum SAN-300 concentrations, VLA-1 receptor occupancy (RO), and safety were assessed through Day 29. American College of Rheumatology (ACR) response criteria and Disease Activity Score 28 based on CRP (DAS28-CRP) were assessed in patients with active RA.

Results: Serum SAN-300 concentrations were undetectable in most subjects at low doses (0.03–0.3 mg/kg IV). In subjects receiving SAN-300 0.6–2.0 mg/kg IV or 2.0–6.0 mg/kg SC, a nonlinear pharmacokinetic profile was observed. Essentially complete VLA-1 RO ($\geq$ 90%) was noted at doses above 0.8 mg/kg IV and 2.0 mg/kg SC, with durable RO ($>$ 50%) observed through Day 8 for SAN-300 2.0 mg/kg SC and Day 15 for SAN-300 4.0–6.0 mg/kg SC. SAN-300 was generally well tolerated. No severe/serious infections were reported. Most adverse events (AEs) were mild or moderate in intensity. The most common AEs upon IV administration were mild or moderate headaches and infusion reactions. Infusion reactions occurred with 0.8–2.0 mg/kg IV; all events improved by 72 h. Among subjects receiving SAN-300 SC, headaches and mild injection-site reactions were most common. Transient, mild to moderate decreases in absolute neutrophil counts (1.1–1.9 $\times$ 10^9/L; normal: 1.9–8.0 $\times$ 10^9/L) were observed, mostly at higher doses. All cases resolved without sequelae. The single patient with active RA who received SAN-300 2.0 mg/kg IV met ACR50 at Days 15 and 29 and achieved a good response per EULAR criteria based on DAS28-CRP at Day 15 (-1.66; absolute score 2.31), and a moderate response at Day 29 (-0.92; 3.05). The placebo patient did not meet criteria for ACR20 or DAS28-CRP response at any time point.

Conclusion: In this first-in-human study, SAN-300, an antibody against novel therapeutic target VLA-1, showed nonlinear pharmacokinetics. However, durable saturation of VLA-1 was observed following IV or SC administration. SAN-300 was generally well tolerated, with the SC formulation mitigating the occurrence of mild or moderate infusion reactions seen at higher IV doses. Given favorable tolerability, encouraging RO, and ease of administration, the SC route of administration warrants investigation in future multiple-dose studies in patients with active RA.

Effects Of Tocilizumab On Serum Cytokines In Rheumatoid Arthritis With An Inadequate Response To Disease-Modifying Antirheumatic Drugs. Sang Jin Lee[1], Kyung Rok Kim[2], Sang Hyun Joo[2], Jae Myung Lee[2], In Ah Choi[2], Joo Youn Lee[1], Hyun Jung Yoo[1], Eun Young Lee[2], Eun Bong Lee[3], Won Park[4], Sung Hwan Park[5], Seung-Cheol Shim[6], Dae-Hyun Yoo[7], Han Joo Baek[8], Hyun Ah Kim[9], Soo Kon Lee[10], Yun Jong Lee[3], Young Eun Park[11], Hoon-Suk Cha[12] and Yeong Wook Song[2]. [1]Department of molecular medicine and biophamaceutical sciences, Seoul National University, Seoul, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University, Seoul, South Korea, [3]Rheumatology, Seoul National University, Seoul, South Korea, [4]Inha University Hospital, Incheon, South Korea, [5]Rheumatology, The Catholic University, Seoul, South Korea, [6]Rheumatology, Eulji University, Daejeon, South Korea, [7]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [8]Rheumatology, Gachon University, Incheon, South Korea, [9]Hallym university, Kyunggi, South Korea, [10]Yonsei University College of Medicine, Seoul, South Korea, [11]Rheumatology, Pusan Nationl University, Pusan, South Korea, [12]Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, South Korea.

Background/Purpose: The objective of this study was to investigate the effects of tocilizumab on serum cytokines in rheumatoid arthritis (RA) patients with an inadequate response to disease-modifying antirheumatic drugs (DMARDs).

Methods: We collected sera from tocilizumab study (CWP-TCZ301), a 24-weeks, randomized, double–blinded trial of tocilizumab in RA patients with an inadequate response to disease-modifying antirheumatic drugs (DMARDs). Serum cytokine levels (tumor necrosis factor (TNF)-α, interleukin (IL)-6, IL-17, IL-21, IL-23 and IL-33) were determined by luminex multiplex analysis at baseline and after treatment (4, 12 and 24 weeks). Therapeutic response was evaluated by American College of Rheumatology 20% improvement (ACR 20) in tocilizumab (n=47) and DMARDs group (n=48) after 24 weeks.

Results: Serum levels of IL-17, IL-21, IL-23 and IL-33 were significantly higher in RA patients than in healthy controls (all $p<0.05$). Early withdrawal patients from the study were excluded in the evaluation. In tocilizumab group, 29 patients were ACR 20 responders and 11 patients were non-responders after 24 weeks of treatment. Baseline serum levels of IL-17 were significantly lower in responders than in non-responders (mean ± SEM, 3.21 ± 1.74 pg/mL vs 15.89 ± 8.27 pg/mL, $p<0.05$). However IL-17 level did not significantly change during tocilizumab treatment irrespective of ACR 20 responsiveness. Levels of IL-21, IL-23 and IL-33 were not significantly different at baseline in responders and non-responders. However they were significantly decreased at 4, 12, 24 weeks in responders ($p<0.005$, respectively), but not in the non-responders. Levels of IL-6, TNF-α were not significantly different at baseline and did not significantly change during tocilizumab treatment. In DMARDs group, 8 patients were ACR 20 responders after 24 weeks of treatment. These patients' baseline serum levels of IL-17 were significantly lower than those of DMARDs non-responders (n=35) (0.46 ± 0.46 pg/mL vs 4.40 ± 2.47 pg/mL, $p=0.001$). Levels of IL-21, IL-23 and IL-33 were not significantly different at baseline and did not significantly change during DMARDs treatment irrespective of ACR 20 responsiveness.

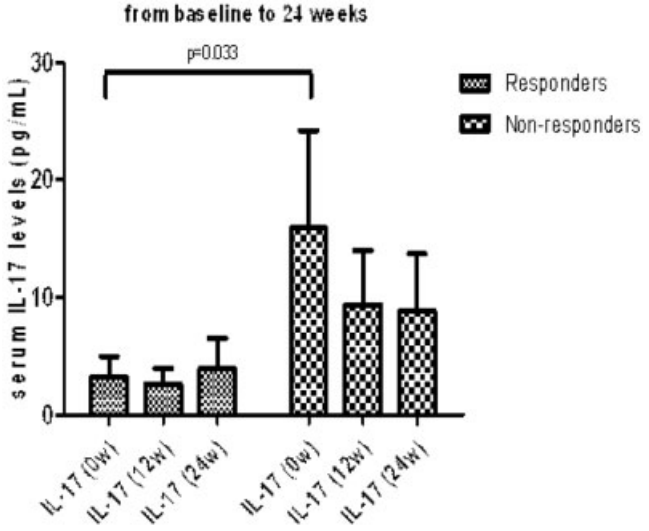

Figure 1. After tocilizumab infusion, the change in serum cytokine levels in ACR 20 responders and non-responders from baseline to 24 weeks

Conclusion: Baseline serum levels of IL-17 were lower in ACR 20 responders after tocilizumab therapy in RA. Serum levels of IL-21, IL-23 and IL-33 were significantly decreased during tocilizumab therapy in ACR 20 responders compared to non-responders.

Predictive Factors Of Response To Tocilizumab In Patients With Active Rheumatoid Arthritis. Maria Victoria Hernández[1], Javier Narvaez[2], Raimon Sanmarti[3], Delia Reina[4], Cesar Diaz-Torne[5], Berta Magallares[5], Arturo Rodriguez de la Serna[5], José María Llobet[5], Hector Corominas[4] and Joan Miquel Nolla[6]. [1]Hospital Clínic of Barcelona. IDIBAPS. University of Barcelona, Barcelona, Spain, [2]Hospital Universitario de Bellvitge, Barcelona, Spain, [3]Hospital Clínic of Barcelona, Barcelona, Spain, [4]Hospital de Sant Joan Despí Moisès Broggi, Barcelona, Spain, [5]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [6]Hospital Universitari de Bellvitge, Barcelona, Spain.

Background/Purpose: To analyze the efficacy and identify predictors of response to tocilizumab (TCZ) in patients with rheumatoid arthritis (RA).

Methods: A multicenter ambispective observational study in 126 patients with active RA treated with TCZ. The variables associated to achieve the therapeutic goal (remission of the disease defined as a DAS28 < 2.6) at 3 and 6 months were identified by a logistic regression model by using the backward approach. SAS 9.3 was used for the management and statistical analysis.

Results: Patients' demographic and clinical characteristics are shown in table 1, as well as the response rates at 3 and 6 months of treatment. TCZ was administered as the first biologic in 33 out of 126 patients, while in the remaining 93 was used after inadequate response or intolerance to > 1 biological therapies (mean 2.18 ± 1.1, range 1–6). Forty-three patients (35%) received TCZ as monotherapy. In the multivariate analysis, the predictive factors that increase the likelihood of clinical remission (DAS28-ESR < 2.6) at 3 months were baseline ESR > 30 mm/h (OR: 19.07, 95% CI: 2.7– 133.7) and the presence of extra-articular manifestations of the disease (OR: 15.5, 95% CI: 2.3– 102.3). The factors that decreased it were of haemoglobin (OR: 0.53, 95% CI: 0.32– 0.91), baseline DAS28-ESR (OR: 0.30, 95% CI: 0.15–0.64) and the number of previous DMARDs and biological therapies used (OR: 0.42, 95% CI: 0.22– 0.78). The only significant factor that reduced the possibility of clinical remission (DAS28-ESR < 2.6) at 6 months was the baseline DAS28-ESR (OR: 0.55, 95% CI: 0.35– 0.88). No relationship was found in the decrease of the neutrophils count or in the positivity of rheumatoid factor/ACPA.

Table 1.

Number of patients	126
Age: (mean ± SD), years	57 ± 13
Gender: (female/male)	108/18
Disease duration: median (range), years	10 (1–41)
Presence of rheumatoid factor/ ACPA	72%/67%
Erosive disease	70%
Systemic extra-articular manifestations	33%
Number of previous DMARDs: (mean ± SD)	2.53 ± 1.4 (1–7)
Baseline DAS28-ESR: (mean ± SD)	5.5 ±1.08
Response rates at 3 and 6 months of treatment	31%/40%
Remission by DAS28-ESR (< 2.6)	48%/64%
Low activity by DAS28-ESR (< 3.2)	25%/31%
Remission by SDAI(< 3.3)	69%/76%
Low activity by SDAI(< 11)	48%/63%
Good EULAR response	15% /16%

Remission by ACR/EULAR criteria.

Conclusion: The high inflammatory activity of the disease (measured by haemoglobin, ESR and DAS28), as well as the presence of extra-articular manifestations and the previous DMARDs and biological therapies may help in the selection of the best candidates for treatment with tocilizumab.

1442

Three-Year Drug Survival and Effectiveness Of Abatacept and Tocilizumab In Patients with Rheumatoid Arthritis Treated In Routine Care. Results From The Nationwide Danish Danbio Registry. HCB Leffers[1], Mikkel Østergaard[2], Bente Glintborg[3], Niels Steen Krogh[4], Ulrik Tarp[5], Tove Lorenzen[6], Annette Hansen[7], Lene Dreyer[8] and Merete L. Hetland[2]. [1]Department of Rheumatology, Frederiksberg Hospital, Frderiksberg, Denmark, [2]Copenhagen University Hospital Glostrup, Copenhagen, Denmark, [3]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup Hospital, Glostrup, Denmark, [4]ZiteLab ApS, Copenhagen, Denmark, [5]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark, [6]Department of Rheumatology, Region Hospital Silkeborg, Silkeborg, Denmark, [7]Department of Rheumatology, Gentofte University Hospital, Copenhagen, Denmark, [8]Copenhagen University Hospital at Gentofte, Copenhagen, Denmark.

Background/Purpose: Treatment with abatacept and tocilizumab has been shown to be efficacious in rheumatoid arthritis (RA) patients refractory to tumor necrosis factor inhibitor (TNFi). However, reports on long term effectiveness in clinical practice are scarce. In this extension of previously published 48-week data[1], we aimed to describe three-year drug survival and clinical response in RA patients treated with abatacept or tocilizumab in routine care, based on data from the nationwide Danish DANBIO registry.

Methods: In the DANBIO registry we identified 341 RA patients treated with abatacept and 790 RA patients treated with tocilizumab. The clinical effectiveness was assessed by drug survival and by changes since baseline in DAS28 and EULAR response rates after 48, 96 and 144 weeks. No imputation of missing values was done. No direct comparison of the 2 drugs was made.

Results: Of the patients receiving abatacept or tocilizumab, respectively, 20%/25% (abatacept/tocilizumab) were male, median (interquartile range, IQR) age 55(47–64)/58(47–66) years, disease duration 4 (1–11)/4 (1–12) years and number of previous biological drugs 3 (2–4)/2 (2–3), >90%>/90% of patients, had previously received ≥1 TNFi.

After 48, 96 and 144 weeks, the drug adherence to abatacept was 47%, 35% and 28% and to tocilizumab it was 61%, 54% and 47% (figure).

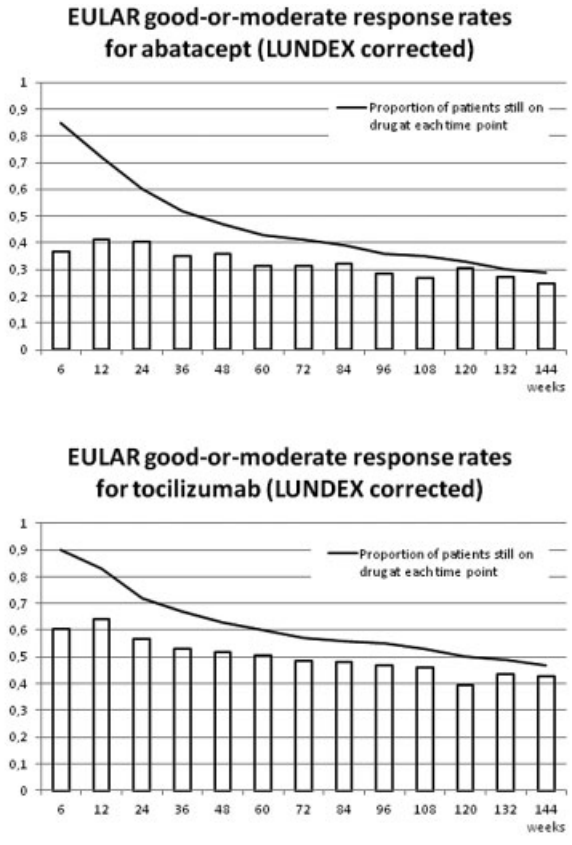

Figure 1. Proportion of patients starting on abatacept or tocilizumab in clinical practice achieving EULAR good-or-moderate response (bars) (LUNDEX corrected).

Median DAS28 at baseline, week 48, week 96 and week 144 in the abatacept group was 5.1, 3.3, 2.8 and 2.7 respectively, and 5.1, 2.6, 2.6 and 2.2 in the tocilizumab group.

At week 48, 96 and 144, the remission rates were 26%, 41% and 48% for abatacept and 47%, 45% and 63% for tocilizumab. Rates of good-or-moderate EULAR response at week 48, 96 and 144 was 76%, 79% and 85% for abatacept and 82%, 85% and 91% for tocilizumab. Response rates after correction for proportion of patients still on drug (LUNDEX values[2]) are presented in figure 1.

Conclusion: In this study of RA patients whereof >90% were previous TNFi failures, 28% of patients who started abatacept and 47% who started tocilizumab still received the drug after 144 weeks. Good-or-moderate EULAR response was seen in the majority (85%-91%) of patients who still received the drugs after 144 weeks, reflecting that almost all patients with poor response was withdrawn from therapy. Due to the non-randomised study design, no direct comparison of the drugs was made.

Is The Risk Of Tumor Necrosis Factor Inhibitor-Induced Lupus The Same With Monoclonal Antibodies and Soluble Receptor? A Case/Non-Case Study In a Nationwide Pharmacovigilance Database. Guillaume Moulis[1], Agnès Sommet[2], Maryse Lapeyre-Mestre[2] and Jean-Louis Montastruc[2]. [1]Toulouse University Hospital, Clinical Pharmacology Department, University of Toulouse, UMR INSERM-UPS 1027, Toulouse, France, [2]Toulouse University Hospital, INSERM U1027, University of Toulouse, France, Toulouse, France.

Background/Purpose: Albeit lupus occurring on each TNFi have been reported, no epidemiological study has been conducted to assess the link between lupus onset and each TNFi drug. Indeed, the risk may differ because of different structural properties. Moreover, there are reports of infliximab-induced lupus without positive rechallenge with etanercept, and etanercept seems beneficial in systemic lupus erythematosus patients with arthritis and seritis. The aim of this study was to describe the cases of TNFi-related lupus reported in the French PharmacoVigilance Database (FPVD), and to assess the putative association with each TNFi.

Methods: All spontaneous reports of TNFi-related lupus recorded in the FPVD between January 2000 and December 2012 were described. We conducted disproportionality analyses (case/non-case method) to assess the link between lupus and exposure to TNFi. Cases were all reports of lupus recorded during the study period. Non-cases were all other reports recorded during the same period. Exposure to TNFi was searched in cases and non-cases. Reporting odds ratios (ROR) were calculated to assess the association. We used exposure to isoniazid (well-known as lupus inducer) as positive control and acetaminophen as negative one. Sensitivity analyses were performed to test for event-related competition bias (removing reports of infections from the model) and for drug-related competition bias restricting to the marketing period of each TNFi and withdrawing well-known lupus-inducers. These were identified from the Chang and Gershwin list (J Autoimmunity 2010), updated through MEDLINE search until 2012 to detect new signals (comparative studies or ≥3 reports).

Results: During the study period, 309 671 spontaneous reports were colligated in the FPVD, of which 5213 (1.68%) involved TNFi. Among these TNFi reports, 39 were lupus in 37 patients: 25 involved infliximab, 9 adalimumab, and 5 etanercept. Male:female sex-ratio was 0.1 and mean age was 44.9 ± 14.4 years. Seventeen patients were treated for rheumatoid arthritis, 15 for inflammatory bowel disease, 4 for ankylosing spondylitis. Median delay from TNFi introduction to lupus onset was 11 months (range: 1–84 months). Cutaneous and rheumatologic involvements were the more frequent. Antinuclear autoantibody were positive in all the patients with this data reported (n=35). Anti-DNA antibodies were positive in 21/27 patients (77.8%). Improvement was observed after TNFi withdrawal (data available for half of the reports). Association between TNFi exposure and lupus was significant for all TNF-alpha antagonists pooled together (ROR=7.72, 95%CI [5.50–10.83]) and for isoniazid (3.5 [1.44–8.49])

but not with acetaminophen (0.28 [0.12–0.63]). It was similar for infliximab (10.97 [7.27–16.56]) and adalimumab (9.03 [4.64–17.58]) but was only 4.02 [1.66–9.75] for etanercept. Sensitivity analyses lead to similar results.

Conclusion: Albeit confidence intervals slightly overlap probably because of lack of power, the association of etanercept and lupus occurrence is estimated the half of the association with monoclonal antibodies in all analyses. Etanercept should be preferred patients who experienced lupus while exposed to monoclonal antibody TNFi.

Immunogenicity Induced By Tumor Necrosis Factor Antagonists In Chronic Inflammatory Arthropathies: Retrospective Study In Clinical Practice Conditions. Jose Inciarte-Mundo[1], Maria Victoria Hernández[2], Sonia Cabrera[3], Virginia Ruiz-Esquide[4], Julio Ramirez[1], Juan D. Cañete[2], Jordi Yague[5] and Raimon Sanmarti[1]. [1]Hospital Clínic of Barcelona, Barcelona, Spain, [2]Hospital Clínic of Barcelona. IDIBAPS. University of Barcelona, Barcelona, Spain, [3]Hospital Clínic, Barcelona, Spain, [4]Hospital Clinic, Barcelona, Spain, [5]Hospital Clínic/IDIBAPS, Barcelona, Spain.

Background/Purpose: Biological therapy has proved efficacious in various chronic inflammatory arthropathies but, in practice, clinical efficacy is reduced in some patients, suggesting drug-induced immunogenicity as a possible mechanism. Our objective was to analyze the development of tumor necrosis factor (TNF) antagonist antibodies (AB) and serum drug levels in patients with loss of treatment or adverse events in clinical practice.

Methods: Descriptive, retrospective study of patients attended by a tertiary hospital rheumatology department between February 2012 and May 2013, who were on active TNF antagonist treatment and suffered loss of efficacy or adverse treatment effects. Patients were included according to clinical judgment. We measured antidrug AB and serum drug levels using an ELISA immunoassay (Promonitor®). Only patients on infliximab (IFX), etanercept (ETN) or adalimumab (ADA) were analyzed. All blood samples were obtained in the 24 h before the next scheduled dose of treatment. Only patients with positive AB were finally analyzed. The following variables were collected: demographic variables; diagnosis and disease duration; previous and current treatment; reason for the analysis; antidrug AB and serum drug levels; and, the clinical decision.

Results: Seventy patients were included; 67% female; mean age 51±14 years. The main diagnoses were: rheumatoid arthritis (RA) (54.3%); ankylosing spondylitis (AS) (20%); psoriatic arthritis (PsA) (10%); and miscellaneous (MISC) (15.7%), which included, among others, Behçet disease, undifferentiated spondyloarthropathy and juvenile idiopathic arthritis. The reason for the analysis was: loss of efficacy in 47% of patients, adverse events in 47%, and partial response in 6%. Seventeen patients (24.3%) developed antidrug AB:11 anti-ADA and 6 anti-IFX, representing 36.6% and 40%, respectively, of study patients on these treatments. Antidrug AB were found directly in 14/17 patients and by a dissociation method in the remaining 3 patients. In 15 patients, serum drug levels were undetectable and in 2 cases (1 ADA and 1 IFX), both analyzed by the dissociation method, suboptimal (suboptimal level ADA: 0.04–0.80 ng/ml and IFX: 0.05–1.50 ng/ml). Diagnoses were: 8 RA; 4 AS; 2 PsA; and 3 MISC. Eight of 17 patients received concomitant synthetic DMARDs (4 leflunomide, 2 methotrexate, 1 sulphasalazine and 1 mycophenolate). The remaining 9 received biological therapy in monotherapy. Nine out of 17 had previously received another biological agent (7 anti-TNF and 2 non anti-TNF), which was discontinued due to inefficacy or adverse events. After development of antidrug AB, 15 patients were withdrawn from current biological therapy: 12 were switched to another anti-TNF agent and 3 to a non anti-TNF drug with a good response. Of the remaining two patients, one was lost to follow up and the other is still receiving the same treatment with methotrexate added with a good response.

Conclusion: In this study, 24.3% of patients with loss of efficacy or adverse events to TNF antagonists developed antidrug AB, which were only observed in patients receiving monoclonal antibodies.

GEMS Audit: An Evaluation Of Routine Use Of Subcutaneous Methotrexate In Rheumatoid Arthritis. Esme Roads[1], Scot Buchan[2] and Charles Li[1]. [1]Royal Surrey County Hospital, Guildford, United Kingdom, [2]Strategen Ltd, Basingstoke, United Kingdom.

Background/Purpose: Methotrexate (MTX) forms the backbone of treatment for the majority of patients with rheumatoid arthritis (RA), and is advocated in most guidelines.[i],[ii],[iii] Existing studies imply in as many as 21% of new patients oral MTX is either ineffective or not tolerated.[iv],[v] In our clinical practice these patients are routinely prescribed subcutaneous (SC) MTX, which has demonstrated improved efficacy and tolerability over the oral formulation.[vi],[vii]To identify outcomes of patients prescribed SCMTX, a retrospective audit was undertaken.

Methods: All RA patients who had received SCMTX at the Royal Surrey County Hospital, Guildford were identified from medical records. Demographic data, reason for switch from oral to SCMTX, continuation rates, eventual requirement of biologic therapy and disease activity scores (DAS) were recorded. Data presented represents audit analysis to date.

Results: We are presenting the first 102 RA patients who switched from oral MTX to SCMTX therapy. Average age of diagnosis was 50 years and 78% of patients were female. Mean duration of oral therapy was 8.8 years, at a mean weekly dose of 20.3 mg. Patients were switched from oral to SCMTX due to lack of efficacy (46%) or tolerability issues (27%). 43% of all patients were on at least two DMARDS and 12% were on three. Patients switching to SCMTX were given a mean weekly dose of 20.49 mg at initiation. The average duration of SCMTX therapy by time of analyis was 2.8 years. 87 patients thereafter remain on SCMTX either alone or in combination with other disease modifying antirheumatic drugs (DMARDs); treatment of 15 (14.7%) required escalation of therapy to include a biologic due to aggressive disease. Continuation rates for SCMTX were 94% at 1 year and 82% at 2 years, with only 8% of patients progressing to a biologic during the two years. In patients who required a biologic and SCMTX the continuation rate was 93% at 1 year and 92% at 2 years. DAS assessments were made over differing time periods, a subset of which was analysed and showed continued DAS improvement over time and a rise in significant improvement (ΔDAS28 >1.2) and remission rates (DAS <2.6).

Conclusion: The GEMS audit has confirmed efficacy and tolerability of SCMTX in patients after failing oral MTX either due to inefficacy or toxicity with high continuation rates and maintenance of disease activity control either with or without biologic therapy. These results further support our routine practice of switch of route of administration of MTX prior to the use of biologics without compromising patient care.

The Efficacy Of Etanercept In Combination With Methotrexate In Moderate To Severe Rheumatoid Arthritis Is Not Dependent On The Dosage Of Methotrexate. T.W.J. Huizinga[1], Fiona Brock[2], Urs Kerkmann[3] and Gaia Gallo[3]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Quanticate, Hitchin, Hertfordshire, United Kingdom, [3]Pfizer Europe, Rome, Italy.

Background/Purpose: Anti-TNF therapy in combination with a synthetic DMARD such as methotrexate (MTX) has been extensively shown to be superior to MTX and anti-TNF therapy as monotherapy, and is recommended in patients with rheumatoid arthritis (RA) who failed to reach treatment target, remission or low disease activity (LDA), in particular when poor prognostic markers are present.[1] When combined with anti-TNF therapy, MTX is usually administered in doses ranging from 7.5 to 25 mg/week. In patients who develop intolerable side effects to MTX during combination therapy, MTX may be discontinued or its dosage reduced. In clinical studies, the anti-TNF agent etanercept (ETN) has demonstrated sustained efficacy after MTX withdrawal in patients with moderate to severe RA,[2] but ETN efficacy across different dosages of concomitant MTX has not been investigated in early to established active RA patients. Based on data pooled from two historic ETN trials (TEMPO[3] and COMET[4]), we evaluated the impact of MTX dosage on clinical, functional, and quality of life (QoL) outcomes in RA patients after 24 months of treatment.

Methods: Patients with active RA in the ETN+MTX combination treatment arms of the TEMPO[2] and COMET[3]studies were stratified into three

subgroups based on the MTX dosage at 24 months, having MTX monotherapy groups as control: low dose (L), <10 mg/week; medium dose (M), 10–17.5 mg/week; and high dose (H), >17.5 mg/week. Data from these patient subgroups were included in descriptive summaries of demographic and disease characteristics at baseline; the following outcomes at 24 months were also evaluated for each subgroup: DAS28 LDA and remission; ACR20, 50 and 70 responses; and changes from baseline in DAS28, HAQ-DI, and EQ-5D-VAS.

Results: At baseline, patients in the ETN+MTX arm (n=276; L=73, M=155, H=48), had a mean age of 51.1, 51.7, and 51.7; weight of 69.6 and 70.2, and 75.0 kg; and female gender in 75%, 75% and 69% for the L, M and H dose groups, respectively. Patients in the MTX arm (n=218; L=39, M=117, H=62) had a mean age of 56.1, 50.7, and 51.8; weight of 67.6 and 71.1, and 70.4 kg; and female gender in 79%, 80% and 81% for the L, M and H dose groups, respectively. Responses to ETN+MTX combination therapy at 24 months were consistently high across MTX dosage groups, with very similar rates of LDA/remission (Table). Improvements in DAS28, HAQ-DI, and EQ-5D were also not dependent on MTX dosage in the combination treatment arm; poorer responses and less improvement were observed in the high MTX dose subgroup.

Table. Clinical, functional, QoL outcomes by MTX dosage in patients in the ETN+MTX and MTX arms across TEMPO and COMET studies[3,4]

	ETN+MTX Arm (n=276)			MTX Arm (n=218)		
	Low MTX Dose	Medium MTX Dose	High MTX Dose	Low MTX Dose	Medium MTX Dose	High MTX Dose
% patients achieving endpoint at 24 months (n/N)						
DAS28 LDA/Remission	68 (48/71)	69 (103/149)	70 (30/43)	53 (19/36)	41 (43/106)	57 (29/51)
ACR20	93 (68/73)	92 (141/153)	89 (39/44)	87 (34/39)	81 (91/112)	63 (34/54)
ACR50	79 (58/73)	78 (120/153)	73 (32/44)	64 (25/39)	55 (62/112)	46 (25/54)
ACR70	56 (41/73)	59 (91/153)	57 (25/44)	36 (14/39)	33 (37/112)	26 (14/54)
Change from baseline to 24 months, mean (SD)						
DAS28	−3.8 (1.2)	−4.0 (1.2)	−4.1 (1.5)	−3.2 (1.3)	−3.2 (1.5)	−2.8 (1.7)
HAQ-DI	−1.1 (0.8)	−1.1 (0.6)	−1.2 (0.8)	−0.9 (0.7)	−0.9 (0.6)	−0.9 (0.7)
EQ-5D VAS	35.6 (28.7)	38.0 (26.0)	32.5 (26.7)	34.1 (25.9)	35.3 (27.5)	19.7 (26.4)

DAS28 LDA, Disease Activity Score based on 28-joint count low disease activity (defined as DAS28 ≤3.2); ACR20/50/70, American College of Rheumatology 20%, 50%,and 70% improvement; HAQ-DI, Health Assessment Questionnaire-Disability Index; EQ-5D VAS, EuroQol-5 total index visual analog scale.

Conclusion: At 24 months, etanercept plus MTX showed similar efficacy outcomes regardless of MTX dosage in patients with RA who participated in the TEMPO[2] and COMET[3]trials.

Success Rate Of 5-Or-More-Week Extended-Interval Therapy With Tocilizumab In Rheumatoid Arthritis Patients In Routine Practice.

Masahiro Minoda[1], Kazuki Yoshida[2], Hideto Oshikawa[1], Hiroto Nakano[1], Naoho Takizawa[1], Kenichiro Tokunaga[1], Tatsuo Kobayashi[1], Mitsumasa Kishimoto[3] and Kazuo Matsui[1]. [1]Kameda Medical Center, Kamogawa, Japan, [2]Harvard School of Public Health, Boston, MA, [3]St. Luke's International Hospital, Tokyo, Japan.

Background/Purpose: Tocilizumab retreatment is effective and well tolerated in patients with rheumatoid arthritis whose disease activity flared after stopping the therapy. Therefore, reducing tocilizumab dose intensity by extending intervals is worthwhile. However, feasibility of entended-interval (≧5 weeks) therapy with tocilizumab for rheumatoid arthritis patients in routine practice is not well known.

Methods: We studied rheumatoid arthritis (RA) patients who used tocilizumab in the Cohort of Arthritis Biologic Users at Kameda Institute (CABUKI) registry from Jan/2003 to Mar/2013. Inclusion criteria were tocilizumab users age 18 years or older and DAS28-ESR <3.2 at the start of interval extension. We studied the success rate of interval extension and baseline factors at the beginning of extended intervals that predicts successful interval extension. We defined interval extension as tocilizumab administration at intervals 5 weeks or longer. The success rate was calculated at 24 weeks. The failure to maintain the extended intervals was defined as experiencing moderate or high disease activity or requiring intensification of DMARDs or glucocorticoids during follow up periods. Analyses were conducted using Fisher's exact test, Mann-Whitney U test, and log rank test.

Results: Among 54 patients who received tocilizumab, 22 patients underwent interval extension. Of 21 patients who were followed for 24 weeks, 13(61.9%) patients were still on extended intervals successfully, but 8(38.1%) patients had failed. Baseline characteristics of interval extension success group and failure group were mean age 58.8 years/61.4 years (P=0.77), female 76.9%/75%(P=1.00), disease duration 6.2 years/12.5 years (P=0.09), RF positive 76.9%/100%(p=0.26), anti-CCP positive 85%/100%(p=0.52), mean DAS28-ESR 1.76/1.86(p=0.70), mean modified HAQ 0.15/0.57(p=0.20) and radiographic erosion 53.8%/87.5%(p=0.17). In the successful interval extension group, disease duration was shorter, mean modified HAQ was smaller, and the number of non-radiographic erosion was smaller than failure group.

Conclusion: Among tocilizumab users in routine practice who underwent extended-interval administration of tocilizumab, 61.9% successfully maintained low disease activity at 24 weeks without shortening of intervals or dose intensification of non-biologic treatment. Interval extension is a feasible treatment strategy in RA patients treated with tocilizumab in routine practice.

Drug Retention Rates Of Biologic Monotherapies For Patients With Rheumatoid Arthritis In Daily Clinical Practice; Using Multicenter Registry In Japan.

Hiroyuki Matsubara[1], Toshihisa Kojima[2], Masatoshi Hayashi[3] and Naoki Ishiguro[4]. [1]Handa Municipal Hospital, Handa, Japan, [2]Nagoya University Hospital, Nagoya, Japan, [3]Nagano Red Cross Hospital, Nagano, Japan, [4]Nagoya Univeristy Graduate School of Medicine, Nagoya, Japan.

Background/Purpose: In general, drug retention rate reflects the effectiveness and tolerability of the drug. In Japan, six biological agents have been approved for the treatment of rheumatoid arthritis (RA). There is few data comparing the retention rates between biological monotherapies for RA patients in daily clinical practice. The purpose of this study is to compare the drug retention rates of three biological monotherapies with different target molecules, etanercept (ETN), tocilizumab (TCZ), abatacept (ABT).

Methods: We collected the data from the patients who started monotherapies with ETN, TCZ, ABT as first-biologics since 2008 and registered in the multicenter, large cohort of RA patients (Tsurumai Biologics Communication Registry; TBCR). We surveyed the following information: demographic data, disease activity (DAS28-CRP) at the baseline of each biological treatment. Drug retention rates were calculated by the Kaplan-Meier analysis and compared using the log-rank test among groups. We investigated drug retention rates for discontinuation due to insufficient effectiveness and adverse events.

Results: We analyzed 279 patients of 2072 patients registered in TBCR until March 2011 (141 patients in the ETN group, 63 patients in the TCZ group, 75 patients in the ABT group). The mean follow up time was 25.7 months. Table shows baseline characteristics of the groups (Table). The patients in the ABT group were older compared with other groups. Cumulative incidence rate for discontinuation due to insufficient effectiveness was significantly lower in the TCZ group (p=0.019, Fig.1A). Cumulative incidence rate for discontinuation due to adverse events was significantly lower in the ABT group (p=0.007, Fig. 1B).

Table. Baseline characteristics of the groups

Variables	ETN (n=141)	TCZ (n=63)	ABT (n=75)	*P* value
Age (mean ± SD)	58.2 ± 15.0	57.7 ± 13.8	67.7 ± 11.2	<0.001
Women (%)	81.2	82.1	72.0	n.s.
Disease duration (years)	12.8 ± 11.6	10.6 ± 10.5	10.0 ± 10.5	n.s.
Disease duration ≤2 years (%)	12.8	20.0	26.9	0.041
Steinbrocker's Stage (%)				
I	10.7	22/6	13.3	n.s.
II	16.0	18.9	22.7	
III	31.3	22.6	32.0	
IV	42.0	35.8	32.0	
Steinbrocker's Class (%)				
I	15.8	24.5	4.0	<0.001
II	33.8	32.1	46.7	
III	33.8	24.5	45.3	
IV	16.6	18.9	4.0	
PSL use (%)	68.8	50.9	41.9	<0.001
PSL dosage (mg/day)	4.9 ± 1.8	4.5 ± 2.2	5.4 ± 3.4	n.s.
DAS28-CRP	4.60 ± 0.98	4.73 ± 1.45	4.29 ± 1.52	n.s.

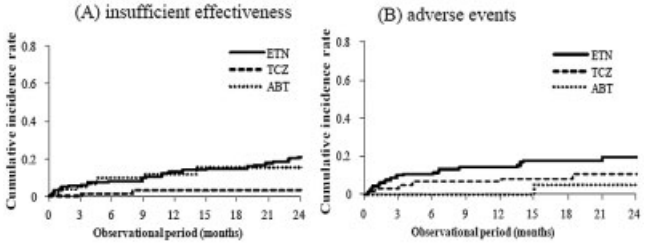

Figure 1.

Conclusion: We demonstrated that TCZ monotherapy had a lower discontinuation rate due to insufficient efficacy and that ABT monotherapy had a lower discontinuation rate due to adverse events.

1449

Comparison Of Effects Of Standard- and Low-Dose Etanercept On Inflammatory Synovitis In Rheumatoid Arthritis Patients As Assessed By Ultrasonography. Kenji Mamoto, Tatsuya Koike, Tadashi Okano, Yuko Sugioka, Masahiro Tada, Kentaro Inui and Hiroaki Nakamura. Osaka City University Graduate School of Medicine, Osaka, Japan.

Background/Purpose: The presence of synovitis has been recognized as one of the most important predictive factors of subsequent structural damage in patients with rheumatoid arthritis (RA). We previously reported that the effects of low-dose etanercept (ETN) (25 mg/week) were not inferior to the effects of standard-dose ETN (50 mg/week) clinically, but in terms of the radiographic non-progression rate, the effects of low-dose ETN were inferior to the effects of standard-dose ETN in the PRECEPT study. It was considered that low-dose ETN may not be able to suppress inflammatory synovitis. The aim of this study was to compare ultrasonographic inflammatory synovitis between patients using standard- and low-dose ETN for RA.

Methods: Patients with RA receiving standard- and low-dose ETN underwent musculoskeletal ultrasonography (US) at 34 synovial sites (30 joints) in the following joints: bilateral first to fifth metacarpopharangeal (MCP) joints (dorsal recess), first interpharangeal (IP) and second to fifth proximal interpharangeal (PIP) (dorsal recess) joints, the wrists (dorsal radial, dorsal median, and dorsal ulnar) and second to fifth metatarsopharangeal (MTP) (dorsal recess) joints. The GS (Gray scale) and power PD (Power Doppler) signals were scored in each joint using a semiquantitative scale from 0 to 3. The GSUS and PDUS scores were compared with the sums of scores obtained for the 34 synovial sites and the maximum score between two groups.

Results: We analyzed 31 and 21 patients who received standard- and low-dose ETN, respectively. The overall comparison showed no significant differences between groups. However, when we analyzed patients in remission and low disease activity, the PDUS score and maximum PD score were significantly higher in the low-dose ETN group. In particular, the PDUS score in wrist were significantly higher in the low-dose ETN group. But, GSUS score showed no significant difference between two groups (Table 1).

Table 1. Clinical and demographic characteristics in patients in remission and low disease activity of DAS28-ESR

	ETN 25mg(n=11)	ETN 50mg(n=15)

Maximum PDUS score	1.73	1.13	P<0.01

Conclusion: Low-dose ETN is not inferior to standard-dose ETN in terms of effects on clinical assessment. However, in terms of ultrasonographic inflammatory synovitis, the effects of low-dose ETN may be inferior to the effects of standard-dose ETN. We consider that synovitis may not be suppressed sufficiently, and therefore joint destruction may progress, in RA patients receiving low-dose ETN.

Safety Of Resuming The Tumor Necrosis Factor Antagonists Therapy In Patients Who Developed Tuberculosis After Use Of Tumor Necrosis Factor Antagonists. Seokchan Hong[1], You Jae Kim[1], Bon San Koo[1], Kyung joo Ahn[2], Wook Jang Seo[3], Yong-Gil Kim[1], Chang-Keun Lee[1] and Bin Yoo[1]. [1]University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, [2]KEPCO medical center, Seoul, South Korea, [3]Seoul Veterans Hospital, Seoul, South Korea.

Background/Purpose: Tuberculosis is one of the most serious adverse events related to tumor necrosis factor (TNF) antagonists in inflammatory diseases. However, there is no consensus on the current treatment guidelines about resuming TNF blockers after development of active tuberculosis infection (TI). Our objective was to analyze the optimal time-point for resuming the TNF antagonist with no relapse of TI.

Methods: Retrospective study has included 683 patients from June 2003 to December 2012 (362 ankylosing spondylitis; 307 rheumatoid arthritis; 10 psoriatic arthritis; 4 Behcet's disease), who have started TNF blockers at a single tertiary hospital. Data on cases of active TI during biologics were collected and the outcomes of resuming TNF blockers were evaluated.

Results: Of the 683 patients, 15 (2.1%) patients (6 female, mean age 47.4 ± 17.5 years) were diagnosed with active tuberculosis during anti-TNF treatment. Diagnoses were: 10 ankylosing spondylitis; 4 rheumatoid arthritis; 1 Behcet's disease. Tuberculosis was detected in one patient by routine CXR and in others by the development of symptoms such as fever. The type of tuberculosis infection was: pulmonary in 7 patients; gastrointestinal in 3; lymph nodes in 2; disseminated in 1, miliary in 1, pericardium in 1. The TNF blocker used at TI diagnoses was; 4 etanercept, 4 adalimumab,

and 7 infliximab. The mean duration of anti-TNF treatment before development of TB was 26.7± 28.1 months. Anti-TNF treatment was reinitiated in 6 (40%) patients; 4 patients during under treatment of TI treatment (mean TI treatment of 1.5 ± 1.0 months) and 2 patients after completion of TI treatment. Four patients reinitiated with the same agents, whereas 2 patients started with another TNF blocker. All six patients successfully completed anti-tuberculosis treatment and showed good responses. The outcomes in patients after reinitiation of anti-TNF treatment were favorable that no patients had a relapse of TI after a mean follow-up duration of 28 ± 18.1 months.

Conclusion: Active tuberculosis infection in relation to TNF antagonist may be safe for resuming the therapy even before completion of TI treatment. Our results may suggest that it is possible to restart TNF blockers if patients were treated concomitantly with adequate anti-tuberculosis treatment.

Comparison Of Clinical Characteristics Of Patients With Rheumatoid Arthritis Receiving Their First Biologic and Biologic-Naïve Patients Considered Biologic-Suitable In The United States. Siva Narayanan[1], Yao Lu[2], Richard Hutchings[2] and Amanda Baskett[2]. [1]Ipsos Healthcare, Columbia, MD, [2]Ipsos Healthcare, London, United Kingdom.

Background/Purpose: Data on clinical status of biologic-naïve Rheumatoid Arthritis (RA) patients who are considered suitable for biologic therapy (by their physicians) is lacking. We assessed clinical characteristics of RA patients who are considered suitable for biologic therapy (by their physicians) in comparison to those currently treated with 1st line biologics in the United States (US).

Methods: A retrospective chart review study of RA patients was conducted among physicians (primarily rheumatologists) in hospitals/private practices to collect de-identified data on patients who were either recently treated with a biologic as part of usual care or considered suitable for biologic treatment. Physicians from the US were screened for duration of practice (3–30 yrs) and patient volume (incl. >2RA biologic patients/week) and recruited from a large panel to be geographically representative. Eligible patient charts (>6 biologic patients, > 2 biologic-suitable (and yet biologic-naïve) patients per physician judgment) were randomly selected from a sample of prospective patients visiting each center/practice during the screening period. Physicians abstracted patient diagnosis, treatment patterns/dynamics and patient symptomatology/disease status. This retrospective de-identified data collection method met the criteria for IRB exemption under federal regulation 45 CFR 46.101(b)(4).

Results: Seven hundred and twenty six eligible RA patient charts were abstracted; 378 (52%) patients were on their first biologic and 175 (24%) patients have never experienced biologic but were considered suitable for one. Mean age was: 1st line-52.8yrs, biologic-suitable-51.5yrs; Female: 1st line-73%, biologic-suitable-76%. Disease severity at diagnosis and current disease severity (both per physician judgment) (mild:moderate:severe) were: 1st line – 6%:74%:14% and 67%:29%:3%, biologic-suitable – 11%,74%, 10% and 25%:66%:9% respectively. Current drug class usage differed between the two groups (1st line/biologic-suitable): non-biological DMARD (57%/88%), steroids (19%/36%), NSAIDs-COX2 inhibitors (6%/10%), NSAIDs- non-COX2 inhibitors (14%/22%), and analgesics (11%/12%). Key lab measures documented were (1st line/biologic suitable): ESR (24.2/40.0 mm/h) and CRP (2.5mg/5.6 dl). Current ACR scores were (1st line/biologic-suitable): no response (2%/19%), ACR20 (12%/36%), ACR50 (18%/15%), ACR70 (20%/5%), ACR90 (26%/1%). Among patients with available data, current HAQ (1st line–0.7, biologic-suitable–1.1), DAS28 (1st line–2.5, biologic-suitable – 4.1), 100mmVAS (1st line – 2.3, biologic-suitable – 4.6), Swollen Joint Count (1st line – 2.0, biologic-suitable – 5.9) and Tender Joint Count (1st line – 2.8, biologic-suitable – 7.0) differed between the patient groups.

Conclusion: Compared to the patients currently treated with 1st line biologic, RA biologic-naïve but suitable patients (per physician judgment) had relatively higher disease burden. Reasons for non-initiation of biologic treatment among 'biologic-suitable' patients warrant further investigation to alleviate disease burden.

An Early Economic Evaluation Of Personalized Treatment With Rituximab By Prediction Of Effectiveness Using The Interferon Type I Signature In Rheumatoid Arthritis. Sandhya C. Nair[1], P.M.J. Welsing[1], Saskia Vosslamber[2], A.E. Voskuyl[2], M. T. Nurmohamed[3], J.W.J. Bijlsma[1], Floris Lafeber[4] and Cornelis L. Verweij[2]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands, [3]VU University Medical Center/Jan van Bremen Research Institute, Amsterdam, Netherlands, [4]UMC Utrecht, Utrecht, Netherlands.

Background/Purpose: Tailoring therapy to individual patients, for instance by predicting its effectiveness has become increasingly important especially with chronic use of expensive biological DMARDs. To evaluate the cost effectiveness of a personalized approach to biological treatment of rheumatoid arthritis RA) patients indicated for rituximab (RTX) using interferon (IFN) type I response genes as prediction tool.

Methods: 26 consecutive patients diagnosed according to 1987 ACR criteria from the VU University Medical Center and READE starting RTX were followed. Baseline IFN type I response genes expression level was used as a biomarker for response to RTX using an optimal cut-off (1). The Positive Predictive Values (PPV) for good and moderate EULAR response were used to simulate the response using a personalized approach, assuming that the response in patients not selected for the RTX therapy was equal to the average response to treatment (biological) in the population. Using a patient level Markov model, response was extrapolated to disease activity (DAS28), functional disability (HAQ), direct and productivity costs and Quality Adjusted Life Years (QALYs) over 5 years using external data. The Incremental Cost Effectiveness Ratio (ICER) comparing the personalized approach to (observed) usual care was calculated from a societal and health care perspective. Although RTX treatment is less costly than other biologicals no differences in drug cost were assumed and testing costs were assumed € 50 per patient. All the analyses were performed probabilistically and a sensitivity analysis was also performed.

Results: 50% were moderate responders and 50% were non-responders (no good responders). Twenty-nine percent decreased more than 1.2 points on the DAS28. Using the selected IFN cut-off, 35% of patients were selected for treatment and the PPV (for moderate response) was 100%. On average € 236 (2.5 – 97.5 percentile range −6,083 to 5,557) were saved and 0.03 QALYs (−0.08 to 0.15) were gained leading to an ICER of €−8099 per QALY gained. In 37% of simulations the personalized approach was found to be cheaper and more effective, in 32% more expensive and more effective, in 16% less expensive and less effective and in 15% more expensive and less effective. Due to the limited data on prediction using IFN so far and the resulting uncertainty the probability of costs-effectiveness did not increase to more than 70%. Using a healthcare perspective the results were less positive with a mean ICER of € 1920 per QALY gained (represents extra costs and QALY, which is within the often mentioned limit of € 20,000/QALY). Decreasing the effectiveness of alternative biological therapy with 10% resulted in a lower probability of cost-effectiveness but average results still indicated cost saving and QALY gain.

Conclusion: Although results are still uncertain due to the limited clinical data, the use of the IFN type I response genes for personalized biologic treatment seems very promising and should continue to be studied in patients indicated for RTX treatment to obtain more precise estimates of cost-effectiveness results.

Repeated High Or Low Multi-Biomarker Disease Activity (VECTRA® DA Algorithm) Scores Associated With Radiographic Outcomes In Patients with Rheumatoid Arthritis Treated with Tumor Necrosis Factor Inhibitors. Shintaro Hirata[1], Wanying Li[2], Nadine A. Defranoux[2], Rebecca Bolce[2], Eric H. Sasso[2], Satoshi Kubo[1], Shunsuke Fukuyo[1], Kentaro Hanami[1], Kunihiro Yamaoka[1], Kazuyoshi Saito[1] and Yoshiya Tanaka[1]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Crescendo Bioscience Inc., South San Francisco, CA.

Background/Purpose: A novel multi-biomarker disease activity (MBDA) score that is based on the serum concentrations of 12 biomarkers has

been shown to correlate with clinical disease activity in patients with rheumatoid arthritis (RA) including patients treated with TNF inhibitors (TNFi). The purpose of this study is to explore the role of MBDA to predict radiographic progression in RA patients treated with TNFi.

Methods: The study was conducted at UOEH, Kitakyushu, Japan, on 141 patients who had received TNFi: adalimumab (ADA), etanercept (ETN) and infliximab (IFX), for at least 1 year. X-rays were taken at baseline (BL) and week 52 of treatment and change (Δ) in modified total Sharp score (mTSS) over 1 year was determined. Clinical disease activity, serum biomarkers were assessed at BL and week 52 in all 141 patients and at week 24 in a subset of 83 patients. Concentrations of VCAM-1, EGF, VEGF-A, IL-6, TNF-RI, MMP-1, MMP-3, YKL-40, leptin, resistin, SAA and CRP were measured using a multiplex immunoassay and the MBDA score (1–100) was calculated using the validated Vectra DA algorithm. Correlations between ΔmTSS and disease activity measures (MBDA, DAS28-ESR, CRP) were examined using Spearman correlation. The association between ΔmTSS and maintenance ofhigh/low MBDA score was assessed in the subset of 83 patients with clinical and biomarker data at all 3 time points (BL, week 24 and week 52) using Fisher's exact test.

Results: At baseline, patients had mean (±SD) values of DAS28-ESR 5.7 (±1.1), MBDA score 61 (±18), disease duration 103 (±121) months, and mTSS 68 (±103). In the overall group of 141 patients, 102 (72%) patients had a ΔmTSS ≤0.5 (non-progressors) and 12 (9%) had a ΔmTSS >3 (clinically relevant radiographic progression) by week 52. ΔmTSS correlated with the yearly average of both DAS28-ESR ($r = 0.26$, $p = 0.002$) and MBDA score ($r = 0.33$, $p < 0.001$). Among the 12 patients with ΔmTSS >3 by week 52, 7 were EULAR good responders and, 8 had a high MBDA score >44.

In the subset of 83 patients with clinical and biomarker data at BL, week 24 and week 52, 10 (12%) patients had ΔmTSS >3. ΔmTSS from BL to week 52 correlated with the MBDA score DAS28-ESR and CRP at week 24 and with ΔMBDA score from BL to week 24 ($p < 0.05$). Patients with high MBDA scores >44 for at least 2 of any of the 3 visits had a greater risk of radiographic progression (ΔmTSS >3; OR =14.9, $p = 0.002$). Patients with a low MBDA score ≤29 for at least 2 of any of the 3 visits had a higher likelihood to be non-progressors (ΔmTSS ≤0.5; OR =13.9, $p = 0.002$). A logistics regression model showed that low MBDA score ≤29 at week 24 had additive association with non-progression (ΔmTSS ≤0.5) above low DAS28-ESR at week 24 ($p = 0.007$).

Conclusion: In patients with RA treated over one year with TNFi, repeated low MBDA scores were associated with no radiographic progression while repeated high MBDA scores were associated with clinically relevant radiographic progression. Disease activity at 24 weeks post-treatment and change in MBDA score from BL to 24 weeks correlated with radiographic progression at 1 year. At week 24, low MBDA score had additive association with good radiographic outcome above low DAS28-ESR alone.

The Effects Of The Spleen Tyrosine Kinase Inhibitor Fostamatinib On Ambulatory Blood Pressure In Patients With Active Rheumatoid Arthritis – Results Of The Oskira Ambulatory Blood Pressure Monitoring Trial.

G Kitas[1], G Abreu[2], K Jedrychowicz-Rosiak[3], J Miller[4], R Nakov[2], S Panfilov[2], J Vencovsky[5], M Wang[6], M Weinblatt[7] and WB White[8]. [1]The Dudley Group of Hospitals NHS Foundation Trust, Dudley, United Kingdom, [2]AstraZeneca, Molndal, Molndal, Sweden, [3]MCBK SC, Grodzisk Mazowiecki, Poland, [4]S.W. Florida Clinical Research Center, Florida, FL, [5]Institute of Rheumatology, Prague, Czech Republic, [6]AstraZeneca, Alderley Park, Macclesfield, United Kingdom, [7]Brigham and Women's Hospital, Boston, MA, [8]Calhoun Cardiology Center, University of Connecticut School of Medicine, Farmington, CT.

Background/Purpose: Fostamatinib (Fosta) is a spleen tyrosine kinase (SYK) inhibitor in clinical trials in patients (pts) with rheumatoid arthritis (RA). Previous clinical studies showed blood pressure (BP) elevation with Fosta treatment using clinical measurements. As 24-hour ambulatory BP monitoring (ABPM) improves the sensitivity of detecting BP changes over the dosing period, OSKIRA-ABPM was developed as a randomized, placebo-controlled clinical trial to assess the effects of Fosta 100 mg twice daily (bid), taken on a background of a disease-modifying antirheumatic agent on ambulatory systolic BP (SBP) in pts with active RA.

Methods: After a screening visit and a 4-wk run-in period, pts were randomized to receive Fosta 100mg bid or placebo (PBO) bid for 4 weeks (wks), followed by a 1-wk washout of study drug. The ABPM was obtained at baseline and Wk 4; clinic BP was assessed at scheduled clinic visits; and home BP during 4 × 1 week periods, including 1 wk pre-randomization and the washout period. The primary safety endpoint was change from baseline in 24-hour mean SBP on Fosta vs PBO. Changes from baseline in 24-hour diastolic BP (DBP), BP assessed by clinic and home measurements, as well as the persistence and/or reversibility of any effect in BP after discontinuation of Fosta treatment were secondary endpoints.

Results: Of 135 randomized pts, 68 received Fosta and 67 received PBO, with balanced characteristics at baseline. There were 2 discontinuations in each group due to adverse events (1 in each group due to high BP), and 2 further discontinuations in the Fosta group that were non-adverse event related. Nine pts in the Fosta group vs 1 in the PBO group received newly prescribed and/or dose increase of existing antihypertensive medication after randomization. Compared to placebo, Fosta increased the 24-hour mean SBP by 2.9 mmHg (95% CI, 0.4–5.5; $p = 0.023$) and the 24-hour mean DBP by 3.5 mmHg (95% CI, 2.0–5.0; $p < 0.001$). There was no impact of Fosta on the circadian variation of BP. Individual changes of >5 mmHg in 24-hour mean SBP were seen in approx. 47% vs 27% of pts, and in 24-hour mean DBP in 41% vs 13% of pts in the Fosta and PBO groups, respectively. Individual changes of >10 mmHg in 24-hour mean SBP were seen in approx. 22% vs 12% of patients in the Fosta and PBO groups, respectively. Pts randomized to Fosta who were treated with antihypertensives or with steroids at baseline had numerically higher BP increases from baseline compared to those without. Baseline treatment with nonsteroidal anti-inflammatory drugs did not affect the BP response to Fosta. The magnitudes of clinic- and home-measured BP changes were similar to that of the ABPM-derived values. No effect on heart rate was observed by any measurement method. The effect of Fosta on clinic BP was seen at Wk 1 and plateaued thereafter. After treatment discontinuation, mean values of BP returned to baseline levels.

Conclusion: Fosta induced small but significant elevations in ambulatory BP in pts with active RA. Most elevations were <10 mmHg in individual pts and these elevations resolved with discontinuation of Fosta by 1 wk. In addition, there were no alterations to the circadian pattern of BP and there were no changes in heart rate.

1455

Comparison Of Serum Matrix Metalloproteinase-3 Levels In Rheumatoid Arthritis After Treatment With Adalimumub Or Abatacept For 24 Weeks.

Yosuke Hattori[1], Atsushi Kaneko[1], Daihei Kida[1], Hisato Ishikawa[2], Toshihisa Kojima[3] and Naoki Ishiguro[4]. [1]Nagoya Medical Center, Nagoya, Japan, [2]Nagoya Medical Center, nagano, Japan, [3]Nagoya University Hospital, Nagoya, Japan, [4]Nagoya Univeristy Graduate School of Medicine, Nagoya, Japan.

Background/Purpose: MMP-3 is an enzyme produced by synoviocytes, and is a marker of synovitis that gives a more direct indication of actual joint destruction than either C-reactive protein (CRP)in patients with rheumatoid arthritis (RA). Our aim in this study is to investigate the impact of the trend of MMP-3 and CRP during the treatment Adalimumub (ADA) and Abatacept (ABT) in the early stage of RA patients.

Methods: Among 548 patients with active RA (DAS28-CRP≥2.7) who were recruited in TBC (Tsurumai Biologics Communication) registry, 303 patients were received ADA (40mg subcutaneously every other week) and 245 patients were received ABT therapy (500mg for<60 kg; 750 mg for 60 kg-100 kg; and 1 gram for>100 kg infusion at week 0, 2, 4 and every 4 weeks). DAS28-CRP remission (DAS28-CRP<2.3) rates at 24 weeks were 34.7% (73/210) for ADA therapy and 19.4% (39/201) for ABT therapy. We analyzed 112 patients who had DAS28-CRP remission at 24 weeks, consisting of 73 patients in ADA group and 39 patients in ABT group respectively. We compared the change in serum MMP-3 and CRP levels from first administration to 24 weeks between the two groups.

Results: While there was significant baseline difference in age, methotrexate (MTX) use and dose between the two groups, there was no significant baseline difference in serum MMP-3 and CRP levels between the two groups (Table). Serum MMP-3 and CRP levels decreased promptly at 4 weeks. The change in

serum MMP-3 levels at 4, 12, and 24 weeks was greater in the ADA group than in the ABT group (Fig. 1-a). However, the change in CRP levels at 4, 12, and 24 weeks had no deference between the two groups (Fig. 1-b). The % change in serum MMP-3 levels at 12, and 24 weeks was significantly greater in the ADA group than in the ABT group (Fig. 2-a). The % change in serum CRP levels at 4 weeks was significantly greater in the ADA group than in the ABT group. However, there was no difference in the % change in CRP levels at 12, and 24 weeks between the two groups (Fig. 2-b).

Table Demographics and baseline clinical characteristics

	ADA (N =73)	ABT (N =39)	*P value*	
Age (years)	54 ±15	67 ±10	<0.01	b
Female, *n* (%)	61 (84%)	32 (82%)	0.84	c
Duration of disease (years)	13 ±13	11 ±13	0.28	b
Stage (Ⅰ.Ⅱ/Ⅲ.Ⅳ %)	41/59	44/56	–	
Class (1.2/3.4 %)	77/23	59/41	–	
Previous biologics, *n* (%)	14 (19%)	10 (26%)	0.58	a
Prednisone use, *n* (%)	43 (59%)	23 (59%)	0.99	c
Prednisone dose (mg/day)	4.2 ±2.4	4.4 ±2.1	0.41	b
Methotrexate use, *n* (%)	68 (93%)	18 (46%)	<0.01	a
Methotrexate dose (mg/week)	8.2 ±2.6	7.0 ±2.8	<0.05	b
DAS28-CRP	4.1 ±0.9	4.3 ±1.2	0.62	b
Tender joint count, 0-28 joints	5.3 ±4.3	5.2 ±4.2	0.82	b

Patient's global assessment	48 ±24	46 ±28	0.46	b
CRP (mg/dl)	2.1 ±2.0	2.5 ±3.3	0.75	b
MMP-3 (ng/mL)	253 ±210	226 ±140	0.95	b

Values are given as the mean ± standard deviation (SD) unless stated otherwise.
P value calculated by using (a) $\chi 2$ test or (b)Mann-Whitney-U test or (c)Fisher's exact test.
C-reactive protein (CRP), DAS28 Disease Activity Score in 28 joints (DAS28-CRP)

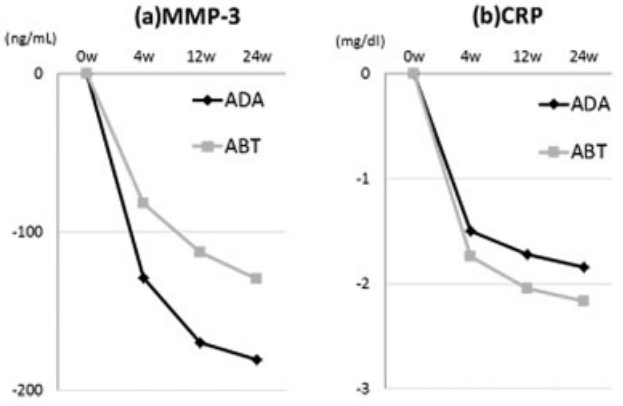

Fig. 1. Change in serum (a) MMP-3 and (b) CRP levels.

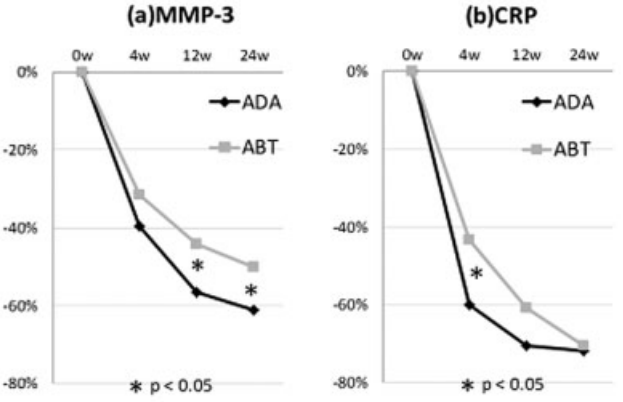

Fig. 2. Change in serum (a) MMP-3 and (b) CRP levels.

Conclusion: ADA showed improvements in serum MMP-3 levels from an early stage in 24 weeks in a comparison with ABT. ADA can suppress synovitis and therefore the progression of joint destruction by strongly inhibiting MMP-3 when it is administered from an early stage.

Golimumab Levels, Anti-Drug Antibodies and Clinical Response In Rheumatoid Arthritis Patients At 28 Week Of Follow-Up.

Eva L. Kneepkens[1], Dora pascual-Salcedo[2], Chamaida Plasencia[2], Charlotte L. M. Krieckaert[1], Desiree van der Kleij[3], Michael T. Nurmohamed[1], Maria Teresa López-Casla[2], Theo Rispens[4] and Gertjan Wolbink[4]. [1]Jan van Breemen Research Institute Reade, Amsterdam, Netherlands, [2]La Paz University Hospital, Madrid, Spain, [3]Sanquin Diagnostic Services, Amsterdam, Netherlands, [4]Sanquin Research, Amsterdam, Netherlands.

Background/Purpose: Low drug levels of anti-Tumor Necrosis Factor (TNF) therapies are related to poorer response in patients with rheumatoid arthritis (RA). Furthermore, anti-drug antibodies (ADA) against several TNF-inhibitors have been described and are associated with lower drug levels and therefore with lower response rates in RA.

Objectives: To study the relation between clinical response, golimumab levels and ADA in RA patients treated with golimumab.

Methods: Prospective observational cohort study of 38 consecutive RA patients treated with golimumab 50 mg subcutaneously (SC) once every month in the Netherlands (n=36) and Spain (n=2), monitored during 28 weeks of follow-up. Golimumab levels and ADA titres were determined retrospectively using an enzyme linked immunosorbent assay and an Antigen Binding Test (ABT), respectively, designed by Sanquin Research, Amsterdam. Response was defined according to the European League Against Rheumatism (EULAR) response criteria. The last observation was carried forward for patients who dropped out before week 28.

Results: At baseline, most patients had an active disease (median DAS28 (IQR) 4.5 (3.1–5.5)), 24 patients used concomitant methotrexate (median mg/week (IQR)) (11.3 (0–25)) and 18 used prednisone (median mg/day (IQR)) (7.5 (5–10)). Fourteen patients had used 1 prior biological (anti-TNF) and 10 patients had used 2 or more prior biologicals (anti-TNF and/or another). At 28 weeks, 10 patients were good, 9 were moderate and 19 were EULAR non-responders. In total, 16 patients dropped-out before week 28; 11 due to inefficacy and 5 due to adverse events.

Median golimumab level at 28 weeks of treatment (μg/mL) (IQR) was 0.8 (0.3–1.9) and varied from undetectable to 3.6μg/mL. Median golimumab levels were lower in non-responder (0.4 (0.2–1.5)) vs. moderate (1.0 (0.2–1.9)) and good responders (1.6 (0.7–2.4)) at 28 weeks of treatment, although this difference was not statistically significant (p=0.08). In 2 patients high ADA titres (between 303 and 1510 AU/mL) were detectable at week 16 which resulted in undetectable golimumab levels. In 1 other patient ADA were detectable (36.8 AU/mL) at week 4 which resulted in a low level of golimumab (0.35 μg/mL). All 3 patients were EULAR non-responder and golimumab was discontinued before 28 weeks of treatment due to inefficacy according to the treating rheumatologist.

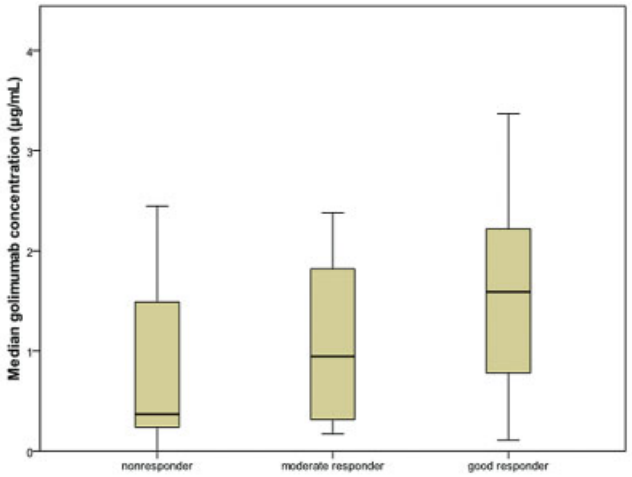

Figure. Median golimumab levels (μg/mL) (last observation carried forward) for EULAR good, moderate and non-responders at 28 weeks of treatment (p=0.08).

Conclusion: In our study of 38 RA patients, golimumab levels were lower in EULAR non-responders compared to moderate and good responders at 28 weeks of treatment. In 3 patients ADA were detectable which resulted in undetectable golimumab levels in two and low golimumab levels in one patient. All ADA positive patients dropped-out before 28 weeks of treatment due to inefficacy.

Inhibitory Effect Of Abatacept On Joint Damage In Rheumatoid Arthritis Patients With Or Without Concomitant Methotrexate: A Retrospective Multicenter Analysis Of 12 Months Of Abatacept Treatment In Routine Clinical Practice. Isao Matsushita, Hiraku Motomura, Eiko Seki and Tomoatsu Kimura. Faculty of Medicine, University of Toyama, Toyama, Japan.

Background/Purpose: Abatacept is approved for use with or without methotrexate (MTX). The purpose of this study was to clarify the inhibitory effect of abatacept on joint damage and its clinical efficacy in rheumatoid arthritis (RA) patients with or without concomitant MTX in routine clinical practice.

Methods: A retrospective multicenter study was conducted. Patients with RA who underwent abatacept treatment for 52 weeks were analyzed.

Results: Forty eight chronologically consecutive patients in the hospitals (4 males, 44 women, mean age of 62.8 years old, mean disease duration of 12.0 years, mean DAS28-CRP of 4.0, rate of MTX use of 56.3%) with active RA who started abatacept therapy were analyzed. All patients fulfilled the ACR 1987 revised criteria. Five patients were withdrawn during 1 year due to insufficient efficacy. The retention rates at 1 year of patients with or without concomitant MTX were 88.9% and 90.5%, respectively. At week 52, 37% and 35% of patients with or without concomitant MTX achieved clinical remission, respectively. There was no significant difference in achievement of remission by the concomitant use of MTX. The ΔmTSS decreased significantly from 9.44 at baseline to 0.86 at week 52. Rates of the structural remission [ΔmTSS: 0.5 or below] was achieved in patients with and without concomitant MTX were 58.3% and 68.4%, respectively. Thus, the radiographic changes were not significantly affected by the concomitant use of MTX.

Conclusion: Abatacept showed good clinical and radiographic effects for RA patients with or without concomitant MTX in routine clinical practice.

Rates Of Switching and Healthcare Costs Associated With Switching Biologic Disease-Modifying Antirheumatic Drugs In a Commercial Population: Evidence From Real-World Observational Studies. A Nadkarni[1], F Lobo[1] and T Juday[2]. [1]Bristol-Myers Squibb, Princeton, NJ, [2]Bristol-Myers Squibb, Plainsboro, NJ.

Background/Purpose: Several biologic disease-modifying antirheumatic drugs (bDMARDs) are approved for the treatment of moderate-to-severe RA. Switching between bDMARD therapies is common in real-world settings, and may have an impact on healthcare costs. This analysis evaluated bDMARD switching and associated healthcare costs in patients with RA across two commercially insured populations in the US.

Methods: Two retrospective cohort studies of adult patients with RA who initiated a bDMARD were conducted using US commercial insurance claims databases. Patients were categorized into first- and second-line bDMARD cohorts. The first-line bDMARD cohort included patients who newly initiated a bDMARD (adalimumab, etanercept, infliximab, or abatacept). The second-line bDMARD cohort included patients who initiated a second bDMARD. Patients in both first- and second-line bDMARD cohorts were required to have continuous eligibility 6 months before (pre-index) and 12 months after (post-index) initiation of first- or second-line bDMARD treatment. Patients in both cohorts were categorized into switchers and non-switchers. Switchers had a claim for a different bDMARD within a 200% gap in days supply for the index bDMARD. Non-switchers stayed on their index bDMARD in the post-index period. Switch rates were compared for each bDMARD. Patients who discontinued their index bDMARD and did not switch in the post-index period were excluded from the analyses. Rates of bDMARD switching, and pre- and post-index healthcare costs for switchers and non-switchers were examined.

Results: The first- and second-line bDMARD cohorts included 10,281 and 2354 patients, respectively, in Study 1, and 6320 and 1297 patients, respectively, in Study 2. In both studies, rates of switching for the first- and second-line bDMARD cohorts were lower for abatacept compared with adalimumab, etanercept, and infliximab (Table 1). Pre- and post-index healthcare costs in both studies were higher for first- and second-line bDMARD switchers compared with non-switchers (Table 2).

Table 1.

	Proportion of first-line bDMARD cohort who switched bDMARD during post-index period		Proportion of second-line bDMARD cohort who switched bDMARD during post-index period	
Index bDMARD	**Study 1**	**Study 2**	**Study 1**	**Study 2**
Adalimumab	8.9%	10.5%*	15.2%	19.1%*
Etanercept	8.5%	9.5%	13.3%	17.4%
Infliximab	5.2%	10.3%	13.5%	22.7%*
Abatacept	2.0%	6.5%	7.4%	12.6%

* $p<0.05$ vs abatacept.

Table 2.

	First-line bDMARD switchers versus non-switchers		Second-line bDMARD switchers versus non-switchers	
	Study 1	**Study 2**	**Study 1**	**Study 2**
Pre-index monthly healthcare costs	$1025 vs $796*	$2417 vs $2081*	$2173 vs $1856*	$3705 vs $3719
Post-index monthly healthcare costs	$3759 vs $2343*	$6081 vs $4415*	$3956 vs $2616*	$8376 vs $5625*

*$p<0.05$.

Conclusion: Patients on first- or second-line abatacept switched less frequently than patients on other bDMARDs. Post-index monthly healthcare costs were higher for first- and second-line bDMARD switchers versus non-switchers, suggesting there may be an economic benefit to using abatacept as the first- or second-line bDMARD in patients with moderate-to-severe RA.

Multiple Cytokine Profiling Predicts The Effectiveness Of Switching Biologics In Rheumatoid Arthritis. Kensuke Koyama, Katsunori Ikari, Atsuo Taniguchi, Shigeki Momohara and Hisashi Yamanaka. Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan.

Background/Purpose: There is some rheumatoid arthritis (RA) patients with poor responses to certain biologics which requires switching to another biologics. However, there is no solid evidence to support such switching of biologics. We examined cytokine profiles for these patients to identify effective switching of biologics.

Methods: IORRA cohort is a hospital-based large observational cohort of Japanese RA patients. Clinical information and laboratory data are collected biannually. The patients who had switched biologics were chosen from the cohort. Serum levels of various cytokines (TNF alpha, IL-6, IL-17A, IL-1 beta, IL-8, MCP-1, TNF R1, TNF R2) before switching biologics were measured by using multiplex cytokine array system. Multiple regression model were used to examine following variables (objective variable: delta DAS28, explaining variable: previous DAS28, various cytokines) in several switching patterns. Statistical significant was established at $p < 0.05$.

Results: Eighty seven patients were identified as first TNF alpha antibody failure (infliximab: 50, etanercept: 21, adalimumab: 16). Thirty patients switched from one anti-TNF alpha antibody to another anti-TNF alpha agent, 36 switched to an anti-IL-6 antibody. Delta DAS28 (Post DAS28-Pre DAS28) set up in accordance with regression coefficient is

shown Figure 1 **(NO GRAPHIC AVAILABLE)**. Constant term, IL-17A and IL-1 beta was identified as significant regression coefficients in switching from one anti-TNF antibody to another anti-TNF alpha agent group. Pre DAS28 was only extracted as significant regression coefficients in switching from one anti-TNF antibody to an anti-IL-6 antibody group. Pre DAS28, TNF alpha, IL-8, MCP-1, TNFR1 and TNFR2 were chosen in concordance with EULAR good and moderate response cases in this group. It was impossible to examine the patients switching from etanercept because of the small number.

Conclusion: Our results suggest that cytokine profile maybe an effective way of predicting of possible switching from one biologic to another. Inefficient biologics switching may expose patients to further unnecessary joint destruction and cost.

10 Years Of Treat-To-Target Therapy In Rheumatoid Arthritis Patients (the BeSt study): Clinical and Radiological Outcomes. I.M. Markusse[1], G. Akdemir[1], M. van den Broek[1], L. Dirven[1], R.J. Goekoop[2], K.H. Han[3], M. van Oosterhout[4], P.J.S.M. Kerstens[5], W.F. Lems[6], T.W.J. Huizinga[1] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Haga Hospital, The Hague, Netherlands, [3]Maasstad Hospital, Rotterdam, Netherlands, [4]Groene Hart Hospital, Gouda, Netherlands, [5]Jan van Breemen Research Institute Reade, Amsterdam, Netherlands, [6]VU University Medical Center, Amsterdam, Netherlands.

Background/Purpose: Long term studies with treat-to-target therapy are essential to guide treatment strategies. We report on a study that compared clinical and radiological outcomes of four treatment strategies in early rheumatoid arthritis (RA) patients after ten years of treat-to-target therapy.

Methods: The BeSt (Dutch acronym for Treatment Strategies) study enrolled 508 patients with recent onset RA. Patients were randomized to 1 of 4 treatment strategies: 1 sequential monotherapy, 2 step-up therapy, 3 initial combination therapy with prednisone, 4 initial combination therapy with infliximab. Treatment adjustments were made based on 3-monthly disease activity scores (DAS) measurements (DAS $>$ 2.4: next treatment step; DAS $\leq$ 2.4 for $\geq$ 6 months: taper to maintenance dose, next if DAS $<$ 1.6 for $\geq$ 6 months: stop last Disease-Modifying AntiRheumatic Drug). Functional ability (Health Assessment Questionnaire, HAQ) was analyzed with a linear mixed model (LMM) with time, treatment and time $\times$ treatment as independent variables. Annual radiographs were scored in one session by two independent and blinded readers (IM and GA) using the Sharp van der Heijde Score (SHS).

Results: Baseline characteristics in all groups were comparable (over all groups mean DAS 4.4, mean HAQ 1.4). 200 of 508 (39%) have dropped out of the study. Of them, 6 returned for the final visit. Thus, in total 314 patients (62%) completed 10 years follow-up.

Mean age of completers was 61 years and 68% were female. Mean (SD) DAS was 1.6 (0.8) and mean HAQ (SD) was 0.6 (0.6), comparable among the groups. 82% had a DAS $\leq$ 2.4, 53% had a DAS $<$ 1.6 (DAS-remission), 15% were in drug free remission (DFR) with a mean (median) duration of 52 (58) months. After 10 years, 39% were still on the initial treatment step. Toxicity was similar in all groups. In table 1, outcomes per treatment strategy are shown.

	Group 1 n=126	Group 2 n=121	Group 3 n=133	Group 4 n=128	p-value
Clinical Outcomes					
DAS, mean ± SD *	1.7 ± 0.7	1.7 ± 0.8	1.5 ± 0.8	1.6 ± 0.8	0.333
HAQ, mean ± SD *	0.6 ± 0.6	0.7 ± 0.6	0.5 ± 0.5	0.6 ± 0.6	0.121
DAS ≤ 2.44, n (%) *	61 (85)	43 (71)	59 (84)	75 (84)	0.102
DAS < 1.6, n (%) *	36 (50)	28 (46)	40 (57)	50 (56)	0.507
Drug free remission, n (%) *	11 (14)	11 (15)	12 (15)	13 (13)	0.604
Still on initial treatment step, n (%) *	21 (28)	13 (19)	33 (43)	52 (59)	<0.001 □
Current use of infliximab, n (%) *	14 (18)	7 (10)	9 (12)	22 (24)	0.080
Drop out, n (%)	50 (40)	53 (44)	55 (41)	36 (28)	0.163
SAE, total n	124	97	126	126	0.665
Patients with SAE, n (%)	60 (48)	50 (41)	61 (46)	63 (49)	0.630
SHS progression					
Year 0–10, median (IQR)*	2.0 (0.0–11.0)	2.5 (0.0–13.5)	3.0 (0.3–11.3)	1.5 (0.0–6.0)	0.390
Patients with ΔSHS > 5, n (%)*	24 (38)	23 (42)	27 (42)	21 (27)	0.190
Patients with ΔSHS > 10, n (%)*	16 (25)	16 (29)	18 (28)	12 (15)	0.196

* Completers analysis; □ Group 1 and 2 vs 4: $p < 0.001$, group 3 vs group 4 $p < 0.05$, group 2 vs group 3 $p < 0.05$

Across groups, the initial functional improvement is maintained after 10 years of follow-up. Over time patients in group 4 have a significantly lower HAQ than patients in group 2 (0.52 versus 0.70, p= 0.03, other comparisons between groups non-significant).

After 10 years follow up there was no longer a significant difference in radiographic damage progression between groups, and progression was low in all groups. In patients with longstanding DFR mean SHS progression was 0.21 (median (IQR) 0.0 (0.0, 0.0)) per person year. Patients in longstanding DAS-remission (defined as mean DAS $<$ 1.6 during year 5 to 10) had a mean SHS progression of 0.56 per year (median (IQR) 0.0 (0.0, 2.0)).

Conclusion: Ten years follow up in the BeSt study shows the benefit of continued treat-to-target therapy, steering at low disease activity. Of 508 patients, 62% completed follow up. After initial improvement no decline in function occurred. 53% of completers were in DAS remission, and 15% in prolonged drug free remission. Radiologic damage progression was low and no longer different between groups.

1461

Corticosteroid Use In Rheumatoid Arthritis Patients On Infliximab: Treatment Implications Based On A REAL-WORLD Canadian Population. Boulos Haraoui[1], Algis V Jovaisas[2], William G. Bensen[3], Rafat Y. Faraawi[4], John T. Kelsall[5], Sanjay Dixit[6], Emmanouil Rampakakis[7], John S. Sampalis[7], Francois Nantel[8], Susan M. Otawa[8], Allen J. Lehman[8] and May Shawi[8]. [1]Centre Hospitalier de l'Université de Montréal, Montreal, QC, [2]University of Ottawa, Ottawa, ON, [3]St. Joseph's Hospital and McMaster University, Hamilton, ON, [4]Rheumatologist, KW Musculoskeletal Research Inc., Kitchener, ON, [5]Mary Pack Arthritis Centre, Vancouver, Vancouver, BC, [6]McMaster University, Burlington, ON, [7]JSS Medical Research, St-Laurent, QC, [8]Janssen Canada Inc, Toronto, ON.

Background/Purpose: The Canadian Rheumatology Association[1] recommends that addition of corticosteroids (CS) should be considered only for the shortest period possible in rheumatoid arthritis (RA) patients treated with a traditional or biologic DMARD based on the patient's clinical status. The objective is to examine the effect of chronic systemic CS treatment at different doses on the incidence of infections in RA patients treated with IFX in a real-life setting. The impact of CS use on the sustainability of remission was also assessed.

Methods: BioTRAC is an ongoing, Canadian, prospective, registry of rheumatology patients initiating treatment with IFX or golimumab as first biologics or after having been treated with a biologic for less than 6 mos. RA patients treated with IFX who were enrolled between 2002 and 2012 were included. Cox regression was used to examine the time-dependent association between systemic CS dose (no CS, ≤5 mg, >5 mg) and the incidence of first infection, while adjusting for possible confounders, and to assess the sustainability of remission.

Results: 838 RA patients were included in the analyses. Mean (SD) age of the patient cohort was 56.6 (13.5) yrs and mean (SD) duration since diagnosis was 10.5 (9.8) yrs. At initiation of treatment, 38.2% of patients

were treated with a systemic CS. After a mean (SE) follow-up of 51.3 (1.7) mos, 310 infections were reported for 19.7% of patients (19.6/100 PYs). Among these, the majority (90.0%) were non-serious infections. Multivariate survival analysis using Cox regression showed that, upon adjusting for enrolment period, age, disease duration, number of steroid administrations, and HAQ-DI, the hazard ratio (HR) (95%CI) for acquiring an infection was 2.48 (1.24–4.98) in patients treated with high dose (>5 mg) CS compared to patients not receiving CS. Treatment with low dose CS was also associated with an increased hazard for infection (HR (95%CI) = 2.12 (0.97–4.66)) which did not reach statistical significance. Consistent with previous studies, increased HAQ-DI (HR (95%CI) = 1.51 (1.15–1.92)) and disease duration (HR (95%CI) = 1.01 (1.00–1.03)) were also identified as significant predictors. CS use was continued in 15% of cases despite the achievement of remission (DAS28-CRP: 15.2%; CDAI: 15.7%). Survival analysis did not show a significant positive effect of steroid use on sustainability of remission [HRDAS28-CRP (95%CI) = 1.40 (0.95–2.06); HRCDAI (95%CI) = 1.19(0.75–1.88)].

Conclusion: Treatment with systemic CS was associated with an increased hazard ratio for acquiring an infection upon adjusting for possible confounders. Despite the achievement of remission, steroid use was continued in 15% of cases without having an impact on sustainability of remission. We show that treatment with systemic CS is an independent predictor of infection in patients treated with anti-TNF agents and suggest that the use of concomitant medications should be considered in the interpretation of safety data.

Unmasking The Tolerability Of Methotrexate In Patients With Rheumatoid and Psoriatic Arthritis: A Retrospective Review Of Discontinuation From a Large UK Cohort. Andra Negoescu[1], Elena Nikiphorou[2], Anshuman P. Malaviya[2], Andrew Badcock[2], John D. Fitzpatrick[2], Calum T. Goudie[2] and Andrew J. Ostor[2]. [1]Rheumatology Research Unit, Addenbrooke's Hospital, Cambridge, United Kingdom, [2]Addenbrooke's Hospital, Cambridge, United Kingdom.

Background/Purpose: Due to its efficacy and perceived safety, methotrexate (MTX) has become the foundation disease-modifying drug for rheumatoid (RA) and psoriatic arthritis (PsA) however its tolerability has not been a focus of research. The objective of our study therefore was to analyse this by identifying RA and PsA patients in whom MTX was discontinued and to determine the reasons for this. We were specifically interested in how long patients remained on MTX prior to withdrawal.

Methods: A retrospective review of our institutions electronic database was undertaken to identify all RA and PsA patients who had been prescribed MTX. Patients who had discontinued MTX were then identified from both the electronic and paper-based records and the reasons for this were categorised. The duration of MTX treatment was then assessed in those who had stopped treatment due to intolerability.

Results: 762 RA and 193 PsA patients had received MTX. In those the DMARD had been stopped in 260 (34%) RA patients and 71 (36%) PsA patients with intolerability cited as the most common reasons for this (60% and 63% in RA and PsA respectively). Haematological abnormalities (leukopenia and thrombocytopenia) were reported more frequently in RA (11.5% vs 6.8% $p<0.05$) and liver enzyme abnormalities more common in PsA (27% vs 12%; $p<0.05$). The most common symptoms resulting in MTX withdrawal were nausea, shortness of breath, feeling generally unwell, headache and fatigue. Other reasons for stopping MTX included: ineffectiveness, planned pregnancy, lifestyle choice and disease remission. The median duration of MTX treatment was 10 months in both groups, mean duration 21 and 18.6 months in RA and PsA groups respectively (Range: 0.25 – 122.25 months for RA, 1.00–79.25 months for PsA). The mode was at 3 months for RA and 1 month for PsA. See figure 1 for duration of MTX treatment.

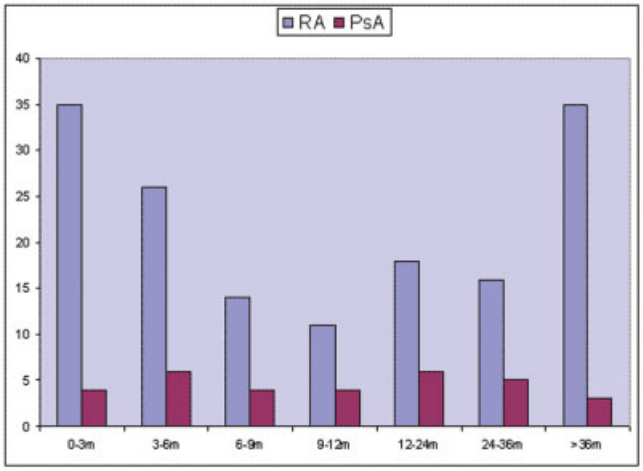

Fig 1. Duration of MTX therapy in patients who stopped treatment due to side effects

Conclusion: Overall one third of patients with RA and PsA stop MTX most commonly due to poor tolerability. In the context of chronic disease the median duration of treatment is short (10 months). Clinicians need to be aware of the frequency of MTX intolerability, and that this may occur early in the treatment cycle, and to alter therapy accordingly to optimise outcomes.

1463

Dietary Impact On Treatment Results Of Methotrexate In Patients With Rheumatoid Arthritis. Cecilia Lourdudoss[1], Alicja Wolk[2], Camilla Bengtsson[3], Lena Nise[4], Lars Alfredsson[3] and Ronald van Vollenhoven[5]. [1]Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), Karolinska institutet, Stockholm, Sweden, [2]Institute of Environmental Medicine (IMM), Karolinska institutet, Stockholm, Sweden, [3]Karolinska Institutet, Stockholm, Sweden, [4]Karolinska institutet, Stockholm, Sweden, [5]Unit for Clinical Research Therapy. Inflammatory Diseases (ClinTrid), Karolinska Institute, Stockholm, Sweden.

Background/Purpose: Some specific diets have been shown to ameliorate rheumatoid arthritis (RA). However, there is generally a lack of studies on any possible dietary impact on the efficacy of anti-rheumatic therapies such as methotrexate. We hypothesized that some dietary nutrients may affect the treatment response. Thus, the aim of this study was to investigate dietary impact on treatment results of methotrexate (MTX) in patients with RA.

Methods: We used data from the Epidemiological Investigation of Rheumatoid Arthritis (EIRA) study as well as from the Swedish Rheumatology Quality (SRQ) register. In EIRA, data on dietary intake at baseline were collected using a previously validated dietary questionnaire. DAS28 values at baseline and at 3 months were obtained from the SRQ and used to calculate EULAR responses.

Statistical analysis was performed using IBM SPSS Statistics 20 and included independent samples t-tests and ANOVA.

Results: This study included 293 RA patients from the EIRA study who started treatment with MTX. 70.6% were females. Mean age was 52.7 years. Most patients were RF positive (63.3%) and ACPA positive (70.0%). In 55.4%, MTX was combined with glucocorticoids (GC). At baseline, 59.3% had high disease activity and 36.4% had moderate disease activity.

Mean DAS28 scores decreased significantly from 5.4 (±1.2SD) at baseline to 3.4 (±1.3SD) at 3 months ($p<0.001$).

After 3 months of MTX treatment, 45.1% of patients had a good EULAR response. Average daily folate intake was 326.9μg in good responders and 318.5μg in moderate/non-responders (not significant). In contrast, the daily intake of long-chain fatty acid C22:5 was higher in good responders versus moderate/non-responders (0.069±0.035 vs. 0.058±0.032, $p=0.011$). In patients who were not on GC at baseline,

good responders had significantly higher vitamin D intake compared to moderate/non-responders (6.58±3.45 vs. 5.01±2.33, p=0.004). Associations were also found between therapeutic response and the intake of other fatty acids and of niacin and selenium in different subsets of patients (table).

		Good response		Moderate/Non-response		
Patient subset	**Nutrient**	**N**	**Mean ± SD**	**N**	**Mean ± SD**	**p value**
Total study sample	Fatty acid C22:5 (g)	119	0.07 ± 0.3	151	0.06 ± 0.03	0.011
Overweight/Obese	Fatty acid C20:4 (g)	57	0.12 ± 0.05	80	0.10 ± 0.05	0.034
Ex smoker	Polyunsaturated fatty acids (g)	46	11.32 ± 4.92	49	9.44 ± 3.64	0.036
Ex smoker	Niacin (mg)	46	17.89 ± 5.71	49	15.58 ± 4.89	0.036
No GC at baseline	Total fat (g)	39	76.21 ± 29.18	85	63.01 ± 27.71	0.017
No GC at baseline	Monounsaturated fatty acids (g)	39	25.73 ± 9.77	85	21.13 ± 8.99	0.011
No GC at baseline	Selenium (μg)	39	36.49 ± 16.37	85	29.85 ± 12.15	0.013
No GC at baseline	Vitamin D (μg)	39	6.58 ± 3.45	85	5.01 ± 2.33	0.004

Conclusion: In early RA, the therapeutic response to MTX at 3 months might be linked to several nutrients. Perhaps surprisingly, daily folate intake did not influence the response to MTX. In contrast, higher intake of C22:5 in the whole cohort, and the intake of various other nutrients, including higher vitamin D, in specific subsets of patients were significantly related to better clinical responses. In conclusion, dietary habits may affect treatment results.

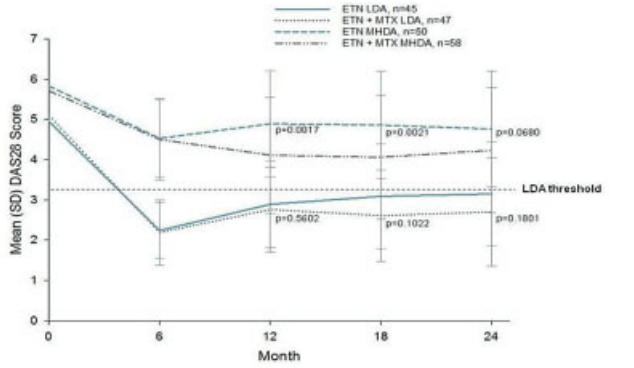
Clinical and Radiographic Outcomes With Etanercept and Etanercept and Methotrexate In Patients With Rheumatoid Arthritis: Two-Year Results From The Canadian Methotrexate and Etanercept Outcome Study (CAMEO). Boulos Haraoui[1], J. Carter Thorne[2], Edward C. Keystone[3], Melanie Poulin-Costello[4], Eric Trottier[5], Andrew Vieira[4] and Janet E. Pope[6]. [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [2]Southlake Regional Health Centre, Newmarket, ON, [3]Mount Sinai Hospital/University of Toronto, Toronto, ON, [4]Amgen Canada Inc., Mississauga, ON, [5]Amgen Canada, Mississauga, ON, [6]St Joseph Health Care, London, ON.

Background/Purpose: Data from the CAMEO study demonstrated that patients with rheumatoid arthritis (RA) who achieved low disease activity (LDA) after 6 months of combination therapy of etanercept (ETN) and methotrexate (MTX) had similar clinical outcomes at 12 months whether they continued ETN+MTX or stopped MTX at 6 months. Yet response was reduced when MTX was withdrawn in patients with moderate or high disease activity (MHDA). Clinical and radiographic data for up to 24 months from the CAMEO study are presented.

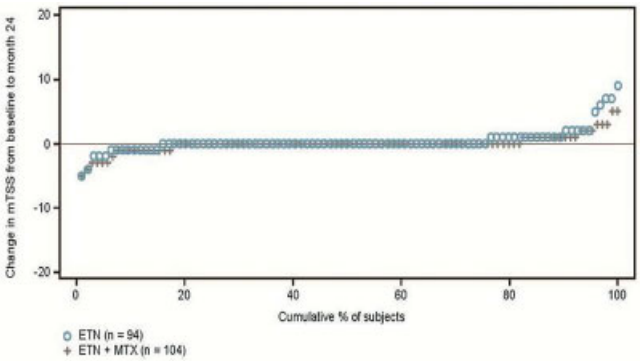
Methods: TNF-inhibitor naïve patients with active RA (defined as ≥3 swollen joints and a Disease Activity Score [DAS28] ≥3.2) despite treatment with MTX (≥15 mg/week, or 10 mg/week if intolerant) for >12 weeks were treated with ETN (50 mg/week SC) and MTX for 6 months. Patients were then randomized (1:1) to switch to ETN monotherapy or to continue ETN+MTX for an additional 18 months. DAS28 was assessed at baseline and at 6, 12, 18, and 24 months/early termination (24m/ET), and X-rays of the hands and feet were taken at baseline and at 12 and (24m/ET).

Results: A total of 258 patients enrolled, and 205 were randomized to either begin ETN monotherapy (n=98) or to continue ETN+MTX treatment (n=107). Seventy-six percent were females with a mean age of 54.7±12.5 years, disease duration of 8.9±8.4 years, and baseline DAS28 score of 5.4±1.1. Overall, patients who reached LDA at month 6 maintained LDA at (24m/ET) whether they were treated with ETN or ETN+MTX; those with MHDA treated with ETN monotherapy had worsening of disease activity, while those treated with ETN+MTX had a sustained response (Figure 1). Radiographic progression between patients treated with ETN or ETN+MTX was similar at 24 months (Figure 2). The proportion of patients with LDA showing no radiographic progression was similar between the ETN and ETN+MTX at both 12 (88% vs. 85%) and (24m/ET) (86% vs. 87%). However, fewer patients with MHDA receiving ETN monotherapy had no radiographic progression compared with ETN+MTX at 12 (68% vs. 81%) and (24m/ET) (64% vs. 76%).



*p-values comparing ETN with ETN+MTX were analyzed using an ANOVA, with terms for treatment, reimbursement type, and disease duration.

Figure 1. Comparisons[a] of mean (SD) DAS28 scores from 6-month randomization to 24m/ET, stratified by disease status at month 6.



*End-of-study assessments are used for patients who prematurely terminated before 24 months

Figure 2. Cumulative change from baseline to month 24[a] in Total Sharp Scores (N=198).

Conclusion: These data clarify the role of long term combination of ETN+MTX in maintaining optimal disease control. For patients who achieve LDA by 6 months, ETN monotherapy provides an effective clinical and radiological alternative to combination therapy for up to 24 months. However, patients with MHDA may need to continue combination therapy, as clinical response may be reduced when MTX is withdrawn.

Adherence To The Recommended Dosing Regimen Of Abatacept In The Real-World Setting In The Action Study: Is There a Dose-Creep In Overweight Patients? H Nüβlein[1], R Alten[2], M Galeazzi[3], H M Lorenz[4], D Boumpas[5], M T Nurmohamed[6], W G Bensen[7], G R Burmester[8], H-H Peter[9], F Rainer[10], K Pavelka[11], M Chartier[12], C Poncet[13], C Rauch[14] and M Le Bars[15]. [1]University Erlangen, Nürnberg, Germany, [2]Schlosspark-Klinik, University Medicine Berlin, Berlin, Germany, [3]University of Siena, Siena, Italy, [4]University Hospital Heidelberg, Heidelberg, Germany, [5]Panepistimio Kritis, Rethymnon, Greece, [6]VU University Medical Center/Jan van Breeman Research Institute, Amsterdam, Netherlands, [7]St. Joseph's Hospital/McMaster University, Hamilton, ON, [8]Charité-Universitätsmedizin, Berlin, Germany, [9]University Medical Center Freiburg, Freiburg, Germany, [10]Hospital Barmherzige Brueder, Graz, Austria, [11]Institute of Rheumatology, Prague, Czech Republic, [12]Chiltern International, Neuilly, France, [13]Docs International, Sèvres, France, [14]Bristol-Myers Squibb, Munich, Germany, [15]Bristol-Myers Squibb, Rueil Malmaison, France.

Background/Purpose: Reduced efficacy for achieving DAS28 <2.6 has been observed for anti-TNF agents in obese patients following 12 months of

therapy. The odds ratio (95% confidence interval) was 2.43 (1.21, 4.88; p=0.01) with initial body mass index [BMI] 20–30 kg/m^2 versus >30 kg/m^2,[1] which in theory could induce dose increases to maintain efficacy. Here we explore adherence to abatacept over 6 months in patients categorized according to BMI.

Methods: ACTION is an ongoing, 2-year, international, non-interventional, prospective cohort of patients with RA treated with IV abatacept. All patients on abatacept treatment for ≥6 months, and with data available for infusion (at initiation and at 6 months) and BMI (at initiation), were considered in this analysis. BMI calculated at abatacept initiation categorized patients into normal (<25 kg/m^2), overweight (25–<30 kg/m^2) or obese (≥30 kg/m^2) subgroups. Within each BMI category, adherence to treatment was assessed in patients who received appropriate dosage by body weight at initiation. Increase in dose and frequency of administration was assessed over 6 months.

Results: An even distribution of patients was observed across the BMI subgroups at abatacept initiation in the overall population (<25 kg/m^2: 399/1048 [38.1%]; 25–<30 kg/m^2: 363/1048 [34.6%]; ≥30 kg/m^2: 286/1048 [27.3%]). Baseline disease characteristics were similar across BMI subgroups, except auto-antibody status, with fewer obese seropositive patients: rheumatoid factor-positive, <25 kg/m^2: 228/315 (72.4%); 25–<30 kg/m^2: 220/293 (75.1%); ≥30 kg/m^2: 132/232 (56.9%); anti-cyclic citrullinated peptide-positive, <25 kg/m^2: 152/213 (71.4%); 25–<30 kg/m^2: 138/204 (67.6%); ≥30 kg/m^2: 87/153 (56.9%). Overall, 737/1048 (70.3%) patients with BMI data available received abatacept for ≥6 months and had infusion data available at initiation and at 6 months. A large proportion of patients received appropriate dosage regardless of BMI: at initiation (<25 kg/m^2: 236/290 [81.4%]; 25–<30 kg/m^2: 224/245 [92.2%]; ≥30 kg/m^2: 182/202 [91.0%]). Adherence over 6 months in patients receiving appropriate dosage at initiation is presented in the table.

	<25 kg/m^2 (n=236)	25–<30 kg/m^2 (n=224)	≥30 kg/m^2 (n=182)
Appropriate dosage at 6 months*	203/215 (94.4%)	197/200 (98.5%)	154/161 (95.7%)
Dose increase over 6 months*	11/215 (5.1%)	2/200 (1.0%)	4/161 (2.5%)
7–9 infusions received**	203/236 (86.0%)	199/224 (88.8%)	150/182 (82.4%)
1 additional infusion received	6/236 (2.5%)	3/224 (1.3%)	2/182 (1.1%)
Increase in dose or in frequency	17/236 (7.2%)	5/224 (2.2%)	6/182 (3.3%)

*Some patients had missing data for dose reported at 6 months; **Corresponding to a ratio of actual to recommended infusions within range of 80–120%
No patient received more than 1 additional infusion. No patient had both a dose increase and an increase in frequency of administration over 6 months.

Conclusion: Analysis of adherence to the recommended dosing regimen of IV abatacept in the ACTION study showed that a large proportion of patients had good adherence at initiation, regardless of BMI. Few patients had an increase in dosage or frequency of administration over 6 months and nobody had both. Overall, there was no evidence for dose creep in overweight and obese patients treated with IV abatacept over 6 months in routine clinical practice.

Survival On Treatment Of The Second Line Biologic Therapy: Switch Or Swap Strategy? Ennio G. Favalli[1], Martina Biggioggero[1], Antonio Marchesoni[2] and Pier Luigi Meroni[3]. [1]Chair and Division of Rheumatology, Gaetano Pini Institute, University of Milan, Milan, Italy, Milan, Italy, [2]UOC Day Hospital Rheumatology, Gaetano Pini Institute, Milan, Italy, Milano, Italy, [3]Division of Rheumatology, Gaetano Pini Institute, Milan, Italy, Milan, Italy.

Background/Purpose: The strategy for the choice of the second biologic agent after the failure of the first TNF inhibitor is still an unclear aspect in the treatment of rheumatoid arthritis (RA). The aim of the study is to evaluate in a real-life setting the survival on treatment of the second biologic agent in anti-TNF non-responders, comparing patients treated with a second anti-TNF (switch strategy) with patient treated with a different mechanism of action (abatacept, rituximab, or tocilizumab; swap strategy).

Methods: We extracted data from a local registry that includes all RA patients treated with biologic therapies between October 1999 and December 2012 in our Rheumatology Unit. We limited our analysis to the period after the first biologic agent other than anti-TNF became available (January 2007-December 2012), in order to minimise differences in exposure among biologics. Patients who stopped a first course TNF inhibitor and started a second line biotherapy since January 2007 were included in the analysis. The rate of drug discontinuation in both subgroups were retrospectively estimated by Kaplan-Meier analysis and compared by log-rank (Mantel-Cox) test.

Results: Between 1999 and 2012, 641 patients were treated with etanercept (n=192), infliximab (n=221), adalimumab (n=192), golimumab (n=14), or certolizumab pegol (n=22) as first line biotherapy. Since January 2007, 183 of these patients discontinued the TNF blocker because of inefficacy (56%) or safety (44%) issues and switched to a second anti-TNF (n=107) or swapped to abatacept (n=21), rituximab (n=40), or tocilizumab (n=15). The drug survival was significantly greater in swap than in switch subgroup (p=0.0009). This difference was confirmed after the stratification of both subgroups according to cause of first anti-TNF discontinuation (inefficacy, p=0.03; safety, p=0.01). No significant differences emerged comparing the retention rate of abatacept, rituximab, and tocilizumab (p=0.2).

Conclusion: In a set of clinical practice, the choice of a second biologic agent with different mechanism of action seems to be a better strategy to treat anti-TNF non-responders, irrespective of the cause of TNF blocker discontinuation.

Adalimumab In Combination With High and Low Dose-Methotrexate In Rheumatoid Arthritis Patients With Inadequate Response To Methotrexate: Pharmacokinetic Results From The Musica Study. Ghada Ahmed[1], Sandra L Goss[1], Cheri E Klein[1], Neelufar Mozaffarian[2], Gurjit S. Kaeley[3] and Walid Awni[1]. [1]AbbVie Inc., North Chicago, IL, [2]Eli Lilly, San Diego, CA, [3]University of Florida, Jacksonville, FL.

Background/Purpose: Rheumatoid arthritis (RA) patients with inadequate response to methotrexate (MTX) may be initiated on combination therapy with anti-TNF agents such as adalimumab. However, it is not known whether MTX doses can be reduced when adalimumab is added. Also, little is known about the disposition of intracellular MTX polyglutamates (PG). This is important because MTX PGs are thought to account for the anti-inflammatory effect of MTX in RA.

Methods: MUSICA was a 24-wk, phase 4, prospective parallel-arm study in patients with moderately to severely active RA and an inadequate response to stable, high dose MTX (≥15 mg/wk for at least 12 wks prior to Screening). Eligible subjects were randomized 1:1 to blinded oral MTX at 20 mg/wk ("high dose") or 7.5 mg/wk ("low dose"). All patients also began open-label adalimumab 40 mg SC every other week. Blood samples were collected prior to dosing at Baseline and every 4 wks to measure adalimumab and anti-adalimumab antibody (AAA) in serum (using validated ELISA assays) and MTX PG 1 to 5 levels in erythrocytes using a validated LC-MS method. A patient was considered AAA+ if he/she had at least one serum sample with AAA level > 20 ng/mL that was confirmed by a confirmatory assay and was collected within 30 days after an adalimumab dose.

Results: Steady-state (SS) adalimumab trough levels were attained by Week 16. At Week 24, mean adalimumab trough concentrations were 8.98 μg/mL (n=155) and 7.46 μg/mL (n=154) in the high and low MTX dose groups, respectively. Overall, 11/309 patients (3.6%) were classified as AAA+ at week 24. The percentages of subjects with at least one AAA+ sample in the high and low MTX dose groups were 1.9% and 5.2%, respectively. For both MTX dose groups, new SS total MTX PG levels appeared to be reached by week 20–24. At week 24, mean total MTX PG1–5 concentrations were 130.30 nM and 60.43 nM for the high and low MTX dose groups, respectively. MTX PG1–2 (short-chain PG) were more prevalent in those treated with low MTX dose (64% of total PG) than high MTX dose (37.5% of total PG). MTX PG4–5 (long-chain PG) were however more prevalent in those treated with high MTX dose (22% of total PG) than low

MTX dose (5% of total PG). Compared to the low dose group, high dose MTX resulted in a less-than-dose-proportional increase in MTX PG1–2 (mean SS levels of PG1+2 were 47.6 nM and 38.6 nM in the high and low MTX dose, respectively), a dose-proportional increase in MTX PG3 (mean SS levels of PG3 were 54.4 nM and 18.8 nM in the high and low MTX dose, respectively), and a more-than-dose-proportional increase in MTX PG4–5 (mean SS levels of PG4+5 were 28.3 nM and 3.03 nM in the high and low MTX dose, respectively).

Conclusion: In RA patients with incomplete response to MTX, slightly higher mean adalimumab serum levels were achieved when combined with high than low MTX dose. A new SS for total MTX PG appeared to be reached by week 20–24. Short-chain PGs were more prevalent in the low MTX dose than high MTX dose; while long-chain PGs were more prevalent in the high MTX dose than low MTX dose. High dose MTX resulted in a less-than-dose-proportional increase in MTX PG1–2, a dose-proportional increase in MTX PG3, and a more-than-dose-proportional increase in MTX PG4–5 compared to the low MTX dose.

Reasons For Discontinuation Of Biologic Agents In Rheumatoid Arthritis Patients. Eric Elkin[1], Martin J. Bergman[2], Tripthi Kamath[3], Sarika Ogale[3], Adam Turpcu[3], Kristin King[4], Jae Oh[4], Monarch Shah[1] and Max I. Hamburger[5]. [1]ICON Clinical Research, San Francisco, CA, [2]Taylor Hospital, Ridley Park, PA, [3]Genentech, South San Francisco, CA, [4]ICON Late Phase and Outcomes Research, San Francisco, CA, [5]Rheumatology Associates, Melville, NY.

Background/Purpose:

Results: from randomized controlled trials indicate that about one-third of rheumatoid arthritis (RA) patients initially treated with anti-TNF agents do not respond, show a sub-optimal response, lose response, or develop adverse events (Kwoh et al 2002). Patients who discontinue their first biologic DMARD therapy might need to switch to a second or subsequent biologic DMARD treatment. The objective of this analysis is to describe reasons for discontinuation of their first anti-TNF for the treatment of RA and subsequently discontinuing either a second anti-TNF or biologic DMARDs with other mechanisms of action (oMOA).

Methods: An observational, non-interventional, retrospective chart review study was conducted in 8 centers in the United States from February to September 2012. Patient charts were eligible if the patient's first biologic DMARD was a anti-TNF; they were 18 years or older at time of the second DMARD; and they were prescribed the second and/or third biologic DMARD during the period July 1, 2006 and October 1, 2011. The proportion of patients stating each reason for treatment discontinuation are described for patients discontinuing anti-TNF vs. oMOA as their second and/or third biologic DMARD.

Results: A total of 176 charts were abstracted for patients who discontinued a anti-TNF as their first biologic DMARD and received a second biologic DMARD. Second biologic DMARD treatments were another anti-TNF for 122 patients and treatments with oMOA for 54 patients. At time of chart abstraction 108 patients had discontinued the second DMARD. Of these, 98 then received a third biologic DMARD (36 anti-TNF and 62 with oMOA) with 43 of these patients discontinuing the third biologic DMARD. Reasons for discontinuation are shown in the table:

	Reasons for discontinuation of Biologic DMARDs				
		Second biologic		Third biologic	
	First anti-TNF (n=176)	anti-TNF (n=122)	oMOA (n=54)	anti-TNF (n=36)	oMOA (n=62)
Discontinued, n (%)	176 (100)	87 (71.3)	21 (38.9)	21 (58.3)	22 (35.5)
Reason, n (%)*					
Lack of initial efficacy	40 (22.7)	35 (40.2)	4 (19.0)	10 (47.6)	12 (54.5)
Failure to maintain response (disease flare)	82 (46.6)	27 (31.0)	7 (33.3)	2 (9.5)	6 (27.3)
Safety/tolerance	30 (17.0)	18 (20.7)	3 (14.3)	4 (19.0)	1 (4.5)
Patient doing well	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)
Patient or physician preference	1 (0.6)	0 (0.0)	1 (4.8)	0 (0.0)	0 (0.0)
Cost, insurance, or formulary	13 (7.4)	1 (1.1)	3 (14.3)	1 (4.8)	2 (9.1)
Other or not reported	13 (7.4)	7 (8.0)	3 (14.3)	4 (19.1)	1 (4.5)

*Among those who discontinued

Conclusion: The most common reasons for discontinuation of the first anti-TNF agent were efficacy related (69.3%). A numerically greater proportion of patients receiving anti-TNF as their second biologic discontinued due to lack of initial efficacy compared with those that received second biologic with other mechanism of action. In addition, safety/tolerance was a more common reason for discontinuation among those receiving anti-TNF than those receiving treatment with other mechanisms of action.

Background/Purpose: TNF inhibitors often represent the 1st biologic prescribed to patients with rheumatoid arthritis (RA). Approximately one third of patients fail to respond. However, therapeutic strategy in patients with insufficient response to a 1stanti-TNF is not codified.

Methods: The "Rotation of anti-TNF Or Change of class of biologic" (ROC) trial (NCT01000441) is a pragmatic open multicenter randomized controlled trial comparing the initiation of a second anti-TNF or of another class of biologic in patients with inadequate response to a first anti-TNF. Patients were randomly assigned in one of the two groups according to a computer generated randomization list using a block design with variable blocks sizes and a stratification on center. The choice of the second anti-TNF (adalimumab, certolizumab, etanercept, infliximab) or of the other biologic abatacept, rituximab or tocilizumab) remained at the appreciation of the clinician. Inclusion criteria were: RA according to ACR criteria, insufficient response to 1 anti-TNF, DAS28 equal or greater than 3.2. Primary outcome criteria was EULAR response at 6 months.

Results: Another class of biologic and a second anti-TNF were respectively initiated in 146 patients (abatacept: 35, rituximab: 41, tocilizumab: 70) and in 145 patients (adalimumab: 57; certolizumab: 23; etanercept: 53; infliximab: 8). Baseline characteristics are summarized in Table 1. EULAR response at 6 months was observed in 74.4% of patients (good: 41.8%/ moderate response: 32.6%) treated with another class of biologic versus 65.7% (27.1%/38.6%) of those treated with a 2d anti-TNF (OR 1.6 (CI95% [0.9; 3.0], p = 0.1). EULAR good/moderate responses at 6 months were

28.1/34.4%, 28.2/35.9%, 55.7/30.0%, 27.3/43.6%, 31.8/31.8%, 26.9/38.5%, and 12.5/25.0% in patients treated with abatacept, rituximab and tocilizumab, adalimumab, certolizumab, etanercept and infliximab, respectively. Low disease activity (LDA) was observed in 47.1% of patients who changed of class of biologic vs 33.6% of patients who had a 2d anti-TNF, and DAS28-ESR remission was observed in 29.0 and 20.4% of patients, respectively.

Conclusion: The ROC trial first demonstrates the efficacy of a second biologic in more than 2 thirds of TNF-IR patients. At 6 months, the proportion of responders between patients who changed of class of biologic and those who had a second anti-TNF was overall similar. EULAR good response, LDA, DAS remission appeared higher in patients who changed of class of biologic compared to those who had a second anti-TNF. Analyses of clinical efficacy of each biologic, changes in synthetic DMARDs and corticosteroids, biologic retention rate and radiographic progression at 1 year are ongoing.

Table 1. Baseline characteristics of patients

	Other class of biologic abatacept, rituximab, tocilizumab, n=146	2d anti-TNF adalimumab, certolizumab, etanercept, infliximab, n= 145
Age/female sex	58.2 (11.1)/82.2%	55.9 (13.1)/ 84.1%
Disease duration	10 [4;17.8]	10.5[4;19.2]
RF+/anti-CCP+	84.6/83.3%	77.1/80.0%
Ever smokers	18.5%	19.3%
Duration since 1st anti-TNF discontinuation, days	17[6–56]	16[7–50.5]
Concomitant corticosteroids	54.8%	51.0%
Synthetic DMARD	76.7%	76.6%
TJC	8[4;12]	6[3;10]
SJC	5[3;8]	4[3;7]

Anti-Tumour Necrosis Factor Alpha Therapy Reduces Platelet Reactivity and Is Associated With Improved Insulin Sensitivity In Patients With Inflammatory Arthritis. Paul A. MacMullan[1], Anne M. Madigan[2], Laura J. Durcan[3], Karl Egan[1], Paola M. Bagaglia[2], Dermot Kenny[4] and Geraldine M. McCarthy[2]. [1]RCSI, Dublin, Ireland, [2]Mater Misericordiae University Hospital, Dublin 7, Ireland, [3]Mater Misercordiae University Hospital, Dublin 7, Ireland, [4]RCSI, Dublin 2, Ireland.

Background/Purpose: Patients with inflammatory arthritis (IA) die prematurely from cardiovascular disease (CVD). The increased CVD risk is not fully explained by traditional risk factors, but is strongly associated with inflammation and is significantly reduced in those who respond to anti-TNF therapy. Platelets also play a crucial role in the pathogenesis of atherothrombotic events. We have previously shown enhanced platelet reactivity in patients with active IA compared to those in remission. Therefore we prospectively assessed the influence of improved disease control with anti-TNF therapy on platelet function, LDL cholesterol, and insulin metabolism in patients with IA.

Methods: Patients with an established diagnosis of IA (rheumatoid, psoriatic, seronegative spondyloarthropathy) and who were due to commence anti-TNF therapy were recruited. Patients with a history of cardiovascular disease (CVD), diabetes mellitus, or receiving anti-platelet therapy were excluded. Demographic data, traditional CVD risk factors and medication use were recorded. Patients were evaluated on 2 separate occasions, before commencing an anti-TNF agent (adalimumab, etanercept, certolizumab, infliximab) and again after 4 months of treatment. Disease activity assessment was comprised of serological markers (ESR, CRP,fibrinogen), patient measures (VASDA),evaluator global assessment, and the DAS-28 score. Patients were classified as responders by reduction of at least 1 disease category in DAS-28 or >50% improvement in VASDA, where applicable. Samples of fasting LDL, glucose, and insulin were obtained. Insulin resistance was assessed using the HOMA-IR method. Platelet responses to multiple concentrations of arachidonic acid, collagen, epinephrine, thrombin receptor activating peptide (TRAP), and ADP were measured simultaneously using a modification of light transmission aggregometry, and log dose-response curves were calculated.

Results: Data from 19 patients were analysed (n=15 responders [mean DAS 28 scores pre and post-treatment, 5.1 vs 3.18, $p<0.01$], n=4 non-responders (mean DAS-28 scores pre and post-treatment, 4.51 v 4.55]). Post-treatment platelet responses to ADP were significantly reduced in responders only (EC50 1.97 vs 1.17, $p<0.001$, while in non-responders, pre and post treatment values were similar (EC50 1.89 vs 1.94). Also, there were no differences in pre/post treatment platelet responses to any of the other agonists for either group. Responders also demonstrated reduced insulin resistance (mean [95%CI] HOMA-IR 1.995 [1.4–2.58] vs 1.19 [0.86–1.52] pre and post treatment, $p<0.01$) compared to non-responders (mean HOMA-IR 1.9 vs 2.05, pre and post treatment, respectively), while mean LDL values were similar across all subjects.

Conclusion: These data are a prospective demonstration of decreased platelet reactivity and improved insulin sensitivity in patients with active IA who respond to anti-TNF therapy, and may represent potential mechanisms by which anti-TNF therapy reduces CVD events in this high risk population.

Tofacitinib For Rheumatoid Arthritis: A Systematic Review and Meta-Analysis. Maria A. Lopez-Olivo[1], Maria E. Suarez-Almazor[2] and Mahesh Bavineni[3]. [1]University of Texas. M.D Anderson Cancer Center, Houston, TX, [2]University of Texas MD Anderson Cancer Center, Houston, TX, [3]Louisiana State University Lafayette, Lafayette, LA.

Background/Purpose: Tofacitinib was developed as a small molecule inhibitor of the Janus kinase (JAK) pathways that are central to the maintenance of the inflammatory state in rheumatoid arthritis.

Methods: To evaluate the efficacy and safety of tofacitinib, we conducted a comprehensive search in the following electronic databases: Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, CINAHL, EMBASE, Web of Science, International Pharmaceutical Abstracts (IPA) database and Biological abstracts from inception through February 2013. We included any randomized controlled trial comparing tofacitinib alone or in combination with any DMARD versus placebo or other traditional or biologic DMARDs for the treatment of patients with rheumatoid arthritis. Study selection, data collection and risk of bias assessment were performed by two independent reviewers. We performed a meta-analysis when there was more than one study reporting in the percent of patients achieving an ACR50 response, clinical remission (DAS <2.6), discontinuations due to adverse events and serious adverse events.

Results: Out of 310 citations, 10 RCTs met our inclusion criteria. Most studies compared more than two doses of tofacitinib, for our review we only evaluated the recommended dose of 5 mg twice daily. Greater percentage of patients in the tofacitinib group achieved an ACR 50 response and clinical remission compared to control (placebo + MTX) at 6–24 weeks (RR 3.4 95% CI 2.3, 5.0 and 3.1 95% CI 1.4, 6.7, respectively). There were no differences between groups in the rate of discontinuations. Serious adverse events were less likely to occur in the tofacitinib group 0.10 (95% CI 0.02, 0.55) at 12–24 weeks. When compared tofacitinib with adalimumab, similar rates of ACR50 response, discontinuations due to adverse events and serious adverse events were observed between groups.

Conclusion: Tofacitinib had better efficacy responses compared to placebo at 6–24 weeks and rates of serious adverse events or discontinuations were similar between groups. Tofacitinib had also similar effects compared to adalimumab. Tofacitinib can be considered an additional therapeutic option with different mechanisms of action to treat patients with moderate to severe disease.

Discontinuation Rates Of Tocilizumab Therapy In Rheumatoid Arthritis Patients In a Nonacademic Clinical Setting. Jaishree Manohar[1] and Charles H. Pritchard[2]. [1]Drexel University College of Medicine, Sarasota, FL, [2]Drexel University College of Medicine, Willow Grove, PA.

Background/Purpose: Tocilizumab(TCZ) and other biologics are expensive and switching between them is difficult. The goal of this retrospective chart analysis is to identify the discontinuation rate of TCZ therapy in patients who have rheumatoid arthritis and to identify characteristics of patients who are able to continue TCZ in nonacademic settings.

Methods: We conducted a review of all patients who received TCZ therapy in our office. Patients were excluded if they were part of the initial TCZ studies, had missing records, left the practice or treated for conditions other than rheumatoid arthritis. All other patients were included. The primary endpoint was the rate of discontinuation of TCZ. The secondary endpoint was to identify the differences in characteristics of patients who discontinued versus continued TCZ therapy.

Results: 104 charts were reviewed and 26 excluded. 59.6% (62/104, 95%CI 50%-69%) of all patients on TCZ therapy discontinued the medication. The most common reasons for discontinuation were ineffectiveness and adverse events. Table 1 describes the characteristics of patients who continued and those who discontinued TCZ use. A higher percentage of patients were on methotrexate in the group who continued TCZ (42.9%) as compared to the group who discontinued TCZ (24.2%, p=0.0242). Prednisone dosage after TCZ use was statistically significant between those who discontinued TCZ and those who continued TCZ, 9.10mg and 4.65mg respectively with a p value of 0.016. In patients who continued TCZ and those who discontinued TCZ HAQ scores (0.929 and 1.237, p=0.009), ESR levels (4.81 and 11.14, p=0.027) and CRP levels (0.18 and 1.15, p= 0.002) after TCZ therapy were statistically different.

Table 1. Characteristics of patients who continued and discontinued Tocilizumab

	Continued Tocilizumab (N=42)	Discontinued Tocilizumab (N=62)	P value
Female gender	40.5% (34)	59.5% (50)	0.97
Male gender	40% (8)	60% (12)	0.97
Age	58.98	60.23	0.62
Duration of disease (years)	2.87	3.09	0.164
Rheumatoid Factor positive	44.4% (16)	55.6% (20)	0.784
RheumatoidFactor negative	41.5% (22)	58.5% (31)	0.784
Anti-CCP positive	43.8% (14)	56.3% (18)	0.86
Anti-CCP negative	41.8% (23)	58.2% (32)	0.86
HAQ score prior to tocilizumab (mean)	1.045	1.281	0.126
HAQ score after tocilizumab use (mean)	0.929	1.278	0.009
ESR prior to tocilizumab use (mean)	23.91	20.03	0.433
ESR after tocilizumab use (mean)	4.81	11.14	0.027
CRP prior to tocilizumab use (mean)	1.96	5.04	0.064
CRP after tocilizumab use (mean)	0.18	1.15	0.002
Methotrexate prior to tocilizumab use (mean)	15mg	13.67mg	0.23
Methotrexate use (%) prior to tocilizumab	42.9%	24.2%	0.024
Methotrexate after tocilizumab use (mean)	14.38mg	14.11mg	0.43
Prednisone dosage prior to tocilizumab use (mean)	9.94mg	7.97mg	0.14
Prednisone dosage after tocilizumab use (mean)	4.65mg	9.10mg	0.016
Number of prior biologics used	2.21	2.45	0.26

HAQ health assessment questions, ESR erythrocyte sedimentation rate, CRP c-reactive protein

Conclusion: We found a higher rate of discontinuation compared to those reported in literature. TCZ discontinuation rates in clinical registries from Japan and Denmark were 30.4–42%[1–2]. The higher rate of discontinuation of TCZ in our study could be because of different clinical practices in nonacademic setting in the USA. We found that patients who continued TCZ therapy did show improvement in HAQ scores, ESR and CRP levels that were statistically different from patients who discontinued TCZ therapy. HAQ scores, ESR and CRP levels may be important predictors of response to TCZ therapy.

Anti-Tumor Necrosis Factor α Therapy (Etanercept) Plus Methotrexate Lowers Serum Amyloid A Levels To a Greater Extent Than Triple Oral Disease Modifying Anti-Rheumatic Drug Therapy In Early Rheumatoid Arthritis Subjects. Ilinca D. Metes[1], Douglas W. Chew[1], Aarat M. Patel[1], G.K. Balasubramani[2], S. Louis Bridges Jr.[3], Jeffrey R. Curtis[3], Stephen R. Wisniewski[2], Larry W. Moreland[1] and Marc C. Levesque[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, [3]University of Alabama at Birmingham, Birmingham, AL.

Background/Purpose: Amyloidosis is often due to an underlying inflammatory disorder, such as rheumatoid arthritis (RA), with organ deposition of serum amyloid A (SAA). Oral disease modifying anti-rheumatic drugs (DMARDs) and biologics can ameliorate RA, reduce SAA levels and improve amyloidosis. Anti-tumor necrosis factor α (TNF) therapy has yielded remarkable benefits in case studies of patients with amyloidosis, and studies suggest TNF regulates SAA production. Our aim was to determine if RA patients treated with the TNF antagonist, etanercept, have greater reductions in SAA levels than RA patients treated solely with oral DMARD therapies.

Methods: Samples were analyzed from RA subjects (n = 755) enrolled in the Treatment of Early RA (TEAR) study, a randomized, double-blind trial. In the TEAR trial, early RA subjects with less than 2 years of disease duration were randomized to either combination etanercept (ETN)/methotrexate (MTX) therapy (n = 244), MTX/hydrochloroquine/sulfasalazine (triple oral) therapy (n = 132) or MTX monotherapy (n = 379). MTX monotherapy subjects with a DAS28-ESR > 3.2 after 6 months of treatment were stepped up to either ETN/MTX (n = 205) or triple oral therapy (n = 93). Serum samples and clinical data were collected when treatment was initiated and at 24, 48 and 102 week follow-up visits. The results from the TEAR trial indicated that there were equal reductions in disease activity in all arms of the study after two years of treatment. A mixed effects model was used to determine whether ETN/MTX treatment compared to triple oral therapy differentially lowered SAA levels. In addition to treatment, fixed effects in the model included time, baseline SAA levels, treatment*time and DAS28-ESR.

Results: There were no baseline differences in age, SAA level, CRP level, RF status, or disease duration between the different treatment arms of the TEAR trial. Overall, there were significant differences in SAA levels by both visit (p=0.0197) and treatment arm (p=0.0130). SAA levels were lower by an average of 66 ranks following treatment with ETN/MTX compared to triple oral therapy. Similar results were found for serum CRP levels by visit (p=0.0254) and by treatment (p < 0.0001), with an even more pronounced mean difference than SAA levels; serum CRP levels were lower by an average of 144 ranks following treatment with ETN/MTX compared to triple oral therapy.

Conclusion: RA subjects treated with ETN plus MTX had a greater reduction in SAA levels than subjects treated with oral DMARD therapy, even after correcting for disease activity. While the TEAR trial was not designed to study amyloidosis, our analysis suggests that RA patients with amyloidosis may derive greater benefit from treatment with TNF antagonists than oral DMARDs in clinical situations where both treatments lower disease activity to the same extent. Interestingly, the differential effect of ETN plus MTX compared to triple oral DMARDs on SAA levels may be less pronounced than the differential effects of ETN plus compared to triple oral DMARDs on CRP levels. The latter may be important when considering use of SAA versus CRP levels as biomarkers for disease activity during treatment with TNF antagonists.

Subcutaneous Delivery Of Methotrexate Is Associated With Improved Treatment Survival Compared To Oral Administration For The Initial Treatment Of Patients With Early Rheumatoid Arthritis. Glen S. Hazlewood[1], J. Carter Thorne[2], Janet E. Pope[3], Juan Xiong[4], Gilles Boire[5], Boulos Haraoui[6], Carol A. Hitchon[7], Edward C. Keystone[8], Diane Tin[2] and Vivian P. Bykerk[9]. [1]University of Calgary, Calgary, AB, [2]Southlake Regional Health Centre, Newmarket, ON, [3]St Joseph Health Care, London, ON, [4]Mount Sinai Hospital, Toronto, ON, [5]Centre Hospitalier Universitaire de Sherbrooke, Université de Sherbrooke, Sherbrooke, QC, [6]Institut de Rhumatologie de Montréal, Montreal, QC, [7]University of Manitoba, Winnipeg, MB, [8]Mount Sinai Hospital/University of Toronto, Toronto, ON, [9]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY.

Background/Purpose: To determine the comparative survival of initial treatment with subcutaneous (sc) methotrexate (MTX) versus oral MTX for patients with early rheumatoid arthritis (ERA) in routine care. Previous work had demonstrated sc MTX was associated with improved DAS28 scores over the first year.

Methods: Patients with early rheumatoid arthritis (ERA) initiating methotrexate therapy were included from the Canadian Early Arthritis Cohort (CATCH), a multicenter, prospective cohort study of patients with ERA. In CATCH patients are treated at the discretion of the rheumatologist and followed every 3 months over the first year according to a standardized protocol. For this study, all patients had an age >16 years, a diagnosis of RA by 2010 criteria, symptom duration < 1 year, used MTX within 3 months of study entry and were MTX-naive or minimally exposed to MTX. We compared the survival between sc and oral administration over the first year. Treatment failure was defined as either a change in route of MTX or addition/switch of any DMARDs other than glucocorticoids. A Cox-Proportional Hazards model was used to adjust for important potential confounders: age, gender, comorbidities, smoking, education, symptom duration, serological status, erosions, baseline DAS28, functional status (HAQ-DI), mean starting dose of MTX (over first 3 months of treatment) and other concurrent DMARDs or corticosteroids.

Results: 674 patients were included (418 oral MTX, 256 sc MTX); mean age 53, 72% female, mean symptom duration 5.2 months, mean baseline DAS-28 5.5. Patients treated with sc MTX were less likely to receive other DMARDs (56% vs. 71%, $p<0.01$), and had a higher mean starting dose of MTX (23 mg vs. 17 mg, $p<0.01$). Other characteristics were similar between groups. Unadjusted Kaplan-Meier curves showed significantly improved survival with sc MTX (figure 1, log-rank $p<0.001$). After adjusting for confounders the association remained significant (Hazard ratio (HR) for treatment failure: 0.58 (95%CI: 0.37–0.92, p=0.02). Older age (HR: 0.98 (95%CI: 0.97–0.99) per year of age) and the use of other DMARDs in combination (HR: 0.53 (0.35–0.81)) were also associated with improved survival. The starting dose of MTX (HR: 0.98 (0.94–1.02)) and all other covariates demonstrated no significant association.

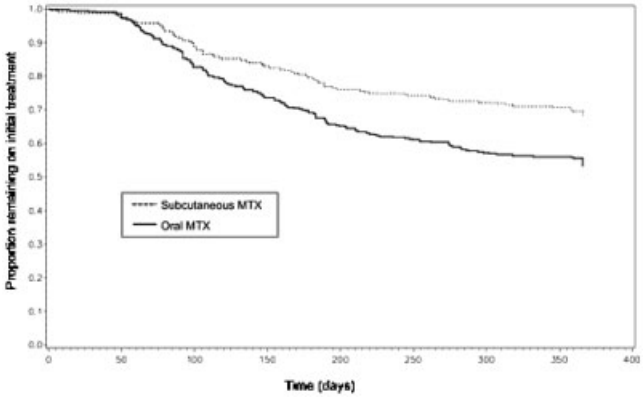

Figure 1. Kaplan-Meier curve comparing unadjusted survival of initial treatment with sc versus oral MTX for patients with early rheumatoid arthritis

Conclusion: Subcutaneous MTX is associated with improved survival over oral MTX for initial treatment in patients with early rheumatoid arthritis. This is not a randomized trial so other confounding could have occurred.

Effectiveness Of Etanercept In Elderly Patients With Rheumatoid Arthritis: A Single Center Retrospective Study. Arthur N. Lau[1], Alpesh Shah[2], Melissa Deamude[3], Cynthia Mech[3], Robert Bensen[2] and William G. Bensen[4]. [1]McMaster University, Hamilton, ON, [2]Rheumatology Health Team, Dr. Bensen's Rheumatology Clinic, Hamilton, ON, [3]Rheumatology Health Team, St. Joseph's Hospital Hamilton, Hamilton, ON, [4]St. Joseph's Hospital and McMaster University, Hamilton, ON.

Background/Purpose: Biological drugs have dramatically improved the prognosis of rheumatoid arthritis (RA), especially in those with early disease. These patientsare often in younger age with fewer co-morbidities. Recent Canadian data suggests the highest incidence and prevalence of RA is in the 55–85 year old age group, often with associated co-morbidities, poly-pharmacy, and often longstanding disease. The purpose of this real world retrospective effectiveness study is to evaluate effectiveness, safety and durability of etanercept initiated in patients over the age of 65 (inclusive).

Methods: This study is a retrospective analysis of all elderly RA patients, started on etanercept for at least 3 months, between Jan 2004 and Dec 2011 at a single center in Hamilton, Canada. Information was collected on demographic variables, previous and ongoing DMARDs/steroids, swollen joint counts (SJC), tender joint counts (TJC), etanercept treatment details, reason for treatment discontinuation and any reported adverse event. Efficacy was evaluated by the change in swollen and tender joint counts over a period of time after etanercept treatment. Treatment effectiveness assessed by calculating the overall drug-survival.

Results: A total of 72 patients from the study period of January 2004 to December 2011 were included in the analysis. A total of 71% of the patients were female, with a mean age of 73.0 ± 5.35 years, and 73.3% were rheumatoid factor positive. 42.6% of patients had a disease duration less than 10 years. The median drug survival was 42 months, with 60% and 50% patients respectively were still on etanercept in the age group of 65–75 and more than 75 years at the end of the study period. Significant improvement in the mean SJC (*p-value* < 0.001) from baseline (8.45 ± 4.81) to treatment at 3 months (4.56 ± 3.92), at 13 months (2.56 ± 2.84) and 23 months (1.85 ± 2.06) was observed. Similar efficacy was observed in patients between age group of 65–80 and over 80 years. Patients with early as well as longstanding RA showed similar sustained improvement in disease activity over time. Concomitant use of DMARDs (methotrexate and leflunomide) reduced significantly (*p-value*< 0.05) after treatment with etanercept. Common reported adverse events were injection site reaction (2.77%), lung infection (6.94%), URTI (4.16%), UTI (8.33%) and other infections (12.5%).

Conclusion: As the demographics of RA changes, knowledge about RA care in the elderly population will be crucial. In this real world effectiveness study assessing RA patients over age 65, our results suggest that etanercept is an effective therapy despite the advanced age, and often long disease duration. There were also no unexpected safety concerns.

A Novel Method Predicting Good Response Using Only Background Clinical Data In RA Patients Treated With Infliximab. Fumihiko Miyoshi[1], Kyoko Honne[2], Seiji Minota[3], Masato Okada[4], Noriyoshi Ogawa[5] and Toshihide Mimura[6]. [1]Saitama Medical University, Saitama, Japan, [2]Jichi Medical University, Shimotsuke, Tochigi, Japan, [3]Jichi Medical University, Shimotsuke, Tochigi, Japan, [4]St. Luke's International Hospital, Tokyo, Japan, [5]Hamamatsu University School of Medicine, Hamamatsu, Japan, [6]Research Center for Genomic Medicine, Saitama Medical University, Saitama, Japan.

Background/Purpose: Treatment using biologics is widely used for rheumatoid arthritis (RA) in these days. Prediction of the clinical response to biologics prior to the administration is important mainly because of their price, efficacy and adverse events. Several methods for predicting the response to biologics have been reported, however, it is hard to know if they are applicable for the real-world patients. The aim of the present study was to generate a novel method for predicting the clinical response to infliximab, using machine-learning algorithm with only clinical data obtained before treatment in real-world RA patients.

Methods: We obtained about 40 components of the clinical examinations from 141 patients with RA (Group-1) before infliximab (IFX) treatment at the Saitama Medical University Hospital and Jichi Medical University Hospital. Patients fulfilling the 1987 revised ACR classification criteria were assessed for overall disease activity using DAS28-CRP before IFX treatment and after 12 weeks and were divided into two groups (responder group and non-responder group) according to EULAR response criteria. These data were used for training. To determine the best machine-learning algorithm and the best clinical parameter set, 50 algorithms in the WEKA software package, which consisted of a collection of machine-learning algorithms for data mining tasks, were compared using the training data. As a criterion for selecting combinations of algorithm and parameter set, the accuracy of prediction was required over 95%. However, the predictive accuracies were lower, mainly in the 70–80%. Therefore, we developed the technique to weight each clinical parameter in the training data, and could generate the high-versatility prediction score over 90 %. Next, the selected combination methods were applied to other clinical data which were obtained from 38 patients with RA (Group-2) before IFX treatment at St. Luke's International Hospital and Hamamatsu Medical University Hospital. Finally, the best prediction method was selected from the combinations of algorithm and parameter set.

Results: The combination of Multilayer Perception algorithm (neural network) and 9 clinical parameters shows the best accuracy performance, compared to the others. This prediction method could completely reproduce (100% accuracy) the result of training data (Group-1). This method was applied to the clinical data of other hospitals (Group-2) and could predict the good or moderate response to IFX with 92% accuracy. The positive prediction value of this method was 93.5%, while the negative value was 85.7%.

Conclusion: We have developed a novel method for predicting the clinical response to IFX, using Multilayer Perceptron algorithm with 9 clinical parameters of RA patients before treatment. This method has predicted the clinical response of IFX on different groups of RA patients with 92% accuracy. We believe that our method for predicting the response to IFX in real-world RA patients has advantages over the other methods in several points including easy usability, cost-effectiveness and accuracy.

Background/Purpose: It is estimated that between 10 and 30% of rheumatoid arthritis (RA) patients are methotrexate (MTX)-intolerant and discontinuation is common in clinical practice. For RA patients' requiring biological treatment and not tolerating MTX, the options are either combination therapy with other disease-modifying antirheumatic drugs (DMARDs) or biological monotherapy. In Denmark it is mandatory to register the patients in the national database, DANBIO. The objective of the present study was to elucidate the prevalence of Danish RA patients currently on biological monotherapy.

Methods: All RA patients, treated with biologics, that were registered in DANBIO, as receiving biological treatment as monotherapy during the period May 1st 2011 to April 30th 2013 were eligible for inclusion. All files of individual patients were reviewed for inconsistence with the treatment registration in DANBIO. Results are presented as descriptive statistics, with no adjustments or statistical models applied.

Results: Twenty-one of 25 Danish rheumatology departments participated in the study. In total 4,744 RA patients were registered in DANBIO as being in biological treatment, of which 4,151 (87.5%, Figure) were treated in the participating departments. Of these, 1,000 (24.1%) were registered as receiving biological monotherapy. 225 (22.5%) of the 1000 were excluded after file review due to use of concomitant conventional DMARDs not registered in DANBIO, leaving 775 (18.7%) in verified currently biological monotherapy. Etanercept, adalimumab, tocilizumab and rituximab were the biological drugs that most often were given in monotherapy (Table).

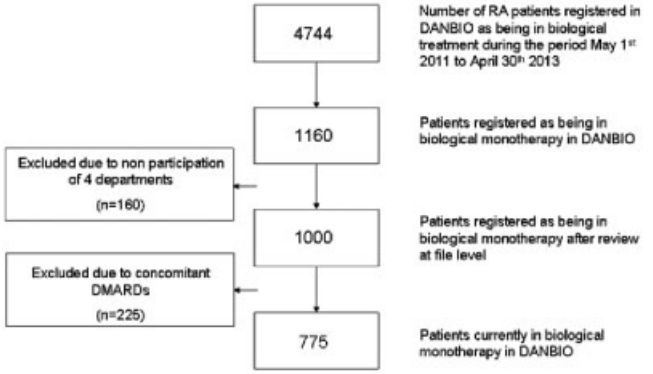

Figure 1. Flow diagram

Table. The distribution of various biologics

	Numbers treated (N=775)	% of total
Abatacept	17	2.2
Adalimumab	165	21.3
Anakinra	3	0.4
Certolizumab	26	3.4
Etanercept	284	36.6
Golimumab	21	2.7
Infliximab	48	6.2
Rituximab	92	11.9
Tocilizumab	119	15.3

Conclusion: In Denmark, 18.7% of biological treatments for RA are prescribed as monotherapy, i.e. without concomitant DMARDS. Monotherapy is prevalent across all biologics, while with a preponderance with adalimumab, etanercept, and tocilizumab, all three having the indication monotherapy.

Relationship Between physicians' Decision To Use Concomitant Glucocorticoid and Remission During Treatment With Tocilizumab In Patients With Background Of Limited Dose Of MTX. Toshihisa Kojima[1], Nobunori Takahashi[1], Koji Funahashi[1], Shuji Asai[1], Masahiro Hanabayashi[1], Shinya Hirabara[1], Nobuyuki Asai[2] and Naoki Ishiguro[2]. [1]Nagoya University Hospital, Nagoya, Japan, [2]Nagoya Univeristy Graduate School of Medicine, Nagoya, Japan.

Background/Purpose: Now, predictive factors at baseline for the good outcome of treatment with biologics are very important not to waste time to treatment goal "remission". It is still arguable how to use glucocorticoid (GC) in treatment strategy of rheumatoid arthritis (RA). Another critical question would be whether MTX is even needed for better clinical outcomes during TCZ treatment in clinical settings with a variety of baseline characteristics, including previous use of other biologics. The aims of this study are 1) to identify the predictive factors at baseline and 2) to clarify the meaning of concomitant use of GC as well as MTX to achieve the remission in treatment with tocilizumab (TCZ), especially with background of limited dose of MTX(≤8mg/week).

Methods: This study included 240 RA patients who received TCZ in the multicenter study group (Tsurumai Biologics Communication Registry; TBCR, 2176 cases treated with biologics were registered until 2011). We explored the differences in baseline characteristics by concomitant use of GC. We also determined the predictive baseline factors for remission (DAS28) at week 52 using multivariate logistic regression analysis.

Results: In Japan, dose of MTX is limited up to 8mg/week until 2011. Baseline characteristics: median (IQR); Age 60 ys (51–67), Disease duration 8.1 ys (3.7–14.5), DAS28-ESR 5.6 (4.8–6.5), MTX dose 8mg(6–8), concomitant MTX 48.8 %, concomitant PSL 67.5 %, previous use of biologics 67.9 %. Remission rate (DAS28) at 52 weeks in our study was 42.9 %. Patients with concomitant GC at baseline had significant higher disease activity (DAS28; 5.8 vs 5.3, p=0.01) and rate of previous biologics use (74.1 % vs 55.1 %, p=0.003), and marginally higher rate of concomitant MTX (53.1% vs 39.7%, p=0.053), compared to patients with no concomitant GC, respectively. The multivariate logistic regression analysis showed predictive factors for remission in patients with high DAS28(≥5.6) at week 52 were follows: no previous use of biologics [OR3.15 (1.20–8.58)], and concomitant MTX [OR3.04(1.23–8.03)] and no concomitant GC[OR3.48 (1.36–9.29)]. Interestingly, that in the patients with low DAS28(<5.6) was only no concomitant GC [OR2.81 (1.21–6.82)]. MTX plays critical roles on RA treatment. However, approximately one-third of RA patients receive monotherapy without MTX due to MTX-induced adverse events. Therefore, the information with treatment background of limited dose of MTX should be important for clinical practice. Decision of prolonged concomitant GC was based on physicians' clinical observation during treatment before initiation of TCZ. This bias could be critical predictive factor not to achieve better outcome.

Conclusion: Remission rate at week 52 in TCZ treatment was predictable by baseline factors in daily practice. In patients with high disease activity, concomitant MTX could be important for achievement of remission with TCZ. Physicians' decision for concomitant use of GC in practice was strongly associated with not-achievement of remission during TCZ treatment with background of limited dose of MTX.

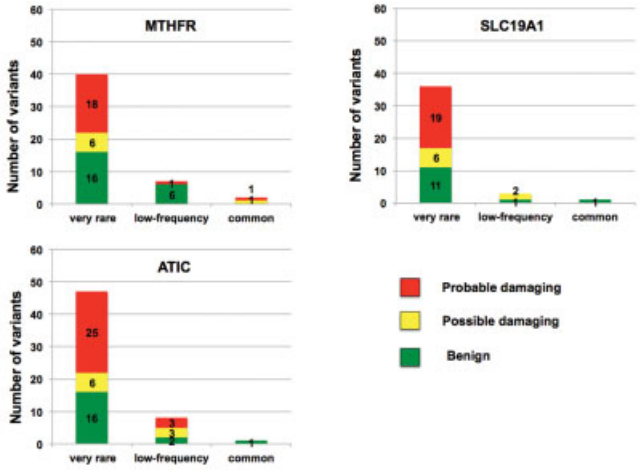
Prevalance Of Rare Variants In Methotrexate Pathway Genes: Implications From The National Heart Lung Blood Institute (NHLBI) Exome Sequencing Project. Fardina Malik. Alton Memorial Hospital, Alton, IL.

Background/Purpose: Inter-individual variation to methotrexate (MTX) therapy in patients with rheumatoid arthritis (RA) is attributed at least in part to the presence of genetic variation in methotrexate pathway genes. However, the majority of the candidate-gene association studies published to date have focused on the effect of common allelic variants on drug efficacy and toxicity. Prevalence of rare variants in methotrexate pathway genes remains largely unknown.

Methods: Variants in 3 major MTX pathway genes (Methylenetetrahydrofolate reductase (MTHFR), solute carrier family 19 member 1 (SLC19A1), and 5-aminoimidazole-4-carboxamide ribonucleotide formyltransferase/IMP cyclohydrolase (ATIC)) were queried using data from NHLBI Exome sequencing project (ESP) which provides high-coverage (average>100x), high quality data for 6,503 individuals of white and black ethnicity (http://evs.gs.washington.edu/EVS/) [accessed in June, 2013, data release ESP6500SI-V2]. Variants were categorized based on their function as well as minor allele frequency: common (>5%), low frequency (0.1–5%), and very rare (<0.1%). Polyphen2 scores were utilized to assess possible impact of aminoacid substitutions on protein structure and function.

Results: Overall, 272 exomic variants were present in MTHFR, SLC19A1, and ATIC genes. Majority of these variants were missense (n=145, 53.3%), followed by coding/synonymous (n=96, 35.3%), utr (n=17, 6.3%), and splice-nonsense-frameshift (n=14, 5.1%) mutations. Only 9 (3.3%) variants were common (MAF>5%), compared to 40 variants with low frequency, and 223 variants with very rare frequency (MAF <0.1%). Overall, 143 variants (52.5%) were private mutations, that is distinct to an individual. Analysis of missense variants accurately identified known common variants of MTHFR pathway including MTHFR 677C>T, MTHFR 1298A>C, SLC19A1 80G>A, and ATIC 347 C>G SNPs. Polyphen2 scoring suggested that 62.1% of missense mutations were potentially damaging to protein structure (Figure).



Conclusion: Exome sequencing data suggests that nearly 1.6% of population carry a potentially pathologic variant in any of the 3 major MTX pathway genes. As the technology and cost of the sequencing platforms improve, exome and/or whole-genome sequencing could potentially improve outcomes in patients with RA on MTX therapy.

Negative Effect Of Glucocorticoids Persistence Therapy On Porosity In Rheumatoid Arthritis Patients Treated With TNFα Blockers. Hubert Marotte[1], Sara Djemouai[2], Béatrice Pallot-Prades[2], Hervé Locrelle[3] and Thierry Thomas[4]. [1]LBTO INSERM U1059 University Jean Monnet, Saint-Etienne, France, [2]University Hospital, Saint-Etienne, France, [3]INSERM U1059 and University Hospital, Hôpital Nord, Saint-Etienne, France, [4]INSERM U1059 and University Hospital, Saint-Etienne, France.

Background/Purpose: Rheumatoid arthritis is the most common joint inflammatory disease associated with an increased risk of bone fractures. The standard of therapeutic strategy is to achieve remission of the disease, which may require a combination of treatment including anti-TNFa therapy and long-term glucocorticoids (GC). While the former has already shown a beneficial effect on bone loss in RA patients, use of GC has two paradoxical effects: it can effectively reduce arthritis and inflammation-induced bone loss while it can also impair bone remodelling balance which results in bone loss. Moreover, GC-induced bone fragility may occur rapidly suggesting deleterious effects on the cortical envelope together with reduced trabecular bone volume. The objective of this study was to assess the effects of GC persistence in RA patients with TNFa blockers on cortical porosity.

Methods: In this pilot study, we selected a group of RA patients in the mid-age range, excluding those below 18 and above 65 years old, with neither concomitant bone disease nor endocrinopathy, to avoid any alteration of bone status unrelated to RA. We enrolled 6 RA patients requiring anti-TNFa therapy because of a methotrexate non-responding disease.

Porosity was assessed by High Resolution Peripheral Quantitative Computerized Tomography (HRpQCT) on radius at the diaphysis site before, 6 and 12 months after introducing anti-TNFa therapy. At the same time, bone mineral density (BMD) was assessed at the radial distal site.

Results: These 8 RA patients (4 men and 4 women) shared the usual characteristic of RA patients with a median age of 49.5 years (range: 35.8–62.4), median disease duration of 3 years (1–11), and a median DAS28 of 4.8 (3.9–6.1) with elevated biological inflammation (ESR: 25 mm/hr (9–68) and CRP at 27.1 mg/L (3–68). Rheumatoid factor and ACPA were present in 71%. Four of the 8 RA patients received GC therapy at the inclusion.

While BMD remained stable under treatment, we observed an increasing of cortical porosity between baseline and 12 month ($P<0.05$). Doses of GC therapy during the 6 last months correlated with the increasing of porosity in the same time ($P=0.042$; $R=0.653$), whereas we observe no correlation during the 6 first months ($P=0.34$; $R=0.122$).

Conclusion: Despite the small sample size of this pilot study, the strong difference between the 2 periods infers that the anti-inflammatory effects of GC participate to the beneficial effects of therapy on bone while persistence of GC on the long term contribute to bone damage with increasing cortical porosity.

1482

Survival Of Biological Treatment In Chronic Inflammatory Arthritis: A Preliminary Analysis Of 13 Years Of Follow Up In Clinical Practice. Gabriela Ávila[1], Sara Marsal[1], Arnald Alonso[1], Carolina Diaz[2], Estefanía Quesada-Masachs[2], María López-Lasanta[1] and Isabel Acosta[1]. [1]Vall d'Hebron Hospital Research Institute, Barcelona, Spain, [2]University Hospital Vall d'Hebron, Barcelona, Spain.

Background/Purpose: The wide use of biological therapies (BTs) has largely modified the therapeutic approach in Chronic Inflammatory Arthritis (CIA). These relatively new drugs have different molecular structure, pharmacokinetic properties and their survival in clinical practice is not well established. The aim of the present study was to analyze the survival of different biological therapies in patients with CIA (i.e. rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA)) and to compare this survival between the three diseases in clinical practice.

Methods: The present study is a retrospective and observational study of patients with CIA treated with BT from December 1999 to December 2012, followed in a university hospital. A large number of epidemiological and clinical data were analyzed (i.e. gender, age, disease diagnosis, date of diagnosis and several variables related to the treatment). Phase I of the study was focused in the analysis of the relationship between clinical (i.e. RF, ACPA, presence of erosions and previous biological therapies) and epidemiologic variables, with the survival curves and treatment discontinuation rate (DR) in RA patients. In Phase II, we compared the survival curves between AS and PsA with RA. Multivariate analysis was used to adjust for potential confounder factors.

Statistical analysis was performed using the R statistical software. Survival curves were generated using the Kaplan-Meier method and compared using the log-rank test. Cox regression analysis was used to detect the rate of discontinuation and to evaluate the effect of different covariates

Results: 300 CIA clinical records were analyzed and data from 291 CIA patients were finally included (RA n=221, AS n=39, PsA n=31). In these 291 patients, a total of 614 BTs were identified (RA n=488, AS n=69, PsA n=57). In Phase I we found that etanercept showed a significant difference in DR ($P=9.08e-5$) when it was compared with other BTs (HR= 0.63 [95% CI, 0.49–0.79). The number of previous BTs (*P*-Value = 2.24 E-0.3) and previous DMARDs (*P*-Value=3.14 E-0.6) were significant variables in DR.

When DR and survival curves were compared between the three CIA we did not find differences in the survival curves in PsA patients compared to RA patients. However, we found a highly significant difference in AS patients compared to the RA patients (*P*- Value= 5.85E-0.5), showing a lower DR (HR= 0.49 [95% CI, 0.35–0.70]).

Conclusion: In our series of patients with chronic inflammatory arthritis treated with biological therapies, we found that etanercept is the treatment with the highest survival in rheumatoid arthritis patients. We also found that ankylosing spondylitis is the chronic arthritis where biological therapies have the longest survival.

Physician and Patient Characteristics Associated With The Decision To Treat Rheumatoid Arthritis Patients With Biologic Monotherapy In Usual Care Settings. Mariely Nieves-Plaza[1], Heather Eng[2], Ilinca D. Metes[3], Ashwini Shewede[4], Stephen R. Wisniewski[2], Ani John[4] and Marc C. Levesque[3]. [1]Univeristy of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA, [4]Genentech Inc., South San Francisco, CA.

Background/Purpose: Approximately 30% of rheumatoid arthritis (RA) patients treated with a biologic, receive the biologic as monotherapy i.e. without concomitant oral disease modifying anti-rheumatic drugs (DMARDs). The purpose of this study was to compare the characteristics of RA subjects treated with biologic monotherapy versus RA subjects treated with biologic therapy combined with oral DMARDs (combo therapy).

Methods: We used data from a longitudinal registry (Rheumatoid Arthritis Comparative Effectiveness Research (RACER)) based at the University of Pittsburgh that includes 1,029 RA subjects with 5,886 usual care clinic visits. We compared the demographic, disease activity, physician and prior treatment characteristics of RA subjects who initiated a biologic therapy since RACER's inception ($n = 473$ subjects with 602 biologic initiations). Using variables with $p < 0.05$ in bivariate analyses, we developed a multivariable random-intercept logistic regression model that accounted for between subject correlations.

Results: Among 602 biologic initiations from Feb 2010 to May 2013, 31.2% of biologic therapy was monotherapy. Individual physicians ($n = 19$) varied widely with a range of prescribed monotherapy from 10% to 55%. In bivariate analyses, monotherapy compared to combo therapy was associated with longer disease duration (16.4 vs. 13.3 years, $p=0.04$), higher alanine aminotransferase (ALT) (29.4 vs. 25.5 U/L, $p = 0.02$), aspartate aminotransferase (AST) (27.1 vs. 22.7 U/L, $p = 0.02$) and alkaline phosphatase (ALP) (85.8 vs. 79.0 U/L, $p < 0.01$), and lower physician visual analogue scale (VAS) scores of global health (2.9 vs. 3.5, $p = 0.02$). As expected, no immediate prior therapy ($p = 0.003$) and previous use of monotherapy ($p = 0.001$) were associated with monotherapy use, whereas previous use of combo therapy was associated with lower use of monotherapy ($p = 0.05$). In multivariable analyses, after adjustment for AST and ALT levels and disease duration, the odds of monotherapy treatment increased 6% per unit increase in ALP level (OR [95% CI]; 1.06 [1.01, 1.11]) and decreased 40% per unit increase in physician VAS (0.60 [0.40, 0.89]).

Conclusion: Liver enzyme elevations and the physician's global health VAS were the strongest predictors of monotherapy use. The presence of liver disease is typically a contraindication to the use of methotrexate and leflunomide and this likely explains the liver enzyme association. Although liver enzyme elevations were associated with use of biologic monotherapy, other comorbidities, as measured by Charlson scores, were not associated with biologic monotherapy use. Surprisingly, our analysis did not find associations of biologic monotherapy use with composite disease activity measures (DAS28, CDAI and RAPID3) or their individual components, except for the physician's global health VAS; worse physician global health assessments were associated with more use of combo therapy. Coupled with the wide variation in physician monotherapy prescribing habits, this suggests that besides liver enzyme elevations, physician characteristics may strongly influence use of biologic monotherapy and will be the focus of future analyses.

Treatment With The Glucagon-Like Peptide-1 Analogue Liraglutide Is Associated With Amelioration Of Disease Activity In a Prospective Cohort Study Of Patients With Inflammatory Arthritis. Catherine Sullivan[1], Gadintshware Gaoatswe[2], James Gibney[3], Marie Louise Healy[4], Michele Doran[5], David Kane[1], Donal O'Shea[2] and Ronan Mullan[1]. [1]Department of Rheumatology, Tallaght Hospital, TCD, Dublin 24, Ireland, [2]Obesity Immunology Group, Education and Research Centre, St Vincent's University Hospital, UCD, Dublin 4, Ireland, [3]Department of Endocrinology, Tallaght Hospital, TCD, Dublin 24, Ireland, [4]Department of Endocrinology, St James Hospital, TCD, Dublin 8, Ireland, [5]St James's Hospital, Dublin, Ireland.

Background/Purpose: Glucagon-like peptide-1 (GLP-1) analogues such as liraglutide, which are used for the treatment of type 2 diabetes (T2DM), mimic the action of endogenous incretin hormones through both enhancing post-prandial pancreatic glucose-dependent insulin release and promoting

early satiety. Recent evidence indicates novel anti-inflammatory effects of GLP-1 analogues, including the amelioration of TNF inflammatory responses on human endothelial cells, and reduction in monocyte TLR2, TLR4 and TNF expression following treatment with GLP-1 analogues for T2DM. We have previously shown decreased inflammatory activity of invariant Natural Killer T (iNKT), modulation of monocyte cytokine secretion and amelioration of skin psoriasis in a cohort of patients with concomitant psoriasis and T2DM. Here we investigate a role for liraglutide in the amelioration of inflammatory arthritis disease activity in a cohort of patients undergoing liraglutide treatment for concomitant T2DM.

Methods: Following institutional ethics committee approval, patients with T2DM and a concomitant diagnosis of either rheumatoid arthritis (n=11) or psoriatic arthritis (n=4) were recruited from rheumatology out patient clinics and commenced on the GLP-1 analogue, liraglutide 1.2mg s/c od. No changes were made to patient Disease Modifying Anti Rheumatic or biological drug therapies for the duration of the study. DAS28 scores, weight, HbA1C, were recorded at baseline and weeks 6, 12 and 24. DAS28 outcomes were defined by EULAR good, or moderate vs non-responders. Results expressed as Mean + SE.

Results: Patients had active arthritis (DAS28 4.38 + 0.4) and inadequate glycaemic control Hba1C (55 + 5.1) at baseline. Following liraglutide therapy 9 patients achieved DAS28 response (DAS28 = 4.2 + 0.8 pre, 2.7 + 0.5 post) vs 6 non-responders (DAS28 = 4.7 + 0.8 pre, 5.0 + 2.7 post). Significant weight loss was seen in DAS28 responders (94 + 5 pre, 90.6 + 5.2kg, p=0.008) but not non-responders (93.8 + 3.3kg pre, 95 + 2.8kg post, p = 0.79). A significant fall in HbA1C was seen in DAS28 responders (60.5 + 6.3 pre vs 45.5 + 2.1 post, p = 0.012) but not non-responders (47.1+9.5 pre vs 39.4+13, p=0.144). A significant fall in SJC28 was seen in DAS28 responders (3.3 + 0.9 pre vs 1.2 + 0.6, p = 0.027) but not non-responders (4.2 + 2.8 pre vs 4.8 + 3.2, p = 0.66). Weight loss following liraglutide was also significantly associated with achieving a DAS28 response by Chi Square analysis (p = 0.044). No significant differences were observed in baseline levels of DAS28, weight, HbA1C, SJC, ESR or CRP analysed according to subsequent DAS28 response grouping.

Conclusion: In a cohort of patients with both inflammatory arthritis and T2DM, clinical efficacy of the GLP-1 analogue liraglutide in reducing HbA1C and inducing weight loss was significantly associated with a concomitant reduction in inflammatory arthritis clinical disease activity by EULAR DAS28 response criteria. Further studies investigating common pathways of inflammation between these diseases may lead to novel therapeutic stretegies in the treatment of inflammatory arthritis.

RNA Transcripts From Peripheral Blood Mononuclear Cells As Predictors Of Clinical Responsiveness In Rheumatoid Arthritis Subjects Treated With Abatacept. Matthew Henkel[1], Fang Du[2], Donald M. Jones[2], Erich R Wilkerson[2], William Horne[2], Jay K. Kolls[3], Marc C. Levesque[2] and Mandy McGeachy[1]. [1]Univeristy of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA.

Background/Purpose: Biologics, including abatacept (CTLA4Ig), improve outcomes for many RA patients. However, approximately 40–50% of RA patients fail to respond to abatacept, and there are currently no biomarkers that predict responsiveness. Analysis of a defined panel of peripheral blood mononuclear cell (PBMC) gene transcripts is a non-invasive and technically feasible approach for routine clinical use to predict abatacept responsiveness. Advances in transcriptome profiling techniques (RNA-Seq) now allow high-throughput "deep-sequencing" of relatively small amounts of input RNA. Direct detection of transcripts by RNA-Seq offers several advantages over conventional microarrays: high sensitivity, low background signal, high dynamic range and accuracy of transcript quantification and high reproducibility.

Methods: We analyzed RNA samples derived from PBMC from 6 subjects treated with abatacept ± oral DMARDs and ± prednisone who were enrolled in the Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry at the University of Pittsburgh. Five of 6 subjects were anti-CCP positive and all 6 RA subjects had active disease at baseline (mean DAS28-CRP ± SD; 4.4 ± 0.7) despite recent TNF inhibitor therapy. Based on DAS28-CRP scores at baseline and at 6 months after abatacept initiation, 3 of the RA subjects were deemed responders (DDAS28-CRP = −1.3 ± 1.0) and 3 non-responders (DDAS28 = 0.1 ± 0.8). PBMC RNA samples from the 6 RA subjects were analyzed by RNA-Seq prior to receiving abatacept and approximately 2 months (6 to 10 weeks) after abatacept initiation. We identified genes that differed at baseline between abatacept responders and non-responders, and for responders and non-responders, genes that changed between baseline and 2 months by ≥ 1.3 fold with $p < 0.05$ (t test).

Results: There was relatively little overlap between responders and non-responders when analyzing RNA transcript changes from baseline to 2 months (< 10 transcripts). A substantially larger proportion of transcripts were significantly altered (increased or decreased) from baseline to 2 months in responders (6339 transcripts) compared to non-responders (117 transcripts). We analyzed expression of genes related to T and B cell function, analyzing baseline predictors of response (different at baseline between responder and non-responder groups) and 2 month predictors of response (different at 2 months versus baseline). We found that PBMC RNA transcripts for IgG isotypes and IL-17 were good 2-month predictors of a 6-month clinical response, but baseline levels of these transcripts did not predict efficacy. In contrast, IL6R transcripts were a good baseline predictor of efficacy but did not change from baseline to 2 months.

Conclusion: These data support the sensitivity of RNA-Seq as an assay for responses to biologic therapies in PBMC from RA patients. These RNA-Seq results, with only three subjects per group demonstrate the great potential of this technique to elucidate both mechanistic and biomarker-related pathways altered in PBMC by therapy. Future studies will validate these results in prospectively collected samples and expand these analyses to other biologic therapies.

ACR/ARHP Poster Session B
Sjögren's Syndrome: Pathogenesis
Monday, October 28, 2013, 8:30 AM–4:00 PM

1486

High Resolution HLA Analysis In Primary and Secondary Sjögren's Syndrome. Gabriela Hernandez-Molina[1], Jose Manuel Rodriguez-Perez[2], Nancy Martínez-Rodríguez[2], Guadualupe Lima[1], Gilberto Vargas-Alarcon[2] and Jorge Sanchez-Guerrero[3]. [1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico, [3]Mount Sinai Hospital, University Health Network, Toronto, ON.

Background/Purpose: The Class II HLA-DR and HLA-DQ alleles have been associated with primary Sjögren's Syndrome (SS) susceptibility. The aim of this study was to explore and compare the distribution of HLA-A, B, DRB1 and DQB1 alleles in patients with primary SS, secondary SS and patients with Connective Tissue Disease (CTD) without (w/o) SS.

Methods: Patients were drawn from a previous study where 50 pSS and 300 CTD patients were randomly selected from our total population of over 5000 patients, and tested for the presence of SS according to the AECG criteria. For the present study we included 28 patients with pSS, 30 patients with sSS and 96 patients with CTD w/o SS with available DNA samples. HLA-A, B, DRB1 and DQB1 were typed by standard PCR-sequencing based typing method. Serum samples were also examined for anti-Ro/SSA and anti-La/SSB antibodies by ELISA. We used the chi-square analysis or the Fisher's exact test and the software EPIINFO.

Results: Overall the alleles A*68:01 (a.f. 0.086 vs. a.f 0.02) and DRB1*1406 (a.f. 0.10 vs a.f. 0.008) were associated with SS (OR 4.43 95% C.I. 1.35–14.48, p= 0.007 and OR 14 95% C.I. 1.68–116, p=0.001, respectively). Patients with pSS had a significant higher prevalence of DRB1*1406 than sSS and CTD w/o SS patients (a.f 0.11, a.f 0.09 and a.f 0.008, respectively, OR 16 95% C.I. 1.59–390 p=0.001). Patients with sSS had a higher frequency of the allele A*03:36 when compared with CTD w/o SS patients (a.f. 0.067 vs. a.f 0.005, OR 13.64 95% C.I., 1.40–327, p=0.01). Then we analyzed the patients according to the positivity to anti-Ro/SSA or anti-La/SSB positivity regardless of SS status. Anti-Ro/SSA positive patients had more frequently the allele B*51:01 (a.f. 0.100 vs. a.f. 0.011, OR 10.11 95% C.I. 1–09-245.99, p=0.02) and DRB1*03:01 (a.f. 0.10 vs. a.f 0.027, OR 4.26 95% C.I. 1.01–18.89, p=0.029). The DRB1*03:01 allele was also more prevalent among patients with anti-La/SSB antibodies (a.f. 0.13 vs. a.f. 0.03, OR 4.26 95% C.I.0.93–18.70 p=0.043), as well as the A*01:01 allele (a.f. 0.20 vs. a.f. 0.05, OR 4.75 95% C.I. 1.32–16.92, p=0.003). When we

analyzed by generic HLA, we also found an association with DQB1*02 (a.f. 0.23 vs a.f. 0.06, OR 4.16 95% CI 1.32–12.93, p=0.003) and DQB1*04 (a.f. 0.43 vs a.f. 0.07, OR 4.04 95% C.I. 1.63–9.99, p=0.005) and the presence of anti-Ro/SSA antibody.

Conclusion: DRB1*1406 identified patients with both SS varieties whereas B*51:01 and DRB1*03:01 patients with anti-Ro/SSA positivity.

Background/Purpose: In primary Sjögren's syndrome (pSS), the pathogenesis of systemic complications remains unclear. Only few gene expression studies were performed and concerned a limited number of patients, without any systemic complications. We therefore analyzed the gene profile of patients according to the international validated systemic disease activity score, the ESSDAI.

Methods: The ASSESS cohort, a multicenter 5-year prospective cohort, has been set up to identify predictive biomarkers of systemic complications in pSS. We selected 45 patients with high, moderate, or low systemic disease activity according to the ESSDAI. ARN extraction was performed from whole blood and was hybridized to Agilent 8×60K microarrays.

Results: 41 patients were women, median age was 61 (25–80) years and median disease duration was 7 years. Median ESSDAI was 6 (0–31), 28 patients had at least one active domain and 18 patients had 2 or more active domains of the ESSDAI. The 45 patients were separated into 3 groups according to the ESSDAI: high (H) (ESSDAI≥15, n= 16), moderate (M) (5<ESSDAI ≤14, n= 8), and low (L) (0≤ESSDAI≤5, n= 21) activity.

16 patients were treated with corticosteroids (2 in L, 3 in M, 11 in H; median dose: 5 mg/day (2–20 mg)), 14 with hydroxychloroquine (6/1/6 in L/M/H, respectively), and 6 with another immunosuppressant. Compared to patients in the L group, patients in the M group had 201 differentially expressed genes (DEG) and patients in the H group had 586 DEG. Most of the DEG belonged to various immune pathways involved in antigen presentation. The expression of BLK and EBF-1, 2 genes involved in B-cell activation and genetic predisposition to pSS, were significantly upregulated in H vs L patients. 79 interferon-regulated genes were differentially expressed, including 39 up- and 40 downregulated, in H vs L patients. In addition, the gene expression profile of distinct systemic involvements only weakly overlapped. Thus, patients with articular involvement (n=5) had 400 DEG compared to those without, patients with lung involvement (n=9) had 305 DEG and patients with peripheral nervous system involvement (PNS, n=9) had 314 DEG. Only 11 genes were common between the list of DEG in articular and lung involvement, 10 were common between lung and PNS and 2 genes were common to the 3 lists.

Conclusion: We identified different gene expression profiles according to the level of the ESDDAI and the nature of systemic involvement. Interestingly, systemic disease activity was not tightly associated with an interferon signature. This might be related to the study of peripheral blood, the effect of hydroxychloroquine and other immunosuppressants, or might suggest that systemic disease activity is not specifically driven by interferons in pSS.

RNA-Sequencing Identifies Novel Differentially Expressed Coding and Non-Coding Transcripts In Sjögren's Syndrome. Indra Adrianto[1], Mikhail G. Dozmorov[1], Graham B. Wiley[1], John A. Ice[1], He Li[2], Jennifer A. Kelly[1], Astrid Rasmussen[1], Donald U. Stone[2], Juan-Manuel Anaya[3], Barbara M. Segal[4], Nelson L. Rhodus[5], Lida Radfar[2], John B. Harley[6], Judith A. James[7], Courtney G. Montgomery[1], R. Hal Scofield[8], Patrick M. Gaffney[1], Jonathan D. Wren[1], Kathy L. Sivils[1] and Christopher J. Lessard[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]School of Medicine and Health Sciences, Universidad del Rosario, Bogotá, Colombia, [4]Hennepin County Medical Center, Minneapolis, MN, [5]University of Minnesota, Minneapolis, MN, [6]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [7]Oklahoma Medical Research Foundation and University of Oklahoma Health Sciences Center, Oklahoma City, OK, [8]US Department of Veterans Affairs Medical Center, Oklahoma City, OK.

Background/Purpose: Sjögren's syndrome (SS) is a common, clinically heterogeneous autoimmune disease characterized by exocrine gland dysfunction that involves both innate and adaptive immune responses. SS etiology is complex, with environmental, genetic, and genomic factors contributing. Of the many genetic associations reported in complex diseases, >80% map to non-protein coding DNA sequences; however, many reside in regions shown to be transcriptionally active. We used RNA-seq to identify differentially expressed (DE) protein-coding (~3% of the genome) and non-coding transcripts in 57 SS cases and 37 healthy controls.

Methods: RNA samples were isolated from whole blood and prepared for sequencing using the NuGEN Encore kit and sequenced using the Illumina HiSeq 2000. Raw FASTQ files were aligned to the human genome using TOPHAT. DE transcripts were determined using DESeq with a false discovery rate q-value of 0.05 and a fold change of >2.

Results: After the alignment, the reads were summarized for 55,076 transcripts across the human genome annotated by Ensembl. A total of 2614 DE transcripts were identified. Of the protein-coding regions, SRP14 was the most statistically DE locus in the case-control analysis (q=2.03×10E–20, FC=2.32). Two other DE protein-coding transcripts of interest were identified: UQCRB (q=1.94×10E-19, FC=2.86) and ATP5I (q=1.88×10E-18, FC=2.34). Biological functions of these genes are unclear. Among the 408 DE non-protein coding transcripts, we observed DE of a long non-coding RNA (lncRNA) at 2p25.1 (q=3.69×10E-5, FC=2.55). lncRNAs are important regulators of the human genome with diverse functions; however, most have yet to be characterized. Bioinformatics evaluation in the 2p25.1 region showed transcription factor binding sites and transcription of lncRNA sequences using immunologically relevant cell lines. To formulate functional hypotheses for the lncRNA at 2p25.1, we evaluated co-expression patterns with protein coding sequences and identified T cell activation and development as the most likely pathways influenced. When evaluating the difference in anti-Ro status, we found the FC increased to 2.85 in anti-Ro(+)patients and decreased to FC=2.24 when anti-Ro(-), indicating a possible relationship to antibody status.

Conclusion: In this SS RNA-seq study, we identified multiple candidate loci and, for the first time, DE lncRNA regions in SS. Although the function of the lncRNAs identified in this study are unknown, many others have been described to function as scaffolds, decoys, signals, and guides for various

proteins by conferring nucleotide sequence specificity not possible by motifs alone. Future studies in SS are warranted to elucidate the functional consequences of these lncRNA.

Comparative Study Of The Transcriptome Of Minor Salivary Gland Of Sjögren's Syndrome Patients Versus Healthy Controls Based On RNA-Seq. Alessia Gallo[1], Shih-Ing Jang[2], Stamatina Danielides[2], Ana Paola Cotrim[2] and Ilias Alevizos[3]. [1]NIDCR, Bethesda, MD, [2]NIH, Bethesda, MD, [3]NIDCR/NIH #10 1N110, Bethesda, MD.

Background/Purpose: Primary Sjögren's syndrome (pSS) is a complex autoimmune disease characterized by a progressive hypofunction of the salivary and lachrymal glands. In order to better understand the pathways potentially involved in the outcome and progression of the disease, we used the latest RNA-Seq technique to characterize the transcriptome of the human salivary gland. Sjögren's syndrome patients' salivary gland and compare it to healthy controls.

Methods: Total RNA was isolated from minor salivary glands stored in RNAlater from healthy volunteers and a primary Sjögren's syndrome patient. The amount and the quality of the RNA was assessed by different system (Nanodrop, Qubit and Bioanalyzer). 2 mg of total RNA were depleted of the ribosomal RNA, fragmented, retro-transcribed and amplified according to the library construction protocols for the Ion Torrent sequencer of Life Technologies. The library quality and enrichment was assessed by Bioanalyzer and Qubit. The libraries obtained were then loaded in the Ion PI chip and ran on the Ion Torrent semiconductor sequencer, system based on the standard pyrosequencing chemistry. The data generated were then aligned to the human sequence databases (hg19) and analyzed with Partek Suite.

Results: The average size library was 160 bp, and the final number of aligned sequences to the human genome database was 2.84E+07 (Healthy Volunteers) and 1.36E+07 (pSS patients). These genome-matched reads were then analyzed with Partek Suite and a list of 43.000 mRNAs was screened in order to find expression differences. Preliminary analysis identified several genes differentially expressed in pSS versus controls. Functional analysis identified both well established in autoimmunity and novel pathways that might play a role in Sjogren's syndrome biogenesis, such as cytokine-cytokine receptor interactions. Analysis of mRNA splicing also identified significant and unexpected differences between pSS and healthy controls.

Conclusion: This is the first known effort for comparison of the transcriptome of Sjögren's Syndrome patients' salivary glands versus healthy controls. Using the latest RNA-Seq technique we were able to identify important pathway and genes differentially expressed that could shed light to the mechanism of salivary gland hypofunction in pSS.

1491

Discovery and Validation Of Novel Micrornas In Minor Salivary Glands Of Sjögren's Syndrome Patients. Alessia Gallo[1], Mayank Tandon[1], Stamatina Danielides[2], Ana Paola Cotrim[2] and Ilias Alevizos[3]. [1]NIDCR, Bethesda, MD, [2]NIH, Bethesda, MD, [3]NIDCR/NIH #10 1N110, Bethesda, MD.

Background/Purpose: Sjögren's syndrome is a complex autoimmune disease of the salivary gland with an unknown etiology, so a thorough characterization of the transcriptome would facilitate our understanding of the disease. We used ultra-deep sequencing of small RNAs of human salivary glands to identify and discover novel miRNA sequences that may play a role in the disease and validated the presence of those novel miRNAs in other human tissues.

Methods: Total RNA was isolated from minor salivary glands of healthy volunteers and patients with either high or low salivary flow. The sequencing was performed on the SOLiD platform (Applied Biosystems), using their Small RNA Expression Kit protocol, which selectively enriches small RNAs (< 300 bp). These sequencing reads were mapped to three different databases, and if reads matched to any of the databases were removed. The unmapped sequences were subsequently examined for other characteristics of microRNA, such as the loop formation of the premicroRNA, with the web-based algorithm miRanalyzer. The novel sequences that possessed the characteristics of microRNAs were subsequently validated with custom desgined TaqMan probes, in several human tissue (bladder, brain, lung, ovary, kidney, adipose tissue, spleen, colon, placenta, thymus, liver and testes total RNA) and a new cohort of minor salivary gland RNA from healthy volunteer and Sjögren's syndrome patients).

Results: There were 121,148 (patient – high flow), 52,568 (patient – low flow), and 174,482 (Healthy Volunteer) unique reads that matched to the human genome. These genome-matched reads generated a total of 222 predicted mature miRNAs. Following the selection process, we identified 44 candidates. Of these candidates, 16 had variable expression among the different human tissues and some of them were differentially expressed between Sjogren's syndrome and healthy control salivary glands.

Conclusion: Sequencing small RNAs in the salivary glands has not been extensively and systematically performed. Our work not only identified novel microRNAs, but also identified differentially expressed microRNAs between healthy controls and Sjögren's syndrome patients

Histone Deacetylase 1 But Not 2 Is Highly Expressed In The Lymphocyte Foci In The Labial Glands Of Patients With Sjogren's Syndrome. Juan Guo and Wei Zhou. Peking University First Hospital, Beijing, China.

Background/Purpose: Sjogren's syndrome (SS) is an autoimmune disease with abnormally infiltrating lymphocytes in exocrine glands expressing Th1 cytokines and increased incidence of lymphoma. Histone deacetylases (HDACs) regulate the state of acetylation of histones and many other intracellular proteins, and their role in the pathogenesis of malignancies has been established. HDAC1 and 2 may also affect the balance of Th1 and Th2 immune response. The aim of this study is to investigate whether HDAC1 and 2 are abnormally expressed in the salivary glands of SS.

Methods: Labial gland biopsies were performed in 55 patients, among them 25 were diagnosed as SS. The expression of HDAC1 and 2 were investigated by immunohistochemistry and immunofluorescence (IF). The HDACs expression level was semi-quatatvely analyzed by counting the number of positively stained cells in randomly chosen microscopic fields. The difference of HDAC expression level in different locus was analyzed by t test.

Results: HDAC1 was highly expressed in the infiltrating lymphocytic foci in the labial glands of patients with SS. The proportion of HDAC1+ cells in lymphocytic foci was higher than that in interstitium (0.66 ± 0.24 vs 0.26 ± 0.08, $p<0.01$). Concerning the expression of HDAC1 in lymphocytes outside the foci, the number of HDAC1+ cells in the interstitium of labial glands was higher in SS patients than that in non-SS patients (21 ± 11/hpf vs 11 ± 6/hpf, $p<0.05$). IF showed that HDAC1 was mainly expressed in CD4+ T cells. HDAC2 was not detected in the labial glands comparing positive control staining of tonsil tissue. The expression level of HDAC1 was not associated with the IgG level and presence of autoantibodies in patients with SS.

Conclusion: The expression of HDAC1 is elevated in the lymphocytic foci in SS and may be involved in its pathogenesis. Thus, inhibiting HDAC1 specifically is a potential therapeutic strategy of SS that is worthy of further investigation.

Increased Expression Of Interleukin 33 In Sera and Salivary Gland From Patients With Sjögren Syndrome. Seung Min Jung[1], Young Sun Suh[1], Jung Hee Koh[1], Jae Ho Lee[1], Jennifer Lee[1], Soo Young Lee[2], Ji Hyeon Ju[1], Kyung-Su Park[1], Dae Chul Jeong[1], Sung Hwan Park[1] and Seung-Ki Kwok[1]. [1]The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, South Korea, [2]The Catholic University of Korea, Incheon St. Mary's Hospital, Incheon, South Korea.

Background/Purpose: Interleukin 33 (IL-33), a member of IL-1 superfamily, exerts pro-inflammatory effect by binding with ST2 expressed on many cell types. Recently, the association of IL-33 with autoimmune disease has been increasingly reported. The aim of this study is to identify the

expression of IL-33 and ST2 in sera and salivary gland tissues from patients with Sjögren syndrome (SS).

Methods: Serum level of IL-33 and expression of IL-33 in salivary gland were assessed in patients with and without SS by ELISA and immunohistochemistry, respectively. Difference in expression of ST2 between patients with and without SS was compared by mRNA level and ST2 positive cells in peripheral blood mononuclear cell (PBMC) from each group. The source of IL-33 in salivary gland of patients with SS was investigated using confocal microscopy system after staining with cytokeratin antibody, CD31 antibody and IL-33 antibody. Additionally, we examined mRNA expression of IL-33 from salivary gland cell line (human head and neck squamous cell carcinoma A253 cell) after stimulation with pro-inflammatory cytokines.

Results: Serum IL-33 level was significantly higher in SS group than that of control group ($p=0.004$). Immunohistochemistry of salivary gland also revealed increased expression of IL-33 in SS group. However, the level of ST2 mRNA in PBMC was lower in SS group than control group, although statistically not significant ($p=0.093$). Consistently, the proportion of ST2 positive cells in PBMC was smaller in SS patients ($p=0.004$). We demonstrated the expression of IL-33 in epithelial and endothelial cells from salivary gland of patients with SS. The expression of IL-33 mRNA in A253 cell was considerably increased after stimulation with interferon gamma.

Conclusion: Our result shows that IL-33 is involved in the pathogenesis of SS. Further research would suggest a new therapeutic approach associated with IL-33/ST2 pathway in SS.

Lesional Intereukin-21 Expression Correlates With Functional Germinal Center Formation and T Follicular Helper Cell Infiltration In The Salivary Glands Of Sjogren's Syndrome. William Murray-Brown[1], Cristina Croia[1], Nurhan Sutcliffe[2], Anwar Tappuni[3], Costantino Pitzalis[1] and Michele Bombardieri[1]. [1]William Harvey Research Institute, QMUL, London, United Kingdom, [2]Queen Mary University of London, London, United Kingdom, [3]Institute of Dentistry, Queen Mary University of London, London, United Kingdom.

Background/Purpose: IL-21 is a pro-inflammatory cytokine that plays a key role in the activation and differentiation of B cells. B cells infiltrate the salivary glands (SG) of Sjögren's syndrome (SS), an autoimmune disease characterized by immune infiltration in the lacrimal and salivary glands leading to exocrine dysfunction. In SS SG, B cells are often organized as functional ectopic germinal centers (GC) and are pivotal in SS pathogenesis. Follicular helper T cells (Tfh) abundantly express IL-21 and contribute to GC B cell affinity maturation via induction of AID, somatic hypermutation and class switching. Here we aimed to investigate IL-21 expression in SS SG and its correlation with key regulators of GC responses and markers of B cell differentiation. Finally, we aimed to assess the relationship between IL-21, infiltrating Tfh cells and the development of functional ectopic GC.

Methods: IL-21 and IL-21R mRNA expression was assessed by Taqman PCR in 28 labial SG of patients with SS and 37 with non-specific chronic sialadenitis (NSCS). Expression levels were correlated with genes regulating ectopic GC formation such as CXCL13 and Ltb and B cell function such as BAFF, AID, Pax5 and Blimp1. In addition, GC formation in the SG was assessed by IHC for B/T cell segregation and follicular dendritic cell (FDC) networks. Finally, Tfh cells infiltration in the SG was assessed by IF for CD3/CD45RO/ICOS and PD1.

Results: SG of SS patients displayed higher expression of IL-21 and IL-21R mRNA compared to NSCS (mean fold increase$\pm$SEM 38 ± 12 vs 5 ± 4, $p=0.02$ for IL-21 and 59 ± 13 vs 12 ± 2, $p=0.01$). In SS, IL-21 mRNA strictly correlated with the levels of CXCL13 (Spearman's $r=0.697$, $p<0.0001$) and Ltb ($r=0.478$, $p<0.001$) which were closely associated with the formation of CD21L+ ectopic GC. Furthermore, IL-21 expression was associated with functional B cell activation as shown by its correlation with AID ($r=0.540$, $p<0.0001$) and Pax5 ($r=0.456$, $p<0.002$). Finally, a subset of CD45RO/ICOS/PD1+ T cells highly resembling Tfh were observed in the presence of ectopic GC characterised by FDC networks but not in FDC- or NSCS SG.

Conclusion: Here we show that IL-21 expression is significantly increased in the SG of SS patients and strongly correlates with ectopic GC formation, functional B cell activation and accumulation of Tfh. These data strongly implicate IL-21 and Tfh cells in the development and maintenance of functional ectopic GC in the SG and could represent novel therapeutic targets in SS.

DNA Methylation In Six Cell and Tissue Types In Sjögren's Syndrome Reveals Distinct Patterns Across Samples and Clustering Based On Disease Status. Alice Baker[1], Diana Quach[1], Hong L. Quach[1], Emon Elboudwarej[1], Lisa F. Barcellos[1] and Lindsey A. Criswell[2]. [1]University of California, Berkeley, Berkeley, CA, [2]University of California, San Francisco, Rosalind Russell Medical Research Center for Arthritis, San Francisco, CA.

Background/Purpose: Sjögren's Syndrome (SS) is a chronic, multisystem autoimmune disease characterized by progressive destruction of the exocrine glands, with subsequent mucosal and conjunctival dryness. Increasing evidence supports a role for DNA methylation status in autoimmune disease risk and severity. Our goal was to characterize methylation profiles in SS subjects and healthy controls across multiple cell and tissue types to identify similarities and differences relevant to disease status and pathogenesis.

Methods: We generated genome-wide DNA methylation profiles using Illumina HumanMethylation450 BeadChips in minor salivary gland biopsy tissue, fresh and banked peripheral blood mononuclear cells (PBMC), CD14+ monocytes, CD19+ B cells, and CD4+ T cells in ten participants (five cases and five controls) from the Sjögren's International Collaborative Clinical Alliance (SICCA; http://sicca.ucsf.edu/; N01 DE32636) repository. Sorting of freshly collected blood samples was performed using MACS® technology. DNA yields for all cell and tissue types were high; all samples were background subtracted and normalized with beta-mixture quantile dilation (BMIQ). After removing SNPS and sites with beta-value detection p-values <0.05, 473,864 CpGs remained in our final data set.

Results: Methylation of individual CpG sites was stable across the six cell types for ~240,000 CpGs (variance<0.001); however, variance was less than 0.0001 for ~94,000 CpGs and exceeded 0.10 for ~900 CpGs. Mean methylation was calculated within each cell and tissue type for all CpGs in the final data set. Mean methylation was moderately to highly correlated between all cell and tissue types in cases, controls, and in a combined data set (r^2: 0.82 – 0.99) with the lowest correlation between salivary gland tissue and CD14+ monocytes and the highest correlation between fresh and banked PBMCs. Methylation levels within 16 putative SS genes were similar between cases and controls. However, median levels of methylation in individual CpGs within *IL10* and *TNFSF4* were 12% and 26% decreased in CD14+ T cells, and CD19+ B cells in cases compared to controls, respectively. Median levels of methylation in individual CpGs within *TNFAIP3* and *KLHL24* were hyper-methylated by 10%, 27%, and 19% in CD4+ T cells, CD19+ B cells and gland tissue biopsy samples in cases compared to controls, respectively. Data visualization of methylation profiles using Multi-Dimensional Scaling applied to several different subsets of CpG revealed distinct separation between cell types in addition to separation based on SS case status. The greatest separation by case status was visible in CD19+ B cells and salivary gland tissue samples.

Conclusion: Our results emphasize the cell and tissue specificity of DNA methylation in addition to differences in methylation based on case status for some cell types. Additional research, including studies of gene expression for regions associated with disease risk or severity, will be required to fully define the role of DNA methylation in SS.

Endosomal TLR Triggering Of B Cells In Sjögren's Syndrome Induces Increased Plasma Cells Differentiation, Ig Class Switch and Immunoglobulin Production. Marie Wahren-Herlenius[1], Susanna Brauner[1], Marika Kvarnström[1], Lasse Folkersen[1], Sabrina Görgen[1], Christina Trollmo[2], Vivianne Malmström[3] and Gunnel Nordmark[4]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institutet, Stochkolm, Sweden, [3]Rheumatology unit, Karolinska University Hospital, Karolinska Institutet, STockholm, Sweden, Stockholm, Sweden, [4]Uppsala University, Uppsala, Sweden.

Background/Purpose: Patients with primary Sjögren's syndrome have B cell disturbances resulting in hypergammaglobulinemia and autoantibody

production. Most patients are not treated by immunomodulatory drugs, enabling studies of an unmanipulated human autoreactive immune system. In this study we used the novel approach of employing vaccination as a tool to analyze immune responses *in vivo*.

Methods: Patients with Sjögren's syndrome receiving no treatment and healthy controls were vaccinated twice against the H1N1 influenza, and monitored by multiple sampling.

Results: Surprisingly, patients developed higher titers of IgG H1N1 antibodies, increased total IgG and increased autoantibody levels in response to vaccination. In addition, an expansion of CD138+ plasmablasts was observed, and up-regulation of several B cell promoting cytokines, including IL-10, IL-6 and IL-7. To dissect the B cell hyperreactivity, immunoglobulin class switch was induced *in vitro* in CD19+IgD+ B cells from patients and controls. Significantly more plasmablasts and higher titers of IgM and IgG were observed in TLR9 stimulated Sjögren-patient derived cultures in vitro. Similar results were obtained by TLR7 stimulation, but not by a-CD40 or BAFF that induce class switch through other pathways. The importance of the endosomal TLR pathway in plasma cell differentiation and immunoglobulin production was further demonstrated by analyzing B cells from patients treated with the drug chloroquine, which targets the endosome. In these patients, no differences were observed in class switch and plasma cell differentiation compared to healthy individuals. This observation was further confirmed by *in vitro* treatment of IgD+ B cells with chloroquine which significantly inhibited class switch and plasma cell differentiation.

Conclusion: In conclusion, we demonstrate for the first time that B cell activation via endosomal TLRs leads to enhanced plasma cell differentiation and class-switch in patients with Sjögren's syndrome, explaining the induction of hypergammaglobulinemia in Sjögren's syndrome patients.

Hypofunction In Intact Cell Lobules Reflect Salivary Flow Rates In Sjogren's Patients. Leyla Y Teos[1], Bill Swaim[2], Ana Paola Cotrim[1], Margaret Grisius[1], Lolita Bebris[3], Indu Ambudkar[4], Gabor G. Illei[5] and Ilias Alevizos[6]. [1]NIH, Bethesda, MD, [2]NIH/NIDCR, Bethesda, MD, [3]NIDCR/NIH, Bethesda, MD, [4]NIDCR, Bethesda, MD, [5]MedImmune, LLC, Gaithersburg, MD, [6]NIDCR/NIH #10 1N110, Bethesda, MD.

Background/Purpose: Neurotransmitter stimulation of fluid secretion in salivary glands is regulated by increases in intracellular calcium concentration. The increase in cytosolic calcium triggers ion channel activities, leading to the secretion of fluid. The latter can be detected as a decrease in cell volume. Patients with primary Sjögren's syndrome (pSS) display dry mouth conditions due to low salivary flow. We hypothesized that alterations in calcium signaling in acinar cells could account for the salivary gland dysfunction seen in pSS.

Methods: The standard salivary gland cell preparation used for studying acinar function is obtained by enzymatic digestion of the gland. This procedure results in considerable loss of tissue and alterations in cellular integrity. Moreover, healthy cells could be selected in the digestion process. We have therefore developed a non-enzymatically dispersed tissue preparation in combination with confocal microscopy, to assess the functional status of minor salivary glands from Sjögren's syndrome patients. We measured agonist-stimulated cytosolic calcium changes as well as cell volume changes by loading the salivary gland cluster-preparations with the calcium indicator, Fluo-2 AM, or cell-volume indicator, calcein. In addition we have examined the morphological characteristics of the glands.

Results: Cell clusters showed well preserved acinar and ductal morphology and displayed dose-dependent response to stimulation by carbachol, both in terms of cytosolic calcium, where intracellular calcium increase and cell volume decreases. Cells from patients with poor flow displayed attenuation of agonist-stimulated cytosolic calcium and volume changes. Additionally, decreases in cell volume predicted salivary flow rates.

Conclusion: We have developed a reproducible system to utilize non-enzymatically dispersed tissue preparations and examine with confocal microscopy the functional status of minor salivary glands. This system allows the exploration of mechanism(s) underlying the decrease in salivary gland function in each individual patient pertaining to the decrease in calcium mobilization. More specifically, this method will allow for the determination of whether the defect is at the level of intracellular calcium release or calcium entry and will also allow for the screening of therapeutic compounds in a personalized way. First, by identifying the secretory deficiencies of each individual pSS patient, and second testing which compounds might be more effective in treating salivary gland hypofunction.

Detection Of $CD4^+CD25^{low}GITR^+$ T Lymphocytes In Sjogren's Syndrome-Interstitial Lung Disease. Wu Zhenbiao[1] and Chen Lina[2]. [1]First Affiliated Hospital, Fourth Military Medical University, Xi'An, China, [2]First Affiliated Hospital, Fourth Military Medical University, Xi'an, China.

Background/Purpose: $CD4^+CD25^{low}GITR^+$ T lymphocytes expressing FoxP3 and showing regulatory function have been recently described in healthy donors (HD). The objective of this study was to determine whether $CD4^+CD25^{low}GITR^+$ T lymphocytes are detected in peripheral blood (PB) and broncho-alveolar lavage (BAL), to investigate their in patients with interstitial lung disease (ILD) secondary to primary Sjogren's syndrome (pSS).

Methods: $CD4^+CD25^{low}GITR^+$ cells circulating in PB and BAL of patients with pSS-ILD were isolated by MACS technique, and their phenotype was studied by flow cytometry and real-time PCR, and their function was studied by in vitro co-culture. $CD4^+CD25^{low}GITR^+$ cells infiltrating salivary glands (SGs) were revealed by immunohistochemistry.

Results: Nineteen patients with idiopathic pulmonary fibrosis (IPF) and 13 patents with pSS-ILD were enrolled in the study. Ten healthy donors were concluded in the study, too. Results indicated that conventional $CD4^+CD25^{high}$ regulatory T cells (Tregs) are decreased, whereas $CD4^+CD25^{low}GITR^+$ cells are expanded in the PB of pSS-ILD as compared with HD and IPF. Phenotypic analysis demonstrated that $CD4^+CD25^{low}GITR^+$ cells display Treg markers, including FoxP3, TGF-β and IL-10, and functional experiments demonstrated that they exert a strong inhibitory activity against autologous effector cells. The number of $CD4^+CD25^{low}GITR^+$ cells infiltrating in the SG were positively correlated with the inflammatory infiltrating of $CD4^+CD25^{low}GITR^+$ cells in BAL.

Conclusion: The present data demonstrate that $CD4^+CD25^{low}GITR^+$ cells are detectable in PB and BAL of pSS-ILD patients. These cells, displaying Treg phenotype and function, are present in SG inflamed tissues and are in accordance with that infiltrating in BAL.

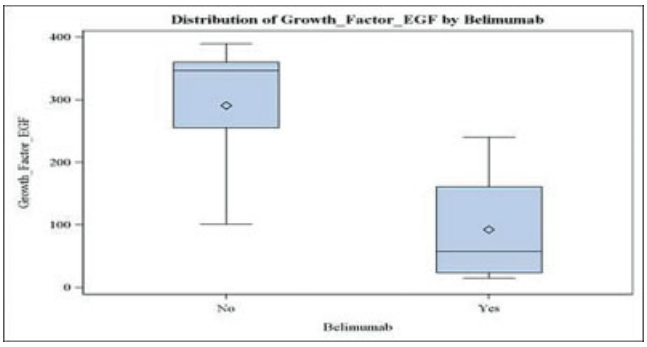
Use Of B Lymphocyte Stimulator Inhibitor Belimumab May Be Associated With a Decrease In the Serum Concentration Of Endothelial Growth Factor In Patients With Primary Sjögren's Syndrome. Slavica Bobic[1], Sabeeda Kadavath[1], Linda Gerber[2], Ekaterini Zapantis[1] and Petros V. Efthimiou[3]. [1]Lincoln Medical and Mental Health Center, New York, NY, [2]Weill Cornell Medical College, New York, NY, [3]LM&MHC/Weill Cornell MC, New York, NY.

Background/Purpose: Primary Sjögren's Syndrome (pSjS) is a systemic autoimmune inflammatory disease that primarily affects the lacrimal and salivary glands and is associated with B cell hyper-reactivity and elevated serum concentrations of Blys. Belimumab is approved for the treatment of Systemic Lupus Erythematosus, where B cell mediated inflammation is commonly seen. In this retrospective study, we examined the off-label use of belimumab in a small cohort of pSjS with systemic manifestations. We analyzed clinical endpoints based on questionnaires and patient reported outcomes (PROs) as well as multiple serum biomarkers, individually measured as part of a multi-biomarker disease activity assay (MBDA), used predominantly in RA. Vectra DA is a cumulative score based on the serum concentrations of 12 serum proteins (biomarkers); although the score has been validated for use in RA, several components of the test have been implicated in the pathogenesis of SjS.

Methods: A retrospective chart review study was conducted at a teaching hospital and nine patients diagnosed with pSjS were identified, as defined by the American-European group consensus criteria. The patient's age ranged from 26 to 73 (mean: 51). All patients studied (1 male, 8 females) had confirmatory minor salivary gland biopsy (focal score>1), 3/9 (33%) were African American and 6/9 (67%) Hispanic. Of the 9 patients studied, 4 were also treated with monthly belimumab infusions (10 mg/kg), as an add-on

treatment to address predominantly extra-glandular manifestation, such as arthritis and fatigue, for approximately 60 weeks. Vectra was done for all patients and clinical improvement was assessed by RAPID-3 and FACIT-F scores during the course of the treatment. Individual biomarker concentrations were compared in the 2 groups using the Wilcoxon Exact test.

Results: The results for EGF biomarker suggest that there is a statistically significant difference between the underlying distributions of the EGF scores of control group and the EGF scores of Belimumab group ($p = 0.03$, $r = -0.71$). The patients on Belimumab had numerically lower serum concentrations of VCAM-1, VEGF-a, IL-6, MMP-3, YKL-40, Leptin, Resistin, SSA, and CRP biomarkers and higher concentrations of the TNF-RI and MMP-1 biomarkers compared to the control group, although the difference did not reach statistical significance. Vectra-DA scores for the belimumab group (mean: 38) and the control group (mean: 31.5) were similar in both groups and were not affected by treatment. Clinical endpoints, such as the RAPID-3 and FACIT scores, did not show a difference between the two groups.



Conclusion: In our pSjS cohort, treatment with Belimumab was associated with significantly lower EGF concentrations, albeit no apparent extra-glandular clinical improvement. Controlled studies and development of more specific disease activity measures are needed.

Umbilical Cord Mesenchymal Stem Cells Inhibit The Generation Of T Follicular Helper Cell In Sjogren's Syndrome. Rui Liu, Min Zhou, Dinglei Su, Xia Li and Lingyun Sun. Department of Rheumatology and Immunology, the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China.

Background/Purpose: The immune suppressive properties of mesenchymal stem cells (MSC) have garnered increasing attention over past decades. Human umbilical cord-derived MSC (UC-MSC) share similar immunosuppressive functions as bone marrow-derived MSC (BM-MSC). Sjögren's syndrome (SS) is a systemic autoimmune disease characterized by extra-glandular abnormalities and overproduction of antibodies. Previous studies showed that MSC transplantation were effective both in an animal model and SS patients. However, the underlining mechanism remains largely unknown. The aim of this study is to investigate whether UC-MSC might suppress the generation of T follicular helper (Tfh) cells in SS.

Methods: The percentages of CXCR5+PD-1+CD4+ cells were analyzed by flow cytometry in peripheral blood mononuclear cells (PBMC) from SS patients and healthy controls. The correlation between frequencies of Tfh cells and levels of total IgG, anti-Ro/SSA and anti-La/SSB in SS patients were assessed. PBMC of SS patients in the presence or absence of PHA were cultured with UC-MSC supernatant or UC-MSC at a ratio of 1 to 1, 1 to 10 or 1 to 100 in a cell-to-cell contact or transwell system for 3 days. CD4+ naïve T cells were isolated from SS PBMC and then co-cultured with or without UC-MSC under Tfh-skewing condition for 2 days (for RT-PCR) or 4 days (for FACS). CD4+ T cells were isolated from SS PBMC and labeled with carboxyfluorescein diacetate succinimidyl ester (CFSE) and then co-cultured with or without UC-MSC in the presence of anti-CD3/CD28 for 4 days. The percentages of CXCR5+PD-1+CD4+ T cells were tested by flow cytometry.

Results: We showed that the circulating percentage of CXCR5+PD-1+CD4+ cells in SS patients were significantly higher than in healthy controls, and positively correlated with levels of anti-La/SSB but not with total IgG or anti-Ro/SSA. UC-MSC inhibited the generation of Tfh cells in PHA-stimulated PBMC dose-dependently in vitro. The differentiation and proliferation of Tfh cells were blocked by UC-MSC significantly and this suppression was mediated by UC-MSC-secreted soluble factors. RT-PCR showed that UC-MSC suppression of Tfh cells was dependent on indoleamine 2, 3-dioxygenase (IDO). Furthermore, UC-MSC supernatant was also able to inhibit the generation of Tfh cells in SS.

Conclusion: These results suggest that Tfh cells may play a pathogenic role in SS. UC-MSC inhibition of Tfh cells may be a potential mechanism for the therapeutic effect of MSC in SS.

Antibodies To Anti-Type -3 Muscarinic Acetylcholine Receptor Are Highly Prevalent To Rabbits Immunized With 4-Hydroxy-2-Noneal-Modified and 60-Kda Ro. Valerie Harris[1], Biji T. Kurien[2], R. Hal Scofield[3], Timothy Gross[3] and Mary Girton[3]. [1]University of Oklahoma Health Science Center, Oklahoma City, OK, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: In Sjörgen's Syndrome, an autoimmune disease, the lacrimal and salivary glands are the primarily affected glands. Previous studies have proposed autoantibodies that target type-3 muscarinic acetylcholine receptors (M3R) found in salivary and lacrimal glands as a clinical marker for SS. In this study, we hypothesize that rabbits and mice immunized with 4-hydroxy-2-noneal (HNE)-modified or unmodified 60-kDa Ro will have increased levels of circulating anti-M3R and anti-Ro antibodies mirroring some of the symptoms of Sjörgen's Syndrome.

Methods: In the first experiment, two rabbits were immunized multiple times with 500μg of 10mM of HNE-modified Ro60 and two rabbits were immunized with 500μg unmodified Ro60. In the second experiment, 50 mice, ten mice from five different strains (SJL/J, DBA, BALB/c, C57BL/6, and PL/J) were immunized subsequent times with 50μg of Ro60 peptide. In the third experiment, fifty mice were in immunized with unmodified Ro60, or low (.4mM), moderate (2mM), or high (10mM)-HNE modified Ro60. ELISA analysis was used to detect the presence of antibodies specific to Ro60, HNE-modified Ro60, and the second extracellular loop (amino acids 213–228) or the third extracellular loop (amino acids 514–527) of the type-3 muscarinic acetylcholine receptor using the serial bleeds from the immunized rabbits and mice.

Results: Immunization with HNE-modified Ro60 or unmodified Ro60 abrogates tolerance to autoimmunity. Rabbits immunized with unmodified Ro60 showed in an induction of antibodies to Ro60 and the second loop (213–228) of M3R, but not 514–527. Conversely, rabbits immunized with HNE-modified Ro60 had suppressed levels of antibodies to either variant of the M3R peptide, but showed a rapid response after immunization with increased levels of anti-Ro60 and anti-HNE Ro60 antibodies. The five strains of mice immunized with HNE-modified Ro60 or unmodified Ro60, as well as, the mice immunized with various concentrations of HNE-modified Ro60 had negligible levels of antibodies directed toward M3R, but both experimental groups showed an induction in anti-Ro60 antibodies.

Conclusion: We previously published data showing that the rabbits and mice immunized with unmodified or HNE-modified Ro60 developed anti-Ro antibodies, as commonly seen in circulation of SS patients. Add to that, this data which shows increasing levels of anti-M3R antibodies in rabbits immunized with Ro60, but not mice. Taken together this data suggests that second extracellular loop of the type-3 muscarinic receptor is a target in the lacrimal and salivary glands during SS autoimmunity progression in rabbits.

1503

The Suppressive Ability Of Altered Peptide Ligands To M3R Reactive T Cells In M3R Induced Autoimmune Sialadenitis. Hiromitsu Asashima[1], Hiroto Tsuboi[2], Naomi Matsuo[1], Chihiro Hagiya[1], Tomoya Hirota[2], Mana Iizuka[1], Yuya Kondo[2], Isao Matsumoto[2] and Takayuki Sumida[2]. [1]Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [2]University of Tsukuba, Tsukuba, Japan.

Background/Purpose: Previous studies have shown that Rag1$^{-/-}$ mice transferred with splenocytes of M3 muscarinic acetylcoline receptor

$(M3R)^{-/-}$ mice immunized with M3R peptides mixture (three N-terminal regions; N1, N2, N3, and three extracellular loops; 1st, 2nd, 3rd) ($M3R^{-/-}$<Mix>→$Rag1^{-/-}$) developed sialadenitis like Sjögren's syndrome (M3R induced autoimmune sialadenitis; MIS). Besides, altered peptide ligands (APLs), the peptides with substitutions in amino acid residues at T-cell receptor contact sites, are reported to regulate the activation of T cells. To develop antigen-specific therapy, we tried to clarify the T cell epitopes of M3R reactive T cells in MIS and also to evaluate the antagonistic APLs.

Methods: 1) Splenocytes of $M3R^{-/-}$ mice immunized with M3R peptides mixture were cultured with each M3R peptide. The cytokines (IFN-g, IL-17, and Il-4) production was measured by ELISA. Similarly, the splenocytes of $M3R^{-/-}$ mice immunized with each N1 and 1st peptide, which was the candidate for the T cell epitopes, and the combination of N1 and 1st peptides were cultured and evaluated.

2) The splenocytes of $M3R^{-/-}$ mice, immunized with N1 alone, 1st alone, the combination of N1 and 1st peptides, or PBS as control were transferred into $Rag1^{-/-}$ mice (each $M3R^{-/-}$<N1>→$Rag1^{-/-}$, $M3R^{-/-}$<1st>→$Rag1^{-/-}$, $M3R^{-/-}$<N1+1st>→$Rag1^{-/-}$, and $M3R^{-/-}$<PBS>→$Rag1^{-/-}$). On day 45 after transfer, the salivary glands of $Rag1^{-/-}$ mice were pathologically examined.

3) APLs of each N1 and 1s peptide were designed.

4) CD4+ and CD11c+ cells were isolated from $M3R^{-/-}$ mice immunized with each N1 and 1st peptide. Each APL was loaded to CD11c+ cells pre-cultured with each suboptimal concentration (N1: 1.5 μM, 1st: 4.5 μM) of N1 and 1st peptide. Afterward, CD4+ T cells were added and cytokines (IFN-g and IL-17) production was measured by ELISA.

Results: 1) Splenocytes immunized with M3R peptide mixture produced IL-17 and IFN-g against N1 and 1st peptide. IL-4 production could not be detected. Splenocytes immunized with N1 and 1st peptide produced IL-17 and IFN-g, but not IL-4, against each corresponding peptide.

2) $M3R^{-/-}$<N1>→$Rag1^{-/-}$, $M3R^{-/-}$<1st>→$Rag1^{-/-}$, and $M3R^{-/-}$<N1+1st>→$Rag1^{-/-}$ developed sialoadenitis. The majority of infiltrating cells in salivary glands were $CD4^+$ T cells, only few with $CD8^+$ T cells and $B220^+$ B cells. The focus scores of these mice (1.0±0.3 in $M3R^{-/-}$<N1+1st>→$Rag1^{-/-}$, 1.3±0.3 in $M3R^{-/-}$<N1>→$Rag1^{-/-}$, and 0.7±0.3 in $M3R^{-/-}$<1st>→$Rag1^{-/-}$) were significantly higher than that of control mice (0.1±0.2 in $M3R^{-/-}$<PBS>→$Rag1^{-/-}$) ($p<0.05$).

3) Seven APLs of N1 peptide (N1-APL 1–7) and eight APLs of 1st peptide (1st-APL 1–8) were designed.

4) N1-APL5 (AA15 N→T), N1-APL6 (AA15 N→C) and N1-APL7 (AA15 N→S) suppressed the production of IFN-g (N1-APL5 38.8±11.6 pg/mL, N1-APL6 54.9±16.5 pg/mL, N1-APL7 38.0±15.7 pg/mL, control 363.6±65.1 pg/mL). 1st-APL8 (AA140 A→M) suppressed both IL-17 and IFN-g production (IL-17: 1st-APL8 403.4±14.1 pg/mL, control 720.3±49.0 pg/mL. IFN-g: 1st-APL8 185.4±1.6 pg/mL, control 268.8±94.8 pg/mL).

Conclusion: The major T cell epitopes in MIS might be both N1 terminal region and 1st extracellular loops of M3R. N1-APL5, 6, 7 and 1st-APL8 were the candidate for antagonistic APLs, which might have a possibility to suppress MIS *in vivo*.

1504

Anti-Inflammation Effect Of Peroxisome Proliferator-Activated Receptor-γ (PPAR-γ) In Non-Obese Diabetic Mice With Sjogren's Syndrome. Bei Xu[1] and Xiaomei Li[2]. [1]The third Affiliated Hospital of Anhui Medical University, The First Hospital of Hefei, Hefei, China, [2]Anhui Medical University Affiliated Provincial Hospital, Hefei, Anhui, China.

Background/Purpose: To investigate the anti-inflammation effect of peroxisome proliferator-activated receptor-γ (PPAR-γ) in non-obese diabetic mice (NOD mice) with sjogren's syndrome

Methods: Twenty 8-weeks-old female NOD mice were randomly divided into 2 groups. rosiglitazone and normal saline were administered in PPAR-γ group and control group respectively. At the age of 12 weeks and 15 weeks, we killed one mouse in PPAR-γ group and control group respectively, and the others were sacrificed at the age of 17 weeks. Blood were obtained by cardiac puncture, and salivary glands were resected. The histopathological change was examined by H&E staining. The level of IL-1β, IL-4, IL-6 and TNF-α in serum were measured by ELISA. Real-time PCR was used to evaluate the mRNA expression level of IL-1β, IL-4, IL-6 and TNF-α in MSG

Results: Compared with the control group, the mice in PPAR-γ group showed that: At histopathological change was significantly ameliorated; At the age of 17 weeks, IL-6 [(25.86±7.32) pg/ml vs (37.41±11.34) pg/ml] and TNF-α [(56.88±22.19) pg/ml vs (78.61±20.76) pg/ml] were expressed significantly lower and IL-4 [(25.76±12.65) pg/ml vs (12.11±3.70) pg/ml] was expressed significantly higher in serum ($P<0.05$); The expression of TNF-α was significantly decreased and the expression of IL-4 was significantly increased in MSG ($P<0.05$).

Conclusion: PPAR-γ can ameliorate Sjogren's syndrome on NOD mice effectively. The mechanism may be related to reduce Th1 cytokines, and promote the direction of Th1/Th2 balance into Th2.

Evaluation Of a Case Ascertainment Tool For Ankylosing Spondylitis and Axial Spondylarthritis Among All Referrals To General Rheumatology Clinics. Eswar Krishnan[1], Michael H. Weisman[2], Atul A. Deodhar[3], Linjun Chen[1] and Lianne S. Gensler[4]. [1]Stanford University, Palo Alto, CA, [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]Oregon Health & Science University, Portland, OR, [4]University of California, San Francisco, San Francisco, CA.

Background/Purpose: Several strategies for distinguishing Ankylosing Spondylitis (AS) and Axial Spondylarthritis (axSpA) from other conditions have been proposed but have only been studied in the context of chronic back pain. Prior strategies have not been evaluated in the context of an unselected rheumatologic population where the prevalence is lower and/or in older age groups. This study evaluates a psychometrically distinct patient questionnaire in an unselected population that includes patients without back pain and those with fibromyalgia.

Methods: The study comprised of 490 consecutive, unselected new patients referred to 4 academic rheumatology outpatient clinics in the period 2011–12. Patients completed a questionnaire prior to clinical evaluation. Inability to obtain informed consent in the English language was the only exclusion criterion. Patients were followed for 6 months from the baseline visit. Protocol specified gold standard for AS and axSpA diagnosis was the rheumatologist assessment (blinded to the results of the questionnaire) based on the history, physical examination, radiographs, and laboratory testing and appropriate work up. Questionnaire summary scores were converted to Z-scores.

Results: The mean (range) age of the study population was 48 (18–91) years; 74% were women. Of the 490 patients 102 tested positive by the questionnaire using original cut off values and 22 received a rheumatologist diagnosis of AS (prevalence 4.4%) and 36 were diagnosed with axSpA (prevalence =7.4%). Results of ROC analyses are shown in Table 1. The areas under the curve for AS and axSpA for patients with and without back pain were 0.74, 0.67, 0.84,0.75 respectively

Table 1. Receiver Operator Curve Analysis for patients with AS and axSpA with and without back pain

	AS		Axial SpA	
Z-score cut off	**Sen**	**Spec**	**Sen**	**Spec**
All patients				
>=−1	95	18	86	17
>=0	86	41	72	41
>=1	36	91	39	90
Patients with Back pain				
>=−1	95	31	89	31
>=0	85	70	69	71
>=1	40	91	38	91

Sen: Sensitivity (%); Spec:Specificity (%).

Conclusion: With adjustments to the score cut-offs, the evaluated patient questionnaire may be used either as a sensitive screening tool or as a specific diagnostic aid in assessing AS and axSpA in non-selected patient populations.

Total Hip Replacement Outcomes in Ankylosing Spondylitis. Susan M. Goodman, Rebecca Zhu, Wei-Ti Huang, Mark P. Figgie, Michael Alexiades and Lisa A. Mandl. Hospital for Special Surgery, New York, NY.

Background/Purpose: Historically, outcomes for total hip replacement (THR) in ankylosing spondylitis (AS) patients were poor, but contemporary outcomes are not well described. We analyzed two-year THR outcomes in a cohort of AS patients compared with osteoarthritis (OA) controls.

Methods: A case- control study was performed using data from a high volume single institution THR registry. AS were identified by ICD-9 code and confirmed by chart review. AS cases were matched 4:1 by age, bilateral, primary or revision procedure, and date of surgery, and availability of 2 year data, after excluding potential controls with ICD-9 codes for other rheumatic disease or fracture. Self-report quality of life and administrative data were obtained pre-operatively and at 2-years. Pain, function, and quality of life scores were compared between groups using standard statistical methods.

Results: 30 eligible AS THR cases were identified between 5/2007 and 10/2010: 21 primary, 2 bilateral, and 7 revisions. Mean age was 52.7 years, (SD 16); more AS were male (80% vs 45%; p-value$<$0.001). AS had worse baseline ASA class (ASA Class$\geq$3: 40% vs 9%; p-value$<$0.001). 2-year self-report data were available on 63% of AS cases. AS had worse pre-operative WOMAC pain (46.1 vs 54.8; p-value=0.05) and WOMAC function (43.5 vs 53.7; p-value=0.04) compared to OA controls but had similar excellent outcomes at 2 years: WOMAC pain (90.6 vs 92.8; p-value=0.5) and WOMAC function (85.4 vs 90.4; p-value=0.18). AS were as likely as controls to have a clinically meaningful improvement (Δ WOMAC $>$10) in pain (87% vs 93%; p-value=0.4) and function (100% vs 90%; p-value=0.2) and were no more likely to have a poor outcome (WOMAC $<$ 60) for pain (89% vs 93%; p-value=0.4) or function (89% vs 93%; p-value=0.5). AS without 2-year data had significantly worse pre-op WOMAC function than AS with data (30.9 vs 44.1; p-value=0.04). However, neither AS nor OA without 2-year data had clinically meaningful differences in pre-op pain scores compared with those with data (AS:45 vs 40; p-value=0.31; OA:53.6 vs. 50.5; p-value$<$0.001). AS SF-12 was lower at baseline (31.3 vs. 36.1; p-value=0.01) and remained clinically significantly worse at 2 years (41.5 vs 50.2; p-value$<$0.001). Scores on the HSS Expectations Survey were high for both AS and OA (77.5 vs 83.3; p-value=0.24), and both were very/somewhat satisfied with their 2-year outcomes (100% vs 96%; p-value=0.4).

Table 1. Total Hip Replacement

	AS (n=30)	OA (n=132)	P-value
Age (SD)	52.7 (16.2)	53.2 (14.6)	0.88
Male, n (%)	24 (80%)	59 (45%)	**<0.001**
WOMAC Baseline Pain (SD)	46.1 (19.3)	54.8 (19.3)	**0.05**
WOMAC 2 year Pain (SD)	90.6 (14.1)	92.8 (12.9)	0.5
WOMAC Baseline Function (SD)	43.5 (22.4)	53.7 (20.4)	**0.04**
WOMAC 2 year Function (SD)	85.4 (17.1)	90.4 (14.4)	0.18
Δ WOMAC $>$ 10, Pain, n (%)	13 (87%)	110 (93%)	0.36
Δ WOMAC $>$ 10, Function, n (%)	13 (100%)	96 (90%)	0.23
Poor outcome @ 2 year, WOMAC Pain $\leq$60, n (%)	2 (11%)	7 (6%)	0.4
Poor outcome @ 2 year, WOMAC Function $\leq$60, n (%)	2 (11%)	8 (7%)	0.52
SF-12 PCS Baseline (SD)	31.3 (8.4)	36.1 (8.1)	**0.015**
SF-12 PCS 2 year (SD)	41.5 (11.0)	50.2 (9.8)	**<0.001**
Expectation Score (SD)	77.5 (17.7)	83.3 (18.1)	0.24
Baseline ASA class, n (%)			**<0.001**
Class 1 or 2	18 (60%)	119 (91%)	
Class 3	12 (40%)	12 (9%)	
Satisfaction at 2 years, Overall, n (%)			
Very Satisfied	14 (78%)	102 (86%)	0.42
Somewhat Satisfied	4 (22%)	12 (10%)	
Neither Satisfied nor Dissatisfied	0 (0%)	2 (2%)	
Somewhat Dissatisfied	0 (0%)	0 (0%)	
Very Dissatisfied	0 (0%)	3 (3%)	

Conclusion: AS patients achieve similar levels of pain relief at 2-years compared with OA controls. These data may overestimate 2-year function in AS, but the majority have significant improvement. Despite having worse pre-operative health status than matched OA controls, THR is an effective treatment for end stage hip arthritis in AS. However, lower 2-year SF-12 PCS scores suggest that some limitations due to health status persist. These data can be used to ensure AS patients have accurate expectations of THR.

Infection Risk in Ankylosing Spondylitis: Results From a Longitudinal Observational Cohort. Dinny Wallis[1], Arane Thavaneswaran[2], Nigil Haroon[1], Renise Ayearst[2] and Robert D. Inman[1]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Long term data on infection risk in ankylosing spondylitis (AS) are sparse and derived mainly from RCTs. Anti-TNF therapy is increasingly used in AS, with infection being the most important adverse event. In rheumatoid arthritis (RA), serious infections are common adverse events of anti-TNF therapy with an incidence of 4–10 per 100 patient-years (pys). We aimed to investigate the frequency of infections in AS and to identify factors predisposing to infection.

Methods: Data were extracted from a longitudinal observational database for patients meeting Assessment of SpondyloArthritis international Society (ASAS) criteria for axial SpA. Infection rates were calculated and multivariate analysis using a GEE model was performed to investigate the association of independent variables with infection.

Results: 440 patients (73% male) were included in the analysis. 259 infections (23 serious, defined as requiring IV antibiotics or hospitalization) occurred during 1712 pys of follow-up. 80% were bacterial and 15% were viral. The most common site of infection was lung, followed by skin, genitourinary tract, upper respiratory tract, sinus and gastrointestinal tract. Ninety percent of infections were treated with antibiotics, of which 10% required intravenous antibiotics.

The overall rate [95% CI] of any infection was 15 [13, 17]/100 pys and the serious infection rate was 1.3 [0.9, 2.0]/100 pys. Of the 264 patients prescribed a biologic drug during a total follow up time of 684 pys on biologic therapy, 127 infections (10 serious) were recorded in 101 patients. The rate of any infection while on a biologic drug was 19 [16, 22]/100 pys and the serious infection rate was 1.5 [0.7, 3.0]/100 pys. Of the 186 patients never prescribed a biologic drug during a total follow up time of 651 pys, 91 infections (12 serious) were recorded in 71 patients. The rate of any infection was 14 [11, 17]/100 pys and the serious infection rate was 1.8 [1.0, 3.0]/100 pys. There was no significant difference in the rates for patients on biologic drugs compared to patients never on biologic drugs for any infection (p=0.78) or serious infection (p=0.19).

In the univariate analysis, DMARD use and glucocorticoid use were associated with an increased risk of infection. In the multivariate analysis, only DMARD use remained significant (OR 1.76 [1.12, 2.76], p$<$0.01). However, the number of patients on DMARDs was small (n=31). Biologic use, age, disease duration, smoking status, BASFI, BASDAI, comorbidity score and hospitalizations were not associated with an increased risk of infection.

Conclusion: Biologic therapy in this longitudinal AS cohort was not associated with an increased risk of infection, while DMARD use appeared to confer risk of infection. However, most infections were not serious and the serious infection rate was much lower than previously reported in RA. Our findings represent a "real-world" experience which includes AS patients with comorbidities which often exclude them from RCTs. The apparent lower rate of infection in patients with AS compared to RA may reflect several factors: the younger age and lower frequency of comorbidities in AS, differing immunogenetic mechanisms in the respective diseases, and differences in treatment.

How Well Are The Assessment Of Spondyloarthritis International Society (ASAS)/Outcome Measures In Rheumatology (OMERACT) Core Outcome Sets For Ankylosing Spondylitis Implemented In Randomized Clinical Trials? A Systematic Literature Review. Wilson Bautista-Molano[1], Victoria Navarro-Compán[1], Robert Landewé[2] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Academic Medical Center, Amsterdam, Netherlands.

Background/Purpose: The Assessment of SpondyloArthritis international Society (ASAS) has selected a core set of variables to include as

standardized endpoints in clinical trials and clinical practice. These core sets received endorsement by OMERACT and specific measurement instruments to assess each of these domains have been chosen. The implementation of the ASAS/OMERACT core sets, though, has so far not been evaluated. The purpose of this systematic literature review, therefore, was to compare the usage of domains and instruments of the core-sets before and after the original publication.

To investigate how well the ASAS/OMERACT core sets for the outcome of ankylosing spondylitis (AS) have been implemented in randomized controlled trials (RCTs) testing pharmacological and non-pharmacological interventions.

Methods: A systematic literature search was performed in electronic databases looking for RCTs in patients with AS. Domains of outcome, and instruments belonging to them, for disease controlling antirheumatic therapy (DC-ART) and symptom modifying antirheumatic drugs (SMARD) were extracted.

Results are reported for clinical trials published before (control trials) in comparison to those published 2 years after the publication of the core set (1 April 2001, implementation trials).

Results: One hundred eight articles reporting results from 91 RCTs, and together including 11.174 patients, fulfilled the selection criteria for this project, and were included in the analysis. Forty-seven RCTs were considered 'control trials' and 44 were considered 'implementation trials'. NSAID and conventional non-biological DMARD therapies were more often tested in the 'control'—than in the 'implementation trials'. Biological DMARDs and physical therapy were more often tested in the 'implementation trials'. The domains 'physical function', 'pain', 'stiffness', 'peripheral joint/entheses', 'acute phase reactants' and 'fatigue', as well as the instruments 'BASFI', 'BASMI', 'CRP' and 'spine radiograph' were more frequently addressed in the 'implementation trials' (Table 1).

Table 1. Usage of ASAS/OMERACT DCART Core Domains and instruments in trials evaluating interventions with DMARD, biologic or corticosteroids

Assessment	Control trials before 2001 (%)	Implementation trials after 2001 (%)	p value
Physical function	**41.7**	**100**	**<0.001**
BASFI	8.3	100	<0.001
Dougados FI	33.3	4.5	0.02
HAQ	8.3	13.6	0.6
Pain	**91.7**	**100**	**0.2**
Night	33.3	45.5	0.5
Global	91.7	100	0.2
Spinal mobility	**91.7**	**86.4**	**0.6**
BASMI	0	54.5	0.001
Spinal stiffness	**91.7**	**100**	**0.2**
Patient global assessment	**66.7**	**81.8**	**0.3**
Peripheral joint/entheses	**33.3**	**100**	**<0.001**
Joint count	33.3	45.5	0.5
MASES	0	9.1	0.3
Berlin	0	4.5	0.4
Acute phase reactants	**83.3**	**95.5**	**0.2**
CRP	58.3	90.9	0.03
ESR	83.3	59.1	0.2
Spine radiograph	**0**	**27.3**	**0.046**
mSASSS	0	18.2	0.1
BASRI	0	13.6	0.2
Fatigue	**0**	**100**	**<0.001**

Conclusion: This systematic literature review suggests that the implementation of ASAS/OMERACT core set has been partly successful. The definition and dissemination of the core set measures for clinical trials in AS has indeed resulted in an improved usage of the endorsed domains and instruments.

Immunogenicity, Adalimumab Levels and Clinical Response In Ankylosing Spondylitis Patients During 24 Weeks Of Follow-Up. Eva L. Kneepkens[1], James C. Wei[2], Michael T. Nurmohamed[1], Kai-Jieh Yeo[2], CY Chen[2], Irene E. van der Horst-Bruinsma[3], Desiree van der Kleij[4], Theo Rispens[5], Gertjan Wolbink[5] and Charlotte L. M. Krieckaert[1]. [1]Jan van Breemen Research Institute Reade, Amsterdam, Netherlands, [2]Chung Shan Med Univ Hospital, Taichung, Taiwan, [3]VU University Medical Center, Amsterdam, Netherlands, [4]Sanquin Diagnostic Services, Amsterdam, Netherlands, [5]Sanquin Research, Amsterdam, Netherlands.

Background/Purpose: Immunogenicity influences adalimumab levels and therefore clinical response in patients with rheumatic diseases.

Objectives: To study the relation between clinical response, adalimumab levels and anti-drug antibodies (ADA) in ankylosing spondylitis (AS) patients.

Methods: Prospective observational cohort study of 115 consecutive AS patients treated with adalimumab in the Netherlands (n=85) and Taiwan (n=30), monitored during a maximum of 24 weeks. Adalimumab levels and ADA titres were determined retrospectively using an enzyme linked immunosorbent assay (ELISA) and an Antigen Binding Test (ABT), respectively, designed by Sanquin Research, Amsterdam. Response to adalimumab treatment was defined as a Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) response (50% improvement or an absolute improvement of 2 points on a BASDAI, scale 0–10) and disease activity was measured using the AS Disease Activity Score, including CRP (ASDAS).

Results: Of 115 patients 78 (67.8%) were male and 95 (82.6%) were HLA-B27 positive. At baseline median BASDAI (IQR) was 6.4 (4.5–7.6) and mean ASDAS (SD) was 3.5 (1.0). After 24 weeks of follow-up 49 (42.6%) patients were BASDAI responders (last observation carried forward). Mean ASDAS (SD) for responders was 1.5 (1.0) vs. 2.6 (1.0) for non-responders ($p<0.001$). Nine patients dropped out: 8 patients due to treatment failure or adverse events and 1 due to loss of follow-up. Thirty-one (27.0%) patients had detectable ADA. Median ESR levels (mm/hour) were significantly different between patients with or without ADA (respectively, 35.5(13.0–52.5) vs.19.0 (7.0–34.0), $p=0.008$). After 24 weeks, median adalimumab level (mg/L) (IQR) was significantly higher for ADA negative than for ADA positive patients (12,7 (8.2–18.0) vs. 1.2 (0.0–2.0), $p<0.001$). At 24 weeks the percentage of detectable ADA was higher in patients from Taiwan 12 (40.0%) vs. Dutch patients, 19 (22.4%) ($p=0.06$). General estimate equation analysis demonstrated a significant association between adalimumab levels and ASDAS ($p=0.02$; RC −1.1; 95% CI −2.0 to −0.2). For BASDAI response no significant association with adalimumab levels was found. Eleven (9.6%) patients had no detectable adalimumab levels and high detectable ADA titres (>100 AU/mL). In these patients CRP and ESR remained elevated, although BASDAI decreased during 24 weeks of follow-up.

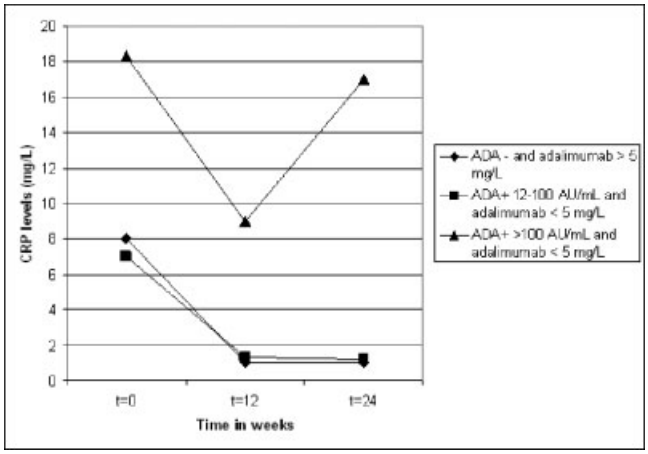

Fig 1. Median CRP levels (mg/L) for AS patients divided in 3 groups: no detectable ADA *titres with normal drug levels (> 5 mg/L); intermediate detectable ADA titres with low drug levels (< 5 mg/L) and high detectable ADA titres with low drug levels (< 5 mg/L) during 24 weeks of follow-up.*

Conclusion: Adalimumab levels are related to clinical response in AS patients and are influenced by ADA detectable with an ABT. Therefore therapeutic drug monitoring should be investigated further as a possible tool to optimise treatment.

1510

Disease Activity In Male Smokers Has A >10-Fold Amplified Effect On Radiographic Damage In Comparison With Female NON-Smokers In Ankylosing Spondylitis. Sofia Ramiro[1], A.M. van Tubergen[2], Robert Landewé[3], Carmen Stolwijk[2], Maxime Dougados[4], Filip Van den Bosch[5] and Désirée van der Heijde[6]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Academic Medical Center Amsterdam & Atrium Medical Center, Heerlen, Netherlands, [4]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France, [5]Gent University Hospital, Gent, Belgium, [6]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: We have shown that disease activity has an effect on radiographic progression over the long-term and that gender and symptom duration are effect modifiers. Smoking has been shown to predict radiographic progression. We sought to investigate whether smoking influenced this longitudinal relationship between disease activity and radiographic damage

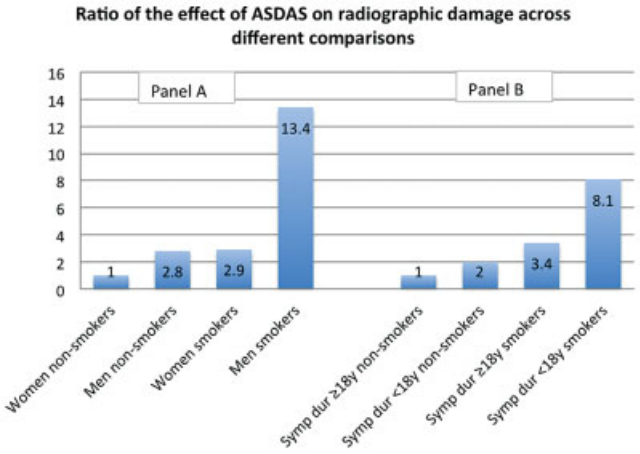
Methods: Patients from the Outcome in AS International Study (OASIS) were followed-up for 12 years, with biannual clinical and radiographic assessments. Two readers independently scored the x-rays according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) and scores were averaged. Disease activity was assessed by the ASDAS-CRP. The relationship between ASDAS and radiographic damage was investigated using generalized estimating equations, with auto-regressive (i.e. adjusted for the 2-year previous mSASSS) models with a 2-year time-lag. Interactions were tested with baseline smoking status and if significant, analyses were repeated in strata.

Results: A total of 127 patients were included (71% males, mean (SD) age 41(12) years, mean symptom duration 18(11) years and 82% HLA-B27 positive). Smoking status modified the relationship between disease activity and radiographic damage significantly ($p<0.001$), and this effect extended to other strata: males ($p=0.002$) and patients with shorter symptom duration (<18y) ($p=0.009$); Overall, an increase in one ASDAS-unit led to an increase in 0.72 mSASSS-units per 2 years. In smokers, this value reached 1.94 mSASSS-units and in male smokers 2.15 mSASSS-units (Table). Comparing the magnitude of the effect of ASDAS on mSASSS in smokers vs non-smokers, smokers had a 5.5 fold amplified effect, whereas male smokers had a 13.4 fold amplified effect compared to female non-smokers. Smokers with short symptom duration had a 8.1-fold amplified effect compared to non-smokers with long symptom duration (Figure).

Table. Longitudinal relationship between ASDAS and radiographic damage in different strata

Stratification for	Effect analyzed	Multivariable regression models (auto-regressive and time-lagged) μ(95%CI)*
Smoking status	– ASDAS in non-smokers (n = 78)	0.35 (0.04; 0.65)
	– ASDAS in smokers (n = 49)	1.94 (1.00; 2.87)
Smoking status & gender	– ASDAS in women, non-smokers (n = 29)	0.16 (−0.13; 0.44)
	– ASDAS in women, smokers (n = 9)	0.47 (−0.12; 1.06)
	– ASDAS in men, non-smokers (n = 49)	0.44 (0.02; 0.86)
	– ASDAS in men, smokers (n = 40)	2.15 (1.01; 3.30)
Smoking status & symptom duration	– ASDAS in symptom duration <18y, non-smokers (n = 39)	0.52 (0.24; 0.80)
	– ASDAS in symptom duration <18y, smokers (n = 31)	2.11 (0.86; 3.36)
	– ASDAS in symptom duration >=18y, non-smokers (n = 35)	0.26 (−0.18; 0.70)
	– ASDAS in symptom duration >=18y, smokers (n = 13)	0.88 (0.15; 1.62)

* Results refer to different multivariable models. De μ indicates the progression in mSASSS per unit increase in ASDAS



Conclusion: Smoking amplifies the effect of disease activity on radiographic damage (5-fold). This effect is further amplified in male smokers (13.4-fold) in comparison with female non-smokers.

What Impairs Balance In Ankylosing Spondylitis? Posture Or Disease Activity? Osman Hakan Gunduz, Emel Ece Ozcan, Esra Giray and Ilker Yagci. Marmara University School of Medicine, Istanbul, Turkey.

Background/Purpose: To compare ankylosing spondylitis (AS) patients and healthy individuals in terms of posture and balance and to identify the factors affecting balance among patients with AS.

Methods: Thirty AS patients (13 women and 17 men) admitted to our outpatient clinic and 33 healthy volunteers (15 women, 18 men) as the control group were included. Both groups were evaluated in terms of balance via Neurocom Balance Master System with weight bearing squat, standing on firm and foam bases when eyes open and closed, walking across, tandem walk, and step and quick turn tests. Postural assessment parameters were tragus-wall distance, Modified Schober test and chest expansion measurements. Pain and disease activity were evaluated with Visual Analog Scale (VAS) for pain level (0–10 cm), and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), respectively.

Results: The mean age of AS and control group were 41.7±7.6 and 41.3±7 years, respectively. There was no significant difference in terms of age, height and body mass index between AS and control groups. Mean disease duration in the AS group was 8.6±8.4 years with a mean BASDAI of 4.7±2.6. Mean VAS for pain, tragus-wall distance, and Modified Schober test were 5.9±2.1 cm, 17.7±5.6 cm and 18.6±2.8 cm in the patient group. Parametric tests were analyzed with independent t-test. AS patients had significantly greater step width ($p=0.024$). Step length ($p=0.011$), walking speed at walk across test ($p=0.002$), and tandem walk test ($p=0.015$) were significantly decreased among AS patients when compared to healthy volunteers.

In AS group, duration of disease was only correlated to step width at tandem walk test ($r=0.443$, $p=0.014$). Modified Schober was negatively correlated to tandem walk step width ($r=-0.418$, $p=0.022$), sway velocity on foam base when eyes open ($r=-0,473$, $p=0.008$), and closed ($r=-0.558$, $p=0.001$). Tragus wall distance was positively correlated to tandem walk step width ($r=0.433$, $p=0.017$). Neither BASDAI nor VAS was correlated to sway velocity on foam base when eyes open and closed, walk across speed, step width, step length, and tandem walk step width.

Conclusion: Walking speed and step length were significantly impaired in AS patients. As Modified Schober test measurement decreases, sway velocity on foam base and step width at tandem walk increase. Tragus wall distance lengthening results in increased step width at tandem walk. To sum up, forward head posture and limited spine flexibility are suggested to be the main causes of balance disorders in AS. Postural changes have more effect on balance than disease activity. Poor posture leads to impaired balance and AS patients adopt compensatory strategies, such as increasing their step width and decreasing their speed, to maintain their balance.

Smoking and Its Relationship With Clinical, Radiological and Functional Status In Patients With Ankylosing Spondylitis. Fernando Andres Sommerfleck, Emilce Edith Schneeberger, Natalia Zamora, Luis Alejandro Cayetti and Gustavo Citera. Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina.

Background/Purpose: In recent years, smoking has been reported as an environmental risk factor that influence the course of certain diseases such as psoriasis, ulcerative colitis and spondyloarthritis (SpA), especially ankylosing spondylitis (AS). Our objective was to investigate the possible effect of smoking on disease activity, functional capacity, quality of life and radiographic damage in patients with AS.

Methods: Consecutive patients ≥ 18 yrs old with AS (ASAS 2009 criteria) were included. We recorded demographic data, age at onset of symptoms, duration of disease, disease-related symptoms, comorbidities and toxic habits (specifically about current or past smoking and number of packs/year (p/y)). Clinical and therapeutic aspects of the disease were collected prospectively in our AS outpatient clinic. Specific questionnaires to determine disease activity (BASDAI), functional capacity (BASFI), quality of life (ASQoL), metrology (BASMI) were performed every 6 months. Cervical, lumbar and pelvic X-rays were performed yearly and read by a single, blinded observer, according to BASRI. Comparison of categorical variables was assessed by Chi 2 or Fisher exact test and continuous variables by T test and ANOVA. Pearson correlation, multiple linear and logistic regression, were used in the analysis.

Results: We studied 147 patients, 111 (75.5%) were male, with a median age of 46 years (IQR 32–56) and a median of disease development of 16 years (IQR 8–25). Fifty one (34.7%) patients had axial commitment and 96 (65.3%) mixed. Medium (IQR) for: BASDAI 4.5 (2.5–6.4), BASFI 4.3 (1.6–6.7), BASMI 4.3 (2.7–6), ASQoL 8 (4–11), BASRI 8.5 (6–12.7) and mSASSS 23 (7 –50.7), respectively. Comorbidities frequency was 130/147 (91.5%) and 17 (11.6%) patients had one or more hip replacements. Smoking was observed in 66 (44.9%) patients (50% were past-smokers), the median pack year was 13.5 (IQR 5–32). In univariate analysis, smoking was associated with worse functional capacity (BASFI 4.9 in smokers vs. non-smokers 3.7, $p = 0.01$) and higher frequency of comorbidities (98.5% in smokers vs. nonsmokers 80.2%, $p < .01$). The association of smoking and worse functional capacity remained as an associated variable in multiple regression analysis after adjusting for disease duration and the presence of comorbidities. (OR: 1.82 95% CI 1.08–3.07).

Conclusion: Smoking adversely affects the functional capacity of our patients with AS. We did not observed that smoking has had a major impact in quality of life, metrology or radiographic damage in our cohort of patients with AS.

Human Leukocyte Antigen Tag Single Nucleotide Polymorphisms in Turkish Population: Polymerase Chain Reaction Restriction Fragment Length Polymorphism May Not Be Appropriate Genotyping Method For These Single Nucleotide Polymorphisms Due To Presence Of Complicating Polymorphism. Servet Akar[1], Yusuf Ziya Igci[2], Ismail Sari[1], Elif Pala[2], Esra Geyik[2], Dilek Solmaz[1], Pinar Cetin[1], Mehmet Nedim Tas[1] and Nurullah Akkoc[1]. [1]Dokuz Eylul University School of Medicine, Izmir, Turkey, [2]Gaziantep University School of Medicine, Gaziantep, Turkey.

Background/Purpose: Ankylosing spondylitis (AS) is strongly associated with HLA-B27. Although AS and HLA-B27 interaction is one of the best known disease associations, accurate HLA-B27 typing is technically challenging. Previously MHC tag single nucleotide polymorphisms (SNPs) rs4349859 and rs13202464 were shown to be able to identify HLA-B27 in European and Asian AS patients. Recently SNP rs116488201 was found to tag HLA-B27 allele in both European and Asian populations. Therefore the objective of our study was to evaluate the performance of HLA-B27 tag SNPs by polymerase chain reaction restriction fragment length polymorphism (PCR-RFLP).

Methods: We genotyped three SNPs (rs116488202, rs13202464 and rs4349859) by using PCR-RFLP. The primers were designed using Primer3 algorithm via primer-BLAST interface. PCR products were digested by using *NlaIII*, *BmrI*, and *TaqαI* restriction endonuclease enzymes. All suspicious and randomly selected samples' results were also verified by using DNA sequence analysis in order to prevent misleading results. HLA-B27 analysis for patient group was performed by using commercially used SSP-typing kit.

Results: In total 207 patients (72% male, mean age 42.3 ± 10.8 years and 146 [71%] was HLA-B27 positive) with AS according to the modified NY criteria and 32 healthy controls (78%male, mean age 52.7 ± 10.8 years and 2 [6%] was HLA-B27 positive) were included in the study. The effect alleles of SNPs rs116488202 (T) and rs4349859 (A) showed a high specificity for HLA-B27 since we did not identified T and A alleles in HLA-B27 negative subjects. However all the SNPs were quite polymorphic in HLA-B27 positives. For the SNPs rs13202464 and rs4349859, our experimental design worked well. However, there is another SNP (rs141774149) in the neighborhood of rs116488202 in which the altered sequence is also recognized by *BmrI* restriction enzyme (Figure 1). *BmrI* enzyme has the ACTGGG (5/4) recognition sequence which complicates the SNP analysis in that region. By using only *BmrI* enzyme digestion method, T allele carrying samples (TT or CT) cannot be exactly discriminated. Then, we decided to make DNA sequence analysis for all samples in order to prevent misleading results.

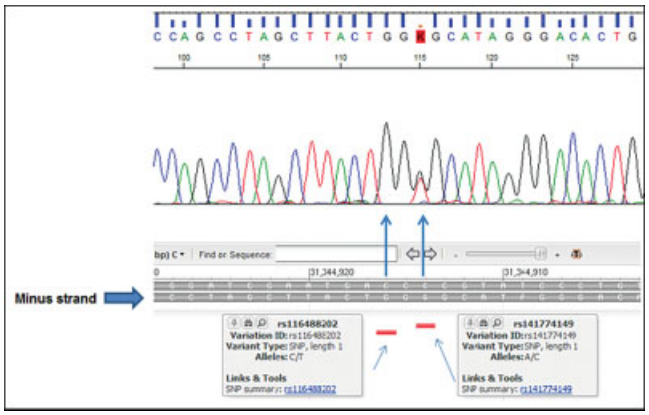

Figure 1. Sequence analysis of an example patient

Conclusion: This study shows that PCR-RFLP may not be appropriate method for genotyping the reported tag SNPsfor HLA-B27. The difficulties we experienced in this study took root from the highly variable sequences in HLA region involving the PCR primer design, PCR optimization, and RFLP analysis. Alternative consequences should be taken into account by the researchers who design and plan to conduct research concerning those variable sequences.

Drug Survival In Patients Receiving Golimumab Treatment 2010–2013. Results From The Swedish Rheumatology Quality Register. Saedis Saevarsdottir[1], Michele Santacatterina[2], Leszek Stawiarz[3], Carl Turesson[4], Helena Forsblad[5], Lennart T.H. Jacobsson[6] and Staffan Lindblad[7]. [1]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [2]Biostatistics Core Facility, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Dept. of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden, [4]Lund University, Malmö, Sweden, [5]Dept of Rheumatology & Inflammation Research, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [6]Department of Rheumatology and Inflammation Research, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [7]Dept. of Learning, Informatics, Management and Ethics; Karolinska Institutet, Stockholm, Sweden.

Background/Purpose: Golimumab is a TNF inhibiting biological drug that was approved in Sweden in 2010 for the treatment of Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Ankylosing Spondylitis (AS). In observational studies, the 24-month adhesion to therapy of TNF inhibitors in bio-naïve patients has ranged from about 50–70% in RA, 55–70% in PsA and 65–70% in AS. The aim of the current study was to evaluate cumulative survival probability of golimumab in clinical practice for these patient groups, as well as in patients registered with other spondyloarthritidies (SpA).

Methods: Data were retrieved for all patients initiating golimumab treatment from 2010 until April 30th2013 from the nationwide Swedish Rheumatology Quality register (SRQ), which hosts the register on biological

treatments, ARTIS (Anti Rheumatic Treatment in Sweden). Survival analysis (Kaplan Meier) was performed with right censoring and log-rank test of equality across strata.

Results: In total, 1681 patients had initiated golimumab treatment during the study period. Of those, 678 (40%) had RA, 364 (22%) had PsA, and 240 (14%) had AS, while 194 (12%) were registered as SpA and 205 (12%) had other diagnoses. The proportions of women in RA/PsA/AS/SpA patient groups were 80%/50%/28%/52%, respectively; and their median age at baseline was 58/50/45/43 years. In patients with RA/PsA/AS/SpA, the proportions receiving golimumab as the first biological treatment were 47%/45%/41%/37%; and the proportions receiving concurrent disease-modifying anti-rheumatic drugs (DMARDs) were 70%/58%/22%/38%.

Table 1. Cumulative survival probability (% (N)) of golimumab treatment for the four main diagnoses, stratified by previous exposure to biological treatment.

Diagnosis	Number of previous biologicals	Baseline	6	12	18	24
RA	**Bio-naive**	100 (318)	78 (206)	65 (138)	59 (111)	56 (77)
	1–2	100 (263)	74 (162)	60 (97)	54 (65)	52 (46)
	3+	100 (97)	66 (56)	45 (33)	42 (24)	32 (14)
PsA	**Bio-naive**	100 (163)	83 (107)	69 (70)	59 (47)	56 (31)
	1–2	100 (150)	79 (89)	62 (51)	55 (33)	51 (20)
	3+	100 (51)	71 (32)	59 (21)	53 (15)	53 (7)
AS	**Bio-naive**	100 (98)	81 (66)	77 (47)	68 (32)	65 (14)
	1–2	100 (118)	80 (79)	70 (54)	59 (31)	57 (22)
	3+	100 (24)	74 (16)	45 (9)	40 (7)	40 (6)
SpA	**Bio-naive**	100 (72)	83 (46)	73 (33)	60 (19)	60 (15)
	1–2	100 (94)	76 (61)	61 (36)	51 (24)	49 (15)
	3+	100 (28)	61 (13)	55 (8)	47 (4)	47 (2)

Cumulative survival probability of golimumab treatment is shown in Table 1, stratified by previous exposure to biological treatment. In RA patients, there was a statistically significant difference in survival probability between bio-naïve patients and those patients who had received 1–2 or 3+ biological drugs before golimumab ($p=0.0018$), a similar trend was observed in patients with AS ($p=0.069$), but interestingly, not in patients with PsoA ($p=0.6$). The number of individuals who had received 3+ biological drugs before golimumab was limited in all patient groups.

Conclusion: In this large nationwide rheumatology register, drug survival in patients receiving golimumab treatment was generally higher in bio-naïve patients compared to patients previously treated with biological drugs. The 24-month adhesion rates in clinical practice appear to be comparable to other TNF inhibitors, whereas further studies are necessary to evaluate the long term performance of golimumab.

Influence Of Taking Structural Lesions Into Account In Addition To Inflammatory Lesions On MRI Of The Sacroiliac Joints On The Classification Of Patients With Possible Axial Spondyloarthritis. Rosaline van den Berg[1], Manouk de Hooge[1], Floris van Gaalen[1], Victoria Navarro-Compán[1], Monique Reijnierse[1], Karen Fagerli[2], Robert Landewé[3], Maikel van Oosterhout[4], Roberta Ramonda[5], Tom Huizinga[1] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [4]GHZ Hospital, Gouda, Netherlands, [5]University of Padova, Padova, Italy.

Background/Purpose: The ASAS definition of a positive MRI of the sacroiliac joints (MRI-SI+) for the classification of axial spondyloarthritis (axSpA) patients includes inflammatory lesions only[1,2]. The role of structural lesions on MRI-SI in classifying patients is unclear[1]. We explored the potential role of structural lesions on MRI-SI in classifying axSpA patients.

Methods: Patients with back pain (≥3 months, ≤2 years, onset <45 years) from the 5 centers in the SPondyloArthritis Caught Early (SPACE)-cohort were included. Patients underwent MRI-SI. MRI were scored by 3 well-calibrated readers independently for ankylosis, sclerosis, erosions, and fatty lesions (FL) (T1-weighted images; STIR viewed simultaneously). Erosions, sclerosis and FL were defined according to the MORPHO definition[3] (≥1 lesion on ≥2 consecutive slices or ≥2 lesion on 1 slice). Ankylosis was defined as ≥1 lesion on ≥1 slice. Lesions were considered present if 2/3 readers agreed. MRI was considered positive for several (combinations of) structural lesions (MRI-SI-s+) using cut-offs based on the acceptance of ≤5% false-positives in patients without SpA. Patients are considered as possible axSpA if not fulfilling the ASAS axSpA criteria[3], but if ≥1 specific SpA-feature (LR+ >6) or ≥2 less specific SpA-features (LR+ <6) are present[4]. We classified possible axSpA patients using MRI-SI-s+ instead of MRI-SI+ and calculated the LR product with LR+ 9.0 for MRI-SI-s+ as if MRI-SI+[4]. Based on the LR product the probability of having axSpA was calculated[4].

Results: Only possible axSpA patients with MRI-SI data were included (n=116). Depending on the used MRI-SI-s+ definition, 1% (ankylosis ≥1) to 6% (erosions ≥2 or FL ≥2) of the possible axSpA patients could be classified as axSpA (table). Combining the various definitions of MRI-SI-s+ results in 14 additional patients (12.1%) classified as axSpA (5 patients with probability ≥80%); 5 patients fulfilled 4 of the proposed MRI-SI-s+ definitions. In patients with a high number of SpA-features, using MRI-SI-s+ to calculate the LR product results in a probability ≥80%, making an axSpA diagnosis very likely. However, in patients with only 1 or a few SpA-features, the probability remains <80%.

ASAS axSpA+ in possible axSpA patients if structural lesions are added	Possible axSpA n=116	Mean (range) no. SpA-features	Probability ≥80%	Probability 50–79%	Probability 20–49%	Probability <20%
Ankylosis ≥1	1 (0.9%)	1 (1)	–	–	–	1
Fatty lesions ≥2	7 (6.0%)	2.3 (1–4)	3	1	1	2
Erosion ≥2	7 (6.0%)	2.1 (2–3)	3	1	2	1
Sclerosis ≥1	1 (0.9%)	1 (1)	–	–	–	1
Any structural lesions ≥5	5 (4.3%)	2.4 (1–3)	2	2	–	1
Any structural lesions (except ankylosis) ≥5	4 (3.4%)	2.8 (2–3)	2	2	–	–
Fatty lesions and/or erosions ≥5	4 (3.4%)	2.8 (2–3)	2	2	–	–

Conclusion: These explorative data point out that structural lesions on MRI of the SI joints might play a role in classifying possible axSpA patients. However, only few additional patients are classified as axSpA with a high probability while the same number of patients with a low probability would (falsely) be classified if structural lesions would be added to the definition of a positive MRI. Further studies are needed to define the best type/combination and cut-off of structural lesions.

Safety and Efficacy Of Etanercept In Early Non-Radiographic Axial Spondyloarthritis: A Randomized, Double-Blind, Placebo-Controlled Trial At 24 Weeks. Maxime Dougados[1], Désirée van der Heijde[2], Joachim Sieper[3], Jügen Braun[4], Walter P. Maksymowych[5], Gustavo Citera[6], James Cheng-Chung Wei[7], Jan Lenaerts[8], Ronald Pedersen[9], Randi Bonin[9], Ehab Y. Mahgoub[9], Bonnie Vlahos[9] and Jack Bukowski[9]. [1]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Charité Universitätsmedizin Berlin, Berlin, Germany, [4]Rheumazentrum Ruhrgebiet, Herne, Germany, [5]University of Alberta, Edmonton, AB, [6]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [7]Chung Shan Medical University Hospital, Taichung, Taiwan, [8]Reuma Instituut, Hasselt, Belgium, [9]Pfizer Inc, Collegeville, PA.

Background/Purpose: Limited data are available on the efficacy of anti-TNF agents in non-radiographic axial spondyloarthritis (nr-axSpA). The objective of this analysis is to compare the efficacy and safety of etanercept (ETN) vs placebo after 12 weeks of double-blind treatment and an additional 12 weeks of open-label ETN treatment in patients with nr-axSpA who had an insufficient response to NSAIDs.

Methods: Enrolled patients satisfied ASAS criteria for axSpA, had been exhibiting symptoms between 3 months–5 years, failed ≥2 NSAIDs (including current one), and a BASDAI score ≥4 despite current NSAID use. Patients were blinded and randomized to ETN 50 mg weekly (QW) or placebo and continued NSAIDs for 12 weeks followed by open-label ETN 50 mg QW for an additional 12 weeks (weeks 12–24). Efficacy outcomes were assessed at week 12 and 24 and safety monitored throughout the study. Analyses used ANCOVA models with baseline score, treatment, region and sacroiliac joints status at baseline (MRI) as variables. LOCF imputation was used for missing data.

Results: 215 patients were randomized and included in the mITT population (ETN=106; placebo=109); mean age at baseline was 32 years (range, 18–49 years); 61% were male; and mean disease duration was 2.4 years (range, 0–16.0 years; median, 2.3 years). At week 12, 208 patients (ETN=102; placebo=106) enrolled in the open-label phase. ASAS40 at 12 weeks was achieved by a significantly greater proportion of patients receiving ETN vs placebo (32.4% vs 15.7%, respectively; $P=0.006$). At week 12, there were substantial differences in clinical outcomes between the ETN and placebo groups, but the differences largely disappeared when placebo patients were treated with ETN in the open-label phase (table). As compared to week 12, an increased proportion of patients achieved all efficacy outcomes at week 24, after the switch to open label ETN. The percentages of patients (safety population) with any adverse events were 57% (63/111) vs 46% (52/113) at week 12 and 34% (35/102) vs 50% (53/106) at week 24 in the ETN vs placebo groups, respectively.

Table. Effects of ETN versus placebo in patients with nr-axSpA (mITT, LOCF[a])

	Week 12 (double-blind period)		Week 24 (open-label period)	
	ETN 50 mg + NSAID (n=106)	Placebo + NSAID (n=109)	ETN 50 mg + NSAID/ETN 50 mg + NSAID (n=102)	Placebo + NSAID/ETN 50 mg + NSAID (n=106)
Parameter, n/N (%)				
ASAS20[b]	53/105 (50.5)	41/108 (38.0)	66/102 (64.7)	75/105 (71.4)
ASAS40[b]	34/105 (32.4)[c]	17/108 (15.7)	45/102 (44.1)	54/105 (51.4)

Different Imaging Abnormalities Suggestive Of Spondyloarthritis Are Present In Early Axial Spondyloarthritis. Data From The DESIR Cohort. Anna Moltó[1], Simon Paternotte[2], Désirée van der Heijde[3], Pascal Claudepierre[4], Martin Rudwaleit[5] and Maxime Dougados[1]. [1]Paris- Descartes University, Paris, France, [2]Paris- Descartes University, Cochin hospital, Paris, France, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Paris-Est University; LIC EA4393; APHP, Henri Mondor Hospital, Creteil, France, [5]Endokrinologikum Berlin, Berlin, Germany.

Background/Purpose: Patients can fulfil the ASAS (Assessment of SpondyloArthritiS) sets of criteria with either objective evidence of sacroiliac joint damage (X-Ray) or inflammation (MRI) ("imaging" arm) or without such imaging abnormalities in B27 patients ("clinical" arm). Currently, there is still a debate regarding the imaging abnormalities permitting to classify a patient as fulfilling the imaging arm. The aim of the study was to evaluate different imaging abnormalities (*e.g.*inflammatory and chronic changes at the sacroiliac joint (SIJ) and spine level) as of potential interest for classification.

Methods: Prospective, multi-centre, observational study. 708 patients with early inflammatory back pain suggestive of spondyloarthritis were included in the DESIR cohort. Data collected: demographics, items of the ASAS criteria, disease activity, severity, quality of life. Inflammatory and chronic changes evaluated using either X-rays or MRI at both the SIJ and spine level by the radiologist/rheumatologist of the participating center. Statistical analysis: patients fulfilling the ASAS criteria were split in two groups (imaging vs. clinical) and within the clinical arm, with regard to the presence of CRP abnormality (e.g. >6mg/L). The other imaging abnormalities suggestive of SpA (e.g. MRI chronic changes of the SIJ, MRI inflammatory and chronic changes at the spine level, and the presence of at least 1 syndesmophyte at the cervical or lumbar level) present in each of the groups were depicted.

Results: 476 (69.8%) of the 708 included patients fulfilled the ASAS criteria, either the imaging (296 (60.1%)) or the clinical (190 (39.9%)) arms. Imaging findings different than the ones of the "imaging" definition of the ASAS criteria were observed (MRI-SIJ chronic changes (53.5% vs. 4.3%), MRI-Spine inflammatory changes (35.0% vs. 12.3%), MRI-spine chronic changes (11.9% vs. 6.4%) and X-ray-syndesmophytes (13.6% vs. 7.0%) in the imaging versus clinical arm, respectively.

The table summarizes the different imaging abnormalities observed.

	ASAS axSpA criteria				
	Imaging			Clinical	
	X-ray+/ MRI+ (132)	X-ray+/ MRI− (55)	X-ray−/ MRI+ (99)	X-ray−/ MRI− Abnormal CRP (33)	X-ray−/ MRI− Normal CRP (154)
MRI SIJ structural changes	93 (70.5%)	27 (54.0%)	33 (33.3%)	3 (9.1%)	5 (3.3%)
MRI Spine inflammatory lesions	55 (42.3%)	9 (18.0%)	36 (36.7%)	7 (21.2%)	16 (10.5%)
MRI Spine structural lesions	20 (15.4%)	5 (10.0%)	9 (9.3%)	2 (6.1%)	10 (6.5%)
X-ray spine	17 (12.9%)	14 (25.5%)	8 (8.1%)	3 (9.1%)	10 (6.5%)

MRI chronic changes of the SIJ were, as expected, more frequently observed in the subgroup of patients with X-ray damage of the SIJ. MRI inflammatory changes of the spine were more frequently observed in presence of other markers of inflammation. In the subgroups of patients without imaging abnormalities but abnormal CRP as much as 9.1% of patients presented with definite X-ray damage of the spine.

Conclusion: This study shows that different imaging abnormalities suggestive of SpA (*e.g.* MRI chronic changes of the SIJ) are present in early SpA, but need to be confirmed by central reading. Descriptive studies of these abnormalities in healthy controls are necessary to confirm (or not) whether these findings might be may be considered for classification in the imaging arm of the ASAS criteria.

Prevalence Of Spondylarthritis In Individuals Needing To Purchase An Orthopedic Mattress Because Of Chronic Back Pain. Ahmet Eftal Yucel, Muzeyyen Temel, Muhtesem Agildere and Mustafa Agah Tekindal. Baskent University Faculty of Medicine, Ankara, Turkey.

Background/Purpose: We hypothesize that the real prevalence of spondylarthritis (SpA) is much higher than reported in the literature. In this study, we aimed to investigate the presence of SpA in individuals who needed to purchase an orthopedic mattress because of their chronic back pain, and to emphasize the importance of determining the main underlying reason for these complaints.

Methods: Two hundred adults aged< 45 years who had purchased an orthopedic mattress because of chronic back pain were called by phone and asked 3 screening questions in order to identify whether their back pain was inflammatory. The questions were about the presence of (1) non-traumatic pain, swelling and stiffness in any joints, (2) lower back pain or back stiffness on awakening which lasted over a period of at least 3 months and which improved with exercise, (3) heel pain more powerful in the morning which lasted over a period of at least 3 months and which

improved with activity. Of 200 individuals, 105 gave positive answers to one or more of the screening questions and 80 individuals [42 women (52.5%), mean age 36.3 ± 6.3] who agreed to clinical evaluation were included in the study. In all evaluated individuals, comparative sacroiliac radiography was taken for the screening of sacroiliitis and lateral radiographies of both feet were taken for the screening of enthesitis. Peripheral blood samples were taken for ESR and serum CRP levels. Patients with suspected sacroiliitis upon direct radiography were examined with sacroiliac MRI. In order to diagnose SpA, the European Spondyloarthritides Study Group (ESSG) criteria were applied.

Results: Among 80 subjects, 65 (81.3%) were diagnosed with SpA, and among these 65 patients, we diagnosed 48 (73.9%) with undifferentiated SpA, 14 (21.5%) with ankylosing spondylitis and 3 (4.6%) with psoriatic arthritis. Thirty seven of 80 subjects (46.3%) were found to have sacroiliitis at different stages and 42 (52.5%) had enthesitis (epin calcanei and/or Achilles enthesopathy) by radiography. ESR and CRP levels were similar in individuals with or without SpA.

Conclusion: We diagnosed SpA in a remarkable percentage of the individuals who were in the need of an orthopedic mattress due to a complaint of chronic back pain. For this reason, we suggest that evaluation of those individuals for SpA will be helpful for early diagnosis, treatment and improvement in the quality of life of the patients. We also think that is important to create awareness about SpA in the general population so that patients will seek out medical diagnosis and treatment instead of transient and inadequate remedies like a new mattress for their back pain.

Meeting The ACR 2010 Fibromyalgia Criteria Worsens Disease Activity and Quality Of Life In Patients With Axial Spondyloarthritis Treated With Infliximab. Mathieu Verdet[1], Clément Guillou[2], Julien Michaud[1], Christopher Banse[1], Sandra Desouches[1], Gilles Avenel[1], Quentin Bréhier[3], Aurélia Bisson-Vaivre[1], Sophie Pouplin[1] and Olivier Vittecoq[4]. [1]Rouen University Hospital, Rouen, France, [2]Inserm 905 & Institute for Biomedical Research, University of Rouen, Rouen, France, [3]Le Havre Hospital, Le Havre, France, [4]Department of Rheumatology, Rouen University Hospital & Inserm 905, Institute for Biomedical Research, University of Rouen, Rouen Cedex, France.

Background/Purpose: Managing axial spondyloarthritis (aSpA) may be difficult because sometimes patients are not good responder to anti-TNF. We made the hypothesis that in certain patients, high disease activity could be due to associated fibromyalgia (FM). Indeed, some patients describe more widespread pain and more associated symptoms than others. The objective of this study was to analyse differences between aSpA patients (ASAS 2009) according to their meeting of the ACR 2010 FM criteria.

Methods: It was a prospective transversal observational study. 51 patients with aSpA satisfying the ASAS 2009 criteria were included during one year. All patients were treated with infliximab. Every patient filled once an auto-questionnaire with items of ACR 2010 FM criteria, Visual Analog Scale (VAS) for pain and global disease activity (GDA), BASDAI, BASFI, FIQ, HAQ, FACIT-13, SF-36 and First Score. We collected items of BASMI, numbers of tender joint (TJ), swollen joint, MASES score and number of Yunus tender points. Erythrocyte Sediment Rate (ESR) and C-reactive protein (CRP) levels and ASDAS score were collected.

Results: Twenty-four patients (47%) met the FM ACR 2010 criteria (FM+). No difference between FM+ and FM- patients for age at inclusion, age at beginning of aSpA, number of infusion and interval between infusions of infliximab. Female proportion was higher in FM+ group (NS) (70% vs 48%; p=0.1). Compared to FM- patients, FM+ patients had higher TJ number (6.4 ± 7.6 vs 1.7 ± 3.5 p<0.0001), MASES (7.67 ± 3.88 vs 2.8 ± 4.08 p<0.0001), Yunus points number (8.75 ± 5.45 vs 3.19 ± 4.11; p<0.0001), Pain VAS (6.19 ± 1.88 vs 3.56 ± 2.74; p=0.0006), GDA VAS (6.25 ± 2.04 vs 3.39 ± 2.36; p<0.0001). BASMI, ESR and CRP levels did not differ between the groups. ASDAS-CRP was higher in FM+ patients (3.05 ± 0.85 vs 1.89 ± 0.66; p<0.0001). BASFI (56.1 ± 26.8 vs 31.5 ± 24.22 p=0.0012), FIQ (63.03 ± 16.25 vs 30.21 ± 17.7, p<0.0001), FACIT-13 (17.49 ± 6.45 vs 33.39 ± 11.44), mental SF-36 (33.19 ± 17.94 vs 62.77 ± 21.9, p<0.0001), physical SF-36 (29.89 ± 16.09 vs 55.05 ± 22.39, p<0.0001) and First score (4.70 ± 1.12 vs 2.41 ± 1.85, p<0.0001) were more severe in FM+ patients.

When we analysed by which arm of the ASAS 2009 criteria, patients were diagnosed with aSpA, we showed that 11% of FM- patients were diagnosed only by the HLAB27 arm compared to 37.5% in FM+ patients (p=0.046).

Conclusion: Patients with axial SpA (ASAS 2009) that fulfilled the FM ACR 2010 criteria were more severe in terms of pain, fatigue, quality of life, mental and physical function and SpA disease activity.

When disease activity is high, despite anti-TNF treatment, assessment of FM ACR 2010 criteria status should be useful to understand the reasons for lack of efficacy.

In a context of FM ACR 2010 criteria fulfilling, when SpA disease activity is high, physicians should consider diagnosis revision if only HLAB27 arm of ASAS 2009 aSpA criteria has been used to make the diagnosis.

A longitudinal study could be interesting in order to assess the benefit of anti-TNF in aSpa patients that also fulfils the FM ACR 2010 criteria before treatment introduction.

Reduction Of Disease Burden On Workplace and Household Productivity In Axial Spondyloarthritis, Including Ankylosing Spondylitis and Non-Radiographic Axial Spondyloarthritis, Over 48 Weeks Of Treatment With Certolizumab Pegol. Désirée M. van der Heijde[1], Jürgen Braun[2], Martin Rudwaleit[3], Oana Purcaru[4] and Arthur Kavanaugh[5]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]Endokrinologikum Berlin, Berlin, Germany, [4]UCB Pharma, Brussels, Belgium, [5]University of California San Diego, San Diego, CA.

Background/Purpose: Axial spondyloarthritis (axSpA) includes both ankylosing spondylitis (AS, meeting modified New York criteria) and axSpA with no sacroiliitis on X-ray (non-radiographic axSpA, nr-axSpA). AS significantly affects work productivity[1] but data is limited for the impact of nr-axSpA on productivity. Previous results show improvements in workplace and household productivity with certolizumab pegol (CZP) vs placebo (PBO) up to Week (Wk) 24 in the RAPID-axSpA study.[2] This report estimates the economic burden of axSpA, AS and nr-axSpA, and examines long-term effects of CZP on productivity outcomes up to Wk48.

Methods: The ongoing RAPID-axSpA trial (NCT01087762) is double-blind and PBO-controlled to Wk24 and dose-blind to Wk48.[3] Patients (pts) had active axSpA according to ASAS criteria,[4] including both AS and nr-axSpA pts. Pts originally randomized to CZP (200mg Q2W or 400mg Q4W, following 400mg loading dose at Wks 0, 2, 4) continued on their assigned dose in dose-blind phase; PBO pts entering dose-blind phase were re-randomized to CZP loading dose followed by CZP 200mg Q2W or CZP 400mg Q4W. The arthritis-specific Work Productivity Survey (WPS),[5] administered Q4W from baseline (BL), assessed the impact of axSpA on workplace and household productivity in the full analysis set (FAS). Disease burden was evaluated at study BL. WPS responses (LOCF imputation) in both CZP groups are summarized descriptively over 48 wks.

Results: BL disease activity was similar for AS and nr-axSpA pts but symptom duration varied (median 9.1 vs 5.5 yrs, respectively). At BL, 69.2% of axSpA pts, 67.4% AS and 71.4% nr-axSpA were employed outside the home. More AS vs nr-axSpA pts were unable to work due to spondyloarthritis (15.7% vs 8.2%). High burden of axSpA on workplace and household productivity was reported at BL, with higher burden in nr-axSpA vs AS (Table). At BL, axSpA pts reported >1 wk of paid work (mean 7.2 days), ~2 wks of household duties (mean 13.3 days), and mean 4.4 days of social activities affected over previous month. Employed pts in both CZP groups reported reductions in workplace absenteeism and presenteeism to Wk24, with further improvements to Wk48 (Table). CZP groups reported continued improvements in household productivity up to Wk48 (Table). Similar improvements were observed in AS and nr-axSpA (Table).

Table. Workplace and household productivity over 48 wks in the RAPID-axSpA trial (FAS population [a])

	axSpA		AS		nr-axSpA	
WPS responses, mean	CZP 200mg Q2W n = 111	CZP 400mg Q4W n = 107	CZP 200 mg Q2W n = 65	CZP 400mg Q4W n = 56	CZP 200mg Q2W n = 46	CZP 400mg Q4W n = 51
Productivity at workplace (employed subjects)						
Work days missed due to arthritis per month [b]						
BL	2.3	1.4	2.4	1.0	2.2	1.9

Household productivity and social participation (all subjects)						
Household work days missed due to arthritis per month						
BL	5.8	4.7	5.2	4.4	6.7	5.0
Wk24	2.3	2.2	2.2	1.8	2.5	2.6
Wk48	1.7	1.7	1.8	1.9	1.6	1.4
Household work days with productivity reduced by ≥50% due to arthritis per month [c]						
BL	7.9	7.0	7.2	6.7	9.0	7.3
Wk24	3.5	3.0	3.1	2.9	4.0	3.2
Wk48	1.9	1.7	2.2	1.6	1.5	1.7
Level of arthritis interference with household productivity (0–10 scale) [d]						
BL	5.0	4.6	5.0	4.7	5.0	4.4
Wk24	2.4	2.2	2.6	2.2	2.3	2.2
Wk48	2.1	1.7	2.2	1.8	2.0	1.6
Days missed family/ social/leisure activities due to arthritis per month						
BL	4.4	3.6	4.0	2.7	4.9	4.7
Wk24	1.1	1.9	1.0	1.8	1.3	1.9
Wk48	0.7	1.0	1.0	0.4	0.5	1.6

[a] FAS; all patients who received ≥1 dose of study medication and had a valid baseline and post-baseline measurement for ASAS20; [b] Based only on employed pts at the specific visit; pts employed at BL (CZP 200mg Q2W/CZP 400 mg Q4W): axSpA (77/80), AS (48/41), nr-axSpA (29/39); [c] Does not include work days missed counted in the previous question; [d] 0–10 scale, 0 = no interference 10 = complete interference.

Conclusion: At BL, similarly high burden of disease on workplace and household productivity was seen in AS and nr-axSpA pts that could lead to a large financial burden for pts and society. This analysis indicates that CZP continued to improve workplace and household productivity in axSpA pts over 48 wks. Similar CZP improvements over time were observed in AS and nr-axSpA.

Latent Tuberculosis Screening and Treatment In Ankylosing Spondylitis Patients Eligible For Anti-TNF Therapy In Endemic Area. Renata Miossi, Karina Rossi Bonfiglioli, Carla G.S. Saad, Ana Cristina Ribeiro, Julio C. B. Moraes and Eloisa Bonfá. Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Background/Purpose: Anti-TNF agents have emerged as an important treatment for rheumatic diseases, particularly for ankylosing spondylitis (AS). Screening and treatment of latent tuberculosis infection (LTBI) is essential before the use of these drugs. However, current recommendationsfor this screening and treatment and their efficacy are still not well established in endemic regions. The purpose of the present study is to evaluate, in an endemic area, the efficacy of LTBI screening and treatment in AS patients under anti-TNF.

Methods: One hundred and ten AS patients eligible for anti-TNF agents were initially screened for LTBI by tuberculin skin test (TST), chest X-ray and history of contact. Patients were regularly followed at 1–3 months interval, from June 2004 to January 2013.

Results: LTBI screening was positive in 48 (43.6%) patients. TST positivity accounted for majority of LTBI diagnosis (46; 95.2%): 39 (81.2%) solely positive TST, 6 (12.5%) with positive TST and history of contact, 1 (2.1%) with positive TST and abnormal chest X-ray and 2 (4.2%) with isolated history of contact. These patients received at least 1 month isoniazid before starting anti-TNF treatment and all of them completed 6 months of isoniazid treatment. Two patients developed TB in spite of LTBI treatment: one was a medical doctor with proven exposure to TB after 8 months receiving adalimumab, and the other became symptomatic right after the second dose of adalimumab, and probably had active TB that was misdiagnosed as LTBI. Sixty seven (60.9%) patients were treated with one anti-TNF, 33 (30%) with two and 10 (9.1%) with three (86 infliximab, 49 adalimumab and 75 etanercept). Thirty three (30%) patients were under prednisone, mean dose 10.6 mg/day. No difference was observed in TST positivity rate in this group comparing with the patients without this drug (48.5% vs. 39%, p=0.40). TST was repeated in 9/64 (14%) patients initially screened negative in case of prolonged discontinuation and reintroduction of biologic treatment (n=2) or clinical tuberculosis (TB) suspicion (n=7). In the latter group, TST conversion was observed in 3 patients diagnosed with active pulmonary TB. Median duration of anti-TNF treatment (2 adalimumab e 1 infliximab) in these three patients before the diagnosis of TB was 1.8 (0.6 – 3.5) years.

Conclusion: Our study provides evidence that TBLI screening and treatment is also efficient for endemic areas. In addition, we report that new exposure accounts for nearly all cases of TB infection and further demonstrate that symptom guided TST repetition is very effective for TB diagnosis during anti-TNF therapy in high TB incidence region.

Remission In Spondyloarthritis: ASDAS and Basdai Thresholds From a Prospective Real Life Study. Marie Godfrin-Valnet[1], Marc Puyraveau[2] and Daniel Wendling[1]. [1]Minjoz University Hospital, Besancon, France, [2]CHU, Besançon, France.

Background/Purpose: Remission is the current target of management of chronic rheumatic diseases. Whereas in rheumatoid arthritis remission criteria have been recently proposed, in spondyloarthritis, no activity score allows a clear definition for remission. SpA activity is evaluated with the BASDAI score (Bath Ankylosing Spondylitis Disease Activity Index) and more recently with the ASDAS (Ankylosing Spondylitis Disease Activity Score). Thresholds for the ASAS score have been proposed to classify disease activity (inactive, moderate, active, very active), but no remission threshold was defined.

The aim of this study was to evaluate a threshold for remission in SpA patients.

Methods: In this prospective study, a questionnaire answering the question: "do you consider the disease in remission at the present time ?" was filled by the patient with Spa (according to ASAS classification criteria) and the rheumatologist. Data allowing BASDAI, ASDAS-CRP and ASDAS-ESR calculation were collected, and PASS (Patient Acceptable Symptomatic State) was also assessed with a specific question at the same time. Thresholds

were defined by building ROC curves for remission according to the patient's and to the rheumatologist's opinion.

Results: One hundred and fifty patients were prospectively included, 67.3 % men, mean age 43.2 ± 11.5 years. HLA-B27 was positive in 84.5 % of the patients; SpA was axial in 81.7 %. Mean CRP was 8.6 ± 13.5 mg/l, and mean ESR 17.4 ± 16 mm/hour. PASS was considered by 56.6% of the patients. For disease activity, 47.3 % of the patients had a BASDAI score less than 4/10, and 19.2 % an ASDAS-CRP score less than 1.3 (inactive disease) (19.4 % for the ASDAS-ESR score). The thresholds of activity scores for remission defines by ROC curves are reported in table:

Threshold of activity score (ROC curves)	Remission «patient» N: 41/128	Remission «physician» N: 49/143	PASS in case of remission «patient» N: 41/128
ASDAS-CRP	≤ 1.6	≤ 1.8	≤ 2.2
95 % CI	0.67–0.84	0.82–0.94	0.82–099
Sensibility %	62.2	75.6	93.3
Spécificity %	86.3	91	100
ASDAS-ESR	≤ 1.7	≤ 2	≤ 2.4
95 % CI	0.71–0,.87	0.76–0. 90	0.76–0.9
Sensibility %	63.9	75.6	71.4
Spécificity %	87	82.2	81.6
BASDAI	≤ 3.6	≤ 3.6	≤ 4.1
95 % CI	0.71–0.86	0.81–0.93	0.80–0.90
Sensibility %	75.6	83.7	75.7
Spécificity %	75.9	79.4	85

Conclusion: This is the first study tempting to define in a large series of patients in real life a threshold for remission in SpA with an ASDAS –CRP less than 1.6. These results corresponding to the patients reported definition are somewhat different from those endorsed by the ASAS classifying SpA as inactive for a threshold less than 1.3. These differences may be related to different study methods: randomized controlled studies, thresholds evaluated by experts at one hand, and real life situation, thresholds evaluated by the patients at the other hand. However, our results are coherent since the remission threshold is lower than PASS, but raise the question of the definition of remission in SpA.

Presence Of Peripheral Arthritis Delays Spinal Radiographic Progression In Ankylosing Spondylitis: Observation Study Of Korean Spondyloarthropathy Registry (OSKAR) Over 5 Years. Tae-Jong Kim[1], Seunghun Lee[2], Kyung-Bin Joo[3], Dong-Jin Park[4], Yong-Wook Park[4], Shin-Seok Lee[4] and Tae-Hwan Kim[5]. [1]Chonnam National University Medical School and Hospital, Gwangju, South Korea, [2]Hanyang University College of Medicine, Seoul, South Korea, [3]Hanynag University, Seoul, South Korea, [4]Chonnam National University Medical School, Gwangju, South Korea, [5]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea.

Background/Purpose: The most unique feature in ankylosing spondylitis (AS) is subchondral eburnation and syndesmophytes, possibly leading to ankylosis and spinal fusion. So far a clear relationship between spinal bone formation and peripheral arthritis in patients with AS has not been established. The aim of this study was to determine whether presence of peripheral arthritis can affect the progression of structural damage in patients with AS.

Methods: A total of 915 patients with AS from the Observation Study of Korean spondyloArthropathy Registry (OSKAR) cohort were enrolled for this analysis. We used a two-step approach to explore the relationships between the peripheral arthritis and the progression of spinal structural damage in AS. First, all OSKAR data were analyzed in relation to the history of peripheral arthritis on cross-sectional survey. Second, we analyzed the radiographic spinal progression over 5 years according to the presence or absence of peripheral arthritis. The modified Stoke AS Spinal Score (mSASSS) were examined by two experienced radiologists to validate the results. The collection of the clinical parameters was conducted to investigate the associations between clinical factors and the radiographic progression.

Results: The agreement between the two readers regarding mSASSS was very good: ICC coefficient 0.75 (95% CI 0.61–0.82) and 0.71 (95% CI 0.58–0.82) at each time. On cross-sectional survey, in spite of adjusting for multiple comparisons by Bonferroni correction, the patients with history of peripheral arthritis had fewer mSASSS unit than those without history of peripheral arthritis (19.56±1.06 vs 22.67±0.81, p=0.005). In a analysis over 5 years, the mean progression of mSASSS in patients with peripheral arthritis was 3.26±0.58 units, while that of mSASSS in patients without peripheral arthritis was 4.97±0.44 units (p=0.024).

Conclusion: The patients with the peripheral arthritis had slower radiographic spinal damage progression than those without peripheral arthritis.

Lower Etanercept Levels Are Associated With High Disease Activity In Ankylosing Spondylitis Patients At 24 Weeks Of Follow-Up. Eva L. Kneepkens[1], Charlotte L. M. Krieckaert[1], Desiree van der Kleij[2], Michael T. Nurmohamed[1], Irene E. van der Horst-Bruinsma[3], Theo Rispens[4] and Gertjan Wolbink[4]. [1]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [2]Sanquin Diagnostic Services, Amsterdam, Netherlands, [3]VU University Medical Center, Amsterdam, Netherlands, [4]Sanquin Research, Amsterdam, Netherlands.

Background/Purpose: Etanercept levels are associated with clinical response in rheumatoid arthritis, however, in a small group of 53 patients with ankylosing spondylitis (AS) this association was not found.[1]

Objectives: To investigate the relationship between etanercept levels and clinical response in a large cohort of AS patients.

Methods: Prospective observational cohort study of 170 consecutive AS patients treated with etanercept 50 mg SC once a week, monitored during 24 weeks of follow-up. Clinical measurements and trough serum samples were obtained at all visits. Etanercept trough levels were determined retrospectively using an enzyme linked immunosorbent assay (ELISA) designed by Sanquin Research, Amsterdam. Response to etanercept treatment was defined as a Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) response (50% improvement or an absolute improvement of 2 points on a BASDAI, scale 0–10) and disease activity was measured using AS Disease Activity Score, including CRP (ASDAS).

Results: Of 170 patients, 122 (71.8%) were male and 130 (82.8%) were HLA-B27 positive. At baseline median BASDAI was 6.0 (IQR 4.8–7.1) and mean ASDAS was 3.5 (SD 1.0). After 24 weeks 98 (57.6%) patients were BASDAI responder (last observation carried forward), mean ASDAS (SD) for responders was 1.6 (0.9) vs. 2.4 (0.9) for non-responders (p<0.001). Of 170 patients 19 dropped out: 16 (84.2%) due to treatment failure or adverse events and 3 (15.8%) due to other reasons. At 24 weeks of treatment etanercept levels were significantly higher in patients with inactive to moderate disease activity (ASDAS <2.1, median (IQR) 3.7 (2.5–5.5)) compared to patients with high to very high disease activity (ASDAS ≥2.1, (median (IQR) 2.3 (1.2–3.7)) (p=0.01). When patients were categorized into quartiles according to the height of etanercept levels at 24 weeks, the lowest quartile (etanercept level < 1.8 mg/L) comprised 35.1% of all patients with ASDAS ≥2.1. The highest quartile (etanercept level > 5.0 mg/L) comprised 33.8% of all patients with ASDAS <2.1 (fig. 1). There were no significant differences at baseline between patients from the lowest quartile compared to patients from the highest quartile.

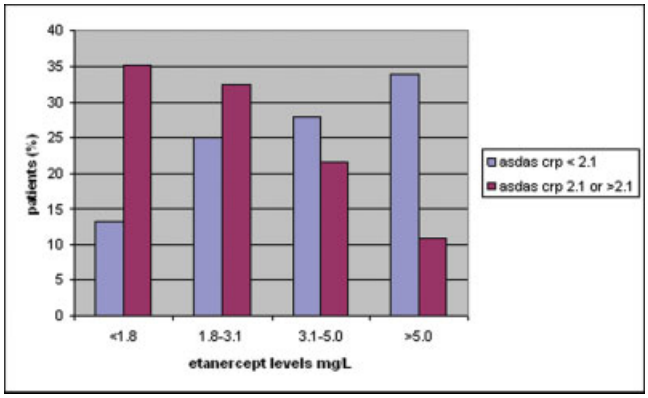

Figure 1. Percentage of patients with ASDAS <2.1 and ≥2.1 stratified according to the height of *etanercept levels. Each group contains 25% of all patients.*

Conclusion: Lower etanercept levels in AS are associated with higher disease activity at 24 weeks of treatment.

Measurement Of Lateral Spinal Flexion and Schober Is Sufficient To Be Informed About Spinal Mobility In Patients With Ankylosing Spondylitis: 12-Year OASIS Results. Sofia Ramiro[1], Robert Landewé[2], Désirée van der Heijde[3], Carmen Stolwijk[4], Maxime Dougados[5], Filip Van den Bosch[6] and A.M. van Tubergen[4]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center Amsterdam & Atrium Medical Center, Heerlen, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Maastricht University Medical Center, Maastricht, Netherlands, [5]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France, [6]Gent University Hospital, Gent, Belgium.

Background/Purpose: We have shown that spinal mobility gets impaired in a fixed order in ankylosing spondylitis (AS), with the highest impairment in lumbar spine. We sought to investigate whether assessing few measures could capture full information on impairment in spinal mobility, which would be useful for clinical practice.

Methods: Patients from the Outcome in AS International Study (OASIS) were followed-up for 12 years in which spinal mobility was regularly measured (see Table). From a previous study in normal subjects (1), percentile curves (2.5th to 97.5th) were obtained for each of the spinal mobility measures (SMMs) (Figure). We added 4 parallel curves representing z-scores of 2.5, 3, 3.5 and 4 respectively (helplines a to d) to be able to plot impaired measures. Each of the SMMs was defined as impaired if the measurement fell below help-line a (first cutoff below normal subjects). The number of observations and of patients using baseline observation only with at least one SMM impaired was calculated. Of those, the proportion of observations or of patients, respectively, with each of the SMMs impaired was calculated. Furthermore, we investigated in how many cases would impairment in spinal mobility be missed if only a fixed number of SMMs was assessed.

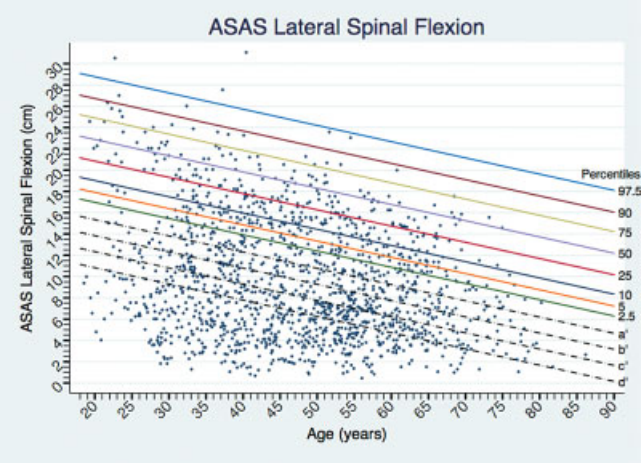

Figure. Lateral spinal flexion in function of age and with the percentile curves and help-lines derived from normal subjects

Results: A total of 216 patients were included (70% males, mean (SD) age 44(13) years, mean symptom duration 21(12) years and 85% HLA-B27 positive). Impairment in spinal mobility was present in 1111 (78%) out of 1422 observations and in 161 (79%) out of the 203 patients with a complete baseline assessment. From the observations (and also patients) with at least one impaired SMM, in 83% (86% of the patients) lateral spinal flexion (LSF) was impaired, followed by Schober in 63% of them (58% of the patients). In one quarter of the observations, 1 SMM was impaired, in 32% 2 SMMs and in 18% 3 SMMs. At a patient-level, 1 SMM was impaired in 30% of the patients, 2 SMMs in 33% and 3 SMMs in 17%. If only LSF was measured, 17% of the observations (14% of the patients) with impairment in SMM would be missed. If additionally Schober was also measured, only 9% of the observations (and also of patients) would be missed (Table).

Table. Impairment of each of the spinal mobility measures in patients with AS in measurements with at least one SMM impaired

	Observation-level n (%) (N = 1111)	Patient-level (baseline assessment) n (%) (N = 161)
Impairment in each of the spinal mobility measures		
Lateral spinal flexion	919 (83)	138 (86)
Schober	696 (63)	94 (58)
Tragus-to-wall distance	490 (44)	62 (39)
Cervical rotation	349 (31)	44 (27)
Intermalleolar distance	207 (19)	27 (17)
Chest expansion	139 (13)	17 (11)
Impairment in spinal mobility missed if only the following measurements are performed		
Lateral spinal flexion	192 (17)	23 (14)
Lateral spinal flexion+ Schober	103 (9)	14 (9)
Lateral spinal flexion+ Schober+ tragus-to-wall distance	44 (4)	7 (4)
Lateral spinal flexion+ Schober+ tragus-to-wall distance+ cervical rotation	14 (1)	1 (1)
Lateral spinal flexion+ Schober+ tragus-to-wall distance+ cervical rotation+ intermalleolar distance	3 (0)	1 (1)

Conclusion: Impairment in spinal mobility can be investigated by assessing only 2 SMMs. We hereby recommend that measurement of LSF and Schober is sufficient to be informed about impairment in spinal mobility in patients with AS. Only if these are impaired it is important to assess additional measures.

Stable Clinical and MRI Response In Patients With Early Axial Spondyloarthritis After 3 Years Of Continuous Treatment With Etanercept, Data Of The Esther Trial. In-Ho Song[1], Kay-Geert A. Hermann[2], Hildrun Haibel[1], Christian Althoff[3], Denis Poddubnyy[4], Joachim Listing[5], Anja Weiss[6], Ekkehard Lange[7], Bruce Freundlich[8], Martin Rudwaleit[9] and Joachim Sieper[4]. [1]Charité Universitätsmedizin Berlin, Campus Benjamin Franklin, Berlin, Germany, [2]Charité Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany, [3]Charite Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany, [4]Charité Universitätsmedizin Berlin, Berlin, Germany, [5]German Rheumatism Research Center, Berlin, Germany, [6]German Rheumatism Research Centre, Berlin, Germany, [7]Pfizer Pharma AG, Berlin, Germany, [8]University of Pennsylvania, Philadelphia, PA, [9]Endokrinologikum Berlin, Berlin, Germany.

Background/Purpose: In patients with early axial spondyloarthritis (SpA) with a disease duration of < 5 years and evidence of active inflammation on whole-body magnetic resonance imaging (wb-MRI) in the spine and/or sacroiliac joints (SIJ) at baseline [1] the long-term efficacy of etanercept (ETN) was assessed over three years.

Methods: In the previously reported ESTHER trial axial SpA patients were treated with ETN (n= 40) versus sulfasalazine (SSZ) (n= 36) in the first year [1]. All patients who were not in remission at week 48 (n=48) were either continuously treated with ETN, or sulfasalazine treatment was switched to ETN treatment. We analysed the clinical and MRI response in he pooled data set of patients who were continously treated with ETN for 3 consecutive years. Data were analysed as observed.

Results: In the pooled group of patients treated continously over 3 years with ETN (n= 60) the BASDAI decreased from 5.7 (standard deviation 1.3) to 2.0 (1.5), the ASDAS from 3.4 (0.8) to 1.2 (0.7). Also mean values for MRI spine and sacroiliac joint scores showed a significant decrease (table 1). ASAS partial remission after three years of ETA was reached by 43%, ASDAS inactive disease by 60% (table 1).

Table 1. Long-term efficacy over 3 years in patients with early axial spondyloarthritis treated with etanercept. Data at baseline (BL), after one year of treatment with etanercept, after two years and after three years of treatment with etanercept.

	ETN, Baseline	Data after one year of treatment with ETN	Data after two years of treatment with ETN	Data after three years of treatment with ETN
BASDAI (0–10)	5.7 (1.3)	2.5 (2.0)	2.1 (1.8)	2.0 (1.5)
BASFI (0–10)	4.4 (2.1)	2.0 (2.0)	1.6 (1.7)	1.4 (1.3)
ASDAS (0–…)	3.4 (0.8)	1.6 (0.8)	1.4 (0.9)	1.2 (0.7)
CRP (mg/l)	10.5 (13.6)	3.5 (4.6)	3.6 (5.5)	2.9 (5.5)
MRI Spine Score (−69)	1.6 (3.4)	NA	0.7 (1.4)	0.9 (1.8)
MRI SI-joint Score (−24)	4.6 (6.3)	NA	3.5 (6.1)	3.3 (6.0)
ASAS40, %	NA	68.4%	67.4%	75.0%
ASAS PR, %	NA	35.1%	53.5%	42.5%
ASDAS inactive disease, %	NA	38.9%	53.7%	60.0%
BASDAI50, %	NA	64.9%	65.1%	72.5%

Data shown as mean values (standard deviation) unless otherwise stated. Abbreviations: ETN: etanercept; ASAS PR: ASAS partial remission; NA: not applicable; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; ASDAS: Ankylosing Spondylitis Disease Activity Score; ASAS: Assessment of SpondyloArthritis international Society; MRI: magnetic resonance imaging; SI-joint: sacroiliac joint.

Conclusion: There was a constant and sustained clinical response in patients with early axial SpA patients treated with ETN over 3 years. The response in this early axial SpA cohort seems to be better compared to established AS cohorts with a longer disease duration (> 10 years) where BASDAI50 response rates of 47% after 3 years of infliximab treatment [3] and ASAS40 and ASAS partial remission rates of 49% and 27%, respectively after 4 years of etanercept treatment [4] were reported.

Routine Assessment Of Patient Index Data 3 Scores Correlate Well With Bath Ankylosing Spondylitis Disease Activity Index In The Assessment Of Disease Activity and Monitoring Progression Of Ankylosing Spondylitis. Abhijeet Danve[1], Kiana Vakil-Gilani[1], Anusha Reddy[1], Annan Sheffield[2], Alexis Dinno[2] and Atul Deodhar[1]. [1]Oregon Health and Science University, Portland, OR, [2]Portland State University, Portland, OR.

Background/Purpose: Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is a composite tool unique to measure disease activity in ankylosing spondylitis (AS) just as Disease Activity Score 28 (DAS28) is for rheumatoid arthritis (RA). Routine Assessment of Patient Index Data 3 (RAPID3) is another composite tool that measures physical function, pain and patient global assessment in various rheumatic diseases. It correlates well with DAS28 in RA. If RAPID3 can also be used to assess disease activity in AS it may save time and costs in busy practices. Objectives of this study were to analyze the association between BASDAI and RAPID3 in patients with AS, and to obtain a cut-off value for RAPID3 which correlates with BASDAI of 4 (indicative of high disease activity).

Methods: An electronic medical record search identified 157 patients with AS at our university who were followed between 2007 to 2012. Of these, 113 patients had BASDAI and RAPID3 measured at each visit (intervals ranged from 1 to 57 months). Nonparametric receiver operating characteristic (ROC) determined a cut-off of RAPID3 best correlating with BASDAI ≥ 4. RAPID3 captures both pain and function, but BASDAI measures predominantly pain without function, so multiple linear regression modeled BASDAI with RAPID3 and RAPID3^2 while controlling for visit number. Individual BASDAI and RAPID3 scores and summaries were plotted and compared over time.

Results: Of 113 patients, 75 (66%) were male and 38 (34%) were female, age averaged 44.3 (SD: 13.7), disease duration averaged 8.4 years (SD 9), 77 (61%) had more than one visit, and 36 (39%) had only one. At baseline BASDAI and RAPID3 averaged 4.17 and 3.79 respectively. BASDAI was explained by RAPID3 ($b = 1.218$; s.e. $= 0.110$, $p < 0.001$), RAPID3^2 ($b = -0.045$; s.e. $= 0.014$, $p = 0.002$), and visit number ($b = -0.141$; s.e. $= 0.038$, $p < 0.001$) with adjusted $R^2 = 0.691$. RAPID3 cut-off was 3.33 for 82.4% correct classification, 87.5% sensitivity and 78.8% specificity.

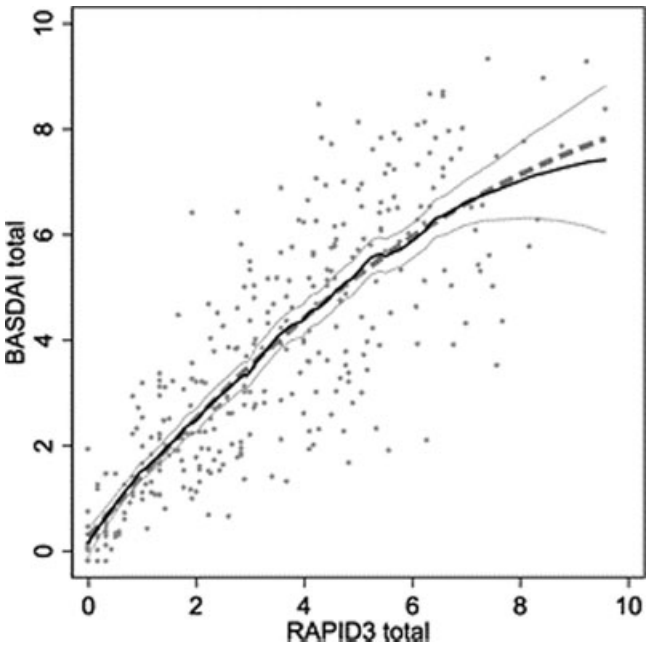

Figure 1. Nonparametric regression of BASDAI on RAPID3 (black with 95% CI in gray) controlling for visit number suggested we model BASDAI as a quadratic function of RAPID3 (thick dashed).

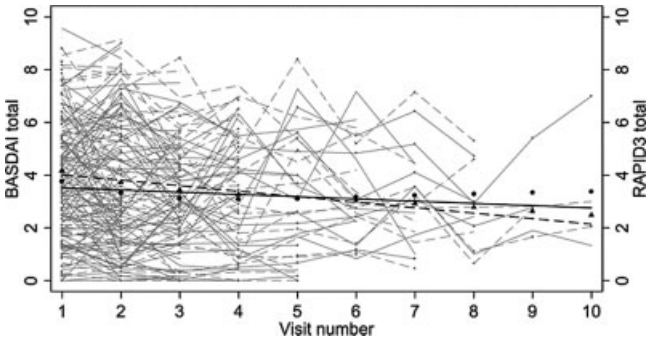

Figure 2. Individual BASDAI (thin dash) and RAPID3 (thin solid); regressions of BASDAI (thick dash) and RAPID3 (thick solid); locally weighted estimate BASDAI (▲) and RAPID3 (■).

Conclusion: RAPID3 correlates well with BASDAI, and along with pain, it provides additional information about patient function. Since it also correlates with measures of disease activity in RA and other rheumatic diseases, RAPID3 could be an attractive measure to be used in busy rheumatology practices.

Patient-Tailored Dose Reduction Of Tumor Necrosis Factor-Alpha Blocking Agents In Ankylosing Spondylitis Patients With Stable Low Disease Activity. Suzanne Arends[1], Eveline van der Veer[1], Fleur B.S. Kamps[1], Monique Efde[2], Martha K. Leijsma[1], Hendrika Bootsma[1], Elisabeth Brouwer[1] and Anneke Spoorenberg[2]. [1]University Medical Center Groningen, Groningen, Netherlands, [2]Medical Center Leeuwarden, Leeuwarden, Netherlands.

Background/Purpose: Tumor necrosis factor-alpha (TNF-α) blocking agents are very effective in controlling inflammation and improving clinical assessments in patients with ankylosing spondylitis (AS). In view of the high costs and possible side effects, our aim was to investigate whether dose reduction of TNF-α blocking agents is possible without loss of effectiveness in AS patients in daily clinical practice.

Methods: Patients included in the Groningen Leeuwarden AS (GLAS) cohort, fulfilling the modified New York criteria for AS, with active disease (Bath AS disease activity index (BASDAI)≥4) before start of anti-TNF-α treatment and stable (≥6 months) low disease activity (BASDAI<4) on conventional dose regime, who started with dose reduction were studied. The dose reduction was patient-tailored and consisted of either lowering the dose or extending the interval between doses. For each specific TNF-α blocking agent, a fixed dose reduction schedule was used and evaluated at each follow up visit and, if necessary, adjusted in response to disease activity, side effects and co-morbidity, Data concerning medication dose, reasons for changing medication dose, and disease activity were collected after 6, 12, 18, and 24 months of dose reduction.

Results: Between November 2005 and January 2011, 49 AS patients with stable low disease activity started with dose reduction of infliximab (n=8), etanercept (n=35), or adalimumab (n=6). 88% of these patients were male, mean age was 46 years (SD±12), and mean duration of symptoms was 20 years (SD±10). Mean BASDAI was 1.8 (SD±1.1) at start of dose reduction, coming from 6.2 (SD±1.2) just before start of anti-TNF-α treatment.

In total, 71%, 54%, 47%, and 42% of the patients maintained on dose reduction after 6, 12, 18 and 24 months, respectively. The mean dose reduction was 37% (SD±11). Disease activity remained low (BASDAI<4) in 86% of the patients who continued dose reduction at 24 months (Table 1).

Of all 25 patients who did not continue dose reduction, 23 (92%) returned to the conventional dose regime and 2 (8%) patients stopped TNF-α blocking therapy (1 adverse events, 1 inefficacy due to antibody formation).

Table 1. Disease activity in AS patients who maintained dose reduction

	6 months	12 months	18 months	24 months
Patients still on dose reduction	35/49	25/46	21/45	18/43
	71%	54%	47%	42%
BASDAI <4	88%	83%	89%	86%

Conclusion: In this observational cohort, long-term dose reduction of TNF-α blocking agents was successful preserving stable low disease activity in a substantial number of AS patients.

1529

Patients With Imaging Abnormalities Of The Sacroiliac Joints Are More Likely To Respond To TNF Alpha Inhibitors In Early Axial Spondyloarthritis. Data From The DESIR Cohort. Anna Moltó[1], Simon Paternotte[2], Pascal Claudepierre[3] and Maxime Dougados[1]. [1]Paris- Descartes University, Paris, France, [2]Paris- Descartes University, Cochin hospital, Paris, France, [3]Paris-Est University; LIC EA4393; APHP, Henri Mondor Hospital, Creteil, France.

Background/Purpose: Efficacy of TNF alpha inhibitors (TNFi) has been clearly established in patients with axial SpondyloArthritis (ax-SpA), but its effectiveness and adherence with regard to specific patient characteristics remains to be evaluated in patients with early disease. The aim of the study was to evaluate the effectiveness of TNFi in a cohort of patients with inflammatory back pain (IBP) suggestive of ax-SpA. Secondary objectives were to estimate the retention rate of TNFi after 2 years of follow-up and the baseline predictors of such retention rate.

Methods: Observational prospective multi-centre study, with 708 patients with early IBP (< 3 years duration) suggestive of ax-SpA. Data included: demographics and disease characteristics of the first two years of follow-up. Statistical analysis: Effectiveness: patients receiving TNFi were matched with patients not receiving TNFi (but receiving usual care) at a 1:1 ratio according to a propensity-score. The primary endpoint of the study was ASAS40, assessed here at the last available visit still on treatment. Exploratory subgroup analyses evaluated the potential interactions existing between baseline characteristics and the treatment effect (p<0.10). Retention rate was estimated for all TNFi using a survival-data analysis by Kaplan-Meier. Cox analyses were performed to identify potential predisposing factors of such retention rate.

Results:

1. Treatment effect: 203 patients (28.7%) received at least one TNFi during follow-up; data for the assessment of the primary endpoint was available in 197 patients (97.0%) receiving TNFi, that were matched according to a propensity score to 197 patients receiving any other usual care. An ASAS40 response at the last available visit (74±30.9 weeks after initiation of TNFi) was achieved in 62 (31.8%) patients receiving TNFi treatment vs. 31 (16.0%) patients receiving usual care (OR = 2.45 [1.50 – 3.99], p=0,004).
2. Exploratory subgroup analyses detected that patients with X-ray sacroiliitis (OR=9.12 [3.22–25.80] and OR=1.32[0.73–2.41], for X-ray sacroiliitis yes/no, p=0.002), MRI sacroiliitis (OR=5.10 [2.28–11.41] and OR=1.32[0.68–2.56] for MRI sacroiliitis yes/no, p=0.011) and fulfilling the imaging arm (OR=5.34 [2.51–11.33] and OR=0.78 [0.32–1.89] for the imaging and clinical arms, respectively, p=0.001) were more likely to achieve an ASAS40 response with TNFi, compared to usual care. No significant interaction was detected between CRP abnormality and treatment effect.
3. Retention rate: Of the 203 patients included, Kaplan-Meier estimates of the proportion of patients still on TNFi over time were 75.2% [69.0–81.3] and 41.2% [33.2–49.1], at 6 and 24 months after initiation, respectively. HLA B27 presence (HR=0.66[0.44–0.99], p=0.044) and X-ray sacroiliitis at baseline (HR=0.48 [0.30–0.78], p=0.003) were associated with a prolonged continuation of the TNFi over time.

Conclusion: In daily practice, use of TNFi was frequent in active early ax-SpA, whatever the subgroup of the ASAS criteria the patients were fulfilling. However patients with imaging abnormalities were more likely to achieve a TNFi response compared to usual care.

Vitamin D Deficiency Is Associated With a More Active and Severe Disease In Early Axial Spondyloarthritis: Data From The DESIR Cohort. Ihsane Hmamouchi[1], Simon Paternotte[2], Didier Borderie[3] and Maxime Dougados[4]. [1]Paris Descartes University, Cochin Hospital, Paris, France, [2]Paris- Descartes University, Cochin hospital, Paris, France, [3]Paris Descartes UNiversity, Pris, France, [4]Paris-Descartes University, APHP, Cochin Hospital, Paris, France.

Background/Purpose: Objectives

a) to describe the vitamin D status b) to assess the relationship between vitamin D status and disease activity/severity and c) to estimate the relationship between vitamin D status and comorbidities in an early axial spondyloarthritis (SpA).

Methods: Patients: 708 patients with early inflammatory back pain suggestive of spondyloarthritis have been included in the DESIR cohort. This analysis was restricted to the patients fulfilling at least one set of criteria for the diagnosis of SpA (e.g. Amor, ESSG or ASAS criteria).

Study design: prospective, multi-centre, observational study.

Data collected: 25OHvitD was measured on baseline frozen stored plasma. Radiological and densitometric variables were collected at baseline as well as the cardiovascular risk factors (high-density lipoprotein (HDL) cholesterol, abdominal obesity, triglycerides, blood pressure and fasting glucose) whereas clinical variables (BASDAI, BASFI, BASMI, ASDAS) were collected at each 6 month interval visits during the 2 years follow-up.

Data analysis: The 25OHvitD insufficiency threshold was defined by the Vitamin D first quartile. Correlations between this insufficiency and the other variables were done using uni- and multivariate analysis.

Results: A total of 653 patients fulfilling at least one of the criteria for SpA were analysed. A 25OHvitD insufficiency was defined by a value below: 13.29 ng/ml. Such insufficiency was more pronounced in winter (37.1% vs. 9.2%) and in non Caucasian patients (50.8% vs. 22.6%).

After adjusting for season and ethnicity, baseline 25OHvitD remained significantly associated with baseline radiological sacroilitis (1.71 [1.13 – 2.57]), baseline ASDAS crp (1.20 [0.99 – 1.46]), and mean BASMI during the 2 years of follow up (1.46 [0.99 – 2.15]). There was no statistically significant correlation between baseline vitamin D levels and bone densitometry or cardiovascular risk factors.

Conclusion: These results indicate that high disease activity and severity in early axial SpA is associated with low vitamin D. Further longitudinal studies are required to evaluate the interest of Vit D supplementation on the long term outcome of the disease.

Disclosure: I. Hmamouchi, None; **S. Paternotte**, None; **D. Borderie**, None; **M. Dougados**, None.

1531

Agreement Between Disease Activity States and Improvement Scores As Defined by Bath Ankylosing Spondylitis Disease Activity Index and Ankylosing Spondylitis Disease Activity Score Cut-Off Values. Dilek Solmaz[1], Pinar Cetin[1], Ismail Sari[1], Merih Birlik[2], Servet Akar[1], Fatos Onen[1] and Nurullah Akkoc[1]. [1]Dokuz Eylul University School of Medicine, Izmir, Turkey, [2]Dokuz Eylul University School of Medicine, izmir, Turkey.

Background/Purpose: BASDAI has been extensively used to assess disease activity in ankylosing spondylitis (AS) BASDAI score ≥4 represent high disease activity and has been suggested as an eligibility criterion for initiation of anti-TNF therapy. ASDAS is a new composite clinical tool to assess disease activity in AS. ASDAS values of 2.1 and 3.5 have been selected as cut-off values to define high and very high disease activity, respectively and ASDAS ≥ 2.1 has been proposed as a suitable cut-off for eligibility for anti-TNF therapy The aim of this study was to estimate the corresponding BASDAI and ASDAS cut-off values for initiation of anti-TNF therapy and to assess the agreement between disease activity states defined by BASDAI and ASDAS values.

Methods: Patients with complete baseline data for ASDAS based on CRP and BASDAI were included. Mean ASDAS and BASDAI values were compared by Spearman correlation. Receiver operating characteristic (ROC) curves were constructed to determine the cut-off value of ASDAS that correspond to BASDAI score of 4 and to asses the cut-off value of BASDAI that correspond to ASDAS values of 2.1 and 3.5 Each cut-off point was calculated on the basis of the best trade-off values between sensitivity and specificity. The Kappa statistic was used to test the agreement between the disease activity states according to ASDAS and BASDAI, as well as the agreement between the clinical improvement as assessed by the two instruments (for patients with available data).

Results: 396 patients (291 M; 44 ±12.0) were identified with complete data at baseline Mean disease duration was 9.4 ± 8.2.Mean BASDAI, and ASDAS scores were 3.6 ± 2.3 and 2.9 ± 1.1 There was good correlation between ASDAS and BASDAI when tested by Spearman ($p<0.001$; $r=0.9$). The best trade-off ASDAS value corresponding to BASDAI score of 4 was 2.9 (80% sensitivity and 77% specificity; AUC: 0.88) whereas the best trade-off BASDAI values corresponding to ASDAS≥2.1 and ≥3.5 were 2.4 (84% sensitivity and 83% specificity; AUC: 0.90) and 3.7 (89% sensitivity and 69% specificity; AUC: 0.87), respectively. Similar cut-off values were obtained for different gender and age groups(≤40/>40 years).Overall percent agreement of BASDAI≥4with ASDAS≥2.1 and ASDAS≥ 3.5were 67 and 76%, with κ valuesof 0.39 and 0.48, respectively. There was a moderate agreement between both the major clinical response measured by BASDAI50 and that by ΔASDAS≥2 ($\kappa=0.441$) and the minimal clinical improvement as measured by ΔBASDAI≥ 2and ΔASDAS≥1.1 ($\kappa=0.545$).

Table 1. Agreement between BASDAI≥4and high and very high disease activity states according to ASDAS

		ASDAS				
		<2.1	≥2.1	>3.5	≥3.5	Total
BASDAI	<4	99	129	211	17	228
	≥4	1	167	78	90	168
	Total	100	296	289	107	396

Conclusion: The ASDAS value that corresponds to the recommended BASDAI cut-off ≥4 for initiation of anti-TNF therapy is higher than the recommended ASDAS threshold of ≥ 2.1. Agreement between high disease activity states as defined by BASDAI and that by ASDAS is only fair, whereas agreement between clinical response as measured by BASDAI and that by ASDAS seems to be better.

Anti-Tumor Necrosis Fator Therapy Is Associated With Resolution Of Erosion In The Sacroiliac Joints Of Patients With Spondyloarthritis. Susanne Juhl Pedersen[1], Stephanie Wichuk[2], Praveena Chiowchanwisawakit[3], Robert GW Lambert[2] and Walter P. Maksymowych[2]. [1]Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, [2]University of Alberta, Edmonton, AB, [3]Mahidol University, Bangkok, Thailand.

Background/Purpose: Radiography of the sacroiliac joints (SIJ) in spondyloarthritis (SpA) is a valuable diagnostic tool but is unreliable and unresponsive for assessment of treatment effects. There is an unmet need for imaging tools to assess the potential disease-modifying effects of therapeutic agents early in SpA when disease is still confined to the SIJ. There has been limited assessment of MRI-based scores for structural lesions in the SIJ, which indicate that scoring fat metaplasia may discriminate between therapies. But the significance of this for structural damage is unclear. The SPARCC MRI SIJ Structural Score (SSS) assesses a broader spectrum of structural lesions and its potential to discriminate between therapies requires evaluation.

Methods: The SSS method assesses fat metaplasia (FAT), erosion (ER), backfill (BF), and ankylosis (ANK) according to standardized and validated definitions (Morpho). It scores 5 consecutive coronal slices anteriorly through the cartilaginous portion of the joint from the transitional slice, defined as the first slice in the cartilaginous portion that has a visible portion of the ligamentous joint. Lesions are scored dichotomously (present/absent) in SIJ quadrants (fat, erosion) or halves (backfill, ankylosis) using a direct online data entry system based on schematics of the SIJ. Scoring ranges are: FAT (0–40), ER (0–40), BF (0–20), ANK (0–20). After a calibration exercise, two readers independently scored 147 pairs of scans conducted at baseline and 2 years from a prospective cohort of patients with SpA who received either standard (n=69) or anti-TNF (n=78) therapies. Baseline status and change scores were assessed by intraclass correlation coefficient (ICC3,1), and smallest detectable change (SDC) was calculated using ANOVA and expressed as an absolute value and as a percentage of the maximum score. Discrimination was assessed using Guyatt's effect size and treatment group differences using the Mann-Whitney test.

Results: Baseline clinical characteristics were similar except for significantly higher CRP and BASDAI in the anti-TNF treated group. Baseline SSS ANK and BF scores were also significantly higher in the anti-TNF treated group ($p=0.014$ and 0.022, respectively). The number (%) of patients with new and resolved erosions at 2 years was 6 (7.6%) and 32 (40.5%) in the anti-TNF group versus 16 (23.5%) and 21 (30.9%) in the standard group ($\chi^2=7.4$, $p=0.02$). Significantly greater increase in SSS Fat and decrease in SSS ER scores was evident in the anti-TNF treated group (Table).

	Baseline ICC [95%CI]	Change ICC [95%CI]	SDC (% maximum range)	Mean BL Score (SD)		Mean change score (SD)		Guyatt's ES	P value
				Anti-TNF	Standard	Anti-TNF	Standard		
FAT	0.72 [0.47–0.84]	0.40 [0.25–0.53]	3.4 (8.5%)	3.6 (5.1)	4.0 (6.6)	0.7 (2.2)	0.2 (1.5)	0.46	0.017
BACKFILL	0.48 [0.24–0.64]	0.49 [0.35–0.61]	4.2 (21.2%)	3.7 (4.5)	2.2 (3.1)	0.1 (2.9)	0.4 (1.9)	0.03	NS
EROSION	0.56 [0.30–0.72]	0.51 [0.38–0.62]	4.7 (11.7%)	2.7 (3.2)	3.6 (4.4)	−1.5 (2.8)	−0.5 (2.7)	0.55	0.017
ANKYLOSIS	0.97 [0.96–0.98]	0.63 [0.52–0.72]	2.1 (10.6%)	7.3 (8.5)	4.1 (7.0)	0.4 (1.6)	0.3 (1.2)	0.33	NS

Conclusion: The SPARCC SSS method for assessment of structural lesions has discriminative capacity in demonstrating significantly greater reduction in erosion in patients receiving anti-TNF.

1533

Work Outcome In Patients With Ankylosing Spondylitis: 12-Year Results From OASIS. Jose Dionisio Castillo-Ortiz[1], Sofia Ramiro[2], R. Landewe[3], D. van der Heijde[4], Maxime Dougados[5], Filip van Den Bosch[6] and Annelies Boonen[7]. [1]Unidad de Investigacion en Enfermedades Cronico-Degenerativas, Guadalajara, Mexico, [2]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [3]Academic Medical Center/ University of Amsterdam, Amsterdam, Netherlands, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France, [6]Department of Rheumatology Ghent University Hospital, Ghent, Belgium, [7]Maastricht University Medical Center, Maastricht, Netherlands.

Background/Purpose: Almost all studies on the impact of Ankylosing Spondylitis (AS) on the employment status or work disability (WD), the far majority of these studies are cross-sectional analyses and none compared work outcome over time with the general population. We aimed at quantifying the long-term impact of AS on participation in labour force over 12 years in a prospective cohort study, at identifying predictors of an adverse work outcome (AWO) and at comparing the incidence of WD over time with the general population.

Methods: Work related information and clinical characteristics were obtained from patients followed in the Outcome in AS International Study (OASIS) during 12 years. Patients who were at risk of having an AWO at any time were included in the analysis (i.e. those working, either at baseline or

starting/resuming work later). AWO was defined as WD or a reduction in the number of working hours. Survival analysis was used to investigate AWO. With Cox regression, first baseline and secondly time-varying predictors (with 2-year time-lag) were identified; the latter adjusted for 2 time dependent variables (change in social security system and market availability of anti-TNF). Incidence rate for WD over 12 years among Dutch patients was compared with the general population using indirect standardization.

Results: Of the 215 (of 216) patients in OASIS cohort with baseline data on work status, 139 (65%) were at risk for AWO (mean age 38(SD 10) years, 75 % male, 81% HLA-B27 positive, mean disease duration 9 (SD 7) years), of whom 11% (n=15) were not working at baseline but resumed work over time. Thirty one of 139 patients (22%) experienced AWO; 12 (39%) became full-work disabled (full-WD), 5 (16%) partial work disabled (partial-WD) and 14 (45%) reduced working hours. For a total 1404, person years, Kaplan Meier analysis revealed a 2.2% of annual rate of AWO. Multivariable Cox analysis showed that higher baseline BASFI (HR 1.3; 95% CI 1.01–1.4) and Dutch origin (HR 3.6; 95% CI 1.3–10.0) predicted long-term AOW. In the time-lagged prediction analysis, higher BASFI (HR 1.3; 95%CI 1.1–1.5) and Dutch origin (HR 3.0; 95% CI 1.2–8.2) significantly predicted AWO over time. Of 130 Dutch patients in working age, 9% (n=12) became WD over 12 years. Among Dutch patients the incidence rate of WD over 12 years was 2.9 (95% CI 1.2; 4.6) and 1.2 (95% CI −0.4; 2.9) times higher compared with the general population, for males and females, respectively.

Conclusion: Even in AS patients with already long disease duration, the disease continues to have a negative impact on work outcome. Self-reported physical function (BASFI) and system characteristics, but not job-type, disease activity or structural damage consistently influence AWO.

Safety and Efficacy Of Golimumab, a Human Anti-Tumor Necrosis Factor Monoclonal Antibody Injected Subcutaneously Every 4 Weeks, In Chinese Patients With Active Ankylosing Spondylitis: 1-Year Results Of a Phase 3, Randomized, Placebo-Controlled Study. Chunde Bao[1], Feng Huang[2], Muhammad Asim Khan[3], Kaiyin Fei[4], Zhong Wu[4], Yanli Zhuang[4], Timothy A. Gathany[5], Chenglong Han[5] and Elizabeth C. Hsia[6]. [1]Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China, [2]Chinese PLA General Hospital, Beijing, China, [3]Case Western Reserve University Hospital, Cleveland, OH, [4]Janssen Research & Development, LLC., Spring House, PA, [5]Janssen Global Services, LLC., Malvern, PA, [6]Janssen Research & Development, LLC./U of Penn, Spring House/Philadelphia, PA.

Background/Purpose: A multicenter, randomized, placebo (PBO)-controlled study of golimumab (GLM) was performed in Chinese pts with ankylosing spondylitis (AS). To assess efficacy and safety of golimumab (GLM) through wk56 in Chinese patients with active AS.

Methods: Chinese pts aged >18yrs with a diagnosis of active AS (Bath Ankylosing Spondylitis Disease Activity Index [BASDAI] >4, and a visual analogue scale [VAS] for total back pain >4, each on a scale of 0–10cm) for >3 months prior to screening were eligible for the study. Pts with prior exposure to anti-TNF agents and those with complete ankylosis of the spine were excluded. 213 pts were randomized (1:1) to q4wk subcutaneous (SC) injections of PBO from wks 0 to 20, followed by GLM 50mg from wks 24 to 48 (Group1, n=105) or GLM 50mg from wks 0 to 48 (Group2, n=108). Group1 pts with <20% improvement from baseline in both total back pain and morning stiffness at wk16 were switched to SC GLM 50mg SC q4wks in a blinded fashion (early escape). At wk 24, all remaining PBO pts in Group1 crossed over to SC GLM 50mg q4wks. The primary endpoint for efficacy was the proportion of patients who achieved ASAS20 response (^{3} 20% improvement in the ASsessment in AS [ASAS] criteria) at wk14. Major secondary endpoints included ASAS20 response at wk24,changes from baseline at wk14 in Bath AS Functional Index (BASFI) and Bath AS Metrology Index (BASMI). Other efficacy assessments included health-related quality of life (SF-36 PCS and MCS scores), and sleep (Jenkins Sleep Evaluation Questionnaire, JSEQ) measures. Antibodies to GLM were evaluated at wk52. The last GLM injection was at wk48; final efficacy assessments were at wk52. Safety was monitored through wk56.

Results: Baseline demographics were comparable in the 2 groups; median age was 29yrs, median weight of 62.0kg, and 83.1% were males. ASAS20 at wk14 was achieved by 49.1% of pts in Group2 vs. 24.8% in Group1 (p<0.001). GLM treatment also elicited a significantly better response than PBO in other efficacy parameters assessed, including ASAS20 response at wk24 (50.0% vs. 22.9%; p<0.001) and mean improvements in BASFI (−1.26 vs. 0.113; p< 0.001) and BASMI (−0.42 vs. −0.19; p=0.021) scores at wk14 and SF-36 PCS and MCS and JSEQ at wk14 and wk24. These improvements in clinical symptoms, physical function, range of motion, as well as significant improvements in SF-36 MCS and PCS were further enhanced through the final efficacy assessment at wk52. Through wk16, 31.4% and 30.6% of pts had adverse events (AEs) in Groups1 and 2, respectively. Through wk56, 41.2% of GLM-treated patients reported AEs, and 2.8% reported serious AEs. Through wk56, infections were reported in 20.9% of all GLM-treated pts. One SAE of tuberculosis pleurisy was reported, and the pt recovered. No opportunistic infections or deaths were reported. Antibodies to GLM were not detected in GLM-treated patients through wk52.

Conclusion: GLM significantly reduced AS symptoms/signs and functional limitations and improved health-related quality of life in Chinese pts with active AS. Treatment with GLM was well tolerated and without unexpected safety concerns.

1535

Phenotype Of Patients and Impact Of The Disease In Early Spondyloarthritis Are Similar Regardless The Arm Of The Assessment In Spondyloarthritis International Society Criteria ("imaging" or "clinical") Fulfilled By The Patients. Data From The DESIR Cohort. Anna Molto[1], Simon Paternotte[2], Désirée van der Heijde[3], Pascal Claudepierre[4], Martin Rudwaleit[5] and Maxime Dougados[1]. [1]Paris-Descartes University, APHP, Cochin Hospital, Paris, France, [2]Paris- Descartes University, Cochin hospital, Paris, France, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Henri Mondor Teaching Hospital, AP-HP, Créteil, France, [5]Endokrinologikum Berlin, Berlin, Germany.

Background/Purpose: Patients can fulfil the ASAS (Assessment of SpondyloArthritiS) sets of criteria with either objective evidence of sacroiliac joint damage (X-Ray) or inflammation (MRI): ("imaging" arm) or without such imaging abnormalities in B27 patients ("clinical" arm). The clinical arm is not well recognized by the medical community and the health care systems. The aim of this study was to compare the phenotype but also the impact of the disease on the daily life of the patients with regard to the 2 different arms (e.g. "imaging" versus "clinical") of early spondyloarthritis patients.

Methods: Study design: prospective, multi-centre, observational study. Patients: 708 patients with early inflammatory back pain suggestive of spondyloarthritis have been included in the DESIR cohort. Data collected: demographics, items of the ASAS criteria, disease activity, severity. Statistical analysis: The patients fulfilling the ASAS criteria were split in two groups regarding the presence of imaging (X-ray or MRI) abnormalities of the sacroiliac joints (e.g. imaging arm), and within the clinical arm, with regard to the presence of CRP abnormality (e.g. >6mg/L).

Results: Of the 708 recruited patients, lack of missing data permitted to classify 682 patients according to the ASAS criteria: 206 (30.2%) did not fulfill them; of the 476 (69.8%) remaining patients, 296 (60.1%) and 190 (39.9%) fulfilled the imaging and clinical arm respectively. Comparison in the patients (age, gender, B27 positivity) and disease (clinical presentation, activity and severity) characteristics fulfilling the two arms of the ASAS criteria for axial SpA showed no differences between both groups except in terms of age, gender and CRP: younger patients, more males and higher CRP values in the "imaging" arm. The multiple logistic regression analysis (by including all variables with a p<0.20 in univariated analyses) confirmed the positive association of male gender (OR 1.70 [1.12 – 2.58]) and ASDAS-CRP (OR 2.44 [1.73 – 3.44]) with the "imaging" arm.

Conclusion: This study suggests that despite some differences (e.g. gender, inflammation) the impact of the disease on daily activities were similar in both arms (e.g. imaging vs. clinical) and therefore therapeutical strategies and access to care in disabled patients should be identical regardless the arm of the ASAS criteria they are fulfilling.

Do Patients With Ankylosing Spondylitis Have An Excess Prevalence Of Chronic Widespread PAIN?: Results From The Scotland and Ireland Registry For Ankylosing Spondylitis (SIRAS) and The Musician Study. Fabiola Azeni[1], Marcus Beasley[2], Linda E. Dean[2], Gareth T Jones[2], Jane Gibson[3], Piercarlo Sarzi-Puttini[4] and Gary J. Macfarlane on behalf of SIRAS and MUSICIAN study investigators[2]. [1]Rheumatology Unit, L.Sacco University Hospital, Milan, Italy, [2]University of Aberdeen, Aberdeen, United Kingdom, [3]Fife Rheumatic Diseases Unit, Kircaldy, United Kingdom, [4]Rheumatology Unit, L. Sacco University Hospital, Milan, Italy.

Background/Purpose: To determine whether there is an excess prevalence of chronic widespread body pain (CWP) in patients with Ankylosing spondylitis (AS).

Methods: Patients were participants in the Scotland and Ireland Registry for Ankyolsing Spondylitis (SIRAS), an ongoing study of patients attending secondary care in Scotland who had received a clinical diagnosis of AS. The study collected information on clinical features, including extra-spinal manifestations, BASDAI and BASFI from medical records, and patient-reported data by self-completion questionnaires (including fatigue measured by the Chalder Fatigue Scale (CFS)). Information on CWP was collected by four-view body manikins and required to satisfy the definition used in the ACR 1990 criteria for FM (ACR-CWP) – i.e. chronic pain (>3 months) in 2 contralateral body quadrants, plus axial pain. We believed the reporting of CWP among AS patients would be strongly influenced by spinal disease and, thus, would be difficult to interpret. Therefore, we evaluated the total number of painful body regions reported (up to a maximum of 30) and used an alternative definition for CWP (aCWP) requiring chronic pain in 2 contralateral body quadrants, but excluding pain in the axial skeleton and/or the buttocks. Population data on the prevalence of CWP (using the same definitions) was from the MUSICIAN study, a large two-centre UK population-based study of pain in adults. Prevalence of aCWP was calculated in AS patients and reported as a standardised prevalence ratio (SPR). Relationships with reporting aCWP in the AS population were evaluated by logistic regression and expressed as odds ratios (OR) with 95% Confidence Intervals (95%CI).

Results: The analysis involved 547 AS patients in SIRAS (71% male; median age 52yrs) and a population sample of 14,680 persons from the MUSICIAN study. The majority of the AS patients (89% of those tested) were HLA B27 positive, 81% had documented sacroiliitis, 34% had peripheral joint involvement and 29% had a history of uveitis. 24% had ever been prescribed anti-TNF drugs. The prevalence of ACR-CWP among AS patients was 55.0% The number of non-spine body regions in which pain was reported was significantly higher in AS patients (median=5) than the general population (median=2) (Mann-Whitney $p<0.001$). The prevalence of aCWP was 53.4% and the SPR in AS patients using this alternative definition was (284; 95%CI 260–307). Prevalence of aCWP was higher among women than men (OR: 1.56; 95%CI: 1.07–2.27), and amongst those of lower education (school vs university education 1.89; 1.14–3.14); those unemployed due to ill-health (5.11; 2.57–10.17, vs those in paid employment); and those with a BASDAI or BASFI score ≥4 (3.94; 2.38–6.49, and 3.75; 2.24–6.25, respectively). Similarly, high levels of fatigue (CFS >4) (2.86, 2.01–4.08) and past or current use of anti-TNF agents (1.63; 1.07–2.49) were also associated with aCWP.

Conclusion: The age and sex adjusted prevalence of CWP (using a modified definition more suited to AS patients) was almost three times higher in AS patients than in the general population, and was related to both individual and clinical factors. The identification of such symptoms in AS patients is challenging but important for management.

Primary & Subsequent Orthopedic Surgeries More Common In Juvenile *Vs.* Adult-Onset Ankylosing Spondylitis. Deepak R. Jadon[1], Ramani Arumugam[1], Gavin Shaddick[2], Alison L Nightingale[2], Athimalaipet V Ramanan[3] and Raj Sengupta[1]. [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]University of Bath, Bath, United Kingdom, [3]University of Bristol Hospital Trust, Bristol, United Kingdom.

Background/Purpose: Patients experiencing ankylosing spondylitis (AS) symptoms [2]16 years-of-age are classified as juvenile-onset AS (JoAS), whilst those ≥17 years adult-onset AS (AoAS). We compared JoAS and AoAS cases with respect to proceeding to orthopedic surgery, date and type of surgery, and revisions.

Methods: A cross-sectional observational cohort study was conducted of all AS patients attending a secondary care rheumatology hospital since 1970.

The following were recorded: sex, age at symptom onset, age at diagnosis, *HLA-B27* genotype status, smoking history, peripheral arthritis, psoriasis, uveitis, enthesitis, inflammatory bowel disease, family history of spondyloarthropathy (SpA), and AS-related orthopedic surgery.

Univariate analyses used t-tests and Fisher's exact tests for continuous and categorical variables, respectively. Multivariate analyses were performed using logistic regression with variable selection based on stepwise selection.

Results: 143 JoAS were compared with 411 AoAS patients. At assessment, JoAS were slightly younger than AoAS cases (mean difference 2.9 years), and had slightly longer disease duration since diagnosis (26.0 *vs.*19.3 years). No statistically significant differences were found between the two groups in terms of sex distribution, *HLA-B27* positivity, psoriasis, enthesitis or uveitis.

JoAS cases (n=29/143) were more likely to have had AS-related surgery than AoAS cases (n=29/411) even after adjusting for longer time since diagnosis (p=0.017).

Direct comparisons were then made of JoAS and AoAS cases proceeding to surgery (*Table 1*). No significant difference was found in the disease durations of JoAS and AoAS surgical cases to first surgery (diagnosis to first surgery, p=0.458; or symptom onset to first surgery, p=0.724).

The likelihood of second surgery (of any type) in AoAS cases was significantly less than for JoAS cases (adjusted analysis: OR 0.277; 95% CI 0.078–0.980; p=0.047).

Considering the likelihood of having a second surgery in the AS surgical cohort, smoking (OR 6.559 for ever having smoked *vs.* never smoked; p=0.097) and *HLA-B27* positivity (OR 1.002; p=0.054) were significant predictors.

Considering the likelihood of having a hip procedure (arthroplasty or resurfacing), family history of SpA (OR 0.999; p=0.05) and age of symptom onset (OR 0.997; p=0.09) were significant predictors.

Most AoAS cases had their hip arthroplasty by 20 years disease duration (n=22), thereafter the procedure was infrequent (n=2 of 36 potential native hips).

Table 1.

	SURGERY																
	1st		2nd		3rd		4th		5th		6th		7th		8th		ROW
PROCEDURE	JoAS	AoAS	JoAS	AoAS	JoAS	AoAS	JoAS	AoAS	JoAS	AoAS	JoAS	AoAS	JoAS	AoAS	JoAS	AoAS	TOTALS

Tendon surgery	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
Hip revision	0	0	2	1	8	5	5	2	4	2	4	0	1	0	1	0	35
ACL repair	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
Shoulder hemiarthroplasty	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1
COLUMN TOTALS	29	29	23	17	12	6	7	3	5	2	4	0	1	0	1	0	
COLUMN TOTALS	58		40		18		10		7		4		1		1		139

Conclusion: This is the largest reported study of detailed AS-related orthopedic surgery data comparing JoAS with AoAS cases. JoAS cases were more likely to proceed to surgery, and have had a second surgery, even after adjusting for a longer disease duration. Smoking and *HLA-B27* positivity were predictors of a second surgery; age of symptom onset and family history of SpA were predictors of hip surgery.

The Age At Onset Of Symptoms Influence The Clinical Expression Of The Disease In Patients With Ankylosing Spondylitis. Natalia Zamora, Emilce Edith Schneeberger, Luis Alejandro Cayetti, Fernando Sommerfleck and Gustavo Citera. Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina.

Background/Purpose: The onset of symptoms before 10 years and after 40 years is uncommon in patients with ankylosing spondylitis (AS). Some authors have found specific characteristics in patients with late-onset AS. Objective: To evaluate demographic and clinical characteristics in patients with conventional and late onset AS.

Methods: Consecutive patients with AS (ASAS 2009 criteria) were included. Age at onset of symptoms, demographic and clinical characteristics were recollected. Presence of comorbidities, as well as specific questionnaires to determine disease activity (BASDAI), functional capacity (BASFI), quality of life (ASQoL) and metrology (BASMI) were assessed. Cervical, lumbar and pelvic X-rays were performed yearly and read by a single, blinded observer, according to BASRI. Descriptive statistics was used, the study population was dichotomized into two age groups in terms of symptom's onset: ≤ 40 years and > 40 years. Categorical variables were compared by Chi2 or Fisher exact test and continued variables by T test and ANOVA. Logistic regression analysis using the two age groups as dependent variable was performed to determine associations and to adjust for covariates.

Results: A total of 147 patients were included, 111 (75.5%) were male, with a median age of 46 years (IQR 32–56), median age of onset of symptoms 25 years (IQR 16–23) and median disease duration of 16 years (IQR 8–25). 18 (12.2%) patients had associated psoriasis, 18 were juvenile onset AS, 8 had inflammatory bowel disease associated (IBD), 5 were undifferentiated and the rest 98 (66.7%) had pure AS. 127 (86.4%) of patients had started the disease ≤ 40 years and 20 (13.6%) > 40 years. The group of patients with late onset AS were most often women [11 (45%) vs 27 (21%)], and patients with early onset had longer disease duration 19.4 vs 11.4 yrs p=0.01. After adjusting for these variables, patients in group > 40 showed a higher frequency of psoriasis (45% vs 11.3%), higher disease activity (BASDAI: 5.9 vs 4.4), worse functional capacity (BASFI:5.6 vs 4.1), and quality of life (ASQoL:11.4 vs. 7.2), but less radiological damage (BASRI:6.75 vs 9.27), p values <0.05 for all comparisons.

Conclusion: Patients with late onset AS are more frequently women with psoriasis and have worse indices of disease activity, functional capacity and quality of life. The presence of less radiological damage in this group deserves further investigation.

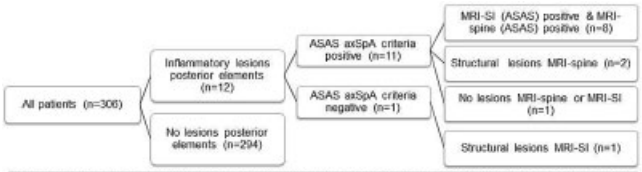
Inflammation In The Posterior Elements Of The Spine Is Infrequent In Patients With Recent Onset Axial Spondyloarthritis, Especially If No Inflammation In The Vertebral Bodies Is Observed. Rosaline van den Berg[1], Manouk de Hooge[1], Monique Reijnierse[1], Victoria Navarro-Compán[1], Karen Fagerli[2], Maureen Turina[3], Maikel van Oosterhout[4], Roberta Ramonda[5], Floris van Gaalen[1], Tom Huizinga[1] and Désirée van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [4]GHZ Hospital, Gouda, Netherlands, [5]University of Padova, Padova, Italy.

Background/Purpose: There is evidence that in almost all patients with longstanding and active ankylosing spondylitis (AS) inflammatory lesions in the posterior elements are as frequent as in the anterior spine[1]. Therefore, it was argued that assessment of posterior structures should be embedded in routine diagnostic MRI assessment of the spine in patients with established AS or suspected of having AS[1]. However, little is known about the prevalence of lesions in the posterior elements in patients with recent onset axial spondyloartritis (axSpA). We investigated the prevalence of inflammatory lesions in the posterior elements in patients with and without inflammation in the vertebral bodies in patients with recent onset axSpA and patients with possible axSpA.

Methods: Patients with back pain (≥3 months, ≤2 years, onset <45 years) visiting the rheumatology outpatient clinics of the five participating centers were included in the SPondyloArthritis Caught Early (SPACE)-cohort (n=345). During the diagnostic work-up, all patients underwent MRI of the spine (MRI-spine). MRIs-spine were scored by 3 independent readers according to the ASAS consensus definition[2] and the Canada-Denmark score[3,4], including assessment of posterior elements[1]. The ASAS consensus definition states that evidence of anterior/posterior spondylitis in ≥3 sites is highly suggestive of axSpA. Therefore, we used a cut-off of ≥3 inflammatory lesions to mark an MRI-spine positive. Definite lesions were considered present if 2/3 readers agreed on it.

Results: Only patients with complete MRI-spine data were included in this analysis (n=306), of which 126 patients fulfilled the ASAS axSpA criteria[5]. In total, only 12/306 patients (3.9%) had inflammatory lesions in the posterior elements; 8 of them (66.7%) fulfilled the ASAS axSpA criteria (imaging-arm) and had also a positive MRI-spine. The remaining 4 patients (33.3%) had lesions in the posterior elements but no inflammatory lesions in the vertebral bodies, yet two out of four had signs of structural lesions (≥3 fatty lesions). Three out of these four patients fulfilled the ASAS axSpA criteria via the clinical-arm. The remaining patient had signs of structural lesions in the SI-joints (MRI) plus 3 other SpA-features (inflammatory back pain, good response to NSAIDs and elevated CRP and ESR) and has a clinical diagnosis of SpA by the rheumatologist.



Flow chart of the patients with inflammatory lesions in the posterior elements. Structural lesions on MRI-spine defined as ≥3 fatty lesions. Structural lesions on MRI-SI defined as ≥5 structural lesions (fatty lesions, erosions, sclerosis and/or ankylosis).

Conclusion: The prevalence of inflammatory lesions in the posterior elements in the SPACE-cohort is low, suggesting that assessment of inflammatory lesions in the posterior elements in addition to the vertebral bodies gives only limited extra information in patients with recent onset axSpA and possible axSpA.

Sustained Clinical Remission In Patients With Non-Radiographic Axial Spondyloarthritis After Two Years Of Adalimumab Treatment. Joachim Sieper[1], Dominique L. Baeten[2], Filip Van den Bosch[3], Suchitrita S. Rathmann[4], Jaclyn K. Anderson[5] and Aileen L. Pangan[4]. [1]Charité Universitätsmedizin Berlin, Campus Benjamin-Franklin, Berlin, Germany, [2]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [3]Gent University Hospital, Gent, Belgium, [4]AbbVie Inc., North Chicago, IL, [5]AbbVie, North Chicago, IL.

Background/Purpose: Adalimumab (ADA) is currently approved in the EU for the treatment of severe non-radiographic axial spondyloarthritis (nr-axSpA), in patients (pts) with an elevated CRP and/or positive MRI who have had an inadequate response to, or are intolerant to NSAIDs. Short-term and 1 year (yr) remission data have been previously reported for the ABILITY-1 trial. The objective of this analysis was to determine drug survival and durability of clinical remission at yr 2 among pts with nr-axSpA.

Methods: ABILITY-1 is an ongoing phase 3, double blind (DB), randomized, controlled trial in pts with nr-axSpA who had an inadequate response, intolerance, or contraindication to NSAIDs. A 12-wk DB period of ADA 40 mg every other week (eow) or placebo (PBO) was followed by an open-label (OL) extension phase in which pts could receive OL ADA 40 mg eow for up to an additional 144 wks. This *post hoc* analysis evaluated the wk 104 efficacy and safety of ADA in the MRI+/CRP+ nr-axSpA subpopulation, defined as pts who had a positive baseline (BL) MRI (SPARCC score ≥2 for either the SI joints or spine) or an elevated CRP at BL. Clinical remission was defined by ASDAS inactive disease (ASDAS ID, ASDAS <1.3) or by ASAS partial remission (ASAS PR). Sustained remission was defined as achieving clinical remission at wks 52, 80, and 104. Clinical responses were summarized by observed case analysis. Safety was assessed in terms of adverse events (AE).

Results: 142 (69 ADA, 73 PBO) of the total efficacy population (N=185) were in the MRI+/CRP+ subpopulation; 107 (75%) had data available for wk 104 analysis. The table lists clinical response and sustained remission rates for the MRI+/CRP+ subpopulation. Sustained remission rates were similar between pts with symptom duration <5 vs. ≥5 years (sustained ASDAS ID 38% vs. 31%; sustained ASAS PR 26% vs. 29%). Among pts exposed to ADA during the study (356.2 patient-yrs [PY] of exposure) there were 8

serious infections (2.2/100 PY, including 1 case of disseminated TB), 1 case of lupus-like syndrome, and 2 deaths (suicide and cardiopulmonary failure due to opiate toxicity). No malignancies or demyelinating diseases have been reported.

Table. Clinical Responses in MRI+/CRP+ Subpopulation (Completers Analysis)[a]

	Week 104 (N=107) (%)	Sustained Remission at Weeks 52, 80 and 104 (%)
ASAS20	82	–
ASAS40	66	–
BASDAI50	69	–
ASDAS inactive disease	49[b]	35[d]
ASAS partial remission	44[c]	28[e]

[a]Data as observed. [b]N=105, [c]N=104; [d]N=101 and [e]N=102 pts with available data at wks 52, 80 and 104.

Conclusion: Almost half of the pts who remained on long-term ADA therapy in ABILITY-1 were in remission at wk 104, the majority of whom were also in this state of remission at wks 52 and 80. Long-term safety data are comparable to the known AE rates with ADA in other rheumatology indications.

Spinal Mobility Gets Impaired In a Fixed Order In Patients With Ankylosing Spondylitis: 12-Year OASIS Results. Sofia Ramiro[1], Robert Landewé[2], Désirée van der Heijde[3], Carmen Stolwijk[4], Maxime Dougados[5], Filip Van den Bosch[6] and A.M. van Tubergen[4]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center Amsterdam & Atrium Medical Center, Heerlen, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Maastricht University Medical Center, Maastricht, Netherlands, [5]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France, [6]Gent University Hospital, Gent, Belgium.

Background/Purpose: Spinal mobility is impaired in patients with ankylosing spondylitis (AS) compared to normal subjects. However, the extent of impairment and the relative contribution of different measures are unknown. We investigated which spinal mobility measures are most frequently impaired in patients with AS and whether a hierarchy for the impairment of the measures could be established.

Methods: Patients from the Outcome in AS International Study (OASIS) were followed-up for up to 12 years in which spinal mobility was regularly measured (measures detailed in Table). From a previous study in normal subjects (1), percentile curves (2.5th to 97.5th) were obtained for each of the spinal mobility measures (Figure). We added 4 parallel curves representing z-scores of 2.5, 3, 3.5 and 4 respectively (helplines a to d) to be able to plot impaired measures. For every observation, and taking patient's age into account, each of the spinal mobility measures was defined as impaired if the measurement fell below each of the cutoffs (2.5th percentile and each of the 4 helplines). The proportion of observations and also of patients (using baseline observation) in which each of the spinal mobility measures was impaired according to each of the cutoffs was calculated. Analyses were repeated in strata according to gender, symptom duration (median and tertiles) and baseline number of syndemophytes (0 vs ≥1 and <5 vs≥5).

Results: A total of 216 patients were included (70% males, mean (SD) age 44(13) years, mean symptom duration 21(12) years and 85% HLA-B27 positive). Lateral spinal flexion (LSF) was always the most frequently impaired measure, sequentially followed by Schober's, tragus-to-wall, cervical rotation, intermalleolar distance (IMD) and chest expansion (CE) (Table). This order was strikingly similar at both the observation-level and the patient-level (baseline observations only) as well as for all cutoffs (with the only exception being the 2.5th percentile, for which CE was slightly more impaired than IMD). Even with stratifications did this hierarchy in general persist.

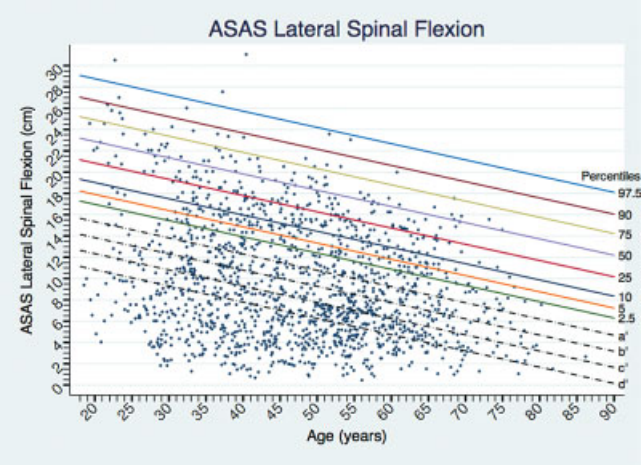

Figure. Lateral spinal flexion in function of age and with the percentile curves and help-lines derived from the normal subjects measurements.

Table. Impairment of each of the spinal mobility measures in patients with AS compared to cutoffs derived from mobility in normal subjects

	Below 2.5th percentile n (%)	Below Helpline a n (%)	Below Helpline b n (%)	Below Helpline c n (%)	Below Helpline d n (%)	Total number of observations (N)
OBSERVATION LEVEL (ALL OBSERVATIONS)						
ASAS Lateral Spinal Flexion (cm)	1052 (73)	933 (64)	818 (57)	673 (47)	321 (22)	1447
10-cm Schober's test (cm)	906 (58)	745 (48)	609 (39)	480 (31)	294 (19)	1551
Tragus-to-wall distance (cm)	679 (44)	532 (34)	363 (23)	*	*	1550
Cervical rotation (degrees)	486 (31)	382 (25)	300 (19)	236 (15)	187 (12)	1555
Intermalleolar distance (cm)	343 (22)	220 (14)	161 (10)	97 (6)	62 (4)	1543
Chest expansion (cm)	412 (27)	151 (10)	37 (2)	5 (0)	1 (0)	1548

*Not possible to derive these values due to mathematical characteristics of the equation for the percentile curves for tragus-to-wall distance.

Reference:

(1) Ramiro et al. Arthritis & Rheumatism 64(12):4173–4174

Conclusion: LSF and Schober's are the most frequently impaired mobility measures in AS, reflecting an earlier involvement of lumbar spine in spinal mobility impairment, followed by the involvement of the thoracic and cervical spine. This fixed order of involvement of the spine persists across different patient groups.

Regular Exercise Is Associated With Better Functional Outcomes In Ankylosing Spondylitis. Lianne S. Gensler[1], John D. Reveille[2], MinJae Lee[3], Mohammad Rahbar[3], Manouchehr Ardjomand-Hessabi[4], Matthew A. Brown[5], Michael H. Weisman[6] and Michael M. Ward[7]. [1]University of California, San Francisco, San Francisco, CA, [2]University of Texas Health Science Center at Houston, Houston, TX, [3]The University of Texas Health Science Center at Houston, Houston, TX, [4]The University of Texas, Health Science Center at Houston, Houston, TX, [5]University of Queensland Diamantina Institute, Brisbane, Australia, [6]Cedars-Sinai Med Ctr, Los Angeles, CA, [7]NIAMS/NIH, Bethesda, MD.

Background/Purpose: Exercise and physical therapy are the cornerstones of non-pharmacologic therapy in Ankylosing Spondylitis. The long-term association of exercise on function has not been evaluated. The

purpose of this study was to assess the role of regular exercise in longitudinal functional outcomes in AS patients.

Methods: This is a prospective cohort of 611 AS patients, meeting the modified New York criteria followed up to 4 years. We collected demographic, clinical and self-reported outcomes every 6 months. Exercise data were also collected every visit, including how many days per week patients exercised. Regular exercise was defined as greater than or equal to 3 times per week. Functional outcomes were assessed by the Bath Ankylosing Spondylitis Functional Index (BASFI). Using mixed models, we assessed univariable associations between independent variables and functional outcome (BASFI) that accounted for correlation of repeated measures over time. Potential confounding and effect modifications were examined and addressed while developing a final longitudinal multivariable model.

Results: There were 611 patients included with a mean age of 41.1 years (SD= 13.6). The cohort comprised 71% males and 76% of patients were white. Mean Disease duration was 17.6 years (SD=13.5). Table 1 shows the univariable associations between BASFI and each independent variable from the longitudinal models. After adjusting for potential confounders, including age, gender, education level, employment status, race, past AS-related joint surgery, occupation, smoking, TNF inhibitor use, disease activity by the Bath Ankylosing Spondylitis Activity Index (BASDAI), disease damage by the baseline modified Stoke Ankylosing Spondylitis Spine Score (mSASSS), depression by the Center for Epidemiologic Studies Depression Scale (CES-D), and past joint involvement, the effect of regular exercise on BASFI remained significant ($p < 0.0001$) over time. Figure 1 shows the adjusted means of BASFI by exercise group over time.

Table 1. Univariable Association between BASFI and other variables

	Mean BASFI										
	Baseline		Year 1		Year 2		Year 3		Year 4		*p*-

Patients With Ankylosing Spondylitis Are Substantially Undertreated For Hypertension and Hypercholesterolemia. Sjoerd C. Heslinga[1], Inge A.M. van den Oever[2], Alper M. van Sijl[2], Irene E. Van der Horst-Bruinsma[1] and Michael. T. Nurmohamed[2]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands.

Background/Purpose: Patients with ankylosing spondylitis (AS) have a decreased life expectancy due to an increased cardiovascular (CV) risk. The general inflammatory process is held responsible together with an increased prevalence of traditional risk factors such as hypertension and hypercholesterolemia. We investigated the prevalence of these CV risk factors in AS patients and whether these are treated according to the present guidelines.

Methods: We evaluated CV risk factors in all patients (n=290) eligible for treatment with TNF inhibitors. All patients fulfilled the New York 1984 criteria for AS. Hypertension was defined as systolic blood pressure (SBP) >140 mmHg and/or diastolic blood pressure (DBP) >90 mmHg. Overweight was defined as body mass index (BMI) >25 kg/m^2. Hypercholesterolemia was defined as LDL> 2.5 mmol/L. The 10- year estimated cardiovascular risk was calculated with the Dutch multidisciplinary guideline for cardiovascular risk management. It is expressed as the risk percentage (%) for cardiovascular events in the next ten years.

Results: More than 40% of patients smoked at baseline compared to 27% in the general Dutch population. Overweight was present in 144 (50%) of patients compared to 26% in the general Dutch population. Of 187 patients the cardiovascular risk could be calculated. Hundred sixty-four patients (88%) had low cardiovascular risk (<10%). Twenty-three patients (12%) had a medium or high cardiovascular risk (>10%). Eleven of these patients (48%) were treated with either antihypertensive agents or statins. In addition, four patients had SBP >180 mmHg, of which two were on antihypertensive agents and four patients had a total cholesterol/HDL ratio of >8, of which one was treated with statins.

Fifty-one out of 270 patients (19%) were on antihypertensive medication on baseline, of which 15 (29.4%) were inadequately treated as they still had higher BPs than treatment targets. Twenty-six out of 270 patients (10%) were on statin treatment, of which 9 (35%) were inadequately treated as they still had higher LDL levels than recommended (>2.5 mmol/L).

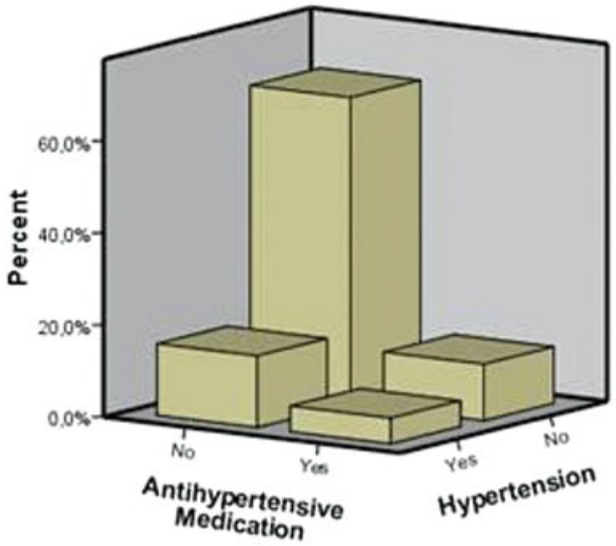

Figure 1. Treatment of AS patients with antihypertensive medication.

Conclusion: One in five AS patients were treated for hypertension and one in ten for hypercholesterolemia. Of these patients approximately one third did not reach the treatment targets. Over half of AS patients with medium to high cardiovascular risk were not treated at all. Obviously, there is an impressive under treatment of cardiovascular risk factors in AS. Hence, more attention for screening as well as proper management of cardiovascular risk factors in patients with AS is urgently needed to lower the cardiovascular risk.

Good Agreement Between The Ankylosing Spondylitis Disease Activity Scores Based On C-Reactive Protein and Erythrocyte Sedimentation Rate. Dilek Solmaz[1], Pinar Cetin[1], Ismail Sari[1], Merih Birlik[2], Servet Akar[1], Fatos Onen[1] and Nurullah Akkoc[1]. [1]Dokuz Eylul University School of Medicine, Izmir, Turkey, [2]Dokuz Eylul University School of Medicine, izmir, Turkey.

Background/Purpose: Recently, ASDAS has been developed as a disease activity measuring tool for ankylosing spondylitis (AS), using a similar methodology to that used for the development of the Disease Activity Score (DAS) in rheumatoid arthritis. Two versions of ASDAS have been proposed, one based on CRP (preferred) and the other based on ESR (alternative).In the light of recent reports showing substantial difference between the two versions of DAS28, it is of interest to assess the agreement between the two ASDAS versions at individual level. Our aim is to assess the agreement between the ESR and CRP-based ASDAS scores in AS patients.

Methods: Data were obtained from the local clinical database which contains slightly over 500 AS patients. Patients with full data at baseline were included in this analysis. Mean ASDAS-CRP and ASDAS-ESR values were compared by Spearman correlation and scatter plot with linear regression analysis. Bland-Altman analysis and kappa statistics were used to assess the agreement between the two ASDAS definitions in the whole group as well as in different gender and age groups.

Results: 396 patients (291 M; 44 ±12.0 years) were identified with complete data at baseline for this analysis. Mean (±SD) disease duration was 9.4 (±8.2) years. Mean (±SD) BASDAI, BASFI and BASMI scores were 3.5 (±2.2), 2.9 (±2.6), 3.9 (±1.9), respectively. HLA B27 was positive in 65% of the patients of whom 83.7% were using NSAIDs and 20.7% were using TNF inhibitors. Mean (±SD) ASDAS scores, based on CRP and ESR were 2.9 (± 1.1), and 2.8 (± 1.0), respectively. There was a strong correlation between the two definitions by Spearman's correlation test ($r=0.9$, $p<0.001$) and linear regression analysis ($R^2=0.82$, $p<0.001$). The agreement was good for both genders and all age groups with weighted kappa values ranging from 0.680 to 0.876 (Table 1). Similar number of patients was classified into the defined categories of disease activity with ASDAS-CRP and ASDAS-ESR (Table 2). Bland-Altman analysis showed excellent agreement between the two scores (ASDAS-CRP – ASDAS-ESR) with a mean difference (bias) of −0.0 ± 0.48 (95% CI −0.04, −0.047). Upper and lower limits of agreement were 0.95 (95% CI 0.87, 1.03) and −0.95 (95% CI −1.03, −0.87), respectively. Mean difference was 0.20 ± 0.49 in females and −0.10 ± 0.44 in males.

Table 1. The correlation and agreement between ASDAS-CRP and ASDAS-ESR values in different gender and age groups

Patient group	Mean ASDAS-CRP	Mean ASDAS-ESR	Spearman correlation coeficient r	Spearman correlation coeficient P	Agreement rate	Kappa value	Weighted kappa value
Females (n=104)	2.8 ± 1.1	3.1 ± 1.0	0.906	<0.001	64.4%	0.455	0.680
Males (n=292)	2.9 ± 1.1	2.7 ± 1.0	0.923	<0.001	73.6%	0.618	0.803
≤40 years old (n=163)	3.0 ± 1.1	2.9 ± 1.0	0.918	<0.001	69.7%	0.549	0.790
41–60 years old (n=193)	2.7 ± 1.1	2.8 ± 1.0	0.888	<0.001	70.5%	0.561	0.740
≥61 years old (n=40)	3.0 ± 1.2	3.0 ± 1.0	0.954	<0.001	74.4%	0.672	0.876
Overall (n=396)	2.9 ± 1.1	2.8 ± 1.0	0.906	<0.001	70.0%	0.567	0.760

Table 2. Agreement between ASDAS-CRP and ASDAS-ESR on the classification of the patients into different categories of disease activity

		ASDAS CRP <1.3	1.3–2.0	2.1–3.5	>3.5	Total
ASDAS ESR	<1.3	13	5	2	0	20
	1.3–2.0	17	40	19	0	76
	2.1–3.5	6	19	137	25	187
	>3.5	0	0	22	91	113
	Total	36	64	180	116	396

Conclusion: The results suggest a good agreement between ASDAS-ESR and ASDAS-CRP for both genders and all age groups.

Serum Periostin: a New Marker Of Local Bone Formation In Early Inflammatory Back Pain: results From The DESIR Cohort. Karine Briot[1], Simon Paternotte[1], Didier Borderie[2], Corinne Miceli-Richard[3], Maxime Dougados[1] and Christian Roux[1]. [1]Paris Descartes University, Paris, France, [2]Paris Descartes UNiversity, Pris, France, [3]Université Paris-Sud 11, Bicêtre Hospital, Kremlin Bicêtre, France.

Background/Purpose: Periostin is a secreted, homodimeric protein that is synthesized by mesenchymal cells of the periosteum, which is involved in osteoblast homeostasis of the periosteum and could be one of the mediators of local bone formation in response to mechanical stress and/or inflammation. Our hypothesis is that periostin could be involved in the syndesmophyte formation in spondyloarthritis. The objective was to assess the relationships between serum periostin levels, bone formation regulators (sclerostin, Dickkof-1 (DKK-1)) and presence of syndesmophyte, in a cohort of early inflammatory back pain (IBP) suggestive of axial spondyloarthritis.

Methods: The DESIR cohort is a prospective, multicenter French cohort of patients with early IBP (Calin or Berlin criteria) (>3 months and <3 years of duration) suggestive of axial SpA, including 708 patients. All SpA patients were naive of any TNF blocker at inclusion in the study. Serum periostin levels were assessed at baseline in the whole cohort by sandwich enzyme-linked immunosorbent assay (ELISA) (Nordic Biosite, Sweden). Demographic characteristics, disease activity parameters, bone mineral density measurements were assessed at baseline and 2 years. DKK-1 and SOST serum levels (by sandwich ELISA), radiographs and MRI of axial skeleton (spine and sacroiliac joints) were performed at baseline. Correlations between serum periostin levels with baseline and 2 year variables were tested.

Results: Serum periostin was available in 701 patients (mean age 33.7±8.6 years, 46.2% of males). Mean (±SD) serum level of periostin was 396.5±461.4 pg/mL. Levels were higher in men (431.5±486.5 pg/mL) than in women (366.4 ±113.7 pg/mL) and decreased with age. Patients with at least one syndesmophyte at baseline had a lowest level of serum periostin than patients without syndesmophytes (222.4 ±286.5 ng/ml vs 412.89 ±471.3 ng/ml, respectively, $p=0.021$). There was a significant correlation between serum periostin levels and baseline sclerostin levels ($r=-0.09$; $p=0.02$) and baseline DKK-1 levels ($r=-0.12$; $p=0.002$). Serum periostin levels were weakly correlated with 2-year changes in disease activity parameters: CRP ($p=-0.1$; 0.027), ESR ($r=-0.14$; $p=0.002$), BASDAI ($r=-0.12$; $p=0.003$) and ASDAS CRP ($r=-0.18$; $p=\leq 0.0001$). We did not find any difference between patients with and without the presence of bone marrow oedema on MRI. Serum periostin was not correlated with low BMD ($Z\leq -2$ at at least one site) and was not a predictor of significant bone loss (decreased in BMD ≥0.03g/cm at at least one site).

Conclusion: This study conducted in a large cohort of patients with early axial SpA shows that low serum level of periostin is associated with local bone formation. Periostin is correlated to serum sclerostin and DKK-1 levels and parameters of inflammation. Relationship between serum periostin and formation of new syndesmophyte will be studied using the 2-year centralized analysis of X-rays and MRI.

Patient-Reported Outcomes of Etanercept in Early Non-Radiographic Axial Spondyloarthritis: A 12-Week, Randomized, Double-Blind, Placebo-Controlled Trial. Maxime Dougados[1], Wen-Chan Tsai[2], Diego Luis Saaibi[3], Randi Bonin[4], Jack Bukowski[4], Ronald Pedersen[4], Bonnie Vlahos[5] and Sameer Kotak[6]. [1]Paris-Descartes University, APHP, Cochin Hospital, Paris, France, [2]Chung-Ho Memorial Hospital, Kaohsiung, 807, Taiwan, [3]MEDICITY S.A.S, Bucaramanga, Santander 681001, Colombia, [4]Pfizer Inc, Collegeville, PA, [5]Pfizer Inc., Collegeville, PA, [6]Pfizer Inc., New York, NY.

Background/Purpose: Limited data are available on the efficacy of anti-TNF agents in non-radiographic axial spondyloarthritis (nr-axSpA). This analysis compares the impact of etanercept (ETN) vs placebo (PBO) on patient-reported outcomes (PROs), after 12 weeks of double-blind treatment in patients (pts) with nr-axSpA who had an insufficient response to NSAIDs.

Methods: Enrolled pts satisfied ASAS criteria for axSpA, had symptom duration of 3 months-5 years and a BASDAI score ≥4 despite current NSAID use. Pts were randomized to ETN 50 mg weekly or PBO with concomitant background NSAIDs. The primary clinical endpoint was ASAS40 at week

12. PROs included BASDAI, BASFI, BAS-G, Work Productivity and Activity Index-Ankylosing Spondylitis (WPAI-AS), Multidimensional Fatigue Inventory (MFI), Nocturnal back pain VAS, total back pain VAS, subject assessment of disease activity (SGA), Short Form (SF-36), Medical Outcomes Study (MOS)-Sleep, Patient Acceptable Symptom State (PASS), Minimal Clinically Important Improvement (MCII), EuroQol (EQ)-5D and Hospital Anxiety and Depression Screening (HADS). ANCOVA models were used with baseline score, treatment, region and SI status as variables. LOCF was used for missing data.

Results: At baseline, MFI general scores (14.7, 15.0 [ETN, PBO]), EQ-5D utility scores (0.52, 0.57), EQ-5D VAS scores (56.5, 56.4) and MOS Sleep Index II scores (45.5, 48.1) were worse than population norms (6.6–8.0[1], 0.86[2], 82.5[3] and 25.8[4], respectively). By week 12, more pts achieved ASAS40 with ETN50 than PBO (32% vs. 16%, P=0.006).[5] By week 12 significant improvements favoring ETN50 vs. PBO were seen in stiffness, joint pain, ease of standing from an armless chair, ease of physically demanding and full-day activities, looking over the shoulder, reaching up high, putting on socks and SGA ($p<0.05$ for all, Table). Mean WPAI presenteeism, SF-36 bodily pain and MOS-sleep quantity favored ETN50 ($P<0.05$), as did the proportion of pts with MCII ($p=0.0458$). Non-significant improvements for ETN50 vs. PBO were seen in bending forward from the waist, WPAI, MFI, MOS-Sleep Problems Index I and II, HADS, EQ-5D and SF-36 total scores ($P>0.05$ for all).

Table. Improvements from baseline to week 12 in PROs (observed cases), adjusted mean change (95% CI)

	ETN50 + NSAID (n=106)	PBO + NSAID (n=109)

Average back pain VAS	−2.01 (−2.70, −1.32)†	−0.98 (−1.64, −0.32)†
Subject assessment of disease activity	−2.12 (−2.76, −1.47)†	−1.19 (−1.81, −0.58)†

*P <0.05 for ETN50 vs. PBO at week 12; †P<0.01 for ETN50 vs. PBO at week 12.

1. Schwarz, R., et al. Onkologie, 2003. **26**(2): p. 140−4. 2. Dolan, P., Med Care, 1997. **35**(11): p. 1095−108. 3. Kind, P., G. Hardman, and S. Marcran, eds., Centre for Health Economics, University of York: York. 4. Hays, R.D., et al., Sleep Med, 2005. **6**(1): p. 41−4; 5. Dougados M. et al. Ann Rheum Dis. 2013; 72 (suppl. 3): Abstract #21799.

Conclusion: The data show substantial improvements in PRO measures for disease specific and functional domains such as BASDAI, BASFI, BAS-G, and pain, but limited improvement on general PRO measures such as sleep, fatigue and general health. Short disease duration, a short placebo-controlled period, and a wide range of PRO scores at baseline may have influenced relative improvements.

How The Delay In Diagnosis Impacts On The Clinical, Functional and Radiographic Status Of Patients With Ankylosing Spondylitis. Is There a Window Of Opportunity?

luis Alejandro Cayetti[1], Emilce Schneeberger[1], Natalia Zamora[2], Fernando Sommerfleck[2] and Gustavo Citera[2]. [1]Instituto de Rehabilitacion Psicofisica, Buenos Aires, Argentina, [2]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina.

Background/Purpose: The delay in diagnosis has deleterious effects in patients with Rheumatoid Arthritis. This fact has not been fully investigated in patients with Ankylosing Spondylitis (AS). Objective: To determine the influence of the delay in the diagnosis, over the clinical, functional and radiographic status in patients with AS.

Methods: Consecutive patients ≥ 18 yrs old with AS (ASAS 2009 criteria) were included. Demographic, clinical and therapeutic aspects of the disease were collected prospectively in our AS outpatient clinic. Specific questionnaires to determine disease activity (BASDAI), functional capacity (BASFI), quality of life (ASQoL), metrology (BASMI) are performed every 6 months. Cervical, lumbar and pelvic X-rays are performed yearly and read by a single, blinded observer, according to BASRI. Delay in diagnosis was assessed as a continuous variable and expressed as median (IQR), but also patients were divided in 3 groups according to the delay in diagnosis. Group 1: ≤ 3 yrs, Group 2: > 3 ≤ 10 yrs, and Group 3: ≥ 10 yrs. Differences were assessed by ANOVA, Chi Square test and multiple regression analysis adjusting for confounders and propensity scores. Dichotomous dependent variable was set using extreme categories (G1 vs. G3).

Results: 147 patients were included, 111 (75.5%) were male, median age 46 yrs (IQR 18–35). Median time delay for the diagnosis was 5 yrs (IQR 2–13). 62 patients (42.4%) belong to group 1 (≤ 3 yrs), 36 (24.5%) to group 2, and 49 (33.3%) to group 3. Patients with juvenile onset were less frequently observed in group 1 (16.7%) as compared to other groups ($p=0.01$). Patients in G1, were significantly older at the time of diagnosis as compared to the other groups (30 yrs, 23 yrs and 22 yrs respectively, $p=0.02$). Presence of tarsitis was more frequent in G1 (58% vs. 25% $p=0.01$). Gender, comorbidities, NSAID, DMARD and biologic treatment were comparable between groups. After a median follow-up time of 12 years and after adjusting for disease duration, BASDAI, BASFI, ASQoL, and BASMI were comparable between groups. There was only a tendency, not reaching statistical significance of a greater BASRI in group 3.

Conclusion: We did not observed that the delay in diagnosis has had a major impact in functional capacity, quality of life or radiographic damage in our cohort of patients with AS.

Effect Of TNF Inhibitors On Bone Mineral Density In Patients With Ankylosing Spondylitis- a Systematic Review and Meta-Analysis.

Nisha Nigil Haroon[1], Jeevitha Srighanthan[2], Nayef AL Ghanim[1], Robert D. Inman[3] and Angela Cheung[1]. [1]University of Toronto, Toronto, ON, [2]University of Toronto, Ontario, ON, [3]Toronto Western Hospital, Toronto, ON.

Background/Purpose: Patients with ankylosing spondylitis (AS) are susceptible to osteoporosis (OP) and have high fracture risk. Currently, no specific strategies are established to treat OP in these patients. TNF inhibitors are now increasingly used for treating AS. If TNF inhibitors are shown to prevent or reverse bone loss, use of bisphosphonates can be avoided. We did a systematic review and meta-analysis to study the effect of TNF inhibitors on spine and hip BMD in patients with AS.

Methods: Two authors searched MEDLINE, EMBASE & Cochrane databases, reviewed abstracts, and extracted data. A third author resolved discrepancies. Eligible studies had at least 70% of subjects satisfying Modified New York AS criteria and a minimum follow-up of 1 year. Case reports and studies on children and adolescents were excluded. The quality of the studies was assessed by Newcastle–Ottawa Quality Assessment Scale. Primary outcomes (BMD at spine, hip & femoral neck) were analyzed at 1 and 2 years. BMD was expressed as the percent change from baseline. Publication bias was assessed by Funnel plots. Statistical heterogeneity was assessed using Q statistic. The overall summary estimate was determined using the random effects model, which was weighted by the inverse variance of the effect size.

Results: Our search was narrowed down to 8 studies (7 observational studies and 1 RCT). BMD data available from 470 patients were included in the meta-analysis. Most subjects were males and their proportion varied from 70–92%. Mean age at enrolment ranged from 36–48 years, and mean disease duration was 9–17 years. Bisphosphonate use was negligible. Little data was available on intake of calcium and vitamin D. The use of TNF inhibitors led to significant improvement in spine and total hip BMD after 1 and 2 years when compared to baseline (Table 1). Femoral neck BMD remained stable at 1 year. The BMD gain was also significant in those treated with TNF inhibitors when compared to controls. In the RCT (TNF inhibitors vs. placebo), the gain in BMD was significantly higher in those treated with TNF inhibitors for 2 years versus those treated with placebo for the first 6 months.

Table 1. Summary estimates of the effect of TNF inhibitors on BMD in patients with AS

Duration of follow up (Years)	Lumbar spine Mean difference, % (95% CI)	Total hip Mean difference, % (95% CI)	Femoral neck Mean difference, % (95% CI)
1 year	5.1 (4.0–6.1)	1.8 (1.0–2.5)	0.73 (−0.8–2.2)
2 years	8.6 (6.8–10.3)	2.5 (1.9–3.0)	Insufficient data

Conclusion: Treatment with TNF inhibitors is associated with improvement in spine and hip BMD in patients with AS. More studies of longer duration and larger sample sizes are needed to better understand the effect of TNF inhibitors on fracture risk.

1549

Prevalence Of Syndesmophytes In Patients With Chronic Back Pain Suspected Of Axial Spondyloarthritis (axSpA) Not Fulfilling The Modified New York (mNY) Criteria. Manouk de Hooge[1], Rosaline van den Berg[1], Floris van Gaalen[1], Monique Reijnierse[1], Victoria Navarro-Compán[1], Karen Fagerli[2], Maureen C. Turina[3], Maikel van Oosterhout[4], Roberta Ramonda[5], Tom Huizinga[1] and Désiréé van der Heijde[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [4]GHZ Hospital, Gouda, Netherlands, [5]University of Padova, Padova, Italy.

Background/Purpose: The mNY criteria[1], which indicate sacroiliitis of at least grade 2 bilaterally or grade 3 or 4 unilaterally, are used to classify patients as Ankylosing Spondylitis (AS). However, little is known about the occurrence of syndesmophytes in the spine in the absence of radiographic sacroiliitis. Therefore we want to investigate if syndesmophytes are prevalent in patients with chronic back pain suspected of axSpA who are not fulfilling the mNY criteria and if syndesmophytes should be included in criteria to define patients as having radiographic axSpA.

Methods: Patients with back pain (≥3 months, ≤2 years, onset ≤45 years) recruited from the 5 participating centres across Europe were included in the SPondyloArthritis Caught Early (SPACE)-cohort. All patients underwent conventional radiographs of the cervical and lumbar spine and sacroiliac (SI)-joints (X-spine and X-SI, respectively). X-spine was scored on the presence or absence of ≥1 syndesmophytes, X-SI was scored according to the mNY[1]. X-rays were scored independently by 3 well-calibrated readers. Lesions on x-ray were considered present if 2/3 readers agreed.

Results: All patients with both X-spine and X-SI data available (n=302) were used for comparison. There were 26 patients (8.6%) fulfilling the mNY criteria and 7 patients (2.3%) with ≥1 syndesmophytes present in the spine. None of those 7 patients showed radiographic sacroiliitis nor active lesions on MRI of the SI joints. Two patients fulfil the ASAS axSpA criteria and 5 patients had SpA features without fulfilling the ASAS axSpA criteria. In table 1 the number and location of syndesmophytes and SpA features are presented. Most patients (n=5) had 1 syndesmophyte. The two patients with >1 syndesmophytes did not fulfil the ASAS axSpA criteria. All patients had syndesmophytes located solely in the cervical part of the spine. None of the patients had psoriasis. Only 2/302 (0.7%) patients would be considered as having signs of radiographic axSpA if syndesmophytes (in absence of radiographic sacroiliitis) would be considered a sign of radiographic involvement.

There were 2 patients (*italic* in table) in whom corresponding syndesmophytes on the MRI of the spine were scored by both readers.

No. of synd.	Location of synd.	No. of SpA features	SpA features	ASAS axSpA criteria
1	cervical	2	IBP+ESR	no
1	cervical	2	IBP+NSAIDs	no
1	cervical	4	IBP+NSAIDs+HLA-B27+pos. fam. hist.	yes
1	cervical	4	IBP+NSAIDs+HLA-B27+pos. fam. hist.	yes
1	*cervical*	*7*	*IBP+NSAIDs+heel pain+dact.+IBD+ ESR+peripheral arthritis*	*no*
2	cervical	2	IBP+NSAIDs	no
3	*cervical*	*1*	*HLA-B27*	*no*

IBP; inflammatory back pain, ESR; elevated erythrocyte sedimentation *rate* and/or C-reactive protein, NSAIDs; good response to non-steroidal anti-inflammatory drugs, HLA-B27; Human Leukocyte Antigen B27, pos. fam. hist.; positive family history, dact; dactylitis, IBD; inflammatory bowel disease.

Conclusion: In this population, syndesmophytes in patients without sacroiliitis on radiographs and MRI are infrequent and solely located in the cervical spine. Indicating that syndesmophytes are not informative in classifying patients as having radiographic axSpA in early disease.

Validation Of The Ankylosing Spondylitis Disease Activity Score and Effectiveness Of Infliximab In The Treatment Of Ankylosing Spondylitis Over 4 Years: The Canadian Experience. Proton Rahman[1], Denis Choquette[2], Majed M. Khraishi[3], William G. Bensen[4], Saeed A. Shaikh[5], Dalton E. Sholter[6], Maqbool K. Sheriff[7], Emmanouil Rampakakis[8], John S. Sampalis[8], Francois Nantel[9], Susan M. Otawa[9], Allen J. Lehman[9] and May Shawi[9]. [1]Memorial University, St. Johns, NF, [2]Institut de Rhumatologie de Montréal, Montreal, QC, [3]MD, Memorial University of Newfoundland, Nexus Clinical Research, St Johns, NF, [4]St. Joseph's Hospital and McMaster University, Hamilton, ON, [5]McMaster University, St Catharines, ON, [6]Rheumatology Associates, Edmonton, AB, [7]Nanaimo Regional General Hospital, Nanaimo, BC, [8]JSS Medical Research, St-Laurent, QC, [9]Janssen Canada Inc, Toronto, ON.

Background/Purpose: The efficacy of anti-TNF in the management of Ankylosing Spondylitis (AS) has been demonstrated in numerous controlled clinical trials. The objective of this study is to assess in Canadian routine clinical practice the 4-year outcomes in patients with AS treated with infliximab (IFX) and the performance of Ankylosing Spondylitis Disease Activity Score (ASDAS), a new disease activity measure in AS.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with infliximab or golimumab as first biologics or after having been treated with a biologic for less than six months. People with AS treated with infliximab who were enrolled between 2005 and 2012 were included in this analysis. Descriptive statistics were produced for clinical outcome measures and patient reported outcomes at baseline and follow-up assessments over four years. Within-group changes were assessed for statistical significance with the paired-samples Student's t-test. The correlation of ASDAS with BASDAI and BASFI was assessed with the Pearson correlation coefficient. The correlation of these measures with MDGA was assessed with the Spearman's rho.

Results: A total of 230 AS patients who had at least one follow-up assessment were included in this analysis, with a mean (SD) age of 45.7 (11.5) years and mean (SD) disease duration since diagnosis of 10.0 (10.1) years. Among these, 167, 116, 74, and 38 had a 12-, 24-, 36-, and 48-month assessment, respectively. At the time of enrollment in the registry, mean (SD) patient parameters were: C-reactive protein (CRP) = 16.9 (20.2) mg/dL, erythrocyte sedimentation rate (ESR) = 25.8 (20.2) mm/hr, morning stiffness = 74.6 (40.2), health assessment questionnaire (HAQ-DI) = 1.20 (0.61), physician global assessment of disease activity (MDGA) = 6.6 (1.9), BASDAI = 6.4 (2.1), BASFI = 6.1 (2.5), and ASDAS = 3.8 (1.0). By 6 months of treatment significant improvements ($P<0.01$) were observed in all clinical and patient outcome parameters studied, which were sustained or further enhanced over 48 months of treatment.

Similar significant changes were observed in ASDAS, BASDAI, and BASFI over time providing evidence of construct validity and sensitivity to change. A strong positive linear correlation between ASDAS and BASDAI ($r=0.85$; $P<0.001$) and BASFI ($r=0.76$; $P<0.001$) was observed. The correlation of MDGA was strong with ASDAS ($rho=0.73$; $P<0.001$) and BASDAI ($rho=0.70$; $P<0.001$) and moderate with BASFI ($rho=0.64$; $P<0.001$).

By 12, 24, 36, and 48 months 66%/72%/77%/75% achieved Clinically Important Improvement in ASDAS ($\Delta \geq 1.1$) and 37%/49%/47%/50%, achieved ASDAS Major Improvement ($\Delta \geq 2.0$), respectively. The proportion of patients with very high disease activity (ASDAS > 3.5) decreased from 62.4% at baseline to 6.9% at 48 months.

Conclusion: The results of this Canadian, longitudinal, real-world observational study demonstrate that treatment with infliximab over four

years is effective in reducing symptom severity and improving outcomes in patients with AS. Furthermore, the data from this registry confirm the validity and sensitivity to change of the ASDAS score in a real-world AS cohort.

The Minimum Clinically Important Improvement and Patient Acceptable Symptom State In Basdai and BASFI For Patients With Ankylosing Spondylitis. Milla Kviatkovsky[1], Sofia Ramiro[2], Robert Landewé[2], Florence Tubach[3], Maxime Dougados[4] and D. van der Heijde[5]. [1]Nova Southeastern University, Miami, FL, [2]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [3]Universite Paris Diderot, Paris, France, [4]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France, [5]Leiden University Medical Center, Leiden, Netherlands.

Background/Purpose: The minimum clinically important improvement (MCII) and patient acceptable symptom state (PASS) are clinically relevant measures that report the patient response and condition. We aimed at estimating the MCII and PASS cut-off values for BASDAI and BASFI in patients with Ankylosing Spondylitis (AS).

Methods: A multinational study including patients with AS receiving NSAIDs for 4-weeks has been used to define PASS and MCII, by using external anchor questions for patient global assessment for BASDAI and functional impairment for BASFI. For PASS, patients were asked to consider the ways AS has affected them during the last 48 hours and if this would be an acceptable state for the rest of their life. Patients who answered "acceptable" met criteria for PASS analysis. For MCII, patients were asked to compare how they felt in the past 48 hours to the start of the study. Secondly, if they felt improved, to consider how important the improvement was. Those reporting moderate or slightly important improvement met criteria for MCII analysis. Subgroup analysis was performed for gender, age, baseline BASDAI and BASFI scores, disease duration, HLA-B27 status and presence/history of SpA extra-articular manifestations. Continuous variables were stratified according to the median value. For MCII in BASDAI, a separate analysis was done on patients with a baseline BASDAI≥4 to represent patients recommended to receive treatment in clinical practice. The 75th percentile approach was used to establish cut-off values.

Results: 283 patients with AS (76% males, 64% HLA-B27 positive, mean (SD) age: 43(14) years and mean disease duration: 13(10) years) were included. Mean baseline BASDAI and BASFI values were 5.0 and 4.6 respectively. Cut-off values for PASS values were 4.1 for BASDAI and 3.8 for BASFI (Table 1). The MCII cut-off was an absolute change of 0.7 BASDAI and 0.4 in BASFI. Subgroup analyses revealed differences between groups if stratified for age, disease duration and baseline value, with differences larger for PASS than MCII. For the sub-analysis of the patient group with a baseline BASDAI score ≥4, the MCII was 1.1 in BASDAI and 0.6 in BASFI for absolute change.

Table 1. MCII/PASS for BASDAI and BASFI with Subgroup Analysis

	BASDAI				BASFI			
	PASS		MCII		PASS		MCII	
	N	Value (95% CI)	N	Value (95% CI)	N	Value (95% CI)	N	Value (95% CI)
Overall Cut Off Values	176	4.1 (3.8, 4.4)	113	0.7 (0.4, 1.0)	165	3.8 (3.5, 4.1)	95	0.4 (0.2, 0.6)
Stratified Analysis								
Women	40	4.2 (3.5, 4.8)	27	0.5 (0.0, 1.0)	34	3.5 (2.7, 4.3)	25	0.5 (0.0, 0.9)
Men	136	4.1 (3.8, 4.4)	87	0.7 (0.4, 1.0)	130	3.8 (3.5, 4.1)	70	0.4 (0.1, 0.7)
HLA B27 Positive	121	4.1 (3.8, 4.4)	75	0.6 (0.3, 0.9)	117	3.8 (3.4, 4.2)	57	0.4 (0.1,0.7)
HLA B27 Negative	28	4.1 (3.5, 4.7)	15	0.5 (0.0, 1.3)	23	3.5 (3.4,4.2)	16	0.7 (0.0, 1.4)
Age ≤41.4 years	79	4.0 (3.6, 4.4)	53	0.7 (0.3, 1.1)	74	2.9 (2.5, 3.3)	49	0.4 (0.0, 0.8)
Age > 41.4 years	91	4.2 (3.8, 4.6)	60	0.5 (0.1, 0.9)	85	4.8 (4.3, 5.3)	46	0.5 (0.2, 0.8)
Disease Duration≤11yrs	82	3.5 (3.1, 3.9)	52	0.8 (0.4,1.2)	83	3.2 (2.8, 3.6)	51	0.5 (0.2, .8)
Disease duration >11 yrs	89	4.4 (4.1, 4.7)	56	0.5 (0.2, .8)	78	4.5 (4.1, 4.9)	39	0.4 (0.0, .8)
Baseline score <median[a,b]	101	3.1 (2.8, 3.4)	50	0.5 (0.2, 0.8)	102	2.9 (2.7, 3.1)	50	0.3 (0.1, .5)
Baseline score≥median[a,b]	76	4.8 (4.4, 5.2)	64	1.2 (0.8, 1.6)	64	5.8 (5.2, 6.4)	50	0.6 (.2,1.0)
Patients with Baseline BASDAI ≥ 4								
Cut Off Values	115	4.5 (4.2, 4.8)	88	**1.1 (0.8, 1.4)**	103	4.6 (4.2, 5.0)	**73**	**0.6 (0.3, 0.9)**

[a]: median Baseline BASDAI = 4.9 [b]: median baseline BASFI = 4.6

Conclusion: PASS for both BASDAI and BASFI are highly variable based on important patient characteristics such as age, disease duration and baseline value. Frequently the PASS value is even higher than the recommended cut-off for start of treatment. Therefore, no uniform PASS can be proposed and this makes this instrument less useful. This applies similarly to the MCII but to a lesser extent. As MCII will mostly be applied in patients who start with new treatment (and a BASDAI ≥4), we recommend a cut-off value for MCII of 1.1 for BASDAI and 0.6 for BASFI.

Effective Prevention Of New Osteitis On Magnetic Resonance Imaging In Patients With Early Axial Spondyloarthritis During 3 Years Of Continous Treatment With Etanercept - Data Of The Esther Trial. In-Ho Song[1], Kay-Geert A. Hermann[2], Hildrun Haibel[3], Christian Althoff[4], Denis Poddubnyy[3], Joachim Listing[5], Anja Weiss[6], Ekkehard Lange[7], Bruce Freundlich[8], Martin Rudwaleit[9] and Joachim Sieper[10]. [1]Charité Universitätsmedizin Berlin, Campus Benjamin Franklin, Berlin, Germany, [2]Charité Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany, [3]Charité Universitätsmedizin Berlin, Berlin, Germany, [4]Charite Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany, [5]German Rheumatism Research Center, Berlin, Germany, [6]German Rheumatism Research Centre, Berlin, Germany, [7]Pfizer Pharma AG, Berlin, Germany, [8]University of Pennsylvania, Philadelphia, PA, [9]Endokrinologikum Berlin, Berlin, Germany, [10]Charité Universitätsmedizin Berlin, Campus Benjamin-Franklin, Berlin, Germany.

Background/Purpose: In patients with early axial spondyloarthritis (SpA) with a disease duration of < 5 years and evidence of active inflammation on whole-body magnetic resonance imaging (wb-MRI) in the spine and/or sacroiliac (SI-) joints at baseline [1] we assessed the degree of fluctuation of active inflammation (bone marrow edema/ osteitis) on MRI during treatment with 3 consecutive years with etanercept (ETN).

Methods: In the previously reported ESTHER trial axial SpA patients were treated with ETN (n= 40) versus sulfasalazine (SSZ) (n= 36) in the first year [1]. All patients who were not in remission at week 48 (n=48) were either continuously treated with ETN, or sulfasalazine treatment was switched to ETN treatment. Wb-MRIs of those 40 patients who reached the end of year 4 were scored for active inflammation (osteitis) in the SI-joint quadrants and spine vertebral units (VUs). We here analysed MRI data in terms of osteitis in the pooled data set of 40 patients who were continously treated with ETN for 3 consecutive years. Data were analysed as observed. Scoring was performed by two radiologists, blinded for treatment arm and MRI time point. For this analysis, the presence or absence of osteitis were only counted if both scorers agreed.

Results: At baseline there were 136 SI-joint quadrants with osteitis (according to both scorers). At year 2 osteitis disappeared in 50% of quadrants (68/136), at year 3 osteitis disappeared in 41% (56/136) of quadrants and osteitis disappeared at both year 2 and 3 in 32% (44/136).

In the spine at baseline 37 vertebral units (VUs) showed osteitis. Of these at year 2 osteitis disappeared in 65% (24/37), at year 3 in 57% (21/37) and in both year 2 and 3 in 51% (19/37).

Of the SI-joint quadrants which did not show osteitis (according to both scorers) at baseline (n= 131) the rate of new development of osteitis was 4% (5/131) at year 2; 7% (9/131) at year 3 and only 1.5% (2/131) at both year 2 and 3.

Of the spine vertebral units which did not show osteitis at baseline (n= 843) the rate of new development of osteitis was 0.8% (7/843) at year 2; 1.3% (11/843) at year 3 and 0.4% both at year 2 and 3.

The mean osteitis spine score (range 0–69) decreased from 1.6 (standard deviation 3.4) at baseline to 0.7 (1.4) at year 2 and 0.9 (1.8) at year 2. The mean SI-joint score (range 0–24) decreased from 6.8 (6.1) at baseline to 2.0 (2.2) at year 2 and 2.2 (2.5) at year 3.

Conclusion: There was a consistently effective suppression of osteitis on MRI in patients with early axial SpA and only a very low rate of new onset of osteitis during 3 years of continous treatment with etanercept. Whether this also prevents the occurrence of bone proliferation has to be proven by longer follow-ups.

Responsiveness Of Health Related Quality Of Life Questionnaires To Treatment With Anti-TNF Therapy In Psoriatic Arthritis. Zahi Touma, Arane Thavaneswaran, Vinod Chandran and Dafna D. Gladman. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Patient-reported outcomes (PRO) on Health Related Quality of Life (HRQoL) are increasingly used to assess responsiveness after treatment. This study aimed to determine the ability of different PRO to asses responsiveness in psoriatic arthritis (PsA) after the initiation of anti-TNF therapy.

Methods: A retrospective analysis was conducted on all PsA patients followed at the PsA clinic who had started and continued anti-TNF therapy and had at least 1 year of follow up.

PRO questionnaires administered at baseline and follow up visits included: patient global assessment (PGA) [very good, good, fair, poor and very poor], Short-Form 36 (SF-36), Health Assessment Questionnaire (HAQ), Functional Assessment of Chronic Illness Therapy (FACIT), Fatigue Severity Scale (FSS), EuroQol-5D (EQ-5D) and Dermatology Life Quality Index (DLQI). PGA after treatment was used as an external anchor to group the patients as: Improved, same or worse.

Ceiling and floor effects were checked at baseline and follow up visits. Distribution-based methods (effect size [ES], standardized response mean [SRM], Guyatt's responsiveness statistic [GRS]) and anchor-based methods (Spearman correlation of the change scores of PRO) were used to assess responsiveness.

A priori hypothesis was that moderate to large responsiveness scores would be observed for the patients who improved or worsened.

Results: 223 patients with active PsA (62% male and 90% Caucasian) were identified. Disease duration at baseline visit was 12.9 (9.2). At follow up visit, 70 patients improved, 126 remained the same and 27 worsened based on PGA.

Ceiling effect: 1) At baseline, a ceiling effect was identified for HAQ, and 3 domains of SF-36 (Role Physical, Social Functioning and Role Emotional) and 2) At follow up, a ceiling effect was identified for HAQ, 4 domains of SF-36 (Physical Functioning, Role Physical, Social Functioning and Role Emotional) and DLQI.

Floor effect: At baseline and follow up, a floor effect was identified for 2 domains of SF-36 (Role Physical and Role Emotional).

In particular SF-36, FACIT, DLQI and FSS indicated moderate to large responsiveness in the patients who improved and worsened (SRM 0.51–1.07 and Guyatt 0.64–3.06). A small SRM (0.25) was observed for HAQ in patients who improved. HAQ and FACIT were not responsive for patients who worsened.

At follow up, strong correlation was observed between the change scores: 1) Δ FACIT and Δ FSS ($r = -0.82$, $p = 0.007$) in patients who improved and 2) Δ FACIT and Δ HAQ ($r = -0.91$, $p = 0.004$) and Δ EQ-5D and Δ SF-36 MCS (0.80, $p = 0.02$) in patients who worsened.

Conclusion: SF-36 and DLQI are responsive questionnaires able to capture improvement and worsening in response to treatment based on patient judgment.

HAQ is extremely nonresponsive and EQ-5D was the worst responsive compared to the other questionnaires. FACIT was responsive and superior to FSS for measuring fatigue in patients who improved on biologics but not for measuring worsening. A larger sample size is needed to decide on the exclusion of either FACIT or FSS.

Real-World Effectiveness Of Infliximab In The Treatment Of Psoriatic Arthritis Over 12 Months: The Canadian Experience. Proton Rahman[1], Majed M. Khraishi[2], William Bensen[3], John T. Kelsall[4], Brian D. Hanna[5], Craig Watts[6], Emmanouil Rampakakis[7], John S. Sampalis[7], May Shawi[8], Susan M. Otawa[8] and Allen J. Lehman[8]. [1]Memorial University, St. Johns, NF, [2]MD, Memorial University of Newfoundland, Nexus Clinical Research, St Johns, NF, [3]St. Joseph's Hospital and McMaster University, Hamilton, ON, [4]Mary Pack Arthritis Centre, Vancouver, Vancouver, BC, [5]McMaster University, Ontario, Kitchener, ON, [6]McGill University and Montreal General Hospital, Sainte-Anne-de-Bellevue, QC, [7]JSS Medical Research, St-Laurent, QC, [8]Janssen Canada Inc, Toronto, ON.

Background/Purpose: The efficacy of anti-TNF in the management of psoriatic arthritis (PsA) has been demonstrated in numerous controlled clinical trials. Longitudinal observational studies assessing the real-world effectiveness of anti-TNF agents are essential in order to demonstrate the true benefits. The objective of this study was to assess in Canadian routine clinical practice the 12-month outcomes in patients with PsA treated with infliximab.

Methods: Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with infliximab or golimumab as first biologics or after having been treated with a biologic for less than six months. People with PsA treated with infliximab who were enrolled between 2005 and 2012 were included in this analysis. Descriptive statistics were produced for clinical outcome measures and patient reported outcomes at baseline and six or twelve months of treatment. Within-group changes were assessed for statistical significance with the paired-samples Student's t-test.

Results: A total of 92 PsA patients were included in the analysis. Mean (SD) age of the patient cohort was 48.7 (9.9) years and mean (SD) duration since diagnosis was 6.8 (9.1) years. The majority of patients were male (52.2%). Upon six months of treatment, statistically significant ($P<0.05$) and clinical meaningful improvements were observed in all parameters analyzed, which were sustained over 12 months of treatment. Mean (SD) patient parameters at baseline and 12 months of treatment were: PASI: 3.3 (5.6) vs. 1.3 (2.2), $P=0.009$; DAS28-CRP: 4.0 (1.3) vs. 2.8 (1.3), $P=0.002$; C-reactive protein (CRP): 13.0 (18.9) vs. 8.2 (12.5) mg/L, $P=0.196$; erythrocyte sedimentation rate (ESR): 21.4 (22.7) vs. 12.9 (15.4) mm/hr, $P=0.171$; morning stiffness: 58.1 (45.3) vs. 40.0 (43.1) min, $P=0.020$; tender joint count (TJC28): 5.9 (5.3) vs. 3.0 (4.7), $P=0.001$; swollen joint count (SJC28): 4.0 (3.8) vs. 1.9 (3.7), $P=0.001$; health assessment questionnaire (HAQ-DI): 1.15 (0.66) vs. 0.86 (0.77), $P=0.001$; patient global assessment of disease activity (PtGA): 5.0 (2.8) vs. 3.5 (2.9) cm, $P=0.005$; physician global assessment of disease activity (MDGA): 5.8 (2.2) cm vs. 2.6 (2.3), $P<0.001$; pain: 46.4 (25.6) vs. 33.1 (28.5) mm, $P=0.013$.

Conclusion: The results of this Canadian longitudinal observational study have shown that a significant burden of illness is observed at initiation of infliximab in PsA patients in routine clinical practice. Treatment with infliximab was effective in reducing symptom severity and improving outcomes in patients with PsA over 12 months.

Anti-TNF Drug Survival In Psoriatic Arthritis Patients Treated In Ordinary Clinical Practice. Glenn Haugeberg[1], Andreas P. Diamantopoulos[1], Agnete Gulati[2], Mari Hoff[3] and Arthur Kavanaugh[4]. [1]Hospital of Southern Norway Trust, Kristiansand, Norway, [2]St. Olavs Hospital, Trondheim, Norway, [3]St Olavs Hospital, Trondheim, Norway, [4]University of California San Diego, San Diego, CA.

Background/Purpose: The use of TNF-inhibitors in psoriatic arthritis (PsA) has been shown to improve clinical and radiographic outcome in randomized controlled trials (RCT) and shown to be well tolerated with a rather low rate of drop outs. However, patients in RCT may not be representative of patients followed in ordinary clinical practice. The aim was to assess drug survival of TNF-inhibitor treatment in patients with PsA treated in an ordinary rheumatology clinic in Norway.

Methods: The PsA patients were recruited from an ordinary rheumatology clinic in Norway. All PsA patients in this clinic are monitored and outcome measures and drug data is registered in a clinical hospital computer database. In the database termination and/or change of therapy had been registered. A survival analysis (Kaplan-Meyer) was performed and survival time for sequential therapeutic regimens were compared by Wilcoxon test. Anonymised data was analyzed using SPSS.

Results: We identified 148 patients with PsA who started treatment with their first TNF-inhibitor (from 2002 through 31.12.2012). During the first year of therapy 52 (35%) of these patients stopped treatment. 54 patients started their second and 22 patients started their third or more TNF-inhibitor, and within the first year 33 (61%) and 12 (55%), respectively, stopped treatment. The rate of patients who stopped treatment was highest in the beginning and lover during follow up. This was also seen for the second and $\geq 3^{rd}$ TNF

inhibitor. Overall drug survival was significantly higher for the first TNF-inhibitor compared to the second drug ($p<0.001$). The median survival time for the first, second and subsequent drug was 24, 7, and 9 months.

Conclusion: In an ordinary clinic setting, patients with PsA have a significantly reduced drug survival for the subsequent TNF-inhibitor if they fail on the first drug. For each drug, the first year of treatment had the highest termination rate.

Paradoxical Psoriasis: Experience Of a Biological Therapy Monographic Unit. Maria Luz Garcia Vivar[1], Silvia Perez Barrio[2], EVA Galindez Agirregoikoa[3], Catalina Gomez Arango[4], Jose Francisco Garcia Llorente[5], Rosa Izu Belloso[6], Esther Ruiz Lucea[5], Ignacio Torre Salaberri[7] and Jesus Maria Careaga Alzaga[8]. [1]Rheumatology department, Basurto University Hospital., BILBAO, Spain, [2]Dermatology Department. Basurto University Hospital, BILBAO, Spain, [3]Rheumatology Department. Basurto University Hospital, BILBAO, Spain, [4]Rheumatology Department, Basurto University Hospital, Bilbao, Spain, [5]Rheumatology Department, Basurto University Hospital, BILBAO, Spain, [6]Dermatology Department. Basurto University Hospital. Bilbao, BILBAO, Spain, [7]Rheumatology Department. Basurto University Hospital, Bilbao, Spain, [8]Dermatology department. Basurto University Hospital, BILBAO, Spain.

Background/Purpose: Anti TNF therapy's efficacy in controlling cutaneous psoriasis has widely been proven, but development of paradoxical psoriasis (PPs) as a side effect can occur. We define psoriasis as a paradoxical effect when it appears as new onset or as a different type of psoriatic lesion; some authors also include worsening of previous psoriasis, when it is clearly related with the treatment.

Methods: We reviewed the medical records from the 371 patients visited in the biological therapy monographic unit and from 150 pateients visited in the psoriatic arthropathy multidisciplinar clinic during 2011 and 2012. We selected 13 patients with suspected paradoxical psoriasis and we analyze clinical data, characteristics and severity of skin lesion, and the change in treatment required to control skin lesion.

Results: From the 13 selected patients, two presented flares of their skin lesions related to the underlying diagnosis of PsA with severe cutaneous disease prior to biological treatment. Therefore, 11 patients fulfilled the previously exposed criteria for PPs; six female and 5 male, mean aged 47 years (from 34 to 78). 7 patients had had no previous psoriatic lesions: 5 were diagnosed with ankylosing spondylitis (one negative HLA B27), one with rheumatoid arthritis and one with juvenile idiopathic arthritis (an adult patient). The remaining 4 patients were mixed forms of PsA, 3 of them had positive HLA B27.

The treatment involved was adalimumab in 7 patients, infliximab in two patients, and etanercept in the remaining two. PPs appeared between 2 and 38 months from the start of the biological therapy (mean 9 months), in 8 patients during the first year of the treatment.

PPs in two patients consisted of desquamative annular lesions that were confirmed by skin biopsy procedure. 7 patients had palmoplantar pustulosis, 4 presented skinfold psoriasis, 4 had scalp lesions, and 6 plaque psoriasis. 7 presented a mixture of different types of cutaneous psoriatic lesions.

The injury was considered mild in 4 cases managed with topical corticosteroid treatment, and moderate to severe in six patients that had to discontinue biologic therapy. Another one needed tapering of the dose of etanercept from 50 to 25 mgs per week. After discontinuation, 4 patients needed a new biological drug (three antiTNF and one ustekinumab), with no cutaneous complication. Skin evolution was satisfactory to improvement in all cases, with practical resolution in two.

Conclusion: Paradoxical psoriasis is a rare complication appearing in less than 3% of our patients under biological therapy. Although it can occur in patients with any diagnosis and receiving any kind of antiTNF drug, we find it more frequently in those patients with spondyloarthropaties during the first year of treatment with monoclonal antibodies. It may be an important and disabling side effect, but withdrawal of the biological drug is not always needed. Switching to another antiTNF when needed seems also a safe therapeutic decision with satisfactory outcomes.

Assessing The Real Life Impact Of Psoriatic Arthritis On Disability, Quality Of Life, and Provider Satisfaction. M. Elaine Husni[1], Daniel Duch[2] and Neil J. Korman[3]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Curatio CME Institute, Exton, PA, [3]University Hospitals Dermatolo, Cleveland, OH.

Background/Purpose: Despite the availability of more targeted therapies for psoriatic arthritis (PsA), an assessment of the impact these have had on patient well-being has not recently been undertaken. We investigated a real world perspective on patient disability, quality of life (QoL), and patient encounters with various health care providers (HCP).

Methods: A cross sectional analysis of data were derived from a 52-question survey on the effect of PsA on the QoL, daily activities, work, patient satisfaction with treatment and physician care was included. The survey was distributed by the National Psoriasis Foundation (NPF) to its members with a prior diagnosis of PsA by a HCP. The survey was developed using validated questionnaires (PDRQ-9, PASE and HAQ20) and also collected information on PsA disease severity and treatment.

Results: 773 survey responses were collected after distribution to 9,336 NPF members (6.7% response rate); 144 responses were removed due to incomplete data. Based on the epidemiologic features of PsA from the medical literature, this survey of 629 PsA patients was representative of other patients with this disease in the US (margin of error, 3.9%)The average age at diagnosis was 41.7±13 years. Comorbidities, PASE and HAQ20 scores for patients in the survey were consistent with those reported in the medical literature. The average HAQ20 disability index score, 0.98±0.66 (Maximum score = 3, highest level of disability) reflects a moderate to severe level of disability. Higher HAQ20 and PASE scores were associated with higher disability, pain and worse overall status. Overall (scale of 0 –very well to 100 –very poor), patients averaged 43.6±28.2 with females statistically worse than males. A majority of patients (61.7%) reported that they were unable to work some days due to their health. A mean of 66.6±104.5 work days (median 15) were missed in the last year; 89.4% of days missed resulted from joint/pain problems.

The most common HCP was a rheumatologist (35.5%; n=223); the proportion of patients treated only by a dermatologist or only by a PCP was 12% (n=76) for each. The PDRQ-9 satisfaction rating for a rheumatologist (36.8) was 22% higher ($P\leq0.001$) than the rating for a PCP (30.1) but not different from dermatologists (33.7). Several patient factors appear correlated with these differences, including the number of prescription drugs and psoriasis severity scores.

Patients rated satisfaction with their treatment on a 5-point scale (1=Very Unsatisfied, 5=Very Satisfied). Etanercept had the highest satisfaction rating and cyclosporine A was lowest. Ratings for the 5 most frequently used treatments reported were:

Etanercept (n=138): 3.93±1.33; very satisfied (VS): 50%
Adalimumab (n=144): 3.48±1.52; VS: 37%
Methotrexate (n=204): 3.45±1.43; VS: 30%
Infliximab (n=51): 3.12±1.58; VS: 26%
Sulfasalazine (n=46): 2.50±1.63; VS: 17%
cyclosporine A (n=19): 2.32±1.46; VS: 6%

Conclusion: Survey results suggest that PsA may be a very aggressive disease and that despite new targeted treatments, many patients are still not doing too well. Limitations do exist with survey methodology however, results may be used to improve patient outcomes and generate critical measures for further study such as provider satisfaction.

Drug Trends In Psoriatic Arthritis. Arane Thavaneswaran[1], Gideon Kalman-Lamb[1], Teneille Loo[2], Vinod Chandran[1] and Dafna Gladman[1]. [1]University of Toronto, Toronto Western Hospital, Toronto, ON, [2]University of Toronto, Toronto, ON.

Background/Purpose: Psoriatic arthritis (PsA) is now recognized as a potentially severe form of arthritis which requires aggressive medical therapy. The aim of this study was to determine trends in drug usage among patients with PsA followed longitudinally.

Methods: 1229 patients with PsA were included from an observational cohort from 1978 to 2013. Descriptive statistics at baseline were conducted to characterize the study population. Comparisons of medication use by decade

(1970–1980, 1980–1990, 1990–2000, 2000–2010, 2010 onwards) were made for NSAIDS (Non-steroidal anti-inflammatory drugs), DMARDs (Disease Modifying Anti-Rheumatic Drugs) and Biologics were conducted frequencies and trend tests.

Results: Demographics at baseline: 56% males with mean (s.d.) age of 44 (13.1) years, disease duration 6.8 (8.2) years, PASI of 5.9 (8.1), active joint count of 11.0 (9.9), and 57% with radiographic damage [modified Steinbrocker score 12.7 (25.2)]. Medication use at baseline: 79% of the patients on NSAIDs, 51% on DMARDs and 7% on Biologics. Over follow-up 89% of the patients took NSAIDs with the highest frequency of use on Indomethacin (43%), Naproxen (40%) and Diclofenac (30%). Of the 75% treated with DMARDs, mostly Methotrexate (MTX) 54% orally and 26% parenterally), sulfasalazine (26%) Leflunomide (14%). 29% were on biologics, most commonly Etanercept (20%) adalimumab 9% and golimumab 4%. There was a clear trend towards decreased NSAID use (p-value<0.0001) but increased DMARD and Biologics use by decade (<0.0001) (Table 1 & 2).

Table 1. Frequency of Medication Use at Baseline by Decade

	DECADE					
MEDICATION	1970–1980	1980–1990	1990–2000	2000–2010	2010 & on	p-value
NSAIDs	41 (71.9%)	240 (87.0%)	214 (84.6%)	375 (73.7%)	40 (66.7%)	<0.0001
DMARDs	25 (45.6%)	118 (42.8%)	129 (52.0%)	276 (54.2%)	35 (55.6%)	0.12
BIOLOGICs	0 (0%)	1 (0.4%)	0 (0%)	55 (11.3%)	16 (25.4%)	<0.0001

Table 2. Combination of Medication use by Decade

	DECADE					
MEDICATION	1970's	1980's	1990's	2000's	2010's	p-value
None	12 (21.1%)	27 (9.5%)	27 (10.6%)	80 (15.5%)	8 (12.7%)	0.27
NSAIDs only	19 (33.3%)	140 (49.1%)	98 (38.6%)	146 (28.3%)	14 (22.2%)	<0.0001
DMARDs +/− NSAIDs	26 (45.6%)	117 (41.1%)	129 (50.8%)	235 (45.5%)	25 (39.7%)	0.73
BLGs +/−DMARDs +/− NSAIDs	0 (0%)	1 (0.4%)	0 (0%)	55 (10.7%)	16 (25.4%)	<0.0001

Conclusion: Medication use over the past four decades shows reduced NSAID use but increased DMARD and Biologics use as the severity of PsA was recognized.

ACR/ARHP Poster Session B
Systemic Lupus Erythematosus - Clinical Aspects II: Central Nervous System Manifestations, Therapeutics
Monday, October 28, 2013, 8:30 AM–4:00 PM

1559

Cyclophosphamide and Rituximab Combination Treatment For Severe Systemic Lupus erythematosus is Effective and Well Tolerated. Ali Shahzad[1], Farheen Jafri[2], Bisharah Rizvi[2], Xiongce Zhao[3], Meryl Waldman[3] and Sarfaraz A. Hasni[4]. [1]NIAMS/NIH, Bethesda, MD, [2]R-Research, Hamilton, NJ, [3]NIDDK/NIH, Bethesda, MD, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD.

Background/Purpose: Systemic lupus erythematosus (SLE) is often complicated by resistance or partial response to initial immunosuppressive regimen and flares after initial response. Optimal management of these patients is unclear due to lack of scientific evidence. There is limited data suggesting that the combination of cyclophosphamide (CYC) and rituximab (RTX) may have efficacy in recurrent and treatment resistant lupus. We present our experience with intravenous (IV) CYC plus RTX combination and its comparison to CYC only therapy.

Methods: Data from SLE patients who were treated with IV CYC monotherapy only or IV CYC and RTX combination from 2000–2013 was retrospectively reviewed. Patient's demographic information, SLE duration, SLE manifestations, co-morbidities, relevant labs, response to therapy and post-treatment infections were recorded every month for the first 6 post –treatment months and then every 3 months up to 60 months (if available) or until last data entry. Patients with incomplete data or insufficient follow-up(less than 6 months post-treatment) were not included. IV CYC monotherapy was given according to the NIH standard protocol for the treatment of lupus nephritis. IV CYC and RTX combination therapy regimen consisted of simultaneous administration of IV CYC and 2 doses of RTX 1000 mg given 15 days apart. Combination regimen was prescribed based on clinician's discretion most commonly for recalcitrant or recurrent flares of lupus nephritis(LN). Predetermined definitions (based on published literature) were used to record flares (renal vs. non-renal) and response (complete, partial or no response). Statistical analysis was done using SAS software (SAS Inc., Cary, NC).

Results: A total of 43 SLE pts. with adequate follow up were identified: 31 (72%) received CYC; 12 (28%) received CYC plus RTX. Indications for combination treatment were partial response or recurrent LN (10/12), CNS lupus(1/12) and treatment resistant extra-renal SLE(1/12). Most (75%) patients treated with CYC and RTX combo were previously treated with IV CYC, most commonly for lupus nephritis. There was no difference in overall survival between CYC only and CYC and RTX combo groups. In patients receiving combo treatment, median duration of follow –up was 36 months (6–50 months) prior to combo treatment and 21 months (6–60 months) after receiving the combo treatment. In the 12 patients who received CYC plus RTX, number of flares before receiving CYC and RTX combo was significantly higher= 38(Renal flares=26; non-renal flares=12) as compared to after receiving combo=13(Renal=3; non-renal=10). There was no significant increase in bacterial, viral or fungal infections after receiving combo therapy.

Conclusion: CYC and RTX combination regimen may have efficacy in reducing renal and non-renal lupus flares. This does not appear to be associated with increased risk of infections. Long term sequelae if any, of this regimen is not known. Our study has inherent limitations due to its retrospective nature and small sample size. Based on these preliminary results we are planning a clinical trial studying the efficacy and tolerability of CYC/RTX combination in patients with recurrent severe SLE.

Clinical Characterization Of Anti-CCP+Ve Systemic Lupus Erythematosus Patients. Samera Vaseer[1] and Eliza Chakravarty[2]. [1]University Of Oklahoma, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: SLE is a heterogeneous autoimmune disease characterized by the presence of autoantibodies and manifestations of numerous organ systems. One of the most common SLE manifestations is inflammatory arthritis, often indistinguishable from rheumatoid arthritis in early stages when other manifestations are not present. Antibodies directed against citrullinated peptides (anti-CCP) were initially thought to be highly specific for RA (specificity estimated at 98%). The prevalence and role of anti-CCP antibodies has not been well characterized in SLE patients.

The purpose of this study is to estimate the prevalence of anti-CCP antibodies among SLE patients and to identify unique characteristics of CCP+ve SLE patients in comparison to CCP -ve SLE patients in a case control fashion.

Methods: The Oklahoma Lupus Cohort is a prospective longitudinal observational cohort. Participants provide written informed consent to participate, and have clinical data as well as peripheral blood specimens collected during routine clinical care. Serologies are obtained on all participants.

SLE patients with positive anti-CCP antibodies were identified and their demographic, clinical, and serological characteristics were compiled through chart review. In order to identify features that are unique to CCP+ SLE, we identified 2–3 controls, CCP- SLE patients matched for age and gender, to each CCP+ case.

Results: Of the total 227 SLE patients with known CCP serologies, 26 (11.5%) were found to be anti-CCP positive (>20 IU). Mean anti-CCP value was 90. Cases were separated into high positive anti CCP group (>60) and low to moderate positive anti-CCP group (<60). 60% were current or former smokers in the high positive group. Ethnic distribution was as follows; Caucasian 60%, African American10%, Native American 20%, and 10% Hispanic.

Majority of CCP+ SLE patients had clinical features similar to CCP negative group with high frequency of sicca symptoms 80% vs. 49% in controls. Inflammatory arthritis, Raynauds, cutaneous manifestations and mucosal ulcers were also frequent, though similar to the control group. The prevalence of renal disease and CNS disease in the CCP+ SLE patients was similar to that reported in the literature.

Aside from ANA, the most prevalent autoantibodies among CCP+SLE patients were anti-Ro/SSA (50%), and RNP (40%). RF was seen in 40% of high CCP+ group compared to 15% in control group.

Conclusion: Anti CCP positive SLE subjects have a high frequency of arthritis and sicca symptoms. CCP+SLE patients share many common SLE autoantibodies with CCP- patients with high prevalence of anti Ro, RNP and RF among this group.

Treat-To-Target In Systemic Lupus Erythematosus: Report From the T2T/SLE Working Party. Ronald F. van Vollenhoven[1], Marta Mosca[2], George Bertsias[3], Annegret Kuhn[4], Kirsten Lerstrøm[5], Josef S. Smolen[6], David A. Isenberg[7], Matthias Schneider[8] and the T2T/SLE Working Party[9]. [1]Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), the Karolinska Institute, Stockholm, Sweden, [2]Rheumatology Unit, Internal Medicine, University of Pisa, Pisa, Italy, [3]University of Crete, Iraklion, Greece, [4]University of Münster, Münster, Germany, [5]Lupus Europe, Farum, Denmark, [6]Medical University of Vienna, Vienna, Austria, [7]University College London, London, United Kingdom, [8]Heinrich-Heine-University, Duesseldorf, Germany, [9]the Karolinska Institute, Stockholm, Sweden.

Background/Purpose: The principle of treating-to-target has been applied successfully to many diseases outside rheumatology and more recently to rheumatoid arthritis. Identifying appropriate therapeutic targets and pursuing these systematically has led to improved care for patients with these diseases and useful guidance for health care providers and administrators. Thus, an initiative to evaluate possible therapeutic targets and develop treat-to-target guidance was believed to be of benefit in SLE as well. An expert panel was convened for this purpose.

Methods: Thirty-four specialists in rheumatology, nephrology, dermatology and/or clinical immunology and a patient representative contributed to this initiative. The majority convened on three occasions. Twelve topics of critical importance for this endeavor were identified and a systematic literature review (SLR) was performed on these topics. The results of the SLR were condensed and reformulated as recommendations, discussed, modified, and voted upon. The finalized bullet points were analyzed for degree of agreement among the panel (strength of recommendation, SoR). The Oxford Center level of evidence (LoE, corresponding to the research questions, not shown) and grade of recommendation (GoR) were determined for each recommendation.

Results: The twelve systematic literature searches and their summaries led to eleven recommendations (Table). LoE and GoR of the recommendations were variable but agreement was >0.9 in each case. An extensive research agenda was identified, and four overarching principles were also agreed upon.

Table.

Overarching Principles	GoR (A–C)	SoR (0–10)
I. The management of SLE should be based on shared decisions between the informed patient and her/his physician(s)		9.48
II. Treatment of SLE should aim at ensuring long-term survival, preventing organ damage, and optimizing health-related quality-of-life, by controlling disease activity and minimizing comorbidities and drug toxicity		9.90
III. The management of SLE requires an understanding of its many aspects and manifestations, which may have to be targeted in a multidisciplinary manner		9.42
IV. Patients with SLE need regular long-term monitoring and review and/or adjustment of therapy		9.81
Recommendations		
1. The treatment target of SLE should be remission of systemic symptoms and organ manifestations or, where remission cannot be reached, the lowest possible disease activity, measured by a validated lupus activity index and/or by organ-specific markers	C(SLE)/A(LN)	9.52
2. Prevention of flares (especially severe flares) is a realistic target in SLE and should be a therapeutic goal.	B(SLE)/A(LN)	9.32
3. It is not recommended that the treatment in clinically asymptomatic patients be escalated based solely on stable or persistent serological activity.	B	9.03
4. Since damage predicts subsequent damage and death, prevention of damage accrual should be a major therapeutic goal in SLE.	A	9.71
5. Factors negatively influencing health-related quality of life (HRQOL), such as fatigue, pain, and depression should be addressed in addition to control of disease activity and prevention of damage.	B	9.03
6. Early recognition and treatment of renal involvement in lupus patients is strongly recommended.	B	9.87
7. For lupus nephritis, following induction therapy, at least 3 years of immunosuppressive maintenance treatment is recommended to optimize outcomes.	A	9.13
8. Lupus maintenance treatment should aim for the lowest glucocorticoid dosage needed to control disease, and if possible glucocorticoids should be withdrawn completely.	B	9.58
9. Prevention and treatment of anti-phospholipid antibody syndrome (APS)-related morbidity should be a therapeutic goal in SLE, but therapeutic recommendations do not differ from those in primary APS.	C	9.52
10. Irrespective of the use of other treatments, serious consideration should be given to the use of antimalarials.	B	9.35
11. Relevant therapies adjunctive to any immunomodulation should be considered to control comorbidity in SLE patients.	C	9.55

Conclusion: Treat-to-target-in-SLE (T2T/SLE) recommendations were developed by a large panel of multi-specialty experts and a patient representative. Although LoE and GoR were variable, agreement was excellent. Prominent features of these recommendations are targeting remission, preventing damage, and improving quality of life. It is anticipated that "treating-to-target" can and will be applicable to the care of patients with SLE.

Elevated Serum B-Cell Activating Factor (BAFF/BlyS) Characterises Disease Relapse Following Rituximab In Systemic Lupus Erythematosus. Lucy M. Carter, David A. Isenberg and Michael R. Ehrenstein. University College London, London, United Kingdom.

Background/Purpose: Numerous reports suggest that B cell depletion therapy (BCDT) using rituximab is effective in patients with systemic lupus erythematosus (SLE). However, two major trials did not confirm these results. We, and others, have shown that the characteristics and kinetics of repopulating B cells are associated with different clinical responses to BCDT. B cell activating factor/B Lymphocyte Stimulator (BAFF/BLyS) is a key mediator of B cell survival and self-tolerance, which is over-expressed in many patients with SLE. The present study examines changes in serum BAFF at disease flares and remission following BCDT and repopulation of peripheral B cells, and assesses the relationship between serum BAFF, B cell number and autoantibody levels according to treatment outcome.

Methods: 35 patients with SLE, treated with one or more cycles of BCDT using rituximab, cyclophosphamide and methylprednisilone, had stored serum samples available for analysis. Patients were followed up until disease flare, further BCDT or for a minimum of 18 months following BCDT. Anti-dsDNA levels, immunoglobulins and CD19+ counts were recorded during follow up. Clinical disease was assessed using the BILAG index. Serum BAFF was measured during disease flare prior to BCDT and at subsequent relapse or remission, using a human BAFF ELISA.

Results: Following initial BCDT, 10 patients remained in remission for the duration of follow up. Twenty-five patients went on to relapse, of which 22 were treated with further BCDT. BAFF levels were positively correlated with B cell numbers ($R = 0.65$, $p < 0.05$) and serum IgG ($R = 0.56$, $p < 0.01$) prior to BCDT, but did not predict subsequent treatment outcome or time to repopulation following rituximab ($p > 0.05$). However, serum BAFF after BCDT and subsequent B cell repopulation was significantly higher at disease relapse compared to levels in patients who remained in remission ($p < 0.01$) but also compared with the disease flare prior to BCDT ($p < 0.05$).

Following BCDT serum BAFF was inversely correlated with B cell numbers at disease flare ($R = -0.44$, $p < 0.05$), with flare at lower B cell numbers associated with the highest BAFF levels. Changes in serum BAFF during relapse or remission strongly correlated with change in anti-dsDNA antibody levels ($R = 0.62$, $p < 0.001$).

Conclusion: The present data suggest a significant role for BAFF in driving disease flare after B-cell repopulation following BCDT. In some patients sequential BCDT promoted ever increasing BAFF levels accompanied by rising anti-DNA antibodies and flare even at low B-cell numbers. Therefore, our data justifies the judicious use of BAFF blockade in a subgroup of lupus patients after BCDT.

Efficacy Of Influenza Vaccination Is Strongly Decreased In Systemic Lupus Erythematosus: A Meta-Analysis Of Literature Data. Laurent Arnaud[1], Alexis Mathian[1], Hervé Devilliers[2], Du Boutin-LE Thi Huong[1], Ahlem Chaib[1], Fleur Cohen-Aubart[1], Julien Haroche[1], Miguel Hié[1], Makoto Miyara[1] and Zahir Amoura[1]. [1]Hôpital Pitié-Salpêtrière, AP-HP, UPMC Univ Paris 06 & French National Reference Center For Systemic Lupus and Antiphospholipid Syndrome, Paris, France, [2]Internal medicine and systemic disease unit, Dijon University Hospital, Dijon, France.

Background/Purpose: Several studies suggest that the efficacy of influenza vaccination may be decreased in systemic lupus erythematosus (SLE). We performed a meta-analysis to assess systematically the immunogenicity of influenza vaccination in SLE, comparatively to healthy subjects.

Methods: All studies published until February 2013, comparing the immunogenicity of influenza vaccination in SLE comparatively to healthy subjects were identified from the MEDLINE, Cochrane and EMBASE databases and included in our meta-analysis. The immunogenicity was evaluated using the proportion of subjects with influenza antibody titers ≥1:40 (seroprotection rate) and the proportion of subjects with either a prevaccination hemagglutination-inhibiting titer <1:10 and a postvaccination titer ≥1:40 or a prevaccination titer ≥1:10 and an increase in the titer by a factor of 4 or more (seroconversion rate). Pooled effect estimates were obtained using a random-effects model.

Results: Of 146 citations retrieved, 16 primary studies including 1010 SLE patients and 578 healthy controls met inclusion criteria. Pooled analysis revealed significantly decreased immunogenicity of H1N1 influenza vaccine in SLE patients compared to healthy controls for both seroprotection rates (Odd Ratio, OR: 0.34 [95% confidence interval, 95%CI: 0.21 – 0.55]) and seroconversion rates (OR: 0.34 [95%CI: 0.21 – 0.56]) with significant statistical heterogeneity for seroconversion ($T^2 = 0.37$; $p = 0.01$; $I^2 = 0.54$). Our meta-analysis also reveals significantly decreased seroprotection rates with H3N2 (OR: 0.34 [95%CI: 0.18 – 0.66]) and B (OR: 0.40 [95%CI: 0.22 – 0.73]) influenza vaccines and non-significantly decreased seroconversion rates for H3N2 (OR: 0.55 [95%CI: 0.21 – 1.45]) and B (OR: 0.44 [95%CI: 0.19 – 1.01]) influenza vaccines. Subgroup analyses considering only SLE patients without corticosteroids and immunosuppressors (n=209) revealed non significantly decreased seroprotection rate (OR: 0.60 [95%CI: 0.35 – 1.01]) and decreased seroconversion rate (OR: 0.64 [95%CI: 0.42 – 0.98]) compared with healthy controls (n=226).

Conclusion: Our meta-analysis demonstrates significantly decreased immunogenicity of influenza vaccines in SLE compared to healthy patients. Subgroup analysis suggests that decreased immunogenicity may be independent of immunosuppressive treatments. Specific vaccination schemes, such as the use of a second injection or the use of adjuvanted vaccines-, should be evaluated in SLE patients.

1565

RNA-Sequencing Confirms Clinical Safety Of Herpes Zoster Vaccine. Christopher J. Lessard, Indra Adrianto, Joel M. Guthridge, John A. Ice, Graham B. Wiley, Stuart B. Glenn, Judith A. James, Joan T. Merrill, Patrick M. Gaffney, Courtney G. Montgomery, Kathy L. Sivils and Eliza Chakravarty. Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background/Purpose: SLE patients have increased risk of Herpes Zoster (HZ). A live-attenuated vaccine is available for healthy persons > 50 years old, but its safety in immunocompromised individuals is unknown. Two areas of possible concern regard the development of vaccine-induced HZ, and increased disease activity following stimulation from an immunogenic vaccine. We sought to evaluate gene expression profiles between SLE patients and healthy controls after VZV vaccination to identify any potential increase in immune system activation or impaired viral control in SLE patients.

Methods: We performed a pilot open-label study of HZ vaccine in 10 SLE patients with low disease activity and 10 healthy, matched controls. Safety outcomes included vaccine-induced HZ or flare of underlying SLE following vaccination. Whole-blood RNA was collected in Tempus tubes to study early changes in immune related pathways at baseline and 2 weeks post-vaccination in a subset of 5 matched pairs of SLE patients and controls. RNA-sequencing was done using an Illumina HiSeq 2000 with the resulting FASTQ files aligned to the human genome using STAR. DEseq was used to determine differential expression with the threshold of $P<0.01$ and fold change (FC) >2 or <0.5.

Results: No subjects developed vaccine-induced HZ during the 12 weeks of the study. SLE patients had quiescent disease at baseline, and no clinical flares were noted. When comparing the baseline samples of the SLE cases to the healthy controls, we identified 107 differentially expressed genes including several that are known to be type I interferon (T1IFN)-inducible (OAS1, OAS2, OAS3, MX1, IFIH1, IFIT2, IFIT3, among others). These genes mapped to pathways involved in response to virus ($P=8.08\times10E{-}20$), immune response ($P=1.15\times10E{-}16$), and T1IFN-mediated signaling pathway ($P=7.17\times10E{-}16$), among others. The analysis of the 14-day post-vaccination visits between SLE case and healthy controls yielded only 37 differently expressed genes. Although some of the same T1IFN-inducible genes were differently expressed (e.g. OAS3, MX1, IFIT2, IFIH1), we observed a statistically significant reduction in the number of T1IFN-inducible genes between the baseline and the post vaccination analyses ($P=0.005$). Moreover, a statistically significant reduction was observed in the FC between the differentially expressed genes that overlapped between the baseline and post-vaccination analyses ($P=8.34\times0E{-}7$). No evidence of HZ viral gene expression was detected in either the cases or controls.

Conclusion: In this pilot study of quiescent SLE patients, HZ vaccine did not lead to clinical flares, nor increased evidence of systemic inflammation or autoimmunity. HZ viremia was not detected. At baseline, differences in gene expression between SLE patients and controls were consistent with other studies of SLE. Changes observed in expression profiles 14 days post-vaccination suggests that the controls have responded to the vaccine and have become more similar to the SLE cases. Future studies with larger samples sizes are needed to determine true flare rates and gage any differences in immune response to vaccine in those patients for whom vaccine might be associated with flare.

Consensus Definition and Preliminary Validation Of a Low Disease Activity State In Systemic Lupus Erythematosus. Eric F. Morand[1], Kate Franklyn[1], Chak S. Lau[2], Sandra V. Navarra[3], Worawit Louthrenoo[4], Aisha Lateef[5], Laniyati Hamijoyo[6], Singgih Wahono[7], Shun-Le Chen[8], Jinou Ou[9], Alberta Y. Hoi[1] and Mandana Nikpour[10]. [1]Monash University, Melbourne, Australia, [2]Queen Mary Hospital, Hong Kong, Hong Kong, [3]University of Santo Tomas Hospital, Manila, Philippines, [4]Faculty of Medicine, Chiang Mai, Thailand, [5]National University of Singapore, Singapore, Singapore, [6]Hasan Sadikin Hospital, Bandung, Indonesia, [7]Universitas Brawijaya, Malang, Indonesia, [8]Shanghai Jiao Tong University School of Medicine, Shanghai, China, [9]3rd Hospital of Sun Yat-san University, Guang Zhou, China, [10]University of Melbourne, Fitzroy, Australia.

Background/Purpose: The definitions of low disease activity state (LDAS) and remission as desirable treatment goals in rheumatoid arthritis have been widely applied in research and clinical practice. In SLE, the measurement of active disease is problematic, and while a definition of remission has been published it was met by <2% of patients (Urowitz, 2007).

A definition of 'lupus low disease activity state' (LLDAS) could, once validated, be applied as a novel outcome measure in observational and interventional studies. We sought to define LLDAS using consensus methodology, and to perform preliminary validation of LLDAS using prospective data from an SLE cohort.

Methods: We defined LLDAS conceptually as 'a state which, if sustained, is associated with a low likelihood of adverse outcome', considering both disease activity and medication safety. A panel of experts from Hong Kong, China, Philippines, Thailand, Singapore, Indonesia and Australia individually generated items for potential inclusion in a definition of LLDAS. Using the Delphi method, these items were scored on a 5-point scale and then reduced. Six experts participated in the first round of Delphi, and items with a mean score > 3 were retained. Eleven experts then participated in a consensus meeting using the nominal group technique, and in a second round of Delphi, in which items with a mean score > 4 were retained. The frequency of attainment of LLDAS and its ability to predict accrual of irreversible organ damage (measured using the SDI) was determined in a longitudinally followed cohort of patients with SLE, using logistic regression.

Results: Fifty-six 'unique' items were initially generated, in two domains: (i) disease activity, and (ii) medication use. Following two rounds of Delphi and a nominal group discussion, unanimous agreement on a definition of LLDAS was reached. The final list of five items defining LLDAS comprised:

1. SLEDAI-2K ≤ 4, with no SLEDAI activity in major organ systems (renal, CNS, cardiopulmonary, vasculitis, hemolytic anemia, fever) and no gastrointestinal activity);
2. No *new* features of lupus disease activity compared to the previous assessment;
3. SELENA-SLEDAI physician global assessment (PGA, scale 0–3) ≤ 1;
4. Current prednisolone (or equivalent) dose $\leq$ 7.5 mg daily; and
5. Well-tolerated standard maintenance doses of immunosuppressive drugs and/or approved biologic agents, excluding investigational drugs.

Among 192 patients with SLE followed for a median duration of 3.37 years, LLDAS was achieved on at least one occasion by 72%. The median cumulative duration of LLDAS was 245 days. Patients in whom the cumulative duration of LLDAS was greater than 245 days had significantly less accrual of organ damage during follow up than patients in whom the cumulative LLDAS duration was less than 245 days (SDI (mean$\pm$SD) 1.01$\pm$1.4 v.1.6$\pm$1.9, Mann-Whitney p=0.023, Odds Ratio=0.8, 95% CI: 0.66–0.97, p=0.025).

Conclusion: We have generated a definition of LLDAS and shown that LLDAS is a predictor of organ damage in SLE. This definition of LLDAS requires further validation, against outcomes including organ damage and death, in a large prospective multicenter cohort. LLDAS may serve as a treatment target in SLE clinical practice and research.

Desensitization To Trimethoprim/Sulfamethoxazole In Systemic Lupus Erythematosus Patients: A Retrospective Cohort Study. Yasuhiro Suyama[1], Mitsumasa Kishimoto[1], Hiroto Nakano[2], Chisun Min[1], Yoichiro Haji[1], Ryo Rokutanda[1], Yuri Ohara[1], Hisanori Shimizu[1], Ken-ichi Yamaguchi[1], Yukio Matsui[1], Kazuo Matsui[2] and Masato Okada[1]. [1]St. Luke's International Hospital, Tokyo, Japan, [2]Kameda Medical Center, Kamogawa, Japan.

Background/Purpose: A high incidence of trimethoprin-sulfamethoxazole (TMP/SMX) hypersensitivity is reported in patients with systemic lupus erythematosus (SLE), and reactions are often severe. Desensitization protocol is widely used for patients who have experienced minor reactions, but is contraindicated in patients with a history of severe drug eruption or hepatitis. We evaluated the safety and efficacy of TMP/SMX desensitization in patients with SLE who had not been previously exposed to TMP/SMX. Specific autoantibody profiles were also assessed as potential risk factors for TMP/SMX hypersensitivity.

Methods: Data from 56 SLE patients who received glucocorticoids and prophylactic TMP/SMX, with or without immunosuppressive agents, from 1997 to May 2013 were retrospectively analyzed. We evaluated 32 SLE patients prescribed a standard prophylactic dose of TMP/SMX (routine care group) and the results were compared with 24 SLE patients given oral TMP/SMX desensitization prophylaxis(desensitization group). We also assessed risk factors for allergic reactions using patients' demographic and laboratory data including specific antibody status. T-test and $\chi 2$ test were performed to analyze the data.

Results: The incidence of TMP/SMX hypersensitivity reactions in the routine care group was 43.8% (14/32) versus 12.5% (3/24) in the desensitization group ($p = 0.041$). The medication was discontinued in all patients who experienced clinical hypersensitivity reactions including high fever, severe drug eruption, and hepatitis; symptoms in the desensitization group appeared milder and never required hospitalization. In the routine care group, there was a higher rate of anti-Ro/SS antibody positivity in patients who experienced hypersensitivity reactions (46.2% in patients with hypersensitivity reactions vs 5.6% in patients with no reaction; $p = 0.008$); no association was found with other specific antibodies. Finally, when only anti-Ro/SS-A antibody positive patients were included in the analysis, there were significantly fewer hypersensitivity reactions in the desensitization group (18.2%) than the routine care group (85.7%) ($p = 0.013$).

Conclusion: We confirmed the high incidence of TMP/SMX hypersensitivity in patients with SLE, especially in whom anti-Ro/SS-A antibody is present. Administration of TMP/SMX per desensitization protocol appears to be effective in decreasing the incidence and severity of hypersensitivity reactions.

1568

A Comparative Study For High Prevalence Of A Positive Family History Of Systemic LUPUS Erythematosus In Juvenile-Onset Systemic LUPUS Erythematosus Versus Adult-Onset Disease. Maumer Durrani, Shirish Sangle, Natasha Jordan and David P. D'Cruz. Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom.

Background/Purpose: The pathogenesis of SLE is complex and poorly understood. Infectious triggers, immunological abnormalities, environmental factors and genetic background play a combined role in disease development. A genetic contribution to SLE has been evident from familial clustering of cases with a monozygotic twin concordance rate of 30–40%. Juvenile-onset SLE doesn't necessarily present identically to adults as described by some investigators suggesting that disease might be more severe in juvenile-onset patients at presentation. We compared family history of SLE, immunology, severity of organ involvement and differences between medications used in both groups.

Methods: Clinical and demographic data was collected on 25 juvenile-onset SLE patients and compared with 65 patients with adult-onset disease. Adult data was collected randomly from our SLE clinics. All patients met the American College of Rheumatology (ACR) classification criteria for SLE. Juvenile-onset was defined as those who were diagnosed with SLE before16 years of age. Data collected included ethnicity, family history of SLE/autoimmune disease, autoantibody profile, lupus-related disease manifestations and medications used.

Results: 36% of juvenile-onset SLE patients have a positive family history of SLE as opposed to 12% of adult-onset disease patients (p=0.011). Family history of other autoimmune conditions such as rheumatoid arthritis, hypothyroidism did not differ significantly between the two groups. In juvenile-onset patients 21(84%) were female and 4 (16%) male. Mean age of disease onset was 13 years (range 10–16 years). 13 (52%) were Afro-Caribbean, 7(28%) Caucasian, 4 (16%) Asian and 1 (4%) was of mixed ethnic origin. In adult-onset disease, 60 (92%) were female and 5 (7%) male. Mean age of disease onset was 29 years (17–50 years). 29 (44%) were Afro-Caribbean, 13 (20%) Asian, 21(32%) Caucasian and 2 (3%) were of mixed ethnicity. 18(72%) patients of juvenile-onset SLE patients had lupus nephritis, 3(12%) had interstitial lung disease, 4(16%) had APS. Only 1(4%) patient had AIHA. 43(66.1%) patients of adult-onset SLE patients had lupus nephritis, 5(7.69%) were diagnosed with interstitial lung disease. 12(18.4%) patients had APS and 4(6.1%) had either AIHA or thrombocytopenia.

Autoantibody Profile	Juvenile-onset SLE (n=25)	Adult-onset SLE (n=65)
ANA	23 (92%)	64 (98%)
Anti-dsDNA	18 (72%)	32 (49%)
Anti-Ro (SSA)	9 (36%)	24 (36%)
Anti-La (SSB)	3 (13%)	7 (10%)
Anti-Sm	7 (31%)	16 (32%)
Anti-RNP	10 (40%)	24 (36%)
Anti-cardiolipin	13 (52%)	19 (29%)
Lupus anticoagulant	8 (32%)	16 (24%)
Anti-C1q	11/17 (65%)	19/30 (63%)
Medications		
Prednisolone	21 (84%)	53 (81%)
Hydroxychloroquine	18 (72%)	54 (84%)
Mepacrine	1 (4%)	5 (7%)
Mycophenolate mofetil	17 (68%)	32 (49%)
Azathioprine	5 (20%)	19 (29%)
Methotrexate	1 (4%)	(3%)
Cyclophosphamide	5 (20%)	10 (15%)
Rituximab	6 (24%)	7 (10%)
Plasmapheresis	2 (8%)	0
Intravenous immunoglobulin	1 (4%)	0

Conclusion: A family history of SLE was significantly more common in juvenile-onset SLE than in adult-onset disease. Frequencies of lupus nephritis and anti-dsDNA antibody positivity were higher in juvenile-onset SLE which may reflect a more severe clinical phenotype. The majority of juvenile-onset SLE patients in our cohort were of African ancestries, who are known to have worse clinical outcomes. Medications and clinical interventions such as mycophenolate mofetil, cyclophosphamide, rituximab were more frequently used in juvenile-onset SLE patients, which supports the likelihood of more severe and difficult to manage disease in this subset of patients.

The Accuracy Of The ICD-9 Code 710.0 To Identify a Cohort Of SLE Patients From The Electronic Medical Record. Arshad Mustafa[1], Jennifer Cai[1], Teresa Bosler[1], Nancy J. Olsen[2] and David R. Karp[1]. [1]UT Southwestern Medical Center, Dallas, TX, [2]Penn State MS Hershey Medical Center, Hershey, PA.

Background/Purpose: The electronic medical record (EMR) is increasingly used as a primary source of retrospective research data from large 'virtual cohorts' of patients. The accuracy of EMR data is not guaranteed. Importantly, when performing case-control studies, the cases and controls may be imperfectly defined by EMR data, particularly for syndromic conditions such as SLE. This study was undertaken to ascertain the accuracy of EMR diagnoses of SLE made by specialists at an academic medical center.

Methods: Cases of specialist-diagnosed SLE were defined as individuals who had billing diagnoses using the ICD-9 CM code 710.0 applied by a faculty rheumatologist, nephrologist, or dermatologist two or more times in a twelve month period. These patients' EMR were reviewed by a single rheumatologist trained in SLE diagnosis and 10% of these charts were independently reviewed by a second rheumatologist for verification. Each patient's EMR was categorized for its support for the diagnosis of SLE using both the 1997 ACR and 2012 SLICC criteria. "Certain" diagnoses had >4 criteria found in the chart; "Likely" diagnoses had <4 criteria but had serology findings specific for SLE (anti-DNA or anti-Sm) and 1 typical clinical feature (e.g., malar rash, arthritis, cytopenia); "Possible" diagnoses had >1 criterion suggesting SLE and no better explanation given in the chart; "Unlikely" diagnoses included a positive ANA and no other findings, or a single clinical finding with temporally inconsistent serology; "Not SLE" diagnoses were documented if another diagnosis for their condition was firmly established.

Results: From a database of almost 4 million patient records, a total of 139 outpatient charts meeting the definition of specialist-diagnosed SLE were identified. 99 (71.2%) were felt to have Certain lupus; 19 (13.7%) were Likely; 14 (10%) were Possible; 4 (2.8%) were Unlikely; 3 (2.1%) were Not SLE. Combining the Certain patients (who meet classification criteria) and the Likely patients who might have 'early' or 'incomplete' lupus, or may only lack proper documentation for SLE, the positive predictive value of repeated ICD-9 710.0 codes is approximately 85%. Conversely, about 15% of patients who carry diagnoses of SLE lack sufficient, easily accessible data in their EMR to support that finding. SLE features that had significantly different prevalence between the Certain/Likely and Possible/Unlikely/Not groups were both lupus-specific: anti-DNA (55.9% vs 19.0%, $p=0.002$), anti-Sm (30.5% vs 0%, $p=0.002$), and nephritis (51.7% vs 0%, $p<0.0001$), as well as non-specific: hypocomplementemia (57.6% vs 9.5%, $p<0.0001$) and lymphopenia (71.2% vs 28.6%, $p=0.0003$).

Conclusion: This study underscores the challenges of using ICD-9 billing codes to identify research cohorts from EMR data. Even specialist physicians persistently label patients incorrectly while their notes and data do not support the lupus diagnosis. Surprisingly, lymphopenia, an inexpensive and widely obtained laboratory parameter, differentiates patients who truly have lupus from patients incorrectly labeled with the disease, and can be used to develop "decision support" features in the EMR to assist with the diagnosis of SLE.

Maintenance Therapy With Taclorimus and Mizoribine Pulse In SLE. Hiroshi Kajiyama, Daisuke Ikuma, Muneo Ota, Yuki Shimada, Kazuhiro Yokota, Yasuto Araki, Kojiro Sato, Yu F. Asanuma, Yuji Akiyama and Toshihide Mimura. Saitama Medical University, Saitama, Japan.

Background/Purpose: It was reported in 2008 that multitarget therapy, consisting of taclorimus (TAC), mycophenolate mofetil (MMF) and glucocorticoid, is effictive and safe in induction therapy of active lupus nephritis. However, its efficacy and safety in maintenance therapy of SLE is not clarified yet. Mizoribine (MZR), an immunosuppressive drug targeting inosine monophosphate dehydrogenase, inhibits de novo pathway for purine synthesis as MMF. Recently, multitarget therapy consisting of TAC, MZR and glucocorticoid has been reported to be effective and safe in maintenance therapy, although the mode of MZR administration widely varies. Intermittent MZR pulse therapy (300mg single dose, once to four times per week) gives higher rise of peak blood concentration to suppress lymphocyte function than low dose daily therapy (50mg three times per day, total 150mg per day). It remains to be elucidated, if intermittent MZR pulse therapy is effective and safe in SLE maintenance therapy.

Methods: Eleven SLE patients (2 males, 9 females) were treated with multitarget therapy with TAC and MZR pulse after the induction therapy. Demographic data, laboratory data (serum dsDNA antibody and serum CH50) and daily prednisolone (PSL) dose and SLE disease activity index (SLEDAI) score were documented at three different time points, first and second add-on of immunosuppressant and recent by medical record review. Average duration is 8.9 ± 12.0 months between the first add-on and the second add-on, and 6.0 ± 4.3 months between the second add-on and recent. Statistical analysis (Kruskal-Wallis test) was done using Prism version 5.0d. Adverse effects and the number of relapse were also documented. Each value was described as mean $\pm$ standard deviation.

Results: Seven of 11 patients presented lupus nephritis. Three of these seven patients treated with methylprednisolone pulse therapy as induction therapy. After induction therapy, TAC in 10 patients and MZR in one patient were started at first add-on, and MZR in 10 patients and TAC in one patient were further added at second add-on. Serum CH50 level significantly increased (first add-on:31.4 ± 11.8 U/mL, second add-on:37.7 ± 11.8 U/mL, recent:46.5 ± 12.7 U/mL, $P=0.00252$). The mean values of SLEDAI score and serum dsDNA antibody level improved, although they did not reach statistical significance (SLEDAI first add-on:4.0 ± 2.8, second add-on: 2.9 ± 1.9, recent:1.8 ± 1.4, $P=0.1095$, dsDNA first add-on:42.9 ± 54.4, second add-on:20.0 ± 11.2, recent:14.3 ± 5.8, $P=0.3$). Daily oral prednisolone dose was significantly reduced (first add-on:26.9 ± 13.7, second add-on:16.7 ± 6.1, recent:10.4 ± 5.0, $P=0.0012$). There was only one patient with relapse during multitarget maintenance therapy, although he treated with methylprednisolone pulse for nephritis in induction therapy. No patients had major adverse effects, resulting in the interruption of the multitarget maintenance therapy. There were three minor adverse events such as transient increase of serum creatinine level and herpes zoster in three patients.

Conclusion: Multitarget maintenance therapy with TAC and MZR pulse is safe and effective enough to reduce daily steroid dose and to minimize relapse without major adverse effects in Japanese patients with SLE.

Efficacy Of Tacrolimus Combination Therapy During The Maintenance Phase Of Systemic Lupus Erythematosus. Kumiko Ohtsuka, Yusuke Miwa, Nao Oguro, Yoko Miura, Sho Ishii, Shinya Seki, Hidekazu Furuya, Ryo Yanai, Ryo Takahashi, Kuninobu Wakabayashi, Nobuyuki Yajima and Tsuyoshi Kasama. Showa University School of Med, Shinagawa-ku Tokyo, Japan.

Background/Purpose: In Japan, a placebo-controlled clinical trial was undertaken to investigate the efficacy and safety of tacrolimus (TAC) for lupus nephritis. Based on the results obtained, administration of TAC at an oral dose of 3 mg/day was effective for the treatment of lupus nephritis.

Objective: The aim of this study was to prospectively evaluate the efficacy and safety of TAC combination therapy during the maintenance phase of systemic lupus erythematosus (SLE).

Methods: From 2009 to 2012, 38 patients were examined over a 1-year study period. If manifestations of mild active SLE, such as arthritis, skin eruptions, or asymptomatic nephritis, worsened and/or decreasing titers of serum complement (C3c) were observed, TAC combination therapy (from 1 mg to 5 mg once daily) was administered (that is, TAC was added to the patient's existing treating regimen, and the dosage of prednisolone (PSL) was decreased). Scores on the SLE Disease Activity Index (SLEDAI), PSL dosage, and serum levels of C3c, anti-dsDNA titers, and proteinuria were examined.

Results: Thirty-eight patients responded to TAC combination therapy. 1) The PSL dose was reduced from 11.7 ± 5.6 to 8.2 ± 4.2 mg/day ($P<0.001$). 2) The serum concentration of C3c increased from 74.7 ± 21.9 to 86.4 ± 17.8 mg/dl ($P=0.006$). 3) Titers of anti-dsDNA antibodies decreased from 39.6 ± 68.0 to 24.8 ± 49.1 U/ml ($P<0.001$). 4) Scores on the SLEDAI improved from 6.2 ± 3.7 to 2.6 ± 2.3 ($P<0.001$). In particular, the following symptoms improved on the SLEDAI: headache (from 7 patients to 1 patient), arthritis (from 3 patients to 0 patients), rash (from 6 patients to 2 patients), alopecia (from 5 patients to 0 patients), mucosal ulcers (from 2 patients to 0 patients), and fever (from 5 patients to 1 patient). Although proteinuria decreased from 0.31 ± 0.70 to 0.31 ± 0.85 g/g of Cr, the difference was not significant ($P=0.47$). In contrast, 8 patients did not respond and/or had worsening SLE and 2 patients discontinued treatment as a result of an adverse effect: muscle cramp or rhabdomyolysis. No patients experienced complications with adverse effects of abnormal urinalysis, and none progressed to renal failure or became candidates for dialysis.

Conclusion: TAC combination therapy therefore is a useful alternative treatment for SLE.

Disclosure: K. Ohtsuka, None; **Y. Miwa**, Asteras, 2; **N. Oguro**, None; **Y. Miura**, None; **S. Ishii**, None; **S. Seki**, None; **H. Furuya**, None; **R. Yanai**, None; **R. Takahashi**, None; **K. Wakabayashi**, None; **N. Yajima**, None; **T. Kasama**, None.

1572

High Type I Interferon In Systemic Lupus Erythematosus Plasma Predicts Future Renal Disease. Kyriakos A. Kirou, Mikhail Olferiev, Elzbieta E. Jacek, Mari Lliguicota, Margaret Robotham, Wei-Ti Huang, Elena Gkrouzman and Mary K. Crow. Hospital for Special Surgery, New York, NY.

Background/Purpose: Type I interferon (IFN-I) is elevated in many patients with SLE and is associated with more severe disease. However, the relationship between elevated levels of IFN-I and disease activity over time has not been defined. We evaluated the biological activity of IFN-I retrospectively in SLE plasma samples collected longitudinally from 60 SLE patients. The IFN-I activity in plasma was determined based on the response of the WISH cell line, which is sensitive to IFN-I stimulation and has a minimum detection level of 6 IU/ml.

Methods: Plasma samples as well as clinical and laboratory data were collected longitudinally. On average, 9 visits (range: 2–20 visits) per patient or 568 data points were collected. WISH cells were stimulated with either recombinant IFN-I standard, healthy donor or SLE plasma for 5 hours. The response of WISH cells was measured by quantitative PCR (qPCR) using interferon response gene IFIT1 as the target and HPRT1 as the reference gene. Patients were divided into two groups based on either low or high IFN-I activity at study initiation. Based on the collected data we built statistical models (linear mixed effect model and generalized linear model) using the level of plasma IFN-I activity at the first patient visit as a predictor of future clinical and laboratory outcomes.

Results: SLE patients with high IFN-I plasma activity at study initiation showed increased IFN-I plasma activity during follow up visits ($p<0.01$). Among the laboratory parameters, the same patients had significant decreases in peripheral blood complement component 3 levels ($p<0.03$), white blood cell count ($p<0.04$), absolute lymphocyte count ($p<0.01$) and had higher erythrocyte sedimentation rate ($p<0.02$) and double stranded DNA titers ($p<0.02$). Patients with high plasma IFN-I activity during the first visit were prone to overall greater disease activity during the study as measured by SLEDAI ($p<0.02$) or BILAG ($p<0.05$). Strikingly, SLE patients with high IFN-I activity in plasma at study initiation were more likely (1.0 versus 0.4 incident per year $p<0,001$) to demonstrate renal BILAG activity.

Conclusion: Lupus nephritis is the most common severe manifestation of SLE and confers an increased risk of death and end-stage renal disease. In this study, we observed that IFN-I activity in SLE plasma could predict future disease activity, particularly involving the kidney. Furthermore, patients with higher plasma IFN-I activity at study initiation maintained elevated levels at future visits. Measurement of IFN-I activity in plasma of SLE patients may help identify patients at high risk for lupus nephritis and thus serve as an important disease monitoring biomarker.

1573

Longer Duration Of B Cell Depletion In Patients With Systemic Lupus Erythematosus Is Associated With a Better Outcome. Sofia Dias[1], Veronica Rodriguez[2], Hanh Nguyen[3], Charis Pericleous[4] and David A. Isenberg[4]. [1]Hospital de Santa Maria, Lisbon, Portugal, [2]Hospital Regional Universitario Carlos Haya, Malaga, Spain, [3]University College of London Hospital, london, United Kingdom, [4]University College London, London, United Kingdom.

Background/Purpose: We were alerted to the possibility of very long term B cell depletion (BCD) in Systemic Lupus Erythematosus (SLE) by a patient treated with rituximab in 2001 whose CD19 counts remain $<0.001\times 10^9$/L 12 years later. The duration of B cell depletion is variable between SLE patients. Because most relapses occur after the return of B cells, our purpose was to analyse clinical and serological features and outcome in patients considering the duration of B cell depletion.

Methods: We analysed our lupus cohort retrospectively to identify those BCD treated patients. We collected data noting the time to return of the B cells, clinical and serological features and classic British Isles Lupus Assessment Group (BILAG) scores and baseline, 6 months and 12 months after the treatment. Logistic regression analysis was made using SPSS Statistics Data Editor software.

Results: A total of 190 courses of BCD in 101 patients in whom we had full serological and clinical data prior to December 2012 were considered.

Among the 101 patients, 94 were female and ethnicities included 40 Caucasian, 28 Afro-Caribbean, 23 Asian, 7 Oriental and 3 others.

57 patients had more than 1 treatment. One patient and one of the infusions of another patient were excluded because of incomplete BCD after the treatment.

32.1% repopulated between 6 to 9 months and 28.6% repopulated after 12 months (figure 1). Two groups were analysed based on the time to repopulation at a defined threshold of 12 months. We included infusions for which the patients had not repopulated but were depleted for at least 12 months. We excluded the infusions for which a follow up was less than 12 months and for which the patients remained depleted. 144 treatments were analysed. 41.7% (group 1) repopulated in less than 12 months and 58.3% (group 2) were depleted for at least 12 months.

An association with longer time to repopulate and lymphopenia ($p=0.008$) at any point in the course of the patient's disease was noted. Inverse association with alopecia ($p=0.033$) and oral ulcers ($p=0.039$) was also noted. No association was found between serological features such as the presence of anti-dsDNA or anti-Sm antibodies or low complement.

The cohort's mean classic BILAG numerical score at baseline was 13.44 (SD=7.55). Group 2 was associated with a higher BILAG score at baseline ($p=0.026$). At 6 months group 2 patients had lower numerical BILAG score ($p=0.002$); at 12 months the same tendency was observed but with no statistical significance. Likewise, there was an association between group 2 patients and no BILAG As nor Bs at 6 months ($p=0.012$). Also a decrease of the BILAG score at 6 months ($p=0.012$) and 12 months ($p=0.012$) in these

patients was noted.

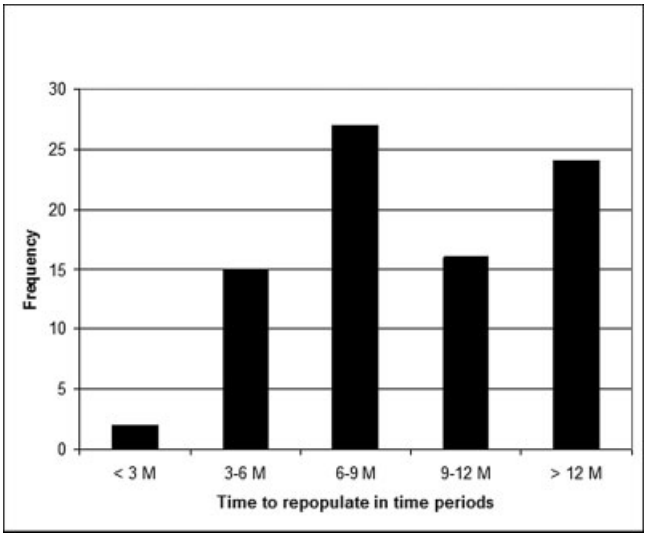

Figure 1. Time to repopulate in time periods.

Conclusion: Despite higher disease activity at baseline, as measured by classic BILAG, patients who were B cell depleted for longer showed some differences in clinical features and, most importantly, had a better outcome at 6 and 12 months.

Favorable Clinical Response To Belimumab At Three Months. Anca Askanase[1], Arthi Reddy[1], Jill P. Buyon[2], Andrew G. Franks Jr.[3], Richard A. Furie[4], Diane L. Kamen[5], Susan Manzi[6], Michelle Petri[7], Rosalind Ramsey-Goldman[8], Chung-E Tseng[2], Ronald F. van Vollenhoven[9] and Daniel J. Wallace[10]. [1]New York University School of Medicine, New York, NY, [2]NYU School of Medicine, New York, NY, [3]New York University, New York, NY, [4]The Feinstein Institute for Medical Research and North Shore-Long Island Jewish Health System, Lake Success, NY, [5]Medical University of South Carolina, Charleston, SC, [6]West Penn Allegheny Health System, Pittsburgh, PA, [7]Johns Hopkins University School of Medicine, Baltimore, MD, [8]Northwestern University Feinberg School of Medicine, Chicago, IL, [9]The Karolinska Institute, Stockholm, Sweden, [10]Cedars-Sinai Medical Center, Los Angeles, CA.

Background/Purpose: Belimumab (Benlysta) is a human monoclonal antibody that inhibits soluble B-Lymphocyte Stimulator and improves SLE disease activity. This study was initiated to evaluate the use and efficacy of Belimumab in academic SLE clinical practices.

Methods: An invitation to participate was sent to 16 physicians experienced in SLE Phase III clinical trials. All agreeing to participate completed a one page questionnaire for each patient (pt) prescribed Belimumab. Information collected included: demographics (age, gender, race/ethnicity), SLE data (duration of disease, SELENA-SLEDAI, clinical manifestation(s) targeted, background medications), and Belimumab information (start date, clinical response, side effects). Clinical response was defined as the investigator's impression of a ≥50% improvement in the initial manifestation being treated and no worsening in other organ systems.

Results: Of 16 invitations sent, nine investigators participated. Questionnaires on 151 treated pts were returned. The mean age was 43.1±11.8 years. 92.1% were female, 69.7% White, 21.2% Black, 6.1% Asian, and 4.5% Hispanic. The average SLE disease duration was 12.9±8.4 years. 3 pts (2.4%) were ANA negative. Concomitant medications included: antimalarials in 71.5%, immunosuppressants in 72.2% (Azathioprine 21.9%, Mycophenolate Mofetil 37.1%, Methotrexate 13.2%), and prednisone in 70.9% (mean dose of 12.3±11.3, 38.3% on ≥10 mg). Only 2.6% of pts were not on any background SLE medications. 12 pts (7.9%) were on anti-malarials alone. The dominant clinical manifestations driving treatment were arthritis in 73.5%, rash in 51.0%, and serositis in 17.2%. Other SLE manifestations were renal 12.0%, hematological 14.6%, and inability to taper steroids 20.5%. 70.2% of pts had ≥2 active manifestations. Data on 115 pts on Benlysta for at least 3 months (mos.) were available for analysis. Of those, 55 (47.8%) clinically responded by 3 mos. with marked improvement in arthritis and/or rash. Similarly, of the 79 pts on Benlysta for at least 6 mos., 46 (58.2%) clinically responded with improvements in arthritis, rash and/or nephritis. Clinical response for each of the SLE manifestations was also evaluated. At 3 mos., 36 of 61 (59.0%) pts with arthritis clinically responded with marked improvement and at 6 mos., 24 of 50 (48.0%). For rash, 19 of 57 (33.3%) pts responded at three mos. and 20 of 40 (50.0%) at six mos. Interestingly, of the 5 pts with renal involvement for whom follow up data are available, 4 of 5 (80.0%) improved at 3 mos. and 2 of 3 at 6 mos. Data on blacks shows a similar pattern of improvement. At 3 mos., 13 of 17 (76.5%) improved and at 6 mos., 13 of 16 (81.2%). Of the 20 (13.2%) pts overall in whom Benlysta was discontinued, 3 had CNS lupus, 1 MI, 3 losses of insurance, 3 infections, 3 infusion reactions, 1 severe arthritis flare, 1 stroke-like symptoms, 1 worsening neuropsychiatric condition, 1 worsening myositis, 1 elective surgery, and 2 no clinical response.

Conclusion: These early data support the use of Benlysta across all ethnic groups and efficacy similar to that reported in the Phase III trials. While the numbers are limited, black pts showed an improvement at 3 mos. Relevant to physician and pt decision-making, improvement was observed within 3 mos.

Identification Of Novel Distinct Autoantigen Clusters Reflecting The Heterogeneity Of Systemic Lupus Erythematosus. Petra Budde[1], Angelika Lueking[1], Stefan Vordenbäumen[2], Heike Göhler[1], Martin Gamer[1], Klaus Marquardt[1], Anna Telaar[1], Daniel Chamrad[1], Carmen Theek[1], Peter Schulz-Knappe[1] and Matthias Schneider[2]. [1]Protagen AG, Dortmund, Germany, [2]Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany.

Background/Purpose: Diagnosis of systemic lupus erythematosus (SLE) is based on a combination of clinical findings and laboratory evidence such as anti-nuclear autoantibodies (ANA), anti-Smith and anti-double stranded DNA (dsDNA) antibodies. However, no biomarker individually displays sufficient performance to diagnose SLE, to predict the disease course or to allow the identification of patient sub-groups. This lack of specific biomarkers also affects clinical development of new SLE therapeutics. Luminex bead-based antigen arrays were employed to characterize in-depth the autoantibody reactivity of SLE as a source to develop improved diagnostic and patient stratification tests for SLE.

Methods: To characterize the autoantigen repertoire in patients with SLE, we performed a large-scale screen of 5,885 recombinant human antigens using the bead-based Luminex xMAP technology. The autoantibody signature of 130 SLE patients was compared against healthy controls (n=350) and samples from patients with other autoimmune diseases including early rheumatoid arthritis (n=75), systemic sclerosis (n=100) and ankylosing spondylitis (n=100). Autoantigens with significant autoantibody response were selected to develop biomarker panels with improved sensitivity and specificity. Spearman's rank correlation of the top 50 SLE antigens was computed to identify novel autoantigen clusters.

Results: The first analysis included the comparison of autoantigen profiles of SLE patients with healthy controls and active disease samples. This led to the identification of 15 novel autoantigens (adjusted p-value<0.05, 1.5 fold increase). To further improve the sensitivity and specificity of single antigens to diagnose SLE, combinatory antigen panels were defined using 26 biomarkers providing appropriate statistical characteristics. Sequential addition and different combinations of new antigens to a panel of known SLE antigens resulted in a stepwise improvement of the classification performance yielding an AUC of 0.94. In the second analysis the new antigens were applied to capture clusters formed by subsets of antigens across different samples. At first, the seven known SLE antigens (Ro52/SS-A, Ro60/SS-A, ribosomal P0, P1, P2, and SmB/B′protein) were subjected to hierarchical cluster analysis and identified two major antigen clusters in SLE patients. Then, a combination of 50 known and new SLE markers was used to test if the new antigens provide independent information to allow further sub-classification of SLE samples based on autoantigen signatures. Seven different antigen clusters were identified offering a new tool for characterizing SLE sub-groups.

Conclusion: Comprehensive profiling of SLE sera enabled the in-depth characterization of the autoantigen repertoire of SLE patients. The combination of established and new antigens significantly increased the sensitivity to diagnose SLE. Based on their autoreactivity profile SLE sub-groups were revealed. However, further studies are needed to link specific antigen clusters to clinical profiles.

Type I Interferon-Mediated Skewing Of The Serotonin Synthesis In Systemic Lupus Erythematosus Is Associated To Cardiovascular Disease. Christian Lood[1], Helena Tydén[1], Birgitta Gullstrand[1], Cecilia Klint[2], Christina Wenglén[2], Christoffer T. Nielsen[3], Niels H. H. Heegaard[4], Andreas Jönsen[1] and Anders A. Bengtsson[1]. [1]Lund University, Lund, Sweden, [2]Ana-Mar AB, Lund, Sweden, [3]Statens Serum Institut, Copenhagen S, Denmark, [4]Statens Serum Institut, Copenhagen, Denmark.

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune rheumatic disease characterized by increased expression of type I interferons (IFNs). Indoleamine 2,3-dioxygenase (IDO), a type I IFN-regulated protein, limits the conversion of tryptophan to serotonin in favor of kynurenine. Serotonin has been implicated in development of cardiovascular disease in the general population, but its role in SLE, a disease characterized with markedly increased cardiovascular morbidity and mortality, is not known. The aim of this study was to investigate if SLE patients had a type I IFN-mediated dysregulation of the serotonin production and whether or not this was associated to cardiovascular disease.

Methods: Serotonin was measured in serum from patients with SLE (n=148) and healthy volunteers (n=79) with ELISA and intracellularly in platelets using flow cytometry and related to cardiovascular disease adjusted for traditional risk factors. Tryptophan and kynurenine were measured by liquid chromatography.

Results: SLE patients had decreased serum and platelet levels of serotonin as compared to healthy volunteers. The serum levels were associated to type I IFNs, compatible with IFN-mediated skewing of the tryptophan metabolism. Serum serotonin levels were inversely associated to disease severity and cardiovascular disease in SLE patients, independently of traditional cardiovascular risk factors.

Conclusion: We suggest that the serotonin system is dysregulated in SLE due to increased type I IFN production. Furthermore, the serum level of serotonin is identified as a novel risk factor for cardiovascular disease in SLE, independently of traditional cardiovascular risk factors.

Comparison Of Clinical and Serological Manifestations Among Juvenile-, Adult-, and Late-Onset Systemic Lupus Erythematosus Patients In Korea. Dong-Jin Park[1], Ji-Hyoun Kang[1], Kyung-Eun Lee[1], Jeong-Won Lee[1], Lihui Wen[1], Tae-Jong Kim[2], Yong-Wook Park[1] and Shin-Seok Lee[1]. [1]Chonnam National University Medical School, Gwangju, South Korea, [2]Chonnam National University Medical School and Hospital, Gwangju, South Korea.

Background/Purpose: Up to 30–40% of patients with systemic lupus erythematosus (SLE) experience their onset prior to adulthood or at over 50 years of age. Patients with juvenile-onset SLE (JSLE) frequently present with severe organ involvement and higher disease activity at the onset of disease. In contrast, patients with late-onset SLE (LSLE) tend to show more insidious onset and mild initial clinical manifestations. However, few studies have investigated differences in clinical manifestations with disease onset in Asian lupus patients. Thus, we investigated whether SLE patients could be distinguished based on the time of disease onset and, if so, whether the groups differed in their clinical and laboratory features in ethnically homogeneous Korean patients.

Methods: We enrolled 201 SLE patients (mean age 34.1±12.7, 184 women) with available clinical data at the time of onset of SLE from the lupus cohort at Chonnam National University Hospital. Sociodemographic, clinical, and laboratory data, including autoantibodies, and concomitant diseases were found at the time of diagnosis of SLE by reviewing the patient charts. We divided SLE patients according to age at SLE diagnosis into three groups: JSLE (diagnosed at ≤ 18 years), adult-onset SLE (ASLE, diagnosed at 19–50 years), and LSLE (diagnosed at > 50 years), and compared baseline demographic, clinical, and relevant laboratory findings. Data were analyzed using the chi-squared test for categorical variables and one-way ANOVA test for continuous variables.

Results: Of the 210 patients, 27 (14.4%), 149 (74.1 %), and 25 (12.4 %) were JSLE, ASLE, and LSLE patients, respectively. Fever, oral ulcer, nephritis, anemia, and thrombocytopenia were more common in JSLE patients than ASLE or LSLE patients ($p < 0.05$, $p < 0.05$, $p = 0.001$, $p < 0.05$, and $p < 0.05$, respectively). On the other hand, Sjögren's syndrome was found more frequently in LSLE patients than JSLE or ASLE patients ($p < 0.05$). SLEDAI-2000 scores at the onset of SLE were 14.6±7.1 in JSLE, 11.1±6.1 in ASLE, and 6.6±2.7 in LSLE, and disease activity was significantly higher in JSLE patients than in ASLE or LSLE patients ($p < 0.001$). Anti-dsDNA and anti-nucleosome antibodies were found more frequently in JSLE patients and less frequently in LSLE patients ($p < 0.05$, $p = 0.005$) and decreased complement levels (C3, C4, and CH50) were more common in JSLE patients and less common in LSLE patients ($p < 0.001$, $p < 0.001$, and $p < 0.05$, respectively).

Conclusion: Our results showed that SLE patients present with different clinical and serological manifestations according to age at disease onset. JSLE patients have severe disease activity and more frequent renal involvement and LSLE patients have mild disease activity, more commonly accompanied by Sjögren's syndrome, at disease onset.

Decreased Sensitivity Of a Commercial Anti-dsDNA Assay In Patients With Moderately To Severely Active Systemic Lupus Erythematosus. Munther A. Khamashta[1], Gabor G. Illei[2], Stephen Yoo[2], Liangwei Wang[2] and Warren Greth[2]. [1]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [2]MedImmune, LLC, Gaithersburg, MD.

Background/Purpose: Anti-dsDNA autoantibodies are highly specific for SLE. Anti-dsDNA positivity is an important eligibility criterion in many SLE studies, and decreases in anti-dsDNA levels are a measure of clinical improvement. Various anti-dsDNA assays have similar performance characteristics in distinguishing SLE patients from controls and those with other diseases. Previous studies have shown that the performance characteristics may change when testing active vs inactive SLE patients. The performance characteristics of a commercially available multilyte assay to the Farr radioimmunoassay (considered a gold standard of anti-dsDNA testing) were compared in adults with active moderate to severe SLE.

Methods: Subjects included adults with moderate-severe active SLE (92% female, median disease duration 6.3 years, mean SLEDAI 2K: 11.3) in an ongoing international, multi-center, double-blind, randomized, placebo-controlled trial. Anti-dsDNA levels were determined by both the Farr radioimmunoassay and the AtheNA Multi-Lyte® ANA-II Plus Test System (AMLII) in the 409/431 randomized subjects who were included in this analysis. Both assays were performed according to manufacturers' instructions in Clinical Laboratory Improvement Amendments (CLIA) certified laboratories. The sensitivity and specificity of the recommended cutoff values for positive (>120) and indeterminate (>100) AMLII assay were assessed using the recommended values for positive (>10) and indeterminate (>5) and cutoffs of the Farr assay. Alternative optimal cutoff values of AMLII for different Farr values were determined by ROC analysis.

Results: Using the recommended cutoff values for positivity, 24% of the patients were anti-dsDNA positive by the AMLII compared to 66% by the Farr assay. When compared to the Farr assay, the recommended cutoff values for AMLII had high specificity but low sensitivity, leading to an unacceptably low concordance with the gold standard of anti-dsDNA testing in this population. Using the optimal cutoff values determined by ROC analysis identified ≥28 (the lower limit of quantifiable detection) as the optimal cutoff for AMLII, which significantly improved the performance of the AMLII (Table).

	Positive		Indeterminate or positive	
Farr cutoff			≥10	≥5
Recommended	AMLII cutoff ≥120	ROC determined ≥28	Recommended ≥100	ROC determined ≥28
ROC AUC	0.84		0.79	
Sensitivity	36%	78%	33%	68%
Specificity	99%	82%	97%	87%
Concordance	57%	79%	45%	72%

ROC: receiver operator curve; AUC: area under the curve. An AUC ≥0.8 represents good diagnostic accuracy

Conclusion: The optimal cutoff value in a population with a high pretest likelihood of anti-dsDNA positivity should be confirmed for any non-gold standard assay if it is being considered to replace a gold standard, such as the Farr assay. Misclassification of a large proportion of subjects with active moderate to severe SLE who are anti-dsDNA positive by the Farr assay as anti-dsDNA negative may lead to unnecessary exclusion of otherwise eligible subjects from clinical trials and may reduce the likelihood of demonstrating a change in the SLEDAI component of composite endpoints in SLE trials.

Novel Risk Factors For Thrombotic Thrombocytopenic Purpura In Systemic Lupus Erythematosus patients. Javier Merayo-Chalico, Diana Gómez-Martín, Roberta Demichelis-Gómez, Sandra Rajme-Lopez, Luis Aparicio-Vera and Jorge Alcocer-Varela. Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubirán, Mexico city, Mexico.

Background/Purpose: Thrombotic thrombocytopenic purpura (TTP) is an uncommon disease characterized by thrombocytopenia and microangiopathic hemolytic anemia and, in some cases, fever, neurologic and/or renal abnormalities. The mortality rate is high despite appropriate diagnosis and treatment. Presence of TTP in SLE is rare (< 2.5%) and diagnosis can be difficult between this two pathologies; sometimes, this results in delayed/suboptimal treatment with higher mortality. The aim of this study was to identify novel risk factors for TTP in SLE and to address the epidemiological profile in this subset of patients.

Methods: We performed a retrospective, case-control study which included patients admitted between January 1994 and March 2013. Three different study groups were included as follows: Cases: TTP/SLE (A) and Controls: non-autoimmune TTP (B) and SLE without TTP (C). TTP was diagnosed by the presence of at least microangiopathic hemolytic anemia, thrombocytopenia < 100,000 cells/μl and high LDH levels. Variables that were measured included: demographic variables, SLEDAI score, clinical and laboratorial parameters (complete blood count, hemolytic parameters and serological tests), treatment, length of hospital stay and mortality. Differences between groups were analyzed by Student t test or U Mann-Whitney. Association between variables was assessed by OR (CI 95%). Multivariate analysis was performed by binary logistic regression model.

Results: Ninety one patients were included: 23 in group A, 22 in group B and 46 in group C. Variables that were associated to TTP diagnosis in SLE patients in comparison to non autoimmune TTP were: lymphopenia (≤1000 cells/μl) (OR 11.5, CI 95% 2.82–47.35), severe anemia (≤7g/dl) (OR 4.9, CI 95% 1.03–7.32) and age (≤30 years) (OR 2.87, CI 95% 1.25–6.55), which remained significantly associated after multivariate analysis. Moreover, after comparing SLE patients with and without TTP, the variables that were related to TTP diagnosis included: severe thrombocytopenia (≤50,000 cells/μl) (OR 17.8, CI 95% 4.66–68.08), severe anemia (OR 8.07 CI 95% 2.33–27.9), history of hematological activity (OR 3.25 CI 95% 1.12–9.39), history of persistent thrombocytopenia (OR 3.21 CI 95% 1.002–10.31), positive antiphospholipid antibody profile (OR 3.11 CI 95% 1.083–8.93) and history of thrombosis (OR 1.20, CI 95% 1.048–1.37). After the multivariate analysis, variables that remained significant were severe anemia (OR 8.9, CI 95% 1.81–43.8) and severe thrombocytopenia (OR 5.71, CI95% 1.5–21.7). Interestingly, we did not find differences in mortality between patients with TTP associated to SLE and non autoimmune TTP.

Conclusion: Patients with TTP associated with SLE are younger than non-autoimmune TTP. Severe anemia, severe thrombocytopenia and lymphopenia are independent risk factors for TTP in SLE. These findings might lead to early diagnosis and treatment as well as lower mortality.

Drug-Resistant Bloodstream Infections In Systemic Lupus Erythematosus Patients: A Clinical Perspective. Ana Barrera-Vargas, Diana Gómez-Martín, Alfredo Ponce de León and Jorge Alcocer-Varela. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.

Background/Purpose: Infections are an important cause of mortality and morbidity in Systemic Lupus Erythematosus (SLE) patients. Different risk factors have been described for the development of infections in SLE, such as immunosuppressive therapy, intrinsic immune system dysfunction, disease activity, and lymphopenia. However, there is no current data on the potential risk factors for drug-resistant bacteria (DRB) in SLE. Bloodstream infections (BI) are common in SLE patients and are associated with increased mortality. An inadequate empirical antibiotic coverage in BI has been associated to higher mortality rates. Moreover, antibiotic resistance has become more prevalent, and it is important to define which patients require broad-spectrum antibiotics (BSA) initially. The aim of this study was to identify risk factors that influence the development of DBR in SLE, in order to determine which patients might benefit from an initial BSA coverage.

Methods: A retrospective, case-control study was performed. All patients fulfilled at least four ACR 1997 criteria for SLE and had an episode of BI between 2001 and 2012. Cases were defined as patients who had BI caused by DRB (*P. aeruginosa*, methicillin-resistant *S.aureus* or extended-spectrum β-lactalamase-producing *E. coli*), while patients in the control group had BI by susceptible strains of *S. aureus* or *E. coli*. Groups were age and gender matched. The variables that were measured included: disease activity, SLEDAI, anti-dsDNA antibodies, C3 and C4 levels, leukocyte and lymphocyte count in the three months prior and at the time of the infection; comorbidities; use of antibiotics or hospitalization in the previous three months; immunosuppressive treatment in the previous year and at the moment of the infection. Differences between groups were analyzed by Student t test or U Mann-Whitney test. Association between variables was assessed by OR (CI 95%). Multivariate analysis was performed by binary logistic regression model.

Results: Forty four patients were included in each group. 93% were female, with ages between 16 and 73. Variables associated with drug-resistant BI were the following: a history of CNS activity (OR 2.66, CI 95% 1.15–6.17); hematological activity (OR 2.11, CI 95% 1.07–4.14), immunosuppressive treatment (OR 1.24, CI 95% 1.02–1.5) and prednisone dose ≥ 20 mg/d at the time of the infection (OR 5.11, CI 95% 2–12.6); low C3 levels previous to infection (OR 2.71, CI 95% 1.25–5.9); and antibiotic use (OR 2.18, CI 95% 1.43–3.32) or hospitalization in the previous 3 months (OR 2.9, CI 95% 1.61–5.2). In the multivariate analysis, variables that remained significant were: low C3 previous to infection (OR 2.83, CI 95% 1.11–7.18), previous hospitalization (OR 2.18, CI 95% 1.21–3.95), and prednisone dose at the time of infection (OR 1.058, CI 95% 1.027–1.089).

Conclusion: Low C3 levels, a recent hospitalization and prednisone dose at the time of infection are risk factors for developing BI caused by DRB in SLE patients. Patients with these characteristics may benefit from initial BSA coverage.

Lipid Lowering Medication Use Is Associated With Reduced Muscle Strength In Systemic Lupus Erythematosus. James S. Andrews[1] and Patricia P. Katz[2]. [1]University of California San Francisco, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA.

Background/Purpose: Premature atherosclerotic coronary artery disease is a major source of morbidity for women with systemic lupus erythematosus (SLE). Lipid lowering medications (LLM) are among the most commonly prescribed medications used to reduce cardiovascular risk. However, LLM use may be complicated by muscle symptoms, including weakness. This study examines the relationship between LLM use and muscle strength in women with SLE.

Methods: Subjects were participants in a longitudinal cohort with documented SLE. All measures were collected during an in-person research visit among a subset of the cohort. Only women were included in the analysis. LLM use was assessed by asking participants, "Do you have or are you being treated for high cholesterol? If yes, are you taking any prescription medicines for it?" Which specific LLM participants were taking was not assessed. Lower extremity muscle strength was assessed by knee torque and chair-stand time. A Biodex® unit was used to measure peak torques of knee extension and flexion at 150 degrees/second adjusted for body weight. Chair-stand time was measured as the time to complete 5 chair-stands from a standard chair without using one's arms. Mean knee torque and chair-stand time were compared between participants taking and not taking a LLM using Student's t-test. Regression analyses controlling for age, SLE duration, prednisone use, and SLE disease activity measured with the Systemic Lupus Activity Questionnaire (SLAQ) modeled the effect of LLM use on lower extremity muscle strength and chair stand time.

Results: Twenty-nine of 137 women (21%) reported taking a LLM. Mean age was 48 (±12) years; duration of SLE was 16 (±9) years. Women taking a LLM, compared to women not taking a LLM, had significantly lower strength on knee extension (mean peak torque 19 [±13] vs 29 [±15] foot-pounds, p=0.001) and on knee flexion (mean peak torque 14 [±9] vs 21 [±11] foot-pounds, p=0.002). Mean chair-stand time was greater for women taking a LLM than women not taking a LLM: 23 (±9) and 18 (±8) seconds (p=0.004). The results did not substantively change after adjusting for the effect of age, SLE duration, prednisone use, and SLAQ score.

Conclusion: Women with SLE who take a LLM, compared to women who do not, demonstrated decreased muscle strength on two objective assessments of lower extremity strength. Additional studies are needed to further characterize the association between LLM use and reduced muscle strength among women with SLE.

The Accrual Of Damage In Corticosteroid-Naïve Patients With Systemic Lupus Erythematosus. Barry J. Sheane, Dominique Ibanez, Dafna D. Gladman and Murray B. Urowitz. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Despite improved survival rates in systemic lupus erythematosus (SLE) over the last 4 decades, organ damage and associated morbidity continues over time. Corticosteroids (CS) contribute to this accrual of damage. Due to the reliance on CS in the treatment of SLE there is a paucity of data on the disease characteristics of those that remain CS-naïve.

We hypothesized that CS-naïve patients with SLE accrue less damage and at a slower rate than CS-exposed patients, and that initiation of antimalarial medication (AM) soon after diagnosis may reduce exposure to CS over time.

Methods: Patients with SLE attending a large lupus clinic with 3 years or more of follow-up from inception, in the absence of damage (as per the SLICC Damage Index (SDI)) or exposure to CS at the inception visit, were included in the analysis. Two groups were identified from this cohort: those who remained CS-naïve up to their last visit at the Clinic and those who were exposed to CS at any point during follow-up. Differences in the rate of exposure to AM, rate of organ damage accrual (SDI ≥ 1) and disease activity at inception (SLEDAI-2K) and over time (adjusted mean SLEDAI (AMS) were examined. Organ-specific damage at the last Clinic visit was sub-classified as: 'definitely steroid-related' (e.g. osteonecrosis), 'possibly steroid-related' (e.g. myocardial infarction), and 'unrelated to steroid' (e.g. chronic kidney disease). A generalized linear model with repeated measures was used to assess the increase in damage over fifteen years in the two groups.

Results: From 209 patients fulfilling inclusion criteria, 84 remained CS-naïve from inception to the last recorded visit, while 125 were exposed to CS at some point during the disease course. Mean disease duration at first exposure to CS was 3.8 ± 5.5 years. Gender, race and age (37 ± 14.2 years in the CS-naïve group vs 35.1 ± 13.5 years in the CS-exposed (p=0.33)) were similar between the 2 groups at diagnosis. Baseline SLEDAI-2K was lower in the CS-naïve group (5.48 ± 3.53) compared with the CS-exposed (8.12 ± 5.93; p<0.0001). The AMS at all time points up to 10 years after diagnosis was significantly greater in the CS-exposed group. In the CS-naïve group, 35.7% developed damage during their disease course compared to 60.8% of the CS-exposed (p=0.0004). Mean SDI was significantly greater 1 year after diagnosis in the CS-exposed compared to the CS-naïve (0.14 ± 0.43 vs 0.02 ± 0.15, p=0.008) and at bi-annual intervals up to 15 years (1.52 ± 1.59 vs 0.54 ± 0.75, p<0.0001). On average, CS-naïve patients accrued damage at the rate of 0.05 per year compared to 0.10 per year in the CS-exposed patients (p=0.003). The increase in damage over 15 years 'definitely' and 'possibly' CS-related was significantly greater in the CS-exposed compared with the CS-naïve (p=0.009 and 0.024, respectively), but not in damage 'unrelated to CS' (p=0.3). Within the first year from inception, 51% of the CS-naïve and 61% of the CS-exposed groups were prescribed AM (p=0.17).

Conclusion: One third of CS-naïve SLE patients accrue damage over time, yet develop less damage and at a slower rate than those exposed to CS. Disease activity is lower in those naïve of CS, while early initiation of AM does not reduce exposure to CS.

Serositis In Systemic Lupus Erythematosus: Prevalence, Recurrence, Treatment and Outcome. Mansour Somaily, Dafna D. Gladman, Dominique Ibanez and Murray B. Urowitz. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Serositis is one of the ACR classification criteria for SLE. Its incidence is variable in studies varying from 12 to 60%.

The aim of this study is to determine the prevalence of serositis, its recurrence, management and complications in a large longitudinal cohort study.

Methods: Patients studied were seen in a long term single center observational cohort study. Pleurisy and pericarditis were diagnosed according to SLEDAI-2K Disease Activity Index criteria, which require objective measures to classify the serositis.

Demographic and clinical data collected at the time of serositis onset included age, gender, age at diagnosis, disease duration, medication used, damage index and SLEDAI assessment. Patients were divided into two groups: 1) patients with no recurrence and 2) those with recurrence. Those patients who had serositis features for more than six months despite appropriate treatment were considered to have refractory disease. Recovery was defined as resolution of pain attributed to the serositis. Descriptive statistics were used.

Results: 214 patients out of 1678 patients in the cohort (12.8%), had serositis during their disease course. This group was made up of 83% Female, 67% Caucasian, 14% Black, 8% Asian and 10% Other. Age at SLE diagnosis was 33 ± 12 years. At onset of serositis, disease duration was 4.6 ± 6.1 years; SLEDAI-2K (excluding serositis items) was 11.3 ± 9.7 and 61 (36%) patients had some damage.

174 patients had no recurrence and 40 patients (18.7%)had recurrence – 31 patients had 2 episodes, 5 patients had 3 episodes and 4 patients had 4 episodes. 12 (0.7%) patients had complications including pleural fibrosis and thickening and pericardial thickening.

202 (94.4%) patients went on to complete recovery and 12 (5.6%) were refractory. Average time to recovery was 8.6 ± 9.6 weeks. Refractory patients had serositis for an average of 1.2 ± 0.5 year.

Excluding refractory patients and comparing patients with recurrence to those without recurrence, there was no difference in sex, age at SLE diagnosis, age and disease duration at serositis onset, SLEDAI-2K or percent of patients with damage. More patients with recurrences had steroids and immunosuppressives compared to the non-recurrence group (100% vs 89% for steroids p=0.05; 36% vs 11% for immunosuppressives, p=0.0002).

Conclusion: Serositis occurs in 12.8% of our patients as defined by SLEDAI-2K. They responded well to corticosteroid but approximately 1 in 5 had a recurrence. Refractory disease is rare. There were no predictive variables for recurrence.

Clinical Correlates Of Chronic Isolated Thrombocytopenia In Patients With Systemic Lupus Erythematosus. Amanda J. Steiman, Dafna D. Gladman and Murray B. Urowitz. University of Toronto, Toronto Western Hospital, Toronto, ON.

Background/Purpose: Past studies have revealed disparity in the clinical significance of thrombocytopenia in systemic lupus erythematosus (SLE), ranging from a benign and incidental finding in some to a life-threatening manifestation, associated with severe disease and a high mortality rate in

others. Some patients evolve to a state of chronic isolated thrombocytopenia (CIT), the clinical significance of which is unknown. It is thus unclear whether this isolated finding warrants prompt, reactive therapy, or whether these patients may be monitored, free from immunosuppressive therapies and their associated toxicities, without risk of worsening disease activity. Thus the purpose of this study was to investigate the clinical correlates of CIT in a large cohort of SLE patients.

Methods: Patients with CIT were identified from the Lupus Clinic database. CIT was defined as at least two consecutive visits, ≤18 months apart, with SLE Disease Activity Index 2000 (SLEDAI-2K) score of 1 from platelets < 100, irrespective of pharmacotherapy. Any divergence from this score ended the thrombocytopenic period. Descriptive statistics were used.

Results: 16/1678 (1%) patients had CIT, occurring over 42 discrete episodes, and spanning 147 visits. The mean duration of a thrombocytopenic episode was 10.9 months, and the mean cumulative duration of isolated thrombocytopenia per patient was 28.6 months. Mean time to first CIT episode from clinic entry was 8.6 years (range 4 months – 31 years). Platelet counts during these periods ranged from 15 – 99, and were associated with antiphospholipid antibody positivity in 6/16 (37.5%). Fifteen patients (93.8%) were known to have thrombocytopenia as an SLE manifestation, associated with other signs/symptom of activity, earlier in their disease course; in the remaining patient it correlated with the introduction of an herbal remedy. There were no clinically significant episodes of bleeding in any of the patients over the visits studied, but critically low counts (≤20) were managed by increasing immunosuppression. Thrombocytopenia was associated with pregnancy in 3/42 (7.1%) of the episodes. Eleven patients (68.8%) were taking steroids at low doses, and six patients (37.5%) each were taking antimalarials or immunosuppressives during the CIT episodes. At times, these therapies overlapped. Four patients (25%) required none of these therapies for the duration of their CIT episodes. Prior to or after a CIT episode, patients were serologically and clinically quiescence in 14/78 (17.9%) instances, had active serology with or without thrombocytopenia in 34/78 (43.6%) instances, and were clinically active in 27/78 (34.6%) instances; there were more than 18 months between visits in three instances.

Conclusion: CIT is a rare event that can occur anytime in the SLE disease course and is usually associated with treatment with low dose steroids and/or immunosuppressives. Patients with this manifestation require close clinical monitoring and cannot be considered to be in remission.

Corticosteroid Use Across 52 Weeks Of Belimumab Therapy In Patients With Systemic Lupus Erythematosus: Combined Analyses From The BLISS Trials. Ronald F. van Vollenhoven[1], Michelle Petri[2], Daniel J. Wallace[3], David Roth[4], Charles T. Molta[4], Anne Hammer[5], Tom Tang[5] and April Thompson[5]. [1]The Karolinska Institute, Stockholm, Sweden, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]GlaxoSmithKline, King of Prussia, PA, [5]GlaxoSmithKline, Research Triangle Park, NC.

Background/Purpose: Patients with systemic lupus erythematosus (SLE) frequently receive corticosteroids (CS) as standard therapy. We examined the effects of belimumab on CS dose across 52 weeks of treatment in two randomized, controlled trials.

Methods: Data from BLISS-52 (NCT00424476) and BLISS-76 (NCT00410384) were pooled (GSK 200317). Patients treated with CS at baseline and randomized to receive belimumab 10 mg/kg plus standard therapy or placebo (standard therapy) were compared. A conservative steroid taper was imposed by each protocol. The primary endpoint was the cumulative change from baseline (average dose over the prior 7 days) in CS dose (prednisone or equivalent) through week 52. Rank analysis of covariance (ANCOVA) was applied. Cumulative dose reductions and increases, and change from baseline in average daily CS dose were examined. Adverse events (AE) were summarized.

Results: At baseline, 966 (Total N=1125, 86%) subjects received CS therapy: 478 belimumab 10 mg/kg, 488 placebo. Most subjects were female (n=910, 94%); mean age was 37.1 (11.5 SD) years, mean SELENA SLEDAI score was 9.8 (3.8 SD) and mean CS dose (prednisone or equivalent) was 12.5 (8.2 SD) mg/day. Baseline parameters for subjects treated with CS were similar between treatment groups. The mean of all cumulative decreases in CS dose was 741 mg for belimumab 10 mg/kg and 542 mg for placebo (p=0.017). The mean of all cumulative increases in CS dose was 1272 mg for belimumab and 1458 mg for placebo (p<0.001). The mean cumulative change from baseline in CS dose was 531 mg for belimumab compared with 916 mg for placebo (p <0.001). The mean change from baseline in average daily CS dose was 1.46 mg for belimumab and 2.51 mg for placebo (p <0.001). The most commonly reported AE among those subjects receiving CS at baseline was headache for both belimumab and placebo groups.

Conclusion: Although there was an increase in total CS dose in both arms over the duration of the trial, this increase was significantly smaller in patients who received belimumab 10 mg/kg plus standard therapy compared with standard therapy alone after one year of treatment. Adverse events for patients treated with CS were comparable among treatment groups.

1586

Defining Hand Arthritis In Systemic Lupus Erythematosus, From An Ultrasound, Magnetic Resonance Imaging and Antibody Status Perspective. Elisabeth M.A Ball[1], Arthur Grey[2], Ai Lyn Tan[3], Eiji Fukuba[4], Gunter Steiner[5], Dennis McGonagle[3], Aubrey Bell[2] and Madeleine Rooney[6]. [1]Queens' University/Musgrave Park Hospital, Belfast, United Kingdom, [2]Musgrave Park Hospital, Belfast, United Kingdom, [3]University of Leeds, Leeds, United Kingdom, [4]Shimane University, Izuma, Japan, [5]Medical University of Vienna, Vienna, Austria, [6]Queens University Belfast, Belfast, United Kingdom.

Background/Purpose: Musculoskeletal involvement in systemic lupus erythematosus (SLE) is common but poorly characterised with only a few Magnetic Resonance Imaging (MRI) or ultrasound (US) studies to date published in lupus arthritis. Erosive disease in SLE associated with rheumatoid factor (RF) or anti-CCP antibody (ACPA) is often referred to as '*rhupus'* to indicate a mixture of the character of RA and lupus. This study used MRI and US to investigate a cohort of hand and wrist SLE disease in comparison to RA and in respect to autoantibody status.

Methods: 50 SLE patients (median (IQR) disease duration 15.5 (9,20) yrs) with joint symptoms and /or objective arthritis, and 40 RA patients (median disease duration 15 (5,23) yrs) had a detailed US scan (Greyscale (GS) and Power Doppler (PD)) of dominant hand and wrist as per standardised protocols. 34 of these SLE patients and 15 RA patients also had a contrast enhanced MRI of their hand which was scored according to the OMERACT RAMRIS system. Extended antibody analysis (which included the anti-RA33 antibody and ACPA) was performed.

Results: There were no normal MRI examinations in the SLE group; 85% of MCP joints in lupus patients showed at least Grade 1 synovitis, compared to 76.7% of all RA MCP joints. *All SLE* wrist joints showed at least Grade 1 synovitis. 61.8% of those SLE patients had MRI determined MCP joint erosion compared to 100% of RA patients. 93.3% had at least one erosion at the wrist with erosions in 45% of the total number (n = 240) of SLE carpal bones. The prevalence of extensor tenosynovitis on MRI at the wrist was greater in the SLE group (20.3%), than in the rheumatoid group (10.7%) (p = 0.05).

Anti-RA33 titres correlated with SLE disease activity (SELENA SLEDAI) scores (p = 0.03) but in addition there was a strong negative correlation with total MRI MCP and total PIP bone oedema (p = 0.013 and p = 0.019 respectively). Only five SLE patients fulfilled the criteria for *'rhupus'* in that they had a positive ACPA or RF in the presence of erosive disease.

There was good correlation of MRI synovitis scores at the MCP joints with MCP ultrasound GS and PD (p = 0.003 and p < 0.001 respectively). There was excellent correlation of MRI and US wrist extensor tenosynovitis scores (p < 0.003).

Patient No.	ACPA	RF	Anti-RA33 (titre)	Total MCP erosion score on MRI (range 0–50)	Total Wrist erosion score on MRI (range 0–100)	Total Extensor Tenosynovitis score on Ultrasound (range 0–18)	Total MCP Bone Oedema (range 0–12)
89	+	−	−(10.2)	24	7	3	0
45	+	−	−(8.4)	0	1	3	0
59	+	−	−(9.5)	22	10	2	6
2	−	+	−(6.8)	n/a	n/a	0	0
3	−	+	−(3.2)	33	7	0	19
6	−	−	+(28)	0	1	0	0
16	−	−	+(52)	2	5	0	0
33	−	−	+(82)	3	1	0	0
37	−	−	+(316)	2	8	0	0
39	−	−	+(96.2)	0	4	0	0
41	−	−	+(83.7)	n/a	n/a	0	n/a
42	−	−	+(78.5)	n/a	n/a	0	n/a
67	−	−	+(40)	14	12	3	0

'+', positive antibody test, '−' negative antibody test, n/a, non-applicable as patient did not have an MRI scan.

Conclusion: This is the largest study to date using MRI in lupus arthritis and the first study to combine US and MRI in the assessment of SLE patients. We have shown that erosive lupus arthritis is independent of RF or ACPA status, challenging the use of the term *'Rhupus'* as the only manifestation of erosive arthritis in SLE. The negative association of bone oedema with anti-RA33 titres would suggest that those patients who have high titres are less likely to have more aggressive arthritis. This association with a more favourable outcome has been reported before in RA but has not yet been studied in relation to lupus arthritis.

Continuous Variables Of Treatment Interventions In Patients Diagnosed With Systemic Lupus Erythematosus Among Commercially and Medicaid Insured Populations In The U.S. Hong Kan[1], Saurabh Nagar[1], Jeetvan Patel[1], Anna Oh[2], Daniel J. Wallace[3] and Charles T. Molta[4]. [1]GlaxoSmithKline, Research Triangle Park, NC, [2]University of California San Francisco, San Francisco, CA, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]GlaxoSmithKline, Philadelphia, PA.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that affects multiple organs including the heart, lungs, kidneys, joints, and the nervous system. Standard therapies for SLE include corticosteroids, antimalarial agents, non-steroidal anti-inflammatory drugs, cytotoxic agents, and immunosuppressive/ immunodulatory agents, some of which can be associated with significant toxicity. The objective of this study is to describe how SLE treatment evolves over time in newly diagnosed SLE patients in the U.S.

Methods: This retrospective, observational cohort study (HO-13–13054) followed incident SLE patients' treatment for 5 years in the Truven commercial and Medicaid claims database. The earliest date of a medical claim with a diagnosis of SLE (710.0x) from Jan 1, 2004 to Dec 31, 2009 was defined as the index date. Patients were required to be ≥ 18 years old at index date, had continuous medical and pharmacy benefits for 24 months prior to index date without SLE diagnosis and 12 months after index date with ≥ 1 SLE-related inpatient claim or ≥ 2 office or emergency room visits with an SLE diagnosis at least 30 days apart. At least one SLE diagnosis on or during 12 months after index date must be made by a rheumatologist, dermatologist, nephrologist, or neurologist.

Results: 4,036 commercially insured incident SLE patients (mean age: 46.9 years; female: 88.8%; mean Charlson comorbidity index (CCI): 1.01; mean follow up: 1,289 (SD: 645) days) and 234 incident patients with Medicaid coverage (mean age: 42.5 years; female: 94.0%; mean CCI: 1.80; mean follow up: 1,389 (SD: 767) days; white: 18.4%, black: 59.4%, Hispanic 1.3%, other: 20.9%) were identified. The number of patients in both cohorts declined over time due to insurance change or death. The proportion of patients with ≥ 1 prescriptions of SLE therapies decreased over 5 years after diagnosis (Table). In the first year after diagnosis, corticosteroid treatment rate was 48.1% and 62.8%, antimalarial treatment rate was 53.4% and 57.3%, and immune suppressive treatment rate was 22.2% and 25.6% in commercially insured and Medicaid insured patients, respectively. Biologic use in the two cohorts was no more than 1.5% throughout the period.

Table. Proportion of Patients with SLE Treatment Over Time in Commercially Insured and Medicaid Incident SLE Patients

	% with ≥ 1 prescriptions, commercially insured SLE patients (%)					% with ≥ 1 prescriptions, Medicaid SLE patients (%)				
Year after SLE diagnosis	1 N=4,036	2 N=4,029	3 N=3,149	4 N=2,144	5 N=1,311	1 N=234	2 N=234	3 N=161	4 N=120	5 N=98
Corticosteroids	48.1	35.3	26.4	22.3	19.2	62.8	44.4	31.1	27.5	20.4
Antimalarials	53.4	42.9	31.7	26.0	22.0	57.3	39.3	29.8	20.0	19.4
Immune suppressives	22.2	19.2	13.9	11.7	10.5	25.6	21.4	17.4	12.5	12.2
Anti-TNFs (including adalimumab, certolizumab, etanercept, golimumab and infliximab)	1.5	1.5	1.2	1.0	0.9	0.4	0.0	0.0	0.0	0.0
Other Biologics (including abatacept, tocilizumab and rituximab)	0.0	0.2	0.1	0.1	0.0	0.0	0.0	0.0	0.0	0.0

Conclusion: Over a 5 year period, SLE patients were treated with less antimalarials, immune suppressive regimens, and targeted therapies than reported in tertiary lupus cohorts. This could reflect poor adherence, inability to afford medication, milder disease, or practitioner unfamiliarity with prescribing agents other than corticosteroids. The decrease in prescriptions over time might relate to response to treatment, lapses in physician or patient education, or exit of more severe patients from the cohorts. Further study is needed to explore the implications of treatment options upon outcomes.

Poor Adherence To Medications For Systemic Lupus Erythematosus Among U.S. Medicaid Beneficiaries. Jinoos Yazdany[1], Jun Liu[2], Graciela S. Alarcon[3], Karen H. Costenbader[4] and Candace H. Feldman[5]. [1]University of California, San Francisco, San Francisco, CA, [2]Brigham and Women's Hospital, Boston, Massachusetts, Boston, CA, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [5]Brigham and Women's Hospital, Boston, MA.

Background/Purpose: Immunosuppressive and anti-malarial drugs are the cornerstones oftreatment for patients with systemic lupus erythematosus (SLE) and have beenshown to improve outcomes, including reduced disease activity, damage andmortality. We examined adherenceto treatment with these medications in a nationwide study of Medicaidbeneficiaries with SLE.

Methods: We used U.S. Medicaid Analytic eXtract (MAX) datafrom 2000–2006 containing person-level files on Medicaid eligibility, utilization and payments. Weidentified patients meeting a validated administrative SLE definition, who hadreceived either an immunosuppressive (oral cyclophosphamide, mycophenolatemofetil, mycophenolic acid, azathioprine, leflunomide, methotrexate, ortacrolimus) or anti-malarial (hydroxychloroquine) drug through an outpatientpharmacy over the period of observation. Pharmacy claims were used to assess adherence to drugs by calculating amedication possession ratio (MPR), defined as the proportion of days covered bythe total days' supply dispensed after the first claim for each drug. We observed each patient over a fixedinterval of 180 days to ensure all patients were studied for the same timeinterval. Data were stratified bysociodemographic characteristics and geographic region and we used Fisher'sexact test to compare MPRs between groups. In addition, we examined the percentage of patientsconsidered adherent, defined as having a MPR greater than or equal to 80%.

Results: 23,187 patients with SLE were taking at least oneimmunosuppressive or anti-malarial drug. Mean age was 38 years (SD 12) and 94% were female. The sample was diverse (40% Black, 34%White, 16% Hispanic, 5% Asian, 5% Other, and 1% Native). Most resided in the U.S. South (36% vs.18% Midwest, 23% Northeast, 22% West). MPRs ranged from 31.1% for tacrolimus to56.9% for hydroxychloroquine (Table). Across all medications, Blacks had loweradherence compared to Whites. Formany medications, Asians had higher adherence than Whites. For example, for hydroxychloroquine, the MPR was significantly higher among Asians (63, SD 27), and lower in Blacks(53, SD 29), Hispanics (57, SD 28), and Native populations (56, SD 26) comparedto Whites (59, SD 31; $p<0.0001$ for group comparisons). MPRs were lowest for patients residingin the Midwest, and highest for those in the Northeast ($p<0.01$ acrossdrugs). A minority of patients had

MPRs greater than or equal to 80% (range 14%for tacrolimus to 40% for mycophenolate mofetil; Table).

Table. Adherence to Commonly Used Medications for Systemic Lupus Erythematosus in a Nationwide Study of U.S. Medicaid Beneficiaries.

Oral Drug	Population Taking Medication, n	Average Medication Possession Ratio (MPR*), SD	Population with MPR greater than or equal to 80%, %
Hydroxychloroquine	23,187	56.9 (30)	31
Azathioprine	6,137	56.5 (30)	31
Methotrexate	5,278	53.1 (31)	27
Mycophenolate mofetil	3,954	56.1 (30)	40
Cyclosporine	1,185	42.9 (31)	20
Tacrolimus	1,020	31.1 (31)	14
Cyclophosphamide	778	41.2 (33)	20
Leflunomide	989	54.4 (31)	29

*Proportion of days covered by the total days' supply dispensed over a 180-day period after the initial drug claim.

Conclusion: Ourstudy demonstrates poor adherence to all classes of medications used to treatSLE among Medicaid beneficiaries. Although adherence was low across all racial/ethnic groupsand regions examined, it was particularly low among Blacks, Hispanics andNative populations, as well as for those residing in the Midwest. These findings suggest that a majorityof Medicaid beneficiaries may be at risk for inadequate clinical responsebecause of poor adherence.

Obesity and Vascular Factors May Play a Role In Persistent Depression Among Individuals With Systemic Lupus Erythematosus. Patricia P. Katz[1], Chris Tonner[1], Laura Trupin[1], Edward H. Yelin[2] and Jinoos Yazdany[1]. [1]University of California, San Francisco, San Francisco, CA, [2]UC San Francisco, San Francisco, CA.

Background/Purpose: Depression is commonly reported in systemic lupus erythematosus (SLE), yet information is lacking about long-term patterns of depression. In particular, because depression is thought to arise at least partially from disease-specfiic sources, information regarding predictors of persistent depression is needed. We examined a longitudinal SLE cohort to identify factors that predicted persistent depression vs. remission.

Methods: Data derive from the UCSF Lupus Outcomes Study (LOS), in which participants with confirmed SLE are interviewed by phone annually. During each interview, the Center for Epidemiologic Studies Depression scale (CESD) is administered. We defined depression using a lupus-specific cut-point of 20 (1). Individuals who were depressed by this criterion at the initial interview were followed through subsequent interview waves. Those whose CESD score remained ≥ 17 (within 0.5 SD of the cut-point) were classified as having persistent depression. Those whose CESD score dropped below 17 were classified as remitting. We then used bivariate and multivariate analyses to define baseline factors associated with persistent depression. Variables examined were sociodemographics (age, sex, education, income), SLE duration, self-rated disease activity (on 0–10 scale), history of cardiovascular events (previous MI or stroke), history of other vascular events (e.g., DVT, PE, or other clot), obesity based on body mass index (BMI≥30), current smoking, and current reported use of antidepressants. Analyses controlled for the number of interviews contributed by each individuals. Individuals who were interviewed at least three times were included in the analysis.

Results: Of 1008 individuals in the analysis sample, 340 were depressed at their initial interview. Among these, 135 (40%) remained depressed through all remaining observations. Factors significantly associated with persistent depression in bivariate analyses were: low education, income below poverty, higher self-rated disease activity, current smoking, history of vascular events other than MI or stroke, obesity, and current use of depression medication (Table). In multivariate analyses, low education, history of other vascular events, obesity, and current use of depression medication were independently associated with persistent depression.

Table. Factors associated with persistent depression in bivariate and multivariate analyses

	Bivariate analyses		Multivariate analysis†
	Remission (n = 205)	Persistent depression (n = 135)	OR (95% CI)
Sociodemographic			
Age (mean±SD)	45 ± 13 yrs	47 ± 10 yrs	1.01 (0.98, 1.03)
Female	94%	94%	1.52 (0.44, 5.30)
Education ≤ high school	18%	36%*	**2.16 (1.17, 3.99)**
Income below poverty	17%	32%*	1.60 (0.84, 3.05)
Health characteristics			
SLE duration (mean±SD)	12 ± 10 yrs	12 ± 10 yrs	0.98 (0.94, 1.02)
SLE disease activity (mean±SD)	5 ± 3	6 ± 3*	1.07 (0.97, 1.18)
Current smoking	8%	20%*	1.37 (0.60, 3.14)
History of MI or stroke	10%	14%	1.63 (0.73, 3.66)
History of other vascular event	15%	27%*	**2.25 (1.14, 4.43)**
Obese (BMI ≥ 30)	27%	42%*	**1.87 (1.07, 3.26)**
Taking antidepressants	42%	48%*	**2.02 (1.12, 3.66)**

* p<.01.
† Multivariate model included all variables shown plus number of interviews contributed.

Conclusion: Forty percent of women who met the depression criterion initially were persistently depressed. Results suggest that obesity and vascular factors may play a role in persistent depression in SLE, and that such depression may be resistant to treatment. Further study is needed to identify mechanisms for those associations.

A CD8 T Cell-IFN-γ-IDO Axis Is Required For Mesenchymal Stem Cell Suppression Of Human SLE. Dandan Wang, Lin Lu, Xuebing Feng, Xia Li and Lingyun Sun. Department of Rheumatology and Immunology, the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China.

Background/Purpose: Stem cell-based regenerative medicine is a promising approach in tissue reconstruction. Mesenchymal stem cells (MSC) show therapeutic effects on human autoimmune diseases including systemic lupus erythematosus (SLE), but the underlying mechanisms remain largely unknown.

Methods: The effects on inhibiting T cell proliferation by allogenic umbilical cord derived MSC were determined. Then MSC functional molecules were examined by real-time PCR under the stimulation of peripheral blood mononuclear cells (PBMC) from healthy controls and SLE patients, respectively. CD4+ and CD8+T cell were purified by microbeads to stimulate MSC, respectively, to determine IDO expression as well as supernatant cytokines, to further get to know which cell subset(s) or which molecule(s) involved in MSC mediated T cell proliferation inhibition. Meanwhile, the possible signaling pathways were assessed. Moreover, we analyzed the correlation between baseline serum cytokines and clinical response of MSC transplantation (MSCT).

Results: UC MSC efficiently inhibited T cell proliferation in both healthy controls and lupus patients, with a more inhibitory effect in lupus T cell. *In vitro* activated lupus PBMC significantly induced MSC to secret TGF-β1, IDO, HGF and IL-6, with a more than 200-fold increase of IDO. The addition of IDO inhibitor could almost completely abrogate MSC mediated T cell proliferation inhibition. Moreover, we found that lupus peripheral CD8+T cell markedly stimulated MSC to secret IDO and supernatant IFN-γ significant increased. The addition of anti-IFN-γ monoclonal antibody could inhibit IDO activity and similarly abrogate inhibition of T cell proliferation by MSC. We further found that lupus CD8+T cell secreted predominant intracellular IFN-γ compared to CD4+T cell or compared to healthy CD8+ or CD4+T cell subsets. Furthermore, in the presence of lupus CD8+T cell, IFNGR/JAK/STATs signaling pathways were activated, then to induce MSC to secret IDO and upregulate IDO activity. However, bone marrow MSC from lupus patients are less response to allogenic CD8+T cell or recombinant IFN-γ stimulation and produce far less IDO, consequently fail to efficiently inhibit

T cell proliferation. In the last, clinical analysis showed that lupus patients had significant higher proportion and absolute number of CD3+CD4-CD8+T cell than healthy controls, and serum IFN-γ markedly increased. Predominant IFN-γ in lupus patients was mainly secreted by CD8+T cell. Baseline serum IFN-γ as well as CD8+T cell levels were significant higher in good responders than in poor responders who underwent UC MSC transplantation.

Conclusion: We uncovered a previously unrecognized CD8+T cell-IFN-γ-IDO axis that mediates the immunotherapy by allogenic MSC in lupus patients.

Efficacy and Safety Of Atacicept For Prevention Of Flares In Subjects With Moderate To Severe Systemic Lupus Erythematosus (SLE). David Wofsy[1], David A. Isenberg[2], Daiana Licu[3], Yong Li[4], Claudia Pena Rossi[3] and Caroline Gordon[5]. [1]University of California San Francisco and NIAID Autoimmunity Centers of Excellence, San Francisco, CA, [2]University College London, London, United Kingdom, [3]Merck Serono S.A., Geneva, Switzerland, [4]EMD Serono, Rockland, MA, [5]University of Birmingham, Birmingham, United Kingdom.

Background/Purpose: Atacicept is a fusion protein that inhibits B-cell stimulation factors BLyS and APRIL. Levels of BLyS and APRIL are elevated in patients with SLE. We report on the efficacy and safety of atacicept in preventing new flares of SLE during 52 weeks on treatment and 24 weeks of safety follow-up in the APRIL-SLE trial.

Methods: Subjects with active SLE (≥1 BILAG A and/or B) were treated with a corticosteroid taper for 10 weeks. Subjects reaching BILAG C or D were randomized 1:1:1 to receive placebo or atacicept 75 or 150 mg twice weekly for 4 weeks, then weekly for 48 weeks. The primary outcome measure was percent of subjects experiencing a flare, defined as a new BILAG A or B, during the 52-week treatment period. Subjects were also followed during a 24-week follow-up period.
