Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) has been acknowledged to increase cardiovascular mortality probably due, in part, to a lipid profile different from that observed in the general population. Tocilizumab (TCZ), is associated with increased lipid levels in the context of decreased levels of inflammatory markers. The mechanisms by which TCZ increases lipids are not yet fully understood. Proprotein convertase subtilisin/kexin type 9 (PCSK9) is a serine protease that regulates cholesterol metabolism through low-density lipoprotein receptor degradation, linked to cardiovascular risk. The purpose of the present study was to examine whether PCSK9 serum levels are related to the abnormalities in the lipid profile that TCZ causes in RA patients.

Methods: The prospective TOCRIVAR study (Clin Trial.gov identifier: NTC01752335) analyzes the influence of TCZ on different cardiovascular risk factors in RA patients. Patients received TCZ

8 mg/kg IV q4w for 52 weeks. None of the patients was under statins treatment. Available serum samples were analyzed at baseline and at weeks 12, 24 and 52. PCSK9, lipoproteins serum concentrations and standard lipid profiles were assessed at every visit. Dual-x-ray-absorptiometry-derived body composition (DEXA) and abdominal adiposity by magnetic resonance imaging, were assessed at basal visits and at the end of the study. Cox-regression analysis was performed to study the influence of TCZ over PCSK9 serum levels and lipid profile, adjusting for body composition and PA.

Results: 26 RA patients, 2 males and 24 females, 52±2 years old, were included in the study. Median PCR (Δ-5.3[-0.2--14.8] mg/dl, p=0.00) and DAS28 (Δ-1.8[-1.5--2.2] p=0.00) were markedly reduced within the first 12 weeks and they remained significantly lower compared to basal visit levels throughout the one year of TCZ treatment. Average total cholesterol, HDL-C, and apolipoprotein A and B levels increased after 3 and 6 months of treatment; however, no statistical significant difference were observed, in these values, between the final visit at 12 months and the basal visit. In contrast, lipoprotein A serum concentration decreased after 6 months of TCZ treatment (Δ-3[-2--12] mg/dl, p=0.03). No changes were observed in triglycerides. PCSK9 basal serum concentration was not modified by TCZ treatment and did not differ respect to each visit (mean differences after 3, 6 and 12 months were, 72[-59-241], 67[-133-147] and 90[-252-137] CI95% ng/ml, respectively). Subcutaneous abdominal fat tissue was inferior after one year of treatment (Δ-1766[-6555--450] cm2, p=0.02); however, visceral abdominal fat tissue (p=0.99), VAAT/SAAT ratios (p=0.72) and the percentage of trunk fat (DEXA) (p =0.26) were not influenced by TCZ treatments.

Conclusion: TCZ-induced changes in the lipid profiles of RA patients are not related to degradation of the low-density lipoprotein receptor mediated by PCSK9. One year of treatment with TCZ does not seem to influence body composition adiposity of RA patients, two elements related with lipid profiles. Interestingly, TCZ treatment causes a marked reduction of lipoprotein a plasma concentration, an independent cardiovascular risk factor.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The application of biologic substances is subject to a risk to develop antibodies against these structures causing adverse events or loss of efficacy. For TNF blocking antibodies such as adalimumab a strong immunogenicity has been demonstrated which is associated with a formation of anti-drug antibodies. In numerous studies the frequency of anti-adalimumab (anti-ADL) antibodies has been described in detail. In our study we aimed to assess the persistence of anti-drug antibodies after termination of adalimumab (ADL) treatment.

Methods: Eighteen RA patients (16 female/ 2 male, mean age 53.1±8.2 years) treated with adalimumab for mean 23.4±17 months (range 4-74 months) were identified as anti-ADL antibody positive and were switched to another biological treatment, 5 patients were treated with another TNF inhibitor (4 with etanercept, 1 with golimumab), and 13 with a B-cell depleting therapy (rituximab). Patients were followed-up for at least two years to analyse the persistence of anti-ADL antibodies. For the determination of anti-ADL antibodies the Promonitor® -anti-ADL assay (Proteomika, Spain) was used according to the manufacturer's instructions. The assay is designed as a bridging assay with a cut-off value of 10 AU/ml. For calculation of results the data analysis software (http://www.myassays.com) was used.

Results: After termination of adalimumab therapy the mean±SD level of anti-ADL antibodies was 491±713 AU/ml (in a range between 13 and >2000 AU/ml). Within the following two years anti-ADL antibody levels decreased significantly ($p<0.05$ t-test for paired samples). In 5 patients anti-ADL antibodies disappeared completely. However, 13 patients remained anti-ADL positive with a mean±SD level of 237±463 AU/ml (range 10 – 1801 AU/ml) two years after termination of ADL therapy. In eight patients a serokonversion was observed within a further follow-up with the last positive result for anti-ADL antibodies after mean 47 months (range 24-72 months). We did not find an influence of the current treatment on the persistence of anti-ADL antibodies. Even in patients receiving a B-cell directed therapy anti-ADL antibodies persisted for ≥ 24 months in 12 out of 15 patients. However, patients with persisting anti-ADL antibodies had been treated longer with ADL and had higher antibody levels after termination of therapy, with mean treatment duration of 25±17.8 months and 15.4±11.3 months and antibody levels of 652±781 AU/ml and 74±50.0 AU/ml after termination of therapy, in patients with persisting antibody levels and patients without anti-ADL antibodies after 2 years, respectively.

Conclusion: Our results clearly show that anti-adalimumab antibodies are stable and persist for several months or even years after termination of therapy. High antibody levels are not completely resolved by several courses of a B-cell depletion therapy. Supported by Pfizer Pharma GmbH

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Multimorbidity is increasingly prevalent in western populations and has the potential to influence disease specific outcomes. Rheumatoid arthritis (RA) is a chronic inflammatory arthritis which has known associations with a number of specific other morbidities such as cardiovascular disease and cancer. However, the effect of the burden of multiple chronic diseases on RA specific disease outcomes is less well described, and may be of particular interest

in patients taking expensive biologic drugs. The aim of this study was to describe the relationship between multimorbidity and disability and disease activity over time in a large cohort of patients with RA taking biologic drugs.

Methods: The British Society for Rheumatology Biologics Register for RA (BSRBR-RA) recruited patients with a physician diagnosis of RA from across the UK starting biologic therapy. This study included only patients starting their first biologic, to exclude morbidity acquired as a consequence of previous biologic treatment. At baseline assessment, data were collected on demographics, multimorbidity, medication and disease specific variables, including disease activity (DAS28 score) and disability (HAQ). HAQ and DAS28 were collected 6 monthly for the first three years. The association at baseline between multimorbidity burden (assessed using the rheumatic diseases comorbidity index (RDCI) (ref)) and the outcomes HAQ and DAS28, adjusting for age, gender, smoking status, year of recruitment, disease duration and rheumatoid factor (RF) positivity was assessed using linear regression models; subsequently mixed effects models were used to investigate the same associations over time. Sensitivity analyses were performed to examine these associations in the subgroup of patients taking tumour necrosis factor inhibitors (TNFi).

Results: A total of 13957 patients were included, 10367 (76%) were female, median (IQR) age was 57 years (49-65) and 8655 (64%) were RF positive. Median (IQR) RDCI at baseline was 1 (0-2). Multimorbidity burden was significantly associated with disability but not disease activity at baseline(table 1); throughout follow up it was associated with both outcomes, adjusted beta (95% confidence interval (CI)) 0.17 (0.16,0.18) and 0.37 (0.35,0.40) for HAQ and DAS28 respectively. Similar results were seen when the analysis was confined to TNFi users alone.

Table 1

	All biologics n=13957		**TNFi users only** n=13094	
Linear regression	*Univariate* Beta (95% CI)	*Multivariate* Beta (95% CI)	*Univariate* Beta (95% CI)	*Multivariate* Beta (95% CI)
HAQ	0.08 (0.07, 0.08)	0.06 (0.05, 0.07)	0.08 (0.07, 0.09)	0.06 (0.05, 0.07)
DAS28	0.03 (0.02, 0.04)	-0.01 (-0.02, 0.01)	0.04 (0.02, 0.05)	-0.01 (-0.02, 0.01)
Mixed effects model				
HAQ	0.11 (0.10, 0.11)	0.17 (0.16, 0.18)	0.11 (0.10, 0.12)	0.17 (0.16, 0.18)
DAS28	0.24 (0.22, 0.26	0.37 (0.35, 0.40)	0.10 (0.08, 0.11)	0.37 (0.35, 0.41)

Conclusion: A higher burden of multimorbidity in patients with RA starting their first biologic drug is associated with more disability and higher disease activity over time. The presence of one or more comorbid conditions is an important factor to consider when assessing outcomes in these patients.

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biological therapy brought an important advance in the treatment strategy for rheumatoid arthritis (RA). However, the safety of biological therapy on RA patients with respiratory involvement such as interstitial lung disease (ILD) and airway disease (AwD) is still controversial. The aim of this study was to assess the association between risk for respiratory adverse events (RAE) and chest High-resolution computed tomography (HRCT) patterns and to detect predictors for RAE among RA patients receiving biological therapy.

Methods: We conducted a retrospective observational study including 235 patients with RA who received biological therapy in the seven years period of 2004 to 2010. The patients were clinically followed up for at least 6 years. Chest HRCT was performed in 214 patients at the induction of biological therapy. The obtained images were reviewed by two experienced thoracic radiologist

independently. According to the detected ILD features (airspace-consolidation, ground-glass opacity (GGO), reticulation, honeycombing) and AwD features (bronchiectasis, bronchiolectasis, traction bronchiectasis, air trapping), we grouped the patients to ILD group (n=63), AwD group (n=30), and no abnormality group (n=121). We investigated the manifestations of respiratory infection, onset or worsening of ILD, and other respiratory events which required withdrawal of biological therapy as incidence of RAE. Cox regression models estimated the risk for incidence of RAE in each group and explored predictors for RAE incidence based on HRCT patterns and baseline characteristics.

Results: The mean age was 57.2 (range 20-84), 86.0% of patients were female, and mean (standard deviation) follow-up was 7.7 (1.3) years. Methotrexate was used in 77.1%, and oral corticosteroids in 37.9% at baseline. HRCT abnormalities were found in 35.8% of the all patients. ILD features were found in 27.8%, AwD in 9.7%. We identified 27 RAE episodes including bacterial pneumonia (10), acute onset or exacerbation of interstitial pneumonia (7), pneumocystis pneumonia: PCP (2), bronchitis (2), organized pneumonia (2), NTM (1), empyema (1), mycotic pneumonia (1), pleuritic (1). The incident rate of RAE was 15.7 cases per 1000 patient-years in all patients, 20.1 in IDL group, 49.5 in AwD group, and 8.75 in no abnormality group. Cumulative incident rate was higher in AwD group than ILD group (figure1). AwD (HR=6.27, 95%CI=2.83-13.9), old age (HR=4.23, 95%CI=2.07-9.41), level of anti-citrullinated peptide antibodies (ACPA) titer (HR=3.19, 95%CI=1.44-7.04) were associated with increased risk for RAE. However, ILD (HR=1.64, 95%CI=0.73-3.67) did not associated with the risk for RAE.

Conclusion: Pre-existence of AwD at induction of biological therapy was associated with higher risk for RAE than pre-existence of ILD. We identified Age, ACPA titer, and pre-existence of AwD as the predictors for RAE.

Pregnancy Outcomes in Patients with Rheumatoid Arthritis Treated with Abatacept – Review of a Safety Database

H Yu, K Angelini, A Dominique and TA Simon, Bristol-Myers Squibb, Princeton, NJ

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Women are affected by RA 3–4 times more often than men. RA treatment choice during pregnancy can be a challenge for women to minimize fetal toxicity while maintaining disease control. The new FDA 'Pregnancy and Lactation Labeling Rule' removed pregnancy categories requiring product labels to be updated.[1] Given limited information, it is important to continually assess available data on RA therapy use during pregnancy.

Methods: All pregnancy cases reported to the manufacturer were re-coded based on ICH E2B (R2) Guideline[2] and MedDRA Points to Consider.[3] A comprehensive, post-coding change evaluation of pregnancy cases from available sources was performed cumulatively up to March 31, 2016.

Results: In total, 356 cases were reported: clinical trials (114), spontaneous/literature (133), patient support programs/Phase IV trials (89), and Organization of Teratology Information Specialists Pregnancy Register (20). Most abatacept exposure was limited to the first trimester (118). Outcomes were reported in 196 cases (Table 1): 48% normal newborn/live births (4 full-term abatacept exposure cases), 21% spontaneous abortions, 9% live births with complications including premature delivery and low birth weight. There were 10 congenital anomalies in patients with multiple risk factors[4] (2 full-term abatacept exposure cases, Table 2).

Conclusion: As shown, reports of spontaneous abortion, premature delivery, and low birth weight among patients treated with abatacept are low and consistent with the literature.[5–8] The available data do not suggest an increased risk of adverse pregnancy outcomes with abatacept in the indicated population. However, abatacept should be used during pregnancy only if the benefit to the mother

justifies potential risk to the fetus.[9] The outcomes of abatacept-exposed pregnancies will continue to be monitored via pharmacovigilance and the Pregnancy Registry. 1. FDA. Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic inflammation is associated with a greater risk of hypertension

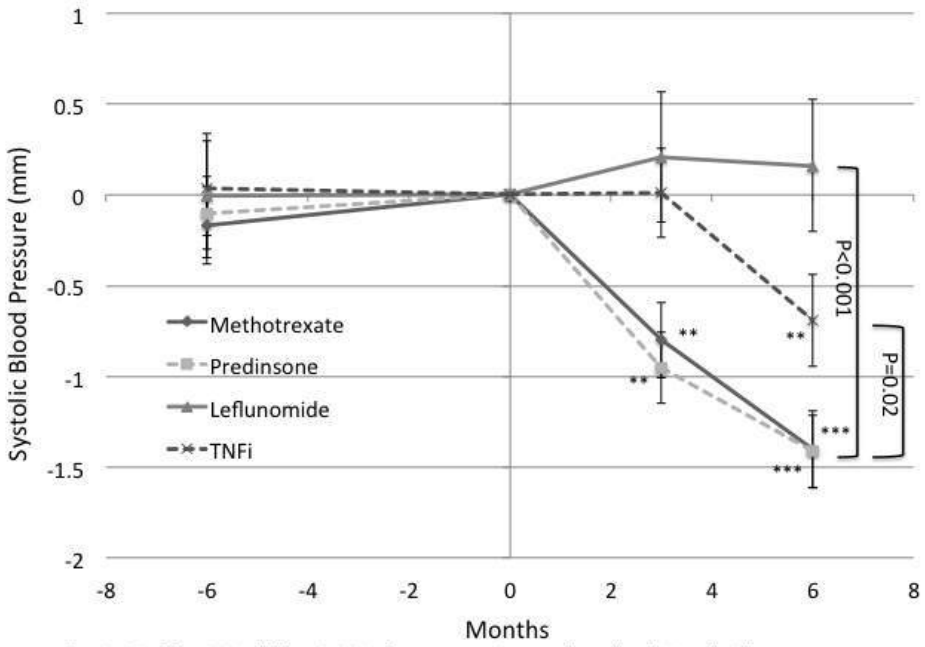
(HTN) while inflammatory cytokines such as TNF-α have been shown to have vasodilator effects. It thus remains unclear how treatment of rheumatoid arthritis (RA) might affect blood pressure (BP). Our goal was to quantify changes in systolic and diastolic blood pressure (SBP, DBP) in the 6 months after initiating new DMARDs in a large administrative database.

Methods: We used 3 VA database sources: the Corporate Data Warehouse (CDW), the Decision Support System (DSS) National Pharmacy Extract, and the Pharmacy Benefits Management (PBM) database. Among patients with at least one diagnosis code for RA, algorithms integrated sources to define unique dispensing episodes of methotrexate, prednisone, leflunomide, and TNF inhibitors (TNFi). The closest values for BP, CRP, CCP, and BMI within 30 days of the treatment start date were used as baseline values. Values -180, 90, and 180 days from the treatment start date (+/- 30 days) were also recorded. A significant increase in BP was defined as an increase in SBP >20 mm or DBP >10 mm. Incident HTN was defined as a new diagnosis code for HTN after the course start. Multiple imputation was utilized to account for missing laboratory values. Propensity analyses using matched-weighting techniques were used to address confounding by indication.

Results: There were 25,811 unique treatment courses in 18,119 patients identified. Overall, there were no changes in BP in the 6-months prior to drug initiation (all $p>0.62$). In contrast, there was a small but significant overall decline in SBP [β: -1.08 mmHg (-1.32, -0.85) $p<0.0001$] and DBP [β: -0.48 (-0.62, -0.33) $p<0.0001$] over the 6 months after initiating drug. The greatest decline was observed among those treated with methotrexate or prednisone (Figure). Patients treated with leflunomide had less decline in SBP and DBP and a greater odds of a significant increase in BP at 6-months compared to methotrexate (Figure, Table). Users of TNFi had less reduction in BP compared to methotrexate, however this difference was attenuated and not significant in sensitivity analyses (Table). The risk of an incident diagnosis of HTN over 3 years was greater for leflunomide [HR 1.42 (1.05, 1.93) $p=0.02$] and similar for prednisone and TNFi (all $p>0.14$) compared to methotrexate (not shown).

Conclusion: Patients initiating treatment for RA, particularly methotrexate, generally demonstrate reductions in BP over 6 months. Leflunomide use is associated with less improvement in BP and a modestly increased risk of incident HTN compared to the use of other DMARDS in a large

Figure: Actual change in systolic blood pressure over the 6-months prior to initiation of treatment and the 6 months after initiation of treatment.



population study.

Table: Associations between prednisone, leflunomide, and TNFi with 6-month change in systolic BP compared to methotrexate after applying matched-weighting techniques to consider propensity for receiving the drug.

		Excluding Concurrent MTX	
			Compared to MTX Alone
Change in SBP vs. Methotrexate (β-Coefficient)			
Prednisone	0.34 (-0.097, 0.78)	0.34 (-0.14, 0.81)	0.39 (-0.15, 0.93)
Leflunomide	1.79*** (1.07, 2.52)	1.71*** (0.87, 2.55)	1.70 *** (0.86, 2.54)
TNFi	0.91** (0.38, 1.44)	0.62 (-0.026, 1.26)	0.56 (-0.0.96, 1.21)

Session Title: Rheumatoid Arthritis – Clinical Aspects - Poster III: Treatment – Monitoring, Outcomes, Adverse Events

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To inform the task force for the 2016 update of the EULAR recommendations for the management of RA on the evidence regarding the efficacy and safety of

glucocorticoids (GCs), conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) and targeted synthetic DMARDs (tsDMARDs) in RA by performing a systematic literature review (SLR). <>

Methods: A SLR update using PubMed, Embase and the Cochrane library was performed (2013 - 2016) to assess the efficacy and safety of GCs, csDMARDs (as monotherapy or combination therapy) and tsDMARDs (tofacitinib and baricitinib) in randomized clinical trials. Meta-analysis was performed when possible. Risk of bias (RoB) was assessed using the Cochrane Collaboration tool.

Results: With regard to GCs, among 348 hits 5 studies were included in the analysis (table 1). Even patients without poor prognostic factors benefit from the addition of GCs to methotrexate (MTX). Lower doses of GCs seem to be as effective as higher doses. Long-term results of the CAMERA II trial showed increased cardiovascular risk for the early RA patients treated for at least 2 years with 10mg/d prednisone (not included in the table). With regard to csDMARDs, among 518 hits 2 new studies comparing MTX monotherapy with MTX in combination with another csDMARD without differences in GCs usage were identified. The tREACH trial, which used tight-control principles, reported a statistically significant benefit of combination therapy over monotherapy at 3 months that had disappeared at 12 months (disease activity, functional ability and radiographic progression) (table 2). In addition, more medication adjustments were needed in the combination group. In the CareRA trial combination with other csDMARDs was not superior to methotrexate monotherapy in early RA and monotherapy was better tolerated. With regard to tofacitinib (n=7) and baricitinib (n=9) RCTs had been meta-analysed showing that both are more effective than placebo on background MTX or de novo MTX (MTX-naïve) in different patient populations (MTX-naïve, csDMARD and bDMARD inadequate responders) with a pooled OR (95% CI) for ACR20 response for tofa and bari vs placebo of 3.1 (2.0-4.7) and 3.6 (2.4-5.5), respectively.

Conclusion: New evidence on the efficacy and safety of DMARDs in RA confirmed the benefit of the addition of GCs to csDMARDs in early RA but pointed to long-term cardiovascular risk. MTX monotherapy is as effective as MTX in combination with csDMARDs but better tolerated. Tofacitinib and baricitinib are effective tsDMARDs in various RA populations.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: *LBH* (Limb-bud and heart development) was recently identified as an RA risk gene that has abnormally methylated loci and a functional enhancer SNP in RA FLS. Low LBH expression has been observed in RA, which affects the cell cycle and contributes to aggressive behavior of RA FLS. We investigated the molecular mechanism of cell cycle regulation by LBH to understand why RA FLS exhibit this characteristic phenotype.

Methods: RA FLS were cultured from synovial tissues obtained at arthroplasty. LBH was knocked down using LBH siRNA, which decreased LBH expression by 88%. Gene expression was measured by qPCR and normalized to ß-actin. Cell cycle analysis was performed with propidium iodide staining and flow cytometry by synchronizing cells by serum starvation and then culturing FLS with

10% FBS. Western blot analysis was used to quantify protein expression and results were normalized to GAPDH.

Results: Cell cycle analysis of RA FLS showed that LBH siRNA silencing decreased S phase progression. The percentage of serum-starved cells in S phase was 2±1%, which increased to 18±4% in control FLS and from 2±1% to 15±4% in LBH-deficient FLS after adding complete medium for 24 hr. However, the percentage of control FLS in S phase decreased to 9±1% in control cells after 38 hr while LBH-silenced cells continued to increased to 25±4% ($p<0.05$ for control vs. LBH-deficient). These data suggest that LBH deficiency delays S phase progression. To understand the mechanism, we explored the influence of LBH on steps that activate the intra-S phase checkpoint. One key element is DNA replication stress, which can cause the DNA replication forks to stall. LBH-deficient FLS displayed 4±1-fold higher phospho-CHK1 at 24 hr compared to control FLS, which is induced by replication stress ($p<0.05$). DNA polymerase alpha catalytic subunit (POLA1) is required for initiation of DNA replication in S phase at the replication fork. LBH silencing reduced POLA1 mRNA by 38% ($p<0.01$) and POLA1 protein by 86% ($p<0.01$) compared with scrambled siRNA.

Conclusion: These data show that LBH deficiency reduces POLA1 expression and induces replication stress, which leads to S phase arrest. Lack of progression through S phase arrest in RA FLS could alter the growth patterns of FLS in RA and contribute to their aberrant behavior. Targeting the cell cycle in RA could potentially overcome these pathogenic steps, allow an appropriate response to replication stress, and allow normal progression through the cell cycle.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA), synovial fibroblasts (SF) are one main contributor of joint destruction since they resist apoptosis and secrete pro-inflammatory cytokines and matrix degrading enzymes. Previous studies already demonstrated the functional expression of several transient receptor potential channels (TRP) such as TRPV1, TRPV2, TRPV4, TRPA1 and TRPM8 in SF. Upon ligation, these receptors increase intracellular calcium but they have also been linked to modulation of inflammation in several cell types. TNF was shown to increase the expression of TRPA1, the receptor for mustard oil (allylisothiocyanate, AITC) and environmental poisons in synovial fibroblasts, but the functional consequences have not been investigated yet.

Methods: TRPA1 was detected by immunocytochemistry and western blot. Calcium signals were determined fluorometrically (Fura-AM red). Cell viability was assessed by quantification of lactate dehydrogenase (LDH) in culture supernatants. IL-6, IL-8 and MMP-3 were determined by ELISA. Proliferation was determined by cell titer blue incorporation.

Results: After 72h, TNF up-regulated TRPA1 protein levels in RASF which was accompanied by increased sensitivity to TRPA1 agonists AITC and polygodial. Under unstimulated conditions, polygodial but not AITC elicited modest calcium flux only in the highest concentrations used (50µM and 25µM). TNF pre-incubation substantially lowered the activation threshold for polygodial (from 25µM to1µM) and enabled AITC-mediated calcium flux, which was inhibited by TRPA1 antagonists A967079 (25µM) and HC030031 (50µM). In addition, TNF stimulation strongly enhanced TRPA1 mediated LDH release by AITC and polygodial, a marker for cell death. TNF not only reduced the threshold of AITC and polygodial but also led to a faster onset of LDH release. Furthermore, TRPA1 activation was associated with decreased proliferation of RASFs with TNF pre-incubation enhancing the anti-proliferative effect of AITC and polygodial. Secretion of IL-6, IL-8 and MMP-3 was attenuated by the TRPA1 antagonist A967079 but also polygodial, although the latter mediated this effect by reducing cell viability.

Conclusion: TNF up-regulates and sensitizes TRPA1 in RASF. Subsequent activation of TRPA1 increased calcium flux and reduced cell viability. Since TRPA1 agonists only showed effects in TNF stimulated RASF, this cation channel might an attractive therapeutic target in chronic inflammation to reduce the activity of pro-inflammatory SF in the joint.

Dissociation of the Inhibitory Apoptosis Stimulating Protein of p53 (iASPP) Binding with Transcription Factor p73 Induces Synovial Fibroblast Apoptosis in the Rheumatoid Joint

Chrong-Reen Wang[1], Shih-Yao Chen[1], Ai-Li Shiau[2], Ming-Fei Liu[1] and Chao-Liang Wu[3], [1]Internal Medicine, National Cheng Kung University Medical College and Hospital, Tainan, Taiwan, [2]Microbiology and Immunology, National Cheng Kung University Medical College, Tainan, Taiwan, [3]Biochemistry and Molecular Biology, National Cheng Kung University Medical College, Tainan, Taiwan

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Apoptosis-resistant synovial fibroblasts (SFs) constitute the major cell component of pannus tissues in rheumatoid arthritis (RA). In tumor cells, the binding of inhibitory apoptosis stimulating protein of p53 (iASPP) with transcription factor p53 family members can inhibit the downstream apoptosis signaling. We hypothesized that iASPP molecule is involved in the RA pathogenesis, and examined whether dissociation of such binding can induce SFs apoptosis in the rheumatoid joint.

Methods: Peripheral mononuclear cells (MNCs) from active RA before and after a TNF inhibitor therapy and osteoarthritis (OA) patients were examined for their iASPP expression by real-time RT-PCR. Synovial tissues and purified SFs from RA and OA patients as well as normal and collagen-induced arthritis (CIA) rats were subjected to immunohistochemical (IHC) and immunofluorescent staining for the expression of iASPP and p73, a member of p53 family. SFs transfected with adenoviral vectors encoding 37 amino acid (Ad37AA), a hybrid small peptide corresponding to p53 residues, were subjected to TUNEL assay and real-time RT-PCR for apoptotic status and the expression of p53 upregulated modulator of apoptosis (PUMA), respectively. The association of iASPP with p73 in Ad37AA-transfected SFs was identified by anti-iASPP immunoprecipitation, followed by anti-p73 immunoblotting assay. Therapeutic effects of intra-articular injection of Ad37AA on CIA joints were evaluated by articular index and histological score. Further synovial IHC staining was performed to analyze PUMA and IL-6 expression levels and SFs densities, and *in situ* apoptotic cells in synovial tissues were detected by the TUNEL assay.

Results: There were reduced iASPP levels by targeting TNF in MNCs from RA patients and increased iASPP levels with co-localized p73 expression in synovial tissues and purified SFs from RA patients and CIA rats. Enhanced cell apoptosis and increased PUMA expression were identified

in Ad37AA-transfected SFs with lower iASPP-associated p73 levels. Articular indexes and histologic scores were reduced in Ad37AA-injected CIA joints with decreased SF densities, increased apoptotic cells, higher PUMA and lower IL-6 expression levels.

Conclusion: Our results demonstrate a pathogenic role of TNF-mediated up-regulation of iASPP and induction of SFs apoptosis by dissociating the iASPP binding with transcription factor p73 in the rheumatoid joint, implicating iASPP as a potential therapeutic target molecule in RA patients.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Periodontitis (PD) is an inflammatory disease of tissues supporting the teeth, caused by microorganisms that adhere to and grow along the tooth's surface. Both PD and pathogens linked to PD have been proposed as risk factors in rheumatoid arthritis (RA). Previous studies have primarily targeted select organisms for investigation, failing to account for the complex nature of the local microbiome involved in PD. Thus, we characterized the subgingival microbiome in patients with established RA, comparing resident microbial communities with those of controls.

Methods: RA patients satisfying the 1987 ACR classification criteria and osteoarthritis (OA) controls underwent full-mouth examination and were classified as having PD based on Machtei criteria. Subgingival plaque was collected from up to 4 sites and pooled. Bacterial DNA was isolated and sequenced using 454 pyrosequencing; trimmed reads were searched against the Human Oral Microbiome Database. Hierarchical cluster analysis with averaging-linkage agglomeration on microbiome profiles were used to classify the samples into 3 clusters. Data were standardized by samples prior to the clustering. With only a 1 patient with membership, Cluster 3 was excluded from further analysis. Logistic regression was used to determine factors associated with membership in Cluster 1 vs. Cluster 2. Factors chosen a priori for analysis included: RA vs. OA case status, PD, smoking status, age, gender, marital status, education, race, body mass index (BMI), and diabetes.

Results: RA (n=260) and OA (n=296) patients were similar in terms of sociodemographic factors except marital status; OA patients were more likely to have diabetes (25% vs. 18%, p=0.04) and had a higher BMI (31.7 vs. 29.8 kg/m^2, p=0.0008); RA patients were more likely to have ever smoked (62% vs. 46%, p=0.0002), have PD (38% vs. 27%, p=0.007), and be married (69% vs. 61%, p=0.06). Patients segregated into 3 groups based on subgingival microbial composition with Clusters 1 and 2 accounting for all but one individual. Factors significantly associated with Cluster membership included PD, age, smoking, and race (Table). There was no association of RA-OA case status with Cluster membership, suggesting similar overall subgingival microbiome composition by arthritis diagnosis after accounting for other factors. Results were unchanged with RA cases limited to those with a positive anti-CCP antibody.

Conclusion: Patients with established RA demonstrated a subgingival microbial composition that was similar to patients with OA after accounting for the presence of PD and other PD risk factors. Further study will be needed to examine whether an abundance of individual bacterial species or microbial diversity is impacted in established RA or whether the overall microbial composition in RA evolves over time with the use of RA therapies and changes in underlying disease activity.

Association of patient factors with membership in Cluster 1 vs. Cluster 2 based on analysis of subgingival microbial composition

Effect	Odds Ratio	95% CI of Odds Ratio		p-value
RA vs OA	1.05	0.69	1.59	0.84
PD	0.23	0.15	0.35	<.0001
Ever Smoking	0.51	0.33	0.79	0.003
Age, years	1.03	1.01	1.05	0.001
White vs. Other	1.73	1.10	2.71	0.02

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-malondialdehyde-acetaldehyde adduct (MAA) antibodies target immunogenic products of oxidative stress, are detected in higher concentration in paired synovial fluid vs serum in RA, and are associated with higher RA disease activity. Moreover, MAA-modified proteins, citrullinated antigens, and immune cells colocalize in RA synovial tissues – suggesting a role in RA pathogenesis. Airway inflammation, a proposed mechanism of disease initiation and a common extra-articular manifestation in RA, is stimulated by MAA in mice. Whether MAA-modification and resulting anti-MAA immune responses occur within the lungs of individuals with RA is unknown.

Methods: Paired serum and sputum samples were collected from subjects with established anti-CCP positive RA (n = 27) and healthy controls (HC; n = 29). CCP2 (IgG), CCP3.1 (IgG/IgA), RF (IgA, IgM, IgG), and anti-MAA (IgA, IgM, IgG) antibodies were measured by ELISA and total Ig by nephelometry. We used Wilcoxon rank-sum tests to compare anti-MAA antibody concentrations between RA and controls and assessed associations with smoking, alcohol, chronic lung disease, and gender; Wilcoxon signed-rank tests to compare paired sputum and serum concentrations; and SpearmanÕs correlations to assess correlations between sputum anti-MAA and RA autoantibodies.

Results: Mean (SD) age was 50 (13) years with 75% female, 71% Caucasian, 11% current and 29% former smokers, and 18% with chronic lung disease. Sputum anti-MAA antibody concentrations in RA and HC are shown in Table 1. Sputum IgA and IgG anti-MAA were higher in RA than HC. After adjusting for total Ig, in both RA and HC, IgG anti-MAA antibody was higher in sputum than serum ($P < 0.001$), while IgM anti-MAA was higher in serum ($P<0.001$), and IgA anti-

MAA did not differ (P = 0.58). In RA subjects, sputum IgM anti-MAA antibody correlated with sputum CCP3.1 (r = 0.42, P = 0.03) and marginally correlated with sputum RF IgA (r = 0.38, P = 0.052). Sputum IgA anti-MAA antibody correlated with serum RF level (r = 0.46, P = 0.02) and sputum IgG anti-MAA antibody did not correlate with other autoantibodies. Sputum IgA anti-MAA antibody, but not IgM or IgG, was higher in current smokers vs non-smokers. There were no other associations between anti-MAA antibody and smoking status, alcohol use, chronic lung disease, or gender.

Conclusion: IgG and IgA anti-MAA antibody are enriched in the sputum of RA subjects, with relative concentrations of IgG higher in paired sputum than serum. These data suggest MAA modification and anti-MAA immune responses within the airways could contribute to disease pathogenesis. Additional studies will be needed to examine the relationship of anti-MAA antibody with measures of airway inflammation and lung function in RA and to determine mechanisms underpinning these associations.

Table 1. Sputum anti-MAA antibody concentrations for rheumatoid arthritis and healthy control subjects.

	Healthy Control	RA	P*
IgA	10.0 (4.0-32.9)	27.5 (5.6-57.3)	<0.05
IgM	4.0 (3.1-18.1)	4.0 (4.0-5.8)	0.91
IgG	4.0 (3.0-4.0)	5.0 (4.0-6.9)	<0.01

A Novel Pharmacological Action of MTX on RA Fibroblast-like Synoviocytes Via Circadian Clock Genes

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The circadian rhythm is disrupted in patients with rheumatoid arthritis (RA), and we have shown that tumor necrosis factor(TNF)-*ƒ¿* inhibits the expression of circadian clock gene Period 2 (Per2) by interfering with D-box motifs to promote the proliferation of RA-fibroblast-like synoviocytes (FLS) (1). Recently, interactions between PER2 and Bcl2 family proteins were reported that forced expressions of Per2 on pancreatic cancer cells resulted in apoptosis-induction (2). In this study, we examined effects of Methotrexate (MTX) on the expression of circadian clock genes in RA-FLS.

Methods: Under treatments of MTX (10nM) on RA-FLS, cell viabilities were determined by WST-8 assay and expressions of PER2 were observed by fluorescent immunostaining. Total RNA was extracted from RA-FLS, treated with MTX(10nM) for 24 to 48hrs, to examine expressions of circadian clock genes, including circadian locomotor output cycles kaput (Clock), brain and muscle Arnt-like protein-1 (Bmal1) and Per 2 by real-time PCR. As transcriptional activators of Per2, the proline and acidic amino acidrich basic leucine zipper (PAR bZip) genes ;D site of albumin promoter binding protein(Dbp), hyrotroph embryonic factor(Tef) and hepatic leukaemia factor(Hlf) were also analyzed. In addition, pro-apoptotic Bcl-2- interacting killer (Bik) was examined as a marker of mitochondria-related apoptosis-induction.

Results: The cell viability of RA-FLS was inhibited by 10nM of MTX for 24h and 32h. MTX enhanced expressions of Per2, Dbp, Tef and Hlf after 24hrs' treatment, and Bik for 32hrs (Figure 1). PER2 protein was highly expressed in apoptotic RA-FLS in fluorescent observations (Figure 2).

Conclusion: Results clearly showed that MTX accelerated PAR bZip genes to bind D-box motif to transcribe Per2, resulted in apoptosis-induction of RA-FLS. This was also supported by the increased-expression of Bik, containing PAR bZip–binding site on its promoter region. We proposed a novel therapeutic efficacy of MTX on RA-FLS via circadian clock genes.

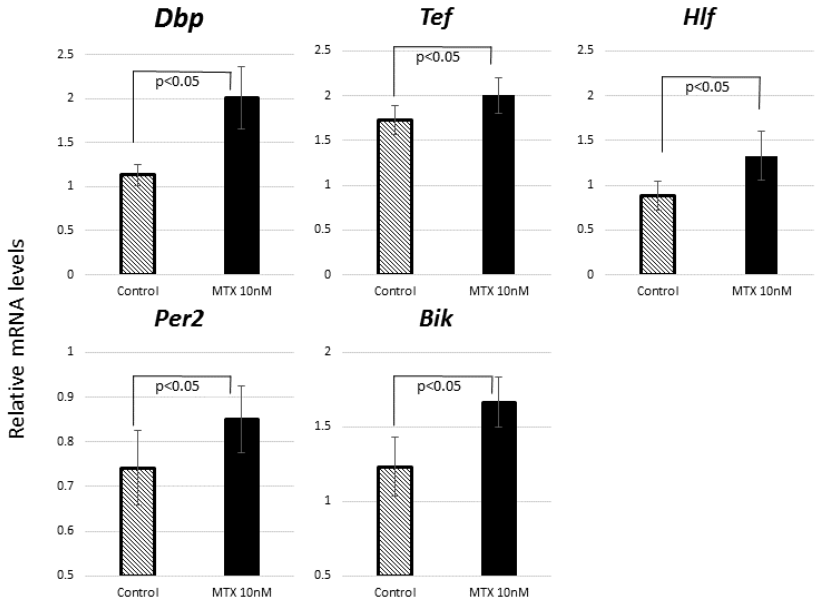

Figure 1. The mRNA expression of PAR bZip genes, *Per2*, and *Bik*. The mRNA expression of PAR bZip genes and *Per2* were increased with the 24hrs' treatment of MTX (10nM), and *Bik* with the 32hrs', compared to control.

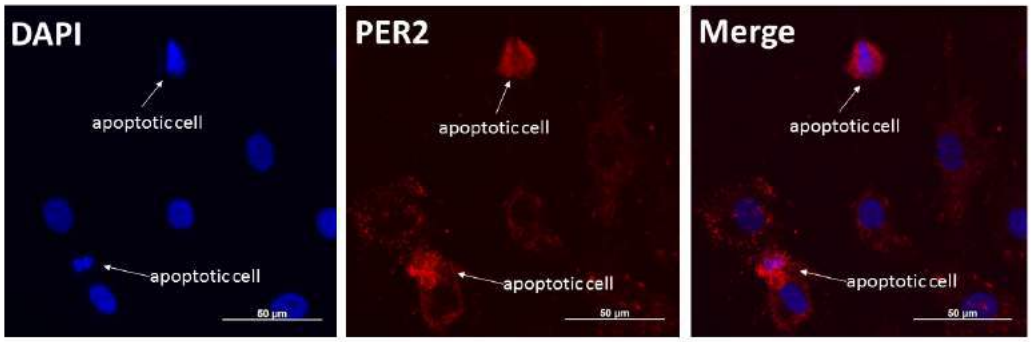

Figure 2. DAPI staining and fluorescent immunostaining of PER2 in 10nM MTX-stimulated RA-FLS. The overexpression of PER2 is observed in apoptotic cells. **Reference:** 1. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The human gut microbiome maintains normal immune homeostasis. Changes to the microbiota evolve with aging and have been implicated in the development of autoimmune disorders like rheumatoid arthritis (RA). Given the observed variability in microbiota composition among healthy individuals, immune responses to commensal microbiota may be more relevant to disease development. We compared adaptive immune responses to gut microbiota in RA patients and healthy controls and determined associations with RA autoantibodies.

Methods: IgG immune responses to intestinal microbiota were detected in sera of RA patients and controls using a protein microarray containing recombinant antigens cloned from murine microbiota that have been previously studied in humans (50 epitopes from >6 bacterial groups). Each antigen was present in quadruplicate per slide. Bound human sera IgG was detected and quantitated using an Axon GenePix 4000B dual laser and its software. Levels are reported as median net fluorescent values with lower detectable cut-off being assigned 0. Anti-citrullinated peptide antibodies (ACPA) were measured by ELISA and rheumatoid factor (RF) by nephelometry. Associations of IgG microbiota responses with subject group and RA antibodies were tested by nonparametric tests. Patterns of microbiota responses were assessed using non-hierarchical clustering. Given multiple comparisons, p values<0.001 were considered significant.

Results: RA patients (n=121; 78% female, mean (SD) age 58 (14) years; 43 with symptoms less than 12 months (ERA)) were compared to healthy controls (n=19, 63% female, mean(SD) age 39 (11)years). All anti-microbial IgG levels were detected in at least some subjects although there was individual variation in the expression patterns. No robust grouping of microbial responses was seen. Levels of 16 anti-microbial IgG titers were significantly elevated in RA compared to controls

whereas levels of 2 anti-microbial IgGs titers were decreased (all $p<0.001$). The epitopes with the highest IgG titers in RA compared to controls were rIB2 (firmicutes/bacteroides) and Pmel. The epitopes with the most reduced IgG titers in RA compared to control were Ftsz (proteobacteria) and rib16 (firmicute). Of four known universal gut microbiotia antigens (rIB1, rIB2, rIB10 and rIB20), only anti-rIB2 IgG levels were increased in RA ($p<0.001$). There were no robust associations of individual IgG titers with ACPA or RF positivity. The levels of five anti-microbial antigen IgG titers (3-2, bir1, cbir15, cbir63, m18-1) were higher in RA of recent onset than long standing RA (all $p<0.0001$).

Conclusion: Adaptive immune responses to selective gut microbiota differ between RA and controls but do not associate with other RA autoantibodies. Although environmental influences such as diet and medication were not addressed here, these results suggest a broader immune response alteration to microbial organisms exists in persons with disease.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Accumulating evidence implicates hypoxia in the pathogenesis of rheumatoid arthritis (RA). The effect of hypoxia on the expression of Slug, a transcriptional repressor that impairs apoptosis of RA fibroblast-like synoviocytes (FLS), remains unknown. The aim of this study is to investigate the role of hypoxia in the expression of Slug in RA FLS and to delineate the signaling pathway involved in the process.

Methods: After RA FLS were exposed to hypoxia, expression of HIF-1a and phosphorylation of ERK, JNK, and STAT3 were analyzed by Western blot. The experiment was repeated with RA FLS pretreated with WP1066, an inhibitor of the JAK/STAT pathway. RT-PCR was performed to measure HIF-1a mRNA and Slug mRNA expressions in RA FLS under hypoxia. RA FLS was transfected with HIF-1a cDNA to investigate the effect of overexpression of HIF-1a on Slug expression. Immunohistochemistry was used to assess the presence HIF-1a and Slug in RA synovial tissue. Microarray analysis was performed to investigate the change in Slug gene expression when FLS were exposed to hypoxia. Finally, the effect of TNF-α on Slug and HIF-1α expressions under normoxic conditions was assessed in RA FLS by Western blot.

Results: Hypoxia induced the expression of HIF-1a and phosphorylation of STAT3, but not JNK and ERK was increased in RA FLS. Pre-treatment of RA FLS with WP1066 before exposure to hypoxia inhibited the expression of p-STAT and HIF-1a. Hypoxic conditions induced Slug mRNA expression from RA FLS, and similarly, overexpression of HIF-1a in RA FLS reproduced enhanced Slug expression. Microarray analysis revealed a significantly up-regulated Slug expression. Immunohistochemical staining showed that HIF-1a and Slug were co-localized in the lining area of RA synovium. Stimulation of FLS with TNF-α alone without hypoxia resulted in increased expression of Slug HIF-1a and Slug.

Conclusion: Our study demonstrates that HIF-1a expression from RA FLS induced by hypoxia or TNF-a alone is mediated through JAK/STAT3 signaling pathway, which ultimately leads to the expression of Slug. Hypoxia-driven pathway of Slug expression may become a novel treatment target in RA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Autophagy is required to ensure cellular homeostasis. Perturbations in autophagy have been reported to be involved in the pathogenesis of several diseases such as cancer and infection. Rheumatoid arthritis (RA) is characterized by exaggerated synovial proliferation in which interleukin-17A (IL-17A) plays a key role. The aims of this study were (1) to evaluate whether IL-17A influences on autophagic flux in the synovium of the patients with RA and (2) to investigate whether the modulation of autophagy can regulate migration and proliferation of fibroblast-like synoviocytes (FLS) from the patients with RA (RA-FLS) under inflammatory milieu.

Methods: Synovial tissue was obtained from the patients with RA or osteoarthritis (OA). FLS was cultured with IL-17A and/or autophagy regulators. The expression of marker proteins for autophagic flux (LC3B, Beclin1, Atg5, p62) and the formation of autophagolysosome (LAMP1) were analyzed by western blot and immunofluorescence study. A migration scratch assay was used to assess FLS migration in response to stimulation with IL-17A. Proliferation of FLS was determined by the viable cell count using trypan blue.

Results: LC3 conversion from LC3-Ⅰ to LC3-Ⅱ was increased in RA-FLS than in OA-FLS. IL-17A upregulated the expression of LC3B, Atg5, Beclin1, LAMP1 in RA-FLS. The accumulation of p62 was also prominent in RA-FLS. Migration and proliferation of FLS stimulated by IL-17A was suppressed by Bafilomycin A1 which prevented the formation of autophagolysosomes. P62-silencing enhanced IL-17A-induced autophagy activation in RA-FLS.

Conclusion: This study reveals that IL-17A stimulates autophagy and that intervention of autophagy can control IL-17A-induced migration and proliferation of FLS. Our results also provide additional evidence for a significant role of autophagy in the pathogenesis of RA. Thus, we suggest that autophagy might be a potential therapeutic target for the management of RA.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is an extra-articular manifestation of rheumatoid arthritis (RA) which contributes to increased morbidity and mortality. Clinico-epidemiological data indicate some overlap in disease course between RA-ILD and idiopathic pulmonary fibrosis (IPF), particularly in subsets of RA-ILD patients with UIP-like pathology. We therefore evaluated levels of specific peripheral blood protein markers in patients with RA-ILD and IPF to determine molecular profiles indicative of shared disease pathogenesis.

Methods: A cohort of patients that met ACR classification criteria for rheumatoid arthritis were enrolled and subclassified as having RA-no ILD versus RA-ILD (mild vs. advanced parenchymal lung abnormalities) based on high resolution computed tomography scans of the chest (HRCT). A cohort of patients with IPF was also enrolled through Brigham and Women's Hospital. Standard solid phase enzyme-linked immunosorbent assays (ELISAs) were used to assess serum levels of matrix metalloproteinase 7 (MMP-7) and interferon-ϒ-inducible protein 10 (IP-10), which had previously been found to be significantly elevated in RA-ILD. Levels of serum biomarkers were compared using Mann U Whitney testing.

Results: 71 patients with RA were enrolled and classified as RA-no ILD (n=22) versus RA-ILD (n=49). Serum specimens were obtained from these patients as well as a comparator cohort of IPF patients (n=44). 72.7% (n=16) of patients in the RA-no ILD group, 63.3% (n=31) of patients in the RA-ILD and 40.9% (n=18) of patients in the IPF group were women. The average age of the patients in the RA-ILD and IPF groups were 65 and 66 years, respectively, vs 50 years in the RA-no ILD group (p=<0.0001). 63.6% (n=28) of the IPF patients, 55% (n=27) of the RA-ILD patients and

36.4% (n=8) of the RA-no ILD patients were smokers. ELISA-based measurement of serum MMP-7 revealed significantly increased levels in patients with RA-ILD and IPF (8.19 ng/ml vs 6.16 ng/ml, p=0.02). IP-10 levels were also significantly elevated in both RA-ILD and IPF patients (209.71 pg/ml vs 187.61 pg/ml, p=0.71). In contrast, patients with RA-no ILD had significantly lower levels of MMP-7 (2.98 ng/ml) and IP-10 (82.32 pg/ml) compared to patients with RA-ILD (MMP-7: p=<0.0001, IP-10: p=0.001) and patients with IPF (MMP7: p=<0.0001, IP-10: p=0.003).

Conclusion: Serum levels of both MMP-7 and IP-10 were elevated in patients with IPF and RA-ILD relative to RA patients without evidence of ILD. This overlap in biomarker signatures encompassing both inflammatory (IP-10) and remodeling (MMP-7) pathways supports a possible link in pathogenesis that may suggest common therapeutic targets in RA-ILD and IPF.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hexokinases (HKs) catalyze the first step in glucose metabolism. HK2 constitutes the principal inducible isoform with a restricted distribution in normal adult tissues. Up-regulated glycolysis and HK2 expression have a powerful growth advantage, which promotes cell proliferation and invasion. Fibroblast-like synoviocytes (FLS) are a key component of rheumatoid arthritis (RA) invasive synovium, and display unique aggressive features, including increased migration and invasion. We have recently showed that RA FLS present an altered glucose metabolism, which modulates FLS mediated functions. To determine whether HK2 is a key regulator

of FLS glycolytic and aggressive phenotype, we examined its role on FLS functions and in an arthritis animal model.

Methods: HK1 and HK2 expression were studied by immunohistochemistry (IHC) in RA and osteoarthritis (OA) synovial tissue. HK2 expression in FLS was studied by double IHC and qPCR in synovial tissue and FLS cell lines, respectively. RA FLS were transfected with HK2 siRNA, or infected with HK2 expressing adenovirus (ad) and the following FLS functions were conducted: migration (scratch assay) and matrigel invasion assay after PDGF stimulation, and metalloproteases (MMP) expression after LPS stimulation. We used $HK2^{F/F}$mice, harboring the ubiquitously expressed tamoxifen inducible Cre (UBCcreERT2) in order to systemically delete HK2. Passive KRN arthritis was induced injecting intraperitoneally 150µl of serum 3 weeks after tamoxifen treatment. Clinical scores were assessed daily and histopathological studies were carried on day 10.

Results: While HK1 is widely expressed in both RA and OA synovial tissue, HK2 is particular of RA histopathology (9/9 RA; 3/9 OA). HK2 is localized in the synovial lining and sublining and it co-localizes with vimentin as a marker for FLS. Basal HK2 expression was increased in RA compared to OA FLS, and its expression increased after LPS and PDGF stimulation. Silencing HK2 in RA FLS resulted in a less invasive phenotype (3.2 fold less invaded area in HK2-silenced FLS, $p<0.05$) and lower levels of MMP3 expression. Consistently, overexpression of HK2 resulted in an increased ability to migrate (scratch length: GFP-ad: 299.1±7.2; HK2-ad 90.7±2.5; $p<0.001$) and invade (3.1 fold invaded area in HK2-ad; $p<0.001$). The UBCcre-$HK2^{F/F}$ mice showed lower clinical and histological arthritis scores than wild type mice (WT) (clinical score at day 10: WT: 9±0.79; UBCCre-$HK2^{F/F}$: 3±0.49 ($p<0.001$)).

Conclusion: HK2 is more abundantly expressed in RA than OA synovial lining, and regulates FLS aggressive functions. HK2 also contributes to arthritis severity in the KRN animal model. Therefore, selective HK2 inhibition might be an attractive potential selective target safer than global glycolysis.

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibroblast-like synoviocytes (FLSs) contribute to synovial hyperplasia in rheumatoid arthritis (RA). Fibroblast growth factor 4 (FGF4) is a potent mitogen for tumor cells. The aim of our study was to investigate the expression of FGF4 in RA patients and its role in RA synoviocyte proliferation. Furthermore, the underlying pathways such as PI3K/Akt, p38-MAPK, and Erk-MAPK pathways were investigated to understand the potential mechanism of FGF4 in the pathogenesis of synovial hyperplasia.

Methods: The serum level of FGF4 were detected by protein arrays in 20 disease modifying antirheumatic drugs (DMARDs) naïve RA patients and in 20 age- and sex- matched healthy controls. The mRNA expression levels of FGF4 in PBMCs isolated from 50 patients with RA, and 50 healthy controls mathed with age and gender were analyzed by real-time PCR. FLSs were isolated from RA synovium, and were co-cultured with different concentrations of recombinant human FGF4 (rhFGF4) for 48 hours. Cell proliferation was quantified by Cell Counting Kit-8 assay and cell cycle distribution were evaluated by flow cytometry. Expression of cell cycle-related proteins were measured by western blot. Western blot analysis was also performed to determined the activation of PI3K/Akt, p38-MAPK, and Erk-MAPK pathways in RA-FLS after being treated with 50 ng/ml rhFGF4.

Results: The serum expression of FGF4 in RA group was higher than that in control group (P<0.05). The FGF4 mRNA was highly expressed in PBMCs of RA, compared with the control group (P<0.05). RA-FLS treated with different concentrations of rhFGF4 (12.5, 25, 50, 100 and 200 ng/ml) showed significantly increased proliferation，with cell proliferation rates of (1.21±0.08), (1.26±0.12), (1.29±0.12), (1.34±0.14), (1.39±0.13), compared with that of controls (1.00±0.00) (P<0.05). Incubation with various concentrations of rhFGF4 (25, 50, 100 ng/ml) resulted in a significant increase of G_2/M+S phase cells compared to controls (P<0.05). And the protein expression of cyclin D1 was also up-regulated after being treated with rhFGF4 (P<0.05). The protein expression of p-Akt, p-p38 and p-Erk was significantly increased in RA-FLS after a 5 min exposure to rhFGF4, compared with the control group.

Conclusion: Our results suggest that FGF4 is highly expressed in serum and in PBMCs of active RA patients. The proliferation of RA-FLS and the cell cycle G_1/S transition were promoted by rhFGF4. And cyclin D1 was up-regulated by treating with rhFGF4, indicating the aberrant activation

of FGF4 may play a role in RA-FLS proliferation, contributing to synovial hyperplasia. It is possible that rhFGF4 promotes the proliferation of RA-FLS via activation of PI3K/Akt, p38-MAPK and Erk-MAPK signaling pathways.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic, inflammatory condition that affects more than 1% population globally. Several studies suggest RA to be controlled by a combination of different genetic & environmental factors. While non-genetic factors remains elusive, a large number of genes/loci have been identified to confer susceptibility to RA. In the first ever GWAS on RA in north Indian populations, we had identified a novel gene *ARL15* (5p15.2) in addition to the already established HLA locus. ARL 15 is a small G Protein belonging to ADP ribosyl family (ARF). The inhibition of this protein family in the Collagen induced Arthritis model of RA has been shown to improve the arthritis score and inflammation. But importantly, expression of either *ARL15* or any other *ARF* genes in synovial fibroblast or in blood samples of RA patients has never been reported. Based on this background, the present study was aimed at functional characterization of *ARL15*, the novel GWAS hit to understand its implications, if any, for RA biology.

Methods: Synovial fluid and tissue samples were collected from each of the RA patients undergoing total knee replacements at AIIMS (As per American College of rheumatology criteria 2010), New Delhi with institutional ethical committee clearance and informed consent. Homogeneity of cells was checked by Fluorescence-Activated Cell Sorting. Presence of ARL15 gene and protein in RASF cells were tested by RT-PCR and western blots. TNF induction and siRNA knock down was carried out to find the expression of genes of interest by RT-PCR. Global expression profiling in knock down and control cells was captured by transcriptome sequencing. Apoptosis of *ARL15* knock down cells were detected by FACS using Annexin V staining. A549 cancer monolayer cells were used for checking the expression of *ARL15*under hypoxic condition.

Results: FACS experiment confirmed the cultures of synovial fibroblasts. RT-PCR showed the presence of *ARF2*, *ARF6* and *ARL15*. Western blot confirmed the presence of ARL15 protein in cell lysates. SiRNA mediated knock down experiments showed differential expression of *GAPDH*, *Adiponectin, Adiponectin receptorI and IL6* genes in RASF. RNAseq validated the above findings and also revealed differential expression of several additional genes involved in *IL6* signaling, RNAseq also indicated the possible role of *ARL15* in hypoxia which was then confirmed using A549 cancer cell line. Annexin V staining of *ARL15*knock down cells showed increase in apoptosis of RASF cells compared to control.

Conclusion: Our results confirm for the first time the expression of ARF genes including *ARL15* in the synovial fluid and tissue derived synovial fibroblast cultures of RA patients and its connection with IL6. Transcriptome sequencing data validated these findings in addition to identifying several other differentially expressed genes related to hypoxia and apoptosis. These preliminary findings taken together with previously available literature indicate the use of ARL15 as potential therapeutic target for RA.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lympho-proliferative disorder (LPD) developing under methotrexate (MTX) administration is a relatively rare but well known complication among rheumatoid arthritis (RA) patients. Spontaneous regression of LPD following MTX withdrawal is a singular aspect of LPD developing during MTX treatment with an incidence of 30-60%. The purpose of this study was to investigate the factors involved in spontaneous regression of LPD following MTX withdrawal.

Methods: This was a multi center retrospective observational study. Medical chart from January 1995 to October 2015 was reviewed. Age, sex, MTX dose, and RA duration matched control patients treated with MTX for more than 6 months were randomly selected. The time of MTX cessation (equally to LPD diagnosis) was defined as week 0, and blood sample was collected at week 0, 4 and 12 for flowcytometry when it was available (7 regressive, 3 persistent, 10 controls). LPD patients were divided into regressive group or persistent group depending on the status of LPD at week 12. Epstein Barr Virus (EBV) antigen specific CD8+ T cells was detected with MHC/EBV peptide tetramer.

Results: Forty-three RA patients complicated with LPD were identified and 76 control patients were selected. Among the 43 LPD patients, 28 were regressive and 15 were persistent. At week 0, the absolute number of peripheral lymphocytes was specifically and significantly decreased in LPD group, compared to control group. Flowcytometric analysis revealed significant decrease in absolute count of CD4+, CD8+ T cells, B cells and NK cells but not in proportion of these cell subsets. However, further subset analysis revealed that the proportion of effector memory CD8+ T cells (EM CD8+), EBV specific CD8+ and T helpler 1 (Th1) subset was specifically decreased in regressive group compared to control group. Following MTX withdrawal, a significant increase of these T cell subsets in addition to total lymphocytes was observed at week 4 and 12, only with the regressive group, but not with persistent group. Pathological category of LPD did not relate to change in lymphocytes.

Conclusion: Our study suggested that decreased lymphocytes at the time of LPD diagnosis and restoration following MTX withdrawal may associate with pathogenesis and clinical course of regressive LPD. Proportion of Th1 cells, EM CD8+, EBV specific CD8+ was restored following MTX cessation, indicating their involvement in regression of LPD.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA), fibroblast-like synoviocyte (FLS) is a key component of invasive synovium and mediates inflammation and destruction of joint. Recently, change of metabolic pathways offers novel approach to understanding the inflammation in RA. However, it has remained unknown how mitochondrial metabolic profiles are associated with inflammation in RA. In addition, production of reactive oxygen species (ROS), formed as byproduct in metabolic pathway is reported to be attenuated by pyruvate supplement in *in vitro* study. This study aimed to evaluate mitochondrial ROS signaling, biosynthetic functions and cytokine production, and the effects of pyruvate supplement in RA-FLS.

Methods: We analyzed mitochondrial ROS signaling and mitochondrial functions by quantitative PCR and western blotting in RA-FLS lysates. Mitochondrial metabolism was evaluated by

mitochondrial respiration using a Seahorse Bioscience Extracellular Flux Analyzer (XF24). The oxidative damage and biogenesis in mitochondria was evaluated by transmission electron microscopy (TEM) and western blotting in RA-FLS. IL-6 was measured by ELISA.

Results: Generation of TNF-α-induced mitochondrial ROS was higher in the FLS from RA patients compared to patients with osteoarthritis (OA). Peroxiredoxin 3 (Prx3), mitochondrial specific H_2O_2-scavenging enzyme, was significantly decreased in the TNF-a stimulated RA-FLS at early time (p=0.019). In addition, we showed increased mitochondrial respiration (p<0.00001), dysfunction of mitochondria and mitophagy including up-regulation of p62 and LC3B in the RA-FLS compared with OA-FLS. These mitochondrial phenotypes of RA-FLS were attenuated by treatment of pyruvate in TEM and western blot analysis. In addition, pyruvate supplement decreased IL-6 release in the TNF-a stimulated RA-FLS.

Conclusion: Pyruvate may act as a new therapeutic metabolite for improvement of mitochondrial dysfunction and proinflammatory cytokine production in RA-FLS.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In the Rheumatoid Arthritis (RA) prodrome, genetic predisposition intersects with environmental risk factors, such as smoking, periodontal disease and respiratory infection, however no studies to date compare the microbiomes of at-risk first-degree relatives (FDR) with Healthy controls (HC) and RA probands. We hypothesized that specific microbial taxa (operational taxonomic units, OTUs) from the oral and fecal microbiota differentiate between RA and HC, and that FDR segregate based on similarity with RA patients or HC.

Methods: We chacterized a prospective cohort of RA probands, FDR and HC. Probands met ACR 2010 criteria and/or had a confirmed RA diagnosis. FDRs included parents, full siblings or offspring of an RA proband; HC were drawn from the community. From all individuals, we obtained demographics, medical history, epidemiological questionnaires and tissue collections. After DNA extraction from tongue and fecal swabs, we undertook targeted 16S rRNA gene sequencing using Illumina MiSeq then used standard QIIME workflows, visualizations with the Phyloseq R package and multivariate statistical analysis using the mixOmics R package.

Results: 116 RA patients, 63 FDR and 43 HC matched for age and gender were recruited. 56% and 57% of RA, 4% and 49% of FDR and 0% and 37% of HCs were ACPA+ and shared epitope positive respectively. 47% RA patients, 30% FDR and 37% HC had ever smoked. Based on multivariate analyses, oral and faecal microbiota were altered in RA relative to HC. The oral community profile in RA was enriched in opportunistic pathogens including *Streptococcus, Veillonella, Staphylococcus* and *Camplylobacter* spp., *Propionibacterium acnes* and *Prevotella melaninogenica.* The fecal community profile in RA patients was enriched in *Bacteroides*, *Enterococcus* and *Pseudomonas* spp., while in HC in *Clostridiales*, particularly members of the *Lachnospiraceae*. By univariate analysis, the abundance particular oral and fecal OTUs was strongly associated with environmental risk factors. For example, a fecal *Peptococcus* sp. was associated with smoking history, dental history and a history of respiratory infection. The oral and faecal OTU profile of some FDRs segregated with the RA patients and some segregated with HC.

Conclusion: We demonstrate distinct oral and fecal community profiles in RA patients relative to HC, which are influenced by environmental risk factors such as smoking, dental or respiratory infection. The oral and faecal associated microbiota of individual FDRs segregates either with RA or HC subjects. Thus, compound genetic and environmental risks may promote inhospitable mucosal environments for commensals abundant in HC, creating niches for opportunistic pathogens before and after the development of RA.

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Accelerated biological aging of blood cells could contribute to the pathogenesis of RA. However, biological age has multiple facets, some as epigenetic aging not yet addressed in RA, and the most studied, shortened telomere length, not replicated in all studies. Recently, DNA methylation age measures (DmAM) have been developed as biomarkers of epigenetic aging that correlate with survival, diseases of old age and fitness in the elderly. We aimed to address biological aging in RA with DmAM and telomere length.

Methods: DNA from blood of 365 patients meeting ACR classification criteria for RA and 375 healthy age-matched controls were analyzed. A DmAM based in 8 CpG sites was assayed by minisequencing after bisulfite modification (1). qPCR was used for evaluation of relative telomere length (2). A second set of 354 ACPA positive RA patients and 335 controls was used for replication of the DmAM results (3). Differences in DmAM and telomere length between patients and controls were evaluated with ANOVA. Cox proportional hazards regression models were used for survival analysis. All analyses were adjusted for age and sex.

Results: The 8 CpG DmAM showed a small premature aging in patients with RA in comparison with controls in the two sample collections analyzed (Table 1). However, premature aging did not persist after correction for changes in blood cell subpopulations (Table 1), and it was not consistently observed with other DmAM (Table 1). In addition, telomere length attrition was not observed in RA patients (Table 1). No association was observed between any of the two age biomarkers and time since disease onset, antibody status, and prevalence of erosions, shared epitope

or smoking (not shown). At the end of data collection, 246 of 734 subjects have died (33.51%). Hazard Ratio (HR) for all-cause mortality was higher for RA patients than for controls (HR = 1.89; 95% CI = 1.45 to 2.45; $P = 2.0 \times 10^{-6}$). However, mortality was not associated with age biomarkers, neither the DmAM, nor telomere length, after adjusting for chronological age.

Conclusion: We observed premature epigenetic aging of small magnitude in blood cells of patients with RA, but the difference is most likely irrelevant as it could be due to changes in blood cell subpopulations or to particularities of the specific DmAM. In addition, we did not observe the reported shortening of telomere length, further questioning the concept of premature biological aging in RA blood cells as a whole. Table 1. Differences in biological age

Sample set	ΔDmAM (years)	95 % CI	*P*	Telomere length (T/S)	95 % CI	*P*

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Galectin 1 (Gal1) is a type of lectin expressed in a wide variety of tissues and organs. In the immune context, is broadly described its function as a negative regulator in different animal models of autoimmune diseases. The treatment with recombinant Gal1 has a therapeutic effect in the murine model of collagen-induced arthritis. In this work we studied the effect of genetic variants on Gal1 gene (*LGALS1*) over the Gal1 expression and its relationship with clinical parameters of severity in patients with early arthritis (EA).

Methods: Princesa Early Arthritis Register Longitudinal (PEARL) study includes patients with early arthritis (EA). Demographic, clinical, laboratory, therapeutic and radiological data are collected along a 5 years follow-up (baseline, 6, 12, 24 and 60 months). Biological samples are obtained at each visit. We analyzed the genotype of 4 single nucleotide polymorphisms (SNPs) present in *LGALS1* by PCR with TaqMan probes (n=540). Next, we fit several multivariate models by generalized estimating equations for repeated measures to analyze the statistical correlation between these genotypes and clinical parameters [Disease Activity Score 28 (DAS28) and treatment intensity] as well as correlation between these genotypes and IL-6, a key inducer of systemic inflammation which is associated with activity and severity of RA. IL-6 serum levels were measured by Enzyme-Linked ImmunoSorbent Assay (ELISA) (n=190 patients with more than 2 visits). Gal1 serum levels were measured by ELISA and western blot (WB) was used to assess Gal1 expression in lymphocytes. Statistical analysis was performed using Stata 12 for Windows (StataCorp PL, College Station, USA). The effect of recombinant Gal1 over IL-6-secretion using anti-CD3/CD28-stimulated lymphocytes of healthy controls was also studied.

Results: We found that EA patients with at least one minor allele of the SNP rs9622682 had significantly lower levels of serum IL-6 (p=0.003 GA genotype and p=0.002 AA genotype). In addition, we observed that EA patients with AA genotype for rs9622682 showed higher levels of serum Gal1 and an increased expression of Gal1 on peripheral blood lymphocytes measured by WB compared to GG patients. That SNP showed partial linkage disequilibrium (LD) (R^2=0.6) with the rs929039 located in the *LGALS1* promoter. The presence of minor alleles of rs929039 displayed a similar effect over IL-6 and Gal1 levels than rs9622682. Different combinations of minor alleles of those SNPs could amplify the increased expression of Gal1 observed in EA patients. On the other

hand, treatment of anti-CD3/CD28-stimulated lymphocytes with recombinant Gal1 reduced IL-6 *in vitro* expression levels in healthy donors.

Conclusion: The presence of minor alleles of SNPs of *LGALS1* rs9622682 and rs929039 may affect the expression of Gal1 and this finding is associated with lower levels of IL-6 in serum of patients with EA, suggesting a potential prognostic value for these genetic variants.

IL-22 As a Biomarker for Erosive Disease in Rheumatoid Arthritis

Jan Leipe, Hendrik Schulze-Koops and Alla Skapenko, Division of Rheumatology and Clinical Immunology, University of Munich, Munich, Germany

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Consistent with models of experimental arthritis implicating IL-22 – as a cytokine produced by immune cells but acting on non-immune cells e.g. fibroblast and osteoclast – in the development of joint destruction could previously demonstrate that elevated IL-22 serum levels were associated with the development of erosive disease in patients with early rheumatoid arthritis (RA).

Methods: To study value of IL-22 as a marker for erosive disease in established RA, to assess whether IL-22 is increased in other joint destructive rheumatic diseases, and to evaluate the influence of comorbidities on IL-22 serum levels. We measured serum IL-22 levels by Enzyme-Linked Immunosorbant Assay (ELISA) and analyzed their correlation to erosive disease (assessed by radiographs of hand and feet) and clinical parameters in patients with established RA (n=142), psoriatic arthritis (n=15), gout (n=15), age-matched patients with hypertension (n=10), diabetes (n=10), coronary heart disease (n=10), and healthy individuals as controls.

Results: 81 of 142 patients with established RA demonstrated elevated IL-22 levels compared with the range of healthy controls. A significant greater percentage of these 'IL-22 high' patients (59%) demonstrated erosive disease compared the 'IL-22 normal' patients (37%, $p<0.05$). In the 'IL-22 high' compared to 'IL-22 normal' group the fractions of patients positive for RF (70% vs 83%) and ACPA (74% vs 64%) were slightly higher, however not statistical significant different. Similar, measures of disease activity including DAS28 (2.3 vs 2.8) and CRP (0.5 vs 0.3 mg/dl) only tended to be higher in the 'IL-22 high' than the 'IL-22 low' group. Irrespective of erosive joint disease, patients with psoriatic arthritis and gout demonstrated lower IL-22 levels compared to established RA and only slightly higher than healthy individuals. Of note, patients with hypertension, diabetes and coronary heart disease had IL-22 serum levels comparable to healthy controls.

Conclusion: High IL-22 levels are associated with erosive disease also in established RA, potentially in parts independent of serology and comorbidities, and might serve as a marker for joint destruction also in this cohort.

Disclosure: J. Leipe, None; **H. Schulze-Koops**, MSD, 5; **A. Skapenko**, None.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a disease of unknown etiology;with a pathogenesis that is due to a mixture of genetic, immunological and environmental factors. A T-cell immune response to the presence of pyrogenic toxin superantigens (PTSAgs) in the joints of RA

patients has previously been described.A link has been proposed between pathogenic micro-organisms and the development of chronic, autoimmune conditions. Potential pathogenic mechanisms include the hygiene hypothesis and molecular mimicry. Due to the widespread prevalence of RA, it has been hypothesised that the pathogenesis could involve a common bacterium.
Previously, *Porphyromonas gingivalis*, a periodontal pathogen, has been suggested due to its ability to citrullinate proteins. In RA one potential bacterial candidate that has been suggested is *Staphylococcus aureus*.

Current published data averages the presence of *S.aureus* at 30% in the general population from nasopharyngeal swabs[1]. Furthermore, our data has found immune complexes containing *S.aureus* antigens are detectable in urine(ref). **Objectives:** To investigate the presence of staphylococcal enterotoxins B and C (SEB/SEC), toxic shock syndrome toxin 1 (TSST-1) and alpha haemolysin (AH) in the urine of patients with RA to support the hypothesis that they may play a role in RA.

Methods: Following ethical approval, mid-stream urine samples were obtained from patients with RA and a control group (patients with closed fractures attending an orthopaedic clinic). Both populations had no active infection(s) and were recruited from British Rheumatology and Orthopaedic departments in the same hospital. Samples were collected and processed aseptically, then analysed by western blot using commercially available primary (sheep) antibodies to SEB, SEC, TSST-1 and AH; and a rabbit anti-sheep HRP conjugated secondary antibody.

Results: The RA population comprises 148 patients (74% females) The control population comprises 70 patients (52% female). Mean age was older in the RA group (63 vs 58 years $p<0.01$) results of the toxins and differences between cases and controls are shown in table 1 (below)

Table 1 Descriptive characteristics of the population(s).

All characteristics	**All (n=219)**	**RA (n=149)**	**Fracture (n=70)**	**Difference P value**
Female (%)	162 (74.0)	110 (73.8)	52 (74.3)	
Mean Age (SD)	62.1 (14.3)	63.9 (12.4)	58.1 (17.1)	<0.0045
Positive AH (%)	73(33.3%)	69(46.3%)	4 (5.7%)	P<0.001
Positive SEB (%)	54 (24.7%)	40 (26.9%)	14 (20%)	P=0.27
Positive SEC (%)	71 (32.4%)	57 (38.23	14(20%)	P=0.007
Positive TSST (%)	0 (0)	0 (0)	0 (0)	.
Any Toxin (%)	103 (47.0)	84 (56.4)	19 (27.1)	

The odds of being toxin positive for each was AH 13.7 (95%CI 4.7,39.6), SEB 1.34 (95%CI 0.66,2.71) and SEC 2.4 (95%CI 1.22,4.8). The odds of any toxin being positive was 3.5 (95%CI 1.9,6.4) and this remained significant after adjusting for age and gender

Conclusion: Our work demonstrates the presence of bacterial toxins in urine from RA patients, with 56% demonstrating the presence of at least one staphylococcal toxin. We also show that *S.aureus* toxins are differentially expressed in this population. The pathological basis of this finding is not clear.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Urokinase-type plasminogen activator receptor (uPAR), is a multi-functional receptor on cell surface, widely present in endothelial cells, fibroblasts, and a variety of malignant cells. Current studies have suggested that uPAR overexpressed on synovial tissues or in synovial fluid or plasma in patients with rheumatoid arthritis (RA). However, there are limited researches regarding the role of uPAR on fibroblast-like synoviocytes of rheumatoid arthritis (RA-FLSs) and its underlying mechanisms.

Methods: All synovial specimens were taken from patients, in which 8 patients with RA (met the 2009 ACR/EULAR criteria) , 4 patients with OA (consistent with 1995 ACR classification criteria) , and 3 patients with severe trauma who had , no other joint abnormalities or systemic disease. To study effects of uPAR on RA-FLSs, chemically synthesized small interference RNA(siRNA) specifically targeting the uPAR gene was transfected into RA-FLS by cationic liposome. Western blot and ELISA were taken to test inhibition efficiency. The proliferative inhibition rate was examined by the CCK8 assay. Flow cytometry was used to determine the change of cell cycle distribution and apoptosis. The migration and invasion ability of RA-FLSs were examined by a

transwell assay. Western blot was performed to detect the influence of uPAR on the PI3K/Akt signaling pathway.Migration and tubule formation assays were used to explore the influence of RA-FLSs uPAR on angiogenesis.

Results: Our studies show that the expression of uPAR protein was significantly higher in FLSs from RA than those from OA or traumatic injury patients. uPAR-siRNA could effectively block the uPAR expression of mRNA, protein level in RA-FLSs and soluble uPAR secretion in cell supernatant. uPAR gene silencing inhibited RA-FLSs proliferation by (28.62 ± 4.82)% at 72h, restrained cell transformation from the G0/G1 phase to S phase obviously, reduced RA-FLSs cell migration by (74.82 ± 2.16)% and invasion by (74.51 ± 4.73)% , and interfered with activation of the PI3K/Akt signaling pathway significantly. Cell supernatants from uPAR gene-silenced RA-FLSs markedly inhibited the migration and tubule formation ability of HUVEC (human umbilical vein endothelial cell) (P <0.05).

Conclusion:

uPAR changes the biological characteristics of RA-FLSs and affects neoangiogenesis of synovial tissues in patients with RA, which may be associated with PI3K/Akt signaling pathway. These results imply that targeting of uPAR and its downstream signal pathway may provide beneficial therapeutic effects in RA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Periodontitis shares pathogenic mechanisms with rheumatoid arthritis (RA) and may trigger its onset. However, little information is available about inflammatory responses in oral fluids of RA patients.

Methods: 33 RA patients (22 new-onset, 11 late RA), all meeting 2010 ACR/EULAR criteria, 20 age/gender-matched healthy subjects (HS) without periodontitis/RA, and 20 patients with chronic periodontitis (CP) without RA were enrolled. 20 analytes including matrix metalloproteinases (MMPs) and innate/adaptive immune mediators were measured by Luminex in serum, saliva, gingival crevicular fluid (GCF), and RA joint fluid (JF). Serum *P. gingivalis* (*Pg*) IgG was measured.

Results: The 33 patients were typical of RA cohorts (85% female, median age 51) and only one currently smoked. The majority (91%) received regular dental care with cleanings every 6 months. 58% had rheumatoid factor (RF) or anti-citrullinated protein antibody (ACPA). Of the RA patients, 10 (30%) had periodontal health, 13 (39%) had gingivitis, and 10 (30%) had periodontitis. Pocket depth (PD), clinical attachment loss (CAL), and bleeding on probing (BOP) were all increased compared with HS ($P<0.002$). Six of 33 patients had *Pg* IgG antibodies, and all 6 had periodontitis ($P=0.0002$). *Pg* antibodies strongly correlated with PD, BOP, and CAL ($P\leq0.0009$). ACPA and RF levels also correlated with CAL ($P=0.03$). Most mediators were significantly elevated in serum of RA patients versus HS; Th-1 mediators predominated in JF. However, RA patients had elevated salivary levels of IL-17, IL-10, IL-8, OPG, MMP-1, MMP-9, and MMP-13 versus HS ($P\leq0.03$). In GCF IL-8, MMP-8, and MMP-9 amounts were higher in RA versus HS ($P\leq0.02$). Notably in RA patients, MMP-8 or MMP-9 levels were even higher in the oral fluids than serum ($P<0.0001$) and JF. Salivary or GCF mediators were elevated in RA patients regardless of periodontitis. While 13 patients had elevation of MMP-8 or MMP-9 in saliva >3 SD above the mean of HC, only 30% had clinical periodontitis. In patients with non-RA CP, levels of MMPs were exceptionally elevated in serum and oral fluids compared to HS and RA, particularly MMP-8 and MMP-9 ($P<0.0001$). Highest levels were seen in GCF, which were 4X higher than serum. The subset of RA patients with CP had similar inflammatory profiles to CP without RA, with exception of a few inflammatory mediators enriched in RA, notably IL-12p70 in saliva ($P=0.001$), IFNα and CXCL10 in GCF ($P\leq0.003$). MMP levels were higher in all sites for non-RA CP ($P\leq0.01$). *Pg* antibodies did not directly correlate with any serum mediator, however in GCF, the most proximal site of periodontitis, they correlated with levels of IFNα, IL-10, IL-12p70, and IL-23 ($P\leq0.05$).

Conclusion: RA patients had oral inflammation despite lack of smoking and regular dental care. Highly elevated MMP levels and correlation between dental parameters and ACPA support pathogenic connections between the diseases. *Pg* antibodies may be a marker of periodontitis in RA patients. However, elevation of MMPs in oral sites, regardless of periodontitis status or *Pg* antibodies, suggests the oral muscosa may be a common, and often unrecognized, site of extra-articular inflammation in RA patients.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Human Etiology and Pathogenesis - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Progressive bone destruction occurs in rheumatoid arthritis (RA) due to imbalance of osteoblast/osteoclast activity. Bone morphogenetic proteins (BMPs) regenerate bone damage by stimulating the differentiation of osteoblasts. Effects of BMPs and their inhibitors in the mechanism of bone destruction have not been identified yet. The aim of this 1 year follow-up prospective study which preliminary results were presented as poster in 2015 ACR Congress is to compare plasma levels of BMP 2, 3, 4, 5, 6, 7, 9, 14, noggin, sclerostin in RA patients and healthy volunteers and to assess correlations of these proteins with disease activity, clinical and radiographic progression in RA.

Methods: 138 RA patients (Group 1=85 using DMARDs, Group 2=53 using anti-TNFα) fulfilling the 1987 ACR criteria and 80 healthy volunteers aged 18-65 years were recruited. All groups were matched by age and sex. 125 RA patients (Group1=77, Group2=48) reached to the end of study.

Tender/swollen joint, ESR, CRP, DAS28-ESR, DAS28-CRP, pain and HAQ were evaluated. Structural damage was measured by modified total Sharp scoring method (mTSS). Plasma levels of BMPs, noggin and sclerostin were measured by ELISA method. Measurement of BMPs and their inhibitors, HAQ, mTSS and clinical assessment were repeated 1 year later in patient groups. Differences between group 1 and 2 were compared by Mann-Whitney U test. Baseline and 1-year datas were compared by Wilcoxon test. P value of 0.05 was considered statistically significant.

Results: Disease duration was statistically longer in anti-TNFα group (p=0.005). In our preliminary results plasma levels of BMP 2, 4, 5, 6, 7, 9, 14 were decreased; however, BMP subgroup inhibitors which are BMP 3, noggin and sclerostin were increased in RA patients. Also, the correlation between BMP 2,5, 14, sclerostin and disease activity scores were statistically significant in DMARD group. In 1 year follow-up datas BMP 2, 3, 4, 5, 7, 9, 14 were statistically significant in DMARD group and BMP2, 3, 7 and 9 were statistically significant also in anti-TNFα group when compared with the plasma levels of healthy volunteers. The comparison of basal and 1 year follow-up BMPs are shown in table 1. There was no correlation between BMP subgroups and HAQ, erosion scores, DAS28-ESR, DAS28-CRP in both of the patient groups in 1 year follow-up datas.

Conclusion: These results imply the relevance of BMPs and their inhibitors mainly with early diagnosis of RA rather than follow-up and prognosis.

Etanercept Treatment Does Not Adversely Affect Traditional Cardiovascular Risk Factors in Patients with Rheumatoid Arthritis

Atul A. Deodhar[1], Bojena Bitman[2], Yue Yang[2] and David Collier[3], [1]Division of Arthritis & Rheumatic Diseases OP09, Oregon Health & Science University, Portland, OR, [2]Amgen Inc., South San Francisco, CA, [3]Amgen Inc., Thousand Oaks, CA

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of cardiovascular (CV) disease. This analysis evaluated changes in metabolic and lipid CV risk factors in patients with RA treated with etanercept (ETN).

Methods: This was an exploratory analysis in a randomized, double-blind, placebo-controlled study to evaluate the efficacy and safety of ETN in patients with moderate RA despite disease-modifying antirheumatic drug therapy. Adults with active, moderate RA (3.2 <DAS28-CRP ≤5.1) for ≥6 months and receiving a stable dose of methotrexate for ≥8 weeks were randomized 1:1 to receive ETN 50 mg or placebo (PBO) weekly for 12 weeks; after week 12, all patients received ETN 50 mg weekly for 12 weeks. Laboratory tests evaluated baseline, week-12, and week-24 levels of metabolic and lipid analytes, and shifts in grade (low, normal, or high).

Results: In total, 210 patients enrolled: 104 PBO and 106 ETN; 77% female, 86% white, and mean (SD) age 56 (12) years. There were 14% with a medical history of type 2 diabetes and 30% a medical history of hyperlipidemia or hypercholesterolemia; 22% were receiving statins, 10% oral antidiabetic medications, 3% insulin, and 52% prednisone. Baseline, week-12, and week-24 values for each analyte are listed below. Over 24 weeks, there were no significant changes in metabolic or lipid analytes. Patients with diabetes and hyperlipidemia resembled the overall study population, except for decreases in fasting glucose and insulin through week 12 and slight decreases in hemoglobin A1C through week 24 in diabetics receiving ETN (n=17). For the majority of patients,

all analytes were in the normal range at baseline and remained normal at week 24.There were no gross abnormalities in liver function tests. Safety results are consistent with the current safety profile.

Conclusion: Treatment with ETN did not adversely affect the levels of traditional metabolic and lipid CV risk factors in patients with RA. Results in patients with diabetes are hypothesis generating and might be clinically relevant if demonstrated in a larger study.

Tofacitinib Do Not Get Worse Subclinical Atherosclerosis Despite up-Regulating Serum Cholesterol in Methotrexate-Resistant Active Rheumatoid Arthritis Patients

Kensuke Kume[1], Kanzo Amano[2], Susumu Yamada[1], Toshikatsu Kanazawa[3], Kazuhiko Hatta[4] and Noriko Kuwaba[5], [1]Rheumatology, Hiroshima Clinic, Hiroshima, Japan, [2]rheumatology., hiroshima clinic, Hiroshima, Japan, [3]rheumatology, hiroshima clinic, hiroshima, Japan, [4]Rheumatology, Hatta Clinic, Kure, Japan, [5]Medical Research, Sanki Clinical Link, Hiroshima, Japan
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have an increased cardiovascular (CV) risk. We should have strategies for primary cardiovascular prevention in RA. Tofacitinib (Tofa) could possibly play a role in up-regulating levels of serum cholesterol[1].But there is no evidence of CV risk management about Tofa. To examine the effect of Tofa plus methotrexate (MTX) on subclinical atherosclerosis in MTX resistant RA patients in a cohort study design.

Methods: 45 RA patients with moderate to severe active disease despite MTX treatment (disease activity score: DAS28>3.2)were received Tofa plus MTX.Arterial structures, carotid intima media thickness(CIMT) and carotid artery plaque(CAP), were measured at baseline and 54 weeks follow-up.Arterial stiffness was assessed with cardio-ankle vascular index (CAVI) and augmentation index corrected for a heart rate of 75 beats per minute (AIx@75) at baseline and 54 weeks follow-up. Clinical data were collected at regular visits. CAVI is very similar to pulse wave velocity (PWV), and CAVI measures arterial wall stiffness independent of blood pressure and it is superior to brachial ankle PWV as an index of arterial stiffness[2].No new all treatments(statin, low lipids drug, and etc.) were allowed.

Results: Treatment with Tofa attenuated CIMT did not produce significant changes(0.92±0.09mm at baseline, 0.91±0.10 mm at 54 weeks: p=0.92), CAP did not produce significant changes(0.68±0.07 at baseline, 0.61±0.10 at 54 weeks: p=0.67)Treatment with Tofa attenuated the CAVI significantly from baseline to 54 weeks follow up(12.76 ± 1.68 and 10.22± 1.18%; p = 0.026). Treatment with Tofa attenuated the Aix@75 significantly from baseline to 54 weeks follow up(37.7

± 5.6, 32.9 ± 5.6 %; p = 0.028). DAS 28-ESR score improved significantly from baseline to 54 weeks(5.31±1.43, 2.23±1.63: p=0.01). On the other hand, fasting serum total cholesterol TC was significantly increased from baseline to follow-up at 54 weeks (185±21.7mg/dL, 201±18.2mg/dL, p = 0.03). No patients suffered from new CV disease.

Conclusion: These findings suggest that combination therapy, Tofa with MTX not only reduced RA disease activity but also limited vascular damage despite up-regulating cholesterol in patients MTX resistant active RA. References:

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tripterygium wilfordii Hook F (TwHF), a traditional Chinese herb, is widely used in China for treating Rheumatoid Arthritis (RA), but limited only for eldly RA patients because of its reproductive system toxicity. We were inspired by external therapy, an immemorial

therapy for thousands of years, and took its advantage to make TwHF topically in order to get an effective and safe treatment for active RA patients.

Methods: In this 4-week double-blinded, randomized, placebo controlled clinical trial, patients were 1:1 randomized to add-on topical TwHF twice a day or placebo for 4 weeks. The primary endpoint was the rate of achievement of 20% improvement in the American College of Rheumatology criteria (ACR20) at week 4. Secondary endpoints were 50% improvement in the ACR criteria (ACR50), 28-joint count Disease Activity Score (DAS28) improvement and safety profiles. Statistical analyses were performed using intention to treat analysis (ITT) set ·

Results: A total of 70 active RA patients were enrolled. At week 4, the ACR20 was 34.3% (12/35) in topical TwHF group and 11.4% (4/35) in placebo group (P=0.015). Similarly, a higher ACR50 responder proportion was seen in topical TwHF group with 17.1% (6/35) comparing to it in placebo group with 2.9% (1/35) (P=0.046). The topical TwHF group also had more improvement than the placebo group on DAS28-ESR (1.1 vs 0.5, P=0.001), DAS28-CRP (1.4 vs 0.7, P=0.001), tender joint count (5.5 vs 2.6, P=0.018), swollen joint count (3.5 vs 1.6, P=0.003) and Physician's global assessment (25.8 vs 13.0, P=0.002), as well as C-reactive protein (11.2 vs 2.7, P=0.048). Initial effect onset time of pain and swelling reductions were significantly shorter in topical TwHF group with Means of both 7 days (range: 2.5 hours to 11 days and 1 to 21 days, respectively) than those of 11 and 17 days (range: 4 to 24 days and 4 to 28 days, respectively) in placebo group (P=0.022, P<0.001), respectively. There were 2 adverse slight skin allergy events in topical TwHF group. No substantive differences in adverse events were observed.

Conclusion: Topical TwHF is an effective and safety complimentary treatment in patients with active RA.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: This study aimed to determine the regulatory role of N-Acetyl-L-cysteine (NAC), an antioxidant, in T cell and osteoclast differentiation in rheumatoid arthritis (RA).

Methods: After RA synovial fibroblasts were stimulated by LPS, the expression and production of RANKL, IL-1beta, TNF-alpha was determined by real-time PCR and ELISA. After human peripheral CD4+ T cells were cultured under Th0 condition, IL-17, IFN-g, IL-4, Foxp3, RANKL and IL-2 expression was determined by flow cytometry and ELISA. Human peripheral blood monocytes were cultured with M-CSF, RANKL, and various concentrations of NAC, followed by staining of the cells for tartrate-resistant acid phosphatase activity to determine osteoclast formation. Osteoclastogenesis was also determined after cocultures of LPS-stimulated RA synovial fibroblasts or Th0-stimulated CD4+T cells and various concentrations of NAC with human PBMC.

Results: When RA synovial fibroblasts were stimulated by LPS, LPS stimulated their production of RANKL, IL-1beta, TNF-alpha and IL-6. NAC reduced the LPS-induced production of proinflammatory cytokines and RANKL in a dose-dependent manner. After human peripheral CD4+ T cells were cultured under Th0 polarizing condition, NAC decreased the proportion of IL-17^{+} and CD4^{+} T cells, and production of IL-17 and RANKL. When human peripheral blood CD14^{+} monocytes were cultured with M-CSF and RANKL, osteoclasts was differentiated, however, NAC significantly inhibited the osteoclastogenesis

Conclusion: NAC inhibits the production of proinflammatory cytokines and RANKL in RA synovial fibroblasts, differentiation of osteoclasts and Th17 cells. NAC could be a new therapeutic medication for regulation of autoimmune reaction and prevention of bone destruction in RA.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial Lung Disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). A potential association of anti-TNFα drugs and conventional disease-modifying anti-rheumatic drugs (cDMARDs), such as methotrexate (MTX) and leflunomide (LFN), with the development of ILD in patients with RA has been suggested. The aim of our study was to assess the efficacy and safety of abatacept (ABA) in RA patients with ILD.

Methods: Multicenter study of RA patients with ILD treated with ABA. ILD was diagnosed by high-resolution computed tomography (HRCT). ABA was used at standard dose (10 mg/Kg/4 weeks i.v. or 125 mg/week s.c.). To assess the efficacy of ABA, we have analyzed the following variables: **a)** 1-point change in the degree of dyspnea according to the Modified Medical Research Council (MMRC); **b)** FVC improvement > 10%; and improvement > 10% in DLCO; **c)** radiological improvement in HRCT scan, and **d)**changes in the joint assessment measured by DAS28 score. Values were compared with baseline. Continuous variables by means of Wilcoxon´s signed rank test, and percentages by using the Chi-squared test or Fisher´s exact test as appropriate.

Results: We studied 55 patients (30 women/25 men) with ILD associated to RA; mean age 62.7±9.05 years. The median [IQR, 25th-75th] duration of RA to ILD diagnosis was 7 [2.33-14.00] years. Patients had received a mean of 2.36±1.9 DMARDs. RA was seropositive in 46 cases (83.6%). Besides HRCT, the diagnosis of ILD was confirmed by biopsy in 10 patients. ILD was considered as drug-related in 14 patients: MTX (n=7), etanercept (n=3), adalimumab (n=3) and certolizumab (n=1). ABA was prescribed as monotherapy (n=28**)** or combined with cDMARDs (n=27); these were LFN (n=7), LFN and cyclosporine (n=1), sulfasalazine (n=2), MTX (n=3), MTX and LFN (n=1), hydroxychloroquine (n=6), hydroxychloroquine and LFN (n=4), and azathioprine (n=3). The results are summarized in **Table**. A significant improvement of the dyspnea was observed. The patients who did not have dyspnea at ABA onset remained asymptomatic during the follow-up. FVC and HRCT showed a significant improvement between 6 and 12 months after the onset of therapy. DLCO remained stable in the majority of the patients. DAS28 also improved. After a follow-up of 8.29±3.82 months, the most important adverse effects were: respiratory infection (n=2), urinary infection (n=1) and infusion reaction (n=1). ABA had to be withdrawn in 7 patients: due to severe infection (n=2); inefficacy in polyarthritis (n=2), lack of pulmonary improvement (n=2) and infusion reaction (n=1).

Conclusion: ABA appears to be an effective and relatively safe therapy in RA patients with ILD. These promising results require to be confirmed in a prospective and randomized study. **TABLE**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anemia in rheumatoid arthritis (RA) patients (pts) has a prevalence of 16%-64% depending on population and severity of disease[1,2,3] and is more common in women, pts with seropositive and erosive disease, and pts treated with systemic corticosteroids.[2] This *post hoc* analysis was performed to determine prevalence of anemia in a contemporary cohort of RA pts treated with conventional disease-modifying antirheumatic drugs (cDMARDs).

Methods: Data were pooled from screening for 2 phase 3 trials conducted from Oct 2012 to Sept 2015 in RA pts inadequately responsive to cDMARDs. Eligibility included ≥6/68 tender and ≥6/66 swollen joints. One study required erosions on radiographs and high-sensitivity C-reactive protein (hsCRP) ≥6 mg/L; the other required hsCRP ≥1.2x upper limit of normal (ULN), or 3.6mg/dL. Prior biologic disease-modifying antirheumatic drugs were prohibited. Analysis included data from pts who failed screening for any reason, such as hsCRP or number of tender or swollen joints below threshold for study entry. Anemia was defined as hemoglobin (Hgb) <8 g/dL, <10 g/dL, or below the age- and gender-adjusted lower limit of normal (gaLLN).

Results: Analysis included 3925 screened pts: 3159 women and 766 men, including 1591 women and 345 men who failed screening. Hgb <8 g/dL was observed in 8 women (0.3%). Hgb <10 g/dL was seen 10x more frequently in women, occurring in 128 women (4.1%) and 3 men (0.4%). When the less stringent definition of <gaLLN was used, anemia was identified in 718 women (22.7%) and 185 men (24.2%). Prevalence of Hgb <gaLLN was 24% among pts ≤65 years and 16% among pts

>65 years. Anemia (<gaLLN definition) was more prevalent among pts with more active disease. Using Simplified Disease Activity Index, prevalence of Hgb <gaLLN in pts who met screening criteria was 0% in pts in remission or with low disease activity, 3.37% in pts with moderate disease activity, and 21.8% in pts with high disease activity. Analysis by tertiles of acute phase reactant levels (hsCRP or erythrocyte sedimentation rate) yielded similar findings.

Conclusion: In a contemporary population of pts with active RA treated with cDMARDs, prevalence of Hgb <10 g/dL was low, but 10x more frequent in women. When anemia was defined as Hgb <gaLLN (rather than as Hgb <10), prevalence was higher in men and women, regardless of age. Hgb <gaLLN was observed more often in pts with more active RA. Inclusion of pts with RA who failed to meet entry criteria of these clinical trials allows assessment of the prevalence of anemia in an RA population treated with cDMARDs. **References**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Bone and cartilaginous metabolites such as matrix metalloproteinase 3 (MMP-3), cartilage oligomeric matrix protein (COMP),receptor activator for nuclear factor κ B ligand (RANKL) and osteoprotegerin (OPG) have the potential to act as biomarkers in rheumatoid arthritis (RA) management. Objective To investigate the clinical utility of bone and cartilage biomarkers in a DMARD-naïve early RA cohort in predicting response to 6 months of therapy with synthetic DMARDs.

Methods: 140 patients with DMARD-naïve early RA (symptoms less than 2 years) were recruited as part of the GREAT study (previously reported[i]).Disease activity was measured at baseline and six months after therapy using the SDAI. Baseline serum MMP-3, COMP, RANKL and OPG were assayed (ELISA).

Results: The majority of patients were of black ethnicity (88.5%) and female (79.2%) with a median age of 47.8 (IQR 14.4). The median symptom duration was 9.7 months (11.4).Rheumatoid factor and ACPA were positive in 81.4% and 84.1% respectively.(Table 1) The median SDAI improved significantly from a median of 41.4 (n=140, IQR 24.1) to 16.4(n=104, IQR 14.8).Baseline MMP 3 and COMP levels were previously reported[i]. Baseline RANKL and OPG were elevated in 20.4 and 38.8 % of patients respectively. The sRANKL/OPG ratio was elevated in 56.3% of patients. Only elevated MMP 3 (p=0.048) and OPG (p=0.016) levels at baseline were statistically significantly associated with a moderate or higher disease activity (SDAI > 11) at 6 months .

Table 1: Baseline demographics of patients (n=140)

	n or Median	**% or IQR**
Black ethnicity (%)	124.0	88.5
Females (%)	110.0	79.2
Age in years, median (IQR)	47.8	14.4
Symptom duration in months, median (IQR)	9.7	11.4
Rheumatoid factor positive (%)	114.0	81.4
ACPA [n=126] (%)	106.0	84.1

Conclusion: Outcome measure of low disease activity (SDAI<11) within 3 to 6 months ofdisease onset is the therapeutic target in the management of patients with RA. The measurement of serum

MMP 3 has performed well as a biomarker in RA having been incorporated into a multi-biomarker assay. In this study, similar to findings elsewhere, low levels of OPG predicted better control of disease activity at 6 months.[ii]Thus, patients with elevated baseline MMP 3 and OPG may be a subgroup of poor responders requiring aggressive management. These biomarkers may be particularly useful in resource poor settings where regular monitoring aimed at tight control and biologic therapy is widely unavailable. References

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Intra-articular steroids are in use since half-a-century, but choice of individual agents remains empirical in the absence of comparative trials. This study compared the efficacy of intra-articular injection of methylpredisolone acetate (MPA) with triamcinolone acetonide (TA) in treatment of acutely swollen knee joint in patients with chronic inflammatory arthritis.

Methods: This was a double-blind randomized controlled trial that included patients with rheumatoid arthritis (RA) or spondyloarthritis (SpA) having an acutely swollen knee (>1 week and <24 weeks). Patients were randomized (1:1) to receive intra-articular injection of either methylpredisolone acetate (MPA) or triamcinolone acetonide (TA) (80 mg, 2ml) and followed over 24 weeks. The primary outcome measure was time-to-relapse and secondary outcome measures were numerical rating scale (NRS) (0-10) of pain and swelling at 4, 12 and 24 weeks, range of motion and adverse effects. In addition assessed change in DAS28-3, Indian health assessment questionnaire and proportion with good improvement (>50% improvement). Primary analysis was intention-to-treat; in addition per-protocol (only completers) analysis also done. Trial # Clinical trials registry of India CTRI/2015/09/006187

Results: This study included 100 patients (RA:SpA=89:11, M:F=24:76). They were randomized (50 each) to MPA and TA, with no significant differences in baseline characteristics. At 24 weeks, 3 patients were lost and 9 relapsed in each group, with no significant difference in mean (+/-SEM) time-to-relapse (20.8±1.0, 20.9±1.0 weeks, p=0.96) (Figure 1). There was also no significant difference in change in NRS pain (-4.4±3.1, -3.9±2.8, p=0.46) and NRS swelling (-4.5±2.9, -3.9±2.8, p=0.36) in MPA and TA groups at 24 weeks from baseline. (Figure 2) At baseline, normal flexion of knee joint was present in 28 and 25 patients (p=0.17), and at 24 weeks, in 38 and 37 patients (p=0.7) respectively. There were no adverse effects in any patient. There was no significant difference in the change in DAS28-3 at 24 weeks from baseline (-1.4±1.1, -1.3±1.3) or in HAQ at 24 weeks from baseline (-0.7±0.5, -0.7±0.5, p=0.80).

Conclusion: There was no significant difference efficacy of intra-articular injection of MPA vs TA in knee arthritis over a period of 24 weeks. Figure 1:Kapan-Meier curve comparing time-to-relapse

in MPA and TA groups

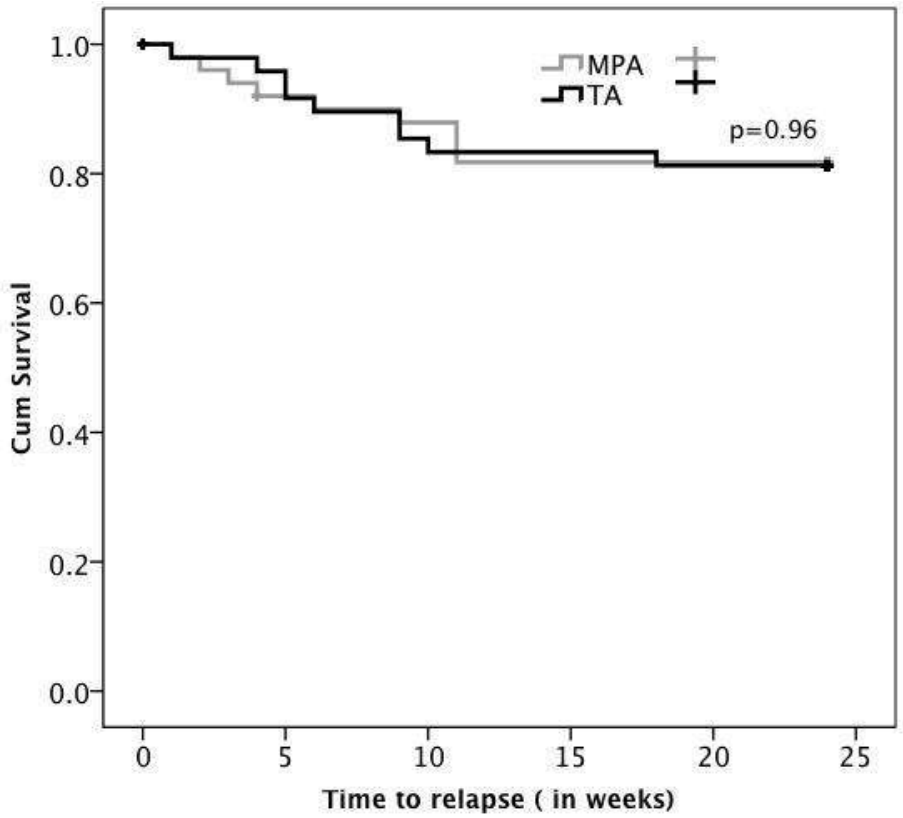

Figure 2: Composite outcomes over 24 weeks in the MPA and TA groups

The Serum Level of Reactive Oxygen Metabolities (ROM) at 12 Weeks during Treatment with Biologic Agents for Rheumatoid Arthritis Is a Predictor for the 52-Week Remission

Arata Nakajima[1], Keiichiro Yamamoto[2] and Koichi Nakagawa[3], [1]Orthopaedics, Toho University Sakura Medical Center, Sakura, Japan, [2]Orthopedics, Toho University Sakura Medical Center, Sakura, Japan, [3]Toho University Sakura Medical Center, Sakura, Japan

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Oxidative stress induced by reactive oxygen species is thought to be an important mechanism that underlies joint destruction and synovial proliferation. We have shown that serum levels of reactive oxygen metabolities (ROM) were associated with CRP and DAS28 in patients with rheumatoid arthritis (RA) and reduced temporally by the treatment with biologic agents (BAs). However, its clinical significance as a biomarker has not been elucidated.

Methods: Forty-eight BAs-naïve RA patients (mean age: 59.3}13.9 y, disease duration: 7.56}11.2 y) were included in this study. Association between serum levels of ROM, CRP, MMP-3, DAS28 (ESR) and HAQ at 12 weeks during the treatment and the remission in DAS28 (ESR) at 52 weeks was investigated. To measure ROM, the d-ROM test was performed using the FRAS4 analyzer (Wismarl, Italy). In order to identify predictor(s) for the 52-week remission, a multivariate logistic regression analysis was performed and an ROC analysis was also performed to determine their cut-off values.

Results: DAS28 (ESR) at baseline was 4.80}1.21 but decreased to 2.23}1.89 at 52 weeks and the remission rate was 70.8%. The serum level of ROM at baseline in the remission group (N=34) was 527.1}131.7 U.Carr (normal range <300 U.Carr), decreased to 334.9}79.1 at 4 weeks, and kept low levels after 12 weeks. On the other hand, in the non-remission group (N=14), the serum level of ROM at baseline was 592.2}112.9 U.Carr, decreased to 449.6}151.7 at 4 weeks, but gradually increased after 12 weeks (Figure 1). Significant factors at 12 weeks between the remission and non-remission group were ROM, CRP, MMP-3, DAS28 (ESR) and HAQ (P <0.05), which were then subject to a multivariate logistic regression analysis. As a result, ROM, other than DAS28 (ESR), was extracted as a predictor for the 52-week remission (odds ratio: 0.985, 95% CI: 0.97-1.000). An AUC of the ROC curve was 0.891, and the cut-off value of ROM that discriminated remission from non-remission was determined to be 381.5 U.Carr (sensitivity: 0.833, specificity: 0.871; Figure 2).

Conclusion: These results suggest that CRP, MMP-3 and HAQ cannot be a predictor for the remission during early stage of treatment with BAs. Instead, ROM at 12 weeks is able to predict the 52-week remission with high accuracy. The serum level of ROM could be a useful biomarker to achieve the remission in the current treat-to-target strategy for RA.

Figure 1. Changes in the serum level of ROM during the treatment in the 52-week remission and non-remission group. ROM, reactive oxygen metabolities.

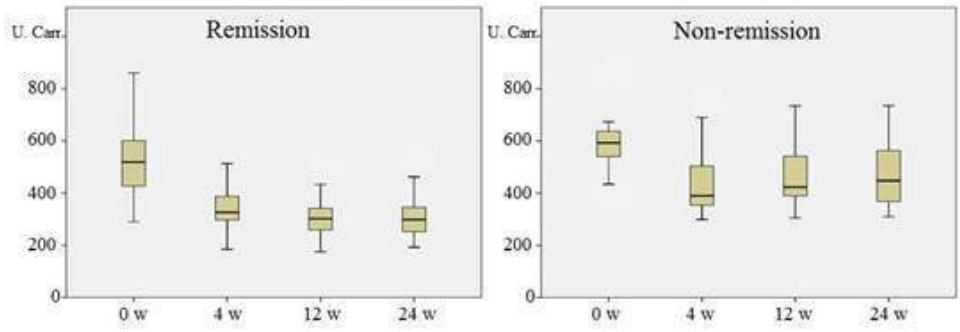

Figure 2. The ROC curves for ROM and DAS28 (ESR) at 12 weeks to predict the 52-week remission. The cut-off value for ROM corresponds to 381.5 U.Carr (indicated as an asterisk).

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To examine the association of cardiovascular, malignant and serious infection events (SIEs) with certolizumab pegol (CZP) use as compared to other TNFi agents in patients (pts) with rheumatoid arthritis (RA).

Methods: RA pts enrolled in the Corrona national registry who were ≥18 years of age when initiating CZP or other TNFi agents (etanercept, adalimumab, golimumab or infliximab) on or after May 1st, 2009 with at least 1 follow-up visit post index drug initiation were identified. Physician-reported cardiovascular events, malignancies and SIEs were captured during the follow-up period, which were measured separately for each adverse event type in pt-years (PY), from drug initiation to either: occurrence of the first event, 90 days following pt/physician-reported discontinuation/switch of biologic (censored), or the 12 month Corrona visit (censored). The analysis before propensity score matching (PSM) included all initiators. After PSM, the analysis included CZP and other TNFi pts matched with a propensity score, to control for disease and pt characteristics that differed between the two groups (age, gender, disease duration, Clinical Disease Activity Index [CDAI] at initiation, and line of therapy).

Results: There were 975 RA pts initiating CZP and 5240 RA pts initiating other TNFi. CZP was initiated later in the treatment course in terms of 1st, 2nd or ≥3rd line of therapy (CZP: 26%, 29%, 45% respectively vs other TNFi: 50%, 30%, 20% respectively; $p<0.001$). Consequently, those initiating CZP were older (median age 58 vs 56 years; $p<0.001$), had longer median disease duration (9 vs 5 years; $p<0.001$), more active disease based on median CDAI (19 vs 17; $p=0.01$), and more functional impairment based on median modified health assessment questionnaire (0.5 vs 0.4; $p<0.001$). At initiation, history of cardiovascular events (5.8% vs 5.4%; $p=0.57$), malignancy (4.9% vs 4.3%; $p=0.38$), SIEs (6.6% in each group; $p=0.93$), and insurance status (yes/no) were balanced between groups. Before PSM, the incidence rates (IR) per 100 PY for cardiovascular events and malignancies were similar in the two groups, while the IR for SIEs was higher in the CZP group (Table). However, PSM resulted in the resolution of clinically significant baseline differences, and, in the 952 propensity score matched initiators, IRs of cardiovascular events, malignancies and SIEs were similar between the two groups (Table).

Conclusion: Accounting for baseline differences using PSM demonstrated that CZP is not associated with an increased risk of cardiovascular events, malignancies or SIEs compared to other TNFi agents utilized in earlier lines of RA therapy. Failure to account for baseline differences (disease duration, disease severity and functional impairment) may have contributed to the difference in SIE IRs between CZP and the other TNFi groups in the cohort before PSM.

	CZP		Other TNFi initiators	
	Number of events [a]	IR [b]/100 PY (95% CI) [c]	Number of events [a]	IR [b]/100 PY (95% CI) [c]
Before propensity score matching	N=975		N=5240	
Cardiovascular event [d]	17	2.02 (1.26, 3.26)	77	1.66 (1.33, 2.08)
Malignancies [e]	15	1.78 (1.08, 2.96)	96	2.08 (1.70, 2.54)
SIEs [f]	59	7.20 (5.58, 9.29)	215	4.71 (4.12, 5.38)
After propensity score matching [g]	n=952		n=952	
Cardiovascular event [d]	17	2.08 (1.29, 3.34)	17	2.05 (1.27, 3.30)
Malignancies [e]	14	1.71 (1.01, 2.88)	20	2.42 (1.56, 3.75)
SIEs [f]	57	7.13 (5.50, 9.25)	46	5.65 (4.23, 7.54)

[a] Events that occurred up to 90 days following discontinuation were considered; [b] Incidence rate is the ratio of events to PY at risk (per 100 PY); [c] 95% confidence interval (CI) for incidence rate based on Poisson distribution assumption; [d] Cardiovascular events include: myocardial infarction, stroke, congestive heart failure with hospitalization, cardiac revascularization procedure, ventricular arrhythmia, cardiac arrest, acute coronary syndrome, unstable angina, transient ischemic attack, hypertension with hospitalization, peripheral arterial thromboembolic event, urgent peripheral arterial revascularization, peripheral ischemia or gangrene (necrosis), or other cardiovascular event; [e] Malignancies include: non-melanoma of the skin, melanoma skin cancer, lymphoma, breast, lung, and other cancer; [f] Serious Infection events include infections for which the patient was hospitalized and/or received IV antibiotics. These events are categorized by type as follows: joint/bursa, cellulitis/ skin, sinusitis, diverticulitis, sepsis, pneumonia, bronchitis, gastroenteritis, meningitis/encephalitis, urinary tract infection, upper respiratory infection, tuberculosis, and other. Information is also provided about organism (opportunistic vs non-opportunistic) when data are available; [g] 23 patients in the CZP unmatched cohort could not be matched by propensity score, due to differences in baseline demographics and/or disease characteristics.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Measurement of plasma anti-TNF concentration, in combination with the assessment of clinical outcomes, may be used to optimize dosing regimens for individual patients (pts). For successful implementation in clinical practice, an assessment of the different quantitative methods available is necessary. Here, we compare two enzyme-linked immunosorbent assays (ELISAs) for the quantitative measurement of plasma certolizumab pegol concentration ([CZP]), using data from the RAPID-PsA trial of CZP in pts with psoriatic arthritis (PsA).

Methods: Pts in RAPID-PsA (NCT01087788) were treated with a CZP loading dose (LD; 400 mg at Weeks [Wks] 0, 2, 4), followed by a maintenance dose (200 mg Q2W or 400 mg Q4W). Plasma samples were taken at baseline, Wks 2, 4, 12, 16, 24, 48, 72 and 96. A bespoke ELISA developed by UCB Pharma, validated in line with FDA/EMA regulatory requirements for bioanalytical methods (assay range: 0.4–33.3 μg/mL), was used to measure plasma [CZP] between 2010–2013. In 2016, a subset of frozen plasma samples was reanalyzed with the LISA-TRACKER® validated diagnostic kit (current range: 0.4–12.0 μg/mL). Paired CZP measurements were plotted and the degree of agreement between both assays was evaluated by the Bland-Altman method. Reproducibility of plasma [CZP] measurement with LISA-TRACKER® was evaluated by measuring in duplicate a set of 207 plasma samples from a different CZP study (NCT01500278).

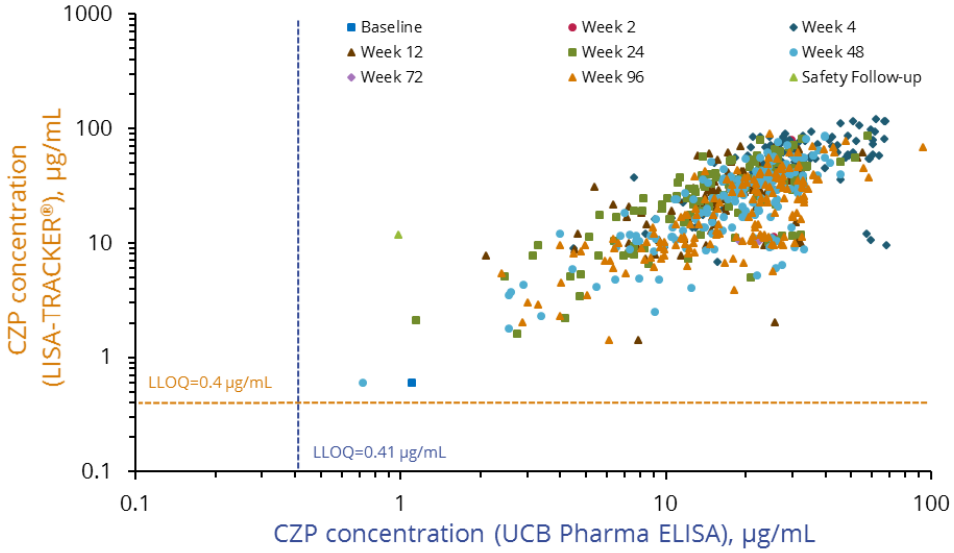
Results: 917 paired CZP measurements from RAPID-PsA pts were analyzed. Plasma [CZP] measured with LISA-TRACKER® showed good correlation with measurements obtained with the UCB Pharma ELISA, particularly for [CZP] between 10–100 μg/mL; [CZP] was highest at Wk 4, corresponding to the end of the LD period (Figure A). Bland-Altman analysis revealed a mean ratio LISA-TRACKER®/UCB Pharma ELISA of 1.19 (95% CI 1.13–1.25); the majority of paired measurements differed less than 3-fold from each other (Figure B). [CZP] <10 μg/mL were associated with greater variability. Reproducibility analysis showed a coefficient of variation of 13.5% for LISA-TRACKER® [CZP] measurements. Observed differences between assays should be interpreted with caution, as LISA-TRACKER® measurements were performed ≥3 years after the original analysis; over time, suboptimal sample storage conditions may have increased the difference in [CZP] detected by the two methods.

Conclusion: CZP concentrations measured with LISA-TRACKER®, a commercially available diagnostic kit, were 19% higher than those measured with the bespoke ELISA developed by UCB Pharma. The two assays showed good agreement, suggesting that data measured with both assays

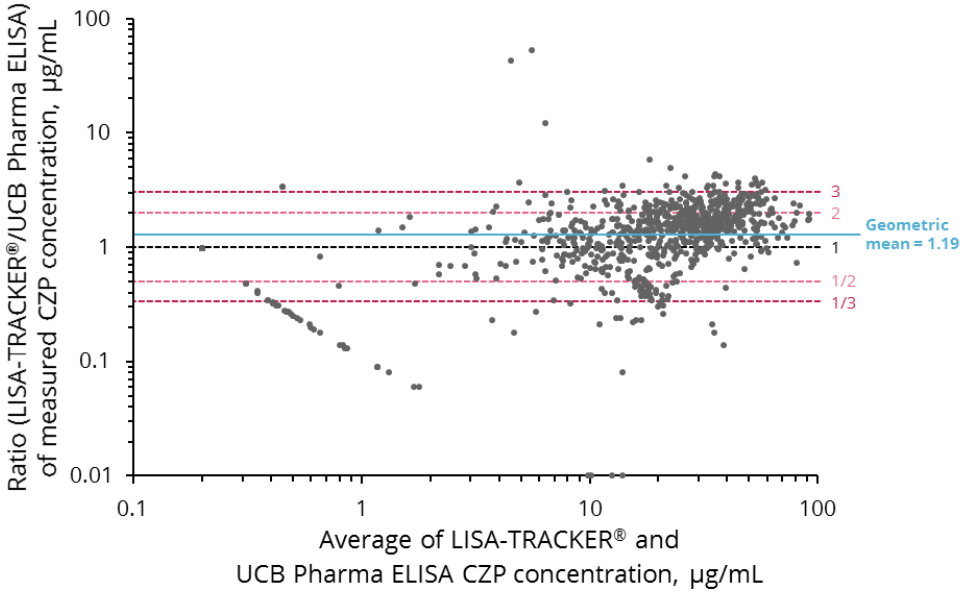
can be extrapolated to clinical practice.

Figure: Comparability of LISA-TRACKER® and UCB Pharma ELISA for the measurement of CZP concentration, tested on plasma samples from RAPID-PsA patients

A) Scatter plot of paired plasma CZP measurements obtained with LISA-TRACKER® and UCB Pharma ELISA (n=917 plasma samples) [a]



B) Bland-Altman plot of the ratio of CZP concentration measured with LISA-TRACKER® and UCB Pharma ELISA vs the mean of the two measurements [b]



[a] Dashed lines represent the lower limit of quantitation (LLOQ) of each assay (LISA-TRACKER® in yellow, UCB Pharma ELISA in blue); CZP measurements below assay LLOQs are not shown; [b] Horizontal lines represent: geometric mean of observed LISA-TRACKER®/UCB Pharma ELISA ratio (blue); no ratio difference (ratio=1; black); 2-fold difference limit (light red); 3-fold difference limit (dark red).

The Efficacy of Additional Immunoadsorption on the Modulation of Disease Activity in Patients with Severe Rheumatoid Arthritis

Xiaodan Kong[1], Changyan Liu[1], Dongyuan Cui[1] and Qi Zhang[2], [1]Department of Rheumatology, The second Hospital of Dalian Medical University, Dalian, China, [2]Department of Rheumatology, The second Hospital of Dalian Medical University, Dalian, Cocos (Keeling) Islands

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Immunoadsorption been used in patients with severe refractory rheumatoid arthritis (RA) was first reported in 1994, and the efficacy is promising. However, the subset of RA patients most likely to benefit from immunoadsorption treatment has not been defined. At present, immunoadsorption is presented as an alternative try for serve RA patients with chronic infection who cannot use anti- tumor necrosis factor (TNF) agents. Today, neutralize TNF, including infliximab (IFX), are widely used in the treatments for patients with serve RA (DAS28-ESR>5.1). However, even treated with IFX, there still approximate 40% of serve RA patients cannot reach low disease activity. Till now, there has no study report the additional immunoadsorption efficacy besides IFX therapy in serve RA patients. In this study, we evaluated the efficacy of additional immunoadsorption therapy besides IFX on disease remission in patients with severe RA.

Methods: 30 patients with serve RA were included in this study. 20 patients were treated with basic infliximab 3 mg/kg + methotrexate (MTX) therapy, and other 10 patients, besides of basic therapy, were previous gave 2 times additional immunoadsorption therapy (to removal of immunoglobulin and other pathogenic factor). IFX 3 mg/kg was infused at weeks 0, 2, 6, 14, 22 and 30. Age, sex ration, mean disease duration, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and Disease Activity Score including 28 joints using ESR (DAS28-ESR) from eligible patients in two treatment groups were collected at weeks 0, 2, 6, 14, 22 and 30 weeks and were compared between the two groups.

Results: The baseline age, sex ration, mean disease duration of RA, DAS28-ESR, ESR level and CRP level were comparable between the two treatment groups (P>0.05). At week 2 and week 6, decreases from baseline in DAS28-ESR, ESR and CRP were greater with additional

immunoadsorption treatment group versus only IFX treatment group (Figure 1, $P<0.05$), and with the exception of ESR and CRP (Figure 1, $P>0.05$), these difference was generally maintained to week 30 (Figure 1, $P<0.05$). At week 2, the percentage of patients receiving additional immunoadsorption therapy who achieved improvements of DAS28-ESR (improvements >1.8) was 80%, which was higher than 60% in only IFX treatment group. At week 30, the percentage of patients receiving additional immunoadsorption therapy who achieved low disease activity or remission was 70%, which was also higher than 50% in only IFX treatment group.

Conclusion: Additional immunoadsorption therapy can rapid relive the disease activity of serve RA patients, and the remission rate of 30W was significantly higher than only IFX treatment. However, due to the limited sample size of this study, the efficacy of additional immunoadsorption needs further observations. Figure 1 Disease activity in patients with severe RA

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic therapy has improved RA management and enabled some patients to achieve remission. Many clinicians decrease the biologic dose for patients in low disease activity (LDA) or remission. However, it is unclear which patients may flare and if flare contributes to radiographic progression. We assessed, post hoc, whether subjects who flared had a higher incidence of radiographic progression and compared subjects with and without flares.

Methods: PRESERVE (ClinicalTrials.gov: NCT00565409) was a 2-period trial in subjects with moderate RA despite MTX. Period 1 was open-label, single treatment induction; all subjects received etanercept (ETN) 50mg+MTX weekly (QW) for 36 wks. Subjects in LDA or remission (disease activity score for 28 joints [DAS28] ≤3.2) during wks 12 to 36 continued to Period 2, the randomized, double-blind phase to evaluate maintenance of LDA/remission. Subjects were randomized to receive ETN 50mg+MTX QW, ETN 25mg+MTX QW, or placebo+MTX QW to wk 88, when flare and radiographic progression were evaluated. Flare was defined 2 ways: 1) loss of LDA with/without DAS28 change of 0.6; and 2) relapse (DAS28>5.1 or DAS28>3.2 at ≥2 time points). Radiographic progression was evaluated according to 4 levels of stringency, based on modified total Sharp score (mTSS): 1) minimally clinically important difference (change of 5); 2) smallest detected difference (change of 2.3); 3) mTSS change >0.5; and 4) mTSS change >0.0. Demographics and baseline (BL) disease characteristics were compared for subjects with vs without flare, defined as loss of LDA and DAS28 change of 0.6. Analysis of covariance and chi-square test were used to compare continuous and categorical outcomes, respectively.

Results: Age, race, BMI, and disease duration did not differ significantly for flare vs non-flare subjects, total N=531. BL DAS28 was higher for flare than non-flare: mean (SD) 4.37 (0.45) vs 4.27 (0.45), respectively, p=0.046. Other BL disease characteristics were similar between the groups. When flare was defined as relapse, significantly more flare than non-flare subjects exhibited all 4 degrees of radiographic progression (table). When flare was defined as loss of LDA with/without DAS28 change of 0.6, there was no significant difference in radiographic progression for flare vs non-flare, but numerically more subjects with flare progressed. This was the trend for all treatments; the numbers were too small to analyze. Numerically more placebo subjects progressed, regardless of flare status or progression category (data not shown).

Conclusion: Using relapse as a rigorous definition of flare, radiographic progression occurs in significantly more flare vs non-flare subjects. This demonstrates that radiographic progression is a

consequence of flare, especially with biologic withdrawal. Patients should be closely monitored if biologic therapy is dosed down.

Table. Radiographic progression in flare and non-flare subjects at week 88

Outcome	Flare Subjects	Non-flare Subjects	P-value*
Flare defined as loss of LDA and DAS28 change of 0.6			
mTSS >0	43/271 (15.9)	31/260 (11.9)	0.2109
mTSS >=0.5	38/271 (14.0)	24/260 (9.2)	0.1045
mTSS >=2.3	20/271 (7.4)	10/260 (3.8)	0.0914
mTSS >=5.0	9/271 (3.3)	2/260 (0.8)	0.0633
Flare defined as loss of LDA			
mTSS >0	44/280 (15.7)	30/251 (12.0)	0.2586
mTSS >=0.5	39/280 (13.9)	23/251 (9.2)	0.1043
mTSS >=2.3	20/280 (7.1)	10/251 (4.0)	0.1338
mTSS >=5.0	9/280 (3.2)	2/251 (0.8)	0.0670

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In several developed countries it has been observed that the incidence of orthopaedic surgery among rheumatoid arthritis (RA) patients has been in decline, despite a concurrent increase among non-RA patients. Whilst the introduction of biologic therapies may be an explanatory factor for the divergent trends, specific data testing this hypothesis is lacking. We set out to estimate the impact of approval and national guidance (National Institute for Health and Care Excellence (NICE) TA36) on anti-tumour necrosis factor alpha (TNF-α) therapy use for RA on rates of total hip (THR) and knee replacement (TKR) among incident RA patients.

Methods: Primary care data (Clinical Practice Research Datalink (CPRD)) for the study period (1995-2014) were used to identify incident adult RA patients. The 5-year cumulative age and sex standardised incidence of THR and TKR was calculated for RA cohorts diagnosed in each six-months of the period 1st April 1995 to 30th September 2009. Interrupted time series analysis was used to estimate changes in level and trend following the publication of NICE TA36 in March 2002. In main analyses a 1-year time lag was used to allow for the delay associated with patients failing conventional DMARD therapy before initiating biologics. In sensitivity analyses a 2-year lag was used.

Results: We identified 17,505 incident RA patients. The number of THR and TKR events occurring within 5-years of diagnosis were 465 and 650, respectively. Throughout the pre-NICE TA36 period the cumulative incidence of THR remained stable at 2.48%. Following publication of guidance there was an immediate level increase (1.71%, P=0.001) but subsequent slope decrease (-0.21% per six months, P=0.001), equating to no significant difference in the mean absolute change in THR compared to that expected given prior level and trend only (using the mid-point of the post-NICE

TA36 period). Conversely, the cumulative incidence of TKR was 2.61% at the beginning of the study period and increased by 0.13% per six months (P=0.005) throughout the pre-NICE TA36 period (figure 1). Publication of guidance was associated with a significant downward slope change (-0.29% per six months, P=0.002), equating to a mean absolute change in TKR of -1.90% (95% C.I. -2.98 to -0.82) compared to values expected given prior level and trend only (figure 1). This represented a relative reduction of 34%. In sensitivity analyses using a 2-year lag, the cumulative incidence of THR was flat for the whole study period whilst results for TKR remained unchanged from the main analysis.

Conclusion: Among incident RA patients in England and Wales, approval of anti-TNF-α therapies and related NICE guidance was associated with reduced 5-year rates of TKR but not THR. Future work to further elucidate the impact of biologic therapies on the need for joint replacement surgery among RA patients is required.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To analyze the effects of therapy with tofacitinib (Tofa), a Janus kinase inhibitor on the bone mineral density (BMD) of the lumbar spine and femoral neck in patients with rheumatoid arthritis (RA).

Methods: Thirty-seven patients with active RA (indicated by a 28-joint disease activity score ESR > 3.2) despite treatment with methotrexate(MTX) 10mg per week were included in this open label prospective study and started on Tofa (10 mg every day). All patients used a stable dosage of MTX, and were not allowed to use steroids or bisphosphonates during the study period. The BMD of the lumbar spine and femoral neck was measured by dual-energy X-ray absorptiometry at baseline and 52 weeks after initiating Tofa. The least significant detectable difference of lumbar spine and femur neck was +/-0.02.

Results: Thirty-one patients completed this study. The BMD of the lumbar spine and femoral neck remained stable after 1 year of Tofa treatment. In 11 patients who had osteopenia at baseline, there was a significant increase in the BMD of the lumbar spine (0.021 ± 0.034; $P < 0.05$) and femoral neck (0.005 ± 0.0125; $P < 0.05$; however it was not satisfied with detectable difference.).

Conclusion: Tofa affects the BMD in patients who had active RA despite treatment with MTX. The BMD of the lumbar spine in patients with normal BMD at baseline was stable. TCZ increased the lumbar spine BMD of patients who had osteopenia at baseline.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: High ACR responses in placebo group have been frequently observed in recent RA trials, most notably, in patients with inadequate response (IR) to methotrexate (MTX) or other disease modifying anti-rheumatic drugs (DMARDs). The factors that contribute to high placebo responses in RA trials were investigated.

Methods: Total 10 ph2 and 3 RA trials in a database were pooled for meta-analysis (981 placebo subjects). All were randomized, double-blind, placebo-controlled trials in active RA MTX/DMARD-IR (N=9) or TNF-IR (N=1) populations in combination with stable doses of MTX (N=8) and/or other DMARDs (N=2). Baseline demographic and disease characteristics of participants were similar across these trials. Placebo response in each ACR component was summarized. Univariate logistic regression was used to identify patient baseline risk factors for placebo response after adjusting for study and time point.

Results: In each of the 10 RA trials, at Week 12, median percent improvement from baseline in placebo group was consistently higher in physician/site staff assessments, ie swollen/tender joint counts, and physician's global assessment of disease activity, compared to patient's assessment of pain, global assessment of disease activity and function (HAQ-DI). Decrease in CRP in response to placebo was also observed (Table 1) however, often with more variability compared to other ACR components (data not shown). Patient baseline characteristics significantly predicting ACR20 placebo response are summarized in Table 2. A higher ACR Placebo response was observed in Latin America compared to Europe in 6 out of 7 RA trials that included Latin American sites (Figure 1).

Conclusion: The assessments performed by investigator or site staff are more sensitive to placebo response compared to the patient reported outcomes. Multiple patient baseline risk factors for ACR20 placebo response were identified and further investigation using multivariate model is warranted to delineate the independent predictors for high placebo response in RA trials. The Latin American region showed a consistently high placebo response across RA trials which often led to diminishing treatment effect detectable in this region.

Table 1: Placebo Response (Median Percent Change from Baseline) in ACR Components at Week 12

Median Percent Change from Baseline at Week 12	Swollen Joint Count	Tender Joint Count	Physician's Global Assessment of Disease Activity	Patient's Global Assessment of Disease Activity	Patient's Assessment of Pain	HAQ-DI	CRP
Study 1 Phase 2 Oral	-46.41	-46.42	-37	-11.48	-16.92	-15.38	-11.85
Study 2 Phase 2 Oral	-52.27	-36.69	-33.98	-26.38	-21.98	-14.84	-23.07

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: An interim analysis of a prospective observational 3+ year study, embedded within the US Corrona Rheumatoid Arthritis (RA) registry (14 years and ongoing), was initiated to evaluate the safety of tofacitinib (tofa) after US Food and Drug Administration (FDA) approval on 6 November 2012. Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Rates of adverse events (AEs) are calculated and reported quarterly.

Methods: Interim results from a planned 5 year study (6 Nov 2012–29 Feb 2016, ~3 years and 3 months) are presented evaluating rates of targeted AEs in 3 populations 1) initiators of tofa 2) initiators of a biologic DMARD (bDMARD) and 3) initiators of a conventional synthetic DMARD (csDMARD). Patients who had at least one visit after initiation were included in this analysis. AE data are captured from prescribing physicians during follow-up. Standardized rates and 95% confidence intervals (CI) were estimated using the age and gender distribution of tofa initiators as the reference population.

Results: Standardized incident AE rates (i.e., new events per 100 patient-years) were calculated for 760 tofa, 4,628 bDMARD and 1,328 csDMARD initiators with 777.31 person-years (PY), 4395.55 PY, and 1059.19 PY respectively. Baseline characteristics were examined; number of years disease duration was longer for tofa patients (mean [SD] 13.4 [9.99] vs. bDMARD 10.1 [9.85] and nbDMARD 4.77 [7.49]) and number of prior bDMARDs as well as number prior anti-TNFs were higher in tofa patients (mean [SD] 2.79 [1.81] and 1.79 [1.19] respectively) as compared to the

bDMARD group (1.41 [1.34] and 1.09 [1.01]) and csDMARD group (0 by definition). Standardized incident rates for infections (figure 1) and cardiovascular disease (CVD), malignancies and gastrointestinal (GI) perforation (figure 2) are shown for the three groups.

Conclusion: In this interim analysis, despite some differences in baseline characteristics, patients initiating tofa, bDMARDs and csDMARDs for the treatment of RA experienced comparable age and gender adjusted rates of serious infections, cardiovascular events and malignancies overall.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: SB2 is approved by the European Medicines Agency as a biosimilar of the reference infliximab (INF). The 30-week and 54-week results of Phase III study have been reported[1,2]. The objective of this transition period of Phase III study is to evaluate the safety, immunogenicity, and efficacy in patients with RA who transitioned from INF to SB2 vs maintained INF and who continued to receive SB2 after Week 54 up to Week 78.

Methods: This is a randomized, double-blind phase III transition study. Patients with moderate to severe RA were randomized in a 1:1 ratio to receive either SB2 or INF at Weeks 0, 2, 6, and then every 8 weeks thereafter until week 46. At Week 54, patients previously receiving INF were re-randomized in a 1:1 ratio to either receive SB2 (INF/SB2) or continue INF (INF/INF) up to week 70; patients receiving SB2 continued to receive SB2 (SB2/SB2) up to Week 70. Safety, immunogenicity and efficacy were assessed up to week 78.

Results: At Week 54, 94 patients from INF were transitioned to SB2 (INF/SB2), 101 patients from INF continued to receive INF (INF/INF), and 201 patients from SB2 continued to receive SB2 (SB2/SB2). The safety profile during the transition period was comparable between INF/SB2, INF/INF, and SB2/SB2. The incidence of adverse events during the transition period was 36.2% in INF/SB2, 35.6% in INF/INF, and 40.3% in SB2/SB2. The incidence of infusion related reaction during the transition period was 3.2%, 2.0%, and 3.5%, respectively. Among the patients with overall negative anti-drug antibodies (ADA) results up to Week 54, ADAs were newly developed in 14.6% (6/41) in INF/SB2, 14.9% (7/47) in INF/INF, and 14.1% (11/78) in SB2/SB2 among patients with negative ADA up to Week 54. The efficacy was sustained and comparable between the

treatment groups.

Conclusion: The safety, immunogenicity, and efficacy profiles remained comparable between the INF/SB2, INF/INF, and SB2/SB2 up to Week 78, revealing that there were no treatment emergent issues or clinically relevant immunogenicity after switching from INF to SB2.

Table. Safety Profile During the Transition Period (From Week 54 to Week 78)

Number of patients with	INF/SB2 (N=94)		INF/INF (N=101)		SB2/SB2 (N=201)	
	n	(%)	n	(%)	n	(%)
At least 1 treatment-emergent adverse event	34	(36.2)	36	(35.6)	81	(40.3)
At least 1 serious adverse event	6	(6.4)	3	(3.0)	7	(3.5)
Serious infections	2	(2.1)	1	(1.0)	1	(0.5)
Active tuberculosis	0	(0.0)	0	(0.0)	0	(0.0)
Infusion-related reaction	3	(3.2)	2	(2.0)	7	(3.5)
Malignancy[a]	2	(2.1)	1	(1.0)	0	(0.0)
Death	0	(0.0)	0	(0.0)	0	(0.0)
Overall ADA positive	43	(45.7)	51	(50.5)	104	(53.6)[b]
Newly ADA positive[c]	6		7		11	

[a] Lip and/or oral cavity cancer and basal cell carcinoma were reported in INF/SB2 and papillary thyroid cancer was reported in INF/INF
[b] Percentage is based on 194 patients with available ADA results
[c] Newly developed ADA in patients with negative overall ADA up to Week 54

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite new effective therapies for Rheumatoid Arthritis (RA), glucocorticoids (GC) are widely prescribed. It is possible that dose and duration of GC therapy may have an impact on the timing of initiation of biologics. The objective of this study is to describe the GC patterns of therapy in patients with RA and its impact on time to biologic initiation in a real-world setting.

Methods: Biologic-naïve patients with early RA (≤1 year) treated with ≥1 csDMARD, who were enrolled in the Corrona registry after June 2008 and had 24 months (m) of follow-up were included in this study. Prospectively collected data on prednisone use reported by treating rheumatologists - was the primary measure to assess the GC use. GC use in milligrams (mg) was stratified into quartiles (Q): $1 \leq Q1 \leq 4.8$, $4.8 < Q2 \leq 5.0$, $5.0 < Q3 \leq 10.0$, $10.0 < Q4 \leq 60$, based on the average dose until the initiation of a biologic or until 24m after enrollment, which ever occurred first. Impact of average GC dose on time to biologic initiation was examined using cumulative incidence rates for each of the GC dose quartiles. Cox-proportional hazards models were used to evaluate the association between time to biologic initiation, GC use and disease activity as measured by clinical disease activity index (CDAI); mean prednisone dose and CDAI were time-varying covariates.

Results: A total of 1,998 patients were included in the study, there were n=1178 who did not take prednisone and of the remaining 820 who were on GC, n=360 initiated a biologic. Overall, 73% were female with an average age of 57 yrs, about 60% were in moderate/high disease activity (CDAI >10) with a mean disease duration of 0.5 yrs at enrollment. The average daily dose of GC was 7.0 mg from enrollment to 24m. Patients in the lower quartile (1-4.8 mg) compared to the highest quartile (>10 mg) of average GC use had significantly lower pain levels (27.4 vs 45.2),

patient global evaluation of disease activity (23.6 vs 42.5), better functional disability as measured by modified Health Assessment Questionnaire (0.2 vs 0.5) and spent lower number of days (198 vs 322 days) in moderate/high disease activity, defined as CDAI>10 (from enrollment to 24m) (all results with p<0.001). Patients on lower doses of GC (in the lowest quartile) had significantly longer time to initiation of a biologic compared to those who were in the highest quartile of average GC use (19.2m vs 9.2m respectively, p<0.001) (figure). A higher mean GC dose was significantly associated with a shorter time to biologic initiation after adjusting for time-varying CDAI (for every 5mg increase, HR: 1.13, p<0.0001).

Conclusion: In this large real world study of newly diagnosed RA patients, treatment with GCs was common and associated with time to biologic DMARD initiation. Patients treated with higher GC doses initiated biologics earlier and spent more time in moderate to severe disease activity prior to biologic initiation compared to those treated with lower GC doses.

Figure: Cumulative incidence curve for time to biologic initiation by mean GC dose category

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Risk of opportunistic infections, particularly mycobacterial infections, is increased among patients with rheumatic diseases treated with anti-TNF α agents. Therefore, screening of patients for latent tuberculosis infection (LTBI) is recommended prior to the initiation of anti-TNF α agents. However, there is a risk of seroconversion even among patients who tested negative for LTBI following treatment with anti -TNF α agents because of immunosuppression and exposure. There is paucity of data regarding the frequency of seroconversion and currently there is no clear recommendation on how often the patients should be screened for latent tuberculosis while receiving anti -TNF α agents.

Methods: We conducted a retrospective chart review of patients with various rheumatic diseases who received anti-TNF α agents from 2004 to 2014 in the VA Medical Center, Memphis TN. Patients with prior history of tuberculosis (TB) or prior treatment with TB medications were excluded. Any concomitant immunosuppressive medications including corticosteroids were also noted. We found a total of 133 patients on anti -TNF α agents, during this period, who had repeat testing for LTBI. All of these patients had tuberculosis screening test before starting anti TNF α agents either by Tuberculin Skin test (TST) or Quantiferon TB Gold Test. TB screening tests were variably repeated on these patients to evaluate for the possibility of seroconversion. Total number of TB screening tests and Chest radiographs each patient had, were also documented. We calculated incidence rate of TB screening test conversion per 100 patient year.

Results: Each of the 133 patients took anti -TNF α agents for a mean of 5.4 years (SD 3.25) and had mean of 3.6 (SD 1.57) TB screening tests. Only 1 out of 133 patients converted from negative TST to positive TST. This gentleman had seropositive Rheumatoid arthritis managed with Infliximab and Methotrexate for 6 years and 2 months before converting to positive TST. Risk of conversion of TB

screening test was calculated as 0.138 per 100 patient year.

Conclusion: Risk of conversion of TB screening tests while on anti -TNF α agents was found to be very low in our veteran population. This is much lower than what has been reported in the literature and worth reporting. We conclude that repeat testing on a scheduled basis is not necessary among low risk patients.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Inhibition of the interleukin IL-6 receptor pathway by tocilizumab (TCZ) is an effective treatment for rheumatoid arthritis (RA). TCZ reduces atherosclerosis markers and improves endothelial function. In peripheral blood, TCZ increases the percentage of natural killer and regulatory T cells and decreases the number of inflammatory Th1/Th17 lymphocytes. Monocytes activation and neutrophil extracellular traps (NETs) are key players in the development of cardiovascular disease; however, the specific effect of TCZ on these cells has not been described yet.**Objective:** To analyze the molecular changes (focused on monocyte and neutrophil

abnormalities) underlying the beneficial effect of TCZ on atherosclerosis and endothelial dysfunction in RA

Methods: Fifteen RA patients received 162 mg/week subcutaneous TCZ as combined therapy. Endothelial function was measured through post occlusive hyperemia using Laser-Doppler. To analyze the specificity of TCZ, blood samples from 5 RA patients at baseline was used to perform in vitro studies. Isolated monocytes and neutrophils were treated in vitro with IL6 and blocking FCRII plus TCZ for 18 and 6 hours, respectively. Oxidative stress markers in leukocytes were analyzed by flow cytometry. NETosis was measured through Sytox staining of DNA fibers. Myeloperoxidase (MPO) and neutrophil elastase (NE) were analyzed in neutrophils by flow cytometry. mRNA expression of peptidyl arginine deiminase (PAD4) was measured by RT-PCR. Percentage of low density granulocytes (LDGs) was analyzed through flow cytometry. mRNA expression of genes involved in monocyte activation, prothrombotic state, lipid uptake and insulin resistance was analyzed in monocytes through RT-PCR. Activation of intracellular pathways was analyzed in monocytes using pathscan intracellular signaling array.

Results: After 6 months of treatment TCZ reduced clinical parameters of inflammation, autoimmunity and joint damage. Endothelial function was significantly restored. TCZ decreased peroxide and peroxinitrite levels in RA leukocytes, most significantly in monocytes and neutrophils. Percentage of LDGs was also reduced after treatment. TCZ in vivo treatment reduced the expression of MPO, NE and PAD4 in RA neutrophils. The generation of in vitro induced NETs was also inhibited by TCZ. The expression of inflammatory and prothrombotic molecules, genes involved in cellular activation and insulin signaling and the activation of various intracellular pathways were modulated in monocytes after in vivo TCZ treatment. All these results were recapitulated after in vitro TCZ treatment of RA monocytes and neutrophils.

Conclusion:

TCZ improves endothelial dysfunction and atherothrombosis through the restoration of the oxidative status, inhibition of the monocyte prothrombotic and inflammatory profile and the generation of NETosis.

Tofacitinib Is Associated with an Impaired Function of NK Cells and a Defective Immunosurveillance Against B-Cell Lymphomas

Gaetane Nocturne[1,2], Farhad Tahmasebi[3], Saida Boudaoud[4], Bineta Ly[5] and Xavier Mariette[6,7], [1]Rheumatology Service, Bicêtre University Hospital, Le Kremlin Bicetre, France, [2]INSERM U1184, Université Paris Sud, Le Kremlin Bicêtre, France, [3]INSERM 1184, Paris Sud University, Le Kremlin Bicetre, France, [4]INSERM U1184, Paris Sud University, Le Kremlin Bicêtre, France, [5]INSERM U1184, Paris Sud University, Kremlin Bicetre, France, [6]Department of Rheumatology, APHP - Hopitaux universitaire Paris Sud, Le Kremlin Bicetre, France, [7]INSERM U1184, Université Paris-Sud, Paris, France, Le Kremlin Bicetre, France

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Disease activity is the main risk factor for developing lymphoma in patients with rheumatoid arthritis (RA). However, the impact of immunosuppressive drugs remains an unsolved question. On one hand they might decrease the risk of lymphoma by controlling activity of the disease. On the other hand, they might alter anti-tumor immunosurveillance as observed in post-transplant lymphoproliferative disorders. Tofacitinib is an oral Janus Kinase (Jak) 3 and 1 inhibitor that has shown positive results in RA patients. Tofacitinib may impair NK-cell function due to its inhibitory action on IL2 and IL15 signaling. Given the fact that NK cells have been recently shown to participate to anti–lymphoma immunosurveillance, we aimed to assess if tofacitinib might impact NK cells function and anti-lymphoma activity.

Methods:

We have studied the consequences of in vitro exposure of NK to tofacitinib (10, 50 and 100 nM) or to DMSO (vehicle) during 6 days in presence of IL-2 (200 UI/ml): phenotype has been studied and then cytotoxicity against 2 non-Hodgkin B-cell lymphoma cell lines [Farage (EBV+) and SU-DHL4 (EBV-)] was assessed.

Results are shown as mean + standard of the mean (SEM). The Mann Whitney test was used to compare samples stimulated with tofactinib and DMSO (controls).

Results:

Firstly, we did not observe difference concerning the survival of NK cells in presence of tofacitinib or controls after 6 days culture. Secondly, we observed that culture in presence of tofacitinib was associated with a modification of NK phenotype with a decreased level of activation with a dose effect (Figure 1A). In addition we observed a decreased expression of activating receptors such as NKp30, NKp44 and NKG2D (Figure 1B-D). Last, we found that tofacitinib blocked NK cell maturation as observed with the significant decreased expression of CD57 on NK cells exposed to tofacitinib at 50 and 100 nM (Figure 1E). Conversely, CD16 expression was not modulated by tofacitinib. These phenotypic abnormalities were associated with an impaired function of NK as assessed by co-culture: degranulation was significantly decreased after exposure to tofacitinib 100nM in case of co-culture with Farage. A trend was observed with SU-DHL4. A trend for decreased NK cells cytotoxicity was observed with the 2 cell lines (Figure 2).

Conclusion:

This study demonstrates that tofacitinib treatment negatively impact the state of activation, maturation and functions of NK cells with impaired degranulation and less efficient lysis of B lymphoma cell lines . These results need to be confirmed in vivo. This negative impact of tofacitinib on NK cells activation and function might participate to the increased risk of herpes zoster infection in patients treated with tofacitinib and suggest to remains cautious about a possible increased risk of lymphoma.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor inhibitor (TNFi) biologics are a mainstay of therapy

for rheumatoid arthritis (RA) patients with disease-modifying antirheumatic drug failure. However, RA patients receiving TNFi biologics can develop anti-drug antibodies that neutralize drug action, decrease drug exposure, and lead to a loss of efficacy. Therefore, an assay that can monitor TNFi biologic immunogenicity and plasma concentrations can indicate when anti-drug antibodies diminish TNFi effectiveness and require drug substitutions. Our aim is to use a novel assay that simultaneously monitors anti-adalimumab (anti-ADA) IgG levels and plasma adalimumab (ADA) concentrations to determine the frequency of anti-ADA antibodies among patients enrolled on the Rheumatoid Arthritis Comparative and Effectiveness Research (RACER) study at University of Pittsburgh Medical Center.

Methods: Our cytometric assay uses streptavidin beads, biotinylated ADA F(ab')2 antibody fragment, biotinylated TNF-α, and anti-Fc antibody for measuring anti-ADA and ADA. A total of 168 normal human plasma samples (negative controls) and 207 RACER patient samples were evaluated using our cytometric assay and an anti-ADA bridging ELISA (116 from patients with no previous ADA exposure and 91 from patients receiving ADA for ≥ 6 months).

Results: Among patients receiving ADA, 49% tested positive for anti-ADA IgG. Surprisingly, 27% of ADA naïve patients were positive for anti-ADA, whereas all control human plasma samples were negative. Comparing our cytometric assay to the bridge ELISA: 78% and 66% of ADA treated and naïve patients were positive for anti-ADA antibodies, respectively. Of those samples positive by our cytometric assay, 94% were also positive by ELISA. Due to the unexpected high positive rate, we measured ADA concentrations before and after adding ADA to the following representative RACER samples: ADA naïve patient samples positive for anti-ADA, control patient samples negative for anti-ADA, and discrepant samples positive by flow cytometry but negative by ELISA. No ADA was detectable among naïve patients, whereas ADA was detectable among patients receiving ADA. Upon ADA addition, lower ADA levels were measured among discrepant samples compared to controls ($P < 0.05$). Furthermore, ADA decreased the anti-ADA levels of controls containing known amounts of anti-ADA IgG by 82%, whereas none of the naïve patient samples decreased anti-ADA levels, suggesting that the positive signals detected were not due to anti-ADA antibodies. Our results confirmed that samples collected from patients with no prior ADA exposure had no detectable ADA or anti-ADA IgG. In contrast, discrepant samples contained anti-ADA IgG antibodies that diminished detection of ADA.

Conclusion: Our cytometric assay can detect anti-ADA antibodies and distinguish anti-ADA immunogenicity from interference by measuring ADA drug concentrations and neutralization. The high positive rates estimated using our cytometric assay are likely due to anti-hinge antibodies and blocking strategies are currently being evaluated. Our method can be easily modified to measure the immunogenicity and drug levels of other TNFi biologics.

Anti-TNF Therapy Is Associated with an Impaired Function of NK Cells and a Defective Immunosurveillance Against B-Cell Lymphomas

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is associated with an increased risk of lymphoma linked to activity of the disease. Immunosuppressive drugs have been suspected to induce an additional risk. Since, NK cells have been recently shown to participate to anti–lymphoma immunosurveillance, we aimed to assess if anti-TNF might impact their anti-lymphoma activity.

Methods:

NK cells have been assessed ex vivo in patients with RA treated with methotrexate (MTX) with (n=19) or without (n=20) anti-TNF. Phenotype has been studied by flow cytometry and function (degranulation and IFNg production) has been assessed after NKp30-cross linking. Then, we have studied the consequences of in vitro exposure of NK to anti-TNF, to TNF-R inhibitors or to controls during 6 days: phenotype has been studied and then cytotoxicity against 2 B non-Hodgkin lymphoma cell lines [Farage (EBV+) and SU-DHL4 (EBV-)] was assessed.

Results are shown as median [interquartile range (IGR)]. The Mann Whitney test was used to compare independent samples.

Results:

Firstly, in patients, we found that the proportion of activated NK cells, assessed by the expression of CD69, was significantly decreased in patients treated with anti-TNF + MTX compared to patients treated with MTX alone (8.9% [2.9 – 40.7] vs 48.4% [27.4 – 58.3], p=0.005). Moreover, we found that NK cells exhibited an impaired function in patients treated with anti-TNF compared to patients treated with MTX alone as assessed by the percentage of degranulation (20.9% [18.5 - 32.9] vs 31.3% [21.5 – 49.1], p=0.04) and the loss of capacity of IFN-γ secretion ((17.4% [8.9 – 25.9] vs to 29.7% [22.5 – 43.1], p=0.007). Secondly, we have confirmed that in vitro exposure to anti-TNF negatively impact NK cells activation and function leading to an impaired anti-lymphoma activity (figure 1A). In all these experiments, no difference was observed between etanercept and monoclonal anti-TNF. Last, we have demonstrated that negative impact of anti-TNF on NK cells may be the consequence of inhibition of TNF-R1 signaling (figure 1B).

Conclusion:

Even if meta-analysis of randomized controlled trials and of registries have not demonstrated to date an increased risk of lymphoma with anti-TNF, cautious must be pursued concerning this possible side effect in patients with long-term exposure. Moreover, negative impact of anti-TNF on NK cells may participate to infectious adverse events.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with RA have previously demonstrated significant differences in morning stiffness (MS), a debilitating symptom of RA, and other disease measures with delayed release (DR)-prednisone versus immediate release (IR)-prednisone in a randomized trial and an open-label switch extension study (1,2). Previous randomized trials did not allow prednisone dose to be adjusted (1). We conducted a prospective open label switch study in the US to see if the results from controlled trials could be replicated in a real world clinical setting.

Methods: Twelve sites within the US enrolled 56 moderate-severe patients with RA into a 12 week study. At baseline patients were switched from IR- to DR-prednisone while maintaining other existing background therapies. MS severity (VAS1-100) the primary outcome, MS duration (minutes), swollen joint counts (SJC), DAS28, MDHAQ, RAPID3 and patient/physician global assessment (PGA/PhGA 10 cm VAS), among others, were measured (change from baseline). The overall group, those completing 10 wks, and those with >60 minutes of MS at baseline were analyzed, specifically. T-tests and Pearson's Correlations were used for significance and associations.

Results: 52 patients had at least one follow-up visit and were similar to patients in the previous controlled trial with regard to baseline mean age (63), DAS28CRP (5.2) but had lower baseline morning stiffness (114 minutes) and shorter duration of RA (5yrs). From a mean starting dose of 6 mg, the dose of prednisone decreased by 13% after switch to DR-prednisone in those treated ≥10 wks while demonstrating significant reductions in SJC, DAS28CRP, PhGA, RAPID3 and MDHAQ pain (all $p \leq 0.04$). Patients on treatment for ≥10 wks and who had baseline >60 min of MS produced similar results in SJC/PhGA as well as reductions in duration and severity of MS (both $p<0.03$, Figure 1). In the later analysis, MS severity (-20%) and duration (-34%) improvements were moderately correlated with each other ($R^2=0.43$) and no other correlations were demonstrated.

Conclusion: Patients switched to DR-prednisone from IR-prednisone in this practice based study maintained or improved their outcomes across a variety of domains and the results were comparable to previous controlled trials in which patients completed at least 10 wks of therapy. Further, there was a reduction in total prednisone dose over the treatment period comparable to the 18% found in a previous analysis (3). References: (1) Buttgereit, et al. Lancet 2008; 371: 205. Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Management of RA patients has improved in the last two decades in part with the use of ultrasound (US) in daily clinical practice. The use of US is helping to improve a tight control of RA patients and to predict clinical flares. Those inflammatory cytokines involved in RA pathology must be related with the US findings. We therefore evaluated the relationship between US patterns and cytokine levels in RA patients before and after IL-6 blockade.

Methods: Peripheral blood was obtained from 30 RA patients, meeting the ACR criteria, that were treated with tocilizumab. In all patients, RA was refractory to treatment with DMARDs, including methotrexate. Tocilizumab treatment was begun following European and Spanish guidelines. Plasma was collected prior to first infusion and at 1, 3, 6 and 12 months after treatment. Laboratory analysis included haemogram, ESR, CRP, RF, ACPAs, IL-17, IL-22, VEGF, IL-6 and sIL-6R. US assessment was registered for each visit for 32 joints and 12 tendons of hands and feet in Gray Scales (GS) and Power Doppler (PD) using a semiquantitative scale (0-3 points). Clinical data collected was DAS28, SDAI and CDAI.

Results: Clinical and demographic baseline data of the patients is shown in table 1. We have found two groups of patients based on the baseline PD values (group 1: 18,9±5,9 vs group 2: 4,8±4,05) As expected, patients in group 1 also had higher GS (group 1: 36,2±14 vs group 2: 12,6±9,8) and DAS28 values (group 1: 6,38±0,69 vs group 2: 5,44±0,9) (Figure 1). Baseline PD correlated with plasmatic IL-17 (R=0,39; p=0,045) and IL-22 concentration (R=0,554; p=0,002), but not with other cytokines. IL-17 and IL-22 were correlated at baseline (R=0,913; p<0,001). IL-17 and IL-22 also correlated with RF titers (R=0,795; p<0,001 and R=0,67; p<0,0001) and VEGF (R=0,935; p<0,001 and R=0,784; p<0,001) values. After 12 months of treatment, we found significant changes in PD (11,81±9 vs 1,76±3,6), GS (25,36±17 vs 4,38±6,8), DAS28 (5,76±0,9 vs 2,8±1,4), IL-6R (447±368 vs 1892±960 ng/ml) and IL-22 (3107±5700 vs 5983±12022 pg/ml). There were no changes in IL-6 (819±896 vs 896±906 pg/ml), IL-17 (1677±3900 pg/ml) and VEGF (849±2115 vs 796±2016 pg/ml) plasmatic concentrations. After 12 months of tocilizumab PD values correlated with IL-17 (R=0,446; P=0,02) and VEGF (R=0,599; p<0,001) concentrations.

Conclusion: There is a correlation at baseline between PD and IL-17 and IL-22. After 12 months of IL-6 blockade there is a significant improvement in clinical and US values without changes in levels of IL-17, IL-6 and VEGF. IL-17 was the only cytokine that correlated with PD levels throughout the study.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Recently issued guidelines suggest that rheumatoid arthritis (RA) patients with previously treated solid malignancy may be treated as patients without such history (1). The recommendation is based on limited evidence and rheumatologists and patients are frequently hesitant to start biologic therapy after a cancer diagnosis. The objective of this study is to describe biologic utilization in real world RA patients following a malignancy diagnosis.

Methods: Patients (pts) with RA enrolled in the Corrona registry and diagnosed with a solid malignancy post enrollment were included in this analysis. Index date was defined as first visit after malignancy diagnosis. Proportion of pts initiating a biologic or targeted synthetic (ts) DMARD after diagnosis was estimated. Median time to the initiation of a biologic/tsDMARD after diagnosis was calculated using the Kaplan-Meier method and proportion initiating biologic treatment in 6-month time windows was estimated using the life-table method.

Results: Out of 42619 RA pts historically enrolled in Corrona, 934 pts had an incident solid malignancy after registry enrollment. 880 pts had at least 1 follow-up visit within 12 months after diagnosis and were included in the analysis. At index visit, mean disease duration was 14.1 years, mean age 66.6 years and 67% (n=592) were females. Mean CDAI for the population was 11.2 and 38.4% (n=329) of pts were in moderate or high disease activity. Total follow-up time after index date was 2585.6 person years. 41.7% (n=367) of the pts were treated with biologics/tsDMARDs within 12 months preceding malignancy and 30.7% (n=270) were on such agents at visit immediately following the diagnosis. Approximately 20% (n=170) initiated or switched a biologic/tsDMARD during the follow-up period, the majority of which started a TNF inhibitor (53.5%) The percentage of pts starting a biologic / tsDMARD and also a TNFi is shown in Table 1. The median time to initiation of the first biologic/tsDMARD was 118.7 months, approximately 10 years.

Conclusion: In real world practice, nearly one-third of RA patients continue therapy with biologic and ts agents after malignancy diagnosis and another one-third initiate biologic therapy within 5 years of solid malignancy diagnosis. The majority of biologic/tsDMARDs initiations was a TNFi. The proportion of biologic initiation is increasing in cancer survivors as time post diagnosis progresses. Reference:

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Patients (pts) with RA often receive concomitant treatment with glucocorticoids (GCs) to control inflammatory symptoms. The purpose of this analysis was to investigate whether the presence or absence of GCs has an effect on the clinical and radiographic efficacy of tofacitinib or MTX administered as monotherapy in MTX-naïve pts with RA.

Methods: ORAL Start (NCT01039688) was a 2-year, randomized Phase 3 clinical trial in which 956 MTX-naïve pts with RA received either tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, or MTX titrated to 20 mg/week over 8 weeks. Pts receiving GCs (≤10 mg/day of prednisone or equivalent) prior to enrollment were required to remain on a stable dose throughout the study. All pts were required to meet the ACR classification criteria for the diagnosis of RA. Primary results have been reported previously. Endpoints

evaluated in this analysis at Months 6 and 24 included ACR20/50/70 response rates, the proportion of pts achieving low disease activity and remission as measured by Clinical Disease Activity Index (CDAI) ≤10 and ≤2.8, respectively, the proportion of pts with no radiographic progression as defined by a change from baseline of ≤0.5 in modified Total Sharp Score (mTSS), and least squares mean (LSM) change from baseline in CDAI, Health Assessment Questionnaire Disability Index (HAQ-DI), Disease Activity Score (DAS28-4[ESR]), and mTSS. This was an exploratory post-hoc analysis without multiplicity adjustment.

Results: Baseline demographics and disease characteristics were similar between treatment groups and among those receiving treatment with and without GCs. For assessments measured at Months 6 and 24, tofacitinib was more effective as monotherapy than MTX, regardless of GC status (Table). At Months 6 and 24, the proportions of pts achieving ACR20/50/70, CDAI ≤10, CDAI ≤2.8, and change in mTSS ≤0.5 were numerically similar between pts receiving tofacitinib with and without GCs, and between pts receiving MTX with and without GCs (Table). A similar trend was observed for LSM change from baseline in CDAI score, HAQ-DI, and DAS28-4(ESR) (Table). LSM change from baseline in mTSS was numerically similar in pts receiving tofacitinib with or without GCs, but showed a trend to be reduced (indicating less radiographic progression) in pts receiving MTX with GCs compared with those receiving MTX without GCs (Table).

Conclusion: GCs in low doses did not appear to impact clinical efficacy or inhibit radiographic progression when administered with tofacitinib monotherapy, and had a limited effect, if any, when given with MTX monotherapy. These findings might reflect the pt population, who had active disease at study entry despite receiving GCs and therefore may not be generalizable to pts starting GCs.

Table. Clinical and radiographic outcomes at Months 6 and 24 in patients receiving tofacitinib or MTX with or without GCs

			Tofacitinib 5 mg BID		Tofacitinib 10 mg BID		MTX

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease is a significant comorbidity among RA patients. As such, dyslipidemia and the effect of DMARD therapy on lipid profiles is an important consideration in RA management. Previous reports show that suppression of systemic inflammation, particularly in early RA, leads to increased cholesterol levels. While the magnitude of this effect appears to vary by treatment and populations studied, there has been limited study of this effect in the important subgroup of MTX suboptimal responders with subsequent escalation of DMARD therapy.

Methods: Statistical analyses were performed using data from the Rheumatoid Arthritis Comparison of Active Therapies (RACAT) trial. Patients with active RA despite treatment with MTX were randomized to receive triple therapy (MTX/HCQ/SSZ) or MTX/etanercept (ET). Those showing inadequate response were crossed over at 24 weeks. Using banked serum from baseline, 24, and 48 weeks (n=204), levels of total cholesterol (TC), LDL, VDL, HDL, and triglyceride (TG) were measured. Changes in lipids between each time point were examined using generalized estimating equations (GEE models), adjusting for baseline characteristics and DAS-28. To further examine the effect of treatment on lipid profiles, we compared changes in the first 24 weeks of exposure to each treatment (patients started on triple therapy plus those crossed over to triple therapy at 24 weeks versus patients started on MTX/ET plus those crossed over to MTX/ET at 24 weeks) using additional GEE models.

Results: There were significant decreases in VDL, TG, and TC:HDL ratio and a significant increase in HDL over observation after controlling for baseline characteristics (Table). With further adjustment for DAS-28, effect sizes were reduced and no longer significant. Comparing the effect of MTX/ET to triple therapy on lipids over the first 24 weeks of exposure, there was a larger decrease in VDL with triple therapy (β=3.32 mg/dL; p=0.037). In adjusted models, the effect size was largely unchanged with p-values of borderline significance (3.08, p=0.056 adjusting for baseline characteristics; 3.10, p=0.055 adjusting for baseline characteristics + DAS-28).

Conclusion: These data show favorable changes in VDL, HDL, TG, and the TC:HDL ratio in RA patients after escalating therapy following treatment failure with MTX. This is driven largely by improvement in DAS-28, differing from previous reports where suppression of disease activity is associated with elevation in cholesterol levels. In addition, data here show a trend toward more favorable levels of VDL with triple therapy relative to MTX/ET, supporting previous work showing more favorable lipid profiles with triple therapy in early RA. Additional research is needed to elucidate the clinical implications of these changes in lipids, as well as the effect of altered lipoprotein function in RA. **Table 1.**

Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Tocilizumab (TCZ), an anti-IL-6 receptor monoclonal antibody, has been recognized as one of the highly effective therapeutic agents in RA, but its contribution to B-cell function remains to be elucidated. Our purpose was to analyze the effects of TCZ on B-cell subpopulation and its ability to produce anti-CCP antibody during the treatment for RA.

Methods: Consecutive RA patients who initiated treatment with TCZ between December 2013 and September 2015 were enrolled in our prospective study. All patients met 2010 ACR/EULAR classification criteria for RA and were treated with 162mg of TCZ subcutaneously every other week. Peripheral blood samples were collected and B-cell subsets were analyzed by flow cytometry at baseline, and during TCZ treatment at week 12 and 24. Clinical parameters, including disease activity and serum level of autoantibodies, were also evaluated in these periods. The protocol of this study was approved by the ethics committee of Hokkaido University Hospital.

Results: Fourteen patients were enrolled but one dropped out because of missing data. Remaining 13 patients were analyzed at the baseline and during the follow-up periods. DAS28-ESR significantly improved at week 12 (2.42 ± 1.14, $p < 0.001$) and week 24 (2.20 ± 1.00, $p < 0.001$) compared to baseline (5.00 ± 1.39). Anti-CCP antibody titers significantly decreased at week 24 compared to baseline

(p = 0.033, Fig. 1). In flow cytometry analysis, the percentages of post-switch memory B cells (CD19+CD27+CD38-IgD-) in the population of CD19 positive cells were significantly higher at week 12 than those at baseline (p = 0.011). The changes in naïve B cells (CD19+CD27-) and those in post-switch memory B cells from baseline to week 24 were inversely correlated (r = -0.703, p = 0.007). Furthermore, the ratios of naïve to post-switch memory B cells (naïve/post-switch) correlated positively with anti-CCP antibody titers regardless of the time-points (r = 0.621, p = 0.024 at baseline, r = 0.623, p = 0.023 at week 12, and r = 0.702, p = 0.007 at week 24, Fig. 2). The changes in naïve/post-switch and the changes in anti-CCP antibody titers also showed positive correlation from baseline to week 12 (r = 0.709, p = 0.007) and from baseline to week 24 (r = 0.588, p = 0.035).

Conclusion: Our study indicated that anti-CCP antibody titers reflect B-cell distribution and that TCZ has a potential to modulate the production of anti-CCP antibody by affecting naïve/post-switch ratio. The increment of post-switch memory B cells after TCZ treatment may reflect the re-distribution of this subset into circulation from arthritic joints, which results in suppressed production of anti-CCP antibody.

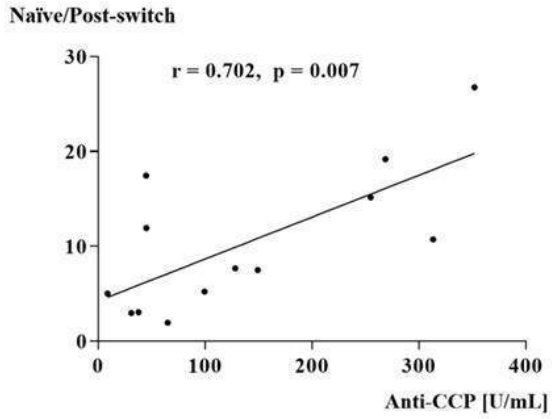

Fig. 2. Correlation between anti-CCP antibody titers and naïve/post-switch ratios at week 24. Correlation coefficient was assessed by Spearman rank method.

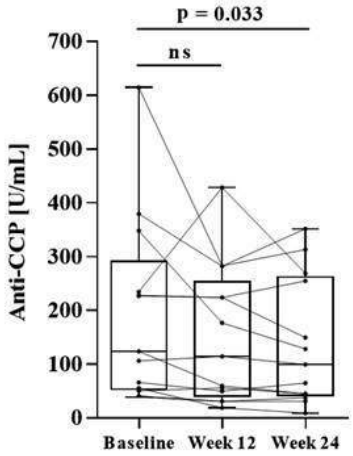

Fig. 1. Time course of the change in anti-CCP antibody titers during treatment with TCZ in RA patients (n = 13). Data are shown as symbols and lines in each patient and also as box plots, representing minimum, first quartile, median, third quartile and maximum. P-values were calculated for comparison between baseline and week 12, or between baseline and week 24, using Wilcoxon signed-rank test.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients are at increased risk for herpes zoster (HZ), and vaccination is recommended in patients over the age of 50 years, prior to starting biologics or tofacitinib, an oral Janus kinase inhibitor for the treatment of RA. In immunocompetent adults aged ≥50 years zoster vaccine has shown 70% efficacy (in 50–59 year-olds over 1.3 years) to 51% efficacy (in ≥60-year-olds over 4.9 years) for the prevention of HZ.[1] We previously reported the safety and immunogenicity of live zoster vaccine in RA patients on background methotrexate (MTX) before initiating tofacitinib or placebo.[2] Briefly, patients with RA who started 3 months of treatment with tofacitinib after zoster vaccination generated immunity to varicella zoster virus (VZV) similar to placebo-treated recipients. Furthermore their VZV immunity at Week 6 post-vaccination was comparable with immunity in healthy people aged 50 years and older.[2] However, the long-term effectiveness of the vaccine in this setting is unknown.

Methods: From a prior cohort of patients (n=100) given zoster vaccine and then randomized 2 to 3 weeks later to tofacitinib 5 mg BID, or placebo, for 12 weeks (A3921237 [NCT02147587]), we evaluated the incidence of HZ post-vaccination during long-term tofacitinib use. At 14 weeks post-vaccination, patients joining the long-term extension (LTE) study (ORAL Sequel; [NCT00413699]) initiated open-label treatment with tofacitinib 5 mg or 10 mg BID at the discretion of the investigator. HZ cases after tofacitinib exposure up to 19 months were evaluated. Among HZ cases, we described and compared measures of VZV-specific immunity with average immunity after live zoster vaccination.

Results: 112 pts were randomized to placebo (n=57) or tofacitinib 5 mg BID (n=55), and 100 of these patients continued to receive tofacitinib in the ORAL Sequel study. The overall exposure to tofacitinib ranged from 9 to 19 months. Two HZ cases occurred, one at 202 days (219 days from vaccination) and another at 267 days (281 days from vaccination) after tofacitinib start. Both were monodermatomal and resolved with antiviral therapy. Review of immunogenicity data at 6 weeks post-vaccination revealed that Case #1 had undetectable ELISPOT measures at baseline and at Week 6 post-vaccination. Case #2 responded adequately to vaccination by both IgG and ELISPOT measures, but had much lower than average post-vaccination IgG levels (Table 1).

Conclusion: The observed HZ incidence rate after vaccination was low among this cohort of tofacitinib-treated patients. Zoster vaccination prior to tofacitinib start is effective at boosting IgG levels and cell-mediated immunity towards VZV, although individuals with poor vaccine response may be more likely to develop HZ. **Reference:** 1. Hales CM et al. MMWR Morb Motal Wkly Rep 2014; 63:729-31. 2. Winthrop K et al. Arthritis Rheumatol 2015; 67 (suppl 10): Abstract 12L.

Table 1. Varicella zoster virus ELISPOT and IgG levels			
	Case #1 (HZ 219 days after zoster vaccine)	Case #2 (HZ 281 days after zoster vaccine)	Study A3921237 Tofacitinib 5 mg BID (N=54)
Mean VZV IFNγ ELISPOT at baseline (SFCs/10^6 PBMCs)	25 (LOD)	41	48
Mean VZV IFNγ ELISPOT at Week 6 (SFCs/10^6 PBMCs)	25 (LOD)	76	70
Change from baseline in VZV ELISPOT at Week 6 (SFC fold-rise; SFCs/10^6 PBMCs)	1.0	1.85	1.50
Mean VZV IgG titer at baseline (gpELISA units/mL)	224	37	201
Mean VZV IgG titer at Week 6 (gpELISA units/mL)	444	71	403
Change from baseline in VZV IgG titer at Week 6 (fold-rise; gpELISA units/mL)	1.98	1.92	2.11
One patient who lacked pre-existing varicella immunity developed disseminated primary varicella from the vaccine strain 16 days post-vaccination (reported previously[2]). This case was excluded from calculations for HZ. CMI, cell-mediated immunity; HZ, herpes zoster; IFNγ, interferon gamma; IgG, immunoglobulin G; LOD, limit of detection; PBMC, peripheral blood mononuclear cell; SFCs, spot-forming cells; VZV, varicella zoster virus

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A portion of patients without clinical response to anti-inflammatory biologics have been shown to develop anti-drug antibodies (ADA).[1] ADA prevalence varies widely among biologics, with variability attributed to several factors, particularly use of a broad range of assay formats. A systematic literature review was conducted to specifically assess immunogenicity of biologics,

differences in ADA assays, and associated clinical outcomes.

Methods: MEDLINE, EMBASE, and Cochrane databases, conference proceedings and review articles were searched for randomized controlled trials and observational studies of biologic therapies published before 4 September 2015 in which assay methods for ADA testing were reported. This analysis focuses on adalimumab and infliximab as they have been available for the longest period, with the greatest number of published studies and reports of immunogenicity.

Results: Of 21,889 publications screened and 358 publications (322 studies) included, 71 and 123 studies of adalimumab and infliximab, respectively, were retained. In >20% of studies in which adalimumab and infliximab ADA were assessed, the assay method was not reported. In most adalimumab and infliximab studies, an ELISA (48/71 and 92/123) or radioimmunoassay (RIA; 17/71 and 16/123) was used (table). ADA+ incidence varied widely in studies of adalimumab and infliximab across inflammatory diseases (table). Clinical and pharmacokinetic outcomes were only reported for ADA+ patients in 39% and 45% of adalimumab and infliximab studies, respectively. ADA formation was consistently associated with lower serum concentrations of both biologics and elevated rates of infusion-related reactions with infliximab.

Table. Incidence of ADA formation in patients treated with adalimumab and infliximab across chronic inflammatory diseases by immunogenicity assay method.

	Adalimumab studies		Infliximab studies	
Immunogenicity assay	ADA+ patients, % (No. of studies)	Assay cut points for ADA+	ADA+ patients, % (No. of studies)	Assay cut points for ADA+
ELISA	1.6–87.0 (26)	0.1–32 AU/mL, 10–20 ng/mL or optical densities of 0.02–1	4.8–79.0 (65)	2–50 AU/mL 5–10 ng/mL; 0.07–2.6 µg/mL; optical densities of 0.12–1.2, or 2x optical density in ADA– samples
Bridging ELISA	0–54.2 (18)		6.8–65.3 (26)	
Acid dissociation ELISA	10.4–35.0 (4)		25.6–35.0 (1)	
RIA	0–61.5 (18)	12 AU/mL; or 2x level in ADA– samples	0–71.4 (17)	10–12 AU/mL, >3% of BL value; or 2x level in ADA– samples
HMSA	4.3–27.0 (5)	1.7 µg/mL	12.7–59.0 (10)	3.1–8.0 AU/mL
ECL	–	–	22.5–49.5 (3)	NR
HPLC	–	–	13.6 (1)	NR
IMPACT	–	–	54.1 (1)	2x level in ADA– samples

AU, arbitrary units; BL, baseline; ECL, electrochemiluminescence; ELISA, enzyme-linked immunosorbent assay; HMSA, homogeneous mobility shift assay; HPLC, high performance liquid chromatography; NR, not reported; RIA, radioimmunoassay

Conclusion: To improve interpretation of immunogenicity data for biologics, greater consistency is needed in reporting of assay methods as well as clinical consequences of ADA formation. Standardization in immunogenicity testing and reporting as recently proposed by Shankar et al[2], application of modern assays with higher sensitivity and lower drug interference, and implementation of international standards for marketed products would allow greater insight into the impact of immunogenicity to biologics. **References: 1.** van Schouwenburg, PA et al. *Nature Revs Rheum*. 2013;9:164-72. **2.** Shankar, G et al. *AAPS J*. 2014;16(4):658-73.

Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at elevated risk for cardiovascular (CV) disease. Patients using tocilizumab (TCZ) may experience increased serum lipid levels. It is not known whether TCZ affects the risk for CV events relative to tumor necrosis factor inhibitors (TNFi) in patients with RA.

Methods: To examine comparative CV safety, we conducted a cohort study of RA patients who newly started TCZ or a TNFi using claims data from Medicare (2010-2013) or commercial health insurance (IMS Health, 2011-2014; MarketScan, 2011-June 2015). All patients were required to have previously used a different TNFi, abatacept, or tofacitinib. The primary outcome was a composite CV end point of nonfatal myocardial infarction and stroke based on a validated claims-based algorithm of high specificity (positive predictive value >94%). For the primary as-treated analysis, follow-up time started the day after TCZ or TNFi initiation and ended on treatment discontinuation plus 30 days, outcome occurrence, disenrollment, death, or end of the study. To control for >90 potential confounders including demographics, previous DMARD use, CV comorbidities, medications, and health care use, TCZ starters were propensity score (PS) matched to TNFi starters, with a variable ratio of 1:3 within each database. We estimated the incidence rate (IR) of composite CV events in the TCZ group compared with the TNFi group separately in each database. Hazard ratios (HRs) from the three PS-matched cohorts were pooled by an inverse variance-weighted, fixed-effects model.

Results: We included 8790 TCZ starters PS matched to 17,821 TNFi starters in all three databases. Mean age of the patients was 72 years in Medicare, 51 in IMS, and 53 in MarketScan. More than 80% of patients were women. At baseline, 72% (Medicare), 73% (IMS), and 66% (MarketScan) of patients used methotrexate. In the as-treated analysis, the median follow-up time varied between 176 days (Medicare) to 205 days (MarketScan) in the TCZ group and 206 days (Medicare) to 231 days (MarketScan) in the TNFi group. Across the three databases, 35 CV events occurred in the TCZ group and 80 occurred in the TNFi group. The IR of composite CV events per 100 person-years ranged from 0.31 (MarketScan) to 0.87 (Medicare) in the TCZ group and from 0.31 (MarketScan) to 1.09 (Medicare) in the TNFi group. The risk for CV events was similar between TCZ and TNFi users across all three databases (Table), with a pooled HR of 0.90 (95% CI, 0.60-1.36) from the as-treated analysis. Adjustment for a potential overlap between the commercial cohorts (IMS and MarketScan) yielded consistent results.

Conclusion: This large multi-database cohort study found no increase in the rate of CV events in patients with RA who switched from a biologic agent to either TCZ or a different TNFi.

Table. HR (95% CI) for composite CV events in TCZ starters versus TNF inhibitors: a 1:3 variable ratio PS-matched analysis

Database	Medicare	IMS	MarketScan	Pooled[a]
As treated	0.76 (0.42, 1.37)	1.11 (0.49, 2.53)	1.01 (0.45, 2.29)	0.90 (0.60, 1.36)
ITT up to 180 days	0.49 (0.21, 1.14)	0.90 (0.32, 2.51)	0.76 (0.26, 2.23)	0.66 (0.38, 1.16)
ITT up to 365 days	0.80 (0.47, 1.38)	0.94 (0.45, 1.95)	0.85 (0.41, 1.76)	0.85 (0.58, 1.23)

CI, confidence interval; DMARD, disease-modifying antirheumatic drug; ITT, intention-to-treat (exposure status at cohort entry was carried forward until the end of follow-up).

The TNF inhibitor group was the reference group.

PS models included >90 covariates, among them demographics, previous DMARD use, CV comorbidities, medications, and health care use.

[a]HRs were pooled by an inverse variance-weighted, fixed-effects model.

Sero-Positivity for Rheumatoid Factor Is an Independent Predictor for Achievement of Good EULAR Response at 24 Weeks in ACPA Positive Rheumatoid Arthritis Patients Treated with Abatacept: Results from Japanese Multicenter Registry

Nobunori Takahashi[1], Toshihisa Kojima[1], Shuji Asai[1] and Naoki Ishiguro[2], [1]Department of Orthopedic Surgery, Nagoya University Hospital, Nagoya, Japan, [2]Nagoya University, Nagoya, Japan

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept is a new class of biologic agent for the treatment of rheumatoid arthritis (RA) that inhibits T cell activation by binding to CD80/86. Although some clinicians feel that the rapidity of treatment response of abatacept is slower than that of tumor necrosis factor (TNF)-inhibitors, some patients can respond to abatacept treatment quite rapidly. Recently, some reports have been published regarding the positive association between sero-positivity for anti-citrullinated protein antibody (ACPA) and clinical efficacy of abatacept in RA patients. The aim of this study was to demonstrate the effect of double-seropositivity for ACPA and rheumatoid factor (RF) on the rapidity of treatment response of abatacept using data from a Japanese multicenter registry system for RA patients treated with biologic agents.

Methods: Participants were selected from the consecutive 508 RA patients treated with abatacept who were registered in the Tsurumai Biologics Communication Registry (TBCR). We excluded the patients with previous biologic agent treatment history since it has been already reported as an independent factor affecting the clinical efficacy of abatacept. A total of 146 biologics-naïve and ACPA positive patients with baseline data of RF were included in this study. We compared the proportion of patients that achieved good EULAR response at 24 weeks between the RF negative and RF positive (>20 U/ml) group within the ACPA positive patients. We defined the ACPA positive as >13.5 U/ml of anti-CCP antibody (3 times cutoff value) to ensure that the positivity was reasonably sure.

Results: In the ACPA positive patients, the percent decreasing of DAS28-CRP scores in the RF positive group were significantly greater than those in the RF negative group at all time points (Figure A, e.g. -32.3 vs -12.6% at 24 weeks, $p < 0.01$). The proportion of patients that achieved the good EULAR response was significantly higher in the RA positive group at 12 and 24 weeks (Figure B). Multivariate logistic regression analysis (adjusted with gender, age, Steinbrockerfs stage, concomitant MTX and oral steroid usage, and DAS28-CRP score at baseline) revealed that the RF positivity, along with the modified HAQ score at baseline, was the independent predictor for the achievement of good EULAR response at 24 weeks (Figure C).

Conclusion: We clearly demonstrated that the positive association of the double-seropositivity for ACPA and RF with the rapid and good clinical response for abatacept in the biologics-naïve RA patients. This new clinical evidence regarding the effect of double-seropositivity is the valuable real-world data for the prediction of clinical efficacy of abatacept in daily clinical practice.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Seropositivity for RF or ACPA is associated with a better short-term effectiveness and drug retention of abatacept (ABA) and rituximab (RTX). Data are very limited concerning the association with long term retention in real life and concerning the association between seropositivity and effectiveness of tocilizumab (TCZ).

Methods: This was a pre-specified sub-group analysis of a multicenter open-label observational study of patients with RA according to 1987 ACR criteria who were initiating RTX, ABA, or TCZ treatment and enrolled in three French Society of Rheumatology prospective registries (AIR for RTX, ORA for ABA, and REGATE for TCZ). Seropositivity was defined by positivity of either RF or anti-CCP. We used a propensity-score approach to adjust for differences in observed factors that might affect both treatment assignment and outcome.

Results: Data on seropositivity were available in 3540 patients out of 4498 patients(87.4%). 72, 76.7 and 80.9% of patients respectively treated with ABA, RTX and TCZ, had RF or ACPA. 3507 patients had a follow-up at 24 months for a total follow-up of 18898 patient-years (RTX, 10545; ABA, 4912; and TCZ, 3441). - Effect of seropositivity on the effectiveness of each drug Drug retention without failure of RTX at 2 years was 68.7[66.4; 71.0]% in seropositive patients and 51.9 [45.6;59.1]% in seronegative patients, HR of discontinuation of 0.56 [0.46;0.69], p< 0.001. Drug retention without failure of RTX at 5 years was 51.0[48.5; 53.5]% in seropositive patients and 30.9 [25.2;38.0]% in seronegative, HR of discontinuation of 0.57 [0.47;0.69], p< 0.001. Drug retention without failure of ABA at 2 years was 41.5[38.0; 45.2]% in seropositive patients and 40.0 [32.8;48.8]% in seronegative patients, HR of discontinuation of 0.92 [0.77;1.11], p=0.41. Drug retention without failure of ABA at 5 years was 22.4 [19.5; 25.7]% in seropositive

patients and 17.0 [11.7;24.7]% in seronegative, HR of discontinuation of 0.89 [0.75;1.04], p=0.17. Drug retention without failure of TCZ at 2 years was 63.4[60.4; 66.5]% in seropositive patients and 62.2 [54.5;71.1]% in seronegative patients, HR of discontinuation of 0.99 [0.73;1.33], p=0.93. No patient has reached the 5 year follow- up visit yet. - Impact of seropositivity on the comparative effectiveness between ABA, RTX and TCZ At 2 years, drug retention without failure among seropositive patients was significantly greater with RTX and TCZ than ABA (hazard ratio 1.99 [95% CI: 1.56;2.52], and 1.72 [95% CI: 1.22;2.42], respectively), with no difference between RTX and TCZ. At 2 years, drug retention without failure among seronegative patients was not significantly different between RTX and ABA (HR 1.39 [0.89; 2.17]). Drug retention without failure among seronegative patients was higher with TCZ than ABA (hazard ratio 1.93 [95% CI: 1.22;3.05], with no difference between RTX and TCZ. At 5 years, drug retention without failure among seropositive patients was significantly greater with RTX than ABA (HR 2.08 [95% CI: 1.75;2.48]. No significant difference was observed in seronegative patients.

Conclusion: Seropositivity for RF or ACPA has no impact on long-term retention for TCZ and ABA, and results in a marked improvement of long-term retention for RTX.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Assessment of safety in randomized controlled trials is limited by trial durations, and selection of patients with few or now comorbidities. Such limitations can be overcome by long term registry studies. We aimed to compare the safety of abatacept,

rituximab and tocilizumab in common practice.

Methods: This was a multicenter open-label observational study of patients with RA according to 1987 American College of Rheumatology criteria who were initiating rituximab, abatacept, or tocilizumab treatment and enrolled in three French Society of Rheumatology prospective registries (AIR for rituximab, ORA for abatacept, and REGATE for tocilizumab). Severe adverse events (death, serious infection, major adverse cardiovascular events [MACEs], and cancer) were validated by chart review by three experts. A serious infection was defined as an infection occurring during treatment with abatacept or tocilizumab, during the three months after withdrawal, or during the 12 months after a rituximab infusion and requiring hospitalization and/or intravenous antibiotics and/or resulting in death. MACEs were defined as death of cardiovascular origin, stroke, or myocardial infarction. MACEs and cancers were considered in the analysis regardless of their time of occurrence, even after registry drug discontinuation. A propensity-score approach was used to adjust the comparison between drugs.

Results: Among the 4498 enrolled patients (median disease duration: 11 [5-18] years; history of cancer: 8.9% of patients; previous serious or recurrent infection: 27.3%), 3507 had a follow-up at 24 months for a total follow-up of 18898 patient-years (rituximab, 10545; abatacept, 4912; and tocilizumab, 3441). At month 24, serious infections occurred in 5.2, 4.6, and 4.9/100 patient/years in patients treated with rituximab, abatacept, and tocilizumab, respectively (abatacept versus rituximab: IRR of 0.79 [0.49; 1.27], p= 0.33; tocilizumab versus rituximab: IRR of 0.93 [0.55; 1.57], p= 0.79; abatacept versus tocilizumab: IRR of 0.85 [0.47; 1.54], p= 0.59). At month 24, MACEs occurred in 0.56, 0.58 and 0.44/100 patient-years in patients treated with rituximab, abatacept, and tocilizumab, respectively (abatacept versus rituximab: IRR of 1.07 [0.54; 2.13], p= 0.84; tocilizumab versus rituximab: IRR of 0.81 [0.30; 2.17], p= 0.67; abatacept versus tocilizumab: IRR of 1.33 [0.47; 3.75], p= 0.59). At month 24, cancers occurred in 1.2, 1.4 and 1.1/100 patient-years in patients treated with rituximab, abatacept, and tocilizumab, respectively (abatacept versus rituximab: IRR of 0.80 [0.41; 1.56], p= 0.51; tocilizumab versus rituximab: IRR of 0.94 [0.43; 2.04], p= 0.87; abatacept versus tocilizumab: IRR of 0.85 [0.39; 1.88], p= 0.69). At month 24, deaths occurred in 1.3, 1.6 and 0.3/100 patient-years in patients treated with rituximab, abatacept, and tocilizumab, respectively (abatacept versus rituximab: IRR of 1.83 [0.87; 3.84], p= 0.11; tocilizumab versus rituximab: IRR of 0.59 [0.18; 2.01], p= 0.40; abatacept versus tocilizumab: IRR of 3.08 [0.78; 12.23], p= 0.11).

Conclusion: In patients with longstanding RA and comorbidities treated in common practice, long term safety seems similar in patients treated with abatacept, rituximab or tocilizumab.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with RA develop bone and joint damage due to chronic synovial inflammation that is mediated by specific cytokines.[1] Cytokines (eg, IL-6) recruit activated inflammatory cells and fibroblast-like synoviocytes to generate a pannus that

results in bone resorption and cartilage destruction. Here we describe that blockade of IL-6 signaling by sarilumab, a human mAb blocking the IL-6Rα, decreased circulating markers associated with the pannus in adults with active, moderate-to-severe RA and inadequate response to TNF inhibitors (TNFi) from the phase 3 TARGET study (NCT01709578).

Methods: Sera were analyzed using ELISAs at baseline and posttreatment (through week 24) from a subset of patients who received placebo or sarilumab subcutaneously (150 or 200 mg every 2 weeks [q2w]) plus conventional synthetic DMARDs (csDMARDs; n=97/group). Percent change from baseline in biomarkers was analyzed using nonparametric methods (ANOVA-type or rank-based analysis of covariance) to evaluate differences between treatment groups at each time point. For exploratory purposes, percent changes from baseline in biomarkers were also compared, separately by treatment group, between ACR50 responders and nonresponders at week 24 using similar methods. *P* values <0.05 were considered significant.

Results: Both doses of sarilumab significantly decreased markers of tissue destruction, synovial inflammation, and bone resorption relative to placebo as early as week 2 for several biomarkers assessed, with greater reductions observed at week 24 (Table). For several biomarkers, numerically greater changes from baseline were observed following treatment with sarilumab 200 mg q2w vs sarilumab 150 mg q2w. Numerical increases observed in osteocalcin (OC) after treatment with sarilumab were not statistically significant compared with placebo. When changes from baseline in biomarkers were examined according to ACR50 response at week 24, larger decreases in MMP-3 and increases in OC were observed in patients achieving ACR50 compared with those who did not achieve ACR50; these changes were significant for the sarilumab 150 mg q2w group (Table). Other biomarkers suppressed by sarilumab treatment (eg, chemokine [C-X-C motif] ligand 13 and RANK ligand) did not significantly differ by ACR50 response (not shown).

Conclusion: Sarilumab significantly reduced biomarkers of bone resorption and joint damage in patients with RA and inadequate response to TNFi. Differences in some biomarker levels observed between ACR50 responders and nonresponders suggest that modulation of these biomarkers may contribute to a decrease in disease activity. **Reference: 1.** Srirangan et al. *Ther Adv Musculoskelet Dis*. 2010;2:247-256.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : The potent and selective JAK1 inhibitor filgotinib (GLPG0634, GS-6034) has been evaluated in a 24-week phase 2B study in combination with methotrexate (MTX) in active rheumatoid arthritis (RA) patients with inadequate response to MTX (DARWIN 1 study). Significant improvement in signs and symptoms was observed after 12 weeks and efficacy was sustained or improved up to Week 24 with a safety profile overall acceptable. In order to gain insight in filgotinib mode of action in RA patients, we analysed the impact of this treatment on serum cytokines.

Methods : Patients with active RA on stable dose of MTX were randomized 1:1:1:1:1:1:1 in a double blind manner to receive either placebo (PBO) or one of three doses of filgotinib (50mg, 100mg or 200mg) as once (qd) or twice daily (bid) regimen for 24 weeks (DARWIN 1 study). At baseline, Week 4 and Week 12, sera were collected from all patients and analysed using the 18-plex panel kit from Merck-Millipore (HSTCMAG-28SK) on BioPLEX-200 apparatus to measure concentration of GM-CSF, IFNγ, IL-1β, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12 (p70), IL-13, IL-17A, IL-21, IL-23, MIP-1α, MIP-1β and TNF-α. Data are presented as means of changes from the baseline.

Results : Following treatment with filgotinib, IL-6 was the cytokine showing greatest decreases in concentration at all time points and doses analysed. The pro-inflammatory cytokine IL-1β was also decreased at Week 12 at higher doses confirming the potent anti-inflammatory activity of filgotinib. Of interest, serum concentrations of IL-2 and IFN-γ, two T_H1 cell markers, reduced significantly at Week 12 at the higher doses used, suggesting that filgotinib may impact the promotion of this cell subset. Notably, this is consistent with the Week 4 decrease in IL-12 concentration, a cytokine that, together with IFN-γ, promotes T_H1 cell expansion. The T_H2-related cytokine IL-13 was decreased at Week 12 at all doses analysed, in contrast to IL-4 and IL-5 that were not impacted by filgotinib treatment. Of interest, concentration of IL-21 (a cytokine produced by T_H17 cells) was decreased after 12 weeks of treatment with the higher dose of filgotinib. Higher doses of filgotinib also reduced levels of the B and T cell development cytokine, IL-7. Finally, MIP-1β concentration was decreased by high doses of filgotinib after 4 weeks of treatment, in line with the effect observed on GM-CSF at all

time points.

Conclusion: Treatment of RA patients with filgotinib led to the decrease of multiple cytokines involved in various aspects of the inflammatory process. Reductions in IL-6 and IL-1β establish the anti-inflammatory activity of filgotinib. Treatment effects on IL-2, IL-6, IL-7, IL-12 and IFN-γ that play a key role in $CD4^+$ T-cell differentiation and expansion further highlight the anti-inflammatory effects of filgotinib, likely by limiting the promotion of T_H1, T_H2 and T_H17 cells. Finally, effects on innate immunity, through MIP-1β and GM-CSF decrease, were also mediated by filgotinib. Taken together, these data further demonstrate the anti-inflammatory activity of filgotinib in line with its efficacy observed in RA patients.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

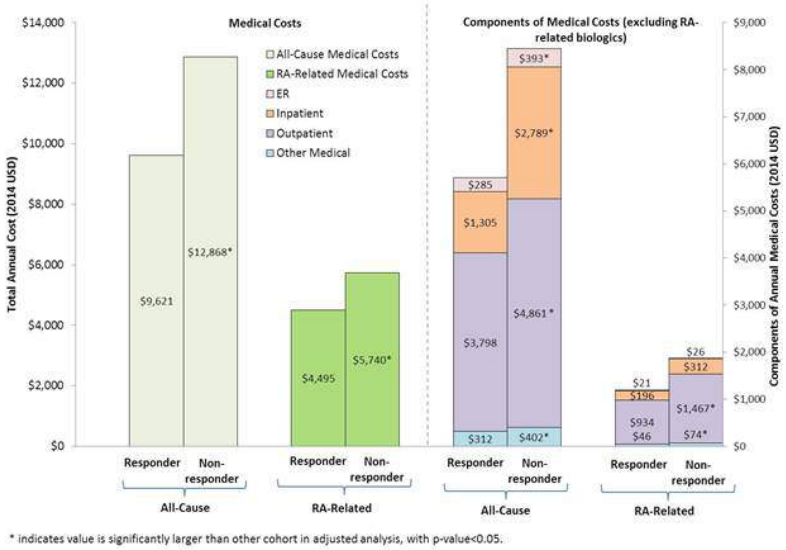
Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic agents are effective in treating patients with rheumatoid arthritis (RA); however, some patients either fail to respond or lose response over time. This study assessed the direct and indirect economic burden among RA patients who had inadequate responses to initial biologic therapy compared with treatment responders.

Methods: Data from 1/1/1998-3/31/2014 were used from a large de-identified, privately insured claims database, which included work loss from a subset of reporting companies. Study sample consisted of patients with ≥1 claim for a biologic DMARD (bDMARD) approved for treatment of RA and ≥2 RA diagnoses in the claim history, with continuous eligibility for 6 months before (baseline) and 12 months after (study period) the date of the first bDMARD claim (index date). Patients were classified as responders and non-responders based on a validated, claim-based algorithm. All-cause and RA-related healthcare resource use and costs, work loss, and indirect costs during the study period were compared for bDMARD responders vs. non-responders. Multivariable regressions were used to adjust for baseline characteristics. As different treatments were approved over time and the pattern of costs and resources use may have changed, subgroup analyses of resource use and direct costs were conducted for patients with index dates in 1998-2007 and in 2008-2013.

Results: This study included 7,540 eligible RA patients, with 2,527 bDMARD responders and 5,013 non-responders; 407 responders and 723 non-responders had work loss data. Compared with responders, non-responders had significantly higher adjusted rates of resource use, including inpatient admissions (incidence rate ratio [IRR]=1.94), outpatient visits (IRR=1.19), emergency department visits (IRR=1.53), and number of prescription fills (IRR=1.09) (all p-values < 0.001). Non-responders had significantly higher adjusted all-cause and RA-related medical costs compared with responders (all-cause: $12,868 vs. $9,621, RA-related: $5,740 vs. $4,495, adjusted p-values<0.001) (Figure 1). Results for subgroup analyses of resource use and direct costs by index date were consistent with the full sample. Non-responders also had significantly more days of work loss compared with responders (22.1 vs. 16.7 days, IRR=1.21, adjusted p-value=0.007) and higher indirect costs ($3,548 vs. $2,890, adjusted p-value = 0.002).

Conclusion: Two-thirds of RA patients had inadequate responses to their initial bDMARD. These non-responders faced a significantly higher burden, including increased healthcare resource use, direct medical costs, and work loss compared to responders. **Figure 1.**



Medical costs of biologic non-responders vs. responders

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Observational studies have already reported the risk of serious infections in rheumatoid arthritis (RA) treated with tocilizumab but in limited samples. The aim of this study was to investigate the predictive risk factors of serious infections in the largest European registry of patients treated with tocilizumab for RA.

Methods: 1491 RA patients included in the French REGistry –RoAcTEmra (REGATE) were analysed to calculate incidence rate of severe infections and to identify independent factors associated with severe infections. Kaplan -Meier method was used to assess probability of remaining severe infection-free. Cox models were performed to identify independent factors associated with severe infections. Variables showing bivariate association with the dependent variable with a P value less than 0.15 were entered into the multivariate model. Multiple imputation was used to compensate missing data in some variables. A P value <0.05 was considered statistically significant.

Results: Exposure was 2,606 person-years (mean age±SD, 56.6±13.6). 125 serious infections occurred in 122 patients (4.7/100 patient-years). Most frequent infections were lung and respiratory tract and skin/soft tissue in 35 (28%) and 32(26%) cases respectively. Three deaths were related to one septic chock secondary to pyelonephritis, one pneumocystosis, and one Haemophilus influenzae infection. Favourable outcome was observed in most cases. Fouropportunistic infections were reported: 1 Pneumocystosis, 1 tuberculosis, 1 Haemophilus influenzae infection and 1infection related to Klebsiella pneumoniae. A pathogen was identified in 41 cases. TCZ was definitively stopped for 35patients. The incidence of serious infection was stable over the first 3 years of follow-up in the registry. Bivariate analysisidentified initial ACPA positivity as the only factor associated with a lower risk of severe infection (HR 0.55 CI95% 0.35-0.86). Factors significantly associated with a risk of severe infections were DAS28-CRP, DAS28-ESR, and number ofpolymorphonuclear neutrophils (PMN) at baseline. Initial PMN above 4.5 G/L (HR 1.62 CI95% 1.06-2.5, p=0.02) and negative ACPA (HR 0.63 CI95% 0.41-0.95, p=0.03) remains significantly associated with severe infections in multivariate analysis after imputation for missing data.

Conclusion: The rate of severe infections in current practice is similar to that reported in clinical trials. High PMN above 4.5 G/L at baseline and negative ACPA are predictive factors of serious infection requiring in this case a tighter surveillance.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment of rheumatoid arthritis (RA) patients by anti-tumour necrosis factors (anti-TNFs), such as golimumab, has improved patient outcomes. However, unmet therapeutic needs exist for a substantial proportion of patients. Mavrilimumab is a fully human monoclonal antibody which inhibits the granulocyte-macrophage colony-stimulating factor receptor α (GM–CSFR-α). Recently, a Phase IIb clinical trial has been completed to evaluate the efficacy and safety of mavrilimumab and golimumab in both disease-modifying antirheumatic drug (DMARD)-inadequate responder (IR) and anti-tumor necrosis factor-inadequate responders (anti-TNF-IR) patients (EARTH EXPLORER 2, NCT01715896). Our current study aims to assess peripheral biomarkers and pathophysiological pathways modulated by mavrilimumab and golimumab in RA patients.

Methods: The Phase IIb trial enrolled patients with active RA (28-joint Disease Activity Score [DAS28]-C-reactive protein/erythrocyte sedimentation rate ≥3.2), ≥4 swollen joints, and inadequate response to ≥1 DMARDs and/or 1-2 anti-TNFs. Patients were randomized (1:1) to receive subcutaneous mavrilimumab 100 mg (n=70) every other week (Q2W) or golimumab 50 mg (n=68) Q2W alternating with

placebo, in combination with methotrexate (7.5-25.0 mg/week) for 24 weeks. Serum levels of 18 RA-associated proteins and 3 protease-derived protein fragments were measured in 71 DMARD-IR and 61 anti-TNF-IR patients at baseline and 4 time points post-administration. Transcriptome sequencing was used to measure gene expression changes in whole blood of RA patients at baseline and day 169 post-administration.

Results: Serum levels of CCL22 (MDC) and CCL17 (TARC) were suppressed by mavrilimumab but not golimumab, while CXCL13 and ICAM1 were suppressed by golimumab but not mavrilimumab. Those four proteins may be specific pharmacodynamic markers for the two biologics respectively. Both mavrilimumab and golimumab induced early and sustained suppression of multiple protein markers in DMARD-IR patients, including CRP, SAA, MMP1, MMP3, IL6, VEGF, IL2R, and CD163. However, golimumab-induced early changes rapidly returned towards baseline levels in anti-TNF-IR patients, while mavrilimumab-induced changes were maintained through day 169. Similarly, mavrilimumab administration was associated with durable suppression of extracellular matrix markers, C1M, C3M, and P4NP7S whilst golimumab only induced a transient change of the three markers in anti-TNF-IR patients. Furthermore, RNA sequencing results demonstrated significant regulation of 1547 transcripts at day 169 after mavrilimumab administration while golimumab had no impact on gene expression in anti-TNF-IR patients. In contrast, significant changes of 1042 and 2058 transcripts were observed in DMARD-IR patients at day 169 post-treatment of mavrilimumab and golimumab respectively.

Conclusion: Our study demonstrated a sustained differential suppression of peripheral disease markers by mavrilimumab but not golimumab in anti-TNF-IR patients, suggesting the potential of greater long-term disease control by mavrilimumab than golimumab in this population of RA patients.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Given that tocilizumab (TCZ) directly inhibits IL-6 signaling and strongly suppresses the inflammatory reaction, there is concern that the signs and symptoms associated with infection are not easily detected in the early phase of infection during TCZ treatment. The aim of this study was to identify initial symptoms before serious infection (SI) developed in TCZ-treated patients using clinical narratives from a postmarketing adverse events (AE) reporting database.

Methods: A postmarketing AE reporting database maintained by Chugai Pharmaceutical Co. Ltd. was used to obtain individual case safety reports including structured (age, sex, drugs, AE term, laboratory test values) and unstructured (clinical narratives) data. Reports had to meet 4 criteria: (1) obtained between April 16, 2008, and April 10, 2015; (2) originated from Japanese patients with RA who received TCZ; (3) included SIs; (4) causality between TCZ and SIs reported by medical professionals. Patient characteristics were summarized by descriptive statistics, and clinical narratives were analyzed by automated text mining to explore symptoms. AEs and symptoms were coded using MedDRA/Japanese version 17.1.

Results: The database included 7653 RA patients with a mean ± SD age of 60.0 ± 12.7 years (<65, 45.8%; ≥65-<75, 22.1%; ≥75, 8.3%; missing, 23.8%). Of these, 1221 patients had reports meeting the 4 criteria (mean ± SD age, 63.4 ± 11.7 years) (<65, 35.5%; ≥65-<75, 25.9%; ≥75, 11.8%; missing, 26.8%) encompassing 1591 reported SIs. The most frequently reported SIs were pneumonia (n = 253, 15.9%), cellulitis (n = 158, 9.9%), and sepsis (n = 80, 5.0%). The date of diagnosis of SI was available for 782 patients: 454 (58.1%) had symptoms during the 28 days before diagnosis of SI, 13 (1.7%) had no symptoms, 276 (35.3%) had symptoms but the date of prodromal symptoms was not identified, and 39 (5.0%) were unknown (Figure). The most common prodromal symptoms among patients who had symptoms during the 28 days before diagnosis of SI were cough (n = 104, 22.9%), pain (n = 103, 22.7%), pyrexia (n = 100, 22.0%), swelling (n = 80, 17.6%), productive cough (n = 49, 10.8%), abdominal pain (n = 49, 10.8%), erythema (n = 47, 10.4%), dyspnea (n = 38, 8.4%), rash (n = 37, 8.1%), and malaise (n = 31, 6.8%).

Conclusion: The presence of prodromal symptoms in patients who developed SIs after TCZ administration was described in most cases. Therefore, data mining of clinical narratives may have additional value in characterizing SIs.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: For the treatment of rheumatoid arthritis (RA) a therapeutic window of opportunity exists– patients treated early have favorable outcomes compared with patients treated after they have progressed radiographically. This study investigated the impact of time of radiographic inhibition on the long-term outcomes of patients who achieved early disease control.

Methods: This analysis studied ten-year data from PREMIER (a phase 3, randomized clinical trial of adalimumab in patients with recent onset RA), and DE-019 (a phase 3, randomized clinical trial of adalimumab in patients with long-standing RA). Radiographic progression was defined as an increase of modified total Sharp score (mTSS) of at least 0.5 units relative to baseline. Patients who achieved remission at year 1 (defined as disease activity score 28-joint count [DAS28] < 2.6) were categorized into four groups according to the time of first recorded radiographic progression: (1) progressed within year 1, (2) progressed between year 2 and 3, (3) progressed between year 5 and 10, and (4) never progressed before the end of 10-year follow-up. Outcomes at year 10 were summarized for each of the groups, including health assessment questionnaire disability index (HAQ-DI), DAS28, simple disease activity index (SDAI), and proportion of patients in remission at the end of follow-up. Tests for trend were conducted for each outcome. A sensitivity analysis imputing year 10 outcomes was conducted using last observation carried forward for patients who did not complete all 10 years of follow-up.

Results: A total of 314 RA patients included in the two trials achieved remission at year 1, among whom 149 completed 10 years of follow-up. Delaying radiographic progression was associated with lower levels of physical dysfunction, as measured using HAQ-DI. The average HAQ-DI at year 10 was 0.53 for progressions within the first year, 0.39 for progressions between year 2 and 3, 0.31 for progressions between year 5 and 10, and 0.14 for patients did not progress before the end of follow-up. The incremental HAQ-DI score between the first year progressions and the no progression groups is approximately 1.8 times the minimal clinically important difference of 0.22. In addition, a linear trend of HAQ-DI was observed across different times to radiographic progression (p-for-trend = 0.01). Disease activity, measured using DAS28, SDAI, and remission at the end of follow-up, was not statistically different across the four groups. Results were consistent in the sensitivity analysis where year 10 outcomes were imputed for patients who did not complete the follow-up.

Conclusion: RA patients achieving early remission experienced normalized physical function. Patients who additionally delayed radiographic progression had an incremental benefit in terms of long-term physical function.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: B cell depletion therapy has provided evidence of the importance of B cells in the pathogenesis of rheumatoid arthritis and other inflammatory diseases. Consequently, targeted B-cell treatments are being investigated in autoimmune disorders. BTK is a crucial kinase in signaling cascades following B cell antigen receptor (BCR) activation in B cells, in Fc receptor binding of immune complexes in myeloid cells, and some toll-like receptor (TLR) signaling events in B cells, myeloid cells, and dendritic cells. GDC-0853 is a small molecule inhibitor of BTK that is highly selective, orally administered, non-covalent, and reversible. GDC-0853 has demonstrated efficacy in pre-clinical autoimmune disease models and is being developed for the treatment of rheumatoid arthritis and

lupus, with future development for other autoimmune indications. This study evaluated the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of GDC-0853 in single ascending dose (SAD) and multiple ascending dose (MAD) studies in healthy adult volunteers.

Methods: GDC-0853 was evaluated in two randomized, double-blind, placebo- controlled phase 1 trials with 53 active and 18 placebo subjects dosed in the SAD study, and 30 active and 10 placebo subjects dosed in the MAD study. The SAD study evaluated 9 cohorts at doses ranging from 0.5 mg to 600 mg; the MAD study evaluated 5 cohorts at doses of 20, 60, 150, and 250 mg BID, and 500 mg QD for 14 days. Safety and tolerability were assessed by clinical, laboratory, and ECG assessments. PK was characterized using a validated LC-MS/MS assay. PD was assessed using phospho-BTK (p-BTK), and cellular activation assays.

Results: GDC-0853 was well-tolerated in both the SAD and MAD studies and there were no dose-limiting adverse events (AEs) and no serious AEs. No subjects withdrew due to an AE, and a maximum tolerated dose was not reached. AEs were all mild and transient. In the SAD study, the most common event reported was headache in 4 subjects (7.5%). In the MAD study, AEs included skin reactions in 3 subjects (rash, contact dermatitis, and ECG site rash in 1 subject each), nausea in 2 subjects (6.7%), and fatigue, contusion, and asymptomatic bacteriuria in 1 subject each. Following oral administration to fasted subjects, rapid absorption was observed (median t_{max} of 1-3 hours). The steady-state $t_{1/2}$ ranged from 8.3-11 hours, and exposures increased approximately dose-proportionally. Three target engagement assays were used to demonstrate dose-dependent inhibition of p-BTK and BTK-dependent cellular activation. Basophil activation via FcεR, B cell activation via the B cell receptor, and constitutive p-BTK activity in whole blood lysates were inhibited in a dose-dependent manner by GDC-0853, with IC50's ranging from 2-9 nM. Basophil and p-BTK activity in the MAD study were used to develop a PK/PD model to support dose selection for the phase II studies.

Conclusion: GDC-0853 was well-tolerated in healthy subjects at doses that inhibit BTK activity. The safety, PK, and PD profiles support further investigation in phase II studies in rheumatoid arthritis, lupus, and other autoimmune indications.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The immunomodulatory actions of human umbilical cord blood (hUCB)-derived mesenchymal stem cells (MSCs) in rheumatoid arthritis (RA) have been studied extensively via *in vitro* or pre-clinical studies, yet few human trials have been conducted

investigating the outcome of hUCB-derived MSC infusion.

Methods: The CURE-iv (**C**linical and safety assessment of human **U**mbilical cord blood-derived mesenchymal stem cell therapy for **RhE**umatoid arthritis patients administered **i**ntra**v**enously) trial was a phase 1, proof-of-concept clinical trial for RA patient with moderate disease activity despite treatment with methotrexate. Patients meeting the 2010 ACR/EULAR classification criteria and with a DAS28-ESR >3.2 were eligible for the trial. Subjects were each given a single intravenous infusion of 2.5×10^7, or 5×10^7, or 1×10^8 cells of hUCB-derived MSCs for 30 minutes; 3 patients in each cluster, with increment of cell numbers when there was no dose-limited adverse events. Clinical and safety parameters were monitored and followed after the infusion period (first 24 hours, 72 hours, 1 week, and 4 weeks). Serum cytokines at baseline and 24 hours after the infusion were analyzed.

Results: Eleven RA patients were screened, 9 of which were enrolled from a single center. The mean age was 57.4 years, 78 % being female, with a disease duration of 9.5 ± 8.7 years, and DAS28-ESR 4.53 ± 1.35. There was no ominous safety signal in all clusters up to 4 weeks after the infusion. One patient stated joint pain 60 min after the infusion (5×10^7 group), but it was thought to be unrelated to the investigational product. ESR and CRP changes at 4 weeks (n=9) were -7.89 ± 10.36 (p= 0.0517), and -0.37 ± 1.09 (p=0.3362). DAS28 and HAQ changes at 4 weeks were -1.60 ± 1.57 (p= 0.0159), and -0.15 ± 0.48 (p= 0.3706), respectively. One patient in the 1×10^8 group showed substantial decrease in all serum levels of IL-1b, IL-6, IL-8, and TNF-a.

Conclusion: This phase 1 clinical trial - a single dose intravenous infusion of hUCB-derived MSCs - for established RA patients was completed without any short-term safety concerns (NCT02221258).

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Early introduction of some biologic (b) DMARDs has been proposed to reduce anti-citrullinated protein antibodies (ACPA) titers in clinical trials settings. However, less information is available about which factors modulate ACPA titers in early arthritis patients under routine clinical practice, including the impact of synthetic (s) DMARDs. **Aim:** To analyze the factors that are related with the variation of ACPA titers in a seropositive early arthritis population under non-protocolized treatment with s and b DMARDs

Methods: We studied 124 patients enrolled in our prospective PEARL (Princesa early arthritis longitudinal) study. Appropriate ethical approval of the registry protocol and informed consent form from patients were obtained. Sociodemographic, clinical, laboratory, therapeutic variables and biological samples were collected by protocol at baseline, 6, 12, 24 and 60 months. Only baseline ACPA positive patients were include in the study (ELISA antiCCP2 IgG Euro Diagnostica Immunoscan CCPlus®, Arnhem, Holanda; positive >50U/ml). ACPA titers were assessed in 471 visits (3.8 visits/patient). The population was stratified into equal quartiles according to baseline CCP2 titers (median, range): Q1 (87, 50 – 160 U/ml), Q2 (308, 161 – 460 U/ml), Q3 (643, 461 – 1280 U/ml) and Q4 (2000, 1281– 5263) U/ml). Disease activity was assessed with DAS 28 and HUPI indexes. To estimate the effect of different variables (including DMARDs) on the variation of ACPA titers, multivariate linear regression models nested by visit and patients were fitted

using the xtgee command of STATA 12.1.

Results: 86 % patients were female, with age at disease onset (median [p25-p75]) 52 [41-73] years, median disease duration at entry 6 [3,6-9] months; 83% of patients met 2010 ACR/EULAR classification criteria for RA at baseline and 93% after two years of follow up. Median DAS28 at baseline was 4,5 [3,5-5,6] and HAQ 1 [0,5-1,6]. No differences in demographic variables, disease duration, activity or functional status were detected between patients clustered in the baseline ACPA quartiles. A significant decrease in baseline ACPA titers can be detected at 6 months (median reduction 48% [15-70]) that was maintained at 1 (44% [12-68]), 2 (49% [15-71] and 5 years (62% [38-72]), (p=0,0002; 0,0049; 0,0001 and 0,0137, respectively). This reduction was also significant in all visits when population were analyzed by quartiles (p=0,0001), with increasing magnitude of change and number of patients with titers reduction in the Q4. In the multivariate analysis, active smoking was associated with higher ACPA titers along the follow-up (p<0,001) while reduction in disease activity was associated with decreasing ACPA titers (p = 0.005). After adjusting for these variables, both synthetic [methotrexate (p = 0.001), leflunomide (p = 0.002), sulfasalazine (p = 0.014)] and biological DMARDs [anti-TNF (P = 0.002), rituximab (p = 0.049)], also account for decrease in ACPA titers as independent factors.

Conclusion: In real clinical practice, an early and sustained reduction in antiCCP2 titers can be detected in seropositive early arthritis patients associated to the decline in disease activity. Both synthetic and biologic DMARDs can also independently explain the decline in ACPA titers.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Data are very limited concerning the safety of multiple retreatments with rituximab (RTX) in rheumatoid arthritis in common practice.

Methods: This is a multicenter open-label observational study of patients with RA according to 1987 ACR criteria who were initiating RTX and enrolled in the French Society of Rheumatology prospective registry AIR (AutoImmunity and Rituximab) Severe adverse events (death, serious infection, and cancer) were validated by chart review by three experts. A serious infection was defined as an infection occurring during the 12 months after a rituximab infusion and requiring hospitalization and/or intravenous antibiotics and/or resulting in death. Cancers were considered in the analysis regardless of their time of occurrence, even after registry drug discontinuation. For serious infections, exposure time was defined as the time between inclusion and the first occurrence of serious

infection, end of follow-up, or last infusion of rituximab plus 12 months for rituximab. For cancers and deaths, exposure time was defined as the time between inclusion and first occurrence of an event or end of follow-up.

Results: Median age and disease duration before RTX in the 1986 enrolled patients were 58 [50-67] and 11 [6-18] years, respectively. 14% of patients had a history of cancer, 34.6% had a history of serious or recurrent infections. Median number of previous conventional DMARDs and of biologics were 3 [2 ;4] and 2 [1 ;2], respectively. Median DAS28-ESR at RTX initiation was 5.53 [4.72; 6.38]. 65.7% of patients initiated RTX in combination with a synthetic DMARD (methotrexate :75.6%). 78.7% of patients received concomitant oral corticosteroids (median dose 10 [7; 15] mg/day. Current total follow-up of the 1984 patients was 10 545 patient-years (mean follow-up : 5.3 years). 1280 patients have received less than 5 cycles of RTX, 551 patients between 5 and 9 cycles and 153 patients 10 cycles or more. Overall, 369 serious infections occurred (5.2 /100 patient-years) : 195 in patients treated with less than 5 cycles of RTX (6.1/100 patient-years), 134 patients treated with 5 to 9 cycles (4.0/100 patient-years) and 40 in patients treated with more than 10 cycles (4.0/100 patient-years). 134 cancers occurred (1.3/100 patient-years) including 85 in patients treated with less than 5 cycles of RTX 1.4/100 patient-years), 42 in patients treated with 5 to 9 cycles (1.2/100 patient-years) and 7 in patients treated with more than 10 cycles (0.7/100 patient-years). 196 deaths occurred (1.9/100 patient-years) including 177 in patients treated with less than 5 cycles of RTX (3.0 /100 patient-years), 17 in patients treated with 5 to 9 cycles (0.5/100 patient-years) and 2 in patients treated with more than 10 cycles (0.2/100 patient-years). RTX was discontinued in 820 patients treated with less 5 cycles, 155 treated with 5 to 9 cycles and 19 in patients treated with 10 cycles or more. Discontinuation was related to serious adverse events in 105 (2.8%) patients treated with less 5 cycles, 29 (18.7%) patients treated with 5 to 9 cycles and 4 (21.0%) patients treated with 10 cycles or more.

Conclusion: The rate of serious adverse events seems similar in patients with multiple retreatments with RTX as in patients less frequently retreated. However, these results must be interpreted with caution taking into account the depletion of susceptible effect (patients who remain on a drug are those who can tolerate it).

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic inflammation of the synovial joints and infiltration by activated macrophages. TNFa is a central mediator in the process, leading to joint swelling and subsequent articular destruction. CD163 is a scavenger receptor expressed by M2C macrophages. We previously reported the soluble (s) form to be

associated with disease activity and reflect discontinuation of anti-TNFa treatment in RA[2]. The mannose receptor, CD206, is also a scavenger receptor, but expressed by M2A-macrophages and dendritic cells. It is involved in collagen internalization and degradation. The soluble form is suggested as biomarker of M2A-macrophage activation. In this study, we investigate sCD206 plasma levels in early RA patients, before, during and after anti-TNF_ treatment.

Methods: Plasma levels of sCD206 was measured by ELISA in samples from 155 early RA patients belonging to the OPERA cohort[1]. Age 53.5 years 70% females, average disease duration: 3 months. Patients were randomized to 12 months conventional methotrexate and placebo (PLA) or methotrexate and adalimumab (ADA) treatment, followed by open-label treatment with DMARD and if needed adalimumab. The disease was assessed at baseline and after 3, 6, 12 and 24 months by: Disease Activity Score (DAS28), Health Assessment Questionnaire (HAQ), C-Reactive Protein (CRP), Swollen Joint Counts (SJC40), Tender Joint Counts (TJC40), Clinical Disease Activity Index (CDAI), Visual Analogue Scale (VAS) for pain, IgM-RF and anti-CCP. Statistical analysis was performed by studentÕs t-test, SpearmanÕs Rank correlation and linear regression.

Results: Baseline plasma level of sCD206 in treatment na•ve RA patients was 0.33 mg/l (CI: 0.33 mg/l Ð 0.38 mg/l) corresponding to the upper part of the reference interval for healthy controls (0.10 mg/l Ð 0.43 mg/l). Anti-TNFa treatment significantly decreased plasma sCD206, whereas discontinuation of anti-TNFa resulted in increasing sCD206 plasma levels. In the PLA group, sCD206 levels was decreased after 3 months, and did not differ from those at baseline after 6 months. In the ADA group, however, levels remained lower than baseline throughout the treatment period (Figure 1). Soluble CD206 correlated with previously measured sCD163[2] at all 5 time points (r^2: 0.24-0.38, $p<0.001$). Soluble CD206 did not correlate with clinical nor biochemical disease markers, however sCD206 increased when adalimumab was discontinued.

Conclusion: Plasma sCD206 decreased with treatment in early RA patients. Treatment with anti-TNFa preserved this decrease in the entire follow-up period; however, discontinuation of anti-TNFa was reflected by increasing sCD206 plasma levels. Soluble CD206 did not reflect disease activity in early RA, but like sCD163, reflected anti-TNFa treatment. Figure 1

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Fostamatinib was developed for the treatment of RA and improved signs and symptoms of RA [1], but did not improve modified Total Sharp Score (mTSS) in the phase III OSKIRA-1 study. Previous publications have shown that interventions with tocilizumab (anti-IL6 receptor antibody) can modulate bone balance, and both cartilage and synovial turnover in a dose-dependent manner [2,3,4,5]. To better understand the underlying mechanism of fostamatinib changes in biomarkers of joint tissue turnover were prospectively evaluated in response to fostamatinib treatment in patients with rheumatoid arthritis (RA) from the Phase III OSKIRA-1 study.

Methods: The biomarker evaluable population included 450 patients from the OSKIRA-1 trial. All patients received methotrexate and were randomly assigned to Group A (fostamatinib 100 mg bid), Group B (fostamatinib 100 mg bid for 4 weeks followed by fostamatinib 150 mg once daily) or placebo. Serum biomarkers of bone resorption (CTX I), bone formation (osteocalcin and type I pro-collagen N-terminal pro-peptide [PINP]), joint tissue degradation (C1M, C2M, C3M and matrix metalloproteinase [MMP]-3) and inflammation (MMP-mediated C-reactive protein [CRPM] and interleukin-6 [IL-6]) were assessed at baseline and Week 24. CTX-I/osteocalcin ratio was evaluated as a measure of bone balance [2].

Results: Fostamatinib significantly reduced a bone resorption biomarker at Week 24, with reductions of 23–28% in CTX-I levels versus placebo (P<0.001), and statistically significantly improved biomarker bone balance versus placebo (P<0.05) (figure). However, no statistical significant changes for fostamatinib versus placebo were observed for C1M, a soft tissue marker shown to be predictive for structural efficacy [5], or for C2M, C3M and CRPM. Fostamatinib showed a significant decrease in MMP-3 levels (P=0.004) and IL-6 levels (P=0.004), although only in the high-dose group for IL-6.

Conclusion: Fostamatinib demonstrated a significant effect on the overall bone balance, but not on other biomarkers of joint tissue turnover, consistent with the structural data. Early and comprehensive analysis of biomarkers that encompass synovium, cartilage and bone metabolism may facilitate early clinical decision-making in RA drug development. *[1]Taylor PC et al. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: South Africa is a tuberculosis (TB) endemic country having one of the highest TB infection rates in the world with close to 1000 cases per 100 000 population per year[1]. Screening for latent TB infection (LTBI) and treatment of any positive patient has reduced reactivation however the chance of TB infection remains high. Use of a biologic therapy with a lower risk of TB infection is a high priority. Bristol- Myers Squibb introduced a compassionate use programme (CUP) for RA patients who had completed long-term extension phases of clinical trials using subcutaneous (SC) abatacept 125 mg per week. **Objective**: The primary objective was to gather information on the retention and safety of SC abatacept use over 30 months on the CUP in a TB endemic environment.

Methods: Demographic, safety and clinical data were retrospectively collected from patient records of 50 patients receiving regular follow up during the CUP (June 2013 to December 2015)

Results: Data were received for 50 patients who completed the CUP. Eighty-six percent of patients (n=43) were still on SC abatacept at the end of 30 months. Discontinuation was due to adverse events 4% (n=2), lost to follow up 4% (n=2) and joint replacement 2% (n=1). Only 4% (n=2) discontinued due to lack of efficacy. Ten percent of all patients (n=5) experienced an adverse event after commencement of the CUP. In total, 7 adverse events were reported; 5 were classified as moderate and 2 as severe. The adverse events were as follows: bunionectomy (n=1; moderate); elbow replacement (n=1; moderate); pneumonia (n=1; moderate); right shoulder acromioplasty (n=1; moderate); right wrist replacement (n=1; severe); spastic colon (n=1; severe) and upper respiratory tract infection (n=1; moderate). No TB cases were recorded and general infections were recorded in 4% (n=2) which is similar to data published from other countries (3.1%) [2, 3]. Seventy percent (n=35) of patients had one or more co-morbidity; of these 43% (n=15/35) were reported to have a co-morbidity that is cardiovascular in nature.

Conclusion: The evidence from the CUP programme provides insight into the retention of SC abatacept treatment as well as the safety of SC abatacept use in a TB endemic country. The results demonstrate that SC abatacept is a well-tolerated and safe treatment option with a good retention rate in South Africa.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Observational studies are critical in assessing medication safety and effectiveness in the real world. Nonrandom assignment can provide insight to how and when medications are prescribed. Since the US introduction of TNF inhibitors (TNFi) in 1998, several newer biologics with varying mechanisms of action are available to patients and physicians. Our objective was to compare characteristics and serious adverse events (serious infections, malignancies and autoimmune diseases) of patients who received abatacept (ABA) compared to those who received other biologic DMARDs (BDC).

Methods: Participating patients with RA in the National Data Bank for Rheumatic Diseases (NDB) provided treatment and other characteristics (sociodemographics and comorbidities) through self-reported biannual questionnaires. Only responses from 2005-2015 were used for greater comparability. Initiators of ABA were matched to patients initiating other DMARDs in a 1:3 ratio. All patient-reported outcomes were verified by medical record review except non-melanoma skin cancer. For cancer and autoimmune outcomes, ITT analyses were performed, holding the exposure constant from the start of treatment until the end of follow-up, and for infections, through its duration plus 90 days. Marginal structural models were used to estimate the effect of treatment on the outcome by an appropriate control for the effects of time-dependent confounders using stabilized weights. Variables included sex, employment, smoking, education, income, BMI, insurance, comorbidity index, RA severity, and co-medications. These results are reported as hazard ratios (HR), estimated through a pooled logistic regression. The analysis was also stratified by prior number of exposed biologics. The primary comparison group were RA patients starting biologic DMARD (BDC), and we also compared with non-biologic DMARD

(DC).

Results: A total of 1456 RA patients initiated ABA and 3222 a BDC during the study, representing total patient years of drug exposure (total follow-up time) of 2396.6 (4613.9) and 8576.5 (10462) respectively. The ABA patients were older, had longer RA duration, worse disease severity, more comorbidities and more exposure to prior DMARD use (Table 1). HRs are presented in Table 2. The results were similar when comparing with those initiating DC (1663 patients with 4340.0 patient years of drug exposure, 5215.7 follow-up time). **Table 1. Baseline mean (SD) characteristics of ABA and biologic comparison cohorts.**

	ABA (N=1456)	**BDC (N=3222)**
Age, yrs	61.57 (12.70)	60.77 (12.89)
Male sex %	14.49	15.70
Education, yrs	13.79 (2.33)	13.79 (2.34)
RA duration, yrs	16.66 (12.24)	16.28 (12.03)
HAQ (0-3)	1.33 (0.66)	1.22 (0.69)
Pain VAS (0-10)	5.61 (2.70)	5.03 (2.81)
Global VAS (0-10)	4.92 (2.41)	4.50 (2.47)
Body mass index (kg/m^2)	29.11 (7.24)	28.87 (7.12)
Cancer ever -%	26.51	26.08
Current smoker- %	4.95	5.52
Past smoker - %	42.86	45.13
IV antibiotics -%	0.41	0.28
Lifetime DMARD use	2.88 (1.86)	2.68 (1.73)
Lifetime biologic use	1.93 (1.14)	1.54 (1.05)
Methotrexate (MTX) -%	51.99	53.79
DMARDs not MTX - %	23.76	26.51
Hydroxychloroquine - %	15.11	17.23
Prednisone - %	42.65	35.63
Comorbidity index (0-9)	2.13 (1.67)	2.01 (1.65)
Hypertension - %	38.55	37.51
Diabetic - %	12.09	12.26

Table 2. Hazard ratios (95% CI) of incident events comparing ABA with other biologics.

	ABA vs BDC	
	Crude	**Adjusted**
All malignancies except skin cancer	1.46 (0.80 – 2.63)	1.18 (0.59 – 2.36)
Skin cancer	1.42 (0.76 – 2.64)	1.08 (0.52 – 2.22)
All hospitalized infections	0.83 (0.43 – 1.58)	0.52 (0.33 – 0.79)
Lupus	1.76 (0.50 – 6.10)	2.89 (0.74 - 11.36)

Conclusion: We found a trend of channeling with ABA, where patients starting ABA had worse disease outcomes and higher prior use of DMARDs. After adjustment there appeared to be less difference in the adverse events studied for both comparisons cohorts with exception of increased lupus co-diagnosis and statistically significant decreased hospitalized infections for ABA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: For twenty years, the Epstein-Barr Virus (EBV) has been suspected to contribute to Rheumatoid Arthritis (RA). Immunity against EBV is impaired in RA. RA patients have high titer anti-EBV antibodies [1]. They also have defective EBV specific suppression by T cells. This contributes to a higher risk of developing lymphoma [2]. We hypothesized that, in RA patients, immunosuppressive drugs may enhance the risk to develop LPD (lymphoproliferative disorders), as it is seen in post transplant patients [3]. We have previously shown that Methotrexate and TNF alpha antagonists do not increase EBV load in RA [4,5]. Our purpose is to monitor EBV load in peripheral blood mononuclear cells (PBMC) of RA patients treated with 2 recent bDMARDs: Abatacept (CTLA4 Ig) a T cell activation inhibitor, and Tocilizumab, an anti IL6 receptor antibody to test whether they may enhance EBV load and lymphoma risk.

Methods: Patients :We included 90 patients with RA, 55 treated by abatacept (+/- methotrexate) and 35 treated with tocilizumab (+/- methroexate) followed at the Sainte-Marguerite Hospital Rheumatologic Department Marseille. All patients fullfilled the 1987 American College of Rheumatology criteria. All patients gave informed consent. (Patients Characteristics, Table1) Quantification of viral load - PBMC were separated on Ficoll gradient

- DNA was extracted and quantified by real time PCR [5].
- Quantification of EBV copy number

The Raji EBV positive Burkitt lymphoma cell line, containing 50 copies of EBV per cell, was used as external standard. Real time quantitative PCR (LightCycler, Roche Diagnostics) was performed on 500 ng of DNA. A 214 bp sequence of the Internal Repeat was amplified. Two internal probes were used to improve specificity. Statistics : Generalized estimating equation were used to test whether EBV load is influenced by treatment

Results: Abatacept does not enhance EBV mean load after 3 years of treatment. No lymphoma occured. Tocilizumab was associated with a significant decreased EBV load during time ($p = 0.021$). None of the patients had a detectable load at 36 months. No lymphoma occured.

Conclusion: Reliable tool to monitor EBV load No obvious change of EBV mean load under treatment with tocilizumab and abatacept Referances 1] Alspaugh M, et al. Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: For patients with rheumatoid arthritis (RA) receiving a biologic disease-modifying antirheumatic drug (bDMARD), the current standard of care is to use the bDMARD concurrently with a conventional synthetic DMARD (csDMARD) such as methotrexate (MTX). However, in reality, many patients may not take MTX for various reasons. This analysis aims to evaluate the trend of using bDMARDs as monotherapy in US RA patients, and to identify patient factors associated with use of monotherapy bDMARD.

Methods: Data were drawn from the Adelphi RA-DSP, a cross-sectional survey of US rheumatologists and their RA patients, using samples from the 1st quarter (Q1) of 2011 and Q1 2014. Rheumatologists provided information on patient demographics, insurance status, drug treatment, and patient involvement in their treatment decisions (scale: 1–5, with 4 or 5 considered to be indicative of high involvement). Patients who were currently prescribed a bDMARD without a csDMARD (monotherapy) were compared to those receiving a bDMARD in combination with a csDMARD (combination therapy). Multivariate analysis was performed to identify independent patient characteristics associated with mono- or combination therapy.

Results: Included in the analysis were 843 RA patient records (2011: n = 453, 2014: n = 390) with mean age of 55.4 years, 72.9% female, 72.1% Caucasian, 67.7% commercially insured, 22.4% on Medicare, and 6.4% on Medicaid. Overall, 20.9% of patients currently received bDMARD monotherapy (n = 176) and 79.1% currently received combination therapy (n = 667). Overall, there was no statistically significant difference in the proportion of patients receiving monotherapy between 2011 and 2014 (20.1% vs. 21.8%, P = 0.553). However, in the subgroup of non-tumor-necrosis-factor-inhibitor (non-TNFi) users (n = 192), significant increase was seen over time in use of monotherapy bDMARD (18.2% in 2011 vs. 32.3% in 2014, P = 0.030). While among TNF users, there was no statistically significant change over time in patients receiving TNFi monotherapy (20.6% in 2011 vs. 18.5% in 2014, P = 0.553). Multivariate analysis showed that, among patients receiving TNFi, they were more likely to receive it as monotherapy if they were Caucasian (odds ratio (OR) [95% CI] = 1.772 [1.015–3.093], P = 0.044). TNFi receiving RA patients were less likely to receive monotherapy when they were insured via Medicare (OR = 0.473 [0.235–0.951], P = 0.036), or were prescribed adalimumab (OR = 0.468 [0.279–0.784], P = 0.004) or infliximab (OR = 0.379 [0.199–0.723], P = 0.003). Among patients receiving non-TNFi bDMARD, they were more likely to receive it as monotherapy when prescribed tocilizumab (OR = 2.233 [1.076–4.635], P = 0.031), but less likely if perceived by rheumatologists to be highly involved in their treatment decisions (OR = 0.289 [0.107–0.783], P = 0.015).

Conclusion: The current study found no significant change in overall monotherapy bDMARD use from 2011 to 2014 in the US. However, there was a significant increase in the use of non-TNFi bDMARD as monotherapy from 2011 to 2014, mostly driven by anti-IL6 therapy.

Effects of Baseline Patient Characteristics on Baricitinib Efficacy in Patients with Rheumatoid Arthritis

Joel M. Kremer[1], Mark C. Genovese[2], David Muram[3], Jinglin Zhong[4], Jahangir Alam[3] and Michael Schiff[5], [1]Albany Medical College, Albany, NY, [2]Stanford University Medical Center, Palo Alto, CA, [3]Eli Lilly and Company, Indianapolis, IN, [4]Quintiles, Rockville, MD, [5]Rheumatology, University of Colorado, Denver, CO

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : This analysis assessed the effects of baseline patient characteristics on the response to baricitinib treatment in patients with rheumatoid arthritis (RA) and incomplete responses to conventional disease-modifying antirheumatic drugs (cDMARDs).

Methods: This post hoc analysis used pooled data from two phase 3, double-blind, randomized, controlled trials of 6-12 months' duration in patients with RA and an incomplete response to cDMARDs. Pooled clinical outcome data (e.g., ACR20 response, change from baseline in DAS28-hsCRP score, percent of patients who achieved SDAI score ≤11) for patients who received baricitinib 4 mg or placebo were summarized based on categories of baseline characteristics: age, gender, ethnicity, baseline disease activity, RF/ACPA serology, and time from RA diagnosis.

Results: Patients who received baricitinib 4 mg (n=714) achieved improved clinical outcomes compared to those who received placebo (n=716) in these trials, regardless of baseline characteristic subgroup (Table). No clear pattern emerged suggesting that any baseline characteristic, including age, gender, ethnicity, RF/ACPA serology, or disease activity at baseline, had a consistent effect on baricitinib efficacy.

Conclusion: No baseline characteristics were found to abrogate baricitinib treatment efficacy. Post hoc analysis of these pooled RA trial data suggests that baricitinib therapy is associated with improved clinical outcomes compared to placebo, regardless of any baseline characteristic categories.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Risk of cardiovascular (CV) disease is increased among rheumatoid arthritis (RA) patients, and high inflammatory burden associated to traditional CV risk factors appears to be the major drivers. Inflammation has a deep effect on metabolism so that lipids may have paradoxical implications in RA, being lower cholesterol levels associated to increased CV risk. Different biologic treatments are effective in controlling inflammation and decreasing the number of CV events, but their effects on lipid profile are conflicting or not well documented. Therefore, the aim of this study was to examine any change between different biologic agents on lipid profile of RA patients.

Methods: Patients affected by RA, according to the 2010 EULAR/ACR classification criteria, exposed at least for one year to RA approved dosage regimens of Abatacept (ABA), Infliximab (INF), or Tocilizumab (TCZ) as first line treatment, or Rituximab (RTX) as second line agent, were retrospectively enrolled in this study. Before and after 24 and 52 weeks from treatment start lipid profile (Total Cholesterol, HDL-C and LDL-C, Tryglicerides) and DAS28 were assessed. The odds ratio (OR) for which treatment approach had the best benefit on patients lipid profile was calculated.

Results: A total of 204 (F/M: 179/25; mean age 54±12 years; mean disease duration 7±3 years) patients were eligible for this study and among them 86 (42%) had received INF, 42 (20.5%) TCZ, 37 (18.1%) ABA, and 39 (19.1%) RTX. After 52 weeks of treatment 101 (49.7%) patients achieved the DAS28-remission: 36 INF, 24 TCZ, 21 RTX, 16 ABA. Moreover we observed a mean increasing of 13% in cholesterol fractions levels compared to baseline (+10% for INF and RTX, +15% for ABA, and +18% for TCZ), with no significant changes in Total Cholesterol/HDL ratio. Among those patients that achieved DAS28-remission, in 63% of TCZ, 50% of INF, 45% of RTX, and 38% of ABA treated patients, respectively, a condition of hyperlipidemia was detectable. Compared to ABA group considered as reference, patients that had received TCZ presented an OR of 2.66 (95%CI 1.07-6.64; P=0.03) to develop hyperlipidemia, while patients that had received INF or RTX presented and OR of 1.64 (95%CI 0.74-3.61) and 1.40 (95%CI 0.56-3.51), respectively. No CV events have been detected during the follow-up period.

Conclusion: We demonstrated that a good disease activity control, and consequently an inflammation decrease, affects lipid profile independently from CV risk. Different biologic agents may have unlike impact on lipid levels, probably by a cytokine modulation on cholesterol metabolism.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Mavrilimumab is an anti-GM-CSF receptor Ab that has recently demonstrated clinical efficacy in Phase 2 studies in rheumatoid arthritis (RA) patients. Predictive biomarkers to identify patients most likely to benefit from new RA therapies such as mavrilimumab would be of great utility. Recent work has demonstrated that a subset of RA patients has autoantibodies to peptidyl arginine deiminase 4 (PAD4), a citrullinating enzyme involved in NETosis and the formation of autoantigens targeted by anti-citrullinated protein antibodies (ACPA). Since PAD4 is expressed by neutrophils and macrophages, key cell types targeted by mavrilimumab, we explored whether anti-PAD4 autoantibodies may be associated with clinical response to mavrilimumab.

Methods: Novel assays to detect autoantibodies reactive with PAD4, PAD3 or PAD2 were developed and used to measure anti-PAD4, PAD3 and PAD2 levels in 288 subjects enrolled in the phase 2a study CP219 and anti-PAD4 and PAD3 levels in 323 subjects enrolled in the phase 2b study 1071. All subjects in the study met the ACR criteria for a diagnosis of RA.

Results: Overall, 35% of the subjects tested positive for anti-PAD4 antibodies and 20% tested positive for anti-PAD3 antibodies. In the phase 2b study 1071 in DMARD-IR patients, the subjects who tested positive for anti-PAD4 were enriched for the presence of ACPA (OR = 54.7, 95% CI = 7.5, 400.0), had higher baseline joint erosion (mean difference = 9.9, 95% CI = 2.6, 17.2) and higher modified total Sharp scores (mean difference = 16.2, 95% C.I. = 3.9, 28.5) than subjects who tested negative. There was a significant treatment-biomarker effect across clinical endpoints ACR20, ACR50, ACR70 and change in DAS28-CRP. Subjects treated with the 150 mg dose of mavrilimumab, the highest dose evaluated, and who tested negative for anti-PAD4 (68% of subjects), had significantly greater benefit from mavrilimumab compared to active placebo (36.7% difference from placebo; odds ratio for ACR50 response = 17.61, 95% CI =3.86, 80.29) relative to subjects who tested positive for anti-PAD4 (8.7% difference from placebo; odds ratio for ACR50 response = 1.46, 95% CI = 0.47, 4.56; P = 0.01 for treatment-biomarker interaction). Similarly, the DAS28-CRP response was enhanced in autoantibody negative (mean difference = -1.44, 95% CI = -1.91, -0.98) compared to autoantibody positive subjects (mean difference = -0.79, 95% CI = -1.45, -0.13; P = 0.022 for treatment-biomarker interaction). Similar trends were observed for an association between greater clinical responses to mavrilimumab relative to placebo in anti-PAD4 negative subjects in the earlier phase 2a trial CP219. Finally, this effect is specific to anti-PAD4 antibodies as no association between response and presence of antibodies to PAD3 was observed, and we only detected very low levels of anti-PAD2 antibodies in the vast majority of RA patients at levels comparable to healthy controls.

Conclusion: Autoantibodies to PAD4 are a promising novel predictive biomarker for the targeted GM-CSF receptor inhibitor mavrilimumab, and further validation of this biomarker in future clinical studies is warranted.

Using Patient Reported Outcomes to Inform a Treat to Target Treatment Approach in RA

Eric M. Ruderman[1], Jennifer Beaumont[2], Emily Bacalao[1], George J. Greene[2], Azra Muftic[2] and David Cella[2], [1]Medicine, Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Medical Social Sciences, Northwestern University Feinberg School of Medicine, Chicago, IL

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The Patient Reported Outcomes Measurement Information System (PROMIS) is an NIH initiative to develop patient-reported outcome measures (PROs) for use across chronic conditions. PROMIS instruments assess outcomes relevant in Rheumatoid Arthritis (RA) including pain interference, physical function social function, fatigue, and depression. We sought to learn whether use of PROMIS instruments could inform the treat-to-target (T2T) approach to RA management, and whether patient reports of disease impact correlate with objective clinical measures. For this study, patients are treated for 1 year using a T2T approach. Using PROMIS item banks, we developed patient-centered targets in five domains: pain, fatigue, depression, physical function, and social function. We report on the preliminary physician assessment of the impact of the PROMIS instruments on their treatment decisions during the year.

Methods: Patients with RA diagnosed by 2010 ACR/EULAR criteria were recruited from our academic clinical practice. At baseline data collection, standard RA assessments included joint counts, RAPID3, and CDAI scores. The research assessment battery included clinical questionnaires, PROMIS CAT's (computer adaptive tests), prioritization of PROMIS domains, and selection of five items that patients felt were most important within their most highly prioritized domain.

Results: The baseline sample consists of 119 RA patients; median age was 57 (range: 21-77) and 91% were female. Approximately 54% (n=57) exhibited moderate or high disease activity (CDAI m=13.4; SD=11.0). At the time of this analysis, 71 patients (60%) had completed 1 year of therapy. CDAI was recorded for 172 post-baseline visits, with 87 (51%) reporting CDAI >10 and 85 (49%) CDAI ≤10. At each visit, physicians were asked whether the PROs influenced their treatment decisions. For patients with CDAI >10 who had a treatment change (in accordance with T2T recommendations), PROs influenced this decision at 18/68 visits. When CDAI was >10 and treatment was not changed, PROMIS data influenced this decision at 15/40 visits. When CDAI ≤10, PROMIS data influenced decisions at 2/17 visits at which treatment was changed and 41/142 at which it was not. When asked whether the PRO data affected their disease management in some other way, physicians reported that it did for 20/262 post-baseline visits.

Conclusion: The PROMIS instrument collects information on patient impact of disease. In 20/85 (23.5%) visits to date, when treatment decisions were made contrary to T2T recommendations, rheumatologists reported that the PROMIS data influenced their care, suggesting that these data may provide relevant information that is not captured on standard, objective disease activity measures. Further analysis will explore other factors that may have affected care decisions, as well as any differential impact of the PRO data on treatment decisions in patients with either low or high disease activity.

Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Tapering of biologics in rheumatoid arthritis (RA) is based on a trial-and-error disease activity guided strategy, because it is not known in advance which patient can successfully taper. Prediction of successful dose reduction or discontinuation of a

biologic could prevent flares and save drug exposition. In the last years, several cohort studies have investigated biomarkers for predicting successful tapering. However, these results have not yet been systematically summarized. The objective of our study was to systematically review studies that address prediction of successful dose reduction or discontinuation of a biologic in RA patients.

Methods: A broad literature search was performed in PubMed, EMBASE and Cochrane Library (November 2015). Studies that examined the predictive value of biomarkers for successful dose reduction or discontinuation of a biologic in RA patients were included. Two reviewers independently selected studies, extracted data and assessed risk of bias. A biomarker was classified as potential predictor if the univariate association was either strong (odds ratio or hazard ratio > 2.0 or < 0.5) or statistically significant. If these data were not provided, other association measures or textual conclusions were used. Qualitative best-evidence synthesis for biomarkers studied multiple times was performed separately for the prediction of successful dose reduction and discontinuation. Biomarkers that were defined in ≥ 75% of the studies as potential predictor were regarded as 'Predictor'.

Results: Out of 3029 non-duplicate articles, 16 articles on 15 cohorts were included. In total, 17/52 and 33/64 biomarkers were studied multiple times for the prediction of successful dose reduction and successful discontinuation of a biologic. Three predictors were identified: higher adalimumab trough level for successful dose reduction (Figure 1); and lower Sharp/van der Heijde erosion score and shorter symptom duration at the start of a biologic for successful discontinuation. Noteworthy, those three biomarkers were only studied twice, meaning that more frequently investigated biomarkers yielded no consistent predictors.

Conclusion: The predictive value of a wide variety of biomarkers for successful dose reduction or discontinuation of a biologic in rheumatoid arthritis has been investigated. We identified only three biomarkers as predictor in just two studies. The strength of the evidence is limited by the low quality of included studies and the likelihood of reporting bias and multiple testing. **Figure 1** Biomarkers for the prediction of successful dose reduction of a biologic

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Prevention of rheumatoid arthritis (RA) was the aim of several clinical trials performed in undifferentiated arthritis (UA). Overall these trials had negative results. As preparatory work revealed that only ~30%, of UA-patients develop RA, we hypothesized that inclusion of patients with a low-risk on this outcome, could dilute a possible positive effect and therefore result in false-negative results. This problem has been described in other fields of medicine and re-analysis of the data after post-randomization exclusion of non-informative patients can be a solution to this problem[1]. We therefore re-investigated the PROMPT-trial[2](1-year course of methotrexate (MTX) versus placebo in UA) after post-randomization exclusion of patients without a high risk on developing RA.

Methods: A validated prediction model[3]was used to determine the risk on RA in all patients included in the PROMPT-trial. Patients with a PPV≥84% (prediction score ≥8) were selected and the efficacy of methotrexate was re-evaluated; similar to previous analyses the primary outcome was progression to RA according to the 1987-criteria during 5 years of follow-up and the secondary outcome was drug-free remission.

Results: Of the 110 included patients, 22 had a high-risk on RA according to the prediction model. In the MTX-arm 6/11 (55%) developed RA after 5 years of follow-up, compared to 11/11 (100%) in the placebo-arm (p=0.011). The time to RA-development was longer in the MTX-arm (median of 22.5 months versus 3 months in the placebo-arm, p<0.001). Drug-free remission was achieved by 4/11 (36%) of patients in the MTX-arm and by 0/11 (0%) of the patients in the placebo-arm (p=0.031). These beneficial effects of MTX were seen in both ACPA-positive and ACPA-negative high-risk UA-patients, but not in ACPA-positive nor in ACPA-negative UA-patients without a high risk on RA-development.

Conclusion: Analysis on patients with a high risk on RA revealed that a 1-year course of MTX delayed and prevented RA-development. This emphasizes the importance of adequate risk prediction in trials that aim to prevent RA. 1. Fergusson D, Aaron SD, Guyatt G, Hébert P. In Vitro Expansion of Treg By Adaimumab Predicts Clinical Response to Therapy in Patients with Rheumatoid Arthritis

Dao Xuan Nguyen, Centre of Rheumatology, Division of Medicine, University College London, London, United Kingdom
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Regulatory T cells (Treg) are potent suppressors of immune responses and are considered a pivotal element in resolving inflammation and autoimmunity. We have previously shown that an increase in CD4 Treg numbers occurs in the peripheral blood of rheumatoid arthritis (RA) patients who have responded to adalimumab but not to the soluble TNF receptor etanercept. Most recently, we demonstrated that adalimumab expands Th17 suppressing Treg by paradoxically promoting membrane TNF–TNFRII binding in RA [1]. We hypothesized that an in vitro Treg expansion assay could predict RA patient's clinical response to anti-TNF antibody therapy.

Methods: RA patients (all fulfilled ACR criteria) who were to begin adalimumab (n=13) were recruited and blood samples taken before (baseline), 3 and 6 months after therapy. Disease activity was assessed using DAS28 and clinical response defined as a drop in DAS28 >1.2 compared to the pre-treatment value. PBMC isolated from RA patients before adalimumab treatment were cultured for 3

day with 10µg/ml adalimumab. On day 3, flow cytomety analysed CD4 and CD8 FoxP3 expression and membrane TNF staining on CD14+ monocytes. Treg expansion was defined as an increase of 45% compared to the unstimulated value.

Results: The addition of adalimumab to PBMC from patients with active RA before adalimumab therapy resulted in a significant increase in monocyte membrane TNF expression (p= 0.0078) and the percentage of CD4 Treg (p= 0.0039) only in patients (n= 9) who then responded to adalimumab therapy as assessed at 3 months post treatment. Moreover, the percentage of CD8+FoxP3+ Treg in PBMC from patients before therapy was elevated by addition of adalimumab in vitro (p=0.0078) and in the peripheral blood of patients analysed at 3 months who responded to therapy. The percentage of CD4 and CD8 Treg expanded by adalimumab in vitro at baseline correlated with the percentage of peripheral blood Treg in patients at 3 months post adalimumab therapy.

Conclusion: CD8 as well as CD4 Treg are expanded by adalimumab in patients with RA. Collectively our data suggest that an in vitro assay based on Treg expansion could predict clinical response to anti-TNF therapy in RA if confirmed in a larger cohort. This predictive test could be of benefit not only as a potential cost saving, prevent risks associated with exposure to numerous anti-TNF agents but represents a step forward to personalised medicine.

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The multi-biomarker disease activity (MBDA) (Vectra® DA) score has been reported to predict disease relapses in patients with rheumatoid arthritis (RA) in sustained remission who tapered disease modifying anti-rheumatic drug in prospective randomized controlled trial.(1) The purpose of the present study was to evaluate MBDA score as predictor of flare or sustained clinical remission after discontinuation of adalimumab (ADA) in patients with established RA from the HONOR cohort.(2,3)It was previously shown that sustained biologic-free remission was possible and associated with deep clinical remission.

Methods: This retrospective sub-group analysis was conducted on 42/51 RA patients from the HONOR study with serum samples available at time of discontinuation. The study enrolled patients receiving ADA and methotrexate who maintained DAS28-ESR remission (<2.6) for ≥24 weeks and who subsequently agreed to discontinue ADA. Clinical disease activity, functional status, and joint damage were recorded at ADA discontinuation (baseline), and after 24 and 52 weeks. MBDA scores, a validated disease activity measure for patients with RA calculated based on serum concentration of 12 biomarkers (remission, ≤25; low, 26-29; moderate, 30-44; high, >44), were determined at baseline.(4) The ability of MBDA scores and patient characteristics to predict flare (DAS28-ESR ≥3.2) or sustained clinical remission (SC-REM) (absence of flare with DAS28-ESR <2.6 at all visits) at 6 months and 1 year were evaluated by the area under receiver operator curves as well as Kaplan-Meier estimates, Wilcoxon rank sum test and Cochran-Armitage trend test. Any p-value <0.05 was considered statistically significant and p-value <0.1 marginally significant.

Results: At ADA discontinuation, all patients had DAS28-ESR <2.6 with 81% female, 69% RF+, 81% ACPA+ and 30- month mean disease duration. The median MBDA score was 24.5 [interquartile range: 14.3, 30.8] with 22 (52.4%) patients in remission, and 6 (14.3%) low, 9 (21.4%) moderate and 5 (11.9%) high MBDA score. At 52 weeks, flare and SC-REM were observed in 12/42 (28.6%) and 19/42 (45.2%) patients, respectively. Rate of flare and percentage of SC-REM by MBDA category (remission/low/moderate/high) were 13.6%/50.0%/33.3% and 60.0% (p=0.033) and 63.6%/33.3%/33.3% and 0% (p=0.0066), respectively. Univariate regression analyses identified MBDA score, DAS28-ESR and disease duration as predictors of flare at 52 weeks ($p \leq 0.05$). In a multivariate linear logistic regression model, MBDA scores were marginally associated with flare and SC-REM after adjusting for disease duration.

Conclusion: These findings suggest that the MBDA score could predict flare and biologic-free SC-REM in RA patients in stable clinical remission, undergoing ADA withdrawal while maintaining MTX treatment in a clinical setting and point-out to the potential utility of the MBDA score for guiding treatment decisions in patients receiving biologics. **References:** 1. Can GP88 (Progranulin) be Used to Predict the Efficacy of Infliximab?

Masao Sato[1], Masao Takemura[2], Yasuko Yamamoto[3] and Kuniaki Saito[4], [1]Rheumatology, Matsunami General Hospital, Gifu, Japan, [2]Advanced Diagnostic System Research Laboratory, Fujita Health University, Toyoake, Japan, [3]Disease Control and Prevention, Fujita Health University, Toyoake, Japan, [4]Disease Control and Prevention, Fjita Health University, Aichi, Japan

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: GP88 (progranulin; PGRN) is a glycoprotein with a molecular weight of approximately 88,000 Da and is thought to play an important role in immune response and tumor proliferation, among other functions. An increasing number of studies have examined anti-inflammatory effect of GP88 in autoimmune diseases. We also reported that GP88 may become a new molecular biomarker for rheumatoid arthritis (RA) (Inflammation 37:1806-13, 2014). We examined the correlation between the efficacy of infliximab (IFX) and serum GP88 concentration in RA patients treated with IFX.

Methods: First, we measured the concentration of GP88 by using ELISA in the serum of 101 RA patients who met the 2010 ACR/EULAR classification criteria and 75 patients with undifferentiated arthritis (UA) prior to starting treatment, who were being treated at a specialist rheumatology outpatient clinic, and compared the results with those from the serum of 149 (men n = 78, women n = 71) healthy individuals undergoing medical check-ups as the control group. Next, we measured GP88 concentration during IFX treatment (start of administration was set as the baseline, and measurements were taken at 14 weeks and 52 weeks or at the time when IFX was discontinued or the dose was changed) by using the frozen stored serum of 50 RA patients who received IFX and were unresponsive to methotrexate.

Results: The GP88 concentration in healthy individuals was 40.5 ± 14.3 ng/mL in men (25–68 years: mean 54.2 years) and 41.0 ± 10.9 ng/mL in women (28–69 years: mean 51.0 years), and there were no gender or age differences. The GP88 concentration was 65.7 ± 2.72 ng/mL in RA patients and 57.4 ± 1.67 ng/mL in UA patients, indicating significantly higher levels in RA patients compared to those in UA patients ($p < 0.01$) and healthy individuals ($p < 0.001$). The background of RA patients treated with IFX was women, n = 40; men, n = 10; aged 26–81 years; mean 60.3 years. The oral methotrexate dose was 6–16 mg/week and IFX dose was 3 mg/kg. The GP88 concentration (mean value) for all 50 patients at each measurement point was baseline: 63.5 ng/mL; 14 weeks: 65.5 ng/mL; and 52 weeks: 69.7 ng/mL. These results indicate an increasing trend, but there were no significant fluctuations. Upon classification of the

groups based on IFX efficacy [effective n = 25 (patients continuing IFX treatment at 52 weeks), primary failure n = 4 (ineffective from the beginning), secondary failure n = 14 (effect weakened midway through treatment), adverse events n = 7 (patients who stopped treatment owing to development of malignant tumor, reaction at administration, among others)], the mean baseline GP88 concentrations (ng/mL) were 62.8, 48.4, 67.1, and 67.5 respectively. These results showed a low level of efficacy in patients with primary failure and higher levels in patients with secondary failure or adverse events. The mean GP88 concentration was 65.2 ng/mL at 52 weeks in responders, but increased to 82.5 ng/mL in patients with secondary failure when they switched from IFX to another drug.

Conclusion: Based on these results, measurement of the GP88 concentration may be useful for auxiliary RA diagnosis, predicting the efficacy of IFX in RA patients, and predicting weakening of the effect during treatment.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: As part of the update of the EULAR recommendations for the management of RA, we performed a systematic literature review to assess the safety of synthetic (s) and biological (b) DMARDs for the management of RA.

Methods: Observational studies comparing any DMARD with another intervention for the management of patients with RA were identified by searches in Medline, Embase and Cochrane datasets (2013-2016). Interventions were any bDMARD, sDMARD or glucocorticoid and a comparator group was required for the study to be included. All safety outcomes were included. Observational studies, including registries, have been chosen, as they better reflect routine care and have a longer follow-up. Risk of bias (RoB) was assessed according to the Hayden's tool.

Results: Of 4,436 articles screened, a total of 25 papers met the inclusion criteria: 15 dealt with serious infections, 4 focused on cancer, 4 on cardiovascular events and 2 on interstitial lung disease. Studies were heterogeneous precluding meta-analysis. Five studies on serious infections were found and they showed no increased risk of serious infections in bDMARDs (both TNFi and non-TNFi) compared to conventional (c)sDMARDs (Table). The 2 low RoB studies showed no increased risk, while 2 of the 3 high RoB studies showed an increased risk of serious infections (Table). Eight studies, 1 at low RoB, 4 moderate RoB and 3 high RoB, showed no difference in the risk of serious infections between different bDMARDs (Table). One study at low RoB found no increased risk of herpes zoster in TNFi or non-TNFi. Based on 3 studies, all at low RoB, (overall) cancer does not occur more frequently in bDMARDs vs csDMARDs. The same holds true for solid cancers (2 low RoB studies). Based on one low RoB study, non-melanoma skin cancer does not occur more frequently in TNFi or rituximab vs csDMARDs; it may occur more frequently with abatacept (aHR 15.3 [95%CI 2.1; 114.0], but this is based on 2 cases only. One low RoB study addressing infections also analysed mortality, finding that mortality may be lower in bDMARDs, namely etanercept (aHR 0.7 [0.5; 0.9]), vs csDMARDs.

Conclusion: No increased risk of infections was found in patients under bDMARDs (TNFi or non-TNFi) vs csDMARDs, which contrasts to previous findings and possibly reflects an adaptation of clinical practice to avoid the risk of infections. No increased risk of malignancies was found, which is in line with previous findings. Table: Risk of serious infectious in patients on bDMARDs (observational studies)

Risk Factors of Pneumocystis Jiroveci Pneumonia (PJP) in Patients with RA and Sulfasalazine As a Possible Protective Agent

Shinji Motojima[1], Tamao Nakashita[2], Akira Jibatake[1], Akira Yoshida[1] and Yoshiki Yamamoto[1], [1]Department of Rheumatology and Allergy, Kameda Medical Center, Kamogawa city, Japan, [2]Department of Rheumatology and Allergy, Kameda Medical Center, Kamogawa-city, Japan

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pneumocystis jiroveci pneumonia (PJP) is a serious complication during the treatment in patients with variety of rheumatic disease. Postmarketing surveillance of infliximab and etnercept in Japan reported that the incidence of PJP was higher than those in Western countries. Harigai et al. reported that in patients under the treatment with infliximab, there are 3 risk factors, i.e., more than 65 years of age, more than 6 mg/day of prednisolone (PSL), and coexisting pulmonary diseases (Harigai M, N Engl J Med 2007). We again tried to find risk factors of PJP in this study and also possible protective factors.

Methods:

Subjects were 310 patients with RA. Out of 310 patients, PJP developed in 26 patients. Patients who took cotrimoxazole were excluded from the control group even duration of administration was short. Diagnosis of PJP was done according to the report of Harigai et al. Diagnosis of PJP was definitive if P. jiroveci was found on microscopical analysis of respiratory samples from patients with clinical manifestations, hypoxemia, and radiologic findings compatible with PJP. The diagnosis of PJP was presumptive if a patient met all three criteria and had either a positive PCR test for P. jiroveci DNA or an increased serum level of (1→3) β-d-glucan with an appropriate response to the treatments for PJP. We picked up items that may relate to the development of PJP, such as age, gender, stage, class, duration of illness, presence of interstitial lung disease (ILD), and drugs for the treatment of RA including the dose. Univariate and

multivariate analysis were done to find out risk and protective factors.

Results: Out of 26 cases of PJP, 4 cases were definitive and 22 cases were presumptive. By univariate analysis, advanced age, advanced stage and class, high daily dose of prednisolone (PSL), and high weekly dose of MTX were significantly related to the development of PJP. Moreover, patients with PJP had significantly higher % of ILD, and higher % use of bDMARDS. However, patients with PJP had significantly lower % use of sulfasalazine (SSZ) (7.7 % vs. 30.0 %). By multivariate analysis, 5 significant positive coefficients for the development of PJP were obtained, i.e. advanced age, advanced class, high daily dose of PSL, high weekly dose of MTX, and use of bDMARDS. Use of SSZ tended to be related to no development of PJP ($p < 0.1$). SSZ has been shown to be protective for P. jiroveci in vitro (Wang J, PRoS Pathogen 2010).

Conclusion: We obtained factors related to the development of PJP which suggest that RA is highly active and advanced. In contrast, SSZ may act as protective agents, but further study is needed to reach definitive conclusion.

Patient Survey Regarding Generic and Bio-Similar Drugs

Tsukasa Matsubara[1], Tamami Yoshitama[1], Kou Katayama[1], Shigehito Kiyokawa[2], Nobumasa Miyake[2], Motohiro Oribe[2], Akira Sagawa[2] and Keiko Funahashi[3], [1]Japanese clinician biologics research group, Kobe, Hyogo, Japan, [2]Japanese clinician biologics research group, Kobe, Japan, [3]Clinical Research, Matsubara Mayflower Hospital, Kato, Japan
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

In Japan the market share for generic drugs is 50%, lower than that in Western nations. This is partially due to Japan's insurance system, but the reasons why the patients themselves turn down the opportunity to switch to a generic drug when asked at the pharmacy are not clear. In addition, the use of bio-similar drugs became possible in Japan in September of 2015, but the degree of knowledge that patients have regarding them is unknown. Therefore we carried out a patient survey about generic and bio-similar drugs.

Methods:

The survey was carried out amongst patients being treated at research group member facilities. It was an anonymous written survey. After the section on patient background (age, gender, disease history) was completed, patients were asked their impressions of generic drugs, their attitudes towards changing to a generic, whether or not they had ever experienced an adverse effect with a generic drug, what knowledge they had regarding bio-similar drugs, and if they had any interest in or experience with using bio-similar drugs. This research and survey was conducted with the approval of the ethics committee.

Results:

Participants were from 20 facilities, 2384 patients, 83% female, with those in their 60s the majority. Many, 43%, had a disease history of over 10 years. Their impressions of generic drugs were equally good and bad, 45% each. However, those that had a bad experience with a generic (lessening of effect or an adverse event) only comprised 7%, leading to the conclusion that the bad impressions were not the result of experience. Regarding the choice of bio-similar drugs, 14% percent had heard of them, and about half stated no interest in bio-similar drugs, even after seeing explanatory materials. Regarding changing to a bio-similar drug, 70% said they would rely on the opinion of their physician. 11% of participants answered that they would switch for the cost benefits.In a recent online survey,

approximately 28% of physicians expressed a desire to use generic drugs, while 65% of patients expressed interest in using them, showing a gap between the two groups. In the current survey we found that there is anxiety regarding adverse events, and that resistance to a change in medication is more common in RA patients than with those of other illnesses. These factors may explain the tendency of RA patients to leave the decision of whether to use a bio-similar drug up to the physician instead of choosing one themselves.

Conclusion:

There is not enough education regarding switching to generic drugs and bio-similar drugs. The authors recommend that new avenues of patient education be explored, in order to help patients feel competent in making decisions about their medications.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of this systematic review was to evaluate the clinical evidence on the efficacy of different drug regimens for the treatment of early rheumatoid arthritis (RA). Different cut-off points have been used to define early RA. For this review we used duration of symptoms of ≤2 years, since this limit has been used in several trials.

Methods: We conducted an overview of systematic reviews. We searched for reviews indexed in The Cochrane Library and PubMed through June 2016. Our search strategy was restricted to reviews published in English with efficacy data. Two reviewers screened the list of included references in each review independently. Specific criteria included: results clearly specified for all patients (or subgroup reported) in study having ≤2 years of duration of RA, and at least six months of therapy and follow-up. Data extraction and assessment of the methodological quality of the trials using the Cochrane risk of bias tool was performed by one reviewer and crosschecked by another. Our primary outcome was the proportion of patients achieving an American College of Rheumatology (ACR) 50% response. Secondary outcomes included ACR improvement criteria of 20 and 70%, and safety. We performed direct comparison meta-analyses when data was available for 2 or more studies with the same interventions and outcomes.

Results: Out of 684 reviews, over 764 relevant citations evaluating steroids, DMARDs or biologics were reviewed. There were 6 type of comparisons, including: i) conventional DMARDs vs placebo; ii) conventional DMARDs monotherapy vs another conventional DMARD monotherapy (e.g., methotrexate (MTX) vs sulfasalazine (SSZ); iii) combination therapy with conventional DMARD vs monotherapy (e.g., MTX+SSZ, MTX+Cyclosporine, MTX+ bucillamine, MTX+ doxycycline); iv) combination therapy with conventional DMARDs and added prednisone vs monotherapy (with or without prednisone); v) combination therapy with conventional DMARDs and added prednisone vs combination therapy with conventional DMARDs; and vi) combination therapy with biologic DMARDs vs conventional DMARD monotherapy. ACR 50 response criteria rates were statistically significantly improved with most combination therapies (except MTX + cyclosporine, MTX + Bucillamine) compared with MTX alone at 1 and 2 years (RRs ranged between 1.4 (95%CI 1.1 to 1.6) and 10.3 (95% CI 1.5 to 69.6)). Similar effects were observed with ACR 20 response criteria rates (RRs ranged between 1.2 (95%CI 1.0 to 1.4) and 3.0 (95%CI 1.3 to 7.1)). No differences were observed among the various conventional DMARD monotherapies examined in these trials.

Conclusion: In patients with early onset disease of less than 2 years and active disease, MTX in combination with other conventional or biologic DMARD results in greater ACR responses compared with MTX or DMARD monotherapy. These findings suggest that patient may benefit by early combination therapy, either at onset, or possibly by adding a second conventional or biological DMARD early on.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There is limited information for the rate of hepatitis B reactivation in inflammatory arthritis patients. We conducted a systematic review and meta-analysis, assessing hepatitis B reactivation rates in patients who were with resolved or chronic hepatitis B, receiving non-biologic DMARDs, TNF-alpha inhibitors or other biologics and whether receiving antiviral prophylaxis.

Methods: We utilized the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) statement as the standard for protocol development. Electronic searches were conducted in Pubmed, Medline and EMBASE using OVID through 12/31/2015. A search strategy was developed for each database by combing the medical subject headings (MeSH) and/or text terms from following inclusion criteria: participants (rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis, with resolved, or chronic hepatitis B infection), interventions (non-biologic DMARDs, TNF-alpha inhibitors and non-TNF biologics), and outcomes (hepatitis B reactivation). Four reviewers independently extracted study data and assessed quality of study with the Newcastle-Ottawa scales. To determine the pooled hepatitis B reactivation rate, the variances of the raw proportions were stabilized using a Freeman-Tukey-type arcsine square root transformation, using a random-effects model.

Results: 25 studies that met our inclusion criteria, including 2 case series, 10 prospective and 13 retrospective observational studies. The overall pooled rate of hepatitis B reactivation was 1.6% (**table1**, 95%CI, 0.8-2.6%, I^2: 51.0%) in patients with resolved hepatitis B and 14.6% (95%CI, 4.3-29.0%, I^2: 89.6%) in patients with chronic hepatitis B. Similar rates were observed in resolved patients on TNF-alpha inhibitors (Pooled rate: 1.4%, 95%CI, 0.5-2.6%) and non-biologic DMARDs (Pooled rate: 1.7%, 95%CI, 0.2-4.2%); whereas a higher rate was observed in other biologics users (Pooled rate: 6.1%, 95%CI, 0.0-16.6%). We also found the reactivation rate was lower in patients with chronic hepatitis B infection who received antiviral prophylaxis on TNF alpha treatments (**table 2**, Pooled rate: 4.4%, 95%CI, 0.4-11.7%), than those who did not (Pooled rate: 15.6%, 95%CI, 2.3-35.7%).

Conclusion: We found the hepatitis B reactivation rate in inflammatory arthritis patients was low in resolved patients and moderate in chronic hepatitis B patients. Further, higher rates were observed in chronic hepatitis B patients without antiviral prophylaxis. **Table 1. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine predictive factors of disease flares, including drug trough serum levels and anti-drug antibodies (Ab) in patients with rheumatoid arthritis (RA) or polyarticular psoriatic arthritis (PsA) in clinical remission (CR) or low disease activity (LDA) receiving TNF inhibitors during a 1-year follow-up.

Methods: Prospective, multicentre study of RA and PsA patients attended in 3 hospital outpatient clinics (Catalonia, Spain) treated with ADA, ETN or IFX for ≥3 months in CR or LDA measured by DAS28-ESR at ≥2 consecutive visits. Ab and trough serum levels (ELISA

Kit Promonitor®, Progenika SA, Spain) were determined at 0, 4, 8 and 12 months. Disease flare was defined as DAS28>3.2 and a delta DAS28 > 0.6 during the 1 year follow-up compared with visit 0.Variables collected: demographic data; disease activity, diagnosis; disease duration; biologic drug; reduced dose, and concomitant csDMARD therapy. Differences between patients with and without disease flare were studied by univariate analysis. Associations between baseline variables and disease flares according to TNFi used were established using multivariate logistic regression analysis.

Results: 187 patients (RA 103 [57%], PsA 81 [43%]), 66% female, mean age 57±12 years, were included. 138 (74%) patients were in CR, 49 (26%) were on LDA, 69 ADA, 83 ETN and 35 IFX. Mean treatment duration was 60±41 months. Thirty-three out of 166 patients (19.9%) who completed follow-up had a disease flare (10 ADA, 13 ETN, 10 INF), 15 at month 4, 13 at month 8 and 5 at month 12. Six patients developed Ab (3 ADA, 3 INF): 3 at visit 0 and 3 during follow-up, of whom five had a disease flare. Patients with disease flares had lower mean baseline trough serum TNFi levels although the difference was significant only for ADA: 1.7 (1.1-2.7) µ/ml vs. 7.1 (3.5-11.4) $p<0.01$, higher baseline DAS28 (2.5±0.7 vs. 2.0±0.6 $p<0.01$), and a lower frequency of remission (54.5% vs. 78.9% $p<0.01$). In ADA-treated patients, but not in those treated with ETN and INF, drug serum levels at baseline were associated with disease flare in the logistic regression analysis (AUC 0.919). No other factors associated with disease flare were identified. During flares, trough serum levels of the three TNFi decreased in comparison with baseline values (median ADA 1.7 *vs*. 0.1, INF 1.3 *vs*. 0 and ETN 1.9 *vs*. 0.3. although the difference was significant only for ETN ($p<0.01$).

Conclusion: Over a one-year follow up, disease flares were observed in 20%of RA and PsA patients treated with TNFi for a prolonged period who achieved clinical remission/low disease activity. Ab explained only 15% of disease flares. A higher DAS28 and lower drug trough serum levels of ADA at baseline (but not ETN or INF) were associated with disease flare. During disease flares, there was a pronounced decrease in TNFi drug serum levels.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: discovery of biomarkers that can identify pretreatment patients who will respond to biologic DMARDs therapy is one of the major interests in RA. We proposed to test the possible predictive role of RF isotypes IgM and Ig A, anti-CCP, anti-mutated citrullinated vimentin (anti-MCV), 14-3-3 eta protein and COMP on a group of patients treated with anti-TNF α agents.We have also assessed the status of these biomarkers and response to biologic therapy.

Methods: prospective and observational study including 64 patients followed 12 months with active RA, uncontrolled by conventional synthetic DMARDs or declared nonresponders to one of the biologic DMARDs and required switch to another biologic DMARDs. Clinical assessment was performed at 0, 6 and 12 months according to ACR criteria approved by OMERACT and evaluation of treatment response according to EULAR criteria (good /moderate /nonresponder).

Results: mean age was 57.55 ± 9.427 years, of the 64 patients included in the study 59 (92.2%) were women and 5 (7.9%) men. At 6 months, 7 patients were declared nonresponders, 38 achieved a moderate response and 19 good response. Following baseline immunological parameters titres and the response at 6 months, general tests have identified significant differences between groups.Tests for identifying differences between the groups showed that lower titres of both RF isotypes , anti-CCP, 14-3-3 eta protein and COMP had predictive value on achieving a good EULAR response at 6 months. Grouping patients in 2 categories (responders/nonresponders), just 14-3-3 eta protein and anti-CCP maintained their predictive value for the response at 6 months.

	Nonresponder	**Moderate response**	**Good response**	**Comparison of responses (p value)**	**Nonresponder**	**Responder**	**Comparison of responses (p value)**
N	**7**	**38**	**19**		**7**	**57**	
RF type Ig M	132.35± 99.602	157.22±131.47	51.36±95.359	**0.01629**	132.35± 99.602	121.93±129.92	0.57168
RF type Ig A	122.81±99.876	102.08±128.33	22.45±61.256	**0.03336**	122.81±99.87	75.54±116.282	0.30787
Anti-MCV	74.04±47.951	80.06±149.543	33.77±113.069	0.45914	74.04±47.951	64.63±139.174	0.86037
14-3-3 eta protein	0.99±0.888	0.28±0.469	0.51±0.580	**0.04518**	0.99±0.888	0.36±0.515	**0.04042**
Anti-CCP	146.16±41.688	113.65±50.448	60.82±26.331	**0.00011**	146.16±41.68	96.04±50.355	**0.02834**
COMP	1042.2±181.71	1032.8±188.67	746.04±130.09	**0.00000**	1042.2± 181.717	937.27±218.10	0.22727

After 12 months, 1 patient was declared nonresponder, 11 achieved moderate response and 14 good response. For this visit, lower baseline titres for RF type Ig M (92.93±120.22U/ml, p=0.01032) and Ig A (49.96±98.08 U/ml,p=0.00247) had predictive value for achieving a good response at 12 months . We didn't obtain other informations grouping patients in 2 categories . Regarding the status of biomarkers and treatment response, the only differences were obtained for COMP (p = 0.0001) at 6 months for good response and RF type IgA (p=0.0041) for good response at 12 months. Using multivariate logistic regression methods we obtained a statistical model for predicting the response at 6 months including normal values for 14-3-3 eta protein, anti-CCP and COMP. The model is a good approximation for the situation analyzed (Hosmer and Lemeshow according test $\lambda^2 = 5.795$, $p = 0.670 \geq 0.05$) with a predictive response accuracy of 89.1%.

Conclusion: because until now has not been discovered a single biomarker capable of distinguishing pretreatment responders versus nonresponder, in the future a version using multiple biomarkers could increase accuracy for identifying pretreatment these patients.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment options in rheumatoid arthritis (RA) have expanded significantly over recent years, and several agents are now available for oral, subcutaneous (SC) or intravenous (IV) use. Route of administration may be an important differentiator between drugs that are used to treat RA, especially if patient preferences influence adherence and outcomes of therapy. The purpose of this study was to investigate patient preferences for attributes associated with RA treatments in Lebanon.

Methods: A national, multicenter, cross-sectional patient survey was designed to collect data across several private and university hospital clinics on the typical RA patient profile. Participants were asked about their use of RA therapies, preferences for oral, IV or SC therapy and their physician's role in their decision-making process. Data were analyzed using the Chi-square test and Mann-Whitney test.

Results: A total of 693 patients, consecutively recruited over a fixed period of 3 months, completed the survey. The median patient age range was 51–60 years (28.7%). The majority of respondents were female (83%). Over 81% of patients had health coverage. A large proportion (80%) of patients had established RA, with only 3% having early RA. One-third of patients (34.2%) were in DAS28 remission, while 32.9% had a DAS28 score of 3.3–5.1. Oral was the most common route of DMARD administration. Almost 60% of patients received medication by this route only, with a further 27% using the oral route in combination (with either IV or SC). Patient route preference mirrored this trend with almost two-thirds of patients (64%) preferring the oral route (**Table 1**). There was a significant association between route of administration and therapy preference. Patients with an IV route had a similar preference for IV therapy (43%) and oral therapy (40%). SC patients also had split preferences, with 41% preferring oral therapy and 38% SC therapy. Those with an oral route overwhelmingly preferred oral therapy (82%) (**Table 2**). The physician's advice was cited as the main influence when choosing a treatment, with over half (53%) of patients giving this as their top choice.

Conclusion: The majority (64%) of patients preferred the oral route of administration. There was a strong correlation between the route of administration in use and the preference. The patients' preferences of administration were influenced mainly by the physician, followed by experience with current or previous treatments. Understanding patient preferences may help to inform provider and payer decisions in treatment selection that may enhance patient adherence to therapy.

Table 1 Patient disease information			
Variable	**Category**	**Number**	**Percentage**

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: In the SIRROUND-D study, sirukumab, a human anti–IL-6 cytokine monoclonal antibody, significantly reduced radiographic progression after 52 wks of treatment vs placebo in patients (pts) with active rheumatoid arthritis (RA) despite DMARD treatment. This post-hoc analysis of data from that study was intended to identify potential predictors of radiographic non-progression after 52 wks of sirukumab treatment.

Methods: In this double-blind, Phase 3 study, 1,670 pts with active RA refractory to DMARDs were randomized (1:1:1) to SC sirukumab 50 mg q4w, sirukumab 100 mg q2w, or placebo q2w. In the placebo group, pts with <20% improvement in swollen/tender joints at Wks 18 or 40 or still taking placebo at Wk 52 were re-randomized to sirukumab . The change from baseline (BL) at Wk 52 in the modified Sharp/van der Heijde (SHS) radiographic damage score was evaluated as a co-primary endpoint. For this post-hoc analysis, radiographic non-progression was defined as a change from BL in the SHS score ≤0. Logistic regression analysis was used to select the list of factors associated with radiographic progression. Regression (with interaction term)/ANOVA was used to find factors that have interaction effects with treatment groups. Odds ratios and relative risk were used to compare radiographic progression between sirukumab and placebo under different levels of the factor. Observed SHS scores were used for all analyses.

Results: In this analysis, 1,374 pts with radiographs taken at BL and post-BL were included. The proportion of radiographic non-progressors (change in SHS ≤0) at Wk 52 was significantly greater with both sirukumab doses (50 mg q4w, 55%; 100 mg q2w, 61%) vs placebo (41%; both P <0.001). Based on logistic regression analyses, both clinical characteristics (RF+, anti- CCP+) and disease activity factors (SHS >median SHS at BL, BL SHS score, disease activity scores, swollen/tender joint counts, CRP, low hemoglobin, CDAI score, SDAI score, and SJC28) were confirmed to be associated with radiographic progression. Based on regression/ANOVA analysis, the following factors were found to have an interaction effect with treatment groups on radiographic progression: CCP+, BL SHS >cohort median SHS, and BL SHS >7.5. Odds ratios showed that pts were significantly more likely to be radiographic non-progressors with sirukumab if they were anti-CCP+, had a BL SHS > cohort median SHS, or had a BL SHS >7.5 (~25% quartile cutoff for SHS). For sirukumab 50 mg q4w and 100 mg q2w vs placebo, respectively, relative risk ratios [RR (95% CI)] confirmed anti-CCP+ (1.28 [0.93, 1.77]; 1.40 [1.01, 1.94]), SHS >median (1.40 [1.05, 1.87]; 1.48 [1.12, 1.94]), and SHS >7.5 (1.53 [1.17, 2.00]; 1.55 [1.20, 2.00]) as predictive factors for radiographic non-progression with sirukumab vs placebo.

Conclusion: In this Phase 3 study of sirukumab in pts with active RA despite DMARD treatment, pts with poor prognostic factors for RA, including those who were anti-CCP seropositive or had a BL SHS score >7.5 or > the cohort median, were more likely to have radiographic non-progression with sirukumab vs placebo.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) is recommended as first-line therapy in patients (pts) with rheumatoid arthritis (RA).[1] However, information is limited regarding factors that may predict a poor response to MTX. The objective of this analysis was to identify predictors of MTX insufficient response (IR) and rapid radiographic progression (RRP) among pts with early RA receiving 6 months (mos) of MTX therapy.

Methods: In OPTIMA, pts with RA <1 year were randomized to receive either adalimumab (ADA) 40 mg every other wk (EOW) + MTX weekly (wkly) or placebo (PBO) EOW + MTX wkly for 26 wks. In PREMIER, pts with RA <3 years were randomized to receive ADA 40 mg EOW + MTX wkly, ADA 40 mg EOW + PBO wkly, or PBO EOW + MTX wkly for 2 years. This post hoc analysis compared MTX-IR pts, defined as not reaching stable low disease activity at wks 22 and 26 in OPTIMA and wks 20 and 24 in PREMIER, with pts who responded to initial MTX monotherapy. Comparisons were also made between pts who did and did not have RRP, assessed by an increase in modified Total Sharp Score (mTSS) of >1.5 from baseline (BL) to 6 mos. In pts with available data, backward logistic regression was used to identify potential predictors of MTX-IR and RRP. Candidate predictors included BL demographics, time-averaged disease parameters for 3 time intervals (through 4 wks, 8 wks, and 12 wks of MTX exposure), and BL disease characteristics for the 12-wk interval. Time-averaged variables were calculated as area under the curve standardized for length of time interval.

Results: This analysis included 525 MTX-IR and 162 MTX responders. Mean disease duration at BL was 6 mo for both groups. The mean Disease Activity Score 28 (C-reactive protein; DAS28[CRP]) was 6.2 vs 5.6, Health Assessment Questionnaire Disability Index (HAQ-DI) was 1.6 vs 1.3, and mTSS was 15.5 vs 12.2 for MTX-IR vs MTX responders, respectively. 171 pts experienced RRP, while 499 pts had no RRP; the mean disease duration at BL was 6 mo for both groups. The mean DAS28(CRP) was 6.4 vs 6.0 and HAQ-DI was 1.6 vs 1.5 for pts experiencing RRP vs pts who did not experience RRP, respectively. Mean mTSS at BL was higher for pts who

experienced RRP (20.7) vs those who did not (12.4). Predictors of MTX-IR and RRP at 6 mos are shown in the **Figure**. Time-averaged HAQ-DI and DAS28(CRP) through 12 wks were the strongest predictors of both MTX-IR and RRP. Additionally, early clinical response (time-averaged DAS28[CRP]) at both 4 and 8 wks was predictive of both MTX-IR and RRP; however, time-averaged HAQ-DI was not predictive until wk 12.

Conclusion: In the OPTIMA and PREMIER trials, post-BL measures of RA activity appeared to be the strongest predictors of subsequent MTX-IR and of RRP. Pts who are likely to progress on MTX or have RRP may be good candidates for switching to earlier step-up therapy to reduce the likelihood of permanent bone damage.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have a lower life expectancy than general population. The impact of RA treatments on global mortality is not known, and only long-term studies can approach it. Our objective was to assess currently available literature on all-cause mortality associated with treatments in patients with RA.

Methods: We systematically searched available literature (Pubmed, Embase and recent abstracts from ACR and EULAR congresses) for studies reporting observed mortality associated with the use of anti-tumor necrosis factor α (anti-TNFα), methotrexate (MTX) and glucocorticoids (GC) in RA, and having a comparison group. The relative risks of mortality associated with the use of respective treatments were collected and pooled in meta-analysis using Review Manager software (Cochrane collaboration). Random effects meta-analyses were conducted, and forest plots were constructed to summarise the risk ratio estimates and their 95% confidence intervals. Data were extracted by one investigator and confirmed by another.

Results: 13995 articles were of potential interest, and 20 finally met required criteria after screening and were included. Follow-up ranged from 2 to 13 years. 9 articles concerned mortality in RA patients treated with anti-TNFα (102621 patients). Observed mortality was reduced in these patients compared with non-users with pooled risk ratio (RR) at 0.73 [95% confidence interval 0.61-0.87], p=0.0004. Regarding MTX, 5 studies were included in the meta-analysis (25252 patients). Reported mortality was also decreased compared with non-users (RR 0.69 [0.49-0.97], p=0.03). Finally, 6 articles concerned mortality in RA patients treated by GC (45292 patients). In these patients, mortality was found to be increased (figure: RR 1.50 [1.17-1.93], p=0.002).

Conclusion: Despite methodological caveats, especially potential indication biases, currently available literature is in favor of a benefit of anti-TNF and MTX on observed mortality in RA, while the use of GC is associated with an increased risk of overall mortality. These data plead for a careful decision making in therapeutic decisions in patients having an apparently controlled disease at the cost of long-term use of GC.

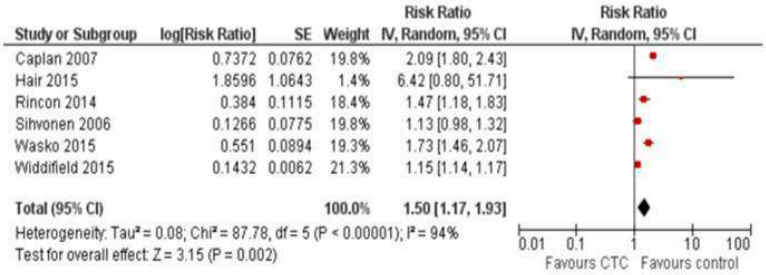

Figure: Pooled risk ratio of observed mortality in patients receiving corticosteroids

Results of a Comprehensive Review of Pulmonary Function and Safety Data in a Phase IIb Clinical Program Testing Anti-GM-CSF Receptor Antagonist Mavrilimumab for Treatment of RA

GR Burmester[1], MA Michaels[2], D Close[3], A Godwood[3], K Middleton[3], P Miranda[4], J Vencovský[5], JM Kremer[6], IB McInnes[7], M Albulescu^[3] and Michael Weinblatt[8], [1]Charité – University Medicine Berlin, Berlin, Germany, [2]MedImmune, Gaithersburg, MD, [3]MedImmune, Cambridge, United Kingdom, [4]Centro De Estudios Reumatológicos, Santiago, Chile, [5]Charles University, Prague, Czech Republic, [6]The Albany Medical College, Albany, NY, [7]University of Glasgow, Glasgow, United Kingdom, [8]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: RA is associated with significant pulmonary comorbidity and declines in lung function over time; but longitudinal assessment of pulmonary abnormalities in the context of RA treatment needs further characterization. Mavrilimumab, an investigational human monoclonal antibody, inhibits GM-CSF by binding to the GM-CSF receptor α subunit. We investigated pulmonary safety of mavrilimumab because of its potential to inhibit alveolar macrophage function.

Methods: Pulmonary monitoring included standardized lung function testing (spirometry and diffusing capacity of lung carbon monoxide [DLCO]), chest X-rays, assessments of dyspnea and pulmonary adverse events (AEs) in two randomized, double-blind, multicenter studies (NCT01706926; NCT01715896) where pts with moderate to severe RA received mavrilimumab or placebo and mavrilimumab or golimumab, respectively, and the long-term open-label extension (NCT01712399) where all received mavrilimumab. All studies excluded pts with clinically significant uncontrolled pulmonary disease. Adjudication of lung function abnormalities and pulmonary AEs was by an Independent Pulmonary Expert Committee.

Results: The 442 pts receiving mavrilimumab had cumulative safety data exposure of approximately 900 pt-yrs and median (min–max) exposure of 2.5 (0.1–3.3) yrs. Baseline (BL) characteristics are shown in the Table. Mean forced expiratory volume in 1 second (FEV_1), forced vital capacity (FVC), DLCO (Figure), and dyspnea (Table) were mostly maintained within 5% of BL values for pts treated during the randomized phases of NCT01706926 and NCT01715896. Few pts showed clinically significant (>20% from BL and <80% predicted) decreases in predicted FEV_1 and FVC (Table); these were mostly transient. Overall, 83 pts (9.24/100 pt-yrs) reported ≥1 pulmonary AE; bronchitis was reported most frequently (pts [per 100 pt-yrs]: 34 [3.78]), followed by respiratory tract infection and cough (14 [1.56] and 12 [1.34], respectively). The rate of pulmonary AEs reported was generally stable over time. No suspected/confirmed pulmonary alveolar proteinosis cases, no pulmonary-related deaths, and only one treatment-related pulmonary serious AE (acute bronchitis) were reported.

Conclusion: Many pts with BL pulmonary comorbidities were identified. Mavrilimumab was not associated with substantial effects on pulmonary function; the rate of pulmonary AEs was stable during the study. This may be the most comprehensive longitudinal study of pulmonary function in RA; further long-term studies should fully characterize these findings and any impact of therapies. ^Joint senior

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The presence of rheumatoid factor (RF) plays an important role in the diagnosis of rheumatoid arthritis (RA). However, whether RF positivity is related to the effects of treatment with biologic disease-modifying antirheumatic drugs (bDMARDS) remains unclear. This study aimed to determine whether RF positivity was associated with the effects of bDMARDS treatment in bio-naïve RA patients.

Methods: We used demographic and clinical data obtained from the Tsurumai Biologics Communication Registry, which comprises Nagoya University and 20 affiliated hospitals in Japan. Patients aged 20–80 years who fulfilled the ACR 1987 revised or the 2010 ACR/EULAR classification criteria for RA were included, whereas those with prior exposure to bDMARDS were excluded. The RF status was defined as negative (0–15 IU/ml) or positive (>15 IU/ml). Linear multiple regression analysis was used to assess the association between RF positivity and the effects of bDMARDS treatment, as defined by DAS28-ESR improvement at week 24. Unstandardized coefficients were calculated. Adjustment variables included sex, age, DAS28 at pre-treatment, tumor necrosis factor inhibitor (TNFi) or non-TNFi, baseline use of methotrexate and glucocorticoids, and baseline stage and class, as defined by the Steinbrocker classification.

Results: Table 1 summarizes the baseline demographic and disease characteristics of the patients. Some characteristics were different between RF-negative and RF-positive patients; however, they were adjusted using linear multiple regression analysis. Unstandardized coefficients are shown in Table 2. The value of interest was −0.38 ($P < 0.05$), suggesting that the DAS28 improvement in RF-positive patients is inferior to that in RF-negative patients to that extent. Other variables affecting the treatment effects were sex, age, TNFi or non-TNFi, which are well-known influential factors for biologic therapy.

Conclusion: This study demonstrated that RF positivity, in addition to some well-known variables, was independently associated with decreased effects of bDMARDS treatment in bio-naïve RA patients.

Table 1. Baseline characteristics of RF-negative and RF-positive patients

	RF negative (n = 110)	RF positive (n = 511)	P value
Age, Mean ± SD years	53.3 ± 14.4	57.7 ± 13.8	<0.05
DAS28ESR at pre-treatment	4.88 ± 1.25	5.27 ± 1.22	<0.05
Sex, % female	89.1	79.6	<0.05
Stage I, II/III, IV, %	50.9/49.1	38.9/61.1	<0.05
Class I, II/III, IV, %	81.8/18.2	73.6/26.4	0.09
Methotrexate use, %	89.1	77.1	<0.05
Oral steroid use, %	50.9	59.9	0.09
Tumor necrosis factor inhibitor, %	82.7	77.1	0.21

DAS28ESR: Disease Activity Score Calculator for RA with erythrocyte sedimentation rate

Table 2. Coefficients of variables in relation to the effects of bDMARDS treatment

	Estimate	Standard error	P value
(Intercept)	0.09	0.42	0.83
RF status (RF-negative patients as reference)	−0.38	0.13	<0.01
DAS28ESR at pre-treatment	0.74	0.043	<0.01
Sex (male as reference)	−0.31	0.13	<0.05
Age	−0.012	0.0039	<0.01
TNFi or non-TNFi (TNFi as reference)	0.35	0.13	<0.01
Methotrexate use	−0.013	0.13	0.92
Oral steroid use	−0.34	0.11	<0.01

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Reactivation of hepatitis B virus (HBV) is one of the most serious complications in rheumatoid arthritis (RA) patients treated with biological disease-modifying anti-rheumatic drugs (bDMARDs). De novo hepatitis induced by HBV reactivation in patients with resolved HBV can easily lead to fulminant hepatitis with poor prognosis. However, few studies have addressed the incidence and risk factors of HBV reactivation in RA patients with resolved HBV by treatment of bDMARDs. The purpose of this study was to identify the prevalence and risk factors for developing HBV reactivation in RA patients with resolved HBV who received bDMARDs therapy.

Methods: RA patients who were newly treated with bDMARDs at our department from April 2009 to March 2016 were reviewed for this study. Of these patients, registered were the patients who had been diagnosed as resolved HBV and whose HBV-DNA was repeatedly measured with the interval ranged from one to three months. The definition of resolved HBV was positive for antibody

against hepatitis B core antigen (anti-HBc) and negative for hepatitis B surface antigen (HBsAg). The study endpoint was reactivation of HBV determined as an HBV-DNA level higher than 2.0 log copies/ml. The association between HBV reactivation and clinical, laboratory and treatment data were retrospectively analyzed.

Results: A total of ninety-six RA patients with resolved HBV were included in this study. In these patients, etanercept was administered in 21 patients, abatacept (ABT) in 18, golimumab (GLM) in17, tocilizumab (TCZ) in 17, infliximab (IFX) in 11, adalimumab in 7 and certolizumab pegol in 5. The median follow-up period was 19 months (interquartile range 5-37 months). Six out of ninety-six patients (6.3%) developed HBV reactivation during the observation periods. ABT was used for 2 patients, IFX for 2, GLM for 1 and TCZ for 1. In five out of the six patients, HBV-DNA levels were below the quantitation limit (< 2.1 log copies/ml) without any antiviral therapy while they continued to receive bDMARDs. In contrast, HBV-DNA level over 2.1 log copies/ml was observed in one patient treated with ABT, however HBV-DNA became negative after the initiation of entecavil therapy. The prevalence of HBV reactivation was significantly higher in the patients negative for antibody against HBsAg (anti-HBs) ($p = 0.047$, Fisher's exact test).

Conclusion: HBV reactivation occurred in 6.3% of RA patients with resolved HBV during the bDMARDs treatment. Absence of anti-HBs can be risk for reactivation of resolved HBV in these patients.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Long-term extension studies and observational drug registers mainly from Western countries or non-endemic areas have reported an increased risk of tuberculosis (TB) infection in patients under biological DMARD (bDMARD) therapy. However, information about TB infection in patients with inflammatory arthropathies in daily clinical practice in endemic areas is limited. Our aim was to describe a series of TB infection in patients who received bDMARD treatment and to identify which patients were able to resume bDMARD therapy.

Methods: We included patients with inflammatory arthropathies treated at Medicarte IPS from March 2009 to March 2016. Medicarte is a referral center for the integral medical care and pharmaco-surveillance of patients under biologic therapies in 13 cities in Colombia for inflammatory arthropathies, mainly rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloartropathies (Spa), psoriasis and inflammatory bowel disease (IBD) among others. Clinical information was obtained from electronic clinical records and medical claims. In addition, clinical records from admissions were reviewed for relevant information related with TB. Only those cases with a confirmed diagnosis of TB, either by sputum, biopsies or tissues cultures were included.

Results: Among 6,508 patients under biological treatment followed in our centers, we identified 54 patients who develop a TB infection. Those patients with diagnosis of IBD (N=3) or psoriasis (N=8) were excluded. 13 cases who only received DMARD therapy [methotrexate (MTX) =2 and leflunomide (LEF)=11] were not included. Finally, our sample included 28 patients with inflammatory arthropathies. 68% of patients were female, with a mean age at the moment of TB infection of 50.5 ± 14.7 years. Diagnoses were: 20 RA; 6 Spa; 1 Psa and 1 Spa related with Crohn's disease. None of the patients had concomitant HIV infection. Pulmonary TB was diagnosed in 15 (53.6%) of patients, followed by disseminated TB in 5 (18%), pleural TB in 3 (11%) and laryngeal, miliary, bone, intestinal and lymph node TB in one case each. At the time of TB infection 64% were under steroids treatment (mean dose 7.9 ± 5.9 mg/d), 32% received MTX, 36% LEF and 21% chloroquine. bDMARD treatment before TB infections were as follows: Adalimumab in 13 (46%) patients, infliximab in 6 (21%), etanercept in 5 (18%), abatacept in 2 (7%) and rituximab and certolizumab in 1 case each.

Mean time of TB treatment was 8.2 ± 2.0 months. Two patients died as a direct consequence of TB infection. Thirteen (46%) out of 28 patients resume bDMARD after TB treatment. Five out of 13 patients reinitiated with the same biological agent. Mean follow-up of bDMARD therapy after TB infection was 15.7 ± 18.1 months. No new cases of TB infection have been reported during the follow-up.

Conclusion: In daily clinical practice in an endemic TB country, around half of patients with TB infection were able to resume bDMARD treatment. Extra-pulmonary TB represented more than 40% of cases of TB. In endemic TB countries, a TB infection does not preclude reinitiating of bDMARD therapy.

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although nonsteroidal anti-inflammatory drugs (NSAIDs) are effective in relieving joint pain in rheumatoid arthritis (RA) patients, long-term use of NSAIDs can cause adverse effects. We aimed to examine the patient-reported outcome (PRO) and its associated clinical factors in RA patients with low disease activity (LDA) after discontinuing NSAIDs.

Methods: This study was a 16-week, multi-center prospective open-label trial. RA patients who achieved LDA (28-joint Disease Activity Score [DAS28] < 3.2) who were on NSAIDs for more than a month discontinued the NSAIDs. Acetaminphen (AAP) was used as the rescue medication. Changes of DAS28 and PRO including pain visual analogue scale (pain-VAS) and Routine Assessment of Patient Index Data 3 (RAPID-3) score were assessed. NSAID was restarted when patient's pain was intolerable with AAP. The endpoint was to analyze the group of patients who continued to withdraw NSAID. Patients were further classified to have "sustained effectiveness" who met the following: 1) pain-VAS ≤30 mm at week16 or increase less than 25% from baseline and 2) RAPID-3 score ≤6 at week16 or increase less than 25% from baseline.

Results: A total of 109 RA patients with LDA were enrolled in the study. At the end of the study, 89 (84.8%) patients had remained without restarting NSAID. In these patients, there was a difference in pain-VAS between baseline and week 16 (P= 0.010). However, changes in RAPID-3 and DAS28 were insignificant (P= 0.128 for RAPID-3 and P= 0.638 for DAS28) Moreover, 66 patients ended up to show sustained effectiveness without restarting NSAID. After adjustments of covariables, we found out joint swelling was the detrimental factor in NSAID withdrawal (odd ratio [OR] 0.150, 95% confidence interval [CI] 0.034-0.666, P= 0.013) and sustained

effectiveness (OR 0.312, 95% CI 0.101-0.964, P= 0.043).

Conclusion: NSAIDs can be attempted to discontinue in RA patients with LDA, especially in patients without joint swelling.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a high risk of developing adverse drug reactions (ADR) in rheumatology due, mainly, to the Disease Modifying Drugs (DMARD) used. After more than twenty years using DMARD, is widely known their efficacy in rheumatoid arthritis (RA), but it is necessary to increase our knowledge of its ADR, especially those that lead to discontinuation in real life. The purpuse of our study was to describe the incidence rate and characteristics of moderate and severe ADR to DMARD in patients with RA.

Methods: Observational longitudinal study was conducted. Recent onset RA patients diagnosed between April 15th 2007 and 31st December 2010 followed in outpatient clinic at Hospital Clinico San Carlos until December 31st2015, which used any DMARD treatment were included. Primary outcome: development of an ADR that required discontinuation of the DMARD (moderate: discontinuation of the drug; severe: discontinuation and hospitalization or death as a result of the ADR). Incidence rates of discontinuation (IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence interval [CI].

Results: We included 293 courses of DMARD treatment in 97 patients (815 patient-years). Of these, 78% were women with a mean age at diagnosis of 55.6 ± 15 years. The median time to the start of the first DMARD was 0[0-41] days. 11.5% were taking biological DMARDs, 60.75% were using combined therapy and 86% were taking corticoids. Treatment was suspended due to ADRs in 110 cases (IR: 13.5 [11.2 -16.3]), being gastrointestinal the most frequent cause (21.4%), followed by infections (15.2%). The IR of moderate ADR was 11.2[9.2-13.8], being 11.1[8-15] for monotherapy regimen and 11.4 [8.8-14.9] for combined therapy. The IR of discontinuation related to synthetic and biological DMARDs was 13.2 [0.9-16.2] and 15.6 [8.6-28.2] respectively. The crude IR of discontinuation for moderate ADRs was higher for Gold (IR: 19.5[11.5-32.9]) and Leflunomide (IR: 20.5[10.7-39.5]) being 7.14 [4.8-10.4] for Methotrexate (MTX). 17.5% of the ADR were severe (n=20) with an IR of 2.5[1.6-3.8] being infections the most frequent cause (65%) followed by cancer (20%), gastrointestinal (10%) and exitus (n=1). The crude IR of discontinuation for severe ADRs was higher for biological DMARDs (IR: 4.2[1.3-13.2]) than for synthetic DMARDs (2.28 [1.4-3.6]). The crude IR of discontinuation for severe ADRs was the lowest for Antimalarials (IR: 1.5[0.5-4.8]) and MTX (IR: 1.3[0.5-3.1]. Regarding types of regimen, the IR of severe ADR on monotherapy was 1.5 [0.6-3.5], and with combined therapy was 3.1[1.8-5.1], being higher when we looked at triple therapy (IR: 4.5 [2.4-8.3]).

Conclusion: This study describes the incidence of ADRs occurred in RA patients taking DMARDs in real life conditions. The IR of ADR estimated was 13.5% patient-years, being 2.5% patient-years for severe ones. MTX was the drug with the lowest IR of ADRs. Regarding severe ADRs caution might be taken for those patients on triple therapy.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the amount and impact of respiratory symptoms in patients with primary Sjögren's syndrome (pSS) and to assess if such symptoms are related to concomitant COPD or ILD.

Methods: Fifty-one consecutive outpatients diagnosed with pSS (median age 61, range 29-82 years, 49 females) and 80 population based controls (median age 61, range 31-80 years, 43 females), denying having been diagnosed with a rheumatological disease, asthma or COPD as well as using bronchodilators and/or inhalation steroids the last 6 months, were included in the study. The pSS patients were evaluated by pulmonary function test as well as CT scans of the lungs. 21 pSS patients fulfilled GOLD criteria for COPD and 9 patients showed radiologic signs of ILD. All subjects also completed a questionnaire on smoking habits from which tobacco consumption could be calculated as well as the St George's Respiratory Questionnaire (SGRQ) on respiratory symptoms. The controls were then stratified into females and males and a linear regression analysis was performed in which age, body-mass index (BMI) and pack-years were added as co-variates to calculate gender, age, BMI and pack-year standardised values for the SGRQ subscores and total score. From the equations of these analyses, expected values for the SGRQ subscores and total score in the pSS patients were calculated. The expected SGRQ-scores were then compared with the actual SGRQ-scores found in the pSS patients. To compare the SGRQ scores in pSS patients with vs. without COPD we calculated the deviation of SGRQ scores from expected values in each pSS patient and compared the groups. The same calculation was performed to compare pSS patients with and without radiologic signs of ILD.

Results: pSS patients had significantly increased SGRQ symptom (25.2 (6.6; 40.5) vs. 2.3 (1.4; 3.8); $p<0.001$), SGRQ activity (39.5 (12.2; 53.6) vs. 12.5 (8.2; 17.5); $p<0.001$), SGRQ impact (9.9 (0; 23.3) vs. 0.7 (0.5; 1.1); $p<0.001$) as well as SGRQ total scores (17.4 (7.4; 34.5) vs. 4.6 (3.3; 6.3); $p<0.001$) in comparison to expected scores based on the results of the population based controls. However, there was no significant difference in the deviation of SGRQ symptom, SGRQ activity, SGRQ impact or SGRQ total scores from expected values in pSS patients with and without COPD or ILD respectively.

Conclusion: In conclusion we showed that respiratory symptoms were more common amongst pSS patients than in the normal population. Concomitant COPD or ILD did not seem to significantly contribute to these, suggesting that other factors are more important in eliciting such symptoms in pSS patients, of which airway sicca is probably the most important. Since pulmonary involvement in pSS is associated with an increased mortality and respiratory symptoms is a poor marker for pulmonary involvement, we suggest that at least PFT should be performed liberally in all pSS patients regardless of symptoms to enable early detection of pulmonary involvement in these patients.

Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: to evaluate if the salivary glands ultrasonographic score (SGUS) is modified during follow-up in primitive Sjögren patients (pSS) and to compare pSS with idiopathic sicca syndromes (non-pSS).

Methods: this study was performed in the Brittany cohort of patients with suspected pSS. All patients had standardized clinical, biological and imaging evaluation. pSS diagnosis was considered according to the AECG criteria. Patients with or without pSS had ultrasonography of both parotid glands and both submandibular glands; they were graded on a 5-point scale (0 to 4). During follow-up, a second ultrasonography was performed. Patients treated with Rituximab were excluded. Salivary-gland ultrasonography was performed by local expert who was unaware of the final diagnosis. We compared the ultrasonographic score between pSS and non-pSS at inclusion and at second evaluation for the sum of the score of the four glands and the maximum score among the four glands.

Results: of the 49 included patients, 29 received a diagnosis of pSS. At baseline, pSS and non-pSS were similar concerning demographics, Schirmer test and salivary flow. Biopsy positivity and SGUS were statistically different at inclusion between pSS and non-pSS ($p<0.001$). Sum of the scores of the four glands and maximum score among the four glands was respectively of 8.9 and 2.7 for pSS and 2.1 and 0.8 in non-pSS. Percentage of patients with at least one score > 2 was respectively of 75.8 % and 25.0 % in pSS and non-pSS. During follow-up, a second ultrasonography of salivary glands was performed with a mean delay of 1.9 (+/-1.6) years. There was no difference between sum of the score of the four glands and maximum score among the four glands at second ultrasonography examination between pSS and non-pSS. Significant difference between sum of the scores of the four salivary glands and maximum score among the four glands of pSS and non-pSS was still present at second salivary glands ultrasonography with ($p<0.001$). No difference was found when parotids and submandibular glands were analyzed apart.

Conclusion: with a mean delay of two years, SGUS is not modified, even in patients with pSS. This observation is also effective in parotid and submandibular glands when taken apart.

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's syndrome (SS) is a systemic auto-immune disease with a heterogeneous clinical presentation. Recently, ACR-EULAR criteria were proposed for classification of SS, which combine features of the ACR and AECG criteria. The aim of this analysis was to assess the performance of the ACR-EULAR classification criteria for SS in a well-defined prospective diagnostic cohort from daily practice.

Methods: The study population consisted of consecutive patients who were referred to the University Medical Center Groningen Sjögren expertise center. Inclusion criteria were suspicion of SS, presence of sicca complaints and age of >18 years. Patients who did not complete the full diagnostic workup were excluded. The standardized diagnostic work-up included evaluation of focus score (FS) in minor salivary and/or parotid gland biopsy, anti-SSA antibodies, unstimulated whole salivary flow (UWS), Schirmer's test and ocular staining score (OSS). Patients had to score ≥4 points to fulfill the ACR-EULAR criteria for SS, receiving 3 points for FS≥1 and anti-SSA positivity, and 1 point for UWS ≤0.1 ml/min, Schirmer ≤5 mm/5min and OSS ≥5. Classification according to ACR-EULAR criteria was compared with clinical diagnosis according to the treating rheumatologist.

Results: Between December 2013 and March 2016, 119 patients were included at the start of their diagnostic work-up, of which 5 were excluded due to missing data. Of the 114 patients, 46 (40%) fulfilled the ACR-EULAR criteria for SS, of which 1 patient was classified as secondary SS. Comparing separate tests between SS (n=46) and non-SS patients (n=68), FS≥1 occurred in 85% vs. 4% of the patients, anti-SSA positivity in 78% vs. 6%, UWS ≤0.1 ml/min in 54% vs. 39%, Schirmer ≤5 mm/5min in 83% vs. 55% and OSS ≥5 in 53% vs. 14% (figure). Preliminary analysis showed that agreement between diagnosis according to the treating rheumatologist and classification according to ACR-EULAR criteria was excellent with Cohen's kappa of 0.87 and an absolute agreement of 94%. The ACR-EULAR criteria had a sensitivity of 95% and specificity of 93%.

Conclusion: In our prospective, multidisciplinary diagnostic cohort derived from daily clinical practice, 40% of the patients fulfilled the ACR-EULAR classification criteria for SS. FS≥1, anti-SSA positivity and OSS ≥5 occurred almost exclusively in SS patients, whereas UWS ≤0.1 ml/min and Schirmer ≤5 mm/5min were often found in non-SS patients too. Agreement between the ACR-EULAR criteria and clinical diagnosis was excellent. The present findings support use of the proposed ACR-EULAR criteria to classify SS patients for clinical diagnostic as well as research purposes. In future analysis, classification of SS according the ACR-EULAR criteria will be compared with classification according to an expert panel of rheumatologists.

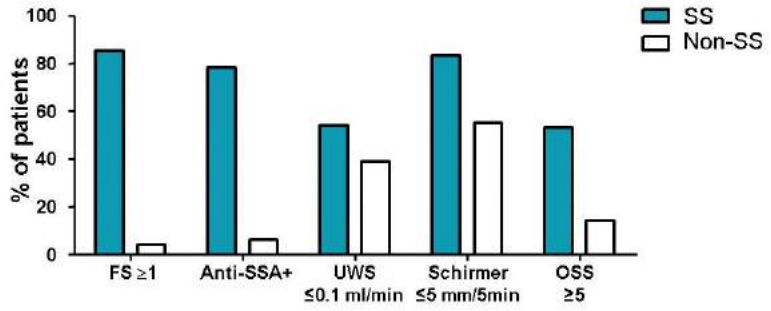

Figure: Proportion of SS and non-SS patients fulfilling the separate ACR-EULAR criteria.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the prevalence of smoking in patients with Sjögren's syndrome (SS) and non-Sjögren's sicca (non-SS sicca), and the association of smoking habits with the clinical, serological, and histopathological manifestations of SS.

Methods: Cross-sectional case-control study of 1288 patients with sicca symptoms (587 SS and 701 non-SS sicca) evaluated in a multi-disciplinary research clinic. Smoking patterns were obtained from questionnaire data and disease-related clinical and laboratory data were compared between current, past, ever, and never smokers.

Results: Current smoking rates were 4.6% for SS patients compared to 14.1% in non-SS sicca (p=5.17x10E-09), 18% in a local lupus cohort (p=1.13x10E-14) and 16.8% in the community (p=4.12x10E-15). Current smoking was protective against SS classification (OR 0.35, 95%CI 0.22-0.56, FDR q=1.35E10-05), focus score ≥1 (OR 0.22, 95%CI 0.13-0.39, FDR q= 6.78x10E-08), and anti-Ro/SSA(+) (OR 0.35, 95%CI 0.2-0.63, FDR q=0.0009); ever smoking was protective against the same features and against anti-La/SSB(+) (OR 0.52, 95%CI 0.39-0.70, FDR q=0.001). Duration of smoking was inversely correlated with SS even after controlling for socioeconomic status, BMI, alcohol and caffeine consumption.

Conclusion: Current tobacco smoking is negatively and independently associated with SS, protecting against disease-associated humoral and cellular autoimmunity. The overall smoking rate amongst SS patients is significantly lower than in matched populations and the effects of smoking are proportional to exposure duration.In spite of the protective effects of tobacco on SS manifestations, it is associated with other serious comorbidities such as lung disease, cardiovascular risk and malignancy, and should thus be strongly discouraged in patients with sicca.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Antimalarials are frequently used in patients with primary Sjögren's syndrome (SS). The aim of this study was to assess their impact on damage accrual among this group of patients.

Methods: We included 377 consecutive patients with the diagnosis of primary SS according to the AECG criteria, attending tertiary referral centers from three countries: Argentina (n=110), Brazil (n= 49) and Mexico (n=218). We retrospectively registered demographics, age at disease onset, disease duration, use of prednisone (PDN), immunusupressors, comorbidities and use of antimalarials (cloroquine or hydroxychloroquine, time of use and indication). We also scored the cumulative ESSDAI at last follow-up as well as the SSDDI.

Results: The mean age at diagnosis was 48.9±12.7 years, 97.3% females, median disease duration 6 years, mean SSDDI score 2.7±1.8 and mean cumulative ESSDAI score 9.3±8.3. There were not differences regarding these variables among countries, with the exception of the SSDDI that was lower in Brazil (1.8±2.3, Mexico 2.8±2, Argentina 3±1.6, p≤0.001) and the median disease duration that was longer in Mexico (7 years, Argentina 4.5 years, Brazil 5 years). Thirty nine percent of patients used PDN, 37.4% immunosuppressors, 23.1% had hypertension, 16.5% dyslipidemia and 6.6% diabetes mellitus. A total of 190 patients (50.3%) had ever used antimalarials, mean use of 43.5±40 months, being the indications: arthritis (65.2%), parotid enlargement (6.3%), only sicca symptoms (19.4%) and other causes (8.9%). When we compared patients with and without antimalarials, the first ones were younger (46.6±11.7 vs. 51.3±13.1, p=0.0001), with a longer disease duration (median 7 vs. 4 years, p=0.0001), used more PDN (44.5% vs. 33.3%, p=0.002) and immunosuppressors (44% vs. 30.6%, p=0.007) and had a lower SSDDI score (2.4±1.7 vs 2.9±1.8, p=0.01). Regarding the domains of the SSDDI, the pulmonary domain was the only one with a significant difference among groups (6.7% with antimalarials vs. 14.9% without antimalarials, p=0.01). Then, we compared patients with a SSDDI ≥3 vs. SSDDI<3, the first ones had longer follow up (6 vs. 5 years, p=0.04), a higher cumulative ESSDAI score (12.4±9.3 vs. 6.7±6.2, p=0.0001) and less use of antimalarials (42.9% vs. 57%, p=0.007). At the logistic regression analysis adjusted by country and disease duration, the following variables were independent predictors of damage: use of antimalarial OR 0.58 (0.36-0.93 CI 95%, p=0.02) and cumulative ESSDAI OR 1.1 (1.07-1.15 CI 95%, p=<0.001).

Conclusion: During the course of disease, half of the SS patients received antimalarials. This drug was associated with a lower damage accrual independently of disease activity and duration.

Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Notwithstanding the reported coexistence of autoimmune thyroid disease (ATD) and primary Sjögren's syndrome (pSS), it is unknown if this association is routinely searched and how it influences the SS phenotype. We aimed to describe the proportion of patients with pSS who has been screened for thyroid disease, the prevalence of ATD and its impact in pSS phenotype in a single tertiary center cohort.

Methods: We retrospectively reviewed the medical charts of 223 consecutive patients (1996-2016) with the diagnosis of pSS according to the AECG criteria. We registered demographics, glandular and extraglandular features, Schirmer-I test, non-stimulated whole salivary flow (NSWSF), ocular staining, serology (anti-Ro/SSA, anti-La/SSA, rheumatoid factor (RF), low C3 ever, low C4 ever, and hyperglobulinemia ever); as well as thyroid function tests (TFT), thyroid disease diagnosis, anti-thyroglobulin and anti-thyroid peroxidase antibodies and thyroid image studies. We scored the cumulative activity with the ESSDAI and damage accrual with the SSDDI at the end of follow-up.

Results: 149 patients (66.8%) had at least a set of TFT, these patients were older and had a longer disease duration than patients without a TFT assessment. Their mean age was 59.7±14.9 years, 95.2% female and median disease duration 10.4 years. Sixty-four of them (42.9%) had thyroid disease, being the main cause ATD in 24 patients (37.5%, CI 95% 27-50; 16 hypothyroidism and 8 hyperthyroidism). Other causes were non-autoimmune hypothyroidism (n=8, 12.5%), multinodular goiter (n=6, 9.3%), coloid goiter (n=4, 6%) and single thyroid nodule (one patient, 1%). We excluded for further analysis a group of 21 patients with hypothyroidism who lacked of anti-thyroid antibodies determination. When we compared patients with ATD (n=24) vs. without ATD (n=104) we did not find differences regarding the age, gender, disease duration, Schirmer-I test, impaired NSWSF, ocular staining, use of immunosuppressors, RF, low complement and hyperglobulinemia; as well as in the glandular and extraglandular features and cumulative ESSDAI (9.04±7.6 vs 11.4±8.9, p=0.19). However ATD patients had a lower prevalence of anti-Ro/SSA (58.3% vs. 88.3%, p=0.001) and anti-La/SSB antibodies (25% vs. 60.6%, p=0.002) than patients without ATD; as well as a lower SSDDI score (2.17±1.2 vs 2.77±2, p=0.05). At the logistic regression analysis, only anti-Ro/SSA and anti-La/SSB remained significant, conferring protection to ATD (OR 0.29, 95% CI 0.10-0.88, p=0.002 and OR 0.31, 95% CI 0.10-0.92, p=0.03, respectively).

Conclusion: Around one third of pSS patients were not evaluated for thyroid disease, and among those evaluated, 37.5% had ATD. These patients had a similar clinical prognosis than those without ATD, but were characterized by a lower prevalence of anti-Ro/SSA and anti-La/SSB antibodies.

Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The EMBODY 1 (SL0009; NCT01262365) and EMBODY 2 (SL0010; NCT01261793) phase 3 studies investigated the efficacy and safety of epratuzumab (Emab; Immunomedics Inc), a CD22-targeted monoclonal IgG1 antibody, in patients (pts) with systemic lupus erythematosus (SLE).[1] The studies showed no significant difference from placebo (PBO) in any of the primary/secondary outcome measures, although B cell-specific immunological activity and a favourable safety profile were demonstrated. An analysis of the subset of pts with secondary Sjögren's syndrome (sSjS) is of special interest due to the pathogenic role of B cells in primary SjS.

Methods: In EMBODY 1 & 2, adult pts with moderately to severely active SLE were randomized to PBO or 1 of 2 dosing regimens of Emab (both received a cumulative dose of 2400 mg Emab delivered over the first 4 weeks [wks] of each of four 12-wk treatment cycles), with the primary endpoint measured at Wk 48.[1] This post-hoc analysis included pts with an additional diagnosis of sSjS who were SS-A positive at baseline. Biological markers (B cells, IgG/IgM, SS-A), primary/secondary outcome measures of SLE disease activity (BICLA, BILAG, PhGA) and overall safety were assessed.[1] For BICLA, missing data were imputed using modified non-responder imputation with p values calculated using logistic regression with factors for treatment, pooled region and baseline disease status. For BILAG and PhGA missing values were imputed using last observation carried forward and p values calculated using ANCOVA adjusted for baseline, region and baseline disease severity.

Results: Across both studies, 170 (11%) SLE pts had sSjS in their medical history; of these, 112 pts (40 PBO, 72 Emab) were SS-A positive at baseline and were included in this analysis. Demographics/disease characteristics did not differ between groups (Table A). A higher proportion of Emab pts achieved a BICLA response at Wks 24 and 48 compared with PBO (Table B). Similarly, reductions from baseline in BILAG total score were numerically greater for Emab than PBO pts at both time points. PhGA did not differ significantly between the two groups; both PBO and Emab pts showed improvements from baseline. During treatment, B cells, IgM, and SS-A decreased in Emab but not PBO pts (Figure, and data not shown); no substantial changes were observed in other parameters including IgG, rheumatoid factor, SS-B. Emab appeared safe and well-tolerated with no difference in the frequency of adverse events from PBO.

Conclusion: In this post-hoc analysis, pts with SLE and sSjS treated with Emab showed improvements in SLE disease activity compared to PBO, with decreases in B cells and B cell-related biomarkers (IgM and SS-A). Further evaluation in a larger SjS population, using SjS-specific outcome measures, is necessary to assess the clinical relevance of the data. **References:** 1. Clowse MEB, Arthritis

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Iguratimod (IGU), a methanesulfonanilide, has been used as a novel disease-modifying antirheumatic drug for

treatment of rheumatoid arthritis in Japan and China. IGU displayed significantly inhibition of immunoglobulin production and suppression of IL-1, IL-6 and TNF. Previous studies have indicated an overt activation of B cells leading to the abnormal secretory function and accompanied by autoantibody production and hypergammaglobulinemia in Primary Sjögren's Syndrome (pSS). The aim of this study was to investigate the efficacy of IGU in combination with conventional treatment in pSS and the effects of IGU on B cell activity.

Methods: A total of 50 female patients diagnosed with pSS meeting the international classification criteria (2002) were enrolled in this study, with a mean age of 29.3 ± 9.7 years. Active pSS patients were randomized (1:1) to conventional treatment (prednisone ≤ 10 mg daily, hydroxychloroquine 400mg daily and new hydrochloride bromide ethyl daily), or IGU treatment (conventional treatment plus IGU 50 mg daily). pSS disease activity was assessed using EULAR Sjögren's syndrome disease activity index (ESSDAI) and EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI). Expression of CD135, IgD, CD38, CD20 and B cell activating factor-receptor (BAFF-R) on peripheral blood B cells were analyzed by flow cytometry in 20 pSS patients before and after treatment at 12 weeks.

Results: As shown in Table 1, at week 12, ESSDAI and ESSPRI were significantly improved but with a much greater gratitude in IGU treated group as compared with those in conventional treatment group ($P<0.05$). There were no obvious adverse events reported in either group. At baseline, pSS patients showed a significant increased expression of BAFF-R, CD38, CD135 and IgD on B cells compared with that in healthy controls. After 12 weeks of treatment, expression of BAFF-R, CD38, and IgD in IGU treatment group decreased significantly than that in conventional treatment group (Table 2) ($P<0.05$).

Conclusion: In subjects with pSS, IGU treatment resulted in clinically meaningful improvements in disease activity compared with conventional therapy. IGU affected B cell frequency and functions in pSS via inhibition of BAFF-R expression on B cells and inhibition of B cell antibody production.

Table 1. Disease activity before and after treatment in pSS patients

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Sjögren's syndrome is an autoimmune disorder that can develop hearing loss, It can be diagnosed with high frequency audiometry. Our study aims to correlate the hearing according to the level of disease activity, using the EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) as an evaluation tool and performing high frequency audiometry and tympanogram in a population with primary Sjögren's syndrome.

Methods:

The audiological evaluation were performed by the same experienced audiologist in an Acoustic Systems soundproof chamber with calibration, model RE-142 manufactured in U.S.A, and Interacustic AC40 audiometer (125-16,000Hz frequencies with bone conduction thresholds at 500-4000Hz frequencies). Pure-tone speech audiometries were conducted measuring speech discrimination thresholds and word recognition. Tympanometry (Audiotest 425 h Interacustic) with acoustic reflex and static acoustic compliance for both ears were tested. Tympanometry was considered normal with middle ear pressures of ± 75 da Pa (deca Pascal: unit of pressure) with compliance of 0.28-1.5ml, and the presence of acoustic reflex when it occurred with stimulation at 70-95 dB in 500; 1000; 2000; and 4000Hz. The tympanograms were classified according to Jerger as types A, As, Ad, B, and C. Hearing loss was accepted if the hearing threshold was 20 dB or higher than 20dB.

Results: A total of 76 patients, 3(3.9%) male and 73(96.1%) women were recruited. The median age was 52.5 years. The disease activity was reported as mild in 23(30.3%) patients, moderate in 28(36.8%) and severe in 25(32.9%). The Pure Tone Average (PTA) in the right ear was 18.72dB (SD11.6) and left ear 20.72dB (SD12.19) in the frequency range 500 to 3000Hz. The comparison between the degree of illness and right and left PTA was P=0.399 and P=0.359 respectively. The PTA in the frequency range 4000 to 8000Hz in the right ear was 29.34dB (SD5.18) and the left ear was 31.40dB (SD17.68), P=0.198 and P=0.115 respectively. The PTA in the frequency range 10000-16000Hz was in the right ear 55.82dB (SD18.10) and the left ear was 55.17dB (SD19.58), P=0.134 and P=0.180, respectively. The prevalence of hearing loss in patients with primary Sjögren's syndrome in high frequencies (10,000-16,000) in the right ear was 62(94.7%) and the left ear 69(90.8%). No significant differences between the degree of disease activity and the level of hearing in patients with primary Sjögren's syndrome were found.

Conclusion:

Despite the high prevalence of hearing loss of high frequencies in this cohort of Sjögren's Syndrome Patients, we observed no correlation with disease activity

Table 1. Pure Tone Average and standard deviation

Test frequency (Hz)	Right ear	Left ear
500-3,000	18.72 ±11.6	20.72 ±12.19
4,000-8,000	29.34 ±5.18	31.40 ±17.68
10,000-16,000	55.82 ±18.10	55.17 ±19.58

Table 2. Mean PTA comparison with ESSPRI using Kruskal-Wallis test

Frequency range	Mean PTA (SD)	*P*

Session Date: Tuesday, November 15, 2016

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Salivary gland ultrasonography is a highly specific tool for the diagnosis of primary Sjögren´s syndrome (PSS). Real time sonoelastography (RTS) is a novel imaging option involving tissue stiffness assessment. Previous works have reported higher RTS values in PSS vs healthy and sicca controls. Herein we evaluated the stiffness of parotid and submandibular glands using RTS and correlated it with a multiparametric approach including morphologic ultrasonographic parameters, profibrotic chemokines and cytokines levels, serology and the presence of minor salivary gland fibrosis.

Methods: We included 26 patients with PSS according to the AECG criteria, who had a salivary gland biopsy with no more than 5 years previous the ultrasonographic evaluation. B-Mode ultrasonography and RTS (ARFI methodology) were performed by a trained radiologist. Parotid and submandibular glands were individually rated for parenchymal echogenicity, homogeneity, hypo-echogenic areas, hyper-echogenic reflections and clearness of borders using the Hocevar scale (global B-mode sum score 0-48 points). RTS was also conducted at both parotid and submandibular glands (8 areas of each gland to obtain a median value) and we registered the median value of shear wave velocity (SVV) expressed in m/s. We assessed the ESSDAI, ESSPRI, non-stimulated whole salivary flow rate (NSWSF), C3 and C4 levels, rheumatoid factor, anti-Ro/La antibodies and salivary levels of CXCL14, CCL28, TRAIL and TGb by ELISA. We also evaluated salivary gland fibrosis with the Masson's trichrome staining.

Results: The mean age was 51.1±11 years, median disease duration 6.1 years, 92.8% females, 92.8% had oral symptoms and 26.9% fibrosis at the minor salivary gland. The global B mode score was of 22.2 points (13-44) and the SVV 2.5 (1.64-3.28) m/seg. We found a correlation between SVV and the global B mode score (t=0.53, p=0.001), SVV between both parotids (t=0.58, p=0.0001) and both submandibulars (t=0.50, p=0.0001); but not between parotids and submandibular glands. The SVV correlated with the NSWSF (t=-0.53, p=0.001), ESSDAI (t=0.31, p=0.03), glandular ESDDAI domain (t=0.36, p=0.02), C4 levels (t=-0.32, p=0.04), but not with age or any other variable including fibrosis and salivary chemokines/cytokines. At the linear regression analysis, the glandular ESSDAI domain (B=0.49, p=0.04), the C4 level (B=-0.02, p=0.05) and the disease duration (B=0.04, p=0.04) correlated with the SVV.

Conclusion: SVV correlated with the ultrasonography morphologic score and glandular activity but not with fibrosis, suggesting that it rather represents glandular inflammation. Further prospective studies are needed to evaluate its sensitivity to change over time.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren syndrome (pSS) is a systemic autoimmune disease involving mainly the exocrine glandular system. Nevertheless, its clinical spectrum includes the development of multiple extra-glandular manifestations that will be determinant for the prognosis and the use of systemic therapy, including biological treatments. The aim of our study was to describe the biological treatments used in a pSS cohort of patients assisted in Spanish Rheumatology Departments.

Methods: This is a multicenter descriptive transversal study of pSS patients fulfilling European/American consensus criteria. Patients were included by randomization from thirty-three Rheumatology departments. Data were collected by reviewing clinical records and interviewing the patients. Signed informed consent was obtained and local ethics committees approved the study. Variables were analyzed by descriptive statistical methods, using means, medians, and rates. Chi-square was used to establish the statistical associations, being considered significant a $p<0.05$.

Results: Four hundred and thirty-seven patients were included. Ninety-five percent of them were women. The median age of the cohort was 58 years. Ten patients had been treated (currently or previously) with anti-TNF agents (2.29%); 31 patients had been treated with rituximab (7.1%); 3 patients had been treated with abatacept (0.69%) and 1 patient had been treated with tocilizumab (0.23%). Patients receiving anti-TNF agents had the following clinical manifestations: articular involvement (4 patients), pulmonar involvement (2 patients), central nervous system (CNS) involvement (4 patients) and cytopenia (2 patients). Patients receiving rituximab had: articular involvement (13 patients), pulmonar involvement (9 patients), renal involvement (6 patients), CNS involvement (5 patients), peripheral nervous system (PNS) involvement (8 patients) and cytopenia (16 patients). Patients receiving abatacept had: articular involvement (1 patient), pulmonar involvement (1 patient), CNS involvement (1 patient) and cytopenia (1 patient). The patient who received tocilizumab had: CNS involvement and cytopenia. All patients receiving biological therapy were ANA positive. Sixty percent of the patients receiving anti-TNF were anti-Ro+; 40% of the patients had anti-La; 10% of the patients had low C3 and C4, respectively; and 30% of the patients had hypergammaglobulinemia. Ninety-four percent of the patients receiving rituximab were anti-Ro+; 61% of the patients had anti-La; 29% had low C3 and C4, respectively; and 64% of the patients had hypergammaglobulinemia. Thirty-three percent of patients receiving abatacept were anti-Ro+; 33% of the patients had anti-La; 33% of the patients had low C3; and 66.7% of the patients had hypergammaglobulinemia. The patient who received tocilizumab was anti-Ro+, anti-La+ and had hypergammaglobulinemia. Hospitalization due to pSS activity was needed in 5 patients receiving anti-TNF agents; in 19 patients receiving rituximab; in 2 patients receiving abatacept and in the patient treated with tocilizumab. Biological treatments were significantly used more frequently in patients with a hospitalization for disease activity ($p<0.05$). The mean of EULAR Sjogren´s Syndrome Disease Activity Index (ESSDAI) was 8.78 in patients receiving anti-TNF agents; 10.39 in patients receiving rituximab; 11 in patients receiving abatacept and 14 in the patient treated with tocilizumab.

Conclusion: Despite the absence of clinical controlled studies demonstrating efficacy and safety, biological frequently used in patients with SSp. The most widely used biological agent is rituximab. Its use is associated with the presence of musculoskeletal, neurological, pulmonary and haematological manifestations, hospitalization for disease activity and a high ESSDAI.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To study long-term work disability (WD) and possible predictors in newly diagnosed patients with primary Sjögren's syndrome (pSS).

Methods: 51 pSS patients (mean age 46 years, range 18-61 years, 50 females) diagnosed with pSS between January 2001 and December 2012 were included in the study. For each patient we randomly selected four reference subjects from the general population matched for age, sex and area of residence as controls. We linked data to the Swedish Social Insurance Agency and calculated the proportion as well as net days of WD in 30-day intervals from 12 months before pSS diagnosis until 24 months after.

Results: WD, consisting of sick leave (SL) and disability pension (DP), was increased in pSS patients in comparison to general population controls (GPC) (Fig 1A and B). Two years after pSS diagnosis the relative risk for overall WD was 2.10 (95% CI 1.34 to 3.30) in comparison with the general population. At diagnosis, 26% of patients were work disabled increasing to 37% and 41%, 12 and 24 months after diagnosis, respectively ($p<0.05$ and $p<0.05$ vs. baseline). Prior work disability status at pSS diagnosis (OR=15.4, 95% CI 2.9 to 81.9; p=0.001), concomitant fibromyalgia (OR=10.5, 95% CI 2.0 to 56.0; p=0.006), and each additional year of age (OR=1.1, 95% CI 1.0 to 1.2; p=0.009) were found to be associated with WD 24 months after diagnosis.

Conclusion: pSS patients showed an increased WD in comparison with the general population. Furthermore, WD in pSS patients increased significantly during the first two years after diagnosis, initially due to an increase in SL and subsequently to an increase in patients receiving a DP. WD at diagnosis, concomitant fibromyalgia and increasing age were associated with long-term work disability.
Figure 1A. The prevalence of any degree of sick leave (SL) and disability pension (DP), for periods of 30 days for pSS patients and the general population controls (GPC) during the 12-month period before and 24-month period after pSS diagnosis.

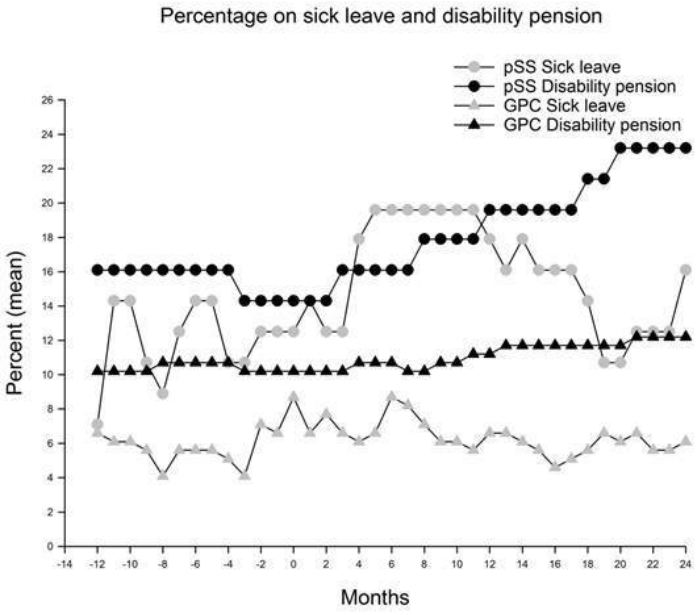

Figure 1B. The net amount of time (number of days out of 30-days periods) the pSS patients and the general population controls (GPC) were on sick leave (SL) and receiving disability pension (DP) during the 12-month period before and 24-month period after pSS diagnosis.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjogren's syndrome (pSS) is a chronic rheumatic disease. The long-term use of drugs and its renal involvement may contribute to low bone mineral density (BMD). Our objective was to investigate the state of bone health in patients with pSS.

Methods: Patients were all Chinese from the outpatient and inpatient clinic of our hospital (Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China). Primary SS was defined according to the revised American-European classification criteria. Each patient had BMD measurement by dual energy x-ray absorptiometry. Diagnoses of osteopenia and osteoporosis were made using calculations based on the World Health Organization T-score (or Z-score in premenopausal women and men younger than 50) criteria (−1.0 to −2.5 SD was osteopenia and ≤−2.5 SD was osteoporosis). Their demographic and clinical features were recorded and analyzed whether they had impact on the results of BMD.

Results: Totally, 128 Chinese patients (male: female=19:109) were studied. 23 of them were premenopausal and the other 86 were postmenopausal. Their ages were 53.2±8.7 years old and their disease durations were 5.6±4.9 years. The serum levels of calcium and phosphorus of most of them were normal (except 3 had hypocalcemia). Their urinary pH were >5.5. Their mean T (or Z) scores of lumbar spine were -2.1±1.3, of femoral neck were -1.7±1.5, and of total hip were -1.1±1.8. 20 (15.6%) patients were with normal BMD results, 42 (32.8%) were osteopenia, and 66 (51.6%) were osteoporosis. 6 patients had history of pathological fracture. The prevalence of impaired bone health (both osteopenia osteoporosis) was significantly higher in postmenopausal than in premenopausal women (39.5% vs. 26.1%, $p<0.05$). BMD results were not correlated with disease duration, the serum levels of calcium and phosphorus, and the usage of glucocorticoids (all $p>0.05$), but significantly correlated with the age negatively ($p<0.01$).

Conclusion: The prevalence of osteopenia or osteoporosis was high in patients with primary Sjogren's syndrome and it was not due to the usage of glucocorticoids.

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a systemic auto-immune disease affecting the exocrine glands leading to sicca complaints. For the diagnosis of pSS, a positive salivary gland biopsy is an important criterion. A salivary gland biopsy can either be obtained from the minor (labial) or major (parotid) salivary gland and is considered positive if focus score (FS) is ≥1. In this study, the parotid gland biopsy (PGB) and labial gland biopsy (LGB) were compared for their diagnostic value in a prospective diagnostic cohort.

Methods: The study population consisted of 94 consecutive patients referred to the Sjögren center of expertise at the University Medical Center Groningen. All patients presented with sicca complaints and had a complete diagnostic workup for suspicion of pSS according to the American European Consensus Group (AECG) criteria. As part of the routine diagnostic workup a PGB was taken. In addition, patients consented for a simultaneous LGB. Biopsies were assessed for FS and presence of lymphoepithelial lesions (LELs).

Results: Of the included 94 patients (mean age (yr) 49.9 SD 13.9), 39 patients were classified as pSS according to the AECG criteria. In the patients classified as pSS, 18 patients (46%) had both salivary gland biopsies positive. In 14 patients (36%) only the LGB was positive, while in 3 patients (8%) only the PGB was positive and 4 patients (10%) both biopsies were negative. Using the AECG criteria, including salivary gland histology, the PGB had a higher specificity (95% vs 88%), but lower sensitivity (54% vs 82%) than the LGB. Patients classified as pSS, according to the AECG criteria, with both salivary gland biopsies positive, were all anti-SSA positive. Of the 14 patients classified as pSS with solely a positive LGB, 9 patients (64%) would not have been classified as pSS according to the AECG criteria if the biopsy had been negative, since these patients all lacked SSA or SSB autoantibodies. In the small group of three patients classified as pSS with a positive PGB and negative LGB, two patients were anti-SSA positive and the remaining anti-SSA negative patient (33%) would not have been classified as pSS if the biopsy was negative. The 4 classified pSS patients with both salivary gland biopsies negative were all anti-SSA positive. Thus, a positive LGB positively influenced the classification as pSS stronger than a positive PGB. Strikingly, although all 14 patients with solely a positive LGB showed a FS≥1, none of these LGBs harbored LELs. In comparison, if both salivary gland biopsies were positive, LELs were found in 79% of the LGBs. Patients with a positive LGB, but negative PGB were significantly older than patients with a positive PGB (57.0yr versus 47.2yr, t-test p=0.021).

Conclusion: This study suggests that anti-SSA negative elderly patients, with a positive labial gland biopsy based upon FS≥1, are at risk of being falsely diagnosed as pSS, since these labial gland biopsies all lack LELs. We therefore propose that LELs are taken into account in elderly patients besides FS≥1. A parotid gland biopsy is more specific and might be recommended especially in elderly patients without SSA antibodies, suspected for pSS.

Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Primary SjogrenÕs syndrome (pSS) is a chronic autoimmune disorder that is characterized clinically by dryness of the eyes (xerophthalmia) and mouth (xerostomia). The assayÕs purpose was to observe which laboratory tests, clinical characteristics or activity index could have correlation with ultrasonography (US) glandular scores in a cohort of 66 patients with xerostomia in pSS, prospectively enrolled from September 2013 to May 2016 in two medical centers.

Methods: The glandular US score was correlated with clinical and laboratory data in 66 patients with pSS according to American-

European Consensus Group. criteria (AECG) (male/female ratio 2/64, mean age 55,55 (11.15) years) and median of disease duration 6.0(2.0-10.0). Imaging findings of US were graded using an ultrasonography score ranging from 0 to 4(1), which was obtained considering the worst score between each parotid and submandibular gland. All laboratory tests were done including Immunoglobulin G (IgG) level and salivary beta 2 microglobulin. Stimulated salivary flux was measured in the same conditions and hour for every patient, with <0,5 ml/min considered abnormal. The xerostomia inventory validated for portuguese language was applied for all patients by a blind investigator(2). One single rheumatologist was responsible for applying the European Sjšgren Syndrome Disease Activity Index (ESSDAI).

Results: Considering each score value in US, our cohort had almost the majority with 3 an 4 scores (83%). The correlation between higher US scores and clinical and laboratorial parameters was not found. However, higher US scores were correlated with high IgG levels (p=0,0134) and low salivary flux (p=0,0059).

Conclusion: Salivary gland US is a useful method in visualizing glandular structural changes in patients suspected of having pSS and it may represent a good option as a first-line imaging tool in the diagnostics of the disease. In our cohort it was important to show that more important changes matched with lower salivary flux and more inflammatory process. Maybe the ultrasonographic approach in earlier times of disease can change this scenario.

Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The use of Hydroxychloroquine (HCQ) in Primary Sjögren's Syndrome (PSS) has been assessed in different studies over the last years, with conflicting results regarding its efficacy in SICCA syndrome and extraglandular manifestations (EGM). The purpose of this study was to compare the incidence rate of EGM in PSS patients with and without HCQ therapy.

Methods: We performed a multicenter retrospective study, including patients with PSS (European Classification Criteria) with at least one year of follow-up. Subjects with concomitant fibromyalgia, autoimmune hepatitis, primary biliary cirrhosis and primary sclerosing cholangitis were excluded. Demographics and PSS characteristics were recorded. The EGM were defined by EULAR SS Disease Activity Index (ESSDAI). Patients were divided into 2 groups according to their use or not of HCQ therapy. We evaluated the use of HCQ and its relationship to EGM. HCQ therapy was defined as the continuous use of the drug for at least 3 months. Statistical analysis: a descriptive analysis of demographics and PSS characteristics was performed. We compared the incidence of EGM between groups defined by HCQ therapy using chi^2 test or Fisher’s exact test.

Results: A total of 221 patients were included (97.3% women), mean age: 55.7 years (SD, 14). Mean age at diagnosis: 48.8 years (SD, 15). Median disease duration: 60 months (IQR 35-84). One hundred and seventy patients (77%) received HCQ. About half of the patients had at least one EGM during the course of the disease, 20% of them developed an EGM before the onset of the SICCA syndrome and 26% simultaneously with dryness symptom. Overall, EGM were less frequent in those on HCQ therapy (36.5% vs 63.5%, p<0,001). Considering each EGM individually, the following manifestations were more frequent in the non-treated group: arthritis (p<0,001), fatigue (p< 0,001), purpure (p=0,01), Raynaud phenomenon (p= 0,003) and hypergammaglobulinemia (p=0,006). (Table I) Immunosuppressive treatment was indicated on 28 patients (12,7%), 13 of which were receiving also HCQ . The first reason for those treatments was the presence of arthritis in 12/28 patients (42.8 %), and the drug used in all the cases was methotrexate. Only three patients required immunosuppressive therapy with cyclophosphamide, due to the presence of glomerulonephritis, vasculitis and interstitial lung disease. None of the patients received biologic therapy.

Conclusion: The lower incidence of EGM observed in patients on HCQ therapy supports its efficacy in PSS. However, further large scale prospective studies are needed to confirm these findings.

Table I: Systemic involvement in PSS patients with or without HCQ therapy

Extraglandular Manifestations (EGM)	*HCQ therapy n (%)*	*No HCQ therapy n (%)*	*p- value*

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To score systemic activity at diagnosis of primary Sjogren syndrome (pSS) using the European systemic activity indexes ESSDAI, clinESSDAI and DAS in order to evaluate their influence in the development of cancer in a large cohort of patients.

Methods: The GEAS-SS multicenter registry was formed in 2005 with the aim of collecting a large series of Spanish patients with primary SS, and included 21 Spanish reference centers with substantial experience in the management of SS patients. By January 2016, the database included 1301 consecutive patients fulfilling the 2002 classification criteria for primary SS. ESSDAI, clinESSDAI and disease activity states (DAS) scores were retrospectively calculated at diagnosis. Neoplasias diagnosed before the pSS diagnosis were excluded.

Results: The cohort included 1202 (92%) women with a mean age at diagnosis of pSS of 52 years. According to the 2002 AE criteria, 1280 patients (98%) had dry mouth, 1235 (95%) dry eyes, 1013/1156 (88%) abnormal ocular tests, 498/630 (79%) positive minor salivary gland biopsy, 835/993 (86%) abnormal oral diagnostic tests, 982/1295 (76%) positive anti-Ro/SSA antibodies and 627/1295

(48%) positive anti-La/SSB antibodies. Other immunological markers included ANA in 1125/1296 (87%) patients, RF in 584/1246 (47%), low C3 levels in 144/1234 (12%), low C4 levels in 163/1219 (13%), cryoglobulins in 70/930 (7.5%) and monoclonal band in 115/1019 (11%). After a mean follow-up of 118 months, 70 (5.4%) patients developed solid cancer and 61 (4.7%) hematological neoplasia; according to the ICD codes, the most frequent neoplasia were lymphoma (n=50), gynecological (n=20), gastrointestinal (n=16) and endocrine (n=8) neoplasias. Systemic activity at diagnosis was significantly higher in patients who developed hematological neoplasia in comparison with those who developed solid neoplasia or those without neoplasia, both for the mean ESSDAI (10.4 vs 5.9 vs 5.7, p<0.001) and clinESSDAI (10.3 vs 5.8 vs 5.7, p<0.001) scores. In addition, high systemic activity (high-DAS) was found in a higher frequency in patients who developed hematological in comparison with those who developed solid neoplasia or those without neoplasia (40% vs 7.7% vs 10.8%, p<0.001). The highest baseline ESSDAI scores were found in patients who developed lymphoma (10.4), skin cancer (10), leukemia (8.8), myeloproliferative cancer (8.5), pulmonary (7.8) and gynecological (7.6) neoplasia (**Figure 1**).

Conclusion: Systemic activity at diagnosis measured using ESSDAI, clinESSDAI and DAS scores is closely related to the development of lymphoma, but not with solid cancer, in patients with pSS. Etiopathogenic factors such as B-cell hyperactivity and cryoglobulinemic-driven immunological responses may play a dual effect, enhancing the risk of development of both systemic involvement and hematological neoplasia.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Salivary gland ultrasonography (SGUS) has recently appeared as a promising tool for a non-invasive diagnosis

of primary Sjögren's syndrome (pSS). However, it is still debated whether it could be used to monitor clinical response during the follow-up. Objective of this study was to assess the usefulness of SGUS in monitoring salivary gland changes and response to treatment in patients with pSS.

Methods: In this longitudinal study, performed from January 2012 to February 2016, 111 patients with pSS (AECG 2002) were prospectively included and regularly followed over the time. The same operator performed SGUS by using a real-time US scanner (Esaote Technos MPX) with a 7.5-12.5 MHz transducer. The following US parameters were recorded: size, parenchymal echogenicity and inhomogeneity in the parotid and submandibular glands (SM) on both sides, number and location of hypoechoic areas, calcifications and lymph nodes. Changes in different SGUS items were analyzed by using MacNemar test for nominal variables and Wilcoxon test for continuous variables.

Results: We included 111 (109 F:2M) patients with pSS (AECG 2002). Out of them, 46/111 patients were enrolled at the diagnosis (i.e inception cohort). Patients were prospectively observed for a median (IQR) follow-up of 2 (1-3) yrs. At the inclusion, 75% of the entire cohort and 65% of the inception cohort presented already abnormalities in the echogenicity (i.e fibrosis) and homogeneity (i.e hyperechoic bands) in at least one of the four glands examined. Over the follow-up, a raise in echogenicity and homogeneity was observed only in less than 10% of the patients (p-value=n.s). Approximately 1/3 of the patients of the entire cohort and 15% of the inception cohort presented either reduced parotid glands or SM glands at the baseline. This percentage increased up to 45% and to 30% in the entire cohort and in the inception cohort respectively, at the end of the follow-up ($p<0.001$). A score ≥ 2 in the localization of the hypoechoic areas either in parotid or in submandibular glands was observed at the baseline in 42% of the patients (35% inception cohort) and was associated with anti-Ro/SSA, hypergammaglobulinemia, low C3, low C4 and leucopenia. Submandibular parenchyma echostructure (i.e number and location of hypoechoic areas) but not parotid echostructure tend to improve over the follow-up, although the difference was not significant.

Conclusion: SGUS represents an interesting tool to monitor the natural history of glandular involvement in pSS. The use of SGUS to monitor response to therapy in pSS warrants further investigation.

Session Date: Tuesday, November 15, 2016

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the common initial clinical presentations of primary Sjogren's syndrome with pulmonary complications, and to explore the differences between patients with extro-glandular manifestations at onset (EGM) and those with glandular manifestations at onset (GM).

Methods: A total of 1341 hospitalized SS patients from 2003 to 2012 were retrospectively reviewed. Of them, 102 hospitalized patients with pSS-associated lung disease were analyzed and recruited.

Results: Fifty one percent were presented with EGM at onset, with significantly shorter disease duration [36.0 (12.0-156.0) vs. 102.0 (48.0-159.0) m，p=0.016]. Although mean diagnose time was equal, only 3.8% of EGM group can be confirmed the pSS diagnose at onset, which was significantly less frequently than that of GM group (34.0%, p=0.000).Case control study revealed that hyperglobulinemia, elevated RF titers and anti-SSA and/or anti-SSB positive were less predominant in EGM group [15.85 vs. 21.20g/L; 22.40 (20.00-171.00) vs. 104 (20.00-237.50)IU/ml; 32.7% vs. 72.0%；p<0.05]. TLC and FVC of predicted value were lower

(87.07±22.76% vs. 96.82±19.78%, p=0.050; 88.30±27.76% vs. 100.18±27.40%, p=0.089）and HRCT score was higher in EMG group [11.50 (7.75-15.25) vs. 8.00 (5.00-13.00), P=0.070].

Conclusion: EMG at onset is common initial manifestation of pSS-associated lung involvement patients. Pulmonary complication is more progressively and severe than those with MG at onset. Anti-SSA positive, elevated RF titer and hyperglobulinemia are not predominant for patients with EMG at onset.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's syndrome (PSS) is a systemic disease primarily characterized by lymphocytic infiltration of exocrine glands, but lymphocytic infiltration, can also can affect extraglandular tissues. Recently, it has been validated the EULAR SS disease activity index (ESSDAI), that is a clinical index that measure disease activity in PSS. The ESSDAI, includes 12 domains (organ systems: cutaneous, respiratory, renal, articular, muscular, peripheral nervous system, central nervous system, haematological, glandular, constitutional, lymphadenopathic, biological). The ESSDAI is now in use as a gold standard to measure disease activity in clinical studies, and as an outcome measure. The purpose of this study is to evaluate the ESSDAI baseline characteristics in a large Spanish multicenter registry of PSS.

Methods: SJÖGRENSER, is a multicenter descriptive transversal study of a cohort of PSS patients fulfilling European/American consensus criteria 2012, collected from Rheumatology clinics all over Spain. Patients were included by randomisation from an anonymised list provided by every department. Two hundred and ninety eight variables were investigated: epidemiological, clinical, serological characteristics, treatments and complications. Specifically, ESSDAI domains were collected. The score may vary between 0-123. It is considered low activity an ESSDAI <5; moderate activity 5-13, and high activity if ESSDAI is ≥14. Variables were analysed by descriptive statistical methods, using means, medians, and rates, with their deviations and interquartile ranges (p25-p75).

Results: Of 437 patients included, 95% were women, with median age (p25-75): 58.63 years (50,02-67,98 years), and age at diagnosis of 50.24 years (42,99-58,29 years), with a disease evolution of disease of 10.4 years (6-16 years). The median of diagnosis criteria of SS was 5 (4-5). Minor salivary gland biopsy was positive in 69%. Rheumatoid factor, AAN, anti-Ro/SSA and anti-La/SSB and cryoglobulins, were positive in 64,76%, 62,23 %, 93,59%, 67,05%, 3% of patients respectively. Cytopenia was present in 27% of

patients and Beta-2 microglobulin serum levels was increased in 22% and C3/C4 reduced in 23% of patients. The median of ESSDAI of our population at enter to the study was 2 (0-4). In 31% of patients, ESSDAI, was 0, in 49% was concordant with low activity, moderate activity in 15% and 5% of patients show high activity. In table, the domains of ESSDAI, at enter to SJÖGREN-SER are shown. Table. ESSDAI results at enter at SJÖGRENSER cohort.

ESSDAI domains	**SJÖGRENSER** **N: 437** **%**
Constitutional	8
Lymphadenopathy	2
Glandular	4
Articular	35
Cutaneous	3
Pulmonary	6
Renal	5
Muscular	0,2
Peripheral nevous system	3
Central nervous system	2
Haematological	27
Biological	28

Conclusion: 1. In SJÖGRENSER, 20% of patients show moderate-high ESSDAI results and haematological, biological and articular domains are present in more than 10% of patients. 2. ESSDAI is a suitable tool to define and compare cohorts of patients with PSS.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The increasing use of ESSDAI and patient reported outcomes (PROs) in primary Sjögren's syndrome (pSS) clinical trials has pointed out that the performance of the single domains and scales of these indices may differ in the short term period. Objective of this study was to analyze the performance of single ESSDAI domains and ESSPRI scales in detecting changes of disease activity/PROs over a 12-month follow-up in real-life and to explore any eventual correlation between ESSDAI and ESSPRI.

Methods: This is a 12-month longitudinal single centre study including consecutive patients with pSS (AECG 2002). All the patients were evaluated at least twice during the study period. At each visit, patients completed the ESSPRI and the same researcher assessed the

ESSDAI domains. Minimal clinically important improvement (MCII), defined as an improvement of at least three points of the ESSDAI, and the patient acceptable symptom state (PASS), defined as an ESSPRI<5 points, were calculated at the end of the follow-up. A ≥30% reduction of the patient's dryness/fatigue/pain VAS was also evaluated as response outcome measure.

Results: We included 275 patients (267F: 8M) with pSS (mean age (DS): 57(13.6) yrs; mean follow-up (DS): 6(5) yrs. Out of them, at baseline: 14/275 (5.1%) presented a high disease activity (ESSDAI≥14), 69/275 (25.1%) a moderate disease activity (5≤ESSDAI≤13) and 192/275 (69.8%) a low disease activity (ESSDAI <5). Patients were treated according to the standard of care therapy for pSS. At the end of follow-up, MCII was reached by 17% of the patients. Levels of disease activity remained stable in the vast majority of the cases (79%) and worsened in 4% of the patients. Among the ESSDAI domains, those that showed the most significant tendency to improve were the "articular" and "cutaneous" domains (p<0.000), whereas "biological" domain tended to remain unchanged. The use of hydroxychloroquine and a high ESSDAI at baseline were associated to MCII (p=0.000 and p=0.002). An ESSPRI<5 was observed in 20.7% of the patients at the inclusion and in 22.2% at the end of the follow-up. ESSPRI remained unchanged in 80.8% of the patients, improved in 10.4% and worsened in 8.8%. A ≥30% reduction of the patient's oral and ocular dryness/fatigue/pain VAS was observed in 17%, 15.6%, 14.1% and 20% of the cases. No correlation was detected between ESSDAI and ESSPRI.

Conclusion: This study highlights the general concept that pSS is a slowly progressive disease and that disease activity and PROs are not correlated. Some domains of the ESSDAI seem to capture changes of disease activity better than others in the short term and this may have a value when using ESSDAI in clinical trials.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is a common clinical feature in patients with primary Sjögren's syndrome (pSS). Objectives of this study were to assess major determinants contributing to fatigue development in a multicenter cohort of patients with pSS and to explore the impact of fatigue on pSS patients treatment in real-life.

Methods: This multicenter cross-sectional involved five Italian reference centers with substantial experience in the management of pSS. We included 360 pSS patients (AECG criteria) seen consecutively. A standardized data set including demographic, clinical and serological disease manifestations and patients' treatment was collected prospectively. The ESSDAI and the SSDDI were used to assess disease activity and organ damage, respectively. Fatigue was assessed according to the fatigue VAS scale of the ESSPRI. Multiple linear regression analysis was used to estimate the effect of each variable on fatigue severity.

Results: We enrolled 360 pSS patients (346 F:14 M); mean age(S.D.) at study inclusion was 58(15)yrs, mean disease duration (S.D.) was 6(7)yrs. Seventy-eight percent of patients (280/360) reported a fatigue score >5. Fatigue VAS scores correlated significantly with the other scales of the ESSPRI (i.e. Spearman r ranging from 0.49 to 0.62) and weakly with the ESSDAI (Spearman r= 0.12, p=0.03). No association was found between fatigue VAS scores and patients' demographics (i.e age at study inclusion, disease duration). In addition we did not find any association between fatigue and patients' serological/biological profile. Fatigue VAS scores were significantly higher in patients presenting inflammatory arthralgias (p=0.02) and fibromyalgia (p=0.000). At multivariate analysis fatigue severity was independently associated with fibromyalgia [OR (95%IC)=2.29 (1.24-4.22)] and arthralgias [OR (95%IC)=1.79 (1.01-3.17)] .

Regarding the impact of fatigue on patients' therapy we found that fatigue VAS scores were significantly higher in patients assuming corticosteroids (p=0.006) and hydroxychloroquine (p=0.001) and that in patients with a fatigue score >5 the prevalence of patients assuming only symptomatic drugs was significantly lower with respect to patients with a less severe fatigue (29.4% vs 45.3%, p=0.01).

Conclusion: In our study, arthralgias and fibromyalgia were the most significant determinants of fatigue in pSS. Fatigue may influence medical prescription of steroids and hydroxychlorochine in pSS in real life.

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren syndrome (pSS) is a systemic autoimmune disease involving primarily the exocrine glandular system. pSS in men is uncommon. Data of pSS in male are controversial. Objectives: The aim of our study was to describe the epidemiological, clinical and serological features of male patients with pSS in a spanish pSS cohort (SJOGRENSER Registry)

Methods: This is a multicenter descriptive transversal study of pSS patients fulfilling European/American consensus criteria, from thirty-three Rheumatology departments. Patients were included by randomisation from an anonymized list provided by every department. Data were collected by reviewing clinical records and interviewing the patients. Informed consent was obtained and local ethics committees approved the study. Variables were analyzed by descriptive statistical methods, using means, medians, and rates, with their deviations and interquartile ranges (p25-p75).

Results: Four hundred and thirty-seven patients with pSS were included. Twenty-one men were identified. The ratio between women and men was 20:1. Median age at the time of the first symptoms was 53 years for men compared with 46 years for women (p=0.026). Median age at the time at pSS diagnosis was 56 years for men and 50 years for women (p=0.041). Twenty nine percent of men had a family history of autoimmune disease, most commonly pSS (40%). All male patients had ocular and oral dry symptoms.The most frecuent extraglandular manifestations in men were hematological involvement (48%) followed by upper airways involvement (38%), asthenia (38%), salivary gland enlargement (33%) and articular involvement (33%). A significant difference between men and women was found in the prevalence of asthenia, 38% for men and 64% for women (p=0.015), and genitourinary manifestations, 5% for men vs 51% for women (p=0.001). Systemic features, salivary gland enlargement, lymphadenopathy, vasculitis, peripheral neuropathy, pulmonary, cardiovascular, central nervous system and pancreatic manifestations tended to be more frequent in male patients, without statistical significance. The most frequent antibodies in male were ANA (95%), Anti-Ro/SS-A (95%), anti-La/SS-B (67%) and RF (76%). No significant differences in serological characteristics were found between men and women.Median score for the EULAR Sjogren´s

Syndrome Disease Activity Index (ESSDAI) was 6.5, for Sjogren´s Syndrome Disease Activity Index (SSDAI) was 1.76, for EULAR Sjogren´s Syndrome Patient Reported Index (ESSPRI) was 4.35, and for Sjogren´s Syndrome Disease Damage Index (SSDDI) was 2.67.ESSDAI and SSDDI tended to be more frequent in males patients compared with women. Morbidities such as hypertension (33%) and diabetes mellitus (10%) tended to be more frequent in male patients compared with women.

Conclusion: The median age at onset and diagnosis of pSS is higher in men. All pSS male patients showed ocular and oral dry symptoms. The most frecuent extraglandular manifestations in men were hematological involvement, upper airways involvement, asthenia, salivary gland enlargement and articular involvement. Most men had ANA and antiRo antibodies. The disease activity and damage indexes were higher in males.

Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To analyse the main characteristics of patients with primary Sjögren syndrome (SjS) with focal lymphocytic sialadenitis (FLS) unrelated to the presence of circulating anti-Ro/La autoantibodies in a large international cohort of patients.

Methods: The Big Data Sjögren Project Consortium is an international, multicentre registry designed, in 2014, to take a “high-definition” picture of the main features of primary SjS at diagnosis by merging international databases including patients fulfilling the 2002 AE classification criteria. Patients came principally from Europe (n=6045), America (n=1134) and Asia (n=940).

Results: The cohort included 7748 (93%) women and 562 (7%) men, with a mean age at diagnosis of primary SS of 53 years. We selected 5245 patients who showed a Chisholm-Mason grade III or IV in minor salivary gland biopsy and that were also tested for Ro/La autoantibodies, and compared the main features at diagnosis between immunonegative patients (n=2073) and those carrying anti-Ro/La antibodies (n=3172). Immunonegative biopsy-proven patients were predominantly White ($p<0.001$), were 7 years older at diagnosis (57.44 vs 50.74 years, $p<0.0001$) and had a higher frequency of oral and ocular dryness ($p<0.001$), a lower frequency of abnormal salivary flows ($p=0.046$) and parotid scintigraphy ($p=0.012$), and a lower frequency of ANA ($p<0.001$), low C3 ($p<0.001$), low C4 ($p<0.001$), rheumatoid factor ($p<0.001$) and cryoglobulinemia ($p=0.001$) in comparison with Ro/La+ biopsy-proven patients (**Figure 1**). Abnormal salivary flows, parotid scintigraphy and ANA remained independent variables statistically associated with negative Ro/La autoantibodies after adjusting by age and gender.

Conclusion: Biopsy-proven patients with primary SS without circulating anti-Ro/SSA and anti-La/SSB antibodies have a specific phenotypic profile at diagnosis of the disease, characterized by an older age, a higher frequency of sicca symptoms, a lower frequency of abnormal diagnostic tests and a milder immunological profile. Patients carrying Ro/La autoantibodies are diagnosed earlier in spite of having sicca symptoms less frequently, probably due to the development of extraglandular features.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To describe the clinical, immunological and histopathological profile of patients with primary Sjögren syndrome (SjS) presenting with isolated circulating anti-La/SS-B antibodies in the absence of concomitant anti-Ro/SS-B antibodies in a large international cohort of patients.

Methods: The Big Data Sjögren Project Consortium is an international, multicentre registry of primary SjS patients fulfilling the 2002 AE classification criteria. By January 2016, the participant centres had included 8310 patients. Determination of anti-Ro/SS-A and anti-SS-B antibodies were made using commercial tests used in daily practice. Patients were classified in 4 groups: A) Double positivity (Ro+La+); B) Isolated Ro positivity (Ro+La-); C) Isolated La positivity (Ro-La+); and D) Biopsy-proven immunonegative (Ro-La-).

Results: Anti-Ro/SS-A and anti-SS-B antibodies were tested in 8213 (99%) patients: 3372 (41%) were Ro+La+, 2546 (31%) Ro+La-, 222 (3%) Ro-La+ and 2073 (25%) were biopsy-proven Ro-La-. Epidemiologically, age at diagnosis of Ro-La+ patients was similar to the two Ro+ groups and was 5.5 years lower than that observed in Ro-La- patients ($p<0.001$). Clinically, Ro-La+ patients had a similar frequency of ocular dryness than Ro-La- patients (a figure significantly higher in comparison with the two Ro+ groups, $p<0.001$), while the frequency of oral dryness was similar to the Ro+ groups and significantly lower than that reported for the Ro-La- group ($p<0.001$) (**Figure 1**). With respect to diagnostic tests, Ro-La+ patients showed similar figures in comparison with the other groups but a significant higher frequency in abnormal diagnostic tests (salivary flows and parotid scintigraphy, $p<0.001$). Minor salivary gland biopsy was

carried out in 147 (66%) out of the 222 Ro-La+ patients, and showed Chisholm-Mason 3-4 grades in 103/147 (70%), a figure significantly lower than that reported for the 2 Ro+ groups (p<0.001). Immunologically, Ro-La+ patients showed a similar immunological profile than that reported for Ro-La- patients, with a significant lower frequency of ANA, RF, hypocomplementemia and cryoglobulinemia in comparison with the 2 Ro+ groups (p<0.001, **Figure 1**).

Conclusion: In the largest reported cohort of patients with primary SjS fulfilling the 2002 AE classification criteria, only 3% of patients had isolated anti-La/SS-B antibodies. This small subset of patients presents a specific clinical and immunological profile that mix some features characteristic of immunonegative patients and some of patients carrying anti-Ro/SS-A antibodies. Further studies are required to confirm this isolated anti-La positivity and should evaluate the differences in systemic activity and outcomes of this subset of patients with respect to the other immunological groups.

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sicca syndrome is a clinical presentation that is common for several systemic diseases that may infiltrate the exocrine glands. The most frequent disease is Sjögren's syndrome (SS), but other systemic diseases such as sarcoidosis, amyloidosis of IgG4-related disease may also infiltrate salivary glands. The objective was to analyze the safety and usefulness of the minimally-invasive biopsy of minor salivary glands in patients presenting with sicca syndrome suspecting a systemic disease.

Methods: We present a retrospective analysis of 901 patients presenting with sicca syndrome (xerostomia, xerophthalmia, positive ocular tests and/or parotid scintigraphy, overwhelmingly negative for anti-Ro/La antibodies) in whom a minimally-invasive biopsy of minor salivary glands was carried out between January 2005 and June 2016. All biopsy samples were obtained with the same technique and following the same study protocol, which included the evaluation of cumulative focus score of lymphoplasmacytic infiltration (Chisholm Mason score, CMs), together with investigation of granuloma, amyloid, IgG4-related disease or lipids.

Results: All biopsies but six disclosed salivary gland tissue. There are 793 (88%) women and 108 (12%) men, with a mean age of 54,46 years (range 14-86). The main histopathological diagnosis included non-specific chronic sialoadenitis (NSCS, CMs=1-2) in 429 (48%) patients, focal lymphocytic sialoadenitis diagnostic of Sjögren syndrome (FLS, CMs=3-4) in 255 (28%), normal glandular tissue (CMs=0) in 148 (16%) and chronic atrophic sialadenitis (CAS, CMs unclassifiable) in 34 (4%) patients. Other infiltrative diseases included lipoid infiltration (n=10), amyloidosis (n=4), IgG4-related disease (n=3) and sarcoidosis (n=1). The highest mean age was found in patients with CAS (66,35 years), followed by those with NSCS (54,66 years), FLS (54,04 years) and normal result (50,82 years) ($p<0.001$). Patients diagnosed with FLS were more frequently women (91% vs 87%, $p=0.05$), had a higher frequency of abnormal ocular tests (91% vs 66%, $p<0.001$), a higher frequency of ANA (59% vs 36%, $p<0.001$), RF (41% vs 18%, $p<0.001$), anti-Ro (28% vs 7%, $p<0.001$) and anti-La (11% vs 2%, $p<0.001$), and a higher frequency of associated autoimmune diseases (20% vs 10%, $p<0.001$). The percentage of patients diagnosed with SS varied according to the association or not with other autoimmune/viral diseases: 27% of patients with no associated diseases vs 34% of those with organ-specific autoimmune diseases, 42% of those with chronic viral diseases and 50% of those with other systemic autoimmune diseases ($p<0.05$). Abnormal ocular tests ($p<0.001$), ANA ($p<0.001$), RF ($p<0.001$) and anti-Ro ($p<0.001$) remained independent variables significantly associated with SS after adjustment by age and gender.

Conclusion: Minimally-invasive biopsy of minor salivary glands is a simple, safe, and reliable tool for the diagnosis of infiltrative systemic diseases of exocrine glands, overwhelmingly Sjögren syndrome but also amyloidosis IgG4-related disease and sarcoidosis. Lack of severe lymphocytic infiltration and atrophic histopathological data closely correlated with an older age.

Session Date: Tuesday, November 15, 2016

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In the classification criteria of Sjögren's syndrome (SS), involvement of the salivary glands is currently assessed by sialography, scintigraphy, sialometry and histopathology. Recent discussions have focused on the diagnostic accuracy of ultrasound (US). The purpose of this study was to determine inter- and intra-observer reliability of US of major salivary glands in patients clinically suspected with SS.

Methods: Eighty consecutive patients clinically suspected with SS were subjected to US as part of their diagnostic work-up. The following US variables of the parotid and submandibular salivary glands were assessed: echogenicity, parenchymal homogeneity, presence of hypoechogenic areas, hyperechogenic reflections and clearness of posterior glandular border (scoring range 0-48)[1]. The cut-off point to define positive or negative US for SS was set at 15 [2] and 17 [1]. Images were scored independently by three blinded observers in 2 sessions with a 2-week interval. Intra- and inter-observer reliability was calculated using Cohen's Kappa and Fleiss' Kappa, respectively, in combination with the percentage of absolute agreement for nominal variables and intraclass correlation coefficients (ICC) for continuous variables.

Results: Intra-observer reliability of the US total score was excellent, with ICCs ranging from 0.89 to 0.96 for the three observers. Inter-observer reliability was good to excellent, with ICCs of 0.84 and 0.76 for the US total score in sessions one and two, respectively. Kappa ranged from 0.60 to 0.83 and percentage of agreement from 80 to 92 depending on the cut-offs applied. Hypoechogenic areas and homogeneity of the parotid glands showed the highest inter-observer reliability with median ICCs of 0.74 and 0.71, respectively. Median kappa for echogenicity was low (0.22). The differences between the three observers were larger for higher US total scores (Figure). Our results suggest that observers may consistently identify in which patients US of the major salivary glands is positive or negative for SS, but scoring the severity of the US findings is more inconsistent.

Conclusion: US of the major salivary glands is reliable in diagnosing SS. There might be, however, some discrepancies between observers in assessing the severity of US findings making it more difficult to detect 'true' changes over time. Thus, when monitoring the progression of SS or treatment efficacy, it is advised that each particular patient is scored by the same ultrasonographer at every time point. **References**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

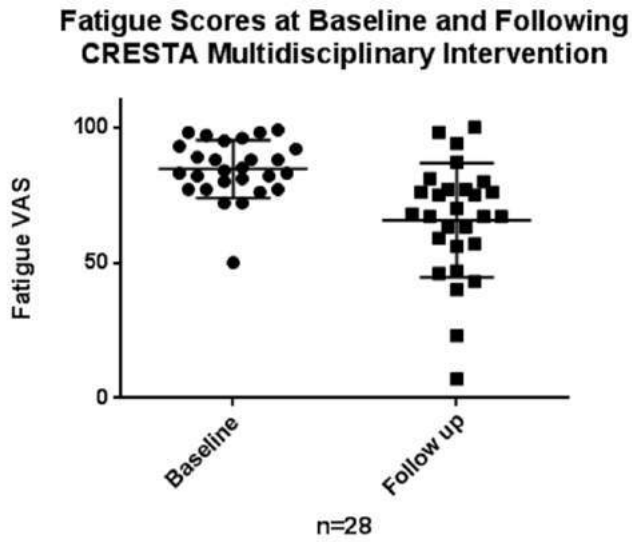
Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's syndrome (PSS) is an autoimmune disease which targets secretary glands resulting in dry eyes and mouth. Approximately 70% of PSS patients experience chronic fatigue. The Newcastle Fatigue CRESTA clinic was recently established in the north east of England to offer multidisciplinary care for people with the symptom of fatigue. A cohort of fatigued PSS patients (n=28) were referred from a rheumatology service to the Fatigue CRESTA clinic in order to support them in managing this troublesome symptom. All PSS patients were assessed by a physician and an occupational therapist at their first CRESTA appointment. They were subsequently offered a therapy intervention tailored to their individual requirements. This may include occupational therapy (activity management, goal setting and graded activity/exercise), physiotherapy (including Pilates based exercises to improve body posture and strength), cognitive behavioural therapy for insomnia, psychological therapy or a combination of several therapies. The aim of this study was to determine whether there was a difference in fatigue scores before and after a multidisciplinary intervention at the Fatigue CRESTA.

Methods: Patient reported outcomes were collected by the referring consultant at baseline and follow up at their routine rheumatology appointments. Fatigue (visual analogue scale 0-100) scores were compared for each consecutive patient pre and post a Fatigue CRESTA multidisciplinary intervention. Data were checked for normality and compared using a paired t-test.

Results: Participants attended a median of 8 appointments at the clinic. The mean fatigue scores improved from 84.52 (SD 10.66) at baseline to 69.61 (SD 15.30) at follow up. This finding was statistically significant ($p<0.001$) and represents a clinically important difference [1].



Conclusion: A tailored multidisciplinary fatigue intervention has objectively improved fatigue severity in this PSS patient group and warrants further investigation. These findings highlight the importance of an individualised, multidisciplinary approach for fatigue management in PSS. SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-SSA/Ro and anti-SSB/La antibodies are present in inflammatory autoimmune disease patient sera, and there are related to different clinical manifestations. It is well known the association between the presence of these antibodies in maternal blood and fetal atrioventricular block. However, there are no much studies about infertility or repeated abortions and anti-SSA/Ro and anti-SSB/La antibodies in broad series. The aim of this study is to characterise a cohort of patients with positive anti-SSA/Ro and/or anti-SSB/La antibodies and to evaluate the prevalence of abortions and neonatal mortality.

Methods: Observational descriptive study with 162 patients older than 15 years old with pregnancies history and positive anti-SSA/Ro and/or anti-SSB/La antibodies from February 2011 to July 2015. We consider healthy women with pregnancies history and with comparable characteristics as negative control group.

Results: We included 162 patients with positive anti-SSA/Ro and/or anti-SSB/La antibodies with a mean age of 50.5±14.2 years old. Main diagnosis were systemic lupus erythematosus (n=85), Sjögren syndrome (n=40), rheumatoid arthritis (n=16), systemic sclerosis (n=6), mixed connective tissue disease (n=3) and other diagnosis (n=12). Lupus anticoagulant was positive in 8 cases and 57 patients showed low complement values. 37% of patients had at least one pregnancy, and the 36.7% aborted during pregnancy. There were no significant differences in the abortion incidence between our cohort of patients and the healthy control group considered. We observed 4 cases of fetal atrioventricular block, all of them with positive anti-SSA/Ro and/or anti-SSB/La antibodies and only in one case also with positive lupus anticoagulant.

Conclusion: In our series, pregnant women with positive anti-SSA/Ro and/or anti-SSB/La antibodies did not show high prevalence of abortion. However, the positivity of these antibodies was statistically correlated with the presence of fetal atrioventricular block.

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: primary Sjogren's syndrome (pSS) articular manifestations include often tender joints and more rarely synovitis. The main objective of this study was to describe characteristics, treatment and outcome of patients presenting pSS-related joint involvement with synovitis.

Methods: we performed a French multicentric retrospective study including all cases of adult-onset pSS (AECG criteria) with at least one clinical and/or echographic synovitis from 1998 to 2015. Data concerning clinical, biological and radiological findings were collected, as well as treatments. Disease activity was assessed using ESSDAI scale. Complete treatment response for joint involvement was defined as disappearance of all signs and synovitis, partial response as more than 50% improvement. Controls with pSS without synovitis were used to determine the factors associated with joint involvement.

Results: we identified 57 patients (93% women) with median age at the diagnosis of joint involvement of 54 years-old (45-63). The number of tender joint was 8 (4-12) with 4 (2-6) swollen joints. Synovitis was clinical in 65.3% patients, and 26 (44.7%) patients had MRI or echographic confirmation of synovitis. No erosion was seen on X-ray in all cases. The more frequent articular finding was a symmetric polyarthritis (68.4%) and the predominant swollen joints were metacarpophalangeal joint (67.9%). C-reactive protein was 5 (3-9.3) mg/l at the time of synovitis diagnosis. Rheumatoid factor and CCP-antibodies were present in 44.9% and 13.7% patients,

respectively. Median ESSDAI scale was 7 (5-9). All patients received at least one therapeutic line. Steroids were used alone in 6 (10.5%) cases, in association with hydroxychloroquine (HCQ) in 19 (33.3%) cases, and in association with methotrexate (MTX) in 18 (31.6%) cases. A second line was initiated for 31 (54%) with HCQ in 13 (41.9%) cases, MTX for 14 (43.6%) patients, and rituximab (RTX) for 10 (34.5%) patients. Thirteen (23%) patients received a third line with MTX in 9 (69.2%) cases, and RTX in 6 (46.2%) cases. In this 101 therapeutic lines, steroids were used in 78 (77.2%) lines with a median amount of 10 (7-12.5) mg/day, HCQ in 57 (57%) lines with a daily dose of 400 mg, MTX in 44 (44%) lines with a weekly-dose of 15 (15-20) mg. RTX was used in 19 (18,8%) lines and TNFa antagonists in 4 (4%) cases. Number of swollen joints, ESSDAI score and steroids dose significantly decreased from the baseline considering HCQ alone (35 lines), MTX (17 lines), and significant ESSDAI score and steroids dose decrease was noted under RTX (19 lines). Number of swollen joints, ESSDAI score or steroids dose reduction decrease was similar considering patients treated by HCQ, MTX or RTX. Comparing 57 pSS with synovitis with 104 pSS controls without joint involvement, cases were younger (54 [23-81] vs. 55 [18-81] years, $p < 0.05$), with more frequent lymph nodes (12.3% vs 1.8%, $p = 0.007$). Patients with joint involvement and synovitis were treated more frequently with HCQ (67% vs. 15%, $p < 0.0001$), steroids (75% vs. 6%, $p < 0.0001$), and methotrexate (37% vs. 0.8%, $p < 0.0001$).

Conclusion: the pSS articular manifestations may include synovitis. Even the use of HCQ, MTH, and RTX seem to be effective for joint involvement, the best regimen remain to be determined.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: New consensual classification criteria for primary Sjögren's syndrome (pSS) have been recently developed, validated, and submitted to ACR and EULAR committees. They differ substantially from previously used AECG criteria in that they consider systemic involvement (defined as ESSDAI score ≥1) as well as sicca symptoms as entry criteria before applying a weighted score. Evaluation of the concordance and differences between the two sets of criteria in independent patient populations is mandatory to establish how future clinical studies using the new criteria will be comparable to previously published studies.

Methods: This cross-sectional study was conducted in the monocentric Brittany cohort (DIApSS cohort) of patients with suspected pSS (sicca symptoms, parotidomegaly or extraglandular manifestations suggestive of pSS). All patients had standardized clinical examination, basic biology, immunological tests and minor labial salivary gland biopsy. Major salivary gland ultrasonography (SGUS) in mode B was performed in all patients by the same experienced operator, who was blinded to the diagnosis. Agreement between the two sets of criteria was assessed using Cohen's κ coefficient and the characteristics of discordant patients were detailed.

Results: 163 patients were prospectively included between 2006 and 2016. Mean age was 56±14 years, female percentage 94%, and mean duration of the symptoms 6.8±7.9 years. More patients fulfilled ACR/EULAR criteria (n=93, 57%) than AECG criteria (n=83, 51%). 80 patients (49%) fulfilled both criteria, 13 (8%) fulfilled ACR/EULAR only, 3 (2%) AECG only and 67 (41%) none of the

criteria. Concordance between both criteria was good (kappa=0.8, agreement 90%). Compared to patients fulfilling both criteria, patients fulfilling ACR/EULAR but not AECG criteria (n = 13) had similar age (56 vs 57 years), shorter disease duration (mean 5.9±8.5 vs 8.2±8.9 years), less frequent sicca symptoms (eye dryness 50% vs 96%, mouth dryness 64% vs 96%) and salivary gland swelling (14% vs 28%). They had characteristic features of pSS, with frequent systemic involvement at diagnosis (88%), positive salivary gland biopsy (86%), abnormal SGUS (67%) and presence of anti-SSA/SSB autoantibodies (57%). Among patients negative for the two sets of criteria, 10% had an abnormal SGUS and received a clinical diagnosis of pSS based on physician opinion.

Conclusion: Agreement between AECG criteria and new ACR/EULAR criteria is good suggesting that they select quite similar patients. ACR/EULAR criteria display a slightly higher sensitivity and are able to detect more patients with early disease and systemic involvement. As previously demonstrated for AECG criteria, SGUS inclusion into ACR/EULAR criteria may further enhance their sensitivity.

Session Date: Tuesday, November 15, 2016

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sensory ataxic neuropathy (SAN) is one of the neurologic complications in Sjögrenfs syndrome (SS). The underlying pathology was lymphocytic infiltration to the dorsal root ganglia (DRG), called dorsal root ganglionitis. 3-Tesla magnetic resonance neurography (3T MRN) clearly delineate DRGs and peripheral nerves, and has been used to evaluate various neurological disorders. However, there has been no reports correlating signal change in DRGs and subtypes of neuropathy. This study aimed to determine whether 3T MRN is useful for the diagnosis of SAN in SS.

Methods: On retrospective chart review from 2014 to 2016, we found that eight patients (including four patients with SS; three fulfilled American-European Consensus Group classification criteria) had been admitted for the evaluation of neuropathy and underwent 3T MRN of lumbosacral plexus. Data were collected on clinical examination including Romberg test and deep tendon reflex, electrophysiological tests, and spinal cord MRI/MRN with a 3T MRI scanner. In MRN, coronal and sagittal short-tau inversion recovery technique was used to detect abnormalities. In each patient with SAN, the signal intensity and size of DRGs were compared with those of non-SAN patients and age-matched control data (cases without systemic neuropathy)

Results: Among four patients with SS, three presented with SAN and one patient showed predominant motor neuropathy. Among four patients without SS, the diagnosis was Guillain-Barré syndrome (N = 3) or idiopathic chronic neuropathy (N = 1). All three patients with SAN showed sensory ataxia with positive Romberg sign, decreased or diminished sensory nerve action potential of sural nerve on nerve conduction study. Five patients without SAN presented with predominant motor symptoms and did not accompany sensory ataxia. On 3T MRN, DRGs in SAN patients were atrophic and their signal intensity were decreased compared to non-SAN patients and control data.

Conclusion: In this study, we described the clinical utility of signal abnormality of DRGs with 3T MRN for the diagnosis of SAN in SS. Larger prospective study would be warranted to establish efficacy of MRN and to elucidate the exact nature of this radiologic finding.

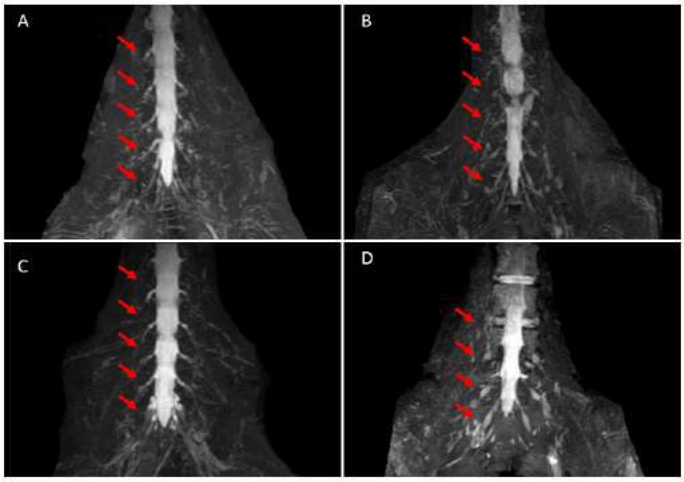

Figure 1. 3T-MRN findings in patients with SS (STIR sequence). Patient 1 (A), 2 (B), and 3 (C) showed atrophic DRGs, with low signal intensity. On the other hand, Patient 4 (D) showed normal-appearing DRGs.

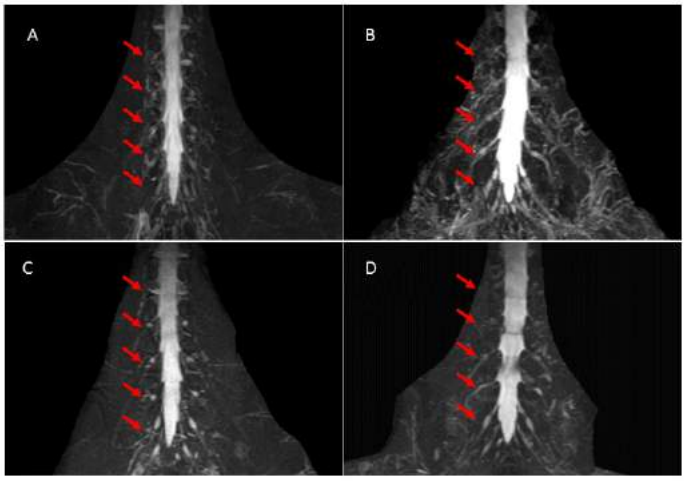

Figure 2. 3T-MRN findings in patients without SS (STIR sequence). Patient 5 (A), 6 (B), and two patients from control data (C, D) showed normal-appearing DRGs

Table. Correlation among clinical, electrophysiological, and radiological findings.

Case	Age/ Sex	Diagnosis	Clinical presentation	Romberg test	DTRs	Neurophysiological test	Posterior column on MRI	DRG on MRN
1	75 F	SS, seropositive SAN	Numbness, hands/feet Ataxia	Positive	PTR 1+ ATR -	Sural N SNAP ↓ Tibial SEP N20 ND	Normal	Atrophy

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Prevalence of symptomatic pulmonary disease in primary Sjögren's Syndrome (pSS) ranges between 9% and 27%. Xerotrachea, small airway disease and interstitial lung disease (ILD) are among the most common manifestations. However, the evidence is conflicting on which of the above mentioned respiratory disorders is the most prevalent in pSS patients. The purpose of the present study is to estimate the prevalence and type of chronic respiratory symptoms in a large cohort of pSS and associate them with disease-specific clinical and laboratory parameters.

Methods: Consecutive patients with pSS were questioned for chronic respiratory symptoms (cough, dyspnea or both). Patients with pre-existing respiratory symptoms before the onset of pSS were excluded from further investigation. The remaining symptomatic patients were assessed clinically, with PFTs (pre- and post-bronchodilator spirometry, static lung volumes and diffusion capacity) and high resolution CT (hrCT) on inspiratory and expiratory phase. Clinical and laboratory characteristics taken from the patient's records were compared between symptomatic and asymptomatic patients and between patients with ILD and other non ILD respiratory disorder related to pSS.

Results: Thus far, 348 patients have been screened from an initial cohort of 723 pSS patients. According to preliminary analysis, chronic respiratory symptoms were detected in 24% (*84/348*) of patients. Two thirds of the cases (*55/84*) were attributed to pSS. PFTs and chest hrCT were performed in 34 patients. Eighteen patients (*18/34 or 53%*) were diagnosed with small airway disease, while only 5 patients (*15%*) had ILD. Xerotrachea was considered responsible for chronic cough, in symptomatic patients with normal PFTs and normal or non-specific CT findings (*11/34 or 32%*). There were no statistically significant differences in clinical and laboratory parameters between symptomatic and asymptomatic patients, patients with ILD, patients with small airway disease or symptoms related to xerotrachea.

Conclusion: Small airway disease is the most common pulmonary manifestation in patients with chronic respiratory symptoms and pSS, while ILD is less frequent than previously thought.

Session Date: Tuesday, November 15, 2016
Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: In previous studies in primary Sjögren's syndrome (pSS), the prevalence of pulmonary involvement varied greatly depending on differences in inclusion criteria, imaging modalities and definitions of pulmonary involvement. The EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) has been developed for standardizing definitions of the main organ involvements. Our aim was to evaluate the prevalence and types of pulmonary involvement in pSS patients and to classify the manifestations using the respiratory domain of the ESSDAI.

Methods: This retrospective cohort study included all consecutive pSS patients, fulfilling the AECG and/or ACR classification criteria, who visited the department of Rheumatology and Clinical Immunology of the UMCG in 2015. Data were obtained from electronic patient records of the first visit in 2015. Pulmonary complaints were defined as persistent cough, dyspnoea during exercise, dyspnoea in rest and recurrent lower respiratory infections. Pulmonary additional tests included conventional chest radiography, (high-resolution; HR) CT and pulmonary function test (PFT). Pulmonary involvement was defined as the presence of conditions 1) for which therapy is needed and/or follow-up is recommended and 2) with (possible) relation with pSS instead of coincidental factors. The respiratory domain of the ESSDAI was determined for all these patients at time of visit. In some cases, the difference between pulmonary manifestations caused by pSS or coincidental factors remained unclear, resulting in a range of assumed to possible pulmonary involvement in pSS.

Results: Of the 262 included pSS patients, 93% were female and mean age was 56 ± 15 years. Pulmonary complaints were present in 88 (34%) patients; 70 (27%) patients with cough, 42 (16%) with dyspnoea during exercise, 17 (7%) with recurrent lower respiratory infections and no patients with dyspnoea in rest. Additional pulmonary diagnostics was performed in 225 (86%) patients; chest radiography in 203 (78%) patients, PFT in 147 (56%) patients and (HR)CT in 87 (33%) patients. Pulmonary involvement was present in 25-39 (10-15%) pSS patients. Overall, most common was interstitial lung disease (ILD), which was present in 15 patients; especially non-specific interstitial pneumonia (NSIP), followed by lymphocytic interstitial pneumonia (LIP) and organising pneumonia (OP). Isolated bronchiectasis and/or bronchopathy was present in 11 patients, pleuritis in 4 patients, pulmonary hypertension in 2 patients and 2 patients had a mucosa-associated lymphoid tissue (MALT) lymphoma in the lung. In total, 16 (6%) patients had a positive ESSDAI for the respiratory domain; 4 patients with low, 11 with moderate and one patient with high activity. Pulmonary involvement in pSS was not scored in the ESSDAI for patients with long lasting features (>1 year) which are assumed to be not active (n=14), MALT lymphoma which was rated in another domain (lymphadenopathy and lymphoma; n=2), or when (HR)CT and/or PFT was not recently performed (n=7).

Conclusion: In this cross-sectional study in daily clinical practice, pulmonary involvement was present in 10-15% of pSS patients. Of all pSS patients, 6% were scored as active on the respiratory domain of the ESSDAI.

Session Title: Sjögren's Syndrome - Poster II: Clinical Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Little is known about the natural history of primary Sjögren's syndrome due to the limited number of prospective cohorts followed up in a yearly manner. International validated disease activity scores were recently established and are now used as inclusion criteria and as primary outcome measures in many randomized controlled trials. This is therefore of critical importance to know the evolution of these scores and the proportion of patients experiencing a change in these scores.

Methods: The ASsessment of Systemic complications and Evolution in primary Sjögren's Syndrome (ASSESS) cohort is a prospective ongoing cohort of 395 patients. All patients have a medical examination every year by a trained physician, who collects the ESSDAI (Eular Sjögren's Syndrome Disease Activity Index), which scores systemic disease activity, clinical ESSDAI (clin ESSDAI, which scores systemic disease activity without the biological domain of the ESSDAI)and the ESSPRI (Eular Sjögren's Syndrome Patient Index), a patient-related outcome which scores dryness, pain and fatigue.

Results: Baseline data At enrollment in the 395 patients of the cohort, median ESSDAI, clin ESSDAI and ESSPRI were 3 [2-8], 3 [0-8] and 5.7 [4-7], respectively. 28.2% and 10.6% of patients had moderate systemic disease activity (5≤ ESSDAI < 13) or high systemic disease activity (ESSDAI ≥ 14), respectively. 62.2% of patients had an ESSPRI≥ 5. Follow-up data During the 5 years of annual follow up, 23.3 and 23.4% of patients with a baseline ESSDAI or a clinESSDAI < 5, respectively, had at least at one follow up visit, an ESSDAI or clinESSDAI ≥ 5. 10.5% and 12.9% of patients with a baseline ESSDAI<14 or clinESSDAI<14, respectively, had at least at one follow up visit an ESSDAI or clin ESSDAI≥14. Regarding changes in domains of the ESSDAI over the 5 years of follow up, the most frequent changes were observed in the biological (46.2% of patients), articular (34.9%), hematological (28.9%), pulmonary (25.1%), and glandular domain (20.5%). 25% of patients with a baseline ESSPRI<5 had at least at follow up one visit an ESSPRI ≥5. 39.8% of patients with baseline ESSDAI and ESSPRI<5 had at least at one follow up visit an ESSDAI or an ESSPRI ≥5.

Conclusion: Systemic manifestations and symptoms evolve over time during the 5-year follow-up in patients with primary Sjögren's Syndrome. Approximately one fourth of the patients with no systemic activity or an acceptable symptoms status at baseline evolved to a status of moderate disease activity or to disabling symptoms, respectively. 40% of patients without any active disease or disabling symptoms at baseline developed systemic complications or disabling symptoms within 5 years.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Identification of disease-associated or protective bacteria may elucidate new biomarkers or probiotic supplements for people suffering from spondyloarthritis (SpA), or for people at-risk of disease development. The colitogenic *Prevotella copri* was associated with new-onset rheumatoid arthritis, and *Prevotella* spp. were increased in the cecum of HLA-B27 transgenic rats. Ankylosing spondylitis patients have increases in several bacterial families including *Porphyromonadaceae*. *Lactobacillus murinus* is protective in a murine model of colitis. Thus, microbes are associated with SpA disease progression but it is unclear how the microbial community structure differs as a result of genetic susceptibility to SpA, or the impact of additional pro-inflammatory triggers or drivers. Since IL-23 is a key driver of SpA, we hypothesized that IL-23 modifies the gut microbiota and the response to pro-inflammatory triggers of SpA.

Methods: BALB/c ZAP-70^{W163C}-mutant (SKG) mice housed under specific pathogen-free (SPF) conditions treated with microbial β-1,3-glucan (curdlan) develop IL-23- and microbiota-dependent SpA-like arthritis and ileitis. Altered Schaedler flora(ASF)-colonized SKG and BALB/c mice were treated one day prior to curdlan, and then weekly, with anti-IL-23 p19-specific mAb or isotype control mAb, or with curdlan or vehicle control. SPF-SKG mice were treated weekly with anti-IL-23 or isotype mAb for 3 weeks, then with curdlan or vehicle control. Fecal samples were collected longitudinally and the microbiota community profiles were analyzed by RT-PCR and next-generation sequencing. Arthritis, spondylitis and ileitis were assessed histologically.

Results: After colonization of germ-free mice with ASF, 4/8 bacterial strains were detected in ASF-SKG and ASF-BALB/c mice: *Clostridium* sp., *Lactobacillus murinus*, *Mucispirillum schaedleri* and *Parabacteroides* sp. Whilst the relative abundance of *Clostridium* sp. and *Parabacteroides* sp. was decreased in SKG, the most abundant bacterial species in both strains of mice was the *Parabacteroides* sp. After curdlan, the abundance of *L. murinus* and *M. schaedleri* but not *Parabacteroides* sp. declined in ASF-SKG mice over time, while the abundance of *L. murinus* and *M. schaedleri* did not decline in mice treated with curdlan and anti-IL-23 mAb. In SPF-SKG mice treated with anti-IL-23 mAb or anti-IL-23 mAb then curdlan, the abundance of multiple *Prevotellaceae* and *Porphyromonadaceae* spp. decreased relative to SPF-SKG mice treated with isotype then curdlan.

Conclusion: Interaction of the microbiota with the immune system of SKG mice alters the composition of both a simplified consortium and an unrestricted bacterial community. Curdlan triggers the decline of a gut-protective species within a simplified consortium. Treatment of SPF-SKG mice with anti-IL-23 mAb not only suppresses SpA development but shifts the fecal microbiota composition and prevents the usual outgrowth of bacteria associated with arthritis and inflammatory bowel disease in response to curdlan.

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: *TBX21* encodes the transcription factor T-bet and is genome-wide significant associated with ankylosing spondylitis (AS). T-bet is implicated in innate and adaptive immunity. However, the role of T-bet in AS pathogenesis is unclear. We recently demonstrated that T-bet expression is enhanced in AS patients and that T-bet controls IFN-gamma+IL-17+ NK cells and CD8 T cells. In the SKG model of spondyloarthropathy (SpA) mice lacking the *Tbx21* gene were protected from peripheral arthritis and gut inflammation. We hypothesized that enhanced T-bet expression in AS alters mucosal immunity in the gut and contributes to enhanced reactivity to microbial challenge. Furthermore we hypothesized that the enhanced T-bet expression seen in AS is antigen-driven and that T-bet+ cells express markers of prior antigen encounter.

Methods: We used 16S RNA sequencing to assess the impact of *Tbx21* on the gut microbiome in fecal samples from wildtype SKG mice or *Tbx21*-/- littermate controls. AS patient PBMC samples were used to investigate the response of T-bet+ cells to in vitro challenge with bacterial stimuli. Finally we looked for evidence of antigen-experience on T-bet+ NK cells and CD8 T cells from AS cases and healthy controls to determine whether these cells are being stimulated in vivo in AS patients.

Results: *Tbx21* influenced the intestinal microbial composition with decreased abundance of inflammatory species such as *Bacteroidaceae, Prevotellaceae, Rikenellaceae, Lachnospiraceae* observed in *Tbx21*-/- compared with *Tbx21*+/+ littermate control SKG mice. T-bet+ NK cells and CD8 T cells secreted IL-17 and IFN-gamma following in vitro challenge with a range of TLR agonists. In the periphery of AS cases T-bet+ NK cells and CD8 T cells displayed phenotypic markers of recent antigen exposure but the frequnecy of circulating memory T cells was profoundly reduced compared with healthy controls.

Conclusion: AS-associated variants in *TBX21* influence T-bet expression and numbers of IL-17 and IFN-gamma secreting NK and CD8+ T cells. T-bet is a major component of inflammatory pathways of spondyloarthropathy in humans and mice and may contribute to inflammation by influencing the gut microbiome and/or through influences on immune cell function in response to microbial challenge.

Identification of a Potential Commensal Immunologic Target in Enthesitis-related Arthritis

Background/Purpose: Research in inflammatory bowel disease (IBD) has identified commensal organisms that stimulate humoral and T cell immune responses. Although there is mixed data on whether similar antibodies are also present in spondyloarthritis (SpA), there has not been a comprehensive effort to identify commensal antigenic targets in SpA.

Methods: We used a novel antigen array developed by one of the co-authors (1) in which lysates of whole bacteria were plated, along with known flagellar and other commensal-derived antigens. Initial screening was performed with pooled serum samples from children

with enthesitis-related arthritis (ERA) and healthy control subjects, testing for IgG and IgA reactivity. Validation was performed with Western blots and with individual serum samples on the array.

Results: The initial screening studies were performed on pools of five ERA subjects and healthy controls. For most of the antigens tested on the array, there were no differences in binding between ERA patients and controls. However, IgG and IgA reactivity against *Prevotella oralis* was present only in the patients with ERA, not in controls or even in the pool of patients with ERA complicated by IBD. Western blots against *P. oralis* with ERA serum identified a high molecular weight glycoprotein that was not targeted by control serum. To confirm our findings, we repeated the array on individual serum samples from 83 patients with ERA (44 male; age 13; 6.0 – 19) and 59 healthy control subjects (33 male; age 13; 6.6 – 18). While there were no differences in IgG or IgA reactivity to most antigens, including the positive control Tetanus toxoid, ERA subjects had increased IgA reactivity against *P. oralis* (net signal intensity [NSI] 3761 versus 1835, p = 0.008; Figure) as well as to *P. buccalis* (NSI 962 versus 618, p = 0.008.) ERA patients also had increased IgG reactivity against *P. buccalis* (NSI 4936 versus 2718, p = 0.003) as well as a modest increase against the previously identified IBD-associated antigen Fla2 (NSI 1310 versus 1007, p = 0.026). Among the ERA patients, there was no association between HLA-B27 status and reactivity against these antigens.

Conclusion: Herein, we introduce members of the *Prevotella* genus, primarily *P. oralis* and *P. buccalis*, as potential antigenic targets in children with ERA. We also demonstrate increased Fla2 reactivity in children with ERA, consistent with data in adults with SpA. (1) Christmann B et al., JACI 2015;136:1378-86

Session Time: 9:00AM-11:00AM

Background/Purpose: HLA-B27/hβ2m transgenic rats (B27 rats), a model of spondylarthritis (SpA) develop spontaneous colitis and arthritis. Recently, in vitro studies demonstrated that altered dendritic cells (DCs) function promoted a biased expansion of pro-inflammatory Th17 cells and alterations of regulatory CD4+ T cells (Treg) function, characterized by heightened IL-17 and decreased Il-10 production. Interestingly, *in vitro* blockade of ICOS-ICOSL interaction reversed IL-10/IL-17 imbalanced production by Treg. These data led us to investigate the *in vivo* consequences of ICOS/ICOSL interaction in experimental SpA using a genetic approach by producing B27 rats with *Icos* deletion (B27.ICOS$^{-/-}$ rats).

Methods: ICOS$^{-/-}$ rats were produced using TALEN technology, and backcrossed onto the B27 transgenic background (F344). B27.ICOS$^{+/+}$ and B27.ICOS$^{-/-}$ rats were weekly weighted, examined and scored for clinical symptoms (colitis, arthritis, alopecia and orchitis). Inflammatory pattern was determined by histological analysis and *ex-vivo* production of pro-inflammatory cytokines.

Results: As expected, chronic diarrhea was the most common manifestation, starting at 9 weeks of age in all B27.ICOS$^{+/+}$ rats. Arthritis and alopecia developed only in some B27.ICOS$^{+/+}$ rats. The clinical score progressively worsened in B27.ICOS$^{+/+}$ rats. In contrast, the B27-ICOS$^{-/-}$ rats did not develop any symptom of disease until age of 16 weeks and attenuated symptoms were observed until 24 weeks, a finding that was confirmed by histopathology analysis. Decreased *in vitro* production of pro-inflammatory cytokines and increased IL-10 production by CD4+ T cells were consistently observed in the B27-ICOS$^{-/-}$ rats.

Conclusion: Those results indicate a protective effect of *Icos* deletion on the onset and severity of SpA in the B27 rat. The protective effect was associated to a decrease of pro-inflammatory T cells and an increased proportion of IL-10-producing CD4+T cells. Those data corroborate previous observation suggesting a key role for ICOS signaling in the imbalanced production of IL-10 and IL-17 by Treg in the B27 rat and highlight ICOS as a putative therapeutic target in SpA.

Regulation of Inflammation By Interleukin-27 in a Rat Model of Spondyloarthritis (SpA)

Quentin Jouhault[1], Maxime A. Breban[2], Luiza Krause[3] and Gilles Chiocchia[3], [1]Infection and inflammation, INSERM-U1173, University of Versailles Saint-Quentin-en-Yvelines, France, Montigny-le-Bretonneux, France, [2]Rheumatology Division, Ambroise Paré Hospital (AP-HP), and Versailles Saint Quentin en Yvelines University, Boulogne-Billancourt, France, [3]Infection and Inflammation, INSERM-U1173, University of Versailles Saint-Quentin-en-Yvelines, France, Montigny-le-Bretonneux, France

Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: SpA is a chronic inflammatory rheumatic disorder with osteo-articular and extra-articular manifestations. HLA-B27/human β2-microglobulin transgenic rats (B27 rat) spontaneously develop a phenotype closely resembling human SpA and represent an adequate model to better understand the mechanisms involved in SpA development. Disease development in these rats is correlated with accumulation of pro-inflammatory interleukin-17 (IL-17)-producing helper T cells (Th17) and abnormal function of dendritic cells (DCs) which enhance the generation of Th17 cells. Moreover, dysregulated production of IL-17 and IL-10 in favor of IL-17 by regulatory T cells (Treg) was recently described, associated with inducible costimulator (ICOS) overexpression. Transcriptomic study of B27 DCs has revealed a decreased expression of IL-27, an anti-inflammatory cytokine able to decrease IL-17 and increase IL-10 production by T cells. Here, we investigated if addition of exogenous IL-27 would contribute to reverse the pro-inflammatory phenotype of T cells observed in the B27 rats.

Methods: Sorted T cell subsets and sorted CD103+ DCs from B27 rats were co-cultured in the presence or absence of recombinant IL-27. Effector T cells and Tregs were cultured 3 days with coated anti-CD3. Naive T cells were cultured 6 days with coated anti-CD3 in Treg- or Th17-polarizing conditions. Cytokine production was evaluated by intracellular staining after PMA/ionomycin stimulation and by ELISA in the supernatants.

Results: The addition of exogenous IL-27 inhibited IL-17 expression and increased IL-10 production on several CD4+ T cells subsets, such as effector T cells or Tregs. Moreover, IL-27 inhibited the development of Th17 and promoted IL-10 production from naïve T cells cultured in Treg- or Th17-polarizing conditions. We also observed a downregulation of ICOS expression on T cells cultured in the presence of IL-27. *In vitro*blockade of IL-10 with a specific antibody demonstrated that this cytokine was not implicated in the modulatory effect of IL-27 on IL-17 production. Moreover, IL-27 still significantly decreased IL-17 production by T cells from B27-ICOS-/- rats, indicating that this effect was also independent of ICOS.

Conclusion: Our results reveal that IL-27 is able to reverse the pro-inflammatory phenotype observed in T cells from B27 rats by reversing the IL-17/IL-10 imbalance in favor of IL-10. Moreover, the effect of IL-27 on IL-17 production was independent of IL-10 and ICOS modulation. Given that IL-17 is a confirmed therapeutic target in SpA, these results suggest that IL-27 may be a new promising therapeutic tool for SpA.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Mechanisms underlying the striking association of SpA with the MHC class I molecule HLA-B27 remain poorly understood. SpA-like disease develops spontaneously in B*2705 transgenic rats in correlation with high HLA-B27 expression levels. This study was undertaken to examine the consequences of expressing HLA-B27 alleles which are differently associated with SpA on their intracellular distribution. It has previously been observed that high expression levels of HLA-B in HeLa cells induced cytoplasmic vesicles formation containing HLA-B molecules and that the density of vesicles was more important for HLA-B27 subtypes associated with SpA than for the non-associated HLA-B*2706 and HLA-B*0702 alleles. Here, we further examined the nature and composition of thoses vesicles and the putative differences between associated and non-associated HLA-B alleles.

Methods: HeLa cells were transfected with complementary DNA encoding for HLA–B proteins fused to yellow fluorescent protein. We studied the composition and nature of HLA-B-containing intra-cellular vesicles by antibodies staining and live-cell imaging.

Results: With increased expression, all HLA-B proteins accumulated in cytoplasmic vesicles. This phenomenon was more pronounced for the SpA-associated HLA-B*2702, -B*2704 and -B*2705 than for the non-associated -B*2706 and -B*0702. We observed comparable staining of those vesicles with HC10 antibody (anti-class I heavy chain) for all HLA-B alleles. In contrast, we observed differential staining with BBM1 antibody that binds to β2m: the SpA-associated HLA-B27 subtypes formed vesicles that were stained significantly more with BBM1 than the non-associated HLA-B*2706 and HLA-B*0702 alleles. On the other hand, we observed no staining of thoses vesicles for EEA1 (early endosome marker), Rab7 (late endosomes marker), LC3 (autophagosomes marker) and Rab6 (Golgi marker) antibodies. However, we found positive staining for ER chaperones (BiP, calreticulin and ERp57) indicating that the HLA-B-containing vesicles belong to the ER. Consistent with such interpretation, those vesicles were still observed using live-cell imaging of HeLa cells transfected with HLA-B after treatment with nocodazole or brefeldin-A that inhibit ER exit. Finally, a lack of staining for tapasin indicated that the peptide-loading complex (PLC) does not localize to those vesicles.

Conclusion: Under conditions of high expression, HLA-B molecules accumulate in vesicles that belong to the ER where they co-localize with chaperones but not with the PLC. Moreover, our data indicate differences between HLA-B-containing cytoplasmic vesicles, depending on the allele: vesicles formed with HLA-B27 subtypes associated with SpA were more abundant and contained significantly more β2m than those formed with non-associated alleles. This report establishes a correlation between the level of predisposition to SpA conferred by HLA-B alleles and their biochemical behaviors that may contribute to their pathogenicity.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis (PsO) is a common inflammatory skin disease that is characterized by acanthosis, impaired immune cell migration, and remodeling of the vascular and lymphatic system. Up to ~30% of PsO patients develop psoriatic arthritis (PsA). The factors that determine the transition from PsO to PsA or vice versa are poorly understood. The lymphatic system may regulate the homing capabilities of disease-associated T-cells and control their migration to skin and extra-cutaneous sites like synovial joints and entheses.

Methods: Primary human dermal lymphatic endothelial cells (LECs) were preincubated for 3 days with TNF (10 ng/mL), IL-17A (100 ng/mL), rheumatoid arthritis synovial fluid (SF-RA; 20% v/v) or psoriatic arthritis synovial fluid (SF-PsA; 20% v/v). After removing the media, LECs were cocultured with allogeneic (CD3-enriched) skin-derived T-cells (SDTC) or peripheral blood mononuclear cells (PBMCs) for 48 hours (each from 3 separate donors) in the presence of 0.3 μg/ml αCD3 and 0.4 μg/ml αCD28. T-cells were then immunophenotyped by flow cytometry on a 4-laser LSRII analyzer using antibodies directed to CD45, CD3, CD4, CXCR3, CCR4, and CCR6. Based on the latter three, the most relevant T-helper (Th) subsets were characterized, including the CCR6+ subpopulations Th17.1 (CXCR3+/CCR4-), Th17/Th22 (CXCR3-/CCR4+), and double positives (DP; CXCR3+/CCR4+), and the CCR6- subsets, i.e. Th1 (CXCR3+/CCR4-), and Th2 (CXCR3-/CCR4+). In addition, we looked at cutaneous lymphocyte-associated antigen (CLA), a skin lymphocyte homing receptor. The percentage of these Th-subsets (normalized to untreated LECs), that were generated upon co-

incubation with LECs, were statistically tested using 2-way ANOVA.

Results: SDTCs upregulated CLA-expression upon incubation on LECs that underwent pretreatment with SF-RA and SF-PsA, as compared to LECs preincubated with TNF or IL-17A. In contrast, this effect was not observed in PBMCs. The increase of normalized mean fluorescence intensity (MFI) for CLA-expression in SDTCs was more pronounced in LECs preincubated with SF-PsA versus SF-RA, and increased 3.3-fold, 2.8-fold and 3.1-fold in the total CD4+ compartment, Th17.1 and DP subsets respectively ($P<0.01$ for all as compared to SF-RA). This finding was not explained by an increase in the proportion of the total CD4+ compartment or Th17.1 and DP subsets within the CLA+ SDTC population.

Conclusion: LECs are directly involved in T-cell homing capabilities, as shown by CLA regulation at the time of STDC activation. CLA regulation occurs in a highly tissue-selective manner. Thus, preincubation of dermal LECs with SF-PsA and to a lesser extent SF-RA reinforced CLA expression particularly in CCR6+ T-cell subsets that are abundant in psoriatic skin. This effect was not seen in CD3-enriched PBMCs, where the CLA+ T-cell proportion is far less. Further studies are underway to show that LECs derived from relevant biological tissues from PsA patients including skin, lymph nodes and synovium may be critical for inducing tissue-imprinting receptors at the time of T-cell activation, and for tissue-restricted migration to both skin and synovial joints and entheses in PsO and PsA.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: CD19+CD24highCD38high B cells have been described to have a regulatory capacity and their frequency is altered in the peripheral blood of patients with various autoimmune diseases. The pathogenesis of AS is not well understood, and evidence suggesting the implication of either autoinflammatory or autoimmune mechanisms has been reported. In addition, increased frequencies of circulating B cells bearing a regulatory phenotype has recently been described in spondyloartrhitis (1). Therfore our objective was to study the frequency of circulating CD19+CD24high CD38high B cells (Breg) in patients with Ankylosing Spondylitis (AS), and test the regulatory capacity of this B cell subset.

Methods: Peripheral blood was drawn from AS patients naïve for TNF blockers (AS/nb) (n=41) and healthy controls (HC) (n=41), that were matched with patients for age and gender. After isolation by Ficoll-Hypaque gradient, PBMCs were stained with antibodies to CD3, CD4, CD19, CD24, and CD38, and examined by flow cytometry. For functional studies, total CD19+ B cells were isolated from PBMCs of 3 HC by magnetical sorting. Breg-depleted CD19+ B cells were obtained after total CD19+ B cells were depleted of CD19+CD24highCD38high B cells by cytometry in a FacsVantage sorter (Beckton Dickinson). Total CD19+ B cells or Breg-depleted CD19+ B cells were established in culture and stimulated through their BCR. Secretion of IFNγ was determined by ELISA in culture supernatants.

Results: When compared with healthy controls, AS/nb patients demonstrated a significantly increased frequency of CD19+CD24highCD38high B cells (Breg). The frequency of circulating Breg was increased not only in AS/nb patients with high or very high disease activity (ASDAS-CRP) >2.1 but also in AS patients with low activity or no activity (ASDAS-CRP< 2.1). The frequency of circulating Breg cells did not correlate significantly with ASDAS-CRP, ASDAS-ESR, BASDAI, CRP or ESR values. Functional in vitro studies showed that the secretion of IFNγ was significantly higher in Breg-depleted CD19+ as compared with total CD19+ B cells,

indicating that Breg have the capacity to downmodulate B cell pro-inflammatory cytokine secretion.

Conclusion: An increased frequency of circulating CD19+CD24highCD38high B cells is observed in AS/nb patients, that is not related with disease activity. Functional in vitro studies confirmed that CD19+CD24highCD38high B cells are able to downmodulate B cell pro-inflammatory cytokine secretion. Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: After more than 40 years of researches, the mechanisms underlying the association of HLA-B27 with spondyloarthritis (SpA) remain poorly understood. The *Drosophila* has been demonstrated to be an extremely useful genetic model in numerous systems. We hypothesized that *Drosophila* might be a relevant model to study HLA-B27 and particularly for deciphering the cellular cascade and the genetic pathways affected by HLA-B27 mutation. To do so we developed HLA-B2705, HLA-B0702 (control) and human Beta-2-microglobulin (hB2m) transgenic *Drosophila*.

Methods: Gateway Technology and UAS-Gal4 system was used for developing transgenic HLA-B/human hB2m *Drosophila*. *UAS-hB2m* transgene was inserted in long arm of chromosome 3 and *UAS-HLA-B2705* and *UAS-HLA-B0702* were alternatively inserted at another position in the short arm of the same chromosome. For each construct, various transgenic lines were obtained and crossed with several tissue specific driver strains, to induce the expression of the coding sequence for *HLA-B0702* and *hB2m* or *HLA-B2705* and *hB2m* placed under the control of UAS sequences.

Results: HLA-B2705/hB2m transgenes were first expressed in *Drosophila* by mean of vestigial Ga4 driver line allowing to produce targeted protein in *Vestigial* domain (dorso-ventral frontier of the wing epithelia). We observed positive staining with HC10 antibodies (class I heavy chain) and W6/32 antibody (HLA-A, HLA-B and HLA-C conformation) for both tested HLA-B/hB2m but only HLA-B27/hB2m was labelled with ME1 (anti-HLA B/C) antibodies, suggesting a different conformation of HLA-B27 and HLA-B7 with hB2m in the wing epithelia. Furthermore, by mean of the nubbin or engrailed drivers which drive the expression in a larger part of the wing, we observed specific loss of posterior cross-vein following HLA-B27/hB2m expression but not HLA-B7/hB2m.

Conclusion: We have established *Drosophila* lines allowing tissue specific expression of different HLA-B alleles. Our data suggest that the expression of HLA-B/hB2m transgenes in epithelial cells leads to a plasma membrane localization for HLA-B2705/hB2m but not for HLA-B0702/hB2m. Furthermore, we observed that tissue specific expression of HLA-B27/hB2m but not HLA-B7/hB2m induced

specific loss of cross-vein suggesting it interferes with developmental pathways involved in differentiation. This is the first time that difference in localization between HLA-B2705, subtype associated with SpA, and HLA-B0702, which is not associated with the disease are reported. These results show that transgenic *Drosophila* might be a pertinent model to decipher molecular mechanisms involved in HLA-B27 trafficking and to better understand potential different behavior of HLA-B subtypes.

Apremilast May Improve Atherosclerosis By Promoting Cholesterol Efflux and Inhibiting Foam Cell Formation in Atherosclerotic Plaques

Hailing Liu[1], Tuere Wilder[2], Aranzazu Mediero[3], Zhimin Wei[1], Carmen Corciulo[2] and Bruce Cronstein[3], [1]Medicine, NYU School of Medicine, New York, NY, [2]Department of Medicine, Division of Rheumatology, NYU School of Medicine, New York, NY, [3]Medicine, Division of Rheumatology, NYU School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Atherosclerosis is characterized by the accumulation of lipid-laden macrophages in the arterial walls. Patients with inflammatory arthritis and psoriasis are at greater risk of developing atherosclerotic plaques with their associated cardiovascular diseases. Recent studies indicate that effective therapy of inflammatory arthritis may reduce the risk of atherosclerotic cardiovascular disease although the basis for this risk reduction is not totally clear. Recently apremilast, an inhibitor of PDE4, has been introduced into the clinical armamentarium for the treatment of psoriasis and inflammatory arthritis. We and others have recently demonstrated that agents, such as adenosine A2A receptor stimuli, that stimulate cAMP accumulation in macrophages can reduce foam cell formation by a protein kinase A (PKA) – mediated mechanism involving enhanced efflux of cholesterol and lipids. We therefore asked whether apremilast might have a similar effect

Methods: RAW264.7 murine macrophage cell line was infected with lentiviruses expressing shRNA to silence PKA, EPAC1 and EPAC2, or scrambled shRNA. Knockdown was confirmed by Western Blot. The effect of apremilast on foam cell formation was tested by examination of 70% confluent cells in 48-well plates following treatment with Interferon-γ (IFNγ, 0.5u/ul) for 24 hours and then treatment with acetylated LDL (50ug/ml) with/without apremilast (10uM) for another 48 hours. Cells were stained with oil-O-red and then cells containing lipid droplets were counted. To determine whether apremilast affected cholesterol efflux cells (70% confluent in 48-well plates) were treated with IFNγ (0.5u/ul) for 24 hours and followed by treatment with acLDL (50ug/ml) for another 24 hours. After treatment with bodipy-cholesterol for 1 hour, cells were cultured in the equilibration buffer for 18 hours and treated with HDL (20ug/ml) and ApoA1(10ug/ml with/without apremilast (AP, 10uM) for 4 hours. 200ul of each supernant /cell lysate (lysed in 1% cholic acid) were analyzed by record fluorescence @482/515nm.

Results: Apremilast treatment reduced foam cell formation in RAW264.7 cells stably expressing scrambled, EPAC1 and EPAC2, but not PKA shRNA (45±2%, 43±5%, 42±1% and -14±6% reduction, respectively, $p<0.001$, ANOVA). Apremilast treatment enhanced HDL-induced and apoA1-induced cholesterol efflux from RAW264.7 cells (2.345 ± 0.03% vs. 1.733 ± 0.08%, $p<0.001$, n=4 and 9.74 ± 0.32% vs.3.96±0.77%, $p<0.05$, n=3). Furthermore, Apremilast treatment enhanced HDL-induced from Raw264.7 cells stably expressing scrambled, EPAC1, and PKA but not in EPAC2 shRNA (0.737±0.6% vs.1.19±0.04% of control, $p<0.05$, ANOVA); apremilast treatment enhanced ApoA1-induced cholesterol efflux from RAW264.7 cells stably expressing scrambled, but not EPAC1, EPAC2, and PKA shRNA (2.62±0.15%, 1.55±0.22%, 1.44±0.04% a vs. 0.95±0.15% of control, respectively, $p<0.01$, $p<0.05$ and $p<0.01$, ANOVA). Thus, these results suggested that 1)apremilast promotes HDL-induced cholesterol efflux through increasing intracellular cAMP with EPAC1dependent mechanism, and apoA1-induced cholesterol efflux through increasing intracellular cAMP with EPAC1, EPAC2, PKA dependent mechanisms, 2) apremilast inhibits foam cell formation through increasing intracellular cAMP by only PKA-dependent mechanism

Conclusion: These results suggest that apremilast may be useful for the treatment/prevention of atherosclerosis in patients with psoriasis

and inflammatory arthritis.

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis is an auto-immune disease of the skin, characterized by inflammation and fibrosis producing patches of red, itchy and scaly skin. Wnt signaling plays an important role in psoriasis by regulating inflammation, keratinocyte proliferation and dermal fibrosis. SM04755, a novel, topical small-molecule Wnt pathway inhibitor was evaluated in a series of preclinical studies to determine its potential to inhibit inflammation, keratinocyte proliferation and dermal fibrosis, thereby improving skin health in psoriasis.

Methods: Wnt pathway inhibition was measured using a cell-based reporter assay. Anti-inflammatory activity was evaluated by ELISA measuring TNF-α and IL-6 secretion in THP-1 monocytes stimulated with Lipopolysaccharides (LPS) and PBMCs stimulated with anti-CD3/anti-CD28. Cytokine induced keratinocyte proliferation was measured in HaCaT cells using an EdU incorporation assay. The effect on fibrosis was assessed in TGF-β stimulated human dermal fibroblasts by measuring smooth muscle actin (αSMA), plasminogen activator inhibitor (PAI-1), connective tissue growth factor (CTGF) and collagen expression by qPCR. Pharmacokinetics were evaluated by topical application in rats and mini-pigs, followed by analysis of compound concentrations in skin and plasma. *In vivo* efficacy was evaluated in an Imiquimod-induced mouse psoriasis model by measuring skin and ear thickness, spleen size and weight, *ex vivo* T cell activation and proliferation, and cytokine levels in plasma.

Results: SM04755 demonstrated potent (EC_{50} =152nM) and selective inhibition of Wnt signaling. SM04755 inhibited LPS- and anti-CD3/anti-CD28-induced TNF-α and IL-6 secretion (EC_{50} =500nM) in THP-1 cells and PBMCs. SM04755 inhibited cytokine induced keratinocyte proliferation (EC_{50} @900nM) and TGF-β stimulated dermal fibrosis as measured by a decrease ($p<0.05$) in gene expression of αSMA (EC_{50} =400nM), PAI-1, CTGF, and collagen in human dermal fibroblasts. Single topical application of SM04755 resulted in skin concentrations >EC50 for >24hrs, with minimal systemic exposure or toxicity. In the Imiquimod-induced mouse psoriasis model, topical SM04755 significantly ($p<0.01$) decreased skin and ear thickness, improved skin appearance, and significantly ($p<0.01$) reduced spleen size and weight as compared to vehicle. Clobetasol, a positive control, decreased skin thickness ($p<0.001$) below that of normal skin (a known adverse effect of steroid treatment). *Ex vivo* T cell activation, proliferation, and cytokine secretion were inhibited with SM04755 treatment compared to vehicle.

Conclusion: In a mouse model of Imiquimod-induced psoriasis, topically applied SM04755 inhibited inflammation, and decreased skin thickness compared to vehicle, with minimal plasma exposure or systemic toxicity. SM04755 has potential as a topical therapy for psoriasis.

Figure. SM04755 reduced the ear thickness and improved skin appearance relative to control in an Imiquimod-induced Psoriasis model in mice

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Autophagy is a process of cellular self-digestion by enzymes originating within the lysosome of the cell. Autophagy primarily acts as a survival mechanism by removing damaged and dysfunctional proteins or organelles. It is well documented that autophagy has a potentially pivotal role in the induction and regulation of inflammatory responses by immune cells. However, a role of autophagy in ankylosing spondylitis has not been clearly elucidated and the association of autophagy-related gene expression levels with inflammatory or osteoproliferative processes observed in ankylosing spondylitis has not been reported. This study was performed to determine the expression levels of several key autophagy-related genes in patients with ankylosing spondylitis and investigate whether autophagy-related gene expression levels are associated with clinical parameters of ankylosing spondylitis and the production of inflammatory cytokines to elucidate the role of autophagy in pathogenesis of AS.

Methods: PBMCs from 43 AS patients and 40 healthy controls were obtained and mRNA expression levels of Atg genes (LC3, beclin1, and ATG5) were determined using quantitative real-time PCR. Ankylosing Spondylitis Disease Activity Score (ASDAS)-CRP and modified Stoke AS Spinal Score (mSASSS) were assessed at the time of blood sampling. Serum concentrations of TNF-alpha, IL-17, and IL-23 in AS patients were determined using enzyme-linked immunosorbent assays.

Results: LC3, beclin1, and ATG5 mRNAs were constitutively expressed in PBMCs of AS patients and healthy controls; however, expression of all three genes was significantly decreased in PBMCs of AS patients compared with those from controls. Expression levels of the autophagy-related genes were not significantly correlated with ASDAS-CRP or serum TNF-alpha, IL-17, and IL-23 concentrations. However, LC3 and beclin1 mRNA levels showed significant negative correlations with mSASSS of AS patients ($r = -0.805$, $p<0.01$ for LC3 and $r = -0.712$, $p<0.01$ for beclin1).

Conclusion: AS patients have decreased autophagy-related gene expressions and AS patients with more advanced spinal damage have further decreased LC3 and beclin1 expression levels. These results suggest that AS patients have defective autophagy activity and that compromised autophagy may contribute to the progression of spinal damage in AS.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Monocytes of patients with Ankylosing Spondylitis (AS) show Toll-like receptor 4 (TLR4) over-expression. Myeloid-related proteins (MRP) 8/14 protein complexes are calcium-binding proteins, which act as endogenous ligands to TLR4. Thus we studied the levels of MRP8/14 in adult AS patients.

Methods: MRP8/14 levels were assessed in 99 adult AS patients satisfying ASAS 2010 criteria and 23 healthy controls by ELISA. Patient disease parameters like patient and physician global assessment, BASDAI, swollen and tender joint count, entheseal count by Maastricht Enthesitis index, Erythrocyte Sedimentation Rate (ESR) and C Reactive Protein (CRP) were also recorded. Levels were reassessed in 23 patients after 2-5 months of treatment with NSAIDs. All values are in median and IQR.

Results: The median serum MRP8/14 levels in patients [34.1 (17.94-264.58) mg/ml] were significantly higher than in healthy controls [5.97 (IQR 4.64-11.43) mg /ml ($p<0.0001$)]. Patients with peripheral arthritis (n=50) had higher levels than those with pure axial disease (n=49) [40.63 (IQR 28.41-73.15) mg /ml vs. 23.72 (11.04-61.55) mg /ml; p=0.012]. Levels of MRP8/14 correlated with ASDAS CRP (r=0.23, 95%CI=0.038-0.422, p=0.02) and CRP (r=0.28, 95%CI=0.081-0.45, p=0.01), and the correlation was better in early disease [≤5 years disease duration, (r=0.40, p=0.007) and (r=0.57, p=<0.0001) respectively]. MRP8/14 levels did not correlate with clinical disease activity measures such as BASDAI, Maastricht entheseal count, and patient and physician global assessment. Baseline levels were higher in treatment responders than in non-responders [51.17 vs. 32.22 mg /ml; p=0.02]. Change in MRP8/14 levels correlated with change in BASDAI and ASDAS CRP (r= 0.489, p=0.018 and r=0·498, p=0.016 respectively).

Conclusion: MRP8/14 levels may be used as a biomarker for activity, peripheral arthritis and response to therapy.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis (SpA) is a common debilitating inflammatory disorder. Pathogenesis of axial SpA (axSpA) including ankylosing spondylitis (AS) is still largely unclear. Diagnosis is difficult, since abnormalities in conventional X-rays develop with a latency of several years and only HLA-B27 is used as laboratory marker. The presence of radiographic sacroiliitis is essential for SpA diagnosis. To prevent destructive effects early diagnosis and intervention in SpA patients may be important. To evaluate antibodies to the human leukocyte antigen class II-associated invariant chain peptide (anti-CD74) as a diagnostic marker of SpA.

Methods: Sera of 117 patients with axial SpA and 38 non-SpA patients were analyzed for IgA and IgG antibodies against CD74 by ELISA. HLA-B27 status was available in 112 patients. All donors provided informed consent for the study approved by the local ethics committee (project number 4928).

Results: Anti-CD74 antibodies were detected in 85.1% of SpA patients but only in 5% of non-SpA patients ($p \leq 0.0001$). Detection of both IgG and IgA anti-CD74 antibodies for diagnosing SpA revealed a sensitivity of 77% and a specificity of 90%. Remarkably, IgA autoantibodies against CD74 alone had a sensitivity of 67% and a specificity of 95%. IgA anti-CD74 antibodies were even more frequent in SpA patients with short disease duration and significantly correlate with more advanced radiological sacroiliitis and reduced spinal mobility.

Conclusion: Anti-CD74 IgA antibodies were strongly associated with SpA. Antibodies against CD74 could provide an important additional tool for diagnosis of SpA.

Session Time: 9:00AM-11:00AM

Background/Purpose: The spondyloarthritides (SpA) are a group of chronic inflammatory disorders involving the axial spine and the peripheral joints. Genetic, functional and clinical trial evidences suggest an important role for IL17A within the context of *type 17* immunity. This study aims to understand the different components of the *type 17* immune axis in patients with SpA compared to healthy controls.

Methods: Peripheral blood was obtained (with ethical approval and informed consent) from 38 patients with SpA, 17 age and sex matched healthy donors, and 14 patients with Rheumatoid Arthritis (RA) matched for CRP. Mononuclear cells were analyzed by flow cytometry using a multicolor antibody panel staining surface phenotypic markers and intracellular cytokines.

Results: Patients with SpA had a higher percentage of CD4 Th17 cells than healthy controls (mean±SD) (1.27±0.69 *vs* 0.67±0.41%; p<0.001). The production of IL17A in the CD8 (1.30±1.01 *vs* 0.40±0.45%; p<0.001) and in the γδ T cell compartment (4.86±7.04 *vs* 1.01±0.85%; p<0.001) was also higher in SpA than controls. Within the *type 17* axis, polyfunctional cells coexpressing IL17A and GM-CSF were increased in the CD4, CD8, γδ and NK compartment in SpA, compared to healthy controls and Rheumatoid Arthritis patients (Figure 1). Analysis of the regulatory T cell pool showed a similar frequency of Tregs in the peripheral blood of SpA patients compared to healthy controls (SpA: 5.4±2.5% vs 4.7±1.9%; p=0.22), although in patients, Tregs appeared enriched in the synovial fluid compared to the peripheral blood (mean of difference±SEM: 8.8±1.3%, p<0.01).

Conclusion: Immunophenotypic analysis of the peripheral blood of SpA patients shows increased levels of *type 17* immunity across multiple lymphocyte compartments, with a specific increase of polyfunctional cells coexpressing IL17A and GM-CSF. This broad skewing towards *type 17* immune response in SpA supports an important role in disease.

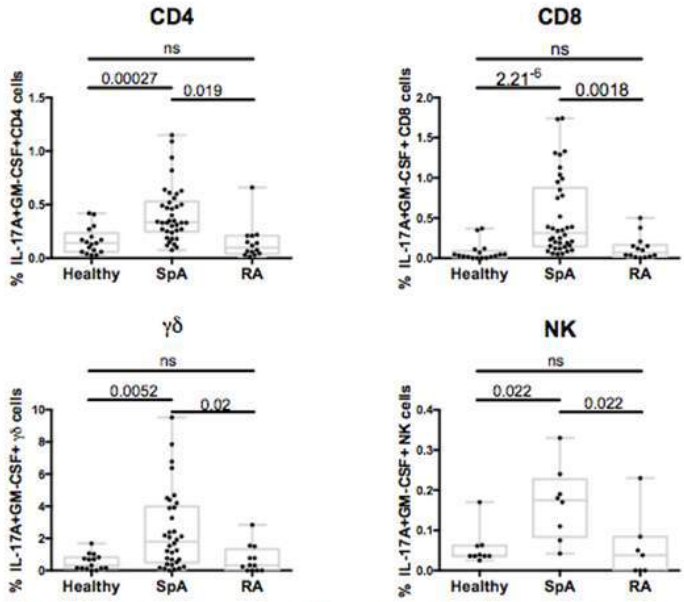

Figure 1. In SpA increased percentages of IL17A+ GMCSF+ cells are seen within the CD4, CD8, γδ and NK cell subsets. IL17A and GM-CSF producting cells were enumerated by FACS after 4 hours stimulation with PMA, ionomycin, brefeldin A and monensin.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The occurrence of bone marrow edema (BME) and fat metaplasia detected by magnetic resonance imaging (MRI) were shown to be significantly associated with syndesmophyte formation in patients with ankylosing spondylitis (AS). The cell type responsible for the fat signal seen in MRI has not been defined to date. Here we histologically analyze the cells seen in fatty lesions (FL) as detected by MRI in spinal biopsies of AS patients and compare them with controls.

Methods: The occurrence of bone marrow edema (BME) and fat metaplasia detected by magnetic resonance imaging (MRI) were shown to be significantly associated with syndesmophyte formation in patients with ankylosing spondylitis (AS). The cell type responsible for the fat signal seen in MRI has not been defined to date. Here we histologically analyze the cells seen in fatty lesions (FL) as detected by MRI in spinal biopsies of AS patients and compare them with controls.

Results: Biopsies mostly obtained from the lower thoracic and the lumbar spine of 13 AS patients (mean age 56.3 years, mean disease duration 26 years) and 6 controls (mean age 53.4 years) were available. Large proportions of AS patients, (12/13, 92%) and non-AS patients (4/6, 67%) had vital bone marrow. Fat cells were found in all 13 biopsies obtained from AS patients from the area of the fat signal vs. only 2 non-AS patients (33%), while inflammatory cells were found in 9 AS patients (69.2%), all of which also had BME on MRI, vs. 3 non-AS patients (50%). Fibroblasts were seen in 3 AS (23.1%) and 2 non-AS patients (33.3%).

Conclusion: The underlying cell types of FL and BME as detected by MRI in these long standing AS patients were fatty and inflammatory cells. The main difference between AS and non-AS patients was the proportion of biopsies containing fat cells. This suggests that fat cells are responsible for the MRI signal, at least in patients with longstanding ankylosing spondylitis.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The microbiome is hypothesized to influence human health and disease. Changes in resident bacteria, termed dysbiosis, occur in spondyloarthritis (SpA) and inflammatory bowel disease (IBD), which is subdivided into Crohn's Disease (CD) and Ulcerative Colitis (UC). However, the immunologic consequences of dysbiosis in SpA and IBD have not been established. Intraepithelial lymphocytes (IELs) are T cells within the intestinal epithelium that are in close contact with bacteria. As such, they are prime candidates to link the microbiome with downstream immune functions that result in SpA and IBD. We sought to correlate IELs with resident bacteria in individuals with SpA and IBD relative to controls.

Methods: Subjects with biopsy-proven IBD, axial SpA fulfilling ASAS criteria, and controls undergoing standard of care colonoscopies were recruited. Subjects with antibiotic use within two weeks, NSAID use, other rheumatic diseases, and enteropathic arthritis were excluded. A rectal swab was obtained for microbiome analysis by 16S sequencing and peripheral blood was analyzed for WBC, CRP, and HLAB27. Colonic pinch biopsies of grossly normal-appearing tissue from all participants were obtained during routine colonoscopy or research flexible sigmoidoscopy. IELs were harvested from the biopsies and characterized by flow cytometry for the surface markers CD3, CD4, CD8α, CD8β, CD45, TCRγδ, and TCRβ. Secreted cytokines, TNF-α, IFN-γ, IL-6, and IL-17A, were measured by ELISA in the supernatants of mitogen stimulated IELs. Cytokine secretion were then ranked and analyzed. Statistical analyses were performed with Kruskal-Wallis and Spearman's Rank.

Results: Thus far 13 controls, 10 cases of CD, 6 cases of UC, and 4 patients with SpA have been evaluated. Our preliminary data demonstrates IELs from subjects with CD had increased IL-17A, ($p=0.03$) TNF-α, ($p=0.04$) and IFN-γ ($p<0.01$) whereas UC had higher IL-1β compared to CD ($p=0.03$) or controls ($p=0.03$). Evaluating cytokines in relationship to the microbiome revealed a correlation between TNFα and the Simpson Index of Diversity in UC (Spearman's rank=0.943, $p<0.01$). In CD, *Fusobacterium* had negative correlation with TNFα+ IFNγ + IL-1β (Spearman's rank=-0.786, $p=0.02$). These relationships were not seen in other groups. The recruited SpA patients so far are all HLAB27 positive Caucasian males with a mean age of 35.8. They had been diagnosed an average of 8.5 years ago and had an average BASDAI of 5.2, and CRP of 10.8 mg/L. Preliminary data of the SpA patients suggests the presence of dysbiosis and a trend towards less IELs compared to controls ($p=0.08$).

Conclusion: Our data indicate differences in IEL populations between UC, CD, and controls. SpA patients are being actively recruited and their data will be analyzed. Reviewing the results from our IBD cohort, we hypothesize that patients with SpA will also have higher levels of inflammatory cytokine expression than controls which will have their own unique relationships with colonic microbiota. Our study is relevant to the pathogenesis of SpA and IBD as it shows that IEL cytokine secretion is associated with dysbiosis and this correlation varies by disease type.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Multiple lines of evidence suggest a critical role for the IL-23/IL-17A axis in spondyloarthritis. In susceptible inbred strains, hydrodynamic injection of IL-23 minicircles into adult mice induces an inflammatory disease with phenotypic features of human spondyloarthritis. IL-23 receptor expressing tissue-resident CD3+CD4-CD8- double negative (DN) innate T cells have been proposed to mediate disease pathogenesis in this model. The goal of this project was to investigate factors controlling the generation and function of these IL-23 responsive innate T cells.

Methods: C57BL/6 wildtype (WT), TCRγδ-/-, IL1R1-/-, IL23R-GFP, Tap1-/- and MHC II-/- mice were analyzed at 8 weeks of age. Single cell suspensions from blood, liver, spleen, skin and the Achilles tendon enthesis were analyzed by multicolor flow cytometry. IL-17A production was measured by intracellular staining after stimulation with cytokines (IL-1β, IL-23 or IL-1β + IL-23) or PMA/Ionomycin in the presence of Golgi-Stop for 4 hours.

Results: In WT mice, the CD3+ DN T cell compartment comprised both TCRαβ+ and TCRγδ+ cells with frequencies varying between tissues. Both subsets were present in MHC class I deficient Tap1-/- mice and in MHC II-/- mice. In TCRγδ-/- mice, an expanded population of DN TCRαβ+ cells compensated numerically for the absence of γδ T cells. Upon in vitro stimulation with IL-23, both

TCRαβ+ and TCRγδ+ subsets depended on an additional IL-1 receptor signal for IL-17A induction. While γδ T cells were the predominant IL-17A producing subset in WT splenocytes stimulated with IL-1β + IL-23, the frequency of total IL-17A positive cells in TCRγδ-/- mice was unchanged, attributable to a compensatory increase of IL-17A production by DN TCRαβ+ cells. PMA/Ionomycin stimulation resulted in the recruitment of additional cell types producing IL-17A including CD4+ TCRαβ+ cells. PMA/Ionomycin-induced IL-17A production did not require IL-1R or IL-23R signals.

Conclusion: Tissue resident CD3+ DN T cells in mice are either TCRαβ+ or TCRγδ+. IL-23 induced induction of IL-17A by either subset is strictly dependent on a second signal through the IL-1 receptor. DN TCRαβ+ T cells compensate for the absence of γδ T cells in TCRγδ-/- mice suggesting functional overlap in vivo.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: A recent study from our group has shown functional impairment and numerical decrease of transitional and memory IL-10-producing regulatory B cells (Bregs) in patients with psoriatic arthritis (PsA) and psoriasis (Ps) (*Ann Rheum Dis* 2015;74**:**423). Other cells such as natural killer (NK) have been involved in the development of PsA and Ps, but their relationship with Bregs has not been studied. The aim of the study was to investigate quantitative and qualitative variations of NK subsets expressing the pro-inflammatory IFN-γ and IL-17 cytokines and their relation with IL-10-producing Bregs.

Methods: Peripheral blood mononuclear cells from 100 subjects including 40 PsA, 40 Ps and 20 healthy controls (HC) were studied. Flow cytometric analysis was carried out with MoAbs against cell surface markers CD56, CD16, CD3, CD7, CD19, CD24, CD27 and CD38. Intracellular expression of cytoplasmic IFN-γ, IL-17 and IL-10 following bacterial CpG (ODN2006) and PMA/ionomycin stimulation was also examined by flow cytometry.

Results: There was a negative correlation between CD3negCD56pos (NK) and CD19posCD24hiCD38hi (transitional) Bregs and between CD3negCD56pos and CD19posCD24hiCD27pos (memory Bregs) ($p<0.05$, for both). IFN-γ-producing NK inversely correlated with IL-10-producing Bregs. IL-17-producing NK were also inversely correlated with IL-10-producing Bregs ($P<0.05$). A very small proportion of NK cell produced IFN-γ plus IL-17. NK from patients with PsA and Ps produced significantly higher IFN-γ compared to HCs, and this was also found for IL-17 ($p<0.05$, for both). Very few CD3posCD56pos (NKT) cells produced IFN-γ plus IL-17 but there was no correlation of these cells subsets with Bregs.

Conclusion: IL-10-producing Bregs is negatively correlated with IFN-γ- and IL-17-producing NK cells in PsA and Ps. This suggests a dominant role of the innate arm of immunity over suppressor adaptive responses, such as those exerted by regulatory B cells.

Differentially Expressed MicroRNA as candidate Biomarker for Disease Activity in Ankylosing Spondylitis

Background/Purpose: MicroRNAs (miRNAs) have evolved as a novel class of biomarkers We proposed to test the hypothesis that patients with ankylosing spondylitis (AS) have an altered miRNA expression profile compared to control subjects and selected miRNAs identified in the study correlate with disease activity as measured by BASDAI and ASDAS and markers of inflammation (ESR and CRP) .

Methods: 51 patients ≥18 years of age with AS based on modified New York classification criteria (grade 3 and 4 sacroiliitis) and 23 (age and sex matched) controls were prospectively recruited. Subjects with active malignancy in last 5 years, rheumatoid arthritis or systemic lupus erythematosus and evidence of HIV or chronic hepatitis B or C infection were excluded. Patients and controls were screened, consented and peripheral blood samples (5 ml) were obtained. The samples were centrifuged at 400 g for seven minutes; plasma transferred to nuclease free tubes and stored at -20°C until analyses. ESR and CRP were measured using routine laboratory methods. Various validated Questionnaires to assess disease, functional activity and patient reported outcomes in AS were administered to the patients. 62 circulating miRNAs in the plasma of all the study subjects were profiled by Firefly Multiplex Circulating miRNA Assay (Abcam) using the Immunology Panel. Forty microliters of plasma samples were first digested using the supplied enzyme mix and then the assay was performed following the instructions provided by the manufactures. The assay beads were scanned on BD Accuri C6 flow cytometer (BD Biosciences). Data were analyzed using Firefly Analyis Workbench (Abcam). Descriptive analyses included continuous variables (the mean ± SD) and the categorical variables (percentage). Linear regression analysis was performed to assess the association between BASDAI, BASMI, ASDAS, Rapid 3, ESR, CRP and differentially dysregulated candidate miRNAs in plasma of patients with AS.

Results: 34 males and 17 females with demographics and clinical characteristics in table 1. Mean (±SD) values of the disease parameters are shown in table 2. miR-181b-5p was differentially expressed in AS patients compared to healthy controls ($p < 0.05$). miR-181b-5p also showed a significant linear relationship with BASDAI score ($p=0.008$) and ASDAS($p=0.054$).

Conclusion: miR-181b-5p correlated with validated tools of disease activity in AS and may be proposed as a potential biomarker for disease activity in AS.

Table 1- Demographics and Clinical Characteristics of the Patients

Mean age in years ± SD	49.8 ± 12.2
% African-Americans	34.6
% Females	33.3
% HLA-B27 positivity	70.0
% Acute anterior uveitis	38.3
% TNF-i use	45.1

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There was a biased repertoire of the immunoglobulin (Ig) heavy chain variable (VH) segment gene in B cells in patients with ankylosing spondylitis (AS). Activation-induced cytidine deaminase (AID) plays an important role in Ig class switch recombination (CSR) and somatic hypermutation (SHM) to generate Ab diversity and B cell tolerance. Peripheral blood mononuclear cells (PBMCs) express five different AID splicing variants [full-length (FL) and splicing variants (sv) 1–4]. In addition, translesion synthesis (TLS) DNA polymerases are involved in the repair of AID-mediated DNA lesions. We have previously reported that Ig SHM and CSR are upregulated in lupus autoimmune mice as a result of enhanced AID expression. In this study, we investigated the expression patterns of AID variants and TLS polymerase in PBMCs of AS patients so as to verify the relationship of the CSR and SHM bias with susceptibility to AS.

Methods: PBMCs were collected from 33 healthy controls (HC) and 62 patients with AS who fulfilled the modified New York classification criteria. We measured the mRNA expression of AID variants and TLS polymerases by quantitative RT-PCR.

Results: The number of subjects expressing sv2 was significantly greater in AS patients compared to HC ($p = 0.031$, odds ratio = 2.77) (Table 1). Next, we investigated whether the treatment with TNF inhibitors (TNFi) affected the gene expression of AID variants. A significantly higher proportion of TNFi-treated group expressed sv2 compared to TNF-naïve group ($p = 0.014$). And we compared the level of AID variants expression between TNFi-treated and TNF-naïve group. The expression levels of FL and sv1 were significantly lower in the TNFi-treated group than TNF-naïve group (FL: $p = 0.002$, sv1: $p = 0.045$) (Table 2). In addition, we investigated mRNA expression levels of TLS polymerases in PBMCs from patients with AS and HC. The expression level of TLS pol was significantly lower in AS patients than in HC ($p = 0.007$) (Table 3).

Conclusion: Our results showed that patients with AS expressed significantly higher levels of sv2 than HC. TNFi treatment restored the gene expression of the AID variants (FL, sv1 and sv2) in patients with AS. Therefore pre-existing TNFa-induced AID expression in B cells may play an important role in the pathogenesis of AS.

Table 1. Frequencies of sv1 and sv2 expressions

AID		No of negative expression (%)	No of positive expression (%)	p-value	OR (95% CI)
sv1	HC	4 (12.1)	29 (87.9)	0.232	
	AS	3 (4.8)	59 (95.2)		
sv2	HC	22 (66.7)	11 (33.3)	**0.031**	2.769 (1.146-6.691)
	AS	26 (41.9)	36 (58.1)		

AID: Activation-induced cytidine deaminase, sv: splicing variants, AS: ankylosing spondylitis
HC: healthy controls, OR: odd ratios

Table 2. Expression levels of AID FL, sv1, and sv2 before and after anti-TNFα drugs treatment in AS patients

AID	anti-TNFα drugs treatment		p-value
	before	after	
FL	n=10 1.230±1.157	n=45 0.427±0.544	**0.002**
sv1	n=10 1.051±0.787	n=44 0.623±0.543	**0.045**
sv2	n=4 0.827±0.637	n=27 0.444±0.484	0.165

AID: Activation-induced cytidine deaminase, FL: full-length, sv: splicing variants,
AS: ankylosing spondylitis, TNF: tumor necrosis factor

Table 3. Gene Expression of TLS polymerases

TLS polymerase	HC (n=53)	AS (n=59)	p-value
polθ	1.208±1.396	1.209±2.023	0.997

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of this study was to evaluate single nucleotide polymorphisms (SNPs) involved in TNFα signaling, NF-κB activation, interferon-γ signaling, or pattern recognition receptor signaling pathways (TLRs and inflammasome) and their association with ankylosing spondylitis (AS) and rheumatoid arthritis (RA) susceptibility. The genotyped SNPs have known functional effects or previously reported associations with chronic autoimmune disease.

Methods: In a cross-sectional study, we genotyped 53 SNPs in 709 AS patients and 58 SNPs in 538 RA patients from Denmark. Prospectively collected clinical data were obtained from the DANBIO registry. Genotype distributions among cases were compared with 796 population-based controls. Odds ratios for minor allele carriers among cases adjusted for gender and age were calculated assuming additive genetic effects. Correction for multiple testing was performed using false discovery rate (FDR), and associations with FDR q-values <0.1 were considered significant.

Results: We find a decreased risk of AS in minor allele carriers of two SNPs in *TNF* (rs1800629: odds ratio(OR)=0.59, 95% confidence interval(CI): 0.47-0.74, $p=3*10^{-6}$, $q=1*10^{-4}$; rs361525: OR=0.48, CI: 0.31-0.75, p=0.001, q=0.02), and of *IL23R* rs11209026 (OR= 0.60, CI: 0.43-0.85, p=0.004, q=0.05). Carriers of the minor allele of *TNFRSF1A* rs4149570 (OR=1.32, CI: 1.14-1.54, $p= 3*10^{-04}$, q=0.007) had increased risk of AS. Among RA patients, no statistically significant associations were observed. However, a previously reported RA risk allele in *PTPN22*(rs2476601) showed a similar trend in this cohort (OR=1.39, CI: 1.06-1.82, p=0.016, q=0.3).

Conclusion: In a Danish population, this study confirms a previously reported locus in the interleukin-23 receptor (rs11209026) as less common in AS patients, and identifies genetic variation in TNFα (rs1800629, rs361525) and TNF receptor-1 (rs4149570) as putative loci associated with AS. Among RA patients, no SNPs reached significant association but the previously reported risk allele *PTPN22* rs2476601 showed a borderline association with disease susceptibility.

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Spondylarthropathies (SpA) comprise a group of rheumatic diseases such as ankylosing spondylitis (AS), arthritis/spondylitis with inflammatory bowel disease, arthritis/spondylitis with psoriasis (PsA), reactive arthritis (ReA) and undifferentiated spondyloarthritis (uSpA). Their genetic background, familial aggregation, pathophysiology and overlapping clinical manifestations suggest a common origin between them. Previous trials have suggested the role of the intestinal mucosa in the etiopathogenesis of SpA. Increased serum levels of IgA and secretory IgA (SIgA) in AS patients have also been reported, but whether SIgA has a role in the pathogenesis of ReA and uSpA remains unknown.

Methods: Cross sectional study. Serum concentrations of SIgA and total IgA were measured using ELISA and nephelometry in patients and healthy subjects. Activity indices (BASDI, Ankylosing Spondylitis Disease Activity Score (ASDAS)) were applied in each patient. Statistical analysis was performed using Stata 11.2® software for Windows. t Student test was used to compare different groups or subgroups. Pearson correlation was used to measure the correlation degree between SIgA, IgA and disease activity. Multiple linear regression models were used to evaluate the strength of the association. The study was approved by the hospital's ethics committee.

Results: 46 patients (78,2% men, mean age 34,8±12,3y) and 53 controls (41% men, mean age 32y) were included. The mean serum levels of SIgA were higher in patients (19,85±9,97 µg/ml) than in healthy subjects (10,82 ±6,5 µg/ml p <0.000). Mean total IgA levels did not show statistical differences between patients and healthy subjects (275±123 mg/dl vs 284,33±107 p=0,72). SIgA levels correlated with disease activity in patients using the following activity index: BASDI (r= -0.42, p=0.0046), ASDAS-CRP (r= -0.37, p=0.014) and ASDAS-ESR (r= -0.45, p=0.0021). Negative correlation between SIgA and all activity index was higher in HLA-B27^{+} patients (BASDI r= -0.70, p=0.0009, ASDAS-CRP r= -0.58, p=0.0093 and ASDAS-ESR r= -0.57, p=0.0083) than in HLA-B27^{-} patients. Multivariate regression models showed linear association between SIgA and BASDI (-0,12 p=0,005), ASDAS-CRP (-0,04 p=0,014) and ASDAS-ESR (-0,048 p=0,002). **Table 1.**

Conclusion: High serum levels of SIgA were associated with decreased activity in patients with ReA and uSpA. SigA is a very important molecule participating in host defense of intestinal mucosa, playing an important role in homeostasis. These findings highlight the importance of the development of new studies to reach a better understanding of the role of the intestinal mucosa in the different SpA phenotypes.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:Psoriatic arthritis (PsA) is a chronic inflammatory disease. It is characteristically associated both peripheral

(arthritis, enthesitis and dactylitis) and axial skeletal involvement. A range of bone pathologies is common in PsA. Bone loss, either locally (erosions) or systemically, may present. Additionally new bone formation may also occur in both peripheral and axial skeleton. However, molecular mechanisms tunderlying these processes have not yet been fully understood. Secreted Wnt receptor antagonists, dickkopf-1(Dkk-1) and sclerostin, are negative regulators of bone formation. And it has been shown that periostin, as a matricellular protein, is involved in the early stages of osteoblast differentiation and bone formation. Therefore the aim of the present study was to evaluate bone formation markers in patients with with PsA.

Methods : In total 70 consecutive PsA patients [49 females (69%); with a median age (interquartile range, IQR) of 43 (17) years] according to the CASPAR criteria and 36 healthy control subjects [(23 females [63%]; with a median age (IQR) 38 (16) years] were included in the study. Serum periostin, Dkk-1 and sclerostin levels were measured by commercially available ELISA kits. We also assessed serum levels of high-sensitivity C-reactive protein (hs-CRP). Disease related characteristics of patients were evaluated by using BASDAI, BASFI, HAQ, DAS28. Because the data were not distributed homogenously the results are presented as median and interquartile range (IQR) and non-parametric tests were used for group comparisons.

Results : In our PsA group , median (IQR) duration of psoriasis and psoriatic arthritis were 13(20) and 6 (8) years, respectively. In total 27 patients were using corticosteroids, 41 metothrexate, 12 leflunomide and 23 tumor necrosis factor inhibitors. Some of the clinical and laboratory characteristics of patients and control subjects were shown in table. As expected serum CRP levels were significantly higher in PsA patients in comparison with control subjects. Serum periostin levels were not statistically different between study groups. However we found that circulating Dkk-1 and sclerostin levels were significantly lower in PsA patients. Serum Dkk-1 levels were associated with serum sclerostin levels (r=0.872 and $P<0.001$) and age (r=0.312 and $P=0.008$). Serum periostin, Dkk-1 and sclerostin levels were not different between PsA patients with and without axial incolvement.

Conclusion : Our results suggested that circulating Dkk-1 and sclerostin may have a role in disease susceptibility. Decreased Dkk-1 and sclerostin levels may contribute to the new bone formation, seen in the disease course, in patients with PsA. **Table1**. Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis (SpA) covers a group of interrelated auto-inflammatory disorders where TNFa is a central mediator of disease. T cells and macrophages are abundant in the sacroiliac joint, and macrophage infiltration is associated with global disease activity. CD163 is a scavenger receptor primarily expressed by M2c macrophages. The soluble (s) form is cleaved from the cell surface by TACE/ADAM17, the metalloproteinase also responsible for the cleavage of TNFa. In RA, sCD163 is associated with disease activity and progression[i]. The mannose receptor, CD206, is a scavenger receptor responsible for collagen internalization and mainly expressed by M2a macrophages. The soluble forms of CD206 and CD163 are suggested as novel biomarkers of M2a and M2c macrophage activity. We investigated plasma levels of sCD163 and sCD206 and their association with disease activity markers in SpA patients.

---

[i] Greisen, S. R. *et al. Clin. Exp. Rheumatol.* (2011)

Methods: Soluble CD163 and sCD206 were measured by ELISA, in plasma (PL) and synovial fluid (SF) from 23 SpA patients with peripheral joint activity, and plasma from 30 SpA patients at initiation of anti-TNFa treatment (baseline) and after 12, 20 and 52 weeks of treatment. Clinical disease was assessed by: BASFI, BASMI, BASDAI, ASDAS, CRP and MRI scoring of the whole spine. Statistical analyses were performed by student's t-test and Spearman's rank correlation.

Results: Synovial fluid levels (10.2 ±4.90 mg/l) of sCD163 were significantly increased compared with PL (2.37 ±1.05 mg/l) ($p<0.001$). Conversely, sCD206 levels in PL (0.25 ±0.08mg/l) were higher than in SF (0.12 ±0.07 mg/l) ($p<0.01$). In addition, PL levels of sCD206 correlated with sCD163 ($r=-0.48$, $p=0.02$), and CRP ($r=-0.50$, $p=0.02$). A strong correlation between PL and SF sCD206 was observed ($r=0.60$, $p=0.003$), which was not the case for sCD163. In the anti-TNFa treated cohort, PL sCD163 at baseline was not increased compared with healthy controls, and was not affected by the treatment regimen. In contrast, anti-TNFa treatment affected sCD206 PL levels, which increased significantly from baseline levels (baseline: 0.16 mg/l and at 3 months: 0.20 mg/l, $p<0.0001$). The high levels were sustained in the entire follow-up period. Soluble CD163 at baseline and at 12 weeks correlated weakly with the BASDAI score at 12 weeks ($r=-0.41$, $p=0.02$ and $r=-0.42$, $p=0.02$), whereas no associations were observed between sCD206 and disease activity- or MRI scores.

Conclusion: In SpA, sCD163 is not increased, but show association with disease activity measured as BASDAI. Conversely, sCD206 was decreased at baseline, but increased as a response to anti-TNFa treatment. This supports that M2 macrophages are involved in SpA, but points to differences between the two subtypes engagement.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Due to the limitation of early diagnosis of ankylosing spondylitis (AS), updated criteria in recent years introduced the concept of axial spondyloarthritis (axSpA) and non- radiographic axial spondyloarthritis (nr-axSpA) and facilitates classification management of disease. It has been controversial whether the two sub-phenotypes are separate or different phases of radiographic progression. Studies has revealed calprotectin as inflammation marker and the Wnt/β-catenin pathway contributed to the bone fusion in AS.

Methods: We enrolled 53 patients with AS, 59 patients with nr-axSpA and 47 healthy individuals. Patients were diagnosed with AS or nr-axSpA according to the modified New York criteria or ASAS classification criteria for axSpA. Laboratory tests including ESR, CRP and human leukocyte antigen (HLA)-B27 were conducted. Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and Ankylosing Spondylitis Disease Activity Score (ASDAS) were evaluated. Imaging assessment was calculated using Spondyloarthritis Research Consortium Canada (SPARCC) scoring system for sacroiliac joints and modified Stoke's Ankylosing Spondylitis Spine Score. Serum levels of calprotectin, GSK-β,β-catenin, RUNX2 were determined by commercial ELISA kit. Data were described as mean and SD. Mann–Whitney U test or Kruskal–Wallis test was used to compare continuous variables. Correlations were assessed using the Spearman's rank correlation coefficient. Statistical analyses were performed with SPSS V.13.0 software. A p value <0.05 was considered statistically significant.

Results: Clinical characteristics and laboratory results were described in Table 1. Serum calprotectin level was higher in AS and nr-axSpA patients than that in healthy individuals. No difference was observed in calprotectin level between AS and nr-axSpA patients. Elevated calprotectin was positively correlated with ESR, CRP, BASDAI, ASDAS as well as SPARCC scoring and had no correlation with BASFI and mSASSS in these two sub-genotypes. No correlation was observed between calprotectin and Wnt/β-catenin pathway markers. Radiographic progression indicated by mSASSS was correlated merely with disease duration instead of other outcome measurements.

Conclusion: Calprotectin does not contribute to the discrimination of AS and nr-axSpA. Patients with nr-axSpA are not necessarily progress to AS. Calprotectin mediated inflammation was not correlated with principle effectors of Wnt/β-catenin pathway, indicating inflammation and bone fusion might be separate process of the disease . Long-term follow-up favors further investigation of value of inflammation subsequent bone information. Table 1 Clinical characteristics and laboratory results in AS and nr-axSpA patients

Session Title: Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Genome-wide association studies (GWAS) in patients and healthy controls have allowed the identification of multiple variants associated with disease risk in Psoriatic Arthritis (PsA). To date, however, there has been no GWAS for PsA phenotypes. The main objective of this study was to identify new genetic variation associated with clinical phenotypes in PsA.

Methods: A total of n=835 patients diagnosed with PsA using CASPAR criteria were recruited for the discovery stage. In each patient >600,000 single nucleotide polymorphisms (SNPs) were genotyped. All patients were Caucasian and of Spanish origin. GWAS were performed for clinical and biological phenotypes associated with joint disease, as well as skin disease related phenotypes. After allelic association analysis, those SNPs with highest level of significance were analyzed in an independent cohort of n=414 PsA patients.

Results: In the GWAS stage, several genomic regions showing high evidence of association with different PsA phenotypes (P<5e-6) were identified. These included association with axial disease pattern, peripheral disease pattern, bone proliferation, degree of radiological sacroileitis and the presence of syndesmophytes. Also, GWAS on cutaneous variables identified two regions associated with nail disease and skin disease severity. Using the replication cohort, the association between one locus and peripheral pattern of disease, and two loci associated with axial pattern were nominally validated.

Conclusion: To our knowledge, this is the GWAS of clinical phenotypes in PsA. New candidate loci associated with axial and peripheral disease have been identified.

Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Studies have shown that psoriasis of the skin, scalp and/or nails precedes the appearance of psoriatic arthritis (PsA) by up to 12 years[1,2]; however, only a single European study from a German registry has examined PsA patients with nail psoriasis in clinical practice.[3] The objective of this descriptive analysis was to characterize the clinical and patient-reported outcomes of PsA patients with nail psoriasis in the US-based Corrona Psoriatic Arthritis/Spondyloarthritis (PsA/SpA) registry.

Methods: This cross-sectional descriptive study included all patients enrolled in the Corrona PsA/SpA registry between March 2013 and March 2016 with a diagnosis of PsA who had non-missing data on physician-reported nail psoriasis. Patients were stratified by presence vs absence of nail psoriasis, defined as having a non-zero response on the nail psoriasis visual analog scale of 0–100. Descriptive analyses of patient demographics, clinical measures, patient-reported outcomes and treatment characteristics were assessed at the time of enrollment and compared between subgroups using *P* values from Wilcoxon rank-sum tests for continuous variables and chi-squared tests for categorical variables.

Results: As of March 2016, a total of 1661 patients with PsA in the registry met the inclusion criteria, including 739 patients (44.5%) with nail psoriasis and 922 patients (55.5%) without nail psoriasis. Both patient subgroups were similar in terms of age, race, body mass index, disease duration, prevalence of most comorbidities (e.g., cardiovascular disease, any cancer, diabetes and serious infection) and biologic use at the time of enrollment; however, patients with nail psoriasis were significantly more likely to be male (53.0% vs 43.8%) and have a higher history of depression (35.9% vs 27.4%), and were less likely to be underweight/normal (13.1% vs 19.0%) compared with patients without nail psoriasis. Patients with nail psoriasis had more moderate/severe psoriasis at enrollment (body surface area [BSA] > 3%) compared with patients without nail psoriasis, and had worse disease as assessed by percentage of affected BSA, achievement of minimal disease activity, Clinical Disease Activity Index scores, physical function, patient-reported pain and fatigue, quality of life and activity impairment (**Table**).

Conclusion: This analysis from the Corrona registry demonstrated that patients with PsA and nail psoriasis at the time of registry enrollment had significantly worse disease activity and had worse patient-reported outcomes compared with those patients without nail involvement. Nail psoriasis is common in patients with PsA; therefore, these findings emphasize the importance of early recognition and management of patients with nail psoriasis.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Reactive arthritis (ReA) are sterile arthritis occurring after extra articular bacterial infection, mainly located in gut or genito urethral mucosa. The aim of this study was to analyze, over 30 years, frequency as well as clinico-biological and therapeutic characteristics of inpatients with ReA, comparing two periods.

Methods: In this retrospective monocentric study, the charts of all the patients followed in our unit between January 1st 1984 and April 2014 with the diagnosis or ReA, according to International Classification Criteria (1), were recorded and clinic biological features,

management and outcome were analyzed, and compared between two periods : from January 1984 to December 1993, and from January 2004 to December 2013.

Results: 62 patients fulfilling international diagnosis criteria were analyzed. We found no significant differences (Table) between the two periods in frequency of new cases, clinical presentation (rheumatologic and extra articular features), biological and microbiological data or outcome.Change in therapeutic management was obvious with lower delay for DMARD initiation and occurrence of anti TNF use in the recent period.

	1984 - 1993	2004 - 2013	p
Number of ReA patients / hospitalizations	15 / 7438	31 / 11 823	NS
Median age at diagnosis	37	30	NS
HLA B27 + (%) / Evidence of infectious agent (%)	91 / 53	63 / 61	NS
Delay between infection/articular symptoms (days) median	5.5	9	NS
CRP (mean) (mg/l)	87	90	NS
TJC / SJC	2.8 / 1.8	3.2 / 2	NS
	1984 - 1993	2004 - 2013	p
Enthésitis (%) / Dactylitis (%)	40 / 13	26 / 29	NS
Extra articular features (%)	47	35	NS
Axial symptoms (%)	33	29	NS
DMARDs use (%)	36	62	NS
Median delay of DMARD introduction (days)	210	50.5	NS
Biologic agents use (%)	**0**	**45**	**0.005**
Remission at last follow-up (%)	57	47	NS

Conclusion: Reactive arthritis is still a current rheumatologic problem, with an apparently stable frequency in a developed country, with a need of early and tailored rheumatologic management.

The Co-Occurrence of Axial Spondyloarthritis and Fibromyalgia: A National Register-Based Study

Gary J. Macfarlane[1,2], Maxwell S. Barnish[1,3] and Gareth T. Jones[3,4], [1]Epidemiology Group, University of Aberdeen, Aberdeen, United Kingdom, [2]Aberdeen Centre for Arthritris and Musculoskeletal Health, University of Aberdeen, Aberdeen, United Kingdom, [3]Aberdeen Centre for Arthritis and Musculoskeletal Health, University of Aberdeen, Aberdeen, United Kingdom, [4]Epidemiology Group, School of Medicine, Medical Sciences and Nutrition, University of Aberdeen, Aberdeen, United Kingdom

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Some patients with axial spondyloarthritis (axSpA) are recognized clinically to have co-morbid fibromyalgia (FM). However, there are no trials to inform how these patients are best managed when axSpA and FM occur together. This study aims to provide data on their frequency of co-occurrence and, amongst persons with axSpA, features which characterize persons with co-morbid FM

Methods: The British Society for Rheumatology Biologics Register in Ankylosing Spondylitis (BSRBR-AS) recruits persons meeting any ASAS definition of axSpA. All patients recruited are naïve to biologic therapy and are either newly starting biologic therapy (biologic cohort) or not (non-biologic cohort). At recruitment, patients self-complete the ACR 2010 modified research criteria (2010m ACR) for FM, Bath measures of disease activity (BASDAI), function (BASFI) and global severity (BAS-G), Quality of Life (ASQoL and EQ-5D), sleep disturbance score (SDS), Chalder Fatigue Scale (CFS), and Hospital Anxiety and Depression Scale (HADS). Clinicians indicated whether they had made a clinical diagnosis of FM; Bath metrology index (BASMI) and Body Mass Index (BMI) were measured. The Index of Multiple Deprivation (IMD) is an area based measure of deprivation based on postcode.

Results: 430 patients provided clinical information and the recruting clinicians considered that 13 had a clinical diagnosis of FM (3.0%), while 274 provided self-report data, of whom 56 (20.4%) met the 2010m ACR FM criteria. Patients who met FM criteria were more likely to be female (difference in proportion 0.21; 95% CI (0.07, 0.36), reported worse BASDAI (mean difference (md) 2.7; 95% CI 2.0, 3.3), BASFI (md 2.7; 1.9, 3.4) and BAS-G (md 2.7; 2.0, 3.5). They reported worse Quality of Life (ASQoL md 6.3; 4.8, 7.8: EQ-5D md -0.23; -0.32,-0.14), higher levels of anxiety (md 3.9; 2.7, 5.1) and depression (md 4.0; 2.9, 5.2), more sleep problems (md 3.7; 2.0, 5.4) and higher levels of fatigue (md 4.0; 3.0, 5.0). There was no difference in age, IMD or whether they were commencing biologic therapy.

Conclusion: There is a large discrepancy between clinical diagnosis of FM and meeting FM research criteria in patients with axSpA. Patients who meet FM criteria show markedly worse markers of axSpA disease activity and generally poorer health. It is unknown whether such criteria are valid in the presence of axSpA, but there may be a large unmet and unrecognised need for treatment of FM symptoms amongst patients with axSpA.

A Prospective Study of Ankylosing Spondylitis in China with Smart Management System for Spondyloarthritis: Study Design and Baseline Characteristics of the 449 Recruited Patients

Xiaojian Ji, Qiongfang Wen, Jinshui Yang, Jian Zhu, Jianglin Zhang and **Feng Huang**, Rheumatology, Chinese PLA General Hospital, Beijing, China

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to set up a large, longitudinal and prospective database to investigate the epidemiology, pathogenesis, diagnosis, and prognosis of ankylosing spondylitis (AS) through mobile health in the Chinese population.

Methods: 449 consecutive outpatients with confirmed AS or spondyloarthritis (SpA) were recruited and followed annually with Smart Management System for SpA (SMSP). Characteristics of registration and demography (age, gender, time of back pain onset, diagnosis, presence of AS-related clinical manifestations, family history) and the current condition (disease activity, severity, treatments, laboratory tests) were collected online with SMSP.

Results: 449 patients (mean age: 29.4±8.5 years, male 84.0 %, HLA-B27 positive rate 81.2%) were included in the analysis. In this cross-sectional analysis, only data at the first visit were used (from May 2014 to December 2014). A history or current symptoms suggestive of peripheral arthritis, enthesitis, acute anterior uveitis, psoriasis and inflammatory bowel disease were observed in 46.4%, 69.1%, 10.5%, 2.4% and 5.8% of the patients, respectively. Differences in symptom duration (≤ 5 years, 5 years to 10 years and > 10 years) were analyzed. The 3 groups did not differ in the frequency of gender, HLA-B27 positivity, family history, arthritis, enthesitis, inflammatory bowel disease, psoriasis, and abnormal CRP. Pain located in thoracic spine (34.1%), anterior chest wall pain (28.1%) and uveitis (18.5%) were detected significantly more frequently in patients with symptom duration of > 10 years.

The association of clinical variables and laboratory markers with patient's poor physical mobility (lumbar flexion Impairment, cervical

flexion Impairment and chest activity limitation) was evaluated with multivariate logistic regression model. The result revealed that 121 patients (26.9 %) had reduced lumbar mobility; 93 patients (20.7 %) had impaired cervical flexion and 104 patients (23.2 %) had reduced chest expansion. The analyses showed that symptom duration is independently associated with poor physical mobility of any of the body parts mentioned above (*OR* = 1.11, *OR* = 1.14, *OR* = 1.13, respectively). Age at onset is only significantly associated with chest expansion limitation (*OR* = 1.06). Cervical spine pain at onset is determined to be closely related to cervical flexion impairment (*OR* = 1.98). Also, smokers and ASDAS are determined to have an unfavorable effect upon outcomes of cervical flexion (*OR*=2.06, *OR* = 1.38, respectively). Smokers, abnormal CRP, and ASDAS correlate with a poor prognosis in lumbar flexion (*OR* = 2.44, *OR* = 2.05, *OR* =1.45, respectively).

Conclusion: This is the first prospective cohort study of ankylosing spondylitis and the first smart management system for SpA in China. With increasing global popularity of smart phone technology, there is a great opportunity for using mobile phone applications for disease management. This large cohort may improve our knowledge on the characteristics, pathogenesis and natural course in Chinese patients with AS.

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis (SpA) includes a wide range of overlapping diseases for which there are a limited number of approved pharmacologic agents that have been shown to modify disease course. To date, tumor necrosis factor inhibitors (TNFi) are the most effective treatments available that improve function and alleviate symptoms. However, the extent to which TNFi ameliorates SpA disease activity in routine care remains unclear. We examined the frequencies of elevated Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) scores in SpA patients receiving TNFi.

Methods: Patients with SpA-related diseases who were receiving a TNFi and enrolled in the Veterans Affairs' Program to Understand the Long-term Outcomes in Spondyloarthritis (PULSAR) registry were eligible for study. Standardized electronic medical record templates obtained at routine clinic visits from Sept. 2007 – June 2016 provided the clinical study data. A modified, validated version of the BASDAI (replacing the term "Ankylosing Spondylitis" with "inflammatory arthritis"), was administered to subjects, and mean BASDAI scores were computed. We determined the prevalence of BASDAI≥4 among subjects with axial SpA, determined by SpA phenotype and use of TNFi.

Results: There were 596 PULSAR patients; 91% were male, 70% were Caucasian and 11% African American. The mean age at SpA diagnosis was 55 years. The majority either had ankylosing spondylitis or psoriatic arthritis. Forty-four percent were HLA-B27 positive, and the mean ESR and CRP value at enrollment was 18 mm/hr and 8.94 mg/L, respectively. Baseline BASDAI of SpA patients (regardless of phenotype) was 5.28. There were 385 on TNFi during the study period (Table). A BASDAI of ≥4 was recorded in approximately 60% of those treated with TNFi, including at their most recent encounter.

Conclusion: In a SpA cohort of US veterans, active disease persisted in a majority of TNFi- treated patients, potentially indicative of the need for more intensive or alternate therapies. **Table: Active BASDAI ≥4 scores in SpA patients receiving TNFi**

	AS	PsA	EAA	ReA
Total (n=596)	260	246	36	54
SpA on TNFi n =385, (% cohort)	172 (66.2%)	167 (67.9)	17 (47.2)	29 (53.7)
BASDAI≥4 ever	145 (84.3%)	136 (81.4%)	11 (64.7%)	22 (75.9%)
BASDAI≥4 (mean, all observations)	132 (76.7%)	118 (70.7%)	10 (58.8%)	22 (75.9%)
BASDAI≥4 (when receiving TNFi)	129 (75%)	115 (68.9%)	9 (52.9%)	21 (72.4%)
BASDAI≥4 (most recent visit)	104 (60.5%)	100 (59.9%)	8 (47.1%)	18 (62.1%)

AS = ankylosing spondylitis, PsA = psoriatic arthritis, EAA = enteric-associated arthritis, ReA = reactive arthritis, TNFi = Tumor necrosis factor inhibitor

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence of HLA-B27 varies between different ethnicities. Its presence is associated with susceptibility to axial spondyloarthritis (axSpA). The aim of this study is to evaluate the prevalence of HLA-B27 in the normal population and in patients with axSpA.

Methods: The prevalence of HLA-B27 in the normal population was evaluated in cord blood and healthy organ transplant donor databases. HLA typing was conducted with sequence-specific oligonucleotide probing and sequence-specific primer technologies. The data of patients with axSpA were collected retrospectively from five different hospitals. Patients with inflammatory bowel disease and psoriasis were excluded. Demographics, age at symptom onset/diagnosis, presence of extra-articular manifestations and use of biologics were obtained.

Results: A total of 136 axSpA patients were included, with a male predominance of 67.4%. The mean (±SD) ages at symptom onset and disease diagnosis were 29 (±10.9) and 33.4 (±10.7) years, respectively. The mean diagnosis delay was 51.7 (± 54.7) months. HLA-B27 was positive in 73 (53.7%) of patients. Male gender and HLA-B27 positive subtype were associated with a younger age at symptom onset/diagnosis (p<0.04), but no significant difference was observed in diagnosis delay, with a mean delay of 53.9±58.2 versus 49.1±50.6 months for HLA-B27-positive and negative patients, respectively (p=0.61). HLA-B27-positive patients were more likely to be on biologics (p=0.037), with no difference in the median number of biologics used. HLA-B27 was found in 82/3332 (2.5%) and 27/1164 (2.3%) in the cord blood and healthy organ transplant donor databases, respectively.

Conclusion: The prevalence of HLA-B27 is low in the Saudi population. A significant diagnosis delay has been observed in patients with axSpA regardless of HLA-B27 status and gender. HLA-B27 is positive in only half of axSpA patients limiting its usefulness.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnosis and assessment of psoriatic arthritis (PsA) and psoriasis (PsO) lesions are mostly done by visual inspection, and when in doubt, supplemented by a biopsy. Although PsA is primarily assessed by physical examination, the utility of ultrasound is beneficial. Here, we test the performance of advanced ultrasound skin imaging software applications in PsO & PsA assessment.

Methods: The rheumatologist and dermatologist performed standard clinical examinations on PsA and PsO patients respectively. Using ultrasound (US), we evaluated the hand, wrist, & symptomatic joints of PsA patients for synovitis & tenosynovitis (nail beds included). Blinded by the clinical results & treatment plans, the epidermal, dermal and subcutaneous tissue thickness of 2 of the most affected lesions were scanned by high frequency B-Mode, automated color Doppler quantification (CDQ) and elastography applications (measuring lesion size, depth, hyperemia and tissue elasticity). The skin tissues adjacent to the psoriatic lesion, and the unaffected skin

on the contralateral side (self-control) were measured for comparison.

Results: A total of 270 skin measurements in, around, & opposite to the 10 psoriatic lesions of 5 PsA/PsO patients were analyzed. Epidermal thickness differed significantly between adjacent and control tissue layers [F (2,27) = 30.95, MSE = 0.76, p<0.001]. Similar findings were evident for dermal thickness differences [F (2,27) = 5.05, MSE = 1.59, p=0.014]. Subcutaneous tissue depths were of no significance. Ultrasound CDQ & elastography revealed hyperemia in 80% of lesions (60% with plaque). Contrary, 20% of lesions showed no obvious Doppler activity, displaying reduced tissue stiffening on elastography (suggesting healed lesions). Two of 10 lesions were soft on elastography (no acoustic shadows) but had low-level CDQ activity (minimum 0.016:0.034 & maximum 0.103:0.135 ratios). In PsA patients, the presence of synovitis (intra &extra-articular Doppler) mostly in DIPs & PIPs, and tenosynovitis of flexor tendons were detected. Hyperemic nail beds (altered microcirculation) and hand psoriasis skin perfusion was evident on US, and confirmed by fluorescence optical imaging (FOI).

Conclusion: Several ultrasound parameters clearly distinguish between affected & normal skin and could be used as quantitative and objective measures in assessing psoriasis lesions. Some US parameters appear to distinguish between adjacent (non-involved) skin & self-control skin, while some show striking heterogeneity between different patients, suggesting that US may help subtype psoriasis lesions, but need to be investigated further. Ultrasound metrics of skin tissue (depth, plaque characteristics, elasticity and Doppler quantification) has potential to compliment the clinical assessment of PsO & PsA patients.

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical trials have demonstrated the efficacy of biologic therapy in improving the clinical and patient-reported outcomes in patients with ankylosing spondylitis (AS); however, there are limited data describing their use in real-world clinical practice. The objective of this analysis was to characterize and compare patients with AS who continued and discontinued their biologic therapy within 12 months of initiation in the US-based Corrona Psoriatic Arthritis/Spondyloarthritis (PsA/SpA) registry.

Methods: This descriptive analysis included all patients with AS aged ≥ 18 years enrolled in the Corrona PsA/SpA registry between March 2013 and March 2016 who received a biologic at the time of registry enrollment and had ≥ 1 follow-up visit. Patients were assigned to a cohort depending on their continued or discontinued use of their biologic agents at the first follow-up visit (mean [SD] follow-up, 8.8 [4.6] months). Patient demographics, clinical presentation, patient-reported outcomes and past/current treatments were assessed and compared between cohorts using *t*-tests for continuous variables and chi-square or Fisher's exact tests for categorical variables. Reasons for discontinuation of the index biologic (e.g., side effects, social reasons, lack of effect, doing well or other) were also described in this study.

Results: Of the total of 167 patients with AS who met the inclusion criteria, 32 patients (19.2%) discontinued the index biologic therapy by the first follow-up visit, including 12 patients who switched to another biologic therapy. Baseline characteristics of patients who continued vs discontinued a biologic by their first follow-up visit were similar with regards to sex, race, education, insurance type and past/current treatments. However, patients who discontinued their index biologic were significantly older (52.6 vs 46.8 years); were more likely to be obese (56.7% vs 33.3%) with greater body mass index (34.0 vs 28.2 kg/m^2); and had significantly worse Bath Ankylosing Spondylitis Disease Activity Index scores (4.8 vs 3.7) and Bath Ankylosing Spondylitis Functional Index scores (4.6 vs 2.8), but similar Ankylosing Spondylitis Disease Activity Scores (1.8 vs 1.9), at enrollment compared with patients who continued their biologic therapy (**Table**). Among the 9 patients (28.1%) who reported a reason for discontinuation, lack of effect (55.6%) was the most common reason, followed by other reasons (22.2%), side effects (11.1%) and social reasons (11.1%).

Conclusion: Results from the Corrona PsA/SpA registry demonstrated that patients with AS who discontinued their biologic therapy by the first follow-up visit were significantly older, more overweight and had worse patient-reported disease activity and function at enrollment compared to those who remained on the therapy. Lack of effect was the most common reason for biologic discontinuation.

Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: This non-interventional, cross-sectional descriptive exploratory analysis aimed to characterize patients (pts) with PsA in the 2015 National Health and Wellness Survey (NHWS) and determine the impact of treatment, or no treatment, on pt-reported outcomes (PROs).

Methods: NHWS is a self-administered, web-based, voluntary, confidential questionnaire that used stratified randomized sampling to provide a representative sample of US adults. Respondents who reported PsA diagnosis were grouped by current treatment: advanced pharmacologic therapies (TNF inhibitors, IL-12/23 and IL-17 antagonists, PDE4 inhibitors) ± other drugs; other pharmacologic therapies (conventional synthetic DMARDs, COX2 inhibitors, NSAIDs, glucocorticoids, topical medications); or no current treatment. Short-Form 36 health survey (SF-36), Work Productivity and Activity Index (WPAI), and Patient Health Questionnaire (PHQ)-9) were investigated and summarized descriptively.

Results: Of 97,700 adults who completed the NHWS, 1059 pts reported PsA diagnosis. Of these, 216 reported treatment with advanced therapies, 206 with other therapies, and 637 reported no current treatment. Age and gender were generally balanced between treatment groups. Prior to treatment with advanced or other therapies, ~88–91% had self-reported moderate or severe PsA, and following treatment, ~54–57% reported moderate to severe PsA, which was similar to those reporting no current treatment (~58%; Table 1). SF-36 and PHQ-9 did not show wide variation in scores across treatment groups. WPAI showed that >40% of pts had work-related impairment due to PsA, despite being treated and having mild to moderate disease (Table 2).

Conclusion: We found that ~60% of pts who reported PsA diagnosis reported no current treatment. Regardless of treatment group, pts reported >20% work loss and >40% work impairment. Among pts treated with advanced and other therapies, >50% reported moderate to severe PsA, suggesting the need for additional therapies and overall better management of PsA to reduce disease activity and improve quality of life. A limitation of this analysis is that pts self-reported PsA diagnosis, and results may differ from pts having physician-reported PsA diagnosis. Further statistical analysis is needed to determine differences between groups and correlation to other health

Table 1. Demographics and characteristics

		Advanced therapies N=216	Other therapies N=206	Not treated N=637
Age in years, mean (SD)		46.0 (14.3)	52.5 (15.0)	44.9 (15.9)
Females, n (%)		98 (45.4)	118 (57.3)	268 (42.1)
White ethnicity, n (%)		141 (65.3)	150 (72.8)	416 (65.3)
PsA severity when treated, n (%)	Mild	93 (43.1)	94 (45.6)	NA
	Moderate	98 (45.4)	97 (47.1)	NA
	Severe	25 (11.6)	15 (7.3)	NA
PsA severity when untreated, n (%)	Mild	18 (8.8)	24 (12.4)	270 (42.4)
	Moderate	79 (38.7)	75 (38.9)	317 (49.8)
	Severe	107 (52.5)	94 (48.7)	50 (7.9)

PsA severity was self-assessed by patients

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients (pts) with psoriatic arthritis (PsA) may experience temporary worsening of symptoms or disease flare, which can be painful enough to interfere with day-to-day activities. The impact of pt perception of severity of disease flare on work productivity, treatment satisfaction, and other pt-reported outcomes (PROs) has not been quantified in detail. The purpose of this analysis is to evaluate the perception of disease flares in pts with PsA and its impact on work productivity and treatment satisfaction in real world setting.

Methods: Adelphi[1] 2014 Rheumatology Disease Specific Programme is a large multi-center, multi-country, cross-sectional survey of pts with a physician confirmed diagnosis of PsA. Pts filled out a self-completion survey providing an assessment of their symptoms (severity of disease and flaring), quality of life (QoL), and satisfaction with disease control. The self-assessment questionnaire also included pt-reported alternative Health Assessment Questionnaire-Disability Index (HAQ-DI, without aids and devices), Work Productivity and Activity Impairment–Specific Health Problem (WPAI-SHP), and treatment satisfaction. Statistical differences between the groups were evaluated using chi-square test (categorical variables) or analysis of variance (ANOVA, continuous variables).

Results: Of the 341 PsA pts analyzed from the Adelphi database, 236 (69.2%) pts experienced temporary worsening of symptoms or disease flare. Among pts who reported experiencing a flare, mean age was 51 years and 54% were female. At survey, 126 (55.3%) pts reported experiencing moderate flare, while 53 (23.2%) and 49 (21.5%) experienced mild and severe flare, respectively. Pt-reported severity of last flare increased significantly with increasing perception of PsA severity at survey (P<0.001), at its worst (P<0.001), or before current treatment (P=0.003, **Table**). The severity of disease flare, as reported by pts, was negatively associated with the ability of pts to go to work and perform well at work (P<0.001) and perform daily tasks (P<0.001). The mean HAQ-DI (P<0.001) and WPAI (P<0.001) scores significantly worsened with increasing severity of disease flare perception. Of the pts reporting mild, moderate, and severe flares, 32 (64.0%), 72 (60.0%), and 26 (53.1%), respectively, were receiving biologic medicine. Pts' satisfaction with the current treatment (P=0.002) was significantly lower with increasing severity of disease flare.

Conclusion: Pt perception of PsA severity increased with the severity of pt-reported disease flare. Increasing severity of disease flare perception was associated with decreased work productivity, reduced ability to perform day-to-day activities, and less treatment satisfaction. Pts reporting moderate to severe disease flare experience significantly higher disease burden. **References:**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Knowledge about the impact of illness perceptions on health-related quality of life (HRQoL) in patients with axial Spondyloarthritis (axSpA) and other forms of chronic back pain (CBP) is lacking. The aim is to explore the association between illness perceptions and HRQoL in patients with short symptom duration of axSpA and other forms of CBP at baseline.

Methods: The SPACE study includes patients with CBP (≥3 months, ≤2 years, onset <45 years) from 5 European centers. Revised Illness Perception Questionnaire (IPQ-R) was completed at baseline. In illness identity dimension, patients reported if they have experienced and believed that a certain symptom is CBP related. Other IPQ-R dimensions used 5-point Likert scales (1 strongly disagree, 5 strongly agree). HRQoL was assessed by 36-item Short-Form (SF-36). Physical (PCS) and Mental Component Summary (MCS) scores were calculated ranging from 0 (worst) to 100 (best). Univariable regression models were built for each IPQ-R subscale as independent and PCS or MCS as dependent variable. The models were adjusted for age and gender and stratified in case of effect modification by gender ($p<0.20$).

Results: 450 patients were included; 176 fulfilled the axSpA ASAS criteria. Mean PCS was 28.3 (SD 16.1) for axSpA patients and 25.4 (SD 14.8) for CBP. As the MCS was only slightly decreased compared to the general population of 50 (SD 10) (48.8 (SD 13.7) axSpA and 48.3 (SD 12.1) CBP patients), analyses focused on PCS. Patients reported a mean of 4.3 (axSpA) and 4.5 (CBP) symptoms to be associated with back pain. Most reported symptoms were pain and joint stiffness. All other dimensions showed a mean of approximately 3, except psychological attributions, risk factors, immunity, and accident (mean approximately 2). All patients attributed their complaints mostly to genetic factors. In both patient groups attribution of multiple symptoms to CBP (Table 1; β=-1.9 axSpA, β=-2.0 CBP) was associated with lower PCS. Stronger belief in severe consequences in male axSpA patients (β=-11.3) and stronger belief in risk factors (β=-6.9) or immunity (β=-8.3) as a cause in male CBP patients were associated with lower PCS. Whereas, in male axSpA patients, being better in understanding their complaints (β=6.2) was associated with higher PCS. In female axSpA patients stronger belief in severe consequences (β=-7.3) and in female CBP patients more negative emotions towards their complaints (β=-3.8) and being better in understanding their complaints (β=3.3) were statistically significant. No gender differences were found for emotional representation (β=-5.0), psychological attributions (β=-3.4), immunity (β=-4.0), or accident (β=-3.0) in axSpA and consequences (β=-8.5) or chance (β=-2.0) in CBP patients.

Conclusion: Negative illness perceptions are associated with lower PCS of HRQoL in patients with axSpA and other forms of CBP.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Group for Research of Psoriasis and Psoriatic Arthritis (GRAPPA)-Outcome Measures in Rheumatology (OMERACT) Psoriatic Arthritis (PsA) working group recently obtained endorsement at the OMERACT 2016 conference for the updated PsA core domain set to be measured in PsA clinical trials. Our objective was to integrate patients in each research phase such that the updated PsA core domain set fully reflects a diverse patient perspective.

Methods: The patient voice was sought through an international focus group study covering five continents, two surveys of patients, a consensus meeting with patients and physicians, as well as active partnership of five patient research partners (PRPs) from GRAPPA in the working group. Patient involvement was regularly discussed during reflection meetings by the research team.

Results: Overall, almost 150 persons with PsA were involved in the study: 1) Systematic literature review. Three PRPs were involved in study protocol development, analysis of results and co-authorship; 2) International focus group study. Ninety patients with PsA participated in 16 focus groups. PRPs gave feedback on the focus group guide, co-moderated focus groups and analyzed and interpreted qualitative data; 3) Surveys. Fifty patients participated in two rounds. Five PRPs participated in the design and analysis of the patient surveys and assisted in writing the introduction text; 4) Consensus meeting. Twelve patients participated in a face-to-face meeting with 12 physicians to agree on a preliminary core domain set. Two PRPs helped in preparing the agenda and patient participant selection.

In total 14 PRPs contributed to one or more of the above research activities. Challenges were identified by physician-researchers (time-constraints and tight deadlines; use of jargon; motivation of PRPs) as well as PRPs (ensuring equal participation and acknowledgement; involvement of pharmaceutical industry).

Conclusion: Collaboration between physician-researchers and PRPs during all core-set development steps enhanced the integration of the patient perspective in a meaningful and representative manner and provided additional face validity. PRP involvement in qualitative data analysis and development of the domain list for the surveys ensured that domains important to patients were maintained throughout the research process and phrased in a manner understandable to patients.

Figure 1. Flow chart of research activities with active participation of patients and patient research partners (PRP) in the update of the OMERACT Psoriatic Arthritis core domain set.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The use of patient-reported outcome measures has become routine in clinical practice and in clinical trials. In order to use any outcome measure in the daily clinic, the natural variation of the outcome measure must be known. Natural variation may also be characterized as measurement error and is assessed in individuals who are considered to be in "steady state". The objective of this study was to examine natural variation of fatigue, pain and patient global assessment (PaGl) in patients with stable spondyloarthropathy (SpA) defined on the basis of BASDAI (0-100).

Methods: 107 SpA patients treated in the daily clinic with a TNF-inhibitor and characterized by stable disease were identified in the Danish rheumatology registry (DANBIO). According to ASAS response criteria for biological treatment in SpA [1] and to previous reports on BASDAI measurement errors [2], stable disease was defined as a change in BASDAI ≤ 20 between two consecutive visits. Paired data from a single set of such two visits were extracted for each patient. Data comprised BASDAI, BASFI, PaGl, pain and fatigue scored on 0-100 visual analogue scales (VAS). Natural variation was examined using the Bland-Altman method with calculations of lower and upper 95% limits of agreement (LLoA;ULoA) between two consecutive assessments and the corresponding bias (mean of individual differences). Associations between intra-individual inter-visit differences (Δ) were described by linear correlation (r) and stepwise multiple regression analyses (partial regression coefficients (rp) and standard errors of estimation (SEE)).

Results: Mean age was 44±14 years, mean BASDAI 35.6±23.8, mean BASFI 33.0±24.8, mean fatigue 49.3±28.2, mean pain 35.6±26.9, mean PaGl 40.8±27.9, mean inter-visit time duration 16±13 weeks (range 3 – 91 weeks) and mean ΔBASDAI 0.0±10.5 (range -20 – 20, NS). Biases were close to 0 for all the variables indicating stable conditions on the group level between the two consecutive visits. On the individual level, however, differences were more pronounced: LoA;ULoA [bias] for fatigue was -37.4;36.2 [-0.6, NS], for pain -34.1;32.5 [-0.8, NS], for PaGl -35.7;32.9 [-1.4, NS] and for BASFI -23.2;22.6 [-0.3, NS]. No significant correlations were found between the absolute Δvalues of BASDAI, BASFI, fatigue, pain or PaGl and the inter-visit time duration (r range -0.1 – 0.2, ns). Δfatigue, Δpain, ΔPaGl and ΔBASFI were only weakly correlated with ΔBASDAI (r range 0.30 – 0.60, $p < 0.01$). In multiple regression analyses, Δfatigue, Δpain and ΔPaGl were best predicted by ΔBASDAI, and ΔBASFI by Δpain (rp range 0.40 – 0.49, $p < 0.0001$). Although these associations were highly statistically significant, SEEs were high (range 10.8 – 15.6) illustrating poor predictability in individuals.

Conclusion: Independently of time duration, fatigue, pain and PaGl fluctuated substantially and unpredictable in individual SpA patients who were considered to be in steady state. A change in these outcome measures of 35 or less (VAS 0-100) may be interpreted to reflect natural variation or measurement error which should be taken into account when managing individual patients in the daily clinic.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies in patients with rheumatic diseases report that negative views of illness are associated with poorer disease outcomes, such as more disability and pain. Little is known about illness perceptions in patients with early axial Spondyloarthritis (axSpA). The aim is to describe illness perceptions and to explore the association with disease activity in patients with early axSpA at baseline.

Methods: The SPACE-cohort includes patients (chronic back pain ≥3 months, ≤2 years, onset <45 years) recruited from 5 participating centers in Europe. Patients completed the Revised Illness Perception Questionnaire (IPQ-R). The illness identity dimension asked patients if they have experienced a certain symptom (15 in total) and if they believed these symptoms are related to axSpA. The other illness perception dimensions (7 dimensions) and causal attributions (5 dimensions) used 5-point Likert scales to score all items ranging from 1 (strongly disagree) to 5 (strongly agree). For the IPQ-R dimensions, see Table 1. Disease activity was assessed by ASDAS (Ankylosing Spondylitis Disease Activity Score, CRP based). Univariable linear regression models were built for each IPQ-R dimension as dependent and ASDAS as independent variable adjusted for age and gender.

Results were stratified when gender was an effect modifier ($p<0.20$). P-values <0.05 were considered to be statistically significant.

Results: Only patients fulfilling the ASAS classification for axSpA (n=162/400) were included. Patients had a mean age of 30.0 (SD 8.0) years and 51.9% were male. The mean disease duration was 13.9 (SD 8.1) months and the mean ASDAS 2.5 (SD 0.9). Patients reported on average 4.3 (SD 2.3) symptoms to be associated with axSpA on average (Table 1). Pain, joint stiffness, fatigue, and sleeping problems were the most reported symptoms according to patients in the illness identity dimension. All other dimensions showed a mean of approximately 3, except psychological attributions, risk factors, immunity, and accident of the causal section, which had a mean of approximately 2. Patients with axSpA attributed their complaints mostly to heredity, chance and bad luck. Three dimensions of the IPQ-R were associated with ASDAS. A higher ASDAS was statistically significantly associated in all patients with stronger beliefs in severe consequences ($\beta=0.26$, $p<0.001$), more negative emotions towards their complaints ($\beta=0.18$, $p=0.027$), and in women with more symptoms attributed to axSpA ($\beta=1.53$, $p<0.001$). There was a trend between a higher ASDAS and less belief in personal control ($\beta=-0.10$, $p=0.082$) and less illness coherence ($\beta=-0.13$, $p=0.083$).

Conclusion: In patients with early axSpA, disease activity is associated with negative illness perceptions, such as attribution of multiple symptoms, believing in severe consequences, and experiencing negative emotions towards axSpA.

Table 1: Baseline characteristics of the Revised Illness Perception Questionnaire (IPQ-R) and linear regression models of ASDAS (CRP-based) and subscales of the IPQ-R at baseline adjusted for age and gender (n=162)

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although remission remains the ultimate treatment goal in psoriatic arthritis (PsA) management, minimal disease activity (MDA), which encompasses remission and low disease activity, constitutes an attainable goal. Given that variability may exist across Canadian provinces both in regard to patient characteristics at anti-TNF initiation and in PsA management in routine clinical practice, the aim of the current analysis was to assess the regional variability in MDA achievement among Canadian patients initiating treatment with anti-TNF in real-world.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for PsA, ankylosing spondylitis, or rheumatoid arthritis with infliximab or golimumab. PsA patients who were enrolled during 2002-2015, had ≥1 follow-up assessment and MDA data available were included. MDA was defined as the fulfillment of ≥5 of the following criteria: TJC28≤1, SJC28≤1, PASI≤1 or BSA≤3, Pain (VAS) ≤15mm, PtGA (VAS) ≤20 mm, HAQ≤0.5, tender entheseal points ≤1. Provinces were regrouped by region: Western (Alberta, British Columbia, and Saskatchewan), Ontario, Quebec and Maritimes. Continuous and categorical variables were assessed with the non-parametric Kruskal-Wallis test and the Chi-square test, respectively.

Results: 223 PsA patients (51.4% male) were included in the analysis. The mean (SD) age was 49.8 (11.1) years, and disease duration was 5.8 (6.6) years. The proportion of patients in BioTRAC by Canadian region was 6.4%, 50.5%, 29.7% and 13.4% for the Western region, Ontario, Quebec and the Maritime region, respectively. The mean (SD) disease duration was significantly different among regions with [Western: 5.00 (5.48), Ontario: 5.76 (6.51), Quebec: 7.47 (7.60), Maritimes: 1.8 (1.9) years; p=0.027]. Baseline disease parameters for TJC, SJC, pain, PtGA, and HAQ-DI were statistically comparable at baseline among Canadian regions. However, significant between-group differences were observed at baseline for mean (SD) enthesitis count [Western: 7.00 (4.21), Ontario: 1.14 (2.90), Quebec: 1.33 (2.14), Maritime: 3.16 (3.88); p<0.001], and PASI [Western: 4.76 (4.98), Ontario: 3.71 (5.51), Quebec: 1.45 (2.94), Maritime: 1.18 (1.32); p=0.001]. At baseline, 6 and 12 months of treatment, 11.7%, 43.5%, and 44.8% of patients achieved MDA, respectively. A statistical trend was observed between regions with respect to MDA achievement at 6 or 12 months of treatment (p=0.127). Ontario and Quebec patients had the highest MDA rates (55.9% and 52.1%), while 44.4% and 18.2% of patients in Maritime and Western provinces presented with MDA, respectively.

Conclusion: MDA achievement rates vary across Canada which could be attributed to differences in the patient profile and in disease duration at anti-TNF initiation.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Concomitant fibromyalgia syndrome (FMS) is a common problem in ankylosing spondylitis (AS) and its recognition is important for optimal management. BASDAI, a disease activity measures for AS has been shown to have poor specificity for AS and was reported to be high in patients with fibromyalgia. Hypothesis guiding our study was that the validated tools of disease activity in AS measure fibromyalgia pain. We studied the association of validated instruments of disease activity in AS with widespread pain index (WPI) and symptom severity score (SS) used in FMS.

Methods: Study was approved by our IRB. We prospectively recruited 62 AS patients ≥18 years of age and meeting the modified New York criteria with grade 3 or 4 sacroiliItis. Demographic and clinical data were collected and stored in Redcap data base. Various questionnaires to assess disease activity and patient reported outcomes in AS were administered to these patients. The frequency of FMS was determined using validated 2010 ACR diagnostic criteria for fibromyalgia. Patient met the fibromyalgia criteria if (i) WPI of ≥ 7 & SS ≥ 5 or WPI 3–6 & SS score ≥ 9,(ii) symptoms were present at a similar level for at least 3 months and (iii) the pain was not attributed to AS by the clinician. ESR and CRP was measured using routine laboratory methods. Descriptive analysis included continuous variables (mean ± SD) and the categorical variables (%). Data were compared by Student's t-test for continuous variables and chi-square for categorical variables. Linear regression analysis was performed to assess the association between BASDAI, BASMI, ASDAS, Rapid 3, ESR, CRP, WPI and SS scores.

Results: 27/62 (43.5%) patients with AS satisfied the ACR diagnostic criteria for fibromyalgia. Patient demographics and clinical characteristics Table 1.The patients with FMS had significantly higher disease activity as compared to patients without FMS (Table 2). There was no significant relationship of BASDAI, RAPID 3, ASDAS-CRP, physician's global and patient global scores, ESR, CRP when tested individually with the WPI and SS scores (Table 3).

Conclusion: Despite 43% prevalence of fibromyalgia in our patients with active AS and high disease activity, the validated tools of disease activity in AS did not measure fibromyalgia related pain and symptom severity.

Table 1- Demographics and Clinical Characteristics of Patients

	Patients who **fulfilled** the ACR Diagnostic Criteria for Fibromyalgia N= 27/62	Patients who **did not fulfill** the ACR Diagnostic Criteria for Fibromyalgia N=35/62	p- value
Mean age in years ± SD	48.9 ± 11.2	48.7 ± 13.2	0.94
% African-Americans	63.16	36.84	0.02

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Posttraumatic stress disorder (PTSD) has a prevalence of 11.5% in the outpatient setting and is associated with increased risk for multiple comorbid psychiatric and medical conditions. Studies have demonstrated an increased risk of incident RA in cohorts with PTSD, as well as increased pain scores in those with both RA and PTSD. We sought to examine variation in patient characteristics, medication use, pain level, and disease activity among Veterans with ankylosing spondylitis (AS) by PTSD status in a Veterans Affairs (VA) outpatient rheumatology clinic.

Methods: Veterans who had one or more visits at an outpatient rheumatology clinic at a single VA site between 1/1/14 and 12/31/15 were identified for inclusion by the presence of an ICD-9 or ICD-10 code for AS. Diagnosis of AS was confirmed by review of documentation by their primary rheumatologist. Chart review was conducted to collect information on PTSD by chart diagnosis, age, gender, race, pain score, medication use (including NSAIDs, synthetic DMARDs, biologics, and opiates), and disease activity measured using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) when documented by the clinician. Characteristics were compared by PTSD status using t-tests for continuous variables and Fischer's exact test for categorical variables.

Results: Of 136 Veterans with ICD-9 or ICD-10 codes for AS, 113 had a rheumatologist diagnosis for AS and were included in the study. Of 113 Veterans, 20 (18%) had a diagnosis of PTSD. Those with PTSD were significantly younger, with a mean age of 52 ± 17 years as compared to those without PTSD, who had a mean age of 59 ± 14 years (p=0.04); both populations were mostly male and white. BASDAI was recorded for 30% with a mean score of 4.3 ± 2.0 indicating suboptimal control of disease. Those with PTSD had higher mean pain (see Table) and BASDAI scores as compared to those without PTSD, with a difference approaching statistical significance (p=0.06 for both comparisons). Prescribed medications were similar for both groups in regards to synthetic DMARDs, biologics, and opioids, although those with PTSD were significantly more likely to receive NSAIDs (p=0.03).

Conclusion: Veterans with AS and concomitant PTSD are younger and have higher reported pain and disease activity scores compared to those without PTSD in this single site study. The documentation of disease activity by validated instruments such as the BASDAI is recommended in the 2015 Treat to Target guidelines for AS, as higher disease activity is associated with increased mortality. This study underscores the importance of identifying PTSD in patients with AS who report higher pain and disease activity. Future research should include identifying and treating concomitant mental health disorders in Veterans with AS, as other studies have shown improvement in chronic pain with treatment of PTSD.

Table. Characteristics of 113 Veterans with Ankylosing Spondylitis by PTSD diagnosis

Characteristic	Total (n=113) Mean ± SD or (%)	PTSD (n=20) Mean ± SD or (%)	No PTSD (n=93) Mean ± SD or (%)	p-value*

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : Psoriatic arthritis(PsA) often affects patients at a childbearing age. The relationship between pregnancy and PsA, in terms of pregnancy outcomes and its effect on disease activity, has not been well studied. The aim of this study is to evaluate the effect of pregnancy on disease activity in PsA

Methods: A retrospective review of files of female patients followed at the Psoriatic arthritis clinic at the Tel Aviv Medical center was performed and patients with at least 1 pregnancy during follow up and one visit during or soon after pregnancy were included in this descriptive study. A thorough review of the files was performed which included the following data: age, disease duration, pattern of PsA, disease activity before during and after pregnancy, record of treatment, including IA injections before and during pregnancy. Postpartum period was defined as up to 1 year after pregnancy. PsA as well as psoriasis activity was defined by treating physician as follow: no disease activity (no active synovitis), mild disease (up to 1 joint involved), moderate to severe disease (more than 2 joints involved). Accordingly, the follow up during and after pregnancy was classified as: improvement, worsening or stable

Results: 13 PsA women and 20 pregnancies were identified. 19 resulted in live healthy babies. The mean age at pregnancy was 31.6 years. Table 1 summarizes the status of disease activity before, throughout pregnancy and during the postpartum period in the whole group. No significant change in disease activity was noticed throughout pregnancy while a significant proportion of patients flared at postpartum Before 12 pregnancies, the patients were treated with TNF α blockers. In 10, the biologic treatment was discontinued close to pregnancy or during the first trimester. In this group, 4 (40%) of patients were classified as mild to severe activity prior to pregnancy. This number increased up to 6 (60%), 7 (70%) and 10 (100%) during the 1st, 2nd trimester and postpartum period respectively. In the 2 patients in whom biologics were not stopped pregnancy, no change in the degree of disease activity was noticed. Interestingly, in the group of non-TNFα treated patients, an improvement in disease activity was observed – the proportion of patients with mild to severe disease activity decreased from 100% close to pregnancy to 71% in the 1st and 2nd trimester and 43% in the 2rd one while an increase to 86% was observed after pregnancy. During 5 pregnancies, corticosteroids were initiated or dosage increased - all in pregnancies where TNF α blockers were stopped before pregnancy. Table 1. Disease activity during pregnancy

No (%)	Before pregnancy	Trimester			Post partum
		1st	2nd	3rd	
No disease activity	7 (37%)	6 (32%)	6 (32%)	8 (42%)	2 (10%)
Mild dis. Activity	4 (21%)	5 (26%)	5 (26%)	5 (26%)	6 (32%)
Moderate to severe dis. Activity	8 (42%)	8 (42%)	8 (42%)	4 (21%)	11 (58%)

Conclusion: Patients with PsA definitively flare after pregnancy. Our results suggest that stopping treatment with TNF α blockers before pregnancy is associated with flare during pregnancy and the postpartum period. It seems that in terms of PsA disease activity, it is recommended to continue treatment with TNF α blockers throughout pregnancy

Subclinical Ungueal Distrophy in Patients with Psoriasis without Joint Involvement:

Is There Any Role for Nail Ultrasound?

Barbara Nascimento de Carvalho Klemz[1], Karine Luz[2], Eugenia Maria Damasio Ohe[3], Adriana Maria Porro[4], Polianna de Oliveira Matos Soares[5], Helder Henrique da Costa Pinheiro[6] and Marcelo Pinheiro[7], [1]Rheumatology Division, Federal University of Sao Paulo (Unifesp/ EPM), Sao Paulo, Brazil, [2]Rheumatology Division, Universidade Federal de São Paulo, São Paulo, Brazil, [3]Dermatology Division, Federal University of Sao Paulo, (UNIFESP/EPM), Sao Paulo, Brazil, [4]Dermatology Division, Federal University of Sao Paulo (UNIFESP/EPM), Sao Paulo, Brazil, [5]Federal University of Sao Paulo (UNIFESP/EPM), Sao Paulo, Brazil, [6]Federal University of Para (UFPA), Belem, Brazil, [7]Federal University of São Paulo, São Paulo, Brazil

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The joint involvement is observed in approximately 30% of patients with psoriasis (Ps). However, no clinical, lab or by imaging strategy is well established to identify them before progression to psoriatic arthritis (PsA). Purpose: To assess the association among the nail involvement and distal interphalangeal extensor enthesopathy (DIP-ExE), evaluated by ultrasound (US), with the subclinical joint involvement, including arthritis, enthesitis and dactylitis in patients with Ps.

Methods: A total of 89 patients with active Ps were included in this cross-sectional study and were compared with 21 healthy controls, paired for sex, age and ethnicity. After evaluation by a dermatologist, including the PASE and the PEST questionnaires, as well as PASI, BSA and NAPSI, the patients were classified in two groups, according to clinical nail involvement (CNI). Moreover, they were also evaluated by a rheumatologist, regarding enthesitis, dactylitis, axial complaints and peripheral arthritis, in order to apply the CASPAR criteria (2006). A third-blind physician performed a global and complete US evaluation, including 1246 enthesis, synovial thickness in 1958 joints, 1 active skin lesion and 2 bed-nails, according to OMERACT (2010), using the MyLab60® (Esaote, Italy). $P<0.05$ was set as statistically significant.

Results: There was no significant difference concerning time of disease, comorbidities, life habits and PASE in patients with CNI when compared to those no nail distrophy. However, patients with CNI (67.4%) had higher number of tender and swollen joints. The presence of nail power-Doppler (N-PwD) and the DIP-ExE was observed in 65-70% of patients with CNI ($p=0.035$). The nail US identified 58.6% of subclinical nail dystrophy and 70.6% had also positive N-PwD ($p<0.001$).

Conclusion: Our results showed that the nail US was able to identify subclinical nail dystrophy and DIP-ExE in almost 60% of patients with active Ps, but no nail or joint clinical involvement, suggesting that it could be used for early screening of patients with increased risk of developing PsA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Femoroacetabular impingement (FAI) is characterized by early pathologic contact of the proximal femur with the acetabulum. Pincer impingement is the acetabular cause of FAI.Whereas cam deformity seen as a flattening of the anterior contour of the head/neck junction or an osseous hump leading a decreased femoral head/neck offset. Patient with FAI presents with a hip or a trochanteric pain usually in the sitting position or during or after activity. It might also be an important cause of hip osteoarthritis (OA). Therefore in this study we evaluated the frequency of cam-type FAI in axial spondyloarthritis (axSpA) patients as a potential alternative cause of hip or trochanteric pain.

Methods: A total 180 patients (107 [59%] male, mean age 41.9 ± 12.8 years) with axSpA according to ASAS criteria and 198 patients (120 [61%] male, mean age 40.5 ± 14.8 years) admitted to the emergency department (mostly due to trauma) and who had pelvic X-ray were included in the study.Patients with hip OA, hip prosthesis, acetabular protrusion or who have radiographs taken improper technique were excluded. An experienced radiologist assessed all anteroposterior pelvic radiographs.

Results: The axSpA group consists 135 ankylosing spondylitis and 45 non-radiographic axSpA patients. The mean duration of symptoms was 13.8 ± 11.3 years in axSpA patients. Radiographic findings of cam abnormality (figure) were significantly more frequent in axSpA patients in comparison with control subjects (30/150 [20%] vs 17/193 [9%] and *P*=0.004). Cam-type radiographic abnormality was only present 2 female control subjects and none of female axSpA patients. FAI was significantly correlated with the presence of HLA-B27 (r=0.213 and *P*=0.048), smoking (r=0.194 and *P*=0.018), height (r=0.283 and *P*=0.001) and gender (r=0.443 and *P*<0.001).

Conclusion: This study for the first time showed that radiographic findings compatible with cam-type FAI were frequent in axSpA patients. In addition to repetitive injury to the proximal femoral physis, new bone formation may be responsible for increased FAI in axSpA. In axSpA patients with hip or trochanteric pain, FAI may be kept in mind as an alternative explanation of the symptoms.

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient reported outcomes (PROs) have been found to be reliable indicators of baseline status, change during treatment, and are predictive of long-term outcome. A EULAR taskforce developed the PsAID questionnaire as an impact measure of psoriatic arthritis (PsA) for use in clinical trials (PsAID9) and routine practice (PsAID12). We set out to validate the PsAID in an independent prospective cohort.

Methods: Data were collected prospectively for a single-centre cohort of PsA patients between July 2015 and January 2016. Clinical

measures and PROs including the PsAID were completed at baseline and the PsAID was repeated at 1 week. The primary objective was to assess the reliability of the PsAID in stable patients with PsA. Construct validity was assessed through correlation of the PsAID with other PROs including HAQ-DI, EuroQol (EQ-5D), Psoriatic Arthritis Quality of Life questionnaire (PsAQoL), Dermatology Life Quality Index (DLQI), visual analogue scale (VAS) scores for patient global assessment (PtGA), and joint global assessment (JtGA), as well as clinical measures. The influence of sex and disease activity as measured by the modified Composite Psoriatic Disease Activity Index (mCPDAI) was also assessed.

Results: Seventy-six patients (37 males) were recruited to the study. The median age was 56 years (IQR 14.25); 57 patients were treated with biologics, and 13 with conventional DMARDs. The median tender joint count was 2 (IQR 7), median swollen joint count was 0 (IQR 2) and median mCPDAI was 2 (IQR 2). Mean (SD) baseline PsAID12 score was 3.11 (2.29) and at 1 week was 3.06 (2.33). Intraclass correlation coefficient (ICC) was 0.93 (95% CI 0.88-0.96). Mean baseline PsAID9 score was 3.30 (2.38) and at 1 week was 3.22 (2.41) and ICC was 0.93 (95% CI 0.88-0.96). There was a weak floor effect with 37% of scores ≤2 and 8% of scores >7. The PsAID correlated strongly with most PROs (Table 1). There was a significant difference between sexes, with a mean PsAID12 in males of 1.97 (2.12) and in females 4.03 (2.01). When individual components of the PsAID12 were analysed females scored significantly higher in 9 of the 12 items. The correlation between the PsAID12, other PROs and clinical measures was stronger in males than females (Table 1). Out of the patients that fulfilled MDA criteria, only 1 patient had a PSAID12 score >4, the threshold for the patient acceptable symptom state (PASS).

Conclusion: In this cohort, the PsAID questionnaire had excellent test-retest reliability. There was a weak floor effect, likely related to the low disease activity of the cohort as measured by the mCPDAI. There was strong to moderate correlation with clinical and PRO measures providing evidence for the construct validity of the PsAID in this cohort, however females scored significantly higher than males with overall weaker correlation. Prospective data collection is underway to assess sensitivity to change.

TABLE 1: Comparison of the PsAID with PROs and clinical measures (Spearman correlation coefficient)

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Enthesitis, dactylitis and nail involvement are part of the core set of domains to be reported in trials of PsA. However, no specific instruments for these domains are recommended in the core set and cutoffs for reporting (ie how to report state or improvement) are also unclear. We aimed to obtain an overview of the instruments and the respective cutoffs used to report state or improvement, for enthesitis, dactylitis and nail involvement in recent randomised controlled trials (RCTs) in PsA.

Methods: A systematic literature review of RCTs on any pharmacological intervention in patients with PsA was conducted, by searching Medline, Embase and Cochrane datasets for the period 2010-2015 (1). Only published papers and only results of the placebo-controlled phases were analysed. The presence and type of all outcome measures reflecting enthesitis, dactylitis and nail involvement were collected. Cutoffs used for each measure (either as state or change, absolute or relative) were also collected. Analyses were descriptive.

Results: Of 2,278 articles screened, 14 trials met the inclusion criteria: 4 (29%) reported on non-biologic drugs (included targeted synthetic DMARDs, 1 trial), 5 (36%) on anti-TNF, 4 (29%) on other biologic modes of action and there was one strategy trial. The trials included a total of 4,744 patients. Five of the trials (36%) did not report any outcome on any of the 3 domains of interest (Table). Enthesitis and dactylitis outcomes were reported in the remaining 9 trials (64%), while nail involvement was only reported in 3 trials (21%). These three outcomes have been measured in several different ways, none of which having been used in more than 3 trials (21%), and the majority of them was actually employed in only 1 (7%) or 2 (14%) trials (table). Table - Outcome measures used in 14 recent trials in PsA

Extra-articular manifestation	Outcome measure	Level of measurement	N (%)
Any	No extra-articular manifestation reported		5 (36%)
Enthesitis	Absolute change in enthesitis score	Change (mean) in Leeds enthesitis index	2 (14%)
		Change (mean) in MASES	1 (7%)
		Change (median) in tenderness at entheses (comprising the MASES, LEI and tenderness at the plantar fascia)	1 (7%)
	Relative change (%) in enthesitis score	% change in MASES	2 (14%)
	Proportion of patients with enthesitis		2 (14%)
	Proportion of patients with change	% of patients with improvement in ≥1 tendon/ligament	1 (7%)
	Resolution of enthesitis	MASES=0	1 (7%)
		Enthesitis score=0 (range 0-4)	2 (14%)
Dactylitis	Absolute change in dactylitis score	Change (mean) in Dactylitis severity score (0-20)	2 (14%)
		Change (median) in Leeds dactylitis index	1 (7%)
		Change (mean) in Leeds dactylitis index	1 (7%)
	Relative change (%) in dactylitis score	% change in a 0-60 score	3 (21%)
	Proportion of patients with dactylitis		2 (14%)
	Resolution of dactylitis	Dactylitis score=0 (range 0-20)	3 (21%)
Nail involvement	Absolute change in score of nail involvement	Change (mean) in modified Nail Psoriasis Severity Index	2 (14%)
		Change (median) in modified Nail Psoriasis Severity Index	1 (7%)

Conclusion: There is substantial heterogeneity in the measurement of enthesitis, dactylitis and nail involvement in recent clinical trials of PsA. This heterogeneity relates to both the instruments used and the evaluation and interpretation of the results. Harmonization of measures to be used in trials and possibly also practive is desirable to allow for optimal assessment and better comparability of the efficacy of interventions. **References** (1) Ramiro et al, Ann Rheum Dis 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have shown associations between swelling or tenderness of specific joints in RA patients and patient pain. This analysis aimed to describe the impact of enthesitis count and enthesitis profile on functional status (HAQ) and patient global assessment of disease activity (PtGA) among SpA patients treated with anti-TNFs under Canadian routine clinical care.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment with infliximab (IFX) or golimumab (GLM) for RA, AS, or PsA, or with ustekinumab (UST) for PsA. In this analysis, AS and PsA patients treated with IFX between 2005-2016 or GLM between 2010-2016, and PsA patients treated with UST between 2014-2016, were included. Based on enthesitis location 8 groups were created: suprapsinatus, medial epicondyle humerus, lateral epinondyle humerus, greater trochanter, quadriceps patella, achilles, plantar fascia, and patellar-tibia. The impact of specific entheseal points on HAQ, PtGA, and pain (only for PsA) was assessed with the independent-samples t-test; general linear models were used to assess the relative impact of each location on these outcomes.

Results: A total of 503 AS patients and 330 PsA patients with 1669 and 1126 assessments, respectively, were included. At baseline, mean (SD) age was 45.4 (13.0) and 51.0 (12.3) years for AS and PsA patients, respectively, and disease duration was 6.6 (9.6) and 5.4 (7.1) years. In terms of disease activity, mean (SD) ASDAS and BASDAI were 3.5 (1.0) and 6.1 (2.2), respectively, whereas, among PsA patients, DAS28 was 4.3 (1.4). Overall, a weak correlation ($r<0.4$) was observed between enthesitis count and HAQ, PtGA and pain in both AS and PsA patients. Presence of enthesitis at all sites, however, was associated with significantly ($P<0.05$) higher HAQ and PtGA irrespective of SpA type. Upon adjusting for age and gender, among AS patients, enthesitis at supraspinatus, greater trochanter, and achilles were the main predictors of higher HAQ and PtGA whereas enthesitis at plantar fascia was associated with higher HAQ only. Among PsA patients, medial or lateral epicondyle humerus and greater trochanter were the main predictors of increased HAQ and PtGA, while patellar/tibia was associated with significantly HAQ only.

Conclusion: Although enthesitis at all sites was associated with significantly higher HAQ and PtGA, individual sites were differentially associated with these outcomes. In AS, supraspinatus, greater trochanter, and achilles were identified as the main predictors of poor patient outcomes, while, among PsA patients, medial/lateral epicondyle humerus and greater trochanter were the most important sites. These results suggest that, in addition to the presence of enthesitis, location of enthesitis may have an impact on patient reported outcomes.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Several questionnaires have been developed to help identify psoriatic arthritis (PsA) among patients with psoriasis (PsO), but there is no screening tool yet tested through joint efforts by Dermatologists and Rheumatologists in Korea. The PsO Epidemiology Screening Test (PEST) is a simple self-administered questionnaire which has been validated in western countries. Our study aimed to investigate the utility and validation of PEST for screening PsA in Korean PsO patients.

Methods: The PEST, consisted of 5 questions, was translated into Korean and then back-translated to English for comparison. This form was tested on PsO patients visiting the Dermatology clinic at 5 hospitals in urban areas. Patients who checked ‘yes' to 2 or more questions were referred to Rheumatology for further evaluation. Patients meeting the classification criteria for psoriatic arthritis (CASPAR) criteria were confirmed to have PsA.

Results: A total of 191 PsO patients from 5 centers were enrolled. The mean age was 45.1 years, and male/female ratio was 1.27. Of these, 150 patients checked ‘yes’ to 0 or 1 question of PEST questionnaire. Among the 41 patients with PEST $\geq$ 2, 35 patients were eventually assessed by a Rheumatologist. Of these subjects, 17 (48.6%) patients were finally diagnosed as PsA. Compared with PsO only patients, PsA patients had higher rate of female and lower rate of phototherapy history, although statistically insignificant. When comparing the characteristics between PsA and non-PsA among the patients assessed by rheumatologist, patients with PsA showed higher patient’s global assessment, physician’s global assessment, and Routine Assessments of Patient Index Data 3 (RAPID3) score than those without PsA. Six patients of the 17 PsA patients (35.3%) had radiographic evidence of sacroilitis. Among PsA patients, the proportion of patients with PEST score of 2 was 47% (8/17). The overall specificity of PEST at a cut-point of 2 was 89.3%. Using the known PEST cut-off score of 3, its specificity increased to 94.0%, but sensitivity dropped to 52.9%.

Conclusion: This study supports that the Korean version of PEST is a convenient tool for screening PsA, and the PEST score of 2 points would be a favorable cut-off value for screening Korean PsO patients. However, its performance and utility in our region need to be further investigated.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: For the axial spondyloarthritis (SpA) population, early recognition is crucial in preventing major morbidity. Despite this, there exists an unacceptably long delay between the onset of symptoms and diagnosis, with an average wait time of 8 years between the commencement of back pain and time when patients are diagnosed by a rheumatologist. Compounding this issue is the uncertainty that exists with respect to initial screening and referral practices amongst primary care practitioners for adults with suspected axial SpA. The purpose of this study was to explore the screening and referral practices for suspected axial SpA in adults with chronic back pain amongst primary care physicians (PCPs), physiotherapists (PTs), chiropractors (DCs) and nurse practitioners (NPs) working in community practice in the province of Ontario, Canada.

Methods: Semi-structured key informant (KI) interviews were conducted with PCPs, PTs, DCs and NPs working in community practice. Interviews were conducted with KIs to address: 1) screening practices for axial SpA; and 2) referral practices for adults with suspected axial SpA. Interviews were conducted in-person or over the telephone. All interviews were recorded and transcribed verbatim. Interview transcripts were analyzed using a compare and contrast analysis by coding groups of words that addressed the research objectives. Two members of the research team undertook this exercise independent of each other and then met to reconcile an understanding of emergent themes. Groups of words with similar meaning were organized into themes. The themes were organized into two main categories: Screening Practices and Referral Practices. NVIVO V9 was used to assist with organization of codes.

Results: A total of 17 interviews were conducted: PCPs (5); PTs (3); DCs (6) and NPs (3). Practice locations for KIs were primarily urban (14 urban; 3 rural). Mean years of practice of key informants was 9.3 years (range, 1-22 years). Overall, 3 themes were identified related to Screening Practices for axial SpA: 1) knowledge of clinical manifestations of axial SpA; 2) role of investigations in early diagnosis, and 3) lack of awareness of assessment guidelines and screening tools. Themes related to Referral Practices included: 1) optimization of technology; 2) referral barriers, and 3) legislative hurdles.

Conclusion: Most primary care practitioners had a general understanding of the clinical manifestations of axial SpA; however, knowledge deficits existed related to rare clinical presentations and the role of investigations in early identification of the disease. With respect to referral practices, there are opportunities to address system-level barriers, including more extensive use of technology (e.g. use of online consultations and electronic referral templates). Our research has identified a number of opportunities for implementation of quality improvement initiatives and indication for collaboration with policy makers and other stakeholders, including patients. These results may be incorporated into a wider research initiative to gain better insight into primary care screening and referral practices for

adults with suspected axial SpA.

Session Type: ACR Poster Session C

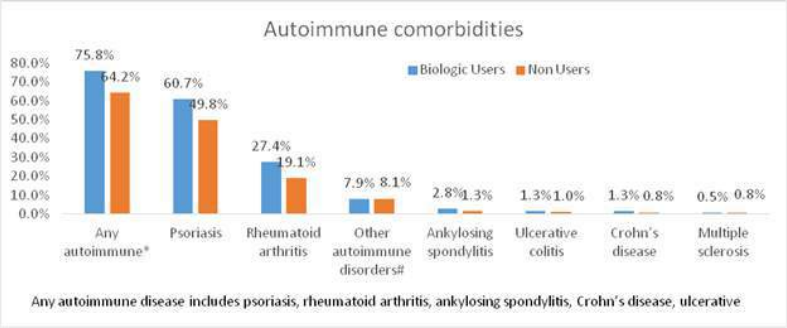
Session Time: 9:00AM-11:00AM

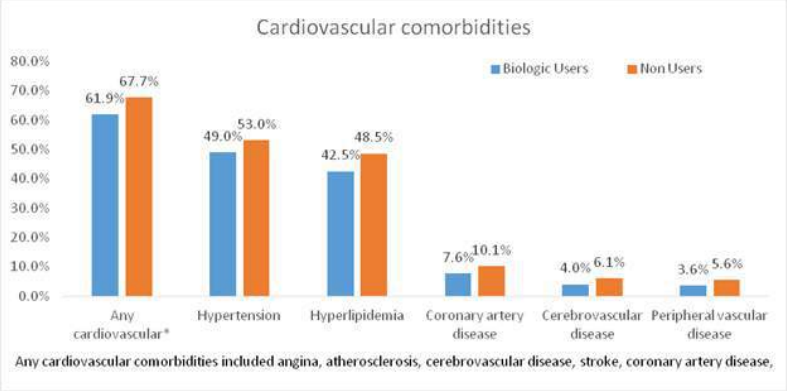
-

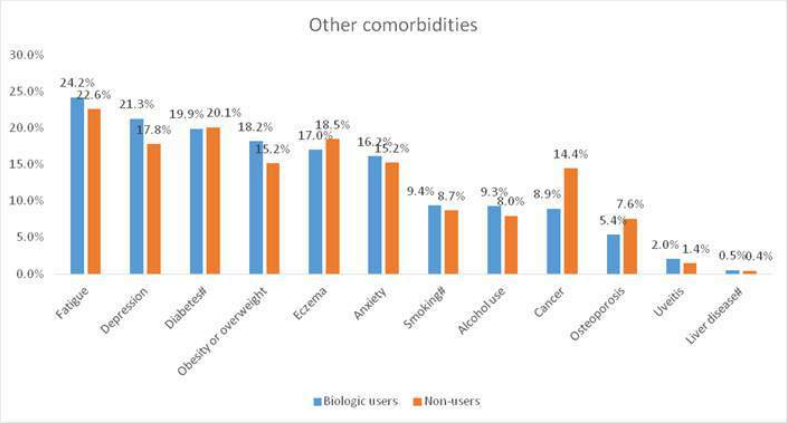
Background/Purpose: Psoriatic Arthritis (PsA) are known to be at higher risk for numerous comorbid conditions. This study looks at the impact of biologic therapy by comparing comorbidities between PsA patients who have biologic therapy versus those who do not, using a large national claims database in the US.

Methods: Adults with ≥1 inpatient or 2 outpatient diagnoses of PsA (ICD-9-CM 696.0) in 1/1/2008 - 9/30/2015 were extracted from the MarketScan Commercial and Medicare Databases. Biologic users had ≥1 biologic claim on or after the first observed PsA diagnosis, and the index date was the first biologic claim date. Non-biologic users had no biologic claim anytime during the study period. Their index date was randomly assigned based on the distribution of the index dates of biologic users. All patients were required to have ≥12 months continuous enrollment prior to index date and were followed for ≥12 months until the earliest of inpatient death, end of continuous enrollment, or end of the data. The prevalence of comorbidities during the follow-up period was examined.

Results: A total of 9,369 biologic users and 11,774 non-users met the study criteria (mean age: 49.8 years for users vs. 55.1 for non-users; male: 45.8% vs. 43.8%; mean length of follow up: 3.0 vs. 3.0 years; mean Charlson comorbidity index: 0.6 vs. 0.8). Compared with non-users, biologic users had significantly higher rates of autoimmune disease, fatigue, depression, obesity or overweight, anxiety, alcohol use, and uveitis, but significantly lower rates of cardiovascular disease, eczema, cancer, and osteoporosis (Figure 1, $p<0.05$ in all cases). Figure 1. Prevalence Rates of Comorbidities in PsA Patients, by Biologic Therapy







not significant (p>0.05).

Conclusion: PsA patients treated with biologics had higher rates of certain comorbidities, such as autoimmune diseases, fatigue, depression, obesity/overweight, and uveitis than those not on biologic therapy and lower rates of cardiovascular conditions, eczema, cancer, and osteoporosis. These results suggest use of biologics have an association with rates of certain comorbidities. Further studies looking at this topic could have an impact in treatment practice.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease Activity index for Psoriatic Arthritis (DAPSA) originally developed from patients with reactive arthritis and validated in psoriatic arthritis (PsA) patients. DAPSA includes swollen joint count (SJC) (66 joint), tender joint count (TJC) (68 joint), CRP (mg/dl), patient global assessment and pain. Although, assessment of 66/68 joints give more information, 28 joint assessment is more feasible, and frequently used in rheumatoid arthritis trials. Objective of this study was to assess correlation of DAPSA 28 joints with DAPSA 66/68 joints in a multicenter PsA registry.

Methods: PsART (Psoriatic Arthritis Registry of Turkey) is a national, web-based registry, including 1081 PsA patients. Overall, 601 patients had complete information about DAPSA score. All affected joints were recorded separately. Original DAPSA calculated to sum of CRP (mg/dl), pain VAS (cm), patient's global assessment of disease activity VAS (cm), SJC (66 joints), and TJC (68 joints). We calculated both 28 TJC/SJC (called DAPSA-28) and 66/68 joints for DAPSA. Spearman correlation was used for statistical analysis.

Results: 396 of 601 (65.9%) were female, mean age was 46.5 (12.6) years, mean PsA duration was 5.4 (6.6) years. Mean DAPSA 66/68 score was 14.5 (13.3) and DAPSA 28 score was 12.9 (9.7). Correlation of DAPSA 66/68 and DAPSA 28 was 0.97. Correlation of SJC 28 and SJC 66 was 0.83 and correlation of TJC 28 and TJC 68 was 0.88. Correlation of TJC 28 and 68 were shown in figure 1. 374 of 601 (62.2%) patients at least one active joint according to 66/68 joint assessment. When we consider those group, correlation coefficients were slightly unfavorable in TJC and SJC (SJC 28 vs 66 r=0.78, TJC 28 vs TJC 68 r=0.78), however almost identical in their DAPSA scores (DAPSA 28 vs DAPSA 66/68 r=0.94). Patients with swollen MTF, ankle and DIF joints were 41 (6.8%), 67 (11.1%), and 60 (10.0%), respectively. By doing a 28 joint count, 47 (7.8%) were missed compared to 66/68 joint count due to the DIP, MTF and ankles being the only site of arthritis.

Conclusion: DAPSA domains are almost universal for all kind of inflammatory arthritis. Simple sum of those domains seem valid and feasible in PsA patients. Although assessment of 66/68 joints is rationalized particularly for patients with distal interphalangeal and foot arthritis, our study showed that there was no added value of using 66/68 joints in the real life setting. On the other hand, almost 8% of patients did not capture when assess only 28 joints.

Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The presence of comorbidities in patients with rheumatic diseases affects functional capacity and quality of life, but also they can limit the therapeutic approach of the disease. Our purpose was to analyze the frequency of comorbidities in patients with Axial Spondyloarthritis (axSpA) and to assess their influence on different aspects of the disease.

Methods: Patients ≥18 years old diagnosed with axSpA (mNY 1987 and/or ASAS 2009 criteria) belonging to ESPAXIA (Estudio de Espondiloartritis Axial IREP Argentina) cohort were included. Demographic data, disease duration, and current treatment were collected. Pain, patient global assessment (VAS), disease activity (BASDAI), functional capacity (BASFI), enthesitis (MASES), axial mobility (BASMI), quality of life (ASQoL) and radiological damage (mSASSS) were assessed. The presence of comorbidities was evaluated and the Charlson comorbidity index was calculated.

Results: 204 patients were included, 74% were male, median age 46 years (IQR 35-57) and median disease duration 19 years (IQR 9-29). Seventy-three patients (35.8%) had at least one comorbidity, being the most common: cardiovascular (40.7%), gastrointestinal (38.7%), endocrine (16.2%), hepatobiliary (11.3%) and respiratory disease (9.3%). Patients with comorbidities were significantly older (56.9±13.6 yrs vs 41.4±12.1 yrs p= 0.0001) and had longer disease duration (26.9±14.4 yrs vs 16.8±11.2 yrs, p= 0.0001). After adjusting for these confounders, patients with comorbidities had worse functional capacity (mean BASFI 4.8± 2.9 vs 3.3± 2.8, p = 0.0001), lower quality of life (mean ASQoL 7.4±5.6 vs 5.8± 5.1, p= 0.02) and higher radiological damage (mean mSASSS 40.4±25.2 vs 20.4±21.7, p = 0.001). In multiple regression analysis, the presence of comorbidities remained significantly associated with worse functional capacity and quality of life. When we divide patients according to the number of comorbidities; 49 (24%) had one comorbidity, 18 (8.8%) two comorbidities and 6 (2.9%) three or more comorbidities, however, the number of comorbidities did not modify our findings.

Conclusion: 35.8% of patients with axSpA presented comorbidities and that was associated with worse functional capacity, poor quality of life and greater radiographic damage, regardless of the number of comorbidities present.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-TNFi agents are effective in the treatment of active AS. Based on the available data, nearly 20% of the AS patients needed to switch their anti-TNF medications to another TNFi agent because of the lack of efficacy (LOE). The reasons underlying the LOE is still remain largely unexplained. Herein we have investigated the characteristics of AS patients who have primary and secondary LOE to TNFi.

Methods: Adult AS patients registered in the axial SpA database who received TNFi treatments were identified. Based on the response to TNFi treatments, these patients were then classified into three groups: primary LOE, secondary LOE and responders. Patients were defined as primary LOE if the first TNFi was stopped within 6 months after start and secondary LOE if the first TNFi was discontinued after a 6-month period. On the other hand, patients who responded to their first TNFi for > 12 mos and currently on same TNFi at the time of last visit were defined as responders. Clinical, demographic and laboratory data were collected and analyzed.

Results: There were a total of 221 patients stratified as follows: primary LOE=51, secondary LOE=83 and responders=87. The mean age and disease duration of the study group patients were 37.4±12.4 and 14.8±10.4 years respectively. 72.4% of the total group was male and B27 positivity was 77.8%. The mean follow-up duration of the responders was 53.4±35.4 months. Comparison of three groups showed that age and disease duration were significantly lower in the primary LOE group compared to secondary LOE ($p<0.05$; 41.9±12.1 vs. 34.7±12.1 and 17±12.3 vs. 12.8±8.9 respectively). Among the clinical variables, the arthritis frequency was significantly lower in the responders group compared to both primary and secondary LOE patients ($p<0.05$; 42.5% vs. 60.8 and 72.3 respectively). The other variables including sex, B27 status, baseline BASDAI, BASFI and CRP, frequency of hip involvement, iritis, enthesitis, dactylitis, psoriasis, IBD and family history of SpA did not differ between the groups. Table 1 represents the characteristics of the three groups. Regression analysis showed that the predictors for primary LOE were increased age and presence of arthritis ($p<0.05$; OR=1.1 and 2.3 respectively). On the other hand negative B27 and arthritis were the predictors for the secondary LOE ($p<0.05$; OR=2.4 and 4 respectively). When we considered TNFi failures collectively the predictors for the non-response found to be the negative B27 and presence of arthritis ($p<0.05$; OR=2.1 and 3.3 respectively).

Conclusion: The results of our study from a longitudinal observational cohort of axial SpA patients indicates that only 39.4% (87/221) of the AS patients were considered sustained responders to TNFi. Our analysis suggests that the most important predictors for lack of response in AS patients were a negative B27 and presence of arthritis. **Table 1:**Clinical and demographical characteristics of the study group

	Primary LOE (n=51)	Secondary LOE (n=83)	Responders (n=87)	p value

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In Rheumatoid Arthritis it has been observed a significant discrepancy in the global assessment of the disease by the patient and physician and this was not extensively evaluated in patients with Psoriatic Arthritis (PsA). The purpose of our study was to evaluate the agreement and the variables that influence global disease assessment by the patient (PGA) and physician (PhGA) in patients with PsA

Methods: Patients with PsA according to CASPAR criteria ≥ 18 years, belonging to RAPSODIA (Registro de Artritis Psoriática IREP, Argentina) cohort were included. Demographic data, clinical features and treatment received were recorded. Peripheral joint assessment was performed by counting 66/68 swollen/tender joints and the following indexes were calculated DAS28, DAPSA, CPDAI and MDA. Cutaneous involvement was evaluated by PASI. Morning stiffness, pain and global assessment of disease activity by the patient and physician were assessed using visual analogue scale (VAS 0-10cm). Patients completed BASDAI, HAQ, BASFI, ASQoL and PsAQoL questionnaires.

Results: 110 patients were included, 56 males (50.9%), with a median age of 55 years (IQR 45-63) and median disease duration of 10 years (IQR 6-17). Pain *m* 5 cm (IQR 2.6-7), PGA *m* 4.25 cm (IQR 2.13-7) and PhGA *m* 3 cm (IQR 1.13-5). The PGA had very good correlation with pain (Rho= 0.76), BASFI (Rho= 0.7) and BASDAI (Rho= 0.7) and acceptable with PsAQoL (Rho= 0.56), and had no correlation with the number of swollen and tender joints (Rho: 0.04 and 0.05, respectively). By contrast, the PhGA had a good correlation with pain (Rho= 0.65), BASDAI (Rho= 0.62) and PGA (Rho= 0.64), acceptable with BASFI (Rho= 0.59), number of swollen joints (Rho= 0.52), number of tender joints (Rho: 0.41) and PsAQoL (Rho= 0.43) and low correlation with PASI (Rho= 0.21). In two multiple linear regression analysis, using PhGA and PGA as dependent variables, pain was the main variable that was significantly associated with both of them (βcoef: 0.529, $p<0.001$ and βcoef: 0.481, $p= 0.002$, respectively). Taking Minimal Disease Activity (MDA) as a measure of ideal state, we performed a logistic regression analysis, considering MDA as a dependent variable. PGA had a greater association as compared to the physician's global assessment [OR: 0.61 (95%CI: 0.42-0.89), $p= 0.01$ vs 0.49 (95%CI: 0.29-0.87), $p= 0.02$]

Conclusion: The evaluation of the global assessment of disease activity in PsA by the patient and physician showed good correlation. Pain was the variable most strongly influenced both assessments. The evaluation of the disease by the patient had more association with MDA.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Ankylosing Spondylitis Registry of Ireland (ASRI) was established in 2013. The objectives of ASRI are to provide descriptive epidemiological data on the axial spondyloarthropathy (axSpA) population in Ireland and to establish a registry for potential future studies of genetics, aetiology and therapeutics. Extra-articular manifestations (EAM), comprising uveitis, psoriasis and inflammatory bowel disease (IBD), commonly occur in axSpA and contribute to the burden of disease. They may also impact choice of treatment. Knowledge regarding the characteristics associated with EAM is limited. The aim of this study is to evaluate the prevalence of EAM in a well characterised axSpA patient cohort, in particular identifying differences in early versus late disease and associated characteristics.

Methods: A standardised detailed clinical assessment is performed on each patient and entered in a database. Disease activity is assessed by Bath AS Disease Activity Index (BASDAI), spinal mobility by Bath AS Metrology Index (BASMI), function by the Bath AS Functional Index (BASFI) and Health Assessment Questionnaire (HAQ) and quality of life by AS Quality of Life (ASQoL). Structured interviews provide patient-reported data, which include the presence of EAM. Statistical analysis is performed using SPSS.

Results: As of June 2016, 564 patients have been entered into the database: 78.2% (n=441) males, mean age 47.1 (SD 12.4), mean disease duration 20.8 years (SD 12.2), mean delay to diagnosis of 8.6 years (SD 7.97), 78% fulfil modified New York criteria. Mean BASDAI is 3.9 (SD2.4), BASFI 3.7 (SD2.6), BASMI 3.2 (SD 2.5), HAQ 0.55 (SD 0.52) and ASQoL 6.4 (SD 5.5). When stratified by disease duration, 23.9% have early disease (less than 10 years). The prevalence of uveitis is 35.5%, psoriasis is 17.8% and IBD is 9.7%. Prevalence of uveitis is significantly higher in women (46.7% versus 32.3%, p=0.003), late disease (39.8% versus 21.7%, p<0.001) and presence of peripheral arthritis (42.4% versus 30.9%, p=0.007). There is a trend towards more prevalent uveitis in non-smokers (40.1%) compared to current (28.3%) or past (35.8%) smokers (p=0.06). The prevalence of IBD is significantly higher in women (16.5% versus 7.7%, p=0.004), patients with elevated CRP at baseline (11.9% versus 5.8%, p=0.045), peptic ulcer disease (21.7% versus 8.6%, p=0.004) and osteoporosis (23.5% versus 8.8%, p=0.005). The prevalence of IBD is not affected by disease duration or smoking status. The prevalence of psoriasis is not affected by early versus late disease, gender or smoking. HLA-B27 status and measures of disease severity have no impact on the presence of any EAM. In regression analysis, being female and disease duration > 10 years are predictive of uveitis. Female gender, elevated CRP at baseline and peptic ulcer disease are predictive of IBD.

Conclusion: EAM are common in this axSpA population. Thirty-six percent of the population have uveitis and 18% have psoriasis. Female gender and late disease predict uveitis. It is important to regularly screen for EAM. Predictive factors may guide screening.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The association of depression with poor health outcomes in rheumatic diseases such as rheumatoid arthritis is well established. However, the impact of depression on disease outcomes in axial spondyloarthropathy (axSpA) is less well defined. The Ankylosing Spondylitis Registry of Ireland (ASRI) was established in 2013. The objectives of ASRI are to provide descriptive epidemiological data on the axSpA population in Ireland and to establish a registry for potential future studies of genetics, aetiology and therapeutics. The aim of this study is to determine the prevalence of depression in a well characterised axSpA cohort and explore relationships.

Methods: A standardised detailed clinical assessment is performed on each patient and entered in a database. Disease activity is assessed by Bath AS Disease Activity Index (BASDAI), spinal mobility by Bath AS Metrology Index (BASMI), function by the Bath AS Functional Index (BASFI) and Health Assessment Questionnaire (HAQ) and quality of life by AS Quality of Life (ASQoL). Structured interviews provide patient-reported data, including the presence of physician-diagnosed depression. Statistical analysis was performed using SPSS.

Results: As of June 2016, 564 patients have been entered into the database: 78.2% (n=441) males, mean age 47.1 (SD 12.4), mean disease duration 20.8 years (SD 12.2), mean delay to diagnosis of 8.6 years (SD 7.97), early disease (<10 years) 23.9%, 78% fulfil modified New York criteria. Mean BASDAI is 3.9 (SD2.4), BASFI 3.7 (SD2.6), BASMI 3.2 (SD 2.5), HAQ 0.55 (SD 0.52) and ASQoL 6.4 (SD 5.5). Prevalence of depression is 11.9%, with no significant difference between genders. The prevalence of depression is higher in patients with peptic ulcer disease (25.5% versus 10.6%, p=0.002), late disease (68% versus 13.5%, p=0.042) and current smokers (16.6% versus 10%, p=0.032). The mean delay to diagnosis was higher in patients with depression than without depression (10.9 ± 8.9 versus 8.3 ± 7.9 years, p=0.02). There is a trend towards a higher prevalence of depression in patients with diabetes (23.1% versus 11.3%, p=0.071). There is no association between depression and BASDAI, BASMI or BASFI. Patients with depression have higher mean ASQoL (9.7 ± 5.6 versus 5.9 ± 5.3, p<0.001) and HAQ scores (0.79 ± 0.57 versus 0.51 ± 0.51, p<0.001). In multiple regression analysis, peptic ulcer disease and ASQoL remained significantly associated with depression, with a trend towards association with current smoking.

Conclusion: Twelve percent of this axSpA population have depression. Presence of depression is associated with worse quality of life and function. However, there is no association between depression and advanced structural disease. AxSpA patients should be actively screened for depression.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To determine the characteristics of psoriatic arthritis patients(PsA) with hyperuricemia(HUC)and their outcomes especially cardiovascular(CVS) and kidney diseases.

Methods: Patients have been followed prospectively at the PsA clinic according to a standard protocol at 6-12 month intervals. We identified PsA patients with at least one visit of HUC(cases) and matched to PsA patients with normal uric acid (NUC, control) based on gender and age +/-5yrs). We defined HUC in Male> 450 mumol/L or Female > 360 mumol/L. Information collected include: demographics, education, employment history, lifestyle habits, medical history including co morbidities, medication use (all collected prospectively and stored in the clinic database). Outcomes of HUC patients especially CVS and kidney diseases after follow-up were recorded. Conditional logistic regression was performed to determine factors independent associated with HUC in PsA patients.

Results: 325 (31.9%) out of 1019 PsA patients had HUC. 318 cases were matched to 318 controls.

Table1: characteristic of PsA patients at baseline

Covariate	NUC (n=318)	HUC (n=318)	p-value
Psoriasis duration n(%)	20 (14.5)	23.7 (14.1)	**0.0016**
PsA duration n(%)	8.4 (8.6)	13.9 (11.9)	**0.001**
Hypertension n(%)	77 (24)	141 (44)	**0.001**
Anginan(%)	2 (1)	10 (3)	**0.037**
Cardiomyopathy n(%)	1 (0)	1 (0)	1
Myocardial infarction n(%)	1 (0)	4 (1)	0.37
Congestive heart failure n(%)	0 (0)	4 (1)	0.12
High creatinine n(%)	6 (2)	26 (8)	**0.001**
Renal stones n(%)	9 (3)	28 (9)	**0.0019**
Diabetes n(%)	25 (8)	48 (15)	**0.0042**
Swollen joints count(SJC) mean (SD)	0.4 (1.4)	0.6 (1.9)	0.21
Tender joints count(SJC)mean (SD)	2.8 (6.8)	3 (6.3)	0.76
PASI n(%)	3.3 (5.4)	4.7 (7.3)	**0.0062**
Hypercholesterolemia n(%)	54 (20)	60 (20)	1
Hypertriglyceridemia n(%)	14 (5)	13 (4)	0.7
High Alanine transaminase (ALT) n(%)	23(9)	34(18)	0.01
High Aspartate transaminase (AST) n(%)	40(14)	70(22)	0.01
Body mass index mean (SD)	28.5 (6.5)	31.7 (5.7)	**0.001**

PASI: Psoriasis Area and Severity Index score

HUC patients had longer disease duration and higher PASI than NUC patients. They had more concurrent co-morbidities including CVS diseases (hypertension and angina) and metabolic co-morbidities such as diabetes and obesity, as well as higher prevalence of kidney stones and higher serum creatinine. Only one patient with HUC was treated with allopurinol at first elevation visit and seven patients during follow-up. Over the follow-up, HUC patients developed more CVS diseases and metabolic changes especially diabetes and hypercholesterolemia. No differences in kidney disease on follow- up were noted between HUC and NUC groups.98(30.8%) of HUC patients had persistent hyperuricemia for more than 2 visits. Multivariate analysis showed an association between hyperuricemia and PsA disease duration, BMI, and high liver function test.

Conclusion: Hyperuricemia is common in PsA patients especially in those with longer disease duration and obesity. Since CVS disease is increased among HUC PsA patients, proper control of serum uric acid and metabolic diseases may play a preventive role in improving PsA outcomes.

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Improvement of physical function and physical activity are important goals in the management of axial spondyloarthritis (axSpA). Although physical function is included in the ASAS/OMERACT core domains for axSpA, a physical activity measurement tool specific for axSpA has not been developed. The Short Questionnaire to Assess Health-enhancing physical activity (SQUASH) is a validated questionnaire that measures the duration, frequency, and intensity of physical activity in five domains (i.e. commute, work, household, recreation and sports). Our objective was to explore the opinion of axSpA patients and experts towards the content and adaptation requirements of the SQUASH in order to develop a disease-specific SQUASH.

Methods: A qualitative study design based on a stepwise approach was used. First, semi-structured, in-depth interviews were performed with 9 professional axSpA experts (e.g. rheumatologists, rehabilitations specialists, physiotherapists) concerning the SQUASH domains and items in relation to the axSpA. Second, a structured focus group concerning the SQUASH domains and items was performed with 8 axSpA patients (7 AS and 1 nr-axSpA) from the GLAS cohort and suggestions for possible adaptations were discussed. Data were recorded, transcribed, and analyzed using an objective thematic strategy. Finally, the SQUASH was adapted based on adaptations suggested by ≥5 experts and ≥5 patients.

Results: The SQUASH was found to be relevant and easy to complete. The experts and patients suggested 33 adaptations of which 16 were implemented. The most important adaptations were: explanation of intensity concepts (e.g. increased heart rate, sweating), changing intensity concepts, standardization of frequency across the entire questionnaire, and adding more specific options to the domains (e.g. exercise therapy, other transportation goals) (Table 1).

Conclusion: The original SQUASH was modified to a more standardized questionnaire in collaboration with both patients and experts to measure physical activity in axSpA. The next step will be to assess the construct validity and the test-retest reliability of this axSpA-specific SQUASH. **Table 1.**Domains, subdomains, activities, frequency, duration, and intensity concepts included in the modified SQUASH.

Domains	Subdomains	Activities	Frequency and duration	Intensity concepts*
Transport	Commuting activities	Walking, cycling	Days/wk, time/day (hrs, min)	Slow/light, moderate, fast/heavy
	Other returning transportation activities	Walking, cycling	Days/wk, time/day (hrs, min)	Slow/light, moderate, fast/heavy
Activities at work or school	Less heavy work	e.g. sitting/standing with some walking	Days/wk, time/day (hrs, min)	-
	Heavy work	e.g. regularly lifting heavy objects	Days/wk, time/day (hrs, min)	-
Household activities	Less heavy work	e.g. cooking, washing, ironing, childcare	Days/wk, time/day (hrs, min)	-
	Heavy work	e.g. scrubbing floors, walking with heavy shopping bags	Days/wk, time/day (hrs, min)	-
Leisure time activities		Walking (recreation), cycling (recreation), gardening, odd jobs	Days/wk, time/day (hrs, min)	Slow/light, moderate, fast/heavy
Sports		To fill in by yourself (e.g. tennis, fitness, skating, swimming, dancing, exercise therapy)	Days/wk, time/day (hrs, min)	Slow/light, moderate, fast/heavy
***Slow/light** refers to a physical activity in which the participant does not experience increased heart rate or increased respiratory rate. **Moderate** refers to a physical activity in which the participant experiences slightly increased heart rate and slightly increased respiratory rate. **Fast/heavy** refers to a physical activity in which the participant sweat, experiences accelerated heart rate, and accelerated respiratory rate.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Data on disease characteristics of geriatric patients (>=65 years) with AS are lacking. The objective of this study is to compare: 1) the clinical profile of geriatric and non-geriatric patients with AS and 2) geriatric AS patients with aged-matched non-AS comparators.

Methods: Data were extracted from a Toronto based longitudinal SpA cohort. Patients with AS were divided by current age into geriatric (age >= 65 years) and non-geriatric (age < 65 years) groups. Clinical and laboratory data were then compared. Data for the non-AS geriatric age-matched control group was obtained from a Toronto tertiary care orthopedics clinic.

Results: There were 48 geriatric AS patients out of 890 AS patients in the clinic (table 1). 322 knee OA patients were included for the non-AS geriatric comparison (table 2). Initial comparison (young vs geriatric AS), showed no differences in sex distribution. Age at time of diagnosis was higher in the geriatric AS patients ($p<0.001$). In terms of clinical activity, there was no difference in mean inflammatory markers or BASDAI scores. Extra-articular manifestations were similar. There was no significant difference between the 2 groups regarding the usage of NSAIDs, DMARDS, corticosteroids and biologics, nor in their side-effects. Only 1% of the geriatric group started biologic therapy at age >=65 yr. Infection frequency was similar between the two groups. Mobility (BASMI) and function (BASFI) scores were higher in the geriatric group ($p<0.001$ and 0.04 respectively). The geriatric group were more likely to have a history of physical trauma/ injury ($p=0.03$). The SF-36 mental component was also higher in the geriatric group. Quality of life scores were similar. Comparison of geriatric AS and geriatric OA patients revealed more males in the AS group. Non-AS patients are more likely to be smokers and have a history of diabetes ($p=0.04$). Functional disability scores were also higher.

Conclusion: We show that geriatric AS patients have reassuringly similar treatment and disease activity parameters, but differed in a select few functional components and comorbidities when compared to the younger population. The younger population was diagnosed earlier than the elder group, which may reflect better disease awareness among physicians over the last few years. When compared to geriatric non-AS controls, there was a higher prevalence of females, diabetes and smokers in the non-AS geriatric patients. Further research into the geriatric AS population is needed to better define and manage their specific needs, especially as this patient population will be substantial in the coming years.

Table 1	Geriatric (age >= 65 years) N=48	Non geriatric AS (age < 65 years) N=842	p value

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Data on body composition (BC) in Ankylosing Spondylitis (AS) are sparse and controversial. Female AS patients have less response to TNF-α blockers and a shorter drug survival. This might be explained by differences in BC, as women have higher body fat (BF) levels and fat produces TNF-α. Our objective was to assess the BC in a cohort of AS patients naïve to TNF-α blockers, and to evaluate the differences between genders and with the reference population.

Methods: Patients included fulfilled the Modified New York criteria and were naïve to TNF-α blockers. Clinical assessments included age, disease duration, extra articular manifestations, therapies, hypertension, diabetes, dyslipidemia, lifestyle (tobacco, alcohol and marihuana use, physical activity), body mass index (BMI), ASDAS CRP and ESR, BASDAI, BASFI, BASMI. BC was assessed by whole body Dual-Energy X-ray Absorptiometry. BF%, Fat Mass Index (FMI), Fat Free Mass Index (FFMI), and android/gynoid (A/G) fat ratio were reported and compared with the reference population (percentiles, stratified by ethnicity, age and gender). Association between variables and differences between groups were assessed using t-test, Chi-Square, Mann-Whitney U test or linear regression depending on the variable.

Results: Seventy consecutive patients were included, 42 (62%) were men. The mean age was 43.9 (11.7 SD). By BMI 35.7% were overweight and 15.7% obese and there were no underweight patients. 62.9% had a BASDAI >4, and the median for ASDAS CRP was 3.4, for BASFI 4 and for BASMI 2. Disease duration, severity, extra articular manifestations, therapies, comorbidities and lifestyle were similar between men and women, except for dyslipidemia, present in 57.1% of men and in 14.3% of women ($p<0.001$). Women had a higher proportion of obese patients by BMI, higher BF % and FMI, and lower FFMI, but the percentile levels for BF% and FMI were similar to men, and better for FFMI. Men had a higher proportion of overweight patients and a higher A/G fat ratio (Table 1). After multivariate analysis, a higher A/G fat ratio was related to dyslipidemia in all patients. In men there was a significant association between BF% and categorical ASDAS CRP, and for FMI and FFMI with HTA. In women there was a significant association between FMI and categorical ASDAS ESR, and between FFMI and psoriasis. In the univariate analysis BASMI was significantly associated with BF% and FMI in men, and BASFI with BF % in women.

Conclusion: Women had higher BF% and FMI than men, but when BF%, FMI and FFMI were compared to the reference population they had a better than average BC. For men it was the opposite, with a trend for higher BF% and FMI percentile levels than women. There was a trend between higher fat percentages and increased disease activity measurements. The association of A/G fat ratio and dyslipidemia was significant independently of sex, which might contribute to the increased cardiovascular risk in AS.

Table 1. Body composition stratified by gender.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab, a fully human anti–IL-17A monoclonal antibody, significantly improved signs and symptoms of psoriatic arthritis (PsA) over 52 weeks (wks) in FUTURE 2 study (NCT01752634).[1,2] Here we present longer-term (104 wks) efficacy and safety data from this study.

Methods: Overall, 397 patients (pts) with active PsA were randomized to receive s.c. secukinumab (300, 150, or 75 mg) or placebo (PBO) at baseline, Wks 1, 2, 3, and 4, and every 4 wks (q4w) thereafter. PBO pts were re-randomized to secukinumab 300 or 150 mg s.c. q4w depending upon ACR20 response at Wk 16; pts were classified as responders (≥20% improvement from baseline in tender and swollen joint counts) or non-responders, with non-responders switching at Wk 16 and responders at Wk 24. Exploratory endpoints assessed at Wk 104 are from pts originally randomized to secukinumab at the beginning of the trial and included ACR20/50/70, PASI 75/90, DAS28-CRP, SF-36 PCS, HAQ-DI, dactylitis, and enthesitis. Data were assessed by multiple imputation applied to missing

binary variables and mixed-model repeated measures for continuous variables. Analyses stratified by anti-TNFα status (anti–TNFα-naïve and anti–TNFα-inadequate response or intolerance to these agents [IR]) were pre-specified and are reported as observed. Safety analysis included all patients who received ≥1 dose of secukinumab and data presented as exposure adjusted incidence rates (EAIR) per 100 pt-years over entire treatment period.

Results: In total, 86/100 (86.0%), 76/100 (76.0%), and 65/99 (65.7%) pts in the secukinumab 300, 150, and 75 mg groups respectively completed 104 wks. At Wk 104, ACR20 response rates in the 300, 150, and 75 mg groups were 69.9%, 64.7%, and 50.1%, respectively. Sustained clinical improvements were observed through Wk 104 with secukinumab across other clinically important domains of PsA (Table). Responses were sustained through Wk 104 in anti–TNFα-naïve pts and anti–TNFα-IR. ACR20 response rates at Wk 104 in anti–TNFα-naïve pts were 80.4%, 86.8%, and 68.6% with 300, 150, and 75 mg, respectively; corresponding rates in anti–TNFα-IR pts were 60.7%, 41.7%, and 43.8%, respectively. Over the entire treatment period (mean [±SD] exposure to secukinumab of 709±210.99 days) the incidence, type and severity of adverse events were consistent with those reported previously. Specifically, EAIR for serious infections/infestations, candida infections, inflammatory bowel disease, malignant/unspecified tumors, and major adverse cardiac events with secukinumab were 1.6, 2.3, 0.5, 1.3, and 0.3, respectively.

Conclusion: Secukinumab 300 and 150 mg provided sustained improvements in signs and symptoms and multiple clinical domains of active PsA through 2 years of therapy. Secukinumab was well tolerated, with a safety profile consistent with that reported previously.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Minimal disease activity (MDA) is now considered an objective target which is more attainable in psoriatic arthritis (PsA) compared to remission (DAS28 <2.6) which is more difficult to achieve and maintain. The criteria for MDA encompass different aspects of this distinct and heterogeneous disease. The aim of this analysis was to assess which unmet criteria were more common among patients who achieved MDA based on patient reported outcomes (PROs) in a real-world, routine clinical care setting in Canada.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis (RA), ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab (IFX) or golimumab (GLM). Eligible patients for this analysis included PsA patients treated with IFX or GLM between 2005 and 2015. MDA was defined as the fulfillment of ≥5 of the following criteria: TJC28≤1, SJC28≤1, PASI≤1, pain (VAS) ≤15 mm, PtGA (VAS) ≤20 mm, HAQ≤0.5, tender entheseal points ≤1.

Results: A total of 223 PsA patients (51.4% male) were included with a mean (SD) age of 49.8 (11.1) years and disease duration since diagnosis of 5.4 (6.3) years. MDA was achieved by 11.7%, 43.5%, and 44.8% at baseline, 6 months and 12 months of treatment, respectively. The most commonly unmet MDA criteria in patients who achieved 5/7 criteria was patient-reported pain (69.2%), PtGA (48.7%), and HAQ (20.5%). The mean (SD) for these disease parameters were 31.8 (13.5) mm for pain, 39.3 (10.9) mm for PtGA and 0.95 (0.46) for HAQ. Furthermore, in these patients the most prevalent combination in unmet criteria was pain+PtGA with 38.5% followed by PASI+pain with 12.8%. In patients who achieved 6/7 MDA criteria, the most commonly unmet criteria included PASI with 21.9%, pain with 18.8% and HAQ with 18.8%. The mean (SD) for these disease parameters were 3.7 (2.1) for PASI, 22.8 (7.9) mm for pain and 0.75 (0.08) for HAQ.

Conclusion: The current analysis has shown that by 6 months of treatment almost 50% of patients achieved MDA. Among patients who achieved 5/7 criteria the most commonly unmet criteria in patients who achieved MDA are PROs including pain, PtGA and HAQ-DI. These results highlight the difference in the perception of disease activity by physicians and patients and in the relative importance placed on specific disease aspects.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Increased risk of several comorbidities has been reported in spondyloarthritis (SpA). Data and knowledge regarding the prevalence of these comorbidities and risk factors in Latin America are limited. The objective of this study is to determine the prevalence and risk of develop comorbidities as assessed in the ASAS-COMOSPA study in patients with SpA in three Latin American countries, and to compare this prevalence with the information in the general population to determine whether the prevalence and the risk of comorbidities is increased.

Methods:

Data from 390 consecutive patients with SpA enrolled in the international cross-sectional ASAS-COMOSPA study from Argentina, Colombia and Mexico were analyzed. The prevalence (95% CI) standardized by age and gender was estimated for arterial hypertension (AHT), tuberculosis (TB), and malignancies (colon, skin, lung, lymphoma, prostate, cervix and breast). Data from the general population (stratified by gender and age group) were obtained from the CARMELA study for AHT, the Global TB report and the GLOBOCAN project for malignancies. The prevalence in SpA patients was compared with the prevalence. in the general population by calculating the age- and gender-specific categories. A standardized risk ratio (SRR) was calculated for corrected age and gender groups between the SpA patients and the data from the general population. SPSS 22 was used to perform the statistical analyses.

Results:

In total, 64% were male, the mean age was 45 (14.7) years and the disease duration was 7.0 (8.1) years. The most common comorbidities were AHT (25.3%), hypercholesterolemia (21.8%), osteoporosis (9.4%) and gastrointestinal ulcer (7.8%). The prevalence of AHT was 25.3% (95% CI 21.2 to 29.4) and was higher compared with the general population (16.3%, 95% CI 15.4 to 17.2). The AHT risk of patients with SpA was increased 8.8 times compared with the general population The overall prevalence of TB was 3.33% (95% CI 1.8 to 5.7), and was higher compared with the general population (0.03%). The total risk of TB was found to increase 14.6 times than expected to general population. There was no a significantly increased prevalence of malignancies compared with the general population.

Conclusion:

In patients with SpA we observed a higher prevalence and risk for AHT and TB in three Latin American countries than expected from the age-and gender-adjusted general population. A systematic evaluation and screening of these comorbidities and risk factors may help to properly monitor and detect these conditions in SpA patients.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The concept of inflammatory back pain (IBP) was proposed in association with ankylosing spondylitis (AS), one prototype of Spondyloarthritis (SpA), more than 60 years ago. Spondyloarthritis (SpA) comprises several rheumatic diseases. Although several criteria sets have been developed, the diagnosis of SpA remains challenging. This study aims to evaluate the frequency of inflammatory back pain (IBP) among Brazilian subjects with chronic back pain (CBP), and to describe the results of rheumatologic evaluation based on the axial SpA classification criteria from the Assessment of Spondyloarthritis International Society (ASAS).

Methods: This was an observational study with retrospective (phase 1) and one-month prospective (phase 2) data collection. Medical records of subjects 18-60 years old, with onset of back pain at age <40 years, and with CBP (pain almost daily ≥3 months), were included in phase 1. Subjects with at least one ASAS screening parameter for IBP were contacted by phone, and confirmed IBP cases were invited to phase 2. At phase 2 visit 1, HLA-B27 and C-reactive protein (CRP) were requested. At phase 2 visit 2, the fulfilment of the ASAS classification criteria for axial SpA was verified. Frequency of IBP among subjects with CBP starting before the age of 40 years was estimated. For subjects included in phase 2, the proportions of positive HLA-B27, AS and non-radiographic axial SpA (nrAxSpA) were calculated.

Results: A total of 363 records of subjects with CBP were reviewed from five sites. Based on medical records and phone contact, 130 subjects had IBP confirmed (35.8%, 95%CI: 30.9-40.7%). From IBP population, only 52 subjects accepted to participate in phase 2. Mean age was 38.8±11.43 years, 64% were female, 85% professionally active, and 14% had family history of IBP related conditions. Time since CBP onset was 12.3±10.09 years and no subject had a prior diagnosis of SpA. Among the 50 patients that completed visit 2, 14% had positive HLA-B27, 82% had lesions of the sacroiliac joint assessed by MRI, 16% had abnormal clinically significant CRP results, and 10% had grade 3-4 lesions assessed by X-ray. The proportions of AS and nrAxSpA cases were 46% and 26%, respectively by ASAS classification criteria.

Conclusion: More than one third of the CBP subjects with onset <40 years had IBP by ASAS criteria. Of notice, subjects with a positive HLA-B27 test did not have prior diagnosis of axial SpA. The results in this Brazilian population suggest that patients with IBP may be under diagnosed, delaying their treatment, and that women may seek more for medical care than men. An eventual selection bias cannot be excluded.

Sleep Disturbance in Psoriatic Disease: Prevalence and Associated Factors

Ian Tin Yue Wong[1], Vinod Chandran[2], Suzanne Li[3] and Dafna D Gladman[4], [1]Faculty of Medicine, University of British Columbia, Vancouver,, BC, Canada, [2]Medicine, Krembil Research Institute, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [3]University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [4]University of Toronto, Toronto, ON, Canada
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriasis is a chronic inflammatory skin disease characterized by scaling, erythematous plaques. Up to 30% of psoriasis patients develop an inflammatory arthritis termed psoriatic arthritis (PsA). Psoriatic disease (PsD) patients report impaired sleep quality, but the relationship between sleep quality and disease and demographic factors has not been examined. This study aimed to determine and compare the prevalence and quality of sleep disturbance in patients with PsA and patients with psoriasis without arthritis (PsC), and to identify associated disease-related and demographic factors.

Methods: The study included 113 PsA (CASPAR criteria) and 62 PsC (evaluated by a rheumatologist to exclude PsA) patients (mean age 57.4±11.6 and 56.9±14.2 years, men 55% and 40%, disease duration 17.1±11.6 and 25.9±17.0 years, respectively), and 52 healthy controls (mean age 42.2±13.6, men 29%). Clinical variables were collected using a standard protocol. The sleep quality was evaluated using the Pittsburgh Sleep Quality Index (PSQI). Other patient reported outcomes collected included the Health Assessment Questionnaire (HAQ), Dermatology Quality Life Index (DLQI), EQ-5D, Medical Outcome Study Survey (SF-36), patient global assessment (PGA) and the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT) Scale. Statistical analysis includes descriptive statistics, Wilcoxon rank-sum test and linear regression.

Results: The prevalence of poor sleep quality was 84% (95/113), 69% (43/62), 50% (26/52) in PsA, PsC and healthy controls, respectively. Total PSQI score was higher in both PsA and PsC patients compared to healthy controls (9.24 and 7.18 vs. 5.67, $p<0.01$) and higher in PsA patients compared to PsC patients (9.24 vs 7.18, $p<0.0001$). PSQI components of sleep disturbances, latency, daytime dysfunction, and subjective sleep quality contributed to worse sleep quality in PsA patients compared to PsC patients ($p<0.01$). Controlling for sex and group, anxiety, EQ-5D and FACIT were independently associated with worse PSQI in PsC and PsA patients ($p<0.05$). Controlling for age, sex, and BMI, actively inflamed (tender or swollen) joints were independently associated with worse PSQI in PsA patients ($p<0.01$).

Conclusion: Patients with PsD have poor sleep quality, especially in those with PsA. Poor sleep is associated with fatigue, anxiety, and lower EQ-5D in patients with PsD. In patients with PsA, poor sleep is associated with active joint inflammation. . However, given this was a cross-sectional study, whether anxiety and lower EQ-5D are the causes or the consequences of poor sleep remains to be determined.

Smoking and Severity of Psoriatic Arthritis

Sahithi Jarugula[1], Bonita Libman[2], Amanda Kennedy[3] and Diantha Howard[4], [1]Internal Medicine, Sahithi Jarugula, S.Burlington, VT, [2]Internal Medicine, University of Vermont Medical Center, Burlington, VT, [3]Internal Medicine, University of Vermont Medical center, Burlington, VT, [4]Statistics, University of Vermont, Burlington, VT

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Smoking is a major modifiable risk factor for various inflammatory diseases including rheumatoid arthritis [1, 2] and psoriasis [3,4,5]. The presence of cyclic citrullinated peptide antibody (CCP) has been associated with smoking in rheumatoid arthritis [1]. Presence of CCP has also been shown to be associated with severe Psoriatic arthritis (PsA) in a few retrospective studies [6,7]. Our aim is to assess the association of smoking and CCP Ab positivity in PsA, with the hypothesis that smoking is associated with severe PsA, and CCP may also be associated with severe arthritis.

Methods: Medical records of patients with PsA followed in our clinic from 2010 to 2015, identified by ICD 9 code were analyzed for demographic characteristics, body mass index (BMI), smoking status, CCP positivity and clinical characteristics for severe PsA. Severe disease was defined as treatment with biologics and/or joint erosions identified on hand and foot radiographs. Chi square statistic was used to assess the relationship between smoking and disease severity. The association of CCP positivity with severe PsA was determined by Fisher's exact test.

Results: One hundred and twelve patients who were ever smokers and one hundred and thirteen never smokers were identified. 30.4% were found to have more severe disease in the ever smoker group and 36.3% were found to have more severe disease in the never smoker group with a relative risk of 0.84 (0.58-1.21, 95% CI)

Conclusion: A relationship between smoking status and disease severity was not identified. There were insufficient numbers of CCP positive patients to establish statistical significance for either positive association with smoking or disease severity. However, CCP positive patients were more likely to be on biologic medications, further studies are needed to establish relationship. References: 1. Klareskog et al. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The SAPHO syndrome (synovitis, acne, pustulosis, hyperostosis, and osteitis) is a rare autoimmune disease characterized by inflammatory osteoarticular and cutaneous manifestations. Despite improvements in diagnostic (e.g. MRI, scintigraphy) and therapeutic options (e.g. NSAR, bisphosphonates and TNF inhibitors) SAPHO syndrome is still diagnosed late and often treatment is challenging. Since data from larger studies are missing we assessed patient characteristics and treatment in our cohort.

Methods: 69 Patients with CRMO were analyzed in a cross-sectional study using medical records and questionnaires with regard to the patient characteristics (age, gender, disease duration, time to diagnosis), perception of satisfaction and disease burden (VAS), clinical manifestations (osteoarticular: osteitis, hyperostosis, spondylitis, and involvement of sternoclavicular and sacroiliac joints; dermatological: acne, palmoplantar pustulosis, psoriasis vulgaris), and treatment modalities (NSAIDs, opioids, steroids, bisphosphonates, antibiotics, biologicals currently or in the past).

Results: The time from onset to diagnosis was 4.0 ± 5.5 years and the age at diagnosis was 46.8 ± 12.8 years. Generally, the patients' overall satisfaction (on visual analogue scale from 0 to 100) with 22.5 ± 27.8 was rather low and overall disease burden with 43.7 ± 24.8 rather high indicating that treatment was suboptimal in a substantial portion of patients. Among other findings, we identified a subgroup of difficult-to-treat patients that were characterized by osteitis of the mandibles (n=9). They experienced stronger immunosuppressive therapies such as steroids ($p=0.03$) and TNFi ($p<0.005$) than patients without mandible involvement. Of note, in

three patients of our cohort who failed treatment including TNFi, we observed a significant improvement after treatment with secukinumab in patient pain, skin manifestation as well as in objective measures of osteoarticular inflammation as demonstrated by decrease of CRP and reduction of activity by MRI and bone scintigraphy.

Conclusion: Treatment of SAPHO is challenging particular in subgroups of patients. Therapies targeting IL-17 might constitute new efficacious treatment options.

Session Time: 9:00AM-11:00AM

Unhappiness is Related to Worse Outcomes for Patients with Ankylosing Spondylitis and Increased Impairment in Daily Life Activities,

Results from a Multinational Real-World Sample

Background/Purpose: This study aimed to explore the relationship of self-reported happiness to disease activity and functional limitation in people with AS.

Methods: Data were from a cross-sectional sample of rheumatologists and their patients (pts) with AS in 15 countries. Physicians collected data on consecutively consulting AS pts including Physician Assessed Severity' (PA severity) (choice of mild, moderate, severe), perceived change in control (choice of improving, stable, unstable, deteriorating) and general health (0 – 100 VAS). Pts completed forms on ratings of current activity and pain, assessments of health related quality of life (SF-36, EQ-5D) and disease activity (BASDAI). SF-36 question 9h (Q9h; mental health domain) asks "How much of the time during the past week have you been happy?"; responses of "All" or "Most" formed *Happy* (Group 1); responses of "A little" or "None" formed *Not Happy* (Group 2); "some" were excluded from the analysis. Groups 1 and 2 were compared using bivariate analysis. SF-36 Question 3 (Q3; physical functioning domain) asks if the pts' health limits them performing 10 daily activities. **Results:** 1,392 pts answered Q9h: 45.7% were assigned to Group 1 (*Happy*), 20.3% to Group 2 (*Not Happy*). Significantly more pts in Group 2 had moderate or severe disease, unstable or deteriorating AS, poorer general health status, worse pain, and more active AS (higher BASDAI) than Group 1 (Figure 1). 1,405 patients answered Q3, of whom 60%, 34% and 6% were considered by their physician to have mild, moderate and severe AS, respectively. The proportion of pts who reported "a lot" of limitation in each of the 10 activities increased with perceived severity (Figure 1). Of pts with severe AS, 47–73% were limited in undertaking normal physical activities, such as climbing several flights of stairs (moderate AS, 23–43%), and 22–43% could not perform activities requiring limited physical effort, such as carrying groceries or dressing themselves (moderate AS, 7–23%). It also shows that among the pts who are impaired 'a lot' for each activity, unhappiness increases with perceived disease severity.

Conclusion: Unhappiness in AS pts is associated with more severe or active disease, and many AS pts are limited in their ability to

undertake everyday activities, with limitation and unhappiness more common with more severe disease. Thus evaluating patient unhappiness via enquiry in routine consultation may help in assessing clinical severity, disease impact, and help inform treatment decisions.

Practicing What We Preach? Do Psoriatic Arthritis Patients Treated at an Academic Medical Center Meet Caspar Criteria?

Sergio Schwartzman, Rima Abhyankar, Margaret Bogardus and Lisa Mandl, Hospital for Special Surgery, New York, NY

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is an autoimmune musculoskeletal disease with protean manifestations, and therefore can be difficult to diagnose. Although no diagnostic criteria are available, the CASPAR classification criteria (CC) have a sensitivity and specificity of 91.4% and 98.7%, respectively. The purpose of this study is to assess the validity of using ICD-9 codes to identify PsA patients for future clinical trials by applying the CC to patients with the ICD-9 code for PsA (696.0).

Methods:

This was a retrospective cohort study. All patients with a billing code of 696.0 seen at a single center from January 1, 2013 through December 31, 2014 were identified. Medical records were reviewed to identify all elements of CC including: Evidence of psoriasis - current psoriasis, personal history of psoriasis, family history of psoriasis; Psoriatic nail dystrophy - onycholysis, pitting, hyperkeratosis; Negative test for rheumatoid factor; Dactylitis - current dactylitis, history of dactylitis; Radiologic evidenceof juxta-articular new bone formation. The percentage of patients who met CC was calculated, and their clinical characteristics described.

Results:

1405 patients were coded as PsA. Of 1278 unique charts available for review, 629 met CC. 96 were excluded due to a concurrent clinical diagnosis of rheumatoid arthritis, inflammatory bowel disease, or gout, leaving 533 (41.7%) with PsA based on CC. Similar age and sex between ICD-9 vs. CC groups; 54.2 years vs 52.8 years; 55.2% vs 52.2% female, respectively. Compared to published data for the classification criteria,[1] in our cohort of 533 patients who met criteria, there was a similar prevalence of psoriasis (98.9% vs 98.3%), a lower prevalence of nail disease (27.0% vs 60.0%) and moderately similar prevalence of dactylitis (31.3% vs 57.5%). Other radiographic evidence of juxta-articular new bone formation was much less frequently reported. (1.7% vs 54.0%).

Conclusion:

In this study of patients with ICD-9 codes for PsA, only 41.7% met CASPAR classification criteria. This underscores differences between PsA patients meeting CC recruited for clinical trials, and those treated in an academic real world setting. These differences are important to understand when assessing generalizability of trial data, and for planning studies of clinical effectiveness in PsA.

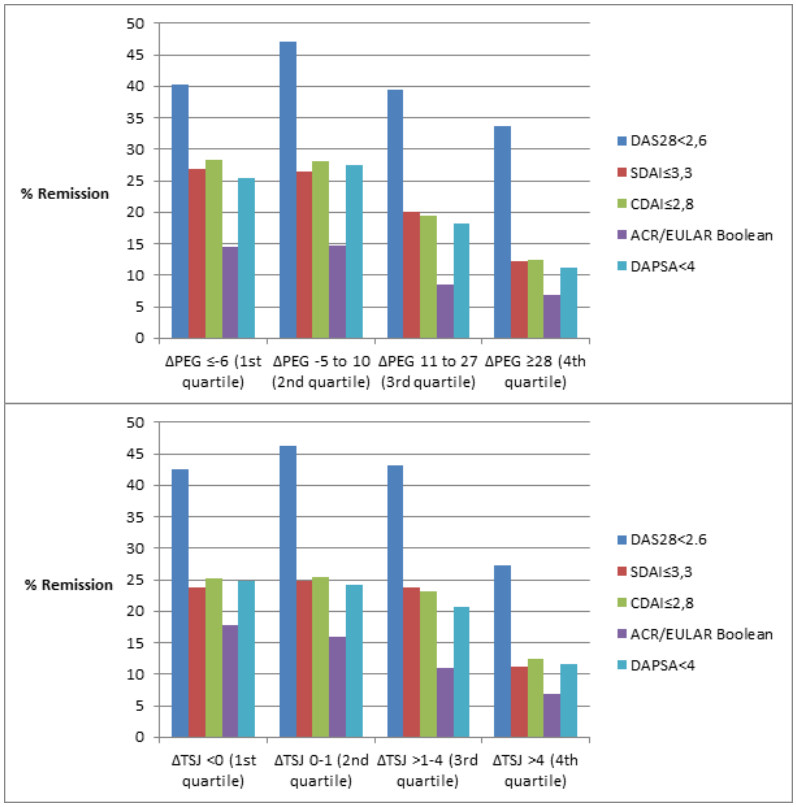
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Discordance between patient's and physician's evaluation of disease activity may be challenging in psoriatic arthritis (PsA). The potential impact of such a difference on treatment outcome is to date unexplored. In this study we aimed to investigate the predictive value of baseline patient's and evaluator's global assessment difference (deltaPEG) as well as tender and swollen joint count difference (deltaTSJ) for achievement of remission in PsA.

Methods: From the prospective, multicenter NOR-DMARD study we included PsA patients starting first-time tumor necrosis factor inhibitors (TNFi) and DMARD naïve patients starting methotrexate between 2000 and 2012. The predictive value of deltaPEG and deltaTSJ on remission, defined by various criteria, was explored in prespecified logistic regression models adjusted for age, sex, disease duration and smoking.

Results: A total of 1236 PsA patients were included (mean (SD) age 48.3 (12.4) years, disease duration 4.8 (7.5) years, 48.4% females, 29.8% current smokers, baseline mean (SD) evaluator's global assessment 34.1 (16.6), patient's global assessment 51.1 (22.6), deltaPEG 17.0 (24.3), median (IQR) 32 tender joint count 5 (8), 32 swollen joint count 3 (5), deltaTSJ 1 (5), DAS28ESR 4.2 (1.3), baseline median (IQR) SDAI 16.9 (12.8), CDAI 8.6 (10.3), modified DAPSA 21.0 (14.1) (including 32 instead of the original 66/68 joint count). Bar charts of percentages of PsA patients in remission at 6 months according to categorization of deltaPEG and deltaTSJ into quartiles showed reduced probability of remission with increasing deltaPEG and deltaTSJ (unadjusted values; figures).



Baseline deltaPEG and deltaTSJ predicted DAS28<2.6, SDAI≤3.3, CDAI≤2.8, ACR/EULAR Boolean and DAPSA<4 remission after 3 and 6 months, except for deltaPEG and DAS28 remission at 6 months (adjusted analyses; table).

	Months	DAS28ESR < 2.6	SDAI ≤ 3.3	CDAI ≤ 2.8	ACR/EULAR Boolean	DAPSA < 4
deltaTSJ	3	0.92 [0.89, 0.96] p<0.001	0.91 [0.86, 0.95] p<0.001	0.93 [0.89, 0.97] p=0.001	0.93 [0.88, 0.98] p=0.004	0.91 [0.86, 0.95] p<0.001
	6	0.94 [0.90, 0.97] p=0.001	0.94 [0.90, 0.98] p=0.003	0.93 [0.89, 0.97] p=0.001	0.92 [0.88, 0.97] p=0.002	0.93 [0.89, 0.98] p=0.002
deltaPEG	3	0.89 [0.84, 0.94] p<0.001	0.98 [0.98, 0.99] p<0.001	0.99 [0.98, 0.995] p=0.001	0.99 [0.98, 0.99] p=0.001	0.99 [0.98, 0.995] p=0.002
	6	1.00 [0.99, 1.01] p=0.94	0.99 [0.98, 0.995] p=0.001	0.99 [0.98, 0.99] p<0.001	0.98 [0.97, 0.99] p<0.001	0.99 [0.98, 0.99] p=0.001

Data are presented as OR [95% CI]

Conclusion: DeltaPEG and deltaTSJ constitute new and important predictors of treatment efficacy in PsA and may be considered in the shared decision of a target in a treat-to-target strategy.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Minimal disease activity (MDA) is now considered an attainable target in psoriatic arthritis (PsA) reflecting a desired state of comprehensive disease control. MDA is defined as the fulfillment of ≥5 of the following criteria: TJC28≤1, SJC28≤1, PASI≤1, pain (VAS) ≤15 mm, PtGA (VAS) ≤20 mm, HAQ≤0.5, and tender entheseal points ≤1. It is made up of objective and subjective outcomes. The aim of this analysis is to assess the contribution of each criterion in preventing the achievement of MDA at 6 and 12 months.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis (RA), ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab (IFX) or golimumab (GLM). Eligible patients for this analysis included PsA patients treated with IFX or GLM between 2005 and 2010. Modified MDA (mMDA) was evaluated by removing patient-reported outcomes, one criterion at a time, and mMDA achievement was defined as patients who met 4/6 criteria.

Results: A total of 223 PsA patients (51.4% male) were included with a mean (SD) age of 49.8 (11.1) years and disease duration since diagnosis of 5.4 (6.3) years. MDA was achieved by 11.7%, 43.5%, and 44.8% at baseline, at 6 and 12 months of treatment, respectively. At 6 months of treatment the proportion of patients who achieved mMDA upon removing one criterion at a time increased to 54.3% for pain removal, 52.2% for PtGA removal, 50.7% for HAQ removal; while the removal of objective measures did not increase in substantial manner the percentage of patients achieving mMDA: 46.4% for TJC removal, 44.9% for PASI removal, 44.2% for SJC removal, and 44.2% for enthesitis removal. Similar findings were seen at 12 months: the proportion of patients achieving mMDA upon removing HAQ was 58.1%, pain was 57.1%, PtGA was 55.2%, TJC was 50.5%, SJC was 48.6%, PASI was 46.7%, and enthesitis was 45.7%. The highest proportion of mMDA achievement at 6 and 12 months of treatment was observed upon the removal of patient reported pain, PtGA and HAQ.

Conclusion: The results of the current analysis have shown that the most common limiting factors in achieving MDA in PsA are patient reported outcomes, including PtGA, pain, and HAQ. Elimination of each of these criteria from the MDA formula would result in as many as 13% additional cases of MDA.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Epidemiological studies have found a high prevalence of obesity in patients with Psoriatic Arthritis (PsA). It was described the association between obesity and severity of psoriasis, but the relationship to the severity of PsA has been less studied. Our purpose was to assess the prevalence of obesity in a cohort of patients with PsA and its association with clinical and sociodemographic characteristics

Methods: PsA patients ≥18 years old according to CASPAR criteria, belonging to RAPSODIA (Registro de Artritis Psoriásica, IREP Argentina) cohort were included. Socio-demographic data, disease duration, type of onset and evolution of PsA, comorbidities, acute phase reactants and lipid profile were collected. Treatment data were collected through direct interview with the patient, complementing with medical history. 66 tender and 68 swollen joints count, enthesitis (MASES), presence of dactilitis, cutaneous (PASI) and nail involvement (PNSS) were evaluated. Disease activity (BASDAI), functional capacity (HAQ, BASFI), quality of life (DLQI, PsAQoL) questionnaires were completed. DAS28, DAPSA and MDA (Minimal Disease Activity) composite indexes were calculated. Visual analog scale (VAS) was used to grade severity of skin psoriasis, pain and patient and physician global assessment of disease activity. Height (cm), weight (kg) and blood pressure (mm Hg) were measured. BMI was calculated. Patients were classified according to WHO in normal (BMI 18.5-24.9), overweight (BMI 25-30) and obesity (BMI ≥30). Obesity was classified as grade I or mild (BMI 30-34.9), grade II or moderate (BMI 35-39.9) and grade III or severe (BMI ≥40). Statistical analysis: Descriptive statistics. T test and ANOVA. Chi^2 and Fisher exact test. Multiple logistic regression (dependent variable: obesity). Univariate general linear model.

Results: 110 patients were included, 56 (50.9%) were men, median age 55 years (IQR 44.7-63.2) and median disease duration of PsA 10 years (IQR 6-17) and median duration of psoriasis was 24 years (IQR: 15.5-33.9). 19 patients (17.3%) met MDA. The median BMI was 28.4 (IQR 15.5-32.2). 23 patients (19.1%) had normal BMI, 48 (43.6%) overweight and 41 (37.3%) obesity. Of obese patients, 33 (80.5%) had mild obesity, 6 (14.6%) moderate and 2 (4.9%) severe. Obese patients had worse functional capacity that patients with normal weight (BASFI 4.4 ±2.8 vs 2.7± 2.5, p = 0.03) and higher pain (VAS 6.7 ±7.6 vs 4.6 ±2.4, p = 0.05). PASI score was higher in obese vs patients with normal BMI (2.8 ±2.9 vs 1.6± 1.7, p= 0.02). There were no differences according to sex, age, comorbidities, laboratory variables, disease duration, or extension of joint involvement. Obese patients had received steroid treatment more frequently in the past, but at the time of study evaluation no differences in treatment were observed. Type II diabetes was significantly more frequent in obese patients 16 vs 0 (p=0.03).

Conclusion: We observed that 81% of PsA patients are overweight or obese. The presence of obesity was associated with higher level of pain, greater skin involvement and worse functional capacity

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: "Composite psoriatic disease activity index (CPDAI)" includes 5 domains: peripheral joints, skin, enthesitis, dactylitis, and spinal manifestations in psoriatic arthritis (PsA) which is a heterogeneous disease known with widely variable clinical courses. Experiences in ankylosing spondylitis (AS) studies suggest that female patients report more symptoms and poorer scores on most of the self-reported questionnaires, including Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and AS Quality of Life [ASQoL]) despite fewer inflammatory spinal lesions or less radiographic damage as objective disease indicators with respect to male patients. The aims of this study are to investigate the relationship of CPDAI with other follow-up parameters and to evaluate gender differences in these measures in PsA patients.

Methods: This cross-sectional study included patients with PsA followed up at a Rheumatology outpatient clinic at a university hospital. Disease activity was assessed in the patients by using the CPDAI, BASDAI, Visual Analogue Scale Global (VAS global) and Disease Activity Score (DAS28). Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels were measured in all the patients. The Psoriasis Area and Severity Index (PASI) was used for the measurement of severity of psoriasis. The Patient Acceptable Symptom State (PASS), BASFI, Bath Ankylosing Spondylitis Metrology Index (BASMI), Health Assessment Questionnaire (HAQ), ASQoL and Dermatology Life Quality Index (DLQI) were also evaluated. The correlations were investigated by Spearman's correlation analysis (rho:<= 0.29 weak, 0.30-0.49 middle, >= 0.50 strong).

Results: There were 117 patients with PsA (78 female) who fulfilled the Classification *Criteria for Psoriatic Arthritis* (CASPAR) (3). Their mean CPDAI score was 3.67 (±2.46). The CPDAI was found to be correlated with tender and swollen joint counts, dactylitis and enthesitis. There was a strong correlation between CPDAI and BASDAI, $DAS28_{ESR}$, $DAS28_{CRP}$ and VAS global. Other follow-up parameters also correlated with CPDAI but no correlation was found between the CPDAI and ESR, CRP and BASMI. Mean CPDAI scores were similar in female and male patients. Female patients with PsA were found as having worse subjective scores including BASDAI, VAS global, BASFI, HAQ, ASQoL scores than males ($p<0.05$). Whereas objective disease parameters such as mean ESR and serum CRP levels, tender/swollen joint counts, DAS28 and BASMI scores were similar in both gender groups (Table 1).

Conclusion: This study confirmed that the CPDAI, a new scale to assess disease activity in PsA patients was well correlated with other disease activity measurements. Although subjective disease scores (BASDAI, VAS global, BASFI, HAQ and ASQoL) was higher in female patients, CPDAI was not affected from gender.

Table 1. Demographic and Clinical Data and Disease Activity Measures in Patients with Psoriatic Arthritis			
	Female patients (n=78)	**Male patients (n=39)**	**p value**
Mean age±SD (yrs)	48.1(±11.7)	45.5 (±12.6)	0.28

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

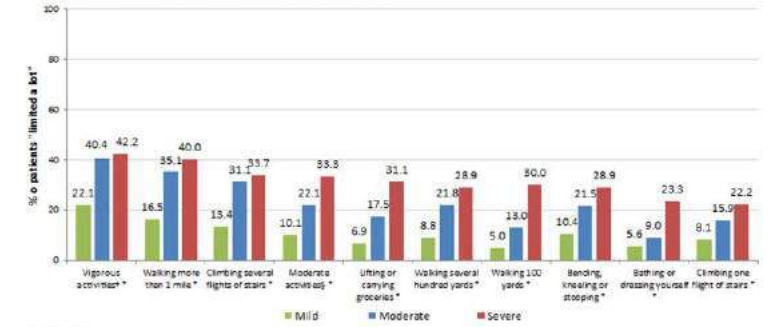
Background/Purpose: This study investigated the impact of psoriatic arthritis (PsA) disease severity on patients' (pts) ability to perform normal daily activities and their reported happiness.

Methods: Data from cross-sectional research with specialists treating pts with PsA in 16 countries were analyzed. Physicians completed a detailed form for consecutive consulting PsA pts recording Physician Assessed severity (PA severity) (choice of mild, moderate or severe), change in severity (choice of improving, stable, unstable, deteriorating), general health (1- 100 VAS), perceived pain (1 – 10 scale), swollen (/ 66) and tender (/ 68) joint counts and severity of skin symptoms (PASI). Pts completed a form rating severity of their PsA (mild, moderate, severe), current pain (1- 10 scale), and their health related quality of life (SF-36). Question 3 (Q3; physical function domain) of SF-36 asks if their health limits pts' performance of 10 daily activities. SF 36 question 9h (Q9h; mental health domain) asks "How much of the time during the past week have you been happy?"; pts answering "All" or "Most" were defined as *Happy* (Group 1), pts answering "A little" or "None" as *Not Happy* (Group 2); "Some" were excluded from the analysis. Bivariate analysis described differences between the Groups.

Results: 1,722 pts completed Q3; 61%, 34% and 5% with mild, moderate and severe PsA, respectively. 1,698 pts answered Q9h - 44.6% in Group 1 and 20% in Group 2. The proportion who reported "a lot" of limitation in the Q3 activities increased with disease severity (Figure 1). Of pts with severe PsA, 33–42% were limited in undertaking normal physical activities, such as climbing several flights of stairs (moderate PsA, 22–40%), and 22–31% could not perform limited physical activities, such as dressing themselves (moderate PsA, 9–30%). Unhappy pts were associated with worse health outcomes when physicians' and pts' perceptions of health status, as well as clinical characteristics, were compared between Group 1 and 2 (Figure 2). A lower level of satisfaction with the control their current treatment provided was also observed among Group 2 ("satisfied": Group 1, 83%; Group 2, 56.9%; *P<0.001*).

Conclusion: Many PsA pts cannot undertake everyday activities that would allow them to lead a normal life. Impairment increases with disease severity and unhappiness is also associated with more severe disease status. Thus strategies to proactively treat PsA to reduce severity should improve important components of health related quality of life.

Figure 1. Limitation of daily activities by PsA disease severity



* p<0.0001

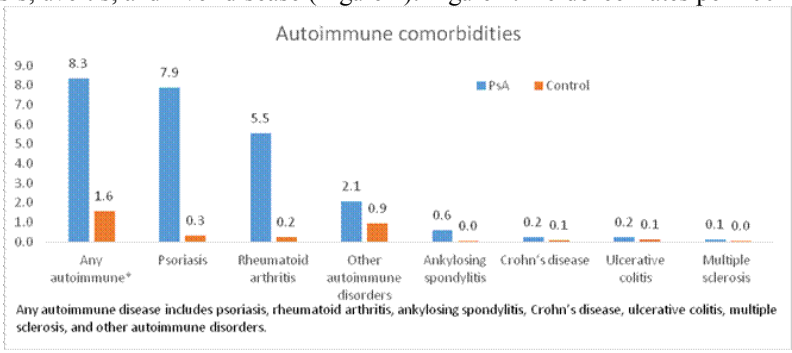
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

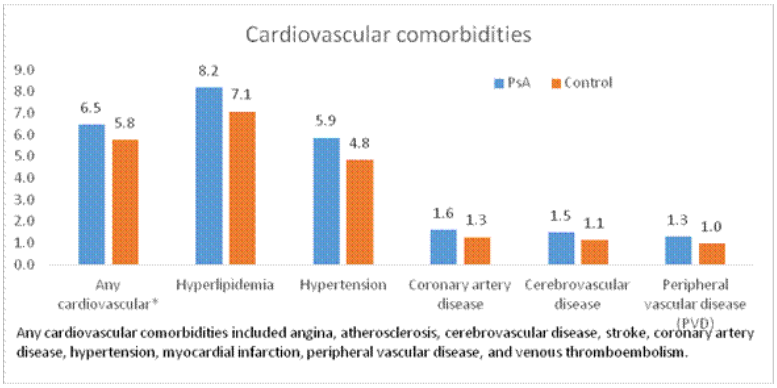
-

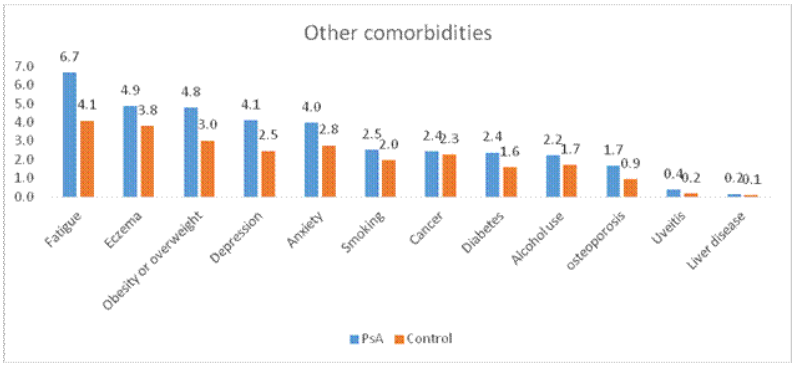
Background/Purpose: PsA is associated with higher rates of developing certain comorbidities, but little has been done to understand the incidence rates of comorbidities in American populations. This study compared incidence rates of comorbidities between patients with newly diagnosed PsA and a matched control cohort without PsA, using a large national US claims database.

Methods: Adults with ≥1 inpatient or 2 outpatient diagnoses of PsA (ICD-9-CM 696.0) in 1/1/2008 - 9/30/2015 were extracted from MarketScan Commercial and Medicare Databases, with the first PsA diagnosis as the index date. Patients had ≥24 months continuous enrollment prior to the index date (pre-period) and were followed for ≥12 months until the earliest of inpatient death, end of continuous enrollment, or end of the data. These PsA patients were matched on calendar year, age, gender, and geographic region to those with no PsA diagnosis anytime in 2007-2015 (controls). The incidence of new comorbidities (not present in the 24-month pre-period) per 100 person-years was estimated and compared between PsA patients and their controls.

Results: A total of 14,898 PsA patients were matched to 35,037 controls (mean age: 53.4 years for PsA vs. 54.8 for controls; male: 44.6% vs. 44.4%; mean length of follow up: 3.0 vs. 3.0 years). Compared with controls, PsA patients had higher incidence rate of autoimmune disease, cardiovascular disease, fatigue, eczema, obesity/overweight, depression, anxiety, smoking, cancer, diabetes, alcohol use, osteoporosis, uveitis, and liver disease (Figure 1). Figure 1. Incidence Rates per 100 Person-Years of New Comorbidities for PsA vs. Controls







Conclusion: PsA patients had high incidence rates of cardiovascular comorbidities, autoimmune conditions, fatigue, eczema, depression, and anxiety than controls. Understanding these comorbidity profiles will help evaluate the impact of comorbid conditions on disease management and costs associated with PsA.

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Estimates of axial involvement in PsA vary from 25% to 70% depending on the inclusion criteria. Three sets of criteria are available for defining inflammatory back pain (IBP) in Ankylosing Spondylitis (AS): Calin, Rudwaleit and ASAS criteria. We aimed to determine whether these criteria are useful screening tools for axial involvement in PsA and to describe the clinical features in PsA patients with IBP, mechanical back pain (MBP), no Back Pain (BP) and silent BP.

Methods: Patients with PsA have been followed prospectively at 6-12 month intervals according to a standard protocol since 1978. Radiographs of peripheral joints and spine are performed at 2 year intervals. All data are tracked in a computerized database. From the database we extracted data at the first visit since 2010 on the presence of back pain, as well as criteria for IBP (Calin, Rudwaleit and ASAS). At each visit a rheumatologist also recorded whether a patient had back pain, and whether it is inflammatory or mechanical based on independent clinical judgement. We tested the agreement between physician assessment (presence or absence of IBP) and IBP criteria. Patients whose radiographic changes met the New York (NY) Criteria for AS or had any radiographic changes consistent with sacroiliitis and/or syndesmophytes on x-ray and/or MRI were analyzed for the agreement with the presence of any BP, IBP by physician assessment, and fulfilling IBP criteria, using the Kappa coefficient. MRI was done only if there was a suspicion of axial involvement but the x-rays were negative. Descriptive statistics are provided.

Results: 171 patients were identified from the database. The patients were mostly male (52%), mean age of onset of PsA was 43.3±13.6, and mean age at first PsA clinic visit was 46.6±13.0 years. All patients had radiographic data available at clinic entry. The prevalence for BP was 56.2% (IBP 38.01%; MBP 18.12%). 27 out of 171 (15.79%) patients with baseline x-rays fulfilled the NY radiographic criteria for AS. 45 out of 171 (26.32%) patients had any radiological sacroiliitis and/or syndesmophytes. 9 out of 31

(29.03%) patients with no axial disease on x-ray had evidence of axial disease on MRI. 18 (24.0%) of the patients with no back pain had "silent" BP (evidence of axial disease on radiology (x-ray or MRI)). The agreement (kappa coefficient) between physician assessment and IBP criteria in all patients was highest for the Calin criteria (0.81, 95% CI (0.72, 0.91)), followed by the ASAS criteria (0.72, (0.61, 0.81)), and the Rudwaleit criteria (0.71, (0.59, 0.83)). There was no significant agreement between the presence of radiographic NY criteria and the presence of back pain, physician assessment of IBP, or the IBP criteria. There was also no agreement between physician assessment of IBP and any radiographic change (syndesmophytes or sacroiliitis of at least Grade 2). Mean BASMI, BASDAI, and BASFI were highest in PsA patients with IBP than those with MBP, no BP or "silent" BP.

Conclusion: Patients with PsA report less back pain than AS patients. The low level of agreement between physician assessment and radiological presence of axial PsA indicates that we should consider axial imaging in all patients with PsA regardless of the presence of the nature of BP.

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The feet are commonly affected in patients with psoriatic arthritis which cause impairment and disability. The purpose of the study is to assess the static and dynamic balances in PsA and to investigate their relation with clinical, functional and radiological parameters of feet.

Methods: Patients diagnosed with PsA according to CASPAR criteria and healthy controls were recruited consecutively into the study. The age, sex and body mass index (BMI) of the cases were recorded as demographic data. The disease activity was assessed by DAS-28 and PASI scores. Fear of falling and falling history in the recent year were recorded. Radiographic assessments of feet were done to consider the deformities (pes planus, hallux valgus, metatarsus primus valgus etc). 'Foot and Ankle Outcome Score' (FAOS) was applied for foot function assessment. The fatigue (Multidimentional Assessment of Fatigue: MAF), depression (Beck Depression Inventory: BDI) and sleep disorders (Pittsburgh Sleep Quality Index (PSQI) of all patients were evaluated. The state of balance of the patients was evaluated by means of 'Berg Balance Scale' (BBS) and also 'Modified Clinical Test of Sensory Interaction and Balance' and 'Unilateral Stance' tests were performed for static balance assessment, 'Step Up/Over' and Tandem Walk' tests were performed for dynamic balance assessment via the '*Neurocom Balance Master*' device available in our clinic.

Results: This study included 100 subjects that consist of 50 PsA patients (40 female) and 50 healthy controls (40 female) and their mean ages were 45.02 (SD:12.81) and 45.12 (SD:10.56) years, respectively. Age, sex and BMI data of both groups were similar. The mean score of DAS-28 and PASI of patients were 3.45 (SD: 0.87) and 7.80 (SD:1.05), respectively. Concerning the balance tests, there were significant differences ($p<0.05$) between patient and control groups about the all tests of sway velocity (except on firm and foam surface), eyes closed test, end sway of tandem walk test, movement time of bilateral step up over test and lift up index of left step up over test. There were not significant correlation of static and dynamic balance parameters with MAF, BDI, PSQI, falling history, fear of falling, DAS28 and PASI. The foot deformities according to X-ray assessment had not significant correlation with FAOS and balance parameters.

Conclusion: The static and dynamic balance disorders are increased in PsA. Because of the balance parameters had not significant

correlation with functional and clinical data they are acceptable as an independent parameters during the course of the disease.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with psoriatic arthritis (PsA) are associated with higher cardiovascular (CV) risks. The efficacy of established CV risk scores for predicting CV risks in PsA patients is unknown. The aim of this study is to evaluate the efficacy of different CV risk scores and their European League Against Rheumatism (EULAR) modified versions for discriminating the presence of coronary atherosclerosis evaluated by coronary Computed Tomography Angiography (CTA) in PsA patients.

Methods: Four different CV risk scores namely Framingham risk score (FRS), American College of Cardiology and American Heart Association (ACC/AHA) 10-year atherosclerotic cardiovascular disease (ASCVD), QRISK II and SCORE, together with their EULAR recommended modified versions (1.5 multiplication) were calculated. Presence of overall plaque (P+) and mixed plaque/non-calcified plaque (MP/NCP+), were identified by CTA.

Results: 88 PsA patients [50 ¡Ó 11, male: 54(61.4%)] underwent CTA were recruited. 84, 74, 88 and 88 patients were eligible to calculate FRS, ASCVD, QRISKII and SCORE respectively. All CV risk scores were significantly higher in both P+ and MP/NCP+ patients [FRS: P+ (13.5 ¡Ó 8.7 vs 6.5 ¡Ó 5.3; p<0.001), MP/NCP+ (13.7 ¡Ó 9.0 vs 7.4 ¡Ó 5.7; p<0.001); ASCVD: P+ (7.0 ¡Ó 5.3 vs 3.4 ¡Ó 3.4; p<0.001), MP/NCP+ (7.1 ¡Ó 5.5 vs 3.9 ¡Ó 3.6; p=0.005); QRISKII: P+ (9.6 ¡Ó 7.8 vs 6.4 ¡Ó 6.6; p=0.047), MP/NCP+ (9.9 ¡Ó 8.2 vs 6.5 ¡Ó 6.3; p=0.035); SCORE: P+ (1.4 ¡Ó 1.4 vs 0.5 ¡Ó 0.8; p=0.001), MP/NCP+ (1.4 ¡Ó 1.4 vs 0.6 ¡Ó 1.0; p=0.004)]. Areas under the receiver operating characteristic (ROC) curves, differentiating P+ and MP/NCP+, were 0.77 (0.67 ¡V 0.88 p<0.001) and 0.73 (0.62 ¡V 0.84 p<0.001) for FRS, 0.76 (0.636 ¡V 0.87 p<0.001) and 0.72 (0.60 ¡V 0.84 p=0.001) for ASCVD, 0.65 (0.53 ¡V 0.78, p=0.018) and 0.64 (0.52 ¡V 0.76 p=0.026) for QRISKII, 0.72 (0.614 ¡V 0.831 p<0.001) and 0.68 (0.56 ¡V 0.79 p=0.005) for SCORE, respectively. 38(45.2%), 23(31.1%), 6(6.8%) and 1(1.1%) patients were classified as having high CV risks according to FRS>10%, ASCVD>7.5%, QRISK II>20% and SCORE>5% respectively. By applying the EULAR multiplication factor, 51(60.7%), 32(43.2%), 22(25%) and 4(4.5%) patients were reclassified as having high CV risks. The sensitivity of FRS>10% increased from 56.9% to 76.5% for P+ (Figure 1), and from 53.3% to 75.6% for MP/NCP+ (Figure 2). Other risk scores generally underestimated coronary atherosclerosis (Figure 1&2).

Conclusion: FRS was better correlated with coronary atherosclerosis than other CV risk scores. EULAR modification further improved the sensitivity of FRS.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory arthritis characterized by enthesitis, that primarily affects the spine and sacroiliac joints. While several studies had described sensorineural deafness in AS patients, conductive hearing loss has

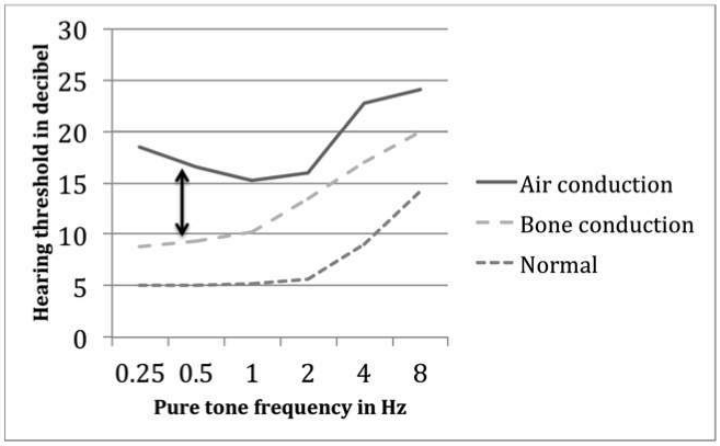
been reported as rare. We studied the prevalence hearing loss (HL) among patients with ankylosing spondylitis.

Methods: We studied 100 patients of ankylosing spondylitis fulfilling modified New York criteria after excluding patients with coexisting external and middle ear pathology. Pure tone audiometry was done in recruited patients. Hearing loss was considered to be present when the audiometric tests disclosed pure-tone thresholds greater than 20 dB (decibel) in at least 2 frequencies (0.25, 0.5, 1, 2, 4, 8 kilohertz (kHz)) of the audiogram. Mild, moderate, moderately-severe, severe and profound hearing loss were defined as hearing loss range 25-40, 40-55, 55-70, 70-90, >90 dB respectively. Clinical details such as age, disease duration, BASDI, BASFI, BASMI, cumulative NSAID dose etc. were noted of each patient. Cumulative NSAID dose was calculating using defined daily dose as given by WHO. All variables are expressed as median (25^{th} -75^{th} Interquartile range)

Results: Ninety-six of the 100 patients were male and the median age was 32 (23-42) years and median duration of illness was 6 (2-12) years. Median BASDAI, BASFI, BASMI and cumulative NSAID dose were 3(1.7-4.9), 2(1-4.15), 3.6(1.6-5.5) and 726 (210-1825) respectively. Of the 48 with hearing loss 28 patients had bilateral hearing loss. Twenty-nine patients had pure conductive hearing loss while 16 had mixed hearing loss (components of both sensory and conductive) and only 3 had pure sensory neural hearing loss. Hearing loss was mild in 38 patients while 10 had moderate to severe hearing loss. Presence of hearing loss was associated with higher age ($p=<0.05$). Conductive HL, when present, was at low frequency (0.25, 0.5, 1 kHz) in 70% cases. Sensorineural HL, when present, was at high frequency (4, 8 kHz) in 75% cases. Mean air and bone conduction of the patients in comparison to normal for age is depicted in Figure-1. There was no association of hearing loss with BASMI, BASDI, BASFI or cumulative NSAID dose.

Conclusion: Hearing loss is common among patients of ankylosing spondylitis (Table-1) and it is predominantly conductive type. HL is usually mild and occurs at low frequency.

Figure 1 Air and Bone conduction of AS patients



AS patients had a wide Air-Bone gap (arrow) suggestive of conductive hearing loss at low frequency

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The ASAS classification criteria have provided new insights in the classification of axial SpA. Some studies suggested different characteristics between the imaging and clinical arms of axial SpA particularly in response to biologics. However, available data is still limited and additional information is required. We present our results in a large group of patients with non-radiographic axSpA (nr-axSpA).

Methods: Patients were recruited from two centers with dedicated programs in SpA. Among the registries of these institutes patients coded as nr-axSpA were identified. Two rheumatologist from each center re-scored the X-rays and excluded those with diagnostic changes of AS. SIJ MRI readings were done according to ASAS recommendations. Clinical and laboratory characteristics were then obtained for each group from the clinical database. Patients were stratified into imaging and clinical arms based on the clinical, imaging and laboratory findings. The imaging arm was further stratified into B27- and B27+ groups.

Results: There were a total of 200 nr-axSpA patients in the combined cohorts. The mean age and disease durations were 38±11.1 and 9.1±8.1 years respectively. 44.5% were male and 59% were HLA-B27-positive. There were 147 (73.5%) and 53 (26.5%) patients in the MRI-positive and clinical arms respectively. 28.6% of the patients have been treated with biologics. Comparison of imaging vs clinical arms of nr-axSpA demonstrated that age, sex, disease duration, BASDAI, BASFI and BASMI indices were similar between the groups. Uveitis and psoriasis were significantly increased in the clinical arm group. In contrast, increased acute phase reactants and

good response to NSAIDs were more prevalent in the imaging arm. Other variables such non-response to biologics were distributed evenly between the groups (Table-1). We compared B27+ vs B27- imaging patients and clinical arm patients (all B27+ by definition). Age, sex distribution and disease durations were similar between these three groups. Increased acute phase reactants and good response to NSAIDs were higher in the both imaging groups compared to clinical arm patients. Biological utilization rates, family history and presence of uveitis were higher in all B27+ patients regardless of whether they were in the clinical or imaging arm. The remainder of the extra-articular features, BASDAI, BASFI and BASMI levels and non-response to biologics were comparable between the three subsets (Table 1).

Conclusion: In this large cohort of nr-axSpA patients the clinical characteristics of nr-axSpA patients classified by the imaging vs clinical arms were comparable. It was of note that there was a comparable TNFi failure due to lack of response in both groups despite the higher CRP in the imaging arm. Our findings provide real world clinical support for the validity of the clinical arm for the classification of nr-axSpA.

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthropathies include a group of disease which have similar clinical, radiographic and genetic features. Uveitis, psoriasis (PsO) and inflammatory bowel disease (IBD) are common extra-articular manifestations (EAMs) in spondyloarthritis and an important part of the ASAS classification criteria for axial and peripheral spondyloarthritis which has an influence on treatment choices. The aim of this study is to compare the burden of disease and clinical features in the patients with axial spondyloarthritis (axSpA) with and without EAMs.

Methods: Adult patients from Erciyes SpA cohort who met ASAS classification criteria for axSpA were included. Patients were assigned into two groups according to having EAMs (uveitis and/or IBD and/or PsO, all were proven by the related specialists). Radiographic axSpA was defined on the basis of presence of at least bilateral grade 2 sacroiliitis according to modified New York criteria, decided by the consensus of three rheumatologists. Patients' demographic and clinical data including symptom duration, VAS-pain, patient's and physician's global assessment, BASDAI were recorded. Short form-36 (physical and mental components, SF-36 PCS/MCS), health assessment questionnaire (HAQ) and ankylosing spondylitis quality of life questionnaire (ASQoL) were used to assess QoL and disability and hospital anxiety and depression scale (HADS) for psychological status. Anthropometric measurements included cervical rotation, tragus-to-wall distance (TWD), chest expansion, lumbar lateral flexion and Schober's test.

Results: A total of 591 patients with axSpA were included, 124 patients (%21) had EAMs (EAM +ve) and 467 patients (%79) did not have EAMs (EAM -ve). Demographic data and all anthropometric measurements were similar between EAM +ve and EAM -ve patients, except for TWD which was higher in EAM +ve patients (whole axSpA, p=0.034 and r-axSpA, p=0.002). EAM +ve patients had higher frequency of HLA B27 and peripheral arthritis than EAM –ve patients in the whole axSpA (p=0.031 and p=0.003, respectively) and r-axSpA (p=0.036 and p=0.001, respectively) groups.

Conclusion: EAMs positive and negative patients with r-axSpA differs in terms of HLA B27 and peripheral arthritis, however subgroups of patients with nr-axSpA and r-axSpA with or without EAMs have similar burden of disease.

Table. Demographic and clinical data in patients with axSpA, nr-axSpA and r-axSpA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory low back pain (IBP) is the important presenting symptom in patients with axial spondyloarthritis (axSpA). Three criteria sets for IBP are frequently assessed in terms of discriminative ability from mechanical LBP, however the gender specific discriminative value of these criteria sets has not been investigated yet. Therefore the aim of this study was to evaluate gender differences in discriminative value of IBP criteria in a patient population of axial spondyloarthritis and non-spondyloarthritis chronic low back pain.

Methods: Adult patients with a history of chronic LBP (> 3 months) and age of onset less than 45 years were screened for ASAS criteria for axial spondyloarthritis (axSpA). Those who were between 18-50 years and met the axSpA criteria were assigned as axSpA group and those who did not met these criteria were assigned as non-SpA chronic LBP group. All of the patients were also screened for the items of IBP criteria according to the Calin, Berlin and ASAS criteria definitions. Receiver operating characteristic (ROC) curve analysis were performed for all the separate items and the criteria as a whole in both male and female patient groups. Area under the curve (AUC) were calculated for each item and criteria sets and statistically compared by using the De Long method.

Results: A total of 136 patients (59 women) with axSpA and 111 patients (48 women) with non-SpA LBP were included. In women, AUC was the highest for insidious onset 0.94 (95% CI 0.88-0.98), followed by alternating buttock pain 0.82, improvement with exercise 0.74, no improvement with rest 0.72, age at onset ≤ 40 years 0.68, morning stiffness > 30 min 0.67, improvement with exercise/not rest 0.66, morning stiffness 0.65, and awakening (second half of the night) because of pain 0.62 with the least value. In men, AUC was the highest for insidious onset 0.87 (95% CI 0.80-0.92), followed by morning stiffness 0.78, no improvement with rest 0.77, alternating buttock pain 0.75, improvement with exercise 0.698, improvement with exercise/not rest 0.696, morning stiffness > 30 min 0.668, awakening (second half of the night) because of pain 0.63, and age at onset ≤ 40 years 0.51 with the least value. AUC values for items in men were relatively lower than women. Similarly, the AUC values for IBP criteria sets were relatively lower in men compared to women. Also comparison of AUC values revealed that Calin criteria had significantly higher values compared to Berlin and ASAS criteria in both genders.

Conclusion: The AUC values revealed that discriminative ability of criteria sets were fair to excellent. All criteria items and sets perform similarly in both genders however criteria items perform relatively better in women than men. Also Calin criteria perfume significantly higher than Berlin and ASAS criteria in both genders.

Table Comparison of AUCs of different criteria sets in men and women

	axSpA vs non-SpA LBP n=136 vs n=111
Men	**AUC (95%CI)**
CALIN (1)	0.87(0.80-0.92)
BERLIN (2) n=76 vs n=59	0.77(0.70-0.84)
ASAS (3) n=76 vs n=60	0.71(0.62-0.79)
1 vs 2, p value	0.0021
1 vs 3, p value	0.0001
2 vs 3, p value	0.058
Women	
CALIN (1) n=57 vs n=47	0.93(0.87-0.97)
BERLIN (2) n=57 vs n=47	0.80(0.71-0.88)
ASAS (3) n=57 vs n=40	0.79(0.70-0.87)
1 vs 2, p value	0.003
1 vs 3, p value	0.0002
2 vs 3, p value	0.949

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Few studies have evaluated the relationship between disease activity/clinical response and patient-reported outcomes (PROs) of pain, fatigue, health-related quality of life (HRQoL), and work productivity in patients with non-radiographic axial spondyloarthritis. In post hoc analyses of findings of the EMBARK study, this association was assessed in patients with active, NSAID-resistant, nr-axSpA.[1-3] (ClinicalTrials.gov identifier: NCT01258738).

Methods: Patients who satisfied Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA (not modified NY radiographic criteria) were randomized to receive etanercept (ETN) 50 mg/wk or placebo (PBO) to wk 12, followed by ETN 50 mg/wk to wk 104. Patients were grouped based on Ankylosing Spondylitis Disease Activity Score (ASDAS) disease activity state (inactive disease [ID] vs active disease) and ASAS40 response (responders vs non-responders) at wk 12 and 104 regardless of treatment group assignment. Changes in least square (LS) means for PROs of pain, fatigue, HRQoL, and work productivity from baseline (BL) to wk 12 and 104 were compared between groups in the modified intent-to-treat (mITT) population with observed cases (ANCOVA; no imputation of missing data).

Results: At wk 12, 61/214 (29%) of patients receiving ETN or PBO achieved ASDAS-ID; 51/213 (24%) achieved ASAS40 response. At wk 104, 123/205 (60%) of patients overall achieved ASDAS-ID and 121/205 (59%) were ASAS40 responders. Patients with ASDAS-ID at wk 12 and 104 had significantly less BL pain and greater HRQoL (SF-36 PCS and AsQoL) than those with active disease; those achieving ASDAS-ID at wk 104 had better BL EQ-5D (P<0.05, all). ASAS40 responders at wk 12 had significantly less total back pain and better health utility (EQ-5D) at BL vs non-responders; ASAS40 responders at wk 104 had significantly less pain and greater

HR-QoL (SF-36 PCS) at BL ($P<0.05$, all). Significantly greater improvements were observed in pain/fatigue (nocturnal back pain, MFI general fatigue), utility (EQ-5D VAS), HR-QoL (SF-36 and ASQoL), and work productivity (WPAI-AS presenteeism) among patients with ASDAS-ID vs active disease (table). ASAS40 response was similarly associated with significantly greater improvements in these PROs.

Table. Changes in LS means from BL to wk 12 and wk 104 for PROs in nr-axSpA patients with ASDAS inactive vs active disease.

PRO	LS Mean Change (SE)			
	Wk 12		Wk 104	
	ASDAS Inactive Disease	ASDAS Active Disease	ASDAS Inactive Disease	ASDAS Active Disease
Nocturnal back pain (0–10 VAS)	-4.1† (0.3)	-1.0 (0.2)	-4.6† (0.2)	-2.1 (0.2)
MFI general fatigue (4-20)	-2.2* (0.4)	-0.5 (0.3)	-4.6† (0.4)	-0.5 (0.5)
EQ-5D (0–100 VAS)	20.6† (2.5)	1.9 (1.6)	26.9† (1.4)	12.0 (1.9)
SF-36 PCS (0–100)	9.3† (0.8)	3.0 (0.5)	13.1† (0.6)	4.7 (0.9)
SF-36 MCS (0–100)	4.7 (1.2)	2.1 (0.8)	6.3† (0.9)	0.5 (1.2)
ASQoL (0–18)	-3.7† (0.5)	-1.3 (0.3)	-5.6† (0.3)	-1.8 (0.5)
WPAI-AS absenteeism (0–100% work time missed)	-7.4 (3.4)	0.0 (2.5)	-8.8 (0.8)	-7.3 (1.4)
WPAI-AS presenteeism (0–100% impairment while working)	-27.1† (3.6)	-4.7 (2.6)	-28.8† (2.0)	-9.5 (3.7)

*$P\leq0.001$; †$P\leq0.0001$ ASQoL, ankylosing spondylitis quality of life; EQ-5D, EuroQol 5-Dimensions; MCS, mental component summary; MFI, Multidimensional Fatigue Inventory; PCS, physical component summary; VAS, visual analog scale; SF-36, 36-item Short Form Health survey; WPAI-AS: Work Productivity and Activity Index in ankylosing spondylitis

Conclusion: In patients with early, active nr-axSpA and an inadequate response to NSAIDs who participated in the EMBARK study, achievement of inactive disease and clinical response were associated with meaningful improvements in PROs of pain, fatigue, and HRQOL. Moreover, improvement in patients' symptoms resulted in improvement in their capacity to work. **References:** 1. Dougados M, et al. *Arthritis Rheum* 2014;66:2091-102. 2. A Modification of the Psoriatic Arthritis Disease Activity Score (mPASDAS) Using SF-12 As a Measure of Quality of Life

Matthew Got[1], Suzanne Li[2], Anthony V. Perruccio[3,4], Dafna D Gladman[1] and Vinod Chandran[5], [1]University of Toronto, Toronto, ON, Canada, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [3]Krembil Research Institute, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [4]Arthritis Program, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [5]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The Psoriatic Arthritis Disease Activity Score (PASDAS) is a newly developed composite disease activity measure that summarizes psoriatic arthritis (PsA) disease activity with a score ranging from 0-10. PASDAS captures articular and extra-articular manifestations of the disease and the impact of the disease on the patient via the following variables: swollen and tender joints, dactylitis, Leeds enthesitis index, C-reactive protein, physician and patient global disease activity, and the physical component summary score (PCS) of the medical outcomes survey Short Form 36 (SF-36). A limitation of PASDAS is that the score depends on the patient completing the SF-36, which requires significant time to complete. A shorter 12-question subset of SF-36, the SF-12, with the same range of values, agrees well with the SF-36 in many patient populations. The current objective was to measure the agreement between PASDAS calculated using the standard scoring formula and a modified PASDAS (mPASDAS) calculated by replacing the SF-36-PCS with SF-12-PCS in the scoring formula.

Methods: 100 patients meeting CASPAR criteria for PsA attending a PsA clinic for follow-up visits were consecutively recruited in June and July 2015. All variables required to calculate PASDAS were collected and PASDAS was calculated for each patient. The 12 item responses for SF-12 were extracted from the SF-36 questionnaires. The mPASDAS was subsequently calculated based on the PASDAS scoring formula where SF-36 –PCS was replaced by SF-12 - PCS. A Bland-Altman plot of the mean differences in scores calculated for PASDAS and mPASDAS measured agreement between the two sets of scores. The misclassification of patients based on disease activity as measured with mPASDAS compared to the classification based on the original PASDAS was also determined.

Results: An analysis of 100 patients [53% male, mean (SD) age 57.3 (11.9) years, mean (SD) disease duration 16.9 (11.7) years] revealed that the mean (SD) PASDAS was 3.29 (1.39) and the mean (SD) mPASDAS was 3.24 (1.27). The Bland-Altman plot produced a mean difference (95%CI) between mPASDAS and PASDAS of -0.05 (-0.07, -0.03). The lower limit of agreement was -0.24 (95%CI -0.21, -0.28) and the upper limit was 0.14 (95%CI 0.10, 0.17). The validity of the limits of agreement was supported by a number of normality tests indicating normally distributed differences. No relationship between the differences and the mean values of the scores exist indicating these limits of agreement are valid across the full range of the measures. Discrepancies were seen in 5 out of the 100 cases resulting in a misclassification rate of 5%. PASDAS classified 33 cases as low disease, 42 cases as moderate disease, and 25 cases as high disease. Using the same cutoff scores, mPASDAS classified 34 cases as low disease, 43 cases as moderate disease, and 23 cases a high disease.

Conclusion: The mPASDAS and PASDAS show strong agreement without clinically significant systematic bias in mPASDAS scores. In clinical settings, the mPASDAS may replace PASDAS in disease activity assessment given the strong agreement, low misclassification rate and significantly reduced patient questionnaire burden.

Immunization with ApoB100 Peptide Vaccine Reduces Atherosclerosis Development in a Mouse Model of Systemic Lupus Erythematosus

Ingrid Yao-Mattisson, Maria Wigren, Gunilla Nordin Fredrikson and Jan Nilsson, Lund University, Malmö, Sweden
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Animal Models - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by impaired self-tolerance causing damage to multiple organs including the cardiovascular system. Current therapies do not decrease the incidence of cardiovascular disease (CVD) in SLE. Previous studies have shown that immunizations with peptides derived from apolipoprotein B (ApoB) reduce atherosclerosis in hypercholesterolemic mice. In the present study we investigated if a vaccine based on the apo B peptide p210 (CVX-

14) can inhibit atherosclerosis in mice with an SLE-like phenotype.

Methods: *:* MRL/*lpr* ApoE$^{-/-}$ mice received subcutaneous injections with PBS, CVX-14 or adjuphos alone at week 6, 9, 11 and 21 of age. Atherosclerosis was assessed by Oil Red O staining of the aorta and plaque inflammation by CD68 immunostaining of aortic root sections and qPCR of carotid arteries. The response to immunization was also assessed by flow cytometry of spleen cells and measurement of antibodies

Results: : Immunization with CVX-14 reduced plaque development in the aorta by 55.5% (p=0.01) and plaque area with positive macrophage staining (CD68) by 66.2% (p=0.005) as compared with the PBS control. Arteries from CVX-14 treated mice were also found to have reduced expression of TNF-a and TGF-b mRNA. Plasma cholesterol was increased in CVX-14 treated mice, but there was no effect on plasma triglycerides, p210 IgG or cytokine levels. Both CVX-14 and adjuphos alone increased the fraction of regulatory T cells in the spleen

Conclusion: Apo B peptide based vaccines represents a possible novel approach for prevention of CVD in SLE that warrants further investigation

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Lupus nephritis (LN) is one of the main causes of morbidity and mortality in SLE. Although a combination therapy using steroids and immunosuppressant such as cyclophosphamide, azathioprine and mycophenolatemofetil has been well established in lupus nephritis, the therapy is often not effective. Establishment of new alternative therapy has been required. Proteasome inhibition by bortezomib has been recently expected to be a novel strategy for LN. However, the precise mechanisms of bortezomib for amelioration of LN have not fully been elucidated to date. Therefore, we conducted this study to clarify the mechanisms of the amelioration for the nephritis in the treatment with bortezomib.

Methods: Bortezomib (0.75 mg/kg) was administered subcutaneously every 3 days to NZB/W F1 mice, and the serum anti-double stranded (ds) deoxyribonucleic acid (DNA) antibody titers and proteinuria levels were monitored every 3 weeks. The kidneys samples were examined histologically or used for real-time quantitative reverse transcription-polymerase chain reaction (RT-PCR) analysis after 18 weeks of treatment. The peripheral blood mononuclear cells (PBMCs) were purified from spleen and used for real-time quantitative RT-PCR analysis. Serum cytokines levels were measured using flow cytometry. Anti-ds DNA antibody was measured by enzyme-linked immunoassays (ELISA). Immunohistochemical analysis was performed in the kidneys samples using antibodies to transforming growth factor (TGF)-β, angiotensin II (Ang II), angiotensin II type 1 receptor (AT1R), type I collagen, immunoglobulin G, CD138 and CXCL-13.

Results: Bortezomib reduced both the serum anti-dsDNA antibody titers and the proteinuria levels in the lupus prone mice. It prevented inflammatory cell infiltrations into and the deposition of immunoglobulin G within the glomeruli. Bortezomib reduced the interferon-g,

interleukin (IL)-4, and IL-10 levels in both the serum and the ribonucleic acid expression levels for these cytokines in the PBMCs. Bortezomib reduced the number of CD 138 positive plasma cells in the glomeruli by downregulating CXCL-13. It prevented type I collagen synthesis by downregulating the expression of TGF-b, Ang II and AT1R, which are involved in renin-angiotensin system (RAS) related molecules.

Conclusion: Bortezomib is an effective therapeutic reagent for LN through multiple mechanisms such as suppressive effects aginst cytokines production, chemokines production, antibodies production, and RAS. In particular, the suppressive effects on the formation of the fibrosis characterized by type I collagen synthesis by downregulating RAS related molecules may be beneficial in the treatment of refractory SLE patients who have refractory LN.

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous clinical data has shown that transplantation of umbilical cord mesenchymal stem cells (UC-MSCs) could effectively alleviate the disease symptoms in both patients with active and refractory systemic lupus erythematosus (SLE). Although MSCs isolated from different tissues were reported to possess immunomodulatory functions, it remains unknown whether they have comparable therapeutic effects in treating SLE patients. Here, employing the SLE mouse model, we assessed and compared the abilities of human UC-MSC, amniotic fluid MSC (AF-MSC), periodontal ligament stem cell (pDLSCs) and dental pulp stem cells (DPSCs) to treat SLE mouse model.

Methods: SLE-like B6.lpr mice were administered MSCs intravenously at age 25 weeks, while the control group received fibroblast-like synoviocytes (FLS). All mice were sacrificed at age 35 weeks. Anti-dsDNA antibody and ANA in the plasma were determined by ELISA. The frequencies of Th1, Th2, Treg, Th17, Tfh, Tfr and plasma cells were determined by flow cytometry. The pathology of kidney was analyzed by H&E and anti-IgG/IgM/C3 immunofluorescence.

Results: We found that all the four kinds of MSCs could significantly ameliorate the pathology of lupus nephritis and serological changes in B6.lpr mice. However, mice treated with UC-MSC and DPSCs prolonged the life span better than AF-MSC and pDLSCs. The concentration of anti-dsDNA antibody was reduced, especially in UC-MSC and DPSCs treated mice. The percentages of Th1 cells reduced after MSCs transplantation except AF-MSC treated group. The proportion of Treg only increased in UC-MSC treated group.

Conclusion: UC-MSC might be the optimum choice for SLE treatment.

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an inflammatory autoimmune disease, involving in dysfunction of many organs. The abnormality of apoptosis plays an important role in the pathogenesis of SLE. Umbilical cord (UC)-derived mesenchymal stem cells (MSCs) have been confirmed to exert therapeutic effects on SLE. However, whether the benefit effects of UC-MSCs on SLE were mediated by regulating apoptosis remains to be elucidated. Mesenchymal stem cells (MSCs) have recently been used successfully in humans to control a lot of diseases. However, the mechanisms involved in their immunomodulatory effects remain a matter of debate. Here we explored whether lymphocytes apoptosis involved in the therapeutic effects of UC-MSCs in lupus mice.

Methods: One million human umbilical cord derived MSCs (UC-MSCs) were injected into B6.lpr mice via tail vein and 6 hours, 24 hours and four weeks later, all the mice were sacrificed, the apoptosis of lymphocyte in peripheral blood and spleen tissues as well as the expressions of Bim and Bcl-xl were detected by FACS, the immune cell subpopulations and cytokines in serum were also examined at 6 hours and 24 hours, respectively. The curative effects were assessed 4 weeks later.

Results: UC-MSCs ameliorated disease progression of lupus mice, by regulating the percentage of immune cells, decreasing spleen weight and repairing kidney lesion. UC-MSCs promoted the lymphocyte apoptosis in peripheral blood and spleen tissues at 6 hours and 24 hours, reduced serum TGF-β1 levels, but did not affect Bim and Bcl-xl expressions in CD4+ and CD8+ T cells. Meanwhile, the percentage of Treg was significantly increased in MSCs transplantation group at both 6 and 24 hours. Reductions in the proportions of plasma cells, Th1,Th2 cells were also evident at 24 hours after MSCs infusion, while the levels of Tfh and Th17 cells had no significant change among different groups neither at 6 hours nor 24 hours.

Conclusion: MSCs may promote the apoptosis of T cells in lupus mice through regulating the immune cell subpopulation, decreasing total TGF-β1 in serum. Bim and Bcl-xl are not involved in it.

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: CC-292 and CC-90008 are covalent Btk/Tec family kinase inhibitors that block Btk activity by binding with high affinity to the adenosine triphosphate (ATP) binding site of Btk and forming a covalent bond with cysteine 384 in the target Btk protein, providing rapid, complete, and prolonged inhibition of Btk activity. Despite similar inhibitory potencies towards Btk enzyme inhibition, CC-292 and CC-90008 differ significantly in their impact on B and T cell, basophil, monocyte, and mDC functions. The objective of this study was to compare the efficacy of two covalent modifiers of Btk/Tec family kinases with different, but overlapping in vitro functional immunoprofiles in the MRL/lpr model of SLE and determine which in vitro immunocyte functions best translate to pathological endpoints.

Methods: Immunoprofiling of B cell function was measured by proliferation, plasmablast differentiation, IgG and IL-6 production, and surface expression of activation markers (CD86, CD40, CD54, and CD69). T cell function was measured by proliferation, and cytokine production. CD8 T cell and NK function was measured by degranulation assays. Monocyte/macrophage and basophil activity was measured by Fcγ Receptor-mediated TNFα production and FcεR-mediated degranulation, respectively. Osteoclast and dendritic cell effects were each assessed by differentiation endpoints from precursor cells. Pathology in the MRL/lpr SLE model was assessed by body, spleen, and lymph node weight gain, dsDNA and ANA autoantibody titers, skin lesions, and kidney function (proteinurea) and lesions (histological assessment).

Results: In vitro, CC-292 and CC-90008 were most similar in their ability to inhibit plasmablast differentiation, antibody secretion, basophil IgE degranulation, T-cell cytokine inhibition, and osteoclastogenesis. Differences were observed in that CC-292 inhibited macrophage Fcγ-induced TNFα, mDC differentiation and weakly inhibited T-cell proliferation, while CC-90008 had no effect on these macrophage and mDC functions and strongly inhibited T cell proliferation. In the MRL/lpr SLE model, CC-292 and CC-90008 both reduced dsDNA and ANA autoantibody titers, proteinurea and kidney pathology. In contrast, CC-90008 inhibited increases in body weight, skin lesions, splenomegaly, and lymphadenopathy, while CC-292 had only partial effects.

Conclusion: The in vitro immunophenotyping of CC-292 and CC-90008 on immunocyte function had translatable correlates to SLE pathology in the MRL/lpr model. While plasmablast differentiation and antibody production correlated with in vitro B cell measures and in vivo autoantibody and kidney pathologies, the in vitro T-cell functions correlated with splenomegaly, lymphadenopathy, and skin pathology. These results indicate that while BTK and associated antibody and kidney function treat an important part of lupus pathology, activity associated with T-cell inhibition may be required for effects on skin and secondary lymphoid organ pathology.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Animal Models - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Dysregulation of innate and adaptive immune responses contributes to the pathogenesis of systemic lupus erythematosus (SLE) and its associated premature vascular damage. To date, no drug targets both systemic inflammatory disease and the cardiovascular complications of SLE. Tofacitinib is a Janus kinase (JAK) inhibitor that blocks signaling downstream of multiple cytokines implicated in lupus pathogenesis. While clinical trials have shown that tofacitinib exhibits significant clinical efficacy in various autoimmune diseases, its role in SLE and on its associated vascular pathology remains to be characterized.

Methods: MRL/*lpr*lupus-prone mice received tofacitinib or vehicle by gavage for 6 weeks (therapeutic arm) or 8 weeks (preventive arm). Nephritis, skin inflammation, serum autoantibody levels and cytokines, mononuclear cell phenotype and gene expression, neutrophil extracellular trap (NET) release, endothelium-dependent vasorelaxation and endothelial differentiation were compared in treated and untreated mice.

Results: Treatment with tofacitinib led to significant improvement in measures of disease activity including nephritis, skin inflammation, and autoantibody production. In addition, tofacitinib treatment reduced serum levels of pro-inflammatory cytokines and interferon responses in splenocytes and kidney tissue. Tofacitinib also modulated NET formation and significantly increased endothelium-dependent vasorelaxation and endothelial differentiation. The drug was effective as both preventive and therapeutic strategies

Conclusion: Tofacitinib modulates the innate and adaptive immune responses, ameliorates murine lupus and improves vascular function. These results indicate that JAK inhibitors have the potential to be beneficial in SLE and its associated vascular damage.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Animal Models - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: SLE is a chronic inflammatory disease triggered by the deposition of autoantibodies. One of the goals for SLE therapy is to suppress the production of the pathogenic antibodies. Bortezomib (Bz) is a proteasome inhibitor and directly targeting antibody-producing plasma cells. Recently, we reported the first randomized control trial to evaluate the effect of Bz for SLE (Ishii et al.. ACR 2015). In that study, we showed that Bz treatment is associated with many adverse reactions for refractory lupus patients. Previously, several reports showed that Bz was effective on and improved survival rate of lupus model mice. However, since Bz treatments for lupus model mice were initiated around the onset of diseases in these reports, it is not clear whether Bz has therapeutic effect on mice with high disease activity as well as preventive effect on low disease activity. In this study, we examined therapeutic effect of Bz on 14 wks-old (high disease activity) MRL/lpr mice and compared the survival curves of 10 wks-(around disease onset) and 14wks-Bz initiated mice.

Methods:

(1) Female MRL/lpr mice at 10 wks- and 14 wks- (n=8, each) were analyzed for anti-dsDNA antibody, weight of lymph nodes and spleen, and cellular subsets of spleen and bone marrow. (2) MRL/lpr mice (14 wks) were treated with (i) PBS (n=13), (ii) Bz (750ug/kg, twice in a week) (n=12), (iii) cyclophosphamide (Cyc) (1mg/body, once in 2 weeks) (n=15) and analyzed for anti-dsDNA antibody, pathological index of glomerulonephritis and plasma cell number at 24 wks-old. (3) Survival curve of 10 wks- and 14 wks-Bz initiated groups were compared.

Results: MRL/lpr mice at 14 wks-old showed more weight of lymph nodes and spleen (p=0.0015, p=0.0013, respectively), and significantly higher anti-dsDNA antibody titer than those at 10 wks (p=0.033) (Fig-1), indicating higher disease activity at 14 wks old. Both treatments with Bz and Cyc significantly decreased the number of spleen cells (p<0.001, p=0.0136, respectively), glomerulonephritis index (p=0.0017, p=0.0034, respectively). Bz significantly decreased plasma cells (p<0.001) and anti-dsDNA antibody titer (p<0.001), while Cyc did not. In survival curve, 14 wks-Bz initiated group showed significantly higher mortality rate than control and 10 wks group (p=0.014) (Fig-2).

Conclusion: In spite of a therapeutic trial, Bz treatment had more toxic effect on mice with higher disease activity. Understanding the mechanism of the toxicity is important for clinical application of Bz to human SLE.

Suppression of IL-1 Signaling Ameliorates Dermatitis in a Murine Model of Systemic Lupus Erythematosus

Jeremy Tilstra[1], Sheldon Bastacky[2] and Mark Shlomchik[3], [1]Rheumatology, Univ of Pittsburgh Medical Center, Pittsburgh, PA, [2]Pathology, University of Pittsburgh Medical Center, Pittsburgh, PA, [3]Immunology, University of Pittsburgh, Pittsburgh, PA

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a prototypical autoimmune disease defined by autoantibody production, immune dysregulation, and end-organ damage. Our laboratory previously showed that MyD88, a signaling component of IL-1 and Toll-like receptors (TLR) 7 and 9, is a central mediator of SLE pathogenesis. Genetic studies have clearly implicated TLR7 and TLR9 in regulating disease. However, though evidence in humans and mouse models suggests a pathogenic role for IL-1, this has not been directly tested. Data from our laboratory suggest that dermatitis in murine SLE is MyD88 dependent but TLR7/9 independent, differing from systemic manifestations of the disease.

Methods: Tissue homogenates from diseased MRL.Fas^{lpr} (MRL/lpr) mice and non-diseased tissues were evaluated by qPCR. MRL/lpr mice were crossed with IL1R1$^{-/-}$ mice and evaluated initially as an F2 intercross cohort, a validated and rapid method for screening for genetic control of autoimmunity in the context of an autoimmune-predisposing genetic background. Subsequently, the *Il1r1* loss of function allele was backcrossed for 7 generations and then made homozygous; this cohort was analyzed for disease pathology at 16 weeks for females and 19 weeks for males. We evaluated proteinuria, renal histology, dermatitis, ANA, and immune cell activation via flow cytometry.

Results: IL-1β mRNA levels were increased in kidneys of MRL/lpr mice with proteinuria nearly 5-fold compared to non-diseased young MRL/lpr mice ($p=0.05$); and in inflamed skin, IL-1β mRNA levels were elevated nearly 50 fold compared to controls ($p<0.005$). There was no significant difference in proteinuria, glomerulonephritis, ANA production, or spleen size. However, dermatitis was significantly reduced in the IL-1R1 deficient F2 Fas^{lpr} mice ($p<0.008$) compared to littermate controls. This finding was recapitulated in the backcrossed cohort wherein we observed decreased rates of dermatitis in the IL1R1$^{-/-}$ mice compared with littermate MRL/lpr controls.

Conclusion: This study supports the theory that there are differential mechanisms for tissue specific manifestations of systemic autoimmune diseases, specifically, while TLR7/9 regulates systemic manifestations of SLE upstream of MyD88, IL-1 regulates dermatitis. Overall these findings provide evidence that IL-1 signaling is a significant contributor to autoimmune dermatitis in the MRL model and may be a potential target for treating cutaneous lupus manifestations.

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) is a severe complication of systemic lupus erythematosus (SLE). Glucocorticoids (GCs) are recommended by ACR as one of the first line treatments for LN. Long-term clinical use of GCs, however, is associated with an array

of significant side effects. To address this challenge, we have developed a novel macromolecular prodrug (ZSJ-0228) of dexamethasone (Dex) that passively targeted to the kidney, thereby effectively attenuates lupus nephritis with improved safety profile.

Methods: Polyethylene glycol (PEG) was conjugated to Dex via hydrazone (an acid-cleavable linker) to create ZSJ-0228. NZB/W F1 female mice (28 weeks old) received monthly i.v. injection of the prodrug or daily i.v. injection of dose equivalent dexamethasone phosphate sodium for 2 months. The albuminuria level was monitored weekly. The end point serum cytokine panel was analyzed. The bone quality was evaluated using m-CT. The in vivo distribution of ZSJ-0228 was assessed using near infrared (NIR) imaging and the cell phenotypes that sequester the prodrug were investigated using flow cytometry.

Results: When compared to dose equivalent daily Dex treatment, ZSJ-0228 markedly improved the survival of NZB/W F1 mice and is significant more effective in normalizing albuminuria; no significant systemic toxicity of GCs (i.e. WBC reduction, adrenal gland atrophy and osteopenia) was observed in the prodrug treated group; and there was a significantly lower serum level of proinflammatory cytokines (MCP-1, IFN-beta, IL-17A and GM-CSF) after 2 months treatment with ZSJ-0228. NIR imaging showed that the prodrug primarily distributed in inflamed kidneys, and FACS results suggest that the Alexa 488-labeled prodrug was mainly sequestered by intraglomerular mesangial cells and proximal tubule epithelial cells.

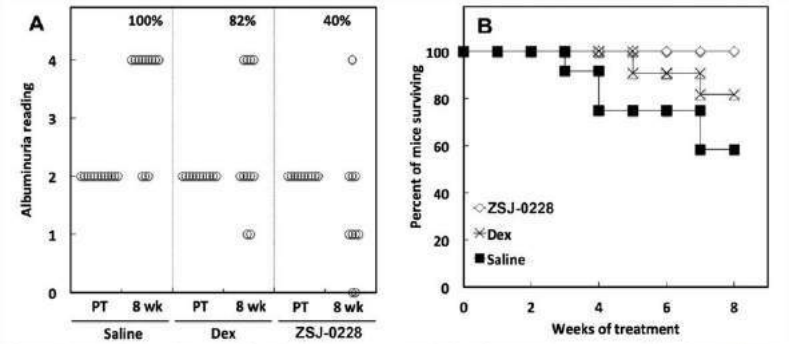

Figure 1. ZSJ-0228 ameliorates albuminuria, improves survival and attenuates severe nephritis in NZB/W F1 mice. (A) Albuminuria reading; (B) Kaplan-Meier survival curve.

Conclusion: Dex prodrug ZSJ-0228 significantly improves the therapeutic efficacy and safety of Dex. Further structural optimization of the prodrug may lead to a new drug candidate for better and safer treatment of lupus nephritis.

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE is a disease that disproportionately affects females. The etiology of the sex bias in this disease is unclear. We previously showed that a functional knockout of estrogen receptor alpha (ERaKO) resulted in significantly reduced renal disease and increased survival in murine lupus. The mechanism of this effect, which requires estrogen, is not known. Interestingly, an ERa-/- (null mutant) mouse is not similarly protected. We and others have demonstrated a role for ERa in dendritic cell (DC) development. Here we

show that selective genetic disruption of ERa in DCs of lupus prone mice results in a survival difference, but only in females, who die prematurely compared with intact females.

Methods: Floxed-ERa and Cre-CD11c strains were backcrossed onto the NZM2410 lupus-prone background for 12 generations. Animals were validated by sorting CD11c+ DCs from Flt3L-cultured bone marrow; CrePos/Floxed-ERa mice had mRNA levels of ERa in DCs reduced by ~90%. Urine and blood were collected at select intervals and mice were sacrificed at 52 weeks, or earlier if they had high proteinuria or >10% weight loss. Spleen cells were isolated and flow cytometry was performed to determine number and subset of DC (cDCs: MHCII+/CD11c++/CD11b+; tolerogenic DCs: MHCII+/CD11c++/CD8a+; and pDCs: MHCII+/CD11c+/B220+/SiglecH+).

Results: n=12 CrePos/Floxed-ERa (DC-specific ERaKO) and n=12 CreNeg/Floxed-ERa animals were entered into the study. There was no significant difference in survival between the 2 groups (males and females). However, considered separately, survival of female lupus prone mice was significantly different. Median age at death was 30.0 weeks (± 1.807) n=6 for the CrePos and 40.4 weeks (± 3.891) n=7 for the CreNeg females ($p<0.042$). At 52 weeks: CrePos (DC-specific ERaKO) 0/6 were alive (0%) vs. CreNeg – 3/7 were alive (43%). Preliminary flow cytometry results revealed decreased percent of CD8a+ tolerogenic DCs in CrePos vs. CreNeg/FloxedERa, as well as increased percent of both CD11c++/CD11b+ cDCs and pDCs in CrePos vs. CreNeg/FloxedERa.

Conclusion: Selective deletion of ERa in DCs of lupus-prone mice results in reduced survival, but only in female animals. These mice had fewer tolerogenic DCs and increased numbers of both inflammatory cDCs and pDCs from spleen, which may partially explain the phenotype. This data joins a growing body of evidence that estrogen and ERa play critical roles in modulating immune cell development and function that impact autoimmune disease.

Session Title: Systemic Lupus Erythematosus – Animal Models - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a prototypic autoimmune disease displaying a heavy female predominance during reproductive years. We have previously shown that toll-like receptor (TLR)7 and TLR8 are significantly up-regulated in peripheral blood mononuclear cells (PBMCs) of SLE patients and further induced with estrogen treatment. Conventionally, TLR7 and TLR8 binding to single-stranded RNA of viral origin to stimulate innate inflammatory responses, but recent studies have discovered that specific micro-RNA (miR) sequences can activate these receptors following packaging and secretion via extracellular

vesicles (EVs). Our objective in this study was to explore the therapeutic potential of using a cocktail of miR antagonists to block TLR7 and TLR8 inflammatory pathways induced by EV-derived miRs in SLE.

Methods: PBMCs were isolated from active SLE patients and adoptively transferred into immunodeficient NOD-scid IL-2rγ (null) mice to produce chimeras containing PBMCs from SLE patients using a similar protocol we have previously established for Sjöjren's syndrome. Prior to transfer, PBMCs were treated with a cocktail of several locked nucleic acid miR antagonists or nonsense, scrambled RNA controls prior to injection. Blood was collected for both flow cytometry and cytokine analysis and tissues were processed for histopathological examination by H&E and immunohistochemistry.

Results: Human T-cells (CD4+ and CD8+), B-cells, monocytes, and NK cells were all successfully recovered from whole blood of chimeric mice at similar levels in both treatment groups 21 days after adoptive transfer. However, inhibition with miR antagonists reduced levels of human IL-2, IL-6, IL-10, and TNF-α relative to scramble (control) treatment. While histopathological analysis revealed little to no inflammation in the skin and ear with either treatment, miR antogonists inhibited the robust responses detected with scramble RNA (control) treatment in the small intestine, liver, and kidney. Further characterization of infiltrates by immunohistochemistry confirmed the presence human CD3+ T-cells.

Conclusion: These data establish a novel human-mouse model to study SLE and provide an experimental platform to further explore the therapeutic potential of suppressing EV-encapsulated miRs that trigger TLR7 and TLR8 signaling.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hyperhomocysteinemia has been correlated with the occurrence of blood clots, heart attacks and strokes. We investigated the association of the Hyperhomocysteinemia with other clinical and laboratory manifestations, in particular with urine protein/creatinine ratio.

Methods: 829 patients with at least one homocysteine measurement since 2014 were included in the analysis. Patients were followed quarterly after cohort entry.

Results: 762 (91.9%) were female. Majority (48.4%) were Caucasian, 42.1% African American. For the first homocysteine measurement, 79.4% were below 15 umol/L. The association of Hyperhomocysteinemia with other clinical and laboratory manifestations is shown in Table 1 and association with organ damage is shown in table 2. Among 829 patients, 604 have at least two homocysteine measurements, 272 have three or more. To account for correlations of measurement within patients, we used GEE model to estimate the association between homocysteine and urine protein creatinine ratio using serial tests of homocysteine. A 10 umol/L decrease in Homocysteine within a person corresponds to an average 0.011 (95% CI:

0.006 to 0.015) unit decrease in urine protein/creatinine ratio (P < 0.0001), after adjusting for sex and ethnicity. The association remains significant (0.004 (95% CI 0.002 to 0.007), P = 0.0005) when only including patients with first homocysteine greater or equal to 15 umol/L and corresponding urine protein creatinine ratio greater or equal to 0.2

Conclusion: homocysteine is showed to be strongly correlated with renal disorder, low GFR and proteinuria. Decreased homocysteine might also indicates improved renal functionality.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sustained complete remission is an independent predictor of good long term prognosis in lupus nephritis (LN). We aimed to examine the predictors of sustained complete renal remission (CR) in patients with LN.

Methods: We reviewed patients with active LN at a single center Lupus Clinic where patients were followed prospectively according to a standardized protocol between 1970 and December 2015. We identified the patients who had a minimum of 5 years of follow-up after the diagnosis of LN. We compared demographic, disease activity, renal histology (according to the World Health Organization/ International Society of Nephrology classification), laboratory and treatment variables at the time of diagnosis of LN in patients who never achieved complete renal remission (group A), those who achieved sustained CR for less than 5 years (group B), and those who had at least 5 years of CR (group C). Proportional logistic regression models were constructed to identify the predictors of sustained CR among the 3 groups in multivariate models controlling for gender, age, disease duration, ethnicity, comorbidity and treatment. Subgroup analyses were also undertaken in patients with biopsy-proven LN.

Results: A total of 427 patients were identified, 82 (19%) in group A, 213 (50%) in group B and 132 (31%) in group C. At the diagnosis of LN, gender, age, SLE duration, ethnic origin, renal biopsy results and treatment were comparable in the three groups. The patients in group C had lower renal SLE disease activity index-2K (renal SLEDAI-2K) and lower frequency of hypocomplementemia (table 1). Multivariate analysis in the whole cohort revealed higher renal SLEDAI-2K had a lower probability of sustained CR (table 2). Subgroup analysis revealed older age had a higher probability of sustained CR (odd ratio (OR) = 1.03; 95% confident interval (CI), 1.00-1.05; P = 0.03) in addition to renal SLEDAI-2K. There was no association between renal histology class III or IV and the probability of sustained CR.

Conclusion: At the time of diagnosis of LN, higher renal SLEDAI-2K predicts less chance of sustained CR.

Table 1 Comparison of clinical variables at the time of LN diagnosis			
Variables	**Group A (N=82)**	**Group B (N=213)**	**Group C (N=132)**

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The durability of renal remission might be a predictor of good long-term renal outcome and survival in patients with lupus nephritis (LN). We aimed to examine the predictors of long-term outcomes in patients with LN who achieve sustained

complete remission.

Methods: We reviewed patients with active LN at a single center Lupus Clinic in which patients had been followed prospectively between 1970 and December 2015. We identified the patients who had a minimum of 5 years of follow-up after the complete renal remission (CR) (defined as proteinuria < 500 mg/24 hours or urine protein creatinine ratio < 0.5 and inactive urine sediment). We compared the outcomes of patients who achieved sustained CR, for a minimum of 5 years (group A) with those less than 5 years (group B). The outcomes were mortality, damage (measured by the SLICC/ACR damage index (SDI)), renal flare (any presence of cast, proteinuria, pyuria or hematuria after CR), end stage renal disease (dialysis or transplant) (ESRD) or estimated glomerular filtration rate (eGFR) < 50 mL/min, doubling of serum creatinine, and infection during 20 years after CR. Cox proportional regression models were constructed to identify the predictors of the outcomes in multivariate models controlling for gender, age, disease duration, ethnicity, hypertension and treatment for each outcomes.

Results: A total of 345 patients were identified, 132 patients in group A and 213 patients in group B. Most of patients were female (85%). Mean age at the diagnosis of LN was 33.94±12.85 years in group A and 31.75±11.41 years in group B. The duration between active LN and CR was 1.04±1.53 years in group A and 1.46±1.88 years in group B (P=0.03). The duration of CR in group A was 11.76 ± 7.34 years but only 1.24 ± 1.24 years in group B (P< 0.001). Death, increasing of renal SDI, renal flare, renal transplantation, ESRD or eGFR < 50 mL/min, and doubling of serum creatinine in group A were significantly lower than group B (Table 1). Multivariate analysis revealed that group A were at a lower risk of death (hazard ratio (HR)=0.20; 95% confidence interval (CI), 0.07-0.61; P=0.004), increasing of renal SDI (HR= 0.41; 95% CI, 0.21-0.76; P=0.01), developing ESRD or eGFR < 50 mL/min (HR= 0.27; 95% CI, 0.12-0.61; P=0.001), and doubling of serum creatinine (HR= 0.29; 95% CI, 0.14-0.61; P=0.001) compared with group B.

Conclusion: Sustained complete remission for at least 5 years is an independent predictor of better prognosis in lupus nephritis in terms of reduced mortality, chronic kidney disease and end stage renal disease. **Table 1** Outcomes over 20 years after complete renal remission in lupus nephritis

	Group A (N=132)	**Group B (N=213)**	**P**
Death, *n* (%)	5 (3.8)	26 (12.2)	0.01
Increasing of SDI, *n* (%)	73 (55.3)	134 (62.6)	0.16
Increasing of renal SDI, *n* (%)	13 (9.8)	53 (24.9)	<0.001
Renal flare, *n* (%)	61 (46.2)	213 (100)	<0.001
Renal transplantation, *n* (%)	2 (1.5)	15 (7)	0.02
ESRD or eGFR < 50 mL/min, *n* (%)	7 (5.3)	37 (17.4)	0.001
Doubling of serum creatinine, *n* (%)	19 (9.8)	45 (21.1)	0.005

Group A=patients who achieved sustained complete remission, a minimum of 5 years; Group B= patients who achieved sustained complete remission, less than 5 years; SDI= SLICC/ACR damage index; ESRD= end stage renal disease; eGFR=estimated glomerular filtration rate.

Effect of Complete or Partial Proteinuria Recovery Compared to No Recovery at 2 Years after the Diagnosis of Lupus Nephritis on Long Term Outcomes

Jorge Medina-Rosas[1], Dafna D. Gladman[2], Jiandong Su[3], Murray Urowitz[2] and Zahi Touma[2], [1]Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [3]Rheumatology, Toronto Western Hospital and University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Proteinuria is the most common manifestation of lupus nephritis (LN) and it is an independent prognostic factor of long term outcomes. Recovery from proteinuria takes time with 52% of patients achieving complete proteinuria remission (CR) by 2 years from diagnosis of LN. We aimed to evaluate the effect of Complete Recovery (CR), Partial Recovery (PR), and No Recovery (NR) at 2 years from diagnosis of LN on long term outcomes.

Methods: Patients are followed at the Lupus Clinic at 2-6 month intervals according to a standard protocol which includes a complete history, physical examination and laboratory evaluation. Patients with LN (defined as proteinuria in a 24-hour urine sample [24H-P] > 0.5 g/day) attending the Lupus Center from 1970-2015 were included. At 2 years from diagnosis of LN, patients were divided in 3 groups (CR, PR, NR) based on 24H-P, and long-term outcomes were studied up to 15 years or last visit available. CR was defined as normal 24H-P (≤ 0.5 g/day), PR was defined as a reduction ≥ 50% in baseline 24H-P without achieving CR and NR was defined as a reduction < 50% 24H-P compared to baseline. Long term outcomes: 1-Renal outcomes (low [eGFR]: < 15 mL/min, end-stage renal disease requiring dialysis or transplantation [ESRD], and a Composite Renal Outcome [low eGFR or ESRD]); 2-Cardio-Vascular (CV) outcomes (angina or myocardial infarction); 3- Damage (SLICC/ACR Damage Index [SDI] ≥ 1); and 4- Death. Non-parametric tests (Log-rank tests) were applied to describe the effect of CR, PR or NR on long-term outcomes. Time-independent and time-dependent Cox proportional hazards models were applied to examine the CR, PR or NR effect by adjusting for demographics, disease, and treatment characteristics.

Results: Of 277 patients, 84.5% were female. Age at LN diagnosis and lupus duration at LN were 34.32 ± 11.66 and 5.40 ± 6.47 years, respectively. Of 277 patients, 63.9% patients achieved CR, 18.41% PR, and 9.75% NR at 2 years. -CR protected from all long-term outcomes compared to PR and NR on Kaplan-Meier analysis and Cox proportional hazards model (Figure 1). However, CR protected against CV outcomes only in the Cox proportional hazards model analysis. - Compared to NR, PR only protected against low eGFR. Neither CR nor PR protected from damage accrual. On time-dependent analysis, when comparing CR to NR and PR to NR, only NR was a risk factor for ESRD when compared to CR (HR=3.93, 95% CI: 1.31-11.73, p=0.01); all the other comparisons were not statistically significant.

Conclusion: CR at 2 years from diagnosis of LN protects against CV (angina or myocardial infarction), renal (low eGFR, ESRD and composite renal outcome) outcomes and mortality. PR protects against low eGFR. Clinicians should aim for CR to prevent long-term outcomes in LN.

Figure 1. Kaplan Meier analysis of long term outcome of low eGFR (<15 mL/min) among patients who achieved CR, PR or NR at 2 years of LN diagnosis

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The exact dose of glucocorticoids (GC) needed for the management of lupus nephritis in an individual patient is unknown. We aimed to compare the renal outcomes between patients with lupus nephritis (LN) treated early with high or low dose glucocorticoids (GC).

Methods: Inception patients (enrolled within one year of diagnosis) aged ≥ 18 years that were newly diagnosed with LN and followed for at least 3 years after LN formed our cohort. Patients are followed prospectively at 2-6 month intervals according to a standard protocol which includes complete history, physical examination and laboratory evaluation. Patients were divided into two groups based on the maximum dose of GC used at the time of LN diagnosis (including one visit before or one after LN). Group 1 patients were treated with a high-dose (>35 mg/d) and group 2 with a low-dose (<35 mg/d) GC. Disease activity was measured by the SLEDAI-2K and accumulated damage by the SLICC/ACR damage index (SDI). All information necessary to complete the SLEDAI-2K and the SDI is collected prospectively. Specific GC-related damage was documented by the presence of any of the following: cataracts, osteonecrosis or osteoporosis. Outcomes were: all cause mortality, SDI increase, and renal outcomes, including: complete renal remission, partial renal remission, renal flare, and end-stage renal disease.

Results: Of 786 inception patients in our cohort, 198 patients met LN definition and had 3 or more years of follow-up after LN. 99 (50.5%) patients received a high dose of GC (HD) with a mean dose of 55.6 ± 17.9 mg/d, and 97 (49.5%) patients received a low dose (LD) with a mean dose of 20.6 ± 8.8 mg/d. The majority of the patients (84%) were female. The mean disease duration from SLE to LN was longer in LD group (1.6 ± 2.4 years compared to 0.8 ± 2.2 years in the HD, p = 0.015). The HD group had higher disease activity than LD group as shown in table-1. The mean cumulative GC dose 6 months after LN was comparable between both groups 7.0 ± 8.3g in LD group and 8.2 ± 7.6g in the HD group (p= 0.31). Cumulative doses were similar five years after LN (22.3 ± 13.4g in LD group and 24.8 ± 14.2g HD group (p= 0.20). The mortality rate, renal outcomes, accumulated damage, and GC-related side effects were similar in both groups. Multivariable logistic regression analysis showed that age at LN and SDI were associated with increased mortality while the use of antimalarial agents had a protective effect. Moreover, age at LN and use of immunosuppressive medications were associated with an increase in damage, while the use of a low versus high doses of GC had no impact on any of the renal outcomes.

Conclusion: High dose GC was used in patients with more active disease but this was tapered more rapidly as the cumulative GC dose at 6 months and 5 years was similar in both groups, with comparable side effects and good renal outcomes and diseases control. GC dose sufficient to control active disease should be used early and tapered quickly for best results and least side effects.

Table 1: Disease characteristics at LN

Variable	Low Dose Group N=97	High Dose Group N=99	P-value
SLEDAI-2K	10.49 ± 6.96	15.55 ± 9.66	<0.001

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

A panel of autoantibodies in combination with C4d-bound complement activation products (CB-CAPs, EC4d and BC4d) has been established as a sensitive and specific testing method for systemic lupus erythematosus (SLE). The purpose of this study was to prospectively establish the performance characteristics of this testing method in an independent cohort of SLE subjects relative to subjects with diseases other than SLE.

Methods:

This cross-sectional prospective diagnostic validation study enrolled consented adult subjects at 12 sites across the USA. Venous blood was collected and transported overnight to a CAP-accredited reference clinical laboratory. The testing logic relied on two consecutive Tiers. In Tier 1, positivity for any of 4-lupus specific markers (inclusive of anti-dsDNA as confirmed by Crithidia, anti-Smith, and EC4d or BC4d levels above the 99th percentile of a control group) resulted a Tier-1 positive test assessment. All Tier-1 negative results were analyzed in a Tier 2, to yield a Tier-2 index score. This Tier-2 index score was inclusive of an ANA component, a CB-CAPs component (as component for complement activation), and a third component composite of autoantibodies for diseases other than SLE. Tier 2 positive test results (index score ≥0.1) were combined with Tier 1 positive test results to yield the overall two-tiered positive test results. Negative test results all presented with an index score lower than 0.1. All testing personnel were blinded to disease diagnosis throughout the study. Test performances in this independent validation cohort were assessed using sensitivity, specificity, positive (+) and negative (-) likelihood ratio (LR) the later reported with confidence intervals (CI).

Results:

A total of 476 adult subjects inclusive of 184 subjects with SLE (all meeting the 1982 ACR criteria revised in 1997), 215 subjects with auto-immune rheumatic and non-rheumatic diseases (inclusive of 77 subjects with autoimmune thyroiditis or hepatitis, 107 subjects with rheumatoid arthritis and 31 subjects with other rheumatic diseases) and a group of 77 subjects with primary fibromyalgia syndrome

(FMS) were enrolled. Tier 1 yielded 45% sensitivity for SLE and 98% specificity in distinguishing SLE from other diseases (LR+: 24.6 [CI95%: 10.1-59.5]), LR-: 0.56 [CI95%: 0.49-0.64]). Tier 2 yielded 48% sensitivity and 91% specificity in distinguishing SLE from other diseases (LR+: 5.6 [CI95%: 3.6-8.8], LR-: 0.56 [CI95%: 0.46-0.69]). All together the performance characteristics of the two-tiered diagnostic method yielded 72% sensitivity for SLE and 90% specificity in distinguishing SLE from other diseases (LR+: 7.0 [CI95%: 4.9-10.0], LR-: 0.32 [CI95: 0.25-0.40]).

Conclusion:

These data indicate that a panel of autoantibodies in combination with C4d-bound complement activation products is sensitive and specific for SLE.

Figure 1: Sensitivity (Sens.) for SLE and specificity (Spec.) for fibromyalgia syndrome (FMS) and other autoimmune (AI) diseases at various tier-2 index scores (maximum theoretical value: 3.4). An index score of +3.5 was assigned to Tier 1 test results (sensitivity=45%). Open circles: observed sensitivities / specificities; solid lines: fitted normal models.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Previous studies have established the value of measuring complement activation products (C4d) bound to platelets (PC4d) for the diagnosis and monitoring of Systemic Lupus Erythematosus (SLE). Separately, Antiphospholipid (APL) antibodies have been associated with complement activation and PC4d expression. In this study, we sought to validate the performance characteristics of PC4d, stratified by the presence or absence of APL antibodies.

Methods:

This multi-centered validation cross sectional study (16 sites in the US) enrolled 402 SLE subjects fulfilling the 1982 American College of Rheumatology Criteria revised in 1997 (mean age 41 years; 91% female), 411 subjects with rheumatic and autoimmune diseases other than SLE (mean age 55, 86% female consisting of 181 rheumatoid arthritis, 90 primary fibromyalgia, 92 other rheumatic diseases, and 48 autoimmune thyroiditis or hepatitis) and 198 healthy volunteers (mean age 41 years; 66% female). PC4d densities were determined using flow cytometry (expressed as mean fluorescence intensity [MFI]). Positive PC4d consisted of PC4d levels greater than 20 net MFI. Anti-cardiolipin IgG, anti-Beta-2-glycoprotein 1 IgG, or anti-Phosphatidylserine/Prothrombin (PSPT) complex IgG antibodies were determined using ELISA (INOVA diagnostics, San Diego, CA). Presence of APL antibodies consisted of any of these antibodies above manufacturer cutoff. SLE Disease activity was assessed using the non-serological SLE Disease Activity Index SELENA modification (ns-SELENA-SLEDAI, without the complement and anti-dsDNA). Performance characteristics were established using sensitivity, specificity, and ROC Curve Area Under the Curve (AUC). Statistical evaluation was by t-test (for disease activity), by chi-squared test for equality of proportions (for sensitivities and specificities) and by the method of DeLong (for ROC Curve AUC).

Results:

PC4d was highly specific in distinguishing SLE from other rheumatic diseases (Table) and normals. Among SLE subjects, 47% (n=187) presented with at least one APL antibody as compared to 21% (n=86) of subjects with other diseases and 15% of normals. PC4d sensitivity for SLE was higher among APL positive subjects by comparison to APL negative subjects (p=0.003). Specificity was not significantly different between APL positive and negative subjects (p>0.372). ROC AUC was significantly higher among the APL positive compared to negative subjects (p=0.002). The incidence of APL antibodies among all PC4d positive subjects was 60% compared to 27% among PC4d negative subjects (p<0.001). SLE subjects presenting with positive PC4d had higher disease activity (4.1±0.5) than those presenting with negative PC4d (3.0±0.2) (p=0.03).

Conclusion:

We confirm that PC4d is highly specific for SLE, and is associated with disease activity.

Table: Performance characteristics of PC4d stratified by the presence of antiphospholipid antibodies (APL)

	All Subjects	APL Negative	APL Positive
Sensitivity	20.1%	14.4%	26.7%
Specificity: Other Diseases	98.1%	98.5%	96.5%
Specificity: Normal/Healthy	99.5%	100%	96.6%
ROC AUC (SLE vs other dis.) (95% C.I.)	0.698 (0.662-0.735)	0.640 (0.590-0.690)	0.761 (0.703-0.818)

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To compare disease characteristics in patients with early and delayed onset of lupus nephritis(LN) and their outcomes after 5 years of follow-up.

Methods: Patients with LN were identified from a prospective cohort of single lupus center. Only patients who entered the cohort within 2 years from SLE diagnosis were considered. Patients who developed LN within 3 years of diagnosis (Early LN group) were compared with patients in whom LN diagnosed after 3 years of SLE diagnosis (Delayed LN).Five outcomes were evaluated: complete renal remission (CR, normalization of all of RBCs, protein, casts, pyuria), partial renal remission (PR, 50% improvement),renal flares (Increase in any of renal SLEDAI-2K score after CR), renal failure, renal damage progression (SDI) and death. Outcomes were assessed by Cox proportional hazard regression analyses.

Results: A total of 277(85%)Early LN patients (83.3% female,61%caucasian) and 49(15%) Delayed LN patients(87.8% female, 65.3% Caucasian)were included.

Variables at LN	Early (N= 277)	Delayed (N=49)	P value
Age*	33.55 ± 13.03	41.97 ± 15.17	<0.001
Disease duration*	0.68 ± 0.69	7.78 ± 4.61	<0.001
SLEDAI-2k score*	12.71 ± 8.59	9.47 ± 6.93	0.013
SLEDAI-2k non renal score*	6.47 ± 6.32	4.57 ± 3.97	0.043
SDI Score*	0.15 ± 0.48	0.82 ± 1.07	<0.001
Low Complements †	155 (56.2%)	25 (51.0%)	0.505
Anti DNA †	152 (59.1%)	27 (55.1%)	0.599
High Serum creatinine†	55 (19.9%)	2 (4.1%)	0.007
GCS use	255 (92.1%)	39 (79.6%)	0.007
Antimalarial use	138 (49.8%)	33 (67.3%)	0.024
IS use	177 (63.9%)	27 (55.1%)	0.241
*Mean ± SD; †n(%); GCS: Glucocorticosteroid; IS: immunosuppressive			

At nephritis, Early LN patients had more active disease but less damage accrual. After 5 years of follow-up, CR was higher in Early LN group. SDI scores increased significantly in the early LN group. There were no differences in renal flares, renal failure or death. Multivariate regression analysis revealed that patients with higher SLEDAI-2K and SDI scores were less likely to achieve CR. Using GCS and IS increased SDI, whereas antimalarial use and high DNA levels were protective. Caucasian ethnicity, older age at diagnosis of LN, early onset of LN, high SDI scores, high SLEDAI-2K scores, low complement levels, and GCSuse, were associated with poorer survival, while the use of antimalarial and IS were protective. Older age at CR was the only factor predicting less renal flares.

Conclusion: Patients with delayed development of LN had a milder disease course and more favorable outcomes than those with early LN.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Cell-bound complement activation products (CB-CAPs) are sensitive and specific biomarkers in the differential diagnosis of systemic lupus erythematosus (SLE) and other rheumatic diseases, as demonstrated in studies that enrolled patients from tertiary care centers. We sought to evaluate now the usefulness of CB-CAPs, as part of a multi-analyte assay, in the setting of community rheumatologists.

Methods:

We conducted a longitudinal, case-control, retrospective review of medical charts of patients for whom a multi-analyte assay with algorithm (MAAA) test was performed in 2014. The selected patients represented a difficult to diagnose population based on standard-of-care immunological tests, inasmuch all patients were ANA positive, anti-dsDNA and anti-Smith negative, and negative for five other autoantibodies (CENP, Jo-1, La, Scl-70, and MCV). The study population consisted of 23 pairs of matched cases (positive MAAA test results) and controls (negative MAAA test results); cases and controls were matched by gender, treating rheumatologist, date of testing (within 90 days), and ANA status (positive or strong positive). Features of SLE, physician diagnosis, and medications were recorded via medical chart review at two time points approximately a year apart, as all patients had remained in the care of the same rheumatologist for 9-12 months after the test was performed.

Results:

Overall, 20 of the 23 cases (87%) and 4 of the 23 controls (17%) were diagnosed with SLE by the treating rheumatologist (test sensitivity=83%; specificity=86%, Table). Anti-rheumatic medications were used in a higher percentage of cases than controls (83% vs. 35% at baseline, p=0.002), suggesting that MAAA positive patients were treated more aggressively, possibly leading to an improvement of the physician's global assessment (from 1.26 ± 0.87 at baseline to 0.70 ± 0.73 at the second time point (p=0.042), on a 0 to 3 scale, for the 11 cases for whom it was recorded). The ACR score at baseline was higher for cases than controls (average 2.9 vs. 2.3, p=0.044) and more cases than controls (43% vs. 17%) fulfilled 4 American College of Rheumatology (ACR) classification criteria of SLE, as expected. However, sensitivity of the of the MAAA test was higher than sensitivity of the ACR classification criteria (p=0.006) (Table). More patients who met the ACR classification criteria had elevated CB-CAPs, compared to patients who did not (43% vs. 22%), consistent with previous studies.

Conclusion:

In this study that included particularly difficult to diagnose patients drawn from a population treated by community rheumatologists, the MAAA test demonstrated sensitivity and specificity comparable to previously published results. CB-CAPs and the MAAA test may be helpful for the diagnosis of SLE especially when current standard-of-care immunological tests and clinical features are insufficient.

Table: Sensitivity and specificity of the ACR score and of the MAAA test.

	Physician DX Non-SLE (n=22)	Physician DX SLE (n=24)
MAAA Negative (controls)	19 (86% Spec)	4 (17% FNR)
MAAA Positive (cases)	3 (14% FPR)	20 (83% Sens)
ACR < 4	18 (82% Spec)	14 (58% FNR)
ACR ≥ 4	4 (18% FPR)	10 (42% Sens)

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis remains one of the most devastating SLE complications, occurring in over 50% of the patients. It is important to identify clinical conditions that precede nephritis for the purposes of patient care and to identify preventive strategies. Most previous studies of predictors of incident nephritis in SLE are cross-sectional or do not incorporate time-varying predictors. We leveraged a large clinical cohort which evaluated patients quarterly to identify fixed and time-varying predictors of lupus nephritis.

Methods: Since 2006, the urine protein/creatinine ratio was measured quarterly in patients in our SLE cohort. This analysis was based on cohort follow-up after 2006 in patients who did not have a history of diabetes and who did not have a prior episode of sustained elevated proteinuria, nor a history of nephritis, renal insufficiency, or failure. Among these patients, we defined an incident case of proteinuria as two or more measures of urine protein/creatinine (or 24-hour protein measure) greater than 0.5 in two visits separated by more than 30 days and less than 180 days, among patients with no prior episodes of proteinuria. We estimated rates of incident proteinuria in subgroups of patients defined by time-invariant and time-varying predictors.

Results: Among 895 patients included in the analysis, 840(94%) were female, and 518 (58%) were Caucasian, 304 (34%) African-American, with mean age of 42 at the start of follow-up. We observed 58 incident cases of proteinura over a span of 4669 person-years of cohort follow-up. The overall rate of incident proteinuria was 12.4 per 1000 person-years. The Table shows the association between select predictors and the rate incident proteinuria. The rate was significantly lower among those of older age, and significantly higher among those who were not Caucasian. Among those with a history of low C3, the rate was 8 times higher, and highest among those with a recent measure of low C3. The rate among those prescribed hydroxychloroquine was similar to those not prescribed hydroxychloroquine. Among those taking medicine for hypertension, the rate among those prescribed ACE inhibitor or ARB was similar to the rate among those prescribed other treatments. Table : Rates of incident proteinuria by patient characteristics.

Subgroup	Observed Number of new cases of proteinuria	Person-years of follow-up	Rate of events per 1000 py's	Rate Ratios	P-value

Recent anti-dsDNA No Yes					
	17	3636	4.7	1.0 (Ref)	
	41	810	50.6	10.9 (6.2, 19.1)	<0.0001
Currently on Plaquenil? No Yes					
	11	699	15.7	1.0 (Ref)	
	46	3783	12.2	0.8(0.4, 1.5)	0.44
Currently on ACE/ARB[1] No Yes					
	10	628	15.9	1.0 (Ref)	
	24	1592	15.1	0.9 (0.5, 2.0)	0.89

Conclusion: Older SLE patients who have not previously had renal involvement are at low risk for developing proteinuria. There was not strong evidence that hydroxychloroquine or ACE inhibitor's reduced the risk of proteinuria. The highest rates of incident proteinuria

were among those with recent low complement. These results suggest that those with declines in complement should be monitored closely for renal disease.

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE patients present with different clinical and serological manifestations according to the age at disease onset. However, it is not known whether there is an association between disease onset age and the clinical presentation of lupus nephritis (LN). Therefore, we investigated whether LN patients could be distinguished based on the time of disease onset and, if so, whether the groups differed in their clinical, laboratory features and long-term prognosis in ethnically homogeneous Korean patients.

Methods: We enrolled 117 SLE patients with available clinical data at the time of renal biopsy for LN from the lupus cohort at Chonnam National University Hospital. We divided the LN patients according to the age at LN diagnosis into three groups [juvenile-onset LN (JLN), diagnosed at ≤ 18 years; adult-onset LN (ALN), diagnosed at 18–50 years; and late-onset LN (LLN), diagnosed at >50 years] and compared the baseline demographic, clinical, histological, and relevant laboratory findings. We also compared the treatment and long-term prognosis of LN according to those three groups.

Results: Of the 114 LN patients, 20 (17.5%), 84 (71.8%), and 13 (11.1%) had JLN, ALN, and LLN, respectively. LLN patients were less educated than ALN and JLN patients ($p < 0.001$). Hypertension and diabetes mellitus at the onset of LN were more common in LLN patients than ALN or JLN patients ($p < 0.001$ and $p = 0.037$, respectively). Regarding the laboratory findings, LLN patients had a higher white blood cell count and lower eGFR than ALN or JLN patients ($p < 0.011$ and 0.002, respectively). Histologically, LLN patients had more chronicity indices and a higher chronic score ($p = 0.006$, $p = 0.019$, $p < 0.001$ and $p < 0.001$, respectively). Anti-Ro antibodies were found more frequently in ALN patients and less frequently in JLN patients ($p = 0.024$) and lower complement levels were more common in JLN patients and less common in LLN patients ($p < 0.011$ and 0.002, respectively). During a mean follow-up of 76.5 months, the development of chronic kidney disease and death from any cause were higher in LLN patients than in JLN and ALN patients ($p = 0.028$ and $p = 0.038$, respectively).

Conclusion: LN patients present with different clinical and serological manifestations according to age at disease onset. Interestingly, LLN patients had more chronicity at the time of renal biopsy, and more deterioration of kidney function and death on long-term follow-up, than JLN and ALN patients. Therefore, LLN patients should be monitored and managed carefully to avoid poor outcomes.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Individual autoantibodies are associated with the clinical features in patients with systemic lupus erythematosus (SLE). However, few studies have investigated differences in disease presentation based on autoantibody profiles in Asian patients with SLE. This study evaluated autoantibody clusters and compared the clinical and serological presentation and clinical outcome in Korean SLE patients.

Methods: The Korean Lupus Network (KORNET) is a nationwide multicenter, hospital-based registry, set up to prospectively assess outcomes in Korean SLE patients. Of the 505 SLE patients enrolled in the KORNET registry from July 2014 to November 2015, the study group comprised 339 consecutive female SLE patients. Seven autoantibodies (anti-dsDNA, anti-Sm, anti-RNP, anti-Ro, anti-La, lupus anticoagulant (LAC), and anti-cardiolipin antibody [aCL]) were selected for cluster analysis using the K-means cluster analysis procedure.

Results: Three distinct autoantibody clusters were identified: cluster 1, anti-dsDNA and anti-Ro; cluster 2, anti-RNP; and cluster 3, anti-RNP, anti-Ro, and anti-La. Compared with patients in clusters 2 (n = 99) and 3 (n = 85), patients in cluster 1 (n = 155) had a shorter symptom duration before SLE diagnosis and higher incidence of biopsy-proven lupus nephritis. Patients in cluster 3 had a higher incidence of discoid rash, central nervous system involvement, lupus pancreatitis, pulmonary arterial hypertension, Raynaud's phenomenon, and premature gonadal failure. In addition, patients in cluster 3 had the lowest proportion of mean prednisolone > 7.5 mg/day in the medication history.

Conclusion: Autoantibody clusters were associated with the clinical features in women with SLE. Clustering autoantibodies could be a valuable approach for differentiating between various clinical subsets of SLE, and may help to guide prediction of the subsequent clinical course and organ damage in these patients.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) is an important cause of morbidity and mortality in patients with systemic lupus erythematosus (SLE), leading to end stage renal failure (ESRF) in up to a quarter of the patients and often necessitating transplantation. Predicting adverse clinical outcomes in such patients remains challenging. We aimed to identify predictors of survival in our cohort of SLE patients undergoing renal transplantation (rTp).

Methods: This was a retrospective analysis of all SLE patients under long term follow up who developed renal failure in the 40 year period (1975-2015) in two tertiary centres. Hospital notes, electronic records and correspondence from Family Physicians and colleagues in other hospitals were reviewed. Cox proportional hazard regression and receiver operator curves (ROC) were used to determine potential predictors. Amongst the factors considered were duration of SLE diagnosis, ethnicity, gender, age at onset of SLE and LN, serology (including dsDNA binding and antiphospholipid antibodies and complement levels), comorbidities (including diabetes, hypertension, dyslipidaemia and cardiovascular disease), class of LN on biopsy, decade of rTp, drugs and adherence to treatment.

Results: Over the last 40 years, from a total of 361 patients with LN, 40 patients (age 35±11 years, 34 female (85%), of which 15 Caucasian (38%), 15 Afro Caribbean (38%), and 10 Asian (25%)) underwent rTp. During a median follow up of 85 months (IQR 63,127) 6 patients died (15% mortality) and the five year survival was 95% (table 1). Univariate analysis only identified time on dialysis prior to rTp as a predictor of survival with a Hazard Ratio of 1.017 for each additional month spent on dialysis (95%CI= 1.000-1.034, p=0.044). ROC curves were used to calculate the optimal maximum time on dialysis prior to conferring an adverse outcome showing that ≥23 months on dialysis had an adverse effect with sensitivity of 0.800 and specificity 0.430 of death (figure1).

Conclusion: To predict adverse outcomes in rTp remains challenging. The only potential modifiable risk identified is time spent on dialysis prior to rTp with patients spending <23 months on dialysis having a beneficial outcome. **Table 1**: Cohort characteristics

	Dead (n=6)	**Alive (n=34)**
Gender	0/6 male	6/36 male
Age at lupus diagnosis (years)	22.8±10.1	20.7±9.5
Age at renal transplant (years)	34.5±12.9	35.2±10.9
Time (duration) on dialysis prior to transplant (months)	67±46	32±33
LN duration at transplant (months)	111±61	209±354
Ethnicity		
Caucasian	2 (33%)	13 (38%)
Black	0	15 (44%)
Asian	4 (67%)	6 (18%)

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) complicates 60% of systemic lupus erythematosus (SLE) patients within 5 years of diagnosis. Glucocorticoids and disease modifying immunosuppressive drugs (IS) are associated with adverse effects, treatment failure and relapses and treatment duration is uncertain. Our aims were to study long-term renal outcomes of LN patients who discontinued treatment after achieving disease remission and to identify predictors of renal relapse off IS therapy.

Methods: This was a retrospective cohort study of LN in our Lupus Clinic who discontinued IS treatment. Patient data was retrieved from October 1991 and through to 1stDecember 2015, or until their last follow-up date. Renal relapse was defined as raised urine protein-creatinine ratio (UPCR) of ≥ 50mg/mmol or ≥50mg/mmol from baseline (equivalent to proteinuria 0.5g/L), or with renal biopsy proven recurrence of nephritis. Predictive factors for renal relapse were identified using logistic regression model. Data analysis was performed using SPSS Version 23.0.

Results: 43 patients were identified, 25 (58%) had sufficient data for analysis. 60% were Caucasians, 28% of Afro-Caribbean origin and 12% were Asian. 23 patients (92%) were female. Mean age at LN diagnosis was 33.5 ± 11.4 years. 7 had class IV and 7 had class V LN (28% for each group). The remaining patients had class III LN (16%), class III/IV LN (12%), and class II LN (8%). An association with anti phospholipid syndrome (APS) was found in 28% and 7 with positive aPL antibodies that remained asymptomatic. Mean duration of LN treatment was 5.6±4.2years. 17 patients (68%) received IV cyclophosphamide (CYC) as induction therapy. Azathioprine was the commonest maintenance agent (76%). Most received hydroxychloroquine throughout maintenance phase (76%). At the time of

treatment discontinuation, mean eGFR was 87.7± 21.87 ml/1.73m^2/min. Mean serum albumin was 41.3± 3.88 mmol/L and mean UPCR was 59.0± 85.11 mg/mmol. Anti- dsDNA antibodies persisted in 24% of the cohort. Despite discontinuation, 80% remained under active surveillance. Only 4 patients lost to follow-up. There was 1 death with cause unknown. Renal relapses were recorded in 7 patients (28%) and 1 patient developed non-renal flare. Mean time to event estimated at 47.2months (95% CI: 36.7,57.7). None developed end-stage renal disease after treatment discontinuation. Young age at LN diagnosis, low C3/C4, high UPCR, low eGFR upon discontinuation of treatment and ethnicity were six predictors of possible renal relapse. Our fitted model was statistically significant, χ^2=18.22, p=0.011 and correctly classified 88% of cases.

Conclusion: Our long-term LN relapse rates after discontinuation of treatment are similar to previous studies. Nevertheless, reliable comparisons are limited by the retrospective nature of our study. It is possible to discontinue treatment for LN but the optimal duration of IS therapy remains uncertain and randomized clinical trials of treatment withdrawal are warranted.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Type I interferon has been implicated in the pathogenesis of systemic lupus erythematosus (SLE), but much less is known about its role in other connective tissue diseases (CTDs). We aimed to determine the prevalence of a type I interferon signature across CTDs, and identify factors associated with elevated interferon activity.

Methods: Subjects were recruited from Central Manchester University Hospitals, UK between May 2014 and March 2016. Patients were categorised by their physician diagnosis into SLE, undifferentiated CTD (UCTD), mixed CTD (MCTD), Sjogren's syndrome (SS) and systemic sclerosis (SSc). RT-qPCR was performed on cDNA derived from whole blood and the median fold change of six interferon-simulated genes (*IFI27*, *IFI44L*, *IFIT1*, *ISG15*, *RSAD2*, *SIGLEC1*) was compared with the median of healthy controls, to create an interferon sensitive gene (ISG) score for each patient. Scores higher than the mean of the controls plus two sd (>2.466) were designated as positive.

Results: We recruited 92 subjects with a median (IQR) age of 48.3 (33.5, 57.4) years. 86 (93.5%) were female, 70/92 (76%) were Caucasian and the median disease duration was 7.21 (3.06, 13.78) years. The most commonly present autoantibodies were anti-U1RNP (25/92 [27.2%]), anti-Ro/SSA (24/92 [26.1%]) and anti-dsDNA (22/92 [23.9%]). In total, 58/92 (63%) subjects had at least 1 positive autoantibody (Ro, La, Smith, RNP, chromatin, Scl-70, dsDNA or anti-CCP). Across all subjects, 31/92 (33.7%) had a positive ISG score. ISG scores were significantly higher in patients with SLE or MCTD, compared to UCTD (p=0.003 across all groups) (figure).

All 3 SSc patients had a negative ISG score. In univariate logistic regression models, a positive ISG was significantly associated with the presence of anti-Smith, Ro, RNP and chromatin antibodies. Rheumatoid factor (but not anti-CCP) was also associated with a positive ISG score. These antibodies all remained significant after adjustment for age, gender, ethnicity (Caucasian or non-Caucasian) and clinical diagnosis (table). A significant association was observed between the number of autoantibodies (range 0-5) and a positive ISG score (OR 2.6 [1.73, 3.81], p<0.001). In a multivariable logistic regression model this observation remained significant after adjustment for age, gender, ethnicity and diagnosis (OR 2.2 [1.44, 3.50], p<0.001).

Conclusion: Expression of a type I interferon signature differs across CTD subtypes and is not observed in UCTD and SSc. The strongest factor associated with a positive ISG score was the type and number of autoantibodies, especially those binding to RNA antigens.

	Unadjusted model		Adjusted model* * for age, gender, ethnicity and diagnosis	
	OR	95% CI	OR	95% CI
Anti-dsDNA	2.50	(0.934, 6.684)	1.55	(0.521, 4.623)
Anti-Smith	**12.2**	**(3.111, 47.914)**	**14.5**	**(2.475, 85.491)**
Anti-RNP	**8.04**	**(2.883, 22.447)**	**5.19**	**(1.517, 17.749)**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent findings indicate that sodium is stored in the body and plays an important role in immune regulation. Studies in animals and humans show that sodium is stored in skin and muscle and can be measured with ^{23}Na magnetic resonance imaging (MRI). In animal models increased tissue sodium is associated with activation of the immune system and a high salt intake exacerbates autoimmune disease. However, there is no information about tissue sodium in human autoimmune disease. We hypothesize that skin and muscle sodium concentrations are higher in patients with systemic lupus erythematosus (SLE) than control subjects.

Methods: Skin and muscle Na^+ content in the lower leg was measured with a $^{23}Na^+$ knee-coil (Rapid Biomedical GmbH, Rimpar, Germany) at a Philips 3.0 Tesla Achieva scanner (Philips Healthcare, Best, the Netherlands) in 7 patients with SLE and 8 control subjects. Phantoms containing aqueous solutions with 10, 20, 30, and 40 mmol/L NaCl were included for calibration. Skin and muscle sodium concentrations between patients and control subjects were compared using Wilcoxon-rank sum tests.

Results: Demographic characteristics and systolic blood pressure (median and interquartile range) of patients with SLE and controls were similar (Table). The median SLEDAI score in patients with SLE was 2 (0-4). Patients with SLE had higher median skin and muscle ^{23}Na concentrations than control subjects. (Table) This association was unchanged after adjustment for age (p=0.06 and 0.05, respectively). Table: Comparison of clinical variables between patients with SLE and control subjects

	SLE (n=7)	Controls (n=8)	p-value
Age	41 (32-56)	34 (28-47)	0.42
Female n (%)	6 (86%)	7 (88%)	0.73
Systolic blood pressure (mm Hg)	129 (114-146)	125 (118-130)	0.39
Skin ^{23} Na+ (mmol/kg)	16.4 (15.0-19.6)	12.4 (10.9-15.9)	0.06
Muscle $^{23}Na+$ (mmol/kg)	17.4 (15.8-19.2)	15.0 (14.5-16.7)	0.049

Conclusion: This proof-of-concept study suggests that patients with SLE have higher skin and muscle sodium concentrations. Further studies are needed to examine the relationship between stored sodium with measures of disease activity, blood pressure, and cardiovascular disease in patients with SLE.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Neuropsychiatric manifestation in systemic lupus erythematosus (NPSLE) is one of the most serious complications of the disease. We have recently demonstrated that the breakdown of blood brain barrier (BBB) plays a crucial role in the

development of diffuse psychiatric/neuropsychological manifestations (diffuse NPSLE), allowing influx of neuron-reactive autoantibodies from systemic circulation into the brain. However, the mechanism of BBB damages remains unclear. Of note, various autoantibodies have been implicated in the pathogenesis in NPSLE. The present study was designed in order to elucidate the roles of serum autoantibodies in the development of BBB damages In NPSLE.

Methods: Paired serum and cerebrospinal fluid (CSF) samples were obtained from 101 SLE patients when they presented active neuropsychiatric manifestations (69 patients with diffuse psychiatric/neuropsychological syndromes [diffuse NPSLE] and 32 patients with neurologic syndromes or peripheral nervous system involvement [focal NPSLE]). IgG anti-NR2 subunit of NMDA receptor (anti-NR2), anti-Sm, anti-RNP and anti-ribosomal P (anti-P) in sera and albumin in CSF and sera were measured by ELISA.

Results: Q albumin (CSF/serum albumin quotient) was significantly higher in acute confusional state (ACS) than in non-ACS diffuse NPSLE (anxiety disorder, cognitive dysfunction, mood disorder and psychosis) or in focal NPSLE. Serum anti-Sm, but not anti-RNP, anti-NR2 or anti-P, was significantly elevated in ACS compared with the other 2 groups of NPSLE. Accordingly, only serum anti-Sm ($r=0.2655$, $p=0.0073$), but not anti-RNP ($r=0.0551$), anti-NR2 ($r=0.0817$) or anti-P ($r=0.1280$), was significantly correlated with Q albumin.

Conclusion: These results confirm that the severity of BBB damages plays a crucial role in the development of ACS, the severest form of diffuse NPSLE. Moreover, the data indicate that serum anti-Sm might play a most important role in BBB breakdown in NPSLE.

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Serological positivity defined by presence of anti-nuclear antibodies (ANA) is frequently used in interventional lupus trials as an inclusion criterion and longitudinal biomarker. As such, consistent and sensitive quantification of ANA during conduct of clinical trials is important. In this study we compared ANA testing results between 3 different commercial laboratories vendors using shared samples to assess variability in analysis.

Methods: Serum samples obtained from commercial sources from 19 anonymous SLE donors meeting ACR criteria were banked and aliquotted. Triplicate samples from each donor were randomized and shipped to 3 different commercial labs for ANA testing with staining patterns (HEp-2.) Reports from each laboratory were unblinded to group each sample replicate for both ANA titer and staining pattern. Inter-sample and inter-laboratory variability were then analyzed descriptively.

Results: Identical SLE patient sera samples analyzed by three laboratories providing ANA testing revealed differences in detection, titer level and staining pattern identification. While high titer ANA were readily detected by all three laboratories, there was significant variability in the assessment of staining patterns by some labs, and patterns present at different titers were often missed. In general, titers within an individual vendor between samples were reported within one fold. Lower titer ANAs <1:160 were more consistently scored as equivocal or absent by some labs, indicating a difference in sensitivity limit utilizing the samples provided. **Table 1.** ANA identification by testing laboratories

Vendor 1	*Vendor 2*	*Vendor 3*
*19/19 (100%)**	*12/19 (63%)**	*13/19(68%)**

*Of note, staining patterns from Vendor 1 had 2/19 samples that missed patterns in one triplicate assessment, Vendor 2 had 6/19 missed patterns in one or more triplicate assessments, and Vendor 3 had 3/19 missed patterns in one or more triplicate assessments.

Conclusion: This study suggests that commercial laboratories exhibited variability in terms of ANA titers and staining patterns using identical samples, especially in those of low titer. This occurred in a format consistent with collection in a clinical study and provision to a central laboratory for analysis. Variability was present between sample replicates and also the level of detection between different commercial labs performing ANA testing. This variability may potentially impact patient enrollment in clinical studies, and also the ability to accurately assess the impact of therapeutic interventions using these serological readouts. A key limitation to this study is that samples were accrued and banked to be sent to the analytical laboratory, and some vendor laboratory methodology may be more prone to latency of assessment than others.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The interferon gamma (IFN-G) release assay (IGRA) estimates probability of latent TB infection (LTBI) based on IFN-G released by whole blood after 18h exposure to TB antigen, mitogen or no stimulation (negative control, NC). In a small percentage of individuals, the NC condition results in markedly elevated IFN-G levels, indicating spontaneous IFN-G production (SIP). Here we examine the clinical, laboratory and demographic features of SIP in a large, academic health care system. We hypothesized that SIP is associated with select immunologic and infectious diseases.

Methods: Analysis of the distribution of over 15,000 IGRA NC results obtained between 2010 and 2015 revealed an abnormally distributed population (n = 108) with values ≥ 5 SD above median (≥ 3 IU/mL). Using this discovery cohort, we catalogued all clinical diagnoses noted in the electronic medical record ± 6 wks of IGRA date. Next, we queried a de-identified clinical data repository (DCDR) for occurrences of related ICD9/10 codes and demographic data in all individuals undergoing IGRA testing (~11,820), comparing HIGH NC group (any NC result ≥ 3, n = 83) vs. LOW NC group (no NC ≥ 3, n = 11,740) with univariate (Chi square and Fisher tests) and multivariate (logistic regression) analyses.

Results: Several ICD9/10 codes were significantly ($p \leq 0.001$) enriched in the HIGH vs. LOW groups: HIV (27.7% vs. 16.0%), LTBI (22.9% vs. 7.6%), SLE (7.2% vs. 1.3%) and hemophagocytic lymphohistiocytosis (HLH) (3.6% vs. 0.1%). After controlling for race and other enriched ICD9/10 codes, these relationships remained significant: HIV (OR 2.16, 95%CI 1.31 – 3.58), latent TB (OR 3.9, 95%CI 2.2-6.7), SLE (OR 3.79, 95%CI 1.56-9.19) and HLH (OR 31.8, 95%CI 8.7-116.2). These relationships were also observed analyzing NC levels as a continuous variable. Univariate sub-analysis of subjects with ICD9/10 codes corresponding with SLE suggested a correlation between HIGH NC values and coincident low serum complement levels ($p = 0.0356$), but not cytopenias or specific autoantibodies.

Conclusion: In individuals undergoing IGRA testing in a large academic health care system, SIP was associated with a limited set of immunologic or infectious diseases. All of the identified diseases are known to involve IFN-G activation. For SLE, SIP may identify a subset of patients with high disease activity and have therapeutic implications. For a very rare disease like HLH, SIP may have diagnostic utility. The importance of SIP in HIV and LTBI remains to be determined.

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by a variability of disease expression, both between individuals and within individuals, over time. The aim of this study is to identify prognostic factors of persistent disease activity and remission.

Methods: Patients enrolled in the Hopkins Lupus Cohort from 1987 to 2014, who had at least 3 visits per year, at least 3 years follow-up and available information on disease activity were included. Three major patterns of SLE disease activity over time (1 year intervals) have been previously described1,2, as defined by the Modified SLE Disease Activity Index – modified to remove serology (M-SLEDAI): long quiescent (LQ), chronic active (CA) and relapsing-remitting (RR). Based on maintenance of the aforementioned patterns over 3 consecutive years, patterns are defined as: Persistent Long Quiescent (pLQ), LQ pattern in each of the 3 years; Persistent Relapsing-Remitting (pRR), RR pattern in each of the 3 years; Persistent Chronic Active (pCA), CA pattern in each of the 3 years; and Mixed, at least 2 different pattern types. Possible predictors of pCA (vs. pLQ, pRR and mixed) and pLQ (vs. pCA, pRR and mixed) were identified by univariate logistic regression analyses. Several baseline demographic and disease characteristics were used as independent variables. The results from theses analyses ($p<0.25$ as the criterion) and correlation analyses (Pearson and Spearman correlations) guided the selection of variables for the multivariate logistic regression analyses. The non-significant variables were removed by stepwise backward selection.

Results: 916 patients were identified. The results of the univariate regression analysis for pCA and pLQ are shown in table 1 and 2, respectively. In the multivariate model, African American race (OR: 2.43, 95% CI: 1.19-4.94) and high baseline SLEDAI (OR: 1.09, 95% CI: 1.03-1.16) remained significant predictors of pCA. Higher education (>12 years; OR: 2.16, 95% CI: 1.11-4.20) and low baseline SLEDAI (OR: 0.62, 95% CI: 0.52-0.75) were significant predictors of pLQ in the multivariate analysis while African American race (OR: 0.36, 95% CI: 0.16-0.78) and female patients (OR: 0.26, 95% CI: 0.12-0.56) were less likely to achieve stable remission.

Conclusion: African American race and high disease activity at the time of diagnosis predict chronic activity in SLE, even after adjustment for education years and income, while higher education, low disease activity at baseline and male sex predict long-term remission. Clinical Trial Simulation Identifies Factors for Patient Engagement in Systemic Lupus Erythematosus and Lupus Nephritis Trials By African-Americans

S. Sam Lim[1], Doug McKinnell[2], M Edward Pierson[3] and Faye O'Brien[3], [1]Medicine, Emory University School of Medicine, Atlanta, GA, [2]Deloitte UK Life Sciences Advisory, London, United Kingdom, [3]AstraZeneca, Gaithersburg, MD

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical trials of patients with systemic lupus erythematosus (SLE) and lupus nephritis (LN) can be confounded by difficulties in engaging patients. Identifying factors of non-engagement informs strategies to increase involvement and compliance.

Methods: A unique approach was used simulating key study visits for an upcoming study involving patients with active SLE/LN and clinical staff from an indigent care hospital in Atlanta, GA. Patients underwent a consent procedure (30–45 minutes), simulated SLE/LN screening visit (2.5 hours), and simulated SLE/LN first dosing visit (4.5–5 hours). Patients and site staff were interviewed to obtain sentiments and perceptions relating to the simulated visits.

Results: Demographics**:** Six African-American patients (1 male, 5 female) aged 27–60 years with moderate to severe SLE/LN were recruited. Although the sample size was small, it provided value owing to its targeted clinical context. Patients differed in cognitive ability and health literacy. Communication: Patients expressed a preference for obtaining general disease and specific trial information from the Internet and stated that both strong online and community support were important. Patients valued help and support to discuss their conditions and options with family and friends. For support groups, the use of lupus community leaders was suggested for communicating the importance and relevance of clinical trial participation. Study sponsors were also advised to engage the lupus community through lupus community leaders. Despite completing full informed consent procedures, not all patients understood the degree of commitment at the time of study enrollment; in addition, a few patients thought the study might cure their disease. Patients suggested developing condensed and/or electronic versions of the informed consent form in text or audio format. Staff mentioned using electronic patient-reported outcome tools, which the patients found acceptable to complete. Patient needs: The extent of disruption to patients' lives due to study participation was cited as a major factor for potential study withdrawal. Limited flexibility in work schedules and inflexible commitments such as child care, leading to financial burden were raised as significant concerns. Although patients were generally happy with their current disease management, they were willing to consider changing their medications for a better outcome. Some patients were motivated by being part of developing a possible cure. The simulation also considered infusion visits, which required coordination between relevant parties, with post-infusion observation times potentially shortened. The duration of study visits (2+ hours) was a concern for patients and made them particularly sensitive to wait times between procedures.

Conclusion: Insights and techniques from this study at an urban indigent care lupus clinic with large numbers of African-Americans can be applied to the design of future clinical trials for patients with SLE/LN in high-risk populations to potentially improve recruitment, retention, compliance and advocacy.

Risk of Renal Failure within 10 or 20 Years of SLE Diagnosis, By Patient Characteristics

Laurence S Magder[1], Erik Barr[2] and Michelle Petri[3], [1]Epidemiology and Public Health, Division of Rheumatology, School of Medicine, Johns Hopkins University, Baltimore, MD, [2]Epidemiology, University of Maryland, Baltimore, MD, [3]Rheumatology Division, Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at elevated risk for lupus nephritis and ultimately renal failure. While some risk factors for renal involvement among patients with SLE are well known, there has not been a recent systematic study of the relationship between SLE patient characteristics and renal failure. We leveraged a large American clinical cohort of patients with SLE to estimate the risk of renal failure within 10 and 20 years of diagnosis overall, and in subgroups defined by clinical and demographic patient characteristics.

Methods: This analysis is based on the time from SLE diagnosis until end of follow-up or renal failure for patients in our cohort. For patients diagnosed with SLE before entering our cohort, the data of diagnosis and clinical manifestations at the time of diagnosis were collected by a comprehensive history at cohort entry. Individuals with renal failure prior to SLE diagnosis were excluded. We estimated the risk of experiencing renal failure over time among all patients and within subgroups of patients using the Kaplan-Meier approach. Cox regression models were used to estimate the joint association between multiple patient characteristics and renal failure.

Results: Among the 2356 cohort patients included, 155 patients experienced renal failure after SLE diagnosis and before the end of their active participation in the cohort. Table 1 shows the relationship between selected patient characteristics and 10 and 20-year risk of renal failure. Table 2 shows association between patient characteristics and rates of renal failure based on a multivariate model.

Table 1: Relationship between demographic factors and risk of renal failure in the Hopkins Lupus Cohort

Subgroup	Estimated percent chance of developing renal failure within 10 years of SLE diagnosis (95% CI)	Estimated percent chance of developing renal failure within 20 years of SLE diagnosis (95% CI)	P-value (log-rank test)
Everyone (n=2356)	5.8 (4.8, 6.9)	9.6 (8.1, 11.5)	
Sex Female (n=2179) Male (n=177)	5.3 (4.3, 6.4) 12.2 (7.7, 19.1)	9.4 (7.8, 11.4) 12.2 (7.6, 19.1)	.021

Year of Diagnosis <1985 (n=296) 1985-1994 (n=634) 1995-2004 (n=947) 2004-2015 (n=479)	5.1 (3.1, 8.4) 6.5 (4.7, 8.9) 5.1 (3.8, 6.9) 4.8 (3.1, 8.4)	11.3 (8.0, 15.8) 9.7 (7.3, 12.9) 6.5 (4.8, 8.8) 4.8 (3.0, 7.6)	.40
Low C3 (ever) No (n=1063) Yes (n=1287)	2.4 (1.5, 3.8) 8.2 (6.7, 1.0)	5.9 (3.9, 9.0) 12.3 (10.1, 14.9)	<0.0001
Low C4 (ever) No (1228) Yes (1121)	3.7 (2.7, 5.1) 7.7 (6.2, 9.7)	7.5 (5.4, 10.3) 11.7 (9.4, 14.4)	0.0071
Anti-dsDNA (ever +) No (n=894) Yes (n=1455)	3.2 (2.1, 4.8) 7.1 (5.7, 8.7)	6.4 (4.2, 9.9) 11.2 (9.2, 13.6)	.0004
ACR Criteria satisfied at time of SLE Diagnosis			
Neurologic No (n=2218) Yes (n=138)	5.5 (4.5, 6.7) 9.8 (5.6, 16.7)	9.3 (7.7, 11.2) 15.6 (9.1, 25.8)	0.012
Photosensitivity No (n=1389) Yes (n=967)	7.1 (5.7, 8.8) 3.9 (2.7, 5.5)	11.9 (9.6, 14.6) 6.6 (4.8, 9.2)	.0068
Mucosal Ulcer No (n=1561) Yes (n=795)	6.4 (5.2, 7.9) 4.5 (3.1, 6.6)	10.5 (8.6, 12.9) 7.7 (5.2, 11.3)	.049
Arthritis No (n=1063) Yes (n=1296)	7.0 (5.4, 8.9) 4.8 (3.6, 6.3)	11.4 (8.9, 14.6) 8.2 (6.3, 10.6)	.045

Table 2: Joint association between multiple variables and rates of renal failure based on a Cox regression model

Variable	Rate Ratio (95% CI)	P-value
Male (vs. female)	2.0 (1.2, 3.3)	0.0069
Age of diagnosis 30-39 (vs. < 30) 40+ (vs. < 30)	0.8 (0.6, 1.2) 0.5 (0.3, 0.8)	0.30 0.0048
Race Black (vs. White) Other (vs. White)	2.1 (1.5, 3.0) 1.5 (0.8, 2.9)	<0.0001 0.18
History of anti-dsDNA (vs. no history)	1.4 (0.9, 2.1)	0.12
History of low C3	1.8 (1.2, 2.7)	0.0050
Neurologic involvement at diagnosis	1.7 (1.0, 2.9)	0.061
Musculoskeletal involvement at diagnosis	0.7 (0.5, 1.0)	0.045

Conclusion: Almost 10% of our patients develop renal failure within 20 years. Risk of renal failure is highest among males, African Americans, those diagnosed with SLE at a younger age, those with a history of low complement, anti-dsDNA and neurologic involvement. Those with musculoskeletal disease at SLE diagnosis appear to have lower risk.

Immunofluorescence Pattern and Titer of the Antinuclear Antibody Test Correlate with Disease Activity in Patients with Systemic Lupus Erythematosus

Mônica Simon Prado[1], Alessandra Dellavance[2], Sílvia H. Rodrigues[3] and Luis Eduardo C. Andrade[4,5], [1]Rheumatology, Escola Paulista de Medicina, Universidade Federal de São Paulo, UNIFESP-EPM, São Paulo, Brazil, [2]Research and Development Department, Fleury Medicine and Health Laboratories, São Paulo, Brazil, [3]Rheumatology Division, Escola Paulista de Medicina, Universidade Federal de São Paulo, UNIFESP-EPM, Sao Paulo, Brazil, [4]Rheumatology, Escola Paulista de Medicina, Universidade Federal de São Paulo, UNIFESP-EPM, Sao Paulo, Brazil, [5]Fleury Health and Medicine, Sao Paulo, Brazil

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antinuclear antibody (ANA) indirect immunofluorescence (IIF) assay on HEp-2 cells (HEp-2-ANA) is an important element for diagnosis and classification of Systemic Lupus Erythematosus (SLE), but is not considered as a parameter for monitoring disease activity. The objective was to determine whether HEp-2-ANA pattern and titer can be relevant for monitoring SLE disease activity.

Methods: 269 patients meeting the ACR criteria for SLE were consecutively retrieved during a one-year interval and classified into 3 groups according to SLEDAI2K: Remission Group (SLEDAI2K=0); Intermediate Group (SLEDAI2K=1-5); Active Group (SLEDAI2K≥6). In addition to HEp-2-ANA titer and pattern, the following putative parameters of disease activity were determined: 1) serum CH100, C3, C4 and C2; and 2) antibodies to native DNA, denatured DNA, C1q, and nucleosome. 101 of the 269 patients were prospectively reassessed after a six-month interval.

Results: there were 256 women and 13 men (37±11.4 years old) with disease duration of 9.3±7.5 years. Active (n=111), Intermediate (n=111) and Remission (n=47) groups did not differ in age, disease duration and gender. As expected, putative parameters of disease activity differed significantly among the 3 groups, indicating that they actually represent three different disease activity stages. Ten patients were ANA-negative (3.7%), equally distributed among the 3 groups (p=0.534). The nuclear homogeneous pattern (HO) occurred in 57 patients (51.4%) of the Active group and in 11 patients (23.4%) of the Remission group (p=0.003). The nuclear fine

speckled pattern (FSp) occurred in 19 patients (40.4%) of the Remission group and in 25 patients (22.5%) of the Active group (p=0.09). Patients with HO pattern had higher SLEDAI (9.2±7.9) than those with FSp pattern (4.8±5.2) (p=0.008). ANA titer was lower in the Remission group (median 1/640) in comparison with the Active (median 1/2560) and Intermediate (median1/1280) groups (p<0.001). In the follow-up analysis, 50 patients remained in the same group (SLEDAI2K change ≤3) and 51 changed disease activity status (SLEDAI2K change ≥4). ANA titer decreased significantly in the 33 patients with decreasing disease activity (p=0.002) but not in the 50 patients with irrelevant change in SLEDAI2K (p=0.677) and in the 18 patients with increasing SLEDAI2K (p=0.080). ROC curve analysis for determination of disease activity showed equivalent areas under the curve (AUC) for ANA titer and all putative disease activity parameters.

Conclusion: ANA pattern and titer are affected by SLE disease activity and can be considered in conjunction with other laboratory and clinical parameters in the assessment of SLE disease activity.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To Compare the induction therapy of lupus nephritis with cyclophosphamide (CYC) high dose or low dose and identify possible predictors of disease remission.

Methods: Retrospective study of patients with systemic lupus erythematosus (SLE), according to ACR criteria, diagnosed with lupus nephritis (LN), histological class III or IV, who underwent induction therapy with CYC high or low dose, respectively: CYC 0,5 to 1 g/m² body surface area monthly for six months or CYC 0,5 g every 15 days for three months. We compared the frequency of renal remission between these two groups, high dose CYC or low dose CYC, right after the induction period and after the 12 and 24 months following. Complete renal remission was defined as proteinuria less than 500 mg/24 hours. Partial remission was defined as a 50% reduction of the proteinuria starting with levels <3g. We collected clinical and laboratorial data before the induction therapy to identify possible predictors of remission.

Results: There were 55 patients, 35 underwent high dose therapy of CYC and 20 underwent low dose therapy of CYC. There were no significant statistical differences in baseline clinical and laboratory features between these two groups. The frequency of complete renal remission right after the induction therapy was 74 % in CYC high dose group compared to 45 % in the CYC low dose group (p = 0.03). 25% of patients in the low dose group, who did not achieved remission after the 3 months of therapy, started new treatment with CYC high dose. At the end of follow-up (24 months), the frequency of remission in CYC high dose group was 86% and did not differ from the CYC low dose group (80%, p=0,21). The initial proteinuria and the serum values of complement, creatinine and albumin before the start of induction therapy, as well as the use of anti-proteinuric and antimalarial drugs have not been predictors of renal remission (p> 0.05).

Table-Comparison of remission frequency between the CYC high dose group and low dose group at the end of induction therapy (after 6 and 3 months respectively)

	CYC HIGH DOSE GROUP	CYC LOW DOSE GROUP	
Achieved Remission n(%)	26 (74%)	9 (45%)	***p=0,03***
Did not achieved remission n(%)	9 (26%)	11 (55%)	

Conclusion: The group of patients undergoing CYC high dose induction therapy achieved higher frequency of remission than the group with low dose of CYC after the induction therapy period. We did not found any predictor of renal remission.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with a wide range of clinical manifestations. Production of autoantibodies is a hallmark of SLE and has been shown to contribute to disease pathogenesis as well as specific clinical manifestations such as nephritis. Despite the importance of autoantibodies in SLE, only a limited number of autoantibodies have been characterized and are utilized as lupus biomarkers, and many of these are not specific for lupus. We sought to address the question of whether broad autoantibody specificity profiling could identify novel and more specific autoantibodies to identify SLE patients, and if certain autoantibody specificities were enriched in patients exhibiting an interferon-I (IFN-I) signature.

Methods: To address this question, we carried out an unbiased analysis using the ProtoArray® platform (detection of >9400 autoantibodies), comparing five racially and ethnically diverse cohorts containing patients of African American, European, and Chinese descent (total of 131 healthy and 193 SLE patients).

Results: Each cohort had a group of SLE patients exhibiting very high autoantibody signals, a group that had moderate signal, and a group that had low signal against most of the 9400 autoantigens. The majority of healthy patients had very low autoantibody signals. Furthermore, we identified a core set of 17 autoantibodies that were significantly upregulated (FC>2, FDR<0.01) in SLE patients compared to healthy patients across all five cohorts. The levels of these core autoantibodies remained longitudinally stable over a 12-week period. We also demonstrated that the expression of these 17 autoantibodies correlated with levels of an interferon (IFN) signature present in whole blood from these patients.

Conclusion: Despite the diverse set of patients in our study, we were able to identify a small set of core autoantibodies that were commonly upregulated in SLE patients in all five cohorts. Importantly, we demonstrate that autoantibodies could be vital in patient stratification or as a biomarker of SLE, as our study reveals that levels of autoantibodies are potentially linked with IFN-I gene signatures.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is clinically heterogeneous disease, with a considerably variability of disease expression among patients. There have been several attempts to classify subsets or cluster of SLE patients according genes, clinical characteristics and autoantibodies. However, information about classification of SLE patients based on urinary biomarkers is scarce. We investigated whether subdivision of SLE is possible using a panel of urine biomarkers by principal component analysis (PCA).

Methods: We included in 100 consecutive SLE patients (ACR criteria 1997) from a tertiary University Hospital. We measured urinary levels of 5 different biomarkers: monocyte chemoattractant protein 1 (MCP-1), neutrophil gelatinase-associated lipocalin (NGAL), TWEAK, Ceruloplasmin (CP), and Transferrin (TF) using a commercial ELISA kits (R&D system and Assaypro, USA). In addition, serum anti C1q antibodies were measured by ELISA (Inova, USA). SLE activity was measured with SLEDAI. The PCA was performed by Statgraphics Centurion XVI.I for Windows (Statgraphics Corp., Rockville, USA). The PCA allowed simultaneous analysis of the relationship between 5 different urine biomarkers, as well as different clinical features and anti C1q antibodies. Creatinine clearance was considered as anchor factor of the PCA.

Results: 100 SLE patients were recruited (88% female) with median age of 33.6 ± 12.4 years and median disease duration of 11.5 ± 14.8 years. Hematologic disease (89%), arthritis (83%), cutaneous involvement (82%), and renal disease (66%) were among most common manifestations. Three components achieved an eigenvalue greater than 1.0. PCA revealed that the first 3 components accounted separately for a variability of 72%. According with those components we identified 3 subsets: Group A) patients with normal renal function and moderate disease activity, group B) patients with high disease activity and high levels of anti C1q, TF and CP and group C) patients with active lupus nephritis with high levels of 24 hours proteinuria, MCP-1, NGAL and TWEAK (Figure). Patients from Group B were older, had a shorter disease duration and higher SLEDAI scores than the other 2 groups.

Conclusion: We identified 3 different subgroups of SLE patients by PCA approach using urine biomarkers and serum Anti C1q antibodies. Whether these subgroups represent a different clinical outcome or a worst prognosis requires further analysis.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

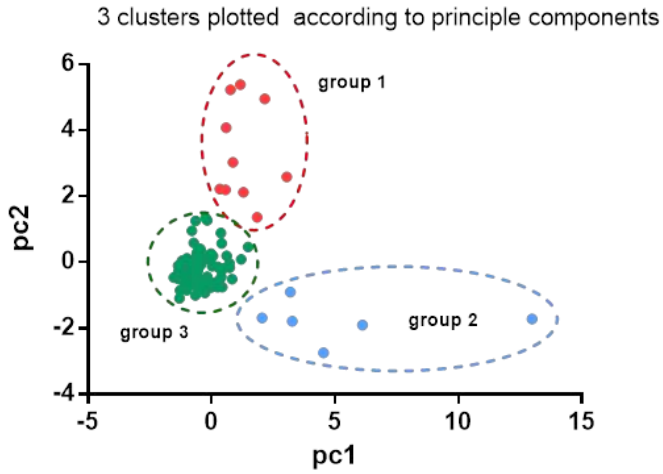
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with SLE have a broad clinical and immunological phenotype in which multiple immune pathways may be sequentially or simultaneously activated. No reliable biomarkers exist to identify active disease across the spectrum of lupus patients. Cytokine expression in serum is often at low levels and therefore traditional ELISA methods have inadequate sensitivity. Custom high sensitivity Multiplex arrays offer the opportunity to measure multiple cytokines within a single serum sample. We aimed to investigate the association between cytokine expression and disease activity in patients with established SLE and determine whether clusters of patients could be identified.

Methods: Female healthy subjects and patients with SLE (≥4 ACR criteria) were recruited between 2007 and 2013 from Central Manchester NHS Foundation Trust. Disease activity was measured using the SLEDAI-2K and BILAG-2004 indices. Active disease was defined as presence of any of: SLEDAI score >4, 1 BILAG "A" score, or 2 BILAG "B" scores. The expression of 10 cytokines (covering B cell, T cell and innate immune pathways) was measured in serum by high sensitivity bead-based Multiplex ELISA (Aeirtec Ltd, UK). Principle component analysis (PCA) of the cytokines followed by unsupervised K-means clustering was used to identify patient groups according to cytokine expression.

Results: We recruited 13 healthy control (HC) subjects and 96 SLE patients with median (IQR) age of 40 (32, 49) and 51 (44, 59) years respectively. The SLE group was 77% (74/96) Caucasian with a median disease duration of 11.7 (6.8, 21.4) years. 22/96 (23%) patients had active disease. The median dose of steroids was significantly higher amongst patients with active disease (12.5 [7.5, 17.5] vs. 0 [0, 5]mg/day, $p<0.001$) but there were no differences in frequency of antimalarial or immunosuppressant use. Compared to HCs, SLE patients had significantly increased levels of CXCL10 and CXCL13. Patients with active SLE had significantly increased levels of BLys, IL-18, CXCL10, IL-17 and pentraxin-3 compared to inactive patients. Cluster analysis revealed 3 groups (high chemokines, including CXCL13 [n=10]; high inflammation initiators including Blys and IFNα [n=6]; all cytokines low [n=93]). All HCs were in group 3. SLE patients in group 1 and 2 had higher disease activity with 7/10 (70%) and 4/6 (67%) active patients compared to group 3 (11/80, 14%). Multinomial logistic regression models identified that group membership was associated with clinical subgroup (HC/inactive SLE/active SLE) and steroid use, but not age, ethnicity or disease duration.

Conclusion: Cytokine profiles are variable in active SLE but at least 2 distinct subgroups are apparent. Patients with inactive SLE have similar profiles to healthy controls. Our findings suggest that distinct immunophenotypes may exist amongst SLE patients and may be



detected using multiplex ELISA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic inflammatory disease characterized by the presence of autoantibodies. Among the complications of SLE, neuropsychiatric manifestations (NPSLE) can be very severe. They should be managed according to the disease pathogenesis. Previously we have shown that autoantibody against the amino acid sequence, DWEYS, a consensus sequence in the extracellular domain of the GluN2A/GluN2B subunits of the N-methyl-D-aspartate receptor (NMDAR) can induce apoptosis of hippocampal neurons through excitotoxicity and cause cognitive disorders in mice. DWEYS peptide reactive antibody displays reactivity to dsDNA with high affinity and is found in patients with NPSLE as well as SLE. Neuromyelitis optica spectrum disorders (NMOSD) are characterized by central nervous system damage, most commonly optic neuritis and acute myelitis, which can also be observed in NPSLE, and the presence of anti-aquaporin-4 immunoglobulin G antibodies (AQP4-IgG) in serum. However, association of NMOSD and AQP4-IgG in patients with NPSLE, especially complicated with manifestations of demyelination, has not been studied. The purpose of this study is to determine the utility of AQP4-IgG in NPSLE with NMOSD based on a large multicenter cohort study.

Methods: Sera of NPSLE patients (n=108), SLE (n=38) and healthy individuals (n=83) were collected from institutes in Europe, Japan and United States. As a disease control group, sera from 35 patients with NMOSD without any other autoimmune diseases were also used for this retrospective analysis. AQP4-IgG in serum were measured by a live cell-based assay using human embryonic kidney cells expressing AQP4. In addition, we measured serum anti-DWEYS antibodies as well as anti-dsDNA antibodies using an ELISA.

Results: Of 108 patients diagnosed as NPSLE, 9 patients had demyelination classified according to ACR nomenclature for NPSLE in 1999, which could be also diagnosed as manifestation of NMOSD. Of the 9 patients with demyelination syndromes, 4 patients exhibited positivity for AQP4-IgG (44%) and 2 were seropositive for both DWEYS peptide and for AQP4-IgG. In all NPSLE patients without demyelination syndromes as well as in all SLE patients without neuropsychiatric syndromes and healthy controls, AQP4-IgG serostatus was negative. In 25/35 (71%) of NMOSD patients without any other autoimmune disease, the AQP4 IgG serostatus was positive. Anti-DWEYS antibody was detected in 1 (2%) of the 35 patients with NMOSD alone. DWEYS peptide reactivity didn't differ between patients with NMOSD alone and healthy controls.

Conclusion: In NPSLE patients with demyelination such as myelitis which is commonly seen in NMOSD, measurement of AQP4-IgG with our live cell based assay has a great advantage for diagnosis. Our results suggest AQP4-IgG testing patients with NPSLE and demyelinating syndrome. It is also possible that there could be other autoantibody specificities causing manifestation of NMOSD in patients with NPSLE negative for AQP4-IgG.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: An aptamer-based screening assay was used to analyze the levels of 1129 different proteins in 24 human urine samples (8 active lupus nephritis (LN), 8 inactive LN, and 8 healthy controls).

Methods: The assay revealed 281 proteins to be significantly elevated in both SLE patients relative to healthy controls and in active LN relative to inactive LN. These proteins were then analyzed to determine their effectiveness as urinary biomarkers for lupus nephritis.

Results: Ingenuity Pathway Analysis revealed that the upregulated proteins belong to known inflammatory, fibrosis, and chemokine/cytokine networks. In an independent cohort of 93 subjects (16 active LN, 52 inactive LN, 25 healthy controls), urine ALCAM, BFL1, calpastatin, hemopexin, PRX6, PF4, properdin, sE-selectin, TFPI and VCAM1 were ELISA-validated and shown to be once again significantly elevated in active LN compared to disease/healthy controls (Fig 1); they also correlated strongly with various clinical or laboratory parameters, including renal-SLEDAI, PGA, eGFR, ESR and C3/C4. In ROC curve analysis, many proteins showed significant AUC in classifying active LN: ALCAM [0.89], calpastatin [0.82], FcgRIIBC [0.70], hemopexin [0.76], PRX6 [0.67], PF4 [0.77], properdin [0.71], TFPI [0.77] and VCAM1 [0.81]. Lasso logistic regression analysis identified a 4-marker-panel (PF4, TFPI, PRX6 and VCAM1) as the best discriminator of active LN, with an ROC AUC value of 0.93. A longitudinal cohort study of 18 LN patients with an average of 3 visits per patient revealed these urine markers to vary considerably in their ability to track with standard disease indices.

Conclusion: Urine ALCAM, BFL1, calpastatin, FcgRIIBC, hemopexin, MCP1, NAP2, PRX6, PF4, properdin, sE-selectin, TFPI and VCAM1 emerge as potential urinary biomarkers of lupus nephritis; further studies are warranted to establish their biomarker potential and pathogenic relevance.

Is Hyperuricemia an Independent Risk Factor for Arterial Thrombosis in Systemic Lupus Erythematosus?

Chi Chiu Mok[1], Ling Yin Ho[2], Chi Hung To[3] and Kar Li Chan[1], [1]Medicine, Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Dept of Medicine, Tuen Mun Hospital, Hong Kong SAR, Hong Kong, [3]Medicine, Pok Oi Hospital, Hong Kong, Hong Kong

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate whether hyperuricemia is independently associated with cardiovascular events in a cross-sectional study of Chinese patients with SLE.

Methods: Consecutive patients who fulfilled ≥4 ACR criteria for SLE were recruited from our rheumatology clinics. Fasting blood was taken for serum urate level, along with other atherosclerosis risk factors that included glucose and lipid profile (total, LDL, HDL cholesterol and triglyceride). Patients were assessed for body weight, body height, waist circumference and the presence of the metabolic syndrome (MetS) as defined by the updated joint consensus criteria, using the Asian criteria for central obesity. The 4-variable estimated glomerular filtration rate (eGFR) was also calculated. Patients were stratified according to different serum urate levels: <0.35mmol/L, 0.35-0.48mmol/L, 0.48-0.60mmol/L and >0.60mmol/L. Comparison of the prevalence of vascular risk factors, the MetS and arterial thrombotic events (acute coronary syndrome, stroke, peripheral vascular event) was made among patients with different levels of serum urate. Cox regression models were established to study whether hyperuricemia was independently associated with arterial events with adjustment of demographic variables, eGFR, vascular risk factors and the antiphospholipid (aPL) antibodies.

Results: 485 SLE patients were studied (93% women; mean age 46.2±14 years); 259 (53%) had renal involvement and 73 (15%) had chronic kidney disease stage 3 or more. Hyperuricemia (urate >0.35mmol/L) was present in 185 (38%) patients. The number of patients who had serum urate levels of 0.35-0.48, 0.48-0.60 and >0.60mmmol/L was 131 (27%), 40 (8.7%) and 14 (2.9%), respectively. Patients with hyperuricemia, compared with those without, were more likely to be men (14% vs 3%; p<0.001), have renal disease (72% vs 42%; p<0.001), hypertension (34% vs 15%; p<0.001), lower eGFR (73.4±34 vs 101±27; p<0.001) but longer SLE duration (14.3±8.7 vs 12.1±7.4 years; p=0.006). The LDL-cholesterol level (3.34±1.37 vs 2.89±1.51mmol/L; p=0.001), triglyceride level (1.62±0.77 vs 1.29±0.78mmol/L; p<0.001), body mass index (BMI) (23.2±4.5 vs 22.3±3.8kg/m^2; p=0.04) and occurrence of the MetS (22% vs 12%; p=0.007) were significantly higher in patients with hyperuricemia. On the contrary, patients with the MetS had significantly higher serum urate levels than those without (0.38±0.11 vs 0.34±0.13mmol/L; p=0.007). Over an observation of 12.9±8.0 years, 50 acute arterial events (17 acute coronary syndrome; 24 stroke, 7 peripheral vascular event and 2 retinal artery thrombosis) developed in 47 patients. The cumulative risk of arterial thrombosis was 5.2% and 6.4% in 10 and 15 years, respectively. Acute coronary events were significantly more common in patients with hyperuricemia than those without (7.6% vs 1.0%; p=0.001). Cox regression analysis revealed that HDL<1.0mmol/L (HR 3.44[1.62-7.27]; p=0.001], lupus anticoagulant (HR 3.84[1.92-7.65]; p<0.001) and age of SLE onset (1.03[1.004-1.05] per year; p=0.02) were independently associated with arterial thrombosis. In separate regression models, elevated urate levels (>0.35, >0.48 or >0.60mmol/L) were not significantly associated with arterial events after adjustment for age, sex, eGFR, smoking, LDL-cholesterol, HDL-cholesterol, triglyceride, BMI, diabetes mellitus, hypertension and the antiphospholipid antibodies.

Conclusion: Hyperuricemia was associated with renal dysfunction, obesity, hypertension and dyslipidemia in patients with SLE. Moreover, elevated serum urate level was also associated with the occurrence of the MetS and acute coronary events. However, in multivariate regression models, hyperuricemia was not an independent risk factor for acute coronary or any arterial events after adjustment for confounding factors.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To study the relationship between serum 25-hydroxyvitamin D3 levels and flares of systemic lupus erythematosus (SLE) in a longitudinal cohort of Chinese patients.

Methods: Patients who fulfilled ≥4 of the ACR criteria for SLE were recruited from our rheumatology out-patient clinics in November 2011. Blood was taken at 10 AM and was assayed for the serum levels of 25-hydroxyvitamin D3 by liquid chromatography tandem mass spectrometry (LC-MS/MS). Patients were stratified according to the 25-hydroxyvitamin D3 levels; group 1 (<15ng/ml, deficiency); group 2 (15-30ng/ml, insufficiency); and group 3 (>30ng/ml, adequate); and were followed longitudinally every 2-4 months for serial assessment of disease activity (by SELENA-SLEDAI) and the occurrence of mild/moderate or severe SLE flares (by SELENA flare instrument). Comparison was made among these groups in the baseline and mean summated SLEDAI over time (area under the curve), and the annual incidence of mild/moderate and severe flares by the one-way ANOVA test.

Results: 276 SLE patients were studied (94% women; age 41.0±13.8 years; SLE duration 8.7±6.6 years). 25(9.1%) patients had eGFR ≤60ml/min. The proportion of patients with 25-hydroxyvitamin D3 levels of <15, 15-30, >30ng/ml was 26%, 54% and 20%, respectively. Patients with vitamin D deficiency (group 1) were significantly younger, had lower body mass index (BMI) but higher baseline eGFR and SLEDAI scores when compared with the other groups. No significant differences in the clinical manifestations were observed among the three groups of patients except for lower prevalence of facial rash in group 3 (p=0.02). After a mean follow-up of 32.5±5.5 months, 153 mild flares and 91 severe flares developed in our patients. The mean summated SLEDAI score over time was: 3.2±2.0 (group 1); 2.4±1.9 (group 2); and 2.7±2.1 (group 3), respectively (p=0.02). The annual incidence of mild/moderate and severe flares was: 0.26±0.39 and 0.20±0.45 (group 1); 0.20±0.33 and 0.09±0.22 (group 2); and 0.20±0.32 and 0.14±0.46 (group 3), respectively (p=NS in all). In a subgroup of 73 patients who did not have clinical or serological SLE activity at baseline (SLEDAI=0), a similar but non-significant trend of higher annual rates of mild/moderate and severe flares over time was also observed in patients with vitamin D deficiency. At the last visit, 27 (10%) patients had new damage scores; 5 patients had new vascular events; and 4 patients had new onset diabetes mellitus. There were no significant differences among the three groups of patients with regard to the incidence of new damage or vascular events over time.

Conclusion: Vitamin D insufficiency and deficiency was frequent in our cohort of SLE patients. Patients with vitamin D deficiency were associated with higher baseline and mean disease activity scores, as well as a tendency of more severe lupus flares over time.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Proteomic screening is an efficient approach for identifying protein biomarkers in various inflammatory diseases. Our preliminary proteomic analysis revealed elevated levels of urinary angiostatin, CXCL4 and VCAM-1 in patients with active lupus nephritis. This study aims to study the performance of urinary angiostatin, CXCL4 and VCAM-1 in differentiating between active renal and non-renal systemic lupus erythematosus (SLE).

Methods: Patients who fulfilled the ACR classification for SLE with active renal disease, active non-renal disease and inactive disease were randomly recruited from our out-patient clinics and hospital admission between 2010 and 2015. A group of healthy individuals were also recruited as controls. Stored urine samples of the participants were assayed for angiostatin (Raybiotech, Inc; Georgia, USA), CXCL4 and VCAM-1 (R&D Systems; Minneapolis, Minnesota, USA) and compared among the different groups. Elevated levels of these markers were defined as values ≥ mean+2SD of the controls. SLE disease activity was assessed by the SELENA-SLEDAI and physician's global assessment (PGA). Specificity and sensitivity of these markers in differentiating between active renal and non-renal SLE was determined by 2x2 contingency tables and compared with conventional markers such as anti-dsDNA and complement C3. In patients with active renal disease, correlation between these urinary biomarkers with clinical renal parameters was also performed.

Results: 227 SLE patients (80 inactive SLE; 67 active non-renal disease; 80 active renal disease; 94% women, age 39.2±13.8 years) and 54 healthy controls (96% women) were studied. All were ethnic Chinese. Urinary angiostatin, CXCL4 and VCAM-1 levels normalized for creatinine were significantly higher in patients with active renal than non-renal disease (angiostatin 1.8±2.7 vs 0.16±0.29 pg/ng; $p<0.001$; CXCL 4.9±1.6 vs 0.5±1.4 pg/ng; $p=0.002$; VCAM-1 41±1.31 $x10^2$ vs 0.72±1.10 $x10^2$ pg/ng; $p<0.001$). The levels of these urinary protein markers were also significantly higher in active non-renal SLE patients than inactive SLE patients or healthy controls. Urinary angiostatin, CXCL4 and VCAM-1 correlated significantly with the renal SLEDAI (Rho 0.66, 0.45 and 0.52, respectively; $p<0.001$ in all) and total SLEDAI score (Rho 0.60, 0.46 and 0.53, respectively; $p<0.001$ in all) in all the SLE patients studied. These urinary markers were also significantly associated with the serum anti-dsDNA and C3 levels. However, only urinary angiostatin correlated with the protein/creatinine ratio (Rho 0.34; $p=0.002$). 73/80 patients with active lupus nephritis had renal biopsy performed within 4 weeks of the urinary sample collection (34% RPS/ISN class III±V; 37% IV±V; 16% pure V; 12% I/II). The three urinary markers could not differentiate active proliferative (III/IV) from non-proliferative (I/II/V) lupus nephritis; and there was no significant correlation between these markers and histological activity indices in patients with class III/IV lupus nephritis. Urinary angiostatin and CXCL4 (specificity 0.75 and 0.78, respectively) were more specific than elevated serum anti-dsDNA and low C3 (specificity 0.28 and 0.21) in differentiating active renal from active non-renal SLE. Urinary angiostatin and CXCL4 were also highly specific (specificity 0.96 and 0.99, respectively) when compared to elevated anti-dsDNA and low C3 (specificity 0.54 and 0.59) in differentiating active SLE from inactive SLE.

Conclusion: Urinary angiostatin and CXCL4 are specific markers for lupus nephritis and may be useful in detecting subclinical / low grade renal disease in patients with active SLE. Further longitudinal studies are necessary to delineate the sensitivity and specificity of these two urinary protein markers in predicting renal flares in SLE patients.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) class III or IV is associated with a poor prognosis for both patient and renal survival. The guideline or recommendation for LN has been recently established by both ACR and EULAR, and changing therapies is recommended for patients who do not respond adequately to the induction therapy for preventing damage accrual. However, it remains major challenge to determine when to switch the treatment. In this study, we determined appropriate period and targeted clinical status to switch the treatment in patients with an inadequate response in lupus nephritis class III or IV.

Methods: Eighty patients with biopsy-proven lupus nephritis class III or IV were retrospectively recruited and divided into 2 groups, with complete renal response (CR) or non-CR at 3 years after induction therapy. We investigated when clinical responses were obtained at each observational period from the baseline to year 3. Clinical responses were divided into 3 groups, CR, partial renal response (PR), and non-PR according to EULAR recommendation. Furthermore, patients were assessed by SDI, SLEDAI, and cumulative dose of corticosteroid for 3 years.

Results: Forty-four patients with CR and 36 with non-CR were enrolled. Cumulative CR rate was 85.0%. There is no significant difference in baseline clinical characteristics other than higher SLEDAI in patients with CR compared to those with non-CR ($p<0.01$). PR rates of patients with CR were significantly higher than those with non-CR from week 12 ($p<0.01$). We identified the achievement of PR at 12 weeks as an independent predictor (Odds ratio 3.57, $p=0.03$) by multivariate analysis. We next divided all patients into 2 groups according to PR achievement at week 12. The cumulative CR rate of the patients who achieved PR at week 12 was significantly higher than those who did not (96.5% vs 69.2%, $p<0.001$) (Figure1A). Moreover, a significantly higher SDI (Figure 1B) and cumulative dose of corticosteroid were seen in the patients who did not achieve PR at week 12 than those who did regardless of their CR status at year 3.

Conclusion: Lack of PR at week 12 predicts a lower likelihood of achieving CR at 3 years. Since achievement of PR at week 12 leads to less damage accrual without regard to CR status at year 3, switching treatment should be recommended for patients who failed to achieve PR at week 12 to reduce accrual of damage.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: B cell Activating Factor of the TNF Family (BAFF) and A Proliferation Inducing Ligand (APRIL) help B cell activation, maintenance and plasma cell survival. Consequently, these facilitate production of pathogenic autoantibodies in SLE and lupus nephritis. B cells infiltration has been demonstrated in kidneys of patients with Lupus Nephritis (LN). Serum levels of BAFF and APRIL have shown inconsistent relationships with lupus disease activity. We evaluated urinary levels of BAFF and APRIL as a biomarker for LN.

Methods: Thirty-six patients with proliferative lupus nephritis (AN), 10 with active lupus without nephritis (AL) and 15 healthy controls (HC) were studied. APRIL and BAFF levels were measured in both serum and urine using ELISA. Urine levels were normalized to urinary creatinine excretion. Urine levels were correlated with conventional disease activity markers like SLEDAI, renal SLEDAI, and proteinuria. Levels were reassessed in 20 AN patients at 6 months, after treatment with cyclophosphamide.

Results: At baseline, urinary APRIL (uAPRIL) and BAFF (uBAFF) were significantly raised in AN patients as compared to controls. [Table1] uAPRIL but not uBAFF had correlation with renal SLEDAI in patients with AN. ($r= 0.36$, $p<0.05$). On ROC analysis, uBAFF (AUC 0.825) and uAPRIL (AUC 0.781)performed better than low C3, C4 and raised anti-dsDNA antibodies in differentiating AN and AL patients. The uBAFF and uAPRIL levels did not correlate with their serum levels suggesting *in situ* generation in the kidneys. On follow up uAPRIL levels reduced (125 pg/mg to 36 pg/mg, $p<0.05$). However uBAFF levels reduced only in 16 responders (158 to 67 pg/mg, $p<0.05$). Two of the 4 non-responders had increase in uBAFF levels.

Conclusion: uBAFF and uAPRIL are potential biomarkers of proliferative lupus nephritis. Table 1: Disease activity and BAFF, APRIL levels at baseline.

Parameter	Lupus nephritis (n=36)	Active non-renal lupus (n=10)	Lupus, non nephritis

Clinical Utility of Circulating Anti-N-Methyl-D-Aspartate Receptor Subunits NR2A/B Antibody for the Diagnosis of Neuropsychiatric Syndromes in Systemic Lupus Erythematosus and Sjogren's Syndrome: An Updated Meta-Analysis

Sen Hee Tay[1], Anna-Marie Fairhurst[2] and Anselm Mak[1], [1]Division of Rheumatology, Department of Medicine, National University Hospital, National University Health System, Singapore, Singapore, Singapore, [2]Singapore Immunology Network, Agency for Science, Technology and Research, Singapore, Singapore

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Neuropsychiatric (NP) events are found in patients with rheumatic diseases, commonly in systemic lupus erythematosus (SLE) and Sjögren's syndrome (SS). The standard nomenclature and case definitions for 19 NPSLE syndromes by the American College of Rheumatology (ACR) Committee on Research cover a wide range of NP events seen in both SLE and SS. Despite advances in the understanding of SLE and SS, NP syndromes continue to pose diagnostic challenges. Correct attribution of NP events is critical in determining the correct treatment and prognosis. Anti-N-methyl-$_D$-aspartate receptor subunits NR2A/B (anti-NR2A/B) antibodies (Abs) have been demonstrated in the sera of SLE and SS patients and have been associated with collective or specific NP syndromes, though not consistently. Interpretation of anti-NR2A/B Abs data in the medical literature is rendered difficult by small sample size of patient groups. By combining different studies to generate a pooled effect size, a meta-analysis can increase the power to detect differences in the presence or absence of NP syndromes. Hence, we set out to perform a meta-analysis to assess the association between anti-NR2A/B Abs and NP syndromes in SLE and SS.

Methods: A literature search was conducted using PubMed and other databases from inception to June 2016. We abstracted data relating to anti-NR2A/B Abs from the identified studies. Random-effects model was used to calculate overall combined odds ratio (OD) with its corresponding 95% confidence interval (CI) to evaluate the relationship between anti-NR2A/B Ab and NP syndromes in SLE and SS patients with and without NP events. We also included our own series of 57 SLE patients fulfilling the ACR 1997 revised classification criteria and 58 healthy controls (HCs).

Results: In total, 17 studies with data on anti-NR2A/B Abs in 2,212 SLE patients, 66 SS patients, 99 disease controls (DCs) (e.g. antiphospholipid syndrome, myasthenia gravis and autoimmune polyendocrine syndrome I) and 538 HCs were used in this analysis. Overall pooled prevalence of serum/plasma anti-NR2A/B Abs was higher in SLE patients [24.6% (95% CI 18.5-32.0%)] and SS patients [19.7% (95% CI 11.8-31.0%)] compared to DCs [14.8% (95% CI 2.2-56.9)] and HCs [7.6% (95% CI 4.6-12.4%)] ($p = 0.001$). There was a significantly greater proportion of SLE and SS patients with NP syndromes who demonstrated positivity for serum/plasma anti-NR2A/B Abs [pooled OR = 1.607 (95% CI 1.041-2.479), $p = 0.032$] as compared to SLE and SS patients without NP syndromes in 13 studies. Usable data for cerebrospinal fluid anti-NR2A/B Abs was available in only 4 studies [pooled OR = 0.831 (95% CI 0.365-1.888), $p = 0.658$]. Among the 19 NP syndromes, serum/plasma anti-NR2A/B Abs were not specifically associated with any NP syndrome, including cognitive dysfunction ($p = 0.259$) and mood disorder ($p = 0.503$). Meta-regression identified proportion of anti-double-stranded deoxyribonucleic acid Ab positivity ($p = 0.009$) and SLE Disease Activity Index ($p = 0.028$) as moderators for the heterogeneity of serum/plasma anti-NR2A/B Abs.

Conclusion: Circulating anti-NR2A/B Abs testing has a diagnostic value for NP syndromes in SLE and SS collectively, but it is not helpful in differentiating specific NP syndromes.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Approximately half of SLE patients develop lupus nephritis (LN), a major cause of morbidity and early mortality. It is known that prolonged renal inflammation is associated with irreversible kidney damage and leads to end stage renal disease (ESRD), making early aggressive treatment mandatory. Failure to achieve therapeutic response or recurrence of renal flare should prompt repeat biopsy, as changes in renal activity and chronicity are known to occur. However, the role of repeat biopsy in determining long-term renal prognosis remains controversial.

Methods: To test the hypothesis that histopathologic worsening between first and second biopsies might be predictive of ESRD and death, the medical records of 141 LN patients with >1 biopsy were obtained from a single large urban medical center. Cases were initially attained using procedure and diagnosis billing codes from 1/1999-1/2015, with subsequent retrospective chart review. Worsening of biopsies was defined as unfavorable histopathologic classification transitions or worsening of chronicity; if neither were present, the patient was defined as non-worsening. Covariates in the Cox proportional hazard models included age at first biopsy, gender, race, initial biopsy class, and initial induction therapy.

Results: Of 630 patients initially screened, 141 had >1 biopsy, with characteristics as noted in Table 1. Advancing chronicity was detected in 48(34.0%) and a renal class switch to higher grade of pathology was found in 54(38.3%). At least one of these biopsy progressions was reported in 79(56.0%) patients. Five years following initial biopsy, 28(35.4%) of those with worsening histopathology on second biopsy developed ESRD, compared to 6(9.7%) of non-worsening patients (Figure 1). After only five years, 10(12.7%) of the worsening histopathology patients had died compared to 2(3.2%) of non-worsening patients. Over a 20 year period, those with worsening of nephritis at second biopsy had a significantly greater risk of ESRD (Hazard Ratio 4.2, p=0.0001) and death (Hazard Ratio 4.3, p=0.022) after adjusting for age, gender, race, biopsy class, and treatment.

Conclusion: A repeat renal biopsy demonstrating worsening pathology is strongly prognostic for poor outcomes and could justify changes in treatment that might not have been assumed necessary on clinical grounds. The high frequency of worsening in nephritis class and chronicity supports the cost effectiveness of repeat biopsy.

Table 1. Patient Characteristics. 141 patients with >1 renal biopsy were included in the study. Demographics, initial biopsy International Society of Nephrology / Renal Pathology Society 2003 classification (ISN/RPS), initial induction immunosuppression therapy, and time between biopsies are displayed. Also included are the events of interest, death and end stage renal disease (ESRD), with median follow-up times for each group.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Even though the survival rate among SLE patients has improved over the past few decades, the mortality rate caused by the acute flare of the SLE is still high. On the other hand, next to no information is available on the prognostic factors related to operations. D-dimer (DD) is especially known to rise in a thrombotic event; the purpose of this research was to learn more on the relationship between the prognosis of admitted patients treated with SLE d/t acute flare and the change in DD.

Methods: The subject of this research was 57 SLE patients whose DD was measured more than 2 times during one's admission. The division criteria of the groups was the amount of change in the of the first and last measured DD result. If the DD value decreased by more than 25% of the first value, the patient was designated as group A while if the value increased by more than 25%, the patient was put in group C. If the patient's change of DD value was within 25% of the first value, the patient was put in group B. Then, the difference in clinical features between each group as well as between group A+B and group C was investigated. The hospitalizations of SLE patients for reasons other than for SLE disease flare such as obvious infection, malignancy and thromboembolism were all excluded.

Results: There was a statistically significant difference between groups A, B, and C in relation to Lupus Nephritis (LN) and hospitalization mortality. In addition, there was a statistically significant difference in LN, C4, anti-dsDNA, anti-Ro, and hospitalization mortality between group A+B and C. *In other words, increased* pattern of DD significantly correlates with *poor prognosis* in hospitalized patients with SLE flares. On the other hand, unlike what we had expected, no meaningful difference was observed between each group and the SLEDAI-2K score, which measures disease activity.

Conclusion: The changing pattern of the DD value is related to the mortality rate as well as the presence of LN of a patient admitted due to SLE flare. This could be used as an adjuctive factor to predict the prognosis of the admission period.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient non-adherence has been reported as a potential adverse outcome predictor in renal transplantation (rTp) for patients with lupus nephritis (LN). We investigated potential factors leading to non-adherence and whether non-adherence is associated with increased rTp graft failure.

Methods: Patients with LN undergoing rTp in two major institutions were retrospectively included in this study, analysing prospectively captured data. The medical notes were reviewed for any documented concerns about non-adherence to prescribed treatment. Laboratory biochemical results (tacrolimus, mycophenalate mofetil (MMF) and ciclospirin levels) were also reviewed for evidence of non-adherence, defined as evidence of sub- therapeutic drug levels in routine measuring in >25% occurrences. Potential associations with poor adherence were examined including age, sex, race, age at SLE diagnosis, age at lupus nephritis diagnosis, age when dialysis was started, duration of SLE diagnosis, duration of lupus nephritis diagnosis, time on dialysis prior to rTp and medication use.

Results: All patients with rTp since 1975 were included. Forty patients had rTp from a total of 361 lupus patients in both centres. For 10 patients there were concerns documented in the medical records for non-adherence. For 9 patients (out of 16 biochemically tested) there was evidence of non-adherence, giving a total of 16 unique patients with concern about possible non-adherence to prescribed treatment for LN. There were no associations between patient demographics and non-adherence. In particular, in this cohort there was no association between age at SLE diagnosis or rTp, gender, race and diagnosis duration or medication prescribed and non-adherence (Table 1). However, having recorded a concern about possible non-adherence showed a trend in associating with increased graft rejection, hazard ratio of 3.40 when concerns existed compared to when no concerns were raised (95% CI=0.732-15.723, p=0.118).

Conclusion: There were no significant factors associating with non-adherence in this cohort. However, a concern about possible non-adherence (either recorded in the notes or as evidenced with biochemical assays) showed a trend towards a 3.4 higher risk of graft rejection. Further larger studies are warranted to investigate further the factors leading to non-adherence, and the true adverse effect of non-adherence on rTp in the context of LN.

	Non-adherent	**Adherent**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) associates with atherosclerotic cardiovascular (CV) disease and related mortality. This is contributed to, but cannot be fully explained, by traditional CV risk factors, treatments and SLE-specific factors. Coronary artery calcium scores (CAC), by computed tomography (CT) measure atherosclerotic burden and can predict CV events. Non-calcified plaque (NCP), common in SLE, can also be quantified and may be more metabolically active and unstable. Routine lipids are unhelpful in distinguishing SLE patients with or without either CAC or NCP. Nuclear magnetic resonance (NMR) spectroscopy allows determination of the size and concentration of lipoprotein classes and subclasses, and has been used to evaluate CV risk in many populations. The aim of this work is to determine whether differences in NMR lipoprotein particle numbers or size can distinguish between SLE patients with and without CAC. An additional aim was to establish whether NMR parameters associate with quantified NCP or calcified plaque.

Methods: As part of a longitudinal lupus cohort, SLE patients, without known atherosclerotic disease, had coronary CT angiography performed. CAC scores were calculated according to the Agatston system. Lipoprotein particle numbers and size were evaluated by NMR. The initial statistical analysis compared those with and without calcified and NCP using t-tests. Further evaluation involved the calculation of correlation coefficients to evaluate the relationship between lipoprotein abnormalities and the burden of calcified and NCP.

Results: Sixty-nine SLE patients were evaluated, 64 (93%) female, 49 (71%) were African-American and 20 (29%) were Caucasian. Significant NCP was present in 41 (59%) and CAC was present in 14 (20%). Individuals with NCP had significantly larger very low-density lipoprotein (VLDL) particles (44.8 ±5.5 nm versus 47.7 ±6.1 nm, p= 0.042). None of the other lipoprotein parameters were significantly different between those who had calcified or NCP. Considering the volume and extent of CAC and NCP; (Table 1) higher triglycerides were observed with increasing levels of CAC. Increasing volumes of NCP were associated with higher LDL particle number and larger VLDL size. The lipoprotein insulin resistance scores were also positively associated with NCP.

Conclusion: The mechanisms underlying atherosclerosis in SLE are poorly understood. NCP is highly prevalent in SLE and may be contributed to by differences in LDL, VLDL and insulin resistance measures, not evaluated in routine lipid profiles. Further longitudinal analysis will determine whether these abnormalities associate with progression of disease and can be considered prognostic markers.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: B cell activating factor (BAFF) is implicated in the pathogenesis of systemic lupus erythematosus (SLE). A

previous small scale study reported that endogenous neutralizing serum anti-BAFF autoantibodies were found in higher levels in SLE patients compared to healthy subjects, and were associated with increased SLE disease severity. We sought to evaluate levels of BAFF and endogenous autoantibodies to BAFF in our oriental SLE cohort, and to determine their correlation with disease activity.

Methods: Serum BAFF and anti-BAFF IgG antibody levels were first assayed in 38 SLE patients and 24 healthy controls by ELISA. Correlation of serum BAFF and anti-BAFF IgG levels with disease activity scored by SLAM-R was determined in a larger cohort of 121 patients. The 121 SLE patients were predominantly female (85.9%), mean age 38.7±12.4 years, mean disease duration 102±89 months; and comprised 80.9 %(98) Chinese, 11.6 %(14) Malay, and 7.4% (9) Indian and other ethnicity; mean SLAM-R score and SDI of 2.8±2.2 and 0.6±0.97 respectively . SLE disease manifestations at the time of sample assay included mucocutaneous in 7(5.8%), fatigue in 4(3.3%), active urine sediment in 33(27.3%), hypocomplementemia in 88(72.7%), and raised anti-dsDNA antibody titres in 80(66.1%). The majority were on corticosteroids (72.7%) and hydroxychloroquine (67.8%). Immunosuppressive drugs included azathioprine in 35.5%, mycophenolate in 5.8%, and intravenous pulse cyclophosphamide in 3.3%.. SLE patients all fulfilled 1997 revised ACR classification criteria.

Results: Serum BAFF was elevated in SLE patients compared to controls; mean 1615pg/ml and 338pg/ml, respectively ($p<0.01$)(Fig 1A); and correlated with anti-dsDNA antibody levels ($r=0.363$, $p=0.025$)(Fig 1B), and SLAM-R scores($r=0.615$, $p<0.01$; $n=121$)(Fig 1C). Significantly higher levels of anti-BAFF IgG were found in over 80% of SLE patients (N/200-3200 serial dilution)(Fig 2A), which correlated negatively with SLAM-R ($r=-0.4161$, $p<0.01$; $n=121$)(Fig 2C), and levels of antidsDNA ($r=-0.335$, $p=0.039$)(Fig 2B) and BAFF($r=-0.459$, $p=<0.01$).

Conclusion: Elevated levels of anti-BAFF autoantibodies were found in over 80% of our oriental SLE patients in negative correlation with clinical disease activity, antidsDNA and BAFF levels. Our findings provide further information about the complexity of BAFF pathophysiology in different SLE disease populations and phenotypes, and may have implications in the selection of patients for the development and utilisation of anti-cytokine therapies.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Systemic Lupus Erythematosus (SLE) have increased risk of cardiovascular disease (CVD). We asked if single nucleotide polymorphisms (SNPs) analyzed by the Immunochip were associated to CVD in SLE, and followed up with bioinformatics and functional analyses.

Methods: SLE patients (Sweden, n=1055) were genotyped using the 200K Immunochip SNP array (Illumina). The allele frequency was compared between patients with and without myocardial infarction (MI)/angina pectoris (AP), ischemic stroke (stroke)/transitory ischemic attack (TIA), pulmonary embolism/deep vein thrombosis and MI/stroke. Data was analyzed using a logistic regression model with sex and disease duration included as covariates. The SNPs showing the strongest association were re-analyzed in a second group of patients of European descent (United States, n=1043). Information regarding TIA and AP was not available for the US patients. Sex, disease duration and two principal components for population stratification were included as covariates. All patients fulfilled the 1982 ACR-criteria for SLE. Bioinformatic analysis was performed using several databases including RegulomeDB, GTEx and UCSC GB.

Results: An association between a locus located on chromosome 14 and stroke/TIA was shown in both the Swedish (OR 1.8, p=0.0002) and the US (OR 1.6, p=0.03) cohort. The SNP is located in an intron and is conserved in animals but not in humans. The gene variant is located in the middle of a Chip-seq peak for STAT1 and a few bases 3´of a USF2-peak. It is a predicted enhancer in B-cells and also an eQTL. By electrophoretic mobility shift assay (EMSA) we have demonstrated that STAT1 is one of the transcription factors binding at the risk loci. In both the Swedish (OR 2.6, p=0.0006) and US (OR 1.9, p=0.04) cohorts an association was demonstrated between a locus located on chromosome 1 and stroke/MI. The locus is a predicted enhancer in B-cells and is located in an intron 3´of a binding site for a cluster of transcription factors and at a Chip-Seq-peak for CTCF. By EMSA, differential protein binding between the alternative and reference allele was demonstrated using nuclear extract from T-cells activated by PMA/ionomycin. When comparing the level of IL10 in SLE patients with and without the risk gene variant the alternative allele was associated with higher serum levels of IL10 (n=255, p=0.001).

Conclusion: The results indicate that multiple genes in different pathways, including B cell function and cytokine signaling, are involved in the development of CVD in SLE. Thus, CVD in SLE is clearly dependent on the autoimmune and inflammatory disease process, which needs to be considered when therapeutic strategies are developed for the premature CVD observed in SLE patients.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Human apoM is a 25kDa apolipoprotein present in 5% of HDL particles in plasma. In mouse models, apoM is antiatherogenic and vasculoprotective and seems to play a role in keeping endothelial barrier integrity. In SLE, decreased plasma levels of anti-oxidant and anti-inflammatory HDL may contribute to the development of atherosclerosis. The aims of the current study were to determine the impact of SLE disease activity and different organ manifestations on apoM levels and investigate if apoM levels reflect endothelial function in SLE.

Methods: Plasma concentrations of apoM were measured with ELISA in two SLE cohorts, all patients fulfilling ≥ 4 American College of Rheumatology (ACR) classification criteria for SLE, and 100 healthy controls (HC). In Cohort I (n= 85, 88% women, mean age 46 years), evaluation time points were selected to include a wide range of manifestations and SLEDAI scores, to assess if disease activity and certain organ involvement affect apoM levels. Cohort II was investigated cross-sectionally (n=148, 87% women, mean age 49 years) in order to measure endothelial function by EndoPAT 2000 (Itamar Medical, Israel), in relation to apoM levels. A low Reactive Hyperemia Index (RHI) value indicates endothelial dysfunction (ED). Serum-HDL and LDL were measured by routine laboratory test to analyse also these lipoproteins in relation to endothelial function. Subgroup analysis of the younger SLE patients (n=64, age 18-45 years) was performed, since the increased risk of cardiovascular disease seen in SLE is most pronounced in this patient group.

Results: In cohort I, the plasma levels of apoM were found to be significantly lower in patients with SLE (median 0.70 μM) as compared to controls (median 0.88 μM, $p<0.0001$). In SLE patients, the apoM concentrations correlated inversely to disease activity (SLEDAI, r= -0.29, p=0.0063) as well as to the acute phase markers CRP (r= -0.25, p=0.0192) and sedimentation rate (r= -0.27, p=0.021). ApoM was significantly lower in patients with active nephritis, leukopenia, anti-DNA antibodies or rash compared to patients without these manifestations: median concentration in μM: 0.54 vs 0.76 p=0.0053, 0.49 vs 0.75 p=0.0042, 0.54 vs 0.76 p=0.0147 and 0.55 vs 0.79 p=0.0077, respectively . In cohort II, using linear regression analysis, there was a positive correlation between apoM levels and the RHI value in the younger SLE patients: β=0.94 CI 95% 0.22,1.65 r=0.32 p=0.011. No correlation was seen between s-HDL levels and RHI: β= -0.075 CI 95% -0.57, 0.42 r= -0.042 p=0.76. Further, we found no significant correlation between s-LDL and RHI: β=0.18 CI 95% -0.013,0.38 r= 0.25 p=0.067.

Conclusion: SLE related inflammation has an impact by lowering plasma apoM, since high SLE disease activity was associated with low apoM levels. Hypothetically this may affect the endothelium. The lower apoM levels seen in the young SLE patients with impaired endothelial function, supports the hypothesis that apoM is important for maintaining endothelial health.

Utility of the Brain Perfusion Single Photon Emission Computed Tomography in Neuropsychiatric Manifestations of Systemic Lupus Erythematosus

Jorge Medina-Rosas[1], Murray Urowitz[2], Jiandong Su[3], Dafna D Gladman[4] and Zahi Touma[2], [1]Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [3]Rheumatology, Toronto Western Hospital and University of Toronto, Toronto, ON, Canada, [4]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnosis of Neuropsychiatric Events (NPE) in SLE is challenging and it is mainly based on the physician judgment. Structural brain imaging has limited utility in the assessment of NPE. We aimed to evaluate the utility of Brain perfusion Single Photon Emission Computed Tomography (SPECT), as a functional imaging, in the assessment of NPE.

Methods: This is a retrospective analysis on data from a single lupus centre. First, all SPECT done at the centre were identified. Second, we determined if the patients had an NPE (as determined by the physician) at the time corresponding to each SPECT. SPECT results were dichotomized as abnormal (hypoperfusion) or normal. Brain anatomical location (frontal, parietal, or others or multiple [4 or more locations]) and laterality (right, left or bilateral) of the SPECT findings were extracted. NPE were divided into focal (seizure, stroke, subarachnoid hemorrhage, aseptic meningitis [AM] or cranial neuropathy [CN]) and diffuse (organic brain syndrome [OBS], psychosis and headache). Patient weighted Sensitivity (Sn), specificity (Sp), Positive Likelihood Ratio (PLR) and Negative Likelihood Ratio (NLR) of the SPECT were determined. LR of 0.5-1 means minimal decrease, 1 no change, 1-2 minimal increase, 2-5 small increase, 5-10 moderate increase and >10 large increase in the likelihood of disease.

Results: 336 SPECT in 162 patients (46% patients had at least one NPE) were identified. 120 (35.7%) SPECT in 75 patients were abnormal (hypoperfusion). Of 75 patients, 93% were females, 68% Caucasian, 13% Black, 12% Asian, and 7% other ethnicities. Of the 88 NPE, 94.1% were diffuse and 26.7% were focal (Table 1). The prevalence of individual NPE on the basis of physician definitive diagnosis was 32.7% for headache 9.9% for OBS, 6.8% for psychosis, 5.6% for cranial neuropathy, 4.3% for seizures, 2.5% for stroke and 0.6% for aseptic meningitis. In diffuse NPE, the most commonly affected localizations of the SPECT hypoperfusion were the temporal lobe (18.8%) on the right side (31.5%). In focal NPE, the most commonly affected localizations of the SPECT hypoperfusion were the fronto-parietal (22.2%), temporal (22.2%) and bilateral (44.4%). Among the 3 most prevalent NPE (headache, OBS and psychosis), SPECT was useful only for headache (PLR 1.4, NLR 0.8). For headache, first, the decision to perform a SPECT should be driven by a high suspicion of lupus activity in a patient who met the definition of lupus headache (persistent nonresponsive to narcotic analgesia headache). Second, the definite diagnosis can be confirmed by an abnormal SPECT. Among diffuse and focal NPE, SPECT was useful for diffuse NPE (PLR 1.2, NLR 0.9) but not for focal NPE (PLR 1.0, NLR 1.0) (table 2).

Conclusion: The decision to perform a SPECT should be driven by a high suspicion of NPE. SPECT can be more helpful in the assessment of diffuse NPE in particular Lupus Headache and OBS/Psychosis.

Table 1. Characteristics of patients with NPE at diagnosis of NPE

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: While autoantibodies production and immune complex deposition are cornered as hallmark features of systemic lupus erythematosus (SLE), there is growing evidence to propose the pathogenic role of cytokines in this disease. The aim of this follow-up study was to evaluate the sera levels of Th1 cytokines and Th2 in SLE patients, associating these cytokines with disease activity, clinical and laboratory manifestations and also, to assess Th1 and Th2 cytokines levels could be potential biomarkers.

Methods: Consecutive SLE patients followed at the Rheumatology unit of the State University of Campinas were enrolled in this follow-up study. Healthy volunteers, matched by age and sex, were included as control group. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Neurological manifestations were analyzed according to the ACR classification criteria. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and long-term therapy. Clinical, laboratory evaluation and blood withdrawal was performed every 4 months for 1 year. Sera for stored. Sera cytokines levels were performed by enzyme linked immunosorbent assay (ELISA) at the end of the study. Data were compared by non-parametric tests.

Results: Two hundred and eighteen (210 women) SLE patients, with a mean age of 42.62 ±11.98 years were included. The control group, matched by age and sex, consisted of 46 (40 women) healthy volunteers with a mean age of 40.04±13.54 years. Only IL-6 remained significantly increased in SLE patients [median sera levels (pg/mL): T_0 2.13; T_1 1.96; T_2 2.52; T_3 2.37] compared to healthy controls [T_0 0.91 ($p<0.001$); T_1 0.91 ($p<0.001$); T_2 0.93 ($p<0.001$); T_3 1.3 ($p=0.042$)] over time. Sera IL-10 levels correlated with disease activity in all evaluations (T_0 $r=0.28$ $p<0.001$; T_1 $r=0.23$ $p=0.001$; T_2 $r=0.19$ $p=0.007$ T_3 $r=0.14$ $p=0.049$). We also observed an association between sera IL-10 levels and nephritis in all evaluations (T_0 $p=0.008$; T_1 $p=0.036$; T_2 $p=0.024$ and T_3 $p=0.005$). In the paired analyses, significant variation in IFN-γ [median sera levels (pg/mL): T_0 25.7; T_1 31.22; T_2 35.98; T_3 26.3; $p=0.026$), IL-12 (T_0 1.86; T_1 0.94; T_2 1.09; T_3 1.34; $p<0.001$), IL-4 (T_0 0.41; T_1 0.34; T_2 0.34; T_3 0.5; $p=0.001$) and IL-10 (T_0 0.98; T_1 0.94; T_2 1.09; T_3 1.34; $p<0.001$) was observed. There was no significant variation in TNF-α (T_0 2.84; T_1 2.67; T_2 2.83; T_3 2.71; $p=0.304$) and IL-6 (T_0 2.13; T_1 1.96; T_2 2.52; T_3 2.37; $p=0.241$). In the paired analyses, we also observed an association between INF-γ ($p=0.039$) and IL-10 ($p<0.001$) and neuropsychiatric manifestations in SLE patients.

Conclusion: IL-10 may be considered a biomarker for disease activity and nephritis in SLE. IFN-γ and IL-10 may identify patients with CNS involvement. Identifying new SLE biomarkers might be a useful tool to sub-classify patients and predict which clinical manifestation these patients might develop.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an inflammatory and multisystem disease. Microparticles (MPs) are cell membrane-shedded fragments released during apoptosis and cell activation. Several diseases are associated with increased number of circulating MPs, and those from the endothelium (EMPs) can trigger neutrophil activation and stimulate coagulation. On the other hand, they act as potent proinflammatory inducers affecting the function of the endothelium. **Objective:** To determine the number of MPs of endothelial origin (EMPs) in women with SLE under treatment, compared to controls, as a tool to assess disease activity.

Methods: This study included 90 women with similar age distributed into 3 groups: Group 1: healthy women (control, n=30); Group 2: SLE patients under treatment with low disease activity (SLEDAI < 4, n=30); Group 3: SLE patients under treatment with /moderate high disease activity (SLEDAI ≥4, n=30). EMPs were purified by ultracentrifugation, labeled with antibody anti-CD51 / 61 and anti - annexin V and then analysed by flow cytometry

Results: The number of EMPs was significantly higher in patients with SLE compared to the control group (p = 0.0178). When SLE patients were stratified according to the activity disease, the number of EMPs was significantly higher in SLE women with moderate / high activity compared to the control group (p = 0.0074). However, no difference was observed between the control group and SLE women with low activity disease. Correlations between the number of EMPs and age (r = -0.3385, P = 0.0123) and between the number of EMPs and SLEDAI (r = 0.2785, p = 0.0377) were observed.

Conclusion: Data from this study suggest that EMPs measurement may be an useful tool in the evaluation of patients with SLE and monitoring of treatment.

Importance of Mixed Speckled/ Homogeneous DFS70 ANA Patterns

Bruce Goeckeritz[1], **Janie Bruce**[1], Sara Carter[2] and John Carter[2], [1]Lexington Medical Center, West Columbia, SC, [2]Lexington Medical Laboratories, West Columbia, SC
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: A Mixed Speckled/Homogeneous (MS/H) pattern is the single most common ANA pattern identified in our community hospital patient population, often in very high titers, and has been associated with a “Dense Fine Speckled” anti-DFS70 ENA specificity. The IFA pattern on a Hep-2 cell substrate is that of dense, finely speckled interphase nuclei with strongly fluorescent mitotic chromosomes—ICAP pattern #2. Patients with a DFS70 positive MS/H ANA are reported to rarely develop systemic autoimmune rheumatic disease (SARD), especially in the absence of significant clinical findings or other significant ENA specificities, prompting suggestion that an isolated DFS70-specific ANA may be an exclusionary finding for SARD.

Methods: All ordered ANAs are tested using Euroimmun Hep-2 substrate slides. All MS/H ANA pattern results are reported as

possibly DFS70-related, with ENA follow-up analysis recommended. ENA profiling uses the Euroimmun Immunoblot ANA Profile 3-plus DFS70 kit which includes a total of 15 separate ENA specificities. Chart reviews were done on these patients to determine if the isolated DFS70 pattern was useful as a rule-out for SARDS.

Results: 2,383 patient samples tested for ANA in a 4-month period showed 632 (27%) to have an MS/H ANA pattern. ENA profiling of these 632 MS/H ANA's showed: · 260 (41%) of MS/H ANA's positive for anti-DFS70, 73% of these an isolated anti-DFS70. · 71 (27%) of DFS70 ANA's showed an additional positive or borderline reaction to other ENA specificities. · 353 (59%) of MS/H ANA's were negative or showed only borderline (3%) reactivity for anti- DFS70; · 263 (75%) of DFS70-negative MS/H ANA's were also ENA profile negative; while the remainder showed varied presence of other ENA specificities. Ongoing chart reviews of patients positive for an isolated anti-DFS70 ANA affirms that evidence of SARD is rare in patients with isolated anti-DFS70 patients in the absence of clinical evidence or other ENA specificities. The presence other ENA specificities at a significant level has clinical relevance specific to those antibodies.

Conclusion: Recognition of an MS/H, Dense Fine-speckled, ICAP AC-2 ANA pattern should be a routine ANA testing service. A mitotic-rich Hep-2 cell substrate is essential for recognition of this and of varied cell-cycle ANA patterns. Recognition of an isolated DFS70 ANA specificity enables reassurance of ANA-positive patients who would otherwise be referred for more extensive testing and monitoring for the presence or development of SARD.

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) remains an important cause of morbidity and mortality in patients with SLE. Tubular atrophy and interstitial fibrosis on initial renal biopsies in Blacks with LN have been associated with poor renal outcomes. This study was initiated to evaluate the histopathologic predictors of poor renal outcomes on initial and subsequent renal biopsies in patients with lupus nephritis in a predominantly Hispanic and Black cohort.

Methods: All SLE patients with two or more renal biopsies performed at CUMC between 1996-2015 were identified from the pathology database; data on 63 patients with regular follow-up at the Columbia University Lupus Center were available for analysis. Demographics, clinical, laboratory and histopathologic characteristics were ascertained. Adverse renal outcomes were defined as a serum creatinine >1.4 mg/dL, ESRD, or renal transplant. Tubular atrophy and interstitial fibrosis was graded by the renal pathologist from mild (10-25% involvement) to severe (>60% involvement). The histopathologic predictors of adverse renal outcomes were evaluated using logistic regression, adjusting for pertinent confounders.

Results: Of the 63 patients, 87% were female, 46% Hispanic, 29% Black. The average age at SLE diagnosis was 27±12, the median time from the first renal biopsy to the occurrence of the first adverse renal outcome was 6 years (4-9) (Table 1). Fifty-three percent of patients with ≥ 2 biopsies had an adverse renal outcome: 31% developed ESRD (of which 58% received a renal transplant), and 22% had a serum creatinine >1.4 mg/dL. The degree of tubular atrophy and interstitial fibrosis (TAIF) in the second renal biopsy [OR 3.5 (CI 1.3-10.6) p=0.03] but not in the first [OR 2.5, (CI 0.7-8.2); p=0.15], was a strong predictor of adverse renal outcomes in a multivariate analysis, after adjusting for hypertension, smoking, race/ethnicity, LN class and activity index. Chronicity index was not a significant predictor of renal outcome in multivariable analysis. All subjects with severe TAIF on the second and third renal biopsies met the

primary outcome. Fibrinoid necrosis, number or type of crescent, number of sclerotic glomeruli and degree of foot process effacement were not significantly associated with a poor renal outcome.

Conclusion: Fifty-three percent of SLE patients that required a second renal biopsy for LN flare in this predominantly Hispanic and Black cohort had adverse renal outcomes within 6 years; 31% developed ESRD. Tubular atrophy and fibrosis were strong predictors of poor renal outcome. Their presence on a second biopsy should prompt intensification of therapy in patients with lupus nephritis to avoid ESRD and adverse renal outcomes.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Peripheral CD4+CD28null T-cells constitute a subset of long-lived cytotoxic CD4+ T-cell with pro-inflammatory functions. This T-cell subpopulation has been reported to be associated with damage in SLE patients, but whether it may be predictive of such occurrence has not previously been reported. The aim of this study was to determine whether this T-cell subset predicts the occurrence of new damage in these patients.

Methods: This longitudinal study was conducted in consecutive SLE patients seen every six months in our Rheumatology Department since 2013. For the purpose of this study, patients in whom CD4+CD28null T-cells had been measured and who had at least one subsequent visit thereafter were included. Variables were evaluated during the same visit in which CD4+CD28null cells were measured (interview, medical records review, physical examination and laboratory tests) with the exception of damage which was evaluated in the subsequent visits. SLE was defined by the 1997 revised and updated ACR criteria. Disease activity was ascertained using the SLEDAI and disease damage with the SLICC/ACR damage index (SDI). Use of prednisone was recorded as current dose and total time of exposure. Use of antimalarials and immunosuppressives was recorded as current, past or never. CD4+CD28null T-cells frequencies were analyzed by flow-cytometry. Survival analyses using univariable and multivariable Cox-regression models were performed to determine the risk of overall damage and per each SDI domain individually as a function of the frequency of this T-cell subpopulation. The multivariable model was adjusted for age at diagnosis, disease duration, socioeconomic status, SLEDAI, SDI, use of prednisone, antimalarials and immunosuppressive drugs at the intake visit. All analyses were performed using SPSS 21.0.

Results: One hundred and nineteen patients were evaluated; their mean (SD) age was 43.5 (11.9) years, 113 (95.0%) were female; all patients were Mestizo (mixed Caucasian and Amerindian ancestry). Socioeconomic level was low in 50 (42.0%), medium in 48 (40.3%) and high in 21 (17.6%) patients. Disease duration was 7.8 (7.0) years. The SLEDAI was 5.3 (4.1) and the SDI 1.0 (1.4). At baseline, the dose of prednisone was 6.9 (5.1) mg/day and the total time of exposure to prednisone was 7.3 (6.8) years; 93 (78.2%) and 13 (10.9%) patients were current and former users of antimalarials. Fifty-six (47.1%) and 28 (23.5%) patients were current and former users of immunosuppressive drugs. The percentage of CD4+CD28null T-cells was 17.4 (14.0). Forty-six (38.7%) patients increase at least one point in the SDI. In the univariable and multivariable analyses, the percentage of CD4+CD28null predicted the occurrence of lung damage [HR: 1.042 (CI95%: 1.001-1.085); p=0.047 and HR: 1.099 (CI95%1.020-1.184); p=0.013, respectively] but neither the total SDI score nor all other SDI domain scores were predicted by the percentage of CD4+CD28null cells.

Conclusion: In SLE patients, CD4+CD28null T-cells predict the occurrence of new lung damage, independently of other risk factors.

Background/Purpose: The determinants of the increased risk of non-Hodgkin Lymphoma (NHL) in systemic lupus (SLE) are unclear. The most common type of NHL in SLE (as in the general population) is the Diffuse Large B-Cell lymphoma (DLBCL) subtype. Our purpose was to identify if known susceptibility loci for DLBCL occur more frequently in SLE.

Methods: We used data from a recent GWAS of SLE conducted in a North American case-control sample of European ancestry Our study comprised 7,219 SLE cases and 15,991 non-SLE controls, genotyped on Affymetrix Genome-Wide Human SNP Array 6.0. We studied 4 loci that have been associated with DLBCL in recent GWAS studies, to determine if these DLBCL-associated SNPs occur more frequently in SLE versus the general population.

Results: For the DLBCL SNP of interest rs2621416 on 6p21.32 (associated with HLA-DOB 1), while the G (versus A) risk allele is a risk factor for DLBCL, the same allele is protective for SLE (odds ratio, OR for the G allele in SLE versus the general population was 0.78, 95% confidence interval, CI 0.63, 0.97, p value 0.023). For the DLBCL SNP of interest rs4530903 on 6p21.32 (associated with HLA-DQA1), while the T (versus C) risk allele is a risk factor for DLBCL, the A allele was possibly protective for SLE (OR for the A allele in SLE versus the general population was 0.72, 95% CI 0.50, 1.02, p value 0.066). For the other two DLBCL SNPs of interest, the SLE OR was close to 1 with a wide confidence interval.

Conclusion: We did not identify an increased occurrence of known susceptibility loci for DLBCL in SLE in these analyses. **Odds Ratio Estimates for SLE risk, for Diffuse Large B Cell Lymphoma (DLBCL)-related SNPs**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Long QT syndrome (LQTS) is characterized by an abnormal QT corrected (QTc) interval prolongation that is associated with increased risk of sudden death. Studies have associated LQTS with several rheumatic conditions, and evidence points towards a link between the degree of systemic inflammation and the duration of QTc interval. Moreover, recent evidence suggests that anti-Ro antibodies may play a role in the QTc prolongation by mechanisms not fully understood, thus constituting a novel autoimmune-mediated LQTS. This study was aimed to assess whether QTc interval prolongation is associated with the presence of anti-Ro antibodies in SLE, particularly with reactivities against Ro52/TRIM21 antigens.

Methods: Consecutive patients fulfilling the 1997 ACR criteria for SLE were included. Patients with history of ischemic heart disease, with implantable pacemakers, and those taking drugs that potentially could affect QT interval (except for antimalarials) were excluded. Patients underwent a resting 12-lead electrocardiogram recording to measure QT interval corrected by BazzetÕs formula. A QTc interval duration greater than 460 msec in women and 440 msec in men was set to be abnormal. Serum anti-Ro and anti-Ro52/TRIM21 antibody levels were measured by ELISA. Data were expressed as frequencies and means (± standard deviation), and differences were tested by YatesÕ continuity corrected chi square or Mann-Whitney tests, while linear regressions were performed to assess linearity between autoantibody levels and QTc duration. The GraphPad Prism 4.02 software was used for calculations.

Results: Sixty-six patients with mean age of 39±13 years (57 female gender) were included. A QTc prolongation was found in 10 patients (15%), with mean QTc interval of 470±18 msec as compared to 414±23 msec in those with no LQTS. Main clinical and demographic characteristics were similar for both groups, except for a lesser use of antimalarials and higher serum creatinine levels in patients with LQTS. Disease activity was similar between groups.Anti-Ro antibody levels were significantly higher in patients with prolonged QT interval (75±66 U/mL versus 29±44 U/mL; P=0.005); similarly, anti-Ro52/TRIM21 levels were higher in those with LQTS (50±55 U/mL versus 14±30 U/mL; P=0.01). Notably, a linear association (see the Figure) between the QTc intervals and levels of anti-Ro antibodies (r^2=0.073; P=0.02) and anti-Ro52/TRIM21antibodies (r^2=0.078; P=0.02) was observed.

Conclusion: Our results strengthen the hypothesis that a specific autoantibody-mediated LQTS occur in SLE patients positive to anti-Ro antibodies. This interference in the ventricular repolarization appears to be associated with increased levels of antibodies against Ro52/TRIM21 antigens, and supports the realization of an electrocardiogram as part of the routinely evaluation in SLE patient with circulating anti-Ro antibodies.

Predictors of Good Long-Term Renal Outcomes in Lupus Nephritis

William Fung[1], Jiandong Su[2] and Zahi Touma[3], [1]Medicine, University of Toronto, Toronto, ON, Canada, [2]Rheumatology, Toronto Western Hospital and University of Toronto, Toronto, ON, Canada, [3]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) manifests with proteinuria and/or active urine sediment. Renal composite indices include proteinuria, urinary active sediment (RBCs, casts) and serum creatinine. Complete proteinuria recovery (CR) is defined as <0.5 g/d but it is currently unclear which proteinuria cutoff best predicts good clinical outcomes.

We aimed to determine: a) the predictive ability of proteinuria, urinary sediment (uRBCs) and serum creatinine (Cr) at 1 year to predict good long-term outcomes, and b) the best proteinuria cut-off at 1 year to predict good long-term outcomes.

Methods: This retrospective analysis was performed on prospective data from a single lupus cohort of 1849 patients. Patients with LN (24-hr proteinuria [24H-P] >0.5 g/d) were identified and baseline was defined as the onset of LN. Patients on whom microscopic urine analysis with at least 7 years' follow-up were studied. Patients with end-stage renal disease (ESRD) or renal transplant/dialysis at baseline were excluded. Good renal outcome was defined as Cr <100 mmol/L and renal transplant/dialysis-free at 7 years.

Receiver operating characteristic (ROC) curves were generated to examine the predictive power of Cr, 24H-P, and uRBCs at 1 year post-LN diagnosis with respect to good renal outcome. Area under curves (AUC) were analyzed for: a) 24H-P at year 1, b) absolute change in 24H-P between year 1 and 7, and c) percent change in 24H-P between year 1 and 7. The proteinuria cutoff was identified by optimizing sensitivity and specificity. Additional sensitivity analyses were conducted for patients with baseline 24H-P of >2.5 g/d, >2.0 g/d, and >1.5 g/d. This analysis was repeated for uRBCs and Cr.

Results: 101 LN patients were analyzed, with baseline 24H-P of 2.36 ± 2.31 g/d. At 7 years Cr was 85.6 ± 40.0 mmol/L. 24H-P of 0.6 g/d at 1 year after LN diagnosis best predicted good long-term renal outcome, with sensitivity 62% and specificity 70% (Fig. 1). In the sensitivity analyses, proteinuria cut-off of 1.0 g/d was identified for groups with baseline 24H-P >2.5 g/d, >2.0 g/d, and >1.5 g/d.

The AUC analysis confirmed that 24H-P at 1 year, but not absolute/percent change, is a predictor of good long-term renal outcomes (Fig. 1, 2). uRBCs did not provide any predictive benefit while Cr at 1 year predicted long-term renal outcome with an AUC of 0.82 (Fig. 2).

Conclusion: Proteinuria of 0.6 g/d at 1 year post-LN diagnosis best predicted good long-term renal outcome. Serum creatinine at 1 year was also a strong predictor of long-term renal outcome, whereas urinary RBCs did not offer any prognostic benefit.

Figure 1. ROC curve for proteinuria at 1 year, absolute change and percentage of change between year 1 and 7

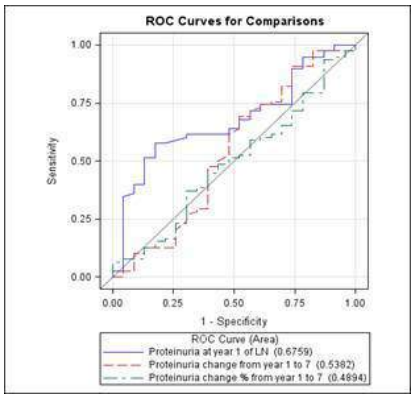

Figure 2. ROC analyses for proteinuria levels, Cr and uRBC at 1 year, absolute change and percentage of change between at year 1 and 7

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Autoantibodies to the dense fine speckled 70 (DFS70) antigen are common among ANA (dense fine speckled pattern) positive healthy individuals and consequently reduce the specificity of the ANA test. This might lead to miss-diagnosis, unnecessary referral, increased healthcare expenditure and even miss-treatment. Therefore, the reliable identification of anti-DFS70 antibodies is of high importance. Recently, different methods were developed to identify samples containing anti-DFS70 antibodies including a chemiluminescence assay (CIA) for the detection of anti-DFS70 antibodies and an indirect immunofluorescence (IIF) immunoadsorption technology which blocks anti-DFS70 antibodies from binding to the native ligand on HEp-2 cells. Here, we assessed the prevelance of anti-DFS70 antibodies in patients with and without systemic autoimmune rheumatic diseases (SARDs) and compared two methods for the detection of these antibodies: IIF and CIA.

Methods: We evaluated 51 ANA-positive sera samples from patients with confirmed clinical diagnosis of SARD, 92 samples from healthy blood donors and 85 samples submitted to a reference laboratory for routine ANA testing. These samples were tested by QUANTA Flash DFS70 CIA on the BIO-FLASH instrument (Inova Diagnostics, San Diego, USA) to measure anti-DFS70 antibodies, and were evaluated by automated IIF (NOVA Lite HEp-2 Select, Inova Diagnostics, USA). Samples were tested with and without DFS70 inhibition. Mono-specificity of anti_DFS70 antibodies was define by successful and complete inhibition of ANA reactivity by the DFS70 antigen in the HEp-2 Select sample buffer.

Results: 24 samples (10.5%) tested by QUANTA Flash DFS70 CIA were positive for anti-DFS70 antibodies. The prevalence of monospecific anti-DSF70 antibodies was significantly higher in healthy subjects than in patients with SARDs (10.2% vs 1.9%, p=0.02). The frequency of anti-DFS70 antibodies in samples submitted to a reference laboratory for routine ANA testing was 27%. A very good agreement was found between QUANTA Flash DFS70 CIA and the DFS pattern identified by automated HEp-2 IIF (kappa=0.97). In 80% of the samples obtained from patients without SARDs, HEp-2 Select Kit effectively inhibited the anti-DFS70 antibodies, reducing false positive ANA results.

Conclusion: Our data confirm that mono-specific anti-DFS70 antibodies are a strong discriminator between ANA positive healthy individuals and SARD patients. In addition, anti-DFS70 antibodies are very common in ANA routine samples. Consequently, the detection of anti-DFS70 antibodies should be included in ANA testing algorithms to aid in the interpretation of ANA positivity without underlying SARD. In addition, anti-DFS70 antibodies should be considered for future revisions of disease classification criteria.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Infection is a major cause of mortality in all stages of SLE. This is likely multifactorial in nature. We hypothesized that some patients with SLE have acquired immunoglobulin deficiency, which may put them at higher risk of infection. We aimed to examine the association and prediction of immunoglobulin levels and the risk for severe infections in lupus patients

Methods: Patients with SLE have been followed prospectively at 2-6 month intervals according to a standard protocol, which includes detailed clinical and laboratory assessments including immunoglobulin levels and recording of infections. All information is recorded in the Clinic database. Damage accrual was measured by the SLICC/ACR damage index (SDI). Included in this study were patients with severe infections, defined by either requiring parenteral antibiotics or 3 infections within 2 years. Controls were patients followed for the same period who did not have infections. Immunoglobulin levels were recorded as low, normal, or high according to the laboratory standard. Persistently low immunoglobulins were defined as two or more low consecutive measurements. Logistic regression analysis was performed to determine first the factors associated with infection and then factors predisposing to severe infection.

Results: We first identified from the database 250 patients with severe infections and 381 patients without infection. Patients with severe infections had lower IgG and IgA levels, and were treated with higher doses of glucocorticoids (GC). Logistic regression analysis revealed that age at SLE diagnosis (OR 1.019 95% CI 1.004,1035, P=0.014), low IgM levels (OR 2.175 95% CI 1.114, 4.245, p = 0.0228) and GCS dose (OR 1.079 95% CI 1.058, 1.101, p = <0.001) were associated with infection, adjusted for other demographic and clinical variables. We then examined 148 patients with persistently low immunoglobulins and no infection at first measurement and compared them to 430 controls for infection outcome. The low immunoglobulin group had more severe infections, higher SDI score, higher GC and immunosuppressive use. Logistic regression analysis revealed low IgG levels (OR 3.546 95% CI 1.852, 6.787, p = 0.0001), low IgM levels (OR 2.209 95% CI 1.274, 3.83, p = 0.0048), female gender (OR 2.285 95% CI 1.019, 5.125, p = 0.045), SDI (OR 1.188 95% CI 1.029, 1.373, p = 0.019) SLE duration (OR 1.056 95% CI 1.03, 1.084, p = <0.0001) to be predictors for severe infection and antimalarial treatment to be protective (OR 0.566 95% CI 0.355, 0.902, p = 0.0166) after adjustment for other demographic and clinical variables.

Conclusion: Our study shows consistent association between low immunoglobulin level and clinically significant infection in lupus patients. Furthermore, low IgG and IgM levels increase the risk of severe infection, while antimalarial treatment is protective. Thus immunoglobulin assessment should be performed routinely in patients with SLE.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The presence of ANCA in SLE had been known for over 25 years with a reported prevalence as high as 31%. However, the relationship between the presence of ANCA and disease activity in SLE has yet to be understood. We aimed to evaluate the prevalence of ANCA in SLE patients and correlate it with lupus activity, organ involvement, association with vasculitis, and prognosis.

Methods: SLE patients have been followed prospectively in the lupus clinic at 2-6 month intervals according to a standard protocol, which includes a detailed clinical history, physical examination and laboratory evaluation. Only patients who were tested at least twice for c and p-ANCA were included. ANCA was considered positive if either c or p-ANCA was detected on at least two occasions. All information necessary to complete the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) and the SLICC/ ACR damage index (SDI) is collected prospectively. Vasculitis is defined by SLEDAI-2K vasculitis definition which includes ulceration, gangrene, tender finger nodules, periungual infarction, splinter hemorrhages, biopsy or angiogram proof of vasculitis, retinal hemorrhage or vasculitis found in renal biopsy. Damage increase was defined by the first increase of SDI score after baseline. Baseline was defined as first ANCA positive or second negative of ANCA tests. Univariate and multivariable Weibull regression was used to analyse the

effect of positive ANCA on the outcomes of vasculitis and organ damage.

Results: Features for 1212 SLE patients who were tested at least twice for ANCA are shown:

	Positive ANCA (127)	Negative ANCA (893)	P valve
Mean age (years)	38.64 ± 14.64	38.93 ± 13.83	0.823
Mean disease duration (years) at baseline	9.51 ± 9.25	8.46 ± 7.95	0.173
SLEDAI at baseline	5.80 ± 5.17	4.82 ± 5.00	0.04
Mean follow up from baseline to last date (years)	13.30 ± 7.08	7.36 ± 6.35	<0.001
Low complement at baseline	64 (50.4%)	338 (37.8%)	0.007
SLEDAI DNA positive at baseline	72 (56.7%)	405 (45.4%)	0.017
Vasculitis incidence	34 (26.8%)	97 (10.9%)	<0.001
SDI increase	81 (63.8%)	307 (34.4%)	<0.001

Regression analyses showed that patients with positive ANCA had more vasculitis (hazard ratio 1.67, CI 1.10-2.55). Furthermore, SDI increase after index was also more frequent in patients with positive ANCA (hazard ratio 1.39, CI 1.13-1.72) adjusted for patients' demographic/disease characteristics/treatment effects. Similar results were observed when analysing c-ANCA and p-ANCA separately.

Conclusion: Positive ANCA was detected on at least 2 occations in 10.5% of the lupus patients. Patients had two or more positive ANCA tests have higher risk of vasculitis and organ damage compared to ANCA negative patients.

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Multiplex assays that measure anti-nuclear autoantibodies (ANA) in real time using whole blood were developed on the Maverick(TM) instrument (Genalyte, Inc., USA). Because the assay takes less than 10 minutes to complete, it would be possible to perform the test in a near patient setting in an outpatient clinic. The purpose of this study was to evaluate the feasibility of using this novel instrument to perform ANA 8 tests in the clinic and to compare those results to the same sample tested in Genalyte's CLIA registered laboratory.

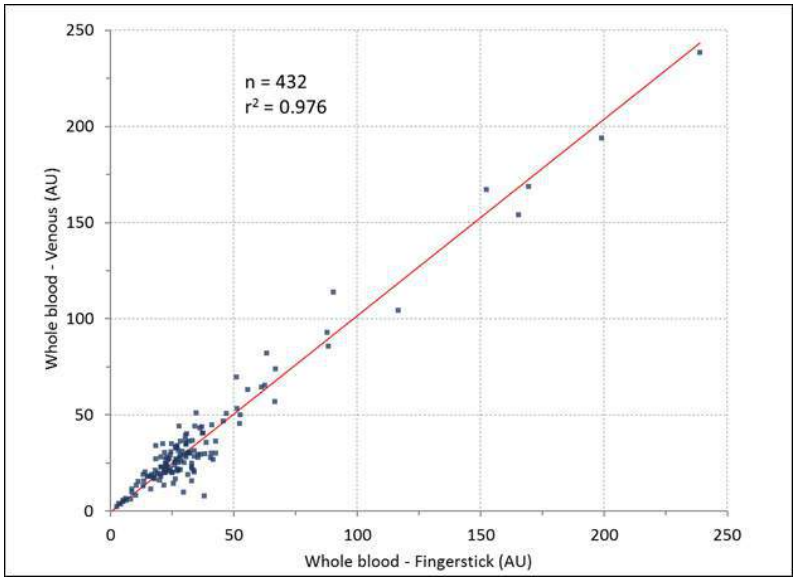
Methods: An Institutional Review Board (IRB) application was approved so that patients who were seeing a rheumatologist and were

going to be tested for ANA using the clinics' standard lab testing procedures could also volunteer to donate additional venous and/or finger-stick blood for further testing. Both the venous and finger-stick blood were immediately tested on the ANA 8 on the Maverick instrument in the clinic. This multiplex immunoassay measures autoantibodies to SS-A 60, SS-B, Sm, Sm/RNP, Scl-70, Jo-1, centromere B and dsDNA. The cutoff between negative and positive was standardized so that 40 AU and greater are positive. Even though results were available in real time, the protocol specified that the doctor would not be given results until the end of the study. 154 samples of venous blood were collected, tested on the Maverick and then returned to the Genalyte CLIA lab for processing into serum for comparison testing on the FIDIS Connective 10 (Theradiag, France). In addition, 54 samples of finger-stick blood were also collected for comparison testing.

Results: The results between whole blood finger stick (WBFS) and whole blood venous (WBVN) tested on the Maverick, and serum tested on the FIDIS for positive, negative and total agreement are shown in the table below.

	Positive Agreement Among 8 Markers	Negative Agreement Among 8 Markers	Total Agreement Among 8 Markers
WBFS vs WBVN	100%	98% to 100%	98% to 100%
WBFS vs FIDIS	100%	96% to 100%	96% to 100%
WBVN vs FIDIS	100%	97% to 100%	97% to 100%

The r^2 correlation between the values for all of the 8 ANA markers from finger stick (54 times 8 yields 432 results) versus venous whole blood is 0.98 as shown below.



Conclusion: This pilot study demonstrated the feasibility of performing multiplex ANA testing on whole blood in a near patient setting in an outpatient clinic. There is extremely high correlation for absolute value between venous blood and finger-stick blood, and between positive and negative results seen with whole blood on the Maverick and serum on the FIDIS. While further studies are required to quantify the impact such a diagnostic system might have on quality of care, there is potential for such a capability to improve timeliness of diagnosis, increase patient centricity and reduce overall healthcare resource utilization.

Antibodies to Double Stranded DNA: Combined Standard ELISA and High-Salt ELISA Assays for the Detection of SLE Disease Activity

Laura Durcan, Jenna Thomason, Daniel Kuo and Mark H. Wener, University of Washington, Seattle, WA
First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Serological markers in systemic lupus erythematosus (SLE) are crucial objective measures included in disease activity indices. Antibodies to double stranded DNA (anti-dsDNA) are included in composite outcomes, and changes in titers in response to therapy are frequently reported in clinical trials. Despite this, there are multiple disparate methods to evaluate anti-dsDNA. The classic Farr immunoassay for anti-dsDNA employs high concentrations of ammonium sulfate, and thus detects only high-avidity antibodies that bind in high ionic strength. The salt-resistant anti-dsDNA assay is considered highly specific for the diagnosis of SLE and reliable as a disease activity marker. In contrast, most ELISAs are performed with buffers of relatively low ionic strength, and thus detect both low-avidity and high-avidity antibodies. We screen for anti-dsDNA using the standard ELISA, and follow-up with a modified high salt ELISA which detects only higher avidity antibodies. Use of both forms of anti-dsDNA has not been evaluated as an additive tool for the assessment of disease activity. We aim to evaluate the sensitivity and specificity of anti-dsDNA measurement by standard and high-salt ELISA assays for the presence of SLE disease activity. We then wished to gauge the additive value of the high salt assay, performed as a reflex, in those with a positive ELISA evaluation, for the assessment of disease activity.

Methods: Patients fulfilling ACR classification criteria for SLE were identified in rheumatology clinic. Demographic data and disease activity (SLEDAI) were recorded. Anti-dsDNA titers were evaluated initially by standard ELISA. On identification of a positive ELISA, a high salt assay was performed reflexively. Active SLE was classified as SLEDAI ≥4. Those with disease activity were compared to those with quiescent disease. Statistical analysis involved the calculation of sensitivity, specificity, positive and negative predictive value of each assay.

Results: Seventy-seven patient encounters were evaluated (69 patients). The mean age was 41 (SD 14) years and 64 (92.8%) were female. The group was composed of mostly Caucasian patients, 39 (56.5%), 10 (14.5%) were African-American, 9 (13.0%) Asian and 8 (11.6%) were Hispanic. Forty-two (54.5%) assessments were of active disease by SLEDAI. Twenty-six (33.7%) had active renal disease. The sensitivity of antibodies to dsDNA for disease activity, by standard ELISA, was 90.5% with a specificity of 35.1%. The high salt avid assay resulted in a lower sensitivity (47.6%) and higher specificity, (78.4%). When considered in combination, given that both are performed, the sensitivity of our protocol was 90.5% with a specificity of 78.4% for disease activity. The correlation between the standard and high-salt anti-dsDNA assay, taking all cases where both was performed was moderate (r= 0.53), often with substantial discordance in results in individual patient specimens.

Conclusion: With an increasing focus on novel markers to evaluate SLE disease activity, there has been little priority placed on the optimal use of pre-existing laboratory tools. Here we demonstrate the clinical utility of a screening ELISA followed by a reflex high salt anti-dsDNA assay. We show high sensitivity and specificity for SLE disease activity through the use of a standard anti-dsDNA ELISA, and a high-salt modified assay that avoids the need for radioactivity and can be readily employed.

ASSAY		%	95% CI
Standard ELISA	Sensitivity	90.5	77.4-97.3
	Specificity	35.1	20.2-52.5
	Positive Predictive Value	61.3	48.1-73.6
	Negative Predictive Value	76.5	50.1-93.2
High Salt ELISA	Sensitivity	47.6	32.0-63.6
	Specificity	78. 4	61.8-90.2
	Positive Predictive Value	71.4	51.3-86.8
	Negative Predictive Value	56.9	42.3-70.7

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Detection of anti-nuclear antibodies for the diagnosis of connective tissue diseases (CTD) often requires complex algorithms to obtain conclusive results , including immunofluorescence on Hep2 cells, ELISA multiplex anlaysis and immunoblotting, which can delay the delivery of results to the physician and the patients. The Maverick™ Detection System (Genalyte, Inc. USA) performs multiplexed detection of autoantibody binding events by measuring the shift in wavelength of ring resonance as the antibodies bind to the antigens on the surface above the rings. The ANA 13 PRI Chips are functionalized with SSA/Ro-60, Ro-52, SS-B, Sm, RNP, PCNA, RiboP, dsDNA, nucleosome, Scl-70, Ku, Centromere B and Jo-1. Just 10 µL of whole blood is required and results are obtained in less than 15 minutes. The objectives of this study were to compare the results obtained in real time on the Maverick with those from the standard procedures in the lab, and to compare those results to the patient's diagnosis.

Methods: Whole blood from 205 consecutive patients followed-up between March and June 2016 at the Pitié-Salpétrière hospital (Paris, France) was analyzed on the ANA 13 PRI. 123 patients had systemic lupus erythematosus (SLE), 13 had Sjögren's syndrome, 10 had primary antiphospholid syndrome, 6 had ANCA associated vasculitis, 5 had Raynaud's phenomenon, 4 had rheumatoid arthritis, 2 had myositis and 1 systemic sclerosis. Other patients had symptoms that required the routine procedures for the diagnosis of CTD with final diagnosis different from CTD. Comparisons were made with results obtained on corresponding sera at the laboratory using IFA screening tests and confirmatory testing with FIDIS multiplex assays (THERADIAG) and when necessary Immunoblotting (D-TEK) or anti-DNA ELISA (DiaSorin), Farr assay and anti-nucleosome ELISA (Werfen).

Results: The Maverick Detection System showed excellent total, positive and negative percent agreement when compared to the final conclusion of the laboratory for Sm, Scl-70, Jo-1, SS-A/Ro 60, SS-B, Centromere, Ku antigens with total, positive and negative percent agreement above 95%, and for PCNA above 92 %. For RNP, total agreement was of 90%, positive was 100% and negative was 88.5%. Interestingly, 17 of 19 samples that were positive for RNP by Maverick but negative by the lab test, and all 8 that were positive for Sm by Maverick but negative by the lab test, were from patients diagnosed with SLE. For anti-nucleosome and anti-DNA the ANA 13 PRI displayed diagnostic performances close to commonly used ELISA systems. For Ro 52 and Ribosome P, the overall agreement and specificity were greater than 90%, but the sensitivity was lower. However, for all cases with false negative results for Ro52 and RiboP with the ANA13 PRI, other specific autoantibodies were present and detected with the ANA13 PRI. Therefore, no diagnosis of CTD would have been missed by using the ANA PRI 13.

Conclusion: The Maverick detection system, which uses whole blood as the matrix and gives results in under 15 minutes, offers a reliable rapid diagnosis solution for the search of autoantibodies in CTD.

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by the production of autoantibodies against nucleic acids and a variety of self-antigens. Recent work indicates that immune complexes containing anti-U1 Ribonucleoprotein (anti-RNP) can drive formation of neutrophil extracellular traps, which in turn can drive interferon-α production by plasmacytoid dendritic cells. (1) We hypothesized that patients with anti-RNP may be more likely to exhibit a specific pattern of SLE disease features, potentially implicating neutrophils in the pathogenesis of those features.

Methods: Clinical data from 160 patients enrolled in the FLARE cohort of SLE patients at Hospital for Special Surgery were reviewed in a retrospective fashion. All patients had been tested for anti-Ro, anti-La, anti-Sm, and anti-RNP at the time of enrollment, and patients were classified as being positive or negative for anti-RNP, whether alone or in combination with other autoantibodies. Each patient's record was reviewed and the presence or absence of a total of 90 disease manifestations and laboratory features at any point in their history were recorded. Differences in the incidence of various phenotypes in different groups were compared between groups using Chi square tests. P values were not adjusted for multiple comparisons in this exploratory analysis.

Results: We identified 83 patients who were positive for anti-RNP antibodies (anti-RNP+), and 77 patients who were anti-RNP negative (anti-RNP(-)). We identified several disease features that differed between anti-RNP+ and anti-RNP(-) patients (Table 1). Specifically, some features classically associated with mixed connective tissue disease were seen more commonly in the RNP+ patients, such as sclerodactyly and myositis. Additionally, a history of vasculitis or elevated serum globulin (>3.5g/dL) were observed more commonly in the anti-RNP+ group. In contrast, anti-RNP(-) patients were more likely to have had a history of immune thrombocytopenic purpura or thrombocytopenia. While there was no significant difference in the prevalence of nephritis overall between the groups, membranous (class V) nephritis was more common in the anti-RNP+ patients, while proliferative (class III/IV) nephritis was more common in the anti-RNP(-) patients.

Conclusion: We demonstrated several disease manifestations which were more likely to be occur in anti-RNP+ individuals, such as vasculitis and membranous nephritis, as well as some which were more likely in anti-RNP(-) patients, such as proliferative nephritis and thrombocytopenia. The role of neutrophil activation and anti-RNP antibodies in these specific disease manifestations merits further investigation. 1. Garcia-Romo, G.S. *et al*. Changes in Urinary Biomarker Levels Can Predict Treatment Responses in Lupus Nephritis

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The relapsing and remitting nature of lupus nephritis (LN) poses a challenge to clinicians who must balance the risk of long term kidney damage with the side effects of treatment. Management of this condition would be greatly aided by the identification of biomarkers that accurately reflect and predict treatment responses. We previously identified and validated a panel of urinary biomarkers that are specifically elevated in SLE patients with active LN as compared to active patients without LN or LN patients in remission. In this study we sought to determine whether changes in the levels of these urinary biomarkers predict treatment responses.

Methods: 21 SLE patients with biopsy-proven LN were followed longitudinally for a minimum of 2 years after treatment. Levels of 15 urinary biomarkers including Clusterin, Cystatin C, NGAL, PF4, vWF,sVCAM-1, GM-CSF, GRO, IL-15, IL-6, MCP-1, Adiponectin, PAI-1, MMP-7, and TIMP-1, were measured by Luminex. Patients were classified as having a complete response (n = 12), partial response (n=4), or treatment (Tx) failure (n=5) at 2 years following Tx, based upon previously established criteria. Urinary biomarker levels were considered abnormal if they were > 2 SD above the mean for 24 healthy controls. Data were analyzed using non-parametric statistics.

Results: At 3-6 months following treatment, the changes in biomarker levels from the first visit were not significantly different between complete responders and partial responders or Tx failures. However, at 1 year (11-17 months) following treatment, 5 urinary biomarkers, sVCAM-1, Adiponectin, IL-15, vWF, and MCP-1, demonstrated significantly different changes from baseline in complete responders as compared to Tx failures, with the majority of responders demonstrating improvement and the majority of Tx failures demonstrating worsening. Since urinary biomarker levels that were not corrected for urinary osmolality correlated best with clinical outcomes, subsequent analyses were done with the uncorrected values. The presence of a normal urinary Adiponectin by 11-17 months was the best predictor of a complete response, with 11 of 12 patients who normalized being complete responders and 1 a partial responder. Similar but slightly less discriminative results were obtained for the other 4 urinary biomarkers. Conversely, the presence of an abnormal urinary vWF at 11-17 months was the strongest predictor of an adverse outcome with 4 of 7 patients with abnormal levels being Tx failures. Notably, all patients that were Tx failures that had normal levels of urinary biomarkers at 11-17 months subsequently developed abnormal levels, whereas patients who were complete responders eventually normalized the majority of these five biomarkers. Partial responders demonstrated normalization with delayed kinetics. Comparison of changes in urinary biomarkers with changes in proteinuria in Tx Failures over time indicated that elevations in urinary biomarkers preceded elevations in proteinuria in some patients.

Conclusion: Measurement of urinary biomarkers can provide valuable insight into treatment responses in lupus nephritis.

An Antigen Microarray to Rule-out Systemic Lupus Erythematosus, the SLE-Key® Rule-out Test, Performs Well As an Aid in Clinical Practice

Donald Massenburg, Justine Oldenberg, Amanda Sell, Tristan Krause and **Alvin F. Wells**, Rheumatology and Immunotherapy Center, Franklin, WI

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The SLE-key® test to Rule Out lupus was developed by ImmunArray Ltd using serum samples of 246 SLE patients and 252 self-declared healthy controls. The test was validated to rule out SLE with 94% sensitivity and 75% specificity and a negative predictive value (NPV) of 93%[1]. Here we evaluate the performance of the SLE-key® test in aiding the management of suspected lupus patients in a large clinical practice.

Methods: We analyzed the SLE-Key® test results from 55 patients being evaluated and managed for SLE at the Rheumatology and Immunotherapy Center, in Franklin, WI. Serum samples were collected from individual subjects with informed consent and sent for testing at VERACIS (Richmond, VA), using the SLE-Key® iCHIP®[2] which contains ~200 antigens and detects profiles of IgG and IgM antibodies. We evaluated the 55 patients clinically using SLICC criteria, and we compared our clinical impression to the SLE-Key® test results. We also evaluated the impact of the test on our subsequent management decisions – terminating evaluation; further evaluation; or initiation of definitive SLE therapy.

Results:

Of the 55 patients tested, 24 were minimally symptomatic, 19 symptomatic patients fulfilled standard SLICC criteria and manifested scores of ≥4, and the remaining 12 patients were symptomatic but did not meet SLICC criteria and manifested a score <4 (Figure 1 shows a flowchart of the study).

The SLE-Key® test confirmed our clinical impression for 30 of the 55 patients (54.5%). SLE was definitively ruled out in 87.5% (21/24) of the minimally symptomatic patients who were assigned to "end of SLE evaluation" with no further follow up or laboratory testing. Of the 19 patients who fulfilled standard SLICC criteria and manifested ACR scores of ≥4, 17 were not ruled out by the SLE-Key® test. In 4 of these cases, clinical impression was revised to 'SLE' based on SLE-key® test results leading to accelerated initiation of therapy.

SLE-Key® test results contributed to a change in clinical diagnosis in 10 patients (18%); in 3 of the minimally symptomatic patients, we revised our diagnosis from "SLE" to "Not SLE" and no further evaluation was needed. In the remaining 7 symptomatic cases, (3 of whom manifested SLICC score of <4) we changed our diagnosis to SLE and accelerated time to therapy.

Conclusion: The SLE-key® rule out test provides a laboratory aid to improve the diagnostic and dispositive efficiency of a new clinical paradigm; thus saving undue concern, time and resources both to the patient and to the healthcare system. In 25/55 patients in this cohort, the SLE-key® test provided actionable clinical information, leading to termination of evaluation for SLE or initiation of therapy. Multi-center validation is warranted to further define the clinical advantages of this serologic test.

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In African-descent patients, lupus nephritis (LN) lead to a worse outcome than in Caucasians. Long term data are rare in countries where black populations have access to free healthcare. Here, we describe the long term prognosis of black Martinican patients with LN.

Methods: Population based, retrospective consultation of 1140 kidney biopsy provided by the pathology unit of the academic hospital of Martinique (French West Indies) from 2002 to 2015. 155 biopsies were related to SLE, concerning 126 patients. All patients diagnosed before 2013, followed a minimum of 24 month in Martinique (or death) after biopsy proven LN (ISN/RPS classification) were included. Complete remission (CR) was defined by no GFR decrease > 10%, no leucocyturia/hematuria and proteinuria ≤ 0.2 g/24h. Partial remission (PR) had the same definition except for proteinuria ≤ 0.5 g/24h. Renal flare flare was defined by an increase >1g/24h of proteinuria if CR, >2g/24h if PR, or a persistent increase >25% of creatinemia. Chronic renal failure (CRF) was defined by GFR<90ml/min/1.72m² (normal if above) and end stage renal disease (ESRD) by requiring chronic dialysis.

Results: 89 patients were included (women 93.3%), and 37 excluded. Mean (±SD) follow up times was 118.3 months (± 73.3). No patient was lost to follow-up. Median age at SLE diagnosis was 27 yo and 30 for LN. The initial mean proteinuria was 3.55g/d (range 0.6 to 27) and creatinemia 118.9 µmol/L (range 26 to 500). Eighteen percent (n=16) had antiphospholipid syndrome. LN was proliferative in 68/89 patients (76.4%): 17 were class III (19.1%), 22 class IV (24.7%), 18 class III+V (20.2%), 11 class IV+V (12.4%). 17 patients were Class V (19.1%), 3 class I (3.4%) and 1 class II (1.1%). Concerning proliferative LN, induction treatment was cyclophosphamide (CYC), mycophenolate mofetil (MMF) and azathioprine (AZA) in respectively 66.1%, 25%, 4.4%. MMF was used as maintenance treatment for 51 patients (75%), CYC and AZA for 5.9% each. All patients received steroids and 91% hydroxychloroquine. At one year, 65/89 had normal GFR (73%), 33 attain CR (37.1%), 9 PR (10.11%), 15 progress to CRF (16.8%), none to ESRD and 3 died (3.3%). During follow up, 23 patients experienced only one renal flare (26.1%), 8 two flares (9.1%) and 1 three flares (1.1%). 68 new biopsies were performed: in 13, class V (76.5%) turn into proliferative LN after a mean delay of 90.2 months. After a mean follow up of 118.4 months: 39/89 (43.8%) achieve CR, 7 (7.9%) PR, 20 (22.4%) progress to CRF, 14 (15.7%) to ESRD and 8 (9%) died. ESRD rates for all 89 patients were respectively at 5, 10 and 15 years : 4.29%, 19,57% and 46.8%**.** Mortality rates for all 89 patients were 5.7% at 5 years, 8.7% at 10, 12.5% at 15, and for proliferative LN patients respectively 7.5%, 12.9%, 17.4%.

Conclusion: Compared to other population based Afro-Caribbean study finding a 31 to 41% mortality rate at 5 years (Nossent et al., ARD 1993; Flower et al, Arthritis Care Res 2012), our data suggest a better prognosis mainly related in our opinion to free access to Healthcare.

Neutrophilia in Systemic Lupus Erythematosus As a Potential Indicator of Disease Activity

Emily E. Lewis[1], W Joseph McCune[2] and Jason S Knight[3], [1]University of Michigan, Ann Arbor, MI, [2]Int Med/ Rheum, University of Michigan, Ann Arbor, MI, [3]Division of Rheumatology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Neutrophilia and elevated neutrophil-to-lymphocyte ratio are being increasingly recognized as reliable markers of inflammation (and usually negative prognostic outcome) in scenarios as diverse as trauma, cancer, and autoimmune disease. While lymphopenia is well established as a marker of lupus activity, why and when lupus patients develop elevated neutrophil counts (neutrophilia) have not been comprehensively explored. Lupus neutrophils are known to produce interferons, release mitochondria, and expel neutrophil extracellular traps (NETs), all of which may be detrimental to the patient.

Methods: From a U.S. lupus cohort of more than 800 patients, we randomly selected 75 patients for a pilot study. Neutrophilia was defined as absolute neutrophil count higher than the upper limit of normal for the institution's laboratory, which was 7.2-7.5 K/µl, depending on the era. Charts were evaluated by two independent reviewers, and each episode was assigned to one of four categories: infection, corticosteroid burst, pregnancy, or unknown. All patients met American College of Rheumatology classification criteria for systemic lupus erythematosus.

Results: In characterizing 75 lupus patients, we identified 2,892 neutrophil measurements over a 20-year period (2001-2016). The median number of neutrophil measurements per patient was 22 (range 2 to 279). Of the 75 patients, 27 patients had no documented episodes of neutrophilia (median number of tests 8, range 2 to 89). We identified 227 unique episodes of neutrophilia (separated by at least 4 weeks, and not part of a continuous event such as an extended hospitalization). Of the 227 episodes of neutrophilia, 26 fell between 7 and 8 K/µl; 72 between 8 and 9; 36 between 9 and 10; 85 between 10 and 20; and 8 between 20 and 30. Of the 227 episodes, 41 were attributed to infection (median neutrophil count 11.2 K/µl), 79 to corticosteroid burst (median neutrophil count 10.8), and 11 to

pregnancy (median neutrophil count 9.5). The most common infections causing neutrophilia were pneumonia and urinary tract infections. 96 cases of neutrophilia (median neutrophil count 8.6) could not be attributed to any of the aforementioned explanations, and we considered that they might associate with heightened disease activity.

Conclusion: Neutrophilia in lupus patients is explained by infection, corticosteroid burst, or pregnancy 58% of the time. In the remaining cases, the explanation is not readily apparent, and analysis is underway to assess the possible contribution of disease activity (preliminary analysis is pointing away from a correlation). These unexplained neutrophilia cases did seem to cluster in a relatively small number of patients, suggesting that there may be particular lupus phenotypes that correlate with neutrophil elevations; analysis is underway in the larger cohort to define those phenotypes. The next phase of this work should also seek to correlate neutrophil counts with not just traditional markers of disease activity, but also novel readouts such as circulating NETs.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The nuclear dense fine speckled (DFS) pattern observed in the ANA assay on HEp-2 cells is strongly associated with autoantibodies to the 70/75kD lens epithelium derived growth factor (LEDGF). Anti-DFS70/LEDGFp75 antibodies are rarely seen as the only autoantibody in individuals with systemic autoimmune rheumatic disease (SARD). Instead, they occur in high titer in a heterogeneous array of non-SARD inflammatory and non-inflammatory diseases, and in 1-9% of the general population. In contrast, the nuclear homogeneous (HO) and coarse speckled (CS) patterns are regularly caused by autoantibodies strongly associated SARD. It is intriguing to investigate the clinical and immunological significance of this peculiar autoimmune response. This study aimed to describe the temporal behavior of DFS reactivity and to compare the associated demographic and laboratory features with those observed in patients the HO or CS patterns and in individuals with non-reagent (NR) ANA.

Methods: We conducted a retrospective analysis of laboratory and demographic associations of the DFS pattern over an 8-year period (Jan/2006 to Dec/2013) using the databank of a large clinical laboratory (average 12,000 ANA/month). We considered only records containing at least one ANA test (NR, DFS, HO or CS patterns) and at least one of the following tests: hemoglobin, CRP, ESR, ferritin, albumin, liver enzymes, glucose, serum complement components, and white/red blood cell count.

Results: 254,840 records were eligible for analysis: DFS (7.1%), HO (0.8%), CS (0.7%), NR (91.4%) The DFS pattern was associated with younger age and male gender, comparing to HO and NR results. Individuals with the DFS pattern had lower frequency of abnormal results in most laboratory parameters in comparison to those with HO or CS patterns, and closely resembled individuals with no ANA reactivity (Table 1). Longitudinal analysis showed that DFS pattern is rather stable along the years, maintaining high titer and rarely changing to other patterns or to non-reagent ANA (Table 2). **Table 1 – Age, gender and frequency of abnormal and normal results for several laboratory parameters according to the ANA pattern**

Studied Variable		ANA PATTERN			
		DFS	HO	CS	NR
Number of cases (%)		17,994 (7.1)	2,115 (0.8)	1,798 (0.7)	232,933 (91.4)

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical trials in lupus nephritis have often been designed to demonstrate renal response (or remission) following therapy based on categorical remission endpoints (often no remission, partial and complete) derived from laboratory measures of renal function and activity. The clinical relevance of these remission categories has been questioned. The primary objective of this study (WEUKBRE6068) was to compare long-term renal survival in patients with complete (CR), partial (PR) or no remission, as defined by criteria used in the Aspreva Lupus Management Study (ALMS) (NCT00377637) and Belimumab International Lupus Nephritis Study (BLISS-LN) (NCT01639339) with the modification of excluding urinary sediments (mBLISS-LN and mALMS), assessed at 24 months following positive lupus nephritis biopsy.

Methods: A retrospective analysis of the prospective Hopkins Lupus Cohort was conducted. Eligible patients had systemic lupus erythematosus (SLE) per revised American College of Rheumatology (ACR) or Systemic Lupus International Collaborating Clinics (SLICC) criteria plus biopsy record of ISN class III, IV, V or mixed lupus glomerulonephritis. The primary endpoint was renal survival (survival without end-stage renal disease (ESRD) or mortality). The primary exposure was remission status (CR, PR or no remission) by mBLISS-LN and mALMS criteria at 24 months post biopsy date. Survival analysis (Kaplan-Meier plots with log-rank test and Cox Proportional Hazards regression) was used to describe subsequent event rates and assess the association between renal survival and remission status at 24 months.

Results: We identified 176 SLE patients with lupus nephritis. At 24 months post biopsy date, more patients met mALMS remission criteria (CR = 59.1%, PR = 30.1%) than met mBLISS-LN criteria (CR = 40.9%, PR = 16.5%). During subsequent follow-up, 18 patients developed ESRD or died. The Kaplan-Meier plots suggested patients with no remission at 24 months post biopsy date were more likely than those with PR or CR to develop the outcome by both mALMS (p=0.0038) (Figure 1) and mBLISS-LN (p=0.0097) (Figure 2) criteria. Based on Cox regression models adjusted for key confounders, those in CR by both mBLISS-LN (HR 0.254, p=0.0176) and mALMS criteria (HR 0.228,p=0.0246) were significantly less likely to experience ESRD/mortality than those not in remission. Similarly, those in PR were less likely to experience ESRD/mortality (mBLISS-LN HR 0.141, p=0.0599; mALMS HR 0.575,p=0.3727)

Conclusion: Renal remission status at 24 months following lupus nephritis is associated with long-term renal survival.

Serum C5a Is Elevated in Lupus Nephritis and in Neuropsychiatric Systemic Lupus Erythematosus through Different Mechanisms

Yuko Sakuma[1], Tatsuo Nagai[2], Taku Yoshio[3] and **Shunsei Hirohata**[4], [1]Department of Rheumatology and Infectious Diseases, Kitasato University School of Medicine, Kanagawa, Japan, [2]Rheumatology and Infectious Diseases, Kitasato University School of Medicine, Sagamihara, Japan, [3]Jichi Medical University, Tochigi, Japan, [4]Kitasato University School of Medicine, Sagamihara, Japan

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Neuropsychiatric manifestation in systemic lupus erythematosus (NPSLE) is one of the most serious complications of the disease. We have recently demonstrated that the breakdown of blood brain barrier (BBB) plays a crucial role in the development of diffuse psychiatric/neuropsychological manifestations (diffuse NPSLE), allowing influx of neuron-reactive autoantibodies from systemic circulation into the central nervous system. Notably, C5a, a split product of C5, has been recently shown to cause BBB damages, as evidenced by the decreased expression of barrier regulating proteins, such as claudin-5 and occludin. However, the relationship between serum C5a and BBB damages in NPSLE has not been explored. On the other hand, although association of C5a with some forms of lupus nephritis (LN) has been implicated, the involvement of C5a in LN has not been examined. The present study therefore explored the levels of C5a in sera from patients with NPSLE and LN.

Methods: Serum specimens were obtained from 29 patients with NPSLE including 18 patients with diffuse NPSLE and 9 patients with neurologic syndromes (focal NPSLE), 25 patients with LN, 26 patients without NPSLE or LN (SLE alone), and from 21 healthy individuals. Cerebrospinal fluid (CSF) specimens were obtained from 29 patients with NPSLE on the same day of the collection of serum specimens. The levels of C5a, C5, C3 and C4 were measured by ELISA. The BBB function was evaluated by CSF /serum albumin ratio (Q albumin).

Results: Serum C5a was significantly increased in 80 SLE patients compared with that in healthy individuals. Serum C5a was significantly elevated in NPSLE as well as in LN compared with that in SLE alone, whereas there were no significant differences in serum C5 among these 3 groups. Serum C4, but not serum C3, was significantly lower in LN than that in NPSLE, indicating the activation

of complement classical pathway in LN, but not in NPSLE. CH50 appeared to be also lower in LN compared with that in NPSLE. Q albumin was significantly elevated in diffuse NPSLE compared with that in focal NPSLE, whereas there were no significant differences in CSF C5a and in serum C5a between these 2 groups. Of note, both CSF C5 and CSF C5a were significantly correlated with Q albumin, whereas serum C5a, but not serum C5, was inversely correlated with Q albumin in NPSLE patients (Figure).

Conclusion: These results have disclosed that serum C5a was elevated in NPSLE as well as in LN through different mechanisms. Moreover, the data indicate that CSF C5a and C5 were elevated in NPSLE due to BBB damages. Finally, inverse correlation between serum C5a and Q albumin suggest that C5a might be consumed during the process of BBB damages.

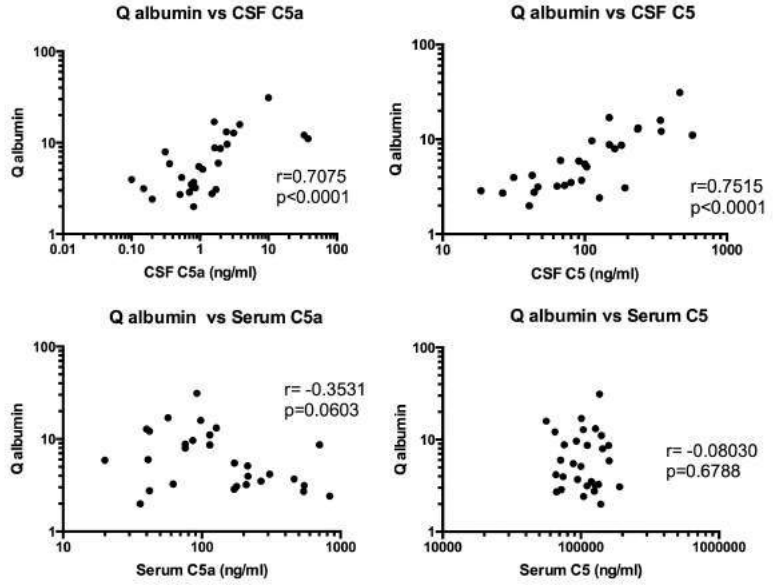

Figure Relationship of blood brain barrier integrity with C5a or C5 in cerebrospinal fluid (CSF) or in serum in NPSLE.

Results from a Phase 0 Longitudinal Clinical Trial in Cutaneous Lupus Erythematosus: Analysis of the Type I IFN Signature in the Skin and Blood and Its Relationship with Disease Activity Scores and Autoantibody Profiles

Jessica Schreiter[1], Jarrat Jordan[1], Matteo Cesaroni[1], Marc Chevrier[2], Alexa Piantone[3], Ian Gourley[3], Jacqueline Benson[1] and Takahiro Sato[1], [1]Estrela Lupus Venture, Janssen Research and Development, LLC., Spring House, PA, [2]Janssen Research and Development, LLC, Collegeville, PA, [3]Immunology Translational Medicine, Janssen Pharmaceutical Research and Development, LLC, Spring House, PA

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Type I IFN (IFN-I)-regulated gene expression is known to be elevated in blood and skin lesions of patients with two different forms of cutaneous lupus erythematosus (CLE): subacute cutaneous lupus erythematosus (SCLE) and discoid lupus erythematosus (DLE). A positive correlation between Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) scores of these patients and blood IFN-I signature has also been described. Using samples from a phase 0 longitudinal clinical study, we

examined the relationship between IFN-I signatures in skin and blood, total CLASI scores, and autoantibody (autoAb) profiles at weeks 1 and 12 of the study.

Methods: Under informed consent, 37 subjects with DLE and 16 subjects with SCLE were recruited for study participation. 18 of the DLE subjects and 12 of the SCLE subjects also had concomitant SLE. Total CLASI scores for each DLE and SCLE subject were collected at weeks 1 and 12 of the study. Lesional and non-lesional skin biopsies were collected at week 1 and an additional biopsy was collected at week 12 from the same region where the lesional biopsy had been collected. Blood RNA PAXgene tubes along with serum were also collected at each time point. In addition, serum, blood RNA PAXgene, and skin biopsies were collected from healthy volunteers at week 1 only. RNA was extracted from both blood and skin and an IFN-I gene expression score was computed using the following genes: IFI44, IFI44L, IFI27, and RSAD2. Serum was profiled for autoAb specificities at both time points using the ProtoArray® platform.

Results: Gene expression in the skin revealed that the IFN-I score was significantly elevated in both lesional and non-lesional skin biopsies from both the SCLE and DLE subgroups when compared to healthy control biopsies. There was no significant difference between skin IFN-I scores in SCLE versus DLE regardless of concomitant SLE and skin IFN-I scores were strongly correlated to blood IFN-I scores in all subsets with or without SLE. Additionally, a positive correlation between skin IFN-I scores and CLASI scores was noted. Many individuals exhibited a decrease in CLASI and skin IFN signature from week 1 to week 12, although a significant correlation was not found across the cohort. AutoAb signal was longitudinally stable in all subgroups; however, only subjects with concomitant SLE had significantly elevated autoAb signals when compared to healthy controls.

Conclusion: Our findings support previous reports of CLASI correlation with blood IFN-induced gene expression and elevation of autoAb signal in SLE subjects. To our knowledge, however, we are the first to show that skin and blood IFN signatures correlate in the same patient irrespective of their subclass of CLE or if they have concomitant SLE. We also show that IFN-I signature is not only elevated in lesional skin of CLE patients, but also in the apparently healthy, non-lesional skin. Additionally, we found that despite the presence of a systemic blood IFN-I signature in CLE subjects with or without SLE, there was no elevation of autoAbs in the non-SLE CLE subjects.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - Poster III: Biomarkers and Nephritis

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) is the leading cause of morbidity and mortality in systemic lupus erythematosus (SLE). The objective of this study is to validate urine platelet factor 4 (PF4) and E-selectin as novel biomarkers for disease activity and renal damage in LN. Both markers were selected based on recently completed proteomic screens of urine from LN patients.

Methods: 113 biopsy-proven LN patients (89 active LN and 24 inactive LN), 45 chronic kidney disease (CKD) patients and 41 healthy controls were recruited for enzyme-linked immunosorbent assay (ELISA) testing of urine PF4 and E-selectin levels. Urine biomarker

levels were normalized by urine creatinine. Disease activity was assessed by the SELENA-SLEDAI. Renal disease activity was assessed by Systemic Lupus International Collaborating Clinics Renal Activity Score (SLICC-RAS) and R-SLEDAI (Total score of the four kidney-related parameters).

Results: Urinary PF4 and E-selectin levels were significantly increased in active LN patients (PF4 [median (Q1-Q3)]: 0.272 (0.0675-1.432) ng/mg; E-selectin: 30.84 (0-76.32) pg/mg) compared to inactive LN (PF4: 0.0225 (0-0.09325) ng/mg, P<0.001; E-selectin: 0 (0-0) pg/mg, P<0.001), CKD (PF4: 0.062 (0-0.18) ng/mg, P<0.001; E-selectin: 0 (0-36.16) pg/mg, P=0.046), and healthy controls (PF4: 0.005 (0-0.017) ng/mg, P<0.001; E-selectin: 0 (0-0) pg/mg, P<0.001), respectively. Urinary PF4 and E-selectin levels were able to discriminate LN patients from healthy controls (Area Under the Curve (AUC) for PF4: 0.84 (*P*<0.001); AUC for E-selectin: 0.77 (*P*<0.001)) as well as active LN from inactive LN (AUC for PF4: 0.79 (*P*<0.001); AUC for E-selectin: 0.80 (*P*<0.001)). The sensitivity and specificity of urinary PF4 (sensitivity: 0.75; specificity: 0.78) in detecting LN activity was higher than that of positive anti-dsDNA (sensitivity: 0.38; specificity: 0.67) or decreased C3/C4 (sensitivity: 0.56; specificity: 0.63). Urinary E-selectin (sensitivity: 0.92; specificity: 0.65) was more sensitive than anti-dsDNA or C3/C4, but less specific than anti-dsDNA in detecting LN activity. A significant positive correlation was noted between urine PF4 and E-selectin levels with SLEDAI (PF4: ρ=0.55, *P*<0.001; E-selectin: ρ=0.30, *P*=0.001), R-SLEDAI (PF4: ρ=0.55, *P*<0.001; E-selectin: ρ=0.41, *P*<0.001), SLICC (PF4: ρ=0.45, *P*<0.001; E-selectin: ρ=0.59, *P*<0.001), urine protein-creatinine ratio (PF4: ρ=0.39, *P*<0.001; E-selectin: ρ=0.58, *P*<0.001) respectively. PF4 also significantly correlated with serum creatinine levels (ρ=0.21, *P*=0.03). Importantly, in a urine/biopsy concurrent cohort, urine PF4 was good at discriminating type IV LN from type II/III LN with an AUC of 0.73 (*P*=0.02). Urinary E-selectin was able to discriminate type II LN from type III/IV LN (AUC: 0.84, *P*=0.03) and type II/III LN from type IV LN (AUC: 0.80, *P*=0.002).

Conclusion: Urinary PF4 and E-selectin are potential diagnostic biomarkers of disease activity in lupus nephritis and proliferative renal pathology. The performance of urinary PF4 and E-selectin in monitoring lupus nephritis should be further validated in larger longitudinal cohorts.

Health-Related Interference of Social Activities and Suicidal Ideation in Systemic Lupus Erythematosus: Georgians Organized Against Lupus Cohort

Charmayne M. Dunlop-Thomas[1], Gaobin Bao[2], S. Sam Lim[2] and Cristina Drenkard[3], [1]Medicine/Rheumatology, Emory University, Atlanta, GA, [2]Medicine, Emory University School of Medicine, Atlanta, GA, [3]Emory University School of Medicine, Atlanta, GA

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Social integration has been found to be a protective factor from suicide-related ideation even after adjusting for mental health predictors. This is especially salient for people with systemic lupus erythematosus (SLE) who may have a wide-range of physical and emotional problems interfering with social activities. Previous cross-sectional data suggested an association between perceived inadequacy of social support and suicidal ideation (SI). To further delve into this concept, we aimed to examine whether 1-year change of health-related interference with social activities would be associated with 1-year increase in SI.

Methods: We examined longitudinal data from the GOAL Cohort, a large population-based cohort of patients with documented SLE from metropolitan Atlanta, Georgia. Since 2011, participants respond annually to a variety of validated self-administered health outcomes. We used the social activities interference question from the SF-12 Health Survey to assess 1-year change in the amount of time physical health or emotional problems hindered social activities. One question from the Patient Health Questionnaire-9 was used to assess 1-year change in the frequency of SI (4-point Likert scale ranging from “not at all” to “nearly every day”). A multivariable logistic regression was used to examine the effect of higher interference of social activities on increased SI, after controlling for demographics and disease-related factors.

Results: Among the 715 SLE participants studied (94% women, 79% Black, 38% uninsured or underinsured; mean age 48) 98

participants endorsed SI at either baseline, Year 1 or both time points. Multivariate analysis of those 98 participants showed that the odds ratio of increased SI at Year 1 was 6.8 for participants who endorsed higher interference with social activities, compared to those who had lower interference. No significant association with increased SI was found when we compared same with lower level of interference with social activities.

Table 1. Predictors of Increased Suicidal Ideation (SI) Over Time in SLE*

Characteristic	OR (95%CI)	P value
Social Activity Interference Change** (ref: Lower)		
Same	1.97 (0.57-6.79)	0.28
Higher	6.77 (1.62-28.24)	0.029
Gender (male)	0.66 (0.06-7.39)	0.74
Race (Black)	7.32 (1.17-45.69)	0.033
Age at survey, per 5 years ↑	0.99 (0.75-1.30)	0.94
Disease duration, per 5 years ↑	1.21 (0.88-1.67)	0.25
Disease activity score, per 1 unit ↑	1.10 (1.01-1.20)	0.026
MCS, per unit ↓	0.94 (0.88-1.01)	0.11
PCS, per unit ↓	0.96 (0.89-1.04)	0.32
Education (less than college)	0.90 (0.25-3.30)	0.87
Un-married	0.41 (0.13-1.30)	0.13
No medical insurance or under insured	0.95 (0.29-3.11)	0.93
Severe organ damage	1.03 (0.28-3.70)	0.97

*Defines as increased frequency of SI over 1 year of follow up, compared to those who remained the same or had lower SI frequency
**Change assessed over 1 year of follow-up

Conclusion: In a population-based SLE cohort with large numbers of African American subjects there is a consistent proportion contemplating suicide in each annual survey. Findings indicate that health-related interference in social activities is a significant contributing factor of SI. This association is particularly significant when there is increasing interference with social activities, which in turn increases the risk of more frequent SI. Social activities can be a resource to enhance social integration. Further development and recognition of social support resources to which SLE patients can be referred are warranted, especially in socioeconomically disadvantaged communities.

Exercise Significantly Improves Cardiorespiratory Fitness and Reduces Disease-Related Fatigue without Adverse Effects on Disease Activity in Systemic Lupus Erythematosus: a Systematic Review with Meta-Analysis

Tom O'Dwyer[1], Laura Durcan[2] and Fiona Wilson[3], [1]Physiotherapy, Trinity College Dublin, Dublin, Ireland, [2]University of Washington, Seattle, WA, [3]Physiotherapy, Trinity College, Dublin, Ireland

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Clinical Aspects and Treatment - ARHP Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematous (SLE) associates with accelerated mortality, frequently attributable to cardiovascular (CV) causes, which is not fully explained by traditional CV risk factors. Individuals with SLE are commonly sedentary with many percieved barriers to exercise. Physical inactivity likely contributes to the burden of CV risk and may also be a significant factor in co-morbid chronic fatigue, poor sleep and fibromyalgia. This meta-analysis evaluates whether exercise has a deleterious effect on disease activity in SLE, and assesses the impact of exercise on cardiorespiratory fitness and fatigue.

Methods: A systematic review and meta-analysis was conducted, including quasi-randomised and randomised controlled trials in SLE comparing at least one exercise group to controls. Studies were retrieved by searching MEDLINE/PubMed, EMBASE, PEDro, AMED, CINAHL and The Cochrane Central Register of Controlled Trials for keywords and medical subject headings relating SLE and exercise. Relevant conference abstracts and reference lists of included studies were manually searched. Two reviewers independently determined study eligibility and assessed risk of bias (Cochrane Risk of Bias tool). Data were extracted using a standardised template. Random-effects meta-analyses were used to pool extracted data as mean differences (MD). Heterogeneity was evaluated with Chi^2 test and I^2, with p-values < .05 considered significant.

Results: The search strategy produced 2980 records. Titles and abstracts screening identified 30 full-texts for eligibility appraisal. Of these, seven were suitable for inclusion in the meta-analyses. Studies included 178 participants and 125 controls; mean age ranged from 31.2 to 52.9 years, and disease duration from 2.5 to 17.9 years. Median (IQR) duration of the interventions was 12 (0) weeks. All interventions included aerobic components, and three also included strength training. There was a high risk of bias relating to blinding of participants and personnel; remaining domains were largely under-reported, with the overall risk of bias unclear. Fig. 1 summarises meta-analyses results. Disease activity was not significantly changed following exercise interventions (MD 0.01; 95% CI, -0.54 to 0.56). Fatigue (MD 0.61; 95% CI, 0.04 to 1.17) and aerobic capacity (MD 1.85 ml/kg/min; 95% CI, 1.12 to 2.57) were significantly improved.

Conclusion: This meta-analysis demonstrates that exercise significantly improves cardiorespiratory fitness and disease-related fatigue in individuals with SLE, without adversely affecting disease activity. This review suggests that exercise may be safely prescribed in this population. Longitudinal studies examining the effects of exercise on CV risk factors in this population are recommended based on the promising findings of this meta-analysis.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although circulating B cells and T cells, including follicular helper T (Tfh) cells, are reported to be involved in systemic lupus erythematosus (SLE) [1,2)], relations between subpopulations and clinical manifestations have not been clearly determined. The aim of this study was to identify abnormalities of the subpopulations in correlation with clinical manifestations in active SLE patients.

Methods: Subsets of peripheral immune cells were quantified using a whole blood flow cytometry in total 51 subjects including 13 active SLE patients who all fulfilled ACR classification criteria and 38 normal healthy controls (NHCs). We compared the proportions of the subsets in SLE patients with those in NHCs and analyzed relations with the clinical parameters.

Results: Mean age of the SLE patients and NHCs was 44.1 and 39.8 years, respectively. All candidates were female. Mean SLE Disease Activity Index was 12. Blood samples of all SLE patients were collected before they received induction therapy. Eight patients were treatment-naïve, while the other patients had treatment with low-dose prednisolone and/or immunosuppressants. Among CD19+ B cells, the proportions of CD38-IgD+ B cells, Bm1 and CD38+IgD+ B cells (Bm2 cells), were lower in SLE patients than in NHCs ($p=0.003$ and $p=0.001$). The proportions of CD38++IgD- B cells (Bm3+Bm4 cells) and CD38+CD24- plasmablasts were higher in SLE patients (both $p<0.001$). Among CD4+ T cells, the proportions of effector memory T cells and HLA-DR+ cells were higher in SLE patients ($p<0.001$ and $p=0.010$). Among CXCR5+ Tfh cells, the proportion of CXCR3-CCR6+ Tfh17 cells was lower in SLE patients ($p=0.001$). In particular, the proportion of CXCR3-CCR6- Tfh2 negatively correlated with the titers of serum complement C3, C4 and white blood cell counts ($\rho=-0.66$, $p=0.021$, $\rho=-0.77$, $p=0.003$ and $\rho=-0.75$, $p=0.003$, respectively), and was higher in SLE patients with skin rash and leukopenia than in patients without them (both $p=0.022$). The correlations of Tfh2 to clinical parameters were similar to those of plasmablasts but opposite to those of Tfh17. (Fig.1) These results support a report in a lupus model mouse in which Tfh2 contributed to the hypocomplementemia-associated pathogenesis [3)].

Conclusion: Proportions of circulating differentiated B cells and T cells were higher in active SLE patients. Tfh2 and plasmablasts negatively correlated with titers of serum complements and were associated with skin rash and leukopenia. Reference 1) Choi J, et al. Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disorder characterized by periods of heightened disease activity. Disease flares significantly affect quality of life and lead to organ damage that accrues over years of waxing and waning disease. African American SLE patients have more severe disease presentation, which is likely a result of differences in immune cell subsets and activation states.

Methods: Peripheral whole blood samples of 10 African American healthy controls and 12 SLE patients with either high (SLEDAI≥4) or low (SLEDAI<4) disease activity were stimulated with T-cell receptor (TCR), B-cell receptor (BCR), and Toll-like receptor (TLR) ligands for either 4 minutes (TLR and BCR) or 30 minutes (TCR) for phospho-protein analysis, and 24 hours for cytokine analysis of cell culture supernatants. Whole blood phenotyping and phospho-protein analysis were assessed by mass cytometry using 24 cell surface markers and 10 intracellular proteins and analyzed by hand gating and viSNE in Cytobank. Plasma cytokine and soluble mediator concentrations of stimulated cell culture supernatants were determined by 37-plex assay and by ELISA. Spotfire (version 6.0.1) and GraphPad Prism 5.04 for Windows (GraphPad Software, San Diego, CA) was used for analysis and Mann-Whitney test was used to compare non-normally distributed data. All SLE patients meet ACR classification criteria.

Results: African American lupus patients with high disease activity had significantly elevated CD24+ granulocytes (p=0.0173), which

negatively associated with IL-8 plasma levels ($p<0.05$) and positively associated with MCP-1 ($p<0.05$) compared to SLE-low disease activity patients. Granulocytes also exhibited a heightened response to TLR9 ($p=0.0062$), TLR4 ($p=0.0446$), and TLR3 ($p=0.0061$) stimulation with higher expression of pSTAT5 and pPLCγ2. Further, transitional B cell frequencies ($p=0.0317$) were also elevated in SLE-high patients versus SLE-low disease activity patients, which correlated with higher levels of Th2 plasma cytokines. Following stimulation with BCR and TLR3 stimulation, SLE-high patient B cells ($p<0.05$) and monocytes ($p<0.04$) had decreased pCREB levels, indicative of activation. Dendritic cells had decreased pSTAT1 ($p=0.0446$) and pSTAT5 ($p=0.0106$) signaling in response to BCR stimulation and decreased pSTAT3 ($p=0.0427$) signaling in response to TLR7/8 stimulation in SLE-high patients compared to SLE-low disease activity patients.

Conclusion: Our results suggest that SLE-high disease activity patients have a favorable environment for granulocyte apoptosis that may work in activating other innate and adaptive subsets to drive disease flare. Further, African American SLE-high disease activity patients are more susceptible to an exaggerated TLR response. Decreased pSTAT1 signaling in dendritic cells of SLE-high disease activity patients could indicate already activated IFN pathways during periods of elevated disease activity.

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE is a highly heterogeneous disease. The identification of disease subtypes with different pathological mechanisms is crucial to identify subjects with different disease progression who may have differential responses to treatment. Since CD8+ T cell exhaustion has been associated with better clinical outcomes, we decided to focus on the CD8+ T cell subpopulations in lupus patients.

Methods: We analyzed 50 SLE patients under standard of care from a single clinical center (Northwell Health Division of Rheumatology). For every patient, we obtained a heparinized blood sample and one PAXgene tube. At the time of phlebotomy, we collected SLEDAI, clinical manifestations and autoantibodies. We used an open population cohort as controls. All protocols were approved by the IRB at NorthWell Health. Whole blood was used for $CD8^+$ T cell phenotyping by flow cytometry, and PBMC were used for phospho-signaling and intracellular cytokine staining. The PAXgene tube was used for mRNA extraction and gene expression on an Affymetrix U-129 chip. The data from the gene expression study was used to evaluate gene modules (*1*). All statistical analysis were performed on JMP10 following published recommendations(*2*).

Results: Terminally differentiated $CD8^+$ T cells are significantly increased in a subset of lupus patients (and confirmed in a second, independent cohort). Importantly, this increase in terminally differentiated $CD8^+$ T cells is particularly noticeable in lupus patients with a history of lupus nephritis ($p<0.05$). SLE patients with higher proportions of terminally differentiated $CD8^+$ T cells have i) higher levels of basal pAKT, ii) a lower capacity to induce pAKT upon CD3/CD28 stimulation iii) a higher proportion of cells that produce

IFNg upon stimulation and iv) higher titers of ANA and anti-RNP70 autoantibodies. Importantly, the fraction of terminally differentiated $CD8^+$cells that is quantifiable by flow cytometry correlates with a genomic signature of cytotoxic activity.

Conclusion: A subset of SLE patients, with a history of lupus nephritis are characterized by a high fraction of terminally differentiated CD8+ T cells and associated secretion of INFg. These data suggest that terminally differentiated CD8+ T cells may drive disease in LN patients and may benefit from therapies that block $CD8^+$T cell activation.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, relapsing autoimmune disease affecting multiple organs and is a highly heterogeneous condition, with wide variations in the presentation and severity of disease and the biological markers identified [1]. We analyzed multi-modal biomarker (mRNA, miRNA, cytokines and autoantibodies) data from ~100 clinically annotated SLE patients under standard of care from a single clinical center (Northwell Rheumatology Clinic) along with ~100 NHVs to identify key dysregulated and co-dysregulated markers in SLE.

Methods: To address the issue of heterogeneity, we applied 2 approaches namely outlier analysis [2] followed by market basket analysis [3] to identify dysregulated and co-dysregulated markers in this multi-modal biomarker rich dataset. We also used pathway analysis and knowledge databases to assess the biological relevance of these markers.

Results: For the whole blood transcriptomic data, on an average, 13% genes were found to be dysregulated in an SLE patient and ~ 6% of genes were found to be dysregulated in at least 25% of SLE patients (Fig.1). Percentage of outlier genes showed weak correlation with SLEDAI scores . Pathway analysis of outlier genes showed an enrichment for IFN signaling pathways (Fig. 2). Market basket analysis identified several high-confidence (>0.8) co-dysregulated associations across a wide proportion of patients. The IFN genes formed the most promiscuous associations. The high-confidence associations were further prioritized based on multi-modality (e.g.

miRNA:mRNA) and opposing regulation.

Conclusion: Several key dysregulated markers were identified in SLE patients using outlier analysis, which might have been otherwise missed by traditional ANOVA-based approaches because of the heterogeneity in patients. Furthermore, the market basket analysis identified several co-dysregulated markers in patient sub-populations which might be missed by traditional co-expression analysis that requires co-dysregulation across all patients. These markers can be drivers and potential patient stratification biomarkers of SLE and might also help to understand the pathophysiology of this heterogeneous and complex disease.

Apoptotic Microparticles, but Not Exosomes, Induce an Inflammatory Response in Synoviocytes

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Circulating microparticles (MPs) and exosomes modulate immune responses and play a role in the pathogenesis of systemic lupus erythematosus (SLE). Exosomes are 50-250 nm in size, while MPs are between 500-1000 nm. These extracellular vesicles vary in their functions and mechanisms of formation. SLE patients have a unique population of inflammatory MPs which carry markers of apoptotic cells. We sought to determine if MPs and exosomes isolated from apoptotic cells in vitro induced an inflammatory response in fibroblast-like synoviocytes.

Methods: Human monocytes (THP-1) were treated with no additives or 100-1,000 U/mL of IFN γ for up to 72 hours to induce apoptosis. Apoptosis was assessed by measuring levels of caspase 3/7. Differential centrifugation was performed to obtain the MP and exosome fractions. A light scattering device (Nanosight) was used to determine the mean size and concentration of particles. Washed MPs and exosomes from apoptotic and normal THP-1 cells were added to human synoviocytes (Cell Applications) and incubated for 24 hours. The human cytokine antibody array (Abcam) was used to assess quantities of cytokines in conditioned media under various conditions.

Results: IFNγ at concentrations of 1000 U/ml successfully induced apoptosis in THP-1 cells as shown by a clear increase in caspase 3/7 levels ($p< 0.03$) (Figure 1). Both mean size ($p<0.05$) and concentration ($p<0.001$) of particles were increased over controls after 72 hours of IFNγ treatment. The addition of equal quantities of exosomes derived from apoptotic and normal cells produced similar synovial cell cytokine levels. In contrast, MPs from apoptotic cells produced a dramatic increase in an array of cytokines largely involving IL-1beta and interferon pathways compared to those from normal cells (Figure 2).

Conclusion: MPs from apoptotic cells induce an inflammatory response in synoviocytes, while this was not true of apoptotic exosomes. Our findings support major differences in the function of these two types of extracellular vesicles. They also lend additional support to a potential role for apoptotic MPs in the manifestations of clinical SLE.

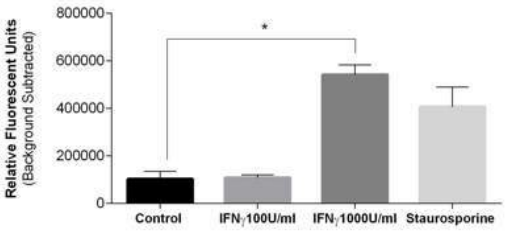

Figure 1. *Interferon γ induces apoptosis. Caspase 3/7 activity was measured as a marker for apoptosis after treatment of THP-1 cells with 1000 u/ml IFN γ. Staurosporine (1 μM) was used a positive control.*

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Recent evidence indicates that high-density lipoprotein (HDL) exerts vasculoprotective activities by promoting activating transcription factor 3 (ATF3), leading to down-regulation of TLR-induced inflammatory responses. Systemic lupus erythematosus (SLE) is associated with increased cardiovascular disease (CVD) risk not explained by the Framingham risk score. Recent studies have indicated oxidized HDL as a possible contributor. We investigated the potential mechanisms by which lupus HDL may lose its anti-inflammatory effects and promote immune dysregulation.

Methods: Control human macrophages were challenged with purified human control and SLE HDL *in vitro* in the presence or absence of TLR agonists and examined for induction of inflammatory markers by real time RT-PCR, confocal microscopy, ELISA and flow cytometry. The effect of an HDL mimetic (ETC-642) was examined *in vivo* in NZM2328 lupus-prone mice.

Results: Compared to control HDL, SLE HDL activates NFκB, promotes inflammatory cytokine production, and fails to block TLR-induced inflammation in control macrophages. This failure of lupus HDL to block inflammatory responses is due to an impaired ability to promote ATF3 synthesis and nuclear translocation. SLE HDL-induced pro-inflammatory responses in macrophages are dependent on its binding to lectin-like oxidized low-density lipoprotein receptor 1 (LOX1R), which promotes suppression of ATF3 activity in a ROCK1/2 kinase-dependent manner. This inflammation can be modulated *in vivo* as lupus-prone mice exposed to ETC-642 show improved ATF3 induction and significant abrogation of pro-inflammatory responses.

Conclusion: Lupus HDL promotes pro-inflammatory responses through activation of NFκB and decreased ATF3 synthesis and activity, in a LOX1R- and ROCK1/2 kinase-dependent manner. HDL mimetics should be further explored as potential therapies to hamper inflammation and reduce cardiovascular risk in SLE.

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Recently, accumulating studies have documented that up-regulated cAMP responsive element modulator α (CREMα) which can inhibit IL-2 and induce IL-17A in T cells plays a critical role in the pathogenesis of systemic lupus erythematosus (SLE). The aim of this research is to investigate the mechanisms that regulate CREMα expression in SLE.

Methods: Histone H3 lysine 4 trimethylation (H3K4me3, a hallmark correlated with transcription activation) amounts at various gene promoters in CD4+ T cells from SLE patients and healthy controls were assayed by chromatin immunoprecipitation (ChIP) microarray. Numbers of H3K4me3, H3K4 methyltransferases SET domain containing 1 (Set1) and mixed-lineage leukemia 1 (MLL1), H3ac and H4ac (both are marks of gene activation), and DNA methyltransferase (DNMT) 3a within the CREMα promoter were measured by ChIP and real-time PCR. DNA methylation (a hallmark of gene silencing) abundance at the CREMα promoter was tested by methylated CpG-DNA immunoprecipitation (MeDIP) and real-time PCR. Levels of CREMα and Set1 mRNA and protein were quantified by real-time RT-PCR and western blotting, respectively. IL-2 and IL-17A productions were detected by enzyme-linked immunosorbent assay (ELISA).

Results: From the ChIP microarray data, we found sharply increased H3K4me3 amount at the CREMα promoter in SLE CD4+ T cells compared to controls. Then by ChIP and real-time PCR, we confirmed this result. Moreover, H3K4me3 amount at the promoter was positively correlated with CREMα mRNA level in SLE CD4+ T cells. In addition, a striking increase was observed in Set1 enrichment, but no marked change in MLL1 enrichment at the CREMα promoter in SLE CD4+ T cells. We also proved Set1 enrichment was positively correlated with H3K4me3 amount at the CREMα promoter, and positively correlated with CREMα mRNA level in SLE CD4+ T cells. Knocking down Set1 with siRNA in SLE CD4+ T cells decreased Set1 and H3K4me3 enrichments, and elevated the levels of DNMT3a and DNA methylation, while the amounts of H3ac and H4ac didn't alter greatly at the CREMα promoter. All these inhibited the expression of CREMα, then augmented IL-2 and down-modulated IL-17A productions. Subsequently, we observed that DNMT3a enrichment at the CREMα promoter was down-regulated significantly in SLE CD4+ T cells, and H3K4me3 amount was negatively correlated with both DNA methylation level and DNMT3a enrichment at the CREMα promoter in SLE CD4+ T cells.

Conclusion: Our findings suggest for the first time that in SLE CD4+ T cells, increased Set1 enrichment up-regulates H3K4me3 amount at the CREMα promoter, which antagonizes DNMT3a and suppresses DNA methylation within this region. All these factors induce CREMα overexpression, consequently result in IL-2 under-expression and IL-17A overproduction, and contribute to the development of SLE at last.

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a complex autoimmune disorder whose pathology appears to involve many immune cell types. While it is clear that autoantibody producing B cells as well as $CD4^+$ T cell help are key contributors to disease, little is known regarding the role of innate lymphoid cells such as Natural Killer (NK) cells in the pathogenesis of SLE.

Methods: We have characterized the phenotype of NK cells by multicolor flow cytometry, proteomics and genomics arrays in a large cohort of patients with SLE.

Results: While the overall percentage of NK cells was similar or slightly decreased compared to healthy controls, a subset of patients displayed a high frequency of NK cells expressing the proliferation marker, Ki-67, which was not found in healthy donors. Only a moderate increase of Ki-67 was observed on other immune cell types such as total CD4+, CD8+ T cells or CD19+ B cells in the same donors. Increased NK cell expression of Ki-67 was found to correlate with clinical parameters. Interestingly, elevated frequencies of Ki67+ NK cells were highly associated with active nephritis. Proteomics analysis and auto-antibody arrays also revealed significant correlations between NK cell expression of Ki-67 and type I interferon (IFN) gene score as well as SLE associated auto-antibodies

Conclusion: These results will contribute to the understanding of the mechanistic role of NK cells in immune-mediated pathology of SLE.

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-1 receptor (IL-1R)-associated kinase 4 (IRAK4) is a key component of the Myddosome complex, which is essential for signalling downstream of IL-1R and most Toll-like receptors (TLRs) except TLR3. Aberrant TLR signalling has been implicated in the development of disease in both murine models of lupus and human systemic lupus erythematous (SLE). Herein we tested the hypothesis that inhibition of IRAK4 kinase activity can dampen the production of pro-inflammatory cytokines, type I interferon (IFN), and potentially autoantibodies.

Methods: An IRAK4 tool inhibitor (compound 1) was used to treat PBMCs from SLE or lupus nephritis (LN) patients followed by TLR7 or IL-1β stimulation overnight. Cytokine (IL-6) production in the culture supernatant was then measured by AlphaLISA. Either fresh SLE/LN whole blood or healthy control PBMCs stimulated with 5% SLE/LN plasma were treated with either 5 μM of compound 1, 20 μM of Hydroxychloroquine (HCQ) or DMSO control overnight, and gene expression was then measured by NanoString with a representative gene panel. The effect of the IRAK4 inhibitor on human plasmablast differentiation driven by TLR7 activation was also examined using freshly isolated B cells activated with a selective TLR7 ligand for 7 days, followed by flow cytometry analysis of the $CD38^{hi}$ $CD19^{low}$ plasmablast population. Lastly, the IRAK4 inhibitor was dosed by chow in a Pristane-induced lupus mouse model. Arthritis score, plasma levels of autoantibodies (anti-dsDNA, anti-Histone, anti-SmRNP, anti-RiboP, and anti-Ro/SSA), and gene expression were followed to evaluate disease development.

Results: Blockade of IRAK4 with a selective inhibitor (compound 1) led to concentration-dependent decrease of inflammatory cytokine (IL-6) production by TLR7 or IL-1β-stimulated SLE PBMCs. In addition, treatment with the IRAK4 inhibitor significantly reduced the expression of IRAK4-dependent genes, many of which were also observed to be elevated in whole blood from SLE and LN patients as well as in healthy control PBMCs stimulated with SLE plasma. Our data suggested that IRAK4 blockade produced unique but differential effects on type I IFN-inducible and other IRAK4-dependent genes compared to HCQ treatment. In contrast to its potent effects in suppressing inflammation/type I IFN-inducible genes, IRAK4 blockade with compound 1 only produced modest inhibition of plasmablast differentiation *in vitro* driven by TLR7, even at a saturating concentration. Lastly, we showed that dosing of the IRAK4-selective inhibitor in a Pristane-induced lupus model produced significant inhibition of joint inflammation measured by arthritis score, but no effect on autoantibody production.

Conclusion: IRAK4 kinase activity is essential for the induction of inflammatory cytokines and chemokines in myeloid cells, but less important for TLR-driven activation of B cells. Pharmacological inhibition of IRAK4 in SLE (and LN) could potentially relieve inflammation by dampening constitutively activated innate immunity and subsequently decrease end organ damage.

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Recently, our group has demonstrated that decreased microRNA-142-3p/5p (miR-142-3p/5p) which contributes to T cell overactivation and B cell hyperstimulation plays an essential role in the pathogenesis of systemic lupus erythematosus (SLE). The aim of this study is to

investigate what regulate miR-142-3p/5p expression in SLE.

Methods:

CD4+ T cells were isolated from SLE patients and healthy controls. Amounts of H3K27me3, EZH2(H3K27 methyltransferases) within the microRNA-142 (miR-142) regulatory region were subsequently analyzed by chromatin immunoprecipitation (ChIP) and real-time PCR in CD4+ T cells from 20 SLE patients and 20 healthy controls. And miR-142-3p/5p expression levels were determined by real-time quantitative polymerase chain reaction.

Results:

By ChIP and real-time PCR experiments, we confirmed increased H3K27me3 enrichment at the miR-142 regulatory region of SLE CD4+ T cells relative to controls. Moreover, H3K27me3 enrichment at the miR-142 regulatory region was negatively correlated with miR-142-3p/5p expression levels in SLE CD4+ T cells. In addition, a striking increase was observed in EZH2 binding at the miR-142 regulatory region in SLE CD4+ T cells compared to healthy controls. We also proved the levels of EZH2 binding were positively correlated with H3K27me3 enrichment at the miR-142 regulatory region, and negatively correlated with miR-142-3p/5p expression levels. Knocking down EZH2 with siRNA in SLE CD4+ T cells led to decreased EZH2 binding and H3K27me3 enrichment at the miR-142 regulatory region, thus increasing the expression of miR-142-3p/5p.

Conclusion:

Our findings suggest for the first time that increased EZH2 binding up-regulates H3K27me3 enrichment at the miR-142 regulatory region, which inhibits miR-142-3p/5p expression in SLE CD4+ T cells, and contributes to the development of SLE at last. These results can help elucidate the molecular pathogenesis of SLE, and provide a novel way and target for effective SLE therapy.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Identifying populations at risk of SLE is essential to curtail inflammatory damage and select individuals for

prevention trials. Blood relatives (Rel) of lupus patients have an increased risk of developing SLE, but no markers which identify individuals at highest risk are known. Using a large resource of SLE patients, lupus relatives, and unrelated controls, this study seeks to identify questionnaire responses and serologic factors that distinguish Rel from SLE patients and unrelated, unaffected individuals.

Methods: This study examined European-American (EA) (n=50) and African-American (AA) (n=50) individuals with medical record-confirmed, classified SLE matched 1:1 by race and gender to unaffected Rel (n=100) and unrelated, unaffected controls (Ctls, n=100). Study participants provided clinical and demographic information, and completed the SLE-specific portion of the CTD Screening Questionnaire (SLE-CSQ). Plasma samples were assessed for autoantibody production by bead-based assays and for 52 soluble mediators (BLyS, APRIL, cytokines, chemokines, and shed TNF receptors) by multiplexed bead-based assays or ELISA.

Results: EA SLE patients had more photosensitivity ($p=0.035$), with AA SLE patients having more discoid rash ($p=0.028$) and nephritis ($p=0.045$). Only 45% of Rel were positive for ANA (by IIF > 1:120) compared to 99% of SLE patients ($p<0.001$) and 21% of Ctls ($p=0.001$). Compared to Rel, Ctls had significantly lower SLE-CSQ scores ($p=0.001$), while SLE patients had significantly higher SLE-CSQ scores ($p<0.001$). Irrespective of race, a strong correlation exists between SLE-CSQ scores, number of ACR criteria, and number of autoantibody specificities ($p<0.001$) across Rel vs. SLE patients and Ctls. In addition, a number of soluble mediators strongly correlated with these 3 variables, including TNF superfamily members BLyS, TNFRI, and TNFRII, IFN-associated chemokines IP-10, MCP-1, and MIG, soluble receptor IL-2Rα, SCF, and IL-10 ($p\leq0.002$ for each mediator). In certain cases, levels of soluble mediators in Rel demonstrated up-regulation similar to SLE or intermediate between SLE and Ctls. Levels of MCP-1 and MIG were similar between Rel and SLE patients, and higher than Ctls ($p\leq0.004$), while levels of BLyS and IL-2Rα were similar between Rel and Ctls, and significantly lower than SLE patients ($p<0.001$). Rel had intermediate levels of TNFRI, TNFRII, IP-10, and SCF between SLE patients ($p\leq0.01$) and Ctls ($p\leq0.03$). In contrast, Rel had significantly higher levels of the regulatory mediator IL-10 than SLE patients ($p<0.001$). All soluble mediator findings were independent of race, except for TNFRI (EA>AA SLE patients, $p<0.001$) and TNFRII (AA>EA SLE patients, $p<0.001$).

Conclusion: Lupus Rel are distinguished from SLE patients and Ctls by inflammatory mediators that correlate with SLE-specific CSQ scores, with increased levels of the regulatory mediator, IL-10, compared to SLE patients. Identification of factors which discern unaffected lupus relatives from SLE patients may be beneficial to identify potential treatments to curtail inflammatory damage for prevention trials.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Upregulation of interferon-β (IFNβ) is an important step in promoting maturation and survival of B cells. Secretion and autocrine action of IFNβ requires assembly of the IFNβ enhanceosome, including IRF3, IRF7 and NF-κB. Interestingly, TLR7 stimulation has been found to induce IRF7 in transitional B cells from SLE patients. The purpose of this study is to determine if IFNβ is upregulated in transitional B cells of SLE patients and if autocrine activity of IFNβ promotes B cell survival.

Methods: Peripheral blood samples were obtained from consented SLE patients with active disease (SLEDAI > 6) during visits to a Lupus Clinic. FACS analysis was carried out using surface staining antibodies IgD, CD24, CD38, CD27 and CD19. Intracellular IFNβ was detected using and antihuman IFNβ (PBL, clone MMHB3). Autoreactive B cells were detected using 9G4. Transitional and mature $9G4^+$and 9G4B cell subsets were FACS sorted. qRT-PCR was carried using validated primers. Purified B cells were stimulated with TLR7 (CL264, 5 μg/ml) and a goat polyclonal antihuman IgM+IgG (5 μg/ml). IFNβ and IFNα/βR blocking was carried out using a polyclonal anti-IFNβ (500 IU/ml, PBL) and an IFNα/βR blocking Ab (anifrolumab, 5 μg/ml, Creative BioLabs), respectively.

Results: There was a significant increase in intracellular IFNβ determined by both FACS analysis and by RT-PCR in $IgD^+CD24^+CD38^+CD27^-$ transitional B cells of SLE patients compared to control subjects ($p<0.01$). IFNβ was upregulated in both the $9G4^+$ and $9G4^-$ subpopulations of B cells. The expression of *Ifnb* in transitional cells further positively correlated with the expression of IFNα genes (*Ifna1*, *Ifna2*, and *Ifna4*) and IFN response genes (*Mx1* and *Ifit4*) ($p<0.05$). TLR7 plus BCR stimulation upregulated IFNβ and resulted in a significant upregulation of CD69 and CD86 at 4 hrs by both transitional and mature B cells, and increase in survival at 60 hrs in B cells from SLE patients. Importantly, IFNβ neutralization inhibited these responses. The inhibition was equivalent to the blockade of IFNα/βR, indicating that although both IFNα and IFNβ were expressed, these early responses required the release and autocrine activity of intracellular IFNβ.

Conclusion: The present results suggest that, in SLE, induction of type I IFN production by early transitional B cells is a 2-step process. IFNβ acts in an autocrine fashion to promote B cell survival and upregulation of IFNa. IFNa does not play an essential autocrine role but may act on other cells. B cell therapies directed at neutralizing IFNβ may be useful, especially in early-stage SLE prior to IFNβ enhanced development of IFNα producing B cells. Inhibition of IFNβ enhanceosome component(s) that are required for IFNβ production, may serve as a novel target for SLE. *(Supported by NIH R01-AI-071110, R01-AI-083705, P30-AR-048311, T32 AI007051, VA Merit Review grant 1I01BX000600, Lupus Research Institute, Lupus Foundation of America.)

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease with an increased atherosclerotic risk compared to healthy population, partially explained by traditional cardiovascular risk factors. Recent data suggest B-cell activating factor (BAFF) as an important contributor in the pathogenesis of both SLE and atherosclerosis. The aim of the current study is to explore whether genetic variants of the BAFF gene increase SLE susceptibility as well as lupus related atherosclerotic risk

Methods: Five single nucleotide polymorphisms (SNPs) of the BAFF gene (rs1224141, rs12583006, rs9514828, rs1041569 and the rs9514827) were evaluated in 234 SLE patients and 200 healthy controls (HC) of similar age and sex distribution by PCR-based assays. Allele, genotype and haplotype frequencies in SLE patients and HC were determined by SHEsis and SNPStats software. All patients underwent ultrasound determination of plaque formation in the carotid arteries. Clinical, laboratory and medication data as well as classical risk factors for cardiovascular disease were recorded in all patients. Patients were followed in the Department of Rheumatology, General Hospital of Athens and Rheumatology Unit First Department of Medicine, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece between 2013-2016 and fulfilled the American College of Rheumatology (ACR) criteria for the classification of SLE.

Results: The prevalence of the minor A allele and the AA genotype of the rs12583006 BAFF variant was significantly higher in SLE patients compared to HC (OR [95%CI]: 1.51 [1.12-2.04], p=0.007 and OR [95%CI]: 2.62 [1.04-6.61], p=0.03 in recessive model, respectively). Haplotypes TACAT and TTTAT also conferred a heightened risk for lupus susceptibility. Moreover, the AA genotype of the rs12583006 BAFF variant was significantly higher in SLE patients with evidence of atherosclerotic plaque formation compared to those without plaque after adjustment for age and sex (OR[95%CI]: 5.4 [1.5-19.7], p=0.007 in the recessive model). No other significant associations were detected

Conclusion: BAFF genetic variants increase susceptibility to lupus and lupus related atherosclerosis. These data imply B-cell related factors as potential contributors in the pronounced cardiovascular risk among lupus patients.

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

- **Background/Purpose:** Systemic lupus erythematosus(SLE) was an autoimmune disease characterized by extensive B cell activation and autoantibody production. Human peripheral monocytes could be categorized into three subsets based on differential expression levels of CD14 and CD16: the classical monocytes (CM, CD14++CD16-), the intermediate monocytes (IM, CD14++CD16+) and the nonclassical monocytes (NCM, CD14+CD16++). NCM and IM were collectively addressed as CD16+monocytes. The three subsets had been described to demonstrate diffierent functions in inflammatory process. However, their effects on B cell response in SLE were not well studied.The aim of this study was to determine the frequencies of these subsets and investigate their possible roles in B cell activation and differentiation under SLE condition.

- **Methods:** The frequencies of monocyte subsets in the peripheral blood of healthy donors (HC) and patients with SLE were determined by flow cytometry (FACS). Monocyte subsets were sorted and co-cultured with CD19+ B cells. B cell were co-cultured for different subsets detection by FACS, while the supernatant were collected for IgG, IgA and IgM detection by enzyme-linked immunosorbent assay (ELISA). The function of monocyte subsets on B cell was defined as the ratio of the effects of monocyte subsets co-cultured with B cell versus the effects of B cell cultured alone.

- **Results:** CD16+monocytes were obviously expanded in SLE, while CM were significantly reduced. Compared to HCs, monocyte subsets in patients with SLE demonstrated different phenotypes about HLA-DR, CD163, CD80, CD86, CX3CR1 and CCR5 expression. CD16+monocytes induced CD19+B cells to differentiate into memory B (MB) and plasma B (PB) cells but inhibited the generation of regulatory B (Breg) cell in HC donors. However, both PB response and Breg differentiation induced by

CD16+monocytes were exacerbated in patients with SLE. IgG secretion from CD19 positive B cells was increased when cocultured with CD16+monocytes in HCs, which was significantly enhanced when co-cultured with CD16+monocytes in patients with SLE. IgA and IgM responses were differentially regulated by monocyte subsets from SLE and HC, respectively. Compared to CM, CD16+monocytes extensively promoted the expansion of IL-17A- and IL-10- producing B cells, suggesting the preferable role of CD16+monocytes in cytokines secretion from B cells in HCs,. In comparison to HCs, the generation of IL-17A-producing B cells in patients with SLE were significantly elevated in the presence of CD16+monocytes, in which the generation of IL-10 producing B cells were obviously attenuated .

- **Conclusion:** CD16+monocytes was enriched and shared different cell-surface marker profiles in SLE. These cells played a predominant role in orchestrating B cell activation and differentiation in SLE.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Natural IgM autoantibodies have been proposed to have protective properties, and decreased levels of IgM to phosphorylcholine (PC) in SLE are associated with higher risk of atherosclerotic plaques and cardiovascular events. In the current study we investigated levels of total IgM and IgM anti-PC levels in different SLE subgroups.

Methods: Serum IgM levels were compared in 322 population controls and 351 SLE patients meeting ACR criteria. SLE patients were subgrouped based on antibody profiles into antiphospholipid (APS)-like (n=54, with ≥2 positive tests among anti-CL/β_2GPI; LA), Sjögren's syndrome (SS)-like (n= 63, with ≥2 positive tests among anti-Ro52/Ro60/SSB), or SLE only with no "secondary syndrome" (n=234). A majority, but not all, of the APS-like and SS-like fulfilled clinical criteria for antiphospholipid syndrome or Sjögren's syndrome. Total IgM levels were determined in the clinical laboratory, and IgM anti-PC measured using PC-BSA by sandwich ELISA. Analyses used the 2-sided Mann-Whitney test or Spearman correlation.

Results: IgM anti-PC levels were moderately but significantly decreased in the SLE patients (41.3±45.3 RU/ml) compared to matched controls (48.9±43.15 RU/ml) (n=316, p=0.002). Similarly, the total IgM levels were only slightly lower in SLE than controls (n=310, 1.22±1.1; 1.26±0.68 mg/ml, p=0.0002). There was a weak inverse correlation with age and disease duration for IgM anti-PC (p=0.02, R=-0.13; p=0.0003, R=-0.19). Importantly, APS-like patients did not have significantly altered total IgM (1.51±1.1 mg/ml) or IgM anti-PC levels (58.7±58.7 RU/ml) compared to controls (IgM 1.26±0.7 mg/ml; IgM anti-PC 48.7±43.2 RU/ml), while the SLE only group had moderately decreased IgM levels (IgM 1.21±1.3 mg/ml, p<0.0001; IgM anti-PC 39.5±43.0 RU/ml; p=0.002), and the SS-like patients had considerably impaired IgM (IgM 0.96±0.6 mg/ml, p<0.0001; IgM anti-PC 23.4±24.2 RU/ml, p<0.0001). There were no statistically significant differences based on age, disease duration, female sex, or anti-dsDNA positivity. In all SLE patients, total IgG levels were significantly increased compared to controls, and were highest in the SS-like group.

Conclusion: Alterations in IgM levels between SLE subgroups further emphasize the immune heterogeneity of patients diagnosed with SLE. Patients have different clinical manifestations, risk of co-morbidities, and which also have distinct immunological features. Future studies are needed to investigate the clinical relevance of depressed IgM levels, and if the moderate IgM impairment in certain SLE patients reflects underlying immunological differences and/or is due to consumption of natural IgM or others causes resulting in skewing of the B-cell repertoire.

SLE Serum Impairs NO Production in Huvecs through Induction of eNOS Uncoupling

Jim Oates[1,2], Diane L. Kamen[3] and Joy N Jones Buie[4], [1]Medical Service, Ralph H. Johnson VAMC, Charleston, SC, [2]Medicine/Rheumatology & Immunology, Medical University of South Carolina, Charleston, SC, [3]Department of Medicine, Division of Rheumatology and Immunology, Medical University of South Carolina, Charleston, SC, [4]Rheumatology and Immunology, Medical University of South Carolina, Charleston, SC

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) induces endothelial cell dysfunction (ECD) that can manifest as glomerulonephritis or atherosclerosis. Lupus-prone mice lacking endothelial nitric oxide synthase (eNOS, a critical enzyme in endothelial cell (EC) function), have more severe proliferative nephritis. We hypothesized that SLE serum would induce ECD in vitro by reducing eNOS expression and increasing uncoupling of eNOS monomers, rendering the enzyme unable to produce protective nitric oxide (NO).

Methods: To address this hypothesis, we determined the extent to which serum from SLE patients induced ECD in vitro, whether serum-induced ECD was associated with reduced eNOS mRNA expression, and whether serum-induced ECD was reversed by addition of L-sepiapterin, a tetrahydrobiopterin donor that induces coupling of eNOS monomers to form functional, NO-producing homodimers. Human umbilical vein endothelial cells (HUVEC) were cultured with 20-50% serum from SLE patients (met ≥4 ACR criteria, mean SLE Disease Activity Index score = 4.6, n = 25) and connective tissue disease-free controls (n = 14) for 24 hours. Endpoints measured were: 1) EC NO production measured by staining with DAF-FM diacetate (an NO fluorescent probe) and performing flow cytometry; 2) EC eNOS mRNA measured via quantitative reverse transcription quantitative polymerase chain reaction (RTqPCR); and 3) Changes in HUVEC eNOS monomer and dimer formation in the presence of patient serum were determined by Western blot. The aforementioned endpoints were reassessed after co-culture of EC with serum and sepiapterin (5 μM). Data were reported as mean ± standard deviation and compared using a Student's t-test or Kruskal-Wallis test.

Results: HUVECs cultured in 50% SLE serum displayed significantly reduced median fluorescence intensity (MFI) indicative of diminished NO production compared to EBM-2 media cultured cells (0.28 ± 0.38 vs. 1.08 ± 0.92 fold change respectively, $p < 0.05$). This reduction was reversed when cells were co-cultured in L-sepiapterin (5μM) and healthy control (n=5) or SLE (n=12) serum (1.13 ± 0.60 and 1.28 ± 2.8, respectively). Conversely, 20% SLE serum increased relative ratios of NOS3 mRNA expression vs. control as measured by reverse transcriptase quantitative PCR (RTqPCR) (1.9 ± 1.0 vs. 1.0 ± 1.2, $p < 0.05$). Western blot analysis revealed increased monomerization in cell cultured using SLE serum. However, preliminary studies suggest that the addition of L-sepiapterin restores dimerization of eNOS homodimers.

Conclusion: These results suggest that SLE serum alone can induce ECD through reduction of functional NO production in EC. The reversal of this in vitro ECD with sepiapterin suggests that SLE serum induces uncoupling of eNOS homodimers, a process that increases eNOS superoxide and reduces eNOS NO production. Both of these changes induce ECD. The observation that SLE serum increased (rather than decreased) eNOS mRNA expression suggests a feedback loop in enzyme expression in response to reduced NO production; although, this hypothesis is not addressed here. Determining the mechanism and molecular pathway through which SLE serum induces ECD could lead to targets for pharmacologic intervention.

Notch Ligand Delta-like Ligand 4 (DLL4) Expression on Dendritic Cells Is Increased in Systemic Lupus Erythematosus

Jevon Fragoso[1], Lijun Meng[2], Yi Zhang[2] and Roberto Caricchio[3], [1]Rheumatology Medicine, Lewis Katz School of Medicine, Philadelphia, PA, [2]Fels Institute for Cancer Research & Molecular Biology, Lewis Katz School of Medicine, Philadephia, PA, [3]Medicine Rheumatology, Lewis Katz School of Medicine, Philadelphia, PA

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Dendritic cells (DCs) activate the immune system with a variety of cytokines and co-stimulatory molecules. Our group recently described the Notch ligand Delta-like Ligand 4 (DLL4) on human DCs and discovered that DLL4+ DCs were critical in regulating Th1 and Th17 differentiation. Due to the association of DCs, Th17 and activity with SLE, the goal of this work was to evaluate DLL4 expression in human SLE DCs.

Methods: Peripheral blood from healthy controls and patients with SLE were collected after obtaining informed consent. A total of 11 SLE patients and 13 sex and aged matched control were investigated. A multicolor flow cytometric analysis using a BD LSRII flow cytometer was used to identify DCs. DLL4 expression was determined by surface staining of $CD1c^+$ DCs and pDCs. DCs were analyzed either in PBS or in the presence of the Toll-like Receptor (TLR) 7 agonist R848. Lupus activity was measured by SLE disease activity index (SLEDAI) and values were extracted from EPIC, the Temple University Hospital's Electronic Medical Record system. Statistical analysis was performed with JMP® Software. Student's t-test, ANOVA, MANOVA, and least squares regression were used with a $p < 0.05$ was considered to be significant.

Results: We found that $DLL4^+$ $CD1c^+$ DCs in lupus patients at rest were 5-fold higher than in controls (p=0.002). Moreover, $DLL4^-$ $CD1c^+$ DCs were 2.1-fold higher in controls at rest (p=0.002). Interestingly also $DLL4^+$ pDCs were 3.3-fold higher in lupus patients at rest (although not significant). After TLR7 stimulation, lupus patients had 3.3-fold more $DLL4^+$ pDCs and those were 3.3-fold more responsive (p<0.001). We next correlated DLL4 expression and disease activity measured by SLEDAI. Interestingly SLEDAI score correlated with DLL4+ CD1c+ DCs after TLR7 stimulation. In lupus patients with no disease activity, $DLL4^+$ pDCs were 3-fold more responsive to TLR7 triggering. Next we correlated DLL4+ DCs with SLE flares and found that $DLL4^+CD1c^+$ DCs were 2.3-fold more responsive to R848 (p=0.03) and 1.2-fold more responsive in a flare (not significant).

Conclusion: Our results suggest that DLL4+ DCs are a marker of chronic activation in SLE patients. Moreover, this particular group of DCs demonstrates propensity to activate upon TLR triggering, a major component of lupus pathogenesis. The SLEDAI scores and flares results findings are consistent. Finally $DLL4^+$ pDCs could be a marker for SLE disease.

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

All lymphocyte populations contribute to SLE pathogenesis, but little is known of the specific gene transcripts particularly involved in each cell type. Activation of the type I interferon (IFN-I) pathway is observed in most lupus patients and is associated with more severe disease. To gain insight into the contribution of major lymphocyte subsets to autoimmune disease we studied gene expression and directed analysis to components of the IFN-I pathway.

Methods:

PBMC were isolated from 15 SLE patients and 10 matched healthy controls. Participating patients met ACR criteria for SLE and were adult females of different ages, racial backgrounds and disease manifestations. Patients had received stable doses of steroids and/or plaquenil but had not received biologics. $CD4^+$T, $CD8^+$T, $CD56^+$NK and $CD19^+$B cell fractions were isolated using magnetic beads, purity was assessed by flow cytometry, and RNA was extracted. Transcriptional profiles were obtained using Affymetrix U133Plus 2.0 microarray chips, and transcripts differentially expressed between SLE and control cell preparations were identified using the limma package. Weighted gene co-expression network analysis was performed using the WGCNA package. A difference in expression was considered statistically significant when $p<0.05$ and absolute fold change was more than two.

Results:

A linear blocking model identified differentially expressed genes in each of the studied fractions (PBMC 122; $CD4^+$T 107; $CD8^+$T 124; $CD56^+$NK 506; and $CD19^+$B 112 genes). A similar list was obtained using gene co-expression network analysis. All cell fractions and the unfractionated PBMC from SLE patients demonstrated the IFN-I signature, with 27 IFN-I-induced gene transcripts common to all fractions. The IFN-I signature correlated with a lower proportion of $CD3^+CD4^+$T (R=

-0.3, $p<0.01$) and $CD56^+$NK (R= -0.6, $p<0.01$) cells and an increase in monocytes (R = +0.6, $p<0.01$) in PBMC as measured by flow cytometry. Other SLE-associated transcripts were independent of the IFN-I signature but were cell-type specific and potentially affect immune functions. IRF7, IRF9, STAT1 and STAT2 were increased in all fractions, but IRF5 showed significant upregulation only in the CD56 cell fraction. Among Toll-like receptors, TLR5 was significantly higher in $CD4^+$T cells while TLR7 was significantly higher in B cells. Expression of IFN-I receptor genes was comparable in all fractions, and IFN-I transcripts were generally undetectable in lymphocytes.

Conclusion:

The IFN-I signature reflects an important pathophysiologic pathway in autoimmune conditions, particularly in SLE. Our data demonstrate that the IFN-I signature is ubiquitous among lymphocyte populations and includes common transcript components. Other pathway transcripts, including IRF5 and TLR7, point to distinct and significant roles of lymphocyte subsets in disease.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a genetically complex rheumatic disease with heterogeneous clinical manifestations. Recent studies have suggested the existence of a genetic basis for the diverse SLE clinical phenotypes. Also, there is increasing evidence indicating that a substantial part of the genetic variation associated with complex diseases could be explained by small-effect genes from common genetic pathways. The objective of the present study was to identify new genetic variation associated with SLE phenotypes using a genome-wide association study at the pathway level.

Methods: A total of 598,258 SNPs were genotyped in a discovery cohort of n=482 SLE patients of southern European ancestry using the Illumina platform Quad610. After quality control analysis, including ancestry estimation using principal-component analysis, genome-wide pathway analysis was performed. A total of 14 clinically relevant SLE phenotypes were tested for association in n>700 reference genetic pathways. Significantly associated pathways (corrected P-value < 0.05) were subsequently tested for validation in an independent cohort of n=425 SLE patients from the same ancestry. Both discovery and validation cohort patients were Caucasian European and from Spanish origin, and were recruited by n=15 rheumatology departments from Spanish university hospitals. The validated genetic pathways were functionally characterized using *in silico* analysis on cell types of relevance in SLE pathogenesis.

Results: In the discovery stage, two genetic pathways were significantly associated with the presence of oral ulcers and antinuclear antibodies in SLE (P_{FDR}<0.05). In the replication stage, we validated the association between oral ulcers and the vascular endothelial growth factor (*VEGF*) genetic pathway (*P*=1.3e-2). Analyzing the transcriptional effect of the topical immunotherapies used for the treatment of oral ulcers in SLE, we found a significant differential expression of *VEGF* pathway genes (P<0.05).

Conclusion: In this work we have performed the first genome-wide association study for clinically relevant SLE phenotype using a pathway-based approach. With this new approach, we have identified and validated the association of VEGF genetic pathway with oral ulcers in SLE. These findings represent an important step towards the characterization of the genetic basis of phenotype heterogeneity in SLE.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) patients have an increased risk of developing clinically apparent cardiovascular disease (CVD) and subclinical atherosclerotic plaque, detectable by vascular ultrasound (US). Although dyslipidaemia and immune dysfunction are widely described in SLE, their role in atherosclerosis is unclear. We propose that *invariant* Natural Killer T (*i*NKT) cells, which respond to lipid antigens presented by CD1d on antigen presenting cells, play a key role in linking the immune system, lipids and CVD in SLE patients. We observed differential defects in iNKT cell number and function in SLE patients with and without pre-clinical atherosclerosis (SLEP), a condition associated with altered lipid homeostasis. Here we investigate how cellular lipid metabolism influences CD1d-lipid antigen presentation in SLE and how this is altered in SLEP.

Methods: Vascular US on 100 patients with SLE but no history of CVD showed 36 had plaque (SLEP) and 64 had no plaque (SLENP). Blood from 40 SLENP, 34 SLEP and 28 female healthy controls (HCs) (mean age 39) was used to assess monocyte and B cell phenotype. Expression and colocalization of CD1d and lipid rafts (LR, plasma membrane signalling platforms), kinetics of immune synapse formation, and subsequent invariant T cell receptor (iTCR) signalling were assessed by flow cytometry and ImageStream. Expression of genes regulating cellular and membrane lipid content were analyzed using qPCR.

Results: LR expression was increased (p=0.01) and CD1d expression reduced (p=0.01) on B cells from SLE patients compared to HCs. This was associated with increased accumulation of CD1d within LRs in SLE compared to HC B cells (p=0.009). Conversely, no differences in LR and CD1d expression and location were detected in monocytes from HCs or SLE patients. The location of CD1d in relation to LRs can influence the potency of *i*NKT cell activation. We found that monocytes formed more stable interactions with *i*NKT cells compared to B cells (p=0.005); these interactions were more rapid between iNKT cells and monocytes from SLEP compared to SLENP patients and HCs and translated to significantly increased *i*TCR-z phosphorylation in SLEP-monocyte/*i*NKT cell conjugates (p=0.05). B cell-iNKT cell interactions were reduced in all SLE patients compared to HCs and resulted in altered down-stream iTCR signalling. Since LRs were unaltered in monocytes, we hypothesized that monocyte intracellular and/or CD1d lipid content may be different in SLE patients. mRNA expression of liver X receptor-α and its target genes (a transcriptional program which decreases cellular cholesterol) were decreased in monocytes from SLE patients (p=0.008) favouring accumulation of intracellular lipids. Furthermore monocyte phospholipid content was increased by culture with serum from SLEP compared to SLENP patients.

Conclusion: We propose that monocytes and B cells interact with iNKT cells differently. B cell-iNKT interactions are perturbed in all SLE patients and are associated with altered LR localization. In the setting of pre-clinical atherosclerosis changes in circulating lipids alter monocyte lipid metabolism and the nature of CD1d-lipid antigen they present.

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: SLE patients experience deterioration in cognitive function over time but attribution to disease-related mechanisms is confounded by medication effects, psychiatric disease, hormonal influences and infection. The hippocampus and thalamus are interconnected subcortical structures associated with memory, attention, and other higher cortical functions. Decreased hippocampal and thalamic volumes have been reported in SLE subjects with and without cognitive and behavioral impairment. By contrast, metabolic changes in these regions have been consistently associated with memory impairment. The purpose of this study is to use magnetic resonance diffusion tensor imaging (DTI) to evaluate changes in the integrity of pathways (i.e., anatomical connectivity) linking these two structures, as well as other pairs of regions exhibiting metabolic abnormalities in SLE subjects.

Methods: 17 SLE patients with inactive disease and no history of CNS involvement and 14 gender, age-matched healthy control (HC) subjects were imaged using DTI with a 3T MRI scanner (57 slices of 2.5 mm thickness, FOV 240 mm, data acquisition matrix 128 x128 zero filled to 256 x 256, TR 15s). Five b=0 images and 33 diffusion weighted images with b=800 s/mm2 were acquired. The DTI images were processed using FSL routines (FMRIB software library: www.fmrib.ox.ac.uk/fsl), and FA and MD maps were calculated. Group tractography was performed to evaluate the integrity (anatomical connectivity) of projection pathways linking areas with significant metabolic abnormalities in SLE subjects.[1] Tracts connecting the hippocampus, thalamus, putamen, and parietal cortex were reconstructed based on clusters identified by voxel-wise comparison of FDG PET scans from SLE and HC subjects using TrackVis software.

Results: Relative to HC, the SLE group displayed a 28% reduction in hippocampal-thalamic (HT) tract count. The basal ganglia-thalamic tract was preserved in the SLE group (% 8.5 difference), whereas hippocampal-parietal tract number was increased (+30%) relative to HC.

Conclusion: This is the first study to show abnormal HT tracts in SLE subjects. Although the SLE subjects had inactive disease and no history of CNS involvement, HT tract number was reduced in this group. Importantly, the hippocampus and thalamus are areas of the brain known to be integral to cognitive processes and metabolic increases in these areas have been found to correlate with memory impairment. In contrast, other tracts between the hippocampus and parietal lobe or basal ganglia and thalamus are preserved or increased. Abnormalities in the HT tract have been associated with impaired learning and memory as well as with increased symptoms in individuals at high risk for schizophrenia. Additional analyses of other imaging studies and neuropsychological testing are planned to evaluate the functional effects of this novel structural finding. 1. Session Date: Tuesday, November 15, 2016
Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic inflammatory disease characterized by the involvement of multiple organs and systems with aberrations in T cell response, especially involving effector and regulatory lymphocytes subsets. Lupus nephritis (LN) has a significant impact on morbidity and mortality of SLE patients. Urinary markers are a potential tool for accurate assessment of LN, because they may reflect immediate local alterations in renal status. The objective of this study is to evaluate the frequency $CD4^+$ T cells in urine and in peripheral blood in LN and to analyze associations with clinical and immunological parameters.

Methods: Peripheral blood mononuclear cells (PBMC) and urinary cells from 17 patients with active LN, 20 disease controls with primary glomerulonephritis (GN) and 10 healthy controls (HC) were analyzed by flow cytometry for the frequency of Th1 ($CXCR3^+CCR5^+$), Th2 ($CCR4^+CD294^+$), Th17 ($CD161^+CCR6^+$) and regulatory T cells (T_{REG} cells) ($CD25^+CD127^{low}$). In LN, $CD4^+$ T-cell subtypes in PBMC were re-evaluated at six months of immunosuppressive therapy with cyclophosphamide or mycophenolate sodium. T-cell subsets were assessed in renal tissue of 12 LN patients who underwent biopsy by immunohistochemistry using the expression of transcription factors as markers: Tbet (Th1 cells), GATA3 (Th2 cells), ROR^{γ} (Th17 cells) and FOXP3 (T_{REG} cells).

Results: $CD4^+$ T cells were decreased in peripheral blood from LN patients compared with primary GN and HC [38.52% ± 10.39 vs. 56.63 ± 9.59 vs. 50.69% ± 8.10; $p = 0.0001$) as well as a lower frequency of peripheral Th2 cells was found in LN compared with HC [2.48% (0.04-16.40) vs. 4.21% (2.98-6.38); $p = 0.025$]. However, no differences were observed in the frequency of urinary $CD4^+$ T-cell subsets between LN and primary GN. When comparing T-cell subsets in peripheral blood from patients with and without proliferative forms of LN, no difference was found. However, a higher frequency of urinary Th17 cells was found in non-proliferative compared with proliferative LN [14.37% (4.42-57.80) vs. 3.85% (1.30-27.00); $p = 0.041$]. $CD3^+$ and $Tbet^+$ cells were found in glomeruli and interstice of LN patients, while FOXP3, RORγ and GATA-3 were present only in glomeruli. Expression of FOXP3 was significantly lower in glomeruli compared with other markers. Peripheral Th1 cells were negatively correlated with urinary Th1 cells (Rho=-0.531; p=0.028) and with Tbet in renal interstice (Rho=-0.782; p=0.004). At 6 months of treatment, LN patients showed a significant increase in peripheral Th17 cells regardless of response to immunosuppressive therapy [1.13% (0.02-8.70) vs. 5.15% (1.35-13.51); $p = 0.008$].

Conclusion: Associations between peripheral, urinary and renal Th1 cells indicate a potential role of Th1 response in LN. Urinary Th17 cells were associated with less severe LN, and peripheral Th17 increased at 6 months of therapy. Differences in $CD4^+$ T cells between LN and primary GN or HC were found only in peripheral blood, not in urine.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: CD52 is a cell-surface glycoprotein that is widely expressed in lymphocytes, monocytes and eosinophils. $CD4^+CD52^{high}$ T cells inhibit the activation of $CD4^+CD52^{low}$ T cells through the release of cell-surface CD52. Soluble CD52, which is cleaved from $CD4^+CD52^{high}$ T cells, works as a ligand of siglec-10 on $CD4^+CD52^{low}$ T cells (1). $CD4^+CD52^{high}$ T cells were reported as distinct population from conventional regulatory T cells. The role of the immune regulation of these cells in systemic lupus erythematosus (SLE) is unknown. We evaluated the $CD4^+CD52^+$ T cells in the human peripheral blood mononuclear cells (PBMCs) of SLE patients and clarified their roles in the pathogenesis of SLE.

Methods: We isolated the PBMCs of 58 SLE patients, 22 non-SLE patients (19 with rheumatoid arthritis, 3 with mixed connective-tissue disease) and 33 healthy controls (HCs). The expressions of $CD4^+CD52^{high}$ T cells and $CD4^+CD52^{low}$ T cells were analyzed by flow cytometry. We also analyzed the correlations with clinical parameters including SLEDAI, anti-ds-DNA antibodies and complement. We then analyzed circulating follicular helper like T cells (Tfh like cells) identified as $CD4^+CXCR5^{high}ICOS^{high}PD\text{-}1^{high}$ and plasmablast identified as $CD3^-CD19^+CD38^+CD27^+$. To determine the genetic characteristics of $CD4^+CD52^{low}$@and $CD4^+CD52^{high}$ T cells from SLE, we performed cDNA microarrays (SurePrint G3 Human GE 8x60K) and examined the function of the genes in *in-vitro*.

Results: We found that the expression of $CD4^+CD52^{low}$ T cells in the SLE was significantly higher than HC and non-SLE. The expression of $CD4^+CD52^{low}$ T cells of the SLE were positively correlated with SLEDAI, anti-ds-DNA antibodies and IgG. The population of Tfh like cells were increased in SLE and its expression was positively correlated with $CD4^+CD52^{low}$ T cells. The microarray analysis revealed that the expression of chemokine receptor 8 (CCR8) is significantly increased in $CD4^+CD52^{low}$ T cells. In addition, in vitro experiments using CD4 T cells from patients with SLE showed that thymus and activation-regulated chemokine (TARC), known as a ligand of CCR8, induced the conversion of $CD4^+CD52^{high}$ T cells into $CD4^+CD52^{low}$ T cells.

Conclusion: Collectively, our data suggest that increased $CD4^+CD52^{low}$ T cells along with increased Tfh like cells are involved in the pathogenic autoantibodies production and that TRAC may contributes to the development of SLE via an aberrant induction of $CD4^+CD52^{low}$ cells. Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease that involves multiple organ systems and periods of variable disease activity. Although SLE, especially in patients with high disease activity, is often associated with increased circulating pro-inflammatory cytokines, a clear understanding of immune dysfunction preceding and during high disease activity is lacking. The identification of genes and gene pathways that are differentially regulated between SLE and healthy individuals, as well as between patients with varying disease activity, may allow better selection of directed therapeutics and development of new targets. To address this knowledge gap, we determined the chromatin accessibility landscape of three distinct compartments of the lupus immune system using the 'Assay for Transposase Accessible Chromatin Sequencing' (ATAC-seq) method.

Methods: Monocytes, B cells, and T cells were sorted by flow cytometry from frozen PBMCs of 9 SLE patients and 5 matched controls. Sorted cell fractions were processed for high-throughput open chromatin profiling by ATAC-seq. Reads were aligned to the hg19 genome and regions of enriched chromatin accessibility "peaks" were identified with MACS2. For each cell type, we identified the consensus set of epigenetically active peaks across all 14 subjects. We conducted enrichment tests of identified loci using the GREAT tool and performed differential accessibility analysis using the edgeR package in R. Transcription factor binding motif enrichment and overlaps with known SLE risk haplotypes were also determined.

Results: All cell types showed similar percentages (39~43%) of coding transcripts with open chromatin in promoters. The peaks unique to each profile were enriched in genomic loci specific to their cellular function: T cell development/activation for T cells, B cell development/activation for B cells, and phagocytosis, apoptotic cell clearance, and inflammatory cytokine regulation for monocytes. Analysis of transcription factor binding motifs in ATAC peaks identified cell type specific promoters including myeloid and lymphoid cell lineage commitment transcription factors. Quantitative analysis revealed chromatin accessibility loci that discriminate between SLE and controls, as well as between high and low disease activity. Of the total 53338 monocyte specific peaks observed in at least 7 samples, 308 peaks allowed us to differentiate between SLE and controls, whereas in T and B cells the numbers were 57 of 34818 and 553 of 39425, respectively. Motif analysis revealed that many consensus peaks occupy binding sites of cohesin complex subunits, suggesting that long-range chromatin interactions may mediate immune responses that drive SLE progression. In addition, of 2519 SLE genetic risk SNPs, 320 were located within an open chromatin peak suggesting functional relevance.

Conclusion: Our data suggest that SLE and controls show cell type specific differences in their chromatin accessibility, and these profiles differ across the spectrum of disease activity. Chromatin profiling, integrated with transcriptome data, may expand our knowledge of how specific cell states drive SLE pathogenesis.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematous (SLE) is a complex autoimmune disease often involving multiple organs. In SLE, immune complexes containing autoreactive antibody and nuclear material activate plasmacytoid dendritic cells (PDCs). Activated PDCs are thought to contribute to disease pathogenesis by secreting IFN-alpha and through presentation of autoantigen to T cells. PDC

activation is regulated by numerous inhibitory surface receptors including ILT7 which serves as a negative feedback pathway to limit PDC IFN production. We and others have linked numerous gene polymorphisms with blood IFN levels, disease severity, and clinical characteristics.

Methods: We studied expression of 12 inhibitory surface receptors on PDCs from a cohort of patients (n>60) and controls (n>20) by quantitative flow cytometry and correlated them with IFN levels, clinical characteristics, and disease severity. ILT7 function was studied by measuring the impact of ILT7 crosslinking on IFN and cytokine output using blood mononuclear cells and purified PDCs from patients and controls. A second inhibitory receptor, CD303, was studied as a comparator.

Results: We find selective downregulation of surface ILT7 expression and decreased ILT7 function by PDCs of patients with high ANA titers (p<.0001 for SLE with high vs low ANA titers).

Conclusion: These data suggest that decreased function of the ILT7 pathway leads to chronic PDC activation in SLE patients. The association with higher ANA titers suggests that dysfunction in this pathway may contribute to the formation of autoreactive antibodies and may contribute to disease pathogenesis in SLE via an impact on the IFN pathway as well as humoral autoimmunity.

Session Title: Systemic Lupus Erythematosus – Human Etiology and Pathogenesis - Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoantibodies in SLE that bind to double-stranded DNA or RNA-binding proteins are strongly associated with high levels of type I interferon (IFN), likely via their ability these antibodies to form nucleic-acid containing immune complexes that can stimulate Toll-like receptors. In this study, we examine whether anti-phospholipid antibodies, which should not have this capacity, are associated with greater type I interferon in SLE patients.

Methods: We studied 392 SLE patients (223 African-American, 101 European-American, and 68 Hispanic-American ancestry) and measured type I IFN in sera. Antiphospholipid (APL), anti-RBP, and anti-dsDNA antibodies were measured in the clinical laboratory, and standard clinical cut-offs were used to define a positive result. Non-parametric analyses were used to compare IFN data with the antibody data in each ancestral background.

Results: African-American subjects with a positive IgG APL antibody test had higher type I IFN levels than those without APL antibodies (p=0.02). This was not observed in the other ancestral backgrounds, and in fact the opposite trend was observed in Hispanic-Americans. African-Americans were less likely to have a positive IgG APL test than European-Americans (p=0.0067, OR=2.3), and those African-Americans with a positive IgG APL test were more likely to also have anti-dsDNA antibodies (p=0.04, OR=2.5).

Conclusion: These data suggest a distinct serological profile in African-American patients, in which a positive APL antibody test corresponds with a significantly greater type I IFN level and more frequent anti-dsDNA antibodies, and this is not shared with other ancestral backgrounds. These data support differences in the molecular pathogenesis of SLE by ancestral background that may impact treatment strategies.

Clinical Predictors for Development of Interstitial Lung Disease in Mixed Connective Tissue Disease

Neha Narula[1], Tathagat Narula[2], Benjamin Wang[1] and Andy Abril[1], [1]Division of Rheumatology, Mayo Clinic, Jacksonville, FL, [2]Pulmonary and critical care medicine, Respiratory Critical Care & Sleep Medicine Associates, Jacksonville, FL

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Mixed connective tissue disease (MCTD) is an immune-mediated systemic disorder characterized by serum autoantibodies against U1-ribonucleoprotein and diverse multisystemic clinical manifestations. Approximately 50% of patients with MCTD develop a radiological pattern of interstitial lung disease (ILD). In this study, we explore the phenotypic and clinical features in patients with MCTD that are associated with development of ILD.

Methods: We performed a retrospective case control study utilizing data from patients evaluated at a single tertiary care center from 2007-2014. Twenty-eight patients who met validated criteria for diagnosis of MCTD were included in the study. Fourteen patients had high-resolution computed tomography or biopsy-proven ILD, and 14 had MCTD without evidence of ILD . We performed a multivariate logistic regression with multiple demographic, clinical, and serologic predictor variables, and ILD as the outcome variable.

Results: Two clinical variables had an association with development of ILD in patients with MCTD:

1. Dysphagia with a R^2 value of 0.33 (p value < 0.001)
2. Raynaud's phenomenon with R^2 value of 0.28 (p value < 0.001)

We did not find a significant association between any other demographic, clinical, or serologic variables and development of ILD in patients with MCTD.

Conclusion: Dysphagia is one of the symptoms of esophageal involvement in patients with autoimmune connective tissue disorders. An association of dysphagia with the development of ILD in our study is in harmony with the existing literature, wherein esophageal dysmotility has been described in a cluster of patients with MCTD and ILD. Scant data, primarily case reports, suggest an association of Raynaud's phenomenon with development of ILD in patients with undifferentiated CTD. To our knowledge, this is the first study highlighting the association of Raynaud's phenomenon with development of ILD in patients with MCTD. This study is limited by its small size and retrospective nature. The mechanistic aspects of the association between Raynaud's phenomenon and ILD remain unexplored. The association of easily elicited historical and clinical features of MCTD with subtle, but worrisome, pulmonary pathology carries the promise of sensitizing the unsuspecting clinician about the entity of ILD in MCTD.

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a systemic autoimmune disease in which the damage of microcirculation is critical to develop the disease. In SSc, vascular complications have very similar pathogenic findings, which are relevant in the disease. For example, digital ulcers (DU) are a frequent complication in SSc patients and pulmonary arterial hypertension (PAH) is one of the leading causes of death. The use of endothelin receptor antagonists (ERAs) has been shown to be useful for the treatment of PAH related to SSc, and to prevent new episodes of DU in patients with the disease. However, it is not known if ERAs are useful for the prevention of PAH.The aim of our study is to determine if ERAs are useful to prevent PAH in SSc patients. Furthermore, we aim to determine if there are any differences in echocardiographic or pulmonary function tests for patients treated with or without ERAs.

Methods: This was a retrospective, multicentre case-control study with 237 SSc patients with DU. Data were analysed during follow-up for patients treated or not treated with Bosentan (BOS) to prevent DU. The occurrence of pulmonary hypertension (PH) was defined by an echocardiogram (ECO) exhibiting systolic pulmonary arterial pressure (sPAP) > 40 mmHg at any stage of the follow up. For all patients, demographic variables, gender, SSc subtype, clinical involvement, autoimmunity data, capillaroscopy findings and different echocardiographic and pulmonary function test data, performed from baseline to follow-up were collected. Statistical significance was denoted by p values less than 0.05

Results: Fifteen patients had ECO values of sPAP> 40mmHg and were excluded from the analyses. Of the remaining 222 patients the majority were women (91%) with a mean age (±SD) of 63.9 (±19.6) years. The first manifestation of the disease occurred at 40.7 (±17.9) years, while Raynaud's phenomenon was the most frequent initial finding (85.6%). Fifty-nine patients (26.6%) were treated with BOS. The most common dose was 250mg daily (60%) and BOS was taken for a median of 34 months. In 21% of patients, PH was suspected due to ECO findings. During the follow up 13.8% of patients treated with BOS presented with PH, in comparison to 23.7% of untreated patients (OR 0.52, 95% CI: 0.22-1.19; p = 0.13). Adjusted regression analyses showed patients not treated with BOS were 3.9 times more likely to develop PH during follow-up (OR 3.913, CI95%:1.32-11.58; p < 0.02). Analysis of the tools of patient evaluation showed that the percentage of diffusing capacity for carbon monoxide (DLCO) in BOS-treated patients did not significantly decrease from baseline to the end of follow-up (61.8±14% vs 57±20.1%, p=0.89). This was statistically significant (p < 0.04) when compared to BOS-untreated patients who showed a significant decrease in the percentage of DLCO at the end of follow-up (65.5±20.2% vs 60.5±19.9%; p < 0.01).

Conclusion: Our retrospective study shows that those patients treated with BOS to prevent UD have a lower risk to develop PH during the disease as well as stabilization of DLCO percentages. Our results support the need for a prospective, randomized, clinical trial to study the effect of ERA in prevention of PAH in SSc patients.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Raynaud's phenomenon (RP) is an early marker of microvascular damage in systemic sclerosis (SSc) and digital ulcers (DU) are a serious complication of vascular dysfunction, occurring in about 50% of SSc patients. DU are painful, difficult to heal, and in some cases progress to gangrene and autoamputation. Current treatments for RP and DU focus on improving distal blood flow using vasodilators, vasoconstrictor antagonists, or drugs which reduce vasospasm. Nevertheless, many patients continue to develop DU over time, suggesting the need for alternative treatment options.

Methods: We reviewed all publications between 1978 and 2016 on the use of therapeutic plasma exchange (TPE) to treat patients with SSc. Out of the 40 papers reviewed, 13 reported effects on RP and DU. Four studies were confounded by simultaneous use of drug therapies and were excluded from the analysis shown in the table.

Results: A commonly reported finding was that a single course of a small number of weekly TPE treatments (typically four) had significant effects on both RP and DU as well as blood flow, microvessel patency, and blood rheology. In many patients, RP disappeared or was significantly improved, and even long-standing digital ulcers began to heal. Several studies documented abnormal blood rheology pre-treatment (elevated whole blood viscosity (WBV) and RBC aggregation) that was significantly reduced after four weekly TPE treatments. The improvements in symptoms and blood rheology were surprisingly long lasting: at least six months and in one study no reoccurrence of DU was observed at three-year follow-up.

Conclusion: In patients diagnosed with SSc, a limited course of TPE treatments appears to lead to significant improvements in RP and DU symptoms as well as objective improvements in blood flow, microvessel patency, and blood rheology that persist for several months. Since TPE treatments have no known direct effects on blood vessels, these results suggest that TPE may have an entirely different mechanism of action. Volkov (2006) noted that WBV is highest in patients with active DU, raising the possibility that the long-lasting normalization of whole blood viscosity and significant reduction of RBC aggregation may directly lead to enhanced microvascular blood flow and thus to improved microvessel patency and SSc symptoms. We recommend that a randomized, double blind, placebo-control study of TPE that includes measurements of blood rheology be conducted to better understand these effects.

Study	Type	N	TPE Protocol	Follow-Up	Summary / Notes
Cotton 1978	PS	12	Varied	Not reported	Letter. Improved microvessel patency in 10/12 Pts. Gangrene reversed in 1 Pt. after 6 TPE.
Talpos 1978	PS	5	1 TPE/week for 5 weeks	6 months post TPE	4/5 patients with DU before TPE. All DU but 1 healed after TPE. Significant improvement in RP and DU post TPE. Blood viscosity sig improved in 3/3 Pts.
Dodds 1979	PS	8	1 TPE/week for 4 weeks	6 weeks post TPE	DU healed in 3/3 Pts. Microvessel patency improved in 6/6 Pts.
O'Reilly 1979	RCT	27 (9 in TPE group)	1 TPE/week for 4 weeks	6 weeks, 6 months post TPE	Microvessel patency significantly improved in TPE group only at 6 week and 6 month follow-up. DU healed after TPE in 3/3 Pts and remained healed at 6 month F/U.
Zahavi 1980	CT	37 (9 Pts. with severe SSc in TPE group)	1 TPE/week for 4 weeks	3 months post TPE	At F/U, microvessel patency improved in 7/8 Pts. and DU healed in 3/3 Pts.
McCune 1983	PS	6	1 TPE or ÒshamÓ TPE/week for 4 weeks	3 months, 6 months post TPE	Complicated design with mixed TPE and autologous ÒshamÓ TPE. 5/6 maintained improvements in RP and DU at 3 month and

					6 month F/U. Some objective measures improved with sham TPE as well as standard TPE.
Von Rhede van der Kloot 1985	PS	14 (7 primary RP, 7 secondary RP)	1 TPE/week for 4 weeks	Post TPE only	RP disappeared or improved in 6/7 Pts. in secondary RP group and 2/7 in primary RP group, DU improved in 3/3 Pts. in secondary RP group.
Ferri 1987	PS	6 (severe SSc)	3 TPE/week for 6 to 8 weeks, then tapering down. Total duration 6 to 14 weeks.	Post TPE only	5 Pts. completed protocol. DU healed or significantly improved in 5/5 Pts. at end of TPE.
Jacobs 1991	PS	18	1 TPE/week for 4 weeks	Three, nine, 24, 36 months post TPE	Post TPE, all Pts. had either complete elimination of TP or significant reduction. Any DU healed. No reoccurrence of DU at 3-year F/U. In 14 Pts. RP returned after 6 to 9 months post-TPE. In 4 Pts, no RP at 3-year F/U. RBC aggregation was significantly less ($p<.001$) post TPE and gradually returned to pre-TPE levels after 9 months.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Current medical therapy to improve hand function has had very limited benefit in patients with systemic sclerosis (SSc). Cells present within a person's own adipose tissue (Adipose Derived Regenerative Cells [ADRCs]) have the potential to improve tissue injury in scleroderma by modulating inflammation, stimulating angiogenesis, improving vasomotor reactivity, and stimulating local repair cells.

Methods: The STAR Trial is a phase III, pivotal, prospective, randomized (1:1), placebo-controlled, multi-center trial to assess safety and efficacy of subcutaneous administration of ADRCs into fingers of patients with hand dysfunction due to scleroderma. Key inclusion criteria include a classification of SSc, based on 2013 ACR/ EULAR classification criteria and a baseline Cochin Hand Function Scale (CHFS) score ≥20 units (suggesting at least moderate hand impairment). All enrolled patients (ADRC and placebo) undergo fat harvest through small volume liposuction (~200 to 400 mL). Lipoaspirate is processed in the Celution® System (Cytori Therapeutics, San Diego) to isolate and concentrate ADRCs, which contain CD34+ multipotent cells, pericytes, endothelial cells, and other cellular constituents. Patients then receive subcutaneous administration of 1 mL test substance (ADRC [4 million cells per finger] or matching placebo [Lactated Ringers containing patient's own blood to visually match the placebo to ADRCs]) into all fingers. Placebo patients may cross-over to open label ADRCs at the end of the trial. Key endpoints include: CHFS, Raynaud's Condition Score (RCS), Scleroderma Health Assessment Questionnaire (SHAQ), global assessments, Hand Mobility in Scleroderma (HAMIS) test, digital ulcer counts/time to new ulcer, modified Rodnan Score (hands only), grip/pinch strength, and analgesic use. Follow up visits are scheduled for weeks 1, 4, 12, 24, 36, 48 weeks.

Results: Trial enrollment has been completed (n=88) with baseline blinded data available from up to 86 patients. Patient demographics from the cohort indicated a mean age 53.2±10.6 years, female 87%, 77% Caucasian, and %limited/diffuse 42/58. Baseline Cochin score

was 42.2±14.2 (0-60) and the baseline RCS was 3.9±2.1 (0-10); 73% of patients had a history of digital ulcers with 39% reported with digital ulcer(s) at baseline. Patients experienced expected adverse events such as liposuction related discomfort and ecchymosis; however, no peri-procedure complications or serious adverse events occurred. No cell related adverse events have been reported. All patients were discharged the same day following fat harvest, cell processing and cell injection. Mean adipose tissue harvest 293±50 mL, ADRC yield 120.6±66 x 10^6 cells, ADRC/gm adipose tissue 3.97±1.82 x 10^5, ADRC viability 89.1±2.7%. Data continues to be collected in the follow-up period.

Conclusion: The STAR trial demonstrates same day fat harvest, cell processing and subcutaneous injection of ADRCs to all fingers in patients with scleroderma is feasible and can be performed safely.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Routine screening for circulating autoantibodies (AAbs) on the initial evaluation of interstitial lung disease (ILD) contributes to the diagnosis of underlying autoimmune disease. However, so far, few studies have focused on the role of AAbs as an independent prognostic factor in ILD, with conflicting results. In the present study, we investigated the possible association of AAbs with functional or radiological progression and survival in patients with ILD.

Methods: We retrospectively reviewed the medical records of patients with ILD followed up in a rheumatology and a respiratory outpatient clinic. Regular clinical, functional and computed tomography (CT) imaging follow-up for at least 2 consecutive years and complete testing for a panel of AAbs most commonly associated with ILD [such as antinuclear antibodies (ANAs) (positive titers ≥1:160), AAbs to extractable nuclear antigens, anti-neutrophil cytoplasmic antibodies, rheumatoid factor or anti-citrullinated protein antibodies] were our inclusion criteria. Eligible patients were subsequently classified into two groups: those without AAbs [ILD/AAb(-)] and those with positive ANAs and/or other specific AAbs, either with or without clinical manifestations compatible with connective tissue disease (CTD) [ILD/AAb(+)]. Serial pulmonary function tests (PFTs), including measurements of forced vital capacity [FVC (% pred.)] and single-breath diffusion capacity [$DLCO_{SB}$ (% pred.)], degree of dyspnea according to modified MRC scale (mMRC) (Grade 0 to 4), baseline and comparative follow-up high resolution CT (hrCT) findings and survival data were also collected. Progression of lung disease on PFTs was defined as a sustained decrease from baseline in absolute FVC of ≥10% and/or absolute $DLCO_{SB}$ of ≥15%. $DLCO_{SB}$<40% pred. on at least two consecutive measurements and disease progression on hrCT were defined as secondary endpoints.

Results: Among 185 patients with ILD initially screened, 78 met our inclusion criteria. Fifty three of them were ILD/AAb(+) and 45 had a definite diagnosis of CTD. Mean age at first outpatient visit was 57.8 years and mean duration of follow-up was 72.6 months.

ILD/AAb(+) patients were predominantly female (*77% vs 28%*), were significantly younger (*54.2 ± 15.1 vs 65.6 ± 13.0 years*), and had longer duration of follow-up (*84.5 ± 58.1 vs 47.5 ± 29.6*), compared with ILD/AAb(-) patients (*p<0.01 for each comparison*). Baseline FVC (% pred.) and $DLCO_{SB}$ (% pred.) did not differ significantly between the two groups. During follow-up, mortality rates and the percentage of patients with sustained FVC or $DLCO_{SB}$ decline, $DLCO_{SB}$ <40% pred., or severe dyspnea (Grade 3-4) were lower in the ILD/AAb(+) group (*p<0.05 for each*). In addition, rates of radiological deterioration were marginally significantly lower (*p=0.079*). In Cox regression for survival analysis, AAb positivity was also associated with a reduced adjusted hazard ratio for death, PFT decline (p<0.001 for each outcome), and radiological deterioration (*p=0.036*).

Conclusion: The presence of positive AAbs in patients with ILD is associated with better survival, less rapid decline of lung function and slower progression of CT findings.

Serum Level of KL-6, a Biomarker of Interstitial Lung Disease (ILD), Is Higher in Diffuse SSc Than in Limited SSc and RA Even When the Activity of ILD Is Low

Tamao Nakashita[1], Shinji Motojima[2], Akira Jibatake[2], Akira Yoshida[2] and Yoshiki Yamamoto[2], [1]Department of Rheumatology and Allergy, Kameda Medical Center, Kamogawa-city, Japan, [2]Department of Rheumatology and Allergy, Kameda Medical Center, Kamogawa city, Japan

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: KL-6 is a glycoprotein expressed on and released from type 2 alveolar cells and the measurement of KL-6 in serum was developed by Kohno et al (Am J Respir Crit Care Med 1993). Serum levels of KL-6 have been reported to be higher in ILD (Ohnishi H, Am J Respir Crit Care Med 2002) and be a predictor of prognosis of ILD (Yokiyama A, Am J Respir Crit Care Med 1998). We also reported that serum levels of KL-6 increased when ILD exacerbated after administration of TNF-inhibitors in RA (Nakashita T, BMJ open 2014). Normal range of serum KL-6 is less than 500 U/ml and serum level of more than 1,000 U/ml is a predictor of poor prognosis. However, we have noticed that in some patients serum KL-6 levels are sustained in high levels even when the activity of ILD deceased. We tried to detect the factors that contribute in sustaining serum KL-6 levels high.

Methods: Subjects were 98 patients including 52 RA, 19 diffuse SSc, and 27 limited SSc. These patients fulfilled the following requirements; 1. presence of ILD proved by chest CT, 2. no changes in chest CT findings for more than 2 years, 3. less than 5 % changes in % VC for more than 2 years, suggesting that the ILD is stable during the period. Serum KL-6 levels were checked periodically, every 2 – 6 months, from the first visit to our department. Nine variables were checked including diagnosis (RA, d-SSc, l-SSC), age, gender, ILD pattern (UIP, NSIP, organizing pneumonia), ILD grade (1 – 3 according to Nakashita), % VC, peak serum KL-6 value, peripheral blood eosinophil count, ANA titer, and RF titer. These variables were statistically analyzed.

Results: Serum KL-6 value was highest in d-SSc followed by l-SSc and RA; the mean values were 776 U/ml, 439 U/ml, and 371 U/ml, respectively ($p < 0.0001$). % VC values were lowest in d-SSc followed by l-SSc and RA; the mean values were 90.1 %, 98.9 %, and 107.2 %, respectively ($p < 0.02$). Multivariate analysis was done using 10 variables to extract factors that contribute to discriminate 2 groups, i.e. a very high KL-6 group (KL-6 >= 900 U/ml) and another group (KL6 < 900 U/ml). In a very high KL-6 group included 10 patients. Factors that contribute to discriminate 2 groups ($p < 0.1$) were diagnosis (RA, d-SSc or l-SSc), % VC, and peak serum KL-6 values. Multiple regression analysis was also done. Multiple regression coefficient was moderately high (0.78), but significant regression factors were diagnosis and peak KL-6 value.

Conclusion: Patients with d-SSc, low % VC and high peak KL-6 value tend to show high serum KL-6 values even when ILD is not active. Our results can contribute to avoid aggressive treatment for patients with stable but very high serum KL-6 levels.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Previously, Early Systemic Sclerosis (Early-SSc) patients were defined as patients with Raynaud phenomenon (RP) and either a scleroderma marker autoantibody or typical capillaroscopy abnormalities or both. Since 2013 the definition of Early-SSc has been updated: Patients should not meet the new 2013 ACR/EULAR criteria for the classification of Systemic Sclerosis (SSc). EUSTAR group also proposed preliminary criteria for the very early diagnosis of SSc which have not yet been validated. Our aim was to revise the usefulness of Le Roy criteria and Very Early EUSTAR criteria in identifying patients at risk of development of SSc.

Methods: Retrospective study of a wide and unselected series of patients with Early-SSc and SSc from a single university hospital from June 2012 to August 2015. We excluded patients who fulfilled 2013 ACR/EULAR criteria at first visit. Patients were classified as Early-SSc following Le Roy criteria and classified as SSc according to the 2013 ACR/EULAR criteria during follow-up. We reviewed EUSTAR criteria in both groups.

Results: We included a total of 56 patients with a mean age of 55±15 years (94.6% women; 5.4% men). At first visit, 15 (26.8%) of our patients fulfilled 2013 ACR/EULAR criteria and were excluded of the final analysis. 37 (66.1%) of our patients fulfilled Le Roy criteria at first visit. The remaining 4 patients (7.1%) did not meet any of these criteria in the first visit. During the follow-up of this group of 41 patients, 37 (90.2%) presented RP and 9 (22%) presented puffy fingers. Antinuclear antibodies (ANA) were present in 34 (82.9%) of the patients, Anti-centromere antibodies in 24 (58.5%) patients and 29 (70.7%) patients presented pathologic capillaroscopic exam. After a mean follow-up period of 26.1±16.6 months, 20 (48.8%) patients fulfilled 2013 ACR/EULAR criteria. The remaining 21 patients remaining classified as Early-SSc following Le Roy criteria. Of the following EUSTAR criteria, only significant positivity of ANA was observed more frequently in patients that fulfilled 2013 ACR/EULAR criteria: ANA (100%vs63.6%;p=0.005), anti-centromere antibodies (65%vs50%;p=0.41), raynaud phenomenon (95%vs85.7%;p=0.31), abnormal capillaroscopic exam (65%vs76.2%;p=0.8), presence of puffy fingers (25%vs19%;p=0.65).

Conclusion: In our study, over the half of the patients initially classified as Early-SSc progressed to SSc during follow-up. EUSTAR preliminary criteria were more frequent in patients who during follow-up fulfilled 2013 ACR/EULAR criteria for SSc, although only the positivity of ANA was statistically significant. Further studies are needed to better characterize the patients with Early-SSc and Very Early-SSc.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a progressive fibrotic and autoimmune disease, which results to severe systemic complications. Rituximab (Rtx), an anti CD-20 antibody, has recently been started to use for complications of SSc especially interstitial lung disease (ILD). We aimed to asses the efficacy of Rtx therapy in SSc patients with ILD.

Methods: 39 SSc patients with progressive ILD disease included in to the study. 35 (89.7%) of these patients had experienced a worsening of ILD after the conventional cyclophosphamide therapy and 4 (10.2%) patients refused using cyclophosphamide because of potential infertility. All patients were treated with Rtx 1000 mg twice/six months. Functional vital capacity (FVC), diffusing capacity for carbon monoxide (DLCO), high resolution computed tomography (HRCT), modified Rodnan skin score (mRSS), Valentini activity index (VAI), Medsger disease severity index (MDSI) were recorded. Patients were eveluated with 6 months intervals for all these parameters. Initial and 12th month values were assessed and data was analysed by SPSS 18.0 (SPSS, Chicago, IL). Paired t and Wilcoxon Signed Ranks tests were used.

Results: Women (37; 94.9%) outnumbered men (2; 5.1%) significantly. Mean age was 58.1±11.8 years. Median disease duration was 30 (18-132) months. Median follow-up time was 25 (18-100) months. Demographic data were given in table 1. All of the patients had active ILD which demonstrated by ground-glass opacification on HRCT. From 35 patients resistant to cyclophosphamide; 26 (66.6%) switched to Rtx monotherapy, 7 (17.9%) continued with Rtx+cyclophosphamide combination therapy, 2 (5.1%) continued with Rtx+mycophenolate mofetil combination therapy. Additionally, 6 (15.4%) patients received IV iloprost and 3 (7.7%) received bosentan. mRSS was 9.1±5.9, VAI was 2.7±0.8, MDSI was 4.4±1.6 before Rtx. FVC (%), DLCO (%) were 86.4±21.0 and 64.2±17.9 respectively. The 12th month values were compared within initial ones and we demonstrated that mRSS (6.9±4.5, $p<0.001$), MDSI (4.0±1.2, $p=0.032$) scores had significant improvement. On the other hand VAI (2.4±0.5, $p=0.051$), FVC (92.1±17.0, $p=0.056$) and DLCO (68.1±16.1, $p=0.271$) values had no significant difference (table 2). Interestingly number of the patients with digital ulcers were decreased from 16 (41.0%) to 9 (23.0%).

Conclusion: In SSc, progression of ILD seems remained stable with Rtx therapy. This might be a good opportunity for the treatment. Skin score improvement in these patients might indicate the benefical effect of Rtx either.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Nearly 90% of patients with scleroderma (SSc) have gastrointestinal tract(GIT) involvement in variable severities and is a challenging process for clinicians.The University of California Scleroderma Clinical Trial Consortium Gastrointestinal Tract 2.0(UCLA SCTC GIT 2.0) is a questionnaire including 34 items, 7 multi-item scales :reflux, distention/bloating, diarrhea, fecal soilage, constipation, emotional well-being and social functioning. By these parameters, a total GIT score is calculated (1). This scale translated in German, Italian, French, Polish, Spanish, Swedish, Dutch before, they are available in http://www.uclascleroderma.researchcore.org/ website (1,2,3). There is no Turkish version of this scale yet. Our aim is to make translation, cultural adaptation of UCLA SCTC GIT 2.0 into Turkish, and assess reliability of the scale in patients speaking Turkish.

Methods: UCLA SCTC GIT 2.0 scale was translated into Turkish according to international guidelines and applied to 97 SSc patients. The questionnaire repeated in 29 patients after an interval of 15 days for determining reliability. For internal consistency, Cronbach's alpha was calculated, reliability coefficient if item deleted and test-retest reliability also determined. External consistency was measured by comparing with the Short Form(SF)-36 by Spearman's correlation analysis (rho: ≤ 0.29 weak, 0.30-0.49 middle, ≥ 0.50 strong).

Results: 97 scleroderma patients were included in this study (female:87.6%, mean age:55.4±11.4). Internal consistency Cronbach's alpha was calculated as 0.89, reliability coefficient if item deleted was 0.89-0.90. External consistency of UCLA SCTC GIT 2.0 was measured by comparing with the SF-36, correlation was meaningful in medium level (Table 1,2).

Conclusion: UCLA SCTC GIT 2.0 scale had strong internal consistency, good reliability and acceptable validity when adapted into Turkish. Turkish-speaking patients with scleroderma, this scale will useful to assess GIT symptoms. The basic constraint of our study was, not using image procedures for objective GIT involvement evidences.

Table 1. Descriptive Statistics and Internal Consistency Statistics.

UCLA SCTC GIT 2.0 Scale	n	Mean score (SD)	Minimum score	Maximum score	Cronbach alpha	Floor Effect %	Ceiling Effect %
Reflux	97	0.64 (0.54)	0.0	2.6	0.83	17.5	0.0
Distension	97	1.02 (0.75)	0.0	3.0	0.58	7.2	1.0
Soilage	97	0.30 (0.72)	0.0	3.0	0.68	82.5	3.1
Diarrhea	97	0.28 (0.47)	0.0	1.5	0.36	69.1	0.0
Social Functioning	97	0.17 (0.32)	0.0	1.3	0.47	67.0	0.0
Emotional Wellbeing	97	0.30 (0.43)	0.0	2.2	0.73	41.2	0.0
Constipation	97	0.63 (0.69)	0.0	2.5	0.56	34.0	0.0
Total GIT score	97	0.45 (0.37)	0.0	1.6	0.82	3.1	0.0

All scales are scored from 0.00(better HRQOL) to 3.00(worse HRQOL) except the diarrhea and constipation (range from 0.00–2.00 and 0.00–2.50, respectively). The UCLA GIT 2.0 provides a total score of GIT severity and calculated by summation of all scales (except constipation) and ranges from 0.00–2.83(2).

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Vascular complications of systemic sclerosis (SSc, scleroderma) can result in ulcers in the distal extremities, which limit function and are often refractory to conventional treatments. Hyperbaric oxygen therapy (HBOT) has been used in the treatment of non-healing wounds, but its utility in patients with SSc is uncertain. The primary objective of this study was to evaluate the safety of HBOT for SSc ulcers. We secondarily evaluated the effectiveness of HBOT for SSc ulcers, and patient selection criteria for treatment of SSc ulcer patients with HBOT.

Methods: We conducted a cohort study of SSc patients who were evaluated for treatment with HBOT in the Toronto Scleroderma Program and the Toronto General Hospital Hyperbaric Unit between 2002 and 2015. HBOT treatments involved 30-50 sessions in a monoplace or multiplace chamber with compression to a maximum depth of 2.5 atm and breathing oxygen for a total of 90 minutes 5 days per week. Ulcers were defined as lesions with a visually discernable depth and loss of epithelial continuity. Reasons for declining access to HBOT, adverse events and effectiveness in ulcer healing were evaluated. An ulcer was categorized as healed if it achieved epithelial continuity or National Pressure Ulcer Advisory Panel (NPUAP) stage X (stable necrotic tissue core or eschar). Transcutaneous oxygen tension criteria for evaluating 'healability' in diabetic foot ulcers were applied as none have been validated for the SSc.

Results: 2261 subjects were reviewed to identify 36 HBOT treated ulcers in 10 SSc subjects. They had a mean ± SD age of 58.0 ± 13.9 years. Eighty-seven percent were female. Ulcer locations included fingertip (n=10 (28%)), hand-PIP/DIP (n=11 (31%)), hand-MCP (n=2 (6%)) and lower extremity (n=10 (28%)). Thirteen SSc subjects did not receive HBOT due to reasons that included lack of achieving "healable" response to oxygen on transcutaneous oximetry and technical limitations in sensor placement options (n=4), presence of moderate - severe pulmonary arterial hypertension (n=2) and confinement anxiety (n=1). Of the HBOT treated subjects, adverse events included brief episodes of otic barotrauma (n=2) and nausea (n=2). Twenty-three (64%) ulcers improved after HBOT.

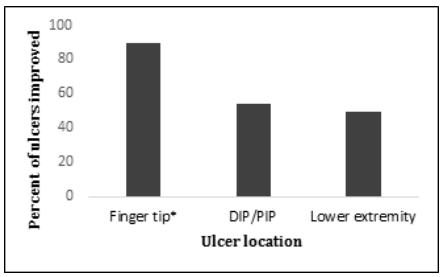

Figure 1. Ulcer improvement by location

Conclusion: HBOT may be an effective option for SSc patients with non-healing ulcers. Therapy was generally well-tolerated, with no significant adverse events although transient self-limiting otic barotrauma was reported. Patient selection criteria specific to the SSc population may need to be developed as the presence of pulmonary arterial hypertension is considered a contraindication to HBOT.

Microvascular Function in Systemic Sclerosis Patients with End-Stage Vascular Manifestations of the Disease

Tracy M. Frech[1], Phillip E. Gates[2], Daniel Machin[3] and Anthony Donato[4], [1]Division of Rheumatology, University of Utah, Salt Lake City, UT, [2]University of Utah and Salt Lake Veterans Affair Medical Center, Salt Lake, UT, [3]University of Utah and Salt Lake Veterans Affair Medical Center, Salt Lake City, UT, [4]University of Utah and Salt lake Veterans Affair Medical Center, Salt Lake City, UT

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Vasculopathy is a prominent feature of systemic sclerosis (SSc, scleroderma) and is involved in end-stage manifestations such as pulmonary arterial hypertension (PAH), digital ulcer (DU), and scleroderma renal crisis (SRC). However, the extent to which vascular function changes in patients diagnosed with SSc is uncertain. We hypothesized that microvascular function assessed by sublingual videomicroscopy would be worse in SSc patients with end-stage manifestations compared to those patients without.

Methods: SSc patients were recruited from the University of Utah SSc Clinic between October 2015 and April 2016 and data were obtained from 34 patients without (ES^-) and 19 patients with (ES^+) end-stage disease (one or more of DU, PAH, SRC). Microvascular function was assessed using sublingual videomicroscopy and automated capture and analysis of vessels between 5 and 25 µm in diameter (Glycocheck). Vessels were grouped into tertiles by diameter (5-9-, 10-19-, 20-25- µm) and analysed for the density of well perfused microvessels (density), red blood cell (RBC) filling percentage, and the depth of penetration of RBCs into the vessel wall (perfused boundary region, PBR; an estimate of glycocalyx integrity). Glycocheck data were analysed using one-tailed independent samples t-test and alpha set at 0.05 (SPSS, IBM).

Results: The mean (±SEM) age of ES^- was 55±2 (all female; 29 Caucasian, 4 Hispanic, 1 Native American) and ES^+ was 57±3 years (3 males; 15 Caucasian, 3 Hispanic, 1 Native American). Mean duration of SSc disease and duration of Raynaud's phenomenon was, respectively, 8±1 and 13±2 (ES^-) and 9±2 and 11±3 (ES^+) years. There were no differences in age, height, weight, BMI, systolic or diastolic blood pressure between groups. When microvessels of all sizes were analysed, there were no differences in microvessel density, RBC% or PBR. When analysed by tertile, there were significant differences in microvessel density (ES^- vs. ES^+: 171±17 vs. 122±15 µm/mm^2) and RBC filling (ES^- vs. ES^+: 72±1 vs. 68±3 %) in the microvessels with largest diameter (20-25- µm), but no differences in PBR. There were no differences in any microvascular measurements in the other (smaller diameter) tertiles.

Conclusion: From this small sample, we found that some, but not all, markers of sublingual microvascular function were worse in SSc patients with end-stage manifestations of the disease compared to those without. Follow-up is needed, but this initial finding suggests that deteriorating microvascular function may be part of the natural history of SSc. These specific aspects of vascular function may be useful targets in the treatment of SSc.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Empiric long-term use of proton pump inhibitors (PPI) are implicated in concomitant renal dysfunction (1) and small intestinal bacterial overgrowth (SIBO)(2). Yet, experts recommend daily empiric PPI even in the absence of reflux symptomatology in SSc patients (3). The Prospective Registry of Early Systemic Sclerosis (PRESS) cohort of early diffuse cutaneous systemic sclerosis (dcSSc) permits determination of the utility of empiric PPI administration in this patient population.

Methods: The PRESS cohort includes dcSSc patients with < 2 years duration who are recruited at 11 United States Scleroderma Centers. Patients participate in detailed baseline and biannual clinical and laboratory assessments that permit examination of patient characteristics, PPI use, renal function and patient-reported clinical outcomes measures including the University of California Los Angeles Scleroderma Clinical Trials Consortium Gastrointestinal Tract 2.0 (GIT 2.0)(4).

Results: As of May 2016, 166 PRESS patients were enrolled (Table 1). At baseline and 6 months, 132 and 67 patients had completed the GIT 2.0 respectively. Of the 88 patients taking a PPI at baseline, 6 had no reflux, 37 had mild reflux, 28 had moderate reflux and 15 had severe reflux. Five patients taking PPI had renal dysfunction at baseline (defined as reduced creatinine clearance). No patient taking a PPI developed renal dysfunction between baseline and 6 months. Only 11 of the 88 patients on PPI lacked bloating or distention at baseline. At 6 months, only 1 patient with a repeat GIT 2.0 was newly prescribed that PPI. This patient lacked renal insufficiency and bloating or distention.

Conclusion: Most dcSSc patients take PPI. PPI use was not associated with incident renal dysfunction over 6 months follow-up. Bloating and distension are common symptoms in dcSSc patients and may be associated with PPI use. Due to recent associations of PPI with SIBO and renal dysfunction experts may consider changes in practice patterns. Cohorts such as PRESS provide the opportunity to understand gastrointestinal disease and renal dysfunction in the dcSSc patient population as well as the opportunity to study potential adverse effects of medications. Table 1: PRESS Patient Characteristics

Characteristic (n=166)	Number or mean

Impact of the Clinical Characteristics of Systemic Sclerosis in Patients Quality of Life

Joana Caetano[1], Luis Melo[1], Susana Oliveira[1] and Jose Delgado Alves[1,2], [1]Department of Medicine IV, Systemic Immunomediated Diseases Unit, Fernando Fonseca Hospital, Amadora, Portugal, [2]CEDOC/NOVA Medical School, Lisbon, Portugal
First publication: September 28, 2016

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a rare heterogenic disease, with visceral, skin and vascular damage associated with a reduced life expectancy, disability and worsening of quality of life. Evaluation of health related quality of life (HRQoL) is important for a more comprehensive approach to SSc patients. The purpose of our study was to assess the impact of SSc clinical manifestations in HRQoL from the patient and physician perspectives.

Methods: 44 consecutive SSc patients with limited (n=32) and diffuse (n=12) cutaneous subsets, from a single referral center and classified according to the 2013 ACR/EULAR criteria, were enrolled, together with a disease-control group of 28 consecutive patients with rheumatoid arthritis (RA). Health Assessment Questionnaire (HAQ-DI) and Short Form 36 (SF36), physical component summary (PCS) and mental component summary (MCS) scales were used to assess HRQoL, and the following ten clinical variables were considered for correlation: time since disease onset (first non-raynaud's phenomenon manifestation), modified Rodnan skin score, calcinosis, digital ulcers (DU), arthritis/myositis, clinically significant pulmonary hypertension (PH), interstitial lung disease (ILD), renal crisis, gastrointestinal (GI) and cardiac involvement. Physician's perception of the impact in HRQoL of each of the variables was assessed - scored from 1 (high impact) to 3 (mild impact). All physicians were SSc experts non-associated to this cohort. T-test and Fisher's exact test were used to compare binary variables. Pearson's correlation was used for continuous variables.

Results: in SSc patients the mean HAQ-DI score was 0.95±0.67 (0-best health), and the mean PCS and MCS scores were 44.3±44.1 and 39.1±13.1 (100-best health), respectively. None of the clinical variables correlated with HRQoL, except the GI involvement (HAQ-DI - p=0.01, PCS - p=0.04, MCS - p=0.005). From the physician's perspective, the 3 clinical variables considered as having a high impact on HRQoL were: 80% PH, 70% DU and 50% ILD. Only 40% of the physicians considered GI manifestations to have a high impact on HRQoL, whilst 20% rated it as having a mild impact. Comparing with RA patients, there was no statistically significant difference in HRQoL. RA patients had mean scores of: HAQ-DI 1.1±0.56 (p=0.41), PCS 35.0±10.0 (p=0.27) and MCS 43.7±12.2 (p=0.14).

Conclusion: SSc has a very significant impact in the quality of life as perceived by the patients. In this study, the GI involvement was the only independent clinical manifestation contributing to a poorer health status in SSc patients. Despite its proven significance, the physician's perspective of the GI involvement is significantly different from patients reinforcing the need for further studies on patient perpective and outcomes measures in SSc.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a multisystem, chronic, autoimmune disease. In this hospital based study, we aimed to evaluate the prevalence and incidence of SSc in our region.

Methods: During the 2003-2015, SSc patients diagnosed in our Department were included. Our Department is the only tertiary center of Rheumatology in this northwestern part of Turkey. The diagnosis of SSc was performed according to ACR 1980 criteria. Clinical and demographical data about SSc patients were obtained from medical charts.

Results: Of the 161 patients (146F, 15M) carrying the diagnosis the diagnosis of SSc, During the study period, the mean annual incidence rate was 2.16/100,000 for SSc. The annual incidence of SSc in women was 3.98/100,000, and in men was 0.4/100,000. In second period of study (2010-2015 vs. 2003-2009), general incidence rate increased especially in males (from 0.27 to 0.53/100,000). By December 2014, the overall point prevalence of SSc in our region was 23.2/100000 in population aged >16 years. The point prevalence in women (42.8/100000) was higher than the point prevalence in men (4.1/100000). Among women, SSc was more prevalent in the fourth and fifth decades of life. Among men, the peak orevalence was in the sixth decade of life. The period prevalence of SSc was 25.9/100000. The period prevalence in women was 47.7/100000 and in men it was 4.8/100000. The median age at diagnosis was 49 (21–84) years for SSc patients. 123 patients (76.4%) had limited cutaneous, 35 patients (22.4%) had diffuse SSc and 2 patients (1.2%) had sine scleroderma. Interstitial lung disease was detected in 55 patients (34.2%), pulmonary hypertension in 69 patients (42.9%), digital ulcers in 46 patients (28.6), arthritis in 47 patients (29.2%) and renal crisis in 2 patients.ANA positivity was detected in 90.1% of patients. Anti-centromer was positive in 26.7% of patients, anti-Scl-70 was positive in 28% of patients, anti-Ro in 15% of patients and anti-RNP in 11.9% of patients. The median follow-up time of all SSc patients was 48 months (3-160). 20 patients with SSc were died (16 females, 4 males). 5 and 10-years survivals of patients with SSc were 93.6% and 83.1% respectively. Univariate analysis revealed that, male sex (p=0.018), age older than >65 years at the time of diagnosis (p=0.016), pulmonary hypertension (p=0.005), digital ulcer (p=0.034), diffuse cutaneous disease (p=0.032), low level FVC (p=0.023) and anti-Scl-70 positivity (p=0.05) were poor prognostic factors. Multivariate Cox regression analysis showed that, male sex (p=0.05) and pulmonary hypertension (p=0.032) were independent poor prognostic factors in our SSc patients.

Conclusion: In conclusion, we found in our study from northwestern part of European Turkey that SSc prevalence (23.2/100,000) and incidence (2.1/100,000) is similar to data form European countries and US studies.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : Systemic sclerosis (SSc) is a rare disease, with a mean incidence 3.8 cases, prevalence 99 per million in Sweden. The two most important blood group systems for hemagglutination are called AB0 and RhD. The AB0 system consists of two antigens, A and B which are oligosaccharide (Os). On the B antigen the terminal monosaccharide (Ms) always is a galactose (Gal), while on the A antigen, the terminal Ms is an acetylgalactosamine (GalNAc). This study examines the prevalence of different AB0 and RhD blood group antigens in SSc patients in comparison with the general Swedish population.

Methods : 150 patients, fulfilling the 2013 ACR/EULAR criteria for SSc, were included in the study. All patients were tested for the blood group antigens AB0 and Rhesus factor (Rh) and antinuclear SSc-associated antibodies (anticentromer; ACA, antitopoisomerase 1; ATA or anti RNA polymerase 3; ARA) were analysed.

According to our hypothesis, antigen present on the erythrocyte’s surface has a significant role in the formation of the SSc disease.

Results: In this studied group, the frequency of B antibodies was significantly lower (21%) compared to the average among the Swedish

population (36%).

Two blood groups, B RhD negativ and AB RhD negativ, were not found among the 150 patients in the study group; compared to the national expected average of 2% and 1% respectively.

The two main findings included 0 RhD positive cases with centromer antibodies (ACA) being 61% and A RhD positive with ACA being 57%.

Conclusion: In conclusion, the natural antibodies present on the surface of the erythrocytes are most likely to influence the emergence of SSc. Therefore, the presence of Gal most likely has a significant defensive roll against the development of the SSc disease.

	Blood group expected incidence % general population in Sweden	All SSc patient
A RhD+	37,00%	40,00%
O RhD+	32,00%	28,00%
B RhD+	10,00%	12,00%
A RhD-	7,00%	11,00%
O RhD-	6,00%	7,00%
AB RhD+	5,00%	2,00%
B RhD-	2,00%	0,00%
AB RhD-	1,00%	0,00%

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Gastrointestinal tract (GIT) involvement occurs in approximately 95% of patients with systemic sclerosis (SSc). There is consensus in the Scleroderma Clinical Trials Consortium (SCTC) Working Group on the importance of validating outcome measures in SSc. The goal of this project was to evaluate patient reported outcome measures in the SSc-associated domain of gastroesophageal reflux disease (GERD) through instrument assessment of responsiveness to change.

Methods: Patients who fulfill 2013 revised ACR/EULAR criteria for SSc and who had (1) GERD symptoms for at least 3 of the past 7 days; and (2) a plan to initiate a change in GERD management were eligible. At baseline, all patients completed GERD assessment questionnaires including: the UCLA GIT 2.0, Quality of Life in Reflux and Dyspepsia (QoLRAD), and in English-speaking countries, the NIH Patient Reported Outcome Measurement Information System (PROMIS®) GI Symptoms Scale. Cronbach's alpha was assessed for the GIT 2.0 and QoLRAD domains; an alpha >=0.70 is considered acceptable for group comparisons. Pearson correlation coefficients were interpreted as proposed by Cohen: 0.0- 0.10, no correlation; 0.10- 0.23, small correlation; 0.24- 0.36, medium correlation; >=0.37, large correlation.

Results: In this ongoing registry, 5 participating international sites have so far recruited 68 GERD patients who completed GIT 2.0 and QoLRAD, and 29 patients completed the NIH PROMIS GI Reflux scale. The diagnosis of GERD was made by clinical symptoms in 67 patients, 3 of whom had their diagnosis confirmed by barium swallow, and two of whom had an endoscopy with evidence of esophagitis. The patient sample has a mean age of 54.9 years, mean disease duration of 10.5 years, and is 83% female. Cronbach's alpha for GIT 2.0 was 0.83 and for QoLRAD domains ranged from 0.92-0.96. The mean scores for Reflux scales on GIT 2.0 (0.96) and NIH PROMIS (57.5) suggested moderate overall reflux symptoms. GIT 2.0 and PROMIS had large correlations with each other and QoLRAD domains (except PROMIS had medium correlation with emotional distress domain of QoLRAD).

Conclusion: This multi-center international prospective study of SSc-GERD suggests that current PROs (GIT 2.0, PROMIS, and QoLRAD) have acceptable reliability and have large correlations among each other (except for 1 domain for QoLRAD with PROMIS). This study highlights challenges for studying GERD in an international cohort, including the infrequent use of invasive studies for GERD diagnosis and the limitations in the availability of translated instruments. Nonetheless, this study underscores the value of international collaboration supported by the SCTC.

Mean score/ Correlations coefficients for the PROs

	GIT 2.0*	NIH PROMIS*	QoLRAD Emotional distress**	QoLRAD Sleep disturbance**	QoLRAD Food and drink problems**	QoLRAD Physical and social functioning**	QoLRAD Vitality**
UCLA GIT 2.0 (Reflux scale)	0.96/ 1.0	57.5/ 0.69	5.21/ -0.66	4.82/ -0.77	*4.70/* -0.75	5.64/ -0.72	*4.82/* -0.73
NIH PROMIS GI Reflux scale		1.0	-0.35	-0.52	-0.58	-0.47	-0.48

** Higher score denotes greater symptoms;** Lower score denotes greater symptoms (3.5-4.9 moderate; <3.5 severe)*

Transition of Nailfold Microangiopathy throughout Different Patterns of Microvascular Damage and Correlations with Organ Involvement in Systemic Sclerosis: A Twelve Year Follow-up

Alberto Sulli[1], Sabrina Paolino[1], Barbara Ruaro[1], Amelia Chiara Trombetta[1], Vanessa Smith[2], Maurizio Cutolo[1] and Carmen Pizzorni[1], [1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, Genova, Italy, [2]Department of Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Nailfold capillaroscopy is the validated technique to assess scleroderma microangiopathy, an early and dynamic event that may progress through different patterns of microvascular damage ("early", "active" and "late") during follow-up (1,2). The time of transition is variable among patients, and it was little investigated (2). Several studies demonstrated correlations between microvascular damage extent and organ involvement degree (2-4). The aim of this longitudinal study was to investigate the time of transition of nailfold microangiopathy throughout different patterns of microvascular damage in SSc, assessing correlations with organ involvement.

Methods: Thirty-four SSc patients according to LeRoy criteria (mean age 57±11 years) with the "early" pattern of nailfold microangiopathy at first capillaroscopic visit were enrolled and followed for a mean time of 12±3 years. Only SSc patients with fully complete documentation were included into the study. The pattern of microangiopathy was recorded and the microangiopathy evolution score (MES) calculated by nailfold videocapillaroscopy (NVC) at each visit, as previously reported (1,2); organ involvement and antinuclear antibody (ANA) profile were also assessed.

Results: After a mean twelve years follow-up, 12 (35%) patients were still showing the "early" scleroderma-pattern, while the NVC pattern of microangiopathy was changed in 65% of the patients. The NVC pattern was found "active" in 10 patients (30%) and "late" in 12 patients (35%). The median time of progression from the "early" to the "active" pattern was 31 months, from "active" to "late" 38 months, and from "early" to "late" 66 months. In the subgroup of patients whose microangiopathy progressed from the "early" to the "late" NVC pattern through the "active" pattern, the median time of progression from the "early" to the "active" pattern was only 14 months, while in the subgroup of patients whose microangiopathy progressed only from the "early" to the "active" NVC pattern it was 42 months. A correlation was confirmed between microvascular damage extent and organ involvement degree, as MES progressively increased and organ involvement was progressively greater in SSc patients with "early", "active" and "late" NVC pattern of microangiopathy, respectively. The median time of progression from "early" to "late" pattern was shorter in SSc patients with either nucleolar IIF ANA pattern or Scl70 autoantibodies.

Conclusion: This study confirms the progression of nailfold microangiopathy through different patterns of microvascular damage in almost 65% of SSc patients. Patients showing a fast progression from the "early" to the "active" NVC pattern of microangiopathy (one year), as well as positive ANA with either a nucleolar IIF pattern or Scl70 positivity should be strictly monitored since at risk of rapid progression to the "late" NVC pattern of microangiopathy which is linked to a larger risk of organ involvement. **References**. 1. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Interstitial lung disease (ILD) is a severe complication of systemic sclerosis (SSc). Immunosuppressives such as cyclophosphamide (CYC) and mycophenolate mophetil (MMF) are used in its treatment with no proven efficacy (1). Rituximab (RTX) appears to be an emerging agent according to case series.

This retrospective study aims to evaluate the efficacy of RTX on SSc-ILD in a group of patients followed in our center.

Methods: A chart review revealed 18 patients (16 women, 2 men; mean age 50.3±12.1 SD years (range 30-72 years), mean disease duration 8.3±9.3 SD years) with SSc who have been diagnosed as having ILD (confirmed by high-resolution thorax computed tomography and pulmonary function tests) and have been treated with one or more cycles of RTX. Efficacy was evaluated according to the criteria of the American Thoracic Society: improvement= an increase in FVC≥10% or DLCO≥15%; worsening= a decrease in FVC≥10% or DLCO≥15%; stabilization= changes in FVC less than 10% or DLCO less then 15% (2).

Results:

The mean follow-up of the patients after starting RTX was 19±11.8 SD months (Table 1). Four patients were treatment naive for ILD when they received RTX (Group 1). The mean duration between the diagnosis of ILD and RTX treatment in Group 1 was 3.5 months (range 0-14 months). The average RTX cycle in this group was 2 with 1 patient also receiving mycophenolate mophetil in combination with RTX. The mean follow-up time after the initiation of RTX in this group was 12.2±6.8 SD months (range 7-22 months). FVC/DLCO was stable or improved in 2/4 compared to baseline and worsened in 2/4 at the end of follow-up at group 1.

Fourteen patients had a 10.2 years-history of SSc and have been treated with immunosuppressives (cyclophosphamide, azathioprine, methotrexate, MMF) for ILD before RTX (Group 2). The mean duration between the diagnosis of ILD and RTX treatment in Group 2 was 71.2 months (range 5-246 months). These patients received a mean of 3 cycles of RTX with 5 receiving MMF (n=3) or AZA (n=2) in addition to RTX. One patient died after 3 months following the first RTX cycle (unknown reason) and 1 was unsuitable for spirometry because of microstomia. Of the remaining 12 patients in Group 2, improvement or stabilisation was seen in 7 and worsening was seen in the remaining 5 patients.

Conclusion:

RTX appears to be modestly effective for ILD of SSc. The duration of ILD as well as the presence or absence of previous immunosuppressive therapy do not appear as playing a role in response.

Table 1: Demographic findings of the patients and their response to RTX treatment

	Group 1 (ILD with short duration and naive to treatment)	Group 2 (ILD with long duration and previous IS therapy)	All patients
Number of patients	4 (22.2%)	14 (77.7%)	18
Sex (F/M)	3/1	13/1	16/2
Mean disease duration	2±0.8 SD years	10.2±9.8 SD years	8.3±9.3 SD years
Follow-up time after initiation of RTX	12.2±6.8 SD months	21±12.4 SD months	19±11.8 SD months
Baseline FVC%	69.2±20.9	65.1±14	
Last FVC%	66.7±13	61.6±19.6	
Baseline DLCO%	57.7±24.1	43.5±12.2	
Last DLCO%	52±18	41.2±21.8	
Outcome: Stable/Improvement (n)	2	7	9
Worsening (n)	2	5	7
Death	0	1	1

Predictors of Poor Hand Function in Systemic Sclerosis

Ashraf Raslan[1] and Vivien Hsu[2], [1]Medicine, Rutgers-RWJ Medical School, Jersey City, NJ, [2]Rheumatology, RWJ Med Schl Scleroderma Prog, New Brunswick, NJ

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a progressive systemic disease that can lead to variable degrees of morbidity and disability. Hand dysfunction in SSc patients [1] can result from pain, swelling and loss of mobility [1][2], affecting activities of daily living (ADLs) and work [3][4]. We aim to identify important clinical predictors of hand dysfunction in SSc.

Methods: We evaluated 192 outpatients who met criteria for SSc [5] and were seen between 2010 and 2015. We collected pertinent SSc clinical information, including laboratory and hand x-ray assessments obtained within 5 years of this analysis. Hand dysfunction was defined as the inability to make a fist due to inability to approximate the fingers onto the palm of the hand. This was corroborated by patientÕs history of difficulty with ADL tasks. We estimated unconditional logistic regression models adjusted for SSc type, current modified Rodnan skin score (mRSS), and overlap with rheumatoid arthritis (RA).

Results: Hand dysfunction occurred in 34% of patients (n=65). Patients with diffuse cutaneous SSc (dcSSc), high mRSS and overlap with RA had significantly more hand dysfunction. In multivariable models, after adjusting for these 3 variables, the following remained strongly associated with hand dysfunction: RNA polymerase III positivity (OR 3.3, CI 1.1-9.6), prior digital tip ulcers (DTUs)(OR 2.6, CI 1.3-5.4), current DTUs (OR 3.2, CI 1.4-7), prior tendon friction rubs (TFRs)(OR 5.0, CI 1.96-13), current TFRs (OR 3.5, CI 1.1-11), prior synovitis (OR 4.7, CI 1.9-26), osteoarthritis (OR 3.8, CI 1.6-8.9) and acro-osteolysis (OR 2.9, CI 1.3-6.6).

Conclusion: Hand dysfunction occurred in a third of our SSc population, and was more common in patients with dcSSc. Digital ischemia and inflammatory features (TFRs, synovitis) were strongly associated with hand dysfunction, which was independent of SSc type, degree of skin thickening, and overlap with RA. Prospective studies are needed to confirm if more aggressive treatment of digital ischemia and musculoskeletal inflammation in SSc patients would lead to less hand contractures and dysfunction.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a low-prevalence disease, characterized by fibrosis and vascular changes. It is the auto-immune rheumatic disease with the highest disease-related mortality and morbidity. Diagnosis of SSc is based on a set of clinical, immunological (specific antibodies) and capillaroscopic features. The progression in treatment modalities and supportive care methods yielded a better survival. However, major organ involvement such as pulmonary hypertension and diffuse interstitial lung disease still carries severe risk for mortality. The survival data and causes of death in patients with SSc is still not available in Turkey. The aim of the present study was to analyze the survival from disease onset and risk factors associated with mortality in 2 different rheumatology clinics of Turkish patients.

Methods: All patients who fulfilled the ACR 1980 criteria and classified with SSc since 2003 to 2016 were evaluated (totally 409 patients). The demographic features including autoantibodies of SSc patients and the mortality date were recorded from medical charts. Factors affecting the survival were calculated statistically by Kaplan-Meier test.

Results: Women (366; 89.5%) outnumbered men (43; 10.5%) significantly. The mean age at the time of diagnosis was 50.6+13.5 years. 241 (58.9%) patients were classified as diffuse SSc, 151 patients (36.9%) were limited SSc and 17 (4.1%) patients were diagnosed as sine scleroderma. 43 (10.5%) of the SSc patients were smoking. Prominent clinical manifestations were sclerodactily (95%), telangiectasis (42.8%), digital ulcers (38.5%), pulmonary fibrosis (40.5%), pulmonary hypertension (37.9%), dysphagia (19.7%), auto-amputation (7%), pleural effusion (5.1%), renal crisis (2.2%), inflammatory myositis (1.1%). At the time of

diagnosis 94.6% of SSc patients were ANA positive; 95 (23.2%) were anti-centromere positive, 126 (30,8%) were anti-Scl-70 positive and 21 (5.1%) were anti-RNP positive. Anti-Ro antibody was positive in 34 (8.3%) and anti-La antibody was positive in 7 (1.7%) patients. The mean follow-up from the time of diagnosis was 51.7+38.6 months and the median follow-up was 48 months (1-300 months). There were a total of 54 deaths in our cohort (13.2%). Overall, 5 years survival was 85.1% and 10 years survival was 75.5%. The probability of survival was reduced in men (5-year survival: 62.1% vs 72%, not-significant, p=0.09), in patients with pulmonary fibrosis (5-year survival: 67.8% vs 83.5%, not-significant p=0.81), renal crisis (40.6% vs 80.5%, p<0.001), pulmonary hypertension (5-year survival: 50% vs 70.7%, p<0.001), coronary arter disease (54.6% vs 83.5%, p<0.001) and in patients with essential hypertension (5-year survival: 44% vs 84.7%, p=0.003) (table 1). Cox regression analysis showed that pulmonary hypertension (OR: 0.39, 95%CI: 1.74-3.5, p=0.007) at the time of diagnosis was an independent factor effecting survival in patients with SSc.

Conclusion: In our SSc patients, we observed reduced survival in patients with pulmonary hypertension, coronary arter disease and essential hypertension. Any antibody including anti-centromer and Scl-70 were not meaningful. Table 1. Survival of Systemic Sclerosis Patients According to Clinical Features

Clinical Features	Survival 5-year %	p value
Pulmonary Fibrosis	67.8 vs 83.5	0.81
Renal Crisis	40.6 vs 80.5	**<0.001**
Pulmonary Hypertension	50 vs 70.7	**<0.001**
Coronary Arter Disease	54.6 vs 83.5	**<0.001**
Essential Hypertension	44 vs 84.7	**0.003**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: ILD is a frequent and potentially severe complication of CTDs. The course of ILD can be difficult to predict in this setting. The term IPAF (Interstitial Pneumonia with Auto-immune Features) has been recently created to design patients not fulfilling the diagnostic criteria for defined CTD. KL-6 (Krebs von den Lungen-6) biomarker, also known as Mucin1, is a glycoprotein produced by type II pneumocytes. Levels of serum KL-6 are well recognized to be correlated to the clinical outcome of idiopathic ILDs. However, its prognostic relevance in CTDs and IPAF-ILDs needs to be better determined.

Methods: The levels of KL-6 of the sera of 129 patients (66 males; age 61 ± 13 years; smokers or ex-smokers: n = 56(43%) have been retrospectively analyzed using the FUJIREBIO Lumipulse Chemiluminescent enzyme immunoassay at the time of ILD diagnosis. Cut-off for normal values has been set to 500 U/mL according to previous published studies. Among the 128 patients, 61 had CTDs-ILD, 21 had IPAF-ILD, 34 had idiopathic pulmonary fibrosis (IPF), and 13 had nonspecific interstitial pneumonia (NSIP). KL-6 levels were correlated with baseline forced vital capacity (FVC) and diffusion capacity for carbon monoxide (DLCO) using the Spearman non parametric correlation test. Correlation of KL-6 levels with the clinical outcome

(improvement/stabilization of ILD or worsening, as defined by a decrease of 10% in FVC or 15% in DLCO/death) at one year were studied using a U Mann-Whitney test.

Results: The mean levels of KL-6 for CTDs, IPAF, IPF, and NSIP were 2204 ± 2285, 2393 ± 2172, 1802 ± 1584, and 1839 ± 1328 U/mL, respectively. KL-6 levels were over the normal value in 87 % (53/61), 90 % (19/21), 91 % (31/34) and 100 % (13/13) in CTDs, IPAF, IPF, and NSIP, respectively. Overall, KL-6 levels were negatively correlated with FVC (r=-0.2, p=0.035) and DLCO (r=-0.28, p=0.004). As regards the clinical outcome of ILD, higher levels of KL-6 were observed in patients with poor outcome (progression/death) when compared to those with better outcome (stabilization or improvement) in CTDs (2855 ± 2490 vs 1932 ± 2166 U/mL, p=0.05). Similar trends were observed in IPF (2351 ± 1908 vs 1107 ± 561, p=0.04) and in NSIP (2628 ± 1667 vs 1360 ± 543.7, p=0.18), while no difference was observed in IPAF (2418 ± 1583 vs 2388 ± 2679, p=0.33).

Conclusion: High levels of KL-6 measured at early time points in the clinical history of CTDs-associated may be predictive of poorer outcomes. Similar trends were observed in IPF and NSIP. Further prospective studies are required to confirm these results.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Vascular involvement has a major impact on the pathogenesis of Systemic sclerosis (SSc) and there is evidence that microvascular damage with endothelial cell activation may direct the phenotypic presentation of the disease. Endothelial Vinculin has a crucial regulatory role during angiogenesis(1). Villano et al., showed that expression of vinculin was significantly higher in endothelial cells challenged with the sera of SSc pts than endothelial cells treated with sera from healthy controls(2). Hence, the dysregulated vinculin expression may add to defective angiogenic processes already present in SSc. We hypothesize that over- expression of Vinculin in SSc may trigger anti-vinculin antibodies (abs) which may contribute to vasculopathic features in SSc. Objective: To measure the levels of anti-Vinculin antibodies in serum of scleroderma patients, in comparison to Healthy controls and to correlate their levels with SSc related outcome measures. M**ethods:** Serum samples from 72 SSc patients meeting the ACR/EULAR 2013 SSc criteria and 50 healthy controls were recruited. Serum levels of anti-vinculin antibodies were determined by ELISA. Clinical data were obtained from charts for statistical correlations.

Results: The 72 SSc pts' characteristics: 32(48.4%) diffuse SSc , mean age: 56.4(SD ± 18); active skin ulcers 17(25.7%), mean GIT 2.0 was 0.373; interstitial lung disease (ILD) 40 (55%)pts; Pulmonary artery hypertension (PAH) 23(31%)pts. Mean anti-Vinculin levels were significantly higher in SSc pts (1 ug/ml SD ±1) than in healthy controls (0.6 ug/ml SD ± 0.6) $p < 0.01$. Figure 1. In the linear regression models, BMI was a significant predictor of higher anti-vinculin (p<0.005). PAH trended to predict higher anti-vinculin (p=0.052). The lack of usual statistical significance may be due to low statistical power of (post-hoc power=0.44) and

might be detectable in a larger sample. Neither Skin ulcer (p=0.752) nor Raynaud's severity by visual analogue scale (p= 0.591) predicted higher anti-vinculin antibodies.

Conclusion: We report for the first time, higher levels of anti-vinculin antibodies(a potential marker of vascular involvement) in SSc patients than controls and a trend to correlation with PAH. Further research is warranted on more SSc patients to evaluate the role of anti-vinculin antibodies as markers of vascular involvement(i.e., PAH) and to identify their role in the pathogenesis of SSc /SSc-PAH.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The Raynaud's Condition Score (RCS) diary is a clinician-derived validated patient-reported outcome (PRO) instrument for assessing the frequency, duration and severity of Raynaud's phenomenon in systemic sclerosis (SSc-RP).

Methods: The Scleroderma Clinical Trials Consortium Vascular Working Group (SCTC-VWG) has been assembled to develop better methods for assessing and managing peripheral vascular manifestations of SSc. SCTC-VWG members (n=28) were invited to participate in a survey gauging attitudes towards the RCS diary and the perceived need for novel tools for assessing SSc-RP.

Results: Nineteen SCTC-VWG members (68% response rate) completed the survey. All were practicing rheumatologists with an interest in SSc (79% treating >15 SSc patients per month) affiliated with academic units based in North America (n=9), Europe (n=8), South America (n=1) and Australasia (n=1). The majority of respondents (95%) had participated in clinical trials of SSc and most (83%) had experience of SSc-RP endpoints. There were mixed views from respondents regarding the extent to which the RCS diary captures its intended conceptual framework (Table). There was broad consensus that RCS diary returns could be influenced by seasonal variation in weather, efforts made by patients to avoid or ameliorate attacks of RP, habituation to RP symptoms, the potential evolution of RP symptom characteristics with progressive obliterative microangiopathy, patient coping strategies, respondent burden and placebo effect (Table). There was consensus that the RCS diary might be a barrier to drug development (79% of respondents agree/strongly agree), that a novel PRO instrument for SSc-RP might aid drug development for SSc-RP (95% agree/strongly agree) and that a novel PRO instrument for SSc-RP should be developed with the combined input of clinicians and patients (84% agree/strongly agree).

Conclusion: The chief limitations of this pilot work are the relatively small survey size and selection bias derived from targeting SCTC-VWG members. Nevertheless, the SCTC-VWG benefits from its composition of highly experienced clinicians affiliated with specialized SSc centers across four continents. A number of perceived limitations of the RCS diary have been highlighted along with concerns that these factors might impede drug development programs for SSc-RP. There is support within the scleroderma community for the development of a novel PRO instrument for SSc-RP. **Table 1. Responses obtained from SCTC-VWG members in survey**

		Extent to which respondents agreed with each statement:					
		Unable to offer opinion	Strongly disagree	Disagree	Neither disagree or agree	Agree	Strongly agree
The RCS diary accurately reflects:	Frequency of RP attacks	1 (5)	1 (5)	2 (11)	6 (32)	8 (42)	1 (5)
	Duration of RP attacks	1 (5)	1 (5)	3 (16)	8 (42)	5 (26)	1 (5)
	Overall severity and impact of RP	1 (5)	1 (5)	2 (11)	6 (32)	7 (37)	2 (11)
The RCS diary returns are influenced by:	Difficulty recognizing attacks of RP	0 (0)	0 (0)	7 (37)	2 (11)	7 (37)	3 (16)

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We sought to assess work productivity, factors associated with reduced productivity, and the relationship between work productivity and health-related quality of life (HRQoL) in systemic sclerosis (SSc).

Methods: This is a cross-sectional study of SSc patients identified through the Australian Scleroderma Cohort Study database. All patients were mailed 2 employment questionnaires (Workers Productivity and Activity Impairment Questionnaire (WPAI) and a self-made questionnaire) and 2 HRQoL questionnaires (SF-36 and PROMIS 29). Summary statistics, chi-square tests and linear regression were used to determine the associations of work productivity.

Results: Of 800 questionnaires, 476 were returned, equating to a response rate of 59.5%. Of those aged under 65 years (standard retirement age in Australia), 55.2% were employed. Unemployed patients were older at the time of survey completion (57.1 vs 53.7, $p<0.001$) and had longer disease duration from the first clinical manifestation of SSc (16.2 vs 14.9, $p=0.01$) than those who were employed. The mean age of unemployment was ten years less than the average Australian retirement age. Disease characteristics by employment status are outlined in Table 1. Of those in paid employment, 16.0% reported missing work (absenteeism) in the past week due to SSc, accounting for 32.9% of their working time. The mean number of missed work due to SSc was 11.4 (±10.9) hours. For all employed patients, the overall mean number of hours worked in the last week was 26.9 (±13.3), well below the average Australian full-time working week (38-hours). Only 27% of patients were working ≥38 hours a week. Of those working, 22% of their working time was impaired due to SSc ('presenteeism'). The mean overall work impairment accounted for 24.4% of working time. Additionally, 37.9% of the patients' daily activities had been prevented due to their SSc. Factors associated with overall work impairment (absenteeism and presenteeism) included a lack of tertiary education ($p=0.04$), synovitis ($p=0.05$) and sicca symptoms ($p=0.03$). Factors associated with impairments in daily activities included a lack of tertiary education ($p=0.04$), interstitial lung disease ($p=0.01$), digital amputation ($p=0.005$) and sicca symptoms ($p=0.001$). Unemployed patients had significantly lower HRQoL scores across a number of SF-36 domains compared with employed patients, which was mirrored in the PROMIS-29 (Table 2).

Conclusion: SSc is associated with substantial unemployment and reduced productivity, which is in turn associated with poor

HRQoL. Raising awareness and identifying modifiable risk factors are possible ways of reducing this burden.

Session Time: 9:00AM-11:00AM

A Comparison of Gastrointestinal Disease Severity in African American and Caucasian Scleroderma Patients

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disease. After skin involvement and RaynaudÕs, the gastrointestinal tract is the most commonly affected organ system with up to 90% of SSc patients affected. A limited number of studies suggest that African American (AA) SSc patients, particularly those with a nucleolar pattern anti-nuclear antibody, may be more likely to develop severe SSc-GI disease than Caucasian (C) SSc patients. The aims of this study are to determine if a patientÕs race or SSc-specific autoantibody profile is associated with the severity of SSc-GI disease.

Methods: A retrospective analysis of patient responses to the University of California Los Angeles Scleroderma Clinical Trials Consortium Gastrointestinal Tract questionnaire (GIT 2.0), demographic information (age, sex, disease duration, disease subtype), scleroderma-specific autoantibody profile (Nucleolar pattern ANA (NUC), anti-centromere (ACA), SCL-70, RNA Polymerase III (POL 3), and U1-RNP and Medsgar Gastrointestinal Disease Severity Score (Medsger GI Score) were extracted from the medical records of 70 AA SSc patients and 84 C SSc patients seen in the department between 2014 and 2016. SSc patients complete the GIT 2.0 at each clinic visit but only the first response was included for data analysis. Statistical analyses were carried out using Shapiro-Wilk, Kruskal-Wallis and Chi-Square tests.

Results: AA pts were younger, more likely to have diffuse cutaneous disease and had shorter disease duration (Table 1). More AA had NUC and U1 RNP antibodies whereas C were more likely to have ACA and Pol 3. The Medsger GI score was slightly higher in AA compared to C (1.29 vs 1.0, p=0.06). AA pts scored significantly higher on the GIT 2.0 in the reflux, diarrhea, and social function sections, as well as the total score (p=0.02). There were no significant associations of the GIT 2.0 with the NUC, although patients with U1-RNP had the highest GIT 2.0 total score and pts with POL 3 had the lowest total score. The GIT 2.0 correlated with the Medsger GI Score (r= 0.431 p<0.001) even though the Medsger GI Score does not include some of the features in the GIT 2.0.

Conclusion: This study suggests that AA may have more severe SSc GI disease as demonstrated by the Medsger GI severity score and the GIT 2.0. Using the GIT 2.0 in clinical practice can easily identify pts with significant GI symptoms, which should be treated. By identifying SSc patients at risk of developing significant GI system involvement, practitioners can perform targeted organ surveillance based on subset risk stratification levels and provide patients with earlier interventions when treatment is most effective. **Table 1**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: PROMIS-29 is a generic health-related quality of life (HRQoL) instrument that was developed as part of the NIH Patient Reported Outcomes (PROs) Roadmap. Our objective was to assess the construct validity of PROMIS-29 in participants with SSc-ILD.

Methods: Ninety-four participants with SSc were recruited from a large Scleroderma Program. Participants included in the study satisfied 2013 ACR/EULAR criteria for SSc and had ILD on HRCT. Participants with FEV1/FVC less than 0.7 were excluded from study. At baseline, participants were administered PROs, consisting of PROMIS-29, Patient global assessment for disease severity on a visual scale (VAS), Dyspnea 12, Modified Medical Research Council Dyspnea Scale (MMRC; dyspnea measure), Leicester Cough Questionnaire (LCQ; cough measure), and the Saint George Respiratory Questionnaire (SGRQ; respiratory disease impact measure). Along with PROs, pulmonary function test (PFT), HRCT, medical history, physical exam, and medications data were obtained. PFT indices (forced vital capacity and DLCO) were compared across PROÕs. Pearson correlation coefficients were calculated and interpreted as proposed by Cohen: 0.0 – 0.10 indicates negligible correlation, 0.10 – 0.23 indicates a small correlation coefficient, 0.24 – 0.36 indicates a moderate correlation, 0.37 is indicative of a large correlation coefficient.

Results: The mean age of participants was 51.6 years, with a mean disease duration of 2.8 years after first non-ReynaudÕs symptom. Of the 94 participants, 60.6% were classified as diffuse SSc, 24.5% limited SSc, 13.8% sine, and 1.1% overlap. Mean FVC was 74.9%, DLCO was 53.5% and 88% had NSIP fibrotic pattern on HRCT. PROMIS-29 scores were 0.2 to 0.9 SD below the US population. Correlation coefficients were highest with PROMIS physical function scale (0.36 to -0.81 for all comparisons; $p< 0.05$). Correlations were higher for dyspnea scales compared to LCQ. The correlation coefficients with physiologic measures (FVC and DLCO) showed negligible-to-small coefficient vs. PROMIS measures.

Conclusion: PROMIS-29 has construct validity for assessment of HRQoL in SSc-ILD. It has moderate-to-large correlations with measures of dyspnea, dyspnea-specific QoL, and cough, and complements physiologic measures. We are currently assessing sensitivity to change in the longitudinal cohort.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: In systemic sclerosis (SSc), microvascular damage progresses from capillary dilation to capillary loss and reactive angiogenesis, as detectable by nailfold videocapillaroscopy (NVC) [1]. The process is systemic and determines multiple clinical manifestations, from the early appearance of Raynaud's phenomenon, through formation of digital ulcers (DUs), until systemic organ involvement [2,3]. Objective of the study was to quantify, in SSc patients, absolute nailfold capillary number/mm and fingertip blood perfusion (FBP) during long-term treatment with the endothelin receptor antagonist (ERA) bosentan (BOSE) and the synthetic analogue of prostacyclin PGI2 iloprost (ILO) by multiple diagnostic tools. Observed values were correlated with clinical outcomes.

Methods: Thirty SSc patients, already receiving intravenous ILO (80 µg/day), for 5 continuous days (every 3 months) were recruited. Fifteen patients continued such treatment (ILO group), while in 15 patients BOSE (125 mg twice/day) was added (ILO+BOSE group), because of the onset of pulmonary arterial hypertension or digital ulcers (DUs). The follow-up was of 4 years (T0-T4). The following diagnostic tests were performed on a yearly basis: absolute nailfold capillary number/mm count by nailfold videocapillaroscopy (NVC), FBP by laser Doppler flowmetry (LDF) evaluation, DUs incidence, diffusing capacity of the lung for carbon monoxide (DLCO), systolic pulmonary arterial pressure (sPAP), renal arterial resistive index (RI) and other biomarkers analysis. From T2 to T4 laser speckled contrast analysis (LASCA) was added. Non-parametric tests were used for statistical analysis.

Results: Only in the ILO+BOSE group, multivariate analysis showed that absolute capillary number/mm and FBP had a progressive increase ($p= 0.01$ and $p<0.0001$, respectively), independently from other clinical variables. In the same group LASCA analysis of fingertips showed a significant improvement ($p= 0.045$). In addition, during follow up there was a significant reduction (80%) in the incidence of new DUs ($p= 0.002$), whereas DLCO and sPAP did not worse. No relevant side effects were observed.

Conclusion: The study shows in SSc patients up to four years of combined therapy, a progressive significant recovery in structure and function of microvasculature, together with improved clinical outcomes, independently from disease severity. 1] Cutolo M et al. SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal involvement is a major complication for patients with systemic sclerosis (SSc). Various radiographic abnormalities are observed, especially in hands, however, the detailed prevalence and the association with autoantibodies are still unclear. Our objective was to clarify the characteristics of radiographic findings in hand X-ray and their association with autoantibodies in SSc.

Methods: One hundred Japanese patients with SSc without rheumatoid arthritis were included. Two directional hand X-ray was examined to evaluate joint and soft-tissue changes. Clinical and serological parameters were collected retrospectively from medical records. The prevalence of abnormal findings in X-ray and the associations with clinical features, SSc subtypes and autoantibodies were analyzed.

Results: The mean age was 65.7 years (range 25-88 years), 89% were female and the mean disease duration was 11 years (range 1-44 years). Twenty-six patients (26%) were positive for anti-Scl-70 antibody, 54% for anti-centromere antibody, 6% for anti-RNA polymerase III antibody, and 6% for anti-U1RNP antibody. Twenty-four percent was diffuse cutaneous SSc and 76% was limited cutaneous SSc. Sixty one patients (61%) showed abnormality in hand X-ray; acroosteolysis in 16%, erosive disease in 20%, calcinosis in 14%, and flexion contracture in 8%. Clustering analysis for clinical features demonstrated that acroosteolysis, calcinosis and flexion contracture were associated with digital tip ulcer, interstitial lung disease and gastrointestinal involvement, but erosive disease was only associated with older age. Anti-Scl-70 was significantly associated with acroosteolysis ($p<0.001$) and anti U1-RNP with acroosteolysis and flexion contracture ($p<0.05$ for both) while anti-centromere was inclined to associate with calcinosis ($p=0.08$).

Conclusion: Abnormal findings in hand X-ray were observed more frequently in SSc patients with longer disease duration, disturbed peripheral circulation, and internal organ involvement. The type of autoantibodies was also associated with the

radiographic findings. These results suggest that X-ray findings may reflect the underlying pathogenesis in SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Periostin is one of the matricellular proteins, a class of ECM-related molecules defined by their ability to modulate cell–matrix interactions. Several lines of evidences suggest that periostin serves as a regulator of wound healing, epithelial mesenchymal transition, and fibrosis. We have previously reported overexpressed periostin levels in patients with systemic sclerosis (SSc) and a correlation between its serum levels and skin thickness score in SSc patients. In this study, we further analyzed circulating periostin levels in associations with clinical phenotypes including organ involvements in larger SSc samples.

Methods: We enrolled 385 patients with SSc and 204 healthy controls, who were recruited form 3 medical centers in Japan. Circulating levels of periostin were determined by enzyme-linked immunosorbent assay, and univariate and multivariate analysis was conducted to investigate their correlations with disease duration, antibody profiles, the modified Rodnan total skin thickness score (mRSS), and SSc-related organ involvements. Furthermore, available serial samples were analyzed to evaluate if a consecutive variation of periostin level reflect a change of mRSS (n = 76).

Results: One hundred and forty-six patients (38%) were classified as having diffuse cutaneous SSc (dcSSc), and 78 (20%), 169 (44%), 29 (8%), 209 (54%), 21 (5%), and 6 (2%) of SSc patients had digital ulcers (DU), interstitial lung disease (ILD), pulmonary arterial hypertension (PAH), gastrointestinal involvement (GI), heart and renal involvements, respectively at initial evaluation. Disease duration from first non-Raynaud symptoms at evaluation was 7.8 ± 7.4 years. Periostin level was significantly elevated in SSc patients than in healthy controls ($P < 0.0001$). Higher periostin levels were observed in patients with dcSSc, shorter disease duration, higher mRSS, and positive for autoantibodies against to topo-I and RNAPIII. Multivariate analysis revealed that elevated periostin was an independent parameter associated with the presence of DU ($P = 0.01$), ILD ($P = 0.0005$), PAH ($P = 0.003$), GI ($P = 0.017$), and heart involvement ($P = 0.024$). In addition, mRSS was strongly associated with periosin level, disease duration, anti-topo-I and anti-RNAPIII antibodies by the multiple regression analysis ($R2 = 0.35$, $P < 0.001$). Finally, serial variation of periostin level correlated with a change of mRSS ($R2 = 0.28$, $P < 0.001$).

Conclusion: Elevated circulating periostin in SSc patients was strongly associated with mRSS and the presence of SSc-related organ involvements. Periostin may be a potential biomarker reflecting for disease severity in patients with SSc.

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In a previous study it was demonstrated that, in patients with systemic sclerosis (SSc) the cumulative number of micro-haemorrhages (MH) and micro-thrombosis (MT) (the so called NEMO score), observed in nailfold videocapillaroscopy (NVC), was strongly predictive of disease activity (DA). [1].The present study is aimed at validating NEMO score as predictor of DA in different cohorts of patients.

Methods: The NEMO score, total number of giant capillaries (GC) and mean number of capillaries (Cs) were computed by eight finger NVC in 122 patients with SSc referring to the Rheumatic Disease Unit of the 'Istituto G.Pini' of Milan, where the preliminary study had been carried out (internal validation). The same procedure was performed in 97 patients collected in a different centre, i.e., the Rheumatic Dept. of the II University of Naples (external validation). In all of the patients DA was assessed at the same time of NVC performance by means of the European Scleroderma Study Group (ESSG) scoring system.

Results: Demographic and clinical characteristics of the patients were summarised in Table 1.

	number of patients	male/ female	patients with lcSSc/dcSSc	age (years) median (range)	disease duration median (range)	patients with a ESSG score≥3
Milan Cohort	122	8/114	60/62	52 (17-82)	4 (0-28)	57
Naples Cohort	97	9/88	72/25	55 (19-79)	6 (0-36)	30
All patients	219	17/202	132/87	53 (17-82)	5 (0-36)	87

lcSSc= limited cutaneous SSc; dcSSc=diffuse cutaneous SSc. Table 2: Main statistical results obtained by the analysis of the two cohorts.

	correlation* between NEMO and ESSG score	correlation* between GC and ESSG score	NEMO ROC^ curve for ESSG score≥3	sens./spec. of NEMO>8 for ESSG score ≥3
Milan Cohort	R=0.69; p<0.0001	R=0.30; p<0.001	AUC°= 0.926	84.2/92.3
Naples Cohort	R=0.76; p<0.0001	R=0.39; p<0.0005	AUC°= 0.930	93.3/76.1

*by Spearman Rank correlation; ^ROC=receiver operating characteristic; °AUC=area under the curve; sens.=sensitivity; spec.= specificity. In a logistic regression model were NEMO, GC e Cs were considered the independent variables and a ESSG≥3 the dependent variable, only NEMO score showed to have a significant predictive value for DA.

Conclusion: This validation study confirms that the presence of a certain number of MH plus that of MT in eight finger NVC may represent a simple screening method to predict the presence of DA in patients with SSc. **References.** 1. Sambataro D, et al. Arthritis Res & Ther 2014;16:462.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To test the association of the severity of nailfold capillaroscopy (NFC) abnormalities with mortality in systemic sclerosis (SSc).

Methods: One hundred and seventy SSc patients underwent an extensive evaluation at baseline following a standard protocol. Capillary loss on NFC was evaluated using the avascular score (AS, ranging from 0 to 3), and the mean number of ectasias, megacapillaries, and hemorrhages per finger was also recorded. After a mean period of 9.3±4.0 years, the life status of the patients was ascertained. Univariate and multivariate Cox proportional hazards models were used for statistical analysis.

Results: Sixty-three patients died. By univariate Cox analysis, the AS was significantly associated with mortality (HR=1.54, 95%CI: 1.13 to 2.09, p=0.006), but the association weakened after controlling for skin score and a combination variables representing results of complementary exams. However, in bivariate analysis, the AS showed a stronger association with mortality than anticentromere and antitopoisomerase I antibodies, severity of interstitial lung disease, and similar to skin score. In secondary analysis, the association of the AS with mortality was particularly strong among patients in the lowest quartile of skin score (HR=2.35, 1.08 to 5.14, P=0.032, controlled for skin score) and limited disease. Other NFC variables were not related to mortality.

Conclusion: The AS is associated with higher mortality in SSc and, despite the weakening of the association after controlling for skin score, performed better in this context than some other variables reflecting disease severity. This association was particularly strong among patients with low skin scores or limited disease.

The Clinical Relevance of Common ANA Patterns in Systemic Sclerosis

Ashraf Raslan[1], Clifford Stermer[2] and Vivien Hsu[3], [1]Medicine, Rutgers-RWJ Medical School, Jersey City, NJ, [2]Medicine, Rutgers-RWJMS, New York, NY, [3]Rheumatology, RWJ Med Schl Scleroderma Prog, New Brunswick, NJ

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antinuclear antibody (ANA) test is positive in nearly 95% of patients with systemic sclerosis (SSc) [1]. We aim to identify the clinical relevance of common ANA patterns in SSc, of which there are only few published studies [2][3].

Methods: We evaluated 186 outpatients who met criteria for SSc [4] and were seen between 2010 and 2015. We collected pertinent clinical information, including ANA patterns (Homogeneous (H-ANA), speckled (S-ANA), nucleolar (N-ANA), centromere (C-ANA), and mixed [3]) performed by Indirect Immunofluorescence (IIF) and SSc auto-antibodies: RNA Polymerase III (POL3), Anti-topoisomerase I (anti-topo I), U-1 RNP, and Anti-Centromere (ACA).

Results: ANA was positive in 92% of patients (n=171) with the following patterns: H-ANA 27%, S-ANA 26%, N-ANA 12%, C-ANA 20% and mixed 14% (homogeneous & speckled 3%, homogeneous & nucleolar 5%, speckled & nucleolar 4%, speckled & centromere 1% and nucleolar & centromere 1%). H-ANA was strongly associated with both anti-topo I (OR 24, CI 10.3-55.8) and diffuse cutaneous systemic sclerosis (dcSSc) (OR 5.5, CI 2.4-12.6). In addition, H-ANA was significantly associated with later age of disease onset, acro-osteolysis, hand contractures, interstitial lung disease (ILD), and lower forced vital capacity (FVC) and diffusion capacity of the lung for carbon monoxide (DLCO). S-ANA was strongly associated with POL 3 (OR 11.4, CI 4.4-29.9), U-1RNP (OR 7.3, CI 3-17.8), and tendon friction rubs (TFRs) (OR 2.8, CI1.3-5.9). C-ANA was strongly associated with limited cutaneous systemic sclerosis (lsSSc) (OR 71, CI 9.4-533), and strongly protective against myopathy (OR 0.1, CI 0.01-0.8), TFRs ($p=0.0002$), hand contractures (OR 0.2, CI 0.08-0.7), and ILD (OR 0.3, CI 0.1-0.7). These patients had higher %FVC ($p<0.0001$) and %DLCO ($p=0.006$). None of the SSc auto-antibodies were associated with the nucleolar pattern.

Conclusion: ANA patterns may be useful in predicting specific SSc auto-antibodies and clinical features. Larger studies could confirm our findings and help further understand the clinical significance of these ANA patterns in SSc. **References:**

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid antibodies (aPL) have been found in patients with various autoimmune and rheumatic diseases, including systemic sclerosis (SSc). However, in the absence of clinical events classically associated with the antiphospholipid syndrome, their significance remains unclear. This study aimed to determine the prevalence of aPL in a cohort of SSc patients, and to assess their clinical associations. AL and VS have contributed equally to this work.

Methods: A total of 249 adult patients who fulfilled 2013 ACR/EULAR criteria for SSc were consecutively included between October 2014 and January 2016. Patients were tested for lupus anticoagulant (LA), anticardiolipin (aCL) and anti-β2glycoproteine I (anti-β2GpI) antibodies. Positive titer was defined as ≥ 10 UGPL/mL (aCL) or ≥ 10 UA/mL (anti-β2GpI). aPL positivity was defined if at least one of the three antibodies was positive. Clinical associations between aPL positivity and thrombosis event, obstetrics event, pulmonary arterial hypertension (PAH) and digital ulcer were studied using binomial logistic regressions. Adjustments were done (i) *a priori* for gender, age, SSc subtype and tobacco history, and (ii) for the characteristics that differed significantly between aPL positive and negative patients. Similar analyzes were performed considering the titers of aCL and anti-β2GpI rather than the aPL status. Because these variables had a majority of zero values, they were categorized, as follows: (i) 0, ≥1 and <5, ≥5 and ≤20 UGPL/mL for aCL, and (ii) 0, ≥1 and <5, ≥5 and <10, ≥10 and ≤100 UA/mL for anti-β2GpI.

Results: The 249 patients were predominantly female (82.3%), with limited cutaneous SSc (81.5%). One or more type of aPL was present in 16 patients leading to a prevalence of 6.4% (95% confidence interval (CI) [3.4-9.5]). aPL positivity was associated with venous thrombosis in univariate analysis (OR=3.91; 95%CI [0.98-13.53]; p=0.027); there was a trend towards an association in multivariate analysis (OR=3.24; 95%CI [0.87-10.9]; p=0.064). aPL positivity was associated with miscarriage in multivariate analysis (OR=4.31; 95%CI [1.09-16.33]; p=0.031). We did not find any association between aPL positivity and PAH or digital ulcer. Titers of aCL ≥5 UGPL/mL were associated with PAH (OR=6.35; 95%CI [1-41.1]; p=0.043) and venous thrombosis (OR=3.69; 95%CI [0.98-12.9]; p=0.043) in multivariate analysis. Titers of anti-β2GpI ≥10 UA/mL and miscarriage were associated (OR=5.25; 95%CI [1.04-27.1]; p=0.041).

Conclusion: This study found a prevalence of aPL in SSc of 6.4% (95%CI [3.4-9.5]) in a French cohort. aPL positivity was associated with venous thrombosis and miscarriage. These data provide additional insights into the vascular involvement of SSc.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

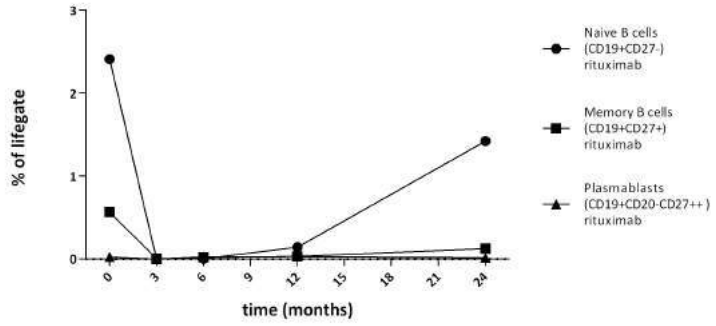
Background/Purpose: Open-label studies provided evidence for possible efficacy of rituximab (RTX) in systemic sclerosis (SSc). Previously, we reported on a randomized placebo-controlled clinical trial in early SSc showing no significant difference in clinical outcomes. In rheumatoid arthritis and systemic lupus erythematodus, clinical efficacy of RTX is associated with the extent of B cell depletion. Therefore, we aimed to investigate the effect of rituximab in SSc on B cells in peripheral blood and skin, as possible explanation for lack of clinical efficacy.

Methods: Sixteen patients fulfilling ARA criteria for SSc were randomized to either placebo or 1000 mg RTX IV on day 1, 15 and at 6 months and followed for 24 months. Immunophenotyping of peripheral blood mononuclear cells (PBMC) by flow cytometry for presence of CD19+CD27- naïve B cells, CD19+CD27+ memory B cells, CD19+CD20-CD27++ plasmablasts and detection of antibody secreting cells (ASC) by Enzyme-Linked ImmunoSpot assay (ELISPOT) was performed at baseline, months 3, 6, 12 and 24. 4 mm skin biopsies of the dorsal forearm were assessed for presence of B cells by immunohistochemistry with CD79a at baseline and 3 months.

Results: Mean age was 44.5 years (SE 5.6), 87.5 % of patients had diffuse cutaneous SSc, median disease duration since non-Raynaud was 1.2 years (interquartile range 0.8-2.8). At month 3, depletion of naïve and memory B cells to very low B cell counts was achieved with RTX. Naïve B cells repopulated first and were clearly detectable at month 12, while memory B cells reached pre-treatment levels only at month 24 (Figure 1). Some patients achieved undetectable counts of naïve B cells or plasmablasts, though no patient had undetectable B cells in all subsets (Figure 2). Persistence of ASC was confirmed by ELISPOT (Figure 3). Scattered B cells (range 2-7) were seen in skin biopsies at baseline (placebo 3 of 8; RTX 2 of 7 biopsies) and at 3 months (placebo 4 of 7; RTX 4 of 7 biopsies).

Conclusion: Treatment with RTX resulted in depletion of peripheral blood B cells to very low, though still detectable counts. Despite this depletion, no clinical effect was observed. Persistence of ASC and persistent detection of B cells in skin at 3 months provide evidence for treatment-resistant populations of B cells in SSc, which might influence treatment response.

Figure 1. Naïve B cell, memory B cell and plasmablast levels in SSc patients treated with RTX

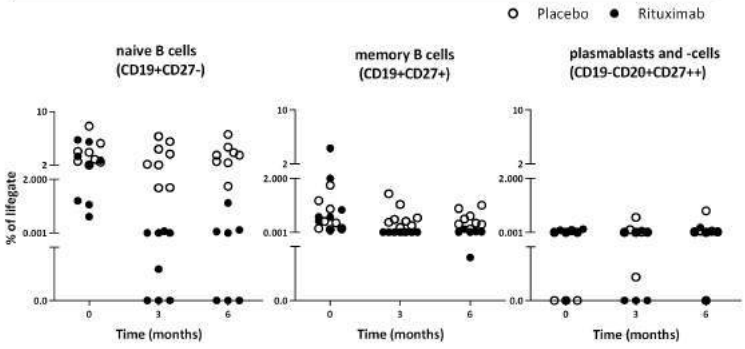


SSc - systemic sclerosis ; RTX – rituximab

Symbols indicate median values per group at given time. RTX: T0, n= 8; T3 n=8; T6 n=7; T12 n=6; T24 n=4; Placebo: T0, n=8; T3, n=8; T6 n=8; T12 n=7; T24 n=7

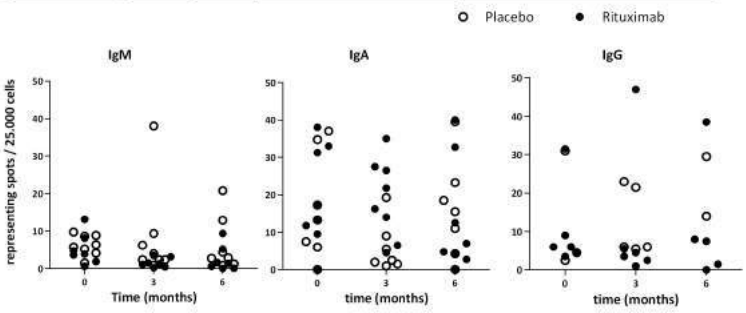
All patients receiving RTX had B cell depletion of naïve and memory cells, 3 months after rituximab treatment. Reduction of plasma blasts was non-significant compared to either baseline (p=0.10) or placebo (p=0.74).

Figure 2. Naïve B cell, memory B cell and plasmablast cell count for placebo and RTX treated SSc patients



SSc - systemic sclerosis; RTX – rituximab
RTX: T0, n= 8; T3 n=8; T6 n=7; Placebo: T0, n=8; T3, n=8; T6 n=8

Figure 3. Antibody secreting cells in placebo and RTX treated SSc patients



SSc - systemic sclerosis; RTX – rituximab
IgA - RTX: T0, n= 7; T3 n=7; T6 n=7; Placebo: T0, n=8; T3, n=8; T6 n=8;
IgM - RTX: T0, n= 7; T3 n=7; T6 n=7; Placebo: T0, n=8; T3, n=8; T6 n=7;
IgG* - RTX: T0, n= 7; T3 n=7; T6 n=7; Placebo: T0, n=8; T3, n=8; T6 n=7
Due to overexpression of IgG expressing cells, in some patients cell counts could not be determined

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The patient perspective captured using Patient-Reported Outcome (PRO) instruments provide valuable insight into the patient condition not always captured by physician-derived assessment tools. Target patient population involvement is considered an essential component of PRO instrument design and is assessed by regulatory bodies when considering labelling claims in medical product development. We have reviewed the level of patient involvement in the development of PRO instruments used in the assessment of systemic sclerosis (SSc).

Methods: A comprehensive literature review was undertaken to identify studies reporting PRO instruments in SSc. Studies were assessed to establish whether the PRO instruments had been developed specifically for SSc or adopted from other disease areas. Studies reporting PRO instruments specific for SSc were scrutinised for evidence of target patient population involvement in the development of the instrument.

Results: A total of 58 PRO instruments that have been used in SSc research were identified. Twelve (21%) of these were developed specifically for outcome assessment within SSc populations (Table). Of these, 5 (42%) had not reported any patient involvement in the development phase of the instrument. Five SSc PRO instruments (42%) involved target patient population in the domain/item generation stage. Four (33%) of SSc PRO instruments had undertaken cognitive interviewing/linguistic evaluation to ensure item wording adequately captured the intended conceptual framework. The SCTC GIT questionnaires and the Systemic Sclerosis Questionnaire had each involved SSc patients in both domain/item generation and cognitive interviewing/linguistic evaluation stages of instrument development.

Conclusion: PRO instruments are particularly valuable in SSc due to the multi-faceted nature of the disease and the paucity of effective objective methods for assessing disease status. The majority of existing PRO instruments used in SSc have not involved significant target patient involvement in their development. By involving patients in the development and design phase of novel PRO instruments in SSc, we can ensure that PRO instruments used in the clinical and research settings adequately capture experiences most relevant to our patients. **Table. Patient involvement in development of SSc-specifc PRO instruments** * Authors report patient involvement but no details supplied.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics - Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: ESOS (European Scleroderma Observational Study) was a prospective observational study of 326 patients with early diffuse cutaneous systemic sclerosis (dcSSc) from 50 centres. Here we describe the burden of disease in terms of disability and fatigue in this very early disease cohort (median disease duration 11.9 months), and explore disease features that associate with this burden.

Methods: Patients completed questionnaires at study entry and at 12 months: the Scleroderma Specific Health Assessment Questionnaire (sHAQ, including HAQ-DI disability index), Functional Assessment of Chronic Illness Therapy [FACIT]-fatigue, the Short Form 36 [SF36] and the Cochin Hand Function Scale (CHFS). Covariates examined included the modified Rodnan skin score (mRSS) and other parameters listed in Table 1. The distribution of the HAQ-DI, fatigue and hand function scores was compared between levels of categorical variables using Kruskal-Wallis' test and correlations with other continuous variables were assessed using Spearman's coefficient (ρ). For continuous variables, correlations between 12-month changes were also computed.

Results: Baseline scores of HAQ-DI, FACIT and CHFS, and associates are shown in Table 1. High levels of skin fibrosis (mRSS) were associated with poor hand function (ρ=0.35) and high HAQ-DI scores (ρ=0.34). The median CHFS (0-90 scale) and HAQ-DI (0-3 scale) scores were higher by 8.5 and 0.6 units (indicating poorer hand function and increased disability) in patients with current digital ulcers. The median HAQ-DI score was higher by one unit in patients with muscle involvement, and was also higher in patients with lung fibrosis and heart involvement. Cardiac, pulmonary and renal involvement were each associated with higher levels of fatigue. Patients currently or previously on corticosteroids had more disability and fatigue than patients who had never been prescribed these. As anticipated, HAQ-DI, FACIT, CHFS and SF36 scores were all highly correlated. The 12-month change in HAQ-DI had a strong association with the change in hand function (ρ=0.56), and increasing levels of skin fibrosis were correlated with increasing HAQ-DI scores (ρ=0.40).

Conclusion:

1. ESOS benchmarks the burden of disability in early dcSSc, with high levels of disability and fatigue, and will provide comparative data for future clinical trials.

2. The degree of disability/fatigue is associated with severity of skin thickening (mRSS), with changes in HAQ-DI over 12 months correlating with changes in mRSS.

3. Impaired hand function is a major contributor to overall disability.

4. Disability and fatigue associate with internal organ involvement, and overall (HAQ-DI) and hand disability with digital ulcers.

Session Date: Tuesday, November 15, 2016
Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: PKC-θ is a member of the $Ca2^{+}$-independent novel PKC subfamily, most abundantly expressed in T-cells, and mediates early antigen recognition signal transduction and cell activation associated with T-cell receptor (TCR) stimulation. Inhibition of PKC-θ by CC-90005, a highly selective and orally active small molecule inhibitor of PKC-θ may provide new therapeutic treatment options for T-cell mediated rheumatic disease indications.

Methods: Human purified T cell cultures or whole blood samples were pre-treated with CC-90005 (0.1-10 μM) followed by anti-CD3 and anti-CD28 TCR stimulation to assess the impact of PKC-θ inhibition on TCR signal transduction, expression of cell surface activation markers, proliferation, and cytokine production. A collagen-induced arthritis (CIA) model in DBA mice was used to assess the therapeutic potential of CC-90005 in treating rheumatoid disease indications. Drug was given once or twice daily in a prophylactic dosing paradigm starting 1 day before collagen sensitization. Paw swelling was measured and scored throughout a 42 day treatment schedule. Cytokine gene expression, protein levels and circulating C-terminal telopeptide collagen breakdown products (CTX-I, CTX-II) were measured on day 42.

Results: TCR stimulation in the presence of CC-90005 resulted in the significant inhibition of T-cell activation in a concentration range of 0.3 to 10 μM in purified human T-cell and whole blood cultures. Consistent with PKC-θ being an early step in the activation of T-cells, inhibition by CC-90005 reduced TCR mediated T-cell activation at the level of target engagement (phosphorylated PKC-θ), signal transduction (phosphorylated ERK1/2 and NFkB; IkBα degradation), and cellular function (surface receptor activation marker expression, proliferation, and cytokine production). In the mouse CIA model of arthritis, reduction of clinical scores was observed at 30 and 100 mg/kg BID accompanied by reduced cytokine expression (IL-1β, IL-17 and IL-22) in the ankle joints and a dose related trend towards reduced serum levels of CTX-I and CTX-II.

Conclusion: CC-90005, a specific inhibitor of PKC-θ, significantly inhibits TCR signal transduction pathways resulting in the inhibition of functional T-cell responses including cell surface activation marker expression, proliferation, and cytokine production. Moreover, inhibition of these T-cell functions showed efficacy in a mouse CIA model of arthritis, suggesting that selective inhibition of PKC-θ is sufficient to provide therapeutic benefit in rheumatologic diseases.

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II
Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous reports showed that both CD4 and CD8 T cells were related to the RA disease activity, such as Th17, follicular helper 2, and activated CD8 T cells. On the other hand, T cells can be divided according to developmental stages, and it is controversial whether T cell proceeds development in RA, partly because aging greatly influences T cell development. Recently, the least developed memory T cell subset, stem cell memory T (Tscm), was found among cells with naive phenotype, therefore, peripheral blood (PB) T cells can be divided into naive (Tn), Tscm, central memory (Tcm), and effector memory (Tem) in CD4, and these plus CD45RA+ effector memory (Temra) in CD8. Although human Tscm were reported in patients with bone marrow transplantation, it has not been studied in autoimmune diseases. The purpose of this study was to elucidate the T cell abnormality among each developmental stages including newly identified Tscm in RA patients.

Methods: PB samples from 56 untreated RA patients and 38 healthy controls (HC), and 14 synovial fluid (SF) samples with paired PB from same RA patients were collected. The proportion of each developmental stage and activating status was determined by flow cytometry. Tn, Tscm, Tcm, Tem, and Temra subset from PB of 6 RA and HC were sorted, and analyzed gene expression by microarray.

Results: PB T cells were greatly influenced by age and individual differences, however, the proportion of developed cells tended to increases in RA. Especially, the proportion of CD4 Tscm was significantly high in RA (p=0.02), and CD8 Tscm also tended to be high. In transcriptome analysis, most of subsets were clustered by developmental stage rather than disease, suggesting that influence of disease was not so big among same developmental stages (Fig 1). Remarkably, CD8 Tem and Temra were apparently different between RA and HC. Pathway/upstream analysis showed that this difference may be derived from cytokines such as VEGF, PDGF, and IL-6. In comparison of T cells in PB and SF, the proportion of developed and activated cells was high in SF (Fig 2). Interestingly, most of CCR7+CD45RO-cells in SF, which had been classified as naive, were actually Tscm. In addition, the proportion of activated CD4 and CD8 Tscm in SF were correlated with RA disease activity.

Conclusion: Although the PB T cell in RA had smaller differences with that of HC than expected, several cytokine signatures were found in CD8 Tem and Temra of RA. In SF, almost all T cells, including cells which has been considered naive, were memory cells. Activating status of Tscm in both CD4 and CD8, correlated with RA disease activity, indicating that these subsets participated in RA pathophysiology.

Session Date: Tuesday, November 15, 2016

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: PD-1 is a co-inhibitory transmembrane protein with a significant effect on immune regulation. Several studies have shown elevated expression levels of PD-1 on T cells isolated from the blood and the synovial fluid of patients with rheumatoid arthritis (RA). Moreover, in some studies, PD-1 expression levels correlated with disease activity scores. The goal of our study was to uncover the signaling pathways downstream of PD-1 in RA T cells as well as its contribution to cellular function. Understanding the biology of PD-1 in RA T cells may lead to novel targets in the treatment of inflammatory arthritis.

Methods: Naïve primary T cells were isolated from RA patients and healthy controls. PD-1 expression was measured by flow cytometry. T cells were stimulated with beads coated with antibodies to T cell receptors as well as PD-L2, a ligand for PD-1. Western blot analysis was used to measure levels of key signaling proteins. Cytokine secretion, calcium influx, and adhesion to coated surfaces were concurrently recorded. Correlation analysis between these variables and clinical parameters were performed.

Results: Compared with healthy controls, T cells isolated from RA patients demonstrate higher plasma membrane PD-1 levels, which correlate with disease activity. When stimulated, these cells secrete more IL-2 in response to T cell receptor ligation, while concurrent PD-1 receptor activation led to an attenuated response. Higher levels of phosphorylated Erk were recorded in RA T cells compared to healthy control T cells. Moreover, stimulation of PD-1 led to Erk inhibition only in the RA T cells, but not in the cells isolated from healthy controls.

Conclusion: Given that PD-1 is a co-inhibitory receptor, one might expect that T cells from patients with autoimmune disease would express lower levels of PD-1 on their surface. In contrast, our data suggests that RA T cells express higher levels of PD-1 and that they are more activated when compared to healthy control T cells. It is not clear whether PD-1 is a cell surface marker of activation or if those T cells are “resistant” to signals downstream of PD-1. In conclusion, PD-1 may serve as a T cell regulator in RA with possible therapeutic potential.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: T cells play a central role in the early stages of rheumatoid arthritis (RA). In this context, we have shown increased proportions of memory CCR6+ Th cells in the blood of treatment naïve patients with early RA compared to healthy individuals. These cells express high levels of IL-17A and are TNFalpha positive. In addition, these memory CCR6+ Th cells induced a proinflammatory loop when co-cultured with RA synovial fibroblasts. This interaction may underlie the development of chronic synovitis. Since the memory CCR6+ T cell populations is a heterogeneous population consisting of e.g. Th17, Th17/Th1, and Th17.1 subpopulations we examined the presence and pathogenic potential of these subpopulations from the blood of treatment naïve patients with early RA.

Methods: Memory CCR6+ Th cell subpopulations from the blood of treatment naive patients with early RA were distinguished based on chemokine receptor expression. Within these populations, cytokine and transcription factor expression were examined. In addition, CCR6+ subpopulations were sorted by FACS from peripheral blood of treatment naïve patients with early RA and analyzed for their pathologic potential in a co-culture system with RA derived synovial fibroblasts (RASF).

Results: Based on the expression of CXCR3 and CCR4 four memory CCR6+ Th cell subpopulations were distinguished: Th17, Th17/Th1, Th17.1, and double negative (DN) cells. All four CCR6+ subpopulations expressed RORC, but differ in IL-17A, IL-17F, IL-22, IFNgamma, and T-bet expression. Furthermore, all four subpopulations showed increased pathological potential in co-culture with RASF compared to naive and the classical Th1 cells. Interestingly, even Th17.1, the subpopulation with the lowest IL-17A expression, displayed high pathological potential as shown by stimulating IL-1β, IL-6, IL-8, COX-2 and MMP-3 expression upon co-culture with RASF.

Conclusion: The memory CCR6+ Th subpopulations differ in IL-17A, IFNgamma and T-bet expression However, all subpopulations express RORC. Interestingly, all subpopulations possess strong pathological potential in stimulating RASF to induce expression of proinflammatory cytokines and MMPs. These findings indicate that in addition to Th17 cells, also other CCR6+ Th subpopulations play a prominent role in the pathogenesis of synovial inflammation despite low IL-17A. Further insight in the molecular phenotype of these subpopulations is warranted to optimize targeted therapy in RA.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: CD11c-Flip-KO (**HUPO**) mice spontaneously develop inflammatory, erosive arthritis. We previously demonstrated that T regulatory cells (Tregs) were reduced in HUPO mice and that the adoptive transfer of Tregs isolated from

spleens of control mice suppressed not only the arthritis but also the expression of autoreactive T cells. The purpose of these studies was to identify the mechanism(s) responsible for the reduction of Tregs in HUPO mice.

Methods: Immune cell phenotype and apoptosis/necrosis were assessed by flow cytometry employing multicolor fluorochrome-antibodies. Conventional dendritic cells (cDCs), Tregs or $CD3^+$T cells are purified by positive or negative selection employing commercially available kits. In vitro cell culture or in vivo adoptive transfer were employed to examine T cell proliferation, Treg development and maintenance. Mice analyzed were HUPO vs. littermates, or *Rag*$^{-/-}$ vs. HUPO-*Rag*$^{-/-}$ as the lymphopenic recipients for in vivo homeostatic proliferation. Cytokines were determined by quantitative ELISA or rt-PCR.

Results: A marked reduction of IL-2 was identified in in vitro spleen culture supernatants of HUPO mice compared with littermate controls. Tregs were also reduced in the spleen cultures and the addition of IL-2 or cDCs increased Tregs but not other T cells. Further, cDCs from HUPO mice were deficient in TGFβ. In vivo, a significant increase of necrotic Tregs was identified in the spleens of young (4 weeks) and old (≥20 weeks) HUPO mice. Consistent with these observations central Tregs, which are highly IL-2 dependent, were greatly reduced in the spleens of young and old HUPO mice. Additional experiments were performed under lymphopenic conditions since the maintenance of Tregs is in part regulated by homeostatic proliferation. HUPO mice exhibit a reduction of cDCs, particularly the CD8a subset and of $CD11c^+$ macrophages. Crossing HUPO and Rag$^{-/-}$ resulted in HUPO-*Rag*$^{-/-}$ line with mild non-progressive arthritis. Following the adoptive transfer of control $CD3^+$ T cells no reduction of Treg homeostatic proliferation was observed in HUPO-*Rag*$^{-/-}$ mice. However at 6 and 20 days following adoptive transfer Tregs became significantly reduced, in the absence of increased cell death, suggesting a reduction of maintenance or increased dedifferentiation of Tregs. Supporting this mechanism the MFI of Foxp3 expression was significantly reduced in the Tregs of HUPO mice and the control donor T cells in the HUPO-*Rag*$^{-/-}$ recipients. Summary: Multiple mechanisms appear to contribute to the reduction of Tregs in HUPO mice. Increased Treg cell death and the reduction of central Tregs may be due to the reduction of IL-2. Increased dedifferentiation may also contribute to the reduction of Tregs in HUPO mice. Further studies with Foxp3-GFP Tregs will help determine the contributions of each mechanism.

Conclusion: IL-2 and TGFβ are the essential cytokines for Treg differentiation and stability. Our observations suggest that IL-2 may be the effective treatment strategies for HUPO arthritis. The documented reduction of IL-2 in patients with RA suggests similar approach might be effective in patients with RA.

Hypomethylation of an Intragenic Alternative Promoter Contributes to Impaired Treg Function in Rheumatoid Arthritis By Transcriptional Interference with Expression of the Treg-Specific Protein, Glycoprotein a Repetitions Predominant (GARP)

Alla Skapenko, Jan Leipe and Hendrik Schulze-Koops, Division of Rheumatology and Clinical Immunology, University of Munich, Munich, Germany

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The expression of Treg specific genes, such as the master transcription factor of Tregs, FoxP3 or the Treg specific surface molecule, glycoprotein A repetitions predominant (GARP) controls the function of regulatory T cells. As Tregs are functionally impaired in rheumatoid arthritis (RA), we have performed an in depth analysis of GARP promoter regulation in healthy controls and in patients with RA.

Methods: CD25+ CD127- CD4 Tregs and CD25- CD4 T cells were isolated from the peripheral blood of therapy-naive RA patients and of age- and sex-matched healthy volunteers by magnetic cell sorting. Genomic DNA was isolated and processed by bisulfite conversion. DNA regions of interest were amplified by PCR using primers specific for bisulfite converted DNA. The PCR products were cloned and subsequently sequenced to compare methylation between controls and RA patients.

Results: Two transcripts transcribed from two alternative promoters were identified for the human GARP gene. While neither transcript was expressed in conventional T cells, both transcripts were detected in Tregs. Luciferase reporter assays with the two isolated promoters in transfected primary CD4 Tregs indicated that both transcripts initiated gene transcription upon T cell specific activation (i.e. mAbs to CD3 and CD28). Treg-specific GARP transcription was initiated by synergistic interaction of Foxp3 with NFAT and was underpinned by permissive chromatin remodeling caused by release of the H3K4 demethylase, PLU-1. The transcript initiated from the up-stream P2 promoter was markedly more abundant, suggesting the P2 promoter to be the main promoter of GARP. Surprisingly, the promoter activity of the full length GARP promoter was markedly reduced when compared to the upstream P2 promoter alone. DNA methylation analysis revealed several CpG island in both promoter regions. While the CpG islands of the P2 promoter were fully demethylated in both, effector and regulatory T cells, they were hypomethylated in the downstream P1 promoter only in activated Tregs. Surprisingly, the transcriptional activity of the strong upstream P2 promoter was down-regulated upon demethylation of the weak downstream P1 promoter, suggesting an inhibitory interaction between both promoters within the full-length promoter sequence. Of great interest, demethylation-induced transcriptional attenuation regulated the magnitude of GARP expression in Tregs. As GARP expression is required for Treg function and Tregs are functionally altered in RA, we finally investigated GARP expression in RA Tregs and found significantly reduced expression in RA. This reduced expression strongly correlated with RA disease activity and was caused by hypomethylation of the downstream P1 promoter in RA Tregs, thereby facilitating increased hindrance of P2-induced GARP transcription.

Conclusion: Our findings describe a novel function of alternative promoters in regulating the extent of gene transcription in human T cells. They further show, that in RA, GARP promoter regions are altered with regard to DNA methylation, which affects GARP expression and, thus, Treg function. Altered promoter methylation of GARP might therefore contribute to RA pathogenesis.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: In clinical daily practice, the response to biologic drugs is unpredictable in patients with rheumatoid arthritis (RA). Thus, there is a crucial need for predictive biomarkers of response. The main objective of our study is to describe the evolution of T and B cells in patients with RA treated with biologics and to investigate whether there is a correlation between the initial rate of blood cells and the clinical response under therapy.

Methods: This was a propective single-center pilot study, descriptive and not randomized. Patients were included with RA fulfilling the ACR/EULAR 2010 criteria, with an active disease according to the DAS28 score despite treatment, and in whom initiation or switch of a biologic (TNF-blockers, tocilizumab and abatacept) except rituximab was required. A control group of patients without any autoimmune disease or immune dysfunction was also assessed. B and T lymphocytes whole blood phenotyping, as well as an analysis of the production of IL-10 were performed by multicolor flow cytometry (FCM) in both patients and controls at baseline (M0) and in patients after 1 (M1), 3 (M3) and 6 (M6) months of treatment. The primary endpoint was the rate and absolute value of B and T cells as a percentage and absolute value measured at each time of the study and compared with disease activity.

Results: Thirty-one patients and 17 controls were included. There was a significant difference between responders and non-responders at M6 according to their initial level of Th17 cells (sifgnificantly decresased in good responders, p=0.005). No significant difference but a trend (p=0.06) was observed for circulating CD24hiCD27+Bregs (higher in good responders). There was no significant difference between responders and non-responders for Treg and CD24hiCD38hi Breg cells. The rate of CD19 + B producing IL-10 obtained by PBMC culturing seemed lower in controls as compared to the patients.

Conclusion: A low initial rate of Th17 circulating cells is associated with a good response to biologics during RA. Th 17 cells may represent a predictive biomarker of response to therapy for RA patients.

Session Date: Tuesday, November 15, 2016

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies by our team and others have shown that CD8 T cells (CD8s) in RA have a pro-inflammatory, cytotoxic effector phenotype and may, therefore, play a major role in RA. The presence of such effector CD8s in the blood and synovial fluid suggests that they have to adapt their metabolism to sustain their functional energetic demands in both oxygenated and in oxygen-deprived environments. Thus we focused on the characterization of the metabolic processes by ^{13}C NMR isotopomer analysis (to simultaneously monitor the glycolytic and citric acid cycle fluxes) in CD8s from RA, PsA and SpA patients comparing to healthy controls (HC). We also assessed whether metabolic changes accompanied alterations in the production of cytokines and cytotoxic molecules. The ultimate goal was to explore the potential of CD8s metabolic processes as new diagnostic tools to distinguish RA from PsA and SpA.

Methods: 50 RA, 17 PsA and 20 SpA patients (all fulfilling the ACR criteria), and 21 age and gender matched HC where recruited at the Heidelberg University Hospital. Blood CD8s were purified by negative selection magnetic separation. CSFE-labeled CD8s were cultured *in vitro* for 3 days in the presence of anti-human CD28/CD3, in medium containing [U-^{13}C]glucose. Proliferation, subset distribution and Caspase 3 and PD-1 expression were assessed by FACS. Cytokines and cytotoxic molecules were quantified by cytometric bead arrays. Changes in metabolic enzymes were quantified by western blot. Changes in lactate and acetate production were assessed by ^{1}H-NMR.

Results: At rest, in HC, SpA and PsA patients levels of [U-^{13}C]lactate, derived from the [U-^{13}C]glucose in the media, were quite low, denoting a basal metabolism not dominated by aerobic glycolysis and consistent with low biosynthetic activity. In contrast, in RA patient's unstimulated CD8s the [U-^{13}C]lactate levels were significantly higher, compatible with higher energetic and biosynthetic/proliferative demands even at rest. Upon *in vitro* activation levels of [U-^{13}C]lactate in the medium increased significantly, particularly in RA and PsA patients, and were consistent with an activation of aerobic glycolysis to cope with the greater biosynthetic demands for phenotypic changes, i.e. the transition from an naïve ($CD45RA^+CCR7^+$) to an effector phenotype ($CD45RA^+CCR7^-$), higher proliferation, and production of pro-inflammatory cytokines (TNF-α; IFN-γ IL-6) and cytotoxic molecules (Perforin; Granzyme B). This profile of arthritic CD8s was confirmed by a significantly higher expression of the enzymes pyruvate kinase M2, hexokinase 2 and lactate dehydrogenase, and reduced glutamate dehydrogenase expression. Receiver operating curves based on the levels of IL-6, TNF-α, Granzyme B, Perforin and [U-^{13}C]lactate could distinguish RA patients from PsA and SpA patients with high sensitivity and specificity (>70%).

Conclusion: CD8s from chronic arthritis patients present a Warburg-like metabolic profile, which may allow them to adapt to the environment of the inflamed synovium, and exert their pro-inflammatory and cytotoxic functions. More importantly, this altered CD8s metabolic profile provided a differential diagnosis for RA (including seronegative) from PsA and SpA.

Endogenous Nur77 Is a Specific Indicator of Antigen Receptor Signaling in Human T and B Cells

Judith Ashouri and Arthur Weiss, Department of Medicine, Division of Rheumatology, 1Howard Hughes Medical Institute, Rosalind Russell and Ephraim P. Engleman Rheumatology Research Center, University of California, San Francisco, San Francisco, CA

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Distinguishing true antigen (Ag) stimulated lymphocytes from bystanders activated by the inflammatory milieu has been difficult. Infiltrating immune cells at sites of inflammation become activated not only through direct Ag stimulation, but also indirectly by other inflammatory mediators. Nur77 is an immediate early gene whose expression is rapidly up regulated by T cell receptor (TCR) signaling. Nur77-GFP transgenes serve as specific TCR signaling reporters in murine transgenic models. In this study, we demonstrate that Nur77 protein expression serves as a reporter of TCR and B cell receptor (BCR) specific signaling in human PBMCs. This can be used as a tool to identify Ag experienced lymphocytes in human disease.

Methods: Intracellular Nur77 protein amounts were assessed by immunofluorescence and flow cytometry in T and B cells isolated from human PBMCs stimulated through their Ag receptors (anti-CD3 or anti-IgM Abs) or with immunostimulants: CpG oligodeoxynucleotides (CpG), IFN-α, or LPS.

Results: We demonstrate that *in vitro* TCR stimulation of human PBMCs from healthy donors rapidly induced Nur77 protein expression and reflected Ag receptor signaling strength, much like CD69, a commonly used marker of lymphocyte activation (**Figure 1**). In a more physiologic approach, PBMCs stimulated with Staphylococcus superantigen (SEE), which polyclonally activates Vβ5.1 expressing T cells through the TCR, resulted in enrichment of Nur77 positive cells in the population of responding cells with the appropriate Vβ (**Figure 2**). However, stimulation with various immunostimulants that do not signal via the TCR (i.e., IFN-α, CpG, LPS) did not induce Nur77 in human PBMCs, in contrast to CD69 (**Figure 3**), reflective of differences in their

upstream specific signaling events. Similarly, Nur77 induction in B cells reflected the strength of BCR signaling after crosslinking with anti-IgM. Likewise, non-BCR specific immunostimulants did not induce Nur77 in human peripheral B cells in contrast to CD69.

Conclusion: Nur77 is a reporter of Ag receptor signalling in peripheral human T and B cells. Furthermore, we demonstrate that Nur77 is a more specific reporter of Ag specific signaling than CD69 in both human T and B cells. This reporter strategy has great potential to identify Ag activated lymphocytes in human disease.

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: HLA class II is the major susceptibility region for systemic lupus erythematosus (SLE) and other autoimmune disorders such as rheumatoid arthritis, multiple sclerosis and type 1 diabetes. The current paradigm is that autoimmune response is the result of breaking tolerance. However, it's difficult to explain the presence of autoreactive Abs and T cells in normal people. Previously we showed HLA-DR3 (DR3) transgenic mice respond best to immunization with SmD and Ro60. To clarify the mechanisms for auto-Ab generation to SLE-related Ags, we undertook a detailed analysis of the anti-SmD T cell responses in $DR3^{+}AE^{0}$ mice.

Methods: T-T hybridomas were generated by fusing lymph node cells from $DR3^{+}AE^{0}$ mice immunized with SmD in IFA with $BW5147TCR^{-/-}$. IL-2 in the supernatants of T-T hybridomas stimulated by SmD with syngeneic splenic cells as APC was determined by ELISA. SmD T cell epitope regions were determined with 15mers overlapping by 3 amino acids covering the span of SmD with the established T-T hybridomas. The core epitopes were determined by alanine substitutions. TCR utilized by T-T hybridomas were sequenced. For response to SmD peptides and its mimics $DR3^{+}AE^{0}$ mice were immunized with 100μg peptide in CFA on day 1 and 50 μg of the immunogen in IFA on days 14 and 28. Sera were collected at 42, 56, 70, 90 and 120 days and assayed for Abs to SLE-related auto-Ags. Two hundred blood samples of healthy donors from Virginia Blood Services were analyzed for their HLA-DR types and auto-Abs titers.

Results: 47 stable T-T hybridomas reactive to SmD were generated by 7 fusions. They reacted with seven SmD antigenic regions. By alanine substitutions, they reacted with varied core epitopes. In some, the flanking sequences contributed to the core epitopes. The TCR of 17 hybridomas were sequenced. They used unique combinations of TCRα and TCRβ. By bioinformatics, we identified more than 10,000 potential bacterial peptide mimics of SmD T cell epitopes. Some of them are from commensal bacteria residing in the mucosal surfaces and skin. The ranking of affinities for SmD T epitopes to DR3 were in the mid-ranges among those of all potential bacterial mimics. 12 bacterial mimics from one of the SmD T epitopes with high, medium, and low affinities for DR3 were selected. Only those with modest binding affinities were able to stimulate relevant hybridomas and to induce auto-Ab in a similar fashion as the corresponding SmD peptide. The 200 blood donors were typed for HLA-DR2, DR3 and DR4. $DR3^{+}$ individuals had higher anti-SmD Abs than those who were negative for DR3 and DR2.

Conclusion: SmD has multiple T cell epitopes and the immune response to SmD is similar of those to conventional Ags with diverse TCRs. The T cells with cross-reactivity to auto-epitopes and to bacterial mimics are those with moderate binding affinities to the relevant DR molecules. They are likely to be positively selective for the purpose of host defense against pathogens. This thesis is supported by the finding of auto-Abs with high titers to SLE-related auto-Ags. These results provide us insight into the origin of SLE-related auto-Abs. On a basic level, they support the thesis that auto-reactive T cells are an inherent part of the normal immune repertoire.

HLA-DR3 Restricted T Cell Response to Smd and Ro60 Reveals Multiple Cross-Reactive Intra- and Inter-Molecular T Cell Epitopes: Unique Antigenic Structures of Lupus-Related Auto-Antigens and the Basis for B Cell Epitope Spreading

Zhenhuan Zhao[1], Jiling Ren[1], Chao Dai[2], Carol Kannapell[1], Qian Wang[3], Felicia Gaskin[4] and Shu Man Fu[5], [1]Medicine/CIIR/Rheumatology, University of Virginia, Charlottesville, VA, [2]Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA, [3]University of Virginia, Charlottesville, VA, [4]Psychiatry and Neurobehavioral Sciences, University of Virginia, Charlottesville, VA, [5]Department of Medicine, University of Virginia, Charlottesville, VA

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Complex auto-Abs targeting nuclear proteins is a hallmark of systemic lupus erythematosus (SLE). It is documented that this complexity is the result of "B cell epitope spreading" with unique patterns. The generation of SLE-related auto-Abs is T cell dependent and preferentially restricted to HLA-DR3 (DR3) and DR2. The current hypotheses for the generation of these auto-Abs such as the "B cell epitope mimicry hypothesis" and the "particle hypothesis" in that a limited auto-reactive T cell population is able to provide T cell help to B cells of multiple specificities, are inadequate to account for the above-stated observations. The results of our analysis of DR3 restricted T cell response to SmD and Ro60 provides an alternative to the current paradigms.

Methods: T-T hybridomas were generated by fusing lymph node cells from $DR3^{+}AE^{0}$ mice immunized with SmD in IFA with $BW5147TCR^{-/-}$. IL-2 in the supernatants of T-T hybridomas stimulated by SmD with syngeneic splenic cells as APC was determined by ELISA. SmD T cell epitope regions were determined with 15mers overlapping by 3 amino acids covering the span of SmD with the established T-T hybridomas. The core epitopes were determined by alanine substitutions. TCR utilized by T-T hybridomas were sequenced. For response to SmD peptides and its mimics $DR3^{+}AE^{0}$ mice were immunized with 100μg peptide in CFA on day 1 and 50 μg of the immunogen in IFA on days 14 and 28. Sera were collected at 42, 56, 70, 90 and 120 days and assayed for Abs to SLE-related auto-Ags.

Results: Multiple T-T hybridomas reactive to SmD were generated by 7 fusions. Many hybridomas were found to be reactive with more than one T cell epitope within SmD. Some of them reacted with SmB and the A protein (ARNP) of the snRNA particle. The core epitopes of 7 SmD peptides were ascertained by alanine substitution and they have no sequence homology. Several of 15mers of these core epitopes induced B cell epitope spreading to SmB, ARNP and certain proteins in the Ro60/La system. Some bacterial peptides induced B cell epitope spreading in a manner similar to that of the SmD peptide. Interestingly, cross reactive B cell epitopes were demonstrated among the SmD peptide and its bacterial mimics. Similar findings were obtained regarding the T cell responses to Ro60 and its 15mers.

Conclusion: The results showed that SLE-related auto-Ags have multiple cross-reactive intramolecular T cell epitopes. This is a feature shared by other auto-Ags such as GAD65 in type 1 DM and myelin basic protein in EAE, a model for multiple sclerosis. Although not the subject of this abstract, there are cross-reactive inter and intra molecular B cell epitopes among the SLE-related Ags. These structural features are likely the reasons why they are the targeted in autoimmunity. The presence of multiple cross reactive intermolecular T cell epitopes provides the basis for DR3 restricted B cell epitope spreading in SLE. The cross-reactivities at both T and B cell levels of the bacterial molecular mimics and their auto-epitopes provide a scenario for the presence of SLE-related auto-Abs in normal DR3 individuals.

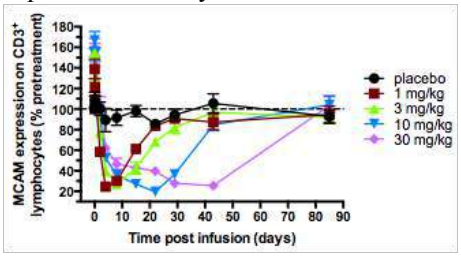
Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Melanoma cell adhesion molecule (MCAM; CD146) is expressed on the surface of Th17 cells, which have the capacity to produce IL-17 and a multitude of other cytokines. The expression of MCAM and production of IL-17 are defining characteristics of Th17 cells. MCAM is hypothesized to be central to the pathogenesis of numerous autoimmune disorders, including psoriasis and psoriatic arthritis by modulating the adhesion and transmigration of Th17 cells through its interaction with vascular Laminin a4 (LAMA4). Unlike targeting an individual cytokine, PRX003, a monoclonal antibody designed to bind MCAM and block its interaction with LAMA4, might prevent the release of IL17 and other cytokines by limiting Th17 cell infiltration and subsequent pathogenic inflammation. The study objective was to evaluate the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and immunogenicity of PRX003 in healthy human subjects.

Methods: In a first-in-human, randomized, double-blind, placebo-controlled, Phase 1, single ascending dose-escalation study (NCT02458677) in healthy volunteers, PRX003 was administered by IV infusion over approximately 60 minutes. Five escalating dose cohorts received 0.3, 1.0, 3.0, 10, or 30 mg/kg of PRX003 or placebo (8 subjects/cohort in a 6:2 ratio) and were monitored for 24 hours and by periodic follow-up for 12 weeks. PD measurements included MCAM expression on circulating T-lymphocytes and serum soluble MCAM.

Results: After a single infusion, PRX003 was well tolerated at doses up to and including 30 mg/kg, the highest dose level tested. No PRX003-related serious or severe adverse events, no dose-limiting toxicities, no anti-drug antibodies or infusion-related reactions were reported. The most common treatment emergent adverse events (TEAEs), regardless of causality, were: headache (n=3, 10%), seasonal allergy (n=2, 6.7%), upper respiratory tract infection (n=2, 6.7%) and transient balance disorder (n=2, 6.7%). All TEAEs were mild to moderate. The PK of PRX003 were consistent with distribution to and saturation of MCAM with sustained exposures that fully saturated MCAM for >43 days at 30 mg/kg. Early and dose-proportional signs of demargination were observed.



This study supports the hypothesis that MCAM occupancy and down-regulation by PRX003 promotes demargination and sequestration of Th17 cells in the vascular space, limiting their extravasation.

Conclusion: These data collectively suggest that PRX003 may block MCAM-mediated extravasation of Th17 cells and support further examination of PRX003 in patients with inflammatory disease. A Phase 1b multiple ascending dose trial of PRX003 in patients with psoriasis (NCT02630901) is ongoing.

Activation Status of Mucosal-Associated Invariant T Cells Sensitively Reflects Disease Activity of Systemic Lupus Erythematosus

Asako Chiba[1], Goh Murayama[2], Mie Kitagaichi[3], Naoto Tamura[4], Ken Yamaji[2], Yoshinari Takasaki[4] and Sachiko Miyake[1], [1]Immunology, Juntendo University School of Medicine, Tokyo, Japan, [2]Department of Internal Medicine and Rheumatology, Juntendo University School of Medicine, Tokyo, Japan, [3]Department of Rheumatology, Juntendo University School of Medicine, Tokyo, Japan, [4]Internal Medicine and Rheumatology, Juntendo University School of Medicine, Tokyo, Japan

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Mucosal-associated invariant T (MAIT) cells are innate-like lymphocytes that express a semi-invariant TCRα chain: Vα7.2-Jα33 in humans and Vα19-Jα33 in mice. MAIT cells are restricted by the MHC-related molecule-1 (MR1) and uniquely recognize microbial-derived vitamin B metabolites presented by MR1. Like other innate-like lymphocytes, MAIT cells are also activated by cytokines in the absence of exogenous antigens. Human MAIT cells are abundant and constitute approximately 5% of peripheral blood T cells, suggesting possible roles of MAIT cells in various types of immune responses. Previously we demonstrated that the frequency of MAIT cells was markedly reduced in patients with systemic lupus erythematous (SLE). In this study, we aimed to investigate whether MAIT cells are involved in the pathogenesis of SLE.

Methods:

Peripheral blood was collected from SLE patients and healthy volunteers. Informed consent was obtained from all individuals according to institutional ethical guidelines. Disease activity was measured based on the SLE disease activity index (SLEDAI) and a SLEDAI score ≥ 5 was defined as active disease. Peripheral blood mononuclear cells (PBMC) were stained with anti-human monoclonal antibodies against CD3, γδTCR, Vα7.2TCR, CD161, CD95(Fas) and CD69, and then analyzed by FACS. The activation status of MAIT cells was assessed by the expression of CD69. MAIT cells were sorted from PBMC of healthy individuals by using magnetic cell sorting (MACS) and FACS Aria. $CD19^+$B cells or $CD14^+$monocytes were isolated from PBMC of healthy controls (HC) or SLE patients by using MACS. MAIT cells were co-cultured with B cells or monocytes in the presence of MR1 ligand (MR1L), and the expression of CD69 on MAIT cells was evaluated by FACS. Cytokine levels in plasma samples and culture supernatants were measured by ELISA and Bioplex assay. PBMC were cultured in the presence of various cytokines, and CD69 expression on MAIT cells was analyzed by FACS.

Results:

MAIT cells from lupus patients with active disease expressed high levels of CD69, a lymphocyte activation marker, and the frequency of $CD69^+$MAIT cells positively correlated with SLEDAI. MAIT cells cultured with lupus monocytes displayed higher levels of CD69 compared with cells cultured with monocytes from healthy controls. The profound MAIT cell activating capacity of lupus monocytes was associated with enhanced IL-12 production in the culture supernatants.The plasma levels of cytokines including IL-6, IL-18 and IFNα positively correlated with the expression levels of CD69 on MAIT cells. MAIT cells were activated by cytokines including IFNα, IL-15, and IL-12 plus IL-18 in the absence of exogenous antigens.

Conclusion:

The activated state of MAIT cells sensitively reflected disease activity of SLE. We revealed two possible mechanisms of MAIT cell activation in SLE. First, we demonstrated that lupus monocytes displayed a profound MAIT cell activation capacity. Second, we found that the elevated levels of IL-18 and IFNα correlated with the activate state of MAIT cells in SLE, and this may elicit the cytokine-mediated activation of these cells. Because these cytokines have been suggested to be involved in the pathogenesis of SLE, activated MAIT cells may play an important in lupus pathology.

Session Date: Tuesday, November 15, 2016
Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies have demonstrated that naturally occurring $CD4^+Foxp3^+$regulatory T cells (nTregs) are unstable and dysfunctional in the presence of pro-inflammatory cytokines. All-trans RA (atRA), the active derivative of vitamin A, has been demonstrated to regulate Treg differentiation and stabilize nTreg in the healthy subjects. We here plan to determine whether atRA can similarly stabilize nTreg cells isolated from patients with active systemic lupus erythematosus (SLE) under inflammatory conditions.

Methods: $CD4^+CD25^+CD127^{-/low}$ human nTregs were sorted from PBMCs in patients with SLE or healthy controls, and then expanded in the presence or absence of atRA for 7 days. These cells were extensively washed and restimulated with or without IL-1β/IL-6 for additional 3 days. Cell suspensions were harvested for cytokine assay with Elisa and cells were stained with flow cytometry analysis. In vitro, suppression assay was performed, $CD3^+CD25^-$T cells labeled with carboxyfluorescein succinimidyl ester (CFSE) were stimulated with anti-CD3 in the presence of APC with or without different populations of nTreg cells. The CFSE dilution was examined by flow cytometry, and the suppression ratio was then calculated. Xenograft-vs-host diseases (xGVHD) models were conducted for determining the suppressive activities of Treg cells in vivo. NSG mice after γ-irradiation irradiation were injected with human CD25-depleted PBMCs with or without expanded SLE nTregs pretreated with atRA, rapamycin, DMSO control, and nTreg that had been exposed to IL-1β/IL-6. Mouse survival was monitored twice per week, and survival curves were analyzed by the log-rank test. Pathology in organ organs, human CD3+ engraftment and IgG were analyzed accordingly. The statistical comparisons were performed by the Student t test by using Prism software (GraphPad).

Results: In the presence of IL-1β/IL-6, atRA also prevents nTregs isolated from active SLE patients from converting to Th1 and/or Th17 cells and sustains their Foxp3 expression and suppressive function in vitro. atRA also diminished IL-1β/IL-6 signaling events by reducing STAT1, STAT3 activation. Adoptive transfer of SLE nTregs pretreated with atRA enhanced their suppressive function on xGVHDs, and only atRA primed nTregs sustained the suppressive effect on xGVHD after stimulation with IL-1β/IL-6.

Conclusion: Our results have demonstrated that atRA also stabilizes the Foxp3 expression and Treg function of patients with SLE, particularly on the inflammatory condition. Thus, a new protocol has been developed that usage of autologous atRA-programed Treg cells likely treats patients with SLE and other autoimmune diseases.

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Follicular helper T (T_{FH}) cells promote humoral responses and serve as a limiting factor for the selection of high affinity germinal center B cells. T_{FH} cell numbers need to be tightly regulated, and T_{FH} cell expansion has been associated with autoimmune diseases including SLE. Rho-associated kinases (ROCKs), ROCK1 and ROCK2, are major downstream effectors of the small GTPase RhoA. The ROCKs regulate both gene expression and cytoskeletal reorganization. Increased ROCK activation has been observed in autoimmune disease both in mice and humans, and ROCK inhibition ameliorates autoimmunity in murine models. However, the underlying molecular and cellular mechanisms by which the ROCKs affect autoimmune disease are currently unknown. Here we investigated the role of ROCK2 in T_{FH} cell expansion under physiological conditions and in autoimmunity by employing mice lacking DEF6 and SWAP-70, which exhibit aberrant ROCK activation, accumulation of T_{FH} cells, and spontaneously develop a lupus-like disease.

Methods: Mice lacking ROCK2 in T cells were generated by crossing $CD4^{cre}$ mice with $ROCK2^{flox/flox}$ mice. The T_{FH} cell compartment was assessed in $CD4^{cre}ROCK2^{flox/flox}$ mice by immunizing with a T-dependent antigen. To evaluate the effect of T-cell ROCK2 on autoimmune disease $CD4^{cre}ROCK2^{flox/flox}$ mice were crossed with $Def6^{trap/trap}Swap\text{-}70^{-/-}$ mice (DKO mice), which develop a lupus-like disease primarily in females. Flow cytometry analysis and ELISAs were used to assess T_{FH} cell expansion and autoantibody production.

Results: The absence of ROCK2 in T cells did not lead to any abnormality in the frequencies or activation state of the T cell compartment at baseline. Lack of T cell ROCK2, however, resulted in a significant decrease in T_{FH} cell formation upon immunization with a T-dependent antigen. This was associated with a reduction in germinal center B cell and plasma cell formation suggesting that T-cell ROCK2 is essential for T-dependent immune responses. To evaluate the contribution of T-cell ROCK2 to T_{FH} cell formation in autoimmunity, we analyzed $CD4^{cre}ROCK2^{flox/flox}$ $Def6^{trap/trap}Swap\text{-}70^{-/-}$ mice (ROCK2ΔT DKO) mice. Upon deletion of T cell ROCK2, the spontaneous increase in T_{FH} cells observed in DKO mice was significantly reduced. This was associated with decreased GC B cells, plasma cell numbers, and diminished anti-dsDNA autoantibody levels.

Conclusion: Our current study indicates that ROCK2 regulates T_{FH} cells both during T-dependent immune responses as well as in autoimmune settings further supporting a role for ROCK inhibition as a potential treatment for SLE and other autoimmune diseases that exhibit dysregulation in T_{FH} cells.

Session Title: T Cell Biology and Targets in Autoimmune Disease - Poster Session II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A host of primary immunodeficiencies, such as autoimmune polyendocrinopathy, candidiasis, ectodermal dysplasia (APECED), immune dysregulation, polyendocrinopathy, enteropathy, X-linked syndrome (IPEX), and STAT5b insufficiency can present as immune dysregulation syndromes. However, in many patients the molecular basis of these abnormalities remains uncharacterized. To investigate potential genetic and molecular links between PID, growth failure and systemic autoimmunity, we recruited a series of siblings with immunodeficiency, short stature, polyendocrinopathy and kidney disease. Since our patients feature growth hormone resistance, PID and systemic autoimmunity, we hypothesized that a functional defect in the signal transducer activator of transcription 5b (STAT5b) would underlie the phenotype.

Methods: Clinical data was extracted from the patients' medical record, patients were evaluated, and skin and blood samples were analyzed in the laboratory. PBMC and dermal fibroblast-derived gDNA was used for targeted gene analysis of known PID-causing genes. Additionally, whole genome sequencing (WGS) was performed on the parents, 3 affected sons, 3 unaffected sons and 2 unaffected sisters. Mutation search were performed with a combination of scripts developed in house and expert review. Cellular phenotyping by flow cytometry, STAT phosphorylation, T-cell proliferation in response to IL-2 and IL-7 stimulation were performed on affected individuals PBMC.

Results: The three affected individuals have a phenotype characterized by short stature with decreased IGF-1 and IGFBP-3 levels, PID with abnormal T-, B- and NK- cell subpopulations, polyglandular endocrinopathy and multisystem manifestations of immune dysregulation. Genetic analysis of candidate genes such as STAT5a/b and JAK-1 revealed no defect. Initial mutation searches were focused on rare protein coding changes that are consistent with X-linked, autosomal recessive or de novo inheritance models, however no probable candidate mutations were identified. Analysis of CNV data and haplotype analysis on X chromosome also came out negative. Linkage analysis identified 4 regions in the genome that have the maximum LOD score achievable for the given pedigree. One of the candidate regions on chr2 harbors a non-coding RNA gene (*RNU4ATAC*) that has been recently published to cause Roifman Syndrome. Our patients bear clinical and phenotypic similarities to those with Roifman Syndrome, suggesting *RNU4ATAC* as a likely candidate gene. We found two rare mutations in this gene that segregated with the disease: c.[13C>T] and c.[116A>C]. The first one has been reported as pathogenic in Roifman Syndrome. The second one is extremely rare (absent in public databases and more than 3700 internal WGS controls) residing in a gene region likely to be important for function. Sequential flow cytometry studies from three affected individuals in the same kindred revealed progressive B cell depletion and low numbers of T regulatory cells. We detected constitutive STAT5 phosphorylation in *ex vivo* CD4+ T cells, however, T cell blasts failed to proliferate in response to IL-2 following mitogen stimulation due to impaired upregulation of the high affinity IL-2 receptor. Therefore, *U4ATAC* may regulate immune cell functions such as T cell activation and the induction of T regulatory cells. Ongoing work in this area involves a combination of molecular and cellular approaches to determine whether *U4ATAC*controls minor splicing of genes important in activated T cells.

Conclusion: Using WGS and mutation analysis, we have found the likely disease-causing mutations in patients with clinical features consistent with Roifman syndrome. Furthermore, our work extends the spectrum of Roifman Syndrome to include immune dysregulation. *RNU4ATAC* plays an essential role in splicing minor introns found in about 800 human genes. Further work may provide novel insights into the molecular pathways that link the development and function of the musculoskeletal, endocrine and immune systems with RNA splicing

Risk of Venous Thromboembolism in Patients with Systemic Vasculitides: A Systematic Review and Meta-analysis

Background/Purpose: Venous thromboembolism (VTE) is a common medical problem with a significant morbidity and mortality. Chronic inflammatory state has been increasingly recognized as an important risk factor for VTE. Several immune-mediated inflammatory disorders, such as systemic lupus erythematosus and rheumatoid arthritis, are associated with increased incidence of VTE in epidemiologic studies. Systemic vasculitides are group of immune-mediated inflammatory disorders characterized by inflammation in blood vessels. Apart from Behcet's disease, it is unclear if these disorders are also associated with increased risk of VTE due to limited data. To further investigate this possible association, we conducted a systematic review and meta-analysis of observational studies that compared the risk of VTE in patients with systemic vasculitides versus participants without systemic vasculitides.

Methods: Two investigators independently searched published studies indexed in MEDLINE, EMBASE and the Cochrane database from inception to March 2015 using the terms for each type of vasculitis in conjunction with the terms for venous thromboembolism. A manual search of references of retrieved articles was also performed. The inclusion criteria were as follows: (1) observational studies evaluating the association between vasculitis and VTE and (2) odds ratios, relative risk (RR) or hazard ratio or standardized incidence ratio with 95% confidence intervals (CI) were provided. Study eligibility was independently determined by the two investigators noted above. Newcastle-Ottawa scale was used to assess the quality of included studies. RevMan 5.3 software was used for the data analysis. Point estimates and standard errors were extracted from individual studies and were combined by the generic inverse variance method of DerSimonian and Laird. Given the high likelihood of between study variance, we used a random-effect model rather than a fixed-effect model. Statistical heterogeneity was assessed using the Cochran's Q test.

Results: Seven studies investigating the risk of VTE among patients with granulomatosis with polyangiitis (GPA), polyarteritis nodosa (PAN) and giant cell arteritis (GCA) were identified. Elevated risk were seen in all three vasculitides (GPA, pooled RR 3.94, 95% CI 1.11 – 14.01; PAN, pooled RR 3.00, 95% CI 2.20 – 4.09; GCA, pooled RR 2.26, 95% CI 1.38 – 3.71). Forest plots are demonstrated in figure 1A-1C, respectively.

Conclusion: Our study demonstrated a statistically significant increased VTE risk among patients with GPA, PAN and GCA.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Behcet's disease is a chronic, systemic vasculitis that can involve all sizes of blood vessels. Sleep disturbance is one of the most particular concerns in patients with Behcet's disease. It has been known that the disease activity of rheumatoid arthritis and ankylosing spondylosis is associated with the sleep quality. However, studies about the sleep quality of patients with Behcet's disease in Korean population are limited. The purpose of this study was to find out the effects of sleep quality on Behcet's disease in Korean population. We also investigated the relationship between depression, quality of life, other clinical findings and Behcet's.

Methods: The study was performed by cross-sectional design in two tertiary hospitals. We surveyed one hundred patients with Behcet's disease. Sleep quality was assessed by the Korean version of Pittsburgh sleep quality index (PSQI). Disease activity of Behcet's disease was evaluated by Behcet's disease current activity form (BDCAF). Depression was assessed by the Korean version of Beck depression inventory second edition (BDI-2). Quality of life was assessed by the Korean version of the Leeds Behcet's Disease Quality of Life Measure (BDQoL).

Results: Among 100 patients, median age was 51 [44.5-56.0] years, median disease duration was 77.5 [24.0-136.0] months and 69% were female. Those who met the diagnostic critera of fibromyalgia were 28 patients. The frequency of poor sleep quality (PSQI ≥9) was 42%. Patients with poor sleep quality tend to have higher BDI2, BDCAF and pain VAS score ($P = 0.022$, $P = 0.005$ and $P < 0.001$). Female rate was significantly higher, and BDQoL was lower in poor sleeper group ($P = 0.004$ and $P < 0.001$). Among 7 PSQI components, daytime dysfunction was higher in patients with high disease activity ($P = 0.03$). Total PSQI score were strongly correlated with BDCAF score, BDI-2 score, BDQoL score, and pain VAS score ($P = 0.02$, $P < 0.001$, $P < 0.001$, and $P < 0.001$, respectively).

Conclusion: The low quality of sleep is associated with disease activity, depression and quality of life in Korean patients with Behcet's disease. Better disease control will improve the sleep quality.

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In non-infectious no anterior uveitis, adalimumab (ADA) is the only biologic drug that has shown efficacy in phase III randomized, double blind studies, such as VISUAL I and VISUAL II. After 80 mg loading dose, maintenance dose is the standard for other indications, 40 mg/sc/2 weeks. Our aim was to asses in patients with Behcet's syndrome with uveitis if once remission was obtained, it was possible to optimize the maintenance ADA dose.

Methods: Multicenter study of 71 uveitis related to Behcet's syndrome and refractory to at least one standard synthetic immunosuppressive drug in which ADA was started at standard dose. In 23 of 71 (32,39%) once remission was achieved, ADA dose was optimized. The degree of ocular inflammation was assessed by "the Standardization of Uveitis Nomenclature (SUN) Working Group" (Am J Ophthalmol 2005; 140: 509-516), and macular thickness by optical coherence tomography (OCT). A comparison was made between the first visit when ADA was started at standard dose, the onset of ADA optimization, and the final visit.

Results:

We studied 23 patients/42 affected eyes (15 men/ 8 women) that had an optimization in ADA dose, the median age was 37.2±13.4 years (range 10-62). Prior to ADA, and as systemic treatment besides oral steroids, they had received intravenous methylprednisolone boluses (n=7), cyclosporine A (CyA) (n=20), methotrexate (MTX) (n=11) and azathioprine (AZA) (n =11). ADA was used in monotherapy (n=5) and in combination with CyA (n=12), MTX (n=4) and AZA (n=2). The average interval from ADA onset to optimization was 15.3±9 months. Of the 23 patients the interval dose of ADA was progressively increased to 3 weeks (n =6), 4 weeks (n =13), 5 weeks (n =1), 6 weeks (n =1) and 8 weeks (n =2).

Only 2 patients had to return to the standard dose of ADA due to reactivation after optimizing, achieving again remission of uveitis. It was also possible to suspend ADA in 4 patients after 35.2±9.3 months in remission, not presenting a new reactivation after a mean of 20±6.9 months following the suspension.

Conclusion: Optimizing ADA therapy, once remission is achieved, seems feasible in Behcet's syndrome with uveitis. However, this data should be verified again in prospective and randomized studies. **TABLE**

	At onset of ADA	**At ADA Optimization**	**At Last Visit**
VA (median [IQR])	0,8 [0,3-1]	1 [0,8-1] *	1 [0,9-1] *
Anterior chamber cells (median [IQR])	0 [0-2]	0 [0-0] *	0 [0-0] *
Vitritis (median [IQR])	1 [0-2]	0 [0-0] *	0 [0-0] *
Retinal vasculitis (% affected eyes)	41.8%	10.8% *	0% *
OCT (µ) (mean ±SD)	306.7±122.9	253±20 *	250.5±17.9 *

* p< 0,05 Between at onset of ADA, At onset of ADA optimization and last visit (Wilcoxon test)

Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet's disease (BD) is a multisystem inflammatory disorder characterized by recurrent oro-genital ulcers, mucocutaneous lesions and serious organ involvement. The goal of this study was to investigate the structure of the salivary microbiome in patients with BD.

Methods: Stimulated saliva samples were collected from 31 BD patients and 15 healthy controls, and detailed oral health indices were recorded. In 9 BD patients a second oral health evaluation and saliva collection was performed following dental and periodontal treatment. High-throughput sequencing of the 16S rRNA V4 region in saliva samples was performed. Sequences were rigorously filtered and grouped into phylogenetically-related operational taxonomic units (OTUs), used to measure bacterial community diversity and richness. OTUs were classified using a 16S rRNA reference database at the species-level. AMOVA and LEfSe analyses were used to measure differences between patients and controls at the community- and species-level, respectively.

Results: Sequence analysis identified a total of 908 OTUs present across all samples. Patients had a microbial community structure that is significantly less diverse than healthy controls. The most overabundant species in BD patients compared to controls was *Haemophilus parainfluenzae*, while the most depleted included *Alloprevotella rava* and species in the genus *Leptotrichia*. Patients receiving periodontal treatment showed improvements in oral health indices, but no short-term differences in bacterial community structure. Neither the BD-associated genetic risk locus within the *HLA-B*/*MICA* region nor being on immunosuppressive medications explained the differences between patients and controls.

Conclusion: This is the first high-throughput sequencing-based evaluation of the salivary microbiome in BD. Salivary microbiome of BD patients has a specific signature characterized by changes at the community and species level.

Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: It is well known that menstruation triggers several conditions such as migraine, recurrent aphtous stomatitis and acne vulgaris in otherwise healthy individuals (1). It may exacerbate chronic autoimmune diseases and familial Mediterranean fever (FMF) (2-4). There is also one study that briefly mentions menstruation causes activation in Behçet's syndrome (BS) (4). We investigated the relationship between menstruation and specifically the skin-mucosa lesions of BS. As controls, we studied FMF patients.

Methods: Premenopausal women with BS and FMF seen consecutively at the outpatient clinic of Cerrahpasa Medical Faculty at Istanbul, were interviewed. BS patients were asked whether they experienced increased skin-mucosa lesions during the menstrual

period. A similar questionnaire assessing this time the frequency of serositis and fever attacks was given to the patients with FMF. As a control the participants were also asked whether they experienced headaches during the same period as well.

Results: A total of 140 BS patients with a mean age of 36±8 and mean disease duration of 9±6 years were studied. While 21 (15 %) were off treatment, 103 (74 %) were using colchicine and the remaining were using other immunosuppressive agents. As shown in the Table, among BS patients, 78 (56 %) associated at least one symptom with menstruation. The most commonly reported symptom related with menstruation was the papulopustular involvement (50 %), followed by oral (30 %) and genital ulcers (21 %) and nodular lesions (21 %). We also studied 185 patients with FMF. Their mean age was 32±8 and mean disease duration was 12±8 years. All patients were using colchicine for a mean duration of 8±7 years. A total of 138 patients (75 %) reported that their attacks overlapped with menstruation. These attacks included mostly peritonitis in 126 patients (68 %), pleuritis in 102 (55 %), and fever in 73 (40 %). Among both BS and FMF patients, similar number of patients (41 % and 41 %, respectively) reported that menstruation triggered headaches.

	Yes	No	do not remember
Behçet syndrome (n=140)			
Oral ulcer, n (%)	42 (30)	45 (32)	53 (38)
Genital ulcer, n (%)	30 (21)	94 (67)	16 (11)
Papulopustular lesions, n (%)	70 (50)	56 (40)	14 (10)
Nodular lesions, n (%)	30 (21)	90 (64)	20 (14)
At least one BS symptom, n (%)	78 (56)	-	-
Headache, n (%)	58 (41)	45 (33)	37 (26)
Familial Mediterranean Fever (n=185)			
Peritonitis, n (%)	126 (68)	51 (28)	8 (4)
Pleuritis, n (%)	102 (55)	74 (40)	9 (5)
Fever, n (%)	73 (39)	100 (54)	12 (6)
At least one FMF symptom, n (%)	138 (75)	-	-
Headache, n (%)	76 (41)	77 (42)	32 (17)

Conclusion: This survey showed that, in about half of the patients with BS at least one skin mucosa lesion is exacerbated with menstruation. Most commonly reported were the papulopustular lesions. Menstruation had a stronger effect on FMF, triggering at least one symptom in about ¾ patients. The main limitation of the study was the self-reported assessment methodology, rather than a prospective diary assessment. Our findings provide further evidence that papulopustular lesions of BS and acne vulgaris are pathologically related (5).

Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic vasculitis comprises a group of diseases characterized by non-infectious inflammation of vessels in various organs. Histopathological confirmation of systemic vasculitis is required for the diagnosis; a biopsy is usually performed in clinically suspect organs, such as the skin, peripheral nerves and kidneys. The biopsy of an involved organ is invasive and carries the risk of complications. By contrast, gastrocnemius muscle biopsy is simple and minimally invasive technique that may be performed by a rheumatologist.

Methods: Retrospective study (1984-2015) Center: tertiary academic hospital, referral area 850.000 inhabitants. We analyzed the database of all muscular biopsies performed at our hospital. We selected all patients undergoing a gastrocnemius biopsy for possible diagnosis of systemic vasculitis, we analyzed the clinical, laboratory, neurophysiological and pathologic data. Biopsies were classified as positive or negative for vasculitis. A positive muscular biopsy was defined by the presence of necrotizing vasculitis or non necrotizing vasculitis seen by optical microscopy. Muscular biopsy was performed in all cases at the medial gastrocnemius muscle by a rheumatologist; all these biopsies were “open” and unilateral. The diagnosis of systemic vasculitis was based on clinical, serological and histological data.

Results: 619 muscular biopsies were performed, 55 were indicated with suspicion of systemic vasculitis, 29 (52.7%) female and 26 male (47.3%), median age 64.4 years (DS 15.22). Of the 55 muscular biopsies, 47 (85.4%) were positive (sensitivity of 85%) and 8 (14.6%) were negative. The final diagnosis was: 41 (74.5%) necrotizing vasculitis (microscopic polyangiitis and polyarteritis nodosa), 5 (9.1%) eosinophilic granulomatosis with polyangiitis, 4 (7.3%) granulomatosis with polyangiitis, 2 (3.6%) mixed cryoglobulinemia, 1 (1.8%) rheumatoid arthritis-associated vasculitis and 2 (3.6%) none diagnosed. Of 45 patients, 24 (53.3%) were ANCA-associated: 20 patients had positive biopsy and 4 negative biopsy. No significant differences were observed between the two groups in any of the assessment categories except in the electomiographic pattern. The positive biopsy group showed electromiographic alterations (p=0.01)Furthermore, the positive biopsy group showed more frequently systemic manifestations such as: weight loss, myalgia, paresthesias, purpura and testicular pain. These differences were not statistically significant. No complications were encountered in the procedure.

Conclusion: Muscle biopsy is a simple, clinically useful, safe and minimally invasive procedure for the diagnosis of vasculitis with high sensitivity. No significant differences were observed in clinical or analytical features between patients with positive or negative biopsy, except in electromyography patients with positive biopsy had more a frequent pathological pattern.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic treatments used in ocular involvement in Behçet's disease are corticosteroids, synthetic and biological immunosuppressants. Because of irreversible ophthalmic complications,it is a priority to know the efficacy of these drugs. Our purpose was to analyze the efficacy and safety of biological therapy vs. cyclosporine A(CyA),azathioprine(AZA)or placebo in reducing the rate of uveitis and improving the visual prognosis of Behçet's.

Methods: A systematic search of literature on MEDLINE,EMBASE,and Cochrane Central Register of Controlled Trials was conducted from inception to July 2015.A hand search was performed by reviewing the references of the included studies and the international congress.Criteria for study selection: 1)adults with Behçet's disease and uveitis, 2)Biological therapies, 3)placebo or

active comparator with CyA or AZA, 4)outcome measures to evaluate effectiveness as a number (no.)of recurrence of uveitis,visual prognosis,cystic macular edema, retinal vasculitis,vitritis,hypopyon,etc; and/or adverse events.Meta-analyses,systematic reviews,clinical trials and observational studies of >10 patients with comparator were included.The selection,review and evaluation of quality of the articles was independently conducted by two reviewers.The Oxford Level of Evidence scale was used to determine the quality of the studies.

Results: Of 195 articles,5 met the inclusion criteria:2 retrospective observational studies and 3 randomized clinical trials in 235 patients with Behçet and refractory uveitis.Age range was 12-69 years with male dominance,and follow up was 1-72 months.Evidence with infliximab(IFX) (2studies) is weak and suggests more effectivenes than CyA in reducing the rate of uveitis in short-term(6m) and more effective than CyA+AZA or methotrexate(MTX) to reduce the no. of retinal vasculitis relapse,and severe complications and to improve visual acuity in long term(LE 4).The weak and insufficient evidence of rituximab(RTX) associated with MTX (1study) suggested similar efficacy to cyclophosphamide(CYM)associated with AZA, improving the total adjusted rate of disease activity without improvement in short-term visual acuity (6m) (LE 3b).Regarding secukinumab and daclizumab vs placebo(1study respectively),the small but acceptable level of evidence suggests ineffectiveness in reducing relapses and in the improvement of visual acuity,with sparing effect on immunosuppressants in short-term for secukinumab (LE 2a-2b). Available evidence reveals few significant adverse events. All studies could be applicable in clinical practice.

Conclusion: With the limited evidence found, IFX appears to be safe and more effectiveness than CyA alone or in combination with other immunosuppressants in reducing short term uveitis relapse and the number of severe long-term complications.RTX is similar to CYM paired with AZA in improving rates of inflammatory activity in short term.Secukinumab as well as daclizumab is not effective in reducing relapses of uveitis but could spare immunosuppressants.The results of this review support the benefit of carrying out further well-designed comparative studies with IFX and RTX.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet's disease (BD) is a complex immune-mediated vasculitis which aetiology remains unknown although some evidences suggest that certain infectious agents and environmental factors may trigger the disease in genetically predisposed individuals. The HLA class I genes are the most important genetic factors in BD although other genes are also involved in the susceptibility to this pathology. To improve the current knowledge of its genetic background, we conducted the first large-scale genetic analysis on Spanish population, with special focus in the HLA region.

Methods: A discovery cohort comprising 278 BD cases and 1,517 unaffected controls were genotyped using the Immunochip platform which is a custom high-density array that allows the analysis of 196,524 genetic variants across 186 known susceptibility *loci* for autoimmune and autoinflammatory disorders. We also imputed HLA data with a previously validated imputation method to perform a more comprehensive analysis of this genomic region. The validation step was performed on an independent replication cohort composed of 130 BD cases and 600 additional controls.

Results: The strongest association signals were observed in the HLA class I region, being HLA-B*51 the highest peak (overall P=6.82E-32, OR=3.82). A step-wise conditional logistic regression with classical alleles identified HLA-B*57 and HLA-A*03 as additional independent markers. The amino acid model that best explained the association, includes the position 97 of the HLA-B molecule and the position 66 of the HLA-A. Interestingly, these class I positions are located in the binding groove of their corresponding molecules. Among the non-HLA loci, the most significant in the discovery analysis were: IL23R (rs10889664: P=3.81E-12, OR=2.00), the JRKL/CNTN5 region (rs2848479: P=5.00E-08, OR=1.68) and IL12A (rs1874886: P=6.67E-08, OR=1.72), which were confirmed in the validation phase (JRKL/CNTN5 rs2848479: P=3.29E-10, OR=1.66; IL12A rs1874886: P=1.62E-08, OR=1.61).

Conclusion: Our results confirm HLA-B*51 as a primary-association marker in predisposition to BD and suggest additional independent signals within the class I region, specifically in the genes HLA-A and HLA-B. Regarding the non-HLA genes, in addition to IL-23R, previously reported in our population; IL12A, described in other populations, was found to be a BD susceptibility factor also in Spaniards; finally, a new associated locus was found in the JRKL/CNTN5 region.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Cystoid macular edema (CME) is the most serious complication of uveitis and the most common cause of blindness in uveitis. Our aim was to compare the efficacy and safety of adalimumab (ADA) vs infliximab (IFX) as the first biologic therapy in refractory CME of uveitis associated to Behçet Disease during one year period.

Methods: Multicenter study that included 175 patients with uveitis associated to Behçet Disease refractory to high dose of corticosteroids and at least one conventional systemic immunosuppressive drug. CME (OCT >300 μm) was present at baseline In 34 of these 175 patients, and it was the main reason for anti-TNFα therapy use. Infliximab (3-5 mg/kg/iv at 0, 2 and 6 weeks and after every 4-8 weeks) was used in 12 cases and ADA (40 mg/sc/2 weeks) in 22 cases. Our main objective was the complete resolution of CME. Secondary objectives were the improvement in visual acuity (VA) (VA improvement of at least 20% in one of the eyes), the complete absence of inflammation in the anterior chamber and resolution of vitritis, retinal vasculitis and retinitis. A bivariate analysis was performed to compare the response of the two types of biologic agents (ADA and IFX). A logistic regression model was performed to evaluate the effect of the biologic therapy on outcome. The analysis was performed using the SPSS version 20.0.

Results: We studied 34 patients (63 affected eyes). There were no significant differences between groups at baseline (IFX vs ADA) in sex (♂/♀; 4/6 vs 11/11; p =0.35), mean age (37.3±10.1 vs 41.5±8.3; p=0.2), positive HLA-B51 (70% vs 80.9%; p =0.5), uveitis duration before anti TNFα onset (median [IQR]; 36 [10-82] vs 33 months [15.5 to 83]; p =0.8), VA (0.4±0.33 vs 0.46±0.29; p =0.44), retinal vasculitis (75% vs 77%; p =0.87), retinitis (46% vs 30%; p =0.2), macular thickening (410.13±140.9 vs 409.46±138.55; p =0.98) and combined immunosuppressive therapy (58.33% vs 59.1 %; p =0.96). However, there were differences in the presence of cells in the anterior chamber (median [IQR] 1 [0-1.2] vs 1 [0-3]; p =0.02) and vitritis (median [IQR], 1 [0-2] vs 3 [0.5-3]; p =0.002). Although CME resolution (main objective) was more commonly found with ADA, no significant differences were found. No significant differences were found between ADA and IFX when the secondary objectives were assessed, even after the adjustment for duration of illness, age and sex **(TABLE)**

Conclusion: Both ADA and IFX are effective in CME associated to Behçet Disease refractory to conventional immunosuppressive therapy. These two anti-TNFα agents show equivalent efficacy. **TABLE**

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The fecal calprotectin (FC) is widely used as a non-invasive method for identifying patients with active Crohn's disease (CD) and ulcerative colitis. Gastrointestinal involvement of Behçet's syndrome (GIBS) shows clinical and

endoscopic similarities to CD. A previous study in a small number of Behçet's syndrome (BS) patients with mainly mucocutaneous lesions showed serum calprotectin levels did not differ between active and inactive patients (1). Another study suggested FC may help to diagnose GIBS patients (2). We are not aware of studies addressing whether FC helps to distinguish active GIBS patients from those in remission. Therefore, we aimed to determine whether FC helped to predict active disease in GIBS patients.

Methods: We collected fecal specimens and serum from 23 GIBS (11 M, 12 F and mean age 44±9 yrs) patients before colonoscopy. The reasons for colonoscopy were assessing active disease in patients presenting with abdominal pain (with or without diarrhea) (n=9) or confirmation of a remission in asymptomatic patients (n=14). Seven of these patients had active GI involvement and the remaining 16 were inactive, based on colonoscopic findings. We also included 22 active and 25 inactive CD patients as controls. We used 150 µg/g as the cut-off for a positive FC level. We also looked at the correlations between FC and serum calprotectin and CRP levels, Crohn's disease activity index (CDAI) and disease activity index for intestinal Behçet's disease (DAIBD) scores.

Results: FC was >150 µg/g in all of the 7 GIBS patients with ulcers compared to 4/16 of GIBS patients without ulcers (OR: 42, 95%CI: 2 to 888). The median FC of active GIBS patients (n=7) was significantly higher than among inactive GIBS patients (n=16) (325 µg/g (IQR: 187-1800) vs 44 µg/g (IQR: 30-154); p=0.002). The mean serum calprotectin level was also higher among the active GIBS patients, however the difference was not significant (173.0 ± 273.7 µg/g vs 102.0 ± 135.4, p=0.13). There was a very low correlation between FC and serum calprotectin levels (r=0.08, p=0.72), a moderate correlation between FC and serum CRP levels (r=0.66, p=0.76), a moderate correlation between FC and CDAI scores (r=0.55, p=0.006) and very low correlation between FC and DAIBD scores (r=0.01, p=0.96). Among CD patients, 16/25 of the active patients and 3/22 of the patients in remission had FC level >150 µg/g (OR: 2.6, 95%CI: 3 to 49). Among the 4 GIBS patients who had high FC levels despite being in remission for gastrointestinal involvement, 1 had active mucocutaneous lesions, 1 had concomitant macrophage activation syndrome, and 1 had polycythemia vera with trisomy 8. None of the patients were receiving NSAIDs that could increase FC levels.

Conclusion: With further work FC may turn out to be a useful non-invasive tool for ruling out active GI lesions in asymptomatic GIBS patients. A high FC level demands caution for the presence of active ulcers especially in symptomatic patients while whether the presence of other BS manifestations can cause false positive results remains to be studied.

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Aortic regurgitation (AR) in Behcet disease is a rare but very fatal condition. Many patients require a second or third operation after simple aortic valve replacement (AVR) as a result of prosthetic valve dehiscence or destruction due

to flare. Recently, several case series have reported favorable outcomes after aortic root replacement (ARR). We evaluated if the surgical outcomes of AR in Behcet disease was dependent on surgical methods or materials. Here, we compared the long-term outcome of AR in Behcet disease who had undergone surgical treatment.

Methods: We have identified 33 patients who had been surgically treated for AR associated with Behcet disease from January 1996 through December 2013. A total of 23 patients fulfilled the international criteria for Behcet disease. AVR was performed in 9 patients and ARR in 14 patients. Bioprosthesis ARR was performed in 8 patients and composite graft ARR in 6 patients. The duration of follow-up was 10.7 years (median; IQR = 8.9-13.5) for the bioprosthesis ARR group and 6.4 years (median; IQR = 4.8-7.7) for the composite graft ARR group. The definition of the event was as follows; aortic valve/graft problem, infective endocarditis, cerebral infarction caused by thromboembolism or re-operation of aortic valve. We compared the events after first operation between the bioprosthesis ARR and composite graft ARR groups.

Results: In the 9 patients with AVR, events occurred in 6 patients (2.3 years after operation [median; IQR = 0.3-10.3]) and 11 cases required re-operation. In the 14 patients with ARR, events occurred in 7 patients (4.7 years after operation [median; IQR = 1.6-6.9] years after operation) and 6 cases required re-operation. However, steroid was prescribed for significantly more patients and with higher dosage in ARR group than those of AVR group.

In the 8 patients with bioprosthesis ARR, events occurred in 6 patients (3.0 years after operatin [median; IQR = 1.5-5.4)) and re-operation was performed in 6 cases. Interestingly, in the 6 patients with composite graft ARR, events occurred in 1 patient (6.2 years after operation [median; IQR = 4.8-7.5]), there was no case requiring re-operation. Kaplan-Meier curves displayed higher event free rate in composite graft ARR group compared to bioprosthesis ARR group (Figure 1). Overall mortality was 14.3% (2 of 8 patients in bioprosthesis ARR group, 0 of 6 patients in composite graft ARR group). The administration of steroid and immunosuppressants after operation were not significantly different between both groups.

Conclusion: In patients with AR related with Behcet disease, the rate of event was lower in patients with composite graft ARR compared to those with bioprosthesis ARR. Composite graft ARR was shown to be a feasible surgical option in patients requiring ARR for aortic root involvement of Behcet disease.

Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

We aimed to describe the Cogan Syndrome, the efficacy of DMARDs and biological targeted agents.

Methods: A national multicenter retrospective study in France including patients from 2001 to 2015. Data were recorded at the time of each treatment initiation, at 6 months, and at the end of each treatment. Efficacy outcomes were the intention-to-treat rates of systemic, ocular and audiovestibular responses during the first 6 months of exposure, the evolution of the steroid doses and the number of relapses. Typical Cogan Syndrome was defined if ocular and audiovestibular involvements and the presence of interstitial keratitis were observed within less than 2 years. The efficacy of biologics was compared to DMARDs with Kaplan-Meier curves.

Results: Sixty two patients were included with median age 37 [2-76] and 31/62 (50%) women. At the diagnosis, 61 (98%) had audiovestibular involvement, with bilateral hypoacousia/deafness, 19 (31%), 38 (95%) 57 (92%) with ophtalmological symptoms (keratitis 54%, scleritis 35%), 42 (68%) systemic symptoms. The time between the appearance of audiovestibular and ophtalmological symptoms was 2 months [ranges; 0-180]. Median ESR and CRP levels were 26 [3-125] mm and 15 [1-355] mg/l. The median follow-up was 34 [0-228] months. Comparing typical Cogan Syndrome to atypical cases (n=31 each), women (68% versus 32%, $p<0.05$), the presence of scleritis/episcleritis (10% versus 55%, $p<0.05$), significantly differed between groups. The first-line treatment was used in 61 (98%) patients and consisted in steroids alone (n=42), with median dose 60 mg/day [20-120], combined with other immunosuppressive drugs in 19 patients (31%)(methotrexate=8; azathioprine= 3; cyclophosphamide=8). Although ocular, constitutional signs and acute phase reactants were improved in nearly 80% of patients, only 28% had complete audiovestibular response. A second-line treatment was used in 44 cases, for relapses (n=27), steroid dependence (n=5), adverse effects or non-response (n=12). Overall, 129 lines of treatment were used in 61 patients and consisted in steroids alone (n=50), with steroids associated with DMARDs (n=69) and biological-targeted drugs (n=10). No difference was noted between 3 treatment regimens for the number of audiovestibular, ocular, systemic involvements, neither for the median dose of steroids, although the number of previous lines of treatment was more important for patients using biologics (1 (1-3) for steroids, 2 (1-5) for DMARDs and 2.5 (2-6) for biologics, $p<0.05$). Although the response rates were similar for ocular and systemic signs, audiovestibular improvement was significantly more frequent under biologics in comparison to steroids alone and DMARDs (80% versus 39% and 35%, respectively, $p<0.05$).

Conclusion: Audiovestibular involvement has a poor prognosis, with less response to treatment than ophtalmological symptoms. Biological targeted drugs seem to improve the audiovestibular impairment, whereas the addition of DMARDs does not improve the audiovestibular outcome.

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary angiitis of the CNS (PACNS) is a rare form of vasculitis confined to the brain and spinal cord, which often presents with severe cognitive and functional deficits. Although we have witnessed a tremendous progress in the recognition and diagnosis of this disease, there is still little known about the quality of life that these patients have following a diagnosis of PACNS. The aim of this study is 1) to evaluate patients' functional capabilities, quality of life, and frequency of depression after being diagnosed and treated for PACNS; and 2) to determine the effect of treatment duration on patient outcomes.

Methods: This is a cross-sectional study from a tertiary referral center. Eligible patient records were identified via retrospective chart review using the ICD-9 code for cerebral angiitis. Patients were included if they met 2 of the 3 following criteria: inflammatory CSF, angiogram typical of vasculitis, or vasculitis present on pathology of the brain. In addition, the diagnosis of PACNS was further agreed upon by 2 rheumatologists in the department who have particular expertise in this disease. Self-reported questionnaires were prospectively collected from eligible subjects. Measure of disability was assessed by the Barthel Index (BI), quality of life was assessed by EuroQOL (EQ-5D-5L), and depression was assessed with Patient Health Questionnaire (PHQ-9). Treatment history was collected from patient report and chart review.

Results: 1855 patient records were identified using the ICD-9 code for cerebral angiitis. 78 patients met inclusion criteria, of which 27 responded to the questionnaires (34.6%). Median follow-up of those who responded was 5.5 years (+/- 4.7 years) since diagnosis of PACNS. Using the Barthel Index scale, 19 of 27 patients (70.4%) scored 85 or more, indicating mild disability. Meanwhile, five (18.5%) patients scored 25 or less, indicating severe disability. Using the EQ-5D-5L questionnaire, 14 of 27 patients (51.9%) had no problems with mobility, 18 (66.7%) had no problems with self-care, 15 (55.6%) had no problems with usual activities, and 14 (51.9%) had no problems with pain, but only 8 (29.6%) had no problems with anxiety. Approximately 70% of patients had minimal or no depression using both the PHQ-9 scale and EuroQOL. There was a slight positive relationship between several of the outcome measures and duration of immunosuppressive therapy, although it is not statistically significant.

Conclusion: This is the longest reported follow-up of patients with PACNS described in the literature to-date. Most patients have mild long-term disability and minimal to no depression, which may be reflective of the advances of treatment. The data shows a slight tendency towards better scores being associated with longer treatments. However, larger studies are needed to verify the extent and strength of these relationships.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Neurosarcoidosis is one of the great mimickers of primary angiitis of central nervous system (PACNS) in terms of disease presentation, imaging and pathologic findings. However treatment strategies are different specifically in term of biologics which is rarely used in PACNS. Therefore, distinguishing these diseases earlier would be important giving the distinct therapeutic implications. We aimed in this original study to distinguish demographic, cerebrospinal fluid (CSF) and laboratory characteristics of both diseases to enhance our diagnostic approach.

Methods: 79 patients with PACNS and 51 patients with neurosarcoidosis were included in the study. All the clinical, CSF and laboratory characteristics at the time of presentation were retrieved from electronic medical records. For comparisons on the basis of diagnosis, numerical variables were compared between groups using either ANOVA or the Kruskal-Wallis rank-sum test. Categorical variables were compared between groups using either Pearson's chi-squared test or Fisher's exact test. All analyses were performed using SAS 9.4 software (SAS Institute, Cary, NC). All testing was two-sided, and considered significant at the 5% level.

Results: Demographic and CSF characteristics, blood CRP, ESR, ANA, RF levels of the patients were shown in the Table. There was a statistically significant difference between diagnoses on two variables. The first was race, where African American patients tended to be diagnosed with neurosarcoidosis and Caucasian patients tended to be diagnosed with PACNS ($p < 0.001$). The second was ANA, where higher levels tended to be associated with neurosarcoidosis ($p = 0.047$), and lower levels tented to be associated with PACNS. Although not statistically significant, two other variables showed promise for distinguishing the two diagnoses: total nucleated cells ($p = 0.067$) and neutrophils ($p = 0.14$). Higher values of total nucleated cells showed some tendency toward neurosarcoidosis, whereas low values showed some tendency toward PACNS. Neutrophil counts in the high range tended to correspond to neurosarcoidosis, whereas neutrophil counts in the low range tended to correspond to PACNS (Figure).

Conclusion: African American race and positive ANA were found to be associated with the diagnosis of neurosarcoidosis rather than PACNS. Total nucleated cells and neutrophil counts in the CSF showed promise in differentiating the neurosarcoidosis and PACNS. A follow-up study with a larger sample size would be required to firmly establish such a relationship. Table. Demographic and CSF characteristics of patients with neurosarcoidosis and PACNS

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Reversible Cerebral Vasoconstriction Syndrome (RCVS) is an important mimic of Primary Angiitis of the Central Nervous System (PACNS). Distinct clinical and diagnostic features differentiate both entities. However no available data exist in comparing the long term outcome of these two patient populations. The aim of this study is to compare the long term outcomes of PACNS and RCVS.

Methods: This is a cross-sectional study from a tertiary referral center. Eligible patient records were identified via retrospective chart review using the ICD-9 code for cerebral angiitis and reversible cerebral vasoconstriction syndrome, and the diagnoses were further agreed upon by 2 rheumatologists in the department who have particular expertise in these diseases. Self-reported questionnaires were prospectively collected from eligible subjects. Measure of disability was assessed by the Barthel Index (BI), quality of life was assessed by EuroQOL (EQ-5D-5L), and depression was assessed with Patient Health Questionnaire (PHQ-9).

Results: Of the 191 patients with RCVS, 45 responded to the questionnaires (23.5%). Of the 78 patients with PACNS, 27 responded to the questionnaires (34.6%). Median follow-up (from diagnosis to date of questionnaires) of those who responded with PACNS was 66 months (+/- 54 months) and with RCVS was 78 months (4-254 months). RCVS patients had significantly better functional capacity than PACNS as measured by Barthel Index (mean 95.9 in RCVS, 79.4 in PACNS, $p = 0.022$). RCVS patients scored significantly better in the self-care subscale of EuroQOL, although the remainder of the quality of life measures (mobility, usual activities, and anxiety/depression) were not statistically significant. Most patients with RCVS and PACNS scored low (minimal depression) on PHQ-9, and the mean PHQ-9 score between both groups was not statistically different ($p = 0.683$).

Conclusion: In a comparison of outcomes of patients with PACNS and RCVS, patients with RCVS were found to have better outcomes in terms of functional capabilities, and may have better quality of life. However, they appear to have a similar rate of depression.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment recommended in severe and/or refractory uveitis of Behçet disease is anti-TNFα therapy, usually infliximab (IFX) or adalimumab (ADA) (Levy-Clarke et al Ophthalmology 2014). However, in some cases these biologic agents are not effective, may be contraindicated or they are not well tolerated. IL-6 is a key cytokine in the pathogenesis of uveitis. Our aim was to evaluate the response to tocilizumab (TCZ) in uveitis associated with refractory Behçet disease.

Methods: Multicenter study of 11 patients with uveitis associated to Behçet disease. Patients had been treated with at least one conventional immunosuppressive drug and in most cases with anti-TNFα agents. The main parameters assessed were the visual acuity (VA) and the degree of intraocular inflammation. Cystoid Macular Edema (CME) was considered when OCT was greater than 300 μm.

Results: We studied 11 patients (7 men/4 women); mean age 38.45±20.42 years. Uveitis was bilateral (n=9) and unilateral (2) **(Table).** The pattern of ocular involvement was panuveitis (n=8; 7 of them with retinal vasculitis, 6 with CME and 1 with papillitis), anterior uveitis (n=2, also with severe arthritis) and posterior uveitis (1 case; also with retinal vasculitis and CME). The clinical course was chronic (n=4) or recurrent (7). Besides oral corticosteroids and before TCZ they had received: intraocular corticosteroids (n=10), i.v. methylprednisolone (10), methotrexate (MTX) (9), (cyclosporin A) CsA (8), azathioprine (AZA) (3), cyclophosphamide (2), mycophenolate (1) and colchicine (1). All of them had received other biologic drugs: Adalimumab (n=8), Infliximab (4), Golimumab (3), etanercept (1), canakimumab (1) and daclizumab (1)**.** In 10 patients TCZ was prescribed at 8 mg/kg/i.v. monthly and in 1 patient 162 mg/week/sc. TCZ was given in monotherapy (n=7) and combined in 4 cases (2 MTX, 1 CsA, 1 AZA). After a mean follow up of 9.5±8.05 months, improvement was observed in the following items: a) Mean VA (0.38±0.32 to 0.73±0.35; p=0.002); b) Median cells in the anterior chamber (1 [0-2.5] to 0 [0-0]; p=0.005; c) Median vitritis (1 [0-2] to 0 [0-0]; p=0.003); d) retinal vasculitis (n=10 eyes [45.45%] with resolution in all cases e) Mean OCT (μ) (from 359.46±115.96 to 257.66±71.7, p=0.0009; f) 8 patients achieved complete remission, g) reduction in median dose of prednisone (30 [20-30] to 0 [0-5]; p=0.1). TCZ was withdrawn in 2 cases, 1 due to an infusional reaction and 1 because of joint impairment.

Conclusion: Treatment with TCZ seems to be effective in patients with refractory uveitis due to Behçet's disease. **TABLE**

Case	Sex/age	*Conventional Immunosuppressive drugs* before TCZ	Biologic drugs before TCZ	*Immunosuppressive drugs* combined with TCZ	Anterior chamber cells (onset/last visit)	Retinal Vasculitis (onset/last visit)	OCT (onset/last visit)

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Peripheral Ulcerative Keratitis (PUK) is a severe inflammation of the outer portions of the cornea that may be associated with systemic conditions. The progression of marginal corneal thinning may lead to perforation of the cornea and to rapid and permanent vision loss in the involved eye. Treatment of PUK is based on corticosteroids and conventional systemic immunosuppressive drugs. Our aim was to evaluate the response to biologic therapy in cases with severe and refractory PUK.

Methods: Multicenter study of 27 (35 affected eyes) patients. All of them presented inadequate response to conventional therapy with corticosteroids and at least 1 systemic traditional immunosuppressive drug. The main outcome measures were visual acuity, signs of inflammation (scleritis and episcleritis), progression to corneal thinning, central keratolysis and ocular perforation.

Results: We studied 27 patients/35 affected eyes (7 men/20 women) with a mean age of 57.2±16.3 years. PUK was primary (n=1) and in the 26 remaining cases, the underlying diseases were Rheumatoid Arthritis (RA) (n=19), Psoriasic Arthritis (2), RA+Felty syndrome+common variable immunodeficiency (1), Behçet Disease (1), Type I diabetes mellitus (1), granulomatous polyangiitis (1) and microscopic polyangiitis (1). They received the following topical therapy: corticosteroids (n=18), antibiotics (17), lubricants (18), autologous serum (11), topical cyclosporin (11) and topical tacrolimus 0.03% (1). Besides oral corticosteroids and before the biologic therapy they had received iv methylprednisolone (n=8), methotrexate (16), oral doxycycline (9), azathioprine (3) and ascorbic acid (2). Moreover, 10 patients required surgery: amniotic membrane (n=7), penetrating keratoplasty (4), conjunctival resection (3), tissue adhesives (2), conjunctival flap (1) and lamellar keratoplasty (1). Anti-TNFα drugs were the most common biologic agents (n=19): Adalimumab (ADA) (10; 37%), Infliximab (IFX) (; 29.6%) and etanercept (n=1; 3.7%). In the remaining 8 cases the biologic agents were rituximab (n=7; 25.9%) and tocilizumab (n=1; 3.7%). The main outcome measures are summarized in the Table. After a mean follow-up of 23.7±20 months, all objective outcomes had improved with a reduction of the median prednisone dose from 33.7 [IQR 17.5-52.5] mg at baseline to 0 [0-2.5] mg (p=0.028). The main observed adverse effects were supraventricular tachycardia (n=1) and pulmonary Tuberculosis (n=1).

Conclusion: In our series, biological therapy, especially IFX and ADA, is effective and relatively safe in patients with PUK refractory to standard systemic treatment. **TABLE**

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Thiopurines are a mainstay for the treatment of autoimmune diseases. However, in inflammatory bowel diseases (IBD), 14-18 % of patients manifest a skewed metabolism of these drugs leading to an overproduction of the 6-methylmercaptopurine (6-MMP) metabolite to the detriment of the active 6-thioguanine (6-TGN) metabolite (Figure 1). These patients are identified as shunters. In IBD, allopurinol is used to reverse this skewed metabolism, thus preventing thiopurines resistance or hepatotoxicity. However, this strategy has hardly been studied in a population with other autoimmune systemic diseases.

Methods: Patients were identified using the central laboratory database and data were retrospectively collected. Clinical and laboratory evolution of patients for whom azathioprine (AZA) was optimized with a xanthine oxidase inhibitor (XOI) was assessed on a 12-month period.

Results: Thirty-four shunters (33%) were identified over 103 patients treated with AZA for autoimmune conditions other than IBD. Twenty shunters were not optimized while 14 shunters were optimized with allopurinol (13) and febuxostat (1). Multiple reasons lead to optimization: 6 patients were depending on corticosteroids, 6 patients were non-responsive to therapy or had a relapse, 3 patients had hepatotoxicity and 3 patients were optimized solely based on their metabolites ratio. The maximal AZA dose decreased form 2.07 mg/kg (interquartile range (IQR): 1.77-2.45) on AZA alone to 0.86 mg/kg (IQR: 0.68-1.07) on AZA-XOI combination therapy. Despite this significant 58% (p=0.003) dose reduction, optimization with a XOI allowed to increase the 6-TGN blood level from 135 pmol/8×10^8 red blood cells (RBC) (IQR: 91-199) to 385 pmol/8×10^8 RBC (IQR: 237-449) (p=0.001) and to decrease the 6-MMP level from 6267 pmol/8×10^8 RBC (IQR: 3858-11306) to 271 pmol/8×10^8 RBC (IQR: 162-528) (p=0.001). All patients resumed a normal 6MMP/6TG ratio (<20) and 2 out of 3 hepatotoxicity resolved. Except for the mean corpuscular volume increase of 12% (p=0.001), the changes in the blood count were not considered clinically significant. Notable infections were reported in 3 patients. After 6 months of optimization, prednisone was reduced by 89% (p=0.005), 12 patients were in remission and 2 in partial remission.

Conclusion: In this retrospective study, the optimization of thiopurines with a XOI was safe and effective. This strategy represents a promising therapeutic option in patients with autoimmune systemic diseases.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The occurrence of lymphoma, especially Hodgkin's lymphoma (HL), in patients with primary central nervous system vasculitis (PCNSV) has been reported but is considered uncommon. The aim of this study was to determine the frequency of lymphoma in a large cohort of patients with PCNSV and compare the presenting clinical, laboratory, and imaging features in those with both lymphoma and PCNSV to those without lymphoma.

Methods: We reviewed all patients seen at the Mayo Clinic, Rochester, MN over the 32- year period of 1982-2014, who were diagnosed with vasculitis and lymphoma. 10 patients associated PCNSV and lymphoma Cerebral biopsy specimens were reviewed by one pathologist (CG) without knowledge of clinical information. We also used as comparator our updated cohort of 158 consecutive patients with PCNSV without lymphoma who were examined at Mayo Clinic over a 29-year period from 1983 to 2011. The diagnosis of PCNSV was based on brain/spinal cord biopsy, or cerebral angiography, or both. Clinical data were collected.

Results: 10/168 (5.9%) patients were found to have both lymphoma and PCNSV: 6 of these 10 had HL and 4 non-HL. In 8 patients PCNSV diagnosis was established by cerebral biopsy and in 2 by cerebral angiography. Two of the 10 patients had brain and spinal cord vasculitis involvement. A granulomatous inflammatory histologic pattern was found in all 8 patients with cerebral biopsies, accompanied by vascular deposits of β-amyloid peptide in 2. In 7 patients (5 HL and 2 NHL) medical diagnostic workup for PCNSV revealed lymphoma. In one other patient PCNSV symptoms appeared during a recurrence of lymphoma, in another 6 months after an allogenic bone marrow transplant for a recurrence of lymphoma, and in one lymphoma occurred 26 years before PCNSV diagnosis. Cerebrospinal fluid (CSF) was negative for herpes virus when assayed by PCR. The 10 patients with lymphoma were compared with the 158 patients with PCNSV without lymphoma. The patients with lymphoma were more frequently males (80% vs 44%, $p = 0.04$). No other significant differences in the clinical manifestations at presentation and CSF findings were observed in the two groups, although cognitive dysfunction was more frequent in patients with lymphoma (80% vs 53%), while visual field defects and intracranial hemorrhage were less frequent (0% vs 19%, and 0% vs 10%, respectively). Systemic manifestations were infrequent in both groups (10% vs 9.5%). More patients with lymphoma showed meningeal gadolinium enhancing lesions on MRI (50% vs 19%, $p = 0.03$). The frequency of PCNSV relapse (20% vs 28.4%) and patients not requiring therapy at last follow-up (30% vs 25.5%) were similar in both groups. Patients with lymphoma had a higher frequency of poor outcomes (modified Rankin disability score > 4) at last followup (60% vs 21,5%, $p = 0.01$). Considering all 168 patients, univariate Cox proportional hazards modeling showed an increased mortality rate in those with increasing age (hazard ratio, HR, 1.3), lymphoma (HR 3.9), cerebral infarction on initial MRI (HR 3.4), and angiographic large vessel involvement (HR 3.9), while mortality rate was lower in those with gadolinium–enhancing lesions on MRI (HR 0.3).

Conclusion: Lymphoma was found in 5.9% of of 168 patients with PCNSV. Lymphoma may occur simultaneously with PCNSV, before or after the diagnosis of PCNSV. Most clinical characteristics of PCNSV were similar in those with or without lymphoma, however, patients with lymphoma had a more severe cerebral vasculitis with increased neurological disability and mortality.

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Since first described by McDuffie *et al.* in 1973, hypocomplementemic urticarial vasculitis (HUV) syndrome has been recognized as a specific autoimmune disorder involving at least 6 months of urticaria with hypocomplementemia in the presence of systemic manifestations, such as arthritis/arthralgia, glomerulonephritis, uveitis and recurrent abdominal pain. Skin biopsy is essential in the diagnosis of HUV and the presence of antibodies against complement protein 1q (anti-C1q) has been judged 'a rule without exception'. The objective of this study was to describe the clinical characteristics and epidemiology of HUV in two geographically areas of Sweden during a 16-year period.

Methods: In the health care districts surrounding the Skåne University Hospital in Lund [mean population years (2000-2015), 950 560] and the Linköping University Hospital in Östergötland [mean population years (2000-2015), 428 503] all patients diagnosed with HUV during the period 2000-2015 were included in the study if they (i) were residing within the study areas at the time of onset of HUV-related symptoms, (ii) had received a diagnosis of HUV during the study period. The diagnosis of HUV was confirmed by medical records review. Only patients meeting the suggested diagnostic criteria for HUV [1] and/or the 2012 Chapel Hill consensus definitions [2] were included.

Results: Sixteen patients (Skåne 7 + Östergötland 9) with a clear female predominance were identified during the study period. Clinical characteristics of the patients are given in Table 1. The pooled annual incidence rate per million inhabitants was estimated to 0.7 (95% CI 0.4-1.1), with a significant higher incidence in Östergötland compared to Skåne [0.5 (95% CI 0.1-0.8) and 1.3 (0.5-2.2), P=0.02]. The prevalence did not differ significantly between the regions, Table 2). Two patients died during the follow-up period. One patient underwent lung transplantation and two patients proceeded to end-stage renal disease.

Table 1

Clinical and laboratory characteristics	
Number of patients	16 (9 Östergötland; 7 Skåne)
Female, n (%)	14 (87.5%)
Age at diagnosis	51 (IQR 40.7-56.7) years
Age at last follow-up	58 (IQR 47.0-67.2) years
Duration of follow-up	94 (IQR 46.5-136.2) months
Diagnosis delay	12 (IQR 5.0-19.7) months
Laboratory results at diagnosis, median (IQR)	
Hemoglobin	124.5 (116.5-131.5)
White blood cell count	7.2 (5.7-11.5)
Thrombocyte count	311 (250-451)
ESR (mm/h)	18.5 (8.5-30.2)
C-reactive protein (mg/L)	14 (10-29)
P-creatinine (µmol/L)	79.5 (57.5-85.0)
eGFR	75.5 (65.2-108.2)
Criteria at diagnosis	
Low complement	15 (94%)
Dermal venulitis	1 (6%)
Arthritis	14 (88%)
Glomerulonephritis (on biopsy)	3 (19%)
Episcleritis/scleritis	3 (19%)
Recurrent abdominal pain	2 (13%)
Anti-C1q antibody	16 (100%)
Histopathology diagnosis	13 (81%)
ESRD	2 (13%)
Death	2 (13%)
Serology data at diagnosis	
ANA positive	7 (44%)
ENA positive	5 (31%)*
Anti-dsDNA antibody	0
Anti-cardiolipin antibody	2 (13%)

* Ro/SSA 3; Ro/SSA+La/SSB 2

Table 2

Patients	N. of patients	Incidence (95% CI)	N. of patients	Point prevalence (95%)
All	16	0.7 (0.4-1.1)	14	9.5 (4.5-14.5)
Women	14	1.3 (0.6-1.9)	12	16.2 (7.0-25.4)
Men	2	0.2 (0-0.4)	2	2.7 (0-6.5)
Östergötland	9	1.3 (0.5-2.2)	7	15.7 (4.1-27.3)
Women	8	2.3 (0.7-4.0)	6	27.1 (5.4-48.8)
Men	1	0.3 (0-0.9)	1	4.5 (0-13.2)
Skåne	7	0.5 (0.1-0.8)	7	6.8 (1.8-11.8)
Women	6	0.8 (0.2-1.4)	6	11.6 (2.3-20.9)
Men	1	0.1 (0-0.4)	1	2.0 (0-5.8)

Conclusion: To our knowledge, this is the first epidemiological study of HUV. The high coverage of patients, which was enabled by the public and tax-funded Swedish healthcare system, constitutes a major strength of this study. The estimation of incidence and prevalence indicate that this condition is rare but not benign. Renal and lung manifestations were severe in some cases which highlights the need for careful screening and monitoring of this potentially serious condition. *References:* 1) Davis MD, Brewer JD. *Immunol Allergy Clin North Am* 2004;24:183-213 2) Jennette JC, et al. *Arthritis Rheum* 2013;65:1-11

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Major organ involvement, especially in young males, is one of the main causes of mortality and morbidity in Behcet's Disease (BD). However, the prognosis and predictors of major organ involvement is unsufficiently studied. We aimed to follow young, male BD patients which have the highest risk for major organ involvement prospectively.

Methods: Thirty-six male patients with BD consecutively consulted in the Outpatient Clinics of Marmara University, 35 males with ankylosing spondylitis(AS),36 healthy males were included in the study. Bilateral upper and lower extremity venous doppler ultrasonography(US) and brachial and carotid arterial US (for assessing endothelial dysfunction) were performed in baseline visit for all groups and in the first year follow-up visit for BD patients. Patients with BD were assessed prospectively with 3-6 months intervals and in any urgent visit.

Results: At baseline, the mean disease duration was 3.3 years in patients with BD. The rate of venous insufficiency was higher in male BD patients without vascular events, compared to healthy controls (BD vs HC: 30.5% vs 0%) and similar to patients with AS (BD vs AS. 30.5% vs 32%). Markers of endothelial dysfunction (FMD and NID) were similar between BD patients and healthy controls, however CIMT (Carotid intima media thickness) was significantly higher in BD (0.54 mm vs 0.47 mm, p=0.033). The mean follow-up duration was 44.6 months. Major organ involvement developed in 4 (11%, 3 vascular and 1 ocular involvement) patients during follow-up. All of them were in the first 2 years of follow-up. Immunsuppresive (IS) therapy was required in 22% (n=8) of patients, due to major organ involvement in 4 (11%) and refractory mucocutaneous symptoms in other four (11%) patients. In the first year follow-up visit, endothelial functions and CIMT were observed to be significantly improved compared to baseline (Baseline vs Follow-up: 6.8±4 vs 10.9±4.5, p=0.003 for FMD**,** 0.55±0.13 vs 0.47±0.1 for CIMT, p=0.004). The patients requiring IS treatment in the follow-up had significantly lower FMD at baseline compared to the rest of the group (4.4 vs 8.5, p=0.005).

Conclusion: Our study demonstrated a lower incidence of major vascular events in male BD patients during prospective follow-up compared to historic controls in the literature. However, our results confirmed an early onset of major organ involvement and IS use in the first year of disease follow-up. The decreased rate of baseline FMD in patients with later IS requirement suggest that FMD can be a predictor for major organ involvement in BD. **Table 1: Clinical charecteristic of patients developing immunosuppressive need during follow-up.**

	IS onset during follow-up.	Reason for IS use	Age	Disease duration when IS started	IS agent
Patient 1	1.month	Pulmonary aneurysm	35	1 year	Azatioprine
Patient 2	7.month	Refractory OU	25	5 years	Cyclosporine
Patient 3	6. month	Deep venous thrombosis	38	10 years	Azatioprine
Patient 4	10. month	Uveitis	20	5 years	Azatioprine
Patient 5	9. month	Refractory OU	28	7 years	Azatioprine
Patient 6	13. month	Refractory OU	23	6 years	Cyclosporine
Patient 7	9. month	Refractory EN	35	1 years	Azatioprine
Patient 8	8. month	Deep venous thrombosis	23	1 years	Azatioprine

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Deep venous thrombosis (DVT) is the most common form of vascular involvement in Behcet's disease (BD). Chronic post-thrombotic syndrome (PTS) develops frequently in patients with DVT and is associated with impaired quality of life (QoL). However, factors associated with PTS and venous disease spesific QoL is unsufficiently explored in patients with VBD.

Methods: This study included 94 patients (Male/Female: 75/19) with VBD and 29 age and gender-matched individuals (Male/Female: 18/11) with DVT associated with non-BD causes. Villalta scale was used to assess PTS. Venous Disability Score (VDS) and Venous Clinical Severity Score (VCSS) were used for the assessment of venous disease. Venous disease-specific QoL was measured through Venous Insufficiency Epidemiological and Economic Study Quality of Life/Symptom questionnaire (VEINES-QoL/Sym). Behçet's Syndrome Activity Score (BSAS) questionnaire was used to assess disease activity.

Results: A high presence of PTS (61.7%) was observed in VBD. The rate of anticoagulant usage was significantly lower (63% vs 100%, p=0.001), and the number of DVT attacks were significantly higher in VBD (1.6 vs 1.3, p=0.001) compared to non-BD. VEINES-QoL and VEINES-Sym VCSS were significantly worse in VBD patients with PTS when compared to patients without PTS. BSAS was also significantly higher in patients with PTS. An inverse correlation was observed between VEINES-QoL and BSAS in multivariate analysis (p=-0.551, p< 0.001). There were no differences between anticoagulant users and non-users regarding the presence of PTS (60.8% vs 63.3%) and scores of all venous assessment tools in VBD (p>0.05).

Conclusion: A high presence of PTS and impaired venous disease spesific QoL, symptom severity and venous disability scores were observed in VBD. Venous disease spesific QoL negatively correlated with general disease activity. Better control of disease activity might decrease development of PTS and improve venouse disease spesific QoL, however, any additional benefit of anticoagulant treatment on the development of PTS and venous QoL was not observed.

Antiphospoholipid Antibodies in Adult IgA Vasculitis: Aps/PT Antibodies As a Potential Marker of Renal Involvement?

Alojzija Hocevar, Jaka Ostrovrsnik, Polona Žigon, Saša Čučnik, Ziga Rotar and Matija Tomšič, Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Increased prevalence of IgA aCL and anti-PS/PT antibodies has been described in adult IgAV, making them potential markers of disease activity[1]. The aim of our prospective study was to evaluate the role of antiphospholipid antibodies (aPL-Abs) on the clinical presentation of adult IgA vasculitis (IgAV).

Methods: Adults with histologically proven IgAV, diagnosed for the first time between 1 January 2013 and 31 May 2016 at our at our secondary/tertiary rheumatology center were included. IgG, IgM and IgA isotypes of anticardiolipin antibodies (aCL), antibodies to β2-glycoprotein 1 (aβ2GP1) and antibodies to phosphatidylserine-prothrombin complex (aPS/PT) were determined at presentation. A cut-off level for positive result was set at 99th percentile for all aPL-Abs. Clinical characteristics of patients with and without aPL-Abs were compared. Additionally, characteristics of IgAV cases with positive IgA aPS/PT were analyzed as subgroup.

Results: During the 41-month observation period aPL-Abs were determined in 89 IgAV patients (53.9 % male; median (IQR) age 67.6 (50.3, 77.3) years). In total 32 patients (36.0%) had aPL-Abs. aCL, aβ2GP1 and aPS/PT were found in 9.0%, 13.5% and 23.6%, respectively. IgA aPS/PT subtype, found in 21.3% was the most common aPL-Ab present in our IgAV patients (Table 1). Characteristics of aPL-Abs negative vs. aPL-Abs positive patients vs. IgA PS/PT positive cases are presented in the Table 2. The presence of any aPL-Abs was associated neither with thrombotic events nor with distinct IgAV clinical manifestation. Yet, aPL-Abs positive IgAV patients had significantly higher erythrocyte sedimentation rate ($p<0.001$), C-reactive protein ($p=0.007$) and serum immunoglobulin A level ($p=0.023$) at presentation. However, IgA aPS/PT positive patients had more commonly had renal involvement than those without this antibody ($p=0.031$; RR 1.9 (95% CI 1.1–3.1)). This was unrelated to increased total serum IgA level. The latter was not a predictor of renal involvement in our cohort ($p=0.177$).

Table 1.	
aPL-Abs	*number of patients*
aCL	8 (9.0%)
IgG	7
IgM	1
IgA	1
aβ2GP1	12 (13.5%)
IgG	6
IgM	3
IgA	7

Expression Profile of Chemokines Is Skewed to Th17/Th22 Recruitment in Circulation of Patients with Behcet's Disease

Hidekata Yasuoka and Tsutomu Takeuchi, Keio University School of Medcine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Behcet's disease (BD) is an inflammatory disease characterized by ocular, mucosal and skin lesions. However, the pathogenesis of BD is still unknown. Characteristics of histologic findings show granulocyte-dominant immune cell infiltration, suggesting dominancy of innate immune response or "inflammation-like immune response" rather than acquired immune response. Thus, BD is recently proposed to categorize as an autoinflammatory disease. To clarify the pathogenesis of BD and have an answer for activation status of immune system, levels of multiple chemokines in the circulating milieu were assessed as a reflection of the local production of chemokines for the recruitment of immune cells.

Methods: Twenty-seven patients with BD (12 active and 15 inactive patients) and 20 healthy controls were involved. Levels of chemokine in plasma were examined by enzyme-linked immunosorbent assay. Various chemokines were assessed, including RANTES (recruitment of general T cells), CX3CL1 (cytotoxic T cells, NK cells, gamma-delta T cells), MCP-1 (monocytes), CXCL9 (Th1 cells including Th1/Th17 cells, effector CD8+ cells), MIP3a (Th17) 、CCL27 (Th22) to cover recruitment of various lymphocytes. Comparison between 2 groups was assessed by non-parametric Mann-Whitney U-test.

Results: Levels of circulating RANTES, CX3CL1, MCP-1, and CXCL9 were comparable in both groups, suggesting that recruitment of general T cells, monocytes, cytotoxic lymphocytes were not expected based on profiles of these chemokines. On the other hand, plasma concentration of MIP3a and CCL27 were higher in BD compared to healthy controls (MIP3a: 39.6 ± 54.3 versus 14.5 ± 8.9, $P < 0.05$, CCL27: 354.2 ± 150.6 versus 238.3 ± 155.5, $P < 0.05$, respectively), suggesting the association with recruitment of Th17 and Th22. Interestingly, levels of CCL20 was comparable between patients with active disease and those without, whereas CCL27 was higher in patients with inactive disease compared to those with active disease.

Conclusion: In patients with BD, expression profile of the chemokine in circulation is skewed rather than global upregulation, suggesting that pathophysiological process in BD is not a non-specific inflammation from the point of view of chemokines. Upregulation of CCL20 in BD patients and downregulation of CCL27 in active patients might associate with regulation of infiltration of Th17 or Th22 to the lesions, and with pathogenesis of BD.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet's disease (BD) is a variable vessel vasculitis which is more common in adults. The most widely used diagnostic criteria for adult onset disease is the International Behçet's Study Group (ISG) criteria. A new set of criteria for the classification of Behçet's disease (BD) in children (the pediatric BD [PEDBD] criteria) has been proposed recently. To evaluate

the disease activity; there are mainly two severity scores the BD dynamic activity measure (IBDDAM) and BD current activity form (BDCAF). We aimed to test the performance of the PEDBD criteria compared to the ISG criteria and to check the correlation between the severity score systems and physician global assessment (PGA) in pediatric BD patients.

Methods: Two centers from Turkey and one center from Israel participated in this study. The disease onset was ≤16 years of age. As controls, pediatric patients with rheumatologic other diseases.

Results: Sixty-eight BD (44.1% male) patients and 93 control patients were included. The sensitivity and specificity of the PEDBD and the ISG criteria were 73.5%/52.9% and 98.9%/100%, respectively. Thirty-two (47%) patients with BD failed to fulfill the ISG criteria. However, almost all of these patients met the PEDBD criteria. The median (min-max) IBDDAM and BDCAF scores at diagnosis were 6 (1-23) and 4 (1-7) and significantly decreased to 1 (0-8) and 1 (0-4) respectively at latest follow-up ($p<0.001$ for both). The median (min-max) PGA score at diagnosis was 5 (2-9) and significantly decreased to 1 (0-7) at latest follow-up ($p<0.001$). IBDDAM had a strong positive correlation with BDCAF ($r=0.637$; $p<0.001$). PGA positively correlated with BDCAF and IBDDAM ($r=0.502$; $p<0.001$ and $r=0.624$; $p<0.001$, respectively).

Conclusion: In our pediatric series, the PEDBD criteria showed better sensitivity than the ISG criteria and the specificities were close. The higher sensitivity is a big advantage for pediatric patients since early diagnosis is very important. Our study also demonstrated that the severity scores were positively correlated with each other and PGA and thus may be used in clinical practice to evaluate children with BD.

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Buerger's disease or thromboangiitis obliterans (TAO) is a nonatherosclerotic segmental inflammatory disease of small- and medium-sized arteries of the distal extremities. This disease mainly affect young male tobacco users but the pathophysiology remains unknown. Most series of TAO come from India and Japan. Herein, we aim report to describe clinical presentation, treatment and long-term outcome in a large cohort of TAO.

Methods: We reviewed the charts of 174 [136 (78,2%) male, sex ratio 3.7, mean age at diagnosis of 38,4 years] consecutive french patients with TAO criteria from two french university center of internal medicine diagnosed between 1967 to 2015.

Results: The mean time between onset of symptoms and diagnosis was of 2.5 ±0.7years. One hundred seventy one (98.3%) patients were tobacco users with a mean consumption of 23.4 pack-years and 34 (19.5%) were cannabis consumers. At diagnosis, 15

patients (8.7%) had deep vein thrombosis, 39 (22.5%) superficial vein thrombosis, 76 (43.9%) Raynaud's phenomenon and 14 (8%) arthralgia. Ischaemia of lower limbs, upper limbs and upper-lower limb were found in 98/173 (56.6%), 44/173 (25.4%) and in 18/173 (10.4%) patients, respectively. After a median follow-up of 3 (IQ25 :1 ; IQ 75 8,8) years, 89/171 (52%) had stopped their tobacco consumption and 26/34 (78.8%) their cannabis consumption. One hundred patients (57.4%) were treated by aspirin alone, 33(19%) by clopidogrel alone and 33 (19%) with both treatment. Ninety five (54.6%) had statins, 53 (30.5%) calcic inhibitors, 91 (52.3%) oral vasodilatators, 28 (16.1%) conversion enzyme inhibitors and 117 patients (67.2%) received at least one infusion of ilomedine. Forty five patients (25.9%) had at least one vascular intervention and 12/45 (26.7%) had an amputation. At the end of follow up, 104/169 patients (61.5%) were asymptomatic, 140/174 (80.5%) were amputation free. Among patient with amputation, 15/34 (44.1%) patients had more than one amputation. Mean time between diagnosis and first amputation was of 2.5 years. Two patients died at the end of folow-up.

Conclusion: TAO is a rare vasculitis, with few data coming from western countries. Functional prognosis is very poor with up to 20% of amputation at 3 years.

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Little is known about the incidence of late-onset relapse in systemic vasculitis. This study examined the incidence of relapse < 2 years and ≥ 2 years after diagnosis in 6 different types of systemic vasculitis.

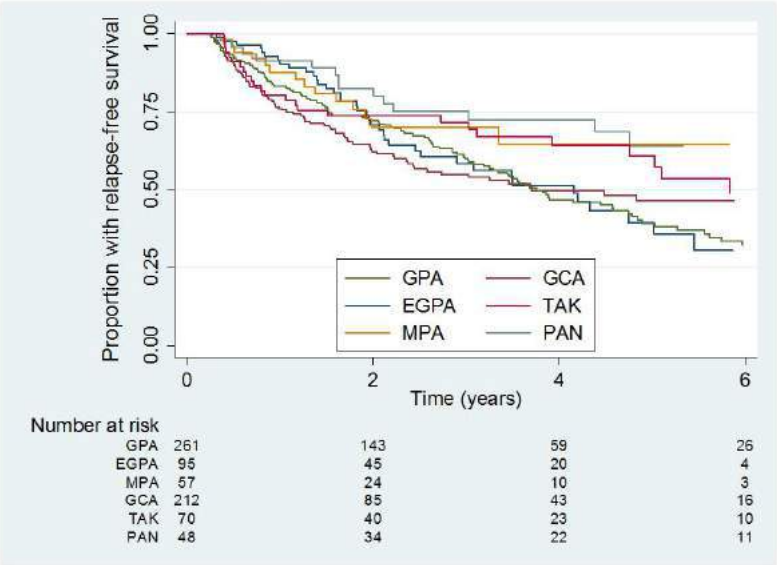
Methods: Data from patients in the Vasculitis Clinical Research Consortium Longitudinal Study, a prospective, multicenter North American cohort, were included if they had no relapse between the date of diagnosis and enrollment into the cohort. 6 vasculitides were studied: granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA), microscopic polyangiitis (MPA), giant cell arteritis (GCA), Takayasu's arteritis (TAK), and polyarteritis nodosa (PAN). For GPA, EGPA, and MPA, the outcome of relapse was defined as new or worsening Birmingham Vasculitis Activity Score > 0; for GCA, TAK, and

PAN, relapse was defined by physician global assessment > 0. Kaplan-Meier curves of the incidence of relapse over time and incidence rates < 2 years and ≥ 2 years from diagnosis were compared within each type of vasculitis. Use of immunosuppressive medications at time of relapse was examined.

Results: There were 743 patients included in this study: 261 GPA, 95 EGPA, 57 MPA, 212 GCA, 70 TAK, and 48 PAN. The Kaplan-Meier curves for relapse-free survival are shown in **Figure 1**. A significant decrease in the incidence rate of relapse over time was seen in MPA and GCA but not in the other types of vasculitis (**Figure 2**). Among those who relapsed, the proportion on non-glucocorticoid immunosuppressive therapy at the time of relapse was not significantly different between the 2 time periods except for PAN. Compared to patients who relapsed within 2 years of their diagnosis, patients with GPA, GCA, and TAK who relapsed after 2 years were less likely to be on prednisone at the time of relapse.

Conclusion: In MPA and GCA, the incidence of relapse significantly decreases after 2 years among those who maintain remission for at least 2 years after diagnosis. However, there are no significant differences in the incidence of relapse after 2 years in GPA, EGPA, TAK, and PAN. Use of maintenance immunosuppressive therapy at time of relapse is not significantly different between those who relapse within or after 2 years, suggesting medications alone cannot account for late-onset relapses. These data indicate that continued close monitoring years after diagnosis is required in patients with systemic vasculitis.

Figure 1. Kaplan-Meier curves for relapse-free survival stratified by vasculitis type.



GPA: granulomatosus with polyangiitis; MPA: microscopic polyangiitis; EGPA: eosinophilic granulomatosus with polyangiitis
GCA: giant cell arteritis; TAK:Takayasu's arteritis; PAN: polyarteritis nodosa

Assessment of Damage in Behcet's Disease: Do We Need a Specific Damage Index?

Ali Ugur Unal[1], Hale Gulcin Yildirim[2], Ceylan Cikikci[2], Gulsen Ozen[3], Nevsun Inanc[3], Pamir Atagunduz[3], Tulin Ergun[4] and Haner Direskeneli[5], [1]Marmara University, School of Medicine, Rheumatology, Istanbul, Turkey, [2]Marmara University Faculty of Medicine, Istanbul, Turkey, [3]Department of Rheumatology, Marmara University Faculty of Medicine, Istanbul, Turkey, [4]Marmara University, School of Medicine, Dermatology, Istanbul, Turkey, [5]Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Behcet's Disease (BD) is a systemic vasculitis characterized by involvement of vessels of any size and type. In the course systemic vasculitis, it is important to distinguish disease activity from damage to prevent unnecessary immunosuppression. Damage is also an important surrogate for long-term outcome in vasculitis. Although a well-established validated damage index, "vasculitis damage index" (VDI) is available for vasculitis, its performance in BD has never been assessed. In this study we assessed the damage in BD by using VDI, to determine whether VDI covers all BD-associated damage and lastly to develop a preliminary BD-specific damage index with the obtained data.

Methods: A total of 139 consecutive patients with BD (F/M: 58/81, mean age 38.9±10.9 yrs, disease duration 9.5±7.4 yrs) from a single center were evaluated for damage in a cross-sectional study using the VDI. Considering the patients data and items of VDI with further literature search for BD-specific damages, new items (detailed cardiovascular, ocular, and vascular involvement-, particularly venous disease-related damages) were added to VDI. This modified VDI (Behcet's Disease-VDI [B-VDI]) was also scored in allpatients.

Results: Seventy seven patients (55.4%) had major organ involvement and 105 (75.5%) patients were on immunosupressive (IS) treatment (Table 1). The mean VDI score was 0.3±0.7 and majority of the patients had score "0" ("0" in 107 [77%], "1" in 22 [15.8%], "2" in 7 [5%], "3" in 1 [0.7%], and "4" in 2 [1.4%] patients). The mean B-VDI score was 0.6±1.1 ("0" in 92 [66.2%], "1" in 25 [18%], "2" in 13 [9.4%], "3" in 4 [2.9%] and "4" in 3 [2.2%] patients, "5" in 1 [0.7%], and "6" in 1 [0.7%] patient) and was significantly higher than VDI ($p<0.001$). The main difference between VDI and B-VDI was in vascular (0.05±0.2 vs 0.3±0.6, $p<0.001$) damage items. Both VDI and B-VDI scores were significantly higher in patients with major organ involvement compared to mucocutaneous BD. Both scores were also positively correlated with the age, disease duration and total duration of IS treatment. When individual organ items evaluated, it was observed that damage in patients with major organ involvement was predominantly associated with ocular and vascular involvements. Although VDI-eye and B-VDI-eye scores were not significantly different (both 0.3±0.6, $p=0.32$), B-VDI-vascular scores were significantly higher than VDI-vascular scores both in the entire cohort and in patients with major organ involvement (0.6±0.8 vs 0.1±0.3, $p<0.001$).

Conclusion: Both VDI and B-VDI capture reliable data on damage among patients with BD. However, VDI does not cover all

vascular involvement-related damages of BD. Addition of new items, especially about vascular damage, to VDI will provide more comprehensive damage assessment in BD. Further prospective followup is required to determine the prognostic value of these damage indices in BD.

Table 1. Baseline demographic and clinical characteristics of patients with Behcet's Disease (n=139)*

Age, years	38.9±10.9
Male, n (%)	81 (58.3)
Disease duration, years	9.5±7.4
Oral ulcer, n (%)	139 (100)
Genital ulcer, n (%)	119 (85.6)
Erythema nodosum/folliculitis, n (%)	110 (79.1)
Arthritis, n (%)	84 (60.4)
Ocular involvement, n (%)	55 (39.6)
Vascular involvement, n (%)	41 (29.5)
Gastrointestinal involvement, n (%)	4 (2.9)
Neurologic involvement, n (%)	4 (2.9)
Glucocorticoid treatment, n (%)	86 (61.9)
Immunosuppressives, n (%)	105 (75.5)
Cyclophosphamide	7 (5)
Azathioprine	77 (55.4)
Others	21 (15.1)
Anticoagulant treatment, n (%)	27 (19.4)

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: An unmet need for reliable, validated, and widely accepted outcome measures for trials in BehetÕs syndrome (BS) was identified through: i) a systematic review; ii) a survey among BehetÕs experts; and iii) an outcome measures interest group meeting during the 16th International Conference on BehetÕs Disease (1,2). The OMERACT BehetÕs Syndrome Working Group has been working to advance outcome measures in BS with the goal of creating a core set of data-driven measures

for use in clinical trials. To identify domains, subdomains, and outcomes to be assessed in trials of BS, a Delphi exercise among BS experts and patients with BS has been initiated. This abstract describes the results for round 1 of the Delphi.

Methods: A list of possible domains, subdomains, and outcomes was prepared using the results of a systematic literature review on outcomes assessed in previous studies in BS, patient priorities identified through qualitative interviews, and expert opinion. A 3-round Delphi was begun among physicians from different specialties experienced in BS and among patients with BS. The patient survey was the same as the physician survey with medical terms explained. The web-based survey was formatted in both English and Turkish and emailed to 123 physicians and 130 patients. Agreement by ³70% of either physicians or patients resulted in an item being accepted.

Results: 74 physicians and 35 patients participated in Round 1. The physicians were experts in BS from 21 countries and from within a wide range of specialties, including Rheumatology (50%), Ophthalmology (12%), Internal Medicine (12%), Dermatology (16%), Gastroenterology (3%), and Neurology (1%). Among the participating patients there was good representation of each type of organ involvement. Table 1 shows the domains to be measured in all trials in BS that received ³70% endorsement by expert physicians and the additional subdomains endorsed for trials for each type of involvement. In addition to all of the domains identified by physicians, ³70% of patients endorsed the assessment of pain, fatigue, sleep, sexual functioning, psychological functioning, and acute phase reactants in all trials of BS.

Conclusion: Multiple disease-related domains in BS have been identified by physicians and patients as important to address in clinical trials, suggesting that a core set for all trials will be needed and subdomains for subsets of disease (specific manifestations) will also be useful. Rating and ranking of these domains and subdomains in the next 2 rounds will enable the development of a core set of domains to be assessed in clinical trials of BS. **Table 1. Domains and subdomains of BehetÕs syndrome endorsed by ³70% of physician-experts as necessary to measure in clinical trials**

Topic of the Clinical Trial in BehetÕs Syndrome						
All Trials	**Mucocutaneous**	**Eye**	**Vascular**	**Nervous System**	**Gastro-intestinal**	**Joint**
Activity	Number of oral ulcers	Visual Acuity	Disease related damage	Headache	Abdominal pain	Number of arthritis episodes
Function	Number of genital ulcers	Blurry vision	Post-thrombotic syndrome	Progression on MRI	Clinical remission	Duration of arthritis episodes
Damage	Pain of oral ulcers	Retinal vasculitis	New venous thrombus	Cognitive functioning	Endoscopic remission	Tender joint count
Remission	Pain of genital ulcers	Cystoid macula edema	Extended venous thrombus	Headache	Diarrhea	Swollen joint count
Patient global assessment	Duration of oral ulcers	Ocular attack	New aneurysm			Physical function
Physician global assessment	Duration of genital ulcers		New arterial thrombus			
Quality of life	Duration of nodular lesions		Hemoptysis			
Work productivity	New organ involvement

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: In Behçet's disease (BD), vascular complications affect more than 30% patients. Cardiovascular involvement is the main cause of death, especially for pulmonary or aortic aneurysms and large vein thrombosis. Immunosuppressants (azathioprine, methotrexate, cyclophosphamide) are not always effective and are often associated with significant side effects. TNF antagonists have been shown to be very quickly effective in severe ocular manifestations of BD. Data on their efficacy in BD vascular complications are scarce. Objectives: To evaluate the efficacy and safety of anti-TNF alpha in severe and/or refractory vascular involvements in BD.

Methods: A multicenter and observational study evaluating 18 patients with severe BD associated- cardiac or vascular disease (defined by international standards) treated with anti-TNF [infliximab (n=15) and adalimumab (n=3)]. Anti-TNF alpha antibodies were initiated because of severe aneurysmal arterial disease [lung (n=4) or the aorta/one of its branches (n=4) or peripheral (n=1)] and/or large vein thrombosis [pulmonary artery (n=7), thrombosis of the inferior vena cava (n = 4) or Budd-Chiari syndrome (n=3)] and/or cardiac involvement [aortic valve disease (n=1), left ventricular aneurysm (n=1), myocardial ischemia (n=1) or intra-cardiac thrombosis (n=2)]. Clinical remission was defined by resolution of clinical and biological symptoms and the absence of occurrence of new vascular lesions or worsening of existing vascular lesions.

Results: Eighteen patients [(89% male) with mean age of 30 [10; 55] years] were included. Fourteen (78%) were refractory to immunosuppressants (n=12) and / or high doses of systemic corticosteroids (n=2). Fifteen patients received infliximab injections [5mg / kg (n=13) and 3mg / kg (n=2)] and 3 adalimumab [40mg / 15 days]. Fourteen patients also received immunosuppressants [azathioprine (n=7), methotrexate (n=5), mycophenolate mofetil (n=2)] and 17 corticosteroids associated with anti-TNF alpha. Vascular lesions observed (before or at the same time of anti-TNF initiation) included: arterial aneurysms (n=11), [pulmonary (n=7), aortic (n=3), spleen (n=1) or peripheral (n = 3)], arterial occlusions (n=3) and / or venous thrombosis [pulmonary embolism (n=9), lower vena cava thrombosis (n=7), deep venous thrombosis of lower limbs (n = 2) or Budd-Chiari syndrome (n=4)]. Eight patients also had cardiac involvement [intracardiac thrombosis (n=4), valvulopathy (n=2), myocardial ischemia (n=2) or pericardial effusion (n=1)]. Vascular remission was achieved in 16 patients (89%), partial (n=3) or complete (n=13). No patients died and 2 relapsed under TNF-antagonists. Two patients who stopped anti-TNFα antibodies [side effect (n=1) and poor compliance (n=1)] had neurological or vascular flare 3 and 5 months after treatment cessation, respectively. Side effects were observed in 4 patients [pulmonary edema (n=1) infection (n=3)], requiring discontinuation in 2 patients. After a median follow up of 15 [4, 164] months, 16/18 were still under anti-TNF [cessation for side effects (n=2)]. The median dose of corticosteroids was

significantly decreased in all patients at 12 months after treatment initiation [30 mg initially versus 6 mg, p=0.004]. At the end of follow-up, 94% achieved a dose of ≤10mg corticosteroids.

Conclusion: Anti TNFα antibodies represent an effective and safe treatment in 89% of BD patients with severe and refractory cardiovascular involvement. Results: Conclusion:

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We identified leukocytoclastic vasculitis (LCV) patients seen over 10 years at our institution. Aims included 1) define cause; 2) record lab, imaging, and ancillary tests used in evaluation; 3) tabulate Medicare reimbursement costs.

Methods: All biopsy-confirmed LCV cases from 1/1/2004 to 12/31/2014 were identified by analysis of suspected cases in Dermatopathology registry. We analyzed pathology reports and only those cases with definite LCV on biopsy and available electronic health record (EHR) progress notes were included in this analysis. Clinical, epidemiologic, and other variables were then extracted from EHR and costs recorded. We calculated total lab and imaging costs, plus average costs/patient. Additionally, we determined if Rheumatology or other consultations were performed.

Results: Mean age of LCV cohort was 53.1 years, with 161 women, 115 men. Immunofluorescence was performed in 161/276 (58 %) biopsies. LCV etiology was divided into 6 major categories (Table 1), with Idiopathic in 41 %; Vasculitis in 32 %; Drug-induced 10 %; Infection-related 9 %; CTD 4 %; malignancy-related 3 %. Vasculitis or CTD accounted for 101/276 cases (Table 1). More than 50 % of Vasculitis cases were due to HSP. The HSP group mean age was 33 years, with 23/52 (44 %) being < 20 years old. Surprisingly, 56 % of our HSP patients were adults. Specific lab and imaging tests are shown in Tables 2 and 3. Total lab costs for all patients were $36,161 or $131/patient. Total imaging costs were $85,700 or $311/patient. Rheumatology accounted for 138/147 requested consultations (94%) at cost of $20,806. Nine renal biopsies were performed at $10,782 cost. Glucocorticoid therapy was used in 148/276 or 54 % cases.

Table 1: Causes of LCV (N= 276)			
1.	**Idiopathic**	**113**	**41%**
2.	**Vasculitis**	**89**	**32%**
	HSP	52	
	Cryoglobinemic	6	
	ANCA associated	10	
	PAN	6	
	Arteritis not otherwise specified	15	
3.	**Drugs**	**28**	**10%**
4.	**Infections**	**25**	**9%**
	Hepatitis C	4	
	Streptococcus	4	
	Staphylococcus	5	
	C-difficile	1	
	Viral	3	
	Other	8	
5.	**CTDs**	**12**	**4%**

Table 2: Labs/Medicare Reimbursement (Costs)			
	Lab	N = 276	Percent Ordered
1	CBC	264	95.6%
2	BMP	263	95.2%
3	LFTs	245	88.7%
4	ESR/ CRP	210	76%
5	ANA	204	73.9%
6	Hepatitis Testing	148	53.6%
7	UA	234	84.7%
8	Streptococcal Testing	34	12.3%
Cost	***Total Imaging costs = $85,700**	**276**	**$311/patient**

Table 3: Imaging Tests/Medicare Reimbursement (Costs)			
	Test	N = 276	Percent Ordered
1	CXR	113	40.9%
2	Echocardiogram	56	20.3%
3	CT Abdomen/Pelvis	51	18.3%
4	CT Chest	48	17.4%
Cost	***Total Imaging costs = $85,700**	**276**	**$311/patient**

Conclusion: Our report of 276 biopsy-confirmed LCV patients seen over this 10 year period may be the largest analysis so performed. Idiopathic (41 %) and Vasculitis (32 %) were the most common causes. Definite Rheumatic disease (Vasculitis/CTD) was identified as cause of LCV in 36 % of patients. Within the Vasculitis group, HSP comprised more than 50 % of that subgroup, with a surprising 56 % adult-HSP. Importantly, our study includes a unique cost analysis for lab, diagnostic imaging, consultations, and renal biopsy. The evaluation of LCV remains clinically challenging and more costly than previously reported.

Session Date: Tuesday, November 15, 2016
Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Immunological classes of adverse events (AEs), including the immune related AEs and the paradoxical effects, have emerged with the used of biologics. Among them, vasculitis associated with TNF inhibitors has already been reported. As infections, cancers, and autoimmune diseases must be investigated in the vasculitis work-up, vasculitis secondary to biologics remain challenging for clinicians. Indeed, we investigate the incidence and the characteristics of vasculitis-associated with monoclonal antibodies (Mabs) and Fc-fusion proteins in real life.

Methods : A retrospective analysis of charts registered in the French National Pharmacovigilance Database (FNPVD) under the diagnosis of vasculitis in adults patients treated with approved Mabs or Fc-fusion proteins was performed between 1985 and 2015. After reviewing of the cases, the demographics and clinical data were recorded. Exposure to biologics proteins was searched to the observatory of drugs, medical devices and therapeutic innovation (OMEDIT) in order to estimate the incidence.

Results: During the study period, 434 423 AEs were registered in the BNPV leading to 143 clinical suspicions of vasculitis. Thus, the incidence of vasculitis is reported in table 1. Among the 143 vasculitis, 79 biopsy-proven vasculitis were analyzed showing a mean age at diagnosis of 51±17 years with a predominantly comprising women (65%). The therapeutic indications were autoimmune diseases in 69 patients, followed by solid cancers, with a significantly longer time to onset of vasculitis between patients with autoimmune diseases as compared with non-autoimmune diseases (244 vs 32 days, $P = .01$). TNF inhibitors were involved in 60 patients (76%). Rituximab, tocilizumab, cetuximab, trastuzumab, abatacept, and ranibizumab were less common. Indeed, patients undergoing anti-TNF biologics had a significantly later occurrence of the vasculitis as compared with the other drugs (318 vs 30 days, $P = .0002$). Cutaneous vasculitis (63%) was the most frequent as compared with systemic vasculitis. No difference was found between patients with cutaneous vasculitis and systemic vasculitis in terms of the age of onset (52 vs 48 years, $P = .2806$), the sex ratio ($P = .1159$), the median time to onset (196 vs 289 days; $P = .258$), and the therapeutic indications ($P = .2482$), except for higher extracutaneous manifestations in those with systemic vasculitis ($P = .0022$).

Biologics	Number of cases (2011-2014)	Number of courses (2011-2014)	Incidence/ 10^4 courses 95% CI
etanercept	7	5075	14 [5-28]
certolizumab	5	3487	14 [5-33]
adalimumab	17	35 020	5 [3-7]
tocilizumab	11	197 425	0,6 [0,3-0,9]
infliximab	15	628 395	0,3 [0,2-0,4]
rituximab	8	560 477	0,1 [0,05-0,2]

Table 1. Incidence of vasculitis under biologics treatment.

Conclusion: Vasculitis associated with Mabs and Fc-fusion proteins are rare and potentially challenging cases. TNF-inhibitors

remain usual suspects, mostly etanercept and certolizumab in our study. However, our data report other biologics that should be kept in mind. Moreover, systemic vasculitis, IgA vasculitis being the most frequent, need a more specific recognition for a specific management, including immunosuppressant.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016
Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Data on adults IgA vasculitis (IgAV) are lacking. This survey was designed to better define clinical spectrum and efficacy of treatments in this population.

Methods: We analyzed data from 260 patients with IgAV included in a French multicenter retrospective IGAVAS survey.

Results: Mean age at diagnosis was 50.1±18 years, and 63% of patients were male. At baseline, manifestations included purpura (100%), arthralgia or arthritis (62%), glomerulonephritis (70%) or gastro-intestinal involvement (53%). Thirty percent of the patients showed renal failure (eGFR <60ml/min/1.73m^2). Median eGFR in patients with renal involvement was 88 mL/min/1.73m^2 (Q1-Q3: 55; 103), median proteinuria level 1.5 g/day (Q1-Q3: 0.6; 3), and hematuria was noted in 88%. Median serum IgA level was 3.6 g/L (Q1-Q3: 2.7; 4.8) and 85/159 patients (53%) presented with elevated IgA levels. Skin biopsy demonstrated leukocytoclastic vasculitis in 205 patients (92%). Direct immunofluorescence revealed IgA and complement deposition in dermis blood vessels in 174/216 (81%) and 47/222 (21%) of patients, respectively. Renal biopsy demonstrated mesangial IgA deposits in 142/144 patients (99%) and extracapillary proliferation in 59/143 patients (41%). Data concerning therapeutic efficacy was available and analyzed in 127 patients. In univariate analysis, global response (complete or partial) was achieved in 80% (64/80) in patients treated with corticosteroids (CS) alone compared to 77% (23/30) in patients treated with CS and cyclophosphamide (CYC) (p=0.17). Multivariate analysis using inverse weighting on propensity score revealed that patients treated with CS plus CYC had higher response rate than patients treated with CS alone [OR (95% CI) 2.33 (1.29-4.18), p=0.005]. Sensivity analysis excluding outliers confirmed this result [OR 1.79 (1.00-3.20), p=0.049]. Conversely, full multivariate model without propensity score did not demonstrate a benefit of CS plus CYC compared to CS alone [OR 0.88 (0.29-2.67), p=0.82], or after adjustment on propensity score [OR 0.90 (0.29-2.78), p=0.86]. After median follow-up of 17.2 months (Q1-Q3: 9.1-38.3) corresponding to 593 patient-years, 8 patients died, including 3 deaths directly related to IgAV (2 mesenteric ischemia and 1 multivisceral failure). Eight patients experienced end-stage renal failure treated by renal transplantation (n=2) or dialysis (n=6). Among patients who received a treatment, 15 experienced minor relapse (14%) and 9 (8%) major relapse during the first 12 months after treatment.

Conclusion: In conclusion, this series provides interesting data on clinical and histological presentation and therapeutic efficacy, suggesting that CS alone appears to be a reasonable first-line therapy in patients with systemic IgAV, while the benefit of adding CYC to CS remains uncertain.

Vaccination and Risk of Childhood IgA Vasculitis (Henoch–Schönlein): A Case-Crossover Analysis

Maryam Piram[1], Fouad Madhi[2], Tim Ulinski[3] and **Alfred Mahr**[4], [1]Pediatrics, Hospital Bicêtre, Kremlin-Bicêtre, France, [2]Pediatrics, Centre hospitalier intercommunal Créteil (CHIC), Créteil, France, [3]Pediatric Nephrology, Hospital Trousseau, Paris, France, [4]Internal Medicine, Hospital Saint-Louis, Paris, France

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The etiology of IgA vasculitis (Henoch–Schönlein, IgAV), the most common systemic vasculitis in children, is unknown, although seasonality in disease onset and clinical observation strongly suggest an etiopathogenic link with preceding infectious episodes. There is also some concern that IgAV may occur after vaccination. Thus, the evidence for the relationship between vaccination and IgAV is essentially based on case reports, and robust pharmacoepidemiological data (e.g., from case–control studies) are lacking. We performed a case-crossover study, a variant of a traditional case–control study in which each case

serves as its own control, to investigate the effect of vaccination on short-term risk of IgAV.

Methods: The study enrolled children (≤17 years old) with newly or previously diagnosed IgAV fulfilling the EULAR/PReS classification criteria and who were seen in 4 pediatric hospitals from 2011 to 2016. Data on vaccinations administered during the 12 months before IgAV onset were retrieved from the children's immunization records. With a case-crossover analysis, we calculated odds ratios (OR) on conditional logistic regression by comparing exposure to vaccination in the 3-month "index period" immediately preceding disease onset with exposure in 3 consecutive 3-month "control" periods immediately before the "index period". A minimal sample size of 150 children was determined to detect a statistically significant OR ≥2.5 under the assumption of a baseline exposure to vaccines of 5% in each 3-month control period. On sensitivity analyses, we used 1 or 2-month windows for the index and control periods.

Results: We enrolled 167 children with IgAV (mean age 6.7 years, 52% boys) for whom complete information on vaccine exposure could be obtained; 42 (25%) received ≥1 vaccination during the 12 months before IgAV onset. The total recorded 54 vaccine doses mainly involved diphtheria-tetanus-pertussis-poliomyelitis (n=14), diphtheria-tetanus-poliomyelitis (n=12), hepatitis A (n=8), meningococcal (n=7), and measles-mumps-rubella vaccines (n=5). Fifteen children (9%) were vaccinated during the 3-month index period as compared to 4% to 7% in the 3 control periods. The OR for IgAV within 3 months of a vaccination was 1.6 (95%: CI 0.8–3.0). Analyses based on IgAV risk within 1 or 2 months of vaccination yielded ORs of 1.4 (95% CI: 0.5–3.5) and 1.3 (95% CI: 0.6–2.6), respectively. Seasonal distribution of IgAV onset was 25%, 35%, 26% and 13% for fall, winter, spring and summer, respectively; the corresponding proportions for seasonal distribution of vaccine administration were 28%, 28%, 13% and 32%.

Conclusion: This study does not support vaccination as a major etiological factor of childhood IgAV.

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Serving as an informal caregiver to a family member or friend with a chronic illness is associated with stress, reduced health status, and financial burden. However, effects of caregiving vary across conditions. We compared caregiving impact among caregivers of systemic vasculitis patients versus caregivers for other conditions.

Methods: Caregivers of systemic vasculitis patients (n=68) were recruited for an online survey via 1) direct mailings to patients in vasculitis registries at two large academic medical centers asking patients to share study information with their "primary vasculitis support person"; and 2) announcements via vasculitis support groups and social media. The survey included validated measures of caregiving activities, impact, and burden. Primary outcomes included number of days in the past 30 days of 1) poor mental health, 2) poor physical health, and 3) poor sleep; as well as 4) greatest caregiving difficulty (financial burden, not enough time for self, not enough time for family, interferes with work, creates stress, affects family relationships, other difficulty, or no difficulty). We constructed a comparison sample of non-vasculitis caregivers using publically available data from the Behavioral Risk Factor

Surveillance Survey (BRFSS), an annual telephone survey of a random sample of community-dwelling, U.S. adults. We used data from five states administering an optional caregiving module in 2009-10, in which those who report providing regular assistance to a friend/family member with a health problem were asked questions about caregiving, including the four caregiving impact and burden items asked of vasculitis caregivers described above. Because analyses revealed that all vasculitis caregivers in our sample were White, non-Hispanic and had health insurance, we limited the BRFSS sample to respondents with these characteristics (n=4,636). Chi-square tests and logistic regression were used to compare the caregiving impact variables for vasculitis vs. BRFSS caregivers before and after controlling for education, age, sex, and relationship to the patient (spouse vs. other).

Results: In unadjusted analyses, vasculitis vs. BRFSS caregivers were more likely to report ≥1 day of poor mental health (72.1% vs. 35.3%, p<.001), ≥1 day of poor sleep (82.4% vs 68.6 %, p<.05), and ≥1 day of poor physical health (51.5% vs. 37.8%, p = .059) in the past month. Vasculitis caregivers were also more likely to report caregiving difficulty (76.5% vs. 58.9%, p<.001), and that caregiving created financial burden (10.3% vs. 4.7%, p<.05) and stress (38.2% vs. 23.3%, p<.01). In multivariate logistic regression models, vasculitis caregivers had increased odds of poor physical health (OR = 1.81, CI 1.10-2.97), poor mental health (OR = 4.51, CI 2.59-7.86), and poor sleep (OR 2.35 CI 1.19-4.63), but no significant difference in caregiving difficulties.

Conclusion: Vasculitis caregivers may experience increased burden and negative impact from caregiving relative to caregivers for patients with other conditions. More efforts are needed to develop supportive interventions to understand and address the specific needs of caregivers of persons with vasculitis.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet's syndrome (BS) is a well-recognized cause of cerebral venous sinus thrombosis (CVST). We assessed the outcome of a large cohort of patients with CVST due to BS attending a single dedicated center.

Methods: We identified 100 (81 M/19 F) patients with BS who were diagnosed as having CVST. All contacted were called back to the outpatient clinic for a clinical, neurological and ophthalmological examination and cranial MRI /MR venography.

Results: Results: The mean age of the patients at the onset of the symptoms was 28 ± 10 years. A total of 48 patients developed CVST before or at the onset of ISG fulfillment, while 52 developed CVST after a median 3 [2-8] years of ISG fulfillment. Superior sagittal (n=47) and transverse sinuses (n=46) were most commonly involved followed by sigmoid sinus (n= 26) and jugular vein thrombosis (n= 15). A total of 59 (53 M/ 6 F) patients had vascular involvement in addition to CVST: these were deep vein thrombosis of the lower extremities (n= 47), pulmonary artery involvement (n = 17), Budd-Chiari syndrome (n= 9), vena cava

superior thrombosis (n= 6) and major arterial disease (n=3). In about half (32/59), CVST preceded any type of additional vascular involvement. Apart from vascular involvement, eye involvement was seen in 37 patients, parenchymal CNS involvement in 8 (all later than CVST) and gastrointestinal involvement in 5. Seven patients (all male) had died, due to causes unrelated with CVST. By the end of the study (December 2015), all remaining 87 patients were alive and contacted with a median follow-up time of 11 [6-15] years. Only 6 patients had a relapsing CVST course. Information about medical treatment was present in detail in 87 patients of whom 75 received short courses of glucocorticoids with (n=12) or without anti-coagulants. A total of 81 patients received immunosuppressive agents, most commonly azathioprine. Four patients underwent lumbo-peritoneal shunting surgery (1 was successful) and 1 with arterio-venous fistula underwent vascular embolization. By the end of December 2015, a total of 50 patients were re-evaluated at the clinic. None had of symptoms of intracranial hypertension. Ophthalmological examination showed that 17 patients had complications such as bilateral optic atrophy (n= 3), bilateral papilledema (n= 5), bilateral optic disc pallor (n=4) and fibrotic scars around optic disc (n= 5). Sensorineural type hearing loss was detected in 4 patients. Neurological examination was found to be normal among 43 patients with isolated CSVT, whereas abnormal in the remaining 7 patients with concomitant parenchymal CNS involvement. Cranial MR/MR venographies at the end of follow-up, were abnormal in 36 patients showing occlusion/ irregularity/ hypoplasia or collaterals in the sagittal (n=19) or transverse sinus (n=17). In the remaining 14, MR venographies were normal.

Conclusion: CVST due to BS is closely associated with vascular involvement in the body and may be considered as a risk factor for future vascular involvement. CVST relapses are rare; however, the course is not uneventful: visual acuity or field may be impaired totally or partially because of optic disc atrophy; in addition hearing deficits may occur.

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Widely various frequencies of sacroiliitis or spondylitis have been reported in different regions of patients with Behcet's Disease (BD). Although BD is also called Silk Road Disease, there are no reports about association of axial arthritis in patients with BD in China.

Methods: To determine the real frequency in our region, we followed up the disease history and routinely performed the axial joints CT scan in the 192 patients with BD who were treated in our hospital from January 2010 to June 2015.

Results: Among them, 28 cases showed sacroiliitis before follow-up (14.58%) and increased to 112 cases after (58.33%). Besides sacroiliitis, 192 cases had recurrent oral aphthous ulcers (100%), 111 cases skin lesions (57.8%), 117 cases genital ulcerations (60.9%), 70 cases ocular symptoms (36.5%), 78 cases peripheral arthritis (40.6%),76 cases axial skeleton involvement (39.6%), and 35 cases heel pain (18.2%). The 112 cases were found different degree of pathological changes of sacroiliac joint by CT scan. Consistently, the frequency of BD patients with SpA increased from 3.6% (ASAS) or 2.6% (Amor) before to 42.19% (ASAS) or

29.69 % (Amor) after follow-up.

Conclusion: The frequency of sacroiliitis and SpA in BD patients was increased by following up disease history and routinely examining sacroiliac joint by CT scan. Moreover, the frequency in our region was significantly higher than that in other regions reported before. All above suggest that missed diagnosis is also a possible reason for the lower frequency of axial arthritis and the BD patients in our region may have more severe manifestations.

SESSION INFORMATION
Session Date: Tuesday, November 15, 2016
Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet's disease (BD) is a multisystemic, chronic relapsing inflammatory disease classified among the vasculitis. Neurological and eye involvement are two of the most serious manifestation of BD and both still represent significant causes of morbidity. The primary aim of the study was to evaluate the long-term outcome in a cohort of patents with BD; the secondary aim was to explore any potential correlation between long-term outcome and demographic and clinical profile.

Methods: The study enrolled 122 patients, all fulfilling the International Study Group (ISG) criteria for BD. The male/female ratio was 1.6:1, with a mean disease duration of 11±4 years. Their mean age was 42±9 years (min:18, max:77), while the mean age at disease onset was 25±4 years. The mean ± SD duration of follow-up at our centre was 10±2 years. Long-term outcome was evaluated by means of disease flares according the BD Current Activity Form (BDCAF), persistent low-level of disease (defined as a level minimal activity of disease requiring only low-medium doses of corticosteroids), and disease damage according the Vasculitis Damage Index (VDI). The statistical analysis was performed using Student t-test, Mann-Whitney-U test, ANOVA and Pearson correlation

Results: The main clinical features presented during the follow-up by the cohort were: mucocutaneous involvement (100%), joint involvement (49%), ocular involvement (40%), neurological involvement (38%), vascular thrombotic events (22%), gastro-enteric involvement (16%). Globally, we observed 108 episodes of disease flare, of which: 25% of patients with neurological involvement, 60% of ocular involvement, 50% of muco-cutaneous involvement, 12% of joint involvement, 50% of vascular involvement and 28% of gastro-enteric involvement. Thirty-four patients presented a persistent low-level disease, that required a medium corticosteroids dose of 4 mg of 6-methylprednisolone. Moreover, 39 patients presented a VDI > 1. A significant correlation was found between disease flares and younger age and male sex; persistent low-level of disease and disease damage resulted significantly associated with early onset of disease and high number of disease flare in the first 2 years of disease. Notably, persistent low-level of disease and disease damage resulted inversely correlated with the use of anti TNF alpha agents, independently of the type of organ involvement.

Conclusion: As literature data suggest, a specific demographic profile exists of poor outcome in BD, represented by young males. The use of anti TNF alpha agents is associated with a positive effect on maintaining remission of disease, most likely due to their steroid sparing effect.

Session Title: Vasculitis - Poster III: Rarer Vasculitides
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Cryoglobulinemic Vasculitis (CV) is a systemic vasculitis affecting small and medium-sized vessels. Following emergence of direct acting antiviral drugs, which paved the way to avoid both the side effects of immunosuppressive treatments; and also Interferon. The aim of our study was to assess the effect of Sofosbuvir in the treatment of HCV- CV manifestations

Methods: This is a multicenter interventional treatment trial, including 26 Egyptian patients and 9 Italian patients with CV, diagnosed according to the Classification criteria of Cryoglobulinemic Vasculitis, which were validated in 2014. Patients were treated with Sofosbuvir following four treatment protocols: 1- Sofosbuvir + Ribavirin for 6 months, 2- Sofosbuvir + Ribavirin + Interferon for 3 months, 3- Sofosbuvir + Daclatasvir for 3 months, and 4- Sofosbuvir + Simeprevir for 3 months. Clinical assessment (according to the Classification criteria of CV), cryocrit %, C4 serum level and serum level of rheumatoid factor (RF), were recorded soon before and at the end of the treatment. Response was assessed as complete, partial or absent (no response). Analytical procedures used were Pearson Chi-Square and Wilcoxon tests as indicated.

Results: 35 patients (24 females, mean age 56 ± 11 y) were enrolled in the study. Sixteen patients showed liver cirrhosis. All patients were Child- Pugh A stage. 13,8,5,9 patients were treated by first, second, third, fourth protocol, respectively. All patients showed a sustained viral response (SVR). All patients had purpura and all of them responded to treatment. 35 patients had Fatigue and 24 patients had fibromyalgia, 34, 22 patients responded respectively. 26 patients had arthralgia and 23 patients had non erosive arthritis, 22, 20 patients responded respectively. 13 patients had Raynaud's phenomenon and 2 patients had fibromyalgia, 12, 2 patients responded respectively after treatment. 25 patients had Peripheral poly neuropathy with total response after treatment in 21 patients. One of our patients had leg ulcer and mono- neuritis multiplex with complete response and completely healed ulcer after treatment. Nephritis was diagnosed in two patients, one of them had proteinuria and renal impairment and another one had proteinuria only, with total improvement of both by antiviral therapy alone. Serum level of Cryocrit (P value < 0.0001), RF (P value= 0.004), C4 (P value= 0.003), significantly decreased after treatment.

Conclusion: Antiviral combination therapy including Sofosbuvir appears very effective in the treatment of the most frequent CV manifestations. Since laboratory signs of CV improved but did not disappear, long-term clinical and biological effects of SVR by Sofosbuvir should be studied

Psychiatric Involvement and Behcet'S Syndrome: Does Bipolar Disorder Represent a Clinical Feature of the Disease?

Rosaria Talarico[1], Elena Elefante[2], Laura Palagini[3], Anna d'Ascanio[4], Chiara Stagnaro[4], Chiara Tani[4], Chiara Baldini[4], Rossella Neri[1] and Marta Mosca[4], [1]Rheumatology Unit, University of Pisa, PISA, Italy, [2]RHEUMATOLOGY UNIT, University of Pisa, Pisa, Italy, [3]Psychiatric Unit, University, PISA, Italy, [4]Rheumatology Unit, University of Pisa, Pisa, Italy

First publication: September 28, 2016

SESSION INFORMATION

Session Date: Tuesday, November 15, 2016

Session Title: Vasculitis - Poster III: Rarer Vasculitides

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Frequency of psychiatric disorders in Behçet's syndrome (BS) is a debated issue: while some experts attribute their presence to the chronicity of the illness, others think that they may be imputable to disease activity or to intrinsic features of the disease. The primary aims were to determine the frequency of psychiatric disorders in BS patients, both with neurological involvement or without; the secondary aims were: to investigate a possible association between disease activity/organ involvement and psychiatric profile of the BS patients and to compare the distribution of psychiatric disorders of patients with BS with those in patients with other chronic diseases.

Methods: One hundred and six-teen BS patients with a diagnosis of BS according the ISG criteria were studied. Demographic profile of the cohort studied are summarised in **Table 1**. Psychiatric disorders evaluated were: bipolar disorder, obsessive-compulsive disorder, depression and sleep disorders. Age and sex matched disease controls of systemic lupus erythematosus (SLE) and chronic arterial hypertension were included.

	Neuro- BS	**BS without neurological involvement**
Number of patients	46	70
M/F	36/10	44/26
Mean age ± SD (min-max) (years)	43±6 (15-68)	42±8 (18-71)
Mean disease duration ± SD (min-max) (years)	9±2 (2-28)	10±2 (3-28)

Table 1. Demographic profile.

Results: Prevalence of psychiatric disorders are shown in **Table 2**.

psychiatric disorders	**Neuro- BS %**	**BS without neurological involvement %**
bipolar disorder	67	64
obsessive-compulsive disorder	46	43
depression	32	36
sleep disorders	11	16

Table 2. Prevalence of psychiatric disorders.

The frequency of bipolar disorder resulted significantly higher than in disease controls ($p < 0.001$). Moreover, we found a

significant correlation between disease activity (evaluated by BDCAF) and the presence of bipolar disorder. No correlations were found between the presence of psychiatric disorders and organ involvement.

Conclusion: Our results show a high frequency of psychiatric disorders in BS patients. This elevated frequency, both in BS patient with or without neurological involvement, strongly suggest that BS patients may be characterised by a specific psychiatric profile. The correlation between disease activity and bipolar disorder could provide the basis for further analysis on lager cohorts, in order to better explore the mechanisms responsible for the occurrence of psychiatric disorders and BS .
